Experimental results in China show that the string length is proportional to the flashover voltage while the string less than 30 pcs. Experimental results in USA and Japan show that: the string length is proportional to the flashover voltage while the string length less than 6m. Voltage distribution of composite insulators under wet filthy conditions is very uneven, so nonlinear relationship can occur at lower voltages. Normally, natural Pollution insulator flashover voltage

higher than the artificial pollution tests, so it can be considered linear, when chosen the string according to the data from artificial pollution tests [5].

(3)The influence of Installation

Different insulator string installation, which flashover voltage is also significant differences. The test results show that the flashover voltage of dual string insulator is 5% ~ l0% lower than the single-string. When the distance between the double string insulator increases, the impact on flashover voltage is significantly reduced.

V-shaped installation can increased flashover voltage of ordinary suspension insulator by 25% to 30% [9], but the improvement is much less on anti-fog insulator.

The influence of weather conditions

Insulator flashover voltage depends not only on the type and degree of Pollution of the insulator, but also on the meteorological conditions, such as humidity, barometric pressure, temperature, and other acidic wet deposition.

(1) Wet condition

Wet weather condition is a necessary condition for the occurrence of flashover, such as fog, dew, drizzle and fog rain, snow and sleet. Wide range of fog occurred long duration, can insulators uniform moisture, concentration of fog, the lower visibility, the greater the harm; Dew is often seen in summer morning, for most industrial Pollution, short wet is not dangerous. Drizzle on the insulator surface is not as humid mist evenly. The duration of the long drizzle risk is very big. Fog, snow and sleet in the melting temperature of the insulator which constitute a serious hazard; Rain generally conducive to clean the surface of the insulator, but may make small pitch insulator flashover occurred in the rain; Direct splashing seawater, salt spray occured in saline areas etc. easily lead to flashover.

(2) Temperature

Mizuno et. deduced relations between insulator flashover voltage and ambient temperature is[10]:

$$U_f \propto \left[1+0.02(t-20)\right]^{-w_t} \tag{5}$$

where, t is Ambient temperature; w_t is ambient temperature impact characteristic index, AC w_t=0.2, DC w_t=0.33. The field test results of Chongqing university verify the validity of the derived results.

(3) Air pressure

The relation between flashover voltage and air pressure is:

$$U_f = U_0 \times \left(P / P_0\right)^n \tag{6}$$

Where, U_f is the flashover voltage under pressure (P, kPa), kV; U_0 is the flashover voltage under standard pressure(P_0=101. 3kPa), kV; n is the pneumatic impact characteristic index, between 0~1. Pneumatic impact characteristic index obtained by different researchers are quite different [11]. In general, n is about 0.5 while the structure of insulator is simple [12]. But in the actual operation, n has a relationship with the voltage type, degree of Pollution, the shape of the insulator.

(4) Rainwater acidity

In insulators artificial pollution tests, clean fog (vapor mist) or salt spray is used, and its acidity does not consider. Actually wet deposition of acidity in many areas has greatly increased, which will induced insulator flashover voltage drop. When ESDD of 0.015~0.1mg/cm^2, pH of 3.0~4.0,

insulator flashover voltage AC decreased by approximately 2.1%~21.7%. The decreased of different types of insulators is different. The decline of porcelain and glass insulators are larger than composite insulators and post insulators.

The influence of non-uniform Pollution

Under natural conditions, the Pollution of the insulator is always uneven. This uneven including upper and lower surfaces of the insulator, different fan on the same surface, and different components of one bunch. Numerous experiments show that, much uneven higher flashover voltage. Artificial pollution tests result is lower than the natural Pollution test, is a manifestation of the uneven.

Summary

Many domestic and foreign research institutions did a large number of experimental in insulator flashover characteristics area, but the test results obtained by various research institutions vary greatly. After analysis it can be seen, these differences are due to the influence of insulator structure, filthy type of experimental ambient temperature and humidity. So need to find a method to correct test results of the research institutes to the same type of insulator, salt density and non-soluble dense composition and temperature were analyzed to verify its legitimacy. Meanwhile, in order to obtain accurate insulator flashover characteristics, need to strengthen the natural contamination experimental study and insulator contamination degree online monitoring.

[a]fanyu@hpu.edu.cn, [b]wuxuefeng@hpu.edu.cn

Keywords: Pressure detection,Three topologies amplification, Differential amplifier

Abstract. An application of intelligent pressure detection and alarm system are studied in this paper . it is consists of the high integration, powerful function new microprocessor control, the internal integration of a large number of analog and digital peripheral module. The system has strong data processing ability. multifunctional intelligent hardware is not only realized in circuit necessary configuration,but also is a small size device. it ensure the intelligence function,and has the advantages of small volume, low cost, integration and strong anti-interference ability .

Introduction

Water resources is an uneven distribution in China, it is rich in some areas and very scarce in the others. Related equipment is often used for water supply I and water pump is now widely used. However, in the water pump water supply system, the pressure which water pipe wall can bear is a very important question [1].

This system is designed specifically for this issue. Pressure detection and alarm are realized in this system. Detecting pipeline pressure is easily real time carried out, if the pressure exceeds a certain value, the alarm system will be worked, and outputing some signal, controlling water pump motor speed to reduce the water flow, thereby the pressure on pipeline wall is reduced [2]. It provides automated and intelligent engineering self protection, avoiding the occurrence of a series of Engineering accident [3].

It is consist of supply circuit, amplifier circuit, A/D conversion and data processing, pressure display and alarm circuit in this paper.

The design of the system

The system principle. Three terminal voltage regulator chip LM7815,is used for voltage conversion from 24V to 15V, Three terminal voltage regulator chip LM7805,is used for voltage conversion from 15V to 5V. The requirement of the magnification is high in the amplifying circuit [4]. The performance of a single integrated or modular operational amplifiers can't meet the requirements generally. It can only be used in less demanding occasions. Operational amplifier input and signal amplification must be used in the system. Taking into account the A/D precision, and the amplified voltage up to 5-7V, A/D574 conversion is used, which can support the unipolar 0-10V and 0-20V the input voltage.

The design of the main work as follows: When the pipe wall subjected to liquid pressure, it makes the piezoresistive pressure sensor bridge unbalance, unbalanced bridge triggers weak electrical signal. The weak signal through three operational amplifier topology instrument for signal amplification is amplified by A/D converter,then is converted to digital signal.When the voltage signal is no more than a certain value, the signal display pressure value in LED [5].When this signal exceeds a certain value, it will make the alarm signal started by the MCU, prevent the occurrence of accidents, at the same time, MCU sends a signal input external frequency converter, adjusting the speed of the pump motor,then the motor speed and the water flow are reduced. The Work flow chart is shown in Fig. 1.

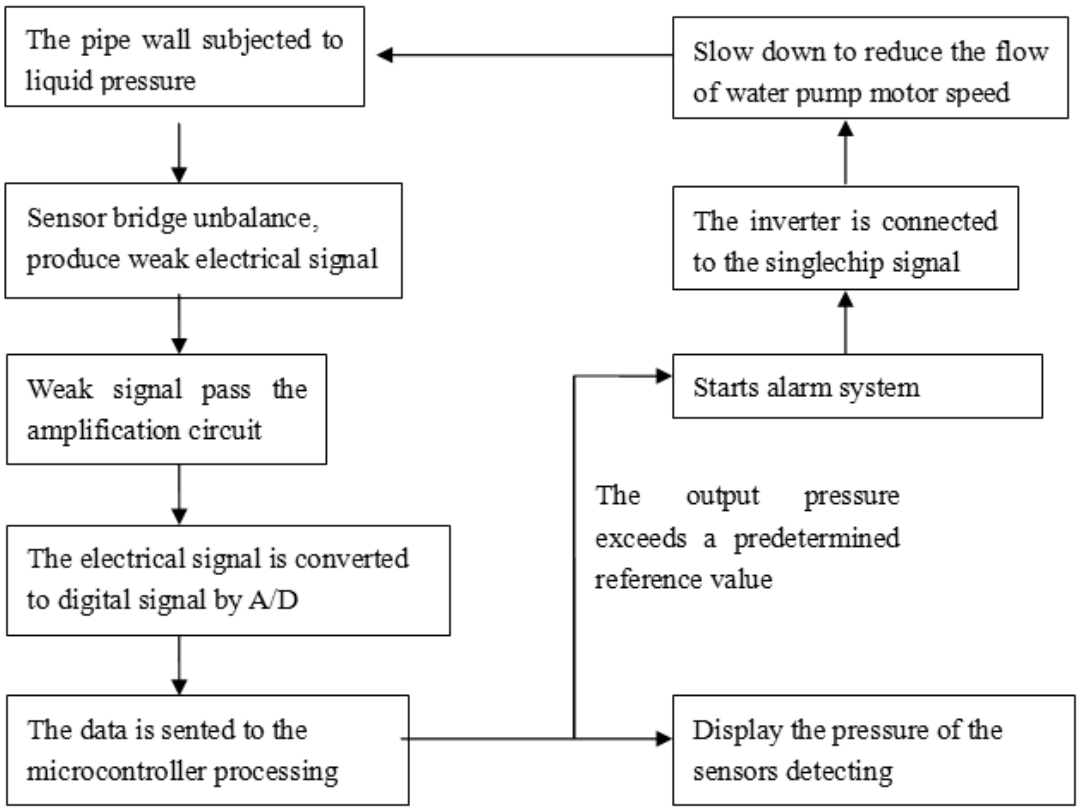

Fig. 1. The work flow chart

The System of Power Supply. It needs 24V, ± 15V and ± 5V supply voltage in the system, while the power supply can not provide more power, so the chips of LM7815 and LM7915 is used to conversion the voltage voltage supply system. The power supply circuit is shown in Fig. 2.

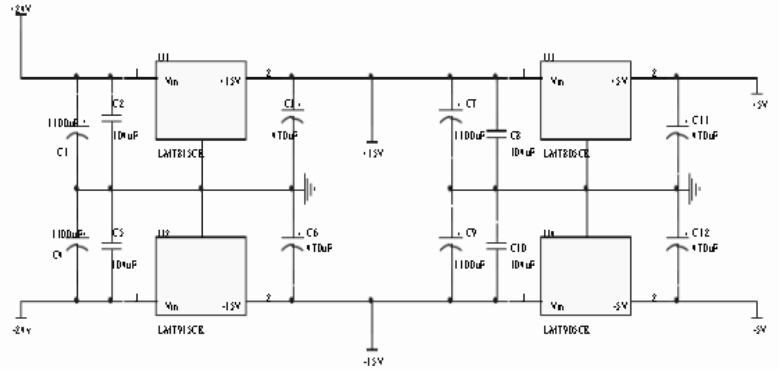

Fig. 2. The power supply circuit

The amplifying circuit. Three topologies amplification circuit is used in the system, and sensitive element is two output mode. It output a voltage signal with two induction of the sensor [6]. It should adopt double signal amplification method. The two signal is shaping and amplification, and then output the data signal processing, The amplifying circuit is shown in Fig. 3.

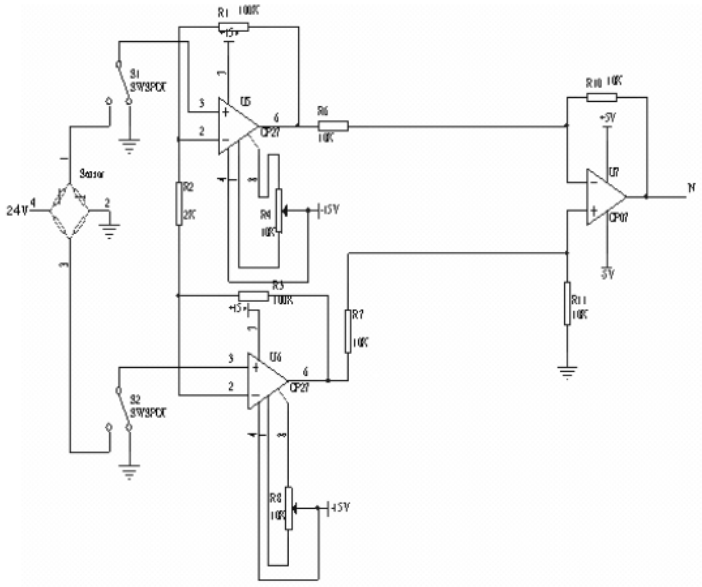

Fig. 3.The amplifying circuit

The real advantage of three topologies not only can get the performance the real difference measurement, but also has very high input impedance. Especially in the occasion of high impedance signal source. And the amplifier gain can be selected resistance by user. Therefore, it is particularly suitable for precision measurement in abominable environment, its main used as a common mode signal superimposed small differential signal preamplifier [7].

The circuit is suitable for special instrumentation amplifier circuit. An instrumentation amplifier is a differential voltage gain device precision, it has some advantages ,such as differential input, single output, high input impedance, low offset current and high rejection ratio. Basic component of the operational amplifier is same in differential amplifier and an instrument amplifier. And a differential amplifier and an instrument amplifier with common mode signal conditions can amplify the weak differential signal, so it has very high common mode rejection ratio. It do not require external feedback network.

A/D conversion and data processing. The task of input channel is converting the analog signal (such as temperature, liquid level, speed, current, voltage, phase, composition) into binary code .The channel is consists of multiple switch, amplifier, sample and hold circuit, analog / digital converter, interface and control circuit. Due to unlike the analog signals, digital signals that form is simple .The characteristics of digital signals are strong anti-jamming and not easy to distortion. It is easy processing, and widely used in digital signal. The A/D conversion intelligent pressure sensor system and microcomputer data processing circuit are shown in Fig. 4.

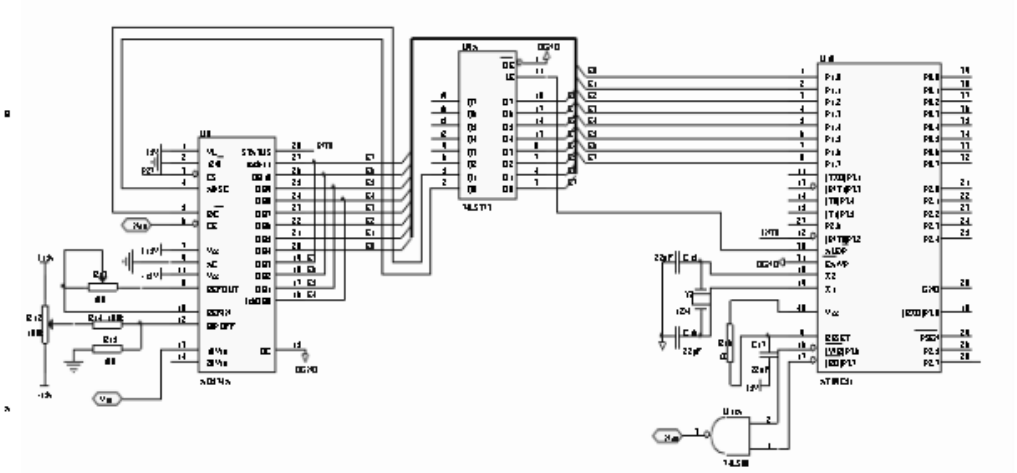

Fig. 4. A/D conversion and AT89C51 MCU circuit diagram

Conclusions

The application of intelligent pressure detection and the theory of alarm system in pressure measurement are studied in this paper. The high integration powerful function and new microprocessor are used in the system. Its internal integrates a number of analog and digital peripheral module, with strong data processing ability. The system configuration is necessary for the realization of multifunctional intelligent hardware within a circuit, and all of the low price, small size devices, it has the advantages of small volume, low cost, integration and strong anti-interference ability.

Keywords: Commutation failure(CF), anomalous, faults levels, effective short circuit ratio(ESCR), coupling impedance.

Abstract. Commutation failure theory of HVDC system is proposed and its reason is analyzed. Faults at inverter bus in multi-infeed HVDC system can cause local commutation failure and even concurrent commutation failure. Anomalous commutation failure is simulated with six kinds of ac system strength, and it is more and more serious at first as the system strength increases then become less serious as the strength becomes stronger. Coupling impedance is changed to get its relationship with anomalous commutation failure.

Introduction

COMMUTATION FAILURE(CF) is an adverse dynamic event that occurs when a converter valve that is supposed to turn off, continues to conduct without transferring its current to the next valve in the firing sequence. Its occurrence causes temporary interruption of transmitted power, and stresses the converter equipment[1] . When the converter fails to regain breakdown capacity in the inverse voltage duration after breakover or commutation process doesn't complete during the time, commutation failure occurs. CF mainly happens at the inverter for the rectifier valve can have inverse voltage in a long time after its current shutoff. CF is one of the most common fault types at the inverter in HVDC system[2]. CF may lead to decline of dc voltage and increase of dc current. If measures haven't been taken properly, it can trigger concurrent commutation failure, which will cause shutting of whole dc system in some serious occasion. This will break up the dc power and influence the safe operation of Grids.

The essence of CF is that the valve extinction angle γ bellows the critical extinction angle γ_{min}. Traditional discriminant method for CF is the measurement of minimum voltage drrop. This method estimates whether CF happened or not by comparing commutation voltage drop with the critical voltage drop, and the latter one is the appraised standard of CF. However, this method neglects the influence of wave distortion, which will cause error in estimating CF. This essay use the extinction angle as the standard of CF, and if $\gamma < 7°$, CF happens.

Commutation failure theory

The converter valve voltage variation is the main reason of CF. Voltage variation can change the voltage zero drift as well as decline the voltage amplitude. The process of commutation can be expressed by commutation area in voltage-time graphic, which is shown in Fig. 1. There are some parameters at the inverter that are firing angle α, commutation angle μ and extinction angle γ, and they satisfy the equation $\alpha + \mu + \gamma = \pi$. Converter commutation area is S_1 which guarantee successful commutation when normally running, related to curve 1. When fault comes (take three phase fault as examples), the commutation voltage amplitude declines, showed as curve 2. As commutation area and firing moment keep constant, commutation duration have to be extended. According to Fig. 1,there gives new parameters μ' and γ'.

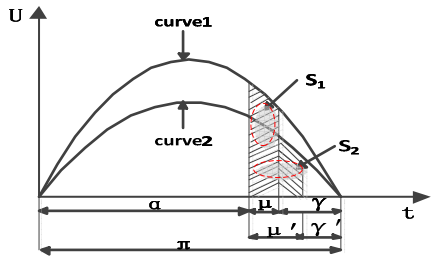

Fig. 1. Decrease of γcaused by voltage amplitude drop.

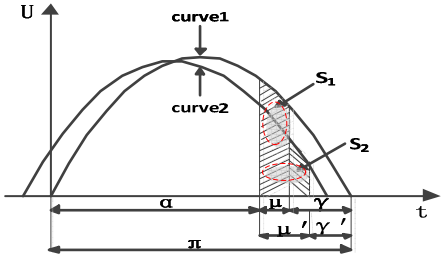

Fig. 2. Decrease of γcaused by voltage zero drift

When commutation voltage is below a certain value, $\gamma < \gamma_0$, and CF happened. The critical voltage drop ΔU is given by

$$\Delta U = 1 - \frac{I_d'}{I_d}\frac{(I_d/I_{dFL})\cdot X_{cpu}}{\left(\frac{I_d}{I_{dFL}}\right)\cdot X_{cpu}+\cos\gamma_0-\cos\gamma}. \quad (1)$$

where

I_d prefault dc current;
I_d' postfault dc current;
I_{dFL} nominal dc current;
X_{CPU} transformer per-unit impedance;
γ minimum extinction angle;
γ_0 extinction angle below which commutation fails.

Voltage zero drift

When asymmetrical faults happens, not only the voltage amplitude declines but also its zero crossing point moves which may also cause decline of γ, and then commutation failure happens. The zero crossing point moving can be called as zero drift, and only the forward moving of zero crossing point can cause CF. Fig. 2 shows the zero crossing point moves forward.

Similarly, here gives another critical voltage,

$$\Delta U = 1 - \frac{I_d'}{I_d}\frac{(I_d/I_{dFL})\cdot X_{cpu}}{(I_d/I_{dFL})\cdot X_{cpu}+\cos(\gamma_0+\varphi)-\cos\gamma} \quad (2)$$

There exists a new character 'φ' at the denominator of formula (2) compared to formula (1), which causes decline of ΔU and increase the probability of commutation failure.

Anomalous Commutation Failure phenomenon in Multi-Infeed HVDC Systems

Electrical coupling relationship exists between different dc system in multi-infeed system. When one of the dc systems encounters CF, other dc systems may be caused concurrent or successive CF. Here gives an example containing two dc systems showed as Fig. 3. Both of the two HVDC system are rated as in the "CIGRE First HVDC Benchmark Model" in PSCAD.

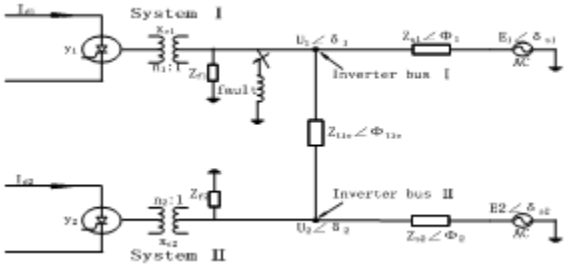

Fig. 3. Schematic diagram of double-infeed system

Suppose that inverter bus Ⅰ has a fault, which causes CF in inverter Ⅰ, the effect of fault can spread to inverter bus Ⅱ through coupled line. Thus inverter Ⅱ will encounter CF too. This concurrent CF has relation to fault level, fault situation and ac system strength. However, the CF of second inverter doesn't follow the first one, but comes out with some anomalous phenomena.

In order to elaborate these phenomena, first we introduce a concept called effective short circuit ratio (ESCR), which can represent the ac system strength. The effective short circuit ratio is an indicator of the performance of a given inverter without any other inverter in operation. Thus the ESCR for the inverter is given by

$$ESCR = \frac{SCL - Q_f}{P_{dc}} \quad (3)$$

SCL is the short circuit level at the given inverter bus due to the entire ac system. Q_f is the reactive power generated by filters and capacitors connected at the bus and P_{dc} is the rating of the given dc system. When calculating ESCR, other inverters must be blocked while their filter banks are in service.

Anomalous commutation failure phenomenon is showed in Fig. 4. The effective short circuit ratio are selected : ESCR1 = 2.5, ESCR2 = 4.5 and the tie line length is 80 km.

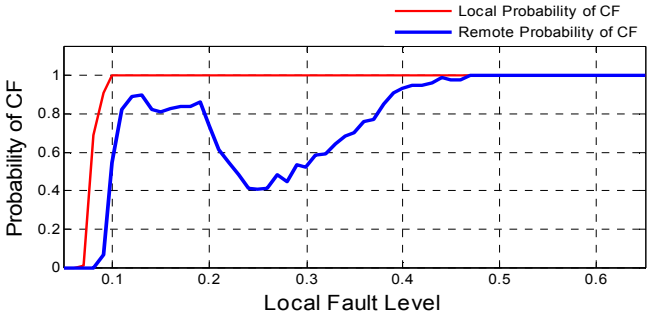

Fig. 4. Anomalous CF in double-infeed system

The local fault level is the level which converter bus encounters fault. Since inductive fault is more serious than capacitive and resistive fault, and it causes CF more easily, so this article just only analysis the inductive fault.

$$\text{Fault Level} = \frac{U^2}{Z_{fault} \cdot P_{dc}} \quad (4)$$

in which $Z_{fault} = \omega \cdot L_{fault}$, U is the nominal voltage of converter bus, Z_{fault} is ground impedance, and P_{dc} is the nominal power delivered by dc system.

Commutation failure is a random event, and we must grasp the statistical magnitude that reflect CF essence to know about the random event[3]. For each fault level, the probability of CF is calculated as the fraction of faults of a total of 100 applied at different points on wave within a cycle that resulted in CF[4]. We can get to know from Fig. 4 that the probability of CF becomes 1 at the 0.47 fault level. This essay set 61 fault levels, from 0.05 to 0.65, the interval is 0.01.

Analysis of anomalous CF phenomenon when changing ac system strength.

Paper [4] promoted anomalous commutation failure phenomenon but did not take deeper exploration. According to Fig. 3, this paper will make a probing analysis of anomalous CF phenomenon, by changing the second effective short circuit ratio and the coupling relationship of the two ac systems. Local CF happens at converter Ⅰ, while remote CF probability is the probability that converter Ⅱ encounters. From Fig. 4, we can see that when the fault level is low, about 0.1-0.2, remote CF probability is at 0.8 or so. As the fault level increase, the remote CF probability decreases at first and then increases. This is called anomalous CF phenomenon. Fig. 4 is the situation of ESCR1=2.5 and ESCR2=4.5, now change the effective short circuit ratio (ac system strength) of ac system Ⅱ, and analysis its influence on anomalous CF. This text gives out six ratios from 2.5 to 5.0

Sixty one times of fault level simulation are needed in each ac system strength, and each fault level needs 101 tines of simulation, so each ac system strength needs 6161 times of simulation in total.

Figure 5 shows the anomalous CF of six kinds of ac system strength. From the figure we can see that anomalous CF phenomenon of inverter Ⅱ are more and more obvious when ESCR2 increases from 2.5 to 4.5. At 0.1 fault level or less than it, the probability from 2.5 to 4.5 has little difference,

but as fault level increases, if the ac system is more stronger, its curve declines more seriously. Look at the curve of ESCR=4.5, when the fault level is between 0.1 and 0.2, the CF probability of inverter Ⅱ is between 0.8 and 0.9, but when the fault level is 0.25, the CF probability of inverter Ⅱ is 0.4. This is the most serious situation, and when ESCR2 equals 5.0, the anomalous commutation failure phenomenon is no longer obvious.

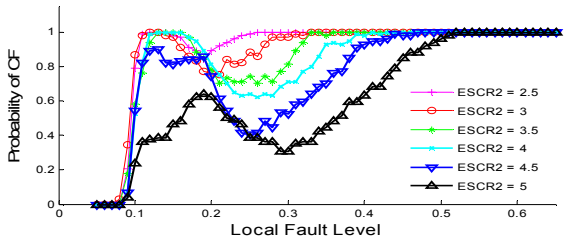

Fig. 5. Anomalous CF of six ac system strength types.

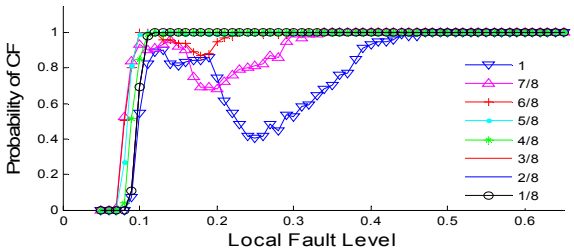

Fig. 6. Anomalous CF phenomenon when changing coupling impedence

Analysis of anomalous CF phenomenon when changing electrical coupling relationship.

Change the coupling impedance value of the double-infeed HVDC system. Take the value 1, 7/8, 6/8, 5/8, 4/8, 3/8, 2/8, 1/8 of original impedance at the most serious situation of ESCR1=2.5, ESCR2=4.5. The result is shown in Fig. 6.

As is shown in Fig. 6, the anomalous CF phenomenon is disappearing with the impedance decreasing. When the coupling impendence is less than 5/8 of original value, converter Ⅱ and converter Ⅰ are encountered concurrent CF almost at the same fault level. And three curves of 3/8, 2/8 and 1/8 coincide totally, and what's more, their probability of CF is 1 when the local fault level is more than 0.1. So the anomalous CF phenomenon has positive correlation with coupling impedance.

Conclusions

1). The paper shows commutation failure phenomenon and gives its detailed analysis. Two reasons of CF is proposed, one is the decline of voltage amplitude and the other is the voltage zero drift. Both are calculated by equations and can be used in practice.

2). Anomalous CF phenomenon is simulated with six ac system strength and eight kinds of coupling impedance. For ESCR1=2.5, ESCR2=4.5, the anomalous phenomenon is most serious and it is less serious when ESCR2 is less than 4.5 or more than 4.5. In addition, as the coupling impendence decreases, this phenomenon also weakens.

Keywords: HVDC, commutation failure, diagnosis, valve voltage, valve current.

Abstract. Commutation failure is one of the most common typical faults of HVDC, and it may result in subsequent commutation failures, even the outage of the HVDC system if without timely and effective regulatory measures. Trigger of the control measures depends on the rapid and accurate diagnosis of commutation failure. In-depth analysis of the commutation failure mechanism indicates its new substantive characteristics: valve voltage being continuously zero and valve current being continuous with high amplitudes, according to which a novel method for fault diagnosis of commutation failure based on voltage or current of the converter valve is proposed in this paper. Simulation results prove the accuracy and effectiveness of this method.

Introduction

Commutation failure is one of the most common typical faults of HVDC. It can cause obvious drop of DC voltage, fast-rising of DC current and decrease of DC power, even subsequent commutation failures if no effective regulatory measures are taken, which may leads to the outage of the HVDC system, and then affects the safe and stable operation of the entire AC-DC power system.

Start of the effective control measures depends on the rapid and accurate diagnosis of commutation failure. Currently, diagnostic methods for commutation failure mainly include extinction angle, minimum voltage drop, minimum commutation voltage-time area, wavelet analysis method, etc. Formula for computation of the minimum voltage drop corresponding to commutation failure under symmetrical and asymmetrical AC faults was derived in reference [1]; however, this derivation was based on an infinite bus system and the quasi steady state equation of converter, and ignored the influence of voltage waveform distortion, which means low accuracy. Combined with influence analysis of commutation angle on commutation process, literature [2] gave the quantitative relation between commutation voltage-time area and commutation failure, considering that the commutation voltage was sinusoidal, DC current and the firing angle was constant during commutation process. According to reference [3], wavelet analysis of DC current and converter bus voltage can not only diagnose the occurrence of commutation failure, but also distinguish the corresponded fault types; But, setting of the threshold value and criterion is related to the structure and parameters of the entire system, and this method is difficult to achieve in engineering practice due to the complexity of the algorithm.

With deep analysis of the commutation failure mechanism, and from the perspective of substantive characteristics of commutation failure, a novel diagnostic method for commutation failure based on valve voltage or valve current is presented. Detailed simulation results based on the CIGRE HVDC standard test system also testify the accuracy and effectiveness of the proposed method.

Commutation Failure Mechanism

Definition of Commutation Failure. When the two valves of converter, for the commutation process can't be completed, or expected valve turns off, the valve fails to restore blocking capacity during the reverse voltage, if voltage on the valve is positive, it immediately re-turns, and inverted commutation occurs, this phenomenon is known as commutation failure.

That is, commutation occurs when the extinction angle γ is less than its critical value γ_{min}, where γ_{min} is the corresponding time for the thyristor to restore forward-voltage blocking capacity, and its value varies between 7 and 10 degrees due to the parameters of thyristors, the magnitude of loaded voltage and current.

Analysis of Commutation Failure Process. Fig. 1 shows the schematic diagram of 6-pulse inverter, where V1-V6 represent the six converter valves triggered in turns; u_a, u_b and u_c denote the power-frequency fundamental wave phase voltage of equivalent AC system; i_a, i_b and i_c represent three-phase alternating current respectively; L_r is the equivalent commutation inductance; L_d is the inductance value of smoothing reactor.

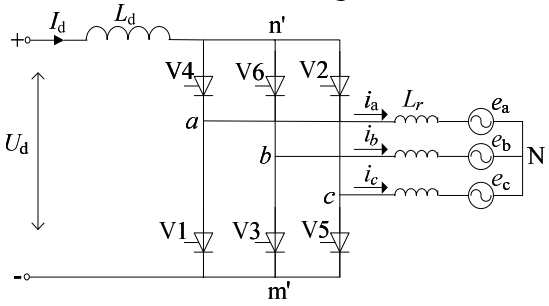

Fig. 1 Schematic diagram of 6-pulse inverter

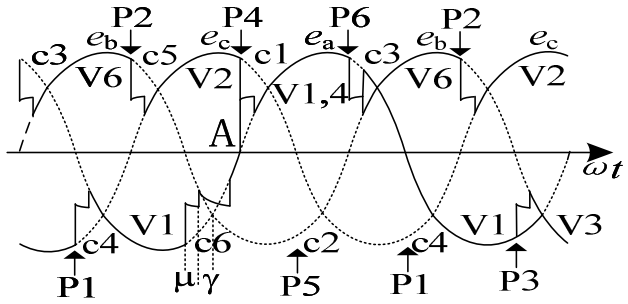

Fig. 2 Waveform of commutation failure of inverter

Taking commutation from V1 to V3 shown in Fig. 2 as an example, after valve voltage zero-crossing point, if V1 can't restore forward blocking capacity due to biggish commutation angle μ when V3 is triggered, thus V1 will re-conduct under forward voltage even without trigger pulse, which means inverted commutation from V3 to V1 will occur and V3 will turn off at point A. Sometimes μ is excessively big so that the commutation can't be completed even by point C6, and then followed by inverted commutation to V1, after which V1 and V2 will keep conducting continuously.

The following valves will be triggered in turns as originally planned if there are no effective measures in action. After conduction of V4, short circuit at the DC side will be caused by V1 and V4, which will inevitably result in fast-rising of DC current, drop of DC voltage and DC power. Because V5 is unable to turn on at point P5 due to backward voltage, the short circuit will continue until the successful commutation from V4 to V6. Then HVDC return to normal operation if no commutation failure happens again. V1 keeps conducting in a cycle during this process, and it is three times of the conducting time of V1 under normal conditions. The electrical degree corresponding to the short-circuit time is $120°+\mu$.

Restricted by the response time of DC current and extinction angle regulator, generally the short-circuit current can't be restrained completely by point P6, so μ is still very big, which means commutation from V4 to V6 will fail and short circuit at the DC side will continue to exist. Usually after 20ms from the moment of commutation failure, the short-circuit current will reach its maximum instantaneous value, which is 2 times of the rated DC current. About 50ms is needed for the DC current regulator at the rectifier side to diminish the DC current to set value or zero. After that, V6 or V4 will be trigged successfully and the short circuit will disappear.

When the value of commutation voltage drop or DC current rise is big, commutation from V2 to V4 may also fail after the failure of commutation from V1 to V3, in other words, two continuous commutation failures. In this case, V1 and V2 will keep conducting state nearly in a cycle, and inverse DC voltage at the inverter side will last 180° (about 10ms), bring down the counter electromotive force at the inverter side and enlarging the DC current.

Seen from the analysis above, if v4 is triggered successfully after the failure of commutation from V1 to V3, then short circuit at the DC side will be resulted in via V1 and V4, lasting about 50ms, and V1 and V4 will keep conducting in more than two cycles; otherwise, V1 and V2 will keep conducting nearly in a cycle.

Criterion for Commutation Failure

Currently, there are various criteria of commutation failure, but most of them are based on the γ_{min}, and derived on condition that some factors are constant during the commutation process, which is unreasonable and leads to low accuracy, limited application range. Commutation failure is the result from interactions among many factors, like DC current, set value of β or γ, converter bus voltage, equivalent commutation reactance, converter transformer transmission ratio, etc. Only considering the influence from some of these factors is likely to cause misjudgment, while it is impractical to take every factor into account. Hence, only by the substantive characteristics can realize the rapid and accurate diagnosis of commutation failure.

Although extinction angle method is based on the essence of commutation failure ($\gamma < \gamma_{min}$), and is the most commonly used method, two points need to be paid attention: first, γ can't be measured directly in practical engineering, and can only be acquired by indirect computing from operating parameters of the DC system, which means it is unable to trace the real-time variations of γ; second, γ_{min} is not constant, varying with the intrinsic parameters of thyristors, loaded voltage and current. In consideration of the two reasons, extinction angle may result in misjudgment in some cases, such as the state adjacent to commutation failure.

From above analysis of commutation process, it can be seen that commutation failure is always accompanied by the continuous conduction of certain valves — at least one cycle, with valve voltage being continuously zero and valve current being continuous with high amplitudes — about two times of the rated DC current, which can be regarded as two new substantive characteristics of commutation failure. Besides, measurement of valve voltage or valve current is very easy in practice. Therefore, the two substantive characteristics both can be used as a new criterion for commutation failure.

Fault Simulation and Analysis

The simulation model is based on the monopolar 12-pulse CIGRE HVDC standard test system, whose rated DC voltage is 500kV, DC current is 2kA and transmitted power is 1000MW. Inductive grounding short circuit is the most common fault in power system. Firstly, a three-phase inductive grounding fault is set in the inverter bus, and the fault occurs at 0.6s, the time of duration is 0.05s, the value of fault inductance is 0.2H, and the total simulation time is 1.2s. Simulation results are shown in Fig. 3-Fig. 6.

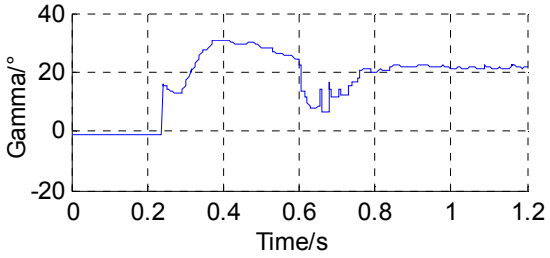

Fig. 3 Waveform of extinction angle

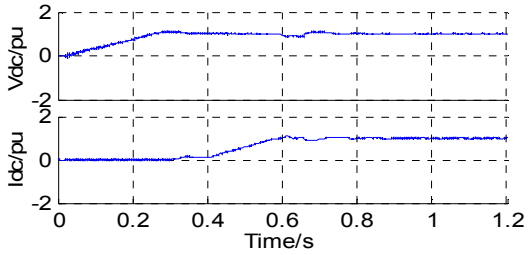

Fig. 4 Waveform of DC voltage and current

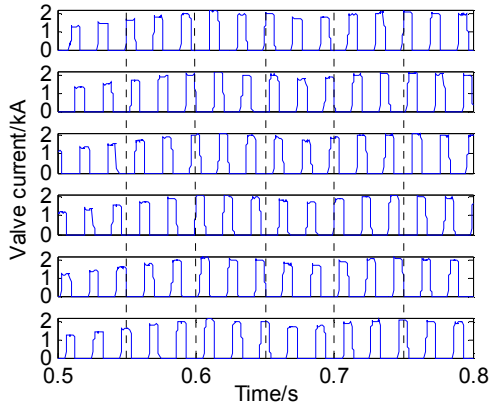

Fig. 5 Waveform of valve voltage

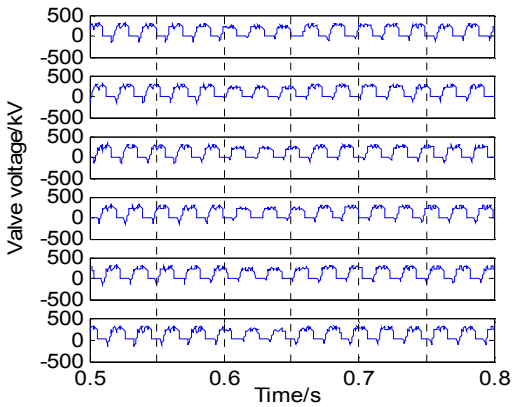

Fig. 6 Waveform of valve current

Fig. 3 shows that the minimum value of γat the inverter side is 6.2° during the fault. A conclusion of commutation failure can be drawn according to extinction angle method, which conflicts with the phenomenon in Fig. 4, for no drop to zero of DC current and fast-rising of DC current happens. Further analysis of valve voltage waveform shown in Fig. 5 and valve current waveform shown in Fig. 6 indicates that each valve is triggered successfully in normal turns; there are merely some small numerical fluctuations caused by the grounding fault; phenomenon of being continuously zero of valve voltage and being continuous with high amplitudes does not appear. Hence, we can come to the conclusion that commutation failure does not occur after the grounding fault, and this agrees with the waveform of DC voltage and current in Fig. 4.

Secondly, fault inductance of the three-phase inductive grounding fault is decreased to 0.1H, and other fault parameters are the same as the first case. Simulation results are shown in Fig. 7-Fig. 9.

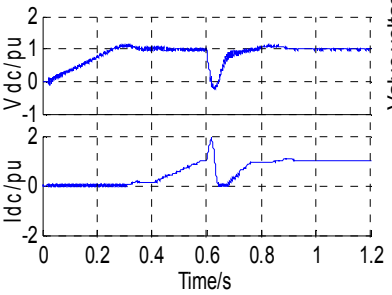

Fig. 7 Waveform of DC voltage and DC current

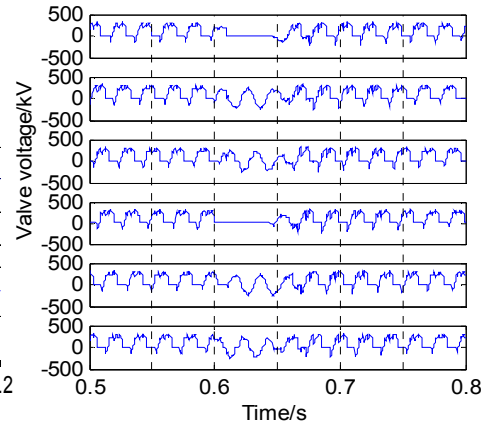

Fig. 8 Waveform of valve voltage

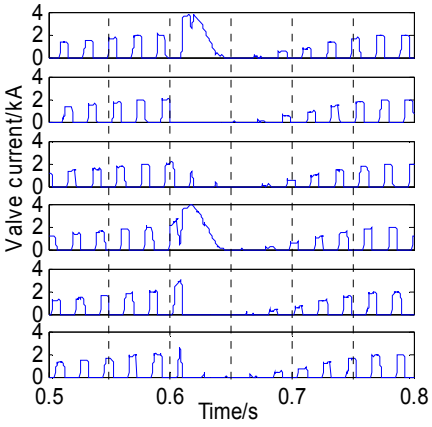

Fig. 9 Waveform of valve current

As shown in Fig. 8 and Fig. 9, V1 and V4 keep conducting during the fault and the duration time is about two cycles for valve voltage being continuously zero and valve current being continuous with high amplitudes which are about two times of the rated DC current. Therefore, commutation failure happens after the grounding fault, and this conclusion is coincident with the drop to zero of DC voltage and fast-rising of DC current shown in Fig. 7.

Simulation and analysis of other two typical faults — single phase grounding fault of AC system at the inverter side and loss of inverter trigger pulse, is also carried out. Simulation results also prove that it is accurate to diagnose whether commutation failure of HVDC occurs or not.

Conclusions

(1) Commutation failure is always accompanied by the continuous conducting of certain valves, and this makes the corresponding valve voltage being continuously zero, valve current being continuous with high amplitudes, which can be regarded as the substantive characteristics of commutation failure besides $\gamma < \gamma_{min}$.

(2) Extinction angle method may result in misjudgment in some cases such as state that is adjacent to commutation failure, due to the influence from calculation errors of $\gamma$and variations of γ_{min}.

(3) A new method for the diagnosis of commutation failure based on valve voltage or valve current is proposed in this paper. Simulation results prove the accuracy and effectiveness of this method.

Abstract. Due to the high current density in 77K, the high temperature superconducting facilities are expected to improve the efficient in power transmission. Superconducting facilities electromagnetic design is highly dependent on the characteristic of the superconducting tape. As a result, the comparison of the effect of different tape in electromagnetic design should be studied. In this paper, several facilities model are used as example to analyze the effect of different tape utilization. The result shows in different application conditions, or, specific benefits are considered, there is a specific tape will be the best choice.

Introduction

Superconductor have many advantage in power applications, such as power cable, fault current limiter as well as power transformer and reactor due to the high current density in superconducting state. In last years, many research in these area have achieved significant improvement especially in DC superconducting cable [1]-[3]. Because of the deeper research of the HTS Roebel cable in the Karlsruhe Institute of Technology [4], the AC losses in the AC applications could be expected to be reduced to a much lower level. Thus, the HTS will be used in more and more power facilities.

Electromagnetic model of the superconducting power facilities, for example, the FEM model, are widely used to analysis the performance of the superconductor and they could be used in the design superconducting magnet. In the magnet design, the tape character has a huge impact on the result, so we need to investigate this kind of effect.

In this paper, we present several electromagnetic models of the superconducting facilities and analyzed the effect on the represent of the device with different tape. The result could help us choose the type of tape when we design the superconducting magnet to obtain a specific function.

HTS Cable

Superconducting cable is expected to solve the limited channel space in the transmission system by using the high current density of the superconductor.

Table 1. HTS Tapes Properties

Type Name	Type-H (Sumitomo)	SCS4050 (Superpower)
Tape thickness	0.35[mm]	0.1[mm]
Tape wideness	4.2[mm]	4[mm]
Critical Current	180[A]	120[A]

Using a double layer (24 tapes each layer) cable as an example in order to analysis the magnetic field distribution. As to compare the different tapes effect, two kinds of tapes are applied as Table 1.

Fig.1 gives the magnetic distribution when a $I = 12 \times 80 \times 0.8A$ current has applied, the axial component and the racial component of the magnetic field have been illustrated in this figure.

The results show that when SCS 4050 tape applied to the model, the maximum of the racial component is 141Gs, while it is 94.9Gs when Type H tape used in this model.

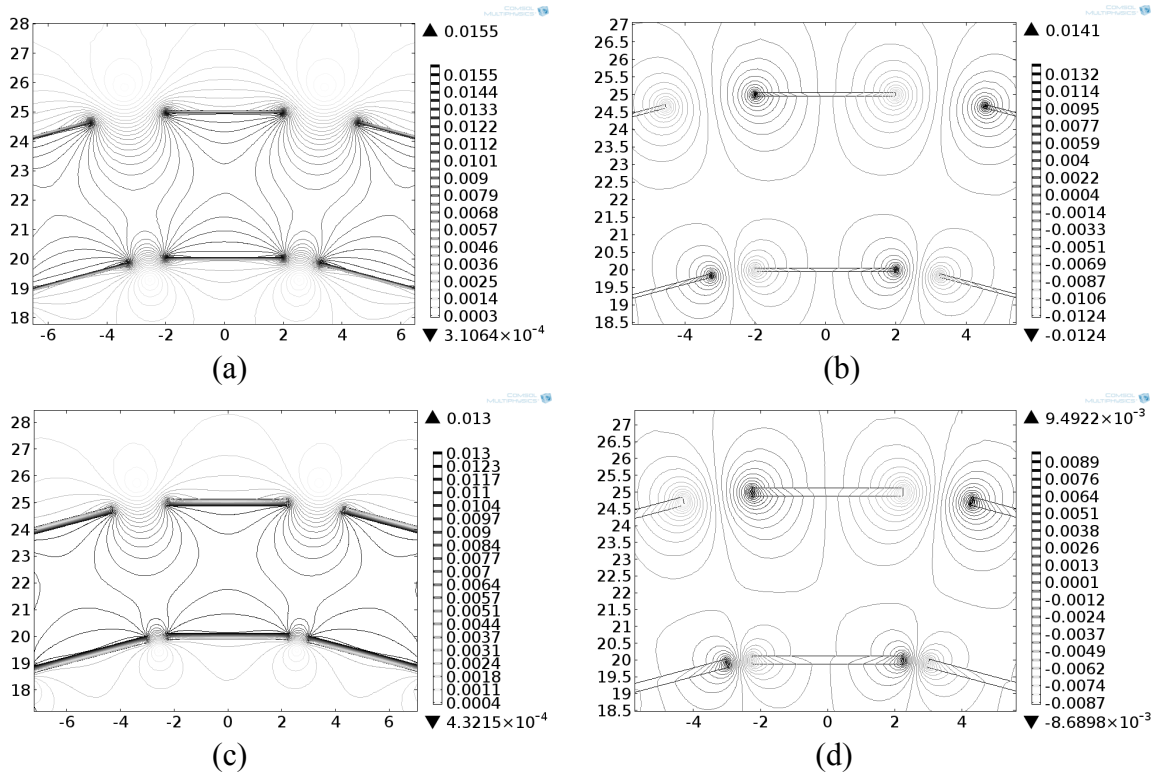

Fig. 1 The magnetic field density distribution of the cable
(a) SCS4050, absolute value (b) SCS4050, racial component
(c) Type H, absolute value (d) Type H, racial component

By using the load line and the B-T relationship of the HTS tapes, the critical current of the superconducting magnet could be obtained. Usually there should be a margin of the working current and the critical current, in this analysis, this margin is set to 0.7. Fig.2 shows the B-I curve and the load line with its cross point.

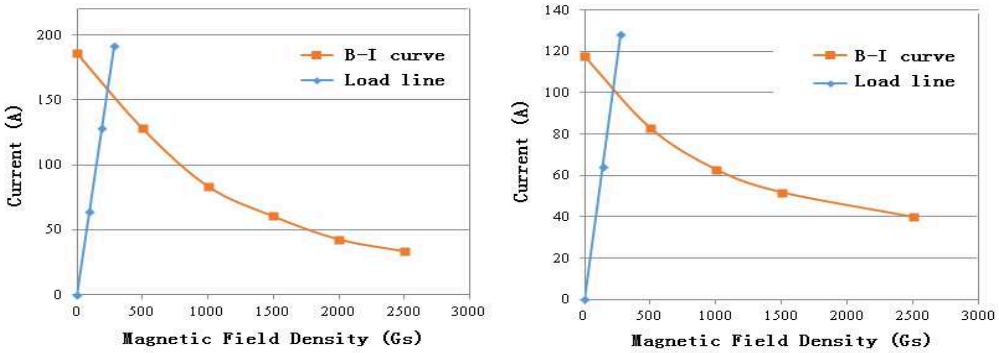

Fig. 2 The calculation of the critical current

The working current of the cable made by SCS4050 tape is 1696.8A and made by Type H is 2721.6A. Both of them have used tape data in 77K. This result indicates the type H type is more efficient for fabricate the power cable.

HTS Transformer

Transformers using HTS tapes are attractive because they are much smaller and have enormous overload capacity. Moreover, the operation of the superconducting transformer do not need insulation oil, that's make it become a more environmentally friendly facility.

To know which kind of tape is more suitable in this application, different types of tapes have been used in a Single Phase HTS transformer model, whose capacity is 110kVA.

The Table 2 listed the specification of the singe phase transformer. Fig 3 shows the geometry model as well as the magnetic field distribution of the calculation result. This general result shows the leakage flux in the transformer is the key factor which determine the critical current of the windings.

Table 2. Specification of a Single Phase HTS Transformer

Specification	Value
Phase	1
Capacity	110kVA
Rated voltage	25kV/365V
Number of turns	Primary 2092/ Secondary 72
Parallel conductors	Primary 1/ Secondary 12

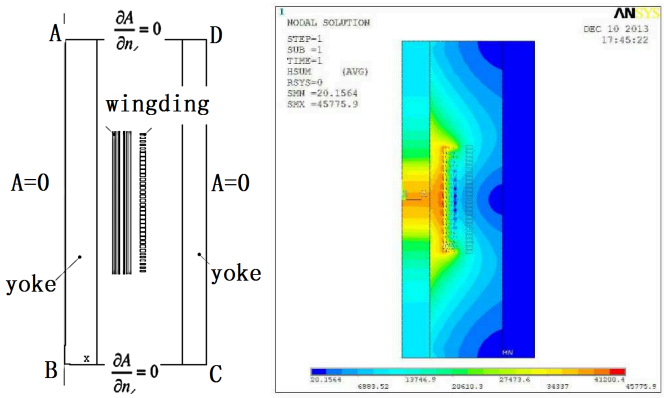

Fig. 3 Geomertry model (left) and the general magnetic field distrbution (right) of a HTS trasformer

In the Secondary winding, the conductor is consist of 12 parallel conductors. Although the current could transfer in these conductors when the winding is quenched, we still using the load line and the B-T relationship of single tape to calculate the critical current.

Fig 4 illustrates the racial component of the magnetic field density in the condition of using the AMSC-copper tape. It shows the maximum magnetic field density is in the third layer of the winding.

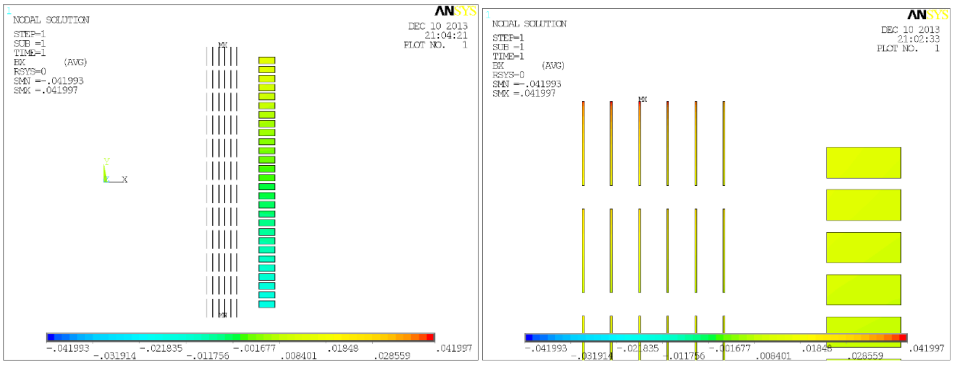

Fig. 4 The racial component of the magnetic field density of a transformer (left: whole windings; right: top of the windings)

The calculation could get the minimum critical current of the winding tape, which is determined the overload capacity: the bigger the critical current is, the larger the overload capacity will be. Table 3 gives the result and it indicates that the FYSC-SC05 has the highest minimum critical current value, so it is the best choice for the transformer.

Table 3 Simulation Result

Types	B_max T）	Br_max T）	Bz_max T）	Ic_min A）
AMSC-Copper	0.050158	0.041993	0.049108	95.84
SP-SCS4050	0.056298	0.047298	0.054786	81.08
Type HT-SS	0.05165	0.043167	0.050951	128.42
FYSC-SC05	0.047957	0.040112	0.047039	207.72
SUNAM	0.055686	0.046665	0.05467	138.82

Conclusions

In this paper, a HTS cable model and a HTS transformer model are analyzed by using different tape, and the result could guide researcher choose the type of conductor. For the cable, the result shows in 77K condition, the 1st generation HTS have significant advantage because of the high current density. As to the HTS transformer, the overload capacity is what we are aimed for and Simulation results shows that the FYSC-SC05 has the highest minimum critical current value, so it is the best choice for the transformer.

A New Method of Evaluating the Sensitivity of Sensitive Load to Voltage Sag

Ruibin Luo[1, a]

[1] Dongguan power supply bureau, Guangdong grid corporation, China

[a]469569945@qq.com

Keywords: sensitive load; voltage sag; load sensitivity; sensitivity evaluation; probability density function

Abstract. This paper proposes a new method to evaluate the voltage sag sensitivity (VSS) of the sensitive load by the combination of several probability density function models, which can fully describe the randomness of load sensitivity. Firstly, five common probability density functions were respectively used to build the mathematical model of voltage tolerance curve (VTC) of sensitive load in uncertainty region. Secondly, the VSS of sensitive load was respectively evaluated by five models, and the weighted sum of five models' results was calculated by unbiased variance method. In the end, the proposed method was verified to be rational according to an application example.

Introduction

With the wide application of sensitive equipments, the voltage sag may cause sensitive equipments fail to work, which arouses the concern of the industrial circles. The probability of sensitive load breaking down in uncertainty region of voltage tolerance curve (VTC) is named voltage sag sensitivity evaluation. Current evaluation methods of voltage sag sensitivity for distribution network loads mainly includes the ITIC curve method, CBEMA curve method [1-3], the fuzzy evaluation method[4,5], the stochastic assessment method[6-9], the combination of fuzzy and stochastic theory method, the evaluation method based on cloud model [10,11] and the evaluation method based on maximum entropy theory [12-14].ITIC and CBEMA curve are fixed. Their duration lasts 0.5 cycle to 1 minute and voltage RMS value lasts 0.1 to 0.1 times the rated voltage, which does not include a full range of voltage sag. The two curves are both experimental curves, and need to have a lot of historical data, therefore the application's performance is not good enough. The fuzzy evaluation method makes use of membership degree that equipment belongs to the normal state to describe the transition state of equipment shifting from safety state to failure state during voltage sag event, and assumes that these verity probability of voltage sag follow Gaussian distributions, so this method is much affected by the selected samples, and the error depends on the number of samples.

The probability density function is used by stochastic assessment method to characterize the randomness of the load's voltage in uncertainty region of voltage tolerance curve, and to evaluate the sensitivity of the voltage sag directly. An appropriate probability density function is the key to improve the accuracy of the results of this method. The accuracy of the method based on cloud model depends on the accuracy of the characterization of voltage tolerance ability of the equipment, so it needs enough field experience. The evaluation method based on maximum entropy theory fully describes the randomness of voltage sag sensitivity. However, compared to the probability density function model, it's relatively complicated because of the computing process.

Probability density functions include uniform distribution, exponential distribution, Gaussian distribution, Rayleigh distribution, Weibull distribution and so on. The current probability evaluation methods use only one probability density function. However, in practice, it is very hard to fully describe the randomness of voltage sag sensitivity by a single probability density function model due to its one-sidedness, which cannot avoid error evaluation results.

This paper proposes a new method of evaluating voltage sag sensitivity, with five probability density functions respectively used to build the sensitivity evaluation model, and the assessed values of five models are added by mean square error method. This method highlights the consistency of the

conclusions of all of the models, meanwhile combines the different information of those models. This method makes full use of all the evaluated information, and the evaluation results are optimized combination, which can adapt to a more general stochastic environment.

This paper is organized as follows: Section II introduces the stochastic model of the voltage tolerance curve. Section III introduces the algorithm principles. Section IV introduces the algorithm design. And the cases are analyzed in section V. Section VI is the conclusions and the end is references.

Stochastic Model of the Voltage Tolerance Curve

Voltage tolerance curve of sensitive load and its uncertain region . The voltage tolerance ability of sensitive load changes along with the change of time and space. Usually, the sensitive equipments mainly include Programmable Logic Controller (PLC), Personal Computer (PC) and AC Speed Drive (ASD) and so on. Thevoltage tolerance curves (VTC) of PLC, PC and ASD are generally rectangular, their uncertain region is shown in Fig.1, and divided by Umin, Umax, Tmin and Tmax, among them, Umin and Umax are the minimum and maximum values of the amplitude of voltage tolerance; Tmin and Tmaxare the minimum and maximum values of duration of load voltage sag. In figure1,the normal operation region is the region that the actual amplitude of a voltage sagU>Umax or duration of load voltage sagT<Tmin,the fault region is the region that the actual amplitude of a voltage sagU<Umax or duration of load voltage sagT>Tmin. Uncertain region is between the two regions, and it can divided into three sub-regions (A, B and C), in which, A zone is the range of U <Umin and Tmin<T <Tmax;B zone is the range ofUmin<U<Umax and T>Tmax;C zone is the range ofUmin<U<Umax andTmin<T<Tmax. The Thresholds of different resistance curves of sensitive loads are shown in Table 1.

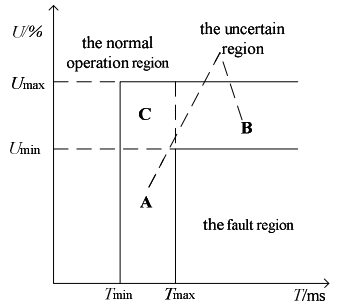

Fig.1 Uncertain region of sensitive load isVTC

Table 1 Threshold of sensitive load VTC

Type	Voltage Amplitudes p.u.		Duration ms	
	U_{min}	U_{max}	T_{min}	T_{max}
PLC	30	90	20	400
ASD	59	71	15	175
PC	46	63	40	205

Probability expression of the voltage tolerance curve of sensitive load. In fact, the position of load voltage tolerance curve is random, that is, U and T are random variables. Suppose that U and T are independent random variables, the probability density of random variables T and U in A zone and B zone are $f_a(T)$ and$f_b(T)$,so that the joint probability density of random variables U and T in C area is:

$$f_c(T,U) = f_a(T) f_b(U) \tag{1}$$

in which, Umin<U<Umax ,Tmin<T<Tmax.

Algorithm Principles

The commonly used probability density function. The commonly used probability density function includes 5 kinds of function, which are Uniform distribution function,Exponential distribution function, Normal distribution function,Rayleigh distribution function and Weibull distribution function.

In which， Uniform distribution is the ideal probability distribution.Exponential distribution belongs to thepartial type function;its characteristic is that it has value in the unilateral interval.Normal distribution, Rayleigh distribution and Weibull distribution belong to the middle type function;their characteristic is the interval symmetry. The characteristics and disadvantages of these 5 kinds of probability density function can be summarized as shown in Table 2.

Table 2 Comparison between five common probability density functions

Density functions	Characteristics	Disadvantages	Remarks
Uniform distribution	Equal probability distribution, in a given area in every point is equal to the probability of the event.	Belongs to the ideal situation; Lack of flexibility,can't fit the actual situation very well.	—
Exponential distribution	Belongs to the monotonically decreasing,the starting point has the maximum of probability density, then backward gradually decreases.	Monotone function,sometimes the error is larger when compared with the actual situation.	—
Normal distribution	There exists a maximum probability density point, the rest probability density values decrease to both sides,from the near to far distance the center, the change is slow down after,and the rate of change is controlled by parameters.	Difficult to determine theParameters.	The difference between these three kinds of function model is the decreasing speed,by selecting different parameters to determine the decreasing speed,to adapt to different practical problems.
Rayleigh distribution	There exists a maximum probability density point, the rest probability density values decrease to both sides,from the near to far distance the center, the change is slow down after,and the rate of change is controlled by parameters.	Difficult to determine theParameters.	
Weibull distribution	There exists a maximum probability density point, the rest probability density values decrease to both sides,from the near to far distance the center, the change is slow down after,and the rate of change is controlled by parameters.	Difficult to determine theParameters.	

Unbiased variance method. Unbiased variance method is one kind of objective method of endow with weight, which determines the weight coefficient in evaluating sensitivity based on variation of evaluating value between various evaluation methods. Assumed that there are n kinds of evaluation methods s_1, s_2, s_3, …, s_n. And m evaluating values x_{i1}, x_{i2}, x_{i3}, …, x_{im} can be obtained by method s_i. Steps of mean square error method to determine the weight coefficient are as follows:

(1)The mean of evaluating value of various evaluation methods is :

$$\overline{x_i} = \frac{1}{m}\sum_{k=1}^{m} x_{ik} \tag{2}$$

In this equation, xik represents kth evaluating value by method si, $\overline{x_i}$ represents the mean of evaluating value by method s_i, i=1, 2,..., n, k=1, 2,..., m.

(2)The variance of evaluating value of various evaluation methods is:

$$s_i^2 = \frac{1}{m}\sum_{k=1}^{m}(x_{ik} - \overline{x_i})^2 \tag{3}$$

In this equation, s_i^2represents the variance of evaluating value by method s_i.

(3)Weight coefficient of various evaluation methods is:

$$a_i = \frac{s_i}{\sum_{i=1}^{n} s_i} \tag{4}$$

In this equation, ai represents the degree of importance of evaluation method sirelative to evaluating object which is called weight coefficient, i=1, 2, ..., n.

Now, use the weighted sum of method s1 and s2 to analyze the reliability of the method.

Assume that the real VSS of the sensitive load is p0, and the evaluating values obtained by s1 and s2 are p1 and p2. So the weighted sum p is:

$$p = \alpha p_1 + (1-\alpha) p_2 \tag{5}$$

In this equation, α is a weight coefficient.

Let the error of evaluation be E=p-p0, then the square error of evaluation is:

$$E^2 = (p - p_0)^2 = [\alpha(p_1 - p_2) + p_2 - p_0]^2 \tag{6}$$

Take a derivative of E2 for optimal results:

$$\frac{\partial(E^2)}{\partial\alpha} = 2E(p_1 - p_2) \tag{7}$$

Then the iterative formula of α is as follows according to steepest descent method.

$$\alpha(n+1) = \alpha(n) - \lambda\frac{\partial(E^2)}{\partial\alpha} \tag{8}$$

In this equation, λ is a control coefficient.

The difficulty of this optimization algorithm is to determine p_0 and control the convergence. In order to simplify calculations, p_0 is defined as:

$$p_0 = (p_1 + p_2)/2 \tag{9}$$

In practical application, especially in the occasion where high control requirement of computing resource is preferred, the direction and number of iterations can be controlled as required.

The random estimation model of VSS. As shown in Fig.2, M_1-M_5 represents 5 different features of voltage sag: the voltage sag events happen in normal operation region, fault region, A region, B region and C region. When M_1 happens, all loads work well, while M_2 happens, all loads are broken. Assume that $T_3$is the duration of voltage sag when M_3 happens. Then when M_3 happens and $T_{min}<T<T_3$, the sensitivity of load is:

$$p_T = \int_{T_{\min}}^{T_3} f_a(T)dt \tag{11}$$

Assume that U_4 is the amplitude of voltage sag when M_4 happens. Then when M_4 happens and $U_4<U<U_{max}$, the sensitivity of load is:

$$p_U = \int_{U_4}^{U_{\max}} f_b(U)du \tag{12}$$

Assume that T5 and U4 are the duration and the amplitude of voltage sag when M5 happens. Then when M5 happens and Tmin<T<T5,U5<U<Umax, the sensitivity of load is

$$\int_{U_5}^{U_{\max}}\int_{T_{\min}}^{T_5} f_{ab}(T,U)dudt \tag{13}$$

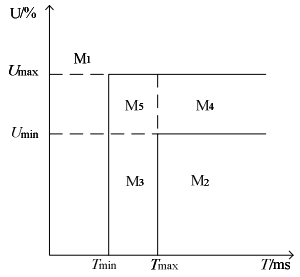

Fig.2 Schematic of sensitive load voltage sag event

Algorithm Design

The processes of weighted comprehensive evaluation algorithm in this paper are as follow:

(1)According to the category of load, identify the uncertain regions of VTC (Tmin, Tmax, Umin, Umax), and classify them into 3 uncertain subregions shown in Fig.1.

(2)Use five common probability density functions to build the evaluation model, and valuate the VSS of sensitive load running in different uncertain subregions according to 5 different features of voltage sag and equations (11)-(13).

(3)According to equations (2)-(4), use unbiased variance method to obtain the evaluation results' weighted value of various probability density function models. For region A, let the weight coefficient of probability density function models si be ai. For region B, let the weight coefficient of probability density function models si be bi. And the weight coefficients satisfy the following conditions:

$$\begin{cases} \sum_{i=1}^{5} a_i = 1 \\ \sum_{i=1}^{5} b_i = 1 \end{cases} \tag{14}$$

(4)According to the weight coefficients ai and bi, the VSS of sensitive load is evaluated by five probability density functions evaluation models, and the weighted sums of these five models in region A, B and C are:

$$p_A = \sum_{i=1}^{n} a_i p_{Ti} \tag{15}$$

$$p_B = \sum_{i=1}^{n} b_i p_{Ui} \tag{16}$$

$$p_C = \sum_{i=1}^{n} c_i p_{TUi} \tag{17}$$

In these equations, p_{Ti}, $_{Ui}$ and p_{TUi} represent the VSS of sensitive load in subregion A, B and C by probabilitydensity functions evaluation model si, respectively. a_i, $_i$ and c_i represent the weight coefficient of model si in subregion A, B and C. And $\sum_{i=1}^{n} a_i = 1, i = 1,2,\cdots,n$, $\sum_{i=1}^{n} b_i = 1, i = 1,2,\cdots,n$, $c_i = \frac{a_i + b_i}{2}, i = 1,2,\cdots,n$.

Simulation Analysis

The paper used Matlab as the auxiliary tool for simulation analysis, and made the evaluation of voltage sag sensitivity of sensitive load of PC. According to the research of literature [7], setting $U_{\min}$, $U_{\max}$, $T_{\min}$, $T_{\max}$ of the model as 46%p.u., 63%p.u., 40ms and 205ms[7] and calculating each weight of probability density function of evaluation model based on unbiased variance method, which was shown in the Table 3.

Table 3 Weights of probability density functions

Probability density functions	Weights		
	Region A	RegionB	Region C
Normal distribution	0.324	0.284	0.304
Uniform distribution	0.165	0.151	0.158
Exponential distribution	0.105	0.145	0.125
Rayleigh distribution	0.246	0.241	0.244
Weibull distribution	0.160	0.179	0.169
Total	1	1	1

According to the result of the weight distribution of Table 3,the evaluation functions of PC voltage sag sensitivity of region A and region B could be obtained:

$$P_A = 0.324P_{T1} + 0.165P_{T2} + 0.105P_{T3} + 0.246P_{T4} + 0.160P_{T5} \quad (18)$$

$$P_B = 0.284P_{T1} + 0.151P_{T2} + 0.145P_{T3} + 0.241P_{T4} + 0.179P_{T5} \quad (19)$$

Where PT1, PT2, PT3, PT4 and PT5 are respectively evaluation values of voltage sag sensitivity of sensitive load PC of each evaluation model.

Therefore, when voltage sag took place in region A and region B，the evaluation values of PC's voltage sag sensitivity were shown in the Fig. 3(a) and Fig. 3(b).It could figure out that the valuation values of various probability density function models were different comparatively and the bias between valuation values, which had been weighted and synthesized, and the evaluation values of various models was smaller.

Similarly, when voltage sag took place in region C, the evaluation function of PC sensitivity was:

$$P_C = 0.304P_{T1} + 0.158P_{T2} + 0.125P_{T3} + 0.244P_{T4} + 0.169P_{T5}$$

According to the comprehensive evaluation value getting from formula (20),we could describe the possibility of trouble happening when loads worked in region C.

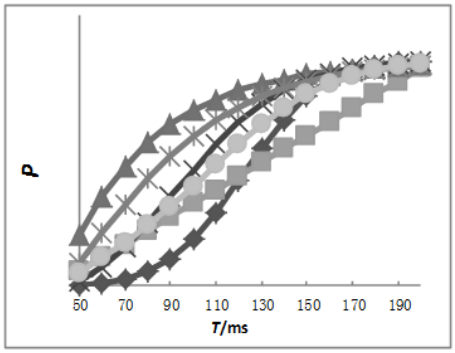

Fig.3(a) The voltage sag sensitivity of PC in region A

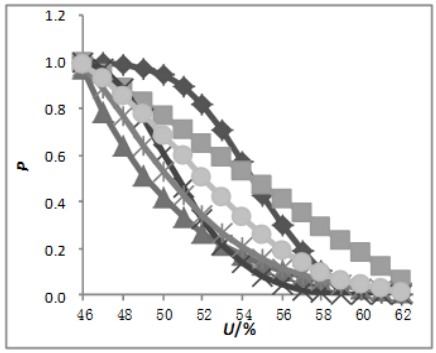

Fig.3(b) The voltage sag sensitivity of PC in region B

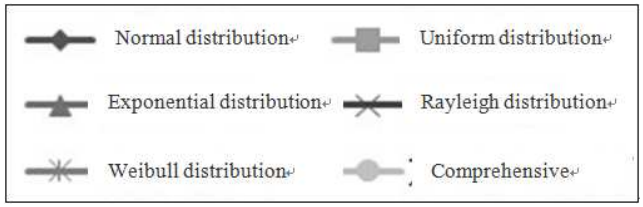

Fig.3(c) Legend

Table 4 Bias and variance between evaluation values and average values in region A

T/ms	Bias

According to the simulation analysis of Fig. 3(a), (b) and Table 4,we could obtain the following conclusions:

(1) The algorithm bias are smaller in this paper. The evaluation bias getting from Weighted comprehensive evaluation algorithm are up to 10-2, 10-3 order of magnitude. These minimum bias is -0.002 and maximum bias is -0.057,which is smaller than far the valuation bias of evaluation model of each single probability density function.

(2) The algorithm has preferable stability. In Table 5,the evaluation bias range of normal distribution is from -0.011 to -0.291, the evaluation bias range of uniform distribution is from -0.015 to -0.192, the evaluation bias range of exponential distribution is from -0.003 to -0.307, the evaluation bias range of rayleigh distribution is from -0.009 to -0.069, the evaluation bias range of weibull distribution is from -0.003 to -0.167, and the evaluation bias range of Weighted comprehensive evaluation algorithm is from -0.002 to -0.057 and its mean square error is only 0.0006,which is up to 10-4order of magnitude. It is thus clear that the fluctuation of sensitivity evaluation value of each single probability density function model is superior. However, the bias of weighted comprehensive evaluation value is smaller relatively and has better stability so that it can work better for the evaluation of voltage sag sensitivity of different sensitive loads.

Conclusion

1) The stochastic evaluation method of voltage sag sensitivity of sensitive load can gain the evaluation value of sensitivity by the probability density function. If we only choose a sort of probability density function, it will be difficult to overcome its one-sideness and possibly get the evaluation value with larger bias.

2) The stochastic evaluation method of voltage sag sensitivity in this paper gains the final comprehensive evaluation value by means of building five models of probability density function respectively and using unbiased variance method for weighting comprehensively the evaluation values of this five models. What the consistent conclusions of each model this algorithm emphasizing remains the different parts to a lesser extent among the valuation results of probability density functions so that it can comprehensively describe the sensitivity's randomness better than single probability density function model.

3) Finally, by the simulation analysis, the proposed method is verified to be rational in the application of random evaluation of voltage sag sensitivity of sensitive load.

4) It is because the method increase the calculated amount that it might cause problems of more space occupation in memory and longer calculation time. Therefore, the method in this paper applies to the occasions which not require accurate calculated results or strongly-real-time calculation.

Keywords: Resonant Grounded System, Fault Line Selection, Single Phase Ground Fault, Sample Entropy (SampEn), Empirical Mode Decomposition (EMD), Intrinsic Mode Entropy (IMEn).

Abstract. When the single phase ground fault occurs in resonant grounded system, there are significant differences in the components of fault phase current between fault line and non-fault line. This feature can be reflected by intrinsic mode entropy (IMEn) of fault current. IMEn is a new signal analysis over multiple oscillation levels. It corresponds to the sample entropy (SampEn) and the empirical mode decomposition (EMD). The results of fault simulations in different conditions indicate that the method is reliable.

Introduction

Fault line selection in resonant grounded system has not been well solved yet. The traditional fault features applied to dealing with this problem contain amplitude, phase, energy and so on. It's a growing trend to uncover the new fault features to improve the traditional methods. The approach to fault line selection using similarity recognition based on time-frequency spectrum is presented in [1]. The method based on energy entropy measure is proposed in [2]. The approach using empirical mode decomposition and Duffing oscillator is proposed in [3].

Intrinsic mode entropy (IMEn) is able to quantify the degree of regularity and complexity in time series over multiple oscillation levels [4]. There are differences in the frequency components of fault phase current between fault line and non-fault line [5]. Then IMEn can be used to indicate these differences and select the fault line. Digital simulations verify the reliability of the proposed method.

Concept of Intrinsic Mode Entropy

IMEn is a combination of Sample entropy (SampEn) and empirical mode decomposition (EMD). Firstly, give the definition of SampEn. Give a time series $x(n)=\{x(1),x(2),\cdots,x(N)\}$, where N is the total number of data points. SampEn algorithm can be summarized as follows:

1) Define m-vectors, from $X_m(1)$ to $X_m(N-m+1)$:

$$X_m(i)=\left[x(i),x(i+1),\cdots,x(i+m-1)\right] \quad i=1,\cdots,N-m+1 \tag{1}$$

2) Define the distance $d_m\left[X_m(i),X_m(j)\right]$ between $X_m(i)$ and $X_m(j)$:

$$d_m\left[X_m(i),X_m(j)\right]=\max_{k=0,\cdots,m-1}\left[\left|x(i+k)-x(j+k)\right|\right] \tag{2}$$

3) Calculate the number of $d_m\left[X_m(i),X_m(j)\right]\le r$ and then divide it by $N-m+1$. The result is defined as $B_i^m(r)$.

4) Define m+1-vectors, and repeat the prior steps. The result is defined as $A_i^m(r)$.

5) Define $A^m(r)$ and $B^m(r)$:

$$\begin{cases} A^m(r) = \dfrac{1}{N-m}\sum_{i=1}^{N-m} A_i^m(r) \\ B^m(r) = \dfrac{1}{N-m}\sum_{i=1}^{N-m} B_i^m(r) \end{cases} \tag{3}$$

6) Calculate SampEn:

$$SampEn(N,m,r) = -\ln\left(A^m(r)/B^m(r)\right) \tag{4}$$

The parameter m determines the length of the sequences to be compared and the recommend value is 2. The parameter r is the tolerance threshold for accepting similar patterns between two segments and is recommended to be within 0.1–0.2 times the standard deviation of the data.

The EMD is an intuitive signal-dependent decomposition of a time series into several intrinsic mode functions (IMF) of different time scale and residual.

$$x(t) = \sum_{i=1}^{n} imf_i(t) + r_n(t) \tag{5}$$

The proposed IMEn consists in computing the SampEn of the cumulative sums of the IMFs obtained by the EMD decomposition. The cumulative IMF sum up to order k is noted C_{IMF}^k and defined by:

$$C_{IMF}^k = \sum_{j=1}^{k} imf_j(t) \tag{6}$$

If n is the total number of intrinsic mode function (IMF), the residual can be regarded as the n+1 mode. So C_{IMF}^{n+1} corresponds to the original signal. The IMEn is then defined as:

$$IMEn(k,m,r) = SampEn\left(C_{IMF}^k(t), m, r\right) \tag{7}$$

The Principle of Fault Line Selection

To be convenient for explanation, single phase ground fault in a resonant grounded distribution network with two outlets is shown in Fig.1.

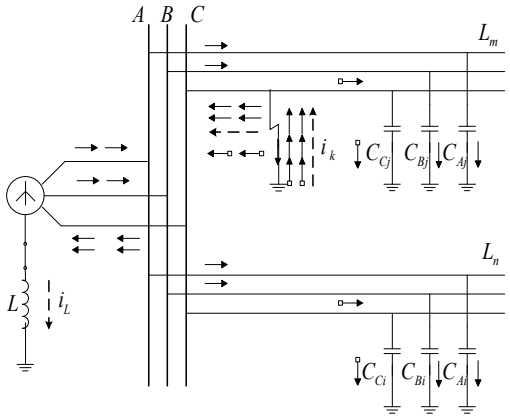

Fig.1 Fault current distribution

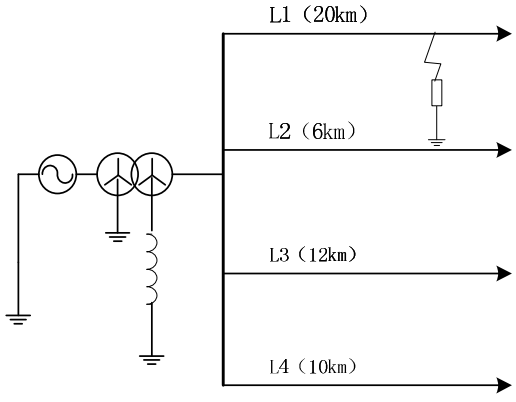

Fig.2 The simulation model of resonant grounded system

As shown in Fig.1, fault phase current in non-fault line contains only transient capacitance discharge current. However, fault phase current in fault line contains not only transient capacitance discharging current but capacitance charging current. The former results from the sudden voltage drop

of fault phase, and its oscillation frequency can reach several Kilohertz. The latter results from the sudden voltage increase of non-fault phase, and its oscillation frequency can just reach hundreds of Hertz [5].

In essence, IMEn is obtained by computing the SampEn of the cumulative sums of each of the IMF. This algorithm is robust to changes in low-frequency components of a signal. As is mentioned above, there are significant differences in the components of fault phase current between fault line and non-fault line. Therefore, the method is very appropriate for fault line selection in the resonant grounded distribution network.

The fault line selection of resonant grounded distribution networks using IMEn contains the following steps:

1) Collect the data of three phase voltage and current. The sampling rate is 10kHz. The sampling time of all signals is 60 ms from the time the fault occurs.

2) Extract the fault current. N stands for the number of sampling time per cycle. $\Delta i(k) = i(k) - i(k-3N)$.

3) Determine the fault phase by the change of phase voltage. If there is remarkable increase in one phase voltage, this phase is selected as fault phase.

4) Fault phase current of all outlets is decomposed by EMD. Determine the number of IMF as 9, with one residual regarded as the tenth IMF, for a total of 10 components.

5) Calculate the IMEn of the 10 IMFs. Finally, ten sets of results will be generated.

6) For each set of IMEn results, choose the minimum $IMEn_i^{\min}$ .Define the reliability index as K_{rel}. Through analysis of the effect of IMEn fault line selection, taking 1.1 for K_{rel} is proper. If the computed result of K_{rel} is less than 1.1, $IMEn_i^{\min}$ of this set of IMEn results does not exist.

$$K_{rel} = IMEn_i^{se\min} \Big/ IMEn_i^{\min} \quad i = 1, 2, \cdots, 10 \tag{8}$$

7) Count the number of $IMEn_i^{\min}$ belonging to the same outlet, and the results are normalized by dividing them by 10. Then some criterion is received.They are P_{L1}, P_{L2}, P_{L3}, P_{L4}.

8) Find the maximum of the criterion. It should belong to the fault line.

If busbar fault occurs, the method above can still be used to select one outlet. Then cut it off from the system. If the fault still exists, busbar fault will be confirmed.

Simulation Analysis

Firstly, establish a 10kv feeder system with 4 outlets. In order to simulate actual system better, this feeder system contains not only 3 overhead lines, but only one cable. Different fault conditions considered are grounding resistance, fault inception angle and fault position. The simulation model is established under the circumstance of MATLAB/SIMULINK. The parameters of overhead lines are shown as follow:

$r_0 = 0.34\Omega / km$, $r_1 = 0.19\Omega / km$; $l_0 = 4.93mH / km$, $l_1 = 1.22mH / km$; $c_0 = 0.0055\mu F / km$, $c_1 = 0.009\mu F / km$.

The fourth line is a 10km-long cable . The parameters of the cable are shown as follow:

$r_0 = 2.5\Omega / km$, $r_1 = 0.27\Omega / km$; $l_0 = 1.12mH / km$, $l_1 = 0.255mH / km$; $c_0 = 0.19\mu F / km$ $c_1 = 0.31\mu F / km$.

The inductance and resistance of the arc suppression coil can be given by formula(9) and (10). P stands for compensation degree and its value is 0.05. Q stands for active power loss and its value is 0.03. According to formula (9) and (10), the value of L and R is 1.54H and 14.5Ω. L1 and L4 are selected as the fault line. The simulation result is shown in Table 1. The simulation result shows that IMEn fault line selection fits for all these situations perfectly.

$$L = 1 \Big/ (1+\mathrm{P}) \times 3\omega^2 C_{\Sigma} \tag{9}$$

$$R_L = Q\omega L \tag{10}$$

Table 1 The results of fault line selection

Fault line	l_f / km	θ/(°)	R_f / Ω	criterion				Result of fault line selection

		0°	1000	0.1	0.1	0	0.7	L4

Conclusions

This paper presents a method for fault line selection in resonant grounded system based on IMEn. Firstly, select the fault phase. Then calculate the IMEn of fault phase current of each line and get the criterion. Choose the biggest one and select the fault line. The simulation results demonstrate that the algorithm is well adapted in resonant grounded system containing overhead lines and cables. For different fault conditions, the accuracy and reliability can be ensured.

Partial Discharge Detection of on-line cables Based on Hilbert Huang Transform

Li Fang

Henan Haihua Engineering Construction Supervision Company ,Zhengzhou,Henan,450003, China

tf2006tf2006@126.com

Keywords: Lock-in amplifier, Cable , Hilbert-Huang transform , Partial discharge .

Abstract. Hilbert-Huang transforms calculation method was used in the study on signal of partial discharge from on-line cable. The partial discharge signal was made to be intrinsic mode function (IMF) by empirical mode decomposition (EMD).The cubic spline interpolation was selected as the interpolation function and ideal envelope curve was achieved to eliminates defects such as overshoot and undershoot effectively. Appropriate lock-in amplifier was choosed and pre-amplifier and phase-sensitive detection circuit was designed to determine the calculation programs. The results showed that the test system can effectively capture the weak PD signals in cable under complex environmental conditions and the PD signal waveform obtained was improved through Hilbert-Huang transforms.The state of insulation and the remaining life of the cable can be judged effectively,which has practical significance for improving the grid security.

Introduction

XLPE cables was introduced into the country in the late of 1980s. Because of the excellent performance and good processing properties of insulating materials, it was widely adopted and gradually replaced the paper insulated power cables in power transmission lines in the country. However, cross-linked polyethylene (XLPE) is a kind of polymer, its purity was easily affected by the synthesis,bubbles could be generated in the manufacture or operation.The electric field strength is much higher than the surrounding medium, due to the small dielectric constant. While in the manufacturing and installation, defects will also be caused.All this factors will cause partial discharge after a few years under work environment of high electric field. Statistics showed that the cable partial discharge was one of the main reasons which damaged the power cable or reduced its operation life. Therefore, timely on-line detecting could monitor cable insulation state,so as to maintain and timely replac defected cable, thus avoiding significant losses. [1] In order to prevent sudden failure and blackouts or damaging of circuit and terminating equipment, reducing losses to the power companies or the user,on-line monitoring of the cable must be used.

In order to get good results, it is important to timely capture the relevant partial discharge signal and calculate its value more accurately. At present, a lot of exploration studies on detection of on-line XLPE cable has been done in domestic and abroad. However, there is not much good practice effect. The main reason is that the actual workig environment of cable is relative complex and bad . The discharge signal is difficult to capture the signal so that the amount of discharge can not be accurately determined. Considering above factors, we designed test systems with digital lock-in amplifier during the partial discharge test , so the weak PD signal was easy to extract.meanwhile Hilbert-Huang conversion was applied, and the relevant calculation program was prepared. [2]Thus partial discharg could be emeasured during the cable was in operation and good results were achieved.

Hilbert - Huang Transform

Basic principle of Hilbert - Huang transform. Because the collected signal contained a lot of nonlinear signals, the effect of calculation according to the traditional Fourier transform was far from ideal. Therefore, the collected signal function should be processed by Hilbert - Huang Transform. Hilbert - Huang algorithm contains two parts. first, the signal could be turned into intrinsic mode function (IMF) by means of Empirical Mode Decomposition (EMD).Second,Hilbert spectrum was

available in the time-frequency plane and could be displayed on the instrument by using Hilbert transform. The maximum and minimum of signal should be fitted during process of Empirical mode decomposition,ensure that the fitted curve contained all the signals. So both envelope curves of the signal was available. [3] During this process, in order to eliminate overshoot and undershoot defects, cubic spline interpolation should be taken as an interpolation function, so the desired envelope curve could be gotten.

Calculation about Hilbert - Huang Transform. Function of acquired signal was set as m(t).Then the envelope curve of starting sequence data could be obtained by taking cubic spline function.After calculating its mean n (t),the difference between the both value is the function without low frequency. namely:

$$u(t) = m(t) - n(t) \tag{1}$$

Repeating the above calculation process until the u (t) was in line with IMF component characteristics,the first IMF component obtained at this time of was the most high-frequency component among signals.namely:

$$f_1(t) = u_{1(n-1)}(t) - n_{1n}(t) \tag{2}$$

Then the difference signal component can be obtained without high-frequency component.

$$v_1(t) = m(t) - f_1(t) \tag{3}$$

So a number of IMF components could be gotten successively.

$$v_n(t) = v_{(n-1)}(t) - f_n(t) \tag{4}$$

When vn (t) was a monotonic function, the process was over.

$$m(t) = \sum_{j=1}^{n} f_j(t) - v_n(t) \tag{5}$$

Then spectrum of the signal obtained by using Hilbert - Huang transform was as follows:

$$H(\omega,t) = \mathrm{Re}\sum_{i=1}^{n} m_i(t)e^{j\omega_i(t)dt} \tag{6}$$

Howevwe spectrum of the signal obtained by using Fourier algorithms was as follows:

$$F(\omega,t) = \mathrm{Re}\sum_{i=1}^{\infty} a_i e^{j\omega t} \tag{7}$$

It is not difficult to see that processing of instantaneous frequency changes for signals with Hilbert - Huang transform is more reasonable. [4]

Partial discharge test. The measuring principle of partial discharge was shown in Figure 5. The pulse could be achieved through the detection resistor when the discharge took place.The reason was that after the partial discharge,the charge which was generated due to the charge exchange effect at both ends of the cable would formed pulse current. [5]When the test loop parameters were certain, the voltage across the sample was as follow:

$$u_x = \frac{q}{C_x + \dfrac{C_k C_d}{C_k + C_d}} \tag{8}$$

The voltage on the detection resistor was:

$$U_{do} = \frac{q}{C_T} \tag{9}$$

Where:

$$C_T = \frac{q}{C_x(1 + \dfrac{C_d}{C_k}) + C_d} \tag{10}$$

The voltages on the detected impedance usually change exponentially with time, i.e.

$$u_d = u_{d0}e^{-\frac{t}{\tau_1}}t = U_{d0}e^{-\beta_1 t} \tag{11}$$

Therefore, the voltage response on the detection impedance was:

$$\int_0^{\infty} u'_d(t)dt = u_{d0}\frac{\alpha_0}{\alpha_0-\beta_1}(\frac{1}{\beta_1}-\frac{1}{\alpha_0}) = u_{do}/\beta_1 \tag{12}$$

Through integral transform, the frequency spectrum could be obtained and partial discharge was shown on the oscilloscope. The frequency spectrum was:

$$\phi(\omega) = \left|S(\omega) = U_{do}\right|(\beta_1^2+\omega^2)^{-\frac{1}{2}} \tag{13}$$

On-line partial discharge simulation test

Partial discharge test. When on-line partial discharge was tested,six cables with different voltage level and size were selected as samples.Before the test,the accelerated aging test was done for the cable samples so as to make them equivalent to the normal operation of 4-8 years.Meanwhile, in order to make sure the samples were in line with the real operating condition as probably as possible the state of the cable run under environmental, the applied voltage was that of the cables working at full capacity. [6]

Results and analysis.

The measured partial discharge waveform from unimproved and improved tester was shown in figure 1 and figure 2 respectively. We can clearly see from the figures that in the the improved waveform obtained, the pulse polarity can be easily judged. [7]It was very convenient to exclude non-discharge point. The waveform was clear and amplitude difference was obviously, helps to analyze reflexing and starting point of discharge and exclude secondary reflection waveform, the accuracy of the test can be improved.

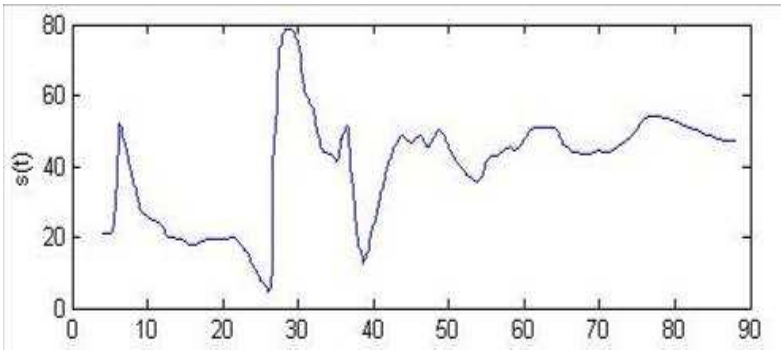

Figure 1 Discharge waveform obtained from Fourier transform

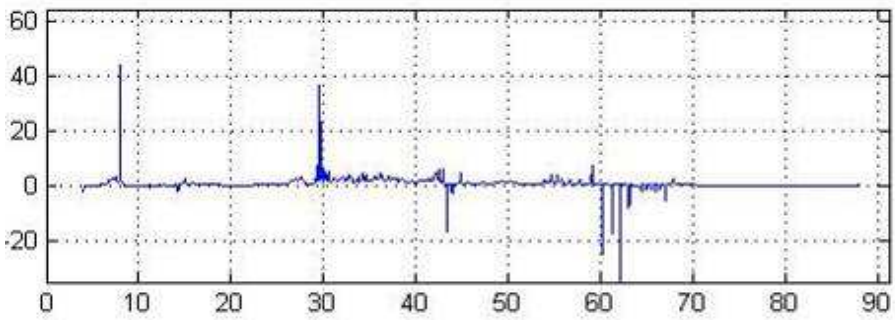

Figure 2 Discharge waveform obtained from Hilbert-Huang transform

The comparative results are shown in table 1 by testing of samples taken from the cable.

Conclusion

1.Lock-in amplifier can reduce efficiently the effect on discharge signal of environmental and cable itself. The weak partial discharge signal of cables can be capture in the complex conditions.
2.The waveform signal of partial discharge processed by Hilbert - Huang was clearer and distinguishable.The polarity and the amplitude of the waveform were determined easily.So the measurement results were more accurate.
3.Based on this study and accumulation of experimental data, the relationship between PD data, insulation condition and remaining life of cable will be deduced.

Table 1 Comparison of test results between the system with conventional test methods

No.	Cable Type	Voltage level kV	Cable length m	Discharge capacity	
				Unimproved	Improved

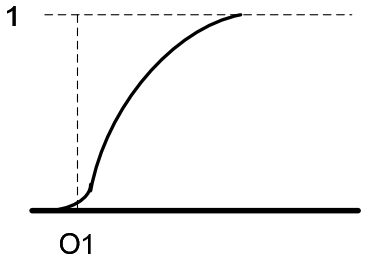
Keywords: impulse measurement system; step response; parameter extraction

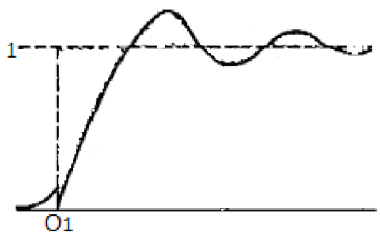
Abstract: A measurement system used for step response of impulse voltage dividers has been designed. This software can be used for various kinds of step response waveforms and can calculate them accurately. The calculation methods used in this system are in full compliance with the requirements in DL/T992-2006 and IEC60060-2. When the software used for the step response of impulse divider，the calculation results meet the requirements of stepwave response parameters with good accuracy. This software is simple to calculate and it can greatly enhance the efficiency of the step response parameter extraction calculations.

Introduction

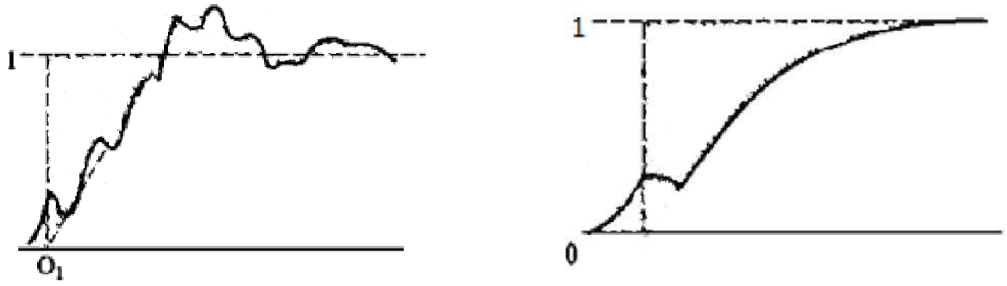
The step response parameters of impulse voltage measurement system are important to represent the dynamic performance of Impulse voltage divider, shock oscilloscope or digital recorder. In the past people usually extract these parameters by manual measurement, but this method is time consuming and the accuracy is not high. With the rapid development of computer digital processing application, now the waveform is collected by computer and the parameters are extracted by computer with data processing. Formerly automatic analysis processing for step waveform is more focused on the step response wave[1] whose front part is relatively smooth, such as figure 1 (a) and (b), the related introduction of step wave analysis processing for rising part with oscillation (figure 1 (c)) or distortion (figure 1 (d)) is less. In this paper, waveforms which are often encountered in actual measurement are analyzed and researched. Then a measurement system for calculating all kinds of step response waveform is compiled. The measurement system can real-time collect response waveform of impulse voltage divider and do calculation analysis, then output the parameters defined in IEC60060-2[2]: partial response time, test response time, stability time and overshoot, and save the collected waveform data.



(a)exponential type Step response wave



(b)exponential type Step response wave with oscillation



(c)step response wave with oscillation on the front waveform (d)Step response waveform with distortion

Fig.1 The waveform diagram of all kinds of step response

The key processing steps of the impulse step response measurement system including:

1. For the signal transformed from oscilloscope, the noise signals were filtered and the waveform was processed by removing to the first quadrant. Then the benchmark level and actual origin can be determined;

2. Determine the apparent origin. For the different types of step response waveform, methods to determine the origin of the apparent are as follows:

A) For the step response waveform with smoothly rising, the calculation program firstly determines the point of maximum slope, tangent and the apparent origin;

B) For the step response waveform with distortion rising , the calculation programs firstly find out the distortion ending point and eliminate distortion part. Then looking back from the distortion point for the maximum slope point, determining the apparent origin by draw the tangent line form the maximum slope point;

C) For the step response waveform with shocking increasing, calculating average cure of the shocking part, then the average curve was used instead of the shocking part . Then determining the apparent origin by draw the tangent line form the maximum slope point.

3. Calculating the reference level of the waveform, then determine the various parameters of step wave response.

The procedures to realize the method to calculate the various parameters of step response based on the Labview will be described in detail as follows.

1.Prcess of Software calculation

In practical application, sometimes real-time impact voltage divider step response waveform was needed to be analyzed, sometimes step response waveform preserved for ever was analyzed. so the calculation software should be used both for real-time response of impulse voltage measurement system and existing waveform data. Figure 2 is a block diagram for the calculation software of process.

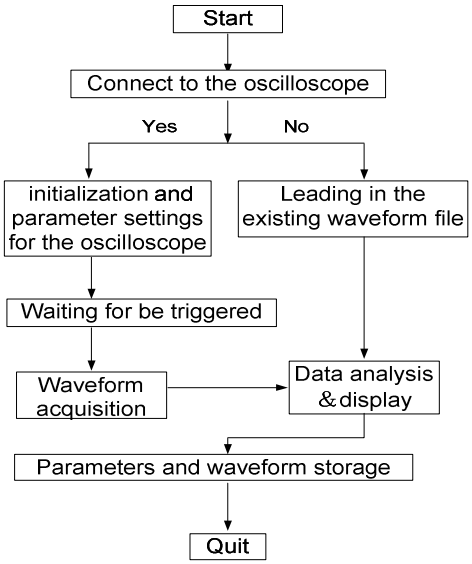


Fig.2 Flow chart of step response of impulse voltage measurement system calculation software

Determination of response parameters

2.1 Waveform acquisition and filtering. For the response waveform transformed from the oscilloscope collecting form impulse voltage divder， firstly the noise should be filtered. Usually the method of noise filtering is wavelet and cubic spine function method[3]. The method used in this calculation program is zero phase filter method based on Labview [4]-[5]. The principle of zero phase filter for the input sequence is firstly forward filter, then the filter sequence is reversal. Finally the results were reversely output. The time-domain said zero phase filter can be expressed as (1) - (4) :

$$y1(n) = x(n) * h(n) \quad (1)$$

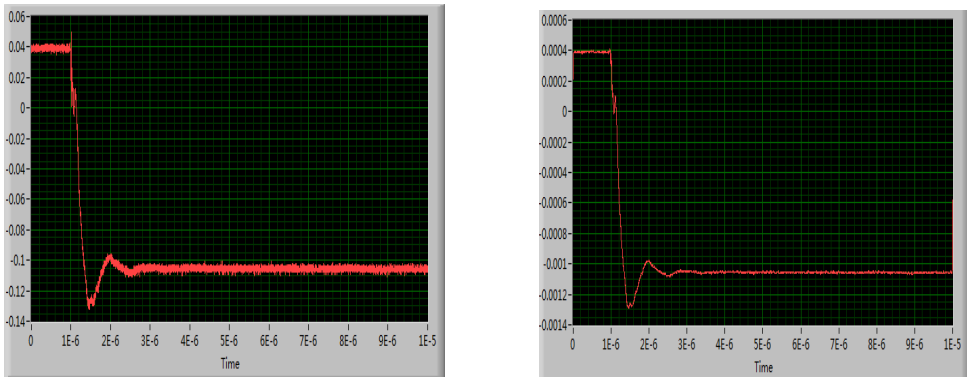
$$y2(n) = y1(N-1-n) \quad (2)$$

$$y3(n) = y2(n) * h(n) \quad (3)$$

$$y4(n) = y3(N-1-n) \quad (4)$$

In equation (1) - (4), x (n) indicates the input data, h (n) is the impulse response digital filter used in the program. y4 (n) is the reverse sequence data after the second filtering ,namely zero phase filter output sequence data. Its implementation is mathematical "reverse" on the time signal sequence processing. Essentially h (n) and h (-n) these two links were used to construct zero phase filter.

In Labview, the filter module can construct the zero phase filter easily. figure 3 (a) is a waveform without zero phase filtering, figure 3 (b) is the waveform filtered with the zero phase filter , so zero phase filter is effective on the waveform visible smooth processing.



(a)Without filtering smoothing waveform (b)After smoothing waveform measurement system

Fig.3 Software for waveform smooth processing

2.2 Reference level. The methods to find out the starting point of step response waveform are slightly different[6] . The method to determine the starting point of the waveform used in this measurement system is as follows:firstly， find out the the peak value point P, then find the point A, when the D-value of point A and the initial point O is m times less than he D-value of point A and the initial point P, that is when $|U_A - U_O|$ J m$|U_P - U_A|$（m is about 0.1%~0.5%）， the point A is the cutoff point of the flat part of the waveform and the start rising point of the waveform. This method is simple and quite correct by verification and successfully meets the needs of subsequent calculation accuracy.

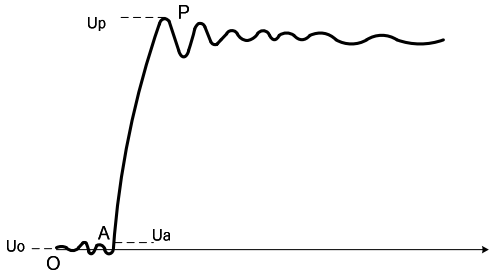


Fig.4 Determination of starting point of waveform

2.3 To calculate the apparent origin. Apparent origin zero point O_1 is the start calculation point of step response waveform. It is the intersection point of the tangent line form the front steep place and the zero line. If there is oscillation in the front part of the response waveform, drawing a tangent line form the steepest place on the center line of the oscillation. If the starting distortion part in the waveform is big, then the distortion part should be ignored when drawing the tangent line. In the impulse response calcultion program, the determination of the oscillation center line is quite important.

For the general step response waveform, as shown in figure 1 (a) and (b), firstly intercepting the voltage value array from the cutoff point of flat part to a maximum point, and then calculating the derivative of all the points in the array , the maximum derivative point is the point of tangency P. Then draw a line with the slope at the tangency P, and the intersection with the horizontal axis is the apparent zero point. Updating the voltage value to 0 before the Apparent zero point .

For the step response waveform with front oscillation , as shown in figure 5, according to the methods in DL/T992-2006[7]: first finding out the each oscillation peak value point in the oscillation waveform , then determine the corresponding time value of each peak point, summing up the time value of the peaks points, determining the average time point.

After finding out corresponding points to the average time value, these average points will be connected in chronological order to form a line. This line can be regarded as the oscillation curve of the center line. And then calculate the maximum slope point P in this line, then update the array before the point P.

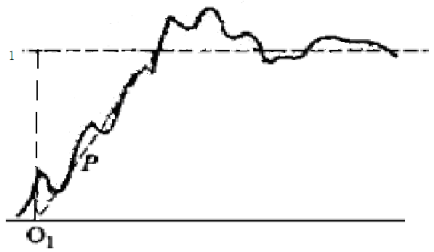

Fig.5 The determination of apparent zero point in response waveform with front oscillation

When there is aberration on the front part of the waveform, as shown in figure 6, first, the ending point of aberration part A should be found out. Then, finding out the point of tangency on the waveform form point A to another point whose value is unit amplitude and update the point array before P.

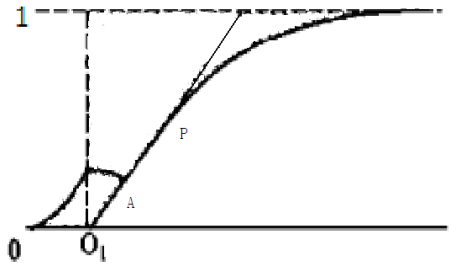

Fig. 6 Determination for Apparent Origin of Waveform with oscillation and aberration

When oscillation and aberration both existed on the front part of the step response waveform, the waveform should be firstly processed by the oscillation calculation program and then be processed by the aberration calculation program to ensure of the accuracy of calculation.

2.4 Calculation of step response parameters. After determination of the apparent origin point and the reference level of the response waveform, the partial response time, experiment response time, stabilization time and the overshoot can be calculated according to IEC60060-2.

Calculation of the measured step response waveform

In order to verify the calculation accuracy of the measurement system, we use the software for daily testing various step wave and calculating response waveform, then compared the software calculation results with manual calculation, to estimate the reliability of the software calculation.

This paper calculated three types of impulse step response waveform, as shown in figure 7, 8, 9, the used square wave power supply is the falling edge square wave, the calculation results are shown in table 1.

Figure 7 is a 200 kV impulse voltage divider step wave response waveform figure. There is no oscillation in the falling part of the waveform. It is the general type of step wave response waveform.

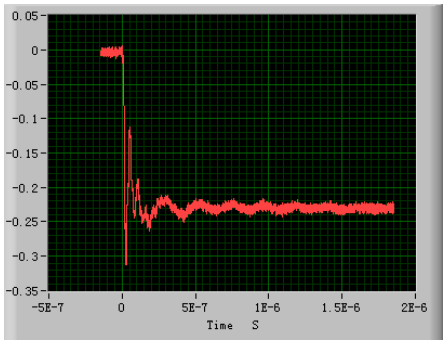

Fig. 7 a 200kV impulse voltage divider step wave response waveform figure

Figure 8 is a 1800 kV impulse capacitive voltage divider step response waveform figure. The falling part of the waveform is with obvious distortion.

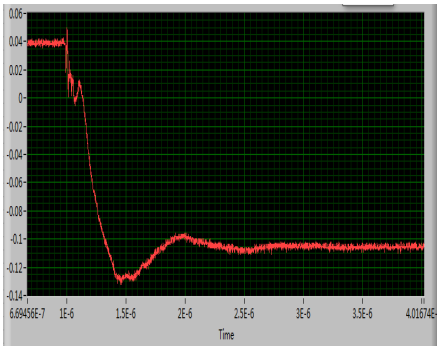

Fig. 8 a 1800kV impulse capacitive voltage divider step response waveform figure(wavefront with distortion)

Figure 9 is a 800 kV capacitive voltage divider step response waveform figure, the falling part of the response waveform is with obvious oscillation.

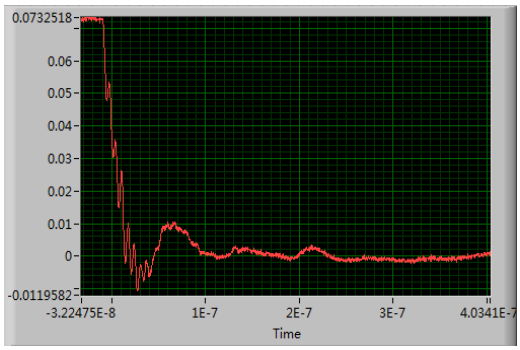

Fig. 9 800kV capacitive voltage divider step response waveform figure(wavefront with oscillation)

Because there is not standard waveform data in IEC60060-1 to evaluate step wave program calculation accuracy, so in this article we judge the calculation accuracy of the software by comparing the software calculation with manual calculation. The compared calculation results are shown in table 1.

Table 1 Comparing the software calculation with manual calculation

Figures	Calculation by	Partial response time ns	Experimental response time ns	Settleing time ns	Overshoot %
Fig7	software	4.56	10.8	51.8	33.19
	manual	4.32	12.0	49.0	33.5
Fig8	software	49	34.7	89.2	17.99
	manual	47	35.2	91.9	17.63
Fig9	software	8.0	14.8	125	13.38
	manual	9.1	16.2	131	13.45

By the computing results of the above three kinds of step response waveform using software compared with the results of manual, you can see the calculation results using step wave response calculation software and manual calculation results are comparable. It shows that the software can calculate accurately according to different types of step response waveform, and can greatly simplify the artificial calculation time.

Conclusion

1) the impulse step wave response measurement system is developed based on Labview platform. It can calculate three different types of impulse step wave response waveform.

2) the calculation processing of the measurement system is completely in accordance with the requirements of the DL/T992-2006 and the processing method is accurate and concise. They guarantee the calculation speed of the software.

3) the computation results using the measurement system to measure impulse step wave response, is comparable to a certain extent with manual calculation results. It can be used to analysis the character of impulse voltage divider in practice and can greatly simplify the computing time, improve work efficiency.

Keywords: PIC/MCC simulation, Glow discharge, Electric field, charged particles

Abstract. The simulation of glow discharge in N_2 in a needle-plane configuration with PIC/MCC method is presented. In the discharge channel the electric field driven by space charges is solved by PIC method, and various collisions between particles are described with MCC method. The electric field intensity, the electric potential and the net charge distribution in the discharge area are obtained. The numerical results are consistent with the corresponding features of glow discharge. This work can provide references to further study of glow discharge.

Introduction

Discharge plasma technology has attracted more and more attention due to its extensive applications in the industrial processing fields such as surface modification, highly pure and ultra-fine material preparations and very large-scale integrated circuit micro fabrication. Researchers in the environmental protection field recently show their interest in sewage treatment using the discharge plasma [1,2,3]. Discharge plasma technology is a new advanced oxidation technology for wastewater treatment. It can degrade the organic macromolecule compounds in the wastewater into non-toxic micro molecules, even directly into carbon dioxide and water. Using discharge plasma to degrade wastewater has many advantages such as potent oxidation, high degradable ratio and simple operation, etc. But the mechanism of this application is not very clear. With the development of computer technology, numerical simulation has become a powerful tool in revealing the physical nature in the process of a certain physical chemistry. We carried out the numerical simulation of some fundamental characteristics including electric field and charged particles distribution for a given glow discharge. N_2 is the dominant presence in the atmosphere and is widely used in many technical and industrial applications. And it is abundant, cheap, inert, non-toxic and non-flammable. As the result, in this paper N_2 is chosen as the working gas. At present, there are three main kinds of physical models used by researchers in doing the simulation. They are named particle model, fluid model and hybrid model. In particle model, electrons, ions and neutral particles are treated as individual particles. In principle, we can get some exact information including the dynamic behavior of charged particles, plasma physical quantities and so on. It can truly reflect the practical move of plasma. In this paper, MCC (monte carlo collision) [4] method is used to describe the interaction between particles. Meanwhile, PIC (particle in cell) is introduced to calculate the space electric field driven by space charges.

Simulation method

As the discharge begins, initial electrons are emitted from the needle cathode. The entry angles are shown as following.

$$\theta = \frac{1}{2}\arccos(1-2R_1), \tag{1}$$

$$\phi = 2\pi R_2, \tag{2}$$

where θ is the polar angle with respect to the axial direction (z-axis) and ϕ is the angle of the projection of the velocity vector in the xy plane, with respect to the x-axis. R_1 and R_2 are random numbers uniformly distributed between 0 and 1. Due to the existence of cosmic radiation, there are some electrons and ions in the space. In the simulation, electrons and ions are uniformly distributed in the space between the needle cathode and plane anode. The velocities of these charged particles follow the Maxwell Speed Distribution Law. The space field driven by the space charge is calculated using PIC method. The total electric field is the sum of the field driven by the applied voltage and the space charge. In the effect of the total field, charged particles follow the Newton's laws of motion.

The collision processes are resolved by MCC method. With it, whether a collision happens or not and which kind of collision will happen can be decided.

PIC method. The space between electrodes is divided into 1D cells. The cell size Δz is calculated:

$$\Delta z = \frac{d}{N}, \tag{3}$$

where d is the gap length and N is the cell number. Before the discharge, the space is electrically neutral. In every time step, the charge density of the charged particles in cells will be allocated to corresponding cell points using the linear interpolation method [5]. Then the electric potentials and the electric field intensities of cell points driven by space charges can be given as following.

$$\frac{\varphi_{i+1} + \varphi_{i-1} - 2\varphi_i}{(\Delta z)^2} = -\frac{\rho_i}{\varepsilon}, \tag{4}$$

$$E_i = \frac{\varphi_{i+1} + \varphi_{i-1}}{2\Delta z}, \tag{5}$$

where φ_{i-1}, φ_i and φ_{i+1} are the electric potential values of the (i-1)th to the (i+1)th three continuous cell points, ρ_i and E_i are the charge density and the electric field intensity of the ith cell point, respectively. From the electric field intensities of cell points, the field intensities of charged particles can be solved.

$$E_c = \frac{E_i(z_{i+1} - z_c) + E_{i+1}(z_c - z_i)}{\Delta z}, \tag{6}$$

where E_c is the electric field intensity of a certain point in the ith cell, E_i and E_{i+1} are the electric field intensities of the ith and (i+1)th two adjacent cell points, respectively. Because the external field value driven by the applied voltage is known from the reference [8], so the total field is obtained by the sum of the charge field and the external field.

MCC method. In every time step, the possibility of collision is calculated:

$$p = 1 - \exp[-n\sigma(\varepsilon)v\Delta t], \tag{7}$$

where n is the gas number density, $\sigma(\varepsilon)$ the total collision cross section and v is the velocity of the charged particle. The collisions considered in this paper are the elastic, excitation, dissociation,

ionization and dissociative ionization collisions [6] for electrons, the elastic and charge transfer collisions for both N_2^+ molecular ions and N^+ atomic ions. The cross sections used in this paper are from Tatsuo's study [7].

At the beginning of every time step, the random number R_3 that is uniformly distributed in the interval [0,1] is generated and compared with the possibility of collision P. If $P>=R_3$, a collision happens; or it does not. To determine what type of collision happens, the total cross section is split up into the fractional cross section for all possible collisions. The possibility of a certain fractional collision is given as following.

$$p_j = \frac{\sigma_j}{\sigma_T}, \tag{8}$$

where P_j is the possibility of the jth type collision. The sum of all possible collision possibilities is equal to 1. Another uniformly distributed random number R_4 in the interval [0, 1] is used to determine the jth type of collision in the formula below.

$$P_1 + P_2 + \cdots + P_{j-1} \le R_4 < P_1 + P_2 + \cdots + P_j. \tag{9}$$

Results and discussion

In this paper, the electrodes are the needle-plane configuration. The needle is cathode and the plane is anode. The simulation is performed with a gas number density of $N_2=2.69\times10^{24}/m^3$ at 1kV.

The external electric field at any point along the z-axis is the formula below [8].

$$E(z) = \frac{2V_0 d}{ln[4d/r][d(2z+r)-z^2]}, \tag{10}$$

where V_0 is the applied voltage, d the gap length, r the tip radius and z is the distance from the needle tip. The values are $d=5\times10^{-3}$m, $r=5\times10^{-3}$m, $\Delta z=2\times10^{-5}$, $N=250$. According the mean flight time, the time step $\Delta t=5\times10^{-13}$s.

A lot of initial electrons are emitted from the cathode. These electrons move to the anode under the influence of strong electric field near the cathode accompanying their kinetic energy increase. Assume that the electron average energy is 0.1eV at $t=0$. In the process of the electron drift motion, various collisions between particles will happen. Inelastic collisions such as ionization and dissociation collisions between electrons and neutral molecules generate a large number of charged particles including electrons and ions. Meanwhile, the velocity of the electron slows down because of the energy loss in the inelastic collisions with N_2 molecules. But it is easy for electron to obtain the energy from the electric field because its mass is far less than that of the ions. As the inelastic collisions process, the avalanche of electron and ions is produced. Due to the opposite drift motion directions of electron and ions they separate. Thus, the net charges appear in different areas between electrodes and drive a space electric field, which distort the external field obviously.

The evolution of two electric field profiles in the gap is shown in Fig. 1. The profile at time $t=0$ is the external field used to make a contrast. In Fig. 1, it is clear that there is an obvious distortion for the electric field at $t=4$ns compared with that at $t=0$. Especially the field in the cathode zone ($z=0.3\sim1.0$mm) has been greatly reduced due to the existence of space charged particles. The field in the positive column area ($z=1.3\sim5.0$mm) is evenly distributed and slightly increased comparing

with that at t=0. In this region the concentrations of electrons and positive ions are approximately equal, that is known as the plasma region.

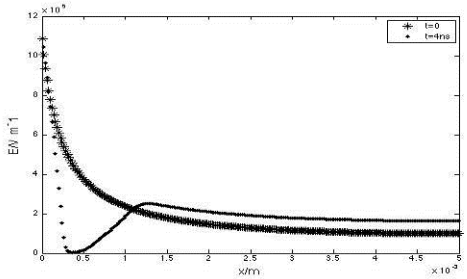

Fig. 1. Total field distribution in the gap at t=4ns

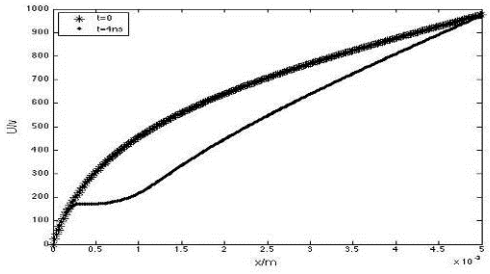

Fig. 2. The electric potential in the gap at t=4ns

The electric potential distribution at two different times is shown in Fig. 2. Similarly the potential drop in the cathode zone has a big change at t=4ns compared with that at t=0 because of the effect of the space charges. The profile at time t=4ns develops slowly even changelessly in the area where electrons stay. And then a linear growth comes in the plasma region. The physical nature embodied from Fig. 1 is consistent with that from Fig. 2，and conforms to the corresponding property of glow discharge.

Fig. 3 shows the net charges distribution in the gap at time t=4ns. Many charged particles are produced from the ionization collisions. Ions are almost stationary in the time scale of motion of the electron avalanche and remain behind. The electron avalanche moves to the anode and achieves a great loss of energy in the inelastic collisions. The downturn of the total field due to the electron avalanche will slow down the electrons further. Finally, net positive charges stay near the cathode (z=0.0~0.3mm) and net negative charges remain far from the cathode (z=0.3~1.0mm) as Figure. 3 shows. The net charges in the plasma region are roughly equal to 0.

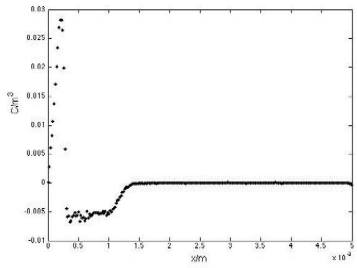

Fig. 3. Net charges distribution in the discharge channel at t=4ns

Summary

Some basic features of glow discharge in N_2 are simulated with PIC/MCC method. In the simulation, the velocity, angles, coordinates and energies of charged particles are calculated. The electric field distribution, the electric potential distribution and the net charge distribution are obtained from Poisson equation. The results show the detailed propagation of charged particles and the variation of the electric field under the influence of charged particles. The glow discharge mainly relies on ionization collisions in the discharge space. The numerical results may provide further understanding of the mechanism of the discharge process and some practical applications such as sewage treatment.

Keywords: Index Terms - Time-delay, Switched systems,Fault diagnosis

Introduction

The actual engineering control systems are nonlinear[1-2] and uncertainty[3-4] at the same time, so the robustness and fault diagnosis of systems are more meaningful[5-6]. Sometimes the system is with switching characteristics, which makes the study of switched systems more meaningful. As one of the nonlinear systems, switched systems exist in the practical systems widely, and the phenomenon of delay exists in industrial control nature, or in the life of people widely[7-8]. So the fault diagnosis research[11-12] of nonlinear switched systems with time-delay [9-10]has attracted the attention of many scholars. Motivated with the above issues, the general form of a class of switched systems with time-delay is described in detail, which also mentioned lemma 1 (Schur complement lemma)and lemma 2, the two lemmas will be applied to the proof process of the conclusion. The core part is observer design for time-delay systems fault, which puts forward the uniformly bounded stable condition of fault estimation error system expressed as the linear matrix inequality, and Lyapunov stability is applied to the strict proof. At last, the simulation of MATLAB in a numerical example proved the validity of the conclusion.

System description

Time-delay switched systems can be described as

$$\begin{aligned}\dot{x}(t) &= A_{\sigma(t)}x(t) + A_{d\sigma(t)}x(t-d(t)) + g(x(t)) + B_{\sigma(t)}u(t) + E_{\sigma(t)}f(t)\\ y(t) &= C_{\sigma(t)}x(t)\end{aligned} \tag{1}$$

where $x(t)\in\Re^n$ express the state vectors of system, $u(t)\in\Re^m$ expresses the system input, $y(t)\in\Re^p$ is the system output, $f(t)\in\Re^r$ is the actuator fault of the system, $A_{\sigma(t)}, A_{d\sigma(t)}, B_{\sigma(t)}, C_{\sigma(t)}, E_{\sigma(t)}$ are the system matrixes with appropriate dimension, for switching signal, $\sigma(t):[0,+\infty)\to\psi=\{1,\cdots,N\}$, where $N\geq 1$, especially, when $N=1$, system become ordinary time-delay systems, when $N>1$,it is supposed that the i subsystem work, that is $\sigma(t)=i$, so the formula was established

$$A_{\sigma(t)}=A_i, A_{d\sigma(t)}=A_i, B_{\sigma(t)}=B_i, C_{\sigma(t)}=C_i, E_{\sigma(t)}=E_i$$

where $(A_i \quad C_i)$ is observable, the matrix E_i is a line full rank matrix, that is $rank(E_i)=r$,the time-varying delay $d(t)$ satisfies $0<d(t)\leq h, \dot{d}(t)\leq\tau$

where h,τ are known constants, actuator fault satisfies the norm bounded condition $\|\dot{f}(t)\|\leq f_1, \|f(t)\|\leq f_2, \phi(\theta)$ is the initial function.

Lemma 1 (Schur Complement lemma), for a given symmetric matrix $\boldsymbol{Q}=\begin{bmatrix}\boldsymbol{Q}_{11} & \boldsymbol{Q}_{12}\\ \boldsymbol{Q}_{12}^{T} & \boldsymbol{Q}_{22}\end{bmatrix}<0$

Where $\boldsymbol{Q}_{ii}$ is a symmetric matrix of $r_i\times r_i$, r_i is a positive integer, $i=1,2$, the following conditions are

(1) $\boldsymbol{Q}<0$; (2) $\boldsymbol{Q}_{11}<0$ and $\boldsymbol{Q}_{22}-\boldsymbol{Q}_{12}^{\mathrm{T}}\boldsymbol{Q}_{11}^{-1}\boldsymbol{Q}_{12}<0$; (3) $\boldsymbol{Q}_{22}<0$ and $\boldsymbol{Q}_{11}-\boldsymbol{Q}_{12}\boldsymbol{Q}_{22}^{-1}\boldsymbol{Q}_{12}^{\mathrm{T}}<0$ 。

Lemma 2 For definite matrix composed of any positive constant $\boldsymbol{Z}\in\Re^{n\times n}$, $\boldsymbol{Z}=\boldsymbol{Z}^{\mathrm{T}}>0$,the scalars are $b>a\geq 0$,the vector function is $\boldsymbol{w}:[a,b]\to\Re^{n}$,the integral inequality was established:

$$(b-a)\int_a^b \boldsymbol{w}^{\mathrm{T}}(s)\boldsymbol{Z}\boldsymbol{w}(s)\mathrm{d}s\geq\left(\int_a^b \boldsymbol{w}(s)\mathrm{d}s\right)^{\mathrm{T}}\boldsymbol{Z}\left(\int_a^b \boldsymbol{w}(s)\mathrm{d}s\right)$$

Time-delay system fault observer design

If there are positive definite symmetric matrices P_i,Q_i and an arbitrary matrix Y_i satisfy the follow matrix inequality $\Xi<0$,then the fault estimation error system is uniformly bounded stable, where

$$Y_i=P_iL_i,\ E_i^TP_i=F_iC_i\quad \dot{\hat{f}}=-\Gamma^{-1}\left(Fe_y+F\dot{e}_y+\sigma\hat{f}\right)$$

The residence time of switching signal meets: $T_a>T_a^*=\dfrac{\ln(\mu)}{\alpha}$

Then the system is asymptotically exponentially stable and there is $\mu\geq 1$, $P_i\leq\mu P_j, Q_i\leq\mu Q_j, Z_i\leq\mu Z_j$

Where:

$$\Xi_{11}=A_i^TP_i+P_iA_i-C_i^TY_i^T-Y_iC_i+Q_i+\alpha P_i-e^{-\alpha h}\frac{1}{h}P_i+D_i+hA_i^TP_iA_i-hC_i^TY_i^TA_i-hA_iY_iC_i$$

$$\Xi_{12}=C_i^TY_i^T\quad \Xi_{13}=P_iA_{di}+hA_i^TP_iA_{di}-hC_i^TY_i^TA_{di}+e^{-\alpha h}\frac{1}{h}P_i$$

$$\Xi_{14}=P_i+hA_i^TP_i-hC_i^TY_i^T\quad \Xi_{15}=(h-1)A_i^TP_iE_i-(h-1)C_i^TY_i^TE_i$$

$$\Xi_{22}=-\frac{1}{h}P_i\quad \Xi_{33}=-(1-\tau)e^{-\alpha h}Q_i+hA_{di}^TP_iA_{di}-e^{-\alpha h}\frac{1}{h}P_i$$

$$\Xi_{34}=hA_d^T\quad \Xi_{35}=hA_{di}^TP_iE_i-A_{di}^TP_iE_i\quad \Xi_{44}=hP-D\quad \Xi_{45}=hP_iE_i-P_iE_i\quad \Xi_{55}=hE_i^TP_iE_i-2E_i^TP_iE_i$$

Proof: Lyapunov function is selected as following

$$V_i(t)=V_{1i}(t)+V_{2i}(t)+V_{3i}(t)+V_{4i}(t)$$

Where $V_{1i}(t)=e_x^T(t)P_ie_x(t)$ $V_{2i}(t)=e^{-\alpha t}\int_{t-d(t)}^{t}e^{-\alpha s}e_x^T(s)Q_ie_x(s)ds$

$$V_{3i}(t)=he^{-\alpha t}\int_{-h}^{0}\int_{t+\sigma}^{t}e^{\alpha s}\dot{e}_x^T(s)Z_i\dot{e}_x(s)dsd\sigma\quad V_{4i}(t)=e_f^T(t)\Gamma e_f(t)$$

Along (1), take the derivative of Lyapunov function :

$$\dot{V}_{1i}(t)\leq e_x^T(t)\left(\left(A_i-L_iC_i\right)^TP_i+P_i\left(A_i-L_iC_i\right)\right)e_x(t)+2e_x^T(t)P_ie_g(t)+2e_x^T(t)P_iA_{di}e_x\left(t-d(t)\right)$$

$$\dot{V}_{2i}(t)\leq-\alpha V_{2i}+e_x^T(t)Q_ie_x(t)-(1-\tau)e^{-\alpha h}e_x^T\left(t-d(t)\right)Q_ie_x\left(t-d(t)\right)$$

$$\dot{V}_{3i}(t)\leq-\alpha V_{3i}+h\dot{e}_x^T(t)Z_i\dot{e}_x(t)-e^{-\alpha h}\int_{t-h}^{t}\dot{e}_x^T(s)Z_i\dot{e}_x(s)\,ds$$

Because of the system so that there is:

$$h\dot{e}_x^T(t)Z_i\dot{e}_x(t)=he_x^T(t)(A_i-L_iC_i)^TZ_i(A_i-L_iC_i)e_x(t)+he_x^T(t)(A_i-L_iC_i)^TZ_iA_{di}e_x(t-d(t))$$
$$+he_x^T(t)(A_i-L_iC_i)^TZ_ie_g(t)+he_x^T(t)(A_i-L_iC_i)^TZ_iE_ie_f(t)$$
$$+he_x^T(t-d(t))A_{di}^TZ_i(A_i-L_iC_i)e_x(t)+he_x^T(t-d(t))A_{di}^TZ_iA_{di}e_x(t-d(t))$$
$$+he_x^T(t-d(t))A_{di}^TZ_ie_g(t)+he_x^T(t-d(t))A_{di}^TZ_iE_ie_f(t)$$
$$+he_g^T(t)Z_i(A_i-L_iC_i)e_x(t)+he_g^T(t)Z_iA_{di}e_x(t-d(t))$$
$$+he_g^T(t)Z_ie_g(t)+he_g^T(t)Z_iE_ie_f(t)+he_f^T(t)E_i^TZ_i(A_i-L_iC_i)e_x(t)$$
$$+he_f^T(t)E_i^TZ_iA_{di}e_x(t-d(t))+he_f^T(t)E_i^TZ_ie_g(t)+he_f^T(t)E_i^TZ_iE_ie_f(t)$$

According to the lemma, it can be obtained:

$$-e^{-\alpha h}\int_{t-h}^{t}\dot{e}_x^T(s)Z_i\dot{e}_x(s)ds\le-e^{-\alpha h}\frac{1}{h}e_x^T(t)Z_ie_x(t)+e^{-\alpha h}\frac{1}{h}e_x^T(t)Z_ie_x(t-d(t))$$
$$+e^{-\alpha h}\frac{1}{h}e_x^T(t-d(t))Z_ie_x(t)-e^{-\alpha h}\frac{1}{h}e_x^T(t-d(t))Z_ie_x(t-d(t))$$

Along (1), take the derivative of Lyapunov function $V_{4i}(t):\dot{V}_{4i}(t)=2e_f^T(t)\Gamma\dot{e}_f(t)$

Because of $FC=E^TP$ and for the system the following inequality exists:

$$-2\sigma e_f^T(t)(e_f(t)+f^*)\le-2\sigma e_f^T(t)e_f(t)+2\sigma e_f^T(t)f^*\le-\sigma e_f^T(t)e_f(t)+\sigma f^{*T}f^*$$

Select $\alpha=\sigma\lambda_{\min}(\Gamma^{-1})$,so it can be obtained:

$$\dot{V}_{4i}(t)\le-\alpha V_{4i}-2e_f^T(t)E_i^TP_ie_x-2e_f^T(t)E_i^TP_i(A_i-L_iC_i)e_x(t)-2e_f^T(t)E_i^TP_iA_{di}e_x(t-d(t))$$
$$-2e_f^T(t)E_i^TP_ie_g(t)-2e_f^T(t)E_i^TP_iE_ie_f(t)+\sigma f_2^2$$

Because $\|g(x_1)-g(x_2)\|\le\|x_1-x_2\|$ is established, so for any positive definite diagonal matrix D_i there is $e_x^T(t)D_ie_x(t)-e_g^T(x(t))D_ie_g(x(t))>0$ As a result: $\dot{V}_i(t)\le-\alpha V_i(t)+\xi^T\Theta_1\xi+\delta$

According to the Schur lemma and the skill of matrix elementary transformation, you can get $\Theta_1<0$ is equivalent to $\Xi<0$, where

$$\Xi=\begin{bmatrix}
A_i^TP_i+P_iA_i-C_i^TY_i^T & & & & \\
-Y_iC_i+Q_i+\alpha P_i & & & & \\
-e^{-\alpha h}\frac{1}{h}P_i+D_i & C_i^TY_i^T & P_iA_{di}+hA_i^TP_iA_{di} & P_i+hA_i^TP_i & P_iE_i \\
+hA_i^TP_iA_i & & -hC_i^TY_i^TA_{di} & -hC_i^TY_i^T & +(h-1)A_i^TP_iE_i \\
-hC_i^TY_i^TA_i & & +e^{-\alpha h}\frac{1}{h}P_i & & -(h-1)C_i^TY_i^TE_i \\
-hA_iY_iC_i & & & & -P_iE_i \\
* & -\frac{1}{h}P_i & 0 & 0 & 0 \\
 & & -(1-\tau)e^{-\alpha h}Q_i & & \\
* & * & +hA_{di}^TP_iA_{di} & hA_d^TP & hA_{di}^TP_iE_i-A_{di}^TP_iE_i \\
 & & -e^{-\alpha h}\frac{1}{h}P_i & & \\
* & * & * & hP-D & hP_iE_i-P_iE_i \\
* & * & * & * & hE_i^TP_iE_i \\
 & & & & -2E_i^TP_iE_i
\end{bmatrix}$$

$\delta=\alpha f_2^2$ So that, there is $V_i(t)\le-e^{-\alpha(t-t_0)}\mu^\beta V_i(t_0)+\frac{\delta}{\alpha}\le-e^{-\left(\alpha-\frac{\ln\mu}{T_a}\right)(t-t_0)}\mu^\beta V_i(t_0)+\frac{\delta}{\alpha}$

Fault estimation error system is uniformly bounded stable. The theorem is proven.

Simulation experiment

In order to verify the feasibility and effectiveness of the theoretical results, a two dimensional time-varying delay system is given, and then the MATLAB/SIMULINK software is used in simulation. In this paper, all the results are given in the form of linear matrix inequality (LMI), they can be solved by LMI toolbox of Matlab, but in the theorem $E^T P = FC$ is required, if the matrixes E, C are square matrixes, they can be solved through the matrix inverse operation, but if when the matrixes are not square matrixes, especially, when the output gain matrices $rank(C) = r < n$ not all of the E, C, P exist the matrix F to meet the condition. To solve $E^T P - FC = 0$ .Through a small enough positive number η, $E^T P - FC = 0$ can be realized. Known matrix and the related parameters of the system are selected :

Subsystem 1:

$$A_1 = \begin{bmatrix} -1 & 0 \\ 0.2 & -0.8 \end{bmatrix}, A_{d1} = \begin{bmatrix} 0.1 & 0.1 \\ 0.1 & 0.2 \end{bmatrix}, B_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, E_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, C_1 = \begin{bmatrix} 0 & 1 \end{bmatrix}$$

Subsystem 2:

$$A_2 = \begin{bmatrix} -5 & 2 \\ 2 & -5 \end{bmatrix}, A_{d2} = \begin{bmatrix} 0.5 & 1 \\ 1 & 2 \end{bmatrix}, B_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, E_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, C_2 = \begin{bmatrix} 0 & 1 \end{bmatrix}$$

$d(t) = 0.3 + 0.2\sin(t)$ $f(t) = 0.4\sin(t-30),$ $0 \le t \le 100$

we can get:

$$P_1 = \begin{bmatrix} 0.6615 & -0.6620 \\ -0.6620 & 3.0555 \end{bmatrix} \quad Q_1 = \begin{bmatrix} 0.0148 & -0.0170 \\ -0.0170 & 0.2375 \end{bmatrix} \quad D_1 = \begin{bmatrix} 0.6127 & 0 \\ 0 & 1.9210 \end{bmatrix} \quad Y_1 = \begin{bmatrix} 0.4334 \\ 3.4081 \end{bmatrix}$$

$F_1 = 2.3935$

Calculating $L_1 = P_1^{-1} Y_1$ can obtain $L_1 = \begin{bmatrix} 2.2619 \\ 1.6055 \end{bmatrix}$;

$$P_2 = \begin{bmatrix} 0.0176 & -0.0084 \\ -0.0084 & 0.0145 \end{bmatrix} Q_2 = \begin{bmatrix} 0.0197 & -0.0183 \\ -0.0183 & 0.0197 \end{bmatrix} D_2 = \begin{bmatrix} 0.0107 & 0 \\ 0 & 0.0108 \end{bmatrix} Y_2 = \begin{bmatrix} -0.0075 \\ 0.0211 \end{bmatrix}$$

$F_2 = 0.0061$ Calculating $L_2 = P_2^{-1} Y_2$ can obtain $L_2 = \begin{bmatrix} 0.3694 \\ 1.6628 \end{bmatrix}$.

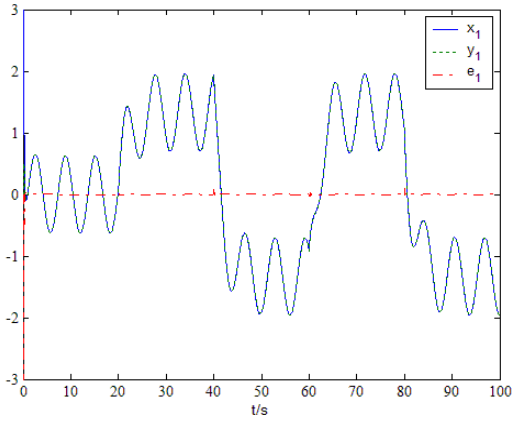

Fig. 1 State and error of the system

As can be seen from the simulation graph 1, in the 30 s before, the simulation is in the absence of fault, the state of the observer y_1 can track the system state x_1 soon. After the 30 s, the system has the fault, but the state of the observer y_1 can also track the system state x_1 very well. Through the error of the simulation e_1, it can be seen clearly that the error between the state of the system and the observer state in the whole simulation process.

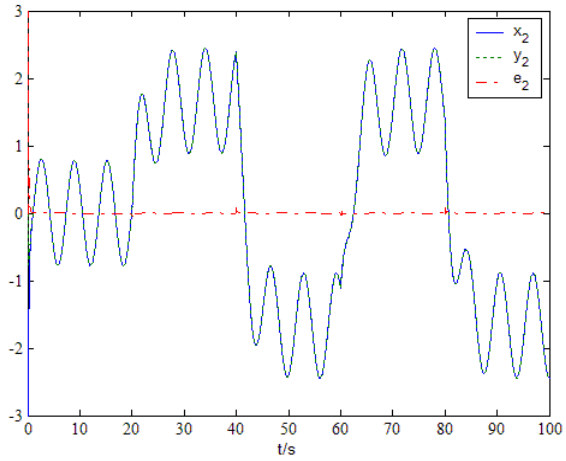

Fig.2 State and error of the system

As can be seen from the simulation graph 1, in the 30 s before,the simulation is in the absence of fault,the state of the observer y_2 can track the system state x_2 soon.After the 30 s,the system has the fault, but the state of the observer y_2 can also track the system state x_2 very well.Through the error of the simulation e_2 ,it can be seen clearly that the error between the state of the system and the observer state in the whole simulation process.

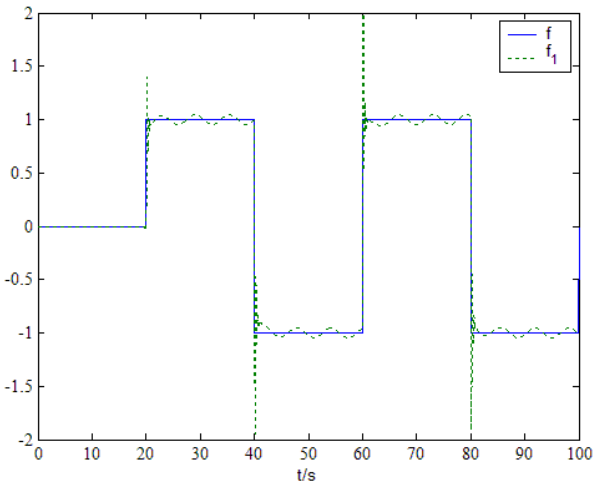

Fig. 3 Error and estimate of the system

As can be seen from the simulation graph 1, in the 30 s before,the simulation is in the absence of fault, the system failure f keeps zero,the state of fault observer f_1 also keeps zero.After the 30 s,the system has the fault, at the same time, the observer of system fault can also track the fault very well.

Conclusion

The fault diagnosis of a class of lag switched systems is studied in the paper. For such a system, the algorithm of adaptive fault estimation algorithm is adopted, through the observer design to the time-delay system fault, it is given in the form of linear matrix inequality (LMI) the uniformly bounded stable condition of the fault estimation error system. And the Lyapunov boundedness theory verify the effectiveness of the conclusion.Then a numerical example is given ,the SIMULINK toolbox of MATLAB give system simulation to verify the correctness and effectiveness of the proposed algorithm.

Keywords: state estimation current measure RPM PMU

Abstract. Aiming at the problem that the current measurements provided by phasor measurement unit (PMU) is difficult to introduce to traditional state estimation, a new method to solve the compatibility problems of PMU and supervisory control and data acquisition (SCADA) is presented in this paper. By the rotated-pseudo-measurement (RPM) method, current measurements are transformed into the pseudo measurements and decoupled in polar coordinates, so that they could taken into nonlinear state estimation. Then the RPM method is simulated compared with the current transformation (CT) method. According to the result, it is showed that the RPM method has many advantages compared with the CT, such as independence of other measurements, small error in propagation and more significant in improving estimation accuracy. Moreover, the RPM method has the compatibility with traditional nonlinear state estimation and the fast calculating speed, which have good prospects of practice.

Introduction

In recent years, phasor measurement technology has been widely used. The PMU makes node voltage phasor and branch current phasor become measurable. Based on Wide Area Measurement System (WAMS), PMU measurement device is considered to bring some significant changes to traditional state estimation in power grid[1~7].

Compared with the traditional measurement devices on the types of measurements, PMU can not only obtain the measurement of the magnitude of voltage and power, but also the phase angle of voltage and current can be collected to measure voltage and current; PMU can be collected within a 50-second section of the data, and each measurement are marked with a time scasle to ensure the synchronization of the measurement. Therefore, compared to SCADA measurements, the PMU measurements are fast and accurate, and can well reflect the dynamic of the power system.

Among the existing power grid state estimation methods, the linear state estimation method and the non-linear method are both widely recognized. They are respectively based on decomposition of Cartesian coordinates and polar decomposition. Since the current measurement can be decomposed and analyzed in Cartesian coordinates easily, its technologies in linear state estimation have been mature.

However, considering the aspects of price and technique, it is impossible for all the nodes in power grid system equipped with PMU. Thus in a long period of time, only a small amount of nodes of the grids are observable in terms of PMU measurements. So it is of practical significant to take SCADA as the main measurement and PMU as a supplement to improve the accuracy of state estimation. In existing study on introduction of PMU, the methods of introduction of voltage and power measurement has been discussed widely, but a better approach to the introduction of the current does not exist yet. For the reason that the current measurement will be complex if decomposed directly in polar coordinates. And we cannot use some features of grid conditions decoupled it, which bring many difficulties to the introduction of the rapid decomposition.

STATE ESTIMATION WITH CURRENT MEASUREMENT

To introduce current measurement, quite a few articles use the equivalent-current -measurement-transformation method. In articles [13], the current measurements are directly changed to other to estimation measurements such as power measurements. The disadvantages are the amplification of transmission error and the decrease of the weighting factor, which lead to the loss of estimation accuracy. In article [15], the current measurement is directly decomposed into the real and the imaginary parts under the assumption that the whole network, voltage phase angle is zero. However, some phase angle may be large in the large power grid, which would bring to large errors to estimation.

To solve the problems the two current measurement methods bring, this article will use the rotation-pseudo-measurement (RPM) method.

It is difficult to introduce branch current measurement $\dot{I}_{ij}$ directly into the non-linear state estimation, because a branch current is the function of the voltage phase angle of both ends of the branch in polar coordinates. In other words, branch current vector will change when the voltage phase angle changes. Generally, the angle θ_i and θ_j, the voltage angle of bus i and bus j respectively, cannot be simply considered as zero. Therefore, function cannot be calculated using the PQ-decoupled method.

Since voltage phase angle of nodes equipped with PMU is know, and take into account that the branch current vectors change with voltage phase angles θ_i and θ_j of both ends of branch, we can construct a pseudo-measurement $\dot{I}_{ij}e^{-j\theta_i}$,where current measurement rotates an angle of $-\theta_i$, and the variable θ_i of the individual branch currents $\dot{I}_{ij}$ is changed to 0. So that we can the fixed angle bus i of a end of the branch current and construct θ_{ij} .By this method, we can use the condition of $\theta_{ij} \approx 0$ in high-voltage transmission network to decouple. Thus derivation is followed:

$$\begin{aligned} \dot{I}_{ij.0} &= \dot{I}_{ij}e^{-j\theta_i} = \left[y_{ij}(\dot{V}_i - \dot{V}_j) + y_{i0}\dot{V}_i \right] e^{-j\theta_i} \\ &= y_{ij}(V_i - V_j e^{-j\theta_{ij}}) + y_{i0}V_i \\ &= (g + jb)\left[V_i - V_j(\cos\theta_{ij} - j\sin\theta_{ij}) \right] + jy_{ic}V_i \end{aligned} \tag{1}$$

Where:

$\dot{V}_i$ and $\dot{V}_j$ is the voltage vector of both ends of branch respectively,

θ_{ij} is voltage phase angle difference of the both ends of the branch,

y_{ij}, g and b are admittance, conductance and susceptance of the branch respectively,

y_{ic} is the line-to-ground admittance.

The pseudo-measurement $\dot{I}_{ij.0}$ of the pseudo-measurement can be decomposed into two variables under Cartesian coordinates: the real part $I_{ij.0}^{re}$ and the imaginary part $I_{ij.0}^{im}$. As is showed followed:

$$\begin{cases} I_{ij.0}^{re} = gV_i - gV_j\cos\theta_{ij} - bV_j\sin\theta_{ij} \\ I_{ij.0}^{im} = gV_j\sin\theta_{ij} + bV_i - bV_j\cos\theta_{ij} + y_{ic}V_i \end{cases} \tag{2}$$

Then we take the partial derivative of the pseudo-measurements real and imaginary parts to V and θ:

$$\begin{cases} \dfrac{\partial I_{ij.0}^{re}}{\partial\theta_i} = gV_j\sin\theta_{ij} - bV_j\cos\theta_{ij} \\ \dfrac{\partial I_{ij.0}^{re}}{\partial V_i} = g \\ \dfrac{\partial I_{ij.0}^{im}}{\partial\theta_i} = gV_j\cos\theta_{ij} + bV_j\sin\theta_{ij} \\ \dfrac{\partial I_{ij.0}^{im}}{\partial V_i} = b + y_{ic} \end{cases} \qquad \begin{cases} \dfrac{\partial I_{ij.0}^{re}}{\partial\theta_j} = -gV_j\sin\theta_{ij} + bV_j\cos\theta_{ij} \\ \dfrac{\partial I_{ij.0}^{re}}{\partial V_j} = -g\cos\theta_{ij} - b\sin\theta_{ij} \\ \dfrac{\partial I_{ij.0}^{im}}{\partial\theta_j} = -gV_j\cos\theta_{ij} + bV_j\sin\theta_{ij} \\ \dfrac{\partial I_{ij.0}^{im}}{\partial V_j} = g\sin\theta_{ij} - b\cos\theta_{ij} \end{cases} \tag{3)(4}$$

In the high-voltage transmission system, the resistance of the transmission line is generally much smaller than its reactance, and the difference of amplitude of the voltage as well as the difference of the phase angle of the both ends of branch is not so large. That is $r \ll x$, $V_i \approx V_j = V_0$ and $\theta_{ij} \approx 0$ .Therefore, it is easy to draw the following conclusions : $g \ll b$, $\cos\theta_{ij} \approx 1$ and $\sin\theta_{ij} \approx 0$. If the formula is further deduced, we get that $g\sin\theta_{ij} \ll b\cos\theta_{ij}$, $\left|g\cos\theta_{ij} \pm b\sin\theta_{ij}\right| \ll \left|g\sin\theta_{ij} \pm b\cos\theta_{ij}\right|$.

Using these two deductions, we can simplify the formula (3)(4). The simplification for two formula (3)(4) are as follow:

$$\begin{cases} \dfrac{\partial I_{ij.0}^{re}}{\partial\theta_i} = -bV_0 \\ \dfrac{\partial I_{ij.0}^{re}}{\partial V_i} = 0 \\ \dfrac{\partial I_{ij.0}^{im}}{\partial\theta_i} = 0 \\ \dfrac{\partial I_{ij.0}^{im}}{\partial V_i} = b + y_{ic} \end{cases} \qquad \begin{cases} \dfrac{\partial I_{ij.0}^{re}}{\partial\theta_j} = bV_0 \\ \dfrac{\partial I_{ij.0}^{re}}{\partial V_j} = 0 \\ \dfrac{\partial I_{ij.0}^{im}}{\partial\theta_i} = 0 \\ \dfrac{\partial I_{ij.0}^{im}}{\partial V_i} = -b \end{cases} \tag{5)(6}$$

According to the formulas (5) (6), we can changes them into Jacobian matrix as follow：

$$\begin{pmatrix} \Delta I_{ij.0}^{re} \\ \Delta I_{ij.0}^{im} \end{pmatrix} = \begin{pmatrix} -B' & 0 \\ 0 & B' \end{pmatrix} \begin{pmatrix} V_0\Delta\theta \\ \Delta v \end{pmatrix} \tag{7}$$

Where

B' and B'' , are the corresponding coefficient matrix for $V_0\Delta\theta$ and Δv respectively, being constants if the network topology and parameter remain unchanged.

As can be seen from the above, the rotation pseudo-measurement method can achieve a decoupling. $I_{ij.0}^{re}$ can be classified as active and compute together with P, while $I_{ij.0}^{im}$ can be classified as reactive and compute together with Q.Therefore, this method can be carried out in conjunction with traditional state estimation based on PQ decomposition method. Through the above transformation, we achieve the introduction of PMU current measurement.

METHODS TO ACHIEVE

The weight of real and imaginary parts by the pseudo-rotation transformation can be determined by the relative error propagation equation:

$$R_{Ire} = \sqrt{\left(\frac{\partial \ln I_{ij.0}^{re}}{\partial I_{ij}}\right)^2 \sigma_{Iij}^2 + \left(\frac{\partial \ln I_{ij.0}^{re}}{\partial\theta_{Iij}}\right)^2 \sigma_{\theta Iij}^2 + \left(\frac{\partial \ln I_{ij.0}^{re}}{\partial\theta_i}\right)^2 \sigma_{\theta i}^2}, \quad R_{Iim} = \sqrt{\left(\frac{\partial \ln I_{ij.0}^{im}}{\partial I_{ij}}\right)^2 \sigma_{Iij}^2 + \left(\frac{\partial \ln I_{ij.0}^{im}}{\partial\theta_{Iij}}\right)^2 \sigma_{\theta Iij}^2 + \left(\frac{\partial \ln I_{ij.0}^{im}}{\partial\theta_i}\right)^2 \sigma_{\theta i}^2} \tag{8)(9}$$

Where:

R_{Ire} is the weight coefficients of the real part of the pseudo-measurement.

R_{Iim} is the weight coefficients of the imaginary part of the pseudo-measurement.

σ_{Iij}^2 , $\sigma_{\theta Iij}^2$ and $\sigma_{\theta i}^2$ are respectively the variance of amplitude of current measurement, the variance of the angle of current measurement, and the variance of phase angle of voltage measurement.

Thus the pseudo-measurement of the real and the imaginary parts of the weight is determined.

In the iteration, the PMU voltage phase angle θ_i^{PMU} ,if precise enough, can be taken directly to construct a pseudo measurement $\dot{I}_{ij}e^{-j\theta_i}$; if not, we can take improved-dynamic estimation method instead: take the rotation phase angle as θ_i^{PMU} before taking a few iterations； after than in each iteration, get the latest state estimation value $\theta_i^{(n)}$ to compose pseudo-measurement together with the original measurement $\dot{I}_{ij}$ .Therefore, the pseudo-measurement values are updated in subsequent

iterations (only a different in angle of rotation). The amount of computation with dynamic improved estimation method is small, which can reduce the error of state estimation when the error of phase angle PMU phase angle error is large.

ALGORITHM PROCESS

The process of mixed nonlinear state estimation is generally the same as the one of traditional nonlinear state estimation. Therefore we just have to make some modifications in the original process. As it is shown as Fig1:

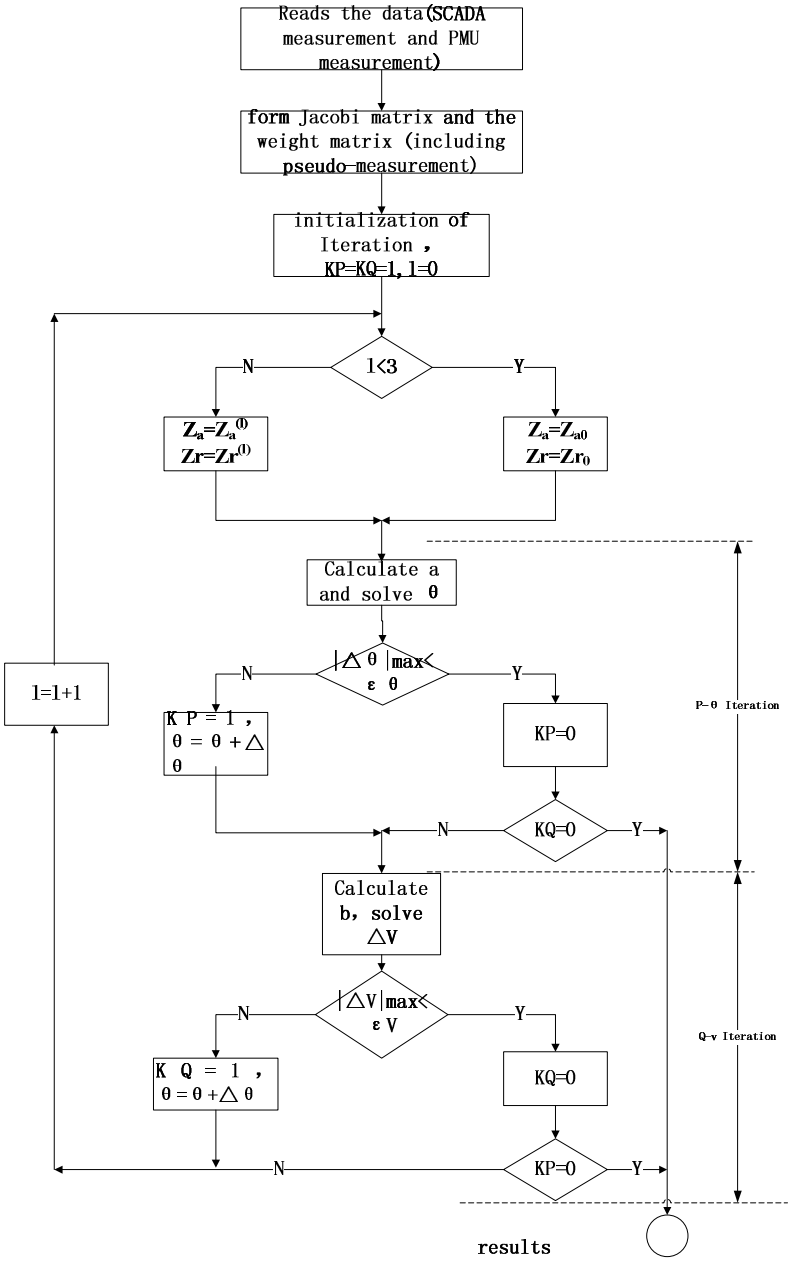

Fig.1 Process of RPM method

ANALYSIS OF EXAMPLE

In this paper, we take IEEE 39 node system as an example, and assume that all nodes are equipped with voltage PMU and all branches with power and current PMU. That is to say each branch of the current is known. Assume that all measurements are normally distributed with mean zero, and that standard deviation of the voltage measurements and power measurements is 0.2,while current measurements' standard deviation is 0.01. The convergence criterion is 10-5.

Table 1 Calculation results of the RPM method and other traditional non-liner estimations method in 39-bus system

Method	The RPM method	The CT method	The traditional method(without current measurement)
Times in multi-iteration	5	4	4
J(x)	34.3175	40.5590	25.7007

As can be seen from Table 1, although there is one more time in multi-iteration the RPM method than the CT method, the former's objective function J (x) is smaller than the latter's, revealing a better estimate performance.

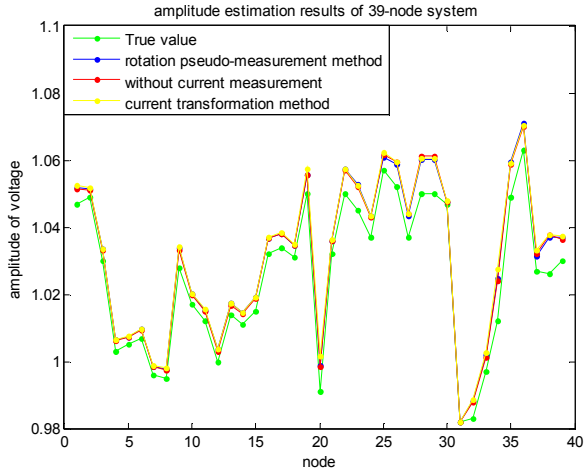

Fig.2 The voltage amplitude of estimation results

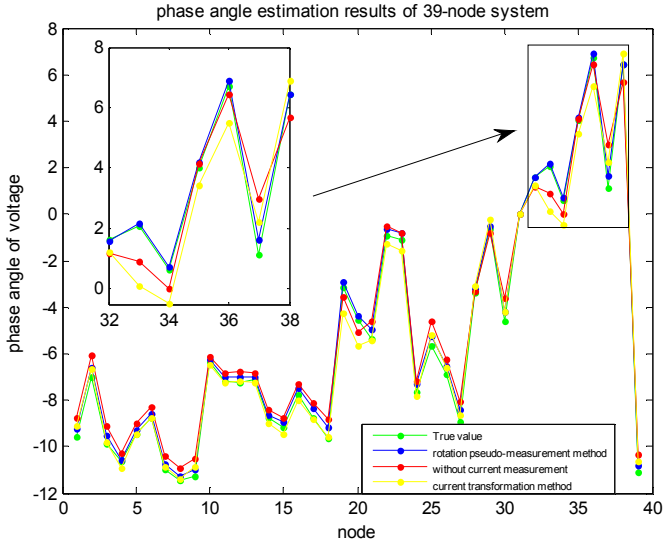

Fig.3 The voltage amplitude of estimation results

As can see from Fig.2, both of the performances of the RPM and the CT method have little influence on the result of the state estimation voltage amplitude. Among the result of the voltage phase angle estimation, the estimation result of the RPM is the closest to the true value in general, meaning a good estimation result. Because of some large errors in the voltage measure, the performance of the CT method is not so satisfying, in which some nodes estimation results are further from the true value. As it is shown in the box in Fig 3.While the RPM method only takes use of voltage phase information, and transmits smaller errors. Moreover, after multiple simulations, it is showed that the performance of RPM is not sensitive to the accuracy of voltage phase angle measurements. In other words, the accuracy of initial voltage measures has little impact on the effect of RPM.

CONCLUSION

This paper presents a method that current measurement is introduced into the nonlinear state estimation by constructing a pseudo-rotation current measurement with PMU voltage phase angle information. And its transmission error is calculated as well. Then IEEE 39 node system with a numerical example to calculate quantitative and qualitative analysis. Simulation results show that the method is simple and effective , with an estimated effect, accuracy higher than the average current transformation method and can be fully integrated into the nonlinear state estimation along with other characteristics. The disadvantage of this method is that if used alone without the other measurements, may result in an estimated without convergence.

KEY WORDS: transmission section; shortest paths; Adjacency matrix

Abstract. A new algorithm based on K shortest paths is presented for quick search of the transmission section, and then the timely electricity network topology is transferred into a directed graph. Using this new algorithm, k shortest paths would be directly searched for; the transmission section influenced greatly by the power flow shift is then obtained quickly. To avoid leaving part of the search because criteria are too small tributary drain election when using a single path to ensure the integrity of the transmission section. Finally CEPRI36 nodes system simulation is analyzed, and the effectiveness of the algorithm is demonstrated.

Introduction

In recent years, a number of major power outages have occurred in domestic and international power systems caused by cascading failures. Economic losses and social impacts are extremely serious, such as the 2003 U.S. / Blackout. After removal of overload branches, the power flows of the entire system will be reallocated, which would determine the transfer of power flows on each overloaded element. Then the recalculation of the whole network power flows is needed, but it will cost too much time. In fact, after resection of overload only a few branches of the branch circuit would be influenced by the power flow shift [2]. So in the large power system if branches influenced greatly by power flow shifts can be searched out quickly, then the analysis of whether the overload will cause the action of backup protection, which is much simpler and faster than the whole network analysis. After breaking off the overloaded branches, branches with the shortest electrical distance would be influenced more greatly than those with long distances. According to the basic principles of the circuit, current and power can only run in the closed loop, which has the lowest impedance.

Analysis of power flow transfer characteristics

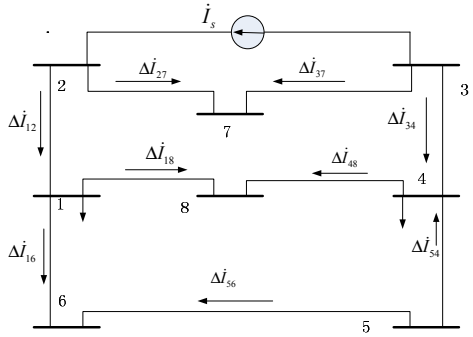

Fig.1 Equivalent network of flow transferring component

An 8-node network diagrams is shown in Fig. 1, when lines are cut off due to overload, active power of each generator and system load stay unchanged, without the consideration of nonlinear components in the system, such as power electronics. According to superposition theorem of the circuit theory, power flows in other lines after removal can be divided to two parts, one is power flows before the removal and the other is transferring components caused by the removal, which could be induced by

$$\dot{I}'_{ij} = \dot{I}_{ij} + \Delta\dot{I}_{ij} \tag{1}$$

Where, $\dot{I}_{ij}$ is the current before removal of L_{23}, $\dot{I}'_{ij}$ is the current after of L_{23}, and $\Delta\dot{I}_{ij}$ is the transferring component caused by the removal of L_{23}, a equivalent network where the L_{23} is replaced with a constant current source I_S (which current is equal in magnitude and opposite in direction before removal of the line L_{23}).

Knowledge of graph theory

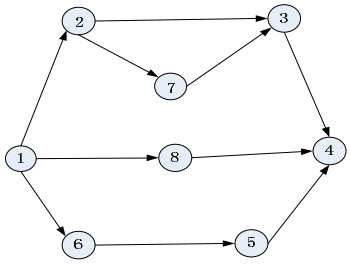

Fig.2 The weighted directed path

If physical characteristics of each component of the power system can be ignored and only research network topology counts, the power system can be abstracted into a graph, which can be expressed as $G(\mathrm{V},\mathrm{E})$, where V means node collections and E represents the line collections. When each line in the graph has a direction, the graph then becomes a directed one. As for a directed line: $E=\{\mathrm{e}_i \mid \mathrm{e}_i =< v_p, v_q >, v_p, \mathrm{v}_q \in \mathrm{V}\}$, G is a weighted graph, graph nodes represent the system buses, while lines represent transmission lines, transformers and other branches. If the edges in the graph not only represents the links between nodes, but also was given a numerical meanings such as length, price, reactance values, etc. The weighted directed path is shown in Fig. 2, the weighted directed adjacency moment can be got from a weighted directed graph, which is expressed as follows

$$a_{i-j} = \begin{cases} 0 & i = j \\ w_{i-j} & i \to j \\ \infty & \end{cases} \tag{2}$$

Where w_{i-j} represents weight between v_i and v_j, and the direction is determined from v_i to v_j, and ∞ means that there is no branch between v_i and v_j, or have a branch but the direction is from v_j to v_i. In this article the branch reactance represents value, G is a directed graph, and A is a N order square matrix.

Connect two nodes v_i and v_j in the graph , and directed edges could be obtained, which constitutes a path between v_i and v_j. The path does not contain any reverse branches, if a branch value e_{i-j} stands for length of the edge, then a path length is the path length of all edges and denoted

$$d(l) = \sum_{e_{i-j} \in l} w_{i-j} \tag{3}$$

Think that there are several paths Between two nodes, if the paths are arranged with length, just as $l_1, l_2, l_{3,} \cdots, l_k$,and which satisfied $d(l_1) \le d(l_2) \le \cdots \le d(l_k)$, they are called the shortest (1 short) path , the second short (2 short) paths, $\cdots$,the first K shortest paths. This article is to find out the K shortest path between two nodes, in order to quickly find the lines influenced mostly by the power flow transfer.

Transmission section search algorithm steps

According to the timely power flow information and the network parameters, the electricity network can be converted into a weighted topology.

(1) Eliminate the grounding branches and the power supply branches ,the power supply nodes and load nodes can be seen as the vertices, branch can be seen as edges and reactance value can be seen as a weight of the edges;

(2) Eliminate the suspension node, which can be expressed in Fig.3.

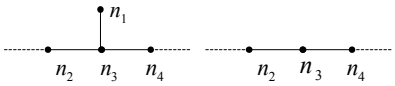

Fig.3 n_1 and n_3 can be merged

(3) Forming a weighted directed adjacency matrix A, if the weighted directed graph has n nodes, then the directed weighted adjacency matrix A is $n \times n$ non-symmetric matrix.

1）for all nodes $v_j(< v_s, v_j >\in E(G))$, $d(v_{j(1)}) = A(s, j)$, $pre(v_{j(1)}) = s$, $prs(v_{j(1)}) = 1$;

2）The end nodes is defined as v_e, if all $v_{e(m)} \in S$, then turn to 7）, if not ,turn to 4）;

3）for all nodes $v_{i(m)} \in \overline{S}$, calculate the $\min(d(v_{i(m)}))$, we call it $\min_{tep}$, which's $v_{i(m)}$ is $v_{p(q)}$,then $S = S \bigcup v_{p(q)}$;

4）for all nodes v_k （$< v_p, v_k >\in E(G)$）,

①if $d(v_{k(q)}) > \min_{tep} + A(p,k)$,then

$d(v_{k(K)}) = d(v_{k(K-1)})$, $d(v_{k(q+1)}) = d(v_{k(q)})$, $pre(v_{k(K)}) = pre(v_{k(K-1)})$,

$d(v_{k(q)}) = \min_{tep} + A(p,q)$, $pre(v_{k(q)}) = p$, $prs(v_{k(q)}) = q$

If not we use $q+1$ replace the q, turn to step1; Turn to step 4;

5）if for all nodes $v_{e(m)}, m = 1,2,\cdots,K$, $v_{e(m)} \in S$, then it has K shortest paths, turn 6）if not ,over;

6）Back from the end node to the source node to find the K shortest paths .

Simulation example

In order to verify the correctness of the algorithm, CEPRI36 node system is used for a simulation. Example 1: branch L_{19-21} simulation, part of the power flow of the transfer coefficients are shown in Table 1, and then use the algorithm searches the first K shortest paths, K value is 4,the search path information is shown in Table 2.

Tab.1 Distribution factors of part line to L_{19-21}

Line	power flow Transfer	Line	power flow Transfer
L_{15-12}	0.6871	L_{13-17}	0.2752
L_{14-15}	0.4308	L_{17-16}	0.2406
L_{19-14}	0.3963	L_{28-13}	0.2363
L_{22-21}	0.2867	L_{23-22}	0.1643
L_{27-28}	0.2824	L_{16-19}	0.1628
L_{12-27}	0.2752	L_{31-33}	0.1124

Tab.2 Path search data of L_{19-21} removal

path	paths	Transmission section
P1	21-16-17-13-28-27-12-15-14-19	L_{15-12}, L_{14-15}, L_{19-14}, L_{22-21}
P2	21-22-20-16-17-13-28-27-12-15-14-19	L_{12-27}, L_{13-17}, L_{28-13}
P3	21-22-23-9-10-11-25-26-12-15-14-19	
P4	21-22-9-10-11-25-26-12-15-14-19	

From the table, we can conclude that the branches which has larger power flow transfer coefficient are contained within the first six shortest path, and we can see that the branches with a larger distribution coefficient are concentrated in the first shortest paths L_{15-12}, L_{14-15}, L_{19-14}, L_{22-21}.

Epilogue

Reasons for the chain overload trip accident are summarized, and then characteristics of overloaded circuit after resection are analyzed. A new K shortest path algorithm based on K shortest paths is presented which is less complex. Multi-path search method avoids leakage election situations caused by only a single one line search. Finally, the simulation verified feasibility and rapidity of the algorithm.

Keywords: TMS320F28335, Rotary Inverted Pendulum, Double-loop PID control, Matlab Model-Based Design

Abstract. Aiming at the characteristic of nonlinear and natural unsteadiness in rotary inverted pendulum system. This kind of system uses the DSP TMS320F28335 of TI as the control and testing core of this system, adopts DC motor JGB37-3530 and motor drive L298, high precision potentiometer WDY35D4 as sample controller. Angle-to-resistance-to-voltage conversion is achieved by potentiometer, sensors export analog voltage to the first-order filter for filtering noise and transmit signal to the interior of TMS320F28335 and take ADC sample, then use digital filter algorithms to filter the signal again. Finally using double-loop PID control scheme to control motor precisely. Both DSP algorithm and program are implemented by Model-Based Design in Matlab, according to the process of model-simulation-code generation, this rotary inverted pendulum realizes the function of pendulum inverted and rotated. Experiments show this system has a stable and rapid transient process, possesses good stability and resisting disturbance.

Introduction

Inverted pendulum system is typical multi-variable, nonlinear, strong-coupling and instability naturally, as a typical control target, it has been subjected to many experts and scholars' concern [1]. Method and technology of control theory of inverted pendulum will serve as a significant role in processing of semiconductor and precision instrument, robotics, servocontrol field, control system of missile intercepts, control technology of aircraft docking [3]. The future for development and utilization is therefore bright. Generally, the analysis and calculation of inverted pendulum motion use physical feedback analysis and movement trace navigation by camera. The complex structure, higher requirements to the sensors and the disadvantages of time complexity are the main shortcomings of physical feedback analysis [3]. While the extremely complex structure, the highly design cost and the disadvantages in practical application are the main shortcomings of movement trace navigation by camera [3]. As for fuzzy control method, highly complex algorithm, lag of response time and bad simulation effect are it main shortcomings [2]. At present, many researches are aimed at the simulation control and researches on real control are most based on linear inverted pendulum. To avoid such advantages that stated above, we start from setting the physical model of Rotary Inverted Pendulum, and then design a control system with relatively low complexity and shorter response time aiming at the problem of balance control of inverted pendulum, which are based on conventional PID control of classical control theory and on linear quadratic regulator (LQR) of optimal control theory. Basing on the simulation test, we also develop experimental study on that system.

Model-Based Design is a front technology of the 21st century and with the help of that technology the development time and cost only has the tradition 1/5 to 1/2 about [13]. This technology has a main feature: the developers only have to care about the algorithm and test case so that they do not need to program or debug code which is done by computer automatically and the whole design is realizing on a uniformly virtual software platform. Therefore, we choose Matlab 2013a as our instrument of Model-Based Design. We link it with CCS which is a software developed by Texas Instruments to develop embedded software. Through Matlab, we also realize continuous test on code and generate code model after simulation.

Establishment of mathematical model

The Rotary system pendulum model, as shown in Fig.1, consists of a base 1, a stent 2, a DC motor 3, a rotary arm 4, an angular displacement sensor 5 and a vertical pendulum 6. The system measures real-time states of vertical pendulum via the angular displacement sensor and sends the states of position, angular velocity and angular acceleration of vertical pendulum to the main control chip. Main control chip adjusts the states of vertical pendulum and then keeps it standing upside down through controlling DC motor's current and torque.

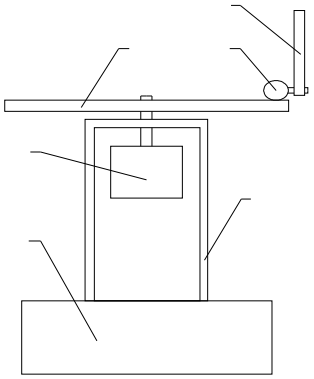

Fig. 1. Rotary Inverted Pendulum model

As shown in Fig.2, simple Rotary Inverted Pendulum consists of a rotary arm and a vertical pendulum. In Fig. 2, l_1 represents the length of rotary arm and l_2 represents the length of vertical arm. We choose counterclockwise direction as the reference direction. θ_1 is the angle of rotation of the rotary arm and θ_2 is the angle of rotation of the vertical pendulum in the plane perpendicular to the arm [12].

This system has 2 DOF motion, in which rotary arm can rotate flatly about z axis so that the rotary arm can make the pendulum into working state in which θ_2 is kept in a small range. We select a minimal length whose distance is l from hinge O and coordinates of this minimal length are

$$x = l_1 \cos\theta_1 - l \sin\theta_2 \sin\theta_1 \tag{1}$$

$$y = l_1 \sin\theta_1 + l \sin\theta_2 \cos\theta_1 \tag{2}$$

$$z = l \cos\theta_2 \tag{3}$$

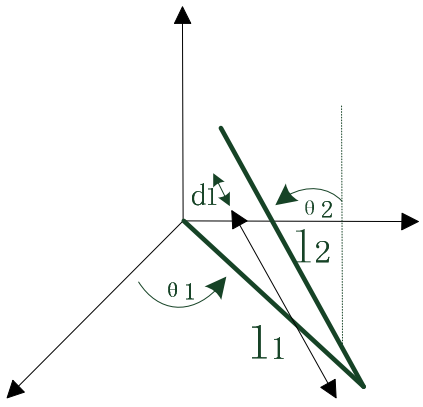

Fig. 2. Mathematical model of Rotary Inverted Pendulum

Suppose that the mass of the vertical pendulum is m_2 and kinetic energy of the pendulum is

$$T_{l_2} = \int_0^{l_2} dT = \frac{1}{6} m_2 [(\theta_1^2 - \theta_1^2 \cos^2\theta_2 + \theta_2^2) l_2^2 + 3 l_1 l_2 \theta_1 \theta_2 \cos\theta_2 + 3 l_1^2 \theta_1^2] \tag{4}$$

There is only kinetic energy on rotary arm and its kinetic energy is

$$T_{l_1} = \frac{1}{2} J_1 \omega_1^2 = \frac{1}{6} m_1 l_1^2 \theta_1^2 \tag{5}$$

The total kinetic energy of the system is

$$T = T_{l_1} + T_{l_2} \tag{6}$$

We select the plane of rotary arm as the reference plane of the zero of potential energy and the total potential energy which is also the potential energy of pendulum is

$$V = \frac{1}{2} m_2 g l_2 \cos\theta_2 \tag{7}$$

The Lagrange's operator is L=T-V. Generalized coordinates of the system are $q=\{\theta_1, \theta_2\}$ and there is no external force on generalized coordinate θ_2. Suppose that F_1 is generalized force and from Lagrange's equations we can get

$$\frac{d}{dt}\frac{\partial L}{\partial q_i} - \frac{\partial L}{\partial q_i} = F_i (i = 1, 2) \tag{8}$$

Thus we get the nonlinear mathematical model as follows:

$$M\ddot{q} + N = F_q \tag{9}$$

Where

$$M = \begin{bmatrix} (J_1 + m_1 l_1^2 + m_2 l_2^2 \sin^2\theta_2) & 2m_2 l_1 l_2 \cos\theta_2 \\ 2m_2 l_1 l_2 \cos\theta_2 & J_2 + m_2 l_2^2 \end{bmatrix} \tag{10}$$

$$N = \begin{bmatrix} -2m_2 l_1 l_2 \sin\theta_1 \theta_2^2 + 2m_2 l_2^2 \theta_2 \theta_1 \sin\theta_2 \cos\theta_2 \\ -m_2 l_2^2 \theta_1^2 \sin\theta_2 \cos\theta_2 - m_2 g l_2 \sin\theta_2 \end{bmatrix} \quad F_q = \begin{bmatrix} u \\ 0 \end{bmatrix} \tag{11}$$

J_1 is the rotational inertia of rotary arm when arm is rotating around Z axis as follows:

$$J_1 = \frac{1}{3} m_1 l_1^2 \tag{12}$$

J_2 is the rotational inertia of vertical pendulum when pendulum is rotating around hinge as follows:

$$J_2 = \frac{1}{3} m_2 l_2^2 \tag{13}$$

Double-loop PID control in inverted pendulum system and simulation by Matlab

After the establishment of the physical model, we can get the module chart of inverted pendulum system as follow in Fig. 3.

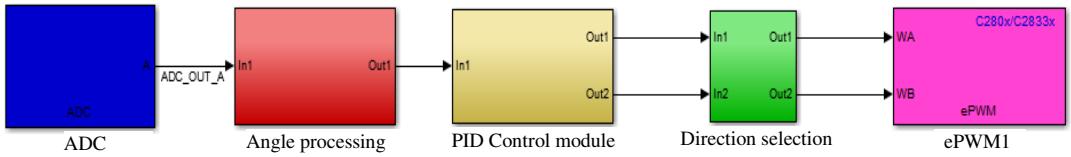

Fig. 3. The module chart of inverted pendulum system

We use double-loop PID control in PID Control module. The structure chart and inner structure chart of this system as shown in Fig. 4 and Fig. 5：

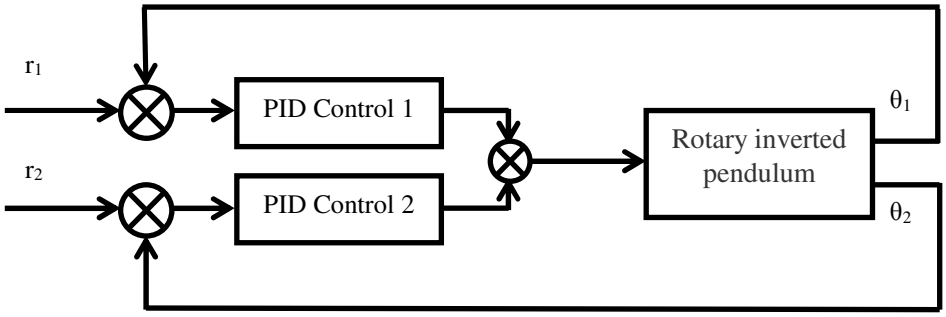

Fig. 4. Double-loop PID control

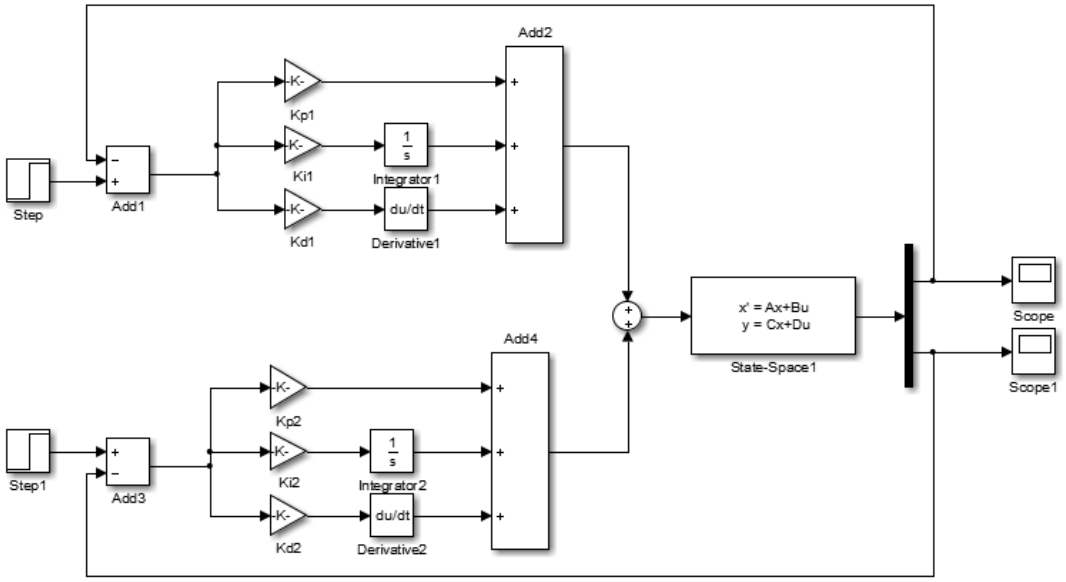

Fig. 5. Simulation of double-loop PID control by simulink

When a proper perturbation is given, by adjusting the parameters continuously, we can determine the parameters in the two PID controller in Table 1.

Table 1. The parameters in the two PID controller

	K_p	K_i	K_d
PID1	-90	-78	-63
PID2	220	50	45

The result of simulation can be seen in Fig. 6 and Fig. 7:

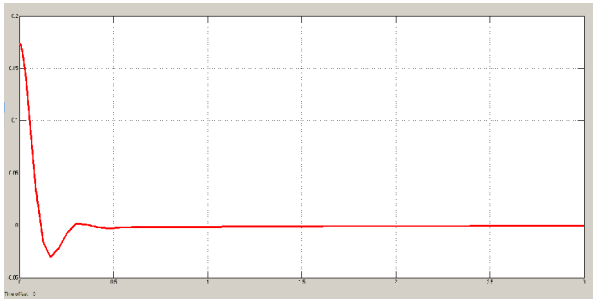

Fig. 6. Rotary arm

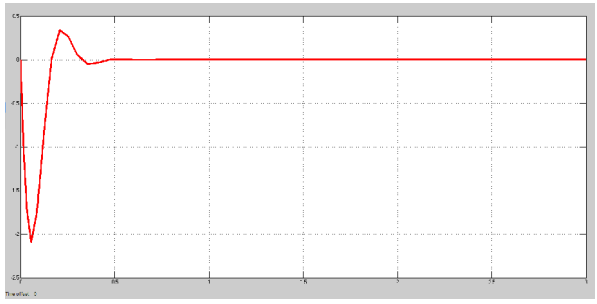

Fig. 7. Pendulum

Finally we make conclusion from those figures: double-loop PID control has basically achieved stabilization of radial arm and pendulum rod. Besides, we also find out that this inverted pendulum system has a low sensitivity to the parameters in PID controller, which means our parameters in PID controller are able to have a appropriate variation range.

Systematic design

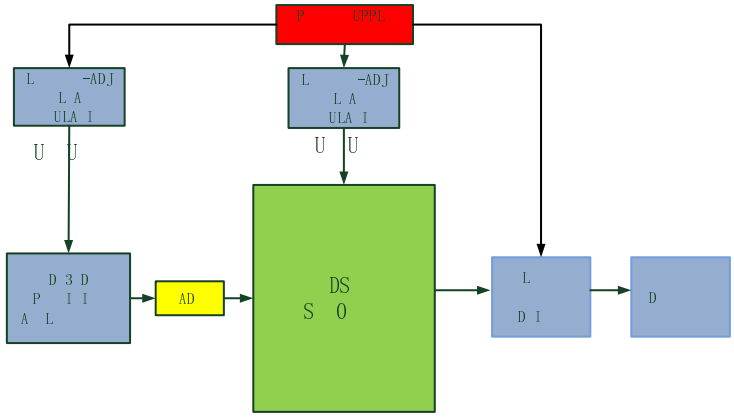

Fig. 8. System structure

We choose TMS320F28335 which is a DSP of Texas Instruments as our main chip of our system. TMS320F28335 has lots of advantages: it has a high computing power, many enhanced modules, many General-Purpose Input/Output ports, a 12-bit ADC with 16 input channels, as well as high freedom. And it can also realize code generation and code debugging with the help of CCSlink kit of Matlab, through which can we link Matlab with CCS. Model-Based Design can reduce the work of developers sharply because developers do not need to program laboriously.

We choose a DC motor as the driving motor and the model of motor is JGB37-3530. The voltage rating of the motor is 12V and its no-load speed is 531r/min. When the motor is running under rated load, its load current is 400mA and its torque is 0.00686 Nm. L298N which is a motor diver ship has many advantages, such as simplicity of its peripheral circuit, high reliability, capability of controlling speed and displacement of DC motors by software, and capability of being driven by DSP directly. We choose WDY35D4—angular displacement sensor of conductive plastics of which the resistance is 10K—as angular displacement sensor of vertical pendulum and we bond the senor to the pendulum tightly so that the axis of the sensor can rotate together with the pendulum without any slide. We should know that the sensor has one-to-one relationship between resistance and pendulum's position. By applying 3V electric voltages to the total resistance of the sensor, we can get voltage signal which is caused by the changing of resistance of the sensor and which is corresponding to the current position of the pendulum. As for power supply module, we choose LM2596S-ADJ which is a 3A step-down voltage regulator. The LM2596-ADJ is capable of driving a 3A load with excellent line and load regulation and of outputting adjustable voltages from 1.2V to 37V. LM2596S-ADJ has packaged a fixed-frequency oscillator and a voltage-reference regulator in it. Thus, using LM2596S-ADJ to build an efficient step-down circuit, we only need little peripheral devices. And yet the conversion efficiency is greater than 75%. We use ePWM module to control the DC motor precisely and test the encoder which is fixed with DC motor's axis to get the status information of the DC motor at the same time. The DC motor has many advantages, such as its stable operation, small vibration, and convenience to maintain and use. Besides those, the DC motor not only has a large range of revolving speed, but also has a high torque. System structure is shown in Fig. 8 and experimental device is shown in Fig. 9.

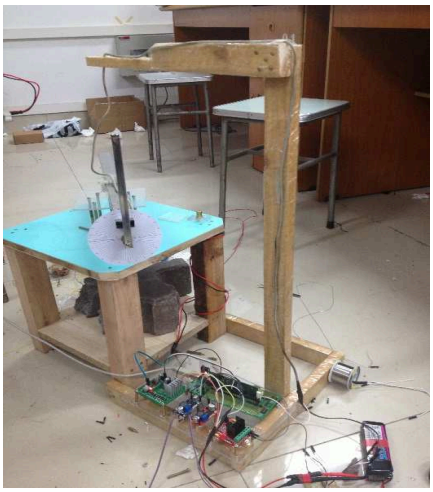

Fig. 9. Experimental device with pendulum standing vertically

Conclusion

After establishing simulation by Matlab, we use TMS320F28335 DSP controller and motor drive to exert control over this kind of rotary inverted pendulum. Besides, using high precision potentiometer WDY35D4 can adjust return signal of position, double-loop PID control can let pendulum rod achieve the function of inverted quickly. As a result, this kind of rotary inverted pendulum has a high ability to achieve inverted stably under partly interference of external environment.

The design of electronic weighing control system based on proteus

Rongxia Sun[1] Xingwang Feng[2] Xing Hao[3] Yingchang Zhou[4]

Shuonan Wang[5]

College of Electronic and Informational Engineering, Hebei University, Baoding 071002）

Key words: AT89C51MCU;A/D exchange;Sensor

Abstract: The control core of this design is MCU AT89C51,with the sensor MPX4115,it can complete the detection of weighting signal.Use the ADC0832 chip to achieve signal conversion, the input use a square 4*4 keyboard,the output display use the LCD LM4229.Use C Language Programing to achieve the modular design of software,use proteus simulation system to achieve the measure of weight of nine kinds of goods,The weighing range from 0.546Kg to 4.980Kg;Its resolution is 0.001Kg;This system has the function of calculating total price,storing single price,alarming when the goods overweights.

Introduction

To measure the weight of the object simply and easily，in this paper,we use proteus simulation method to design the software and hardware of electronic scale whose control core is AT89C51MCU.

Hardware system design

This design system use three modules to design the program of the electronic scale.They are data collection,human-computer interraction and minimum system.The system structure is shown in Figure 1.

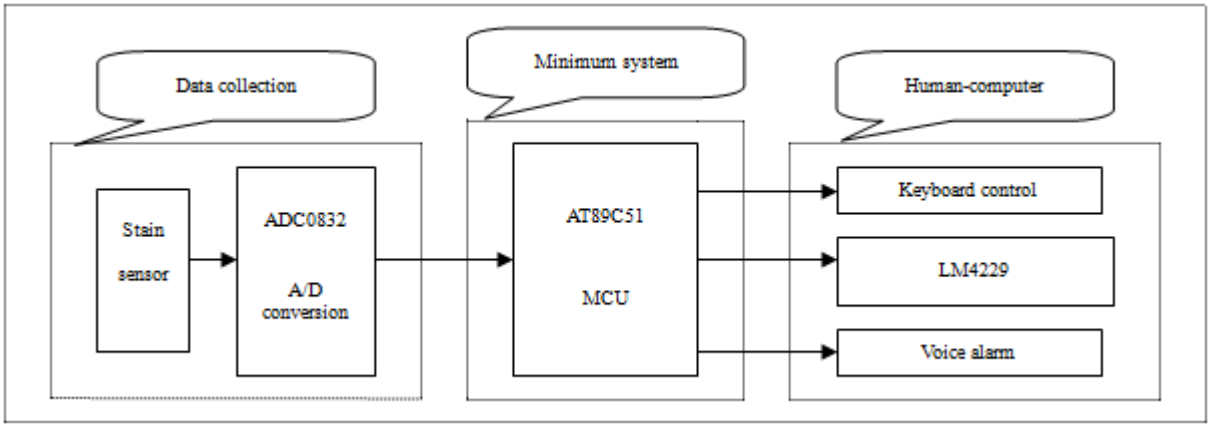

Figure 1 The electronic scale system block diagram

Working principle：firstly,use the sensor to detect the weight of the object and convert it into a voltage signal.Then use amplifier circuit enlarge linearly voltage precisely.Then convert the amplified analog voltage signal to digital signal through A/D converter circuit and take it to MCU.Then through MCU control LCD display and finally it shows the weight of the object in the LCD display.

Data collection

1.1.1 Data input detection

In the proteus simulation，The data input detection use the sensor MPX4115.Its pin 1 is connected with the pin CH0 of the chip ADC0832,input the signal which is detected by the sensor to the chip ADC0832,and it attach DC voltmeter.Pin 2 and pin 3 connect ground and power respectively.

1.1.2 Signal conversion

Use the chip ADC0832 to achieve A/D conversion.Its port VCC and GND connect ground and power respectively.The pin CS is the enable pin,the low is effective and it links the port P3.5.Pin CH0 links the pin 1 of the sensor,receive the signal which comes from sensor.Pin D0 and D1 link the port P3.7.Pin CLK links the port P3.6,receive the clock signal came from MCU.

1.2 MCU controlling

Use AT89C51MCU to achive weight control.The port P1 links keyboard,receives keyboard signals and makes corresponding control.The port P0 links LM4229 data terminal to output data.The port P2 links LM4229 control terminal and control its display.The port P3.0 links alarm circuit.It will control LS1 alarm when the weight is excessive.

Human-computer interaction

1.2.1 Display module

The display section use LM4229 in human-computer interaction module.The pin D0-D7 link the port P1,it receives data came from MCU.CE is the enable pin, the low is effective and it links the port P2.7.The pin RST links the port P2.3.V0 links the power.The C/D, RD, WR function as follows: WR=0, C/D=1 Write Command， WR=0, C/D=0 Write Data,RD=0, C/D=1 Read Command,RD=0, C/D=0 Read Data,the low is effective.FS1 controls the size of the display font. The effect of HALF is to stop vibration.

1.3.2 Keyboard Input

The keyboard input use the 4×4 matrix keyboard,its test is divided into two groups,one group is row line,one group is column line,the button is on the intersection of the row and column lines.The matrix keyboard need less I/O interfaces,One M×N matrix keyboard only need M+N pieces of test lines when it connects with host computer.

Software System Design

The software design part of the weighing system mainly includes main program,display subroutine,data acquisition subroutine,keyboard Subroutine and overload alarm subroutine.

2.1 The main program design

The design of the weighing system adopts modular design method,the main program is divided into several small modules,then draw the procedure flow charts of each module respectively, compile each module applications respectively according to the structure of the procedure flow charts,finally connect each module into a complete program.The procedure flow chart of the main program is shown in figure 2.

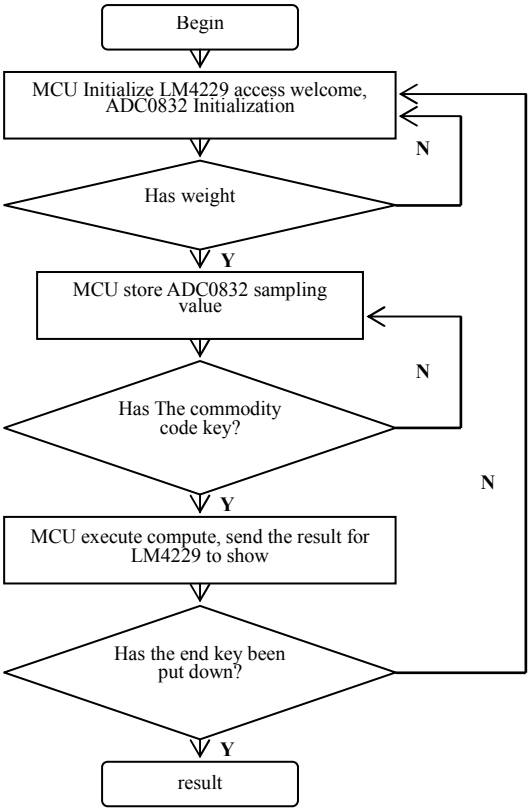

Figure2 The flow chart of the main program

2.2 The display subroutine design

Firstly, write control operation words in the display.Then write the initial row address, move the pointer to the left, until all the data is finished. The show subroutine flow chart is shown in Figure 3.

```
write_data(place&0xff); //Written to address high
write_data(place/256); //Written to address low
write_com(0x24); //Set address
write_com(0xb0); //Set data is automatically written
write_data(ASC_MSK[(c1-0x20)*16+k]);
write_com(0xb2); // Reset automaticly
```

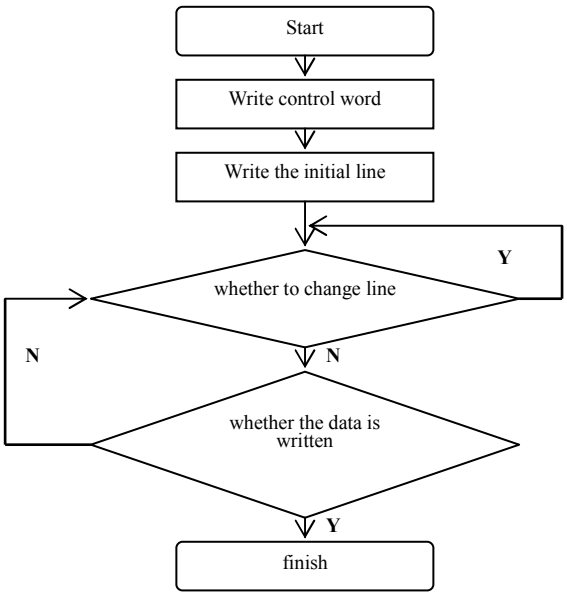

Figure 3 The display subroutine flow chart

2.3 The sampling subroutine design

MCU switchs on ADC0832 through swigging down CS and swigging up CLK , then it can take sample to the voltage signal . Once start up 8 CLK pulses ,DATA get a full 8bit data .At this point the MCU sends an interrupt request，the level of CS is set high, the level of CS is set low and the data is returned.Data collection section is finished by ADC0832 with the main four parts of initial, reading data, returning data and ending. After the ADC0832 initialized, convert the 0~7 analog signal of one channel to digital signal 00H-FFH.Then store it into specified unit in the internal RAM of the 8051.The sampling subroutine flow chart is shown in Figure 4.

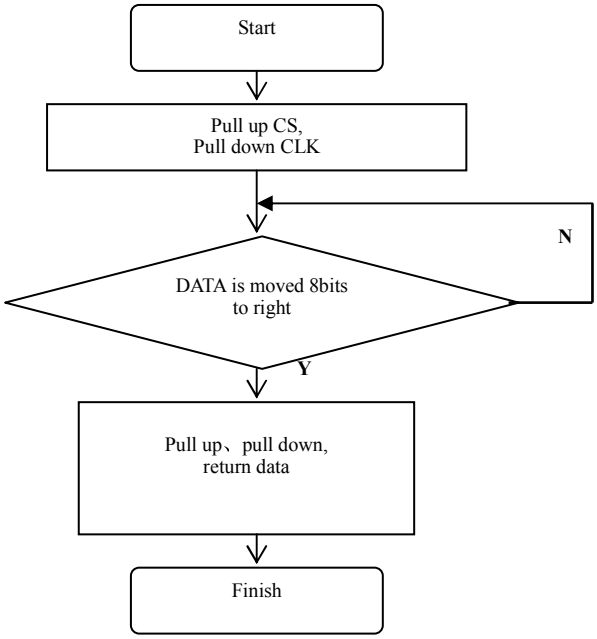

Figure 4 The sampling subroutine flow chart

2.4 The keyboard control subroutine flow chart

Adopt a 4 * 4 matrix keyboard,MCU queries timely.Firstly,The MCU transmits line scan code, and then scan the column, when a low level has been found in a column, the corresponding value is returned to the keyboard. If you did not find the description of the current line,then it means no key is pressed and line scan right one, proceeding column scanning.According to the corresponding key value, MCU can determine the pressed key. Analyzing button code in the program can be in the first place, and sends it to the corresponding numeric keypad representative memory cell according to the code, and then select functions or data processing. Keyboard control subroutine flowchart is shown in Figure 5.

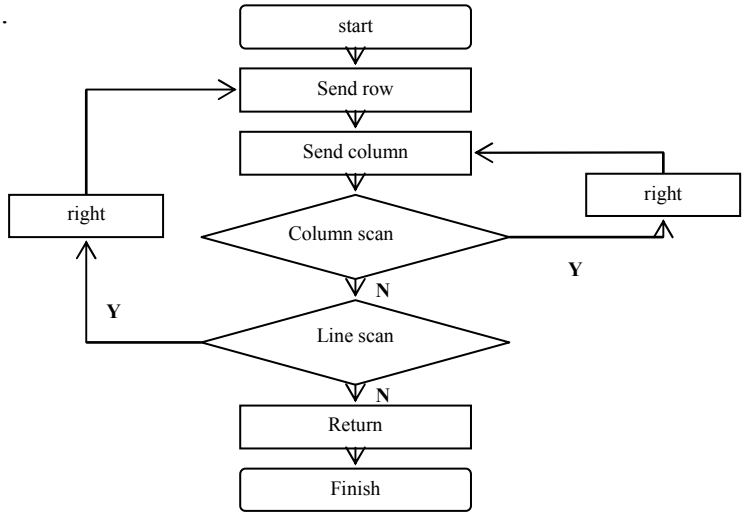

Figure 5 The keyboard control subroutine flow chart

The Simulation Experiment

The result of proteus simulation is shown in the figure 6.

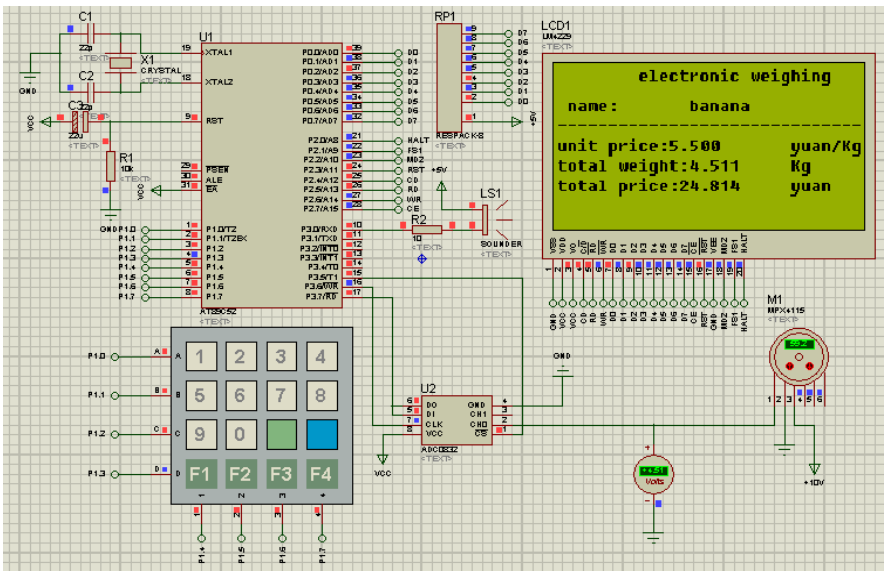

Figure 6 The proteus simulation

The electronic scale sets 16 keys,of which the "0"means cancel,and "1"～" 9 "reprsent the different prices of different comodities,each of them stands Banana, apple, orange, mango, pear, watermelon, orange, peach, sugar cane,and other keys can support the service of chosing the price of comodities.When the input voltage of sensor is +10V,the circuit will work normally, regulating the value of MPX4115 will change the weight of the comodities,and when the value of the voltmeter is greater than 4.980V, the alarm circuit will start to work.

Conclusion

The following functions have achieved though the simulation experiments weighing system: Weighing range 0.546Kg ~ 4.980Kg; Controlling the keyboard can display the unit price of banana, apple, orange, mango, pear, watermelon, orange, peach, sugar cane.Its resolution is 0.001Kg; When weight measured exceeds 4.980Kg, the alarm circuit would keep going until the weight dropped into 4.980kg.The total price of the product can calculate automatically according to the weight and unit price that 4 * 4 matrix keyboard selects.

Keywords: Smart grid, Maturity, Fuzzy comprehensive assessment

Abstract: Smart grid must be evaluated correctly so that its development stage is determined and weak links, restrict factors in development are found. Based on it, the path from the stage to the next stage is planned for power enterprises. In view of the poor accuracy of conventional assessment methods, caused by subjective factors and uncertainty, the fuzzy comprehensive assessment method is applied to assess smart grid. Firstly, a smart grid assessment system is founded based of IBM's smart grid maturity model, and then method and procedure of fuzzy comprehensive assessment method are introduced. The study on an example shows that this approach is effective and feasible.

Introduction

Smart grid is the inevitable development trend of modern power grid and it has played an important role in response to the energy crisis and environmental degradation. Smart grid construction is a great and complex system engineering. The comprehensive and scientific assessment on smart grid have important theoretical significance and practical value for smart grid planning, construction, operation and management because by the assessment the difference from the goal and the direction needed to be readjusted can be identified.

Accurate assessment of power grid needs a correct evaluation system. Amounts of research have been done in this respect at home and abroad. The study focuses on assessment system founding in many research institutions, which shows that the assessment plays an important role in guiding and promoting of smart grid development[1]. Many smart grid assessment systems have been proposed which include IBM Smart Grid Maturity Model (SGMM)[2], Smart Grid Development Evaluation Index System of the U.S. Energy Department[3], the EU's Smart Grid Revenue Assessment System[4] and Resource-saving and Environment-friendly Grid Index system of Beijing State Power Economic Research Institute[5]. Due to different national circumstances and different power development situations, a variety of smart grid evaluation systems all have respective focus. As one of the earliest famous institutions to promote the smart grid development, IBM proposed SGMM in 2009 and the model has been applied to more than 50 power companies in the world.

Traditional scoring method is often used in smart grid evaluation. The evaluation procedure is simple, but the method is arbitrary and the results are inaccurate. In addition, some uncertainties in the evaluation process of the smart grid may also lead to big error between the evaluation results and the actual data. A dynamic evaluation method based system dynamics model for smart grid is proposed in reference [6]. Because its starting point is the smart grid investment, the rationality and validity has yet to be verified if other factors are considered. Fuzzy theory is one of the uncertain system theory and the fuzzy evaluation method has been widely used in many fields[7~9]. In order to decrease the error caused by subjectivity and uncertainty, the fuzzy evaluation method is employed to access smart grid in this research and the effectiveness of the method is proved through an instance.

Smart Grid Maturity Model

SGMM, proposed by IBM mainly, is an index system to measure the level of smart grid construction. By using the model, the current stage of smart grid can be determined, the difference from goals can be identified and the direction can be readjusted. The clear business model and the detailed plan can be guided to found for grid enterprises and the development path from this stage to the next maturity stage can be established.

A. Five Stages of Smart Grid Construction

According to planning, construction, operation and management of the power grid, SGMM divides smart grid development into five stages as follows.

Stage 1-Awareness and Starting: The stage is smart grid conceptual stage. Smart grid is paid attention and the grid enterprise has an aspiration to develop it. The smart grid is not yet planned but the construction of non-system business module may have been started.

Stage 2-Independent Business Investment: At least one of major business areas of smart grid began to be invested and constructed. The areas are electrical information collection, Demand Side Management (DSM) or the deployment of a distributed intelligent monitoring network which can improve the reliability of the power grid.

Stage 3-Business Integration: Many parts of smart grid began to be integrated with each other. The integration of two or more business areas is achieved, or the industry chain is upgraded.

Stage 4-Enterprises Optimization: Role and effectiveness of smart grid are understood profoundly. Enterprise-wide comprehensive observation and integrated control can be achieved across business, and then a new economic or business model may be founded.

Stage 5-Innovation and Promotion: Enterprises have the ability to take full advantage of the opportunities such as new business, operation and environment to grow and develop.

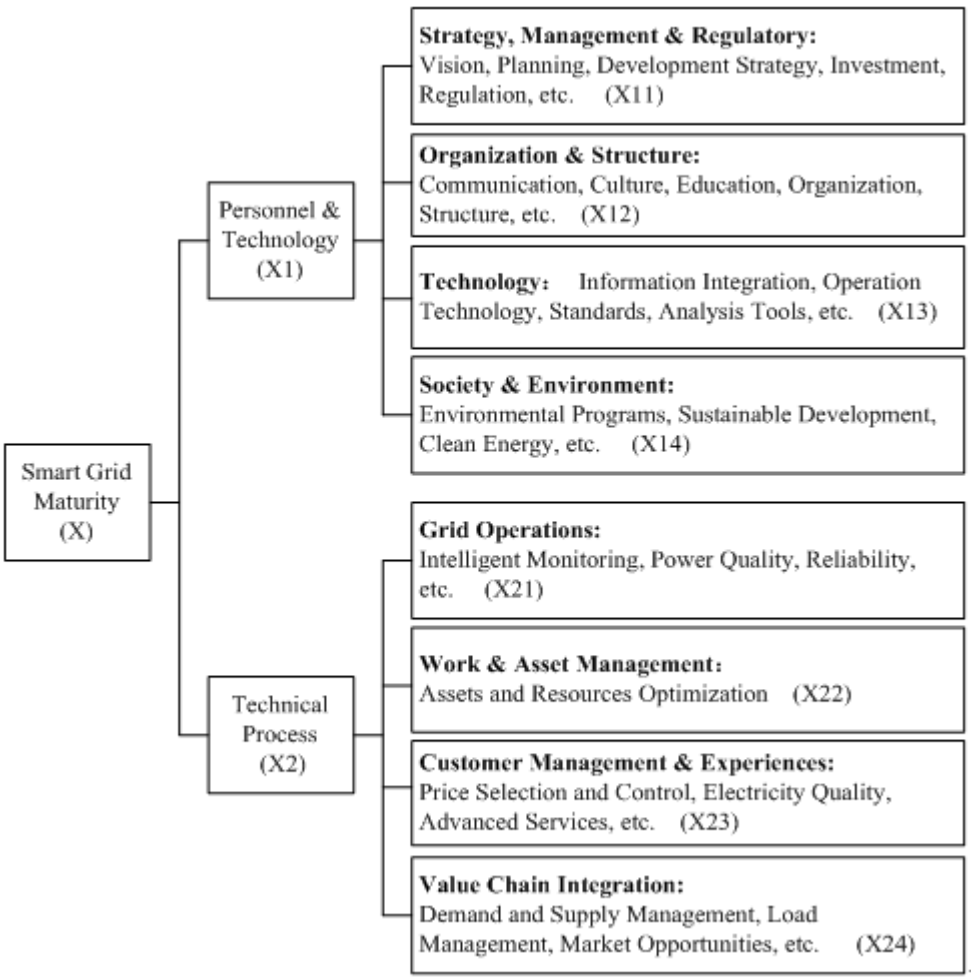

Fig.1 IBM smart grid maturity model

B. Smart Grid Maturity Assessment System

For SGMM, maturity of smart grid is analyzed comprehensively from two areas of Personnel & Technology and Operational Processes, eight dimensions (indexes) of Strategy & Regulatory, Organization & Structure, Technology, Society & Environment, Grid Operations, Work & Assets

Management, Customor Management & Experience, Value Chain Integration. The number of specific technical indexes of eight dimensions is up to 200 and the system is still improved. IBM Smart Grid Maturity Evaluation System is shown in Figure 1 (only some main technical indexes are given due to space constraints).

From Figure 1, it is shown that the system includes three levels of the total target level (first-level index), the criterion level (second-level index) and the sub-criteria level (third-level index), and the system is a comprehensive hierarchical structure evaluation model which is composed of one first-level index, two second-level indexes and eight third-level indexes.

1) Factors set of all levels

In the index system shown in Figure 1, the factors set of the first-level (the total target level) is {X}; the factors set of the second-level (the criterion level) is {X1,X2}; the factors set of the third-level (the sub-criterion level) is {X11,X12,X13,X14; X21,X22,X23,X24}.

2) Weights set of all factors

In general, the importance of various indexes in same level is different, and the weights of important indexes should be bigger. Weight values may be assigned directly according to experience, and can also solve by use of Analytic Hierarchy Process or entropy method. For the system shown in Figure 1, the weight set is expressed as following.

The criterion level: $A=\{a_1, a_2\}$

The sub-criterion level: $A_i=\{a_{i1}, a_{i2}, a_{i3}, a_{i4}\}$, $i=1,2$

Which, a_{ij} is the weight of No.j factor in the sub-criterion level, No.i factor in the criterion level. The weights satisfy the following equation.

$$\begin{cases} a_1 + a_2 = 1 \\ \sum_{j=1}^{4} a_{ij} = 1, \quad i = 1,2 \end{cases} \tag{1}$$

3) Remark set

Evaluation results of each factor can be represented with 5 stages of SGMM, and stage 1~5 are indicated v_1~v_5 respectively.

Fuzzy Comprehensive Assessment of Smart Grid Maturity

A. Determination of Fuzzy Assessment Set

An assessment team which consists of m experts evaluates eight third-level indexes by using fuzzy evaluation method. Suppose that the number of experts who believe the sub-criterion level factor X_{ij} as v_1~v_5 is p_1~p_5, then the fuzzy evaluation set of factor X_{ij} is following:

$$\begin{aligned} R_{ij} &= \left\{ \frac{p_1}{m}, \frac{p_2}{m}, \cdots, \frac{p_5}{m} \right\} \\ &= \left\{ r_{ij1}, r_{ij2}, \cdots, r_{ij5} \right\} \end{aligned} \tag{2}$$

the fuzzy evaluation set of criterion level factor X_i is following:

$$R_i = \begin{bmatrix} r_{i1.1} & r_{i1.2} & \cdots & r_{i1.5} \\ r_{i2.1} & r_{i2.2} & \cdots & r_{i2.5} \\ r_{i3.1} & r_{i3.2} & \cdots & r_{i3.5} \\ r_{i4.1} & r_{i4.2} & \cdots & r_{i4.5} \end{bmatrix} \tag{3}$$

B. The First-level Fuzzy Evaluating

All sub-criterion level factors for the No.i factor of criterion level are evaluated and the evaluating result (i.e., equation(3)) is the fuzzy matrix of the factors. The matrix is multiplied by weight matrix of all sub-criterion level factors, and then the membership degree matrix that the evaluation results belong to v_1~v_5 can be obtained.

$$B_i = \begin{bmatrix} b_{i1} & b_{i2} & \cdots & b_{i5} \end{bmatrix} = A_i \bullet R_i \tag{4}$$

Which, b_{ij} is the membership degree that the evaluating result of Criteria i (i=1,2) belongs to Stage j (i.e. v_j, j=1,2,…,5).

C. The second-level fuzzy evaluating

The result of the first-level evaluating (i.e. equation (4)) is multiplied by weight matrix of all criterion level factors, and then the membership degree matrix that the evaluation results belong to v_1~v_5 can be obtained.

$$B = \begin{bmatrix} b_1 & b_2 & \cdots & b_5 \end{bmatrix} = A \bullet B_i \tag{5}$$

Which, b_1~b_5 is the membership degree that the smart grid maturity belongs to v_1~v_5.

Case Study

Maturity of a regional power grid is analyzed. All indexes are assessed by 15 experts and the number of experts who believe that eight sub-criterion level factors belong to v_1~v_5 is shown in Table 1.

Table1 The assessment results for every factors

Index Number	Index Name	The number of votes for various stages				
		Stage 1	Stage 2	Stage3	Stage4	Stage5
X_{11}	Strategy, Management & Regulatory	5	5	4	1	0
X_{12}	Organization & Structure	4	6	3	2	0
X_{13}	Technology	6	5	4	0	0
X_{14}	Society & Environment	4	5	6	0	0
X_{21}	Grid Operations	5	5	4	1	0
X_{22}	Work & Assets Management	4	5	3	2	1
X_{23}	Customor Management & Experience	6	6	3	0	0
X_{24}	Value Chain Integration	5	4	5	1	0

Two factors of the criteria layer are weighed equally, that is A={0.5,0.5}. Each factor weight of the sub-criteria level is worked out by entropy method:

$$A_1=\{0.252,0.217,0.366,0.165\}$$
$$A_2=\{0.364,0.216,0.229,0.191\}$$

The fuzzy evaluation sets of criterion level factors X_1 and X_2 are determined according to equation (2), (3):

$$R_1 = \begin{bmatrix} 0.333 & 0.333 & 0.267 & 0.067 & 0 \\ 0.267 & 0.4 & 0.2 & 0.133 & 0 \\ 0.4 & 0.333 & 0.267 & 0 & 0 \\ 0.267 & 0.333 & 0.4 & 0 & 0 \end{bmatrix}$$

$$R_2 = \begin{bmatrix} 0.333 & 0.333 & 0.267 & 0.067 & 0 \\ 0.267 & 0.333 & 0.2 & 0.133 & 0.067 \\ 0.4 & 0.4 & 0.2 & 0 & 0 \\ 0.333 & 0.267 & 0.333 & 0.067 & 0 \end{bmatrix}$$

The sub-criteria layer factors are evaluated according to equation (4) and the membership matrixes that the evaluation results belong to v_1~v_5 are worked out:

$$B_1 = A_1 \bullet R_1 = [0.332, 0.348, 0.274, 0.046, 0]$$

$$B_2 = A_2 \bullet R_2 = [0.334, 0.336, 0.25, 0.066, 0.014]$$

The criteria layer factors are evaluated according to equation (5) and the membership matrix that the evaluation results belong to v_1~v_5 are worked out:

$$B = A \bullet B_i = [0.333, 0.342, 0.262, 0.056, 0.007]$$

Because $\max_{1\le i\le 5}\{b_i\} = b_2$, the maturity of the regional power grid is stage 2(v_2), that is the independent business investment stage according to the principle of maximum degree of membership. However, it is only in the initial stage of v_2 because of the very close between b_1 and b_2.

Conclusion

The subjectivity of traditional evaluation methods and some uncertain factors in the evaluation process make the evaluation results inaccurate. Based on IBM's smart grid maturity model, fuzzy comprehensive evaluation method is employed to evaluate Smart Grid Maturity. From the calculation and analysis results on an example, it is proved that the method is simple and the smart grid can be evaluated objectively, scientifically and accurately.

Keywords: Solid oxide fuel cell (SOFC), microgrid; mode transition, bi-directional DC-DC converter, droop control.

Abstract. This paper presents a control strategy of solid oxide fuel cell (SOFC) generation system integrated into microgrid. To enhance the dynamic response of SOFC, storage battery is paralleled via a DC bus, and the hysteretic control of bi-directional DC-DC converter is adopted. The common DC-AC inverter adopts an improved droop control. The active synchronization control is applied to ensure the smooth mode transition of microgrid. The simulation results show the dynamic performance of SOFC generation system in different operation modes.

Introduction

Microgrid is a controllable unit containing distributed generation (DG), load and energy storage device. Solid oxide fuel cell (SOFC) has been widely concerned due to the characteristic of leak-tightness, high efficient comprehensive utilization and long service life, etc [1]-[3]. The electrochemical characteristics and models of SOFC have been widely researched in many articles. References [4] and [5] study the model of grid-connected fuel cells, whereas the research about inverter control strategy is relatively simple. The proposed SOFC model in [6] doesn't consider about controlling the output power by adjusting the fuel flow. With the deepening research, the studies about fuel cells for distributed generation and its application in microgrid increase gradually. But in most of the recent studies, the control method of SOFC is taken to be simple and the fuel cells are usually combined with other micro source. Furthermore, there is less research about the transition of micro-grid operation modes.

The SOFC generation system model and its control strategy adapting to grid-connected, islanded and transition between the two modes is proposed in the paper. DC-AC inverter adopts loop control with synchronization control for reconnection to realize the grid-connection smoothly. At the DC bus side, the storage battery (BESS) is in parallel with fuel cells through the bi-directional DC-DC converter. The hysteretic charging and discharging control is adopted to improve the dynamic response of SOFC. At last, Simulation of microgrid containing SOFC generation system in PSCAD/ EMTDC is conducted to analyze the response characteristics of SOFC in different modes and mode transition.

Modeling of SOFC

The constant fuel utilization control mode of SOFC is adopted in this paper. To remain the fuel utilization unchanged, the load current feedback is used to control the rate of fuel flow which is inputted into the fuel processor, thus a link between load and fuel input quantity is built. The block diagram of SOFC is shown in Fig. 1.

The load current I_{fc} of SOFC is taken as feedback. After a first-order inertia link with time constant T_e (T_e=0.8s), representing the electric dynamic response time of fuel cells, stack current I of SOFC is produced. Through the first-order inertial link (T_f = 5 s), which stands for the fuel processor chemical reaction process, the hydrogen flow $q_{H_2}^{in}$ is generated by stack current I, fuel efficiency u_{opt} and hydrogen reaction coefficient K_r. Then obtain the oxygen flow $q_{O_2}^{in}$ according to the oxygen-hydrogen ratio r_{HO}, and the unit of $q_{H_2}^{in}$ and $q_{O_2}^{in}$ is mol/s. p_{H_2} , p_{O_2} , p_{H_2O} and are the pressure of hydrogen, oxygen and water vapor. E_0, η_{ohm}, η_{act} and η_{con} are separately battery unit standard electromotive force, ohmic polarization loss, activation polarization loss and concentration polarization loss.

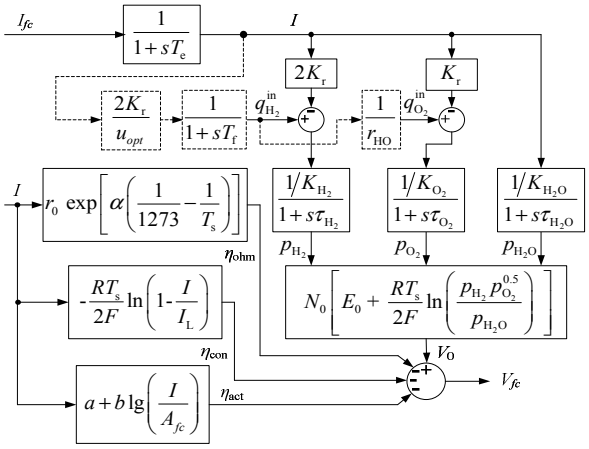

Fig. 1 SOFC dynamic model

Control of SOFC Generation System

The structure of SOFC generation system is shown in Fig. 2, which contains SOFC module, boost converter, DC-AC inverter, storage battery, bi-directional DC-DC converter.

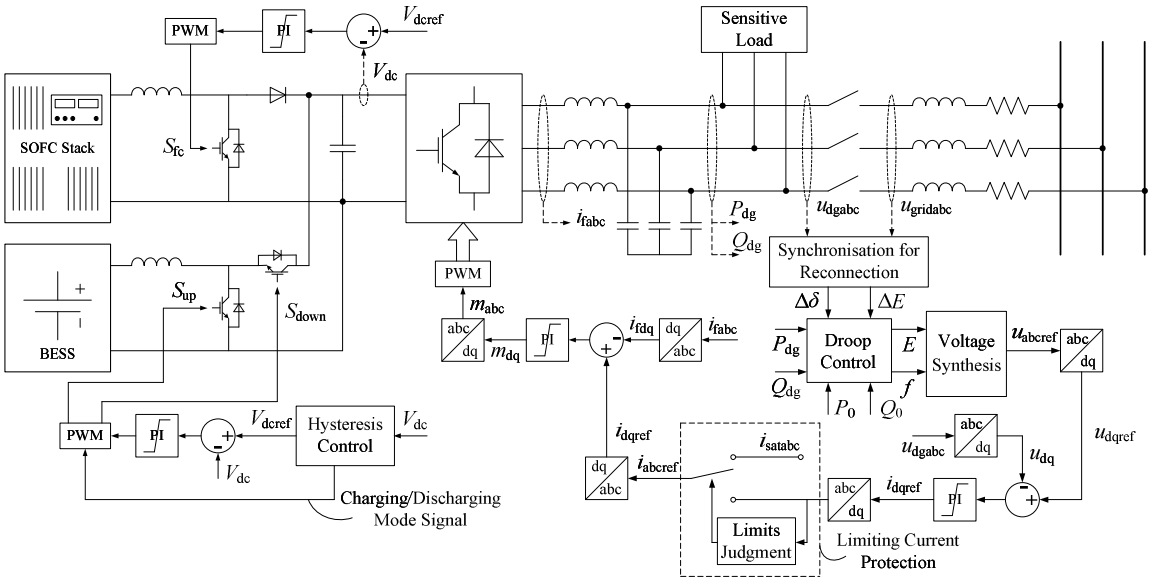

Fig. 2 Structure of SOFC generation system

According to the electrochemical properties of fuel cell, its output DC voltage has a large variation range with the change of load or temperature. Therefore, a boost conversion circuit is contacted at the DC output terminal of SOFC to satisfy the stable operation of inverter for the need of DC bus voltage. As the power regulative speed of fuel cells is slow, which cannot bear the rapid change of load, a storage battery is paralleled in the DC side of SOFC system, and bidirectional DC-DC converter is

used to realize the charging and discharging control of energy storage battery. SOFC module and storage battery are connected to the AC network through the common inverter, and its *LC* filter is used to filter high frequency harmonic.

Boost Converter Control. Based on the DC voltage deviation signal, the duty ratio can be obtained through PI link to control the operation of power switch S_{fc} through PWM modulation. Fig. 3 is the closed-loop transfer function block diagram of the boost converter, where the voltage feedback control function $G_c(s)$ uses PI hysteretic compensation and V_m is the amplitude of the sawtooth wave of PWM modulator.

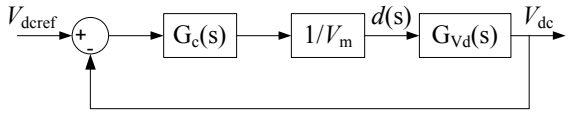

Fig. 3 Block diagram of the close-loop for the boost converter

Bi-directional DC-DC Converter Control. In order to improve the power regulation speed of SOFC system, storage batteries as quick response power source is paralleled with the SOFC in the DC bus side through bi-directional DC-DC converter to ensure the voltage of dc bus satisfy inverter. When the battery is charging, DC converter works in buck mode with power switch S_{up} shutting off and S_{down} working; otherwise, when discharging, the converter works in boost mode with power switch S_{dowm} shutting off and S_{up} working.

Voltage feedback PI control is also used in bi-directional DC-DC converter. The operating lifetime of storage battery has close relations with its charging/discharging frequency. The hysteretic charging/discharging control strategy of dc bus voltage is adopted in this study, which can reduce the redundancy charging/discharging times and extend the whole life of the system. Fig. 4 shows the block diagram of voltage hysteretic charging/discharging mode, where the time constant T_u of low-pass filtering link is 0.02s.

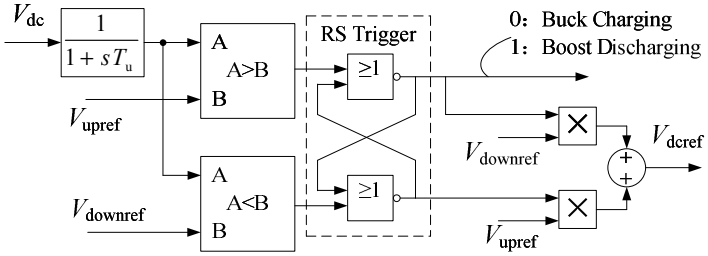

Fig. 4 Control block of voltage hysteretic charging/discharging strategy

DC-AC Inverter Control. To ensure the normal operation and smooth switch of the SOFC system under the grid-connection and islanded modes of microgrid, *E-f* droop control strategy is adopted for DC-AC inverter. By setting droop coefficient reasonably, the output voltage magnitude and frequency of SOFC system under different operation conditions is ensured change in a smaller range. The module of inverter control contains a synchronization block for safe reconnection between islanded microgrid and large power system illustrated in Fig. 2. Synchronization can by achieved by inputting the amplitude difference of voltage ΔE and phase difference $\Delta\delta$ on both sides of PCC node through synchronization link, and then being added to the output E and *f* of droop control link after the PI regulation.

Simulation Analysis

A microgrid model is established in the PSCAD/EMTDC shown as Fig. 5, where SOFC is the micro source and BESS as storage. The dynamic simulation in grid-connected mode, islanded mode and switch between the two modes is analyzed.

At *t*=6s, microgrid switches from grid-connected mode to islanded mode. In islanded mode, SOFC provides electrical energy and storage battery charges and discharges through bi-directional DC-DC converter automatically. Stable power supply of the local load is guaranteed by the coordinate of both of them. At *t*=7.7s, the voltage amplitude and phase of PCC of the microgrid side begin to be synchronized with those of the grid side. At *t*=8s, microgrid returns to the grid-connected mode.

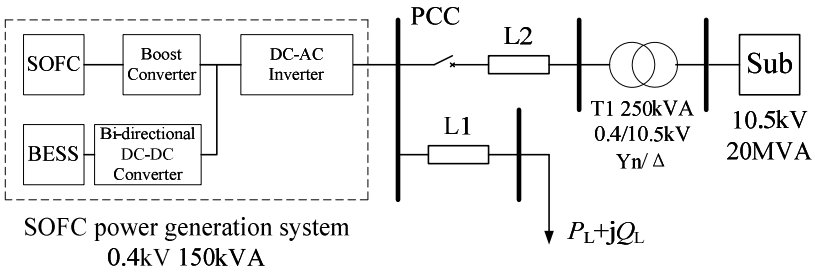

Fig. 5 Microgrid structure

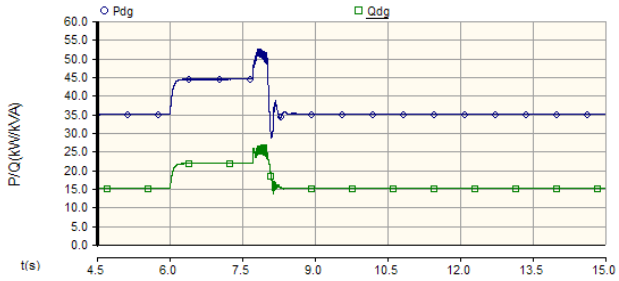

Fig. 6 Output power of generation system

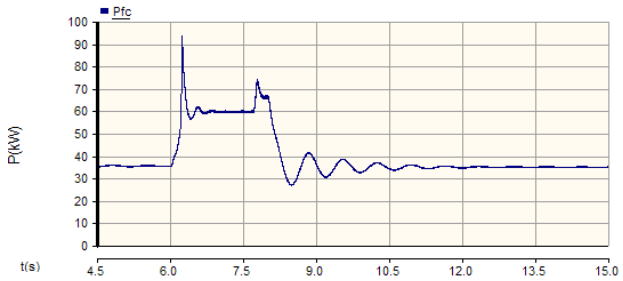

Fig. 7 Output active power of SOFC stack

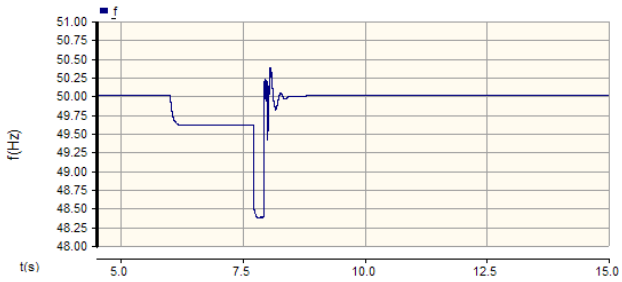

Fig. 8 Frequency response of the modes transition

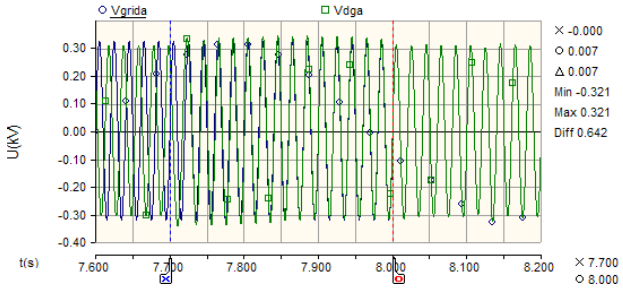

Fig. 9 Synchronization progress of voltage at PCC

Fig. 6 reflects the changes of output power of SOFC power generation system from *t*=6s when the system disconnects with the power grid to *t*=8s when it re-connects. Under grid-connected mode, the local load of microgrid absorbs part of the power from the large power grid. Therefore, after decoupling and turning to the islanded mode, the output active and reactive power of SOFC generation system increases thus the output power P_{fc} of SOFC battery stacks also increases, as shown in Fig. 7.

The variation of the system frequency when operation mode switches is shown in Fig. 8. Under the islanded mode, although losing supports from the large power grid, the islanded microgrid can operate stably with the help of the coordination of SOFC battery-stacks and storage battery. The microgrid frequency decreases slightly according to the active power increment and the droop coefficient. When reconnection synchronization, since the origin values of the phase angle deviation $\Delta\delta$ on both sides of the PCC is negative, the frequency drops for a short time at the beginning of synchronous process. After 0.3s synchronous process, the voltage phase and amplitude of PCC at microgrid side keeps consistent with those at the large power grid side, shown as Fig. 9. The output power of SOFC generation system comes back to the value before islanded after successful reconnection.

Conclusion

The SOFC model with constant fuel utilization rate control is proposed in this paper. Paralleled with SOFC at DC bus through bi-directional DC-DC converter, the storage battery makes up the shortcoming of the slow dynamic response speed of SOFC. The droop control mode adopted by DC-AC inverter ensures the microgrid containing SOFC operate stably under the islanded and grid-connected modes, and switch between the two modes. Simulation results show that the proposed SOFC generation model is able to reflect the electrochemical properties of SOFC correctly and its control strategy can ensure the stable operation of the microgrid in various operation conditions.

Keywords: microgrid, microsource, wind energy, photovoltaic (PV), modeling.

Abstract. Modeling of the wind and PV hybrid microgrid is carried out by PSCAD/EMTDC. The model includes direct-drive wind power generator, Single-stage photovoltaic power generation system and storage battery. Simulate and analyze the operating characteristics of the microgrid running in grid-connected and islanding mode, which take into account the actual wind speed and light intensity. The simulation results show that the battery is able to regulate the voltage of the point of common coupling and smooth the power fluctuation of wind generator and PV generation system in the grid-connected mode. The microgrid can isolate itself from the grid in a rapid and seamless fashion when the battery adopting P/V and Q/f control strategy based on the droop characteristics.

Introduction

Microgrid is an independently controllable system which composed of distributed generators (DG), energy storage devices and load, and in situ to provide electricity and heat [1]. The microsource includes microturbines, fuel cell, PV panel, wind generator and so on. Among them, the wind and PV power generation are the fastest growing DG technologies in recent years. They have become the most potential for development of renewable energy technologies.

The reliability of wind and PV hybrid microgrid is higher than that of independent wind or PV microgrid due to they have a natural complementation, and it can also deploy the capacity of storage device rationally [2]. Reference [3] established a model for wind and PV hybrid grid system that connected with DC bus. Reference [4] designed a power control strategy for a wind, PV and fuel cell hybrid and independent system. But they all didn't consider whether the microgrid can isolate itself from the grid or not.

This paper proposes a control strategy of energy storage batteries running in grid-connected and islanding mode. The operating characteristics of the microgrid running in grid-connected and islanding mode have been verified and analyzed by the model of the wind and PV hybrid microgrid that carried out by PSCAD/EMTDC, which take into account the actual wind speed and light intensity.

Modeling of Wind and PV Hybrid Microgrid

The structure of wind and PV hybrid microgrid, which consists of PV array, wind power and storage battery, is shown in Fig. 1, In which, the direct-drive variable speed wind power generator access to the common frequency AC bus via the rectifier inverter device and transformer T1, the PV arrays incorporated into the distribution network by PV inverter, the energy storage device that uses batteries can achieve active power flow in both directions through the interface inverter.

PV Inverter Control. The voltage of the DC capacitor should be regulated properly, so that the PV array will be able to work at the maximum power point under different light intensity and ambient temperature, and therefore we need the maximum power point tracking (MPPT) module. In this paper, the incremental conductance method is used for tracking and calculations, reference [5] provided the specific algorithms and processes. The block diagram of PV inverrter control is shown in Fig. 2.

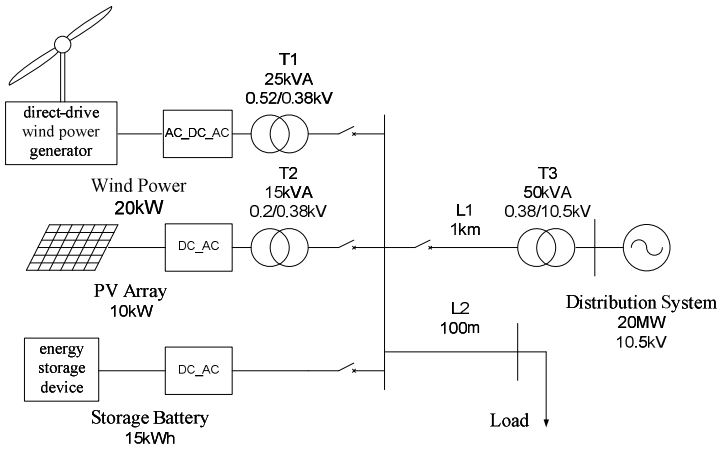

Fig. 1 Structure of wind and PV hybrid microgrid

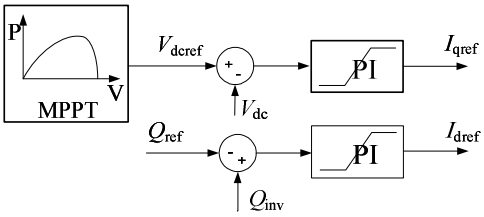

Fig. 2 Block diagram of PV inverter control

Wind Power Generator Converter Control. The wind power generator uses PQcontrol strategy. Track to the maximum output power $P_{\max}$ [6], its active power reference P_{ref} can be obtained in which the maximum use of renewable energy can be ensured. The active power reference P_{ref} can be written as,

$$P_{ref} = \eta \cdot P_{\max} = \eta \cdot \frac{1}{2} \cdot \rho \cdot A \cdot C_P^{\max} \cdot \frac{\omega_w^3}{\lambda_{OPT}^3} \tag{1}$$

where, ω_w is the rotational speed of the wind turbine, ρ is the air density of wind farms, A is the area of the blade. As a result of the fixed-pitch wind turbine, set the pitch angle β=0º, and then the optimum tip speed ratio λ_{OPT}=2.3875 [3] when wind energy utilization factor $C_p(\lambda_{OPT}) = C_{p\max}$.

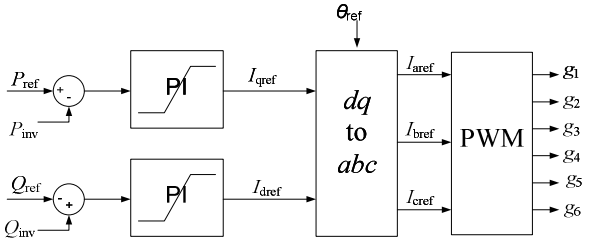

Fig. 3 Block diagram of wind power generator converter control

The block diagram of wind power generator converter control is shown in Fig. 3. The delivery, direct axis current reference I_{qref}, I_{dref}, which are generated by the active and reactive power error signal through the PI controller, and then through the Park transformation to get the three phase reference current I_{aref}, I_{bref}, I_{cref}, finally the voltage source inverter trigger signal can be obtained from

the PWM trigger pulse generator, as a result the decoupling control of the active and reactive power of wind turbine can be achieved.

Battery Inverter Control. To simplify the analysis, use DC voltage source as the battery model, and dodn't consider the charge-discharge process of the battery. Due to the frequency depends on the reactive power and voltage depends on the active power in the low voltage network, the battery adopting P/V and Q/f control strategy based on the droop characteristics. The block diagram of battery inverter control is shown in Fig. 4.

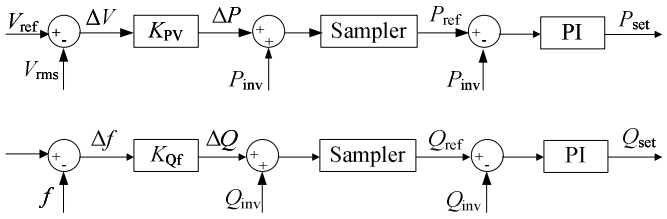

Fig. 4 Block diagram of battery inverter control

Note that, in order to maintain the stability of system frequency, we need to simulate the reference sine wave of phase voltage of distribution system as the input of the phase-locked loop (PLL) of battery inverter when it is running in islanding mode [7].

Simulation of Wind and PV Hybrid Microgrid

The structure of wind and PV hybrid microgrid is shown in Fig. 1. Assume that the local load is constant power load, and treat impedance elements as the models of lines L1 and L2 that the unit impedance parameter is 0.642+*j*0.083Ω/km. The specific parameters of hybrid microgrid are shown in Tab. 1 [3].

Tab. 1 Hybrid microgrid parameters

PV array			
Rated power [kW]	53	Rated power [kW]	20×9×53=9.54
The series number	20	Open circuit voltage [kV]	434
The parallel number	9	Short circuit current [kA]	26.8
Battery			
Capacity [kW·h]	15	Rated voltage[V]	400
Wind turbine		**Synchronous generator**	
Blade radius [m]	3.7	Rated voltage [kV]	0.52
Air concentrations [kg·m^{-3}]	1.225	Rated Capacity [kVA]	25
Rated speed [m·s^{-1}]	12	Motor poles	42
Cut-in speed [m·s^{-1}]	4	Rated frequency [Hz]	25.9
Cut-out speed [m·s^{-1}]	25	Inertia constant [s]	0.4

Grid-connected Mode. The active power of wind and PV work at the maximum power point and their constant reactive power reference is 0, the battery only participate in the regulation of active power, so the reactive power is also 0, and the local load is 15+*j*3kVA, in which the system is running in grid-connected mode.

The active and reactive power of microsources and DG in connection mode is shown in Fig. 5. From Fig. 5, the output active power of wind and PV fluctuate according to the time, the battery can adjust its output active power and maintain the stability of the load voltage when it adopting *P/V* and *Q/f* control strategy based on the droop characteristics, and its active power that injected in distribution system will change. Because of the reactive power of wind and PV microsource is 0, the reactive power that consumed by load, and transformer and line are all come from distribution system.

The RMS voltage and frequency of load bus are shown in Fig. 6. Due to the regulation of voltage of battery, the RMS of load bus voltage remains at 1.0 when the output active power of wind and PV change. The frequency of the load bus is around 50Hz, which varies range is ±0.06Hz.

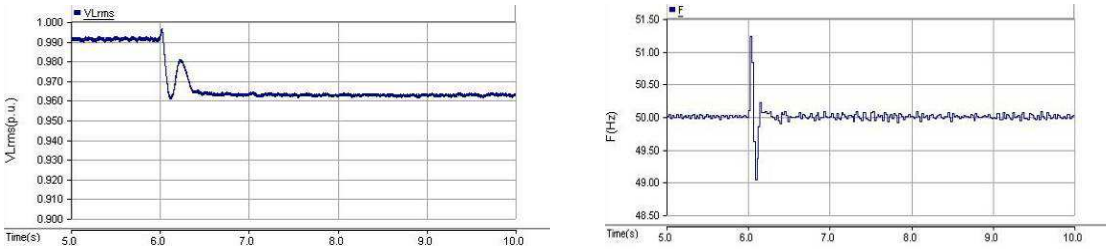
Fig. 7 Active and reactive power of distribution grid and microsources during islanding

Before switching into islanding mode, the local load is 15+*j*3kVA. And the figure shows that the output of the wind, PV and battery are 5.6kW, 5.0 kW and 8.0kW. After meeting the local load, the excess active power of the wind and PV hybrid microgrid will be injected into distribution system.



(a) Voltage of load bus (b) Frequency of load bus

Fig. 8 Voltage and frequency of load bus during islanding

Assuming the load remains unchanged when the microgrid switching into islanding mode at which t=6s. The regulation of voltage switch to voltage/frequency of battery. The battery adopt *P/V* and *Q/f* control strategy based on the droop characteristics and its active power is reduced to 4.0 kW. The RMS voltage and frequency of load bus are shown in Fig. 8 when it operated on islanding mode. According to the figure the per unit of voltage of load bus is about 0.96. During thd switching process, the maximum frequency of the load bus doesn't exceed 51.5Hz and the lowest was 49.0 Hz, eventually, after 0.5s, it stabilizes in the vicinity of 50 Hz. And its varies range is ±0.1Hz when the microgrid operated on islanding mode.

Conclusions

This paper established the model of the wind and PV hybrid microgrid by PSCAD/EMTDC. Simulate and analyze the operating characteristics of the microgrid running in grid-connected and islanding mode, which take into account the actual wind speed and light intensity. As is demonstrated in the test result, the battery is able to smooth the power fluctuation of wind generator and PV generation system in the grid-connected mode and the microgrid can isolate itself from the grid in a rapid and seamless fashion when the battery adopting *P/V* and *Q/f* control strategy based on the droop characteristics.

Keywords: microgrid, inverter, droop control, feed-forward current.

Abstract. This paper proposes an improved droop control strategy. Its principle is an introduction of feed-forward bias currents based on conventional droop control, which makes the inverter work as grid supporting sources in the grid connected mode. When the main grid voltage suffers any variation, the inverter will respond with variation of active power and reactive power, so that it can restore the main grid voltage and frequency and increase stability of the main grid. In the island mode, the proposed control method can allocate load power proportionally as expected and make soft changes between island mode and grid connected mode. At last, verify the effectiveness and reasonableness of the proposed control strategy through simulation.

Introduction

With the energy and environmental issues increasingly severe, and users more demanding for power quality, distributed generation (DG) is paid widely attention for its advantages of renewable energy sources and little environmental pollution [1]. But a large number of distributed power generations connecting the grid can cause some problems, which can influence grid reliability and deteriorate power quality, like as voltage flicker generation or increase of harmonics [2]. In order to solve the difficulties and problems brought by distributed generations and improve the power quality, the concept of microgrid is proposed. The microgrid is considered to be composed of kinds of distributed generations, loads, monitoring and controlling devices, and can run in the island mode and the grid connected mode [4].

The control structures of microgrid are classified into three types, which are master-slave control, peer control and hierarchical control. Master-slave control and hierarchical control need communication between DGs, once the communication fault occurs, the microgrid system won't run normally. In the peer control structure there is no need communication between DGs, droop control based on local information is used as the control strategy[6]. The advantages of droop control are low cost and easy to expand while the disadvantage is easy to lose stability when the voltage and frequency of the main grid suffers any excursion from the normal value.

The improved droop control proposed by this paper is based on the conventional droop control. In the island mode, the proposed control method can allocate load power proportionally as expected, and make soft changes between island mode and grid connected mode. In the grid connected mode, when the main grid suffers any variation, the voltage and frequency will differ from the normal value, the control strategy will play a role in restoring the grid voltage and frequency to make sure the whole system is stable.

Study of control strategy

Droop control is widely used in uninterruptable power paralleled systems, its basic principle is in imitation of the external characteristics of synchronous generator to achieve uniform distribution for load power between inverters of DGs, this method uses the microgrid voltage and frequency as communication link, which make the inverters share load demand without physical connections, so this control method is used in peer control strategy for the control of inverters of DGs.

Conventional droop control can be expressed as:

$$f - f_n = -k_p(P - P_n). \quad (1)$$

$$U - U_n = -k_q(Q - Q_n). \quad (2)$$

Where K_p and K_q are respectively the droop characteristics constants, f is the output frequency of the inverter, U is the output voltage of the inverter, f_n and U_n are respectively the rated frequency and voltage of the inverter, P_n and Q_n are respectively the rated active power and reactive power of the inverter.

The main control scheme of the voltage source inverter in microgrid system used for both island mode and grid connected mode is presented in Fig.1. The outer voltage loop is used for determining the current reference used in inner current loop and stabilizing the voltage magnitude of AC side of the inverter. The inner current loop is used for current control in order to track current quickly. It can be observed that this method adds feed-forward bias currents I_{d_bias} and I_{q_bias}, compared to the conventional droop control. These bias currents can allow the inverter to make a grid supporting labor in the grid connected mode, which can make microgrid system more stable. In this case, the inverter works as inverse droop control that active power and reactive power is respectively a function of voltage and frequency. In the island mode, I_{d_bias} and I_{q_bias} are set to zero. Voltage reference of q-axis U_{qref} is set to zero for both working modes, while voltage reference of d-axis U_{dref} and frequency reference f_{ref} will depend on the working mode.

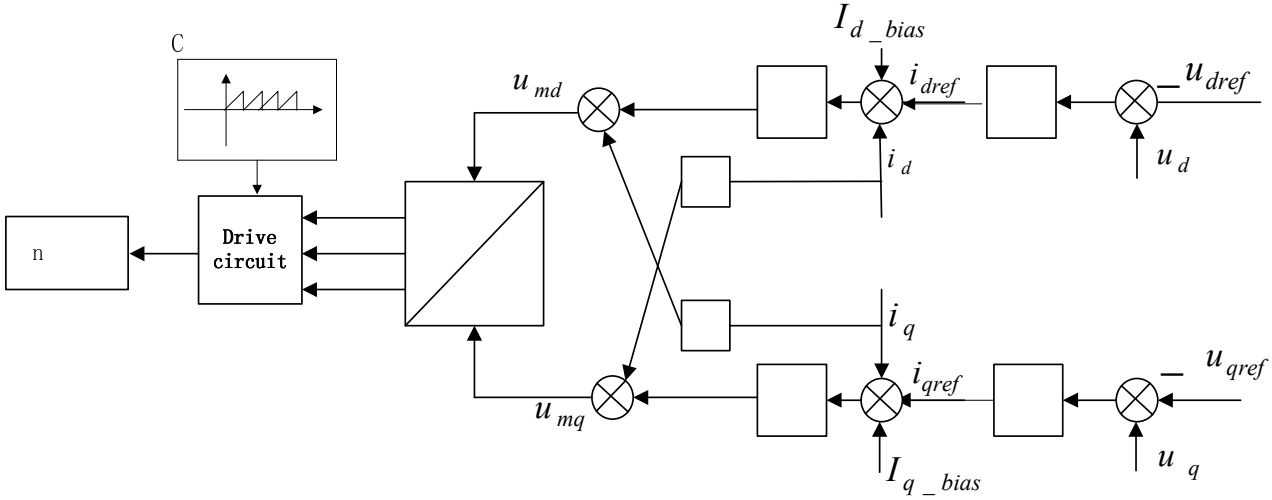

Fig.1 Main control scheme

The island mode

Firstly, voltage and frequency are obtained according to following formulas (3) and (4).

$$U_{dref} = U_0^* - K_p(Q - Q_n). \quad (3)$$

$$f_{ref} = f_0^* - K_q(P - P_n). \quad (4)$$

Where P and Q are the measured active power and reactive power, P_n and Q_n are the rated active power and reactive power, the droop characteristic slope K_p and K_q are calculated by following formulas (5) and (6).

$$K_p = \frac{U_{\max} - U_n}{Q_{\max} - Q_n}. \quad (5)$$

$$K_q = \frac{f_{\max} - f_n}{P_{\max} - P_n}. \quad (6)$$

Where $U_{\max}$ and $f_{\max}$ are the maximum allowable voltage and frequency, $P_{\max}$ and $Q_{\max}$ are the maximum output active power and reactive power of the inverter. The value of droop characteristic slope can affect the stability of system. Generally, the larger the droop characteristic slope is, the smaller the stability margin of system is.

In conventional droop control, U_0^* and f_0^* are respectively the rated active power and reactive power, which respectively equal to 380V and 50Hz.

This paper proposes the sync control based on conventional droop control when the microgrid system is in the island mode. In this case, U_0^* voltage and frequency f_0^* can be calculated by equations (7) and (8). This control method can regulate the difference of the voltage and frequency of the main and the microgrid before connecting the grid, which can make soft changes at the time of connection to the grid. So it should be used in the island mode before connecting the grid.

$$U_0^* = U_n - (K_{p1} + \frac{K_{i1}}{s})(U_g - U_{mg}) \text{ .} \tag{7}$$

$$f_0^* = f_n - (K_{p2} + \frac{K_{i2}}{s})(\theta_g - \theta_{mg}) \text{.} \tag{8}$$

Where U_g is the magnitude of the main grid voltage amplitude. U_{mg} is the magnitude of the microgrid voltage amplitude. θ_g is the phase of main grid voltage and θ_{mg} is the phase of microgrid voltage. K_{p1} and K_{p2} are the proportional parameters of PI controllers, K_{i1} and K_{i2} are the integral parameters of PI controllers, these parameters are very important since there exists a large displacement between voltages, high value of these parameters can result in a large variation of the microgrid frequency. So the output of PI controller must be limited in order to maintain the frequency within a specific band.

The grid connected mode

In this mode, the voltage reference U_{dref} and frequency reference f_{ref} mentioned in the main control scheme are equal to the values of the main grid voltage and frequency which are obtained by measuring. The feed-forward bias currents I_{d_bias} and I_{q_bias} are enabled, and the values are obtained according to equations (9) and (10).

$$I_{q\_bias} = \left[K_{p3} + \frac{K_{i4}}{s} \right] \left[(Q - Q_n) - \frac{1}{k_q}(U_d - U_n) \right]. \tag{9}$$

$$I_{d\_bias} = \left[K_{p4} + \frac{K_{i4}}{s} \right] \left[(P - P_n) - \frac{1}{k_p}(f - f_n) \right]. \tag{10}$$

In this case, the microgrid inverter works as grid supporting source, the active power and reactive power of the inverter vary with the value of the main grid voltage and frequency excursion from the normal value. If the value of the main grid voltage and frequency are 380V and 50Hz at the time of island connecting to the main grid, the inverter will output the rated active power and reactive power. If the voltage and frequency of the main grid suffer any variation, the reactive power and active power of the inverter will change because of this control method, so as to restore the main grid voltage and frequency to the normal value, as a function of supporting the main grid. This control method can mitigate the instability when the problems arise at connection to the main grid, otherwise, under those situations any attempt of connecting to the grid can lead to the loss of the main grid stability.

Simulation results

This section will present the simulation results to verify the proposed control scheme in PSCAD. The values of the main grid voltage and frequency are respectively 380V and 50Hz. At the beginning, the microgrid system is in island mode, the control method is conventional droop control, the load active power and reactive power are respectively 14kW and 0kVAr.

At 0.1s, activate the sync control. At 0.3s, change the load to 17kW and 4kVAr. At 0.5s, the microgrid and the main grid get connected. At 0.7s, the load power changes to 19.2kW and 6.5kVAr. At 0.9s, the value of grid voltage changes from 380V to 376V. The simulation results are presented in Fig.2.

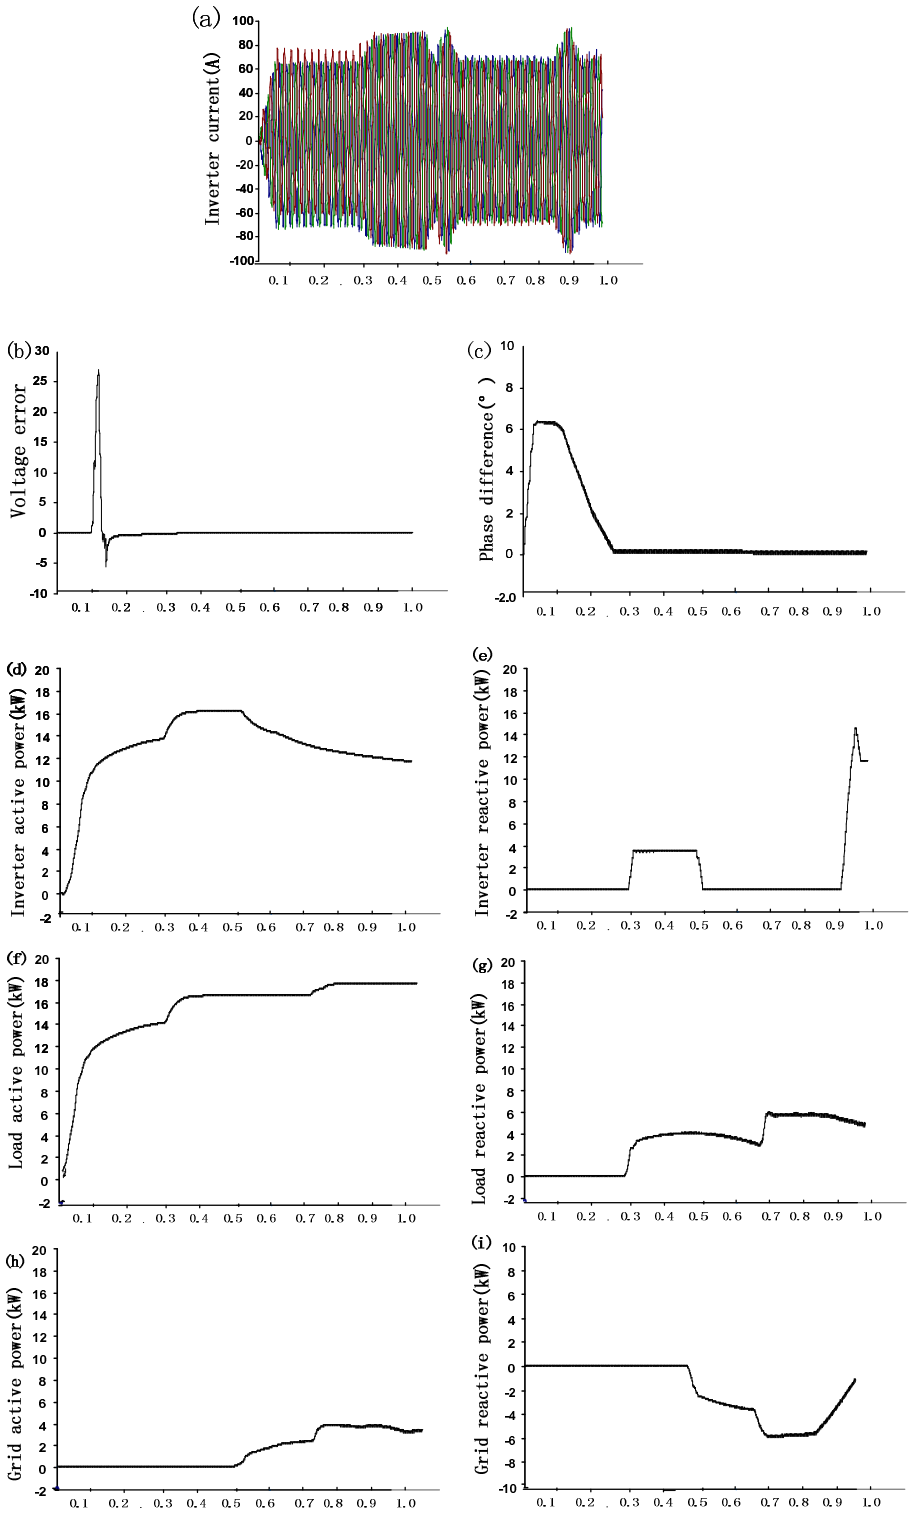

Fig.2. Simulation results

It can be observed that:
(1) At the beginning, no voltage errors but 6°phase shift between the microgrid and the main grid. After activate the sync control (0.1s), the phase shift is regulated to 0°before connection to the main grid. After the load change (0.3s), we can see that only the inverter changes correspondingly from Fig.2b-i.
(2) At the time of connection (0.5s), the main grid voltage and frequency are the rated values, 380V and 50HZ, and the inverter outputs the rated power, 14kW and 0kVAr, the other power 2kW and 4kVAr is provided by the main grid, observed in Fig.2d-i.
(3) After the load changes (0.7s), the main grid voltage and frequency are still the rated values, and the inverter still outputs the rated power, now the main grid increases the power to 5.2kW and 6.5kVAr, which is shown in Fig.2d-i.
(4) When the value of the main grid voltage decreases to 376V (0.9s), now the inverter working as a grid supporting source increases the reactive power to 12kVAr, of which 6.5kVAr is consumed by load, 5.5kVAr is absorbed by the main grid to restore the voltage, which can be observed in Fig.2d-i. Similarly, if the value of the main grid frequency increases, the active power of the inverter would decrease to restore the frequency. Under these situations, if the conventional droop is used, the power of inverter would not change, thus could result in instability of the main grid.

Conclusions

In the island mode, the sync control can regulate phase shift between the voltages of microgrid and the main grid and can make soft changes between island mode and grid connected mode. The main benefits of this control scheme arise when the microgrid is connected to the grid, when the main grid suffers any disturbance, the feed-forward bias currents will make the active power and reactive power of the inverter vary with the value of the main grid frequency and voltage excursion from the rated value, which make a grid supporting labor and increase the stability of the microgird system.

Keywords: smart meter; remote monitoring; distribution grid; power industry; energy efficiency.

Abstract. As an important part of Smart Grid, smart metering attracts more and more attention all over the world. It is the way for energy consumer to sense the benefit of smart grid directly. Smart meter is an advanced energy meter that measures consumption of electrical energy providing additional information compared to a conventional energy meter. This paper discusses various applications and technologies that can be integrated with a smart meter. Smart meters can be used not only from the supply side monitoring but also for the demand side management as well. It plays an important role to monitor the performance and the energy usage of the grid loadings and power quality. In addition, This paper gives a comprehensive view on the benefit of smart metering in power network such as energy efficiency improvement.

Introduction

Nowadays, Smart Grid and Smart Metering are both the hot topics [1-3]. They are driven by the climate change and the reduction of carbon emission. Smart meter is an advanced energy meter that measures the energy consumption of a consumer and provides added information to the utility company compared to a regular energy meter. Smart meters can read real-time energy consumption information including the values of voltage, phase angle and the frequency and securely communicates the data. The ability of smart meters for bidirectional communication of data enables the ability to collect information regarding the electricity fed back to the power grid from customer premises.

Smart meters can be used to monitor and also to control all home appliances and devices at the customer's premises. They can also collect diagnostic information about the distribution grid, home appliances, and can communicate with other meters in their reach. They can measure electricity consumption from the grid, support decentralized generation sources and energy storage devices, and bill the customer accordingly. Data collected by smart meters is a combination of parameters such as a unique meter identifier, timestamp of the data, and electricity consumption values. Smart meters can be programmed such that, only power consumed from the utility grid is billed while the power consumed from the distributed generation sources or storage devices owned by the customers are not billed.

Remote Monitoring

By using smart meter and basic software for monitoring the low voltage grid, energy supplier can monitor their grid easily and find the place of illegal energy usage in their grid.

A. History detection of illegal electricity usage

In October 2004 Hakki cavdar suggest a new method for detection of illegal usage based on automatic meter reading. First we talk about his hypothesis to describe better of his new method. He assume that illegal usage of electricity may be happened in following ways [4].

1) Using the mechanical objects: A subscriber can use some mechanical objects to prevent the revolution of a meter, so the disk speed is reduced and the recorded energy is also reduced.

2) Using a fixed magnet: A subscriber can use a fixed magnet to change the electromagnetic field of the current coils. As we know, the mechanical energy meter is based on the electromagnetic field.

3) Using the external phase before meter terminals: This method gives subscribers free energy without any record.

4) Switching the energy cables at the meter connector box: In this way, the current does not pass through the current coil of the meter, so the meter does not record the energy consumption.

As Cavdar said first two methods are valid for mechanical meter and in digital meter subscriber cants use energy in illegal way, but the last two methods are valid for both mechanical and digital energy meters. The proposed system for detection of illegal usage of electricity is shown in fig. 1 power line carrier signal can transfer only in low voltage side of distribution transformer, and PLC signal's that blocked in transformer cant' pass it, so this topology must be repeated for each transformer. In his method each energy meter is equipped with PLC modems and digital energy meter IC. PLC modem must be send and receive data via power line by modulating or demodulating data over or from carrier frequency that travel over power line 220V signal, PLC signaling must be in CENELEC or FCC standards, EN50065-1 is formed by CENELEC, and frequency bands and signaling level for each usage is shown. [5]

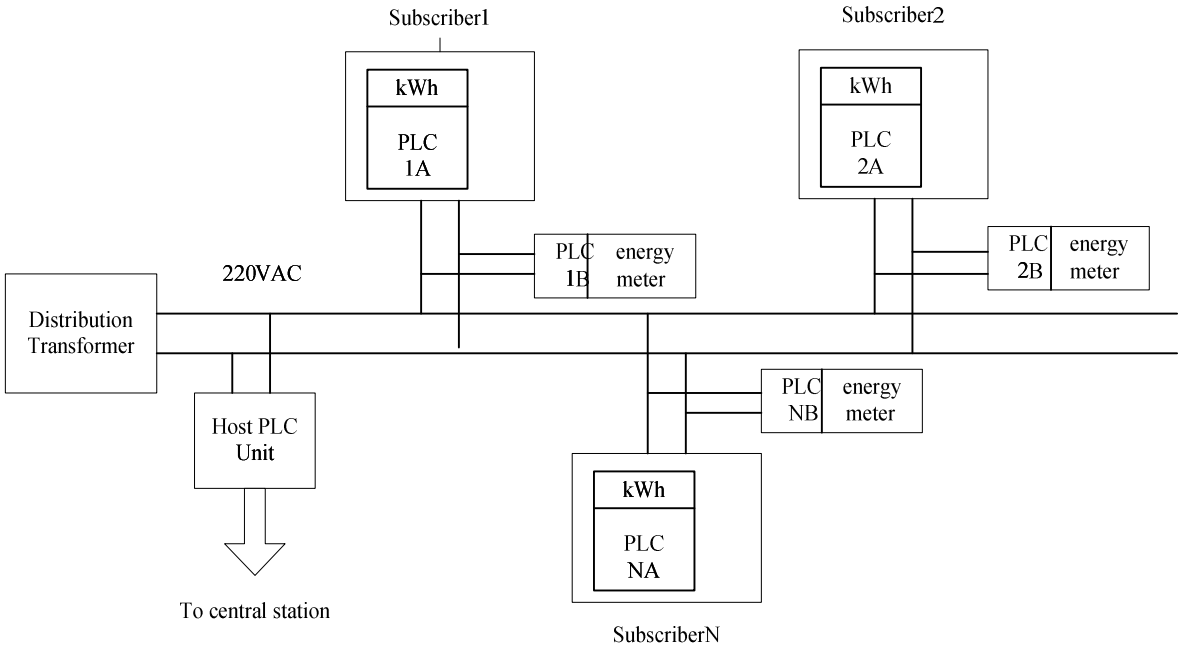

Figure 1. Cavdar's method for illegal usage of electricity.

In many cases, in which some one using extra cable before mechanical part terminal, if we assume that the digital unit be before this illegal connection his method can show the illegal connection, but in many cases and many countries such India the illegal node in many cases connect directly to power line of street and the load feed directly from main power line without any energy meter and any record of energy consumption data. From a reality point cavdar's method is only valid for detecting illegal usage of electricity in one low voltage grid, but for showing the place of illegal connection this method in many cases has now usage, in this effort we want to introduce new way for finding a place of illegal electricity usage based on smart metering.

B. New method for finding an illegal connection

The new method that we want to describe is based on smart metering.In fig. 2 the basic block diagram of smart meter is shown, as you see in fig. 2. this kind of energy meter has more ability than just automatic meter reading, one unit of smart meter act as traditional AMR, this unit measure energy consumption based on mechanical measuring or digital measuring. In mechanical kind measurement is based on disk and electromagnetic field. In mechanical AMR an optical sensor use for detection of disk movement, this sensor send digital pulse to microcontroller unit, and a counter

in microcontroller of energy meter counts disk routing, by counting the disk routing system can measure energy consumption. In digital AMR the energy meter IC such ade7751 calculates energy consumption based on voltage and current data that received from current and voltage transformer. Relay is another part of smart meter, by using this unit energy suppliers can turn on or off energy meter from distance without any physical attempting, the control command send from energy supplier via power line carrier signal.

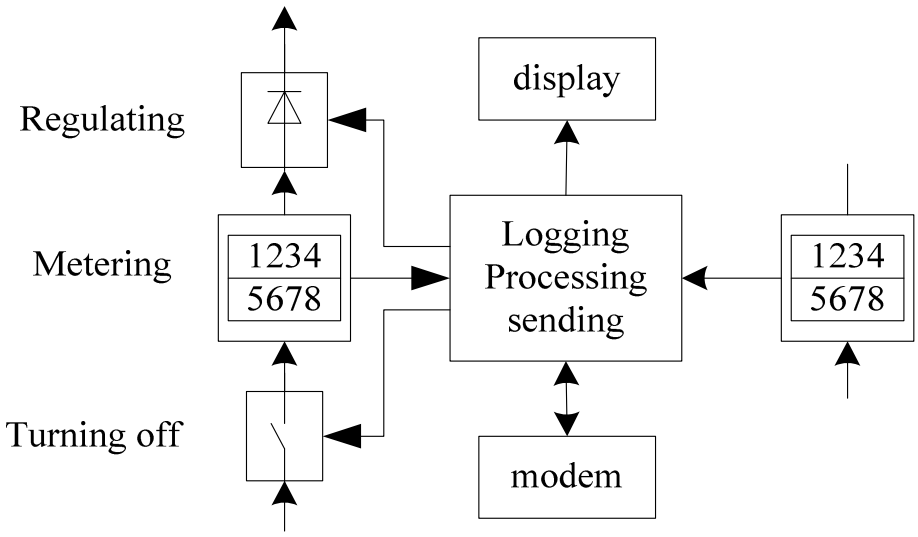

Figure 2. Smart metering block diagram.

Low voltage distribution grids

According to low cost smart meters requirements a simple method providing weekly basic statistical information about voltage levels at costumer's sites was applied. Lowest minimum but also highest maximum voltage values were observed at sites away from stations. Especially the increase of voltage is caused by unbalanced load. The results presented demonstrate that such observations are useful for the planning of low voltage grids. Further investigations are ongoing and more detailed analysis tools for better understanding the behavior of low voltage grids are planned[6].

The voltage level is one of the most important criteria for planning and operating rural distribution grids especially incase of decentralized generation. Changes in the European Standard EN 50160 and its meaning to regulation in European countries are currently discussed. In rural distribution grids reduced availability of voltage tolerance(e.g. preserved part of voltage tolerance for decentralized generation) results into decreasing transmission capacity of the distribution network. Today's methods of managing voltage levels in low voltage grids are simple estimations and reinforcing measures in case of customers complaints. The gap between estimation results and real conditions could be used for operating low voltage grids more cost-efficiently. To identify this gap and deliver adequate solutions, measurement results from several representative nodes of such low voltage grids are needed. Further on this will be the basis for the development of intelligent controlling of active grid components(e.g. active loads, plants, voltage regulators).

Because of striking costs, periodic observations or even monitoring of voltage levels on several points of each LV-grid branch cannot be done by extra installation. But each meter of an automated metering system has a three phase voltmeter and is set up for communication (e.g. power line).The idea is to use these options for permanent voltage level observations.[7]

1) A fully automated organization and presentation of data

2) A compression of data for transmission and storage.

3) Further it is presupposed that a standard meter can be programmed for these functions without any additional costs for extensions of hardware.

Further investigations in respect to voltage unbalance measurements and phase separated 15-min-average value seem to be necessary. For detailed low voltage grid analysis a concept supporting trigger functions was set up. The implementation of these tools and the verification of practical use are part of a planned research project. For put into practice the presented methods standardized procedures for determining voltage band reserve have to be developed. Future options of the smart metering system can be used as an effective tool for analyzing low voltage grids and the implementation of a smart grid low voltage distribution management, control and documentation system. Such functions are also very important for increased integration of decentralized generation to the grid. Nevertheless setting up and operating such systems is some effort and therefore a cost benefit analysis has to be performed.

Power industry & energy efficiency

Over the next five years, smart metering will be installed with all Norwegian electricity customers. The Norwegian energy sector moves toward a significant technology shift, perhaps one of the most extensive projects in the history of Norwegian grid operation. The stakes are high, but with careful planning and good technology choices the project has good chances of success. Even though only 11 % of the country's households currently have smart metering installed, nearly 60% of all electricity customers are positive or very positive towards not having to read the meter themselves in the future, and the general trust in the new technology is high. Most customers (83%) are of the opinion that readings will be at least as accurate as manual readings. However, the willingness to pay for the new technology is very low, but it is increasing over time. Many consumers are of the opinion that the rationalization the grid operators achieve though smart metering and communication automatically should benefit the customers. This could make it difficult for suppliers to request payment for the services, and is a challenge the grid operators need to prepare themselves for[8].

It is highly uncertain whether the new technology would lead the electricity customers to switch consumption to off-peak periods, when the prices are lower. Norwegian consumers are used to low prices and want to use the power when they need it. The interests in utilizing the services opened for by the new technology are moderate at the moment. In time, however, selling value added services might be a good opportunity for the grid operators to maintain and strengthen the customer relation. This is one way to avoid becoming one of the many invisible providers of necessary goods. A strong and distinct customer relation contributes to strengthening the individual company and the sector's reputation, and makes the customers feel that the power sector is making everyday life easier.

Nowadays, more and more people are encouraged to adopt Renewable Energy in order to reduce in greenhouse gas emission, and also the very important issue of climate change. And the smart meter provide knowledge, increase awareness and affect customers' behavior and attitude in using renewable energy. In the future, renewable energy is the trend to reduce the carbon emission and gas emission from the power generation. Although, it may not be cheap from the generation cost at the moment but customer can try our best to reduce the impact due to climate change. Hence, if every household can use electricity and gas efficiently, there is a need to minimize power generation as well.[9]

In the view of current abilities in smart metering, new meters are only expanded in providing real-time information without giving any constructive suggestion to consumers. The smarter meter not only provides services on real-time information, but also helps in establishing an optimal energy-consuming plan for a specific user by the AI technologies integrated into the meter. The introduction of AI technology offers chances in recognizing energy consuming patterns automatically and accurately other than consumers themselves [10].

A smart meter that deals with different energy-supplying forms will be required in the future. AI technology to find out an optimal plan for complex usage from different types of energy resources is necessary. This smart meter will form an instrumentation part of a micro-grid which further

aggregates together to develop a smart grid. It is foreseen that the cost of smart meters could be reduced significantly; therefore it will be widely used by many countries.[11,12]

Conclusion

The most important application of smart metering system is smart meter. Smart meter is fundamentally different from ordinary meters. It can provide a real-time, accurate, record of the gas and electricity you are using, different times and different costs. Smart meters allow people to see clearly how much electricity and gas they are using and send the data to energy firms automatically. As a part of smart grid technology, smart metering is the expanding of electricity and gas meters. Instead of the meter readings and bill-estimation, the data of the amount of electricity and gas could be collected real-time and accuracy for customers and source suppliers. Customers will benefit from this application on leaning how much energy they used at once and choice of optimal energy consumption could be made.The work is partially supported by the science and technology project of Harbin city under Grant 2002AFCXJ001.

Keywords: Smart distribution grid; Distribution automation; Self-healing; Power supply capacity; Power supply quality

Abstract. Self-healing is an important feature of smart distribution grid. Self-healing control for smart distribution grid covers risk prevention and operation optimization before accidents, in addition, it covers fault location, fault isolation and power restoration. The research of self-healing control theory, risk assessment, fault diagnosis and safety warning for smart distribution grid provides technical supports to help build a safe, reliable, efficient, high-quality, flexible and compliant smart distribution grid.

Introduction

Distribution network is located in the end of power system, responsible for important tasks of power distribution and customer service[1]. Power supply capacity and power supply quality to users must be guaranteed and achieved through distribution network, which makes smart distribution grid the focal point of smart grid research[2]. Smart distribution grid differs from traditional distribution grid in that the former contains distributed generation, and has characteristics such as large-scale, complex and multi-point wide surface[3,4]. Operation modes and control strategies of smart distribution grid changed from that of traditional distribution grid, which proposed the needs of "self-healing" control technology[5].

Self-healing control technology

Distribution network self-healing control serves for smart distribution grid, transports by sensing collection and communication technology, bases on data mining, condition monitoring and grid early-warning, takes status assessment and analysis decision as core, controls with distribution equipment, in order to achieve optimal operation of the system, risk prevention and fault disposal[6,7]. The whole self-healing control technology contains two main lines and three major tasks. Structure diagram of self-healing control strategy is illustrated in fig.1.

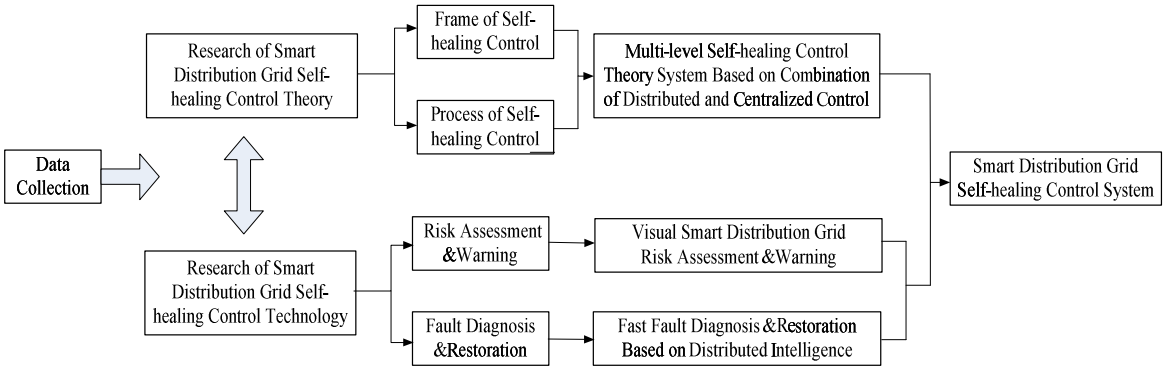

Fig.1 Structure diagram of self-healing control strategy

The two main lines contain research of self-healing control theory for smart distribution grid and research of self-healing control technology for smart distribution grid. The three major tasks contain research of multi-level self-healing control theory system based on combination of distributed and centralized control, research of visual smart distribution grid risk assessment and warning, and research of fast fault diagnosis and restoration based on distributed intelligence. The first task belongs to Line One, the second and third tasks belong to Line Two. The research of Line One and Line Two is non-independent, in the research of theory system, the main function and key technology of self-healing must be well considered. The established theory system of multi-level self-healing control theory system based on combination of distributed and centralized control must integrate risk control and emergency control (including fault diagnosis and power restoration) proposal. In the research of technology, the key technology must be consistent with the self-healing theory, combines the advantages of distributed control and centralized control framework, to achieve multi-level risk control and emergency control.

Main tasks of self-healing control technology

Self-healing control theory system for smart distribution grid. Self-healing control technology for smart distribution grid adopts a hierarchical distributed control system, is composed of multiple parts nested within each other. Various parts such as information system, dispatching automation system, substation automation system and distribution system combine self-healing control system for smart distribution grid. The service stream contains operation assessment, optimization control, coordinated control, risk control, emergency control and restoration control. Top-level structure diagram of self-healing control for smart distribution grid is illustrated in fig.2.

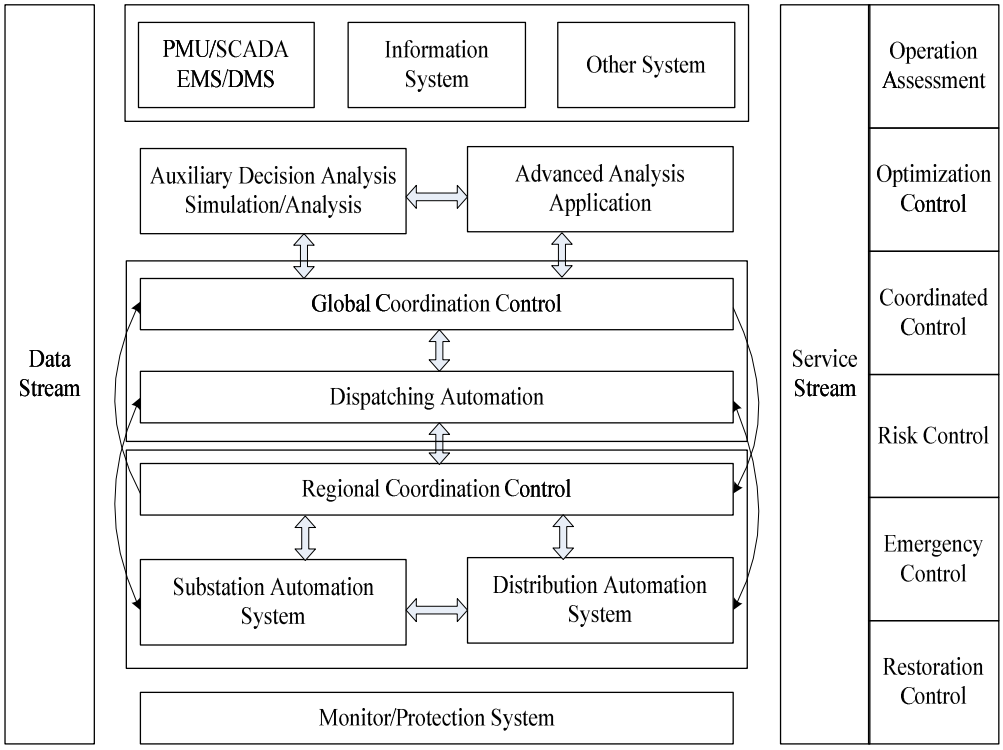

Fig.2 Top-level structure diagram of self-healing control for smart distribution grid

Smart distribution grid risk assessment and warning technology. In this task, first step, historical data of actual distribution network operation in the past 20 years should be collected from production management department of distribution network. The important collection data contains distribution network component reliability, various types of abnormal events/ operating characteristics before distribution network accident, distribution network component outage reasons, outage duration, outage consequences and other historical operation data. Study smart distribution

grid online risk assessment index system, evaluation methods, probabilistic characteristics of distribution network operation risk factors, risk assessment models, quantitative indicators and calculation methods based on data collection. Second step, generate smart distribution grid risk warning and location technology. Accordingly, study automatic configuration and calculation methods of reducing smart distribution grid risk strategy. Third step, integrate these research results above-mentioned, complete the "smart distribution grid risk assessment and safety warning technology research" report, and develop visual smart distribution grid risk assessment and warning subsystem. The subsystem should be able to display risk assessment and early warning indicators / information in a reasonable manner online and visual. Roadmap of smart distribution grid risk assessment and warning technology is illustrated in fig.3.

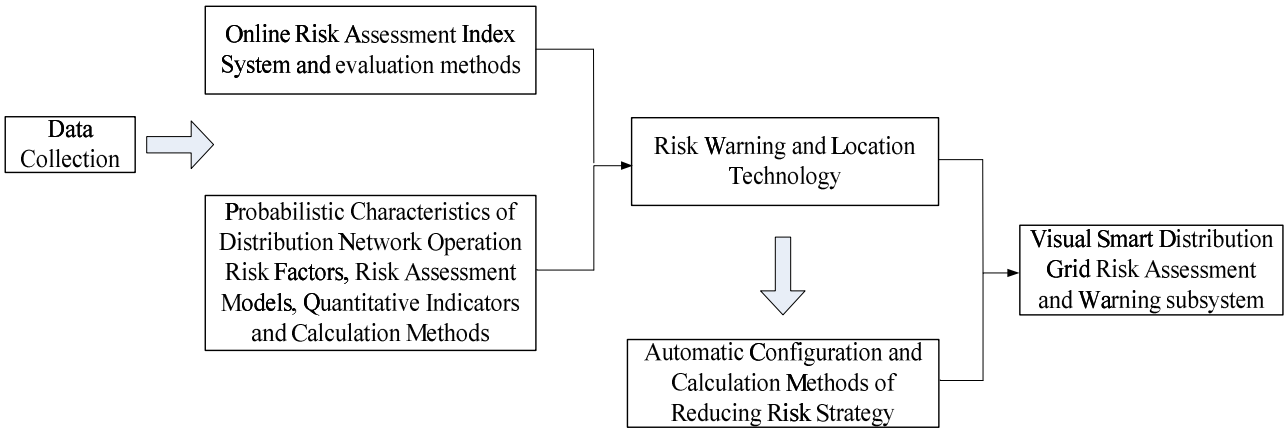

Fig.3 Roadmap of smart distribution grid risk assessment and warning technology

The research results of this task can be used in risk assessment index calculation, risk assessment warning/ location and identification of risk status, judgment, prevention, and control function of smart distribution grid self-healing system.

Smart distribution grid fault diagnosis and power restoration technology. In this task, first of all, historical data during distribution network fault in the past 20 years, switch type, common fault isolation and power restoration mode should be collected from production management department of distribution network. Accordingly, summarize the common faults of distribution network and the fault isolation methods/power restoration modes based on existing equipment. Study the spatial and temporal characteristics caused by various types of faults in order to get the diagnosis criterion. According to existing equipment information, such as switch type and installation location, study multi-level protection configuration and online tuning methods. By integrate the two above-mentioned points, generate fast fault identification, location and isolation methods based on combination of distributed and centralized control. Therefore, study the fast power restoration methods in non-fault region adapted to distribution network structure. Based on the study of traditional grid fault diagnosis method, analyze the impact on fault characterization of the introduction of distributed power, study the fault diagnosis technology of distribution network including distributed power. At last, integrate these research results above-mentioned, complete the "smart distribution grid fault diagnosis and power restoration technology research" report, and develop multi-level emergency control subsystem. Roadmap of smart distribution grid fault diagnosis and power restoration technology is illustrated in fig.4.

The research results of this task can be used in emergency/restoration status evaluation and control function of smart distribution grid self-healing system.

Application

Self-healing control system adopts centralized structure, makes full use of sophisticated network management technology, database middleware, object-oriented and component technology for construction. Follow the IEC 61968-1 standard system interface information exchange model (IEM), in strict accordance with message transport mechanism for information exchange through information exchange bus with other systems.

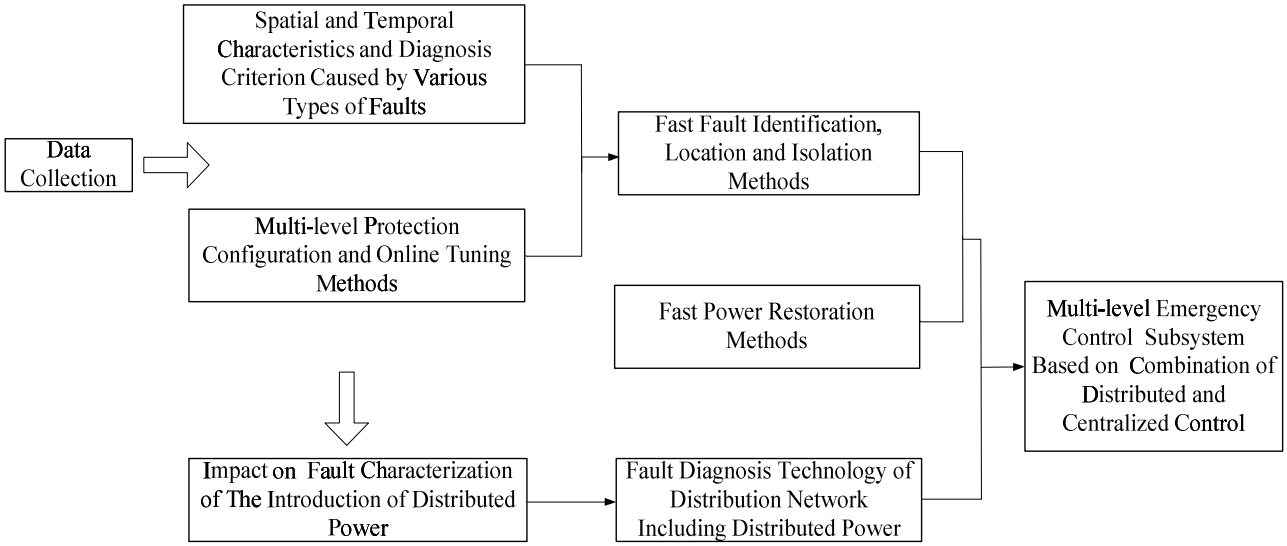

Fig.4 Roadmap of smart distribution grid fault diagnosis and power restoration technology

Conclusions

Distribution network occupies a significant position in power system. Self-healing is an important feature of smart distribution grid. Compared with the emphasis on fault handling in distribution automation system, self-healing control not only focuses on status while and after the accident, but also emphasizes the risk prevention, self-organization, adaption and operation optimization capabilities before accidents. Self-healing control has great significance for the protection of reliable, high-quality and efficient smart distribution grid.

Keywords: Smart Grid, Aggregation Signcryption, Identity-based Signcryption, Batch Verification.

Abstract. Smart grid puts forward high requirements for the equipment to access authentication, which achieves openness and real-time performance in mart grid. The users' identities need to protect, in the meanwhile, identity authentication and data encryption should be efficient. According to the characteristics of smart grid, this paper proposed an identity-based aggregation signcryption scheme which combined pseudonymous ID with batch verification. The scheme adopted the pseudonym technology to achieve the user identity anonymity, and adopted the signcryption to complete digital signature and encryption in one time. This paper presented the aggregation signcryption for different multiple users by dynamic equation, which can compromise the security and computation overhead to meet the requirements of smart grid. This scheme can reduce the computational burden of aggregators with security of communication data. Moreover, this scheme solved the difficult problem of the management of pseudonymous ID, and improved the efficiency of the whole system. Therefore, this scheme meets the requirement of real time and high efficiency in smart grid.

Introduction

Different from the traditional power grid, smart grid can achieve elaborate and intelligent management based on lots of interactive data. And smart grid can achieve the data transmission and information control in two-way, high-speed and real-time parameter sampling [1]. Equipment to verify will bring tremendous computational pressure to the authentication server, so that it cannot be timely response, which will lead to delay for authentication with sharp increase. In smart grid, periodic data collection activities are faced with the risk of sensitive personal information leakage [2]. The existing privacy protection for real-time electricity data mainly achieves through data aggregation and homomorphic encryption [3,4,5,6], but all these programs do not provide protection for user identity from the access. Based on the above characteristic in smart grid, this paper proposes an identity-based aggregate signcryption scheme which combines pseudonymous ID and batch signature verification. The scheme adopts the pseudonym technology to meet users' privacy protection in the access terminal, the signcryption technique complete digital signature and encryption at a time. The scheme aggregates multiple users' signcryption which makes use of dynamic equation. This scheme can reduce the computational burden at the same time ensure communication data security.

In 1997, the signcryption technique is first proposed by Zheng[7] to complete digital signature and encryption in the same logical steps. Compared with the traditional signature then encryption, signcryption has higher efficiency in computation and communication and more secure in the whole scheme. In 2002, Malone-Lee presents Identity-based signcryption[8] which combines identity-based cryptography with signcryption. In 2010, identity-based signcryption scheme for smart grid was proposed by Hayden et. al [9]. The next section describes an identity-based aggregation signcryption scheme which combines pseudonymous ID and batch signature verification.

The Scheme of Identity-based Aggregation Signcryption in Smart Grid

The system of smart grid includes service provider (SP), central aggregator (CAG), local aggregator (LAG), trusted third party (TTP) and users (US). US need first register their smart meters (SM) in SP.

In the course of data collection, SM directly send data to LAG, then LAG collect the data from SM and send aggregated data to CAG.

System Initialization

SP selects parameters and sends it to key generating server (KGS) to generate desired parameters.

(1) KGS generates additive group G and G' with prime order q and multiplication group G_T. P is a generator of G and P' is a generator of G'. e: $G \times G \to G_T$ is a bilinear map of Weil pair.

(2) SP selects five hash function, H_0:$\{0,1\}^* \times G \to Z_q^*$, H_1: $G_T \to \{0,1\}^l \times G$, $H_2 : \{0,1\}^l \times \{0,1\}^* \times G \times G_T \times \{0,1\}^* \times G \to G$, $H_3 : \{0,1\}^* \to G'$.

(3) SP selects two random number $s_1, s_2 \in Z_q$ as its master key (s_1, s_2), and its public keys are $P_{pub1} = s_1 \cdot P$ and $P_{pub2} = s_2 \cdot P$. (s_1, s_2) is embed in equipment with tamper resistant, and P' and P_{SP} are embed in SM ahead of schedule.

With the above steps, SP publicizes the common public parameter *param*=(q, G, G_T, G', e, P, P', P_{pub1}, P_{pub2}, P_{SP}, H, H_0, H_1, H_2, H_3), and itself public key P_{sp}.

Register

Every US must register in SP before their SM join to smart grid at the first time, so US need provide their real identity *RID*. SP generates and sends a *permit* to US, and SP saves *RID* and *permit* at user information table (UIT). In the meantime, LAG and CAG also need register in order to obtain their public key certificate *Cert*.

Pseudonym and Key Generation

When US input correct *RID* and valid *permit*, SM will start and generate pseudonym $ID=ID_1 \| ID_2$ with $ID_1 = r \cdot P'$ and $ID_2 = RID \oplus H(r \cdot P_{sp})$, r is a random number with time variable. Then US randomly selects $x_i \in Z_q^*$, and computes $X_i = x_i P$, $SK_1 = s_1 \cdot X_i$, $SK_2 = (x_i + s_1 \cdot q_i)$, $q_i=H_0(ID,X_i)$, with its secret key $SK=<SK_1,SK_2>$ and public key $PSK=<X_i,q_i>$. LAG randomly selects $y \in Z_q^*$, with its secret key $SK_{LAG}=y$ and public key $P_{CAG}=yP$.

Signcryption

SP need periodically gather statistic information of electric consumption, and US sends information to SP including electric consumption information $m_{\text{Statistics}}$ and real-time electricity request m_{Request}.

(1) When user U_i sends message $m_{\text{Statistics}}$, LAG verifies the user's signature of $m_{\text{Statistics}}$ and then signs and transmits verified $m_{\text{Statistics}}$ to CAG. The step is as follows.

(*a*) U_i selects a random number $u_i \in Z_q^*$, and computes $W_i = u_i P$, $w_i = (P_{pub1}, P_{LAG})^{u_i}$, $h_{1i} = H_1(w_i)$, $R_i = H_2(m_{\text{Statistics}}, ID_i, X_i, w_i, ID_{LAG}, P_{LAG})$, $V_i = u_i P_{pub2} + \text{SK}_2 \cdot R_i$;

(b) Assume $m_{1i} = m_{\text{Statistics}} \| t_1$, with timestamp t_1. U_i computes ciphertext $c_i' = (m_{1i} \| V_i) \oplus h_{1i}$;

(c) U_i sends the signcryption ciphertext $\sigma_i' = (c_i, W_i, V_i, X_i, t_1)$ to LAG.

(2) When user U_i sends message m_{Request}, LAG verifies the user's signature of m_{Request}. Then LAG aggregates all the m_{Request} to M_{Request}, and then signs and transmits M_{Request} to CAG. The step is as follows.

(*a*) U_i selects a random number $u_i \in Z_q^*$ and computes $W_i = u_i P$, $w_i = (P_{pub1}, P_{LAG})^{u_i}$, $h_{2i} = H_1(w_i)$, $R_i=H_2(m_{\text{Request}}, ID_i, X_i, w_i, ID_{LAG}, P_{LAG})$, $V_i = u_i P_{pub2} + \text{SK}_2 \cdot R_i$.

(b) Assume $m_{2i} = m_{\text{Request}} \| t_2$, with timestamp t_2. U_i computes ciphertext $c_i'' = (m_{2i} \| V_i) \oplus h_{2i}$.

(c) U_i sends the signcryption ciphertext $\sigma_i'' = (c_i, W_i, V_i, X_i, t_2)$ to LAG.

Signcryption Aggregation

Since the interval time is short in real-time electricity request, LAG will receive lots of signcryption information at the same time. In order to speed up the verification and increase efficiency, LAG

should aggregate the signcryption. LAG computes $V_{agg}=\sum_{i=1}^{n}V_i$, signcryption aggregation is $\sigma_{agg}=<\{c_i,W_i,X_i,ID_i\}_{i=1}^{n},V_{agg}>$ for *n* different users with message $(m_{21},m_{22},\cdots,m_{2n})$.

Unsigncrypt and Transmit

When LAG receives electric consumption information (*c*, *W*, *V*, *X*), LAG first check the validity of timestamp *t*, that is LAG computes $\Delta t=t_T-t$, of which t_T is the system time with messages received. If Δt does not conform to the requirements of the system rules, (*c*, *W*, *V*, *X*) will be considered invalid. If Δt conforms to the requirements of the system rules, LAG will unsigncrypt and then signcrypt and transmit message to CAG. The step is as follows.

(1) LAG computes $w_i=e(W_i,SK_{LAG}\cdot P_{pub1})$ using LAG's secret key SK_{LAG} and TTP's public key (p_{pub_1},p_{pub_2}). Then LAG recovers $m_{1i}\|V_i=c_i\oplus H_1(w_i)$.

(2) LAG computes $R_i=H_2(m_i,ID_{1i},X_i,w_i,ID_{LAG},P_{LAG})$.

(3) LAG verifies whether or not $e(V_i,P)=e(W_i,P_{pub2})\ e(R_i,X_i+q_iP_{pub1})$. If equation is established, LAG selects a random number $a\in Z_q^*$ and computes

(*a*) $k_1=hash(aP)$, $(k_2,k_3)=hash(aP_{CAG})$;

(*b*) $c=E_{k_2}(\sigma'\|t_3)$, $w=kH_{k_3}(c\|k_1\|ID_{LAG}\|ID_{CAG})$;

(*c*) $s=a(w+SK_{LAG})^{-1}\bmod q$, $T=wP$.

LAG sends (c,T,s) to CAG as signcryption of message σ_i'. After CAG receives message, it first computes $k_1=hash(sT+sP_{LAG})$ and $(k_2,\ k_3)=hash(SK_{CAG}\cdot sT+\ SK_{CAG}\cdot sP_{LAG}\ )$, $r=kH_{k_3}(c\|k_1\|ID_{LAG}\|ID_{CAG})$. Signed message is availably if and only if $rG=T$ with $\sigma_i'\|t_3=D_{k2}(c)$.

When LAG receives real-time electricity request, LAG first checks the validity of timestamp *t* the same as the step above. When timestamp *t* is available, LAG will verify and aggregate the signcryption. The step is as follows.

(1) LAG computes $w_i=e(W_i,SK_{LAG}\cdot P_{pub1})$ using LAG's secret key SK_{LAG}. Then LAG recovers $m_{2i}\|V_i=c_i\oplus H_1(w_i)$.

(2) LAG computes $R_i=H_2(m_{2i},ID_i,X_i,w_i,ID_{LAG},P_{LAG})$.

(3) LAG verifies whether or not $V_{agg}=\sum_{i=1}^{n}V_i$ and $e(\sum_{i=1}^{n}V_i,P)=e(\sum_{i=1}^{n}W_i,P_{pub2})\cdot\prod_{i=1}^{n}e(R_i,X_i+q_iP_{pub1})$. If two equations are both established, LAG outputs m_{2i}. If not, LAG verifies the signcryption one by one.

Since batch verification of signatures has forgery attack, Ref.[10] presented dynamic equation which can resist forgery attack. So the scheme in this paper makes use of dynamic equation of batch verification. The step is as follows.

(1) LAG selects $k_i\in Z_7$ with dynamic change, for *n* messages $(m_{21},...,m_{2n})$ with signatures $(V_1,...,V_n)$. LAG computes $e(\sum_{i=1}^{n}k_iV_i,P)=\prod_{i=1}^{n}e(k_iV_i,P)=\prod_{i=1}^{n}k_i\cdot\prod_{i=1}^{n}e(V_i,P)$.

(2) LAG verifies the equation $e(\sum_{i=1}^{n}k_iV_i,P)=\prod_{i=1}^{n}k_i\cdot e(\sum_{i=1}^{n}W_i,P_{pub2})\prod_{i=1}^{n}e(R_i,X_i+q_iP_{pub1})$. If the equation are verified, LAG aggregates all users' electricity request $M_T=\sum_{i=1}^{n}m_{2i}$ at time *T*. Then LAG signcrypts M_T and transmits it to CAG.

Security Analysis

The scheme in this paper combines pseudonym with signcryption, which can realize identity authentication for SM in smart grid. The security of this scheme is based on difficult problem of

Computer Differ-Hellman. Therefore, this scheme can resist replay attack and has the character of unlinkability, traceability, and unforgeability.

In [9], when n users send n messages using signature verification one by one, there are $4n$ pairing operation in all. There are only n+3 pairing operation in the scheme of this paper. The signcryption can improve efficency compared with signature then encryption. Aggregation signcryption can verify multiple different messages in the meantime. Thus LAG and CAG can quickly and effectively to respond, which can greatly save the compute and storage consumption. The data transmission scheme proposed in this paper adopts to pseudonym technology when US communicates with LAG. At the same time, signcryption key is generated based on the pseudonym. Therefore, the proposed ID based aggregation signcryption scheme is simple in calculation, low in overhead, fast in transmission speed.

Summary

In this paper, an identity-based aggregation signcryption scheme is proposed in smart grid. The scheme adopts pseudonymous ID to achieve the users' privacy protection in the access terminal. The scheme uses the aggregation signcryption for different multiple users by dynamic equation, which can compromise the security and computation overhead to meet the requirements of smart grid. This scheme can reduce the computation burden for aggregator at the same time to ensure communication security, which can meet the requirement of real time and high efficiency in smart grid.

Keywords: multi-fault location; equivalent fault model; fitting degree; wide-area measurement system; least square method; virtual fault location

Abstract. This paper presents a fitting degree-based multi-fault location algorithm for complex large power grid utilizing wide-area information. Firstly, fault injection current of the equivalent fault points is used in the equivalent model. Then the correlation matrix is formed by the network topology and associated nodal injection current and a network is formed to determine the location of faults. When multiple faults occur, the addition of the current of each two fault lines is calculated and the real-time current is measured. Then by calculating the minimum of fitting degree between two current values, fault line and virtual fault location can be determined. The simulation results of 10-generator 39-bus system verify the validity and feasibility of this algorithm.

Introduction

In recent years, with the continuous development of the power grid and the reinforcement of its main structure, the trip of a single element under normal operation mode is generally not a strong impact on the grid. However, frequently, there are various types of fault, i.e. more than one fault occurred in a short time. It will pose serious threat to the safety and stable operation of power grids, and it will become a failure mode which may lead to significant loss of load and result in serious damage to electrical components .The complexity of the power grid structure makes the traditional protections which are based on the amount of local backup settings more difficulty. The uncertainty of power grid structure and operating conditions has intensified the contradiction among selectivity, sensitivity and reliability of backup protection. It is necessary to improve the adaptability and intelligence of back-up protection levels for the rapid development of grid. Thus, the study on wide-area backup protection of multiple faults is of significance.

With wide-area synchronized phasor measurement technology, the information resources of the relay system have changed fundamentally. It makes a big change to relay on the configuration, the principle of setting and achieving technology and other aspects. Wide-area backup protection system can collect more information, but do not have to sacrifice time to ensure the selective action. According to wide-area information, we can locate the fault, in such cases of the main protection tripping and breaker fault. It can not only overcome the problem of too much time consuming, but also will prevent protection malfunction caused by overload of adjacent lines after a fault backup.

Presently, the research on backup protection is focused on the fault location methods based on wide area measurement. Reference [1] presents a new fault location method for transmission network using sparse (phasor measurement unit) PMU measurements. A new concept of fault location factor is defined to reflect the location of the fault. Then the matching based fault location method is presented. The fault location is estimated by matching measured factors with the calculated ones. Reference [2] presents a general fault location approach utilizing only voltage measurements from one or more terminals by taking advantage of network analysis based on bus impedance matrix technique. Reference [3] proposes fault location algorithms by utilizing sparse current measurements. Bus impedance matrix techniques are utilized to find a direct solution and the need of iterative searching of the fault location is eliminated. Algorithms for scenarios where current phasors or current magnitude are available from one or two branches are developed. In reference [4], global information

has been introduced into the backup protection system. By analyzing and computing real-time PMU measurements, basing on cluster analysis theory, hierarchical cluster analysis technology is used to locate fault line.

In order to further enrich and improve the fault location methods this paper presents a fitting degree-based branch of the faults location method. Firstly, fault injection current of the equivalent fault points is used in the equivalent model. Then the correlation matrix is formed by the network topology and associated nodal injection current and a network is formed to determine the location of faults. When multiple faults occur, the addition of the current of each two fault lines is calculated and the real-time current is measured. Then by calculating the minimum of fitting degree between two current values, fault line and virtual fault location can be determined. 10-generator 39-bus New England system simulation results verify the effectiveness and validity of the algorithm.

Multi-fault location

In the fault network, the model of fault branch b_0 is shown in Fig.1.The model uses lumped parameters, and the branch impedance is z. y1, y2 are the admittances to ground. K1 and K2 are two terminals of the line. The distance between failure point and the node K1 is a times of the total line. $\dot{I}_{\mathrm{f}}$ is the fault injection current. $\dot{U}_{\mathrm{f}}$ is the voltage of fault point. $\dot{I}_{\mathrm{K1}}$ and $\dot{I}_{\mathrm{K2}}$ are the currents inject into the terminals. $\dot{U}_{\mathrm{K1}}$ and $\dot{U}_{\mathrm{K2}}$ are the voltage of K1 and K2.

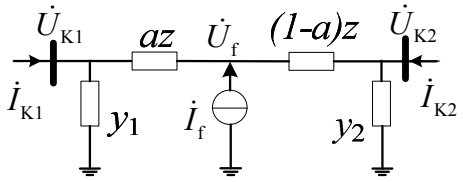

Fig. 1. Fault transmission line

By solving the nodal voltage equation, we can draw the following equivalent circuit as Fig.2 shows:

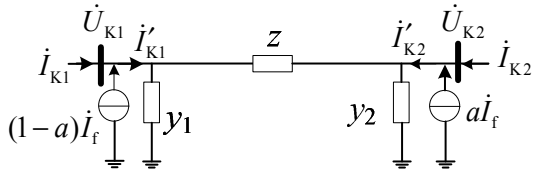

Fig. 2. Equivalent model of fault transmission line

Fig.2 shows that the equivalent model distributes the additional current to the terminals of the branch. The structure and parameters of the branch remain unchanged, so the admittance matrix does not change and then the computation is reduced. According to superimpose theorem, node of the branch current configuration PMU column vector can be expressed as follows:

$$\vec{\mathbf{I}} = \mathbf{P}\vec{\mathbf{R}} - (1-a)\dot{I}_{\mathrm{f1}}\vec{\mathbf{g}}_{\mathbf{K1}} - a\dot{I}_{\mathrm{f1}}\vec{\mathbf{g}}_{\mathbf{K2}} - (1-b)\dot{I}_{\mathrm{f2}}\vec{\mathbf{g}}_{\mathbf{K3}} - b\dot{I}_{\mathrm{f2}}\vec{\mathbf{g}}_{\mathbf{K4}} \tag{1}$$

$$\mathbf{P} = (\mathbf{Y_B}\mathbf{A}^T + \mathbf{Y_{B1}}\mathbf{A}_1^T)\mathbf{Y}^{-1} \tag{2}$$

where P is the correlation matrix, $\mathbf{Y_B}$ is the branch admittance matrix, $\mathbf{A}$ is the node-to-branch incidence matrix, $\mathbf{Y_{B1}}$ is branch-to-ground admittance matrix, $\mathbf{A_1}$ is node-to- branch incidence matrix and T represents the matrix of transpose.

From the previous analysis, the matrix can be formed in the system during normal operation. The fault location process remains the same. $\vec{\mathbf{g}}_{\mathbf{K1}}$ is a column vector and its element corresponding to K1-K2 (from K1 to K2) is 1, and the remaining elements are zeros. $\vec{\mathbf{g}}_{\mathbf{K2}}$ is a column vector and its element corresponding to K2-K1 (from K2 to K1) is 1, and the remaining elements are zeros. $\mathbf{Y}$ is the admittance matrix of network, $\vec{\mathbf{R}}$ is current column vector which inject into network nodes.

Basis of the preceding additional fault current distribution principle, steady-state fault slip faults at both ends of the network nodes only in K1 and K2 are the injection currents, which can get into the current node column vector:

$$\vec{\mathbf{R}} = [0 \cdots (1-a)\dot{I}_{f1} \cdots a\dot{I}_{f1} \cdots (1-b)\dot{I}_{f2} \cdots b\dot{I}_{f2} \cdots 0] \tag{3}$$

$\vec{\mathbf{g}}_{K1}$ and $\vec{\mathbf{g}}_{K2}$ represent K1th and K2th column of matrix **P** respectively.

$$\vec{\mathbf{I}} = [\vec{\mathbf{P}}_{k1} - \vec{\mathbf{g}}_{k1}\ \vec{\mathbf{P}}_{k2} - \vec{\mathbf{g}}_{k2}\ \vec{\mathbf{P}}_{k3} - \vec{\mathbf{g}}_{k3}\ \vec{\mathbf{P}}_{k4} - \vec{\mathbf{g}}_{k4}] \bullet [(1-a)\dot{I}_{f1}\ \ a\dot{I}_{f1}\ \ (1-b)\dot{I}_{f2}\ \ b\dot{I}_{f2}]^T \tag{4}$$

Equation (4) is always effective to the fault line and it is not effective to the normal branch. For the location of fault is random, the fault line and fault position are unknown before the fault point is located. The fault line and fault location can be found by solving the equation (4) of each branch. For any two branches b (k1-k2) and b (k3-k4), assume the fault occurs where the distance between the fault point1 and k1 is a times of the total line b (k1-k2), point2 and k3 is b times of the total line b(k3-k4). Solve (5):

$$\vec{\mathbf{I}} = [\vec{\mathbf{Q}}_{K1}\ \vec{\mathbf{Q}}_{K2}\ \vec{\mathbf{Q}}_{K3}\ \vec{\mathbf{Q}}_{K4}][(1-a)\dot{I}_{f1}\ \ a\dot{I}_{f1}\ \ (1-b)\dot{I}_{f2}\ \ b\dot{I}_{f2}]^T \tag{5}$$

$$\begin{cases} \vec{\mathbf{Q}}_{K1} = \vec{\mathbf{P}}_{K1} - \vec{\mathbf{g}}_{K1} \\ \vec{\mathbf{Q}}_{K2} = \vec{\mathbf{P}}_{K2} - \vec{\mathbf{g}}_{K2} \\ \vec{\mathbf{Q}}_{K3} = \vec{\mathbf{P}}_{K3} - \vec{\mathbf{g}}_{K3} \\ \vec{\mathbf{Q}}_{K4} = \vec{\mathbf{P}}_{K4} - \vec{\mathbf{g}}_{K4} \end{cases} \tag{6}$$

Equivalent transformations are made as follows:

$$\mathbf{M} = [\vec{\mathbf{Q}}_{K1}\ \vec{\mathbf{Q}}_{K3}\ \vec{\mathbf{Q}}_{K2} - \vec{\mathbf{Q}}_{K1}\ \vec{\mathbf{Q}}_{K4} - \vec{\mathbf{Q}}_{K3}] \tag{7}$$

$$\vec{\mathbf{N}} = [h_1\ h_2\ h_3\ h_4]^T \tag{8}$$

$$\begin{cases} h_1 = \dot{I}_{f1} \quad h_2 = \dot{I}_{f2} \\ h_3 = a\dot{I}_{f1}\ \ h_4 = b\dot{I}_{f2} \end{cases} \tag{9}$$

$$\vec{\mathbf{I}} = \mathbf{M}\,\vec{\mathbf{N}} \tag{10}$$

For the number of branch current is more than the number of variables, so the equation can be solved by least square method:

$$\vec{\mathbf{N}} = (\mathbf{M}^T\mathbf{M})^{-1}\mathbf{M}^T\,\vec{\mathbf{I}} \tag{11}$$

$$\begin{cases} a = h_3 / h_1 \\ b = h_4 / h_2 \end{cases} \tag{12}$$

If $a \notin [0,1]$ or $b \notin [0,1]$, it indicates that the according lines are not the right combination, but if $a \in [0,1]$ and $b \in [0,1]$, then the combination is considered as a suspected one. Substitute all the suspect lines to (5) and calculate $\vec{I}_m$ of these lines which are equipped with PMU. The relative distance between $\vec{I}_m$ and the measured current $\vec{I}$ by PMU is defined as the fitting degree *T*:

$$T = \frac{\left\| \vec{\mathbf{I}}_{\mathbf{m}} - \vec{\mathbf{I}} \right\|_2}{\left\| \vec{\mathbf{I}} \right\|_2} \tag{13}$$

Theoretically, the fitting degree of the fault combination is zero. However, for the existence of errors, the actual fitting degree is not zero. From plenty of simulations, it is reliable to set T=1 as the boundary value. If fitting degree of a combination is smaller than 1, the combination can be considered as a suspect one. For the normal combination, the fitting degree should be bigger than 1. So the fault line and the fault location can be defined.

Example Test System

This algorithm is tested on a 10-generator 39-bus New England system. A comprehensive analysis of the algorithm and its validation are given.

The faults are set in the branch8 and branch35 at 0.25s. Two fault types are analyzed.

Case1: Three-phase short circuit in both branch8 and branch35 and the fault points are set 40% length of each line.

Three of all the combinations are analyzed. The simulations of T of these combinations are shown in Fig.3.

Firstly both *a* and *b* are judged whether they are in the interval of [0, 1]. In mode2, both *a* and *b* are bigger than 1, so mode 2 is not a suspect combination. Mode1 and mode3 are suspect combinations because they satisfy the conditions that both *a* and *b* are in the interval of [0, 1]. Then the fitting degree T of each mode is compared to the boundary value. The fitting degree of mode1 is 0.2667 which is smaller than 1 and the fitting degree of mode 3 is 2.368 which is bigger than 1. So mode1 is judged as the fault combination.

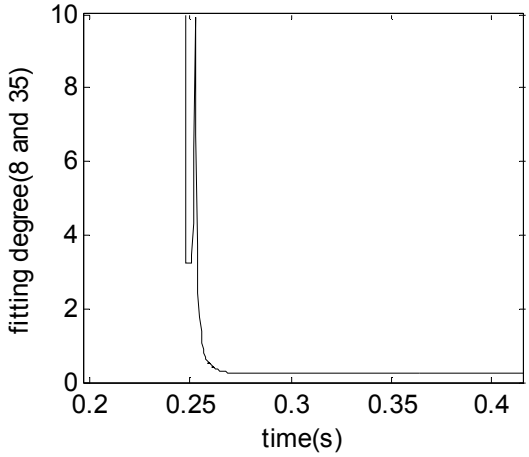

Fig.3. Fitting degree T (8 and 35)

Case2: AB two-phase short circuit in branch 8 and three-phase short circuit in branch 35. And the failure points are set 60% of each line.

The analysis process is the same as case1 and the simulations of T of these combinations are shown in Fig.4.

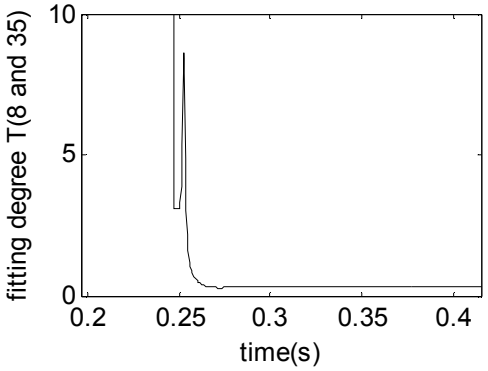

Fig.4. Fitting degree T (8 and 35)

Conclusion

The nodal admittance matrix Y and the correlation coefficient of the network can be formed when the system runs normally. The two matrixes remain unchanged and are applied to define the fault line and fault location after the fault occurs. Compared to searching the fault location based on traverse,

there is no need to change the matrix by the method proposed in the paper. So the recalculation of the admittance and its inverse matrix is voided. The algorithm is applied to each combination directly and there is no need to search by each step, so the computation is reduced enormously.

Keywords:credibility theory,information network,smart grid,security assessment,countermeasure

Abstract. With the development of the smart grid , information network security assessment affects the safe operation of the smart grid . In this paper, the improved credibility theory and analytic hierarchy process , combined with structural features of the smart grid network , From the wide area network , access network, enterprise local network , local area network and the CPN-site and home users to assess the impact of the five aspects of information networks for smart grid security operation. And make the case for more security strategy to improve the reliability of the smart grid operation , thus providing a basis for guiding the development and safe use of electricity grid users .

Introduction

Due to the rapid growth of China's future demand for electricity , smart grid development trend of China's power grid [1] . Different countries and different institutions for their own understanding and their own business, economic interests , such as the smart grid concept has a different understanding [2-4] . But the smart grid is still roughly the same basic idea , the use of modern communications , computing, control technology , power grid can adapt to optimize the operation of a variety of normal operation, the operation mode adjustment , and can take the initiative and respond to grid disturbances predictive method [5] .

Information network will go deep into the smart grid , electricity production efficiency and management level will be greatly improved , and for power users , there will be a better user experience and more economical electricity [6] . However, while the benefits , we must consider the level of information in the process of rapid development, it also brings a lot of security risks. In recent years , more and more hackers use information networks for business , industry and other institutions malicious intrusion , eavesdropping , tampering and information [7,8] . This information along with the development of the smart grid , also significantly increased their security risks and may even lead to a chain of large area blackout [9,10] . Therefore, the smart grid information network security assessment is essential.

Firstly, through a wide area network, access network , enterprise local network , local area network and the CPN -site and home users to establish a security assessment of five system , the introduction of smart grid credibility theory of information network security evaluation. Finally, the smart grid information network to improve the safety level of security and defense measures for the safe operation of the smart grid to provide a reference .

Smart Grid Information Network Security Assessment Index System

In traditional grid, the grid is to communicate through a dedicated network , and its main source of danger from the threat of internal network. The smart grid is an open system , there is a public communication network of information between the various aspects of the interaction , and links within itself also has an internal communications network . The interaction between the user information can be the grid . In this case, the information network itself has vulnerabilities , the impact on the smart grid hazard is greatly increased. In this paper, the establishment of a smart grid information network security evaluation index system based on network components , shown in Table 1 .

Table 1 Smart Grid information network security evaluation syste

Index	Use
WAN	1.Providing power data network , Internet networking and routing functions; 2.Label Switching backbone network to provide isolation of different business flow.
AN	1.To access WAN , MAN provides physical channel; 2.Available metropolitan Ethernet access Through wireless access WAN; 3.Available fiber access.
LAN	Power company intranet.
FAN	1.Production control area power plant and interconnection equipment; 2.Used to transmit data, such as data collection instrument; 3.Transmission, distribution, consumption data collection , monitoring and surveillance;
HAN	1.Provide fiber access to intelligent residential quarters users; 2.Remote meter reading, Internet access; 3.Smart home, smart meters and appliance control.

Safety assessment model based on credibility theory

Smart grid uncertainty , fuzziness and randomness , so the past are analyzed separately using probability theory and fuzzy theory, which caused the result is often one-sided. The use of credibility theory , can be a combination of random and fuzzy safety assessment for random fuzzy optimization modeling uncertainties dual problem solving work can be carried out smoothly laid a theoretical foundation , making the results more accurate.

Credibility Theory. According to the credibility theory four axioms [11-12] get triangular fuzzy variables $\xi = (r_1, r_2, r_3), r_1 < r_2 < r_3$ the membership function and the distribution of credibility are:

$$\mu(x) = \begin{cases} \dfrac{x - r_1}{r_2 - r_1}, r_1 \le x \le r_2 \\ \dfrac{x - r_3}{r_2 - r_3}, r_2 \le x \le r_3 \\ 0, \qquad Other \end{cases} \tag{1}$$

$$\Phi(x) = \begin{cases} 0, & x \le r_1 \\ \dfrac{x - r_1}{2(r_2 - r_1)}, & r_1 \le x \le r_2 \\ \dfrac{x + r_3 - 2r_2}{2(r_3 - r_2)}, & r_2 \le x \le r_3 \\ 1, & x \ge r_3 \end{cases} \tag{2}$$

Improved AHP. AHP weighting method for solving first evaluated in accordance with the internal logic to evaluate the indicators form an ordered hierarchy model ; followed by judgment matrix , using expert assessment of the index compared with each other . Solving the characteristic equation of the maximum eigenvalue of the corresponding feature quantity ; normalized eigenvector weight vector can be obtained .

Factors for a layer , the relative importance of the various factors associated with the level is expressed as the judgment matrix . By comparing the elements to be marked scale of 1-9 .

As can be seen from the table to determine the characteristics of the matrix P as follows :

1) $u_{ij} > 0$

2) $u_{ij} = \dfrac{1}{u_{ji}}, i, j = 1, 2, \cdots, n$

3) $u_{ii} = 1$

Definition, reciprocal matrix P, symmetric matrix $B = \lg P(b_{ij} = \lg u_{ij})$, and A is the optimal transfer matrix B . Therefore, by definition, intended to optimize the matrix P obtained transfer matrix P^*:

$$P^* = 10^{A_{ij}} \tag{3}$$

$$A_{ij} = \sum_{k=1}^{n} (u_{ik} - u_{jk}), \forall i, j \tag{4}$$

Based on the above , the optimal transfer matrix P^* is the same, so the consistency test may be directly obtained weights .

Algorithm steps. This paper has two levels indicators for more level indicators can be so :

First, $A = \{A_1, A_2, \cdots, A_n\}$ target layer were determined by an index layer improved AHP, Right weight vector $A_i = \{A_{i1}, A_{i2}, \cdots, A_{im}\}$, $P = (P_1, P_2, \cdots, P_n)$ and $P_i = (P_{i1}, P_{i2}, \cdots, P_{im})$.

The second step can be obtained membership of the index factor $A_{ij}(i = 1,2,\cdots,n; j = 1,2,\cdots,m)$ review of d_l （l=1, 2, …, k） h_{ijl} according to the Delphi method.

The third step is the introduction of the credibility of the above theory, solving the fuzzy expected triangular fuzzy variables $E[f(\xi)]$, then use the credibility inversion theorems formula for solving univariate A_{ij} measure to assess the credibility of the vector r_{ij} , and its be normalized .

$$C_r\{\xi \in B\} = \frac{1}{2}\left(\sup_{x \in B} \mu(x) + 1 - \sup_{x \in B^C} \mu(x)\right) \tag{5}$$

$$r_{ijl}^{k} = \frac{r_{ijl}'^{k}}{\sum_{l=1}^{n_k} r_{ijl}'^{k}} \tag{6}$$

By solving the above , r_{ij} in accordance with the sequence number order, constitute a layer of factor A_i on the credibility of the evaluation matrix :

$$R_i = (r_{ijl})_{m \times k} \begin{bmatrix} r_{i11} & r_{i12} & \cdots & r_{i1k} \\ r_{i21} & r_{i22} & \cdots & r_{i2k} \\ \cdots & \cdots & \cdots & \cdots \\ r_{im1} & r_{im2} & \cdots & r_{imk} \end{bmatrix} \tag{7}$$

The use of fuzzy linear transformation, the credibility measure to assess the credibility of the assessment matrix into vector about A_i , s_{il} indicates the status of the objective merits of the extent of A_i 's .

$$S_i = P_i * R_i = (s_{i1}, s_{i2}, \cdots, s_{ik}) \tag{8}$$

Measure to assess the credibility of the target layer matrix A can be arranged through the n- index layer A_i fuzzy subsets , we get:

$$R = (s_{ij})_{n \times k} \begin{bmatrix} s_{11} & s_{12} & \cdots & s_{1k} \\ s_{21} & s_{22} & \cdots & s_{2k} \\ \cdots & \cdots & \cdots & \cdots \\ s_{n1} & s_{n2} & \cdots & s_{nk} \end{bmatrix} \tag{9}$$

Finally, the evaluation matrix R fuzzy linear transformation , you can get the target layer A comment on the credibility of the assessment of vectors:

$$S = P * R = (s_1, s_2, \cdots, s_k) \tag{10}$$

According to the principle of maximum credibility measure , s_l maximum , this time to assess the results of d_l reviews .

Defensive countermeasures and suggestions

Smart grid security hazard a huge impact on the grid , in order to avoid harm, should establish a complete set of smart grid information network security defense system.

1) Security Policy

As a smart grid security policy on the basis of the rapid development of smart grid information network security compared to traditional grid , with network wide , interactive and more features , requiring new features for the national grid to develop a " dual network dual machine, partition Fenwick , secure access , dynamic perception, lean management , comprehensive protection , "the defense strategy , and therefore should be based on this , the smart grid hazard defense.

2) Security Technology

Strongly support smart grid security needs and technology, strengthen research and development from the information collection, interaction , and processing sectors . Smart meters , sensors , gateways and other equipment, which widely used in smart grid , to ensure their physical security, information security is essential ; adopt effective anti-intrusion systems and data encryption technologies will effectively protect network security ; operating system security updates, vulnerability scanning ; improve early warning, emergency response mechanism , the formation of effective protection security technology platform .

Conclusion

While the rapid development of smart grid , smart grid hazard also changed . This paper analyzes the network structure of the smart grid , from wide area networks, access networks, enterprise local area network , local area network and the CPN -site and home users the information analyzed five aspects of the smart grid network hazard . And protection against the above proposed strategy in terms of security policy, security technology, security training , to provide a reference for the security and defense of the smart grid , smart grid wish to be more stable operation.

Keywords: Micro-grid, Transient power quality, Energy storage, Super-capacitor, Power compensation

Abstract. Massive applications of the power electronic devices and non-linear loads lead to various power quality problems during the microgrids grid-connecting. Aiming at improving power quality of micro-grid, the structure of SCs' main circuit and control circuit are designed. The model of super-capacitor energy storage system (SCESS) is established. A simulation model of micro-grid is also built up by using MATLAB and the simulation is conducted for different situations. Moreover, under Goldwind micro-grid platform, according to the result of MATLAB modeling and simulation, the SCESS effectively improves the transient power quality of the system.

Introduction

With the development of power system, the micro-grid has received much attention in recent years, which is expected to become competitive with conventional energy sources. As the functional part of energy buffering in micro-grid, energy storage systems is taking more and more effect in improving power quality and system operational stability. The super-capacitor (SC) energy storage device is considered as an auxiliary power source to compensate the energy gap when needed. Super-capacitors are attractive as they have a higher power density (kW/kg) than batteries, appropriate energy density, high charge and discharge rate. In addition, SCs has many advantages, such as convenient control, high conversion efficiency, wide working temperature range and no pollution [1].

The super-capacitor energy storage device is composed of several groups of super-capacitors, storing the electric energy as electric-field energy. When system voltage fluctuating, the device is accurate and efficient for supporting active power and compensating reactive power to micro-grid and power grid, which promotes a smooth transition of system and improves the power quality[2].
In this paper, the structure of SCs' main circuit and control circuit are designed. The model of super-capacitor energy storage system (SCESS) is established. A simulation model of micro-grid is also built up by using MATLAB and the simulations are conducted for different situations. Moreover, under Goldwind micro-grid platform, according to the result of MATLAB modeling and simulation, the SCESS effectively improves the power quality of the system.

Principle and Model of SCESS

Super-capacitor energy storage system consists of super-capacitors, AC-DC rectifier, bi-directional DC-DC converters, DC-AC inverter and controller. The corresponding topological structure chart of SCESS is shown in Fig. 1. SCESS is parallel on DC bus of micro-grid. The operating principle of SCESS is that the three-phase alternating current turns into direct current through rectifier. After that, the inverter converts DC to a controllable AC. SCs stores DC power from rectifier while the system operates properly. If the system fails or fluctuates, SCs feed power to the system through inverter rapidly and accurately, achieving balanced and stability control of electric energy [3]. For example, SCs provide power to system while the inverter voltage being higher the system voltage; otherwise SCs absorb power.

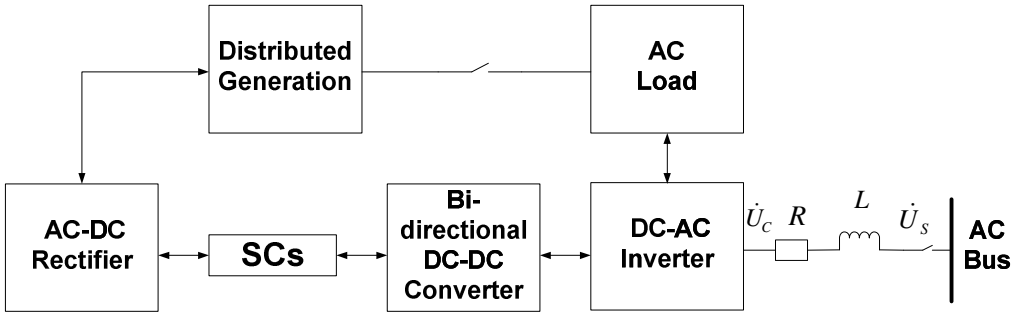

Fig. 1 Topological structure chart of SCESS

The super-capacitors group is supposed to be consist of m×n single super-capacitors, in which there are n branches. Each branch includes m single super-capacitors connected in series. C_F is the equivalent capacitance of single super-capacitor, and r_{ESR} is its equivalent resistance. The equivalent resistance of super-capacitors group is calculated applying equation (1).

$$r_i = \frac{m}{n} r_{ESR} \tag{1}$$

The equivalent capacitance of super-capacitors group is calculated applying equation (2).

$$C_{SC} = \frac{m}{n} C_F \tag{2}$$

The stored energy of super-capacitors group is calculated applying equation (3).

$$E = \frac{1}{2} CV^2 \tag{3}$$

Where, C is the capacitance of super-capacitors, V is the operating voltage of super-capacitors.
Given the voltage variation range of single super-capacitor at (U_{SC1}, U_{SC2}) during the discharge process. U_{SC1} is the minimum DC bus voltage when inverter operates normally, and U_{SC2} is the minimum DC bus voltage at the initial time of failure. Then total energy the super-capacitors group releases is calculated applying equation (4).

$$E = \frac{n}{2m} C_F \left[(mU_{SC2})^2 - (mU_{SC1})^2 \right] = mnC_F \left(U_{SC2}^2 - U_{SC1}^2 \right) \tag{4}$$

In this way, the total energy the super-capacitors group releases is irrelevant to the approach of series and parallel while quantity and voltage of single super-capacitor don't change. And the time that SCs could support power to the system after interruption of power supply can be calculated applying equation (5). Where, P is the load power.

$$t = \frac{1}{2} \frac{C}{P} (U_{SC2}^2 - U_{SC1}^2) \tag{5}$$

Case study description and hardware design

As the basis for this study, the experimental domestic microgrid of Goldwind Science & Technology Microgrid platform has been considered. The microgrid model is established based on MATLAB , which comprises micro turbine, wind turbine (WT), photovoltaic cell (PV) as generation units, thermal loads as consumption units, lithium ferrous phosphate battery (LFP), all vanadium flow battery (VRB) and SCs as energy storage units. The model is validated through the test under the Goldwind platform, as depicted in Fig. 2. In addition, the rated power of micro turbine, WT , PV, (LFP) , VRB and SCs are 130 kW, 2.5 MW, 150 kW, 100 kW, 100 kW, 100 kW respectively. The normal power output of WT is 1MW, and the total load value is about 1.2 MW.

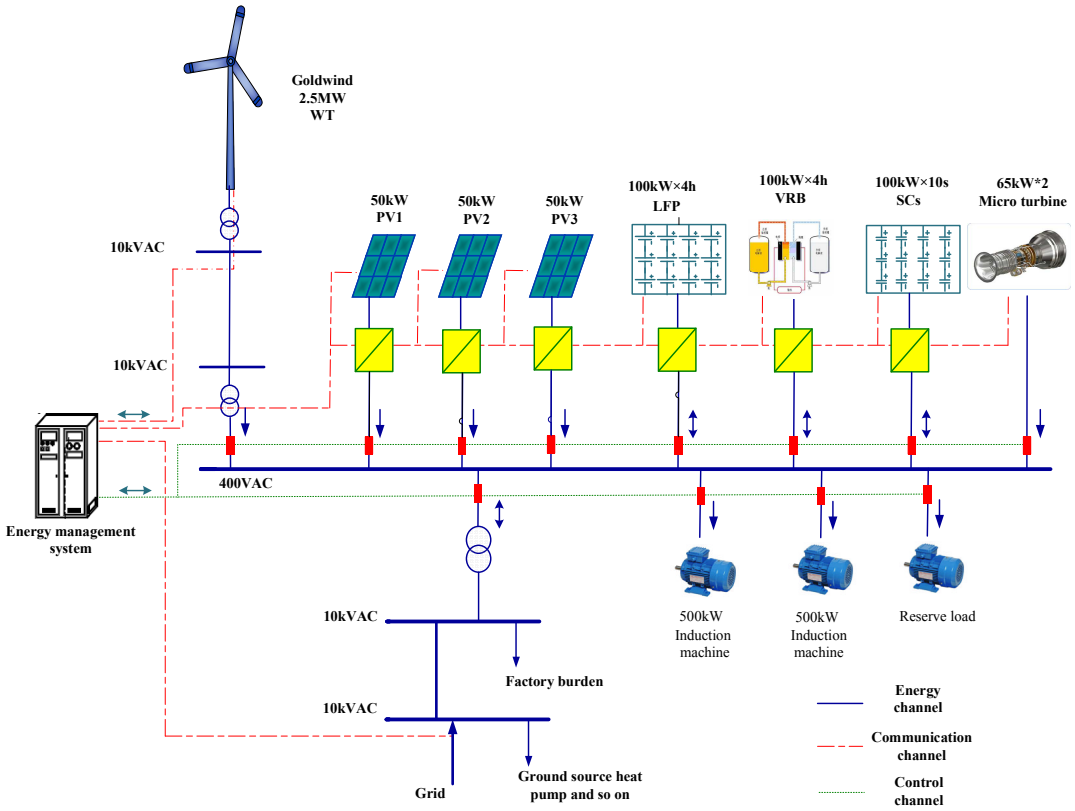

Fig.2 The hardware model of Goldwind microgrid

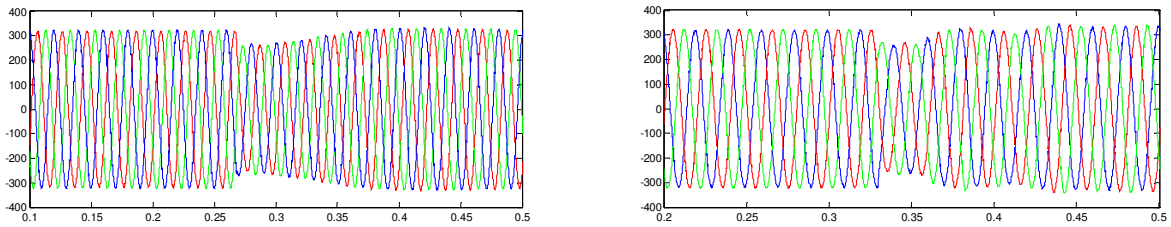
During the grid- connected operation, the control strategy used to be P/Q control method, while some DGs are under V/f control model during islanding operation, such as WT, PV and so on.

It's important to selecting the parameter of SCs. According to the quantity and the minimum discharge voltage of single super-capacitor applied to equation (3) and (4), the capacity of SCs will be settled.

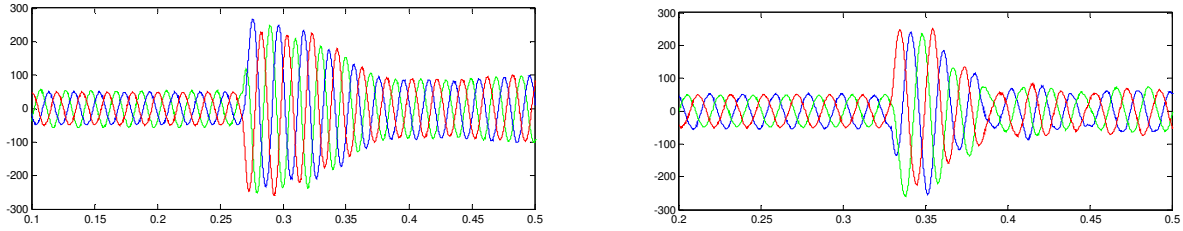
The simulation results and analyses

Grid-connected operation and stand-alone operation are two typical operation modes in microgrid. Microgrid operation mode smooth transition is the key technique to guarantee the system working well. When the operation switch from Grid-connected operation to stand-alone operation, voltage sag will take place. Then the SCESS is used to improve the transitions between operating modes.



(a) Without SCs compensation (b) With SCs compensation

Fig.3 Detail of the triphase voltage during switching operation



(a) Without SCs compensation (b) With SCs compensation

Fig.4 Detail of the three-phase current during switching operation

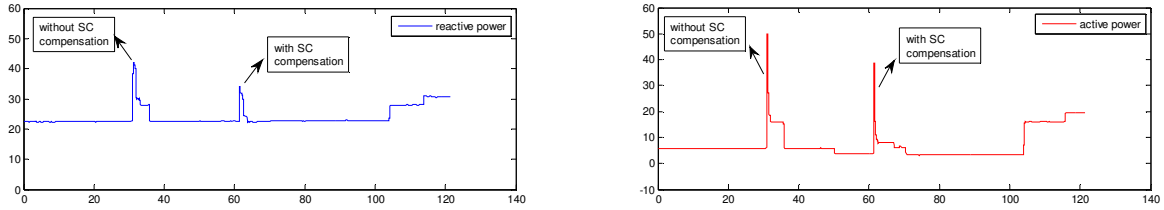


Fig.5 Inhibition effect on reactive power and active power when without SCs or with SCs compensation

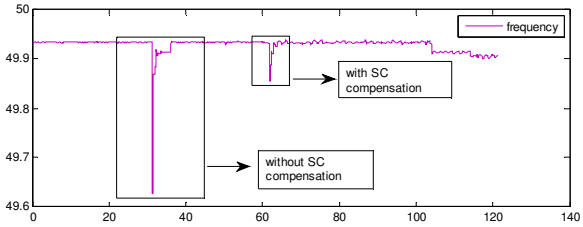

Fig.6 Inhibition effect on frequency when without SCs or with SCs compensation

In order to validate the whole hardware design, the prototype has been experimentally tested both in the condition of that without SCs compensation and with SCs compensation.

The Fig. 3 shows that the three-phase voltage returns to a new stable states in about 0.15 s without SCs compensation during switching operation, while it returns to a new stable states in about 0.05 s with SCs compensation. Similarly, the three-phase current with SCs compensation reaches a new stable condition faster than without SCs compensation during switching operation as depicted in Fig. 4. Moreover, Fig. 5 and 6 present waveforms that are also obtained during switching operation, which show that the SCs compensation contributes to reducing major fluctuations of reactive power, active power and frequency.

Conclusions

From Figs. 3, 4, 5 and 6, it is concluded that SCESS could improve the power quality and system operational stability, and conduce to promoting the microgrid to attaining new equilibrium. In a word, the super-capacitor energy storage system will take more and more effect in microgrid, as the indispensable energy buffer.

Keywords: Insulator leakage current; wavelet transform; optimal wavelet basis

Abstract. Insulator leakage current contains important information which can reflect the condition of insulators. However, it is always swallowed by many other noises which hinder us to get precise signals. Wavelet transform is a kind of new method which has been widely used in signal-de-noising because of its good frequency effect. However, suitable wavelet bases should be used to guarantee better effect. In this paper, we compared three groups of wavelet basis: db/coif/sym in hunt for the most relative suitable wavelet basis for insulator leakage current signal. Experiment results prove the conclusion later.

Introduction

Insulator Leakage Current (ILC) is one of the most important monitoring parameters of transmission line safety. It contains important information such as insulator state, leakage current state, hydrophobicity, aging state and many other key information which can be used to evaluate insulator contamination and make predictions ahead of time. Hence, it is of great importance to evaluate pollution flashover. However, ILC is often mixed with many noises in the process of collection and detection, which causes greater difficulty to extract further information. Therefore, to get ILC de-noised is essential. To get the best de-noising signal method, many experts and scholars have made great attempts, thus many methods appeared and are used gradually in our daily life, including: Empirical Mode Decomposition de-noising method[1], self-adaptation eliminating-noise-method based on HHT transform[2], EMD decomposition and time-frequency analysis method for de-noising and wavelet de-noising.

Among these methods, wavelet de-noising is one of the most popular methods that has been widely used in the field of signal processing in the past 10 years. It has good characteristics of multi-resolution analysis, thus it has advantages to present the local feature of the signal in time domain and frequency domain. Besides, it is very flexible, different results will be got if different wavelet basis will be chosen when dealing with the same signal. Hence, to select the optimum wavelet base according to the specific signal is a tough problem [3]. In the field of wavelet de-noising, many experts and scholars had attempted in depth and expressed different views on choosing suitable wavelet bases, yet a complete study on choosing the optimal wavelet basis for insulator leakage current development is vacant. In this paper, we try to find the proper wavelet basis among three classic groups of wavelet basis function: db/coif/sym; them make a comparison between those wavelet basis according to the subtraction of the original signal and the decomposed signal, and eventually draw the conclusion of the optimal wavelet basis for leakage current signal. Finally, an experiment is conducted to test the result.

Principle of wavelet transform in de-noising

Discrete wavelet transform

According to reference [4], the integral transform can be described as

$$W_f(a,\tau) = \int_R f(t)\overline{\varphi_{at}(t)}dt = (f, \varphi_{at}(t)) \tag{1}$$

Where signal $f(t)$ is known as the continuous wavelet transform, where

$$\varphi_{at}(t) = \frac{1}{\sqrt{a}}\varphi(\frac{t-\tau}{a}) \tag{2}$$

is known as the wavelet basis function, which is translated and scaled by a mother function. If the following function is satisfied, then $f(t)$ can be called as wavelet basis function.

$$\int_R \frac{|\hat{\varphi}(w)|^2}{w} dw < \infty \tag{3}$$

Where $\hat{\varphi}(w)$ can be got after the Fourier transform of $\varphi(t)$. In the discrete case, discrete wavelet function is defined as

$$\phi_{j,k}(t) = 2^{-j/2}\phi(2^{-j}t - k) \tag{4}$$

Then the discrete wavelet transform of the signal is defined as

$$D[W_f(j,k)] = 2^{-j/2}\int_R f(t)\overline{\phi(2^{-j}t-k)}dt \tag{5}$$

Wavelet decomposition and reconstruction method of de-noising

Suppose $f(i)$ is the real signal; $c(i)$ is the noise; $s(i)$ is the collect signal compounded with real signal and the noise. Then, $s(i)$ can be described as:

$$s(i) = f(i) + \sigma \times c(i), \quad (i = 0,1,2,\cdots,n-1) \tag{6}$$

In actual project, low frequency or more smoothly signals are always helpful whereas high frequency signals are noises which should be wiped out. De-noising procedure can be described as:

(1) Decompose the signal according to wavelet principle by choosing proper wavelet basis function and the number of decomposition layers N.
(2) Quantify the decomposition of the high frequency coefficient according to the threshold.
(3) Reconstruct the signal according to the principle of inverse transformation of wavelet, ultimately we can achieve the goal of eliminating noise.

Select the wavelet base

Since select the best wavelet base is of great importance in the process of signal de-noising, several characteristics of wavelet base should be taken into consideration: the orthogonality, symmetry, regularity, compactly supported, smoothness, vanishing moments and so on. Among them, the symmetry related to whether the filter characteristic of wavelet has linear phase, furthermore it can be used to test signal distortion; regularity is used to ensure the smoothness of the signal; compact support ensures excellent local time-frequency features, and are also conducive to the possibility of algorithm; smoothness is related to the frequency resolution. However, these characteristics mentioned above cannot be guaranteed thoroughly, for example: symmetry and orthogonality of wavelet bases is not compatible. Therefore, simulations of optimum wavelet base of leakage current should be conducted after theoretical analysis.

TABLE I. CHARATERISTICS OF THE THREE DIFFERENT WAVELET BASIS

Wavelet base	representation	orthogonality /Double orthogonality	symmetry	Compactly supported	Vanishing Moments	Support length	Filter length
Daubechies	db N	Yes	approximate symmetrical	Yes	N	2N-1	2N
Coiffets	coif N	Yes	approximate symmetrical	Yes	2N	6N-1	6N
Symlets	SymN	Yes	approximate symmetrical	Yes	2N	2N-1	2N

Table1 lists all the properties of the three kinds of wavelet bases, from which we can see that they all have orthogonality and symmetry, and are compactly supported.

Simulation and analysis

In this experiment, Matlab is used for simulation. First the origin clear signal (2500 sampling points) is added with a white noise, then the default threshold is generated according to the function *ddencmp*. Next, the function *wdencmp* is used for de-noising. Eventually, the effect of the de-noising can be judged by making a comparison between the deviation of the noised-signal and the original signal. The number of decomposition layer N is set to 3 to 5 according to a reference[5] , therefore, we finally determine by experiment that N is 5. Because the simulation process has a certain randomness, we take 5 times for each wavelet and get the average as the final result. Two different scales of noise: light noise and heavy noise are discussed repectively.

We choose Signal Noise Ratio(SNR) to evaluate the residuals. SNR can be defined as follows:

$$SNR = 10 * \lg(\sum s^2(n) / \sum p^2(n)) \tag{7}$$

Where $s(n)$ is the amplitude of de-noised signal, $p(n)$ is the amplitude of noise. SNR shows the proportion of denoised-signal and noise: a larger SNR promotes a better effect of wavelet de-noising. Figure 1 is the result of de-noising simulation.

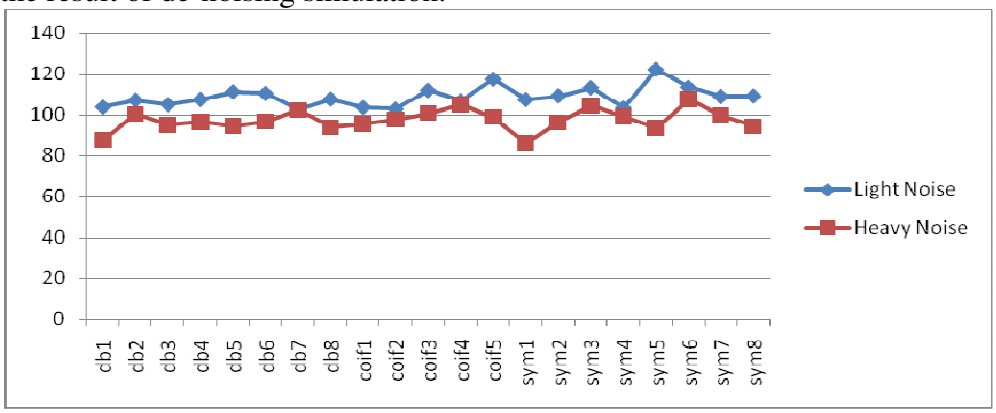

Figure 1. SNR of signal de-noising based on different wavelet basis

TABLE II. SNR OF DIFFERENT SCALE NOISES

order	Light Noise		Heavy Noise	
	Wavelet base	SNR	Wavelet base	SNR
1	sym5	122.2494	sym6	107.6558
2	coif5	117.4651	coif4	105.235
3	sym6	113.5321	sym3	104.5024
4	sym3	113.3299	db7	102.4369
5	coif3	112.0206	coif3	100.8336

According to SNR, Table2 list the best five wavelet bases in light and heavy noise environment respectively. Next the image of de-noising effect is shown by Matlab as Figure 2. Sym6 and db2 are chosen to denoise the signal in heavy noise as an example. It is obvious that the de-noised signal is smoother if the optimal wavelet base (sym6) is chosen.

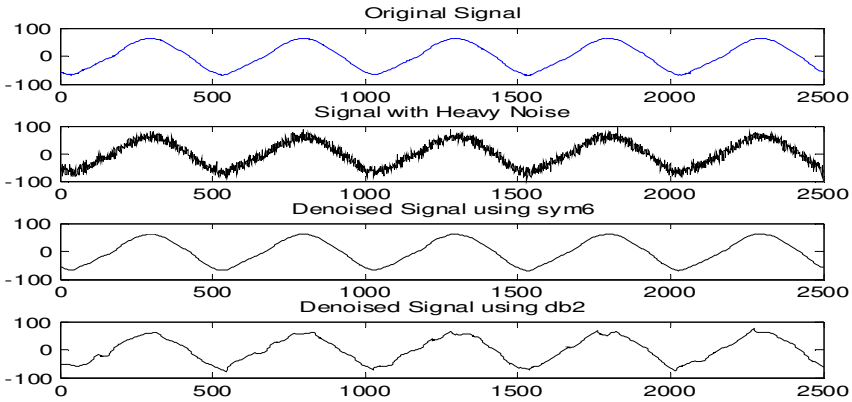

Figure 2. Image of de-noising effect based on sym6/db2

Experiment based on real signal

In this section, the actual leakage current signal is collected and tested according to the conclusions above. However, as the phenomenon of point discharge is very important in this issue, the effect of both signal de-noising and point discharge keeping are both important. Therefore, we choose sym5 as the wavelet base to denoise the collected signal.

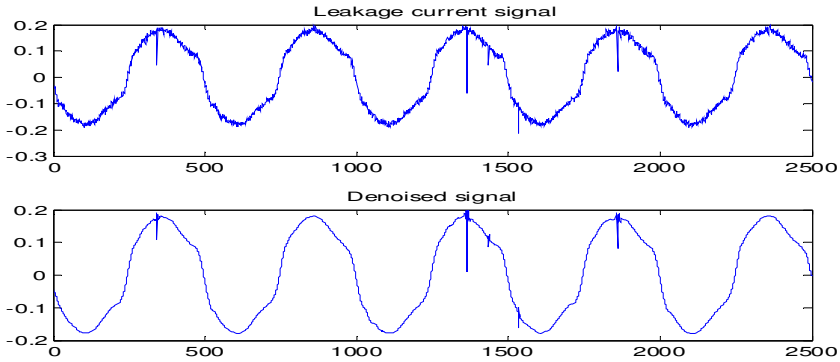

Figure 3. The real collected leakage current signal and de-noised signal using sym5

Figure 3 shows that denoised signal is smoother and point discharges have been kept well. Therefore, sym5 is a suitable wavelet base.

Summary

Based on the principle of discrete wavelet transform, this paper explores for the optimal base of insulator leakage current signal de-noising. Through simulation of the contamination of insulator leakage current de-noising, result shows that sym5 is the best wavelet base in light noise environment while sym6 is the best wavelet base in heavy noise environment. Experiments proved our conclusion later.

Keywords: AC Submarine Cable; induced voltage; shielding effect; horizontal arrangements; laying length

Abstract: The induced voltage generated by AC submarine cables would effect the normal operation of communication cables nearby. The paper calculated the induced voltage generated by AC submarine cable according to formula and procedures related to magnetic induction. The maximum parallel length between submarine cable and communications table was calculated under horizontal arrangement, and shielding effect was taken into account to the impact of the results. The causes of various induced voltage on communication cable were analysed under normal operation and various fault conditions. The results show that the induced voltage on communication cable is proportional to the parallel length and inversely proportional to parallel spacing. When the parallel length does not exceed a certain value, the induced voltage is in the allowable range and will not affect the normal operation of the communication cable.

Introduction

Submarine cables have been laid in more and more areas recently. Faraday's law of electromagnetic induction shows that AC transmission line will produce an alternating magnetic field in the adjacent areas, which induces vertical electromotive force in the adjacent communication cables and affecting the normal operation of communication cables. The induced voltage from submarine cables in fault states to the nearby communication cables would endanger the personal safety of telecommunications maintenance staff and telecommunications equipment[1,2].

For engineering applications, induced voltage communication lines from submarine cables to adjacent parallel communication cables was calculated under normal operation and fault states, and the maximum length of submarine cable in parallel with the communication cable was calculated in the paper.

Calculation Method

Communication cables generally use coaxial cable, which is consist of a center conductor and shield. When a current in the shield, induced voltage is generated on the center conductor, the magnetic flux generated by current of the shielding would linkage with the center conductor and magnetic coupling interference cannot be suppressed if the shield is grounded at both ends. The

shield has no current path when shield is grounded at one end, so the charge induced on the shield can be vented into the ground and magnetic coupling be eliminated.

Magnetic shielding effect of AC cable sheath is related with the sheath grounding mode. Sheath single-point grounding at one end and protective grounding on other end for short single-core cables, the induced current in the sheath is substantially zero in this case, without shielding to the magnetic field generated by core wire. When both ends of sheath are directly grounded, the magnetic field on the sheath can be offset by the magnetic field generated by the core wire in this case. However, the efficiency of transmission line will be reduced greatly and the loss generated by sheath current heat is very large. It is not allowed in the case of normal operation. When protection is breakdown under short fault state, both ends of sheath are grounded and the sheath has the magnetic shielding effect.

The actual frequency shielding factor of 220kV cross-section 600mm^2~800mm^2 cable corrugated aluminum sheath is probably between 0.05 and 1. For the short-circuit current, the center frequency of standard 8/20 lightning current wave is 25 KHz, and the actual shielding factor is probably between 0.05 and 0.1. The shielding factor in the paper is 0.7 referring to related date of inherent shielding factor of communication cables[3].

The formula calculating mutual inductance between the two insulated single conductors under the ground recommended by "The electromagnetic coupling between AC transmission line and telecommunication lines " is as follows[4,5]:

$$M = \frac{\mu_0}{4\pi}\left[2\ln\frac{D}{d} + 2\ln(\frac{2}{j^{1/2}\gamma\alpha a}) + 1 + \frac{4(b+c)}{a} - j^{1/2}\frac{4}{3}(\alpha|b+c|) \right] \quad (1)$$

In the formula: A is a close distance between the two cables (m); b and c respectively sensor cable and induced cable depth (m); σ is earth apparent conductivity (s / m); γ equals 1.7811;

$d = \sqrt{a^2 + (b-c)^2}$ (m); $D = \sqrt{a^2 + (b+c)^2}$ (m); $\alpha = \sqrt{\omega\mu_0\sigma}$ (1/m).

The formula of vertical magnetic induction electromotive force on the telecommunication lines from "design rules of dangerous effects from cable to telecommunication lines" is as follows:

$$Es = \sum_{i=1}^{n} \omega M_i L_{pi} I_s K \quad (2)$$

In the formula, ω is the current angular frequency of transmission line (rad/s), ω=2πf, *Mi* is the mutual inductance in paragraph *i* between cable and telecommunication line at 50Hz(H/km), L_{Pi} is the proximity length in paragraph *i* between cable and telecommunication line(A), *Is* is short-circuit current (A), K is integrated electromagnetic shielding factor of various grounding conductor in close paragraph at 50Hz, *f* is current frequency of cable(Hz).

Longitudinal magnetic induction EMF from AC submarine cable to communication line

The impact on the coax cable was considered under normal operation and fault conditions.

There are generally three arrangement types of power cables: horizontal arrangement, vertical arrangement and triangle arrangement. The induced voltage from AC submarine cable to communication cable was calculated under three types of arrangement when normal operating. For example of horizontal arrangement, induced voltage on communication line was calculated under fault state. Figure 1 shows horizontal arrangement of submarine cable.

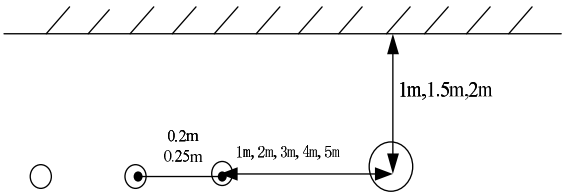

Fig.1 Submarine horizontal arrangement schematic

Normal operation

Calculation conditions: fixing center space between electrical cables and communication cables at 1m, submarine cables normal operating current at 1kA. Considering slightly different of induced voltage along the communication cable, maximum value was analyzed[6].

For the most serious cases, the communication cable shield was not grounded and there was no magnetic field on the communication cable. The relationship of induced voltage and parallel length of communication cable under three arrangements is shown in figure 2.

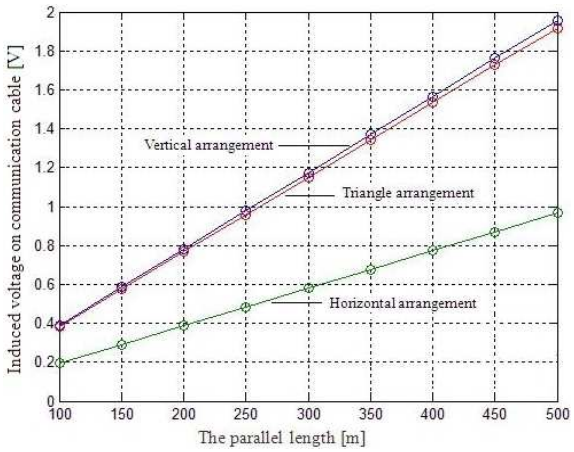

Fig.2 The relationship of induced voltage and parallel length under three arrangements

In figure 2, the induced voltage on communication cable is proportional to the parallel length. Comparing the three arrangements, the induced voltage on parallel communication cable is the minimum under horizontal arrangement and is very close under vertical arrangement and triangular arrangement.

The induced voltage variation with parallel length considering shielding is shown in figure 3. Considering the shielding effect of the communication cable, the overall level of induced voltage on communication cable decreased 0.7 times as the induced voltage not considering shielding.

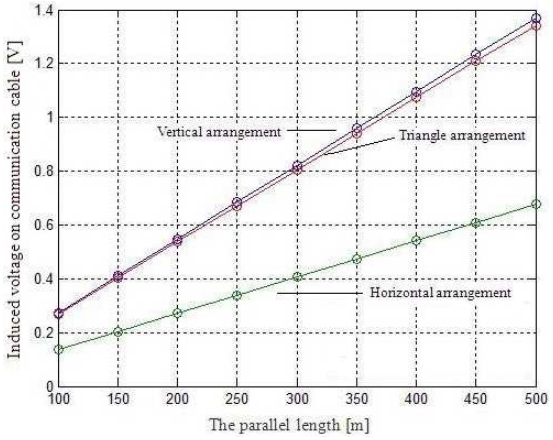

Fig.3 The relationship of induced voltage and parallel length considering shielding

Submarine cable in fault

When submarine cables were in fault, the variation of induced voltage was calculated at horizontal arrangement.

Calculation conditions: fault phase short-circuit current at 20kA, normal operating phase current at 1kA[7,8]. Calculation model is shown in figure 4.

When the protection of power cable acted and the cable sheath grounded at both ends, the circuit current in core wire and sheath would form a loop, and the sheath made better effort of shielding. The shielding factor was taken as 0.1. The distribution of induced voltage in communication cable is shown in figure 5 when submarine cable in different fault state at horizontal arrangement.

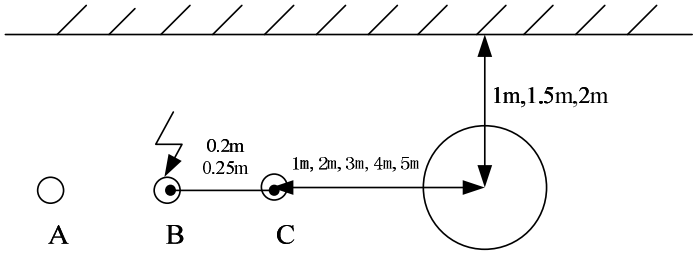

Fig 4 Horizontal arrangement schematic of submarine in fault state

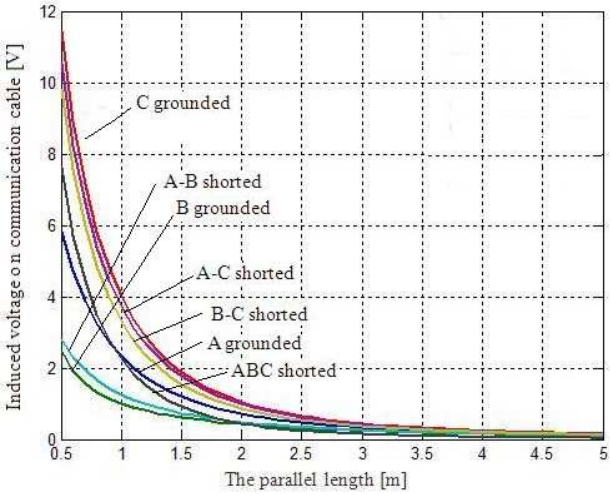

Fig.5 Induced voltage under horizontal arrangement in different fault states

The induced voltage on communication cable at different parallel spacing is shown in table 1, voltage unit, V.

Tab.1 Induced voltage on communication cable under horizontal arrangement at different spacing

short-circuit condition	different parallel spacing of submarine cable and communication cable				
	0.5m	1m	1.5m	2m	2.5m
A grounded	5.8	2.3	1.2	0.7	0.5
B grounded	2.5	1.0	0.6	0.4	0.3
C grounded	11.5	4.0	1.9	1.0	0.7
A-B shorted	2.8	1.3	0.7	0.5	0.3
A-C shorted	10.6	3.7	1.8	1.0	0.6
B-C shorted	9.8	3.3	1.5	0.9	0.5
ABC shorted	7.6	2.3	0.9	0.4	0.2

In table 1, the transient induced voltage is the largest when C-phase grounded under horizontal arrangement. This is mainly due to that the transient magnetic field generated by short circuit current cancels each other out at two-phase or three-phase short-circuit state. The C-phase is the closest to communication cables, there is no magnetic field generated by other phase circuit current to offset magnetic field generated by C-phase.

The impact of spacing between Submarine cables and communication cables on induced voltage

Fixing the parallel length of submarine cable and communication cable at 100m, depth at 1m and current 1kA, the variation of induced voltage under different parallel spacing is shown in figure 6.

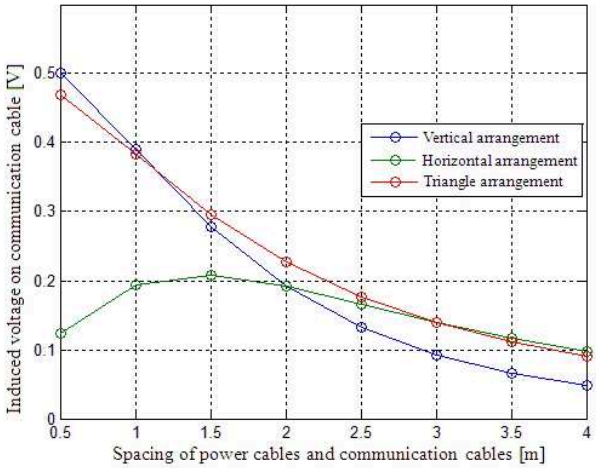

Fig.6 Induced voltage under different parallel spacing

The induced voltage on communication cable is inversely proportional to parallel spacing. Considering the mutual influence of three phases[9], the variation of induced voltage will change in case of small spacing. In figure 6, the induced voltage on communication cable is inversely proportional to the parallel spacing when parallel spacing is over 2m.

The maximum laying length

The allowable voltage on communication lines caused by magnetic is provided in CCITT "protective guidelines" and GB6830-86 "the tolerable limits of danger on telecommunication lines from power lines": when power lines operation normally, the allowable voltage on core line is 60 V; when power lines in fault, (1)430V, non-high reliability transmission lines, fault clearing time in less than 3s; (2)650V, high reliability circuit, fault clearing time in less than 0.5s. When power lines operation normally, the maximum induced voltage is approximately 2V at 500m parallel length without considering shielding[10,11].

Taking the proportional relationship among induced voltage with parallel length and current, the maximum parallel length between submarine cable and communication cable is 15km. After considering shielding, the maximum parallel length is up to 21km.

When submarine cables in fault, the maximum transient induced voltage on communication cable is 11.5V, the maximum parallel length between submarine cable and communication cable is 5.65km. After considering shielding, the maximum parallel length is up to 8km.

The impact of parallel spacing on submarine cable and communication cable is shown in table 2.

Table.2 Parallel induced voltage at depth 1m and current 1kA

Spacing [m]	Maximum induced voltage at parallel 100 m [V]	Maximum parallel length [km]
0.5	0.5	12
1	0.4	15
1.5	0.3	20

Conclusion

The paper calculated the vertical induced voltage from submarine cables to communication cable and the maximum length of submarine cable in parallel with the communication cables. The results show that the induced voltage is inversely proportional to spacing length of submarine cables in parallel with the communication cable.

Fixing center spacing between electrical cables and communication cables at 1m, submarine cables normal operating current at 1kA, the maximum parallel length between submarine cable and communication cable is up to 21km in the shielding. When submarine cables in fault and current at 20kA, the maximum parallel length between submarine cable and communication cable is 8km.

The calculating of induced voltage on communication cable adjacent submarine cable and the parallel length between submarine cables and communication cable can provide a reference for the laying of submarine cables.

Keywords: Air-core reactor; magnetic field; scaling rules; simplified model

Abstract: With the development of electric power system, Power-frequency Magnetic Field (MF) has become a matter of concern recently. In order to speed up the computation and modeling process, the small-scale experimental technique and simplified model for air-core reactors are introduced as a novel way to assess the MF of air-core reactors in this paper. Firstly, the scaling rules of the parameters for air-core reactors are summarized. Then, the scaling rules modification is put forward to reduce the error. Thirdly, three simplified models were established for air-core reactors, including one loop model, two loops model and three loops model. It is concluded after that the two loops model in configuration 2 can be considered as the optimal simplified model.

Introduction

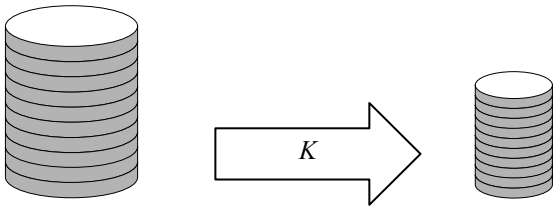
With the fast development of electric power technology in China, especially the increased construction of distributed generation and modern systems, the reactive power compensation is needed to improve voltage quality and reduce power loss. Dry-type air-core reactors, due to its uniform distribution of starting voltage, good linearity, small loss and low noise, have been widely used in electric power system. However, air-core reactors generate Power-frequency Magnetic Field (PFMF) in its normal operation threating the safe and stable operation of some other equipment in substation. Besides, the space MF of air-core reactors may put a potential threat to the health of the working staff and general public. Thus, air-core reactors have become the main source of electromagnetic contamination in substations[1-2].

Aiming at the problem of MF distribution of the air-core reactors, masses of work have been done at home and abroad. Many accurate calculation methods for evaluating the MF of air-core reactors have been proposed, including analytical, semi-analytical and numerical methods[3]. Besides, experimental method is widely used in the MF calculation. Among them small-scale experiment method is more accurate and convenient method. But in the practical application, it is difficult to make precise small-scale model, which greatly limits the application of small-scale experimental method.

In this paper, the scaling rules of parameters of air-core reactor are summarized firstly, then put forward three typical corresponding correction strategy under the premise of magnetic induction intensity keeps unchanged. Beyond this range, it is necessary to develop a new simplified model replaced the accurate small-scale model to save computation time.

Scaling rules of air-core reactor

It is assumed that the sources and devices of a system are purely conductive with high σ and $\mu=\mu_0$. Meanwhile, the sources operate within a quasi-static frequency range. Dry-type air-core reactor of coating parallel structure has been widely used in practice when considering the heat radiation and other problems. The reactor of coating parallel structure is equivalent completely to simplified single envelopment model which can be obtained by single conductor linear superposition. In the engineering practice, superposition principles are used in the calculation of MF generated by reactor neglecting adjacent effect and end effect. On these grounds, an air-core reactor model was set up by the single wire winding, as is shown in Fig.1 (a). According to the scaling rules, with the scaling factor k ($0<k<1$), the original reactor can be shrunk to a small-scale one, namely small-scale model I (Fig.1(b)). The parameters of theoretical scaling rules of air-core reactor are shown in Tab.1.



(a) The original model (b) The small-scale model I

Fig.1 The origin model and The small-scale model I

Tab.1 Parameters of theoretical rules of air-core reactor

	Wire thickness	Wire surface	Model height	Model radius	frequency
The original model	W	A	H	D	f
Small-scale model	kW	k^2A	kH	kD	k^2f
	Voltage	Current	Resistance	Inductance	MF
The original model	U	I	R	L	B
Small-scale model	kU	k^2I	$k^{-1}R$	kL	kB

Scaling rules modification

With the scaling rules, it is possible to build the small-scale models for air-core reactors and measure the MF in interested area around them. However it is often been affected by many objective conditions in the scaling process, modifications for scaling rules are needed. For three typical cases on the small-scale models, by maintaining the MF, puts forward corresponding correction strategy.

(1) According to the scaling rules introduced, with the scaling factor k, the wire thickness around the model is too thick to bend, and it is difficult to build model in lab. There are two methods to reduce the wire thickness. The first one is to leave space between wires (shown in Fig. 2(a) model II). The second one is to make the coil with two or more same wires in parallel, then join their terminals together (shown in Fig.2(b) model III). The above two models, the number of turns of the coil remains unchanged, and the current flowing through the coil is equal to model I (Fig 1(b)), thus the MF B keeps unchanged.

(a) The small-scale model II (b) The small-scale model III

Fig.2 The second and third model made with thin wires

(1) In some cases, the wire thickness may be too thin or there may be many turns in the original model, then a thicker wire will be easier to be built. In order to keep the same B, a factor will be multiplied to the original current, then the current should be twice as the original value.

(2) It is not necessary to apply a current as it is scaled by the scaling rules, because when the scaling factor is small, the scaled current is low. In order to reduce the error and to prevent the problems that caused by a low current, a larger current can be used, based on different situations. If the current is k times the scaled current, then the MF measured under this current will multiply k^{-1}.

Experiments of Simplified Models for Air-core Reactors

Based on scaling rules and scaling model of air-core reactor, it is possible to find an optimal simplified model using small-scale experimental technique to speed up the computation and modeling process. The simplified and the original model are shown in Fig.3.

(a) The original model (b) One loop model (c) Two loops model (d) Three loops model

Fig.3 Simplified models of the air-core reactor

The original model was shown in Fig.3 (a). The height of this coil is *l=134mm,* the diameter is *D=138mm,* number of turns is *N=120,* and the current flowing through the coil was 0.03 A, frequency of the power was 50 Hz. Then the MF around the original coil was measured in radial and axial direction respectively. Fig.4 shows the hardware set-up of the instrument.

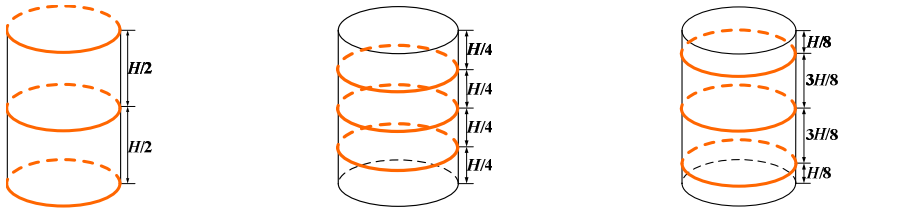
As is shown in Fig.3 (b), the first model is to concentrate all the coils in one loop to represent the original coil. In this experiment, a loop of 40 turns was made for simplicity, which has the same diameter with the original coil. In order to keep the same current density flowing through the coil with the original reactor, a current of 0.09 A was used in the experiment.

The second simplified model is to use two circular current loops to represent the original coil, as shown in Fig.3 (c). In the experiment, each loop had 40 turns. In order to keep the same current density flowing through the coil, a current of 0.045 A was applied in the experiment. The two loops were placed at two types of separations with each other, as shown in Fig.4.

(a) Configuration 1 (b) Configuration 2

Fig.4 Two loops model of different configurations

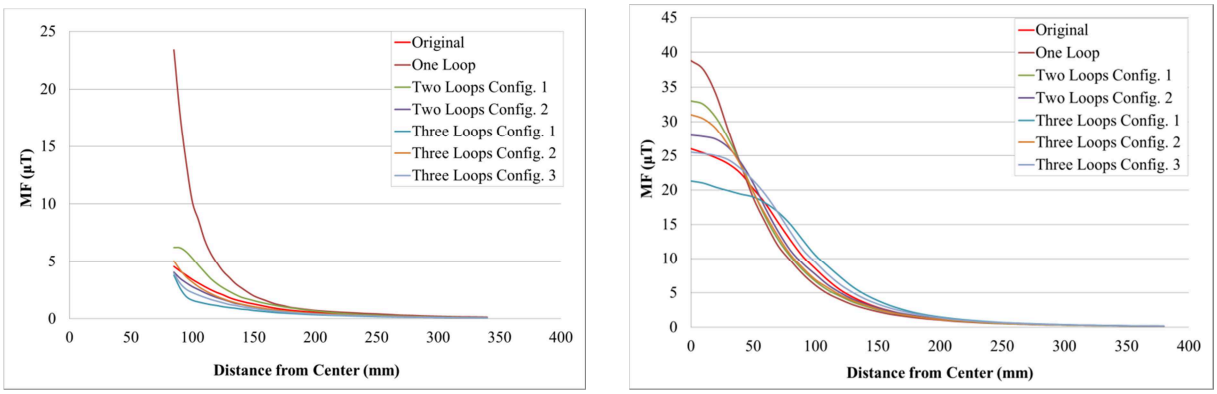
The third simplified model is to use three circular current loops to represent the original coil, as shown in Fig.3 (d). In the experiment, each loop had 40 turns. In order to keep the same current density flowing through the coil, a current of 0.03 A was applied in the experiment. The three loops were placed at three types of separations with each other, as shown in Fig.5.



a）Configuration 1 (b) Configuration 2 (c) Configuration 3

Fig.5 Three loops model of different configurations

Based on the measurement results, the curves of MF versus distance from center can be drawn in the radial direction and axial direction respectively, as shown in Fig.6. In 200 mm, six simplified model can replace the original model approximately in the radial direction and axial direction. However, in the range of 200mm, the measurement error is large, and the main reason is the large size measurement instrument probe.



(a) MF in the radial direction (b) MF in the axial direction

Fig.6 Comparison of MF of different simplified models

Considering the simplicity of model establishment and the accuracy, the configuration 1 of two loops is the optimal model of the six configurations. It is much easy to establish the structure in a short time to simulate the MF around the air-core reactor. In this configuration, measurement results are more accurate in the distance of 1.5 times the diameter of the reactor. In engineering practice, reactor diameter and height were 1m~2m, while the public scope of activities is usually more than 1.5 times the diameter of the reactor. Therefore, the simplified model has an important practical significance in the prediction of MF distribution of air-core reactor.

Conclusion

In this paper, the scaling rules for air-core reactors is summarized first and three typical corresponding correction strategies are put forward according to different situation. Then, three simplified models were built for air-core reactors , including one loop model, two loops model and three loops model, and they all match the original model well. Especially when the current loops are placed at the position of 1/3 and 2/3 of the length of the coil, a simplified model (configuration 1) is of the highest accuracy. The results provide a basis for simplifying the computation process and speeding up the operation of experiment.

Keywords: Permanent-magnet-biased saturation based fault current limiter (PMFCL), modeling, simulation, experiment

Abstract. The fault current limit technology based on the principle of permanent-magnet-biased saturation has several outstanding advantages in both economy and technology. A modeling method of PMFCL based on the finite element analysis platform – Maxwell is presented in this paper. The current limiting mechanism of line-type PMFCL is analyzed, on the basis of which the 2D and 3D models are established in Maxwell, and the corresponding experiments are designed as well. Comparisons between the simulation and experimental results indicate that the modeling method is reasonable. Research achievements of this paper provides theoretical basis for further studies of PMFCL.

Introduction

The short-circuit current level of power system is rising because of the growing scale of power grid, the rapid growth of power system load, etc. The power system voltage and frequency will be unstable with large circuit, and equipment insulation will be damaged because of high temperature and strong electrical force sent out by itself. At present, PMFCL is a means of effective implementation with excellent technical and economic characteristics.

The study of PMFCL design of large capacity and magnetic fluid thermal coupling field is desperately needed in high voltage power system. However, a reasonable simulation is the basis of it. The 2D and 3D models are firstly established by ANSOFT software based on the current limiting mechanism of PMFCL. Then the results of these two models are obtained by solving the analysis. Afterwards, the prototype experiments are done and a series of data is available naturally. Finally, the simulation results are compared with that of the prototype experiments.

Current Limiting Mechanism Analysis of PMFCL

The curves reflect the relationship between the core flux of PMFCL named φ_e and the winding current I in Fig. 1.The broken line –ABCDE is the work trajectory of half- wave current limiting in iron-cores, among AB represents the positive saturation zone of PMFCL while BD denoting the desaturation zone and DE is the negative saturation zone respectively. Under normal conditions, the strong magnetic field generated by permanent magnet makes the iron-cores stay in the saturated zone in which the winding characterize as low impedance. When there are short-circuit fault occurs

in system, magnetomotive force generated by the fault current will offset the magnetic force of permanent magnet gradually, and the work state of iron-cores will enter into the desaturation zone in which the winding characterize as high impedance. The magnetic force generated by strong alternating current makes the core into negative saturation zone if the current is still increase to greater than i_{max}, PMFCL is in loss of current limiting capability at this time.

In Fig. 1 , two stages are employed to denote the change of flux distribution of PMFCL in the current limiting area: 1) current limiting stage Ⅰ which corresponding to the point B to point C; 2) current limiting stage Ⅱ which corresponding to the point C to point D. Furthermore, the material parameters of PMFCL are shown in Table 1.

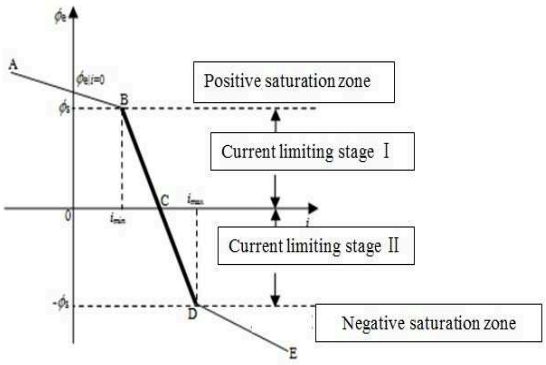

Fig. 1 The φ_e-i curve of linear PMFCL

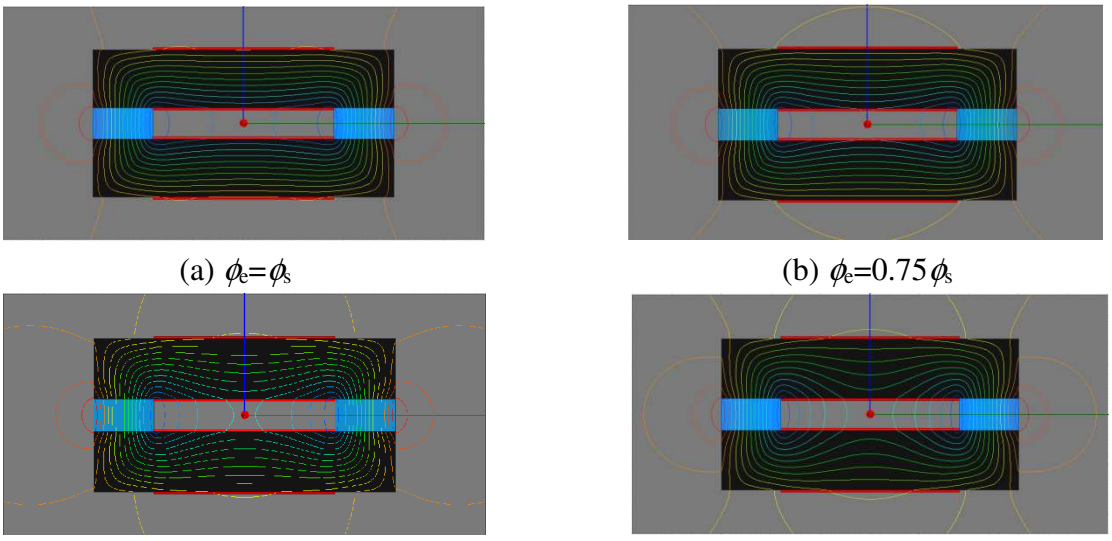
Table 1 Material parameters of PMFCL

Components Materials	Magnetic parameters	Structure parameters
Iron-cores (ferrite,R2K3D)	B_s=1.78T	l_e=3×10^{-1}m
	μ_s=6.28×10^{-5}Wb/(A·m)	S_e=9×10^{-4}m^2
	μ_u=3.14×10^{-3}Wb/(A·m)	W=3×10^{-2}m
Permanent Magnet (NdFeB, N35)	B_r=1.22T	l_m=3.2×10^{-2}m
	H_c=8.68×10^{5}A/m	S_m=9×10^{-4}m^2
	μ_m=1.4×10^{-6}Wb/(A·m)	W=3×10^{-2}m
Winding	None	D=1.1×10^{-3}m
		N=300

Study of 2D Modeling

The 2D model of PMFCL is built by Maxwell release 15.0; there are four pictures of magnetic field distribution in current limiting stage Ⅰ as shown in Fig. 2. The figure indicates that permanent magnet can impact the magnetic flux of iron-cores through the area of winding package, the reverse magnetic field enhanced gradually while the winding current is increasing, and the magnetic flux of PMFCL is distorted, hence the biased magnetic field is greater than the reverse magnetic field of winding when iron-cores are working at extreme saturation stage.

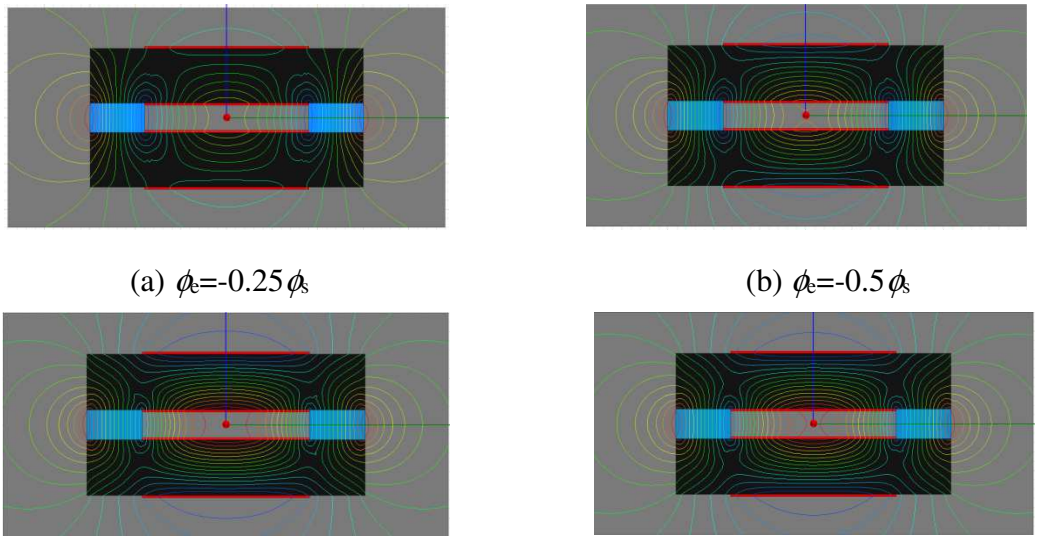


(a) $\phi_e=\phi_s$ (b) $\phi_e=0.75\phi_s$

(c) $\phi_e=0.5\phi_s$ (d) $\phi_e=0.25\phi_s$

Fig. 2 Magnetic field of PMFCL in current limiting stage Ⅰ

There are four pictures of magnetic field distribution in current limiting stage Ⅱ as shown in Fig. 3. The reverse magnetic field is inside the two dotted lines while permanent magnetic field is outside of them. The reverse magnetic field enhanced gradually and the area through by reverse magnetic flux is being larger as shown in the figure, the reverse magnetic field of winding is greater when iron-cores are working at negative saturation stage.



(a) ϕ_e=-0.25ϕ_s (b) ϕ_e=-0.5ϕ_s

(c) ϕ_e=-0.75ϕ_s (d) ϕ_e=-ϕ_s

Fig. 3 Magnetic field of PMFCL in current limiting stage Ⅱ

Study of 3D Modeling

The process of both 2D and 3D model is almost similar but the construction of 3D model should be paid attention to a few respects like mesh operation, solution region and design of boundary conditions, the 3D model is shown as Fig. 4, in addition the excitation of 2D and 3D model is realized by import external circuits, the external circuit is shown in Fig. 5. There are about 8 groups of external circuits to simulate the two current limiting stages shown in Fig. 2 and Fig. 3, and the difference between them is the magnitude of current, the waveform of current which flow through the winding as Fig. 6. At last, the 3D model is solved after confirming the correct.

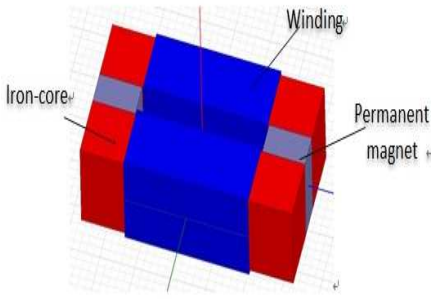


Fig. 4 3D geometric model

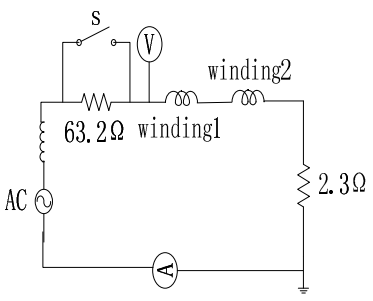

Fig. 5 External circuit

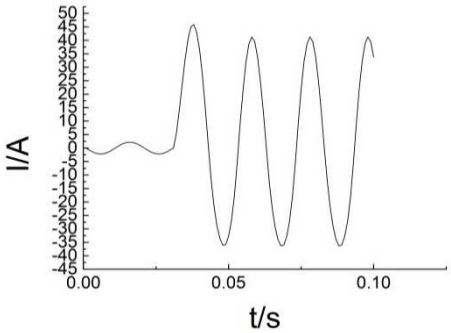

Fig. 6 Waveform of current

Experimental Verification

Experiments are important to verify the rationality of modeling. The values of circuits are the same no matter in experiment or in simulation, and there are also several groups of experiments to correspond the simulation. The parameters of external circuits are as follow: the internal inductance of power source is 6.5mH, the resistance of winding is 2.3 Ω, the resistance of the load is 63.2 Ω, the wiring diagram is shown as Fig. 7.

Fig. 7 Experimental wiring diagram

(1) The experiments indicate that the maximum value of magnetic flux in iron-cores are just zero when the voltage value of power source U_{ss} is 137.9V, and measure the data to draw curves that represent the relationship between the magnetic induction intensity B_e and time t as shown in Fig. 8(a), thereby the source voltage 137.9V is brought into the simulation models and gets the curve B_e-t as shown in Fig. 8(a). When the short current can't make the core flux in reverse, the error between simulation result and experimental results is 13.3%.

(2) The experiment indicated that the maximum value of magnetic flux in iron-cores are just reverse saturation when the voltage value of power source U_{ss} is 206.9V, and measure the data to draw curves that represent the relationship between the magnetic induction intensity B_e and time t as shown in Fig. 8(b), thereby the source voltage 206.9V is brought into the simulation model and gets the curve B_e-t as shown in Fig. 8(b). When the short current is enough to make the core flux in reverse, the error between simulation result and experimental results is 4.9%.

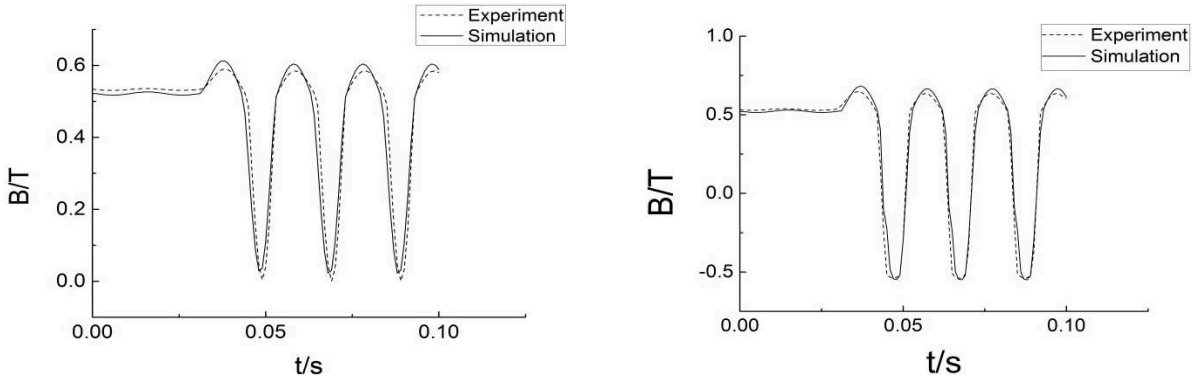

Fig. 8 The B_e-t curves of PMFCL

Conclusions

The analysis result of the 2D model shows that PMFCL has two working stages with the increasing short current: permanent magnet will play a role in limiting the current when the magnetic road is made of permanent magnet and the whole iron-cores; permanent magnet can't effect the current when the magnetic road is formed by air gap and iron-cores which are wrapped in winding. The modeling method is effective because of the small errors between the two kinds of results by comparing the simulation results with experimental results. Thereby it provides basic basis for the PMFCL design of large capacity and the study of magnetic fluid thermal coupling field, etc.

Keywords: H-GIS, SF_6, analysis of gas composition, internal discharge

Abstract: Analysis the 500kV H-GIS equipment failure, determine for the circuit breaker chamber internal discharge fault according to the protection action and the use of the analysis of SF_6 gas composition, a detailed analysis of the possible causes of failures, and according to the disintegration test results, to confirm the final reason for internal foreign bodies caused by discharge. Finally, put forward some prevention measures and suggestions for the accident.

Introduction

Because the cost of GIS bus is higher, and the future expansion inconvenience, etc, combine the advantages of open bus bar and GIS, H-GIS (Hybrid GIS) arises at the historic moment. Besides using traditional external tube bus, H-GIS completely consistent with the rest component of GIS. Domestic or foreign research and practical operation experience shows that, compared with using traditional AIS, GIS/H-GIS have higher reliability, maintenance cycle is longer, the maintenance cost is lower[1]. But if the internal failure, due to its complex structure, fault accurate positioning and maintenance is difficult.

5053 interval of the 500 kV substation G is the product of T company, model is GSR-500R2B, in August 2008, the production, in July 2009, putting into operation. The trip happened without any operation, this paper analyzes the accident.

After the accident

1.1 The operation mode before the failure

500 kV substation G system wiring diagram is shown in Fig.1. 500 kV bus I, bus II was running; The first string 5011, 5012 breakers and ZG I loop were running; The second string 5021, 5022, 5023 breakers and G 1 # main transformer , ZG II loop were running; The fourth string 5041, 5042 breakers were in the hot standby state; The fifth string 5051, 5052, 5053 breakers and G 3 # main transformer, GX line were running; The sixth string 5062, 5063 breakers were in the hot standby state.

Before failure, there was no operation; It cloudy, wind 4 ~ 5 level, the highest temperature was 23 ˚C, minimum temperature was 13 ˚C.

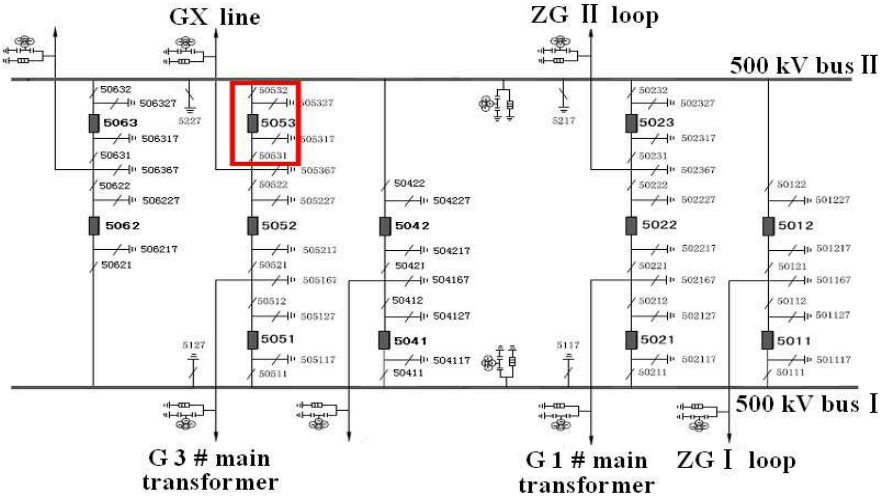

Fig.1 500 kV substation G system wiring diagram

1.2 The fault and protection action situation at the scene

03:32:53 on September 24, 2013, 500 kV substation G 5053 breaker tripping, 500 kV GX line tripping reclosing after success, the load current is 582 A, the voltage of 500 kV bus II was 0. Optical differential protection (WXH803, RCS931)of the GX line action, two sets of bus differential protection (BP2B, WMH800)of the bus II action, the first and second group of the breakers(5052, 5023,5053,5012) tripping exports, 5052 breaker reclosing protection action. On-site inspection by the operation personnel, find the appearance without exception.

The fault location

Due to the complicated structure of GIS/H-GIS, it is difficult to maintenance. Through the fault location, we can find the faulty air chamber, and maintenance it only, which can greatly reduce the maintenance time.

2.1 The method of the fault location

There are two kinds of method for the fault location in general. One is using UHF to monitor the GIS/H-GIS partial discharge on-line; Another is using the SF_6 gas composition analysis technology. This time we choose the second.

2.2 The introduction of the SF_6 gas composition analysis technology

When the discharge and overheating fault are occurring in SF_6, it will produce a series of gaseous impurities, such as SOF_2, SO_2F_2, SO_2, H_2S, CO, HF and CF_4, etc[2-4]. Detecting the characteristic components content (especially SOF_2+SO_2) is sensitive, accurate, and the advantages of small interference by external environment, so the technology can provide accurate and reliable diagnostic basis for fault location after the accident.

2.3 The results of the SF_6 gas composition analysis

September 24, 2013 morning, the test personnel had analyzed the SF_6 gas composition of the 5053, 50531, 50532, 50531 breakers' phase C air chamber and the 5053 breaker's phase B air chamber. The mode of the test instrument is RA500FAP. The specific test data is as follows:

number	air chamber	phase	SO_2 （uL/L）	H_2S （uL/L）	CO （uL/L）	humidity （uL/L）	Purity （%）	result
1	50531	C	0	0	17	——	——	qualified
2	50532	C	0	0	7	——	99.43	qualified
3	5053	C	564	0	8	78	99.80	unqualified
4	5053	B	0	0	6	——	——	qualified
5	5052	C	0.9	0	6	56	99.98	qualified

Test result: According to GB/T8905-2008<The guidelines for the gas management and maintenance in SF_6 equipment >, the content of SO_2 ,in the 5053 breaker's phase C air chamber, is 564 uL/L , greater than normal (2 uL/L), exceeding bid badly. It can be identified as the gas discharge in the 5053 breaker, causing the trip.

Analyze the possible cause of the gas discharge

1) Overvoltage

External overvoltage, such as Lightning overvoltage, and internal overvoltage, such as operating over-voltage, could cause spark discharge inside the equipment. However, there was no thunderstorm, no operation, no signs of overvoltage, before the accident, so this reason could be eliminated.

2) Operating at low pressure

In the case of SF_6 gas pressure is low, its insulating performance degradation. If operating at this time, it will cause internal discharge, because the ability of extinguishing arc is insufficient. According to the site condition, the air chamber pressure is normal and without any operation, it can eliminate the cause.

3) Internal conductor surface has sharp corners

Due to poor manufacturing process, the conductor surface has sharp corners, triggering point discharge. Such problems can be found in factory test. However the test is qualified, so we can rule out the reason.

4) The internal insulation materials have defects

There are a variety of insulation materials in the GIS/H-GIS, such as basin-type insulator, insulating rod, support insulating tube, etc. If there are air gaps or impurities in the insulation materials, its insulating performance will gradually decline, in the process of the running, until they are breakdown. According to the last experiment records before the failure, there is not any problem. But it cannot be ruled out that, the changes of external conditions make its rapid degradation in a relatively short time. Therefore, we need to detect to further confirmation.

5) The internal parts are loose or fractured

Due to the product assembly or parts quality have problems, making the shake in the running or normal operation. The shake will loosen or fracture its internal parts (fixed bolts, etc.) and make them the displacement. It makes the insulating distance between the conductor and the grounding shell not enough, causing the internal discharge. We need to disassembly for further judgement, according to the traces of the discharge, and the internal checking.

6) The air chamber has impurities

If the air chamber has metal particles, powders or other impurities, it will seriously distort the local electric field, causing the internal discharge, at the time of the shake or airflow, which make them move to some particular place. We need to disassembly for further judgement, according to the location and traces of the discharge, and the internal particle detection.

Disassembly checking

According to the above cause analysis, we contrapose the last three causes, who need to disassembly for further judgement, carry out the targeted examinations and relevant tests. The disassembling the phase C of the 5053 interval, will be carried out in T company.

4.1 The appearance inspection of the parts

Found that:

(1) There are obvious traces of discharge on the inwall of the support insulating tube and the surface of two core insulating rods. The locations of them are mainly corresponding. And the surface of them are relatively smooth. As shown in Fig.2. The ambilateral fixed metal parts of the support insulating tube have obvious traces of discharge, too. And their locations are mainly corresponding as well, so it should be the discharge channel, as shown in Fig.3.

(2) The fixed bolts near the discharge area are not loose or fractured. The contacts and other parts are in good condition, without displacement.

(3) There are not obvious impurities (metal particles, etc.) on the bottom of the air chamber, flanges and bolts.

(4) The greases on the spindle of the crankcase have obvious overflow. There are oily matter on the bottom of the crankcase and the surface of the spindle, as shown in Fig.4.

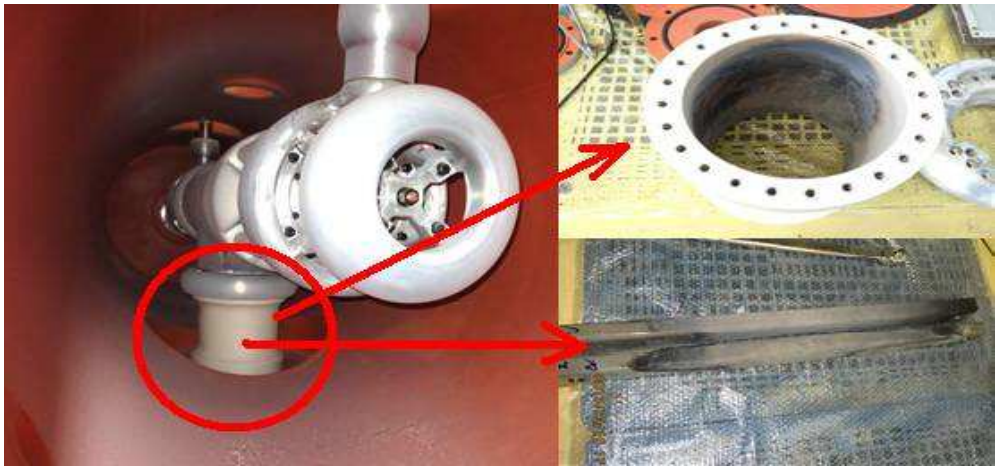

Fig.2 The empyrosis of the support insulating tube and the core insulating rods

Fig.3 The empyrosis of the ambilateral fixed metal parts of the support insulating tube

Fig. 4 The oily matter in the crankcase

4.2 test

Manufacturer have carried out the X-ray examination, material analysis and measuring vitrified temperature (Tg) to the support insulating tube and the core insulating rods, do not find any internal defects. Composition analysis of the residues in the tank shows that they are gray powders, main ingredients include C, F and O elements. Among them, C and O element mainly come from insulating tube and insulating rod. F element is mainly derived from SF_6. Mg, Si, Fe and zinc element come from the shield ring. There are no other suspicious components.

Determine the cause of the fault

According to the injury of the insulation materials, we can determine the discharge is not outward development from the inside insulating parts. If it develops from inside to outside, the surface should be crack or bulge, rather than flat, but the reality is on the contrary, as shown in figure 2. The test data of the manufacturer indicates that the internal insulating parts have not air gap or impurities, proves the previous view. So the fourth possible cause (The internal insulation materials have defects) could be eliminated.

According to the internal inspection, the fixed bolts near the discharge area are not loose or fractured. The contacts and other parts are in good condition, without displacement. So we can eliminate the fifth possible cause (The internal parts are loose or fractured).

The test results show that there are not obvious impurities (metal particles, etc.) on the bottom of the air chamber. However based on the analysis of the location, traces and channel of the discharge, combined with the exclusive method, it can be identified as the sixth possible cause (The air chamber has trace metal particles or other impurities, causing the discharge)

There are four conditions, the air chamber has impurities. (1) The dust-free environment of the GIS/H-GIS manufacturing workshop does not meet the requirements, especially in the final assembly workshop, the metal particles, powders or other impurities are easy to entrance into it; (2) in the process of assembly, friction between the conductors will produce metal powders or debris, left in some covert places; (3)The factory did not complete more than 200 times mechanical operations, according to the anti-accident measure. The contacts are not getting enough mechanical break-in, so it is easy to produce metal powders in the normal operations.(4) The metal powders, produced in the mechanical break-in, are not clean thoroughly.

The location of the metal particles, powders and other impurities in the air chamber is random. They are usually located at the bottom of the air chamber. When there are inflation, deflation or operations, it will produce the shake or airflow, changing their location. The residual trace metal particles or impurities in the air chamber, may move to the inwall of the support insulating tube. The greases in the crankcase (as shown in figure 4) volatilize in the long term, it will come into

being the trace oil film on the inwall, making them sticking on it.In the specific strong electric field, metal particles will distort the local electric field seriously[5]. The high field strength makes the ionization zone arising on the cutting-edge of the metal particles. There are processing the electron avalanche endlessly, producing a lot of space charge. It forms an avalanche of electron gradually, and leads to the disruptive discharge eventually, as shown in figure 3.

The preventive measures and suggestions

Combined with the H-GIS internal discharge fault, and puts forward some preventive measures and suggestions, for reference only.

1. The advice for the manufacturer and installation unit :

(1) Make sure the dust-free environment meet the requirements in the assembly workshop;

(2) Ensure completing more than 200 times mechanical operations, according to the anti-accident measure, to make the contacts get enough mechanical break-in. And clean the metal particles thoroughly during the operations.

(3) The greases or sealing greases, used in assembly, should be appropriate;

(4) In the assembly process, should keep the environment clean, and equip a vacuum cleaner to remove impurities thoroughly.

2. The advice for the equipment operation unit:

(1) The operation personnel should strengthen the monitoring, especially in the first year after the installation or overhaul. According to the statistical data of countries such as Canada, in the first year after the installation or overhaul of GIS/H-GIS, the equipment failure rate is 0.53 times/interval, and reduce to 0.06 times/interval in the second, reduced 8.83 times, and then tends to be stable. GIS/H - GIS is the most prone to failure in the first year.

(2) Install the UHF partial discharge on-line monitoring device, to real-time monitoring the running status of the equipment.

Keywords: Electron beam; high current; high voltage; theoretical model; foil-less diode; PIC simulation.

Abstract. The theoretical analysis and numerical simulation of electron beam generation in foil-less diode are presented. The theories of OAL, CL, and equilibrium beam model are briefly compared. All the theoretical models can give a relatively accurate solution of electron gun, and the equilibrium beam model is more appreciated. A PIC simulation tool UNIPIC is introduced and is used to analyze the behaviors of a foil-less diode. Under the conditions of 180 kV incident voltage wave and 2.5 T axial magnetic fields, we obtained the 250 kV, 1.5 kA output beam current which can be used in high power microwave generators.

Introduction

Microwave vacuum electronic device is an important kind of electronic device which are widely used in contemporary defense equipments and national economic areas. In national defense equipment, It's the heart of radar, communication, electronic countermeasure, remote sensing and precision guided equipment; In information system, as the source of radio or television station, microwave and satellite communication forwarder, receiver and the display of color TV set, even all kinds of display devices have been widely used in our work and life already. Electron gun is an important part of vacuum electronic devices such as travelling wave tube and backward wave oscillator. Foil-less diode is one of the vacuum electron gun which can generate intense electron beam [1].

The uniform linear electron beam can be produced in a foil-less diode which consists of a coaxial transmission line of outer conductor radius, whose centre conductor is truncated to form a cathode. Both the anode (outer conductor) and the cathode can be shaped to vary the beam characteristics [2]. This “foil-less diode”, as shown in Fig.1, employs a large axial magnetic field to provide insulation and to guide the electrons into a beam. Foil-less diodes produce highly annular beams which possess high current density [3]. The earliest electron guns were designed using electrolytic tank experiments coupled with analytic theory. Over time, advances in synthesis techniques and computational abilities have significantly enhanced capabilities for interpolation, extrapolation, and even complete redesign of such electron guns. Virtual computer simulation is fast becoming the design tool of choice [4].

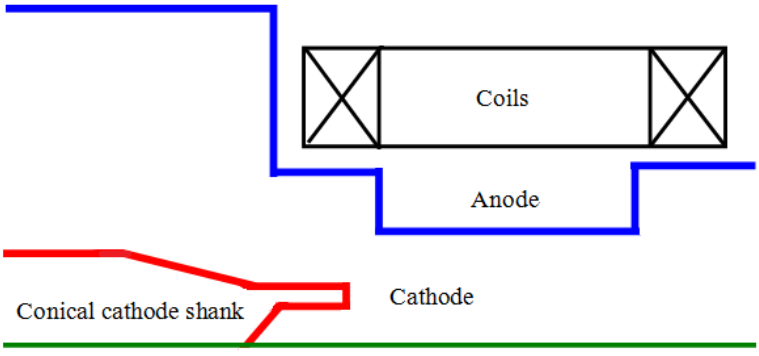

Figure 1. Structure of foil-less diode

THEORETICAL MODEL OF FOILLESS DIODE

2.1 OAL model

The model of OAL is essentially a "corner diode" [5]. As an idealized geometry, the anode is a semi infinite cylindrical conductor at potential $\phi = 0$ and the cathode surface is maintained at a constant potential $\phi = -\phi_0$ at the end of the anode cylinder. For the diode, the cathode outer radius is r_2 while the inter is r_1, the beam thickness is Δ and its distance to the anode wall is δ. In OAL model, the electron motion is constrained to be one dimensional by a very strong applied axial magnetic field and the voltage is assumed to be ultra relativistic. Based on the assumes, when $\Delta \ll \delta$, according to OAL model the diode total current and impedance are given approximately by

$$I_{OAL} = \frac{1700(\gamma_0^{2/3} - 1)^{3/2}(r_b / \delta)}{\ln(8\delta/\Delta)} \tag{1}$$

$$Z = 30\frac{\delta}{r_b}\ln(\frac{8\delta}{\Delta}) \tag{2}$$

where $\gamma_0 = 1 + e\phi_0 / mc^2$, is the constant of relativity, and $r_b = (r_1 + r_2)/2$.

2.2 CL model

The model of CL is similar to OAL model except that the electric potential is allowed to vary over an arbitrary boundary. In principle it gives a more accurate representation of experimental cathode geometries [6]. The solution for the potential of the cathode surface is not a constant but is a function of both r and z, which is may be written as

$$\phi(r,z) = \frac{2}{\varepsilon_0 R^2}\sum_{n=1}^{\infty}\frac{\rho_n}{k_n^2}(1 - e^{-k_n z})\psi_n(r) + \frac{1}{2\pi\varepsilon_0 R^2}\sum_{n=1}^{\infty}\phi_n e^{-k_n z}\psi_n(r) \tag{3}$$

where $\psi_n(r) = J_0(k_n r)(J_1(k_n R))^{-2}$, and $k_n = \lambda_n / R$ in which the λ_n are the roots of the J_0 Bessel function. Finally the diode current can be given approximately according to CL model by

$$I_{CL} \approx 4\pi\varepsilon_0 \frac{(\gamma_0^{2/3} - 1)^{3/2}(mc^3 / e)}{2\ln(\mathrm{R/r_b})} \tag{4}$$

where R is the anode radius of the diode. Obviously, the CL model is close to the fact compared with the OAL model, but more complex, so the model is not much applied in studies.

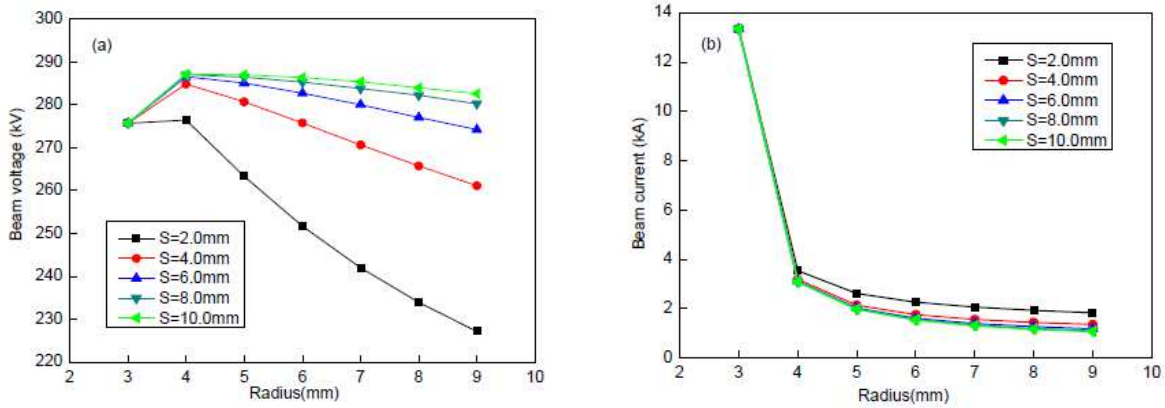

Figure 2. Dependence of output behaviors of electron gun on the anode radius

2.3 Equilibrium beam model

In OAL and CL models, the diode current is equal to the space-charge limited current. Indeed it was found in studies that only adapt to low voltage while at higher voltages the equilibrium of the beam yields a current substantially less than the space-charge limit. Thus, the equilibrium beam model was

put forward. In the model, to a good approximation, the beam can be modeled as a relativistic cold fluid [5-7]. The equilibrium equation in this model consists of the radial force balance equation together with Ampere's law and Poisson's equation. The model gives diode current formula as

$$I_{equ} = 3400((\gamma_0 /(1+4\ln(R/r_b))^2)-1)^{1/2} \quad (5)$$

where γ_0, R and r_b all have the same meaning above.

PIC SIMULATION OF FOILLESS DIODE

3.1 Simulation tool UNIPIC

From 1960, many useful codes were developed for simulating a variety of electron guns. Commercial software packages for electron gun design are available in various forms [8]. UNIPIC is a novel simulation program that can be configured at run time by selecting appropriate geometry, material properties, boundary conditions, field algorithms, particle algorithms, and output specifications [9]. Default configurations provide good accuracy in reasonable time for novice who does not wish to or may not know how to specify some aspects of an electromagnetic PIC simulation. The fields in Maxwell's equations are represented on a finite-difference grid.

3.2 Simulation results

We investigated the output behaviors of the electron gun by varying the anode radius, while the other parameters keep constant. The amplitude of incident voltage wave equals 180 kV, and the guiding magnetic field is equal to 4.0 Tesla. Fig.2 shows the results of parametric scanning. The two diagrams respectively represent: (a) Total diode voltage, and (b) Beam current. That is, the total diode voltage after superposition and the beam current generated in diode. Each category corresponds to 5 different longitudinal gap distances between cathode and anode, which is defined as S.

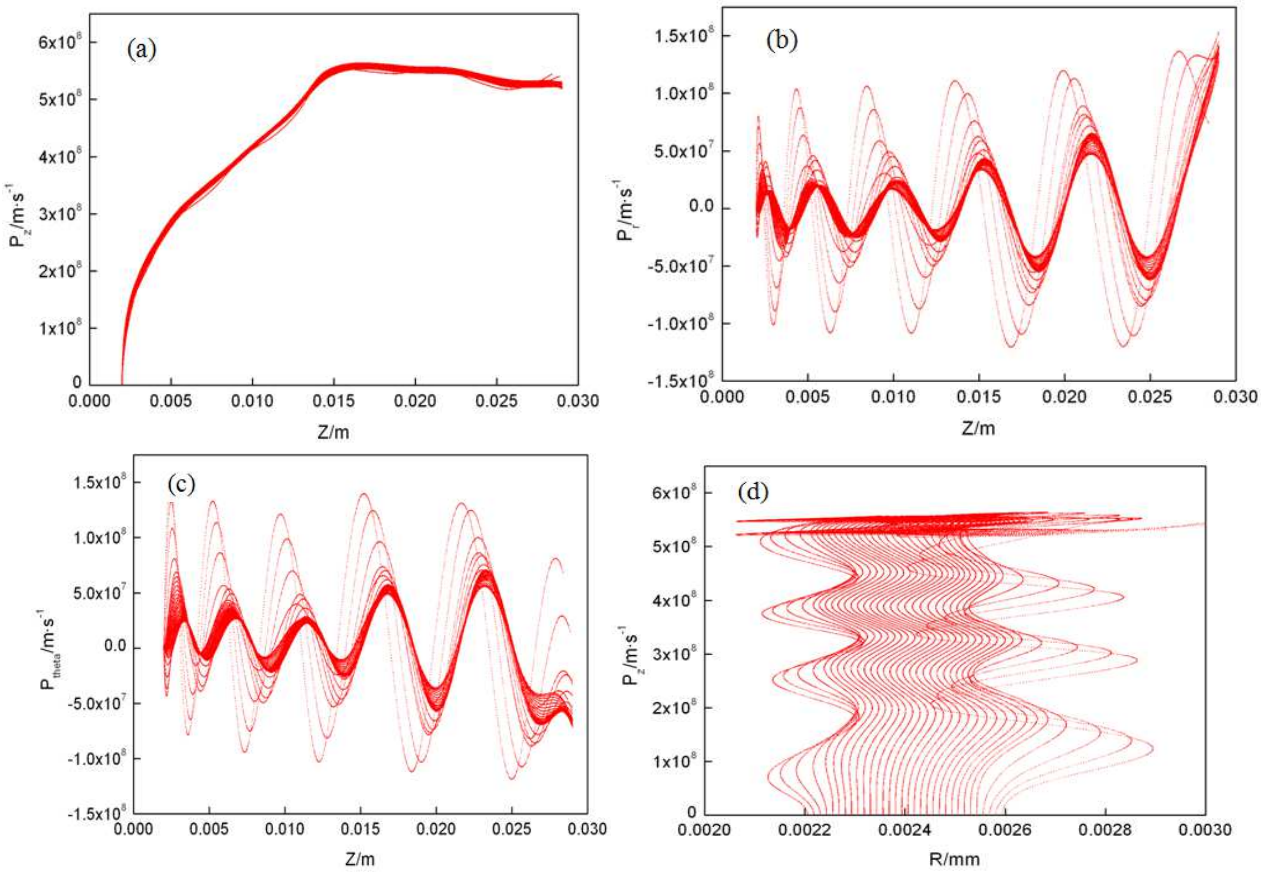

Figure 3. Phase space of electron beam (B=2.5 T)

Fig.3 shows the phase space of electron beam under the condition of 2.5 T magnetic fields. The four diagrams respectively represent: (a) Longitudinal momentum along z axis, (b) Radial momentum along z axis, (c) Angular momentum along z axis, and (d) Longitudinal momentum along r axis. It can be seen that the longitudinal momentum was increased along z axis because of the acceleration of electron beam under the high voltage; the radial momentum have the vibration characteristic because of the rotation effect of electron in magnetic field; and the angular momentum vibration are usually due to the Lamor rotation.

Conclusion

In this paper three main theoretical models of foil-less diode are reviewed. It is found that compared with basic OAL model, the CL model can carry electric potential which could vary over an arbitrary boundary. And the equilibrium beam model produces a current less than the space-charge limit at higher voltages, while the beam can be regarded as a relativistic cold fluid. Besides the analytic theory, the PIC simulations of the diode are also performed using a novel simulation tool UNIPIC. With 180 kV incident voltage and 2.5 T axial magnetic fields, the device can generate electron beam with the voltage of around 250 kV and current of 1.5 kA.

Keywords: Partial Discharge; XLPE cable; HFCT sensor; UHF sensor; AE sensor; temperature sensor.

Abstract. In this article, a portable XLPE cable insulation detection device is introduced. Such a device utilizes electromagnetic coupling, UHF electromagnetic wave and acoustic emission to detect partial discharge signals in power cables. By analyzing the partial discharge signals and cable temperatures, the insulation status of XLPE power cables is judged.

Introduction

Since the introduction of XLPE cables, they are widely used in distribution power grids due to their good insulating performance, safety and reliability when supplying power, ease of manufacturing and installation convenience. However, XLPE cables are affected by electric fields, heat effects, mechanical stress, chemical corrosion and environmental conditions. Because of the important role XLPE cables play in power transmission and transformation, serious economic loss are often caused. [1,2]

Partial discharges are the main reason of XLPE cable insulation ageing, as well as an important sign and behavior of insulation deterioration. By detecting PD signals in cables, insulation problems in cables can be effectively discovered. Partial discharge detection usually represents partial discharge status by physical quantities, which are able to express phenomena caused by partial discharges. When partial discharges happen in XPLE cables, electric pulse, electromagnetic radiation and ultrasonic waves are generated, and there are means of detecting, namely electromagnetic coupling, UHF methods and ultrasonic methods, respectively. Besides, when severe deterioration happens in some part of a cable, partial overheat will occur. By measuring the temperature of such parts, the fault can be distinguished effectively. By analyzing XLPE cable temperature and the high frequency current pulse signals, high frequency electromagnetic wave signals and ultrasonic signals generated when partial discharges happen, cable insulation status estimations are performed.

Hardware Structure of the System

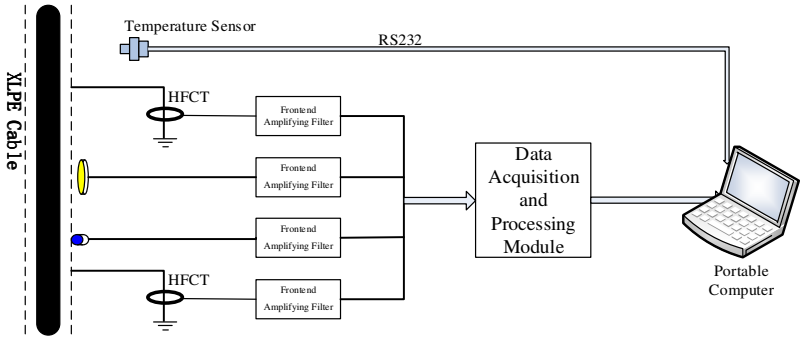

Fig. 1 Portable XLPE Cable Insulation Detection Device Schematic

Fig. 1 is the schematic of the portable XLPE cable insulation detection device. From the figure we can see that the device is composed of 2 major parts, namely sensors and detection terminal. The sensor part is composed of HFCTs (High Frequency Current Transformers), an UHF (Ultra-High Frequency) sensor, an AE (Acoustic Emission) sensor and a temperature sensor. It is mainly used for detecting pulse currents, electromagnetic radiations, ultrasonic waves and temperature generated by PDs in XLPE cables.

High Frequency Current Transformers (HFCTs）. HFCTs are commonly used in cable partial discharge detections. Based on electromagnetic coupling, the sensors are wide-band Rogowski coil current sensors with iron oxide cores.

It is required that HFCTs should be able to effectively filter interferences and extract PD signals. The sensors used in field detections are split-cored HFCTs with built-in amplifiers. Cable bodies are like inducting antennas. Cable detection experience shows that HFCT detection results contain a lot of radio interference [3]. To effectively extract PD signals, selectable amplification ratios of 20 dB and 40 dB are adopted in preposed amplifiers. Meanwhile, the amplifiers' sampling band is between 300 kHz and 25 MHz[4]. In field detections, install the split-cored HFCT around the grounding lead of the metal screen on the cable end. When PD occurs in the cable, pulse current will be inducted in the metal screen. The current will flow through the grounding lead and be detected by the HFCT.

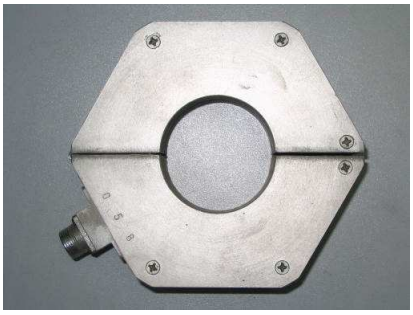

Fig. 2 High Frequency Current Transformer (HFCT)

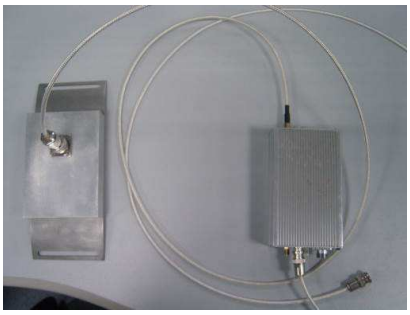

Fig. 3 Ultra-High Frequency (UHF) Sensor

Ultra-High Frequency (UHF) Sensor. UHF sensors' detected frequency bands are high. It means that they are far away from low frequency bands, which contains a great amount of noisy interference. UHF sensors are thus strongly anti-interference. Meanwhile, narrow-banded interferences (such as radio interference, cellular phone signals, etc.) can be recognized by methods like spectrum and waveform interference. Therefore, UHF detecting techniques are suitable for partial discharge detections[5,6]. Shown in Fig. 3 are the UHF sensor and its signal conditioning unit. The UHF sensor is a microstrip antenna with a bandwidth from 500 MHz to 1.5 GHz. UHF amplifier has 2 output channels, namely conditioned output and UHF output, which are used for PD signal detection and positioning, respectively [7] .

Ultrasonic Sensor. Shown in Fig. 4 is the combination of the ultrasonic sensor and its proposed amplifier. The ultrasonic sensor used in this device is a piezoelectric acoustic emission sensor. The maximum bandwidth of the sensor is 20 – 180 kHz. The sensitivity is 85 (-75) V/ (m/s) [V/ubar](dB). The output signal is a differential signal. The proposed amplifier is voltage type. It is composed of a 2-stage amplifier and a 4^{th}-order high-pass filter. It is mainly because that the detected signal is very weak, sometimes in microvolts or even less. So signals should go through such multistage amplification before they finally meet the requirement of data acquisition and processing.

Temperature Sensor. Temperature is the most obvious quantity in cable insulation detection. By measuring the temperatures of critical parts and vulnerable parts like XLPE cable bodies, joints, ends, etc., the condition of cable insulation deterioration can be effectively judged. This set system has an on-line infrared (IR) temperature sensor, which can measure temperatures without contacting the object being

measured. It is composed of a IR temperature converter and a box containing electronic components. The converter is used for sensing the temperature, while the box converts the sensed signal to digital signals that can be processed by industrial computers.

Fig. 4 Ultrasonic Sensor

Fig. 5 MID IR Temperature Sensor

Software Structure of the System

The software part is an important component of the system. The software unit is used for controlling sensor signal sampling, processing signals sampled, extracting PD features. It's expert system judges the insulation condition of XLPE cables by analyzing the data. The software part is mainly composed of the following modules: data acquisition, signal processing, feature extracting, diagnosis and interface display. The flow chart is shown in Fig. 6.

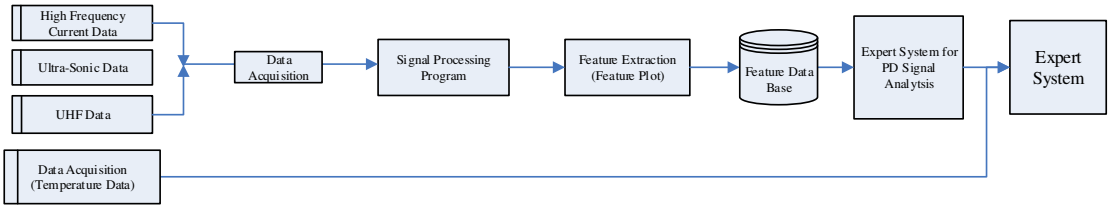

Fig. 6 System Software Flow Chart

Data Acquisition Program. The signals acquired by the system are PD signals and temperature signals. According to certain configured parameters, the data acquisition system controls signal acquisition from corresponding sensors. The acquired data will be saved to specified folders.

PD Signal Processing Program. Field detection will be effected by strong noisy interferences. The effective filtering such noises is the premise of accurately acquiring PD signal and analyzing cable insulation condition. The major function of the PD signal processing program is to filter these interferences in field. Due to that the forms of interferences in fields are diverse; it is very hard to use only one method to effectively filter all interferences. Thus different filtering methods should be applied to different interferences [8,9]. The PD signal processing program has adopted multiple filtering algorithms including FIR filtering, FFT filtering, wavelet filtering, etc.

Design of PD Feature Extracting Program and Feature Data Base. The PD feature extracting program is used for constructing the feature diagrams of PDs and extracting discharge fingerprints. PD feature diagrams include 5 kinds of 2-dimensional diagrams like maximum discharge to phase distribution, average discharge to phase distribution, etc. and the 3-dimensional φ-q-n diagram. Discharge fingerprints are extracted from 2-dimensional diagrams mainly includes kurtosis, skewness, etc.

For the convenience of future data comparison, analysis and research, a PD feature data base is constructed to store feature diagrams and discharge fingerprints of different types of discharges.

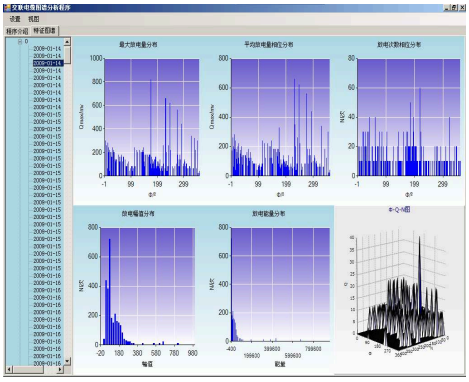

Fig. 7 Feature Diagrams

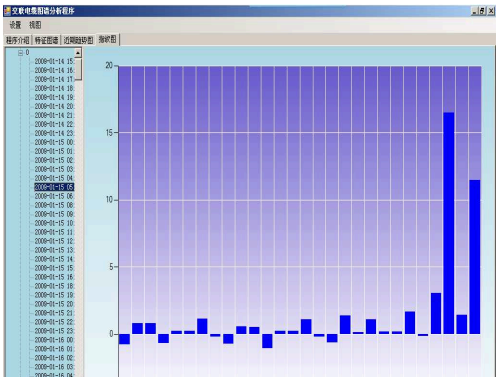

Fig. 8 A Fingerprint

Conclusion

The development scheme of portable partial discharge detection device for cable accessories is introduced in this paper. The paper mainly introduced the hardware structure and the software part. Field test results show that such device functions well.

Keywords:adaptive fuzzy clustering partial discharge stochastic pulse interference

Abstract. To suppress the stochastic pulse interference in XLPE Cables, this paper uses equivalent time-frequency method to extract pulse feature values, adaptive fuzzy clustering to classify pulses, phase concentration as an index to distinguish PD and stochastic pulses. Analysis results of on-site data show that this method can effectively suppress stochastic pulse interference in the PD signal, providing a useful theoretical and practical basis to assess the state of XLPE cable insulation.

Introduction

Partial discharge (referred to as PD) is important factors and external performance causing cross-linked polyethylene (XLPE) cable insulation damaged [1]. Partial discharge test for XLPE cable is to assess the state of the cable insulation and an important means of preventing cable accidents [2]. In the field tests of PD, the random pulse interference has similar time domain and frequency domain characteristics with PD signal and is difficult to remove, so the suppression method has important practical significance in cable PD field testing.

In the current random pulse interference suppression studies, literature [3] proposed a suppression algorithm based on pulse waveform feature recognition; In the study of recognition algorithm, literature [4] proposed an algorithm to suppress random pulse interference based on PSO algorithm training neural network; Literature [5] did fuzzy clustering and gray clustering on the pulse, to achieve the removal of random pulse interference. This paper is based on the fuzzy clustering and theoretical results of random pulse interference suppression. For broadband partial discharge online detection of XLPE cable, we propose a randomized pulse interference identification method combining adaptive fuzzy clustering and phase concentration analysis. It is based on adaptive fuzzy clustering to get pulses categories, and calculates concentration of half-cycle for each pulse to determine the category of the pulse and achieve the random pulse interference removal.

Fuzzy C-Means clustering principle

Fuzzy C-Means clustering is classifying the samples by optimizing the iterative algorithm based on the distance between samples to obtain its membership degree. When the fuzzy C-means clustering algorithm process samples with unknown number of categories, the number of categories of clustering options is an important factor to determine the success of clustering algorithm. In the actual application, the number of clusters is often not directly determined. Therefore, this paper uses an adaptive fuzzy C-means clustering algorithm.

Suppose the data matrix $X=\{x_1,x_2,...,x_n\}\subset R^s$ and there are n samples which can be divided to c cluster (1<c<n). $V=\{v_1,v_2,...,v_c\}$ is the clustering central matrix, $U=[u_{ij}]_{c\times n}$ is the membership matrix and u_{ij} indicates the degree of j-th data elements x_j belonging to the i-th category. $u_{ij}\in\left\{u_{ij}\,|\,0\le u_{ij}\le 1,\sum_{i=1}^{c}u_{ij}=1,0<\sum_{j=1}^{n}u_{ij}<n\right\}$

The distance of sample x_j to the i-th clustering center v_i is:

$$d_{ij}=\|x_j-v_i\| \quad (1)$$

Objection function of clustering is:

$$J_m(U,V)=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^m d_{ij}^2 \quad (2)$$

The central vector of the overall sample is:

$$\bar{x}=\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^m x_j / n \quad (3)$$

The adaptive function of the cluster numbers[6] is:

$$F(c)=\frac{\sum_{i=1}^{c}(\sum_{j=1}^{n}u_{ij}^m)\left\|\bar{x}-v_i\right\|^2/(c-1)}{\sum_{i=1}^{c}\sum_{j=1}^{n}u_{ij}^m\left\|x_j-v_i\right\|^2/(n-c)} \quad (4)$$

Adaptive fuzzy clustering algorithm steps [6] are as follows:

(a) Give the initial cluster numbers $c=2$ and the iteration criteria $\varepsilon>0$ .Initialize the clustering central matrix $V^{(0)}$, $F(1)=0$, $k=0$;

(b) Calculate the membership matrix of k-th iteration $U^{(k)}$:

$$u_{ij}^{(k)}=\frac{1}{\sum_{t=1}^{c}(\frac{d_{ij}^{(k)}}{d_{tj}^{(k)}})^{\frac{2}{m-1}}} \quad (5)$$

If $d_{rj}^{(k)}=0$, $u_{ij}^{(k)}=1$. If $i\ne r, u_{ij}^{(k)}=0$.

(c) Calculate the cluster center $V^{(k+1)}$ of $k+1$ -thiteration $V^{(k+1)}$:

$$v_i^{(k+1)}=\frac{\sum_{j=1}^{n}(u_{ij}^{(k)})^m x_j}{\sum_{j=1}^{n}(u_{ij}^{(k)})^m} \quad (6)$$

(d) Determine if $\| V^{(k+1)} - V^{(k)} \| \leq \varepsilon$ is correct. If it is correct, stop the iteration. Otherwise, $k = k+1$, repeat the iteration from step (a).

(e) Calculate $F(c)$. In the range of $2 < c < n$, if $F(c-1) > F(c-2)$ and $F(c-1) > F(c)$, c is the best cluster numbers and clustering process ends. Otherwise, add 1 to c and repeat iteration from step (a).

Fuzzy clustering based on pulse waveform characteristics

Pulse waveform extraction. Extract pulse waveform for pulse signal, and you will obtain a pulse waveform array and an array of pulse position. A pulse waveform array records amplitude of pulses in each sample point, pulse position array records sampling time of each point in the pulse. For a signal collected in a power frequency cycle, suppose there are N sampling points, K pulses, wherein, the p-th pulse signal includes n sampling points.

$t_p = \{t_p^1, t_p^2, ..., t_p^q, ..., t_p^n\}$ represents the sampling time of each point in p-th pulse

$s_p(t_p) = \{a_p^1, a_p^2, ..., a_p^q, ..., a_p^n\}$ represents amplitude function of p-th pulse in time domain.

Equivalent time-frequency analysis. In the time domain, the value describing a time-domain waveform pulse signal characteristic is equivalent time.

Time center of p-th pulseis:

$$T_p^0 = \frac{\int_1^n t_i \cdot s_i(t_i)^2}{\int_1^n s_i(t_i)^2} \tag{7}$$

Equivalent width of pulse waveform signal in the time domain is:

$$T_p = \sqrt{\frac{\int_{i=1}^n (t_p^i - T_p^0) \bullet s_p(t_p^i) dt}{\int_{i=1}^n s_p(t_p^i) dt}} \tag{8}$$

In the frequency domain, the value describing frequency domain waveform characteristic of a pulse signal is equivalent frequency.

Make FFT (Fast Fourier) transformation for the pulse and obtain the amplitude of the p-th pulse sequence in the frequency domain: $S_p(f_p) = \{A_p^1, A_p^2, ..., A_p^{n/2}\}$.

The frequency is: $f_p = \{f_p^1, f_p^2, ... f_p^q, ..., f_p^{n/2}\} = \{\frac{fs}{N}, \frac{2fs}{N}, ..., \frac{q \times fs}{N}, ..., \frac{nfs}{2N}\}$.

The frequency focus of p-th pulse is:

$$F_p^0 = \frac{\sum_{i=1}^{n/2} f_i \cdot S_i(f_i)^2}{\sum_{i=1}^{n/2} S_i(f_i)^2} \tag{9}$$

Equivalent width of pulse waveform signal in the frequency domainis:

$$F_p = \sqrt{\frac{\int_{i=1}^{n/2} (f_p^i - F_p^0) \bullet S_p(f_p^i) df}{\int_{i=1}^{n/2} S_p(f_p^i) df}} \tag{10}$$

From equation (7) - (10), the PD signal is converted to an equivalent T and F vectors. The dimension is reduced for the PD signal containing a high-dimensional information and domain and frequency characteristics of the PD signal are retained in a great extent, which provides a good clustering characteristics for fuzzy clustering of the pulse.

Removal of random pulse interference

Through broadband electromagnetic coupling method, collect five power frequency cycle (100ms) of XLPE cables PD signals in the substation site in 20M sampling rate. After noise cancellation of white noise, narrowband interference, periodic pulse interference, the discharge signal still has random pulse interference and high intensity, as shown in Fig. 1.

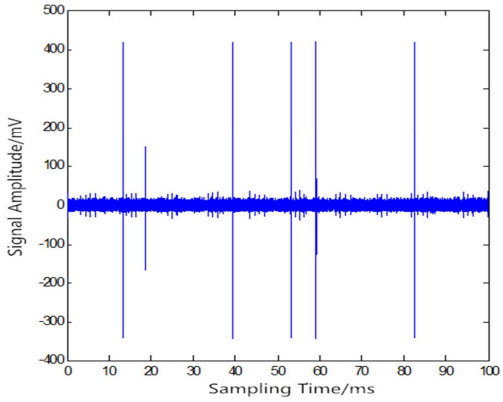

Fig. 1 PD signal before noise cancellation of random pulse interference signal

Since random pulse interference has random distribution in the whole power frequency cycle and PD pulses have a strong concentration in the positive and negative half-cycle power frequency cycle, design the following principles suppressing random pulse interference: First, take equivalent time frequency of a pulse the feature and use an adaptive fuzzy clustering algorithm to classify; second, take phase distribution concentration of various pulses as an indicator to distinguish whether it is random pulse interference.

Pulse adaptive clustering. Select 100 groups of PD data which didn't not eliminate random pulse interference, extract pulse waveform characteristic value TF using the equivalent time-frequency method, adaptive fuzzy C-means cluster for the pulses, and adaptive function of the number of clusters:

$F(2)=345.9$, $F(3)=1454.4$, $F(4)=2087$, $F(5)=2023.7$. Optimal number of classes is 4 and the pulse is divided into four clusters, as shown in Fig.2.

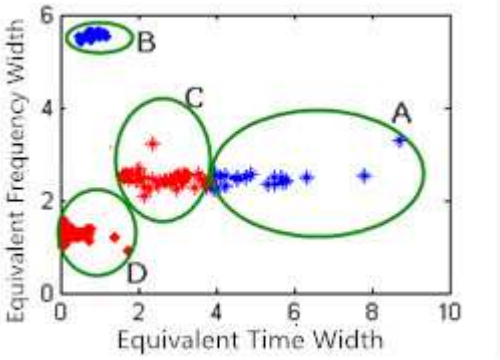

Fig.2 Adaptive fuzzy clustering diagram of the pulse

Pulses are clustered into A, B, C, and D four classes. But we still cannot determine which type is PD and which type is random pulse interference. In order to solve this problem, phase concentration analysis is used to identify the pulse.

Phase concentration analysis. In this paper, phase standard difference of various types of pulse is the index measuring the concentration density. As the standard difference is greater, the concentration is lower, the phase distribution is more widely, and the likelihood of being random interference is greater. Extract phases of four signals in the positive half-cycle (0-180 degrees) and negative half cycle (180 degrees to 360 degrees). Calculate phase standard differences of four pulse signals in the positive and negative half-cycle (Table 1).

Table 1 Phase Standard Difference for Signals of 4 types

Type	Standard Difference	
	0°-180°	180°-360°
A	55.6671	56.9703
B	57.7207	61.7910
C	59.2903	45.2781
D	14.2041	12.2675

As can be seen, phase standard difference of class D of signal is minimum.i.e. phase concentration of class D pulse is highest, and phase standard differences of A, B, C three classes of signals are larger. Based on the phase distribution knowledge of PD signal discharge pulse and random pulse interference, PD signals are mainly distributed in the first and third quadrants, focusing on near 90o and 270o and random pulse interference randomly is distributed from 0o to 360o. Thus the D class signal whose phase standard difference is minimum in positive and negative half-cycle is partial discharge signals; while A, B, C types of signals whose phase standard differences are larger are random pulses interference signals.

For the data in Figure 1, in the signal pulse sequence, remove the A, B, C three types of pulses, you can get a clear PD signals, as is shown in Fig.3.

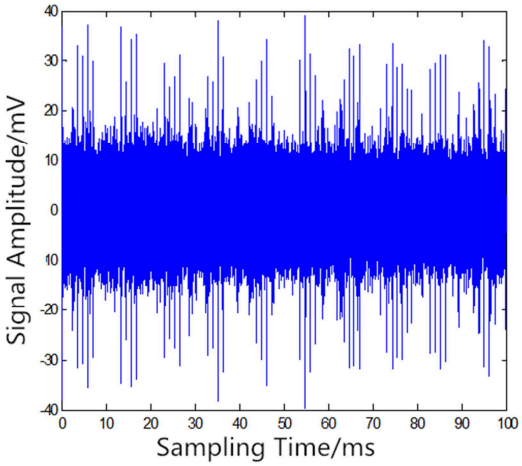

Fig.3 Adaptive fuzzy clustering eliminating noise results

Conclusion

This paper presents a new method for removing random pulse interference of XLPE cables partial discharge detection field signal. This method takes adaptive fuzzy clustering for the time-frequency characteristics of pulse signals which are collected in the field, and concentration of each class of pulse phase in the positive and negative power frequency half cycle is the index of distinguishing PD and random pulse. On-site data processing results show that this method can distinguish PD and random interference pulse.

Keywords: UHV; power grid; short circuit currents; limitation measures.

Abstract. Ultra-high voltage (UHV) projects are making power system growing lager and resulting in sharp increase of short circuit currents in some area especially in the vicinity of UHV access points. The paper presented the damage of short circuit current increases and common methods to limit fault current. Taking the construction and development of UHV grid in a province of central China as background, the over short circuit currents in 500kV Grid within UHV were showed and several countermeasures including choosing proper UHV access scheme, implementing UHV substation lower voltage bus partition running, installing reactors, optimizing power grid network based on UHV connection point were proposed and then verified by PSASP simulation. The results show those measures are useful to reduce the short circuit current to a reasonable level.

Introduction

UHV grid provides an effective solution to the energy and environmental problems that we are facing today, for it can allocate resources in a large scale with great efficiency and be a strong support for renewable energy power generation. According to the State Grid Corporation's development plan of UHV, by 2015, three vertical UHV lines from the north to south of China and three horizontal UHV lines from the west to east of China and all relevant DC project will be approved. By 2020, five vertical and five horizontal UHV lines and 20 UHVDC projects will be put into operation [1].

UHV projects have higher requirements for grid transmission capacity and reliability, making its scale to expand and reducing electrical distance gradually. The impedance of grid will decrease and short circuit currents will increase year by year which are more apparent in some 500 kV substations associated to UHV grid [2]. When the short circuit current exceeds the capacity of the circuit breaker, the fault can't be properly cut out, resulting in system instability and equipment damage. Therefore, balancing short circuit capacity of the power grid and limiting the short circuit current at a reasonable level should be put into first consideration when we build UHV projects.

In this paper, taking a province of central China as an example, short circuit currents of 500kV grid within UHV is simulated in PSASP6.28 software, which surpass the breaker capability in some area. Then several methods to limit fault current based on UHV construction are proposed and validated. Finally, some related countermeasures are suggested to guarantee the safety of power system.

Hazards of short-circuit current increases

The increase of short-circuit current makes circuit breakers, disconnecting switch, current transformers, buses and other equipment bear a large current surge. We have to choose larger capacity equipment which results in significant investment increment.

Temperature of transmission lines will rise according to short-circuit current increases, making the clamp portion of wires overheated and also intensifying the fault point damage, such as insulators broken, wires fused or other issues.

It constitutes a threat to gird safety if fault current grows too high that circuit breakers can't remove the failure effectively, causing the failure to expand in a larger area, endangering the operation of the whole power system.

Single-phase short-circuit current also increases. Asymmetrical short-circuit current will produce a strong unbalanced alternating magnetic field and then add hazards to communication lines [3].

Also, it results in the increase of step voltage and touch voltage near the tower, endangering neighboring humans and animals.

Comparative analysis of short circuit current limitation measures

Restructuring power grids, installing impedance equipment and adopting new technology are three common methods to suppress short-circuit current at home and abroad [4-6].

Restructuring power grids

Rationally allocate power source. By strictly controlling generator or UHV access point, it can balance grid short-circuit capacity and help limit short-circuit current. This method is sometimes limited by the energy supply or plant sites.

Substation bus partition running can increase system impedance, effectively reducing short-circuit currents. It is easy to operate but would lower grid safety margin and operation flexibility, even cause uneven load distribution.

Optimize network structure. Load centers are of high transient stability so we can untie some tight transmission loops, reduce substation in and out lines, use high-capacity transmission wires to meet the transmission requirements and increase electrical distance, maintaining reasonable impedance between power substations.

Operate power grids under district and voltage level classification. It is effective to reduce short circuit current but may also lower grid reliability, security, stability and capacity.

Installing impedance equipment

Using high impedance transformers or generators is an effective way to suppress the fault current. But they increase voltage angle difference, affect the quality of power supply, and also increase power losses under normal condition. Installing series reactor has the same disadvantage, but it can reduce the short-circuit current with small equipment investment. In addition, adopting low reactance at the neutral point of transformer has apparent effect on lowering single-phase to ground fault current but little effect on limiting three-phase short circuit current.

Adopting new technology

Using back to back device in the same place to divide AC system into sub running areas can limit the short-circuit current. It makes grid operation complex and has bad influence on system security. Besides, this equipment is very expensive.

Installing new generation current limiting devices is another way to lower fault current, including SFCL, FCL, FCL-TCSC, FCL-UPFC, etc [7-10]. Those devices have low impedance under normal condition and provide high impedance when fault occurs. But their application has the following problems: high cost, immature technique, small capability, control difficulty.

Application of limiting measures after the grid accessing UHV

Short-circuit current level without limiting measures

According to grid 2015 and 2018 plan of the province in the central China, three-phase short circuit currents of the 500kV bus node without any limitation measures are simulated in PSASP6.28 software and those buses that fault currents beyond the circuit breaker capacity are shown in Table 1, in which T stands for UHV substation lower voltage buses, N represents 500kV substation buses. The

circuit breaker capacity of 500kV grid in this province is 63kA. Fig.1 shows the grid network structure of the province in 2018.

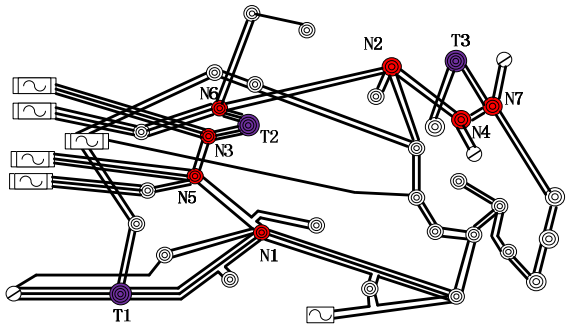

Fig.1. Grid network structure of the province in 2018

N7	62.13	**69.79**

Table 2 Fault currents before and after UHV substation bus partition running(kA)

Bus	2015		2018	
	before	after	before	after
T1a	—	—	**80.57**	59.47
T1b	—	—	**80.57**	59.23
T2a	**83.28**	49.47	**89.02**	52.73
T2b	**83.28**	43.29	**88.98**	45.54
T3a	60.72	43.07	**73.93**	42.82
T3b	60.72	36.81	**73.97**	49.65
N1	51.83	50.83	**69.13**	**67.28**
N2	**65.27**	**64.51**	**78.14**	**76.97**
N3	**69.53**	49.28	**73.76**	52.13
N4	59.91	58.59	**72.00**	**70.09**
N5	**72.85**	**65.34**	**80.52**	**72.62**
N6	**78.39**	53.88	**83.64**	57.60
N7	62.13	57.91	**69.79**	**64.69**

The calculation shows that sites of short circuit currents that excess the regulation standard are mainly near the UHV access point, and there are 4 substations including 5 buses in 2015. And in 2018, the short circuit current level of 500 kV grids will continue to increase with new UHV projects put into operation. Those sites that fault currents surpass the breaker capability will increase from the original 4 to 10 including 13 buses.

Fault current limitation measures for UHV access

Determine proper UHV access schemes, such as adopting high impedance transformer in UHV substation, choose suitable connection method and access point according to the power balance requirements and former flow distribution to avoid lines and transformers overloading.

Implementing UHV substation lower voltage bus partition running is useful to suppress fault circuit of UHV substation and their connection substation. Results are compared in Table 2.By taking this method, short-circuit currents has been effectively controlled, less than switches capacity except N2 and N5 in 2015. Short circuit current of N2 is still 64.51kA, through load flow calculation, its highest value is 62.02kA.We need not to consider any other limitation method. N5 substation's short circuit current value is 65.34kA. Adopting series reactors on its exports double lines can reduce short-circuit current by 6.08kA, down to 59.26kA. However in 2018, this method can only solve part

of over fault current problem. Short-circuit currents of N1, N2, N4 and N5 substation are still far more than their switching capacity. Those problems need to be solved in the planning stage by grid network optimization according to the construction of UHV.

For limit short circuit currents of N1 and N5 substation, based on the T1 UHV construction, implement 500kV network optimization by reducing the N1 substation transmission lines and adding a new wire, shown in Fig.2 and Fig.3. Recheck fault currents after network optimization, their values of N1, N5 station are decreased to 64.89kA and 43.93kA. N5 station's short circuit current can be controlled also by adding series reactors in its connection transmission lines.

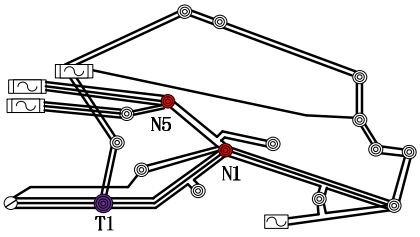

Fig.2. Network before optimization

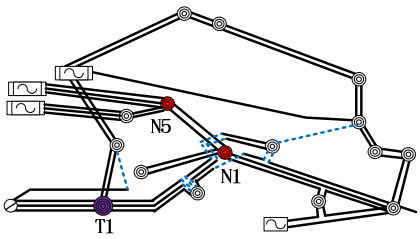

Fig.3. Network after optimization

In order to limit short-circuit currents of bus N2, N4, N7, expand the electromagnetic loop and weaken the function of each station. With new UHVDC accessing in, we can untie N4-N7 double lines, using UHVDC access point to form a network ring; simultaneously untie N2-N6 double lines, create a new substation, increase two transmission lines and use original N2-N6 wires to develop a larger loop. Grid structure before and after optimization near T3 are shown in Fig.4.and Fig.5. After optimization, short circuit currents of N2, N4, N7 are down to 62.89kA, 54.72kA, 49.57kA, below the switch breaking capacity.

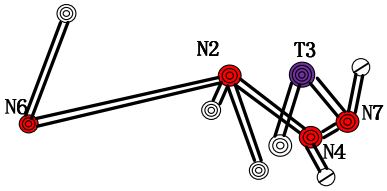

Fig.4. Network before optimization

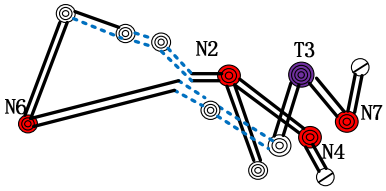

Fig.5. Network after optimization

N-1 check shows that the grid of this province after network optimization has reasonable flow distributions and can maintain transient stability.

Ways to deal with problems of fault current increases

Limiting measures are useful to control short-circuit current. But their level increases with the grid size year by year. For the security and stability of power system, improving operational management and control technologies are just as important as building strong power grid.

First, retain untied lines if possible to obtain support from the surrounding grid when the fault occurs. Secondly, install security and stability control devices in case that grid sub area running reduces power supply reliability. Finally, strengthen analysis of power grid operation to insure power equilibrium on the bus when implement UHV substation lower voltage bus partition running.

Conclusions

With construction of UHV grid and expansion of power system, the problem of short-circuit currents of 500kV grid exceeding the standard value will be exacerbated, especially in UHV access area. Several measures need to be taken from the long-term development of power grids, in which a rational network structure plan is the fundamental one. Appropriately adjusting the power grid operation mode is a more convenient way to reduce short circuit currents if the system is strong

enough. And installing series reactors can suppress the short circuit current with a little increase in investment. By reasonably selecting UHV access scheme, implementing UHV substation lower voltage bus partition running, installing reactors, optimizing power grid network based on UHV construction ,short circuit currents are successful controlled in the province of central China after UHV projects accessing in according to PSASP simulation. Results show those measures are useful to reduce the short circuit current to a reasonable level, which can provide a reference for network planning and the implementation of UHV projects.

Keywords: Vibration Signal, High Voltage Circuit Breakers, Fault Diagnosis, Extreme Learning Machine

Abstract. In order to improve the diagnosis method of the existing high-voltage circuit breaker fault, demonstrated a new diagnosis methord of mechanical failure of high voltage circuit breaker based on vibration signal. According to the factors of high voltage circuit breaker failure and the features of Single-hidden Layer Feedforward Neural Network, SLFN, a method of high voltage circuit breaker fault diagnosis proposed based on Extreme Learning Machine (ELM). Finally, the experiment proves the effectiveness of this method for breaker fault diagnosis based on vibration signal analysis and ELM.

Introduction

High voltage circuit breaker plays an important role in the control and protection of power system, its safe and reliable operation becomes one of the common concerns in the research field. Once breakdown it will cause huge losses, even threat the safety of personnel [1-2]. Breaker moving process will produce severe vibrations, the vibration of the vibration signal contains a wealth of information about the state of the circuit breaker, so breaker status will be reflected in the vibration signal, we need to study the vibration signal of the circuit breaker to diagnose the mechanical operation of high voltage circuit breaker status [3].

Extreme Learning Machine is a newly proposed method in recent years, based on Single Hidden Layer Feedforward Neural Networks. ELM algorithm generated threshold connection weights between the input layer and the hidden layer and the hidden layer neurons randomly, and no adjustment in the training process, just need to set the number of hidden layer neurons, we can obtain the optimal solution; it can learn fast and has the good generalization performance. Currently, ELM has been used in long-term load forecasting of power systems and power line construction cost estimates and other fields [4]. However, application in high-voltage circuit breaker fault diagnosis method need to be expanded.

In this paper, the history of engineering samples and laboratory testing data is used in the research of breaker fault diagnosis based on ELM, provide new ideas in the future for the study of fault diagnosis and monitoring of circuit breaker.

Theory of Extreme Learning Machine

For n different samples (x_i, t_i), there is $x_i = [x_{i1}, x_{i2}, \cdots, x_{in}]^T \in R^n$, $t_i = [t_{i1}, t_{i2}, \cdots, t_{im}]^T \in R^m$

The number of hidden layer nodes is N, the unified model of former single hidden layer feedforward neural networks which has a stimulate function $g(x)$ is:

$$\sum_{i=1}^{N} \beta_i g_i(x_j) = \sum_{i=1}^{N} \beta_i g(w_i \cdot x_j + b_i) = o_j \qquad j = 1, \cdots, N \tag{1}$$

w_i is the weights connected to the i-th hidden node and the input node, β_i is the weights connected to the i-th hidden node and the output node, b_i is the threshold of the i-th hidden layer node. The option -al excitation function is Sigmoid, radial basis function and so on.

β_i, w_i and b_i satisfies the following formula: $\sum_{i=1}^{N} \beta_i g\left(w_i \cdot x_j + b_i\right) = t_j \quad j = 1, \cdots, N$ (2)

The formula matrix is: $H\beta = T$ (3)

Matrix H is called the Output matrix of the neural network. From the above, w_i, b_i is fixed, so training a single hidden layer neural network is equivalent to seek a least squares solution $\hat{\beta}$ of linear systems $H\beta = T$ simply. However, in common applications, the number of hidden nodes N is much less than the number of training samples n, H matrix is not square, there is no w_i, b_i, $\beta(i = 1, \cdots, N)$ to make $H\beta = T$. The minimal norm least squares solution of linear systems described above are:

$$\hat{\beta} = H^{-1}T \tag{4}$$

H^{-1} is a Morre-Penrose generalized inverse matrix of matrix H.

Circuit Breaker Fault Diagnosis Model Based on ELM

Extracting Eigenvectors. (1) Use point-by-point filtering in Lab VIEW for filter based on circuit breaker vibration signal in the normal state. The waveform before and after filtering shown in Figure 1.

(2) Decompose the filtered signal in each state by EEMD. IMF component of the normal state of brake vibration signal decomposed by EEMD is shown in Figure 2; take the first 5 for example. Extract the energy entropy of each IMF component functions as shown in Table 1.

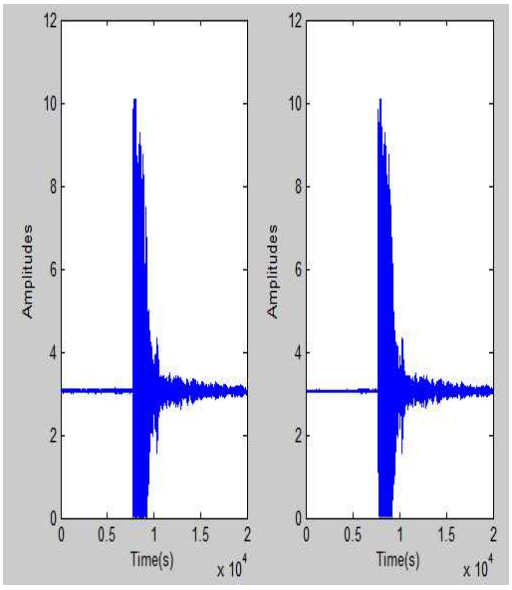

Figure 1. Point-by-point filtered waveforms before and after

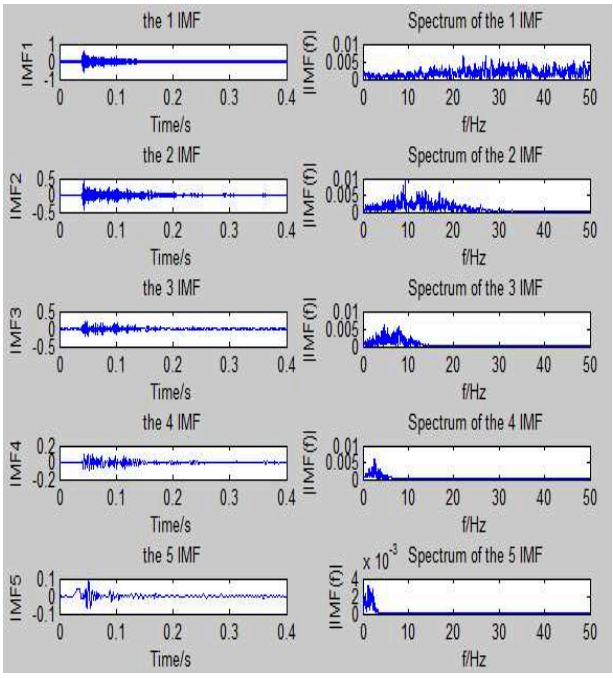

Figure 2. EEMD decomposition results

Table 1. Energy entropy of each component of the IMF

signal	E0	E1	E2	E3	E4	E5	E6	E7
Normal state	1.3375	1.5062	1.9116	2.2603	1.7260	2.0715	2.7317	3.0571
Fault state 1	1.8643	2.8030	2.7890	3.2948	3.1103	2.9971	3.2677	3.5595
Fault state 2	1.6870	1.7737	2.5444	2.5195	2.9480	2.8237	3.4730	3.6349
Fault state 3	1.5260	1.8367	1.8932	2.4591	2.8670	2.8917	3.0125	3.2593

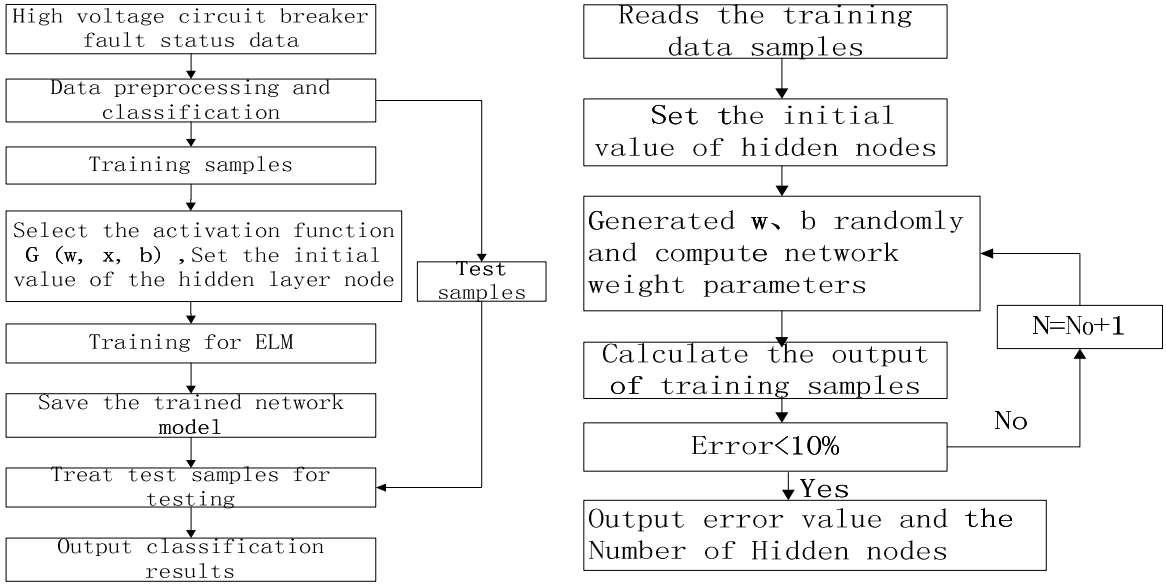
(3) The energy entropy in (2) constitutes the characteristic quantity for each sample, which will be used as the input features of extreme learning machine. ELM input feature quantity can be expressed as:

$$e=(e_0,e_1,e_2,e_3,e_4,e_5,e_6,e_7)=\left(\frac{E_0}{E_\Sigma},\frac{E_1}{E_\Sigma},\frac{E_2}{E_\Sigma},\frac{E_3}{E_\Sigma},\frac{E_4}{E_\Sigma},\frac{E_5}{E_\Sigma},\frac{E_6}{E_\Sigma},\frac{E_7}{E_\Sigma}\right) \tag{5}$$

Wherein: $E_\Sigma=\sum_{i=0}^{7}E_i$. The number of neurons in the input layer of ELM is $n=8$.

(4) Determine the excitation function of Extreme Learning Machine model. The sigmoid function is selected for this experiment.

Fault Diagnosis Model Based on ELM. Breaker troubleshooting flowchart is showed in Figure 3.



(a) ELM diagnostic process model (b) ELM training process

Figure 3. Breaker troubleshooting flowchart based on ELM

Experimental Analysis

Using ZN28A vacuum circuit breaker simulates normal, opening lock hook insufficient lubrication, operating coil faults and fault buffer failures. Using L0102T piezoelectric acceleration sensor gets vibration signals. Vibration signals were collected 100 groups of four states, 60 groups for training ELM, 40 groups for testing (10 groups of normal, 30 groups of fault).

(1) Set the initial hidden nodes, through training single hidden layer feedforward neural network, when the network learning ability and accuracy meet the requirements, determine the neural network weights parameter according to the formula (3) and (4) .

(2) Input the test sample to the trained network to obtain experimental estimation results.

(3) Input the under test 30 groups of fault signal to the diagnosis network, the test results shown in Figure 4. Visible, NO.11 groups of data is determined error; the classification accuracy was 96.67%.

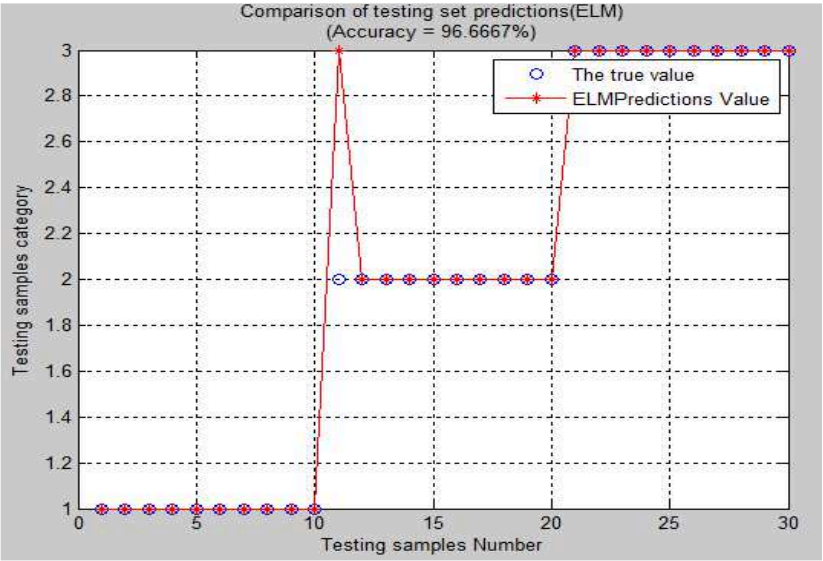


Figure 4. Analysis the classification results of ELM

Conclusion

Analyzing the collected vibration signal through point by point filtering, filter the mixed invalid signal during the measure process, then through EEMD decomposition, acquire the IMF components and its energy eigenvalues as the extreme learning machine input. By classifying the test sample to verify the results proved the extreme learning machine can be used to identify the circuit breaker failure, but, ELM training requires a lot of data, online status is still insufficient to meet this condition, so this method need for further improvement.

Keywords: EEMD; Relevance vector machine; High voltage circuit breaker; Fault diagnosis

Abstract.Mechanical failure of high voltage circuit breaker accounted for the largest percentage of, it is necessary to diagnosis the mechanical fault .The acoustic signal of high voltage circuit breaker contains a large number of mechanical state information, can put the acoustic signal characteristics as a basis for high voltage circuit breaker fault diagnosis. M - RVM expanding traditional RVM to multiple categories, very suitable for fault diagnosis of high voltage circuit breaker.In this paper, the M-RVM combined with EEMD method for high voltage circuit breaker mechanical fault diagnosis, the experimental results show that the method has a good diagnosis effect.

Introduction

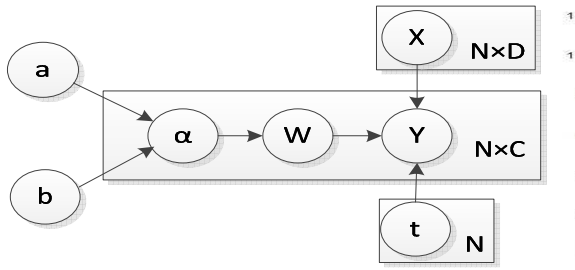
According to CIGRE for high voltage circuit breaker reliability the investigation and statistical analysis of the high voltage switch incidents in China show that in 80% of all high voltage circuit breaker fault fault belongs to the mechanical properties[1], to improve the running reliability of high voltage circuit breaker and ensure the quality of power grid is necessary for the mechanical fault diagnosis. In the high-voltage circuit breaker open or closing will occur during mechanical friction and impact and is accompanied by a loud noise, the resulting acoustic signal contains a large amount of machinery in the state information and sound waves through the non-contact measurement method, it is suitable for application in high voltage and strong electromagnetic environment characteristics, thus high voltage circuit breaker mechanical fault diagnosis can based on the acoustic signals of high voltage circuit breaker open or closing process[2].

In the past, the most frequently fault diagnosis method is artificial neural network (Artificial Neural Network, ANN) and support vector machines (Support Vector Machine, SVM), but the inherent defects exist in some aspects[3]: Local optimal problem and the problem of dimension disaster affect the accuracy of ANN algorithm, at the same time, ANN has a slow convergence speed, easily trapped in local minimumdefects;the SVM regularization coefficient determined difficulties, kernel function must satisfy macy's theorem and so on inherent limitations .Multiclass Relevance Vector Machine as a structural model using hierarchical Bayesian statistical learning algorithm proposed by the Damoulasy in 2008,compared with ANN and SVM[4]:M-RVM sparse stronger, low computational complexity, test time is short; direct multi-classification, and output membership probabilities for each category, and therefore can provide more information for decision making.

EEMD as a new signal processing method can handle nonlinear and non-stationary signals is well suited for acoustic signal processing and analysis. This article through the EEMD method for high voltage circuit breaker break-brake acoustic signal is decomposed, calculate the order of the intrinsic mode function energy and entropy as acoustic signal energy feature vectors, and enter into the M-RVM in high-voltage circuit breaker mechanical fault diagnosis.

M-RVM mode

In contrast with the original RVM, multiclass relevance vector employ the multinomial probit likelihood and provide probabilistic outputs for class membership.The M-RVM model structure is shown in figure1.



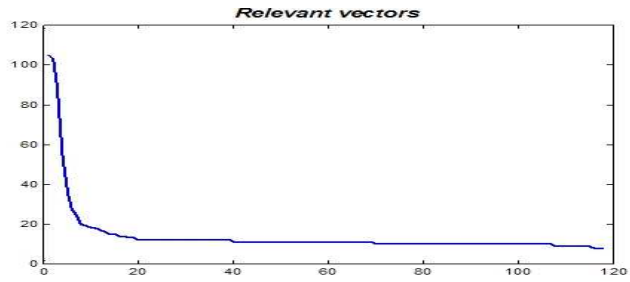


Fig.1 M-RVM model structure Fig.2 Iterative process

Training set is $X=\{x_i,t_i\}_{i=1}^{N}$, x_i $R^{N\times D}$, the category labels t $\{1,\cdots,C\}$, N is the total number of samples, D is the number of features , C is the number of categories. We apply kernel function K $R^{N\times N}$ in each feature space ,each row k_n of the kernel K expresses the tightness of the nth observations with other observed values.The learning process involves the inference of the model parameters $W^{N\times C}$, which by the quantity $W^T K$ act as a voting system to express which relationships of the data are important in order for our model to have appropriate discriminative properties.

Multiclass relevance vector by introducing auxiliary variables Y $R^{N\times C}$ that act as the regression targets of $W^T K$,we regress on Y with a standardized noise model[5],

$$y_{cn}|w_c,k_n \quad N_{y_{cn}}(w_c^T k_n,1) \tag{1}$$

The auxiliary variables are endowed with independent standardized Gaussian probability distributions to ensure statistical identifiability and enable closed-form iterative inference. The regressors W express the weight with which a data point "votes" for a specific class, the auxiliary variables Y express a class membership ranking system, given a sample n,we assign it to the class c with the highest y_{cn} . The continuous nature of Y allows not only multiple class discrimination via the multinomial probit link $t_n=i$ if y_{in} y_{jn} $j\neq i$ but also a probabilistic output for class membership via the resulting multinomial probit likelihood function ,

$$P(t_n=i|W,k_n)=\varepsilon_{p(u)}\left\{\prod_{j\neq i}\Phi\left(u+(w_i-w_j)^T k_n\right)\right\} \tag{2}$$

Where u~ N(0,1) and Φ the Gaussian cumulative distribution function. w_{nc} $N(0,\alpha_{nc}^{-1})$, α_{nc} priori parameter matrix elements in α and α_{nc} obey super-parameters *a, b* of the Gamma distribution[6].

Here we use a "top down"M-RVM model, first load the entire training set to the model and then continuously removed the sample which has no information from the entire training set,the iterative process as shown in figure2.

The training procedure involves consecutive updates of the model parameters based on a standard expectation maximization(E-M)scheme.First, according to E-step and Fig1 carried out α priori parameters update:

$$P(\alpha|W,a,b)\propto P(W|\alpha)P(\alpha|a,b) \tag{3}$$

Due to w_{nc} $N(0,\alpha_{nc}^{-1})$,and $\alpha\sim G(a,b)$, thus $\alpha_{nc}|w_{nc},a,b\sim G(1+a,w_{nc}^2+b)$ .So in E-step to update α by using the expectations of the Gamma distribution ,

$$\alpha_{nc}=\frac{1+a}{w_{nc}^2+b} \tag{4}$$

If for the *ith* sample we have α_{ic} 10^6 , then it is removed from A ,and update W_i,K_i,α_i . The weight parameters are updated based on the M-step.

$$\hat{W}=(K^T K+\alpha)^{-1}K^T Y \tag{5}$$

Finally,by using E-step and according to formula (6), (7) we update the auxiliary variable Y .If $c\neq i$,then

$$\tilde{y}_{nc} \leftarrow \hat{w}_c^T k_n - \frac{\varepsilon_{p(u)}\{N_u(\hat{w}_c^T k_n - \hat{w}_i^T k_n, 1)\Phi_u^{n,i,c}\}}{\varepsilon_{p(u)}\{\Phi(u + \hat{w}_i^T k_n - \hat{w}_c^T k_n)\Phi_u^{n,i,c}\}} \tag{6}$$

and $\Phi_u^{n,i,c} = \prod_{j \neq i,c} \Phi(u + \hat{w}_i^T k_n - \hat{w}_j^T k_n)$ .For class i have

$$y_{in} \leftarrow \hat{w}_i^T k_n - (\sum_{j \neq i} y_{in} - \hat{w}_j^T k_n) \tag{7}$$

According to equation (4) (5) (6) (7) at each iteration of the model parameters are updated.

Experimental Analysis

During the experiment, we use acoustic sensor for a ZN28A type vacuum circuit breaker were collected from normal state and fault simulation state in case of no-load break-brake acoustic signals (acquisition time of about 0.3s), simulated fault status including the base of a slightly loosen bolts base bolt looseness fault fault (I) and delay caused by insufficient lubrication fault fault (II), and use vector $[001]^T$,$[010]^T$,$[100]^T$ represents each state. Selection of acoustic sensors 502A-type pickups, this model pickups with high sensitivity, wide operating voltage range, low noise, low distortion, small features, built-in power supply reverse protection circuit, the connection is simple and convenient.

Feature Extraction. Based on the condition of high voltage circuit breaker break-brake acoustic signals(Fig.3) and ambient noise(Fig.5) power spectrum analysis(Fig.4,Fig.6) found that above 3000 Hz acoustic signal have with low energy, the 500 ~ 3000 Hz acoustic signals lasted for about 10 ms and are mainly concentrated in 0.02 s around, and contains a large number of high-voltage circuit breaker mechanical status information,below 500Hz low frequency components exist in the entire opening process.

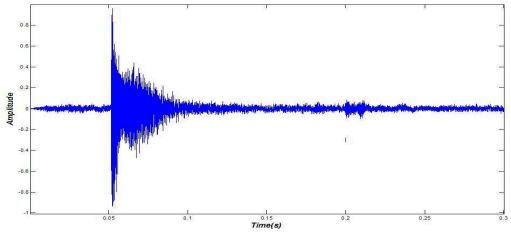

Fig.3 Acoustic signals in the process of high voltage circuit breaker points brake

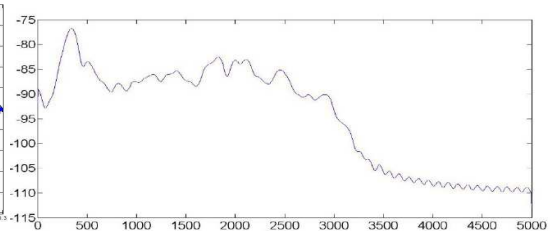

Fig.4 High voltage circuit breaker break-brake acoustic signal power spectrum

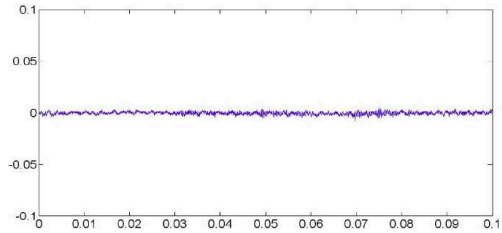

Fig.5 Points in the process of the brake environmental noise signal

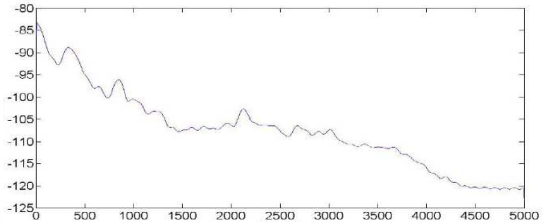

Fig.6 Environment in the process of high voltage circuit breaker points brake noise signal power spectrum

We here by EEMD method of 500 ~ 3000 Hz acoustic signal decomposition, the decomposed each IMF energy entropy as a high voltage circuit breaker fault diagnosis signal feature vector T.Due to the T value is bigger, in order to facilitate analysis and processing for normalized T. Some energy entropy is shown in table 1.

Tab.1 Some Energy Entropy

State	Energy entropy
Normal	0.9081 0.9695 0.9006 0.8986 0.9172 0.9357 0.9404 0.9452 0.7983 0.9925
Fault I	1.2240 1.2917 1.2004 1.2086 1.2153 1.2158 1.3374 1.2390 1.2475 1.2536
Fault II	1.1843 1.0832 1.0524 1.1516 1.1458 1.1821 1.0750 1.2301 1.1647 1.1368

Based On High-voltage Circuit Breaker Status M-RVM Classification. Experiments, we got 150 groups of experimental data(each state has 50 groups), in order to avoid skewed data problem, among them the 105 group as the training sample(each state has 35 groups),the remaining as test sample.

In order to prove the M - RVM can be used in fault diagnosis and has a good diagnosis effect at the same time, we put the M - RVM and nu - SVC support vector machine (SVM) is used for high voltage circuit breaker mechanical fault recognition, and compare the result.Two kinds of kernel function of the model adopts the radial basis function (RBF),For nu - SVC we adopt cross validation and PSO method of penalty factor C and kernel parameter g optimization, optimal parameters $c = 4.77$, $g = 1.41$ is shown in figure8.

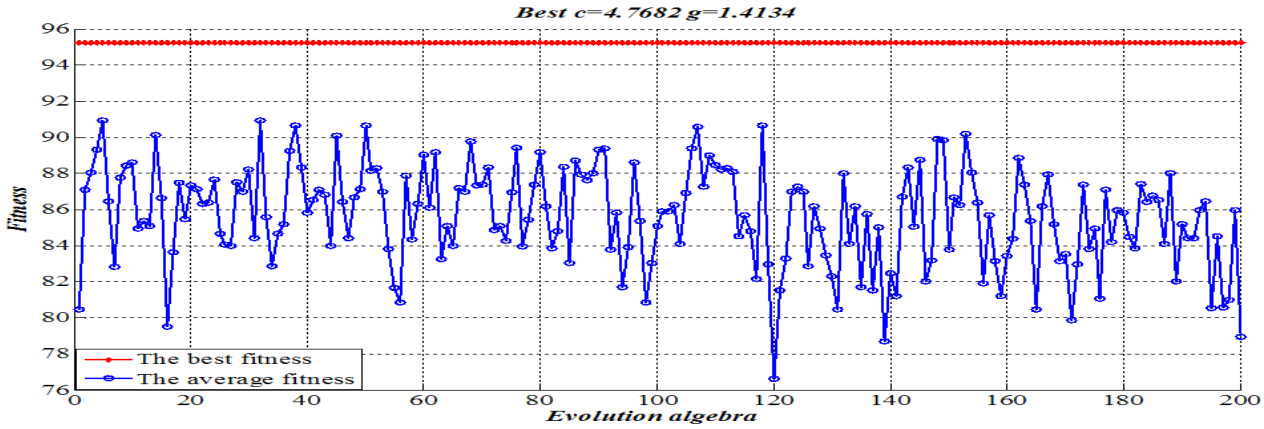

Fig.8 PSO parameters optimization

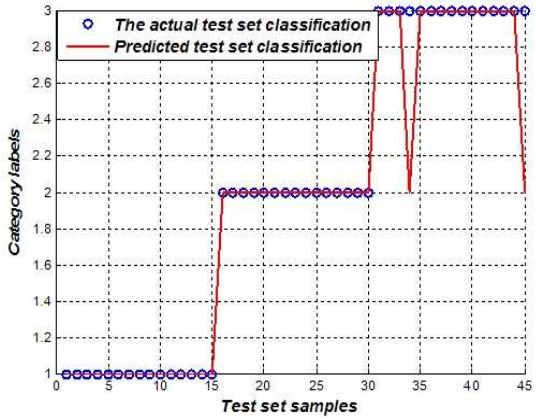

Fig.9 Result of SVM

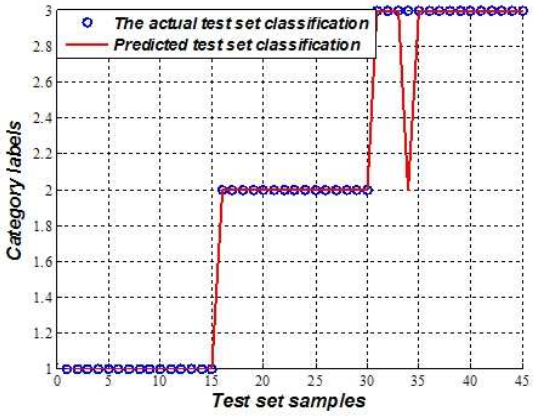

Fig.10 Result of M-RVM

The result of SVM and M-RVM are shown in figure 9 and figure10.Table 2 lists the high voltage circuit breaker mechanical fault diagnosis accuracy. Through the analysis of table 2 shows the method proposed in this paper can well used in high voltage circuit breaker mechanical fault diagnosis.

Tab.2.Results Are Different Methods To Test Set .

Failure type	Training sample	Test sample	Accuracy%	
			SVM	M-RVM
Normal	35	15	100	100
Fault I	35	15	100	100
Fault II	35	15	86.7	93.3
Counter	105	45	95.6	97.8

Not only M-RVM gives the diagnosis, but also the output of the circuit breaker corresponding probability P of each state, which provides the basis for further inspection for the circuit breaker. Part of the probability P as follows:

$$P = \begin{bmatrix} 1.0000 & 0.0000 & 0.0000 \\ 0.3575 & 0.3215 & 0.3210 \\ 0.2369 & 0.5264 & 0.2367 \\ 0.1142 & 0.7218 & 0.1640 \\ 0.1461 & 0.2144 & 0.6395 \\ 0.0006 & 0.3611 & 0.6384 \end{bmatrix}$$

Conclusion

This paper EEMD method is applied to decompose the brake process of high voltage circuit breaker acoustic signals, the decomposed each IMF energy and its energy entropy as a state of high voltage circuit breaker different feature vector.Then combined with M - RVM is applied to high voltage circuit breaker mechanical fault diagnosis, and gives the concrete realization method of the model and diagnostic process, through the experimental analysis of the fault diagnosis model has a good diagnosis effect.

Keywords: Motion Parameters of the Moving Contact, K-means Clustering Algorithm, Image Segmentation,

Abstract. High voltage circuit breaker's motion parameters of the moving contact is one of the key performance indicators in the evaluated of breaker. By means of extracting color features of *LW10B-252* circuit breaker by image segmentation, then determining its center point of the minimum circumscribed rectangle, getting the movement distance of center point and the use of time in adjacent images, realization motion parameter's measurement of the moving contact. This paper presents a algorithm based on improved k- means clustering algorithm to extract the color characteristics of the mechanical linkage of breaker, at the same time contrast with classical *OTSU* method and *RGB* color segmentation method. Experimental results show that the k- means clustering algorithm have a better segmentation result.

Introduction

In power system, the mechanical properties parameter of high voltage circuit breaker (*HV*) is an important basis of judgment and guarantee the normal work of the circuit breaker, it has a close relationship with safe and reliable of power grid [1]. In the test of high voltage circuit breaker's mechanical characteristic parameters, the parameters about breaker's moving contact is very important. So far, the measurement of the parameters is adding sensor, the way of 'contact' measurement is inevitable fixture installation, it is time-consuming and tedious, the most important thing is the installation been fixture affect the accuracy of the test results directly. At the same time because of variety of sensor type, its standard is not unification, the application of these methods can't be universal. So looking for a reliable, stable, convenient, rapid and accurate testing method is necessary.

At present, computer vision is widely used in the field of the electric power system fault and had get fruitful results [2].However It has a less application in the parameters testing of high voltage breaker's moving contact, and such way is not systematic and normalized, at the same time the key points in the selected aspects of measuring target is not too much introduction. This paper proposes a systematic way based on k-means clustering algorithm image segmentation. The first is get movement image of mechanical linkage by precise camera, to extract the study area of the mechanical linkage through improved k-means clustering algorithm image segmentation, calculating the external rectangular, with its center as a measurement of punctuation, finally determine the position of the center coordinates and the corresponding time, getting the coordinates and the change of the time, at last determine the trajectory by mathematical fitting method.

Image segmentation based on improved k-means clustering algorithm

The choice of the coordinate space

K- means clustering algorithm is a real-time unsupervised clustering algorithm ,it is put forward by Mac Queen, it has a simple principle and easy to deal with large amounts of data. Before using K-means clustering algorithm image segmentation we should to specify the number of clustering, the initial value of initial clustering center, the number of iterations or convergence condition, according

certain similarity measure criteria to assign each data to recently or similar clustering center, then formation of class, choose clustering center again, through the repeated iteration until convergence or end when the largest number of iterations is reached.

The color image obtained by the camera is belongs to *RGB* color space. *RGB* color space has a larger defect, it is that the brightness of the color cannot be separated with the chromaticity measurement. Although the color of the study area is fixed, but the change of light intensity can lead to the change of chromatic spaces, it's a certain effects on the image segmentation based on color. But the *L * a * b* color space is good to avoid the defect. *L * a * b* color space separate color and brightness thoroughly so that it overcome the influence of illumination of color differentiation. At the same time, the experiment of the study area is red, Match with magenta in *+a** axis.

The choice of initial clustering center and the way of distance measure

K-means clustering are for image segmentation, the algorithm process:

(1) Selecting a picture of a size of *m * n*, and *k* pixel as a kind of initial cluster centers of the clusters, *k = 1, 2, 3...k*;

(2) Calculating distance each pixel point with cluster center *s= 1, 2, 3...m t= 1, 2, 3...n, j=1，2, 3…k*

$$d(x_{(s,t)}, \mathrm{c}_j(I)) = \min\left\{d(x_{(s,t)}, c_j(I)), j = 1,2,...,k\right\} \tag{1}$$

(3) Calculate new clustering center

$$c_j(I+1) = \frac{1}{N_j}\sum_{i=1}^{N_j} x_{(s,t)} \tag{2}$$

(4) Judge: if $c_j(I+1) \neq c_j(I), j = 1,2,3,...,k,$, returned; Otherwise, the end of the algorithm.

K-means clustering algorithm is a continuously iterative process, the main factors of influencing the clustering results are as follows: number of clustering *k*, the initial clustering center c_j and the distance between objects $d(x_{(s,t)}, c_j(I))$. By the actual visual characteristics of the human eye, the color order of human eye can distinguish generally less than 60, but the number of class of color image segmentation has a lot smaller than this value. Actual class number is determined according to the specific application environment and the aim of segmentation. Due to the objective function minimization as a condition of the end of the clustering in k-means clustering, if random selection the initial clustering center, the k-means clustering algorithm is easy to get into the local optimum or has a wrong clustering results. The algorithm has a strong sensitivity to the initial clustering center, different initial clustering center could lead to a completely different effect. So the choice of initial clustering center and the size of object's distance is a key to the success of the k-means clustering algorithm.

The characteristics of the k-means clustering algorithm shows that the effect of clustering quality mainly depends on the initial clustering center and distance between the selected object, based on the circuit breaker image characteristics, from the initial clustering center and the optimal selection of weighted Euclidean distance $d(x_{(s,t)}, c_j(I))$ two aspects to improve k-means clustering algorithm.

There are many way to choice initial clustering center ,such as experienced selection method, the classification of the stochastic averaging, data sampling method, the density method, and the genetic algorithm, simulated annealing algorithm and particle swarm optimization [3]. Such ways solve the problem of the initial clustering center optimization to a certain extent, but at the same time there are some problems such as the algorithm complexity, it lead the algorithm has a very slow convergence speed, sometimes even no convergence. So above methods is not appropriate color image segmentation. But if the selection of the initial clustering center can satisfy the following two conditions. It is a very good solution to solve the problem of clustering center selection.

(1) There is one and only one cluster centers in each class;

(2) The choice of initial clustering center distance color as far as possible big and should be close to the center of the class.

In view of the above two conditions and the features that it is easy to distinguish image color, under the premise of class number *k* has been determine, order to extract each regional color target classification statistics of every image as the initial clustering center. In order better to solve the problem of color difference because of visual perception, difference illumination and natural conditions. At the same time in order to improve the accuracy of recognition, it should be further enlarge sample target classification and statistics calculate the initial clustering center in color area.

First of all, it necessary to establish an image library, the image library contains a variety of color classification. Combination *L *, a *, b ** coordinate characteristics with circuit breaker image characteristics to improve the clustering center. Classification of color image library is established, image library is the clustering center, among them

$$l_i = \frac{1}{\sum_{j=0}^{p_i} M_{i,j} * N_{i,j}} \sum_{j=0}^{p_i} \sum_{y=0}^{N_{i,j}-1} \sum_{x=0}^{M_{i,j}-1} f_l(x,y) \tag{3}$$

$$a_i = \frac{1}{\sum_{j=0}^{p_i} M_{i,j} * N_{i,j}} \sum_{j=0}^{p_i} \sum_{y=0}^{N_{i,j}-1} \sum_{x=0}^{M_{i,j}-1} f_a(x,y) \tag{4}$$

$$b_i = \frac{1}{\sum_{j=0}^{p_i} M_{i,j} * N_{i,j}} \sum_{j=0}^{p_i} \sum_{y=0}^{N_{i,j}-1} \sum_{x=0}^{M_{i,j}-1} f_b(x,y) \tag{5}$$

Among them： p_i as belonging to the number of the *i* samples, $M_{i,j}$ $N_{i,j}$ as belonging to the *i* classification of the size of the j sample; $f_l(x,y)$， $f_a(x,y)$， $f_b(x,y)$ as belonging to the values of corresponding samples pixels $f(x,y)$ in the space of *L * a * b.*

K-means clustering algorithm use Euclidean distance function to measure similarity between data points commonly. The calculation method of the traditional Euclidean distance think that all attributes of the data set in the clustering effect is the same, using this method to calculate the Euclidean distance can not accurately reflect the similarity between samples. According to human visual characteristics, tonal information is the main reason of the human eye to distinguish different colors, and then is the degree of saturation and brightness information. Therefore when using Euclidean distance as the distance criteria, actually neglected the role of the object component, after we are introduction of the weighted coefficient, on the one hand, it can give full play to the role of the correlation $d(Y_j, c_i)$, on the other hand can optimize clustering results by adjusting relevance weights. Weighted Euclidean distance measurement of correlation is:

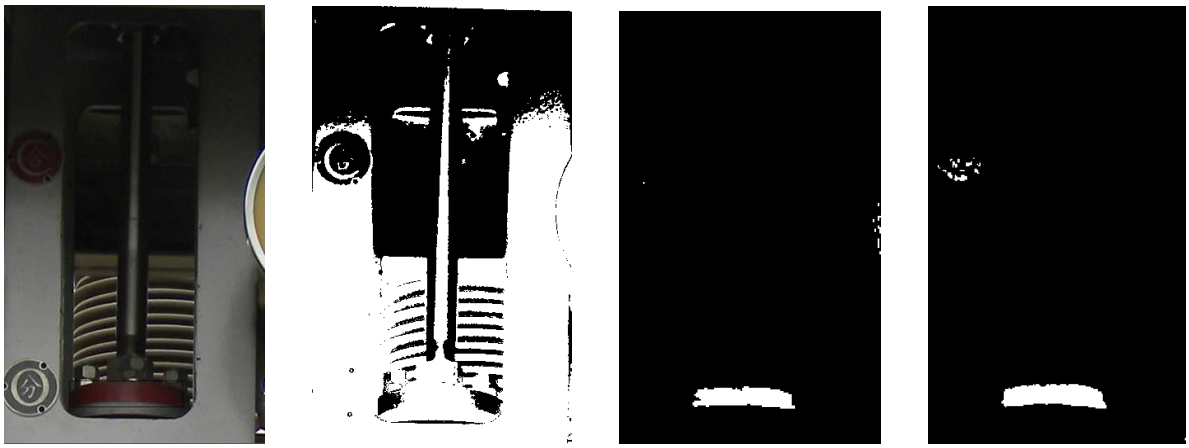
$$d(Y_j, c_i) = \sqrt{[\alpha(l_j^y - l_i^c)]^2 + [\beta(a_j^y - a_i^c)]^2 + [\gamma(b_j^y - b_i^c)]^2} \tag{6}$$

Among them: $i = 1,...,k, j = 1,...,n$； Y_j as belonging to the image of a pixel； c_i as belonging to the cluster center； α, β and γ as belonging to the weights of three components； l_j^y, a_j^y, b_j^y, l_i^c, a_i^c and b_i^c as belonging to the three color component respectively [3].

Due to the *L * a * b* color space separate color and brightness thoroughly, it overcome influence of illumination of color differentiation, the factors affecting the size of the weighted Euclidean distance is mainly on the **a* and **b*, the weighted of and **b* should as far as possible big, and because the object of study mainly distributed on **a* coordinates, so it should have a maximum value, after repeated experiments, the best values are: 0.01, 1.00, 0.1.

Computer simulation results and analysis

According to the above model and algorithm, this paper uses the *Matlab* programming to illustrate the effectiveness of the k-means clustering algorithm, comparing it with classical *OTSU* segmentation algorithm and segmentation algorithm based on *RGB* respectively. We use a *LW10B - 252* type circuit breaker image as the research object. The image size of it is 2300 * 3880, the results as shown such Fig. 1.



(a) original image (b) the classical *OTSU* (c) *RGB* (d) this paper

Fig.1 :The segmentation result of different methods

Fig.1(a) is mechanical connecting rod image which is connect to the moving contact, Fig.1(b) is the classic *OTSU* segmentation results, due to the complexity of the background color, the image segmentation effect is poorer. Fig.1(c) is a *RGB* segmentation results which is based on *RGB* color depth different. Fig.1(d) is the segmentation results of this paper. Form the figure we can find Fig.1(c) lose more pixels than Fig.1(d) in the target area, so that there is a bigger influence to measurement accuracy of the experimental data. Through the above analysis can know, k-means clustering algorithm has a better image segmentation in complex background, at the same time better retain the image edge details.

The determination of segmentation evaluation index

In this paper, by measuring the mechanical movement of the connecting rod to indirect gain movement parameters of the moving contact, thought above method to segment the target area, to calculate the target area of the minimum circumscribed rectangle, with the center of the rectangle as the target, by measuring the displacement of the target to determination motion parameters of the moving contact. For this purpose, the segmentation result affects the final experiment results directly, in view of the different types of images, the final segmentation quality evaluation indexes are different. In order to obtaining minimum circumscribed rectangle by the segmentation algorithm, this paper proposes a new evaluation criterion, to judge a good segmentation effect, the result as shown.

We can get a rectangular angle of each pixel location by the experiment, in the upper left corner as the origin of coordinates, the rectangular coordinates of original image and the result map as follows

Table 1 Rectangular coordinate point coordinate

	Upper left corner coordinates of rectangular	Bottom right corner coordinates of rectangular	Rectangular center coordinates
Original image	（631.3331）	（1595.3563）	（1113.3447）
RGB	（645.3387）	（1544.3597）	（1095.3492）
This paper	（648.3358）	（1590.3587）	（1119.3473）

Their corresponding coordinates are painted by the same proportion in the coordinate system is shown in Fig.2. The red rectangle is correspond to Fig.1(a) rectangular area, it is the original image area, blue rectangle is correspond to Fig.1 (c) rectangular area, the green rectangle is correspond to Fig.1 (d) rectangular area.

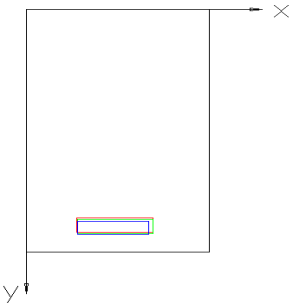


Fig.2 The projection of the axis of Fig.1

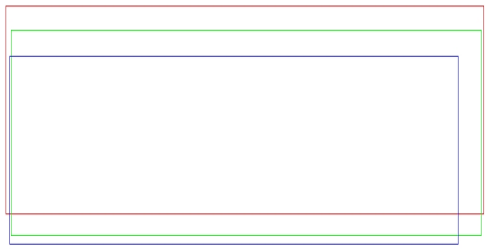

Fig.3 Rectangular area enlargement results of Fig.2

The Fig.3 shows the k-means clustering algorithm has a better result, rectangular area is closer to the original image, it mean than the loss of pixel is less, and the rectangular center is closer to the original image, so it has a small effect on the experimental results.

Conclusions

Experiments show that k-means clustering algorithm in the process of computer vision measure circuit breaker parameters play a key role, it ensures the accuracy of the results and provides important data support for the subsequent circuit breaker on-line monitoring and diagnosis. Although the function and structure of circuit breaker in the actual has a big difference, the circuit breakers have similar mechanical linkage structure connecting to the moving contact. We can add appropriate red rectangle icon or *LED* lighting with a rule shape on the mechanical linkage structure，this provides universality for k-means clustering algorithm.

Keywords: Current source inverter, CSI-SPWM, CSI-TPWM, CSI-HVUSSPWM

Abstract. This paper presents a new *csi-hvusspwm* technology with many advantages such as the better output waveforms and the high utilization ratio of dc voltage based on the study of the *csi-spwm* technology and *csi-tpwm* technology. Theoretical derivation and modulation principle of *csi-hvusspwm* technology are described in detail. Finally, the simulation results validate the feasibility and effectiveness of this novel technology.

Introduction

With the development of the superconducting magnetic energy storage technology, current source inverter has become one of the most widely used inverter topology in AC drive and renewable energy power generation and other fields due to its advantages such as simple topology structure and reliable short-circuit protection [1-7]. At present, the mature modulation methods usually have selective harmonic elimination (*she*) technology, trapezoidal pulse width modulation (*tpwm*) technology, sinusoidal pulse width modulation (*spwm*) technology and so on [8]. However, sinusoidal pulse width modulation technology can produce a better output waveform, but requires a higher sampling frequency, so that the switching frequency of inverter is higher. Generally, the switching frequency is low for high-power inverters, and spwm-inverter with low switching frequency will produce huge amounts of low-order harmonics and a narrow pass-band, greatly reduce the performance of the control system [9]. Compared with SPWM technology, the output waveform of *tpwm* technology is not good, but the utilization ratio of the dc current is high and the switching frequency is low. In order to make *csi* has the better modulation output waveform, this paper presents a new modulation method which is high voltage utilization similar sinusoidal pulse width modulation (*hvusspwm*) technology. *Hvusspwm* technology has the advantage of *tpwm* and *spwm*.

Current Source Inverter Circuit

Fig. 1 shows the topology of a typical three-phase current source inverter, which consists of a current source, the load for star connection, six *gto* power switching elements. Three-phase *csi* principles: the state of the power switches $s_1 \sim s_6$ is expressed with bi-logic variables 0 and 1, which 0 for off and 1 represents conduction. Compared to the voltage source inverter (*vsi*), the working mode of *csi* requires one and only one switch is turned on at the same time in upper and lower half-bridge. The switch state variables satisfy the following constraints: $s_1+s_3+s_5=1$, $s_4+s_6+s_2=1$. This paper introduces the trio-logic phase switch status variables for describing the working state of *csi*.

$$S_j = \begin{cases} 1 & \text{The upper bridge arm switch turn-on; the lower bridge arm switch turn-of} \\ 0 & \text{The upper and lower bridge arm switches turn on or turn-off} \\ -1 & \text{The lower bridge arm switch turn-on; the upper bridge arm switch turn-off} \end{cases}$$

Where j=a, b, c

The relationship of phase switch status variables and a single switch state meet: $S_a=S_1-S_4$, $S_b=S_3-S_6$, $S_c=S_5-S_2$.

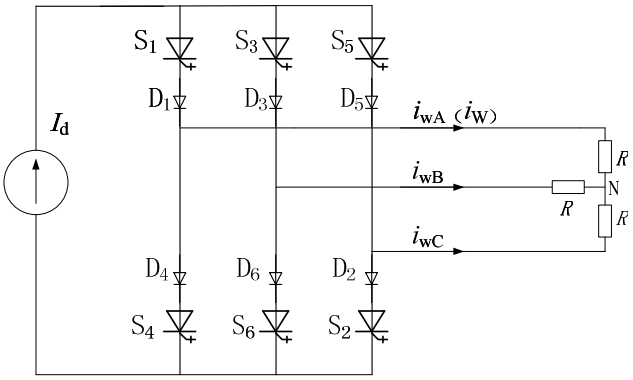

Fig. 1 Circuit topology of current source inverter

Current Source Inverter Modulation Technique

The requirements of three-phase *csi* for three-phase *pwm* signal is only two switches turn-on, which one lies in the upper bridge arm and the other lies in the lower bridge arm at any time (except during commutation). If only one switch is turned on, the current will lose the continuity and the current source will produce an extremely high voltage which will damage to the switches. If more than two switches are simultaneously turned on, *pwm* current will no longer meet the defined switching waveform. This is the important reason that the three-phase *csi-pwm* control becomes more complex than voltage-type [10].

Trapezoidal PWM. Trapezoidal pwm (*tpwm*) technology is a relatively common modulation method of *csi*. Fig. 2 shows *tpwm* schematic. Trapezoidal pwm technology obtains the symmetrical pwm waveform of the gate driving signal v_{g1} of the power switch S_1 in the first half cycle by comparing the trapezoidal modulating reference waveform v_m with the triangle carrier waveform v_{cr} in the oblique section of 0^0-60^0 and 120^0-180^0. The pwm waveforms of the power switches S_1~S_6 gate driving signal are queued in order delay 60^0. Then the pwm waveform of the current i_w is obtained by comparing the pwm waveforms of the gate driving signals v_{g1}~v_{g6}.

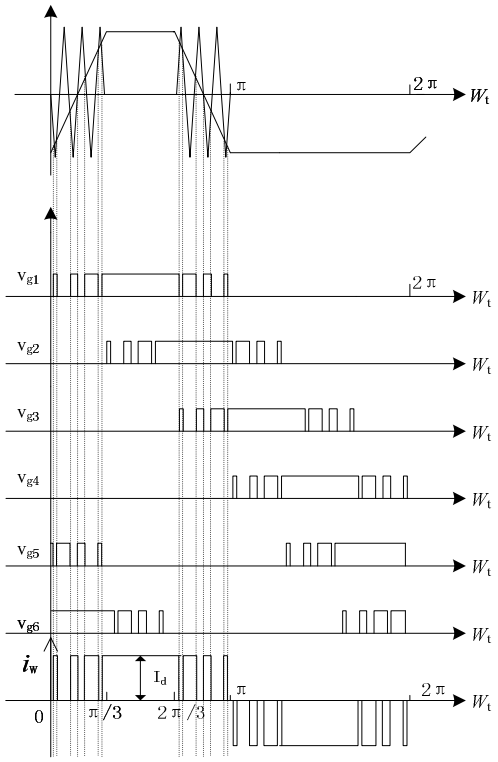

Fig. 2 Trapezoidal pwm modulation schematic

Sinusoidal PWM. As is shown in Fig. 3, *csi-spwm* technology adopts the control strategy of dynamic trio-logic *spwm*, which transforms the bi-logic *spwm* signals F_a, F_b, F_c into the trio-logic signals Y_a, Y_b, Y_c. Transform relations as follows[11]:

$$\begin{bmatrix} Y_a \\ Y_b \\ Y_c \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ -1 & 0 & 1 \end{bmatrix}\begin{bmatrix} F_a \\ F_b \\ F_c \end{bmatrix} \tag{1}$$

The control strategy meets the requirements of three-phase *csi* for three-phase pwm control signal, so the relationship between the output current and the input modulation signal is a linear, which to ensure the normal operation of three-phase *csi*.

HVUSSPWM. The comparative analysis of *tpwm* and *spwm* shows that the output current waveform of *csi* using *spwm* is better, but the switching frequency is higher and the *dc* current utilization is lower; while the *dc* current e utilization of *csi* using *tpwm* is higher and the switching frequency is lower, but the output current waveform is worse. A new *hvusspwm* modulation method is proposed for achieving better waveform output and higher utilization ratio of *dc* current based on the above analysis. As is shown in Fig. 4, *spwm* is used within 0^0~60^0, 120^0~240^0, 300^0~360^0 and Similar *tpwm* is used within 60^0~120^0, 240^0~300^0 in each cycle of the reference waveform.

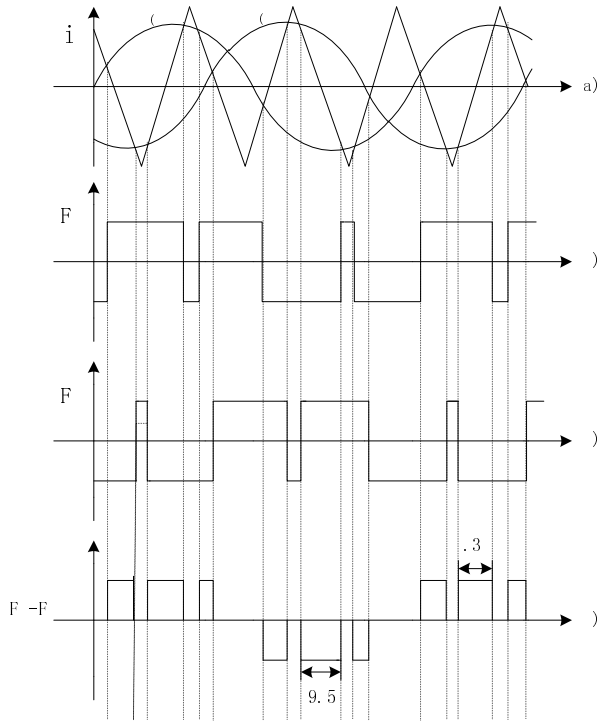

Fig. 3 SPWM modulation schematic

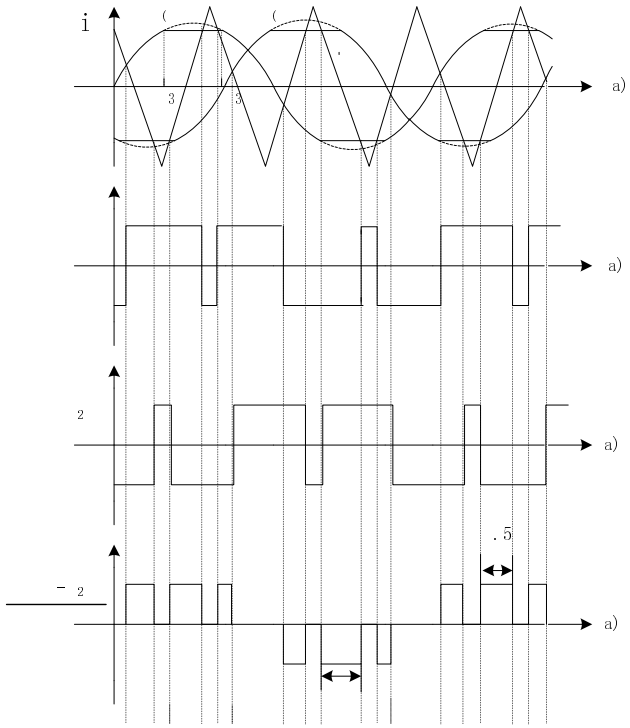

Fig. 4 HVUSSPWM modulation schematic

By comparing Fig. 2, Fig. 3 and Fig. 4, we can know that the switch sampling of *hvusspwm* technology is more uniform than one of *tpwm* technology; the dc current utilization rate of *hvusspwm* technology is higher than one of *spwm* by comparing the pulse width of the same position (10> 9.5,4.5> 4.3) in Fig. 3 and Fig. 4. Therefore, *hvusspwm* technology is a better modulation method in *csi*.

Simulation results and Experiment results

In the paper, simulation experiments are carried out in accordance with three-phase *csi* topology of Fig. 1. Because the *csi* current and the load don't matter, for the sake of discussion, the load in the simulation is purely resistive load. Parameters of simulation system are set as follows: I_d=1000A，

R=1 Ω, output current frequency is 20 Hz, Triangular carrier frequency is 500Hz, M=1. The simulation waveforms (A phase) and the spectrum (A phase) of *tpwm*, *spwm* and *hvusspwm* are respectively shown in Fig. 5, Fig. 6, Fig. 7. The experimental data of *tpwm*, *spwm*, and *hvusspwm* are shown in Table 1.

Table 1 The data sheet of simulation experiments

Modulation technique	Fundamental amplitude(V)	% of Fundamental									
		5	7	11	13	17	25	29	31	35	37
TPWM	1052	0.39	0.2	0.03	0	0.12	1.06	2.33	2.34	1.06	0.43
SPWM	868	0.03	0.13	0.03	0.02	0.02	0.06	0.05	0.14	0.07	0.06
HVUSSPWM	943	0.28	0.09	0.1	0.02	0.04	0.01	0.07	2.9	0.04	0.02

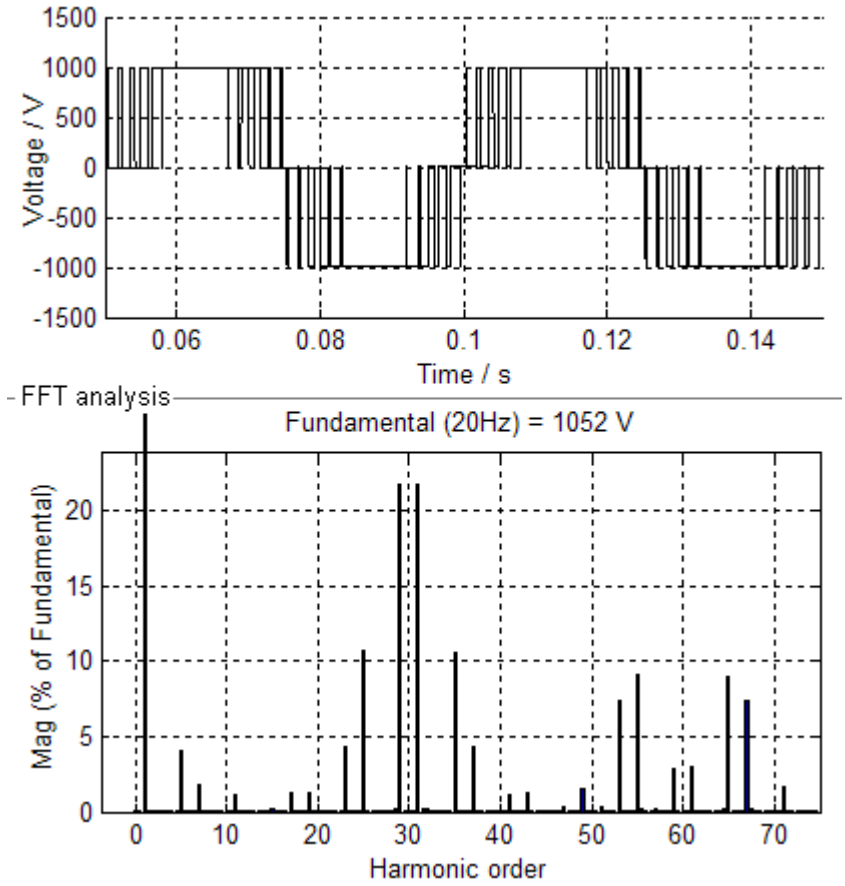

Fig. 5 Output current waveform and the spectrum of TPWM at 20 Hz

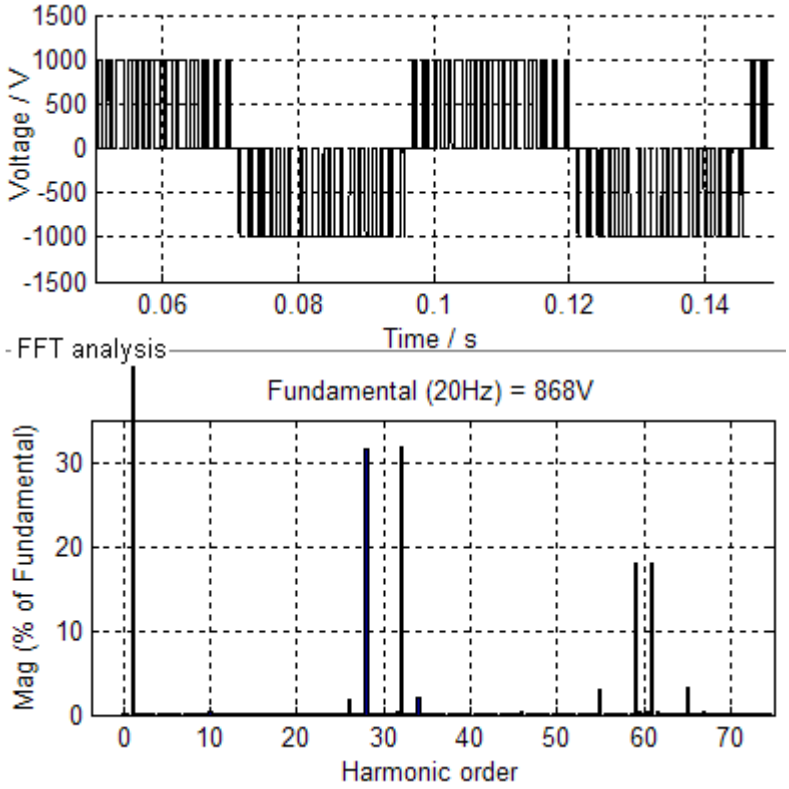

Fig. 6 Output current waveform and the spectrum of SPWM at 20 Hz

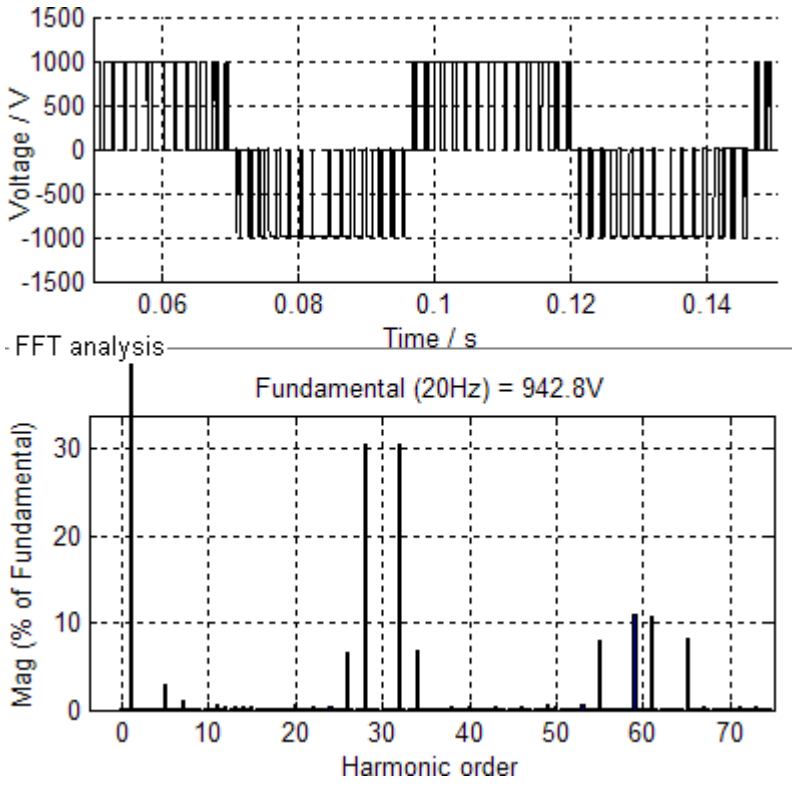

Fig. 7 Output current waveform and the spectrum of HVUSSPWM at 20 Hz

By the comparative analysis of the experimental data, we know that the relative content of 25th harmonic and the following harmonics of *hcusspwm* technology are so small that the output current waveform is better, and the utilization ratio of *dc* current is high. Therefore, *hvusspwm* technology is a better *csi-pwm* technology.

Summary

Hvusspwm technology achieves the output of the high utilization ratio of *dc* current and the good waveform in a relatively lower switching frequency, so that it is a better modulation method for the application of *csi* in the field of high-voltage and large-capacity variable frequency drive.

Abstract.The high-voltage DC power supply for electron beam furnace belongs to Special Power Supplies. It has the characteristics of high voltage and high power. At present, the high voltage DC power supplies for electron beam furnace are mostly controlled by the silicon controlled rectifier operated by power frequency, which not only has the disadvantages of large volume but also doesn't has the characteristics of anti-short circuit capacity, rapid protection and restart. This characteristic affects the service life of the electron gun and the quality of the smelting. To solve the above problems, a high frequency resonant converter has been used in high voltage power supply, reduced the volume of power supply and the switching loss, and achieved rapid protection and restart. Simulation and experimental research show that the power supply can meet the requirement of smelting.

Introduction

The electron beam (EB) furnace is a device used for smelting high-reactivity metal under low vacuum. It mainly consists of furnace body, the electron gun, high-voltage DC power supply and control system, etc. [1] The high-voltage DC power supply is for accelerating electrons produced by electron gun. Electrons are accelerated in the electric field formed by high-voltage DC power supply, and electron beam is formed by the focusing and deflection coil. The electron beam with high-speed hits the metal surface, and the electrons'kinetic energy converts thermal energy, which can melt metals. Traditional Boost converters with industrial frequency transformer control the output voltage by controlling the thyristor conduction angle, which not only have large volume of transformer and filter but also have large voltage ripple. This study is based on the DSP control digital high-frequency high-voltage power supply. It is composed by thyristor rectifier and IGBT inverter. The structure of the inverter is full-bridge series resonance. Inverter works with constant frequency. High voltage controlled by DC-bus voltage.

Circuit Topologies and Working Principles.

Topology Structure of High Voltage DC Power Supply.

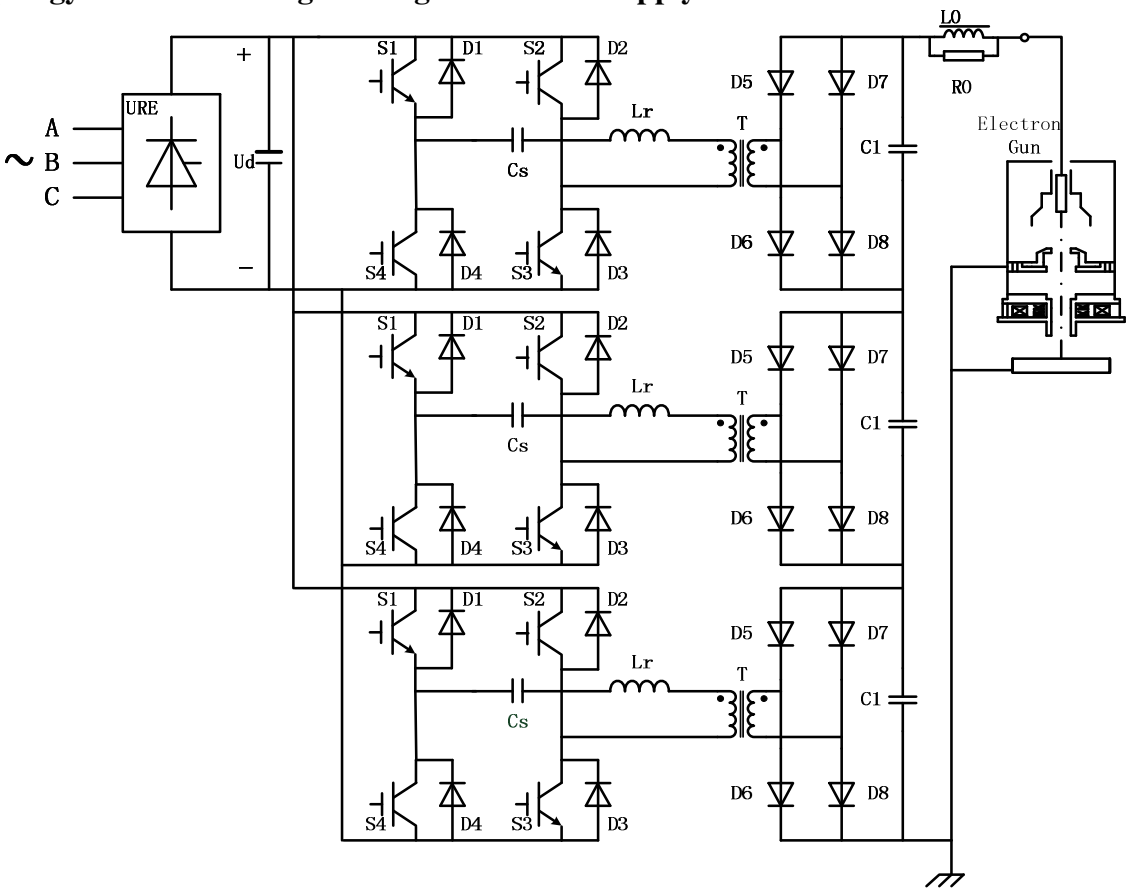

Fig. 1 The main circuit topology structure

The topology structure shown in figure 1 is mainly composed of three-phase thyristor controlled rectifier (URE), high-frequency inverter, high-frequency high-voltage transformer, high voltage silicon stack, high-voltage filter capacitor, high-voltage current-limiting inductor and electron gun. It has the energy delivered mode of AC-DC-AC-DC. We get the DC bus voltage U_d by thyristor controlled rectifier, which input is Three-phase 50Hz AC voltage（AC-DC）. High frequency inverter converts the DC power into the low-voltage AC power（DC-AC）. High-frequency high-voltage transformer takes the low voltage and changes it to high voltage. High voltage silicon stack connected to the output terminals of transformer, and converts high-voltage AC power to high-voltage DC power（AC-DC）. Take the input-parallel output-series based on full-bridge topology for reducing the transformer ratio, which can reduce the distributed capacitance of transformer. L_0 is the choking-winding for limiting the di/dt value at the time of short-circuited.

Operation Principles of the Inverter.

According to the relationship of the resonance frequency of the inverter f_r and switching frequency f_s, there are three operating modes of series resonant inverter[2][3]:

(a) $f_s < 1/2\, f_r$

The inverter works in discontinuous current mode (DCM). Switches turn on and off under ZCS condition. It can easily achieve soft-switch in all range, and has the constant-current characteristics.

The disadvantage of this mode is:

(1). The DC-bus voltage utilization ratio is low, which can lead to the increase of transformer ratio.

(2) Peak current through switches is high under the condition of the same power output.

(b) $1/2\, f_r < f_s < f_r$

The inverter works in current continuous mode (CCM1). Switches can turn off at zero voltage, but hard-opening.

(c) $f_s > f_r$

The inverter works in current continuous mode (CCM2). Switches can turn on at zero current, but hard-off.

Steady-State Analysis of High-Frequency Inverter

For the convenience of analysis, assume that the following conditions are established [4].

1. The resonance frequency f_r is equal to the switching frequency f_s.
2. Regardless of the dead zone, Duty ratio D = 50%.
3. Turn off one couple of switches and turn on another couple（S1, S3 or S2, S4）at the same time, when the resonant current reaches zero at the end of the half resonant period. the after-flow diode keeps closed.

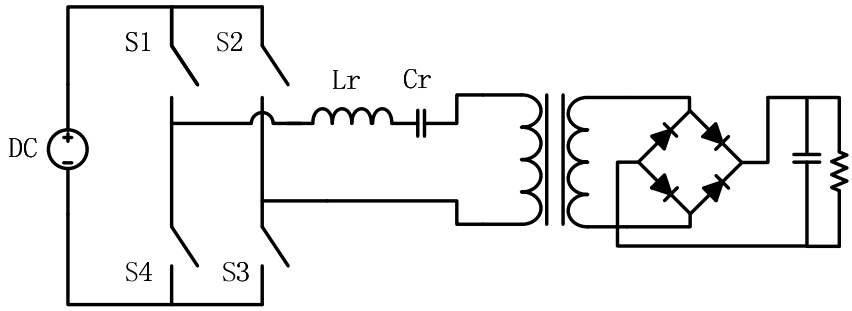

Fig. 2 A series resonant converter incorporanting a full-bridge switch network.

From the perspective of the energy transfer, resonant converters transfer energy relying on fundamental wave. Thus, the fundamental wave method can be used for steady-state analysis.

The input voltage of the L-C resonant network is square wave voltage (frequcncy is switching frequency f_s, amplitude is DC-bus voltage U_D, duty cycle is 50%). its input voltage waveform can be expressed in the Fourier series:

$$v_s(t) = \frac{4U_{in}}{\pi} \sum_{n=1,3,5} \frac{1}{n} \sin(n\omega_s t) \tag{2-1}$$

The fundamental component is (showed in Fig.3):

$$U_{base} = \frac{4U_{in}}{\pi} \sin \omega_s t \tag{2-2}$$

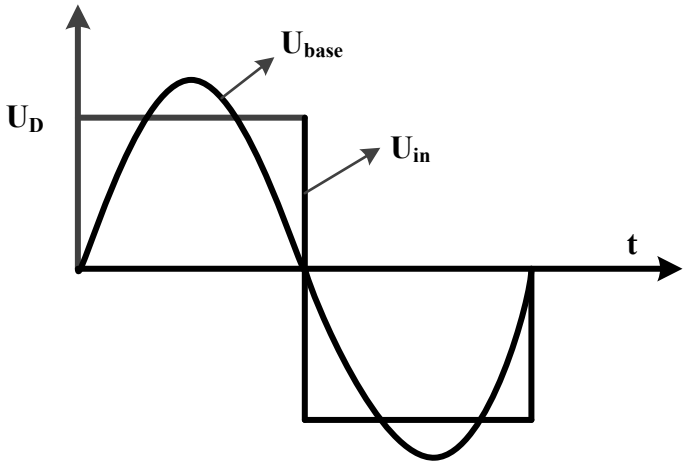

Fig. 3 Switch network output voltage U_{in} and its fundamental component U_{base}

Where $\omega_s = 2\pi f_s$, and the amplitude of U_{base} is $\frac{4U_{in}}{\pi}$.The transfer function of the resonant network can be described as:

$$H(j\omega) = \frac{1}{\sqrt{1+Q^2\left(\frac{\omega_s}{\omega_r}-\frac{\omega_r}{\omega_s}\right)^2}} \qquad (2-3)$$

Where $Q = \frac{\omega_r L_r}{R_e}$, $\omega_r = \frac{1}{\sqrt{L_r C_s}}$, $\omega_s = 2\pi f_s$, $R_e = \frac{8}{\pi^2}R_0$. R_e is the equivalent load of the transformer and rectifier-filter network. R_0 is the equivalent load Converted to the primary winding of transformer.

When $\omega_s = \omega_r$, The resonant network has the biggest voltage gain that equals 1. Resonance current is:

$$i_R(t) = \frac{U_{base}}{R_e} = \frac{\pi U_{in}}{2R_0}\sin\omega_s t \qquad (2-4)$$

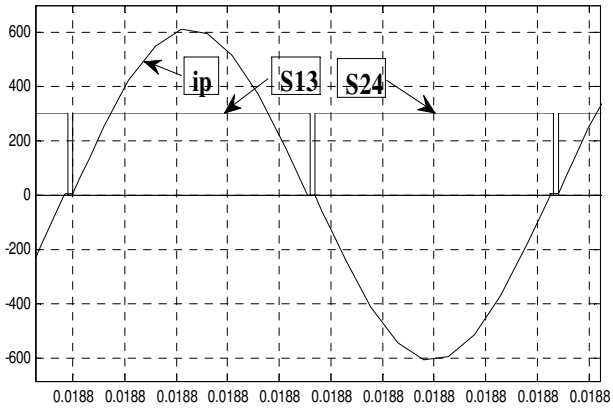
Voltage Regulating Methods

There are three basic control methods (PWM, PAM, and PFM) and their combined methods. Take the PAM method in this paper. The inverter works with constant frequency. High voltage controlled by DC-bus voltage. Switching frequency is close to resonance frequency, which is Slightly smaller than the resonant frequency. Switches can turn off at zero voltage, and turn on at very low resonant current.

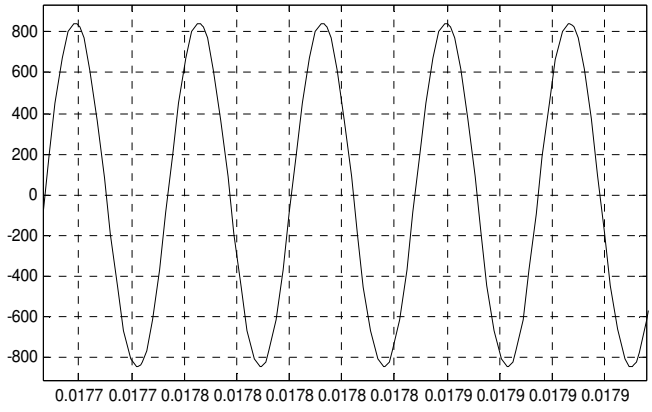
Simulation research and analysis

Simulation Conditions

DC-bus voltage U_{in}=400V. Resonant capacitance Cs=5.23uF. Resonant inductance L_r=10uH. Resonant frequency f_r=22kHz. Resonant period T_r=45us. Switching frequency f_s=21.27k. Switching period T_s=47us. Duty ratio D=49%. Transformer ratio n=25. Load resistance R_L=2000Ω.



(Fig. 4 Ip is resonant current; S13and S24 is the driving waveform of switches)

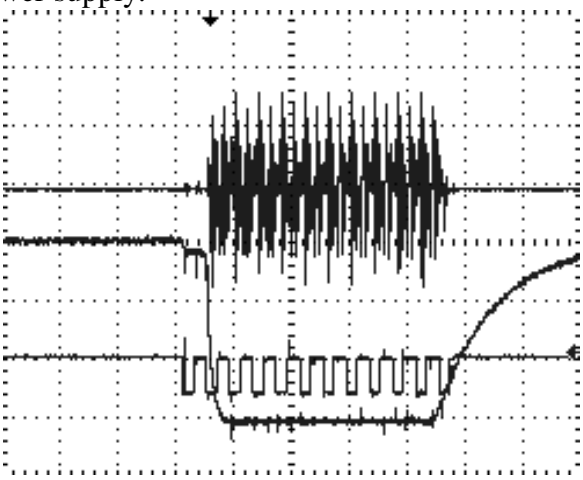


(Fig. 5 The voltage waveform of resantant capacitor)

The output high voltage is -30kV, and output power is 450kW. The peak current is 600A (showed on Fig.4). The peak voltage of the two end of resonant capacitor is 840V (showed in Fig.5). Switches turned off at zero current.

Experimental Result

At present, the power systerm only works in lower load restricted by experimental conditions. Waveforms in Fig.7 are high voltage output, driving waveform, and resonant current respectively. Current and driving waveform only shows its envelope. Fig.8 shows the high voltage output with light load. High voltage output can be Adjusted linearly in full range by controlling the output voltage of the rectifier. Series resonant converter has the characteristic of constant current,and it takes advantage of the leakage inductance of the transformer. Additional resonant capacitor has the function of avoiding the magnetic flux imbalance. It's a good choice for high-voltage high-power switching power supply.



(Fig. 7 High voltage output, the transformer primary winding current, driving waveform. horizontal axis: 250ms/DIV vertical axis: 10kV/DIV)

Keywords: Electric field; phase sequence layout; overhead line; charge simulation method.

Abstract. This paper discusses effect of phase sequence layout on electric field under overhead lines. Charge simulation method is used. Examples of two circuit overhead lines and four circuit overhead lines show that phase arrangment of lowest height conductors has major influence and phase arrangment of middle height conductors has lesser influence on electric field under overhead lines. Interlacing placed lowest height conductors with different phase and phase arrangement of middle height conductors different from that of lowest height conductors help to reduce electric field.

Introduction

Extra high voltage overhead lines produce intense electric field above the ground. It may be harzard to health of human bodies and attracts public concerns. Several factors such as height of overhead lines, space between conductors, conductor arrangements and use of shielding lines have been studied to show their influences on electric field under overhead lines [1]-[3]. And a few methods have been used in calculation of electric field produced by overhead lines. This paper will analyze the influence of phase sequence layout on electric field under overhead lines by charge simulation method.

Charge simulation method used in calculation of electric field under overhead lines

Charge simulation method is an often used method in calculation of electric field. It's based on the Uniqueness Theorem of electromagnetic fields. Discrete simulation charges are used to replace continuous distributed free charges on surface of conductor and bound charges on interface of different dielectric. Electric field can be calculated by superposing electric field generate by these discrete simulation charges.

Setting simulation charges q_j (j=1,2,…,n) and selecting equal number of matching points at surfaces of conductors with their potential values being known φ_i(i=1,2,…,n), equations of potential on matching points can be expressed by simulation charges as

$$\left.\begin{aligned} \varphi_1 &= p_{11}q_1 + p_{12}q_2 + \cdots + p_{1n}q_n \\ \varphi_2 &= p_{21}q_1 + p_{22}q_2 + \cdots + p_{2n}q_n \\ &\vdots \\ \varphi_n &= p_{n1}q_1 + p_{n2}q_2 + \cdots + p_{nn}q_n \end{aligned}\right\} \tag{1}$$

where p_{11}, p_{12}, … , p_{nn} denote electric potential coefficients. p_{ij} denotes the electric potential coefficient of the j-th simulation charge to the i-th matching point and is affected by dielectric constant and relative position between the j-th simulation charge and the i-th matching point.

Values of simulation charges can be calculated by solving (1). Electric potential and electric field strength at any point can then be calculated by these simulation charges.

Overhead line is not infinite straight line, so its electric field is a three dimension problem. A overhead line is divided into sections of finite length straight lines. Line charges are are used to model conductor sections. Electric field of overhead line is superposition of that by decomposed finite length

straight line charges. Setting local z axis on a finite length straight line, electric potential produced by the finite length straight line charge can be expressed as

$$\varphi = \int_{z_0'}^{z_l'} \frac{\tau}{4\pi\varepsilon_0\sqrt{\rho^2+(z-z')^2}}\,\mathrm{d}z' = \frac{\tau}{4\pi\varepsilon_0}\ln\frac{z_0'-z+\sqrt{\rho^2+(z_0'-z)^2}}{z_l'-z+\sqrt{\rho^2+(z_l'-z)^2}} \tag{2}$$

where z'_0 and z'_l denote z coordinates of two end points of the finite straight line, (ρ, z) denote coordinates of field point, τ denotes line charge density, ε_0 denotes dielectric constant of air.

The ground is a conductor. Influence of infinite large plane ground is taken into account by use of method of images.

Electric field under overhead lines with different phase sequence layout

To study the influece of phase sequence layout on electric field under overhead lines, two examples are calculated. One is two circuit overhead lines. The other is four circuit overhead lines.

Electric field of the two circuit overhead lines. Line voltage of the two circuit overhead lines is 330kV. Conductor arrangement is shown in Fig.1. In order to analyze influence of phase sequence layout on electric field, six phase sequence arrangements shown in Table 1 are calculated.

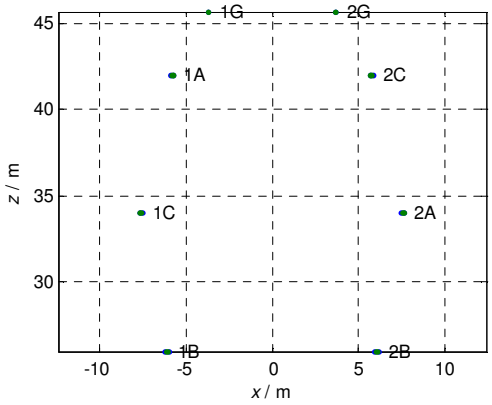

Fig. 1. Configuration of conductors of the two circuit overhead lines

Table 1. Phase sequence arrangements of the two circuit overhead lines

1	2	3	4	5	6
1A 2A	1A 2C	1A 2B	1A 2A	1A 2C	1A 2B
1B 2B	1B 2A	1B 2C	1B 2C	1B 2B	1B 2A
1C 2C	1C 2B	1C 2A	1C 2B	1C 2A	1C 2C

Distribution of electric field 1.5m above the ground at the lowest position of overhead lines and along direction vertical to overhead lines is shown in Fig. 2. It shows difference of electric field of the six arrangements. Maximal electric field of arrangement 1 is the biggest. Maximal electric field of arrangement 5 is the smallest. Arrangements 2 and 3 also have smaller values of maximal electric field. To the two circuit overhead lines, electric field is mainly influenced by two lowest height conductors. In arrangements 1 and 6, two lowest height conductors are in same phase. And they have larger maximal electric field than other arrangements. In arrangements 2 to 5, two lowest height conductors are in different phases, so they have smaller maximal electric field. Two middle height conductors also influence electric field. If their phases are different from that of lowest height conductors, there will be less values of maximal electric field. Arrangement 5 is in this case. Its lowest height conductors are in phase C and phase A which are different from each other. And its middle height conductors are both in phase B which are different from phase C and phase A.

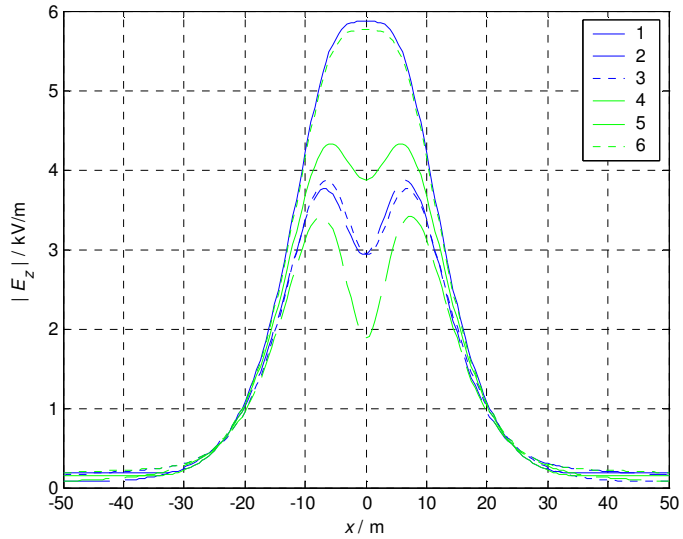

Fig. 2. Electric field of the two circuit overhead lines at 1.5m above the ground

Electric field of the four circuit overhead lines. Line voltage of the four circuit overhead lines is 500kV. Conductor arrangement is shown in Fig.3. In order to analyze influence of phase sequence layout on electric field, six phase sequence arrangements shown in Table 2 are calculated.

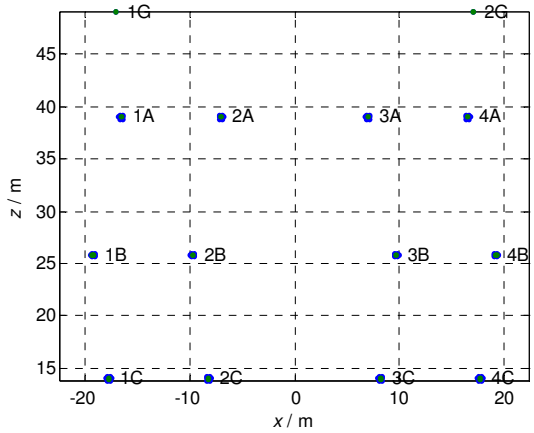

Fig. 3. Configuration of conductors of the four circuit overhead lines

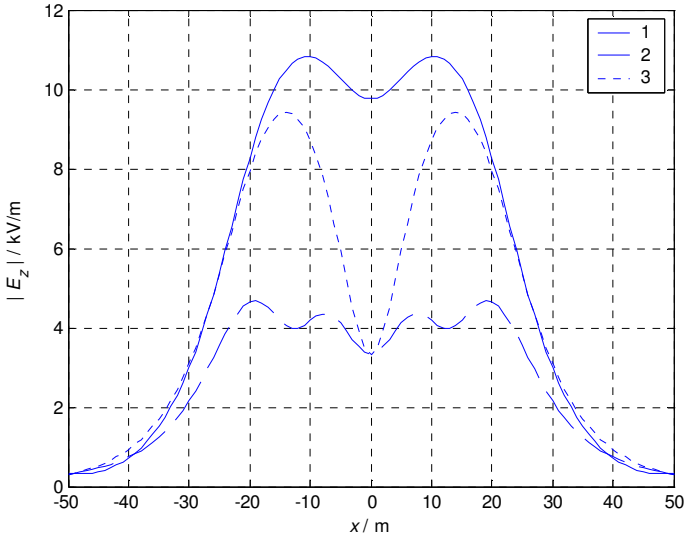
Table 2. Phase sequence arrangements of the four circuit overhead lines

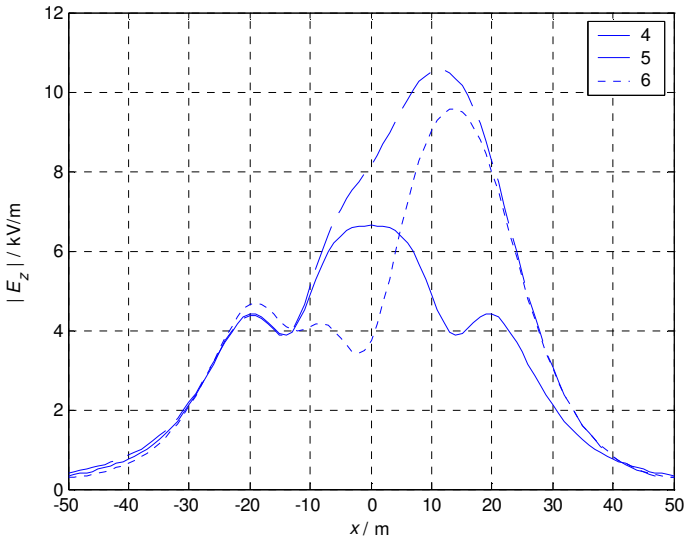
1	2	3	4	5	6
1A 2A 3A 4A	1A 2C 3A 4C	1A 2A 2C 4C	1A 2C 3C 4A	1C 2A 3A 4A	1A 2C 3A 4A
1B 2B 3B 4B	1B 2B 3B 4B	1B 2B3B 4B	1B 2B 3B 4B	1B 2B 3B 4B	2B 2B 3B 4B
1C 2C 2C 3C	1C 2A 3C 4A	1C 2C 3A 4A	1C 2A 3A 4C	1A 2C 3C 4C	3C 2A 3C 4C

Distribution of electric field 1.5m above the ground at the lowest position of overhead lines and along direction vertical to overhead lines is shown in Fig. 4. It also shows influence of phase sequence layout on electric field. Arrangements 1 and 5 have the biggest values of maximal electric field because at least three adjoining lowest height conductors are in same phase. Arrangements 3 and 6 also have bigger values because they have adjoining lowest height conductors of same phase. Arrangement 2 has the smallest value of maximal electric field because its lowest height conductors are interlacing placed with different phase.

Electric field influenced by phase sequence layout. Results of Fig.2 and Fig.4 all show that interlacing placed lowest height conductors with different phase can produce less electric field.



(a) Arangments of 1, 2 and 3



(b) Arangments of 4, 5 and 6

Fig. 4. Electric field of the four circuit overhead lines at 1.5m above the ground

Conclusions

In the paper, influence of phase sequence arrangement of conductors on electric field of overhead lines is studied. Electric field is calculated by charge simulation method. Results show that phase arrangment of lowest height conductors has major influence on electric field under overhead lines. And middle height conductors have also certain influence. Interlacing placed lowest height conductors with different phase help to reduce electric field.

Keywords: electronic beam welder; high voltage power supply; ZCS

Abstract. A 60kV/6kW high voltage power supply for electronic beam welder (EBW) based on LC series resonance is designed. It adopts pulse frequency modulation (PFM) way to adjust the output voltage, and it has over-current and over-voltage protection. The test proves that high voltage power supply has reached zero current switching (ZCS) on and ZCS off, and satisfied the actual requirements of welding technology.

Introduction

Electronic beam welding is a kind of technology which uses electronic beam as heat source. When the cathode filament of electronic gun is heated to a certain temperature, it will outcome electron. Electrons are accelerated in electronic gun and focused by electromagnetic lens to the beam of high intensity and high energy. When the beam bombards welding surface, its strong kinetic energy turns to heat energy flashily. It can molten metals to achieves the welding purpose[1].

The electron beam welding has high energy density, and EBW has been widely applied in air space, the car and shipping industry. Traditional electron beam welding machine power supply system adopts the technology of the power frequency or medium frequency, with high volume, low efficiency and poor stability of electron beam. To solve these problems, we developed a 60kV/6kW high voltage power supply with high efficiency and stability for electronic beam welder.

The Principle and Circuit Design of High Voltage Power Supply

A. The Principle of High-voltage Power Supply

The main circuit of high voltage power supply system is shown in Fig. 1. The smooth DC voltage can be obtained after three-phase AC is rectified and filtered. Full-bridge (FB) inverting circuit completes DC/AC transformation. AC square-wave boosts to about 60kV by high-frequency transformers in oil tank, then the output is rectified and filtered by the inductor to ensure a stable DC high voltage output. High voltage feedback signal is obtained by precision resistance network. After A/D data acquisition and DSP adjustment operations, we only need to change the frequency of pulse and it can change the output high voltage to achieve closed-loop control purpose.

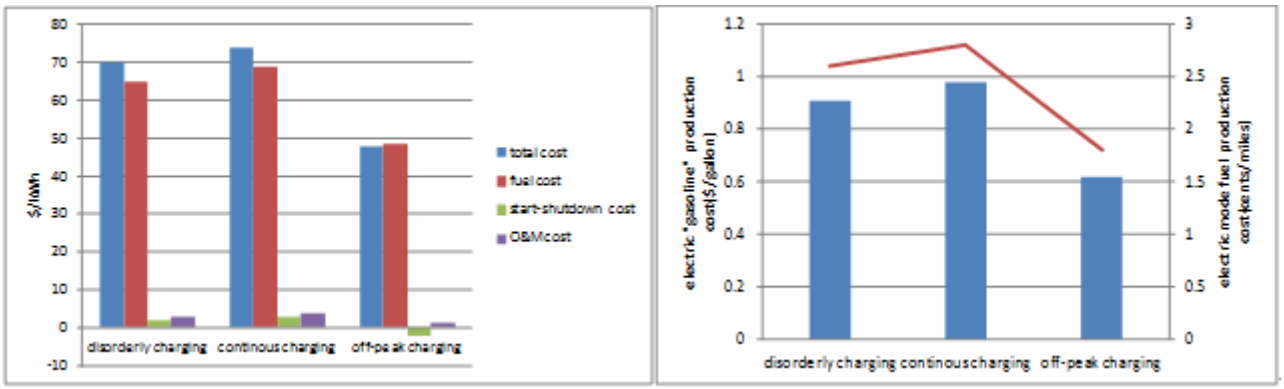

Fig. 1. Main circuit of high voltage power supply

B. Full-brige Series Resonant Inverting Circuit

According to the relationship between switching frequency and resonant frequency , power supply which is adopted series resonant inverting circuit has three working modes. ① < , discontinuous current mode (DCM). In this mode, switch works in soft switching condition which is zero-current turning on, zero -current/zero-voltage turning off. So it is suitable for small power supply. ② 2 < $_s$ < , continuous current mode (CCM). In this mode, resonant circuit is rendered capacitive, and switch works in soft turning off and hard turning on. So it is very suitable for large power supply. ③ f > f , CCM, this mode is generally adopted rarely[2].

The basic full-bridge series resonant circuit is shown in Fig. 2. The transformer T is used to transform energy and isolate.

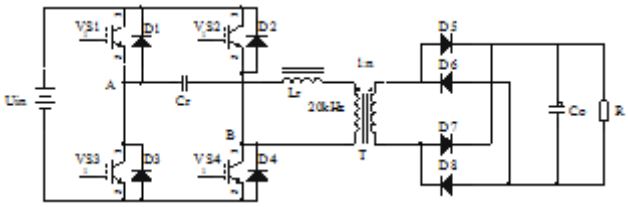

Fig. 2. Basic full-bridge series resonant circuit

In basic series resonant circuit which is composed of DC supply $_i$, resonant inductor and resonant capacitor , we assume that the initial time is , the initial current of is , and the initial voltage of is . According to L + U = and $_u$ = i_L , the expressions of resonant inductance current and resonant capacitor voltage are shown as follows[3,4].

$$i_{Lr}(t) = I_{L0}\cos\omega_r(t-t_0) + \frac{U-U_{C0}}{Z_r}\sin\omega_r(t-t_0) \tag{1}$$

$$u_{Cr}(t) = U - (U-U_{C0})\cos\omega_r(t-t_0) + Z_r I_{L0}\sin\omega_r(t-t_0) \tag{2}$$

Where ω is inductance angular frequency ω = , is characteristic impedance, = .

The main waveforms are shown in Fig. 3. The full-bridge series resonant converter works in < $_r$ working mode. A switching cycle includes two resonance cycle and six working modes . Because the article length is limit, this article does not describe six working modes in detail and the detailed description is available in reference.

The series resonant converter has the following advantages[5].

(1) Switch is zero-current turning on, zero-current or zero-voltage turning off, and anti-parallel diode turns on and off naturally, which greatly reduces the switching loss.

(2) Due to the presence of resonant capacitor C, it is ability to effectively protect power transformer from burning when it takes place biasing magnet.

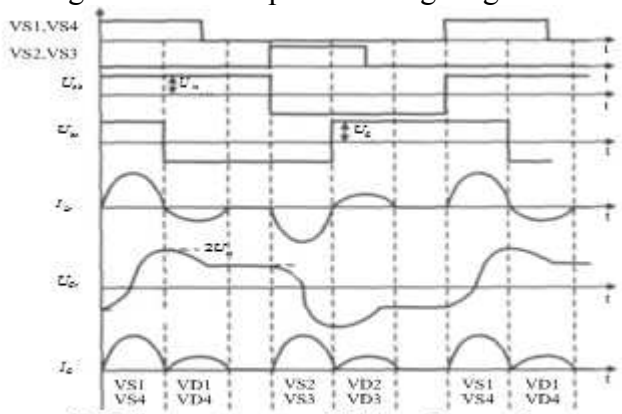

Fig. 3. Resonant current and driving pulse waveform.

C. High-voltage rectification and signal feedback

The high-voltage rectifying circuit is composed of high-voltage silicon stack, the output filter inductor, the protection circuit and the sampling circuit. The high voltage feedback and beam current feedback signals are obtained through using precise resistance network. There has electrical isolation between main circuit and control circuit, so DSP control board can be well protected.

D. DSP control board

Control circuit includes DSP(TMS320F28335), CPLD, and driver circuit. AD converter changes analog feedback signals into digital data. After DSP uses digital data gathered by AD to operate and adjust, DSP outputs the corresponding PWM signal impulse. Driver circuit mainly completes PWM signal isolation and amplification. CPLD mainly completes comprehensive fault, logic judgment and prohibition of PWM pulse. As long as there is any fault, it can quickly prohibit PWM output and cut off high voltage power supply, which achieves the purpose of protection.

Control Strategy and Implementation of Software

System software includes DSP procedure and CPLD procedure. DSP mainly completes algorithms, generates PWM pulses and communicates with touch-screen. CPLD mainly completes comprehensive fault, logic judgment and prohibition of PWM pulse.

DSP software program is composed of the main procedure and numbers of subroutines. Such as procedure of communication with touch -screen, sampling subroutine, welding logic procedure, PWM interrupt procedure, etc. Programming languages adopts C language [6].

After entering the PWM interrupt, the flowchart shown in Fig. 4, firstly, feedback from various signals are sampled and processed. And then it will produce respective PWM pulses after high-voltage supply, filament supply, gate bias supply and beam PI operation respectively. The PWM pluses is amplified and isolated by the driver circuit to drive IGBT, which realizes closed-loop control of the entire power supply system.

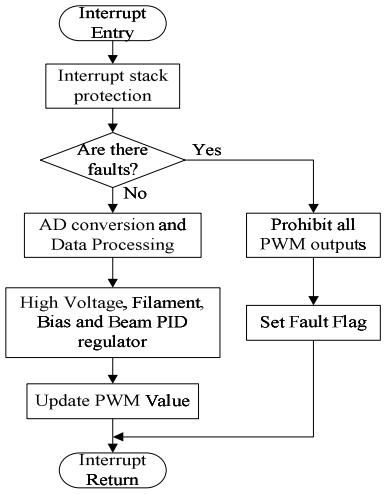

Fig. 4. Interrupt function flowchart

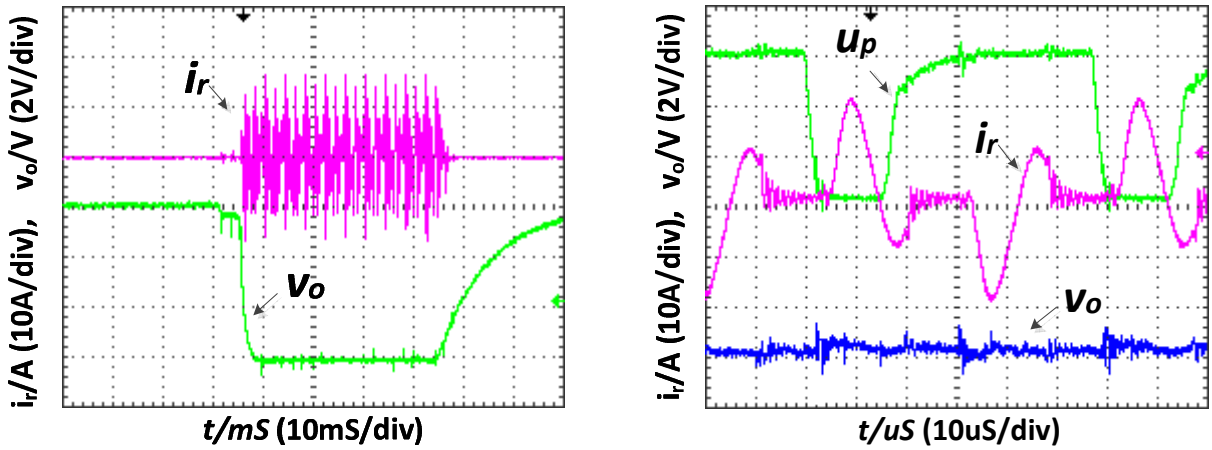
The power supply adopts full-digital interface. All parameter settings set up directly through the touch-screen, which has realized full-digital operation of high voltage power supply. What's more, touch-screen can display the main real -time parameters of high-voltage supply system, such as output voltage, running state, fault information etc.

The analysis of experimental results

The experimental waveforms are shown in Fig. 5. Where Vo is the high voltage feedback ,iR is the high voltage transformer primary current ,and up is the PWM signal with low active. the high voltage sampling ratio is 1:20,000. Figure 5a shows that high voltage can quickly boost to 60kV

within 10ms without overshoot, and it has very stable with small ripple. From the Figure 5b we can know that IGBT operates at ZCS on and ZVS/ZCS off mode with very high efficiency and low harmonic. So it can be able to achieve very good welding effect.



(a) 60kV high voltage without load (b)High voltage and beam current welding waveform

Fig. 5.Actual high voltage waveforms

Conclusion

The inverting high voltage power supply for EBW based on DSP (TMS320F28335) has high accuracy, small volume, all-digital etc, and it's all parameters can be set and stored directly through the touch-screen, What's more, all IGBTs operate at ZCS on and ZVS/ZCS off mode with very high efficiency and low harmonic . Experiments prove that the high voltage power supply has very high performance and it can be able to directly replace existing high voltage power supply system for EBW.

Keywords: ferromagnetic resonance, measures, harms, reasons

Abstract. Over-voltage in the power system can be caused by a lot of reasons , including higher frequency ferromagnetic resonance overvoltage which occurs in normal operation and causes great harm. Overvoltage events often result in damages to electrical equipment or even power outages . In this paper, ferromagnetic resonance is analyzed to study harm , causes, conditions , and phenomena and to handle resonance and develop practical preventive measures. The related analysis is important to work for the future operation of the power grid to prevent and limit the ferromagnetic resonance over voltage which provides some help to further ensure the safety and stable operation of the power grid .

Introduction

Ferromagnetic resonance over-voltage is essentially due to grid neutral point of instability caused by the ferromagnetic nonlinear magnetizing inductance capacitance of the system's resonant electromagnetic voltage transformer . Ferromagnetic resonance is one of the power system common phenomenon[1][2] , and resonance overvoltage incidents sometimes accompanies with it . Since many inductive and capacitive elements exist in the power system , when the operating system fails, the inductance and the capacitance elements constituting the various oscillation circuit may , under certain conditions, cause a resonance phenomenon , resulting in some parts of the system with severe over-voltage components . It endangers the safety of electrical equipment and impacts protection device reliability. If certain conditions are met ,it may also stimulate the longer duration of ferromagnetic resonance over-voltage , resulting in large-scale power grid stability destruction and damage to the equipments .

Ferromagnetic Resonance Over-voltage Hazards

Resonance voltage transformer primary winding is with large current , yet when one side of the fuse blows, the injection may cause voltage transformer coil burning or explosion , causing the switch to trip causing widespread blackouts work , destroy the system, the safe operation of the power grid to bring great threat.

Caused the bus three phase, two -phase and single-phase ground voltage increases , the formation of over-voltage , so that the bus insulating sleeve or other device flashover and damage , lightning or explosion .resonance voltage transformer primary side bus blown fuse may cause the malfunction of the low -voltage protection , nuisance tripping or system bus load solution crack, collapse of the power grid and other serious accidents .

Organization of the Text Reasonsof Ferromagnetic Resonance

Many of the power system components are part of inductive or capacitive in nature, such as power transformers, transformers , generators, Petersen coil for inductive components, or series compensation and the parasitic capacitance capacitors , high voltage equipment for the capacitive element , and the line between the ground conductor and the conductor for the presence of both the horizontal longitudinal inductance and capacitance exist , these elements form complex LC oscillation circuit , the energy in a certain role , with the specific parameters of the resonant circuit phenomenon occurs .

Pairs of load bus charging overvoltage caused by ferromagnetic resonance

Before transmission operation to load the bus , if the first input bus voltage transformers , power transformers and enable charging for the bus , because the bus to ground capacitance and voltage transformer inductance constitute oscillation circuit . Capacitance and inductance values will cause a near equal ferromagnetic resonance over-voltage phenomenon , resonance over-voltage .

Single-phase voltage to generate magnetic resonance

In ungrounded system, bus load outlet due cause insulation breakdown flashover occurred arc grounding wires blown, close to the power side of a take away on the ground , qualifying two-phase operation. Then the connected outlet and transformer magnetizing impedance circuit capacitance changes, form a series resonant circuit . When the equivalent inductance and capacitance in parallel with non- capacitive two-phase fault , the entire power supply system does not produce series resonance. And when the equivalent inductance and capacitance in parallel two-phase non-fault is

inductive and capacitive parameters and fault relatively close , then passed to the resonance over-voltage on the bus , causing the bus voltage transformers generate magnetic resonance voltage.

Voltage transformer core saturation resonance overvoltage

Ferromagnetic resonance and core saturation , generally TV core premature saturation voltage characteristics deteriorate , more prone to use the neutral ground of ferromagnetic resonance , particularly in ungrounded systems TV time .

Switching operation caused by ferromagnetic resonance overvoltage

When the process of switching operation in run mode resonance conditions exactly constitutes a vote of three-phase circuit breaker or a different period , will cause the voltage and current fluctuations caused by ferromagnetic resonance . When equipped with a shunt capacitor circuit breaker disconnect fracture , such as capacitance and inductance of the loop parameters TV capacitors in parallel can also occur when the ferromagnetic resonance over-voltage match .

Ferromagnetic resonance caused by the sudden closing Overvoltage

Equipment reactance ωL, series and parallel capacitance 1/ωC form loops. When ωL = case 1/ωC loops appear , this will be a resonant circuit . Since the capacitance in the circuit is basically the same frequency invariant constant ; generally by the inductive coil with a core , in the voltage generating mutations rapidly saturated core , the core saturation inductance becomes small, and generate magnetic resonance voltage suddenly appeared ωL = 1/ωC after closing.

Common Power System Harmonic Elimination Program

Installation harmonic elimination device

Harmonic elimination device[3][4] , also known as the second harmonic elimination , is mounted on the voltage transformer (PT) in open delta winding. Normal operation or single-phase ground fault occurs when the device does not operate , while ferromagnetic resonance occurs when determining the grid , it will make the positive and negative ends of the triangular openings in parallel in two alternating zero trigger thyristor conduction ferromagnetic resonance and damping to limit when the self- resonant eliminate thyristor deadline , you can repeat the action if necessary. During the start-harmonic elimination device ,thyristor full conduction , low resistance state , the resistance of a few to tens of mΩmΩ. Such a small high-frequency damping resistor value is sufficient , baseband and divide three kinds of resonance , but for the entire grid is valid, that is, a system simply select a station transformer harmonic elimination device can be installed .

Installation harmonic elimination damper

Harmonic elimination damper , as LXQ damper is actually a non-linear harmonic elimination resistor R0 connected in series between the voltage transformer primary side neutral point , it uses neutral damping resistor to eliminate resonance. Grid during normal operation, the voltage harmonic elimination <500V, R0 showed high resistance values ??(up to several hundred kΩ), a large damping effect, so that the resonance is not easy to develop in the initial stage ; When the grid of single phase , the harmonic elimination the higher voltage (10kV grid and its value about 1.7 ~ 1.8kV), R0 was low (tens of kΩ), to meet the PT open delta voltage insulation monitoring requirements no less than 80V , but still damped harmonic ; when the power grid when arc grounding , R0 can still maintain a certain resistance , transformer inrush current limiting . The device has a resonance and eliminating PT saturation limit inrush two functions.In the installation of the secondary side of the transformer zero-sequence voltage harmonic elimination -type PT retrofit harmonic elimination device

In the installation of harmonic elimination device

For the installation of the zero-sequence voltage transformer harmonic elimination -type PT, will be installed in the computer harmonic elimination of its zero- sequence voltage transformer secondary side TV0 , when the system ferromagnetic resonance occurs other transformers , harmonic elimination will under the action of the zero -sequence voltage action , TV0 almost secondary side is shorted , TV0 and TV1 are reflected in the high voltage winding leakage reactance , zero sequence impedance transformer leakage inductance becomes a small value , equivalent to a temporary network neutral point directly to ground resonance will disappear. TV0 secondary harmonic elimination in this type of installation PT computer harmonic elimination device helps the entire harmonic elimination grid. Intelligent scheduling for grid , the grid is lost brain center , the integrated use of a variety of advanced technology and intelligent means of the transmission grid be active , intelligent monitoring , analysis, early warning , decision support , and self-healing controls for dispatch center Yun Fang , following intelligence business support means security, scheduling , planning, automation, and other full-service professional, provides for the transmission grid to provide strong technical support. Several intelligent application for the professional needs is the key to building support systems integration technology is the foundation .

Installation of automatic tuning system neutral Petersen Coil

The principle of automatic tuning grounding compensation device , through lump sum , full complement of running up and under way , can solve resonance problems. Currently automatic tuning grounding compensation device mainly consists of five major components : ground transformers, electric arc suppression coil , computer control section , damping resistor section dedicated transformer neutral point and non-linear resistors. Artificial neutral grounding transformer is used as

an access point arc suppression coil . Petersen coil current through the load switching regulator and implement remote automatic control , using pre-conditioning methods, namely, in the normal operation mode , the network parameters according to changes at any time to adjust Petersen coil tap into the best position. Use of computer controller for automatic tracking and automatic tuning. By measuring the displacement of the main phase voltage and current and the voltage between the neutral point , it is possible to calculate an accurate judgment , issued a directive automatically adjusted to show the relevant parameters: capacitive current , the inductor current , residual current and voltage offset . Recall , alarm , automatic printing and signal sent away to meet the needs of unattended substation .

Common Power System Harmonic Elimination ProgramGrid Operationto Preventthe Ferromagnetic Resonance Measuresand Methods

Resonance , should be immediately put into a standby equipment , such as transformers, etc. into spare change network parameters to eliminate resonance.Resonance , as a standby power supply bus can be switched to the backup power to the system parameters change , eliminate resonance.Resonance , a voltage transformer fuse is blown, eliminate resonance itself ; voltage transformer fuses in the fuse yet , you should stop using them immediately about the loss of pressure protection device easily mistaken move ; shall promptly replaced after the fuse , recovery voltage transformer running.Resonance method , due to the voltage transformer primary winding current is large , you should pull the voltage transformer or prohibit the use of direct access to a fuse to eliminate resonance.It can be used to change the sequence of operations necessary to avoid resonance conditions during operation. As the charge generated in the resonant load bus , the load line can be put in the methods used to change the resonance conditions.Reducing the voltage transformer stations, in the same system should minimize the number of voltage transformer station , especially limiting voltage transformer neutral grounding several .To improve the quality of the circuit breaker maintenance to ensure the same period of the closing operation.Maintaining good plant , station equipment, to avoid flashover or grounding accidents caused by resonance over- voltage.Changing the operation mode to avoid an empty bus and load transformer operation.

Summary

Many inductive core elements exist in the power system ,and under certain conditions , they may induce ferromagnetic resonance over-voltage ,which endangers the safe operation of the power grid and equipment. Based on analysis of the ferromagnetic resonance over-voltage hazards,the paper talks about arising events due to ferromagnetic resonance, the common power system harmonic elimination program , comprehensive introduction in grid operation and measures to prevent the ferromagnetic resonance method. This paper trys to further the work of the future grid operation

preventing and limit the generation of ferromagnetic resonance overvoltage. It provides some help to further ensure the safe and stable operation of the power grid . There are some limitations in terms of this analysis inevitably which need further research.

Keywords: Process Variation.Interconnect. SIPPs parameters. Test structures Design. Automatically realized.

Abstract. With the interconnection density and doubling the number of layers in VLSI, Interconnect line width,pitch,and the thickness of the dielectric layer will changed within the same chip caused by the process variation. and the interconnect parasitics changes ultimately affect circuit performance and yield.IC designers need an accurate BEoL corner model to help circuit design. Standard Interconnect Performance Parameters (SIPPs) is standard method to measure ultra-large scale integrated circuit BEOL performance. Designed parallel plate, layer-skipping parallel plate, comb meander, comb meander for via resistance test structures to extract SIPPs according to their sensitivity differences to different test structures, and realized them in CIF format file with High-level Perl language automatically. Then change to GDSII format file that wafer used widely by Cadence layout software, and pass electrical rule checks. Greatly improved the efficiency of test structure's design and realized. Lay the foundations for formulation of Design for Manufacturability physical design rules and further research interconnection statistical models under nanometer technology with more unique physical phenomena.

Introduction

With the application of dual Damascus process and copper interconnect technology, IC manufacture technology scales to the nanometer region, number of transistors on circuit becomes more and more, interconnect layers increase to ten layers or more. Manufacture process becomes more and more complicated accordingly. It include lithography, etching, deposition, chemical mechanical polishing Alternately during interconnect manufacturing process, and some parasitic effects or defects caused by theses process steps are the main issues for IC yield decrease [1,2,3]; As the production quantity of very large scale integrated circuit (VLSI) is fairly large, process variation will be raise during any manufacturing process, In order to analyze a process technology Really, must do a certain number of statistics to the chips [4,5]. Due to the effects of the interconnect manufacture is the main influence to the IC manufacture yield, so we need to quickly and accurately know the present situation of the manufacture process as it rapidly development, and use this information to establish accurately process model to increase IC manufacture yield.

How to quickly generate a large number of interconnect test structures for detecting Back End of the Line (BEOL) conditions during chip manufacturing, is issues faced by most people. In order to analysis the process statistically, the designers often generate a huge number of test structures manually in the former, The efficiency in this way is very low, and increased risk of structural errors as manual intervention. In this paper, we use High-level Perl language to generate interconnect test structures automatically in CIF format files, and then convert to GDSII format files which accepted widely in the industry by other electronic design automation (EDA) tools, and use the layout tools to do electric rule check. This can quickly reduce the time to design and generate test structures, achieve faster and more production efficient, and also have some stability and accuracy.

Nanometer Interconnect Test Structures Generation for process parameters monitor

SIPPs is the abbreviation for Standard Interconnect Performance Parameters, This standard is formulated by an international organization of Silicon Integration in 1998, which participated by

many industry leading companies. It's current version has been developed to V1.06. It is designed to provide a standard method of BEOL performance; it provides a parametric representation to almost all factors in BEOL process, simplifying the overly complex factors.

The test structures we designed, which goal is BEOL process of the interconnection. As to these interconnections, the method industry most commonly used is parametering of them, that's to find some parameters which can represent the majority nature of interconnect features. they are Low-K-A thickness, Low-K-A permittivity, Via resistance, Via diameter, Nitride-A thickness, Nitride-A permittivity, Metal thickness, Sheet resistivity, CD (Critical Dimension) bias, Low-K-B permittivity, Nitride-B thickness, Nitride-B permittivity. When wafer fabs get standard format SIPPs through measured some test structures, use industry Precise Field Solver tools to build a set of all possible situations, and then they stored the calculated results in a database [6, 7]. In order to estimate delay, crosstalk of design, the users can use the database to extracted their own electricity-related parasitic by EDA tools. It mostly use this method in present EDA tools of industry, such as commonly used Synopsys Star-RCXT and Mentor xCalibre,and so on [8,9].

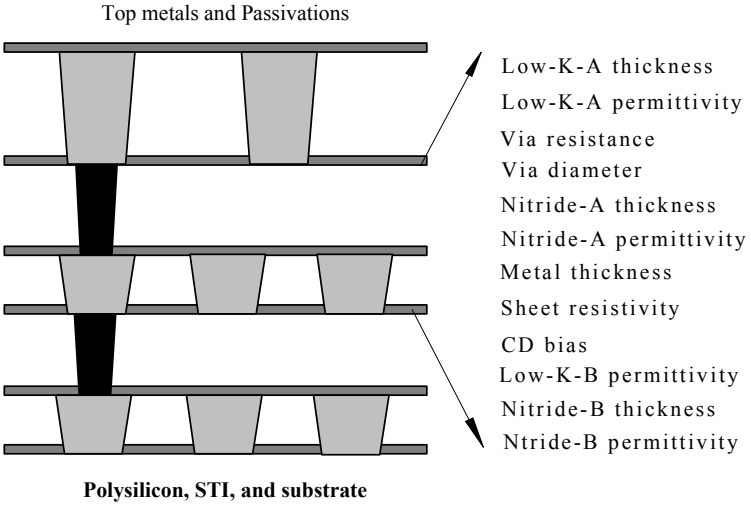

Fig.1 SIPPs parameters and copper interconnect

The Figure 1 is a total of 12 parameters; they can be divided into two categories. One is not easily change; they are mainly on the Nitride and via diameter, including five parameters: Nitride-A thickness, Nitride-A Permittivity, Nitride-B thickness, Nitride-B Permittivity, via diameter. The role of these parameters to the result is not as important as others during extracting electricity-related parasitics. The other parameters are seven necessary parameters of SIPPs which are easily to change. These parameters can be used to estimate the process variations during VLSI chip manufacture. In addition to two parameters related with permittivity, the other five parameters have more than ten percent greater variations during manufacture, which will be a very huge challenge to the Corner analysis and modeling,and this also affect chip yield ultimately.

Major Test structures design

In order to extract SIPPs as shown in Table 1, we designed parallel plate, layer-skipping parallel plate, comb meander, comb meander for via resistance test structures orderly. Each type test structure has its specific purpose, it use the sensitivity that every parameter has different sensitivity to different type test structure. It increases the effection of specific parameters and reduces the effection sensitivity of non-test parameters during test structure design. This will make the test structure has very high sensitivity to a particular parameter.

Tab.1 SIPPs and corresponding test structures

Test structures	First Order	Second Order
Parallel Plate	Low-K-A permittivity	Low-K-A thickness
Layer-skipping Parallel Plate	Metal thickness	Low-K-B permittivity
Comb Meander	Sheet resistivity CD bias Metal thickness Low-K-B permittivity	
Comb Meander For Via Resistance	Via resistance	Via capacitance

Parallel plate test structure mainly used to extract Low-K-A permittivity and Low-K-A thickness of SIPPs. This test structure is used to observe the characteristics of dielectric layer that between metal layers, and most affected the characteristics of dielectric layer is its thickness and permittivity.

When design Layer-skipping Parallel Plate test structure, the middle metal layer is ignored. In general, it is similar with the parallel plate test structure; the only difference is that it skipped a metal layer. For example, if the test structures designed mainly to extract second metal layer M2 parameters, it will include all the other parallel plate layers except M2. Combined with the following Comb Meander test structures, it can extract interconnect thickness parameter of SIPPs.

Comb Meander test structure is a special test structure, it can be used to measure two electrical properties, capacitance, and resistance. Moreover, As the measurement of resistance and capacitance is at the same time, so both of them have the same process variations, which is more conducive to Corner model accuracy. Figure 2 is Comb Meander test structure diagram, the main test structure is placed in metal layer i and (i +1), other layers are placed metal plate except these two metal layers. The lower left corner is the interconnection of upper and lower comb, In order to avoid short-circuit, this part is connected by via to another metal layer. As it is very short compared to the total length of comb, it's influence to SIPPs error can ignore. Moreover, in order to reflects the CD bias directly, it has placed ruler test structure which has same width and spacing in Layer (i +2) or (i-2).

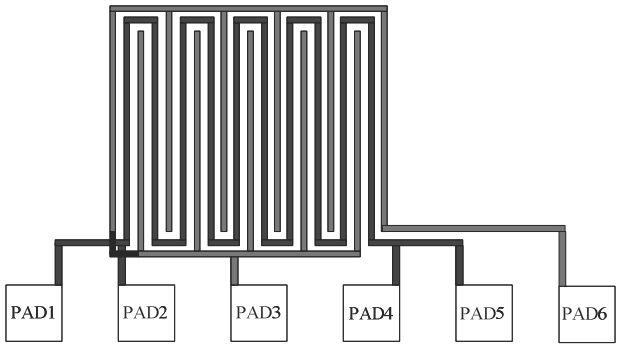

Fig.2 Comb Meander test structure

This test structure has width that of 6 PAD, It measured the meander resistance of the test structure, It is a 4-points Kelvin resistance test structure, we get the meander resistance by poured into a current between PAD1 and PAD5, and then measured the voltage between PAD2 and PAD4; Then get the sheet resistance of SIPPs. we can obtain two capacitance in this test structure, one capacitance is between upper and lower comb and the meander placed between them, the other capacitance is between comb-meander and upper parallel plate metals. We can obtain Metal thickness, CD bias, Low-K-B permittivity of SIPPs by using both capacitances. In order to extract the parameters of SIPPs, PAD1, PAD2, PAD3, PAD4, PAD5 should connect to sense when measuring,

and PAD6 should connect with drive; The other way is that PAD1, PAD2, PAD4, PAD5 connect to sense, PAD3, PAD6 connect to drive. Figure 3 is the layout result generated by Perl language.

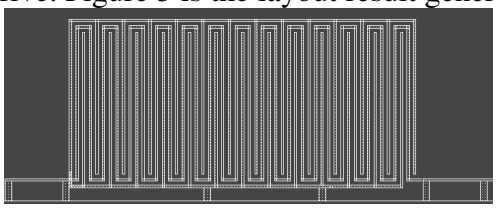

Fig.3 Layout of Comb Meander test structure

Comb Meander for via Resistance is another test structure, It's only different with comb meander test structure is that the meander is changed into via chain, as Fig 4 shows. As the meander is changed to via chain as more as possible; we will get a total resistance linked up by many via resistance when using Kelvin 4-point test method, and then get via resistance of SIPPs. We can also get a capacitance by this test structure, it also can extract Metal thickness, CD bias of SIPPs which extracted by former comb meander test structure. Figure 5 is part of the test structure layout generated automatically.

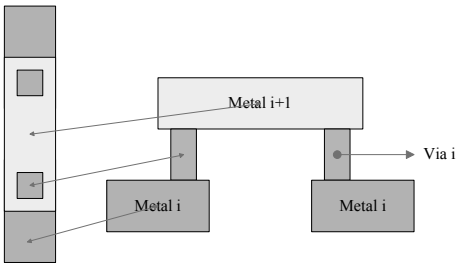

Fig.4 Comb Meander For Via Resistance test structure

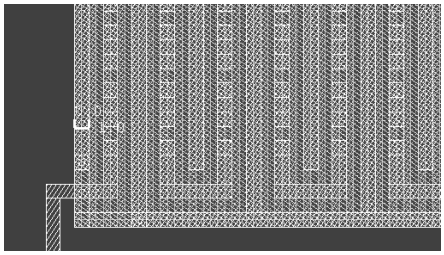

Fig.5 Layout of Comb Meander for Via Resistance test structure

Test structures Realization

The test structures realization flow as fig 6 shows. We need to prepare some relevant information Firstly; there is layer information of layout, which includes the GDSII layer numbers. Only with it, we can get the correct layer when generating the layer by Perl language. The other is the information of test structures, it include layer name, metal width, metal space and so on. These datas should decide when design the test structure according to parameters extracted. At last, generate all the test structures according to the following flow chart by Perl language.

```
#!/usr/bin/perl
if ($#ARGV != 2) {
  print "usage: perl sample.pl struct_file layer_map out_cif_dir \n";
  exit; }
print "usage OK \n";
# Some fixed key words
$struct_key_word = "S65";
$parallel_plate_type = "pp3D";
$comb_meander_type = "comb3D";
$via_resistance_type = "via";
# Declare a CIF file name's prefix
$cif_file_prefix = "dummy";
```

```
# Let Perl's memeory start to manage
# the input arguments
$struct_file = $ARGV[0];
$layer_map = $ARGV[1];
$out_cif_dir = $ARGV[2];
# An overall CIF output file dir is good
system ("mkdir -p -m 777 ./$out_cif_dir");
# Initialize some indices and parameters
$total_gds_layer_count = 0;
$total_metal_layer_count = 0;
$width = 0.0;
$spacing = 0.0;
……
```

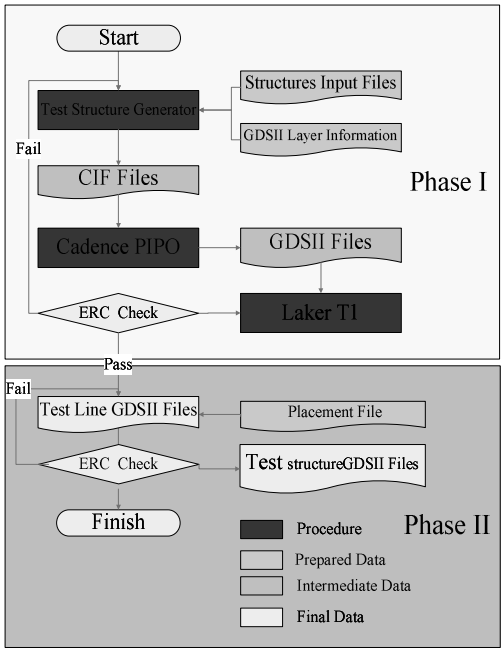

Fig.6 Test structure realize Flow chart

Results and discussion

The platform we realized all test structures is Sun's FireV490 machine, the operating system is under SunOS 5.8, Perl language version is v5.6.0, Cadence IC version is 5.10.41. We generate all the test structures targeted to extract 8 metal layers parameters of SIPPs according to design rule(0.065um Logic 1P8M Salicide 1.0(G) or 1.2(LL)/1.8/2.5.or 3.3V Design Rule, Version 1.0)during experiment. For each layer interconnection, we have designed 16 different metal width and space, a total of 152 test structures. Then estimate time and resources spent during whole experiment and the results of experiment.

First, it reads all the test structures and generate appropriate CIF format file, it took 50 seconds of CPU time, and Then Translate the CIF format file into DFII format file that Cadence's layout stander format file and read, a total of 15 minutes and 42 seconds was spent. Then put all of the test lines into a unit, do electric rule check of all structures again, The results is as Figure 7 shows :both short or open check of test structures have passed. Finally, translate all test structures into GDSII forma filets that wafer use widely. The GDSII file size is 216.4M. It took a total of 18 minutes 6 seconds during second phase.

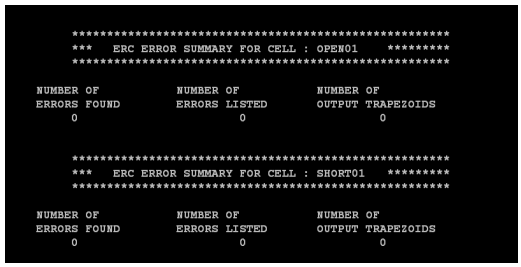

Fig.7 Electric Rule Check result of test structures

We have designed a set of test structures and realized them by High-level Perl language automatically. It includes parallel plate, layer-skipping parallel plate, comb meander, comb meander for via resistance test structures and test structures to eliminate their error. It saved all test structures and GDSII layers numbers of layout information Correspond with these test structures into text file, then realized with High-level Perl language automatically by transferring the two files.

The test structure kits designed mainly for nanometer process node, to get standard interconnect performance parameters SIPPs of nanometer process, then have accurate assessment of current technology level. And establish process Corner modeling and provide design for manufacturability (DFM) physical design rules and nonlinear resistance SPICE models of Interconnect to designers. It Not only makes Just taking a short time to prepare the input files when needed a large number of test structures to do statistical analysis to generate the test structures, but also reduce errors Generated due to human intervention. Moreover, the test structures can track process nodes automatically, as long as modify the input files; the program can generate new test structures to evaluation the next process node performance automatically.

Keywords: network reconfiguration, genetic algorithm, paralleling computing, all spanning trees of undirected graph, decimal coding, distribution network.

Abstract. Network reconfiguration is of theoretical and practical significance to guarantee safe and economical operation of distribution system. In this paper, based on all spanning trees of undirected graph, a novel genetic algorithm for electric distribution network reconfiguration is proposed. Above all, all spanning trees of simplified graph of distribution network are found. Tie branches are obtained with spanning tree subtracted from simplified graph. There is one and only one switch open on each tie branch. Decimal identity number of open switch on each tie branch is taken as the optimization variable. Therefore, length of chromosome is very short. Each spanning tree corresponds to one subpopulation. Gene operations of each subpopulation are implemented with parallel computing method. Individuals of offspring after gene operation automatically meet with radial and connected constraints for distribution network operation. Disadvantages of conventional genetic algorithm for network reconfiguration that a large amount of unfeasible solutions are created after crossover and mutation, which result in very low searching efficiency, are completely overcome. High calculation speed and superior capability of the proposed method are validated by two test cases.

Introduction

In order to improve the reliability of power supply, urban distribution network is designed to be a looped net structure. For the sake of reducing short circuit current and facilitating protection relay settings, distribution network takes open loop operation mode. On distribution network, there are a large number of sectionalizing switches and a small amount of tie switches. By adjusting switches state, distribution network reconfiguration can reduce power loss, isolate fault, balance load, and improve voltage. At present, distribution automation demonstration projects is in full swing in many large and medium sized cities in China. Distribution Automation System (DAS) can manually, interactively or automatically adjust switches state which lay a solid foundation for the application of distribution network reconfiguration.

Network reconfiguration is a large scale, nonlinear, mixed integer programming problem, mainly including branch-exchange method[1-3], optimal flow method [4-5], genetic algorithm[6-15], heuristic method[16-18], mixed method[19], etc. Because genetic algorithm has the merits of independency of initial values, good robustness, capabilities of finding global solutions, it wins many scholars' attention.

In the early genetic algorithm for network reconfiguration, binary coding scheme is widely used, in which, each gene of chromosome corresponds to one switch. If gene is 0, then it indicates switch open. While if gene is 1, it indicates switch closed. This coding scheme is easy to implement and understand. However, a large amount of switches that cannot be opened in practice participate in coding. Therefore, the chromosome is too long, and in the process of crossover and mutation, too much unfeasible solutions are brought about, which result in extremely low search efficiency.

In [7], an improved genetic algorithm for network configuration is proposed, in which, only the switches located on a loop of distribution network participate in binary coding, unfeasible solutions after crossover and mutation are ameliorated. Nevertheless, the ameliorating process is time

consuming. In [8], coding genes of switches located on same loop are in one block, and coding genes of adjacent switches adjoin are proposed. But in this method, at each generation, crossover operation can only be implemented on one gene block, and mutation operation can only be done on one gene. Furthermore, in the process of mutation, unfeasible solutions are brought about. Consequently, the search efficiency of this method is comparatively low. In [9], a decimal coding scheme that the identity number of open switch located on loop is coded with an integer is proposed. In this method, if there is not any one switch located on more than one loops, then no unfeasible solutions are produced in the process of gene operation. Unfortunately, if there is switch located on more than one loops, many unfeasible solutions are produced.

In this paper, a novel genetic algorithm based on all spanning trees of undirected graph for distribution network reconfiguration is proposed. Above all, in the graph of distribution network, branches not located on any loop are removed, and adjacent branches whose crossing points have a degree of two is incorporated into one edge. Thus, an undirected simplified graph of distribution network is obtained. All spanning trees of this simplified graph are found with a program using backtracking and a method for detecting bridges based on depth-first search. Tie branches are obtained with spanning tree subtracted from the simplified graph. There is one and only one switch open on each tie branch. Once the switch on each tie branch is open, all other switch must be closed so as to meet the radial and connected constraints for distribution network operation. Which tie branches and which switch on each tie branch is chosen to be open are determined by genetic algorithm.

In this paper, a decimal coding scheme that the whole switch number of each tie branch constitutes the base vectors, and identity number of open switch on each tie branch is taken as the optimization variables are proposed. With such a coding scheme, the length of chromosome is equal to the number of independent meshes on the graph of distribution network. Therefore, it is very short. In the genetic algorithm, one sub-population corresponds to one spanning tree. Selection, crossover, mutation, reinsertion operations are all taken in sub-population with paralleling computing method. Individuals of offspring after gene operation automatically meet radial and connected constraints for distribution network operation. None unfeasible solutions are produced and none ameliorating operation is need. The disadvantages of conventional genetic algorithm for distribution network reconfiguration that a huge number of unfeasible solutions which result in very low search efficiency brought in the process of crossover and mutation operation are completely overcome. When the specified number of evolution generation is reached, the chromosome whose objective function value is minimal in the whole population is output as the global optimal solution. Two simulation cases indicate the proposed algorithm greatly improve calculation speed.

Model of Network Reconfiguration

The objective is that power loss is minimal after network reconfiguration under necessary constraints for distribution network operation. The objective function is formulated as Eq.1.

$$\min\ f = \sum_{i=1}^{n} \frac{P_i^2 + Q_i^2}{U_i^2} r_i k_i \tag{1}$$

Where P_i, Q_i are active and reactive power flowing through the terminal of branch i, respectively; U_i is the terminal node voltage of branch i; n is the total number of branches; r_i is the resistance of branch i; k_i is the switch state of branch i, which is a 0 or 1 discrete variable, with 0 indicating switch open, and 1 indicating switch closed; f is the active power loss of network, which can be obtained by power flow calculation.

Node voltage and branch power must meet the following constrains.

(a) Node Voltage Constraint

$$U_{i\min} \le U_i \le U_{i\max} \tag{2}$$

Where $U_{i\min}$, $U_{i\max}$ are the upper and lower voltage constraints for node i, respectively.

(b) Branch Power Constraint

$$S_i \le S_{i\max} \tag{3}$$

Where S_i , $S_{i\max}$ are the calculated and allowed maximal power value flowing through branch i respectively.

When node voltage or branch power exceeds constraint, a penalty function will be taken into account in f . The more is the constraints being exceeded, the more is penalty function.

All Spanning Trees of Simplified Graph and Relevant Concepts

All Spanning Trees and Tie Branches of Simplified Graph.

In order to decrease the number of spanning trees and reduce calculation complexity, adjacent branches located on a loop whose crossing point have a degree of 2 are incorporated into one edge, and branches not located on any loop can be removed from the graph of distribution network. Thus, the graph of distribution network can be simplified to a graph G . Spanning tree of G is a sub-graph of G , in which, any two nodes have one and only one simple path. Spanning tree of G has all nodes of G , but do not have all edges of G . Different spanning trees are composed of different edges. Tie branches are supplementary set of spanning tree. That is, tie branches equal to spanning tree subtracted from G. The number of edges in tie branches equals to the number of independent mesh in G . In this paper, we introduce the method in [20] to find all the spanning trees and corresponding tie branches of G .

Fig.1 is IEEE typical three feeder test system, in which, dotted line are the branches on which tie switches located. In order to facilitate finding all the spanning tree, bus 1, 2 and 3 are connected together. With adjacent branches located on a loop whose crossing point have a degree of 2 incorporated into one edge, and branches not located on any loop removed Fig.1 is simplified to Fig.2. It can be seen from Fig.2, edges (1), (3), (4), (5) constitute a spanning tree while edges (2), (6), (7) are the corresponding tie branches. Edges (1), (2), (4), (5) constitute another spanning tree while edges (3), (6), (7) are the corresponding tie branches. All spanning trees and the corresponding tie branches of Fig.2 are listed in 2th and 3th column of Table 1.

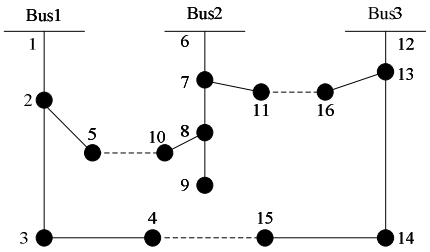

Fig.1 IEEE typical three feeder test system

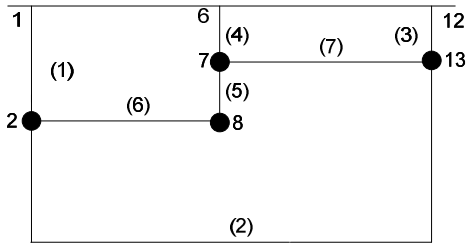

Fig.2 Simplified system

Base Vector of Tie Branches.

Base vector is composed of total switch number on each tie branch. Taking tie branches (1), (2), (4) for example, as shown in the second row, third column of Table 1, there is 1 switch on edge (1), 5 switches on edge (2), and 1 switch on edge (4). Thus, the base vector of this tie branches is $(1\ 5\ 1)$. All the base vectors of Fig.2 are listed in 4th column of Table 1.

Candidate Solutions.

Any combination of open switches that meet the radial and connected constraints for distribution network operation is defined as a candidate solution for network reconfiguration. The optimal solution can only be one of the candidate solutions. One candidate solution can be created if and only if open one switch on each tie branch. As to each spanning tree, the number of candidate solutions equals to the product of each component of the corresponding base vector. For example, shown as the 2^{th} row, 5^{th} column of Table 1, number of candidate solutions corresponding to 1^{th} spanning tree is $1\times5\times1=5$. That is, there are 5 combinations of open switches meeting the radial, connected constraints for distribution network operation. The total number of candidate solutions of network reconfiguration equals to the sum of candidate solutions corresponding to each spanning tree. Shown as the 26^{th} row, 5^{th} column of Table 1, there are 190 candidate solutions for the IEEE typical 3 feeder test system.

Coding Scheme and Gene Operation

Coding Scheme.

In this paper, decimal coding scheme is introduced. Subpopulations are one-to-one relevant to spanning trees. The length of chromosome is equal to the number of tie branches, which is equal to the number of independent meshes of distribution network. In contrast to conventional binary coding scheme, the proposed decimal coding scheme can greatly shorten the length of chromosome. The value of each gene is a non negative integer, indicating the open switch identity number on corresponding tie branch. The value of each gene is smaller than corresponding component of corresponding base vector. When we talk about a chromosome, we must point out the subpopulation it belongs to. If two chromosomes have the same genes but belong to different subpopulations, they have different meanings. For example, if chromosome $(0\ 0\ 0)$ belongs to 1^{th} subpopulation corresponding to 1^{th} spanning tree in Table 1, it implies the 0^{th} switch of tie branch (1), (2), (4) are

open. Otherwise, If chromosome $(0\ 0\ 0)$ belongs to 2^{th} subpopulation corresponding to 2^{th} spanning tree in Table 1, it implies the 0^{th} switch of tie branch (1), (4), (6) are open.

Creation of Initial Population.

Number of individuals in each subpopulation can be different according to the candidate solutions for the corresponding spanning tree. For example, because there are 15 candidate solutions correspondent to the 3^{th} spanning tree in Table 1, individuals number of the 3th subpopulation can be chose to be 2. While there are 45 candidate solutions correspondent to the 10^{th} spanning tree in Table 1, the individuals number of the 10^{th} subpopulation can be chose to be 6.

Fitness Value of Chromosome.

The open switches in the distribution network can be obtained by decoding the chromosome in each subpopulation. Network power loss is calculated with parallel back forward sweep power flow calculation method introduced in [21]. Power losses, with their corresponding chromosomes are sorted in ascending order. Order numbers in descending order are uniformly spaced mapped to real numbers 0~2. That is, the fitness value of chromosome with biggest power loss is mapped to 0, while the fitness value of chromosomes with smallest power loss is mapped to 2. The intervals of fitness value between any two adjacent chromosomes after sorted are equal.

Gene Operation.

Gene operation includes selection, crossover, mutation, and reinsertion, all of which are implemented in each subpopulation with parallel computing. After specified number of evolution generation, the individual whose objective value is minimal in the whole population (not in subpopulation) is output as the optimal solution.

(a) Selection

In each subpopulation, because numbers of individuals are different, numbers of individuals are selected to perform gene operation are different. Roulette method are introduced for selection.

(b) Crossover

Crossover is to exchange the number at the same position of parents, with a specified probability. For example, shown as Table 2, if the crossover probability is specified to 0.7, the offspring of parents chromosomes $(4\ 2\ 1)$, $(2\ 1\ 2)$ may be $(2\ 1\ 1)$, $(4\ 2\ 2)$.

Table 2 Crossover operation

parents			offspring		
4	2	1	2	1	1
2	1	2	4	2	2

(c) Mutation

Mutation is to replace the gene of parent with a non negative integer smaller than the corresponding component of base vector. For example, shown as Table 3, if the mutation rate is specified as 0.01, and the base vector is $(5\ 3\ 3)$, the chromosomes $(4\ 2\ 1)$, $(2\ 1\ 2)$, after mutation may be $(3\ 2\ 1)$, $(2\ 2\ 2)$.

Table 3 Mutation operation

parents			offspring		
4	2	1	3	2	1
2	1	2	2	2	2

(d) Reinsertion

As to each subpopulation, after crossover and mutation, specified numbers of individuals whose fitness values are smallest are removed from the parents. Then, the offspring are inserted into the

parents. Thus, in each subpopulation, new individuals are created while multiple old elite individuals are retained and population sizes are kept constant.

Parallel computing.

Coding, creation of initial population, calculation of fitness values and gene operations are all implemented in subpopulation. There is little coupled calculation between subpopulations. Therefore, it is very suitable for parallel computing. The calculation speed is highly improved, with parallel computing.

Flow chart of the proposed algorithm.

The flow chart of the proposed algorithm is shown as Fig.3. When the specified number of evolution generation is reached, the individual whose objective value is smallest in the whole population (not in the subpopulation) is output as the optimal solution of the network reconfiguration problem.

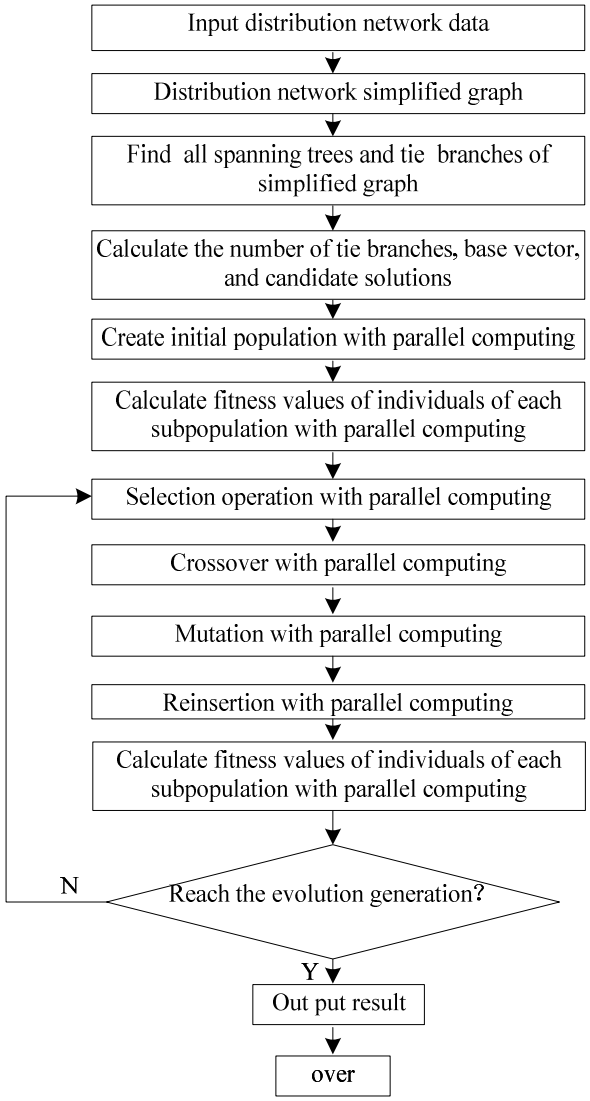

Fig.3 Flow chart of the algorithm

Simulation Case

Two simulation cases are taken to test the capability of the proposed method under the condition that there is single power supply and multiple power supply. In order to facilitate recording data, the optimal solution is determined with the proposed method. Then the optimal solution is taken as the program termination condition. All the relevant programs are written by MATLAB language.

Case 1: shown as Fig.1, there are the 3 feeders, 16 nodes, 3 independent meshes in this distribution network. Fig.2 is the simplified graph of Fig.1. There are 24 spanning trees and total 190 candidate solutions for Fig.2. The length of each chromosome is 3. Because the total amount of candidate solutions is very small, in each subpopulation, chromosomes are chosen to be one-to-one relevant to candidate solutions. That is, method of exhaustion is introduced to directly find the optimal solution.

Case 2: shown as Fig.4, there are 69 nodes, 73 branches, 5 independent meshes in this distribution network. Fig.5 is the simplified graph of Fig.4. There are 463 spanning trees and 377417 candidate solutions for Fig.5. The length of each chromosome is 5. The number of subpopulations equals to that of spanning trees. In the 37 subpopulations which correspond to the most candidate solutions, there are 4 individuals for each population. While in the rest 426 subpopulations, there are 2 individuals for each subpopulation. Therefore, there are 1000 individuals for the whole population. The crossover rate is 0.7, and the mutation rate is 0.01. The program is performed 50 times.

Reconfiguration results and relevant statistical data for case 1 and 2 are shown as Table 4 and Table 5.

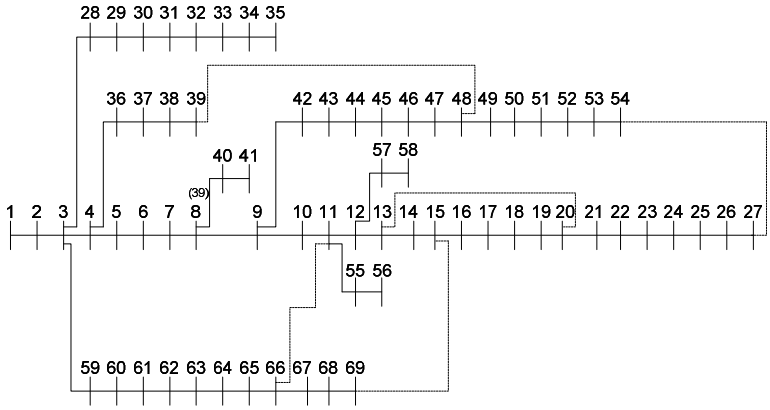

Fig.4 American PG&E69 nodes distribution network

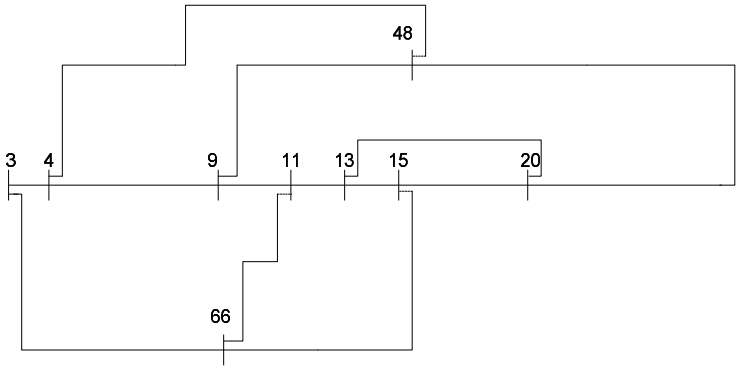

Fig.5 Simplified graph of Fig.4

As for the 16 nodes system, it takes 0.012s to find the optimal solution. As for 69 nodes system, it takes 6.22 times of average evolution generation and 0.534s to find the optimal solution, much better than the results of reference [8]. The reason why the reconfiguration results of the proposed method are different from that of reference [8] is that because there are no loads at nodes 45, 46, 47, open switches on the branches 44-45, 45-46, 46-47, 47-48 have the same effect.

It can be seen from the cases that the proposed method has very high search efficiency and calculation speed.

Table 4 Reconfiguration results of the two distribution network

Distribution system	Open switches before reconfiguration		Open switches after reconfiguration	Power loss before reconfiguration [kW]	Power loss after reconfiguration [kW]	Power loss descent rate
16nodes	5-10, 11-16, 4-15		4-15, 8-10, 7-11	511.4	466.1	8.85%
69nodes	11-66, 15-69, 27-54, 13-20, 39-48	Results in[8]	11-66, 14-15, 50-51, 13-20, 47-48	229.5	102.10	55.5%
		Results in this paper	11-66, 14-15, 50-51, 13-20, 46-47	229.5	101.01	56.0%

Table 5 Evolution statistics

Distribution system	Minimal generation to get global optimum results [generation]	Maximal generation to get global optimum results [generation]	Average generation to get global optimum results [generation]	Average calculation time[s]
16nedes	1	1	1	0.012
69nodes	Results in[8] 21	32	22.40	25.423
	Results in this paper 1	16	6.22	0.534

Conclusions

In this paper, a genetic algorithm based on all spanning trees of simplified graph of distribution network for network reconfiguration is proposed. The total candidate solutions and their distribution can be precisely calculated, which can supply information for determining the numbers of subpopulations and individuals in each subpopulation. The disadvantages of conventional genetic algorithm for distribution network reconfiguration that a large amount of unfeasible solutions are created in the process of crossover and mutation is completely overcome. Therefore, search efficiency of the proposed algorithm is highly improved. The identity number of open switch on each tie branch is taken as the optimization variable and decimal coding scheme is introduced. As a consequence, the length of chromosome is greatly shortened and storage space is minimized while calculation speed is improved. There is little calculation coupled between subpopulations. So it is very suitable for parallel computing. Two cases indicate the proposed algorithm has the merits of high calculation speed and superior capabilities.

Keywords: power system, load model, induction motor, static load, distribution network, load aggregation.

Abstract. This paper proposes a methodology for the aggregation of distribution network, induction motors and static loads. This methodology can aggregate induction motors and static loads model into one composite load model with distribution network considered. The absence of simplifications, the proper aggregation of distribution network and the adequate handing to motor mechanical load allow this methodology shows pretty good accuracy. A simple simulation test is also taken to validate the proposed methodology.

Introduction

In power system, The model of each component is the base of simulation. Load model plays one of the key roles on power system dynamics[1-3]. Because of its time variability, randomness and complexity, load model is the bottle beck of improving the accuracy of simulation. In practice, thousands of induction motors loads and static loads scatter in a large distribution network. The distance from induction motors loads and static loads to the 220kV bus of substation is different. How to precisely simulate the overall effect of induction motors loads and static loads is a challenge. Limited by memory capacity and speed of computer, it is not practical to simulate substation in detail. In load modeling, component-based approach is adopted widespread[4]. In component-based load modeling approach, aggregation algorithm is crucial to the accuracy of the load model. Because parameters of induction motor have extraordinary impact on power system dynamics, aggregation of induction motors is focused on. So as far, there are kVA-weighted averages aggregation method, no-load and block-up-roll based aggregation method, static equivalent circuit of induction motor based aggregation method and dynamic equivalent circuit of induction motor based aggregation method. In [5], with the impact of loading factor and critical slip of induction motor on the transient stability of system analyzed, a improved MVA-weighted averages aggregation method is proposed. But this method is still a heuristic method, lack of strict theoretic basis. In [6], with the skin effect considered, leak reactance of stator and rotor are divided to two parts respectively. Thus, the impedance parameters of induction motors add to seven ones. In [7], a no-load and block-up-roll based induction motor aggregation method is proposed. In [8], based on electromechanical model of induction motor, a static aggregation method is proposed, with the assumption that the stator resistance is zero, the mechanical torque is constant and the leak reactance of stator is equal to the leak reactance of rotor. In [9] and [10], the steady equivalent circuit of induction motor is transformed to a three impedances paralleled form, resulting in the aggregation complexity of motors is drastically reduced, but because the steady slip of motors are not considered, active and reactive power absorbed by induction motors is not equal before and after aggregation.

In the load aggregation method mentioned above, the induction motors are assumed to connect to the same bus, that is, the effect of distribution network is not considered. But in practice, induction motors and static loads scatter in a large distribution network. The value of equivalent distribution reactance plays significant influence on the transient and voltage stability of power system. With the distribution network considered, this paper propose a strict load aggregation method. The absence of simplifications, the proper aggregation of distribution network and the adequate handing to motor

mechanical load allow this methodology shows pretty good accuracy. A simulation test is also taken to validate the proposed method.

Shown as Fig.1, a substation is composed of transmission lines, transformers, capacitors, induction motors loads and static loads. Simulation achieves computationally feasible only if the substation be equivalent to a simple model. Shown as Fig.2, the synthesis load model (SLM) that takes the distribution network into account, is a proper load model structure.

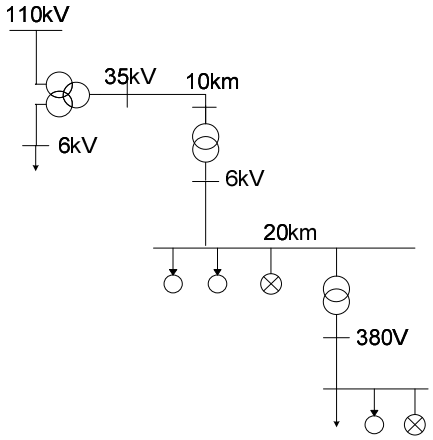

Fig.1 Distribution network diagram

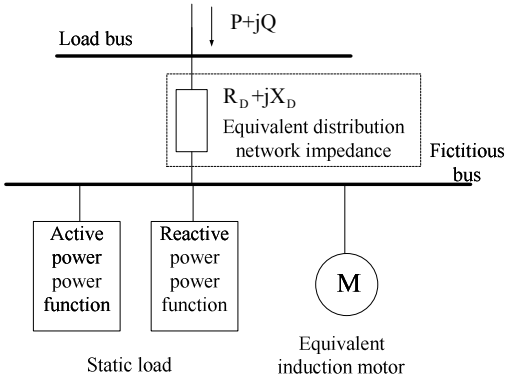

Fig.2 SLM model

Aggregation of Distribution Network

Suppose the number 0 bus is the main bus of substation; number 1～k buses are load buses; k+1~m are connection buses. The buses voltage equation of distribution network is:

$$\begin{bmatrix} \dot{I}_A \\ \dot{I}_B \end{bmatrix} = \begin{bmatrix} Y_{AA} & Y_{AB} \\ Y_{BA} & Y_{BB} \end{bmatrix} \begin{bmatrix} \dot{U}_A \\ \dot{U}_B \end{bmatrix} \tag{1}$$

where, $\dot{I}_A$ is the steady current vector injected into the main bus and the load buses; $\dot{I}_B$ is the steady current vector injected into connection buses; $\dot{U}_A$ is the steady voltage vector of the main bus and the load buses; $\dot{U}_B$ is the steady voltage vector of connection buses; Y_{AA} is the self- admittance matrix of 0 ～k buses; Y_{AB} , Y_{BA} are mutual admittance matrixes between 0～k buses and k+1~m buses; Y_{BB} is the self-admittance matrix of k+1~m buses. Eq.1 can be expanded to the following two equations:

$$\dot{I}_A = Y_{AA}U_A + Y_{AB}\dot{U}_B \tag{2}$$

$$\dot{I}_B = Y_{BA}\dot{U}_A + Y_{BB}\dot{U}_B \tag{3}$$

Because the current injected into the connection buses are zeros, we have:

$$\dot{U}_B = -Y_{BB}^{-1}Y_{BA}\dot{U}_A \tag{4}$$

Substituting for $\dot{U}_B$ from Eq.4 in Eq.2, one deduces:

$$\dot{I}_A = (Y_{AA} - Y_{AB}Y_{BB}^{-1}Y_{BA})\dot{U}_A \tag{5}$$

Thus, the connection buses is eliminated. The distribution network can be simplified to the form shown as Fig.3.

According to the principle of equivalence of active and reactive loss on the distribution network before and after aggregation, the equivalent impedance of distribution network is:

$$Z_{D,eq} = \left[\sum_{i=1}^{k} U_i^2 \hat{y}_{i0} - \sum_{i=1}^{k-1} \sum_{j=i+1}^{k} \dot{U}_i \left(\hat{\dot{U}}_i - \hat{\dot{U}}_j \right) \hat{Y}_{ij} \right] / I_s^2 \tag{6}$$

where, $\dot{U}_i$ is the steady voltage phasor of the i^{th} load bus; $\hat{\dot{U}}_i$ is the conjugate complex of $\dot{U}_i$; $\hat{\dot{U}}_j$ is the conjugate complex of the steady voltage of the j^{th} load bus; $\hat{y}_{i0}$ is the conjugate complex of to-ground-admittance of the i^{th} bus; $\hat{Y}_{ij}$ is the conjugate complex of the mutual admittance between i^{th} and j^{th} load bus; I_s is the steady current injected to the main bus from transmission system. The steady voltage of the fictitious bus is:

$$\dot{U}_f = \dot{U}_s - Z_{D,eq}\dot{I}_s \tag{7}$$

where, $\dot{U}_s$ is the steady voltage of the main bus; $\dot{I}_s$ is the steady current phasor injected into the main bus. Thus, shown as Fig.4, each load bus can be connected to fictitious bus through an ideal phase shift transformer. Then all induction motor loads and static loads can be transferred to the fictitious bus according to their per unit parameters. Therefore, the aggregation of loads can be done in such a way that all loads is under the same bus.

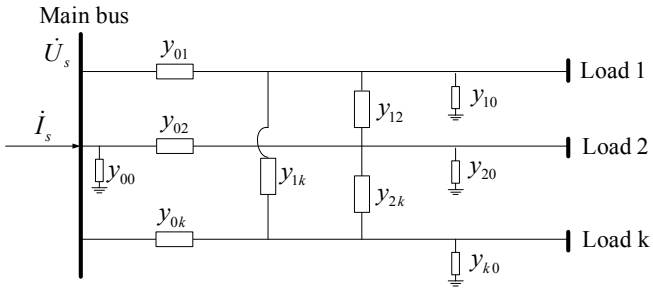

Fig.3 The implied figure of computing distribution network

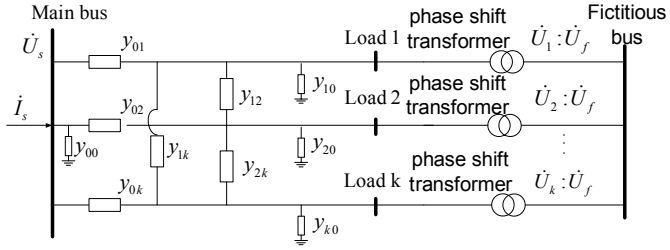

Fig.4 The implied figure of displacing load

Aggregation of Induction Motors

Equivalent Circuit of Induction Motor.

Steady equivalent circuit of induction motor is shown as Fig.5 and the dynamic one is shown as Fig.6.

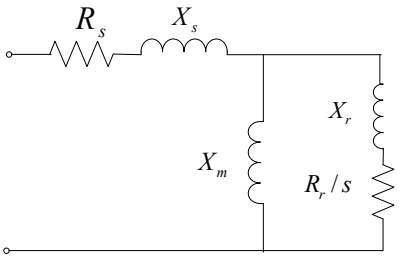

Fig.5 Steady equivalent circuit of induction motor

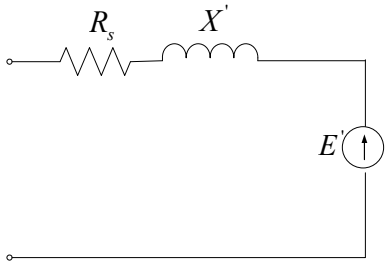

Fig.6 Transient equivalent circuit of induction motor

In steady state, according to Thevenin theorem, seen from the rotor resistance of induction motor, the steady equivalent impedance of induction motor is:

$$Z_e = R_e + jX_e = (R_s + jX_s)//jX_m + jX_r = (R_s X_{sm}^2 - jX_p X_{rm})/(X_P^2 + R_s^2 X_{sm}^2) \tag{8}$$

where $X_{sm} = X_s + X_m \quad X_{rm} = X_r + X_m, X_p = X_s X_m + X_r X_m + X_s X_r$.

The steady equivalent voltage is:

$$U_e = X_m / \sqrt{R_s^2 + X_{sm}^2} U_f \tag{9}$$

The steady electric torque of induction motor is:

$$T_e = \frac{U_e^2 (1-s) R_r / s}{\omega_s [(R_r / s + R_e)^2 + X_e^2]} \tag{10}$$

The mechanical torque of induction motor has the following form:

$$T_m = T_0 [a(1-s)^2 + b(1-s) + c] \tag{11}$$

where, $a+b+c=1$ and T_0 is a constant. According to $T_e=T_m$, the steady slip of induction motor can be calculated. From Fig.6, the steady electromotive is:

$$\dot{E}^{'}=j(X-X^{'})\dot{U}_f/[jsZ^{'}T_{d0}^{'}+Z^{'}+j(X-X^{'})] \tag{12}$$

Aggregation Method.

The dynamic model of induction motor is:

$$d\dot{E}^{'}/dt=-js\dot{E}^{'}-[\dot{E}^{'}-j(X-X^{'})\dot{I}]/T_{d0}^{'} \tag{13}$$

$$\dot{U}_f=\dot{E}^{'}+(R_s+jX^{'})\dot{I} \tag{14}$$

$$T_j ds/dt=T_m-T_e \tag{15}$$

$$T_e=\mathrm{Re}(\dot{E}^{'}\hat{\dot{I}}) \tag{16}$$

where $T_m=(A\omega^2+B\omega+C)T_0$ $A\omega_0^2+B\omega_0+C=1$ $\omega_0=1-s_0$; $T_{d0}^{'}=(X_r+X_m)/(\omega_s R_r)$ is the open circuit time constant; $X=X_s+X_m$ is the open circuit reactance of stator of induction motor; $X^{'}=X_s+X_r X_m/(X_r+X_m)$ is the transient reactance of induction motor; T_j is rotor inertia time constant of induction motor.

Let $\dot{E}^{'}=Ee^{j\delta}, \dot{U}_f=Ue^{j\theta}$, $j(X-X^{'})/(R_s+jX^{'})=Z=Ke^{j\alpha}$ $R_s+jX^{'}=Z^{'}=\left|Z^{'}\right|e^{j\beta}=\left|Z^{'}\right|e^{j(90^{\circ}-\alpha}$, substituting them into Eq.13, Eq.15 the dynamic model of induction can be transferred to the following form:

$$dE/dt=-[E-KU\cos(\theta+\alpha-\delta)+KE\cos\alpha]/T_{d0}^{'} \tag{17}$$

$$d\delta/dt=-s+[KU\sin(\theta+\alpha-\delta)/E-K\sin\alpha]/T_{d0}^{'} \tag{18}$$

$$T_j ds/dt=[EU\cos(\delta-\theta-\beta)-E^2\cos\beta]/\left|Z^{'}\right|-T_m \tag{19}$$

There many induction motors connected to the fictitious bus, the Norton equivalent circuits are shown as Fig.7. The equivalent transient impedance is:

$$Z_{eq}^{'}=1/(\sum_{i=1}^{n}1/Z_i^{'}) \tag{20}$$

The equivalent steady electromotive is:

$$\dot{E}_{eq}^{'}=\sum_{k=1}^{n}\left(\dot{E}_k^{'}/Z_k^{'}\right)Z_{eq}^{'} \tag{21}$$

From Eq.20, it has:

$$\left|Z^{'}\right|=\left|Z_{eq}^{'}\right| \tag{22}$$

$$\beta_{eq}=Ang\left(Z_{eq}^{'}\right) \tag{23}$$

$$R_{s,eq}=Re(Z_{eq}^{'}) \tag{24}$$

$$X_{eq}^{'}=\mathrm{Im}(Z_{eq}^{'}) \tag{25}$$

From Eq.21, it has:

$$E_{eq}=\left|\dot{E}_{eq}^{'}\right| \tag{26}$$

$$\delta_{eq}=Ang\left(\dot{E}_{eq}^{'}\right) \tag{27}$$

$$\alpha_{eq}=90^{\circ}-\beta_{eq} \tag{28}$$

In steady state, the left side of Eq.17 is zero, the equivalent impedance is:

$$K_{eq}=E_{eq}/[U\cos(\theta_0+\alpha_{eq}-\delta_{eq})-E_{eq}\cos(\alpha_{eq})] \tag{29}$$

According to the definition of Z_{eq} ,the equivalent reactance is:

$$X_{eq}=X_{eq}^{'}+K_{eq}\left|Z_{eq}^{'}\right| \tag{30}$$

$$X_{m,eq}=1/\left(\sum_{k=1}^{n}\frac{1}{X_{m,k}}\right) \tag{31}$$

$$X_{s,eq}=X_{eq}-X_{m,eq} \tag{32}$$

$$X_{r,eq}=\left(X_{eq}^{'}-X_{s,eq}\right)X_{m,eq}/\left(X_{eq}-X_{eq}^{'}\right) \tag{33}$$

According to [6], the transient electromagnetic torque of each motor reaches its peak value after it starts for 13 ms. The peak transient electromagnetic torque is:

$$T_p = V_t^2 R_r [1+\sqrt{1+(X_s+X_r)^2/R_r^2}]/[R_r^2+(X_s+X_r)^2] \quad (34)$$

The peak transient electromagnetic torque of the equivalent motor is equal to the sum of that of the individual motor:

$$T_{p,eq} = \sum_{i=1}^{n} T_{p,i} \quad (35)$$

According to Eq.35, the rotor resistance of the equivalent motor can be obtained. Therefore, the time constant of rotor circuit is:

$$T'_{d0,eq} = (X_{meq} + X_{req})/(\omega_s R_{r,eq}) \quad (36)$$

In steady state, the left side of Eq.18 is zero. Substituting Eq.36 into Eq.18, the steady slip of the equivalent motor is:

$$s_{eq} = [K_{eq} U \sin(\theta_0 + \alpha_{eq} - \delta_{eq})/E_{eq} - K_{eq}\sin\alpha_{eq}]/T'_{d0,eq} \quad (37)$$

In steady state, the left side of Eq.19 is zero. The steady mechanical torque of the equivalent motor is:

$$T_{m0} = [E_{eq} U \cos(\delta_{eq} - \theta_0 - \beta_{eq}) - E_{eq}^2 \cos\beta_{eq}]/|Z'_{eq}| \quad (38)$$

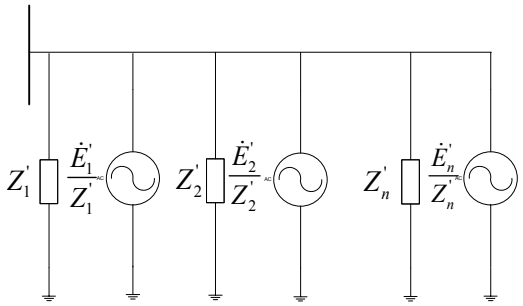

Fig.7 Steady equivalent circuit of manyinduction motors under the same bus

In steady state, the kinetic energy should be equal to the sum of that of individual motor. The inertia time constant can be obtained as follows:

$$H_{eq} = \sum_{i=1}^{n} H_i (1-s_i)^2/(1-s_{eq})^2 \quad (39)$$

The aggregation of mechanical load is as follows:

1) Choose the fictitious bus voltage with a series of discrete values equidistantly in a certain range (such as 1.2-0.1 p.u.).
2) As to every discrete voltage value, calculate the steady slip of every motor.
3) Calculate the active power absorbed by every motor.
4) According to that the active power absorbed by the equivalent motor is equal to the sum of that of the individual motor, calculate the steady slip of the equivalent motor.
5) Calculate the electromagnetic torque of the equivalent motor according to Eq.4.
6) In steady state, the mechanical torque is equal to the electromagnetic torque, therefore, a pair of slip -mechanical torque $(s_{eq}, T_{m,eq})$ can be obtained.
7) The complete mechanical torque characteristics can be obtained by Interpolation and fitting method.

Aggregation of Static Loads.

Generally, the power function model of static load is as follows:

$$P = P_0 \left(\frac{U}{U_0}\right)^{p_u} \quad (40)$$

$$Q = Q_0 \left(\frac{U}{U_0}\right)^{q_u} \quad (41)$$

The model of the equivalent static load should be:

$$P_{eq} = \sum_{k=1}^{n} P_k \quad (42)$$

$$Q_{eq} = \sum_{k=1}^{n} Q_k \tag{43}$$

To get the power function model of the equivalent static load, it has:

$$P_{0,eq} = \sum_{k=1}^{n} P_{0k} \tag{44}$$

$$Q_{0,eq} = \sum_{k=1}^{n} Q_{0k} \tag{45}$$

$$p_{u,eq} = \sum_{i=1}^{n} \rho_{pi} p_{ui} \tag{46}$$

$$q_{u,eq} = \sum_{i=1}^{n} \rho_{qi} q_{ui} \tag{47}$$

Where, $\rho_{pi} = P_{0i} / P_{0,eq}$, $\rho_{qi} = Q_{0i} / Q_{0,eq}$.

Validation Test

The proposed methodology has been tested on a simple distribution network. Shown as Fig.8, four induction motors , a electric arc furnace and a fluorescent ramp scatter in a distribution network. The model of the electric arc furnace and a fluorescent ramp are the ones recommended by IEEE. The inner impedance of the voltage resource is 0.00527+j 0.0378.

The parameters of the four individual motors and of the equivalent motor is shown in the appendix. Impedance between bus 6 and 5 and that between bus 6 and 4 have been incorporated into M4 and M3 respectively. The equivalent impedance of distribution network is 0.0158+j0.0567. The index of active and reactive power of equivalent static load is 4.0649 and 1.65. All parameters are in per unit on base power of 10 MVA.

The simulation is taken in such a way that at 0.05s , a voltage dip of 20% of bus 1 takes place and is cleared at 0.35s. Fitting results of active and reactive power is the criterion to judging the effectiveness of this methodology. Voltage curve of bus 1 is shown in Fig.9. Active and reactive curves before and after aggregation are shown as Fig.10 and Fig.11. It can be seen from Fig.10 and Fig.11 that the fitting result is pretty good.

Conclusions

This paper propose a static methodology of aggregation induction motors and static loads, with distribution network considered. The accuracy of fitting result before and after aggregation is validate by an example.

Keywords: fuzzy control; wide-area damping control; time delay; power system stability

Abstract. A method is proposed to design a wide-area damping controller (WADC) based on fuzzy control to dampen the low-frequency oscillations of interconnected power systems. First, the inputs and expected outputs of a fuzzy logic controller are analyzed. Then, a universe of fuzzy sets, membership functions and fuzzy rules are determined based on the relationship between inputs and outputs, and the fuzzy logic controller is constituted. The WADC consists of a fuzzy logic controller and a gain. The gain is obtained using particle swarm optimization. A four-machine two-area power system is simulated using the Matlab/Simulink software to test the performance of the fuzzy-based WADC. The simulation results indicate that the designed controller can compensate for communication delay and improve interconnected power system damping.

Introduction

With the expansion of the power system, the inter-area low frequency oscillation between power grids has become a significant problem in power system stability. Traditional power system stabilizers, which use local variables as input signals, cannot suitably solve this problem [1]. A wide-area measurement system (WAMS) can provide wide-area feedback signals. These signals can be used in excitation control to enhance multimachine system damping and to restrain low frequency oscillations. In practical engineering, a time delay inevitably exists during the communication of a wide-area signal. This delay will reduce the control effects [2].

A few methods are used to reduce the negative impact of the time delay. Reference [2] developed a switched control algorithm for an excitation control using a wide-area signal with a time delay. This algorithm can reduce the impact of time delays. Reference [3] investigated an adaptive wide-area damping control based on federated Kalman filters. Reference [4] proposed a stability criterion for a wide-area damping controller (WADC) based on the Padé approximation.

Fuzzy control is a type of nonlinear control that does not require a complicated mathematical model. Furthermore, it has good robustness and adaptability. Reference [5] designed a fuzzy logic WADC to compensate for the continuous latency and damp the inter-area oscillations. The oscillatory signal $\Delta\omega$ is a hypothetical sine wave, and it is analyzed in a period of oscillation when fuzzy rules are determined. However, the actual oscillatory signal is not a sine wave.

This report applies fuzzy control to wide-area damping control to compensate for a communication delay in the wide-area measurement system. The method of designing the fuzzy wide-area damping controller (FWADC) is described. Based on a power system toolbox and the fuzzy logic toolbox of Matlab, a four-machine two-area power system is simulated to analyze the performance of the designed controller with different time delays.

Design of FWADC

Modern generators are typically equipped with a high initial response excitation system with high-ceiling voltage to enhance the transient stability of power systems. An excitation system with a PSS can improve the dynamic stability of a power system. Wide-area signals provided by the

WAMS, such as the rotor speed of the generator, the power angle and the tie-line power, can be used in additional excitation control to increase the interconnected power system damping. This report selects different generator speeds as the inputs for wide-area damping control and applies fuzzy control to compensate for the communication delay. A block diagram of the automatic voltage regulator (AVR), PSS, and WADC of generator *i* is provided in Fig. 1.

In Fig. 1, $G_{PSS}(s)$ is the transfer function of the traditional PSS, and $\Delta\omega_i(t)=\omega_i(t)-1$ is its input, where $\omega_i(t)$ is the speed of generator *i*. The input of FWADC is $\omega_{ij}(t-T_d)=\omega_i(t-T_d)-\omega_j(t-T_d)$, where $\omega_j(t-T_d)$ is the wide-area signal from generator *j*. T_d is the communication delay. A block diagram of the FWADC is provided in Fig. 2. The inputs for the fuzzy logic controller are $e=\omega_{ij}(t-T_d)$ and $ec=\dot{\omega}_{ij}(t-T_d)$, where u is the output of the fuzzy logic controller.

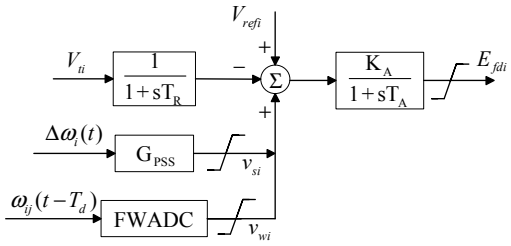

Fig. 1 AVR, PSS and FWADC

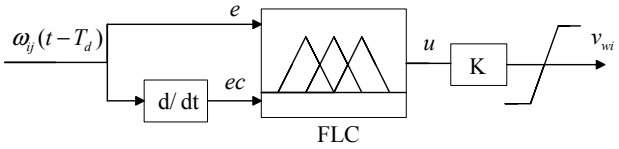

Fig. 2 Block diagram of FWADC

As provided in Fig. 3 [6], a four-machine two-area power system is used to illustrate the design method of the FWADC.

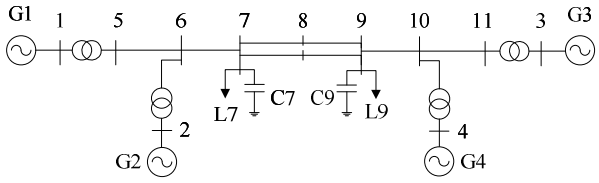

Fig. 3 Four-machine two-area power systems

All four generators are equipped with the local PSS. The transfer function of the PSS is given as follows: $G_{PSS}=20\frac{10s}{1+10s}\left(\frac{1+0.05s}{1+0.03s}\right)\left(\frac{1+3.0s}{1+5.4s}\right)$.

In Fig. 1, the output limit of PSS is ±0.2 pu. The output limit of E_{fdi} is ±5 pu; T_R=0.02; K_A=200; and T_A=0.001. Other parameters can be obtained in reference [6]. Generators 1 and 2 have wide-area damping controllers with inputs $\omega_{14}(t-T_d)$ and $\omega_{24}(t-T_d)$, respectively.

A three-phase short-circuit fault was applied to bus 7 in Fig. 3, and the short-circuit fault lasted for 0.12 s. The results of the time domain simulation are provided in Fig. 4. Curves 1 and 2 in Fig. 4 are the angle differences $\delta_{14}(t)$ and $\delta_{24}(t)$, respectively, when the generators are equipped with only PSSs and no WADCs. Curves 3 and 4 are the angle differences $\delta_{14}(t)$ and $\delta_{24}(t)$, respectively, when generators 1 and 2 are equipped with WADCs without time delay. The WADCs use a conventional proportional control strategy. Fig. 4 indicates that the WADC can obtain a good control effect without time delay when a conventional proportional control strategy is applied. In this condition, the input of WADC is $K\omega_{ij}(t)$, which indicates that the WADC's output v_{w1} is essentially in phase with its input $\omega_{14}(t)$ while v_{w2} is essentially in phase with $\omega_{24}(t)$. Thus, when

the input of the FWADC is $\omega_{ij}(t-T_d)$, the FLC must have the ability to compensate for time delay so that the FLC's output u is in phase with $\omega_{ij}(t)$ to achieve a control effect as good as that without time delay.

Fig. 5 is used to demonstrate the method of determining fuzzy rules [5]. Curve 1 in Fig. 5 is $\omega_{14}(t)$ when only the PSS is applied. Curve 2 is $\omega_{14}(t-0.3)$, and curve 3 is $\dot{\omega}_{14}(t-0.3)$.

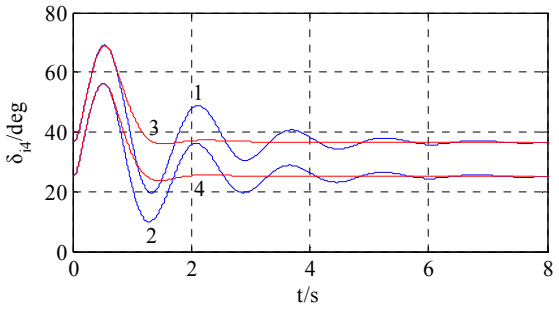

Fig. 4 Curves of rotor angles for T_d=0 s

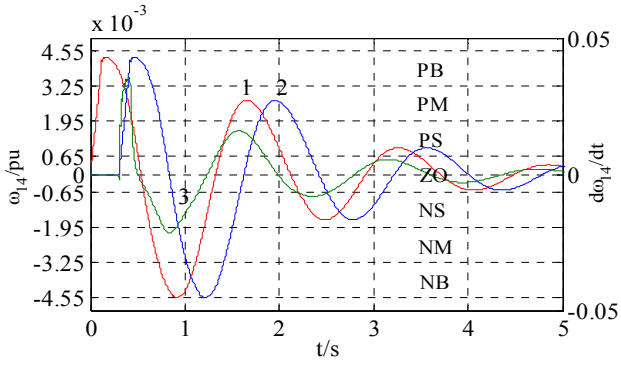

Fig. 5 Determination of fuzzy rules

The universe of fuzzy input and output variables e and u includes seven fuzzy subsets: NB (negative big), NM (negative medium), NS (negative small), ZO (zero), PS (positive small), PM (positive medium) and PB (positive big). The universe of fuzzy input variable ec includes two fuzzy subsets: N (negative) and P (positive).

The fuzzy input and output variables select a triangular function as their membership function. The membership functions of fuzzy input variable e and output variable u are provided in Fig. 6. The membership function of fuzzy input variable ec is presented in Fig. 7.

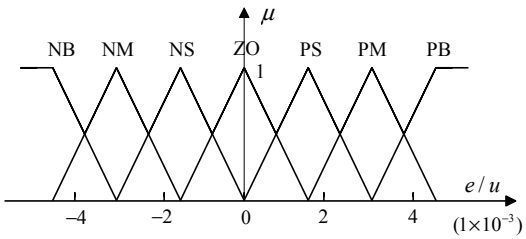

Fig. 6 Membership function of e and u

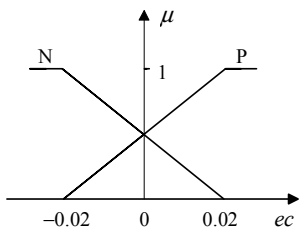

Fig. 7 Membership function of ec

For a four-machine two-area system, the objective of determining fuzzy rules is to ensure that the FLC's input u is in phase with $\omega_{ij}(t)$. The fuzzy rules for generator 1 at T_d=0.3 s are provided in table 1.

Table 1 Fuzzy rules of generator G1

u		e						
		NB	NM	NS	ZO	PS	PM	PB
ec	N	NB	NB	NB	NM	NB	NM	NS
	P	PS	NS	PM	PM	PM	PM	PM

Simulation analysis

The four-machine two-area power system is tested to analyze the performance of the FWADC.

The appropriate universe of variables is determined according to Fig. 5. The universe of input variable e and output variable u is [-0.00455, 0.00455], and the universe of input variable ec is [-0.02, 0.02].

The time delay is approximately 0.1 s for a fiber-optic link [7]. As for the small time-delay, the designed FWADC in this report can easily achieve a good performance. Thus, the details are ignored at T_d=0.1 s.

The time delay is approximately 0.3 s for a telephone link [7]. The fuzzy rules at T_d=0.3 s are provided in Table 1. Details of the FLC are set based on the analysis above. The four-machine two-area power system is simulated, and the results are provided in Figs. 8 and 9.

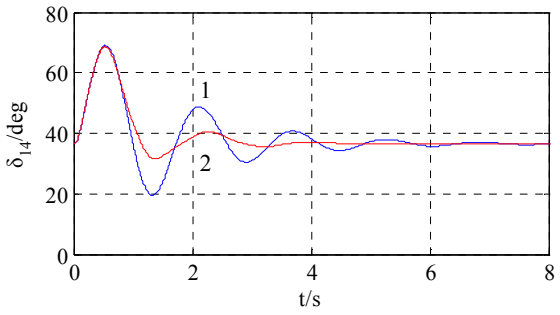

Fig. 8 Curves of rotor angle δ_{14} for T_d=0.3 s

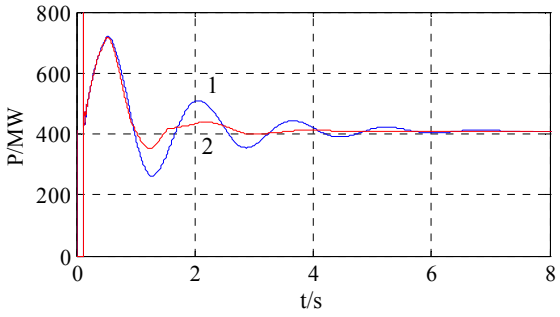

Fig. 9 Tie-line power for T_d=0.3 s

Curve 1 in Figs. 8 and 9 shows the simulation results with PSS and without WADC. Curve 2 in Fig. 8 and Fig. 9 is the results with FWADCs equipped in generators 1 and 2 at T_d=0.3 s. The two figures indicate that the designed FWADC can clearly improve power system damping.

Conclusion

In this report, the communication delay of the WAMS is considered, and fuzzy control is applied to compensate for the delay. The process of determining the universe of fuzzy sets, membership functions and fuzzy rules are analyzed. A simulation of the four-machine two-area power system indicates that the presented method can suppress the adverse effects of time delay, enhance interconnected power system damping and restrain low frequency oscillations.

Keywords: Distribution network; Genetic Algorithm; Yearly comprehensive costs; Multi-island group strategy

Abstract: In view of faults which the traditional genetic algorithm (GA) have such as slow convergence speed and easy to fall into the local optimum. This paper put forward a genetic algorithm which is based on the multi-island group strategy, and applied it to the distribution network planning. The paper has established a planning model which takes the yearly comprehensive cost as objective function and discusses the repair methods of islands, solitary chain and closed-loop to meet with the requirements of grid radial. Finally, the proposed method is planning on a 54-node grid to prove the effectiveness of the algorithm and model.

Introduction

Distribution network planning is based on the existing network structure, power distribution network planning and load forecasting, according to the existing power grid structure and the economic development, to make the working economy of the power distribution network to achieve the optimal, and to have a higher quality of power supply and power supply reliability by reasonably choosing new circuits such as transformer and other electric equipment[1].

With the increasing of the distribution network scale, using the traditional mathematical programming method to solve the distribution network planning problem is becoming harder and harder. Therefore, a large number of intelligent algorithms have sprung up in recent years including genetic algorithm [1], the ant colony algorithm[2], the tabu search algorithm[3], etc. The ant colony algorithm[2]determine the upward node of each new node by transition probability, but you must generate new expression if you want to add new options factors in the transformation probability, which will heavily affect the stability of the planning results and are not suitable for flexible application. The tabu search algorithm[3]often lead to phenomenon of coding too long and the planning result change along with experience, which will lead to low optimization efficiency . The genetic algorithm has considered the nonlinear characteristic of the optimization problem and the discontinuous characteristics of the constraint and can provide multiple sets of optimization solutions, which are more suitable for solving the distribution network planning problem.

This paper established a model of distribution network planning which take the minimum comprehensive yearly cost as the objective function and adopt the genetic algorithm (GA) based on the multi-island group strategy to solve the model. Then through comparing with the mode only considers the initial investment and other algorithms, the paper uses a 54-node case to have proved the effectiveness of the model established in this paper.

The mathematical model of distribution network planning

The objective function. The distribution network planning model in this paper take minimum yearly comprehensive cost of the power grid as the objective function [4], namely

$$\min f(X) = \sum_{i=1}^{n} (C_{1i} T_i x_i + C_{2i} \tau_{\max i} \Delta P_i) \tag{1}$$

where f(X) represents yearly comprehensive cost of power grid and n represents the number of the erection line; $C_{1i}=\gamma_i+\alpha_i$， γ_i is the return on investment, and αi is the depreciation maintenance fee of equipment; T_i is the cost of new branch *i* cost (yuan). As n decision variables, X=(x1,x2,...,xn) on behalf optional *n* lines in the distribution network planning problem and when i are being built, xi takes 1, otherwise xi takes 0 ; C_{2i} represents the unit electricity price (yuan/kWh) ; τ_{maxi} is the maximum load availability hours(h),ΔP_i is the active power loss of the branch(kW);C_{1i}Tixi is the investment cost of the grid.$C_{2i}\tau_{maxi}\Delta P_i$ is the the cost of power grid loss。

The constraints. Line constraints:

1) power balance constraint

$$\sum P_{ij} = P_{Gi} - P_{Di} (i, j \in N) \tag{2}$$

2) power flow constraint

$$-P_i^{\min} \le P_i \le P_i^{\max}, i \in m + m_0 \tag{3}$$

3) number constraint of Line corridors that allow to wire

$$0 \le x_i \le x_i^{\max}, x \in Z, i \in m \tag{4}$$

Spatial constraint:

1) all the nodes have power supply

2) the ring network is not allowed

Genetic algorithm on the base of multi-island group strategy.

The basic principle of multi-island group strategy. This paper scatter all creatures participating in the evolution in two island groups. Individuals in one island group evolution by the mutation strategy same with traditional genetic algorithm, which is known as gentle island group D_m. The mutation rate threshold of individuals on another island group can be changed dynamically to simulate that the natural environment as a whole is rapidly changing, and this island group is called turbulent island group D_n. Principle of double island swarm is shown in Figure 1.

In order to reserve the optimal solution during evolution of the species, the improved algorithm has taken elitist strategy, where elite individuals from the two island groups will be compared each generation and the best h species will be selected to save in another island group, called elite island group D_h. The individuals in D_h are saved to replace h individuals which have the worst fitness value in the two island groups D_m and D_n in the next generation. Individuals in elite island group have without crossover and mutation, and the island is only used to retain the elite individuals in the other two island groups and to make mutual transmission.

The maximum variation rate setting mode. (1)When aggregation phenomena appears among better solutions, the mutation rate increases.
(2) when the number of the elite individuals in D_n transfer to D_h increases, the mutation rate should reduce.

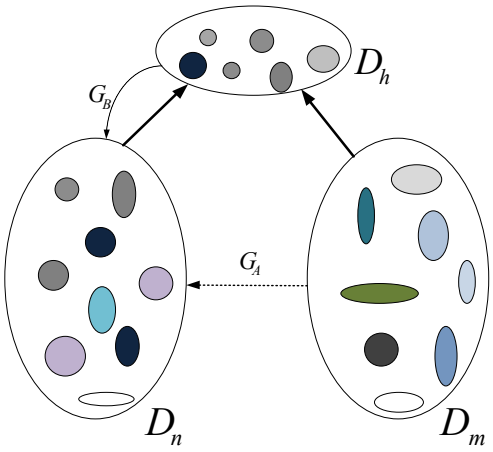

Fig.1 Principle of multi-island algorithm

Combined with the principles above, the largest mutation rate formula is as follows:

$$P'_{m\max} = P_m + \alpha_1 G_A + \alpha_2 G_B \tag{5}$$

Where Pm is the original mutation rate of turbulent island group and α_1,α_2 is the clustering coefficient and strength coefficient, characterizing the influence of aggregation phenomenon in D*m* and the increase of elite individuals in D_n to the variation rate. G_A and G_B are variables which are expressed by 0 and 1 corresponding to the phenomena of aggregation in D_m and the increase of the individual number D_n transferring to D_h.

Network repair program

For the three kinds of problems generates in initialization and genetic operation, namely solitary chain and ring network[5], The repair plan is as follows.

Solitary chain repair. Solitary chain refers to that two or more load nodes connect to each other (it may constitute a loop), but there's no pathway between any node and the power supply, causing the solitary chain can't electricity. Repair method: select any one line to be built that connect load node in solitary chain and the powered grid, so that the entire solitary chain are supplied with power.

Ring repair. When a series of load nodes are linked end to end, a closed-loop is formed, which will bring great inconvenience to the power flow calculation of radial distribution. Repair method is as follows: disconnecting a feeder in a closed network loop, or a feeder that connects pairwise multiple power make each network a radiation network supplied with single power.

Island restoration. A load node without power supply in distribution network is called island. The repair of Island is similar to the method of island chain, the only difference is that every load node must be connected with a network that has been supplied with power by a feeder to get power in Island repair[6].

Cases analysis

The initial network frame and its parameters .The initial network frame is shown in figure 2. The solid line shows the existing network and node, and the dotted line is the extend node network.

The case results and analysis. After the analysis of distribution network planning by improved genetic calculation, the yearly minimum comprehensive cost scheme is shown in figure 3:

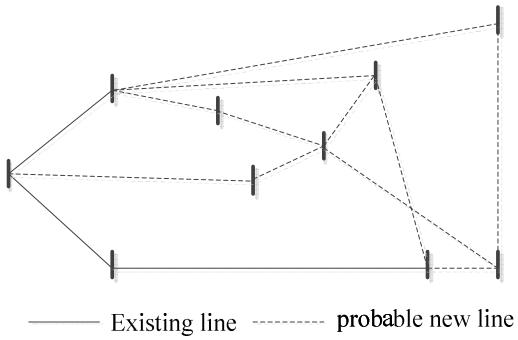

Fig.2 Initial network frame diagram

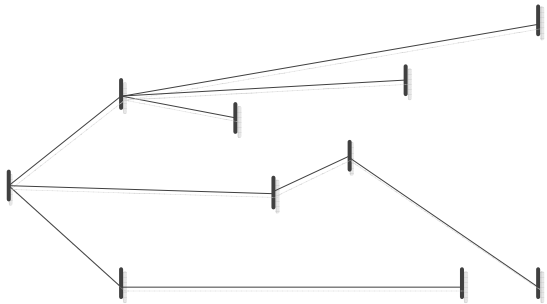

Fig.3 The yearly minimum comprehensive cost solution circuit diagram

The specific circuit connection and circuit parameters of the optimal scheme is shown in the following table 1.

By the data available in the table2, the initial investment of the initial investment model is smaller than that of the yearly comprehensive cost model, but the yearly running cost of the former are much higher than that of the latter, and clearly the final total cost of the model in this paper is much less, which fully shows the advantage of the model in this paper.

Tab.1 Year minimum comprehensive cost

Sending node	Receiving node	R[Ω]	X[Ω]	Active of Sending node[MV]	Active of receiving node [Mvar]
0	1	0.246	0.463	1.20	0.90
1	2	0.898	0.931	1.50	1.13
2	5	0.633	0.515	1.20	0.90
2	8	0.422	0.333	0.50	0.38
2	4	0.868	0.760	0.40	0.30
5	6	0.456	0.354	0.75	0.55
4	3	0.726	0.613	0.60	0.45
4	9	0.112	0.150	0.55	0.41
6	7	0.754	0.556	0.80	0.60

Tab.2 Comparison of two kinds of model

Cost model	Initial investment [wanyuan]	Operation cost [wanyuan]	Yearly Comprehensive cost [wanyuan]
model in this paper	10.05	33.42	43.47
the initial investment model	7.81	56.44	64.25

In this paper, the minimum comprehensive cost model has considered the initial investment and the yearly operation cost, the following table is the comparison of case result of the model in this paper and the model only considering the initial investment.

In this paper, a standard Ackley is used to compare the improved genetic algorithm, traditional genetic algorithm and particle swarm optimization (PSO). The comparison result shown in Fig.4 shows that the convergence speed of improved genetic algorithm is more quickly and search capability is stronger.

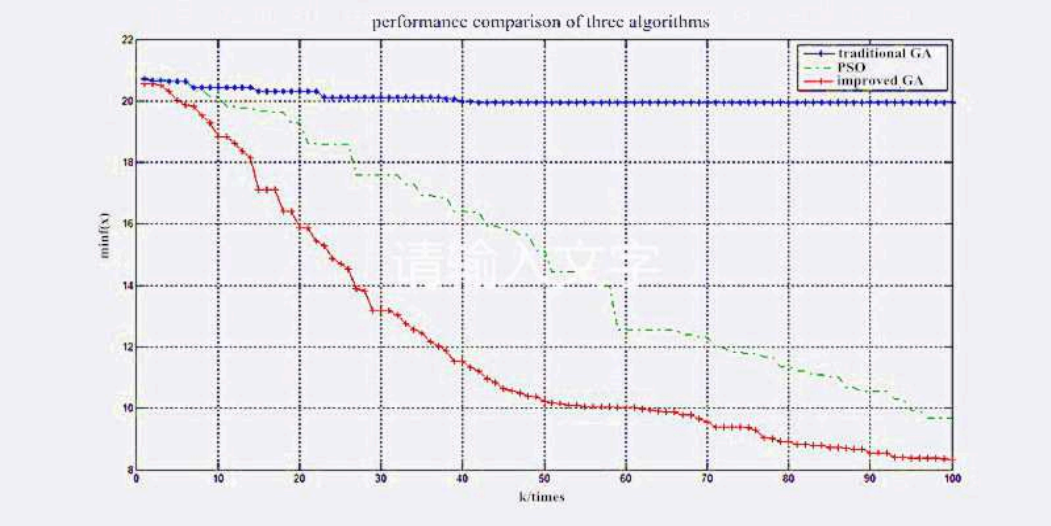

Fig.4 Performance comparison of three algorithms

Conclusions

This paper has established a distribution network planning model which takes the comprehensive annual cost as the objective function and has applied the improved genetic algorithm to solve the model. The multi-island group strategy has been proposed in this paper many islands strategy, which can automatically adjust the evolution strategy by the dynamic change of variable rate threshold. Compared to the traditional algorithm, the improved genetic algorithm has faster convergence speed and stronger optimization ability. Compared to the distribution network planning model only considering the initial investment cost, the optimal scheme under the model put forward in this paper has less operation cost and lower yearly comprehensive cost.

Abstract. It is common practice to use 2nd order polynomial load model for steady-state power flow calculation. The paper describes the experiment for obtaining static load characteristics and the technique for identifying coefficients of the load model based on remote metering system data.

Introduction

There are two most common ways of load representation in mode calculation, namely, constant value of power and static load characteristics.

Presently, the first method is used more often, as obtaining of static load characteristics is a very complicated problem. This assumption is acceptable, but it can result in large error in some situations. Moreover, more accurate static load characteristics allow reducing error in power flows limited by stability conditions [1].

Large load nodes consist of different consumer types. Different consumer types have various static load characteristics. It is usual practice to use 2nd order polynomial as model, because $P(U)$ and $Q(U)$ dependences of the most widespread consumer types is closed to quadratic dependences:

$$Q(U) = Q_n(x)\left(a_0 + a_1\frac{U}{U_r} + a_2\left(\frac{U}{U_r}\right)^2\right). \quad (1)$$

Generalized static load characteristics can only be obtained by experiments: load supply conditions are changed, and then corresponding power changes are fixed. The main power system parameters affecting the load power are frequency and voltage. Frequency fluctuations are negligible, therefore static load voltage characteristics will be referred to as simply static load characteristics.

The problem is that static load characteristics can be obtained if load structure is constant. It means that technical process intervention in power changes should be excluded. However, it is connected with technical complexity and quite often, it is impossible to conduct such experiment. Therefore special algorithms of experiment conducting and data processing should be developed.

Automated electrical systems department of the Ural Federal University has been working on the problem in recent years. As a part of the study, some methods of characteristics definition based on measurement data were developed.

For the purpose of testing developed methods, some experiments were conducted in the node of Russia power system. The task was to obtain static load characteristics for two large enterprises. Data obtained as a part of the experiment were processed by means of developed methods.

Preparation to the experiment

Firstly, a number of steady modes were calculated based on the network diagram. This diagram is shown below. It consists of two power plants (power plant 1, power plant 2) and three substations (substation 1, substation 2 and substation 3).

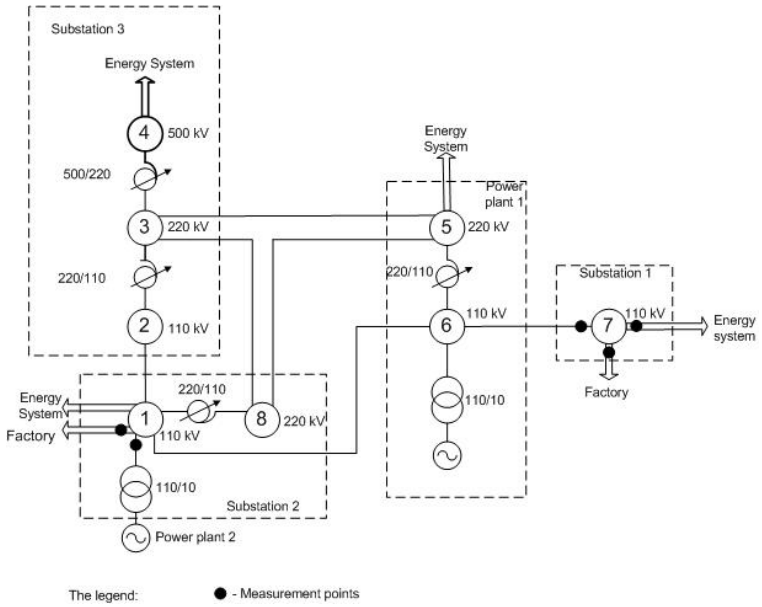

Figure 1 Scheme of investigating node

As a part of calculation results analysis, it was founded that the desired range of voltage fluctuation can be reached using following regulating means: excitation system of synchronous generator in power plant 1, excitation system of synchronous generator in power plant 2, tap-changer of 500/220 kV autotransformer in 500 kV neighboring substation, static capacitor bank 110 kV in neighboring substation.

The Experiment

The Experiment involved sequential voltage changes on the 110 kV buses of substation 1 and 110 kV buses of the substation 2 by regulating means mentioned above.

Due to a great number of measuring points and lack of opportunity to connect directly to the substation current circuits, telemetering data were used.

Voltage changes were the following:

$$U_r \to U_{\max} \to U_r \to U_{\min} \to U_r . \quad (2)$$

Voltage changing step in regulation points should be more than quantum of telemetering, it has been achieved by step size more than 0,5-1 kV. Retracing of control voltage values is necessary to identify opportunity of using the data by means of rapid assessment (fig.2).

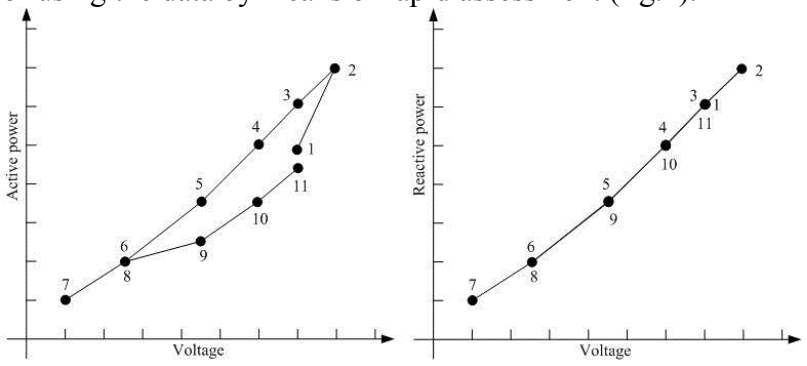

Figure 2 Active and reactive power as a function of voltage. Numbering corresponds to the order of measurements.

Significant load changing could happen for reasons beyond the control. Rapid assessment identifies whether the change was significant. Load changing can be concerned as significant, if the difference between total capacity in the beginning of experiment (point 1, fig. 2) and in the end (point 11, fig. 2) is more than 10 %. In this case, experiment should be repeated. If dispersion of experimental data is negligible, then obtained arrays of voltage, active and reactive power are handled by developed methods.

The maximum voltage value on 110 kV bus was 124 kV, the minimum voltage value was 106 kV. However, actual range was less.

As a part of experiment, it was obtained: values of active and reactive power of incoming line, voltage values of upper (110 kV) and low (10 kV) voltage buses, values of active and reactive power of outgoing lines.

Dynamics of the controlled mode parameters (voltage and active power) on the upper voltage buses is pictured on fig. 3-4.

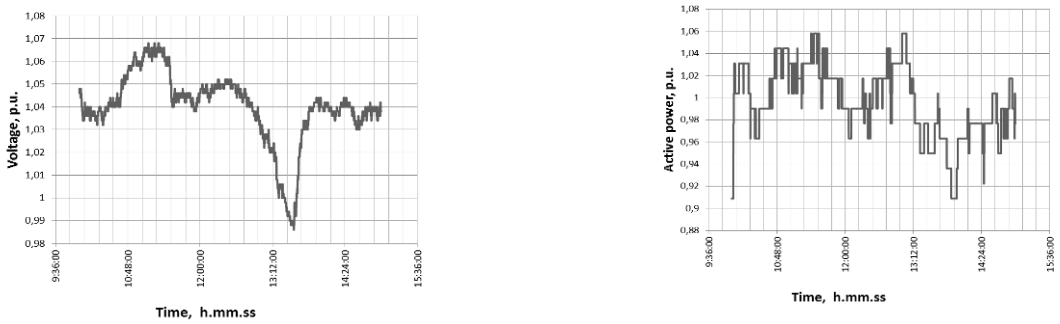

Figure 3 Dynamics of the controlled mode parameters (voltage and active power)

Experimental voltage-power dependence is shown on figure 4.

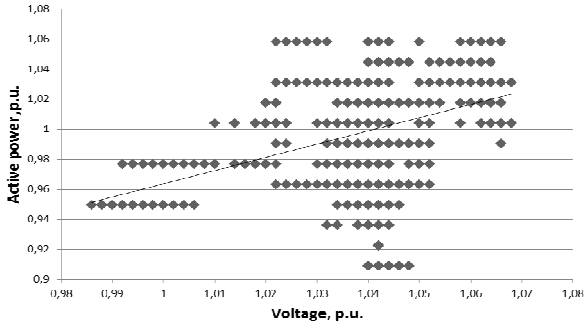

Figure 4 Experimental dependance active power to voltage

It is clear from the picture that one value of voltage corresponds to different values of active power. It means that changes of customer's load have occurred during the experiment. Also other factors could have an influence on the voltage, such as an error of measurement tools, quantization error and so on.

The analysis shows that experimental data should be pretreated with the purpose of elimination of the technological process effect. Arrays of voltage, active and reactive power for each low voltage bus system are initial data.

Data processing

Data processing was carried out by three methods: based on investigation of derivatives, based on the analysis of voltage fluctuations on the adjacent buses, based on the computational simulation experiment.

Method based on investigation of derivatives. The technique is to find the slope of the polynomial curve. At the first stage, a small interval, for instance 10 points, is adopted. As power and voltage increments are small, then it is possible to equate the ratio of the power increment to voltage increment and slope of the tangent. Thus, the slope of the tangent can be determined as derivative of polynomial Eq.1:

$$\tan\varphi = a_1 + 2a_2 U'_{p.u.}, \quad (3)$$

where $\tan\varphi$ - slope of the tangent

$U'_{p.u.}$ -average voltage in the interval

a_1, a_2 –coefficients of polynomial.

On the other hand, taking into account small of increments:

$$\tan\varphi = \frac{P_1 - P_2}{U_1 - U_2}, \tag{4}$$

where P_1 and P_2 are maximum and minimum values of the power respectively, in the time interval under study.

Then the interval is moved by one point and calculation is repeated. There can be runouts in the experimental data, therefore some filtration algorithms should be used.

As a result, overdetermined system will be obtained:

$$\begin{cases} a_1 + 2a_2 U'_{p.u.}(1) = (\tan\varphi)_1 \\ < \ldots > \\ a_1 + 2a_2 U'_{p.u.}(m) = (\tan\varphi)_m \end{cases}, \tag{5}$$

where m- the number of equations after filtering.

In matrix form, Eq.5 can be written according to the Eq.6:

$$\overline{U}\,\overline{A} = \overline{T},$$

$$\overline{U} = \begin{pmatrix} 1 & 2U'_{p.u.}(1) \\ < \ldots > & < \ldots > \\ 1 & 2U'_{p.u.}(m) \end{pmatrix}; \tag{6}$$

$$\overline{A} = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}; \overline{T} = \begin{pmatrix} (\tan\phi)_1 \\ < \ldots > \\ (\tan\phi)_m \end{pmatrix}.$$

The system solution by means of the least square methods can be represented as:

$$\overline{A} = \left[\overline{U}^T \overline{U}\right]^{-1} \overline{U}^T \overline{T}. \tag{7}$$

Coefficient a_0 can be founded from relation:

$$a_0 = 1 - a_1 - a_2. \tag{8}$$

Method based on the computational simulation experiment. The method is based on mathematical models, which include separate electrical receivers in the form of different equivalent electrical circuits. Also the method relies on the systems of equations which describe the behavior of an object in steady states.

Model is compiled in the software, and then a series of calculations of steady states is made. Polynomial coefficients are indicated using the method of the least squares.

The features of this method are:

- the absence of necessity in full scale tests;
- the inaccuracy of the statistical characteristics of loads depends on the degree of the mathematical model specification and adopted assumptions. The structure of the model and the typology of the analytical scheme also depend on structure, quality and availability of input data on the object of study.

Method based on the analysis of voltage fluctuations on the adjacent buses . This method as well as the method based on investigation of derivative deals with telemetry data.

The basic idea of this method is the following: each of the low voltage bus section is connected with high voltage buses, which are joined by a parallel job. During voltage changes on the high voltage bus, the voltage and load changes on one bus section will have the same direction as the voltage and load changes on another. Consequently, if we consider the two bus sections and take only the points where the voltage and power of both sections are changed in the same direction. Then on the remaining points static load characteristics can be obtained by method of the least square method.

These methods are described in [2].

The results are shown on fig.7.

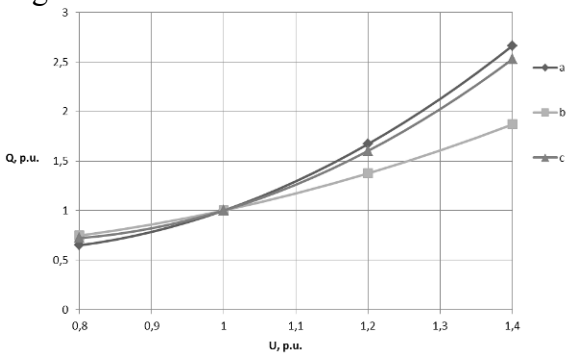

Figure 7. Static load model for the industrial factory

a- Method based on the investigation of derivatives;
b- Method based on the computational simulation experiment;
c- Method based on the analysis of voltage fluctuations on the adjacent bus

As it can be seen, the obtained curves are quite close to each other in the range around nominal value. Hence it can be assumed that the proposed algorithm identifies coefficients of static characteristics of the load voltage with sufficiently low inaccuracy.

It should be noted, that data were obtained around nominal value, therefore it is impossible to accurately determine static load characterisics for low and high values. To solve this problem practical data should be obtained for a wider range of values. But it is impossible to conduct this experiment for technical reasons.

Summary

Method based on computational simulation experiment is effective, but rather time-consuming. Method based on investigation of derivatives and method based on the analysis of voltage fluctuations are rather low work content. Moreover the last method can be used for automated analysis of static characteristics of major load centers.

It should be noted that characteristics obtained by three methods are rather close to each other.

Keywords: medium-speed pulverizer, large delay, AGC, energy saving and consumption reducing

Abstract. Large delay is the main characteristics of medium-speed pulverizer system which used in subcritical and supercritical unit. By introducing and analyzing the operating principle and working process, considering energy saving and consumption reducing, and combined with the performance requirement of AGC (Automatic Generation control), recommend solutions were put forward. It can effectively solve AGC control problems of load and pressure control accuracy and ensure frequency stability of the grid, provide a reference for similar units.

Introduction

Power grid frequency is one important indicators of power quality, it reflects the balance between the generation of active power and actual electricity usage, and it is an important control parameter of the power system operation. Currently, frequency compensation is mainly used for thermal power.

The safety and efficiency of the majority of users of electrical equipment and power equipment have a close relationship with power grid frequency. Equipment of users is generally driven by the motor, the same as equipment of power plant. The frequency fluctuation has a critical influence over them. With the development of science and technology, some new electronic equipment and precision processing equipment put forward higher request to power grid frequency, the frequency fluctuations will lead to lower product quality or equipment damage. According to the IEEE 446-1995 standard and BS EN50160:1995 standard, ±0.5Hz is the maximum tolerance of the frequency fluctuations of many devices. The occurrence of unexpected failures in the power grid will break the balance between the generation of active power and load. With the development of the power system, single device failures bring a growing loss of generating power grid. Only relying on manually adjust the power generation output will require a longer time to achieve a new balance. Solve these problems, the way is only one that is the techniques of primary frequency compensation and automatic generation control (AGC, the equivalent of secondary FC). It's a good idea to use different logical controls according to its own regulation performance, to maintain the balance of power system supply and demand automatically, thus ensuring the quality of the power system frequency.

To meet the power requirements of power quality and according to the latest standards, unit power and pressure control has been redesigned and verification. Especially, the large delay problem of widely used medium-speed pulverizer system has been analyzed and proposed effective solutions.

Status of AGC Control

Traditional AGC in the power plant control structure is shown as Fig.1. The standalone AGC commands from energy manage system(EMS) will be sent to remote terminal unit(RTU) of power plant side, then by the RTU via I/O hard-wired to send to unit coordinated control system (CCS), to complete the adjustment task of unit's AGC system.

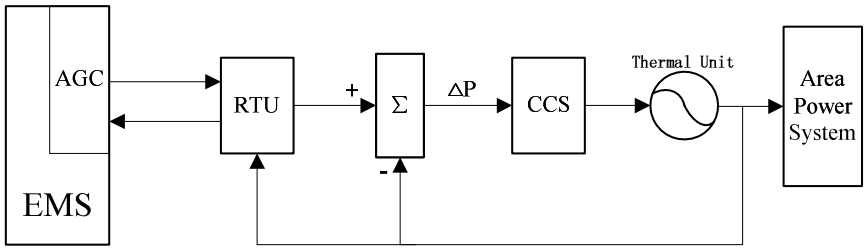

Fig.1. Dispatch center control schematic diagram of a single thermal power unit

According to the rules of Dispatch center, the operation of AGC must to be run in accordance with the scheduling curve, it put forward higher requirements on control system of the unit. The full load of power generation is the test of the device; the variable load is the test of the whole control system. How to on the basis of existing equipment, optimize the control strategy, realize the load control requirements, and ensure stable operation of the unit, is a problem that must be considered.

Adjustment rate, adjustment accuracy and response time is three main criteria of AGC assessment. As shown in Fig.2, it is a set point control process of a typical AGC unit. $P_{\min,i}$ is the lower limit of the unit adjustable output, $P_{\max,i}$ is the upper limit of its adjustable output, P_{Ni} is its rated output, P_{di} is a critical power point of its start and stop grinding. The whole process can be described as, T0 time ago, the unit work stably near the output P1. T0 time, AGC control program sent power command P2 to unit, the unit start up. To the time T1, unit reliable across the P1 adjustment dead zone, and to the T2 time, unit work into the rev grinding range. Until T3 moment, the rev grinding process is over; the unit continues to raise its power. To T4 time, unit first time work into the dead zone adjustment range, then near P2 unit adjust slightly and has a stable value. Until T5 time, AGC control program sent a new unit set point command, the power is P3, unit began to a new work.

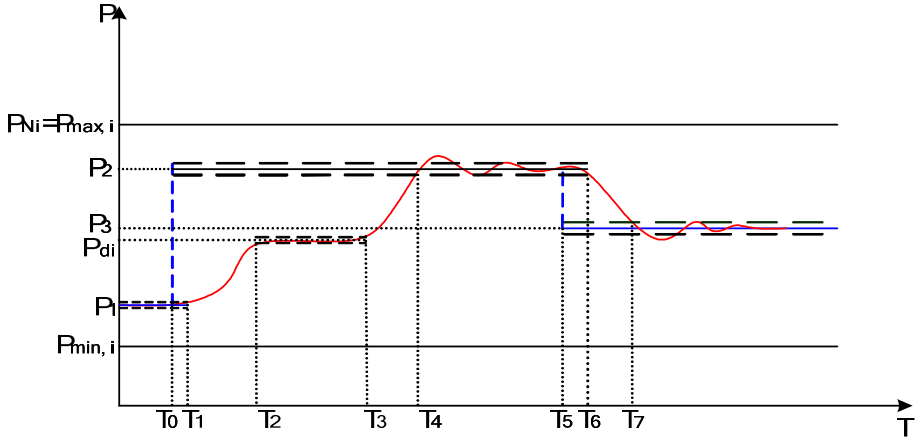

Fig.2. Typical AGC unit set point control process

Adjustment rate. According to the requirement of Dispatch center, In general, the rate of Pulverizing System and drum boiler unit is 1.5% of unit's rated active power, thermal power units with intermediate storage pulverizing system is 2% of unit's rated active power, circulating fluidized bed coal-fired units is 1%, supercritical once-through boiler unit is 1.0%.

Adjustment accuracy. It is the difference between the actual output of unit and the set point of EMS when unit work stably after a response, permissible deviation is 1% of unit's rated active power.

Response time. Response time refers to, after the EMS system send commands, on the basis of the original output point, the time that the output of generating unit reliably adjust to across adjusting dead zone to need. AGC response time of thermal power unit should be less than 1 minute.

Characteristics and Main Problems of Coal Pulverizing System

300MW and more than 300MW units mostly used pulverizer system. For example, the work process of medium-speed pulverizer system is as follows, boiler demand to be sent to coal feeder, the coal from the coal bucket conveyor to the mill and the mill to be ground into the pulverized coal. The

advantage is that the system is simple, less equipment, coal is no intermediate stop, air temperature is not too high, dangerous explosion is appear rarely. But, there are two main disadvantages. One is output required to run the mill with the boiler load change, therefore, can not run often in economic output. Two, when the boiler load changes need to adjust the amount of coal by coal feeder, so time delay is bigger.

Main control way of system is to guarantee to the amount of coal following the changes of coal feed rate command, to adjust the hot primary air damper opening control changes in the total amount of wind followed by the amount of fuel command (after line correction), to adjust the cold primary air damper opening degree control the export of wind mill flour mixture temperature is maintained constant.

Main Problems. For pulverizing system in the AGC mode, when the change range of load is small, generally does not need to start and stop coal mill, but when the load changes is in a wide range, it need to start and stop coal mill. In the process of start and stop coal mill, there are a series of operations and it will take some time. It will cause to fluctuations of coal, wind and first pressure. Sometimes it needs to change the load to absorb energy imbalance between the turbine and boiler, cause the unit's load fluctuation, and affect AGC adjustment control accuracy. Quality of coal drastically change sometimes make the tuned parameters not adapt to the control system, must to be adjusted again.

Solution Design and Effect

For example, 600MW supercritical unit are typically designed to six sets of pulverizing system, five sets is running and one is set aside. To solve the fluctuation problem of the mill start and stop process, we need to take a test to achieve the pure delay time of A, B, C, D, E and F pulverizer system. Because the analysis conclusion we have achieved that in the initial amount of coal pulverizing system starts with the load response is pure delay, there is the step response from the balance; therefore, we design a linear correction function according to the initial coal to solve the problem. When the system start with an initial amount of coal, the automatic coal pulverizing system remained coal unchanged in the pure delay time. After the delay time, when the initial amount of coal began to affect the heat load on the boiler, the effective amount of coal began to calculate according to the coal correction function. By taking this strategy, volatility problems of pressure and load when the mill systems start and stop are eliminated.

To improve the response speed of the load, the dynamic process air must be allowed to overshoot. For enhancing the air of feedforward action, a load variation feedforward signal is introduced into the air volume control circuit of primary air fan (PAF). It can make full use of the coal in the powder storage when unit need to quickly response to load and the boiler combustion rate change quickly, and shorten the boiler pure delay time. Block diagram is shown in Fig.3, generate a function curve F(x) of PAF setpoint pressure based on the actual load of the unit and adjust the pressure setting in real time. Meanwhile, by increasing the feedforward correction amount to PAF pressure, can shorten the delay time of 1.5-2.5 min, and can improve the AGC generator response speed.

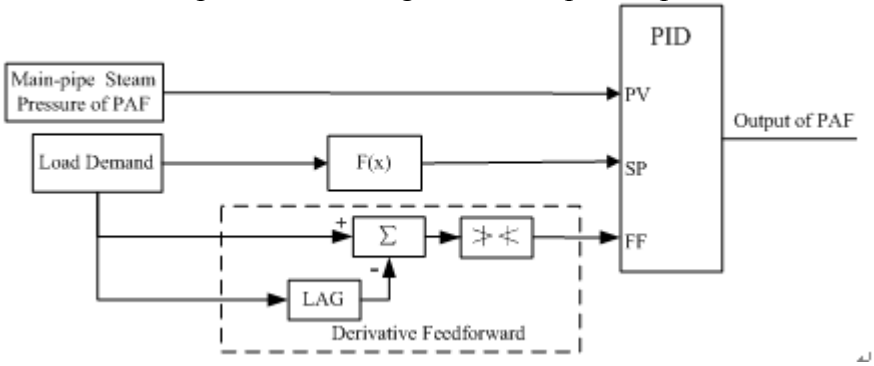

Fig.3. Block diagram of primary air fan control

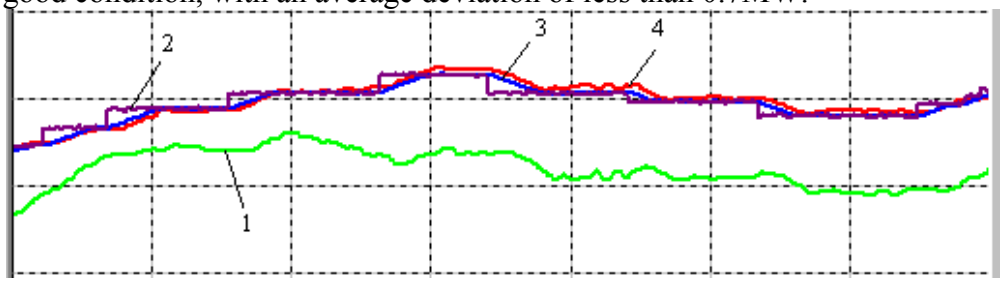
In other words, the regulation of PAF is similar to the regulation of force draft fan (FDF), following up the principle that wind is to be increased before coal when unit's load is in growth stage and wind is to be reduced after coal when unit's load is in falling stage, so, due to the change of PAF pressure and air volume, we can take advantage of pulverized coal inside pulverizers to accelerate the response speed of load and shorten the boiler delays.

It was applied to a 600MW medium-speed pulverizer unit, when the load demand changes, the regulation of PAF will produce a dynamic differential feedforward output to accelerate the unit response speed in AGC mode. As Fig.3 shown, we can clearly see that the actual power tracking AGC demand in good condition, with an average deviation of less than 0.7MW.



1-output of PAF, 2-AGC demand, 3-Rated load demand, 4-unit load

Fig.4. Load control curve of AGC mode

Conclusions

By analyzing the large delay of medium-speed pulverizer system which used in the thermal power unit, considering energy saving and consumption reducing, and combined with the performance requirement of AGC, recommend solutions were put forward. The practical application results show that it can effectively solve AGC control problems of load and pressure control accuracy, ensure frequency stability of the grid and the economic benefits of units can be further improved, provide a reference for similar units.

Keywords: uC_OS-II, Fuel Supply Systems, Electronic Control

Abstract. The uC_OS- II embedded real-time operation system is used to improve the original designed fuel supply system of a Stirling engine which governed by the electronic control system based on a rotating speed control method. Task modules for each level are built and the fail-safe modules are also improved in this paper. The developed fuel supply system is investigated through experiment, and test results show that the new real-time operating system works stably and realizes the fuel supply fast adjustment.

Introduction

Stirling engine is a piston engine of external heating (or combustion) which works by the way of a closed regenerative cycle, it uses gaseous as a working fluid [1]. Fuel injector of Stirling engine is continuously open, the accuracy and stability of the fuel injection quantity per unit time needs to be ensured in order to get a good atomization and combustion stability of the engine in various operating conditions.[2]. Conventional Stirling engine fuel electric control system changes the fuel supply by adjusting rack displacement of a high-pressure piston pump [3]. Here we provide a time-based speed regulator control mode, simulates and analyzes the pressure fluctuations under different operating rotation rate [4], proposes and implements some of the fail-safe control strategy [5]. But accompanied by the increase in fuel electric control system module, the control strategy is more complex. Continue to follow the traditional single-threaded, before desktop programming approach will lead to code complexity and increase development cycle, reduce the reliability and maintainability.

Based on the rotating speed control method, we design the fuel supply system module hardware, introduce the uC_OS-II embedded real-time operating system, and establish hierarchical modules according to the functional requirements of each task, carry out experiments under the control of real-time operating fuel supply system.

Establishment of experimental platforms

Platform structure. Stirling engine combustor fuel electric control system shall provide accurate, stable, continuous fuel, and can timely change depending on the engine air supply. Experimental platform built on uC_OS-II core embedded control systems. Fuel electric control system experimental platform is shown in Fig.1, including the fuel injection system based on rotating speed control method, uC_OS-II embedded control system (ECU), upper monitor (to send a signal of the required oil quantity to the ECU), acquisition and analysis system of output signal, analysis systems, mechanical connections and corresponding protection devices. The platform can achieve dynamic and static testing of various components and systems.

Main components of the platform. Experimental platform structures refer to the high pressure common rail diesel systems, using a three-phase rare earth permanent magnet AC servo motor system to drive the high-pressure pump to provide high-pressure fuel for the system, the high-pressure fuel is delivered to the injectors by accumulator regulator. Fuel injector is a swirl atomizing injector produced by the DELAVAN Company, with the pressure difference at both ends of the injectors, the fuel rotates high-speed in the vortex oil tract and ejects from the nozzle atomization.

The injection rate which is decided by the injection pressure determines the atomization quality of the nozzle [2]:

$$\text{Flow rate}=CA\,(2gh)^{0.5} \quad (1)$$

Among them: Flow rate is described as the injection rate(kg/s), C as the dimensionless coefficient of swirl atomizing nozzle, A as the nozzle area for swirl atomizing nozzle(m^2), g as the acceleration due to gravity, h as the pressure head(m).

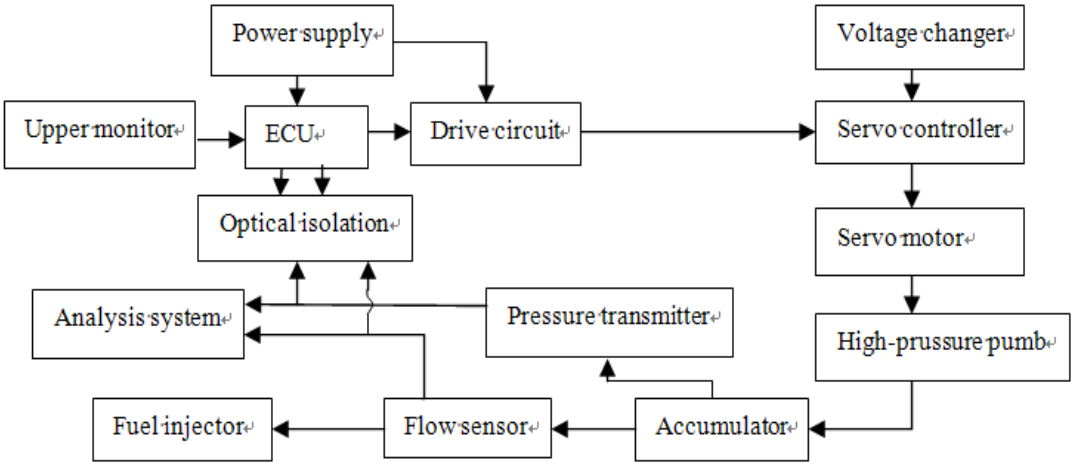

Fig.1 Test platform of fuel electric control system

A Model213 piston type flow sensor based on volumetric measurement principle which is produced by MAX company is used as the flow sensor, it outputs 112 square wave pulse signal with the frequency in proportion to flow for per ml fuel. The Kistler 4262A pressure transmitter outputs a pressure signal. Data acquisition system is composed of high-speed data acquisition box WaveBook/512 and DasyLab configuration software. Servo controller needs a 0-10V DC analog input for speed control. The PWM microcontroller output is a square wave, needs to be converted to DC analog, a servo motor drive circuit is shown in Fig.2.

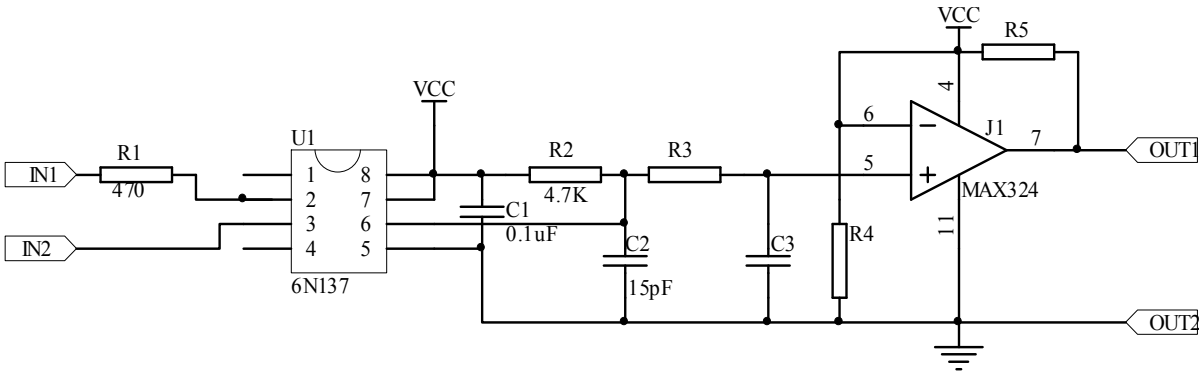

Fig.2 Servo motor drive circuit

Division of tasks and analysis based uC_OS-II nuclear.uC_OS-II is a complete, portable, curing, cutting preemptive real-time multitasking kernel [6]. Its core is stable, reliable, has been implemented to run on 8-64 from more than 40 different microprocessor architectures. Most

programs using ANSI C language, 64 tasks can be run at most, each task gets a different priority, and the system is always running in the ready state with the highest priority task. Here we use Freescale's MC9S12DG128 processor [7], transplant uC_OS-IIV4.51 in codewarrior 4.6 development environment.

System involves the following 10 tasks: 1 startup and hardware initialization task; 2 flow acquisition task; 3 accumulator pressure acquisition task; 4 flow control signal acquisition task; 5.PID control task; 6 digital tube display refresh task; 7 upper monitor communication task; 8 system status monitoring task; 9 error code acquisition record task; 10 fail-safe protection task.

Depending on the different requirements of real-time control system, all tasks can be divided into four levels, namely: initialization tasks, real-time tasks, time-sharing tasks and hidden tasks. Initialization tasks began to run when the system is powered and delete themselves after running, In this process, hardware resources are initialized and other tasks are established; Real-time tasks run higher priority tasks, including flow acquisition tasks; accumulator pressure acquisition task; flow control signal acquisition task and PID control task; time-sharing tasks run lower priority tasks, such as task 6-8; hidden tasks which run security tasks work only when system status monitoring task detects abnormal state of the system, Otherwise it's dormant. For example, when the flow sensor is detected fault, fail-safe protection task will start to detect flag and trigger the following three functions: 1 set PID control value as the pressure signal to replace the flow signal; 2 raise the priority of the accumulator pressure collection task, reducing priority of the flow acquisition task; 3 mark the corresponding error code, lit the error warning lights.

Experiment results. Flow signal is collected under steady-state operating conditions, with 100 kHz sampling rate in 100 seconds, MATLAB is used to convert square wave pulse signal into waveform. Flow set values for the measured value of 31.2kg/h is given in Fig.3, The measured mean value is 31.2149kg/h, variance is 0.0037kg/h, flow range is 0.3865kg/h, and deviation is ± 0.47% relative to the rated working flow (40kg/h). Fig.4 gives flow changing amplitude under different rotating speed in steady working condition.

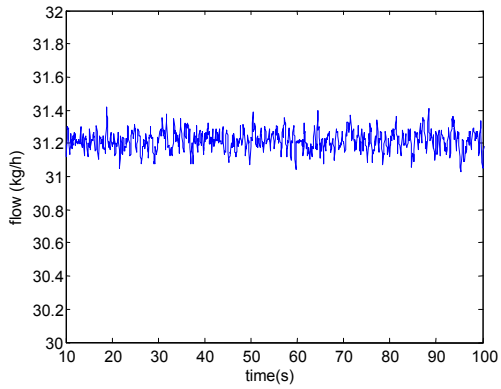

Fig.3 Stable Flow (preset value is 31.2kg/h)

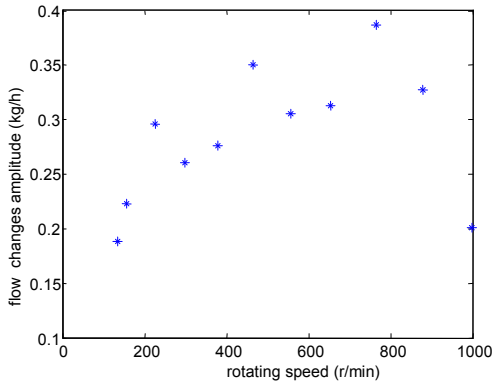

Fig.4 Flow fluctuation in stable condition

Corresponding gear is set for pre-set operating point, a gear correspond to a rotating speed from low to high, shifting different gears to change the rotating speed and collecting flow signal can detect the dynamic response ability of the system. Fig.5 is a gear shifting from 4 to 5, a vertical line stands for the shift points, and measured adjustment time is about 632ms in the condition so that gear shifts rapidly with no overshoot. Fig.6 gives adjustment time for shifting each gear. High and low gear shifting needs a long adjustment time, the middle gear adjustment time is short. The reason is that the pressure fluctuation is influenced by the rotating speed especially when rotating speed is low. With the increase of the rotating speed, the pressure fluctuation decreases, so is the adjustment time. Pressure and speed is a power relationship

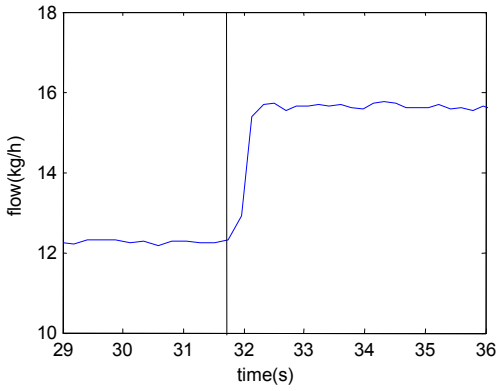

Fig.5 Flow response of gear-shifting (from 4 to 5 gear)

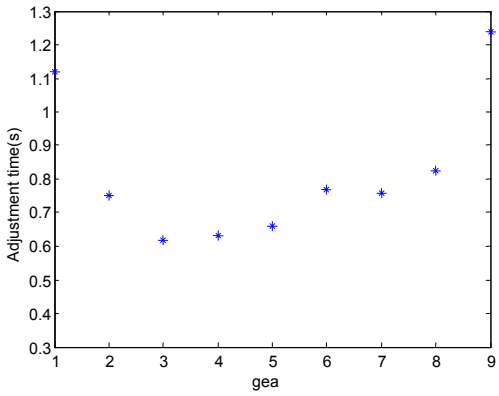

Fig.6 Flow response time for gears-shifting

Conclusion

Based on a rotating speed control method, introducing a uC_OS-II embedded operating system, we build a new Stirling engine combustor fuel electric control system, establish task module of different levels and priorities, improve the hardware and software unit, test the improved system work condition. After using uC_OS-II, the system adds support for time-sharing tasks and makes the fail-safe protection task more modular, the test results show that the new real-time operating system can adjust fuel supply quickly and stably.

Research on Flow Transferring Identification Method Based on WAMS

Yan Xu[1, a], Ping Han[1,b]

[a]xy19761001@aliyun.com, [b]hanping_1991@sina.com

Keywords: Flow Transferring Identification; Overload; Distance Relay

Abstract. In power system, flow transferring can cause non-fault overload. Traditional zone 3 distance relays cannot distinguish overload caused by faults or by transferred power flow and may operate incorrectly, thus cause cascading trips, even blackout. Based on wide area measurement system (WAMS), this paper proposes two criteria to realize flow transferring identification function. First, three-phase voltages and currents are measured and compared with those calculated before fault, which should be applied to the given identification criteria. Then, the logical relationship for flow transferring identification are put forward to prevent distance relays from incorrect behavior caused by non-fault overload and unblock zone 3 distance relays when fault occurs. Through the simulation results, the effectiveness of the proposed method is verified.

Introduction

Power system relay protection is of great significance to the security and stability of power system. Once there is any fault in the system, if protective devices can operate correctly, rapidly and reliably, fault can be cleared on time to be stopeped worsening system's operating condition. Otherwise, the process of system collapse may be promoted and cascading trips will lead to large-scale blackouts. When power system is heavily loaded, blackouts will occur as a result of flow transferring after a faulted line is cleared. The clearance of a faulted line might cause flow transferring, which results in overload on other transmission lines. Zone 3 distance relays will trip to remove these lines and then overload will become more severe; eventually will lead to blackouts [1-2]. When the main protection of a transmission line fails to trip, the backup protection plays a key role to clear the fault. Unfortunately, the existing protections only utilize local data to determine whether eliminating the faulted element or not and do not have the capability to distinguish between overloads caused by faults and by flow transferring. Although the protective relays operate correctly, the process of system collapse is promoted.

In recent years, scholars at home and abroad have raised some methods to avoid distance relays of backup protection operating incorrectly when other transmission lines overload after the faulted line is cleared. *Y. Serizawa et al.* have proposed a system of current differential backup protection for a bus bar and transmission circuits connected to that bus bar on an inter-station or wide-area basis [3]. Since the wide-area system consists of too many components such as terminal equipment and telecommunication equipment, the reliability and availability of the system may become a major concern. Conventionally, the overload caused by transferring flow is calculated by existing method AC power calculation. However, with the number of nodes increasing in modern power grid, there is hardly enough time to analyze the whole network by AC power calculation in case of emergency [4]. *X. Z. Dong et al.* have proposed a system protection scheme based on local information [5], but the availability of the proposed flow transferring identification is not verified through final simulation.

Recently, the advent of WAMS (Wide Area Measurement System) opens a new gate for power system wide area backup protections, because it makes synchronous data acquisition, exchange and analysis possible [6-7]. In this paper, a new flow transferring identification method based on WAMS is presented. First, the functions of wide area measurement system (WAMS) are introduced shortly. Then, two identification criteria are given in detail and logical relationship to prevent distance relays from incorrect behavior caused by non-fault overload are listed. Finally, the simulation results show that the proposed method works well. The advantages are summarized.

Structure and Functions of Wide Area Measurement System

Wide area measurement system consists of three parts: phasor measurement units (PMU) installed at power plants and substations, grid-covered communication network, and the control system of the EMS and SCADA [8]. After measured by PMU, the electrical quantities such as three-phase voltages and currents will be transmitted to scheduling control center through communication network, as is shown in Fig. 1.

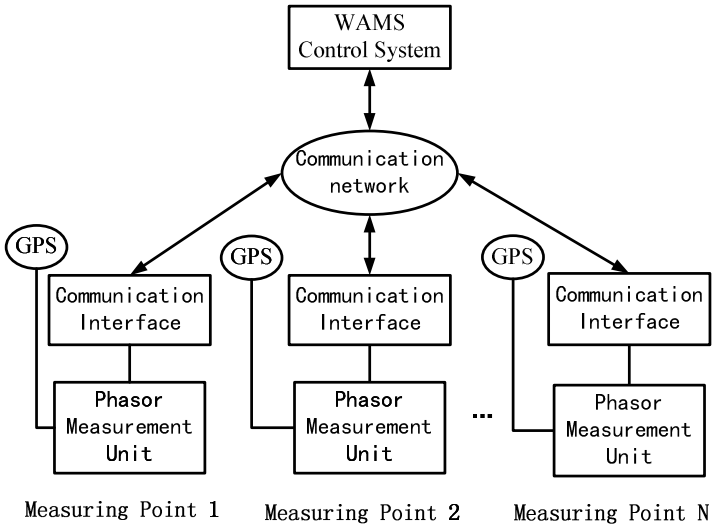

Fig. 1. Structure of Wide Area Measurement System

The key of the data validity of the phasor measurement unit is the synchronization. GPS-based synchronized phasor measurement unit can provide accurate measurement of node voltage phasor, branch current phasor, the power angle, and can provide fast calculation and transmission of power flow and phase angle information. The power system information at scheduling control center can be updated every 20-50 ms, so the supervisory center can deal with synchronous data taking the whole system status into account and make real-time control strategies [8].

Flow Transferring Identification Method

Identification Criterion 1. Three-phase currents will keep symmetric when overload occurs, and the current increments are equal. While when an asymmetric short circuit fault occurs, fault component of three-phase currents are not equal. Using linear transformation, currents can be divided into three symmetric components: positive sequence, negative sequence and zero sequence components. If it is an earth fault at the same time, zero-sequence current will exist. According to Superposition Theorem, the positive sequence component of the post-fault current can be divided into two parts: the pre-fault current and fault component. The pre-fault current is considered as normal component and it does not own fault features. The fault component has nothing to do with the pre-fault current, so it can be calculated through subtracting the pre-fault current from the current at the measuring point after fault occurs, as is shown in Equation (1):

$$\Delta \dot{I}_1 = \dot{I}_1 - \dot{I}_0 \tag{1}$$

where $\Delta \dot{I}_1$ represents the fault component current phasor; $\dot{I}_1$ and $\dot{I}_0$ represent the post-fault and pre-fault current phasors measured by WAMS at measuring point, respectively.

Based on formula (1), identification criterion 1 is given to distinguish between fault and overload:

$$\left|\dot{I}_0\right| + \left|\dot{I}_2\right| \geq m\left|\Delta \dot{I}_1\right| \tag{2}$$

where $\Delta\dot{I}_1$ is the positive sequence current increment measured by WAMS at the measuring point; $\dot{I}_2$ and $\dot{I}_0$ are negative sequence and zero sequence current phasors measured by WAMS at the measuring point, respectively. Taking the uncertainty of the measurements into consideration, the value of *m* should be about 0.8. This identification criterion will not be influenced by the differences between phases or fault impedance, and it can work well in case that power flow swings.

The positive sequence current increment $\Delta\dot{I}_1$ can be obtained through subtracting stable current before protection starts from the positive sequence current measured by PMU at the measuring point after zone 3 distance relays starts. Since current increases gradually when overload occurs, the stable current before protection starts can be obtained by calling back the measured pre-fault current from WAMS control system.

Analysis is in detail:

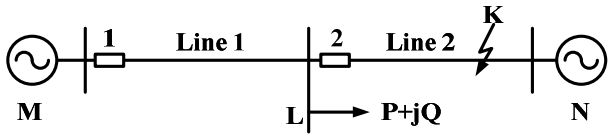

Fig. 2. Power System

Seeing from Fig. 2, if an asymmetric fault occurs at point *K* on Line 2, the positive, negative and zero sequence fault components measured at protection 1 are represented by $\Delta\dot{I}_{Ma1}$, $\Delta\dot{I}_{Ma2}$ and $\Delta\dot{I}_{Ma0}$. The three sequence currents flowing out of fault point are represented by $\dot{I}_{ka1}$, $\dot{I}_{ka2}$ and $\dot{I}_{ka0}$. The current distribution factors at protection 1 are represented by C_{M1}, C_{M2} and C_{M0}. To simplify calculation, assume $C_{M2}=C_{M1}$. Thus, three fault components at protection 1 can be calculated as: $\Delta\dot{I}_{Ma1}=C_{M1}\dot{I}_{ka1}$, $\Delta\dot{I}_{Ma2}=C_{M2}\dot{I}_{ka2}$ and $\Delta\dot{I}_{Ma0}=C_{M0}\dot{I}_{ka0}$.

There are three cases that should be discussed in detail. If the fault is A-phase earth fault, according to symmetric component method, the amplitudes of three sequence currents flowing out of fault point are equal: $\dot{I}_{ka1}=\dot{I}_{ka2}=\dot{I}_{ka0}$. According to (2), there is:

$$\begin{aligned}\gamma^{(1)}&=\frac{\left|\dot{I}_{Ma2}\right|+\left|\dot{I}_{Ma0}\right|}{\left|\Delta\dot{I}_{Ma1}\right|}\\&=\frac{C_{M2}\left|\dot{I}_{ka2}\right|+C_{M0}\left|\dot{I}_{ka0}\right|}{C_{M1}\left|\dot{I}_{ka1}\right|}\\&=\frac{C_{M2}+C_{M0}}{C_{M1}}\\&=1+\frac{C_{M0}}{C_{M1}}\end{aligned}\tag{3}$$

If the fault is two-phase short circuit fault, assuming the fault occurs between B-phase and C-phase, the relationship of three sequence currents satisfy the equations $\dot{I}_{ka1}=-\dot{I}_{ka2}$ and $\dot{I}_{ka0}=\mathbf{0}$. So there is:

$$\gamma^{(2)}=\frac{\left|\dot{I}_{Ma2}\right|+\left|\dot{I}_{Ma0}\right|}{\left|\Delta\dot{I}_{Ma1}\right|}=\frac{C_{M2}}{C_{M1}}=1\tag{4}$$

If the fault is two-phase earth fault, also taking B-phase and C-phase as an example, the relationship of three sequence currents satisfy the equation $\dot{I}_{ka1}=-(\dot{I}_{ka2}+\dot{I}_{ka0})$. So there is:

$$\gamma^{(1,1)}=\frac{\left|\dot{I}_{Ma2}\right|+\left|\dot{I}_{Ma0}\right|}{\left|\Delta\dot{I}_{Ma1}\right|}=\frac{Z_{\Sigma0}+\frac{C_{M0}}{C_{M1}}Z_{\Sigma2}}{Z_{\Sigma0}+Z_{\Sigma2}}\tag{5}$$

Identification criterion 1 is also applicative when fault occurs in other phases. The same reasoning process is also applied to protection 2. The worst condition is that the fault occurs at Bus *N* adjacent to neutral grounding transformer. The value of C_{M0} will become so small that the ratio γ may be smaller than 1 to cause confusion when identification criterion 1 is in use. This problem will be solved by identification criterion 2 in the next section.

Identification Criterion 2. If a two-phase or three-phase short circuit fault or a two-phase earth fault occurs on a line, the voltage between two faulted phases at point *K*— the arc voltage— is no more than 6 percent of the rated voltage in general [9]. Taking advantage of this feature, identification criterion 2 is given as follow:

$$\left|U_{\varphi\varphi}\cos(\varphi+90°-\varphi_{line})\right|<kU_N \tag{6}$$

where $U_{\varphi\varphi}$ represents the amplitude of the phase-to-phase voltage measured by WAMS at the measuring point; φ represents the angle between current phasor and voltage phasor measured by WAMS at the measuring point; φ_{line} represents the positive-sequence impedance angle of the transmission line; U_N is the rated voltage. The value of *k* should be about 0.6.

Take two-phase earth fault as an example. Analysis is in detail:

Suppose that the fault occurs between B-phase and C-phase at point *K*. The arc resistance of each phase is represented by R_o. According to Ohm's law, the phase-to-phase voltage measured at protection 1 in Fig.2 can be calculated as:

$$\begin{aligned}\dot{U}_M &= \dot{I}_M Z_{l1} + \dot{U}_L \\ &= \dot{I}_M Z_{l1} + \dot{I}_L Z_{l2} + \dot{U}_{arc}\end{aligned} \tag{7}$$

where $\dot{U}_M$ and $\dot{I}_M$ represent the voltage and current phasors between B-phase and C-phase measured by WAMS at protection 1, respectively; $\dot{U}_L$ and $\dot{I}_L$ represent the voltage and current phasors between B-phase and C-phase measured by WAMS at protection 2; Z_{l1} represents the impedance of line 1 and Z_{l2} represents the impedance from bus *N* to the fault point *K*; $\dot{U}_{arc}$ represents the voltage phasor between B-phase and C-phase at fault point *K*, also called arc voltage. Phasor diagram in Fig. 3 shows the relationship between voltages and currents.

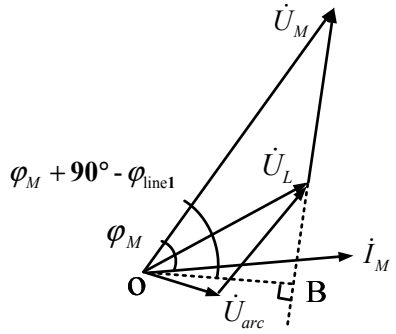

Fig. 3. Phasor diagram

In Fig. 3, φ_M represents the angle between $\dot{U}_M$ and $\dot{I}_M$ measured by WAMS at protection 1. φ_M represents the impedance angle of line 1. According to Ohm's law and Parallelogram Rule, the size of OB can be calculated by:

$$OB = U_M \cos(\varphi_M + 90° - \varphi_{line1}) \tag{8}$$

According to the geometric shortest perpendicular distance principle, the size of *OB* represents the smallest voltage possibly measured at protection 1. Based on different ranges of *OB* when fault or overload occurs, identification criterion 2 is proposed. If a transmission line overloads, the size of *OB* will keep no less than 80 percent of the rated voltage. Because zone 3 distance relays of protection 1 is the backup protection of line 2, when fault occurs, the size of *OB* is influenced by load on bus *L*. In order to get the maximum of *OB*, suppose three-phase short circuit fault occurs on bus *N*. Considering the greatest influence of load impedance, regard the load equivalent impedance as pure resistance. The size of *OB* is usually less than 30 percent of the rated voltage, even when load impedance is very large.

If the fault is two-phase or three-phase short circuit fault, analysis is similar and identification criterion 2 is also applicable.

Flow Transferring Identification Method. Both identification criteria discussed above can identify different types of fault, as is shown in Table 1.

Table 1. Types of fault that both criteria can identify

	Sing-phase earth fault	Two-phase short circuit fault	Two-phase earth fault		Three-phase short circuit fault
			$C_{M1} > C_{M0}$	$C_{M1} < C_{M0}$	
Criterion 1	√	√		√	
Criterion 2		√	√	√	√

From Table 1, the types of fault that can be identified through criterion 1 are sing-phase earth fault, two-phase short circuit fault and two-phase earth fault on condition that C_{M1} is smaller than C_{M0}. Similarly, the types of fault that can be identified through criterion 2 are two-phase short circuit fault, two-phase earth fault no matter C_{M1} is smaller than C_{M0} or not, and three-phase short circuit fault. Thus, the combination of these two identification criteria can distinguish between overload and all types of faults to prevent zone 3 distance relays from incorrect behaviors.

Logical relationship of the proposed identification criteria is shown in Fig. 4.

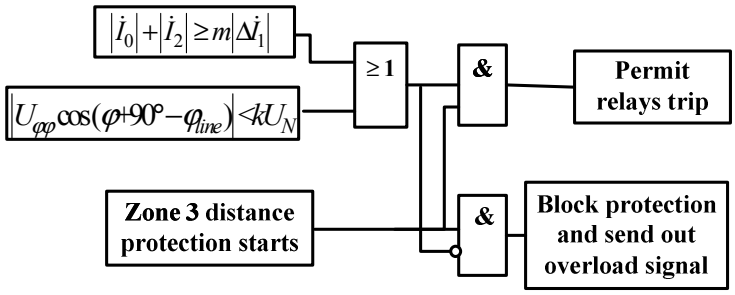

Fig. 4. Flow transferring identification strategies

From Fig. 4, if neither of the two criteria is satisfied, power flow transferring will be identified and zone 3 distance relays will be blocked reliably. Otherwise, protective relays will be permitted to trip until transmission line fault is cleared. For example, if a fault occurs on line 2, as shown in Fig. 2, zone 3 distance protection at protection 1 will start. Then relays at protection 2 will trip the line, which may result in overload on line 1. After the faulted line is removed, flow transferring identification will be in process to determine whether block zone 3 distance relays or not rather than permit them to trip when actuation time is up.

Simulation Results

The 3-nodes system in Fig.5 is set up to test the performance of the proposed power flow transferring method in this paper. The system frequency is 50Hz and the rated voltage is 500kV. All lines are installed with distance relays of directional impedance characteristics as their backup protection. Calculation results of the two ratios *m* and *k* in case of all faulted and transferring overloads are included.

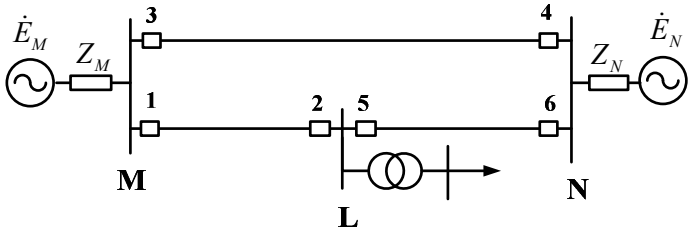

Fig. 5. Simulation system

Reliable Operation of Zone 3 Distance Relays When Fault Occurs. The case that fault occurs on the middle of the line from bus *L* to bus *N* is used to show the reliability of the identification method. 0.2 seconds later, relays at protection 5 and 6 trip to remove the line between bus *L* to bus *N*. From the fault occurring on, changes in voltage amplitude and current amplitude of A-phase measured at protection 1 are shown in Fig. 6.

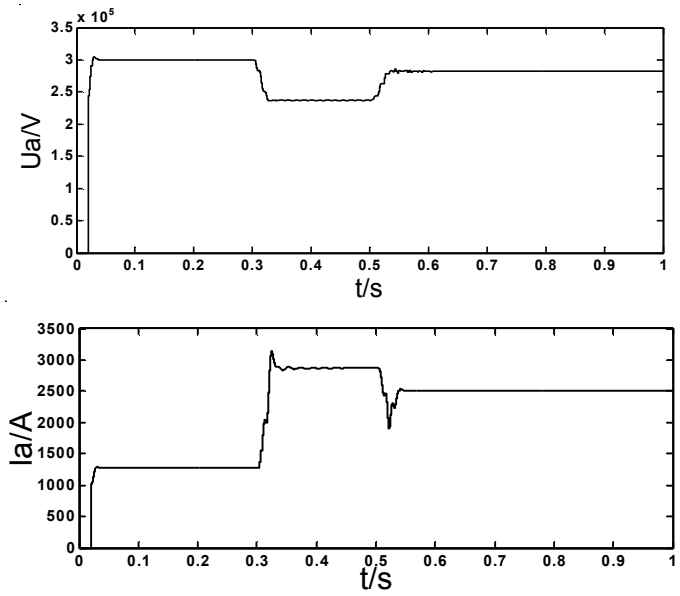

Fig. 6. Voltage and current curves

Seeing from Fig. 6, after the faulted line is removed, much flow is transferred to other lines such as the line from bus *M* to bus *L*, causing these lines overloaded. Through calculation, changes on the values of *m* and *k* are listed below. All the four types of fault are taken into consideration. Calculation results of the two ratios at protection 1 and 3 are shown in Table 2, where there are $m=\frac{|\dot{I}_0|+|\dot{I}_2|}{|\Delta\dot{I}_1|}$ and $k=\frac{U_{\varphi\varphi}\cos(\varphi_{\varphi\varphi}+90°-\varphi_l)}{U_N}$.

Table 2. Simulation results if fault occurs on bus 5

Protection	$m^{(1)}$	$m^{(2)}$	$k^{(2)}$	$m^{(1,1)}$	$k^{(1,1)}$	$k^{(3)}$
1	1.0386	1	0.0852	0.7204	0.0852	0.0852
3	2.0249	1	0.0946	1.0071	0.0946	0.0946

From calculation results of the ratios *m* and *k* in Table 2, if transmission line fault occurs, either of the two flow transferring identification criteria will be satisfied and zone 3 distance relays will be permitted to operate in case of main protection failure.

Reliable Blocking of Zone 3 Distance Relays When Non-fault Overload Occurs. After the relays trip to clear fault on the transmission line from bus *L* to bus *N*, much flow will be transferred to the line between bus *L* to bus *M*, resulting in measured impedance increasing to start zone 3 distance

protection. Calculated through the electrical quantities measured by WAMS at protection 1, the values of *m* and *k* can be obtained as 0 and 0.8379, respectively. Neither of the two identification criteria is satisfied, so zone 3 distance protection will be blocked reliably to prevent relays from incorrect behavior.

Conclusion

Non-fault overload caused by power flow transferring may lead to incorrect behavior of backup protective relays, which is considered as one of the main factors of cascading trips. Taking advantage of wide area measurement system (WAMS), this paper proposes a new flow identification method. The simulation results show that the proposed method works well with reliable operation in case that internal fault occurs. The identification criteria will not be influenced by the types of load or fault location, and it will not change the existing distance protection, either. The value of *m* and *k* can be set beforehand and small adjustments to them according to real scene are allowed.

Keywords: Setting Adjustment Algorithm, Setting Detection, Setting Rectification, Interphase Current Protection, Coverage.

Abstract. In order to avoid incorrect setting from being a hidden fault source which threats the stable operation of power system, setting adjustment algorithm of line protection is proposed. Through setting detection and setting rectification the algorithm amends incorrect setting and reduces the number of mismatch protection to the greatest extent. A method of calculating high step coverage of interphase current protection based on node impedance matrix is also proposed in this paper. The example shows the proposed algorithm is practical.

Introduction

Relay protection is an important secondary system. It plays an important role on stable operation of the power system. Many serious power outages, such as "11.9" blackout accident in the northeast power grid of North America in 1965 and "8.14" blackout accident in America and Canada in 2003, are related to incorrect operation of relay protection device directly or indirectly [1]. Therefore it is urgent to improve reliability of relay protection.

Whether relay protection device could operate correctly largely depends on relay setting. Inaccurate relay coordination or change of operation mode may make relay setting incorrect under the current operation mode. In order to avoid incorrect relay setting from being a hidden fault source [2], efforts have been made on online check [3]. When an incorrect relay setting is checked, relay coordination workers should recalculate and work efficiency is low. If reference setting can be offered by software automatically after incorrect setting is checked, work efficiency will improve significantly. Based on online check, the paper makes further research and presents setting adjustment algorithm. Through setting detection and setting rectification, the algorithm could adjust incorrect relay setting. A method of calculating high step coverage of interphase current protection is also presented.

Concept of Setting Adjustment and Its Process

Setting adjustment refers to checking and correcting the relay setting which does not meet selectivity and sensitivity under the current operation mode. It includes setting detection and setting rectification. Setting detection checks whether all the protection in power system meets selectivity and sensitivity. For incorrect setting, setting rectification gives reasonable reference setting and reduces the number of mismatch protection to the greatest extent.

Setting adjustment involves in protection which needs coordination calculation, including zero sequence current protection, interphase current protection, interphase distance protection and ground distance protection. The flow chart of setting adjustment is shown in Fig.1.

Setting Detection

Setting detection is preparation stage of setting rectification. Setting detection can filter the protection whose setting does not need to change so as to avoid setting changing in large quantities. Setting

detection includes selectivity detection and sensitivity detection. If the protection passes all the detections, the setting does not need to change. Otherwise the setting needs to change.

The flow chart of setting detection is shown in Fig.2.

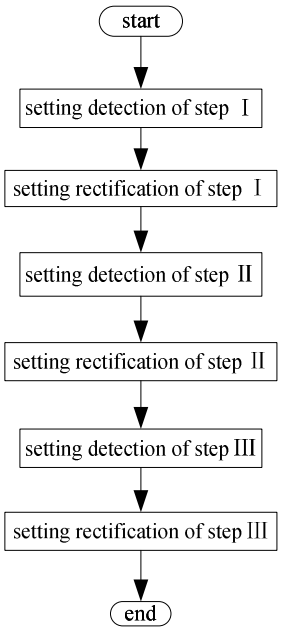

Fig.1 Flow chart of setting adjustment

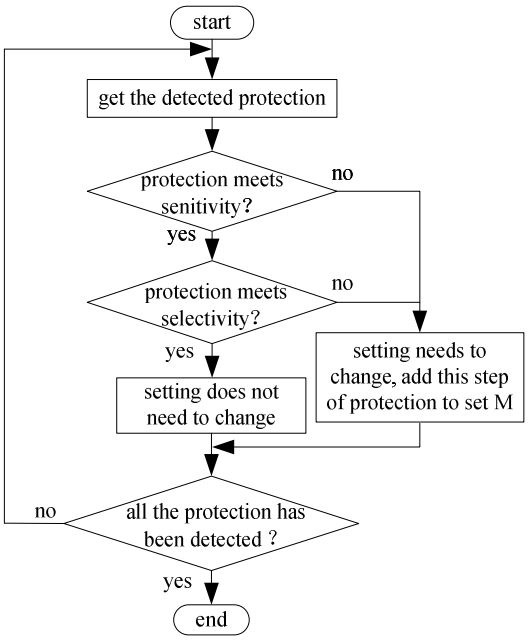

Fig.2 Flow chart of setting detection

The method of sensitivity detection is to calculate sensitivity of the original setting. If the sensitivity is no less than minimum requirement, the protection passes sensitivity detection. Otherwise the setting needs to change. There are two methods of selectivity detection, namely selectivity detection based on protection coverage and selectivity detection based on comparison.

Selectivity detection based on protection coverage contains the following steps.

(i) Search adjacent subordinate protection for step M-1 and step M whose operating time is nearest to the operating time of detected protection. Detected protection's operating time should be greater than step M-1's and less than step M's.

(ii) Calculate coverage of detected protection and step M of adjacent subordinate protection.

(iii) Compare the coverage and judge whether the detected protection meets selectivity. If the detected protection's coverage is greater than step M-1's, the protection passes selectivity detection. Otherwise the setting needs to change.

Traditional way of calculating coverage is golden section method or binary search method which needs much repeated calculation. In order to improve efficiency, researchers have made great efforts on fast coverage calculation [4,5]. However, a method of calculating high step coverage of interphase current protection is expected. A method proposed in this paper will be discussed in Chapter 3.

Selectivity detection based on comparison adopts comparison instead of quantitative calculation. Compare the original setting and the setting under the current operation mode and determine which detected protection meets selectivity. Taking distance protection as an example, the method contains following steps (Z_{set} is the original setting).

(i) For step I of distance protection, calculate the setting under the current operation mode. If $Z_{setI} < Z'_{setI}$ the detected protection passes selectivity detection; otherwise the setting needs to change.

(ii) For step II of distance protection, calculate the setting $Z'_{setII\cdot1}$, $t'_{setII\cdot1}$ and $Z'_{setII\cdot2}$, $t'_{setII\cdot2}$ under current operation mode which coordinates with longitudinal differential protection and step II of adjacent subordinate protection respectively. When $t_{setII} < t'_{setII\cdot2}$, if $Z_{setII} \le Z'_{setII\cdot1}$ the detected protection passes selectivity detection; otherwise the setting needs to change. When $t_{setII} \ge t'_{setII\cdot2}$, if $Z_{setII} \le Z'_{setII\cdot2}$ the detected protection passes selectivity detection; otherwise the setting needs to change.

(iii) For step III of distance protection, calculate the setting $Z'_{set\text{III}\cdot 2}$, $t'_{set\text{III}\cdot 2}$ and $Z'_{set\text{III}\cdot 3}$, $t'_{set\text{III}\cdot 3}$ under the current operation mode which coordinates with step II and step III of adjacent subordinate protection respectively. When $t_{set\text{III}} < t'_{set\text{III}\cdot 3}$, if $Z_{set\text{III}} \le Z'_{set\text{III}\cdot 2}$ the detected protection passes selectivity detection; otherwise the setting needs to change. When $t_{set\text{III}} \ge t'_{set\text{III}\cdot 3}$, if $Z_{set\text{III}} \le Z'_{set\text{III}\cdot 3}$ the detected protection passes selectivity detection; otherwise the setting needs to change.

Selectivity detection based on protection coverage can judge selectivity more intuitively and its calculation is more accurate. When difference between the coverage of detected protection and adjacent subordinate protection is small, messages can be sent to relay coordination workers. However, this method needs larger workload. Selectivity detection based on comparison can only judge selectivity qualitatively. Its principle is similar to relay coordination's and the workload is smaller.

Setting Rectification

Concept of line line's rank should be introduced firstly. Line of first rank is the detected protection's adjacent subordinate line. Line of second rank is line of first rank's adjacent subordinate line and the rest can be done in the same manner.

Step I's setting after rectification is the relay setting which is calculated under the current operation mode. The setting of other steps can be calculated as follows.

(i) Make the protection i whose setting is incorrect coordinates with protection's low step in the line of first rank and calculate the result. If the result meets sensitivity it can be regarded as protection i's new setting. Otherwise make the protection i coordinate with higher step until the result meets sensitivity. If protection i has several lines of first rank, make protection i coordinate with every line and select maximum (current protection) or minimum (distance protection) from all the results.

(ii) When protection i coordinates with the same step of protection in line of first rank and the result still can not meet sensitivity, the same step of protection's setting in line of first rank should be adjusted. The method is adjusting the cooperative relationship between line of first rank and its corresponding line of second rank.

According to different relay coordination plan, setting rectification's steps can be changed properly. However, setting rectification may not cut mismatch protection totally especially when long lines connect to short lines or complex ring exists in power grid. Manual regulation is in need sometimes.

Method of Calculating High Step Coverage of Interphase Current Protection

As shown in fig.3, side m in line mn installs interphase current protection. Dotted line in fig.3 can be any network structure. Suppose the end point of its high step coverage is node f whose distance to the line head is K of total line length. The impedance of line mn is z_{mn} and the impedance of line ij is z_{ij}.

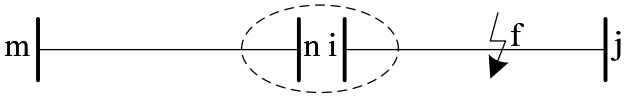

Fig.3 Circuit diagram

Unit current is injected into node f. $U_k^{(f)}$ is voltage of i when f is injected unit current and other expressions have similar meaning. According to the reciprocity theorem,

$$U_k^{(f)} = U_f^{(k)} = U_i^{(k)} - k(U_i^{(k)} - U_j^{(k)}) = (1-k)U_i^{(k)} + U_j^{(k)} = (1-k)U_k^{(i)} + U_k^{(j)} \quad (1)$$

Mutual resistance of fault point f is:

$$Z_{kf} = (1-k)Z_{ik} + kZ_{jk} \tag{2}$$

Current equation of fault point f is:

$$1 + \frac{U_i^{(f)} - U_f^{(f)}}{kz_{ij}} + \frac{U_j^{(f)} - U_f^{(f)}}{(1-k)z_{ij}} = 0 \tag{3}$$

$$1 + \frac{Z_{if} - Z_{ff}}{kz_{ij}} + \frac{Z_{jf} - Z_{ff}}{(1-k)z_{ij}} = 0 \tag{4}$$

Self-impedance of fault point f is:

$$Z_{ff} = (1-k)^2 Z_{ii} + k^2 Z_{jj} + k(1-k)(2Z_{ij} + z_{ij}) \tag{5}$$

When two-phase short circuit happens in the node f, positive sequence current and negative sequence current of fault point is:

$$I_{f(1)} = -I_{f(2)} = \frac{1}{Z_{ff(1)} + Z_{ff(2)}} = \frac{1}{2Z_{ff(1)}} \tag{6}$$

Positive sequence current and negative sequence current of node m and n is:

$$\begin{cases} U_{m(1)} = 1 - Z_{mf(1)} I_{f(1)} \\ U_{m(2)} = -Z_{mf(2)} I_{f(2)} = Z_{mf(1)} I_{f(1)} \\ U_{n(1)} = 1 - Z_{nf(1)} I_{f(1)} \\ U_{n(2)} = -Z_{nf(2)} I_{f(2)} = Z_{nf(1)} I_{f(1)} \end{cases} \tag{7}$$

Positive sequence current and negative sequence current of line mn is:

$$\begin{cases} I_{mn(1)} = \dfrac{U_{m(1)} - U_{n(1)}}{z_{mn(1)}} = \dfrac{Z_{nf(1)} - Z_{mf(1)}}{z_{mn(1)}} I_{f(1)} \\ I_{mn(2)} = \dfrac{U_{m(2)} - U_{n(2)}}{z_{mn(2)}} = \dfrac{Z_{mf(1)} - Z_{nf(1)}}{z_{mn(1)}} I_{f(1)} = -I_{mn(1)} \end{cases} \tag{8}$$

The current of line mn is:

$$I_m = \sqrt{3} I_{f(1)} = \sqrt{3} \frac{Z_{nf(1)} - Z_{mf(1)}}{2Z_{ff(1)} z_{mn(1)}} = I_{set} \tag{9}$$

where I_{set} is the setting of protection m. And we get the quadratic equation in one unknown

$$AK^2 + BK + C = 0$$

$$\text{where } \begin{cases} A = \dfrac{2}{\sqrt{3}} I_{set} z_{mn(1)} (Z_{ii(1)} + Z_{jj(1)} - 2Z_{ij(1)} - z_{ij}) \\ B = \dfrac{2}{\sqrt{3}} I_{set} z_{mn(1)} (2Z_{ij(1)} - Z_{ii(1)} + z_{ij(1)}) - (Z_{nj(1)} - Z_{ni(1)} + Z_{mi(1)} - Z_{mj(1)}) \\ C = I_{set} z_{mn(1)} \dfrac{2}{\sqrt{3}} Z_{ii(1)} + Z_{mi(1)} - Z_{ni(1)} \end{cases}.$$

When three-phase short circuit happens, the equation can be derived in the same way.

Example analysis

The local connecting diagram of a power grid is shown in fig.4, letters in the diagram is protection's name and number is the impedance of corresponding line. Taking distance protection as an example, availability of the algorithm proposed in this paper is discussed as follows.

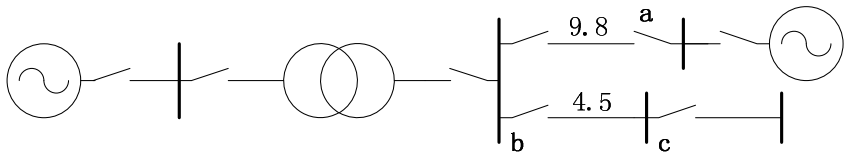

Fig.4 Local connecting diagram of a power grid

When the system operates normally, setting of protection a and b is shown in table 1. For some reason the transformer stops running. Protection a does not meet selectivity after setting detection as it's the coverage of step II stretches into protection b's step II and the operating time is the same. The setting of protection a is adjusted through detection rectification. When protection a coordinates with protection b's longitudinal differential protection the setting could not meet sensitivity. Therefore it coordinates with protection b's step II and the setting meets sensitivity. Setting after setting rectification is also shown in table 1.

Table 1 Setting before and after adjustment

protection's name	step	Setting before adjustment	Setting after adjustment
a	I	7.84 Ω , 0s	7.84 Ω , 0s
	II	16.68 Ω , 0.5s	13.24 Ω , 1s
b	I	3.60 Ω , 0s	3.60 Ω , 0s
	II	6.75 Ω , 0.5s	6.75 Ω , 0.5s

Conclusions

The paper presents setting adjustment algorithm. Through setting detection and setting rectification, the algorithm could adjust incorrect relay setting and reduce the number of mismatch protection to the greatest extent. The algorithm is easy to computer implementation and can improve working efficiency. The example shows the proposed algorithm is practical.

Keywords: Relay protection, Differential protection, Transformer, Matlab function, Simulation.

Abstract. This paper establishes a simulation model of a simplified power system with transformer differential protection based on an embedded Matlab function block. The differential protection consists of percentage restraint differential protection, second harmonic restraint, differential current instantaneous trip protection and over-excitation protection. The model is able to correctly simulate the transformer's inrush current and internal and external faults. The results from the simulation show that the circuit breaker correctly operates for a transformer internal fault and provides a good braking effect for an external fault. In addition, the protection model is able to identify the inrush current of the transformer and avoid a protection mis-trip event.

Introduction

The embedded Matlab function block is an easy and convenient method used to write m-code that can be incorporated into a Simulink model [1]. In contrast to the s-functions block, m-code or C is more casual and simple to add in an embedded function block because the user is not required to strictly follow the function template rules. Most of the power system simulation can be constructed by combining an embedded Matlab function block and a SimPowerSystems block.

Electric power plays an important role in the economy and in our lives, and power system protection is used to ensure secure and stable operation of power systems. Simulation of relay protection contributes to the development of relay protection and analysis of relay protection operation. It is well known that the transformer is one of the most important pieces of equipment in power systems, and thus far, differential protection is still the primary protection scheme for power transformers. In this paper, a transformer protection model is developed in the Matlab/Simulink environment to evaluate the impact of faults on the differential relay. The model uses percentage differential protection to distinguish internal faults from external faults. Inrush current due to transformer energization can appear as a fault to the protection system. Therefore, the second harmonic restraint method is adopted to block the differential relay against inrush current. The concept of differential protection is briefly illustrated in Fig. 1 [2]. Generally, the current flowing into the transformer is compared with the current flowing out of the transformer. If the currents are in balance, the operating current will be zero, which indicates that the transformer is functioning in a healthy manner; the currents are not in balance, other methods are required to identify the transformer fault-type.

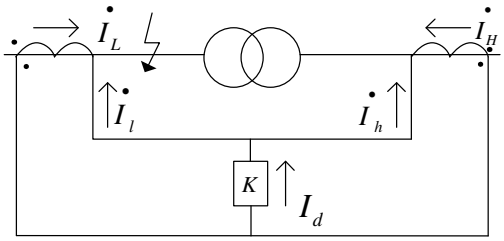

Fig. 1. Transformer differential protection

Structure of the Simulation Model

The transformer differential protection is simulated using Matlab/Simulink. Fig. 2 shows the simulation model of a simple system with the 20 MVA-110/10.5 kV YNd11 transformer. The parameters of the system are as listed follows:

Differential Protection Subsystem. The block diagram of differential protection is shown in Fig. 3. The figure demonstrates that the protection system consists of percentage differential protection, differential current instantaneous trip protection, second harmonic restraint and over-excitation protection. The gain block is used as a current converter. Using the Fourier block and the magnitude - angle to the complex block, we can easily identify the fundamental component, the second harmonic component, the fifth harmonic component and the three-phase current vector. In the embedded function block, the protection criteria are written directly according to the operation logic. The three-phase breaker block is set in external control mode. When the control signal turns to 0, the breakers are opened.

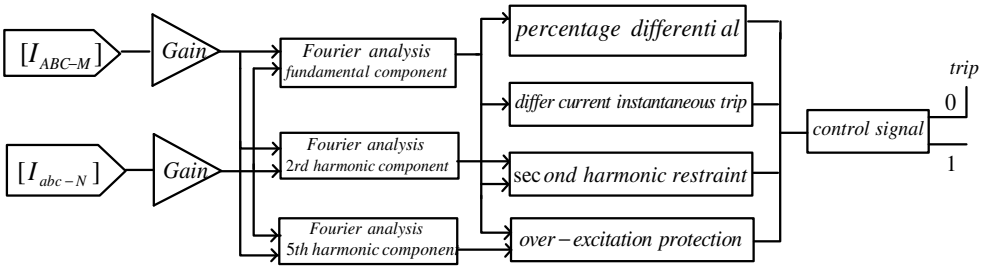

Fig. 3. Differential protection subsystem

The conventional differential protection calculates the differential current and the restraint current using the following equations:

$$I_d = |\dot{I}_A - \dot{I}_a'|. \quad (1)$$

$$I_r = (|\dot{I}_A| + |\dot{I}_a'|)/2. \quad (2)$$

$$\dot{I}_a' = (\dot{I}_a - \dot{I}_c)/\sqrt{3}. \quad (3)$$

where $\dot{I}_A$ and $\dot{I}_a$ are the vector current of phase A in the high-voltage and low-voltage side of the transformer, respectively, and $\dot{I}_a'$ is the vector current of phase *a* after phase shift compensation.

The percentage differential protection is a component of Fig. 3 and is used to explain the Matlab/Simulink simulation. The simulation model for percentage differential protection is presented in detail in Fig. 4. The differential current calculated block and the protection block are modeled using the embedded Matlab function block, and the embedded Matlab m-code is written directly according to the operational logic and equations (1), (2), (3) and (4).

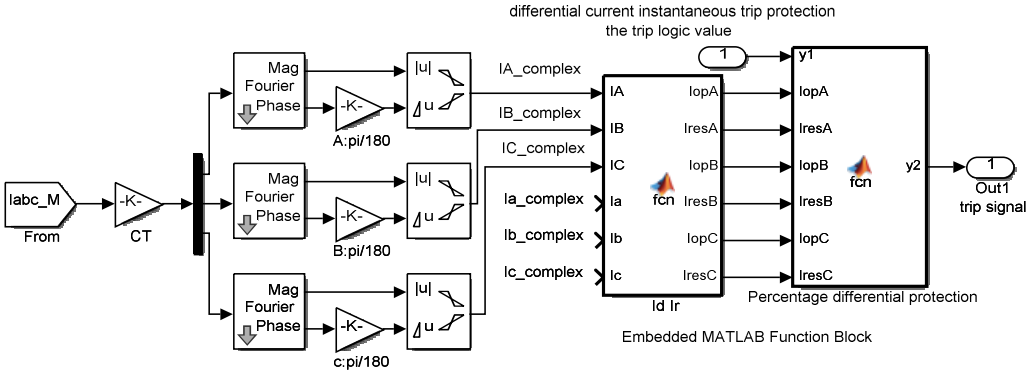

Fig. 4. Percentage differential protection

a) the differential current calculated block:

function [I_{opA},I_{resA},I_{opB}, I_{resB},I_{opC},I_{resC}]= fcn(I_A,I_B,I_C,I_a,I_b,I_c)
I_{aa}= (I_a-I_c)/sqrt(3); %phase shift compensation
I_{bb}= (I_b-I_a)/sqrt(3);
I_{cc}= (I_c-I_b)/sqrt(3);
I_{opA}= abs(I_A-I_{aa}); %differential current of phase A
I_{resA}= (abs(I_A)+abs(I_{aa}))/2; %restraint current of phase A
I_{opB}= abs(I_B-I_{bb});
I_{resB}= (abs(I_B)+abs(I_{bb}))/2;
I_{opC}= abs(I_C-I_{cc});
I_{resC}= (abs(I_C)+abs(I_{cc}))/2;

b) the percentage differential protection block:

function y_2 = fcn(y_1,I_{opA},I_{resA},I_{opB},I_{resB},I_{opC},I_{resC})
I_{r1}=2.0994; % 0.8*In
I_{r2}=7.87275; % 3*In
k_1=0.5;
k_2=0.7;
I_{opmin}=0.7873; % 0.3*In
y_2=10;
if y_1= =0
if
((I_{opA}>I_{opmin}&&(I_{opA}-I_{opmin})>k_1*(I_{resA}-I_{r1})&&(I_{opA}>k_2*(I_{resA}-I_{r2})+k_1*(I_{r2}-I_{r1})+I_{opmin}))||(I_{opB}>I_{opmin}&&(I_{opB}-I_{opmin})>k_1*(I_{resB}-I_{r1})&&(I_{opB}>k_2*(I_{resB}-I_{r2})+k_1*(I_{r2}-I_{r1})+I_{opmin}))||(I_{opC}>I_{opmin}&&(I_{opC}-I_{opmin})>k_1*(I_{resC}-I_{r1})&&(I_{opC}> k_2*(I_{resC}-I_{r2})+ k_1*(I_{r2}-I_{r1})+I_{opmin})))
y_2=1;
else
y_2=0;
end
end

Percentage differential protection is applied to distinguish between an internal fault and an external fault in the transformer. If the operating current exceeds a certain ratio of the restraint current, the

differential relay will operate [3, 4]. The algorithm for percentage differential protection is described by (4).

$$\begin{cases} I_d > I_{op.\min} & I_r \le I_{res1} \\ I_d > I_{op.\min} + K_1(I_r - I_{res1}) & I_{res1} < I_r \le I_{res2} \\ I_d > I_{op.\min} + K_1(I_{res2} - I_{res1}) + K_2(I_r - I_{res2}) & I_r > I_{res2} \end{cases}. \tag{4}$$

where K_1 and K_2 are constants.

Inrush current occurs during energization of a transformer and consists of a large transient current caused by saturation of the magnetic core [5]. The relay may mis-operate due to an inrush current. The second harmonic restraint method is the most commonly applied protection method in this case. Various studies have shown that the differential relay will not operate when

$$I_{op2} / I_{op1} > K_{2.\text{set}}. \tag{5}$$

where $K_{2.\text{set}}$ is a constant and I_{op2} is the second harmonic component of the operating current.

It is common practice to use the fifth harmonic of the operating current to avoid differential protection operation if the transformer experiences over-excitation [6, 7]. The differential protection operates if

$$I_{op5} / I_{op1} > K_{5.\text{set}}. \tag{6}$$

where $K_{5.\text{set}}$ is a constant and I_{op5} is the fifth harmonic component of the operating current.

Performance Evaluation

The performance of transformer differential protection can be examined in the Matlab/Simulink environment using the proposed model. If the differential current is eight times larger than the rated current, the differential current instantaneous trip protection will operate immediately; if not, the ratio restraint criteria are used to identify the fault-type. If the differential current enters the operation zone, second harmonic restraint and over-excitation protection are still required to discriminate the fault from the disturbances.

Fig. 5 shows the current waveforms for a healthy transformer, and the simulated currents agree well with the calculated results. Due to the star-delta winding connection of the transformer, the phase angle of the three-phase current in the high-side star winding lags behind the phase angle in the delta winding side [8]. The result of the phase shift compensation is depicted in Fig. 6.

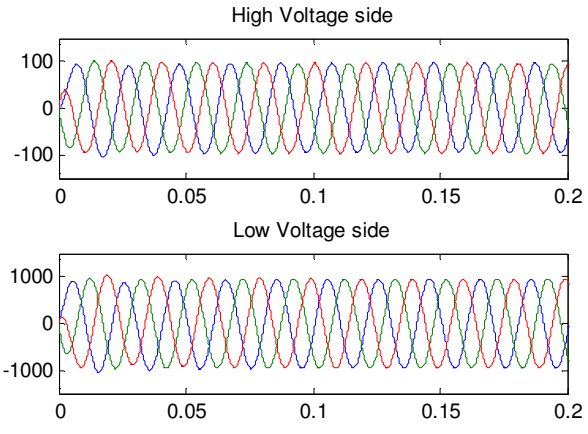

Fig. 5. Current waveforms

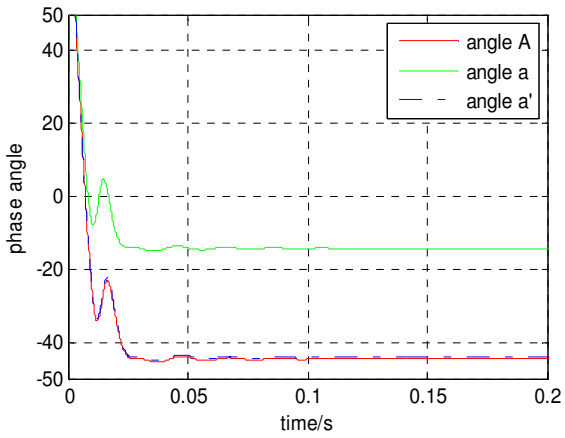

Fig. 6. Phase shift compensation

The currents in the transformer and the curve of the trip signal during a fault are shown in Fig. 7. A three-phase internal fault occurs at 0.1 s, and a trip decision is activated immediately.

To investigate the performance of the differential protection, the results of a three-phase external fault at 0.1-0.2 s are indicated in Fig. 8. Obviously, no trip signal is issued in the external fault case.

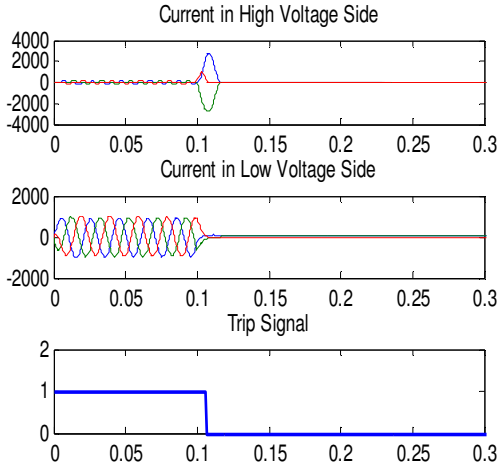

Fig. 7. Results of internal fault

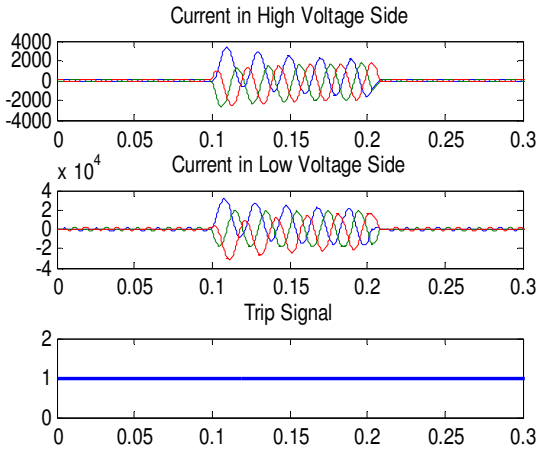

Fig. 8. Results of external fault

Conclusion

The paper proposes a simulation model of transformer differential protection using an embedded Matlab function block. The model is able to correctly discriminate an internal fault from an external fault. For an external fault, no trip signal is activated in this situation. In contrast, it is clear that a trip signal is activated during an internal fault. In the embedded function block, the protection criteria are written directly according to the operational logic, and the results validate the accuracy of the model.

Keywords: Phase-shifting transformer; transmission capability; Sichuan power grid; power flow

Abstract. In this paper, the feasibility analysis of the utilization of phase-shifting transformers (PSTs) to improve the AC outward transmission capacity of Sichuan power grid (SCPG) is presented. Firstly, the authors analyze the working principle of PST, as well as the rules for selecting its location. Then, the AC outward transmission limit of SCPG is studied with PSASP software. Finally, the PST is used to change the power flow distribution of lines on border of SCPG. Simulations results show that the PST can significantly improve the AC outward transmission capacity of SCPG. At the same time, short-circuit current of SCPG is also reduced.

Introduction

Sichuan power grid (SCPG) is connected with Central China power grid (CCPG) merely through the border of Sichuan-Chongqing that is composed by Honggou–Banqiao double lines (simply called as Hongban lines) and Huangyan-Wanxian double lines (simply called as Huangwan lines). During the "Twelfth Five Year Plan" of China, the AC outward transmission capacity of SCPG will be extensively restrained by the transmission limit of the border of Sichuan–Chongqing power grid with the commissioning of some large hydropower stations, represented by Xiangjiaba hydropower station and Xiluodu hydropower station etc.. It has been one of the key issues to increase the outward transmission capacity of the border of Sichuan–Chongqing for SCPG, even for CCPG.

Phase shifting transformer (PST) is capable of controlling the power flow in certain power flowing towards certain direction and thus changes the distribution of power flow in loop grid. In turn, the overload on transmission lines or the main equipment of transformers can be avoided, enhancing the reliability. Moreover, a reasonable distribution of power flow is thereby realized to improve the transmission capacity of borders [1]. In addition, as mentioned in some literatures [2], PST also plays a certain role in reducing short circuit current. Authors in [3] points out that thyristor technology-based static PST improves the stability of power system, suppressing oscillations through proper controlling means.

1930s, American researchers firstly utilized PST to improve the distribution of power flow of electromagnetic loop in 66 kV and 132 kV [4]. In [5], PST was used to control the power flow of loop grid, in order to decrease loss and eliminate overload. In [6], PST was firstly realized on a power grid of 500 kV [7]. Holland, Italy and England also have the record of using of PSTs [7-9]. It can be concluded that PSTs are widely used in overseas power systems and application records can be observed on various voltage levels. Based on these engineering application experiences, IEEE has formed a standard for the application of PST, which provides guidance for formulating the application technology condition, equipment specification, and field test requirements of PST [10]. Relevant researches in China were initiated in 1980s. Chinese researchers and workers have profoundly investigated the principle, design method, and feasibility simulation etc. of PST [1-2]. In [11], an ultra-high voltage (UHV) PST was designed and its electromagnetic transient characteristics were analyzed. However, there is still no record of application of PSTs in China.

The AC outward transmission capacity of SCPG is fundamentally limited by the uneven distribution of power flows between Hongban lines and Huangwan lines. Under the current operation,

the ratio of power flow between the two lines reaches to 2:1. During the "Twelfth Five Year Plan" of China, this ratio may rise up to 5:1. With the operation of a large number of thermal power plant units in northern Chongqing, such uneven distribution is prone to be greatly widened. In adverse circumstances, the ratio might rise up to 7:1. This uneven power flow leads to the result that Hongban lines reach its stability limit untimely, while Huangwan lines cannot be fully utilized due to the over-small power flow. The AC outward transmission capacity of SCPG is thereby greatly limited. The pressure of outward transmission would be eased with the completion of the 1,000 kV Ya'an-Wuhan AC UHV. However, the difficulty of construction and other irresistible factors provide the project progress with great uncertainty. Therefore, in view of existing power grid resources, it is of great importance to study the utilization of PSTs to control the power flow distribution and improve the AC outward transmission capacity of SCPG.

In this paper, the basic principle of PST, methods of location selection, and design methods are briefly introduced. Then, the feasibility of application of PST on the border of Sichuan-Chongqing to increase the AC outward transmission capacity of SCPG is analyzed. Case studies based on PSASP suggested that PST significantly improved the transmission limit of border of SCPG. Moreover, the simulations also validates that the PST plays a role in reducing the short-circuit current of 500kV buses in SCPG.

The Basic Principle of PST

Principle of Phase Shifting. As shown in Fig. 1, a PST is generally composed by a series transformer and a parallel transformer. The series transformer is connected in Y/△ mode, while the parallel transformer is linked in Y/Y mode, with the neutral point connected with the ground. The primary winding of series transformer is connected in series with the line. The intermediate tap is linked to the primary winding of parallel transformer. Parallel transformer is in parallel with the line. The secondary winding of the parallel transformer, which is equipped with a polarity selector K_{ZF} and tap point control, is linked with the secondary winding of the series transformer in phase sequence relationship of A→C, B→A, and C→B.

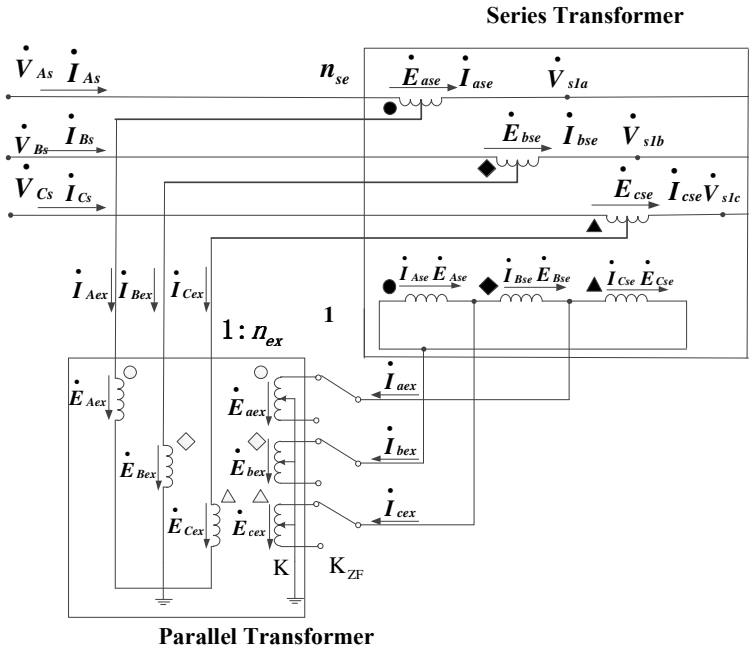

Fig. 1 Typical diagram of PST

During operation, the parallel transformer provides an exciting voltage for the series transformer. Under such exciting voltage, an additional voltage $\dot{E}_{ase}$ is accessed at the primary winding of the

series transformer. The additional voltage $\dot{E}_{ase}$ has 90 ° lead or lag, controlled by the polarity selector K_{ZF}, compared with the voltage $\dot{V}_{As}$ at the sending end system where the PST accesses. The phase relationship can be shown in Fig. 2. Therefore, a phase difference α between the output voltage $\dot{V}_{s1a}$ and input voltage $\dot{V}_{As}$ of PST is introduced, achieving the aim of adjusting the voltage phase, which is shown in Fig. 3.

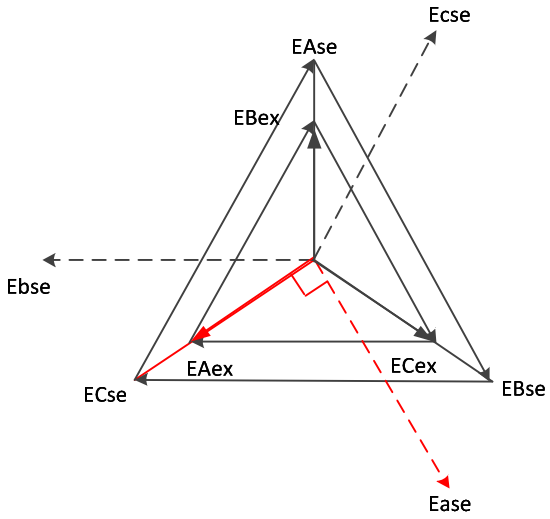

Fig. 2 Voltage phase relationships between the winding of PST

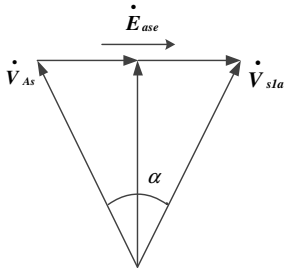

Fig. 3 The princple phase shifting

Model of PST. In simulations, a PST is modeled as a leakage reactance Z_{PST} connected with an ideal transformer, which could be expressed in Fig. 4. In Fig. 4, G_m and B_m are set to be infinite and R_{PST} is 0. In other words, the excitation conductance, excitation susceptance, and leakage resistance could be neglected. T_k is normally selected to be 1. The ideal control angle α is $\alpha = \alpha_J - \alpha_{I'}$, excluding the influence of the leakage reactance. In case of the leakage reactance $Z_{PST} = jX_{PST}$, the actual control angle $\alpha' = \alpha_J - \alpha_I$ of PST shows certain differences with the ideal α.

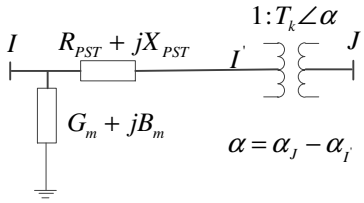

Fig. 4 Model of PST for simulation in PSASP

Control the Power Flows. Considering a single transmission system with between two nodes , if the phase angle of voltage on the receiving bus is set to be 0° , the active power transported over the transmission line is:

$$P = \frac{U_1 U_2}{X_L} \sin \delta \tag{1}$$

where, U_1 and U_2 are the voltage magnitudes on the sending and receiving ends, respectively; δ is the phase angle of voltage on the sending bus; X_L is the line impedance.

If the line is connected with a PST, the transmission power of the line changes to be:

$$P = \frac{U_1 U_2}{X_L + X_{PST}} \sin(\delta + \alpha) \tag{2}$$

As suggested by eq. (2), following results could be concluded: 1) A PST changes the transmission power between the sending and receiving ends. If there are other lines connected to the same sending and receiving ends, the distribution of the power flows between these lines are changed; 2) The PST enables transmitting the same power using a smaller phase angle difference between the sending and receiving ends. Moreover, the maximum transmitting power is reduced; 3) The leakage reactance X_{PST} introduced by PST can be seen as a series resistance, which increase the electrical distance between the installation bus of PST and the system. Therefore, the short circuit current on the installation bus of PST can be reduced.

The Design of PST

The capacity of a PST is the maximum transmission capacity of the line where the PST is placed. According to [3], the series transformer and parallel transformer have a same capacity. Assuming that the maximum transmission capacity of the line is S and the phase angle of the PST is adjustable in a range of $\pm\alpha$, the capacity of the series transformer and the parallel transformer could be obtained by:

$$S_S = S_P = S \sin \alpha \tag{3}$$

where S_S and S_P are the capacity of the series transformer and the parallel transformer, respectively. Since usually α is very small, it can be known that the capacity of series transformer and parallel transformer is far lower than the total capacity of PST.

Application of PST to Tmprove the AC Outward Transmission Capacity of SCPG

The AC Outward transmission path of SCPG, which is also called as the border of Sichuan and Chongqing, is composed by the 500 kV Hongban lines and Huangwan lines, as shown in Figure 5.

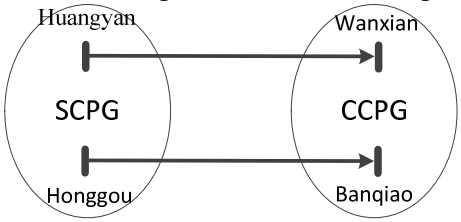

Fig. 5 Border of Sichuan and Chongqing Power Grid

Design of PST for the border of Sichuan and Chongqing. According to the limit capacity of 1900 MW for a single 500kV line, the rated power of PST in one of Hongban lines could be selected as 2,000 MVA.

Analysis reveals that the PST can achieve a desired power flow shifting by a smaller shifting angle. Thus the phase-shifting angle is designed to be ±10. The capacity of the series transformer and parallel transformer could be calculated by $2000 \times \sin 10^\circ = 347$ MVA thereby. As a result, the capacity of the transformers is 350 MVA. In the long-term, Hongban lines is possibly replaced by heat-resisting wires, the capacity of single line will rise to be 3,000 MW. In this condition, the

capacity of the series transformer and parallel transformer is 555 MVA, according to the design capacity of the PST (3,200 MVA). Thus the capacity could select as 560 MVA.

Verification for the designed PST. The designed PST is implemented as a model of Figure 4 and simulated in the software of PSASP based on the operation data of CCPG. The simulation results are summarized in Table 1.

As indicated in Table 1, without the PST, the power flow ratio after the N-1 contingencies of Hongban lines is 0.861. Moreover, under such operating mode, the power flow ratio of Hongban lines and Huangwan lines is 2:1. Based on the limit capacity of 1,900 MW for a single line of Hongban lines, the AC outward transmission capacity of SCPG is about 3,300 MW. With the installation of PST, the power flow ratio after the same fault of N-1 contingencies is significantly reduced. And the AC outward transmission capacity of SCPG increases to 5,090 MW, which is 1,800 MW larger than that without PST. In other words, the PST significantly improves the distribution of the power flow on the border and increases the transmission capability of SCPG.

Table 1 Simulation results after installation of PST for Hongban lines

Phase of Shifting	Power flow（MW）		N-1 of Hongban lines		Outward transmission capacity of SCPG （MW）
	Hongban lines	Huangwan lines	Hongban line （MW）	Power flow ratio	
0	2677	1327	2305	0.861	3300
-1°	2101	1873	1564	0.744	4830
-2°	2070	1902	1541	0.744	4900
-3°	2034	1938	1521	0.748	4960
-4°	2004	1970	1501	0.749	5030
-5°	1969	2001	1481	0.752	5094

During the “Twelfth Five Year Plan”, the short-circuit current of 500 kV buses in SCPG will have a remarkable increase, with the continuous strengthening of the structure of SCPG and the commissioning of large power stations, represented by Jinping power station, Xiangjiaba power station, and Xiluodu power station etc. Some breakers of 500 kV buses have approached to their breaking capacity and threatened the safe operation of power grid. According to the “Twelfth Five Year Plan” of Sichuan power grid, it would be urgent to suppress the short-circuit current in SCPG in the next 5 years.

As shown Fig. 4, in the equivalent circuit of the PST, the PST is equivalent to a series resistance connected to a transformer with a changeable phase. The connection of the series resistance X_{PST} has a good performance for reduce the short-circuit current. Table 2 shows the short-circuit current of 500 kV buses with short-circuit current exceeding 45 kA before and after installation the PST in Hongban lines. It can be seen that, the installation of PST significantly declines the short-circuit current of Honggou and those of other stations.

Table 2 The short-circuit currents of buses in SCPG before and after the installation of PST at Hongban lines

Bus name	short-circuit current（kA）		Bus name	short-circuit current（kA）	
	Before	After		Before	After
Honggou	54.13	49.51	Xufu	46.83	46.15
Dongpo	50.55	50.13	Ziyang	45.6	44.93
Taoxiang	48.64	48.42	Neijiang	45.16	43.25
Jianshan	48.55	48.34			

Summary

This paper provides an overview of the application of phase-shifting transformers around the world, analyzes the basic principle of PST, as well as the location and capacity of the phase-shifting transformer design. Finally, the PST is used to change the power flow distribution of lines on border of SCPG, and improve the AC outward transmission capacity of SCPG. Simulations with SCPG

using PSASP software show that: 1) the PST can increase the AC outward transmission capacity of SCPG by about 1800MW; 2) the short circuit current is also reduced, due to the leakage reactance of PST; 3) the transient stability after installation of PST needs to be further studied.

Keywords: modular multilevel converter(MMC); sub-module controller (SMC) SM fault steady-state test platform

Abstract Compared with Line-Commutated-Converter High Voltage Direct Current (LCC-HVDC), the primary and secondary systems of modular multilevel converter based HVDC (MMC-HVDC) are more complicated. And control and protection function of sub-module controller (SMC) have great influence on the operation of MMC-HVDC system. This paper investigates the design method of SMC and sub-module (SM) steady-state platform. First, the structure of the primary system and the electrical parameters of the 21-level MMC-HVDC are designed. Second, the architecture of the control system and SM fault protection strategy are proposed, and the control program is developed and debugged. Then SM steady-state test platform and the relevant control and protection are designed. Finally, the steady-state test and the system test of the physical MMC-HVDC simulation system are conducted. The test result shows that the sub-module is of good property and SMC can communicate with upper control layer efficiently, control and protect the SM efficiently.

Introduction

Modular Multilevel Converter (MMC) is a multi-level voltage source converter (VSC) topology [1], [2]. High DC voltage is obtained by superposition of a number of sub-modules, which could avoid direct series press-packed connection of the semiconductor devices and hundreds of output voltage levels can be achieved. Compared with the 2- and 3-level VSC, the MMC output voltage harmonic contents and switching losses are reduced greatly and the voltage level can be changed flexibly[3], [4]. In VSC-HVDC applications, the use of MMC topology has become an international development trend.

So far, studies on MMC mainly concentrated on its modeling, modulation and control strategies, [5]-[9], etc. But almost no references did research on the design of MMC-HVDC physical device or control systems. In [10] MOSFET is integrated with sub-module controller (SMC) in designing SM and CompactRIO is taken as pole controller & protection system (PCP) to design MMC-HVDC dynamic simulation device which is fit for research application. Ref. [11] introduces dynamic simulation method for valve based controller (VBC) and put forward a capacitor voltage balance method. Ref. [12] and [13] mainly focus on the hierarchical structure of controller. Ref. [14] designs and develops hardware, software and protection strategy of VBC, which have already been applied in Shanghai Nanhui wind farm integration project.

MMC-HVDC physical simulation primary system is designed in this paper. Control system uses hierarchical controlled manner, from top to bottom the control system is made up of the operator control system (PC), PCP, VBC and SMC. Two types of SM faults are studied and the corresponding protection strategies are proposed. A steady-state test platform is designed for the SMC and SM. Results of SM steady-state test proved the validity of SMC. MMC-HVDC system experiment results verified that communication between SM with VBC, SM fault protection and other functions can be achieved.

MMC-HVDC physical system

***A*. MMC converter and SM structure**

As shown in Fig.1, the MMC contains six symmetrical arms, and each arm contains N SMs which were connected with a reactor L in series. An upper and a lower arm constitute a phase unit. The output voltage of converter can be adjusted by allocating the number of SMs in the inserted state of the upper and lower arms, and DC voltage can be maintained constant for the number of inserted SMs in 3 phase units are equal at anytime.

SM consists of two IGBT used as switches and a dc energy storage capacitor. A thyristor and a contactor are used as bypass switch. T1 and T2 represent IGBT, D1 and D2 represent the IGBT anti-parallel diode, C1 represents the DC side capacitor, S is mechanical bypass switch of SM, which can bypass SM for a long time, T is electronic bypass switch for fast protection of D2. According to switching states of T1 and T2, the state of SM can be divided into inserted, bypassed and blocked.

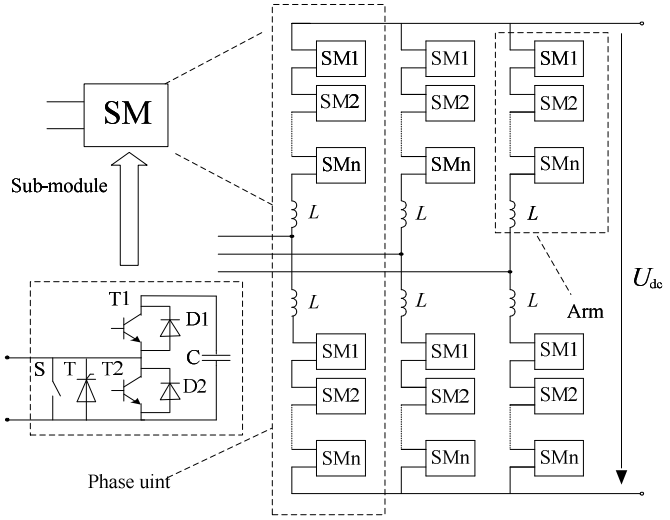

Figure 1. The topology of MMC

When the SM is transferred from inserted to bypassed state or from bypassed to inserted state, as characteristic of the IGBT are not identical, T1 and T2 may be switched on at the same time, so the capacitor is shorted. Therefore, it is necessary to set dead time for the two IGBTs, the setting method of dead time is adding blocked state into the SM switching operation. The output voltage is distorted, the fundamental component is reduced, and the harmonic component is increased by the dead time. It is more difficult for arm current direction detection. However, in order to prevent the SM capacitor form being shorted, dead time of the upper and lower IGBT is set in software in this paper.

***B*. Primary system of MMC-HVDC**

The rated power of MMC-HVDC physical system is 100kW, the rated DC voltage is ± 2kV. Each arm of converter has 22 sub-modules, and of which two SMs are used as spinning reserve. Main circuit of physical simulation system is depicted in Fig. 2.

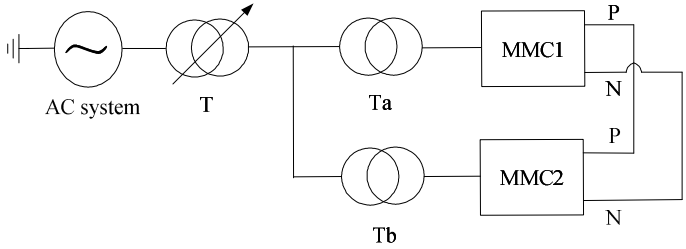

Figure 2. The primary system of MMC-HVDC physical simulation system

The rated input voltage of the regulator T is 380V, and the output voltage is raged from 0 to 430V. Rated capacity of converter transformer Ta and Tb is 120kVA, and the transformation ratio is 0.38/2 and the positive leakage inductance of the transformer is 0.1 p.u.. There is 50% taps on transformer

secondary side, and transformer connection group can be changed with power off. Fuses are equipped in the converter transformer secondary side, converter arms and DC lines. Current limiting resistor is 50Ω, and reactor of arm is 20mH. Three-phase PT and single-phase CT is used in main circuit. Active interfaces are reserved in the converter transformer primary side, secondary side and the DC side, so the filtering and fault simulation could be increased according to the need. Resistor is used to represent DC line and 1MΩ grounding resistors are set at both beside ends of the inverter. 15mH smoothing reactors are added at one end of the positive and negative DC bus. MMC-HVDC physical simulation system is shown in Fig. 3.

(a) (b)

Figure 3. MMC physical system (a) Two ends MMC (b) Three phase arm

C. Control system of MMC-HVDC

Hierarchical control method is used in control system. PC displays primary system voltage and current signals, and controls active and reactive power. PCP receives reference value of active and reactive power from PC, calculates modulation ratio M and phase angle δ. VBC completes sorting of capacitor voltages and distributes trigger signals of SMs to SMC. SMC triggers SM and protects the IGBTs. PCP processing functions are jointly implemented by digital signal processor (DSP) and field-programmable gate array (FPGA). FPGA is also used as processor of VBC and complex programmable logic device (CPLD) is used as processor of SMC. The hierarchical c ontrol system architecture is shown in Fig. 4.

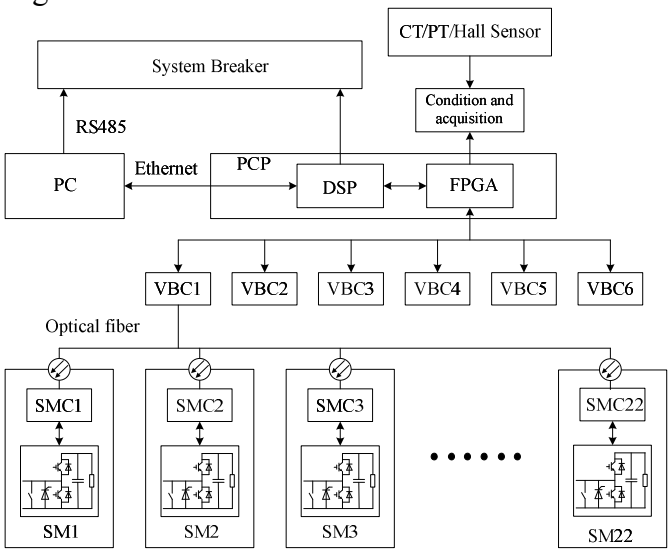

Figure 4. The architecture of control system

System status information is received by the host computer via an Ethernet from PCP, and the needs of human-machine interface displays and real-time control algorithms are taken into consideration. To ensure the rapidity of the protection system, breakers are controlled by PCP directly

and also operated by PC remotely. VBC communicated with SMC by a multiplexed pair of optical fibers for the asynchronous communication between VBC and SMC, which minimize the number of optical fibers and reduce the complexity of the control system.

Four operating states are set for the MMC-HVDC system: self-test, rectification, normal operation and shutdown. The main purpose of self-test state is checking whether control system hardware and communication between all layers of control system is normal when the primary system is power off. Under the coordination control, the MMC-HVDC can run at a stable state, with fixed DC voltage, fixed active power, fixed AC voltage and fixed reactive power.

Sub-module Controller

SMC is responsible for capacitor voltages conversion and SM status monitoring, and sending information to VBC through the fiber. Control information is received simultaneously from VBC to control IGBTs, and dead time of the two IGBTs is achieved in software. Mechanical bypass contactor and electronic thyristor are controlled. Hardware architecture of SMC includes AC power source, control chip, optical fiber, IGBT trigger voltage sampling and AD conversion, electronic bypass and mechanical bypass trigger, fault detection. Software features are displayed in the following Fig. 5. There are two types of SM fault: SMC communication fault and SM internal fault.

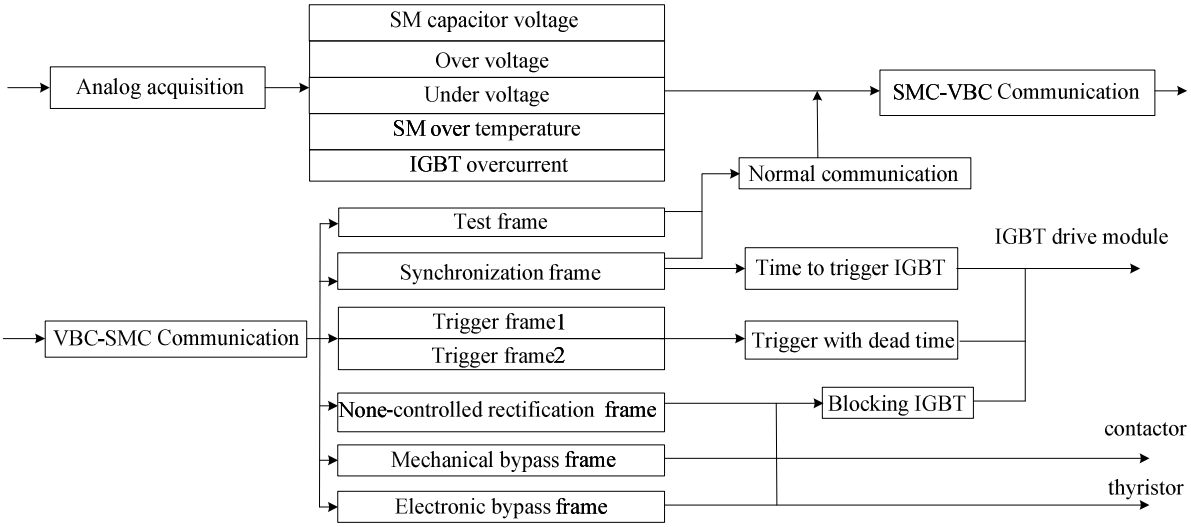

Figure 5. The program function of SMC

***A*. SMC communication fault**

Communication fault detection module detects the faults of received data, which includes overtime, the frame format error, and parity check error. Receiving data overtime refers to none of data or only a synchronous frame without any control frame is received from VBC in a control period. When receiving data overtime is detected, the fault is reported to VBC. Receiving frame format error means received data frame format of SMC does not match any normal frame. After a communication error is detected, fault is reported and the fault number is counted. SMC uses the correct control frame of last period for SM control.

***B*. SM internal fault**

After the control system is powered, SM status is monitored. Over voltage and under voltage is detected via SMC analog circuit. To prevent protection malfunction, SMC detects start time of over voltage or under voltage, the fault is confirmed only if the abnormal condition last for a certain time. Else, fault is ignored. Over temperature is achieved through the thermostat switch. Temperature switch is closed when over temperature fault occurs, so voltage level is changed to high by the conversion circuit to send fault to processor. When the IGBT over current fault occurs, the IGBTs are blocked by drive module quickly and fault information is sent to the processor.

At the start of one control period, capacitor voltage of SM and status of SM will be uploaded to the VBC, which will send control information to the SMC before the end of the control period. If a SM fails, the failure information in a period initial stage will be uploaded to the VBC, which will receive all fault information to determine whether the fault number of SM is less than the number of redundancy SM. If number of failed SM in the arm is less than or equal to two, bypass the corresponding SM, and insert redundancy SM. If the number of failed SM is greater than two, then upload a fault signal to PCP, and keep the open number of SM in the last control period before the PCP control the physical simulation system to stop. VBC sends stop request to the PCP, and PCP sends a stop command to the VBC. After receiving the stop command VBC to block all the SMs. Taking the VBC request to PCP the stop instruction time into accounts, SMC will receive control instructions of VBC in the next control cycle; SMC maintains the cycle state before stop instruction. When the SM fails, the control system can deal with failure in two control period.

SM steady-state test platform

A. Primary system of test platform

SM steady-state test platform consists of adjustable DC voltage source, a current limiting resistor, the DC capacitor and two IGBTs with anti-parallelled diodes. Test platform connect with the measured module through the right port, between which are the reactors. Since two SMs are packaged as a power unit, the two SMs are simultaneous measured in series. Fig. 6 shows the primary system of steady-state test platform.

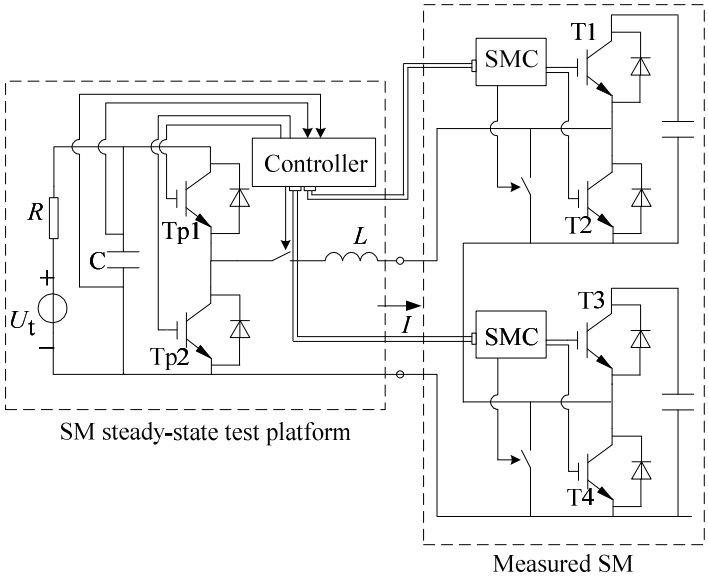

Figure 6. The primary system of SM steady-state test platform

Test platform and two SMs IGBT are controlled by SPWM, in which the test platform signal Tp1 and measured SM signal T1, T3 are the same; Tp2, T2 and T4 of measured SM control signal are the same. Two groups of signals are contrast.

When steady-state test platform is unloading, the test platform port output square wave. When TP1, T1 and T3 are switched on, the output voltage of the test port is Ut, otherwise when TP1, T1 and T3 are switched off, the output voltage is 0. After effection of smoothing reactor, the load current is sine wave with high frequency harmonics.

B. Controller design of test platform

The controller of steady-state test platform not only controls IGBT triggers of the test platform, but also controls the IGBTs of measured SM. In order to meet the different testing requirements of SM, different load currents can be adjusted by regulating DC output voltage and SPWM modulation.

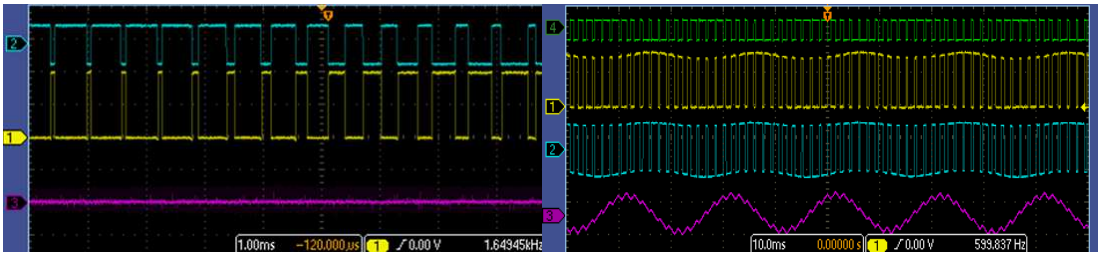
A custom serial communication protocol is adopted for test platform controller to communicate with the measured SMC. IGBT trigger signal, bypass signal and other information are sent to SMC, which will then send capacitor voltages and SM states back. Communication data is exchanged between test platform controller and measured SM with a fixed period.

Experiment result

A. SMC steady-state test

Voltage of DC source Ut is regulated and the oscilloscope is connected to the output of the SM test platform to measure the output voltage. Fig. 7(a) shows the waveform of no-load test. Curve 1 is load voltage of the test platform. Curve 2 is Tp2 of the test platform. Curve 3 is inductive load current. The result is consistent with theory. And by adjusting the control button of testing platform to change SPWM modulation, the output voltage waveform modulation can be changed accordingly.

Switch on the load side, gradually increasing Ut, SM capacitor voltage and test platform voltage, and RMS of load current are displayed on the LCD screen of controller. The load current which is sine wave with high frequency harmonics and voltage waveforms of the measured SM are observed by oscilloscope. Fig. 7(b) shows voltage and load current of SM. Curve 1 is the output voltage waveform of the test platform. Curve 2 is Tp2 of the test platform. Curve 3 is the load current waveform. Curve 2 is T2 of the measured SM.



(a) (b)

Figure .7 Test voltage and current(a) Unload test(b) Load test

B. System test

To test the communication between SMC and VBC, SM fault protection, the system test of physical system of MMC-HVDC are done. Fig. 8 shows capacitor voltages of 22 SMs in upper arm of phase A recorded by PC at a low rate over an extended period, when the system is stable and DC voltage is 4kV. Fig. 8 shows that the capacitor voltages are maintained at about 200V.

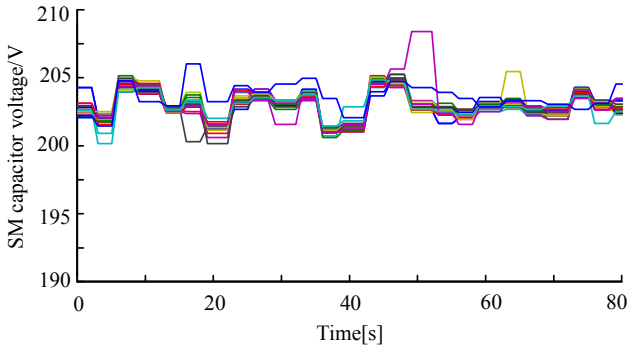


Figure 8. Capacitor voltages of upper arm in phase A

Experimental results also show that the SMC can protect the corresponding SM and send the fault information to VBC, when communication fault and over voltage or under voltage fault happened.

Conclusion

This paper introduces the primary system of MMC-HVDC physical system and the control system architecture. SMC and SM fault protection strategy are studied in details, and the SM steady-state test platform and MMC-HVDC physical simulation system are established. Experiment is done to test performance of the system. The conclusions are as following:

Hierarchical architecture is adopted for control system which is divided into PC, PCP, VBC and SMC, the communication between different control layers is determined, functions of the control layers are definited, respective control programs are developed.

The hardware and software of steady-state platform is reasonablely designed, which can ensure the efficient of SM test. The steady-state operating characteristic of SM is examined, which can verify the correctness of the SMC and SM.

Hardware architecture and software design of SMC have reference value for engineering applications.

Keywords: Convergence of iterative process, Hessian matrix, Static stability, Optimization, Power flow.

Abstract. In this paper, it is show how the second derivatives of the Hessian matrix influence on the convergence of the power flow calculation. Convergence conditions of the Combined Newton's method using 14 nodes IEEE testing schemes are investigated. The method can be used to determine the control actions to pull the operating point into the feasibility domain.

Introduction

The operting point of power electrical systems (PES) is subject to various disturbances - the fluctuation of the load, topology change, emergency (scheduled) off (on) of electrical equipment and so on - and you want to know the limits of change, both in terms of static stability of the power flow PES, and its existence.

In commercial programs, limiting regimes are usually repeated calculation of power flow in a given direction weighting. This approach is reliable and easy to implement, but because of the method used by the ideology of "trial and error" when calculating is largely determined by specifying the weighting step.Therefore, issues of improvement and development of new methods of power flow calculations are rather topical [1].

Theoretical background

Powert flow equations. The system of power flow equations are expressed:

$$\Delta W(X,Y) = 0, \tag{1}$$

where W(X,Y), X, Y are power unbalance vectors, dependent and independent variables, respectively. Separation of independent and dependent variables reflects the fact that the number of variables (parameters) exceeds the number of equations [2].

Second-order method of optimization. One way to find the minimum of thew objective function within the contrains [2, 3]:

$$F = [W\text{-}W(X,Y)]^T \cdot [W\text{-}W(X,Y)]. \tag{2}$$

The function minimum (2) is reached at the point where derivatives on all required variables are equal to zero:

$$dF/dX = -2dW/dX \cdot [W\text{-}W(X,Y)]^T. \tag{3}$$

The Hessian matrix, prepaid in the process of solving (2), contains two items:

$$H = [dW/dX]^T \cdot [dW/dX] - [d^2W/dX^2] \cdot [W\text{-}W(X,Y)]. \tag{4}$$

Jacobian and Hessian are different in form during the power flow calculation. This Hessian property is allows you to find the existing parameters of the operation point (power flows and voltages), even if the divergence of the Newton Raphson method for the initial conditions.

From (4) we see that the Hessian depends not only on the magnitude and angles of voltages, but also from the set of nodal capacities. The occupancy of the Hessian matrix is higher than the Jacobian matrix. This is due to the fact that the Jacobi matrix are non-zero elements - only the nodes of the first zone, that is, nodes that are directly connected. The Hessian matrix contains, besides the nodes of the first zone, nodes of the second zone, bringing the number of nonzero elements more. Figure 1 shows the nodes of the first zone (№ 8 and 11) and the second zone (№ 1, 2, 5 and 9) for node 6.

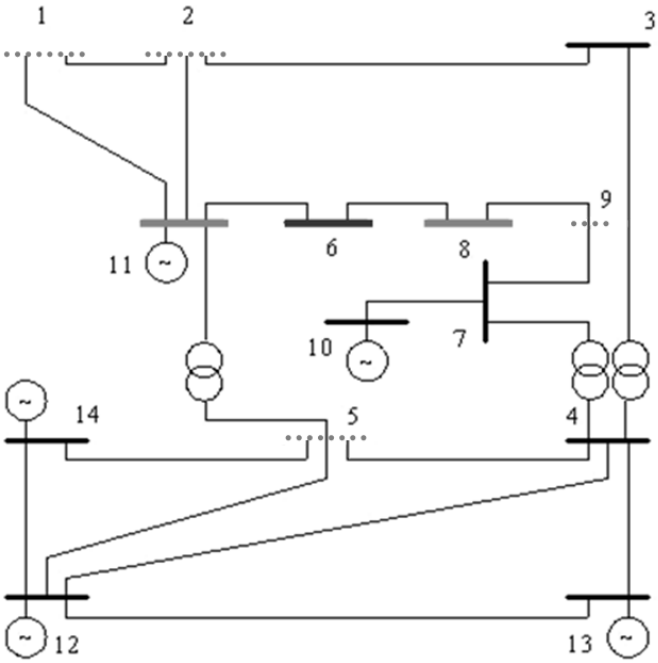

Figure 1. 14 nodes IEEE test scheme with marked first (—) and second (···) zones for node 6.

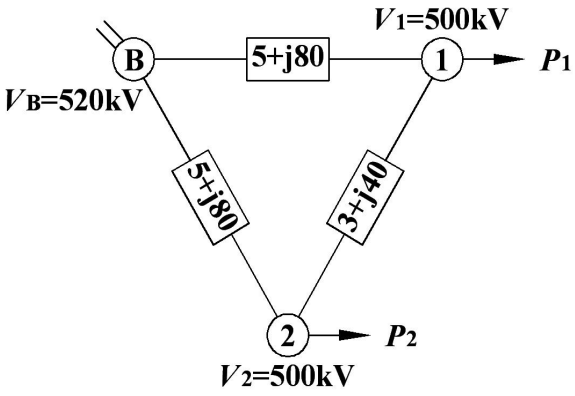

Figure 2. The test scheme

The term dW/dX2·[W-W(X,Y)] plays an important role in steady state calculation, when the operating point out of feasibility boundary. Due to this term, the Hessian matrix is not singular on the feasibility boundary of the solution [5].

Convergence of Combined Newton's method

Convergence of Combined Newton's method was investigated based on program MathCAD for 14 nodes IEEE test scheme (figure 1). The 14 node is infinity bus, nodes 10, 11, 12, 13 are active buses. Absolute values of voltage magnitudes are fixed at all buses. Initial nodal capacities (loading is positive value, generation is negative one) and voltage are shown in table I.

Table 1. Initial data

Bus number	1	2	3	4	5	6	7
P [MW]	90	80	70	100	40	50	70
V [kV]	115	115	115	230	230	115	115
Bus number	8	9	10	11	12	13	14
P [MW]	100	190	-350	-200	-800	-900	-
V [kV]	115	115	115	115	230	230	230

Results of power flow calculation are presented in table 2.

Table 2. Results of power flow calculation.

Scheme state	Combined Newton's method					Newton-Raphson method, № iters
	№ iters	P_{10}, MW	P_{11}, MW	P_{12}, MW	P_{13}, MW	
Normal	3	-350	-200	-800	-900	3
Off 4-13	3	-350	-200	-800	-604	Misconvergence
Off 12-13	5	-350	-200	-800	-742	Misconvergence
Off 4-7 and 4-9	6	-567	-70	-800	-900	Misconvergence

As you can see from the table 1, not all calculated nodal powers equal initial ones. This is due to the fact that initial nodal powers were outside of the boundary of existence domain. If we use Newton-Raphson method, we'll not get the solution, because N-R method with so initial data is misconvergence. Applying objective function (2) allowed us to find solution and this solution is the nearest to initial state point. Therefore Newton's method of optimization corrected nodal powers so, that difference between calculated and initial powers will be minimal.

Importance of the second derivatives s method

Influence of the full Hessian matrix has been investigated on the three-buses test scheme parameters of which are presented in Figure 2. Results of the power flow calculations are presented in the table 3. The term d2W/dX2·[W-W(X,Y)] of Hessian matrix designate as "The second component of the Hessian at the solution point".

Table 3. Results of power flow calculation.

6	P_1= 571 MW, δ_1=-67,70° P_2= -6250 MW, δ_2=-100,58°	P_1= 4355 MW, δ_1=-193,85° P_2= -430 MW, δ_2=772,86°	P_1= 7038 MW, δ_1=-26,85° P_2= -9896 MW, δ_2=72,52°

Conclusions

Combined Newton's method is efficient to calculate the steady state of the EPS because of higher efficiency of the solution for the modes in the vicinity of the existence of solutions, as well as beyond it.

Accounting for the second derivatives of the area of the positive features of the Hessian of the Jacobian, which in turn allows the operating conditions are in negative values of the Jacobian.

The difference of the Hessian, in turn, leads to the need to analyze the primary approach, otherwise you can be either in the negative Hessian, either in a positive Hessian, but not the one where the point is the desired solution.

Keywords: HVDC, subsynchronous oscillations (SSO), supplementary subsynchronous damping controller (SSDC)

Abstract. Supplementary subsynchronous damping controller (SSDC) is an effective countermeasure to damp the subsynchronous oscillation (SSO) caused by HVDC. On the basis of analyzing the mechanism of inducing SSO by HVDC, the principle of damping SSO by SSDC and SSDC design methods are expounded. A SSDC is designed for a practical power plant in China, and the correctness and validity of the SSDC control strategies are proved with time domain electromagnetic simulation results.

Introduction

As an extremely serious stability problem, Power system subsynchronous oscillation (SSO) first appeared in the long distance transmission system with series capacitance compensation, and then is founded in the HVDC system with steam-turbine generator shaft torsional oscillation caused by inappropriate control strategies [1-5]. With the rapid development of HVDC in China, the problem of SSO caused by HVDC became more and more prominent, so it is necessary to study damping measure of SSO caused by HVDC transmission.

A traditional method to overcome power system subsynchronous oscillation is using additional excitation control. However, its main drawback is that the response speed is not fast enough. Although using FACTS devices such as SVC, TCSC and filter to damp SSO can overcome shortcomings of additional excitation control, it requires additional equipment [6]. Additional subsynchronous oscillation damping controller (SSDC) was proposed by EPRI to damp SSO caused by HVDC system [7]. The basic principle of SSDC is to provide appropriate positive damping for steam-turbine generators in the subsynchronous frequency range. At present, there have been many scholars succeed in designing SSDC and obtained certain damping effect by using advanced control algorithm [6, 8-10]. On the basis of analyzing the mechanism of inducing SSO by HVDC, SSDC design and analysis methods are discussed in this paper. And then, a SSDC for a practical engineering is designed.

The mechanism of SSO caused by HVDC system

The change and interaction process of AC/DC system state variables can be shown in Fig.1. According to Fig. 1, the mechanism of SSO caused by HVDC system can be analyzed as follows [11]: If a small disturbance of electromagnetic torque is added to steam-turbine generator shaft, causing torsional modal rotation speed and angle fluctuate ($\Delta\omega$ and $\Delta\theta$), will lead to corresponding fluctuation of generator voltage amplitude and phase (ΔU and $\Delta\theta_U$), resulting in fluctuation of converter bus voltage amplitude and phase. Under an established DC control mode and operation condition, the HVDC trigger-delayed angle will fluctuate ($\Delta\alpha$), resulting in fluctuation of DC voltage (ΔU_{dr}), and then causing DC current or DC power fluctuate (ΔI_d, ΔP_d), This deviation will be fast corrected and adjusted by constant-current controller of HVDC rectifier, causing the generator electromagnetic torque fluctuate (ΔT_e), and eventually cause feedback on unit shaft. If the phase lag

(including additional phase lag caused by closed-loop control system) between the speed change and the resulting generator electromagnetic torque change exceeds 90 degrees, a torsional interaction with positive feedback characteristic will be formed to constantly help increasing perturbation amplitude, leading to unstable shaft torsional oscillation.

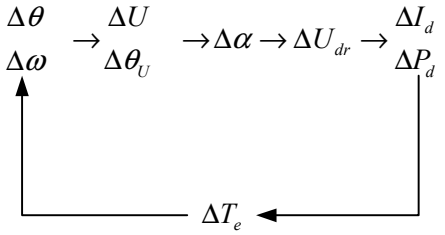

Fig. 1 Schematic diagram of SSO caused by HVDC

The principle of damping SSO by SSDC

According to complex torque coefficient method, power system electrical damping coefficient D_e can be expressed by Eq. 1

$$D_e = \mathrm{Re}\left(\frac{\Delta T_e}{\Delta\omega}\right) \tag{1}$$

Where ΔT_e is the variation of generator electromagnetic torque and $\Delta\omega$ is the deviation of generator speed. Power system electrical damping properties are determined by phase difference between ΔT_e and $\Delta\omega$. If the absolute value of this phase difference is less than 90 degrees, the power system electrical damping is positive and SSO will not occur. However, if the absolute value of this phase difference exceeds 90 degrees, the power system electrical damping is negative and the phenomenon of SSO may occur. The phase relationship between ΔT_e and $\Delta\omega$ is shown in Fig. 2.When the phase lag from $\Delta T_e$to $\Delta\omega$ is between 90 degrees and 270 degrees, namely when ΔT_e is located in third (or fourth) quadrant, the power system electrical damping coefficient (D_e) is negative, SSO may occur. At this point, if an additional electromagnetic torque in the first quadrant can be provided, making $\Delta T_e''$ which is the sum of phasor ΔT_e and phasor $\Delta T_e'$ located in the first quadrant, the power system electrical damping coefficient (D_e) is positive, SSO can be damped [12, 13].

As can be seen from Fig. 2, the effect of additional electromagnetic torque $\Delta T_e'$ provided by SSDC depends on magnitude of $\Delta T_e'$ and phase difference between $\Delta T_e'$ and $\Delta\omega$. The smaller the phase difference between $\Delta T_e'$ and $\Delta\omega$ or the bigger the magnitude of $\Delta T_e'$, the greater the effect of additional electromagnetic torque.

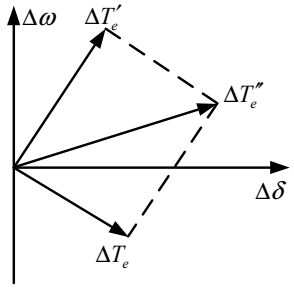

Fig. 2 The phase diagram of electromagnetic torque variation and speed deviation

SSDC design methods

SSDC design principle. According to DC system operation requirements, and considering using SSDC to participate in controlling SSO problem, SSDC design should follow basic principles as follows [14] :

(1)Be able to provide enough positive electrical damping for nearby steam-turbine generator under various operation modes.

(2) There is a certain gain margin and phase margin, and does not affect the regulatory function of DC control system.

(3) Does not affect the electromagnetic transient response characteristics of the DC system.

(4) Does not amplify characteristics and non-characteristic harmonics of AC/DC side in HVDC system.

(5) Its input signals should be easy obtained locally for DC converter station.

(6)Does not cause multiple interactions between DC rectifier stations or inverter stations

Input signal Selection. As for SSDC design, the input signal should have characteristics of the realizability and effectiveness. Realizability refers to using signal can be measured, and should try to avoid interference and noise attenuation caused by signal transmission process, making SSDC controller easier to realize. Effectiveness means the power system SSO characteristics can be accurately reflected by SSDC input signal, and the SSDC input signal has better controllability and observability, making controller play a better role. Therefore, converter bus voltage frequency and amplitude, AC current of converter transformer, DC current, DC voltage, DC power and generator rotating speed to be studied can reflect SSO characteristics. All of these can be used as SSDC input signal.

Control system Structure design. The SSDC control system can be designed by narrowband-pass mode-control method or broadband-pass optimal-design method. The SSDC designed by narrowband-pass mode-control method must be based on accurate modeling of shaft or accurate torsional natural frequency. Aiming at torsional natural frequency of steam-turbine generators which may have the possibility of SSO, this kind of SSDC designs narrowband-pass filter to carry out modal phase compensation and gain adjustment, thus realizes providing positive modal damping for generator. SSDC designed in this way can significantly improve the electrical damping of controlled modal, but may cause negative damping influence on other adjacent generators. The SSDC designed by broadband-pass optimal-design method designs a band-pass filter in a frequency range where units may have the possibility of SSO. The band-pass range is generally the low-pass band of HVDC. In this frequency range, this kind of SSDC provides common phase compensation for all oscillation modes. SSDC designed in this way needs to adopt optimization algorithm for parameter setting, and can provide strong positive damping for serious oscillation modes. Generally speaking, compared with narrowband-pass mode-control method, the positive damping it can provide is relatively small, but will enhance damping of all units in system.

As shown in Fig. 3, the control system of SSDC designed by narrowband-pass mode-control method consists of signal input, modal control, phase compensation, gain adjustment and amplitude limiting process.

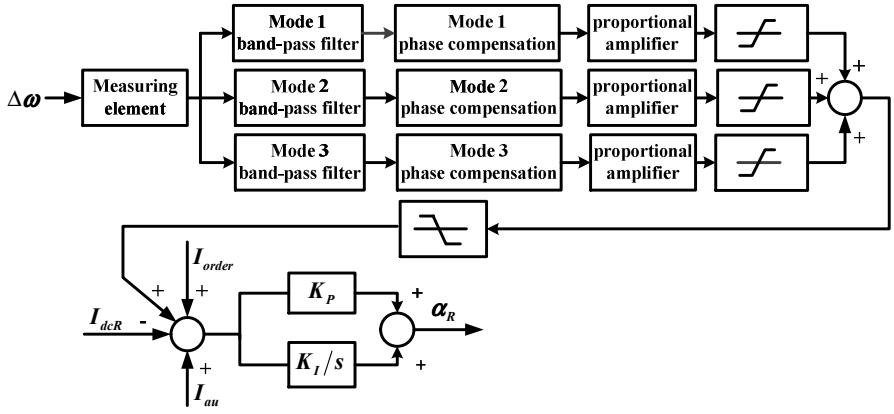

Fig. 3 The control system structure of SSDC designed by narrowband-pass mode-control method

In Fig. 3, I_{order} *i*s instruction value of HVDC constant current control; I_{dcR} is the DC current of HVDC rectifier; I_{au} is the additional control signal of HVDC; α_R is the trigger-delayed angle of HVDC rectifier.

Time domain simulation

The simulation system adopted in this paper is shown in Fig. 4.The two steam-turbine generators of plant A have the possibility of SSO. From previous shaft modeling and calculation, we can get the steam-turbine unit torsional natural frequency of 12.92 Hz, 22.50 Hz and 26.02 Hz.

According to SSDC design methods mentioned above, this paper designs a narrowband-pass SSDC for mode one of two steam-turbine generators in plant A. In order to validate the correctness of analyzing SSO mechanism and effectiveness of damping SSO by designed narrowband-pass SSDC, this paper simulated an operation condition that when HVDC is on double-pole operation condition, A phase to ground short-circuit fault occurs at Bus one in 18 seconds and the fault lasted 0.05 seconds. Figure 5 and Figure 6 respectively represent generator #1 shaft torque curve of each segment and mode one speed deviation under the condition with SSDC and without SSDC. In these figures, HP-IP represents high pressure cylinder to intermediate pressure cylinder, IP-LP represents intermediate pressure cylinder to low pressure cylinder, LP-G represents low-pressure cylinder to the generator and $d\omega$ represents speed deviation of mode one.

Fig. 6 Mode one speed deviation curve of generator #1

Conclusion

(1) This paper analyzed the mechanism of SSO caused by HVDC, expounded the principle of damping SSO by SSDC and discussed the selection of input signal, the controller structure in the process of designing SSDC and so on. Besides, the characteristics of different design methods are analyzed.

(2) Based on the above analysis, this paper designed a SSDC for a practical engineering. We can know that electrical damping of the system is significantly improved after the SSDC is put, the system SSO is damped obviously.

Keywords: Microgrid, Combined heat and power (CHP), Renewable energy resources, Coordinated optimal dispatch.

Abstract. The advantages of high energy efficiency and economic benefit promote the wide application of combined heat and power system (CHP) based microgrid. Firstly, a mathematical model of the CHP based microgrid is developed. Then, a cost function for the coordination of heat and electric load is proposed. Finally, an optimal dispatch model is developed to achieve the economical and coordinated operation of the CHP based microgrid system. Simulation results verify effectiveness of the proposed dispatch model, which is a powerful tool for the energy management of CHP based microgrid with renewable energy resources.

Introduction

The combined heat and power systems (CHP) are widely used in microgrids (MGs) due to the increasingly serious energy crisis and environmental pollution problems [1-4]. The CHP system utilizes waste heat to provide the thermal loads, which can improve the energy efficiency and decrease the production cost. Meanwhile, the MG not only can satisfy the requirements of a particular power quality of local loads, improve power supply reliability, but also can restore as much load as possible within the out-of-service area when a fault happens in the distribution network [5]. Therefore, the CHP based microgrid has the advantages of low pollutants emission, power quality improvement, and high reliability, *etc*.

Several studies have been carried out to investigate the CHP based microgrid system. A CHP based microgrid system was investigated in [7] and [8]. Ref. [9] optimized the operation of a fuel cell power plant with a CHP based microgrid system by using particle swarm optimization algorithm. In [10], different optimal power flow (OPF) models for the micro-sources in a CHP based microgrid system are constructed separately to minimize the total annual cost.

In this paper, a CHP based microgrid system is developed, which includes wind turbines (WTs), photovoltaics (PVs), micro-turbines (MTs), heat exchangers, gas fired boilers (GFBs), battery storage systems and thermal/electrical loads. Then, a coordinated optimal dispatch model of the CHP-based microgrid system is developed according to the power and load forecasting data over a 24-hour time interval with multi-objectives of the mimimum production cost and the minimum coordination cost.

CHP based Microgrid System with Renewable Energy Resources

The CHP based microgrid system with renewable energy resources developed in this paper is shown in Fig. 1.

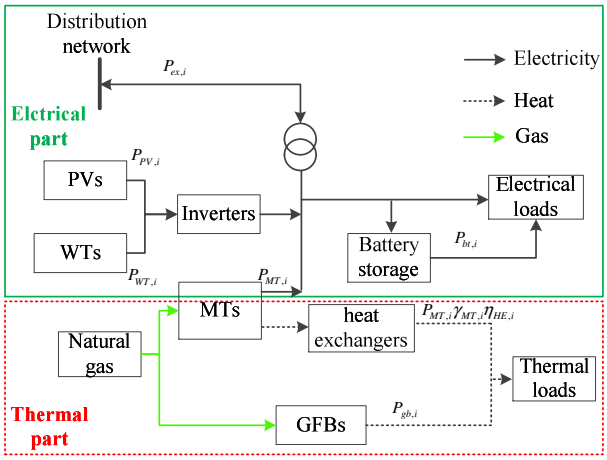

Fig. 1 A CHP based microgrid with renewable energy resources

The CHP based microgrid system consists of two parts:

1) The electrical loads are supplied by the electrical part, which consists of the WTs, PVs, battery storage systems and MTs. The WTs and the PVs utilize renewable energy sources to provide power for the electrical loads. The state of charge (SOC) of the battery storage system can be adjusted according to the operation status of the CHP based microgrid system in real time. The elecrical part can exchange power with the upstream distribution network. When the power output is larger than the eletrical loads, the power can be sold to the upstream grid, and when the outout power is lower than the eletrical loads, the system need to purchase power from the upstream grid.

2) The thermal loads are supplied by the thermal part, which consists of the MTs and GFBs. The MTs and the GFBs utilize natural gas to provide heat for the thermal loads. The MTs can provide both power and heat, which are responsible for the coordination of heat and power loads.

Modeling of the CHP-based Microgrid System

Production Cost. The production cost include the cost for providing power of the WTs and PVs, the cost for exchanging power with the upstream grid, the cost for purchasing natural gas for the MTs and GFBs and the maintenance cost for all the devices in the system. The function of the production cost is shown as follows:

$$C1=\sum_{i=1}^{24}[\frac{C_{ph,i}+C_{se,i}}{2}P_{ex,i}+\frac{C_{ph,i}+C_{se,i}}{2}\left|P_{ex,i}\right|+C_{gas}\left(\frac{P_{MT,i}}{\eta_{MT}}+\frac{P_{gb,i}}{\eta_{gb}}\right)+P_{MT,i}C_{MT\_om}+$$
$$P_{MT,i}\gamma_{MT}\eta_{HE}C_{HE\_om}+P_{gb,i}C_{gb\_om}+\left|P_{bt,i}\right|C_{bt\_om}+P_{WT,i}C_{WT\_om}+P_{PV,i}C_{PV\_om}] \quad (1)$$

where: $C1$ is the function of the production cost; $P_{ex,i}$ is the exchange power with the upstream grid in time i; $P_{MT,i}$ is the power output from the MTs in time i; $P_{gb,i}$ is the thermal power output from the GFBs in time i; $P_{bt,i}$ is the charging or discharging power of the battery storage system in time i; $P_{WT,i}$ is the power output from the MTs in time i; $P_{PV,i}$ is the power output from the PVs in time i; $C_{ph,i}$ is the price to purchase electricity in time i; $C_{se,i}$ is the price to sell electricity in time i; C_{gas} is the price for natural gas; C_{MT_om}, C_{HE_om}, C_{gb_ocm}, C_{bt_om}, C_{WT_om} and C_{PV_om} are the maintenance cost for MTs, heat exchangers, GFBs, battery storage systems, WTs and PVs separately; η_{MT}, η_{gb} and η_{HE} are the efficiency of the MTs, GFBs and heat exchangers; γ_{MT} is the thermoelectric ratio of the MTs.

Coordination Cost of Heat and Power. A cost function for the coordination of heat and power is proposed based on the different properties of the thermal and power loads and the different production states of generation units is developed in this section.

- **Definition of the Thermoelectric Ratio and Thermoelectric Load Ratio**

Definition 1: The thermoelectric ratio is defined as the ratio of the thermal production from the MTs to the power output from the MTs:

$$k = \frac{H}{P} \tag{2}$$

where: H is the thermal production from the MTs; P is the power output from the MTs.

Definition 2: The thermoelectric load ratio is defined as the ratio of the thermal loads to the power loads:

$$K_i = H_{Di} / P_{Di}, \quad i = 1, 2, 3, \ldots, 24 \tag{3}$$

where: H_{Di} is the thermal loads in time i; P_{Di} is the power loads in time i.

- **Modeling of the Coordination Dispatch of Heat and Power**

The cost for the coordination of heat and power is proposed to solve the different properties of the thermal and power loads based on the rated thermoelectric ratio under the condition of satisfying the thermal and power loads, thereby reaching the mimimum coordination cost for the CHP based microgrid system.

The function of the cost for the coordination of heat and power is shown as follows:

$$\begin{aligned} C2 = \sum_{i=1}^{24} [& C_{ph,i} \max\left\{ -\left[\sum_{m=1}^{N_p} P_m(i) + \left(1 - \frac{k}{k_i}\right) \sum_{k=1}^{Nc} P_k(i) - \sum_{n=1}^{N_h} H_n(i) \right], 0 \right\} - \\ & C_{se,i} \max\left\{ \left[\sum_{m=1}^{N_p} P_m(i) + \left(1 - \frac{k}{k_i}\right) \sum_{k=1}^{Nc} P_k(i) - \sum_{n=1}^{N_h} H_n(i) \right], 0 \right\}] \end{aligned} \tag{4}$$

where: $C_{ph,i}$ is the price to purchase electricity in time i; $C_{se,i}$ is the price to sell electricity in time i; k is the thermoelectric ratio and k_i is the thermoelectric load ratio in time i.

Optimization Problem of the CHP based Microgrid System. The mathematical formulation of the optimization problem for the CHP based microgrid system is mathematically expressed as:

- **The Multi-objective Optimization**

The multi-objective function is expressed as:

$$f = \min(C1, C2) \tag{5}$$

where: $C1$ is the production cost of the CHP based microgrid system in one day; $C2$ is the coordination of heat and power cost of the CHP based microgrid system in one day. So the objective function is to minimize the production cost and the coordination cost. If the individual objective is to minimize $C1$, the shortage of electricity can be purchased from the upstream grid, which makes $C2$ relatively high; and if the individual objective is to minimize $C2$, the system will improve the power exchange to the upstream grid to make profits, leading $C1$ greatly increased. Therefore, the multi-objective optimization taking both production cost and coordination cost into consideration can reach a comprehensive optimal dispatch scheme for the CHP based microgrid system.

- **Constraints**

1) Electrical power balance:

$$P_{ex,i} + P_{MT,i} + P_{WT,i} + P_{PV,i} + \frac{P_{bt,i}}{\eta_{ch}} - P_{D,i} = 0 \tag{6}$$

$$P_{ex,i} + P_{MT,i} + P_{WT,i} + P_{PV,i} + P_{bt,i}\eta_{dis} - P_{D,i} = 0 \tag{7}$$

where: P_{Di} is the power loads in time i; η_{MT} is the efficiency of the MTs; η_{ch} is the charging efficiency of the battery storage systems; η_{dis} is the discharging efficiency of the battery storage systems.

2) Thermal power balance:

$$P_{MT,i}\gamma_{MT}\eta_{HE} + P_{gb,i} - H_{Di} = 0 \tag{8}$$

where: H_{Di} is the thermal loads in time i.

3) Exchanging power with the upstream grid:

$$P_{ex,\min} \le P_{ex,i} \le P_{ex,\max} \tag{9}$$

where: $P_{ex,min}$ and $P_{ex,max}$ are the minimum and maximum exchanging power with the upstream grid in time i.

4) Operational constraints for the MTs, heat exchangers, GFBs and the battery storage system:

$$P_{MT,\min} \le P_{MT,i} \le P_{MT,\max} \tag{10}$$

$$P_{HE,\min} \le P_{MT,i}\gamma_{MT}\eta_{HE} \le P_{HE,\max} \tag{11}$$

$$P_{gb,\min} \le P_{gb,i} \le P_{gb,\max} \tag{12}$$

$$P_{bt,\min} \le P_{bt,i} \le P_{bt,\max} \tag{13}$$

$$\sum_{i=1}^{24} P_{bt,i} = 0 \tag{14}$$

$$W_{bt,\min} \le W_{init} - \sum_{i=1}^{24} P_{bt,i} \le W_{bt,\max} \tag{15}$$

where: $P_{MT,min}$ ($P_{MT,max}$) is the minimum (maximum) power output from the MTs in time i; $P_{HE,min}$ ($P_{HE,max}$) is the minimum (maximum) thermal power output from the heat exchangers in time i; $P_{gb,min}$ ($P_{gb,max}$) is the minimum (maximum) thermal power output from the GFBs in time i; $P_{bt,min}$ ($P_{bt,max}$) is the minimum (maximum) charging and discharging power of the battery storage systems in time i; $W_{bt,min}$ ($W_{bt,max}$) is the minimum (maximum) power storage of the battery storage systems. The equation (15) is formulated to make the finally power storage equal to the initial power storage in the battery srotage systems.

Simulation and results

Case Study. In this section, step controlled primal dual interior point method is implemented to optimize the operation of a CHP based microgrid over a 24-hour time interval [11]. The CHP based microgrid is shown in Fig. 1, and the WTs power output, PVs power output, the forecasting thermal and power loads over a 24-hour time interval are shown in Fig. 2 and Fig. 3. The parameters used during the simulation are summarized as follows: $P_{ex,min}$=-400kW, $P_{ex,max}$=400kW, $P_{MT,min}$=0kW, $P_{MT,max}$=150kW, $P_{bt,min}$=-10kW, $P_{bt,max}$=10kW, $P_{gb,min}$=0kW, $P_{gb,max}$=150kW, C_{gas}=0.2CNY/kWh, C_{MT_om}=0.04CNY/kWh, C_{HE_om}=0.025CNY/kWh, C_{gb_om}=0.03CNY/kWh, C_{bt_om}=0.02CNY/kWh, C_{WT_om}=0.11CNY/kWh, C_{PV_om}=0.08CNY/kWh, γ_{MT}=0.6801, η_{MT}=0.2716, η_{gb}=η_{HE}=η_{dis}=η_{ch}=0.9. The time-of-use price of the area are summarized in Table 1.

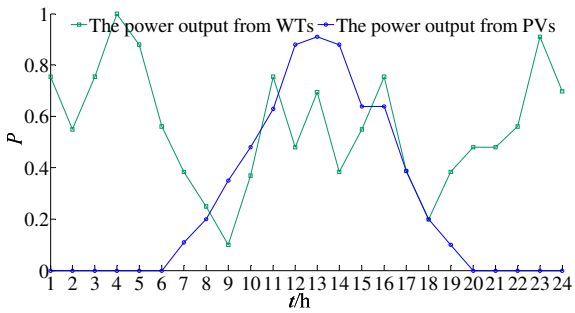

Fig. 2 WTs power output and PVs power output over 24-hour time interval

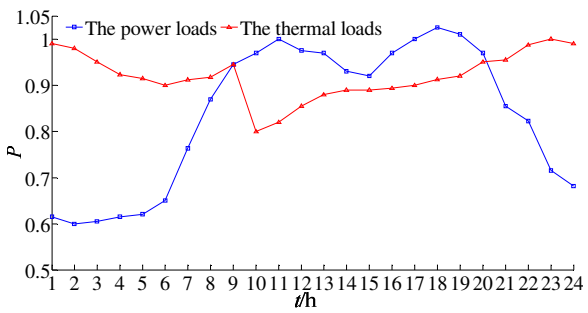

Fig. 3 Forecasting thermal and power loads over a 24-hour time interval

Simulation Results. The simulation results include two parts: the first part is the simulation results for the single-objective of minimizing the production cost and the coordination cost separatly; the second part is the simulation results for the multi-objective considering the production cost and coordination cost.

- **The simulation results for the single-objective optimization**

The optimal results by single-objective are shown in Table 2. The minus value in coordination cost represents that the CHP based microgrid system has made profit over 24-hour time interval.

The simulation results (shown in Table. 2) suggest that when the single-objective is minimizing the production cost, the heat and power production will cost lower (1801.6<2648.7) and the corresponding coordination of heat and power will cost higher (-912.4>-1257.6), and vice versa. The optimal dispatch of the CHP-based microgrid system based different single-objectives are shown in Fig. 4 and Fig. 5.

Table 1. Time-of-use price of the area

Time/h	C_{ph} /(CNY/kWh)	C_{se}/(CNY/kWh)
(10,15], (18,21]	0.7749	0.6150
(7,10], (15,18], (21,23]	0.4551	0.3567
(0,7], (23,24]	0.1599	0.1230

Table 2. Optimal results by single objectives

Objective	$C1$ /CNY	$C2$ /CNY
Production cost	1801.6	-912.4
Coordination cost	2648.7	-1257.6

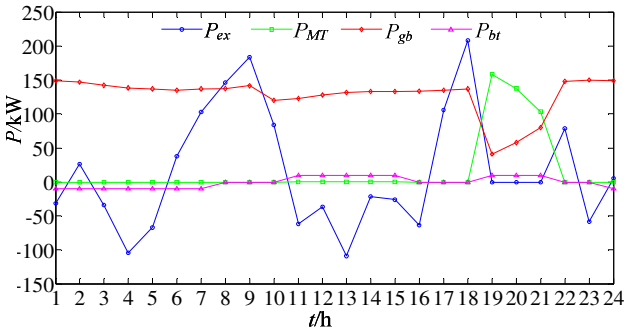

Fig. 4 Optimal dispatch of the system based on minimizing the production cost

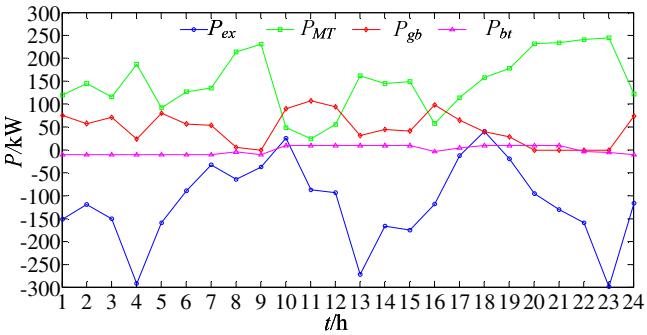

Fig. 5 Optimal dispatch of the system based on minimizing the coordination cost

- **The simulation results for multi-objective optimization**

The optimal results by multi-objective are shown in Table 3. The minus value in coordination cost represents that the CHP based microgrid system has made profit over 24-hour time interval.

The simulation results (shown in Table. 2 and Table. 3) suggest that if the individual objective is to minimize the production cost, the shortage of electricity can be purchased from the upstream grid, which makes the coordination cost relatively high; and if the individual objective is to minimize the coordination cost, the system will improve the power exchange to the upstream grid to make profits, leading the production cost greatly increased. Therefore, the optimal dispatch of the CHP based microgrid system can be obtained by applying the multi-objectives which taking both production cost and coordination cost into consideration. The results (shown in Table. 3) show that the CHP based microgrid system can find a optimal dispatch scheme, which not only has the relatcively low production cost, but also has relatively low coordination of heat and power cost.

Table 3. Optimal results by multi-objectives

Objective	$C1$ /CNY	$C2$ /CNY
Multi-objectives	1816.3	-1010.1

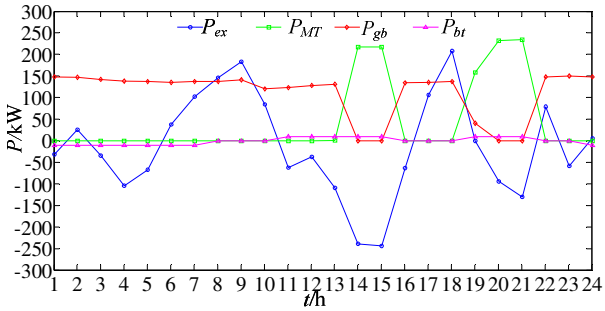

Fig. 6 Optimal dispatch of the system based on minimizing the coordination cost

Summary

This paper has developed a CHP based microgrid system model with renewable energy resources. Based on this developed model, a multi-objective optimal dispatch model for the CHP based microgrid is proposed in this paper taking both the production cost and coordination cost into account. The production cost is the operation cost for the system, while the coordination cost is led by the coordination for the unbalanced thermal and power loads, which have differnt control goals. Therefore, the multi-objective optimization can reach a comprehensive optimal dispatch scheme for the CHP based microgrid system. With the combination of time-of-use electricity price during the day, the constraints of equipment operation, balance of thermal and power loads, etc. are considered. Simulation results show that the multi-objective optimal dispatch model is able to provide a high efficient utilization of energy source and economic power dispatching scheme.

Keywords: Ultra High voltage; Jiangxi power system; stability assessment

Abstract. In order to face the challenge of our economy and the environment, it is needed to speed up the energy structure transition and UItra High voltage (UHV) transmission has become an inevitable choice. Researches on the influence of UHV project to Jiangxi power grid are carried out in this paper. Using advanced digital power system simulator (ADPSS), the real-time simulation model of Jiangxi power grid is build up including the UHV project. Based on the simulation model, the problem of low frequency oscillation in Jiangxi power system is studied after the UHV power transmission project accessed. The influence of the UHV transmission line faults on system stability of Jiangxi grid is also researched.

Introduction

In modern society, the use of electricity is closely related to each person. With the development of economy and civilization, the power load is increasing, the power network is becoming bigger and bigger and the power network voltage is getting higher and higher. UItra High voltage (UHV) [1-4] can realize power transmission with long distance and large capacity, which can decrease the transmission cost. Therefore, the developed countries such as American, Japan, the former Soviet Union and Italy had dedicated UHV transmission technology. At present, the 1000kV UHV AC transmission line from Jindongnan to Jingmen has been run successfully which constructed by the State Grid Corporation of China (SGCC) as a demonstration project. Another UHV AC lines Huainan-Shanghai and Zhejiang-Fuzhou will be put into operation soon. These projects indicate that the application of UHV in China has entered a new stage. UHV transmission has become an inevitable choice.

There are the following reasons which urge UHV use in China:

(1) In China, the geographical distribution of energy and load is imbalance. The energy resources are mainly distributed in the north and northwest area, but power consumption is mostly in east and central area. These two places are far away from each other.

(2) UHV transmission can greatly ease the tense of coal transportation. For a long time in the future, the situation of coal dominated energy structure will not change fundamentally. Power generation needs lots of coal. Coal transportation need much transport capacity of road and railway. UHV transmission instead of coal transportation will be a better choice.

(3) Since 2013, China suffered the fog haze weather. Thermal power generation is one of the most important reasons. Increase clean energy supply in northwest can greatly reduce coal-burning pollution, which need UHV power platform.

(4) UHV transmission line will occupy less land than 500kV transmission line compared with the same capacity. At the same time, UHV transmission has less loss. So it has particularly advantage in China middle-east area which land resources is scarce.

It is short of energy resources in Jiangxi province. With the development society economy, the tension between power supply and demand will be gradually aggravated. Therefore, it is urgent for Jiangxi to build UHV power supply corridor which can realize electricity import from other province.

In this paper, the influence of UHV access to Jiangxi power grid is analyzed based on real-time digital simulation [5-6]. Using simulation device of ADPSS, the real-time simulation model of Jiangxi grid is constructed with UHV accessed. The problems such as the low frequency oscillation and transient stability are investigated.

UHV Transmission Planning

In period of the twelfth Five-Year planning, construction of UHV line in SGCC will be gradually accelerated. According to the 2015planning, three vertical and three horizontal and one ring UHV network will be built in Sanhua synchronized power grid.

By the end of 2020, strong and smart grid will be constructed in China by SGCC with five vertical and five horizontal UHV lines. This huge power network will connect with the major coal bases, large hydropower bases, large nuclear power base, and large-scale renewable energy bases. It will link China Southern Power grid by UHV transmission line as well.

Jiangxi power grid is located in the eastern end of central china power grid. It associates with central china power grid by Xianning-Mengshan parallel transmission lines and Cihu-Yongxiu line. Through these three lines, the max received power is 3000MW. With the release of the national "steady growth" policy effect and application of the original Central Soviet area revitalization planning, it is expected that in the future Jiangxi power grid electricity level will have a large growth. The peak load in 2020 will reach 34000MW and the power shortage well reach 12000MW.

At the beginning of the Thirteen Five Planning, UHV power transmission line will connect with Jiangxi power grid to solve power supply problem. In 2016, Wuhan-Nanchang UHV power transmission project will be built. A 1000kV UHV substation will be constructed in Nanchang with two UHV lines connected with UHV Wuhan substation. There will be four 500kV lines connected Nanchang UHV substation with Jinxian and Fuzhou 500kV substation.

In view of the UHV transmission capacity, detailed analysis must be carried out to ensure the safe and stable operation of Jiangxi power grid before UHV power transmission project accessed.

UHV Power Transmission Modeling

Using as a reference of the 1000kV Jindongnan-Nanyang demonstration project, LGJ-630x8 wire is chosen as the UHV line type of Wuhan-Nanchang. The wire parameters can be seen in table 1. Length of the UHV line is 310km. When choosing UHV line parameters, if the concentrated circuit model is used, it will reduce the simulation accuracy because of neglecting the wave propagation process of long distance lines. Therefore it is more accurate by using sectional circuit simulation. Three segment line models are adopted in this research.

Table 1 LGJ-630x8 line parameters

R(Ω/km)	L(Ω/km)	C(μF/km)
0.0082	0.26	0.014

The main transformer capacity of Nanchang UHV substation is 2*3000MVA. Referring to transformer parameters of UHV demonstration project, the specific parameters are shown in table 2.

Table 2 UHV transformer parameters

Rated capacity of high-voltage side	3000MVA
Rated capacity of mid-voltage side	3000MVA
Rated capacity of low-voltage side	1000MVA
Short-circuit voltage(high-mid)(%)	19
Short-circuit voltage(mid-low)(%)	40
Short-circuit voltage(high-low)(%)	63
Tap position	mid-voltage side
Voltage regulation level difference (%)	1.25
Voltage regulation range (%)	±5

Compensation capacity of shunt reactor on the transmission line can also refer to the UHV demonstration project. The shunt reactor is divided into two parts and hung on the two ends of the line. 40% and 60% of the compensation capacity is installed at the beginning and the end of one UHV line. On the other UHV line, 60% and 40% of the compensation capacity is installed at line two ends. Considering the steady state voltage level and economic point of view, compensation degree of the shunt reactor is preferred 70%.

Except the UHV related elements, other elements use the planning data model which North China Grid and Central China Grid are connected. By this way, the real-time simulation modeling is completed with consideration of UHV accessed Jiangxi power grid. The whole simulation model covers north and central China UHV, each 500kV and 220kV network node.

Influence of UHV on Jiangxi Grid

(1) Load Flow Analysis

After Nanchang UHV AC substation put into operation, there will be five power transmission line connected Jiangxi grid with Central China grid. These lines include two UHV lines and three 500kV lines. The power flow distribution is roughly as follows: the total received power by Jiangxi grid is 4280MW. The power supply by UHV Transformer is 2570MW, and other 1710MW power is burdened by three 500kV contact line. The power flow from the UHV transformer will supply the load of Nanchang and western area in Jiangxi. The power flow from 500kV tie line will supply the load of Jiangxi northern area.

(2) Small Disturbance Stability Analysis

Oscillation modes correlated with generator in Jiangxi are shown in table 3. The damping ratios shown in table 3 are less than 5%.

Table 3 Oscillation mode concerned with Jiangxi grid

No.	Characteristic Values	Frequency Hz	Damping Ratio (%)	mode
1	-0.018+j8.879	1.413	0.201	Oscillation mode between Shangyoujiang hydropower plants and Jiangxi main network
2	-0.066+j11.678	1.859	0.569	Oscillation mode between Shihutang hydropower plants and Jiangxi main network
3	-0.083+j11.202	1.783	0.739	Oscillation mode between Baozhishi and Zhelin hydropower plants

It is shown in table 3 that no negative damping oscillation modes exist in Jiangxi power grid after UHV line accessed. The weak damping mode associated with the Jiangxi grid are small hydropower relative oscillation mode between Jiangxi power grid or small hydropower, which belongs to the mode oscillations within the region. UHV transmission lines are tie lines, therefore the oscillation modes caused by UHV lines must be modes between Jiangxi grid and Central China grid. The newly increased mode corresponding frequency will below 1Hz. As no modes fit the conditions above, it means that the UHV power transmission will not bring low frequency oscillation to Jiangxi grid.

(3) Transient Stability Analysis

In research of UHV transmission line fault effect on system stability of Jiangxi, N-1 and N-2 fault types is considered on UHV transmission lines. Three-phase fault is selected as it is the most unfavorable to system stability. Output of Nanchang UHV substation is selected as the fault location. When N-1 fault on UHV transmission line occurs, voltage and power angle variations before and after the faults are shown in Fig. 1 and Fig. 2.

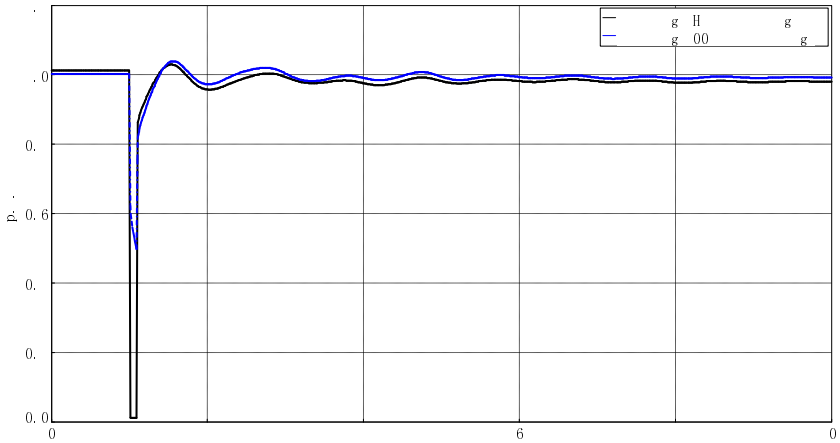

Fig. 1 Voltage variations curves when UHV lines N-1

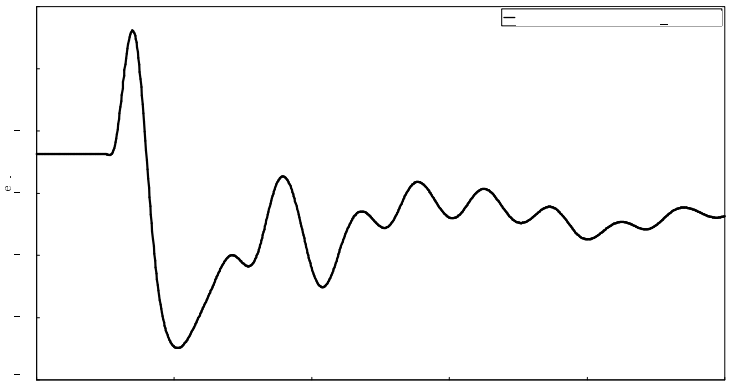

Fig. 2 Power angle variation curves when UHV lines N-1

It can be seen from Fig. 1 and Fig. 2 that the bus voltages quickly restore to more than 0.90p.u. after the fault is cleared. 1s later, the voltage restore more than 0.95p.u.. 10s later, the angle oscillations largely disappear, and the power system maintain the angle stability.

The process of N-2 fault on UHV double lines is as follows: two lines single-phase permanent short circuit of different phase on Nanchang side, single-phase tripping, and two lines three-phase jumped after single-phase reclosing failure. Voltage and power angle variations before and after the faults are shown in Fig. 3 and Fig. 4 when N-2 fault occurs.

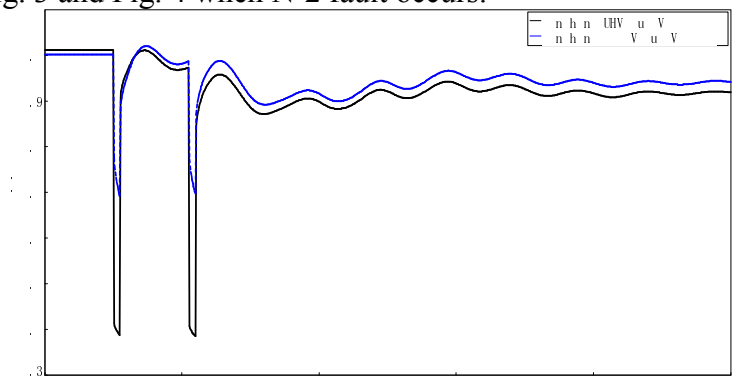

Fig. 3 Voltage variations curves when UHV lines N-2

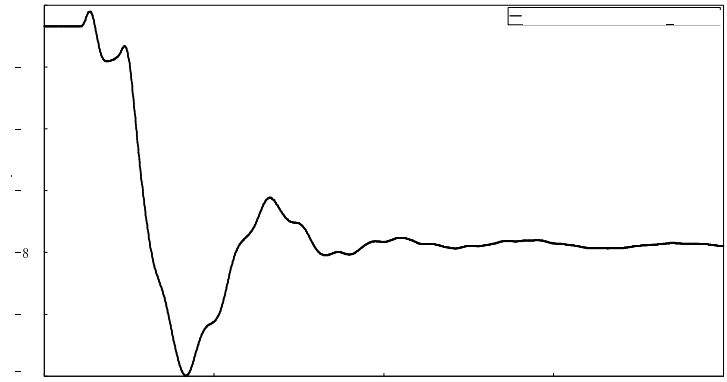

Fig. 4 Power angle variation curves when UHV lines N-2

It can be seen from Fig. 3 and Fig. 4 that the bus voltages quickly restore to more than 0.9p.u. after the fault is first cleared. After the fault is second cleared the voltage quickly restore more than 0.85p.u. and more than 0.9p.u. 3s later. 10s later, the angle oscillations largely disappear, and the power system maintain the angle stability.

Based on the above analysis, we can see that Jiangxi power system will not lose stability when N-1 or N-2 faults on Wuhan-Nanchang UHV transmission lines occurred.

(4) Short Circuit Current Calculation

After UHV transmission line connected to Jiangxi power grid, the network will link more closely. So the system short-circuit current level will increase. Effects of UHV lines connection on the short circuit current are studied in the following. Variations of 500kV and 220kV bus short-circuit current level in Jiangxi power grid is separately calculated considering UHV project accessed.

Table 4 Variation of 500kV bus current Short circuit [kA]

Bus	No UHV accessed	UHV accessed	Difference
Fuzhou	36.4	50.0	13.6
Jinxian	30.2	48.1	17.9
Nanchang	37.6	48.4	10.8
Yongxiu	43.0	48.2	5.2

Table 5 Variation of 220kV bus current Short circuit [kA]

Bus	No UHV accessed	UHV accessed	Difference
Changdong	39.5	42.4	2.9
Jinxian	38.2	43.0	4.8
Nanchang	42.9	46.2	3.3
Wugang	34.6	37.8	3.2
Xiangtang	31.8	34.9	3.1

It can be seen from table 4 and table 5 that UHV grid seriously affects short-circuits current level in Jiangxi power system. The increases of 500kV bus short-circuit current are larger than that of 220kV system. The buses with the largest short-circuit current increase are Fuzhou and Jinxian bus which are 500kV access points of UHV substation. Therefore, after UHV landing in Jiangxi, the short circuit current probably exceed the switch breaking capacity. At that time, limitation measures such as electromagnetic loop decoupling and lines breaking must be taken to decrease the short-circuit current.

Summary

UHV transmission is gradually applied in China with advantages of long transmission distance and huge transmission power capacity. Jiangxi as a province lack of energy resources, it is urgent to utilize UHV line accepting clean power supply from remote place. In this paper, the problems possible caused UHV access is analyzed in Jiangxi power grid. The results show that UHV transmission will bring no small disturbance and transient stability problems to Jiangxi power grid, but it will increase the short circuit current level and corresponding control measures should be taken in advance.

Keywords: energy management system (EMS), orthogonal transformation, Generalized Tellegen's Theorem, state estimation.

Abstract. One of the most important ways to enhance the speed of state estimation is to establish the constant matrix Jacobian. This essay puts forward a new type of orthogonal transformation state estimation method based on Generalized Tellegen's theorem. This paper uses orthogonal transformation method to improve state estimation's numerical stability, and makes the algorithm enjoy an ideal convergence. Moreover, it has strong compatibility of various distribution measurements. The method put forward in this essay has been verified through IEEE-30 Node System, and the efficiency of it has been fully proved by the example results.

Introduction

With the development of China's extra-high voltage and smart grid construction, state estimation is becoming more and more important. Thus, it is of greater importance to acquire rapid, reliable and accurate state estimation.

Power system weighted least squares state estimation method brought forward by F.C.Schweppe et al in 1970 has relatively high estimated quality and convergence. For the ideal normal distribution measurement, this kind of method produces optimal and unbiased estimated results. There is no doubt that Power system weighted least squares state estimation method is the classical algorithm and theoretical basis, yet it is to be improved in its rapidity.

In recent years, the state estimation method based on equivalent current transformation has been widely studied[1-5]. The literature 6 discusses the relationship between research and training education. Through this method, the measured power measurement can be transformed into an equivalent current measurement, and the voltage obtained through iteration can be used to revise the equivalent current constantly till it converges. This algorithm has realized constant Jacobian matrix in a true sense, and the automatic decoupling of the information matrix can be achieved when the weights of the active and reactive power measurements are equal or more or less the same. However, when the slip current amplitude measurement is considered, there may be multiple solutions, and the number of iterations is greater than the least-squares method. It remains the focus of the study on how to improve the numerical stability.

Orthogonal transformation method can improve state estimation's numerical stability. This essay focuses on a new type of orthogonal transformation state estimation method based on Generalized Tellegen's theorem, and applies the thought of flow calculation based on Generalized Tellegen's theorem to the state estimation. This paper uses givens orthogonal transformation method to improve state estimation's numerical stability， and makes the algorithm enjoy an ideal convergence. Moreover, it has strong compatibility of various distribution measurements.

Givens orthogonal transformation method

Givens rotation transformation is one of the most commonly used method for determining the orthogonal matrix.

If the type shown in equation (1) exists.

$$Ax + B = 0 \tag{1}$$

In formula (1),A—— m×n dimensional matrix； B—— m×1 dimensional matrix.

Givens rotation transform is a sub- matrix transformation of coefficient matrix, defining the n × n matrix Q, In addition to its elements $Q_{pp} = Q_{qq} = \cos\theta$, $Q_{pq} = -Q_{pq} = \sin\theta$, $p < q$, the other elements are the same as the corresponding elements of the unit matrix.

Series of Givens matrix G is left multiplied by the formula (1). Formula (2) is established.

$$\begin{cases} G_m G_{m-1} \ldots . G_2 G_1 A = \begin{bmatrix} R & 0 \end{bmatrix}^T \\ G_m G_{m-1} \ldots . G_2 G_1 B = \begin{bmatrix} e & g \end{bmatrix}^T \end{cases} \tag{2}$$

As can be seen from the above analysis , Givens transformation to transform some of the elements of the coefficient matrix. Therefore, Givens transformation can be used for power system state estimation to improve convergence.

Orthogonal transform state estimation method

The main measurements of SCADA system are node injection power measurement $\dot{S}_{m,i}$,branch power measurement $\dot{S}_{m,ij}$. Its measurement equation is shown in formula(3) .

$$\begin{cases} \overset{*}{S}_i = \overset{*}{U}_i \sum_{j=1}^{n} Y_{ij} \dot{U}_j \\ \overset{*}{S}_{ij} = \overset{*}{U}_i Y_{ij} (\dot{U}_i - \dot{U}_j) + \overset{*}{U}_i \dot{U}_i Y_{i0} \end{cases} \tag{3}$$

In the formula(3), $\dot{U}_i$ is the node voltage; Y_{ij} is the branch admittance; Y_{i0} is half of the Line capacitance to ground susceptance; Lines and transformers both adopt equivalent circuit of type π.

After equivalent transformation, it can be transformed into:

$$\begin{cases} \overset{*}{S}_{m,i} / \overset{*}{U}_i = \sum_{j=1}^{n} Y_{ij} \dot{U}_j \\ \overset{*}{S}_{m,ij} / \overset{*}{U}_i = Y_{ij} (\dot{U}_i - \dot{U}_j) + \dot{U}_i Y_{i0} \end{cases} \tag{4}$$

Formula (4) is abbreviated as shown in formula(5).

$$\begin{cases} \dot{I}_{m,i}^{eq} = \overset{*}{S}_N / \overset{*}{U}_i = Y_N \dot{U} \\ \dot{I}_{m,B}^{eq} = \overset{*}{S}_B / \overset{*}{U}_i = Y_B \dot{U} \end{cases} \tag{5}$$

Differentiating formula (5), the obtained is shown in formula(6).

$$\begin{cases} \Delta \overset{*}{S}_N / \overset{*}{U} - \overset{*}{S}_N * \Delta \dot{U} / \overset{*}{U}^2 = Y_N \Delta \dot{U} \\ \Delta \overset{*}{S}_B / \overset{*}{U} - \overset{*}{S}_B * \Delta \dot{U} / \overset{*}{U}^2 = Y_B \Delta \dot{U} \end{cases} \tag{6}$$

In the formula(6),

$$\overset{*}{S}_N / \overset{*}{U}^2 = \left[P_N \left(e^2 - f^2\right) + 2efQ_N \right] / \left(e^2 + f^2\right)^2 + j\left[-Q_N \left(e^2 - f^2\right) + 2efP_N \right] / \left(e^2 + f^2\right)^2 \tag{7}$$

$$\overset{*}{S}_B / \overset{*}{U}^2 = \left[P_B \left(e^2 - f^2\right) + 2efQ_B \right] / \left(e^2 + f^2\right)^2 + j\left[-Q_B \left(e^2 - f^2\right) + 2efP_B \right] / \left(e^2 + f^2\right)^2 \tag{8}$$

Formula (6) can be collectively represented as:

$$\Delta Z_m^{eq'} = (H + D)\Delta \dot{U} \tag{9}$$

Of which, $\Delta Z_m^{eq'}$ is the variation of the equivalent current measurement corresponding to $\Delta \overset{*}{S}_N / \overset{*}{U}, \Delta \overset{*}{S}_B / \overset{*}{U}$, while matrix D is the coefficient matrix corresponding to $\overset{*}{S}_N / \overset{*}{U}^2, \overset{*}{S}_B / \overset{*}{U}^2$.

Introduce the formula (9) into the least squares objective function:

$$J(\dot{U}) = [\Delta Z_m^{eq'} - (H + D)\Delta \dot{U}]^T R^{-1} [\Delta Z_m^{eq'} - (H + D)\Delta \dot{U}] \tag{10}$$

The formula (10) treated accordingly into the form shown in the formula (11).

$$\begin{aligned} J(\dot{U}) &= \left[\Delta Z_m^{eq'} - (H + D)\Delta \dot{U} \right]^T M \left[\Delta Z_m^{eq'} - (H + D)\Delta \dot{U} \right]^* \\ &= \left[\Delta \tilde{Z}_m^{eq'} - \left(\tilde{H} + \tilde{D}\right)\Delta \dot{U} \right]^T \left[\Delta \tilde{Z}_m^{eq'} - \left(\tilde{H} + \tilde{D}\right)\Delta \dot{U} \right]^* \end{aligned} \tag{11}$$

In the formula (11), $\Delta \tilde{Z}_m^{eq'} = M^{1/2} \Delta Z_m^{eq'}; \tilde{H} = M^{1/2} H; \tilde{D} = M^{1/2} D$.

If there is an orthogonal matrix, the formula (12) is satisfied.

$$\begin{cases} Q\Delta \tilde{Z}_m^{eq'} = [\Delta I \quad b]^T \\ Q\left(\tilde{H} + \tilde{D}\right) = [A \quad 0]^T \end{cases} \tag{12}$$

The objective function can be further converted to the formula (13).

$$\begin{aligned} J(U) &= \left[\Delta \tilde{Z}_m^{eq'} - \left(\tilde{H} + \tilde{D}\right)\Delta \dot{U} \right]^T Q^T Q \left[\Delta \tilde{Z}_m^{eq'} - \left(\tilde{H} + \tilde{D}\right)\Delta \dot{U} \right]^* \\ &= \| Q\Delta \tilde{Z}_m^{eq'} - Q\left(\tilde{H} + \tilde{D}\right)\Delta \dot{U} \|_2^2 \\ &= \| \Delta I - A\Delta \dot{U} \|_2^2 + \| b \|_2^2 \end{aligned} \tag{13}$$

Because the norm is greater than or equal to zero, when the formula (14) is satisfied, $J(U)$ will reach the minimum $\|b\|_2^2$.

$$A\Delta \dot{U} = \Delta I \tag{14}$$

$J(U)$ will reach the minimum $\|b\|_2^2$.

Therefore, just follow the Givens transformation method to construct the matrix *Q* can transform *A* and *b*, the state vector can be got.

Orthogonal Transformation State Estimation Based on Generalized Tellegen's Theorem

The following formula (15) can be acquired according to the generalized Tellegen small perturbation theorem[7].

$$\delta \dot{U}_i = -\tilde{U}(i)^T \delta A \cdot \Delta \dot{U}_0 + \tilde{U}(i)^T \delta \Delta I \tag{15}$$

$\tilde{U}(i)$ can be acquired through the adjoint equation shown in the formula (16)

$$\tilde{A}(\tilde{U})\tilde{U}(i) = \tilde{B}(i)^T \tag{16}$$

$\Delta\dot{U}_0$ can be acquired through the following formula (17)

$$\Delta I_0 = A(U_0)\Delta U_0 \tag{17}$$

What has to be acquired during the whole computing process are ΔU_0 and $\tilde{U}(i)$.If $A(\dot{U})$ and $\Delta I(\dot{U})$ are nonlinear, ΔU_0 can be acquired by adopting numerical iterative method, but it is enough for the linear equation to be solved only once to get $\tilde{U}(i)$.During the whole process of state estimation, what needs to be done is to acquire $\tilde{U}(i)$ calculating the factor table on $\tilde{A}(\tilde{U})$ which is $A(U_0)^T$ only once. In the subsequent iterative process, only $\delta\Delta I(\dot{U})$ and $\delta T(\dot{U})$ are needed to be solved.

$\delta\Delta I$ is the difference value of the equivalent measurement ΔI in each iteration and equivalent measurement ΔI_0 in the first calculation, which is the variable quantity of the equivalent measurement. δA is the difference of the information matrix in each iteration and the information matrix corresponding to $\dot{U}_0$.

It can be concluded from the above analysis that the method put forward in this essay, compared with the traditional state estimation based on generalized tellegen's theorem, enjoys better convergence. Moreover, its calculation accuracy is improved compared with the traditional estimation method of equivalent transformation state.

Numerical example

This essay, taking IEEE 30 node system as an example, conducts a comparative analysis in three aspects. The example assumes a normal distribution in which the SCADA system measurement error distribution with mean is 0 and a standard deviation is 0.02; and convergence accuracy is 10−6 . Using state the amount of amplitude and the absolute error of the phase angle δ_V and δ_θ as computational performance indicators, the value achieved is equal to the absolute value of the estimated value and the corresponding true value difference. Numerical example 1 has respectively computed and compared the iterations, computing time, and performance indicators such as δ_V and δ_θ of the algorithm proposed in this essay, the method of least squares algorithm and the traditional equivalent current transformation state estimation method, and the results are shown in table 1.

Tab.1 The comparison of algorithm stated in this essay and other kinds of algorithm in performance

information	iteration	computatin time(ms)	δ_V/pu	δ_θ/pu
WLS method	4	193	0.0063	0.0102
the traditional state estimation based on generalized tellegen's theorem	4	127	0.006	0.0107
Method in this essay	3	121	0.0059	0.0100

It can be concluded from table 1 that the method has been improved in the convergence compared with the least squares method and the traditional equivalent current transformation state estimation method. the calculation time is shorter than the least-squares method. Moreover, the estimated accuracy is basically consistent with the least squares method. This further verifies the correctness and practicability.

Conclusions

This essay focuses on a new type of orthogonal transformation state estimation method based on Generalized Tellegen's theorem, and uses givens orthogonal transformation method to improve state estimation's numerical stability, and makes the algorithm enjoy an ideal convergence. And has the same calculation accuracy with the least squares state estimation method.

Keywords: energy management system(EMS),wide-area measurement system(WAMS),state estimation, Taylor series.

Abstract. Take full advantage of the PMU's accurate mass measurement data is the effective method to improve the calculation accuracy of power system state estimation. This essay puts forward the state estimation method of power system based on the Taylor series method. It analysis of power system operating conditions based on the real-time measurement of Wide area measurement system, divides the state time, establishes the equation of state of the measurement data by curve fitting method in the period of state time, creates a new state estimation calculation method by Taylor series method, constructs a new voltage characteristic curve calculation method, determines the system state and achieve the continuity of power systems steady-state analysis. The method put forward in this essay has been verified through IEEE-30 Node System, and the efficiency of it has been fully proved by the example results.

Introduction

The phasor measurement unit(PMU) provides accurate , high-precision phase angle information to the power system, and taking full advantage of PMU measurements can improve the estimation accuracy and processing speed of power system state estimation , it also can provide accurate, real-time grid data for subsequent advanced application software.

The current state estimation method [1-6] uses only a time or several sections of grid data, and gets a true reflection of the system state (the voltage phase of power system) taking numerical analysis method, but it unable to achieve the continuity analysis of power system steady state. PMU measured massive data will be subject to existing state estimation methods' the calculation speed and the limited use of the state time data. The voltage and current phasor measured by PMU have higher accuracy, but still there are some errors and it may still affect the analysis results in the direct use of the current technology level; Therefore, the study of a state estimation method can make full use of vast amounts of data PMU measurements, and can ensure rapid computational speed has very important practical significance.

This essay puts forward a new state estimation method of power system based on the Taylor series method. It analysis of power system operating conditions based on the real-time measurement of Wide area measurement system and divides the state time, then it establishes the equation of state of the measurement data by curve fitting method in the period of state time and creates a new state estimation calculation method by Taylor series method, constructs a new voltage characteristic curve calculation method. Finally, it determines the system state and achieve the continuity of power systems steady-state analysis.

State Time Divide

State time power system can be divided as follows. firstly, this paper set a fixed time interval as a state time according to the actual situation of power system operation. Then, it determines whether the occurrence of adverse circumstances within the state time such as topology changes , sudden load change and PMU data loss based on measured data. If the system does not have these adverse circumstances occur during this state time it is a state time. If any one or both adverse events occur

during this time the process, it is divided into two states to the adverse circumstances places the moment as the dividing line.

Voltage Characteristic Curve

Firstly, This paper uses curve fitting method to determine the time function of each measurement according to real-time information PMU measurements. The time function is represented by the following formula (1)-(4).

$$I_{ma} = a_0 + a_1 t + a_2 t^2 + ... + a_n t^n \tag{1}$$

$$I_{mb} = b_0 + b_1 t + b_2 t^2 + ... + b_n t^n \tag{2}$$

$$U_{ma} = c_0 + c_1 t + c_2 t^2 + ... + c_n t^n \tag{3}$$

$$U_{mb} = d_0 + d_1 t + d_2 t^2 + ... + d_n t^n \tag{4}$$

I_{ma}, I_{mb} are the real part and imaginary part of the transformed branch current measure. U_{ma}, U_{mb} are the real part and imaginary part of the transformed bus voltage measure. T is time variable.

For power systems, the measurement function is shown in formula (5).

$$Z(t) = h\left[\dot{U}(t)\right] + \xi \tag{5}$$

In formula (5), $\dot{U}(t)$ is voltage characteristic curve, $h\left[\dot{U}(t)\right]$ is the measurement function equation, ξ is random error.

Differentiating formula (5), the obtained is shown in formula (6).

$$Z^{(1)}(t) = H\left[\dot{U}(t)\right]\dot{U}^{(1)}(t) \tag{6}$$

In formula (6), $H\left[\dot{U}(t)\right] = \partial h\left[\dot{U}(t)\right] / \partial \dot{U}(t)$ is Jacobian matrix, $\dot{U}^{(1)}(t)$ is the first derivative of state quantity.

While getting the m-order derivative of formula (6) with respect to time *t*, formula (7) is acquired by binomial theorem.

$$Z^{(m)}(t) = \sum_{j=0}^{m-1} C_{m-1}^{j} H^{(j)}\left[\dot{U}(t)\right]\dot{U}^{(m-j)}(t) \tag{7}$$

In formula (7), C_{m-1}^{j} is the binomial coefficients, $H^{(j)}\left[\dot{U}(t)\right]$ is the j-order derivative of Jacobian matrix, $\dot{U}^{(m-j)}(t)$ is the (m-j)-order derivative of $\dot{U}(t)$.

According to formula (7)，the derivative binomial equation of the measurement data shown in formula (8) can be obtained.

$$Z^{(m)}(t) - \sum_{j=1}^{m-1} C_{m-1}^{j} H^{(j)}\left[\dot{U}(t)\right]\dot{U}^{(m-j)}(t) = H\left[\dot{U}(t)\right]\dot{U}^{(m)}(t) \tag{8}$$

Because of the linear relationship between branch current measurement, voltage measurement measured by the PMU and state. The measurement function can be written as formula (9).

$$Z = h\left[\dot{U}(t)\right] = H \cdot \dot{U}(t) + \xi \tag{9}$$

In formula (9), H is Jacobian matrix, ξ is random error.

So formula (10) can be acquired.

$$H^{(j)}\left[\dot{U}(t)\right] = O, j \geq 1 \tag{10}$$

In formula (10), O is zero matrix.

The derivative binomial equation of the measurement data can be further written as formula (11).

$$Z^{(m)}(t) = H \cdot \dot{U}^{(m)}(t) \tag{11}$$

The formula (12) can be got by multiplying $H^T R^{-1}$ both sides of the formula (11).

$$H^T R^{-1} H \dot{U}^{(m)}(t) = H^T R^{-1} Z^{(m)}(t) \tag{12}$$

In formula (12), R^{-1} is the coefficient matrix, H^T is the transposed matrix of Jacobian matrix.

The formula (13) can be got by multiplying $H^T R^{-1}$ both sides of the formula (12). While the voltage characteristic curve's all order derivatives can be calculated by formula (13).

$$\dot{U}^{(m)}(t) = \left(H^T R^{-1} H\right)^{-1} H^T R^{-1} Z^{(m)}(t) \tag{13}$$

Further expression of the voltage characteristic curve is determined as shown in formula (14).

$$\begin{cases} U_a(t) = e_0 + e_1 t + e_2 t^2 + ... + e_n t^n \\ U_b(t) = f_0 + f_1 t + f_2 t^2 + ... + f_n t^n \end{cases} \tag{14}$$

According to Taylor's formula, the voltage characteristic curve should satisfy formula (15).

$$\begin{cases} U_a(t) = U_{a0} + \frac{U_a'(t)}{\partial t}(t - t_0) + \frac{U_a^{(2)}(t)}{2!}(t - t_0)^2 + ... + \frac{U_a^{(n)}(t)}{n!}(t - t_0)^n \\ U_b(t) = U_{b0} + \frac{U_b'(t)}{\partial t}(t - t_0) + \frac{U_b^{(2)}(t)}{2!}(t - t_0)^2 + ... + \frac{U_b^{(n)}(t)}{n!}(t - t_0)^n \end{cases} \tag{15}$$

In formula (15), $U_a'(t)$, $U_a^{(2)}(t)$ …. $U_a^{(n)}(t)$ is 1-order , 2-order .... n-order derivative of $U_a(t)$. $U_b'(t)$, $U_b^{(2)}(t)$ …. $U_b^{(n)}(t)$ is 1-order , 2-order .... n-order derivative of $U_b(t)$.

Taking the initial time $t_0 = 0$, the formula (15) can be simplified to formula (16).

$$\begin{cases} U_a(t) = U_{a0} + \frac{U_a'(t)}{\partial t} t + \frac{U_a^{(2)}(t)}{2!} t^2 + ... + \frac{U_a^{(n)}(t)}{n!} t^n \\ U_b(t) = U_{b0} + \frac{U_b'(t)}{\partial t} t + \frac{U_b^{(2)}(t)}{2!} t^2 + ... + \frac{U_b^{(n)}(t)}{n!} t^n \end{cases} \tag{16}$$

The formula (17) can be got by the comparator (16) and formula (14).

$$\begin{cases} e_0 = U_{a0}, e_1 = \frac{U_a'(t)}{\partial t}, e_2 = \frac{U_a^{(2)}(t)}{2!}, ..., e_n = \frac{U_a^{(n)}(t)}{n!} \\ f_0 = U_{b0}, f_1 = \frac{U_b'(t)}{\partial t}, f_2 = \frac{U_b^{(2)}(t)}{2!}, ..., f_n = \frac{U_a^{(n)}(t)}{n!} \end{cases} \tag{17}$$

Numerical example

This essay, taking IEEE 30 node system as an example, assumes that all nodes are equipped with PMU, the simulation data takes flow results as the true value. The generation and load values for each

section of the overall grow 1%. The example assumes a normal distribution in which the SCADA system measurement error distribution with mean value is 0 and a standard deviation is 0.02; and convergence accuracy is 10e−6 . Using state the amount of amplitude and the absolute error of the phase angle δ_V and δ_θ as computational performance indicators, the value achieved is equal to the absolute value of the estimated value and the corresponding true value difference.

To verify the numerical properties of the proposed algorithm, the case analyzes the mutation case that important nodes of a sudden load from increase 1% to drop 3%, the Performance Characteristics of the algorithm proposed in this essay, the method of least squares state estimation and traditional linear dynamic state estimation method, and the results are shown in table 1.

Tab.1 The performance comparison of algorithm stated in this essay and other kinds of algorithm in mutation load

information	computatin time (ms)	δ_V/pu	δ_θ/pu
WLS method	483	0.0072	0.0131
Traditional dynamic state estimation	264	0.1370	0.5326
Method in this essay	179	0.0075	0.0130

As can be seen from Table 1, in the special case of a sudden change in load occurs, the accuracy of the proposed method is higher compared to traditional linear dynamic estimation. Mainly because of the linear dynamic state estimation accuracy greatly affected by forecasting state, the forecast accuracy is poor when sudden load change state take place, affecting the estimation accuracy of the dynamic state estimation. This algorithm overcomes the fault of traditional linear dynamic state estimation influenced by the forecasting state.

Conclusions

The new state estimation algorithm of this paper has fast computing speed characteristics , and realizes the full utilization of the massive PMU data, this algorithm has higher calculation accuracy in the special circumstances of load suddenly changes, ; It makes the continuous analysis of the power system static analysis.

Keywords: AHP, judgment matrix, evaluation for line selection device, weight vector.

Abstract: The evaluation of small current grounding line selection device plays an important guiding part in fault diagnosis and device promotion. But the current methods focus on the evaluation of individual indicator and can not form systematic evaluation of the programs.This paper firstly makes use of AHP method to evaluate small current grounding line selection device, and establishes the evaluation system of small current grounding line selection device. During the weight solution process, this paper uses three scale method to determine the comprehensive weight of individual indicator, and achieves a combination of expertise and quantitative, qualitative assessment of the results. The practical case analysis of small current grounding line selection device proves the validity and practicability of this method, which is of great theoretical and practical significance.

Introduction

At present, the operating mode of ungrounded or resonant grounding is usually used in 6~35kv medium and low voltage distribution network in China[1-2], which is also known as small current grounding. Single-phase ground fault is one of the common faults in small current grounding system. Due to small fault current, unstable arc and other factors, line selection of grounding fault is difficult, especially for resonant ground running mode, line selection problem has not been solved well.

With the development of the reliability and automation level of the distribution network, we urgently need to improve accuracy and reliability of the automation line selection technology and the corresponding automatic line selection device. Traditional evaluation of small current grounding line selection device is often focused on a single indicator, such as the accuracy of fault line selection, the economy, the applicability of the device. These indexes can evaluate the performance of small current grounding device from different sides and different levels, but lack the overall evaluation and do not have a strong guiding role in small current grounding line selection. So we require a systematic, scientific assessment method.

This paper presents a systematic method that can quantitatively assess the small current grounding line selection device overall—evaluation system of small current grounding line selection device. This method, which is based on the analytic hierarchy process (AHP) [2-3], can evaluate the comprehensive index of small current grounding line selection device, analyze small current grounding fault more scientifically and more effectively, and guide the development of small current grounding line selection device.

The basic idea of analytic hierarchy process

AHP is a multi-scheme or multi-objective decision-making method which does a quantitative analysis of non-quantitative incident and an objective analysis of the subjective judgment in the decision-making process. The method combines quantitative analysis with qualitative analysis, and judges the relative important degree of each measure by the experience of policy makers. It divides the elements that are closely related to decision into different levels, such as target, criteria, scheme, then on this basis, we can analyze it qualitatively and quantitatively.

First of all, the thought of AHP is that: the problems are broken into different constituent elements depending on the characters and requirements of the problem, and according to the

correlation between factors' influence and subordinately relations, factors are gathered in different chromatography. Secondly, by introducing measurement theory, people's judgment is quantified with a relative scale, and the judgment matrix is established layer by layer [4], then the weight of the judge matrix is solved. Finally, the comprehensive weight of the scheme is calculated. The steps of comprehensive evaluation based on AHP include:

(1)Establish the hierarchical structure model;
(2)Construct judgment matrix;
(3)Solve the weight of judgment matrix;
(4)Hierarchical ranking and consistency check;
(5)Calculate the comprehensive weight and rank;

Establish comprehensive evaluation system of small current grounding line selection device

The assessment system flow chart of the small current grounding line selection device is shown in Fig.1.

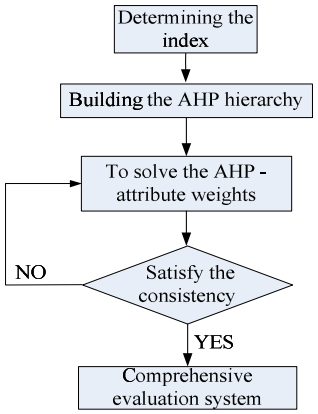

Fig.1 Assessment system flow chart of the small current grounding line selection device

The comprehensive assessment of the small current grounding line selection device is based on the scientific theory of systematic analysis, results of objective and quantitative are given according to the requirements of comprehensive, reasonable and rigorous, This paper establishes the comprehensive index evaluation system of small current grounding line selection device, the evaluation process includes the following four parts:

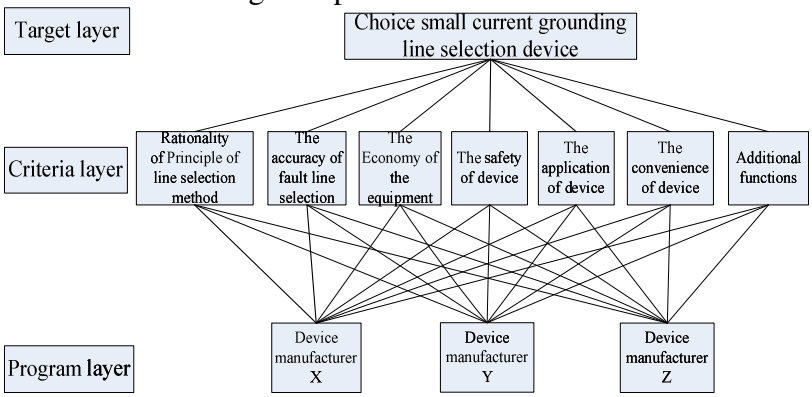

Fig.2 Hierarchy chart of small current grounding line selection device evaluation system

1）Establish a hierarchy: AHP is the key technology to establish the evaluation system when analyzing complex problems in the evaluation. Breaking down complex problem by establishing a clear hierarchy is its key. This paper uses the basic idea of analytic hierarchy process to propose the evaluation system of the small current grounding line selection device of Tianjin Power Grid by combining the actual situation in the area. Its hierarchical structure diagram is shown in Fig. 2.

2）Analysis, calculation and evaluation of single index: In the evaluation system of the small current grounding line selection device of Tianjin Power Grid, many factors need to be considered during the calculation and evaluation of each individual index, such as the determination of index evaluation standard, each index score standard， as well as the weight of single index. Among them, the evaluation standard is mainly based on the regulations of relevant guides and experts experience. Determining the score according to expert advice. The weight of single index is determined by feature vector of the judgment matrix .

3）Comprehensive score method: The score of single index reflects the specific situation of the small current grounding line selection device from different sides, but not enough to explain the overall situation. Therefore, we need to use the AHP method to calculate layer by layer until the comprehensive score of the line selection device is calculated. The calculation equation is:

$$W^{(3)} = \sum_{j=1}^{n=7} w_j^{(3)} w_j^{(2)} \tag{1}$$

In Eq.1, $W^{(3)}$indicates the score of the criteria layer to target layer in the hierarchy, the greater $W^{(3)}$ is the better the device is. n expresses the number of attribute j in the program layer. $w_j^{(3)}$ indicates the score of the program layer to criteria layer in the hierarchy. $w_j^{(2)}$ expresses the weight of criteria layer's attribute j to target layer.

4）Analysis of problems: This study proposes the comprehensive index evaluation system of small current grounding line selection device, the comprehensive analysis method combines the part with the whole. In the single index calculation process, whether there are any problems is automatically recognized by evaluating data, and the details of the existing problems are recorded. While the analytic hierarchy process (AHP) is used to calculate the comprehensive score, the existing problems in the line selection device are hierarchically counted, and the seriousness of problems is sorted. This provides a theoretical basis for the supplement and improvement of line selection device.

The example analysis

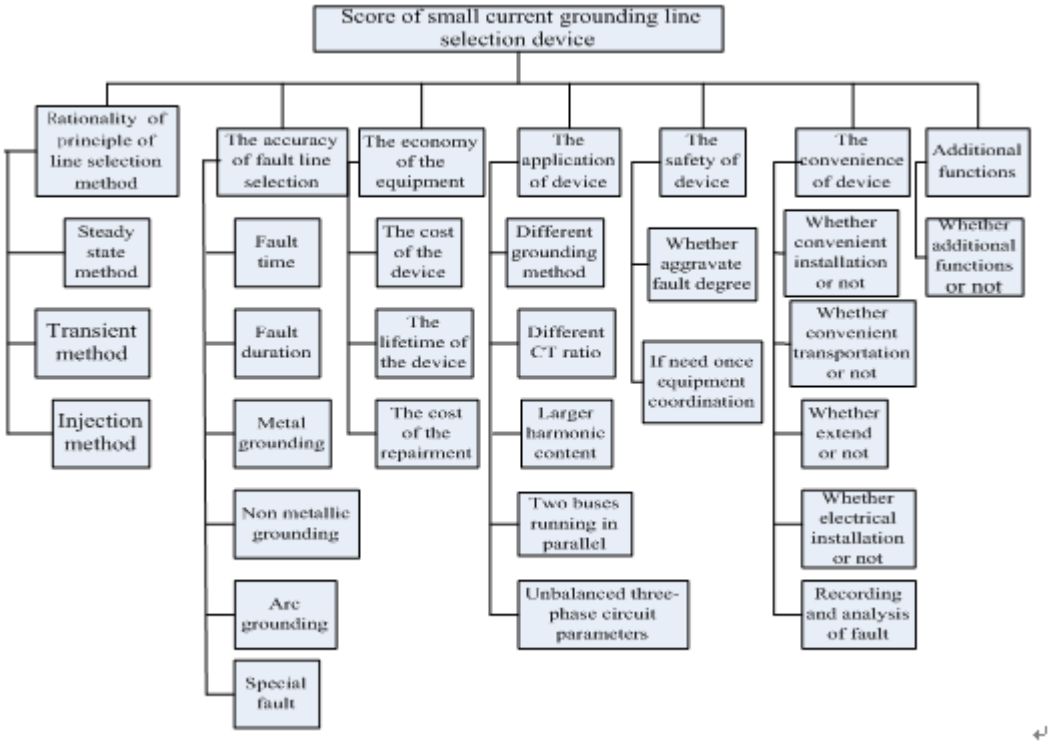

Fig.3 Small current grounding line selection device evaluation system

This paper uses the analytic hierarchy process to analyze the instance of solving weight value of each index. First of all, the process of solving the weight of the first layer is illustrated. Indicators of the layer include:c_1-rationality of principle of line selection method; c_2-the accuracy of fault line

selection; c_3-the economy of the equipment; c_4-the application of device; c_5-the safety of device; c_6-the convenience of device; c_7-additional functions[5]. As shown in the Fig. 3。

(1)Establish comparative matrix

According to the need of line selection, we can make the relative importance by combining with data analysis and expert opinion. In view of the seven level indicators, comparison matrix is constructed by using three scale method:

$$A_1=(a_{ij})=\begin{bmatrix} & c_1 & c_2 & c_3 & c_4 & c_5 & c_6 & c_7 \\ c_1 & 1 & 0 & 0 & 0 & 0 & 2 & 2 \\ c_2 & 2 & 1 & 2 & 2 & 2 & 2 & 2 \\ c_3 & 2 & 0 & 1 & 1 & 1 & 2 & 2 \\ c_4 & 2 & 0 & 1 & 1 & 1 & 2 & 2 \\ c_5 & 2 & 0 & 1 & 1 & 1 & 2 & 2 \\ c_6 & 0 & 0 & 0 & 0 & 0 & 1 & 2 \\ c_7 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

(2)Construct the judgment matrix by using pole ratio method[6].

$$A=(a_{ij})=\begin{bmatrix} & c_1 & c_2 & c_3 & c_4 & c_5 & c_6 & c_7 \\ c_1 & 1 & 0.4411 & 0.6044 & 0.6044 & 0.6044 & 1.5490 & 3.9698 \\ c_2 & 2.2671 & 1 & 1.3703 & 1.3703 & 1.3703 & 3.5118 & 9 \\ c_3 & 1.6545 & 0.7298 & 1 & 1 & 1 & 2.5628 & 6.5680 \\ c_4 & 1.6545 & 0.7298 & 1 & 1 & 1 & 2.5628 & 6.5680 \\ c_5 & 1.6545 & 0.7298 & 1 & 1 & 1 & 2.5628 & 6.5680 \\ c_6 & 0.6456 & 0.2848 & 0.3902 & 0.3902 & 0.3902 & 1 & 2.5628 \\ c_7 & 0.2519 & 0.1111 & 0.1523 & 0.1523 & 0.1523 & 0.3902 & 1 \end{bmatrix}$$

(3)Compute the weight vector and consistency check

1) Solve the eigenvector of judgment matrix from criteria layer to target layer：

$$\begin{aligned} w^{(2)} &= (w_1^{(2)}, w_2^{(2)}, w_3^{(2)}, w_4^{(2)}, w_5^{(2)}, w_6^{(2)}, w_7^{(2)}) \\ &= (0.1096, 0.2484, 0.1813, 0.1813, 0.1813, 0.0707, 0.0276) \end{aligned}$$

2) Solve the maximum eigenvalue of judgment matrix：

$$\lambda_{\max} = 7.00016$$

The consistency check of criteria layer to target layer can be calculated:

$$CI = \frac{(\lambda_{\max} - n)}{(n-1)} = \frac{0.00016}{6} = 0.000027 \tag{2}$$

Random consistency index:

$$RI = 1.32$$

The consistency ratio:

$$CR = \frac{CI}{RI} = \frac{0.000027}{1.32} = 0.0000202 < 0.1 \tag{3}$$

Thus, the non-consistence of the judgment matrix is within the permissible range. We can use the eigenvector as weight:

$$\begin{aligned} w^{(2)} &= (w_1^{(2)}, w_2^{(2)}, w_3^{(2)}, w_4^{(2)}, w_5^{(2)}, w_6^{(2)}, w_7^{(2)}) \\ &= (0.1096, 0.2484, 0.1813, 0.1813, 0.1813, 0.0707, 0.0276) \end{aligned}$$

Table 1 The weight vector and the consistency check of judgment matrix B1to B7

	B1	B2	B3	B4	B5	B6	B7
	0.637	0.540	0.136	0.279	0.467	0.547	0.122
$w_k^{(3)}$	0.105	0.297	0.625	0.649	0.067	0.345	0.320
	0.258	0.163	0.238	0.072	0.467	0.109	0.558
$\lambda_{\max}$	3.039	3.009	3.018	3.065	3.00	3.054	3.018
CI_K	0.019	0.005	0.009	0.032	0.00	0.027	0.009

According to the calculation method above, the weight vector and the consistency test of judgment matrix B1to B7 from scheme layer to criteria layer are calculated.

The table shows $RI = 0.58$, after calculation of B1- B7 and get $CR<0.1$, so all records satisfy the consistency test. Now we get weight vector of scheme layer to criteria layer:

$$W^{(3)} = (W_1^{(3)}, W_2^{(3)}, W_3^{(3)}, W_4^{(3)}, W_5^{(3)}, W_6^{(3)}, W_7^{(3)})$$

$$= \begin{bmatrix} 0.6370 & 0.5396 & 0.1365 & 0.2790 & 0.4667 & 0.5469 & 0.1220 \\ 0.1047 & 0.2970 & 0.6250 & 0.6491 & 0.0667 & 0.3445 & 0.3196 \\ 0.2583 & 0.1634 & 0.2385 & 0.0719 & 0.4667 & 0.1085 & 0.5584 \end{bmatrix}$$

So the weight vector of the scheme layer to the target layer is calculated:

$$W^{(3)} = W^{(3)} \times W^{(2)} = (0.4058, 0.3615, 0.2329)^T \quad (4)$$

The consistency ratio of total hierarchical order is:

$$CR = \frac{a_1 CI_1 + a_2 CI_2 + \ldots + a_7 CI_7}{a_1 RI_1 + a_2 RI_2 + \ldots + a_7 RI_7} = \frac{0.013}{0.58} = 0.02 < 0.1 \quad (5)$$

Therefore the total hierarchical order meets the consistency test. Then the weight of X, Y, Z device manufacturer is respectively 0.4058, 0.3615, and 0.2329. Device manufacturer X gets the highest weight, so the device manufacturer X is the best choice.

Conclusion

In this paper, the analytic hierarchy process (AHP) is used in the assessment of the small current grounding line selection device. And the structure detection and performance evaluation of the small current grounding line selection device in Tianjin Power Grid is set up. All attributes of evaluation index of line selection device are reflected comprehensively. In the process of solving weights, judgment matrix formed in this paper is different from the general judgment matrix which uses1-9 scale formation, the consistency and rate of convergence etc are more practical. The degree of the importance of relationship between two indexes is considered completely, and the consistency check is verified in detail. This evaluation system can be well applied in detection and performance assessment of the small current grounding line selection device in Tianjin Power Grid, and this system is of great theoretical and practical significance.

Keywords: offshore platforms, renewable resource, volatility of CO_2 emission price, low-carbon effect, latin hypercube sampling, optimal sizing of distributed generation.

Abstract. This paper introduces renewable energy to ensure offshore platforms as a stand-alone microgrid operate reliably economically in low-carbon environment, considering volatility of CO_2 emission price. A probability distribution model and economic model containing investment cost and low-carbon effect is established respectively, using latin hypercube sampling(LHS), meanwhile, the stochastic power is adopted to judge whether the built planning model can meet power flow constraint, Monte Carlo method is used to simulate characteristics of distributed generation(DG), a probabilistic power flow is made to illustrate reliability index. The model takes the types, sites and sizes of DG as decision variables, economy and environment as the objective function, particle swarm algorithm is proposed to solve the multi-objective optimization problem .A case study based on data from offshore oilfield is presented to verify the advantages of the improved optimal sizing method.

Introduction

Recently, most of the countries all over the world have paid great attention to CO2 emission. To meet its obligations to reduce CO2 concentrations under the Kyoto Protocol, the European Union(EU) established the first cap-and-trade system for CO2 emissions in the world starting in 2005.Our country proposes the target to save energy and reduce pollutant emission[1].

DG has conformed to the development of low-carbon in recent years. Microgrid technology provides a flexible and efficient platform for DGs and renewable energy .

At present, domestic and foreign scholars do researchs about DGs. In[2] bacterial foraging algorithm is proposed to solve the optimal sizing problem of hybrid solar-wind DG in microgrid. An optimal configuration model of microgrid power supply based on maximizing net benefits is proposed in[3]. Mohamed F, Koivo H present a generalized formulation to determine the optimal operating strategy and cost optimization scheme as well as the reduction of the emissions for a MicroGrid [4]. When solving the problem about distributed power optimization of microgrid ,economy, reliability, environment is all considered in works [2-4]. However, low-carbon model, carbon price fluctuations and other uncertainties about carbon emissions, which brings new challenges to optimize the allocation of microgrid, works above do not fully consider.

This paper firstly takes carbon price fluctuations into optimal sizing of distributed generation . In order to improve the effectiveness of sampling for wind speed and solar radiation, LHS is introduced innovatively.

Power Generation Modeling

Wind Turbine Generator (WG). Based on a large number of historical data ,the wind speed obeys two-parameter Weibull distribution approximately, the probability density function as fomula(1)

$$\varphi(v) = \frac{k}{c}(\frac{v}{c})^{k-1} e^{-(\frac{v}{c})^k} \tag{1}$$

Where v is wind speed, m/s. k is the shape parameter, k =1.8~2.3 in general; c is the scale parameter which reflects the average wind speed, distribution probability density function shows as fomula(2)

$$F(V) = p(v \le V) = 1 - \exp[-(\frac{v}{c})] \tag{2}$$

Where range of $F(V)$ is [0,1]，dividing it into N parts， generating random number from 0 to1,then convert it to random numbers as equation (3)

$$U_n = \frac{U}{N} + (n-1)/N \tag{3}$$

Where, n=1,2…N， U is a random number in the range (0,1), U_n is a random number in the n-th interval.

Use inverse function to convert these random numbers to random variable v, then latin hypercube sampling for the velocity is completed. Relationship about wind turbines between power output and actual wind speed can refer to work[5].

Photovoltaic power generation. Power output of photovoltaic varies as solar radiation conditions changes. First, sampling for solar radiation and skies coefficient, then simulating power output of photovoltaic[6]. Fomula is shown as

$$P_{PV} = \eta S I_\beta \tag{4}$$

Where, S is size of battery; I_β is solar radiation hourly accepted by PV panels in per unit area ; η is conversion efficiency of battery at the moment of t.

Gas Turbine Generator(GS). Adopting dual fuel generator set is a characteristic of power station at offshore platform, where uses oil associated gas as main fuel. Characteristics of energy consumption-power described as fomula(5)

$$V_f = \sum_{i=1}^{N} K_f E \tag{5}$$

Where, V_f is natural gas consumed per unit time, m^3. K_f is coefficient of natural gas.

Battery Storage (BS) and Super Capacitor(SC) Modeling. Cycle life of battery is short, power density is low, charging time is long, while volume of super capacitor is small, weight is light, power density is high, cycle life is long, therefore,BS and SC is adopted as hybrid energy storage.Models of BS and SC refer to work[7].

Objective Function

System Economic Model .Under low-carbon economy, it aims at achieving minimum economic cost annually, realizing new energy saving and emission reduction significantly, meanwhile ensuring system operate reliabily.

Initial investment cost, operation and maintenance costs, low-carbon effect, penalties and subsidies expenses are included in comprehensive economic cost, which is made as the objective function, formulated as(6)

$$E = E_{az} + E_{om} + E_{fuel} + E_{co_2} + E_{cf} + E_{sub} \tag{6}$$

Initial Investment Cost

$$E_{az} = \sum_{i=1}^{p} \frac{r(1+r)^{n_i}}{(1+r)^{n_i} - 1} \cdot C_{gi} \tag{7}$$

Where, E_{az} is equivalent cost of equipment investment every year, C_{gi} is installation costs of the i-th power, n_i is the life of the i-th power, r is interest rate.

Operation and Maintenance Costs

$$E_{om} = \sum_{i=1}^{p} K_{om_i} P_{gi} \tag{8}$$

Where, E_{om} is annual operating cost, K_{omi} is scaling factor between maintenance costs and capacity of the i-th power, RMB/kW.

Fuel costs
$$E_{fuel} = c(\sum_{i=1}^{p} K_{fi} E_i - E_{in}) \tag{9}$$

Where, E_i is power generation of the i-th gas turbine , K_f is fuel provided to the gas turbine（m^2/kWh ）,E_{in} is the total amount of natural gas that platform can be supplied, c is fuel price.

Low-carbon effect.Under emission trading scheme, CO2 emission is strictly restricted, CO2 emission index can participate in the market as a commodity trading, thus, influence brought by CO2 emission price can not be ignored. Based on historic date , the CO2 emission price is approximately by a Weibull PDF which can be expressed by (10) and whose curve is shown in Fig.1

$$f(x) = \frac{2.78}{19.56}(\frac{x}{19.56})^{1.78} e^{-(x/19.56)^{2.78}} \tag{10}$$

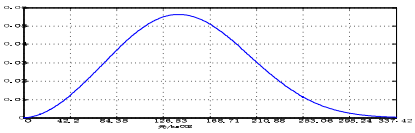

Fig.1 Weibull PDF modeling CO_2 emission price

From the environmental point of view, in order to achieve energy conservation, development and utilization of new energy sources and energy storage charging is promoted, carbon price is calculated step by step from formula (11) to (13)

$$X_i = K_{co_2 i} \cdot V_f - A_{WPC} - A_i \tag{11}$$

$$A_{WPC} = \beta_{CO_2} \sum_{t=1}^{8760} \sum_{i=1}^{m} N_i P_i \tag{12}$$

$$E_{co_2} = \sum_{i=1}^{N_g} \pi_{co_2} \cdot X_i + E_{PV} \tag{13}$$

Where, X_i is emissions of i-th generator per hour(tCO_2/h) , A_i is carbon emissions allowed every generator per hour, A_{WPC} is reduction of CO_2 emission due to renewable energy generating and storage charging . K_{CO2}i is CO_2 emission coefficients of natural gas. π_{co_2} is emission price, N_g is generator number, E_{pv} is costs of photovoltaic power generation.

In the model above, generators can sell their emission allowance surpluses or buy the shortage in allowance from the emission trading market.

Penalties and subsidies expenses.In order to ensure power supply reliably and avoid energy waste so as to optimize configuration, penalties and subsidies expenses is introduced as fomula(14)

$$E_{cf} = k_{pl} E_{lp} + k_{pw} E_{pw} \tag{14}$$

Where, k_{pl} is penalty coefficient due to power storage, E_{lp} is power shortage each year, k_{pw} is penalty coefficient due to energy waste**,** E_{pw} is electricity surplus each year.

Power subsidy.To encourage the development and utilization of renewable energy, the government gives subsidies to support .

$$E_{sub} = c_{sub} \sum_{t=1}^{8760} \sum_{i=1}^{m} N_i P_i \tag{15}$$

Where, C_{sub} is subsidy price, N is number of installations of turbine and solar panels, P is power supply of renewable energy.

Equality constraints.The main consideration is the balance of power system as fomula(16)

$$\begin{cases} \sum P_g = \sum P_l + \sum P_{loss} \\ \sum Q_g = \sum Q_l + \sum Q_{loss} \end{cases} \tag{16}$$

Inequality constraints
$$\mathrm{SOC}_{\min} \le \mathrm{SOC} \le \mathrm{SOC}_{\max} \tag{17}$$

Where, SOC is charge state of battery, SOC_{min}, SOC_{max} is lower and upper limits, which is usually set at 20%, 100%..

Voltage constraints
$$v_{i\min} < v_i < v_{i\max} \tag{18}$$

Where v_{imax}, v_{imin} is upper and lower voltage at Voltage node j.
Reliability of system.In this paper, load power shortage rate (loss of power supply probability, LPSP) characterized system reliability. To ensure system reliability, load power shortage rate is limited within a certain range[8] .

$$lpsp = \frac{\sum_{i=1}^{8760}(P_{li} - (P_{WTi} + P_{PVi} + P_{c1i} + P_{c2i})}{\sum_{i=1}^{8760} P_{li}} \le lpsp_{\max} \tag{19}$$

Where, P_{li}, P_{WTi}, P_{PVi}, P_{c1i}, P_{c2}i is the power of load, wind turbine, photovoltaics, batteries, capacitors.

Solution of Optimization Model

Option 1. In order to avoid oil associated gas waste, diesel-powered generators are used at first, when the oil associated gas supply is not enough, wind turbine, and photovoltaic cells are put into operation, if power generation exceeds or lacks, energy storage devices play a role of peak load shifting.
Option 2 In order to improve the utilization of renewable energy, wind turbines and photovoltaic cells are put into use firstly, diesel generators secondly, scheduling strategy energy storage is consistent with option 1.

Optimal allocation based on particle swarm optimization algorithm, PSO

PSO is adopted to solve the model of optimal allocation. Procedure is followed as below
1)Select the initial particle. Roughly determine the feasible region, generate a random initial population:
$[n_{PV}, n_{WG}, n_{bat}, n_{sc}, n_{WG}, n_{dis}]$.
2)Dealing with constraints.Using penalty function to handle particles that not meeting the constraints in iterative process, new objective function derived from orginal objective function and penalty terms. This article applys rate of node voltages off-limit δ as penalty term , fomula as (20), Process shows as Fig.2

$$f = \max E + K\sum_{i=1}^{m}\delta_i \tag{20}$$

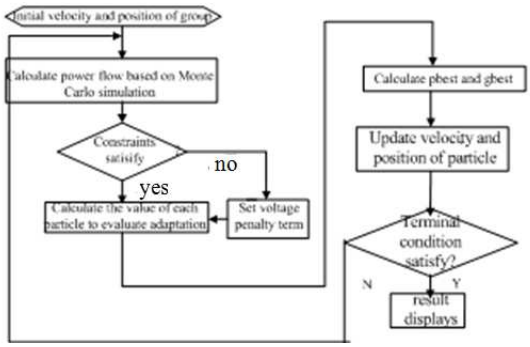

Fig.2Flow chart of sizing DG based on PSO algorithm

Results and discussion

Fig.3 is a simplified diagram of offshore oilfield, which is a 14-node system. The field includes five power centers, 1,2,3,12,13. Distributed generations locate at platform 2, 3, 12, 13.

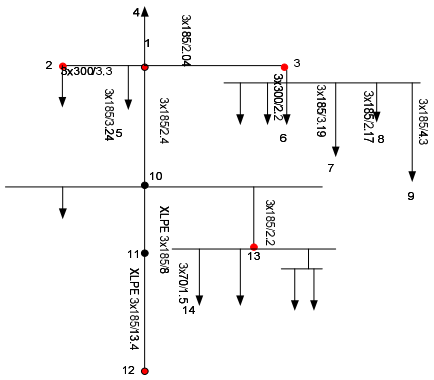

Fig.3 Diagram of offshore platforms microgrid system

Select typical months of offshore platforms microgrid to simulate weather condition, results of simulation show as Fig.5 and Fig.6.

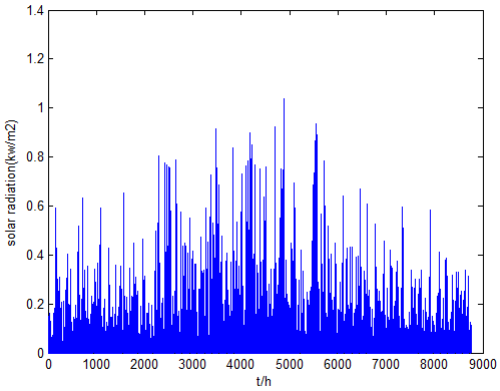

Fig.5 Simulation of annual solar radiation

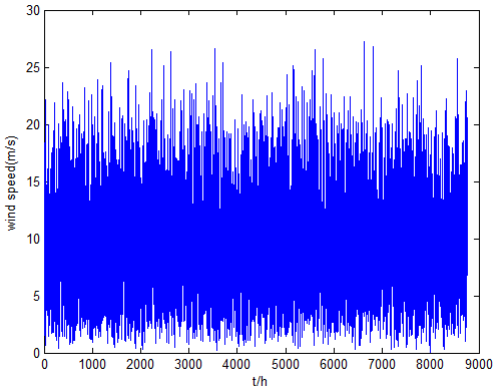

Fig.6 Simulation of annual wind velocity at the location of Microgrid

Results of optimal siting and sizing of distributed generation shows as Tab.1 and Tab.2.

Tab.1 Planning of schemes

DG types	option1	option2
PV	448,408,817,336	2063,736,383,2513
MT	8,6,1,4	10,43,18,25
GS	7	1
BS	218	1332
SC	176	275

Tab.2 Cost of planning schemes

option	Investment	Low-carbon effect	Punishment cost	Total cost
Option1	178369	9964	288	168693
Option2	247584	28645	2646	221585

Results above shows that initial investments and operating costs of renewable energy are higher than conventional units, great benefits bought by low-carbon can not be ignored, thus renewable energy generation has great potential, energy storage contributes to increase capacity of renewable accepted by grid. Further study will be needed.

Conclusion

In this study, considering carbon price volatility agrees to actuality, renewable energy can realize energy saving and emission reduction, PSO algorithm can obtain optimal solution to minimize the total cost .

Keywords: second-order Kuramoto model, frequency synchronization, power system, transient stability, network topology, region of attraction

Abstract. Based on frequency synchronization theory of the second-order non-uniform Kuramoto model, a novel approach for power system transient stability analysis is put forward by establishing the correspondence between the classic power system model and the second-order non-uniform Kuramoto model. This method relates network parameters with the region of attraction of the disturbed system's stable equilibrium and thus the transient stability information of the disturbed system can be obtained by comparing the initial configuration with trapping region of the stable equilibrium of the disturbance-canceling system. The application of our approach to single machine infinite bus system shows that this method features a fast computation speed. It can determine the transient stability of the system when a certain perturbation acts on as well as offer the stability margin of the disturbed system, which is of great importance for practical use.

Introduction

Power system stability has been considered as a critical issue for secure system operation since 1920s. As one of the common forms in power system stability problems, transient stability never fails to draw the academic's and industry's attention [1]. Generally speaking, approaches for transient stability analysis essentially fall into such categories of time-domain simulation methods and direct methods which present advantages but also disadvantages [2]. As power grids integrate an increasing number of highly stochastic renewable energy sources, the transient stability of power systems turns to be more severe than anytime before. Therefore, an open problem is the quest for simple and practical criteria to investigate the transient stability of a disturbed system.

It is recognized that the second order non-uniform Kuramoto model is strikingly similar with the classic power system model employed in transient stability, and more importantly, the frequency synchronization in the Kuramoto model exactly equals to the transient stability in the power system [3,4]. Recently, Xue, one of the authors of this paper made a breakthrough in studying the frequency synchronization of the second-order non-uniform Kuramoto model. Using Lojasiewicz gradient inequality, Xue et al. studied the potential function of the coupled oscillator, and established the relation between network topological connection strength and trapping region of the system's synchronized solution, based on which, the synchronized solution's attraction domain can be conveniently estimated by network parameters (*cf. theorem 2.1 in [5]*), which open up a new way for investigating the region of attraction of the stable equilibrium with direct methods of power system transient stability analysis. This paper, applying the latest frequency synchronization theory of second-order non-uniform Kuramoto model to power system, provides a novel perspective for the research of transient stability.

Classic power system model and second-order non-uniform Kuramoto model

Classic power system model. Let $\delta_i = \delta_i(t)$ be the rotator angle of generator i. M_i, D_i, and P_{mi} stand for the inertia constant, damping constant and input active power of the ith generator separately, G_{ii} and $|Y_{ij}|$ are the self-conductance of the ith generator and modulus of mutual admittance between the ith and jth generators in the reduced network, and $|E_i|$, $|E_j|$ represent the magnitudes of voltage behind transient reactance of the ith and jth generators respectively. Then $P_i = P_{mi} - |E_i|^2 G_{ii}$ donates the injection active power of generator i and $P_{\max ij} = |E_i||E_j||Y_{ij}|$ depicts the maximum active power transferred between generators i and j. Under the common assumption of network-reduced model of power system, ignoring the transfer conductance, the swing equation of each generator for a disturbed power system containing n generators can be expressed as [6]:

$$M_i\ddot{\delta}_i + D_i\dot{\delta}_i = P_i + \sum_{j=1}^{n} P_{\max ij}\sin(\delta_j - \delta_i),\quad i = 1,2,\ldots,n \tag{1}$$

All parameters are given in per unit system, except for M_i, D_i which are given in s^2/rad and s/rad.

Second-order non-uniform Kuramoto model. Let $\theta_i = \theta_i(t)$ be the phase of the ith oscillator in the coupled nonlinear dynamic system, the second-order non-uniform Kuramoto model read as [5]:

$$m_i\ddot{\theta}_i + d_i\dot{\theta}_i = \Omega_i + \sum_{j=1}^{n} a_{ij}\sin(\theta_j - \theta_i),\quad i = 1,2,\ldots,n \tag{2}$$

Where m_i, d_i and Ω_i represent the inertia constant, damping constant and natural frequency of the ith oscillator respectively, and a_{ij} describes the interaction between the ith and jth oscillator.

Second-order non-uniform Kuramoto model based criteria for transient stability investigating

Under the assumption that the ratios of the damping constants to inertia constants of every generator in the system are identical ($\alpha_1 = \alpha_2 = \cdots = \alpha_i$), power system (1) turns into a homogeneous damped system. Let $\boldsymbol{\delta}(t) = (\delta_1(t),\ldots,\delta_n(t))$ and $\boldsymbol{\omega}(t) = (\omega_1(t),\ldots,\omega_n(t))$ be the ensemble of rotator angles and rotator angular velocities of all the generators respectively; while $\boldsymbol{\delta_0} = \boldsymbol{\delta}(0)$ and $\boldsymbol{\omega_0} = \boldsymbol{\omega}(0)$ donate the prescribed initial data of $\boldsymbol{\delta}(t)$ and $\boldsymbol{\omega}(t)$.

Define $\delta_m = \min\limits_{1\le i\le n}\delta_i$, $\delta_M = \max\limits_{1\le i\le n}\delta_i$, $D(\delta) = \delta_M - \delta_m$, $\dot{D}(\delta_0) = \dfrac{d}{dt}D(\delta(t))|_{t=0^+}$,

$$C(\delta_0,\omega_0,\alpha) = \max\left\{D(\delta_0), D(\delta_0) + \frac{1}{\alpha}\dot{D}(\delta_0)\right\},\ D(\overline{P}) = \max_{1\le i\le n}\{P_i/M_i\} - \min_{1\le i\le n}\{P_i/M_i\}$$

$$L = \min_{1\le i\ne j\le n}\left\{(\frac{1}{M_i} + \frac{1}{M_j})P_{\max ij} + \sum_{k\ne i,j}\min\{\frac{P_{\max ik}}{M_i}, \frac{P_{\max jk}}{M_j}\}\right\}$$

In the context of transient stability analysis, the frequency synchronization theory of second-order non-uniform Kuramoto model discussed in [5] (*cf. theorem 2.1*) can be adapted as following:

Lemma 1. Assuming that upon the removal of disturbance, the parameters of system (1) satisfy

$$L > D(\overline{P})/\sin D_c \tag{3}$$

Where D_c is determined by $\frac{\sqrt{2D(\overline{P})}}{\alpha}\frac{\sqrt{D_c-\tan(D_c/2)}}{\pi-2D_c}=1,\ \ D_c\in(0,\pi/2)$ (4)

If the initial configurations (the state variables' values at the instant of disturbance removal) meet

$$0<C(\delta_0,\omega_0,\alpha)<\pi-K \tag{5}$$

With K being determined by $\sin K=D(\overline{P})/L,\ \ K\in(0,D_c)$ (6)

Then, power system (1) can keep transient stability after disturbance canceling.

Example

The single machine infinite bus (SMIB) system is shown in Fig. 1. Circuit CCT 2 suffered a solid three-phase fault at point F which was cleared after the isolation of CCT 2.

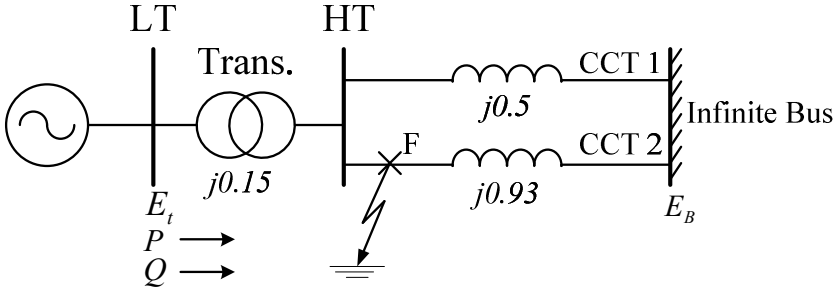

Fig. 1 SMIB system

Parameters of this SMIB system are in per unit on 2220MVA, 24kV base and the system's rated frequency is 60Hz.Other parameters of this SMIB system are listed in Table 1 bellow:

Table 1 SMIB system's parameters

parameter	P	Q	E_t	E_B	X'_d	M [s^2/rad]
value	0.9	0.436	1.0∠28.34°	0.90081∠0°	0.3	0.01857

Table 2 shows requisite parameters for Lemma 1 to determine the SMIB system's transient stability.

Table 2 Parameters of fault-cleared network

parameter	value	remark
L	59.3703	$D_c\in(0,\pi/2)$
$D(\overline{P})$	48.4703	$L>D(\overline{P})/\sin D_c=53.4304$
D_c	1.1365	Eq. 3 and Eq. 4 are satisfied
K	0.9552	region of attraction of stable equilibrium $\pi-K=2.1864$

The SMIB system's state variables at the moment of fault removal are obtained by solving the SMIB system's state equations during the time interval between fault-occurring and fault-clearing. Different fault clearing times t_c correspond to different parameter initial configurations $C(\delta_0,\omega_0,\alpha)$, which is illustrated in Table 3.

Table 3 Initial configurations of the fault-cleared network at different fault clearing time

initial configuration	Fault clearing time t_c [s]		critical fault clearing time obtained by Lemma 1[s]
	0.240	0.241	
$C(\delta_0,\omega_0,\alpha)$	2.1832	2.1864	0.240

To verify the accuracy of the critical fault clearing time obtained via Lemma 1, a time-domain simulation of the SMIB system was conducted in a four-second-duration from the moment of 1 second to 5 second with a step of 0.001s and then we got the critical fault clearing time as $t_{cr} = 0.267$ s. Swing curves of the generator rotor angle are shown in Fig. 3.

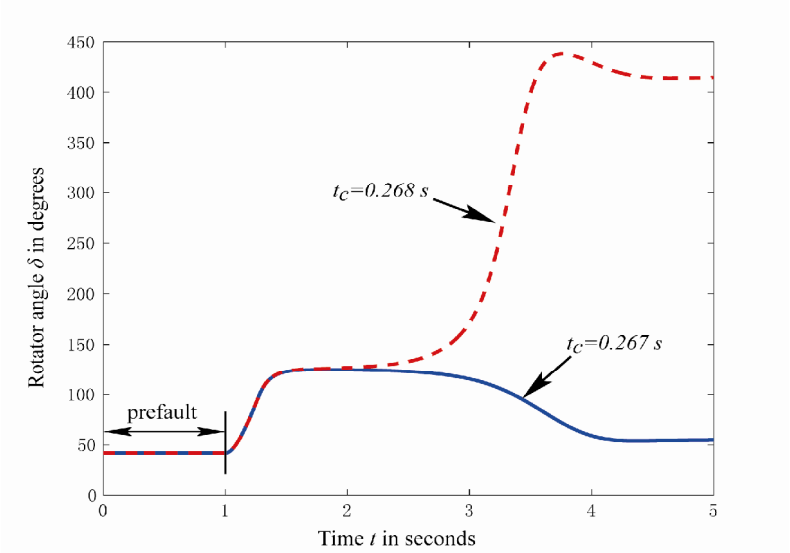

Fig. 3 Swing curves of the generator rotator angle at different fault clearing time

Contrasting the critical fault clearing time obtained by Lemma 1 to that solved by time-domain simulation method, it can be seen that Lemma 1 led to a conservative but acceptable result, it is a sufficient condition to determine the system's transient stability.

Conclusions

In this paper, we correlate the classic power system model to the second-order non-uniform Kuramoto model and then present a Kuramoto model based transient stability analysis methodology. Example given in the paper demonstrates the specific calculation procedure and computational accuracy of this method. Relative to traditional power system transient stability analysis approaches, our method reflects the transient stability of the system from the connection strength of the network's topological graph, provides a simple algebraic operation to estimate trapping region of the disturbed system's stable equilibrium, and exhibits the transient stability scenarios of the post-fault system by comparing initial configuration with the attraction domain. Our technical approach characterized by high computational efficiency which is beneficial to the guidance of power systems' on-line operation.

Keywords: SFLA; genetic algorithm; multi-objective optimization; distribution network reconfiguration.

Abstract. The article studies on the application of the shuffled frog leaping algorithm (SFLA) in power distribution network reconfiguration, taking the minimum loss and voltage quality of distribution network as a multi-objective function. The article improves the initial solution generation strategy of traditional genetic algorithm, which ensures the initial solution is feasible solution. Shuffled frog leaping algorithm and genetic algorithms are combined and proposed as shuffled frog leaping genetic algorithm (SFLGA). The algorithm uses the efficient coding strategy based on the basic loop and initial solution generation strategy, improves the calculation efficiency. The algorithm is verified by simulation results from test case on IEEE 33-bus system with distributed generations.

Introduction

Power system contains electricity generation, electricity transmission and electricity distribution [1]. The safe and stable operation of the distribution network will have a direct impact on the users. In China, loss of distribution network accounted for more than 80% of power system loss, further reduce the loss of distribution network is of great potential [2]. Improvement and development of distribution network automation system can produce huge economic and social benefits. Distribution network reconfiguration is an important means to control and run the distribution network [3-5].

There are several algorithms to solve the distribution network reconfiguration problem [6]: traditional mathematical optimization, heuristic algorithms, artificial intelligence algorithm. Among many artificial intelligence algorithms, genetic algorithm stands out and has been widely applied on pattern recognition, adaptive control and combinatorial optimization because of its advantages such as its search strategy and optimization process does not depend on the characteristics of gradient information. But the traditional genetic algorithm appears to produce infeasible solutions and converge to local optimal solution, which means 'premature' problem.

Based on the characteristics of the above algorithms, this article combines the practical problems of distribution network reconfiguration, proposes shuffled frog leaping genetic algorithm. The algorithm is verified by simulation results from test case on IEEE 33-bus system with distributed generations, it's proved feasible and effective.

Multi-objective optimization model for distribution network reconfiguration

Distribution network reconfiguration is a multi-objective optimization problem. Researchers usually often take the minimum loss and voltage quality of distribution network as a multi-objective function.

This article uses sum of line loss to describe the loss of network and uses voltage-balance index to describe the quality of voltage, expressions show as blow:

$$L = \sum_{k=1}^{N_b} R_k (P_k^2 + Q_k^2) / U_k^2 \tag{1}$$

$$V_{bal} = \sum_{k=1}^{N_b} \frac{max[U_i, U_j]}{min[U_i, U_j]} \tag{2}$$

In the above expressions, L is the sum of network loss, N_b is the quantity of lines in the network, V_{bal} is voltage-balance index. This article uses a weighted approach to switch the network configuration into a single objective problem. Define a new variable:

$$C = \omega_1 V_{bal} + \omega_2 L \tag{3}$$

In the above expression, ω_1 and ω_2 are weighting factors of voltage quality and network loss, their sum is 1. In this way, variable C contains two kinds of information.

Distribution network reconfiguration need to meet the following constraints:(1)meet the power flow equations.(2) meet the power flow equations.(3)voltage and current does not exceed the limitation.(4)distribution network can not exist isolated node.(5) distribution network always have a closed loop in construction and a open loop in operation, so the structure of distribution network after reconfiguration must be radiated. Inequality constraints can be added via a penalty function to the objective function. According to the analysis above, we can construct the fitness function F:

$$f = C + \sum_{j=1}^{N_b} \alpha_j (I_j - I_{j\lim})^2 + \sum_{k=1}^{N_b} \beta_k (U_k - U_{k\lim})^2 \tag{4}$$

$$F = 1/f \tag{5}$$

f is objective function, F is fitness function, α_j, β_k are penalty coefficient. $I_{j\lim}, U_{k\lim}$ are limitations of node k.

Theory of SFLGA

SFLA is a metaheuristic evolutionary algorithm proposed by Eusuff and Lansey, it has fast convergence ability and strong ability to jump out of local optima. Genetic algorithm recombinant individuals that have some structural features, to seek out common ground between individuals and approach the optimal solution. This paper combines these two algorithms for solving distribution network reconfiguration.

2.1 Chromosome coding strategy

This paper argues that most of the distribution network breakers are closed, if we take the state of each breaker as a control variable causes that chromosome length is too long, which's unnecessary. Distribution network always have a closed loop in construction and a open loop in operation. Closing all breakers will form several loops in distribution network, and we define the loop as basic

loop when it contains the minimum number of branches. Using the number of basic loop as coding characteristics will improve coding efficiency. As demonstrated in the figure 1, there are five loops in the network, encoding in loops can reduce unnecessary coding and decoding step.

2.2 Frog generation strategy

Previous studies always generate initial individuals by random which have low proportion of feasible solutions. This paper proposes a method to generate the initial individual, which can ensure each individual is a feasible solution.

(1) Ensure that each basic loop has an open breaker.

(2) Loops that have cutting breakers will not cut a second breaker. This rule limits the infeasible solutions.

(3) This paper choose the loop to cut in random sequence, which ensures to take all feasible solutions.

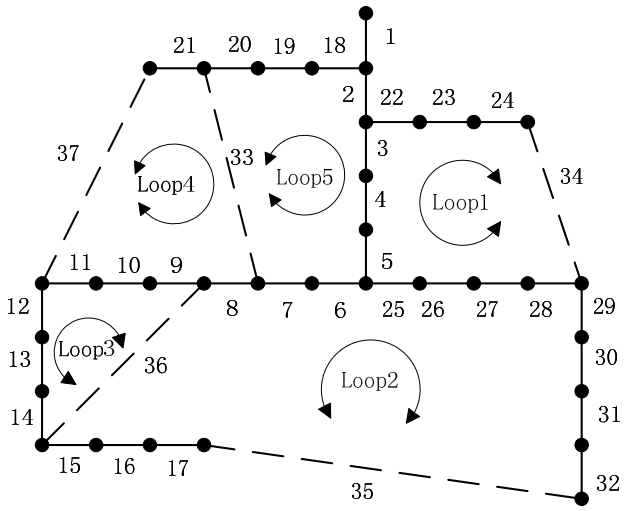

Fig.1 IEEE 33-bus system

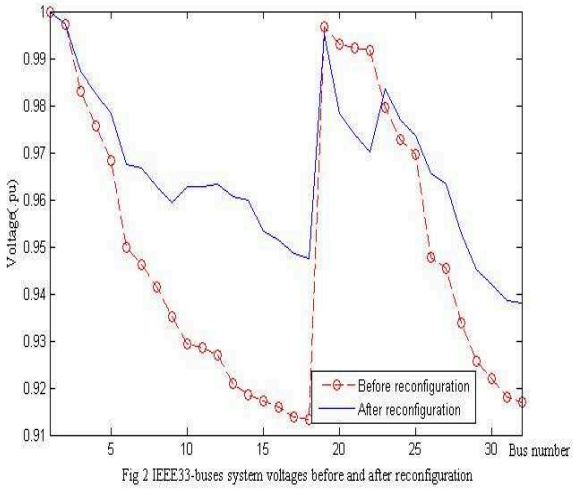

Fig 2 IEEE33-buses system voltages before and after reconfiguration

2.3 Process of SFLGA

SFLGA consists of two parts: the global information exchange and local search. Process of using this algorithm to solve distribution network reconfiguration problem is as follows:

Step 1: Set the initial parameters. The initial number of frogs is F , number of groups is m , global iterations N_g , local iterations N_1 ,crossover and mutation rate P_c and P_m .

Step 2: Produce F frogs as the initial population. Coding strategy and population generation strategy can guarantee that every frog is feasible solution.

Step 3: Calculate the fitness function. Do power flow calculation for each frog, get net loss, voltage quality and then calculate fitness value of each frog.

Step4: Divide the frogs into m groups in the rules below:

$$Y_s = \{X_s + m(h-1), h = 1,2,...,n\} \ (s = 1,2,...,m) \tag{6}$$

Step5: local search. Do local search in every group.

Step6: Mix all of the groups. Merge all frogs and repeat the step4, 5, 6 until the operation reaches the global iterations.

Test case calculation and analysis

This paper use IEEE 33-bus system as test case. This case has 37 branches, 33buses, rated voltage is 12.66kV. Parameters in the algorithm is set as $F=100$, $N_g=50$, $m=10$, $P_c=0.9$ $P_m=0.05$.

Table 1: Reconstruction program

Program	Branches to cut	Loss[kW]	Lowest voltage in system[.pu]
The initial structure	33,34,35,36,37	203.43	0.9128
Reconfigurated structure	34,32,14,9,7	139.35	0.9473

According to the results in Table 1 we can obtain that IEEE 33-buses system has a loss up to 233.43kW with its initial structure, after reconfiguration, system loss reduces to 139,35kW, reduced by 32%. Lowest node voltage has been increased from the initial 0.9128 to 0.9473 ,which is shown in figure 2. The effect of the algorithm is significantly.

Summary

This article combines SFLA and GA to solve distribution network reconfiguration. Using the encoding strategy according to the basic loop can guarantee all initial solutions are feasible. In this paper, frogs are sorted by fitness and initial population is divided into several groups, so that genetic algorithm is well used within the groups. This algorithm is of high efficiency and has a strong ability to jump out of local optima. The algorithm is verified by simulation results from test case on IEEE 33-bus system with distributed generations.

Keywords: HVDC, Sub-synchonous oscillations (SSO), Supplementary Sub-synchronous damping controller(SSDC), Phase compensation

Abstract. SSDC(Supplementary sub-synchronous oscillation damping controller) is one of effective measures to suppress the SSO(sub-synchronous oscillations) caused by HVDC. The article researched the phase compensation method of SSDC on the basis of studying the SSO and the SSDC mechanism in depth. We verified the validity of the method used by designing SSDC in an large domestic HVDC simulation model. And we find that the SSDC designed can effectively increase the positive electrical damping in the sub-synchronous frequency range with the sub-synchronous frequency scanning to suppress the SSO.

Introduction

With the rapid development of China's power industry, large-scale long-distance transmission is inevitable. SSO of the power system is a serious stability problem which first appeared in the long-distance transmission power project with series capacitor compensation . In 1977, the United States，a power plant named Square Butte first discovered the steam turbine shafting torsional oscillation caused by HVDC. In recent years, HVDC project is developing highly , SSO issue about it has become increasingly serious.

SSDC is the main efficient measure to suppress the SSO caused by HVDC. There is no agreed requirement so far at home and abroad about the SSDC control structure, phase compensation methods and so on. Article[4] has used the $H\infty$ robust control theory to design the SSDC in the HVDC transmission system , and made the SSDC designing to be a mixed sensitivity problem solving $H\infty$ robust control theory. Article[5] is based on the method of prony algorithm to compute the system transfer function, which is applied to SSO analysis and SSDC designing in the AC / DC hybrid transmission system. Article[6] designed the SSDC based on the complex torque coefficient principle and fuzzy immune method , which can adjust the controller parameters according to the control signal . Article [7] applied the genetic algorithm to solve the mini and max controller parameters optimization in value, so that SSDC can suppress the SSO effectively in a wide range of load conditions and the degree of compensation. Articles above had made a certain effect about SSDC design, but the principle of SSDC phase compensation is not so clear. In this paper, we have designed the single channel SSDC, and the phase compensation method is clear, simple, and finally through the domestic actual HVDC project we verified the practical value of the SSDC.

Through small signal testing method, we can obtain the phase frequency characteristics curve from constant current reference links ΔId to ΔTe. If the phase difference of ΔTe and $\Delta\omega$ is as small as possible ,the system can get the maximum electrical damping and this way is reasonable.

HVDC SSO mechanism and SSDC designing principles

SSO caused by HVDC. The direct reason of the occurrence of HVDC rectifier turbine SSO is the negative damping caused by HVDC current loop control system. The state change and interaction process of the variables in the AC-DC system[8] can be shown by Fig. 1 and Fig. 2.

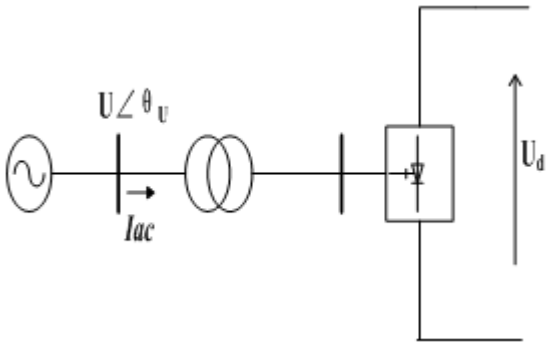

Fig. 1 HVDC Simplified Model

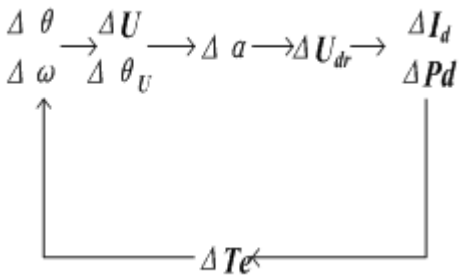

Fig. 2 SSO in HVDC Mechanism Simplified Diagram

If Turbine Shaft has a small disturbance by electromagnetic torque, this will result in fluctuations in the speed and angle of a torsional vibration modes（$\Delta\omega$ and $\Delta\theta$）. This will lead terminal voltage amplitude and corresponding phase fluctuations （ΔU and $\Delta\theta U$）, which leads to fluctuations in the amplitude of the converter bus voltage and phase and at last the amplitude and phase of commutation bus voltage will have a change. In the set current control mode and operating conditions, the trigger delay angle（$\Delta\alpha$）in HVDC will change and the DC voltage（ΔUd）changes as a result, which causes the DC current or DC power（ΔId, ΔPd） fluctuations. The HVDC rectifier current controller will be fixed quickly and adjusted correctly according to this bias, causing fluctuations in the electromagnetic torque of the generator（ΔTe）and, eventually, the feedback influences the generator shaft. If the phase lag of the generator speed changes and the resulting changes in the electromagnetic torque (including closed-loop control system additional phase lag) exceeds 90 °, it will form a positive feedback nature of the torsional vibration interaction and constantly increase vibration amplitude, leading to the shaft torsional vibration instability.

SSDC principle. According to the complex torque coefficient method $Dn = Dmn + Den$, Dn is the total damping of turbine generator at a generator, *Dmn* is the mechanical damping at this mode and Den the electrical damping. The mechanical damping is positive, when the electrical damping of the system in a mode is positive, the total system damping is positive too. If the system has series compensation capacitor or HVDC, it may produce negative electrical damping. And when $Dn = Dmn + Den < 0$,the system will be not stable. Under the disturbance effect, it will enhance the role of the turbine generator shaft torsional vibration, the system sub-synchronous oscillation will diverge. The electrical damping coefficient of the system is $De = Re(\Delta Te/\Delta\omega)$. ΔTe, $\Delta\omega$ are respectively the generators electromagnetic torque variation, speed error. Obviously, as shown in Fig.3,when the phase difference of ΔTe and $\Delta\omega$ between -90 ° to 90 °, the electrical damping is positive. Therefore, the phase difference between electromagnetic torque $\Delta Te'$of SSDC channel and $\Delta\omega$ is smaller（-90°~ 90°， it will take -45~45° in the project),and the amplitude of $\Delta Te'$is larger, the electrical damping may be larger, then, we can suppress the SSO.

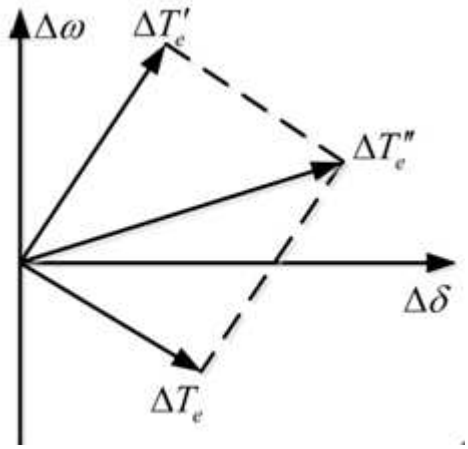

Fig.3. Electromagnetic torque vector diagram

Summary: The principle of the SSDC suppressing SSO is similar to PSS restraining the low frequency oscillation: taking the system signal $\Delta\omega$ or Δf, then through the appropriate proportion link and the phase link ,it can produce additional torque $\Delta Te'$ through the constant control circuit. At last, $\Delta Te'$ and the system old electromagnetic torque ΔTe will produce the new $\Delta Te''$,and enhance the system electrical damping. Therefore, the reasonable selection of SSDC parameters, s critical for suppressing sub-synchronous resonance effect.

SSDC control structure and parameters designing

Similar to PSS, SSDC includes DC link, filter, phase compensation, gain adjustment and limiter link. Control system architecture can be used through a multi-channel narrowband method and can also be used through a single channel broadband method. The multi-channel narrowband method must be based on the accurate shaft model or correct access on the natural shaft torsional vibration frequency. The single channel broadband method does not ,it has more universal and practical value and uses optimization method and provides better electrical positive damping of sub-synchronous frequency range (10-40Hz) . Considering the practical engineering, sub-synchronous frequency ranges from 10 to 30Hz . The different mode frequency phase compensation is not large, so we use broadband multi-channel control structure, as shown in Fig. 4:

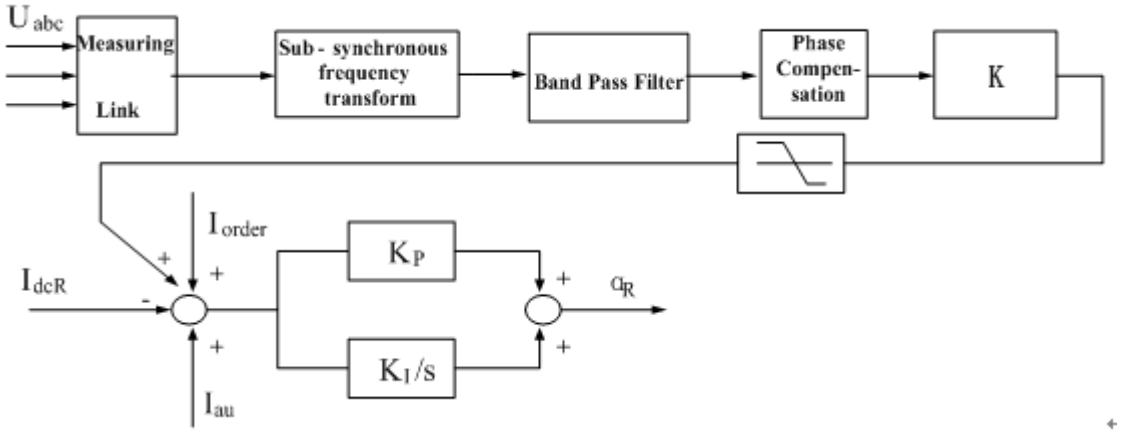

Fig.4 SSDC Control Structure

Designing the phase compensation link of broad band pass SSDC should take into account the most serious oscillation mode and the system operation ways. What's more, we should account the compensation parameter using the optimization and make the SSDC have certain robustness. According to the previous SSDC damping SSO principle and the analysis of controlling structure of broad band pass SSDC. Phase compensation link in the SSDC need compensate the sub-synchronous frequency converter phase-lag and the phase-lag caused by the converter bus voltage

sub-synchronous component and the generator rotor speed deviation. Through the analysis , when the electromagnetic transient state caused by the system fault is finished, the system entered into a stable sub-synchronous oscillation process, and the phase-lag in sub-synchronous generator component torsional oscillations and sub-synchronous component in converter bus voltage can be $\alpha=(180-\theta_0)$。And that θ_0 is the phase-lag between generator terminal voltage phase and converter bus voltage phase , associated with the generator output and system structure, which is the phase difference can be obtained by solving the steady-state flow, you can also get the measurements obtained by PMU in WAMS system. The phase compensation is mainly using the $((1+sT1)/(1+sT2))^n$ at the mode frequency, and the relevant parameters are shown in equation(1)-(3) :

$$a = T2/T1 = (1-\sin\varphi)/(1+\sin\varphi) \quad (1)$$

$$T1 = 1/\omega x\sqrt{a} \quad (2)$$

$$T2 = aT1 \quad (3)$$

ωx is modal angular frequency point which needs phase compensation ,φ is the compensated phase degree at this point. If the compensated phase degree is too large, we can use more links like this for compensation to get better feature.

SSDC gain is directly related to the damping it provides. Generally the gain is larger, the greater the electrical positive damping that SSDC can provide. In the premise of not affecting the stability of the system, the gain is chosen by the limiting requirements and the inhibition of SSO steady state amplitude. In general, the phase of SSDC correction is determined, we can regulate the SSDC by adjusting the proportion coefficient to provide electrical damping.

SSDC design and simulation in domestic HVDC system

First we design the famous HVDC/AC system in China with the PSCAD/EMTDC and the structure is shown in Fig. 5：

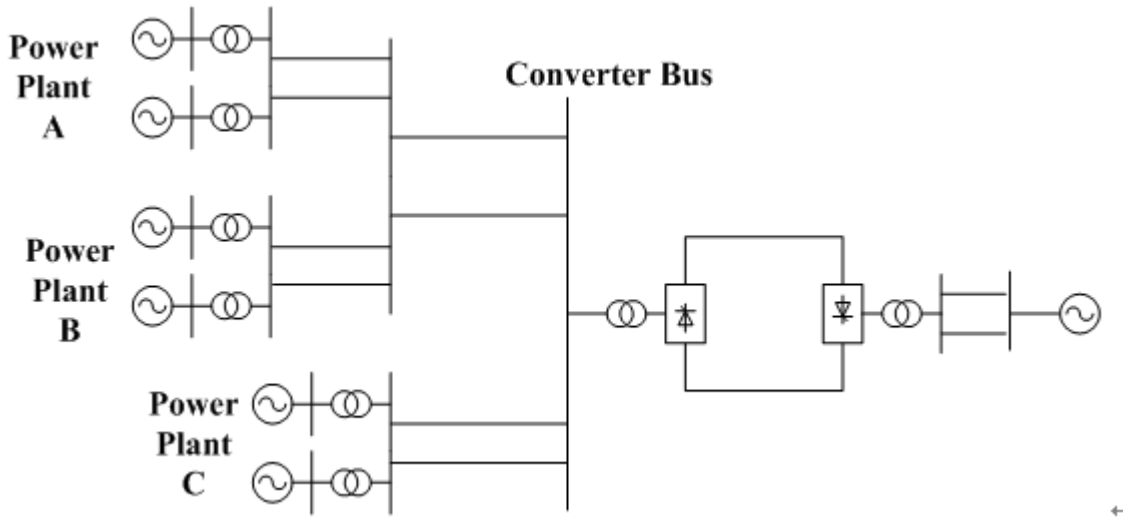

Fig.5 Simple Structure Diagram of a Domestic HVDC System

The actual operation of the HVDC system appears SSO problem in the turbine generator of C power plant. After calculating 3 mode shaft torsional oscillation frequencies of C power plant are 12.9132Hz, 22.5132Hz,26.0202Hz; Design the appropriate broad band pass SSDC according to the answers above for this problem. At last, we chose the pass band of the broad band-pass SSDC filter being 10-40Hz,and especially for the most serious mode, the phase to compensate of the system being 120° after measurement.

Set the 3 phase grounded fault at18s on the converter bus, and clear it at 0.05s, after the simulation, we found that the mode speed error dw, shaft torque T are as the following shown in Fig. 6 and Fig.7:

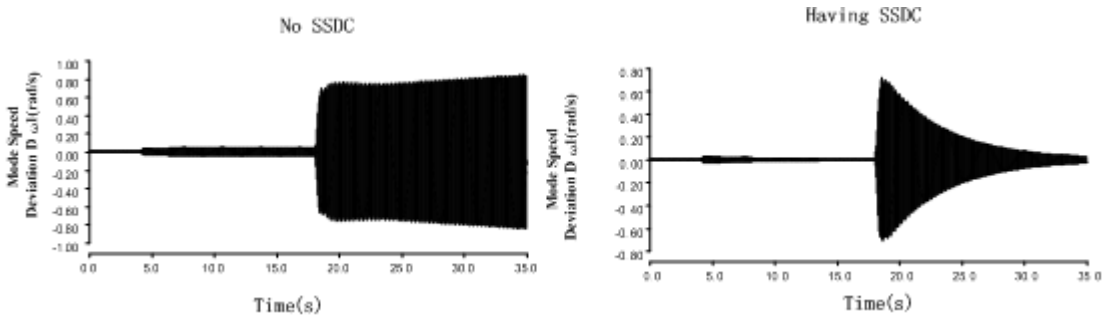

Fig. 6 Mode Speed error dw

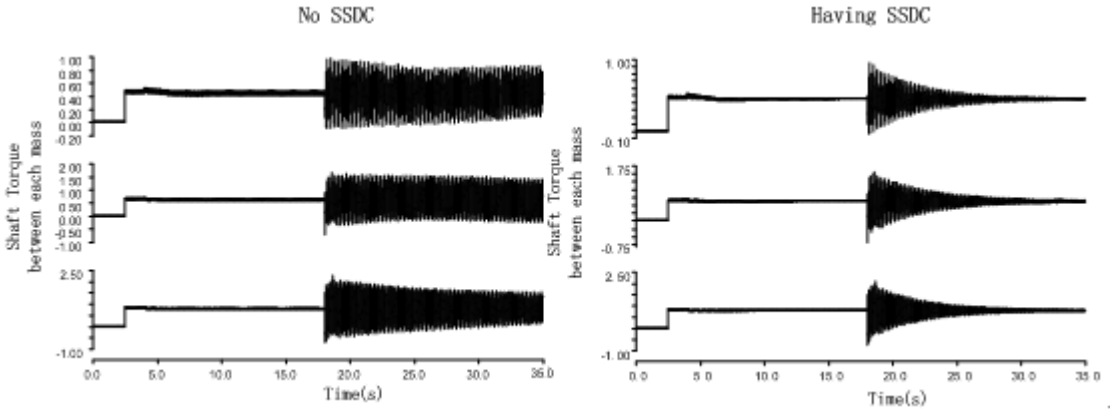

Fig. 7 Shaft Torque

After the simulation， we can know that electrical damping of the system is significantly improved after the SSDC is put, the system SSO is damped obviously. And the mode speed error dw and shaft torque fall into the reasonable value in 15s to ensure the safe and stable system generators operation.

Conclusions

1).We designed the appropriate SSDC and verified the validity by modeling using the PSCAD/EMTDC.

2).Through comparing with and without SSDC electrical damping Scanning, SSDC can effectively improve the system electrical damping and has a significant effect to suppress the SSO in HVDC.

Key word Internet of things; Intelligent building; Power Minitoring; ZigBee; GPRS

Abstract: With the improvement of living standards, people want to have a comfortable, convenient, safe working and living environment. In this context, the traditional architectural forms has been unable to meet the basic needs of the people. Therefore, in recent years, the intelligent building has been rapid development in our country.

In the intelligent building, electrical equipment occupies a very important position. For reliability and safety considerations, the power requirements of various equipment in intelligent building is very high.

This paper designs a kind of intelligent building power monitoring system based on Internet of things. This system treating embedded hardware as the core, basing on ZigBee wireless communication technology for signal transmission, using GPRS communication technology to remote monitoring system, achieved the control of a variety of equipment in the power system in the intelligent building of local . The test result shows that this system runs stably, and has practical application value.

Introduction

The first intelligent building in the world is the City Place Building which was built in Hartford of America in 1984. While in our country, intellegent building has also entered a rapid development period since 1990s. These developments comply with people's basic requirements for comfortble, convenient and safe work and study environment. Therefore, intelligent building is the product of social development, its degree of intelligence certainly will be improved gradually with the development of science and technology.

The intelligent building is a kind of special buildings, it uses digital communication technology, control technology, computer networking technology, television technology, optical fiber technology, sensor technology, database and other high and new technologies. It is based on these technologies, makes use of all kinds of power electronic equipments to constitute corresponding intelligentized system and complete the function of intelligent control. For this reason, the power electronic equipment is the body equipment to constitute intelligent building. If we want to keep thess power electronic equipments' normal operation, we must ensure the security and reliability of power system[1].

Aiming at above probelems, the intelligent building power monitoring system based on Internet of Things is presented in this paper. This system utilizes Internet of things technology to build a

local and remote monitoring system, which treats embedded hardware as the core and bases on ZigBee wireless communication technology and GPRS communication technology for system communication. This system achieved effective monitoring to intelligent building power system.

The analysis of Internet of Things applied to intelligent building power monitoring system

The Internet of Things is a global attention and research hot technology in recent years. By RFID, infrared sensor, GPS, laser scanner and other information sensing equipments, according to promissory agreement ,it can connect any items with Internet to do information exchange and communication in order to achieve intelligent identification, location, tracking, monitoring and management.

Most Internet of Things application system are composed of sensor layer, transport layer and application layer. For intelligent building power monitoring system, the three-layer structure is also an essential basic structure.

The sensor layer of intelligent building power monitoring system is composed of all kinds of equipments with sensory ability, including camera, GPS, sensor, M2M terminal, sensor network, sensor gateway and so on. These equipments are installed in power equipment monitoring area, or embedded in power system equipment, to perceive and distinguish objects, collect and capture voltage ,electric current, temperature and other relevant information in all kinds of power system, and provide essential data for monitoring center. At the same time, these equipments also need to adjust the running status of power system according to monitoring center instruction. The transport layer is the solid structure which is responsible for the data transmission. This system utilizes two kinds of communication protocol, one of them is ZigBee wireless sensor network, the other one is GPRS wireless communication unit based on Ethernet. The ZigBee wireless sensor network builds the core of local control communication, and GPRS builds the remote one. Effectively combining these two forms can achieve the local and remote monitoring function of the power system. The application layer is the top of the whole monitoring system. Its main function includes displaying data, summarizing data, reporting status, giving command and so on. These functions can be achieved by related development tool, such as VC++.

The study of local power monitoring system structure based on ZigBee wireless sensor network

The ZigBee wireless sensor network is a multihop self-organizing network which is composed of a mass of deployed in monitoring area microsensor nodes and formed by means of wireless communication mode. It mainly includes four parts: sensor unit(composed of sensor and analog-digital conversion function modules), processing unit(composed of embedded system, including CPU, memorizer and so on), communication unit(wireless transmission module, etc) and power unit. The sensor unit is responsible for collecting environmental information and data conversion. The processing unit is the operation core which controls the whole sensor nodes, it processes data collected by itself and sent by other nodes, operates network protocol to make sensor nodes interconnect into network in order to work together. The communication unit is responsible for communicating with other sensor nodes and exchanging control message and data message. The power unit provides energy for every unit[2] .

The wireless sensor network is a new information acquisition platform, it can real time monitor and collect information of all kinds of detected object in the network distribution area. In this sense, the wireless sensor network can include sensor layer function and a part of communication layer

function of the power monitoring which is based on the Internet of Things. It can send these information to geteway note expediently in order to detect and track complicated objective in designated area, so it has the characteristic of rapid unwinding and strong invulnerability. At the same time, compared with traditional wired sensor network, the wireless sensor network has the advantage of less cost, easier installation, less maintenance and renewal charge. So the wireless sensor network is right for the design of intelligent building power monitoring system under the special conditions.

The intelligent building power system is a complicated system. In the use of it, most operating parameter of the electrical equipment need real-time monitoring. While the scheme of wireless sensor network can achieve these functions expediently. The general structure design is as shown in Figure 1.

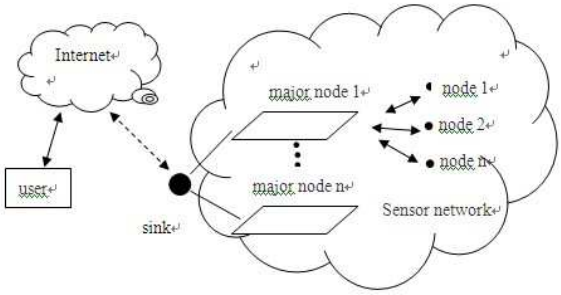

Figure 1 The structure of the overall system

Known from the figure, we can set a host node in every power system, and set several slave nodes at every monitoring points in every power system. Slave nodes collect local data and send to host nodes, and host nodes are linked to local monitoring center, thereby the local monitoring function can be realized.

The structure of every node is almost the same. They play roles of sensing, processing information, collecting and sending information. The concrete structure is as shown in Figure 2.

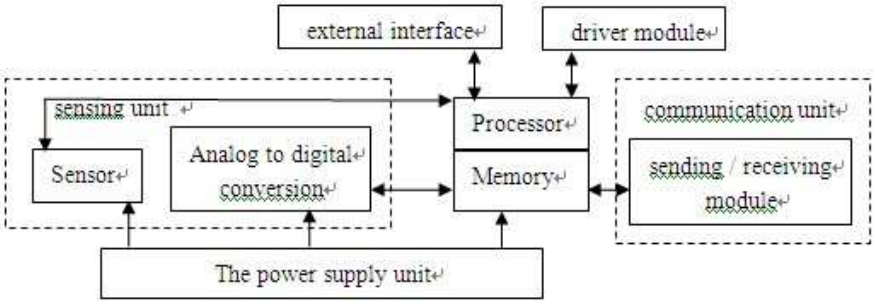

Figure 2 Wireless sensor network node structure

The sensor unit in the figure is composed of multiple voltage, electric current, temperature and humidity sensor, and it can collect data and convert analog data to digital data. The processing unit chooses TI's MSP430F149 as MCU to control the collecting, sending and processing of data of node. This MCU is power supplied by 3.3 V, its fundamental features include ultra-low power dissipation and high accuracy. The wireless receive/send module uses Chipcon's RF transceiver chip CC2430 which meets the standards of IEEE802.15.4.

The structure of telecommunication with GPRS communication module

The remote data transmission of this system uses GPRS technology and the specific module is ZTE's ZXGM18G. This GPRS module can support data, voice, SMS, fax and other communication

modes. Aftering doing level switch by chip MAX3245, this module can be linked to serial port RS232 and use General AT command complied with international standards to control. It has been widely used in wireless public telephone, industrial monitoring, automobile navigation, vehicle dispatching, emergency services, remote monitoring, banking and finance, commercial retail and other fields. This design takes MSP430F149 as the core, and provides two-channel port linked to GPRS. The UART is GPRSmodem and it can provide complete serial port for Dial-up. The structure of GPRS communication module can remotely transmit data, at the same time it can also locate error and judge operation status by chip status register.

The design of whole system structure and software

The whole structure of intelligent building power monitoring system is as shown in Figure 3. The middle layer is communication layer, the bottom layer is data collection layer composed of wireless sensor network and the top layer is application layer. The monitoring center is set up in the application layer and the software system developed by development tool VC++ is in the center. The software system is composed of five parts and it is used to remotely monitor the power electric parameter in intelligent building. Its main functions include: displaying, storing and printing the voltage, electric current, temperature and humidity data of every group of power; displaying and printing the operation normal data of power; displaying, storing and printing the fault information and maintenance information; contrastively analyzing the runtime value and standard value; alarming and recording the fault point; and so on. The concrete functional procedure is as shown in Figure 4. The power running status database is set up in the software system. The database uses SQL Server 2005 to store running status normal data, running status data and fault data in case of using when system monitoring and operating maintenance.

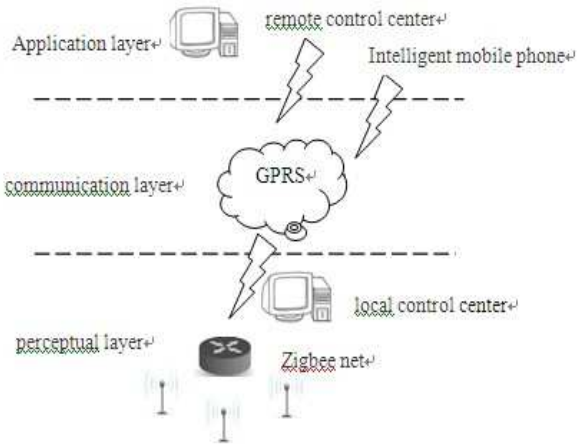

Figure 3 The structure of the overall system

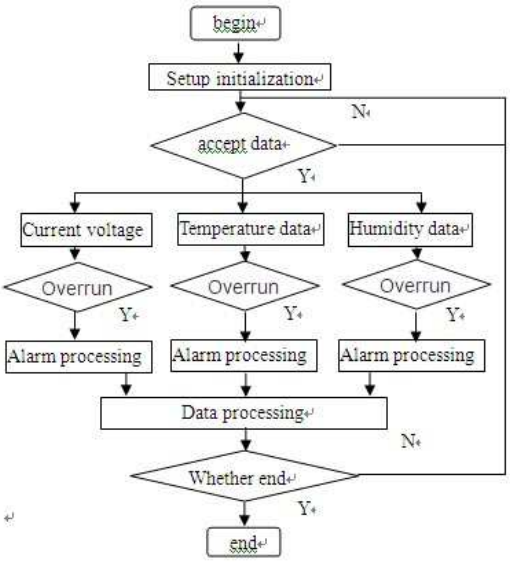

Figure 4 The software function flow chart

Conclusions

Along with the sociometric development, the intelligent building will show its superiority increasingly. The intelligent building power monitoring system, which is based on the Internet of Things technology, utilizes the way of the combination of wireless sensor network and GPRS, takes MSP430F149 microprocessor as control core, uses ZigBee technology to achieve local

communication of each subsystem and control center; and also achieves remote monitoring of the system by GPRS technology, real time monitors the intelligent building power system effectively, in order to grasp the power running state in time and alarm and report the fault point timely. The test shows that the power monitoring system which is researched in this paper can achieve communication among each node and ensure that the whole system operate stably and reliably, and has well practice guidance function.

Keywords: Metal-oxide Surge Arresters, Medium Voltage Power System, Electrical Characteristics, Selection and Application

Abstract. The index system for electrical characteristics of metal-oxide surge arresters is proposed and established, which is based on rated voltage (U_r), continuous operating voltage (U_c), nominal discharge current (I_n), overvoltage protection and insulation coordination including lightning overvoltage protection level, operating overvoltage protection level and coordination coefficient (K_s). The study considers both selection and application of overvoltage protection devices for the electrical equipments in 3-35kV medium voltage power system, and comparatively calculates and analyzes the main parameters between two types metal-oxide surge arresters (without gaps and containing series gapped structures), and illustrates their technical features and puts forward suggestions on how to improve the effective utilization. The results of 10kV power distribution system are simulated to show that the conclusions are feasible and available in the practical engineering application.

Introduction

In modern AC power systems, metal-oxide surge arresters have been gradually replacing the traditional silicon carbide arresters, which have become the more advanced overvoltage protection devices for the electrical equipments. The core parts of metal-oxide surge arresters is the metal-oxide resistors with nonlinear current-voltage characteristics: high resistance under the normal power frequency voltage, the leakage current is only microampere level; when withstanding overvoltage, the arresters have a low resistance in conducting state, releasing the overvoltage energy to limit the damages on the electrical equipments effectively. Comparatively, metal-oxide surge arresters changed the current-voltage characteristics to improve the flow capacity when overvoltage, so that the characteristics of arresters have undergone fundamental changes. According to the structures, they mainly divided into three types: without gaps, containing series gapped structures and containing parallel gapped structures [1].

In the paper, for the hidden dangers existed in the application of metal-oxide surge arresters, we take the electrical characteristics of two types (without gaps and containing series gapped structures) in 3-35kV MV power system to study, comparatively calculate and analyze the parameters for selection and application, and illustrate technical features to promote the correct usage of arresters, and further to improve the effective utilization for overvoltage protection of electrical equipments.

Electrical Characteristics

In addition to the basic conditions of environment, operating situation and mechanical strength, the index of electrical characteristics for metal-oxide surge arresters mainly include: rated voltage (U_r), continuous operating voltage (U_c), nominal discharge current (I_n), overvoltage protection and insulation coordination [2-3]. Where, U_r and U_c are associated with system neutral grounding modes.

Rated Voltage (U_r). U_r refers to the maximum effective value of power frequency voltage between terminals in the arrester, which is also known as the starting voltage of arresters [4]. The classification of U_r with different grounding modes is shown in Tab. 1, and where, U_m refers to the maximum work voltage of power system.

Tab. 1 Rated voltage of metal-oxide surge arresters

Grounding Modes	Arresters without gaps	Arresters containing series gapped structures
Low-resistance grounding	$U_r \geq 1.1U_m$	$U_r \geq 1.1U_m$ No distinction of the specific grounding modes [5].
Non-grounding or high-resistance grounding	$U_r \geq (1.25 \sim 1.3) \times 1.1U_m$	
Grounding via arc-suppression coil	$U_r \geq (1.25 \sim 1.3)U_m$	

Continuous Operating Voltage (U_c). U_c refers to the effective value of power frequency voltage between terminals in the arrester. The classification of U_c with different grounding modes is shown in Tab. 2.

Tab. 2 Continuous operating voltage of metal-oxide surge arresters

Grounding Modes	Arresters without gaps	Arresters containing series gapped structures
Low-resistance grounding	$U_c \geq U_m / \sqrt{3}$	$U_c \geq 0.8U_r$ No distinction of the specific grounding modes [5].
Non-grounding or high-resistance grounding	$U_c \geq 1.1U_m$	
Grounding via arc-suppression coil	$U_c \geq U_m$	

Nominal Discharge Current (I_n). I_n refers to the lightning impulse current peak values with 8/20μs shock wave, and are divided into three grades as the different operating conditions of arresters: 5kA, 2.5kA and 1.5kA. The classification of I_n is shown in Tab. 3.

Tab.3 Nominal discharge current of metal-oxide surge arresters

	Arresters without gaps			Arresters containing series gapped structures		
I_n	5kA	2.5kA	1.5kA	5kA	2.5kA	1.5kA
U_r	$Ur \leq 132kV$	$Ur \leq 36kV$	$Ur \leq 207kV$	$3kV \leq Ur \leq 52kV$	$3kV \leq Ur \leq 52kV$	$3kV \leq Ur \leq 52kV$

Overvoltage Protection and Insulation Coordination. The protection levels referring to the arresters residual voltage or discharge voltage should be lower than the insulation levels of the protected electrical equipments, and also have a certain margin. Different arresters have different protection levels, and therefore, they need to be checked with insulation coordination in selection and application. The index of overvoltage protection and insulation coordination is shown in Tab. 4.

Tab. 4 Overvoltage protection and insulation coordination of metal-oxide surge arresters

Overvoltage Protection and Insulation Coordination	Arresters without gaps	Arresters containing series gapped structures
Lightning overvoltage protection level	Taking the highest value in following: w The maximum residual voltage under 1/20μs steep impulse current / 1.15; w The maximum residual voltage under 8/20μs nominal discharge current.	Taking the highest value in following: w The maximum residual voltage under 1/20μs steep impulse current / 1.15; w The maximum residual voltage under 8/20μs nominal discharge current; w Lightning impulse discharge voltage; w Front of wave impulse sparkover voltage / 1.15.
Operating overvoltage protection level	The maximum residual voltage under 30-100μs operating impulse current.	No required.
Coordination coefficient (K_s)	K_s = Insulation level / Overvoltage protection level, and should be no less than the following values 1) K_s for lightning overvoltage ≥1.4; 2) K_s for operating overvoltage ≥1.15.	

Selection and Application

As 10*kV* power distribution system for example, taking $I_n = 5kA$ [2-3], we performed the selection and verification of U_r, U_c, overvoltage protection and insulation coordination, and compared the two types of metal-oxide surge arresters combined with the typical parameters.

Arresters without Gaps. For the different grounding modes, the calculation formulas of U_r and U_c are respectively shown in Tab. 1 and Tab. 2. The calculations and recommendations with different grounding modes are shown in Tab. 5.

Tab. 5 Calculations & Recommendations of arresters without Gaps

Grounding Modes	U_r (kV)		U_c (kV)	
	Calculations	Recommendations	Calculations	Recommendations
Low-resistance grounding	13.2	12	6.9	9.6
Non-grounding or high-resistance grounding	17.16	17	13.2	13.6
Grounding via arc-suppression coil	15	15	12	12

In Tab. 5, when it showed a big difference between calculations and recommendations, we could use Eq. 3 and Eq. 4 to determine whether U_r and U_c meet the requirements based on [2].

$$U_r \geq U_m \tag{1}$$

$$U_c \geq 0.8U_m \tag{2}$$

The typical residual voltages of arresters without gaps are shown in Tab. 6. Taking the corresponding value of lightning impulse withstand voltage and transient power frequency withstand voltage of 10*kV* electrical equipments separately to be equal to 75*kV* and 42*kV*, the results show that K_s for lightning overvoltage has met the requirement of insulation coordination with a slight margin of operating overvoltage by the calculation of Tab. 4, which are shown in Eq. 3 and Eq. 4.

Tab. 6 Typical residual voltages of arresters without gaps

The maximum residual voltage under steep impulse current (*kA*)	The maximum residual voltage under nominal discharge current (*kA*)	The maximum residual voltage under operating impulse current (*kA*)
51.8	45	38.3

$$K_s \text{ for lightning overvoltage} = 1.67 \geq 1.4 \tag{3}$$

$$K_s \text{ for operating overvoltage} = 1.1 \leq 1.15 \tag{4}$$

Arresters Containing Series Gapped Structures. For the different grounding modes, the calculations of U_r and U_c have none distinction, which are respectively shown in Tab. 1 and Tab. 2. The calculations and recommendations values with different grounding modes are shown in Tab. 7.

Tab. 7 Calculations & Recommendations of arresters containing series gapped structures

Grounding Modes	U_r (kV)		U_c (kV)	
	Calculations	Recommendations	Calculations	Recommendations
Low-resistance grounding Non-grounding or high-resistance grounding Grounding via arc-suppression coil	13.2	12.7	10.2	10.2

The typical residual voltages of arresters containing series gapped structures are shown in Tab. 8. Taking the corresponding value of lightning impulse withstand voltage of 10*kV* electrical equipments to be equal to 75*kV*, the result shows that the factor K_s for lightning overvoltage has met the requirement of insulation coordination [3] by the calculation of Tab. 4, which is shown in Eq. 5.

Tab .8 Typical residual voltages of arresters containing series gapped structures

The maximum residual voltage under steep impulse current (kA)	The maximum residual voltage under nominal discharge current (kA)	Lightning impulse discharge voltage (kA)	Front of wave impulse discharge voltage (kA)
47.2	41	45	56.5

$$K_s \text{ for lightning overvoltage} = 1.53 \geq 1.4 \quad (5)$$

Comparison and Discussion

Metal-oxide Surge Arresters without Gaps. There are many advantages of simple structure, excellent protection performance and effect. But also, their abilities to withstand transient overvoltage are weak, and the long-term repeated continuously actions easily accelerate aging. Therefore, they are mainly used in 110kV high-voltage power systems and above [6].

Metal-oxide Surge Arresters Containing Series Gapped Structures. Due to the increase of gaps, they can not only prevent resistance directly withstanding system voltage and transient overvoltage, effectively extending the service life, and also can reduce the number of metal-oxide resistors. They have excellent technical and economic performance, low residual voltage values, which are more suitable for MV power system.

Conclusions

According to the statistics, in the explosion of metal-oxide surge arresters, there are more than 60% accidents caused by manufacture quality and improper selection. Among them, the improper selection of rated voltage and continuous operating voltage of arresters without gaps, and the manufacture quality defects by structure design of arresters containing series gapped structures are the main reasons. Therefore, in the practical engineering application, it should be paid attention to the correct choice of metal-oxide surge arresters rated voltage and continuous operating voltage and the verification of frequency voltage withstand time characteristic curve, and the confirmation of overvoltage protection capacities. Meanwhile, the arresters should be checked with overvoltage protection and insulation coordination to ensure effective overvoltage insulation protection of the electrical equipments. In the MV power systems, it should be combined with the actual situation and operating experience to complete the corresponding selection and application [7].

Study on large- scale distributed power access to distribution networks for the impact of the loss in the power

Bolun Wang[1,a]

Shandong University, Shizhong District, Jinan 250002, China

634420080@qq.com

Keywords: New energy access to distribution networks the network loss.

Abstract: Near the load of distribution network access distributed networks, the entire distribution network load distribution will change, system trend then change, then the trend of the distribution network can also be changed from the original "one-way flow" to "two-way flow". For synchronous generator connected to the power distribution network, the input active power and reactive power at the same time to the system, can reduce the loss and the voltage distribution network can play a supporting role, but for asynchronous induction generator connected to the power distribution network, the input to the system active power and reactive power absorption, reduce the power factor of the grid. By trend analysis found that introducing asynchronous induction generator to increase distribution network loss, deterioration in transmission line voltage level. Distributed generators after introducing the distribution network could reduce may also increase the system network loss.

Introduction

Entering the new century, with the development of world economy, the human face more serious problems such as population growth and environmental pressures. Clean and efficient power development, no doubt, is one of the important measures to solve these problems. Especially from the beginning of the last century, western developed industrial countries is emerging to develop new type high efficiency green independent power of the boom, since then the Distributed power supply (Distributed Generation) the term arises at the historic moment. Distributed power include: solar power stations, wind power, geothermal power plants, micro gas turbines, fuel cells, biomass power device and the energy storage device, such as a kw power to tens of megawatts. The power supply for electric power department, all electric power users or a third party. Its working mode is mainly to its close to the user side to install, make its can be directly with public independent power transmission and distribution network, provide power for a small amount of users, can also be incorporated into the power grid with public power grid power, to provide users with flexible working patterns can satisfy the specific requirements of power system and the user [1,2].

In addition, the emergence of the distributed power due to the following reasons: 1) the large-scale development of city, opening up new distribution line corridors, more and more difficult, and can be placed directly on the users nearby of distributed power supply device is a kind of feasible alternatives: 2) previous power system model is: concentrated power, long distance transmission and large power grid interconnection. In this system, the local accident can spread easily, for the whole power grid may be adversely affected, severe cases can cause blackouts and power grid collapse; In recent years in western countries several blackout accidents to a certain extent, reflects the traditional power system faults. In order to change this vulnerability, avoid a chain reaction, guarantee the safe and reliable power supply, spread power such as the configuration of distributed power supply device, can under the condition of the power grid collapse and unexpected disaster to maintain the supply to important users; 3) power supply for remote distributed user, close to the user configuration of distributed power supply measures with the existing distribution network than simply increase capacity to more economic, faster and more convenient to use, effective; 4) distributed power supply technology, many are environmental protection and energy saving, can satisfy the need of sustainable development; Especially the parallel operation mode has been a lot of energy experts say is the important direction of future power industry [3,4,5,6].

For distributed power supply and power grid operation problems, mainly has the following several aspects,it shown by Fig 1.

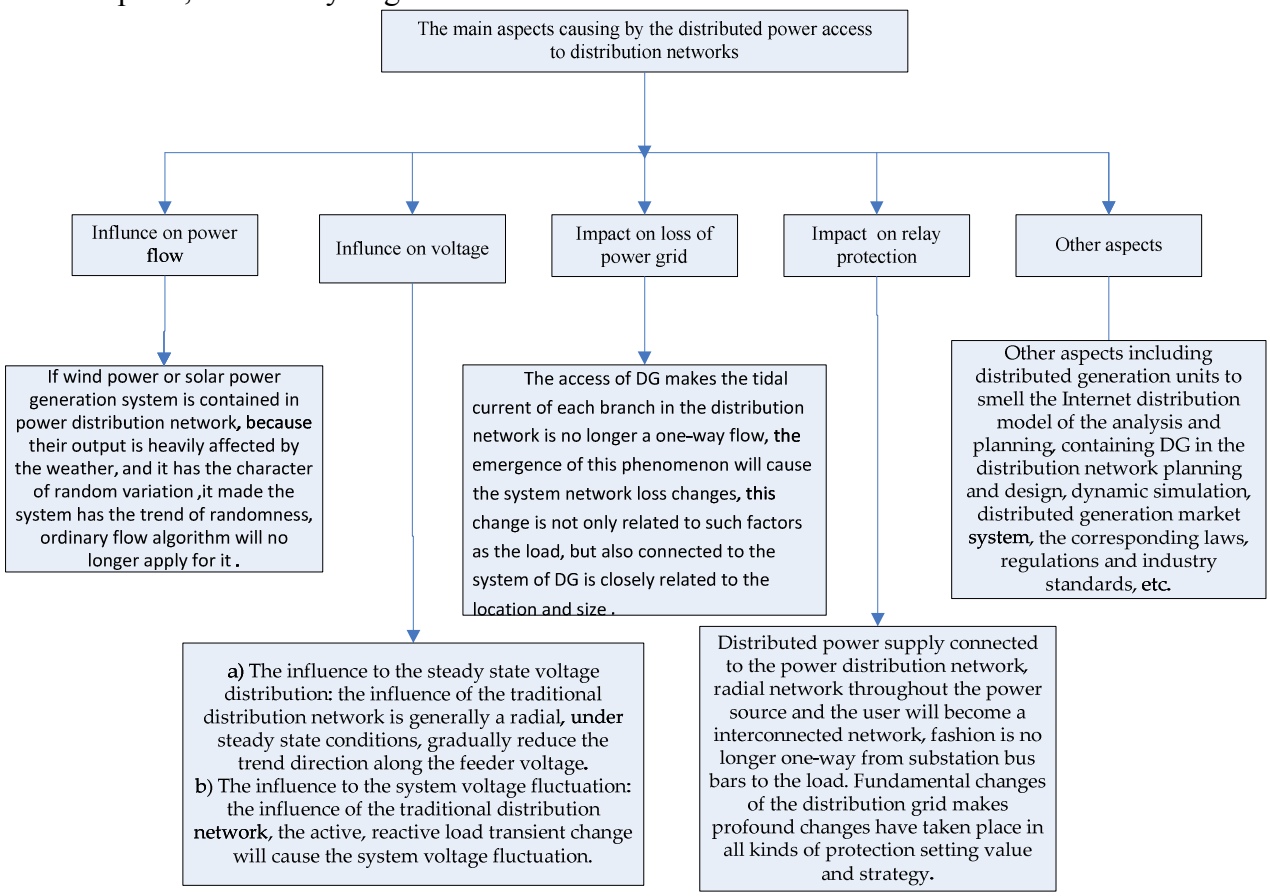

Fig 1 The main aspects causing by the distributed power access to distribution networks

Organization of the Text

DG access network loss changes after distribution network model analysis

1 The ideal model of the system

Compared two simple distribution network model: the model I system a not access distributed power (DG); Model II system connected to a distributed power supply. Both models in the end of the transmission line .

Containing the same load, assumes that the load with Y type access system and three-phase load balance, the power factor of load with a fixed from the system absorbs the active power and reactive power; On the transmission line is not long, can assume a power line voltage the same everywhere, and transmission line on voltage little change before and after the introduction of DG. Model I as shown in figure 2, model II as shown in figure 3.

In the articles ,used in the symbols of the instructions are as follows:

G : the distance from the power supply to the DG, unit of km

L : the distance from the power supply to the load, the unit of km

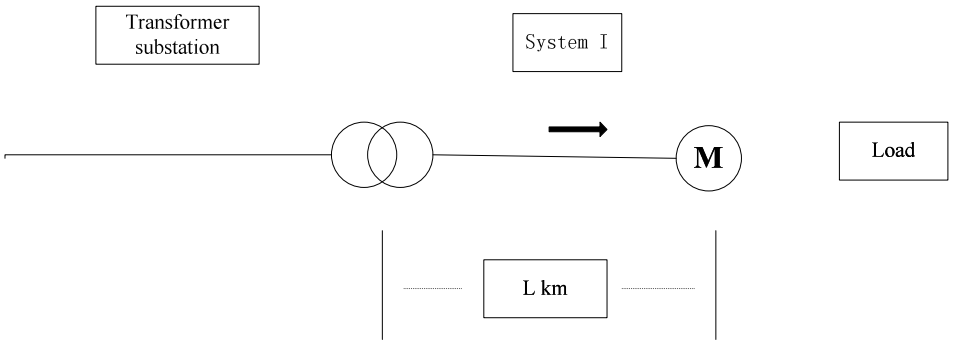

Fig 2 Model I (system I ,without DG)

I_g :single-phase current output from power DG, the unit of A

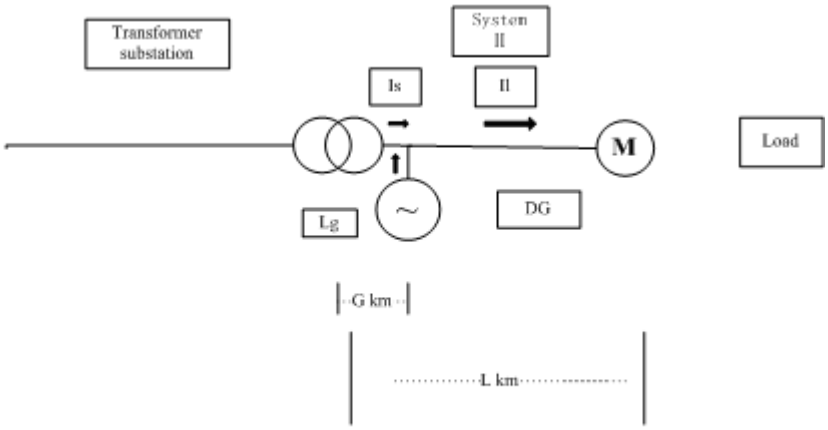

Fig 3 Model II (system II ,with DG).

I_l :single-phase current flows into the load, the unit of A

I_s : single-phase current output from power , the unit of A

2 The analysis of the loss changed after the DG in the model system access to distribution network

Load connected to the system inevitably produces the network loss. For system loss on one branch, its size depends on the current through the branch, and the branch resistance size, thus reducing the branch resistance and flow of electric current can achieve the purpose of reduce the loss. Distributed power supply is introduced on the load side, which can reduce system branch in the current, so can reduce the loss on the branch. The following from the simple model which can get the analysis of current changes in changes in the network loss.

System load for:

$$S_L = P_L + jQ_L \tag{1}$$

Type P_L ： the load active power consumption, unit w

Q_L ： the load reactive power consumption, unit Var

Single-phase current flows into the load:

$$I_L = \frac{P_L - jQ_L}{3V} \tag{2}$$

Type V the system transmission line voltage are, unit V

In model I，,the system loss is:

$$Loss_1 = \frac{rL(P_L^2 - jQ_L^2)}{3V} \tag{3}$$

Type r ： the system transmission line voltage are, unit Ω/km

In model II，,the system loss is:

$$I_G = \frac{P_G - jQ_G}{3V} \tag{4}$$

Type P_G ： the load active power consumption, unit w

Q_G ： the load reactive power consumption, unit Var

After the distributed power supply connected to the system, according to the DG access to the location of the power loss on the feeder can be divided into two parts: the first part is the power and power loss between the DG loss， here we call it $Loss_A$, the second part is the loss between the DG and load of power ,here we call it $Loss_B$.

$$I_L = I_S - I_G \tag{5}$$

$$Loss_A = 3rGI_S^2 = \frac{rG(P_L^2 + Q_L^2 + P_G^2 + Q_G^2 - 2P_LP_G - 2Q_LQ_G)}{3V^2} \tag{6}$$

On to the second part, due to the access to DG side load current before and after I_L change, so after the introduction into the DG network loss $Loss_B$ and before the introduction of DG is the same:

$$Loss_B = 3r(L-G)I_L^2 = \frac{r(L-G)(P_L^2 + Q_L^2)}{3V^2} \tag{7}$$

After the introduction of DG into the model Il ,the network loss in the transmission line L total amounts :

$$Loss_2 = Loss_A - Loss_B = \frac{rL}{3V^2}(2P_LP_Q + 2Q_LQ_G - P_G^2 - Q_G^2)\left(\frac{G}{L}\right) \tag{8}$$

From the above it can be seen that when $\Delta Loss > 0$, the introduction of DG can reduce network loss, on the contrary, when $\Delta Loss < 0$, While the introduction of DG increased the original line network loss.

Conclusion

The reasonable capacity of distributed power supply connected to the right place and with power factor operation is not only can largely reduce the network loss, but also suitable for distribution network and voltage support and safety and reliability of distribution network has a positive role in such aspects, the economic and reliable operation of the distribution network is very good.

Key Words: steam pipe network;transformation;mathematical mode;flow field analysis

Abstract. As Zibo power plant original steam pipes for a long time to run, the strength decreased and resistance was large, transformation was proposed to optimize. A mathematical model of the main steam pipe network was established to analysis changes of temperature, pressure and velocity vector before and after transformation. After transformation, the loss was significantly reduced,so transformation successfully achieve the optimization, adjustment and analysis functions of the main steam pipe network.

Introduction

Cogeneration is an important energy cascade utilization form. Because of its many advantages of energy-saving, environmental protection, economic and other domestic, it has become the main form of central heating in modern town international. The steam pressure is often more important than the temperature parameters in the turbine generate electricity, and power loss of temperature is greater than the pressure loss, it should try to avoid loss of pressure and temperature. In this paper, Zibo power plant main steam pipe network system, for example, conducted an investigation and computational analysis of its operation status and reduce pressure drop and temperature loss by energy-saving measures. Although the safety and reliability of the steam pipe network conducted many studies in many countries, mostly for the hot water pipe network, the steam pipe network system yet detailed algorithms. Irrationality steam pipe network layout, the difficulty of network operation and the lack of successful ways to learn from the experience, make this study practically significant[1,2].

An example of the steam pipe network transformation

Overview of Zibo Power Plant. Object of study is the Zibo thermal power plants, which now has six boiler rooms and 64 heat transfer stations, pipe network extending more than 420 km. Existing total heating area is 650 square meters, heating cover the entire scope of Zhangdian District of Zibo City,High Technology Development Zone and the New City.

Transformation range.(1) Transformation Cause: The original main steam pipe running for about three years, its creep is serious and strength is decreased. For the future operation to stay hidden danger, and the main steam pipe had greater resistance, an urgent need for reform.

(2) Transformation Content: 1 #, 2 # boiler and main steam pipe of 1 # turbine.

(3) Transformation principles: Try to go according to the original arrangement of pipes ,embedded originally reserved for the use of pipe hangers, while reducing the flow resistance losses.

Rehabilitation programs.(1) Change the original Φ193.7 * 22.2 main steam pipe to Φ219 * 18, the original Φ273 * 30 main steam pipe to Φ273 * 20, partial adjustment of Φ351 * 30;
(2) Adjust pipe material from 10CrMo910 to12Cr1MoVG;
(3) Take a single mother pipe program, remove the ring main pipe, pressure reducer to reduce the temperature of the main steam pipe leads directly from the mother, two manual segmentation reducing valves, electrical isolation to keep a door;
(4)Adjust diameter of 1 #, 2 # boiler and main steam pipe of 1 # turbine ment to DN250.Remove 1 #, segmented valve on the main pipe between the boiler # 2 (two), an increase of 3 # boiler with segmented valve.
(5) Valves can be approximated as 0.85 times the transformation of the main steam pipe diameter.

Numerical modeling of the main steam pipe network

In model building process, the steam pipe to model as a whole. Take y-axis is vertical, positive upward; x-axis direction is east-west, east is positive; z-axis direction is north to south, the south is positive, the established pipeline model diagram as shown in Fig 3.1[3,4].

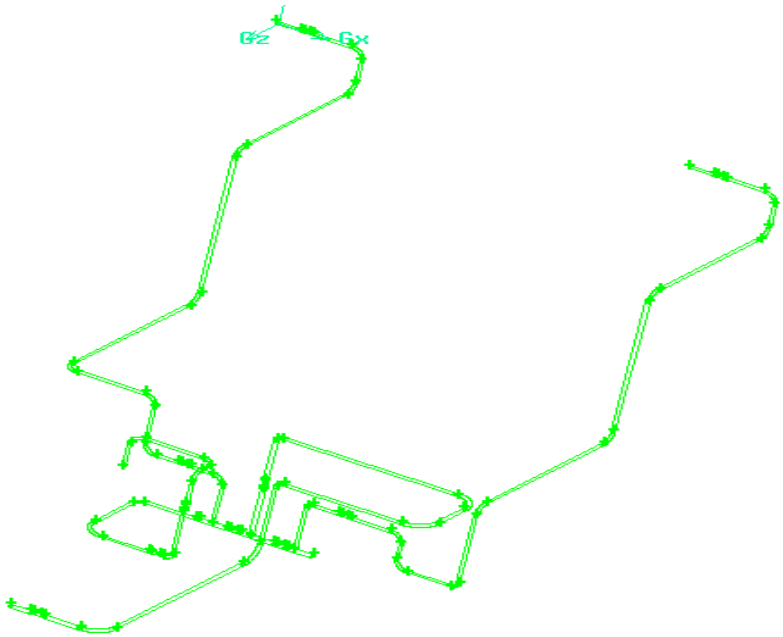

Fig 3.1 Pipeline model diagram

The main steam power plant boundary conditions of temperature and pressure pipe network settings are as follows:
(1) 1 #, 2 # steam import using pressure inlet boundary condition, its speed is determined by the inlet pressure and diameter;
(2) steam outlet using the default outflow boundary conditions;
(3) wall boundary conditions that no velocity slip wall, pipe wall is assumed to be adiabatic boundary;
(4) water vapor is a continuous medium, fluid flow is turbulent, incompressible Newtonian fluid.The vapor density is 0.5542 kg / m³, viscosity is 1.34kg/（m•s）, specific heat capacity is 2014 J / (kg • K), thermal conductivity is 0.0261W / (m • k). 1 # inlet pressure is 9730000Pa, inlet temperature is 811K; 2 # inlet pressure is 9810000Pa, inlet temperature is 809K.

The simulation results analysis

Using simulation software to establish the mathematical model of steam pipe network, entering the actual network operating parameters to accomplish simulation and analysis, together with the necessary shidechakan work, we can comprehensive, quantitative evaluation of pipe heat loss situation.

We used simulation software to establish a mathematical model of this power plant steam pipe network, entering the actual network operating parameters, together with a few necessary Shidechakan work, through simulation of different conditions, the simulation results obtained, then calculate, research and analysis, ultimately to achieve a comprehensive, quantitative evaluation of pipe heat loss situation[5]. The following is the simulation results and analysis.

Temperature Analysis. Through simulation software，drawing temperature distribution of the pipe network as shown in Fig 4.1-4.2.

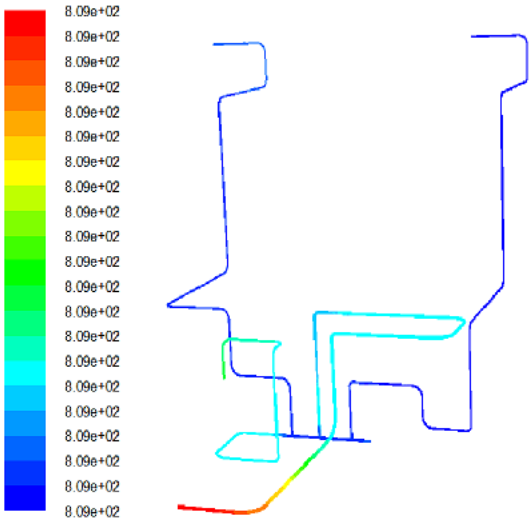

Fig 4.1 Befoer transformation

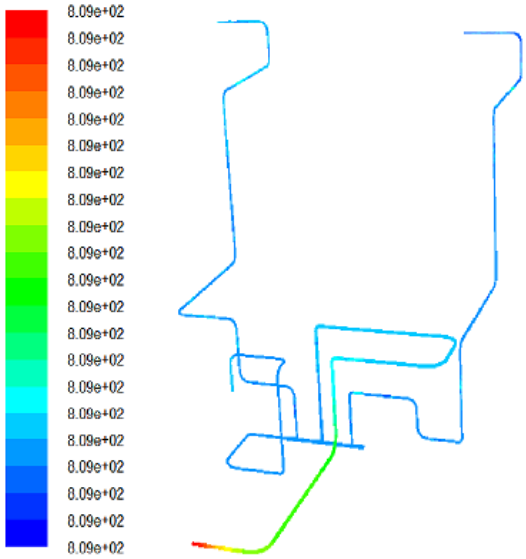

Fig 4.2 After transformation

As can be seen from the temperature distribution, steam mixture of the two different temperatures with the flow through a pipe, the temperature of the mixture is between two speeds, and the longer the pipe, the temperature dropped into the gradient. Close to the interface at a temperature close to the temperature of the fluid close.

Pressure Analysis. Through simulation software，drawing pressure distribution of the pipe network as shown in Fig 4.3-4.4.

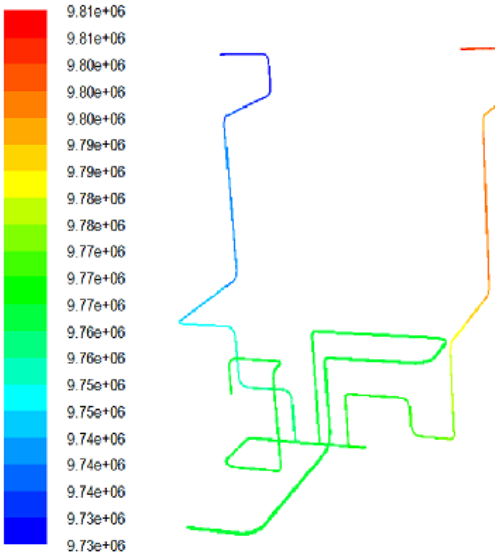

Fig 4.3 Befoer transformation

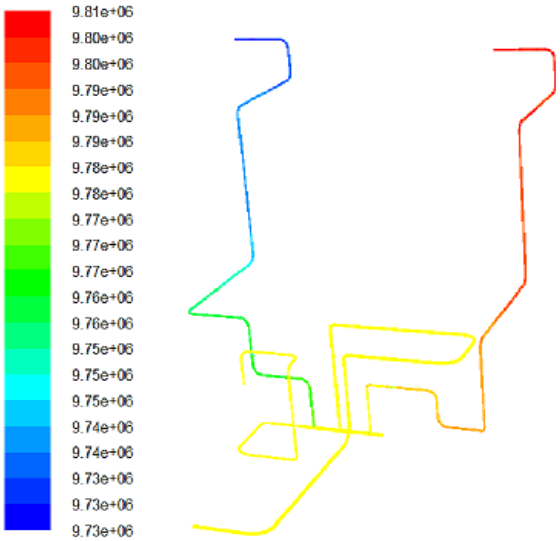

Fig 4.4 After transformation

As can be seen from the pressure distribution, the two strands of different vapor pressure of the mixed flow through the same pipe after the pressure in the pipeline at the junction is relatively large, but with the increasing distance pipeline, the pressure is gradually reduced, the mixing the end of the pipe fluid pressure to a minimum.

Velocity vector analysis. Through simulation software，drawing velocity vector distribution of the pipe network as shown in Fig 4.5-4.6.

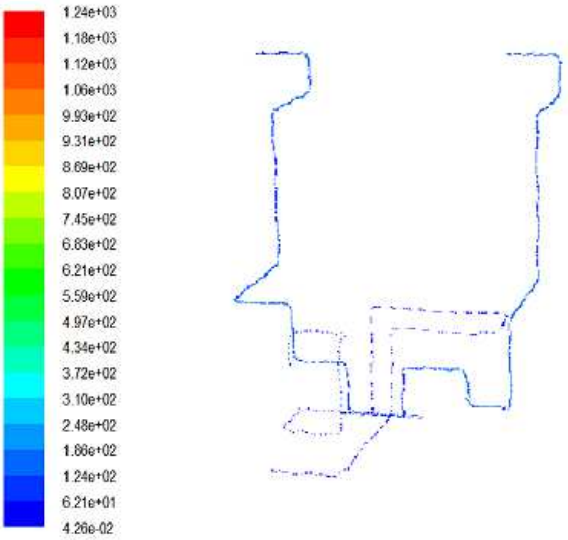

Fig 4.5 Befoer transformation

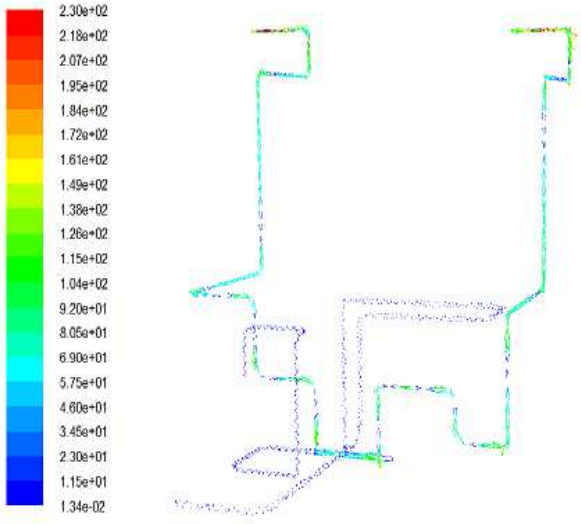

Fig 4.6 After transformation

As can be seen from velocity vector, when two fluids of different speeds after mixing flow through the same pipe, the pipe junction to get maximum speed and turbulence. As the distance becomes large pipeline velocity decreases, the distribution is similar to the temperature distribution.

Through simulation, the main steam pipe steam flow before and after the transformation, when the changes and export pipeline pressure loss including: Before transformation pressure drop is 41523Pa, after transformation pressure drop is 24137Pa; after transformation the outlet pressure is increased by 58.14% than that of the former, pressure losses are significantly reduced.

Conclusions

Zibo power plant operating conditions of the main steam pipe network to simulate multiple , based structural optimization of steam pipe network to provide a reference and basis through . Work done and conclusions are summarized as follows :

(1) By comparison, after transformation the outlet pressure is increased by 58.14% than that of the former. So the main steam pipe network, pressure losses are significantly reduced after transformation, the steam pipe network mathematical model established is reasonable, and it is successful transformation .

(2) Through simulation software, drawing velocity, temperature and pressure distribution of the pipe network, in practice, that the production of selected and appropriately selected to optimize the design diameter of the pipeline structure , according to the distribution pipe to these quantities, for software sampling can do a better theoretical basis for the practice.

(3)In technical analysis and balance adjustment process ,we can Conclusion, in the case that the heat source matches heat user, scientific and reasonable resistance to steam and heat pipe network comprehensive and systematic balance adjustment is to improve thermal efficiency and ensure steam pipe network security, improve plant efficiency is an important measure.

Torque Ripple Suppression of Switched Reluctance Motor Based on Torque Sharing Strategy

Qian Zhang[a], Ying Zhao[b], Hao Mu, Shuai Liu, Yiheng Li

Department of Power Engineering, Chongqing Communication Institute,

Chongqing, China

[a]479855782@qq.com, [b]zhaoying2666@163.com

Keywords: Switched reluctance motor; Torque sharing; RBF neural network; Current compensation

Abstract: The torque ripple is the main disadvantage of switched reluctance motor (SRM). In order to reduce the torque ripple of SRM, and improve the performance of the system, the torque sharing strategy was combined with RBF neural network for the purpose of torque ripple suppression by controlling the winding current of each phase. In consideration of the possible error of network, the real-time current compensation was taken to compensate the loss of torque which could suppress the torque ripple of the system in further. The results show that he torque ripple of SRM was suppressed effectively.

Introductions

SRM has a series of advantages such as simple structure, agile control, excellent capability of fault tolerance, etc. All these merits made it widely used in the fields of both military and civilian [1-3], however, the nonlinear characteristic of SRM will generate large torque ripple, which limits the popularization and application of SRM. Therefore, effective control strategy should be taken to reduce the torque ripple of SRM which is of great importance to improve the performance of the system.

Strategy of torque ripple suppression

Because of the nonlinear characteristics of torque, the change rates of torque of each phase are different during the commutation of current, which makes the total torque of SRM appears larger fluctuation. Therefore, realizing smooth transition of torque plays an important role to inhibit the torque ripple of SRM. The essence of Torque Sharing Function (TSF): Realizing smooth commutation of torque by distributing the total torque of SRM to each phase, and ensure that the total torque keeps a constant value [4]. Since it is difficult to control torque of SRM in direct, the torque of each phase distributed by TSF need to be transformed to the corresponding expected current by torque inverse model, the hysteresis comparator makes the winding current of each phase to follow the expected current with small error, so as to achieve the aim of indirect torque control. The general structure of the SRM control system as shown in Fig.1.

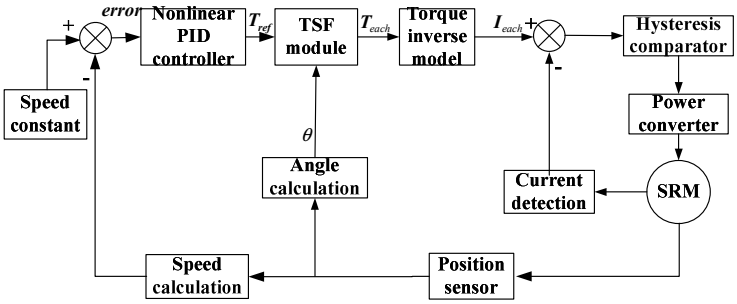

Fig.1. The structure of SRM TSF system

The system as shown in figure.1 adopts double closed loop control: speed loop and current loop. The expected torque T_{ref} was realized by PID speed controller, and the current I_{each} of each phase was realized by torque distribution module and torque inverse model.

Speed controller. The expected torque was realized by speed controller, and the relationship between torque and speed shown as formula (1):

$$T_e = J\frac{d\omega}{dt} + T_L + F\omega \tag{1}$$

Assume that the speed is a constant value, then there is an equation $d\omega/dt = 0$, and the formula (1) can be simplified as formula (2).

$$T_e = T_L + F\omega \tag{2}$$

The value of T_L and $F\omega$ is approximately remain unchanged when Δt takes a value small enough.

$$\begin{cases} \Delta T_e = J\dfrac{d\omega}{dt} \\ \dfrac{d\omega}{dt} = \dfrac{\Delta\omega}{\Delta t} \end{cases} \tag{3}$$

ΔT_e of expression (3) is the increment of torque within the time Δt.

$$\Delta T_e = K_P \Delta\omega \tag{4}$$

The choice of TSF. TSF describes the relationship between torque and rotor position angle of SRM, the form of the function is not unique, but must meet the need of function (5)[5]:

$$\begin{cases} T_j = T_{ref} f_j(\theta) \\ \sum_{j=1}^{n} f_j(\theta) = 1 \\ 0 \le f_j(\theta) \le 1 \end{cases} \tag{5}$$

The parameter of function (5) represented as follow: n is the phase number of SRM; θ is the relative position of phase winding and rotor; $f_j(\theta)$ represent torque distribution function; T_{ref} is the total expected torque of SRM; T_j is the expected torque of each phase.

There are some commonly used TSF such as trapezoidal function, cosine function, etc[6]. While there is no essential difference between each TSF, the only different between each function is just the shape of torque edge during commutation. The cosine function was used as the torque distribution function in this paper; the expression shown as function (6).

$$f_k(\theta)=\begin{cases} 0.5-0.5\cos\dfrac{\pi}{\theta_1-\theta_{on}}(\theta-\theta_{on}) & \theta_{on}\le\theta\le\theta_1 \\ 1 & \theta_1\le\theta\le\theta_{off} \\ 0.5+0.5\cos\dfrac{\pi}{\theta_1-\theta_{on}}(\theta-\theta_{off}) & \theta_{off}\le\theta\le\theta_2 \\ 0 & else \end{cases} \tag{6}$$

In equation (6), θ_{on} corresponding to opening angle of current electricity winding; θ_{off} represents the turn-off angle of current electricity winding; $\theta_1-\theta_{on}$ signify the overlapping conduction angle of two phase winding, θ_{on} meet the relationship as $\theta_{on}<\theta_1<\theta_{off}$, the best value of two phase overlap angle is 7.5°. The shape of TSF used in this paper shown as in Fig.2.

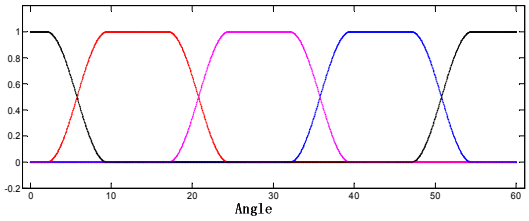

Fig.2. The shape of TSF

The torque inverse model based on RBF neural network. The expected torque of each phase was obtained by torque distribution function, while the essence of the torque control is the control of the current. Because of the strong nonlinear characteristics of SRM, it is difficult to obtain the expectations current match the corresponding torque of each phase by specific analytical solution. As a nonlinear network, Radial Basis Function Neural Network (RBF NN) can approximate any nonlinear Function with arbitrary precision [7], so that the relationship of torque, angle, and current could be expressed by RBF Network very well. The structure of RBF neural network as shown in Fig.3.

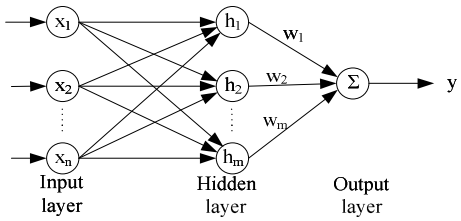

Fig.3. The structure of RBF neural network

The training sample data of RBF neural network were obtained by sampling the characteristic curve of angle and torque, the surface of training sample data as shown in Fig.4 and Fig.5.

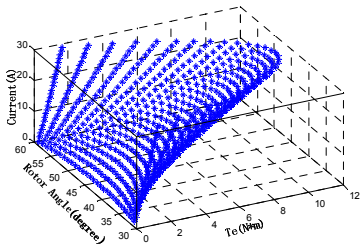

Fig.4. The surface of training sample data

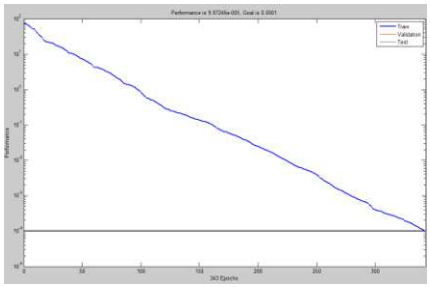

Fig.5. The network training process error curve

The network training process error curve as shown in figure 3.18, it can be seen that the error of the network is 9.98246 e-5 which is less than the pre-selected target 0.0001 when the network stop training, the output of the trained RBF neural network and the error curve between output of the trained RBF neural network and the sample data as shown in Fig.6 and Fig.7:

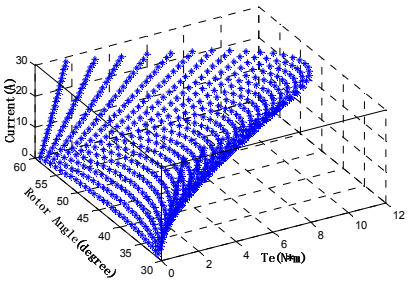

Fig.6. The output of RBF neural network

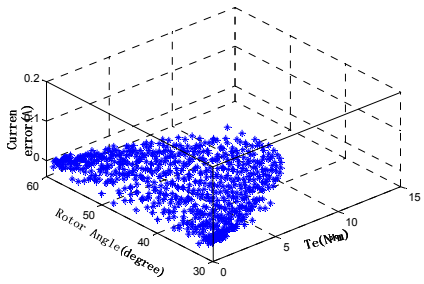

Fig.7. The error curve between output of RBF and sample data

Current compensation. There will be some errors inevitably during conversion from torque to corresponding expectations current because of the certain errors of RBF neural network， therefore， the torque of each phase cannot follow the expected torque very well which will cause torque ripple. Putting that in perspective, the segment of current compensation was proposed to compensate the losses of torque of each phase which will have a good effect for suppressing torque ripple. The simulink module of current compensation as shown in Fig.8.

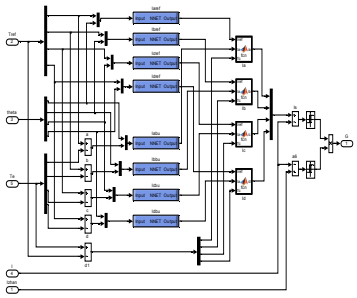

Fig.8. The simulink module of current compensation

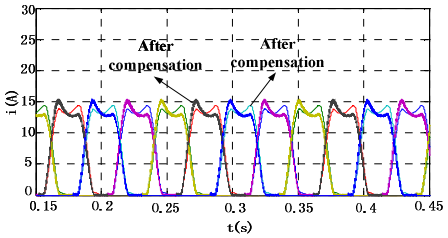
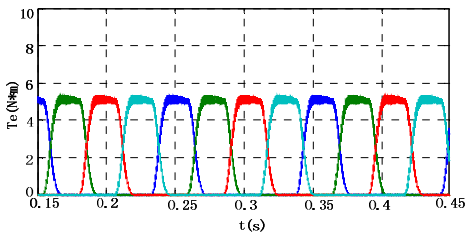
Simulation analysis of TSF

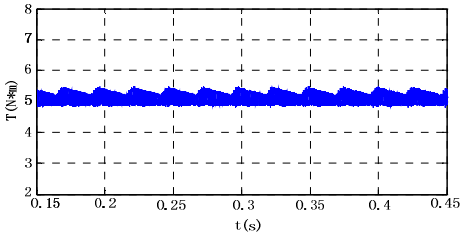
The winding current is very small almost to zero under no-load cases, in order to observe the effect of current compensation for suppressing torque ripple of the system, the speed was set as 100 r/min, the load was set as 5N·m, the PI parameter was set as $K_p = 1, K_i = 0.1$, the simulation time was set as 0.5s. The simulation results as shown in Fig.9.



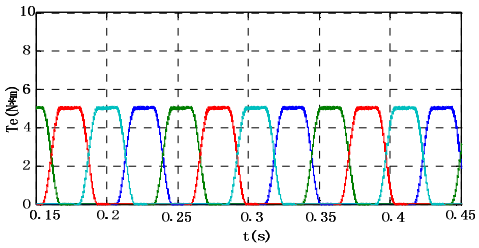
(a) Current contrast before and after current compensation



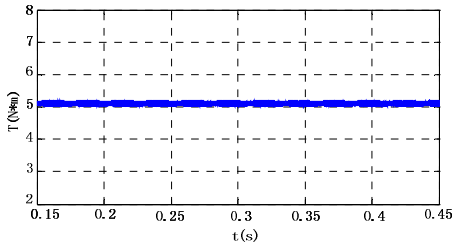
(b) The torque of each phase before current compensation



(c) The total torque before current compensatio



(d) The torque of each phase after current compensation



(e) The total torque after current compensation

Fig.9. The simulation results before and after current compensation

It can be seen from the diagram; the torque ripple decreased obviously by current compensation, and torque of each phase realized smooth commutation.

Summary

The torque distribution control strategy was adopts in this paper to distribute the total expected torque to each phase; since it is difficult to control the torque of SRM in direct, the RBF neural network was proposed to obtain the expected current corresponding to expected torque. The segment of current compensation was proposed to compensate the losses of torque of each phase for the possible errors of network. Researches have shown that the torque distribution control strategy can effectively reduce the torque ripple of SRM, and plays an important role in improving performance of the system.

Keywords: electricity market; power system loss allocation; cooperate game; Shapley value; power flow; pool transaction; bilateral transaction

Abstract. The allocation of power system loss under hybrid transmission modes was investigated. First, a concept and method for converting a bilateral transaction into its two equivalents pool transactions were proposed. Then, a model based on Shapley value was designed to allocate the power system loss in the framework of equivalent pool transactions. The Shapley solution in cooperative game theory was employed to allocate the power system loss to each load pool transaction that includes the equivalent ones. The proposed method is applicable for electricity markets containing pool and bilateral transactions. It satisfies electric circuit laws and provides economic signals to users. The effectiveness of the proposed method is verified by the IEEE 5-bus test system.

Introduction

The current electricity market transaction model is divided into bilateral trading pattern and associated trading pattern. Other hybrid models are the expansion combined by bilateral and associated trade transactions. The transmission loss produced by all transactions in the system may account 5%-10% of the total generation [1]. Therefore, a fair and reasonable method to allocate the power loss is a problem cannot be ignored, but no method is widely accepted by now.

So far, many methods of power system loss allocation have been put forward. Using marginal cost theory in economics, a method based on marginal loss coefficient to allocate the network loss has been raised [2]. To solve the problem that marginal loss coefficient method cannot guarantee that the actual allocation of power system loss equal to the real allocation, paper [3] came up with a proportional method to adjust the unbalance. Paper [4] proves that node reactive power impacts the allocation result. The method based on marginal loss provides economic signals, but the different setting of slack bus lead to result divergence. Besides, this kind of methods is too sensitive to system data, and the result is also lack of feasibility and transparency [5]. In recent years, the concept of game theory are brought to power system, some researchers use game theory to solve the problem of loss allocation. Paper [6] proposes an approach of transmission cost allocation based on the Shapley Value, and paper [7] apply this method to system loss allocation. This approach can solve the problem that the allocation may lead to different results due to different sequences joining in the network, and it may also provide economic excitation signals. Paper [8] brings another method in cooperative game theory – Nucleolus. On a bilateral transaction mode, the result of system loss allocation is fair and effective. When the market consists of different types of patterns, paper [9] transforms bilateral trades into associated trades, and calculates the fixed transmission cost allocation using Nucleolus method.

Equivalent From Bilateral Transaction To Associated Transaction

In bilateral transaction mode, generators sign contracts directly with users and determine the trading volume and price. In associated transaction mode, the trades between generators and users transit through the power pool. Although at economic level, the two modes are different, in the physical level, all of electric power is generated by power plants, and conveyed to the users by

transmission network. Therefore, we can believe that both bilateral transaction and associated transaction can be treated as equal to the electric power flowing through the power grid.

Suppose generators at node i provide power P_{ij} to users at node j according to a bilateral contract stipulation, from the network point of view, the actual effect of the physical processes is to increase power P_{ij} in at node i and power P_{ij} out at node j. If thegenerating capacity of the original associated transaction at node i is G_i and the load capacity at node j is D_j, the value of generating capacity at node i and load capacity at node j after the equivalence from bilateral transaction to associated transaction are as follow:

$$G_i' = G_i + P_{ij}, D_j' = D_j + P_{ij}$$

Generators and users are the subscribers of the entire network. The essence of any transaction mode is power transmission from generators to users. Although on a bilateral transaction mode, the specific relationship between generators and users is clear, the order to join the network may lead to different net loss due to the presence of the cross item. The equivalent from bilateral transaction to associated transaction and allocation to each transaction is a more equitable allocation plan.

Power Loss Allocation Method Based On Shapley Value

Cooperative Game Theory

Cooperative game theory is an effective mathematical model that addresses benefits sharing issues in multi-party coordinating situations. If a problem deals with n (n>1) participants, they have the possibility to make an alliance, and all members of the league (the players) will take joint actions through full consultation in order to maximize the league benefit. It is the cooperative game of n participants.

A variety of methods can be used to solve cooperative game, such as the nucleolus, the nuclear, the bargaining sets, Shapley value, etc. Shapley value is used to solve the loss allocation problem.

Shapley Value Solution

Shapley value is a solution concept introduced by American researcher Shapley in 1953. Shapley value allocates the union total revenue by each player's marginal contribution to the alliance, which can ensure the fairness of the approach.

The Shapley value can be calculated by

$$\Phi_i(v) = \sum_{S:i\in S} \frac{(n-|S|)!(|S|-1)!}{n!} \times [v(S) - v(S-\{i\})], \quad i = 1,2,...,n \qquad S \subset I$$

where S represents all the coalitions containing participant i; $|S|$ is the number of transactions in coalition S; n is the number of transactions taking part in the allocation; $v(S)$ represents the function of coalition S; S-$\{i\}$ represents removing the player i from coalition S; $v(S)$-$v(S$-$\{i\})$ represents the contribution player i accedes to coalition S, namely, $v(S)$-$v(S$-$\{i\})$ is marginal profit of coalition S.

Power Loss Allocation Based On Shapley Value

Suppose in a regional electricity market, there are M bilateral transactions and N associated transactions. All bilateral transactions should be changed to associated transactions at certain nodes first. Then the equivalent associated transactions is now $n=M+N$, namely, there are n participants taking part in the loss allocation. Using Shapley value method to allocate the power loss to n transactions, the steps are as follows:1) List all the associations S of the transaction alliance. For n players, there are 2^{n-1} transaction associations.2) Calculate the active power loss $P_{Loss}(S)$ in each transaction association S.3) Calculate different Shapley value $\Phi_i(P_{Loss})$ for transaction i using Shapley value formula. $\Phi_i(P_{Loss})$ is the active power loss for transaction i. To calculate reactive power loss, replace all the $P_{Loss}(S)$ of the steps above to $Q_{Loss}(S)$. The result is reactive power loss for transaction i.

Numerical Examples

The diagram of the 5-bus power system is shown in Fig. 1. Two generators and five loads exist in the system. The branch parameters of the system are given in table 1.

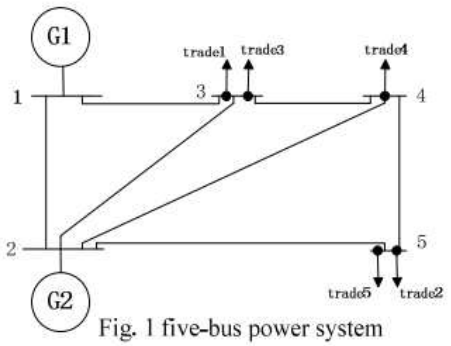

Fig. 1 five-bus power system

Tab. 1 Five-bus power system parameters of lines

Start Node	End Node	R/p.u.	X/p.u.	B/p.u.
1	2	0.02	0.06	0.0
1	3	0.08	0.24	0.0
2	3	0.06	0.18	0.0
2	4	0.02	0.18	0.0
2	5	0.08	0.12	0.0
3	4	0.01	0.03	0.0
4	5	0.03	0.24	0.0

There are five transactions in this market. Transaction 1 and 2 are bilateral transactions; transaction 3, 4 and 5 are associated transactions (pool transaction). The transaction data are given in table 2.

Tab. 2 Five-bus power system date of transaction

Trans No.	User	Supplier	Transaction Quantity	
			P/MW	Q/MVar
1	3	1	30	18.59
2	5	2	60	37.18
3	3	Pool	37.5	23.24
4	4	Pool	60	37.18
5	5	Pool	30	18.59

Tab. 4 Results of loss allocation

Trans No.	Active Power Loss /MW
1	1.0374
2	4.1086
3	1.2924
4	2.1688
5	2.1140
Total	10.7212

First the two bilateral transactions are equated to pool transactions. At node 1 there are *(30+j18.59) MVA* generating capacity increase, and node 2 *(60+j37.18) MVA*. At node 3 there are *(30+j18.59) MVA* load increase, and node 5 *(60+j37.18) MVA*. The whole system is equivalent to a regional power market with five pool transactions.

Computing the optimal power flow on the condition of minimum network loss using PSASP software, so each network loss of the transaction combinations is available. Only active power loss data are shown in table 3.

Tab. 3 Network losses of five-bus power system

Transaction Combination	Active Power Loss/MW	Transaction Combination	Active Power Loss/MW	Transaction Combination	Active Power Loss/MW	Transaction Combination	Active Power Loss/MW
1	0.1653	1&5	0.8056	1&2&4	4.7607	2&4&5	6.8531
2	1.8601	2&3	2.6462	1&2&5	5.2542	3&4&5	2.7847
3	0.2602	2&4	3.6089	1&3&4	2.7027	1&2&3&4	6.8013
4	0.622	2&5	4.4088	1&3&5	1.774	1&2&3&5	6.8629
5	0.4392	3&4	1.5285	1&4&5	2.4973	1&2&4&5	8.2925
1&2	2.4413	3&5	0.9523	2&3&4	5.1134	1&3&4&5	4.2001
1&3	0.8667	4&5	1.5966	2&3&5	5.5252	2&3&4&5	8.7201
1&4	1.2992	1&2&3	3.7091				

The loss transaction 1 should undertake using Shapley value is calculated by

$$\Phi_1(P_{Loss}) = \frac{4!\times 0!}{5!}P(1) + \frac{3!\times 1!}{5!}\{[P(1,2)-P(2)]+[P(1,3)-P(3)]+[P(1,4)-P(4)]+[P(1,5)-P(5)]\}+$$
$$\frac{2!\times 2!}{5!}\{[P(1,2,3)-P(2,3)]+[P(1,2,4)-P(2,4)]+[P(1,2,5)-P(2,5)]+[P(1,3,4)-P(3,4)]$$
$$+[P(1,3,5)-P(3,5)]+[P(1,4,5)-P(4,5)]\}+\frac{1!\times 3!}{5!}\{[P(1,2,3,4)-P(2,3,4)]+[P(1,2,3,5)-P(2,3,5)]$$
$$+[P(1,3,4,5)-P(3,4,5)]+[P(1,2,4,5)-P(2,4,5)]\}+\frac{0!\times 4!}{5!}[P(1,2,3,4,5)-P(2,3,4,5)]$$
$$=1.0374(MW)$$

Similarly, loss the rest transactions should bear can be calculated. The result is shown in table 4.

The allocation result shows that whether individual transaction or transaction coalition as well as the whole allocation, the result of the allocation method is rational. The reasons are as follow:1) The loss allocation result for individual transaction is greater than the loss of certain transaction working in the system alone. 2) For any of the transaction coalition, the sum of the loss allocation to every coalition member is greater than the loss of the transaction coalition. Because of the presence of cross item, the result is reasonable and capable of being accepted by the coalition member.3) For the power network of the entire region, the sum of all loss allocation to transaction coalitions is equal to the total loss of the major league. The loss allocation is consistent with the real loss.

Conclusion

Based on cooperative game theory, a novel Shapley value theory-based method for power loss allocation under hybrid transaction modes is introduced. With the method, the physical route of the transactions can be recognized, and sequences of transactions acceding to coalition are taken into consideration. Moreover, the impacts of different market participants on network power losses are also taken into consideration.

The idea of equivalent from bilateral transactions toassociated transactions considers the whole regional power market as an entirety formodeling and analysis. So the results are convincing.

In addition, after calculating the loss allocation, whether the results need to be fixed for bilateral transactions and associated transactions is under discussion.

Keywords: Mengxi UHVDC; Energy Demand; Power Flow; Access Point;

Abstract. A province in the central China faces the problem of energy shortage, 800kV Mengxi UHVDC project will effectively broaden the energy input channels of the province, enhance energy supply security, and reduce the pressure on coal transportation. This paper analyses the load, power supply and power shortage of a central province, and explored the role of Mengxi UHVDC project played in improving the energy demand in the Central China power grid. By comparing the different access plans to the grid, this paper demonstrated that it's more appropriate to divide the Mengxi UHVDC into 1000kV and 500kV at the inverter side for consuming the power of UHVDC and protecting the normal power supply.

Introduction

Hydropower resources have been fully developed in a central province. Backup power supply of thermal power has been less, and subject to coal supply. So far, the installed capacity of wind power, biomass and other new energy are small-scale. Nuclear power can't form the productive forces during the Twelfth Five-Year Plan Period [1-2]. However, the growth of installed power generation capacity, the per capital generated energy and outside delivery electric quantity in a northern province rank first in China.

The construction of Mengxi UHVDC project can well support the UHVAC project as a preparation, meet the urgent demand for the northern power resource electricity in central resource-poor province. What's more, it can also change the situation that North China grid and central China grid have remained one-way communication for a long time, enhance the level of security and stability, and improve the power transmission capacity from north to the central grid.

The placement of UHVDC project should fully consider the impact of landing position and access way on power flow, stability of the entire grid[3-7]. In article [8], it takes the 1000kV Jindongnan-Nanyang-Jingmen UHVAC project as an example to expound the Jingmen substation placement and access system solutions. In article [9], it analyzes the security and stability issues of UHVAC access of Jiangsu power grid. In article [10], it studied the Zhuzhou convert station access system solution of Xiluodu–Zhuzhou ±800kV UHVDC project from the perspective of geography, economy and so on. This article attempts to explore the access plan to the central province of Mengxi UHVDC project from the perspective of consuming the power flow.

An analysis of energy demand in Central China Power Grid

Figure 1 is a schematic diagram of the grid structure in a central province. In order to analyze the power flow conveniently, this paper divides the province into three regions - east, west and northwest.

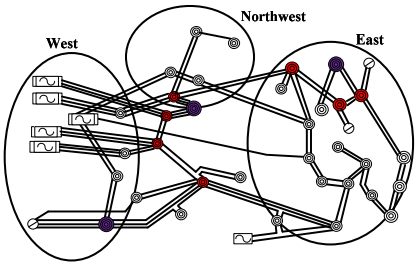

Fig.1 The schematic diagram of the grid structure in a certain central province

The electric power receiving space of the three regions is shown by Table 1. Loads are concentrated in East region, where the electric power receiving space account for more than 50% of the province's electricity demand. West is the power supply concentrated area; while the northwest is mountainous, and the load base is low. According to the results of load forecasting in Table 2, the electric power balance calculation result is shown in Table 3.

Tab.1 The electric power receiving space of the central province (Unit: million kw)

province	2015 wet	2015 dry	2020 wet	2020 dry
	810	950	2270	2230

Role that Mengxi UHVDC project plays in improving energy demand in Central China Power Grid

Mengxi UHVDC project is the need for the energy development strategy in Central China Power Grid

The energy resources and its impact on electricity production

Less coal, less oil and less gas, these are the energy status of the province [3]. Hydropower resources development rate is over 90%, and the potential for further development is relatively limited [2-3]. Energy external dependency is higher .

Due to less resources and high load from Table 3, it indicates that the province's largest electricity shortfall is 900 million kilowatts in 2015, and by 2020, it will be up to 22.5 million kilowatts. So the province has to accept the transferred electricity from other province to keep co-ordination of supply and demand.

The solution of electricity shortfall

From Table 2, the load develops rapidly during the Twelfth Five-Year Plan Period. In 2015, the unified schedule maximum load will reach to 33.6 million kilowatts, while the average annual growth rate of electricity consumption will be 10.7%. With the economic development, electricity demand is bigger in the future. It must input a lot of energy from outside when the province is in the absence of sufficient resources.

(1) Import coal for power generation from other provinces. Input the coal from outside the province in long distance and large capability, will not only cause an increase in the cost of electricity production, but also bring a tremendous risk to the power supply in the province.

(2) Actively fight for the electricity share of the Three Gorges Dam. The electricity share allocated to the province by the Three Gorges Dam is only about 15%.

(3) Develop nuclear power. Development of nuclear power is not only the objective requirements to optimize the energy structure and safeguarding the economic and social sustainable development, but also is the requirement of adjusting structure of power source.

(4) Accept electricity from other province on a large scale. The province has achieved grid interconnection and exchange with some provinces through the AC lines.

From the above analysis, it indicates that under the condition of increasing pressure on coal transportation and limited ecological carrying capacity, except for optimizing the structure of power source on the basis of consuming hydropower in the priority, exploring sources of renewable energy, and developing the nuclear power, the most effective way to solve the electricity shortfall is to embrace electricity from other provinces on a large scale.

Mengxi UHVDC project is the guarantee of the grid's security and stability

The grid of the province is the center of the national grid, and become a hub and a trafficking corridor of optimizing allocation of resources between the three gorges hydropower station, the northern coal-fired power, and the southwest hydropower. Grid security is mattered [3]. North and Central grid still remains single transmission line connected by UHVAC project, once surrounding provinces emerge a big load shedding incidents, it will endanger the safe operation of the Central China Power Grid.

In order to improve the reliability of power transmission, construction of Mengxi UHVDC project should be accelerated, to form a support project with UHVAC project as a preparation to meet the province's urgent needs for the northern electricity resources, and change the single contact situation between the North China power grid and Central China power grid so as to enhance the level of security and stability, and improve the power transmission capacity from north to the central grid, ensure the province's energy security.

Analyze the placement of Mengxi HVDC project through Power flow

Taking 2020 as calculating level year, the largest electricity shortfall in east is about 13.8 million kilowatts, and the placement of Mengxi UHVDC project located in the east region of the province can ensure the power balance. The following discussion can be divided as two plans: access to the 1000 kv power grid and access to 500 kV power grid of Mengxi UHVDC project in 2020 wet season.

Mengxi UHVDC project access to 1000kV grid

In the abundance of hydropower, the electric power receiving space of west is 5.7 million kilowatts. Considering feeding in 2.3 million kilowatts of hydropower, 6.5 million kilowatts are from UHV substation, the power surplus of the west is about 3.1 million kilowatts. In the east, the electric power receiving space is about 13.8 million kilowatts, under the total consideration of 6.3 million kilowatts are from the UHV substation, 7.5 million kilowatts are from the UHVDC. the power of the eastern part is balanced. The electric power receiving space of the northwest is about 3.2 million kilowatts, and it is supplied by the surplus power of the west.

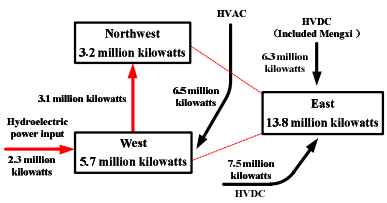

Fig.2 Mengxi UHVDC project access to 1000kV grid

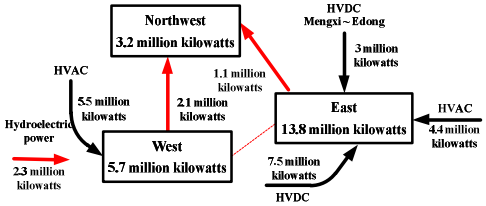

Fig.3 Mengxi UHVDC access to the 500 kV grid

Due to the Mengxi UHVDC Project access to the 1000kV grid, in order to meet the electricity demand, it needs to download large amounts of electricity from the grid before UHVAC to meet the normal power supply.

Mengxi UHVDC project access to 500kV grid

When access to 500kV grid, The electric power receiving space of west is 5.7 million kilowatts, considering feeding in 2.3 million kilowatts of hydropower, 5.5 million kilowatts are from UHV substation, the power surplus of the west is about 2.1 million kilowatts. In the east, the electric power receiving space is about 13.8 million kilowatts, under the total consideration of 4.4 million kilowatts are from the UHV substation, again 3 million kilowatts are from the UHVDC. the surplus electricity of the eastern part is about 1.1 million kilowatts. The electric power receiving space of the northwest is about 3.2 million kilowatts, and it is supplied by the surplus power of the west and east.

Based on the province's power flow analysis, the province need to download a lot of power from the UHVAC grid to meet the province's the normal power need when Mengxi UHVDC project access to 1000kV grid, and the AC UHV variable capacitance load ratio of the province is as low as 1.34. However when it access to 500kV grid, it is more appropriate to directly consume the power of UHVDC grid and protect the province's normal power supply.

According to the preliminary plans, Mengxi UHVDC project should access to 1000kV grid. However, the province's electricity shortfall will be more than 22 million kilowatts by 2020, at that time it needs to accept the external power to meet load demand. It it is bound to squeeze the main transformer capacity of UHV substation when Mengxi UHVDC electricity is consumed. Therefore, Mengxi UHVDC inverter side should be divided to 1000kV grid and 500kV grid to safeguard the security and stability.

Program analysis of Mengxi UHVDC project access system

Based on the power flow analysis, this paper proposes two 500kV access programs: two of the Mengxi DC outlets connect to the substation C and the other two DC outlets connect to the substation E; Mengxi DC outlets connect to the system by dual-π type from substation D-substation E with double-circuit line. The mode of connection is shown in Figure 4, 5.

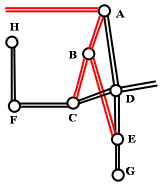

Fig.4 Wiring diagram of option 1

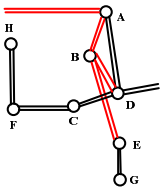

Fig.5 Wiring diagram of option 2

Option one and option two all access Mengxi UHVDC to the east power grid. Option one can reduce the pressure on evacuating the power flow from substation D ~ substation E to make the power flow of the east more reasonable. By analyzing, the short circuit current of substation C, substation D, and substation F will become overload in 2018. So this paper recommends option 1 and suggests disconnecting the double lines of substation C-substation D, use low-end access system of Mengxi UHVDC project to form the ring network of east.

Conclusions

The most effective solution to solve the electricity and resource shortfall is to input electricity from other province on a large scale. It also suggests continuing to enhance the size of the province's power grid interconnection with the grid outside the area, and improve the ability to accept power outside the region.

Mengxi UHVDC project access to the central province will bring new challenges. On one hand, it will solve the electricity shortfall effectively form a "strong DC-AC grid" with the UHVAC power grid project to meet the provincial demand for the power resources in the north. On the other hand, it can change the one-way communication situation between the north grid and central grid.

After a comprehensive analysis, this paper preliminary recommends Mengxi UHVDC invert side should have 1000kV and 500kV high-low side access options, high-end access to substation A, and the low-end side has four outlets - two access to substation C, other two access to substation E. By then the central grid will enter a new phase of DC outgoing, fed coexist and AC-DC hybrid. It creates the condition that the central province can consume the power delivered from the north province.

Keywords: wavefront identification, Harris Corner Detector, traveling wave, fault location, waveshape

Abstract. Wavefront identification is important for traveling based fault location. In order to improve its reliability, a novel wavefront identification method based on Harris corner detector has been proposed in this paper. The principle of single-ended traveling wave fault location was briefly introduced at first, and the features of wavefronts generated by faults on transmission lines were analyzed. The arrival of traveling waves' wavefronts is considered as corner points in digital image of waveshape. The corner points can be extracted precisely by Harris corner detector, and both false corner points and non-fault caused disturbance can be eliminated according to the calculated distance between two neighbour corner points and the angle of the corner point. The proposed method is proved feasible and effective by digital simulated test.

Introduction

Accurate fault location technique is essential for speeding up the determination of transmission line's trouble and restoration of power supply, and has been always attracted many studies for decades [1]. Traveling wave fault location technique has the advantage of high theoretical accuracy, immune to power swings and CT saturation, intensive to various fault conditions. Reliable detection of the available traveling wave forefront is the key technology for traveling based fault location. Many research works have been dong and many signal processing methods such as difference, correlation, matched filtering and wavelet transform have been applied in wavefront identification [2]. Nevertheless, it is still difficult to detect and identify fault reflected wave effectively and reliably at present, and this makes single-ended method difficult to be implemented automatically. In this paper, from the perspective of digital waveshape image processing, a new wavefront identification method is proposed, and is proved feasible and effective by digital simulated data test.

Feature analysis of wavefronts for single-ended traveling wave fault location

Single-ended traveling wave fault location calculates the fault distance according to the time required for the fault generated traveling wave traveling from the bus to the fault position and back, as is shown in Fig.1. The equation of computation is shown as Eq.1 [1].

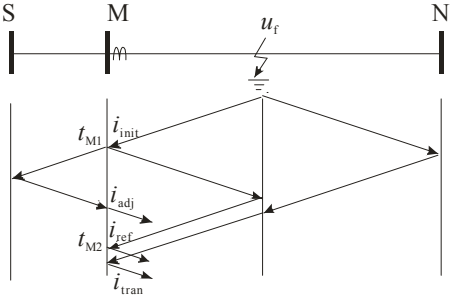

Fig.1 Lattice diagram for the propagation of the fault induced traveling waves

$$x_{\mathrm{M}} = \Delta t_{\mathrm{M1}} v / 2 = (t_{\mathrm{M2}} - t_{\mathrm{M1}}) v / 2 \tag{1}$$

where, t_{M1} and t_{M2} is the arrival time of the initial surge and the reflection wave from the fault point at terminal M; v is the velocity of propagation for traveling waves.

When a fault occurs on the transmission line, the transient current travelling wave recording device equipped at M busbar terminal senses four kinds of surges: initial surge, reflection waves from the fault point, transmitted waves from remote busbar reflection and reflected waves from the end of adjacent healthy line, as is shown in Fig.1. The derivation of the four kinds of traveling waves produce the expressions as is shown in Eq2~Eq5 [3]:

$$i_{\mathrm{init}} = (-1 + \beta_{\mathrm{M}}) e^{-\gamma x} u_f / (Z_{\mathrm{C}} + 2R_f) \tag{2}$$

$$i_{\mathrm{ref}} = (-1 + \beta_{\mathrm{M}}) \beta_{\mathrm{M}} \beta_f e^{-3\gamma x} u_f / (Z_{\mathrm{C}} + 2R_f) \tag{3}$$

$$i_{\mathrm{tran}} = (-1 + \beta_{\mathrm{M}}) \beta_{\mathrm{N}} \alpha_f e^{-\gamma(2l - x)} u_f / (Z_{\mathrm{C}} + 2R_f) \tag{4}$$

$$i_{\mathrm{adj}} = \alpha_{\mathrm{M}}^2 \beta_{\mathrm{K}} e^{-\gamma(x + 2l_K)} u_f / (Z_{\mathrm{C}} + 2R_f) \tag{5}$$

where u_f represents the initial faulted voltage source in superimposed network, l represents the length of faulted line MN, x represents the distance between fault point and monitored busbar, l_{K} represents the line length of shortest line connected with busbar, R_{f} represents the fault resistance， α_{M}, β_{M}, α_f, β_f, separately represents the voltage transmission and reflection coefficient at busbar M and fault point, γ, Z_{c} represents the attenuation and surge impendence of the line.

When traveling waves arrives at the mointored bus, the observed signal changes sharply. Thus, wavefronts of traveling waves can be represented by the corner points on digital image of waveshape. The busbar of critical substation equipped with transient current traveling wave recorders can be considered as a rich node, and this multi-line connection feature determines the polarity differ between the reflection waves from fault point and refraction waves of remote busbar, and also determines the low amplitude of disturbance caused by reflection waves from end of the healthy lines [3]. Therefore, the subsequent surges reflected from faulted point presents the regular change in amplitude and slope attenuation, this makes the distinction of fault reflection waves can be realized via extracting the corner points which meets certain constraint of angle and amplitude.

Harris corner detector

Harris corner detector is based on the local auto-correlation function of a signal, where the local auto-correlation function measures the local changes of the signal with patches shifted by a small amount in different directions [4]. It has strong invariance to rotation, illumination variation and image noise. The principle of Harris corner detector is stated as follow.

For a digital image I, given a shift (u,v), the auto-correlation function is defined as Eq.6.

$$E(u,v) = \sum_{x,y} w(x,y) \left[I(x+u, y+v) - I(x,y) \right]^2 \tag{6}$$

By approximating the shifted image using Taylor expansion, the function can be described as Eq.7 and Eq.8.

$$E(u,v) \simeq [u,v] \boldsymbol{M} \begin{bmatrix} u \\ v \end{bmatrix} \tag{7}$$

$$\boldsymbol{M} = \sum_{x,y} w(x,y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \tag{8}$$

where, $w(x,y)$ is the Gaussian window; I_x and I_y denotes the partial derivatives in x and y; Matrix $\boldsymbol{M}$ represents the intensity structure of the local neighborhood.

Invariant description can be made according to the eigenvalues of matrix $\boldsymbol{M}$. If both eigenvalues have large positive values, that is, the local autocorrelation function is sharply peaked, then shifts in any direction will increase, thus it means a corner is determined.

In order to avoid the direct computation of eigenvalues of $\boldsymbol{M}$, the cornerness measure is usually implemented as Eq.9.

$$R = \det(\boldsymbol{M}) - k\,\mathrm{trace}^2(\boldsymbol{M}) \tag{9}$$

where, $\det(\boldsymbol{M}) = \lambda_1\lambda_2$; $\mathrm{trace}(\boldsymbol{M}) = \lambda_1 + \lambda_2$; k stands for empirical constant, usually k=0.04~0.15.

Identification of wavefronts based on Harris corner detector

As analyzed before, when traveling wave arrives at the mointered bus, the obvious corner point occurs in the waveshpe. The wavefronts identification in traveling wave fault location can be considered as the detection of corner points on digital image of waveshape, and the corners can be judged by the cornerness measure. However, threshold must be set properly, in order to avoid the detection of false corners which may have a relatively large cornerness value due to noise. Considering the analyzed feature of attenuation in amplitude and slope of the successive waves, additional rules can be formed to eliminate the false corner points and preserve the corners related with initial surge and fault reflection waves. On the basis of this concept, the proposed method is composed by 3 procedures: pretreatment, Harris corner detection, and false corner points elimination.

Pretreatment. Select the faulty phase current and display the waveform in experienced window. The length of the displayed data can be determined according to the time interval of the wave propagates 5 times length of the faulty line. Flip the waveshape if the value of first surge peak is negative, in order to keep the slope of the initial surge always positive.

Harris corner detection. Form the primary corner points set via computing the cornerness measure by using Eq.9, and then calculate the distance and slope between each adjacent corner points.

False corner points elimination. Consider the fact that the initial surge has the strongest amplitude and steepest slope, elimination is implemented with following constraints: i) Length constraint. Preserve the corners of which the distance between two adjacent corners is exceeding the threshold. ii) Slope constraint. Eliminate the successive corners which are steeper than slope of initial surge, preserve the corners of which the angle is close to the initial surge. And then the set of the corner points ordered by horizontal coordinate of the points is finally formed.

Result and discussion

Taking a 220kV transmission system model in PSCAD/EMTDC shown in Fig.2 as an example, The length of the line MN is 100km. The frequency-dependent transmission line model is used and both calculation step and sampling step in simulation are set as 1μs.

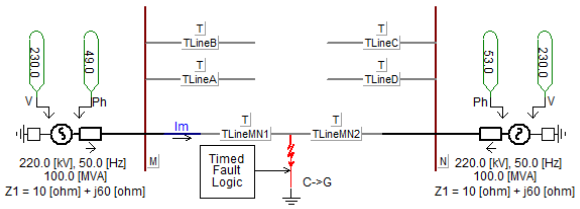

Fig.2 Diagram of simulated 220kV transmission systems in PSCAD/EMTDC

When a C-g fault occurs on the line MN 20km from the bus M, the simulated waveform of each phase current is shown in Fig.3a, and the faulty phase traveling wave current displayed in empirical window is shown in Fig.3b. By implementing Harris corner detection, 19 corner points was detected primarily, as is shown in Fig.4a. And 5 corner points was finally determined by performing false corner points elimination, according to the constraint of the length and slope between two neighbor corner points, as is shown in Fig.4b.

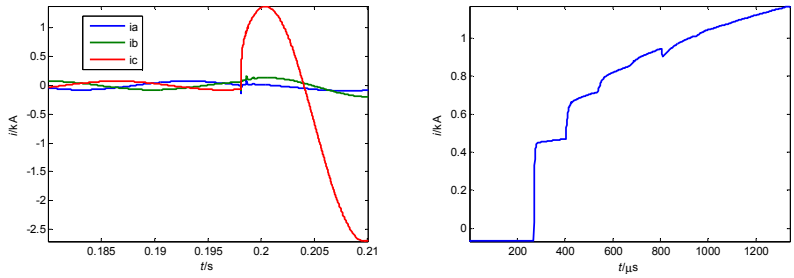

Fig.3: (a) Each phase current in large window (b) Faulty traveling wave current in emprical window

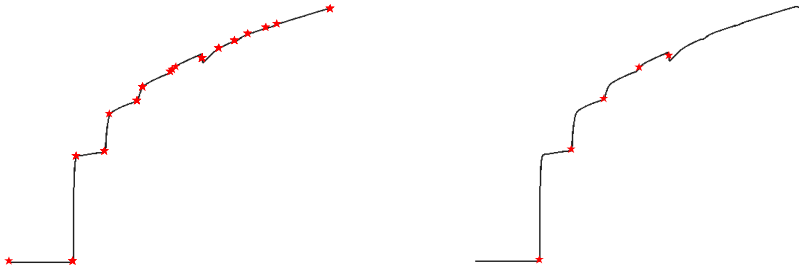

Fig.4: (a) Result of primary corner detection (b) Final result after false corner points elimination

The horizontal pixel of 5 detective corner points is 342,434,527,629,717. The total horizontal pixel of the waveshape is 930, and the total sample data of the wave shape is 1341. Convert the first interval between the two corner points into real time interval: Δt_{M1}=(434-342)/930*1341=132.66μs. Substituing Δt_{M1} and v=0.298km/μs into Eq.1, the calculated fault distance is 19.77km, which is highly close to the 20km simulated fault condition.

Conclusions

Multi-line connection feature determines the polarity differ between the reflection from fault point and refraction of remote busbar, and also determines the low amplitude of disturbance waves caused by refraction from healthy lines. Arrival of traveling waves' wavefronts can be represented by the corner points on digital image of waveshape, and the identification of wavefronts can be implemented by piecisely extracted the corner points via Harris corner detection. False corner points and disturbance waves can be eliminated according to the calculated distance between two neighbour corner points and the angle of the corner point. Digital simulation test shows that the result of fault location is available and reliable according to the wavefronts identified by the proposed method.

Keywords: Medium-frequency furnace. Rectifier circuit. Inverter circuit. Pulse Width Modulation(PWM) .

Abstract. The work process of medium-frequency power supply is complicated .Its waveform is complex and can not be measured conveniently. Therefore,This paper focuses on the analysis of operating principles and control methods of medium- frequency power supply, to determine its basic structural units.A simulation model of medium-frequency power supply which is controlled by pulse width modulation(PWM) is built with the electromagnetic transient analysis software PSCAD. The simulation and analysis of the medium-frequency power supply circuit are performed on the basis of the model.The simulation waveform can reflect the working process of medium-frequency power supply accurately. So this paper will provide a reliable basis for further research of medium-frequency furnace.

Introduction

In recent years, medium-frequency furnace is widely used in metallurgy, iron and steel industries .Modern and large-scale medium-frequency furnaces, because of its large capacity and high power consumption, have great influence on the electric net-work, especially in generating harmonics, voltage fluctuations and flicker. In addition to affecting stable operation of the thyristor devices and precision instruments, it will also endanger power distribution and a large number of users and itself yield and quality.

Accurate analysis of the electromagnetic working process of medium-frequency furnace is critical to solve a series of power quality problems which are caused by medium-frequency furnace. It also play an important part in analysis and control of power system. Therefore, this paper analyzes the working principle of medium frequency power supply in detail and establish an accurate medium-frequency power supply model. This model will provides a frame of reference for future research.

Medium-frequency Power Supply

Medium-frequency furnace is a "AC - DC - AC" frequency conversion equipment, medium-frequency power supply is a core part of the furnace. firstly, the rectifier circuit of medium-frequency power supply make the three-phase AC voltage which frequency is 50 HZ into a DC voltage. Then, using the smoothing filter to filter out clutter. At last, the DC voltage will be converted into medium-frequency voltage by inverter circuit. Generally ,the frequency of output power is $150 \sim 10000$HZ . The medium-frequency current is flowing though the metal ,at the same time ,electromagnetic induction is generated in internal of metal which will Heat and melt metal.

2.1 Circuit of rectifier and filter

The rectifier circuit of medium-frequency power supply generally adopts three-phase fully-controlled bridge rectifier circuit, which has many advantages ,such as high output voltage and small ripple, high frequency of ripple and fast dynamic response. So the rectifier circuit can help get smooth DC voltage. The three-phase AC voltage(50HZ) will be rectifier into a smooth DC voltage. Then , the DC voltage will be more smooth through the filter reactor. Filter reactor can not

only play the role of gentle pulsating DC voltage, can also have the effect of isolating interference and Impact resistance. When the inverter failed, filter reactor will resist the impact of the surge current and reduce impact damage to the internal circuit device .

The output voltage of three-phase fully-controlled bridge rectifier circuit,as follows:

$$U_d = 2.34 \times U_2 \times \cos\alpha \tag{1}$$

In the formula, U_d :Output DC voltage average; U_2 :Grid phase voltage; α : Trigger phase angle.

2.2 Serial inverting circuit

Generally ,the inverter circuit of medium-frequency power supply is single-phase full-bridge inverting circuit. In this paper, the medium-frequency power supply uses single-phase serial inverting circuit. Its inverter circuit and load circuit is in series form. The load of Inverter circuit can be thought of as L, R, C oscillation circuit, L for inductance oven's inductive coil , R for resistance (usually very small), C for compensating capacitance. Its natural frequency of the load circuit is f_0 , $f_0 \approx 1/2\pi\sqrt{LC}$ .The working frequency of the inverter circuit is higher than the inherent frequency of the load. The load is of low impendence to high frequency harmonic current which is existed in input medium-frequency trapezoidal current. But, it is of high impendence to medium-frequency harmonic current so that the output voltage is close to sine wave. The relationship between the load voltage and output DC voltage as follows: $U_L = 1.11 \times \frac{U_d}{\cos\varphi}$, φ for the load power factor angle.

Simulation Model Based on PSCAD

On the basis of above analysis, medium-frequency power supply model is established in PSCAD, which rectifier circuit is six-pulse rectifier , as shown in Fig. 1.The left part is rectifier circuit, which change three-phase electric power into DC voltage Udc and DC current Idc. The right part is inverting circuit, which change DC voltage Udc2 into AC voltage U0.

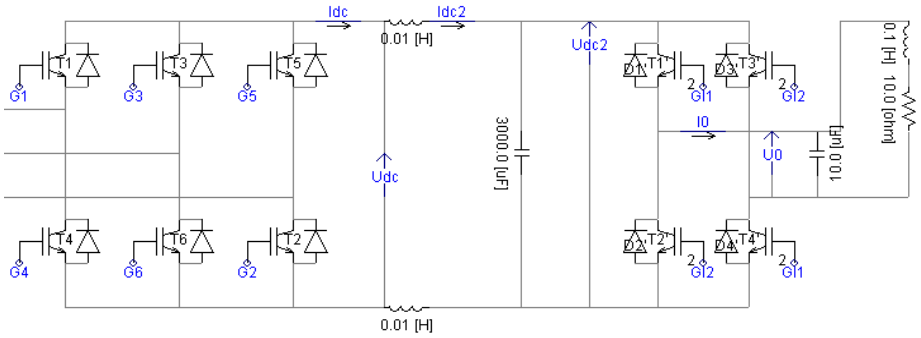

Figure 1. Simulation model of medium-frequency power supply

3.1 Simulation Model of rectifier circuit

The rectifier adopts six-pulse rectifier circuit and three-phase fully-controlled bridge rectifier. The bridge arms are form of serial full-control insulated gate bipolar transistor (IGBT) .IGBT can easily control the current on and off, so the converter bridge has the ability to turn off automatically. IGBT thyristor use default Settings.

The control circuit of rectifier adopts pulse width modulation(PWM) technology to control thyristor on and off .The park transformation converts input three-phase voltage equation into the model in a synchronously rotating reference frame, to realize the decoupling control of active power and reactive power. PWM pulse generating circuit is shown in Fig. 2.

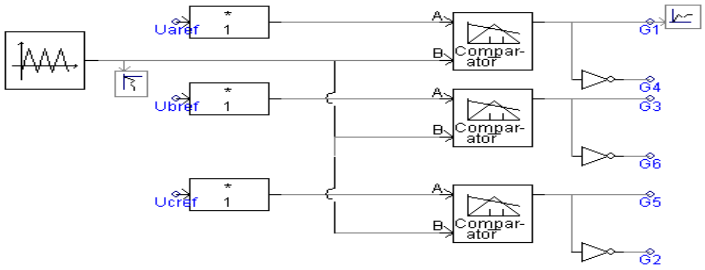

Figure 2. Pulse generating circuit

G1 and G4 are different control signals whose angle are difference of 180 degrees. They control VT1 and VT4 on and off, respectively .In the same way, the G3 and G6, G5 and G2 are two pairs of opposite control signals. The function of these control signals is to control trigger of the six thyristor according to the order of the 1-2-3-4-5-6 cycle. These opposite signals can guarantee that there is a thyristor conductive both in the group of common cathode and anode at the same time, to ensure that the circuit of the load and power supply are always keep open. Below for each other instead of G1 and G4 pulse signal.

Setting the AC line voltage is 380V and frequency is 50 HZ.AC current change into DC voltage though the rectifier circuit. The output DC current waveform is shown in Fig.3.

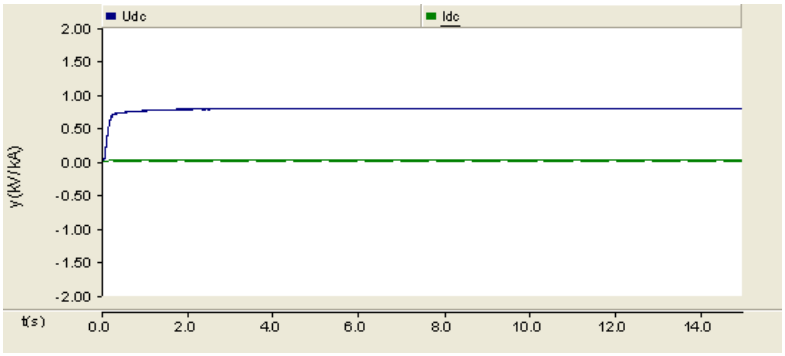

Figure 3. DC power waveforms

From the simulation results we can see that rectifier circuit convert sinusoidal AC voltage and sinusoidal AC current into DC voltage and DC current.The designed rectifier has fulfilled expected operation process successfully and got the eligible output waveform. The designed rectifier and control method is verified correctly.

3.2 Simulation model of inverting circuit

The inverter circuit of medium-frequency power supply is composed of four IGBT thyristors. $VT_1 \sim VT_4$ are controlled by two pairs of opposite control signals .So the frequency of the PWM signal is the work frequency of the inverter circuit.Changing the frequency of the PWM signal can control the frequency of load voltage waveform of medium-frequency furnace. Setting the frequency of the PWM control signal as 500 HZ. The output voltage waveform is shown in Fig. 4.

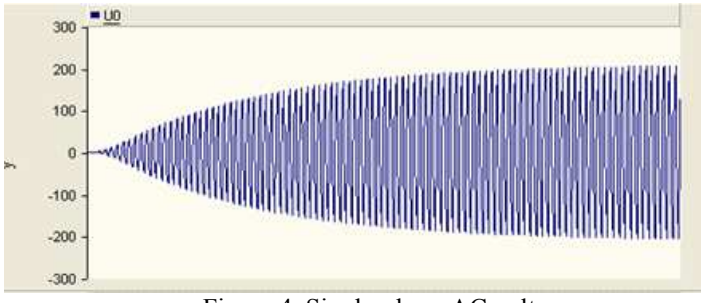

Figure 4. Single-phase AC voltage

When gate voltage on VT1'and VT4' is positive and the voltage on VT2' and VT3' is negative, the VT1' and VT4' is conductive and VT2' and VT3' is off. When VT1 'and VT4' begin to conduct ,IVT1 'and IVT4' will be a positive peak, as shown in Fig. 5. Then, the two currents is not increase gradually, but remains the same.The reason is that there is no serial inductance in inverter circuit.Similarly, when VT2 'and VT3' is off and IVT2' and IVT3 'will be a negative peak.Then the amplitude mutation to a stable value and remains the same, waiting for the arrival of the next peak.

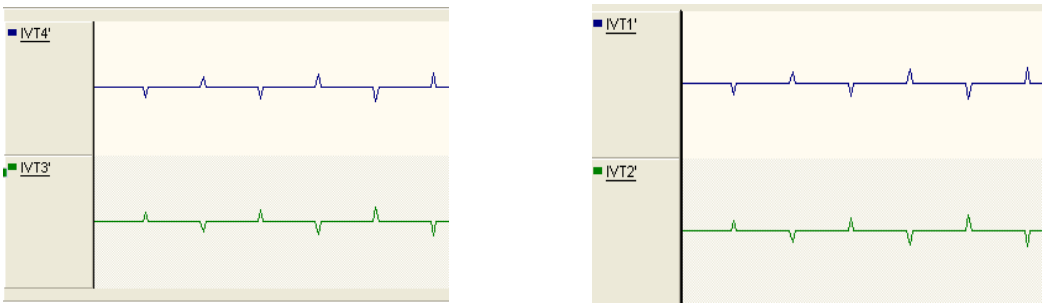

Figure 5. Current waveform of IGBT

Conclusion

In recent years, the use of medium-frequency furnace in China's metallurgy, iron and steel industries has been increasing in number and capacity.A series of power quality problems caused by medium-frequency furnace are increasingly serious.In this paper, the simulation model of six-pulse rectifier medium-frequency power supply is built in PSCAD simulation environment on the basis of analyzing the working principle of medium-frequency furnace. Simulation shows that the result is an accurate reflection of the working process of the medium-frequency power supply.It provides a reference for the later simulation and analysis of medium-frequency furnace .And it also has a certain practical significance.

Keywords: Shan-xi Province Electric Power Company, Ultra High Voltage, Operation and Maintenance

Abstract: Compared with the traditional power grid, UHV power grid has the characteristic of stronger system function, higher control requirement, and also set a higher request to the daily maintenance management. The operation and maintenance experience of Shan-xi province electric power company on the UHV power grid proved the importance of establishing the new mode of management, strengthen the application of automation technology, ensure the technology and resources guarantee. In order to improve the efficience and quality of UHV power grid operation and maintenance, we should speed up the formulation of operation guidelines for UHV live working and strengthen personnel training and reserve technical talents.

Introduction

Compared with the traditional equipment, great changes have taken place in the operation and maintenance of the UHV equipment, and those conventional methods of maintenance have been unable to meet the changes brought by new demand. At present, the operation of the UHV equipment and maintenance methods are lack of experiences in the world scope, need us to constantly explore and practice operation rules and characteristics, to achieve the upgrade of UHV operation and maintenance technology. This paper takes UHV operation practice of Shan-xi Province Electric Power Company as an example, analyzes operation characteristics of UHV power grid, summarizes experience, and puts forward the corresponding improvement measures.

Demonstration project of 1000kV Jindongnan-Nanyang-Jingmen UHV AC pilot, is China's first UHV power grid, is also the world's first commercial operation UHV transmission line. At present, Shan-xi Province Electric Power Company is responsible for operation and maintenance of 1000kV Changnan line (Shan-xi section), including a UHV electricity substation-Changzhi Substation.

Analysis of the characteristics of UHV power grid operation and maintenance

Compared with the traditional power grid, UHV power grid has the characteristic of stronger system function, higher control requirement, and also set a higher request to the daily maintenance management.

Compared with 500kV power grid, UHV power transmission system has realized bidirectional, full voltage, and high power operation, can suffer all kinds of operation tests, and shows the good dynamic operation characteristics and anti disturbance ability, its function has been enhanced significantly.

The UHV line power fluctuations will not only cause electric power wattless voltage fluctuation, occupy the stability margin, but also cause no power surging trend of nearby power grid and central point of grid voltage fluctuation, that will threat to the safe operation of UHV equipment and power grid, the impact is far from 500kV system can match, so, requirement of stability control on the UHV is much higher than that of 500kV system.

Because of bulk power transmission of UHV power line, once the fault it will have great influence on the whole power grid. For guaranteeing the safe and stable operation of UHV power grid, we must rely on deep technical supervision. If comprehensive technical supervision was adapted to the UHV equipment, we can find the problem earlier and avoid risk timely.

Main practices of Shan-xi Electric Power Company in constructing UHV power grid operation and maintenance system

1. Establish standardized management system

Since the UHV commissioning, Shan-xi Province Power Company follow the principle of "simple, practical and convenient", in accordance with the requirements of "Standardization, modularization and maneuverability", established and improved standardized work instructions of line operation, operation management standards for substation , standardized operating procedures of UHV operation, repair and test work.

2. Implement 1000kV UHV equipment support system

Investigate the hidden danger of equipments regularly. In order to ensure the quality of UHV equipment, Shan-xi Province Electric Power Company made standardized approval processes and procedures for UHV projects, implemented dynamic acceptance and technical data sampling to ensure that the UHV project operates with zero defect. Shan-xi Province Electric Power Company also carried out comprehensive, detailed equipment hidden danger investigation works, aiming to prevent blackouts, personal injury, malignant mis-operation, serious equipment damage, forced outage and so on.

Strengthen the "10+1" equipment monitoring mode. "10" refers to the 10 sets of on-line monitoring equipments, with which operation and maintenance personnel can analyze the running state of the equipment in the control room. "1" is to strengthen the off-line data analysis and management, by the regular manual oil chromatographic analysis, infrared temperature measurement, ultraviolet imaging, gas leakage detection, combined with the analysis of on-line monitoring data, Shan-xi Province Electric Power Company realized the real-time control of UHV equipment health status.

Monitor key operation data with "Hawkeye" device. With the operation data received from the background telemetry, remote, on-line monitoring and on-site inspections, Shan-xi Province Electric Power Company made key data monitoring pictures in the monitoring of the background, put the main data into a simple "Hawkeye" interface, showed the contrast of the measurement, monitoring and standard values in the monitoring interface. By setting the over limit alarm functions, Shan-xi Province Electric Power Company can guarantee the key data "do not go beyond the prescribed limit" and keep the equipment in control.

Carry out state evaluation and improve the operation efficiency. The state evaluation can be divided into regular evaluation and dynamic evaluation. Regular evaluation takes 3 months as a evaluation period, evaluates the UHV power line within the prescribed period. Dynamic evaluation is to revise the results of periodic evaluation dynamically base on the state of operation and power line protection work, so as to optimize the running state of UHV equipments.

3. Optimize 1000kV UHV operation support system

Construct a lean and efficient UHV transmission line patrol management mode. In order to adapt to the regional characteristics and technology characteristics of UHV in Shan-xi, Shan-xi Province Electric Power Company reformed the UHV patrol management mode, combined the expert field patrol and helicopter altitude patrol, established a three-dimensional(expert collaborative patrol line, the helicopter patrol line, cross Patrol) patrol management mode.

Implement the "1+3" substation equipment inspection mode. "1+3" substation equipment inspection mode means that the operation and maintenance personnel make full use of the fixed video camera system, PDA intelligent inspection system, robot intelligent inspection system and carry out a comprehensive, all-round inspection on the equipments of substation, based on regular on-site manual inspection. By this patrol mode, the daily inspection quality of the equipment can be improved.

4. Strengthen the 1000kV UHV emergency system

Establish the UHV "four in one" intensive care system. According to the principle of "cost savings and efficiency improving", Shan-xi Province Electric Power Company established the "four in one" special care system, which is composed of the operation companies, equipment manufacturers, technical supervision companies, engineering installation and construction companies. The special care system includes the normal interaction system with the construction team near the UHV transmission line, the priority supply system of emergency material with equipment factory, and the assistance mechanism of technology supervision with Shan-xi Electric Power Research Institute. By the special care system, Shan-xi Province Electric Power Company can integrate all emergency resources effectively, optimize the management of repair spare parts, and realize the emergency repair seamless docking and all-weather rapid reaction.

Create the "4+1" security system. 1000kV UHV Changzhi Substation security system is composed of "high voltage pulse electronic fence", "building and equipment access control system", "the 68 roads industrial video surveillance system", "24 security cameras" and "8 security personnels". The "4+1" security system can ensure 24 hours inspection and video without intermittent, besides that, its security cameras have the image capture function, can automatically alarm under abnormal circumstances. Such multiple means can ensure that the substation security work has no danger of anything going wrong.

Difficulties and problems in maintenance of UHV transmission line

Line environment is complex and maintenance is difficult. In southeastern of Shan-xi province, topography and micro meteorological areas are widely distributed, but special design was not applied to adopt to the significant characteristics of UHV running environment, so the equipments in UHV power grid cannot withstand natural disasters and external damage, risks of line fault caused by bad weather conditions and external damage still exists. Line construction and illegal coal-bed methane mining in 1000kV Changnan line area is increasing, especially, in the area that UHV line pass through, there are many large scale forest farm and the forest coverage rate has reached more than 40%, straw burning occurred from time to time raises the possibility of large area fire greatly, that may cause some threat to the stable operation of UHV power grid.

Lack standardized live working rules. The difficulty of live working on 1000kV UHV transmission line is the high voltage, high operational altitude and large weight of insulator string. At present, there is no live working rules for 1000kV UHV transmission line, no matter the electric field distribution, area of operation, safe distance, and the insulation of finite length, are to be determined through simulation of strict test, which cause delays and extra costs.

Conclusions

Although Shan-xi province electric power company has accumulated rich experiences in UHV power grid maintenance, but in order to improve the efficiency and quality of UHV transmission line operation, it still needs to further strengthen the construction of operation and maintenance system for UHV power system, optimize the operation management mode.

Investigate risks of UHV transmission line, revise state diagram of line channel dynamically, evaluate the line state, and determine the risk points about key time and key section. In addition, according to the seasonal characteristics, special state inspection for special areas should be organized and the state inspection should be differentiated.

Speed up the formulation of operation guidelines for UHV live working. In order to standardize the UHV power grid live working rules, standards for UHV should be developed as soon as possible, some related requirements need to be clear. Thus, we can save the operation cost, reduce the incidence of accidents in operation and improve the efficiency of maintenance.

Strengthen personnel training and reserve technical talents. With the UHV grid operation technology advances, electronic equipments will play a more important role in the operation and maintenance of UHV power grid, but the basic function of technical personnel will never change. Therefore, we should make full use of existing intelligent systems, such as robot intelligent inspection system, fixed infrared temperature measurement system, at the same time, we should pay more attention to the talent team construction, strengthen training of related professional knowledge and skills, reserve specialized personnel, aiming to meet the needs of operation and maintenance work.

Keywords: Power system reliability, security calculations, contingency analysis,simultaneous failures, combination of simultaneously failed elements,n-1 criterion, lost load damage.

Abstract. Nowadays contingency analysis being a part of a power system security calculations is a mandatory procedure for a short-term operational stage of the electrical power system (EPS). Nevertheless, there are still a lot of problems, concerning security calculations. For instance, recent studies have shown necessity to consider simultaneous failures of several power system elements during contingency analysis. This brings complexity and voluminosity of security calculations to the new level.On the one hand, analysis of all possible contingency combinations results in unreasonably high computing time. On the other hand, many contingency combinations, especially with verylarge number of simultaneously failed elements (SFE), have little impact on overall result of security estimation due to very low probability of such combinations. This paper presents novel mathematical algorithm allowing estimation of significant number of simultaneously failed elements (SNSFE). Proposed algorithm was tested on the 14-bus IEEE reliability test system. Results show adequate accuracy of the technique and also confirm the necessity to simulate simultaneous failures of several network elements.

Introduction

It is possible to point out three types of reliability, depending on the system of assumptions andapplied mathematical tool: diagram reliability (structural reliability), balance reliability (adequacy) and regime reliability (security).

In terms of structural reliability (SR), there is no failure if at least one conducting path connecting the power supplying node with the node under analysis exists [1]. In other words, it is assumed that tie capacities are unlimited. Also, security restrictions, such as voltage bounds, are ignored.Thus, diagram reliability allows analyzing reliability of power system network in general or, in other words, reliability of power system topology.

From mathematical point of view, the main goal of adequacy is to identify probabilistic characteristics (such as distributive function, frequency, expected value, variance) of power (or energy) shortage in a separated concentrated power system connected with other systems through tie lines with limited capacity [2]. Basing on these characteristics, it is possible to calculate lost load damage (LLD) expected value(EV), hence, to solve the investment problem. Therefore, balance reliability calculations are necessary to justify investments into power system.

Regime reliability (RR), in turn, defines capability of EPS to work without deviation of state parameters (SP), such as nodal voltages, power flows and thermal capacities out of permissible boundaries, after random disturbances, such as failure of transformer, power line or generator.As a result, RRaims to protect system from total outageand to minimize overall LLD EVas it will be noted further.

Security calculation problem

Security problem consists in simulation of possible failures and analysis of resulting post-contingency states. If the failure results in SP boundaries violation, in order to recover permissible SP, it is necessary to implement control actions (CA).These CA may include adjustment of transformer ratios, actual and reactive generation, and the state change of static capacitor banks, static compensators and hydro generators. In the absence of spare capacity, it is necessary to cut off

energy consumption. In this case, the optimal cutting problem is solved, according to the criterion of minimal LLD. Resulting damage, with a certain weighing coefficient defined by probability of the failure includes in EV of overall damage, which is one of the most important security indices.

As a matter of fact, RR problem results in multiple calculations of post-contingency states, where one or several elements are assumed to fail.The number of SFE depends on the calculating criterion $n-m$, where n is the total number of elements and m is the number of SFE. Global experience shows the necessity to analyze post-contingency states in accordance with $n-2$ or even $n-3$ criteria [3]. This is determined by the fact that maximum of LLD EV, generally, corresponds to 2 or 3 simultaneous failures.Recent studies have shown that in certain power systems number of analyzed SFE has to be even higher [4].

The key problem connected with the number of analyzed SFE is the extremely growing computational time.Simulation of simultaneous failures significantly complicates the security estimation procedure, due to the very rapidly increasing number of calculations. Indeed, the number of calculations increases in accordance with binomial coefficient:

$$C_n^k = \frac{n!}{k! \cdot (n-k)!}, \tag{1}$$

where$n$ is the total number of network elements, k is the number of SFE.

For instance,analysis ofpower system of a medium size containing about 100nodes and 150 branchesfor one, two and three SFEwould require 250, 31 125 and 2 573 000 computations correspondingly.

Thus, full contingency search results in impossibly high computing time. On the other hand, many contingency combinations have little impact on overall EV of LLD, due to the very low probability of such combinations. Therefore, it would be very useful to estimate significant number of SFE (SNSFE).

Significant number of simultaneously failed elements calculating technique

SNSFE value may be estimated, basing on maximum LLD criterion. EV of overall LLD is defined as follows:

$$D = \sum_{S_i \in S} \mathcal{P}_i D_i, \tag{2}$$

where $S = \{S_i\}$ is a set of all possible contingency combinations; $\mathcal{P}_i$ is the probability of combination S_i; D_i is EV of state i.

Let D^{max} is the maximum damage, corresponding to the most unfavorable combination of SFE. In this case, the following inequality is valid:

$$D < D^{max} \sum_{S_i \in S} \mathcal{P}_i. \tag{3}$$

In the idealized case, when all network elements have the same failure probability q, for instance $q = q^{max}$, each combination may be defined by the number of failed elements k. Probability of such state defines as follows:

$$\mathcal{P}_i = C_n^k q^k p^{n-k}, \tag{4}$$

whereC_n^k is binominal coefficient, defined according to eqn. (1).

Substituting of eqn. (3) to inequality (2) results in:

$$D < D^{max} \sum_{k=0}^{n} C_n^k q^k p^{n-k}. \quad (5)$$

The sum in the right part of inequality (5) may be presented as two sums, corresponding to significant and insignificant contingency sets:

$$D < D^{max} \left(\sum_{k=0}^{m} C_n^k q^k p^{n-k} + \sum_{k=m+1}^{n} C_n^k q^k p^{n-k} \right), \quad (6)$$

where$m$ is SNSFE in significant contingency set.

Inequality (6) may be presented as follows:

$$D < D^{max} \left(B(m,n,q) + \tilde{B}(m,n,q) \right) = D^{max} B(m,n,q) + \varepsilon, \quad (7)$$

where$B(m,n,q)$ is integral function of binominal distribution (IFBD); $\tilde{B}(m,n,q)$ is co-function of binominal distribution (CFBD); ε is permissible damage calculation error (PDCE).

According to inequality (7) PDCE determines as:

$$\varepsilon = D^{max} \tilde{B}(m,n,q). \quad (8)$$

Thus, permissible value of CFBD is defined as:

$$\tilde{B}(m,n,q) = \frac{\varepsilon}{D^{max}}. \quad (9)$$

Eqn. (9) allows finding SNSFE m as probability quintile, meeting eqn. (9).

Several rude assumptions, connected with LLD EV and probability of failure, have been made during development of eqn. (9). A more precise solution may be obtainediteratively.

The first approximation of maximum LLD D^{max} is calculated by the assumption that SNSFE m equals to two or three, depending on the analyzed network. This is based on the fact that, probably, maximum of LLD EV corresponds to two or three simultaneous failures. A new value of SNSFE obtained according to eqn. (9),corrects initial SNSFE and iterative calculating procedure runs again.

It's worth noting that branch failure probability is significantly higher than node failure probability. Thus, it may be reasonable to estimate SNSFE separately for nodes and branches and then find a weighted value of SNSFE, where the number of nodes (or branches) stands for the weight of node SNFSFE (branch SNSFE):

$$m = \frac{m^{nd} n^{nd} + m^{br} n^{br}}{n^{nd} + n^{br}}, \quad (10)$$

wherem^{nd} and m^{br} are the number of node and branch SNSFE correspondingly; n^{nd} and n^{br} are the number of nodes and branches in the network correspondingly.

Case study

The proposed technique was tested on the 14-bus IEEE reliability test system. Initial data was elaborated with element failure probabilities and node lost load damages. Failure probability was set to 0.01 and 0.1 for nodes and branches correspondingly. LLD for all nodes was set to 1 relative unit (r. u.). Initial approximation of SNSFE was 2.PDCE was set to 1% D^{max} and 0,1% D^{max} for branch and node calculations correspondingly. As a result, node SNSFE was 2 and branch SNSFE was

5.Weighted value of SNSFE was 3.76. Since SNSFE is calculated according to maximum criterion,fractional part of SNSFE may be ignored. Therefore, with high degree of accuracy, it is possible to say that maximum of LLD EV corresponds to 3 SFE. Since resulting SNSFE was different from the initial, second iteration was necessary. At the second iteration node SNSFE was 2 and branch SNSFE was 6. The weighted value of SNSFE was 4.35. The third iteration didn't change the resulting SNSFE. So, the final value of SNSFE was 4.

The proposed technique was verified by full contingency search. Its results are presented in table 1.

Table 1: The results of full contingency search.

Number of simultaneously failing elements	1	2	3	4	5
Lost load damage expected value,[r.u. per year]	270.98	839.21	1111.04	934.21	219.03
Computing time, [min.]	0.25	5.26	123.51	552.20	3709.87

As it is clearly seen from table 1 maximum of LLD EV corresponds to 3 SFE and SNSFE is 4. So resulting SNSFE totally corresponds to estimated SNSFE. Hence, it is possible to say that proposed technique is accurate enough.

Summary

Number of simultaneously failed elements is one of the key issues in security calculations.On the one hand, maximum of LLD EV, generally, corresponds to simultaneous failure of several power system elements. On the other hand, many contingency combinations have a little impact on overall EV of LLD, due to the very low probability of such combinations. Full contingency search results in unreasonably high computing time. This paper presents technique estimating significant number of simultaneously failed elements almost without additional computational load. The proposed technique was tested on the 14-bus IEEE reliability test system. Results show adequate accuracy of the technique and confirm the necessity to simulate simultaneous failures of network elements.

Keywords: Power factor; Voltage loop parameter; Visualization

Abstract. Build a mathematical model by using the voltage loop of UCC28019 to get open loop transfer function. And use MATLAB to obtain variable range of voltage loop parameter when system is stable, in the mean time, use system time domain performance as objective function to optimize the parameter, based on system stability. The user can get better parameters on the three-dimensional image clearly and directly, for there is no complex formula and theoretical derivation in process of optimizing. Hardware circuit experiments verify the effectiveness of the proposed method.

Introduction

Improve the effective utilization of energy and green environmental protection is the theme of this century, and power electronic devices harmonic pollution and low power factor problem get more and more attention. In this paper, a power supply which output power is 72W is designed: the input AC voltage (*Uin*) range from 20*V* to 30*V*, the output DC voltage (*Uout*) is 36*V*±0.1*V*, the power factor is above 0.97.To get high output power, we select a PFC device--UCC28019.It can obtain the unity power factor with minimal harmonic distortion and employ double closed-loop structure of the voltage and current in the internal circuit. The parameter being set appropriate or not directly determine the performance of the system. By using three-dimensional (3D)visualization algorithm towards Power Factor Correction (PFC) voltage loop periphery parameter , the design in this paper can get the distribution of concerned information and degree of difficulty won't be raised while system order improve which is intuitive, simple and practical.

Control System Analysis

Switching mode power supply based on UCC28019 includes power circuit and control circuit.The parameters of the power circuit will not be discussed here. The function and implementation mechanism of control circuit are mainly analyzed as followed.

(1)The circuit can assure input current waveform and input voltages in same phase without distortion and harmonic. There is a current loop inside UCC28019 whose duty circle can be adjusted according to period quickly and can follow the input voltage sine wave changing when work in closed-loop.

(2)The circuit can keep the output voltage constant when load current changes. Compared sampling voltage with reference voltage of the internal operational amplifier inside voltage loop, UCC28019 can ensure the output voltage as a constant by adjusting amplitude of reference current sine waveform.

(3)The difficulty of the design as well as the focus of this paper is the input voltage compensation should be variational to keep input power being equal to the output power when input voltage changes by adjusting input current RMS. If the input voltage varies in a long period, there will be a changing trend for output power. Though the external voltage control loop will compensate this change, the parameter is not a simple linear control. In order to make the loop stability, unity gain crossover frequency must be kept lower than the zero frequency in right half plane. Therefore in the compensating network, large drift of unity gain crossover frequency need a slowly fall which may produce a poor transient response. In order to compensate for this effect, a very low band-pass filter is designed in the voltage loop to compensate input voltage RMS. As a result of correspondence

between frequency domain index and time domain index, compensation device parameters of voltage loop is designed in this paper aiming at time domain performance.

Model Voltage Loop

Look up the inside structure of UCC28019 [1], the voltage loop block diagram is shown in Fig.1.

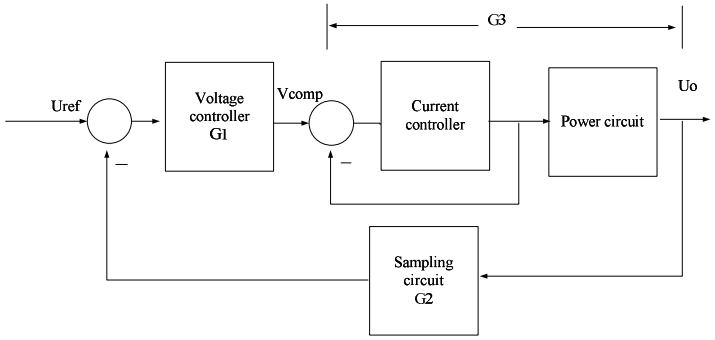

Fig.1 Voltage loop block diagram

Fig. 2 is voltage controller circuit, Fig. 3 is sampling circuit

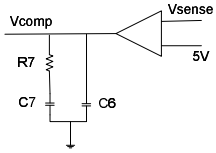

Fig.2 Voltage controller circuit

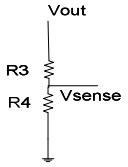

Fig.3 Sampling circuit

From Fig. 2, Fig. 3, calculate module transfer function

$$G_2 = Vsense / V_{out} = R_4 / (R_3 + R_4) = 50K / (50K + 310K) = 5/36 \quad (1)$$

$$G_1 = V_{comp} / V_{sense} = (1 + sR_7C_7)gmv / (C_6 + C_7)s(1 + sR_7C_6C_7 / (C_6 + C_7)) \quad (2)$$

gmv is a constant whose value is $42 \times 10^{-6} s$.

G3 is the inherent part of system. [1]

$$G_3 = (M_3 V_{out} / M_1 M_2) / (s / w_1 + 1) = 49.5 / (s / 10.7 + 1) \quad (3)$$

$$w_3 = K_{FQ} M_1 M_2 V_{inrms}^3 / K_1 R_2 V_{out}^3 C_{out}, M_3 = 0.512, M_1 = 0.484, M_1 M_2 = 0.372, K_1 = 7, V_{inrms} = 24, \mathrm{V}_{out} = 36$$

In order to be convenient for the analysis, here, take *Vsense* as the output of the system, then the voltage loop is unit feedback system and the open-loop transfer function is:

$$G = 6.875(1 + sR_7C_7)gmv / (s / 10.7 + 1)(C_6 + C_7)s(1 + sR_7C_6C_7 / (C_6 + C_7)) \quad (4)$$

The value of C_6 decides the length of the system boot time. Set the C_6 = 0.1 uf here.

Parameters Visualization Design

Use MATLAB to obtain variable range of voltage loop parameter when system is stable. Use time domain performance as objective function to draw 3D surface diagram and 3D contour diagram and find right parameter correspond to a nice system performance from diagram conveniently and directly. Parameter *R7, C7*optimization program block diagram is shown in Fig.4.

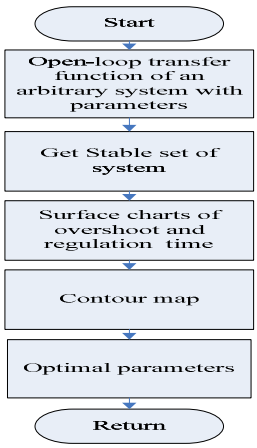

Fig.4 Program flow charts

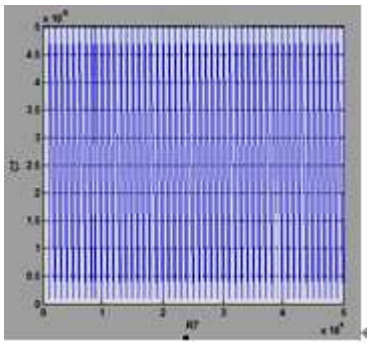

Fig.5 R6,C7 stable sets

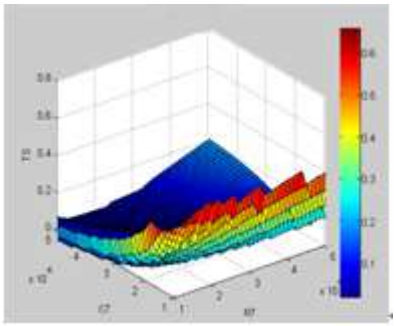

Fig.6 Regulation time 3D surface diagram

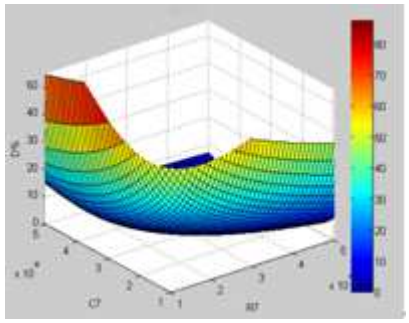

Fig.7 Overshoot 3D surface diagram

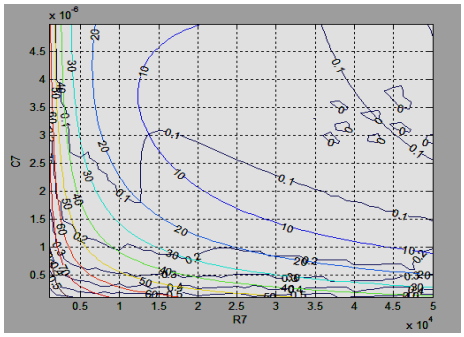

Fig.8 Regulation time and overshoot 3D contour diagram

(1) Parameter Stable Set

Get the system characteristic equation from system open-loop transfer function G and then getsystem characteristic root. Combined with judging condition of system stability, the range of R7, C7 when system is stable can be obtained rapidly. R6,C7 stable set is shown in Fig.5.

(2) Dynamic Performance Optimization

According to the system transfer function, the step response of the system can be obtained and then can acquire the relation of overshoot, regulation time and parameter R7, C7.These messages can be get from Fig.6, Fig.7, and Fig.8.

1) The result of optimization parameters often is not limited to a finite number of analytical solutions; instead, it is countless numerical solution of certain scope.

2) Using data visualization can clearly show cause-and-effect relation between the parameter and effect of the design in a global scope.

3) Taking different data sets can visualize the problems of Contradictory and restrict to each other.

Select parameters correspond to the crossing point when regulation time is 0.1 s and overshoot is zero in Fig.8:R7=4.2k, C7=3.4uf.select R7=4.2k, C7=3uf actually.

Experimental Results and Analysis

According to the power supply design requirements, the maximum input current RMS is $3.83A$. The input current RMS peak value is $5.41A$ .the input current maximum average value is $3.45A$ .Input inductance current maximum peak value is $5.95A$ .Then calculate related parameter based on the value showed above. Hardware circuit rectifier bridge output connect a low ESR 155 CBB capacitor to filter out high frequency components of the rectifier output voltage ; Boost inductance choose circular silicon aluminum iron core, select the inductance value as $128\mu H$;Select two 4700 μF capacitors in parallel as output filter capacitor C_{out} ;filter capacitor C_9 is $0.47\mu F$ .The value of the resistance R_9 on the input voltage VIN side is 10K. R_6 is *170K*. The capacitor C_8 on the input voltage side is $10\mu F$ .The capacitor of current loop C_5 is *1nF*.The hardware circuit is shown in Fig.9.The measured wave form of rectifier bridge output side is shown in Fig.10, it shows that current waveform synchronize with tracking voltage waveform, which achieve high power factor output, the power factor is above 0.987.

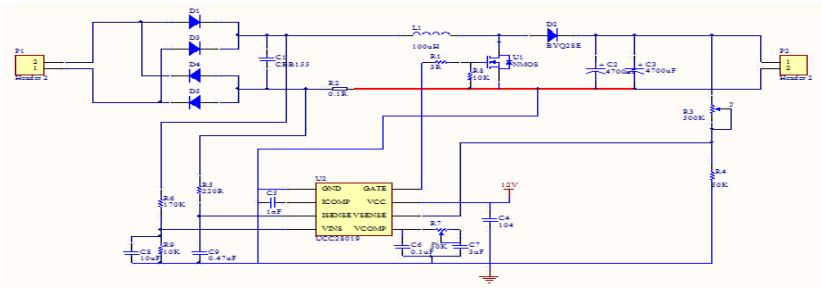

Fig.9 Hardware main circuit diagram

Fig.10 Rectifier bridge Voltage and current output

Conclusions

PFC voltage loop of 3 D visualization algorithm design in this paper based on stable set, use time domain performance as the objective function, is intuitive, simple, and practical. Hardware circuit experiments verify the effectiveness of the proposed method. The method can be transplanted to other circuit system by simple modification, therefore, it worth high application.

Keywords: power flow balance; entropy; power system static security assessment; limit violations.

Abstract. Research of power flow evenness has great significance for grid steady state analysis. This paper researched for a method for power flow evenness analysis through entropy theory. According to current power flow distribution and branch power limits, the branch load ratio distribution could be obtained, and the power flow entropy was calculated based on discrete information entropy theory. The study case indicates that the power flow entropy effectively describes the power flow evenness. With certain system load level, the system security level will be dramatically declined when power flow evenness reduces to a certain level, which is demonstrated in the case meanwhile. Power flow evenness analysis based on entropy theory is applicable in power system static security assessment.

Introduction

Modern large scale power system has the characteristics of interconnectedness, dynamic nature, nonlinearity, randomness and real time performance [1]. With the access of intermittent energy, power system in the environment of "source-grid-load" interactive operation [2] is exposed to more uncertainties. Under this circumstance, the various states of system power flow distribution in real time influences the security of power system operation. Consequently, research for power flow distribution evenness is necessary and significant. Power flow evenness analysis is an effective method for grid steady state analysis. Branch power off-limit is likely to appear at low power flow evenness, and large scale cascading failure might be caused further [3]. In power system static security assessment, power flow evenness analysis is conducive to optimizing the power flow distribution and reducing system operation risk. Extracting the power flow distribution characteristic quantity and establishing power flow evenness evaluation indicator is a great challenge for power system analysis. Research on methods for power flow evenness analysis is significant and impending.

With the development of the information theory, entropy is gradually applied in fields such as available transmission capacity evaluation, optimal power flow, probabilistic load flow and fault detection [4-7]. Entropy describes the degree of system disorder. The higher the degree of a system in order, the smaller the entropy is. It could serve as an important parameter for power flow evenness description. Therefore, the application of entropy to power system flow evenness analysis has practical significance and feasibility.

This paper researched for power flow evenness analysis through entropy theory. According to branch load ratio distribution, the power flow entropy index was calculated based on discrete information entropy theory. Power flow distribution evenness analysis could be used to power system static security assessment considering N-1 branch outage and node power injection disturbance.

Information Entropy Theory

Entropy describes the degree of system disorder. With the development of entropy theory, it leads in more specific definition and becomes an important parameter in various disciplines and fields.

Basic theory description. When entropy was led in information theory, the concept of information entropy was proposed, which solved the problem of information quantization. The more orderly a system, the less the information entropy is; conversely, the less orderly a system, the higher the information entropy is. On this basis, information entropy could be regarded as measurement of system ordering degree. The definition of discrete information entropy is shown in Eq. 1:

$$H = -C\sum_{i=1}^{N} p(x_i)\ln(p(x_i)) \tag{1}$$

Where, C is a constant; $p(x_i)$ is the probability when the value of information source x is x_i. As:

$$\lim_{p\to 0+} p\ln p = 0 \tag{2}$$

When $p(x_i) = 0$, $p(x_i)\ln(p(x_i))=0$.

Properties of entropy. The information entropy has the following properties.

Non-negativity: Entropy is greater than or equal to zero, namely $H_s \geq 0$;

Extremum: According to probability theory, $H \leq \ln N$. N is the total number of events within the system. Meanwhile, if and only if $p_1 = p_2 = ... = p_N$, the equal sign works, when the system has maximum entropy;

Symmetry: $H(p_1,...,p_n)$ is independent of the order of $p_1,...,p_n$.

Power Flow Distribution Evenness Analysis Based on Entropy

When the system is in a certain load level, may all line load ratios are near the average load ratio. May also some line load ratios are greater than the average and meanwhile some other line load ratios are far less than the average. Different power flow distribution evenness might lead to different results. Quantify the power flow evenness by entropy theory in the following steps.

Calculate the load ratio of each line: For a certain operating state of the system, calculate the load ratio of each line by Eq. 3:

$$\mu_i = \left|P_i^0 / P_i^{\max}\right| \quad i = 1,2,...,N_l \tag{3}$$

Where, $P_i^{\max}$ is the active power transmission capacity of line i; P_i^0 is the active power of line i in current operating state; μ_i is the load ratio of line i; N_l is the number of system lines.

Load ratio distribution statistics: Set a constant sequence $U=\{U_1,U_2,...,U_k,...,U_{N_l+1}\}$, n_k is the number of lines which $\mu_i \in (U_k,U_{k+1}]$. Obtain the probability for lines distributed in each load ratio intervals:

$$p(k) = n_k / \sum_{k=1}^{N_l} n_k \tag{4}$$

Where, $p(k)$ refers to the probability for the lines distributed in $\mu_i \in (U_k,U_{k+1}]$.

Calculate system power flow entropy by Eq. 1. Where, $p(k)$ is $p(x_i)$, and N_l is N.

Analysis for different system operation states: On account of the great influence of system load level on its safe operation, power flow evenness analysis should be processed in the same load level. Calculate the average load ratio for each operation states by Eq. 5.

$$\overline{\mu} = \sum_{i=1}^{N_l}\left|P_i^0\right| / \sum_{i=1}^{N_l} P_i^{\max} \tag{5}$$

Put the operations with similar load level in the same class, and analyze the influence of power flow entropy on system security under a certain load level.

When all line load ratios lie in the same interval, the power flow entropy is 0. This is the most orderly state of power flow distribution, when lines of large capacity take heavy load, and lines of small capacity take lesser load. When there are no 2 line load ratios in the same interval, the power flow entropy reaches maximum:

$$H_{\max} = -C \ln(1/N_l) \tag{6}$$

This is the most uneven state of power flow distribution. In this instance, lines of large load ratio will be overload in all probability when encounter disturbance, even cause cascading failure. And the capacity of lines in very low load ratio has not been fully used.

Case Study

In IEEE300 case, operating states in different system load levels and power flow entropies were studied. For each operating state, the average number of branch power limit violations under N-1 branch outage was calculated and displayed in Fig. 1. In this paper, $U=\{0,1/N_l,2/N_l,...,1\}$ and $C=\ln 10$.

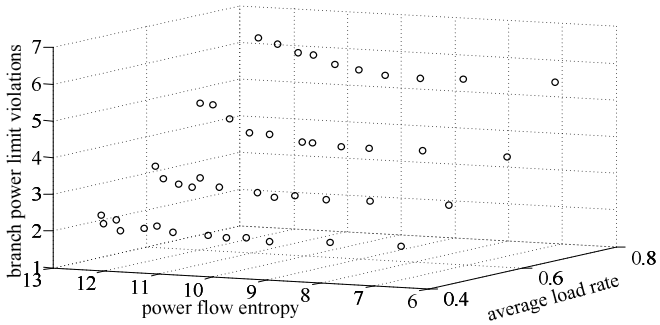

Fig.1. 3D figure of system security under N-1 branch outage in different power flow entropy

In Fig. 1, the average number of branch power limit violations under N-1 branch outage is related to the power flow entropy and system load level, and increases accordingly. In a certain system load level, when power flow entropy is less than a specific value (namely the power flow distribution is more even), the number of branch power limit violations basically remains unchanged. Otherwise, the system security will dramatically decline. Namely, the number of branch power limit violations will increase. This case study indicates that power flow entropy influences the system operating security.

In IEEE300 case, operating states in different system load levels and power flow entropies were studied. For each operating state, the average number of branch power limit violations under node power injection fluctuations (20%) was calculated and displayed in Fig. 2.

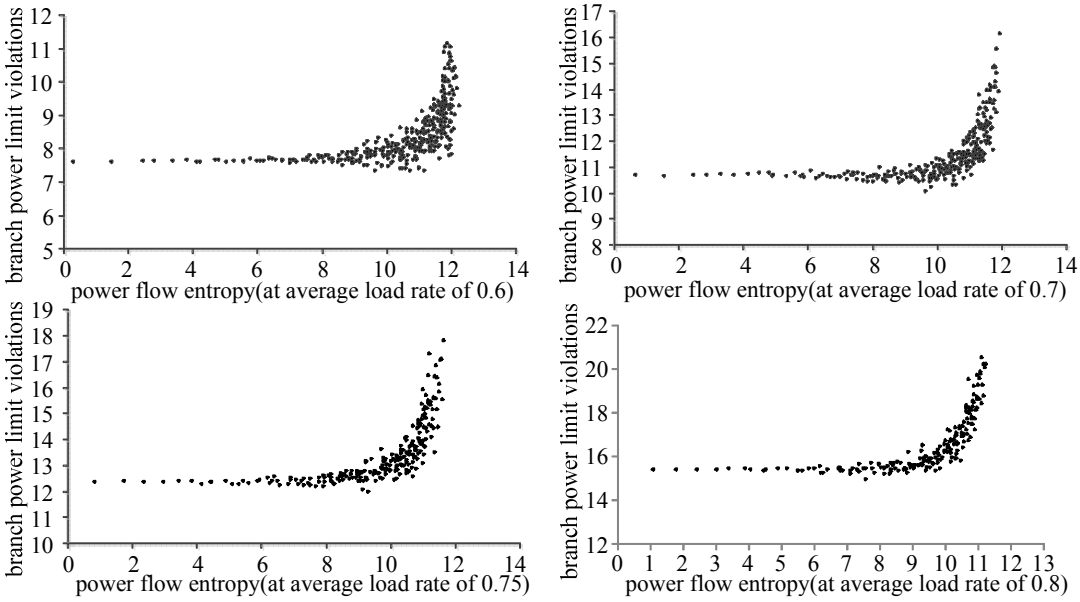

Fig.2. System security under node power injection fluctuations in different power flow entropy

From Fig. 2, similar conclusions to Fig. 1 could be received. The average number of branch power limit violations under node power injection fluctuations is related to the power flow entropy and system load level, and increases accordingly. In a certain system load level, when power flow entropy is less than a specific value, the number of branch power limit violations basicly remains unchanged. Otherwise, the system security will dramatically decline, which indicates that the power flow entropy influences the system operating security.

Conclusions

This paper proposed a method for power flow evenness analysis based on entropy theory. According to branch load ratio distribution, the power flow entropy index was calculated based on discrete information entropy theory. The study case indicates that power flow entropy effectively describes the power flow evenness and system security is related to the power flow entropy and system load level. Power system security will be likely to decrease with low power flow evenness.

Conclusions were received from this paper that power flow evenness analysis based on entropy theory is applicable in power system static security assessment. In certain system structure and load level, system operating security could be improved by optimizing the power flow distribution. In power system static security assessment, power flow evenness analysis is conducive to optimizing the power flow distribution and reducing system operation risk.

Keywords: static voltage stability, SVC, STATCOM, reactive power compensation

Abstract. Nowadays, unbalanced loads or nonlinear loads produce a bad effect on the power quality of utility mains. Also, it is necessary for reactive power to be compensated because the most of industrial loads is inductive and make a lagging displacement power factor. Reactive power compensation utilizing STATCOM is one of the most important methods to improve power quality. In this paper, the technical feature of STATCOM is introduced and then a comparison with SVC is made. The effect of STATCOM on static voltage stability in power systems has been studied. Based on PSD-BPA software, effect of STATCOM is determined. Static voltage stability margin enhancement using STATCOM and SVC is compared in the modified IEEE 14-bus test system. Test results show very encouraging result.

Introduction

Recently, most of the critical loads in an industrial low voltage AC system have an unbalanced and/or nonlinear characteristic because it is a single-phase rectifier with a capacitor or thyristor-based three phase rectifier. The unbalanced and nonlinear characteristic of the load has an undesirable effect on the power quality of input utility mains and adjacent load side. Therefore, reactive power should be generated and compensated properly to improve the power quality of input utility mains.

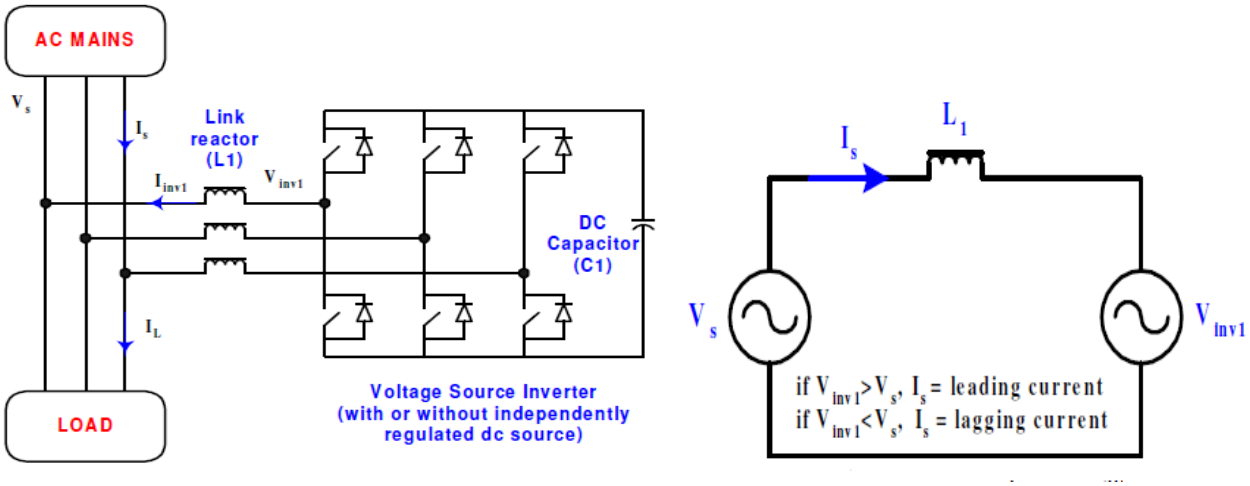
Voltage instability is mainly associated with reactive power imbalance. The loadability of a bus in the power system depends on the reactive power support that the bus can receive from the system as the system approaches the maximum loading point (MLP) or voltage collapse point, both real and reactive power losses increase rapidly. Therefore, the reactive power supports have to be local and adequate.

Typically, the response time and the bandwidth of the closed voltage regulation loop of the STATCOM which is a shunt-connected synchronous voltage source are significantly better than those of the SVC which is a shunt-connected reactive admittance. Consequently, STATCOM can be more effective than SVC in an industrial low voltage AC system.

In this paper, operational principle and basic control loop of STATCOM are described. Also, control loop to compensate the unbalanced load and nonlinear load is discussed in detail. Its performance of the control loop of STATCOM in unbalanced and/or nonlinear load conditions is verified by PSIM simulation software. These results can be used for the software implementation in the prototype STATCOM system

System configuration of STATCOM

STATCOM based on VSI (voltage source inverter) is a synchronous voltage source connected to the utility mains in parallel through a link reactor (L1) as shown in Fig. 1(a).
Switching device can be GTO for high voltage, high power application or can be IGBT for low voltage, low power application. It is necessary to note that the size of dc capacitor in STATCOM is considerably smaller than the general ac capacitor for direct power factor compensation.



(a) Configuration (b) Single phase equivalent circuit

Fig.1 STATCOM system based on VSI

Comparison between STATCOM and SVC

There are two type of controllable reactive power (shunt) generator. One is a static var compensator (SVC) whose output is adjusted discontinuously to inject or absorb the reactive current. It can be treated as a shunt-connected reactive admittance. For example, thyristor-controlled reactor (TCR), thyristor-switched reactor (TSR) and thyristor-switched capacitor (TSC) are typical SVC system. The other one is a static synchronous compensator (STATCOM) whose output is adjusted continuously to inject or absorb the reactive current. It can be treated as a shunt-connected synchronous voltage source. Comparison results between SVC and STATCOM is shown in Table 1.

Tab.1 Comparison between SVC & STATCOM

Items	SVC	STATCOM
Continuity of control	Discontinuous	Continuous
Control	Phase control	PWM Control
Phase delay (max.)	0.5 ~ 1 cycle	Very few
Low-order harmonics	Much	Small
Installation space	Large.	Small
Size of reactive components	Bigger	Small
Loss	Bigger	Very small
Response	Slow	Very fast

Generally, STATCOM is more effective and more rapid compensator than SVC regarding to V-I characteristic, V-Q characteristic, transient stability and response time [1]. Many researches about the analysis and design method of STATCOM system had been already done at reference [2~4].

Simulation of Applying STATCOM

IEEE 14-bus test system as shown in Fig. 2 is used for voltage stability studies. The test system consists of 5 generators and 11 PQ bus (or load bus). The simulations use BPA simulation software. BPA is power system analysis software, which can be used to investigate voltage stability of the test power system.

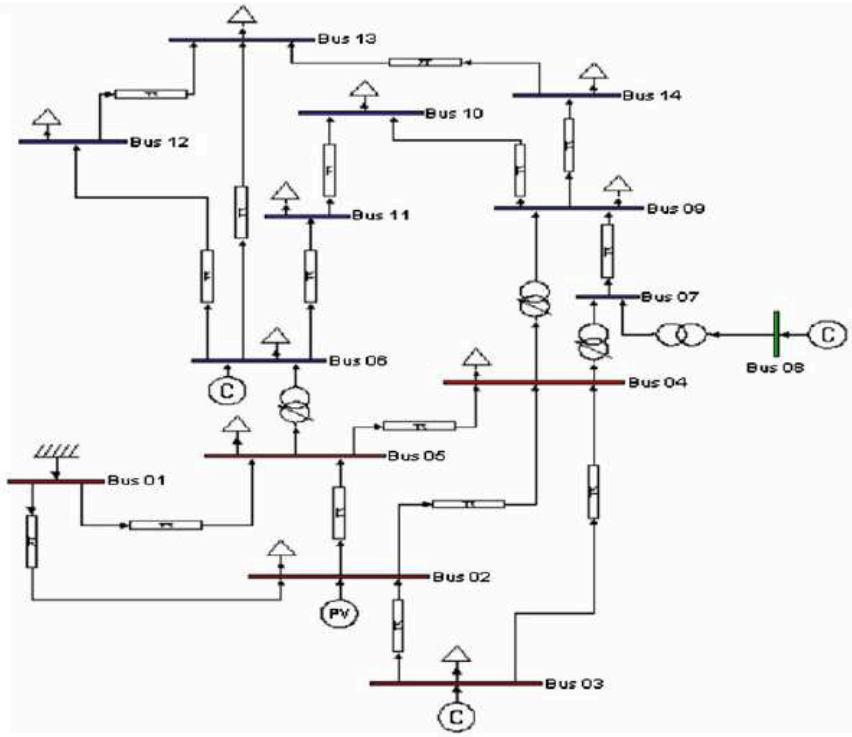


Fig. 2 IEEE 14-bus test system

The behavior of the test system with and without FACTS devices (SVC and STATCOM) under different loading conditions is studied. The location of the FACTS controllers is determined through bifurcation analysis. A typical PQ model is used for the loads and the generator limits are ignored. Voltage stability analysis is performed by starting from an initial stable operating point and then increasing the loads by a factor λ until singular point of power flow linearization is reached. The loads are defined as:

$$P_{\mathrm{L}} = P_{\mathrm{L0}}(1+\lambda) \tag{1}$$

$$Q_{\mathrm{L}} = Q_{\mathrm{L0}}(1+\lambda) \tag{2}$$

Loss of loads in system will happen after three-phase short-circuit faults. It is a serious threat to the system's normal production and causes great economic losses. In this section, a scheme of reactive power compensation is proposed that install SVC or STATCOM in low-voltage side of the transformer in power grid. A simulation is needed to research the effectiveness of reactive power compensation utilizing SVC and STATCOM and make a comparison between SVC and STATCOM. The installed location and capacity of STATCOM should be determined. Usually, placing adequate reactive power support at the weakest bus enhances static voltage stability margins.

Then, we replace SVC with STATCOM to do the same simulation experiment. It turns out that the needed capacity of STATCOM is less than SVC. A comparison between SVC and STATCOM can be made. Voltage changes of 'Bus 7' with the same capacity of SVC or STATCOM is shown in Fig. 3. Obviously, the bus has a faster rate of voltage recovery by installing STATCOM than SVC.

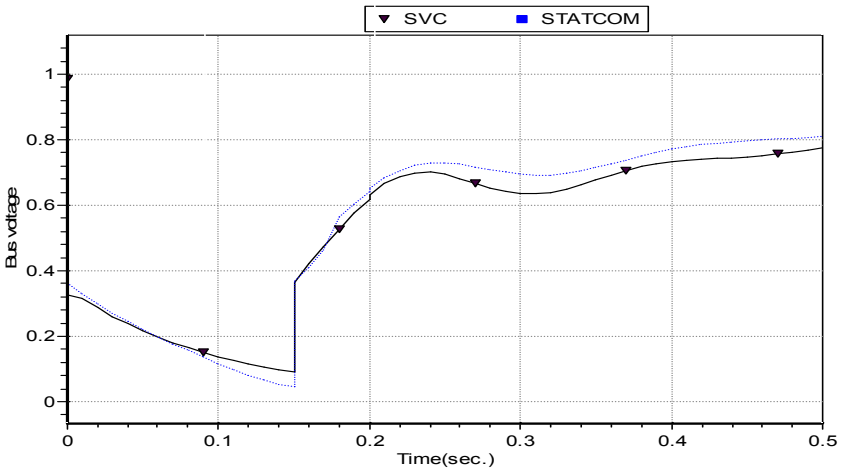

Fig. 3 Voltage changes of 'Bus 7'

Conclusion

In this paper, voltage stability assessment of the modified IEEE 14-bus test system with STATCOM and SVC is studied. STATCOM provides higher voltage stability than SVC. Two types of controllable reactive power compensator discussed. A reasonable simulation experiment is established to test and verify the dynamic stability improvement by using STATCOM. Test results show very encouraging result. Generally, STATCOM is more effective and more rapid compensator than SVC regarding to Tab.1and Fig. 3.

Consequently, STATCOM can be more effective than SVC in an industrial low voltage AC system. However, it costs more by installing STATCOM than SVC.

Keywords: excitation control; OLTC; coordinated control; phase-advancement operation; smart grid.

Abstract. Nowadays the main electrical wiring in medium-size and large-size thermal power units is mostly unit wiring. In the quarter of small reactive power load, some generators need to work in phase-lag operation during the daytime and in phase-advancement operation at night to meet the demand of voltage quality of their plant's high-voltage side. This operation, however, will lower the voltage of auxiliary power and do harm to system's stability. This paper proposes a kind of coordinated control strategy for generator-transformer's voltage regulation. In this strategy, the main transformer should be on-load tap charger and the controller regulate the generator voltage and transformation ratio simultaneously when needed, thus the voltage quality of both high-voltage side and auxiliary power side can be insured and the generator no longer work in phase-advancement operation. This control strategy can be a meaningful proposal for AVC in smart grid in the future. Simulation result shows the stability and reliability of the proposed control strategy .

Introduction

Nowadays the main electrical wiring in medium-size and large-size thermal power units is mostly unit wiring. In the quarter of small reactive power load, some generators need to work in phase-lag operation during the daytime and in phase-advancement operation at night or even work in phase-advancement operation all-time to meet the demand of voltage quality of their plant's high-voltage side[1-3]. This operation can lower the voltage of the end of transmission lines, but also lower the voltage of auxiliary power and affect the normal operation of various types of auxiliar machines as a side effect. In addition, multiple units work in phase-advancement operation simultaneously can reduce the stability of the power system[4].

Since the 1950s, the excitation control strategy developed from classical control theory to modern control theory[5-7]. Many experts and scholars have proposed numerous control strategies based on different theories in recent years. However, their proposals can't solve the above-mentioned problem as the control objectives of their proposals are all to maintain the generator voltage[8-11]. This paper proposes a kind of coordinated control strategy for generator-transformer's voltage regulation. In this strategy, the main transformer in corresponding plants should be on-load tap charger and the controller regulate the generator voltage and transformation ratio simultaneously when needed. Regulating the transformation ratio is the process of coarse adjustment while regulating the generator voltage is precise adjustment. Two parties work together to meet the demand of voltage quality of both plant's high-voltage side and auxiliary power side under the condition that the generator no longer need to work in phase-advancement operation. The proposed control strategy makes full use of OLTC[12,13], and can be an meaningful proposal for AVC. Simulation result shows that the proposed control strategy is stable and effective.

Mathematical model

Consider the generator-transformer unit as shown in Fig.1, the transformer is elected to be on-load tap charger.

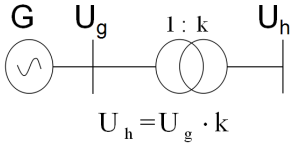

Fig.1 Simplified diagram of a generator-transformer unit

At present most generation units are equipped with static self-excitation system in China, which obtain power from the generator and transform it into field current by silicon controlled rectifier. The control loop of static self-excitation system consist of measuring part, excitation controller, power unit and generator, as shown in Fig.2[14].

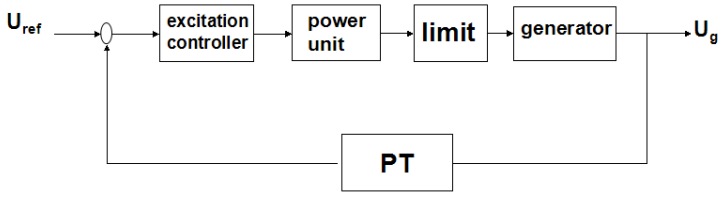

Fig.2 Control loop of static self-excitation system

The transfer functions of PT and static self-excitation controller are $G_t(s)=\frac{K_r}{T_r s+1}$, $G_e(s)=\frac{T_1 s+1}{T_2 s+1}\cdot\frac{T_3 s+1}{T_4 s+1}\cdot\frac{K_a}{T_a s+1}$ respectively while the restriction of exciting voltage can be represented as a limiting link. The process of generator voltage changing with field current can be considered as a gain link $G_g(s)=K_g$, as its transition time is shorter than the simulation step.

The mathematical model of OLTC can be established using mechanism modeling methods. For simple, the transfer function of tap position indicating is $G_l(s)=\frac{1}{T_l s+1}$ and the process of transformer's tap adjustment can be expressed as $G_w(s)=\frac{1}{T_w s+1}$.

Control Principle

Control objectives. The coordinated control strategy for generator-transformer's voltage regulation must insure the voltage quality of plant's high-voltage side under the condition that the generator won't work in phase-advancement operation. Refereeing to DL/T650-1998 <Specification for potential source static exciter systems for large turbine generators>, the control objectives of the proposed strategy can be formulated as follows: ①the generator won't work in phase-advancement operation all-weather; ②the response time of voltage of plant's high-voltage side should be lesss than 0.1s; ③the overshoot of step response should be less than 2%～4% of the setpoint while the damping ratio less than 0.1, regulating time less than 1s and the steady-state error less than 0.5kV.

Control scheme. During the process of adjusting the voltage of the plant's high-voltage side, regulating the transformation ratio is coarse adjustment for the sake that the transformer tap can't be adjusted continuously while regulating the generator voltage is precise adjustment as the generator voltage can be. For a given regulating process, assume that the initial value and setpoint of voltage of the plant's high-voltage side are U_{h0} and U_h, those of generator voltage are U_{g0} and U_g and those of transformation ratio are k_0 and k.Obviously $U_{h0}=U_{g0}\cdot k$ if ignore the voltage loss of transformer. The adjustable range of the stator voltage is (U_{gmin},U_{gmax}) when the generator works in phase-lag operation. In other words,if the generator works in phase-advancement operation, that

voltage will below U_{gmin}.The adjustable range of transformation ratio is $(k_{\min},k_{\max})$.In one case that the predetermined changing amount of voltage of the plant's high-voltage side is less than $(U_{\text{gmax}}\text{-}U_{\text{g0}})\cdot k_0$ or $(U_{\text{g0}}\text{-}U_{\text{gmin}})\cdot k_0$, regulating the generator voltage merely can achieve the control target and the generator won't work in phase-advancement operation.In the other case that the predetermined changing amount is greater than that, both the generator voltage and the transformation ratio should be adjusted to insure that the generator won't work in phase-advancement operation.To estimate the changing amounts of generator voltage and transformation ratio in the control loop preliminary, a coordination coefficient denoted as A can be used assuming that there is a positive correlation between that changing amounts. The size of A can be tunning according to the given control requirement. Obviously the equation has a unique solution

$$\begin{cases} U_{\text{g}}\cdot k=U_{\text{h}} \\ \dfrac{|k\text{-}k_0|}{|U_{\text{g}}\text{-}U_{\text{g0}}|}=A \end{cases}$$

which shows the rough changing amounts of generator voltage and transformation ratio.The controller select the transformer tap position which is closest to the above-mentioned solution, and then regulate the generator voltage precisely on that basis.

Construct a control loop as shown in Fig.3. Calculate the values of $(U_{\text{gmax}}\text{-}U_{\text{g0}})\cdot k_0$ and $(U_{\text{g0}}\text{-}U_{\text{gmin}})\cdot k_0$ first and dispose a logic trigger device in the control system. If the setpoint of voltage of the plant's high-voltage side is between $U_{g\min}\times k_0$ and $U_{g\max}\times k_0$, the controller trigger the small control loop and regulate the generator voltage merely while the transformation ratio is constant; if the setpoint is out of that range, the controller will trigger the large control loop and regulate the generator voltage and transformation ratio simultaneously. In the large loop, the circuit

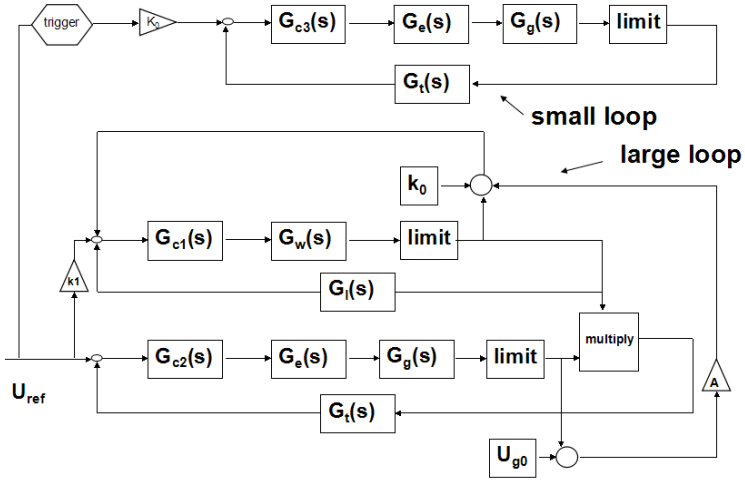

Fig.3 Control block diagram

that involves the excitation controller is main loop while that involve the transformer tap controller is vice loop. The small loop only include one controller. Those controllers are all proportional-integral controllers and successive approximation approach can be adopted to tunning the two controllers in the large loop. For simple, $G_g(s)=K_g$ in the main loop can be amalgamated into $G_e(s)$,so the generalized controlled object becomes to $G_e(s)=\dfrac{T_1s+1}{T_2s+1}\cdot\dfrac{T_3s+1}{T_4s+1}\cdot\dfrac{K_a}{T_as+1}$.

Stability analysis of control system. To calculate the input - output transfer function of this system, the control block diagram should be simplified as shown in Fig.4.

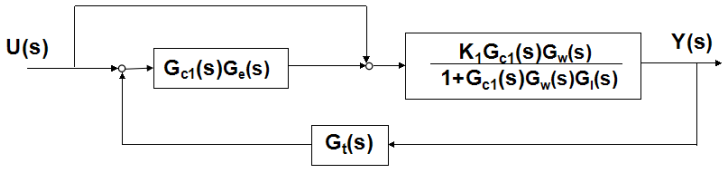

Fig.4 Simplified control block diagram

The input - output transfer function of this system is

$$H(s)=\frac{Y(s)}{U(s)}=[1+G_{c2}(s)G_e(s)]\cdot\left[\frac{\dfrac{K_1G_{c1}(s)G_w(s)}{1+G_{c1}(s)G_w(s)G_l(s)}}{1+\dfrac{K_1G_{c1}(s)G_{c2}(s)G_w(s)G_e(s)G_t(s)}{1+G_{c1}(s)G_w(s)G_l(s)}}\right]$$

$$=\frac{K_1G_{c1}(s)G_w(s)+K_1G_{c1}(s)G_{c2}(s)G_w(s)G_e(s)}{1+G_{c1}(s)G_w(s)G_l(s)+K_1G_{c1}(s)G_{c2}(s)G_w(s)G_e(s)G_t(s)}$$

It is not hard to verify that the whole system is stable if and only if the above transfer function is stable.

Illustrative examples

Consider a typical 300MW thermal power units, corresponding coefficients are

$T_1=T_2=T_3=T_4$=2.0s , K_a=20 , T_a=0.02s , T_t=0.03s , T_w=0.02s , T_l=0.02s

$U_{g\min}=19.5\text{kV}$, $U_{g\max}=20.5\text{kV}$

The scale of voltage tap of the main transformer is $\pm2\times2.5\%$ .The initial values of generator voltage and transformation ratio are $U_{g0}=20\text{kV}$ and k_0=12.1. Tuning the coordination coefficient and the three PI controllers as

$$A=0.32,\quad K_{c1}(s)=0.002+\frac{0.1}{s},\quad K_{c2}(s)=0.05+\frac{0.6}{s},\quad K_{c3}(s)=0.018+\frac{0.6}{s}$$

The simulation model of control system is shown in Fig.5

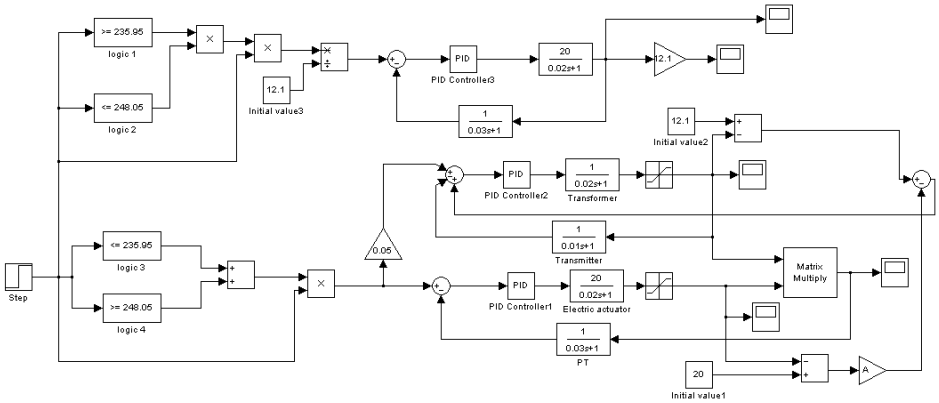

Fig.5 Simulation model

Firstly, consider the situation that the setpoint of voltage of the plant's high-voltage side is between 235.95kV and 248.05kV. The step response of generator voltage is shown in Fig.6 when

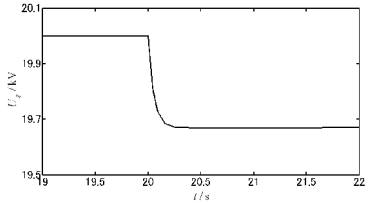

Fig.6 Step response when the setpoint is 238kV

the setpoint is set to be 238kV. The delay time and settling time are $t_d = 0.0389\text{s}$ and $t_s = 0.168\text{s}$ respectively. There is no overshoot, oscillation and any steady-state error. The adjustment process meets the control requirements as the damping ratio is larger than 1.

Then consider that the setpoint is lower than 235.95kV. The voltage tap of the main transformer should be adjusted to $235.95/20\text{kV}$ and the generator voltage should be 19.665kV if setting the setpoint to be 232kV. The step response of voltage of the plant's high-voltage side, generator voltage and transformation ratio is shown in Fig.7. The delay time and settling time of the

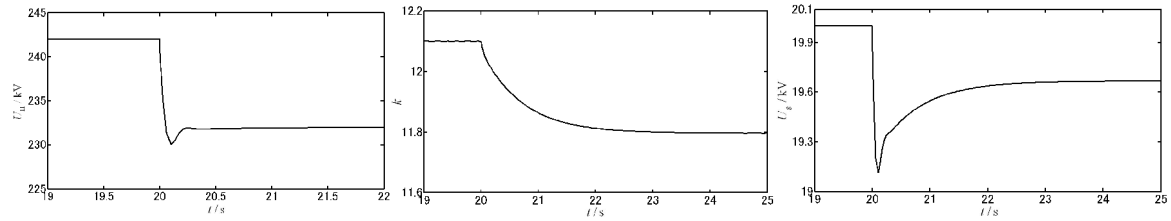

Fig.7 Step response when the setpoint is 232kV

response of voltage of the plant's high-voltage side are $t_d = 0.0193\text{s}$ and $t_s = 0.1815\text{s}$ respectively. The ratio of overshoot than the setpoint value is 1.05% .The steady-state values of transformation ratio and generator voltage are 11.7965 and 19.666kV respectively, which is consistent with the theoretical values. The adjustment process also meets the control requirements as the damping ratio is about 0.9.

The simulation result shows the good accuracy and rapidity of the proposed control system. Calculate the characteristic equation of the closed-loop transfer function as $Q(\text{s}) = 4.8\times10^{-7}\text{s}^7 + 1.36\times10^{-4}\text{s}^6 + 0.0149\text{s}^5 + 0.833\text{s}^4 + 24.5\text{s}^3 + 308.5\text{s}^2 + 121.6\text{s} + 12$

The Eigen values are $\lambda_1 = -1.1185$, $\lambda_{2,3} = -0.3554 \pm 0.3103i$, $\lambda_{4,5} = -0.5$, $\lambda_6 = -0.0023$, $\lambda_7 = -0.0018$ .Obviously the control system is stable as those close-loop poles are all locate in the left half of 's' plane.

Summary

This paper proposes a kind of coordinated control strategy for generator-transformer's voltage regulation. In this strategy, the main transformer should be on-load tap charger and the controller regulate the generator voltage and transformation ratio simultaneously when needed, thus the voltage quality of both high-voltage side and auxiliary power side can be insured and the generator no longer work in phase-advancement operation. This control strategy can be an meaningful proposal for AVC in smart grid in the future. Simulation result shows that the proposed control strategy is stable and effective.On the basis of this paper, bringing the circumstances of each power plant's transformer tap into AVC system is a worthy research topics in the reactive / voltage management area in the future.

Keywords: Gas-turbine; General Carnot Cycle; Combustion in the Turbine

Abstract. Based on polytrophic process of air compression and gas combustion inside the turbine isothermally, an approximate gas-turbine with General Carnot cycle and relevant implementing schemes are suggested. Its performance was predicted with mathematics model compared with traditional one. The results show that the heat efficiency of the suggested gas turbine is higher than the traditional one. The suggested cycle combines the gas cycle and steam cycle, of which the NOx emission can be easily decreased

Introduction

Advanced gas-turbine is the key equipment of the power equipment in 21 century. In order to improve the thermal efficiency of gas-turbine, conventional methods consist of improving the efficiency of the compressor and turbine, increasing the press ratio, using more advanced material and increasing inlet temperature of turbine. However, it is very difficult to improve the efficiency of compressor and turbine markedly under the existing art and craft of design and manufacture. Improving press ratio was mainly limited by material and power output. More high quality material used in the turbine will increase the cost of gas-turbine obviously. Improving the inlet temperature of turbine requires better thermal defend for gas-turbine, because it is not only need more high temperature endurably material but also increase the flux of the cooling air. Actually, in some aircraft engines, the flux of the cooling air could achieve 10-20% [1] of the whole air flux in the core engine, excessive cooling air will disadvantage for the thermal efficiency. On the other hand, excessive highly turbine inlet temperature caused higher temperature in the combustor, which could reach 2200K now. Under this temperature, the turbine NOx emission increase obviously.

In the cyclic process of the gas-turbine, consuming work will increase in the air compress process because air temperature increase. So spraying water into compressor could decrease the consuming work obviously in the process of air compress, and the air compress process changes into a polytrophic process. The advantage of this method could omit the huge middle-colder and relative system, and simplify the structure of gas-turbine. Li [2] gave an example of SIA-02 type gas-turbine feed on methane, and researched the cycle of the gas-turbine which was sprayed water into stage of compressor. The results showed that spraying water into compressor stages could reduce compressing work, decrease the outlet temperature of compressor, and increase the power output. In addition that, the variation of efficiency of the system related with the flux of spray water. If turbine inlet air temperature keeps unchanging, the efficiency had a maximum value with the increasing flux of spray water, and if power output was constant, the efficiency decreased with the increasing flux of spray water. In fact, there was no regenerator in Li's research, if the regenerator was taken into account, the results may be different.

When high-temperature and high-pressure air in the process of applying work inside the turbine, the air temperature decrease sharply, and this will reduce the air work capacity. But the air work capacity will enhance if air temperature keep constant in the process of applying work, and it will become an isothermal process. In actual gas-turbine, people hope the fuel could combustor rapidly

and completely in combustor, so the thermal-defense of combustion chamber is very difficult because the temperature in the combustion chamber is very high. If we properly decrease temperature of the combustion chamber and make partial fuel jet into turbine to keep combustion. In this situation, the air could expand in turbine and react with the fuel at the same time. The reaction heat could keep a constant air temperature in process of expanding, this will be another direction of increasing the thermal-efficiency of gas-turbine.

Sirignano W A [3][4] researched the affection of applying the combustion inside turbine technology in improving the thrust of unit windward area and dropping fuel consuming of aero-engine. They also compared the combustion inside turbine with conventional aero-engine with or without afterburners, their research indicated that combustion inside turbine could improve the aero-engine performance obviously.

Exhaust temperature of the turbine is very high because of combustion inside turbine, so the regenerator is necessary for the turbine. The temperature of air from compressor will increase after the pre-heating in regenerator and increase further in pre-combustion chamber that in order to satisfy work output and maintain rapid reaction.

From the analyses above, an approximate generality Carnot thermal cycle was proposed: in the air compression process, water was sprayed in at proper position for absorbing the heat quantity generated from compression, this will render air compression easily. After compression, the air pass through the regenerator and flow into pre-combustion chamber and turbine orderly. Then air expand and react with fuel in turbine simultaneously. The exhaust air flows into atmosphere after passing through regenerator to complete the whole thermal cycle. The cycle discussed above is the Approximation General Carnot Cycle (AGCC) which is proposed in this paper. The gas-turbine system applied AGCC is revealed in Fig.1. The key advantage of AGCC is even though the combustion temperature is lower than the conventional Brayton recycle, but the thermal efficiency of AGCC could be the same or higher than the Brayton recycle. Besides that, the lower combustion temperature could restrain the generation of thermal force NOx, so the whole emission of NOx was reduced.

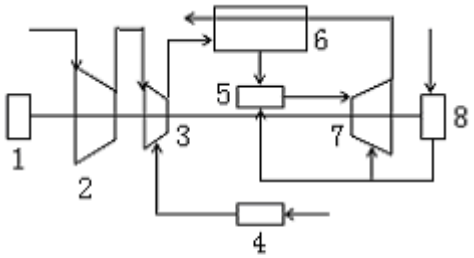

Fig.1 System of Gas-Turbine with an approximate Generality Carnot Cycle

Performance prediction model

According to calculation, the temperature of air arise up to nearly 406k when air is compressed from T_o=298K and P_o=0.1MPa to 0.3MPa after an isentropic compression process. And the water saturation temperature at 0.3MPa Tm is approximate equal to 406K as shown in Fig.2.

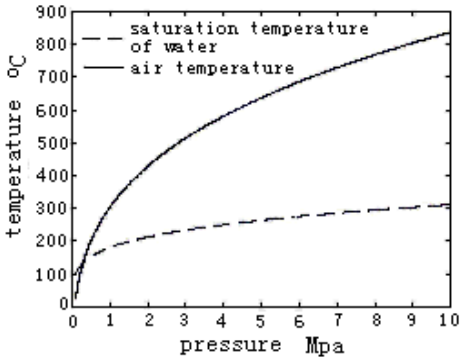

Fig.2 Comparison between saturation temperature of water and air temperature from isentropic compression in same pressure.

As we can see from Fig.2, it is proper to spray water into compressor when air pressure exceed 0.3MPa, because water in compressor change into boiling steam rapidly after 0.3MPa. While pressure is below 0.3MPa, water changes into steam depend on diffusion process mainly. At that condition, the water drop which evaporation incompletely would harm to the compressor blade. Therefore, mathematic model could be established to calculate maximum flux of spray water and the thermal efficiency of the system according to the analysis above. Some assumptions of the model is following:

1) Air and steam can be treated as ideal gas;
2) Air flows into compressor initially without steam.
3) The specific heat of air and steam were constant, and c_p=1.005kJ/(kg·K);
4) Air was compressed by low-pressure compressor from the initial condition of 298K and 0.1MPa, when air pressure exceeds 0.3MPa, high-pressure compressor was used and cooling water was sprayed in.

Fig.3 displays one stage of compress process. η_c is efficiency of compressor, h_a and h'_a are enthalpy of air at inlet and outlet of one stage of compressor. h_{wg} and h'_{wg} are enthalpy of steam at inlet and outlet of one stage of compressor respectively. Δw_i is shaft work that is consumed in one stage of compression, and h_{wl} is enthalpy of water sprayed into one stage compression.

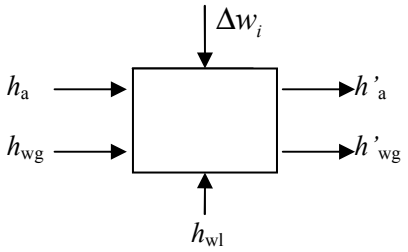

Fig.3 Calculation model of a stage compressor

According to energy conservation:

$$h_a^{'} + m_0 h_{wg}^{'} + q = h_a + m_0 h_{wg} + \Delta w_i \tag{1}$$

In the equation, m_0 is water flux which is sprayed in one kilogram dry air, q is the quantity of heat released from compression that will be absorbed by sprayed water in the process of evaporation:

$$q = \Delta m_i (h_{wg}^{'} - h_{wl}) \tag{2}$$

Supposed polytrophic coefficient is α because air compression is a polytrophic process:

$$T(\pi_1 P) = T(P)\pi_1^{\frac{\alpha-1}{\alpha}} \tag{3}$$

α can be expressed as:

$$\alpha = \ln \pi_1 / \ln \frac{\pi_1 T(P)}{T(\pi_1 P)} \tag{4}$$

Therefore:

$$\Delta w_i = (R + mR_w)\frac{\alpha}{\alpha - 1}T(P)\left(\pi_1^{\frac{\alpha-1}{\alpha}} - 1\right)/\eta_c \tag{5}$$

η_c is the efficiency of compressor.

Consider consuming work of low-pressure compressor which is:

$$w' = \frac{kRT_0}{k-1}\left(\left(P_m/P_0\right)^{\frac{k-1}{k}} - 1\right)/\eta_c \tag{6}$$

So the total work consumed in process of air compression is:

$$w = \sum_{i=1}^{n}\Delta w_i + w' \tag{7}$$

Extra water should be sprayed in before air spraying into high-pressure compressor in order to adjust air temperature at Tm, because the water can absorb part of heat, which come from losing work in the low-pressure compressor. And the extra water needed to adjust air temperature in the high-pressure compressor to Tm should be:

$$\Delta m = w'(1 - \eta_c)/\left(h_{wg|0.3} - h_{wl}\right) \tag{8}$$

$h_{wg|0.3}$ is saturation enthalpy of water at the pressure of P_m, so:

$$m = \sum_{i=1}^{n-1}\Delta m_i + \Delta m \tag{9}$$

After compression, air should pass through the regenerator before spray into pre-chamber. On one hand, the regenerator can increase air temperature to get a better combustion condition; on the other hand, it will decrease thermal loss of exhaust. Suppose P, T are pressure and temperature of compressor outlet, ε and δ are thermal ratio and pressure loss ratio of regenerator, T* is inlet temperature of turbine, respectively. So the quantity of heat should accede to pre-chamber is:

$$Q_1 = \left(c_p + mc_{pw}\right)\left(T^* - T\right)(1 - \varepsilon) \tag{10}$$

The work output quantity of turbine is equal to the heat quantity, because air temperature in turbine is constant:

$$Q_2 = (R + mR_w)T^*\eta_t \ln\frac{P(1-\delta)^2}{P_0} \tag{11}$$

R_w is gas constant of steam; η_t is efficiency of turbine, respectively.

The whole efficiency of system is expressed as:

$$\eta_1 = \frac{Q_2 - w}{Q_1 + Q_2} \tag{12}$$

If we define temperature rise ratio as:

$$\tau = T^*/T_0 \tag{13}$$

Define $n = \dfrac{1-k}{k}$ (14)

So the efficiency of conventional gas turbine with regenerator expressed as:

$$\eta_2 = \frac{\tau\eta_t\left(1 - \pi^n(1-\delta)^{2n}\right) - \left(\pi^{-n} - 1\right)/\eta_c}{\tau\left(1 - \varepsilon + \varepsilon\eta_t\left(1 - \pi^n(1-\delta)^{2n}\right)\right) - \left(1 + \left(\pi^{-n} - 1\right)/\eta_c\right)(1-\varepsilon)} \tag{15}$$

π is whole pressure ratio.

If there is no pressure loss in regenerator, then ε=0，δ=0， and the system without regenerator, this is the conventional brief cycle gas turbine. Equation (15) could be simplified as:

$$\eta_3 = \frac{\tau\eta_t/\pi^{-n} - 1/\eta_c}{(\tau - 1)/(\pi^{-n} - 1) - 1/\eta_c} \tag{16}$$

Results and Analysis

Some related data from literature [5][6]were used in calculation in this paper, the initial air temperature and pressure were 298K and 0.1MPa, temperature of water was 298K, respectively. The result is showed in Fig.4 to Fig.8.

Fig.4 compared efficiency of gas-turbine with an AGCC and conventional gas-turbine with or without regenerator influenced by overall pressure ratio. With pressure ratio increasing, efficiency of conventional gas-turbine with or without regenerator has a maximum, while the efficiency of gas-turbine with an AGCC increases rightly, although pressure ratio is bigger. Efficiencies of gas-turbine with an AGCC and gas-turbine with regenerator influenced by turbine inlet temperature are compared in Fig.5. We can see that the difference of efficiency of the two gas-turbine are decreasing with the inlet temperature increasing. The pressure ratio selected in Fig.5 is corresponding with the maximum efficiency pressure ratio of gas-turbine with regenerator in Fig.4. Because the work output of small pressure ratio gas-turbine is small, so its application will have some limit.

Efficiencies of gas-turbine with an AGCC and conventional gas-turbine influenced by turbine inlet temperature, efficiency of turbine and compressor were revealed in Fig.6~Fig.8. From the pictures, we can see that efficiency of gas-turbine with an AGCC is influenced smaller than the gas-turbine without regenerator by turbine inlet temperature, efficiency of turbine and compressor smaller. It implies that we can increase efficiency of gas-turbine distinctly based on fundamental of turbine and compressor existing manufacture.

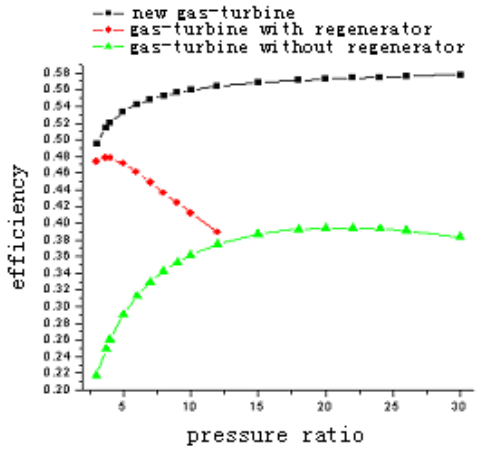

Fig.4 Relationships comparison of thermal efficiency of three types of cycle and pressure ratio. Efficiency of compressor: 0.88, efficiency of turbine: 0.90, thermal ratio: 0.90, pressure loss ratio: 0.05, turbine inlet temperature: 1300K.

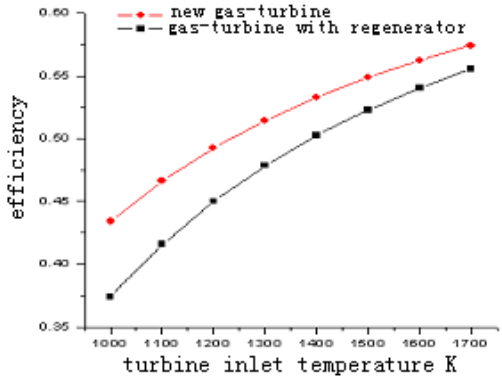

Fig.5 Relations between efficiencies of two types of gas-turbine and turbine inlet temperature change.

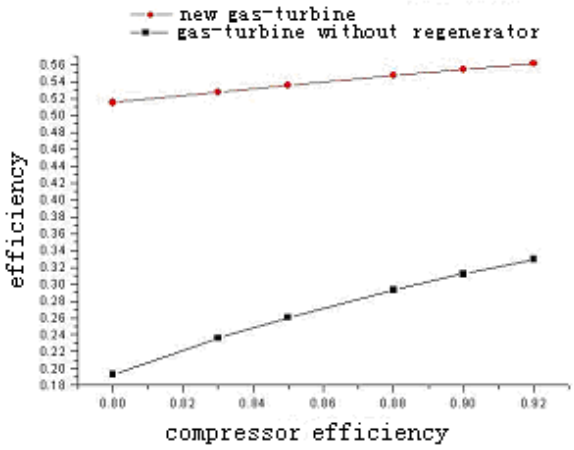

Fig.8 Relations between efficiencies of two types of gas-turbine and change of efficiency of compressor.
Efficiency of turbine: 0.90, turbine inlet temperature: 1300K, thermal ratio: 0.90, pressure loss ratio: 0.05, pressure ratio: 30, high pressure ratio: 10.

Discussion and Conclusion

Combustion is essentially a chemistry reaction under a given temperature region. If conditions are satisfied, it can be completed rapidly and spontaneously. Inside the turbine, temperature is very high and air is enough, so the reaction of fuel and air may continue even though there have no stabile burning region. Furthermore, air and fuel could contact sufficiently inside the turbine because of the stirring of the blades and the turbulence of air.

Based on the structure of gas turbine, fuel is sprayed into turbine might through the small hole bored on the immobile blades or the ejector nozzle lay between the immobile blades. This means the spaces between two blades becomes mini-type combustors. What we called combustion technology inside turbine might be a technology that heat released from sprayed fuel equaled to the work output of this stage. But this method would destruct flow field, make the structure and process control of turbine more complicated and occur partial overheat region. The structure of turbine blades is displayed in Fig.9.

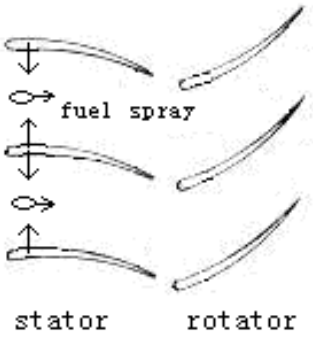

Fig.9: Combustion inside vane channel.

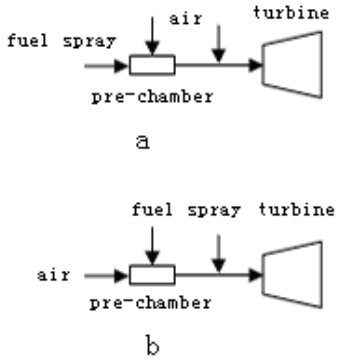

Fig10 Combustion inside the turbine.

On the other hand, we can divide the main airflow into two parts, one flows into pre-chamber with the whole fuel sprayed into, and could form a rich-fuel combustion state. So the high temperature gas with incomplete combusting fuel would flow into turbine and react with the other airflow continually when they are mixing, as the Fig.10 (a) displays.

Or the air flowed into pre-chamber wholly while fuel sprayed in two stages. One fuel-flow sprayed into pre-chamber and the remains sprayed into before turbine, this means that the fuel reacts with remained oxygen in the high temperature gas and export work, seen in Fig.10 (b).

The two models both make the turbine become a big combustor with stirrer. In order to avoid reaction much rapid or much slow, the position and flux of fuel spray, mixing process of fuel and high-temperature fume, concentration of reactors and temperature field of turbine must be think carefully, and the turbine might be redesigned. Both the two models have some analogies with the technology of high-temperature-air-combustion [7][8]. Thereby the process of combustion inside the turbine comes true.

The combustion process inside the turbine is very complicated. For liquid fuel, we hope the process of atomization, vaporization, mixing and combustion would be finished completely, on the other hand, the liquid fuel should avoid to spray onto the surface of blades in the small spaces, since it will be harm to turbine blades. Besides that the process of soot production is to be thought carefully. These need research systematically in serial problems such as: turbine structure, blade air-film defense, flow field and temperature field and process control. In present, the technology of combustion inside the turbine still is a conception, and application in practice has no report, therefore, the relative experiments should be necessary.

Compared to conventional gas-turbine, the efficiency of the AGCC gas-turbine have obvious improvement. Moreover, sensitivity of AGCC gas-turbine to the temperature, efficiency of turbine and compressor is lower than conventional one. So higher efficiency might be achieved even though low reaction temperature as long as the reaction could continue. And this low temperature is benefited for turbine thermal-defense and reducing NOx emission. Furthermore, efficiency of gas-turbine could be enhanced greatly based on existing technical foundation.

In addition that improving efficiency of modern gas-turbine would be influenced by increasing cooling air flux in gas-turbine, but apply technology of combustion inside the turbine could increase air utilization in maximum degree, because the cooling air flowed into turbine can occur re-burning action. This will be benefited to improve efficiency of gas-turbine. Although achieving the process of combustion inside the turbine has many big difficulties, it is deserved to research farther.

Key words: Ferromagnetic power ; DSP; controller; FPGA;SPI

Abstract: For the output requirements of low ripple voltage and high precision exciting current for ferromagnetic power, The combination of DSP and FPGA is put forward to the magnet power supply controller design scheme, First ,The power source controller hardware system is given, then the signal conditioning circuit, the intermediate link of data processing and the backend driver circuit of system is Introduced in detail, Finally gives control process of the program of the controller software design for the main program and PWM dead zone.

Introduction

Magnet power supply mostly as a special power supply offers specific exciting current for magnet to generate required magnetic field,it is widely used to apply for accelerator, mass spectrometer and so on equipment.The magnet power basic requirements from the magnetic field characteristic, so the magnet power supply based on digital power controller in order to output high precision and high stability exciting current provide an important guarantee[1-2]. This paper introduces magnet power supply controller adopt double CPU structure of DSP and FPGA, FPGA control the high-resolution converter AD7679 to sample the signal, the data acquired can be sent to DSP by SPI interface of DSP, then the output of DSP after operation processing to control the magnet power supply PWM wave with dead time.

General Structure of Controller

Magnet power controller is adopt DSP TMS320F2812 as digital processing module, Through the use of Altera's FPGA controls AD to sample data, data transmission can be realized through SPI interface of DSP and FPGA. The controller communicate with upper computer by the SCI serial port of DSP, it will display and control the running condition of magnet power supply, Main circuit and driver circuit implementation isolation by the backend drivers. General structure of controller is shown in Fig.1.

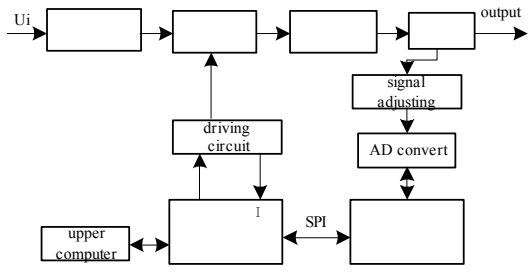

Fig.1 Structure diagram of the magnet power supply controller

Signal Conditioning Circuit

The main function of signal conditioning circuit is signal magnifying and low-pass filtering. To ensure the collection signal of the A/D converter limit between 0 to + 5V, prevent the large current

signal generated the high input voltage damage the port of A/D, level limit protection circuit is designed. A/D converter input adopts finite difference method, the single-ended signals is converted to differential signal, achieve proportional amplifier, Filtering the high frequency noise effectively, to facilitate high precision acquisition of the input signal of A/D. The circuit for the signal amplitude limit, isolation, filtering and amplifying is shown in Fig.2.

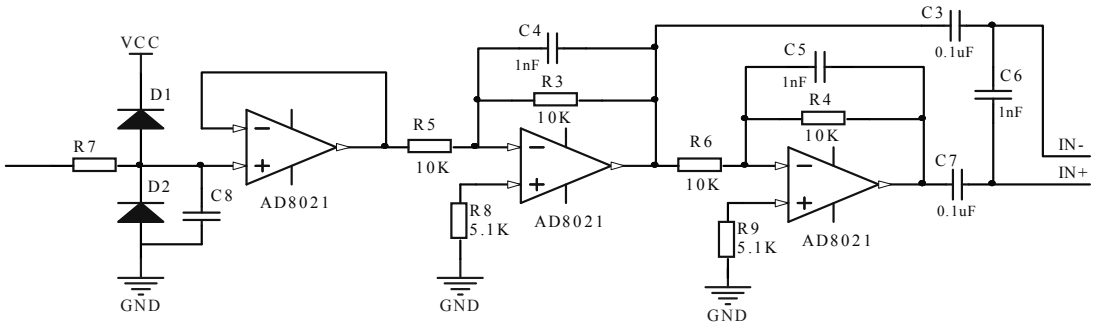

Fig.2 Signal conditioning circuit

The FPGA control of the AD

This design adopts the 18 bit completely differential successive approximation type ADC AD7679, with 570 Kbps sampling rate, at the same time, with 5V or 3V digital logic level compatible. In order to prevent the sample point on pulse switch enables the system oscillation, the DSP sends a switching impulse to FPGA a synchronous signal at the same time, make appropriate delay, FPGA give the ADC sampling command after signal spike pulse disappears. AD operation is divided into four states: idle, start the AD conversion, waiting for the results AD conversion and read the AD conversion. On the falling edge of CONVST signal open conversion process, BUSY will automatically set 1, keep the conversion. When the BUSY signal into a low level and CONVST keep high electricity, AD7679 in the stage of data collection. The FPGA control of the AD is shown in Fig.3. The actual circuit, Between FPGA and AD converter to join four channel magnetic separation device ADuM1412 for data isolation.

Communication Between DSP and FPGA

TMS320F2812 inside with a SPI interface, by defining the control registers, and set up the DSP as the main equipment, to provide the clock signal for communication, the FPGA as a from device. Because of the DSP and FPGA pin voltage to match the I/O interface (3.3V), Don't need level conversion circuit. Set the FPGA to send data in clock pulse rising along, when falling edge in the receive data. Since the FPGA always remove the highest data when sending data, the remaining data left one respectively, so The received data of DSP must be bit by bit left to realize data received. When the SPI STE pin for the lower levels, the FPGA bit by bit to send data; When the SPI CLK pins for high levels at ordinary times, DSP bit by bit to read data, and left after a wait for the next SPI CLK for high level; When SPI STE pin for high levels, DSP has been receiving the data of FPGA sending, after eight

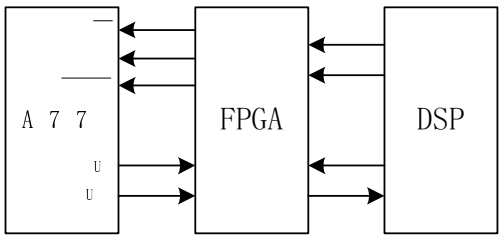

Fig.3 DSP control of the AD and circuit of communication between DSP and FPGA

clock, to complete a sequence of SPI , The received data will be stored in the defined array by DSP. DSP and FPGA communication pin connection is shown in Fig.3.

Driver Circuit Design

Drive circuit use high-speed photoelectric coupler HCPL-4503 to fast realize signal conversion and isolation. The fault signal be sent to PDPINTx pins after by photoelectric coupler isolation TLP521-1, the PWM output pins into a high impedance state, at the same time to generate an interrupt, blockade drive signal, shut down power devices. Driver circuit is shown in figure.4.

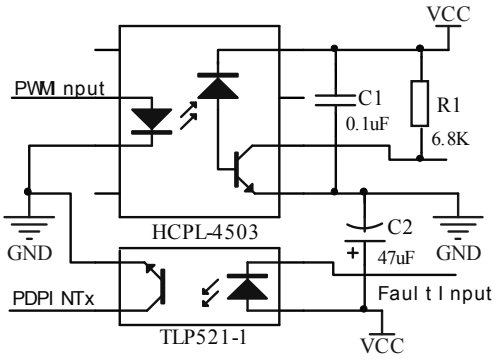

Fig.4 Backend driving circuit

Conteroller Software Design

When the interrupt occurs, DSP program will be jump to the corresponding scale judgment according to the priority of the interrupt response and interrupt subroutine, realize their respective functions. the main program flow chart is shown in Fig.5.

In order to prevent switching devices conduction at the same time of the converter bridge arm up and down, driving signal need to have a dead zone. Set (8-11)bit of dead zone control register DBTCONx of DSP for the dead zone of the timer, its time cycle is m, (2-4)bit for the dead zone of timer reserve scale factor x/p , if the general timer clock cycles is t, the dead band time $t_s = m \times p \times t$. Dead zone parts control process is shown in Fig.6.

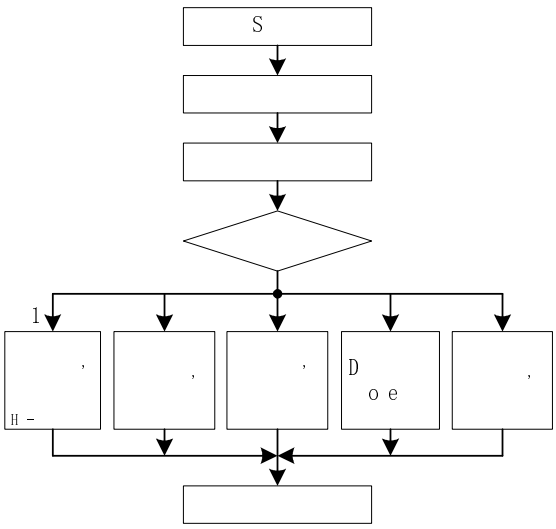

Fig.5 Flowchart of main program

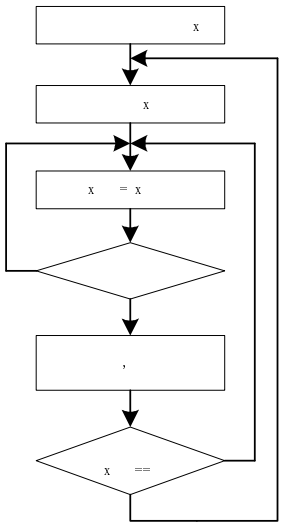

Fig.6 Control-flowchart of dead zone

The configuration of baud rate by SPIBRR registers programming implementation of DSP, Must be pay attention to use system clock synch realize SCLK signal, to reduce the SCLK cause communication error. The communication flowchart of SPI between DSP and FPGA is shown in Fig.7.

Summary

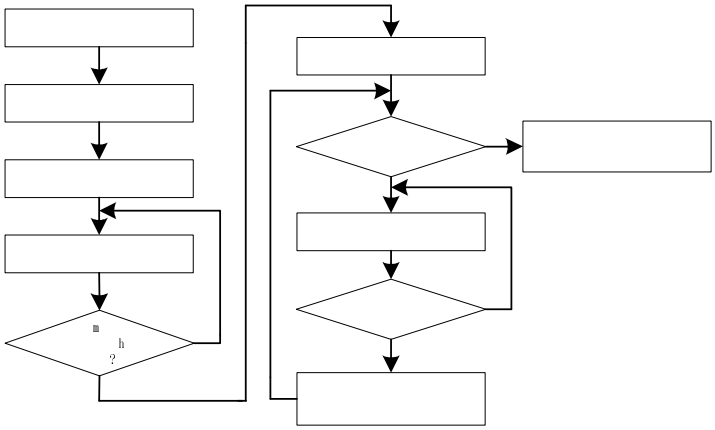

Fig.7 Flowchart of SPI communication between DSP and FPGA

The magnet power supply controller which adopted DSP+FPGA architecture has superiority of both signal processing chips, improve calculation speed and accuracy effectively. In the subsequent research,According to the need to set up the corresponding parameter, Select the appropriate control algorithm, In order to meet the magnet power supply low ripple output and high accurate current control requirements.

Keywords:electric power system security; iron-core saturation; double expontential function fitting algorithm

Abstract. Saturable magnetic circuit is a common phenomenon in power system. It can lead to waveform distortion, coefficient of self inductance decrease and measurement error increase. So establishing a mathematical model for saturable magnetic circuit and revealing the mathematical relationships in saturable phenomenon. It is helpful to reliable and safe operation of power system. This paper base on double expontential function fitting algorithm and simplex algorithm to establish the function relationship between relative permeability and magnetic field intensity. Applying for the model,we can obtain the waveform of magnetic flux in transformer core and transformer voltage waveform. The research has certain significance in the abstract and foreground in the application for the study of saturable phenomenon.

Introduction

BH curve is the key to studying saturable phenomenon. Generally speaking,the BH curve can be determined in laboratory. Therefore there is no simple formula for this kind of curve. But if you look at the mathematics of the problem, BH curve can be gotten according to the polynomial fitting, cubic spline interpolation and so on. The data of curve fitting would be in error. Because calculation of secondary voltage transformers and magnetic flux of iron core have many procedures, calculation error has the trend of becoming bigger. Therefore, in this paper a new method of fitting $\mu_r H$ (μ_r: relative permeability) curve is proposed.

Applying for the model, we can reduce the amount of calculation and lower the calculation error.

Model Building

It is well known that experimental BH curve of silicon steel sheet,as shown in figure(1).

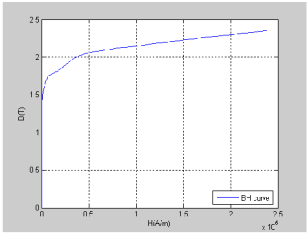

Fig. 1. BH curve of silicon steel sheet.

The relationship between relative permeability and magnetic field intensity, expressed by the simple equation(1). $\mu_r H$ curve shown in figiure(2).

$$\mu_r = \frac{B}{\mu_0 H} \tag{1}$$

In equation(1), the μ_0 is permeability of vacuum, μ_r is relative permeability, B is magnetic induction intensity,H is magnetic field strength.

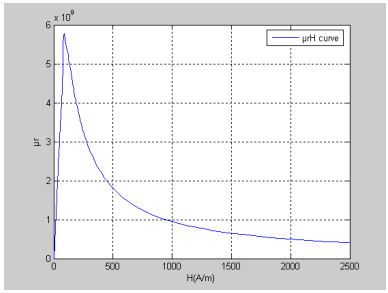

Fig. 2. $\mu_r H$ curve of silicon steel sheet.

Now, we utilized the curve-fitting to establish $\mu_r H$ fun-ction. $\mu_r H$ curve look like a impulse function. So double expontential function fitting algorithm can express $\mu_r H$ curve. The expression can be given as equation(2).

$$y = A(e^{-\alpha x} - e^{-\beta x}) \tag{2}$$

In equation(2). A, α , β is the fitting coefficient.

The basic ideas concerning curve fitting is that find the optimum solution of A, α , β , and make difference between the data of the curve fitting and the experimental data as small as possible. The error function can be given as equation(3).

$$E(A,\alpha,\beta) = [\mu_r - A(e^{-\alpha H_e} - e^{-\beta H_e})]^2 = \min \tag{3}$$

In ordor to find the optimum solution of A, α , β , we need solving the partial derivatives of E function. Then make partial derivatives of E function equal to zero,It can be shown as equation(4).

$$\begin{cases} \dfrac{\partial E(A,\alpha,\beta)}{\partial A} = 0 \\ \dfrac{\partial E(A,\alpha,\beta)}{\partial \alpha} = 0 \\ \dfrac{\partial E(A,\alpha,\beta)}{\partial \beta} = 0 \end{cases} \tag{4}$$

The simplex method is used to solve the system of algebraic equation(4). Since our prices are closely calculated, $A = 2.3584^{10}$, $\alpha = 0.0059429$, $\beta = 0.010769$. $\mu_r H$ curve as shown in figure(3).

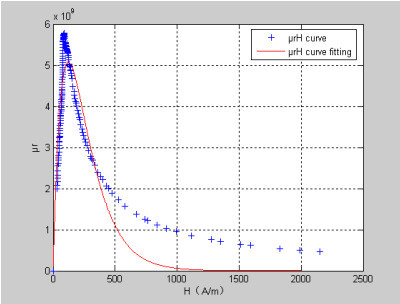

Fig. 3. $\mu_r H$ curve fitting.

From the $\mu_r H$ curve (figure 3), the fitting data accords with the experiment data basically. Fitting function can be shown as equation(5).

$$\mu_r = 2.3584^{10}(e^{-0.006H} - e^{-0.011H}) \tag{5}$$

The function relation between exciting current and magnetic field strength in transformer can be shown as equation(6).

$$H = \frac{NI_e}{l} \tag{6}$$

In equation(6). I_e is exciting current, N is turns,l is loop length.

Eq.(6) substituted in Eq(5), The function relation between relative permeability and exciting current can be express as equation(7).

$$\mu_r = 2.3584^{10}(e^{-0.006\frac{NI_e}{l}} - e^{-0.011\frac{NI_e}{l}}) \tag{7}$$

Model Application

Using the model(7), the magnetic flux and induced electromotive force in transformer core can be calculated. Model of power transformer as shown in the figure(4). Coil(1) is primary winding. The parameters as shown in the Table Ⅰ.

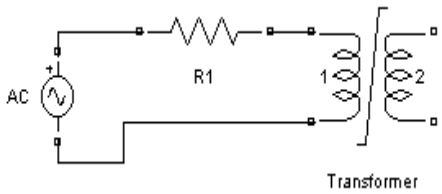

Fig. 4. Model of power transformer.

Table 1. Transformer Parameter

The capacity / frequency of transformer : 150MVA/ 50Hz					
Loss resistance / remanence flux of iron core:1.0805e+006ohm/ 0T					
Loop length / sectional area of iron core: 2m/ 1 m^2					
	Coil resistance R1	Coil leakage inductance L1	Nominal voltage peak	Nominal current peak	Turns of coil
Coil(1)	1.1111 ohm	0.11789H	500kV	300A	500
Coil(2)	1.1111 ohm	0.11789H	230kV	500A	300

According to Faraday law of electromagnetic induction, Induced electromotive force at primary winding can be expressed as equation(8).

$$e = \mu_r \mu_0 N(\frac{dH \cdot S}{dt}) \tag{8}$$

Suppose exciting current equals rated current. Using the model(7), the iron core magnetic flux-time function picture as shown in the figure(5).

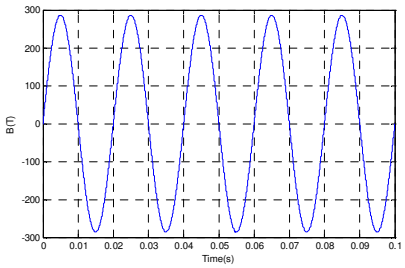

Fig. 5. Iron core magnetic flux-time function picture.

When iron core is not saturated,the magnetic flux-time function is a sine function. So using the model(8), the induced electromotive force at secondary winding is a sine wave as shown in the figure(6).

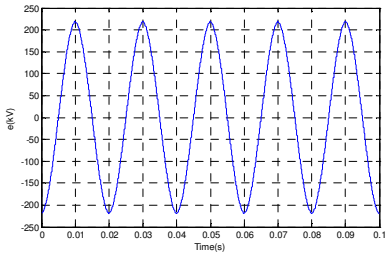

Fig. 6. Induced electromotive force -time function picture.

Suppose exciting current is greater than rated current. Using the model(7), the iron core magnetic flux-time function picture as shown in the figure(7).

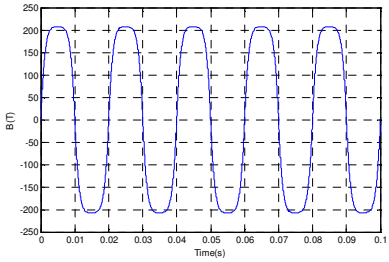

Fig. 7. Iron core magnetic flux-time function picture.

Because of core saturation, magnetic induction intensity in the iron core is a flat wave. Using the model(8), the induction electromotive force at secondary winding is a peaked wave. It shown in figure(8).

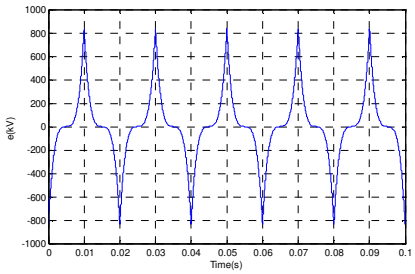

Fig. 8. Iron core induction electromotive force -time function picture.

Conclusion

Detailed calculations shows that it the result of the model(7) is in accordance with the theoretical analysis. So the model is feasible and available. These research and practices are useful references to us.

Keywords: Micro-grid, Micro-source, Droop Control, PWM Control, Proportional Integral, Converter.

Abstract. Considering decentralization of the micro-source units and loads in the micro-grid and concentrating on generation types and models of the storage devices, *droop control* strategy is used in controller design for the distributed generation units. The generation units adopting droop control method based on the droop characteristics can facilitate load power sharing when the powers of loads vary, and can also maintain the system frequency when a unit fault occurs and the micro-grid islands. Then, the operation variations of the micro-grid are analyzed when it runs with load changes in islanding mode and runs with the load power of micro-source varied suddenly. The corresponding rules of the active power, voltage and current for each micro-source and the frequency for the micro-grid are obtained. The simulation data results show the correctness and validity of the droop control strategy.

Introduction

Micro-grid is an independently-controllable power system and the combination of micro-sources, loads, power electronic devices etc. It can fully use the advantage of distributed power generation and overcome the disadvantage of what distributed power generation brings in power distribution network. Micro-sources include Photovoltaic Cell, Fuel Cell, Micro gas turbine, wind power generator, storage battery, super capacitor, fly-wheel storage etc. Micro-grid can operate in grid-connection mode or islanded mode and switch seamlessly between the two modes [1].

Micro-source generates DC by DC converter or rectifier, then through inverter it produces AC, thus form a distributed micro-source which can be connected to micro-grid. Generally, the control strategy for inverter adopts constant PQ control, constant V/f control [4] or droop control. An inverter that adopts PQ control is equivalent to a current source, whose output power is determined by the initial power setting value and not affected by internal power change of micro-grid, applying to the micro-sources don't need the outside support of voltage and frequency. An inverter that adopts V/f control is equivalent to voltage source [5], whose output power is determined by the internal power change of micro-grid and can regulate power, applying to the micro-sources having power storage devices. For parallel-connected micro-source in micro-grid, when grid-connectedly operating, its voltage and frequency is supported by power distribution network. When islanded operating, because of the breaking of power distribution network, the system need a certain number of V/f controlled micro-sources to support the voltage and frequency of micro-grid. Or, all micro-sources adopt droop control to maintain the gird's voltage and frequency together.

For the island micro-grid which uses ocean wave and current as power sources, due to natural causes, the difference between actual condition and rated condition is very big, causing the actual output power of micro-grid is lower than the rated power, unable to set the main control unit of the system in advance, or the main control unit cannot meet the voltage and frequency requirements for the system. If all micro-sources use droop control strategy, it can make all the power involved in micro-grid's voltage support to ensure stable voltage and current, avoid power fluctuation in the main control unit causes the risk of instability.

Droop Control

Droop Control Principle. By imitating traditional generator's characteristics, droop control use the perceptual line impedance's droop character of paralleled active power with frequency, reactive power with voltage amplitude which are approximation of the droop curve to adjust the frequency and amplitude of output voltage. So the essence of droop control is: micro-source measures its own emitted power, according to droop character, then converts the power signal to output voltage amplitude and frequency control signal as instruction; According to the adjusted power, it reversely reacts on output voltage and frequency signal to realize self-adjusting and automatic power distribution.

Inverter's droop control principle is shown in Fig 1. For Fig 1(a), when a distributed power supply active output power increases, the operating point of the distributed power moves from A in Fig. 1(a) to B. So does Q-V droop control principle, which is shown in Fig. 1(b).

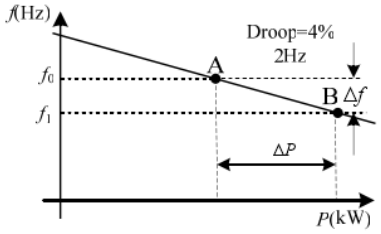

Fig. 1(a) P-f droop control principle

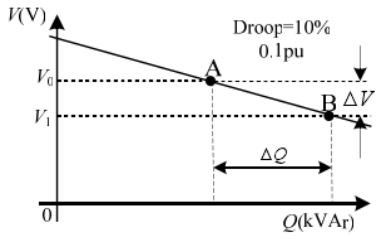

Fig. 1(b) Q-V droop control principle

Droop Character. For a micro-source controlled by inverter in micro-grid, the output power can be modeled as:

$$P_i = \left(\frac{UU_i}{Z} \cos \delta_i - \frac{U_i^2}{Z} \right) \cos \theta + \frac{UU_i}{Z} \sin \delta_i \sin \theta \tag{1}$$

$$Q_i = \left(\frac{UU_i}{Z} \cos \delta_i - \frac{U_i^2}{Z} \right) \sin \theta - \frac{UU_i}{Z} \sin \delta_i \sin \theta \tag{2}$$

U is the voltage of micro-grid, U_i is the output voltage of micro-source, δ_i is the phase difference between U_i and U, Z and θ are respectively the amplitude and phase of output resistant.

In micro-grid, because δ is very small, so $\sin \delta \approx \delta$ and the power calculations can be simplyfied as:

$$P_i \approx \frac{UU_i}{\omega L_i} \delta_i \tag{3}$$

$$Q_i \approx \frac{U(U_i - U)}{\omega L_i} \tag{4}$$

Micro-grid's voltage phase is determined by the line impedance, so it is considered as constant in the short term.And phase voltage of the inverter is determined by integration of frequency to time, So phase angle is proportional to the frequency, the relation between droop is below and shown in Fig. 2:

$$f^* = f_0 - m(P - P_0) \tag{5}$$

$$U^* = U_0 - n(Q - Q_0) \tag{6}$$

m and *n* are respectively the droop coefficent of frequency and voltage, f_0, U_0 are respectively rated frequency and voltage. P_0, Q_0 are respectively rated active output power and reactive output power. P, Q are respectively actual active output power and reactive output power. f^*, U^* are respectively referentce frequency and voltage at present.

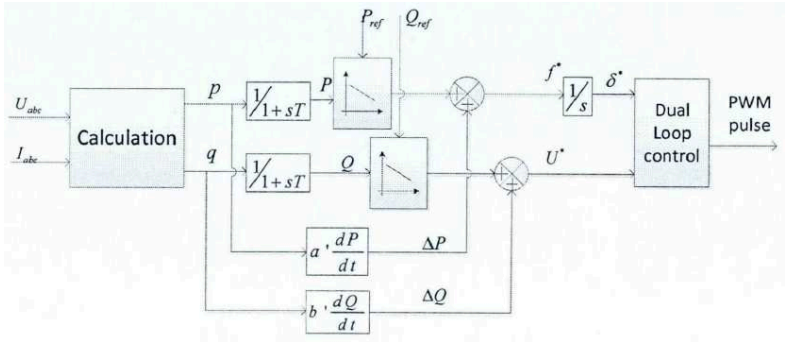

Fig. 2: Diagram of droop control for inverter

Voltage Output Control

Voltage-Current Dual Loop Control. Detect 3-phase load voltage U_{abc}, load current I_{abc} and inverter output current i_C, through the axis conversion shown in equations(7)(8) aquires values of d, q axis, voltage controller and output voltage feedback form voltage loop, corresponding currents are i_{Cdref}, i_{Cqref}. Assuming $U_d^* = U_R$, $U_q^* = 0$. Under the voltage loop control, output voltage can stabilise. Current controller and output current feedback form current loop, whose output vectors are u_d, u_q.

$$\begin{bmatrix} u_d \\ u_q \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\omega t & \cos\left(\omega t - \frac{2\pi}{3}\right) & \cos\left(\omega t + \frac{2\pi}{3}\right) \\ -\sin\omega t & -\sin\left(\omega t - \frac{2\pi}{3}\right) & -\sin\left(\omega t + \frac{2\pi}{3}\right) \end{bmatrix} \begin{bmatrix} u_A \\ u_B \\ u_C \end{bmatrix} \tag{7}$$

$$\begin{bmatrix} i_d \\ i_q \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\omega t & \cos\left(\omega t - \frac{2\pi}{3}\right) & \cos\left(\omega t + \frac{2\pi}{3}\right) \\ -\sin\omega t & -\sin\left(\omega t - \frac{2\pi}{3}\right) & -\sin\left(\omega t + \frac{2\pi}{3}\right) \end{bmatrix} \begin{bmatrix} i_A \\ i_B \\ i_C \end{bmatrix} \tag{8}$$

Using output voltage vector u_d, u_q and voltage vector SPWM control modulation, PWM pulse signals of 6 switched of inverter are aquired. Under the voltage-current dual loop control shown in Fig 3, inverter can output stable sinusoidal wave voltage.

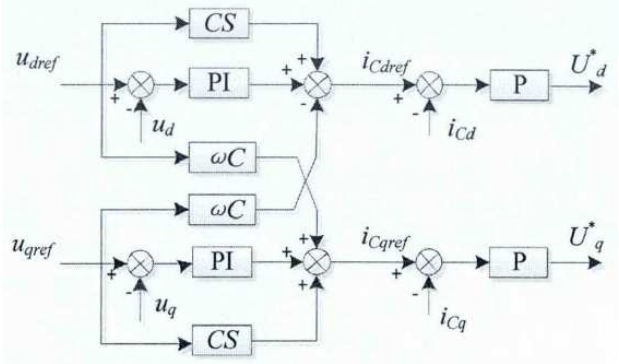

Fig. 3 Diagram of voltage-current dual loop control

Proportional Integral. Proportional Integral (PI) modulation combines negative voltage feedback to realize indifference regulation. Current internal loop controlling capacitor current is better than controlling inductive current as former can improve system response speed. When carrier frequency is far greater than system frequency, integral control is used.

Simulation Analysis

Simulation Parameters. In the simulation, system parameters are set as: Micro-source DC-side voltage V_{dc}=800V, PWM generator carrier frequency f_s=8000Hz, filter inductance L=3mH, filter capacitor C=1500uF, voltage loop PI controller K_p=10, K_i=100, current loop PI controller K_p=10, droop control coefficient $m=10^{-5}$, $n=3\times10^{-4}$, P_{ref}=15000W, Q_{ref}=0. Active power load of Load 1 is 10^4 kW, active power load of Load 2 is 5×10^3 kW. Simulation time is 0.4s, simulation discrete time is 5×10^{-5}s。 Load 1 is connected at first. Load 2 connect to micro-grid at 0.2s and break at 0.3s. Simulation results show in Fig. (4).

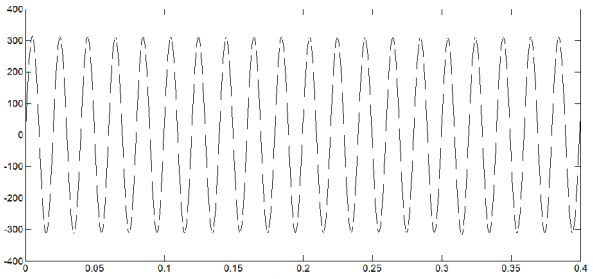

Fig. 4(a). Voltage of micro-grid system

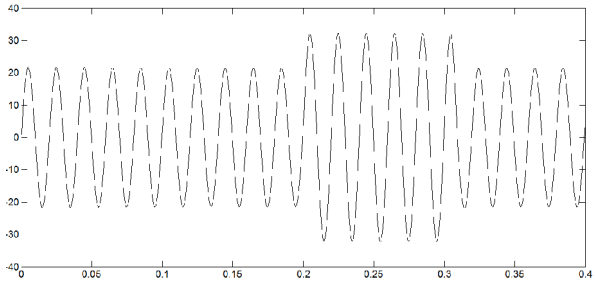

Fig. 4(b). Current of micro-grid system

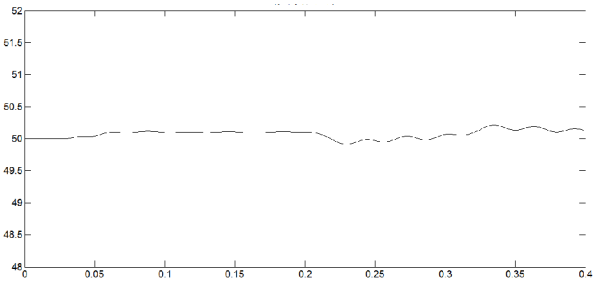

Fig. 4(c). Frequency of micro-grid system

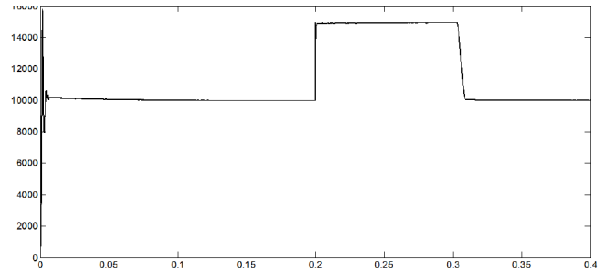

Fig. 4(d). Active output power of micro-grid

Result Analysis. Simulation results are shown in Fig. 4. For Fig. 4(a), AC peak voltage of system is 310V, which means AC V_{rms} is 220V. When breaking Load 2 at 0.3s, the voltage is still 310V, indicating the voltage control is effective.

For Fig. 4(b), between 0.2s and 0.3s, because load power increases from 10kW to 15kW, the output current increases to a multiple of 1.5.

For Fig. 4(c), the frequency of system declines after 0.2s and increases after 0.3s, and the values of declining and increase accord with the value of droop control principle, also range in the 50 ± 0.5Hz, demonstrating droop control adopts adjusting frequency to adjust active output power.

Fig. 4(d) shows the active output power of system, after the start of simulation, the miro-grid can output 10kW active power in a short time. At 0.2s, the system begins to output 15kW. At 0.3s, the system downs its output to 10kW. The output power can meet the load power.

Conclusions

By MATLAB/Simulink software, the simulation of the droop control for single Micro-source grid system is verified. The results manifest that droop control strategy can ensure power balance between micro-source and load when system's output power varies. And it keeps the stability of voltage and

frequency in islanded operation, which satisfies the requirements of system's power quality that the load demand. It proves the feasibility and reasonability of the application of droop control strategy in the island micro-grid.

Keywords: PID; Fuzzy Control; Fuzzy PID

Abstract. PID controllers are widely used in industrial process control. The determination of the conventional PID controller parameter tuning is based on obtaining the mathematical model of controlled objects and according to certain rules, which is difficult to adapt to complex control systems. In this paper ,against its adverse effect parameter tuning, long time debugging, defects and poor adaptability of the controlled object，the fuzzy control and PID control are combined and the fuzzy PID controller is proposed. Then, I combine the examples of thermal power units using MATLAB to simulate. The simulation results show that the fuzzy self-tuning PID controller not only has the advantages of fuzzy control such as fast, adaptability, etc, but also the characteristics of high accuracy PID control, which make the system has a good control effect.

Introduction

In industrial control, PID controllers are widely used for its advantages as simple device, easy parameter adjustment and etc. In PID control algorithm, parameter tuning is very important, which directly affects the control performance. For simple control objects or known models, the use of traditional PID control parameters tuning method generally can get good control performance. However, conventional PID control is mainly used to control linear controlled object with exact models, but for some time-varying and nonlinear systems, it is difficult to achieve desired control effects. The best parameters adjustment method of conventional PID control has not been automated, which rely on manual tuning method of trial and error requires not only a wealth of skills and experience, and very time consuming. Fuzzy control does not depend on precise mathematical model of controlled object, but a way of summarizing manual automatic control based on the experience. This article shows a fuzzy PID controller based on the fuzzy control theory. In this paper, PID control and fuzzy PID control are used for the actual thermal power system simulation, and their control effects are observed and compared.

PID control

PID control is proportional (P), integral (I), differential (D) controller, which is a linear control. Its role is to take the difference of the setpoint value r(t) and the actual output of the controlled parameter y (t) as the input of the controller, then the controller generates control volumes according to the percentage of deviation, proportional-integral and proportional integral derivative. The result of the sum of the three operators, we get the output of the PID controller. In the continuous-time domain, PID controller algorithm is expressed as equation (1):

$$Y(t) = K_p\left[e(t) + \int_0^t e(t)dt/T_i + T_d d\,e(t)/dt\right] \tag{1}$$

In equation (1), $Y(t)$ is the output, $e(t)$ is the deviation, K_p is the proportionality coefficient, T_i is the integral time coefficient, T_d is the derivative time coefficient.

PID algorithm schematics is shown in figure (1) .

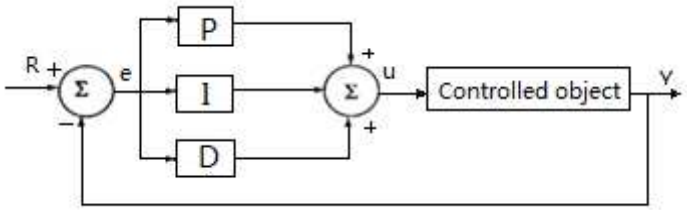

Fig. 1. PID algorithm schematics

In the computer control system, the digital PID controller is generally used. This controller is discretized using differential equations. At the sampling time t=KT (T is the sampling period), equation (2) can be obtained:

$$Y(t) = K_p\left\{e(t) + \frac{T}{T_i}\sum_{i=1}^{k} e(i) + \frac{T_d}{T}\left[e(k) - e(k-1)\right]\right\} \tag{2}$$

Under normal circumstances, PID controller in accordance with the control principle of steady, accurate and fast to adjust the three parameters. At the same time, PID controller needs to taking into account the diversity of object features, different control targets set and optimized in order to achieve satisfactory control effect. The PID controller parameter optimization problem is to use the algorithm to optimize the three parameters K_p, T_i, T_d in equation (2).

Conventional PID parameter optimization methods are generally single-objective approach, which is difficult to take into account of the three indicators, resulting in less than optimal parameters, poor performance and poor adaptability on the operating conditions, less than ideal control effect, so that the application of the PID controller is limited. Therefore, this article uses the Particle Swarm Optimization (PSO) on PID parameter optimization.

Fuzzy Control

Fuzzy control is the use of fuzzy set theory, which turns the human expert control strategy using natural language into algorithm language that a computer can accept in order to simulate human intelligence and achieve effective control of the production process. Fuzzy control system is a computer control system, generally similar to the composition of a digital control system, and only the digital controller is a fuzzy control algorithm operation. Fuzzy control system block diagram is shown in figure (2).

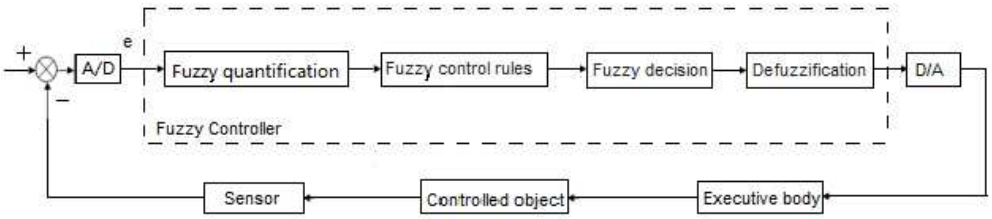

Fig. 2. Fuzzy control system block diagram

Fuzzy controller generally consists of the following four components:

(1) Fuzzy quantification (fuzzy interface): Fuzzy controller receives the exact digital amounts that represent the system deviation signal transferred from the digital A / D converter, therefore, the exact function of the part is converting the exact deviation amount into a digital amount of blur. If the fuzzy controller is a dual input, you should also calculate the deviation of the rate of change according to the deviation, and then convert it into a blur. This process makes the exact amount of input convert into the amount of blur represented by fuzzy set membership function.

(2) Fuzzy control rules: Also known as the knowledge base, which is used to store knowledge fuzzy reasoning required. Generally, we acquire knowledge according to the control experience of experts and the design of knowledge base is usually performed offline. However, with the increasing demand for the control, it also can be designed as online learning, such as changing the parameter of language value, control the number or form of rules and the like.

(3) Fuzzy decision: Also known as the fuzzy inference engine, which is the core part of the fuzzy controller. It uses knowledge of fuzzy control rule base to simulate human reasoning process, and gives the appropriate output. So it has the ability to simulate human reasoning fuzzy.

(4) Defuzzification (exact oriented interface): The output we've got is a fuzzy variable and we must use a exact amount to control. Thus, the task of defuzzification is to convert the fuzzy output obtaining by fuzzy calculation into the exact digital amount that can be received by actual systems, and use a D / A converter to convert it to a analog and then send it to actuators.

Fuzzy PID Control

About fuzzy controller design, it is not based on the mathematical model of controlled objects to set the parameters, thus, the fuzzy control has some adaptation to nonlinear and time-varying controlled objects, that is has a advantage of good robustness. In addition, as long as the system is stable, the desired control action frequency is very low, so that the actuator does not require frequent moves, which is a special project needed feature. However, the biggest problem of fuzzy control system is that it can't guarantee that the system no static error and it does not meet many of the needs of engineering problems. PID controller has characteristics such as a simple principle, easy to use, robustness, control quality of the process's lower sensitivity to process changes, the controller parameter tuning easier, no static droop characteristics, has been leading the field of industrial process control controller. Therefore, the combination of fuzzy control and PI control constitutes a complex controller to play the advantages of both controllers, which can expand the applications of fuzzy control.

Fuzzy control and PID control series

In the basic fuzzy control system, the output of fuzzy control table to go through a output link into actual control amount and then applied to the controlled object. There are two commonly used output links: output proportional and integral output. The proportion of the output is the basic fuzzy controller and its step response faster, but also have poor control. There are many forms integral output, such as series an integrator between the fuzzy controller and the controlled object. Static output allows the system integrator difference is small, but with slow corresponding, large overshoot, and the system is easy unstable. Therefore, this approach is not recommended.

Parallel fuzzy control and PID control

Compound fuzzy control system fuzzy controller with PID controller in parallel is shown in figure (3). In this control mode, it is equivalent to parallel a non-linear proportional link in the proportion links of PI controller in order to improve the speed of adjustment.

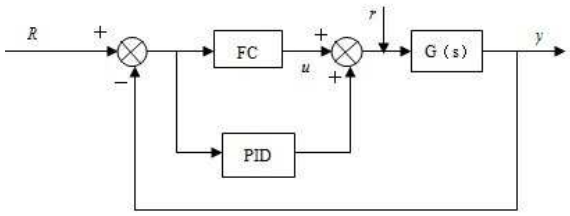

Fig. 3. Compound fuzzy control and PID fuzzy controller parallel system structure.

Fuzzy self-tuning PID control

PID control requires very precise model of the structure, but in practical applications, most industrial processes have different levels of nonlinear, parameter variability and model uncertainty and thus using conventional PID control cannot achieve precise control for industrial process. The fuzzy control has weak dependence on the mathematical model and the process does not need to establish precise mathematical model, just need to send the fuzzy rules and related information (such as evaluation, initial PID parameters) into the computer as a knowledge repository. Then the computer control system according to the actual situation takes the use of fuzzy reasoning can automatically adjust to the optimal PID parameters, and that is the fuzzy adaptive PID control.

Fuzzy PID parameters self-tuning control takes error *e* and error rate of change *ec* as fuzzy PID input, so can meet the different moments of *e* and *ec* on the PID parameter tuning requirements. Modify PID parameters K_p, T_i, T_d online use fuzzy control rules then it constitutes a self-tuning fuzzy PID controller. The control system architecture is shown in figure (4).

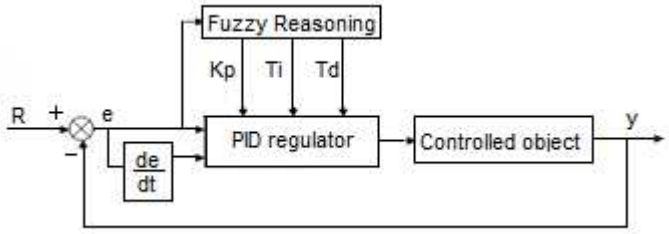

Fig. 4. Fuzzy PID control system structure.

The simulation results and analysis of a PID controller and a fuzzy PID controller

The article takes air volume furnace pressure transfer function and water volume main steam temperature transfer function of a thermal power plant as models, uses the traditional PID control and fuzzy PID control to optimize PID controller parameters and simulation.

The transfer function model of air volume furnace pressure of a thermal power plant is shown in equation (3):

$$G(s)=\frac{0.74}{(3s+1)^2} \quad \text{(System I)} \tag{3}$$

The transfer function model of water volume main steam temperature of a thermal power plant is shown in equation (4):

$$G(s)=\frac{-11.32}{(192.5s+1)^3}e^{-8.4s} \quad \text{(System II)} \tag{4}$$

The two systems are used in a single-loop control structure, and the same controller. These two systems are first with PID control and then with fuzzy PID control. Comparison and analysis of the effects of two control methods will be shown.

Simulation results and analysis. The simulation result is shown in figure(5).

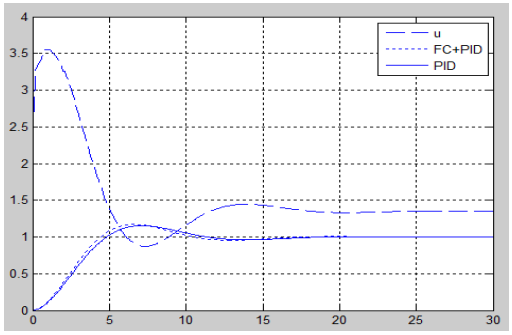

Fig. 5. Simulation of System I.

Shown as figure (5), the control effects of traditional PID control and fuzzy PID control basically meet the performance requirements (overshoot $\varphi < 15\%$, 0.75 <decay rate M_p <0.95, rise time, settling time, etc.), and the control effect is almost the same. Comparing the two methods, the rise time of fuzzy PID control is shorter than the traditional PID control, so the fuzzy PID controller responses faster. Generally speaking, for the system I: $G(s) = \dfrac{0.74}{(3s+1)^2}$, fuzzy PID control slightly better than the traditional PID control.

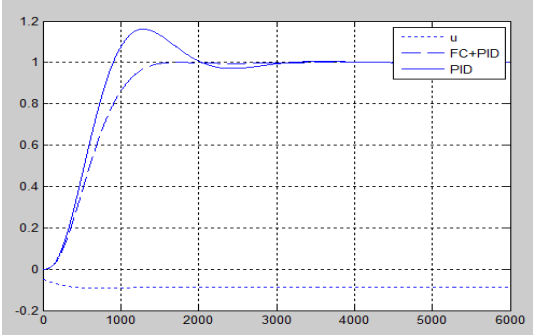

Fig. 6. Simulation of System II.

Shown as figure(6), System II using traditional PID control has overshoot, fast response, long time to adjust; using fuzzy PID control, there is no overshoot, response speed is slightly slower than the traditional PID and adjust time is shorter. Compared to the two methods shows that the fuzzy PID control enables the system without overshoot, but also greatly shorten the adjustment time and the adjustment is better than traditional PID control.

Compared the curve of the controller output u in Figure 5 and Figure 6, it shows that u in Figure 5 has a large output fluctuation and tends to balance in the final; u in Figure 6 has small output fluctuation and becomes more balanced quickly. That is fluctuations in the System II controller output is smaller than in System I. It can be seen that the fuzzy PID control has strong control ability for controller output of small inertia coefficient systems (such as System I) and poor control ability for big ones (such as System II). But for the system output 'y', the control effect is ideal.

Conclusion

In this paper, principles of traditional PID control, fuzzy control, fuzzy PID control are simply explained and based on examples of a thermal power plant uses traditional PID control and fuzzy PID control two methods to simulate with MATLAB, and then compare the control effects of the two methods.

From the simulation results in figure(5)and figure(6), it can be seen that the traditional PID control system has a large overshoot, long transition time and poor stability. However, Fuzzy PID controllers are better than conventional PID controller on overshoot and response time and the system stability is significantly improved. In the parameter tuning process, the PID parameters can be automatically adjusted according to error and error rate of change of the system so it has a better adaptability. This method can be applied to fuzzy control of complex systems, this kind of fuzzy

PID control has advantages of fuzzy control, such as flexibility, fast response, high control accuracy, high robustness; On the other hand, it can build a variety of complex fuzzy PID control systems and observe the results in a very intuitive SIMULINK environment so as to overcome the engineering practice blindness. Thus, combining the fuzzy control with PID control organically, you can achieve good control effects.

Keywords: Small Hydro Power Plant, Magnetic Control Reactor, Optimization Model, Particle Swarm Optimization.

Abstract. Hydropower is the most widely used renewable energy for electricity generation in China, and small hydro power plant (SHPP) is a flexible way of electricity generation in water-rich remote area. Voltage at the end of distribution network may be increased over the acceptable range due to the connection of SHPPs. Magnetic control reactor (MCR) is usually used to reduce the voltage by consuming reactive power. A mathematical model for calculation of the optimal capacity of MCR is proposed in this paper, and particle swarm optimization (PSO) is adopted to solve the optimization problem. Two cases based on the IEEE 33-bus test system are used to validate the proposed method. In the given cases, system voltage is adjusted to the acceptable range.

Introduction

Electrical energy is important to the world and its production increases the carbon emission due to the use of fossil fuel [1, 2]. The increasing environment pressure facilitates the need of clean energy, such as solar energy, wind energy, hydropower, etc. Hydropower is the most widely used renewable energy for electricity generation in China, providing over 20% power consumption annually. Small hydro power plant (SHPP) is one of the most flexible and effective ways of electricity generation in remote area especially in water-rich region, which plays an important role in the improvement of the living standard [3, 4].

However, there are some problems when SHPP connected to the grid, one of which is the voltage violation. SHPP is usually connected at the end of low voltage distribution power system, and its capacity is much bigger than load demand, which results in the voltage increase. Sometimes, the voltage near SHPP connection bus is even beyond the acceptable range. To reduce the high voltage to an appropriate range around the rated value, a shunt reactor is needed. Magnetic control reactor (MCR) is a kind of capacity adjustable shunt reactors, which can be used to lower the voltage by absorbing reactive power. The capacity of MCR determines the bus voltage reduction value, so it is necessary to obtain the optimal MCR capacity. Many studies have been done on maximizing access power and introduction limits of distributed generation [5-7], and the reactive power is usually treated as means of improving the voltage [8-10], but few of them focus on the reactive power absorption. Background with the reality of SHPPs in the southern part of Shaanxi Province, this paper mainly focuses on the reactive consumption of the distribution power system with SHPPs.

A mathematical model is proposed to calculate the optimal capacity of MCR, and particle swarm optimization (PSO) is adopted to solve the optimization problem. Furthermore, two cases featured in single SHPP and three SHPPs are presented to get the optimal MCR capacity, and the method is proved effective.

METHODOLOGY

Mathematical Model. The optimal MCR capacity calculation for distribution power system integrated with multiple SHPPs is shown below.

Objective Function. The object of the SHPP owner is to minimize the total capacity of MCR, which is shown in Eq. 1.

$$\min \sum_{s=1}^{m} Q_{cs} \tag{1}$$

where m is the of number of MCR installation sites, Q_{cs} is the MCR capacity at bus s ($s = 1, 2, \cdots, m$).

Constraint Conditions. There are two kinds of constraints, equality constraints and inequality constraints. The former is power flow equation and the latter is the bound of variables, which is shown below.

Power flow equation:

$$\begin{cases} P_i = P_{Gi} - P_{li} = V_i \sum_{j=1}^{n} V_i \left(G_{ij} \cos\theta_{ij} + B_{ij} \sin\theta_{ij} \right) \\ Q_i = Q_{Gi} + Q_{ci} - Q_{li} = V_i \sum_{j=1}^{n} V_j \left(G_{ij} \sin\theta_{ij} - B_{ij} \cos\theta_{ij} \right) \end{cases} \tag{2}$$

where P_i, P_{Gi}, P_{li} is the active power injection, generation and consumption at bus i, $Q_i, Q_{Gi}, Q_{ci}, Q_{li}$ is the reactive power injection, generation, compensation and consumption at bus i, V_i and θ_i is the voltage and phase angle at bus i, G_{ij} and B_{ij} is the line admittance between bus i and j.

Power limits of SHPPs:

$$0 \le P_{Gs} \le P_{Gs\max} \tag{3}$$

$$Q_{Gs} = k_s P_{Gs} \tag{4}$$

where P_{Gs}, Q_{Gs} is the active power and reactive power of SHPP s, $P_{Gs\max}$ is the upper power limit of SHPP, k_s is a constant determined by power factor of SHPP.

Compensation capacity limits of MCRs:

$$0 \le Q_{cs} \le Q_{cs\max} \tag{5}$$

where $Q_{cs\max}$ is the upper power limit of MCR.

Voltage amplitude limits:

$$U_{i\min} \le U_i \le U_{i\max} \tag{6}$$

where $U_{i\min}, U_{i\max}$ is the lower and upper bound of voltage at bus i.

The optimization model can also be applied to distribution power system with single SHPP, and the objective function is shown in Eq. 7.

$$\min Q_c \tag{7}$$

where Q_c is the MCR capacity and all the constraints are identical.

Optimization Algorithm. Considering the complexity of the optimization problem, a particle swarm optimization algorithm is adopted to calculate the optimal MCR capacity [11], and the flowchart is shown in Fig. 1. In the following cases, the particle number and the iteration are both set as100.

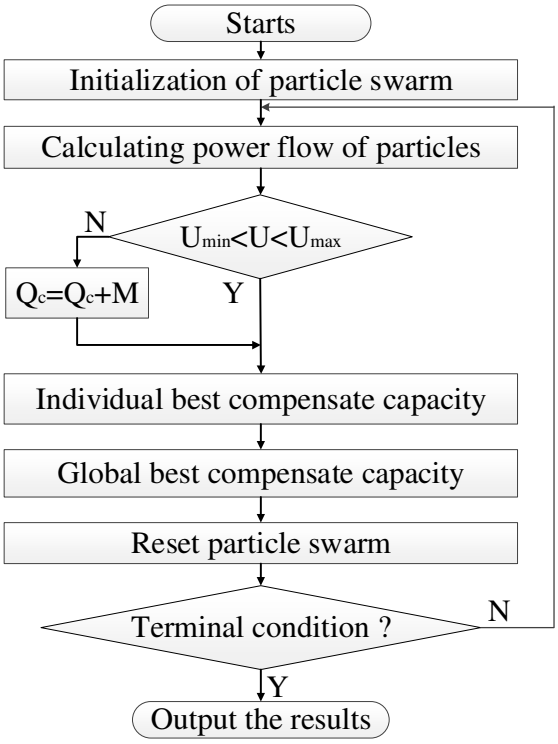

Fig. 1 Flowchart of PSO

Numerical Results

In this section, two cases based on the IEEE 33-bus test system is used to solve the proposed model and the results are provided. The voltage at bus one is set as 10.5kV, and the lower and upper bound of voltage is 0.93kV and 10.5kV respectively [5]. The power factor is 0.8, so k_s equals 0.75.

Case One: Single Small Hydro Plant. In this case, SHPP and MCR are connected at bus 18, and the SHPP capacity is $1600+j1200$ kVA, which is shown in Fig. 2.

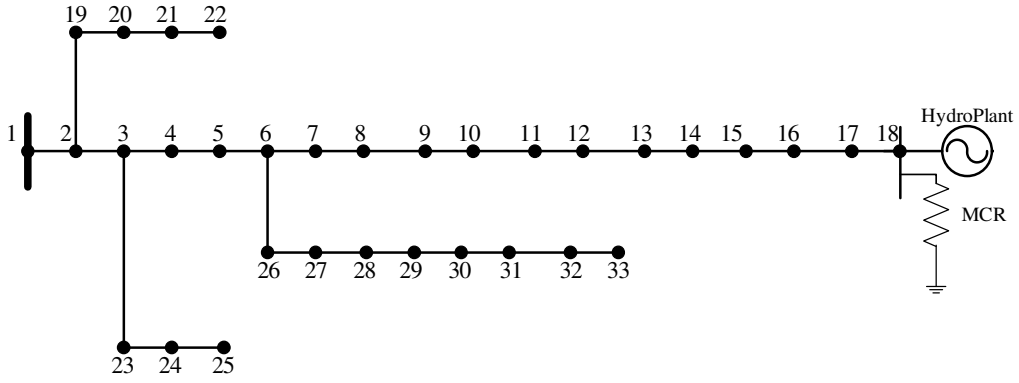

Fig. 2 Diagram of IEEE 33-bus system with single SHPP

The results of single MCR compensation is illustrated in Table 1.

Table 1 Results of single MCR compensation

Bus	Capacity（kVar）	Voltage without MCR（kV）	Voltage with MCR（kV）	Percentage（%）
18	1496	11.7	10.5	-10.25

In Table 1, the optimal capacity of MCR is 1496kVar, and voltage of bus 18 is 11.7kV without MCR, which is much higher than upper limit. By installing MCR, the voltage is reduced 10.25% to

10.5kV, which is within the voltage range. Voltage of all the buses in the system is illustrated in Fig. 3.

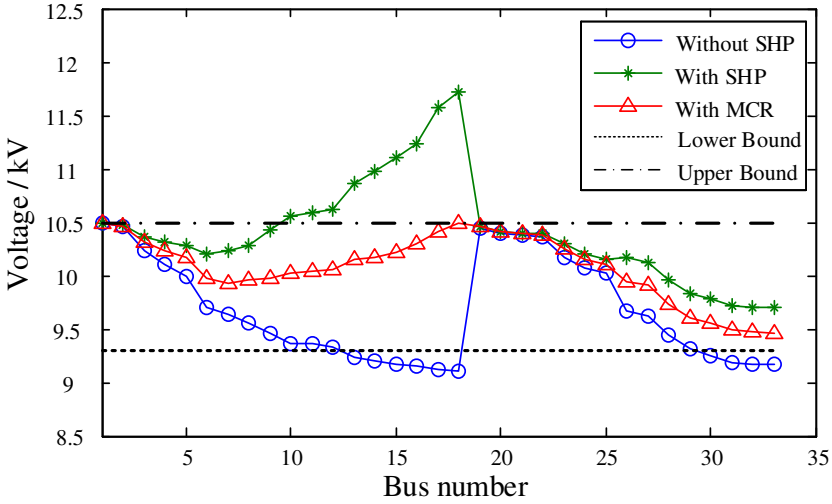

Fig. 3 All buses voltage of the system with single SHPP

Voltage from bus 10 to bus 18 is higher than the upper voltage limit before installing MCR, and the system voltage is reduced within the proper range after installing MCR.

Case Two: Three Small Hydro Plants. In this case, SHPPs and MCRs are connected at bus 18, 22, 33, and SHPPs capacity are $1600+j1200$ kVA, $800+j600$ kVA, $1600+j1200$ kVA respectively, which is shown in Fig. 4.

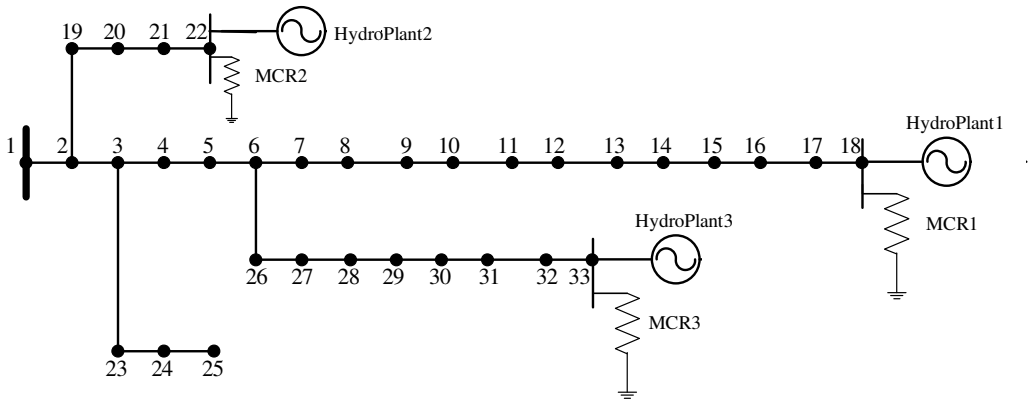

Fig. 4 Diagram of IEEE 33-bus system with three SHPPs

The results of multiple MCRs is illustrated in Table 1.

Table 2 Results of multiple SHPPs compensation

Bus	Capacity（kVar）	Voltage without Compensation（kV）	Voltage with Compensation（kV）	Percentage（%）
18	1837	12.2	10.5	-13.93
22	998	10.8	10.5	-2.78
33	1112	11.3	10.5	9.73

In Table 2, the optimal capacity of MCRs installed in bus 18, 22 and 33 is 1837kVar, 998kVar and 1112kVar respectively and voltage is 12.2kV, 10.8kV and 11.3kV without MCRs, which is much higher than upper limit. By installing MCR, the voltage is reduced to 10.5kV by 10.25%, which is within the voltage range. Voltage of all the buses in the system is illustrated in Fig. 3.

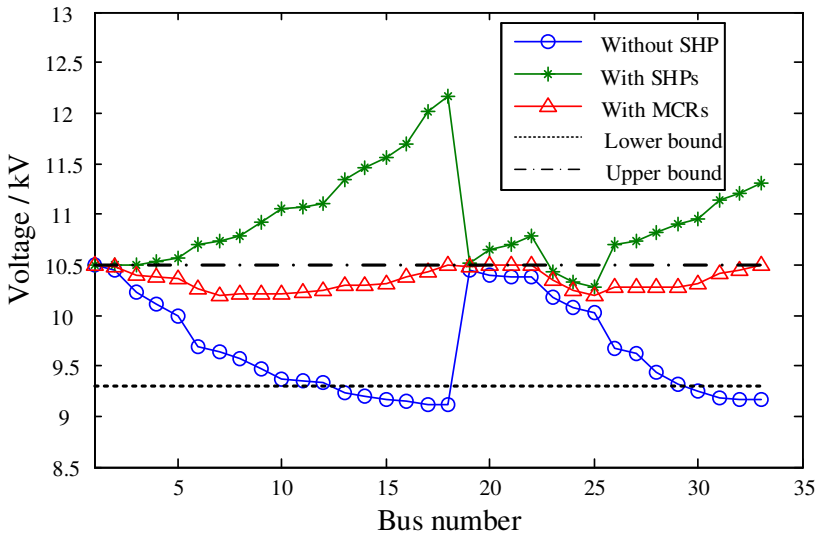

Fig. 5 All buses voltage of the system with three SHPPs

The system bus voltage is almost higher than the upper voltage limit before installing MCRs, and the voltage is reduced to the voltage range.

Conclusions

In order to mitigate the voltage problem in distribution power system integrated with small hydro power plant through reactive power compensation, an optimization model to calculate the optimal MCR capacity is proposed in this paper. From the results of two cases based on the IEEE 33-bus test system, voltage is reduced remarkably and is within the acceptable range. Transformer tap is fixed in the paper, and further studies will be continued with the consideration of adjustable transformer tap.

Key words: digital device test automatic testing; test system; IEC61580

Abstract: Aiming at the digital device test, design a automatic test system, introduced the concept, architecture and technology. The PC sends SMV to digital device based on IEC61850-9-2, Then receive real data from device through the PC serial based on IEC103, constructing a loop, then completed the test. Software static structure adopts the modular programming, dynamic data exchange uses multithread. According to the configured test case, test items can be completed automatically. The system is based on PC, compared with the traditional test instrument to save hardware cost. With the help of calculation and control capabilities of the PC, realize the automatic testing, make people liberation from repetitive work, more focused on the analysis of test results, improve test quality and efficiency.

Introduction

Digital device is an important part of power system, its normal work of great significance to ensure the safe and stable operation of power system. The digital device tested effectively, very important to ensure the normal and stable of the whole power system. With the development of science and technology make a spurt of progress and the coming of digital era, digital substation[1] has become the development direction of the future substation technology. The testing specification of digital device Based on the IEC61850 communication is not the same as usual. the digital device's sampling value, input/output value are based on the digital signal, so can simulated by PC, and digital relay protection testing automatically become possible.

Automatic measuring technique is introduced in this article, for measurement function of the digital device, realize the automatic test. Provides an automatic test scheme for the Testing personnel. Set the test case, automatic testing can be unmanned, and generate test results. In addition, the system provides debugging interface for test personnel, can by a single test case, also can set breakpoints to check and locate defects.

Test architecture

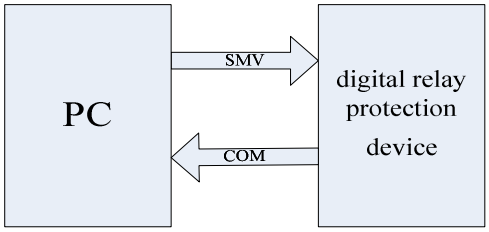

Fig.1 Simulating surroundings on test system

Figure 1 is a simulation environment of the automatic test system[2], it is a closed loop structure. In this system, the PC based on IEC61850-9-2 protocol send predetermined SMV messages to the digital Device and calculate the expected results, in the second time delay (customizable), PC call

data from digital Device through serial port based on IEC60870-5-103, and then put up the measured value and the expected values are compared, concluded that the results.

Test system software design

2.1 Software architecture

In order to facilitate code reuse, expansion and reduce the cost of maintenance, this system uses the development method of modular, hierarchical design. Between the various functional modules design idea of high cohesion, low coupling, in addition to the host program, all of other modules use dynamic link library in technology, module between synchronous multithread and signal mechanism. The test system software architecture is shown in figure 2.

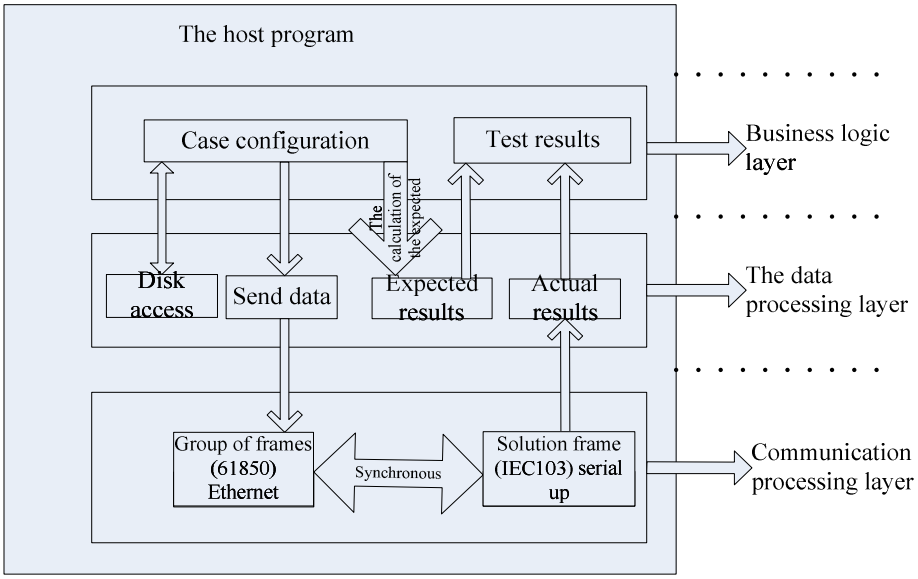

Fig.2 Software structure of test system

The host program is the main program of the system, Contain business logic layer, data processing layer, communication layer. To connection the hierarchy and module， realize the function of start and stop operation. In addition to providing global message processing and recording the running log operation. The following three levels: the system business logic layer, data layer, communication layer are introduced.

2.2 Business logic layer

Business logic layer mainly realizes the Processing of test configuration and results. Configured test case includes two parts，test instrument configuration and state sequence configuration.

The test instrument configuration to achieve communication and digital device, network configuration, serial configuration; channel analog correlation, channel number, channel packet types and ratings settings; group SMV frame related appid, priority, sampling points set[3].

State sequence configuration include the data source configuration, sending data source with the state sequence pattern, in order to make the sequence in each state or state combination simulation of a fault, the continuous playback of multiple faults in order to realize the automatic measurement, automatic testing unattended. Each state in the sequence contains not only to value information transmitted sample, also contains the current state of the actual results allowed error range.

Processing test results is in accordance with the error range of the fault condition of the requirements, the data processing layer to calculate the expected results and actual results data are compared, and finally generate test results and to submit the report. Test report is generated

automatically, in the test report in addition to each gives the conclusion on the measurement test content, test results are also with each dynamic test case, the test results contain "OK", "FAULT", "UNKNOWN" status, covering the test configuration used in all test cases project.

2.3 The data processing layer

Data processing layer consist of four function blocks. Access of test case，generation send data, calculate the expected results, deal actual results.

Access of test case to provide interface of test cases to save and read from disk, since the state sequence relates to the data quantity is relatively large and the structure is complex, the memory mapping technology, avoids the troublesome operation of the complex structure of disk reads and writes, in the test cases stored and read time showed superior performance.

Generation send data mainly completes to each channel test cases sampled values in discrete and harmonic superposition. discrete sampling values is based on amplitude, initial phase, the number of sampling points and other information which configured in case, using sine wave discrete algorithm[4]. Harmonic superposition of harmonic[5] according to the frequency, amplitude information configured in test cases . Each channel can be stacked 2 to 50 harmonic data[5].

Calculate the expected result is according to sampling and harmonic information, Based on the principle of digital device, to calculate the expected test results of measured values. The line voltage and line current can use results from channel sampling value configuration, the main phase voltage, active power, reactive power, apparent power and so on are need to calculate.

The actual result here is acquired from the IEC60870-5-103 frame which processing in layer solution frame.

2.4 Communication processing layer

SMV messages based on IEC61850-9-2, Serial messages based on IEC60870-5-103 were completed in Communication processing layer. The synchronization is to ensure that the measured data from the IEC60870-5-103 message and the sampling data of current state are Correspond, in order to protect the business logic layer processing test results when the expected value and the actual value of comparable.

2.4.1 SMV packet sending module

SMV message frame based on IEC61850-9-2 specification, frame content depends on the test configuration module configuration.

PC simulation of the SMV message sent is a problem of technology, digital device requires very high received SMV message real-time, 50HZ frequency, according to the sampling rate and ASDU numbers in frame, the transmission rate requirements are also different, as shown in table 1.

Tab.1 Sending speed rate and sampling rate at 50Hz

Sampling rate (points / Cycle)	ASDU numbers of one Frame （points/Frame）	The sending rate(frames per second)	Transmission interval(MS)	Maximum allowed message sending interval (MS)
200	2	5000	0.2	5
200	5	2000	0.5	5
200	10	1000	1	5
80	5	800	1.25	5
80	10	400	2.5	5

From table 1 we can see, when the sampling rate is 200, each frame of the message contains 2 ASDU, requirements on the transmission rate of 5000 frames per second, which is average every 0.2ms would send a message, the largest interval does not exceed 5ms. The PC in the data preparation and transmission timing control put forward higher requirements. The conventional PC based computing power, the cache technology, to continue to prepare the data to be transmitted is feasible, but due to the non real-time operating system PC is based on the message mechanism, the precision of time control in about 10ms under the general situation, be far from the transmission precision 0.2ms.

In this issue we through technology exchange preselected multimedia timer and system timer interrupt two schemes, finally through the practice of using the system timer interrupt to achieve timing control. System timer interrupt the use of 8253 PC in the programmable timer / counter chip, to meet the demand for control.

2.4.2 IEC60870-5-103 message up module

Digital device provides external serial port which follows the IEC60870-5-103 protocol, other device can get sampling values and other information via this serial port. Our automatic testing system is to grasp this point, first establish communication with device through the serial port, and then upload information in accordance with the IEC60870-5-103 standard. According to the demand of the system, the module is divided into three layers, as shown in figure 3.

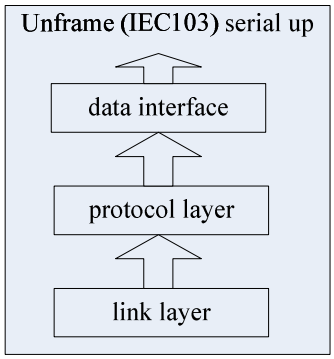

Fig.5 Relational heirarchical structure of IEC103

The link layer is responsible for establishing IEC103 communication, to ensure the general operation of communication link, and complete the command of receiving and sending message. Protocol layer based on IEC60870-5-103 protocol, is responsible for the formation of the device commands, analyzing information from the device callback. The data interface provide information for upper layer application(data processing layer), analysis out the real-time data information from protocol layer ， According to the need to provide to the upper application.

The serial code technology we adopted Microsoft stable MSComm control, combining with the multithreading technology, guarantee for real-time and reliability of receiving message processing.

Application

The system can play a big role in the test of the digital device, complete all test project configuration (Table 2).

Tab.2 Measurement items statistics of measurement system

Testing options		Test cases and requirements	Completion
Base options	Ia，Ib，Ic，Ua，Ub，Uc，Uab，Ubc，Uca，P，Q，f，S，COSφ	fundamental wave environmental testing	Automatic
		Superposition of harmonic (2-50) test	Automatic
Extend options	3I0 real，3I0 imaginary，3U0 real，3U0imaginary，3I0 real part of five harmonics，3I0 imaginary of five harmonics，3U0 real part of five harmonics，3U0maginary of five harmonics	fundamental wave environmental testing	Automatic
		Superposition of harmonic (2-50) test	Automatic

A friendly man-machine interface to the cases configuration was designed, convenient configuration input, including each channel phase voltage, current, superposition of multiple harmonic, the program automatically calculate the expected value according to the input cases, get actual results from the device, gives the test report by comparison.

After the completion of test case allocation, only need to click the test button, the test system can in the unattended condition, the maximum traversal algorithm, to complete test and gives test report. Its advantages in practical application process:

1) Can run on PC , Compared with the traditional test instrument, cost is lower than 5% (currently on the market a lot of testing algorithms are based on the tester ,not PC).

2) automatic test function based on the powerful computing ability and multi task processing characteristics of PC , greatly improves the test efficiency, this is the general testing instrument cannot handle.

3) To save human resources, avoid omission caused by long time repeated work paralysis.

4) Processing ability based on PC, human can't reach the depth and breadth of the testing procedure.

The product is put into use is important to the quality of protection device. In addition to a certain type of protection device, only need to configure a set of use cases, then we can reuse in the future.

Conclusion

This paper introduces the automatic test system of digital device ， which when doing the task, realize the automatic test of true. Enable testers get rid of complicated manual operation in the test time, dedicated to testing research and theory analysis, and make greater contribution to the development of testing field. In addition, the system only need a computer can, simple structure, reliable performance. The system carries out IEC61850-9-2 and IEC60870-5-103 standards, play a positive role for digital device to achieve interoperability of different manufacturers.

Keywords: Voltage control, independent control of active and reactive power, DFIG, Field-oriented control, wind turbine, power system.

Abstract. This paper shows the modeling and the effectiveness of wind turbine for voltage improvement of power systems. The wind turbine is based on a doubly-fed induction generator (DFIG). A field-oriented control is used to control of the power flow exchanged between the DFIG and the power system. A simplified wind turbine model based on independent control of active and reactive powers is used in this paper. The proposed methodology is tested in the single machine power system connected to a wind farms in the case of sudden voltage variations.

Introduction

Power system is increasingly confronted with problems related to the production, transport and distribution of energy. Despite the multitude of strategies and means of protection, power systems are confronted by numerous constraints such as the increase in demand, disturbances, planning, interconnection and network complexity. It is imperative to provide detailed information for each option. An important study that should be included in the design of electrical networks is controlling and improving the voltage stability, the main causes for occurrence of voltage instability are: Voltage sources are too far from load centers; High Reactive Power Consumption at Heavy Loads; Poor coordination between multiple FACTS;…, etc [1-5].

Production of electricity from wind power, as a renewable energy source, is continually attracting the attention of investors, researchers and electrical utilities. Integration of wind power into the power system has been studied by many authors. Wind power influences several power system characteristics from economic dispatch to stability and quality issues.

Many types of generators have been used to convert wind power into electricity, especially the Doubly-Fed Induction Generators (DFIG) which is becoming increasingly popular in large wind power conversion systems due to their various advantages. [6,8]. A DFIG in a wind turbine has the ability to generate maximum power with varying rotational speed, to control active and reactive by integration of electronic power converters such as the back-to-back converter[9-11].

This paper is organized as follows: The first part studies wind park model and the dynamics of the DFIG model establishing the Field-oriented control strategy (FOC) with PI current and power controllers [12-14]. The second part shows the modeling of power system and reactive wind controller. The discussion and analysis are presented in the third part, which the equivalence modeling of a wind park involves combining all turbines with the same mechanical natural frequency into a single equivalent turbine.

2. Wind Generator Model

2.1 Wind Turbine Model

The mathematical relation for the mechanical power extraction from the wind can be expressed as follows:

$$P_{aer} = \frac{1}{2} C_p(\lambda, \beta) \rho S v_{wind}^3 \tag{1}$$

Where:

P_{aer} is the extracted power from the wind; ρ : is the air density (kg/m^3); S : is the turbine swept area (m^2); v_{wind} : is the wind speed (m/s); β : Blade pitch angle (deg); λ : is the ratio of blade tip speed to wind speed defined by:

$$\lambda = R\Omega_t / V_{wind} \tag{2}$$

C_p is the performance coefficient of the turbine, C_p is often given as a function of the tip speed ratio λ; Ω: the wind turbine rotational speed (rad /sec); R: the wind turbine radius.

The expression of the power coefficient Cp is given by the following equation [15]:

$$C_p(\lambda,\beta) = (0.35 - 0.0167(\beta - 2))\sin\left(\frac{\pi(\lambda + 0.1)}{14.34 - 0.3(\beta - 2)}\right) - (0.00184(\lambda - 3)(\beta - 2)) \tag{3}$$

The mechanical torque of the turbine is given by the following relationship

$$C_t = \frac{P_t}{\Omega_t} = \frac{1}{2\lambda}\rho\pi R^3 v^2 C_p(\lambda,\beta) \tag{4}$$

Knowing the speed multiplier G (coupling),the generator speed is given by:

$$\Omega_t = \Omega_{mecg} / G \tag{5}$$

The mechanical power available on the shaft of the electric generator is expressed by:

$$P_{mg} = \frac{1}{2} C_p\left(\frac{\Omega_{mec} R}{G v_{wind}}\right)\rho\pi R^2 v_{wind}^3 \tag{6}$$

2.2. Modeling and Stator Flux Oriented Control of DFIG

The DFIG wind turbines utilize a wound rotor induction generator. The concept is based on two back-to-back voltage source converters connecting the grid and the rotor windings. The stator windings are connected directly to the grid [12-14]. The general model of the DFIG obtained using Park transformation is given by the following equations [13-15].

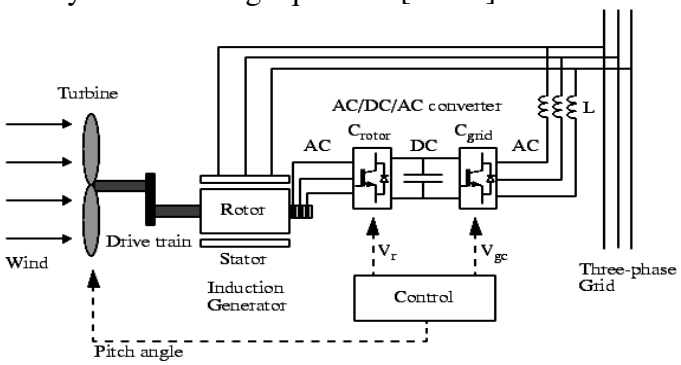

Fig. 1. The Wind Turbine and the DFIG System

$$\begin{cases} V_{ds} = -R_s.I_{ds} + \frac{d}{dt}\phi_{ds} - \omega_s\phi_{qs} \\ V_{qs} = -R_s.I_{qs} + \frac{d}{dt}\phi_{qs} + \omega_s\phi_{ds} \\ V_{dr} = R_r.I_{dr} + \frac{d}{dt}\phi_{dr} - \omega_r\phi_{qr} \\ V_{qr} = R_r.I_{qr} + \frac{d}{dt}\phi_{qr} + \omega_r\phi_{dr} \end{cases} \tag{7}$$

$$\begin{cases} \phi_{ds} = -L_s.I_{ds} + M.I_{dr} \\ \phi_{qs} = -L_s.I_{qs} + M.I_{qr} \\ \phi_{dr} = L_r.I_{dr} - M.I_{ds} \\ \phi_{qr} = L_r.I_{qr} - M.I_{qs} \end{cases} \tag{8}$$

The electromagnetic torque and its associated motion equation are expressed respectively by:

$$C_{em} = p\frac{M}{L_s}\left[\varphi_{qs} i_{dr} - \varphi_{ds} i_{qr}\right] \tag{9}$$

$$J\frac{d\Omega}{dt} = C_{em} - C_r - f\Omega \tag{10}$$

To achieve a stator active and reactive power vector independent control, by orienting the reference (d,q) so that the axis is aligned with the stator flux [13-15], the following solutions can be obtained:

$$\phi_{ds} = \phi_s \quad and \quad \phi_{qs} = 0 \tag{11}$$

$$C_{em} = -p\frac{M}{L_s}\varphi_{ds} I_{qr} \tag{12}$$

According to the adopted assumptions and mathematical substitutions, the voltage expressions are:

$$\begin{aligned} V_{dr} &= R_r.I_{dr} - g\omega_s\left(L_r - \frac{M^2}{L_s}\right)I_{qr} \\ V_{qr} &= R_r.I_{qr} + g\omega_s\left(L_r - \frac{M^2}{L_s}\right)I_{dr} + g\omega_s\frac{M\phi_s}{L_s} \end{aligned} \tag{13}$$

The active and reactive power expressions are:

$$\begin{cases} P_s = V_s I_{qs} = -\dfrac{\omega_s \phi_s M}{L_s} I_{qr} \\ Q_s = V_s I_{ds} = -\dfrac{\omega_s \phi_s M}{L_s} I_{dr} + \dfrac{\omega_s \phi_s^2}{L_s} \end{cases} \tag{14}$$

Figures 2 and 3 show the performance of the active–reactive power control.

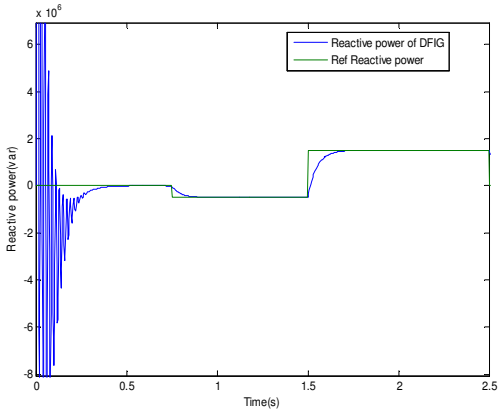

Fig. 2. Active power of DFIG using F.O.C

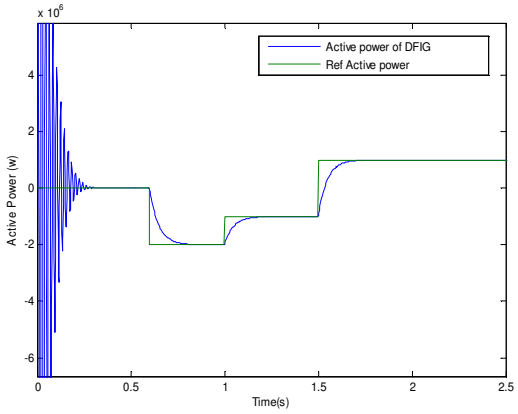

Fig. 3. Reactive power of DFIG using F.O.C

3. Modeling of Power system

A single machine power system is used to demonstrate the fundamental concepts and principles of voltage control using wind turbine when subjected to large disturbances (Fig. 4).

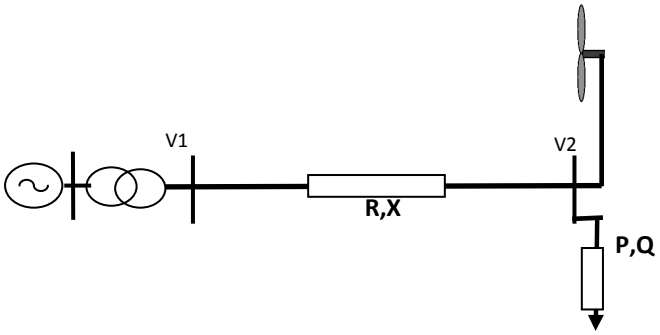

Fig. 4. A Single machine power system with wind generator

-P and Q are the active and reactive powers respectively of load, R and X are resistance and reactance line respectively, V_1 and V_2 are voltage of bus 1 and 2 respectively.

The voltage at the Bus 2 can be determined as follow:

$$V_2 = V_1 - \Delta V \tag{15}$$

The relationship between voltage gradient and the flow of active and reactive power on a radial distribution line can be expressed as follows:

$$\Delta V = (\mathrm{P}\, R + Q X)/V_n \tag{16}$$

The voltage can increase or decrease depending on the amount of the reactive and active power flux and on the network characteristics.

4. Modeling of Wind Power Controller

The rapid controllability of the DFIG can be used to significantly enhance the power system voltage control. The wind power controller used for this purpose is given in figure.5, where k_{wind} and T_{wind} are the gain and time constant of the wind power controller respectively, in which the output power controller ($C_{controller}$) will be used as specific or reference power to be produced by the DFIG.

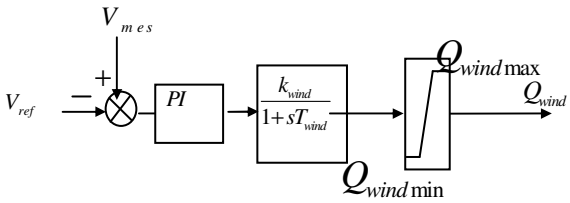

Fig. 5. Reactive wind power controller.

Where :

V_{ref} ,V_{mes} are the reference and the measured voltage bus respectively.

The proposed power modulation Q_{wind} has been incorporated in the power system in which any deficit or excess of voltage is compensated by the DFIG. The equation (22) can written by:

$$\Delta V = \mathrm{P}\, R + (Q - Q_{wind})\, X / V_n \tag{17}$$

5. Results Analysis

The feasibility and efficiency of the proposed controller have been tested on a single machine test system connected to a wind farms as shown in Fig.4, a sudden variation of voltage of generator is applied at t=3s (V_1= 0.9 V_{ref}) and at t=5s (V_1= 1.1 V_{ref}) .

Figure 6 shows the reactive wind power produced by DFIG after the disturbances in order to restore the voltage of bus N°2. Figure 7 shows the comparative bus voltage (N°2) with and without controller. It's clear that the proposed controller significantly improve the bus voltage rapidly.

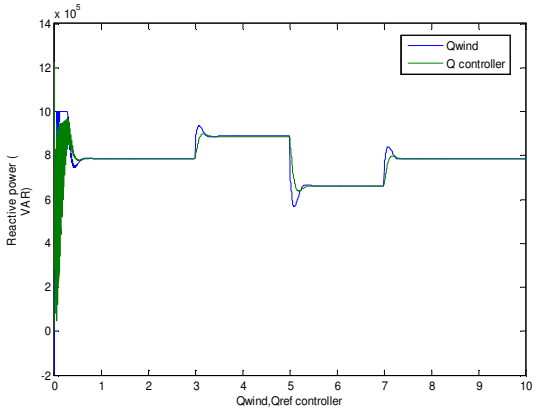

Fig. 6. Reactive power of wind turbine injected after disturbances

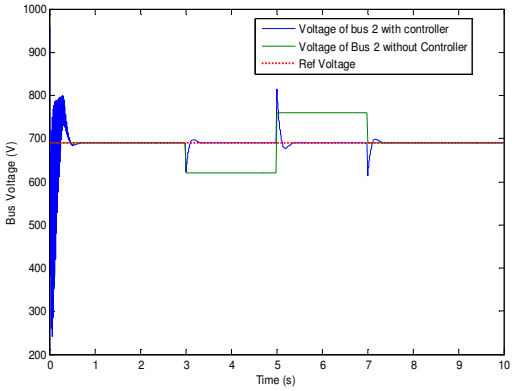

Fig. 7. Voltage control using reactive wind controller

6. Conclusion

In this paper, a new control strategy of reactive wind power has been successfully applied to improve the power system voltage. In which the wind turbine is based on a doubly-fed induction generator (DFIG). A field-oriented control is used to control of the power flow exchanged between

the DFIG and the power system. The rapid controllability of injected active provided by wind turbines are used to control and improvement of the voltage. Results indicate that the reactive wind power control can significantly improve the system performance, the efficiency of the wind farms is more important when the percentage of the installed wind power over the total production is higher.

Keywords: permanent magnet synchronous motor； sensorless； back electromotive force; TMS320F2808

Abstract. This paper will introduce the sensorless vector control system of permanent magnet synchronous motor,it adopts the PLL structure to correct motor back electromotive force for the motor rotor speed/position estimation and vector control algorithm to realize speed and current loop control of PMSM.This paper established a mathematical model of the PMSM,design of system software and hardware,the principle of speed/position estimation method and simulation of system in Matlab/Simulink.Finally,it introduces the experiment of whole system in TMS320F2808-based PMSM experiment platform,the simulation and experimental result verify feasibility,fast response and practicability of the system.

Introduction

Permanent magnet synchronous motor has the following advantages: low rotor losses and moment of inertia, good acceleration and deceleration performance, smooth torque, high efficiency[1]. Compared to the DC motor, it no mechanical commutator and brushes, which makes system maintenance of low cost, high reliability, compared with asynchronous motors, no reactive excitation current, high power factor[2]. Because of these advantages, making it has widely applied in various industrial applications.In conventional permanent magnet synchronous motor vector control system, commonly used optical encoder or resolver and other mechanical sensors to detect the rotor speed / position, but these mechanical sensors will lead to high system cost and poor reliability. To solve this problem, various sensorless control strategies has become a research focus in AC drive field.

Speed/position estimation method currently used in permanent magnet synchronous motor vector control system is mainly divided into two categories[3]:one is the high-frequency signal injection method, and the other is calculated based on the motor model and parameters, including state observer, flux observer and back electromotive force method. This paper will adopt the back-EMF observation and phase-locked loop (PLL) a combination of speed/position estimation algorithm[4] and also be introduce system software and hardware design, and ultimately the simulation and experimental result verify feasibility,fast response and practicability of the system.

The mathematical model of PMSM

The PMSM has the magnet on the rotor, and it is usually designed to generate sinusoidal back EMF. And there are no field winding and no damper windings either at the rotor. And the field flux is

constant because of the permanent magnet. The effective air gap is larger compared to the wound rotor synchronous machine because the relative permeability of the magnet is almost unity like air. By omitting damper winding circuits and by replacing the field winding circuit by a constant current source,the equivalent circuit can be modified as Figure 1.

Based on the equivalent circuit of permanent magnet synchronous motor, the mathematical model[5]in the d-q axis can be obtained, including voltage equation(Eq. 1, Eq. 2),flux equation(Eq. 3, Eq. 4), torque equation(Eq. 5)and the equation of motion(Eq. 6).

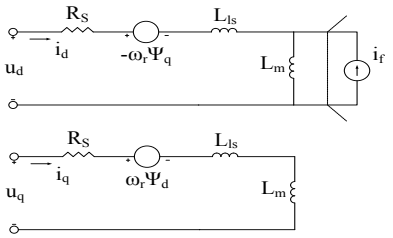

Fig.1 The equivalent circuit of permanent magnet synchronous motor in the d-q axis

$$u_d = R_s i_d + p\psi_d - \omega_r \psi_q \tag{1}$$

$$u_q = R_s i_q + p\psi_q + \omega_r \psi_d \tag{2}$$

$$\psi_d = \psi_f + L_s i_d \tag{3}$$

$$\psi_q = L_s i_q \tag{4}$$

$$T_e = \frac{3}{2} n_p L_m i_f i_q = \frac{3}{2} n_p \psi_f i_q \tag{5}$$

$$T_e - T_l = \frac{J}{n_p}\frac{d\omega_r}{dt} + B\omega_r \tag{6}$$

Overall design of the system

Hardware design of the system. Hardware circuit of sensorless vector control system for permanent magnet synchronous motor can be divided into two parts: the main circuit and control circuit. In the main circuit, the voltage inverter circuit uses intelligent power module (IPM), which integrates a 6-channel PWM output and fault alarm.Main circuit further includes a EMC filter circuit, a rectifying circuit, a pre-charge circuit, IPM drive circuit and phase current sampling circuit; Control circuit includes TMS320F2808 DSP chip and the peripheral circuit including the auxiliary power source, PWM driving circuits, communications circuits, E^2PROM memory circuit.Electric circuit and electronic circuit will be isolated by the optocoupler. Hardware block diagram is shown in Figure 2.

The principle of double closed loop vector control. Rotor field oriented control (ie vector control) of permanent magnet synchronous motor make the rotor flux as the stator and gap flux's reference frame.The purpose is the decoupling between the torque component and the excitation component of stator current,so that AC motor can be controlled like DC motor. As the air gap flux equal permanent magnet rotor flux and the armature reaction flux the stator currents generated, excitation current component i_{dref} should be set to zero, d-axis gas gap flux only equal to Ψ_f and d-axis armature reaction flux is zero for field-oriented control of constant torque mode. This article focuses on field oriented control under constant torque mode, Figure 3 shows the block diagram of the control system.

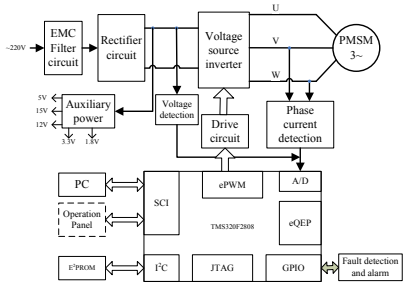

Fig.2 System hardware block diagram

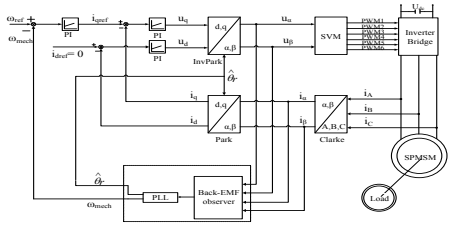

Fig.3 The block diagram of sensorless field oriented control for PMSM

Rotor velocity/position estimation method. In this paper, the velocity/position estimation algorithm based primarily on the mathematical model of the motor, the back electromotive force calculation and PLL. Since there will be inevitably error between the actual back-EMF and calculated back-EMF in the sensorless field-oriented control of PMSM,so the deviation of the rotor position angle will also appear. Figure 4 shows the relation of back electromotive force vector and estimated position angle[6].

Based on the above analysis, the d-axis component of the back-EMF is not zero would lead to the deviation of velocity/position estimated results, but it can be eliminated by PLL to correct q-axis component of the back-EMF. Voltage equations can be written as equation (5) and (6) in the estimated rotating coordinate system. θ_{err} is defined as equation (7).

Where θ_r is the actual rotor position angle, $\hat{\theta}_r$ is estimated rotor position angle. Equation (5) can be obtained when the system is running at steady state, if the angle of the estimated position and the actual position angle is consistent, then the d-axis component of the the back-EMF must be zero.The estimator is shown in Figure 5.

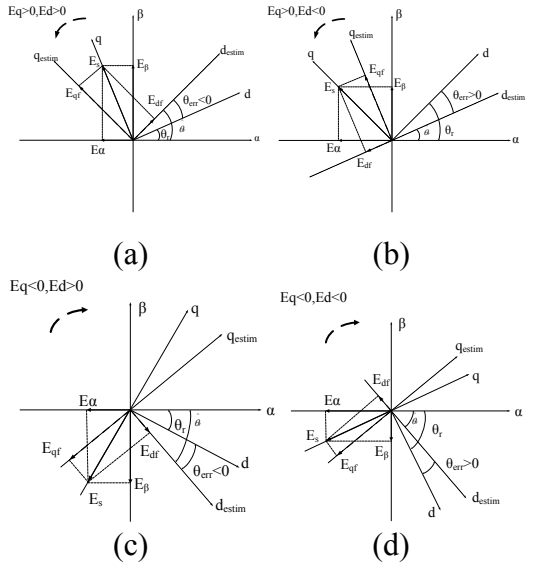

Fig.4 The relation of back electromotive force vector and estimatied position angle

$$u_d = R_s i_d + L\frac{di_d}{dt} - \omega_r L_s i_q - \omega_r \psi_f \sin\theta_{err} \tag{5}$$

$$u_q = R_s i_q + L\frac{di_q}{dt} + \omega_r L_s i_d + \omega_r \psi_f \cos\theta_{err} \tag{6}$$

$$\theta_{err} = \theta_r - \hat{\theta}_r \tag{7}$$

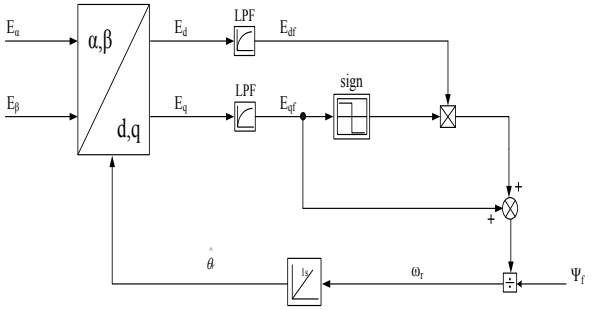

Fig.5 The block diagram of rotor speed/position estimation

In the two-phase stationary coordinate system, the back electromotive force α, β components can be obtained by detecting the stator voltage u_α, u_β and stator current i_α, i_β. It is calculated according to equation (8), (9).

According to Park transformation,the back electromotive force d, q components in the rotating coordinate system can be obtained.Then the back electromotive force d,q components are filtered through a low-pass filter, aims to reduce the noise introduced by the current differential.PLL correction part correct the back-EMF q axis component e_{qf} with the back-EMF d axis component e_{df} based on e_{qf} direction.Then the estimated angular velocity is obtained by dividing the permanent magnet flux Ψ_f and the estimated position angle is obtained through the integral operation.The principle see equation (10), (11).

$$e_\alpha = u_\alpha - R_s i_\alpha - L_s\frac{di_\alpha}{dt} \tag{8}$$

$$e_\beta = u_\beta - R_s i_\beta - L_s\frac{di_\beta}{dt} \tag{9}$$

$$\omega_r = \frac{1}{\psi_f}(e_{qf} - sign(e_{qf}) \bullet e_{df}) \tag{10}$$

$$\hat{\theta} = \int \omega_r dt \tag{11}$$

Software design of the system. The software design of system mainly composed of three parts: the initialization procedure, the main program and interrupt service procedure.The operating mode of peripheral resources in DSP chip as well as each variable is initialized in initialization process.Main program mainly execute keyboard scanning, status and parameters display, communication with computer.

The interrupt service routine is a core part of the software, mainly to complete the system control algorithms, data acquisition, protection and fault handling. In each PWM cycle interrupt service routine for the stator phase currents and bus voltage values are sampled, and the implementation of the current loop and speed loop, and then through the SVPWM modulation algorithm calculates a duty cycle of the next PWM cycle duty. System execute core algorithm in each PWM cycle interrupt service routine every 100us, Figure 6 is a flow chart of PWM period interrupt service routine.

Experimental Analysis

System Simulation and result Analysis. According to the theoretical analysis, in order to verify the feasibility and performance of this system, it was simulated on Matlab/Simulink platform, where the motor rated frequency was 150Hz, the inverter switching frequency of 10kHz, the system sampling frequency was 10kHz, the low pass filter was 100Hz in the speed feedback channel. Simulation block diagram is shown in Figure 7.

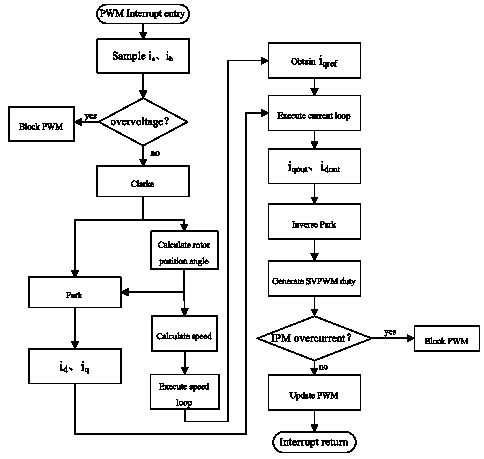

Fig.6 Flow chart of PWM period interrupt service procedure

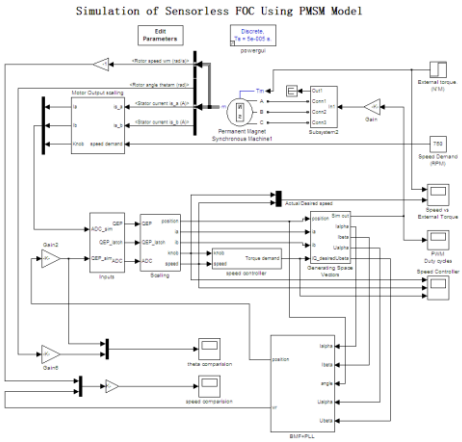

Fig.7 Simulation block diagram of the system

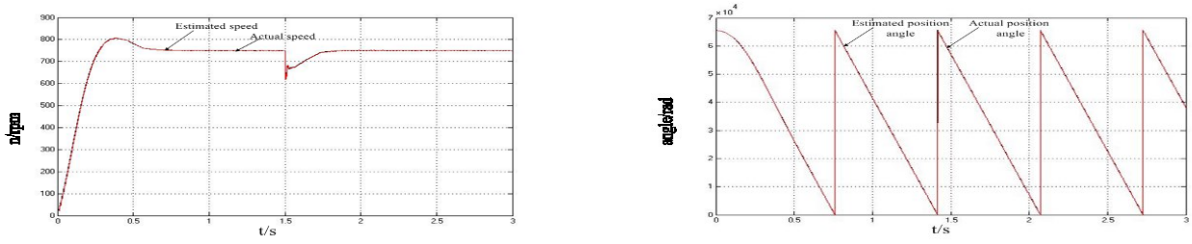
When given speed command was 1500rpm , the motor started from no load state,then suddenly gave rated load torque 2.39N • M at 1.5s.In this case simulation environment time was set 3s in order to observe the system performance . Figure 8 (a) shows the change of the estimated speed and the actual speed, (b) shows the waveform of the estimated and the actual rotor position angle.



(a) (b)

Fig.8 The estimated, actual speed and angle waveform under 1500rpm

Due to data processing in the simulation experiment was simulated DSP data processing ,so the rotor position angle was unit16 in picture (b). As could be seen from Figure 8, the estimated results

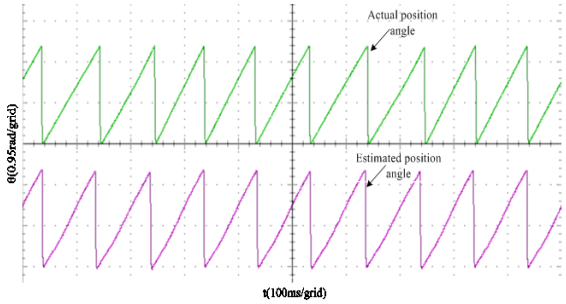
were very close to the actual speed value and speed still converge to given speed with a small overshoot after sudden change of load.

System experiments and results analysis.PMSM parameters was shown in Table 1.The control circuit was based on TMS320F2808 DSP , the digital control period of 100us and the dead time of 3us. The power module used IPM of FSBB15CH60 in main circuit. In order to compare experiment results, the motor was mounted on the incremental encoder of 2500 lines.

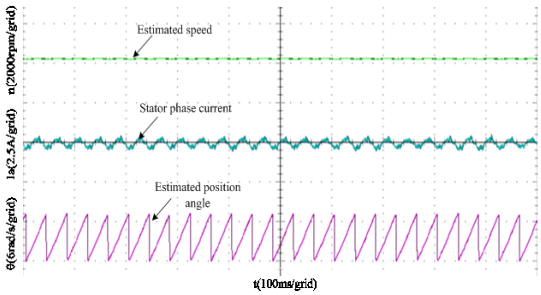
Tab.1 The parameters of PMSM

parameter	value	parameter	value
Rated power/W	750	Line-Line R/Ω	1.4
Rated torque/N•M	2.39	Line-Line L/mH	7.5
Rated current/A	3.9	back-EMF constant /V/krpm	50
Rated frequency/Hz	150	poles	3
Rated speed/rpm	3000	DC bus voltage/V	300

To verify the performance of system, in view of the low speed motor operation quality is an important indicator of system performance, so the PMSM operated with 200rpm at no load[7].The experimental results is shown in Figure 9.



(a)Actual and estimated rotor position angle



(b)Estimated speed/position angle and stator phase current

Fig.9 Steady-state experiments with 200rpm

Experimental results indicated:1)Estimation error of rotor position angle was small; 2) Stable position angle and current signal was able to ensure the operation of PMSM at low speed;

To verify the dynamic performance of system, given speed command changed from 200rpm to 3000rpm,then from 3000rpm to 200rpm.The result of dynamic response test is shown in Figure 10.Experimental results indicated that the system had good speed tracking,small overshoot and fast dynamic response.

To further test load capacity, the system run on MAGTROL HD-715-8NA-0100-type hysteresis dynamometer load platform at rated load 2.39N • M.The experimental result is shown in Figure 11.

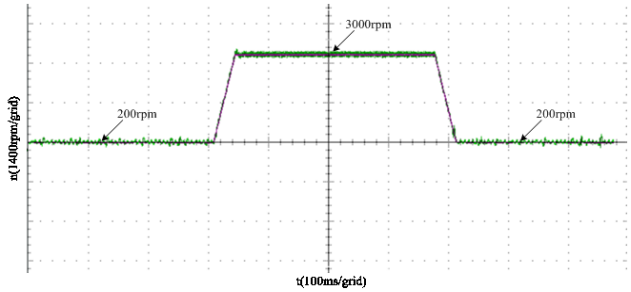


Fig.10 Dynamic response with speed command change

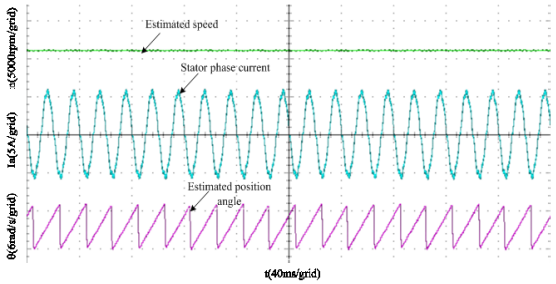

Fig.11 Experimental result with 2.39 N•M rated load

Conclusion

The sensorless vector control system of permanent magnet synchronous motor, using speed/position estimation algorithms a combination of the back-EMF observation and phase-locked loop (PLL) possess reliable structure,good feasibility and practicality in many occasions. Experimental results can be described as follows:

(1) This system using the estimation algorithm can effectively detect the rotor position and speed.

(2) In the no-load testing, the system had small steady-state error and estimation error of rotor position angle.

(3) In the load testing,the system possess strong load capacity and good dynamic performance.

Abstract. The multifunctional stepper motor is built on the basis of ordinary stepper motor, combined with single chip microcomputer control system, dedicated driver chip STK672-040 and chip ULN2003A function, it can not only do the actual stepping motor testing but also can set out the particular function of stepper motor. In addition, the system can link an external circuit and cooperate with the external circuit to complete the work required.

Introduction

Stepper motor is a kind of servo motor. Stepping motor is controlled by electric pulse signal and converts electrical pulse signal into the motor controlled by corresponding linear displacement or angular displacement. Each pulse signal can make the stepping motor rotate a certain angle, namely interval angle. Pulse frequency determines the speed of motor rotation, the total number of pulse determines the angle of rotation, the change of winding current order can change the direction of motor rotation. The structure and control of stepper motor's open loop servo system is simple and easy to adjust. In the cases where precision and speed is not highly demanded it has certain use value. Stepper motor can be said to be the important member of the family of motor and has some significant advantages: a concise control circuit, high reliability, flexible software programming and strong logicality. As a executive component, motor has the characteristics of precise stepper and rapid start-up under rated load Step. Performing as an important element, stepper motor has been widely used in the automatic control system. Corresponding stepper motor extension model is shown in figure 1:

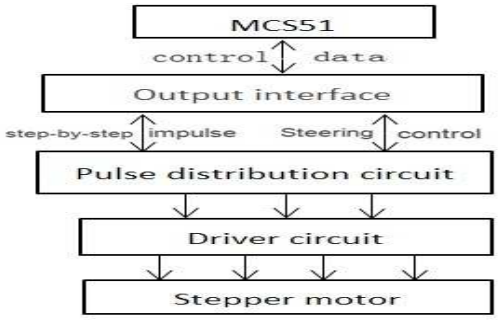

Fig 1 Stepper motor extension application mode

The drive of stepper motor

Principle of stepper motor driver. Although there are many kinds of stepping motor, but all their control modes are the same, all need to be driven by pulse current. if it is calculated by one turn with 20 excitation signal, the stepping motor each step forward in 18 degrees. In this way, pulse number is proportional to the Angle of rotation, and the positive and reverse of motor controlled by the pulse sequence.

Stepper motor excitation method is composed of half step excitation and whole excitation, specific content is as follows：

1 phase excitation method. Exactly the same time conduction a coil.Small torque, vibration but its consumption is small, high accuracy, every step forward in 18 degree. Positive rotation excitation sequence is shown in fig2:

STEP	A	B	C	D	STEP	A	B	C	D
1	1	0	0	0	3	0	0	1	0
2	0	1	0	0	4	0	0	0	1

Fig 2 Positive sequence: A→B→C→D→A

2 phase excitation method. Exactly the same time conduction two coils. Its most prominent feature is large torque, small vibration, 18 degree every step forward. Positive rotation excitation sequence is shown in fig 3:

STEP	A	B	C	D	STEP	A	B	C	D
1	1	1	0	0	3	0	0	1	1
2	0	1	1	0	4	1	0	0	1

Fig 3 Positive sequence: AB→BC→CD→DA→AB

1-2 phase excitation. The 1 phase and 2 phase alternate conduction.Its smooth operation, high resolution, each step forward 9 degrees. Positive rotation excitation sequence is shown in fig 4:

STEP	A	B	C	D	STEP	A	B	C	D
1	1	0	0	0	5	0	0	1	0
2	1	1	0	0	6	0	0	1	1
3	0	1	0	0	7	0	0	0	1
4	0	1	1	0	8	1	0	0	1

Fig4 Positive sequence: A→AB→B→BC→C→CD→D→DA→A→AB

Stepper motor driver chip. Integrated ULN2003A is a kind of High current-driven Darlington transistor array, usually used for PLC and single-chip microcomputer, digital output card, the control circuit of the intelligent instrument, and can be directly used to drive the relay load, etc. ULN2003A, it's features include high working voltage, wide temperature range, high current gain, Strong load capacity, etc. It is suitable for all kinds of high power drive system.

STK672-040 is produced by SANYO company is a hybrid integrated stepper motor driver chip, its internal consists of two parts, power and control. The control part is mainly composed of a sine wave generating circuit and current distribution switch, three input logic to control the electric mode. STK672-040 can realize the motor control system that can achieve low vibration, high speed, low noise, fast response and high efficient.

Control system and circuit design

The part of single chip microcomputer control circuit. MCU is the chip level of computer, which is a kind of integrated chip composed by CPU, RAM, ROM, timing/number, and a variety of I/O. It

has many advantages such as excellent performance price ratio, high integration, small volume, high reliability, strong control function, low voltage, low power consumption. The multi-function stepper motor controlled by MCU is very promising. The circuit is mainly based on MCU, stepper motor as the executive element, start chip, conversion chip as an assistant, which make the stepper motor function can be extended. This system is mainly aimed at four phase stepper motor design and control, the STK672-040 and ULN2003A driver chip are prepared for the system of the multi-function, their control mode is in the same way , So the two drive chip not contradictory. The single-chip computer peripherals input interface, which can finish all kinds of the specific needs of the stepper motor work mode. Single chip microcomputer control circuit is shown in fig 5.

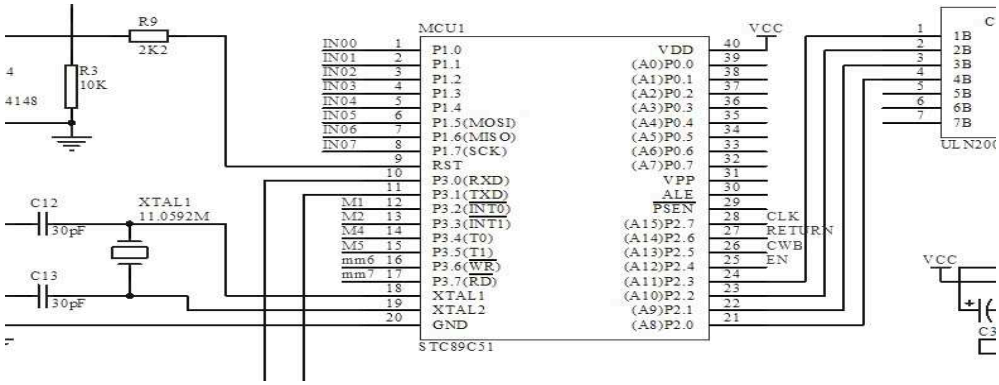

Fig5 SCM control circuit

Stepper motor control serial port. MAX232 belongs to the MAX220 - MAX249 series line of receiver / driver, designed for v. 28 / v. 24 and TIA - 232 - e/EIA communication interface, The drive cannot provide the supply of 12V power.Through the similar max232 chip to level conversion, making SCM match the serial port voltage.This part of the circuit controlled by single-chip microcomputer P2 feet, the main control is the signal of output and input. When D1 is lit, the motor forward transmission; and light emitting diode's D2 is lit, the motor rotates in the reverse direction; In D3 is lit, the motor stalling. Via serial port receives information, Data conversion by the chip ULN2003A, to Provide specific impulse, Drive the stepper motor rotation.Serial interface circuit is shown in figure 6:

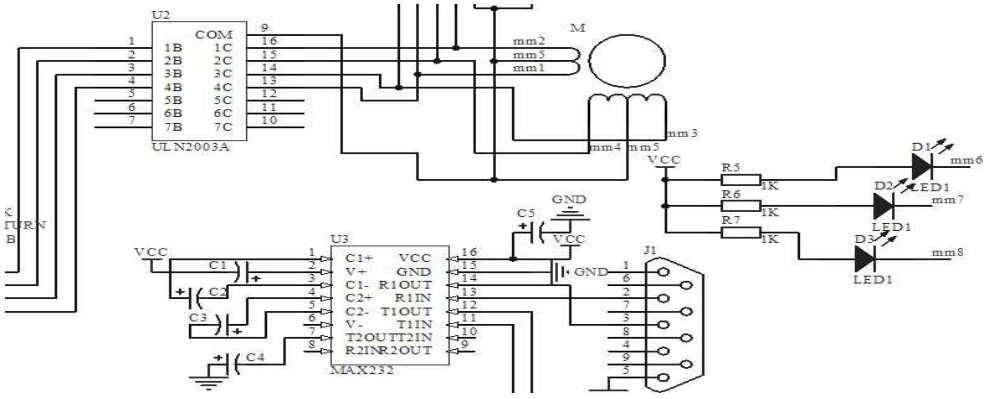

Fig 6 Serial interface circuit

Stepper motor control keyboard. STK672-040 chip is mainly complete the distribution of power and pulse signal, single chip microcomputer through the input signal of pressed key adjust the output signal of STK672-040 and control the rotation of the stepper motor. P3 interface in figure is mainly used for the data communication between single chip microcomputer and chip. M1, M2 is used to control the incentive mode of motor; M4, M5 is used to set the track of motor. The CLK pin is used to input pulse to STK672-040 chip.The circuit can simulate the specific pulse circuit and

applied to some experimental study on step motor system.Keyboard input circuit is shown in figure 7:

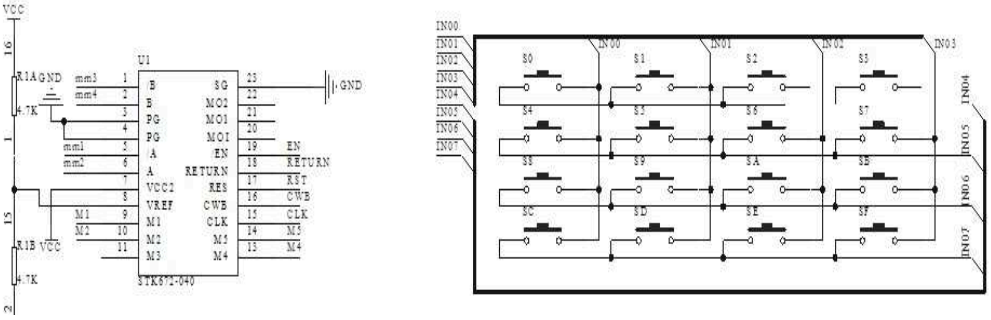

Fig 7 Keyboard input circuit

Stepper motor input circuit and I/O interface. In order to expand the application of stepping motor, this system design a stepper motor external entrance, by external signal directly supply MCU,Single chip microcomputer system analysis and signal processing, sending chip ULN2003A corresponding pulse signal, which can drive a stepper motor action is needed to complete in an external circuit. The external circuit is variously, but the start and driving of step motor is not much change. Setting the inherent system unit between step motor and MCU, no matter how complex the external circuit is, the function of stepper motor can be change according to the requirement of the circuit. Specific I/O interface is shown in fig 6.

The program design process

According to the design of this system, stepping motor as an objective element, when enter a program into the microcomputer, stepper motor execute the command according to the corresponding instruction. But for this system, the programming operation is very simple and fast, even in most cases, and can undertake simple adaptation according to established procedures, what's more, because this system adopts the chip are common multi-functional chip and the principle of design is simple and easy to understand. This paper separately explains the various functions of the module, according to the function of the module and the description of pin, according to the following programming flowchart can easily perform specific functions. The program flow chart shown in fig 8 .

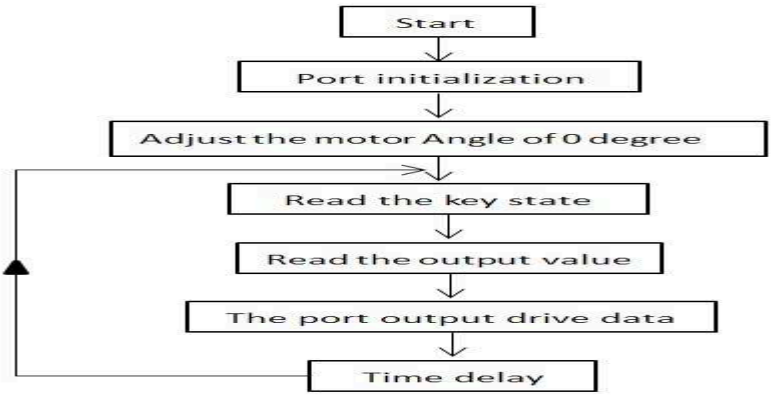

Fig 8 Program flow chart

Conclusion

The multi-functional stepper motor system introduced in the paper has the significant advantages: simple circuit structure, low cost, high reliability, simple and flexible software programming. It can realize the automatic control of productive process and have a good man-machine interface. Once the system is operated, it can have a strong anti-interference, reliable operation and less maintenance. Thus, it can obtain good effect. Nowadays, in the equipment with an automatic control system, the application of stepper motor is more and more, so the control of the stepper motor is to become a widespread but immature problem. Applying the single chip microcomputer to generally realize multi-function stepper motor, it will have the advantages like stable operation, simple control and short development cycle, which is a feasible scheme.

Keywords: MUSIC. four-order-cumulat. rotor broken-bar. stator winding inter-turn short circuit.

Abstract. In this thesis, fault characteristic frequency can not be accurately detected if they are drowned by noise. A novel method which is Multiple Signal Classification(MUSIC) based on four-order cumulate is provided to diagnose motor broken rotor bars and stator winding inter-turn short circuit. Because four-order accumulation is able to depress noise meanwhile fault information can be obtained accurately through this way presented even with small samples. Simulation results shown that the method were higher in resolution of frequency, more accurately in fault detection and less in computational complexity.

Introduction

As motor fault cause loss of production. In all of the motor fault it was approximately 10%and 15% for motor broken rotor bars and stator winding inter-turn short circuit[1].

Now we used diagnostic methods to solve the equation which is established by the physical and mathematical model. But this way is failed for complexity relationship of electromagnetic in the failure motor[2.3]. At the same time the method of artificial neural network could effectively classify and identify the characteristics[4]. This way can avoid the complicated analytical techniques but it can not be used directly to the site.

If the motor rotor was breakdown, the symmetrical current is damaged. There appears sideband in the stator fundamental frequency. Its characteristic frequency is $f_b = (1 \pm 2s)f$, f is current base-band, s is slip. When it is short circuit between stator winding there is higher harmonic and their frequencies are away from the fundamental. The fault feature is found out by detecting the harmonic components of the stator current.

In this paper, MUSIC method which is based on cross-high-order cumulate is provided for diagnosing stator inter-turn short circuit and rotor broken-bar because this way can depress non-correlative noise and correlative gauss noises by Cross high order accumulation. The fault signal space can be decomposed into signal and noise signal subspace.

MUSIC Method Based on Four-order Cumulate

Commonly this ways which diagnose induction motor broken rotor bars is stator current spectrum analysis. Generally the normal asynchronous motor is passed on symmetrical three-phase coupled voltage. When the motor fault, the rotor will flow symmetrical three-phase current with frequency sf_1 (where s is the slip). There will be fundamental frequency band around the edges in the current in the stator. Its characteristic frequency is $f_b = (1 \pm 2s)f_1$,where f_1 is the fundamental frequency; s is slip. The number of broken rotor bars can be predicted if the composition and the frequency f_1 of the difference between the sizes of the current amplitude can be known. The motor load and the power provided voltage were fluctuation so causing s is volatility. Then broken rotor bars characteristic frequency f_b is changing. Because the fundamental frequency f_1 and f_b are very closely. The f_b can

easily be fundamental frequency f_1 side-lobe "annihilation". When the motor load changes frequently, using the traditional method of spectral analysis should be significantly affected, or even impossible to accurately extract the characteristic frequency f_b.

When the stator winding inter-turn short circuit occurs, it will generate current frequency $f_{st} = f_1[k \pm \frac{n}{p}(1-s)] = nf_r \pm kf_1$ (where f_1 is the frequency of power, s is lisp, p is Number of pole pairs, $k = 1,3,5\cdots$, $n = 1,2,3,\cdots,(2p-1)$, f_r is Rotor rotational frequency $f_r = (1-s)f_1 / p$).By detecting spectral components occurs the stator fault can be distinguished. The f_r and ksf_1 is constantly changing. Therefore the diagnosis of short circuit of stator significantly was affected by using the spectral analysis of traditional method. Even around the edges can not be accurately extracted frequency nf_r component.

Therefore, people put forward the diagnostic method which is f_b and f_{st} -characteristic frequency signals from the original "stripping" out. This paper presents MUSIC method based on cross-high-order cumulate based. The high-order cumulate include more wealth of information, and depress the unknown spectrum of non-correlative noise and correlative noise.

Cross high order accumulation can depress non-correlative and correlative noise. In the literature [5]and [6]has been proven.

Among MUSIC method based on cross-high-order cumulate, cross-high-order cumulate was adopted and decomposed signal SVD. Fault signal space will be divided into two orthogonal sub-space, space-signal and noise-space. We use the noise-space-based signals to estimate the parameters. This part is smoothing the noise impact. And in the detection of the motor broken bars, the voltage or current can be seen as "signal" to transform and handling.

The fault signal $x(n)$ and $y(n)$ established are stator current which were mixed with additional color-noise sine signal, namely:

$$\begin{aligned} x(n) &= \sum_{i=1}^{q} a_i \exp[j\omega_i n + \varphi_x] + \xi_x(n) + \eta_x(x) \\ y(n) &= \sum_{i=1}^{q} \beta_i \exp[j\omega_i n + \theta_i + \varphi_y] + \xi_y(n) + \eta_y(n) \end{aligned} \tag{1}$$

Which: α_i, β_i were harmonic signal amplitude; θ_i was phase difference of the signal $x(n)$ and $y(n)$; ω_i was signal frequency; φ_x and φ_y were random initial phase and range evenly distributed between $(-\pi, \pi)$; ξ_x, ξ_y, η_x and η_y were spectral density were unknown and zero mean color noise that in Which η_x and η_y were correlative non-Gaussian noise; $\xi_x; \xi_y$ were non-correlative non-Gaussian noise; ξ_x *and* ξ_y and η_x *and* η_y were independent.

It is the four order-cumulate for $x(n)$ and $y(n)$:

$c_{xyyy}(k_1, k_2, k_3) = cum_4\{x(n), y(n+k_1), y^*(n+k_2), y^*(n+k_3)\}$, $c_{xyyy}(m,0,0) = E[x(n)y(n+m)y^*(n)y^*(n)] = -\sum_{i=1}^{q} \alpha_i \beta_i^3 e^{-j\theta_i} e^{-j\omega_i m}$,order $c_{xyyy}(m) = c_{xyyy}(m,0,0)$.While its corresponding $h \times h$ Victoria expansion order among the four accumulated matrix is:

$$c_{xyyy} = \begin{vmatrix} c_{xyyy}(0) & c_{xyyy}(-1) & \cdots & c_{xyyy}(-h+1) \\ c_{xyyy}(1) & c_{xyyy}(0) & \cdots & c_{xyyy}(-h+2) \\ \vdots & \vdots & & \vdots \\ c_{xyyy}(h-1) & c_{xyyy}(h-2) & \cdots & c_{xyyy}(0) \end{vmatrix} \tag{2}$$

Available: $c_{xyyy} = FE^{j\theta}PF^H$, In the formulas:

$F_i = \begin{bmatrix} 1 & e^{j\omega_1} & e^{j\omega_2} & \cdots & e^{j(q-1)\omega_1} \end{bmatrix}^T$ $F = [F_1 F_2 .. F_q]$ is Victoria complex matrix of $h \times q$

$E^{j\theta} = diag\left[e^{-j\theta_1} \quad e^{-j\theta_2} \quad \cdots \quad e^{-j\theta_q}\right]$, $P = diag[-\alpha_1\beta_1^3 \quad -\alpha_2\beta_2^3 \quad \cdots \quad -\alpha_q\beta_q^3]$(q is c_{xyyy} Rank).

It shows that C_{xyyy} is non-conjugate symmetric matrix and its SVD type:

$$C_{xyyy} = U\Sigma V^H \tag{3}$$

Where U and V were left and right singular vector of matrix C_{xyyy} ; $\Sigma = diag(\sigma_1, \cdots \sigma_i)$, where $\sigma_i (i = 1,2, \cdots, n)$ is all non-zero singular value and according to descending order (that is $\sigma_{i+1} \le \sigma_i$).

In the formula: $V = [V1, V2]$, $V1$ is a singular vector composed of q which is in the former composed of V ; $V2$ is a singular vector composed of $(h-q)$which is in the last composed of V ;namely left singular vector matrix U express block into $U = [U1, U2]$.

The matrix has sinusoidal harmonic component which are ; while characteristic equation for the root is, $v_i(0) + v_i(1)z^{-1} + \cdots + v_i(h-1)z^{-(h-1)} = 0$ $(i = q+1, \cdots, h)$.In formula (3), the root of $(h-q)$ characteristic equation have one and only q which are $e^{j\omega_1}, e^{j\omega_2}, ..., e^{l\omega_q}$.

When using $h >> q$ -order the expansion equation, this method greatly improve the accuracy of the estimated harmonic frequency and resolution, the failure is in the estimated harmonic frequency signal. But it produced (h-q)-by-Kan. As the root is corresponding to the peaks, pseudo-peak will be inevitably [7] meanwhile this is the cause of pseudo-peak. The various existing modern spectrum estimation algorithm that can not removed the roots, so there are different levels of the pseudo-phenomenon. This is calculation pseudo-spectral:

$$S(f) = \frac{1}{\left| A^H L \right|^2} \tag{4}$$

Which $A = \left| \sum_{i=q+1}^{h} v_i(0) \sum_{i=q+1}^{h} v_i(1) \cdots \sum_{i=q+1}^{h} v_i(h-1) \right|^T$, $L = \left[1 \quad e^{2\pi f} \quad \cdots \quad e^{2\pi(p-1)f} \right]^T$.

q -frequency harmonics were chose as a sine frequency estimates which $S(f)$ obtain the maximum. This is MUSIC method based on cross-high-order cumulate for the parameters estimated.

Simulation and Experimental

Motor main data:Model is Y100L1-4; Power:2.2kw; Voltage: 380V;Current: 5A; Speed: 440r/min; $s = 0.04$;Stator Turns:86,Sampling Frequency: 1000 Hz. The load is furnace: Voltage:250V, Current:10A.

The fault detection scheme is fig.1. In the system there is a single signal which is a sinusoidal sequence. Then we use the reference signal according to the actual situation. The original signal can be equivalently represented by the formula (1), in practical application is very easy to implement[8-10].

As well as the short circuit which is the stator inter-turn short circuit fault at 2.3%. And we can obverse the broken bars at changing load.

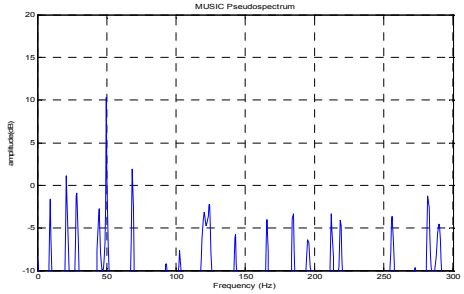

Fig.1 Spectrum of stator circuit(A-phase)

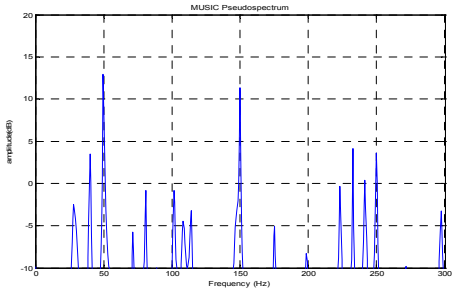

Fig.2 A-phase winding inter-turn short circuit(2.3%)

There is the frequency spectrum when the motor operates normal(fig.1).We can seen the maximum peak at f=50Hz and the peaks large changes of the third harmonic at 2.3%. In figure 2 there is the fifth harmonic in the biggest change. This is obtained fault frequency by calculating. The results consistent (150 ± 12) Hz in line.

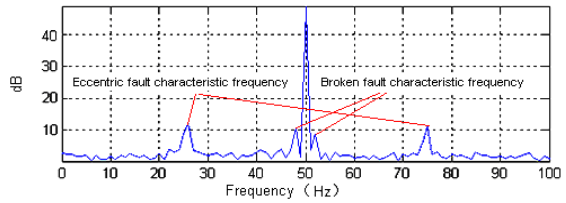

Fig.3 An eccentric + current spectrum (full)

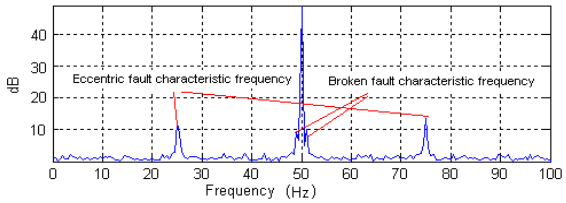

Fig.4 An eccentric + current spectrum (67% load)

Motor fault characteristic frequency component will increase as the load increased correspondingly for example fig.3and fig.4. With the increasing in the number of broken bars, the degree of fault is heavier correspondingly.

In literature [4]put forward a number of broken bars of the prediction formula:

$$n = \frac{2R}{10^{\frac{N}{20}} + 2P} \tag{5}$$

In the formula(5): n -Prediction of the number of broken bars; R -Core rotor slot number; N -DB difference peak is between $(1-2s)f_1$ frequency components and the fundamental frequency spectrum; P -the number of motor pole pairs.

Summary

Broken rotor bars and stator winding inter-turn short circuit fault are multiple failure for cage asynchronous motor. In practice, it is possibility for double fault. So using a single fault diagnosis method may make false. Therefore it is essential for rotor bar breaking and stator windings double fault characteristics being studied. In the paper, it is the biggest feature for the MUSIC method based on cross-high-order cumulate that is based on the original signal extrapolation and has inhibitory effect on the noise; Frequency estimation of fault signals has higher resolution. The simulation showed that the fault characteristics summed up for systematically the cage induction motor rotor bar breaking and Stator Windings. Clearly reveals the relationship between the two and provides an important theoretical basis for the realization of rotor bar breaking and stator winding short circuit.

Keywords: multi-Agent system, intelligent forecast, DGA, blackboard model, SVM.

Abstract. In view of the research in the existing forecast model and transformer DGA methods, this paper presents the collaborative model of intelligent concentration forecast of dissolved gases in transformer oil based on multi-Agent system, for improving the predictability of transformer fault. It presents the main function of each Agent, blackboard and JADE bus in this model, discusses the collaborative process of intelligent concentration forecast of dissolved gases in transformer oil based on multi-Agent system, and designs a combination forecasting architecture and a method of composition forecasting. Finally it indicates the feasibility and effectiveness of the intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent system according to the application examples.

Introduction

Currently transformer fault diagnosis system is used to judge whether the transformer fault or not, or Diagnosis of failure positions and failure causes after the failure. Dissolved gas analysis(DGA) is one of the widely used methods [1-2] . The method is through the detection and diagnosis of collection sample to evaluate the running situation of transformer. The evaluation method is adopted by the single forecast model and combined forecasting model [3-4]. Because of many factors that affect the concentration of dissolved gases in transformer oil, when with a single forecasting model to forecast, as its own limitations, the prediction accuracy and stability is not high. And combination forecast research is predicted variable weight values, a lot of evidence that combination forecast is often better than its individual forecast [5]. But the existing combination forecasting results are in the training stage of the model realizes the variable weight value, and at the time of the actual forecast model, weights of each model is the same, it would limit the accuracy of prediction model and the suitability. Therefore, in order to realize the true meaning of variable weight combination forecasting, to increase the ability of transformer fault prediction, this paper introduces a multi Agent system in the field of artificial intelligence.

Multi Agent system (MAS) [6] is a branch of distributed artificial intelligence (DAI); it can make logically and physically dispersed system parallel to solve the problem coordinately. Adopt multi Agent control, not the pursuit of a single large and complex system, but, according to the requirement of the control system is divided into multiple Agent from the function, multiple Agent communication each other, coordinate each other, together to complete a large complex system control task. This system not only has the characteristic such as the resources to be Shared reliability Strong real time Easy to expand, etc as the general distributed system, but also through the coordination and collaboration between each Agent can solve the problem of large-scale complex, make the system has the very strong flexibility and robustness. Until now, the literature on multi Agent system in the transformer oil dissolved gas concentration prediction has not found yet. This article through to the existing intelligent forecast method research based on the basic structure and characteristic of the Agent, this paper puts forward a more Agent concentration of dissolved gas in transformer oil intelligent prediction model.

Based on multi Agent system of transformer oil dissolved gas concentration in the intelligent forecasting collaboration model

Based on multi Agent system of transformer oil dissolved gas concentration in the intelligent forecasting collaboration model is as Fig. 1 shows. The model is divided into five layers: display layer, intelligent agent application layer, intelligent agent core layer, data access layer, data resource layer.

(1) display layer: The user interface is based on JAVA technology with the characteristics of traffic ability, portable, and cross-platform. Take advantage of visual and various chart technology, provides the transformer monitoring and maintenance staff are very friendly interactive interface At the same time also provide personalized service for users of the system interface.

(2) Intelligent agent application layer: This layer is mainly consist of the blackboard, control management Agent, intelligent user Agent, data pre-processing Agent, forecast expert Agent management, combined forecast Agent, and self-learning Agent.

(3) Intelligent agent core layer: Consist of Agent public facilities and JADE [7] platform bus. JADE platform bus offer a basic services collection for different Agent, including control management Agent, (AMS), Agent communication channel (ACC), directory query device (DF), and Agent security, consistent persistence, communication and naming, etc. Agent Public facilities for various Agents in and out of the system, management of safety certification, registered, generate and recall migration.

(4) Data access layer: The data access layer provides intelligent agent core layer of the access control of data resources. Different business logic to database have different levels of access, to ensure the security of data access The layer of communication between various Agent and JADE platform adopts the ACL communication through a JDBC connection.

(5) Data resource layer: Adopt SQL Server XML database to store all kinds of information. Data resource layer includes: Oil gas in the database, to store the basic information of the gas content in transformer oil, such as H_2, CH_4, C_2H_6, C_2H_4, C_2H_2, CO, CO_2; Knowledge base; Depositing a prediction model for transformer fault diagnosis knowledge, such as expert experience and solving process, etc; At the same time also deposit Agent related knowledge, such as semantic, perception and reasoning, etc.; Predict library deposit forecast result of each prediction expert and combination forecast Agent; Error library: deposit each time prediction error of various experts and combination forecast Agent.

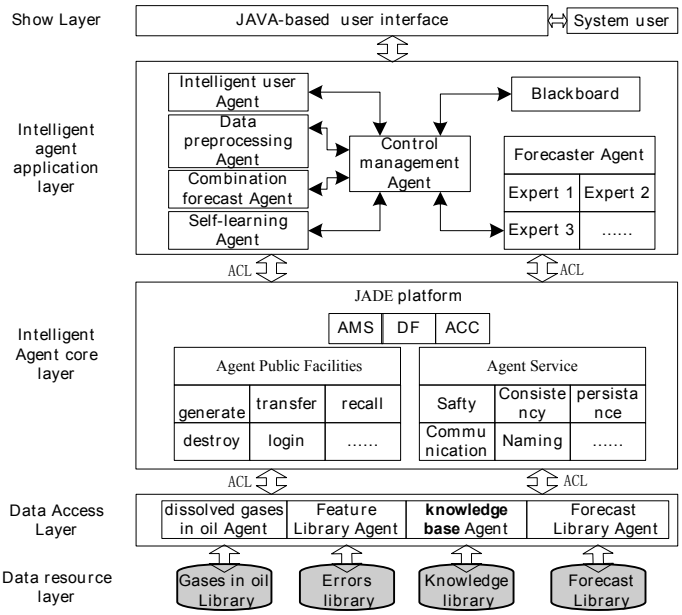

Fig.1 Collaborative model of intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent

The collaborative process of intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent

The collaborative process of intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent, as shows in Fig.2. The collaborative process adopts the Agent technology in classic blackboard model, interaction between multi Agent are as follows

(1) First, Data pretreatment Agent will come from the transformer DGA data in standardizing, Standardized values in the range of [0, 1], offer characteristic data for Each forecasters as they need, And send the data to the blackboard corresponding layer. Then control Agent post the task to the blackboard, and request the domain experts to predict together.

(2) This article main forecasters include linear model, index model, power model, GM(1,1) model, and Verhulst model, According to their own experience, They together make predictions in a moment and the same DGA data, then the predicted results sent to the prediction results layer of blackboard.

(3) Combination forecast Agent obtain the prediction results of experts in the field from the blackboard, through the SVM (support vector machine) algorithm for combination forecasting get the final prediction results.

(4) Since the learning Agent will point to the forecast as a process of experience, deposited in the knowledge base, adjust the predicting model according to predicting the actual value. Then update each expert credibility and priority access to resources.

(5) Finally, the intelligent user Agent transmutes the result on the blackboard layer to the users in a friendly way.

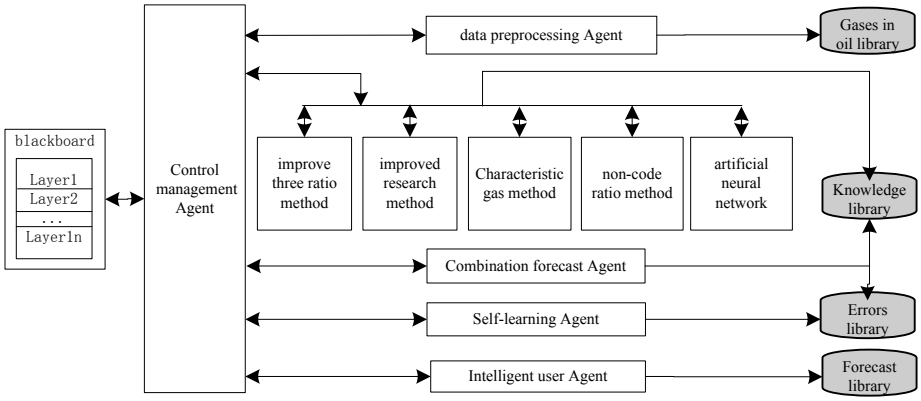

Fig.2 The collaborative process of intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent

Combination forecast Agent architecture and prediction methods

(1) Architecture

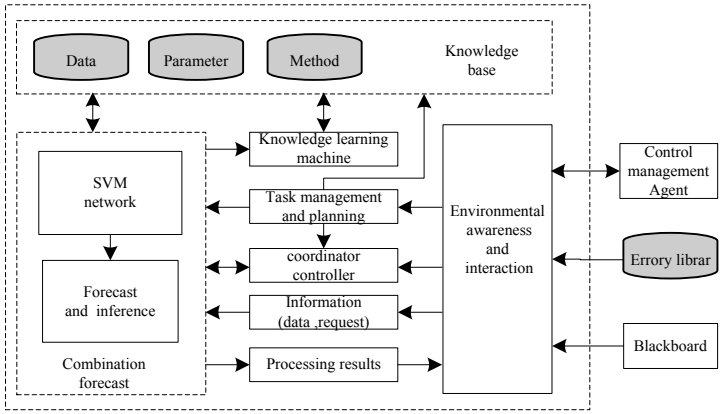

Fig.3 The architecture of combination forecasting agent

Combination forecast Agent mainly consist of environmental perception, learning machine, task management and planning, coordinator controller, information, result and the knowledge base, as shown in Fig 3.

First through combination forecast Agent interact with control management Agent, get the Combination forecast demand, and perceive the change of the blackboard, in order to get the experts at the beginning of the prediction results, then carries on the task management and planning work. Through coordinating the relationship between each function module, will have to deal with information input combination forecast machine. This article adopts the SVM algorithm to forecast

twice, finally through the environment interaction to transfer prediction results to the blackboard. The learning machine can dynamic update SVM network according to the prediction error every time, and form changeable weight combination forecast.

(2) Combination forecast method

Base on SVM regression of Non-linear combination forecast theory is to input the forecast result of forecast expert at a certain moment as the SVM sample. Take the actual Data capacity of solution gas in the transformer oil at the moment as exportation, Adjust the relevant parameters and through study and test for different input vectors corresponding output values. So by a certain samples training this model, nonlinear combination forecasting can be achieved. In this paper, model and standard error of each model, adopt mean absolute percentage error as evaluation index of model prediction accuracy [8]:

$$E_{Tr} = \frac{1}{n_{Tr}} \sum_{i=1}^{n_{Tr}} \frac{|\hat{y}_{Tri} - y_{Tri}|}{y_{Tri}} \times 100\% \quad (1)$$

$$E_{Te} = \frac{1}{n_{Te}} \sum_{i=1}^{n_{Te}} \frac{|\hat{y}_{Tre} - y_{Tre}|}{y_{Tre}} \times 100\% \quad (2)$$

$$E_s = E_{Tr} + E_{Te} \quad (3)$$

1) in formula: $\hat{y}_{Tri}$, y_{Tri}, n_{Tr} as the training set fitting values, actual value and sample capacity; E_{Tr} as fitting error; i as a certain moment.

2) in formula: $\hat{y}_{Tre}$, y_{Tre}, n_{Te} as Test data fitting values, value and sample capacity; E_{Te} as forecast error.

3) in formula: : E_s as the sum of error of fitting and extrapolation, It as a comprehensive index for measure of the precision of forecast model.

Application example

In this paper, it adopts five kinds of methods to forecast transformer oil dissolved gas concentration and Instance to forecast prediction model. The corresponding relation between serial number and model name is as follows: E1 express linear model, E2 express exponential model, E3 express power model, E4 express GM(1,1)model, E5 express Verhulst model, E6 express present model, according document [8]and present model, list three groups of actual data for H_2 gas dissolved in transformer oil and forecast data and error data from each forecast model, as Tab.1 and Table 1 show.

Table.1 Comparison of various forecasting methods on the H_2 sample value

model\year	1993	1994	1995
actual value	22.4	23.7	24.8
E1	23.60	24.97	26.33
E2	23.50	25.08	26.77
E3	23.79	24.77	25.60
E4	24.23	24.30	24.39
E5	22.47	23.81	25.73
E6	22.81	23.67	24.51

Table 1 illustrates that, the forecast result from the forecast model mentioned in this paper much more approach the actual value than single forecasting model. Table 2 illustrates that, minimized error to sample data fitting error E_{Tr}, is GM(1,1) model E4, the error is 4.47%., the minimized error to extrapolation error fitting E_{Te} is thesis forecast model E6, the error is 1.17%. According to the precision comprehensive index of thesis forecast model E_S can be see, the error of thesis forecast is 5.66%, the single forecasting model have lower error than single forecast model.

Table.2 Comparison of forecast errors

model\ error (%)	E_{Tr}	E_{Te}	E_s
E1	8.59	6.17	14.76
E2	8.30	7.95	16.25
E3	7.37	3.23	10.60
E4	4.47	1.67	6.14

Conclusion

To predict the dissolved gas in transformer oil can help predict transformer fault in time, on the basis of the research on the existing prediction system and transformer DGA method, design transformer oil dissolved gas concentration in the intelligent prediction model based on multi Agent system. In the examples of application, base on DGA data, the system require linear model, index model, power model, GM(1,1) model, and Verhulst model, Five forecasters independent forecasts on the concentration of dissolved gas in transformer oil. On the basis of the forecast results, the combination forecast Agent trough the SVM network algorithm, and gives the final prediction results. Finally comparing the actual results show that feasibility and effectiveness of intelligent concentration forecast model of dissolved gases in transformer oil based on multi-Agent system.

Abstract: Aimed at the problem of speed identification for the asynthetic motor speed-less sensor vector control system, based on basic equations of vector control and centered by the current model and voltage model of rotor flux linkage, after the establishment of the rotor speed identification module by module reference self- adaptation theory(MRAS), this paper builds the MRAS speed-less sensor vector control system and establishes the system simulation model in Simulink software environment. Simulation results show that: the system has good dynamic and static characteristics and stability.

CLC: TM343.2 **Document Code:**A

Introduction

Asynchronous motor vector control (vector control, VC) with dynamic and static performance suchas high control accuracy, good low-frequency characteristics and quick torque response is widely applied in high-performance AC motor drive field. But the speed feedback signal with conventional vector control gets speed information through speed sensor. As a result, the cost of the system is increased, but the reliability of the system is reduced, the application of the system is limited and the performance of the speed control system is affected. Vector control without speed sensor technology gets physical quantities such as voltage and current from the motor side. This technology estimates the motor speed by calculation, which eliminates the hassle of speed sensor hardware detection, reduces system cost and improves system stability. Have a simple algorithm, small calculation, real-time speed and good stability of model reference adaptive system of nonlinear time-varying system based in many fields has been widely used. So I used MRAS to estimate the motor speed.

Vector Control

1.1. Fundamental

Asynchronous motor vector control principle simulates asynchronous motors as DC motors to get better control performance, according to the dynamic mathematical model of the motor, and taking advantage of PARK transformation and CLARK transformation. Under the premise producing the same rotation MMF, stator currents i_A, i_B, i_C in the ABC three-phasecoordinate system can be converted to currents iα,iβ in α β two phase static coordinate system,through CLARK transformation(3s/2s), and then α β two phase static coordinate system can be convertered to dq two phase rotating coordinate system through PARK Transform (i.e. 2s / 2r transform), as a result, the stator current of the motor is decomposed into orthogonal excitation current id and the torque

current i_q. In this way, when observer rotates with the coordinate standing on the core, the AC motor can be equivalent to a DC motor . Therefore, we can control the AC asynchronous motor with the method of controlling the DC motor. The schematic diagram is shown in Figure 1. i_A, i_B, i_C is the three-phase AC input current, ωr is the output speed.

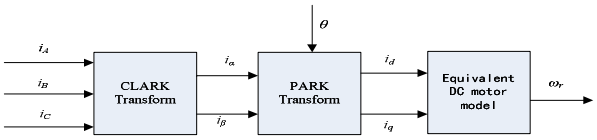

Figure 1. Vector control schematics

1.2.Current model of rotor flux

The mathematical model of the asynchronous motor shows that the motor is a multivariable, nonlinear and strongly coupled system. So if we want to control AC motorsas controllingDC motors, the vector must be transformed.

By vector transformation, we can get the voltage equation of the motorin the dq coordinate system:

$$\begin{bmatrix} u_{s\alpha} \\ u_{s\beta} \\ u_{r\alpha} \\ u_{r\beta} \end{bmatrix} = \begin{bmatrix} R_s + L_s p & 0 & L_m p & 0 \\ 0 & R_s + L_s p & 0 & L_m p \\ L_m p & \omega_r L_m & R_r + L_r p & \omega_r L_r \\ -\omega_r L_m & L_m p & -\omega_r L_r & R_r + L_r p \end{bmatrix} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ i_{r\alpha} \\ i_{r\beta} \end{bmatrix} \tag{1}$$

In the two-phase stationary coordinate system, the component quantity of the rotor flux on αβ axis is:

$$\psi_{r\alpha} = L_m i_{s\alpha} + L_r i_{r\alpha} \tag{2}$$

$$\psi_{r\beta} = L_m i_{s\beta} + L_r i_{r\beta} \tag{3}$$

Therefore, corresponding current equation is:

$$i_{r\alpha} = \frac{1}{L_r}(\psi_{r\alpha} - L_m i_{s\alpha}) \tag{4}$$

$$i_{r\beta} = \frac{1}{L_r}(\psi_{r\beta} - L_m i_{s\beta}) \tag{5}$$

According to related derivation , the current model equation of the asynchronous motor rotor flux is:

$$\psi_{r\alpha} = \frac{1}{T_r \rho + 1}(L_m i_{s\alpha} - \omega T_r \psi_{r\beta}) \tag{6}$$

$$\psi_{r\beta} = \frac{1}{T_r \rho + 1}(L_m i_{s\beta} - \omega T_r \psi_{r\alpha}) \tag{7}$$

Thus, the current model equation of the rotor flux in the rotating two-phasecoordinate systemis:

$$\psi_r = \frac{L_m i_{sm}}{T_r \rho + 1} \tag{8}$$

Motor slip formula is:

$$\omega_s = \omega_1 - \omega = \frac{L_m i_{st}}{T_r \psi_r} \tag{9}$$

1.3 The voltage model of rotor flux

The voltage equation of the rotor flux can be got according to the ordinal transformation in the α β two-phase static coordinate system of asynchronous motor is:

$$\psi_{r\alpha} = \frac{L_r}{L_m}[\int (u_{s\alpha} - R_s i_{s\alpha})dt - \sigma L_s i_{s\alpha}] \quad (10)$$

$$\psi_{r\beta} = \frac{L_r}{L_m}[\int (u_{s\beta} - R_s i_{s\beta})dt - \sigma L_s i_{s\beta}] \quad (11)$$

MRAS speed identification based on rotor flux

Basic principle of MRAS: for a system which the mathematical model can be built and parameter or variable can not be fully measurable, a self adaptation structure which can change a certain or some parameters in the system can be designed by using the input deviation between a reference model and an adjustable model. In this structure, through parameters or variable, the output value of the adjustable model can be changed to make the output deviation between the reference model and the adjustable model be zero.[3]

The voltage model and current model formula of the rotor flux (8) (10) (11), and the motor slip formula (9) show that current model contains speed entry, but voltage model does not, so we take the voltage model of the rotor flux as reference item, the current model of the rotor flux as adjustable item, and then design self adapatation control system based on Popov stability theory. Adaptive law formula of the Speed Identification is:

$$\omega_r = (K_p + \frac{K_i}{s})(\psi_{\alpha r}\psi^*_{\beta r} - \psi_{\beta r}\psi^*_{\alpha r}) \quad (12)$$

System Simulation

3.1 Simulation Model

Based on Matlab/Simulink7.11.0 (R2010b), this paper simulate the MRAS speed calculation system of the asynchronous motor. Simulation motor parameters are: u=260v，f=50Hz，n_p=2，R_s=0.435Ω，L_{ls}=0.002mH，R_r=0.816Ω，L_{lr}=0.002mH，L_m=0.069 mH，J=0.19kg.$m^{2\circ}$. Stator and rotor winding resistor inductance is 0.071mH, leakage coefficient is 0.056, the rotor time constant is 0.087. Emulation circuit is shown in Figure 2

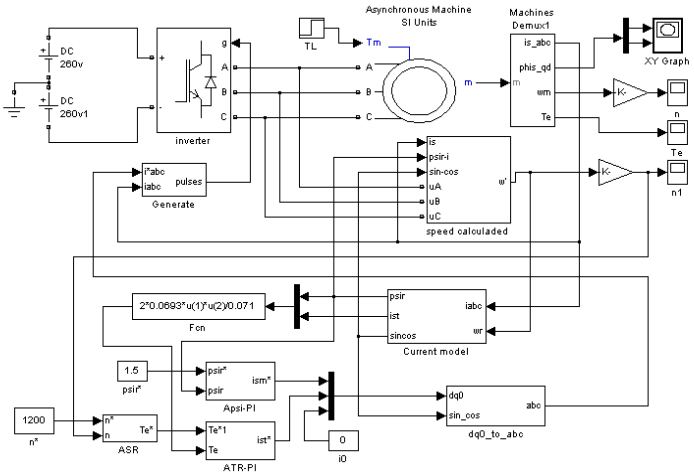

Figure 2 System Simulation Model

3.2 Simulation results

Simulation parameters: Motor starts with no-load, the given speed is 1200r/min, when t = 0.6s, the motor plus load torque TL = 55N.m. Figures 4, 5, 6, 7 are the actual motor speed, the estimated speed, the motor output torque and the stator flux. Figure 3and Figure 4 shows that the speed

difference between the measured motor speed and estimated speed is small, the system can get the same control effect as the speed sensor vector control. Figure5, the motor output torque response curve shows that, the torque responses rapidly and accurately, ripple is small, when the speed reaches the set value, the torque rapidly converges to the vicinity of the load torque stably, which gives the motor a higher speed adjustment performance. Figure 6shows that the stator flux trajectory is approximately similar toa circular flux.In the entire speed adjustment process, the motor load flux fluctuations are small when the motor load speed changes, which reflects that the system can realize excitation and torque decoupling of asynchronous motors, to reach the speed adjustment performance of the DC motor approximately .

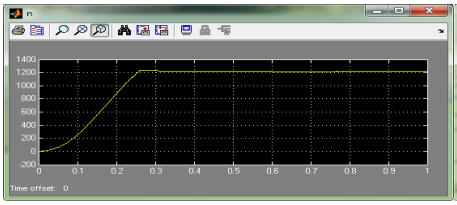

Figure 3. Actual speed

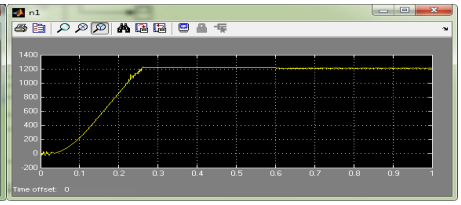

Figure 4. Speed Estimation

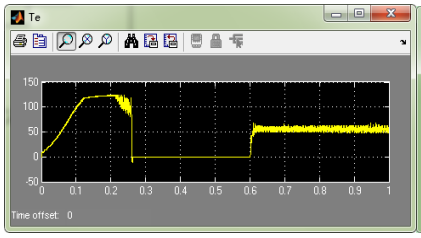

Figure 5. Motor output torque

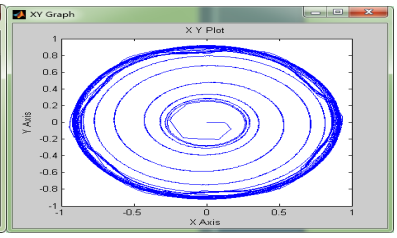

Figure 6. Motor stator flux

Conclusion

Simulation results show that: speed-lesssensor vector control system with good dynamic and static performance and stability, has a certain robustness, which can identify motor speed fast and accurately and guide practical engineeringsignificantly in theory.

Keywords: induction motor; fault diagnosis; rotor fault; spectrum correction

Abstract. The extraction method of induction motor's fault character based on coordinate transformation could restrain the influence of fundamental component leakage by translating fundamental component into DC component. The amplitude of the fault character frequency component was inaccurate by spectrum analysis taking no account of the leakage of itself. So rotor fault diagnosis method of induction motor based on discrete spectrum correction technology is proposed. This method which did not depend on spectral function of the window function improved the traditional phase difference correction method, and the stator current signal analysis by means of an appropriate window function is performed to reduce the interference between each frequency. The proposed method could detect the existence of fault character frequency component and its frequency and amplitude. The simulation and experimental results indicated that using this method could get better precision of frequency and amplitude of the fault character frequency component.

Introduction

Rotor fault is a common fault of the induction motor. At present, there are many methods used to detect rotor fault[1-7]. Stator current signal monitoring can be made into non-intrusion style, and has a wide prospect. When the rotor of induction motor broke down, the fault character frequency component $(1\pm 2ks)f_0$ appeared in stator current signals. However, because the slip ratio is very small when the motor runs steadily, it caused that the strongest fault character frequency component is very close to the fundamental component and the amplitude of the fault character frequency component is relatively smaller than that of fundamental wave. Documents now available usually describe the translation of fundamental component into DC component through a variety of methods (e.g. expanding Park translation method[1-2], Synchronous rotational coordinate system translation method[3], Hilbert translation method[4, 5], etc.). Operating like this belongs to qualitative analysis of fault discrimination. To realize the quantization of the fault degree, the amplitude of the fault character frequency component must be accurately measured.

When FFT and spectrum analysis are applied practically, the exact amplitudes and phases of all components can be obtained by correcting the components of frequency spectrum. At present, scholars have done a lot of research work in discrete spectrum correction[8]. Among them, the phase difference correction method is applied widely in engineering fields because it is convenient to realize, has higher precision and the good ability to overcome the noise[9-11]. This thesis researched a kind of improved phase difference correction method to correct the frequency spectrum of the stator current signals, count the amplitudes of the fault character frequency component accurately, and provided the algorithm theoretical basis for the quantitative evaluation of rotor fault.

Phase difference correcting method and its improvement

Assume harmonic signal $x(t) = A\cos(2\pi f_0 t + \theta)$, its Fourier transform is transformed into

$$X(f) = \frac{A}{2}e^{-j\theta}\delta(f + f_0) + \frac{A}{2}e^{j\theta}\delta(f - f_0) \tag{1}$$

In the equation: $f = kf_s / N = k\Delta f$, N is the sampling numbers, f_s is the sampling frequency, Δf is frequency resolution ratio.

Adding the window $w_T(t)$ (the length is $T(T=(N-1)/f_s)$) to the signal $x(t)$. $w_T(t)$ is obtained by moving the symmetrical window $T/2$ to the right. the window spectrum function of $w(t)$ is $W(f)$, the window spectrum function $W_T(f)$ of $w_T(t)$ relative to $W(f)$ has a Phase shift factor $e^{-j\pi fT,}$ that is

$$W_T(f) = W(f)e^{-j\pi fT} \tag{2}$$

According to the convolution theorem, the Fourier transforms of the signals adding window $x(t)w_T(t)$ is

$$X_w(f) = \frac{A}{2}W(f + f_0)e^{-j[\pi T(f+f_0)+\theta]} + \frac{A}{2}W(f - f_0)e^{-j[\pi T(f-f_0)-\theta]} \tag{3}$$

FFT analysis of N point is done on $x(t)w_T(t)$, assuming $f_0=(k-\Delta k)\Delta f$, wherein k is integer, and $\Delta k \in [-0.5, 0.5]$ is normalized frequency correction. then the peak value of discrete frequency spectrum should appear at the k spectral line, and its corresponding phase is

$$\varphi_0 = \theta - \pi T(k\Delta f - f_0) = \theta - \pi\Delta k \tag{4}$$

Move the center of the window function $w_T(t)$ to the right again for uT, now the phase shift is $e^{-j2\pi ufT}$, and similarly, FFT analysis of N point is done and then phase of the signal after adding the window is

$$\varphi_1 = \theta - \Delta k\pi - 2\pi u\Delta k = \theta - (\pi + 2\pi u)\Delta k \tag{5}$$

phase difference calculated from equations （4） and （5） is

$$\Delta\varphi = \varphi_1 - \varphi_0 = -2\pi\Delta k \tag{6}$$

in above equation, value of $\Delta\varphi$ is in the range of （-2π，2π）, and its main value range is （$-\pi$，π）. Therefore, the phase difference $\Delta\varphi$ is properly adjusted:

$$\Delta\varphi = \begin{cases} \Delta\varphi + 2\pi & \Delta\varphi < -\pi \\ \Delta\varphi - 2\pi & \Delta\varphi > \pi \end{cases} \tag{7}$$

Then the normalized frequency correction is $\Delta k = -\frac{\Delta\varphi}{2\pi u}$. Assuming that the coefficient of the k *spectral line* at which the peak value appeared is $X(k)=R_k+jI_k$, then the respective correcting formulae of both amplitude of the signals and the phase is $A = \frac{2|X(k)|}{W(\Delta k)}$ and $\theta = tan^{-1}(\frac{I_k}{R_k}) + \Delta k\pi$. The above is based on the time shift's phase difference method[7].。Besides the time shift's phase difference method[8-11], there are still other phase difference methods based on

adding different length or different types of symmetrical window function. Essentially speaking, all of the methods take the advantage of the character that both of the phase and the frequency correcting quantity have the linear relation in the main lobe of the window function, through counting FFT twice to get the phase difference of the spectrum peak to count the frequency correcting quantity and further correct the frequency and phase.

The correction of amplitude completely depends on the spectrum function $W(f)$ of the window function. Adding different windows, the spectrum function $W(f)$ of the window function is different, the amplitude correction formula is also different. Actually, even if it is commonly used window function, its spectrum functions are complex, and can only be approximately manipulated when counting. And some window functions themselves are rather complex and hard to extract the analytic expression of the spectrum function from them. That greatly limited the flexibility of window function selection in different applications, so the amplitude correction must be improved.

By multiplying the signal $x(t) = A\cos(2\pi f_0 t + \theta)$ with a complex signal $e^{j2\pi\Delta k\Delta ft}$, a complex signal $x_e(t) = A\cos(2\pi f_0 t + \theta)e^{j2\pi\Delta k\Delta ft}$ is obtained, then the Fourier transform with $x_e(t)$ is

$$X_e(f)=\frac{A}{2}e^{-j\theta}\delta(f+f_0-\Delta k\Delta f)+\frac{A}{2}e^{j\theta}\delta(f-f_0-\Delta k\Delta f)=\frac{A}{2}e^{-j\theta}\delta(f+k\Delta f-2\Delta k\Delta f)+\frac{A}{2}e^{j\theta}\delta(f-k\Delta f) \tag{8}$$

Add the window $w_T(t)$ with the length of T(T=（N-1)/f_s, f_s is the sampling frequency) to the signal $x_e(t)$, then the Fourier transform of the signal with window added $x_e(t)w_T(t)$ is

$$\begin{aligned} X_{ew}(f) &= X_e(f)*W_T(f) \\ &= \frac{A}{2}W(f+k\Delta f-2\Delta k\Delta f)e^{-j[\pi T(f+k\Delta f-2\Delta k\Delta f)+\theta]}+\frac{A}{2}W(f-k\Delta f)e^{-j[\pi T(f-K\Delta f)-\theta]} \end{aligned} \tag{9}$$

Obviously, if overlap of minus frequency is not considered, then when f=$k\Delta f$, the following formula is obtained

$$X_{ew}(k\Delta f)=\frac{A}{2}W(0)e^{j\theta} \tag{10}$$

that is the coefficient of the k spectral line of discrete spectrum for window added signal $x_e(t)w_T(t)$.

$$X_{ew}(k)=\frac{A}{2}W(0)e^{j\theta} \tag{11}$$

Amplitude equation and phase correction equation for $x(t)$ are $A=\frac{2|X_{ew}(k)|}{W(0)}$ and $\theta=\tan^{-1}(\frac{I_k}{R_k})$.Wherein: R_k and I_k are solid part and void part of X_{ew}（k）respectively. $W(0)$ is DC component of $w_T(t)$. It is not necessary to know expression of the window spectrum function, and it can be obtained by just taking average value of the window at N point.

Therefore, the calculation steps of spectrum correction method based on improved phase difference correction are: First step: to get normalized frequency correction quantity Δk of the signal $x(t)$ by utilizing phase difference method. Second step: Multiply signal $x(t)$ with a complex signal $e^{j2\pi\Delta k\Delta ft}$, to get a complex signal x_e(t).

Third step: Add window to complex signal x_e(t), calculate X_{ew}（k）by using DFT and then, correct amplitude and phase as above equations.

Simulation study

If the frequency of power supply of the induction motor is f_0=49.72Hz，$2sf_0$=1.64Hz，then when the rotor runs wrong, the stator current of the induction motor phase-A can be expressed as:

$$i_a = 10\cos(2\pi 49.72t + 32\pi/180) + 0.15\cos(2\pi 48.08t + 73\pi/180) + 0.11\cos(2\pi 51.36t - 13\pi/180) \quad (12)$$

Wherein: 48.08Hz component and 51.36Hz component are components of $(1\text{-}2s)f_0$ and $(1+2s)f_0$ respectively.

Because the stator current signal i_a is generated by mixing frequency-closed signals, its frequency is the intensively distributed frequency spectrum. In order to remove the interference of each frequency component, the choice of window function is very important, and the window function of which the side lobe decays fast must be selected.

Kaiser window is a group of self-defined adjustable window functions, composed by zero order Bessel function. The ratio of its main lobe energy to that of its side lobe is nearly the largest, and the ratio of the width of the its main lobe to the height of its side lobe can be freely chosen, and it has the character that the peak value of the side lobe is small and the rate of decay is large. Its time domain expression is:

$$w(n) = \frac{I_0\left[\beta\sqrt{1-\left(\frac{n}{N/2}\right)^2}\right]}{I_0(\beta)} \quad 0 \le |n| \le \frac{N}{2} \quad (13)$$

Wherein: $I_0(\beta)$ is modified zero-order Bessel function of the first kind, β is shape parameter of the window function, and N is length of the window function. The larger the shape parameter β, the smaller the peak value of the side lobe of Kaiser window function frequency spectrum, and the larger the rate of decay.

Based on adjustable feature of Kaiser window, this paper selects Kaiser window when adding window to stator current signal.

From simulation current signal of equation (17), the sampling frequency is 1024Hz，and make the spectrum point as 4096 points. Adding Kaiser window of β=10 to sampled data, and process with the improved phase difference correction method as mentioned previously. Simulation results are shown in Table 1 below.

Table 1 Correction results of the stator current simulation signal

Actual value	Actual frequency	48.02	49.72	51.36
	Actual amplitude	0.15	10	0.11
	Actual phase	73	32	-13
Corrected value	Correction frequency	48.07800	49.71998	51.36239
	Correction amplitude	0.14790	9.99993	0.10794
	Correction phase	73.58594	32.00894	-13.76456
Error	Relative error of frequency	0.00399	0.00005	0.00479
	Relative error of amplitude (%)	1.399	0.0006	1.873
	Error of phase (degree)	0.58594	0.00894	0.79456

Table 1 shows that after correcting, the respective relative errors of the amplitudes of the 48.08Hz frequency component and the 51.36Hz frequency component are 1.399% and 1.873%, while the respective phase errors are 0.58594° and 0.79456°. It is mainly because the foundation

component is excessively strong, and its amplitude is nearly 100 times of those of the 48.08Hz and 51.36Hz components, and the frequency spectrum leakage has effects on the 48.08Hz and 51.36Hz components. In contrast, because the amplitudes of the 48.08Hz and 51.36Hz components are smaller, and have less effect on foundation component, the correcting precision of the foundation component is higher.

To further improve the correcting precision of the fault character frequency component, we can use the frequency, amplitude and phase after the fundamental component is corrected to generate a sine sequence, and then minus the sine sequence from original sampling sequence to filter out the fundamental component in the signals completely, and then correct it to obtain an higher precision. The correction result is illustrated in Table 2: obviously after the fundamental component is filtered out, the 48.08Hz and 51.36Hz fault character frequency components both reached to a highest correction precision.

Table 2 Correction results of the stator current simulation signal filtered out fundamental component

Actual value	Actual frequency	48.08	51.36
	Actual amplitude	0.15	0.11
	Actual phase	73	-13
Corrected value	Correction frequency	48.08010	51.36014
	Correction amplitude	0.14998	0.109998
	Correction phase	72.99474	-13.00894
Error	Relative error of frequency	0.00019	0.00028
	Relative error of amplitude (%)	0.0106	0.0019
	Error of phase (degree)	0.00526	0.00894

Analysis of measured data

The experiment platform used the frequency conversion timing system as shown in figure 1. The motor drove the AC synchronization generator and the resistive loads. The motor is the Y132M-4 induction motor. The output frequency of the inverter f_0 is 45Hz, and the data sampling frequency is 25kHz.

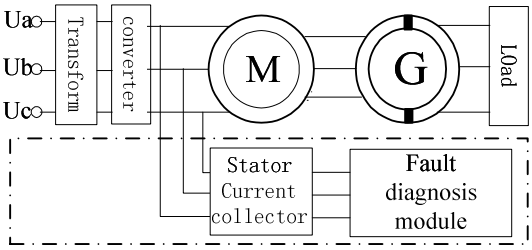

Fig. 1 The experiment scheme of detecting faults

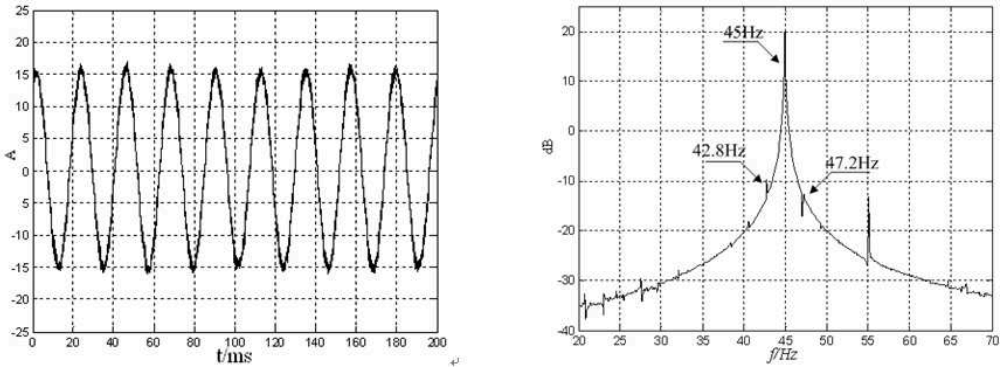
The experiment is carried on when the rotor bar 1 was broken, after the motor ran steadily, the measured stator current wave shape and frequency spectrum of motor phase-A is shown in Diagram 2. Now $2sf_0$=2.2Hz is counted out according to the measured motor rotary speed. Diagram 2(b) is from adding rectangular window to 10s data and do FFT directly on it. In the diagram, a peak point appeared at 42.8Hz fault character frequency, while a sinking gap appeared at 47.2Hz , which was caused by the leakage of the frequency spectrum of the fundamental component, so all the

measured amplitudes were not correct. Even if the 45Hz fundamental component was close to 20dB as shown in diagram 2(b), that is 10A or so, while from diagram 2(a), the amplitude of the fundamental component should be about 15A, which means the leakage was quite serious.



(a) A phase stator current shape (b)The frequency spectrum of A phase stator current

Fig.2 A-phase stator current

Extract a data with 7.5s length, and respectively count the data of the former 5s and latter 5s by adding Kaiser window, and firstly, correct the fundamental component with the improved phase difference method presented in this thesis to get accurate information of the frequency, amplitude and phase of the fundamental component, and then use the obtained information to form a sine sequence. Using the stator current signals minus the sine sequence could filter out the fundamental component in the stator current signals. Then, correct the frequency components of $(1\text{-}2s)f_0$ and $(1+2s)f_0$ in sequence, a better effect was obtained. The correction results are shown in table 3 below.

Table 3 Correction results of fundamental component and fault characteristic frequency components

	f_0	$(1\text{-}2s)f_0$	$(1+2s)f_0$
Frequency (Hz)	44.95	42.79	47.11
Amplitude (A)	15.355	0.129	0.151

Conclusion

The detection of induction motor's rotor fault based on stator current signals could avoid the influence of fundamental component leakage by translating fundamental component into DC component with coordinate transformation. However, the leakage may happen on the fault character frequency component itself , if it is ignored, the detected amplitude of the fault character frequency component is still inaccurate. This thesis improved the traditional phase difference correcting method first to make it never rely on the spectrum function of the window function when it is correcting the amplitude value, and then reduced the interference between the frequency components by choosing the proper window function to process the induction motor's stator current signals, and then corrected the frequency spectrum of the stator current with the improved phase correcting method, in this way, we could not only detect the existence of the fault character frequency component, but also obtained the exact information of the frequency and the amplitude of the fault character frequency component, and provided the algorithm support for further quantizing the fault severity。The simulation and experiment results proved：with the introduced research method in this thesis, by choosing proper window function, the frequency and amplitude of the fault character frequency component obtained by counting have higher precision.

Keywords: load modeling, induction motor, power system simulation, fuzzy C-means clustering, dynamic aggregation.

Abstract. Parameters of induction motors have crucial effects on power system simulation. This paper proposes a dynamic aggregation method of induction motors. In this method, firstly, starting off the electromechanical models of induction motors, taking the coefficients of the electromechanical equations and steady state slips of motors as the characteristic vectors, motors are grouped with fuzzy C-means clustering method. Then, electromechanical equations of the equivalent motor are obtained by averaging that of the individual motors in the same group. Finally, parameters of equivalent motors are calculated based on the relationship of transient impedance before and after aggregation, and the principle that active and reactive power loads are equal before and after aggregation. Simulation results show that the proposed method can improve the precision of simulation

Nomenclature

R_s	Stator winding resistance of motor (p.u.).
X_s	Stator leakage reactance of motor (p.u.).
X_m	Magnetizing reactance of motor (p.u.).
R_r	Rotor resistance of motor (p.u.).
X_r	Rotor leakage reactance of motor (p.u.).
H	Rotor inertia constant (s).
a	Torque coefficient in proportion to square of speed.
b	Torque coefficient in proportion to speed.
ω	Rotor speed (p.u.).
ω_s	Angle frequency of power system(rad/s).
I_d , I_q	d -axis and q -axis stator current.
V	Bus voltage.
$E_d^{'}$, $E_q^{'}$	d -axis and q -axis transient EMF.
eq	Subscript denoting constant or variable of equivalent motor.
i	Subscript denoting constant or variable of the i^{th} motor.
T	Superscript denoting the transpose of a matrix.
0	Subscript denoting steady state variable value.

Introduction

Model of each component is the base of power system simulation. Load model is the bottleneck of improving the precision of power system simulation due to its complexity. In load model, parameters of induction motors have crucial effects on voltage stability and angle stability [1-4].

In practice, thousands of induction motors scatter in a large distribution network. Simulation studies cannot be computationally feasible unless groups of individual induction motors are aggregated into a single equivalent one.

There are mainly two approaches to build load model: the component-based approach and the measurement-based approach. The component-based method from the investigation information, adopts aggregation algorithm to obtain the composite load model of a substation. There exist mainly four aggregation methods of induction motors: kVA weighted average method [4, 5], power invariance method [6,7], no load and block up working conditions of motor based method [8,9], dynamic equivalent circuit of induction motor based method [10].

In [4], based on the steady state equivalent circuit of induction motors, the parameters of the equivalent motor are obtained by kVA weighted averaging that of individual one. This method can easily obtain parameters of the equivalent motor, but reactive power load cannot be equal before and after aggregation. In [5], Guo et al believe that load factor and critical slip have notable impact on transient stability of power system and an improved kVA weighted average aggregation method of induction motor is proposed. In [6,7], the steady state equivalent circuit of individual induction motor is transformed to the form of three paralleled impedances, based on which groups of motors are aggregated to a single one. This method is strict based on the steady state equivalent circuit of motors. As opposed to kVA weighted average method, this method does not discriminate big motors from small ones, as a result, dynamic characteristics dominated by big motors is not retained. In [8], with the skin effect of motor taken into account, leakage inductance of stator as well as that of rotor is separated into two parts. Thus, electric parameters of motor reach to seven. In [8, 9], an aggregation method of motors is proposed based on no load and block up working conditions of motors. Because this method does not take the steady state working slip of individual motor into consideration, the dynamic errors of active and reactive power loads are comparatively large.

All the methods mentioned above, belong to static aggregation method. The dynamic error is comparatively large. In this paper, motors connected to the same bus are grouped by fuzzy C-means clustering method based on their coherency and a dynamic aggregation method of motors is proposed. The effectiveness of this method is also validated by a simulation case.

Model of Induction Motor

Equivalent Circuit of Induction Motor.

The steady state equivalent circuit of induction motor is shown as Fig.1, while the transient equivalent one is shown as Fig.2 [10].

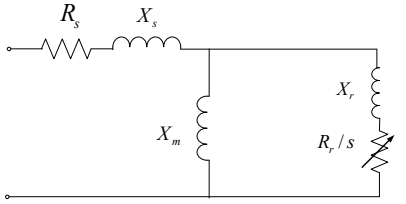

Fig.1 Steady equivalent circuit of induction motor

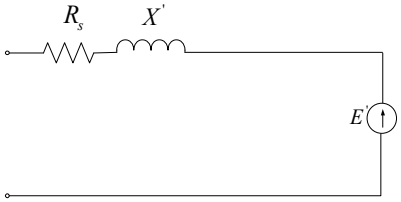

Fig.2 Transient equivalent circuit of induction motor

According to [11], with the stator resistance neglected, the simplified electromechanical model of induction motor is

$$T' \frac{dE'_q}{dt} = -E'_q + \frac{X - X'}{X} V + T' \omega_s (\omega - 1) E'_d \tag{1}$$

$$T^{'}\frac{dE_d^{'}}{dt}=-E_d^{'}-T^{'}\omega_s(\omega-1)E_q^{'} \tag{2}$$

$$2HX^{'}\frac{d\omega}{dt}=VE_d^{'}-T_{m0}\left(a\omega^2+b\omega+1-a-b\right)X^{'} \tag{3}$$

Where,

$T^{'}=T_0^{'}X^{'}/X$

$T_0^{'}=(X_r+X_m)/(\omega_s R_r)$

$X=X_s+X_m$

$X^{'}=X_s+X_rX_m/(X_r+X_m)$

Initialization of Induction Motor.

According to Thevenin Theory, seen from rotor resistance to stator, the equivalent impedance of induction motor on steady state is

$$Z_e=R_e+jX_e=(R_s+jX_s)//jX_m+jX_r=\frac{R_sX_m^2+j(X_pX_{sm}+R_sX_{rm}^2)}{R_s^2+X_{sm}^2} \tag{4}$$

Where

$X_{sm}=X_s+X_m$

$X_{rm}=X_r+X_m$

$X_p=X_sX_m+X_rX_m+X_sX_r$

$R_e=\frac{R_sX_m^2}{R_s^2+X_{sm}^2}$

$X_e=\frac{X_pX_{sm}+R_sX_{rm}^2}{R_s^2+X_{sm}^2}$

The equivalent voltage is

$$V_e=\frac{X_m}{\sqrt{R_s^2+X_{sm}^2}}V \tag{5}$$

The electromagnetic torque of induction motor on steady state is

$$T_e=\frac{V_e^2(1-s)R_r/s}{\omega_s\left[(R_r/s+R_e)^2+X_e^2\right]} \tag{6}$$

The steady state slip of rotor s_0 can be obtained according to Eq.7.

$$T_e=T_{m0}\left[a(1-s)^2+b(1-s)+1-a-b\right] \tag{7}$$

The active and reactive power loads of motor are

$$P=real\left(\frac{V^2}{R_s+jX_s+\frac{(R_r/s_0+jX_r)*jX_m}{(R_r/s_0+jX_r+jX_m)}}\right) \tag{8}$$

$$Q=imag\left(\frac{V^2}{R_s+jX_s+\frac{(R_r/s_0+jX_r)*jX_m}{(R_r/s_0+jX_r+jX_m)}}\right) \tag{9}$$

Motor Grouping Based on Fuzzy C-Means Clustering Method

Introduction of Fuzzy C-Means Clustering Method.

The idea behind fuzzy C-means clustering method is that it introduces the concept of membership from fuzzy mathematics. As opposed to hard C-means clustering method, fuzzy C-means clustering

method can obtain the membership of each class for every sample. The advantage of fuzzy C-means clustering method relies on that it reflects better the real world by expressing the intermediary property of samples.

The procedure of fuzzy C-means clustering method is as follows.

P1) According to the number of classes pre-specified, c clustering centers are produced at random.

P2) Square of distance d_{ik}^2 between each characteristic vector of sample x_k and each clustering center w_i is calculated as Eq.10.

$$d_{ik}^2 = \|x_k - w_i\|^2 = (x_k - w_i)^T (x_k - w_i) \tag{10}$$

P3) Suppose u_{ik} is the membership of i^{th} class for k^{th} sample and N is the number of samples, u_{ik} satisfies Eq.11.

$$\sum_{i=1}^{c} u_{ik} = 1, u_{ik} \in [0,1], \forall k = 1,2,\cdots N \tag{11}$$

Objective function is formulated by Eq.12.

$$J(U,W,\lambda) = \left\{ \sum_{k=1}^{N} \sum_{i=1}^{c} (u_{ik})^m (d_{ik})^2 + \sum_{k=1}^{N} \lambda_k \left(\sum_{i=1}^{c} u_{ik} - 1 \right) \right\} = \sum_{k=1}^{N} \left\{ \sum_{i=1}^{c} (u_{ik})^m (d_{ik})^2 + \lambda_k \left(\sum_{i=1}^{c} u_{ik} - 1 \right) \right\} \tag{12}$$

Where $\lambda_k (k = 1,2,\cdots N)$ is Lagrange multiplier, and real number $m \in [0,2]$ is a weighting index. According to Kuhn-Tucker Theory, the necessary conditions of the objective function minimization are

$$u_{ik} = \frac{1}{\sum_{j=1}^{c} \left(\frac{d_{ik}}{d_{jk}} \right)^{2/(m-1)}} \tag{13}$$

$$w_i = \frac{\sum_{k=1}^{N} (u_{ik})^m x_k}{\sum_{k=1}^{N} (u_{ik})^m} \tag{14}$$

By iteration, memberships and clustering centers are updated until difference between the latest two objective function values is lower than a threshold value or the most iteration number is reached.

Choice of Characteristic Vector.

Suppose there are n induction motors connected to the same bus. If the steady state slip s_0, initial transient EMF E_0' and the coefficients of the electromechanical equations of individual motor T', $2HX'$, $(X - X')/X$, $aT_{m0}X'$, $bT_{m0}X'$, $(1-a-b)T_{m0}X'$ are the same, then the n motors can be seen as only one motor. In practice, this condition cannot be satisfied, but motors with close parameters and initial states values can be classified into the same group and be seen as one motor. In this paper, for convenience, we choose $(T', HX', (X - X')/X, aT_{m0}X', bT_{m0}X', (1-a-b)T_{m0}X', s_0)$ as the characteristic vector for motor grouping. Difference of rotor speed ω for motors in the same group is thought to be trivial and neglected, that is, motors in the same group are considered as coherent.

Normalization of Characteristic Vectors.

To eliminate overshadows from big numbers on small ones, characteristic vectors must be normalized. Suppose row vector y_i is the characteristic vector of i^{th} sample, $Y = (y_1^T, y_2^T \cdots y_n^T)^T$ is the characteristic matrix, y_{ij} is the j^{th} coordinates of y_i and the i^{th} row, j^{th} column element of Y, row vector $y_{i,nom}$ is the normalized characteristic vector, $y_{ij,nom}$ is the j^{th} coordinates of $y_{i,nom}$, then $y_{ij,nom}$ can be calculated as Eq.15.

$$y_{ij,nom} = \frac{y_{ij} - \min_i(y_{ij})}{\max_i(y_{ij}) - \min_i(y_{ij})} \tag{15}$$

Aggregation of Induction Motors

Aggregation of the Simplified Electromechanical Equations of Motors in the Same Group.

Averaging the simplified electromechanical equations of individual motors in the same group, we can obtain the simplified electromechanical equations of the equivalent motor as Eq.16~Eq.18.

$$\frac{1}{n}\frac{d(\sum_{i=1}^{n}T_i^{'}E_{qi}^{'})}{dt}=-\frac{1}{n}\sum_{i=1}^{n}E_{qi}^{'}+\frac{V}{n}\sum_{i=1}^{n}\frac{X_i-X_i^{'}}{X_i}+\frac{1}{n}\omega_s(\omega-1)\sum_{i=1}^{n}T_i^{'}E_{di}^{'} \tag{16}$$

$$\frac{1}{n}\frac{d(\sum_{i=1}^{n}T_i^{'}E_{di}^{'})}{dt}=-\frac{1}{n}\sum_{i=1}^{n}E_{di}^{'}-\frac{1}{n}\omega_s(\omega-1)\sum_{i=1}^{n}T_i^{'}E_{qi}^{'} \tag{17}$$

$$\frac{1}{n}\sum_{i=1}^{n}2H_iX_i^{'}\frac{d\omega}{dt}=\frac{V}{n}\sum_{i=1}^{n}E_{di}^{'}-\frac{1}{n}\sum_{i=1}^{n}T_{m0,i}\left(a_i\omega^2+b_i\omega+1-a_i-b_i\right)X_i^{'} \tag{18}$$

Eq.16~Eq.18 can be simplified to Eq.19~Eq.21.

$$T_{eq}^{'}\frac{dE_{q,eq}^{'}}{dt}=-E_{q,eq}^{'}+\frac{X_{eq}-X_{eq}^{'}}{X_{eq}}V+T_{eq}^{'}\omega_s(\omega-1)E_{d,eq}^{'} \tag{19}$$

$$T_{eq}^{'}\frac{dE_{d,eq}^{'}}{dt}=-E_{d,eq}^{'}-T_{eq}^{'}\omega_s(\omega-1)E_{q,eq}^{'} \tag{20}$$

$$2H_{eq}X_{eq}^{'}\frac{d\omega}{dt}=VE_{d,eq}^{'}-T_{m0,eq}\left(a_{eq}\omega^2+b_{eq}\omega+1-a_{eq}-b_{eq}\right)X_{eq}^{'} \tag{21}$$

Where

$$E_{q,eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}E_{qi}^{'} \tag{22}$$

$$E_{d,eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}E_{di}^{'} \tag{23}$$

$$\frac{1}{n}\frac{d(\sum_{i=1}^{n}T_i^{'}E_{qi}^{'})}{dt}\approx T_{eq}^{'}\frac{dE_{q,eq}^{'}}{dt} \tag{24}$$

$$\frac{1}{n}\frac{d(\sum_{i=1}^{n}T_i^{'}E_{di}^{'})}{dt}\approx T_{eq}^{'}\frac{dE_{d,eq}^{'}}{dt} \tag{25}$$

$$T_{eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}T_i^{'} \tag{26}$$

$$\frac{X_{eq}-X_{eq}^{'}}{X_{eq}}=\frac{1}{n}\sum_{i=1}^{n}\frac{X_i-X_i^{'}}{X_i} \tag{27}$$

$$H_{eq}X_{eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}H_iX_i^{'} \tag{28}$$

$$a_{eq}T_{m0,eq}X_{eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}a_iT_{m0,i}X_i^{'} \tag{29}$$

$$b_{eq}T_{m0,eq}X_{eq}^{'}=\frac{1}{n}\sum_{i=1}^{n}b_iT_{m0,i}X_i^{'} \tag{30}$$

Approximation effects caused by Eq.24, Eq.25 can be estimated by Eq.31, Eq.32.

$$\left|\frac{1}{n}\sum_{i=1}^{n}T_i^{'}E_{qi}^{'}-T_{eq}^{'}E_{q,eq}^{'}\right|\le\sqrt{\frac{\sum_{i=1}^{n}\left(T_i^{'}-\frac{1}{n}\sum_{k=1}^{n}T_k^{'}\right)^2}{n}}\sqrt{\frac{\sum_{i=1}^{n}E_{qi}^{'2}}{n}} \tag{31}$$

$$\left|\frac{1}{n}\sum_{i=1}^{n}T_i^{'}E_{di}^{'}-T_{eq}^{'}E_{d,eq}^{'}\right|\le\sqrt{\frac{\sum_{i=1}^{n}\left(T_i^{'}-\frac{1}{n}\sum_{k=1}^{n}T_k^{'}\right)^2}{n}}\sqrt{\frac{\sum_{i=1}^{n}E_{di}^{'2}}{n}} \tag{32}$$

It can be seen from Eq.31, Eq.32 that the variance of $T^{'}$ in the same group smaller, the better of the approximation effects. The small variance of $T^{'}$ in the same group can be guaranteed with the fuzzy C-means clustering method, by optimization of the objective function.

Calculation of Parameters for the Equivalent Motor.

According to Norton Equivalent Theory, transient equivalent circuit of motors connected to the same bus is shown as Fig.3.

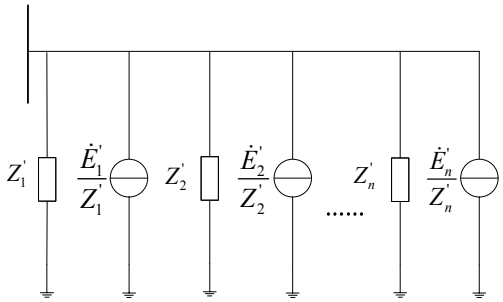

Fig.3 Transient equivalent circuit of induction motors

The transient impedance of the equivalent motor can be obtained by Eq.33.

$$R_{s,eq}+jX_{eq}^{'}=\frac{1}{\sum_{i=1}^{n}\frac{1}{R_{si}+jX_i^{'}}} \tag{33}$$

Substituting $X_{eq}^{'}$ from Eq.33 into Eq.26~Eq.28, the values of H_{eq}, $T_{0,eq}^{'}$, X_{eq} can be obtained, and Eq.34~Eq.36 holds.

$$\frac{X_{r,eq}+X_{m,eq}}{\omega_s R_{r,eq}}=T_{0,eq}^{'} \tag{34}$$

$$X_{s,eq}+X_{m,eq}=X_{eq} \tag{35}$$

$$X_{s,eq}+\frac{X_{r,eq}X_{m,eq}}{X_{r,eq}+X_{m,eq}}=X^{'}_{eq} \tag{36}$$

Generally, magnetizing inductance $X_{m,eq}$ is much larger than leakage inductances of stator and rotor $X_{s,eq}$, $X_{r,eq}$. Thus, $X_{s,eq}$, $X_{r,eq}$, $R_{r,eq}$ can be approximately calculated by Eq.37~Eq.39.

$$X_{s,eq}=X_{eq}-\sqrt{X_{eq}(X_{eq}-X_{eq}^{'})} \tag{37}$$

$$X_{r,eq}=X_{eq}^{'}-X_{s,eq} \tag{38}$$

$$R_{r,eq}=\frac{X_{eq}}{\omega_s T_{0,eq}^{'}} \tag{39}$$

Shown as Eq.40, Eq.41, the magnetizing inductance $X_{m,eq}$ and steady state slip $s_{0,eq}$ of the equivalent motor can be obtained according to principle that the active and reactive power absorbed by motors before and after aggregation are equal.

$$P_{eq}=\sum_{i=1}^{n}P_i \tag{40}$$

$$Q_{eq}=\sum_{i=1}^{n}Q_i \tag{41}$$

Substituting $s_{0,eq}$ into Eq.6, and $T_{m0,eq}$ can be obtained by Eq.42.

$$T_{m0,eq}=T_{e0,eq} \tag{42}$$

Substituting $T_{m0,eq}$ and $X_{eq}^{'}$ into Eq.29, Eq.30, a_{eq}, b_{eq} can be obtained.

Simulation Case

A simple simulation case is taken to validate the proposed method. Shown as Fig.4, three motors M_1 to M_3 are connected to bus B_2 through an ideal transformer, while six motors M_4 to M_9 are directly connected to bus B_2. Impedance parameters of the nine motors are cited from [13]. The chosen base power value is 373 kVA. The impedance of Z is $0.03 + j0.142$ ohm. The torque-speed characteristics of the nine motors are assumed to be constant, that is to say, a and b are zeros. Voltage disturbance is done on bus B_1 and active and reactive power response are measured on bus B_2.

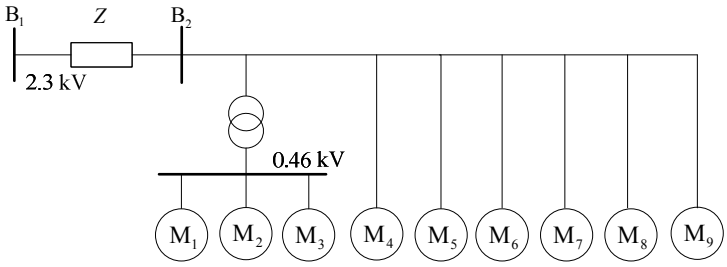

Fig.4 Simulation system

Grouping of Motors and Aggregation Results.

Table 1 lists the characteristic vectors of the nine motors. The results of fuzzy C-means clustering are shown as Table2. Obviously, the memberships of class one for motors M_1 to M_3 overwhelm that of class two. On the contrary, the memberships of class two for motors M_4 to M_9 overwhelm that of class one. So motors M_1 to M_3 are divided into group one, while motors M_4 to M_9 are divided into group two.

Table 1 Characteristic vector of each motor

Simulation Results.

Shown as Fig.5, the first simulation is done in such a way that a voltage dip of 50% occurs at $t = 0.1$ second, and is cleared later at $t = 0.7$ second. Curves of active and reactive power absorbed by motors before and after aggregation are judging criteria of aggregation effects. Figures 6-11 show the dynamic response of different machines. The solid lines represent active or reactive power load before aggregation and the dashed lines represent active or reactive power load after aggregation.

Seen from Figs.6-7, it is observed that fitting effects with two equivalent motor are remarkably superior to that with only one equivalent motor. This observation leads to the conclusion that it is not always advisable to represent all motors with a single equivalent one.

Curves of active and reactive power load of the first and second group of motors before and after aggregation are shown as Figs.8-11. It can be observed that the curves of active and reactive power of each group before and after aggregation agree well.

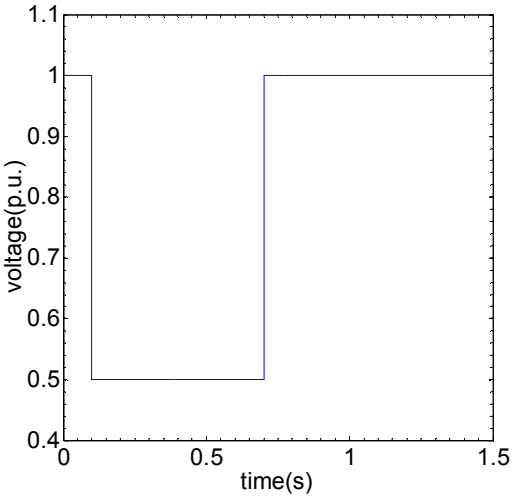

Fig.5 Curve of interrupted voltage

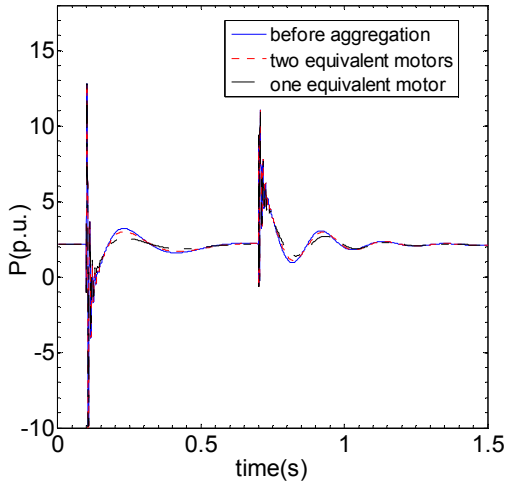

Fig.6 Sum of active power of the 9 induction motors before and after aggregation

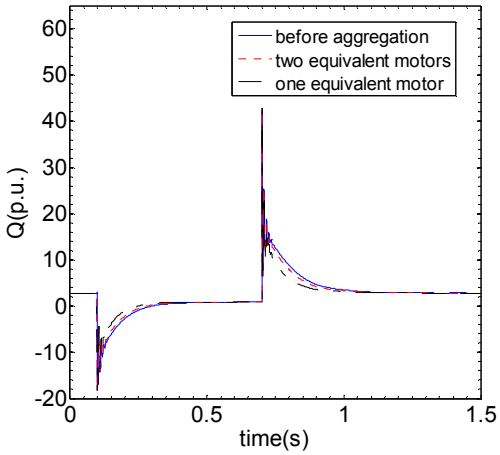

Fig.7 Sum of reactive power of the 9 induction motors first before and after aggregation

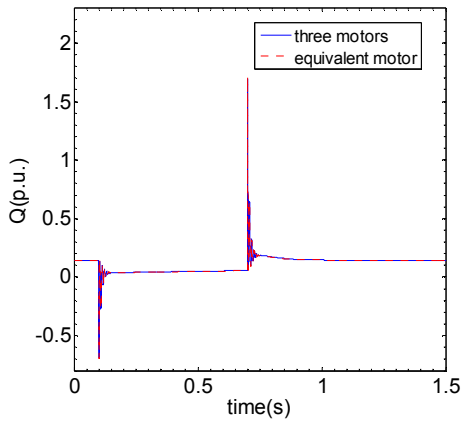

Fig.8 Sum of active power of induction motors of the group and before and after aggregation

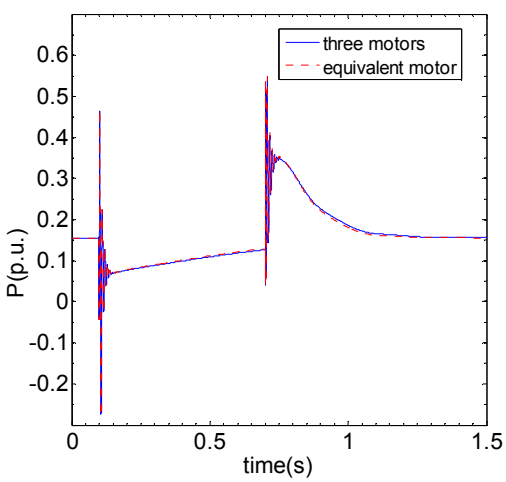

Fig.9 Sum of reactive power of induction motors of the first group before and after aggregation

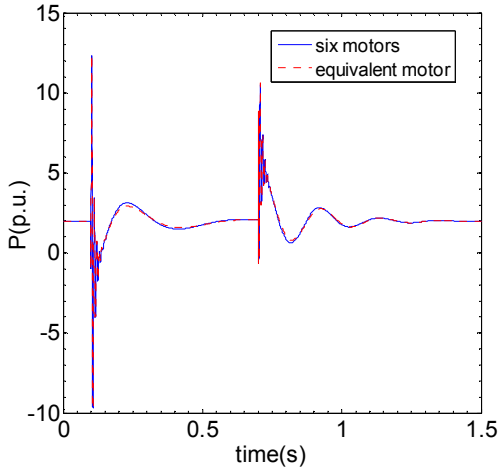

Fig.10 Sum of active power of the second group of motors before and after aggregation

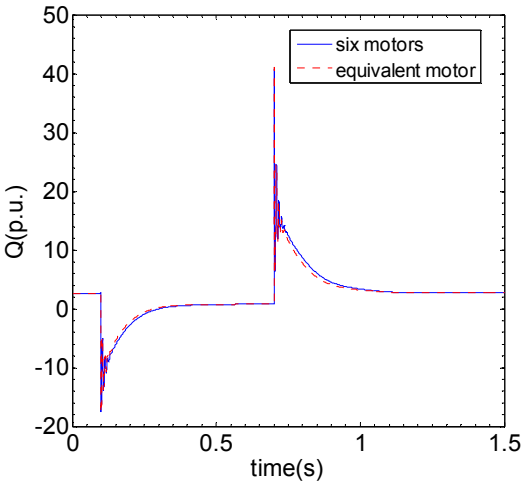

Fig.11 Sum of reactive power of the second group of induction motors before and after aggregation

Comparison with Selected Methods.

Shown as Fig.12, the second simulation is done in such a way that a voltage dip of 10% occurs at $t = 0.1$ second, and is cleared later at $t = 0.7$ second. Curves of active and reactive power of motors before and after aggregation with proposed method, with kVA weighted average method [4] and with power invariance method [7] are shown as Figs.13-14. From Figs.13-14, it is easy to observe that the dynamic errors of active and reactive power with power invariance method are quite noticeable. Figure 15 is the local amplified figure of Fig.14, from which we can observe that the steady state reactive power of the equivalent motor with kVA weighted average method is not equal to that of motors before aggregation.

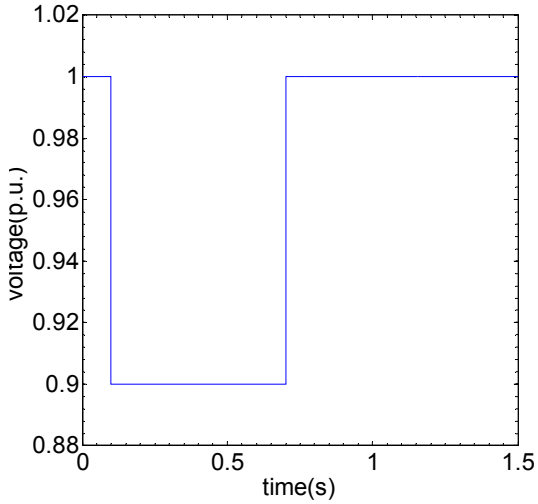

Fig.12 Curve of interrupted voltage

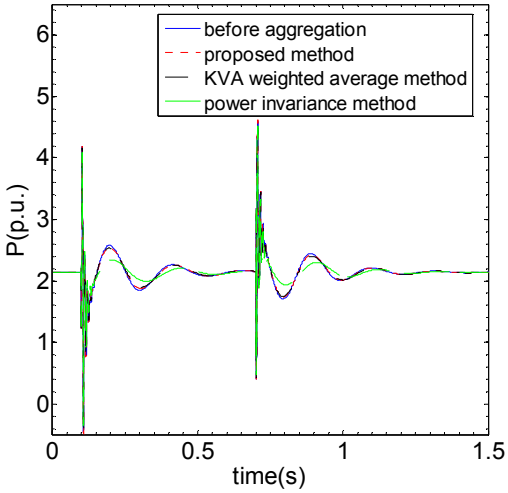

Fig.13 Active power comparison with other methods

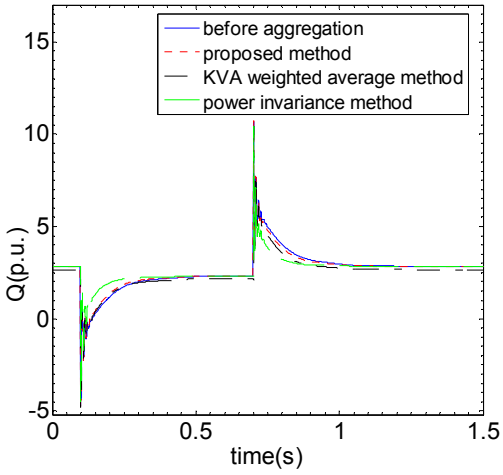

Fig.14 Reactive power comparison with other methods

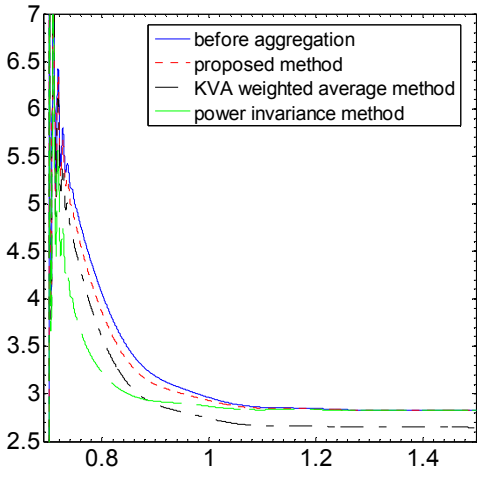

Fig.15 Local amplified figure of Fig.14

To evaluate the accuracy of different methods quantitatively, the relative root mean error between active and reactive power of motors before and after aggregation can be formulated as Eq.42, Eq.43.

$$E_p = \sqrt{\frac{\sum_{l=1}^{L}\left[\hat{P}(l)-P(l)\right]^2}{\sum_{l=1}^{L}P^2(l)}} \tag{42}$$

$$E_q = \sqrt{\frac{\sum_{l=1}^{L}\left[\hat{Q}(l)-Q(l)\right]^2}{\sum_{l=1}^{L}Q^2(l)}} \tag{43}$$

Where L is the sample points of simulation, $P(l)$ and $Q(l)$ are respectively the active and reactive load at the l^{th} step before aggregation, while $\hat{P}(l)$ and $\hat{Q}(l)$ are respectively the active and reactive load at the l^{th} step after aggregation. The relative root mean square errors of active and reactive power by different methods are shown as Table 4.

Table 4 Comparison of fitting errors with selected methods

Different Methods	E_p	E_q
kVA Weighted Average Method	0.0098	0.0743
Power Invariance Method	0.0404	0.1392
Proposed Method	0.0063	0.0282

From Table 4, it is appropriate to reach the conclusion that the proposed method reduces the fitting errors of active and reactive power sharply.

Conclusions

This paper directly starts off the electromechanical equations of induction motor. With coefficients of electromechanical equations and steady state slip chosen as the characteristic vector, motors are grouped by fuzzy C-means clustering method. Motor in the same group are aggregated with dynamic aggregation method. By the simulation case, the relative root mean errors of active and reactive power respectively reduce from 0.0098, 0.0743 of kVA weighted average method and, 0.0404, 0.1392 of power invariance method to 0.0063 and 0.0282.

Keywords: vehicle power supply, AC and DC mixed output, double-loop PWM control,

Abstract. The paper proposes a AC and DC mixed output VPS(vehicle power supply). It is composed of a two-stage circuit with the input stage and the output stage. The input stage contains a single-phase PWM inverter, a HFT (high-frequency transformer) and an uncontrolled rectifier. The single-phase PWM inverter adopts the open-loop control strategy to convert the low DC voltage into a high-frequency one with square wave. The HFT enhances the voltage and insulates the low-voltage side from the high-voltage side. The uncontrolled rectifier transforms the square voltage into DC voltage. In the output stage, one output uses single-phase PWM inverter and the other uses a DC chopper, both of which adopt the double-loop PWM control mode. The mode consists of an outer voltage loop and an inner current loop to produce desirable voltage and power. With the two-stage control strategy, ideal output currents and the output voltages are obtained, and the input power factor is controllable. The VPS model is established on MATLAB/SIMULINK, and this system is also implemented in laboratory based on DSP TMS320F28335. The results of simulation and experiment verify the proposed VPS system.

Introduction

The electrical systems in the early automobiles are introduced mainly for lighting, cranking, and battery charging purposes. But, in the recent years, electrical and electronic system components, circuits, and accessories in the automobiles have steadily increased, both in complexity and quantity. This has motivated the research in restructuring the entire power system architecture in the vehicle. As a DC-AC or DC-DC conversion device, vehicle power can be connected directly between battery and all kinds of electrical drives, such as laptops, GPS navigator, and car refrigerator. VPS has brought a lot of convenience to people's life and is a kind of regular automobile electronic product. The traditional vehicle power supply, where it takes inverter and power frequency transformer, is big and low efficiency. With the development of power electronic devices and power electronic technology, the efficiency of the inverter circuit which adopt high frequency transformer is higher than before[1]-[4]. When used in automobiles, the VPS can not only enhance the voltage, but also improve the power quality, which leads to a wide application prospect[5]. Currently, the study of the VPS have focused on the topologies and control strategies[6].Reference[7] introduces the control strategy of typical VPS, where it takes single-loop control in the output side. It is difficult to obtain a good effect of current control.This paper adopt the double-loop control in the output side to get ideal waveforms.Traditional VPS only gives one output, and obviously it cannot adjust to variable loads. Therefore, this paper presents a new type of VPS-AC And DC mixed output VPS. The paper analyzes the basic principle and control strategies of the proposed system, and accomplishes the dynamic simulations and experiments to verify the proposed VPS system.

Construction of VPS system

The VPS is composed of the primary side converter and the secondary side converter, with the HFT. The input DC voltage is modulated into the high-frequency square waveform by the primary side converter, and then coupled to the secondary side. The high-frequency square waveform of the secondary side is converted into the waveform required by secondary side converter. Its Realization is DC-AC-DC-AC and DC-AC-DC-DC converter, which is shown in Fig.1.

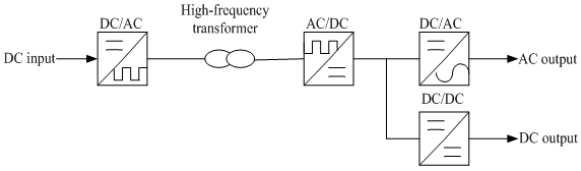

Fig.1 Principle diagram of VPS

The structure of DC-AC-DC-AC and DC-AC-DC-DC converter is more complex than the tradition DC-AC-AC converter. But the control performance of the former is better. The output current and the output voltage can be controlled by the PWM[8].The proposed DC-AC-DC-AC and DC-AC-DC-DC converter topology is shown in Fig.2. This topology is composed of two-stage power circuits. The input stage contains three parts, namely the single-phase PWM inverter, the HFT and the uncontrolled rectifier. The single-phase PWM inverter adopts the open-loop control strategy to convert the low DC voltage into a high-frequency one with square wave. The HFT enhances the voltage and insulates the low-voltage side from the high-voltage side. The uncontrolled rectifier transforms AC into DC. In the output stage, one output uses single-phase PWM inverter and the other uses a DC chopper, both of which adopt the double-loop PWM control mode. The mode consists of an outer voltage loop and an inner current loop to produce desirable voltage and power. With the two-stage control strategy, the VPS's output currents and the output voltages have ideal waveforms, and the input power factor is controllable.

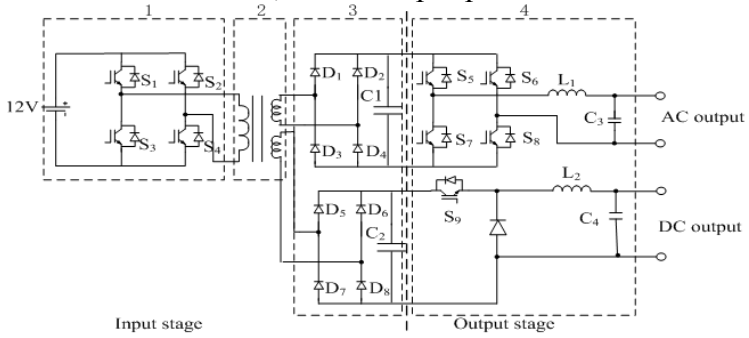

Fig.2 DC-AC-DC-AC and DC-AC-DC-DC converter topology of VPS

Principle of VPS

A. Control Strategy of Input Stage

According to the relevant knowledge of circuit and motor, we know that the high switching frequency is the most direct and effective way to reduce the volume and the weight. So we take the single-phase PWM inverter to enhance the frequency of primary side voltage, where it takes open-loop control to modulate the DC voltage into the high frequency square waveform with duty cycle of 50%. The open-loop control block diagram is shown in Fig.3. We compare zero and bipolar triangle carrier wave to get the switch signal.

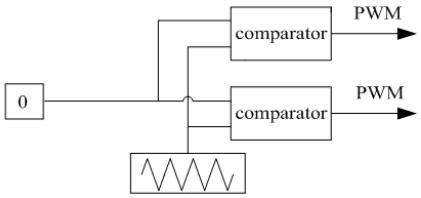

Fig.3 Control principle diagram of single-phase PWM inverter

B. Control Strategy of Output Stage

In output stage, one output takes single-phase PWM inverter, another output takes DC chopper, where they all adopt double loop PWM control mode which consists of outer voltage loop and inner current loop, to outputs the desired voltage and power to the load. The double-loop control block diagram is shown in Fig.4.

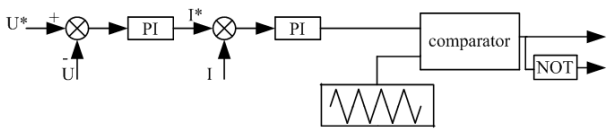

Fig.4 Double-loop control block diagram

Simulation results

The VPS model applied to automobile is established in Matlab/Simulink, as shown in Fig.5.The model parameters are as follows: ①input side: battery voltage 12V. ②High-frequency transformer: ratio of transformation is 1:50, frequency 5 kHZ ③DC voltage side: capacitance 500 μF(AC output side) and 300 μF(DC output side), ④AC output side: filter inductance 3 mH, filter capacitance 15 μF, the reference value of peak voltage is 311V, load resistance 100Ω and 0.05mH. DC output side: filter inductance 0.5 mH, filter capacitance 470 μF, the reference value of voltage is 50 V, load resistance 100 Ω and 0.005 mH.Fig.6 shows the simulation waveforms, including the input voltage, the primary voltage, and the secondary voltage of HFT, DC voltage, load voltage, and load current. Fig.7give the FFT analysis of the AC output current. According to the FFT analysis, we get the THD of output current is 0.90%. So the waveforms of output current is perfect to adjust to the load.

Experimental results

This system is also realized in the laboratory based on DSP TMS320F28335, where is in charge of collecting and processing data, and compiling control algorithms. There are a total of 4 IGBT modules and the corresponding drive modules in the VPS experimental system. The system is shown in Fig.8. The system parameters are as follows: ①input voltage 12V. ②High-frequency transformer: ratio of transformation is 1:50, frequency 5kHz ③DC voltage side: capacitance 500 μF(AC output side) and 300 μF(DC output side)④ AC output side: filter inductance 3mH, filter capacitance 15μF, load resistance 100Ω , DC output side: filter inductance, filter capacitance 470 μF, load resistance 100 Ω . We set the reference value of peak voltage in AC output side at 330V and 50V separately. We get the corresponding waveforms as shown in Fig.9. We set the reference value of voltage in DC output side at 50V and 20 V separately. We get the corresponding Waveforms as shown in Fig.10.

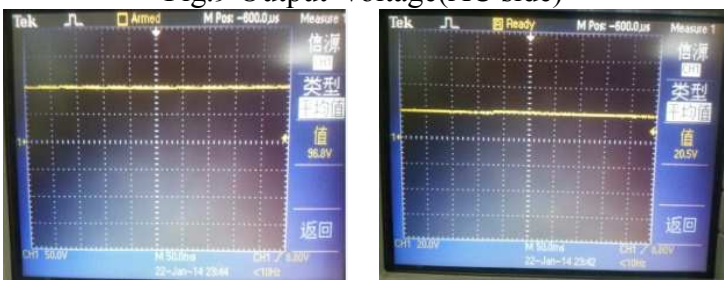

Fig.10 Output voltage(DC side)

Conclusion

In order to adjust to a variable load, this paper presents a new type of Multiple Output VPS. The efficiency of this type of VPS is high and the THD of output current is low. This paper analyzes the basic principle and control strategies of the proposed system, and finishes the dynamic simulations and experiments to verify the proposed VPS system. The results of simulation and experiment show that the output voltages have ideal waveforms, and verify the proposed power electronic transformer system.

Abstract. This paper describes the speed regulation of a magnetic gear integrated permanent magnet synchronous motor. The operating principle of the motor is discussed and the torque transmission is analyzed using finite element method; hence the motor model is established. The speed regulation is analyzed under vector control, and the simulated results verify the feasibility of speed regulation control.

Introduction

Magnetic gear has good potential for torque and speed transmission in industrial applications with some advantages such as no mechanical loss and maintenance-free operation that are not achieved using conventional mechanical gear. Furthermore, its instinct overloading protection feature can avoid many mechanical problems, such as broken teeth and backlash. A variety of magnetic gears have been proposed, and magnetic gears employing magnetic flux harmonics is drawing attention with useful torque transmission obtained[1].

A novel structure in which the magnetic gear is integrated with a brushless motor was reported. Torque can be transmitted between a low-speed rotor and a high-speed rotor through the modulation of ferromagnetic pole pieces [2]. The high-speed rotor is driven by the electromotive force generated by the coils of stator, and the low-speed rotor rotates in accordance with the gear ratio. Therefore, the magnetic-geared motor is a type of low-speed, high-torque actuator.

However, the brushless permanent magnet (PM) motor has such problems as torque ripple and current ripple. In order to solve these problems, a magnetic gear integrated permanent magnet synchronous motor is proposed. Besides, its smooth speed regulation can broaden the range of the application.

This paper describes the operating principle of the motor and analyzes the electromagnetic and mechanical transmission using finite element method (FEM). The steady-state and transient performances of motor are studied to obtain the motor model for speed regulation. The speed regulation system is established under vector control, and the speed adjusting characteristics is simulated and analyzed.

Motor Structure and FEM Analysis

Fig.1 gives the configuration of the magnetic gear integrated motor. This motor is designed with 3 pole-pair PMs in the high-speed rotor, 22 pole-pair PMs in the low-speed rotor. Between the high-speed rotor and low-speed rotor is 25 modulating ferromagnetic pieces. These ferromagnetic modulation pole pieces are used to modulate the space harmonics of the air gap flux density. The stator is inside the motor carrying a set of three-phase, 3 pole-pair concentrated windings.

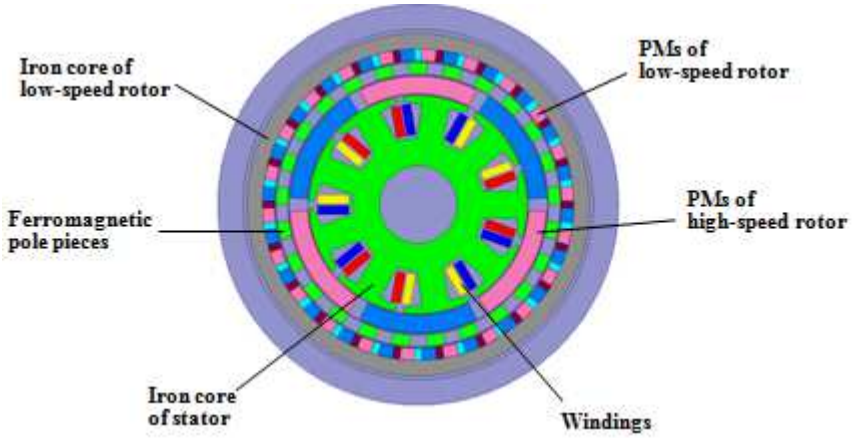

Fig.1. Magnetic gear integrated permanent magnet synchronous motor.

According to [3], the number of pole pairs in the space harmonics of the flux density distribution and the speed of the space harmonics produced by PMs of either rotor is given by

$$p_{m,k} = |mp + kn_s| \quad (1)$$

$$\Omega_{m,k} = \frac{mp}{mp + kn_s}\Omega_r + \frac{kn_s}{mp + kn_s}\Omega_s \quad (2)$$

where m=1,3,5, ⋯, ∞, k=0,±1, ±2, ±3, ±∞, p is the pole pair number of the high-speed rotor, n_s is the number of the ferromagnetic pole pieces, and Ω_r is speed of the high-speed rotor. $p_{m,k}$ is the pole pairs of the low-speed rotor, Ω_s is speed of the ferromagnetic pole pieces, and $\Omega_{m,k}$ is the speed of the space harmonics of the low-speed rotor. The largest space harmonic component is obtained when m=1, k=-1. When the ferromagnetic pole pieces is static, the speed of the low-speed rotor is

$$\Omega_{1,-1} = \frac{p}{p - n_s}\Omega_r \quad (3)$$

For this motor, the gear ratio is G_r=Ω_r/$\Omega_{1,-1}$=-22/3=-7.33. The stator windings with three-phase current produced electromagnetic torque that drives the high-speed rotor, and the torque is transmitted through the ferromagnetic gear to the low-speed rotor. In this case, the rated speed is 700 rpm for the low-speed rotor and 700*7.33=5133 rpm for the high-speed rotor.

FEM is employed to analyze the electromagnetic and mechanical transmission of the motor. The motor has three air gaps. Fig.2 shows the magnetic flux density and their corresponding harmonic spectra in the air gap between the stator and the high-speed rotor. It can be seen that the harmonics component with 3 pole pairs is the major component, due to the PMs of the high-speed rotor. Fig.3 shows the magnetic flux density and their corresponding harmonic spectra in the air gap between the high-speed rotor and the ferromagnetic pole pieces, and the main component is also 3 pole pairs. After the modulation, the main component becomes 22 pole pairs (Fig.4).

In order to get the static performance of the magnetic gear, set the high-speed rotor rotating at the rated speed while the ferromagnetic pole pieces and the low-speed rotor fixed. Fig. 5 shows the corresponding static torque obtained by conducting the simulation. It can be seen that the transmitted torque versus electrical angle is a sinusoidal wave, and the torque ratio of the low-speed rotor with respect to the high rotor is 7.33.

The theoretically expected transmitted torque versus angle characteristic can be described by

$$T_{G1} = T_{G1peak}\cos(\theta_H + \theta_L) \quad (4)$$

$$T_{G2} = T_{G2peak}\cos(\theta_H + \theta_L) \quad (5)$$

where T_{G1} and T_{G2} is respectively the gear coupling torque on the high-speed and low-speed rotors. θ_H and θ_L is respectively the electrical angle of the high-speed and low-speed rotors. The simulation gives the peak of gear coupling torque, as T_{G1peak}=17.7 Nm and $T_{G2\,peak}$=130 Nm, and the torque ratio agrees with the gear ratio.

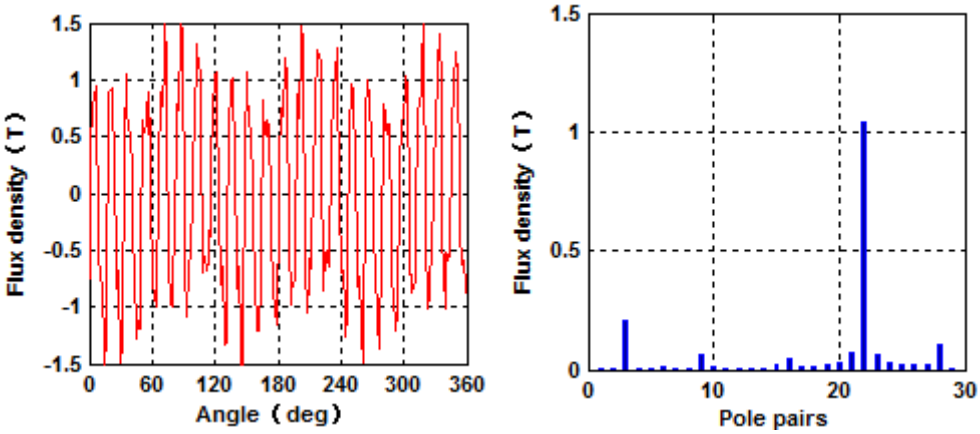
Fig.3. Flux density in the air gap between the high-speed rotor and the ferromagnetic pole pieces. (a) Waveform. (b) Spectrum.



(a) (b)

Fig.4. Flux density in the air gap between the ferromagnetic pole pieces and the low-speed rotor. (a) Waveform. (b) Spectrum.

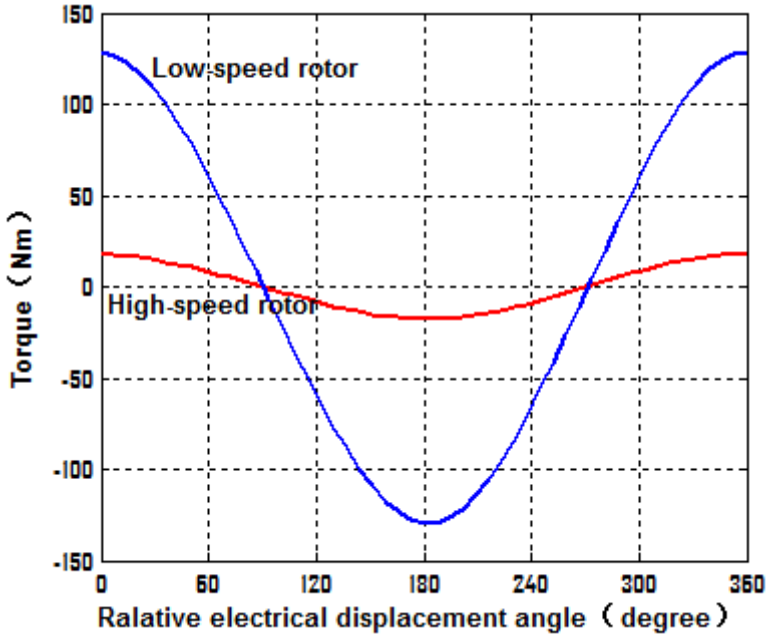


Fig.5. Static holding torque versus electrical displacement angle.

Motor Modeling and Control System

With the ferromagnetic pole pieces fixed, the electromechanical characteristic can be described by

$$\frac{J_H}{p_H}\frac{d^2\theta_H}{dt^2} = T_{EM} - T_{G1} \tag{6}$$

$$\frac{J_L}{p_L}\frac{d^2\theta_L}{dt^2} = T_L - T_{G2} \tag{7}$$

where T_{EM} is the electromagnetic torque produced by the stator windings, and T_L is the load torque. p_H and p_L represent the pole pair number of the high-speed and low-speed rotors. J_H is the inertia of the high-speed rotor, while J_L is the equivalent inertia of the load and low-speed rotor [4].

For this magnetic gear integrated PM synchronous motor shown in Fig.1, it can be shown that the motor can be divided into two parts. One is a PM synchronous motor with the load torque T_{G1}, which changes with the position of both rotors, and another is a magnetic gear driven by the transmitted torque T_{G2} and the real load torque T_L. In this way, the motor can be represented by the equivalent model shown in Fig.6.

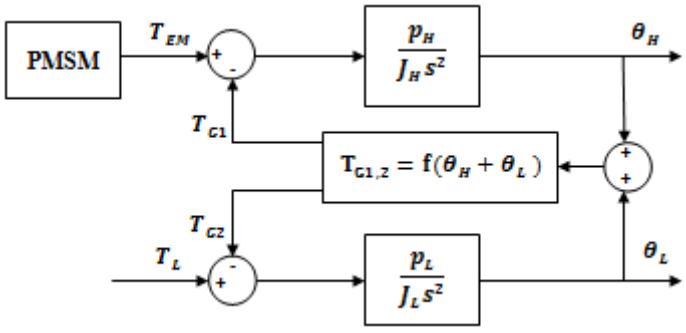

Fig.6. Equivalent model of the motor.

In order to adjust the speed, the high-speed rotor is rotated under vector control with the model of motor in Fig.6. The control block diagram is shown in Fig.7. In this control system, two closed loops are conducted and the current control loop use one feed forward loop and two feedback loops to get the reference of voltage. The target d-axis current is set as 0 A, while the target q-axis current varies with the load torque.

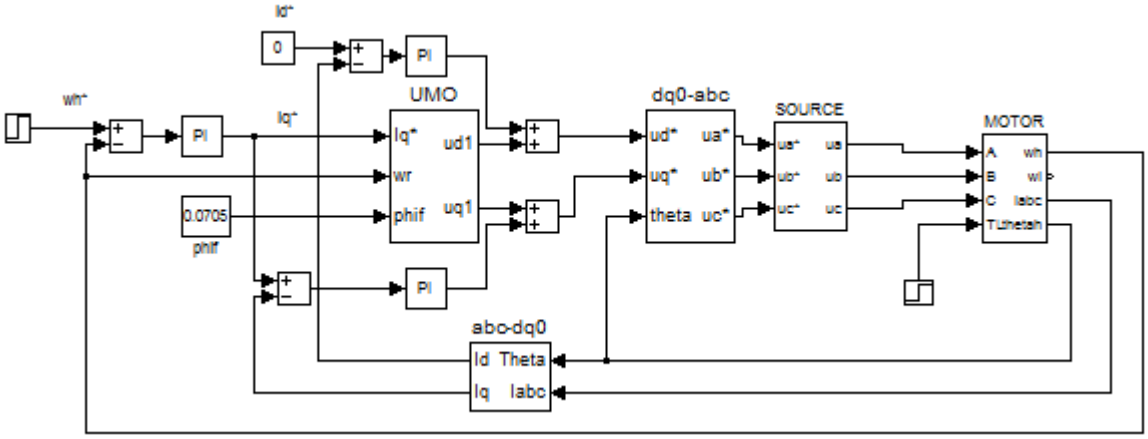

Fig.7. Control system of the motor.

Speed Regulation Analysis

In this simulation, the load torque is 50Nm, and the speed regulation range is from 300 rpm to 700rpm. Fig.8 shows speed waveform of the motor starting process. Reference speed of high-speed rotor is 300*7.33=2200 rpm. The speed volatility rises and stay stable after t=0.4 s. Speed in steady state is respectively 2200 rpm for high-speed rotor and 300 rpm for low-speed rotor, which agrees with the gear ratio.

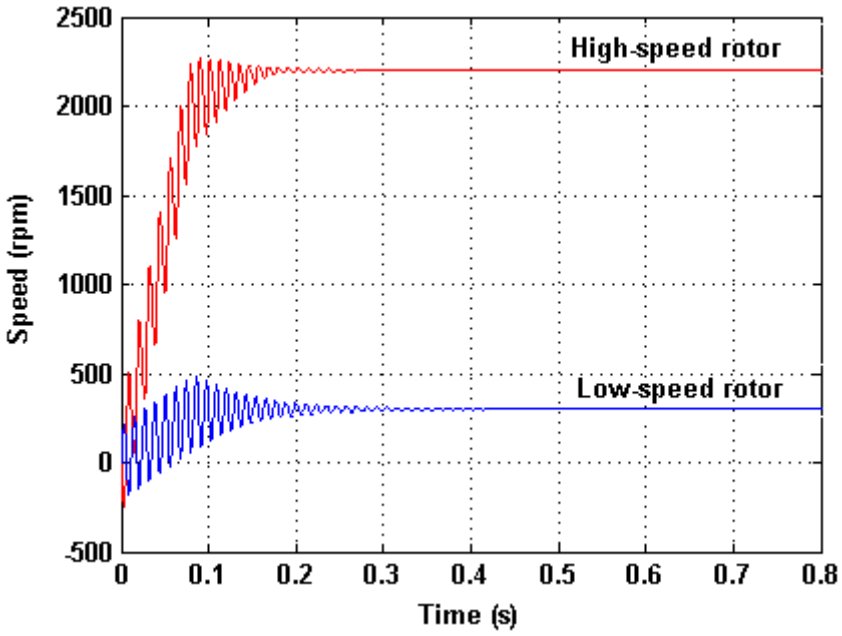

Fig.8. Speed waveforms for the starting process.

The speed reference of high-speed rotor is changed from 2200 rpm to 700*7.33=5133 rpm at t=3 s. Fig.9 shows speed waveform of speed adjusting process when reference speed of low-speed rotor changes from 300 rpm to 700rpm. It can be seen that the speed rises less volatility than the starting

process and stay stable after t=3.5 s. Speed in steady state is respectively 5133 rpm for high-speed rotor and 700 rpm for low-speed rotor, which verifies the effectiveness of the speed regulation strategy.

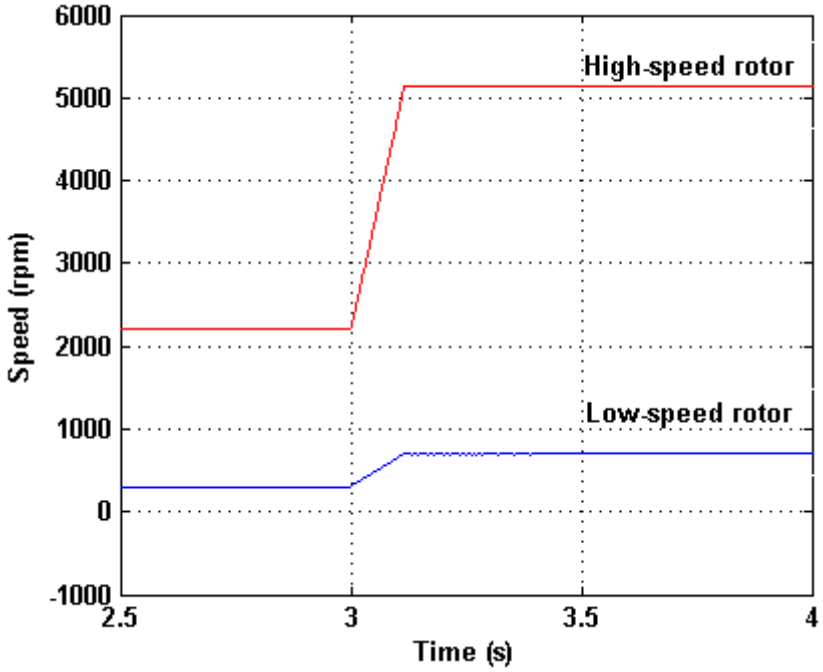

Fig.9. Speed waveforms of rotor for speed adjusting process.

The coupling torque of the magnetic gear on high-speed side is shown in Fig.10. The coupling torque changes versus the displacement of two rotors, and stay stable when the speed ratio remains 7.33. The couple torque influence the adjusting of speed, especially in the starting process. In the steady state the coupling torque on high-speed side is 6.82 Nm and 50 Nm on low-speed side, which consist with the gear ratio.

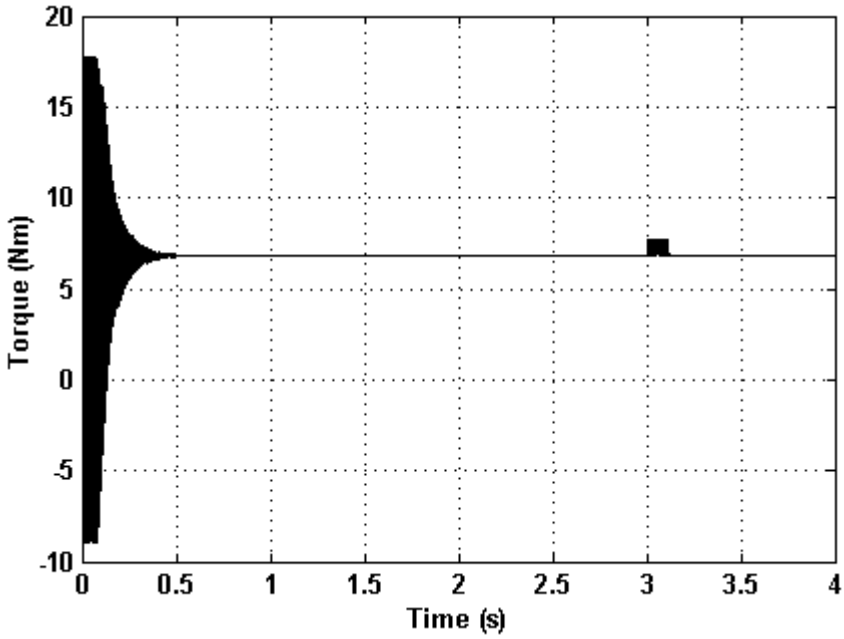

Fig.10. The coupling torque of the magnetic gear on high-speed side.

Conclusion

A magnetic gear integrated with PM synchronous motor is analyzed with FEM. The equivalent model of this motor is established though detailed dynamic analysis. The speed regulation and transmission torque characteristics are analyzed with vector control applied to the equivalent motor model. The simulation results verify the effectiveness of the speed regulation strategy.

The research of servo motor control strategies for the mobile gantry milling machine

Fangyuan Li[1, a]

[1] Zhejiang Business Technology Institute, Ningbo, Zhejiang, 315012, China

[a]muzi_woody@163.com

Keywords: Servo Motor, Mobile Gantry Milling Machine, Master-slave Control, Adaptive-Neuro Fuzzy, ANFIS Architecture.

Abstract. It is known for the traditional milling machine in operation at low speed and efficiency. This paper describes the research of servo motor control strategies for the mobile gantry milling machine. The principles of AC servo motor dynamics, master-slave servo control, and adaptive -neuro fuzzy inference system based on controller are illustrated. Using these strategies when the master servo motor is interference by the external signal, the reference speed of the slave servo motor can follow just like the master motor. Finally the mechanical coupling can be eliminated and the mechanical damage can be avoided.

Introduction

The columns of the traditional milling machine are fixed and the table containing the work piece is fed along the rail longitudinal. Due to the large weight of the machine moving parts, it is difficult to obtain the high acceleration. At the same time due to the length of the table limit and saving footprint workplace requirements, the structure of the fixed goalposts can not meet the requirements for the high-speed milling machining of the large work pieces.

Under the condition of the dynamic, static rigidity, as for the high-speed mobile gantry milling machine, the table and the work piece remain stationary, the goalposts move along the longitudinal rail. Because of the relatively small mass movement of the columns, the high acceleration characteristics can be obtained.

The moving parts which are composed of the large beams, the matched holder, the gantry, and so on, do not always form a symmetrical structure and symmetry force. Although exactly the goal posts on both sides are same, eventually the gantry frame on both sides of the column can not guarantee the consistency of the movement which may cause the inconsistency of the gantry frame and damage the driving part and the work piece. So keeping both sides of the columns synchronous driving is a key technology to eliminate the mechanical coupling and avoid the mechanical damage in order to ensure the machining accuracy.

In the recent years, the development of the intelligent control is very quick, especially the fuzzy control which is not entirely dependent on the object's mathematical model, is suitable for uncertain systems and nonlinear systems to solve many difficult problems for the classical control. This paper introduces the fuzzy PID controller as a speed regulator, using the dynamic compensation method for adjusting the proportional gain, so that the two motors are synchronized.

AC Servo Motor Dynamics

Fig. 1 is the mobile gantry milling machine driven by double servo motor [1]. The model of the system consists of a motor coupled to a gear box and an inertia load rigidly fixed to output shaft. The control torque (Tc) for the AC servo motor is described as

$$T_C = \mathrm{k}_1 \mathrm{E(t)} - \mathrm{k}_2 \dot{\theta}(\mathrm{t})$$

Where Tc = Control torque (Nm)
k1 & k2 = motor constants (Nm/V, Nm/rad/s) - identified parameters from experimental test.
$\dot{\theta}$ = angular velocity of the AC servo motor (rad/s)
E = rated input voltage (v)
The dynamic equation of the mechanical system is given by

$$T_C = J\ddot{\theta} + B\dot{\theta} + T_L$$

Where θ = angular position of the AC servo motor (rad)
$\ddot{\theta}$ = angular acceleration of the AC servo motor (rad/s^2)
B = Friction coefficient
J = Moment of inertia (Kg.cm^2)
Taking laplace transform the above equations becomes

$$K_1E(s) - k_2s\theta(s) = Js^2\theta(s) + Bs\theta(s) + T_L(s)$$

The master and slave motor can adopt the same equation except the constant factors are different, such as Moment of inertia (J), Friction coefficient (B).

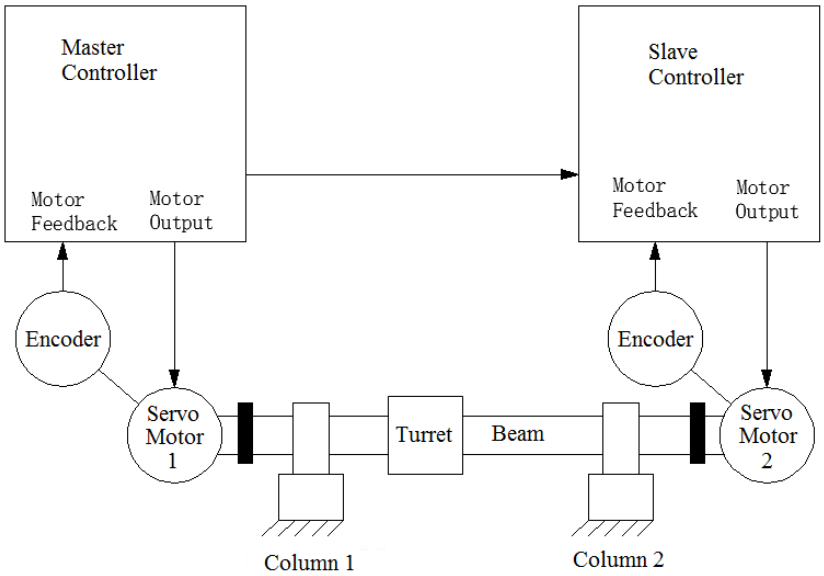

Fig. 1 Mobile gantry milling machine driven by a double servo motor

Master-Slave Servo Control

In the Synchronous Servo System of the mobile gantry milling machine, two servo subsystems move according to the same speed for a given signal. One of the servo systems is defined as the driving shaft which is called as master [2]. And the other is defined as driven shaft which is called as slave. So that a separate master-slave drive is constituted.

Among the master-slave control structure, only the master motor adopts the position control and the speed command signal of the slave motor is from the output of the position controller of the master motor. When the master is interference by the external signal, the position feedback changes, and the slave motor reference speed also changes just like the master motor. So that it will improve safety factor of the control system's coupling structure. The synchronous control system structure diagram is shown in Fig. 2.

In Fig. 2, P2 is the position feed-forward controller and P1 is the position proportional controller. Fuzzy PID controller is the speed controller in order to achieve the fast and accurate response to the input signal. PI controller is the force compensation of the dynamic deformation. Using PI controller too large synchronization error of the biaxial can be avoided among the high-speed operation.

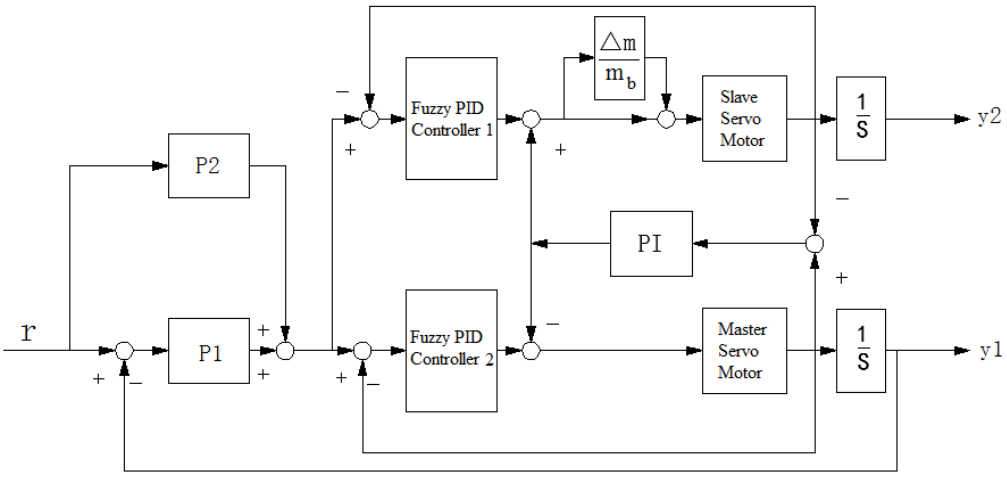

Fig. 2 Synchronous control system structure diagram

The purpose of the synchronous control system is to correct any angular error of the columns. Two drives are used in a master-slave setup. Through torque and speed control of the servo motors, the two columns are synchronized.

When the mobile gantry milling machine achieves the two-dimensional motion control, the turret position change of Y-axis servo motor often leads to the equivalent inertia change of X-axis servo motors. So the extra dynamic load compensation should be adopted, that is the function of $\triangle m/m_b$ shown in Fig. 2.

Adaptive -Neuro Fuzzy Inference System Based On Controller

Adaptive Neuro-Fuzzy Inference Systems are fuzzy Sugeno models put in the framework of adaptive systems to facilitate learning and adaptation. Such framework makes FLC more systematic and less relying on expert knowledge [3]. To present the ANFIS architecture, two-fuzzy rules are based on a first order Sugeno model:

Rule 1: if (x is A1) and (y is B1) then (f1 = p1x + q1y + r1)

Rule 2: if (x is A2) and (y is B2) then (f2 = p2x + q2y + r2)

One possible ANFIS architecture to implement these two rules is shown in Fig. 3. Note that a circle indicates a fixed node whereas a square indicates an adaptive node (the parameters are changed during training). In the following presentation *OLi* denotes the output of node *i* in a layer *L*.

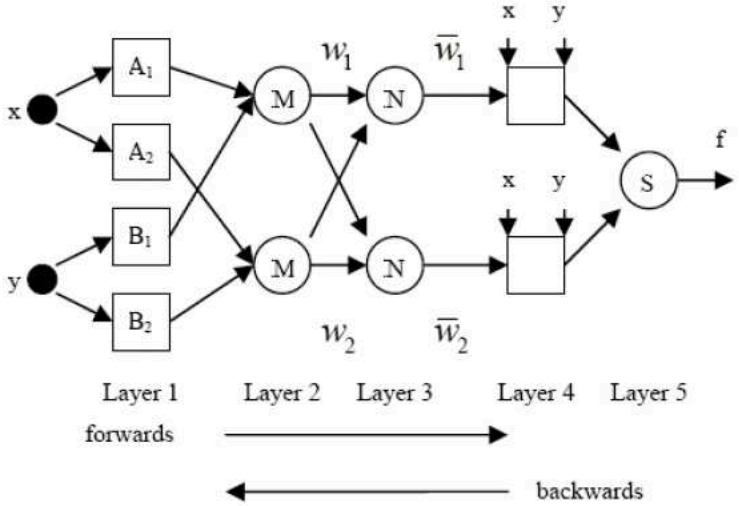

Fig. 3ANFIS architecture

ANFIS algorithm is composed of fuzzy logic and neural networks with 5 layers [4]. Properties of layer described for x, y as an input variables. The ANFIS architecture is not unique. Some layers can be combined and still produce the same output.

The following formulas are listed from layer 1 to layer 5.

$$O_{1,i} = \mu_{Ai}(x) = \frac{1}{1+\left[\left(\frac{x-c_i}{a_i}\right)^2\right]^{b_i}}$$

$$O_{2,i} = \omega_i = \mu_{Ai}(x).\mu_{Bi}(y)$$

$$O_{3,i} = \overline{\omega}_i = \frac{\omega_i}{\omega_1 + \omega_2}$$

$$O_{4,i} = \overline{\omega}_i f_i = \overline{\omega}_i (p_i x + q_i y + r_i)$$

$$O_{i,5} = f = \sum_i \overline{\omega}_i f_i = \frac{\sum_i \omega_i f_i}{\sum_i \omega_i}$$

In this ANFIS architecture, there are two adaptive layers[4]. Layer 1 has three modifiable parameters (*ai*, *bi* and *ci*) pertaining to the input MFs. These parameters are called premise parameters. Layer 4 has also three modifiable parameters (*pi*,*qi* and *ri*) pertaining to the first order polynomial. These parameters are called consequent parameters.

Fig. 4 shows the curves of the slave motor using ANFIS controller about the current-time response under the 300 Nm load and 50 radian/s reference velocity. As for the master motor, the response is same.

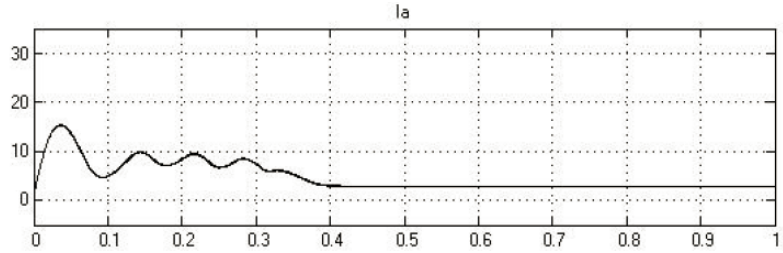

Fig. 4 ANFIS controller current-time response

Conclusion

Based on the analysis of the main reasons among the mobile gantry milling machine where the dual X-axis servo motor drives are not synchronized, the dynamic load compensation the adaptive-neuro fuzzy PID control are proposed. From the simulation curve it can be seen that the accuracy of double motor synchronization can be achieved.

Keywords: Sub-synchronous oscillation(SSO), HVDC, Damping characteristic, Digital time-domain simulation

Abstract. Sub-synchronous oscillation (SSO) caused by highly non-linear HVDC devices can lead to shaft failure and electrical instability of a turbo-generator at oscillation frequency lower than power grid frequency. With increasing HVDC installed in power systems, analysis of SSO becomes a great concern of electrical engineers. In this paper, the reason and process of the SSO are presented by analyzing equations of the mass-springs model. Research methods of SSO are reviewed in HVDC system. And advantages of digital time-domain simulation are demonstrated through combining with algorithm of Prony.

Introduction

High voltage direct current(HVDC) is an application of power electronics technology in the field of power system. HVDC system consists of three parts which are rectifier station, DC transmission line and inverter station. The structure of HVDC system is essentially an AC-DC-AC current conversion system. The typical HVDC system, bipolar HVDC transmission system, is shown in Fig. 1.

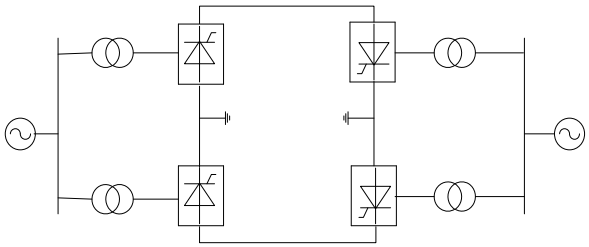

Fig. 1 The diagram of bipolar HVDC transmission system

The HVDC system has significant advantages in long-distance, large-capacity, underground and submarine cable transmission. It also plays an important role when two non synchronous systems are connected. However, because of the fast power control, HVDC system may cause the interaction between turbo-generator shaft and hybrid AC-DC system, and even sub-synchronous oscillation(SSO)[1,2,3] . Traditional AC system uses series capacitor compensation to improve the performance of stability and transmission capacity. The line inductance and compensation capacitor constitute a resonant circuit with a LC resonant frequency. And generator shaft has a natural torsional frequency. System suffers turbulence when two frequencies are complementary or approximately. There will be large-scale power exchange with frequency lower than grid frequency. This power oscillation, between the generator and power transmission system, will cause the generator shaft damage, named sub-synchronous resonance (SSR). Compared to AC system, the oscillation of AC-DC-AC system is due to the application of convertor station. Therefore, oscillation in HVDC system is called SSO instead of SSR[4].

Researches on SSO mainly focus on two aspects below now. Some papers is committed to novel methods to gain more accurate mechanical and electrical damping characteristics of SSO. In [5], author applies time-varying dynamic vector method to analyze the SSO of HVDC system, giving the relationship between characteristic value of HVDC system and parameters' variety of control system.

Another literatures work on inhibitory methods of SSO. In [6], thyristor controlled series compensation (TCSC) is added to the traditional supplementary excitation damping controller(SEDC) to restrain SSO. And the parameters of suppressors are designed newly. The rest of this paper is arranged as follows. Next section mainly describes the mechanism of SSO in HVDC. Then two detailed methods solving problems of SSO are illustrated. Finally, The concluding remarks are given.

Mechanism of SSO in HVDC System

Oscillation Problems in Power System. Power system has two types of oscillation problems, the SSO and low-frequency oscillation (LFO). SSO is caused by the electromechanical coupling interaction. LFO is a continuous low-frequency power oscillation owing to small disturbance and insufficient damping between generator rotor and transmission system. This paper mainly studies the SSO caused by HVDC.

Torsional Vibration of Shaft System of Large-Capacity Generator. SSO is a complex oscillation owing to the electromechanical coupling effect between shafting mass-springs system(Fig. 2) and hybrid AC-DC power system. To transmit higher power at longer distance, the large-capacity turbo-generators' shafts have unique characteristics. With increasing capacity of single turbo-generator and corresponding increase in power density, length of the shaft is greatly extended. So the shaft's cross-sectional area declines in relatively. Entire shaft can no longer be regarded as a rigid body. It is a mass-springs system with two ends freeing.

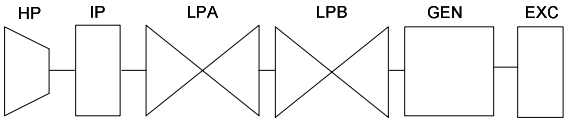

Fig. 2 The model of turbo-generator shafting

The principle of torsional vibration is given below using the model of two-mass-springs shaft. In this model, M_1 and M_2 are time constant of rotatory inertia. ω_1, ω_2 are rotor speed. δ_1, δ_2 are rotor angle. Assumptions are that no mechanical damping and external force when vibrations occurring. And K_{12} is elastic coefficient of model. Normalized value equation of motion is given below.

$$\begin{cases} M_1 \dfrac{\mathrm{d}^2\delta_1}{\mathrm{d}t^2} + K_{12}(\delta_1 - \delta_2) = 0 \\ M_2 \dfrac{\mathrm{d}^2\delta_2}{\mathrm{d}t^2} + K_{12}(\delta_2 - \delta_1) = 0 \end{cases} \tag{1}$$

Linearized form of (1) is given (2).

$$\begin{pmatrix} M_1 p^2 & 0 \\ 0 & M_1 p^2 \end{pmatrix} \begin{pmatrix} \Delta\delta_1 \\ \Delta\delta_2 \end{pmatrix} + \begin{pmatrix} K_{12} & -K_{12} \\ -K_{12} & K_{12} \end{pmatrix} \begin{pmatrix} \Delta\delta_1 \\ \Delta\delta_2 \end{pmatrix} = 0 \tag{2}$$

(3) is characteristic equation of (2).

$$\begin{vmatrix} M_1 p^2 + K_{12} & -K_{12} \\ -K_{12} & M_2 p^2 + K_{12} \end{vmatrix} = 0 \tag{3}$$

Assuming $\lambda = p^2$, (3) can be expressed as (4).

$$(M_1\lambda + K_{12})(M_2\lambda + K_{12}) - K_{12}^2 = 0 \tag{4}$$

The solution of the equation (4) is (5).

$$\begin{cases} \lambda_1 = 0 \\ \lambda_2 = -\dfrac{K_{12}(M_1 + M_2)}{M_1 M_2} \end{cases} \tag{5}$$

P can be obtained in (6) from (5).

$$\begin{cases} p_{1,2} = 0 \\ p_{3,4} = \pm j\sqrt{\dfrac{K}{M}} = \pm j\omega_n \end{cases} \tag{6}$$

In (6), $K=K_{12}$, $M=M_1M_2/(M_1+M_2)$. (6) shows that $P_{3,4}$ is a pair of conjugate complex roots. When subjected to disturbance, shaft may suffer the torsional oscillations at relative frequency ω_n. And the oscillations will decay if there exists damping. Actually each mass-spring have instantaneous velocity at different magnitude and phase. Interaction of two mass-springs results in rotating torque along the direction of rotation. The rotating torque is the reason for fatigue accumulation of shaft. Crack or even shaft fracture will appear for a long time.

Process of SSO in HVDC System. Electrical disturbances of generator and mechanical disturbances of turbine, as the incentives, can cause torsional vibration of shaft system. Torsional vibration may results in fluctuations of AC voltage. Commutation voltage and phase will change because of the fluctuations. Then the normal operating point, voltage, current, power of DC and trigger angle, will deviate.

HVDC system will try to eliminate the deviation by closed loop control. This will affect the output of DC power. The balance is broken down between electromagnetic torque and shaft. And perturbation is occurring. When the error of phase is greater than 90° between speed changes of generator($\Delta\omega$) and electromagnetic torque perturbation(ΔT_e), it will lead to negative damping. Once the negative damping is stronger than the mechanical positive damping, the shaft of generator will occur torsional vibration. Power transmission with a constant current(or constant power) control is independent of the AC system frequency. So HVDC system has not damping effect on frequency oscillation. When the following negative factors occur simultaneously, it is possible to produce SSO. These negative factors, including:

1) The distance is very near between turbine and rectifier station of HVDC.
2) The steam turbine and the AC network is a weak link.
3) The rated power of turbine and transmission are in the same order of magnitude.

The mechanism of SSO in HVDC system is shown in Fig. 3.

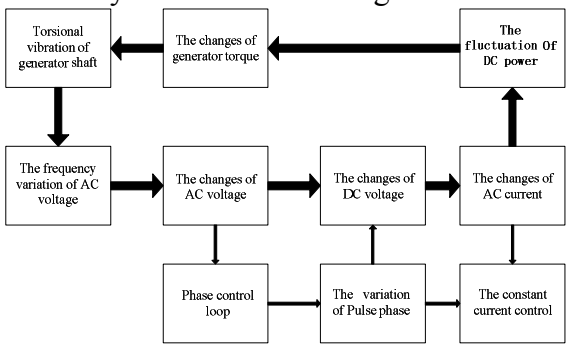

Fig. 3 The mechanism of SSO in HVDC system

Analysis methods of SSO

Traditional analysis methods of SSO are based on the linear system model, including: analysis of characteristic roots method, sweep frequency and equivalent impedance method, Sweep and complex torque coefficient method, sweep and multivariate Nyquist criterion method. When nonlinear and coupled characters of devices considered, the SSO analysis method will be different.

To solve this problem, an essential method is that establishing HVDC system mathematical model considering the nonlinear and coupling characters. In [7], two models are established by Dong-Joon Kim, a static mathematical model for studying of HVDC power flow, and a dynamic mathematical model for analysis of characteristic roots in SSO problem. Establishing mathematical model is strict, accurate and logical. But model is complicated. And according to the different emphasis of the research, simplifications and assumptions must be done. It may influence the accuracy of the this method. So method based on digital time-domain simulation is an another effective choice in the case where the exact expressions are not needed.

Digital time-domain simulation solves differential equations which describe the state of the system essentially. Since the method based on a rigorous mathematical deduction, there is no restriction on

the parameters of the model. Thus, the shaft of the generator can expressed by mass-springs model with finer division of the distribution parameters. So a more detailed description of the generator, control method, switching operation and fault conditions can be given. Because the SSO issues involving electromagnetic and electromechanical transient process, time-domain electromagnetic transient simulation model should be adopted. Fig. 4 shows the waveform of electromagnetic torque variation of generator appearing in SSO by PSCAD / EMTDC.

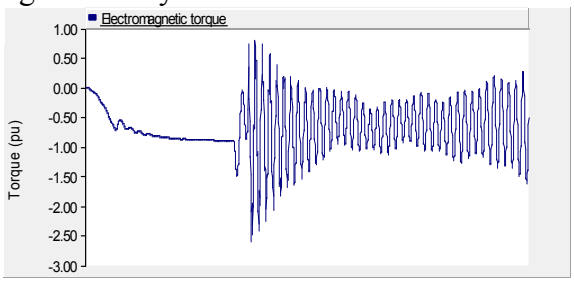

Fig. 4 The wave of electromagnetic torque in SSO

From the simulation, failure results in SSO at 1s. Electromagnetic torque of turbo-generator, suddenly oscillates viciously from the stable value. The simulation waveform is analyzed by algorithms of Prony or TLS-ESPRIT in method of digital time-domain simulation.

In 1957, Prony put forward a mathematical model based on a set of complex exponential functions to describe the equidistant sampling data combinations. This is named algorithms of Prony later. Prony algorithm can be applied directly in analysis of equidistant sampling data to estimate the signal frequency, initial phase and a series of informations. The analysis of simulation data based on Prony algorithm avoids the inaccuracy of linear model and complicacy of nonlinear model. And the sampling period is 1s. The sampling interval is 2ms. The results of Prony algorithm in Fig.4 are that the oscillation frequency 21.170Hz and damping ratio 5.870. The detailed calculations and steps refer to [8]. Although digital time-domain simulation method cannot directly obtain the influence of the parameters and the control methods, important parameters concerned in SSO analysis, such as oscillation frequency, damping ratio and the characteristic values, can be obtained by algorithm of Prony or TLS-ESPRIT.

Summary

In the HVDC connected hybrid AC-DC parallel system, the generator is especially vulnerable to SSO owing to large-scale applications of nonlinear devices. The SSO occurs for two main reasons below. One is that the shaft model of large-capacity steam turbine generator is different from the traditional rigid shaft system, putting up the characteristics of mass-springs system. The another main reason is the negative damping characteristics of generator because of fast power control relying on the nonlinear converter devices. The research methods of SSO in HVDC system, is different from the one of traditional AC transmission system owing to its nonlinearity, coupling. The digital simulation method is an effective, intuitive and simple one.

Keywords: permanent magnet synchronous machine, field oriented control, Hall effect sensor.

Abstract. Field oriented control (FOC) of permanent magnet synchronous machine (PMSM) is of very importance in electrical vehicle (EV) applications due to low acoustic noise and smooth operation. Nowadays the resolver is most widely used to predict the PMSM rotor position. However, with cost consideration this paper proposes a FOC of PMSM based on Hall effect sensor, , which is very useful in practical applications because of low price and high reliability. Since the Hall effect sensor is an absolute position sensor with 60-degree resolution, the position initialization process is not needed and the reversal rotation risk can be avoided. To improve resolution the interpolation method implemented by software is employed. And the high performance of this proposed method is validated by some experimental results.

Introduction

In electric vehicle (EV) applications permanent magnet synchronous machine (PMSM) is widely used according to some advantages, such as simple structure, high power factor, high efficiency, good dynamics, relative small size, low acoustic noise, and easy maintenance. These high performance of PMSM can be performed by means of field oriented control that requires information of rotor position. Therefore, the position sensor is used to obtain the absolute rotor position information to exactly control the motor torque. Generally a resolver is widely used in EV applications. These sensors increase not only the machine size but also the cost of drive [1,2].

To solve these problems many authors proposed sensorless control algorithms using different control methods that are mainly divided into two groups: 1) control strategies based on the voltage equation of machine and 2) control strategies based on signal injection techniques [3]. Control strategies based on the voltage equation can be only applied into the medium and high-speed operation due to the concern with the magnitude of back-EMF. Control strategies based on signal injection have no lower limitation. However, it is difficult to apply the control strategies to practice easily due to machine parameters sensitivity or complex calculations. So far most results in sensorless control method have remained at the theoretical level or still in the laboratory.

This paper proposes a FOC of PMSM based on Hall effect sensor with software interpolation, which can be considered as an intermediate stage of development between the general incremental encoder based and sensorless based PMSM control methods. The hardware of this proposed method is exactly same as that of general brushless DC (BLDC) machine. In comparison with the general incremental encoder and resolver the price of Hall effect sensor is very low and can be neglected. The size of Hall effect sensor is also rather smaller. Moreover, this proposed Hall effect sensor based PMSM is of high reliability without the reversal rotation risk and can easily be implemented in practical applications.

FOC of PMSM Based on Hall Effect Sensor

A permanent magnet brushless machine generally consists of a wound stator, a permanent magnet rotor assembly, and an internal or external device to sense rotor position. The sensing device provides logic signals for electronically switching the stator windings in the proper sequence to maintain

rotation of the magnet assembly. Two configurations of permanent magnet brushless machine are usually considered: one is the trapezoidal type; the other is the sinusoidal type. Depending on how the stator is wounded, the back-electromagnetic force (BEMF) will have a different shape. To obtain the maximum performance from each type of permanent magnet brushless machine, an appropriate control strategy has to be implemented. The trapezoidal BEMF motor called BLDC uses a two phases on strategy, whereas the sinusoidal BEMF motor called brushless AC (BLAC) offers its best performances by using three phase on strategy with sinusoidal currents [4]. Usually the BLAC is also called PMSM.

The power circuit of a three-phase voltage source inverter (VSI) with star-connected permanent magnet brushless machine is shown as Fig. 1. Each phase winding is connected to one inverter leg. The dc link voltage V_{dc} can be applied to the phase winding by switching on some semiconductors (S_1 to S_6) of inverter. The amplitude of the voltage applied to phase winding is controlled by the PWM technique.

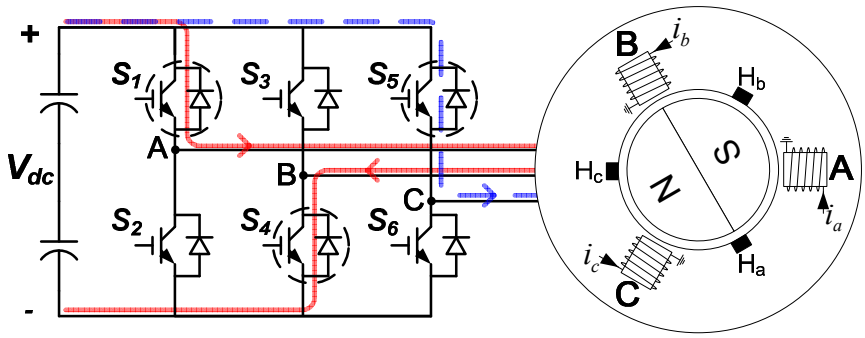

Fig. 1. Three-phase VSI bridge circuit with permanent magnet brushless machine.

BLDC mode operation. As shown in Fig. 1 three Hall effect sensors are embedded into the stator on the position with a 60º phase shift from the phase windings. Whenever the rotor magnetic poles pass near the Hall effect sensors, they give a high or low signal, indicating the N or S pole is passing near the sensors. Therefore, the exact sequence of commutation that is shown as Fig. 2(a) can be determined based on the combination of these three Hall effect sensor signals (H_{cba}). Within 360º, one electrical revolution, the communication sequence is 5, 1, 3, 2, 6, 4 in decimal form. Then the windings are energized following the sequence using a two phases on strategy. In the analysis we assume that the rotor is rotating in a counterclosewise (CCW) direction. The rotor position that is rotating from the starting point 210º to 270º is considered in the first sector 5 because the Hall effect sensor value keeps the value of 5. In this region the stator magnetic field F_{ab} shown in Fig. 2(b) is generated by switching the semiconductors S1 and S4 on shown in Fig. 1. The current will be following from phase-A to phase-B (A to B in the rightmost column in Table 1). The corresponding phase magnetic fields F_a and F_b are generated in the directions of 0º and 300º with same amplitude. Therefore, the resultant magnetic field F_{ab} is in the direction of 330º. Torque is produced because of the interaction between the magnetic field generated by the stator coils and the permanent magnets. Ideally, the peak torque occurs when these two fields are at 90° to each other. The phase difference between the two magnetic fields is between 120º and 60º in which region the generated average toque is largest. In order to keep the motor running, the magnetic field produced by the windings should shift position, as the rotor moves to catch up with the stator field. For example the energized currents should be from phase-A to phase-C in the next communication sequence (sector 1). It means that the resultant stator magnetic field rotates 60º forward in CCS direction. This magnetic field rotation is repeated for the following sequences. What is known as six-step commutation defines the sequence of energizing the windings. The relationship among the Hall effect sensor value, electrical angle, and energized current is shown in Table 2.

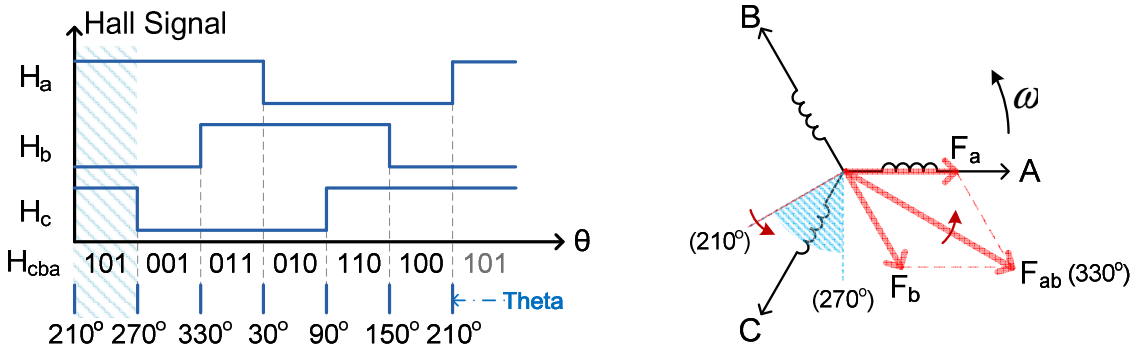

Fig. 2. Hall signals and magnetic field vectors, (a) Hall signal commutation sequence, (b) magnetic field vectors.

Table 1
Six-step commutation of BLDC motor

H_{cba} value		Electrical angle	Electrical	Energized current
binary	decimal	on entering edge	angle section	
101	5	210	210-270	A to B
001	1	270	270-330	A to C
011	3	330	330-30	B to C
010	2	30	30-90	B to A
110	6	90	90-150	C to A
100	4	150	150-210	C to B

PMSM mode operation. From the viewpoint of control there are three main differences between the BLDC mode operation and PMSM mode operation. One is the position refresh time, the second is the control strategy, and the third is the dead-time consideration. The detail comparisons of these three aspects are listed in Table 2. The position information of PMSM requires much more accurate than that of BLDC. The high precision position sensors, such as incremental or absolute encoder, and resolver, are used in PMSM control system. These high precision sensors increase not only the machine size but also the cost of drive. Therefore, to overcome the above drawbacks of the general PMSM in this paper we propose a novel and simple FOC of PMSM based on Hall effect sensor. The hardware of this control system and the positions of Hall effect sensors mounted on PMSM, together with the Hall signals, are exactly same as those of BLDC machine shown as Fig. 1. Because the values of the absolute positions, 210º, 270º, 330º, 30º, 90º, and 150º, obtained by Hall effect sensors shown as Fig. 2(a) are always correct. How the positions between these every 60º can be obtained is the key to the solution of achieving the FOC of PMSM.

To obtain the position information, the interpolated signals are software generated by digital signal processor (DSP) every period of PWM. Fig. 3 illustrates Hall signals together with software interpolation and corresponding predicted rotor positions. The time interval of two adjacent interpolated signals is the PWM period T_{PWM}. Therefore, the total number of the interpolated signals in every sector represents the 60 electrical degrees. In the next sector this total number is considered as a reference of 60º. The count number in the next sector will be used to compare with the 60º reference to predict the present position of the rotor. Then the FOC of PMSM can be executed. Corresponding to the rotor position of PMSM in Fig. 1 the semiconductors S1, S4, and S5 are switched on, and the stator magnetic field F_{abc} generated by three phases energizing windings shown in Fig. 4 is in the direction of 300º which is perpendicular to rotor permanent magnet.

The number of the interpolated signals is different in every 60 electrical degrees under different speed. Although the error of estimated rotor position based on the interpolated signals may exist, especially in the transient process, it can be corrected on every rising or falling edge of Hall signals.

Table 2
Main difference between BLDC and PMSM from the viewpoint of control

Difference	BLDC mode operation	PMSM mode operation
Position refresh	Every 60-degree	Every PWM interrupt
Control strategy	Two phase on	Three phase on
Dead-time consideration	No consideration	consideration

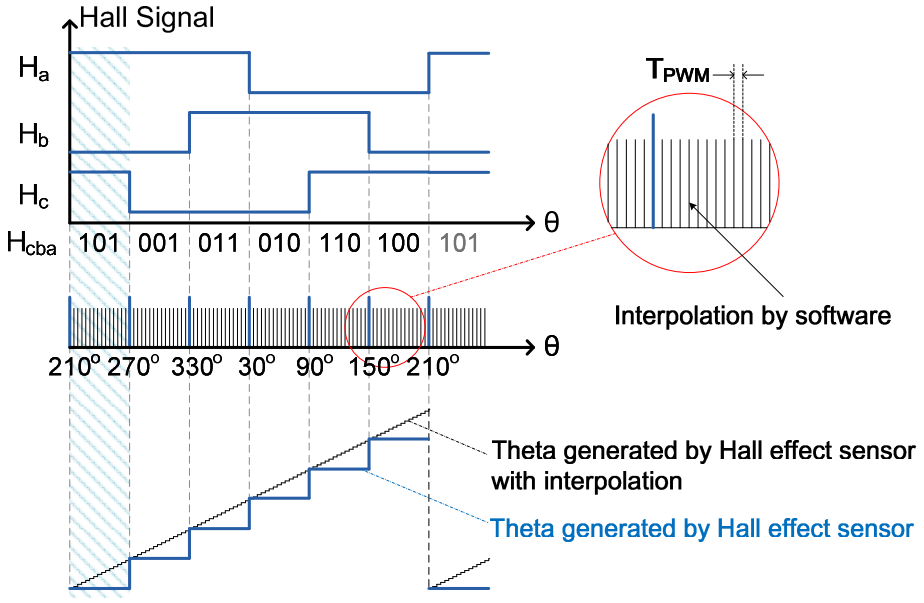

Fig. 3. Hall signals together with software interpolation and corresponding rotor position.

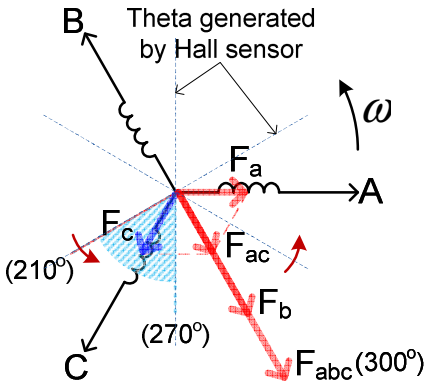

Fig. 4. Magnetic field vectors in PMSM.

Experimental Results. To validate this proposed method, we construct the control system of PMSM illustrated as Fig. 5. The proposed FOC of PMSM based on Hall effect sensor is implemented, together with the dead-time compensation [5]. The experimental results of the rotor position and phase-A current waveforms of PMSM are shown in Fig. 6.

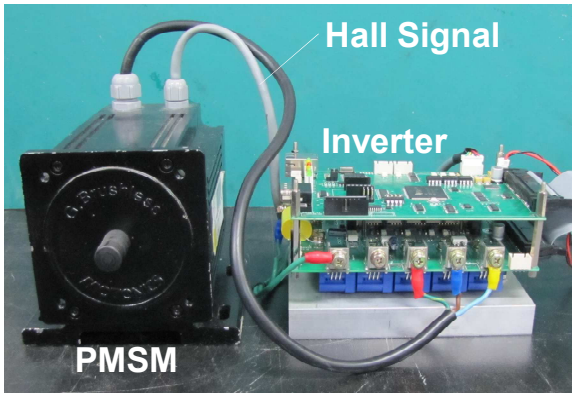

Fig. 5. Detent forces of two different winding types of PMLSMs.

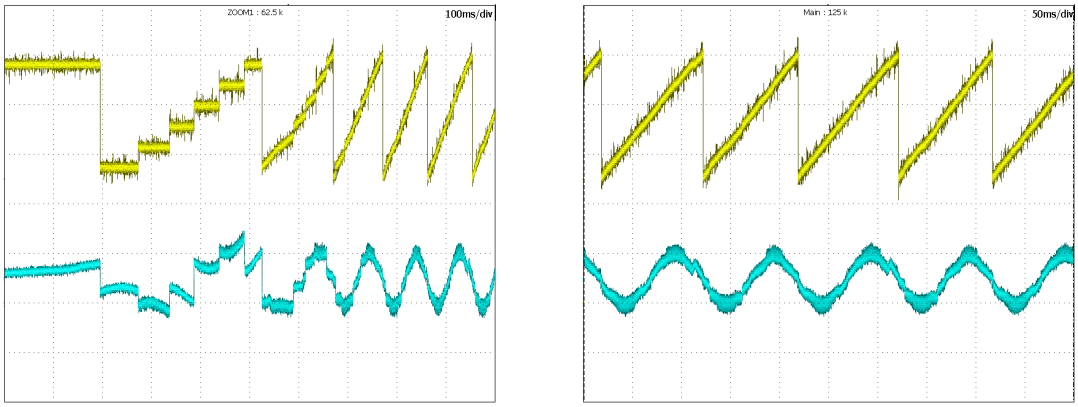

(a) (b)

Fig. 6. Rotor position and phase-A current waveforms, (a) starting waveforms of PMSM with Hall effect sensor with/without interpolation, (b) steady-state waveforms of PMSM with interpolated Hall effect sensor.

The start procedure waveforms are illustrated as Fig. 6(a). During the first electrical revolution the rotor position of which the resolution is 60 electrical degrees is only generated by Hall effect sensor. The current waveform is also changing every 60 electrical degrees interval. From the next revolution the rotor position is generated by Hall effect sensor with interpolation. In the second and third revolutions the predicted rotor position contains a large position error as the rotor speed is increasing in the transient-state. And these predicted position errors can be corrected on every rising or falling edge of Hall signals. In these two revolutions the phase-A current is also distorted because of the predicted rotor position errors. The steady-state waveforms are shown as Fig. 6(b). It also contains some rotor position errors that are caused by the position precision of the mounted Hall effect sensors. The higher the position precision of mounted Hall effect sensor is, the more sinusoidal the current is.

Conclusion

The proposed method of FOC of PMSM based on Hall effect sensor is very useful in practice. The estimated rotor position is predicted by using the interpolated signals which are generated by software every period of PWM. The hardware is exactly same as that of BLDC. In comparison with general sensor based PMSM system the cost is much lower. Moreover, this method can be extended to the position sensorless control of PMSM because the 60-degree information can be very easily obtained according to the back EMF waveforms. Compared with general position sensorless control method the advantage of this one is that the algorithm is more simple and easily implemented.

Keywords: LLC; Topological Group; Resonant converter

Abstract. LLC resonant converter can adjust the output for a wide range of source and load with a small fluctuation of switching frequency, so it is used widely. This paper introduces all arrangements of LLC topological group, then proposes a new topology which is consist of Type-4 and Type-11 that used widely，in this paper we also give its calculate method of resonant frequency. Lastly we get gain characteristics of the topologies in the PSpice simulation environment and analyse the influence factors on adjustment ability in certain load range .

Introduction

The series resonant converter (SRC) and the parallel resonant converter (PRC) which have two resonator components have been studied thoroughly [1]. The structures of SRC and PRC are simple, but their defects limit their industry developing. For improve the performance of resonant converter, Rudy Severns gived exhaustive topological groups of three resonator components according to their arrangements [2]. The topological groups include 18 kinds of LLC topologies. Type-4 [3], Type-10, Type-11, Type-13 and Type-17[4,5] have been studied, but no detailed analysis have been published yet. This paper give the 18 kinds of LLC topologies, and analyses three kinds of quasi-isometric topologies which are consist of Type-4 and Type-11, then give their calculate method of resonant frequency and gain characteristics.

LLC Resonant Topological Group

Fig. 1 is the exhaustive topological group of LLC resonant:

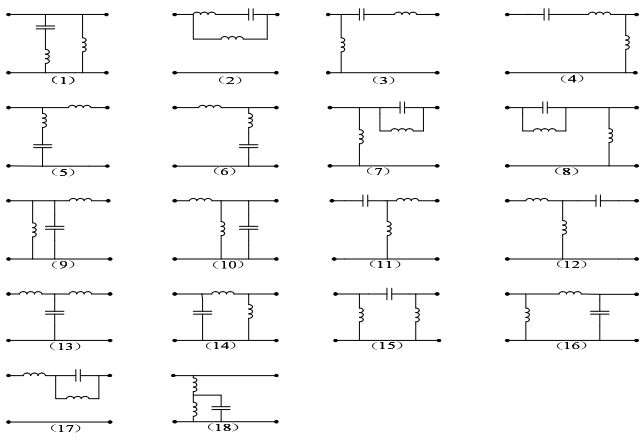

Fig. 1 LLC resonant topological group

Topological isomorphism in power electrics is the topologies have same mapping graph node, in the actual circuit is the circuits have same kind and quantity of components with same electrical properties. In Fig.1 each topology has different characteristics, but their common points is the additional resonator component would not destruct the characteristics of SRC or PRC while it is only used to improve them, so it can be treat as isomorphism or quasi- isomorphism.

Type-4 and Type-11 in The Bi-directional LLC Resonant Converter

Take full bridge topologies for instance as Fig.2

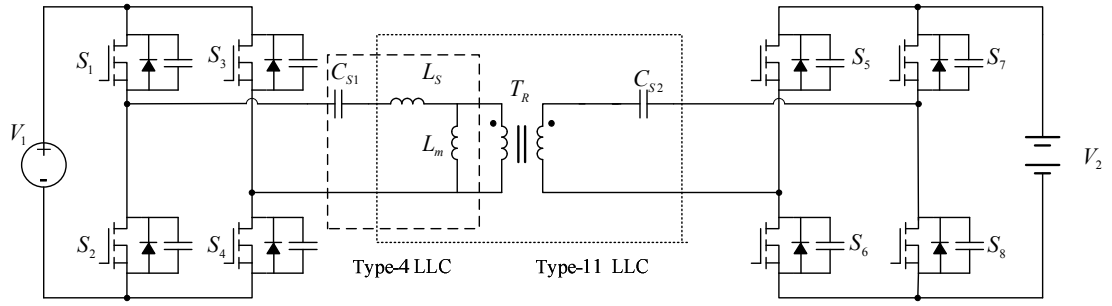

Fig. 2 Type-4 and Type-11 LLC Bi-directional resonant topology

In the forward direction mode the resonant circuit can be treat as Type-4 resonant circuit, and in the backward direction mode the resonant circuit can be treat as Type-11 resonant circuit. In order to analyse the characteristics of the two directions mode, we can use their AC equivalent circuits as the forward direction mode shown in Fig.3 and the backward direction mode shown in Fig.4.

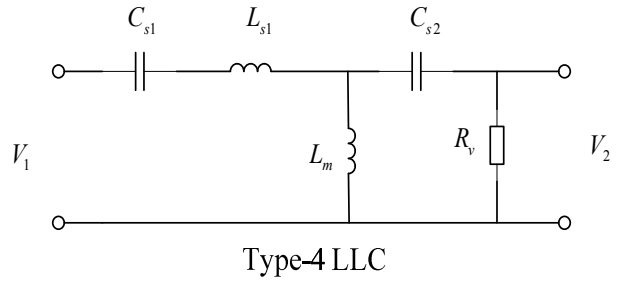

Fig. 3 Forward direction mode

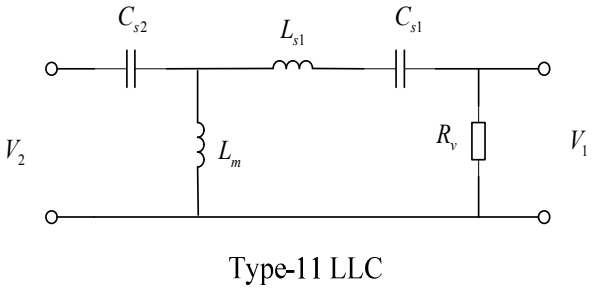

Fig. 4 Backward direction mode

In order to calculate the resonant frequency of heavy load in forward direction, it should meet

$$\begin{cases} -j\dfrac{1}{\omega C_{S1}} + j\omega L_{S1} + \dfrac{j\omega L_m \cdot \left(-j\dfrac{1}{\omega C_{S2}}\right)}{j\omega L_m - j\dfrac{1}{\omega C_{S2}}} = 0 \\ f_1 = \dfrac{\omega}{2\pi} \end{cases} \tag{1}$$

The second resonant frequency can be calculated by simplified Eq.1 as shown in Eq.2

$$\begin{cases} \omega^4 \cdot \left(C_{S1}C_{S2}L_m L_{S1}\right) - \omega^2\left(L_{S1}C_{S1} + L_m C_{S1} + L_m C_{S2}\right) + 1 = 0 \\ f_1 = \dfrac{\omega}{2\pi} \end{cases} \tag{2}$$

The first resonant frequency in light load mode is equal to Type-4 as shown in Eq.3

$$f_2 = \frac{1}{2\pi\sqrt{\left(L_{S1} + L_m\right)C_{S1}}} \tag{3}$$

In order to calculate the resonant frequency of heavy load in backward direction, it should meet

$$\begin{cases} -j\dfrac{1}{\omega C_{S2}} + \dfrac{j\omega L_m \cdot \left(j\omega L_{S1} - j\dfrac{1}{\omega C_{S1}}\right)}{j\omega L_m + j\omega L_{S1} - j\dfrac{1}{\omega C_{S1}}} = 0 \\ f_1 = \dfrac{\omega}{2\pi} \end{cases} \tag{4}$$

The second resonant frequency can be calculated by simplified Eq.4 as shown in Eq.5

$$\begin{cases} \omega^4 \cdot \left(C_{S1}C_{S2}L_m L_{S1}\right) - \omega^2\left(L_{S1}C_{S1} + L_m C_{S1} + L_m C_{S2}\right) + 1 = 0 \\ f_1 = \dfrac{\omega}{2\pi} \end{cases} \tag{5}$$

The first resonant frequency is

$$f_2 = \frac{1}{2\pi\sqrt{L_m C_{S2}}} \tag{6}$$

Analyse Eq.2 and Eq.5 we can know the resonant frequency in heavy load mode of this topology is equal, so the topology can realize bi-direction work in the same frequency.

Simulation Analysis of Gain characteristics

Analyse the fundamental-wave gain characteristics of the topology in the PSpice simulation environment and design parameter as following

The input voltage is 200V-400V, output voltage is 200-400V, output current is 0-20A, $L_S = 30uH$, $L_m = 130uH$, $C_{S1} = 200nF$, $C_{S2} = 200nF$, $n = 1$,and using the method of calculation we build can get the second resonant frequency is 64.926KHz, then normalize them.

The gain characteristics of the topology are shown in Fig.5, Fig.6.

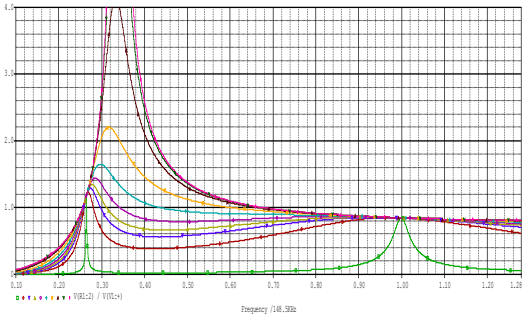

Fig. 5 Gain Characteristic of Type-4 and Type-11 Mixed Bi-direction LLC Resonant Converter in Forward Direction Mode

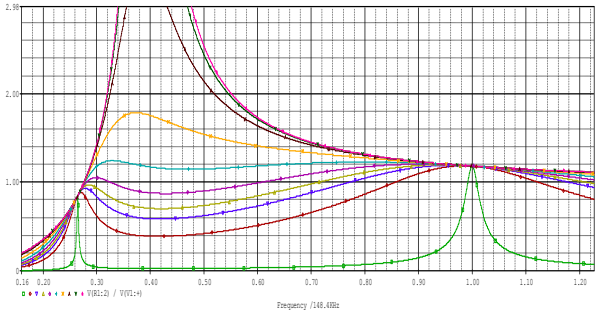

Fig. 6 Gain Characteristic of Type-4 and Type-11 Mixed Bi-direction LLC Resonant Converter in Backward Direction Mode

We know via the simulation analysis that the gain value of Type-4 and Type-11 mixed bi-direction LLC resonant converter in forward direction mode is less than 1, the gain value of Type-4 and Type-11 mixed bi-direction LLC resonant converter in backward direction mode is much more than 1, but it adjustment range of load is small, because the secondary capacitor participates in the resonance, then make frequency sweep of the secondary capacitor to learn its influence in Fig.7,and Fig.8

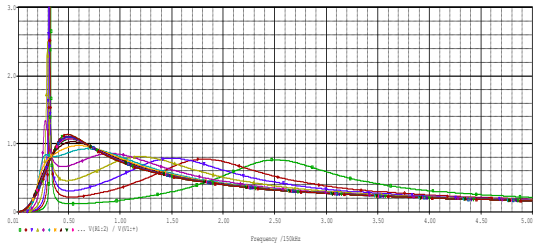

Fig. 7 Gain Characteristic of Type-4 and Type-11 Mixed Bi-direction LLC Resonant Converter in Forward Direction Mode By frequency sweep of the secondary capacitor

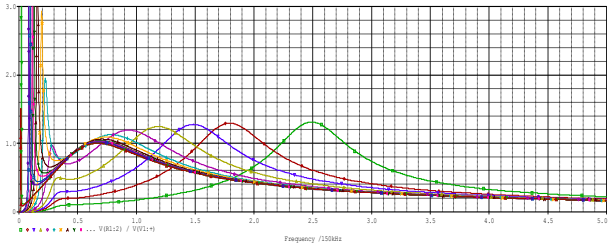

Fig. 8 Gain Characteristic of Type-4 and Type-11 Mixed Bi-direction LLC Resonant Converter in Backward Direction Mode By frequency sweep of the secondary capacitor

We can know the gain is in inverse proportion to the secondary capacitance, and the resonant point move to right with the reducing of the secondary capacitance. So the secondary capacitance value should be large in order to make the circuit meet the requirements of large load range.

Conclusions

LLC resonant converter can adjust the output for a wide range of source and load with a small fluctuation of switching frequency, so it is used widely. In this paper we talk about the theory of LLC resonant groups and exhaustively give the arrangements of LLC topological groups, then propose a new topology which is consist of Type-4 and Type-11 that used widely and build its mathematic models. Finally we prove its correctness and get gain characteristics of the topologies in the PSpice simulation environment, prove the adjustment ability of Type-4 and Type-11 mixed bi-direction LLC resonant converter has a good gain characteristic but can be effected by the secondary capacitance.

Keywords: HTS reactor, conceptual design, harmonics analysis, FEM

Abstract. Since Ultra High Voltage (UHV) transmission lines have the high charging capacitance, continuous reactive power compensation is vital for efficient operation of long transmission power lines or cables. A continuous reactive compensation will reduce the transmission losses and increase the transmission capacity of active power. In order to achieve the continuous reactive power compensation, we choose the magnetic saturable type reactor. The principle of a magnetic saturable reactor requires a high current ampere-turn coil as its dc bias, and this coil is necessary to use a high temperature superconducting (HTS) winding. As the first stage of the study, we have constructed a 220V small-scale prototype which the dc bias is made of copper coil instead of the HTS coil. The copper coil of the dc bias in small-scale reactor has the same ampere-turn with a 220V HTS controllable reactor (HCR), so its performance keeps the same except the HTS part. Based on this, we made a conceptual design for a 35kV/5Mvar HCR. The output property and harmonic property have been studied by simulation and experiment. The results prove that it can obtain a continuous controllable reactive power output.

1. Introduction

With the development of modern industry, the stability of power system and improvement of power quality are becoming more and more important. The control of the reactive power is a crucial subject to hit the mark for a transmission network, especially for excessively-high voltage long-distance transmission lines. To meet such demand, many kinds of devices are developed, such as, synchronous condensers, conventional shunting reactors, static var compensators and controllable reactors. Each of them has their own advantages and disadvantages. There are some types of controllable reactors available: the thyristor controlled reactor [1,2], the transformer type controlled reactor [3] and the magnetic saturable reactor [4-8]. Our research concentrates upon the magnetic saturable reactor. The reactor studied in this paper combined the superconducting technology with the magnetic saturation technology. It can automatically and smoothly adjust its inductance. It can provide a continuous reactive power compensation to suppress system over voltage, reduce the transmission losses and increase the transmission capacity of active power. However it requires a high current ampere-turn coil as its dc bias, and this coil is necessary to use a HTS winding.

In this paper, a series of experiments of a 220V small-scale prototype are conducted to validate the design and simulation results. A conceptual design of 35kV/5Mvar HTS controllable reactor is presented.

2. Structure and Working principle

The simplified structure of HCR is shown in figure 1. Its working principle is like a saturable type superconducting fault current limiter (SFCL). It is made up of two same racetrack shape iron cores and three windings, including one control winding and two working windings. The two working windings are constructed on the left and right limbs separately and connect in subtractive series so that their magnetic flux is offset by each other in the middle iron core limb. A dc bias winding, made of HTS tapes, is arranged on the middle iron core limb as the control winding.

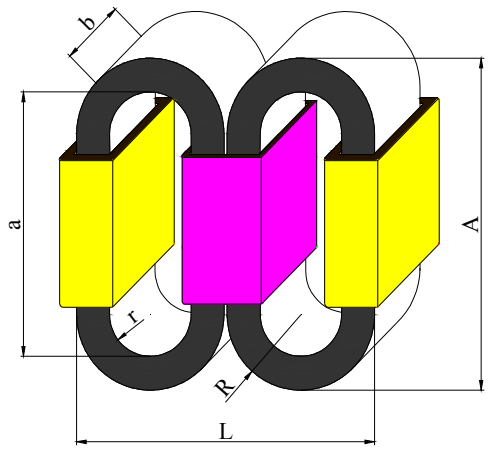

Fig .1 Schematic structure of the HCR

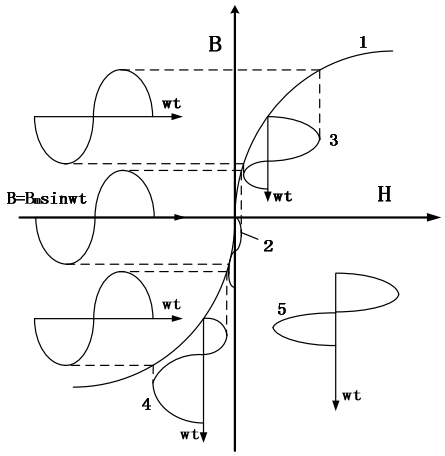

Fig. 2 Principle of the saturation core

As shown in figure 2, the saturation of HCR is changed by the value of the DC component which makes the magnetic flux of the iron core raise or decrease. The working current of HCR is controlled by regulating the DC voltage. Based on this, the capacity of HCR can be smoothly regulated. When the excitation current is 0A, the magnetic field intensity of the HCR is the curve 2. When regulating the DC voltage, the excitation current rise, curve 3 and 4 denote the magnetic field intensity of the HCR's left limb and right limb, respectively. So curve 5 denotes the magnetic field intensity which is the sum of the curve 3 and 4.

3 Simulation Model and Test results of a small-scale single phase HCR

The output current should be accurately simulated in the model, and the fundamental magnetic circuit equation is used to establish the simulation model of HCR. The simulation model is established on the assumption that: (1) the AC and DC voltage source is ideal which means voltage source has no harmonic component; (2) since the racetrack shape iron core has almost no leakage magnetic field, the leakage inductance is negligible.

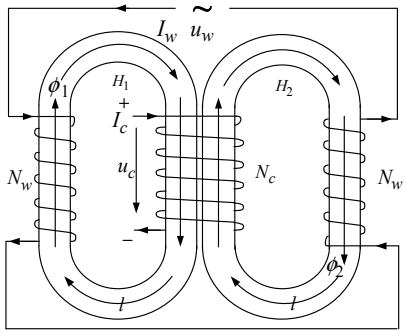

Fig.3 Physical quantities and forward directions in HCR

As shown in figure 3, for a single turn coil, the main magnetic flux Φ_1 and Φ_2 can be determined by

$$\phi_k = B_k \cdot S \quad (k = 1, 2) \tag{1}$$

The DC and AC circuit should meet Kirchhoff's Voltage Law, which has a relation as

$$\begin{cases} u_w = I_w r_w + N_w \, d\phi_1 / dt + N_w \, d\phi_2 / dt \\ u_c = I_c r_c + N_c \, d\phi_1 / dt - N_c \, d\phi_2 / dt \end{cases} \tag{2}$$

Based on Ampere circuital theorem in magnetic circuit, the fundamental magnetic circuit equation can be expressed as below

$$\begin{cases} N_w I_w + N_c I_c = H_1 l \\ N_w I_w - N_c I_c = H_2 l \end{cases} \tag{3}$$

Where N_c is control winding turns and N_w is working winding turns, I_c and I_w are winding current and control current respectively, u_w and u_c are working winding voltage and control winding voltage respectively, Φ_n (n=1,2) is main magnetic flux of winding, r_c and r_w are winding resistance. l is the length of the equivalent magnetic circuit, S is the cross-sectional area of the iron core, B_n (n=1,2) is magnetic flux density, H_n (n=1,2) is magnetic field intensity.

The combination of equations (1)–(2) results in magnetic flux density's equation:

$$\begin{cases} B_1 = \int_0^t 1/2\left(\dfrac{u_w - I_w r_w}{N_w S} + \dfrac{u_c - I_c r_c}{N_c S}\right)dt \\ B_2 = \int_0^t 1/2\left(\dfrac{u_w - I_w r_w}{N_w S} - \dfrac{u_c - I_c r_c}{N_c S}\right)dt \end{cases} \tag{4}$$

From formula (3), we can obtain the HCR's output current i_w,

$$I_w = l/2N_w(H_1 + H_2) \tag{5}$$

Therefore the relationship between magnetic flux density B and magnetic field intensity H can be represented by

$$\begin{cases} H_1 = f(B_1) \\ H_2 = f(B_2) \end{cases} \tag{6}$$

The formula (1)-(6) give the mathematical model of the HCR. The Specifications used in the simulation are shown in Table 1. In the model, if the working voltage U_w and control voltage U_c are given, the output current of the main coil, the magnetic flux density and the magnetic field intensity can be obtained. In this paper, we care about the output current of the main coil.

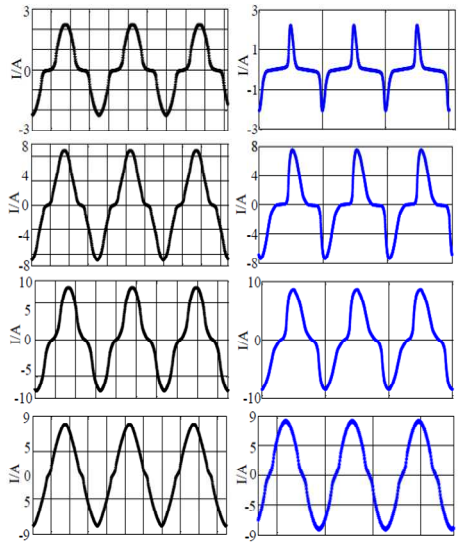

Fig.4 The wave form of I_w, test results (blue solid line) versus simulation results(black solid line), from top to bottom, the excitation currents are 0.5A, 3A, 9A, 18A ,respectively)

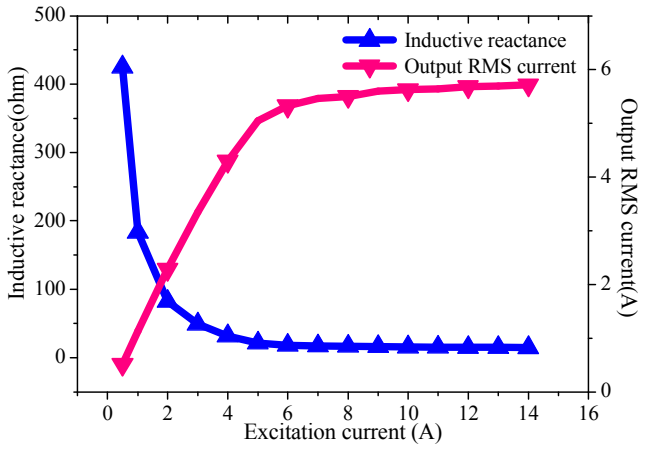

Fig.5 Output inductive reactance and output RMS current as a function of excitation current

Table 1 Specifications of the small-scale prototype used in the simulation

Voltage of working winding u_w	220 [V]
Number of control winding turns N_c	1350
Number of working winding turns N_w	650
resistance of control winding r_c	6 [Ω]
resistance of working winding r_w	0.4 [Ω]
length of the equivalent magnetic circuit l	0.614 [m]
cross-sectional area of the iron core S	0.00378 [m^2]

The working winding is fed by a variable voltage regulator operating at frequency of 50 Hz. The control winding is fed with a direct current source. The DL750 type oscillographic recorder is used to record the working current Iw and voltage uw in the working winding. Figure 4 shows the working current Iw as functions of time when Ic is held constant at 0 A, 3 A, 9 A, and 18A. Figure 5 shows the root mean square (RMS) values of output Iw after filtering harmonic component and the output inductive reactance as a function of control current.

As shown in figure 5, a little current variation will lead to a sharp decline in the inductance of HCR when the excitation current is between 0.5A and 4A. When the excitation current is over 8A, the inductance variation curve becomes flattened, and the core goes gradually into a deep magnetic saturation state.

4 Harmonic analysis of HCR

The induct electric potential in control winding e_c and working winding e_w can be obtained by the equation

$$\begin{cases} \mathrm{e}_w = \mathrm{e}_{w1} + \mathrm{e}_{w2} = SN_w(dB_1/dt + dB_2/dt) \\ \mathrm{e}_c = \mathrm{e}_{c1} - \mathrm{e}_{c2} = SN_c(dB_1/dt - dB_2/dt) \end{cases} \tag{7}$$

Since the two racetrack shape iron cores are axis symmetric and the magnetization curve of iron core is odd symmetric, the magnetic flux density in iron core 1 and 2 has a relation as

$$\begin{cases} B_1(\omega t) = -B_2(\omega t + \pi) \\ B_2(\omega t) = -B_1(\omega t + \pi) \end{cases} \tag{8}$$

In general, the magnetic flux density in iron core is not sinusoidal. Based on Fourier analysis, the magnetic flux density in iron core 1 and 2 can be formulated as

$$B_1(\omega t) = B_\mathrm{d} + B_{1m}\sin(\omega t - \phi_1) + B_{2m}\sin(2\omega t - \phi_2) + \ldots + B_{km}\sin(k\omega t - \phi_k) \quad (k = 1, 2\ldots) \tag{9}$$

$$B_2(\omega t) = -B_\mathrm{d} + B_{1m}\sin(\omega t - \phi_1) - B_{2m}\sin(2\omega t - \phi_2) + \ldots + (-1)^{n+1}B_{km}\sin(k\omega t - \phi_k) \quad (k = 1, 2\ldots) \tag{10}$$

The combination of equations (7) and (9) results in induct electric potential in control winding and working winding

$$e_c = 2B_d + \omega N_c S[4B_{2m}\cos(2\omega t - \phi_2) + \ldots + 4kB_{2km}\cos(2k\omega t - \phi_{2k}) \quad (k = 1, 2\ldots) \tag{11}$$

$$e_w = 2\omega N_w S[B_m\cos(\omega t - \phi_1) + \ldots + (2k+1)B_{2km}\cos[(2k+1)\omega t - \phi_{2k+1}] \quad (k = 1, 2\ldots) \tag{12}$$

Through above analysis, the voltage and current in control winding only have even-order harmonic component, while the output voltage and current in working wording only have odd harmonic component theoretically. In order to verify the validity of the theoretical analysis, we have carried through harmonic analysis of the actual output I_w and the voltage of the main coil.

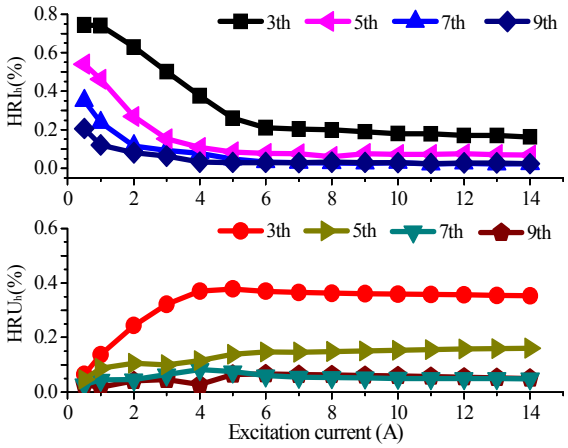

Fig.6 The odd order harmonic ratio of current HRIh and voltage HRUh as a function of excitation current

Figure 6 illustrates that the odd harmonic component of the output current and voltage of the main coil are remarkable, which is a prominent disadvantage of saturable type reactor. So some improvements are needed to decrease the harmonic component. To a three Phase HCR, the 3th

harmonic component is easy to be dispelled by circuit connection, and higher harmonic component can be decreased with a filter. Another way to decrease the harmonic component is to improve the design of the iron, for instance, inserting virtual air gap to the core [9], using the multi-Stage iron et al [10].

5 Design of a 35kV/5Mvar HTS controllable reactor

In this section, the design procedure of the HCR is presented. This procedure consists of determination of core dimensions, determination of winding quantities and dimensions.

The rated voltage U_n and rated output capacity of the single-phase HCR are $35/\sqrt{3}$ kV and 5 Mvar, respectively. The specification of HCR is shown in Table 2.

Table 2 Specification of HCR

Q_n (Mvar)	U_n (kV)	I_n (A)	η(%)	L (H)	X (Ω)
5	$35/\sqrt{3}$	247	50% ~ 100%	0.52~0.26	163.2~81.6

η is the regulating range of the output reactive power; L and X are the variation range of the output inductance and reactance, respectively. According to the design requirement, the core material selects cold-reduced silicon sheet in the thickness of 0.35 mm. The AC main coils use conventional metal copper conductors. The DC control coils use YBCO HTS tapes, which are cooled by liquid nitrogen. The wire type is Amperium 12 made by AMSC. Its critical current at 77 K is 175 A. The thickness and width are 0.2 mm and 12 mm, respectively.

The design procedure of HTS's main parameters is as follow: the core diameter of left/right main coil can be obtained by $D = K_D \sqrt[4]{Q_n} / 2$ .The lamination factor K_D is 0.95. Before calculating the quantities of the main coil W, the magnetic flux density B'_m of the main coil is selected as 1.5T. Then, W can be determined as $W = U / (\sqrt{2}\pi f B'_m A_z)$, where f is frequency of AC current; A_Z is effective cross-sectional area of the core. Details of the core structure are given in Table 3. The parameters of the coil are listed in Table 4.

Table 3 Details of HCR structure

a (mm)	b (mm)	r (mm)	R (mm)	A (mm)	L (mm)
1560	410	260	470	1980	1890

Table 4 Parameters of HCR coils

Quantity	DC coil	AC coil 1	AC coil 2
Inner size (mm×mm)	445×425	225×425	225×425
Outer size (mm×mm)	455×435	297×497	297×497
Height (mm)	600	910	910
Number of turns	1000	244	244

Based on the design specification of the HCR, the inductance variation is numerically solved by Finite Element Method (FEM) analysis. The inductance of the main coil is calculated corresponding to increasing steps of current from 1A to 55A.

From figure 7, it can be seen that a little current variation will lead to a sharp decline in the inductance of HRC when the excitation current is between 1 A and 5 A. When the excitation current is over 6 A, the inductance variation curve becomes flattened, and the core goes gradually into a deep magnetic saturation state. When the excitation current are 7A and 14 A, the corresponding inductance are 0.52 H and 0.26 H, respectively. The magnetic flux density distribution of the core is shown in figure 8.

In the current range of 7 A~14 A, the core center column goes gradually into the magnetic saturation state, and magnetic flux density in the core side yokes also increased gradually. When excitation current is 7 A, the maximum and minimum magnetic flux density are 1.73 T and 1.51 T, respectively. When excitation current is 14 A, the maximum and minimum magnetic flux density are 1.82 T and 1.56 T, respectively. The gap between the maximum and minimum values is not large.

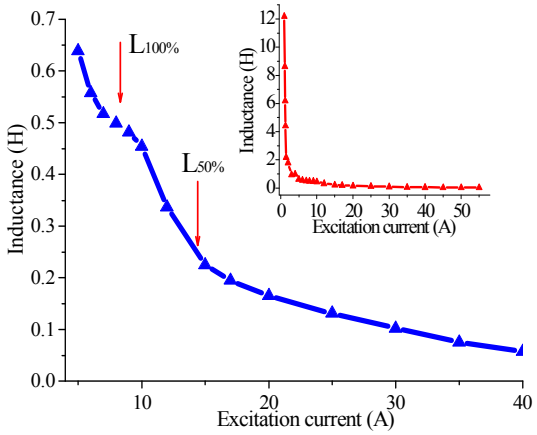

Fig.7. HCR reactor inductance versus DC excitation current

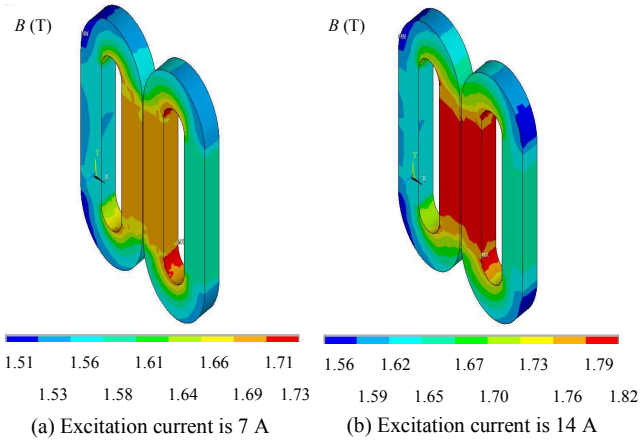

(a) Excitation current is 7 A (b) Excitation current is 14 A

Fig.8. Magnetic flux density distribution of the RC core

6 Summary

A detailed procedure of establishing the small-scale HCR's mathematical model is proposed. Test and simulation results of the small-scale HCR indicate that the reactor can smoothly regulate the output inductive reactance and the range of regulation is large. Beyond that the harmonic component of the HCR needs to be controlled. Then a basic conceptual design of a 35kV/5Mvar has been presented. Based on the design, FEM simulation has been carried out to verify the validity of the design.

A flyback switching power supply based on L6561for LED

Zhu Lei Shao[1, a]

[1] College of Electrical and Information Engineering, Xuchang University, Xuchang 461000, China

[a]cyzyszl2@163.com

Keywords: Single-ended flyback; switching power supply; LED driver.

Abstract. A flyback switching power supply was designed, which can drive LED stability. The switching power supply is the single-ended flyback structure, and based on PWM driver chip L6561. The input voltage range of the switching power supply is 85V to 265V. The output voltage is 15V and the maximum output current is 2A. The switch power supply is suitable for mobile phone, office equipment and LED. According to experiment, the switching power supply can steadily drive 5 LED, the ripple factor of output is 1.33%, the power efficiency is 85.7%.

Introduction

With the development of technology, the switching power supply is playing a more and more important role in the electronic equipments. The switching power supply is often used in special equipments, which provides necessary voltage and current for the normal operation of the circuit. The more complicated the equipment is, the less weight the switching power supply is required. Because the operation of some equipments require stable direct current, the switching power supply must own the ability of transforming current. At the same time, the Switching power supply should own high efficiency for saving energy. Based on the current-mode PWM controller L6561, a new type of single-ended flyback switching power supply is designed.

Working principle of circuit

The switching power supply is the core device of the power electronic equipment, which can output stable voltage and current by feedback control. The switching power supply has some common topologies, such as, forward, flyback, push-pull, half-bridge and full-bridge. The design of switching power supply for LED adopt flyback, it is shown in Fig. 1.

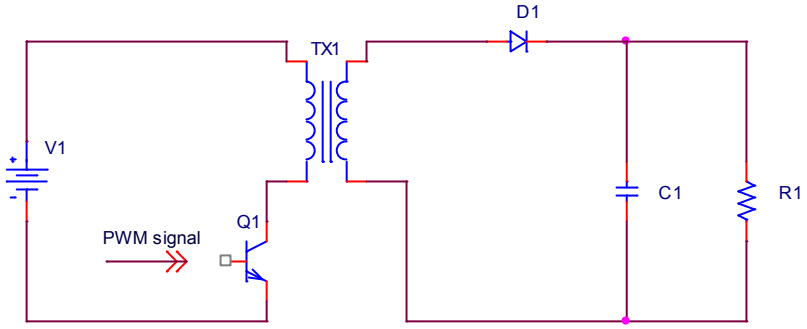

Fig. 1 The schematic of flyback switching power supply

The flyback switching power supply has the characteristics of reverse polarity converter. It has the advantage of fast response and simple structure of compensation circuit. The flyback switching power supply is made up with the power switch Q1， the high-frequency transformer TX1, the rectifier tube D1, the filtering electric C1, the feedback control circuit and PWM drive.

When the power switch Q1 turns on, the primary side of the transformer TX1 begins to store energy, the current of primary side increases gradually, the rectifier tube D1 cut off, the capacitor C1 provides current to the load R1. When the power switch Q1 turns off, the rectifier tube D1 is on, the energy of transformer TX1 charges the capacitor C1, and provides current to the load R1. The formula of output voltage is shown in formula (1).

$$V_o = \frac{N_2}{N_1}\frac{DV1}{1-D} \tag{1}$$

In formula (1), V_o is the output voltage, N_1 is the winding number of primary side, N_2 is the winding number of secondary side, D is duty ratio of PWM signal.

Design of switching power supply

The flyback switching power supply system is composed of the rectifier filter circuit, L6561 drive circuit, the voltage feedback circuit and the current feedback circuit. The function of the system is converting alternating current to steady direct current, and drives the load. L6561 will change the open time of power switch by sampling the output voltage and the current of the primary side of the transformer. L6561 is the core of feedback control circuit, which makes output voltage steady in 15V. The advantages of the design circuit are fast reaction speed, simple control circuit and steady output. The circuit topology of flyback switching power supply is shown in Fig. 2.

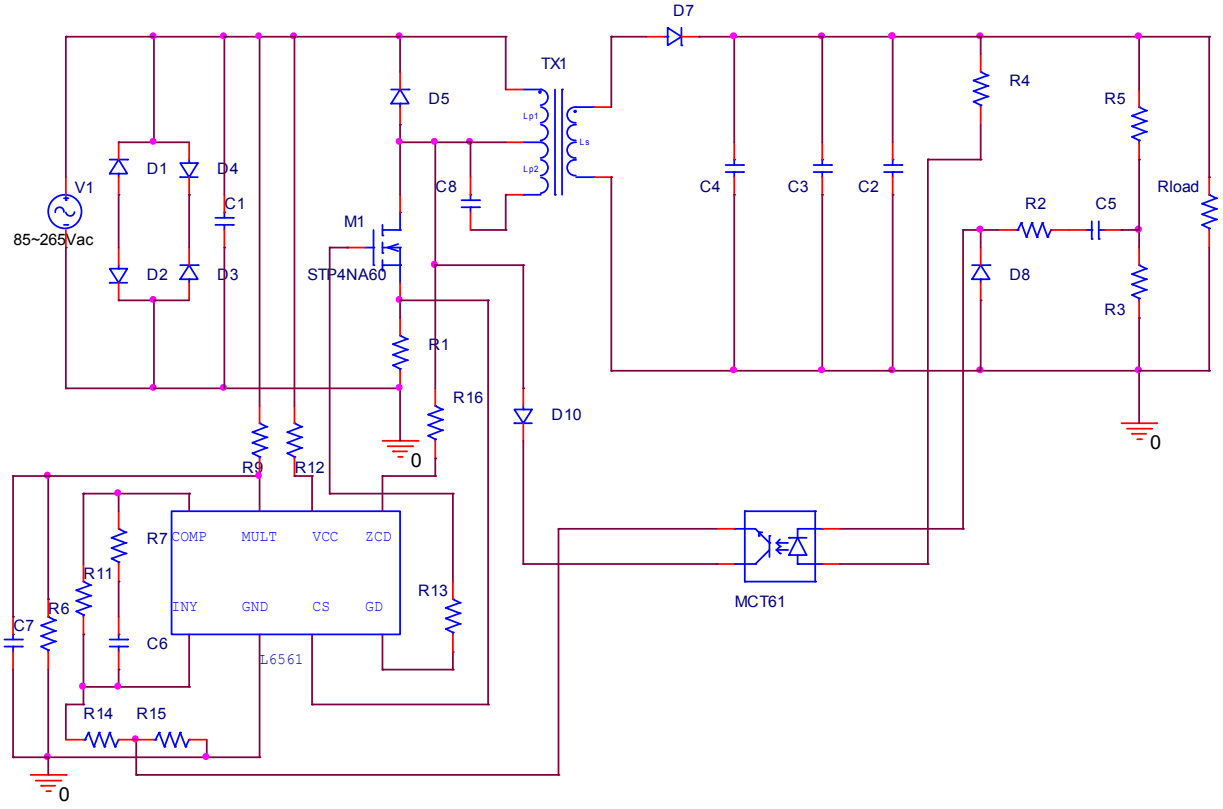

Fig. 2 The circuit topology of flyback switching power supply

TX1 is the transformer of flyback switching power supply, which can store electric energy and separate electric grid. While the output voltage is minimum, the output frequency is the largest. According to faraday law of electromagnetic induction, the formula (2) can be get.

$$\frac{V_{in(\min)} D_{\max}}{L} = \frac{V_{or}(1 - D_{\max})}{L} \tag{2}$$

In the formula (2), V_{or} is refraction voltage of secondary to elementary, L is elementary inductor, $D_{\max}$ is the maximum duty ratio of PWM signal, it can be get in formula (3).

$$D_{\max} = \frac{V_{or}}{V_{or} + V_{in(\min)}} \tag{3}$$

The current of the primary side of the transformer can be get in formula (4).

$$I_p = \frac{2p_{0(\max)}}{V_{in(\min)}\eta D_{\max}} \tag{4}$$

The inductance of primary side of the transformer can be get in formula (5).

$$L_p = \frac{V_{in(\min)}^{\ 2} D_{\max}^{\ 2}}{2P_{in(\max)}} = \frac{V_{in(\min)}^{\ 2} D_{\max}^{\ 2} \eta}{2P_{o(\max)}} \tag{5}$$

The winding number of primary side of the transformer can be get in formula (6).

$$N_p = \frac{LI_p}{B_{\max} A_c} = \frac{V_{in(\min)} D_{\max}}{F B_{\max} A_c} \tag{6}$$

By calculating, the transformer parameters can be get. The winding number of primary side of the transformer N_P=41, The inductance of primary side of the transformer L_p=510uH, The winding number of secondary side of the transformer N_s=8, The winding number of auxiliary N_f=8.

Analysis of experimental results

In order to verify the performance of the switching power supply, the flyback switching power supply is established in PSPICE. The circuit parameter settings are as follows. The input voltage range is 85v to 265V. The output voltage is 15V. The maximum output current is 2A. The ripple factor of output is 5%. The power switch adopts MOSFET STP4NA60. The drain source voltage waveform of MOSFET is shown in Fig. 3. The output voltage waveform of switch power supply is shown in Fig. 4.

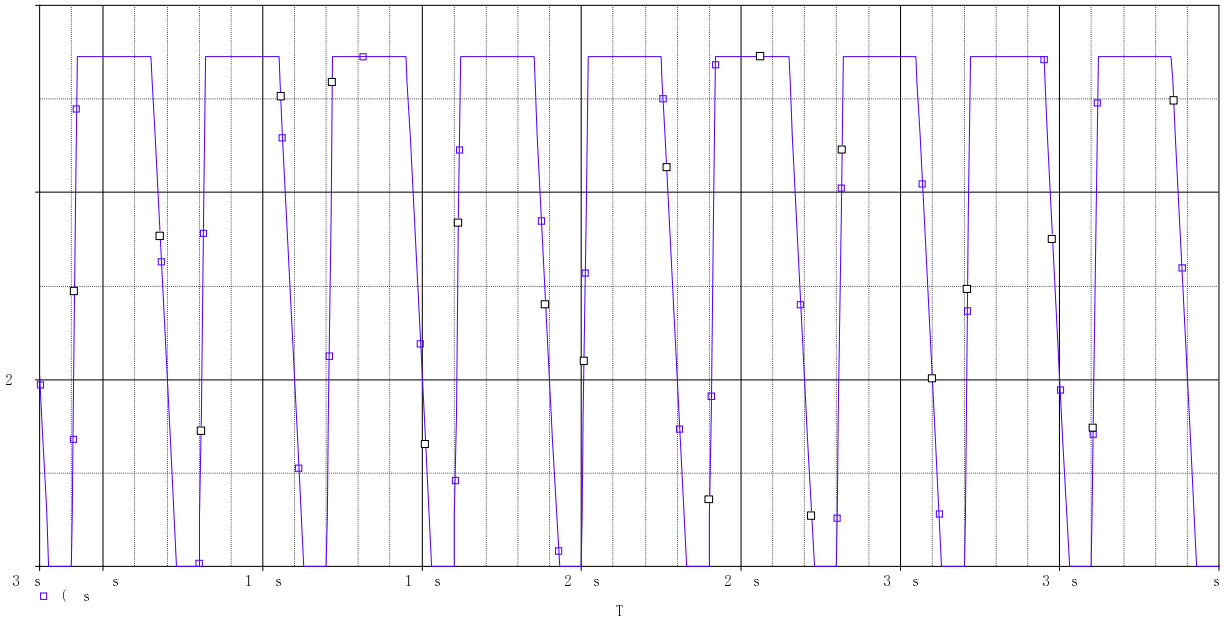

Fig. 3 The drain source voltage waveform of MOSFET

As shown in Fig. 3, the maximum drain source voltage of MOSFET V_{ds} is 545V, which includes the maximum input peak voltage V_P, the transformer primary side to the secondary side refraction voltage V_T, and The primary side of the transformer leakage inductance voltage V_L. V_P is 375V. V_T is 100V. V_L is 70V. $V_{ds} = V_P + V_T + V_L$ =545V. The working frequency of MOSFET is 25 kHz.

As shown in Fig. 4, the output voltage of flyback switching power supply is 15V. When the output voltage is stable, the ripple wave of output voltage is 0.2V, so the Ripple factor of output voltage is 1.33%, which meets the design requirements of the Ripple factor less than 5%. The output voltage can be long-term stable in 15V, so the flyback switching power supply is suitable for driving LED.

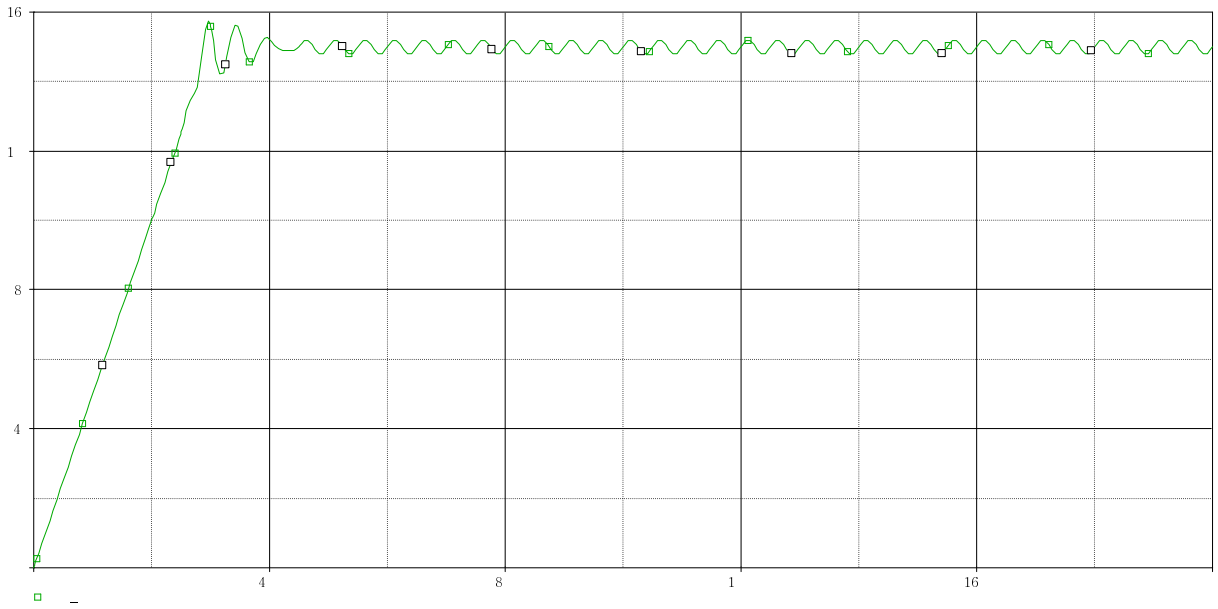

Fig. 4 The output voltage waveform of switch power supply

Conclusions

A new type flyback switching power supply based on L6561 is designed. According to experiment, The output voltage can long-term stable in 15V, while the input voltage is 85~265V. The Ripple factor of output voltage is 1.33%, which meets the design requirements of the Ripple factor less than 5%. The largest output current can be 2A. The flyback switching power supply meets the design requirements, which can stable drive LED.

Keywords: Oscillator; Switching Power Supply; Sawtooth Wave

Abstract. Based on the CMOS technology, the sawtooth wave oscillator used in switching power supply is designed. In the condition of 27 ˚C and 4 V power supply voltage, the oscillation frequency of sawtooth wave oscillator is 246.61 KHz. The oscillation frequency of sawtooth wave oscillator changes between 245.94 KHz and 247.89 KHz when the power supply voltage changes between 3V and 6V. The maximum deviation is ±0.52%. From the experimental results, the sawtooth wave oscillator has good linearity, the effect of temperature and power supply to the oscillation frequency of sawtooth wave oscillator is very little. The CMOS sawtooth wave oscillator is suitable for switching power supply.

Introduction

The switching power supply has the advantages of small volume and high efficiency, which is widely used in electronics, telecommunications and aerospace fields. At present, the switching power supply adopts the technology of pulse width modulation control, while the sawtooth wave oscillator is the core module of pulse width modulation circuit. The performance of Sawtooth wave oscillator directly affects the performance of switching power supply. So the sawtooth oscillator must be stable output in the environment of voltage and temperature changes. A sawtooth wave oscillator for switch power supply is designed, which adopts the structure of RC oscillator.

Working principle of sawtooth wave oscillator

The schematic diagram of the sawtooth wave oscillator is shown in Fig. 1. The circuit consists of current source I_1, capacitance C_1, switch K and control circuit. The switch K turns off when the output voltage is low level. The current source I_1 charges the capacitor C_1, and voltage V_s rise. The control circuit makes the output voltage V_m is high level when the voltage exceeds the threshold. The high level voltage V_m makes the switch K turn off, the capacitor C_1 discharge by switch K, and the voltage V_s is changed into low level. The circuit circle works that produces sawtooth wave V_s.

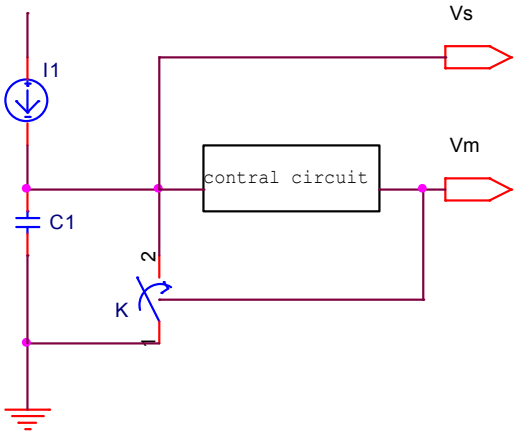

Fig. 1 The structure of sawtooth wave oscillator

Design of sawtooth wave oscillator

The circuit topology of sawtooth wave oscillator is shown in Fig. 2. The reference signal V_{ref} is 1.25V. Sawtooth wave output signal is V_S. The current source consists of the error amplifier A_1, the CMOS transistor M_1, M_2, M_5 and the resistor R_1. The negative feedback system is composed by the error amplifier A_1, the CMOS transistor M1 and the resistor R_1.

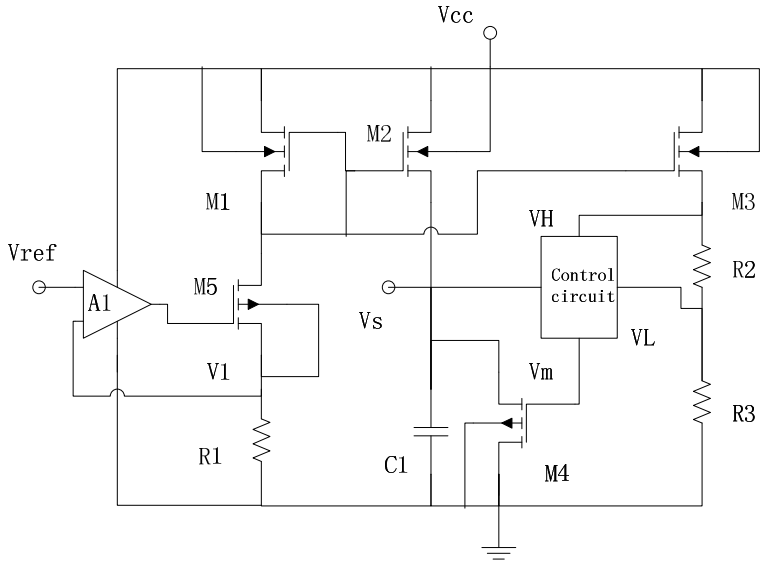

Fig. 2 The circuit of sawtooth wave oscillator

The error amplifier A_1 makes V_{ref} equal to V_1, the current I_{R1} of R_1 can be got in the formula (1).

$$I_{R1} = \frac{V_{ref}}{R_1} \tag{1}$$

The CMOS transistor M_1 and M_2 construct current mirror, the charging current I_1 can be got in the formula (2)

$$I_1 = \frac{(W/L)_3}{(W/L)_2} I_{R1} \tag{2}$$

In the formula (2), $(W/L)_2$ is length-width ratio of the CMOS transistor M_2, $(W/L)_3$ is length-width ratio of the CMOS transistor M_3.

The CMOS transistor M_4 and M_2 construct another current mirror, The leakage current I_{M4} of M_4 can be got in the formula (3)

$$I_{M4} = \frac{(W/L)_4}{(W/L)_2} I_{R1} \tag{3}$$

The current I_{M4} creates the threshold voltage V_H and V_L by R_2 and R_3, the threshold voltage V_H and V_L can be got in the formula (4) and the formula (5).

$$V_H = I_{M4}(R_2 + R_3) \tag{4}$$

$$V_L = I_{M4} R_3$$

Analysis of experimental results

In order to verify the performance of the sawtooth wave oscillator, the sawtooth wave oscillator was built in Pspice. The power supply voltage is 4V. The charge and discharge capacitance C_1 is 50pF. The environmental temperature is 27 ˚C. The sawtooth wave signal V_s and the charge and discharge

control signal V_m are shown in the Fig. 3. As can be seen from the waveform, the frequency of sawtooth wave signal is 246.61KHz. When the control signal V_m is low level, the CMOS transistor M_4 turn off, the current source charge the capacitor C_1 , and the voltage V_s liear rise. When the control signal V_m is high level, the CMOS transistor M_4 turn on, the capacitor C_1 discharge, and the voltage V_s drop rapidly.

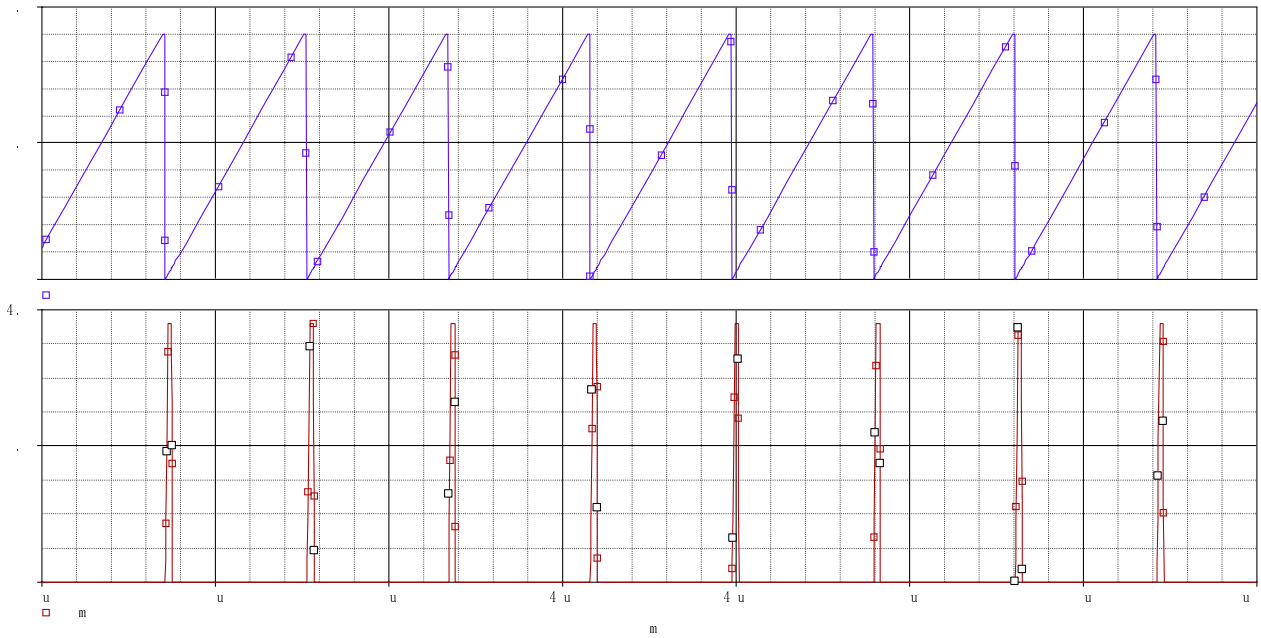

Fig. 3 The sawtooth wave signal Waveform and the charge and discharge control signal Waveform

It is shown in table 1 and table 2 that the changes of sawtooth wave frequency in different temperature and power supply voltage. The sawtooth wave frequency increase gradually when the power supply changes from 3V to 6V. The sawtooth wave frequency also increase gradually when the temperature changes from 0˚C to 70˚C.

Table 1 The relationship of sawtooth wave frequency and power supply voltage

Power supply voltage/V	Period/us	Frequency/KHz
3	4.006	245.94
3.5	4.057	246.49
4	4.055	246.61
4.5	4.051	246.85
5	4.049	246.97
5.5	4.046	247.16
6	4.034	247.89

Table 2 The relationship of sawtooth wave frequency and temperture

Temperature/˚C	Period/us	Frequency/KHz
0	4.096	244.14
10	4.072	245.58
20	4.084	246.06
27	4.055	246.61
30	4.053	246.73
40	4.051	246.91
50	4.045	247.22
60	4.043	247.34
70	4.042	247.40

Although the sawtooth wave frequency changed, the change is very small. The sawtooth wave oscillator owns high precision. The changes of temperature and power supply voltage have very little influence on the output of the sawtooth wave oscillator, which meets the requirements of the switching power supply.

Summary

A sawtooth wave oscillator for switching power supply is designed. The constant current source technology is adopted in the circuit, which effectively improves the linearity of the sawtooth wave oscillator. From the experimental results, the output of sawtooth wave oscillator is least affected by the changes of temperature and power supply voltage. The performance of the sawtooth wave oscillator meets the requirements of the switching power supply.

Keywords: SVPWM, Inverter, Dual loop control, Voltage Stability.

Abstract: Space vector pulse width modulation (SVPWM) technology can significantly reduce the harmonic content of the inverter output voltage and increase voltage stability compared to other modulation techniques. This paper apply the SVPWM technology in the micro-grid inverter side load voltage stability control, on the basis of dual loop vector inverter control and the basic principles and algorithms of SVPWM. The MATLAB/Simulink simulation show that the response based on SVPWM inverter system changes very rapid load ,the AC side load voltage and frequency control is also very stable.

Introduction

Micro-grid is an independent power supply system composed of a set of distributed generation device, in Fig. 1, in the microgrid the energy storage device is battery, and in the system battery as energy storage devices, the inverter has connected the DC side power supply to the AC side, the AC side load voltage quality depends on the DC side voltage and inverter capacity, when the DC side voltage is stable, the inverter control algorithm determines the quality of the AC voltage. There were two typical ways to inverter control algorithm: the traditional method of sine pulse width modulation (SPWM) and the space voltage vector pulse width modulation (SVPWM), the existing literature[1] is pointed out that the SVPWM can significantly reduce the harmonic components of inverter output voltage, and the control methord is simple and digital realization is easy , it has greatly trend to take place of the traditional SPWM. Literature[2]-[4] describes the control of wind power grid-connected inverter. This paper apply the SVPWM technology in the micro- grid inverter side load voltage stability control, on the basis of dual loop vector inverter control and the basic principles and algorithms of SVPWM,in order to research the ability of SVPWM technology to control the AC voltage.

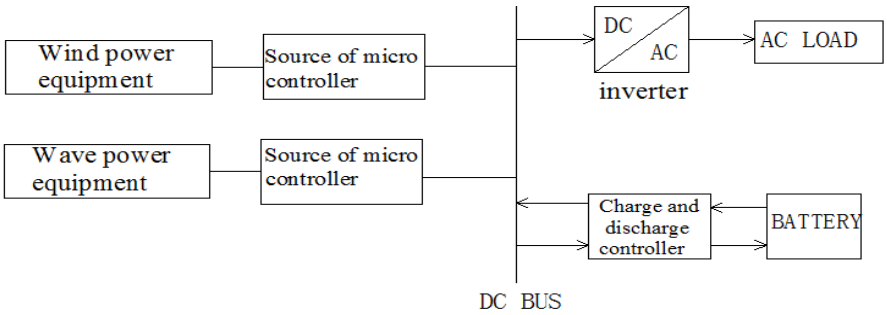

Fig. 1 OES(Ocean Energy Source) integrated power supply system structure

Inverter double closed-loop vector control strategy

Fig. 2 is three-phase voltage type inverter main circuit structure, according to the circuit principle，three phase inverter circuit model is analyzed.Through the CLARK transform and PARK transform,we can get the direct-axis component and quadrature-axis component of AC-side voltage and current, through decoupling control to the direct-axis and quadrature-axis of the AC component, and then through the PARK, deliver inverse transformation of the two phase voltage parameters of static coordinates to SVPWM controller. Voltage and current double closed loop control based on vector coordinate transformation model [3] has shown in Fig. 3:

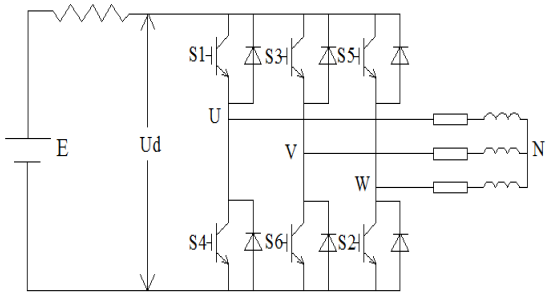

Fig. 2 3-phase voltage type inverter structure

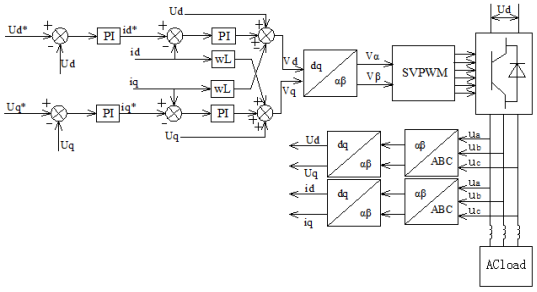

Fig. 3 Dual loop control mode

Set a three-phase sine wave electricity ideal reference voltage as follow:

$$\begin{cases} U_a = 220\sqrt{2}\cos(\omega t) \\ U_b = 220\sqrt{2}\cos(\omega t - 2\pi/3) \\ U_a = 220\sqrt{2}\cos(\omega t + 2\pi/3) \\ \omega = 2\pi f = 100\pi \end{cases} \quad (1)$$

Make CLARK transformation and PARK transformation to the Ua, Ub, Uc:

$$\begin{cases} U_{d^*} = 220\sqrt{2} \\ U_{q^*} = 0 \end{cases} \quad (2)$$

Compare the dq- axis component of the voltage reference Ud^*, Uq^* to the actual dq-axis voltage component Ud, Uq ,the result work as the reference voltage id^* iq^*, id^* iq^* is adjusted through the PI regulator,compare with the actual dq -axis voltage component, obtained vd, vq, vd, vq and then through the PARK inverse transform get v_α, v_β, finally sent v_α, v_β into SVPWM , get six switching signals of PWM wave.

The Principle of SVPWM

SVPWM is a circular magnetic field which start from the perspective of three phase AC motor, induction motor input continuous three-phase sine voltage to obtain the constant amplitude. In the case of voltage source inverter supply power, with balanced three-phase sine voltage produced by the circular magnetic field as a benchmark, PWM waveforms produce by the choice of the inverter switch state, makes the actual flux trajectory approximate to circle flux trajectory. Space vector modulation is based on the combined action of a finite space vector generation process to determine the location of the space to meet anywhere and a certain amplitude range required vector. In the PWM cycle formation the needed space vector by changes the distribution of each phase conduction time. General civil load is balanced load and three-phase needs to power supply in the same time, and voltage is sinusoidal, In order to obtain a symmetrical three-phase voltage parameters ,we can be modeled AC motor control methord to control the switching state of battery back-end inverter.

Three-phase Phase-Locked Loop of Inverter

The amplitude of three-phase voltage output can be directly calculated, but the phase and frequency of the output waveform and the phase angle of PARK transformation, need to be determined by phase-locked loop, phase-locked loop model [5] has shown in Fig. 4.

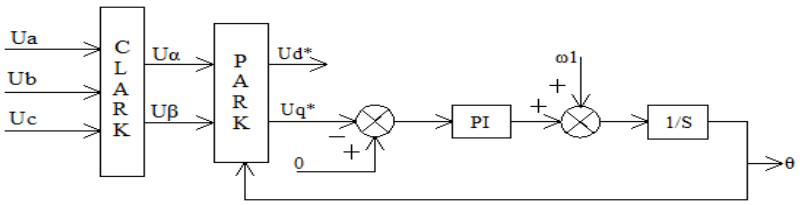

Fig. 4 Three-phase phase-locked loop control flow chart

Three-phase phase-locked loop using the synchronous rotating coordinate system to detect angular frequency and phase information, and then compare to the synchronous signal in the phase-locked loop, the frequency and phase of internal signal phase locked loop can be adjusted to the comparison results, when the angular frequency ω^* of the phase-locked loop output is equal to actual angular frequency ω, and their phase is same, the phase-locked loop being locked, $U_q = 0$.

Inverter control algorithm simulation and analysis

According to the inverter double closed-loop vector control strategy and SVPWM algorithm, each simulation module of the design of inverter control program has shown in Fig. 5.

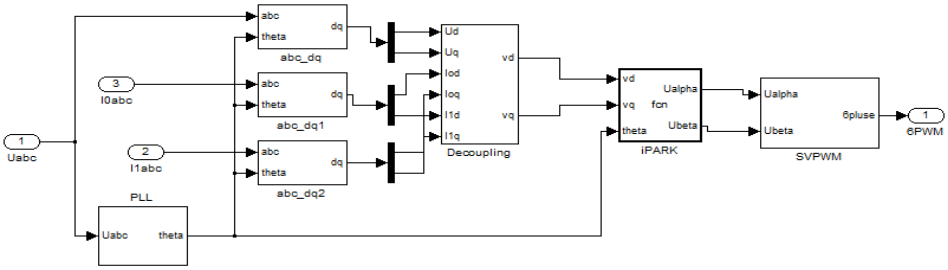

Fig.5 Double closed-loop decoupling and SVPWM control module

The input signal inculde the load voltage,current vector and AC-side current vector, the load voltage get the system voltage angular frequency through three-phase phase-locked loop module, to transform the voltage angular frequency by three vector coordinate respectively, obtained dq axis component of each vectors, and then through decoupling control module and PARK inverse transformation get voltage components in two-dimensional coordinates, finally sent voltage components into SVPWM control module will get six PWM switch signals.

To rule out the battery performance impact on the process of simulation, the simulation used DC voltage source to replace batteries, set DC side voltage at 600V, three-phase load is pure impedance load, set both load for 10 kw, at the start of the simulation, only load 1 access, in 0.5s, load 2 cut in, when it is 1s, load 2 cut out. Fig. 6 is inverter vector control simulation program block diagram.

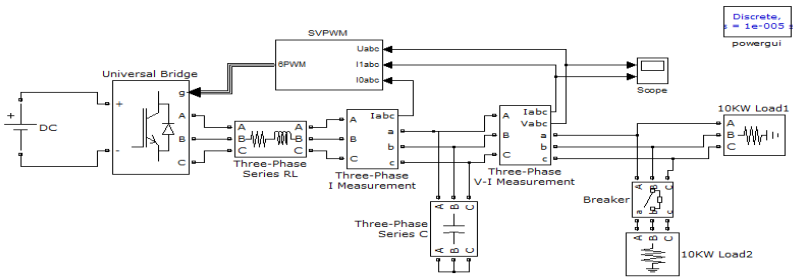

Fig. 6 Inverter vector control simulation program block diagram

By the Fig. 7 and Fig. 8, you can see that at the beginning of the program ,three-phase AC voltage is running at small fluctuations, but then quickly reach the set three-phase sine wave, when load increase at 0.4s, the AC voltage is almost no change, current doubles, when load decrease at 0.8s, voltage does not change, current drop to the initial value, it is visible that in the case of DC side capacity is enough, t SVPWM control strategy has the very good effect o maintain the stability of the load voltage, also can be seen from Fig. 9 that during the whole operation process, the frequency of the ac voltage has slight fluctuations near 50 Hz, frequency deviation limits within ± 0.2 Hz, meet the requirements of power system frequency deviation limits.

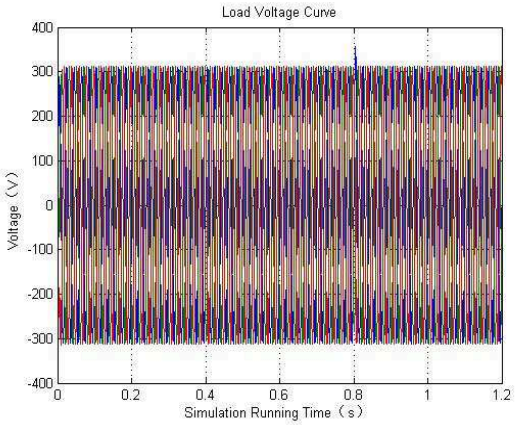

Fig. 7 The curves of load bus voltages

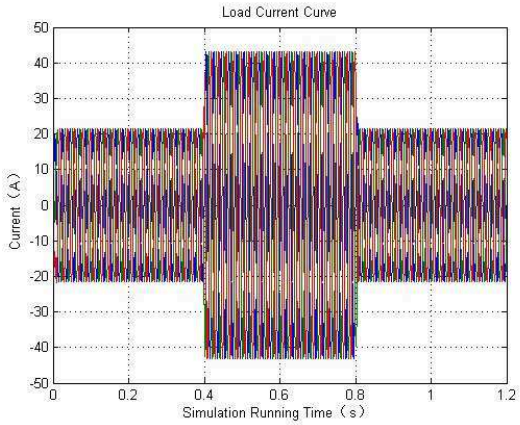

Fig. 8 The curves of load current

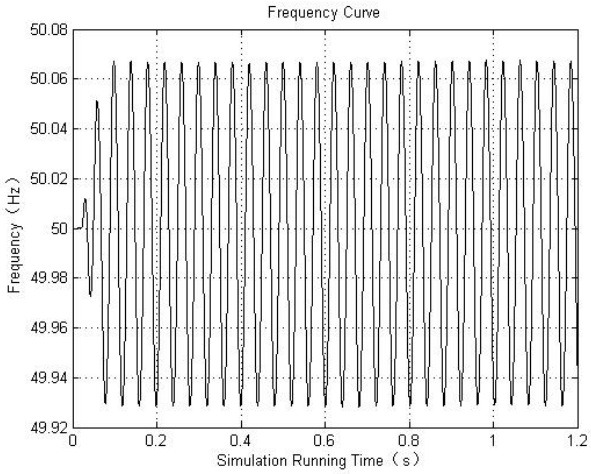

Fig. 9 Frequency curve

When run time and load parameter is set at the same situation, the single inverter SVPWM control process also implements that using SPWM realizing master-slave control the function of the double inverter like the literature [6], visible under the conditions that inverter DC side capacity is same to the system capacity, this design is better than double inverter design in the document [6] on the cost, and the SVPWM is easy to realize digital realization compared with SPWM, and has higher practicality.

Conclusion

This paper introduces the principle of voltage and current double closed-loop inverter based on SVPWM vector control technology, and simulation to the control process through MATLAB/Simulink software, the output waveform of simulation indicate that when the control algorithm put into operation, can quickly stable voltage, timely response to load changes, to maintain the stability of the AC voltage, and with less harmonic components at the same time. Prove that the voltage and current double closed-loop SVPWM control technology can be applied in the control of microgrid inverter AC side voltage stability.

Keywords: Active Power Filter, Fuzzy Control, PI Control, Three Level.

Abstract: This paper presents a new method which combines the fuzzy theory with the traditional PI control to obtain the accurate tracking of the compensating current of the active power filter (APF) in full frequency range. Online adjustment of the parameters of the controller is realized by using fuzzy reasoning and defuzzication, so as to achieve the accurate tracking of the compensating current and thereby improve the capabilities of the APF to suppress the harmonics effectively. Simulation analysis and experiment results verify the effectiveness of the presented method.

Introduction

With the wide application of power electronic devices, such as nonlinear loads, the problem of harmonic pollution in power system is increasingly serious, which caused great influence on safe and economic operation of power system [1]. So we must take effective measures to improve it. As a new compensation device, active power filter (APF), which was capable of track complex harmonic both frequency and amplitude changes, and its compensation characteristics were affected little by changes in grid parameters, thus received wide attention [2].

Timely and effective control of the compensation current is a key link of APF, due to the current signal of harmonic current detection link get instruction current, compensation current must quickly and accurately track the signal, which is hard to do in the general case [3]. For this, many scholars have done a lot of work to study the compensation current control problem, to ensure to achieve the ideal compensation effect of APF. [4] using the upper and lower limits of instruction signal to form the hysteresis loop, hysteresis control on the difference of output current and the compensation current reference value. This method has advantage of quick response, does not contain specific times harmonic but defects exist in uncertainty of the switching frequency. [5] used the state information of the current sampling time, estimated next sampling period for compensation current, calculate the power switching device turn on and turn off pulse, deadbeat control on the compensation current. The method has fast dynamic response, but more dependent on the system parameters and has poor anti-interference ability. Specific to the disadvantage of the traditional PI control, which bandwidth is limited and cannot effectively track all frequencies of APF compensation current, this paper combines fuzzy control with PI control to constitute a composite control, which combines the advantages of both, and can compensate for lack of another, not only has rapid system response, but also ensures the control accuracy of the system. Finally, the effectiveness of the proposed composite control strategy is verified based on the MATLAB/SIMULIK simulation and hardware experiment platform.

The mathematical model of active power filter

The research object of this paper is shunt diode clamped three level active power filter, to simplify the analysis, introducing the concept of switching function, the bridge arm of each phase is equivalent to a single pole three throw switch, then the simplified circuit of the APF main circuit as shown in Fig. 1.

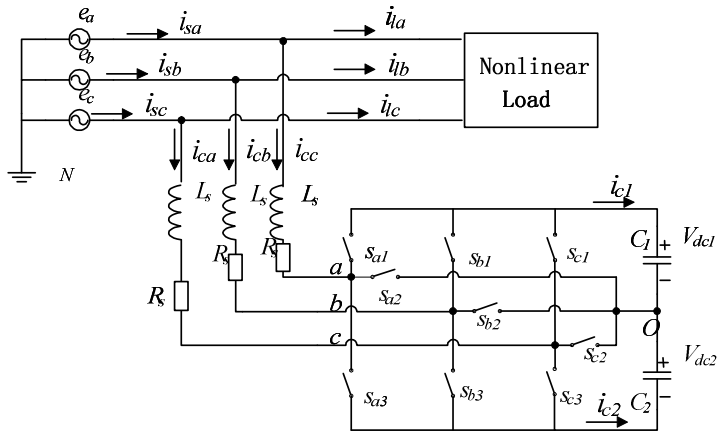

Fig. 1 Three level APF simplified circuit diagram

The switching function [6] $s_{ij}(i=a,b,c;\ j=1,2,3)$ is defined as Eq. 1:

$$\begin{cases} s_{ij}=1, & \text{the switch is closed} \\ s_{ij}=0, & \text{the switch is off} \end{cases}, \tag{1}$$

and s_{ij} satisfy the constraints of Eq. 2:

$$\sum_{j=1}^{3} s_{ij}=1 \qquad (i=a,b,c). \tag{2}$$

When $S_{j1}=1$, the above two switch tubes conduct, when $S_{j2}=1$ the middle two switch tubes conduct, when $S_{j3}=1$ the underneath two switch tubes conduct.

Through coordinate transformation, available mathematical model of the three level APF under the dq rotating coordinate system is shown in Eq. 3:

$$\begin{cases} L_s\dfrac{di_{cd}}{dt}=-R_s i_{cd}+\omega L_s i_{cq}+e_d-u_{cd} \\ L_s\dfrac{di_{cq}}{dt}=-R_s i_{cq}-\omega L_s i_{cd}+e_q-u_{cq} \\ C_1\dfrac{du_{dc1}}{dt}=S_{d1}i_{cd}+S_{q1}i_{cq} \\ C_2\dfrac{du_{dc2}}{dt}=-S_{d3}i_{cd}-S_{q3}i_{cq} \end{cases} \tag{3}$$

Three level APF switch function, the ac output voltage, the dq transform of three-phase grid voltage is shown in Eq. 4 and Eq. 5:

$$\begin{cases} \begin{bmatrix} S_{d1} & S_{q1} \end{bmatrix}^T = T_{abc/dq} \begin{bmatrix} S_{a1} & S_{b1} & S_{c1} \end{bmatrix}^T \\ \begin{bmatrix} S_{d3} & S_{q3} \end{bmatrix}^T = T_{abc/dq} \begin{bmatrix} S_{a3} & S_{b3} & S_{c3} \end{bmatrix}^T \end{cases} \tag{4}$$

$$\begin{cases} u_{cd} = S_{d1} u_{dc1} - S_{d3} u_{dc2} \\ u_{cq} = S_{q1} u_{dc1} - S_{q3} u_{dc2} \end{cases} \tag{5}$$

In the formula, there is:

$$T_{abc/dq} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\theta & \cos(\theta - 2\pi/3) & \cos(\theta + 2\pi/3) \\ -\sin\theta & -\sin(\theta - 2\pi/3) & -\sin(\theta + 2\pi/3) \end{bmatrix},$$

$\theta = \omega t = 2\pi ft$, θ is synchronous rotary angle, $\omega = 2\pi f$ is spatial vector synchronous rotational angular frequency. After simplification, we get:

$$\begin{cases} L_s \dfrac{di_d}{dt} = -R_s i_d + \omega L_s i_q - u_d + e_d \\ L_s \dfrac{di_q}{dt} = -R_s i_q - \omega L_s i_d - u_q + e_q \end{cases} . \tag{6}$$

It can be seen from Eq. 6, APF is a system of strongly coupled, nonlinear characteristics, which need a high performance dynamic static controller to compensation current control.

Fuzzy PI control

Fuzzy PI control block diagram is shown in Fig.2, its basic principle is to develop "if-then" fuzzy rule form, and these results and system parameters are stored, the *e* is error between compensate current and harmonic current, the *ec* is the variety rate of error, then put them into fuzzy PI controller, after processing, get the ΔK_p , ΔK_i in that situation, online adjust the original PI parameters.

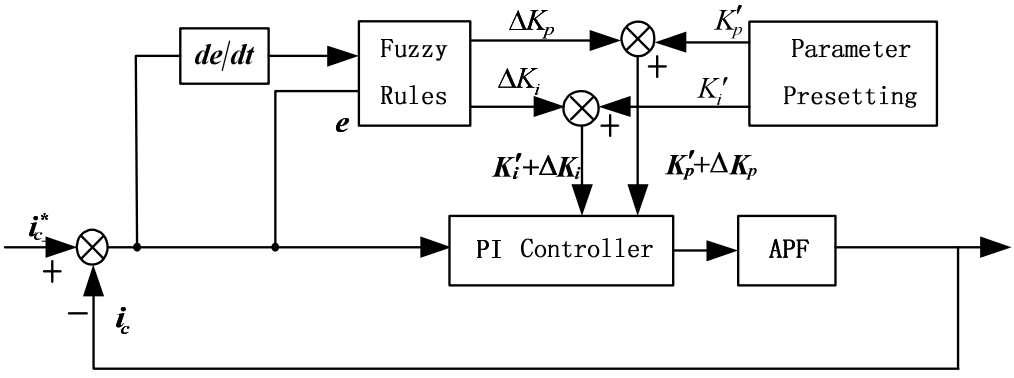

Fig. 2 Fuzzy PI controller structure diagram

Fuzzy inference of fuzzy control can only deal with fuzzy variables, so the input values should be changed into fuzzy values. The fuzzy language of input values is: negative big (NB), negative medium (NM), negative small (NS), zero (ZO), positive small (PS), positive medium (PM), positive big (PB). The fuzzy rules are the cores of the fuzzy control, the proportion gain K_p can reflect the error e, if the error e is large, in order to quickly suppress, the value of K_p will be larger; conversely, if the error is small, to prevent large overshoot that will leads the system oscillation, the value of K_p will be smaller. Considering the error variety rate ec, when ec and e are the same sign, the output value will deviate from the stable value, at this time the value of K_p should be increased; conversely, the value of K_p should be reduced. The fuzzy control regulation of ΔK_p is shown in Table 1.

Table 1 Fuzzy regulation control table of ΔK_p

e	ec						
	NB	NM	NS	ZO	PS	PM	PB
NB	PB	PB	PM	PM	PS	ZO	ZO
NM	PB	PB	PM	PS	PS	ZO	NS
NS	PM	PM	PM	PS	ZO	NS	NS
ZO	PM	PM	PS	ZO	NS	NM	NM
PS	PS	PS	ZO	NS	NS	NM	NM
PM	PS	ZO	NS	NM	NM	NM	NB
PB	ZO	ZO	NM	NM	NM	NB	NB

The function of the integral gain K_i is to reduce the static error. If its value is too large will increases the system's overshoot. In order to prevent the integral saturation, when the value of error e is large, make K_i=0; when the value of error e is small, let K_i effect, and take it greater when error e is smaller, to reduce the steady state error. The fuzzy control regulation of ΔK_i is shown in Table 2.

Table 2 Fuzzy regulation control table of ΔK_i

In the fuzzy inference, the output value defuzzification, transform into the accurate value, and then output ΔK_p, ΔK_i, available online modified PI formula are shown in Eq. 7:

$$\begin{cases} K_p = K_p' + \Delta K_p \\ K_i = K_i' + \Delta K_i \end{cases} . \tag{7}$$

The simulation and experimental analysis

In order to verify the feasibility of the fuzzy PI control strategy for three level active power filter, the above scheme is validated on the MATLAB / SIMULINK simulation platform and hardware test platform. The simulation parameters and experimental parameters are the same: the three-phase power supply voltage is 220V, frequency is 50Hz, the system impedance is negligible. Harmonic source is the three-phase uncontrolled rectifier bridge with a resistance-inductance load, the resistor R=12Ω, inductor L=1mH. Inductance of incoming line of the APF is 1.2mH, switching frequency is 5KHz.

Fig.3 shows the current and harmonic analysis waveform of the uncontrolled bridge rectifier with a resistance-inductance load before compensation, there are a lot of harmonic before compensation, for example in phase A current, total harmonic distortion THD=23.65%. Simulation waveforms of traditional PI control after compensation is shown in Fig.4. Fig.4(c) shows the waveforms of the tracking current and instruction current, both almost consistent in the waveform curve trend, but the amplitude and phase have error, this is due to the traditional PI control can not achieve tracking without steady-state error.

Fig. 5 Simulation of fuzzy PI control compensation effect, (a) Current waveform after compensation; (b) Phase A current harmonic after compensation; and (c) Current tracking waveform

Three level active power filter fuzzy PI control experiment platform is set up based on DSP and FPGA control chip. The TMS320F28335 chip is chosen for the DSP, the XC2S200FPGA of XILINX chip is chosen for the FPGA. The DSP is mainly used for double closed loop control and SVPWM arithmetic processing [7], FPGA is used to achieve pulse generation of each arm. The 8 channel, 16 bit AD7606 is used for sampling. The 7MBP150RA120 of Fuji IGBT-IPM is adopted for main circuit.

Fig.6 shows the grid voltage and current waveforms before compensation when no controlled rectifier bridge is with a resistance inductance load. From the figure, the current harmonic content is high, and distortion is serious, which will cause serious harmonic pollution to power grid. Fig.7 shows the grid voltage and current waveforms after compensation when use the fuzzy PI control of APF. From the figure, a high sinusoidal current waveform is achieved after compensation. The current harmonic content is small, a well harmonic governance capabilities is achieved. Fig.8 shows the grid current and DC side voltage waveforms before and after the APF is put into. When the APF is put into, the intended effect of compensation can be achieved after a period of transient process. The system has rapid dynamic response and high precision of harmonic detection and compensation control. It has a good dynamic and static performance.

Conclusions

1. This paper constitutes a new hybrid control strategy by combining fuzzy control with PI control. The novel method can improve the traditional PI control, which has the disadvantage of cannot effectively track all frequencies of APF compensation current because of the bandwidth limit.
2. Through fuzzy reasoning and defuzzification, online adjustment of the PI parameters is achieved, which can improve the regulator full frequencies tracking performance to instruction current, and optimize the response ability of the harmonic compensation current.
3. Finally, based on the MATLAB/SIMULIK simulation and DSP+FPGA experiment results verify the effectiveness and feasibility of the proposed method.

Keywords: inverter, nonlinear loads, dual loop control, current feed-forward, pole assignment

Abstract. A new approach of dual closed-loop control strategy is proposed, and the internal cause of the inverter output voltage waveform distortion is analyzed in this paper. The ability to resist load disturbance is improved by load current feed-forward compensation in the approached scheme. With inner current loop improving the speed of dynamic response, nonlinear load adaptability is enhanced. Pole assignment method is used to design controller parameters, the control scheme is simulated in PSCAD/EMTDC, the nice performance of the proposed control strategy is verified by the simulation results.

Introduction

Single phase inverters have been widely used in UPS and other industrial equipment. The control methods of inverter including single closed-loop control, dual closed-loop control, deadbeat control, repetitive control, fuzzy logic control, etc [1,2]. The dual closed-loop control is one of the developing directions of high performance inverters.

A single phase inverter applying dual closed-loop with load current feed-forward compensation control technique is researched. Controller parameters are obtained with pole assignment technique [3,4]. The principle for the control system can improve the adaptability of nonlinear load is illustrated in terms of equivalent output impedance. The simulation results verified the designed inverter can achieve good static characteristics with nice dynamic response even with nonlinear loads.

Mathematical model of single-phase inverter

The main circuit structure of a single phase full bridge inverter is shown in Fig.1.

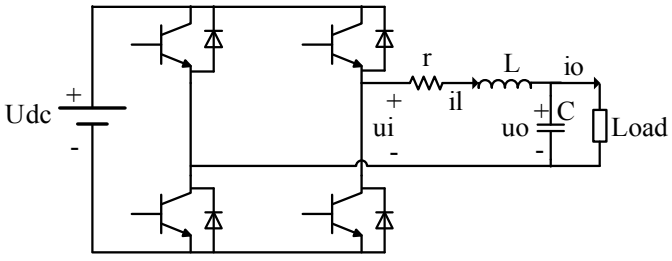

Fig.1 Schematic diagram of single phase full bridge inverter main circuit

In Fig.1, U_{dc}, u_i and u_o indicate the DC bus voltage, filter input voltage and output voltage of inverter. i_l, i_c and i_o indicate inductor current, capacitor current and load current. r indicates parasitic resistor and dead time effect equivalent resistance. L,C indicate Filter inductance and capacitance respectively. Choosing the u_o and i_l as state variables, the state equation becomes as:

$$\begin{bmatrix} \dot{u}_o \\ \dot{i}_l \end{bmatrix} = \begin{bmatrix} 0 & \frac{1}{C} \\ -\frac{1}{L} & -\frac{r}{L} \end{bmatrix} \begin{bmatrix} \dot{u}_o \\ \dot{i}_l \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{1}{L} \end{bmatrix} u_i + \begin{bmatrix} -\frac{1}{C} \\ 0 \end{bmatrix} i_o \qquad y = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{bmatrix} \dot{u}_o \\ \dot{i}_l \end{bmatrix}. \tag{1}$$

According to (1), the transfer function is derived as:

$$U_o(s) = \frac{U_i(s)}{LCs^2 + rCs + 1} + \frac{-(Ls + r)}{LCs^2 + rCs + 1} I_o(s) = G_i(s) \cdot U_i(s) - Z_o(s) \cdot I_o(s). \tag{2}$$

Internal cause of output voltage waveform distortion

The nonlinear load model. Due to the nonlinear load contains the nonlinear components such as diodes, silicon controlled rectifier, even if the load voltage is standard sine wave, load current still contains a lot of harmonics. Diode uncontrollable rectifier circuit is a sort of commonly used nonlinear load, it serves as an important means of testing the performance of power source. The typical nonlinear LCR single-phase load is shown as Fig.2.

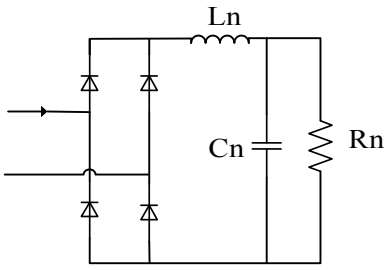

Fig.2 Typical model of nonlinear load

Open loop characteristic of single phase inverter. According to (2), inverter output voltage consists of two parts, thus the inverter can be regarded as the series of an ideal voltage source and the equivalent output impedance of the inverter. $Z_o(s)$ can be taken as the equivalent output impedance. Taking the inverter designed in this paper as an example, with main parameters as: L=0.8mH，C=90uF，r=0.1Ω，the frequency characteristics of inverter output impedance can be derived as Fig.3.

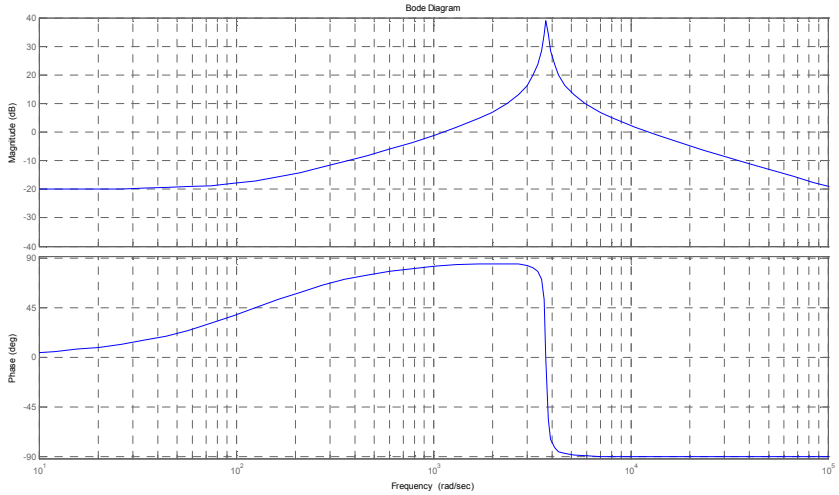

Fig.3 The bode diagram of inverter output impedance

According to Fig.3, the amplitude of output impedance increases with the rising of frequency at low-frequency stage. For nonlinear load, the harmonic current shock is huge, the output impedance causes larger harmonic voltage drop, thus lead to output voltage distortion. That is the internal reason of voltage waveform distortion caused by nonlinear load.

Control system design

The dual closed-loop with load current feed-forward compensation control scheme is shown as Fig.4. The load current feed-forward can enhance the ability to resist load disturbance, the inner current loop increases bandwidth of the inverter control system to achieve faster dynamic response and strengthen the adaptability for nonlinear load [5-7].

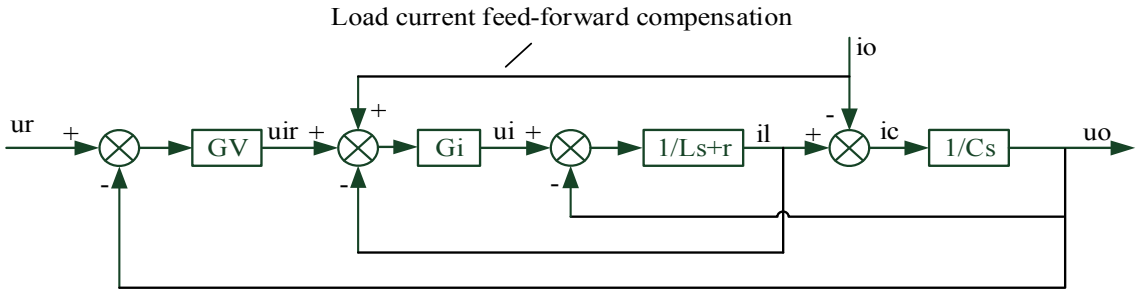

Fig.4 The block diagram of dual loop with feed-forward control scheme

Design of parameters. The proportion-integral control is adopted to regulate the output voltage in the outer loop and the inductor current in the inner loop. The regulator becomes as:

$$G_v(s) = k_{1p} + \frac{k_{1i}}{s} \quad , \qquad G_i(s) = k_{2p} + \frac{k_{2i}}{s} \quad . \tag{3}$$

According to (3) and Fig.4, we can get the dynamic characteristics of closed-loop output voltage as:

$$U_o(s) = \frac{\frac{k_{1p}k_{2p}}{LC} + \frac{k_{1p}k_{2i+}k_{1i}k_{2p}}{LC}s + \frac{k_{1i}k_{2i}}{LC}}{D(s)} U_r(s) - \frac{\frac{1}{C}s^3 + \frac{r}{LC}s^2}{D(s)} I_o(s) = G_{ur}(s)U_r(s) - Z_o(s)I_o(s) \, , \tag{4}$$

with

$$D(s) = s^4 + \frac{r + k_{2p}}{L}s^3 + \frac{k_{1p}k_{2p} + Ck_{2i} + 1}{LC}s^2 + \frac{k_{1p}k_{2i} + k_{2p}k_{1i} + 1}{LC}s + \frac{k_{1i}k_{2i}}{LC} \, . \tag{5}$$

Set the dominant pole of the fourth order system as $s_{1,2} = -\zeta_r\omega_r \pm j\omega_r\sqrt{1-\zeta_r^{\,2}}$, the non-dominant pole as $s_3 = -m\zeta_r\omega_r$, $s_4 = -n\zeta_r\omega_r$, the expected characteristic equation becomes as:

$$D_r(s) = (s^2 + 2\zeta_r\omega_r s + \omega_r^{\,2})(s + m\zeta_r\omega_r)(s + n\zeta_r\omega_r) \quad . \tag{6}$$

Set m=n=10, expected damping ratio as $\zeta_r = 0.8$, natural frequency as $\omega_r = 3000 \mathrm{rad/S}$, comparing (5) with (6), we can get:

$$G_v(s) = 0.4496 + \frac{866.6481}{s} \qquad G_i(s) = 42.14 + \frac{430680}{s} \tag{7}$$

Analysis of output impedance frequency response characteristic. According to (4) and (5), the equivalent output impedance of the inverter can be characterized by

$$Z_o(s) = \frac{Ls^3 + rs^2}{LCs^4 + (r + k_{2p})Cs^3 + (k_{1p}k_{2p} + Ck_{2i} + 1)s^2 + (k_{1p}k_{2i} + k_{2p}k_{1i})s + k_{1i}k_{2i}} \, . \tag{8}$$

Controller parameters are given in (7), the Bode diagram of output impedance can be shown as Fig.5.

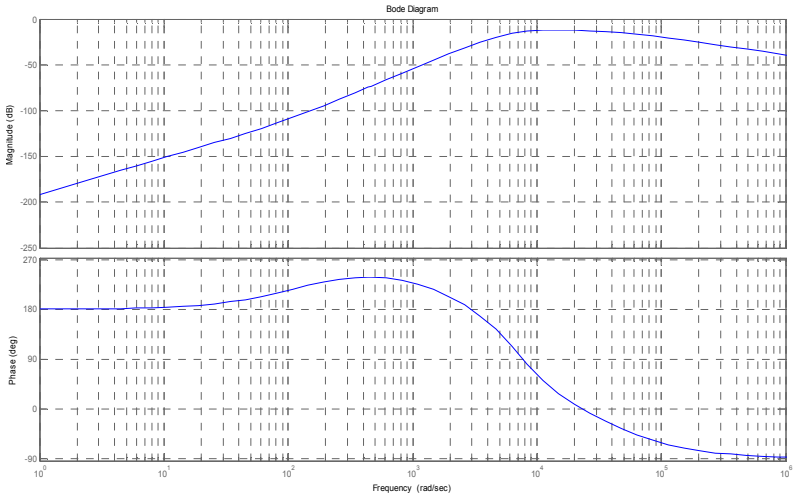

Fig.5 The bode diagram of inverter output impedance

Comparing Fig.5 with Fig.3, the output impedance in each frequency band is largely damped due to the designed control scheme, so nonlinear load adaptability is reinforced.

Simulation test

The parameters used for the simulation are shown below.

DC voltage: $U_{dc} = 400V$, Output AC voltage: $U_o = 220V$, f=50HZ, Filter inductance: L=0.8mH, Filter capacitor: C=90uF, Equivalent resistance: r=0.1Ω, Switching frequency: $f_s = 8kHZ$.

The waveforms of load current and output voltage in the case of sudden increase of load are shown as Fig.6 and Fig.7, respectively. In the case of sudden decrease of load, the waveforms are shown as Fig.8 and Fig.9. Under the condition of rectifier nonlinear load, the waveforms of load current and voltage are shown as Fig.10 and Fig.11. The nonlinear load model adopted in the simulation is shown as Fig.2, with the parameters as: $L_n = 1.0mH$, $C_n = 400uF$, $R_n = 10\Omega$.

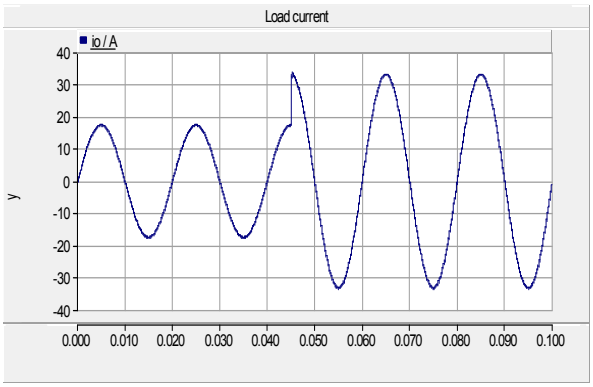

Fig.6 Load current for sudden increase of load

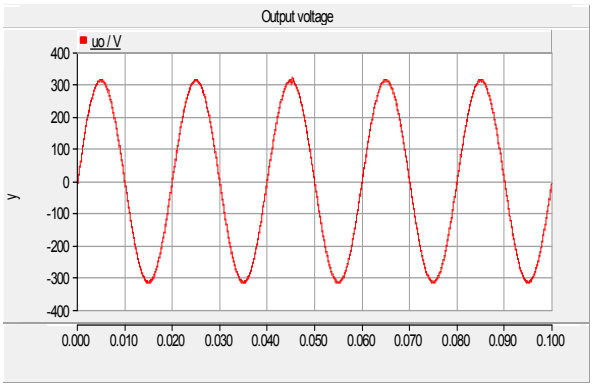

Fig.7 Output voltage for sudden increase of load

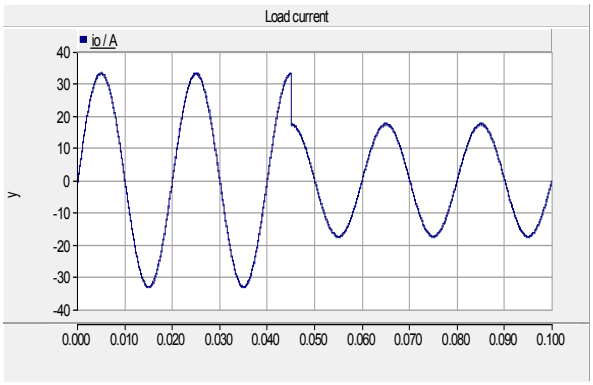

Fig.8 Load current for sudden decrease of load

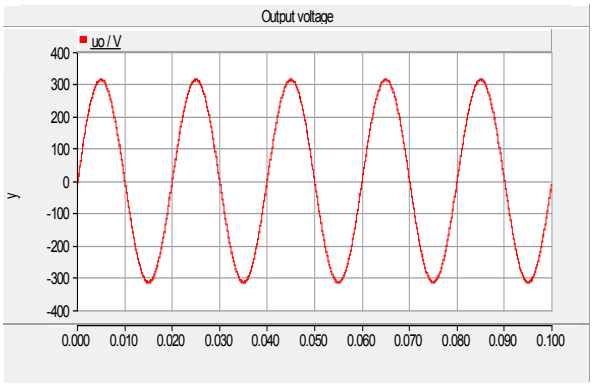

Fig.9 Output voltage for sudden decrease of load

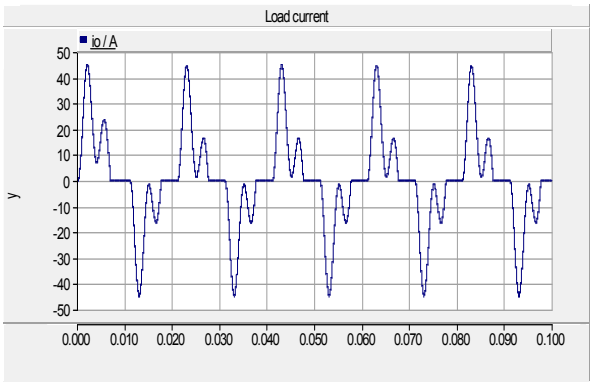

Fig.10 Load current for nonlinear load

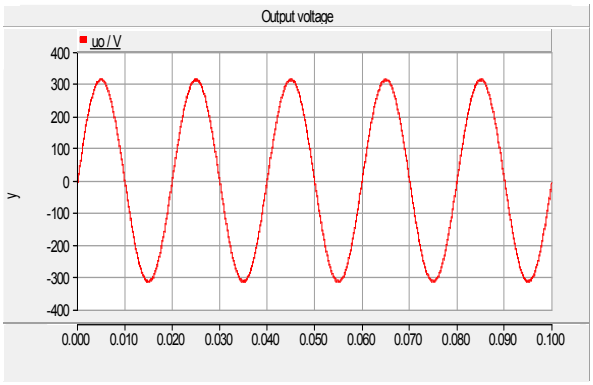

Fig.11 Output voltage for nonlinear load

From Fig.6 to Fig.9, we can get that the load current can be changed instantly during the load mutation with little output voltage fluctuation. The output voltage variation is not more than 3.76%, and the recovery time is less than 0.5ms, the dynamic response is fast. The THD is only 0.0754% under the condition of resistance load. According to Fig.10 and Fig.11, the load current is seriously distorted under the condition of nonlinear load, while the output voltage is a good sinusoidal wave with the THD is only 0.6461%.

Conclusions

Due to the inverter output impedance, nonlinear load current harmonics lead to output voltage wave distortion. In virtue of the proposed dual loop with feed-forward control scheme, the output impedance is damped and dynamic response accelerated. The simulation results show that the presented control scheme can obviously improve dynamic characteristics. The output waveforms under the condition of nonlinear load are satisfied for the low THD.

Keywords: Coordinated control, MPPT, Multiport converter, Matlab, Simplorer

Abstract. According to the requirements on multiport and power flow in the application of renewable energy, a novel multiport converter based on magnetic coupling is proposed in this paper. This multiple converter is capable of charging and discharging the battery while supplying the load. Theoretical method for the analysis of a three-port converter based on magnetic coupling is presented. The principle of the control loop for the converter is given that the maximum power point tracking (MPPT) is applied for the Photovoltaic (PV) part and the independent control is for the power flow part respectively. In addition, this proposed control method is also available for multiple modules. The simulation model is built by Simplorer-Matlab software and the simulated results demonstrate that this proposed converter can realize the power distribution very well. The control strategy proposed is of great isolation and low mutual interference between different ports so that the converter can reliably operate.

Introduction

With the rapid development of renewable energy, various new types of converters are developed in order to combine multiple energy sources to meet the requirement of power flow between each unit. Comparing with traditional ones, most converters applied in renewable energy system have the characteristics of multiport with bidirectional power flow. And the control methods are also simple and effective as well [1-3].

Multiport converter is applied to convert power or voltage among ports by using only one converter. Electric coupling and magnetic coupling, as shown in Fig.1, are the most commonly used for connecting different ports in a multiport converter. Electric coupling is mainly achieved by the DC bus while magnetic coupling by a transformer. Ref [4] presents the fundamental form of a multiport converter based on electric coupling that a switch module is used for putting into the multiple low-power energy harvesting sources while a Boost circuit following is applied for supplying the load. Ref [5] changed the single switch that described in [4] into two parallel-connected switches in the pre-stage and the bidirectional power flow is achieved in the followed stage by applying a bidirectional Buck-Boost circuit. Ref [6] utilizes a transformer as a unit for energy storage and transformation. The input ports which are connected to the Photovoltaic (PV), the grid and the battery respectively supply the two output ports on the load side by a multi-winding transformer. Besides, the battery can be charged or discharged. However, the multiple-input boost converter proposed in Ref [4] cannot extract power from multiple low-power energy harvesting sources simultaneously due to its parallel structure, resulting in the low use efficiency. In the Ref [6], it can operate bi-directionally without any need for additional converters, but a five-port transformer is difficult to design undoubtedly. Hence, a simultaneous power-feeding converter with a three-port transformer is proposed in this paper.

The main advantage of an electric coupling multiport converter is simple to achieve and easy to control. However, the limitation of these topologies is that only one power source is allowed to transfer energy into the load at a time to prevent power coupling effects and without the isolation leads to low reliability [7]. A magnetic coupling multiport converter is more capable of controlling the power flow of each port, but the transformer in this converter is complex in structure. Along with the operating principle and the power control strategy, a coordinated controlled three-port converter

based on the magnetic coupling is proposed in this paper to achieve the power flow by isolating the electric circuit, which has a simpler structure than the traditional multiport magnetic coupling converters. Besides, the extension of multi-module PVs is more achievable.

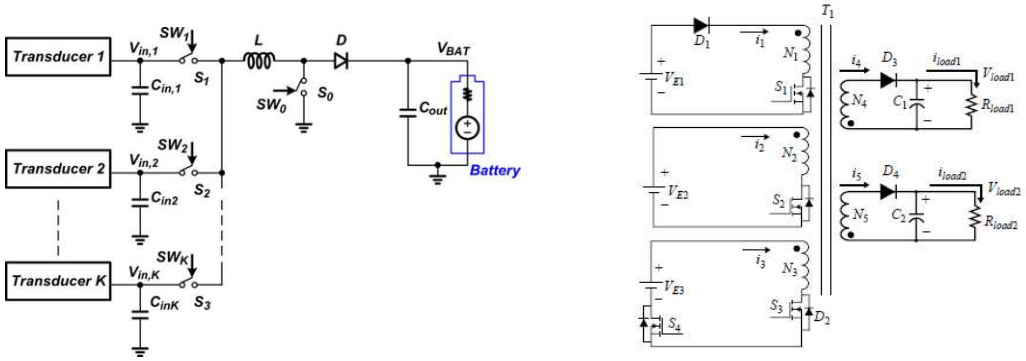

Fig.1 a) Multiple-input boost converter b) Multiple-input multiple-output converter

Operation Principle

The proposed multiport converter is illustrated in Fig.2. The converter, which contains three ports (PV port, battery port, load port respectively) is mainly constituted by a three-winding isolated transformer. The two input ports which connect to PV array and battery both adopt the fundamental full-bridge circuit to realize the bidirectional power flow easily. The output port which connects to the load obtains power by rectifying from secondary wingding of the transformer. Moreover, the converter can successfully transfer power from the different voltage sources to the load individually or simultaneously, and the PV array is capable to supply the load and battery at the same time when the battery is out of charge.

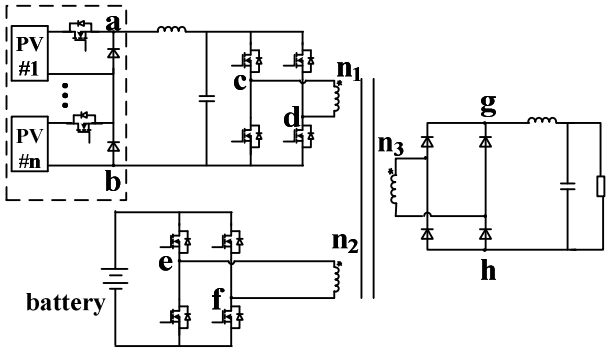

Fig. 2 Topology of proposed converter

The basic PV parallel module or serial module is adopted by coordinated control according to the power requirement. The parallel module need a current divergence control strategy, which is quite complex when the number of module increases. The serial module control is relatively simple, because the total PV array voltage (V_{ab}) changes little when the number of modules is larger than 15. In this paper, the circuit of Buck is chosen as the module unit due to its simple structure and control method.

According to the analysis above, the converter can operate in four modes: I. Both PV port and battery port supply the load. II. PV port supplies both the battery and load. III. Only battery port supplies the load. IV. Only PV port supplies the load

In the mode III and mode IV, only one port supplies the load, and the other port operates without control, so the paper focuses on the former two modes. Mode I and mode II are of the same operation state in state II and state IV.Besides, there are just the switch pairs S_7/S_{10} and S_8/S_9 work the other way around, so this part shows operation state in mode I only. Assuming all the switches and the transformer are ideal, the following part demonstrates the operating state of the mode I and mode II with the only PVs at the head and the tail.

On the basis of the operating condition of each switch, it can be divided into four states in the Mode I.

State I: As shown in Fig.3 (a), with S_1, S_2, S_3 and S_6 turned ON for a span, the total voltage of PV array puts on the primary winding, which values V_{ab}. Meanwhile, the battery port also supplies the load through the switches of S_7 and S_{10}. The secondary rectifier diodes of D_3 and D_6 persistently conduct, resulting in the voltage of the rectifier rising to (n_3/n_1) $V_{ab.}$ Energy of the primary side is transmitted to the secondary side, and windings of transformer storage power at this phase.

State II: As shown in Fig.3 (b), with S_3 and S_6 turned ON for a span, the total voltage of PV array values 0. Meanwhile, the voltage of the battery port changes to 0 as well, and the diodes in parallel to the switches offer an access for the power releasing of transformer. The secondary rectifier diodes of D_3, D_4, D_5 and D_6 conduct, leading to voltage rectified also changing to 0. Windings of transformer release power at this phase. When the windings release its stored energy completely, and the secondary rectifier diodes turned OFF, this state ends.

State III: As shown in Fig.3 (c), with S_1, S_2, S_4, S_5 turned ON for a span, the total voltage of PV array puts on the primary winding, which values $-V_{ab}$. Meanwhile, the battery port also supplies the load through the switches of S8 and S9. The secondary rectifier diodes of D_4 and D_5 persistently conduct, resulting in the voltage of the rectifier rising to (n_3/n_1) $V_{ab.}$ Energy of the primary side is transmitted to the secondary side, windings of transformer storage power at this phase.

State IV: As shown in Fig.3 (d), with S_4 and S_5 turned ON for a span, the total voltage of PV array values 0. Meanwhile, the voltage of the battery port changes to 0 as well, and the diodes in parallel to the switches offer an access for the power releasing of transformer. The secondary rectifier diodes of D_3, D_4, D_5 and D_6 conduct, leading to voltage rectified also changing to 0. Windings of transformer release power at this phase. When the windings release its stored energy completely, and the secondary rectifier diodes turned OFF, this state ends.

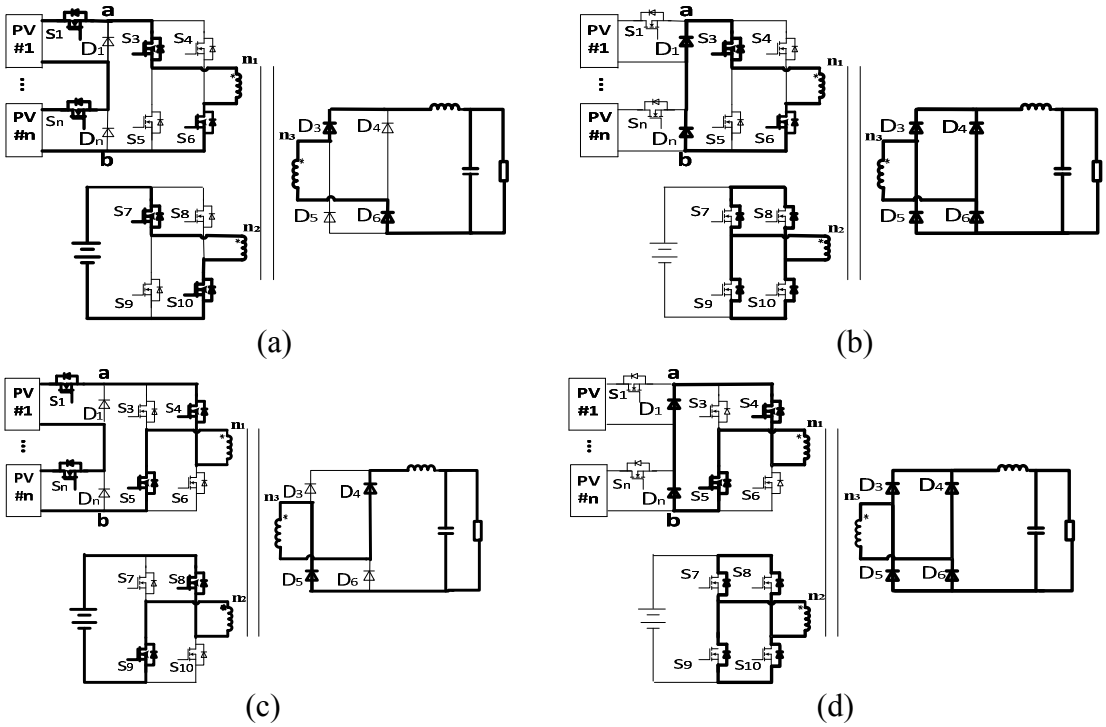

Fig. 3 a) Stage I b) Stage II c) Stage III d) Stage IV

Control Strategy

The converter is consists of numerous switches, so a coordinate control strategy is indispensable. The principle is that switches of Buck are controlled to adjust the total voltage of the PV array for MPPT, while switches of full-bridge inverter are regulated to realize the power flow. In order to obtain the maxim efficiency in the PV port, each module demands for MPPT control respectively. The symmetric alternating voltage of primary winding is essential to avoid the magnetic saturation in the transformer [8]. Thus, the following requirements are necessary:

I. The switch pairs, S_7/S_{10} and S_8/S_9, which belong to identical full-bridge inverter are supposed to share the same duty-cycle; the same with the switch pairs, S_3/S_6 and S_4/S_5.

II. Power storage and release should be achieved in half cycle by the full-bridge inverter of battery port.

III. The switching frequency of the Buck is required to be an even multiple than that in the inverter.

To simplify the control loop, settings are defined as follows. The switching frequency of S_l and S_n is double than that in the inverter. Switch pairs S_3/S_6 and S_4/S_5, which are in PV port, complementarily conduct with the duty-cycle maintaining 50%. The duty-cycle of switch pairs S_7/S_{10} and S_8/S_9, values 25%. Control signal in mode I is illustrated in Fig.4. When the converter changes to mode II, signals of switch pairs S_7/S_{10} and S_8/S_9 turn in opposite and other signals remain the same correspondingly, which is not repeated here.

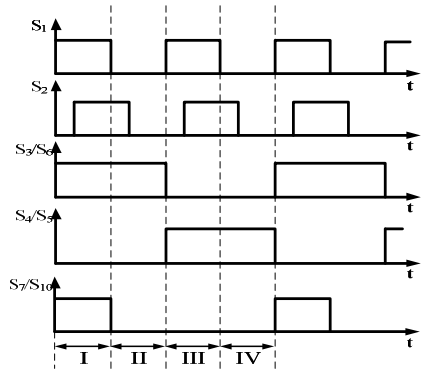

Fig. 4 Proposed control strategy

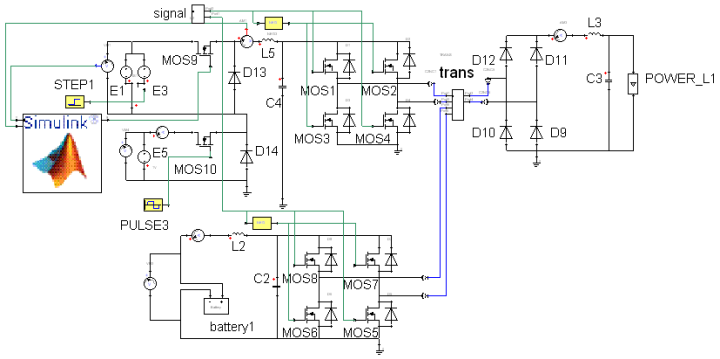

Fig. 5 Converter model in sim2sim simulation platform

Simulation

The simulation presents both steady-state and dynamic-state performance. The converter is modeled with two PVs by Simplorer.

Steady-state Simulation. Power flow is demonstrably verified in this part. The converter model is shown in Fig. 5. Given different input voltages of PV port, assume two groups to research mode I and mode II: i. Total PV voltage (Vin_1) =12V, the voltage of battery (Vin_2) =12V. ii. Total PV voltage (Vin_1) =16V, the voltage of battery (Vin_2) =12V

The Fig.6 and Fig.7 show the performance under two conditions above. Each one illustrates concern on the power flow of the converter. In the figure, P_{out} represents output power; P_{in1} represents input power of PV port and P_{in2} represents input power of battery port.

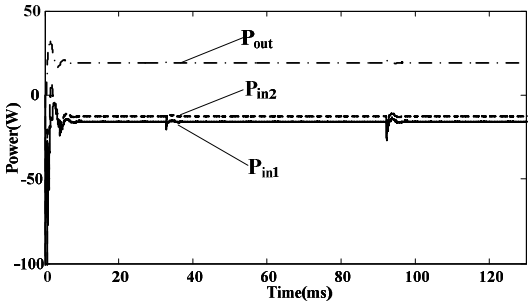

Fig.6 Power in Vin_1=12V, Vin_2=12V.

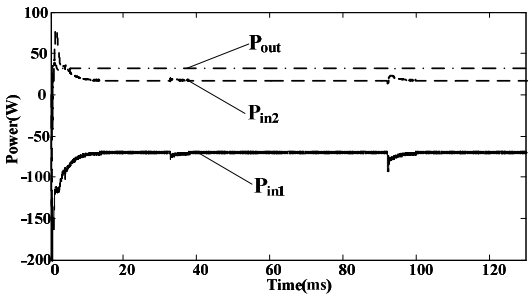

Fig.7 Power in Vin_1=16V, Vin_2=12V

It can be observed that, in the Fig.6, P_{in2} is below 0, showing that the battery is discharging at this circumstance. Conclusion can be drawn that the converter operates in mode I. Fig.7, on the contrary, shows that the converter operates in mode II with the same analysis. The two figures all together reveal that the proposed converter can be shifted between the two modes, supplying the load and achieving the bidirectional power flow.

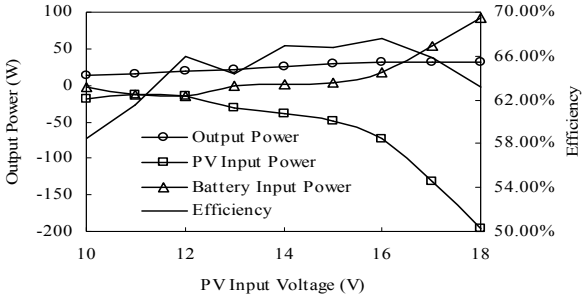

Fig.8 Efficiency curve

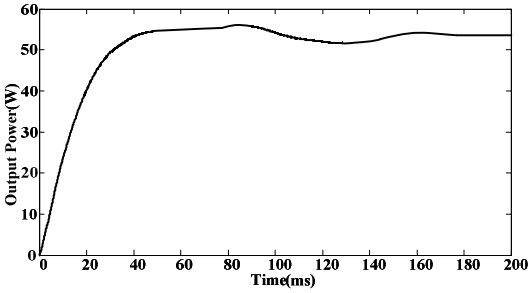

Fig.9 Waveform of power in the dynamic-state

In addition, assuming Vin_2 is constant, which values 12V, changing Vin_1, an efficiency curve can be drawn, as shown in Fig.8. It shows that when Vin_1 reaches 15V, the converter shifts to mode II from mode I. Meanwhile, the battery port changes to absorb power instead.

Dynamic-state Simulation. The output voltage of PV may change slightly due to the variation of light, temperature and other integrated factors. Dynamic-state simulation is used to test the performance of the system in the presence of such small disturbance. The simulation model is constructed on the Sim2sim which is a union simulation platform based on Matlab/Simulink and Simplorer. Perturbation and observation method is applied in the MPPT control of the Buck circuit in the head of PV module. The input voltage of the Buck circuit in the tail of PV module is V_{i2}=36V. The battery voltage V_{i3}=13.8V and the load power is 200W. Simulation results when the input voltage of the first Buck circuit Vi_1 falls from 36V to 30V are plotted in Fig.9.

The disturbance is exerted at t=80ms. As shown in Fig.9, the load becomes stable after about 100ms. This dynamic-state simulation has demonstrated that the system can effectively suppress the output voltage disturbance of the PV array and stabilize the load within a reasonable range after adding MPPT control to the ports of the PV array.

Conclusions

The three-port converter discussed in this paper has overcome the problems that the energy flow rarely achieve as an electric coupling converter and the multiple-winding transformer is difficult to manufacture as a magnetic coupling converter. By coordinating each switch, energy can flow between the three ports. Such a converter is mainly supplied by the PV array. Meanwhile, the battery port can provide or absorb energy according to the actual operating conditions. The operating principle and control strategy of this novel three-port converter is analyzed in this paper and the simulation shows the validity and effectiveness of the new topology.

Keywords: small-signal stability; microgrid; eigenvalue; perturbation; damping ratio; modal analysis

Abstract. This paper presents a perturbation based method for small-signal stability analysis in microgrid based on the uncertainty of microgrid parameters. The small-signal state-space model is built including the dynamic characteristics of the controllers, the power measurement and the system circuit and load dynamics model. The system eigenvalues of operating point at a steady-state in microgrid are obtained by the model. Based on perturbation theory, the corresponding low-frequency eigenvaluea and damping ratio of the microgrid system are calculated when the microgrid parameters changing in the range. Then the relationship between small-signal frequency stability and parameters changes can be determined. The validity of the proposed method and the importance of the stablility analysis of the microgrid small-signal are proved by the simulation results.

Introduction

The microgrid which is under performance of island mode, must be able to maintain its own voltage and frequency. In traditional power grid, frequency can be maintained by large inertia generator which existed in large-scale power plants, voltage can be maintained by adjusting the reactive power. In microgrid, due to the application on a large number of interface inverters, the system has very small or no inertia and poor overload ability, intermittent of output power in distributed power supply which generated by renewable energy and variation of load power, have increased the difficulties of conformity for microgrid frequency and voltage, this may lead to oscillatory instability when microgrid received disturbance.

So far, there is no systematic and complete stability analysis model and method for small-signal in microgrid due to the late development of the distributed generation technologies. The system overall modeling for network, load and inverter in microgrid is performed in[3].The ideal modeling is adopted for inverter, i.e. assume that the bandwidth of closed cycle controller inside inverter is larger than the bandwidth of power controller, current and voltage references can be traced quickly and precisely by closed cycle controlling in inverter, for inverter with smaller capacity, the switching frequency is high, and aforementioned assumption is feasible, but for inverter with large capacity, the bandwidth of the internal controller are limited by the reduction of switching frequency, this will lead to ignorance of some important dynamic properties if the ideal model of the invertered is still applied. Modeling for grid and load has considered the dynamic charateristics of the integrated circuit. Finally the model is applied for analyzing the variation of the eigenvalue of state matrix A in microgrid when the specific parameters changed, then the influence situations of stability on small signal which is impacted by specific parameters in microgrid are obtained. It shows that this kind of stability analysis for small signal is reasonable, however, uncertainty of operation which is caused by uncertainty of parameter variations in microgrid has not taken into account.

The system eigenvalues at a operating point in steady state are obtained in the first place in this paper, then the uncertainty of operation which is caused by uncertainty of parameter variations in microgrid has taken into account, the perturbation theory are applied for the new eigenvalues and eigenvectors under possible operating mode in microgrid and the modeling analysis is performed. Finally the effectiveness of the proposed method is verified by MATLAB simulations.

Space Model of Small Signal in Microgrid

The structure of microgrid is shown in Fig. 1. Micro-source 1 and Micro-source 2 are both connected with power system by inverters, which are controlled in mode of droop control of P-f and Q-V. Microgrid frequency is determined by power system when microgrid is in-grid, therefore the islanding situation is analyzed.

The principle of P-f and Q-V droop controlling is shown in Fig. 2. Instantaneous active power and reactive power of micro-source output are calculated by measured voltage and current. Then average power is obtained from low-pass filter, which is compared with reference power. Micro-source output frequency and voltage amplitude are made out by droop control.

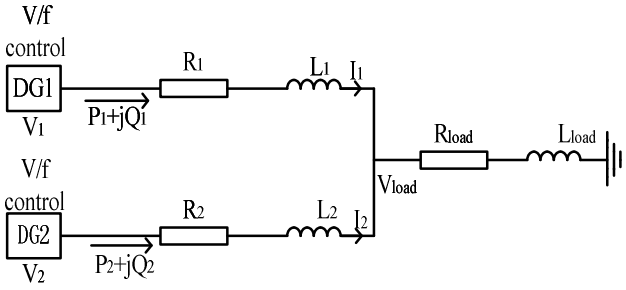

Figure 1. Equivalent circuit model

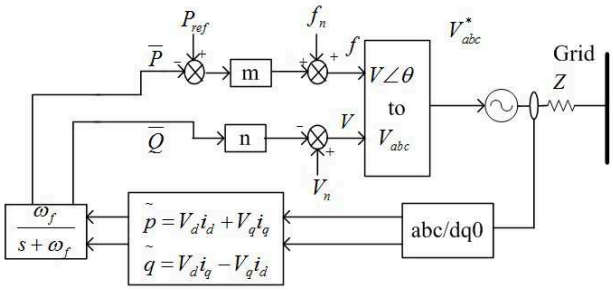

Figure 2. Structure ofP-f&Q-Vdroop controller

The instantaneous power calculation and the low-pass filter model are shown as follows.

The instantaneous power of distributed generation output can be obtained by the following formula:

$$\begin{cases} p_i = V_{di} i_{di} + V_{qi} i_{qi} \\ q_i = V_{di} i_{qi} - V_{qi} i_{di} \end{cases} \tag{1}$$

Linearization of Equation (1) is shown as follow:

$$\begin{cases} \Delta p_i = \Delta V_{di} i_{di0} + V_{di0} \Delta i_{di} + \Delta V_{qi} i_{qi0} + V_{qi0} \Delta i_{qi} \\ \Delta q_i = \Delta V_{di} i_{qi0} + V_{di0} \Delta i_{qi} - \Delta V_{qi} i_{di0} - V_{qi0} \Delta i_{di} \end{cases} \tag{2}$$

where Vdi0, Vqi0, idi0, iqi0 are voltages and currents of output axis d and axis q in distributed generation at steady state operating point, respectively.

The values of average power P and Q through low-pass filter when real-time active or reactive power is obtained by power calculation are shown as follow:

$$\begin{cases} \overline{P_i} = \dfrac{\omega_{fi}}{s+\omega_{fi}} p_i \\ \overline{Q_i} = \dfrac{\omega_{fi}}{s+\omega_{fi}} q_i \end{cases} \tag{3}$$

The linearization model for controller is shown as follows.

For each distributed power supply which is applied by droop controller, the mathematical expression for controller can be described by the following equations:

$$\begin{cases} \omega_i = \omega_{ni} - m_{pi}(\overline{P_i} - P_{refi}) \\ V_i = V_0 - n_{qi}(\overline{Q_i} - Q_{refi}) \end{cases} \tag{4}$$

Embedded (3) into (4), linearize at one point which is implemented by Taylor seried, the constant and one-time term are reserved, assume that $\Delta\omega ni=0$， $\Delta V_0=0$, then:

$$\begin{cases} \dot{\Delta\omega_i} = -\omega_{fi}\Delta\omega_i - m_{pi}\omega_{fi}\Delta p_i + m_{pi}\dot{\Delta P}_{refi} + m_{pi}\omega_{fi}\Delta P_{refi} \\ \dot{\Delta V_i} = -\omega_{fi}\Delta V_i - n_{qi}\omega_{fi}\Delta q_i \end{cases} \tag{5}$$

The value of δi can be obtained by following equation:

$$\delta_i = \arctan\frac{V_{qi}}{V_{di}} \tag{6}$$

where： $V_{di} = V_i\cos\delta_i$; $V_{qi} = V_i\sin\delta_i$ 。

Linearized Equation (6), the result is shown as follow:

$$\Delta\delta_i = k_{di}\Delta V_{di} + k_{qi}\Delta V_{qi} \tag{7}$$

where $k_{di} = -V_{qi0} / (V^2{}_{di} + V^2{}_{qi})$; $k_{di} = V_{di0} / (V^2{}_{di} + V^2{}_{qi})$.

Due to:

$$V_i = \sqrt{V^2{}_{di} + V^2{}_{qi}} \tag{8}$$

Linearization of Equation (8) is shown as follow:

$$\Delta V_i = l_{di}\Delta V_{di} + l_{qi}\Delta V_{qi} \tag{9}$$

where $l_{di} = V_{di0} / \sqrt{V^2{}_{di} + V^2{}_{qi}}$ $l_{qi} = V_{qi0} / \sqrt{V^2{}_{di} + V^2{}_{qi}}$.

Perturbation Theory and Modal Analysis Theory

The eigenvalues of system state matrix A and the relationship of the left and right eigenvectors are shown as follow:

$$\begin{cases} \mathrm{A}\varphi = \lambda\varphi \\ \phi^{\mathrm{T}}\mathrm{A} = \lambda\phi^{\mathrm{T}} \end{cases} \tag{10}$$

where A is state matrix of the system, λ is eigenvalue, φ and ϕ are corresponding left and right eigenvector, respectively;

There exist a variable ΔA in state matrix when a parameter changes, the relationship of the eigenvalues and eigenvector become:

$$(\mathrm{A}+\Delta\mathrm{A})(\varphi+\Delta\varphi)=(\lambda+\Delta\lambda)(\varphi+\Delta\varphi) \tag{11}$$

The values of system eigenvalues and right eigenvector after disturbance are shown as follow:

$$\begin{cases}\lambda^{'}=\lambda+\Delta\lambda\\ \varphi^{'}=\varphi+\Delta\varphi\end{cases} \tag{12}$$

According to perturbation,

$$\begin{cases}\Delta\lambda=\phi^{\mathrm{T}}\Delta\mathrm{A}\varphi\\ \lambda^{'}=\lambda+\Delta\lambda\end{cases} \tag{13}$$

A is seen in the afore-equation: the eigenvalues of $\mathrm{A}^{'}$=A+ΔA can be obtained by left and right eigenvectors and variable ΔA of matrix A which A has not been transformed.

Simulation Analysis

As is shown in Figs.1 and 2, the controller and circuit parameters of microgrid are shown as follow: the value of R_1+X_1 is (0.001+j0.0628) Ω, the equivalent circuit impedance R_2+X_2 is(0.001+j0.1256) Ω; the load impedance R_{load}+X_{load} is (2+0.314) Ω ;low-pass filter cutoff frequency ω_{f1} and ω_{f2} are 40 rad/s; frequency droop gain m_{p1} and m_{p2} are1.256 × 10^{-4}rad/(s • W) and 3.14 × 10^{-4} rad/(s • W) ,respectively; voltage droop gain n_{q1} and n_{q2} are 1×10^{-4} V/var and 5×10^{-4} V/var, respectively; regular operating frequency ω_n is 314 rad/s; voltage amplitude $V_0$is 311 V when there is no reactive power; rated active power P_{ref1} and P_{ref2} are 50 kV and 20 kW, respectively.

The eigenvalues of system at steady-state operating point when microgrid operated stably are calculated, -1.7653±0.3144i; -0.0235±0.2969i; -0.0199±0.0983i; -0.0001± 0.0096i; -0.0396±0.0013i; the electromechanical oscillation mode are the most commonly concern in stability analysis for small-signal in power system, i.e. low-frequency oscillation mode which rated at $0.2H_z$ ~$2.5H_z$. Therefore, main low-frequency eigenvalues -0.0190±0983i which real part close to imaginary axis are analyzed for eigenvalues of state matrix A of microgrid.

The uncertainty interval of equivalent circuit impedance in the system distributed at [0.85, 1.15] X_1 , [0.85, 1.15] X_2,i.e.X_1~[0.055264,0.072200],X_2~[0.011053,0.14440].Perturbation are used for calculating variations of main low-frequency eigenvalues of the system when the equivalent line impedance changes.

Conclusion

A small-signal state-space model of microgrid is built in this paper. This model concludes the inverter model and the dynamic network and load model. With this model, taking the parameter uncertainty into account, the low-frequency eigenvaluea and damping ratio of the microgrid system are calculated based on the perturbation when the microgrid parameters changing in the range. The analysis result of the low-frequency eigenvalues shows that the system may be unstable when the equivalent line impedance between distributed generations is very small. Increasing of the power controller droop gain will make the stability of the system worse. The system is less stable when the load impedance is much large. Time-domain simulation results verify the correctness of the eigenvalues calculation.

Keywords: electron beam welder, STM32, Digital, The cathode filament.

Abstract. The electron beam welding has high energy density, and has been widely applied in air space, the car and shipping industry. Traditional electron beam welding machine power supply system adopts the technology of the power frequency or medium frequency, with high volume, low efficiency and poor stability of electron beam. I put forward a digital filament power control scheme based on STM32, and introduce the hardware and software implementation method in detail. Experiments show that it can realize soft-start and soft-down process, and also be quickly identified and promptly forbid the output when filament fracture, which realize the intellectualization of filament power supply.

Introduction

Electronic beam welding is a kind of technology which uses electronic beam as heat source and it`s working principle is shown in Fig. 1. When the cathode filament of electronic gun is heated to a certain temperature, it will outcome electron. Electrons are accelerated to or close to the speed of light in electronic gun and focused by electromagnetic lens to the beam of high intensity and high energy. When the beam bombards welding surface, its strong kinetic energy turns to heat energy flashily. It can molten metals to achieves the welding purpose [1].

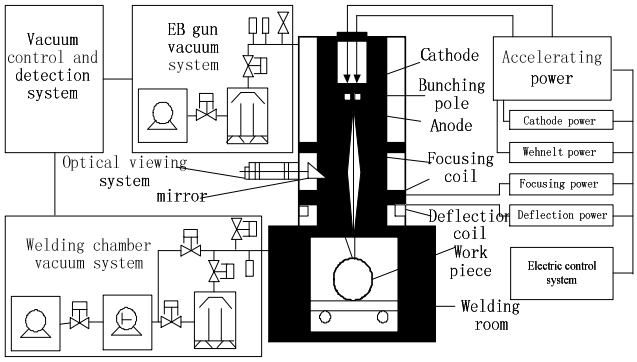

Fig. 1. The working principle of electron beam welder

Filament power is mainly used for heating the filament, which make its heat emission electrons, after controlling the filament heating power supply output voltage or current can achieve the goal of control overflow electronic, thereby indirectly control the electron beam size. In the process of actual welding, need the cathode filament can stable transmission electron and electron density within the electron gun is almost maintained constant, so it has a high requirement on the filament heating power.

The Existing Problems

In-depth study on the cathode filament heating power of the relevant literature, this paper [2] points out that the resistance of the filament in a cold only about one over ten of the thermal state, if use the primary side voltage control, power supply will have a great impact current on the cathode

filament, this will affect the service life of the filament and working state of the electron gun. And is described in the literature [3] if the filament transformer primary side adopts steady flow method, if burning filament in work break, second side current is almost zero, as a result of the action of a closed-loop controller will be the primary side current increase, making the original side voltage to maximum, so easy to damage the inverter circuit. Aiming at the problems mentioned in the above literature, I put forward a kind of limiting filament power supply output voltage is out of control.

System Structure and Design

Fig. 2 shows that the filament power is mainly composed of EMC filter, rectifier circuit, Buck circuit, full bridge inverter circuit, signal processing circuit, control circuit, fault protection circuit and high frequency transformer rectifier circuit, etc. Buck circuit is to realize the regulation of dc voltage amplitude and the full bridge inverter circuit is to complete DC/AC conversion. So we only need to change the duty cycle of IGBT of Buck circuit and it can change the output voltage or current to achieve closed-loop control purpose.

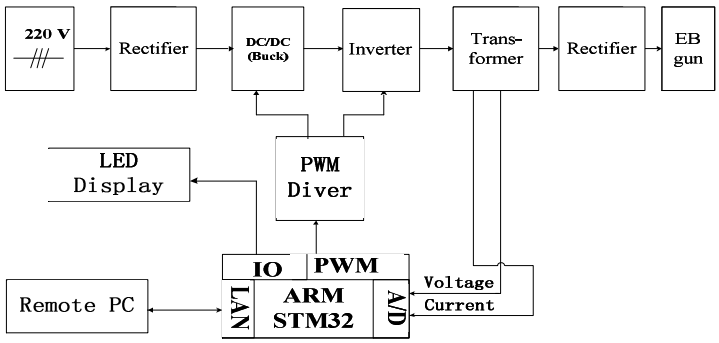

Fig. 2 The filament power supply block diagram

A. The Key Parameter Computation of Buck Circuit

Typical Buck circuit is shown in Fig. 3. The switching frequency is selected at 20,000Hz. Due to adopt a square wave full-bridge inverter and, don't change the duty cycle of PWM wave, so the full-bridge inverting circuit, transformer, rectifying and filter circuit can be equal to a DC voltage amplifier whose voltage gain is K. It only has a tiny lag which we don't have to consider.

Filament heating power supply is used for heating filament, and it can control the current through the filament which indirectly control the beam current when jointing.

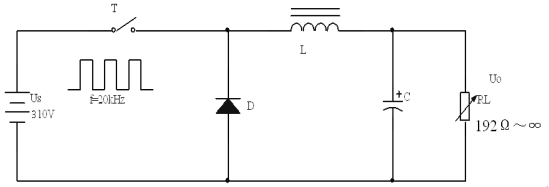

Fig. 3 Buck equivalent circuit of filament power

According to technological requirements, filament power whose maximum output voltage about 6 volt (corresponding to the filament transformer primary side input voltage is about 240 volt), and the output current is adjustable from 0 to 30 ampere, so the filament power supply output power changes form 0 to180 watt. In consideration of full bridge inverter circuit efficiency around 80%, the output power of Buck circuit is from 0 to 300 watt, which is equal to a load variable resistance from 192Ω to ∞.

The current ripple of Buck circuit is decided by the filter inductance, and the voltage ripple is decided by filter capacity [4]. The selection of capacity is relatively easy. The design of power inductance and filter capacitor is introduced as follows.

Inductance calculation formula $L=\frac{U_d-U_o}{\Delta I_L}DT$ (1)

Capacitance calculation formula $C=\frac{D_0}{8L_0f^2}\cdot\frac{U_0}{\Delta U_0}$ (2)

Where, U_d = = . 5 = 5 μ , current ripple ΔI_L=0.2I_d. Put these parameters into formula (1) and get the inductance value L=3.84mH. Consider actual situation, and finally choose the output filtering inductance L=4.5mH. Also Put the parameter into the formula (2) and get the minimum output capacitance C=5.6uF.The actual selection of output capacitance is C=10uF.

B. The CPU Control Circuit

CPU is the core part of the filament power supply, which mainly responsible for data acquisition, PI closed-loop control, PWM wave output, abnormal protection, parameter setting and external communication. CPU is selected as STM32F107 by ST company [5]. The chip adopts ARM 32-bit Cortex M3 as the core, and the highest frequency is up to 72 MHz. The chip has rich communication unit, including Ethernet interface, the asynchronous serial interface, USB devices, CAN devices, SPI and I2C module. Filament power also includes drive circuit, signal modulation circuit, protection circuit, communication circuit, display circuit and so on.

C. Filament Power Digital PI Closed Loop Control

With the output power gradually increasing of Buck circuit, the working mode of Buck circuit will change from DCM into CCM state. Therefore, the controlled system is a typical nonlinear control system [6].The digital PI control is adopted in the filament power supply.

When the filament in the cold state, if we adopt feedback voltage control and open filament power, which is bound to make a big impact current on the filament and it will affect the service life of cathode filament .To avoid this situation, the filament transformer primary side current control mode is adopted. If using current control, when the filament fracture, the inverter would output the high voltage that device is easily damaged. In order to solve those problems, it is necessary to limit the output voltage, and prompt the user filament fracture failure in time, then automatically output voltage down to zero.

The system software design

CPU mainly completes algorithms, generates PWM pulses, fault protection, data display and remote communication. System software is mainly to the STM32 chip programming. Programming languages adopts C language .

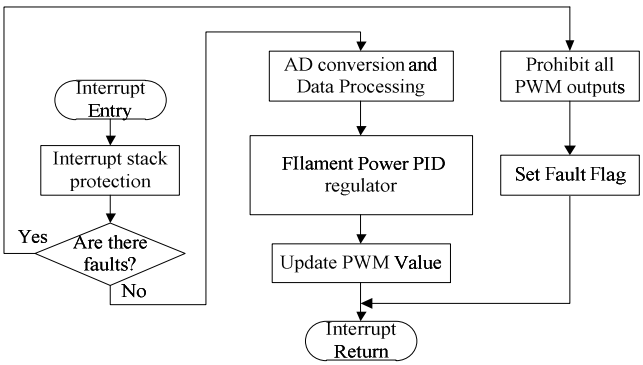

Fig. 4 Interrupt function flowchart

After entering the PWM interrupt, the flowchart shown in Figure 4. Firstly, feedback from various signals are sampled and processed. And then it will produce PWM pulses for filament supply. The PWM pluses is amplified and isolated by the driver circuit to drive IGBT, which realizes closed-loop control of the entire power supply system.

The Experimental Results

Very thin slices of tungsten filament is usually used for Electron beam welder cathode filament, and its resistance is usually extraordinary small .It is usually need to add adjustable voltage from 0 to 6 volt on both ends of the filament, and the maximum current through filament can be up to 30 ampere . We use the filament power on an electron beam welding machine by a well-known manufacturer, and some working waveforms of filament power are shown in Fig. 6.

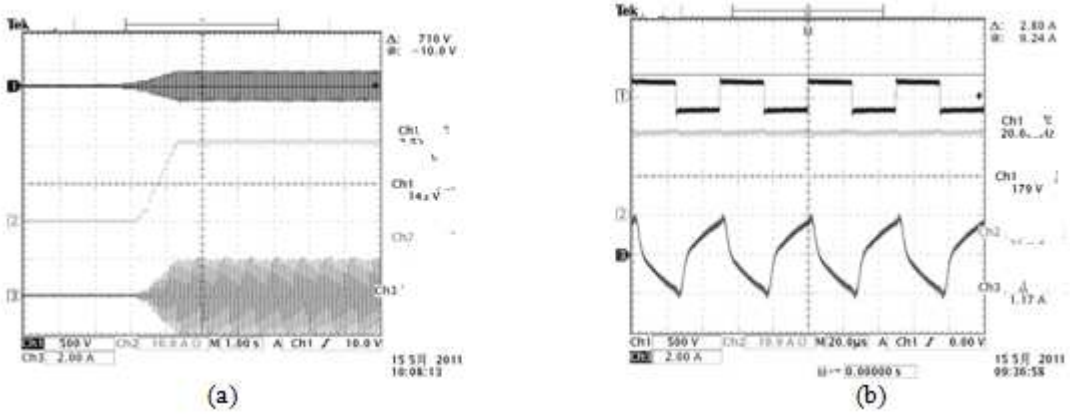

Fig. 6 (a) is filament power starting waveform and (b) is filament power steady-state waveform at 20 A

Ch1, Ch3 are filament transformer primary side voltage and current waveforms, and Ch2 is filament current waveform. We can see that filament power can well realize the soft start in fig 7 and almost no overshoot. And also we found that filament current ripple is very small in fig 8, which is controlled within 5%. These prove filament power has achieved good control effect.

Summary

Digital filament power based on Arm (STM32F107) has high precision, small size, full digital etc. All parameters can be set directly through the HMI or remote PC. It can realize soft-start and soft-down process, and also be quickly identified and promptly forbid the output when filament fracture.

Study on Buck-Boost Integrated Type Three-Port Converter

Zhu Lei Shao[1, a]

[1] College of Electrical and Information Engineering, Xuchang University, Xuchang 461000, China

[a]cyzyszl@163.com

Keywords: DC-DC converter; buck-boost integrated type; three port converter

Abstract. Aiming at simplifying the structure of power supply system of new energy, a buck-boost integrated type three-port converter is designed in this paper. The three-port converter can replace three separate converters, which makes the system structure is simplified and manufacturing cost is reduced. The three-port converter realizes the current expansion and ripple suppression by adopting inductor interleaved parallel bridge arm structure. The topology and control strategy of the three-port converter are analyzed in this paper. From the experimental results, the inductor current ripple and realization of soft switch meet the design requirement. The buck-boost integrated type three-port converter is applicable to the new energy power supply system.

Introduction

With the development of new energy application technology, the converter is more and more applied in new energy power supply system. All kinds of new energy power supply system include energy storage module and power conversion module, which contains a plurality of converters. With the increase of the number of converters, the structure of system becomes complex, and the manufacturing cost becomes high. The multi-port converter can replace multiple independent converters, and it can control the input power, the energy storage module and the load at the same time. The application of three-port converter makes the system structure is simplified and manufacturing cost is reduced.

A buck-boost integrated type three-port converter is designed in this paper, which can realize the free energy transmission between three ports. Comparing with the traditional three-port converter, the buck-boost integrated type three-port converter has a simpler circuit structure, and power switch can turn on in zero voltage. The adopting of coupling inductor makes symmetric bridge arm structure and reduces the inductor current ripple. The buck-boost integrated type three-port converter is suitable for large current power supply system.

Circuit topology and control strategy

The ports of three-port converter are defined as port1, port2 and port3. The full bridge structure unit and half bridge structure unit are respectively arranged at both sides of the transformer TX1. The buck-boost bidirectional conversion and the full bridge structure unit are integrated together. The buck structure unit and the boost structure unit share a group of bridge arm of full bridge structure unit. The connection point of the high voltage port of buck-boost structure unit and the full bridge structure unit are port1. The low voltage port of buck-boost structure unit is port2. The port3 transmit energy to port1 and port2 by transformer and half bridge structure unit. The circuit topology of the buck-boost integrated type three-port converter is shown in Fig. 1.

In order to control the voltages and currents of ports, PWM phase shift control strategy is adopted in three-port converter. The power switches of bridge arm alternately conducted for avoiding short circuit of voltage source. The power switch M1 and M2 control voltages and currents of port1 and port2, and the duty ratio of M1 and M2 is D and 1-D. The driving signal of M1 ahead of driving signal of M2 about half cycle for getting AC voltage of no DC component in the middle of the bridge. In order to transfer energy between the ports, the circuit units of both sides of the transformer adopt phase shift control strategy. The shifting-phase angle is φ, which is the phase angle of driving signal of M5 advancing driving signal of M1. The duty ratio of M5 and M6 are 0.5. The direction and amount of energy transmission between ports is controlled by adjusting the phase angle.

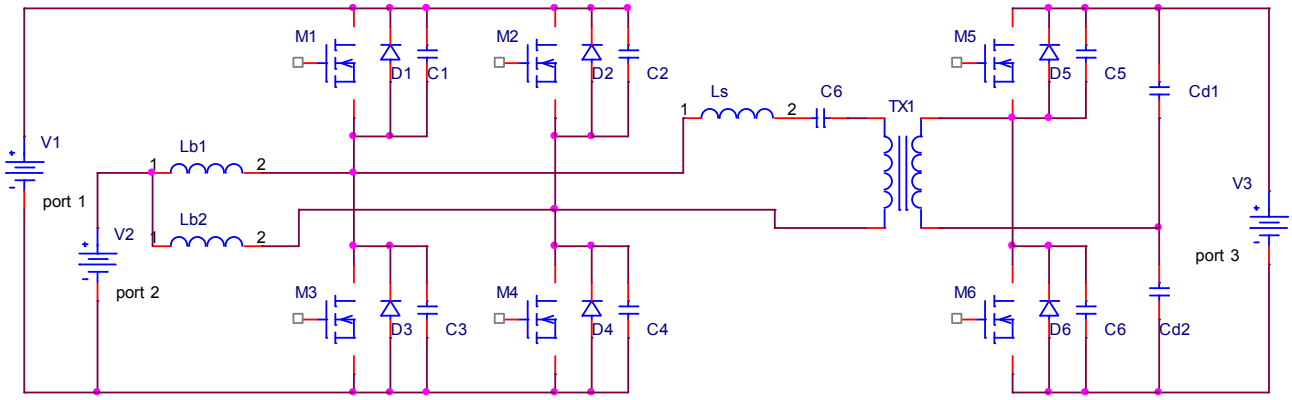

Fig. 1 The circuit topology of buck-boost integrated type three-port converter

Analysis of inductor current and port current ripple

The reverse coupling inductor can obtain bigger equivalent inductance, which can make the volume of magnetic core be reduced. The inductive coupling coefficient is k, which indicates the close degree of coupling. When the duty ratio is less than 0.5, the inductor current ripple Δi_{Lb1} and Δi_{Lb2} can be got in formula (1).

$$\Delta i_{Lb1} = \Delta i_{Lb2} = \left(\frac{V_1}{1+k} - V_2 \right) \frac{DT_s}{(1-k)L_b} \tag{1}$$

In the formula (1), V_1 is the voltage of port1, V_2 is the voltage of port2, and D is the duty ratio of power switch. T_s is the period of driving signal, and L_b is the value of L_{b1} and L_{b2}. When $(1-k)L_b$ is a constant, the bigger the inductive coupling coefficient k is, the smaller the inductor current ripple is. When the duty ratio is bigger than 0.5, the conclusion is similar to formula (1).

To make the comparison, the different topologies of inductor current ripple in port2 can be got in formula (2), formula (3) and formula (4).

$$\Delta i_2^{(1)} = \frac{V_1 - V_2}{L_b^{(1)}} DT_S \tag{2}$$

$$\Delta i_2^{(2)} = \frac{V_1 - 2V_2}{L_b^{(2)}} DT_S \tag{3}$$

$$\Delta i_2^{(3)} = \frac{V_1 - 2V_2}{(1-k)L_b^{(3)}} DT_S \tag{4}$$

$\Delta i_2^{(1)}$ is the inductor current ripple of a single inductor, $\Delta i_2^{(2)}$ is the inductor current ripple of parallel inductance, and $\Delta i_2^{(3)}$ is the inductor current ripple of coupling inductance. From the formula (2), (3) and (4), reducing current ripple of port2 should satisfy the condition as formula (5).

$$\lambda \geq 1 - \frac{1}{1/D - 1} \tag{5}$$

In the formula (5), $\lambda = L_b^{(2)} / L_b^{(1)}$, D is the duty ratio of power switch. If $(1-k)L_b^{(3)} = L_b^{(2)}$, $\Delta i_2^{(2)} = \Delta i_2^{(3)}$. When three-port circuit meet the formula (5) and $L_b^{(3)} = L_b^{(2)} / (1-k)$, the current ripple can be effectively reduced.

Analysis of soft switching condition

The soft switching technology can reduce the power consumption of converter. When the duty ratio is less than 0.5, the condition of soft switching is analyzed. The condition of soft switching of M1 to M4 can be got in formula (6) and formula (7)

The condition of soft switching of M1 and M2 is formula (6)

$$i_1(t)-(I_{Lb}-\frac{1}{2}\Delta i_{Lb}^{(1)})-\frac{1}{2}\Delta i_{Lb}^{(2)}>0 \tag{6}$$

The condition of soft switching of M3 and M4 is formula (7)

$$i_1(t)+(I_{Lb}+\frac{1}{2}\Delta i_{Lb}^{(1)})-\frac{1}{2}\Delta i_{Lb}^{(2)}>0 \tag{7}$$

In the formula (6) and (7), $i_1(t)$ is the current transformer, I_{Lb} is the DC component of the inductor current, which can be got in formula (8). $\Delta i_{Lb}^{(1)}$ is the inductor current ripple of L_{b1}, $\Delta i_{Lb}^{(2)}$ is the inductor current ripple of L_{b2}.

$$I_{Lb}=\frac{P_2}{2DV_1} \tag{8}$$

In the formula (8), P_2 is transmission power of port2, V_1 is the power supply voltage of port2. D is the duty ratio of power switch.

The inductor current ripple $\Delta i_{Lb}^{(1)}$ and $\Delta i_{Lb}^{(2)}$ can be got in formula (9) and (10).

$$\Delta i_{Lb}^{(1)}=\frac{DV_1}{L_b^{(1)}}(1-D)T_S \tag{9}$$

$$\Delta i_{Lb}^{(2)}=\frac{DV_1}{L_b^{(2)}}(1-D)T_S \tag{10}$$

In the formula (9) and (10), $L_b^{(1)}$ is the value of L_{b1}, $L_b^{(2)}$ is the value of L_{b2}. T_S is the period of power switch driving signal.

Experimental verification

In order to verify the circuit performance, the buck-boost integrated type three-port converter is built in PSpice. The circuit parameter settings are as follows. The port1 voltage V_1 is in 200V to 260V, the port2 voltage V_2 is in 100V to 120V, and the port3 voltage V_3 is in 200V. The power switching frequency f_S is 50kHz. The DC isolation capacitor C_b is 8uF. The series inductance L_S is 94uH. The transformer turns ratio n is 2. The divider capacitor C_{d1} and C_{d2} are both 1000uF. The coupling coefficient k is 0.5. The coupling inductance L_b is 67uH. When three-port converter is in full load condition, the waveforms of circuit nodes were shown in Fig. 2.

As shown in Fig.2, the transformer primary voltage Vab is shown on the top of the figure, the transformer secondary voltage Vcd is shown in the middle of the figure, and the coupling inductor current ILb is shown in the bottom of the figure. Because Vab is ahead of Vcd, port1 transmits energy to port2 and port3. The transformer primary voltage range is from -320V to 320V, and the transformer secondary voltage range is from -160V to 160V. When the port1 does not work, Vcd will be ahead of Vab. The port2 transmits energy to port3. With the increase of the inductance coupling coefficient, the current effective value of power switch will decrease gradually. So increasing inductance coupling coefficient can effectively reduce the current stress of power switch, and the power consumption of the circuit is reduced. But the inductance coupling coefficient should be small for getting a wide range of soft switching. So the selection of the inductance coupling coefficient should consider the efficiency of circuit and soft switching conditions at the same time. Three-port converter can transmit energy between three ports normally, and the power switches are working in the soft switching conditions.

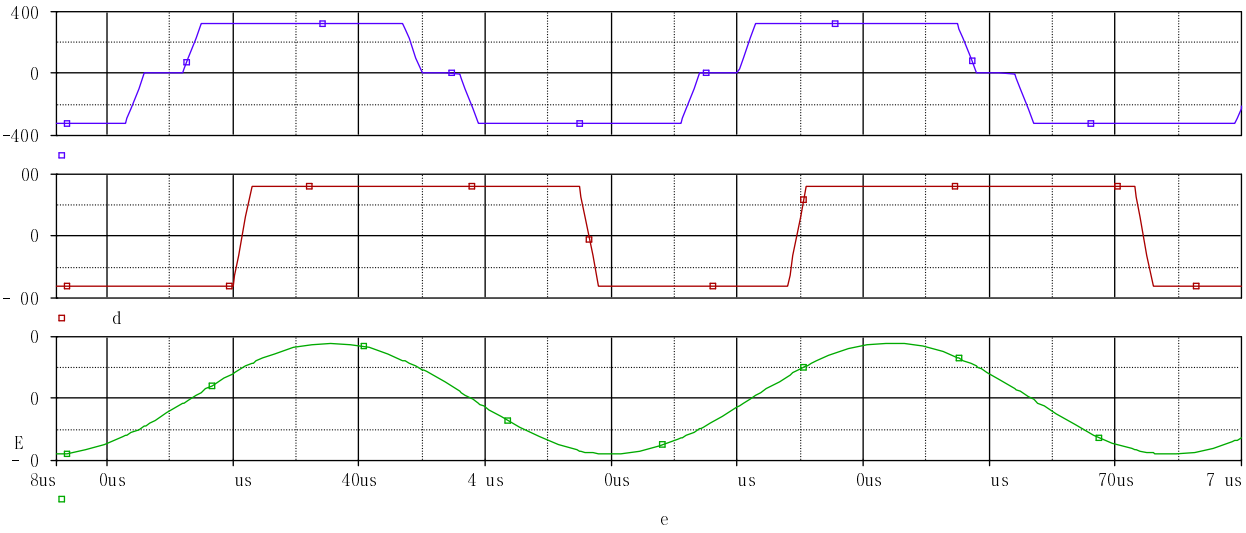

Fig. 2 The waveforms of circuit nodes in full load condition

Conclusions

A buck-boost integrated type three-port converter is designed in this paper, which can simplify the structure of power supply system. The three-port converter has the advantages of simple structure. The two bridge arms of three-port converter are symmetrical and inductor is in interleaved parallel connection state, which realizes the current expansion and ripple suppression at the same time. By reasonably selecting coupling coefficient, inductor current ripple is effectively reduced, and soft switching range is enlarged. From the experimental results, the buck-boost integrated type three-port converter has high efficiency, and the design of three-port converter meets the design requirements.

School of Mechanical and Electrical Engineering, Chongqing Creation Vocational College, China

[a]email: 18811778@qq.com

Keywords: SBL, DMT, RVM, channel estimation, regression analysis

Abstract. This paper introduces the power line communications channel estimation method based on sparse Bayesian regression, it is through the use of Bayesian learning framework that provides a sparse model in the presence of noise accurate channel estimation model. Improved channel estimation using the power line for the system to consider the frequency domain equalization (FREQ) transmitter and receiver, the bit error rate and comparing the two methods for generating various channel estimation techniques, and (BER) performance curves simulation the results show that the performance of the method is better than the previous method of least squares technique.

Introduction

Power Line Communication (PLC) and more attention, because they represent two LAN access and efficient and economical solutions. Multi-Carrier (MC) based system is popular for wireline and wireless communications because of its many advantages, the use of DMT is well suited PLC channel [4] which has the advantage of flexibility and without regard to the loading position of signal to noise ratio (SNR). During modem initialization phase, the frequency response of the channel SNR estimate is usually performed measurements. When this paper, we use Bayesian regression and sparse mode, channel estimation, reducing the signal to noise ratio is low.

System Model

System block diagram of Figure 1, showing a discrete multitone (DMT) link, comprising: a DMT modulation, channel model, DMT demodulator, and the frequency domain equalizer.

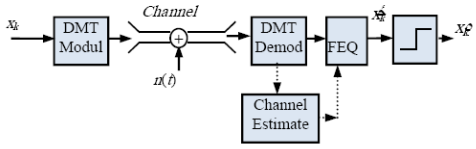

Fig.1-1: DMT system block diagram with FEQ at receiver

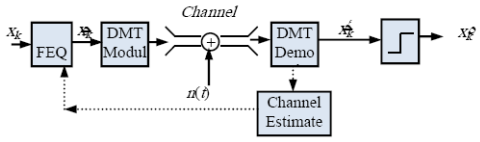

Fig.1-2: DMT system block diagram with FEQ at transmitter

DMT-speed transfer [3] data stream, while the R, N low-rate stream to a subcarrier. For any data stream using N R / N indicates that it is sent to a 2N-point Fast Fourier Transform (IFFT) block, the N complex frequency domain to the time domain data conversion, as shown in Figure 2. V is an extended cyclic data to 2N time domain samples of the formation of cyclic extension DMT.

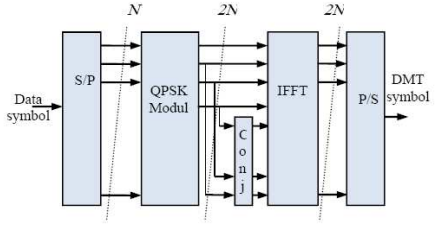

Fig.2: Block diagram of the DMT modulator

The use of DMT which is similar to the asymmetric digital subscriber line (ADSL) configuration, but is fixed for each subchannel modulation (i.e., QPSK). V cycle length of the data included in the

selection channel interference (ISI) and inter-channel delay spread such that the maximum time span cyclical DMT.

The PLC Channel Model

Power line network and the traditional media, such as topology and physical properties of different twisted pair, coaxial or fiber optic cables, the complexity PLC so that when high frequency signals [2], the first is caused by attenuation of the line length and increasing the frequency of the transmitted signal low-pass behavior, the second is caused by impedance mismatch at the branch multipath propagation. In this article, we will use the access domain measurement model is used for signal transmission [2] to simplify the PLC channel model is described as follows:

$$H(f)=\sum_{i=1}^{M} g_i e^{-(a_0+a_1 f^k)d_i} e^{-j2\pi f\frac{d_i}{v_p}} \quad (1)$$

Where M is the total number of paths, gi is the weighting factor of the corresponding path, di is the path length, vp is the phase velocity. Parameters a0, a1, and k low-pass characteristic described channel. PLC channel noise can be colored Gaussian noise with a high-power low-frequency modeling. Noise power spectral density N (f) = N0 + N1e-f/f0 [8], where N0, N1, and F0 are equal -140dB/Hz, -38dB/Hz, and 0.7MHz. The PLC channel model is simple, suitable for simulation and analysis of system performance PLC.

Linear System Representation of Signal Transmission

We will consider in the PLC channel has a CIR does not exceed the CP. Thus, the inserted sample V CP and dropping the first transmitter receiver provides real-valued time domain samples sampled (baud) of the received DMT is more than one data block:

$$r = Cx + n \quad (2)$$

Where the vector r= [R0，R1，R2，...，R2N-1]Tcontaining the time domain samples of the received vector x= [X0，X1，X2，...，X2N-1]T containing the transmitted the time-domain samples and the vector n= [N0，N1，N2，...，N2N-1]T containing the sample is limited to the average frequency power (variance) of the additive noiseσN2. Matrix multiplication operator in (2) circular convolution is no inter-symbol interference (ISI). The cyclic matrix is expressed as

$$C=\begin{bmatrix} h_0 & 0 & \cdots & 0 & h_L & \cdots & h_1 \\ h_1 & h_0 & & & & & \vdots \\ \vdots & & \ddots & & & & h_L \\ h_L & & & & & & \\ 0 & h_L & & & & & \\ \vdots & \ddots & \ddots & & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & h_L & \cdots & h_1 & h_0 \end{bmatrix} \quad (3)$$

$$\begin{bmatrix} R_0 \\ \vdots \\ R_{2N-1} \end{bmatrix}=\begin{bmatrix} H_0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & H_{2N-1} \end{bmatrix}\begin{bmatrix} X_0 \\ \vdots \\ X_{2N-1} \end{bmatrix}+\begin{bmatrix} N_0 \\ \vdots \\ N_{2N-1} \end{bmatrix} \quad (4)$$

When in the frequency domain（X = W2N-1 [X0，X1，X2，...，X2N-1] T）of the transmission data generation, and the received samples are converted into the frequency domain（W2N1= [R0, R1, R2，...，R 2 N-1] T）, the resulting input-output relationship is very simple:

W2Nn=[N0，N1，N2，……N2N-1] T. From (4) we can see that the symbols for each frequency-domain symbols received in each subchannel is simply a scaled version of the transmission frequency domain plus Gaussian colored noise. Furthermore, each subchannel can be processed independently of the other subchannels. In other words, the CP and the converted block transmission time dispersive channel is 2N parallel flat narrow-band channels, each channel gain Hk or tone additive Gaussian noise with so called discrete multitone transmission (DMT).

Channel Estimation

When initialization channel estimation, using a pseudo-random sequence of frequency-domain

$$R_b = X_b H + N \quad (5)$$

$$H_k=\sum_{n=0}^{L-1} h_n e^{-j2\pi n/2N} \quad (6)$$

In (5), R b is the received signal vector 2N × 1 times, the transmission signal of the diagonal matrix Xb, N is the noise vector of 2N complex comprising subcarriers, H is a complex vector containing the entire transmitter and receiver channel gain between.

The current problem is that the frequency domain channel estimate vector, Hk, (K = 0,1,2,3, …, n-1) time-domain FFT L tap gains unknown sample interval, which contains the desired selection L the maximum delay spread, and does not exceed the CP length, V. tone of each of the 2n channel frequency domain model:

Where h is the channel taps in discrete time n. From (5) to perform channel estimation, we first training symbol by the conjugate of each frequency domain to produce a vector is [7]:

$$T_b = X_b^H R_b = X_b^H X_b H + X_b^H N \quad (7) \qquad t_b = h + n' \quad (8)$$

Where the superscript H, said conjugate transpose.

In the noise free case, the frequency domain channel gain in type 7 Tb contains the complete. When the channel impulse response values for the duration of compulsory sample number zero is larger than the cyclic prefix, so it will need to modify the LS estimation [11]. We will use a similar to that used for the relevance vector machine (RVM) model, the inverse Fourier transform of the DMT channel estimation (10) fitted regression model as follows:

tb =[t0，t1，t2，...，t2N-1] T, is a time-domain signal, target vector of h =[h0，h1，h2，..., hV, 0，...，0] T 2N x 1 channel vector, and the vector N' = [h0, H1, H2,..., h2N-1] T contains the band limited Gauss the noise variance σ'2

In order to avoid the influence of noise to observe the formula in the H model (8) in the TB, will use the sparse Bayesian regression, it has set the regression weight appropriate for automatic performance of zero, to avoid fitting in signal noise. Assume that the channel can use the function y (n) approximation is a linear combination of functions:

$$y(n) = \sum_i w_i \varphi(n - i) \quad (9)$$

Simulation Results

In the MATLAB simulation is used to evaluate the performance of DMT/ RVM system. The simulation parameters were: DMT 2N= 512 FFT size, cyclic prefix length. =64. Sub channel tones used for 6-255, which uses QPSK modulation scheme, each sub carrier. The additive channel noise is band limited Gauss color and power Delta n2. Channel in the actual power line length to generate the L=43. model parameters of the model: k = 1, a0=0, a1=7.8 * 10-10 s/ m and the path parameter gi={0.64, 0.38, -0.15, 0.05} and the corresponding DI / M ={200222.4244.8267.5}.

In Figure 3, we present an example, the target vector equation of time domain samples (8), in the noise free case, the channel impulse response and superimposed in the same product.

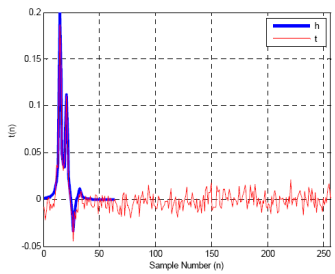

Fig.3: An example target vector

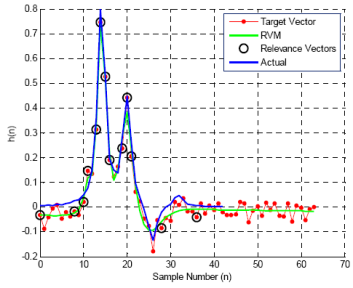

Fig.4. Channel impulse response and its estimate obtained using the RVM method

These channels are assumed to remain constant guide each detection frequency sequence in the. Figure 4 depicts the actual in cyclic prefix range of sampling channel if it is equal to zero time values larger than the cyclic prefix. The target vector is drawn at the same time range equivalent to least square channel estimation (LS). Bias sparse regression algorithm to deal with the target vector

samples, to filter out noise at 5 dB snr. Non zero regression weight position determination and circular plot. In 65 weight, defines 13 nonzero weights, from a total of 65, the remaining 52 are sparse mode is set to zero.

That estimate the impact on each sub carrier frequency attenuation of channel impulse response (equilibrium), from Figure 5 we see model, sparse channel estimation in the frequency domain of the adjacent smooth with changes between tone and closer to the ideal frequency response.

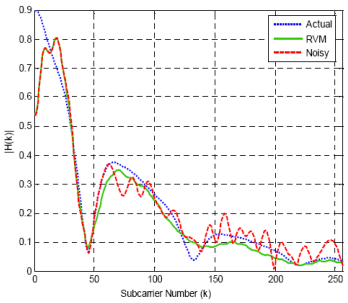

Fig.5. Frequency response of actual and estimated channel

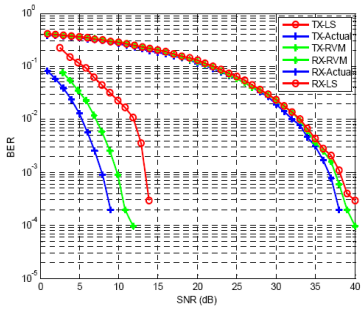

Fig.6. BER curves with equalization at transmitter and receiver

At the same time, based on the curve of bit error rate performance of the actual channel (perfect estimation) is added as a reference marker for the performance of the same plot in figure 6. We also compare the map accurate channel estimation is achieved when the 6 letter in the receiver, the transmitter. We can make two suggestions: first, this is obviously, the letter in the transmitter receiver is much better than that in the same channel estimation. Second, when the signal at the receiver in the channel estimation error rate performance has a limited effect on accuracy improvement (Rx marker), and bit error rate curve is almost the same channel, the channel estimation, sparse regression, and LS channel estimation. Equilibrium process of fading in low signal to noise ratio in this case, the channel for improved accuracy is not important.

Conclusion

In order to achieve the full utilization of the available bandwidth of DMT data transmission system of power line, channel equalization is a prerequisite. In this paper, we propose an improved channel estimation method, the sparse Bayesian regression method based on DMT communication system by RVM. The method in the accuracy of channel estimation to improve frequency equalization. Frequency domain equalization in the transmitter at the receiving end to estimate curve than the BER performance of precision is more sensitive and has a better channel. The least square method of sparse proposed regression method is superior to the traditional.

Key words: anti-islanding detection, passivity, EL model, grid-connected inverter.

Abstract. Based on the basic principles of anti-islanding detection, this paper puts forward an anti-islanding(AI) detection method which combined/q-axis voltage decoupling and positive feedback with Euler-Lagrange(EL) model .The proposed method is classified as an passive islanding detection method and it is based on the voltage change at the point of common coupling (PCC) that occurs in islanding .In the method, Add the d-axis decoupling voltage of PCC to the d-axis reference current of the EL model. A simulation study shows that the method is simple and feasible.

Introduction

Single-stage photovoltaic (PV) system has the advantages of not having geographical constraints and sustainable development. PV becomes an important electricity generation which to replace the traditional generation and to ease the energy shortage situation. Since the connected-grid photovoltaic system becomes more and more available in our daily lives, we must focus on the problem of anti-islanding detection.

The meaning of Islanding phenomenon is that the grid turns on electrical failure or interrupts the power supply of natural factors and other reasons, the grid-connected PV system is still supplying the load to the surrounding, thus forming a self-contained power supply company uncontrollable island [1]. Reclosing islanding can cause problems; against normal power supply automatic or manual recovery interference and bring to the relevant personnel shock-hazard [2]. Researching islanding detection is significance.

Anti-Islanding detection method consists of detection grid side and detection inverter-Side. Grid side detection can be divided into detection which based on power line carrier communication, based on monitoring and data collection methods law and so on. Inverter side detection methods are divided into passive detection and active detection [3]. Passive detection which includes: voltage / frequency detection, voltage harmonics detection, voltage phase mutation detection, critical power change rate detection. Active detection includes: active power perturbation method, reactive power compensation method, active frequency offset method, sliding mode frequency shift method, specific frequency impedance measurement method, Sandia voltage shift method [4,5].

Passive detection methods are directly measuring the output power of the inverter or the changes of voltage and frequency in the PCC to determine whether the islands happen. Proactive detection method without detecting blind spots, no non-detection zone (NDZ), but larger output harmonics and the control algorithm is more complex, which is difficult to achieve practical application [6,7].

As a result, this article puts forward an anti-islanding detection method which combines d/q-axis voltage decoupling and positive feedback with Euler-Lagrange (EL) model.

The topology and modeling of photovoltaic inverter system

The single-stage photovoltaic grid-connected inverter topology is shown in Fig. 1.

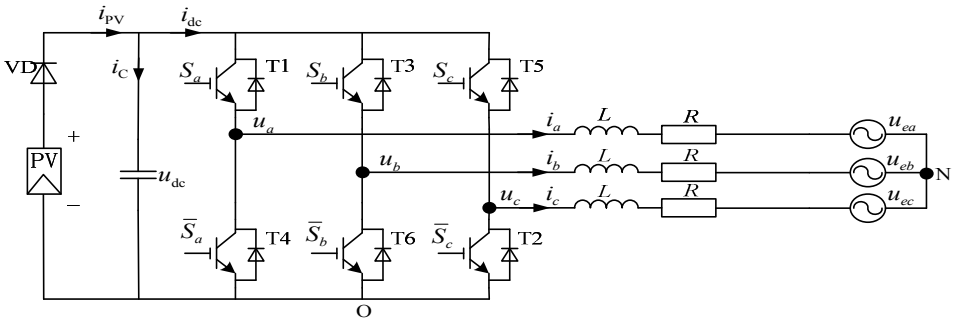

Fig.1. Grid-connected PV inverter topology.

Fig. 1 is the PV grid-connected inverter topology, in the case of three-phase balanced grid voltage, PV grid-connected inverter mathematical model of the three-phase abc coordinates is [8]:

$$\begin{cases} L\dfrac{di_a}{dt} = -Ri_a + u_{dc}\left(S_a - \dfrac{1}{3}\sum_{j=a,b,c} S_j\right) - u_{ea} = -Ri_a + u_a - u_{ea} \\ L\dfrac{di_b}{dt} = -Ri_b + u_{dc}\left(S_b - \dfrac{1}{3}\sum_{j=a,b,c} S_j\right) - u_{eb} = -Ri_b + u_b - u_{eb} \\ L\dfrac{di_c}{dt} = -Ri_c + u_{dc}\left(S_c - \dfrac{1}{3}\sum_{j=a,b,c} S_j\right) - u_{ec} = -Ri_c + u_c - u_{ec} \\ C\dfrac{du_{dc}}{dt} = -i_{pv} - S_a i_a - S_b i_b - S_c i_c \end{cases} \tag{1}$$

In Eq. 1, S_a, S_b, S_c is the inverter switching function respectively, S_j is defined as unipolar binary logic switch function, when the $S_j(j=u,v,w)=1$, it should turn on the up bridge arm, turn off the down bridge arm, when the $S_j=0$, it should turn off the up bridge arm, turn on the down bridge arm. L is the inverse output reactors, R is the internal resistance of the equivalent resistance of resistor and u_{dc} is the inverter system for the DC-side bus voltage, i_{pv} is the DC current supplied by the PV array for, i_{dc} is the current flowing to the inverter, i_a, i_b, i_c is the inverter output phase current, u_a, u_b, u_c is the variable-side three-phase AC phase voltage, u_{ea}, u_{eb}, u_{ec} phase grid side three-phase AC voltage.

Due to time-varying three-phase sinusoidal ac voltage exists in the mathematical model of three-phase ABC coordinate system, in order to facilitate the design of the controller, through the transformation matrix:

$$\boldsymbol{Q}_{abc/dq0} = \frac{2}{3}\begin{pmatrix} \cos\omega t & \cos(\omega t - 120^\circ) & \cos(\omega t + 120^\circ) \\ \sin\omega t & \sin(\omega t - 120^\circ) & \sin(\omega t + 120^\circ) \\ \dfrac{1}{2} & \dfrac{1}{2} & \dfrac{1}{2} \end{pmatrix}$$

To convert it to the mathematical model of the two-phase synchronous rotating d/q-axis coordinates system

$$\begin{cases} L\dfrac{di_d}{dt} = -Ri_d + \omega L i_q + u_d - u_{ed} \\ L\dfrac{di_q}{dt} = -Ri_q + \omega L i_d + u_q - u_{eq} \\ \dfrac{2}{3}C\dfrac{du_{dc}}{dt} = -\dfrac{2}{3}i_{pv} - i_{dc} = -\dfrac{2}{3}i_{pv} - S_d i_d - S_q i_q \\ u_d = S_d u_{dc},\ u_q = S_q u_{dc} \end{cases} \tag{2}$$

The above formula, i_d and i_q are in the d/q-axis component of the current output terminal, u_{ed} and u_{eq} are the output terminal voltages in the d/q-axis component, S_d and S_q are the switching functions in the d/q-axis component.

Islanding detection methods and passivity control algorithms

Islanding detection methods

For RLC load, as defined in standards, is assumed. The relationships between the RLC load active/reactive power and the voltage/frequency are [4, 5]:

$$P = V^2 / R \quad (3)$$

$$Q = V^2 (\omega C - 1/\omega L) \quad (4)$$

For voltage feedback, the mechanism is described as in Fig. 2. When the inverter-sensed output voltage is increasing, the AI feedback will command the inverter active-power output to be increased. Due to the load characteristic in (3), the voltage will keep increasing in order to balance the active power. The increased voltage will further drive the inverter active power up due to the AI feedback. As a result, the voltage will be eventually out of the nominal ranges so that the islanding can be detected. Similar but opposite destabilization occurs when the sensed voltage is decreasing initially.

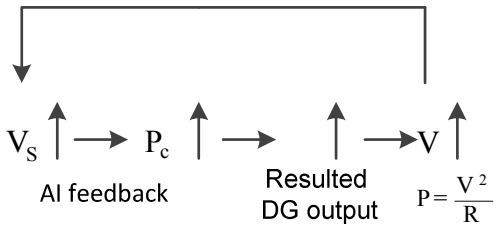

Fig. 2. Voltage positive feedback concept.

Fig. 3 illustrates a d-axis voltage-feedback scheme. When the inverter-sensed and computed d-axis voltage are increasing, the AI feedback will command the inverter d-axis current reference to be increased.It will result in increasing active-power output. Due to the load characteristic in (3), the voltage will keep increasing in order to balance the active power. The increased voltage, and thus d-axis voltage, will further drive the inverter active power up due to the Anti-islanding feedback. As a result, the voltage will be eventually out of the nominal range so that the islanding can be detected. Similar but opposite destabilization occurs when the sensed voltage is decreasing initially. Flow chart of the algorithm is as Fig.3:

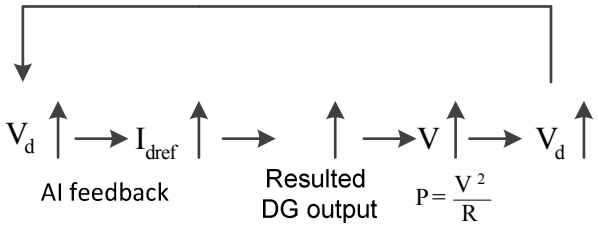

Fig. 3. Voltage positive-feedback in d-axis.

According to the principle of voltage feedback and d/q –axis decoupling, the flowchart of the anti-island detection is showing as in Fig. 4:

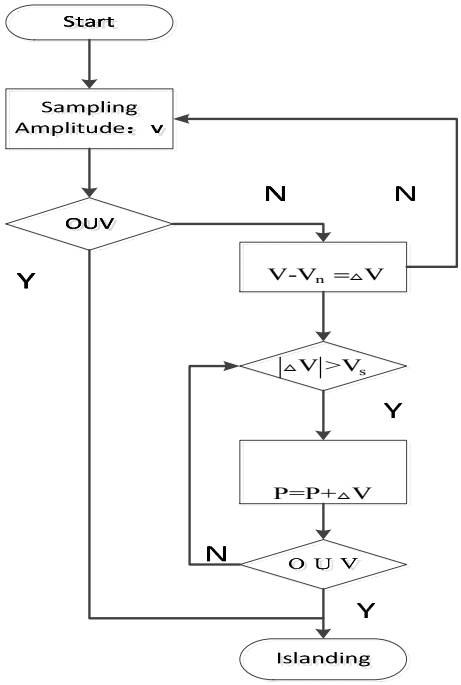

Fig. 4. Islanding detection flow chart.

Passive control algorithm

The EL form of (1) is [9, 10]

$$\boldsymbol{M}\ \dot{\boldsymbol{x}} + \boldsymbol{J}\,\boldsymbol{x} + \boldsymbol{\Re}\ \boldsymbol{x} = \boldsymbol{u} \tag{5}$$

Where $\boldsymbol{M}$ is Positive definite diagonal matrix, $\boldsymbol{J}$ is anti-symmetric matrix and reflecting the internal interconnection structure for symmetric, $\boldsymbol{\Re}$ is positive definite matrix which is reflecting the dissipation characteristics of the system, $\boldsymbol{u}$ is the energy exchange between the system and external. The Matrix expression is shown in *M.x.u.J.R*:

$$\boldsymbol{M}=\begin{pmatrix} L & 0 & 0 \\ 0 & L & 0 \\ 0 & 0 & 2C/3 \end{pmatrix},\boldsymbol{x}=\begin{pmatrix} i_{\mathrm{d}} \\ i_{\mathrm{q}} \\ u_{\mathrm{dc}} \end{pmatrix}=\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix},\boldsymbol{u}=\begin{pmatrix} -u_{\mathrm{od}} \\ -u_{\mathrm{oq}} \\ 0 \end{pmatrix}$$

$$\boldsymbol{J}=\begin{pmatrix} 0 & -L\omega & -S_{\mathrm{d}} \\ L\omega & 0 & -S_{\mathrm{q}} \\ S_{\mathrm{d}} & S_{\mathrm{q}} & 0 \end{pmatrix},\boldsymbol{\Re}=\begin{pmatrix} R & 0 & 0 \\ 0 & R & 0 \\ 0 & 0 & \dfrac{i_{\mathrm{pv}}}{u_{\mathrm{dc}}} \end{pmatrix}$$

When the system operating steady-state and the expect power factor is 1, the DC voltage is equal to the maximum power point of the output voltage, so the expectation equilibrium point is $x_1^* = i_{\mathrm{d}}^*$ (i_{d}^* which is desired AC side of the line current d-axis value) $x_2^* = i_{\mathrm{q}}^* = 0$ (i_{q}^* is the desired AC side of the line current q-axis value), $x_3^* = u_{\mathrm{dc}}$ (u_{dc} is the desired voltage value across the capacitor).

Selection system error memory functions as follow:

$$H_{\mathrm{e}} = \frac{1}{2} x_{\mathrm{e}}^{\mathrm{T}} \boldsymbol{M}\ x_{\mathrm{e}}, \qquad x_{\mathrm{e}} = x - x^* \tag{6}$$

Where x^* is expectation equilibrium which points of the system .In order to accelerate the convergence speed, added damping to the system, making dissipation term is $\boldsymbol{\Re}_{\mathrm{d}} x_{\mathrm{e}} = (\boldsymbol{\Re} + R_{\mathrm{a}}) x_{\mathrm{e}}$. Rewrite (5) to:

$$\boldsymbol{M}\dot{x}_{\mathrm{e}} + \boldsymbol{\Re}_{\mathrm{d}} x_{\mathrm{e}} = u - \left[\, \boldsymbol{M}\dot{x}^* + \boldsymbol{J}(x^* + x_{\mathrm{e}}) + \boldsymbol{\Re} x^* - R_{\mathrm{a}} x_{\mathrm{e}} \,\right] \tag{7}$$

$$\dot{H}_e = -\frac{1}{2} x_e^T (\mathfrak{R} + R_a) \dot{x}_e < 0$$

Select the control law Eq. 8:

$$\boldsymbol{u} = \boldsymbol{M}\dot{x}^* + \boldsymbol{J}x + \mathfrak{R}\, x^* - R_a x_e \tag{8}$$

Because $\boldsymbol{M}\dot{x}^* = 0$. The switching function of the system is:

$$\begin{cases} S_d = \dfrac{u_{ed} - \omega L i_q + i_d^* (R + R_{a1}) - R_{a2} i_d}{u_{dc}} \\ S_q = \dfrac{u_{eq} + \omega L i_d - R_{a2} i_q}{u_{dc}} \end{cases} \tag{9}$$

Substituting (9) into equation (5) can be obtained equation (10)

$$\begin{cases} \dfrac{L}{R + R_{a1}} \dfrac{d i_d}{d t} + i_d = i_d^* \\ \dfrac{L}{R + R_{a2}} \dfrac{d i_q}{d t} + i_q = 0 \\ C u_{dc} \dfrac{d u_{dc}}{d t} = \dfrac{3}{2} u_{ed} i_d^* - \dfrac{3}{2} R i_d^{*2} - \dfrac{u_{dc}^2}{R} \end{cases} \tag{10}$$

Eq. 10 Show that the control law (9) can achieve good dynamic and static decoupling of the system and improve the static and dynamic performance of the system.

According to above control theory of PV system based on voltage feedback and passivity, System structure of anti-islanding detection can be obtained as shown in Fig. 5.

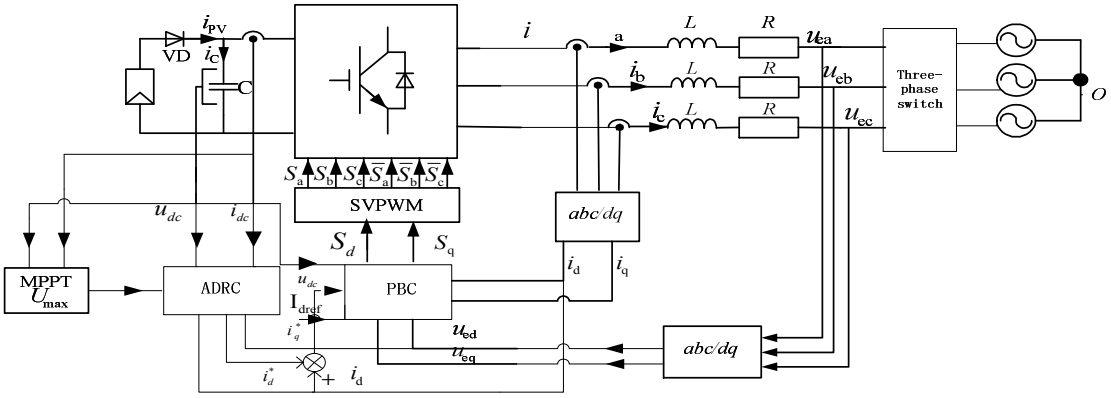

Fig. 5. Anti-islanding detection system structure.

Using Matlab / Simulink software simulation system is shown in Fig. 5. Where in the three-phase grid-equilibrium phase peak voltage 220V, the inverter output inductance of the reactor 15 μF , the reactor internal resistance resistor and inverter system is 0.2 Ω, the capacitor capacitance of 2200 μF , taken as 20 Ω. Fig. 6 and Fig. 7 illustrate the simulation waveforms when the load is only R load. Fig. 8 and Fig. 9 illustrate the simulation waveforms when the load is RLC load. As can be seen from Fig. 6, without using any islanding detection method and turning off the network side 0.15s, disconnect the power generation system is a remote island, the output side voltage hardly changed. As can be seen from Fig. 7, the use of the text islanding detection method proposed in 0.15s

network side is disconnected and the power generation system is islanding state, we can see the system at 0.154s, the voltage exceeds the detection voltage and detects the islanding.

Fig. 8 indicates that without any anti-islanding method when it breaks the three-phase switch at 0.15s, the output voltage is nearly unchanged. Fig. 9 indicates that the anti-islanding method when it breaks the three-phase switch at 0.15s, the islanding can be detected at 0.155s.

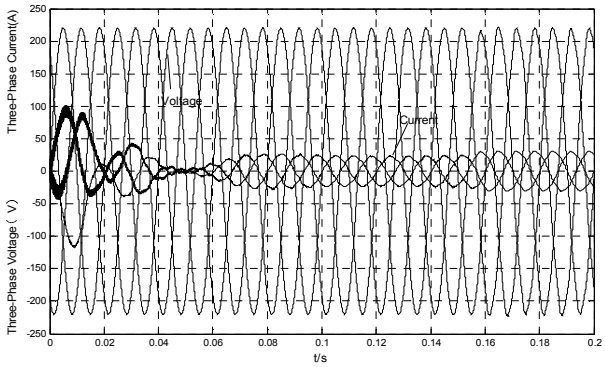

Fig. 6. Without anti-islanding(R Load).

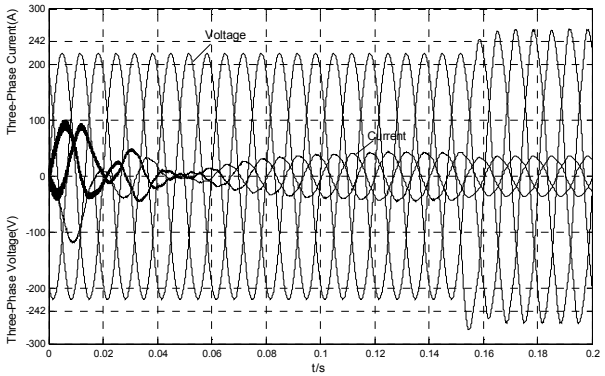

Fig. 7. With anti-islanding(R Load).

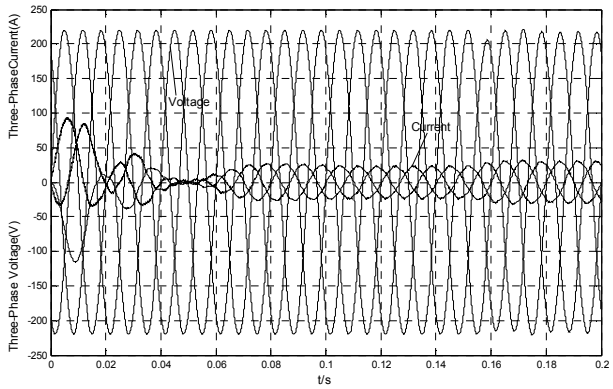

Fig. 8. Without anti-islanding (RLC Load).

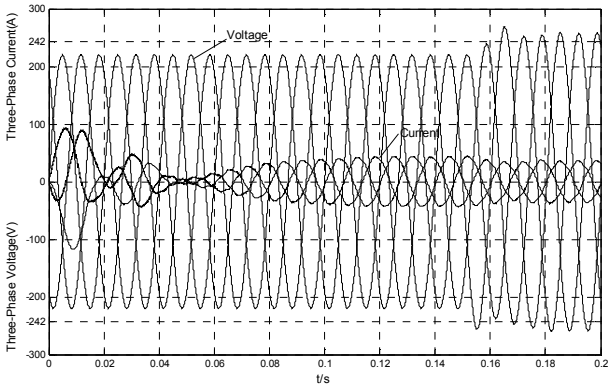

Fig. 9. With anti-islanding (RLC Load).

Conclusions

This paper presents anti-islanding detection method which consists of voltage positive feedback and passivity based on control strategy. The grid voltage of PCC through d/q-axis decoupling and then add into the d-axis reference current of the EL model consist a voltage positive feedback. This anti-islanding method which only uses voltage positive feedback has characteristics of simple structure and small input costs. What's more, this method can quickly detect the island, play a protective effect on the devices and have a certain application prospects in the actual project.

Keywords: AFDPF, SMS, Islanding Detection, Grid-Connected inverter

Abstract. Due to the perturbation between multiple PV Grid-connected power system can't be synchronized easily, the islanding detection often lose efficacy when multiple PV Grid-connected inverters are running simultaneously. The paper show the in-depth analysis of the principle and the advantages and disadvantages of the detection method of AFDPF and SMS, a composition controller is designed aim at the non-detection zone in multiple PV Grid-connected system in the practical application. Through the software simulation, it shows that the method mentioned in the paper practically improves the effect of the islanding detection.

Introduction

When the grid switches off, the photovoltaic power generation system maintains power supply to the local load as an isolated power, consequently, creating an "islanding effect". Islanding effect not only can cause damage to the user's devices, may also make the photovoltaic power generation system overload operation and get burned when the load capacity is greater than the PV's. At the same time the safety of the maintenance staffs are also subjected to great hidden danger, and the grid is not safe because of the current surge when it recover after fault repair. Therefore, grid-connected PV system must have ability of timely detect the islanding and stop running automatically in a short time.

At present, the islanding detection has two kinds of method based on the changes of the detection object, namely, passive and active detection. Passive detection method checks whether the voltage amplitude, frequency and harmonic content at the grid-connected interconnection deviate from the range set by the standard of grid connection. Its working principle is simple, easy to implement, but detection blind area would be produced if the output power of inverter is similar to load power. Active detection method is to give a small disturbance to inverter (such as voltage amplitude). The effect brought by the disturbance is very small when network works in normal because of its clamp effect, so it can be neglected. However, once the grid failures happen, the disturbance will accumulate rapidly and exceed the allowed scope, triggering islanding protection circuit. Active detection method detection has small blind area, and it's more precise, but its control is more complicated, and reduces the quality of the inverter output power to a certain extent.

In the practical engineering, when multiple sets of PV grid –connected inverter are running at the same time, due to the possible disturbance between multiple photovoltaic power generation system are not synchronized, the effects of an island detection will be affected seriously. This paper analyzes the advantages and disadvantages of the AFDPF and SMS islanding detection method. Their compound was applied to more than one inverter grid case, thus to provide guide to the actual photovoltaic power generation systems engineering method.

Island detection principle

When the power grid work in normal, photovoltaic power generation system connects to power grid in public point A, they together supply power to RLC load, as is shown in figure 1.

When network work in normal, photovoltaic power generation system output active power (P) and reactive power (Q)to the load, and grid output power to the common point A, active power(ΔP), reactive power(ΔQ) , and the active power (P_{load})and reactive power(Q_{load}) of load, so the power balance equation of A point can be written as:

$$P_{load} = P + \Delta P \quad , Q_{load} = Q + \Delta Q$$

If the power outputted by photovoltaic power system is balanced with load power, namely ΔP =0, ΔQ =0, in this case, the voltage amplitude, frequency of the common point barely change. PV generation system continue to provide power to the load, thus a state of islanding effect without monitoring is generated at the common point.

If ΔP or ΔQ is big enough, and when the grid disconnect, only the inverter supply to the load as a current source, the inverter output power and load power do not match at this moment, so the common point voltage amplitude or frequency would change, and when exceed the normal scope, the inverter voltage amplitude frequency protection circuit detects islanding and take an action, so as to realize an islanding protection.

Commonly detection method

Active frequency drift detection. AFD detects islanding through importing a zero time to the signal of the inverter output current. If the half wave of a given current by PV generation system has been completed, but the common point half-wave voltage has not, the given current should be forced to be zero and keep a time length of t_z .Once the voltage of common point reaches zero, the given current of PV generation system immediately start the next half wave, as shown in figure 2, so that the frequency of the PV generation system is always slightly lower or higher than the common point's of previous period.

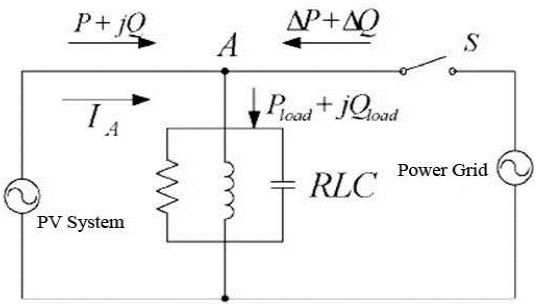

Fig.1 The equivalent circuit of island effect.

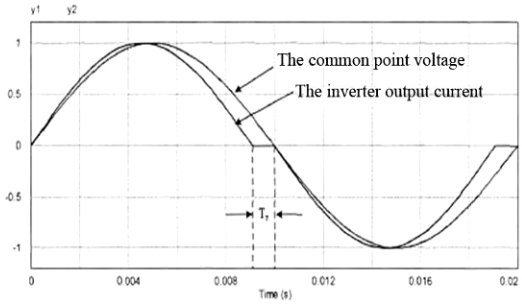

Fig.2 The oscillograph of the given current and the common point voltage

When the network works normally, the grid controls the magnitude of the common point's voltage frequency; when the grid blackout happens, the output current of inverter flows the resistive load, leading the voltage response of the load following the current wave distortion and reaching

zero in a shorter period of time, causing phase error between output voltage and current. To eliminate phase error the inverter will increase the frequency of current output, causing the voltage of resistive load passing zero in advance, then Inverter test phase error and increase the current frequency again until the frequency offset is beyond the scope set so that can be detected.

AFDPF introduce a positive feedback of frequency based on the frequency deviation of AFD, thus speeding up the common point voltage frequency deviation from normal, further reducing the measuring blind area. There is a 0.5 wt_z phase error between AFDPF current waveform and the base wave. If t_z is small enough, the current harmonic would be very small. The inverter output current and common point voltage phase can be represented as:

$$\theta_{AFDPF} = \frac{wt_z}{2} = \frac{\pi cf}{2} = \frac{cf_0 + k(f - f_g)}{2}\pi \tag{1}$$

In this expression, cf_0 is truncation coefficient under no frequency error; f is the voltage frequency of the common point; f_g is the rated grid frequency, k is feedback gain. In the case of ignoring the harmonic, the AFDPF current can be represented as:

$$i_{AFDPF} = I_{AFDPF}\sin(2\pi ft + \theta_{AFDPF}) \tag{2}$$

For RLC load in parallel, the disadvantages of active frequency drift method is the detection blind area exists when capacitive load is large. Because the load impedance angle of capacitive load less than zero would partly offset the phase advance effects brought by frequency deviation method, slowing down the speed of system frequency deviation, so that the system can not be able to quickly and accurately determine islanding.

Slip-Mode Frequency Shift Method. Slip-Mode Frequency Shift Method (SMS) is a kind of islanding detection method based on the common point voltage phase error. Figure 3 is the schematic diagram of SMS, its principle is taking the common point voltage frequency of last time cycle on the phase-locked loop as the current frequency in the next cycle of PV generation system, the starting moment of the next cycle is determined by the rise time of the common point voltage passing zero.

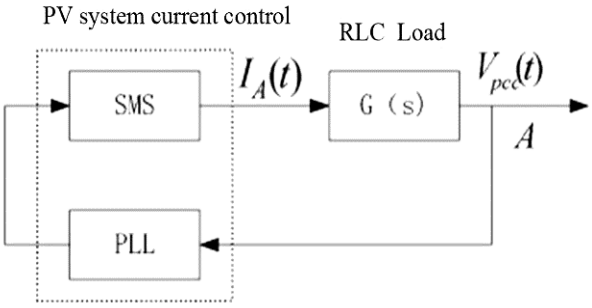

Fig.3 Schematic plot of the SMS

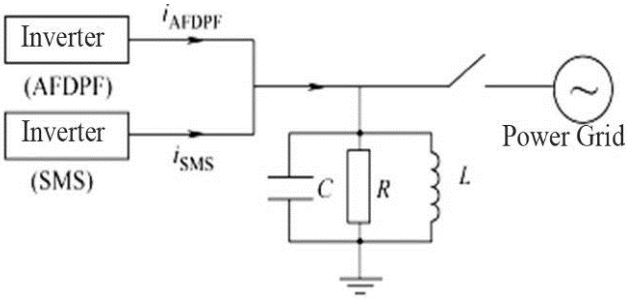

Fig.4 Schematic plot of multiple PV Grid-connected system

The SMS algorithm controls the initial phase of current, and generally takes:

$$\theta_{SMS} = \theta_m \sin\left(\frac{\pi}{2} \times \frac{f - f_g}{|f_m - f_g|}\right) \tag{3}$$

Among them, θ_{m} is the maximum phase shift angle, f is the common point voltage frequency, f_g is the rated power grid frequency, f_m is the maximum frequency when the maximum phase shift.

The output reference current of Inverter can be represented as:

$$i_{SMS} = I_{SMS}\sin(2\pi ft + \theta_{SMS}) \tag{4}$$

Once the grid interrupts, due to the phase of the current IA is always lead (or lag) the common point's voltage phase, and because of the effect of the phase lock loop, the frequency gradually increase (or decrease) until beyond the normal range at last and the islanding is detected. The SMS algorithm is simple in implementation, and has outstanding ability to detect islanding, etc. But if the phase offset got by SMS algorithm is zero, islanding may not be detected, resulting in a blind detection area, and the blind can not be eliminated but to shrink it.

AFDPF and SMS composite detection method

In order to overcome the blind detection area problem that multiple sets of inverter are running at the same time, we can combine AFDPF and SMS their respective characteristics. This article adopts this way, in order to facilitate analysis, choosing two PV grid inverters to supply power as is shown in figure 4.

The resultant current expressions has been given in reference [3]:

$$i = I_{SMS}\sqrt{1+m^2+2m\cos(\theta_{AFDPF}-\theta_{SMS})}\sin(2\pi f+\varphi) \tag{5}$$

Among them, m is the ratio of i_{AFDPF} and i_{SMS}, φ can be represented as:

$$\varphi = \arctan\left(\frac{m\sin\theta_{AFDPF}+\sin\theta_{SMS}}{m\cos\theta_{AFDPF}+\cos\theta_{SMS}}\right) \tag{6}$$

It is observed that：

$$\min(\theta_{AFDPF},\theta_{SMS}) < \varphi < \max(\theta_{AFDPF},\theta_{SMS}) \tag{7}$$

When an AFDPF inverter and a SMS inverter connect to the grid, the phase angle of resultant current is between the angle of two inverters' output current. In AFDPF method, the change direction of phase angle is kept for the existence of positive feedback. in other words, the two inverters' phase disturbance directions caused by frequency change are in the same direction. Therefore, as long as each inverter can effetely detect islanding when work alone, islanding could still be detected after they connect to the grid. But if the resonance frequency of RLC load in parallel is close to the grid's frequency, islanding effect will be difficult to be detected when the grid switches off for the system's frequency changes little. Thus, a factor, if we want to detect islanding precisely in extremely hard operating conditions, is required, which is the growth rate of phase angle of inverter output current is faster than the RLC load in parallel. For AFDPF method, the feedback gain should satisfy the following condition:

$$k \geq \frac{4Q_f}{\pi f_g} \tag{8}$$

In this formula, Q_f is the quality factor of load, generally $Q_f < 2.5$, to make it better compatible with SMS method, the truncation coefficient in SMS algorithm formula (2) can be improved as:

$$cf = \begin{cases} k(f - f_g) - cf_0 & f \geq f_g \\ k(f - f_g) + cf_0 & f \leq f_g \end{cases} \tag{9}$$

According to this formula, phase disturbance directions of AFDPF and SMS method are the same for any common point frequency and any RLC load, the positive and negative values are consistent as well.

Model simulation

In this paper, a PV generation system model is built on the basis of above analyze. The grid blackout happens at 0.1s, the model simulation monitors the voltage, current and islanding signal after the grid switches off. The model is shown in figure 5 and the system's parameters are shown in table 1.

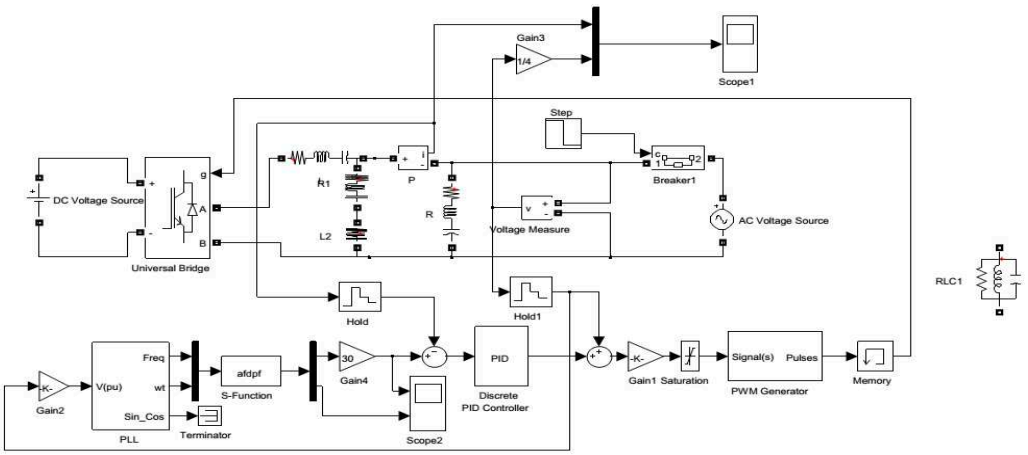

Fig.5 The simulation model of islanding detection

Table 1: System simulation specifications

Parameters	Value
Public grid	220V/50 Hz
Frequency protection threshold	50 ± 0.5 Hz
SMS parameters	$\theta_m = 10°$, $f_m = 53$Hz
Load quality factor	$Q_f = 2.5$
Load active power	10 kW

The simulation results is shown in figure 6, seeing from the figure, the power grid power switches off at 0.1s, and the system frequency exceeds the upper limit frequency 50.5Hz after 0.18s later, islanding is detected immediately, then the inverter driving signal is blocked. Test results meet the standard testing time of IEEE Std. 2000-929 . According to formula (6), (7), the method is also suitable for more than two inverters parallel operation.

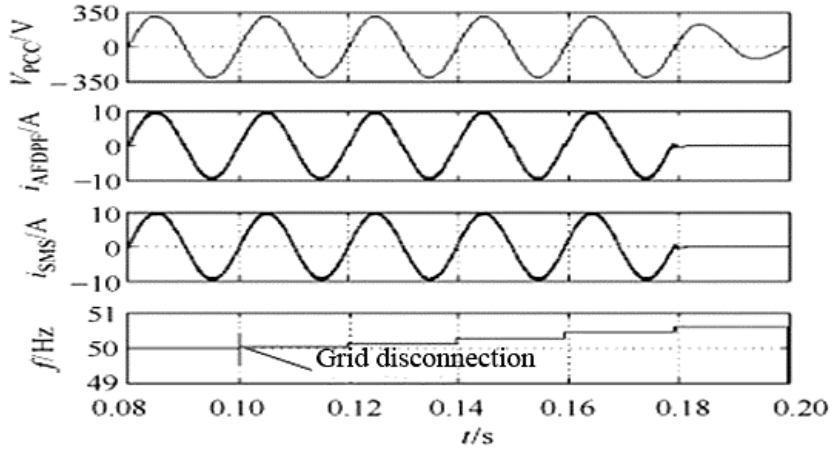

Fig.6 The result of simulation

Conclusion

This article has deeply analyzed AFDPF detection method and SMS detection method, aiming at the problem that the disturbance synchronism is difficult to realized to detect islanding when multiple inverters running at the same time, combined AFDPF with SMS and simulated in MATLAB, and the result shows its fast and precise performance in detecting islanding, accordingly providing a guided way for multiple sets of inverters' parallel operation.

Keywords: Electric locomotive; Electric energy metering; STM32F103R8T6

Abstract: The paper introduces the structure of locomotive energy consumption monitoring system, technical parameters and the method of software design. The system uses electric energy metering chip CS5463, ARM kernel STM32F103R8T6, GPRS wireless communication module and RS485 communication interface to realize the multi-system locomotive AC and DC measurement, remote meter reading and other devices and locomotive communication connection. The liquid crystal display LCD stores the locomotive power information, the current, voltage, power and energy data with their own real-time clock time-sharing data fragmentation such as type test on the system, the system of high precision, strong anti-interference ability, low power consumption, safety etc.

Introduction

With the rapid development of electronic technology , energy metering energy monitoring device as a tool widely used in the national economy , especially in the electric locomotive .However,China 's energy resources are relatively tight, energy consumption monitoring system is not yet mature , reasonable ,so effective measure for energy is becoming increasingly important.Currently, electric locomotives measure energy consumption is often used mechanical energy monitoring devices and electronic monitoring devices,mechanical devices has low accuracy, weak immunity, low efficiency, mechanical loss.while high-precision electronic devices ,efficient use big,stability,security and high overload capacity and strong.

Therefore, as for the comparison between the mechanical energy consumption monitoring device and electric energy consumption monitoring device , this paper designs a kind of energy consumption monitoring system based on embedded system. It can detect electric locomotive real-time electricity information and remote wireless meter reading. the System consists of a dedicated high-performance energy measurement chip (CS5463), the power supply circuit and ARM microprocessors (STM32F103R8T6) etc. By high isolation, high-precision voltage transformers and current transformers or sensors to detect locomotive voltage, current, real-time calculation of electric power, and accumulated power consumption and locomotive traction regenerative braking power fed back into the grid.

The overall structure of a system

System composition

Electric locomotive energy consumption monitoring system shown in Figure 1, mainly by the energy measurement chip CS5463 [1], microprocessor STM32F103R8T6, clock circuits,

programmemory, display driver circuit, RS485 communication module, RS232 communication module, power supply circuit. Energy measurement chip CS5463 mainly to the acquisition of electric locomotives input current and voltage signals, information and computing power to get the locomotive, its information stored in FLASH memory. Microprocessor STM32F103R8T6 CS5463 collected primarily for computing power locomotives and locomotive power of information processing and display, cumulative feedback power locomotives, locomotive cumulative power consumption; and the locomotive current, grid voltage, locomotive power and consumption data combined with its own real-time bell to store data sharing segment, primarily in order to provide real-time clock chip for real-time display current battery information; metering system provides an RS485 communication interface to connect energy monitoring devices and other devices in the car. RS232 interface is mainly used for debugging the factory.

In order to ensure that the system electromagnetic compatibility [2], anti-jamming capability, the system should have three-way power input of certain protective measures should be taken so that the output power (energy measurement mode, the microprocessor module, wireless communication module) correctly isolation.

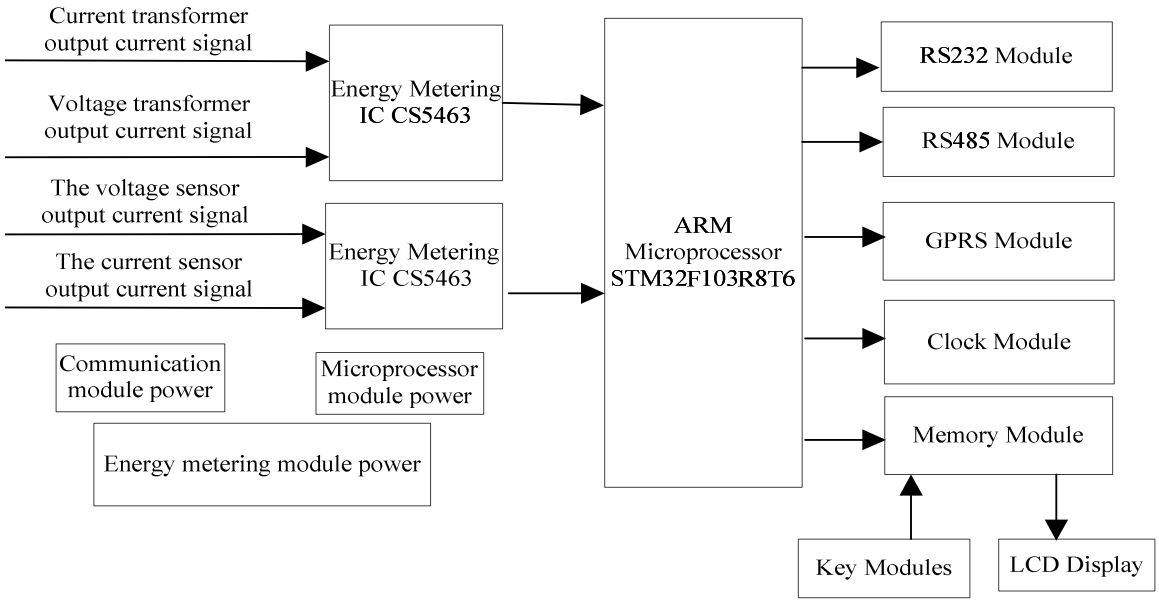

Fig. 1 Electric locomotive structure of energy consumption monitoring device

Sampling module power

Electric energy sampling module composed of electric energy metering IC CS5463 and current,voltagesamplingcircuit. CS5463 using current transformer for high current transform locomotive input for the current signal is small, the voltage transformer high voltage locomotive entered into a low voltage signal. The bidirectional serial communication with the microprocessor communication, with phase compensation, temperature sensor, and correction calibration functions.

The current sampling circuit and voltage sampling circuit uses the differential input circuit, when the locomotive DC voltage sampling, voltage sensor input rated voltage to the DC current through the shunt50mA,sampling circuit, resistance(R40 , R43) voltage sampling circuit output voltage value UIN (165mV), as the CS5463 of VIN+ and VIN--, the specific circuit as shown in figure 2.

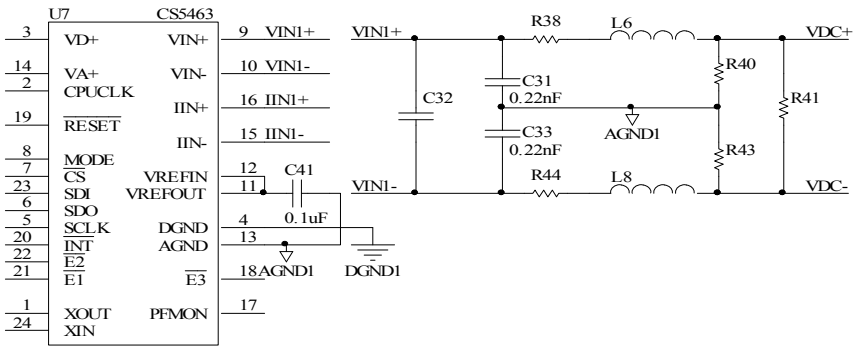

Fig.2 DC voltage sampling circuit

When direct current locomotives sampling, the current sensor rated current into DC current 400mA, through a resistor (R50, R51, R52) output voltage signal UIN (140mV), as CS5463's IIN1 + and IIN -. The CS5463 is connected with the microprocessor, the voltage and current signals inputted data operation to get the power of information Specifically, as shown in figure 3

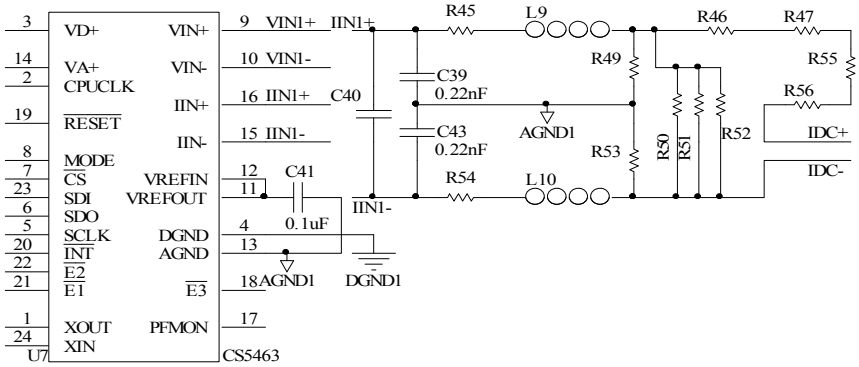

Fig.3 DC current sampling circuit

When the locomotive AC voltage sampling, voltage transformer output voltage signal 150V through the resistor divider (R26, R18, R22), filter (R17,C16, C18) is transformed into a 100mV voltage signal; when the current AC locomotive sampling, current transformer through the divider circuit, filter circuit converts the current signal into voltage signal output of locomotive. Specific AC voltage and AC current sampling circuit as shown in Figure 4.

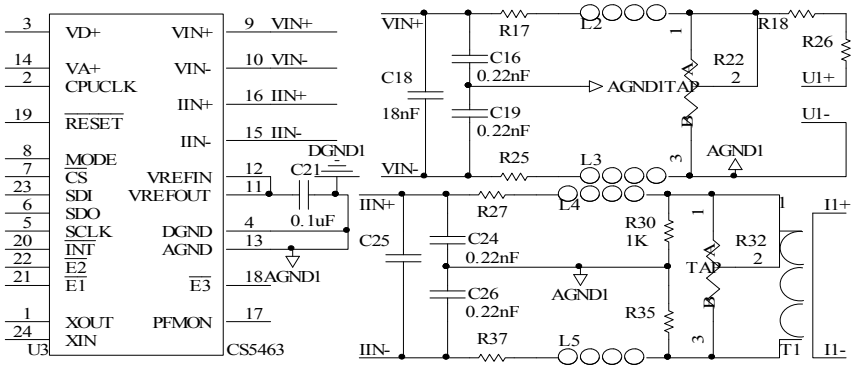

Fig.4 The sampling circuit of AC voltage and current

central processing module

The central processing module consists of 32 bit high performance ARM series microprocessor STM32F103R8T6, keyboardcircuit, RS48 communication module, 12864 display module,the SD2404 clock module, power module and GPRS wireless communication module, the microprocessor STM32F103R8T6 with measurement chip CS5463 by SPI interface, two keys are connected with the microprocessor I/O, microprocessor working in the range of -40 ℃—— +85 ℃, and has the advantages of strong anti-interference ability, high reliability, strong

function. The embedded microcontroller as the electric energy metering chip, mainly to complete the electric energy data processing, display and storage. Power supply circuit adopts double power supply, a spare battery and power supply(AC/DC) function, ensure the locomotive uninterruptible power supply, prevent the loss of information for electric locomotive.

power module

According to the requirements of power metering device, a power supply system and auxiliary power supply in two ways, the two kinds of power supply through the rectifier, filter are connected in parallel, the rectifier and filter two ways to isolate two kinds of power supply, so that the two power supply is not influence. and the power supply circuit measurement module and communication module needs mutual isolation, the DC-DC mode to achieve mutual isolation between the power:the input voltage regulator module 110V, can realize the mutual adaptive AC and DC, from interference at the input of the power access varistor protection power supply.

Wireless communication module

RS485 module

RS485 communication interference, power supply module, RS485 signal input and signal output should take certain measures [3] isolation. Among them, power supply using DC-DC magnetic isolation, input signal using optocoupler isolation, transceiver with strong anti-interference capability, low power MAX487, with magnetic isolation output signal. RS485 uses standard electrical standard interface, communication baud rate to 19200, mainly composed of MAX487 module, optical module and the external resistor.MAX487 can send data, and can receive data.

GPRS module

In order to ensure the energy consumption monitoring system of locomotive all-weather monitoring center and ground communication, power consumption has become a key factor in the GPRS module selection ,therefore, instinct consumption monitoring device based on MC55[4] wireless communication module Siemens production company, MC55 built in TCP/IP protocol, has not only the general voice, SMS, GSM module, MODEM wireless data service connect function, also has the data transmission of TCP/UDP and FTP, SMTP, protocol. Users only need to edit the AT instruction can check GPRS network, remote communication vehicle and the ground monitoring center. The MC55 range of working voltage is 3.3-4.8V, maximum current of 2A, and has the advantages of high integration degree.

System Specifications

Display range: LCD display, power 8-bit data, before the decimal point 5, after three;
consumption: less than 5W; Voltage channels: input AC voltage: 100 ~ 300V, rated 150V; input DC voltage: -71.4 ~ 71.4 mA, nominal 50mA; auxiliary supply voltage: DC110V (-30% ~ +25%); Accuracy: Active ± 0.5, reactive power ± 2.0; current channel: Input AC Current: 0 ~ 1.5A, rated 1A; input DC Current: -700 ~ 700 mA, rated 400mA ;Communication Interface: RS485 interface, GPRS interfaces; storage depth: stored once per minute,the capacity to store 30 days.

system software design

The system every 10 seconds to refresh the cumulative traction power consumption and regenerative braking feedback to grid electricity, which showed forward active，forward reactive power, Reverse reactive power，and the voltage, current. So the display using 3 seconds timer interrupt to update the data, followed by cycle display locomotive power information.

System uses Keil4 as development environment, based on the embedded μC/OS II operating system [5], using C language programming, modular approach to design. The main program is shown in Figure 5,it is the core of the system. Power on reset, the system into the main program, the program is first initialized to operation, including variable initialization for all sub components and global initialization, judging if power supply is power off, if the power supply powerdown, calling the data storage module, the information storage locomotive power letter letter to FLASH memory, at the same time the system into a low power state, effectively extend the standby battery time. Since the system uses two kinds of remote communication party tried to realize remote wireless meter reading, Therefore, the program uses RS485 bus communicating with TAX2 module, Using interrupt timer count way to achieve power information collection, display.

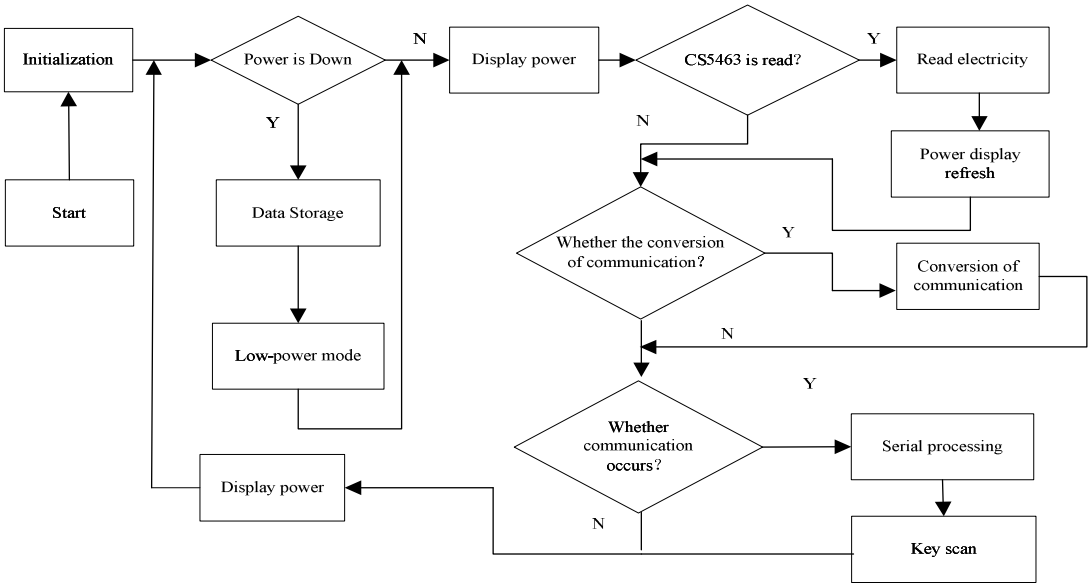

Fig.5 The main program flow chart

prototype testing

Detection accuracy

Electric locomotive monitoring system to measure the energy consumption of the core, but also to ensure the accuracy of measurement of the primary condition for the normal operation of the locomotive, mainly in order to measure the accuracy of the test locomotive voltage, current, active power, reactive power and power factor, to the national standard GB / T 17215.322-2008 as the standard for precision testing.

Developed by Zheng zhou Huate Control Technology Co.Ltd. precision test station of WT-T160 on locomotive energy consumption device parameters testing, accuracy class 0.2. Loading metering chip (CS5463) program can be done after the locomotive energy consumption monitoring device precision test, the choice of two locomotive energy consumption monitoring device prototype to verify the analysis, as shown in table 1.

Table 1 shows: Input AC rated voltage 150V, rated current of 1A, adjust system output current 1.2Ib, ib, 0.5Ib, record voltage, current and power factor. Under current output unchanged, adjust the power of 0.5L, 1.0,0.8 C, record the voltage, current and power factor. By contrast with the standard measurement system to obtain accuracy of the system, the experimental results showed that: active energy measurement accuracy is 0.5 and reactive energy measurement accuracy 2, which have achieved the desired effect.

Conclusions

The electrical energy special-purpose chip CS5463 and ARM core chip STM32F103R8T6 are combined with operating system C/OS II to design energy consumption monitoring system of locomotive. The system can display real-time locomotive voltage, current, power, power factor, power consumption of locomotive traction , regenerative braking feedback to the electricity grid and to wireless remote meter reading. The system satisfies the GB/T17215.322-2008 international standard. The software uses the modular thought and the DL/T 645 communication protocol. Energy consumption monitoring device accuracy grade of this design: active power level 0.5 and reactive power level 2, widely used in electric locomotive, electric automatic meter reading, remote monitoring and management system.

Keywords: GPSS, State feedback, Low-frequency oscillation

Abstract: By analyzing the control principle of power system stabilizer (PSS)，shows that the robustness of PPS is not ideal. Using the methods of state-space pole placement designed the governor-side power system stabilizer GPSS,and built a simplified model of the power system with simulink. The simulation experiment results made in the MATLAB shows that GPSS has good inhibitory effect of low-frequency oscillations.

Introduction

The continuous expansion of the scale of the power system, large capacity units, especially fast excitation device into operation, result in deterioration of the damping characteristics of the power system, causing low-frequency oscillation. The low-frequency oscillation is that under certain circumstances, negative damping system provided offset the original positive damping of system turbine, field winding, and mechanical, the damping is too small or the total result is negative, then if the system is disturbed, the disturbance will continues to enlarge in the negative damping effect, forming a low-frequency oscillation. Low-frequency oscillations will seriously affect the safe operation of the power system stability and generators, and may even cause damage to the power system blackouts.

Currently, the power system stabilizer (PSS) is the most common method of suppressing low-frequency oscillations. PSS is a kind of additional excitation controller, using generator speed deviation, frequency deviation, power or linear combination of the three as an input signal to compensate for the phase lag generated by the excitation system.

PSS is designed primarily for the exciting side of the phase compensator, and the study of the governor-side power system stabilizer GPSS has also been conducting. HAO Yushan et al analyzed and verified the feasibility of GPSS, Concluded that governor time constant and the gap dead-band do not affect the function of GPSS, and GPSS has good robustness of the system operation mode and working conditions[1-2]. Gu Gendai presented that using additional high-frequency periodic signal ‘rolling’ governor gap to realize linearization for eliminating the self-oscillation caused by the nonlinear governor gap[3]. Lin Qiyou, Chen Xingying et al designed GPSS for multi-machine system[4]. GPSS brought positive damping to local machine, while not giving negative damping to others, thus, GPSS has better robustness than PSS.

Analysis of power system stabilizer PSS

PSS achieves phase compensation by a lead - lag element, Fig.1 shows the model of phase compensation. According to the single - infinite system Philips-Heffron model, we can derive the generator speed, power angle and electromagnetic power phase diagram, Fig.2 shows the principle of PSS phase compensation.

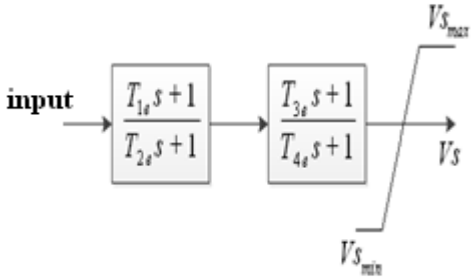

Fig.1 Model of PSS phase compensation

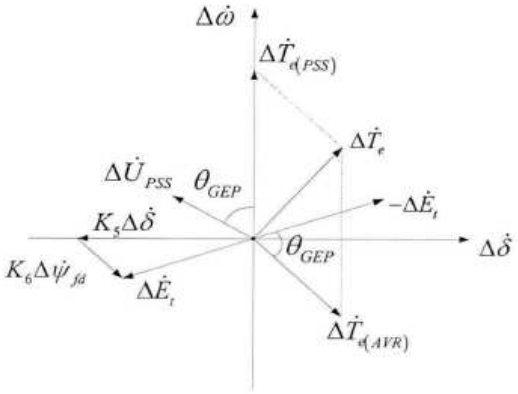

Fig.2 Damping torque synthesis principle

When the Synthetic phasor of electromagnetic torque generated by the excitation device and PSS appears in the first quadrant of the plane, the total system damping torque is positive. By tuning parameters in phase compensation aspects of PSS and compensating the phase between the electromagnetic torque generated by PSS and speed deviation, PSS can produce pure positive damping torque, thereby increasing the system damping.

PSS is widely used, and is also the most mature technology of low frequency oscillation suppression device by far. However, due to the generator excitation system is closely related to the power system operation mode and working conditions, PSS is difficult to be extended to multi-machine system. In addition, PSS control performance is largely determined by the mounting position of the stabilizer, the robustness of the system is not ideal.

Design of GPSS

In fact, research on GPSS began in the early time, However, due to the oil motive response was too slow, cannot keep control instructions at that time, control effect of GPSS has been unsatisfactory, thus affecting its application. But, with the gradual development of manufacturing technology, the time constant of the oil motive got smaller and smaller, have been able to keep control instructions and timely response.

Fig.3 shows the influence of the oil motive's time constant on the output.According to Fig.3, we know: Smaller time constant of the oil motive, more responsive output, greater adjustment range.

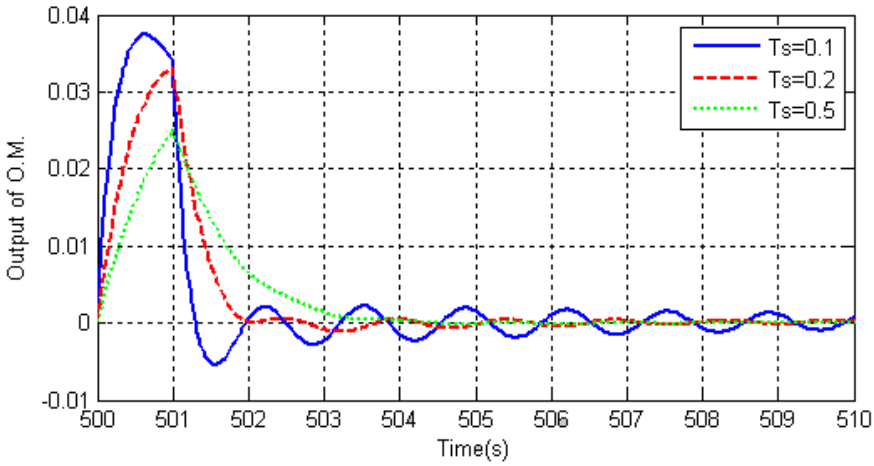

Fig.3 The influence of time constant on oil motive output

GPSS also generates a pure damping torque by the controller, like PSS, to suppress low-frequency oscillation. Let the system state space expression for: $\dot{\boldsymbol{x}} = \mathrm{A}\boldsymbol{x} + \mathrm{B}\boldsymbol{u}$, By configuring the desired poles to determine the state feedback control law: $\boldsymbol{u} = -\boldsymbol{k}\boldsymbol{x}$. In the entire system, we choose the output of oil motive, the output of high-pressure cylinder, generator speed and power of grid as State variables. Considering the system's need for additional damping, when configuring poles, the damping factor of dominant poles may be appropriate to some large. In this context, Let dominant pole be $-2 \pm \mathrm{j}2$ and vice pole be $-10, -10$, then we can obtain feedback gain matrix $\boldsymbol{k}$ by solving the state space expression.

Simulation of GPSS

Fig.4 shows the overall structure of the system simulation model.

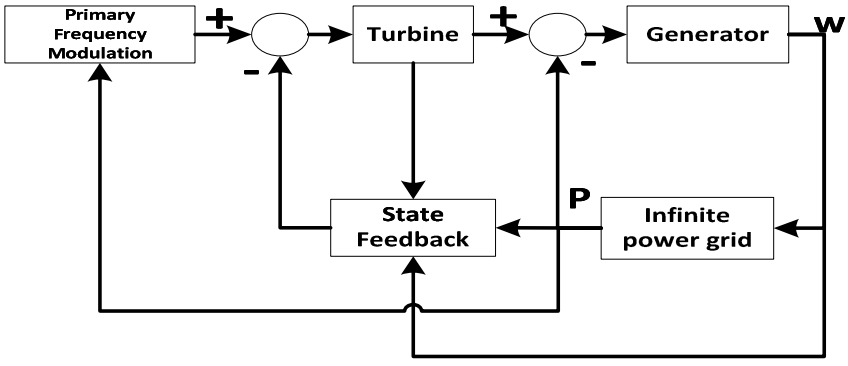

Fig.4 Simplified structure of the power system

Among it , the turbine including oil motive, high-pressure cylinder and reheat links. The oil motive and high-pressure cylinder simplified into first order damp elements, the time constants is Ts and Th:

$$G_1(s) = \frac{1}{T_s \cdot s + 1} \tag{1}$$

$$G_2(s) = \frac{1}{T_h \cdot s + 1} \tag{2}$$

The reheat links is described by the transfer function $G_{rh}(\mathrm{s})$:

$$G_{rh}(\mathrm{s}) = \frac{\alpha T_{rh} \cdot s + 1}{T_{rh} \cdot s + 1} \tag{3}$$

The generator is represented by an integration element with a gain $\frac{1}{T_a}$:

$$G_r(\mathrm{s}) = \frac{1}{T_a \cdot s} \tag{4}$$

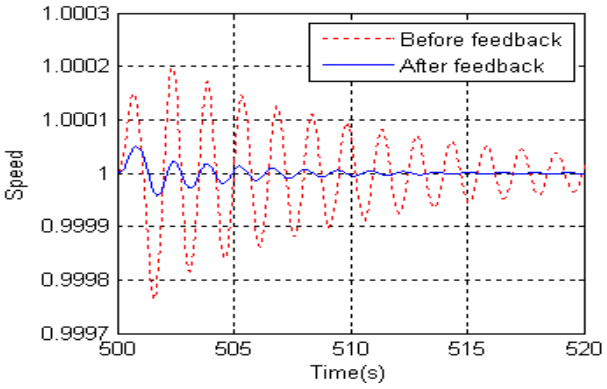
The infinite grid is represented by $G_R(s)$:

$$G_R(s) = C_D + \frac{1}{T_R \cdot s} \tag{5}$$

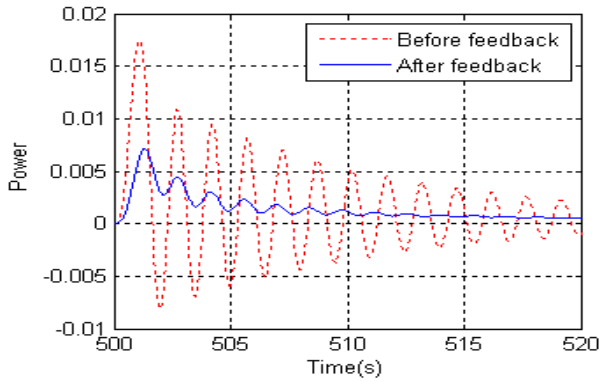
Then we built a simulation model using the Simulink of MATLAB and did the simulation experiments.

Results of Simulation

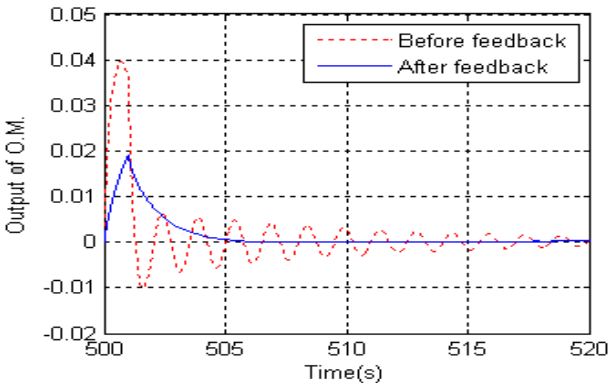
After 500 seconds at the stable operation of the system, set an impulse interference with a per unit value 0.05, getting the simulation curve of generator speed, output of oil motive and grid power fluctuations versus time, the simulation results as shown in Fig.5:



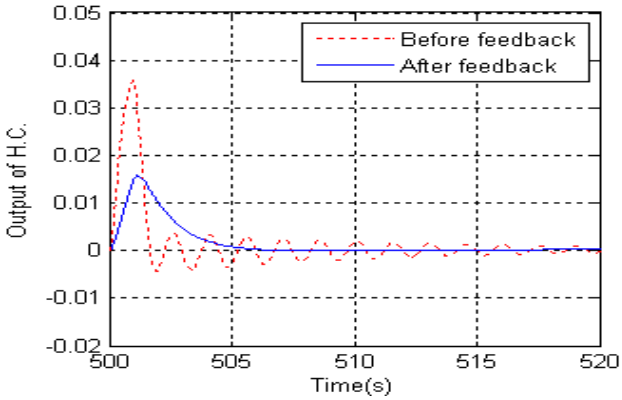
(a) Speed versus time



(b) Power versus time



(c) Oil motive output versus time



(d) High-pressure cylinder output versus time

Fig.5 Simulation results

Conclusions

Due to the state feedback control by the configuration desired poles, governor-side power system stabilizer has a good inhibitory effect for low-frequency oscillations. Also, due to the multi-machine decoupling, the system robustness of GPSS is better than PSS, GPSS can be used as a new power system stabilizer to promote application.

Keywords: Dielectric elastomer, multi-layer, generator, harvesting circuit

Abstract. As a member of Electroactive Polymers (EAPs), dielectric elastomer (DE) has shown considerable potential for energy harvesting applications. After the basic principle of DE energy harvesting is studied, a multi-layer DE generator using VHB 4910 (3M, USA) is specially designed and fabricated. Then, an improved energy harvesting circuit is designed to make use of harvested electrical energy. Finally, energy harvesting experiments are implemented under the constant charge (open-circuit) condition and the results prove that the multi-layer DE generator fabricated can produce enough energy to constantly drive a light emitting diode. The harvested electrical energy has good consistent with generated electrical energy and the maximum energy harvesting efficiency η_h can reach 89%.

Introduction

Dielectric elastomers (DE), a member of electroactive polymers (EAPs), are capable of exhibiting large strains under an electric stimulus [1]. Dielectric elastomers have drawn much academic attention as actuating materials due to their advantages, such as low cost, light weight, fast respond speed, high efficiency, large deformation and long fatigue life [2-3].

As we all know, the generator mode of dielectric elastomers is the reverse process of the actuator mode, firstly discovered by Pelrine *et al.* in 2001 [4]. Different designs of dielectric elastomer generators (DEGs) have been put forward by scholars worldwide. DEGs have been demonstrated capable of harvesting energy from environmental sources including water current [5], ocean waves [6], and wind [7], as well as human motion such as heel striking [8] and knee bending [9]. The maximum harvested energy of above designs are mostly within a range of 0.02~0.4 J/g, far less than the theoretical prediction given by Koh A *et al.* [10] (nearly 2.7J/g per energy cycle). In 2010, McKay *et al.* [11] proposed a "self-priming" circuit which can be used as an inverse charge pump.

In this paper, based on the analysis of an energy harvesting cycle, an annular multi-layer DEG device is designed and fabricated. In addition, an improved harvesting circuit is presented and simulated. Then energy harvesting experiments are implemented to drive a light emitting diode continuously. Finally the results prove the feasibility of multi-layer DEG and the improved harvesting circuit. Since the complexity of multi-layer DEG, the results may be not the optimal one, still and all, it can provide a new direction in improving the performance of DE energy harvesting devices.

Basic principle of DE energy harvesting

The DE energy harvesting is a cycle process converting the mechanical energy into electrical energy. Before entering the operating cycle, the DE membrane is usually pre-stretched to a certain ratio.

To illustrate the DE energy harvesting process, a simplified working cycle which can be divided into four working phases is shown in Figure 1. Tensile Phase (from a to b): the DE membrane is mechanically stretched to a certain location, mechanical energy converted into the elastic potential

energy of the material. Charge Phase (from b to c): the membrane is charged by a bias voltage. Recovery Phase (from c to d): since the external load reduces, the membrane is relaxed with the combined effect of the elastic restoring force and the Maxwell stress, the capacitance decreased, converting the strain energy to electrical energy. The last is Discharge Phase (from d to a), the charges are removed and the membrane completely recovers to its initial working state.

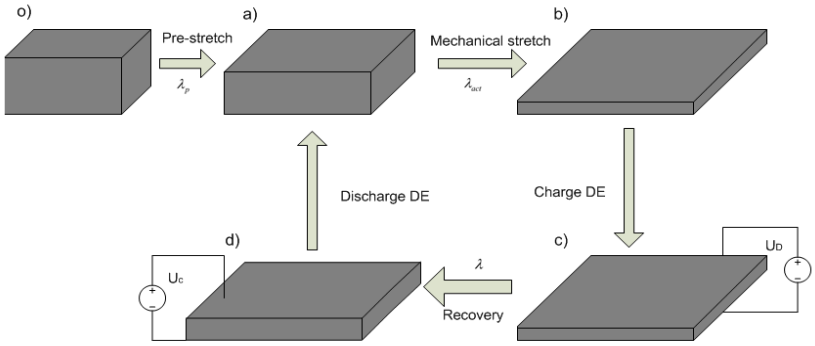

Figure 1 Schematic of the DE membrane energy harvesting cycle

Dielectric elastomers, in essence, are a type of variable capacitors. The capacitance C, can be expressed by equation (1) as follows

$$\mathrm{C} = \frac{\varepsilon \mathrm{A}}{\mathrm{z}} = \frac{\varepsilon P}{z^2} \tag{1}$$

where ε is the permittivity of DEG, A is the area of electrode, z is the thickness of DE membrane and P is the volume of the membrane.

Since the DEG works under constant charge condition, namely $\mathrm{Q} = C_C U_C = C_D U_D$, the capacitance and voltage at state c and d can be either measured or calculated according to the above formula. The electrical energy generated in each cycle can be obtained, namely

$$\Delta \mathrm{W}_E = \frac{1}{2}(\mathrm{C}_D U_D^2 - C_C U_C^2) = \frac{1}{2} C_D U_D (U_D - U_C) \tag{2}$$

where C_C and C_D denote membrane capacitance at states c and d, while U_C and U_D are voltages across the membrane at the two states accordingly.

Preparation of a multi-layer DEG

The dielectric elastomer used in this study is VHB 4910 (3M, USA). In our design, a pre-stretched DE membrane is fixed by two annular frames and the active working area of the DE membrane is an annular region with an inner diameter of 30 mm and an outer diameter of 80 mm.

A multi-layer DE generator contains several units and each unit consists of two layers of DE membrane. The fabrication process of the two-layer unit is shown in Figure 2, which mainly includes the following steps: 1) Prestretching. The DE membrane VHB4910 is equi-biaxially pre-stretched to a certain ratio. 2) Boundary Fixing. Put the two frames (made of lightweight ABS plates with thickness of 1mm) at the center and the edge of the membrane respectively, note that frames is attached only to one side of the membrane. Two copper foils are spliced on the two sides of DE membrane as electrode connectors. 3) Coating electrodes. 846 type conductive carbon grease (MG Chemicals) is coated on both surfaces of DE membrane as compliant electrodes. 4) Assembling. The above procedures are repeated on another DE membrane. Then put two single DE

membranes together, insure that the membranes are sandwiched between two pairs of frames. Finally we cut off the redundant membrane outside the frame.
To fabricate a multi-layer DEG which contains more than two layer membranes, we only need to stack up several units and make sure they are connected to each other in parallel.

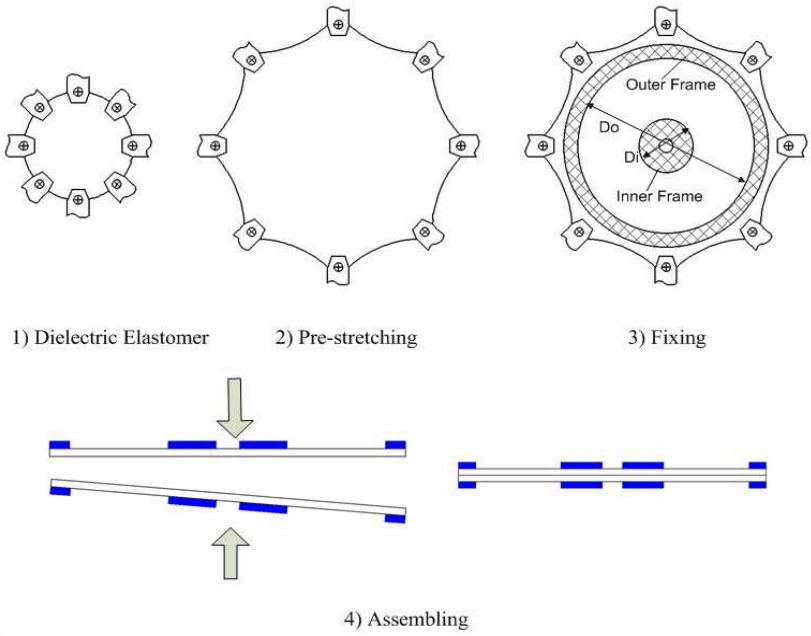

Figure 2 Fabrication process of a two-layer unit

Improved energy harvesting circuit

Considering the special energy generating mode, we designed a simple but useful circuit for energy harvesting. It consists of two capacitors and a rectifier bridge, shown in Figure 3.
Capacitor C1 is used to filter out the AC component caused by DE generated energy and keep the voltage of DEG on a relative steady value. In other words, we only make use of the generated electrical energy and remain the initial electrical energy on the device. Capacitor C1 is required to be a high voltage capacitor with relative high capacitance comparing with DEG. In our experiment, we use a 2000V/1μF and a 2000V/0.1μF capacitor respectively and the result shows that the 1μF capacitor can harvest more energy. The capacitor C2 is used to harvest electrical energy, which required to have a large capacitance value. In our experiment, a 50V/10μF capacitor is used. The energy can drive the load R directly or be stored into a battery for further usage.

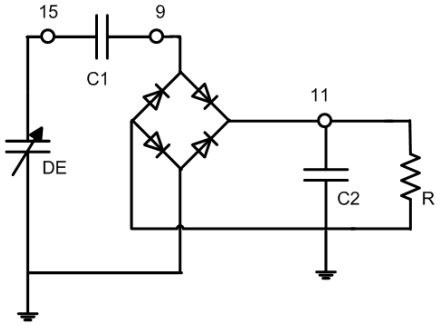

Figure 3 Improved energy harvesting circuit

Assume that the capacitance of DEG changes in sine form, the frequency is 4Hz and the capacitance varies from 2.84~6.31nF. The capacitance of DEG should be $C(t) = 1.735\cos(4 \cdot 2\pi t - \pi) + 4.575\text{nF}$. NI Multisim software is used to do the electrical analysis. In the analysis, we set the load R to ∞ so that the voltage increment on capacitor C_2 is exactly the energy harvested by the circuit. First we add an initial voltage of 1000V on DEG. A Zener diode can be introduced into circuit to control the maximum voltage value at 10V. The output voltage wave form in 10 seconds, is shown in Figure 4.

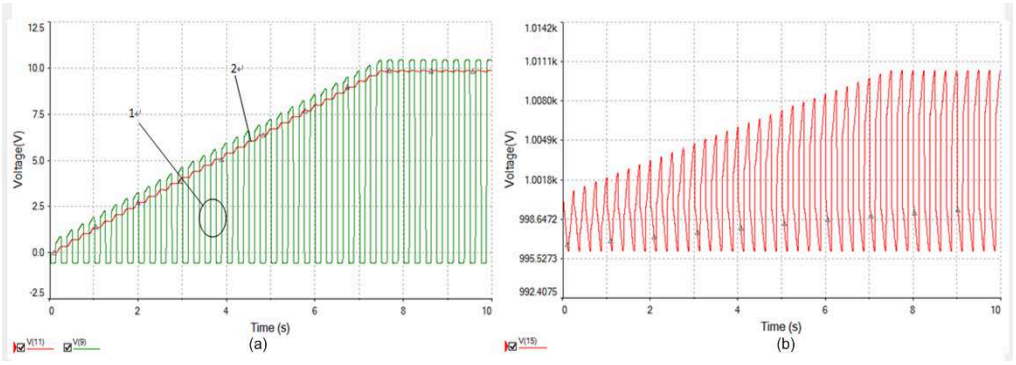

Figure 4 Output voltage wave form on node (a) 9 and 11 (b) 15 with a Zener diode in circuit

Curve 1 in Figure 4(a) shows the voltage on node 9, which is the AC component filtered by C1. Curve 2 shows the voltage on node 11, which is the harvesting voltage across capacitor C2. Figure 4(b) shows the voltage on node 15, which illustrates voltage fluctuation on DEG. It can be seen that the remaining energy on DE generator will keep stable and only change slightly with the harvest energy. We can obtain the voltage fluctuate on DEG is about 1.3%, which can be neglected.

Experimental tests

1.1. Experimental Setup

Figure 5 illustrates the experimental setup for energy harvesting tests, which consists of an annular multi-layer DEG, an oscilloscope (JC1062CA), a high-voltage probe(TREK P6015A, 1000:1) and a voltage amplifier (TREK MODEL 610E) which is controlled by a signal generator(Agilent 33220A).

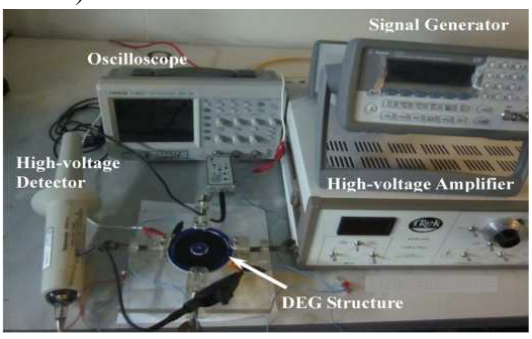

Figure 5 DEG energy harvesting experimental setup

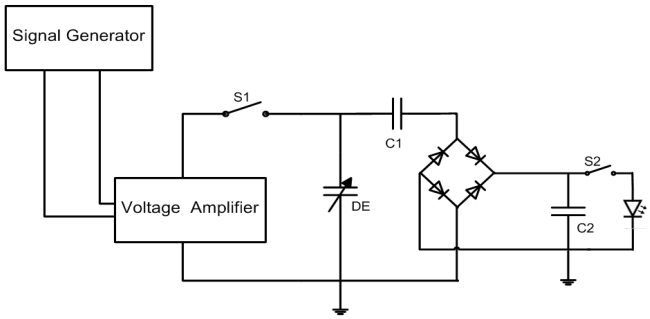

Figure 6 Schematic diagram of experimental circuit

Figure 6 shows schematic diagram of experimental circuit. The constant charge condition is easily achieved by switch S1 in practice. In the experiments, after the DEG is stretched to the certain stretch displacement, switch S1 is connected to charge the DEG. After DEG is charged, switch S1 is disconnected to ensure that the device recovers under the open-circuit condition. Then DEG device is stretched and recovered repeatedly by hand/motor, constantly converting mechanical energy into electrical energy and stored in the capacitor C2. Switch S2 is used to control whether the generated electrical energy is accumulated in capacitor C2 or consumed to drive the light emitting diode.

1.2.Experimental results and discussion

1.2.1. Generated electric energy

In order to obtain the amount of electrical energy generated (increased), the initial capacitance of a single unit need to be measured, combined with output voltage which can directly read from the oscilloscope. Generated energy of single unit per cycle can be calculated through Eq. (2). Since the units of a multi-layer DEG are connected in parallel, the total generated electrical energy can be calculated as

$$\Delta W_{Et} = n\,\Delta W_{Eu} \tag{3}$$

where n denotes the number of units in a multi-layer DEG.
In our investigation, a ten-layer DEG is fabricated, the bias voltage, pre-stretch ratio λ_p and stretch displacement h are 400V, $\lambda_p = 3$ and $h = 30\text{mm}$ respectively. The total electrical energy generated per cycle equals 1.29 mJ. (where corresponding output voltage is 860V, initial capacitance is 2.8nF and number of units in DEG is n=5).

1.2.2. Harvested electric energy

To evaluate the performance of the multi-layer DEG and harvesting circuit, the amount of harvested electrical energy should be paid more attention. As mentioned in Section 4, a capacitor of 50V/10μF is used to store electrical energy, thus harvested electric energy can be obtained through the measurement of the voltage across capacitor C2 (harvesting voltage), namely

$$\Delta W_h(i) = \frac{1}{2} C_h U_h^2(\mathrm{i}) \tag{4}$$

where C_h is capacitance of capacitor C2, i is the number of working cycles, $\Delta W_h(i)$ and $U_h(i)$ denote the harvested electrical energy and harvesting voltage after i working cycles, respectively.
Figure 7 shows the relationship between harvesting voltage U_h and number of working cycles. It can be seen obviously that harvesting voltage increases approximate linearly with the number of working cycles.

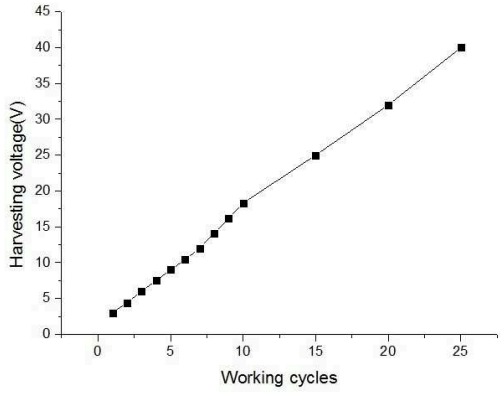

Figure 7 Harvesting voltage at different working cycles

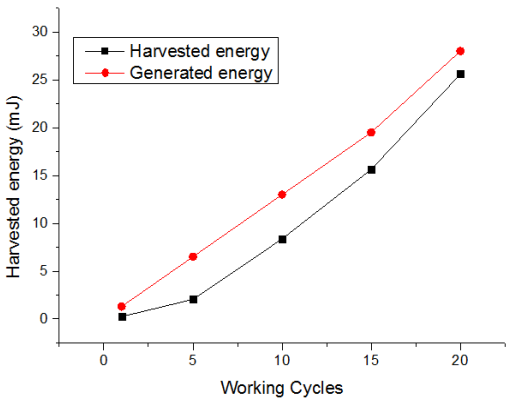

Figure 8 Comparison between harvested and generated energy vs. working cycles

Figure 8 shows comparison between harvested electrical energy and generated electrical energy at different working cycles. It can be observed that the generated electrical energy and harvested electrical energy results are comparable each other. The maximum energy harvesting efficiency η_h

can reach 89% (where η_h is the ratio between harvested energy and generated energy). This is possibly because the energy consumed by the components in harvesting circuit. What's more, a multi-layer DEG has a thickness of about 10mm, which result in a little error in the parameter of stretch displacement h.
In energy harvesting experiments, it can be observed that an annular ten-layer DEG can harvest enough electrical energy to drive a light emitting diode continuously.

Conclusion

In this paper, an annular ten-layer DEG device is specially designed and fabricated. Then an improved energy harvesting circuit is presented to make use of harvested electrical energy. Energy harvesting experiments are implemented to investigate its energy harvesting performance under the charge-constant condition. The experiments indicate that through stretch-recover the DEG device repeatedly, mechanical energy can convert into electrical energy and effectively drive a light emitting diode. In addition, The maximum energy harvesting efficiency η_h can reach 89%. Energy harvesting efficiency η_h can be further improved by increasing the active working area of DE membrane and enhancing the performance of energy harvesting circuit.

Keywords: automated meter reading system, bad data detection, state estimation, energy flow problem, accuracy class, metering error, observability, measurements.

Abstract. Reliability of measurements received from automatic meter reading (AMR) systems is important. This paper presents method of bad data detection. The method allows to estimate the value of systematical error of each AMR complex in case of sufficient statistical sampling.

Introduction

All measurements of the electric energy EE) contain mistakes. In a general EE measurement can be presented as a sum of true, but unknown meaning of the measured magnitude W_i^{true}, a systematical component of error δ_{Wi} and a random error σ_{Wi} which has a zero expectation and nonzero dispersion:

$$W_i^{msm} = W_i^{true} + \delta_{Wi} + \sigma_{Wi}\,. \tag{1}$$

Maximum permissible measuring error for the i-th energy complex is defined by[1]

$$\delta_i = 1{,}1\sqrt{\delta_{Ii}^2 + \delta_{Ui}^2 + \delta_{EMi}^2 + \delta_{link\_i}^2}\,,\ \% \tag{2}$$

where δ_I, δ_U, δ_{EM} are accuracy ratings of a current transformers, voltage transformers and an energy meter, correspondingly; δ_{link} is a drop of voltage in a cable line.

However, during operation, the actual EE measurement error can exceed permissible limits defined (2). Another way of researches is equipment functional state assessment system [2]. In state estimation (SE) theory incorrect measurements are called bad data. Bad data are to be revealed and eliminated as quick as possible. Analytical methods of bad data detection are least expensive.

Theoretical Background

Within frameworks of SE theory the equations containing all measured variables refer to as testing TE. [3-5] describes bad data detection method based on solving the testing equations system. TE technique is built on the fact that equations of state have small connection. Thus the measured EE flow clearly depends on few other flows. Sizable mismatches (imbalances)likely will correspond to equation containing bad data. Obviously it is necessary just to compare energy flows at the beginning and at end of the branch to validate them. The correct nodal balance or balance in separate circuit fragment indicates the correctness of measurements included into the balance equation.

The TE method also allows to form system of validating equations for each measurement. Dimension of this system is defined by total number of TE. That is each measurement can be recalculated using linear combinations of other measurements.

Reliability of measurement is rated according to difference between its recalculated value and measurement itself. Total variance is calculated for each validating equation D_i. The expression for determining the calculated value for measurement can be obtained from minimized objective function:

$$F = \sum_{i=1}^{N} \frac{1}{D_i} (W^{calc} - W_i^{calc})^2, \quad (3)$$

where D_i is the total variance if the i-th validating equation, W^{calc} is desired value of energy flow, W_i^{calc} is value of energy flow obtained by calculation the i-th validating equation.

Calculated value for measured energy flow is counted upon the formula:

$$W^{calc} = \sum_{i=1}^{N} \frac{1}{D_i} W_i^{calc} \cdot (\sum_{i=1}^{N} \frac{1}{D_i})^{-1} \quad (4)$$

Calculated EE flows values W_i^{calc} are determined on the input data basis which is measured flows W_i^{meas}. Accounted parameters completely match state equations system in contrast of measurements.

Computing of calculated EE flow value corresponding to the measurement using the system of verification equations allows to determine measurement error during each measurement interval under consideration.

The higher the precision of AMR complexes, the smaller the difference ΔW_i between measured W_i^{meas} and calculated W_i^{calc} values of EE flow. Thus, the relative value of the estimated error corresponds to the actual error of AMR complex:

$$\delta_W = (\Delta W_i / W_i^{meas}) \cdot 100 \ \% \quad (5)$$

Availability of numerous time intervals for calculation allows collecting statistical information about calculated errors of each AMR complex. Further processing of these data can help to detect presence and determine the magnitude of systematical error of corresponding AMR complex.

The expectation value of calculated errors series corresponds to the constant component of AMR complex error, i.e. systematical error. Accordingly, carrying out such calculations allow to distinguish AMR complexes in need of immediate metrological verification.

The results of calculations for each AMR complex can conveniently be presented as dynamic error distribution graph and histogram of error deviation from its expectation. The form of diagrams would show the presence of systematic error.

Calculation of Systematical Error

Calculations for part of Russia energy system are produced to demonstrate the effectiveness of the method under discussion. The considered network consists of four nodes ring and three radial branches. Calculations are carried out for 792 hour intervals.

Parameters of transmission lines and transformers are used as initial data for equivalent circuit construction. The source of 792 measurement intervals is AMR system. Losses in each network fragment are taken into account.

The system of TE is formed by excluding all unmeasured variables from system of state equations of EFP [6], i.e. system of balance equations in nodes and branches of equivalent circuit.

Initial EFP state equations system for equivalent circuit under consideration can be presented as:

$$\begin{aligned}
&W_2 + W_4 + W_5 + W_{12} + W_{13} + W_{14} + W_{15} + W_{16} + W_3 + W_{11} + W_{10} = 0 \\
&W_{23} + \overline{W_{3-31}} = 0 \\
&\cdots \\
&W_{40} + \overline{W_{7121-712}} = 0 \\
&W_{14} + W_{18} + \Delta W_{1-2mex} = 0 \\
&\cdots \\
&\overline{W_{712-7121}} + \overline{W_{7121-712}} + \Delta W_{712-7121mex} = 0
\end{aligned} \quad (6)$$

Configuration of equivalent circuit is presented on Fig. 1.

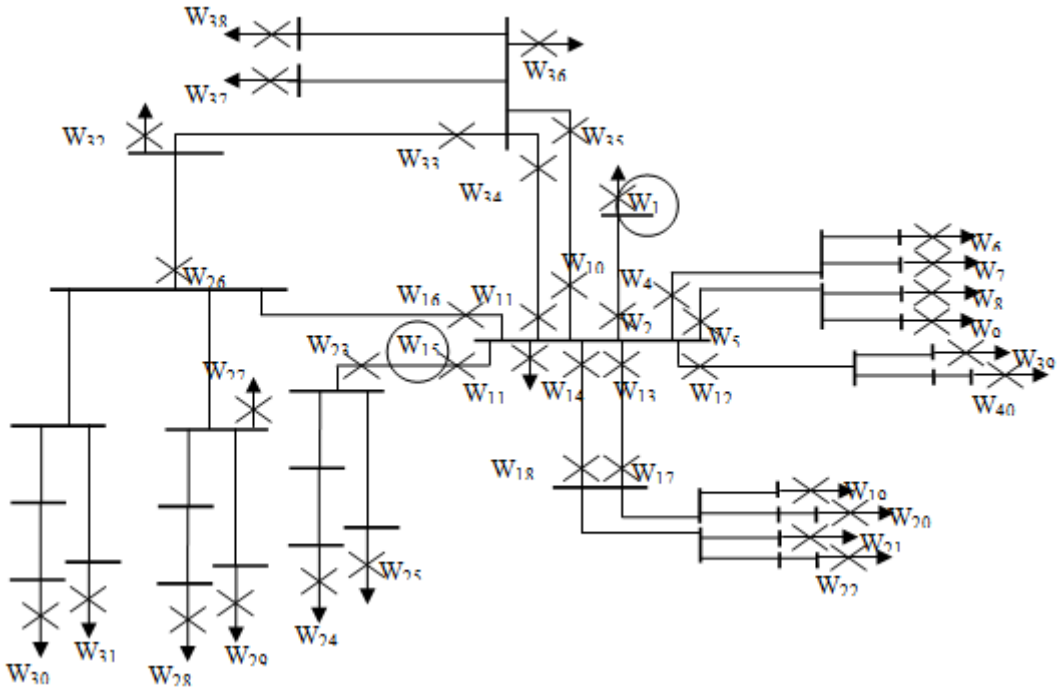

Fig.1 Configuration of equivalent circuit

Next step is to draw up a series of verifying equations for each measurement. Energy complexes errors determined by the formula (1) and error of technical losses calculation are assumed 1%and 10% correspondingly.

This system for measurement W_1 is**:**

$$
\begin{aligned}
&W_1 = W_2 - \Delta W_{1-13}\\
&W_1 = -(W_4 + W_5 + W_{12} + W_{13} + W_{14} + W_{15} + W_{16} + W_3 + W_{10} + W_{11}) - \Delta W_{1-13}\\
&W_1 = -(W_6 + W_7 + \Delta W_{1-111-112} + W_5 + W_{12} + W_{13} + W_{14} + W_{15} + W_{16} + W_3 + W_{10} + W_{11}) - \Delta W_{1-13}\\
&W_1 = -(W_4 + W_8 + W_9 + \Delta W_{1-121-122} + W_{12} + W_{13} + W_{14} + W_{15} + W_{16} + W_3 + W_{10} + W_{11}) - \Delta W_{1-13}\\
&W_1 = -(W_4 + W_5 + W_{39} + W_{40} + \Delta W_{1-7} + \Delta W_{7-711-7121} + W_{13} + W_{14} + W_{15} + W_{16} + W_3 + W_{10} + W_{11}) - \Delta W_{1-13}\\
&W_1 = -(W_4 + W_5 + W_{12} + W_{17} + \Delta W_{1-2(1)} + W_{14} + W_{15} + W_{16} + W_3 + W_{10} + W_{11}) - \Delta W_{1-13}\\
&\ldots
\end{aligned}
\qquad (7)
$$

Series of calculated values for each measurement is computed from the verification equations system. Table 1 presents computing results for the first four time intervals for measurement W_1 .

Table 1. Calculated values of W_1

Time interval PArameter	01.11.12 00.00-01.00	01.11.12 01.00-02.00	01.11.12 02.00-03.00	01.11.12 03.00-04.00
W_1 [kWh]	257600	268000	281400	291800
$W_1^{расч}$ [kWh]	253894	264517	277355	287806
$W_2^{расч}$ [kWh]	256446	267025	279819	290270
$W_3^{расч}$ [kWh]	256969	267649	280330	290826
$W_4^{расч}$ [kWh]	256619	267267	280004	290477
$W_5^{расч}$ [kWh]	256540	267227	280020	290505
$W_6^{расч}$ [kWh]	239500	250833	264334	274270
…				

Errors of measurements on each time interval are calculated according to the formula (5) using calculated values. Table 2 presents results for the same four time intervals for W_1 .

Table 2. Errors of measurement W_1

Time interval Parameter	01.11.12 00.00-01.00	01.11.12 01.00-02.00	01.11.12 02.00-03.00	01.11.12 03.00-04.00
W_1 , [kWh]	257600	268000	281400	291800
W_1^{calc} , [kWh]	254623	265341	278223	288625
δ_W , [%]	1,16	0,99	1,13	1,09

Error distribution and histogram for AMR complex W_1 are presented on Fig. 2a and 2b.

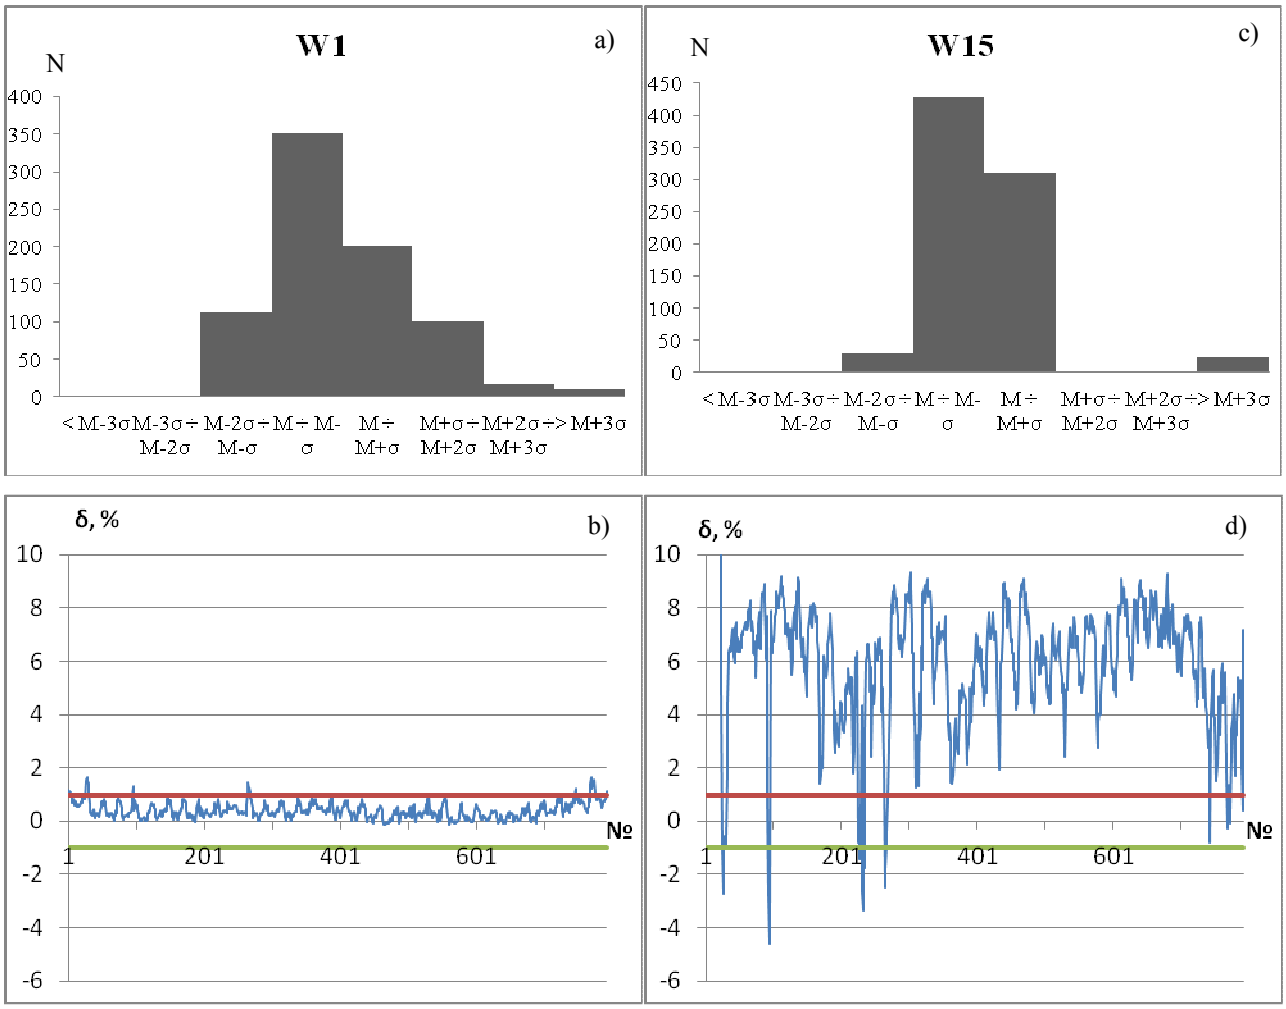

Fig 2. a, c – Histogram for measurements W_1 and W_{15} correspondingly, b, d – error distribution for W_1 and W_{15} correspondingly.

Serviceability criterion for any AMR complex is defined according to formula:

$$M_{W_i} \le \delta_{\lim_i}, \tag{8}$$

where M_{W_i} is the expectation of calculated errors series for W_i , $\delta_{\lim_i}$ is the maximum permissible error of AMR complex defined by (2).

The magnitude of calculated error expectation is 0.4% which does not exceed the limiting meaning of AMR complex error (which is 1%), so this AMR complex considered serviceable.

Similar calculations were performed for AMR complex W_{15}. The expectation is 5.8% that exceeds the maximum permissible margin of error. It should be recommended to carry out immediate metrological verification of this complex.

Summary

1. Ensuring the reliability of AMR system metering information is important. Only metrological methods are not sufficient to provide verification of measurements. Mathematical approaches require the least cost.
2. Bad data detection methods developed in frameworks of SE theory are the most effective methods of measurement reliability control.
3. Analytical methods based on TE along with verification allow to produce estimations of measurements. If there are sufficient retrospective it is possible to estimate systematical error of AMR complexes. Thus analytical approaches allow to excersize self-diagnosis of AMR system during metrological verification intervals.

Keywords: power transformer, functional state, test, diagnostics, hybrid neural networks, Takagi-Sugeno fuzzy method.

Abstract. This paper addresses the problems, connected with implementation of 110-220 kV power transformer structural model for automated equipment functional state assessment system based on test and technical diagnostics data. This article describes the basic construction principles of hybrid neural network using Takagi-Sugeno fuzzy method. The paper also provides the statistical data analysis results for power transformers (of real energy grid part) to define fuzzy neural network criteria (layers).

Introduction

Today failure statistics analysis shows that the main causes limiting the electricity consumer's power supply are the equipment deterioration high degree, operation and repair errors, defects of manufacture and equipment installation. But the decision to replace or electrical substations equipment upgrades must be justified by its actual state, potential risks and economic expediency. Therefore the equipment functional state assessment system is one of the key issues in modern Grid Enterprise Asset Management (EAM).

Problem definition and solution

The modern Grid Enterprise Asset Management (EAM) is constructed on the principles of installing additional sensors and equipment monitoring systems at substations. But today the enterprise, on the balance of which there are a large number of substations, have neither technically or economically possible to install additional equipment functional state assessment system for each equipment at substations, particularly in remote areas. In turn each company must properly manage its technical assets (including repair, replacement, retrofit, renovation, maintenance of equipment, etc.) and the correct and timely identification of system bottlenecks (at substations or some substations) depends on the distribution of financial flows.

Thus the effective management of technical assets is provided a minimum of costs and therefore to make maximum use existing equipment technical state assessment methods, which in modern Russian power industry technical diagnostics methods and equipment test methods are presented. Therefore the authors in this paper proposed for the automated control system to realize the technical assets based on test data and technical diagnostics, which in turn are regulated by regulatory documents and are required at the moment.

It should be noted that this method is not appropriate for the assessment of equipment each part separately and only for the integrated (complex) substations assessment and only to solve the EAM task is effective. For the modeling of such systems in this case possible to use the hybrid neural networks, those combine the methods of fuzzy logic and artificial neural networks. In this paper, the Takagi-Sugeno fuzzy control method is used.

Power transformer model

This article presents the example of actual state system realization for 110-220 kV power transformer for the integrated substation assessment. The model consists of two main objects: "passport data" equipment and "technical components" (it is possible to use regime parameters as in [1]). If the object "passport data" includes manufacturer's data and the represents a simple object then the object "technical components" is a complex subject and consists of 9 simple sub-objects:

1. core;
2. winding;
3. solid insulation;
4. oil;
5. cooling system;
6. high-voltage bushing;
7. tank and auxiliary systems;
8. on load tap changer (OLTC);
9. contact connection.

Each of sub-object is characterized by different defects (possible) types each of them can be determined using different test methods shown in Table. 1. In this case, the model mathematical formulation is performed using the Takagi-Sugeno fuzzy method. Simulation of hybrid systems of this type in the software package Matlab is realized.

Proposed approach firstly results in the creation of neural network specific construction and secondly - in network connections' weights determination. This fuzzy neural network forms a fuzzy rules and membership functions adapts in the learning process by modification of connections' weights [2]. In Takagi-Sugeno fuzzy method the rules presented in the form functional binding (1) rather than as an output variable membership to the fuzzy sets

$$R^{(k)}: IF(x_1 \ is \ A_1^k \ AND \dots AND \, x_n \ is \ A_n^k) \ THEN \ y = f^{(k)}(x_1,...,x_n) \quad (1)$$

where $R^{(k)}$ - fuzzy rules ($k = 1,...,N$,where N - number of fuzzy rules); A_i^k - fuzzy sets (where $i = 1,...,n$); $x_1,...,x_n$ - input variables; y - system output is a input variables function. Each rule will produce its own numerical value of the control action [3].

There are a number of curves typical forms to define the membership functions. In this case for each input variable by the degree of membership for each of the states using membership functions LR-type is determined [4]: $\mu_i(x) \in R \to [a;c]$, where R - set of real numbers, $[a,c]$ - range of the variable, b - the most possible value of the variable.

$$\mu_i(x) = \begin{cases} 0, & x \le a \\ \dfrac{x-a}{b-a}, & a \le x \le b \\ \dfrac{c-x}{c-b}, & b \le x \le c \\ 0, & c \le x \end{cases} \quad (2)$$

Membership functions in this case are the linguistic functions "state" includes four possible states in terms of technical operability:

- good condition D_1, when the equipment meets all technical requirements. Good condition is always an operable one;
- fault and operable condition D_2, when technical requirements are met for object properties, which characterize the ability to perform predetermined functions;
- fault and inoperable condition (repairable) D_3, when the equipment is unable to perform the predetermined function, but it is possible and economically feasible to carry out service works;

– inoperable and non-repairable D_4, when service is technically impossible or economically unfeasible [5].

General view of membership functions in Fig.1 is shown. It is necessary to determine the memberships of parameters to following criteria set are presented in Table 1.

These criteria are defined on the basis of statistical data (analysis of 92 substations of Sverdlovsk region from 2000 to 2013 years) by selecting the direct related factors and determining correlations.

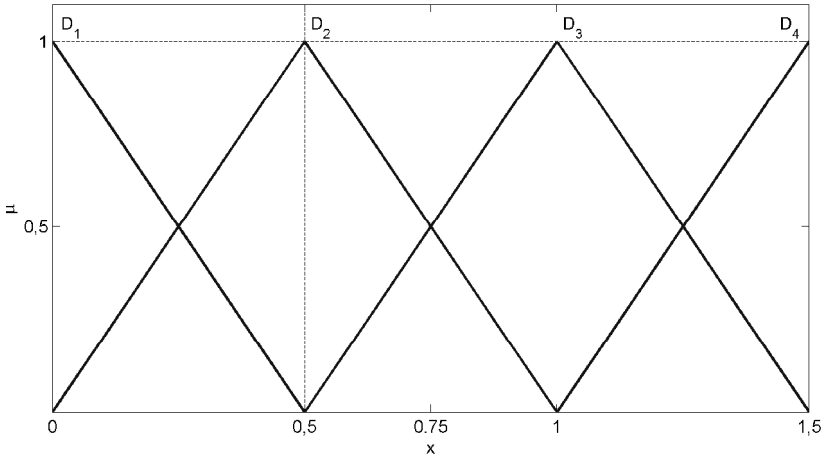

Figure 1 - Membership function

Table 1
Membership criteria for the input parameters

№	Transformer part	Defect type	Diagnostic and tests methods
1.	Core	a. varnish insulation defect between the magnetic plates; b. insulation defect between the core and fastenings elements; c. insulation defect between the core and LV winding; d. defect of core grounding; e. asymmetry of the core due to winding defect.	a. load losses test; partial discharges test; b. load losses test; partial discharges test; c. insulation resistance test and capacitance test by zones; d. insulation resistance test capacitance test by zones; e. load losses test.
2.	Winding	a. displacement and deformation of coil windings; b. defect connections of tap windings; c. defect connections between winding.	a. short-circuit resistance test; vibroacoustic test b. DC resistance test; c. DC resistance test.
3.	Solid insulation	a. breakdown longitudinal insulation; b. deterioration of the insulation; c. wetting insulation; d. partial discharges in insulation; e. decrease of the polymerization index.	a. induced high frequency voltage test; no-load test; b. opacity oil test c. wetting insulation assessment; d. chromatographic analysis; e. assessment of availability of furan compounds in the oil and degree of polymerization.

Table 1 Continuation

№	Transformer part	Defect type	Diagnostic and tests methods
4.	Oil	a. oil humidity; b. contamination; c. sludge; d. variation in electrical characteristics; e. variation of acid value; f. variation of closed cup flash point; g. variation of dielectric loss tangent; h. variation of water-soluble acids and alkalis; i. availability of ionol; j. gas oil ratio.	chromatographic analysis and physico-chemical analysis of oil
5.	Cooling system	a. stator windings insulation defect; b. bearing damage of electric pump; c. pollution of tubes coolers.	a. insulation resistance test; b. listening and measuring levels of noise and vibration; c. oil differential temperature test at the cooler.
6.	High-voltage bushing	a. cracks and chips of porcelain insulators; b. pollution of the insulator external surface; c. oil leak; d. variation of composition and oil content; e. variation in electrical characteristics; f. partial discharges; g. capacity increase of basic insulation.	a. thermal imaging control; b. thermal imaging control; c. overpressure test; thermal imaging control; d. chromatographic analysis and physico-chemical analysis of oil. e. control under operating voltage.
7. 8.	OLTC	a. oil leak; b. variation in electrical characteristics of oil and wetting insulation c. contact defects.	a. thermal imaging control; oil level measuring; b. oil humidity test; c. DC resistance test;
9.	Contact connection	a. heatings contacts in places of fastening to bushing.	a. thermal imaging control.

Afterwards, one should define the linear relation between the input and output parameters and specify production rules, basing on Table 1 data and specific boundary values for each test method and parameter rules, basing on Table 1 data and specific boundary values for each test method and parameter.

Summary

This article presents the model of the power transformer functional state by using fuzzy characteristic functions LR-type. Based on the statistical data of the power equipment failures and transformers diagnostics and tests are formed correlation dependences between the defects types and diagnosable parameters. These connections form the basis of power equipment assessment. This paper describes the model of automated control system, which is used for power equipment technical state assessment, based on diagnostics and test data, and can be considered as one of the main ways of power industry enterprise cost cutting.

Keywords: circuit breaker, mechanical vibration signal, fuzzy C clustering analysis, classification performance.

Abstract. With permanent magnetic actuator monostable circuit breaker as the research object, it gets three different running status signal data, normal circuit breaker closing state , break-brake spring single loss and Institutions unsmooth Through constructing data acquisition platform. The performance of the three methods of feature extraction is compared, short-time Fourier transform, wavelet packet energy entropy and Hilbert huang transform, through fuzzy c-means clustering analysis algorithm. Through the comparative study, it is concluded that adopt wavelet packet transform method to get the best classify performance of time-frequency entropy vector .

Introduction

Circuit breaker mechanical vibration signal is a typical non-stationary signal, the signal contains information of abundant working status and fault characteristic. The signal characteristic value can be extracted by time-frequency analysis method. The typical time-frequency analysis contains short-time Fourier transform, wavelet transform and Hilbert huang transform, etc. And signal feature extraction result affect much the performance of state classifier equal with the diagnostic method, the characteristics extracted is very different through different categories. It is easier to design a better performance classifier. On the contrary, if the characteristics extracted is little different through different categories, the training of the classifier and the study take a long time, the precision of design is also difficult to guarantee. Therefore, it need to analyze the classification performance of feature vector, to choose the optimum method of feature extraction, provide characteristic data basis for fault diagnosis of the next step[1~3].

With permanent magnetic actuator monostable circuit breaker as the research object, it gets three different running status signal data, normal circuit breaker closing state , break-brake spring single loss and Institutions unsmooth Through constructing data acquisition platform. The performance of the three methods of feature extraction is compared, short-time Fourier transform, wavelet packet energy entropy and Hilbert huang transform, through fuzzy c-means clustering analysis algorithm.

Circuit breaker mechanical vibration signal acquisition

In view of the vibration signals of circuit breaker, it designed and developed the data collection system. The system consists of sensor, communication unit and upper machine. lower machine adopts DSP28335 microcontroller and ADS8364 analog-to-digital conversion chip. communication unit adopts RS485 serial communication bus. upper machine adopts VC++ application development environment and MS SQL Server relational database. Mechanical vibration signal sensor adopts LC0159 type piezoelectric acceleration sensor, which sensitivity is 10mV/g, range is 500g, frequency range is 1-12000Hz and is directly installed in the B phase outside of circuit breaker shell with persistence flow power module. The actual measurement figure collection as shown in Fig.1.

The acquisition system is a total of 6000 data in 150ms, through sampling frequency of 40 kHz. Under the condition of no-load closing, it analyzes three signal of each state, the circuit breaker normal, the operation and the transmission mechanism unsmooth and break-brake spring single off. The measured data diagram as shown in Fig.2-4. the measured data of vibration signal needs to be done to eliminate trend before the eigenvalue extraction processing.

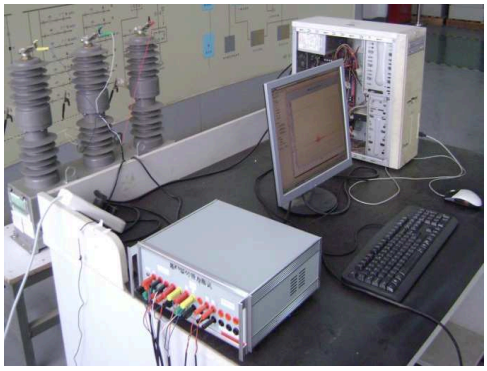

Fig.1 Acquisition field of circuit breaker mechanical vibration data

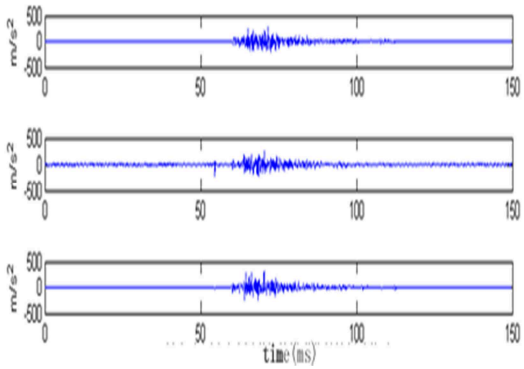

Fig .2 Mechanical vibration signal of normal closing

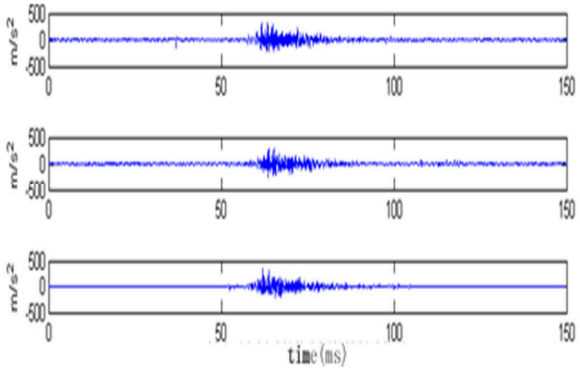

Fig.3 Mechanical vibration signal of break-brake spring single shed

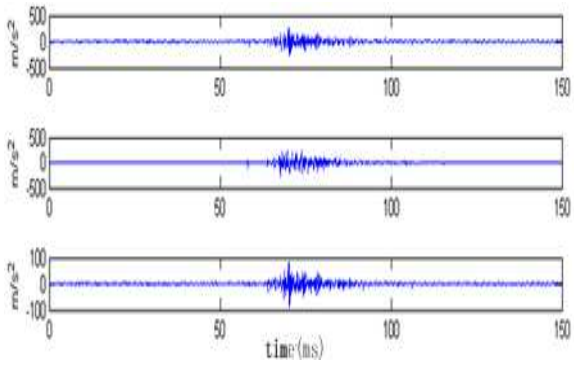

Fig.4 Mechanical vibration signal of mechanism unsmooth

Eigenvalue extraction of three kinds of time-frequency entropy vector

(1) vibration signal characteristic value is extracted by Short time Fourier transform

Principle of short time Fourier transform (STFT) is the non-stationary signal add a time window, which approximate consider the signal is smooth in small section time[4]. Such short transient time domain signal can be treated by Fourier transform. According to the vibration data in Fig.2-4, it establish characteristic data of length 256, the energy spectrum of the signal is extracted by short time Fourier transform as shown in Fig.5.

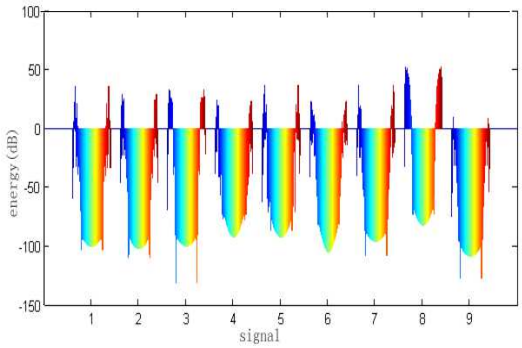

Fig.5 Short FFT energy spectra of circuit breaker vibration signal

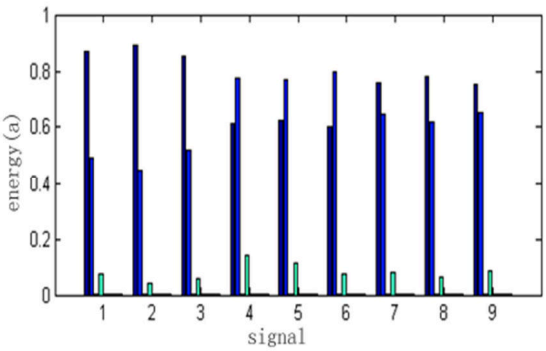

Fig.6 Wavelet packet energy spectrum of circuit breaker vibration signal

(2) vibration signal characteristic value is extracted by wavelet packet energy entropy method

Wavelet transform has the ability of denoting local signal characteristics in the time-frequency domain, but only decompose the low frequency part of signal, not decompose the high frequency part of signal[5]. And wavelet packet decompose the part of low frequency and high frequency signal at the same time. In fault diagnosis of circuit breaker, when the circuit breaker operation state is abnormal, the energy of each frequency components of circuit breaker vibration changed corresponding, the change of one or several frequency components maps the fault mode of circuit

breaker. According to the vibration data in Fig.2-4, it extract the energy spectrum of the signal through three layers db10 wavelet packet transform, as shown in Fig. 6.

(3) vibration signal characteristic value is extracted by Hilbert huang transform

Hilbert - Huang Transform (HHT) mainly includes two parts, the Empirical Mode Decomposition (EMD) and Hilbert spectrum analysis[6]. According to the vibration data in Fig.2-4, the energy spectrum of the signal is extracted through Hilbert - huang transform, as shown in Fig.7.

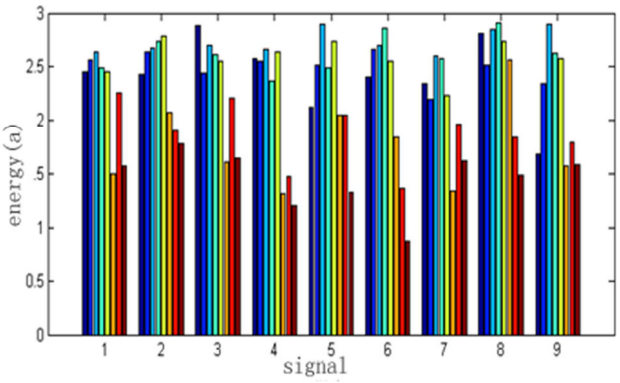

Fig.7 HHT energy spectra of circuit breaker vibration signal

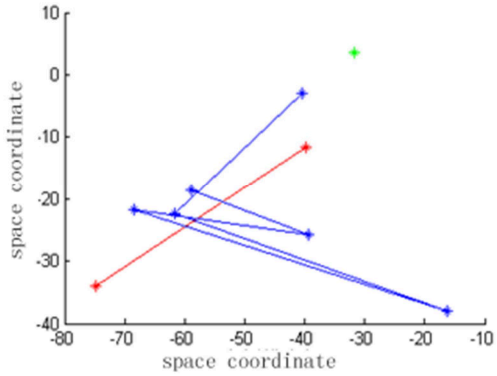

Fig.8 FCM clustering analysis diagram of the characteristics data of short-time FFT

Effectiveness analysis of the three kinds of time-frequency entropy vector

Clustering is understood as a collection of similar objects. Clustering analysis is an unsupervised learning method, and find the data underlying similarities[7].

Fuzzy c-means clustering (FCM) is a very typical fuzzy clustering method, it determine the best classification through the goal function iterative optimization. It define A data set $\{X_k\}_{k=1}^n$, and divide into class C by FCM algorithm. Its goal function express as follows.

$$J(U,V)=\sum_{i=1}^{c}\sum_{k=1}^{n}u_{ik}^{m}\|x_k-v_i\|^2 \tag{1}$$

It satisfies the following conditions：

$$\sum_{i=1}^{c}u_{ik}=1\,|\,0\le u_{ik}\le 1,\forall k=1,2,\cdots,n \tag{2}$$

$$0<\sum_{k=1}^{n}u_{ik}<n \tag{3}$$

In formula, U as the membership degree matrix, u_{ik} as membership degree of data points x_k to cluster center points v_i, m as membership weighting coefficient, V as matrix of clustering center. According to the Lagrange algorithm to get the iterative formula:

$$u_{ik}=\frac{1}{\sum_{j=1}^{c}\left(\frac{\|x_k-v_i\|}{\|x_k-v_j\|}\right)^{2/(m-1)}} \tag{4}$$

$$v_i=\frac{\sum_{k=1}^{n}u_{ik}^{m}x_k}{\sum_{k=1}^{n}u_{ik}^{m}} \tag{5}$$

FCM algorithm clusters data through the iteration formula (4) and (5).

According to the fuzzy c-means clustering analysis theory, it compares the three methods of feature extraction of vibration signal analysis under different condition of circuit breaker. its results of the clustering analysis through Short time Fourier transform is shown in Fig.8. its results of the clustering analysis through Wavelet packet transform is shown in Fig.9. its results of the clustering analysis through Hilbert huang transform is shown in Fig.10.

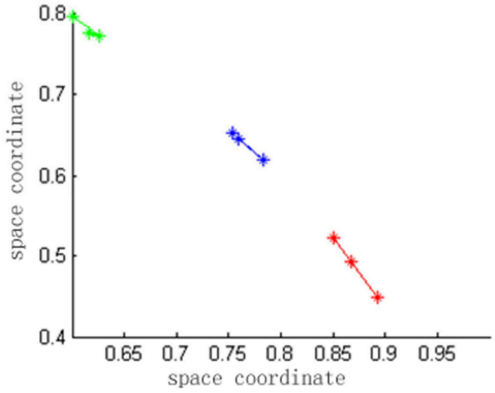

Fig.9 FCM clustering analysis diagram of characteristics data of wavelet packet

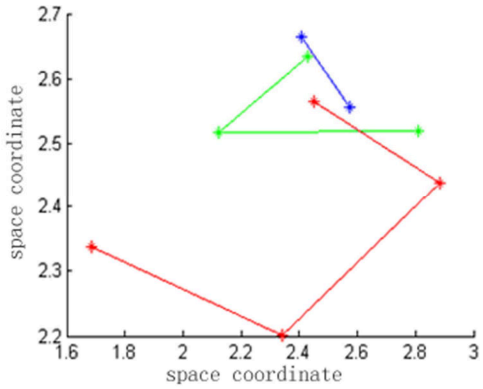

Fig.10 FCM clustering analysis diagram of HHT characteristics data

It concluded from the above figure, the characteristic value of circuit breaker vibration signal extracted through wavelet packet energy entropy, that achieve the best classification effect. Clustering results are consistent with implementation classes, the energy entropy vector clustering results are very different with implementation classes through the other two methods.

Conclusion

With permanent magnetic actuator monostable circuit breaker as the research object, it gets three different running status signal data, normal circuit breaker closing state , break-brake spring single loss and Institutions unsmooth Through constructing data acquisition platform. The performance of the three methods of feature extraction is compared, short-time Fourier transform, wavelet packet energy entropy and Hilbert huang transform, through fuzzy c-means clustering analysis algorithm. Come to the following conclusions:

(1)It gets the best classify performance of time-frequency entropy vector obtained Through Wavelet packet transform method. Clustering results are consistent with implementation classes

(2)The energy entropy vector clustering results are very different with implementation classes through Short-time Fourier transform and Hilbert huang transform.

Keywords: Photovoltaic inverter, unbalanced grid fault, distribution grid, power control, current harmonics.

Abstract. This paper studies the instantaneous output power characteristics of photovoltaic inverters and its flexible power control strategy under unbalanced grid faults. Then the optimal parameters model of the power control is established with minimum integrated fluctuation amplitude of the active and reactive power as a goal when the constraint of the output current harmonic distortion of photovoltaic inverters is taken into account. Finally, the optimal power control of photovoltaic inverters based on dead-beat current tracking is realized and the feasibility of the proposed control strategy is verified with the power system transient software PSCAD/EMTDC.

Introduction

More distributed generators (DG) has been embedded in distribution networks with increased penetration of renewable power [1, 2]. Photovoltaic (PV) has played a vital roll in DG systems for its easy installation and proven technique. In the actual operation of power grid, unbalanced faults happen more frequently than balanced faults, which will lead to oscillation of output power and output current increasing which will further bring about harmonic distortion of PV inverters. Hence, it is of necessity to study on PV inverter operation characteristics under unsymmetrical voltage and analyze the improved control in allusion to unbalanced faults.

Photovoltaic inverter control strategy under unbalanced grid faults includes two parts: reference current calculation and current tracking control. A dual control strategy was proposed to calculate positive and reactive current reference while keeping the DC voltage constant [3]. Resonant control could be added to proportional integral (PI) and improved current reference algorithm considering power oscillation caused by filter inductor [4, 5]. However, the research mentioned above has improved control strategy by considering only operation restrain but without the impact caused by injection current in the presence of faults. In allusion to active power control, reference [6] has proposed five kinds of control strategies and compared their characteristics of inverter output power oscillation and current harmonics with each other. According to the above, [7, 8] proposed the control strategy in which the amplitude of output double-frequency power oscillation of inverters is continuously adjustable within the limit value of DC voltage fluctuation.

This paper proposes a power control strategy of PV inverter under unbalanced grid faults and derivates the total harmonic distortion (THD) formula of reference current. In addition, establishes an optimal model of power control parameters. The current tracking part of PV inverter is designed based on the strategy of deadbeat control and the feasibility of the proposed control strategy has been verified by the power system transient software PSCAD/EMTDC.

Power Control of PV Inverter under Unbalanced Grid Faults

The structure of three phase PV generation system, which consists of PV array, single polarity inverter and control, is shown in Fig. 1.

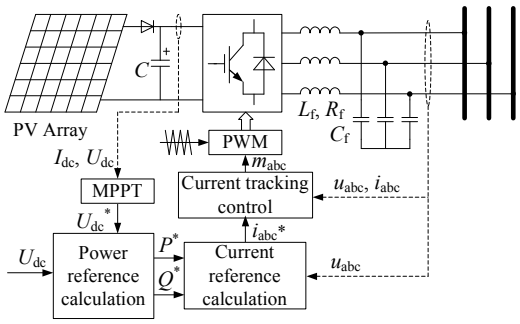

Fig. 1 Grid-connected PV generation system structure

The terminal voltage and current of PV inverter only contain positive and negative components under unbalanced faults which can be written in space form like $\boldsymbol{u}=\boldsymbol{u}^+ + \boldsymbol{u}^-$ and $\boldsymbol{i}=\boldsymbol{i}^+ + \boldsymbol{i}^-$, where $\boldsymbol{u}^+=[u_a^+, u_b^+, u_c^+]^T$, $\boldsymbol{u}^-=[u_a^-, u_b^-, u_c^-]^T$, $\boldsymbol{i}^+=[i_a^+, i_b^+, i_c^+]^T$ and $\boldsymbol{i}^-=[i_a^-, i_b^-, i_c^-]^T$. The terminal voltage is,

$$u(t)|_{a,b,c}=\sqrt{2}U^+\cos[\omega t-(m-1)\frac{2\pi}{3}+\varphi_u^+]+\sqrt{2}U^-\cos[\omega t+(m-1)\frac{2\pi}{3}+\varphi_u^-] \tag{1}$$

Set voltage vector $\boldsymbol{u}_\perp=[u_{\perp a}, u_{\perp b}, u_{\perp c}]^T=[u_b-u_c, u_c-u_a, u_a-u_b]^T/\sqrt{3}$, and $\boldsymbol{u}_\perp=\boldsymbol{u}_\perp^+ + \boldsymbol{u}_\perp^-$. Then the three phase instantaneous active power and reactive power of PV inverter can be written as ,

$$\begin{cases} p=\boldsymbol{u}\cdot\boldsymbol{i}=\boldsymbol{u}^+\cdot\boldsymbol{i}^+ + \boldsymbol{u}^-\cdot\boldsymbol{i}^- + \boldsymbol{u}^+\cdot\boldsymbol{i}^- + \boldsymbol{u}^-\cdot\boldsymbol{i}^+ \\ \quad =3[U^+I^+\cos(\varphi_u^+-\varphi_i^+)+U^-I^-\cos(\varphi_u^--\varphi_i^-)+U^+I^-\cos(2\omega t+\varphi_u^++\varphi_i^-)+U^-I^+\cos(2\omega t+\varphi_u^-+\varphi_i^+)] \\ q=|\boldsymbol{u}\times\boldsymbol{i}|=\boldsymbol{u}_\perp\cdot\boldsymbol{i}=\boldsymbol{u}_\perp^+\cdot\boldsymbol{i}^+ + \boldsymbol{u}_\perp^-\cdot\boldsymbol{i}^- + \boldsymbol{u}_\perp^+\cdot\boldsymbol{i}^- + \boldsymbol{u}_\perp^-\cdot\boldsymbol{i}^+ \\ \quad =3[U^+I^+\sin(\varphi_u^+-\varphi_i^+)+U^-I^-\sin(\varphi_u^--\varphi_i^-)+U^+I^-\sin(2\omega t+\varphi_u^++\varphi_i^-)+U^-I^+\sin(2\omega t+\varphi_u^-+\varphi_i^+)] \end{cases} \tag{2}$$

In order to maintain the active and reactive power of PV and consider the limit of the harmonic distortion of output current under unbalanced faults, the current reference can be obtained from (2)

$$\boldsymbol{i}^*=P^*(\boldsymbol{u}^+ + \alpha\boldsymbol{u}^-)\Big/\left(|\boldsymbol{u}^+|^2+(1+\alpha)\beta\boldsymbol{u}^+\boldsymbol{u}^- + \alpha|\boldsymbol{u}^-|^2\right) \tag{3}$$

Then the output current harmonics and the amplitude fluctuation of active and reactive power can be adjusted by means of changing the coefficient α and β ($\alpha\in[0, 1]$ and $\beta\in[-1, 1]$) in (3).

Formula Derivation of Current Harmonics of PV Inverter

Suppose the ratio of negative sequence voltage to positive sequence voltage is $U^-/U^+=n$, and based on (1) and (3), we can get the currents of three phases,

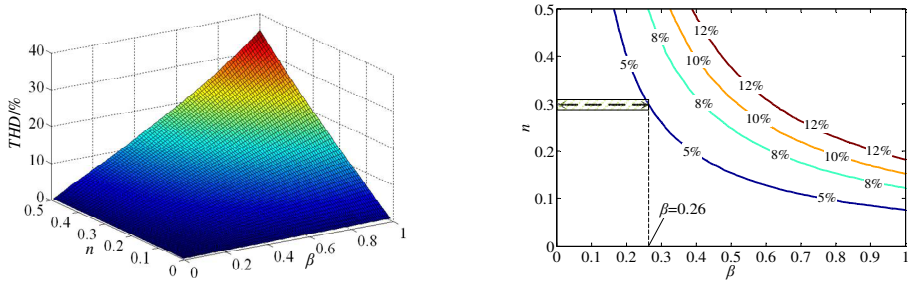
$$^*(t)|_{a,b,c}=\frac{\sqrt{2}}{3[1+\beta(1+\alpha)n\cos(2\omega t)+\alpha n^2]U^+}\left\{P^*[\cos(\omega t-(m-1)\frac{2\pi}{3})+\alpha n\cos(\omega t+(m-1)\frac{2\pi}{3})]\right\} \tag{4}$$

Set $A=\beta(1+\alpha)n$, $B=\alpha n^2$, $C=\sqrt{(1+B)^2-A^2}$, $T=1/f$. Take the current of phase a in (4) as an example, the root-mean-square value of fundamental current and of the full-wave current are I_{1rms} and I_{rms}, and then we can get the THD of phase a current reference in (4),

$$THD=\sqrt{\frac{I_{rms}^2}{I_{1rms}^2}-1}=\sqrt{\left(\sqrt{\frac{1}{T}\int_0^T[i_a^*(t)]^2dt}\right)^2\Big/\left(\frac{1}{2T}\int_0^T i_a^*(t)\cos(\omega t)dt\right)^2-1}=\sqrt{\frac{A^2}{2C(1+B-C)}-1} \tag{5}$$

Fig. 2(a) has shown the characteristics of current harmonics distortion with coefficient n and β (when P^*=1.0pu and α=0.2). The harmonics distortion will decrease as the coefficient n and β decrease. Fig. 2(b) has shown the contour lines of the total current harmonics distortion of 5%, 8%,

10% and 12%. When n=0.3 caused by grid unbalanced faults, current reference harmonics distortion will exceed the rules limit 5% if β>0.26, and current harmonics injecting into grid from the inverter can be reduced by decreasing the coefficient β.



(a) Three-dimensional mesh (b) Contour lines

Fig. 2 Three-dimensional mesh and contour lines of total current harmonic distortion

Optimal Parameters of PV Power Control and Its Implementation

Power Control Parameters Optimization. Substituting (3) into (2), we can get the instantaneous active and reactive power of the PV inverter, and then the maximum value of the active and reactive power fluctuation can be obtained,

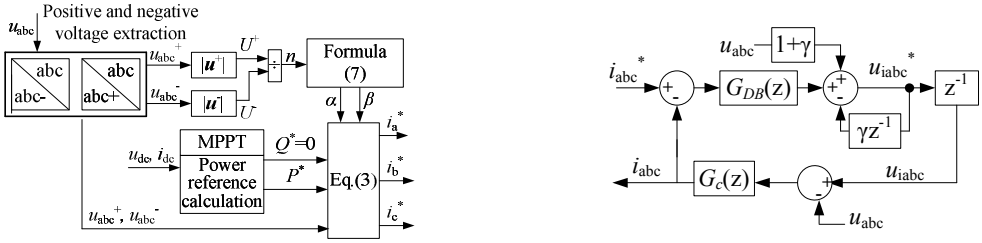
$$\tilde{p}_{\max} = P^* \frac{(1-\beta)(1+\alpha)n}{1-\beta(1+\alpha)n+\alpha n^2} \quad , \quad \tilde{q}_{\max} = P^* \frac{(1-\alpha)n}{1+\alpha n^2} \tag{6}$$

According to (6), the reactive power fluctuation is only related to α, and its amplitude fluctuation will increase with the decrease of the coefficient α. However, the fluctuation of active power is determined by both α and β. Hence, the active and reactive power fluctuation amplitude of PV inverter is effectively adjustable through the control of the coefficient α and β on the premise that all the coefficients are in the feasible region limited by harmonic distortion. This paper has built the optimal selection model of the coefficient α and β, aiming at getting the minimum synthesis power fluctuation with the constraint condition of current THD limit. The model is,

$$\begin{aligned} &\min f = \omega_p \frac{(1-\beta)(1+\alpha)n}{1-\beta(1+\alpha)n+\alpha n^2} + \omega_q \frac{(1-\alpha)n}{1+\alpha n^2} \\ &s.t. \quad 0 < \sqrt{\frac{A^2}{2C(1+B-C)} - 1} < THD_{\max} \end{aligned} \tag{7}$$

where ω_p and ω_q are the weight coefficients of active and reactive power fluctuation, and $\omega_p+\omega_q=1$. $THD_{\max}$ is the maximum limit value of PV current THD. We take $THD_{\max}$=5% in the study and solve the optimization problem of α and β with constrained cyclic coordinate descent method [9].

Implementation of PV Power Control Based on Deadbeat Current Tracking. The structure of the power control system for PV inverter is shown in Fig. 3. The optimal coefficient α and β can be calculated by (7). The three phase current reference i_{abc}^* of the dead beat current tracking inner loop, whose structure is shown in Fig. 3(b), can be obtained by (3).



(a) Power control outer loop (b) Dead beat current tracking inner loop

Fig. 3 Power control outer loop and current control inner loop of photovoltaic inverter

The function of dead beat current control in Fig. 3 is $G_{DB}(z)=(1-\gamma z^{-1})/[\lambda(1-z^{-2})]$ where $\gamma=e^{-(Rf/Lf)Ts}$ and $\lambda=[1-e^{-(Rf/Lf)Ts}]/R_f$ are the current control parameters, T_s is the sampling period, z^{-1} is unit delayed in discrete system and the transfer function of the inverter is $G_c(z)=\lambda/(1-\gamma z^{-1})$. The Z function of the output current i_{abc} of the PV inverter can be expressed as,

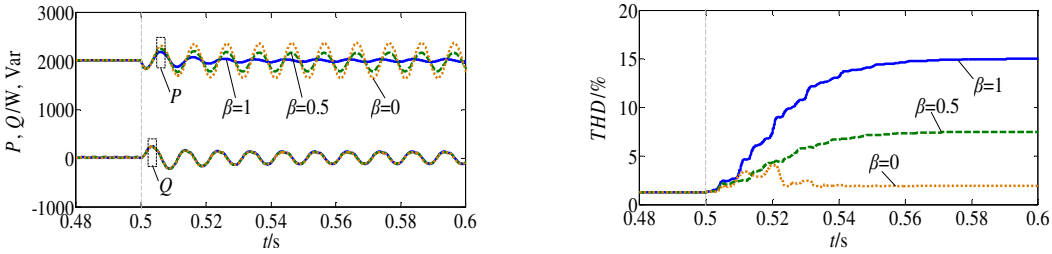
$$i_{abc}=\frac{z^{-1}}{1+(1+\gamma)z^{-1}-z^{-2}-\gamma z^{-3}}i^{*}_{abc}-\frac{\lambda(1-z^{-1}-z^{-2}+z^{-3})}{1+z^{-1}-(1+\gamma+\gamma^{2})z^{-2}+\gamma^{2}z^{-4}}u_{abc}=G_i(z)i^{*}_{abc}+G_u(z)u_{abc} \tag{8}$$

Simulation Results and Analysis

In order to test the feasibility of the method, proposed in this study, namely power control of PV inverter under unbalanced grid faults, we have built a PV generation system model in PSCAD/EMTDC as is shown in Fig. 1. In the model, the ac and dc nominal voltages are 220V and 1000V, the rated apparent power is 2.5kVA, the carrier frequency is 16kHz,and L_f=12mH, R_f=0.4Ω, C_f=0.7μH, T_s=31.25μs.

Analysis of Current Harmonics Characteristics. Suppose that the output active power P_0=2kW under normal operation, and the grid unbalanced fault at t=0.5s leads to n=0.2, set α=0.5.

In Fig. 4 the power fluctuation and current THD of the PV inverter under different coefficient β before and after the grid faults are shown. The current THD of inverters will rise with the increase of β while the active power fluctuation will decrease, and the reactive power fluctuation is only related to α. The current THD in Fig.4 is 14.94%, 7.46% and 0.61% as β=1, 0.5 and 0, and the calculated value of (4) of current THD are 15.21%, 7.41% and 0 which basically fit the simulation value.



(a) Active and reactive power (b) Current total harmonic distortion

Fig. 4 Output powers and current harmonics of photovoltaic inverter for different coefficient β

The current THD goes beyond the limit 5% when β=1 and 0.5. When β=0, the active power fluctuation is still large though the current THD is tiny, so that under such condition, only by combining power fluctuation with current THD can we choose reasonable parameters.

Parameter Optimization of Power Control. Suppose n=0.4 and α=-1, β=0, and then test the two conditions under ω_p=0.6, ω_q=0.4 (case 1) and ω_p=0.2, ω_q=0.8 (case 2). Fig. 5 shows the changing trajectory of power control parameters under different weight coefficients. From the optimization model of (7), we can obtain the optimal control parameters of case 1 and 2 are separately α=-0.782, β=1 and α=1, β=0.144. Both the two sets of control parameter will enable the current THD of the PV inverter to get close to the limit 5%.

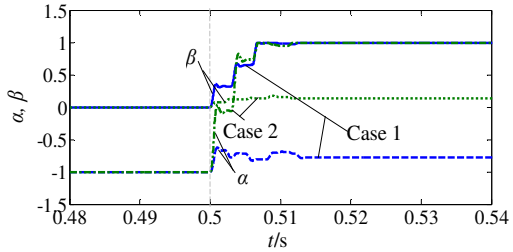


Fig. 5 Power control parameters in case 1 and case 2

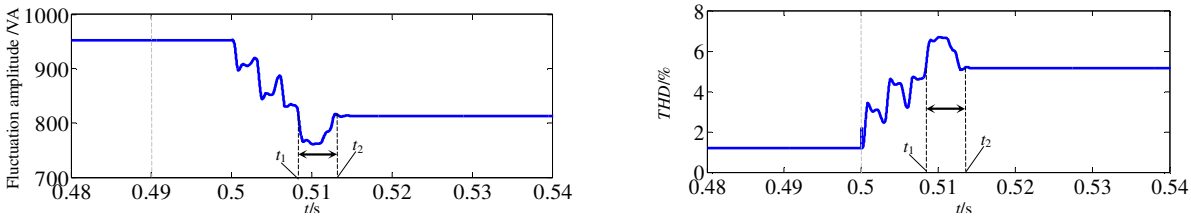

(a) Integrated power fluctuation (b) Current THD

Fig. 6 Integrated power fluctuation and current THD in case 1

Fig. 6 has shown the changing curves of integrated power fluctuation and current THD when the control parameters are being adjusted in case 1. Integrated power fluctuation drops fast after grid faults and the current THD of PV inverter will exceed the limit 5% even though the amplitude of power fluctuation is small among the interval t_1 and t_2. The operation point of control parameters can stabilize at the optimal operation point at last by the optimization method of power proposed above.

Conclusions

This paper has proposed a kind of power control strategy of PV inverter considering the current harmonics constraint of PV system under unbalanced grid faults. As is demonstrated in the test result, the parameter optimization method proposed above can ensure that the PV output current THD be constrained within the limit 5% and that the integrated power fluctuation of active and reactive power reduce to the minimum. It has realized a flexible active and reactive power control of PV under grid faults by bringing in power-regulation coefficients.

Keywords: Modular Multilevel Converter, MMC-HVDC, PSCAD/EMTDC.

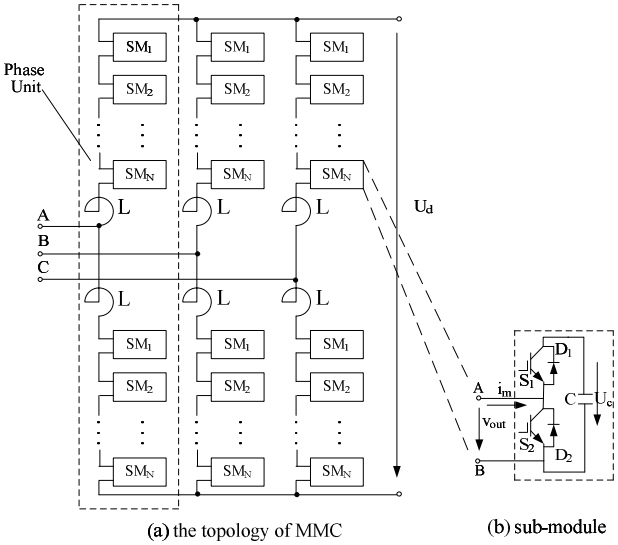
Abstract. In order to study the steady-state performance of modular multilevel voltage source converter (MMC-HVDC), a 21-level MMC-HVDC system is modeled by PSCAD/EMTDC software. This system uses the DC voltage and active power controls, which are designed by the fundamental operation principles and mathematical models of MMC-HVDC. By analyzing the steady-state performance of MMC-HVDC, the corresponding simulation waveforms verify the correctness and validity of the simulation model.

Introduction

HVDC (high voltage direct current) has received increasing attentions in recent years due to the requirement of high power and voltage level in power industrial applications. VSC (voltage sources convert) -HVDC has shown that it is possible to combine excellent output voltage waveforms with very high efficiencies[1,2]. VSC-HVDC is probably the most promising converter topology for applications such as grid access for regenerative energy sources, supply of passive loads and power supply of megacities[3].

So far, the realized VSC converters for HVDC applications are main based on 2 or 3-level technology, which with the drawbacks of a low-voltage level, high switching frequency and a distortion of voltage waveform has to be filtered. To solve the aforementioned problems, a modular multilevel converter (MMC) topology has been proposed[4]. Fig.1(a) shows a circuit configuration of a three phase MMC, each of which is a stack of cascaded multiple bidirectional sub-modules shown in Fig. 1(b). This technology makes the individual semiconductors have much lower switching frequency resulting in lower switching losses, and consequently, lower total losses of the transmission system compared to 2 or 3-level VSC[5]. In addition, MMC is consist of the same sub-modules, simplifys the control methods and reduces the manufacturing cost.

This paper deals with a modular multilevel converter with focus on working principle, mathematical model, control methods, using PSACD/EMTDC to simulate, analyzing steady-state characteristics.



(a) the topology of MMC (b) sub-module

Fig.1 The topology of MMC

Fundamental Operation Principle and Mathematical Model

Fig.1(b) shows the topology of sub-modules. Sub-modules are equipped with capacitors C . By using IGBTs S_1 and S_2, each sub-module can be switched between a state with full module voltage and a state with zero module voltage in both current directions. Table 1 lists all states of a sub-module.

Table 1 States of a sub-module

Mode	S1	S2	Current Direction	V_{out}	State
1	0	0	A to B	U_s	Lock (charge)
2	0	0	A to B	U_s	full (charge)
3	0	1	A to B	0	zero (bypass)
4	0	0	B to A	0	Lock (bypass)
5	1	0	B to A	U_s	full (discharge)
6	0	0	B to A	0	zero (bypass)

In order to keep MMC operating in stable-state，there are three constraints should be subject to:

1. To maintain a stable DC voltage, the amount of sub-modules working in a state with full module voltage in each phase must be equal.
2. In each phase, the total number of sub-modules working in a state with full module voltage in upper and lower legs is always constant. For example, the number of upper legs increases 1, lower legs should be decreases 1.
3. Weather charge or discharge, the voltage of sub-modules capacitance value should always close to the initial value. An algorithm was introduced to balance voltage of each sub-module capacitance[6].

An equivalent circuit is presented in [7]. The equivalent circuit is a virtual equivalent model, rather than an actual circuit.

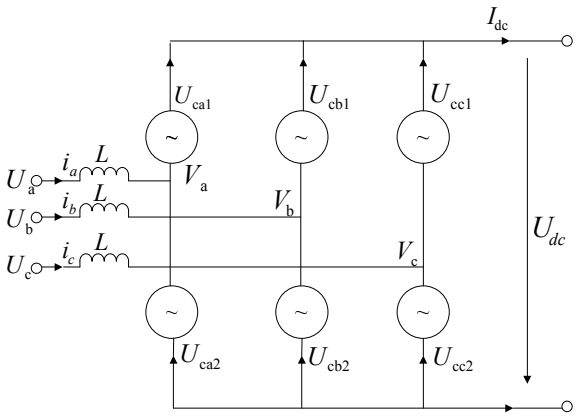


Fig.2 MMC simplified equivalent circuit

The circuit equation can be obtained from Fig.2:

$$\begin{cases} L\dfrac{di_a(t)}{dt} = u_a(t) - v_a(t) \\ L\dfrac{di_b(t)}{dt} = u_b(t) - v_b(t) \\ L\dfrac{di_c(t)}{dt} = u_c(t) - v_c(t) \end{cases} \tag{1}$$

It's hard to control active and reactive power independently, as variables of three-phase stationary coordinate system change with time. So it should be conversed to the synchronous rotating coordinate system with Clark transformation and Park transformation.

Clark transformation (abc -axis to $\alpha\beta$ -axis)

Park transformation ($\alpha\beta$ -axis to dq -axis)

$$\begin{bmatrix} f_\alpha \\ f_\beta \end{bmatrix} = \frac{2}{3}\begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \end{bmatrix}\begin{bmatrix} f_a \\ f_b \\ f_c \end{bmatrix} \quad (2) \qquad \begin{bmatrix} f_d \\ f_q \end{bmatrix} = \begin{bmatrix} \cos wt & \sin wt \\ -\sin wt & \cos wt \end{bmatrix}\begin{bmatrix} f_\alpha \\ f_\beta \end{bmatrix} \quad (3)$$

f can be any electrical quantities, like current, voltage etc. Substituting f_α, f_β in Eq. 2 by Eq. 3:

$$\begin{bmatrix} f_d \\ f_q \end{bmatrix} = \frac{2}{3}\begin{bmatrix} \cos wt & \cos(wt-\frac{2\pi}{3}) & \cos(wt+\frac{2\pi}{3}) \\ -\sin wt & -\sin(wt-\frac{2\pi}{3}) & -\sin(wt+\frac{2\pi}{3}) \end{bmatrix}\begin{bmatrix} f_a \\ f_b \\ f_c \end{bmatrix} \quad (4)$$

Hence, i_{sd}, i_{sq} can be given by:

$$\begin{cases} L\frac{di_{sd}}{dt} + Ri_{sd} = U_{sd} - V_d + wLi_{sq} \\ L\frac{di_{sq}}{dt} + Ri_{sq} = U_{sq} - V_q - wLi_{sd} \end{cases} \quad (5)$$

V_d, V_q, d-axis and q-axis component of voltage from converters arm midpoint; i_{sd}, i_{sq}, d-axis and q-axis component of current from AC side.

Eq. 6 is derived from Instantaneous Power Theory [8]:

$$\begin{cases} P = 1.5(U_{sd}i_{sd} + U_{sq}i_{sq}) \\ Q = 1.5(U_{sq}i_{sd} - U_{sd}i_{sq}) \end{cases} \quad (6)$$

When system operates in steady-state, U_{sq}=0 and $U_{sd} = U_s$, so $P = 1.5U_s i_{sd}$, $Q = -1.5U_s i_{sq}$. Active power and reactive power are decoupled in synchronous coordinate system, and are proportional to i_{sd}, i_{sq} respectively.

MMC Control Strategy

Current loop controller

Eq. 5 presents i_{sd} is influence on V_d, wLi_{sq} and U_{sd}. Also, i_{sq} is influenced on V_q, wLi_{sd} and U_{sq}. V_d' and ΔU_q are defined to keep i_{sd} from the impact of wLi_{sq}. Similarly, V_q' and ΔU_d are defined.

$$\begin{cases} V_d = U_{sd} - V_d' + \Delta U_q \\ V_q = U_{sq} - V_q' + \Delta U_d \end{cases} \quad (7)$$

$V_d' = L\frac{di_{sd}}{dt} + Ri_{sd}$, $V_q' = L\frac{di_{sq}}{dt} + Ri_{sq}$, $\Delta U_d = wLi_{sq}$, $\Delta U_q = wLi_{sd}$. V_d' and V_q' are first-order differential voltage components that can be presented as PI parts.

$$\begin{cases} V_d' = K_{p1}(i_{sd}^* - i_{sd}) + K_{I1}\int(i_{sd}^* - i_{sd})dt \\ V_q' = K_{p2}(i_{sq}^* - i_{sq}) + K_{I2}\int(i_{sq}^* - i_{sq})dt \end{cases} \quad (8)$$

i_{sd}^*, i_{sq}^*, active and reactive current reference value. Substituting Eq. 7 and Eq. 8 into Eq. 5 yields:

$$\begin{cases} \frac{di_{sd}}{dt} = \frac{1}{L}\left[K_P(i_{sd}^* - i_{sd}) + K_I\int(i_{sd}^* - i_{sd})dt\right] \\ \frac{di_{sq}}{dt} = \frac{1}{L}\left[K_P(i_{sq}^* - i_{sq}) + K_I\int(i_{sq}^* - i_{sq})dt\right] \end{cases} \quad (9)$$

Eq. 9 indicates i_{sd} and i_{sq} can be decouple controlled. Eq. 10 is transformed from Eq. 9 by Laplace formula:

$$\begin{cases} i_{sd} = \dfrac{1}{sL}(K_P + \dfrac{K_i}{s})(i_{sd}^{\ *} - i_{sd}) \\ i_{sq} = \dfrac{1}{sL}(K_P + \dfrac{K_i}{s})(i_{sq}^{\ *} - i_{sq}) \end{cases} \tag{10}$$

According to Eq. 10, the current loop control is designed as shown in Fig.3.

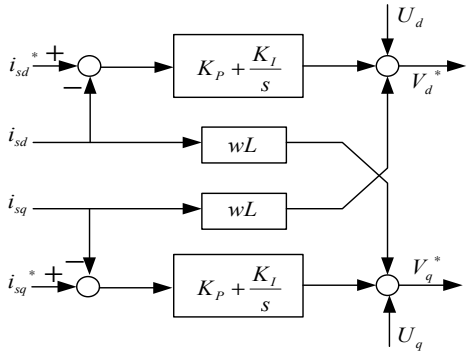

Fig.3 Current loop control

Voltage loop control

As shown in Fig.4, Δi_d is the difference between measured value and reference active power, and after a PI part. The reference value $i_{sd}^{\ *}$ is the sum of Δi_d and the estimated value $i_d^{'}$. Also $i_{sq}^{\ *}$ is sum of Δi_q and $i_q^{'}$ in Fig.5.

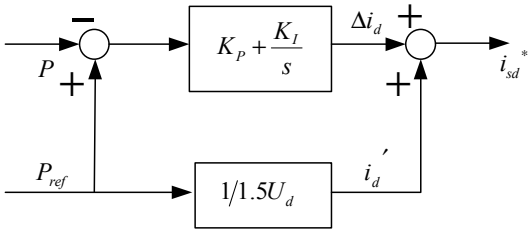

Fig.4 Active power control

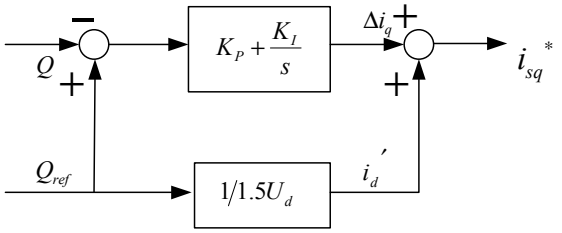

Fig.5 Reactive power control

DC voltage control

Fig.6 shows the topology of DC voltage control. The part of active power compensates the fluctuations of reactive power. The comparision between DC voltage (U_{dc}) and the reference value (U_{dcref}), and the PI part are used to make U_{dc} track U_{dcref}.

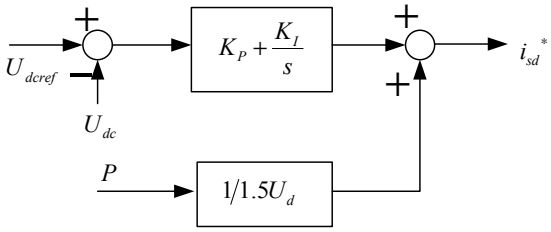

Fig.6 DC voltage control

Modeling of MMC-HVDC

According to the above control methods, a three-phase, 21-level MMC-HVDC energy system is developed based on PSCAD/EMTDC in Fig.7. In the model, there are 20 identical sub-modules and a converter reactor connected in per phase arm. MMC-1 uses the active and reactive power control (P_{1ref}=400kVA, Q_{1ref}=0). MMC-2 has the same structure, using the reactive power and DC voltage control (U_{dcref}=400kV, Q_{1ref}=0). Table 2 presents the simulation parameters.

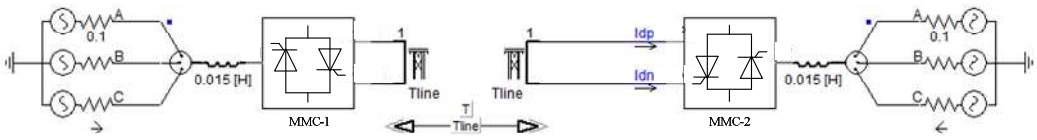

Fig.7 MMC-HVDC

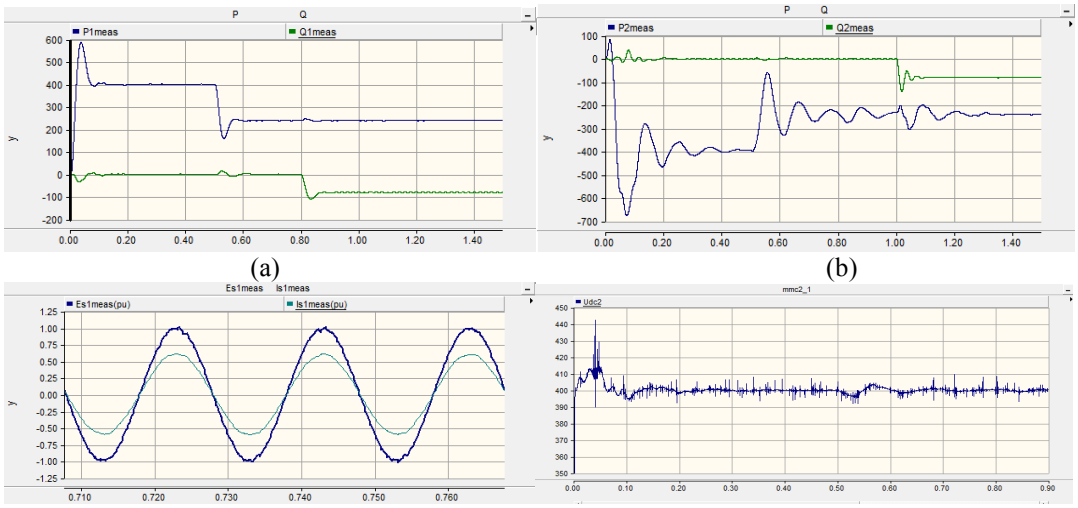
Table 2 CIRCUIT PARAMETERS ON EXPERIMENT

AC side Line-to-Line voltage	$110\,kV$
DC bus voltage	$400\,kV$ ($\pm 200\,kV$)
Submodule capacitors	$3000\,\mu F$
The initial value of capacitor voltage	$20\,kV$
Overhead line length	$20\,km$
AC inductor	15 mH
Transformer ratio	$110/220\,kV$ (Y/Δ)

Simulation and Analysis

Stable operation

The system operates in initial state. When t=0.5s, set P_{1ref}=240 kVA; t=0.8s, set Q_{1ref}=80 $kVar$; t=1.0s, set Q_{2ref}=-80 $kVar$. Subscript 1, 2 present MMC-1 and MMC-2 electrical quantities.



(a) (b)

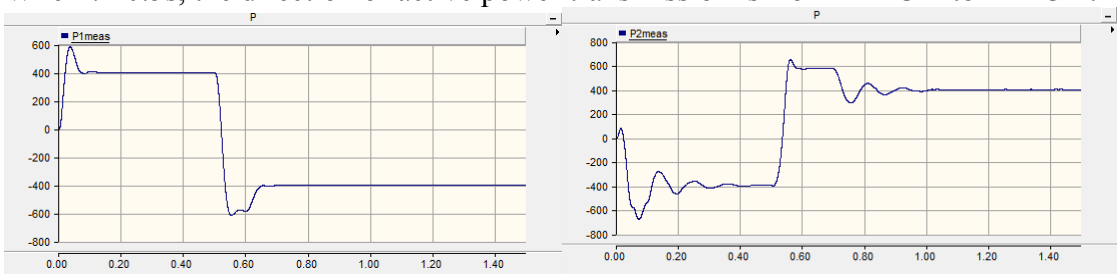
(c) (d)

Fig.8 Stable opertion

Fig. 8(a) and (b) show MMC-1 and MMC-2 active and reactive power value track the changes of P_{ref} and Q_{ref}. When active or reactive reference values is changed, the other is unaffected. As shown in Fig. 8(c), MMC-1's AC side output phase voltage waveform is approximately sinusoidal. Fig. 8(d) presents DC bus voltage remains around 400 kV throughout the process.

Reverse active power

When t=0.5s, the direction of active power transmission is from MMC-2 to MMC-1.



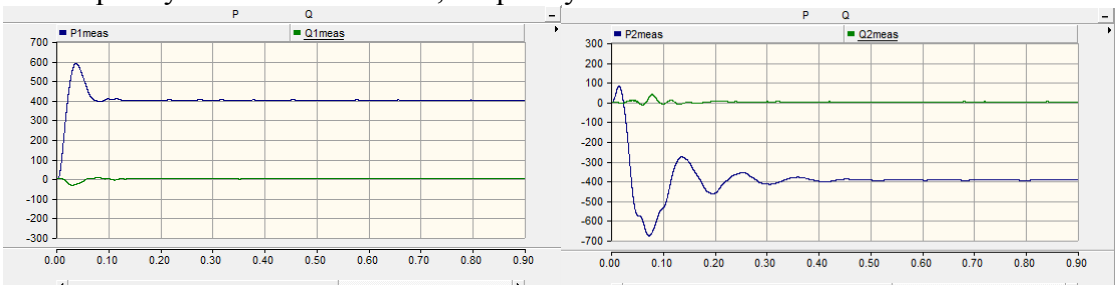
(a) (b)

Fig.9 Active power reversion

Compared with Fig. 9(a) and (b), active power of MMC-1 and MMC-2 are almost symmetrical. And process of reversion is quick and smooth.

Asynchronous interconnection

Set frequency of MMC-1 to 50Hz, frequency of MMC-2 to 60Hz.



(a) (b)

Fig.10 Asychronous association

As shown in Fig. 10(a) and (b), the controllers can connect two ends of asynchronous grids smoothly.

Conclusions

This paper has described fundamental operation principle, mathematical model and control methods including current loop, voltage loop and DC voltage controls. To validate the performance and advantages of MMC, a 21-level MMC is constructed on PSCAD/EMTDC program. MMC-1 uses the active and reactive power control, while MMC-2 using the active power and DC voltage control. The simulation shows that the designed controller can effectively control the steady-state process. With all above detailed analysis and demonstration, it is not difficult to get the conclusion that MMCs will play an important role in power electronics application.

Abstract: Photovoltaic systems can not meet the needs in the power grid without the impact, due to its penriodicity, intermittent and randomness, thus the key to solve the core technology of photovoltaic power generation system is important to achieve PV grid-connected. This article explains the two-stage topology system control and modeling of single-phase PV grid-connected: Modeling of DC / DC converter provides basis for maximum power point tracking; DC / AC inverter in grid-connected modeling offer efficient communication basis for grid-connected, it research on the control strategies for DC / DC and DC / AC circuit: that PV grid-connected complete alternating current of unit power factor using the booster circuit and inverter control structure, in order to offer photovoltaic systems flexible grid-connected the foundation.

Introduction

Solar energy as a major clean energy, provides a sufficient condition for main grids supplement, but due to the affect of different seasons and alternaton of day with night .photovoltaic system gives expression to its own periodicity, intermittent and randomness, as the future primary energy supply resources, it only provide power value at the current stage, but because of their own shortcomings it can not offer sufficient capacity value, therefore that PV flexible grid-connected comes true has practical significance.

Single-phase photovoltaic systems of flexible grid-connected and control

In the photovoltaic power generation systems, photovoltaic maximum power point tracking and grid-connected technology strategy is the key of photovoltaic systems interconnection thchnology, during self-optimizing process at the maximum power point tracking how timely and accurate capture of the maximum power point , which provide efficient conversion effective protection for solar panels . and photovoltaic grid-connected project, which need bring DC photovoltaic panels into alternating current by an inverter into the grid, which will require boost circuit and full-bridge inverter circuit structure and network to complete. Thus, two-stage topology exists in the china's photovoltaic power generation systems, DC / DC link achieves maximum power point tracking and timely boosts voltage, DC / AC link transforms solar energy into alternating current output, which ensure that the grid same frequency and phase voltage and unity power factor grid-connected. Figure 1 is single-phase photovoltaic grid-connected systems

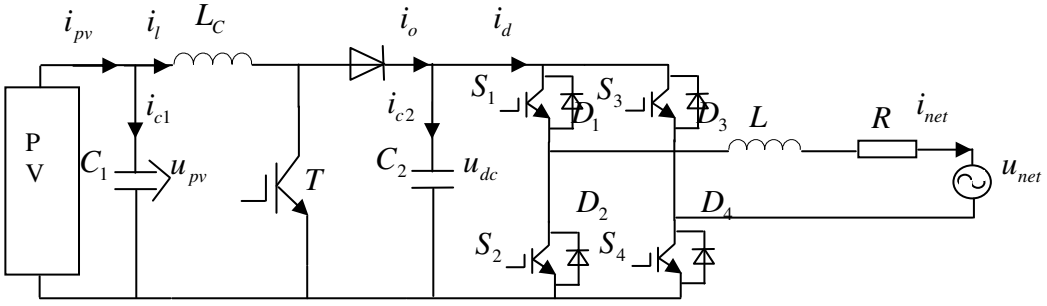

Fig.1 Single-phase PV grid-connected

Topology photovoltaic grid system using the two-stage topology , as shown in this article, the DC / DC boost circuit completes to the maximum power point tracking, and to inverter DC / AC dual loop device session accomplishs stability control of Dc voltage and unity power factor non-impact on the grid-connected. i_{pv} is the output current of the PV array, i_l is the inductor current, i_{c1} is the capacitor current of the photovoltaic array output; i_{net} is the current of photovoltaic grid systems; u_{net} is the grid voltage; L is inverter filter inductor; R is filtering resistor and the inverter equivalent impedance of the external circuit.

The mathematical modeling of DC/DC converter

According to the topology of photovoltaic grid systems, DC / DC converter mathematical modeling:

Switching function are indicated $S_{k1}: S_{k1} = \begin{cases} 0 & Ton \\ 1 & Toff \end{cases}$ .Mathematical model based on the switching function is turned on and off: $\begin{cases} \dfrac{du_{pv}}{dt} = \dfrac{i_{pv}}{C_1} - \dfrac{i_l}{C_1} \\ \dfrac{di_l}{dt} = \dfrac{u_{pv}}{L_C} - \dfrac{S_{k1}u_{dc}}{L_C} \end{cases}$ .Select the state variables $X = [i_l \ u_{pv}]^\tau$; Input variables $U = [i_{pv} \ u_{dc}]^\tau$; The output variables $Y = [i_l \ u_{pv}]^\tau$ State equation can be written as:

$$\dot{X} = AX + BU$$

$$Y = CX + DU$$

$$\frac{d}{dt}\begin{bmatrix} u_{pv} \\ i_l \end{bmatrix} = \begin{bmatrix} -\frac{1}{C_1} & 0 \\ 0 & \frac{1}{L_C} \end{bmatrix}\begin{bmatrix} i_l \\ u_{pv} \end{bmatrix} + \begin{bmatrix} \frac{1}{C_1} & 0 \\ 0 & -\frac{S_{k1}}{L_C} \end{bmatrix}\begin{bmatrix} i_{pv} \\ u_{dc} \end{bmatrix} \quad A = \begin{bmatrix} -\frac{1}{C_1} & 0 \\ 0 & \frac{1}{L_C} \end{bmatrix} \quad B = \begin{bmatrix} \frac{1}{C_1} & 0 \\ 0 & -\frac{S_{k1}}{L_C} \end{bmatrix} \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad D = 0$$

The transfer function $G(s) = \dfrac{Y(s)}{U(s)} = -\dfrac{S_{k1}}{C_1 L_C S^2 + (L_C - C_1)S - 1} = \dfrac{1}{SC_1 + 1} \cdot \dfrac{-S_{k1}}{SL_C - 1}$

DC/DC converter to achieve maximum power point tracking

In the DC bus side increases PI controller，which controls deviation of the actual value of its reference value of the DC bus voltage control, in order to ensure that the DC bus side voltage stability.which to achieve the maximum power point of the PV array output using regulating DC / DC converter duty cycle by the PWM generator. MPPT controller uses self-optimizing control method itself by constantly detecting the output voltage of the PV array to determine the maximum power point. G1 (s), G2 (s), G3 (s) is respectively a PI controller, the boost circuit, MPPT controller transfer function.

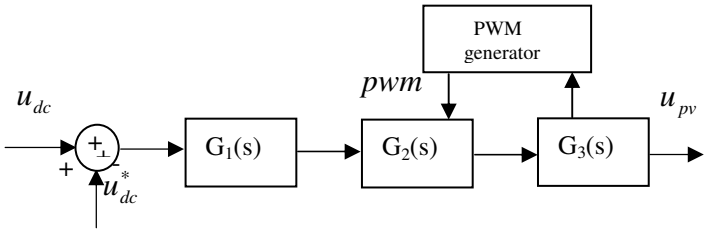

Fig2 Based on the dc bus voltage stability of MPPT control principle diagram

Mathematical modeling of inverter grid-connected

As the full-bridge inverter bipolar modulation leakage current is very small, which decreases the efficiency is not suitable for the grid-connected inverter that there is no transformer, so using single polarity modulation, single-phase grid-connected inverter switching states are, S_1 and S_4 equal to

begin; S_2 and S_3 equal to begin; S_1, S_2 and D_3 equal to begin; S_1, S_3 and D_1 equal to begin; S_2, S_4 and D_2 equal to begin; S_2, S_4 and D_4 equal to begin; however S_1 and S_3 equal to begin and S_2 and S_4 equal to begin, when the output voltage of the existence of two zero voltage state, so in DC / AC inverter switching
function:

$$S_{k2}=\begin{cases}1 & S_1 \text{ and } S_4 on\\ 0 & S_1 \text{ and} S_3 or S_2 \text{and} S_4 on\\ -1 & S_2 \text{and} S_3 on\end{cases} \qquad \begin{cases}\dfrac{di_{net}}{dt}=\dfrac{S_{k2}}{L}u_{dc}-\dfrac{Ri_{net}}{L}-\dfrac{1}{L}u_{net}\\ \dfrac{du_{dc}}{dt}=-\dfrac{S_{k2}}{C_2}i_{net}+\dfrac{S_{k1}i_l}{C_2}\end{cases}$$

Select the state variables $X=[i_{net}\ u_{dc}]^{\tau}$, Input variables $U=[i_l\ u_{net}]^{\tau}$, The output variables $Y=[i_{net}\ u_{dc}]^{\tau}$

$$A=\begin{bmatrix}-\dfrac{R}{L} & \dfrac{S_{k2}}{L}\\ -\dfrac{S_{k2}}{C_2} & 0\end{bmatrix} \quad B=\begin{bmatrix}0 & -\dfrac{1}{L}\\ \dfrac{S_{k2}}{C_2} & 0\end{bmatrix} \quad C=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} \quad D=0$$

The transfer function $G(s)=\dfrac{Y(s)}{U(s)}=\dfrac{S_{k2}^3+S_{k2}RC_2S+S_{k2}LS^2}{LC_2S^2+RC_2S+S_{k2}^2}$

Achievement of DC/AC innverter grid-connected

Single-phase grid-connected inverters adopts double loop PI control algorithm, which to achieve voltage outer control and current inner control combined. Outer voltage control mainly effects DC voltage stability, and ensures maximum output power point boost circuit. If the outside temperature rises, the output power of the PV array is increased, the DC voltage also increases, so the outer ring under the influence of PI controller, so the amplitude is increased, while the lower inner PI control, will soon follow, so into the grid voltage increases, the voltage fed to the outer ring to adjust again.

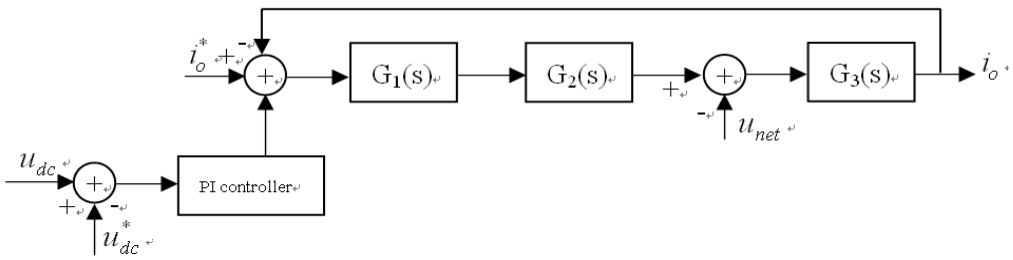

Fig3 Based on unit power factor grid-connecte inverter control principle diagram

Thus it can be seen that the inverter grid-connected current is influenced by the power grid voltage disturbance variable $u_g(s)G_3(s)$, which brings the grid voltage feed-forward into inverter input side, can counteract the effects of grid current from that power grid voltage, so the grid current closed loop control system increases power grid voltage feed-forward link.

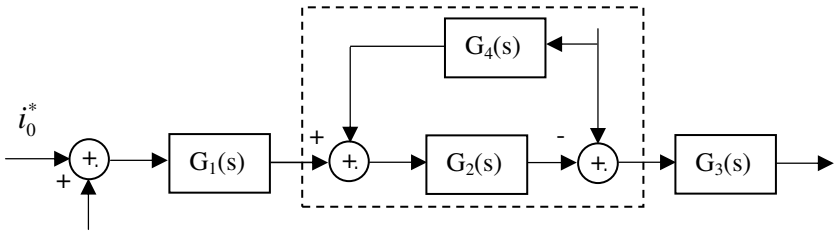

Fig4 Power grid voltage feed-forward control system block diagram

The single-phase flexible photovoltaic grid-connected system simulation

To verify the control algorithm of maximum power point tracking and grid current, with Matlab / Simulink simulation conducted photovoltaic grid system. The picture shows the simulation waveform.

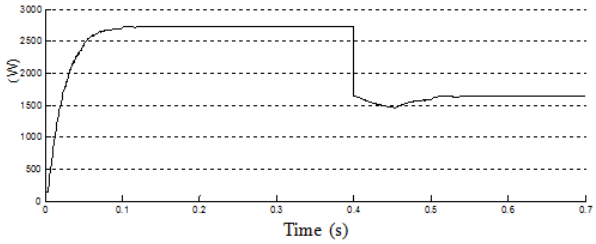

Fig 4 Photovoltaic array output waveform

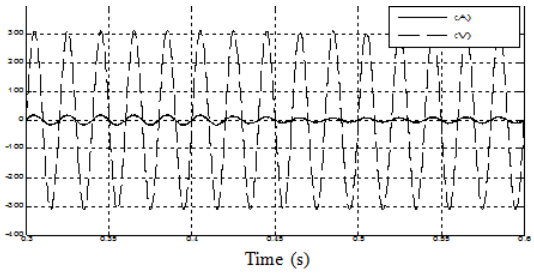

Fig 5 Inverter grid current voltage waveform

Parameters are as follows: u_{dc} total range is 380 ~ 450V, RMS voltage grid $U_{net} = 220V$, set the reference current and the same frequency and phase grid voltage, grid current waveform simulation with the same frequency and grid voltage sine wave phase to meet the design requirements, while maximum power point tracking simulation, assuming constant temperature, light intensity determines the maximum power output of photovoltaic panels. Simulation results show that the output power can be an effective real-time tracking.

The conclusion

In this paper, two-stage double-loop control structure to complete the single-phase photovoltaic flexible topology and network control strategy research, meet and network with current and the main power grid between the frequency and phase. Simulation results show the effectiveness of the method, and net

current real-time. Photovoltaic power generation system, there are still many technical problems to be solved, and the maximum power point tracking and grid inverter is the crux of the problem, of which there are island effect to prevent, and also need to find a more reliable, more accurate detection method, this article describes two topology control systems, the main relationship of the two topologies mutual decoupling detailed analysis for the realization of photovoltaic grid, a smooth switching off-grid, as well as network functions to achieve fast and opened up broad prospects.

Keywords: HVDC, VSC, Control Strategy, Passive Network, MATLAB Simulation.

Abstract. The mathematical model VSC-HVDC system in dq reference frame is derived.For the VSC-HVDC system of transmitting power to passive network ,a constant DC voltage is used in the rectifier-side;a constant AC voltage controller is used in the inverter-side.Digital simulation models are set up by MATLAB/Simulink. Simulation results verify that VSC-HVDC has a independent control of active and passive power,and demonstrates superiority of transmitting active and passive power simultaneously when connecting to passive network.

Introduction

Based on the self-commutation devices and the technology of PWM, VSC-HVDC system has a flexible and quick control on both active and reactive power. And the system is furnished with SCC(self-commutated converter), which enables it to power passive nerwork even without external power supply. Therefore, VSC-HVDC promises to develop greatly in the field of transmission and distribution [1,2].

The rectangular coordinate form of VSC-HVDC system equations is deduced. A steady state model is put forward as well [3,4].Corresponding contol strategies are discussed in detail in both discrete time state space and continuous time state space [5,6].

Under the DQ synchronization reference frame, the mathematical model of VSC-HVDC system is established. And the control strategy is proposed, which consists of inner-loop current control and outer-loop voltage control. A constant AC voltage control unit is designed for supplying power to passive network. FInally,the simulation model of VSC-HVDC power to passive network is set up with the help of MATLAB / Simulink. When simulating different transmission conditions,the superiority of VSC-HVDC is obvious.

Mathematical Model of VSC-HVDC

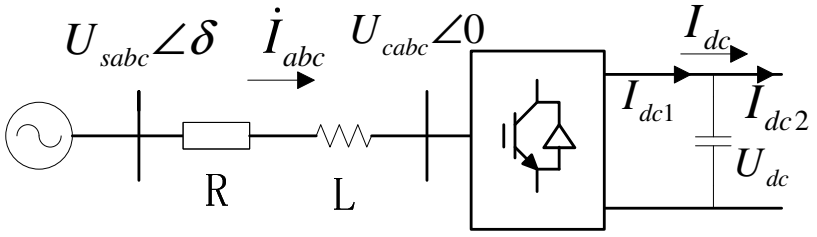

Fig.1 Structure of Voltage Source Control

As is shown in Fig.1, u_{sa}, u_{sb} and u_{sc} represent bus voltage of the AC power system side,and u_{ca}, u_{cb} and u_{cc} represent bus voltage of the converter side. C is a parallel capacitor in DC side. u_{dc} and i_{dc} respectively represent the DC voltage and DC current. i_a, i_b and i_c represent AC current of the converter side. L is the equivalent inductance and R is the equivalent resisitance.

The voltage function of AC power side can be given in the form

$$\begin{bmatrix} u_{sa} \\ u_{sb} \\ u_{sc} \end{bmatrix} = \begin{bmatrix} u_{ca} \\ u_{cb} \\ u_{cc} \end{bmatrix} + R \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + L \frac{d}{dt} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} \tag{1}$$

Through PARK transformation ,the quadrature axis and direct axis component of voltage and current under The two-phase synchronous rotating coordinate system can be obtained as follows.

$$\begin{cases} u_{sd} = u_{cd} + Ri_d + L\dfrac{di_d}{dt} - \omega L i_q \\ u_{sq} = u_{cq} + Ri_q + L\dfrac{di_q}{dt} + \omega L i_d \end{cases} \tag{2}$$

The function of switching power between the converter and the network can be written as follows.

$$\begin{cases} P = \dfrac{3}{2}(u_{sd} i_d + u_{sq} i_q) \\ Q = \dfrac{3}{2}(u_{sq} i_d - u_{sd} i_q) \end{cases} \tag{3}$$

Where

$$\begin{cases} u_{sd} = u_s \\ u_{sq} = 0 \end{cases} \tag{4}$$

Then The function of switching power can be rewritten in the form

$$\begin{cases} P = \dfrac{3}{2} u_s i_d \\ Q = -\dfrac{3}{2} u_s i_q \end{cases} \tag{5}$$

Therefore,P and Q and be controlled respectively by i_d and i_q ,which means the successful implementation of the decoupling control of active and reactive power.

Design of Controller

According to the engineering experience,there are four basic control modes: constant DC voltage control, constant power control, constant AC voltage control and variable frequency control [7].

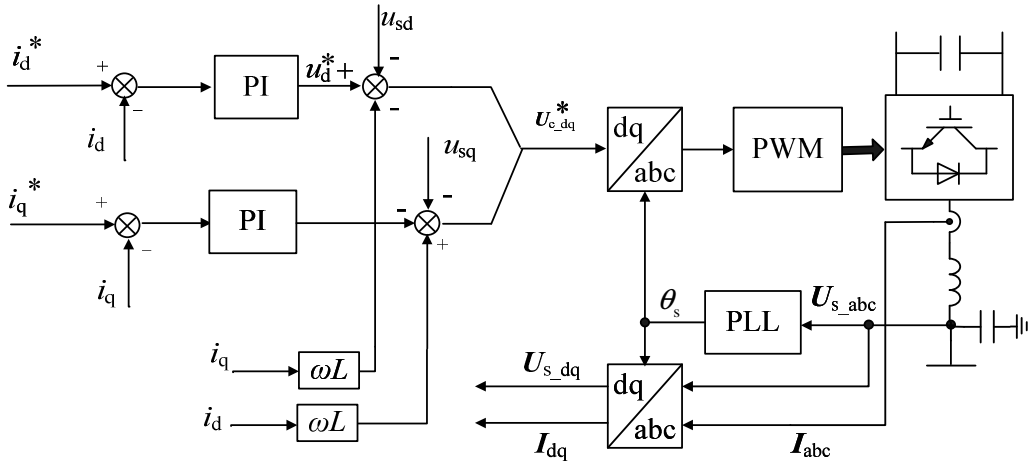

Fig.2 Block Diagram of Inner Current Control

Block Diagram of Inner loop current control is shown in Fig.2,PI regulator are used,and its output can be given as follows.

$$\begin{cases} u_{\mathrm{d}}^{*} = -(L\dfrac{\mathrm{d}\,i_{\mathrm{d}}}{\mathrm{d}\,t} + Ri_{\mathrm{d}}) = \left(K_{\mathrm{p}} + K_{\mathrm{i}}/s\right)\left(i_{\mathrm{d}}^{*} - i_{\mathrm{d}}\right) \\ u_{\mathrm{q}}^{*} = -(L\dfrac{\mathrm{d}\,i_{\mathrm{q}}}{\mathrm{d}\,t} + Ri_{\mathrm{q}}) = \left(K_{\mathrm{p}} + K_{\mathrm{i}}/s\right)\left(i_{\mathrm{q}}^{*} - i_{\mathrm{q}}\right) \end{cases} \tag{6}$$

Where u_d^* and u_q^* are the outputs of the PI regulator. i_d^* and i_q^* are the reference values of the inner loop current conntrol, which are given by outer loop voltage control.

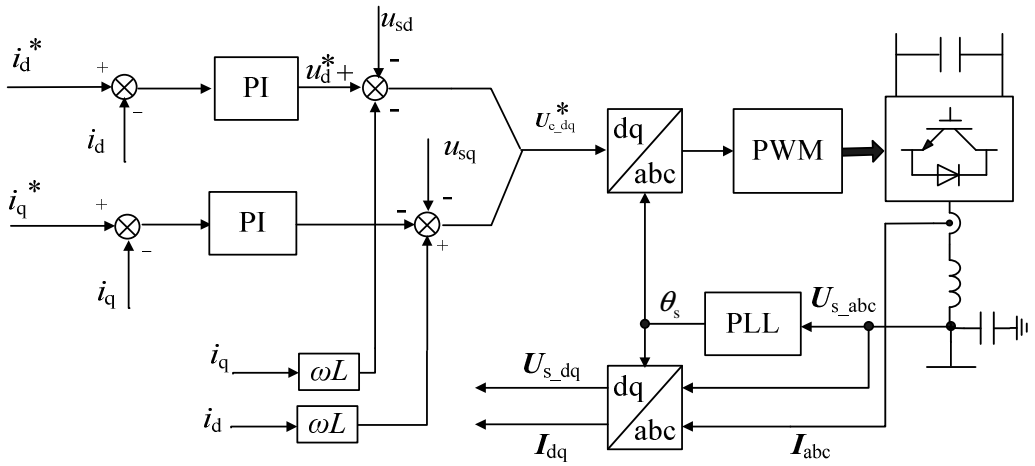

Fig.3 Block Diagram of Constant DC Voltage Control

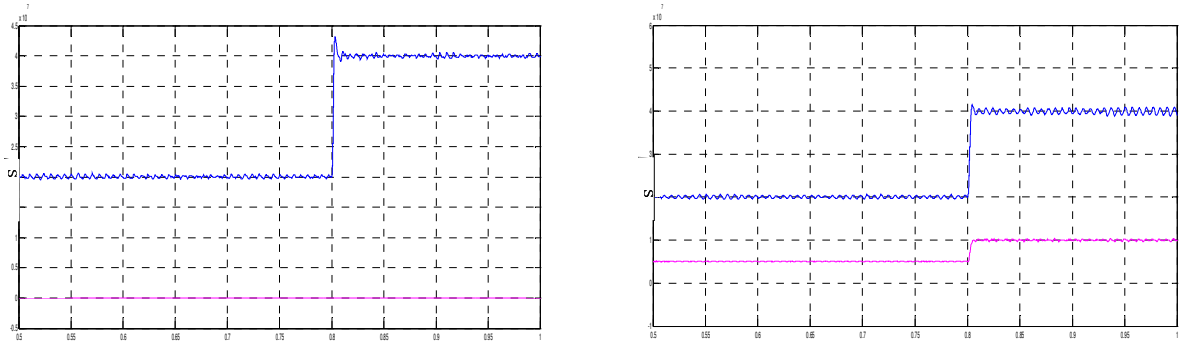
Block Diagram of Constant DC Voltage Control is shown in Fig.3, PI regulator is used to eliminate the steady state error.Compare u_{sd} and u_{sq} with $[1,0]^{\mathrm{T}}$. And the error need regulating by PI regulator according to the formula (2).

Simulation of Supplying Power to Passive Network

In the model established by Matlab / Simulink,the main parameters are as follows. The rectifier parameter is 150kv/50Hz. The low pass filter parameter is 3Mvar. The PWM switching frequency is 2500Hz, and SPWM is adopted. The voltage in DC side is 300kv,and the capacitor in this side is 200 μF. Line length is 75 km. The resistance is 0.0130 Ω/km,and the inductance is 0.159mH/km. The

capacitance is 0.231 μ F/km. In the inner current control,Kp=5 and Ki=20. In the outer voltage control,Kp=0.4 and Ki=500. The sampling time is 5 μ s.

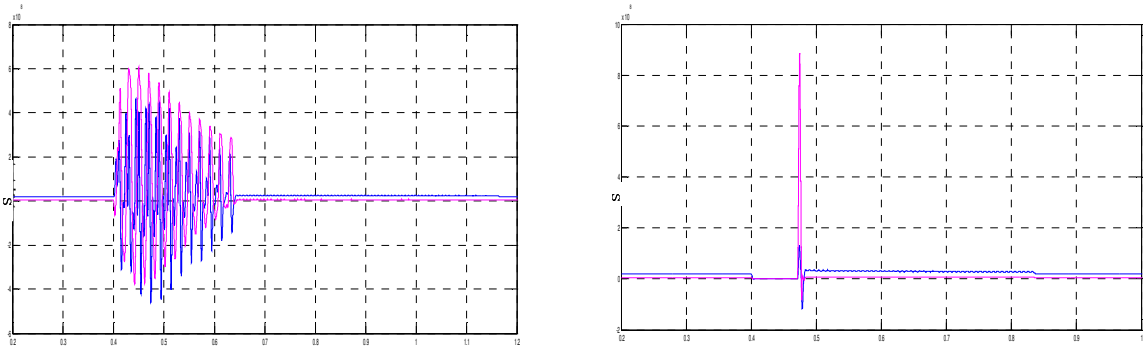


(a)load increased by 20MW (b)load increased by 20MW+5MVar

Fig.4 Simulation waveform for load change at the passive side

(i)Change of load in the passive network

As is shown in Fig.4(a), the load was 20MW at the begining , and it increased by 20MW at 0.8s. The simulation waveform is shown in Fig.4(b), the load is 20MW+5MVar, and it increased by 40MW+10MVar at 0.8s. Load can be controlled independently through this control strategy. Reactive power can be transmitted as well as active power at the same time.



(a)single phase grounding fault (b)three-phase short circuit fault

Fig.5 Simulation waveform for short curcuit faut at the passive side

(ii)Short circuit faults

The load in the passive network was 20MW+5MVar at the beginning,and a short circuit fault happened at 0.4s, which lasts 1/15s. When a single phase grounding fault happens, the simulation waveform is shown in Fig.5(a). And when a three-phase short circuit fault happens, the simulation waveform is shown in Fig.5(b). As far as the VSC-HVDC is concerned, a steady state will return in a period of time.

Conclusions

Through the analysis on the VSC-HVDC mathematical model,a conclusion can be drawed that active and reactive power can be respectively controlled by i_d and i_q. MATLAB/Simulink was utilized to establish the simulation model of supplying power to the passive network, where constant DC voltage control and constant AC voltage control strategies are designed. The results show that VSC-HVDC can well satisfy the requirements of supplying power to passive network, and show the superiority of power transmission.

Protection Scheme for Distribution Network with Distributed Generation

Chongxin Xu[1, a *], Yanjun Jiao[1, b]

[1]School of Electrical and Electronic Engineering, North China Electric Power University, Baoding, Hebei, 071003, China

[a]sdxuxin12354@163.com, [b]jiao_yanjun@263.net

Keywords:distributed generation; distribution network; PSCAD/EMTDC; protection scheme;.

Abstract. Power generation becomes a main way of using new energy. However, the access of distributed generation(DG) causes the ordinary protection system develop a series of problems. In this paper, the structure of distribution network with DG is introduced firstly.Secondly,it is analysed that the effect that DG brings to distribution network protection, and then a new protection scheme of distribution network with DG is put forward. The segment I, II of direction three-current protection on the line which is at the upstream of DG, and the next line's segment I, II consists of a simple communication unit. Through the comprehensive judgment of two protections' action results, fault can be isolated in minimum range quickly and accurately. Finally, the correctness and feasibility of the new protection principle are verified by simulating a 10KV distribution system.

Introduction

DG is generating unit with small capacity, in the user field or near field.It's constructed to reach the special needs of individual customers,or to support the economic operation of distribution network, or both of them. As a useful supplement to the centralized power generation, it is of great practical significance to develop DG industry, which mainly depends on its economical, environmental protection, flexibility and specific peaking function [1-2].

It has many advantages that distributed generation connects with distribution network, but the negative impact brought by DG can not be ignored. DG accessed to low voltage distribution network, makes the distribution system from a single supply radial network into two-terminal or multiport active networks. The topological structure,current size and direction of the distribution network will change. The existing protection devices, designed for single supply radial network, are unable to meet the requirements of reliability, rapidity, accuracy and so on [3].

The Structure of Distribution Network Containing DG

Because of DG's accessed, the topological structure and current direction of distribution network may change. The selectivity, sensitivity and reliability of distribution network protection may be affected. The structure of distribution network with DG mainly includes the following [4].

1) DG is connected to the distribution network feeder on the first bus, as shown in Fig.1. In normal conditions, DG and system power supply operate parallelly, can be equivalent to a power supply.

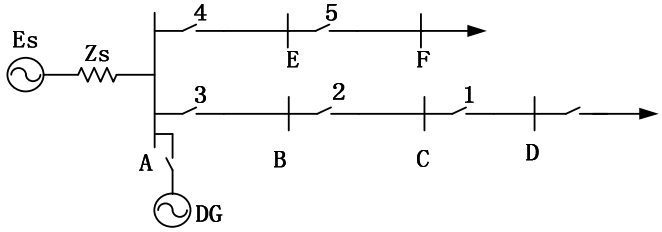

Fig.1 DG Accessed to Feeder on the First Bus

2) DG is connected to the distribution network feeder on non-end bus, as shown in Fig.2.DG supplies power to the load through the line BD.

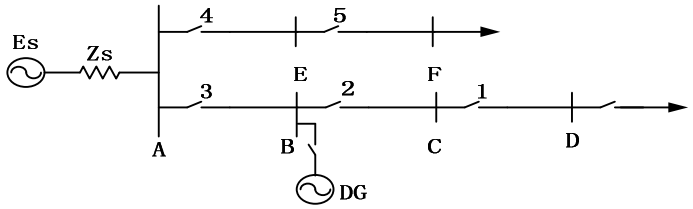

Fig.2 DG Accessed to the Feeder on Non-end Bus

3) The DG is connected to the distribution network feeder on the last bus, as shown in Fig.3. DG directly supply power to the load through bus D.

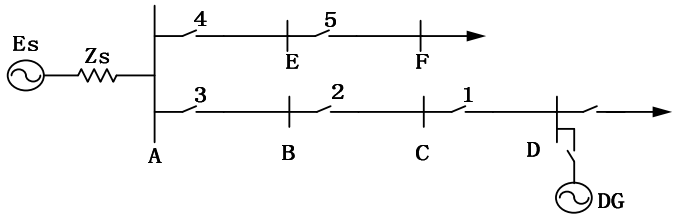

Fig.3 DG Accessed to the Feeder on the Last Bus

4) Multiple DGs access to distribution network feeder. DGs may be accessed differently,when a power distribution system has multiple DGs, but still can be divided into the above three categories according to the access point.

The impact of DG on distribution network protection

At present, the distribution network is mostly a single supply radial network. At the configuration of the existing protection, when DG accessed to distribution network ,there will have a great impact on the protection for the distribution network [5-6].

As is shown in Figure 4, the DG access to distribution network on the bus B.

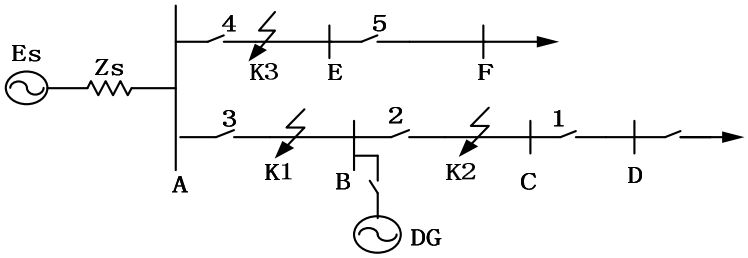

Fig.4 DG Accessed to Distribution Network on the Bus B

1) When a fault occurs at K1, protection 3 will act and separate the fault line from the system side. However, the fault still exists , and short circuit current will still be provided to the fault point by DG. In order to make the fault line resection, circuit breaker must be installed in bus B side,and line AB should be resected at both sides. Thereafter, due to the presence of DG, line BD can turn into islanded operation.

2) When short-circuit fault occurs at K2, because of the existence of the DG, there will have both the fault current flow from the system and the improving current from DG at the same time through protection 2. The scope of current quick-break protection of the protection 2 will extend.what's more, the scope may extend to the line CD,and then the conservation of protection 1 with 2 will be lost, also the selective can not be guaranteed, As for the limited current quick-break protection of protection 2 with 3. At the same time, the fault current flowed through protecting 3 will be weakened because of DG,and the scope of protection will be shortened. In some severe cases, limited current quick-break protection of protection 3 will cannot be as the backup protection of next line downstream.

3) When a fault occurs at K3, the fault should have be isolated only by protection 4. However, fault current with reverse direction which is provided by DG,will flow through the protection 3. When the fault current provided by DG is large enough, The protection 3 may misact and loss its selectivity.

New protection scheme for distribution network

There is no need to install protective devices on the other side of the line in the scheme. Only three-current direction protection should be installed on the original power supply side of each line which is on the upstream of DG. Then we can save the cost of circuit breaker, and avoid the problems caused by themselves [7].

The fixed value of section I of three-current direction protection should be set according to the principle that the protection can act reliably when short circuit happened at the end of the line with maximum operating mode, and the action time is 0. II, III segment action currents are still set by ladder time characteristic principle. Protection I, II segment of each line and protection I, II section of the next line constitute a communication unit. Protection I, II segment of this line will be unlocked when protection I, II section of the next line does't act. On the contrary, protection I, II segment of this line will be locked. Therefore, when fault happened in the line, the protection I or II segment will act, and cann't receive the locked message. Once this case is identified, remote control information will be sent to the next line's protection,and circuit breakers at two sides will trip at the same time, so as to cut off the fault line. The block diagram of action principle is shown in figure 5.

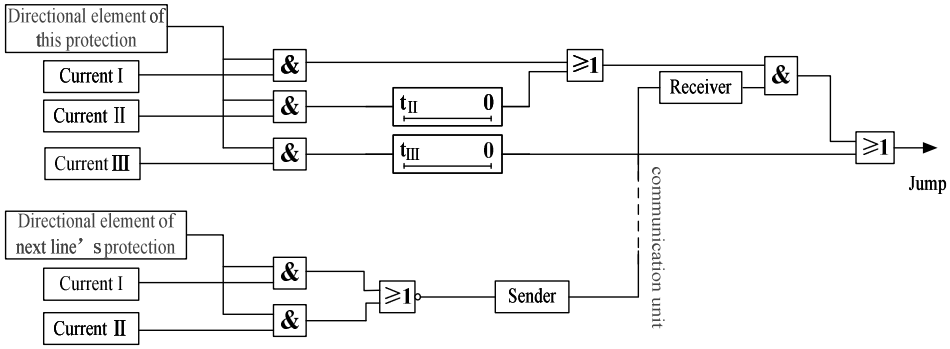

Fig.5 Current Protection Action Principle Diagram

However, for the last line on the upstream of DG, circuit breaker and directional element is need at the end of the line, because the communication unit is constituted only in this line. when protection I or II of the line acts and the power direction are positive direction both sides of the line, this line will be identified to be faulted, and then circuit breaker both sides should trip.

Because the lines at the downstream of DG don't change into two-terminal or multiport active networks, three-current protection is enough. in order to guarantee the protection selectivity, the influence of increasing current must be taken into account.

Protection action analysis

Figure 6 shows a distribution network system in a city, and let's take this system as the example to show the proposed protection scheme.

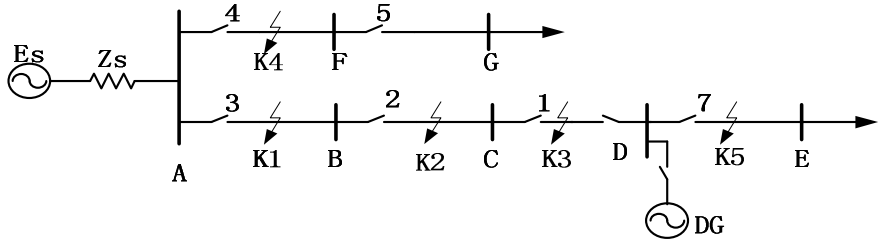

Fig.6 Distribution Network System Model

1) When a fault occurs at K1, direction element and current I or II of protection 3 will act, while the direction element of protection 2 does not act, because the power direction of protection 2 is "-". According to the protection scheme proposed in this paper, the protection 3 and 2 constituted a communication unit. Protection 2 will send the signal of unlocked to protection 3, and line AB will be judged as fault.Circuit breaker of protection 3 trips and sends the control information to protect 2, then circuit breaker of protection 2 trips,too.

2) When a fault occurs at K2, direction element and current I or II of both protection 3 and 2 act, but direction element of protection 1 does not acts. Therefore, protection 3 receives the signal of locked from protection 2, while protection 2 receives the signal of unlocked from protection 1.Circuit breaker of protection 2 trips and sends the control information to protect 1, then circuit breaker of protection 1 trips,too.

3) When a fault occurs at K3, current I or II of protection 1 acts, and the power direction of protection 1 and 6 were identified as "+". The fault will be judged on the line CD, and circuit breakers at two sides of line CD trips.

4) When a fault occurs at K4, directional element of protection 1, 2 and 3 was judged as negative direction, so the protections will not act. Protection 4 acts to isolation the fault feeder.

5) When a fault occurs at K5, requirements of selectivity and reliability can be achieved, because action value of protect 7 is set according to the capacity of DG.

Simulation

According to Fig. 4, distribution network simulation model is established. The reference capacity, S_B is 500MVA, the reference voltage, U_B is 10.5kV. The system impedances (maximum and minimum) are $x_{s\max}=0.126\Omega$ $x_{s\min}=0.091\Omega$.The load parameter is $Z_{LD}=(30+j15.7)\Omega$, equaling to a single feeder load about 4MVA. The capacity of DG is 5MVA. Each line's parameters as shown in the following table.

Tab.1 Impedance Parameters of Each Line

Line	Impedance	Line	Impedance	Line	Impedance
AB	0.54+j0.694	CD	1.813+j0.651	AF	1.08+j1.388
BC	0.54+j0.694	DE	3.626+j1.302	FG	1.554+j0.558

The simulation analysis is carried out, while the simulation model of this system is built by PSCAD/EMTDC. According to general configuration three-current protection, values of segment II of protection 3, 2 and 1 are calculated: I_{3dzII}=4375A, I_{2dzII}=2224A, I_{1dzII}=1093A; and the value of segment III of protection 7 is I_{7dzIII}=429A.

Short circuit current, that flows through the protection of the line, when three-phase fault occurs to a line's end, is shown in Table 2.

Tab.2 Short Circuit Current

Line	Fault current A	Line	Fault current A	Line	Fault current A
AB	6323	CD	1679	AF	3308
BC	3298	DE	814	FG	1817

The analysis of simulation results:

1) When a fault occurs to the end of line AB, the fault current of Protection 3 is detected: I3=6323A. Because of I3>I3dzII, according to rule (1), segment II of protection 3 acts,while the direction element of protection 2 does not act. Without locking signal, protection 3 trips, and send the remote control information to protection 2. Then protection 2 trips,too.

2) When a fault occurs to the end of line BC, the fault current of Protection 2 is detected: I2=3298A. Because of I2>I2dzII, according to rule (2), protection 3 receives locking signal 2 sent from protection 2 and does not trip, while protection 2 trips without locking signal. At the same time remote control information is sent to protect 1, and the circuit breaker of protect 1 act.

3) When a fault occurs to the end of line CD, the fault current of Protection 1 is detected: I1=1679A. Because of I1>I1dzII, according to rule (3), segment II of protect 1 acts, while direction elements of protection 6 and 1 act. Circuit breakers of protection 1 and 6 trip at the same time, while protection 3 and 2 receive locking signal.

4) When a fault occurs to the end of line DE, the fault current of Protection 7 is detected: I7=814A. Because of I7>I7dzIII, according to rule (5), segment III of protect 7 acts and the fault is isolated after circuit breaker of protection 7 tripped,while other protections receive locking signals.

As is shown in the simulation and analysis, the protection scheme advanced can absolutely meet the requirements of reliability, selectivity sensitivity.

Conclusions

With DG accessed to distribution network, traditional protection scheme can not meet the requirement of reliability, selectivity, sensitivity and quick-acting. This paper introduces a new protection scheme for distribution network with DG.The segment I, II of direction three-current protection on the line which is at the upstream of DG, and the next line's segment I, II consists of a simple communication unit. Through the comprehensive judgment of two protections' action results, fault can be isolated in minimum range quickly and accurately. The scheme proposed in the paper not only meets the requirements of relay protection, but also has three advantages. 1) The simple structure and reliable; 2) Don't need to change the fixed value,when a new DG accesses into; 3) For all the lines between the original power supply and DG, fault can be isolated quickly.

Key words: Mining Shovel; Crowding system; Dynamics ; Vibration ; Dynamic load coefficient

Abstract. To highlight the main factors, only the crowding shaft was taken as elastic component, while the other crowding system parts, such as girth, driving shaft and swing arm were taken as rigid components; the effects of damping were ignored; the dynamical model of mining shovel's crowding system was simplified to a two degree of freedom model; mathematical and mechanical models were derived by Lagrange equation method; the locked rotor condition, when the bucket rod was perpendicular to the boom, was used as the calculation condition; the calculated dynamic load coefficient of the crowding system was compared with that in multi degree of freedom model and the result shows: to simplify calculation, it is practicable to replace multi degree of freedom models with two degree of freedom models in the preliminary design stage.

Introduction

Due to the complexity of the crowding system of mechanical mining shovel, static calculation methods are usually used in the present strength calculation of crowding systems, while actual dynamic loads when working are miscounted; the field test results proved：loads of crowding systems at work changed with soil properties；due to the frequent starting and braking, locked rotor could be arisen at any time and the dynamic loads were very obvious; therefore, in order to improve the reliability of structure parts and system performance , it is quite necessary to conduct dynamic research.

Derivation of differential equation of crowding system

For the sake of detailed dynamic calculation and analysis of crowding system [1], it was assumed as following:

1）The belt between crowding motor and reduction gearbox, transmission shafts of reduction gearbox, gears and boom were rigid components;

2）The final crowding shaft was elastic shaft and the effect of damping was neglected.

Then, the obtained model [2] was simplified to a two-freedom model. The rotation angle of motor (θ_0) and crowding smaller gears (θ_4) were selected as general coordinates and the

dynamic calculation of crowding system was obtained as illustrated in Fig.1. The kinetic and potential energy of crowding system were derived as following:

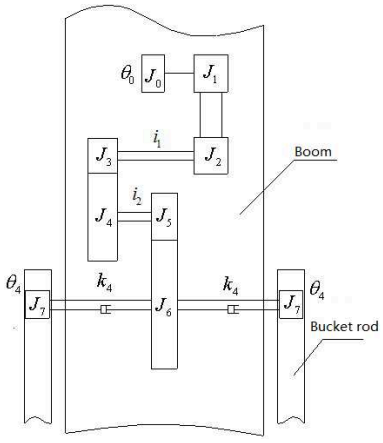
1）kinetic energy of the crowding system

$$T=\frac{1}{2}\cdot J\cdot\dot{\theta}_0^2+J_7\cdot\dot{\theta}_4^2+\frac{1}{2}\cdot\left(m_d+m_c\right)\cdot\dot{\theta}_4^2\cdot R_3^2 \quad (1)$$

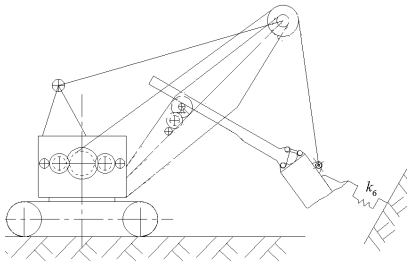
where J is the whole moment of inertia of hoist and transmission system and can be expressed as

$$J=J_0+J_1+J_2+J_3+\frac{J_4}{i_1^2}+\frac{J_5}{i_1^2}+\frac{J_6}{i_1^2 i_2^2} \quad (2)$$

m_d is the mass of the bucket rod;
m_c is the mass of the empty bucket;
R_3 is the radius of the smaller crowding gear;
i_1 is the first transmission ratio of the crowding reducer;
i_2 is the transmission ratio of the crowding reducer;
J_0 is the moment of inertia of the crowding motor (J_0=53.100kg·m^2);
J_1 is the moment of inertia of the driver gear (J_1=13.475kg·m^2);
J_2 is the moment of inertia of the driven belt pulley (J_2=12.902kg·m^2);
J_3 is the moment of inertia of the gear No 1(J_3=0.617kg·m^2);
J_4 is the moment of inertia of the gear No 2(J_4=270.44kg·m^2);
J_5 is the moment of inertia of the gear No 3(J_5=2.007kg·m^2);
J_6 is the moment of inertia of the gear No 4(J_6=1153.073kg·m^2);
J_7 is the moment of inertia of the smaller crowding gear (J_7=31.157kg·m^2);
k_4 is the torsion stiffness of the crowding shaft (k_4=10960.00×10^{4}N·m/rad);
k_6 is the soil rigidity in crowding direction (k_6=40000.00×10^{4}N/m).



(a) Calculation diagram of crowding system



(*b*) Calculation diagram of whole mining shovel crowding system

Fig. 1 Dynamic calculation diagram of crowding system

2）The potential energy of crowding system [3]

$$V = k_4 \cdot \left(\theta_4 - \frac{\theta_0}{i_1 i_2} \right)^2 + \frac{1}{2} \cdot k_6 \cdot (\theta_4 \cdot R_3)^2 \quad (3)$$

The generalized force, that is, the kinetic moment ($Q_1 = Q_y(t)$) output by crowding motor acted on general coordinate θ_0 of the motor. There is no generalized force acted on the other general coordinates.

By substitution of the Eq. (1）,（2）and the generalized force into Lagrange equation, the below equations were derived:

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{\theta}_i}\right) + \frac{\partial V}{\partial \theta_i} = Q_i \qquad i=1, 2, 3 \quad (4)$$

The following two degree of freedom differential equations could be also obtained:

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{\theta}_0}\right) + \frac{\partial V}{\partial \theta_0} = Q_y(t)$$

$$J \cdot \ddot{\theta}_0 + 2k_4 \cdot \left(\frac{\theta_0}{i_1 i_2} - \theta_4 \right) \cdot \frac{1}{i_1 i_2} = Q_y(t) \quad (5)$$

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{\theta}_4}\right) + \frac{\partial V}{\partial \theta_4} = 0$$

$$2J_7 \cdot \ddot{\theta}_4 + R_3^2 \cdot (m_d + m_c) \cdot \ddot{\theta}_4 + 2k_4 (\theta_4 - \frac{\theta_0}{i_1 i_2}) + k_6 R_3^2 \theta_4 = 0 \quad (6)$$

The Eq. (4) ,（5）could be expressed by matrix:

$$[M] \cdot \{\ddot{X}\} + [K] \cdot \{X\} = \{Q\} \quad (7)$$

where $[M]$ is the mass matrix;

$[K]$ is the stiffness matrix；

$\{X\}$ is the displacement vector;

$\{Q\}$ is the column vector of the stimulating vibration loads;

$$[M] = \begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix} \quad (8)$$

where $m_1 = J$；

$m_2 = 2J_7 + R_3^2 \cdot (m_d + m_c)$.

$$[K]=\begin{bmatrix} k_{11} & k_{12} \\ k_{21} & k_{22} \end{bmatrix} \tag{9}$$

where

$$k_{11}=\frac{2k_4}{i_1^2 i_2^2} \qquad k_{12}=-\frac{2k_4}{i_1 i_2}$$

$$k_{21}=-\frac{2k_4}{i_1 i_2} \qquad k_{22}=2k_4+k_6 R_3^2$$

$$\{X\}=\begin{Bmatrix} \theta_0 \\ \theta_4 \end{Bmatrix} \tag{10}$$

$$\{Q\}=\begin{Bmatrix} Q_y(t) \\ 0 \end{Bmatrix} \tag{11}$$

Dynamic loads calculation of the crowding system

2.1Calculation of exciting loads response

The eigenvalue question of the Eq.（6）is:

$$[K]\{A\}=\omega^2[M]\{A\} \tag{12}$$

where ω is the natural frequency;

$\{A\}$ is the natural vibration mode;

The eigenvalue equation is:

$$\Delta(\omega^2)=\begin{vmatrix} k_{11}-\omega^2 m_1 & k_{12} \\ k_{21} & k_{22}-\omega^2 m_2 \end{vmatrix} \tag{13}$$

$$=(k_{11}-\omega^2 m_1)(k_{22}-\omega^2 m_2)-k_{12}k_{21}=0$$

For the substitution of the related data, the natural frequency was obtained as follow:

$$\omega_1=13.1473 \text{ rad/s}, \qquad \omega_2=187.6364 \text{ rad/s}$$

ω_1, ω_2 was substituted into eigenvalue Eq.（12）and the natural vibration mode was under normalization process. Therefore, the following results were obtained:

$$\begin{Bmatrix} A^{(1)}{}_1 \\ A^{(1)}{}_2 \end{Bmatrix}=\begin{Bmatrix} 1.0000 \\ 0.0217 \end{Bmatrix}, \qquad \begin{Bmatrix} A^{(2)}{}_1 \\ A^{(2)}{}_2 \end{Bmatrix}=\begin{Bmatrix} 1.0000 \\ -0.5382 \end{Bmatrix}$$

For the sake of regularizing the natural vibration mode, the regularized vibration mode was obtained as follow:

$$\begin{Bmatrix} u^{(1)}{}_1 \\ u^{(1)}{}_2 \end{Bmatrix}=\begin{Bmatrix} 0.1059 \\ 0.0023 \end{Bmatrix}, \qquad \begin{Bmatrix} u^{(2)}{}_1 \\ u^{(2)}{}_2 \end{Bmatrix}=\begin{Bmatrix} 0.0213 \\ -0.0114 \end{Bmatrix}$$

The stimulating vibration load: $Q_1 = M_{\max y} \cdot \sin\left(\frac{\pi}{2.5} \cdot t\right)$.

The steady-state response of the system acted on the stimulating vibrationforce was obtained:

$$\{X\} = \begin{pmatrix} \theta_0 \\ \theta_4 \end{pmatrix} = \begin{pmatrix} 0.1608 \\ 0.0035 \end{pmatrix} \cdot \sin\left(\frac{\pi}{2.5} \cdot t\right) \quad (14)$$

2.2 Calculation of crowding shaft loads

Under the locked rotor condition when the bucket rod was perpendicular to the boom [8,9], the expression of dynamic load was :

$$M_4 = 2 \cdot k_4 \cdot \left(\frac{\theta_0}{i_1 i_2} - \theta_4\right) \quad (15)$$

The equation（13）was substituted into the Eq.（13） and the further result was obtained as:

$$M_4 = 2k_4 \left(0.0218 - 0.0214\right) \cdot \sin\left(\frac{\pi}{2.5} t\right) \quad (16)$$

The original data was substituted into the Eq.（15） and the change law with time of dynamic loads of the crowding shaft was calculated as illustrated in Fig.2.

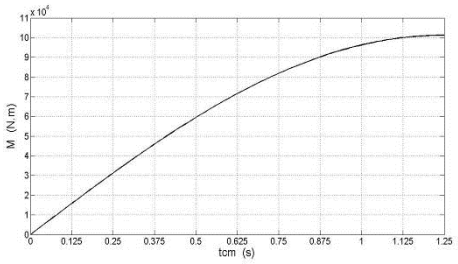


Fig. 2 Dynamic load of the crowding shaft change law with time

From the Fig.2, it could be deprived that : the maximum crowding dynamic load $M_{\max d}$ =10.1213×10^4 N·m ,the static load M_j=25.8441×10^4 N·m（based on the maximum power） and the coefficients of dynamic load were[10]:

$$K_{ye} = \frac{M_{\max d} + M_j}{M_j} \quad (17)$$

$$K_{ye} = \frac{M_{\max d} + M_j}{M_j} = \frac{10.1213 + 25.8441 \times 10^4}{25.8441 \times 10^4} \approx 1.392$$

They were compared with dynamic parameters derived from the multi degree of freedom model [11] as illustrated in Table 1.

Table 1 Comparison of dynamic parameters between two degree of freedom model and multi degree of freedom model

Terms	Multi degree of freedom model	Two degree of freedom	Comparisons
Coefficients of dynamic load K	1.408	1.392	1.408 1.392 /1.408≈1.14%
Maximum dynamic oad $M_{\max d}$ (N·m)	105105	101213	(105105 101213 /105105≈3.7%

From the Table 1: the gap between the obtained coefficients of dynamic load based on the above two model types is very narrow. Thus, it is practicable to replace multi degree of freedom models with two degree of freedom models in the preliminary design stage.

Conclusions

For the sake of above analysis and calculation，conclusions as follow are draw:

The calculation model and methods are correct and the obtained results are of great significance;

The analysis and calculation will become easier when multi degree of freedom models are replaced with two degree of freedom models.

Keywords: load ratio, diesel, liquefied natural gas, dual-fuel engine

Abstract. In order to study the application of the liquefied natural gas (LNG) on diesel engine, a turbocharged diesel engine was converted into a dual-fuel engine ignited by diesel fuel. The effects of load ratio on fuel economy and emissions of dual-fuel engine were compared and analyzed at engine speed of 1200 r/min, 1600 r/min and 2200 r/min. The experimental results show that, the specific fuel consumption is reduced with the increase of load ratio at different speeds. As the load ratio increases, CO emission of dual-fuel reduces, but it increases slightly at high loads and full load. When the load ratio is less than 40%, HC emission of dual-fuel is reduced significantly with the increase of load, but increases when the load ratio continues to increase, and finally HC emission is stable. When the load ratio is less than 40 %, NOx emission is relatively low, as the load ratio increases, increases sharply, but at high loads and full load, reduces slightly.

Introduction

The history of natural gas as automobile fuel could date back to the early development of internal combustion engine. Because of the inconvenience of storing and supplement, natural gas had been replaced by diesel fuel and petrol fuel. With the rapid development of the auto industry, our country's vehicle quantity is also increasing rapidly. Automobiles bring convenience while the environmental pollution and the shortage of petroleum. The demand of environmental protection and the shortage of petroleum resources have challenged the traditional petroleum fuels and its combustion forms of engines. So it is significant that clean alternative fuel is explored to promote auto industry continuously. Among the variety of alternative fuels, natural gas embraces the characteristics such as abundant resources, higher octane value, higher calorific value and lower pollution, and is regarded as a very promising cleaning vehicle fuel [1]. Therefore, it will be a new direction for developing the natural gas, and it is also an effective method to solve the petroleum crisis and environment problems.

The combustion process of LNG-diesel dual-fuel engines is complicated when compared with gasoline engines and diesel engines. The fuel injectors squirt a small amount of pilot diesel into cylinder while the piston is approaching to TDC in compression stroke. Millions of ignition sources come into being after the spontaneous combustion of diesel fuel, then ignite NG pre-mixture. Dual-fuel engines have the characteristics both premixed combustion of gasoline engines and diffusion combustion of diesel engines. LNG-diesel dual-fuel engine has been received more and more attention for its advantages such as good emission performance, convenient modification and flexible usage [2].

Experimental set-up

Experimental apparatus. Layout for tests on the engine is shown in Fig. 1. The dual-fuel engine is modified by YC6J270-30 diesel engine. The main characteristics of engine are shown in Table 1.

Electronically controlled LNG fuel delivery system is equipped on the original diesel engine, to control the injection parameters accurately. LNG delivery system is composed of cylinder for LNG, vaporizer, pressure regulator, buffer tank, safety valve, injector and mixer. Nature gas mixes with fresh air in the mixer and intake manifold, and finally enters into the engine cylinder. The pilot diesel to ignite the NG-air charge is injected to the cylinder before TDC and ignited in compression stroke, then the flame spread throughout all fuel-air mixture.

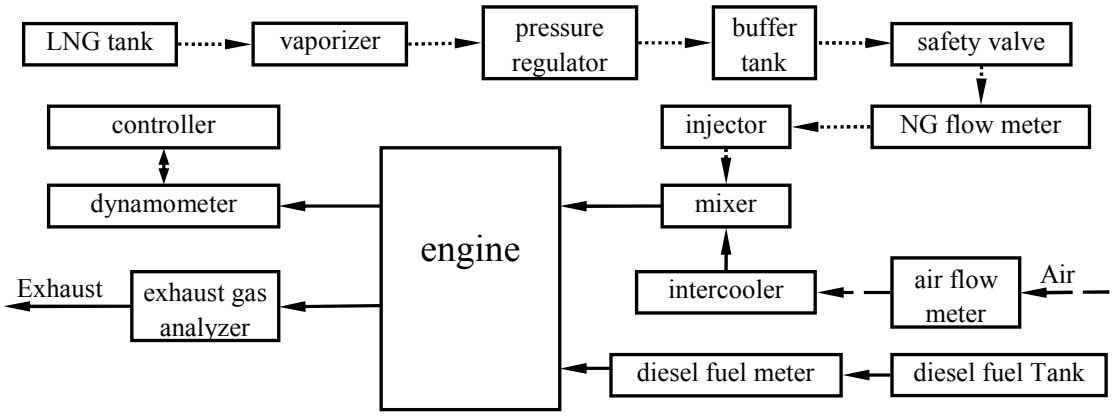

Fig. 1 Layout for the tests

Table 1 Engine characteristics

Model	YC6J270-30
Type	Vertical in-line, Water-cooled, 4 stroke, Electronic control, Direct injection
Bore [mm]×Stroke [mm]	105×125
Compression ratio	17.0:1
Number of cylinders	6
Displacement [L]	6.49
Intake way	Turbo-charging, Inter-cooling
Electronic control system	High pressure, Common rail
Rated power/speed [kW/r/min]	199/2500
Rated torque/speed [N·m/r/min]	950/1200-1700

Experimental procedure. Engine performance tests were conducted on a direct-injection dual-fuel engine with electronic control. The inlet air temperature is controlled at 40˚C. Measurements are taken at three different engine speeds of 1200 r/min, 1600 r/min and 2200 r/min, and twelve different engine loads corresponding to 10%, 20%, 25%, 30%, 35%, 40%, 50%, 60%, 70%, 80%, 90% and full load. At a constant engine speed, an effort has been made to keep the pilot diesel fuel constant, while the load ratio of dual-fuel engine is adjusted by the amount of LNG fuel until the desired load ratio is obtained. The values of load ratio, engine speed, consumption of LNG and diesel and the emissions of CO, HC and NOx were recorded at different operation conditions. By analyzing experimental data, the effects of load ratio on performance and emissions of dual-fuel engine can be studied.

Data processing. When the engine is fuelled with LNG-diesel dual-fuel, the fuel consumption consists of diesel consumption and LNG consumption. The LNG consumption is commuted to diesel consumption according to the low calorific value [3], so the overall dual-fuel consumption is given by:

$$m_{df} = m_d + \frac{H_{uNG}}{H_{ud}} \times m_{NG}. \quad (1)$$

where m_{df} is the consumption of dual-fuel, m_{NG} is the consumption of NG, H_{uNG} is the low calorific value of NG (49.54 MJ/kg), m_d is the consumption of diesel, and H_{ud} is the low calorific value of diesel (42.50 MJ/kg).

The specific fuel consumption of dual-fuel engine refers to the fuel consumption of unit effective power [4], given by:

$$b_e = \frac{m_{df}}{P_e} \times 10^3. \quad (2)$$

where P_e is the effective power.

Results and discussion

Fuel consumption. For the load characteristics at 1200r/min, 1600r/min and 2200r/min, the specific fuel consumption of LNG-diesel dual-fuel is shown in Fig. 2. When the load ratio is larger than 40 %, the specific fuel consumption of dual-fuel is reduced slightly with the increase of load, and its value is relatively low. However, when the load ratio is less than 40 %, the specific fuel consumption is increased significantly as the load ratio reduces.

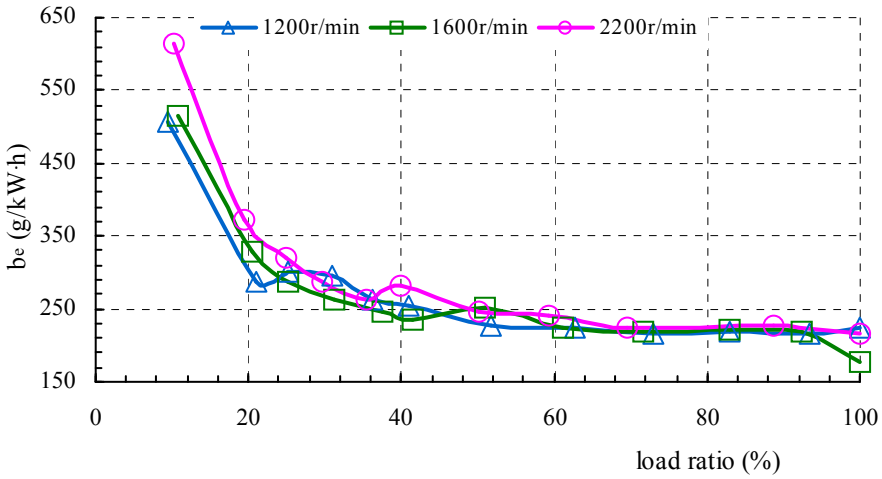

Fig. 2 The fuel consumption of the load characteristics

The concentration of NG-air mixture is low due to the less NG supply when the load ratio is less than 40 %. The NG-air mixture is not completely burned as the flame is missing in some places. Dual-fuel engine's combustion efficiency is low. The concentration of NG-air mixture is low due to the less NG supply when the load ratio is less than 40 %. The NG-air mixture is not completely burned as the flame is missing in some places. Dual-fuel engine's combustion efficiency is low. Therefore, the specific fuel consumption of dual-fuel increases rapidly with the reduction of load ratio. At middle and high loads, the reduction of the specific fuel consumption is determined by the mixture concentration and the high temperature in cylinder. As a result of the good quality of NG-air mixture and high efficiency of dual-fuel, the specific fuel consumption of dual-fuel is low at middle and high loads.

CO emission. For the load characteristics at 1200r/min, 1600r/min and 2200r/min, the CO emission of LNG-diesel dual-fuel is shown in Fig. 3. At middle and low loads, the CO emission of dual-fuel is reduced with the increase of load ratio. But at high loads and full load, the CO emission of dual-fuel is increased slightly.

CO is a kind of combustion intermediate product, and CO emission is mainly controlled by chemical reaction mechanism of fuel. The creation of CO is related to the mixture concentration and fuel composition. The change in CO emission is the result of the two factors that exert effects at the same time. When the engine is fuelled with dual-fuel, NG pre-mixture is too lean to burn completely at low loads, the flame can not spread throughout the whole combustion chamber because of the low flame spread speed. What is more, CO can not be oxidized as a result of the low combustion temperature in cylinder. In consequence, CO emission of dual-fuel is high at low loads. With the increase of load ratio, the NG-air mixture becomes richer, and so the possibility of incomplete combustion becomes less. Combustion process can be extended to the whole combustion chamber. On the other hand, exhaust temperature increases gradually as the load ratio increases, to oxidize CO into CO_2. Therefore, the LNG-diesel dual-fuel engine's CO emission is sharply reduced. At high loads and full load, the increase of CO emission of dual-fuel is due to the absent oxygen occurs in some areas during combustion period.

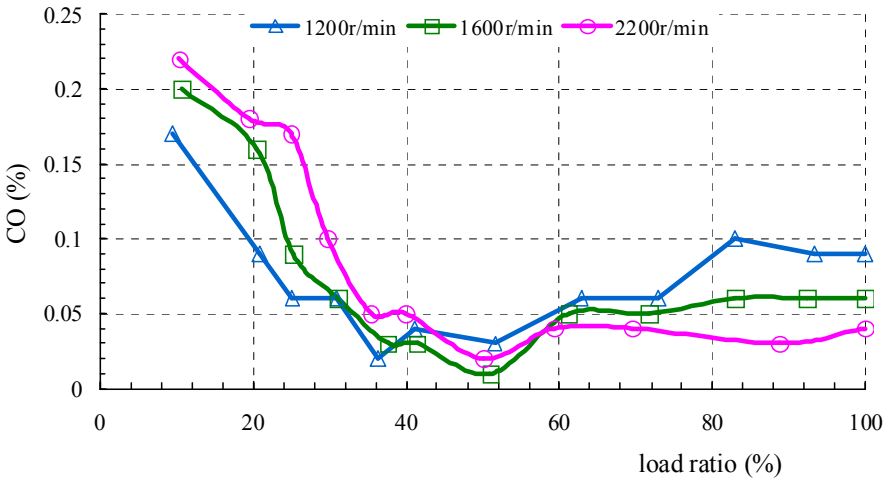

Fig. 3 The CO emission of the load characteristics

HC emission. For the load characteristics at 1200r/min, 1600r/min and 2200r/min, the HC emission of LNG-diesel dual-fuel is shown in Fig. 4. When the load ratio is less than 40 %, HC emission of dual-fuel is reduced significantly with the increase of load. But it increases when load ratio continues to increase, and finally HC emission is stable.

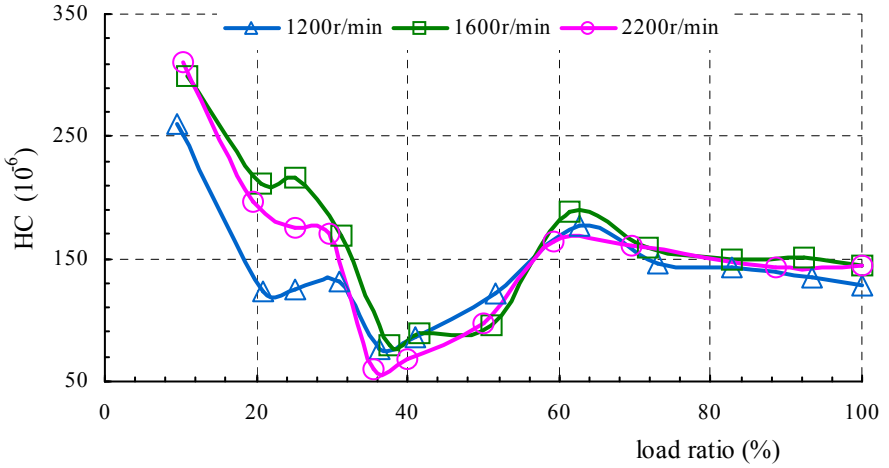

Fig. 4 The HC emission of the load characteristics

HC emission is mainly derived from incomplete combustion, quenching areas near the combustion chamber walls and the narrow crevices between piston top and cylinder. HC is a product of incomplete combustion. At low loads, NG and diesel gotten into the cylinder are few, mixture is too lean to make the flame rapidly spread throughout the combustion chamber, which leads to the high unburned HC emission of dual-fuel engine. With the increase of load ratio, HC emission of dual-fuel is reduced sharply, which is caused by three key factors: the first is that the mixture becomes richer, which improves the combustion conditions and gets high combustion efficiency; the second is that the thickness of quenching areas near the combustion chamber walls reduces slightly; and the third is that the rise of combustion temperature in cylinder makes the unburned HC completely oxidized. When load ratio is larger than 40%, HC emission increases because the NG-air mixture is directly scavenged to outside from cylinder in the overlap period, and the NG mixture can not be completely burned as the flame is missing in some places, what's more, the NG-air mixture in the narrow crevices between the piston top and cylinder and near the combustion chamber walls is difficult to burn [5].

NOx emission. For the load characteristics at 1200r/min, 1600r/min and 2200r/min, the NOx emission of LNG-diesel dual-fuel is shown in Fig. 5. When the load ratio is less than 40 %, the NOx emission of dual-fuel is relatively low. As the load ratio increases, NOx emission is increased sharply. But at high loads and full load, it reduces slightly.

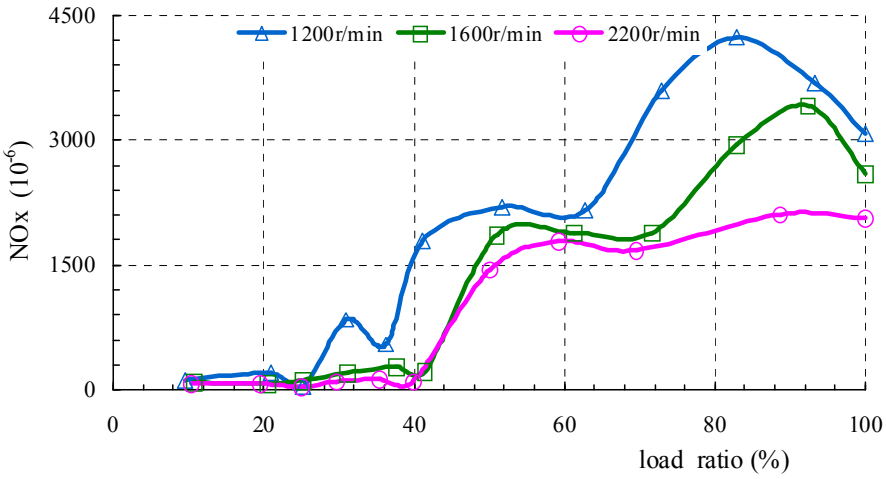

Fig. 5 The NO_X emission of the load characteristics

The formation of NOx is determined by the combustion temperature, the mixture concentration and the reaction duration. At low loads, excess air coefficient is large. Although there is plenty of oxygen in NG-air mixture, the combustion temperature in cylinder is low. Thus, the LNG-diesel dual-fuel engine’s NOx emission is low. As the load increases, the supply of LNG increases, resulting in good quality of the mixture and high combustion efficiency of dual-fuel. High pressure and combustion temperature in cylinder contribute to the formation of NOx. Therefore, NOx of dual-fuel is increased rapidly when the load ratio is larger than 40%. At high loads and full load, despite of the higher maximum combustion temperature, oxygen in mixture is too few to produce NOx. Therefore, the LNG-diesel dual-fuel engine’s NOx emission is reduced slightly.

Conclusions

1) With the increase of load ratio, the specific fuel consumption of dual-fuel reduces at different speeds.
2) At middle and low loads, the CO emission of dual-fuel is reduced with the increase of load ratio. But at high loads and full load, the CO emission is increased slightly.
3) When the load ratio is less than 40%, the LNG-diesel dual-fuel engine’s HC emission is reduced significantly with increase in the load. But it increases when load ratio continues to increase, and finally HC emission is stable.
4) When the load ratio is less than 40%, the NOx emission of dual-fuel is relatively low. As the load ratio increases, the NOx emission is increased sharply. But at high loads and full load, it reduces slightly.

Keywords: Ambient pressure; Injection pressure; Spray penetration; Spray cone angle; Spray area

Abstract: we studied the spray characteristics of n-butanol/diesel fuel blends using a high-speed camera and schlieren system, and analyzed the effect of different fuels, ambient pressure and injection pressure conditions on the spray penetration, spray cone angle, spray area, et al. The results showed that, at the same injection pressure, as the increase of ambient pressure, the spray cone angle of the same volume of fuel increases gradually, the spray penetration and the spray area decreases; under the same ambient pressure, the spray penetration, spray cone angle and spray area increase gradually with the increasing injection pressure, but when the injection pressure increases enough, the parameters are roughly the same; and the parameters basically all increase with the adding of n-butanol.

Introduction

With the increase of car ownership, energy crisis and environment pollution are the main problems that we are facing. Recent years, alternative fuel in the aspect of energy conservation and emissions reduction aspect has made abundant research results [1]. Renewable alcohol fuel is considered to be one of the effective ways to reduce engine emissions, and n-butanol is more and more applied in experimental study [2]. Spray characteristics have a direct impact on engine combustion and emissions. The text is experimental study on spray characteristics of n-butanol/diesel blends through the spray penetration, spray cone angle and spray area [3].

Experimental Equipment and Process

The experimental equipment is shown in Fig.1. It includes fuel injection device, constant volume combustion bomb, schlieren system and a high-speed camera.

The experiment used n-butanol/diesel blends with volume scores of n-butanol are 5% (N5), 10% (N10) and 20% (N20); the motor

speed is 800r/min, the ambient pressure is 1MPa, 2MPa and 3MPa; the volume of the injected fuel is 14mm^3 and 24mm^3, and the corresponding injection pressure is 70MPa, 80MPa, 90MPa and 110MPa, 120MPa, 130MPa. The process of spray is recorded by a high-speed camera (the shooting speed is 1000 frames per second), we dispose the pictures through MATLAB program, and get the spray penetration, spray cone angle and spray area of each picture, then analyze the changing rule of spray characteristics at different conditions[4].

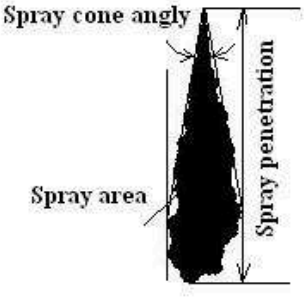

Fig. 2 The spray structure schematic diagram.

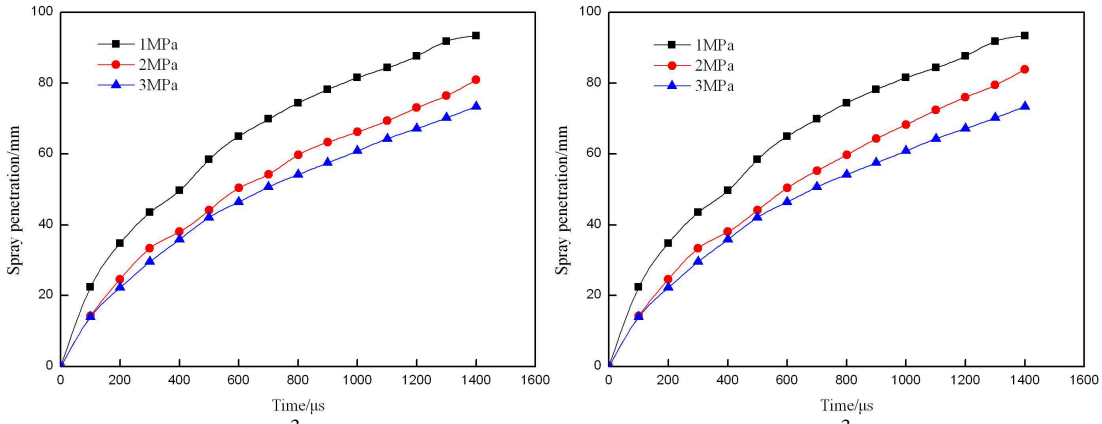
Experimental Results and Analysis

At present, the macroscopic parameters of spray characteristics have no unified standard in the word[5]. In this paper, in order to deal with spray images conveniently through using MATLAB program, the spray penetration, spray cone angle and spray area are definite as shown in figure 2 (the black region is the spray area).

The Influence of Ambient Pressure on the Spray Characteristics

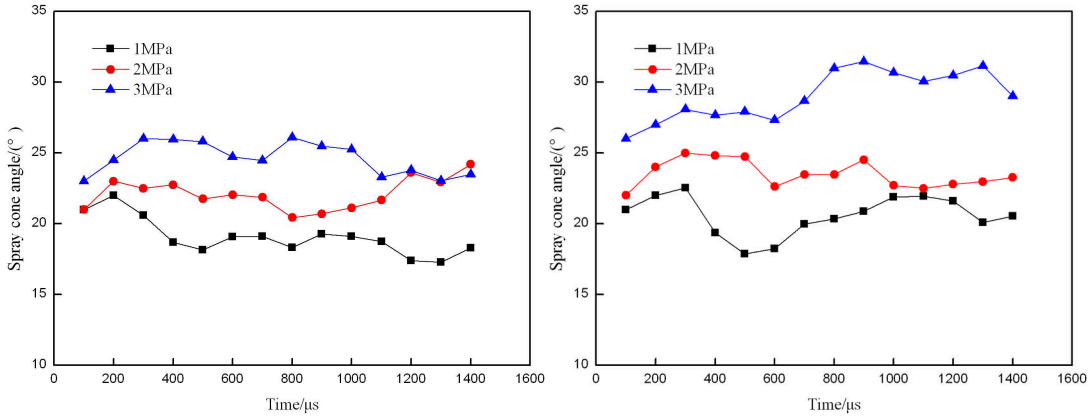


(a)14mm^3 80MPa (b)24mm^3 120MPa

Fig. 3 The spray penetration of N20 under different ambient pressure.

The changing curve of spray penetration of the same volume of N20 at different ambient pressure is shown in figure 3. As we can see from graph (a), when the injected fuel is 14mm^3 and the injection pressure is 80MPa, the spray penetration of spray evening as the ambient pressure is 1MPa is 12mm longer than that as the ambient pressure is 2MPa, and 17mm longer then that as the ambient pressure is 3MPa, obviously, the effect of ambient pressure on spray penetration is bigger. With the increase of ambient pressure, the spray penetration decreases gradually, and the trend is more obvious in the spray evening. It is because that, as the increasing ambient pressure, the density of environmental media is also increases, so the resistance that the spray faced is more larger[6]; as the spray beginning, the liquid drop is bigger and the speed is higher, so the resistance is relatively smaller, on the contrary, more closer to the spray evening, the effect of the resistance is more larger.

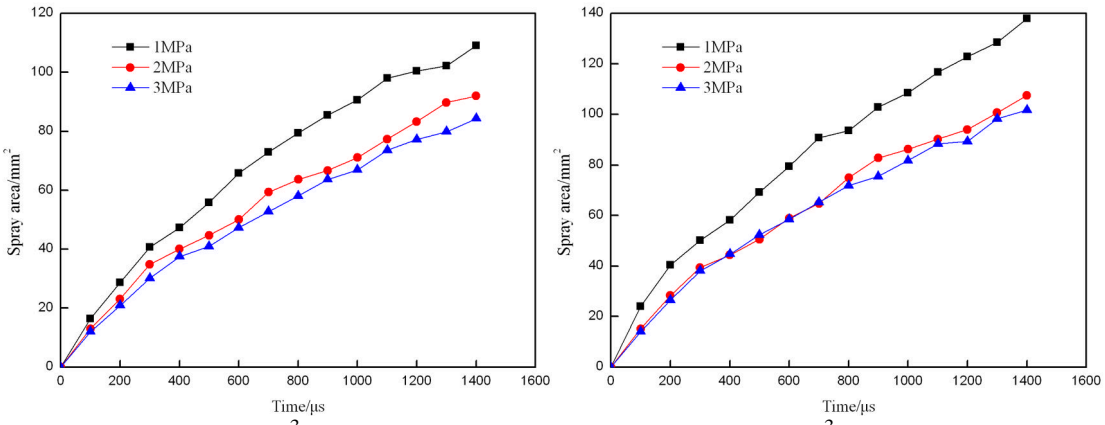
The changing curve of spray cone angle of the same volume of N20 at different ambient pressure is shown in Fig. 4. From graph (a) and (b), we can see that, under a certain injection pressure, the spray cone angle of the same volume fuel increases as the increasing ambient pressure, and this trend is more obvious in graph (b). Under the same condition, when the spray penetration is longer, the lateral average diameter is generally smaller. When the volume of injected fuel is 24mm^3 and the injection pressure is 120MPa, the pressure difference of the both ends of the injection nozzle is larger, the speed of spray beginning is higher, as the increasing ambient pressure, the density of



(a)14mm^3 80MPa (b)24mm^3 120MPa

Fig. 4 The spray cone angle of N20 under different ambient pressure.

environmental media is increases, the interaction of liquid drops and surrounding gas enhances, the entrainment effect caused at the external rim of the spray also enhances, so, the trend that the spray cone angle increases with the increasing ambient pressure is more obvious [7].



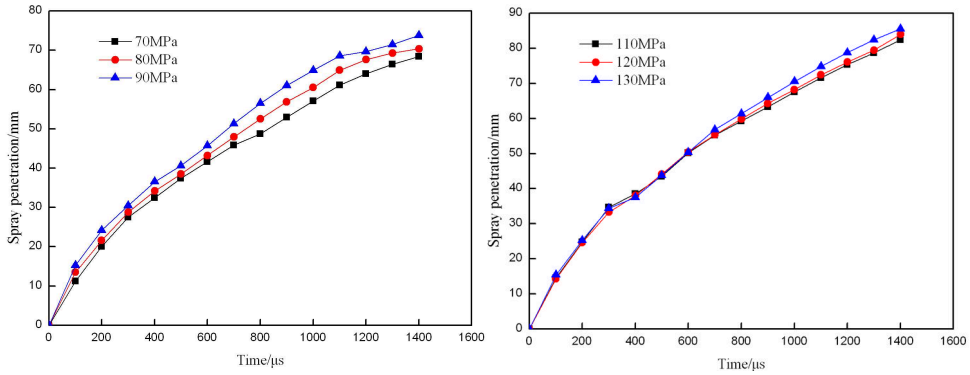
(a)14mm^3 80MPa (b)24mm^3 120MPa

Fig. 5 The spray cone area of N20 under different ambient pressure.

The changing curve of spray area of the same volume of N20 at different ambient pressure is shown in Fig. 5. When the injection pressure is 80MPa, the speed of spray beginning is lower, the kinetic energy exchanged with the surrounding gas is lesser, so the effect of the changing gas density is larger. When the injection pressure is 120MPa, the speed of spray beginning is higher, the exchange of kinetic energy with the surrounding gas increases, entrainment effect enhances, the spray cone angle increases and the spray area also increases, the phenomenon is shown in graph (b).

The Influence of Injection Pressure on the Spray Characteristics

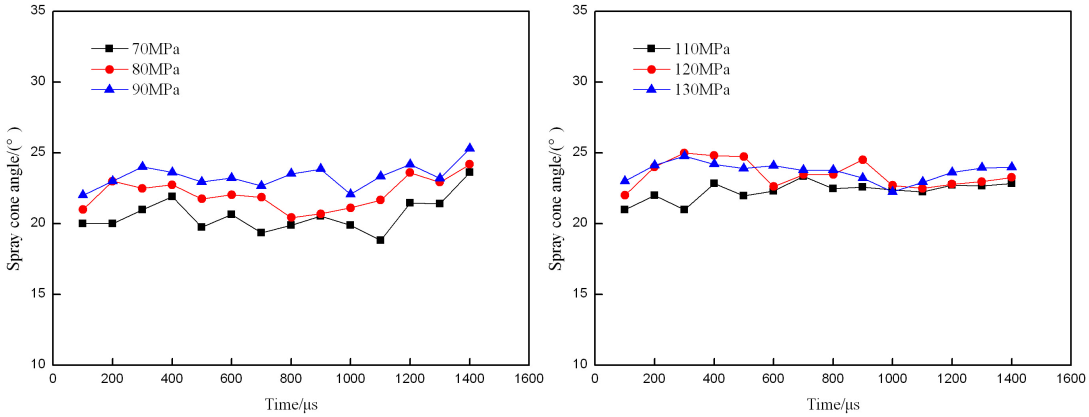
Fig. 6 shows the changing of spray penetration of the same volume of N20 at different injection pressure as the ambient pressure is 2MPa. From the figure, with the increase of injection pressure, the spray penetration of the same volume of fuel increases and the changing trend is basically consistent; when the injection pressure increases enough, the spray penetration is roughly constant. As shown in graph (a), within a certain range, as the injection pressure increases, the speed of spray beginning also increases, the influence of the surrounding media is weaker, the spray penetration corresponding enlarges; when the injection pressure increases enough, the speed of spray beginning is higher, the exchange of kinetic energy with the surrounding gas increases, the influence of the surrounding media enhances, consequently, the increase of the spray penetration slows down, so the result is shown as in graph (b), the spray penetration of the same volume of fuel is roughly constant as the increase of injection pressure[8].



(a)14mm^3 (b)24mm^3

Fig. 6 The spray penetration of N20 under different injection pressure.

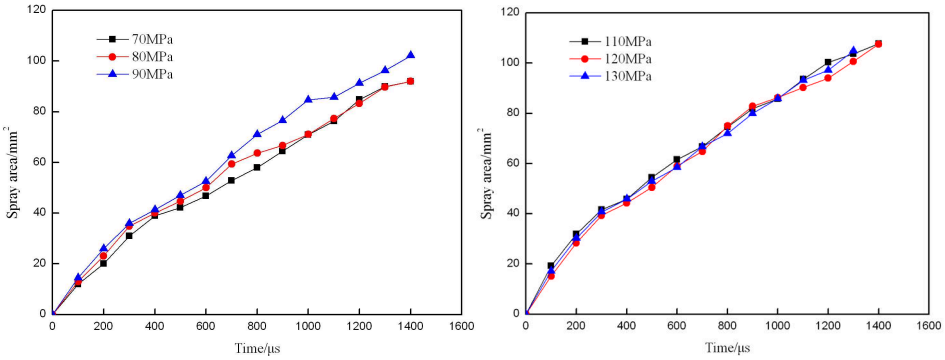
Fig. 7 shows the changing of spray cone angle of the same volume of N20 at different injection pressure as the ambient pressure is 2MPa. As shown in figure (a), the spray cone angle increases with the increase of injection pressure, but the difference is small; As shown in figure (b), the spray cone angle as the injection pressure is 120MPa is slight larger than that as 110MPa, but basically consistent with that as 130MPa. From the analysis in Fig. 6, within a certain range, as the injection pressure increases, the kinetic energy of liquid drops increases, the exchange of kinetic energy with the surrounding gas enhances, the atomization quality improves, the spray penetration corresponding enlarges; when the injection pressure increases enough, the entrainment effect caused at the external rim of the spray further enhances, the atomization quality further improves, the Sauter mean diameter (SMD) of liquid drops decreases, the drops are easy to evaporate, and the spray penetration decreases slightly [9].



(a)14mm^3 (b)24mm^3

Fig. 7 The spray cone angle of N20 under different injection pressure.

Fig. 8 shows the changing of spray area of the same volume of N20 at different injection pressure as the ambient pressure is 2MPa. When the volume of injected fuel is 14mm^3, the spray area increases with the increase of injection pressure, but the difference is small; when the volume of injected fuel is 24mm^3, the changing trend of spray area under the different injection pressure is the same and the changing curve is basically coincident. From the analysis in figure 6 and 7, when the injection pressure is lower, the exchange of kinetic energy with the surrounding gas is lesser, the changing trend of spray area is basically consistent with that of spay penetration; when the injection pressure is higher, the entrainment effect is stronger, so the changing trend of spray area is basically consistent with that of spay cone angle.



(a)14mm^3 (b)24mm^3

Fig. 8 The spray area of N20 under different injection pressure.

The Influence of Different Mixing Proportions of Fuel on the Spray Characteristics

To the different fuel, the difference of spray characteristics mainly depends on the difference of the physical property parameter, the parameters include density, surface tension, viscosity and volatility. The physical property parameter is shown in table 1. From the table, we can see that, with the adding of n-butanol ratio, the density, kinematic viscosity and surface tension of the mixing fuel decrease gradually, but the rangeability of density and surface tension is small.

The changing curve of spray characteristics of different fuel as the ambient pressure is 2MPa, the volume of injected fuel is 24mm^3 and the injection pressure is 120MPa is shown in Fig. 9. In the figure, with the adding of n-butanol ratio, the spray penetration and spray area increase gradually, the spray cone angle of N10 is larger than that of N5 and close to that of N20.

We know that the density difference of the three fuel is tiny, so the change of kinetic energy caused by density is small and the corresponding change of spray penetration is also small; but higher viscosity and surface tension make the resistence of the fuel received in the nozzle hole enlarge, the speed of the spray beginning decreases, then the spray penetration also decreases. So the spray penetration increases with the adding of n-butanol [10].

Tab. 1 The physical property parameter of each fuel

Items	N5	N10	N20
Density/×10^3·kg·m^{-3}	0.857	0.854	0.849
Kinematic viscosity(25℃)/ mm^2·S^{-1}	4.54	4.36	3.70
Surface tension(20℃)/ mN·m^{-1}	26.85	26.27	25.88

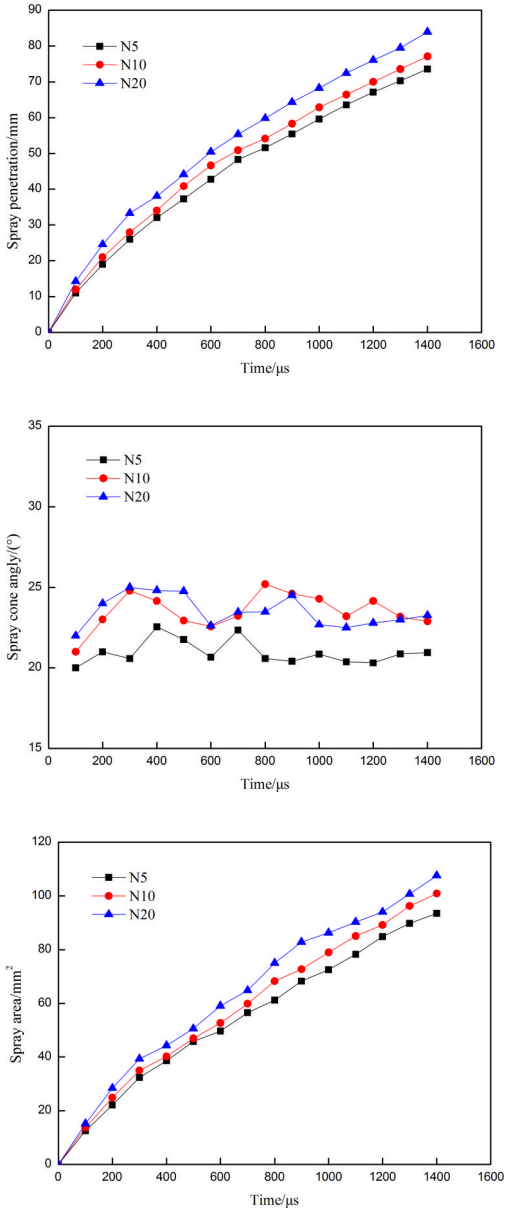


Fig. 9 The spray characteristics of different fuel.

In normal conditions, larger the viscosity and surface tension, the liquid drops will more hard break, the spray cone angle will be smaller. With the increase of n-butanol, the viscosity and surface tension decrease gradually, the drops break more easily, the mixture with surrounding gas is better, the spray cone angle is bigger; the atomization of N20 is better, the SMD is smaller, the drops is easier to evaporate, the spray cone angle corresponding decreases [11].

The spray area is the integrated embodiment of spray penetration and spray cone angle. From the analysis above, we know that, with the adding of n-butanol, the spray area increases, the mixture of spray and surrounding gas is better, the atomization quality is better.

Conclusions

(1) The influence of ambient pressure on the spray characteristics of N20 is larger. Under a certain injection pressure, as the increasing ambient pressure, the spray cone angle of the same volume of N20 increases gradually, but the spray penetration and spray area decrease gradually.

(2) The influence of injection pressure on the spray characteristics of N20 is smaller. Under the same ambient pressure, with the increasing injection pressure, the spray penetration, spray cone angle and spray area increase gradually, but when the injection pressure increases enough, the parameters are roughly the same.

(3) With the adding of n-butanol ratio, the spray penetration, spray cone angle and spray area basically increase gradually, but the spray cone angle of N10 is close to that of N20.

Keywords: Rotating machinery, Fault diagnosis, Extreme learning machine

Abstract. The authors present extreme learning machine (ELM) as a novel mechanism for diagnosing the faults of rotating machinery, which is reflected from the power spectrum of the vibration signals. Extreme learning machine was originally developed for the single-hidden layer feedforward neural network (SLFN) and then extended to the 'generalized' SLFN. We obtained the fault feature table of rotating machinery by wavelet packet analysis of the power spectrum, then trained and diagnosed the fault feature table with extreme learning machine. Diagnostic results show that the extreme learning machine method achieves higher diagnostic accuracy than the probabilistic neural network (PNN) method, exhibiting superior diagnostic performance. In addition, the diagnosis of fault feature table adding noise signal indicates the extreme learning machine method provides satisfactory generalization performance.

Introduction

Extreme learning machine (ELM) is a new algorithm overcoming the inherent shortcomings of traditional single-hidden layer feedforward neural network (SLFN). The new algorithm randomly chooses the input weights and the thresholds without adjustment during the training process and tends to provide faster learning speed and better generalization performance than traditional training methods. In this study, we extract the feature vectors of rotating machinery faults by wavelet packet analysis and diagnose the faults with extreme learning machine, obtaining satisfactory diagnostic results.

Extreme learning machine

For N arbitrary distinct samples $(\boldsymbol{x}_i, \boldsymbol{t}_i)$, where $\boldsymbol{x}_i=[x_{i1}, x_{i2}, ..., x_{in}]^T \in \mathbf{R}^n$, $\boldsymbol{t}_i=[t_{i1}, t_{i2}, ..., t_{in}]^T \in \mathbf{R}^m$; standard SLFNs with L hidden neurons and activation function $g(x)$ are mathematically modeled as

$$\boldsymbol{o}_j = \sum_{i=1}^{L} \beta_i g_i(\boldsymbol{x}_j) = \sum_{i=1}^{L} \beta_i g(\boldsymbol{w}_i \cdot \boldsymbol{x}_j + b_i), \quad j=1, 2, ..., N. \tag{1}$$

where $\boldsymbol{w}_i=[w_{i1}, w_{i2}, ..., w_{in}]^T$ is the weight vector connecting the ith hidden neuron and the input neurons; $\beta_i=[\beta_{i1}, \beta_{i2}, ..., \beta_{in}]^T$ is the weight vector connecting the ith hidden neuron and the output neurons; b_i is the threshold of the ith hidden neuron; $\boldsymbol{w}_i \cdot \boldsymbol{x}_j$ denotes the inner product of $\boldsymbol{w}_i$ and $\boldsymbol{x}_j$.

That standard SLFNs with L hidden neurons and activation function $g(x)$ can approximate these N samples with zero error means, i.e., there exist β_i, $\boldsymbol{w}_i$ and b_i such that

$$\sum_{i=1}^{L} \beta_i g(\boldsymbol{w}_i \cdot \boldsymbol{x}_j + b_i) = \boldsymbol{t}_j, \quad j=1, 2, ..., N. \tag{2}$$

The above N equations can be written compactly as:

$$\boldsymbol{H}\beta = \boldsymbol{T}. \tag{3}$$

where

$$\boldsymbol{H}(\boldsymbol{w}_1,\cdots,\boldsymbol{w}_L,b_1,\cdots,b_L,\boldsymbol{x}_1,\cdots,\boldsymbol{x}_N)=\begin{bmatrix} g(\boldsymbol{w}_1\cdot\boldsymbol{x}_1+b_1) & \cdots & g(\boldsymbol{w}_L\cdot\boldsymbol{x}_1+b_L) \\ \vdots & \cdots & \vdots \\ g(\boldsymbol{w}_1\cdot\boldsymbol{x}_N+b_1) & \cdots & g(\boldsymbol{w}_L\cdot\boldsymbol{x}_N+b_L) \end{bmatrix}_{N\times L}. \tag{4}$$

$$\beta=\begin{bmatrix} \beta_1^T \\ \vdots \\ \beta_L^T \end{bmatrix}_{L\times m} \text{ and } \boldsymbol{T}=\begin{bmatrix} \boldsymbol{t}_1^T \\ \vdots \\ \boldsymbol{t}_N^T \end{bmatrix}_{N\times m}. \tag{5}$$

$\boldsymbol{H}$ is called the hidden layer output matrix of the SLFN; the ith column of $\boldsymbol{H}$ is the ith hidden neuron's output vector with respect to inputs $\boldsymbol{x}_1, \boldsymbol{x}_2, \ldots, \boldsymbol{x}_N$.

The gradient descent algorithms are generally used in traditional SLFNs to search the minimum of $\|\boldsymbol{H}\beta-\boldsymbol{T}\|$. However, it is clear that gradient descent based learning methods are generally very slow due to improper learning steps or may easily converge to local minimums [1]. To solve these problems, Huang et al. have proposed a simple learning algorithm for SLFNs called extreme learning machine (ELM) [2].

Unlike the traditional function approximation theories, which require to adjust input weights and hidden layer biases, the feedforward networks with arbitrarily assigned input weights and hidden layer biases and with almost all nonzero activation functions can universally approximate any continuous functions on any compact input sets. The input weights and the hidden layer biases of SLFNs need not be adjusted at all and can be arbitrarily given. For fixed input weights $\boldsymbol{w}_i$ and the hidden layer biases b_i, to train an SLFN is simply equivalent to finding a least-squares solution of the linear system $\boldsymbol{H}\beta=\boldsymbol{T}$:

$$\left\|\boldsymbol{H}(\boldsymbol{w}_1,\cdots,\boldsymbol{w}_L,b_1,\cdots,b_L)\hat{\beta}-\boldsymbol{T}\right\|=\min_{\beta}\left\|\boldsymbol{H}(\boldsymbol{w}_1,\cdots,\boldsymbol{w}_L,b_1,\cdots,b_L)\beta-\boldsymbol{T}\right\|. \tag{6}$$

The smallest norm least-squares solution of the above linear system is:

$$\hat{\beta}=\boldsymbol{H}^{\dagger}\boldsymbol{T}. \tag{7}$$

where $\boldsymbol{H}^{\dagger}$ is the *Moore–Penrose generalized inverse* of output matrix $\boldsymbol{H}$. This special solution have the properties of the minimum training error, smallest norm of weights and best generalization performance [3].

The learning speed of ELM can be thousands of times faster than traditional feedforward network learning algorithms like back-propagation algorithm while obtaining better generalization performance.

Extraction of Fault Features

The wavelet packet analysis, an improved method of wavelet transform, can decompose the signal into different frequency bands, belonging to band analysis techniques. As same as Fourier spectrum analysis, the theoretical basis of wavelet band analysis is Parseval energy integral equation. The energy of *f(x)* on the time domain is

$$\|f\|^2=\int_{-\infty}^{\infty}|f(x)|^2\,dx. \tag{8}$$

And the wavelet transform of *f(x)* is

$$C_{j,k} = W(2^j, 2^j k) = 2^{-\frac{j}{2}} \int_R \overline{\Psi}(2^{-j}x - k) f(x) dx \,. \tag{9}$$

According to Paseral identity,

$$\int_{-\infty}^{\infty} |f(x)|^2 \, dx = \sum_{k=1}^{n} |C_{j,k}|^2 \,. \tag{10}$$

From the above equation, the wavelet transform coefficients $C_{j,k}$ has the dimension of energy, and therefore can be used for energy analysis.

Current study on fault diagnosis of rotating machinery has been in-depth and comprehensive that the feature vectors of power spectrum from rotating machinery vibration signal can be easily and effectively extracted by multi-resolution analysis [4]. And the wavelet packet analysis is applied to the energy analysis on the common faults of rotating machinery.

The peak energy values of nine different frequency bands extracted from the vibration signals of rotating machinery are selected as the features [5]. We can obtain a variety of fault characteristics after a lot of experiments and establish the correspondence between the faults and features. The correspondence between the features and six common faults of rotating machinery, such as misalignment, is gathered as shown in Table 1.

Table 1 Fault feature table of rotating machinery

Fault Type	Vibration Frequency								
	0.01~ 0.39f	0.40~ 0.49f	0.50f	0.51~ 0.99f	1f	2f	3~5f	odd f	>5f
Imbalance	0	0	0	0	0.9	0.05	0.05	0	0
Rotor impact	0	0.3	0.1	0.6	0	0	0	0	0
Misalignment	0	0	0	0	0.4	0.50	0.10	0	0
Oil whirl	0.1	0.8	0	0.1	0	0	0	0	0
Radial rubbing	0.1	0.1	0.1	0.1	0.2	0.1	0.1	0.10	0.1
Pedestal looseness	0	0	0	0	0.2	0.15	0.4	0	0.25

Diagnostic results

To verify the diagnostic accuracy of ELM for common faults of rotating machinery, we adopt probabilistic neural networks (PNN) and ELM for training and judgment of fault features. First, the diagnostic models are trained with the fault feature samples. Then, we diagnose the faults by the trained models.

Let D_1 be the data matrix of fault samples before adding noise, and D_2 be the data matrix of fault samples after adding noise. The data matrix containing noise is obtained by the following formula

$$D_2(i, j) = D_1(i, j)\left(1 + \alpha \cdot \text{rand}(1)\right). \tag{11}$$

where α is the noise control coefficient; rands(1) is a function that generates a random number between -1 and 1. Five hundred groups of data samples are generated for each fault types by using the above formula such that we obtain a total of 3,000 groups of samples, including 1800 groups as the training set and 1200 groups as the test set.

The noise control coefficients are set in a range from 0 to 0.4 at intervals of 0.01. We train the ELM and PNN models with the training set at each α value, and then diagnose the test set by the trained models. The diagnostic results are shown in Fig. 1.

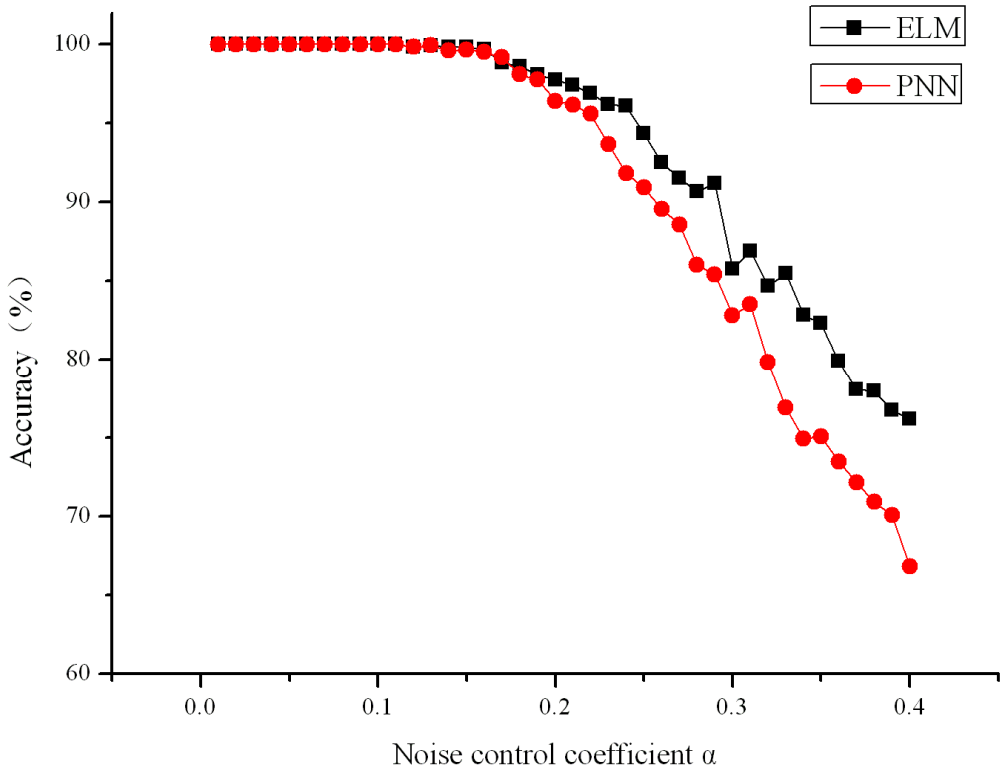

Fig. 1 Diagnostic accuracy of ELM and PNN

It can be seen from Fig. 1 that the diagnostic accuracy of both methods are affected by the noise control coefficient, and decrease with the increase of noise. The declining rate of accuracy in ELM model is significantly lower than PNN model. And the ELM model achieves a higher diagnostic accuracy under an identical noise sample and shows better generalization performance.

Conclusions

In this study, we propose a fault diagnosis method of rotating machinery by using wavelet packet analysis and extreme learning machine. We obtain the fault feature table from the wavelet packet decomposition of power spectrum in the vibration signals of rotating machinery. Then the fault feature table is noised to be the training and test samples. Diagnostic results show that the ELM method achieves higher diagnostic accuracy than the PNN method, exhibiting superior performance to effectively diagnose the faults of rotating machinery.

Keywords: intake temperature, combustion, pumping loss, emissions

Abstract . The optimum inlet temperature for different engine conditions was calculated based on the same knock probability with full load by CFD Fire software, and then the effects of inlet air heated on combustion，pumping loss and emissions of gasoline engine were also studied. The results showed that the highest intake temperature at intake pressure 50kPa operation can be 368K without knock, and that for 100kPa condition was 322K. Heating inlet air can enhance combustion, and the maximum combustion pressure was increased by 26.8% and IMEP by 4% at the case of 368K/50kPa condition compared with inlet pressure of 40.5kPa and temperature of 298K condition consuming same fuel. Pumping loss can also be reduced by increasing intake temperature. However, emissions of NO_X and CO were increased because of higher intake temperature.

Introduction

The most likely condition to exhibit knock for gasoline engine was heavy load. While, it was impossible for light load trapping less air flow to be auto-ignited, and the pressure wave produced after ignition was also not so strong to compress ignition the end un-burn mixture. Although knock can break the stability of engine operation and cause degradation of engine, some studies showed that critical knock condition can improve the power and economy performance of engine without damage[1]. So it is possible for the gasoline engine to get better fuel economy with all engine operation conditions approaching critical knock.

Knock tendency can be enhanced by heating intake in simple but effective ways. It can increase the temperature of mixture in combustion chamber and knock index during later compression stroke and improve combustion and thermal efficiency of engine. At the same time, heating inlet air can cause some abnormal combustion phenomena, such as knock or heavy knock and even HCCI once the inlet air was overheated[2,3]. Therefore, the work in this paper mainly studied the optimum intake air temperature of different engine condition and the effect of intake air temperature on combustion and emission performance by CFD software AVL-FIRE.

Numerical modeling approach

In this paper, the study was based on a 1.8L turbocharged gasoline engine with following geometry and parameters as showed in Table 1. The 3D-model without intake port used to calculate was prepared by reverse engineering and was meshed from intake valves closed timing 230°CA to exhaust valves opened timing 516°CA by the FAME Engine Plus function of FIRE software, which marks top dead centre at exhaust stroke as 0°CA. Figure1 shows the 3D computational mesh of the engine chamber at TDC. The maximum size was 1mm and the minimum was 0.5mm.

Table 1 Engine specifications

Engine	L4,16-valves	Stroke [mm]	84.2
Displacement [Liter]	1.798	Bore [mm]	82.5
Connecting rod length [mm]	148	Compression ratio	9.6

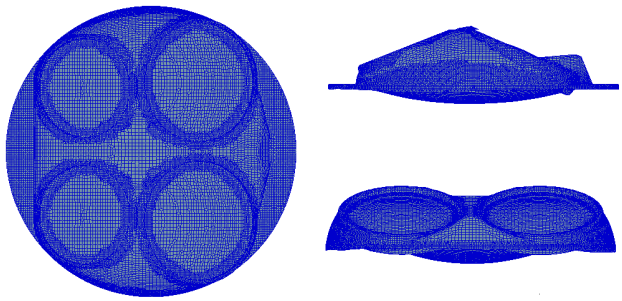

Figure1 Computational mesh for FIRE simulation

Usually, computational accuracy was significant affected by boundary conditions and initial conditions. The piston top was defined as moving wall, while other surfaces were defined as fixed wall. All the boundary valves and initial valves were showed in table 2 as follow.

Table 2 Boundary valves and initial valves

Intake valve temperature[K]	360	2000/4000rpm initial tumble ratio	0.7/0.85
Exhaust valve temperature[K]	580	2000/4000rpm initial TKE[m2/s2]	34/68
Chamber top temperature[K]	550	Equivalence ratio	1
Piston top temperature[K]	450	50/100kPa ignition angle[deg]	340/345
Liner temperature[K]	600	Fuel	Gasoline

In this modeling process, correlative flame model ECFM applied to homogeneous premixed combustion and Heywood original model used to calculate NO mass fraction were selected. Especially, knock model (shell model with temperature coupling) utilized to simulate auto-ignition. To explore the effect of intake temperature on different engine operating conditions such as speed at 2000rpm and 4000rpm and intake pressure of 50kPa and 100kPa, the optimum intake temperature of these conditions that exhibits the same knock probability with full-load at 2000rpm was computed at first. And then, the next work of this article mainly focused on the combustion and emission characteristics at 2000rpm with intake pressure of 50kPa and optimum intake temperature of 368K. Meanwhile, comparison with normal intake temperature condition but consuming the same air and fuel mass with the optimized condition was conducted to demonstrate the effect by means of heating intake air[4].

Computational results and analysis

Intake air temperature Optimization

Knock occurrence can not be calculated accurately by the present Fire software. Mean FQ reaction rate one of the intermediates in shell chain reaction or knock reaction rate were commonly used to evaluate knock probability. Due to slower flame-spreading speed and longer time for mixture heated in the edge of chamber, it was more easy to exhibit knock phenomenon at low speed and heavy load for gasoline engine[5,6]. The mean FQ reaction rate was calculated for 2000rpm and full load condition with intake temperature 306K and intake pressure 165kPa which did not appear knock phenomena according to experimental data. So the mean FQ reaction rate at 2000rpm and

full load was used as reference point. What was showed in figure 2(a) was the mean FQ reaction rate changing with crank angles at 2000rpm and full load, and the maximum was 1.33s^{-1} emerging at 403 CAD. Mean FQ reaction rate curves of 100kPa and 320K, 100kPa and 322K, 100kPa and 323K from 340 CAD to 440 CAD at 2000 rpm were showed respectively in figure (b) (c) (d). As you can see from figure 2(b), the mean FQ reaction rate was almost zero indicating knock happening unlikely. And the maximum mean FQ reaction rate showed in figure 2(c) was quite close to that of full load operation demonstrating the same knock probability with full load. While in figure 2(d), the maximum mean FQ reaction rate was 3.9s^{-1} that was almost triple the full load operation, so the knock probability was increased obviously. What were showed in figure 2 (e) (f) (g) were the mean FQ reaction rates for intake pressure of 50kPa with different intake temperature. The case with intake temperature of 368K whose mean FQ reaction rate was about equal with the full load operation was identified as the optimal temperature condition. Besides, mean FQ reaction rates equaling with full load operation of different cases at 4000rpm were illustrated in figure 2 (h) (i), and the optimizing temperatures were 374.5K and 413K for intake pressure of 100kPa and 50kPa respective.

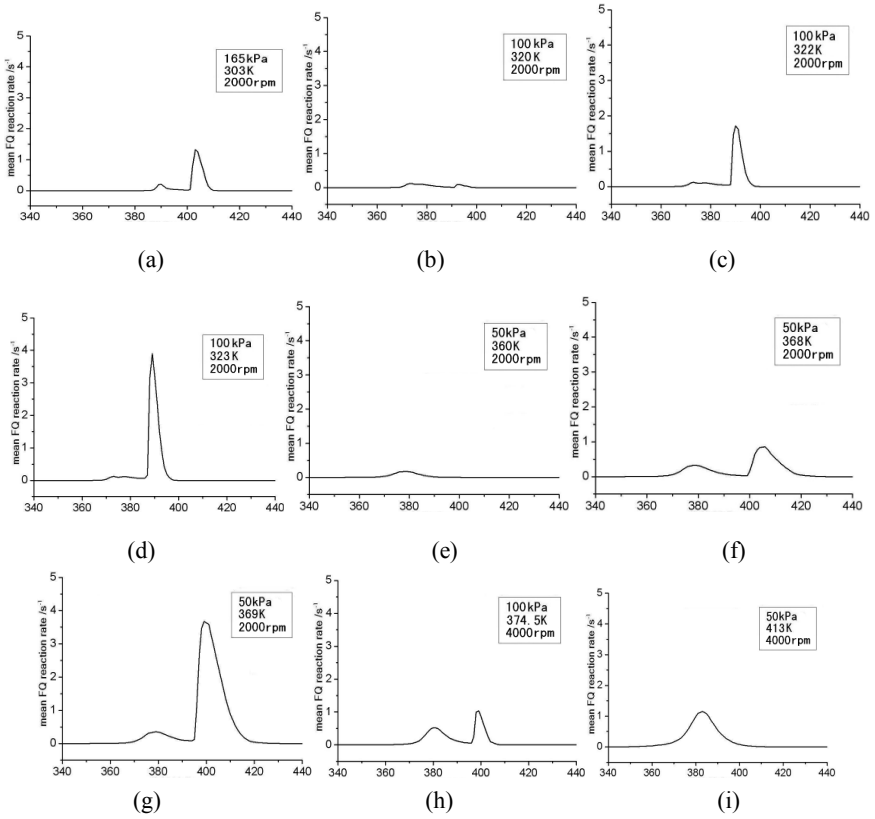

Figure 2. Curve of mean FQ reaction rate for different conditions

By contrasting figure 2 (b)(c)(d) and figure 2 (e)(f)(g), it can be come to the law that the higher intake temperature, the greater FQ reaction rate. In-cylinder temperature increased with intake temperature at the end of compression stroke, which was heated up to ignition points with high intake temperature. Combining stronger combustion pressure wave resulting from the enhancement of high intake temperature, the knock probability of end mixture was increased. Comparing figure 2(c) with figure 2(h) and figure 2(f) with figure 2(i), we concluded that the optimized temperature with higher speed could be increased, which also demonstrated low speed operations have much easier access to knock than high speed operations. So there is different optimized intake temperature for different engine conditions.

Combustion improvement

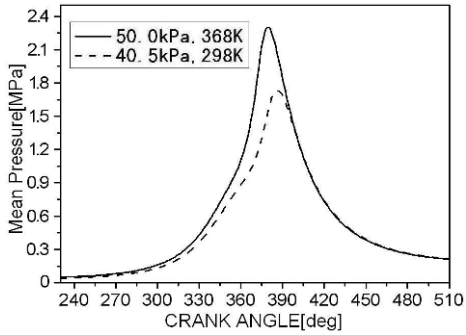

Figure 4. Mean cylinder pressure diagrams

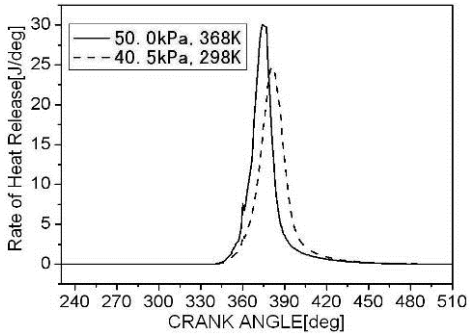

Figure 5. Heat release rate diagrams

In order to explain the effect of heating intake air on combustion process, cases at 2000rpm with intake temperature/pressure of 368K/50kPa and 298K/40.5kPa were calculated. Intake temperature 368K and pressure 50kPa was the case optimized in the upper portion of the paper and exhibiting same knock index with full load. Intake temperature 298K and pressure 40.5kPa was the case trapping air at room temperature and consuming same fuel mass with 368K/50kPa condition. Mean in-cylinder pressure curve and heat release rate curve of these two cases were showed in figure 4 and figure 5 respectively. For the case of 50kPa/368K, mean pressure rose more rapidly than that of 40.5kPa/298K condition, and the maximum pressure was 2.3MPa that was 32.9% higher. As shown in figure 5, the peak heat release rate of 368K/50kPa was 21.4% higher than 298K/40.5kPa operation, and the crank angle of peak heat release rate was also 7 deg earlier. Besides, the combustion duration was shortened by 12.6%. So it can be concluded that increasing the temperature of intake air helped to format flame kernel and develop initial flame stably so as to reinforce combustion and improve thermal efficiency. IMEP（indicated mean effective pressure）of 368K/50kPa and 298K/40.5kPa conditions can be known further by integrating cylinder pressure curve and then divided it by cylinder volume. The IMEP for 368K/50kPa condition was 0.514MPa and that of 298K/40.5kPa was 0.497MPa, which increased by 3.4%.

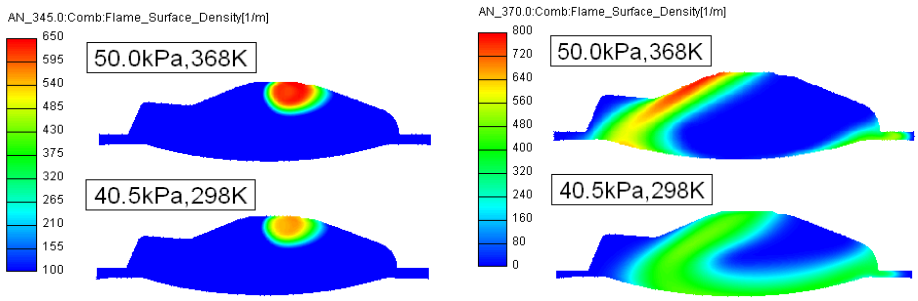

Figure 6. Slices of flame surface density at 345 CAD and 370 CAD

To further analyze the effect of increasing intake temperature on combustion at a micro level, the vertical slices of flame surface density for these two cases were showed in figure 6. It was obvious that the flame surface density around spark plug of 50kPa/368K was greater than 40.5kPa/298K at 345 CAD illustrating the improvement of flame formation and propagating. Furthermore, wider flame front was emerged for the case of 50kPa/368K at 370 CAD, which indicates faster flame-spreading speed with higher intake temperature too. Because temperature primarily affects molecule Brownian motion in combustion process, the higher temperature was, the more active molecule Brownian motion was. In a word, the mixing of burned fuel gas and un-burn fuel gas was enhanced.

The mean in-cylinder temperature of these two cases changed with crank angle was showed in figure 7. The mean in-cylinder temperature of 50.0kPa/368K was still higher than 40.5kPa/298K condition before 400 CAD. While, both of the mean in-cylinder temperature curves trended towards overlap after 400 CAD. Exhaust temperature was not increased though intake temperature was increased. That is because of shorter combustion during and faster heat release rate for intake heated condition. Instead, the case of 40.5kPa/298K had longer combustion during and longer heat release degrees. So the exhaust temperatures of these both were nearly equal at later stage.

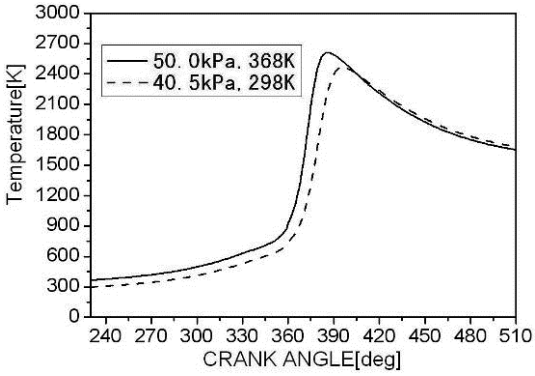

Figure 7. Mean in-cylinder temperature diagram

Pumping loss reduction

As we all know, gasoline engine load was regulated by throttle. Actually, it was volume flow adjusted by throttle instead of mass flow. Not only can heating intake air promote combustion, but also reduce air density to enlarge air volume under the same mass flow rate. Under the condition of stoichiometric burn, the higher the intake temperature was, the larger the intake air volume was needed with the same fuel consumption. As a result, pump loss could be reduced by wider throttle open resulting from intake air heated. Based on ideal gas state equation $PV=mRT$, intake temperature and intake pressure were proportional as engine displacement and air mass flow being constant. Intake pressure of 50kPa and intake temperature of 368K operation trapped the same air mass with 40.5kPa/298K condition. That is to say, the case heated to 368K at 50kPa achieves a 6 percent wider throttle open than 40.5kPa/298K operation in spite of consuming same fuel mass (setting intake pressure of 165kPa as WOT). As for the case of 100kPa/322K, the throttle was 4.5 percent wider than the case of 92.5kPa/298K.

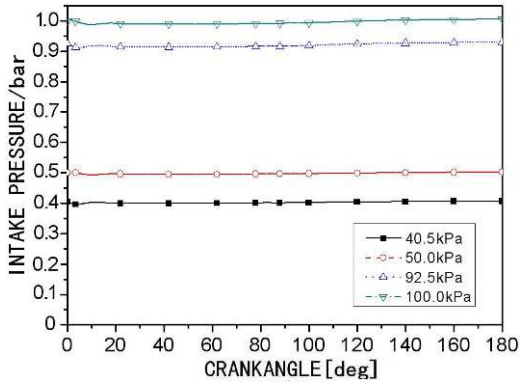

Figure 8. Intake pressure as a function of crank angle

In order to qualitative analysis the effect of heating intake air on pump loss, four cases of inlet port pressure 100kPa, 92.5kPa, 50kPa, 40.5kPa whose pressure changing as a function of crank angle during intake stroke were calculated by the same 3D-model but with intake manifold showed in

figure 8. The inlet pressure of these four cases kept nearly constant from TDC to BDC. Negative work was done when intake pressure was lower than one bar, which was known as pump loss. Pump loss during intake stroke of these four cases can be known by integrating the pressure curves. And the pump losses were 0J, 3.4J, 22.3J, 26.6J corresponding to intake pressure of 100kPa, 92.5kPa, 50kPa, 40.5kPa respectively. So as long as the intake air at part load operation was heated to the temperature value exhibiting same knock tendency with full load, it seems that very obvious improvement was obtained in reducing pump loss. For example in figure 8, the case of 322K/100kPa(intake temperature and pressure) had hardly any pump loss compared with that of 298K/92.5kPa condition which consumes same fuel mass but does not apply heating intake air. And for 368K/40.5kPa condition with intake air heated, 16.2% pump loss was reduced.

Emissions

The factor of generating nitrogen oxide for combustion is high temperature and enough oxygen, so the reaction of oxygen and nitrogen was enhanced by heating inlet air. The comparison that NO mass fraction at 2000rpm 368K/50.0kPa condition with 298K/40.5kPa (consuming the same fuel and air mass) condition were showed in figure9. We can see that the NO mass fraction arose sharply at about 380 CAD and the maximum for 368K/50.0kPa was 1.275% that was more than twice compared to the case of 298K/40.5kPa. This figure also indicated that the main reaction field for NO production was in the range of 380-410 CAD, and it was difficult to be eliminated before exhaust valves were opened once the NO was produced. The slices of temperature field for these two cases were showed in figure 11. It was obvious that the case of 368K/50.0kPa was higher than 298K/40.5kPa condition and the high temperature zone was wider too. This would state higher and wider temperature zone resulting from heating intake air was the major factor in NO production.

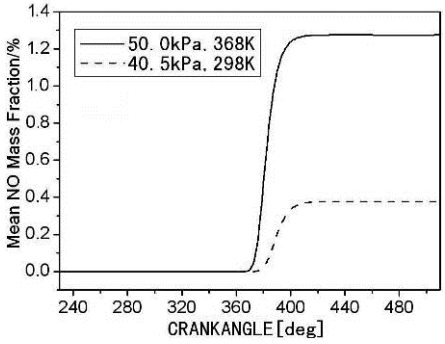

Figure 9. Mean NO mass fraction diagram

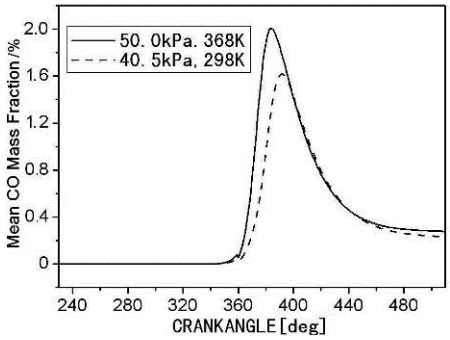

Figure 10. Mean CO mass fraction diagram

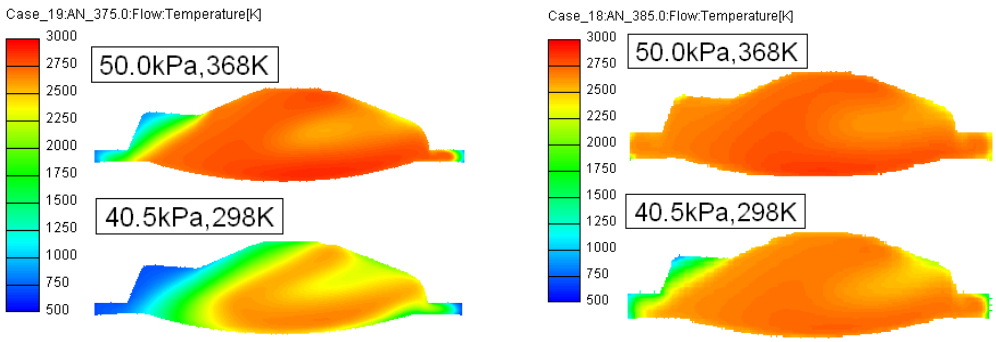

Figure 11. Slices of temperature field at 375 CAD and 385 CAD

When oxygen molecule is insufficient around carbon molecule in combustion process of fuel, the carbon molecule always reacts firstly to carbon monoxide and then the carbon monoxide reacts with excess oxygen brought by air motion in cylinder to carbon dioxide. And the carbon molecule can also react with carbon dioxide to carbon monoxide at high temperatures. So the trend of CO production with changing crank angle exhibited increasing first and then decreasing depicted in figure 10. At the later combustion process, high temperature became a more critical factor for carbon monoxide turned into carbon dioxide. The temperature in cylinder emerged a sharper fall for higher temperature condition due to faster combustion speed, so the production for NO was increased by heating intake air along with more NO production previous. As figure 10 showed, although these two cases consumed same fuel quality, there was a 19.5% increase in NO production for the case of 368K/50.0kPa than 298K/40.5kPa condition when exhaust valves were opened.

Conclusion

As changing of engine speed and load, the intake temperature should be adjusted for optimum engine performance. More specifically, higher intake temperature was applied for light load to promote combustion and reduce the pump loss, while lower intake temperature was kept for heavy load to increase airflow and reduce knock tendency.

a) Not only can heating intake air temperature improve combustion process, but also increase mean in-cylinder pressure and thermal efficiency, but also not increase exhaust temperature.
b) Increasing intake temperature can enlarge increase the air volume of a given mass flow rate, so the pump loss can be reduced resulting from the wider throttling.
c) Although it can increase mean in-cylinder temperature by higher intake temperature, it will bring the engine more production of CO and NO_X emissions.

Keywords: Variable valve timing, Miller cycle, Combustion characteristics, Emission characteristics

Abstract. On the basis of original engine, high compression ratio miller cycle can be realized, through perfecting the inlet cam profile, using higher geometry compression ratio, combining VVT control technology. The results indicate that the miller cycle achieved by VVT control technology can reduce pumping loss, and improve the effect utilization of energy. The combustion heat release rate is lower than the original engine, and combustion heat release are mainly concentrated on TDC later, lower the burning temperature. Compared with the original engine, NO_X emissions decrease significantly, but CO and HC emissions increase somewhat.

Introduction

Traditional otto cycle engine can't use the high compression ratio because of limitation of deflagration. Miller cycle can reduce the effective compression ratio by closing the inlet and exhaust valve behindhand, and improve thermal efficiency by high expansion ratios. Miller cycle engine can reduce pumping losses, fuel consumption rate and NO_X emissions [2-3]. Low effective compression ratio can prevent the deflagration and increase power, and also can reduce the institutions of engine and heat load, equivalent to improve the durability [3].

Through a comparative study of the otto cycle and miller cycle, it can be found that the purpose of low fuel consumption can be achieved by improving variable intake timing VVT and variable chamber volume [4-5]. The simple way of achieving miller cycle is to increase the compression ratio and inlet valve closed late [6]. This article realized miller cycle by controlling VVT on a motor gasoline engine, and also studied and analyzed the combustion and emission characteristics of engine.

Experimental facilities and research method

The experiment was conducted on a port fuel injection vehicle gasoline engine, with its compression ratio is 10.4. The specific parameters are shown in Table 1, and the bench experiment system is shown in Fig.1. The main equipments used in the experiment have YiKe hydraulic dynamometer, AVL7351CME type fuel consumption instrument, AVLZI31-Y5S type sensor, ETAS LA4 air-fuel ratio instrument. VVT is controlled by the Delphi MT22.1 open ECU, and emission characteristics is measured by HORIBA MEXA-7100DEGR type emission instrument.

On the basis of original engine, this paper makes the intake duration increase by replacing the inlet cam profile, increases geometry compression ratio by replacing piston, and achieves miller cycle of high compression ratio by combining with VVT control technology. Combined with the common working conditions of passenger vehicles, conduct a load characteristics experiment of 2000r/min on the original engine (otto cycle) and miller cycle. In the test, adjusting the inlet and exhaust VVT and ignition advance angle make specific fuel consumption and cycle fluctuation minimum, which keep excess air coefficient 1 and water temperature between 85oC to 90oC. In heavy load test, adjusting the air-fuel ratio makes the exhaust temperature below 850oC to protect

three-way catalytic converter and both fuel consumption. If there is deflagration, the ignition angle delay 1 to 2oCA. Because intake duration of miller cycle is longer than the original engine, inlet angle close later than the original engine, thus increase the throttle opening to maintain air input.

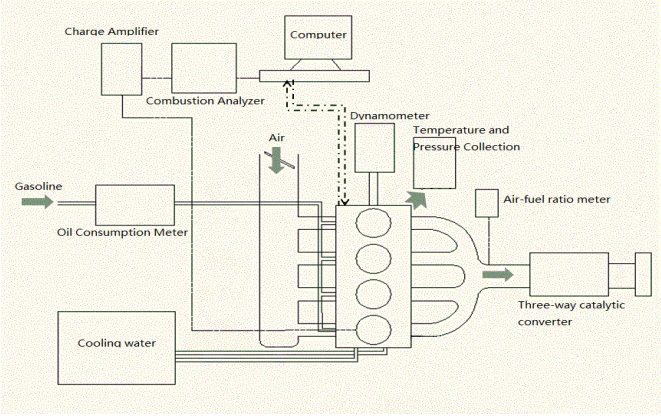

Fig.1. Schematic diagram of the test rig.

Table 1 Main technical parameters of gasoline engine

Model	Inline, DVVT
Bore / mm	78
Stroke / mm	83.6
Rod length / mm	134.7
Displacement / L	1.6
Compression ratio	10.4
Maximum torque / Nm	150
Power / kW	82/6000r/min

Experimental results and analysis

Variable valve timing (VVT). In the experiment, intake duration of the original engine (otto cycle engine) and the miller cycle engine are 265°CA and 285°CA, through the adoption of different inlet cam profile. The increase of intake duration of miller cycle is conductive to provide plenty of fresh impulse to cylinders, which can meet the needs of the combustion process in cylinder. At the same time, the original engine and miller cycle engine use different structure of pistons, and geometry compression ratio are 10.4 and 12.6. The adjusting of intake late closing angle and exhaust advance angle is combined with the variable timing VVT, the effective compression ratio and expansion ratio are shown in Table 2. Under the common effect of variable timing VVT and geometry compression ratio, the effective compression ratio of miller cycle reduce at low and middle loads, but the effective expansion ratio has an obvious increase in the entire loads. Effective compression ratio and effective expansion ratio will affect the cycle thermal efficiency and fuel economy collectively.

Table. 2 Comparison of effective compression ratio and effective expansion ratio

BMEP	Effective Compression Ratio		Effective Expansion Ratio	
/100kPa	Otto	Miller	Otto	Miller
2	5.95	5.52	8.77	11.37
4	6.45	5.05	9.45	11.4
6	7.24	6.05	9.45	11.4
8	8.14	8.61	8.6	9.75
9.5	8.95	9.52	8.35	9.33

Pumping loss is the main causes of poor fuel economy of otto cycle engine. In the experiment, in order to ensure adequate air inflow, according to different conditions to optimize the throttle opening. After optimization, the throttle opening of miller cycle is average 13.3% larger than that of original engine. The increase of throttle opening is helpful to decrease the throttling losses near throttle, and also can improve the intake pressure. Figure 2 shows that the intake pressure of miller cycle is about 12.7% larger than that of original engine. Under middle and low loads, the intake pressure increase quickly with the increase of loads. While in high loads, intake pressure increase gently. And the technology of late inlet valve close (LIVC) could part replace throttle to adjust the load. As shown in Figure 3, compared with the original engine, the pumping loss of miller cycle reduce obviously. Because the intake pressure increase, and the increase of expansion ratio also will lead to exhaust pressure reduce. Pumping loss of miller cycle engine is average 53.3% lower than that of original engine at 2000r/min.

Thus it can be seen that, miller cycle engine can reduce pumping loss significantly, improve the effective utilization of energy, and reduce the fuel consumption through using variable valve timing technology VVT.

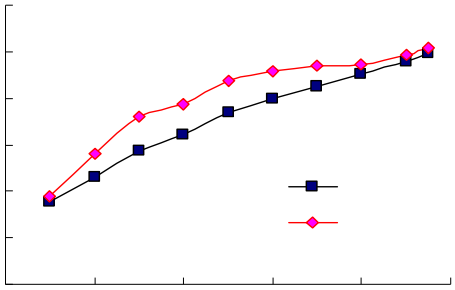

Fig. 2.Comparison of intake pressure

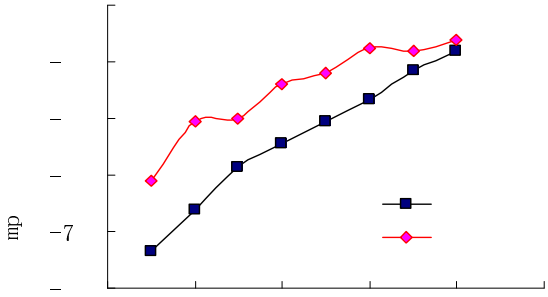

Fig. 3. Comparison of pumping loss

Combustion process analysis. Figure 4 shows that the combustion heat release rate changes with the crank angle under different loads of 2000r/min. Figure 5 shows the contrast of ignition advance angle under different loads of 2000r/min. As is shown in Figure 5, compared with original engine, the ignition advance angle reduce to avoid detonation combustion. And because the effective compression stroke of miller cycle is small, the air motion inside the cylinder is relatively weak, the burning speed slow, these lead to the combustion process of miller cycle focus after the top dead center.

As is shown in Figure 4, the heat release rate of miller cycle is slower under low loads. This is because that compared with the original engine, the effective compression ratio of miller cycle is low, and the throttle opening is bigger, thus the air motion inside the cylinder is relatively weak. These lead to that the burning speed slow and the peak heat release rate is lower. Under high loads, because of the increase in effective compression ratio, the air motion produced in compression process enhance, burning speed is accelerated, and the peak heat release rate increase.

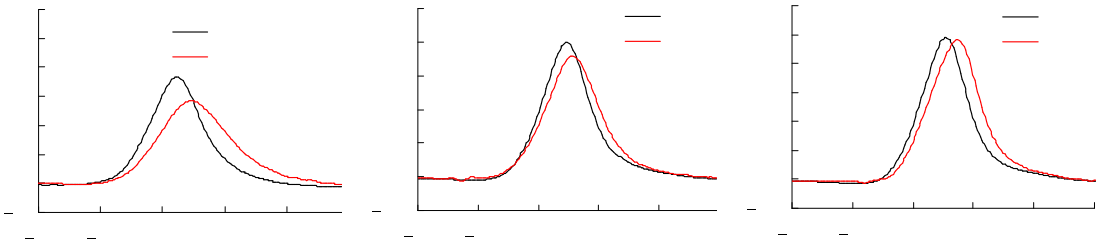

Fig. 4. Comparison of combustion heat release rate (dQ/dθ)

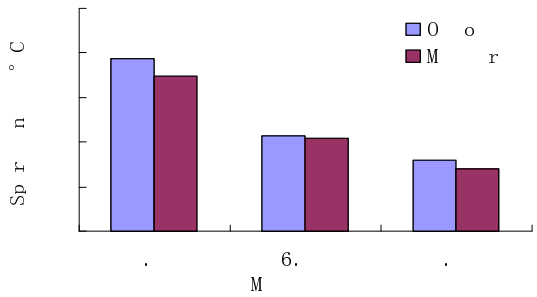

Fig. 5 Comparison of spark angle

Table. 3. Comparison of combustion temperature and exhaust temperature

BME P/kPa	combustion temperature/K		Exhaust temperature/K	
	Otto	Miller	Otto	Miller
200	2543	2398	699	666
600	2550	2418	735	719
800	2450	2380	759	732

Table 3 shows the contrast of maximum combustion temperature and exhaust temperature under different loads of 2000r/min. Because the combustion heat release rate of miller cycle is slower than original engine, and combustion focus on later top dead center, the combustion temperature

decrease somewhat. Because of the increase of expansion ratio, the exhaust temperature of miller cycle decrease somewhat, compared with original engine.

Emission analysis. The main source of NOx emissions is the nitrogen in the air which participated in combustion. The generation mechanism of NOx is Zeldvich mechanism[7]. NOx formation is mainly related to temperature and excess air coefficient. Excess air coefficient in this experiment keep 1, through regulating. So the combustion temperature has a great influence on NOx emissions. Figure 6 shows the contrast of NOx emissions. As is shown in the figure, compared with original engine, NOx emissions of miller cycle have obvious lower in the whole loads. NOx emissions of miller cycle reduce 50% at low load, and 30% in middle and high loads. This is because combustion temperature in cylinder of miller cycle reduce.

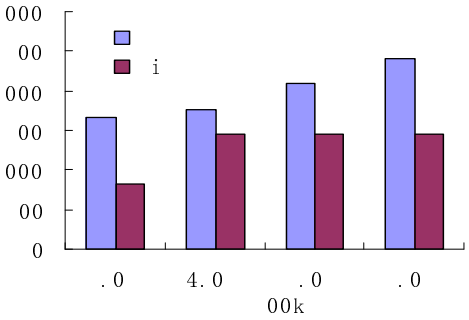

Fig. 6. Comparison of NOx emissions

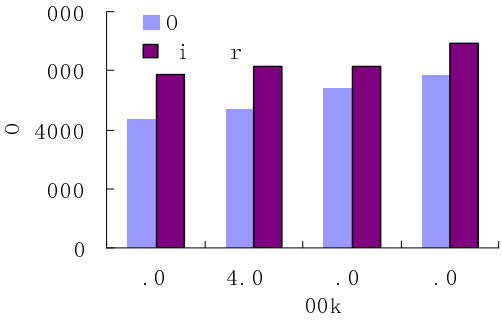

Fig. 7. Comparison of CO emissions

CO emissions is a result of incomplete combustion of fuel in cylinders, which is intermediate products caused by the lack of oxygen[8]. Figure 7 shows the contrast of CO emissions. As is shown in the figure, compared with original engine (otto cycle), CO emissions of miller cycle increase somewhat, especially in middle and low loads. Although the excess air coefficient is kept 1, there will be the phenomena of part hypoxia influenced by burned gases. And the combustion process of miller cycle mainly focus on the top dead center later, the combustion temperature is reduced, then the incomplete combustion increases, this lead to CO emissions increase.

HC emissions of gasoline engine is mainly the product of incomplete combustion, and the quality of mixed gas is one of the important factors that affect the combustion. Figure 8 shows the contrast of HC emissions. As is shown in the figure, compared with original engine (otto cycle), HC emissions of miller cycle increase somewhat in the whole loads. This is mainly caused by residual gas in the cylinder. The inlet and exhaust overlap angle of miller cycle engine is increased (Figure 9), through the regulation of variable timing VVT. This lead to residual gas in the cylinder increase, which would hinder the formation of flame center and flame spread, even interrupt the flame spread. This lead to the increase of HC emissions because of incomplete combustion.

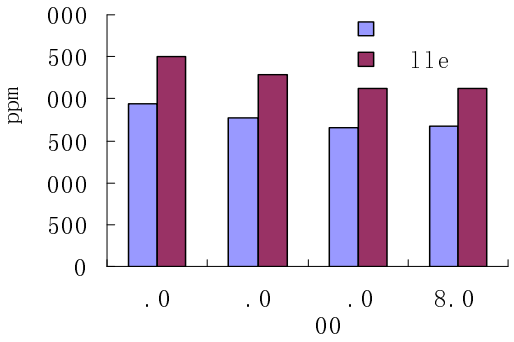

Fig. 8. Comparison of HC emissions

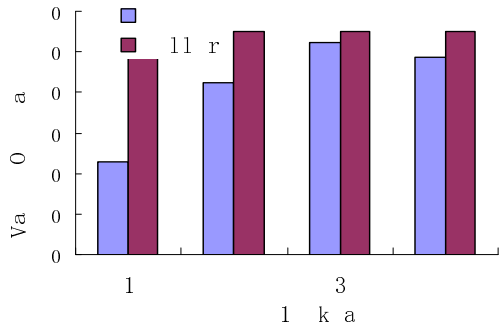

Fig. 9. Comparison of valve overlap

Conclusions

(a) By perfecting the inlet cam profile, using higher geometry compression ratio, and combining VVT control technology, the engine can achieves miller cycle of high compression ratio. The pumping loss can be reduced and the effective utilization of energy can be improved.

(b) The combustion heat release rate of miller cycle achieved by VVT control technology is slower than that of the original engine, and combustion heat release are mainly concentrated on TDC later. The combustion process can be improved through inlet pressurization and combustion system optimization.

(c) The miller cycle achieved by VVT control technology can reduces the combustion temperature, which can reduce NOX emissions effectively, but CO and HC emissions increase somewhat.

Keywords: Auto-ignition Quality; Particle Size Distribution; Morphology.

Abstract. The effect of fuel auto-ignition quality on particle size distribution and particulates morphology were investigated for the purpose of revealing the relationship between cetane number and particles emission. Experiments were conducted on common-rail direct injection engine under steady-state operating condition. Two basic diesel-like fuels were used in this study, hydrogenation diesel and straight-run diesel. The test fuels which have various cetane number were made up of these two basic ones. The results indicate that with increasing the fuel cetane number, a significant decrease of nucleation mode particles is found. For particle number size classification, the percentage of SOF has the same trend as the number of nucleation mode particles which size below 22nm and similar result is found between the percentage of dry soot and particles above 50nm.

Introduction

The diesel engine has a considerable advantage in regards to power output, durability and fuel economy when compared with other types of internal combustion engines. However, it is necessary to reduce exhaust emissions, especially NOx and PM. The use of Exhaust Gas Recirculation (EGR) offers areas of low combustion temperature inside the cylinder. Therefore NOx emissions decrease by reduction of production of thermal-NO. But particle emissions increase with the lack of oxygen. The emissions of exhaust diesel particles in the atmosphere are well known as hazardous substance for the human health. Therefore, more and more new technologies were applied on diesel engines, such as increasing fuel injection pressures, variable geometry turbochargers (VGT) and diesel particulate filters (DPF), particulate mass emission decreased with the increasing of particle number consequently [1]. Many toxicological and epidemiological studies established adverse health effects by PM, especially the ultra-fine particles with diameters below 100 nm [2].

Particles in diluted diesel exhaust are classified into three size modes, the nucleation mode (< 50 nm), the accumulation mode (50～1000nm) and the coarse mode (>1000 μ m) [3]. Many researchers have found that ultra-fine particles were sensitive to combustion parameters, such as fuel properties, injection strategies and EGR [4]. As is known to all, fuel auto-ignition quality is an important factor on combustion and emission, most of the studies were conducted with model fuel, such as n-paraffin, i-paraffin hydrocarbons and aromatic hydrocarbons. However, commercial diesel which actually used is consisted of hundreds of hydrocarbon components, studies based on model fuels cannot explain the authentic cause on combustion and emission [5,6]. Therefore, the aim of this work is to perform a comparative study on fuel auto-ignition quality in terms of particle emission and experimentally addresses the effect on particulates morphology. The diesel engine used in this study was equipped with a common-rail fuel injection system and without after-treatment devices.

Experimental Set-up

A four-cylinder four-stroke light-duty, intercooled diesel engine is chosen for the experiments. The engine is equipped with a Bosch high-pressure common-rail fuel system. Main parameters of the engine are listed in Table 1.

Table 1: Engine Specification

CATEGORY	PROPERTIES
Engine Type	Common Rail Turbo Charged with Intercooler
Bore	93 mm
Stroke	102 mm
Displacement	2.771L
Compression Ratio	17.2:1
Max Torque	260 N • m / 2000 rpm
EGR system	Disconnected

Table 2 shows a summary of the main properties. The hydrogenation diesel and straight-run diesel are main components in commercial diesel and have a distinct auto-ignition quality. Therefore, their blends, rather than model components (such as n-paraffin, i-paraffin hydrocarbons and aromatic hydrocarbons), could simulate the practical diesel properties well. CN44, CN55 and CN60, with different cetane number, are made by blending a hydrogenation diesel component and a straight-run diesel. In order to avoid the effect from the fuel used in previous tests, the engine was run at high load for half an hour before any new measurements were taken.

Table 2. Main Properties of Fuel

		Hydrogenation diesel	Straight-run diesel	CN44	CN55	CN60
Hydrogenation diesel		100%	--	100%	46%	25%
Straight-run diesel		--	100%	0%	54%	75%
Cetane number		44	66	44	55	60

The dilution system consisted of a partial-flow two-stage dilution system and particle filter sampling equipment. However, unlike Particle Measurement Program, the dilution system used in experiment did not have the CVS and heated evaporation tube. Instead, a cold partial-flow two-stage dilution system was used to dilute the raw exhaust gas. In order to avoid the raw exhaust components adsorbing unburned hydrocarbon and accumulating into particle groups, the dilution process should be rapidly. This also could prevent larger particles from diminishing during heated evaporation. By this way, the results will be close to actual environment. In our present work, the effect of dilution ratio (DR) on PSD had been discussed and a modest DR (about 200) might be benefit to rapid freezing which could terminate the particles' condensation. In this paper, the DR was kept constant at 200 by controlling the quantity of dilution air.

Test Conditions

In order to obtain a more repeatable result, the engine mode was selected at equivalence ratio=0.6 of the max torque speed, 1800r/min. The mode represents 75% of the max torque. The cooling water temperature and oil temperature were maintained at a constant range during the experiments. After fuel changing, residual fuels in the fuel supply line and fuel flow meter were completely drained by operating under heavy load for 30 minutes in order to prevent mixing of fuels. At the same time, residual volatile substance on inner wall of exhaust pipe will be removed because of the high temperature.

Results and Discussion

The influence of fuel auto-ignition quality on the exhaust particle size is shown in Figure 1(a). The majority of the particles with these three fuels are located in the diameter region of 5–300 nm and the peak value of nucleation mode is located between 10nm and 25nm. With increasing the fuel cetane number, a significant decrease of nucleation mode particles is found. This may be due to the short ignition delay which reduces the premixed burning portion and increases the diffuse portion. This will be benefit for producing more carbonaceous particles, these particles largen by accumulating and then carbonaceous agglomerates are formed. Due to large specific surface area of carbonaceous agglomerates, it is an excellent carrier for unburned hydrocarbon substance and hence the nucleation mode particle number is limited. Figure 1(b) and Figure 1(c) are volumetric distribution and superficial distribution. These two figures indicate that accumulation mode particles which take up more volume and superficial area would be more contributive to the adsorption of unburned substance.

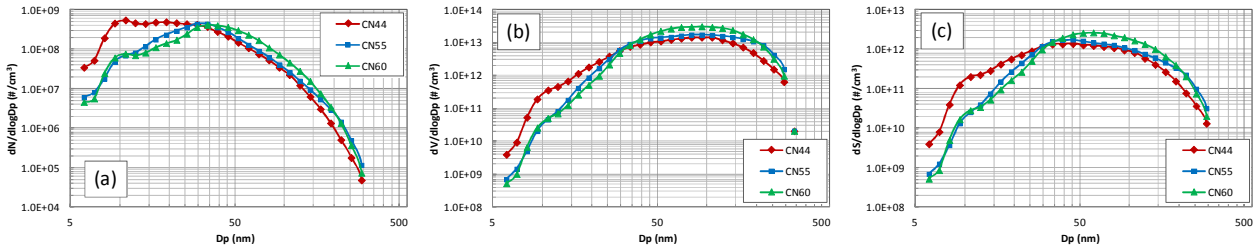

Fig.1: (a) Particle number distribution (b) Particle volumetric distribution(c) Particle superficial distribution

Figure 2(a) shows the influence of auto-ignition quality on particle sizes at the same operating condition. Just as mentioned above, high cetane number fuel tends to produce more accumulation mode particles with reducing the nucleation mode particles emission. Consequently, the percentage of nucleation mode particles decreases obviously with the cetane number becomes higher. The percentage of ultrafine particles, include nucleation mode particles and part of accumulation mode particles, is relatively stabilized. To study the effect of the auto-ignition quality on the PSD a bit further, the influence of cetane number on the particle size classification is shown in Figure2(b). The particle number of all the size classes below 22 nm is decreased with the cetane number increased. On the contrary, the number of particles above 22nm increase and the number of the particles located in the range of 15nm-22nm changes slightly. Figure2(c) indicates that the percentage of SOF has the same trend as the number of nucleation mode particles which size below 22nm. Meanwhile, similar result between the percentage of dry soot (DS) and particles above 50nm.

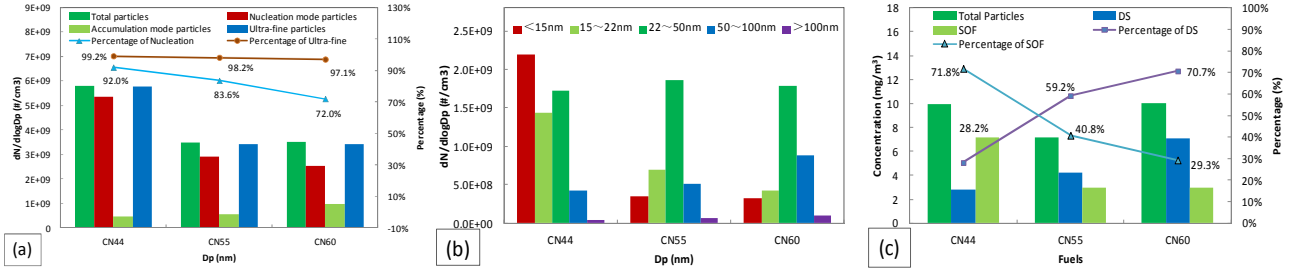

Fig.2: (a) Number of particles in different mode(b) Particle number size classification(c) DS and SOF mass concentration

Scanning electron microscope (SEM) images (Figure 3) were taken for the samples collected on the filter paper from the partial-flow dilution tunnel for different fuels. These samples were magnified by 8000 times. It can be seen from the images that most of the particles are nano-particles. Meanwhile, the agglomeratic particles number with CN60 is larger than that with CN44 and CN55. These results fall in line with the particle size distribution findings.

Fig.3. Characteristic of particulates morphology

Conclusion

Present study explores the the effect of fuel auto-ignition quality on particle size distribution and particulates morphology in a common-rail direct injection engine under steady-state operating condition. On the basis of the results of present experiments, the conclusions were summarized as followed:

(1) With increasing the fuel cetane number, a significant decrease of nucleation mode particles is found. The results of volumetric distribution and superficial distribution indicate that accumulation mode particles which take up more volume and superficial area would be more contributive to the adsorption of unburned substance.

(2) High cetane number fuel tends to produce more accumulation mode particles with reducing the nucleation mode particles emission and the percentage of nucleation mode particles decreases obviously with the cetane number becomes higher. The percentage of ultrafine particles is relatively stabilized.

(3) The particle number of all the size classes below 22 nm is decreased with the cetane number increased. Besides, the number of particles above 22nm increase and the number of the particles located in the range of 15nm-22nm changes slightly. The percentage of SOF has the same trend as the number of nucleation mode particles which size below 22nm. Meanwhile, similar result between the percentage of dry soot(DS) and particles above 50nm.

(4) For particulates morphology, the results indicated that the agglomeratic particles number with CN60 is larger than that with CN44 and CN55 which fall in line with the particle size distribution findings.

Keywords: scooter, modal analysis, finite element method, natural frequency

Abstract. Based on Solidworks software, the three-dimensional model of two wheels scooter is set up. The finite element model of two wheels scooter is generated. Modal analysis of driving system and telescopic mechanism of bar on two wheels scooter is investigated. The first five orders natural frequency and major modes of driving system and telescopic mechanism of bar are clarified. The method and the result can be used as a reference of dynamic design and lay foundation for calculation and analysis of dynamic response for the two wheels scooter.

Introduction

Nowadays, the scooters are rich in species numbers on the market such as two wheels scooter, three wheels scooter and four wheels scooter. Some scholars have devoted themselves to the research on scooter. Introducing scooter into floor cleaning is presented by Ref [1] and it can significantly shorten the housework time and reduce the work pressure. Adopting Fatigue/ANSYS, a software module is developed by Ref [2]. On the platform, visual analysis of fatigue life and design optimization can be carried out for the scooter. The 3D solid model and assembly of the scooter stepping on both feet is obtained with Pro/E software by Ref [3]. The simulation analysis on motion machanism of scooter is investigated and the displacement variation curve of scooter is given out. In a word, the two wheels scooter is the foundation of scooter. Therefore, this paper intends to set up the three-dimensional model of two wheels scooter. Modal analysis of driving system and telescopic mechanism of bar on two wheels scooter is obtained by Solidwoks software, which is significant for the dynamic design and dynamic response analysis of two wheels scooter.

Basic Theory of Modal Analysis

Based on the finite element theory of elasticity[4], the motion differential equations of system can be expressed as:

$$[\mathrm{M}]\{\ddot{q}\}+[C]\{\dot{q}\}+[K]\{q\}=\{Q(t)\} \tag{1}$$

Here [*M*] is mass matrix, [*C*] is damping matrix and [*K*] is stiffness matrix. $\{\ddot{q}\}$, $\{\dot{q}\}$ and $\{q\}$ are vectors of acceleration, velocity and displacement respectively. $\{q\}=\{q_1,q_2,\cdots,q_n\}^T$. $\{F(t)\}$ is the exciting force vector of system and $\{F(t)\}=\{f_1,f_2,\cdots,f_n\}^T$.

For undamped free vibration, Eq.(1) can be expressed as:

$$[M]\{\ddot{q}\}+[K]\{q\}=0 \tag{2}$$

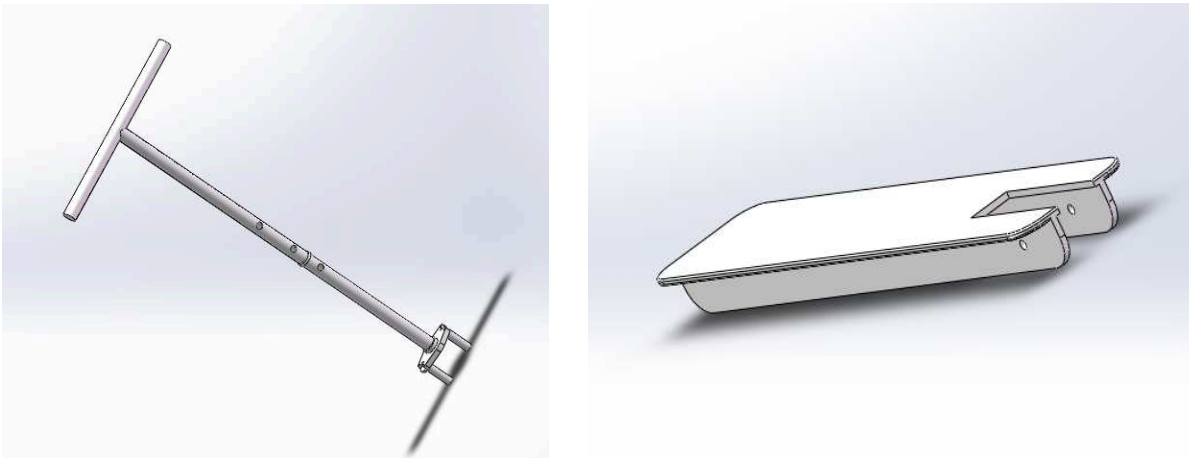
The corresponding eigenvalue equation can be obtained:

$$([K]-\omega_i^2[M])\{q\}=0 \tag{3}$$

Here ω_i is the i order natural frequency, and i=1,2，…，n.

Three-Dimensional Model of Two Wheels Scooter

Based on the configuration of certain scooter, the three-dimensional model of the scooter is set up. The key components are shown in Fig.1 and the structure of two wheels scooter is shown in Fig.2.



(a) Telescopic mechanism of bar. (b) Driving system.

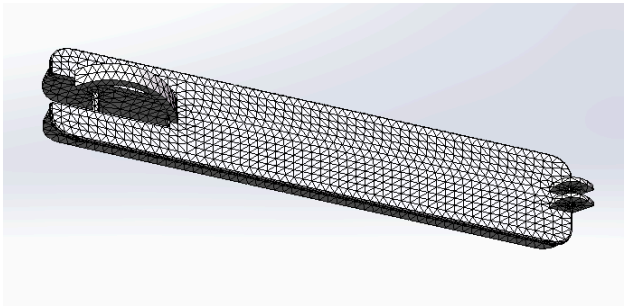
Fig.1 The key components of two wheels scooter.

Fig.2 The structure of two wheels scooter.

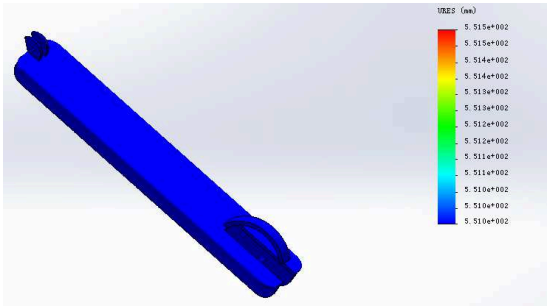
Modal Analysis of Two Wheels Scooter

Based on the three-dimensional model of two wheels scooter, the finite element model of two wheels scooter is generated. And modal analysis of driving system and telescopic mechanism of bar on two wheels scooter is investigated.

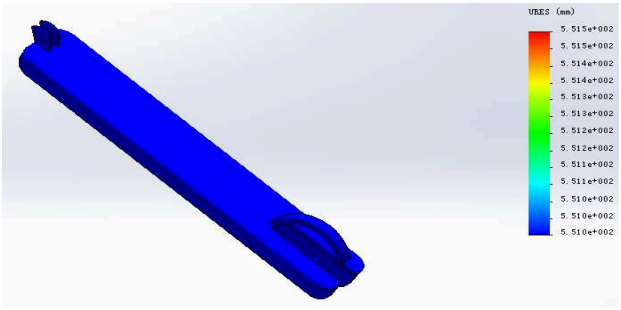
Modal Analysis of Driving System. The mesh generation diagram of driving system and the first five orders major modes of driving system are shown in Fig.3.



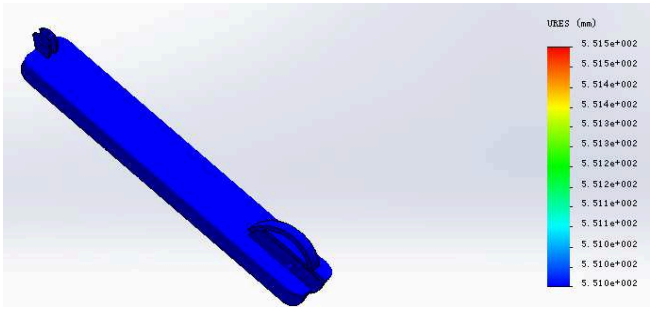
(a) The mesh generation diagram.



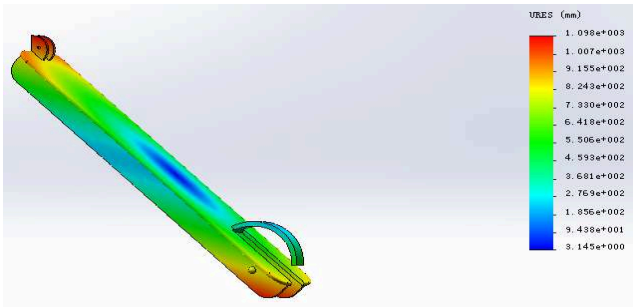
(b) one order mode.



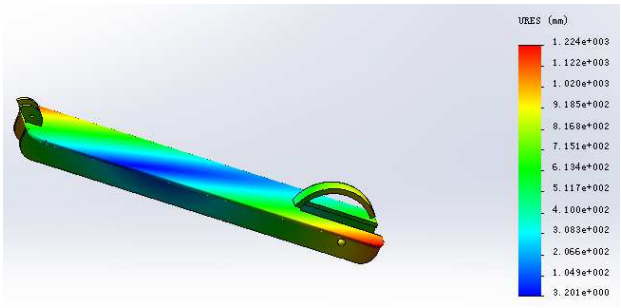
(c) two order mode.



(d) three order mode.



(e) four order mode.

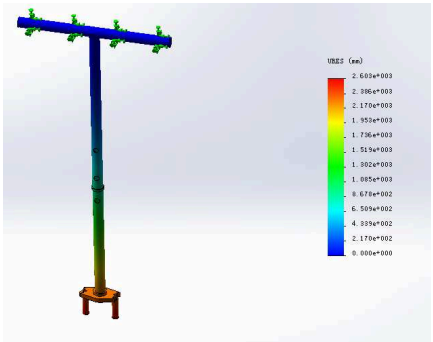


(f) five order mode.

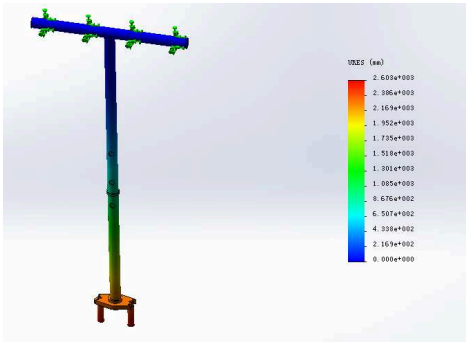
Fig.3 The major modes of the first six orders for driving system.

Modal Analysis of Telescopic Mechanism of Bar. The mesh generation diagram of telescopic mechanism of bar and the first five orders major modes of telescopic mechanism of bar are shown in Fig.4.

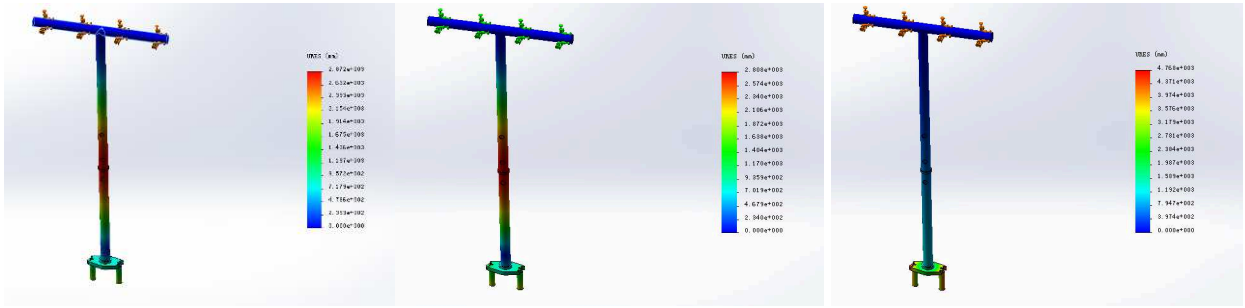
(a) The mesh generation diagram.



(b) one order mode.



(c) two order mode.



(d) three order mode. (e) four order mode. (f) five order mode.

Fig.3 The major modes of the first six orders for telescopic mechanism of bar.

Result of Modal Analysis. Analysis type is set to modal analysis and the order is set to 5. The natural frequency of the first five orders is listed in Table.1.

It is concluded in Table.1, Fig.3 and Fig.4 that for avoiding the resonance phenomenon in two wheels scooter, the response frequency of external-excitation should evade the natural frequency of driving system and telescopic mechanism of bar.

Table 1 The natural frequency of the first five orders.

Order	1	2	3	4	5
Driving System(Hz)	28.7	53.762	97.424	255.47	405.9
Telescopic Mechanism of Bar(Hz)	28.302	28.955	221.25	227.86	410.34

Conclusions

This paper focuses on three-dimensional model of two wheels scooter. Modal analysis of driving system and telescopic mechanism of bar on two wheels scooter is investigated by Solidwoks software. The natural frequency and major modes of the first five orders for driving system and telescopic mechanism of bar on two wheels scooter are clarified. The method and the result facilitate the dynamic design and dynamic response analysis of two wheels scooter.

Keywords: Turbine model, Model modify, BPA, Real data revise

Abstract. In the present power system stability analysis, BPA model for turbine and governor is commonly used. It simplifies the actual turbine system to a large extent, therefore the model simulation results may deviate from the actual conditions. In order to improve the actual data simulation accuracy, this paper compared the real and simulation data of power, high pressure cylinder (HPC) exhaust pressure and reheat pressure. Then calibrated and optimized the established model using the data of field operation. Meanwhile, the model modified method using actual data is given and guidance of parameters tests is offered.

Introduction

At present, the power system stability analysis often uses the model provided by "PSD-BPA Transient Stability Program User Manual" (referred to as: BPA model) as the turbine and governor model. It actually made a lot of simplifications on real turbine system and considered high, medium and low volume module, and the heat volume module etc. The natural power overshooting factor is also taken into consideration for enthalpy drop. However, the simulation results may deviate from the actual situation. To improve the accuracy of the simulation model, it needs to be verified and optimized with the actual operation data.

Min Luo et al.[1] proposed a practical load model well-integrated with the BPA, using the approach to load dynamic modeling during asymmetric disturbance to optimize the identification. And verified it with a simulation example. Peng Wei et al.[2] used the no—load test and other field measurements to get the model characteristics and dynamics characteristics of the excitation system therefore studied the stability of the generator in the BPA. Yunfeng Tian et al.[3] analyzed the thermodynamic process within reheating turbine and combined with the on-site test results, improved traditional steam turbine model for power grid stability calculation.

In this paper, the model modified method using actual data is given and guidance of parameters tests is offered.

Introduction of BPA model

According to the model provided by "PSD-BPA transient stability User's Manual (Version 4.15)" (hereinafter referred to as BPA), the turbine system model structure includes high, medium and low-pressure cylinder modules and reheater module etc., as shown in Fig.1. The parameters are shown in Table 1.

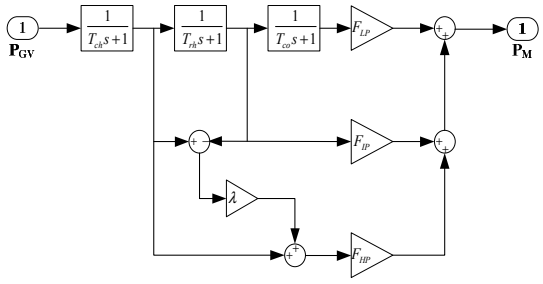

Fig. 1 Turbine model structure in BPA

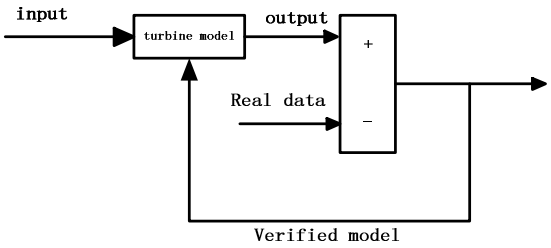

Fig. 2 Diagram of model validation method

Table 1 Parameters of turbine model

T_{CH}	Steam volume time constant[s]
F_{HP}	Ratio of power of high pressure cylinder(HPC)
T_{RH}	Time constant of reheater
F_{IP}	Ratio of power of intermediate pressure cylinder
T_{CO}	Time constant of cross-over steam line
F_{LP}	Ratio of power of low pressure cylinder
λ	Natural power overshooting coefficient of high pressure cylinder

Typical data：

F_{HP} = 0.3, F_{IP} = 0.4, F_{LP} = 0.3, T_{CH} = 0.1~0.4s，T_{RH} = 4~11s，T_{CO} = 0.3~0.5s

Verified methods and description of real data

To verify the accuracy and precision of the model, the actual data is needed. Verified method is to input the actual data to the turbine model. Based on the deviation of the model output and the actual data, the model is revised until the model output and the actual output are the same, as shown in Fig 2. This paper compared the actual value with simulation about power, HPC exhaust pressure and reheat pressure. The test data is from a 660MW supercritical coal-fired air-cooled generator. Test data is shown in Figure 3.

Contrast of real power and model simulation power. Turbine model can only get mechanical power, while the actual one is electric power. Through the rotor and the network model, can mechanical power obtains the electric power. Rotor time constant can be got by calculation, thus the stand-alone infinite grid model is needed, as shown in Fig. 4. The regulating stage pressure is as input and electric power is as output. The actual measured electrical power and electrical power of model can basically be the same by adjusting the infinite grid model frequency and damping ratio, as shown in Fig. 5.

As can be seen from Fig. 6, there is a certain lag between the simulation and actual measured electric power. This is because the measurement of regulating stage pressure is to use a very long pipe to lead steam and measures it at the end of the pipe. Due to the volume effect of pipeline and sensors' inertia, the experimental data lag behind the real pressure. Therefore, an advance correction module is added to amend the regulating stage pressure, as shown in Fig. 7.

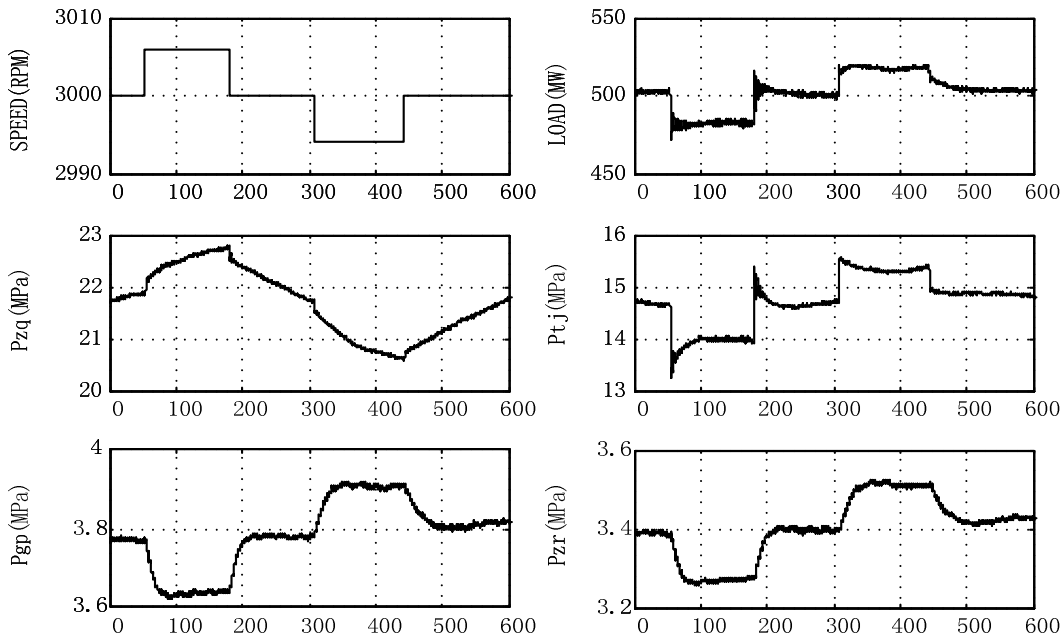

Fig. 3 Real testing data of parameters

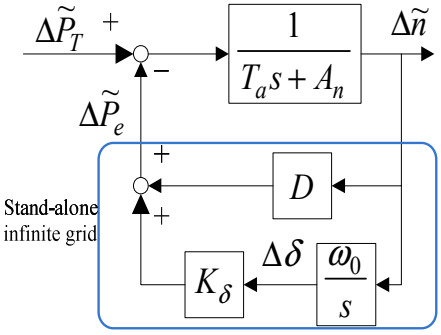

Fig. 4 Stand-alone infinite grid

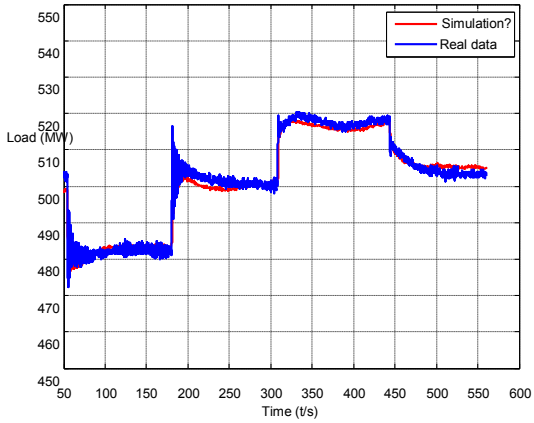

Fig. 5 Comparison of real and simulation power

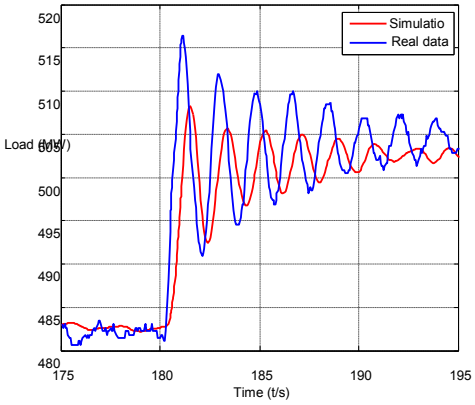

Fig. 6 Local map of the comparisons of real and simulation power

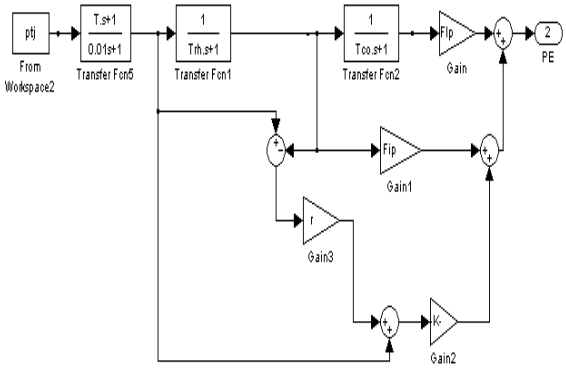

Fig. 7 Turbine modified model

Comparing the results obtained as a revised Fig. 8, Fig. 9, the frequency, amplitude and trend of electric power in the simulation results basically matches with the actual measured data.

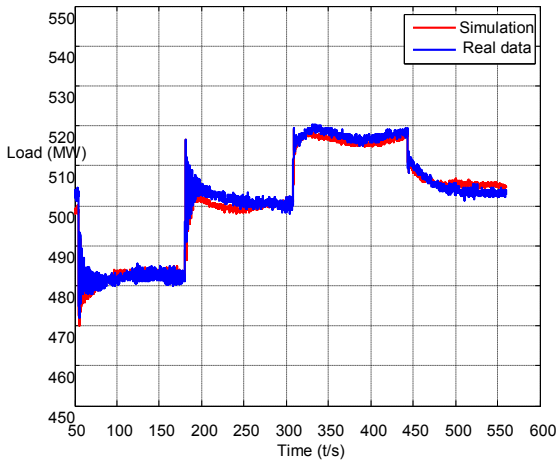

Fig. 8 Comparison of real and simulation power(modified)

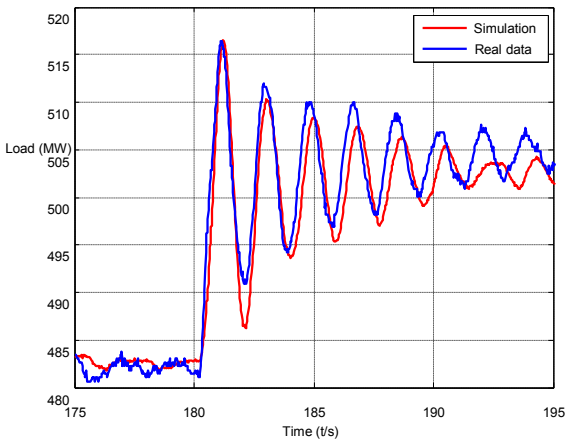

Fig. 9 Local map of Fig.8

Contract of real and simulation exhaust of HPC. The steam flow through flow path and enthalpy drop determines the turbine work jointly. But previous model does not consider the impact of enthalpy drop, so we introduced natural power overshooting factor[3].

From the perspective of turbine structure, from the high-pressure cylinder exports to the reheater outlet, pressure dynamic change has two main aspects. One is the volume effect, another is pressure loss. The volume effect can be described by reheat volume module, while the pure delay can show the pressure loss.

Therefore, in the actual HPC exhaust pressure simulation, a pure delay can be added before reheat volume to get the HPC exhaust pressure. From the actual data, the pure delay is 1.5s. Verification results is shown in Fig. 10 and local map is shown in Fig. 11.

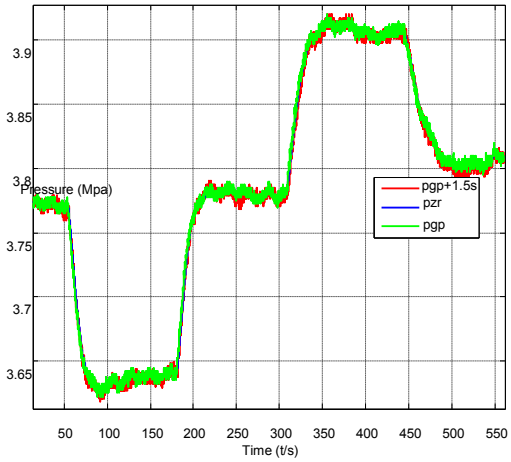

Fig. 10 Comparison of HPC exhaust pressure with reheat pressure before and after adjustment

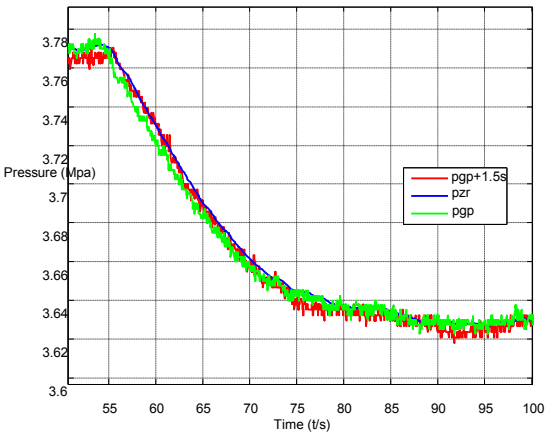

Fig. 11 Local map of Fig.10

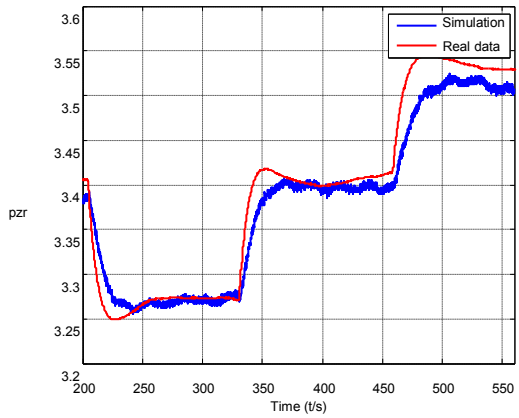

Fig. 12 Comparison of real and primary simulation reheat pressure

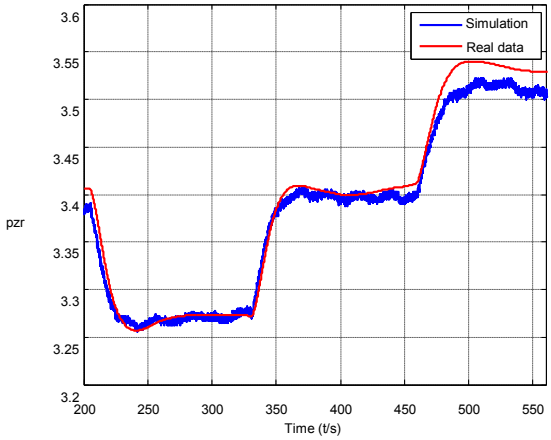

Fig. 13 Comparison of real and simulation with reheating system reheat pressure

Contrast of real and simulation reheat pressure. Using pressure from regulating stage as input and reheat pressure as output to verify the actual results with model simulation. There is a large variation between the original model simulation results and actual experimental data and real data responds more slowly, as shown in Fig. 12. This is because there is a big overshoot in input parameter simulation data. This is mainly because of the regenerator, a big inertia storage part, lies between the regulating stage and reheat pressure[4]. Therefore, the simulation result of reheat pressure for a model with regenerative system matches with the real data better, as shown in Fig. 13.

Conclusions

This paper compared the actual data of power, HPC exhaust pressure and reheat pressure with the BPA model simulation results and analyzed the causes of errors. Therefore calibrates and optimized the established turbine and governor. It proved the accuracy and advantages of the modified steam turbine and governor system mode and gave the correction model approach using actual data, thus provided guidance on the parameters for test trials.

For example, the lack of regenerative system is the cause for overshooting in reheat pressure calibration using conventional model. By comparing the real data and simulation model, it proves the importance of regenerative system in model.

When using the real data to validate the model, the phase problem needs to be considered and the problem is generally caused due to the sensor. So the data needs to be corrected according to the actual situation.

Key Words： Solidworks,Multifunctional Automatic Replacement Truck,Design.

Abstract. This article from the market background and market current situation analysis, on the current market of forklift insufficiency and flaw analysis, found a multi-purpose vehicle is very suitable for the market current situation, so the multifunctional automatic change of engineering vehicle design. Then the main function are introduced, design, calculation, through modeling, error analysis and Solidworks analysis, design a reasonable multi-functional automatic replacement vehicle structure. finally introduced multi-function automatic change the character of engineering vehicles, introduce market prospect

Designing backgrounds

Traditional engineering vehicles according to the structural type of the main points of excavator, crane, grab, jumbo, normally use to do only one thing , such as in the same construction sections for different types of construction, it will require a different type of truck to construction waste greatly, a relatively new type of multifunctional truck has been exist , But excavator, crane, grab, jumbo need artificial replacement, such as great potential safety hazard, multi-functional automatic replacement truck is a kind of multifunctional device can automatically change the previous construction engineering vehicles, reduce the labor, reduces the construction cost, automatic replacement, convenient and quick.

Physical design

The design of construction equipment is placed. Multifunctional automatic replacement truck's rotating arm is the main work device, at the front of the activities arm plate can be equipped with many construction equipment, such as digging shake, crane, grab a car, such as jumbo, the articulated device at the front of activity board can be convenient and quick to complete construction equipment replacement, According to the different bodily form feature behind the respectively, to design different fixtures.

As shown in figure 1, behind the multifunctional automatic replacement truck with the placement of fixtures of drilling, respectively, asynchronous gripper, dig shaking and hook. According to their size, respectively fixed in the back of a multifunctional automatic replacement truck, can convenient to access at any time.

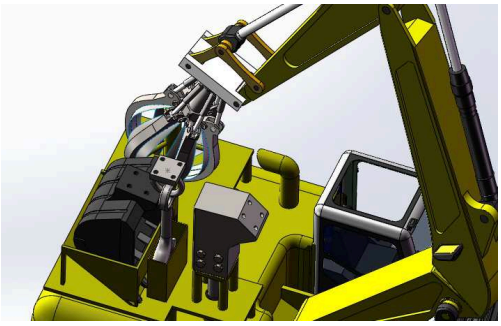

Figure 1. The construction unit is placed behind it

Multifunctional automatic replacement truck construction equipment installation. The automatic replacement truck is on the basis of ordinary excavator to be modified, ordinary excavator is only one scoop, and the dig shaking is fixed on the excavator arm, In addition to dig, we also increased the asynchronous gripper, drilling and hook. After the activity of the arm between the front-end and back-end, there is a small turntable to arbitrary Angle rotation, different construction equipment such as digging, asynchronous gripper, drilling and hook on the corresponding position behind the excavator, has activities in excavator arm on the front panel, activity board has four automatic screw bolt device, In the different construction device is equipped with four devices can be connected to activity on a board. As shown in figure 2, is hook and arm are connected through the board, as shown in figure 3,dig shaking and arm are connected through the board, Figure 4 for asynchronous gripper and arm are connected through the board, figure 5 for plate and arm are connected through activities board, The construction unit in active plate can fast connection and separation, greatly improve the speed and efficiency of the equipment replacement, and it does' t need artificial replacement at the same time, also more safety. Reduced the labor intensity and multi-usage function..

Figure 2 Hook

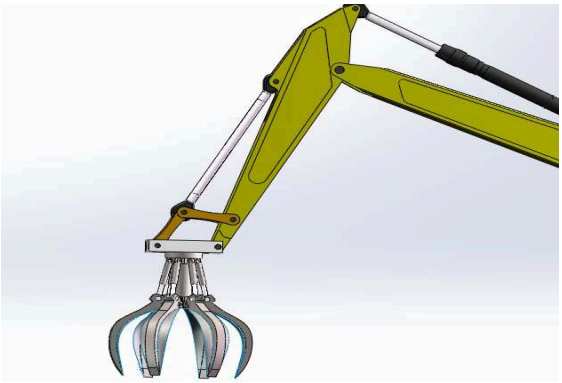

Figure 4 Asynchronous gripper

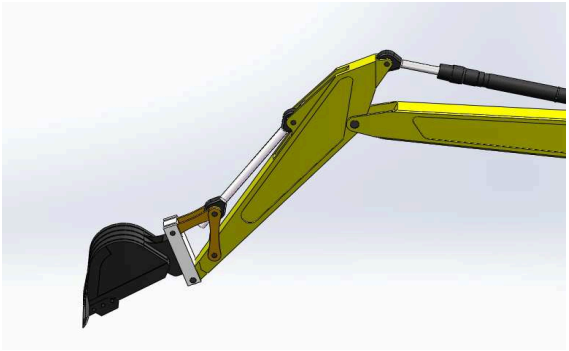

Figure 3 Scoop

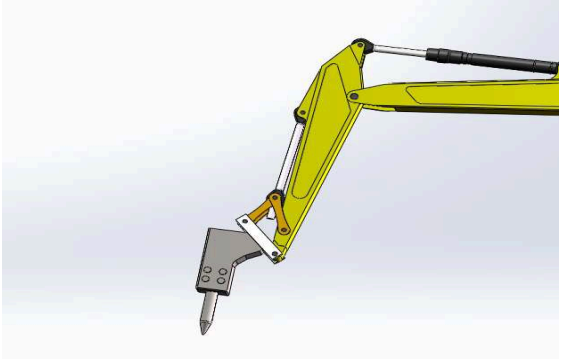

Figure 5 Bit

The automatic replacement process of multifunctional automatic replacement truck. Traditional excavator between car body and chassis can rotate, but the arm is not alone. a small turntable between front-end and back-end of the activities arm, can be to any Angle of rotation, Different construction equipment such as digging, asynchronous gripper, drilling and hook on the corresponding position, behind the excavator has activities board, activity board with four devices in excavator arm on the front panel, automatic screw bolt in the different construction device is equipped with four devices can be connected to activity on a board.

Such as the need to change different construction unit, just need to excavator arm after spin 180 degrees, and move to the corresponding required for the position of the construction unit, the activity board device and construction joint, the spin or device on the activity board began to spin, So that the construction unit change to the active arm up, and then rotating the small turntable that between front-end and back-end in the arm to move, which can carry out the construction. Device just need to change for different construction excavator arm after spin 180 degrees, then the movement to the corresponding construction set the required position, put down the construction unit, construction on the loosen activity board device, with the same way to change of other construction equipment.

Multi-functional automatic replacement truck automatic replacement system has following functions: free to change any set with construction, convenient and flexible, make the multifunctional automatic car replacement truck operation scope, further improve the work efficiency. Figure 6 is a multifunctional automatic replacement truck's arm rotated to the rear for asynchronous process of gripper construction equipment. Figure 7 for multi-function automatic replacement truck's arm rotated to the rear for digging shaking the process of construction equipment. Figure 8 is a multifunctional automatic replacement truck's arm rotation to the rear for hook the process of construction equipment. Figure 9 is a multifunctional automatic replacement truck's arm rotated to the rear is bit change process of construction equipment.

Figure 6 Rotate and gripper

Figure 8 Rotate with the hook

Figure 7 Rotate and scoop

Figure 9 Rotate and bit

The advantages of the multi-functional automatic change truck

Multifunctional automatic replacement truck can use a variety of auxiliary equipment, and automatic replacement device construction, can effectively to complete a variety of different assignments, truly become a multi-functional engineering machinery. The characteristics of the multifunctional automatic replacement truck are:

1. flexibility, Multifunctional automatic replacement truck after the activities of the arm between the front-end and back-end, there is a small turntable to arbitrary Angle of rotation, the flexibility of movement to different construction equipment such as digging, asynchronous gripper, drilling and hook the location, to achieve fast automatic replacement, which can replace any desired construction equipment.

2. versatility, Multifunctional automatic replacement truck wide range of uses, it can continuous operation for a long time. A series of quick replacement affiliated construction equipment to choose from, including digging shake, asynchronous gripper, drilling and hook, etc. Don't need to buy other models, the placement of the construction equipment on the truck's back position, construction equipment can be taken at any time, improve truck multi-usage, improve work efficiency.

3. Stability and security. Multifunctional automatic replacement truck construction equipment on the truck behind fixed place, uniform weight distribution, access at any time, convenient and quick

Through analysis to the multifunctional automatic replacement truck of design, modeling, multi-functional automatic car replacement truck is feasible. The market demand for multi-functional automatic replacement of engineering machinery, for multi-use of engineering machinery is in short supply. Multifunctional automatic replacement truck improve job performance, multi-usage, automatic replacement, without other auxiliary help, do not need artificial replacement of construction equipment, will bring a new revolution of the truck. With economic development, the growing construction industry, the demand for all kinds of loading and unloading machinery also continued to expand. For multifunctional automatic replacement truck is a multifunctional mechanical engineering vehicles, by replacement of construction equipment, automatic, jumbo can realize mining, crane, grab car free conversion. Multifunctional automatic replacement truck in the modern construction industry has an important significance.

Keywords: slide valve and pilot valve, hydraulic servo system, jam fault, fault diagnosis, strong tracking filter, parameters estimation.

Abstract. Jam fault occurs most times in the hydraulic servo system, and is the one of the factors that mainly influences the reliability of the system. For parallel-operated turbine, the jam faults of regulating system are elusive and fatal. In order to monitor operation condition and improve the reliability of the system online, the model of jam fault had been built, the sizes of the dead zones which describe jam fault had been viewed as unmeasured parameters, which avoided the model uncertainty brought by the linearization of nonlinear system, and strong tracking filter had been used to estimate unmeasured parameter. Simulation and experimental results verified that, this technique could accurately, synchronously estimate respective degrees of jam faults of slide valve and pilot valve online whether in daily operation or moving test.

Introduction

Slide valve and oil servomotor is one of common structures of hydraulic servo system .It controls the turbine inlet through converting a given signal to a sufficient output power capability of the trip in order to manipulate the control valve. While the most frequently occurring fault is jam. It will seriously affect the reliability of the whole system if jam fault occurs. So it significances for online diagnosis and detection of oil motive spool jam fault，especially fault information is given in the early. But it is difficult to detect the jam fault reliably and feasibly because of concurrency fault sources and gradient of dry friction.

In order to detect the degree of jam fault of slide valve and oil servomotor, we build the mathematical model of slide valve oil motive, which parameterizes the jam fault directly and uses the dead zone to characterize the degree of jam fault. Then we use STF (Strong Tracking Filter) to joint estimate system status and parameters to be estimated. Thus we can achieve jam fault diagnosis of slide valve online. Simulation results demonstrate the effectiveness of this method.

Parameter estimation of nonlinear systems based on strong tracking filter

EKF(Extended Kalman Filter) is common used in the parameter identification of nonlinear models, There is often some uncertainty for the model of dynamic systems, but the robustness of EKF about the model uncertainty is poor, thus causing imprecise of identification, even divergent phenomena .STF is reformed from EKF. It has strong robustness about the model uncertainty

Discrete state-space models describe nonlinear time-varying stochastic system

$$x(k+1) = f(k,u(k),x(k)) + \Gamma(k)v(k) \tag{1}$$

$$y(k+1) = h(k+1,x(k+1)) + e(k+1) \tag{2}$$

Where $x \in R^n$ is the state variables, $u \in R^q$ is input vector, $y \in R^m$ is output vector. Process noise $v(k)$,observation noise $e(k)$ are separately p dimension and m dimension uncorrelated zero mean Gaussian white noise, and has the following statistical properties

$$E[v(k)v^T(j)] = Q_1(k)\delta_{k,j} \tag{3}$$

$$E[e(k)e^T(j)] = Q_2(k)\delta_{k,j} \tag{4}$$

Where $Q_1(k)$, $Q_2(k)$ are separately covariance matrix of process noise $v(k)$ and observation noise $e(k)$, $Q_1(k)$ is non-negative definite symmetric matrix，$Q_2(k)$ is symmetric positive definite matrix. $\delta_{k,j}$ is Kronecker delta function.

Model of slide valve and oil motor with jam faults based on strong tracking filter

2.1 State space description of jam fault model
We get

$$\begin{cases} T_h\dot{d} = f_1\left(u,d,y,C_h\right) \\ T_s\dot{y} = f_2\left(d,C_s\right) \end{cases} \tag{5}$$

Assuming the sampling interval is T, discrete state space can be described as：

$$\begin{bmatrix} d(k+1) \\ y(k+1) \end{bmatrix} = \begin{bmatrix} \frac{T}{T_h} f_1\left(k,u(k),d(k),y(k),C_h(k)\right) + d(k) \\ \frac{T}{T_s} f_2\left(k,u(k),d(k),C_S(k)\right) + y(k) \end{bmatrix} \tag{6}$$

The only that can be measured is the oil motive displacement output y,so the observation equation is:

$$y(k+1) = \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix} x(k+1)^T \tag{7}$$

2.2 Solving of jam fault model
State-space model can be expressed as:

$$x(k+1) = f\left(k,u(k),x(k)\right) \tag{8}$$

$$y(k+1) = h\left(k+1,x(k+1)\right) \tag{9}$$

The partial derivative term is:

$$F\left(k,u(k),x(k\mid k)\right) = \begin{bmatrix} \frac{T}{T_h}\frac{\partial f_1}{\partial d}+1 & \frac{T}{T_h}\frac{\partial f_1}{\partial y} & \frac{T}{T_h}\frac{\partial f_1}{\partial C_h} & \frac{T}{T_h}\frac{\partial f_1}{\partial C_s} \\ \frac{T}{T_s}\frac{\partial f_2}{\partial d} & \frac{T}{T_s}\frac{\partial f_2}{\partial y}+1 & \frac{T}{T_s}\frac{\partial f_2}{\partial C_h} & \frac{T}{T_s}\frac{\partial f_2}{\partial C_s} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{10}$$

$$H\left(k+1,u(k+1),x(k+1\mid k)\right) = \frac{\partial h\left(k+1,x(k+1)\right)}{\partial x} = \begin{bmatrix} 0 & 1 & 0 & 0 \end{bmatrix} \tag{11}$$

Because f_1 and f_2 are piecewise functions, we think jam fault occurs at the cut-off point. The specific solving results are as follows:

$$\frac{\partial f_1}{\partial d} = \begin{cases} -1 & \left|u-y-d\right| > C_h \\ 0 & \left|u-y-d\right| \le C_h \end{cases} \tag{12}$$

$$\frac{\partial f_1}{\partial y}=\begin{cases}-1 & |u-y-d|>C_h\\ 0 & |u-y-d|\le C_h\end{cases} \tag{13}$$

$$\frac{\partial f_1}{\partial C_h}=\begin{cases}1 & u-y-d<-C_h\\ -1 & u-y-d>C_h\\ 0 & |u-y-d|\le C_h\end{cases} \tag{14}$$

$$\frac{\partial f_1}{\partial C_s}=0 \tag{15}$$

$$\frac{\partial f_2}{\partial d}=\begin{cases}1 & |d|>C_s\\ 0 & |d|\le C_s\end{cases} \tag{16}$$

$$\frac{\partial f_2}{\partial y}=0 \tag{17}$$

$$\frac{\partial f_2}{\partial C_h}=0 \tag{18}$$

$$\frac{\partial f_2}{\partial C_s}=\begin{cases}1 & d<-C_s\\ -1 & d>C_s\\ 0 & |d|\le C_s\end{cases} \tag{19}$$

Simulation results and analysis

In order to verify the jam fault diagnosis method of slide valve oil motive above is effective，we build simulation models on Simulink and analysis by simulation.

Initial state: $[0 \quad 0 \quad 0.01 \quad 0.2]^T$

The initial state estimate covariance matrix: $P(0|0)=diag[1000,1000,1000,1000]$

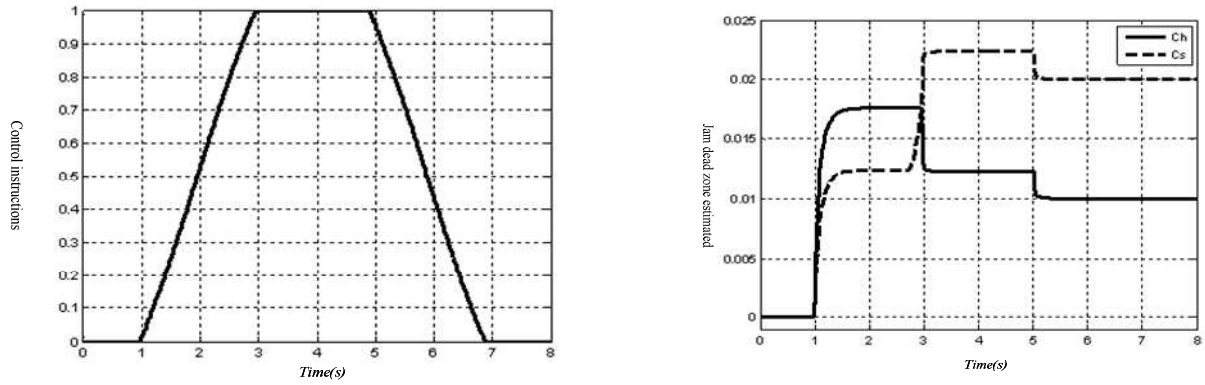
System noise covariance matrix: $Q_1=diag[0.1,0.1,0.1,0.1]$

Measurement noise covariance matrix: $Q_2=diag[0.1]$

Filters and other parameters in the model are shown as Table 1.

Table.1 Parameters of the simulation

Parameter	Value
Forgetting factor	0.95
Weakening factor	1
Spool death zone	0.01
Oil motive death zone	0.02
Sampling period	0.0001
Spool time constant	0.01
The time constant of oil motive	0.2



(a) (b)

Fig.1 a) Analog input signal b) Size of dead zone estimated

Fig.1 shows the simulation result of using STF when the excitation signal is the main steam valve activity test input signal. We get $C_h = 0.01$, $C_S = 0.02$,and their deviations are less than 0.1%.

After a lot of simulation experiments，we find:

1, the filter could not work effectively when no action of slide valve oil motive.

2, the filter can identify the size of dead zone only if the action of slide valve oil motive changes direction.

3, the filter can identify the size of dead zone only if the excitation signal is large enough.

Conclusions

This paper presents a accurate model describes slide valve oil motive jam fault in STF., which can avoid the uncertainty of the linearization of nonlinear systems .Only in the case of oil engine output can be measured，through joint estimating the state of the systems and the parameters describes jam fault, we can diagnose jam faults of slide valve and the oil motive. Simulation shows this method can detect and separate the jam fault of slide valve oil motive both in the daily operation of the unit or the main steam valve testing activities, it can even estimate jamming degree. What is more, it significances for online diagnosis and detection of oil motive spool jam fault，especially fault information is given in the early.

Keywords: Turbine model, Characteristic parameters, Stability of grid

Abstract. With the rapid development of China's interconnected power grid, power system operation environment has become increasingly complex. The safety and stability of the power system requirements are also increasing. Turbine is an important basis for the analysis of power system stability. This paper studied the influence of turbine parameters related to network on the stability of the grid from the perspective of the frequency domain, and obtained the impact properties of turbine speed control system parameters related to different oscillation frequency of the power system. The conclusions are validated from time domain. So that when analyzing the stability of the power system, a more targeted turbine model according to different research purposes can be chosen because the parameters' importance can show the necessity of the modules.

Introduction

The power system operating environment has become increasingly complex, and the stability and security requirements of the power system have become more sophisticated. Random perturbations can cause power system's frequency, power and other parameters fluctuations or oscillations and have become a serious threat to the power system security and stability[1].Turbine model is an important foundation for analyzing the power systems' dynamic characteristics when various disturbances exists in the steady state. In current power system stability analysis, for turbine dynamic model, classical Cascade combination model is the mainstream. Because the model is too simplified, many problems appear in the application. Many scholars increased or improved part of the module on the basis of the classical model to improve the performance and made appropriate analysis.

Yunfeng Tian et al [2] improved the accuracy of the dynamic response of the turbine model by setting the high-pressure cylinder power natural overregulation factor. Xiaoqiang Liu et al [3] and Ge Jin et al[4] considered the impact of the main steam pressure model on unit primary frequency characteristics. Jiachuan Li[5], Rui Wang[6], Hui Liu et al[7]put emphasis on the boiler-turbine unit coordinated control of primary frequency characteristics.

Current situation shows that there exists no systematic analysis for the turbine model adaptation in power system simulation. Therefore, this paper established the steam turbine model, studied turbine characteristic parameters on the stability of the grid from the perspective of the frequency domain, and got the influence characteristics of a turbine combined with its speed control system related to network parameters on different oscillation frequencies of the power system.

Turbine model

This paper established a typical single reheat, single axle, four -cylinder exhaust steam turbine unit model, which mainly included steam volume effects module (describing the main dynamic characteristics at all levels of cylinders), rotor module, reheat system module, and heat recovery system module.

The volume time constant T_0 is:

$$T_0 = \frac{l\rho_0 A}{nAv_0\rho_0} = \frac{l}{nv_0} \tag{1}$$

Where the inlet pipe length is l, cross-sectional area is A, the designed flow rate of steam flow in the pipeline is v_0, rated conditions density is ρ_0.

Steam volume effect module is shown in Fig. 1:

Turbine generator unit rotor equation is

$$\chi_P - \chi_{NL} - \beta\chi_n = T_a \frac{d\chi_n}{dt} \tag{2}$$

While $\beta = (\frac{\partial N_f}{\partial \omega})_0 \frac{\omega_0}{N_{T0}}$, $T_a = \frac{J\omega_0^2}{N_{T0}}$

Where the rotor soaring time constant is T_a, self-balancing factor is β, a dimensionless quantity, which indicates a factor associated with the additional loss.

Have Laplace transform at both ends of Equ.2, then

$$\chi_P(s) - \chi_{NL}(s) = (\beta + Ta \cdot s)\chi_n(s) \tag{3}$$

According to Equ.3, the module is shown in Fig.2:

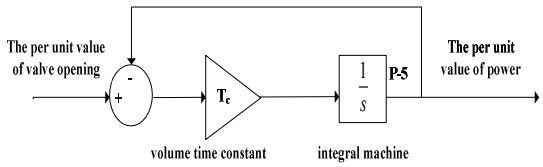

Fig. 1 Steam volume effect module

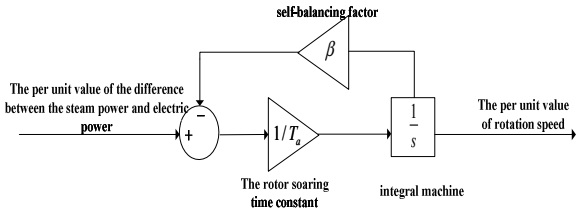

Fig.2 Turbine rotor simulation model

Reheat system model is mainly volume effect, the simulation module is shown in Fig.3.

Improved turbine characteristics related to network analysis model is shown in Fig.4.

Fig.4 Overall Schematic diagram Turbine

Frequency domain analysis for turbine characteristics related to network impact on the stability of grid

On the basis of the establishment of the turbine model, we carried out research on turbine parameters impact on the stability of the grid. Research method is to change a certain parameter, if it will cause changes in the frequency domain characteristics of the turbine system's specific band, then it indicates when the grid disturbance frequencies is in this band, this parameter's uncertainty will have an impact on the secure and stability of the grid.

Simulation results. Depending on the research objectives, actual measurement parameters tests are conducted, and the influence of disturbance of a particular frequency band is got, including where the parameter is to play a leading role in influencing and where are secondary. Turbine characteristic parameters related to network considered in this paper include steam volume time constant, reheat volume time constant, regenerator inertia time constant and the time constant of the hydraulic servo-motor. Simulation conditions and Bode plots are shown below.

Table 1 Values of main parameters

Serial number	Parameter	Symbol	Primitive value
1	Controller proportional element	Kp	1
2	Controller integration element	Ti	10
3	Normal regulation time constant of high pressure hydraulic servo-motor[s]	Tvh1	0.9
4	Volume time constant of high pressure cylinder[s]	TH	0.1279
5	Reheat volume time constant[s]	Trh	8.29
6	regenerator inertia time constant [s]	TrJG/TrJI/TrJD	20

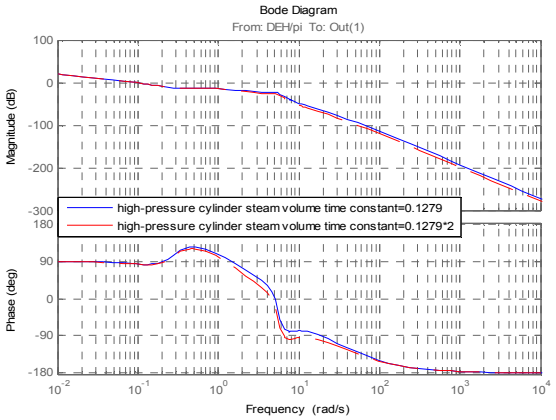

Fig. 5 Influence of high-pressure cylinder steam volume time constant on the system frequency domain characteristics

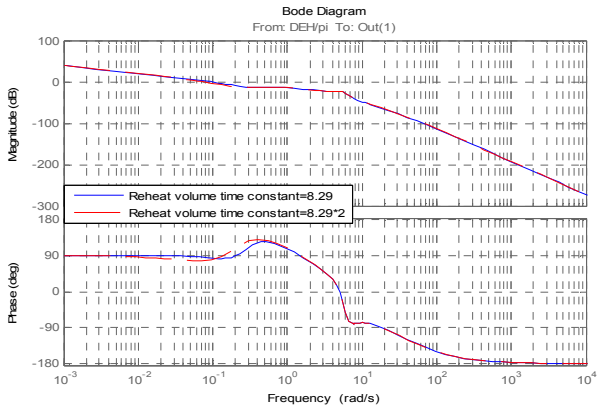

Fig. 6 Influence of intermediate-pressure cylinder steam volume time constant on the system frequency domain characteristics

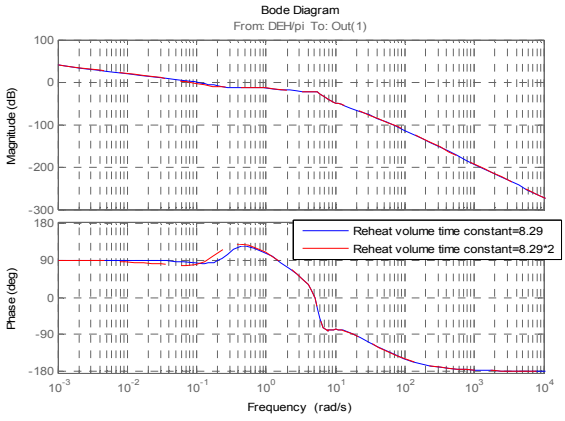

Fig.7 Influence of reheat volume time constant on the system frequency domain characteristics

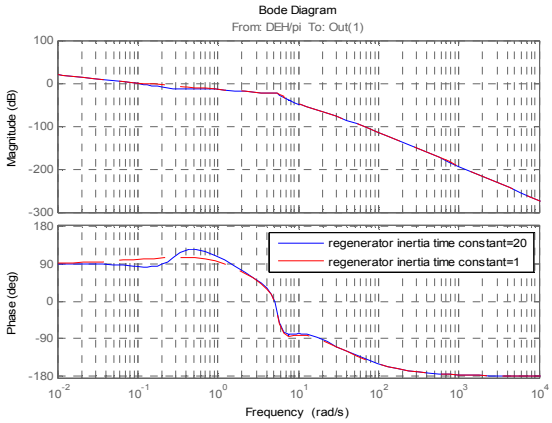

Fig.8 Influence of regenerator inertia time constant on the system frequency domain characteristics

As can be seen from Fig.5, the volume time constant of the high-pressure cylinder increases lead to the decrease of system bandwidth. When the system disturbance frequency is in the range of $\omega > 6rad/\sec$, the volume time constant of the high-pressure cylinder has an impact on the system's amplitude-frequency characteristics; when the system disturbance frequency in the range of $\omega = 0.02 \sim 2rad/\sec$, the volume time constant of the high-pressure cylinder has a rather large impact on the phase-frequency characteristics of the system. Considering the grid disturbances frequency is $f > 0.11Hz$, take the impact of the time constant of the high-pressure cylinder volume into consideration. From Fig.6, intermediate-pressure cylinder steam volume time constant generally has no impact on the system frequency domain characteristics.

As can be seen in Fig.7, reheat volume time constant has a big effect on the system low frequency region, particularly within the range $\omega = 0.01 \sim 0.5 rad/\sec$, i.e. $f = 0.0016 \sim 0.08 Hz$. So the grid frequency within this range need to consider the effect of reheat volume time.

As can be seen from Fig.8, within the range $\omega = 0.02 \sim 2 rad/\sec$, i.e $f = 0.003 \sim 0.318 Hz$, regenerator inertia time constant has a big effect on the system low frequency region.

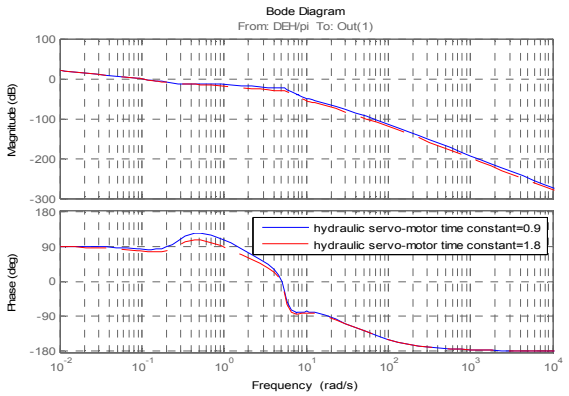

Fig.9 Influence of time constant of the hydraulic servo-motor on system frequency domain characteristics

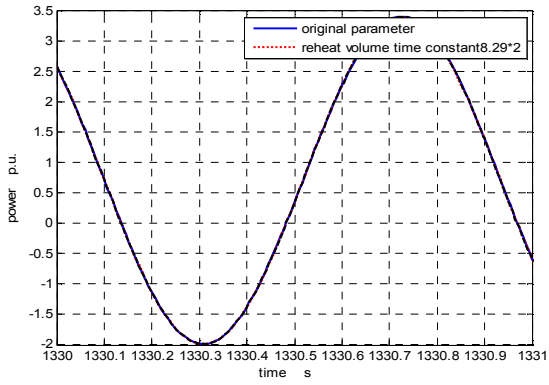

Fig.10 Influence of reheat volume time constant on the stability of grid

As can be seen from Fig.9, the system disturbance frequency $\omega > 1 rad/\sec$, the time constant of the oil motive influences the system amplitude-frequency characteristics greatly. When ω=0.1~3$rad/\sec$, the time constant of the oil motive effects the system phase frequency characteristics. When the grid disturbances frequency is $f > 0.016 Hz$, the time constant of the hydraulic servo-motor effect need to be considered.

Summary. This chapter considered turbine parameter uncertainty affecting the stability of the grid from the perspective of the frequency domain.

Time domain validation analysis

The influence of turbine power system network parameters on the different oscillation frequencies is obtained from frequency domain analysis. In order to more fully illustrate the problem, the conclusion is validated from time domain.

Effect of steam volume time constant and the volume time constant of high pressure cylinder.

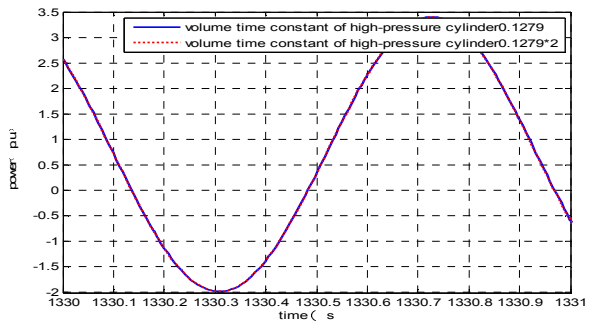

Fig.11 Influence of volume time constant of high-pressure cylinder on the stability of grid

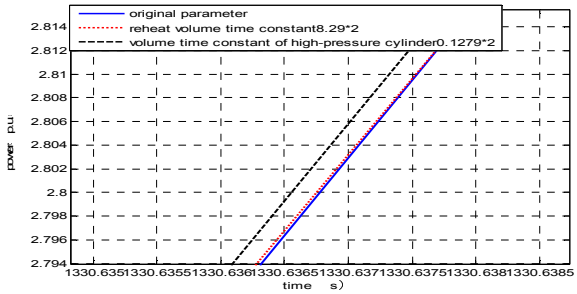

Fig.12 Comparison the influence of reheat volume time constant and volume time constant of high-pressure cylinder on the stability of grid

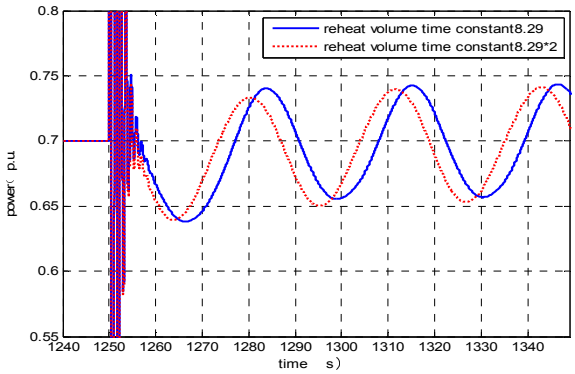

Fig.13 Influence of reheat volume time constant on the stability of grid

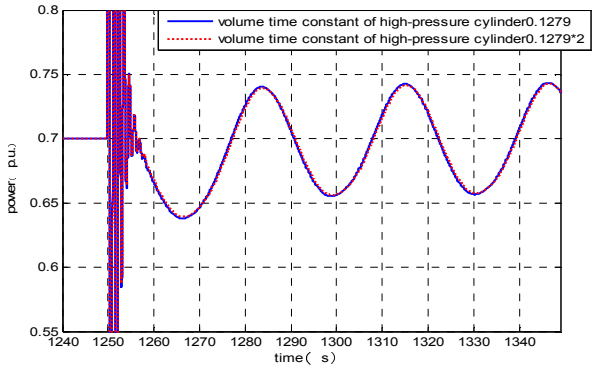

Fig.14 Influence of volume time constant of high-pressure cylinder on the stability of grid

Summary analysis. Take the high-pressure cylinder for example, when the grid disturbance is 1.2HZ, the analysis of the frequency domain shows that the reheat volume time constant changes have no effect on the stability of the grid, while changes in the volume time constant of the high-pressure cylinder influence the grid stability. The conclusion is verified from the time domain, but due to the stand-alone infinite power grid consideration and the controller design, the frequency is after the system cut frequency, thus the proven effect is not obvious. Therefore further demonstrate of this point is needed. When the grid disturbance is 0.04HZ, from the frequency domain analysis, changes in the reheat volume time constant have a great influence on the stability of the grid, while changes of the volume time constant of the high pressure cylinder do not impact the stability of the grid. For the frequency of the disturbance is in the vicinity of the shear frequency of the system, the difference between two parameters on the stability of the grid is obvious, which demonstrates our conclusion in the frequency domain analysis.

Conclusions

This paper established a revised turbine model as a basis to study turbine parameters' related to network influence on the grid stability from the perspective of the frequency domain, and obtained the turbine speed control system parameters related to the power system network effect of different characteristics of the oscillation frequency. The conclusion is validated from time domain. Therefore, when analyzing the stability of the power system, a more targeted turbine model according to different research purposes can be chosen because the parameters' importance can show the necessity of the modules.

For example, in the low-frequency oscillations (0.2Hz ~ 2.5Hz frequency disturbances), the establishment of the turbine should consider the module of hydraulic servo-motor, high-pressure cylinder, the rotor, while re-heater, the regenerator and other modules can be ignored. However, for long distance transmission case, re-heater and regenerator modules both need to be considered in the model.

Keywords: COGAG, Engaging process, Dynamic simulation

Abstract. This paper establishes the COGAG system simulation model in the environment of SIMULINK and ADAMS with the method of coupled simulation based on multiple simulation platforms; simulates and analyses the COGAG engaging process with the simulation model. Dynamic change rules of some key parameters such as speed, moment, power are obtained and analysed detailed, which plays an important role in development and application of COGAG device.

Introduction

Combined Gas turbine and Gas turbine (COGAG) system is widely used in ship machinery propulsion. It can effectively avoid the operation of gas turbine in low condition to improve the reliability and economy of the ship operation, compared with other power device. In order to reduce the test work, debase the risk of trial, save the cost and shorten the development cycle in the process of COGAG development , the comprehensive simulation on it is very necessary [1].

As the COGAG is a very complicated nonlinear system, the transmission device (especially SSS clutch) of COGAG is greatly simplified in the most simulations and analyses, the simplified model unable to fully reflect the dynamic characteristics and the specific engaging process. This paper adopts the method of coupled simulation based on multiple simulation platforms, establishes the simulation model of transmission device(SSS clutch, gear box) and other modules (gas turbine, engaging controller, propeller) in the environment of SIMULINK and ADAMS, and then take a systemic simulation and analysis on the engaging process and load distribution.

Simulation modeling

Introduction of COGAG. COGAG device is mainly composed of prime movers (double same gas turbine), transmission device(SSS clutch, gearbox, transmission shafts) and propeller, the typical arrangement is shown in Fig.1. The engaging process of COGAG can be summarized as follows: a gas turbine(1# gas turbine) is working with a certain load, another gas turbine (2# gas turbine) participates in the work and gradually maintains the same speed with the working gas turbine through the SSS clutch and gearbox; at the same time, the two gas turbine share the power together according to a certain proportion. When the ship need to improve the speed or increase the power, engaging process is necessary. The quality of engaging process directly affects the quality of COGAG as a power device, therefore, the study on the engaging process is important and necessary.

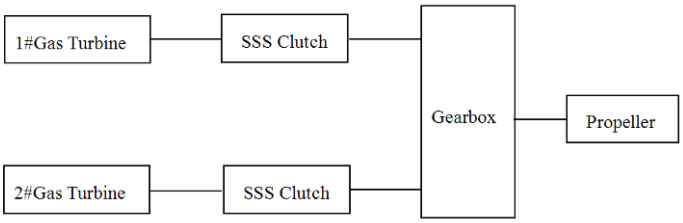

Fig.1 Typical arrangement of COGAG

The simulation model of COGAG system. The zero dimension variable specific heat simulation model of a gas turbine with three rotors was composed of compressor, combustor, turbine, volume, rotor, engaging controller and propeller, which were established in the environment of SIMULINK.

The simulation model as shown in Fig.2 took the outgassing process of compressor and the cooling process of turbine into account [2-5].

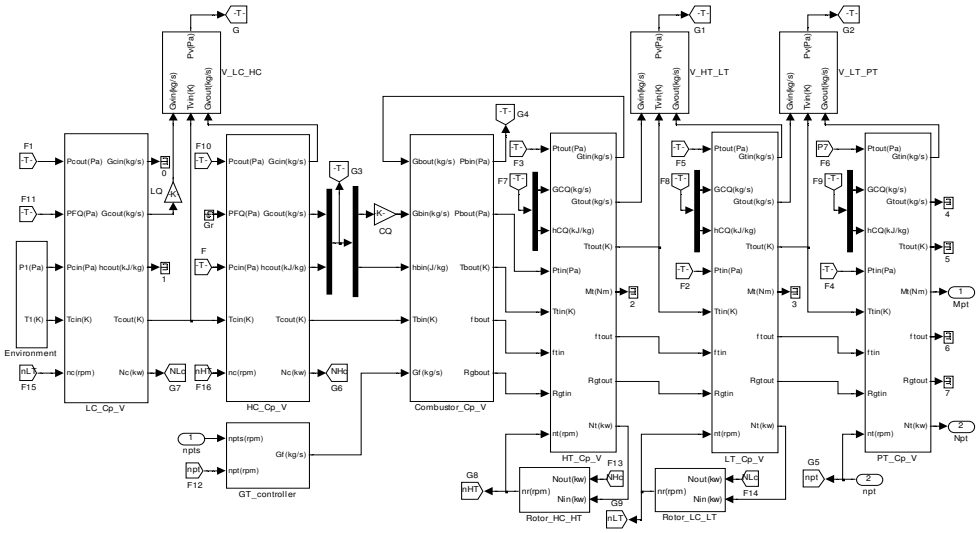

Fig.2 The model of a gas turbine with three rotors in SIMULINK

This paper established the model of the transmission device containing SSS Clutch and gearbox in the environment of ADAMS, according to the characteristic that the mathematic model of the transmission device was built based on the principle of mechanical system [6-9]. The simulation model was shown in Fig.3.

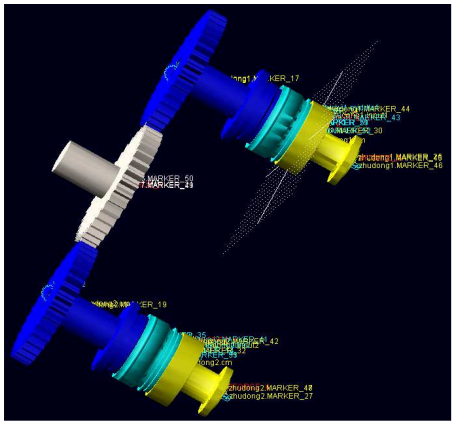

Fig.3 The model of transmission device in ADAMS

The whole COGAG model combined in the environment of SIMULINK was shown in the Fig.4. In the model, COGAG_controller and Propeller respectively represented the simulation model of engaging controller and propeller; SSS_clutch_and_Gearbox was the connector as a part of ADAMS between SIMULINK and ADAMS .

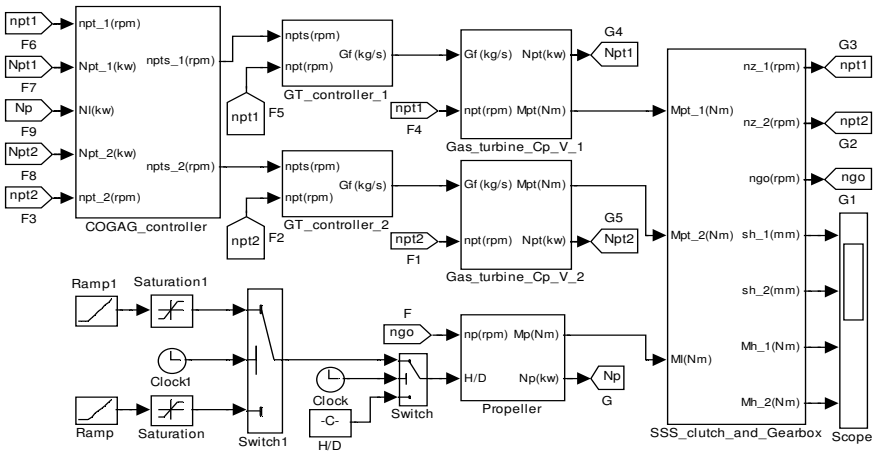

Fig.4 The whole COGAG model in SIMULINK

Results and analysis

The total simulation time was 20s, using ode14x fixed step algorithm, and the simulation step was 0.02s. Simulation process was summarized as follows:

(1) In the initial state, 1# gas turbine power turbine was running stable at speed of 2800rpm, the output power was 21000kw, of which 400kw was used to overcome resistance; 2# gas turbine power turbine was running stable at speed of 2800rpm, the output power was 400kw, all for overcoming resistance; 1# SSS clutch (connected to 1# gas turbine) was in engaged state; 2# SSS clutch (connected to 2# gas turbine) was in disengaged state; gearbox ratio was 19, the output shaft was connected directly to the propeller.

(2) Starting engaging at 10s, the power allocation coefficient of engaging controller was 0.5(1# gas turbine and 2# gas turbine had an average allocation of power after the engaging).

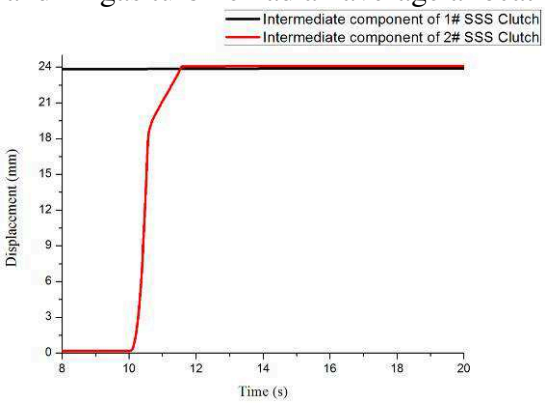

Fig.5 Displacement of middle ware

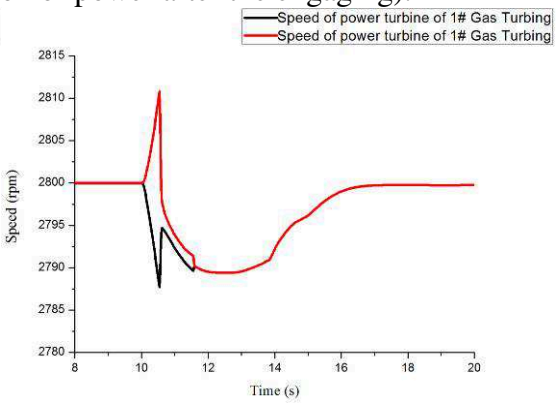

Fig.6 Speed of gas turbine

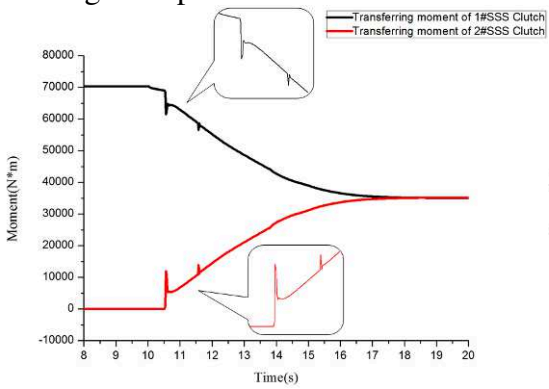

Fig.7 Moment of middle ware

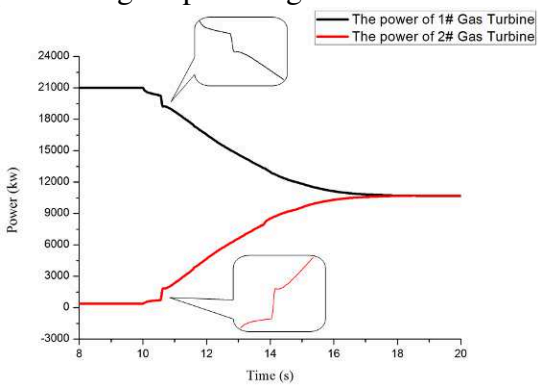

Fig.8 Power of gas turbine

The simulation results were analyzed as follows:

As shown in Fig.5, 2# SSS clutch middle ware started moving from 0mm displacement when starting engaging, gradually closer to the driving part along helical spline; within 0mm ~ 16mm distance range, the oil chamber damping almost did not work, and the axial movement of middle ware was fast; when the distance was greater than 16mm, the oil chamber damping started working, axial movement of middle was slowing down; and the time required of the engaging process was about 1.6s, finally the middle ware collided with the driving part, stopping axial movement and the engaging process was completed. During the engaging process, the displacement of the 1# SSS clutch was always 24mm, then the clutch always maintained engaged state.

As shown in Fig.7, the transferring moment of 2#SSS clutch increased gradually; When there was almost no effect of oil chamber damping, the transferring moment was very little; When the oil chamber damping had effect, transferring moment was increased suddenly; When the middle ware compacted the driving part, the transferring moment of middle ware increased suddenly again, but its amplitude was small; Subsequently, under the effect of engaging controller, the drive torque increased persistently, until the load distribution completed around 20s. The transferring moment of 1#SSS clutch middle ware decreased gradually, its change rule was basically opposite to 2#SSS clutch. As shown in Fig.8, the change rule of the output power of gas turbine was basically same as the above process, it was unnecessary to go into details here.

As shown in Fig.6, the speed of power turbine of 2# gas turbine was higher than power turbine 1# during the engaging process; After the oil chamber damping of 2#SSS clutch acting, the transferring moment of clutch middle ware increased suddenly and the speed of driving parts suddenly decreased; The moment transferred to 1# clutch driven parts via the gearbox, the speed of middle ware and driving parts increased suddenly under the effect of oil chamber damping; Although the output power of 2#gas turbine increased persistently, the effect of oil chamber damping was same, caused the speed of power turbine decreased slowly; Meanwhile, the output power of 1# gas turbine persistent decreased caused the speed of output shaft decreased slowly too; When the middle ware compacted the driving parts of 2# SSS clutch, the speed of output shafts of two gas turbines changed suddenly again, but the amplitude was small, the tendency and reasons of variation was same as the effect of oil chamber damping; Subsequently, under the effect of engaging controller, two gas turbines completed load distribution, and their output speed gradually stabilized at 2800rpm.

Conclusions

This paper simulated and analyzed the engaging process of COGAG based on coupled simulation method with SIMULINK and ADAMS, achieved relatively comprehensive dynamic change rules of the displacement of clutch middle ware, the transferring moment of clutch, the power and speed of gas turbine, and characteristics of other components. The results of simulation indicate that during the COGAG engaging process, the speed, moment, power, and other key parameters' variation were reasonable. The coupled simulation method can reflect the specific dynamic change rule of components during the engaging process further. It has very important effect to the research, production and application of COGAG.

Key words: cavitating flow; diesel injector nozzles; visualization; back pressure.

Abstract: A study was carried out on the influence of different back pressures on internal flow of diesel injector nozzles. For this study, a flow visualization experimental system equipped with a pressurized chamber was setup. Experimental results show that, with the injection pressure remain constant and increase back pressure leading to the cavitation area diminished gradually and even disappeared. With a same pressure difference, higher back pressure test condition promoted the outlet mean velocity and inhibited the occurrence of cavitation inception, which demanded a larger pressure difference to make it happen. Moreover, it also resulted in a relatively large flow losses to the single phase flow compared to the cavitating flow.

Introduction

Recent studies have shown that the cavitating flow in diesel injector nozzles affect spray characteristics and therefore atomization behavior, which is decisive for diesel engine performance and pollutant formation[1]. Numerous researches have been carried out to investigate the formation mechanism and characteristics of internal cavitating flow[2-3]. However, most researches focused on the nozzle structures, with limited attention paid to the in-cylinder compression pressure(back pressure), which must have a strong influence on the cavitation distribution in nozzle orifices[4].

The Cavitation number (K) was defined as $K= (P_1-P_V)/(P_1-P_2)$.Where, P_1 is the injection pressure, P_2 the back pressure, P_v the saturated vapor pressure of the fuel. The value of K decreases as injection pressure increases or back pressure decreases. As K is smaller, the higher tendency to cavitate. Additionally, studies show that different nozzle structures have different critical Cavitation number K_{crit}, which indicates the start of cavitation. Another significant parameter is the discharge coefficient C_d. This parameter is defined as the relation between the real mass flow rate and the theoretical one, given by Bernoulli's equation: $C_d=\frac{Q_m}{A\sqrt{2\rho(P_1-P_2)}}$, where, Q_m is the actual flow rate, A the cross-sectional area, ρ the fuel density.

In this paper, a flow visualization experimental system equipped with a pressurized chamber was setup to investigate the effect of different back pressures on internal cavitating flow. The relationship between key parameters including K, Reynolds number Re, pressure difference ΔP, C_d were also discussed.

Visualization experimental setup

Fig.1 shows the basic experimental set-up. It was mainly consisted of the fuel injection system, the fuel supply system and the image acquisition system. It should be noted that the enlarged nozzle replica was designed and manufactured according to the similarity principle which ensured the internal structure and layout of nozzle unchanged. Bottled nitrogen is used to pressurize the fuel in the reservoir to supply fuel to the testing nozzle. A pressure gauge is located near the entrance of the injector to adjust and obtain the injection pressure. A flow rate meter is installed between the fuel tank and pressure gauge to provide flow rate value. The testing nozzle is placed between a light

source and a high speed camera, giving back lighting. All the captured images were digitally captured and stored in a computer. Table.1 shows the main parameters determined according to the similarity principle.

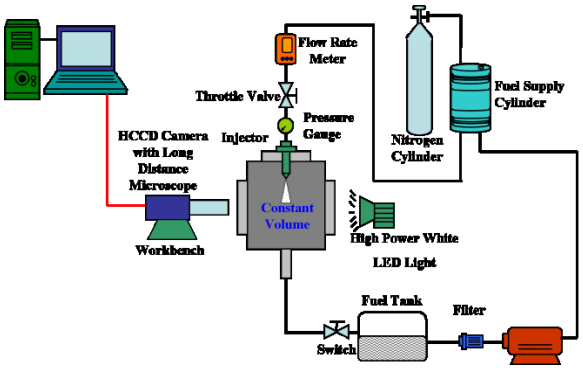

Fig.1 Schematic diagram of the nozzle flow visualization system

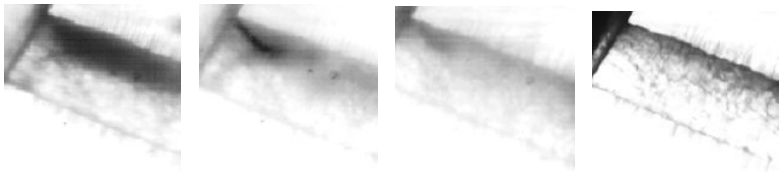
Table.1 Experimental parameters

Nozzle material	acrylic
Scaled-up times	5
Inclination of orifice（°）	70
Length of orifice（mm）	6.4
Orifice diameter（mm）	1.6
Working fluid	0# diesel
Fuel density（kg/m^3）	855
Fuel viscosity（Pa·s）	3.4

Experimental results and discussion

3.1 Analysis of cavitating flow development

Fig. 2 shows the cavitation variations happened during the experiments. These images were taken under the condition of keeping the injection pressure 0.7Mpa unchanged, while increasing back pressure P_2 from 0.2MPa to 0.45MPa.



P_2=0.2MPa. P_2= 0.35MPa P_2=0.42MPa P_2=0.45MPa

Fig 2. The influence of different back pressures on cavitation distribution

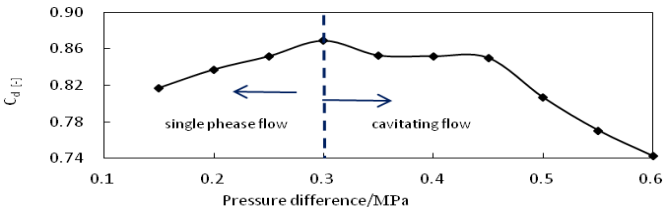


Fig.3 Correlation between C_d and ΔP

It can be seen from Fig. 2 that when P_2 was 0.2Mpa (i.e. maximum pressure difference), cavitation distribution area got most widespread. Then with the increase of back pressure, cavitation area diminished gradually. Moreover, when P_2 reached to 0.42Mpa, well developed cavitating flow faded to the critical condition of cavitation inception. Increase back pressure a step further, cavitation phenomenon completely disappeared. Fig.3 shows the correlation between ΔP and C_d for this experiment. It can be seen that in the single phase flow regime, C_d was not a constant value as Nurick proposed[5]. This was because that the flow resistance caused by the nozzle geometry was more prominent at small pressure difference, resulting in much more flow losses and smaller C_d.

With the increase of ΔP, internal disturbance increased and flow resistance diminished, leading to the raise of C_d. However, with the occurrence of cavitation phenomenon, discharge coefficient dropped sharply. This was because the mass flow choking effect in the orifice induced by the cavitation phenomenon. It is worth mentioning that there do exist hysteresis between the sharp diminishing start point of discharge coefficient and the cavitation inception.

3.2 Effect of back pressure on internal flow

Fig.4(left) shows the correlation between ΔP and C_d under different back pressures. It was obvious that with the increase of back pressure, the occurrence of cavitation inception became harder and called for a higher ΔP to make it happen. This was mainly because that the gas nucleus number of fluid is a key factor that affect cavitation inception, while large pressures at inlet and outlet effectively reduced the production of bubbles in the flowing liquid, therefore higher back pressure inhibited the cavitation phenomenon.

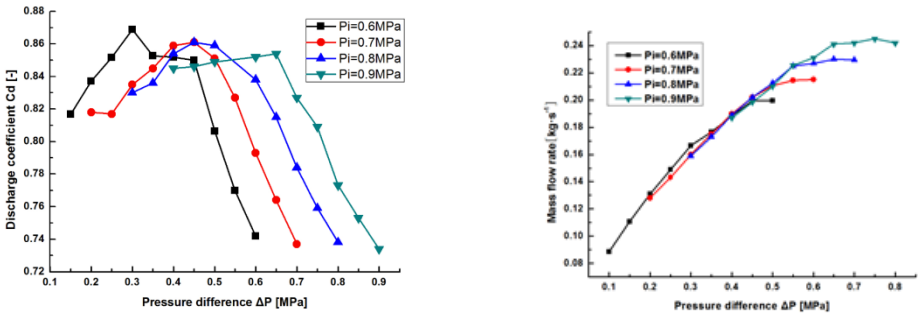

Fig. 4 Correlation between ΔP and C_d(left); correlation between ΔP and mass flow rate under different back pressures(right)

This can also be seen in Fig. 4(right) which shows the correlation between ΔP and mass flow rate. It was obvious that under the condition of same ΔP, higher back pressure leading to a larger flow rate, which can be interpreted as the area occupied by cavitaiton was very small under this condition.

In order to further investigate the effect of flow turbulence on flow losses, correlation between C_d and Re was obtained and drawn in Fig.5 (left). It can be seen that with the increase of Re, C_d decreased quickly after the cavitation phenomenon occurred. But Re corresponding to the blocking effect were different under different back pressure conditions, and higher back pressure meet with a higher Re. Therefore, it can be concluded that: under different back pressure conditions, flow losses of single phase regime was mainly caused by the flow turbulence and it was small; while in the cavitating flow regime, relatively large flow losses was produced by the occurrence of cavitation phenomenon.

Fig. 5(right) shows the correlation between K and outlet mean velocity. It can be seen that under the condition of sameΔP, after the occurrence of cavitation phenomenon, higher back pressure increased the mean velocity of fuel.

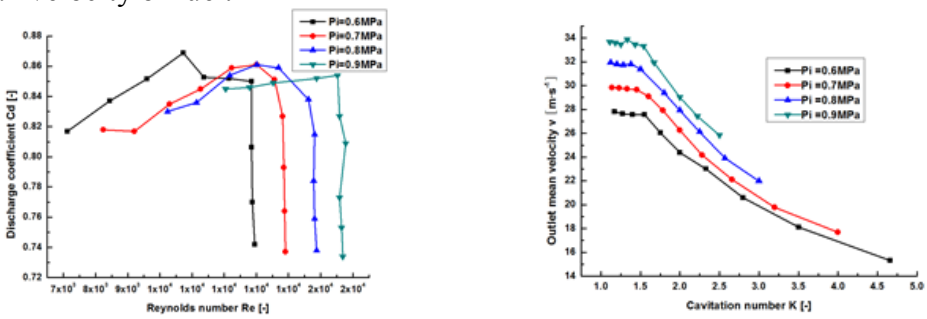

Fig. 5 Correlation between Re and C_d under different back pressures (left); correlation between K and mean velocity under different back pressures(right)

Conclusions

A flow visualization experimental system was setup to investigate the effect of different back pressures on internal flow. The main conclusions are as follows:

When injection pressure remains constant, the cavitation distribution area diminishes gradually and even disappeared as back pressure increases.

For cavitation inception phenomenon, higher back pressure condition calls for a larger ΔP between the nozzle inlet and outlet to make it happen, which indicates that higher back pressure condition inhibits the occurrence of cavitattion phenomenon. For cavitaing flow, under the condition of same ΔP, higher back pressure leads to a smaller cavitation distribution area. A hysteresis phenomenon exits between the sharp diminishing start point of C_d and cavitation inception.

In single phase flow regime, with a same ΔP, higher back pressure causes a larger flow losses due to the flow turbulences; while in cavitating flow regime, with a same ΔP, higher back pressure results in a smaller flow losses which was mainly caused by the occurrence of cavitation phenomenon. Additionally, flow losses cause by cavitation phenomenon is much larger than that cause by flow turbulences. Moreover, with a same ΔP, higher back pressure leads to a higher outlet mean velocity.

Keywords: Hydraulic scissor lift platform; Design calculations; Component modules;

Abstract. Based on the structure, the hydraulic scissor lift platform can be divided into different component modules. The maximum lifting force is calculated in accordance with its structure features, and then the safty is analyzed.

The maximum thrust of the Hydraulic cylinder

The hydraulic scissor lift platform studied in this paper is SJPT-Series- mobile hydraulic lifting platform SJPT10-8 models. The main mechanical parts of the platform includes the platform, six scissor arms, chassis, five groups of inner frame and outer frame and other components. Maximum lifting height is 8m; Lifting capacity is 1000kg; Maximum overall dimension is length 2330mm x width1500mm x height 2700mm; Workbench size is length 1820mm x width 1200mm; Mating power is 2.2kw; Total weight is 2000kg[1] .

In accordance with the numbers of scissor arms which is pushed by hydraulic cylinder, it can be divided into three basic component groups: a hydraulic cylinder to promote a scissor arm, a hydraulic cylinder to promote two scissor arms, a hydraulic cylinder to promote three scissor arms[2].

The basic component groups of the hydraulic scissor lift platform studied in this thesis is a hydraulic cylinder promoting three scissor arms. The structure diagram is shown in Figure1.

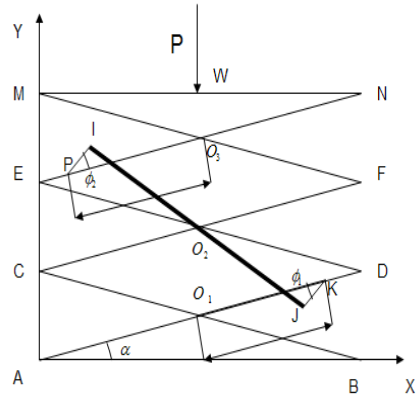

Figure 1 Structure diagram of the hydraulic scissor lift platform

l_1——The length of the lower hydraulic cylinder earrings

l_2——The length of the upper hydraulic cylinder earrings

K——The upper endpoint of the lower hydraulic cylinder earrings

P——The lower endpoint of the upper hydraulic cylinder earrings

J——The lower endpoint of the lower hydraulic cylinder earrings

I——The upper endpoint of the upper hydraulic cylinder earrings

L——Pin hole center distance of the scissor arm

l_1=210mm， l_2=210mm， L=1760mm， $\Phi_1 = \angle JKO_1 = 33^\circ$ ， $\Phi_2 = \angle O_3PI = 33^\circ$ ， a=O_3P=760mm，b=JK=760mm

In the same load, the position which the hydraulic scissor lift platform sufferes maximum thrust is the lowest position of the entire system, so the angle α between bottom scissor arm and the horizontal is taken as $\alpha=10^\circ$.

Considering the actual working conditions of the different staff operation and work-load, bias load issues may arise，therefore, calculation and check are carried out in accordance with unilateral weight, so under the condition of bias load the load which suffered by the hydraulic lift platform can be calculated as:

$$P = 0.5P_1 + 0.5P_2 \tag{1}$$

In the above,the P is the unilateral weight of the platform; P_1 is lifting weight; P_2 is the overall weight: P_1=1000kg, P_2=2000kg,So P=1500kg.

Here, the virtual displacement method is applied.

Them the virtual work formula can be calculated as:

$$\sum F_i \cdot \delta r_i = 0 \tag{2}$$

Analytical expression is:

$$\sum (F_{xi} \cdot \delta x_i + F_{yi} \cdot \delta y_i + F_{zi} \cdot \delta z_i) = 0 \tag{3}$$

Therefore, the thrust which is required by a single hydraulic cylinder can be drawn based on virtual displacement method. Firstly, list the coordinate equation of J point:

$$J_x = \frac{L}{2}\cos\alpha + b\cos\alpha - l_1\cos(\varphi_1 + \alpha) \tag{4}$$

$$J_y = \frac{(6i-5)}{2}L\sin\alpha + b\sin\alpha - l_1\sin(\varphi_1 + \alpha) \tag{5}$$

The coordinate equation of I point:

$$I_x = (\frac{L}{2} - a)\cos\alpha + l_2\cos(\varphi_2 + \alpha) \tag{6}$$

$$I_y = (3i-1)L\sin\alpha + (\frac{L}{2} - a)\sin\alpha + l_2\sin(\varphi_2 + \alpha) \tag{7}$$

The coordinate equation of J point can be divided into:

$$\delta_{jx} = [-\frac{L}{2}\sin\alpha - b\sin\alpha + l_1\sin(\varphi_1 + \alpha)]\delta_\alpha \tag{8}$$

$$\delta_{jy} = [\frac{(6i-5)}{2}\cos\alpha + b\cos\alpha - l_1\cos(\varphi_1 + \alpha)]\delta_\alpha \tag{9}$$

The coordinate equation of I point can be divided into:

$$\delta_{Ix} = [-(\frac{L}{2} - a)\sin\alpha - l_2\sin(\varphi_2 + \alpha)]\delta_\alpha \tag{10}$$

$$\delta_{Iy} = [(3i-1)\cos\alpha + (\frac{L}{2} - a)\cos\alpha + l_2\cos(\varphi_2 + \alpha)]\delta_\alpha \tag{11}$$

The coordinate equation of W point:

$$W_y = 3iL\sin\alpha \tag{12}$$

The coordinate equation of W point can be divided into:

$$\delta_{wy} = 3iL\cos\alpha \cdot \delta_\alpha \tag{13}$$

At the point of I, the angel between virtual displacement in the direction of Y and virtual displacement in the direction of X can be marked β; At the point of J, the angel between virtual displacement in the direction of Y and virtual displacement in the direction of X can be marked Ψ.

Therefore:

$$\tan\beta = \frac{\delta_{Iy}}{\delta_{Ix}} = \frac{(3i-1)\cos\alpha + (\frac{L}{2} - a)\cos\alpha + l_2\cos(\varphi_2 + \alpha)}{-(\frac{L}{2} - a)\sin\alpha - l_2\sin(\varphi_2 + \alpha)} \tag{14}$$

$$\tan\psi = \frac{\delta_{jy}}{\delta_{jx}} = \frac{\frac{(6i-5)}{2}\cos\alpha + b\cos\alpha - l_1\cos(\varphi_1 + \alpha)}{-\frac{L}{2}\sin\alpha - b\sin\alpha + l_1\sin(\varphi_1 + \alpha)} \tag{15}$$

Virtual work formula:

$$-P\delta_{wy} + F\sum_{i=1}^{n}\cos\beta\cdot\delta_{Iix} + F\sum_{i=1}^{n}\sin\beta\cdot\delta_{Iiy} - F\sum_{i=1}^{n}\cos\psi\cdot\delta_{jix} - F\sum_{i=1}^{n}\sin\psi\cdot\delta_{jiy} = 0 \tag{16}$$

Among them, When n = 1, stand for the case of a hydraulic cylinder promote three scissor arms;
When n = 2, stand for the case of a hydraulic cylinder promote six scissor arms;
According to the actual situation of this analytical study, take n=2.

Therefore, Virtual work formula can be changed:

$$-P\delta_{wy} + 2F\cos\beta\cdot\delta_{Ix} + 2F\sin\beta\cdot\delta_{Iy} - 2F\cos\psi\cdot\delta_{jx} - 2F\sin\psi\cdot\delta_{jy} = 0 \tag{17}$$

Simplify:

$$F = \frac{P\delta_{wy}}{2(\cos\beta\cdot\delta_{Ix} + \sin\beta\cdot\delta_{Iy} - \cos\psi\cdot\delta_{jx} - \sin\psi\cdot\delta_{jy})} \tag{18}$$

Substitute all the expressions:

$$F = \frac{6PL\cos\alpha}{2\left\{-\cos\beta[(\frac{L}{2} - a)\sin\alpha + l_2\sin(\varphi_2 + \alpha)]\right\} + \sin\beta\sum_{i=1}^{2}\left[(3i-1)\cos\alpha + (\frac{L}{2} - a)\cos\alpha + l_2\cos(\varphi_2 + \alpha)\right] - 2\left\{\cos\psi[-\frac{L}{2}\sin\alpha - b\sin\alpha + l_1\sin(\varphi_1 + \alpha)]\right\} - \sin\psi\sum_{i=1}^{2}\left[\frac{(6i-5)}{2}\cos\alpha + b\cos\alpha - l_1\cos(\varphi_1 + \alpha)\right]} \tag{19}$$

Substitute related data: $\tan\beta = -22.786^\circ$

So, $\beta = 93.7225^\circ$, Similarly too, $\Psi = 95.533^\circ$

Substitute related data into 2.23, the maximum thrust F can be drawn: 34282N.

Stress analysis in hinge joint of the hydraulic scissor lift platform

Considering the analysis is the instantaneous state at the initial position of the hydraulic scissor lift platform, therefore, the problem can be simplified as a issue which solving stress analysis in a system of static equilibrium. So, scissor arm force model can be simplified correspondingly: without considering the effects of inertia force , bias load as well as the weight of the hydraulic cylinder. For this model of a hydraulic cylinder promote three scissor arms, the hinge joint most bottom scissor arm has the maximum force. So the calculation should start from the very next level. If it meets the requirements of the stability and rigidity of other strengths, the other layers are bound to meet .As shown in Figure 2 and Figure 3.

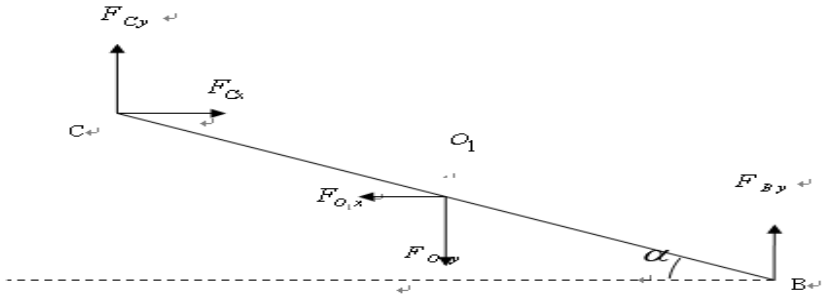

Figure 2 Force diagram of the bottom scissor arm BC

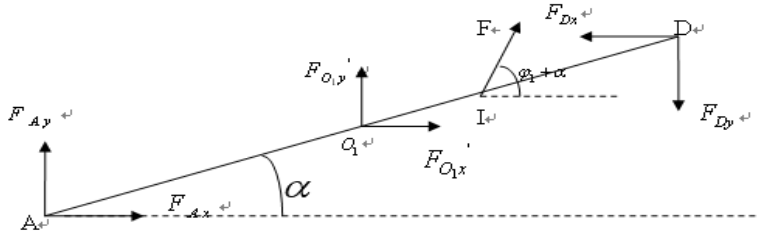

Figure 3 Force diagram of the bottom scissor arm AD

The Analysis of the Unilateral scissor arm

$$F_{Ax} = 0 \tag{20}$$

$$F_{Ay} = F_{By} = \frac{P}{2} = 7500N \tag{21}$$

The balance equation of BC

The balance equation of the direction force of X

$$F_{Cx} = F_{O_1x} \tag{22}$$

The balance equation of the direction force of Y

$$F_{Cy} + F_{By} - F_{O_1y} = 0 \tag{23}$$

Take moments of C Point

$$-F_{O_1x} \cdot CO_1 \cdot \sin\alpha - F_{O_1y} \cdot CO_1 \cdot \cos\alpha + F_{By} \cdot BC \cdot \cos\alpha = 0 \tag{24}$$

List the balance equation of AD

The balance equation of the direction force of X

$$F_{O_1x} + F\cos(\varphi_1 + \alpha) - F_{Dx} = 0 \tag{25}$$

The balance equation of the direction force of Y

$$F_{Ay} + F_{O'_1y} + F\sin(\varphi_1 + \alpha) - F_{Dy} = 0 \tag{26}$$

Take moments of O_1 Point

$$\begin{aligned} &-F_{Ay} \cdot AO_1 \cdot \cos\alpha - F\cos\alpha(\varphi_1 + \alpha) \cdot O_1I \cdot \sin\alpha \\ &+F\sin(\varphi_1 + \alpha) \cdot O_1I \cdot \cos\alpha + F_{Dx} \cdot DO_1 \cdot \sin\alpha - F_{Dy} \cdot DO_1 \cdot \cos\alpha = 0 \end{aligned} \tag{27}$$

Solve equations（20-27） can be obtained:

$F_{Dy} = 14591N$, $F_{Dx} = 32425N$, $F_{O_1x} = 7353N$, $F_{O_1y} = -16289N$, $F_{Cx} = 7353N$, $F_{Cy} = 23789N$

Stability analysis on the hydraulic cylinder piston of the hydraulic scissor lift platform

According to the hydraulic cylinder stroke and the actual working conditions and other conditions, the model chosen in this paper is CDL1MP5: AL- 40-125mm; Material is 45 steel; Piston rod diameter d=70mm;Piston rod length l=1132mm; Hydraulic cylinder length 1089mm;

Maximum force $F_{max} = 13.413KN$; Elastic modulus $E = 210GPa$; Proportional limit $\sigma_p = 280MPa$; Yield limit $\sigma_s = 350MPa$.

Calculate flexibility. Piston rod can be simplified into a rod which one end is fixed and the other is hinged, so the length factor $\mu = 2$.

Because the piston rod cross-section is circular, so

$$i = \sqrt{\frac{I}{A}} = \frac{d}{4} \tag{28}$$

Therefore the flexibility

$$\lambda = \frac{\mu l}{i} = \frac{\mu l}{\frac{d}{4}} = 129 \tag{29}$$

Among them, l——Piston rod length

D——Piston rod diameter

λ——flexibility

According to $\lambda_p = \sqrt{\frac{\pi^2 E}{\sigma_p}}$, Critical flexibility can be drawn $\lambda_p = 86$

$\lambda \geq \lambda_p$

Therefore Piston rod is greater flexibility piston rod, so the Euler formula can be used,

Calculation the critical force:

$$\sigma_{cr} = \frac{\pi^2 E}{\lambda^2} = \frac{\pi^2 \left(210 \times 10^9\right) Pa}{129^2} 1.244 \times 10^8 Pa \tag{30}$$

Critical load is:

$$F_{cr} = \sigma_{cr} \frac{\pi^2 d^2}{4} = \sigma_{cr} \frac{\pi^2 \left(70 \times 10^{-3} m\right)^2}{4} = 4.7859 \times 10^4 N \tag{31}$$

$F_{cr} = 4.7859 \times 10^4 N \geq 34282$

So the stability of the piston rod to meet requirements, which guarantees the stability of the lifting platform movement to some extent

Conclusion: SJPT10-8 types of hydraulic lift platform of maximum thrust of 34282 n, and SJPT10-8 types of materials also can meet the demand of application.

Keywords: diesel engine; fuel common rail; feedforward; rail pressure control.

Abstract. Wartsila RT- flex 60C diesel engine is selected as the object to research pressure control of fuel common rail system, building the system simulation model, and analyzing main factors influencing rail pressure in the system. it was concluded that they were diesel engine speed, load. In the process of MATLAB/Simulink simulation, the rail pressure control logic was designed by adopting maps with the two factors as independent variables to get theory feedforward quantity of fuel rack, feedback quantity of fuel rack is obtained by fuzzy PID control. The simulation experiments show that the improved control method reduces the rail pressure fluctuation, at the same time the overshoot volume of dynamic rail pressure control is greatly reduced, response velocity quickened. The control method has been used in a Marine simulator.

Introduction

Fuel common rail system controls the quantity of fuel injection, injection timing by using the way electronic control, makes the operation more flexible and accurate, becomes more and more popular in Marine diesel engine. Fuel rail pressure has a direct impact on injection timing, injection quantity.

Paper [1] established the steady-state simulation rail pressure, does not do dynamic simulation; Paper [2] established a dynamic simulation of marine fuel common rail pressure, but used the traditional PID control; Paper [3] established a control strategy that improve the fuel system of rail pressure, but the application object is car, therefore, it is necessary to make the further research of the Marine diesel engine fuel common rail pressure control [3].

The easiest way to adjust the rail pressure is that calculated directly the oil pump rack value with the rail pressure as input by the PID algorithm, it's just the feedback control, belong to the lag operation, it is difficult to avoid the overshoot, the control effect is limited, only rely on feedback lag operation, due to the marine diesel engine models and inertia very large. Marine fuel rail system specification stated that the rail pressure is regulated directly by the amount of fuel supply pump, making the amount of oil supply as another consideration, adopting the method of feedforward and feedback, the experiment proved to improve the response speed and accuracy of the rail pressure control. The specific calculation diagram is shown in Fig.1.

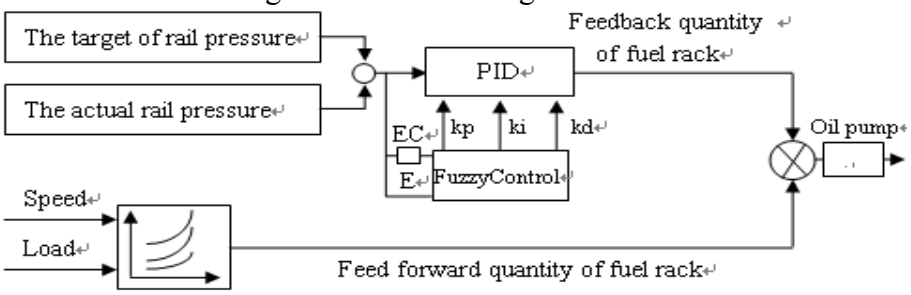

Fig.1. The control method of rail pressure

In this control method, got the real-time theory feedforward quantity of fuel rack with the speed and load as the feedforward input by the interpolation algorithm and look-up the MAP figure was produced by the bench experimental data was provided by the diesel engine manufacturers . In the feedback control, got feedback fuel rack with the rail pressure as input by the fuzzy control and adjusting the PID control parameters real-timely,. The more accurate the amount of feedforward rack

is, the smaller the amount of feedback rack would be, so as to achieve the control effect with faster and less overshoot. Finally, compare the control effect of the traditional PID control method with this article's the rail pressure control method by simulation experiments.

Fuel common rail system model of the RT-flex60C

Fuel common rail system of Marine diesel engine mainly consists of fuel pump, fuel rail, injectors, ECU electronic control unit and a variety of sensors, etc. From the control point of view, the key of the system is ECU electronic control unit which controls the oil supply of high-pressure fuel pump and the switch of fuel injector solenoid, so as to achieve these two critical control function that the fuel rail pressure and the width of fuel injection pulse.

Fuel rail system of diesel engine established mathematical model of the components according to the fluid mechanics and Newton's second law. In order to calculate conveniently, made the following assumptions during the modeling process the system: (1) the local loss of import and export are negligible, does not consider the system leakage; (2) does not consider friction resistance; (3) servo track the instantaneous equilibrium state and throughout the state are equal; (4) the system maintains a constant temperature liquid flow, and do the incompressible unsteady flow.

Model of the fuel injection system. Fuel injection system consists of rail valve, injection solenoid valve, injector and injection control unit ICU, etc. ICU control the fuel injector system, the 60-90Mpa fuel of fuel common rail is injected into the combustion chamber with the best injection timing, injection pulse-width. The quantity of fuel injection is related to the fuel common rail pressure and injection pulse-width. Their relationship is given as follows:

$$Q_p = \eta T_{WV} \sqrt{P_g} \tag{1}$$

In Eq. (1), Q_p denotes the fuel injection quantity; η denotes the constant of injection; T_{WV} denotes injection pulse-width; P_g denotes the common rail pressure.

The constant of injection η is a constant value from this formula; T_{WV} is related to the load, the greater the load is, the larger fuel injection pulse width is at the rail pressure under certain circumstances.

Model of the fuel rail pressure. A certain container, the amount of the liquid into the container is equal to the sum of the amount of liquid compression caused by pressure changes and the amount of the liquid out the container. It can be obtained mathematical models for each subsystem of the fuel common rail, the following is fuel common rail system mathematical model:

$$\frac{dP_g}{dt} = E(Q_b - Q_p)/V \tag{2}$$

In Eq. (2), E denotes elasticity modulus; Q_b denotes the supply oil from high pressure oil pump to the fuel rail oil; V denotes the volume of common rail.

From the paper [1] $E = 11.92p + 1230$, So we can find elastic modulus is only related to the rail pressure.

$$Q_b = A\frac{dh_z}{dt} = A \bullet \omega \bullet \frac{dh_z}{d\theta} \tag{3}$$

In Eq. (3), A denotes the area of oil pump plunger; ω denotes the speed of cam shaft; h_z denotes the stroke of plunger; θ denotes the angle of camshaft turned; $\frac{dh_z}{dt}$ denotes the speed of plunger movement; Plunger area A is constant value. Plunger velocity is controlled by the cam movement speed, the cam movement speed is controlled by the crankshaft speed； the crankshaft speed is determined by diesel engine load and speed. The volume of common rail V is constant value. Therefore, by formula (1) and formula (2), the fuel injection quantity is determined by the load and rail pressure, and the rail pressure is determined by diesel engine load and speed. So that we can find the decisive factor of the fuel rail pressure is determined by diesel engine load and speed.

The control method of rail pressure

Feedforward control. By the previous analysis, the decisive factor of the fuel rail pressure is the diesel engine speed and load, so get the real-time theory fuel rack values by look-up table with the two factors as input by interpolation algorithm and the MAP figure produced by the bench experimental data was provide by the diesel engine manufacturers.

Feedback control. Get quickly theoretical amount of fuel rack by feedforward control, but due to the intelligent diesel common rail system is very complicated, there is a certain rail pressure fluctuations, so that the control is fast and less overshoot to fine-tune the fuel rack by fuzzy control.

Fuzzy control adopts 2 × 3 Mamdani inference system, two inputs are e (system error) and ec (error rate), there outputs are three PID control parameters d_{k_p}, d_{k_i}, d_{k_d}. The change of the common rail pressure is between 0 and 90 MPa, so e and ec are in the range [0, 90], the value is 90 that it is greater than 90. Established fuzzy comprehensive domain to e, ec quantitative is {0,1,2,3,4,5,6,7,8,9} and their quantitative factor is 0.1. The domain of d_{k_p}, d_{k_i}, d_{k_d} is [0, 1]. E, ec corresponding input and output language variables and language values of d_{k_p}, d_{k_i}, d_{k_d} are Z, S, M and B four fuzzy subset, Z denotes Zero, S denotes Small, M denotes Medium, B denotes Big.

In this system, the membership functions of the variables are the triangular membership function. Output adopts the maximum membership degree method. PID parameters can be achieved self-tuning and the regulation characteristics of the system are improved. Adjustment may be expressed as:

$$K_p = K_p(0) + P_{K_p} \times d_{K_p} \tag{4}$$

$$K_i = K_i(0) + P_{K_i} \times d_{K_i} \tag{5}$$

$$K_d = K_d(0) + P_{K_d} \times d_{K_d} \tag{6}$$

In Eq. (4), Eq. (5), Eq. (6), $K_p(0)$, $K_i(0)$, $K_d(0)$ are the initialization values of the PID parameters; d_{K_p}, d_{K_i}, d_{K_d} are the change value of the PID controller parameters; P_{K_p}, P_{K_i}, P_{K_d} respectively are quantification factor d_{K_p}, d_{K_i}, d_{K_d}.

Simulation Models

The fuel system simulation model is divided into ECU control unit and fuel common rail system unit according to RT-flex60C machine structural characteristics and working principle, establish a simulation model of each system is based on the mathematical model by Matlab / Simulink simulation software and packaged each subsystem, the total simulation model is shown in Fig.2.

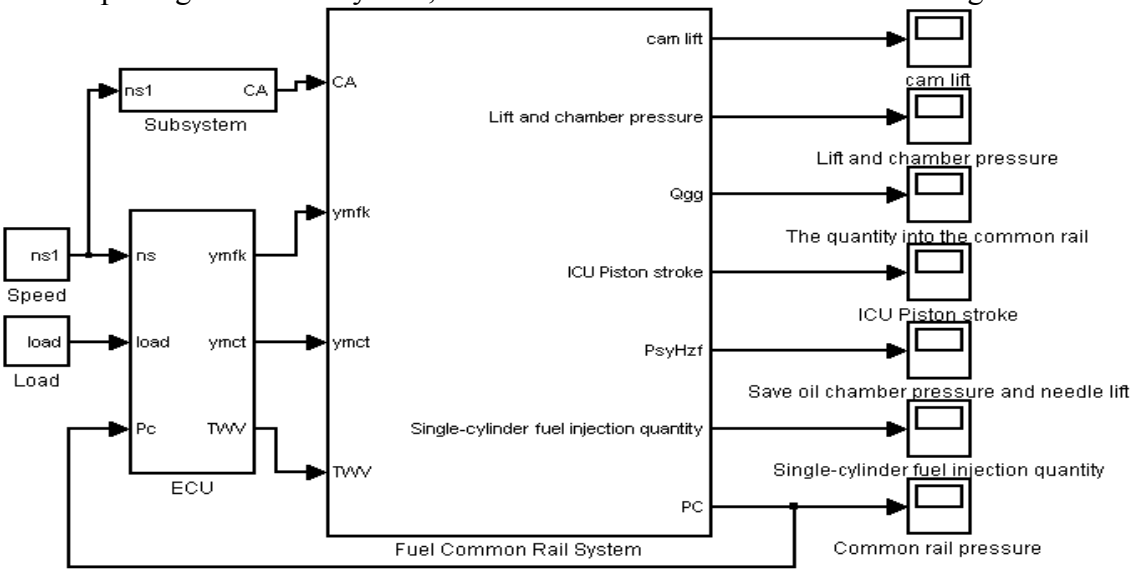

Fig.2. Common rail fuel system simulation model

Fig.3 is a package of ECU modules, included the target rail pressure look-up module, rail pressure fuzzy control module (get the fuel rack feedback value ymfk), theory of fuel rack look-up table module (ymct), fuel injection pulse-width look-up table module (TWV); the more accurate the feedforward fuel rack value is based on look-up table for diesel engine speed and load is, the smaller feedback fuel rack value is, the more stable rail pressure control would be.

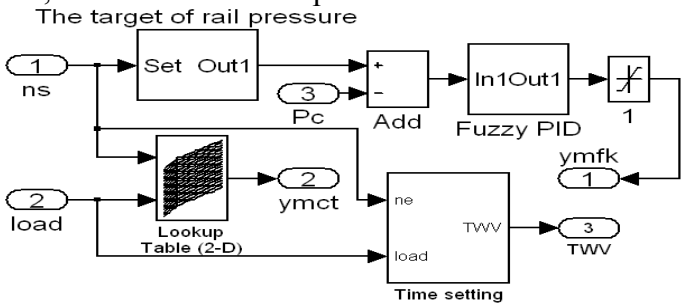

Fig.3 ECU control module

The simulation experiments and discussion

Use ode4 algorithm in MATLAB/Simulink simulation, the step length is 0.003. Common rail fuel pipe and intermediate reservoir volume are 0.5 and 0.25. The engine load is set to 99.9% and the speed is set to 114rpm at steady-state, the engine load is changed from 50% to 100% and the speed is changed from 91rpm to 114rpm at dynamic state. Respectively, do the simulation experiment by using the traditional PID control and that improved feedforward and feedback fuzzy PID control strategy. The following is the result of the experiment.

Figure 4 is the dynamic control effect contrast figure of the rail pressure that the diesel engine load and speed are changed, we can find that the response time of the rail pressure from 60 to 90 MPa is reduced and pressure to follow is faster from the improved control method; traditional PID control in rail pressure conversion has a certain overshoot, the feedback control is more precise, so overshoot is very small, rail pressure fluctuations is small, after the control is improved, getting a precise amount of pre-control by look-up table, and then optimizing the role by fuzzy PID control, so that this is very beneficial to the stable operation of diesel engine .

Fig.5 and Fig.6 are the steady-state rail pressure control, work only fuzzy PID feedback control at the steady-state. The traditional PID control rail pressure fluctuation is about 1.16 MPa that the load is 50% and the speed is 91rpm from Fig.5, but the improved rail pressure fluctuation is less than 0.11MPa. Figure 6 shows that the higher the load is, the greater the rail pressure is, the rail pressure fluctuation is increased, but it is a convergent fluctuation; Rail pressure fluctuation is less than 0.19 MPa after the control method is improved, volatility is far less than 5%, it meets the needs of actual situation.

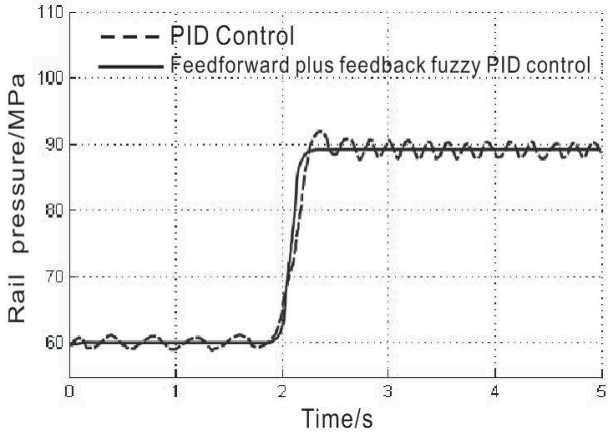

Fig.4. Dynamic simulation curve rail pressure

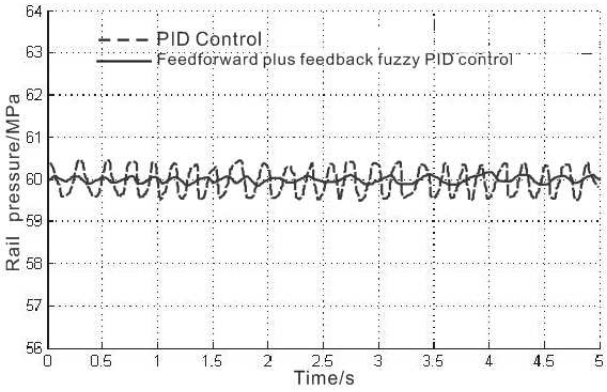

Fig.5. The rail pressure simulation curve when the load at 50% and the speed at 91 rpm

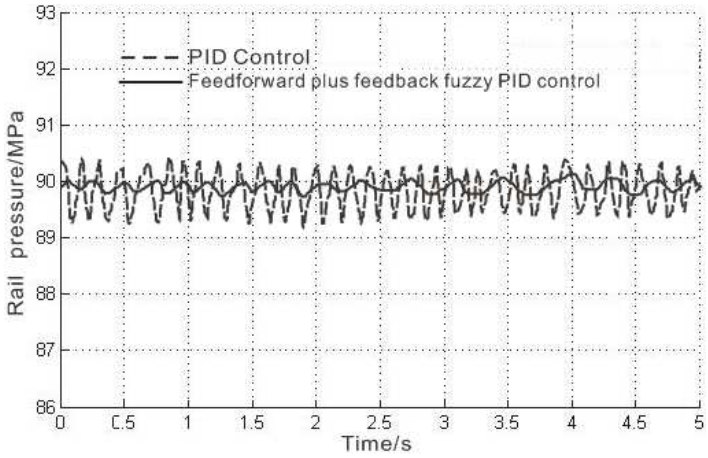

Fig.6. The rail pressure simulation curve when the load at 100% and the speed at 114 rpm

Conclusions

Fuel common rail system is an important part of intelligent Marine diesel engines, uses appropriate methods to improve its rail pressure control effect is an important reference for the independent research and development of common rail diesel engine fuel system. This article research conclusion is as follows: Established a MAP figure of feedforward fuel rack by the bench test data, feedforward fuel rack is obtained by look-up table with the engine speed and load as an input, the amount of feedback control is reduced, has greatly reduced the amount of system overshoot; makes the feedback control more precise with rail pressure as input in the feedback control by the method of fuzzy control and real-time self-tuning control parameters; the steady state rail pressure and dynamic rail pressure fluctuation are reduced and the response time is more faster by simulation experiments that the control method is improved, proved that the improved method is effectiveness.

Keywords: distributed generation (DG), distribution network, revised back/forward sweep method, power losses

Abstract. The impact of distributed generation (DG) on distribution power losses is closely related to DG technologies and load distribution. DG units are modeled as PQ, PQ(V) and PV nodes in power flow calculation. A revised back/forward power flow method is employed to calculate distribution power flow with various types of DG units. Power losses are computed when different types of DG units are connected to heavy load, general load and light load area apart. Simulation on IEEE 33-bus distribution network shows that connecting DG to heavy load area helps to maximize the loss reduction. And the installation of DG consuming reactive power will increase network losses unless reactive power compensation device is installed accordingly.

Introduction

With increasing penetration of DG connection, the distribution network power flow has changed a lot, thus changing the network losses. This is closely related to the DG technologies used and the load distribution of the DG access area [1].Several organizations in recent years have conducted research on the impact of DGs on distribution power losses. DG units are usually modeled as PQ node with constant active and reactive power output in power flow calculation [2].

However, for DGs which can't be modeled as PQ node, such as DGs with constant active power output and voltage control, and DGs with reactive power associated with output voltage, whether their impacts on power losses are similar to PQ model should be studied respectively. This paper considers the characteristics of different types of DGs, and models DG units as PQ, PQ(V) and PV node according to their constructive technology [3, 4]. Then a revised back/forward power flow method is employed to calculate distribution power losses with different kinds of DGs. Energy losses are computed and compared when different types of DG units are connected to heavy load, light load and general load area apart.

Distribution Power Flow Calculation with DGs

Traditional distribution network structure is radial or near radial. By using this feature, back/forward method is widely used in distribution power flow calculation. This algorithm includes a backward and a forward iterative processes. However, after DG units connecting to the distribution network, the original single-power supply system has changed into a multi-power supply system. The traditional back/forward method can't deal with various types of DG units [5]. Therefore, the traditional method needs to be revised for different types of DG model.

PQ node of DGs usually can be modeled as negative load and its active and reactive power are equal to the DG but have an opposite flow direction. Therefore, the current flow of the DG can be expressed as follows:

$$\dot{I} = [(-P - jQ)/(e + jf)]^{*}. \quad (1)$$

where e is the real part of the DG output voltage, f the imagine part of the DG output voltage, P the DG active power output, and Q is the DG reactive power output.

For some DGs with asynchronous generators, the active power is known and the reactive power is calculated as a function of the port voltage of the generators. This kind of DGs can be modeled as PQ(V) node in power flow calculation. The simplified model shown in Fig. 1 is assumed [6].

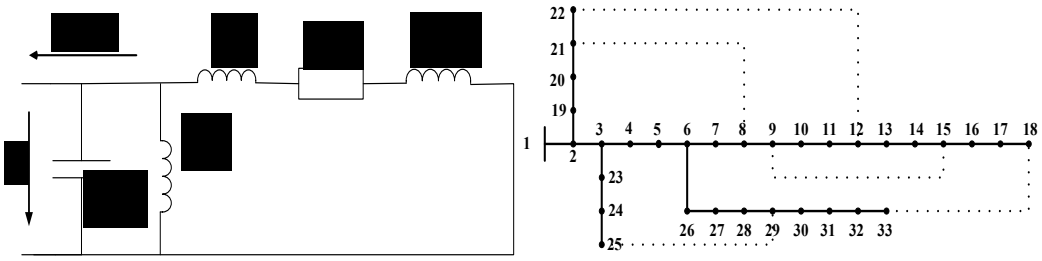

Fig. 1 Simplified model of asynchronous generator Fig. 2 IEEE 33 nodes test system

In Fig. 1, x_m represents the excitation reactance, x_1 the leakage reactance of stator, x_2 the leakage reactance of rotator, x_c the shunt capacitor reactance of DG port, R_2 the rotator resistance, and s is the slip rate of the generator. The stator resistance is ignored in this model.

According to Fig. 1, the injected reactive power of the asynchronous generator Q is described as a function of DG port voltage V:

$$Q = -\frac{V^2}{x_P} + \frac{-V^2+\sqrt{V^4-4P^2x^2}}{2x}. \tag{2}$$

where V is port voltage of DG, $x = x_1 + x_2$ and $x_P = \frac{x_c x_m}{x_c - x_m}$.

For DGs which take synchronous generator with the ability of excitation control as interface, there are generally two ways to control the excitation of the generator. They are voltage control and power factor control [7, 8]. DGs with voltage control can be treated as PV node while DGs with power factor control can be treated directly as PQ node in power flow calculation. However, for DGs which take synchronous generator without excitation as interface, they are modeled as PQ(V) nodes, and they need some special handling in power flow calculation. Consider a non-salient pole synchronous generator, the power output is expressed as follows:

$$P = \frac{E_{DGq}V}{X_d} sin\delta. \tag{3}$$

$$Q = \frac{E_{DGq}V}{X_d} \cos\delta - \frac{V^2}{X_d}. \tag{4}$$

where X_d represents the synchronous reactance, δ power angle, and E_{DGq} is no-load electromotive force of DG.

In power flow calculation, the output active power of DG is known. Therefore, the reactive power Q is described as a function of DG port voltage V:

$$Q = \sqrt{(\frac{E_{DGq}V}{X_d})^2 - P^2} - \frac{V^2}{X_d}. \tag{5}$$

Eq. 5 and Eq. 2 have similarities, but the reactive power Q in Eq. 2 is negative while in Eq. 5 is positive. This means that the asynchronous generator actually consumes reactive power.

When dealing with PQ(V) node in power flow calculation, the node voltage is amended after each iteration, and DG reactive power is computed based on this new voltage magnitude. Thus, in the first iteration, PQ(V) node is temporarily converted by Eq. 2 or Eq. 5 to PQ node in order to use

classical back/forward sweep algorithm. Then use Eq. 1 to simulate the DG node as injected current for power flow calculation. In the second iteration, the reactive power is computed based on the amended voltage. In this step, PQ(V) node is converted to PQ node again, and the reactive power is different from the last iteration. This iteration process is repeated until it converged.

For PV node, in order to guarantee the voltage magnitude and the active power unchanged in each iteration, a voltage source is introduced to inject a certain amount of current to the node. With this method, the voltage magnitude of PV node is set to the given value V'_{PV}. The added voltage source $\Delta\dot{V}_{PV}$ can be expressed as follows:

$$\Delta\dot{V}_{PV} = V'_{PV} - \dot{V}_{\mathrm{PV}}. \tag{6}$$

Whether to compensate PV node by injecting reactive current depends on the added voltage source magnitude. If $\left|\Delta\dot{V}_{PV}\right| < \varepsilon$ (ε as the convergence precision), the voltage of PV node converges to the given voltage magnitude V'_{PV}, else if $\left|\Delta\dot{V}_{PV}\right| \geq \varepsilon$, a certain amount of current injection is needed to ensure that the PV node will converge to the given voltage value. The Injected compensation current $\Delta\dot{I}_{PV}$ can be calculated as below:

$$\Delta\dot{I}_{PV} = Z_{ii}^{-1} \times \Delta\dot{V}_{PV}. \tag{7}$$

where $\Delta\dot{I}_{PV}$ is the injected compensation current of PV node, Z_{ii} the self-impedance of PV node. If there are more than one PV node in the network, Z_{ii} represents the input impedance matrix of the network port. Specifically, the diagonal entry of Z_{ii} is the self-impedance (the sum of all the impedance from PV node to the root node) of PV nodes, and the off diagonal element of Z_{ii} is the mutual impedance (the sum of all the impedance of the common path of two PV nodes) between PV nodes.

The problem of PV reactive power out-of-limit can be solved with the traditional method. That is, in iterative process, if the reactive power of PV node is out of limit after correction, it will be converted to PQ node with reactive power set to upper limit or lower limit of the PV reactive power limits.

Impact of DGs on Power Losses

When different types of DGs are connected to distribution network, their impact on the network losses differs as the load level of connection area changes from heavy load, general load to light load. Therefore, simulation is carried out respectively in the test distribution system shown in Fig. 2. System bus voltage is set to 1.02, the base power is 1MVA, the base voltage is 10kV, and the convergence precision is set to 10^{-6}. The parameters of different kinds of DGs are illustrated in Table 1.

Table 1 Parameters of different kinds of DGs

DG type	Parameters
PQ	$P = 0.424MW$ $Q = 0.220Mvar$
PQ(V)	$P = 0.424MW$ $E_{DGq} = 10.5kV$ $x_d = 14\Omega$ $x_p = 35.6\Omega$ $x = 1.38\Omega$
PV	$P = 0.424MW$ $V = 10.2kV$

Table 2 Network power losses before and after DG connection (in per unit)

Load level / DG type	Heavy load	General load	Light Load
Without DG	1.3463	0.5176	0.2916
PQ	1.1848	0.4435	0.2490
PV	1.2187	0.4590	0.2578
PQ(V) (consume reactive power)	1.5879	0.5633	0.3132
PQ(V) (produce reactive power)	0.8948	0.4024	0.2597

Assume that in the IEEE 33 nodes system shown in Fig. 2, heavy load, general load and light load is connected to node 11 to 18 separately. In these three load level, different types of DGs are connected to node 17. Network power losses are calculated before and after DG connection. The simulation result is shown in Table 2.

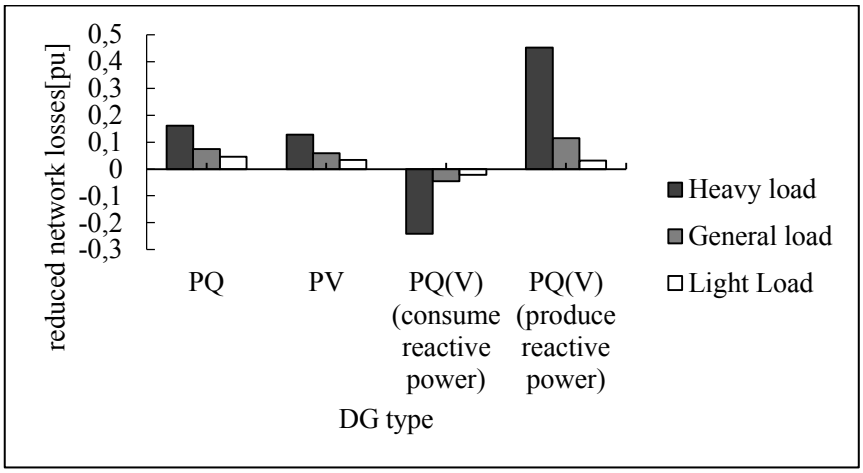

Fig. 3 Reduced network losses after DG connection

The network losses have been reduced after DG connection except PQ(V) type DG with reactive power consumption. The reduced network losses after DG connection are computed and plotted in Fig. 3. Negative value means that the network loss is actually increased after DG connection.

The result shows that the impact of DGs on distribution power losses is closely related to DG technologies and load distribution. Whatever the load level in DG connection area, the network loss can be reduced after connection of DGs with the type of PQ, PV and PQ(V) producing reactive power. However, the extent of loss reduction is closely related to the load level in connection area. Specifically, connecting DGs to heavy load area has the maximum loss reduction, then general load area, and connecting DGs to light load area has the least loss reduction. For DGs consuming reactive power, compensation device should be installed sufficiently, otherwise this type of DGs will increase network losses.

Conclusions

This paper fully summarizes and analyzes the impact of different types of DGs on distribution power losses. A revised back/forward power flow method for radial distribution system with DGs has been developed. Losses were computed and compared when different types of DG units were connected to heavy load, light load and general load area apart. Simulation result shows that connecting DG to heavy load area helps to maximize the loss reduction. And connection of DGs consuming reactive power will increase network losses unless reactive power compensation device is installed.

Keywords: Electricity competitiveness, evaluation, PCA, compatibility degree

Abstract. This paper constructs the evaluation index system of electricity competitiveness in terminal energy consumption, evaluates the electricity competitiveness in Ningxia region from 2005 to 2011 using principal component analysis (PCA), and compares the evaluation results of PCA, the linear weighted method, the comprehensive index method and TOPSIS-grey correlation method. The compatibility degree and difference degree of each method are analyzed and calculated to verify the applicability of the PCA. The results show that PCA is the most scientific and appropriate evaluation method.

Introduction

By analyzing and evaluating the electricity competitiveness in terminal energy consumption, we not only can understand and grasp the competitive situation of electricity, will also be able to find the influence factors of electricity competitiveness and provide reference for the design of corresponding improvement strategy. How to evaluate the electricity competitiveness in terminal energy consumption more scientific and reasonable needs to be solved.

Throughout the research of the domestic and foreign scholars, the research on the competitiveness of power enterprise and competitiveness of energy is much more than the research of electricity competitiveness. Literature[1] uses the value chain to analyze the competitiveness factors of power generation enterprise. Literatures[2] evaluates the competitiveness of power supply enterprise by the entropy weight method. Considering the cost of long-term production, policy support and the cost of external factors, Georg Caspary assesses the likely competitiveness of different forms of renewable energy in Colombia over the next 25years. Scholars Fan Zhongqi analyses the competitiveness of China's coal industry with porter's diamond model[3]. Literature [4] evaluates and analyzes the competitiveness of Beijing's terminal energy price. Literature [5] analyzes the changes of energy consumption structure from the perspective of time. Literatures[6] builds the evaluation index system of power competitiveness in terminal energy consumption, providing a great help for the construction of index system in this paper.

Principal component analysis (PCA) is an effective multivariate statistical comprehensive evaluation methods, it can "regather" the data indicators through the linear transformation under the premise of information loss as little as possible. It gives up a small part of information at the same time to get the multidimensional index data well simplified. In addition, the PCA can effectively avoid the influence of human factors in the process of index weight determining and eliminate relevant effects between the index data. This paper evaluates the electricity competitiveness in Ningxia region from 2005 to 2011 with PCA. In order to verify the applicability of the method, this paper compares the evaluation results of PCA, the linear weighted method, the comprehensive index method and TOPSIS-grey correlation method. Finally, the compatibility degree and difference degree of each method are

analyzed and calculated to compare the pros and cons of each evaluation method. The results show that PCA is the most scientific and appropriate evaluation method.

The construction and pretreatment of the evaluation index

In order to reflect the changes of electricity competitiveness in terminal energy consumption in Ningxia region, describe and evaluate its variations objectively, this paper combines with their own situation and characteristics of Ningxia region, and constructs the evaluation index system of electricity competitiveness in terminal energy consumption as shown in Table 1.

Table 1 The evaluation index system of electricity competitiveness in terminal energy consumption

The evaluation target	The evaluation factors A	The child evaluation factors B	The evaluation index C
Electricity competitiveness in terminal energy consumption	The ability to occupy electricity market (A_1)	Terminal electricity consumption (B_{11})	Terminal electricity consumption of the whole society (C_{111})
			Terminal electricity consumption of the energy-intensive industries (C_{112})
			Terminal electricity consumption of residents living (C_{113})
		Terminal electricity consumption growth rate (B_{12})	Terminal electricity consumption growth rate of the whole society (C_{121})
			Terminal electricity consumption growth rate of the energy-intensive industries (C_{122})
			Terminal electricity consumption growth rate of residents living (C_{123})
		The proportion of electricity in terminal energy (B_{13})	The proportion of electricity in terminal energy consumption (C_{131})
			The proportion of electricity in energy-intensive industries (C_{132})
			The proportion of electricity in residents living (C_{133})
	Electricity products (A_2)	Electricity products quality (B_{21})	Supply voltage qualification rate (C_{211})
			Power supply reliability rate (C_{212})
			The proportion of new energy access (C_{213})
		Electricity products price (B_{22})	Average residents tariff (C_{221})
			Large industrial tariff (C_{222})
	The ability of power supply	The operation and management (B_{31})	The population of power supply (C_{311})
			Annual peak load (C_{312})

The evaluation target	The evaluation factors A	The child evaluation factors B	The evaluation index C
	enterprise (A_3)		Line loss rate (C_{313})
		Demand side management (B_{32})	The proportion of users performing TOU (C_{321})
	The competitive environment (A_4)	Level of economic development (B_{41})	GDP (C_{411})
			Per capita GDP (C_{412})
			The proportion of second industry output value in output value (C_{413})
			The proportion of tertiary industry output value in output value (C_{414})
		Level of social development (B_{42})	Per capita disposable income of urban residents (C_{421})
			Per capita net income of rural residents (C_{422})
			Urbanization rate (C_{423})
		Level of technological development (B_{43})	The proportion of R&D expenditure in GDP (C_{431})

Principal component analysis

2.1 The basic theory of principal component analysis

The basic principle of principal component analysis is that transforming the correlation matrix internal structure of the original index variable to converting many indexes into a handful of independent comprehensive index, namely the principal components, selecting a few principal components, constructing the comprehensive evaluation function with each variance contribution rates of the principal component as the weight, and. In this paper, the higher the score of synthetic evaluation function, the electricity competitiveness in terminal energy consumption of the corresponding year is better.

The basic steps of PCA：

(1)According to the specific index system, collect original data. The original data matrix can be

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ x_{m1} & x_{m2} & \cdots & x_{mn} \end{bmatrix}$$

Where, m is the number of years, n is the index number of index system, x_{ij}(i=1,2,…m; j=1,2,…,n) is the value of index j in i year.

(2) Process the original data to be consistent and dimensionless.

(3) Calculate the correlation matrix $R = (r_{ij})_{m \times n}$, r_{ij} is the correlation coefficient between index i and index j.

(4)Calculate the characteristic root and characteristic vectors of the correlation coefficient matrix, and order $\lambda_1 \geq \lambda_2 \geq ... \geq \lambda_n$. Characteristic value is the variance of the main component, reflecting the role of the various principal components playing in the description of the evaluation object.

(5)Calculate the variance contribution rate of each principal component.

$$\alpha_i = \frac{\lambda_i}{\sum_{i=1}^{n} \lambda_i} \quad (1)$$

(6)Select the principal component. Generally, the principal component of which characteristic root is greater than 1 will be taken. The principal component is a linear combination of the original index. The coefficients of the index are different and there are positive and negative. The absolute value of coefficient reflects the contribution of the principal component making to the property. If several variable coefficients are almost the same, the main component can be regarded as a combination of these indicators' characteristics.

(7)Calculate composite scores. With the contribution rate of each principal component as the weight, weighted average the main constituents.

2.2 Case study

In this paper, the hierarchy of index system is so many that the evaluation elements need to be layered when evaluating. Several principal components will be selected in each layer to participate in evaluation. In the end, the comprehensive score of each layer will be linear weighted to get the final total score which represents the electricity competitiveness in terminal energy consumption.

The scores of each evaluation factor and comprehensive evaluation value are shown in table 2. The ranking of electricity competitiveness in terminal energy consumption of Ningxia is: 2011>2010>2009>2008>2007>2006>2005, indicating that the electricity competitiveness in Ningxia region increases steadily year by year.

Table 2 Each evaluation factor's score and comprehensive evaluation value

Year	A_1	A_2	A_3	A_4	Comprehensive evaluation value	Ranking
2005	0.054	0.045	0.122	0.080	0.300	7
2006	0.066	0.036	0.132	0.085	0.319	6
2007	0.070	0.024	0.141	0.096	0.331	5
2008	0.065	0.025	0.144	0.113	0.347	4
2009	0.074	0.020	0.149	0.122	0.365	3
2010	0.099	0.019	0.156	0.140	0.415	2
2011	0.127	0.016	0.173	0.161	0.478	1

The change trend of each factor score can be visually seen from Fig. 1. The score of A_1 decreases first, and then increases, presenting "U" type trend. It's closely related to energy policy of Ningxia region and economic situation of the country in recent years. The score of A_2 reduces year by year. The scores of A_3 and A_4 increase year by year on the whole. As can be seen from the historical data, terminal electricity consumption of the whole society of Ningxia region continued to increase and the proportion of electricity in terminal energy consumption was growing in the past seven years. In 2006, terminal electricity consumption of the whole society increased by 23.98% from 2005, energy intensive industries terminal power consumption increased by 27.48%, and the growth was bigger compared with other years. The growth rate of terminal electricity consumption of the whole society and energy-intensive industries is not so high in 2007. In 2008, due to the global financial crisis, the growth rate of terminal power consumption was smaller and the ability of dominating the electricity market was weakened. Economy recovered gradually in 2009, and the score of A_1 increased, the ability of dominating the electricity market gradually began to recover. In 2011, the proportion of electricity in terminal energy reached 31.18%, reached the highest level in history. And it is the result of continuously adjustment the industrial structure and the transforming the mode of energy-using in Ningxia region. Also, it's reflecting that the achievement of energy policy in Ningxia region is significant. A_2 index declines, which is closely linked to the rise of electricity price in Ningxia region. It indicates the rise of electricity price has certain extent effect on electricity competitiveness in terminal energy consumption and related departments should pay attention.

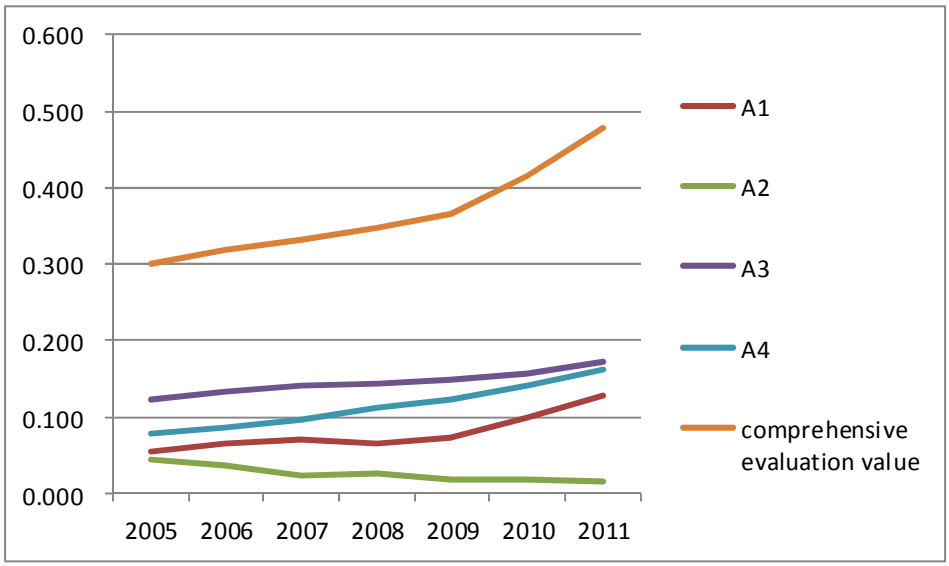

Fig. 1 Each evaluation factor's score and comprehensive evaluation value

2.3 The contrastive analysis with other algorithms

In order to verify the validity of PCA, linear weighted method, the comprehensive index method and TOPSIS-grey correlation degree are also used to evaluate the electricity competitiveness for the comparative analysis in this paper. The specific results of all the methods are shown in table 3. The results show that the ranking of different evaluation methods are various, but on the whole, the electricity competitiveness of Ningxia region presents growing trend.

Table 3 Ranking of each evaluation method

Year	Linear weighted method	Comprehensive index method	TOPSIS-grey correlation method	PCA
2005	7	7	7	7
2006	6	4	6	6
2007	4	3	4	5
2008	5	6	3	4
2009	3	5	5	3
2010	2	2	1	2
2011	1	1	2	1

Next, the compatibility degree and difference degree will be used to analyze the superiority and inferiority of each evaluation method.

Let $h+1$ be the number of evaluation methods and n be the number of years. The rank correlation coefficient of evaluation method i and evaluation method j can be calculated as follows, which reflects the related degree between them.

$$r_{ij} = 1 - \frac{6}{n(n^2-1)} \sum_{k=1}^{n} (a_k^{(i)} - a_k^{(j)})^2 \quad (i, j = 1, 2, \cdots, h+1) \tag{2}$$

Where, $\{a_k^{(i)}\}$, $\{a_k^{(j)}\}$ are respectively the year k' ranking of evaluation method i and evaluation method j.

The compatibility degree of a certain evaluation method refers to the weighted average of the rank correlation coefficient of the other evaluation methods. Therefore, the compatibility degree of a certain evaluation method $y = \{y_k\}$ with other methods can be calculated as follows.

$$r_y = \sum_{j=1}^{h} w_j r_{yj} \tag{3}$$

Where, $\sum_{j=1}^{h} w_j = 1$, $w_j > 0$ is the weight of evaluation method j which is usually $\frac{1}{h}$. Obviously, if each evaluation method is independent, the greater the compatibility degree is, the more representative the evaluation method is. The smaller the difference degree is, the better the evaluation method is.
From table 4, we can see that the compatibility degree of PCA is the biggest, and its different degree is the smallest. So the ranking of PCA is the most reasonable and scientific. Therefore, the PCA has strong applicability on the evaluation of electricity competitiveness.

Table 4 The compatibility degree and difference degree of each method

Evaluation method	Compatibility degree	Ranking	Difference degree	Ranking	Comprehensive ranking
Linear weighted method	0.845	2	0.419	2	2
Comprehensive index method	0.75	4	0.635	3	3.5
TOPSIS-grey correlation method	0.798	3	0.676	4	3.5
PCA	0.869	1	0.394	1	1

Summary

(1)This paper constructs the evaluation index system of electricity competitiveness in terminal energy consumption. And the principal component analysis is used to evaluate the electricity competitiveness in Ningxia region from 2005 to 2011. The evaluation results show that the rise of electricity price has a significant impact on the electricity competitiveness. In addition, the electricity competitiveness in Ningxia region increases steadily year by year and it reached the highest level in history in 2011. In a word, the electricity competitiveness in Ningxia region has great potential growth space in the future.
(2)This paper compares and analyzes the evaluation results of PCA, the linear weighted method, the comprehensive index method and TOPSIS-grey correlation method. And the applicability of the PCA is verified through the calculation of compatibility degree and difference degree of each method. The results show that PCA is the most scientific and appropriate evaluation method.

Keywords: pumped storage, fuzzy, entropy weight method, comprehensive evaluation,capacity

Abstract: To determine the pumped storage capacity is a comprehensive decision-making problem. This paper presents the entropy weight method to decide the weight in fuzzy comprehensive evaluation. Example analysis shows the effectiveness of the proposed methods.

Introduction

Pumped storage(P-S) is today viewed as the most suitable technology for accepting large amount wind power and meeting the peak load in power system[1-4]. However, how much P-S should be installed is worth to discuss[5].

In the past the optimum P-S capacity is often determined by individual factors, such as unit operating cost, power shortage time probability[6], peak-regulation proportion[7], wind and nuclear power capacity[8], generator utilization hours, etc.

To determine the P-S capacity is a comprehensive decision-making problem, at present the main methods are analytic hierarchy process(AHP)[9], fuzzy comprehensive evaluation and principal component analysis(PCA)[10]. The index weights are dependent on experts judgment in AHP, which is highly subjective and contingent. Athough PCA does not require subjective judgment, but it is based on the evaluation dimension reduction, using the cumulative variance contribution rate of more than 75% of the main ingredients to replace the original target, easy to lose the original information.

In this article, the entropy weight method is led into fuzzy comprehensive evaluation, such that the weights can be determined objectively[11,12]. Finally, case studies validated the correctness and rationality of the proposed method.

Pumped-storage capacity evaluation indexes

The benefits of P-S station can be divided into static and dynamic benefit[13-15], such as capacity benefit, peak-valley regulation, coal saving benefit, environmental benefit, spare capacity, frequency and phase modulation, load tracking and black start, etc. To simplify the analysis, here we select a few representative evaluation indexes:

2.1 Capacity benefit

P-S capacity benefit refers to equivalent thermal power capacity which can be replaced by P-S. The installed P-S capacity is not the more the better, too much P-S capacity will lead to waste. The equivalent coefficient of thermal will declined when the P-S capacity is over the demand capacity.

2.2 Coal saving benefit

Coal saving benefit refers to the difference of coal consumption in the case of P-S is involved in running and not running. Due to P-S can improved thermal units operation mode, the system's coal consumption rate will dropped. However, the P-S should be maintained the proper capacity, rather than the bigger the better.

2.3 LOLP

LOLP (Loss of Load Probability) is insufficient power load probability, it means that power generation system margin is less than zero probability in the system. The smaller value of LOLP, the higher reliability of power system.

$$LOLP = P(X \geq C_s - L) \tag{1}$$

where: X refers to system outage capacity; C_s is system installed capacity; L is the daily maximum load.

2.4 Peak-regulation proportion

System peak-regulation proportion is the ratio between adjustable units capacity and total system capacity. Assuming that all P-S capacity are in full use, and P-S unit can generate at rated full output.

$$R_G = \frac{P_{\max} - P_{\min} - 2P_{P-S}}{P_N} \times 100\% \tag{2}$$

where: R_G is the system peak-regulation proportion; P_{max} is maximum output of all units and P_{min} is minimum; P_N is all units rated output; $P_{P\text{-}S}$ is the required P-S capacity.

Only peak-valley difference accounted for the proportion of maximum load is less than or equal to the system peak-regulation proportion that the system's peak contradiction can be resolved.

Fuzzy comprehensive evaluation introduction

Establishing evaluation factors set $U=\{u_1, u_2, ..., u_n\}$, here it refers to the considerations to determin the optimal capacity of P-S, these factors are used to evaluate objects. Then establishing judgment set $V=\{v_1, v_2, \ldots, v_n\}$, here it refers to the various plans of P-S capacity. Finally, establishing a judgment matrix from U to $F(V)$ of fuzzy mapping.

$$f : U \to F(V), \forall u_i \in U$$

$$u_i \mapsto f(u_i) = \frac{r_{i1}}{v_1} + \frac{r_{i2}}{v_2} + \cdots + \frac{r_{im}}{v_m} \qquad 0 \leq r_{ij} \leq 1, 1 \leq i \leq n, 1 \leq j \leq m \tag{3}$$

The fuzzy matrix R can be induced by fuzzy relations , it is named as single factor judgment matrix, then a comprehensive evaluation model (U, V, R) is formed.

$$R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1m} \\ r_{21} & r_{22} & \cdots & r_{2m} \\ \cdots & \cdots & \cdots & \cdots \\ r_{n1} & r_{n2} & \cdots & r_{nm} \end{bmatrix} \tag{4}$$

the ith indicator entropy is defined as

$$H_i = -k \sum_{j=1}^{n} f_{ij} \ln f_{ij} \qquad (i = 1,2,...,n) \tag{5}$$

where: $f_{ij} = r_{ij} \Big/ \sum_{j=1}^{m} r_{ij}$, assume that when $f_{ij} = 0$, then $f_{ij} \ln f_{ij} = 0$; $k = 1/\ln m$.

The index weight set $A=\{a_1, a_2, ..., a_n\}$, where the entropy weight is

$$a_i = (1 - H_i) \Big/ (n - \sum_{i=1}^{n} H_i) \tag{6}$$

Take the vector A as the weight vector which reflects the various indicators' role in the decision-making process. Here, A is multiplied with the fuzzy matrix R to get the global evaluation vector $B = A \circ R$, which are the values of synthesis-evaluation scores.

$$b_j = \bigvee_{i=1}^{n}(a_i \wedge r_{ij}) \qquad j = 1,2,\cdots, \ m \tag{7}$$

According to the principles of maximum membership degree, that the maximum of B is the final result[16].

Example analysis

This paper takes the system in [17] as examples for analysis. Here we formed 5 P-S capacity plans, they are 400MW, 800MW, 1200MW, 1600MW, 2000MW. When different P-S are put into the system, the parameters are shown in Tab.1 and degrees table are shown in Tab.2 respectively. Where C_T is alternative capacity coefficient, F_C refers to the system annual coal consumption, S_C is the saving coal, R_G refers to the peak-regulation proportion.

Tab.1 The parameters corresponding to different pumped storage capacity

plan	P-S(MW)	C_T	F_C (10^4t)	S_C(10^4t)	R_G(%)	LOLP(h/y)
1	400	1.1	3029.38	29.62	34	6
2	800	1.0775	3012.35	47.9	38	5
3	1200	1.0617	3011.02	48.64	42	5
4	1600	1.0281	3014.98	45.26	46	5.5
5	2000	1.013	3019.65	40.54	50	8

Tab.2 Close to the degrees table of each index

plan	C_T	F_C	S_C	R_G	LOLP
1	1	0.9939	0.609	0.68	0.833
2	0.9795	0.9996	0.9848	0.76	1
3	0.9652	1	1	0.84	1
4	0.9346	0.9987	0.9305	0.92	0.909
5	0.9209	0.9971	0.8335	1	0.625

The evaluation set V={400,800,1200,1600,2000}, factor set U={ C_T , F_C , S_C , R_G ,LOLP}, experts evaluation matrix

$$R = \begin{bmatrix} 0.1 & 0.3 & 0.3 & 0.2 & 0.1 \\ 0.1 & 0.3 & 0.3 & 0.2 & 0.1 \\ 0.1 & 0.3 & 0.3 & 0.2 & 0.1 \\ 0.1 & 0.15 & 0.2 & 0.25 & 0.3 \\ 0.1 & 0.25 & 0.35 & 0.2 & 0.1 \end{bmatrix}$$

the weight matrix is A=(0.0127,0.0042,0.3856,0.2415,0.3559), B =(0.1,0.3,0.35,0.2415,0.2415).

The maximum value of option 3 is the best solution, that is, the system should be installed 1200MW P-S capacity. The result is consistent with literature[17], which shows that the approach is successful.

Conclusion

To determine the P-S capacity is a multi-index comprehensive evaluation problem. The entropy weight method is introduced into the fuzzy comprehensive evaluation to determine the index weights,

which can effectively avoid the influence of subjective factors in evaluation process. Example analysis proves that the method is feasible and practical.

Keywords: Thermal Power Plant, Security Management Capability, ISM, AHP

Abstract. This paper sets the thermal power plant security management system as the research object. First of all, with the application of the Interpretative Structural Modeling (ISM), we establish a multi-level hierarchical structure model on analysis of the influencing factors of thermal power plant security management. Furthermore, based on the structure model, we use the Analytic Hierarchy Process (AHP) to determine weights of all the influencing factors, in order to identify the main factors. Finally, according to the identified main factors, we provide several suggestions for security management of thermal power plant.

Introduction

The thermal power plant is one of the most basic entities in electric power industry, and the security of production is not only the most urgent requirement in the production process but also a prerequisite to ensure safe and stable operation of the power grid. Thus, for thermal power plants we need to stir our concern about the factors that affect security management capability, and explore the power plant's control force of its organizational structure and production security systems. Only in this way can we formulate targeted improvement measures for system's weaknesses and fundamentally avoid blindness management and traditional experience management. Ultimately, we can improve the security management level. Liu Tiezhong etc. [1,2] put forward that the so-called enterprise security management capability is one knowledge-accumulating collection of security management process with the factors including "employee ", " equipment ", " environment", " system" , and it's also the ability formed during the process of security management. Enterprise security management capability is the decisive force to the security management level, and ultimately manifests the performance of security production condition. Security management capability is the comprehensive result of numerous factors, the complex relationship between which will lead to the vague security management system structure. Based on the above understanding and aiming at the characteristics of enterprise security management capabilities, we use the Interpretative Structural Modeling(ISM) to establish interpretation chart for the influencing factors of security management combined with the actual situation of thermal power plant security management. Then we use Analytic Hierarchy Process (AHP) to analyze and identify the main factors and their weights to provide reference for thermal power plants implementing effective and targeted management.

1 Impact analysis of thermal power plant security management

1.1 Analysis of influencing factors

Liu Tiezhong etc. [1-2] put forward that the so-called enterprise security management capability is one knowledge-accumulating collection of security management process with the factors including "employee ", " equipment ", " environment", " system" , and it's also the ability formed during the process of security management. Luo Yun etc. [3] proposed that effective enterprise security

management is the use of human and material resources with wisdom of all staff, and through the joint efforts to achieve harmony between human and machine, equipment, technology, environmental condition during production process, finally to achieve the goal of security production. Therefore, it requires enterprise to have a thorough security management organization, systematic management means and approach and requires all levels of employees full of responsibility. Based on the reference to previous research, combining the characteristics of thermal power plants [4], we summarized that the factors that have an effect on the thermal power plant security management capability include the personnel quality, equipment status, environmental conditions and institutional conditions. Based on the above analysis, the specific security management influencing factors we conclude are shown in Table 1.

Table 1 Security Management Influencing Factors

	Influencing Factors	S_i
Personnel Quality	operation habits	S_1
	cultural knowledge and operation skills	S_2
	working attitude	S_3
Equipment Status	equipment operation specification	S_4
	maturity level of security equipment and facilities	S_5
Environmental Condition	enterprise security culture	S_6
	security working environment	S_7
Institutional Condition	emphasis of leadership	S_8
	healthiness degree of security management systems and procedures	S_9
	inspection and supervision of the department of management departments to monitor	S_{10}
	emergency disposal mechanism	S_{11}

1.2 Interpretative Structural Modeling (ISM) for thermal power plant security management system

Interpretative Structural Modeling (ISM) is put forward and developed by an American professor named Warfield in 1973, which is used to analyze complex issues related to the social and economic system [5,6]. The characteristic of ISM is that it can decompose the complex system into several subsystems (elements). With the advantage of people's experience and knowledge and help of computer technology, the system will eventually be constructed into a multi-level hierarchical structure model.

(1) Identification of the reachable matrix

According to the influencing factors shown in table 1, we can establish a reachable matrix M through expert interview advice, which can describe the final level that elements can reach after a length of access roads in system. Shown as follows, element 1 indicates that the row elements have a binary relationship with column elements directly or indirectly (including the elements' own auto-correlation), as element 0 indicates that the row elements have no direct or indirect binary relationship with column elements.

$$M=\begin{bmatrix}1&0&0&1&0&0&0&0&0&0&0&1\\0&1&0&1&0&0&0&0&0&0&0&1\\0&0&1&0&0&0&0&0&0&0&0&1\\0&0&0&1&0&0&0&0&0&0&0&1\\0&0&0&0&1&0&0&0&0&0&0&1\\1&0&1&0&0&1&0&0&0&0&1&1\\1&0&1&0&0&0&1&0&0&0&0&1\\1&1&1&1&1&1&0&1&1&1&0&1\\1&0&1&1&0&0&0&0&1&0&0&1\\0&0&0&1&1&0&0&0&0&1&0&1\\0&0&0&0&0&0&0&0&0&0&1&1\\0&0&0&0&0&0&0&0&0&0&0&1\end{bmatrix}$$

(2) Interstage division between elements

After obtaining the reachable matrix, next main procedure of establishing the structure model is the interstage division. Interstage division is used to divide all the elements into different levels (layers) based on criteria of reachable matrix. In the matrix, reachable set $R(S_i)$ indicates the set of all elements that S_i can reach, which includes all the column elements that equal to 1 in line i of matrix M ; Antecedent set $A(S_i)$ indicates the set of all elements of S_i , which includes all the row elements that equal to 1 in column i of matrix M . Results are shown in Table 2.

Table 2 Reachable set, antecedent set and their intersection

i	$R(S_i)$	$A(S_i)$	$R(S_i)\cap A(S_i)$
1	1,4,12	1,3,6,7,8,9	1
2	2,4,12	2,8	2
3	1,3,12	3,6,7,8,9	3
4	4,12	1,2,4,8,9,10	4
5	5,12	5,8,10	5
6	1,3,6,11,12	6,8	6
7	1,3,7,12	7	7
8	1,2,3,4,5,6,8,9,10,12	8	8
9	1,3,4,9,12	8,9	9
10	4,5,10,12	8,10	10
11	11,12	6,11	11
12	12	1,2,3,4,5,6,7,8,9,10,11,12	12

According to $R(S_i)\cap R(S_i)$, we can divide the influencing factors into different levels. Thus, the calculated factors that influent thermal power plant security management capability are divided into Level 1: $L_1=\{S_{12}\}$ .After redlining the rows and columns where S_{12} belongs to, we obtain Level 2: $L_2=\{S_4,S_5,S_{11}\}$ .Repeating the former procedure, we obtain Level 3: $L_3=\{S_1,S_2,S_{10}\}$, Level 4: $L_4=\{S_3\}$, Level 5: $L_5=\{S_6,S_7,S_9\}$ and Level 6: $L_6=\{S_8\}$.

(3) Establishment of structure model and interpretative structural model

According to interstage- arranged reachable matrix, we create a multilevel hierarchical structure diagram for the system of factors that influent thermal power plant security management capability in Figure 1. With the corresponding factors' names substituted into structure model, the interpretative structural model is established as shown in Fig. 1.

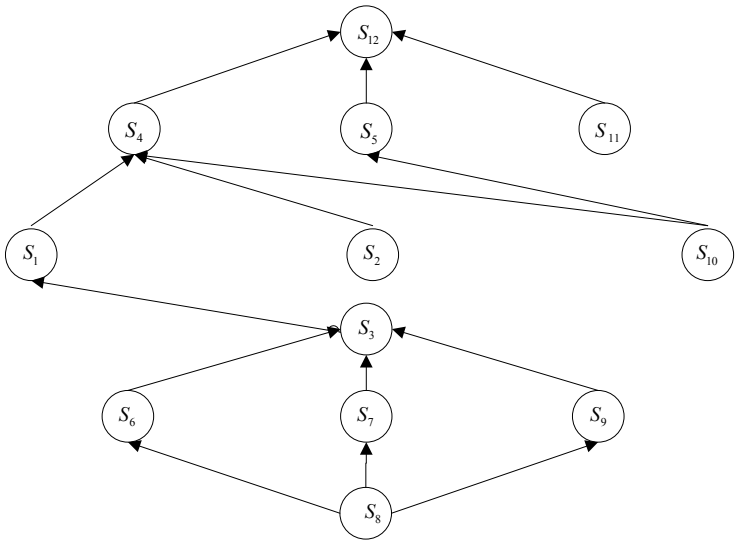

Fig. 1 Multilevel hierarchical structure diagram for influencing factors' system

(4) Determination of the weights of influencing factors

As a multi-criteria decision method, AHP method is able to integrate different subjective judgment so that it can simplify the complex system into pairwise comparisons and simple calculations between elements [7,8]. The main procedures of AHP method include the establishment of the index system, establishment of judgment matrix , calculation of the weight vector, consistency checking, calculation of comprehensive weights and so on. First, according to the ISM results, we select the elements in layered model as the index system. Secondly, based on the principles and procedures of AHP method and inviting relevant experts, we construct the comparison judgment matrix for the various factors which are in the same level and affect the factors in upper level. To complete this procedure we start from level 1(surface influencing-factor level) in hierarchical structure model with pairwise comparison method and 1-9 comparison scale. Thirdly, with similar method the judgment matrix of the middle and deep influencing-factor level can be constructed. The judgment matrix of surface influencing-factor level is shown in Table 3.

Table 3 Various factors weight table

type of table	judgment matrix $A=\{a_{ij}\}$				weight W	CR
weight table of second-level factors	S_{12}	S_4	S_5	S_{11}		
	S_4	1	3	3	0.6	0
	S_5	1/3	1	1	0.2	
	S_{11}	1/3	1	1	0.2	
weight table of third-level factors	S_4	S_1	S_2	S_{10}		
	S_1	1	4	3	0.63	0.09
	S_2	1/4	1	2	0.22	
	S_{10}	1/3	1/2	1	0.15	
weight table of fifth-level factors	S_3	S_6	S_7	S_9		
	S_6	1	1	4	0.46	0.01
	S_7	1	1	3	0.42	
	S_9	0.25	1/3	1	0.13	

2 Analysis of influencing factors for thermal power plant security management capability

According to Fig. 1 and Table 3, we analysis the relationship between each influencing factors as follows:

(1)The factors that have a direct influence on the security management capability of thermal power plant are: whether equipment operation conforms to the specification, maturity level of security equipment and facilities and emergency disposal mechanism. Among the above factors, equipment operation specification has a larger weight of 0.6, which indicates that the occurrences of thermal power plant accidents are often caused by violation operation of production line operators, on the other side, which also means the proper operation is of great importance for the security management capability of thermal power plant.

(2)The factors of operation habits, cultural knowledge and operation skills, inspection and supervision of the department of management have a direct influence on whether equipment operation conforms to the specification. Specifically, operation habits have the largest influencing weight of 0.63. In the practice, older employees who have longer length of service are always acting empirically. They believe that acting empirically is the safest way, and they tend to pass on their experience to young operators unconsciously when training them. Furthermore, the heavy operation tasks in thermal power plants are liable to cause employees' extreme fatigue, and in such condition people tend to act according to their experience, because acting empirically is often time-saving and caters to some employees' attitude of laziness. But they are not clearly aware of that their laziness may affect the normal use of equipment and even cause accidents. Among other mentioned factors, cultural knowledge of employees is weighted 0.22. Cultural knowledge level of employees will affect their security awareness and execution. Skills and experience of employees mainly emphasize the learning ability, analytical skills, security knowledge, operation skills, adaptive capacity for new knowledge, new equipment and new requirements. The above factors all have an impact on the equipment operation.

(3)Working attitude of employees directly affects the operation habits, which is influenced by enterprise security culture, security working environment and security management systems and procedures. The weight of security working environment is 0.42. The high temperature, strong noise and mess in workplace are liable to cause individual's psychological and physical discomfort which results in negative influence on employees' job morale and passive working attitude. The factor enterprise security culture is weighted 0.46. As the negative security environment directly affects employees' awareness and psychology of security, the enterprise security values could not root in employees' mind. The phenomenon reflects that employees are not authentically liable to approve of and participate in the construction of security culture, because most individuals tend to learn by imitation driven by psychology of conformity, which would lead to unsafe operation habits.

(4)Emphasis of leadership is a deep influencing factor towards capability of thermal power plant security management, as it affects enterprise security culture, security working environment and the construction of security management system directly.

3 Suggestions for thermal power plant security management

(1)Enhance employees' security training

From the analysis given above, operation and working attitude of employees have a greater impact on security management of thermal power plant. On one hand, enterprise should emphasis on training to employees' operation skills, on the other hand, enterprise should be responsible to carry out security education consistently. Scientific and effective security can not only correct and improve individual unsafe mental factors, but also improve the security quality of individuals in terms of the security of cognition, emotion and volition.

(2)Increase enterprise security investment

Increasing investment on security means the improvement of working condition, which indicates comfortable labor protection, reduced labor intensity and so on. Updating old equipment is another form of investment, which results in less machine failure as much as possible. As we all know,

superior security equipment and facilities can provide more efficient protection for personnel and production equipment in accidents and finally minimize losses.
(3)Construct a favorable security culture and improve security management system
Enterprise security culture potentially influences security awareness and psychology of employees, so a favorable security culture atmosphere is supposed to be constructed which requires total participation of all individuals. Along with the construction are the formation of security assessment mechanism and the establishment of the security system of rewards and penalties. The collective leadership of thermal power plant should pay particular attention to security management, making good examples by enforcing security regulations actively. The leading group is also responsible to establish a top-to-bottom security supervision system to ensure that enterprise security management concepts root into the heart of every employee.

Summary

(1) First of all, we build a security management system for thermal power plants' security-influencing factors on the basis of previous studies. The factors include: equipment operation specification, maturity level of security equipment and facilities, emergency disposal mechanism, operation habits, cultural knowledge and operation skills, inspection and supervision of the department of management, working attitude, enterprise security culture, security working environment, healthiness degree of security management systems and procedures, emphasis of leadership.
(2) Secondly, as the influencing factors of security management capability for thermal power plants are various and complex, we build a multi-level hierarchical structure model based on the Interpretative Structural Modeling (ISM). Then we analyze the hierarchy and relationships of various factors from a qualitative point of view, laying the foundation for quantitative analysis.
(3) Thirdly, we use Analytic Hierarchy Process (AHP) to analyze the factors' weights of each influencing layer, in order to clarify the importance of each factor and to improve the reliability and validity of analysis. Finally, we provide some suggestions for security management of thermal power plants on basis of the analysis results above.

Keywords: distribution network;loss analysis;saving energy and decreasing loss

Abstract: The thesis describes the loss model of distribution network and gives the transformer loss model and line loss model, Then it proposes some loss reduction measures at the stage of planning and design as well as operation and maintenance. Finally, according to the main problems about the loss reduction measures in China, it puts forward some countermeasures to reduce line loss .

Distribution network as part of the end for power configuration which is directly connected with the users of demand side. The loss of distribution network has been high because of feeder radius, complex voltage grade and a large number of devices on the network. The line loss of distribution network represents a major component of the line loss in the whole power system, the line loss of 10kv and below distribution network accounts for about 78% in it according to statistical analysis[1-2]. So, under the current energy shortage situation, there is a great economic and social significance to adopt the reasonable measures to save energy and decrease loss in distribution network.

Analysis of distribution network loss

Power loss of distribution network mainly includes the transformer loss and line loss[3], as shown in (1), saving energy and reducing loss needs to be optimized separately for each factor.

$$\begin{cases} \Delta W = \int_0^T \Delta P(t) d(t) \\ \Delta P = \Delta P_T + \Delta P_L \end{cases} \tag{1}$$

W ΔP_T is the transformer loss and ΔP_L is the line loss.

The active power loss of line

$$\begin{aligned} \Delta P_L &= 3 \times I_L^2 R_L \\ &= 3 \times (\frac{P}{\sqrt{3} U \cos\varphi})^2 \times R_L \\ &= \frac{P}{U^2 \cos\varphi^2} \rho l / A \end{aligned} \tag{2}$$

Where P is the line active power; U is the line operation voltage; $\cos\varphi$ is the line power factor; ρ is line resistivity;l is line length;A is line section area. As table 1 shows that the relationship between the energy consumption factor of line in distribution network and example for the saving energy and decreasing loss.

Table 1 Relationship between the energy consumption factor of line in distribution network and example for the saving energy and decreasing loss

Stage	Influence factors	Relationship	Example for the saving energy and decreasing loss
Equipment manufacturing	ρ	direct proportion	Replace aluminum conductor with copper wire
Planning and design	l	direct proportion	Industry substations and transformers planning to load centers, reduce line twists coefficient
	A	inverse ratio	Expand the line diameter
	U	inverse square	6kV high-voltage motor upgrading to 10kV
Operation and maintenance	P	proportional to the square	Using demand-side management to balance the load of each period
	$\cos\varphi$	inverse square	Devoting some compensators of reactive power

The active power loss of transformer

The total power loss of the transformer is composed of two main parts:the iron loss and copper loss, which can be given as follows:

$$\Delta P_T = P_{Fe} + P_{Cu} = (\frac{U}{U_N})^2 P_0 + (\frac{P}{S_N \cos\varphi})^2 P_k \tag{3}$$

Where P_{Fe} is the eddy current loss in the excitation branch; P_{Cu} is the resistance loss in transformer winding; U is the operating voltage; UN is the rated voltage; P0 is the no-load loss; Pk is the on-load loss. As table 2 shows that the relationship between the energy consumption factor of transformer in distribution network and example for the saving energy and decreasing loss.

Table 2 Relationship between the energy consumption factor of transformer in distribution network and example for the saving energy and decreasing loss

Stage	Influence factors	Relationship	Example for the saving energy and decreasing loss
Equipment manufacturing	P_0	invariable loss	Application of iron core transformer ,amorphous alloy transformer and other high quality transformer
	P_k	direct proportion	The original wire transformer into copper transformer
Planning and design	S_N	copper loss as the inverse square; Iron loss is directly proportional to S_N.	It runs in the economic load rate interval when the transformer planning

Operation and maintenance		proportional to the square	Using demand-side management to balance the load time and trying to make the transformer load rate operation on economic region
	$\cos\varphi$	inverse square	Switching capacitor

The main loss reduction measures of the distribution network based on the analysis of the loss model

The main loss reduction measures in the planning and design. The main loss reduction measures in distribution network planning and design is mainly reflected in the wires, transformers and power quality control.

Economic load levels of wire. The design of distribution line and the selection of cable type has many criteria. Usually , there are contradictions between the higher engineering design standards and the increased costs. So for a variety of design to meet technologies requirements, the relative economics of the program will be the most important determinant. The operation cost of large cross-section conductor (variable loss) is usually smaller than the relatively small cross-section wire, but it requires a higher initial investment. Since there are some accumulation losses in the line service period ,it should make trade-offs between the initial investment and operating costs during the planning period.

Factors affecting the total cost over the life of the power transmission lines include construction cost, operation and maintenance cost, power consumption cost and so on.

Economic load levels of transformer. Economic load levels of transformer also need to consider the initial cost and operation cost of the whole life cycle. Like the line, factors that affect the total cost of the whole life cycle include construction cost, operation and maintenance cost, power consumption cost and so on.

Experience shows that the economic load level of transformer should be in the ratings of around 75% on load saturation area or low growth area, while on the high load growth area the value should be in the ratings of around 50% [4].

Power quality control. All users want to get high-quality power ,but much non-linear load(such as thyristor rectifier, inverter, DC converter ,etc) in the users absorbs or injects harmonic current from the power grid, which causing distortion of the grid voltage. In addition, the power quality has deteriorated seriously by increased non-linear and impact load, power grid failure caused by unbalanced voltage, decreased dynamic voltage and so on ,as well as harmonic wave ,which reduces the reliability of power supply. Descending power quality makes the sensitivity power device of the user side is not working properly, resulting in huge economic losses. Therefore, the power quality problem is particularly outstanding and to improve the power quality for the economic operation of distribution network is significant.

Power quality control is the only means to improve power quality indicators. It is not only a necessary condition for high-quality power supply, but also the main means for saving energy and reducing loss. The main contents of power quality control include harmonic suppression, voltage adjustment, frequency regulation, three-phase voltage unbalance governance, flicker elimination, transient voltage control and so on. Commonly used power quality management and control measures have passive power filter,（PPF）, active power filter （APF）, active power line conditioner（APLC）, dynamic voltage restorer[5]. Commonly used power quality management and

control methods are not simply for a certain type of power quality indexes, but some means can achieve multiple power quality control purposes.

The main loss reduction measures in the operation and maintenance

Reactive power compensation technology. Reactive power compensation technology is to reduce power consumption and improve the quality of the grid voltage by means of reactive power compensation equipment provides additional reactive power to improve the power factor of the power system. When the reactive power compensation device is installed, the reactive power of transformers and all the connected lines from the point to the power point will be reduced, which can make the power loss of the point before the series element is reduced. The power factor of the load is lower , the reactive power of the load delivered from the power through line and the corresponding components in the power supply and distribution system is larger, thus the loss of the power supply and distribution system is also larger. After the reactive power of the distribution network is compensated, the current flowing through the line and transformer is reduced, which correspondingly decreases the reactive power loss on the line and transformers. Common reactive power compensation equipment includes synchronous compensator, capacitor compensation, static var compensator and so on.

Rationally adjusting the operation voltage. Rationally adjusting the operation voltage is to guarantee voltage quality by adjusting the generator terminal voltage and the tap changer of transformer and devoting capacitors on the bus line and regulating voltage with synchronous condensers. According to the equation (2) and (3) shows that the active power loss of power distribution equipment is inversely proportional to the square of the operating voltage U, so rationally adjusting the operating voltage can save energy and decrease loss.

Economic operation of transformer. To determine the economic operation of transformer should be calculated [7-8] that the power system operates by way of the minimum energy consumption in order to achieve the purpose of economic. Economic operation of transformer is classified into many ways: A single double-winding transformer economic operation, more than one of the same type of double-winding transformer economic operation, many different types of double-winding transformer economic operation and so on.

As a single double winding transformer economic operation, the efficiency of transformer is the highest and the operation of transformer is the most economic, when no-load loss is equal to the load loss .

As more than one of the same type of double-winding transformer economic operation, using n transformer parallel operation is economic when the maximum total load of the substation is greater than the value of critical load of n and n-1 transformer. Otherwise ,using n-1 transformer parallel operation is economic,

As many different types of double-winding transformer economic operation, It should be calculated the critical load tables for various combinations of mode, and then select the most economical combinations according to the load substation.

Using energy-efficient distribution transformer. Energy-efficient transformer is to save energy and decrease loss by reducing the iron loss of the transformer. It includes regulated capacity transformer, amorphous alloy transformer, single-phase distribution transformer and so on.

Regulated capacity transformer is a kind of regulating operation capacity transformer with a load capacity regulating switch according to the size of the actual load. Compared with the S9 transformer, the no-load loss of regulated capacity transformer can be decreased by 30%, the

no-load current can be decreased by 70%. For seasonal difference area, the annual operation cost of regulated capacity transformer can be decreased by about 45%.

Amorphous alloy transformer is to save energy and decrease loss through reducing no-load loss. Compared with the S9 transformer, the no-load loss of amorphous alloy transformer can be decreased by 70%-80%, the no-load current can be decreased by about 50%. Thus, it has low operation cost and obvious energy-saving result. Energy efficiency is the highest when the load factor of amorphous alloy transformer is in between 20% -30%.With the increase of transformer capacity, energy efficiency is also improved. Usually, selecting the capacity of amorphous alloy transformer should be more than 200kVA. But the application is limited because of its high price, low yield and special structure, it is only suitable for installation in areas with light load or no-load operation.

Single-phase distribution transformer is divided into single-phase three-wire transformer and single-phase two-wire transformer according to the different connection methods in low-voltage side of transformer. When the total transmission power of single-phase transformer is same, the single-phase three-wire connection mode can reduce by 1/4 length of low-voltage distribution line. When the two shunt load balancing, the single-phase three-wire connection mode can reduce by 1/2 power consumption of low-voltage line loss. Therefore, it is recommended that the use of single-phase three-wire power distribution technology. In the single-phase three-wire distribution mode, in order to avoid the user side voltage increase, it should be grounded in the neutral point of single-phase transformer low-voltage outlet (ground) and neutral point of the user side.

The problems about the loss reduction measures in China

In recent years, although China has developed many new technology of energy saving , but it did not focus on the long-term development and the overall economic benefits. In power supply and distribution system, there are still a great potential for energy saving and technology upgrade space, mainly as follows:

Cost-benefit analysis method of power network planning is relatively simple

Cost-benefit analysis method of investment for power grid planning in China is relatively simple, more attention to reliability, and can not achieve the coordinated development of economy and reliability of the whole power grid. Also, for a long time, conductor selection mainly based on the economic current density at planning stage, while the latest economic current density in China was issued in 1987 by the former Ministry of Water Resource and Electric Power, and now the metal material price, electricity price, the manufacturing process, load condition are changed, its effectiveness is not applicable to the present stage.

The economic operation level of the power grid needs to be improved

The load distribution is not balanced. The heavy and light load transformer contained within the same network leads to a serious deviation from the economic operation range, thus increasing the power loss. This imagination can be found to varying degrees at all the grid.

Reactive power compensation is difficult to meet the requirements. Low reactive power compensation and poor regulation ability increases the power loss and declines in the quality of power users. In addition, the power loss is also increased by the lack of users capacitor.

Have not been able to achieve the dynamic management of grid operation. Some areas invest blindly just to reduce the loss, can not be in the way of dynamic management of grid operation to achieve the purpose of saving energy and reducing loss.

High prevalence and obsolete equipment is universal

Due to the lack of funds,the distribution network construction is lagging behind and it is difficult to replace or modify the old equipment. A large number of high energy-consuming equipment is still used in the individual area, such as: S7-type and below S7-type distribution transformers. Even though some areas have used energy-saving transformer, they can not achieve the ideal results. For example, no load transfer capacity transformer has been applied in some areas, but many people do not grasp the correct way to use, thus resulting in distribution transformer capacity regulating function is underutilized, the large capacity operation mode is not adjusted as the load capacity increases and the burned accident of transformer capacity regulating is occured frequently.

Using some kind of isolated technological measures of loss reduction

In the energy-optimized of practical distribution network, it seems that only a "stop-gap" to take some kind of energy-saving measures and it do not focus on the long-term development and overall economic benefits. Such as: only a wire to replace or only in low-voltage reactive power compensation to change the line power flow to achieve the loss reduction effect is not enough, then, the former will influence the capacity or position of the reactive power compensation, the latter will influence the current carrying capacity and the cross-section selection of conductor. So, a few isolated measures do not have an ideal effect.

Countermeasures to reduce the line loss

Strengthening the cost-benefit analysis of the investment of distribution network planning. In the process of formulation and implementation to reduce line loss, we must consider the cost of investment and the loss reduction effect, let the investment income as an important basis for evaluation and carry out a comprehensive analysis of technical and economic, use the limited funds and create the best investment benefit.

Improving the economic operation level of the power grid. Adjusting the operation way of power grid according to the variation of load and outaging part of no-load transformer through the rational allocation of power flow and main transformer load rate, which can make the system in the economic operation way.

Strengthening the operation management of reactive equipment, improving automatic monitoring means and the operation rate of the reactive compensation device, and increasing evaluation efforts against reactive compensation device switching.

It is method to achieve the purpose of saving energy and reducing loss by strengthening the dynamic management of the power grid operation, optimizing the operation mode, shortening the cycle of adjustment operation mode according to the change of load level.

Intensifying the technological renovation of the power grid equipment. To reduce the loss of distribution network, the measures should be taken as follows: extension of high voltage power supply to the load center, increasing the wire section, shortening the supply radius of distribution network, reducing the bypass power supply, a planned step to change and eliminate the high loss distribution transformer, replacing the aging into the family line.

Strengthening the collaborative optimization of various energy saving measures. Energy saving and consumption reduction of distribution network is a system engineering and involves the aspects of power grid. To achieve the collaborative optimization in a variety of energy-saving

measures has a very important practical value for making the energy-saving modification plan of distribution network of global optimization. It should be plan the reasonable grid layout, evaluate energy saving measures of the distribution network and implement these measures according to actual condition of power network, formulate comprehensive renovation of energy saving optimization scheme in accordance with engineering practice, which ultimately achieve the goal of energy saving and loss reduction.

Conclusion

This paper mainly introduces some technique measures to reduce the loss of power system planning and operation. As can be seen, our measures in saving energy and reducing loss are still immature, It should be consider the reduction loss problem of power grid from long-term development, the economic operation, power grids, operation management and investment return and bring the power loss reduction index into all aspects of grid operation.

Keywords: power plants; installed capacity; standard coal consumption rate; power supply; power generation; auxiliary power

Abstract: Through the analysis of some parameters of Chinese power plants operation in recent years, forecasting that at a certain period in the future, total installed capacity of 6000 kw or more units will have the growth rate of 7% - 8%.China's power supply coal consumption rate will continue to become lower by 3-5g/kwh every year.

Introduction

Nowadays, conventional coal or gas fired power plants are the dominant way to generate electricity in the world. However, the problems of pollution emissions, greenhouse gas emissions etc are getting more and more attention. The conventional power industry is under huge pressure with the renewable energy targets and carbon taxes set by various governments. A real technical revolution is needed to change the power industry into an environmentally friendly industry.

The growth of world energy consumptions and the need to meet the increasingly stringent environmental regulations make the repowering of existing coal-fired power plants an attractive option for boosting the generating capacity at competitive cost [1-3].

With the increasing depletion of fossil fuels, how to effectively use the heat released by fossil fuels has become the focus of current research. China is one of the countries which are heavily dependent on coal-based energy supply and coal- fired power generation ac-counts for 80% of the total electricity generation in China[4]. Due to many reasons such as design or operation, the temperature of the exhaust flue gas of a pulverized CFPP (coal-fired power plant) can be reached to 150℃ which makes the heat loss with the exhaust flue gas the biggest among the heat losses of a boiler. Preliminary estimates show that the waste heat resources contained in exhaust fl ue gas equals to 70 million tons of SCE (standard coal equivalent), in other words, there are almost 70 million tons of SCE in the form of waste heat released to atmosphere in China every year, causing energy waste and greenhouse effect[5-7].

With the great development of such fluctuant renewable energies as wind and solar power, more and more thermal power plants have been forced to compensate the loss of generation as the power source reserves for the grid stability.

Status of Chinese power plants

As is shown in Fig.1, in China, 6000 kw or more of the total installed capacity of the units is almost every year to increase around 100 million kw from the year of 2008 to 2013. The growth speed of the total installed capacity of the units is very great. About five years from the year of 2008 to 2013, 6000 kw or more of the total installed capacity of the unit increased from 793 million kw to 1.247 billion kw, added about 454 million kw, increased by 36.4%. The growth rate of 6000 kw or

more of the total installed capacity of the unit is between 8%-9% every year. This growth rate fits in the growth rate of China's national economy. So the power plant unit total installed capacity of annual growth can be reflected from the side of a country's economic development level. According to expert estimates, the level of economic growth in China in the future within a period of time, will still remain between 7% - 8%, therefore, can be estimated that China's total installed capacity of power plant, there will be 7% - 8% a year growth rate[8-9].

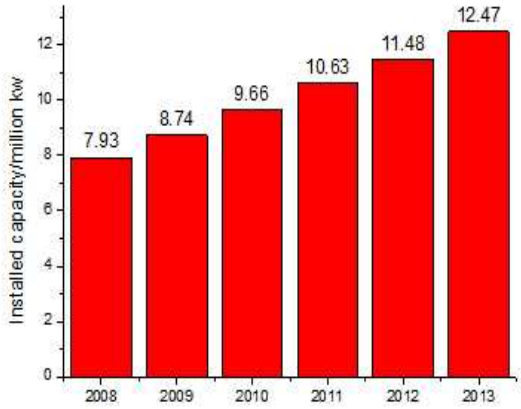

Fig.1 Situation of the total installed capacity from the year of 2008 to 2013 in China (more than 6000kw units)

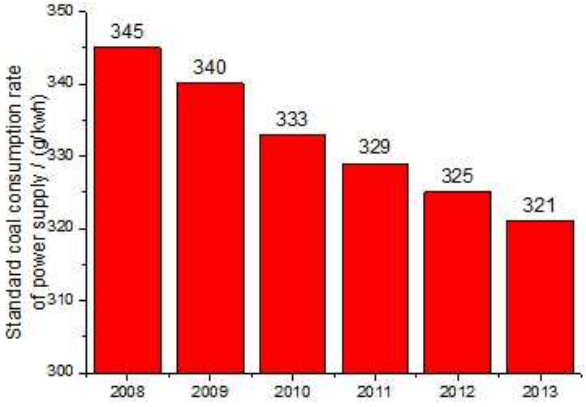

Fig.2 Standard coal consumption rate of power supply from the year of 2008 to 2013

Can be seen from the figure 2, more than 6000 kw of power supply coal consumption of units, from 2008 in 345 g/kwh, dropped to 2013 in 321 g/kwh, reduced about 24 g/kwh, reduced about 7.48%, the power supply coal consumption each year will have to reduce about 4-5 g/kwh. In December last year 1 - the national total capacity 5.24511 trillion kwh, compared with 2008, will save 1.259 billion tons of standard coal. In 2013, the total energy consumption in China reached 3.76 billion tons of standard coal, coal 3.5 billion tons (2.5 billion tons of standard coal), accounting for 33.48% of total consumption, made important contribution for our country's energy conservation and emissions reduction. National thermal power unit power supply coal consumption of 321 g/kwh, national 12th five-year plan for energy conservation and emissions reduction goals ahead of time (325 g/kwh), coal unit power supply coal consumption continues to the world advanced level. But China power plant energy conservation and emissions reduction potential is very big, there is a certain gap with the developed countries in the world. China's power supply coal consumption will continue to be a year there will be 3-5 g/kwh.

Can be seen from the Fig.3, more than 6000 kw power standard coal consumption rate of the unit from 322 g/kwh in 2008 dropped to 2012 in 305 g/kwh, every year there are 2-8 g/kwh. Contact with figure 2, be able to get power plant auxiliary power of standard coal consumption rate, as shown in figure 4.As can be seen from the Fig.4, 2008 to 2009, auxiliary power standard coal consumption rate fell sharply, later growth slightly, and then continue to decline. From then on, the auxiliary power standard coal consumption rate to maintain the low level. According to the report, the power plant by the original factory electricity accounts for about 10% of the total generating capacity, reduced to 5%, now that the energy consumption of the power plant level fell sharply, energy-saving effect is remarkable.

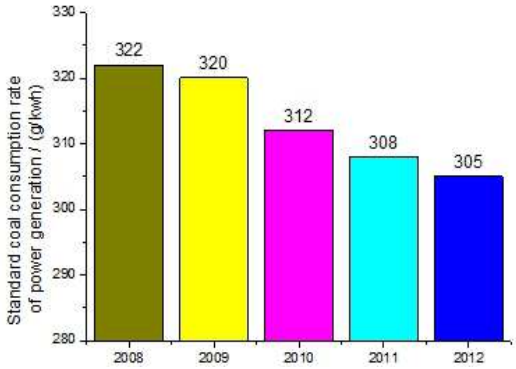

Fig.3 Standard coal consumption rate of power generation from the year of 2008 to 2012 in China

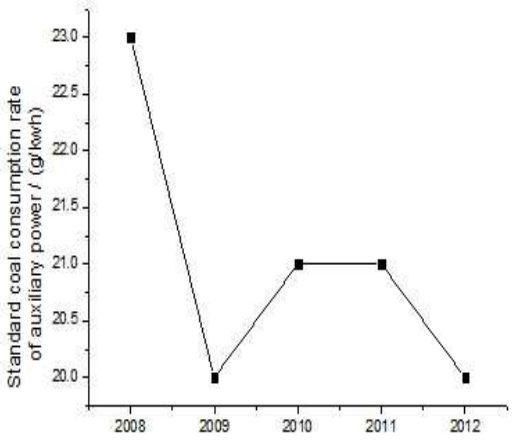

Fig.4 Standard coal consumption rate of auxiliary power from the year of 2008 to 2012 in China

Can be seen from the Fig.5, the proportion of thermal power unit capacity, it depends on China's energy structure, followed by water and electricity, and then the wind power and nuclear power. According to China's electric power network, by the end of December 2013, the whole caliber power equipment capacity of 1.24738 billion kilowatts, up 9.2% from a year earlier. The hydropower installed capacity of 280.02 million kilowatts, up 12.3%;Thermal power installed capacity of 862.38 million kilowatts, increased by 5.7%, compared to the clean energy capacity of continued ascension. In 2013, the national power of new production capacity (formal) with a 94 million kw, and among them, the hydropower 29.93 million mw, 36.5 million mw thermal power.

As is shown in Fig.6, in recent years by the new energy capacity of constantly improve and power supply and demand factors, such as the country's 6000 mw and above average power generation equipment utilization hour continues to decline, in 2013 to 2013 hours, compared with 68 hours.

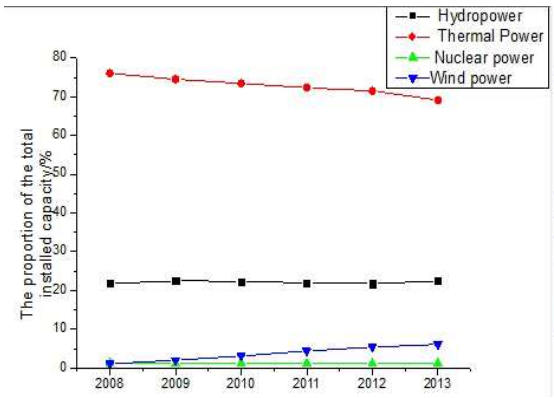

Fig.5 Proportion of some kinds of power plants as to the total installed capacity in China

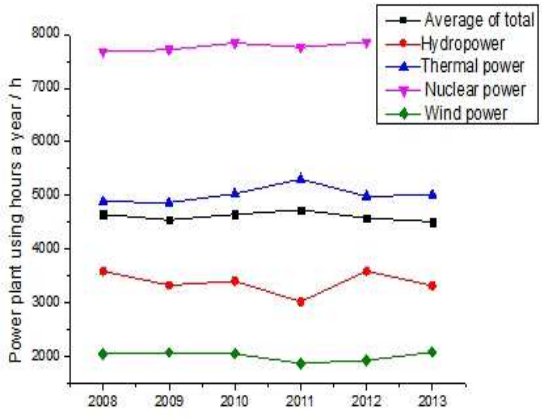

Fig.6 Power plant using hours a year in China from the year of 2008 to 2013

Summary and Conclusions

Through the analysis of some parameters of Chinese power plants operation in recent years, forecasting that at a certain period in the future, total installed capacity of 6000 kw or more units will have the growth rate of 7% - 8%.China's power supply coal consumption rate will continue to become lower by 3-5g/kwh every year.

New power plants will choose large capacity and high parameter unit equipment; in the energy-saving reconstruction of existing units, a press more than one batch of waste heat recovery equipment will be used, such as screw expander, heat pump, etc.; the automation level of power plant will be further improved, the frequency conversion technology will be more and more used in pump and fan and other equipment; renewable energy and traditional energy coupling, constitute a mixed heat power generation system, mixed with coal-fired units such as solar energy power generation system; all-round optimization operation mode change, such as no fan . Stop the pumps and downtime, unilateral, circulating pump and downtime, circulating water pump operation mode optimization, the optimization of open cooling water system, the coal pulverizing system operation optimization, optimization of constant pressure and sliding pressure operation mode, etc.; some other technology applications, such as the application of new type thermal insulation coating in power plant piping, etc.

Keywords: Security constrained economic/environmental dispatch,Constrained multi-objective differential evolution, Feasible region and infeasible region

Abstract. An enchanted multi-objective differential evolutional algorithm was proposed, and was applied to solve the environmental economic dispatch problem. Duo to the weakness of random initial population, the orthogonal method was used in the initialization. Based on survival of the fittest, improved differential operation was proposed, combined with the corresponding parameters control method proposed. With the combination of B-coefficient method and restrain dominance, the process of solving equation and selection operation were used to make the individuals meet the equality constrain. Then the algorithm was tested on the IEEE-30 test system, the results are compared with the results of non-dominated genetic algorithm-II, ulti-objective differential evolution and the known results in the papers, and the validity is verified.

Introduction

Due to the power generation of thermal units,the release of sulphur oxides（SO_x）, itrogen oxides（NO_x）and carbon dioxide (CO_2)has already caused high pollution and greenhouse effect. Under the background of energy conservation, power supply should be not only of high economy and reliability, but also to reduce the emission to the environment.

Common measures such as the installation of desulfurization equipment,building a carbon capture plant and its improvement and EED are taken to improve the operation of generation units. But the most effective method can be EED in a short term.

Fuel costs of thermal units and pollution emissions are mutually exclusive, which means pollution emissions are the highest when costs are lowest and pollution emissions are the lowest when costs are high. EED problem are proposed against this contradiction, which realize the system economy and satisfactionof emission index through optimizing the load distribution of units on the premise of system safety and stable operation. EED has been widely researched by scholar at home and abroad, in classic solution of EED problems, multi-objective problems are always converted to single objective problem to get the model solved, but the weight is difficult to determine and the Paretofront can't be achieved when the trade-off relationship of objective function isnonlinear[1]. Objective functions are linear decomposed and linear programming are applied in each part to simplify the calculation, but it can't express the trade-off relationship of objective functions[2], EED problems are converted to single objective problem under the constraint of emissions but only get an approximate solution after many times adjustments[3].

Heuristic algorithm is applied in EED problems in recent years, such as NSGA-II，evolutionary programming,multi-objective particle swarm algorithm, Multi-objective Differential EvolutionMODE [4-9]. MODE is widely used in EED problem solutions for its global search capability and easy implementation[8,12].

But of the classical EED problem does not take thetransmission linelosses constrain into consideration, and the solution got by those classical method may not satisfy the power balance constrain. And the value-point effect is not taken into consideration. So in this paper, all of these constrains are included. As the DEMO[10] method id used to solve unstrained multi-objective optimization problems, a newly EMODE based on DEMO andconstrained handle technique[11]was proposed to solve the security constrained EED problem.Experiments have been carried out on the standard IEEE 30-bustest system and the results are compared to different techniquesreported in literature. The effectiveness and potential of the proposedEMODE approach to solve the security constrained EED problemare demonstrated.

Problem statement

The EED problem is to minimize two competing objective functions,fuel cost and emission, while satisfying several equality andinequality constraints. Generally the problem is formulated as follows.

Problem objectives. 1.Minimization of fuel cost

When the value-point effect is taken into consideration, the total fuel cost $F_c(P_G)$ can be expressed as[5,7]:

$$F_c(P_G)=\sum_{i=1}^{N}(a_i+b_iP_{G_i}+c_iP_{Gi}^2+|d_i\sin(e_i(P_i-P_{\min,i}))|) \tag{1}$$

Where N represents the total number of generators;$a_i,b_i,,c_id_ie_i$arethe cost coefficientsof the i-th generator, and $P_{Gi}$is the real power output of the$i$-th generator.

2.Minimization of emission

The atmospheric pollutants such as SO_x, $O_x$andCO_2caused by fossil-fueled thermal generatorshould bemodeled separately. However, for comparison purposes, the total emission of these pollutants E(P_G) whichis the sum of a quadratic and an exponential function canbe expressed as[14]:

$$E(P_G)=\sum_{i=1}^{N}10^{-2}(\alpha_i+\beta_iP_{Gi}+\gamma_iP_{Gi}^2+\xi_i\exp(\lambda_iP_{Gi})) \tag{2}$$

where α_I, β_I, γ_I, ξ_I and λ_I are the emission coefficientsof the ith generator.

Problem constrains. 1.Generation capacity constraint

To maintain the generator operating stablely, the real and reactive power output of each generator is restricted by lower and upper limits as follows:

$$P_{Gi}^{min}\le P_{Gi}\le P_{Gi}^{max},i=1,...,N \tag{3}$$

where:$P_{Gi}^{min}$and P_{Gi}^{max} represent the lower and upper boundary of the ith generator's real power capacity respectively.

2.Power balance constraints

The total real power generated should meet the demand P_D and the real power loss in transmission lines P_{loss}:

$$\sum_{i=1}^{N}P_{Gi}=P_D+P_{loss} \tag{4}$$

There are two ways to calculate P_{loss}, such as B-matrix loss formula method[4,9] and power flow method[6-7]. And the B-matrix method is deployed here to calculate the real power losses:

$$P_L=\boldsymbol{P}_G^T\boldsymbol{B}\boldsymbol{P}_G+\boldsymbol{P}_G^T\boldsymbol{B}_0+\boldsymbol{B}_{00} \tag{5}$$

Where $\boldsymbol{P_G}$is the vector of all the generators' real power output,$[P_{G1}\ldots P_{GN}]$; **B**, $\mathbf{B}_0$, $\mathbf{B}_{00}$ are the coefficients of the B-matrix. Then the above equation can be re-written as:

$$\begin{aligned} P_L = &\sum_{i=1}^{N-1}\sum_{i=1}^{N-1} P_{Gi}B_{ij}P_{Gj} + 2P_{GN_G}(\sum_{i=1}^{N-1} B_{Ni}P_{Gi}) \\ &+ B_{NN}P_{GN_G}^2 + \sum_{i=1}^{N-1} B_{0i}P_{Gi} + B_{0N_G}P_{GN_G} + B_{00} \end{aligned} \tag{6}$$

Substituting （6）into （4），the power balance constrain can be formulated as：

$$\begin{aligned} &B_{NN}P_{GN_G}^2 + 2(\sum_{i=1}^{N-1} B_{Ni}P_{Gi} + B_{0N_G} - 1)P_{GN_G} + \\ &(P_D + \sum_{i=1}^{N-1}\sum_{i=1}^{N-1} P_{Gi}B_{ij}P_{Gj} + \sum_{i=1}^{N-1} B_{0i}P_{Gi} - \sum_{i=1}^{N-1} P_{Gi} + B_{00}) = 0 \end{aligned} \tag{7}$$

As shown in (7),the real power of N-th generator is an dependent variable of the other generators' outputs. So in our work, only N-1 generators' real power are taken as controllable variables, and the left one is obtained by (7).

EMODE

EMODE. Even DEMO can efficiently converges to the true Pareto front and uniformly spreadsindividuals along thePareto front, some weaknesses do exit, such as hard to choose the control parameters. What's more it is proposed for unconstrained problems, when it comes to constrained problems, how to handle the constrains is not yet proposed. So the newly algorithm called EMODE is proposed, canbe described in the following steps:

Step 1: Initialize

DEMO is a robust algorithm, and the final solution is not sensitive to initialization. But the computation timeis relatedto the distance between the initial guesses and the optimal solution. So theorthogonaldesign is used to generate a population of size $N_P$as the initial population.

Step 2:Mutation operation& Crossover operation

The traditional mutate operation is taken according to the following equation:

$$v_i^{G+1} = x_{r1}^G + F \bullet (x_{r2}^G - x_{r3}^G) \tag{8}$$

where r1, r2 and r3 are mutually different integers which are randomly selected with uniform distribution from the set{1,…,Np} ,and also different from the individual's index i,i=1,2,…Np; F is the mutation parameter.

As (8) shows, the searching ability of DE is mostly affected by F. To balance the global search and local search, the mutation strategy following is deployed in this paper:

$$v_i^{G+1} = \begin{cases} x_{r1}^G + F_l \bullet (x_{best}^G - x_{worst}^G) & if\ rand \le \tau \\ x_{r1}^G + F_g \bullet (x_{r2}^G - x_{r3}^G) & else \end{cases} \tag{9}$$

where rand is a uniform random number generation with [0,1]; τ is the control parameter to decided when to use the first kind of mutation strategy, in this paper it was set to 0.5; $F_l$and F_g are the mutation parameters , randomly generated from [0.4,0.6]and[-1,1] respectively;x_{best}^G and x_{worst}^G are the best and worst individual in the present population, respectively.

Following the mutation operation, crossover is applied to the individuals in the population.For each mutant vector, x_i^{G+1},an index of $rnbr_i \in$ {1,…,Np} is randomly chosen with a uniform distribution, and a trial vector is generated via:

$$x_{ij}^{G+1} = \begin{cases} v_{ij} & if\ rand \le CR\ or\ j = rnbr_i \\ x_{ij}^{G} & otherwise \end{cases} \tag{10}$$

where j=1,2,…,N is the parameter index; CR is a crossover rate in the range[0,1], and the strategy proposed in Ref[13] is deployed here to decide the value of CR in each generation:

$$CR_G = CR_{\max} + (CR_{\max} - CR_{\min})(1 - G / G_{\max})^k \tag{11}$$

Where CR_G is the crossover rate for the G-th generation;CR_{max} is the maximum crossover rate ,set to 0.95;CR_{min} is the minimum crossover rate, set to 0.5; G_{max} is the maximum iteration; k is the growth index, taken as 4 here.

Step 3:Selection operation

Even the power balance constrain(4) is transferred into a quadratic equation (7) ,the solution of (7) may be infeasible, as violation of the generator's capacity constrain (3).So the selection operation of EMODE is carried out after the one-to-one competition between the trial and parent individuals based on the concept of restrain dominance, unlike the MODE method proposed in Ref[12].

Definition 1: restrain dominance

$x_i$is said to restrain dominance x_j ,$x_i \prec_c x_j$,when:

1)$x_i$is feasible, and $x_i$is infeasible;

2)$x_i$is infeasible, and $x_i$is infeasible, and the total constrain violation of $x_i$is smaller than x_j's;

3)$x_i$is feasible, and $x_i$is feasible, and$x_i \prec x_j$.

where$x_i \prec x_j$ stands for the concept of dominance.

Definition 2: dominance

$x_i$is said to dominancex_j,$x_i \prec x_j$,when:

$$\begin{cases} f_i(x_i) \le f_i(x_j), \forall i \in \{1,2,...,N_f\} \\ f_i(x_i) < f_i(x_j), \exists i \in \{1,2,...,N_f\} \end{cases} \tag{12}$$

where $N_f$is the number of objectives, as proposed in this paper N_f was set to 2; $f_i(x_i)$ represents for the ith objective function value of individual x_i.

After the competition procedure, a population of size between Np and 2Np is formed. In Order to maintain the populationsize constant, the truncation based on non-domination and crowdingdistance calculation is carried out.

Step 4:non-domination and crowdingdistance calculation

In order to exploit the information the infeasible individuals carry and balance the search between feasible region and infeasible region, the constrain handling technique proposed in[11] is employed.

Because of that the non-domination and crowdingdistance calculation procedure is carried out on the population's objective functionvalues, to implement the constrain handling technique mentioned above, these values should be modified.The modified objective value hastwo components: distance measure and adaptive penalty.The details can be found in Ref[11].

After the objective functionvalues' adjustment, the non-domination and crowdingdistance calculation is carried out. The best $N_p$individuals are selected as theparent vectors for the next generationbasedon its ranking and crowding distance.

Step 5:Stopping Rule

The search can be interrupted after a givennumber of generations, or when no significant improvementin the solution occurs. Here EMODE is run for a fixed numberof generations; if the criterion is not satisfied then the procedureis repeated from step 2 creating the new populationfrom the parent population.

Step 6:Stop

Experiments

Having been applied for the first time, the proposed EMODEtechnique was tested on the standard IEEE 30-bus 6-generator testsystem as several techniques have been tested on this standard systemwithreported results in the literature. The single-line diagramof the IEEE test system and the detailed data aregiven in [2,7]. The values of fuel cost, emission coefficients and B coefficients are given in[14].

To demonstrate the effectiveness of the proposed approach,two cases with different complexity have been considered as follows:

Case 1：The value-point effect is not considered.

Case 2：The value-point effect is taken into consideration.

The parameters used for all cases were: Np were set to 36;the maximum number of generations$G_{max}$was set to 100, the total load P_D was set to 2.834pu on a 100MVA base.

To verify the effectiveness of our algorithm, the proposed uniform distribution index and coverage index were introduced:

$$S=\sqrt{\frac{1}{N_{PF}}\sum_{i=1}^{N_{PF}}(d_i-\overline{d})^2}\ /\ \overline{d} \tag{13}$$

$$I_c(A,B)=\frac{|\{b\in B;\exists a\in A:a\prec b\}|}{|B|} \tag{14}$$

Where S is the uniform distribution index, and the smaller of S means the better of the Pareto front;$d_i$is the Euclidean distance between the i-th non-dominated solution in the Pareto front and the nearest non-dominated solution;$\overline{d}$ is the average value ofd_i;N_{PF} is the number of non-dominated solutions in the Pareto front;I_c represents the percent of solutions in set B dominated by solutions in set A, and the higher of I_c means the better of A and worst of B.

The best economic dispatch solution and best emission dispatch solution of Case 1 are shown in Tab.1.Comapred to the results given in [15],the solutions in EMODE have the advantage in economic and emission, and the fuel cost and emission are reduced by 0.0012$/h and 0.001 t /h ,respectively. What's more, the uniform index *S* indicates that the EMODE obtain the most uniformly spread solutions. The convergence index I_c demonstrates the algorithm's convergence performance.

Case 2

The Pareto front obtained by the EMODE in Case 2 is shown in Fig.1,and the best economic dispatch solutions and the best emission dispatch solutions are shown in Tab.2.As shown in Fig.1,when the value point is taken into consideration, the Pareto front of EED is discontinuous.

When it comes to emission, EMODE obtains the best plan ,and dominates the other two. Further, compared to NSGA-II and DEMO, the fuel cost of the best economic plan in EMODE is reduced by 6.8789$/h and 1.2551$/h,respectively. What's more, 75.00% and 48.44% of non-dominated solutions in NSGA-II and DEMO are dominated by the solutions obtained by EMODE. Finally, *S*index indicates that EMODE always obtains the most uniformly spread solutions.

Conclusion

In this paper, a novel enhanced multi-objective differential evolution algorithm has been proposed and applied to environmental/economic real power dispatch problem. The proposed EMODE technique presents a constrained version of the conventional DEMO technique and utilizes its effectiveness to solve the constrained multi-objective optimization problems. The EED problem is formulated with competing fuel cost and environmental impactobjectives.What's more, the real power losses and value-point effect are also taken into consideration.

The results show the efficiency of the proposed EMODE method to solve EED problemwith real power losses and value-point effect integrated.And the results also reveal proposed algorithm has the capacity to maintain the divergence of the population and converges to the true global Pareto front in the same iterations.

Keywords: Matter-element model Site selection optimization; Thermal power plant; Comprehensive evaluation; Rough set; Multi-objective programming

Abstract: The site selection optimization for thermal power plant will directly impact the economic operation and sustainable development. On the basis of constructing index system for site selection of thermal power plant, the method of rough set is applied to obtain the index weights, which are determined only by the system potential information. Through the method of expert decision-making, the quantitative and qualitative information is integrated, and the priority of the alternatives is obtained. The multi-objective model for site selection optimization is built up to balance the economical efficiency and the average comprehensive efficiency. In consideration of decision-makers' predilection and heat load demand, the two goals of cost minimum and average comprehensive efficiency maximum are achieved at the same time. Case analysis indicates that the method for site selection optimization of thermal power plant proposed in this paper possesses some advantages, such as scientificity and practicability.

Introduction

Along with the consciousness enhancement of people environmental protection, the issue of resource conservation and environmental protection has gradually become the focus of hot spots. There are many ways for city central heating, such as cogeneration, centralized coal-fired boiler, household gas boiler, heat pump heating, low temperature radiation heating, phase change thermal storage heating, geothermal heating, low temperature nuclear and solar heating, etc. Considering from China's national conditions, as well as from the perspectives of saving resource, reducing environment pollution and technical maturity, some studies concluded that the optimal model for central heating in China is still combined heat and power generation （CHP） within quite a period of time in the future [1-5].

The site selection issues related to energy mainly focus on the thermal power plant site selection[6-8], the nuclear power station site selection[9, 10], the solar energy power station site selection[11, 12], wind/solar hybrid power station site selection[13], the photovoltaic power station site selection[14-16], the wind wave energy power station site selection[17], etc. And the research methods are mainly stochastic dynamic programming [7], fuzzy set[9, 12], TOPSIS[8-10], AHP[9, 12, 14], entropy[10], ideal matter-elemnet extension[13], the Texel-Marsen-Arsloe Spectrum[17], et al. In particular, Barda, Ramos, KAI, et al. respectively studied the problems of site selection for thermal power plants in France, Brazil, and the United States [6-8]. The common problems in the

process of site selection are that the evaluation index system is not very reasonable, qualitative indexes and quantitative indexes are not well combined together, and the general evaluation function is only a single target, et al.

Unreasonable site selection for thermal power plant can cause heating costs increasing, resource wasting and environmental pollution, and bring great negative influences to society. Therefore, the site selection optimization for thermal power plant is of important practical significance.

Rough set operation system does not need any prior knowledge, can dig up the implicit information automatically, and completely avoid the human disturbance. In this paper, the exploratory study on the thermal power plant site selection optimization is discussed on the basis of constructing the index system of thermal power plant site selection using the methods of rough set theory and multi-objective programming.

Establishing index system

The main influencing factors of thermal power plant site selection are: (1) the availability of land(AL), (2) the construction cost(CC), (3) the heat pipe laying cost(HPLC), (4) the distance from the center of the heat load(DCHL), (5) the thermal load demand(TLD), (6) the grid access structure(GAS), (7) coal & water availability(CWA) and (8) environmental factors(EF), etc.

Modeling

Parameters and variable definition

Model parameters are as follows: $i \in I$: subscript of the central heating areas; $j \in J$: subscript of alternative locations; $m \in M$: subscript of thermal power plant heating capability levels; C_m : heating capacity of level m; F_j^m : construction and operation costs of the thermal power plant built at location j with the heating capability level m; a_i : the heat load of the central heating area i; D_{ij} : unit transportation cost from thermal power plant j to the central heating area i;

The decision variables are defined as follows:

$$X_j^m = \begin{cases} 1, \text{build a thermal power plant of level m at location j} \\ 0, \text{otherwise} \end{cases}$$

Z_{ij} : the percentage of the heat load in area i transported by thermal power plant j ;

The multi-objective optimization model

The multi-objective optimization mathematical model of site selection for thermal power plant is as follows:

$$\min \sum_{m}\sum_{j} F_j^m X_j^m + \sum_{i}\sum_{j} a_i Z_{ij} D_{ij} \tag{1}$$

$$\max \frac{1}{\sum_{m}\sum_{j} X_j^m} \sum_{m}\sum_{j} W_j X_j^m \tag{2}$$

$$\text{s.t.} \quad \sum_{j} Z_{ij} = 1, \forall i \in I \tag{3}$$

$$\sum_{m} X_j^m \le 1, \forall j \in J \tag{4}$$

$$\sum_{i} a_i Z_{ij} \le \sum_{m} C_m X_j^m, \forall j \in J \tag{5}$$

$$X_j^m \in \{0,1\}, \forall j \in J, m \in M \tag{6}$$

$$Z_{ij} \ge 0, \forall i \in I, j \in J \tag{7}$$

The objective function (1) is to minimize the total costs, including construction cost and transportation cost. The objective function (2) is to maximize the average comprehensive benefits of building thermal power plant. Where, W_j is the comprehensive evaluation value of the alternative sites. Formula (3) ensures that every district heating area's needs are met. Formula (4) ensures that only one thermal power plant at most is built at an alternative site. Formula (5) ensures that the heat load provided by a thermal power plant do not outnumber its maximum design capacity. Formula (6), (7) are the constraints of the variables.

Case analysis

There are four kinds of thermal power plant capacities, and the building costs of different capacities thermal power plants in different alternatives are shown in table 2.

Table 2. Building and operation costs (unit: one hundred million Yuan)

Alternatives	Capacity (MW)			
	125	250	300	375
1	6	11	16	21
2	5.5	10	15	20
3	5	10	15	20
4	6.5	12	17	22
5	5.8	11.5	16	20

There are four central heating areas. Assume that heat load will not change significantly in these areas in quite a long time in the future. Unit transportation costs (including heat loss) from each alternative to each central heating area are shown in table 3.

Table 3. Unit transportation costs (unit: ten thousand Yuan/ MW)

Load areas (demand)	Alternative sites				
	1	2	3	4	5
1（130MW）	132	141	130	136	125
2（120MW）	140	156	128	138	132
3（110MW）	128	154	152	159	142
4（110MW）	125	132	129	133	126

The objective functions (1) and (2) are integrated into the following form by the weighting method:

$$\min \omega_1(\sum_m \sum_j F_j^m X_j^m + \sum_i \sum_j a_i Z_{ij} D_{ij}) - \omega_2(\sum_m \sum_j W_j X_j^m)\ ,\quad \omega_1 + \omega_2 = 1$$

Different values are assigned to ω_1 and ω_2 to calculate the non-inferior solutions of the programming. Calculation results by lingo13.0 are shown in Table4:

Table4. The non-inferior solutions under different weightings

ω_1	0.0	0.1～0.3	0.4～0.5	0.6～1.0
ω_2	1.0	0.9～0.7	0.6～0.5	0.4～0.0
OBJ1	54.71	28.31	27.11	26.37
OBJ2	0.78	0.81	0.82	0.83
Amount	5	4	3	2

The explanations of the table above: OBJ1 and OBJ2 are these two objective functions, and respectively represent the thermal power plant construction costs and average comprehensive benefits. ω_1 and ω_2 can be viewed respectively as the importance of two goals. From table 4, we can see that goal 1 achieves the minimum, and goal 2 achieves the maximum when the weights of ω_1 and ω_2 changes respectively in the range of 0.6 ~ 1.0 and the range of 0.4 ~ 0.0. From Table4, the

conclusion can be drawn that the heat load demand of the four central heating areas can be met only by building two thermal power plants. At this point, the corresponding decision variables are as follows:

$$X=\begin{bmatrix}0&0&0&0&0\\0&1&1&0&0\\0&0&0&0&0\\0&0&0&0&0\end{bmatrix},\quad Z=\begin{bmatrix}0&0&1&0&0\\0&0&1&0&0\\0&1&0&0&0\\0&1&0&0&0\end{bmatrix}$$

That is to say, only two thermal power plants with capacity of 250 MW need to be built at the second and third alternative sites. The one at the second alternative site supplies heat to the third and the fourth central heating areas, and the other at the third alternative site supplies heat to the first and second central heating areas. In this way, the building cost reaches the minimum, and at the same time, the average comprehensive benefit reaches the maximum.

Conclusions

Site selection for thermal power plant is directly related not only to energy conservation and emissions reduction, but also to economic and stable operation of the power plant. It is more advantageous to make scientific decision for thermal power plant site selection optimization through the methods of rough set and expert group decision. It is a complex system engineering to evaluate thermal power plant site selection. In this paper, the evaluation index system is simplified with the purpose of illustrating the feasibility of this method. In the subsequent research work, we will intend to do further research to perfect the evaluation index system. In addition, it is a worth the effort direction to combine the rough set and other soft computing methods (such as fuzzy set and artificial neural network, genetic algorithm, etc.), play their respective advantages, and design hybrid intelligent evaluation system.

Urban Power Supply System Risk Assessment

Qingmin Si, Xingbai Zhang, Xueying Jiang, Lei Tian, Gongxin Yu

School of Safety Engineering, Shenyang Aerospace University, ShenYang, China

siqingmin@163.com

Keywords: urban power supply system, urban public safety, risk assessment system, grey AHP

Abstract. Urban power supply system has close relationship with urban public safety. The main risk factors, accident types and the risk degree of failures or accidents in urban power supply system are analyzed. And, it has established the public safety risk assessment system of urban power supply system. In order to show that the assessment system has good applicability in the risk assessment of urban power supply system, the power supply system safety of one urban is assessed using established risk assessment system.

Introduction

Urban power supply system is the most basic urban municipal public facilities, and is the lifeline to ensure urban normal order. The power supply system which is safe and reliable has been the important factor to ensure the urban stability. However, urban power supply system is facing more and more risks. Correctly risk assessment for urban power supply system is the key to do well in urban electric power construction.

Risk identification and analysis of urban power supply system

The main risk factors which may cause failure or accident of urban power supply system are as followed: power transmission grid system, protection system, user system, safety management system and external environment system.

1) Power transmission grid system

The power transmission grid operation state has essential important impact on the urban power supply system safety, because it is constantly changing with the passage of time. Power transmission grid safety has a total of five criterias: power grid, scheduling and operation mode, relay protection, communication and scheduling automation, primary electric equipment[1].

The safety of power grid is affected by many factors, like electric source safety, power grid structure, stability, non-power compensation, short-circuit current, over voltage, current-carrying safety etc.

2) Protection system

It mainly includes: the automatic recovery system, automatic alarm device, lightning protection system, fire fighting system, typhoon and flood control, prevent freezing, seismic system and damage prevention system, etc.

Once the auto reply system does not exist or malfunction, it will have a great influence on production and residents' safety. The existence of the automatic alarm device for power grid failure or a certain area in danger, management personnel can timely access to information and for repair and processing. Influenced by a lightning strike, transmission line tripping circuit failure events occurred more frequently, seriously affect the stability of the power grid operation[2]. Due to power system fault caused by short circuit or insulation resistance is too small or breakdown caused power cables such as temperature, will make the cable caused by rapid burning fire. The seriousness of fire and secondary accidents occurred frequently makes us have a higher requirement for fire protection system. Once earthquake, typhoon, flood or freezing disaster happens, it will influence range, large losses, difficult recovery.The external force damage the common challenges facing the gradually become the major national power grid.

3) User system

It mainly reflects on the quality of the users and their interact.Power utilization nature is determined by the users' types. Different users' types will produce various influences on the safety of power grid. On the contrary, suddenly interruption of power supply for all kinds of users have different degrees of influence.User self-help ability but also the power grid safety goals setting, in the case of user self-help ability strong, power grid failure can avoid bigger losses.

4) Safety management system

Safety management institutions is essential.The system establishment regulate people's behavior, the good management system, can accurately identify risks, especially to find the weak link, objective assessment and release risk, to carry out the targeted prevention measures, control the risk in advance, reduce the risk to a minimum. Regular inspection of the assessment, you can find out equipment defects and inherent danger point and the environment, to further consolidate the safety of power grid. Grid emergency preplan for urban public safety can not be ignored, the influence of against blackouts and other major accident emergency drills, can in real time to reduce the loss caused by accident.

5) External environment system

The safety of the equipment itself, the design of the safe distance and the state of the surrounding environment makes different impact on the surrounding environment of power grid[3]. Protection and isolation measures can effectively prevent the electric shock accidents, ensure public safety grid runtime.Daily maintenance can reduce the incidence of accidents.Maintenance of equipment and the team from the accident point distance and time of arrival, indirect decide the progress of the accident, reasonable allocation of maintenance and rescue human, determines the urban power grid safety.

Urban power supply system of risk assessment system

Urban power supply system risk assessment system[4] is shown in Tab.1

Tab.1 Risk assessment system of urban power supply system

Target layer	Criterion layers	Index layers
Urban power supply system risk S	power transmission grid system U_1	power grid safety V_{11} scheduling and operation mode V_{12} relay protection system safety V_{13} communication and scheduling automation safety V_{14} primary electric equipment safety V_{15}
	protection system U_2	automatic recovery system V_{21} automatic alarm device V_{22} lightning protection system V_{23} fire fighting facilities V_{24} Seismic system V_{25} typhoon and flood control, prevent freezing V_{26} damage prevention system V_{27}

For some complicated factors, the division of three level index is needed[7].

Application analysis

One urban is divided into five regional power, during normal operation of the grid, the load is 1014.5MW. In normal mode, the 220kV system, the total length is 453.7km,voltage is maintained at 231.1kV ~ 227.2kV, the maximumtransmission power flow dual loop is 2*161.2MW, 110kV system, the total length is 717.6km, voltage is maintained at 107.4kV ~ 117.1kV, the maximum transmission power is 2*75.6MW double loop. In the 220kV main substationmain transformer substation, a maximum overloadcapaurban ratio reached nearly 144%[8].

1) Determine the standard grade assessment index and weight

Using the AHP to determine the weight of U_i and V_{ij} [9]. As shown in *Tab*. 2.

2)Calculate the grey assessment coefficient, weight vector and weight matrix[10]

The assessment of the 4 grey classes. Grey number is e, e=1,2,3,4, said "excellent", "good", "bad". The assessment index of V_{ij}, grey assessment coefficient V_{ij} belongs to the eassessment grey types, denoted as X_{ije}. Total greyassessment of total ash belonging to the category of greyassessment of various number, denoted as X_{ij}. There are$X_{ije}=\sum f_e(d_{ijm})$，m∈[1，10]，$X_{ij}=\sum X_{ije}$，e∈[1，4].

All the assessment experts on the assessment index of V_{ij}, the rated objects that grey assessment e gray weight,denoted as r_{ije}, then, $r_{ije} = X_{ije} / X_{ij}$.

The vector can be composed of V_1,V_2,V_3,V_4, corresponding to matrix D_1, D_2, D_3, D_4.

As shown in Tab. 2.

Tab.2 Index score and gray weight vector

Experts / Index	1	2	3	4	5	6	7	8	9	10	r_{ij1}	r_{ij2}	r_{ij3}	r_{ij4}

3) Comprehensive assessment

Comprehensive assessment of index layer Vi, and the assessment results can be recorded as B_i, then: $B_i = U_{ij} \times D_i$ .By the comprehensive assessment index layer V_i results B_i, criterion layer U for grey assessment grey assessment weightmatrix R, comprehensive assessment criteria layer U resultsdenoted as B, are: $B=U\times R$.

Reference grey level evaluates the object system ofcomprehensive assessment. According to the comprehensive assessment results of B, the maximumprinciples for determining the rated objects belong to greylevel, and finally calculate the comprehensive assessment value. $S=B\times C^{T}$, where C^{T} is the grade of gray clusterassignment according to the "gray level" comprehensive assessment value. According to the corresponding interval is divided into corresponding levels as shown in *Tab.*3.

Tab.3 Index grade standard

Index	Comprehensive assessment value	Grade	Index	Comprehensive assessment value	Grade
One level	$3.3192\leq S\leq 3.5999$	excellent	Three level	$2.9435\leq S\leq 3.1108$	medium
Two level	$3.1108\leq S\leq 3.3192$	good	Four level	$2.7692\leq S\leq 2.9435$	bad

The assessment of urban V_{ij} are good indicators. Thecomprehensive assessment results of $S=B\times C^{T}=3.00672$. The whole urban power supply system of safety assessmentfor "the three level", "medium".

Conclusions

1) It give a comprehensive analysis of the five major risk factors which may lead to the urban power supply system failure or accident: power transmission grid system, protection system, user system, safety management system and external environment system..

2) Based on the risk analysis results, it has established the public safety risk assessment system of urban power supply system. The system consists of five indicators in criterion layer, twenty-four indicators in index layer.

3) The power supply system safety of one urban is assessed using established risk assessment system. The application results show that the assessment system has good applicability in the risk assessment of urban power supply system.

Keywords: Power system reliability, adequacy, Monte-Carlo simulation, power pool, supplied demand technique, stochastic network reduction.

Abstract. This paper presents an iterative power system balance reliability calculating technique ensuring better convergence and faster calculations. The technique is called "supplied demand". Nodal power imbalance is considered as the primary stochastic value under analysis. An analytical solution does not contain probability density functions. It results in faster calculations. Results were verified by Monte Carlo Simulation and showed high accuracy of the technique.

Introduction

The main objectives and tasks for power pool reliability calculations in terms of ensuring the power and energy balances have been formulated and described in [1 – 4]. Electrical power system (EPS) balance reliability (BR) calculations are performed both in planning and operating stages of the EPS. The calculations are aimed at determining and allocating the distribution system real and reactive power reserves, justifying the integration of generation facilities and tie lines, scheduling the main equipment overhauls, pricing power and energy.

From mathematical point of view the key problem of BR calculations is to determine the probability characteristics, i.e. distribution function (DF), frequency, expected value (EV) and variance of the power and energy shortage in electrical power systems connected in power pool with limited capacity of tie lines. Basing on the received distribution functions it is possible to estimate expected value of lost load damage,hence to justify investments in EPS development [1, 3].

The structure of the initial data for BR calculations is presented in its reduced form in the description of Melentiev Energy Systems Institute test system [5]. Typically, initial data for BR problem is as follows:power pool topology, unit set and nodal load characteristics, tie line set and capacity probabilistic characteristics, power pool key element specifications and overhaul schedules, equipment commissioning and decommissioning plans.

In certain situations the generation subsystem of a concentrated EPS is presented as one equivalent unit [1]. More often it is presented as groups of similar units withbinomial probability distribution of their states. In further these groupsare combined in probabilistic series [3]. In addition, resulting probabilistic sequence is often approximated by certain continuous distribution, such as normal, gamma, etc. In general, the type of approximating distribution depends on load probability distribution, which is the most significant stochastic variable. This approximation causes a simulation error and should be substantiated for each calculation.

Tie lines are usually represented by capacity probabilistic series. In this case approximation of probabilistic series by continuous distribution is extremely inadvisable, due to a small number of line states (on and off).

A number of leading scientific organizations working on BR problem made a comparison of different BR calculation techniques [6]. The comparison showed a significant difference of the calculation results. In fact it is very difficult to point outmost accurate solution.However, as a general rule, Monte-Carlo simulation (MCS) is used as a reference technique.The key problem of MCS is associated with high computational load. As a result it is preferred for long-term calculations of network investments, when calculating time isn’t very important.

More recently, however, emphasis in adequacy calculations has been made on analytical methods. First of all, this is caused by extension of BR calculations to the sphere of operational calculations. In this case, BR calculations, on the one hand, allow optimizing commercial and operating reserves, but on the other hand, require a fast calculating technique [7].

Iterative approach for balance reliability problem

BR problem may be presented as a problem of supplying demand for a capacity margin (CM), when load L_i and spare capacity G_i have a stochastic nature. The power imbalance (PI) $N_i = L_i - G_i$ characterizes the power shortage in EPSi,which works separately from power pool (i.e. it isn't connected with other EPS). If $N_i < 0$ system has spare capacity, that could be provided to interconnected system j through tie line $i - j$. The tie line has capacity in the forward direction π_{ij} and capacity π_{ji} in the backward direction [7, 8].

Assume that each EPS has DF $F_i(x)$, EV $\overline{N}_i$ and variance D_i of stochastic variable N_i. Denote demand of EPS j for an spare capacity of EPS i by $N_{i(j)}$.Due to the impact of other interconnected systems, EPS i has a system demand$N_i^S = \sum_{j \neq i} N_{i(j)}$. The system demand has DF $F_i^S(x)$, EV $\overline{N}_i^S$ and variance $\overline{D}_i^S$. Taking into account the impact of other systems, summarized PI in EPS$i$is$N_i^\Sigma = N_i + N_i^S$.If capacity margin of tie $i - j$ is limited by the interval $(-\pi_{ji},\ \pi_{ij})$ then the PI reduced probability distribution function is defined as:

$$F_{i(j)}(x) = F_j^\Sigma\left(x, -\pi_{ji}, \pi_{ij}\right) = \begin{cases} 0, & x < -\pi_{ji}; \\ F_j^\Sigma(x), & -\pi_{ji} < x < \pi_{ij}; \\ 1, & x \geq \pi_{ij}. \end{cases} \quad (1)$$

Mutual aid or PI alternation results in the alternationof N_i^S. This alternation, in its turn, changes resulting probabilistic characteristics of all interconnected power systems. This fact determines correlation between all interconnected subsystems. Calculating $N_{i(j)}$ for every $i$and j, with account for subsystems interaction, gives a solution for BR problem. Nevertheless, at this moment, the problem in such a formulation may not be solved analytically.

In order to get a solution, it is possible to apply a capacity market model. According to this model, at the first stage, subsystems exchange spare capacity with near subsystems. Then exchanging capacity is being adjusted, due to the impact of distant subsystems. The transient process goes on until it results in a certain steady state. Changes in mutual aid in this steady state are caused only by fluctuations of PI. In terms of BR problem, such exchanging process is defined by the recurrence:

$$F_{i(j)}^{(k+1)} = \left(F_j^\Sigma(x)\Big|_{-\pi_{ij}}^{\pi_{ji}}\right)^{(k)}. \quad (2)$$

Convergence of the process in eqn. (2) depends on the way PI is redistributed. For instance, in a simple additive model, where, during calculation of $N_{i(j)}$, EPS j is presented by full PI N_j^Σ, positive feed-back should occur. Indeed, in a circular structure with three interconnected EPS i, j and k PI $N_{i(j)}$ increases PI N_i^Σ. It results in an increase of $N_{(k)i}$, therefore, an increase of $N_k^\Sigma, N_{j(k)}, N_j^\Sigma, N_{i(j)}$. At the same time, counter-current flow techniques, for instance, allocation of PI in proportion to the demand of the near systems enhances negative feedback, thus, convergence of the calculating process.However, these techniques don't ensure the desired robustness, due to different proportionality factors for load and generation. This fact brings up a necessity to account load and generation impact separately. Nevertheless, at the level of a single EPS these variables are united, which breaks down the regulating effect.

Supplied demand technique

The iterative procedure, presented by eqn. (2), results in the definition of PI in tie $i-j$. This PI is defined by the demand for a capacity margin both from EPS j ($N_{i(j)}$) and EPS i ($N_{j(i)}$). These variables form PI in tie $i-j$, but don't finally define it. PI in line is defined by the supplied demand, both from EPS j and EPS i.It is assumed that at each stage of multi-stage PI definition process DF $F_i^{\Sigma}(x)$ is known. In addition, it is necessary to know DF of the summarized power demand of EPS i without EPS $j$impact $F_{i/j}^{\Sigma}(x)$. This DF allows accounting impact of near subsystems in a proper way.

In order to decrease symbolic burden, PI distribution functions $F_{i/j}^{\Sigma}$ and $F_{j/i}^{\Sigma}(x)$ hereinafter are denoted as F_i and F_j correspondingly.

In a two-node network PI in tie $i-j$ is defined by a difference between the demand of EPS $j$supplied by EPS $iN_{ij(j)}$and the demand of EPS $i$supplied by EPS $N_{ij(i)}$:

$$N_{ij} = N_{ii(j)} - N_{jj(i)}. \tag{3}$$

Distribution function of PI N_{ij} is as follows:

$$F_{ii(j)}(x) = \begin{cases} V_i(-x)F_j(x), & x \geq 0; \\ R_i(-x)F_j(x), & x < 0, \end{cases} \tag{4}$$

where $R(x) = 1 - F(x)$ is an additional DF. In contrast with DF $F(x)$, function $V(x)$ indicatesthat stochastic variable ξ includes the right limit $V(x) = \mathcal{P}\{\xi \leq x\}$, when $F(x) = \mathcal{P}\{\xi < x\}$. This becomes important, when DF has a simple discontinuity, like DF of spare capacity. On the other hand, when DF is continuous $V(x) = F(x)$.Due to the smoothing effect of stochastic load,PI DF hereinafter is assumed to be continuous.

It is possible to represent PIEV in tie $i-j$as a sum of four components:

$$\overline{N}_{ij} = \overline{N}_{ij(j)} + \overline{N}_{ij(i)} + \overline{N}_{ij(\pi_{ij})} + \overline{N}_{ij(\pi_{ji})}, \tag{5}$$

where$\overline{N}_{ij(j)}$ and $\overline{N}_{ij(i)}$ are defined by supplied demand of EPS j and EPS i correspondingly; $\overline{N}_{ij(\pi_{ij})}$ and $\overline{N}_{ij(\pi_{ji})}$ are defined by tie line capacity π_{ij} and π_{ji}correspondingly.

Supplied demand from EPS j is defined as:

$$\overline{N}_{ij(j)} = \left[M_j F_j(x) - \sigma_j^2 f_j(x)\right]\Big|_{-\pi_{ji}}^{0} - \int_{-\pi_{ji}}^{0} xF_i(-x)dF_j(x) + \int_{0}^{\pi_{ji}} xF_i(-x)dF_j(x). \tag{6}$$

Equation (6) contains integrals. It is very useful to replace them by analytical expression. EPS load is usually described bynormal distribution, while generation subsystem is described by binomial distribution. It should be noted thatbinomial distribution asymptotically approaches normal distribution, when number of generators is growing. Therefore normal distribution is a good approximation of PI DF. Normal distribution has analytical expression of reduced EV.

After integration by parts eqn. (6) will be following:

$$J_{ij}(a,b) = \left\{F_i(-x)\left[M_j F_j(x) - \sigma_j^2 f_j(x)\right]\right\}\Big|_{a}^{b} + M_j \int_{-b}^{-a} F_j(-x)dF_i(x) - \\ -\sigma_j^2 \int_{-b}^{-a} f_j(-x)f_i(x)dx. \tag{7}$$

Equation (7) contains two integrals that are similar to convolutionsof PI DF and PI density function correspondingly. The only difference appears inintegration finite limits. However, if PI DF of EPS i is described by reduced normal distribution, the integrals define DF and density function of PI N_j and reduced PI$N_i|_{-b}^{-a}$. Then:

$$J_{ij}(a,b) = \{F_i(-x)[M_j F_j(x) - \sigma_j^2 f_j(x)]\}\Big|_a^b + \left[M_j F_{j+i_{-b}^{-a}}(0) - \sigma_j^2 f_{j+i_{-b}^{-a}}(0)\right] \times \\ \times [F_i(-a) - F_i(-b)] \quad (8)$$

As a result eqn. (6) is presented as follows:

$$\bar{N}_{ij(j)} = M_j\big(F_j(0) - F_j(-\pi_{ji})\big) - \sigma_j^2\left(f_j(0) + f_j\big(-\pi_{ji}\big)\right) - J_{ij}\big(-\pi_{ji}, 0\big) + J_{ij}\big(0, \pi_{ij}\big) \quad (9)$$

Power imbalance $N_{ij(i)}$ is calculated similarly:

$$\bar{N}_{ij(i)} = M_i\big(F_i(0) - F_i(-\pi_{ij})\big) - \sigma_i^2\left(f_i(0) + f_i\big(-\pi_{ji}\big)\right) - J_{ji}\big(-\pi_{ij}, 0\big) + J_{ji}\big(0, \pi_{ji}\big) \quad (10)$$

Resulting equations (9) and (10) were verified by MCS. Results show that analytical solution is the marginal result for MCS.Thus supplied demand technique it is accurate enough. Software based on the proposed technique calculated BR of test systemincluding 41 nodes [5] in 0.1 sec. Consequently the technique is also very fast.

Summary

This paper presents balance reliability calculation technique referred to as supplied demand. It calculates expected value of power imbalance in tie line without numerical integration. The technique was verified by MCS. Results show that the analytical solution is the marginal result for MCS. Moreover, the calculation speed is also very high. Hence supplied demand technique is recommended for power system balance reliability calculations.

Key words: Power system, load forecasting, regression analysis

Abstract: Power system load forecasting is an important job for power system scheduling, planning and planning departments. In the long run, the accuracy of load forecasting is closely related to reasonable extension and renovation of power grid development. On the basis of collecting historical load data of a region, considering the co-integration theory and error correction, the author adopts regression analysis to predict of the load development of the region in the next five years, then finally puts forward the new way of enhance load forecasting accuracy in the future.

Introduction

With the rapid development of power grid today, electricity workers are paying more and more attentions to load forecasting. As a traditional problem to research in the field of power system, considering its economic, social, weather and so on, load forecasting [1, 2] is used to estimate and speculate the development of load in advance, after analyzing and researching the historical data ,then exploring the internal relation and its development change rule.

So far, a variety of load forecasting methods are being used. In general, they can be divided into two types: classical forecasting method and modern load forecasting method. Among them, classic prediction method includes trend analysis, time series method and regression analysis; modern load forecasting methods includes grey mathematics theory, expert system method, neural network theory and fuzzy load forecasting. [3] In this article, the regression analysis method will be adopted.

Regression analysis

According to reference [4], in the premise of collecting and counting the historical data, regression analysis method is to obtain the function (or curve) which can describe the relationship between these related factors by using mathematical methods, then apply the function (or curve) for load forecasting at a certain moment of the future. The types of regression equation with one unknown are as follow:

type of equation	equation
general type (standard equation)	$y = a + bx$
Power function	$y = ax^b$
Exponential function	$y = ae^{bx}$
Logarithmic function	$y = a + b\ln x$

Via mathematical transformation: taking the logarithm on both sides of these non-standard equations, then they can be changed into standard linear equations as $y = a + bx$. After working out the estimated value of coefficients a ， b in the regression equation based on the samples, the value of the independent variable x can be calculated by the predictive value of the dependent variable in the regression equation.

If the regression equation is a standard one, assuming that a set of values (sample) (x_i, y_i) (I = 1, 2, 3，…n) is known, which is made up of the variables x and its corresponding random variables y, then the steps of calculating the standard equation coefficient a and b are as follows:

Calculating the average of x, y:

$$\bar{x} = \frac{1}{N}\sum_{i=1}^{N} x_i, \quad \bar{y} = \frac{1}{N}\sum_{i=1}^{N} y_i \tag{1-1}$$

Calculating the variance and covariance L_{xx}，L_{yy}，L_{xx}:

$$L_{xx} = \sum_{i=1}^{N}(x_i - \bar{x})^2, \quad L_{yy} = \sum_{i=1}^{N}(y_i - \bar{y})^2, \quad L_{xy} = \sum_{i=1}^{N}(x_i - \bar{x})(y_i - \bar{y}) \tag{1-2}$$

Calculating the coefficient:

$$\hat{b} = L_{xy} / L_{xx}, \quad \hat{a} = \bar{y} - \hat{b}\bar{x} \tag{1-3}$$

Obtained the regression equation:

$$y = \hat{a} + \hat{b}x \tag{1-4}$$

If the regression equation is a non-standard one, to the power function form, the form of exponential function and logarithm function form regression equation, it should firstly transform the original samples to the corresponding samples ((x'_i, y'_i), (x_i, y'_i) and (x'_i, y_i), (i=1, 2, 3,..., n), and then the corresponding coefficients can be determined, according to the above steps.

These established regression equation must be tested by correlation coefficient and standard deviation to confirm whether they can be used in load forecasting.

Correlation coefficient r:

$$r = \frac{\sum_{i=1}^{N}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{N}(x_i - \bar{x})^2 \sum_{i=1}^{N}(y_i - \bar{y})^2}} = \frac{L_{xy}}{\sqrt{L_{xx} L_{yy}}} = \hat{b}\sqrt{\frac{L_{xx}}{L_{yy}}} \tag{1-5}$$

Standard deviation S*:

N>30: $$S^* = \sqrt{\frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{N-2}} \tag{1-6}$$

N<=30: $$S^* = \sqrt{\frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{N-2}} + \sqrt{1 + \frac{1}{N} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^{N}(x_i - \bar{x})^2}} \tag{1-7}$$

In the above equations, N stands for samples, $\hat{y}_i$ is the estimated value of y_i, x_0 is the predicted value of year, for example, when predict the twelfth year, then x_0 equals twelve.

Correlation coefficient is always less than or equal to 1, its value reflects the relevance between x and y. The larger the value of r is, the more closely relevance between x and y is, therefore, using equation $y=a+bx$, more reliable results of load forecasting will be got. R=0 means x and y are uncorrelated, equation $y=\hat{a}+\hat{b}x$ can't be described the relationship between x and y. So the correlation coefficient is used to determine whether the corresponding regression equation is available. The smaller the standard deviation S is, the less prediction error will exist. That is to say, using the regression equation to get the prediction value is closer to the actual value. Therefore, standard deviation is used to choose the final regression equation from all the feasible regression equations.

Co-integration theory and error analysis

The traditional regression model ignores the non-stationary time series, so fitting equation may appear "spurious regression", finally due to an inaccurate prediction, although the process of applying the model to predict is simple[5]. So introducing co-integration theory and error correction model to deal with the non-stationary time series long-term equilibrium.

For a vector time sequence $\{X_t\}=(X_{1t}, X_{2t},..., X_{nt})'$, if all the components sequence is I(d) sequence, which is d order integration, there is a Nx1 order sequence β(β≠0):

$$\beta X_t = \beta_1 X_{1t} + \beta_2 X_{2t} + \ldots + \beta_n X_{nt} \tag{1-8}$$

If the equation above is (d-b) order integration, vector $\{X_t\}$ is d, b order co-integration, and vector β is a co-integration vector [6].

The purpose of the co-integration test is to determine whether a set of linear combination of the unsteady sequence have co-integration relationship. It can also determine whether the linear regression equation is reasonable[7]. Engle-Granger[8] co-integration test is an important method.

Co-integration theory consider that the dependent variable can be explained by a linear combination of the independent variables, there is a stable equilibrium relationship between them, the dependent variable can't be constitute a residual error sequence by the explained independent variable. The residual error sequence should be stable, namely, there is a co-integration relationship between dependent and independent variables, and this method is to test the unit root of residual error regression equation.

The steps of co-integration test are as follows:

(1) confirm the order of variable: using he unit root test to test whether variable X_t and Y_t have the same single order;

(2) Estimate the long-term equilibrium relationship: on the basis of step 1, the long-term equilibrium model can be set as $y_t = \beta_0 + \beta_1 x_t + u_t$;

(3) Check the residual sequence, whether it is smooth and steady.

Granger theorem shows that unless there is a co-integration relationship between non-stationary variables, it can inevitably establish error correction model; if the error correction model can be established, using non-stationary, variables, then there must be a co-integration relationship between these variables [9].

Autoregressive Distributed Lag model (Auto regressive Distributed Lag, ADL) is a common model, the expression of this model is a "long-term equilibrium" relationship between variables.

First-order autoregressive distributed lag model, ADL (1, 1):

$$y_t = \beta_0 + \beta_1 y_{t-1} + \beta_2 x_t + \beta_3 x_{t-1} + u_t \tag{1-9}$$

The load forecasting process

Based on the collected historical load data of a region, adopting monadic regression analysis method, and introducing association deals and error analysis, the article predict the total power consumption and maximum load in the next five years.

Basic steps of load forecasting program writing:

(1) Input samples, transform the samples;

(2) Calculate the average and variance of each sample;

(3) Get the coefficients of the regression equation;

(4) Calculate the correlation coefficient of the regression equation and determine the feasible regression equation

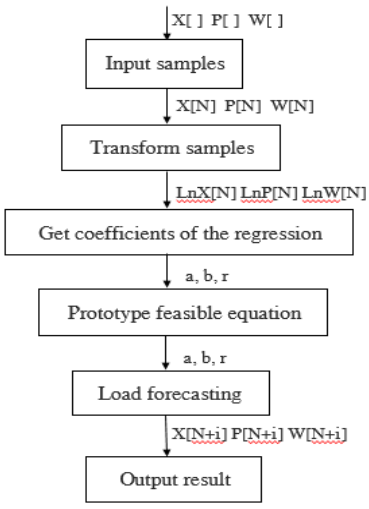
(5) Find the prototype of the feasible equation;

(6) According to the principle of minimum standard deviation, determine the final regression equation;

(7) Using the selected regression equation to do load forecasting;

(8) Output the load forecasting result.

According to the load forecasting process, the data flow diagram is as follows:



N: the number of sample data, in this program N = 6;

X[ ]: year;

P [ ]: power supply, (units: kWh);

W [ ]: the biggest power supply load, (units: MW);

a, b: the coefficient of function;

r: the correlation coefficient;

X[N+i]: the year of load forecasting, i=1,2,3,4,5;

P[N+i]: the power supply of load forecasting, (units: kWh);

W[N+i]: the biggest power supply load of forecasting, (units: MW);

The results of load forecasting

Collect and sort historical electricity load data of the region during year 2008 to 2013, including the total power consumption and the maximum power load in the region. The statistics are as follows in Table 1:

Table 1 2008～2013 historical electricity load data

year	total power consumption (1 Million kWh)	The maximum power load	
		（MW）	Growth Rate (%)
2008	3.0175	69.59	/
2009	2.9019	70.34	1.08
2010	4.0438	99.15	40.96
2011	5.5954	125.98	27.06
2012	7.8741	157.15	24.74
2013	10.2451	176.98	12.62

Using the load forecasting program, input historical electricity load data (samples) year by year, then run the program, the value of whole society power consumption and the maximum power load in the next five years (2014～2018) will be output, the load forecasting results are as follows in Table 2:

Table 2 2014～2018 load forecasting results

year	total power consumption (1 Million kWh)	The maximum power load	
		（MW）	Growth Rate (%)
2014	10.8551	197.16	/
2015	12.3660	221.48	12.33
2016	13.8769	245.79	10.98
2017	15.3880	270.11	9.89
2018	16.8989	294.43	9.00

The Growth trend of whole society power consumption and maximum power load are expressed in fig.1 and fig.2.

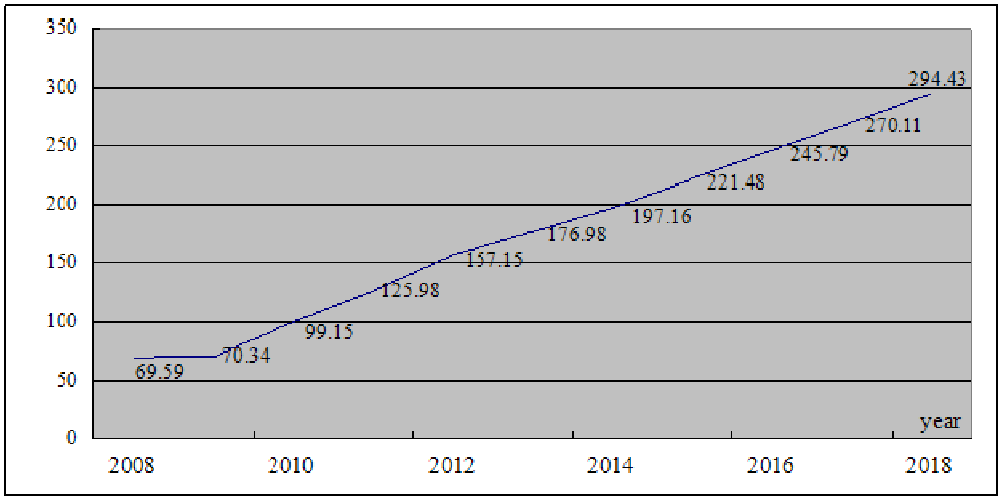


Fig.1 Maximum power load (MW)

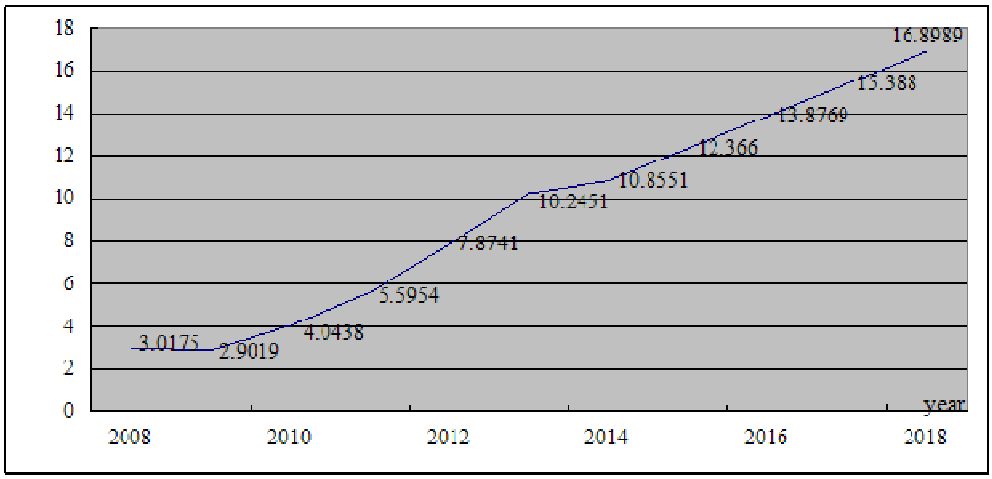

Fig.2 Whole society power consumption (1 Million kWh)

The load forecasting results indicate that both total power consumption and maximum power load are presented the Growth trend year by year, and their growth is relatively stable. The annual growth rate of total power consumption and largest power supply load are respectively about 12% and 10%, which shows that electric power industry is developing steadily.

Conclusions

Load forecasting is affected by the economic development, weather and other factors. In order to get a more accurate prediction results, the non-stationary time series of these factors need considering. So co-integration theory and error analysis are considered based on the traditional regression analysis to avoid "spurious regression" in this article.

In this article, there still have some deficiencies, which need to go deep into study in the future. Implementing the following principles [10]: The principle indicates that the power consumption and the trend of power supply load are more greatly affected by the development law in recent historical time. On the contrary, the development law of load long-time ago has a weak correlation with load forecasting. After introducing this principle, if analysis and correct the historical load data advisably, the accuracy of load forecasting results will be further improved. In conventional prediction, residual treated in each period is usually used.

Keywords: smart micro-grid; business operation mode; technical economy evaluation.

Abstract. To make the advantages of smart micro-grid in economy and environment to the greatest extent, many countries choose to make detailed research on the business operation mode and technical economy of micro-grid. Based on the related research, this paper generalizes several typical user modes, and then provides a reasonable technical route to study the operation mode and technical economy of micro-grid. For its business operation mode, not only the existing proposals are analyzed, but also are its method of calculating the cost and benefits of this program. Finally, specific plans about how to assess the technical economy are also analyzed.

Introduction

During the primary development period of micro-grid, most attentions are put on the planning, control and operation of the micro-grid as well as research and development of related key technologies and devices [1, 2]. On the contrary, the attention on the input-output economy benefits and the application value of following promotions are obviously not enough. Meanwhile, it is also lack of reasonable policies and economic incentives, which leads to the low acceptance of micro-grid. Now the scope of micro-grid is also infinite and the business operation mode is not certain, leading to the confusion of the subjects of micro-grid establishment and business operation. Some enterprises even simply connect the distributed renewable energy sources to the power grid to operate as a micro-grid. To meet the requirements of user-side distributed generations connecting to the power grid, it is urgent to research the business operation mode and demand response strategies of micro-grid.

Technical route

For the business operation mode, several studies have been done as follows. Under the background of Chinese electricity market, an investment-benefits model to evaluate the balance between investment and benefits in different business operation mode for participants, including consumers, business operation organizer and government, is established. In paper [3], based on the investment-benefits model and the analysis on the inner relations among market participants, a business operation mode which is adaptable to the current situation of user-side micro-grid such as housing estate/ home, enterprise/ industry estate is proposed. Therefore, in the following work, we can analyze the application range and generalization performance of the typical business operation mode from multi-perspective, such as energy efficiency, energy consuming habits, load type, characteristics of distributed renewable energy sources and return of investment. Based on the characteristics of different user types, climate and areas, the optimal business operation mode for typical area and energy consumers can be further explored.

In paper [4], combined with the construction of demonstration engineering practice, the evaluation method of technological economy for user-side micro-grid is studied for the whole life circle. The input-output of this programme under different business operation mode is also assessed to provide a basis for the sustainable development of micro-grid. Paper [5] establishes a comprehensive index assesment and analysis model, which considers the reliability, security, quality of electric energy, ecomomical efficiency, environmental efficiency and business operation cost/benefits. Based on the model, a generalized index assesment and analysis method is proposed.

Therefore, it is advisable to evaluate the technological economy efficiency from the perspective of full life circle. According to analyzing the uer-side micro-grid in the developers, energy consumers and the whole interaction environment, the input-output model under typical business operation mode can be established. In the whole lofe circle of micro-grid programme, there are many aspects such as the assessment of manufacturability, cost evaluation, assembling ability and maintainability and so on. The indexes that can reflect and evaluate the business operation performance exactly are tobe selected to analyze with the consideration of demand response strategies and energy consuming efficiency . Finally, the influence of aspect, including the diversity of distributed energy resources, the energy composition and the ratio between distributed energy resources and energy storage system, on the cost and benefits of the system business operation performance can be analyzed.

Based on the above analysis and summary, the technical route of the research on business operation mode and technological economy evaluation is shown in Fig.1.

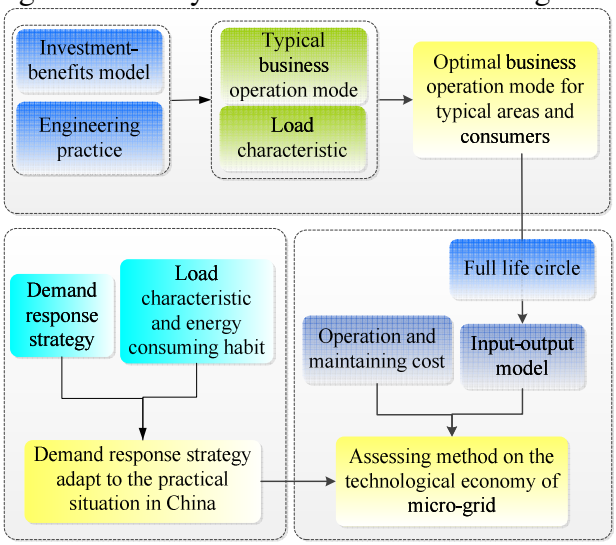

Fig.1 Technical route of business operation mode and technological economy evaluation

Business Operation Mode

In recent years, with the rapid development of distributed energy resources, developed countries such as United States, Japan, European countries and part of developing countries all concentrate on the practical application of micro-grid. Now they have achieved satisfactory performance by setting a series of standards, compensation mechanism to promote the development of micro-grid [15]. It can be found that all the program overseas has the following common characteristics: the construction of micro-grid is promoted by the joint efforts of enterprises and government; in order to guarantee the benefits of operation organizer, they all pay much attention to the setting a series of related policies such as the benefits distribution mechanism and cost compensation mechanism; during the period of initial development, the program relies on the support of related incentive policies. The operation organizers have some preferential policies for the close relationship with government; all the operation organizers concentrate on the application of new technologies and corresponding assessment of the operation performance.

According to the difference between the ownership and operation rights of housing estate micro-grid, paper [6] briefly introduces several business operation modes in this kind of energy consuming area and then provides the corresponding investments and economic benefits of energy consumers and electric companies. Based on the analysis of the current business operation development of micro-grid, paper [7] studied the investments and economic benefits in the independent business operation mode and then offered some advices to guarantee reasonable benefits of operation organizers. Safeguard mechanism such as electricity price mechanism, grid-connecting admission mechanism and cost compensation mechanism are suggested to establish. The influence of distributed generations, interruptible load and reactive power compensation on node capacitance on

the short-term business operation performance needs to be considered. Besides the fluctuations of energy demand and variation of the electricity price also need to be considered. Paper proposes a two-stage processing scheme and related mathematical model. The first stage of model is day-ahead operation mode and the second stage of model is real-time operation mode involving power distribution system. The day-ahead operation mode provides the decision results to the real-time operation mode, which means the real-time decision of power distribution system takes the day-ahead decision into consideration.

Based on the above research and analysis, we can summarize and conclude the typical business operation mode as for types under the special background and condition of Chinese electricity market. For the three participants of energy consumers, operation organizer and government, the four typical modes are “power grid company invest + power grid company operate”,” power grid company invest + energy consumers operate”,” power grid company incest + third party operate” and “energy consumers invest + energy consumers operate”. The influence on the benefits of program participants is evaluate from many aspects, including electricity mechanism, energy price, operation mode of micro-grid as well as difference between load demand and supply. Combined with the case study of actual projects, the optimal business operation mode for housing estate/home, enterprise/ industrial estate and other type of user-side micro-grid can be obtained respectively.

Technical Economy Evaluation

Fees lower than real cost produces serious financial balances, making operation and maintenance unfeasible and leading to the desertion of micro-grid projects by the local operator. To avoid this probelm, many countries have studied the technical economy evaluation of micro-grid in depth. Developed countries strats from the energy demand of electricity market and environment protection to promte the energy supply reliability and meet various requirements raised by different energy consumers. Furthermore, in order to reduce the cost, the economic policies of tax conssessions and finacial subsidies are set and enacted. Paper [3] takes Spain as example to make the technological economy evaluation on the PV rural electrification projects. The distribution of real costs (installation, operation and maintenance, management) is presented from the operational data of the energy service compancy during 5 years. The influence of some key aspects such as battery and geographical dispersion is also discussed.

Based on the summary and conclusion of the existing studies, for the whole life circle of this project, there are three periods in the business activities: installation period, operation and maintenance period and management period. And the cost structure of the micro-grid project is shown in Fig.2.

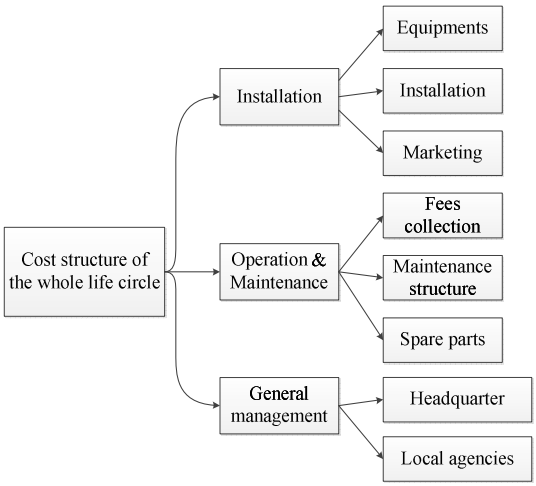

Fig.3 Cost structure of smart micro-grid project

The installation period contains both the fees of equipment and installation and the expenditure in marketing. The equipment cost is greatly influenced by the sell price of PV modules, batteries and son on. Considering the variation of the price of batteries and corresponding components in the

distributed energy resources (such as PV cells) in the market, the sensitivity analysis need to be conducted, which means to assess the effect of equipment prices on the total cost.

Operation cost mainly relates to the cost in fees collection. Maintenance includes both spare parts and the maintenance structure. For rural areas, it is not so convenient to collect fees as the urban areas. It demands a great effort in human capital and mobility, which justifies its high cost. The maintenance structure refers to the direct costs of this activity related to staff, offices, stores, vehicles, fuel, telephone, etc. Spare parts refers to the expenditure produced in the process of mantenance, including the repair and subsititute charges of devices (such as batteries, smart meters etc.).

The management period lasts from the end of installation period to the end of whole project. Take a project with 10 years life circle as example, if the first three years is the installation period, the remaining 7years is the management period. During the seven years, the management cost is relative even. For the operation and maintenance cost, it holds small share in the first three years while in the following seven years occupies a huge share in the annual year cost.

Conclusions

For the business operation mode, the realization method varies by the area and user type. This paper analyzes the evaluation method of technical economy from the perspective of whole life circle. In the following research, it is advised to combine the load characteristics and energy consuming habits of special area to study. To cater to the typical business operation mode, the demand response strategies and standards for certain areas are also need to be proposed.

Keywords: PV (photovoltaic), Distributed, Electricity Subsidies, Feed-in Tariff, Net Metering, Self Consumption

Abstract. To support the development of the PV industry, the China National Energy Bureau has issued some policies to stimulate the domestic PV market consumption, such as the "Golden Sun Demonstration Project", "Building Integrated PV" policy. But these policies have some great vulnerability. Many developed countries, such as Germany, Japan, USA; they have some mature PV price settlement policies, such as Feed-in Tariff, Net Metering and Self Consumption. Therefore, according to the needs of domestic situation, China National Energy Bureau needs to refer to those developed countries' mature PV price settlement policies to formulate a PV price settlement policy. This policy must suit China PV market. And this policy should guide the development of domestic PV market correctly. Herein, I put forward some recommendations to improve our PV price settlement policy.

Instruction

China government began to implement the "golden sun demonstration project" from 2009 to support the development of domestic PV, which focuses on supporting user side of photovoltaic grid connected. This policy uses in accordance with the installation to subsidy every unit of electricity, which caused a lot of projects to use loopholes in the policy to obtain subsidies phenomenon. After the Chinese government learned the "golden sun demonstration project" lessons, according to the European experience, they take the electricity subsidy policy. This measure improves the utilization rate of fiscal funds. However, electricity subsidies are divided into several forms. In this paper, several forms of electricity subsidies are discussed. According to this discussion, we want to explore which kind of form is conducive to the development of Chinese photovoltaic power generation. [1]

European electricity subsidy policy

European electricity subsidy policy mainly has three forms. They are Feed-in Tariff, Net Metering and Self Consumption. [2]

Feed-in Tariff. The Feed-in Tariff policy is used in the form of two lines of revenue and expenditure. The form is that the electricity generated by PV power station is sold to the grid, and the electricity used by users is bought from the grid in retail price. Feed-in Tariff mainly has three forms: Standard FiT, Variable FiT and Premium FiT.

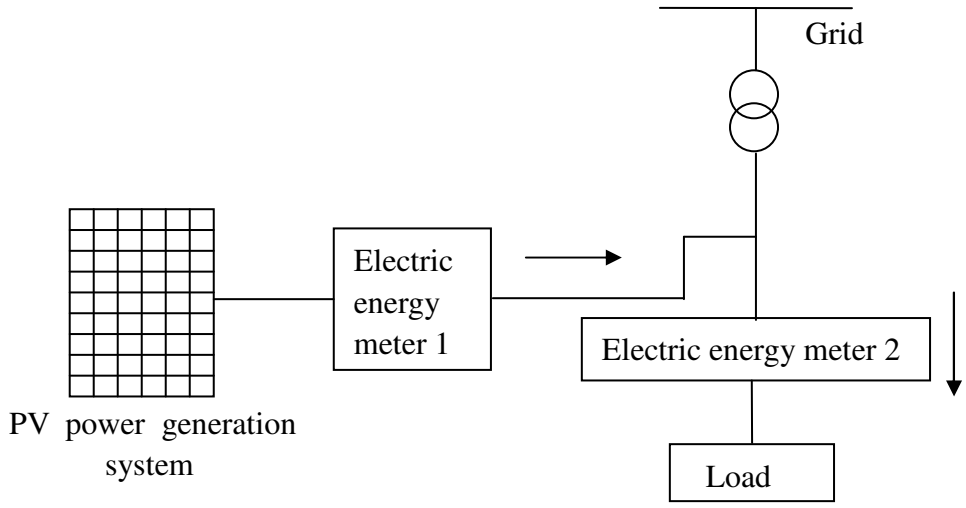

Fig. 1 Sketch of PV power generation system of Feed-in Tariff

In Fig. 1, electric energy meter 1: all of the electricity from PV power generation system, but also sold to grid electricity. Electric energy meter 2: the user purchase from the grid.

In the Feed-in Tariff, the point, which connect PV power system and grid, and electricity meters are mounted outside of users' electricity meters. [3]

The advantages of electricity price policy are: the PV power generation party can sign the purchase contract with the electric company, which can make the income of the power generation side security. It has no influence on the efficiency of Power Grid Corp. Disadvantages are: small power stations cannot issue formal invoices to Power Grid Corp. This will lead to some problems on the tax and business.

Net Metering. A part of power generate by PV power generation system are used by user, and remaining power are sold to grid, and then user buy a portion of electricity from grid to use. The part of spontaneous occupied don't be measured. Only calculate the difference between the power that is bought from power grid and electricity that is sold to power grid. This difference called net power. Money that should pay for net power to Power Grid Corp is calculated according to the retail price of electricity. Users can get subsidies of total amount of electricity that is generated by PV power generation system from the Power Grid Corp. The principle of design the PV power generation system is that the generating capacity throughout the year must be less than power consumption throughout the year.

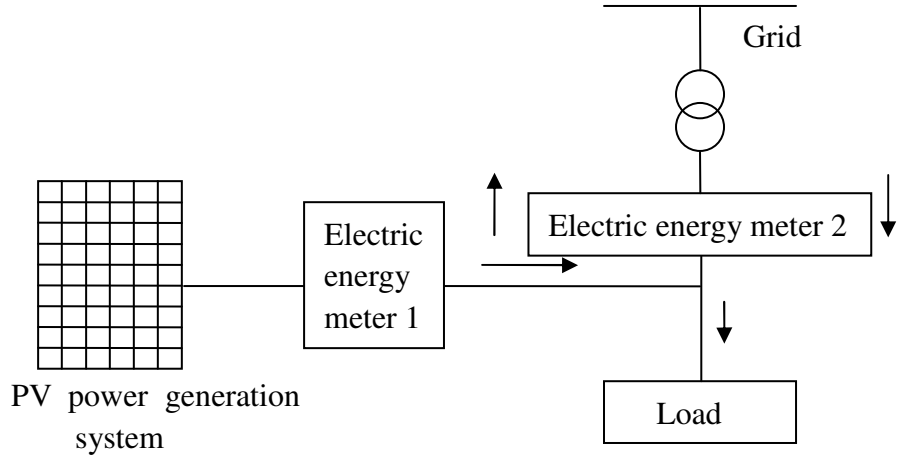

Fig. 2 Sketch of PV power generation system of Net Metering

In Fig. 2, electric energy meter 1: all of the electricity from PV power generation system. Electric energy meter 2: power that is bought from power grid and electricity that is sold to power grid.

The advantages of the Net Metering policy are followings. First, users needn't install energy storage device, so that the users can save some costs. Second, the power consumption is more than power generation. Therefore, users don't sell electricity to the Power Grid Corp. Problems on tax will not produce. The disadvantage is that PV power generation system will affects the efficiency of the Power Grid Corp.

Self Consumption. For power that is generated by PV power generation system, users can use a part of it, and the rest of the electricity can be sold to the grid. If power that users required is not enough, they can buy electricity from the grid by retail price. Electricity that is sold to grid can be settled by the published photovoltaic power tariff.

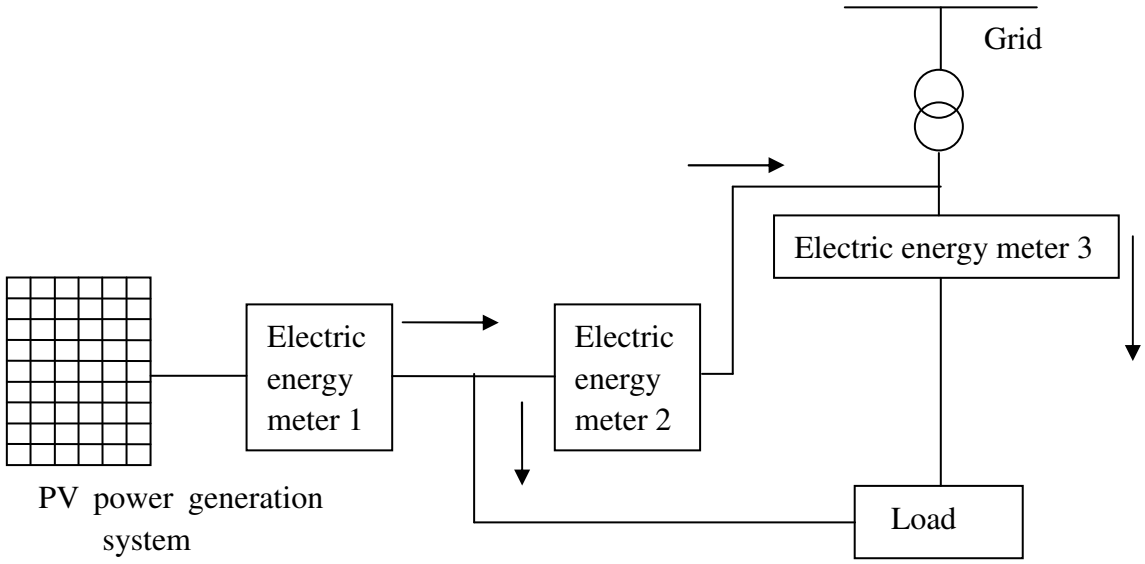

Fig. 3 Sketch of PV power generation system of Self Consumption

In Fig. 3, electric energy meter 1: all of the electricity from PV power generation system. Electric energy meter 2: electricity that is sold to grid. Electric energy meter 3: electricity that is bought from grid.

The advantage of self consumption policy: the electricity that is generated by PV power generation system and then directly used by user and power is bought from grid can offset each other, reducing the transaction between the user and the Power Grid Corp. Disadvantages are the followings. Electricity that is generated by PV power generation system and then directly used by user is not traded, so there will be some losses on tax for country. Electricity that is sold to grid will be traded with Power Grid Corp. It will produce some business and tax issues.

The current policies of PV in China

Although the price of electricity generated by PV power generation in China is not at the same level with the electricity of public grid, PV electricity used by industry and commerce will reach parity consumption level. So, it is necessary to investigate the policies of PV electricity.

In 2013 March, the National Development and Reform Commission issued a draft, which name is" *Notice about Perfecting PV Electricity's Price*". The draft regulates that current policy of PV electricity's price as follows.

(1) For the large PV power station, there are four type of price for four areas: class Ⅰ region is 0.75 Yuan/kWh; class Ⅱ region is 0.85Yuan/kWh; class Ⅲ region is 0.95 Yuan/kWh; class Ⅳ region is 1 Yuan/kWh.
(2) For the distributed generation system, electricity back into grid is purchased by Power Grid Corp for price of the coal-fired electricity. And each unit of electricity is given 0.35 Yuan additional.[4]

The Feed-in Tariff policy is used on large PV power stations, and the policy that used on distributed PV generation systems is similar to the Self Consumption. However, in some countries, such as Germany, electricity generated by PV power generation is inexpensive. No longer to give additional subsidies to the spontaneous occupied part. So the current PV power price policy implementing in China is more complex than in foreign.

Recommendations to model of Chinese PV power generation business

(1) In order to facilitate developers' intervention, the Feed-in Tariff policy can be used on PV station, which will make the developers' profit transparent and security.
(2) For distributed PV generation system under Self Consumption, according to the difference of solar energy resources in different areas, Power Grid Corp can make different subsidies. Whether how much does every unit of electricity cost, the revenue of PV power generation party can be controlled in the same level.
(3) With the rise of price of electric power in grid, electricity generated by PV power generation system for most users will be reach parity consumption level. Due to Net Metering is easy to be operated, I recommend that Net Metering can be used on distributed PV power generation system which are built when electricity generated by PV power generation system achieve parity consumption level.

Keywords: dual-power PV-grid system, PV energy system, off-grid power supply, solar hybrid system, dual-power system

Abstract. The Dual-power PV-grid energy system was initiated to reduce the capital installation cost of PV energy system and to make use the lower tariff rate offered at off-peak period. In this paper, the system configuration, architecture and operation of the system are described and discussed. The prototype has been developed and runs 24-hours to supply the load. Meteorological and electrical data collected prove the successful of such system. The system is expected to reduce 89% of electricity bill with estimated cost of energy (COE) of USD1.15/kWh. It is suggested that the dual-power PV-grid system is beneficial to serve as an alternative implementation of the off-grid PV energy system.

Introduction

A photovoltaic energy system is most promising renewable energy sources [1-4]. In fact, only about 0.1% of this energy has been utilized so far [5], indicating the potential in the future. Even though there has been a steady decline in the cost of PV generators in the past few years [6, 7], the installation cost is still considered as expensive with payback time of more than 20 years.

Furthermore, the PV energy system alone is not technically viable for continuous power supply [8, 9] an it is necessary to combine the system with other renewable energy sources or back-up with generators or battery system [10-12]. In the dual-power PV-grid energy system, the battery autonomy is reduce to a day, thus reducing the number of PV panels and batteries, consequently reducing the cost of installation [13-15]. The change over circuit is used to connect the load to the PV-battery system during the day (7.00am – 6.59pm) and change connection to the grid in the night time (7.00pm – 6.59am) or during unreliable solar energy. The system is also capable in manipulating low off-peak tariff offered during the night. This paper discusses system configuration, operation and cost evaluation of the proposed system. The discussion and analysis was done based on the prototype of 2.4 kW dual-power PV-grid energy system implemented at the guard house in Universiti Tenologi MARA (UiTM) Pulau Pinang.

System Configuration and Operation

System Design

The system comprises PV arrays, the inverter with a built-in charge controller and the switch-over circuit as depicted in Fig.1. The system operates 24 hours to supply power to the load consisting air-conditioning, CCTV and lighting system.

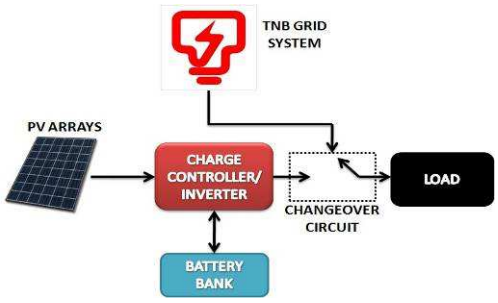

Fig.1: The dual-power PV-grid Energy system in UiTM Pulau Pinang, Malaysia.

A prototype system with below specification has been developed to meet the energy requirement:-

PV size : 14 X 175 W monocrystalline PV modules with a total rated power of 2.4 kW, 48 V
Battery Size : 24 X 2V/500 Ah connected in series to obtain 48 V/500 Ah
Load(s) : Air-conditioner, CCTV, computer, lamps
Converter : bi-directional, 3000 VA, 48 VDC ~ 230V SPWM AC, 50Hz, built-in charge controller

Mode of System Operation

During the day, the converter operates synchronously with the grid supply. A built-in PWM PV charge controller / regulator ensures that the batteries are charged at maximum power point. In the event of insufficient power supply from the PV, the battery will make up the shortfall. The battery charging process will automatically occur from the grid whenever the battery voltage falls below a preset value in order to maintain the battery bank at its float voltage. If no grid connection is provided, the inverter operates as a stand-alone inverter with the batteries being charge from the PV array. Meanwhile, during the off-peak, the utility grid supplies the energy from 7.00 pm until 6.59 am. The battery will be charged using grid current via bi-directional converter from 1.30am to 5am. The switch-over circuit comprises of relay timer which connect the load to the PV system during the on-peak demand and change connection to the grid in the off-peak demand.

Data Acquisition System

The data taker (DT80) collects the analogue data from analogue channels and converts the signals to digital signals and transmits to the data acquisition PC. The collected data are summarized in the Table 1.

Table 1: List of Measurements Data

Analogue sensor	
PV array current (DC), I_{PV}	Inverter PF
PV array voltage (DC), V_{PV}	Inverter Frequency
Battery current (DC), I_{bat}	Irradiance (W/m2), Irradiance
Battery voltage (DC), V_{bat}	Ambient temperature, T_{amb}
Inverter current (AC), I_{inv}	Ambient Rh, Rh_{amb}
Inverter voltage (AC), V_{inv}	

Fig.2 shows some of measured meteorological and electrical data of the system.

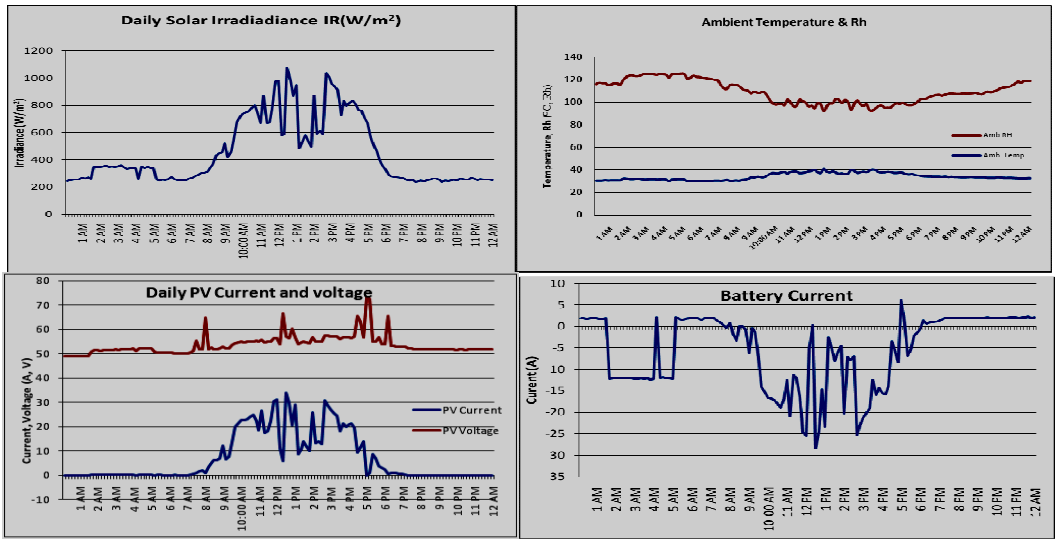

Fig.2: Some Meteorological and Electrical Data Monitored by the Data Logger.

Cost-benefit Evaluation

Hybrid Optimization Model for Energy Renewables (HOMER) software provided by National Renewable Energy Lab (NREL) was used to compute the cost analysis of the system. The radiation data, daily energy usage and an estimated cost of each component in the dual-power PV-grid plant were used as an input to the software. Table 2 shows the comparison between estimated number of batteries and PV panel and total capital cost for dual-power PV-grid energy system and standalone PV systems. The calculation was made based on the daily energy usage of 8.508 kWh/Day and market prices of the PV panel and battery.

Table 2: Number of Batteries and PV Panel and Estimated Cost for Dual-Tariff PV and Stand Alone PV Systems.

	Dual-power PV-grid Energy System	**Off-grid PV System**
Number of Batteries (500 Ah)	24	48
Number of PV Panels (175W)	20	26
Estimated Capital Cost (USD)	38,600	58,000

The software generates the net present cost and the cost summary as tabulated in Table 3 and Table 4 respectively. The cost of unit energy (COE) was estimated to be USD 1.15/kWh.

Table 3: Net Present Cost of the System (USD)

Component	**Capital**	**Replacement**	**O&M**	**Fuel**	**Salvage**	**Total**
PV Modules	25,000	7,903	0	0	-4,430	28,473
Battery	11,000	3,387	4,629	0	-1,898	17,118
Converter	2,600	755	771	0	-140	3,986
Overall System	38,600	12,045	5,400	0	-6,468	49,577

Table 4: Cost Summary of the System

Total Net Present Cost	USD 49,577
Levelized Cost Of Energy	USD 1.15/Kwh
Operating Cost	USD 858/Yr

Table 5: Electricity Bill for the Dual-power PV-grid System and the Normal System

	Dual-power PV-grid System	Normal System
Daily Energy Usage (kW/day)	1.632	10.104
Monthly Usage (kW/month)	48.96	303.12
Cost per Month (USD)	2.62	24.70
% reduced in electricity bill = 89.4%		

Conclusion

The dual-power PV-grid energy system promotes electrical energy usage during off-demand period and offers alternative solution to off-grid power generation. In this system, the load will be supplied by PV-battery system during on-demand higher tariff period and utilizes the grid supply including battery charging process during off-demand period. The successful implementation of such system is beneficial to the environment and lucratively cut the capital cost for PV system installation. The system expected to reduce the electricity bill by 89% with estimated COE of USD 1.15/kWh.

Keywords: PV power plant, financing channel, Asset-backed securitization

Abstract. At present, it universally exists that the financing problem confronts photovoltaic (PV) power plant construction in our country. The PV power plant construction in industry falls into the capital-intensive enterprises with the feature of long-time development, substantial investment needed but relatively fixed income. Thereby, it is greatly appropriate for solar securitization to address the financing needs of the industry with its characteristic and realize diversified financing channels. In this paper, firstly, the feasibility and necessity of ABS financing for PV industry is discussed. Then, we elaborate the current four construction modes of PV power plant, namely, transfer of beneficial interest of power charge, credit increment of financing platform company, BOT (build-operate-transfer), and financing leasing, according to which the financial institution designs the asset-backed securities supported by the beneficial interest of the power plant. Further, we analyze the main problems and challenges of carrying out the ABS business. Countermeasures and suggestion ns are put forward finally.

Introduction

The PV power plant construction is a capital-intensive project with great demand of capital investment in pre-construction. In 2012, the capacity of Chinese PV cell packs was about 23 GW, occupying 58% of total global capacity. At present, 10 billion Yuan of funds is required for the construction of 100MW PV power plant in China and we aim to create a PV industry with more installed capacity of 14GW in 2014 and a gross installed capacity of 50GW by 2020. Thereby, the widespread financing problem is increasingly acute, innovative means of financing and diversified financing channels are called for while traditional means of financing are far from enough to solve this problem.

The asset-backed securitization or ABS, one kind of emerging structured finances, relies on the capital markets to raise funds. The construction project of PV power station, however, with the feature of large investment and long construction period, is in line with the requirement of stable asset base and predictable cash flow of the ABS business. As a result, the ABS securitization business can be carried out to address the financing needs.

There lies great significance in exploring the ABS business of PV plant to crack the financing problems, accelerate the pace of constructing PV power plants, and provide valuable experience for the development of other renewable energy industry.

Overview of the ABS Business

The asset-backed securitization or ABS, as one kind of structured finances, means a technique or process enabling an array of assets (the “Assets” or “Underlying Assets”), which are capable of generating predictable and stable cash flows income in the future, to be converted into certain securitization products via particular structural arrangement and coupling with corresponding credit enhancement, and which products can be traded on the financial market and possess certain credit rating.

The ABS is an emerging product in the financial sector during the recent 30 years, and it evolved in the USA and developed rapidly in Europe, Japan, etc., and currently it spreads over worldwide in a quick speed. As to the ABS in China, since initially launched in 2004, it mainly consists of two systems: (i) one is the securitization of credit assets, which is originated by the banks and other financial institutions, and traded on the national inter-bank bond market upon the approval of the China Banking Regulatory Commission (the "CBRC"), and (ii) the other is the securitization of enterprises' assets (including the state-run institutions' assets), (the products of) which are issued by the securities companies through a Special Scheme and in the form of ABS, and traded and listed on the Shanghai Stock Exchange or the Shenzhen Stock Exchange upon the approval of the CSRC. In addition, the insurance companies, fund management companies, trust companies and other institutions are also allowed to conduct the ABS Business in accordance with the relevant rules regulating such business in their respective sectors.

Necessity and feasibility analysis of solar securitization

In the last decade, the PV industry in China has developed rapidly, with the joint promotion of the market and policies. China's PV modules' production is ranked top in the world, making a significant impact on the world's renewable energy development and solar PV industrial sector. Meanwhile, China's solar PV industry is facing several challenges, especially financial issues. Exploring new financing channels such as asset-backed securitization has become imperative of PV power plant construction. Currently, high cost, narrow financing channels, huge fund gap and a range of issues in PV industry are urgently calling for the ABS business to help to solve.

The financing status-quo of PV industry. Since 2013, the state has adopted a number of policies to support the development of PV industry and encourage the orderly construction of photovoltaic power plants. However, due to lack of capital, financing gap, and the long construction period of PV power stations, the process of PV plant construction has been seriously affected. There is still a large gap between the potential of PV market based on available resources and current levels of market development.

Currently, the main factors contributing to financing barriers for PV plant construction in China in existence are:

(1) There are limited financing channels, single way and backward means of financing, and dependence on national financing policies and commercial bank loan;

(2) Financing sources of funds are too focused on bank

(3) Financing structure is irrational, the ratio of indirect capital is too large, while direct financing takes up too small proportion

(4) Financing costs remain high and the PV industry is only now making the jump from niche markets, which are difficult and expensive.

Consequently, exploring new financing ways and improving financing structure to solve the financing problem of PV power plant construction are currently the primary task confronting China.

The necessity of the ABS in PV industry.

Large scale and huge financing needs of PV plant construction. In the national energy work conference in 2014, the National Energy Board finalize that the 2014 domestic PV installed capacity will be added by 14GW. According to the current average construction costs, capital needed to build 100MW PV power plant is about 10 billion Yuan, which means financing investment of about 140 billion is required with new added capacity by 14GW. Meanwhile, according to the "solar power development "second five" plan" issued by National Energy Board, China's PV gross installed capacity aims to reach 50GW by 2020. Faced with such a huge demand for funds, it is so tough to

meet the demand for PV power plant construction to merely rely on traditional means of financing. The construction layout of solar power is shown in Table.1.

Table .1 The construction layout of solar power [MW]

Solar Power System	2010	2015	2020
1.Solar power station	450	11000	23000
PV station	450	10000	20000
CSP station	0	1000	3000
2.Distributed PV system	410	10000	27000
Amount	860	21000	50000

Data source：《solar power development “second five” plan》

Urgent needs of broadening financing channels for PV station. The financing is a major problem in the process of PV plant construction, which is far too tough to be solved solely by current financing channel. Therefore, what should be done right now is, to actively expand financing channels, to diversify financing options, to optimize the capital structure and innovatively try to carry out the ABS mode, for finding new ways to solve the financing problem, under support of national policy.

The advantages of ABS . The asset-backed securitization is an innovative way of financing with the following special advantages compared with traditional financing:

(1) Ease of trade

One advantage of asset-backed securities for buyers and sellers is the ability to trade in assets that would otherwise be difficult to trade in primary existing form. And the financing process is relatively easy, short-period and low-cost.

(2) Abundant financing source and risk sharing, particularly for buyers, the ABS is able to spread risk over a number of investors.

(3) Increased Loans for Borrowers

For borrowers, asset-backed securities increase the availability of loans.

(4) It can expand the proportion of direct financing, decrease debt ratio of company, and vitalize high-quality solar power station assets.

The feasibility of ABS business for PV station.

The characteristic of PV station meets the requirement of ABS. The key to carry out ABS business is to provide predictable and stable cash flow from the underlying asset pool. It is more favorable when the industry served by the underlying asset pool is specially supported by the state. Despite the high cost of PV power plant construction and huge initial investment, once the PV network being built and kept in low-cost operation, considerable electricity and more fixed income annually (for 20 years or so) can be earned. The cash flow can be sufficient and stable, with strong product attributes of the "fixed income", which fully complies with the requirements of ABS thereby making it suitable for development of securitization products.

The environment for ABS business in PV industry is provided. The ABS is a direct financing in the capital markets, and reasonable capital market structure is a prerequisite for carrying out asset securitization. With the constant improvement of China's financial system, the establishment of a multi-level capital market provides a good opportunity for the ABS business in PV industry.

Related laws, regulations and policies with continuous improvement are promulgated, which both effectively controls the risks in the financial markets and provide conditions to carry out the ABS. In *the Administrative Provisions on the Securities Companies’ Asset-backed Securitization Business,* issued by CSRC in 2013, specific form of ABS is explicitly stipulated for PV power plants, which contributes to the development of solar securitization.

At the same time, all kinds of financing entities participating in the capital markets, with government's cultivation and their marketing experience, are getting more and more matured. Their professional quality and comprehensive ability have been greatly improved, which lead to the maturity of capitalized operation.

There have been successes in ABS in China. In December 2005, the China Development Bank successfully issued initial credit asset securitization, followed by several successful cases. In particular, in May 2006, Special Assets Management Scheme of Charges for Electricity of Huaneng Nancang River made a hit in the Shenzhen Stock Exchange. All the successful cases have accumulated a wealth of experience for China's power enterprises to carry out ABS business.

The ABS modes of PV station

Implementation of ABS business for PV power plants has already had its necessity and feasibility. And according to the specific requirements of the financing body and PV power plant construction, there are different ways of ABS to be chosen. Currently, there are four construction modes for China's PV power plants, namely, transfer of beneficial interest of power charge, credit increment of financing platform company, BOT (build-operate-transfer), and financing leasing.

Transfer of Beneficial Interest of Power Charge (TBIPC). The TBIPC model is the most basic model (Chinese-style transfer), in which securities companies and Financing Platform Companies (construction-operation company, namely, the installer) enter into a income beneficiary transfer contract about the power stations in the future, establish a Specific Asset Management Plan (SAMP), issue asset-backed securities by beneficial interests, and obtain transferee price beneficial interests. Investors make an inquiry and subscribe the shares of SAMP. The final gains of investors are power purchase price with the deduction of operating expenses for the installers and management fees for securities companies. The flowchart of TBIPC is shown in Figure. 1.

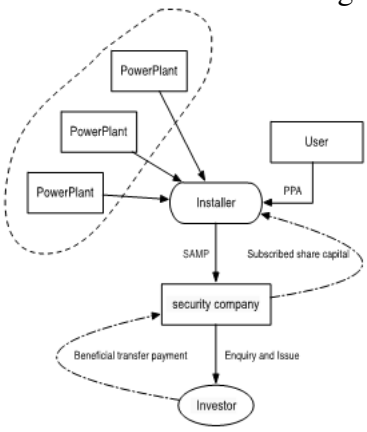

Figure.1: TBIPC

Credit Increment of Financing Platform Company (CIFPC). The most distinguishing characteristic of the CIFPC model from the TBIPC model is that PV power stations are acquired by Financing Platform Company, then realized asset transferring and withdrawing by ABS, and the purchase price are paid by the Financing Platform Company to the initial possessor of PV power stations. This mode is mainly applied to privately-owned and small and medium-sized enterprises, which can take advantage of high-quality credit standing and professional competence of financing platform to reduce financing costs against their own poor credit conditions. The flowchart of CIFPC is shown in Figure. 2.

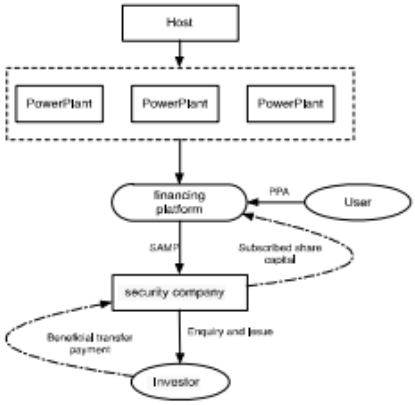

Figure.2: CIFPC

BOT (build—operate—transfer). There have been many large infrastructure projects, such as expressways and power plants, which are being constructed or have been operated by private firms under a procurement system called build-operate-transfer (BOT). Under the system, the franchisee (project sponsor) is responsible for financing, construction, and operating a facility and he, in return, has been granted a right to generate revenue from the facility for a specific period. After the concession period, the facility will be transferred at no cost to the franchiser, who usually is the government. The major motivator for the BOT system is that the host government need not spend any public funding but still can provide a public facility to her people. Meanwhile, the franchisees can enjoy a high potential profit from a successful BOT project. The flowchart of BOT is shown in Figure. 3.

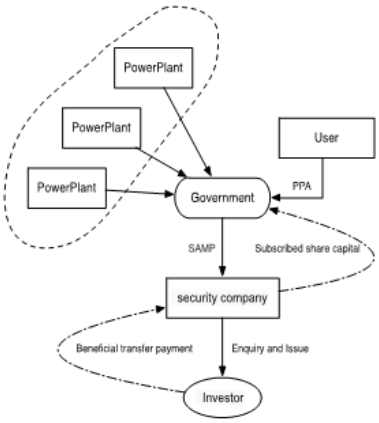

Figure.3: BOT

Financial leasing. Financial leasing is the activity in which the lessor:
Concludes a delivery contract with the supplier of the lease object whereby he/she obtains the ownership right of the lease object, with the lessee determining both the supplier and the lease object.

Concludes with the lessee the financial lease contract whereby he/she transfers to the lessee the authorization for keeping and using the lease object over a predetermined term and the lessee pays the agreed fee in agreed installments.

Advantages of lease financing: Less upfront cash needs to be outlaid; The risk of financing entity and project construction risk are diversified; There is typically an option to buy the equipment at the end of lease term; It offers fixed rate financing and potential tax benefits. The flowchart of Financial leasing is shown in Figure. 4.

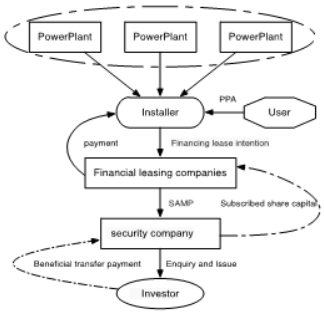

Figure.4: Financial leasing

Suggestions on implementing PV stations

Improving legal system. The further development of ABS depends on the support of appropriate corresponding laws and regulations. It is necessary to build up a complete legal system for SPV identification, the audit of ABS issuers and credit rating enhancement, the definition of bankruptcy isolation and a series of processes, in order to eliminate the obstacles to carry out the laws and regulations on asset securitization, improve operational efficiency, and reduce financing costs.

Encouraging the development of market intermediaries and promoting its operation standardization. The ABS, as a structured financing, needs participation and collaboration of investment banks, accounting firms, credit rating agencies and other intermediaries, to promote rationalization of the transaction structure, to reduce non-systematic risk, and to enhance confidence of investors. China should set up an ad hoc securities firm as soon as possible to specially conduct ABS business, and increase efforts to foster a number of widely recognized credit rating agencies and credit enhancement ones.

Completing accounting advice and tax system for ABS business. On the one hand, accounting standards should be amended as soon as possible, to make it clear for true sale, off-balance sheet and other accounting treatment. On the other hand, the existing heavy taxes of securitization business and the problem of double taxation need to be changed and replaced by providing tax support. Reduce stamp duty on securities transactions and tax rate of income taxes for investors, and give certain concessions to business tax, stamp duty for the promoters.

Fostering investor. It is the demand of investors that maintains the existence of any financial product. Financing PV plant construction through ABS business requires widening participation of investors in order to increase the total amount of financing, reduce financing costs, and further spread risk. However, the main investors in China's capital market are not diversified enough with low degree of specialization thereby making the market capacity not big enough and the transaction less active.

Keywords: PV industry; financing problem

Abstract. As China domestic photovoltaic (PV) policy forms a closed loop; PV subsidy, grid-connected and other issues have been solving gradually, PV financing problem, which becomes the greatest bottleneck of Chinese PV industry to restrict its development, is highlighted increasingly. In this paper, based on analyzing the current PV financing situation, we discuss the reasons for PV financing difficulties, and put forward some suggestions to help to solve it.

Introduction

The PV industry in China is one of the few strategic emerging industries with international competitive edge. There has published a number of policy measures to promote the healthy development of Chinese PV industry in 2013. At present, being in a world leading level, Chinese PV cell production accounts for 70% of global market share, the conversion efficiency of crystalline silicon photovoltaic cells reaches 20%. However, the PV industry is capital-intensive, which requires a lot of capital investment. As PV subsidy, grid-connected and other issues have been solved. Financing problem has become the biggest bottleneck of development of the photovoltaic industry.

Development and financing status quo of Chinese PV industry

Development status of Chinese PV industry. Chinese PV industry ushers in a historic turning point in 2013 with great support of a number of government policies. At present, China has become not only the world center of PV manufacturing, but the world's second largest PV market. As the data display in 2013, our polysilicon production is about 8 tons with year-on-year growth of 12.7%, and ranks first in the world for three consecutive years. Chinese PV modules production is approximately 26GW with year-on-year growth of 13% and ranks first in the world for seven consecutive years. The global PV added installed capacity is 36GW, while new installed capacity in China reaches 10GW with year-on-year growth of 122 percent ranking first in the world. According to the "Twelve-Five Planning", China's PV power generation capacity is aimed to reach 50GW by 2020. Chinese PV power-generating capacity is expected to add more than 14 GW in 2014, while distributed ones are added to 8GW accounting for about 60%. This series of data indicates that our PV industry has made great achievements, full of great prospects and potential.

However, in the case of Chinese PV industry ushering in a second take-off, some long-term restricting factors, such as the prominent contradiction of overcapacity; excessive dependence on international markets; the high cost of power generation; financing difficulties, etc., have not been properly addressed. It is urgently needed the multi-cooperation of the state, enterprises and other parties to work out these problems together.

Financing situations of Chinese PV industry. As the PV industry is capital-intensive, the process from polysilicon purification in industrial chain upstream to the construction of PV power generation system downstream requires a lot of capital investment. "Several Opinions of the State Council on Promoting the Healthy Development of Photovoltaic Industry", which mitigates PV subsidy and grid-connected and other problems, is promulgated in 2013 and highlights the financing difficulties shown below.

Large capital requirement and funding gap. Currently, under the impetus of various favorable policies, Chinese PV industry enters a second phase of rapid development, with substantial capital investment in need. According to the National Energy Board, domestic PV installed capacity is expected to add 14GW in 2014. While 10 billion Yuan is required for building a 100MW PV power plant in current cost level, there is 140 billion Yuan needed for 14GW. What is more, the "Solar industry 12th Five-Year plan" refers to that Chinese PV power generation capacity should reach 50GW by 2020. Faced with such a huge demand for funds in future, the PV industry is badly in need of finding a way to conquer the financing obstacle.

Limited financing channels and high dependence on subsidies. Due to the joint effect of various reasons, the current financing channel of PV market is very simple, which is mainly dependent on policy-type bank loans and government subsidies. There is statistics showing that Chinese PV enterprises in the start-up stage and growth stage rely on bank loans to obtain funds to a large extent, which accounts for about 80% of the total funds. In such a case, either the bank loan being not in the place or shift of national industrial policy can exacerbate the financing plight. It is necessary to pay more attention to explore innovative financing channels.

Unreasonable financing structure. The proportion of indirect financing is too large, while that of direct financing is too small, which may be partly blamed on the lack of enthusiasm for exploring innovative financing mechanisms under government subsidies. Moreover, multi-level capital market structure is still under construction; the relevant laws and regulations and institutional framework are deficient, making it tough for PV companies to use modern financial products to meet the fund requirement.

High financing costs. Chinese PV industry is currently in a transitional phase, with affects of production overcapacity and "double reverse". However, there are indeed certain limitations on loan size and loan conditions for PV business in most banks, except those favorable policies. Thus, a lower interest rate credit is unable to get for PV enterprises; collateral, guarantees, entrusted loans and other ways are used to obtain funds, lifting financing costs much higher.

Analysis on financing predicament of Chinese PV industry

Internal factors.

Higher business risk. PV industry is a new energy industry faced with higher business risk. Because of the two-out pattern of Chinese PV industry and excessive dependence for PV products on international markets, operating uncertainty is increased, which, furthermore, makes investors reluctant to provide funds to the PV business.

Non-standard management system. Financial system and internal supervision systems are not perfect in PV enterprise. The managers are lack in risk awareness and make business management not standardized. Moreover, less corporate assets, weak ability to withstand external shocks and so on are all making it a higher rate of PV business failure. As a result, the banks, a major provider of funds, are unwilling to bear the high "market risk" and "credit risk", making it much more difficult for PV ventures to rely solely on bank loan financing.

High technical costs. PV industry is high-tech with high degree of specialization. It requires certain knowledge about technical expertise for investment and financing analysis, which restricts investors to make rational investment decisions and adversely affects PV financing. Furthermore, PV companies have business information more non-transparent relative to other companies. For fear that core technology and trade secrets may be revealed. This information asymmetry results in higher investment risk and higher costs for investors.

External factors.

Domestic market is breaking the ice with international market downturn. Currently, European countries cut PV subsidies under economic downturn. The overall declines in market demand make Chinese PV companies that rely heavily on the European market have serious shock.

Besides, the EU and the U.S. have started anti-dumping, anti-subsidy investigations on the Chinese PV companies, which exacerbate the crisis of the entire PV industry. The ratio of liabilities to assets remains high, and financial risks are increasing. Although China is actively promoting the development of distributed PV industry, vigorously developing the domestic PV market, the effect is not yet apparent due to the short time.

Large gaps in PV subsidies and incomplete policies. Government subsidies are major funding source for Chinese PV business. The main subsidy is provided by the National Renewable Energy Development Fund, which has a funding gap of about 20 billion Yuan at presence, and will reach 80 billion in 2015, making it so difficult for the government subsidies to be in place. Moreover, the details of related policies need further improvement, and it is more important for regional departments to implement the requirements of policies well, to create a favorable environment for the development of PV industry.

Deficient financial system. From the perspective of the bank, the characteristics of high risk, large investment of PV industry contradict the principle of safety and profitability that commercial banks focus on, so the credit ceiling for PV business is very low. Meanwhile, policy-type bank loans have policy constraints, etc., making financing much more difficult, especially for small and medium private enterprises.

Tentative IPO makes those PV companies which have listed potential and want to be financed through the listing lose their opportunity. At the same time, financial service system for PV industry is not perfect, where limited financial support is mainly provided for large, state-owned enterprises, so that SMEs have no access to appropriate financial services. Moreover, asset securitization, debt financing and other innovative financial instruments are difficult to apply to PV business due to the underdeveloped capital markets in China.

Although venture capital (VC), with features of “high-risk, high-yield”, should have been an effective way to meet PV financing demand, due to its inadequate laws and incomplete withdrawal mechanism, venture capital investments in PV industry is rather limited.

Countermeasures and suggestions on solving financing dilemma

Improving self-financing ability of PV companies.

Improving enterprise managerial skill to ensure operating stability. Domestic PV industry is mainly dependent on the international market, so PV companies should pay close attention to international market dynamics, relevant policies; follow the rules of international trade and make timely response to market risks.

PV companies should improve internal management systems of their internal shareholder committee, board of directors, board of supervisors, etc.; establish effective power supervising mechanism, and form standardized modern enterprise management system. Meanwhile, perfecting internal control system and financial management and strengthening risk awareness of managers are also needed to be done right now.

Expanding financing channels. The market-led PV companies under government support should establish a diversified, multi-channel investment and financing mechanism; explore innovative financing methods; expand financing channels. Companies should actively use a variety of innovative financial products; learn from the experience of European countries; explore asset securitization, debt financing, lease financing and other business to increase the proportion of direct financing and improve financing structure.

Strengthening the construction of corporate credit. Good credit condition is the key for survival and development of modern enterprises. There exists that some PV companies have poor awareness of credit in China. Meanwhile, there are non-transparent operations, information asymmetry that adversely affect PV financing. Therefore, enterprises should strengthen their own credit construction; improve operational transparency; disclose management information and financial reports by qualified regularly, and consciously accept the supervision of investors, thereby

increasing investors' confidence for PV enterprise and obtaining financial support as much as possible.

Building sound financial service systems.

Strengthening financial support of bank credit. Bank credit is the most important source for PV companies funding. Currently, credit funds for PV business are mainly the policy-related bank loans from China Development Bank, while commercial banks invest a little in view of "credit risk", "market Risk" and other factors. Consequently, on the one hand, it is needed to increase bank credit funds to support PV enterprises; appropriately lower lending standards and to reduce the approval process. On the other hand, banks should give priority to support businesses with good operating conditions, huge potential and policy support. The post-lending management should also be done to timely prevent credit risks and guarantee credit safety.

Making full use of the capital market to raise funds. Making market-oriented operation based on modern financial instruments by the capital market is the fundamental way to solve the PV financing problem. China should timely restart IPO to make some PV companies with high-tech and broad market prospects have financing priority, to encourage PV enterprises to use the capital markets to raise funds.

China should accelerate the pace of financial reform and improve the market-oriented level of Chinese financial markets to provide support for innovative financial instruments and financial products. Furthermore, we are required to explore third-party financing platform, investment trusts equity financing, debt financing, crowd funds and many other modern financial products, following the tide of the Internet finance.

Improving VC mechanism. The characteristics of PV business meet the requirements of VC, so it is an effective way to bring VC into PV industry to solve the financial problems. China should improve the VC mechanism including exit mechanism as soon as possible; promulgate relevant laws to protect the interests of VC institutions and expand funding sources.

Promoting relevant policies to be nuanced and implemented.

Improving financial support system. Currently, financial support system of Chinese PV business has been basically formed, however, it needs to be further improved. Firstly, the funding gap should be resolved as soon as possible to make subsidies be in the place. At the same time, the government should reduce subsidies by more favorable guidance. Secondly, the PV industry is not only an emerging high-tech energy industry but environmental protection industry, so we can study on implementing preferential tax policy on it to gain certain tax breaks.

Improving relevant laws and regulations. It cannot be without the support of relevant national laws and regulations for PV companies to solve the financing problem, especially in the current situation of Chinese capital market imperfections. Based on the specific developing situation of PV industry, China should amend and promulgate timely relevant laws and regulations to provide protection for establishing a diversified, multi-channel PV financing system.

Keywords: hazy, exergy efficiency, steam cooler, temperature difference, optimalize.

Abstract. We took 600 MW sub critical unit of Taishan power plant as the research object and modeled. Analyzed the thermodynamic system by exergy method. Got the amount of exergy loss, the exergy efficiency of regenerative heater and so on. Found out the distribution of different kinds of exergy loss in the power plant with giving out the scientific and reasonable explanation and the weak point. Then increased the efficiency of thermal system by adding external steam coolers for high pressure heaters.

Introduction

Since 2013,The widespread haze occurred frequently in China[1-2].If we want to government atmospheric haze successfully, It can't do without the analysis and improvement of thermodynamic system in thermal power plant.Usually there are two kinds of method to analysis thermodynamic system, which are heat method and exergy method. The first method is based on the first law of thermodynamics which has been used a long time;The second method also consider the second law of thermodynamics.It main focus on how much energy can be used in a certain environmental condition.People have to pay more attention on developing and utilizing energy reasonably because of the energy tension.So the exergy method is increasingly seen as important in recent years. Today has been a consensus that must use the exergy method if people want to tap existing potential of energy saving deeply[3-4].Now most of the structures of the 600 MW steam turbine unit system are the same,This article selected the typical 600 MW subcritical unit of Taishan as the research object and modeling, and its principle thermal system structure is shown in Figure 1.

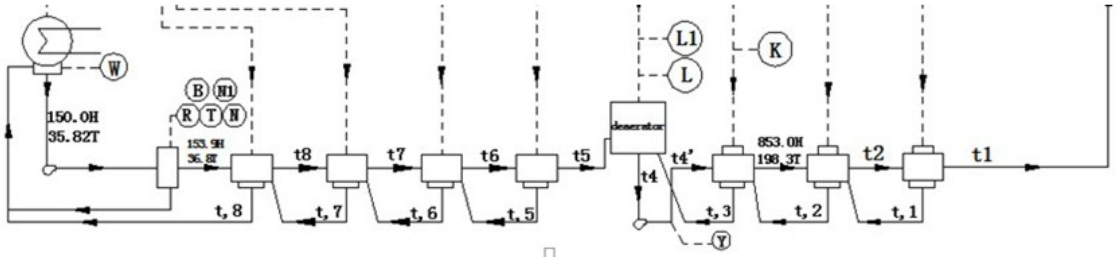

Fig. 1 The structure diagram of 600MW steam turbine of Taishan

The exergy analysis of the thermal system.

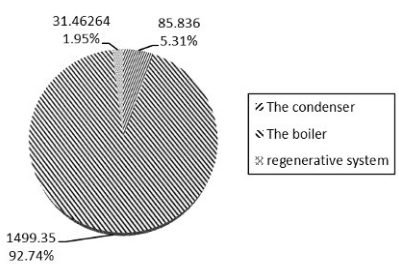

Fig. 2 The exergy loss distribution of boiler, condenser, regenerative heater of power plant

Exergy loss distribution of the thermal system. First collected raw data and calculated.Then drew the pie chart in order to show the loss distribution better.The Figure 2 shows that most of the exergy loss of power plant is in the boiler, the second is in the condenser. The conclusion of the traditional calculation method points out the efficiency of boiler of Taishan power plant is 93.75%, and most of the heat losses occurs in the condenser. It can completes and supplements the conclusion based on the first law of thermodynamics. Although the results of method of heat point out that the heat energy loss is small in the boiler, but it is overheating steam in the boiler, there is a big temperature difference of heat transfer,which causes a lot of energy loss. It is mainly exhaust gas which has been used in the condenser. Although the quantity is big, but quality is low.

Analysis of exergy loss of regenerative system. Firstly, Collected raw data, inquired the entropy of working fluids under different status. Secondly, Got the amount of the exergy loss, the exergy efficiency of regenerative heater and so on according to the formulas of exergy. The benchmark is 298.15K and 0.1Mpa in the process of calculation, which specified in the national standard guidelines for the analysis with exergy method(GB/T1490994). The results are shown in table 1.

Table 1. The exergy situation of each regenerative heater

	extraction factor	exergy drop of steam extraction	exergy rise of feedwater	exergy drop of drain	the amount of exergy loss	the amount of exergy enter	exergy efficiency	the rate of exergy loss
1	0.0722	964.8470	66.481	0	3.18095	69.66195	0.95434	0.00197
2	0.0829	929.8953	77.865	84.958	5.35729	83.22229	0.93563	0.00331
3	0.0385	1047.3910	47.565	51.958	6.12731	53.69230	0.88588	0.00379
4	0.0423	843.7798	39.695	18.876	8.70100	130.27800	0.93321	0.00538
5	0.0354	693.0598	27.602	63.456	3.17037	24.53432	0.87078	0.00196
6	0.0223	539.0534	14.165	15.044	1.58974	12.55345	0.87336	0.00098
7	0.0315	451.8340	17.152	18.531	2.04489	15.32054	0.86653	0.00127
8	0.0265	287.8353	9.304	9.369	1.29110	8.49239	0.84797	0.00080

Draw the line chart of each regenerative heater in order to be more intuitive to analyze, according to the data of table 1. The line charts are shown in Figure 3, 4, 5, and 6.

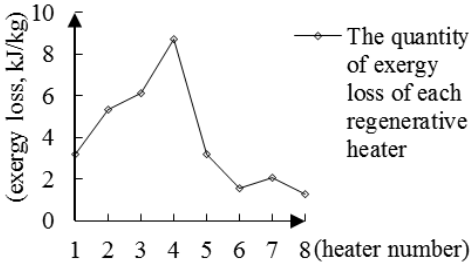

Figure 3. The quantity of exergy loss of each regenerative heater

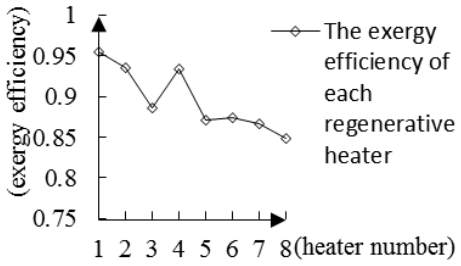

Figure 4. The exergy efficiency of each regenerative heater

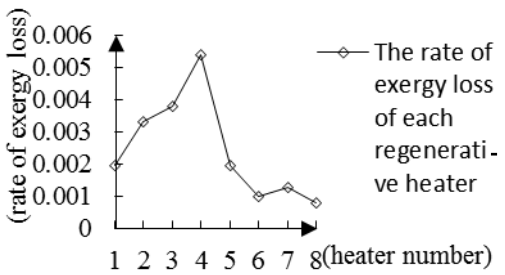

Figure 5. The rate of exergy loss of each regenerative heater

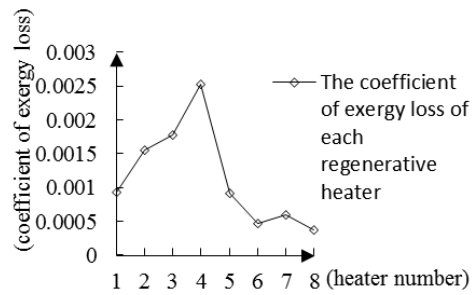

Figure 6. The coefficient of exergy loss of each regenerative heater

The Figure 3 shows that the exergy loss of high-pressure heater general higher than that of low-pressure heater in the regenerative system. The largest amount of exergy loss occur in the deaerator. Just consider the amount of exergy loss can't get the perfect degree of the device, also need to analyze its exergy efficiency. The Figure 4,5,6 show that though the exergy loss of deaerator 4 is the largest, but its exergy efficiency is higher than other heaters, which conform to the actual situation. The steam mixes with feedwater directly in the deaerator because of the deaerator is mixing heat exchanger. So the latent heat of vaporization of steam moves to feedwater entirely[5].

$$\triangle t=t,i-ti=0. \quad (1)$$

As shown in Eq.1. So compared with the surface heater, The exergy efficiency of mixing heater must be higher.

We can realize that the exergy loss of working fluids not only related to their own state, but also related to the state of environment by the calculation formula of exergy. The environmental status wich specified in the national standard is used to be a benchmark status usually.However, the actual environment status changes with the time and area. We inquired the relevant parameters under different temperature respectively for no.1, no. 2 high pressure heater and no.5, no. 6 low pressure heater. The results are shown in Figure 7.The Figure 7 shows that more loss with higher temperature. The influence of temperature change on the high-pressure heater is bigger than the low-pressure heater, which is consistent with the results in the literature8[6].

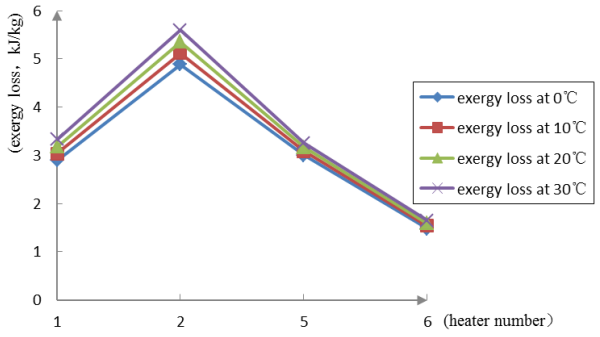

Fig. 7 The influence of temperature

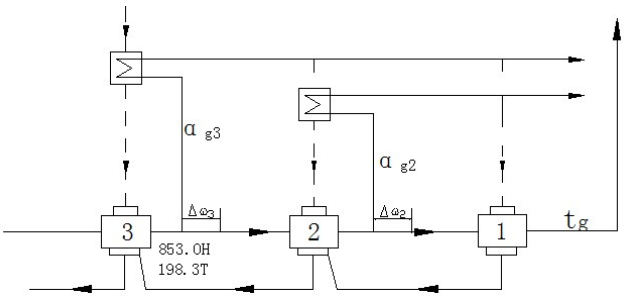

Fig. 8 The schematic of improvement

The improvement of the thermal system

From the analysis of previous section, we know that the most of exergy loss caused by heat transfer temperature difference.The figure 1 shows that all of bleeder heaters equipped with drain cooler in addition to the deaerator.These measures reduce heat transfer temperature difference effectively. But the extractive steam’s temperature is very high because it is high pressure steam.So we can further consider adding an outer steam cooler for no.2 and no.3 bleeder heater respectively.It is shown in Figure 8[7]. By passing a part of the feed water to steam cooling, it both reduces the temperature difference and can distributes to the appropriate level according to the quality of energy.

The effect of improvement mainly has four aspects. Taking no.3 heater as an example to analyze the effect. The first is because part of the feed water flow out, it make the quantity of extraction steam needed for the no. 1 and no. 2 heater is reduced, which can save energy of Eq. 2. Second, The additional equipment will increase the pressure loss of extraction steam inevitably. It make heating for feedwater is insufficient and loss energy of Eq. 3. Third,The feedwater takes away part of heat by steam cooler,which make the quality of the steam to reduce.So the quantity of extraction increase, it causes a energy loss of Eq. 4.The last affect is circulation heat changes, As shown in Eq. 5.

$$\alpha_{g3}(\tau_2\eta_2+\tau_1\eta_1). \quad (2)$$

$$\triangle\omega_3(\eta_2-\eta_1)(1-\alpha_{g3}). \quad (3)$$

$$\alpha_{g3}\eta_3(\tau_2+\tau_1+\theta_3). \quad (4)$$

$$\triangle Q = \alpha_{g3}\theta_3(\eta_i - \eta_3). \quad (5)$$

The sum of these four aspects is the variation of equivalent heat drop of new steam due to the improvement. The calculation results as shown in table 2.

Table 2. The analysis results of improvement program

heater number	fractional flow α_{gi}	the increment of equivalent enthalpy reduction△H[kJ/kg]	efficiency improvement△ η [%]	coal consumption rate savings△ b[g/kW • h]
2	0.042	0.248	0.173	0.213
3	0.042	0.541	0.198	0.244

The table2 shows, through using the outer steam cooler, We can use the energy gradient, reduces the irreversible loss in the process of heat transfer, achieve the effect of reducing coal consumption.

Conclusions

Study results are as follows:

1. Most of the exergy loss of power plant is in the boiler, the second is in the condenser, the last part is in the regenerative heaters. It is different from the traditional view and can completes the conclusion based on the first law of thermodynamics.

2. The exergy loss mainly occur in the heat exchange process, and it mainly caused by temperature difference.

3. More loss with higher temperature, So the energy loss under summer conditions is more than other seasons.The influence of temperature change on the high-pressure heater is bigger than the low-pressure heater.

4. We improve the efficiency of thermal system by adding an outer steam cooler for no.2 and no.3 bleeder heater respectively.

We have a new understanding about the energy loss, energy saving and system improvement by using the exergy method. It has very important practical significance, provides reference for energy conservation and emission reduction of power plant.

Keywords: Equivalent Enthalpy Drop; Variable Conditions; Economic Diagnosis; Steam Initial Parameters

Abstract. Economic diagnosis of thermal power units is to determine the economy of its operating parameters and operating modes by quantitative and qualitative analysis, which is significant to economic operation and energy saving of power plant. On the basis of equivalent enthalpy drop method and the theory of variable conditions, the economic diagnosis model of operating parameters was established. As main steam temperature and main steam pressure for example, economic diagnosis of a 660MW supercritical steam turbine unit was performed. The result demonstrates that improving the main steam temperature or main steam pressure can reduce heat consumption of the unit. The essence of improving the initial steam parameters is to improve the average temperature of the steam cycle endothermic process, thus improving the circulation efficiency and reducing heat consumption. The economic impact of main steam temperature is up to $0.61\ \mathrm{g\cdot(kW\cdot h)^{-1}}$, while which of main steam pressure is little. Therefore, by increasing the initial steam parameters, especially the main steam temperature, to improve the economy of the entire power plant is the main way to enhance the efficiency of power plant in the current.

Economic Diagnosis Model of Operating Parameters

Economic diagnosis of thermal power units is of great significance to economic operation and energy saving of power plant. As a way to determine the economy of operating parameters and operating modes, economic diagnosis can qualitatively analyze the rationality of operation modes and operation parameters, and quantitatively analyze the standard value of operating parameters and the economic influence of the deviation from standard value. On the basis of equivalent enthalpy drop method and the theory of variable conditions and considering the difference between the economic impact of the standard values and deviations of operating parameters, the economic impact of parameter deviations will be quantitatively calculated.

In this paper, a 660MW supercritical unit is the research object, and the economic diagnosis model of the operating parameters of the unit was established. In the case of main steam temperature and main steam pressure, the deviations were calculated between operation value and standard value of the main operation parameters and the size of economic impact of these deviations.

Equivalent enthalpy drop method is a new thermodynamic theory. The use of the theory for economic diagnosis of thermal system of power plants is simple, accurate and convenient. Equivalent enthalpy drop refers the real capacity for work of 1kg new steam of regenerative extraction turbine. Extraction equivalent enthalpy drop refers the real capacity for work after excluding 1kg heater extraction back to turbine [1].

The operating parameters of the turbine include main steam temperature, main steam pressure, reheat steam temperature, reheat steam pressure loss, etc. On the basis of equivalent enthalpy drop method and considering the difference between the economic effect of the standard value and the diviations of the operating parameters under different conditions and systems and interactions between multiple deviation factors, a quantitative method of calculating the economic impact of the deviations of operating parameters was proposed.

By using the theory of variable conditions, the mathematical model of economic dianosis of main steam temperature and main steam pressure are given as below [2].

$$\Delta b = f(\Delta x, N_d, t_{ob}, N) = b(x, N_d, t_{0b}, N) - b(x_b, N_d, t_{0b}, N) \quad (1)$$

On the type, Δb is standard coal consumption variation, x_b represents the standard value of operating parameters (calculated in accordance with variable conditions or check correction curve). x is the operating value (calculated in accordance with variable conditions or check correction curve).

Economic Diagnosis of Main Steam Temperature

In this paper, a 660MW supercritical unit is the research object. The unit is supercritical, once reheat, single shaft, 3-casing 4-exhaust, and direct air-cooled. Rated power: 643MW. Maximum power: 713MW. Rated main steam amount: 1874.1t / h. Maximum principal amount of steam: 2120t/h. Rated steam parameters: 24.2MPa/566 ˚C. Reheat steam parameters: 3.975MPa/566 ˚C. Rated back pressure: 15kPa. Ensure heat consumption: 7758 $kJ\cdot(kW\cdot h)^{-1}$. Rated speed: 3000r/min. The principled thermal system diagram in THA conditions is shown in Figure 1.

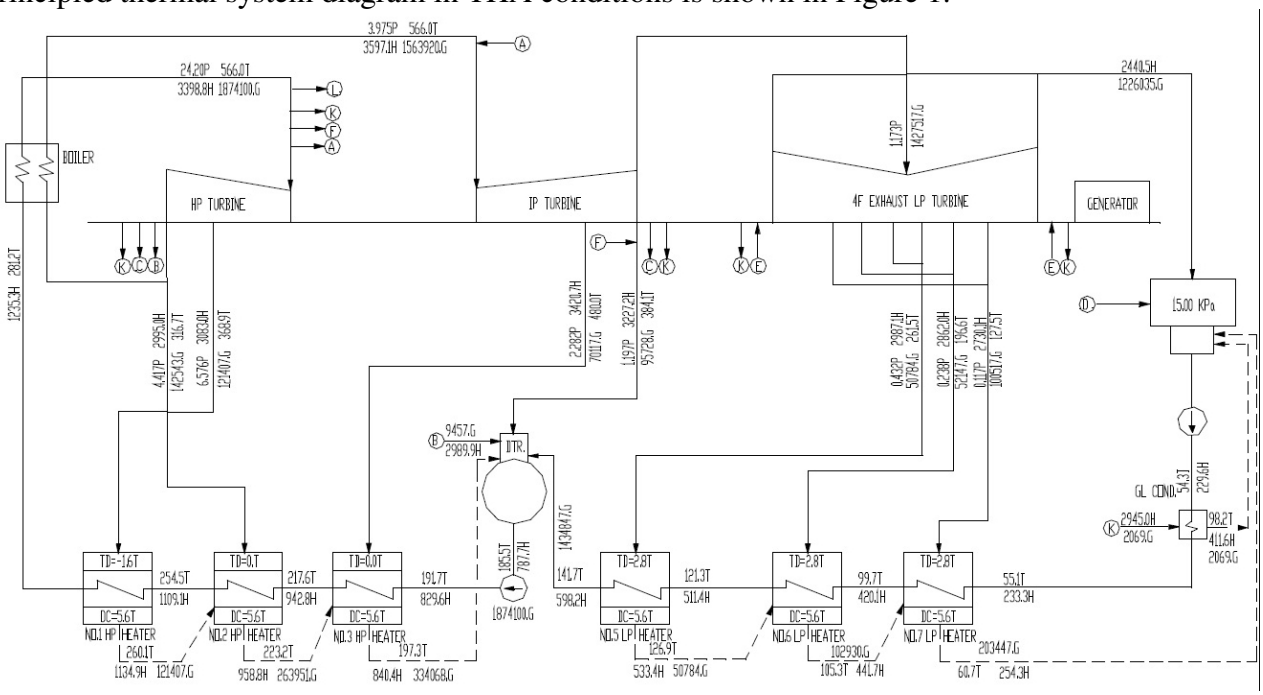

Figure1 Principled thermal system diagram in THA conditions

As initial steam parameters for example, economic diagnosis of the unit is performed. Initial steam parameters include main steam temperature and main steam pressure. According to the principle of the thermal system of power plant, the change of initial steam parameters will have a great impact to the efficiency of power plant. The essence of improving the initial steam parameters is to improve the average temperature of the steam cycle endothermic process, thus improving the circulation efficiency and reducing heat consumption.

The correcting curves of the changes of main steam temperature to the power and heat consumption of the unit are shown in Figure 2 and Figure 3. According to the correction curve and using the above calculation model, the results of economic influence of main steam temperature is shown in Table 1. Among them, heat consumption difference and coal consumption difference are respectively the difference of heat consumption and coal consumption between runtime value and standard value, in units of $kJ\cdot(kW\cdot h)^{-1}$ and $g\cdot(kW\cdot h)^{-1}$. When heat consumption difference or coal consumption difference is negative, the economy of operation parameters is ideal [3,4].

From the calculation results, heat consumption deduces as the main steam temperature rises. By increasing the initial steam parameters to improve the economy of the entire power plant is the main way to improve the efficiency of power plant in the current and future for a long period of time around the world. In the production stage, the combustion should be adjusted to rated new steam parameters. The impact on the economy of main steam temperature is up to $0.61\,g\cdot(kW\cdot h)^{-1}$.

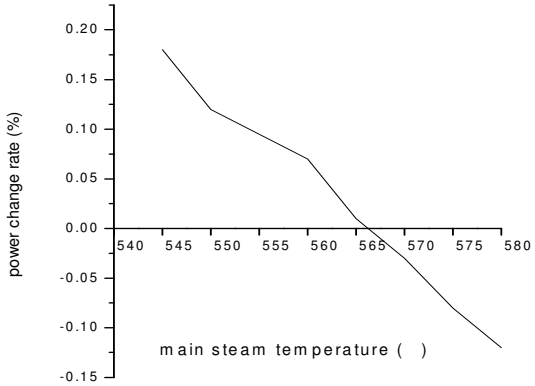

Figure2 Correcting curve of the changes of main steam temperature to power

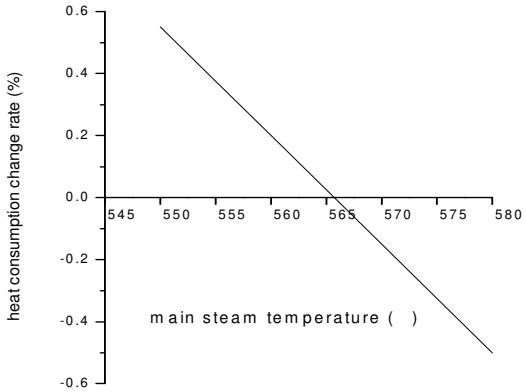

Figure3 Correcting curve of the changes of main steam temperature to heat consumption

Table 1 Economic influence of main steam temperature

Conditions	THA	VWO	TRL	TMCR	500MW	643MW
Runtime value of main steam temperature[°C]	562.8	560.4	561.1	562.5	561.39	564.25
Standard value of main steam temperature[°C]	566	566	566	566	566	566
Heat consumption difference[$_{kJ\cdot(kW\cdot h)^{-1}}$]/	5.82	14.92	13.67	9.26	10.90	6.95
Coal consumption difference[$_{g\cdot(kW\cdot h)^{-1}}$]	0.24	0.61	0.56	0.38	0.03	0.28

Increasing main steam temperature will increases exhaust steam dryness and reduces steam moisture loss of low-pressure cylinder. Meanwhile, increasing main steam temperature also increases the main steam specific volume, other things equal, the turbine blade height on high pressure side will increase, which will correspondingly reduce the steam leakage loss on high pressure side, thus improving the relative efficiency of the turbine.

Economic Diagnosis of Main Steam Pressure

The correcting curves of the changes of main steam pressure to the power and heat consumption of the unit is shown in Figure 4 and Figure 5, and the economic diagnosis of main steam pressure is shown in Table 2.

Within the range of engineering applications, for a sufficiently large steam volume flow, the increase of main steam pressure can improve the cycle efficiency. As shown in Figure 4, under the same conditions, the increase of main steam pressure makes larger unit power. Especially for heat supply units, as a result of the presence of heating steam flow, the volume flow of steam entering the turbine greatly increased, so the main steam pressure of heat supply units is higher than which of condensing unit under the same power. Improving the main steam pressure can significantly reduce heat consumption, as shown in Figure 5, main steam pressure increases 0.2MPa, heat consumption decreases by 0.1%.

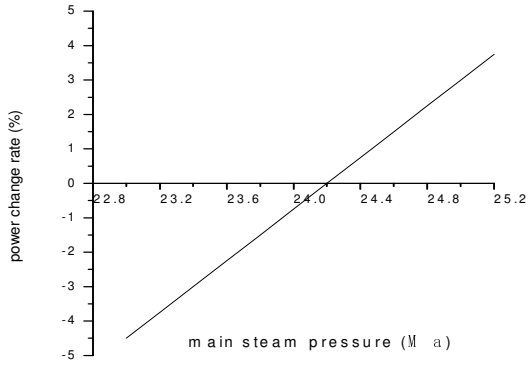

Figure4 Correcting curve of the changes of main steam pressure to power

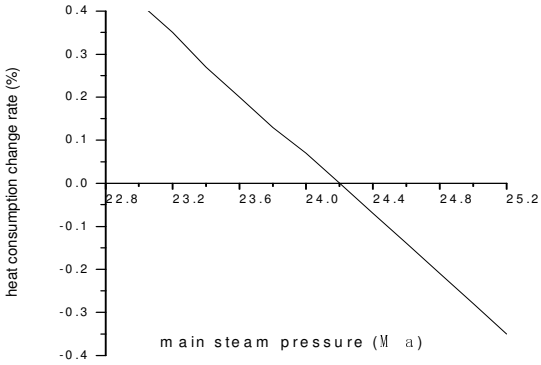

Figure5 Correcting curve of the changes of main steam pressure to heat consumption

Table 2 Economic influence of main steam pressure

Conditions	THA	VWO	TRL	TMCR	500MW	643MW
Runtime value of main steam temperature[°C]	23.94	23.9	24.29	23.96	21.22	24.28
Standard value of main steam temperature[°C]	24.2	24.2	24.2	24.2	21.15	24.2
Heat consumption difference[$_{kJ\cdot(kW\cdot h)^{-1}}$]/	6.58	7.51	-2.28	6.02	-1.73	-1.93
Coal consumption difference[$_{g\cdot(kW\cdot h)^{-1}}$]	0.27	0.31	-0.09	0.24	-0.09	-0.08

Conclusion

Improving the main steam temperature or pressure can both reduce heat consumption of the unit. The substance of improving the initial steam parameters is to improve the average temperature of the steam cycle endothermic process, thus improving the circulation efficiency and reducing heat consumption. Increasing main steam temperature will reduces steam moisture loss of low-pressure cylinder and improves the relative efficiency of the turbine. Improving the main steam pressure can significantly reduce heat consumption. When main steam pressure increases 0.2MPa, heat consumption decreases by 0.1%. For a sufficiently large steam volume flow, the increase of main steam pressure can improve the cycle efficiency. The main steam pressure of heat supply units is higher than which of condensing unit under the same power. The economic impact of main steam temperature is up to $0.61\ g\cdot(kW\cdot h)^{-1}$, while which of main steam pressure is little. By increasing the initial steam parameters, especially the main steam temperature, to improve the economy of the entire power plant is the main way to improve the efficiency of power plant in the current and future for a long period of time around the world.

Keywords: State estimation; Practical analysis; Simulation platform

Abstract: In the process of practical application of state estimation in the actual dispatching system, there are many factors that affect the accuracy of state estimation results. This paper based on the simulation platform of the dispatching system and used the operation data of the actual power grid to simulate the operation of power grid, then analyzed the various factors that have influence on the results of state estimation, which provided effective technical support for practical application of state estimation.

Introductions

State estimation is one of the key software of automatic dispatching system. From the application point of view, the basic goal of state estimation is to provide quasi real-time data, which is more accurate, complete and reasonable quasi than telemetry data, for online analysis.

The online application of domestic state estimation in Supervisory Control and Data Acquisition (SCADA) has gone through from the bad data check to the real-time cross-section data services. In recent years, automatic dispatching system is more goal-oriented at real-time cross-section services. However, there are many limitative factors in the process of practical application of state estimation in the actual dispatching system. In this paper, we used dispatching simulation platform to conduct a simulation experiment and analyzed the influence of the main factors that affect practical state estimation, it provided effective technology support for practical state estimation.

The main factors influencing the practical state estimation

State estimation of power system rely on the telemetry and remote signaling data communication information in SCADA, the network topology analysis and identification of remote communication to get connection model of the current power grid; exclude minority occasional bad data of the measured data through detection and identification of suspicious data; correct the parameters does not match the actual device through parameter identification; finally, conduct state estimation calculation to get more accurate data than the telemetry data. In state estimation calculation, the model and the telemetry data have greater impact on the results of state estimation.

1.1Model problems

The calculation model in state estimation is updated according to the real-time remote letter values in SCADA and parameter values of the network equipment in database. Model errors mainly in: (1) Remote letter error in SCADA. Although the state estimation have bad data detection and identification function, but there are “leakage identification” and “mistaken identification” phenomenon, which will lead to topological errors; (2) Parameter changes after the equipment is bound to run certain number of years, but the parameter values stored within the system are not updated in real-time, this result in equipment parameter error; (3) Wind, snow, lightning and other climate change makes equipment and circuit parameter changes will result in equipment outage, make

the connection of equipments is not timely update in the model base of dispatching system and lead directly to the grid model is not allowed.

1.2Telemetry problem

Telemetry data from the device to the dispatching system generally experienced data acquisition, data transmission and data processing. The telemetry problem reflected in the dispatching system can be attributed to data incorrect and inconsistent latency.

(1)Telemetry value incorrect

There are three main causes that lead to telemetry incorrect data of dispatching system, data acquisition error and error, data conversion and transmission error and data processing.

(2)Measurement of time-delay inconsistency

① Data delay

Measurement data from acquisition to the automatic dispatching system of the whole process needs to experience the prose of the substation sampling, substation data upload, master station receives data, master station processing the data and master station application and storage, etc. As shown in Fig.1, the time of the sampling data uploaded from the device to the sub-station is Δt_1 , which is less than two seconds, and from the sub-station to direct mining system master data is Δt_2 , which is less than three seconds, if the system is in better conditions, it will be less than one second, and the time from master-station receiving to the real-time database updates is $\Delta t_3 + \Delta t_4$ seconds. Under the current level of technology, in the case of uploading the data from the subordinate station to the superior master station, every transponder will increase about 5 seconds of delay.

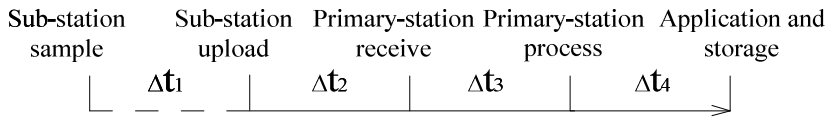

Fig.1 Key nodes of data transmission and processing

② Measurement inconsistency caused by the fluctuation of overall load

Due to the composition and characteristics of the various regions are identical, the load fluctuations of each region is also different. With the substantial increase of air conditioner, electric vehicles and other civilian load, a large number of institutions and schools and even some factory work concentrated in certain time periods, which lead to the overall load in many areas showing high volatility of periods, some areas in 10 to 30 minutes, its load fluctuations may reach 20 to 30% of its maximum daily load. Objectively, such a wide range of load fluctuations will be reflected in the power flow of volatility characteristics of the equipment, and different communication delay will also result in poor consistency of data used in state estimation.

③ Measurement inconsistency caused by the impact load and intermittent energy

Impact load (such as electric furnace steelmaking, heavy machinery, electric train, etc.) have a relatively clear variation characteristics, and its range can reach tens of mw, the change process can be completed in a few seconds, this leads to the section measuring data used in state estimation exist a few megabytes or even tens of megabytes of data inconsistency. And the intermittent and volatility the output of intermittent energy is very large. The fluctuations of the centralized access point power injection of impact load and intermittent power will cause a big change of the measured data of related equipment, and measurement time delay inconsistent will have great influence on the calculation results of state estimation.

④ Measurement inconsistency caused by equipment failures and improper operation

When equipment is in maintenance and failure, a large number of equipment in the power grid will outage or be put into operation. Lines, transformers, generators and other equipment breaking and put into operation, the change of parameter of the Direct Current(DC) system or the DC system lockout and the actions of automatic device etc., will make power flow redistribution in a short time (within one second) then cause large changes in the power flow. The change of power grid operation will

result in the data of rapid mutation and even the whole network data, and data transmission delay will lead to poor consistency of data used in state estimation. The accuracy of the results will also receive great influence.

Mathematical simulation of power grid operation

In good running condition of the power system should not contain system error, under normal circumstances, a measured value from remote sensing devices and power grid parameter values can be described by true value plus a random error:

$$V = V_t + V_{er} \tag{1}$$

Where V is the simulated values, V_t is the true value, V_{er} is a random error. The probability distribution law of random error is:

(1) The probability of different sizes error to occur is various, and the small error probability is larger than the big error probability, but maximal error probability is very small.

(2) The probability of positive and negative error is same, so its distribution curve is symmetric to zero.

The nature is well represented by a normal distribution and its value is subjected to:

$$V_{er} \sim \sigma \bullet N(0,1) \tag{2}$$

In the formula, σ is the standard deviation of random errors, $N(0,1)$ is standard normal distribution function with mean 0 and variance 1.

Normal random error simulation is divided into two steps:

Step 1) Produce uniformly distributed random numbers with mean 0 and variance 1 in interval $(-1,1)$.

If the probability density function of continuous random variable is:

$$p(x) = \begin{cases} \dfrac{1}{b \times a} & x \in (a,b) \\ 0 & x \notin (a,b) \end{cases} \tag{3}$$

And x is the uniformly distributed random variable in interval (a,b), its sampling value is subject to uniformly distributed random variable, the generating process is as follows:

First, put the initial x_0 into the equation $x_{n+1} = 5x_n$ to generate uniformly distributed random number ξ in the interval $(0,1)$, then, according to the equation $x = a + \xi(b-a)$ generate uniformly distributed random numbers in the interval (a,b).

Step 2) According to the central limit theorem, use the sum of uniformly distributed random numbers to form a normal distributed random noise.

The practical analysis of state estimation

Using disturbance simulation module in data simulation layer of experimental verification platform to simulated disturbance scenarios and achieving grid disturbance by means of software.

Take the various factors that affect the telemetry passing rate of state estimation, such as: measurement error of simulated power system, parameter fluctuations of transmission line device and measurement of time delay, and its probability distribution features into consideration. Under the condition of different disturbance, telemetry qualified rate and the objective function of state estimation is different .Then, analyze the tendency of the indicators of state estimation.

3.1 The introduction of the simulation platform of dispatching system

Build a complete experiment simulation system by using PSS/E software as a computational engine. Experimental verification platform use the realistic simulation data to drive dispatching system and organically integrated with dispatching system. Then, study the change of statistical indicators of

dispatching system state estimation after setting different disturbance cases. Experimental verification platform consist of simulation layer, data layer, and EMS analog emulation layer, whose architecture diagram is shown in Fig.2.

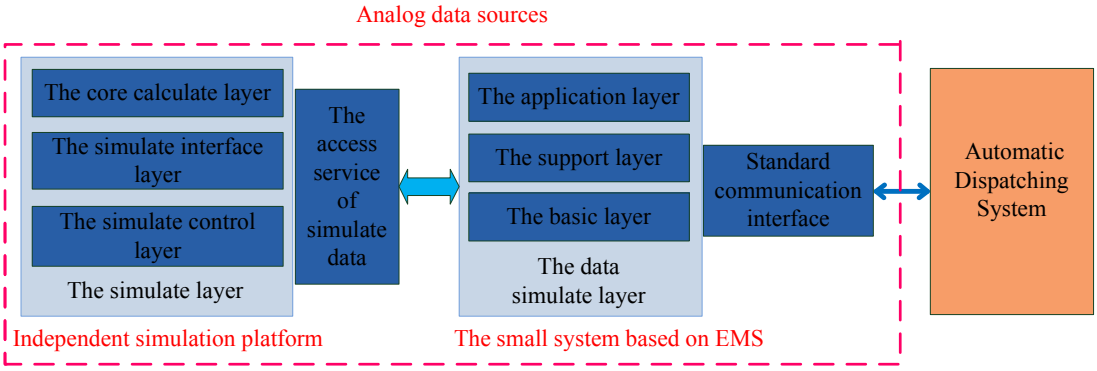

Fig.2 Architecture diagram of experimental verification platform

3.2 The implementation flow

The Automatic Dispatching system experiment platform use analog data to drive the data acquisition, data collection and other various application of the master system to realize the realistic simulation grid operation. Set various disturbances in actual simulation power grid and study the change of index in the master system state estimation.

The main steps are as follows:

Step 1) Simulation computer simulate the daily operation data of power grid;

Step 2) Data emulation layer to get the whole network operational data, simulate disturbance scenario and form various types of disturbance data;

Step 3) Send disturbance data, which is formed in data simulation layer, to the testing platform and the SCADA application;

Step 4) State estimation calculated according to the real-time data in SCADA. Compare and analyze the results of state estimations that based on power flow and many disturbance factors.

The example analysis of disturbance simulation

To verify the influence that the amount of random measurement error, parameters fluctuations of power transmission lines and measurement delay have on state estimation, this paper choose a regional dispatching support system of a smart grid to conduct the experimental verification. In the experiments, the number of the nodes calculated is 1079, the number of branches is 1949 and the number of stations is 530.

4.1 The measured perturbation data based on the normal distribution

The analog measurement value is described by the power flow calculation value and random error. According to the type of measurement and the data acquisition and accuracy requirements of substation, the specific method of calculating the values of active and reactive power and voltage of measured points. The method is shown in formula (4):

$$\begin{aligned} Value\ of\ measured\ point = Value\ of\ measured\ point + \frac{1}{3}k \quad Value\ of\ measured\ point \times a_m \\ + Full\ scale\ value\ of\ measured\ point \times b_m \end{aligned} \tag{4}$$

Where a_m is the error coefficient of measurement, b_m is the error coefficient of converter and transformer and k is a normal distributed random noise with mean 0 and variance 1. In this experiment, the histogram and fitting curve of the normal distributed random noise is shown in Fig.3, the mean is 0.0046, variance is 1.0168 and normal random points is 10373.

(1)When the error coefficient of power measurement is $a_m = 0.5\%$ and $b_m = 0.35\%$, the error coefficient of voltage measurement is $a_m = 0.2\%$ and $b_m = 0.3\%$.

(2)When the error coefficient of power measurement is $a_m = 0.2\%$ and $b_m = 0.35\%$, the error coefficient of voltage measurement is $a_m = 0.3\%$ and $b_m = 0.3\%$.

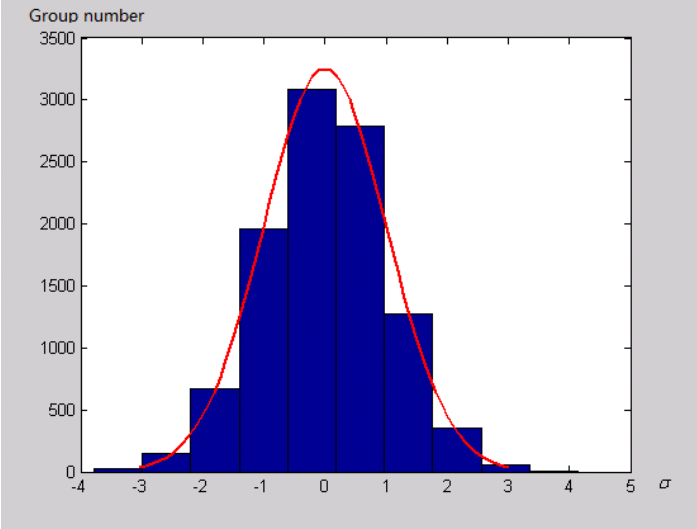

Fig.3 The normal random noise histogram and curve fitting

4.2 The simulation of parameter fluctuations

Experiment 1: According to the length of the transmission line simulate the fluctuations of reactance parameter of line

Take reactance value of every kilometer transmission line is 0.35 Ω, but for 100KM line, when the voltage level of transmission line is 220kV, its per-unit value of reactance is $X = (0.35 \times 100) / \frac{230^2}{100} \times 100 = 6.61$, when the voltage level of transmission line is 500kV, its per-unit value of reactance is $X = (0.35 \times 100) / \frac{525^2}{100} \times 100 = 1.27$.

Accordance with the rules that the fluctuation of the reactance of line longer than 100km is 1% and the line longer than 300km is 2%~4% to design reactance parameters, the specific method is as follows:

When the voltage level of transmission line is 220kV, the per unit value of reactance of 100km line is 6.7 and the line longer than 300km is 20. When the voltage level of transmission line is 500kV, the per unit value of reactance of 100km line is 1.3 and the line longer than 300km is 4. The fluctuation coefficient k is between -1 and 1 and in accordance with normal distribution. The formula to calculate is as follows:

$$X' = X_0 + X_0 \times coef_{flu} \times (\frac{k}{3.0}) \tag{5}$$

In the formula (5), $coef_{flu}$ is the fluctuation coefficient of reactance of the line, which is decided by the size of reactance.

It should be noted that the above per unit value refers to the reactance value, which is expanded after one hundred times, the same as follows.

Experiment 2: Analog the volatility of the reactance parameters of transmission line

For all the power transmission line parameters, the fluctuation of the reactance parameters rates is according to are 1%, 3%, 5%, 7%, 9%, 11%, the fluctuation coefficient of k is between -1 and 1 in accordance with normal distribution. In the formula (2), the reactance value of the parameter variation rate is from 1% to 11%.

Experiment 3: Analog the volatility of the resistance parameters of transmission line

In the formula $r_t = r_{20}[1+\alpha(t-20)]$, $\alpha = 0.00361/^{\circ}C$ (when t is less than seventy degrees Celsius) for aluminum conductor. When t equal to 20, 30, 40, 50, 60, 70, the change rate of resistance were 0%, 3.6%, 7.2%, 10.8%, 14.4%, 18%. Set the temperature of wire conductor, which is associated with the current load rate of the wire conductor, then conduct experiments of resistance volatility of transmission line, volatility coefficient is shown in formula (6).

$$k = 0.36\% \times \frac{i}{i_{\max}} \times 50 = 0.18 \times \frac{i}{i_{\max}} \tag{6}$$

In the formula (6), $i_{\max}$ is the limited value of the current flowing through the transmission line, i is the current of transmission line, which is calculated by power of line (active and reactive power) and bus voltage.

Experiment 4: The joint fluctuations of resistance and reactance

The resistance parameter of line is decided by the experiment of fluctuations in resistance. The reactance parameter of the transmission line is changing between 1% and 11% in accordance with the normal distribution characteristics.

4.3 The analysis of the impact of the measurement time-delay on state estimation

The load of system change in different ramp rate, in this situation, due to the different features of direct mining station and data forwarding station delay, we set different delay interval (0 second, 5 seconds, 10 seconds and 15 seconds), which means the measured data is divided into four periods. According to the station area partition delay range, the substation in 220 kV level, some is 15 seconds delay and some is 10 seconds delay; the substation in 500 kV level, some is 5 seconds delay and some is 0 second delay. Simulate the time-delay data of state estimation in master station system, and compare the change of the related indexes.

In the test platform, change the two time interval of the load curve in simulation layer to achieve the load with different ramp rates.

With different ramp rate of load, the change of eligible rate of state estimation is shown in Fig. 4 and the change value of the objective function in the state estimation is shown in Fig. 5.

Different ramp rate of load make the data obtained in state estimation is not consistent with the real-time data. It is obvious that when increase the ramp rate of the load gradually, the latency of measured data will result in the increase of the imbalance power of the computing nodes, the consistency of the time section will be destroyed, the imbalance power of measurement system become bigger, thus make the qualified rate of state estimation decrease and residual become larger.

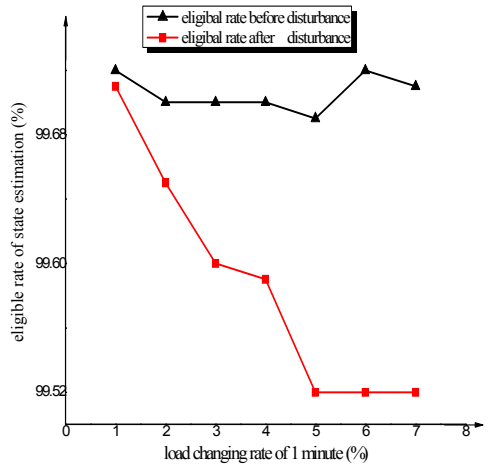

Fig.4 The change of eligible rate of state estimation under different load changing rate of 1 minute

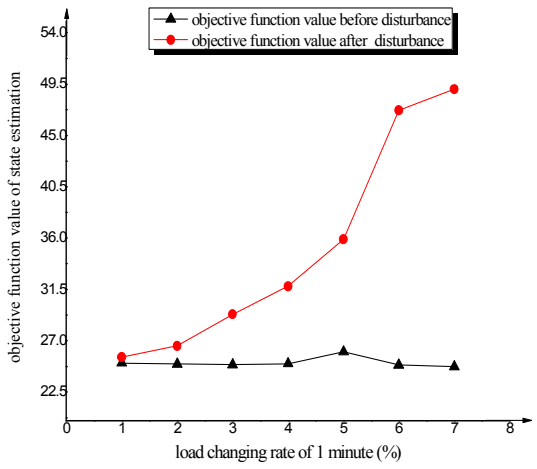

Fig.5 The change of objective function values under different load changing rate of 1minute

4.4 Comprehensive experiment of disturbance factors affected the indicators in state estimation

The setting table of comprehensive test case is shown in Tab.1, the experimental results are shown in Fig.6 and Fig.7.

Based on the analysis of the experiments, analyze the change trend between all kinds of statistical indicators of state estimation and disturbance factors, it is easy to see that the inevitable measurement error in the system, the change of environmental temperature of grid equipment, parameter error of transmission line and the ramp rate of load (without considering measurement system on the basis of gross error), the qualified rate indexes of state estimation fell to a certain extent, the objective function values, which is of one of the index to measure the precision of state estimation, gradually become larger. Under the action of these factors, residual error of the system increased, the reliability of calculation decreased.

Tab.1 The set table of comprehensive experiments

Experiment 1 of comprehensive factors	Random measured error of reactance parameters in system + the fluctuation of reactance parameters based on the length of line + fluctuation of resistance + 4% load fluctuation in one minute
Experiment 2 of comprehensive factors	Random measured error of reactance parameters in system + 3% fluctuation of reactance parameters + fluctuation of resistance + 4% load fluctuation in one minute
Experiment 3 of comprehensive factors	Random measured error of reactance parameters in system + 5% fluctuation of reactance parameters + fluctuation of resistance + 4% load fluctuation in one minute
Experiment 4 of comprehensive factors	Random measured error of reactance parameters in system + 7% fluctuation of reactance parameters + fluctuation of resistance + 4% load fluctuation in one minute

Conclusions

With the expansion of the scale of power grid and the formation of UHV AC /DC hybrid power grid, the intermittent and randomness of renewable resources, the introduction of market mechanisms, the introduction and implementation of energy conservation and emissions reduction policy, which have made the operation mode of power grid become more and more complex and maintain the safe operation of the power grid is become more difficult. The influencing factors of state estimation are become more complex, the difficulties of the practical state estimation to overcome have become more and more. This paper analyzes the main factors affecting the results of state estimation, and through the simulation experiment of experimental verification platform analyzes the impact of various factors on the state estimation, provide strong technical support for practical functions of state estimation, such as the online analysis of power system and automatic dispatching system, and provide technical support for the improvement of safe and economic operation of the power grid.

Keywords: microgrid; microgrid energy management system; structure design; LabVIEW

Abstract. Microgrid can be applied in different locations, relative to traditional power technology. It can improve the reliability of users of electricity and power system operation. Distributed power in microgrid needs real-time and multi-objective optimization management. This paper discusses functions and structure of microgrid energy management system(MGEMS) when connected with the main grid. Problems in long-term and short-term energy management of microgrid are discussed. From the point of view of the software platform, the system structure of MGEMS software are proposed. On this basis, this paper discusses the way to construct modules of MGEMS and their functions.

Introduction

Microgrid[1] is proposed by the Consortium for Electric Reliability Technology Solutions (CERTS) in the 90's of the last century. Distributed energy in the microgrid is called the microsource[2].

Microgrid consists of lager number and lager kinds of generating equipment, relative to traditional power technology. It can be used in large and medium-sized sports venues as power reserve, also be used in natural disaster reconstruction. So microgrid can improve the operation safety and reliability of power grid indirectly[3]. Therefore, the design of microgrid energy management platform becomes an urgent problem to be solved.

LabVIEW can manipulate the database using automation technology. The database has strong data management functions, such as data query. SQL query language is generally used for database application. By using Database Connectivity Toolkit of LabVIEW, the user don't need to consider the details of the database and understanding some common sense of the database is enough[4]. Powerful database operation function and convenient user interface creating function make the application convenient, which using LabVIEW software to build energy management system for microgrid.

From the point of view of system structure of the microgrid energy management system, the way to construct functions of each modules in microgrid energy management system are be introduced in this paper. Finally, this paper points out some issues about microgrid in islanding mode.

Key functions and control cycle of MGEMS

Energy management system(EMS)[5] is the general term for the modern power grid dispatching automation system. It provides real-time information, scheduling management and control of power grid for power grid dispatching management to ensure the safe operation of power grid and improve power quality and the economic operation of the power grid. Drawing on the existing EMS research results, in order to give full play to various distributed energy efficiency and achieve efficient, economic, safe, and reliable operation of the microgrid system, establishing a set of microgrid energy management system has become a problem to be solved.

Key functions of MGEMS MGEMS is the core of the microgrid system coordination control, which should achieve the following key functions[6]:

①Provides the power and voltage set point for each distributed energy controller in microgrid system; ②Ensure to meet the thermal load, electrical power load demand in microgrid system; ③Ensure that the microgrid system can meet the operating agreement between systems and microgrid; ④Try to make the minimum energy consumption and the system loss; ⑤Make distributed power supply the highest efficiency and try best to absorb renewable energy; The key function of MGEMS as shown in figure 1.

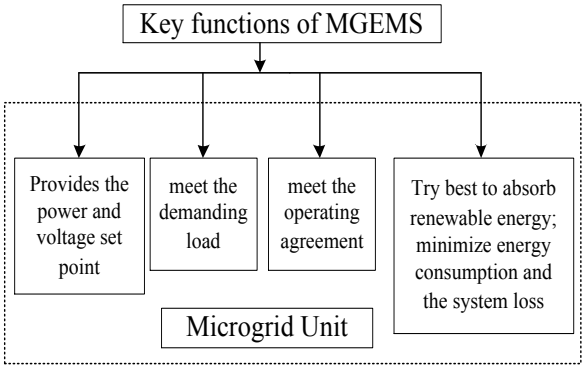

Fig.1 Key functions of MGEMS

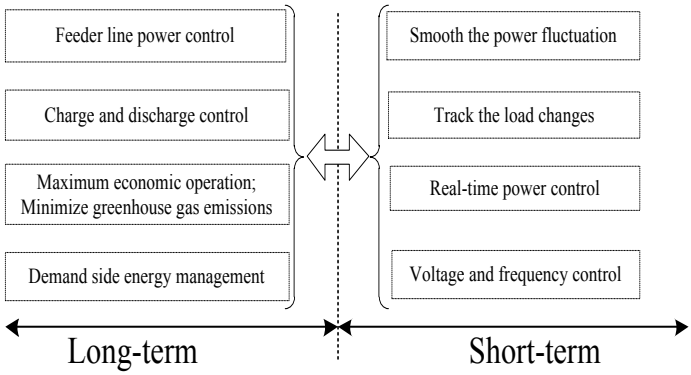

Fig.2 Control cycle classification of MGEMS

Control cycle of MGEMS According to the control cycle length, microgrid energy management platform can be divided into short-term and long-term management[7].

Short-term energy management includes: smooth the power fluctuation; track the load changes fastly and effectively; real-time power control of equipment in microgrid; voltage and frequency control. Long-term energy management includes: feeder line power control between microgrid and distribution network system; charge and discharge control according to the price mechanism of distribution network system; distributed power supply's maximum economic operation; minimize greenhouse gas emissions control; demand side energy management. Control cycle classification of MGEMS as shown in figure 2.

System structure of MGEMS

On the basis of computer operating system, MGEMS can be divided into three levels: software support platform, mathematical modeling and application function module. Scheme of MGEMS software configuration shown in figure 3.

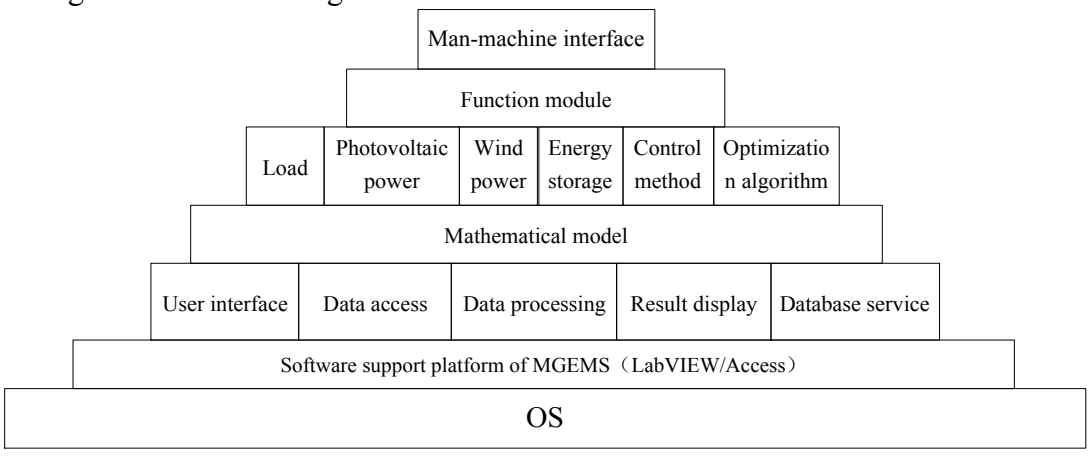

Fig.3 Scheme of MGEMS software configuration

On the basis of user interface, data access, data processing, result display and database service, MGEMS set up the mathematical model of the units in microgrid system, such as load, photovoltaic power generation, wind power, energy storage unit etc.. On the other hand, MGEMS sets up the control method and optimization algorithm for management of the microgrid system. MGEMS build the function module and man-machine interface for the related person to use, though the integration of relevant mathematical model, control method and optimization algorithm.

Modules of MGEMS

Microgrid energy management system mainly includes six modules: the database module, real time measurement and display module, renewable energy and load forecasting, micro economic scheduling module, capacity optimization module and flow analysis module.

Database module Database module includes the establishment, connection and operation of the database, which provides the following function:

①The MGEMS inquires about the basic information of the Access database, such as information contained in the database table, the types of the table data; ②The MGEMS operates on the access database tables, such as creating tables, deleting tables, inquiring specific table information; ③The MGEMS operates on data records, such as adding (delete, query) data records to the table.

We can see above, combining some access processing functions and MGEMS together is the main function. Some basic information and parameters of microgrid are stored in the database for MGEMS query and use in practical applications; and the data processed by the MGEMS can also be stored in the database for future reference.

Real-time measuring and displaying module The main function of this module is real-time measuring and displaying the microgrid status information and some power information on the primary node. This information includes: the active and reactive power of each load point, the real-time output of renewable energy, the switching power of the PCC(Point of Common Coupling) between microgrid and the main network, and the voltage size of the main network node, the frequency of the microgrid and so on.

Renewable energy and load forecasting module The main function of this module is to forecast the output of the renewable energy in microgrid and the power of the loads. Using the Neural Network method, by setting some parameters of neural network and training samples, to predict the wind speed, light intensity in the microgrid, and then to predict the output of wind turbine and other renewable energy generation like photovoltaic. Load forecasting similar.

Economic dispatch module After the access to energy supply and demand forecast information, Economic Dispatching Control(EDC) execute the optimization calculation of microgrid, combining with the information of distributed energy unit arrangement and microgrid's interaction program with the main network. Then the set point commands could be sent to related units in the microgrid[8,9].

During the real-time operating of microgrid, operation parameters and equipment state information, acquired by the monitoring equipment in microgrid, should be sent to EDC for decision making. At the same time, the results of microgrid EDC optimization provides basis for combination arrangement of DER unit and microgrid's interaction program with the main network. EDC can also takes the controllable load management into account. Information flow of EDC application as shown in figure 4.

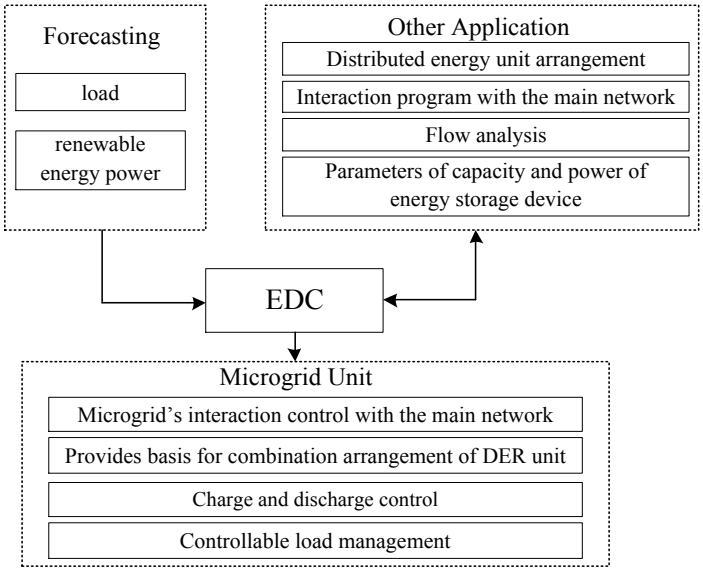

Fig.4 Information flow of EDC application

Capacity optimization module The main function of this module is to analyze configuration parameters of capacity and power of energy storage device that fit the best effect of smoothing wind power fluctuation. By setting power standard deviation of wind turbine and energy storage device as the optimization goal and setting characteristics of energy storage device as constraint conditions, the mathematical model of storage capacity optimization is established[10].

To optimize the model, we use typical daily active power turbine data. Then we get the configuration parameters of capacity and power of energy storage device, based on the calculation results. Finally, choose one group as the desired capacity and power of energy storage device by analyzing the effect of smoothing wind power fluctuation and the cost of energy storage device.

Flow analysis module Flow analysis module, taking the parameters of element in the microgrid from the database access, check the security of the microgrid system combined with the results of EDC. Flow analysis module applies the Newton-Raphson algorithm, and the calibration results can be fed back to the EDC for correction.

One block diagram window of MGEMS based on LabVIEW is shown in figure 5.

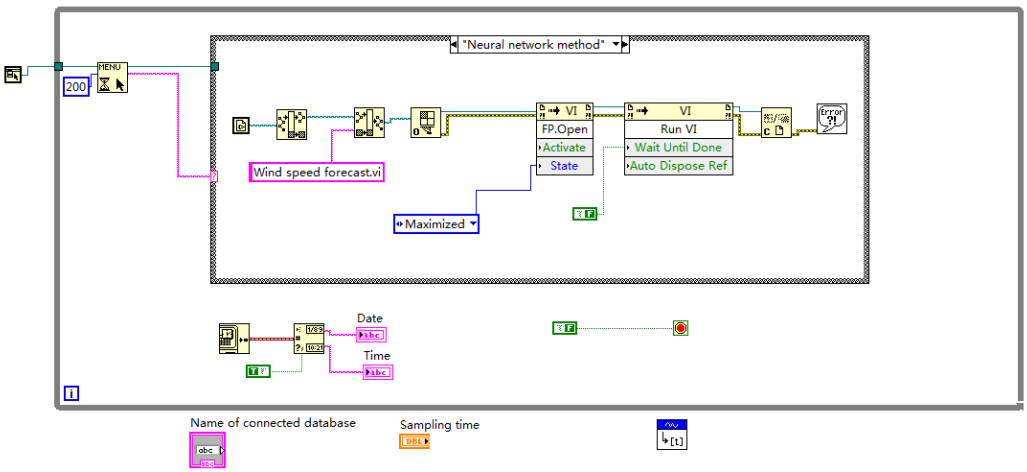

Fig.5 Block diagram window of MGEMS based on LabVIEW

Conclusions

The rapid development of distributed renewable energy and microgrid technology puts forward new requirement for EMS, which making the scheduling decision. The development of EMS, achieving safety, reliability, economic operation of the microgrid system, has a great significance.

This paper introduces the concept, characteristics and functions of microgrid, as well as the main problems facing in the development of micro grid. The feasibility to build the MGEMS using LabVIEW software is explained and the functions of MGEMS and its structure are made clear. Then the various MGEMS modules and their functions are explained in detail.

Functions of MGEMS in islanding mode, such as Optimized operation, synchronization and system splitting control, are the issues for further discussion.

Keywords:transmission network; planning alternatives; comprehensive assessment; index system

Abstract. In view of the lack of comprehensive and quantitative evaluation means for transmission network planning currently, a comprehensive assessment index system adapted to the characteristics of the transmission network planning is proposed, including6 strategic layer indices(safety and reliability, economic efficiency, flexibility and coordination, smart and green, controllable risk and social benefits), 16 target layer indices and 57 operating layer indices.And the assessment standard for each indexis determined to provide objective, comprehensive and systematic evaluation of transmission network planning alternatives as well as prepare for realization of the comprehensive evaluation of transmission network planning.

Introduction

Transmission network planning is the basic of the power system construction. A reasonable planning is necessary to ensure the power system security, stability and economy,as well as minimize wasted power system construction investment. Recently, with the economic and technological developmentin China, the grid plan should meet higher requirements for power quality and reliability put forward by power customers. So determining how to evaluate the planning and describe the result of the grid planning quantitativelybecomesa key problem. Therefore, a reasonable comprehensive assessment index system for alternative transmission network planning is needed to evaluate the pros and cons of the planning quantitatively.

Traditional evaluation of grid usually focuses on flow distribution,stability level,short-circuit level and economic evaluation of the planning alternative, including assessment of reliability, security, economy and other individual indices. Recently, researches on comprehensive evaluation have been emerging. Reference [1] proposes a comprehensive evaluation index system and method for distribution network planning, whichincludes 5 first grade indices: supply security, reliability, economy, flexibility and coordination, and contains a number of subordinate indices. However, as the transmission network and distribution network play different roles in the power system, the evaluation index system does not apply to the transmission network planning.Reference [2] evaluates the power system operating state from five aspects: safety, reliability, economy, stability and flexibility.However, the assessment index system focuses on the evaluation of power system operating state, whichcannot reflect the planning characteristics. Reference [3]divides the grid

assessment indicesinto transmission and distribution network, and makes further division in each category according to planning and running stage. Then a power network evaluation index system framework, including transmission network planning evaluation index system, transmission network after the evaluation index system, distribution network planning evaluation index system, and distribution network after the evaluation index system, is formed.But the transmission network planning evaluation index system is not comprehensive enough. There are other studies[4-7] about evaluation index system for the smart grid development. As forresearches on comprehensive evaluation of transmission network planning, reference[8] considers reliability, economy, social impact, adaptability and includes 12 indices such as line load rate; reference [9] evaluates the transmission network planningfrom four criteria layers:technology, economy, environmental impact and adaptability, including 15 indices such as load cut probability.

Transmission network planning is associated with the grid development strategy. Grid development should meet the social and economic development requirements and coordinate with the economy and reliability. Grid structure should be able to adapt to a variety of possible operating means, and ensure future needs of the load growth and network expansion. Power system should allocate resources optimallyand serve the low-carbon society and sustainable economic development as well as to be more intelligent, efficient, reliable and environment-friendly.

This paper studies the existing grid evaluation index system, focuses on the transmission network planning characteristics, and puts forward a comprehensive assessment index system, including safety and reliability, economic efficiency, flexibility and coordination, smart and green, controllable risk and social benefits to evaluate transmission network planning quantitatively.

Construction Principles of Index System

When establishing evaluation index system, each index should reflect the actual situation of the grid as comprehensively as possible, without missing any important indices. What's more, information validity, data collection and calculating complexity should also be considered. Therefore, the design of the index system needs to meet the following principles:(1) Consistency with the evaluation objectives;(2) Availability;(3) Comparability; (4) Mutual independence;(5) Overall completeness.

Contents of Index System

According to the construction principles of index system, a comprehensive evaluation index system for transmission network planning is established, combined with the actual characteristics and purpose of the transmission network planning.

Six strategic level indices is determined by the long-term development strategy of the power system,including safety and reliability, economic efficiency, flexibility and coordination, smart and green, controllable risk and social benefits. Then decompose the strategic levelhierarchically into target layer according tothe assessment purpose. The operating level indices are further division of the target level indices, which can be quantified and comparable.

Safety and Reliability.Safety and reliability is the basic requirement of electricity customers' demand. Security refers to the ability of power system to maintain the supply properly sectionfor a set of contingency at any time. Reliability refers to reliability of continuous supply under the premise that the power system meets the safety requirement. Safety and reliabilitylayer includesthree target layer indices: grid structure, power supply capacity and stability level.

Grid structure index reflects the ability to maintain normal power supply under a failure, and power contact tightness. It consists of five operating layer indices: N-1 passing rate, N-2 passing rate, average power supply radius, short-circuit current level, effective short-circuit ratio.

Power supply capacity index evaluates main transformer regional supply capacity, local power supply ability as well as the dependence of the regional power grid on external power. It consists of four operating layer indices: capacity-load ratio of each voltage level, power installed capacity ratio below 500kV, external input capacity ratio, station capacity variance of each voltage level.

Stability layer index assesses power system transient stability situation in the case of a certain fault. It consists of three operating layer indices:N-2 instability fault number, reactive power compensation, spinning reserve rate.

Economic Efficiency. Economic evaluation of network planning is an important mean to improve the economic efficiency of power grid construction projects. Economic efficiency indices evaluate utilization efficiency of equipment and investment efficiency.

Equipment utilization efficiency indices assess transmission lines and transformer load, reflecting the grid operating efficiency, including five operating layer indices: average line load rate of each voltage level, line voltage load rate distribution of each voltage level, average transformer load rate of each voltage level, transformer load rate distribution of each voltage level, utilization rate of annual maximum load.

Investment efficiency indices analyze supply satisfaction and economic benefits of power system investment, from the aspects such as capital investment, supply gain and loss reduction benefit, including increased electricity sales by unit investment, increased load by unit investment, line loss rate, decreasednetwork loss benefit, annual cost of unit load.

Flexibility and Coordination. Local overload or light load will affect the grid safety, reliability and economy tremendously, as power system is inseparable. Coordination is also needed between the high and medium voltage transmission network, otherwise the fragile part would weaken power supply level of the strong part. The load volatility requiresflexible changes of connection scheme after a certain fault. Flexibility and coordination indices reflectcoordination between installed capacity, load and grid equipment scale; substation capacity; as well as match of linescale and supply margin.

The coordination development between power grid and power supply target layer includes four operating indices: ratio of line length and generator capacity, ratio of line length's growth rate and generator capacity's growth rate, ratio of substation capacity and generator capacity, ratio of substation capacity's growth rate and generator capacity's growth rate.

The coordination development between power grid and power supply target layer includes three operating indices: ratio of substation capacity's growth rate and load's growth rate, ratio of line length increment and load increment, ratio of substation capacity increment and load increment.

The coordinated development between power grid in each voltage grade target layer includes five operating indices: ratio of outgoing line number of lower voltage and substation number of higher voltage, ratio of substation capacity between lower voltage and higher voltage, ratio of substation number between different voltages, ratio of substation capacity between different voltages, ratio of line length in different voltage grades.

The flexibility target layer includes five operating indices: ability to transfer power supply, extensible margin of substation capacity, transmission capacity margin of transmission section, line interval margin, channel margin.

Smart and Green. Smart and green indices evaluate intelligent devices and consumptive ability of new energy, including two target layer indices: intelligence level of transmission and transformation and ability to access new energy.

The intelligence level of transmission and transformation target layer includes six operating indices: intelligent substation's capacity ratio, compact-line' length ratio, large cross-section line' length ratio, reactive compensation capacity ratio of STATCOM, line' length ratio of flexible AC(DC) transmission, saved land amount.

The ability to access new energy target layer includes two operating indices: renewable energy' installed capacity ratio, renewable energy' generating capacity ratio.

Controllable Risk. Controllable risk indices assess accident risk, investment risk and ability to withstand natural disasters and otherrisks.

Accident risk indices analyzeaccident risks that should be checked in the power system planning stage, based on the document 'electrical safety accident emergency handling and investigation regulations' issued by the State Council (State Council Decree No. 599), including load reduction ratio of double and above circuit lines trip on the same tower (N-2 fault) andload reduction ratio of single HVDC bipolar latch (N-2 fault).

Investment risk indices focus on financial recovery ability and income level of grid projects, including two operating layer indices: dynamic payback period and internal rate of return(IRR).

Ability to withstand risks indices assess the ability of power system to withstand natural disasters and other risks like man-made or external damage based on the file 'grid security risk management (Trial)' (national energy security [2014] No. 123) 20140319) issued by the National Energy Board, consisting of two operating layer indices:ability to withstand natural disasters and ability to withstand other risks (human or external damage).

Social Benefits. Social benefits indices reflect the impact of grid development on the society, economy and environment, including new energy efficiency and energy-saving emission reduction efficiency.

New energy efficiency target layer consists of two operating indices: coal amount of reduced fossil energy consumption and treatment cost of reduced pollutant emissions.

Energy-saving emission reduction efficiency target layer consists of two operating indices: CO_2 emissions reduction and SO_2 emissions reduction.

Evaluation Standard of Indices

Evaluation standard(scoring criteria) of each underlying index (operating layer index)is necessary in the comprehensive evaluation process of the network planning program.

For quantitative indices, the evaluation standard can be divided into four basic types: cost type, benefit type, interval type and other type.

Cost-type index (inverse index) refers to indices of which the value the smaller the better, such as line loss rate, dynamic payback period, N-2 instability fault numberand so on. Linear function is used to score cost-type index, as Eq.1.

$$y = 100 \times \frac{X_{\max} - X}{X_{\max} - X_{\min}} . \quad (1)$$

Where, X represents the index value; *Xmax, Xmin* is the value bound of the index in accordance with relevant guidelines, conditions or experts constraints; y represents the index score(0-100).

Benefit-type index (positive index) refers to indices of which the value the bigger the better, such as N-2 passing rate, increased load by unit investment, internal rate of return, and so on. Linear function is also used to score benefit-type index, as Eq. 2.

$$y = 100 \times \frac{X - X_{\min}}{X_{\max} - X_{\min}} . \quad (2)$$

Interval-type index refers to indices of which the value falls within a rangeor on one point the best, such asaverage power supply radius, spinning reserve rate, channel margin and so on. Zigzag function is used to score the interval-type index, as Eq. 3.

$$y = \begin{cases} 100 \times \frac{X - X_{\min}}{a - X_{\min}} & X < a \\ 100 & a \le X \le b \\ 100 \times \frac{X_{\max} - X}{X_{\max} - b} & X > b \end{cases} . \quad (3)$$

Where, *a, b* represent the bound of the interval.

If the interval-type index value has no limit, which means it can be $[-\infty, +\infty]$.Then the scoring function can be replaced by mixed function,as Eq. 4.

$$y = \begin{cases} 100 \times e^{k_1(X-a)} & X < a \\ 100 & a \le X \le b \\ 100 \times e^{k_2(b-X)} & X > b \end{cases} . \quad (4)$$

Where, *k1, k2* represents the parameters of the exponential function selected according to the actual situation.

Other-type index refers to those that do not belong to the above three types, such as N-1 passing rate. Usually technical guidelines for network planning stipulate that the power system of key province and city must meet N-1 principle. That means N-1 passing rate must be 100 %, otherwise the index score would be 0.

Qualitative indices cannot be scored using correlative functions directly as quantitative indices. They can be grading scored according to experts' experience. The judgment is generally divided into 5-9 grades with vague language statements. For example, five grade evaluationcan be described as 'excellent', 'good', 'medium', 'poor' and 'terrible'. Indices like 'line voltage load rate distribution of each voltage level','transformer load rate distribution of each voltage level' and 'ability to withstand natural disasters'.etc. belong to this type.

Conclusions

This paper studies the evaluation of transmission network planning, establishes a systematic and comprehensive assessment index system for transmission network planning, and proposes a number of new indices, such as 'annual cost of unit load' based on Life Cycle Cost (LCC) theory, reflecting grid investment efficiency; 'line interval margin' highlighting the grid flexibility; 'intelligent substation's capacity ratio' reflecting the intelligence level of transmission network; 'dynamic investment recovery period', ' IRR' reflecting grid investment risk;'ability to withstand natural disasters', 'ability to withstand other risks (human or external damage)' reflecting the ability of power system to resist risks; 'treatment cost of reduced pollutant emissions' highlighting the benefits of the new energy.

The comprehensive assessment index system established in this paper can be used for longitudinal assessment about the development of the planning in different periods, helping planners grasp the trend of network development and enhance the target of network planning; as well as be used for horizontal assessment about various planning programs, highlighting features and pros and cons of different plans.

Work of the next step includes: 1) verify and improve the comprehensive assessment index system according to specific transmission network planning programs. 2)study grid evaluation methods[8-13], determine each index weight andintegrate multi-index scores into a composite score accurately, in order to evaluate different network plans comprehensively.

Appendix

Table 1 Structure of the assessment index system

Strategic layer	Target layer	Operating layer
Safety and reliability	Grid structure	N-1 passing rate
		N-2 passing rate
		Average power supply radius
		Short-circuit current level
		Effective short-circuit ratio
	Power supply capacity	Capacity-load ratio of each voltage level
		Power installed capacity ratio below 500kV
		External input capacity ratio
		Station capacity variance of each voltage level
	Stability	N-2 instability fault number
		Reactive power compensation
		Spinning reserve rate
Economic efficiency	Equipment utilization efficiency	Average line load rate of each voltage level
		Line voltage load rate distribution of each voltage level
		Average transformer load rate of each voltage level
		Transformer load rate distribution of each voltage level
		Utilization rate of annual maximum load
	Investment efficiency	Increased electricity sales by unit investment
		Increased load by unit investment
		Line loss rate
		Decreasednetwork loss benefit
		Annual cost of unit load
Flexibility and coordination	Coordination development between power grid and power supply	Ratio of line length and generator capacity
		Ratio of line length’s growth rate and generator capacity’s growth rate

		Ratio of substation capacity and generator capacity
		Ratio of substation capacity's growth rate and generator capacity's growth rate
	Coordination development between power grid and power supply	Ratio of substation capacity's growth rate and load's growth rate
		Ratio of line length increment and load increment
		Ratio of substation capacity increment and load increment
	Coordinated development between power grid in each voltage grade	Ratio of outgoing line number of lower voltage and substation number of higher voltage
		Ratio of substation capacity between lower voltage and higher voltage
		Ratio of substation number between different voltages
		Ratio of substation capacity between different voltages
		Ratio of line length in different voltage grades
	Flexibility	Ability to transfer power supply
		Extensible margin of substation capacity
		Transmission capacity margin of transmission section
		Line interval margin
		Channel margin
Smart and green	Intelligence level of transmission and transformation	Intelligent substation's capacity ratio
		Compact-line' length ratio
		Large cross-section line' length ratio
		Reactive compensation capacity ratio of STATCOM
		Line' length ratio of flexible AC(DC) transmission
		Saved land amount
	Ability to access new energy	Renewable energy' installed capacity ratio
		Renewable energy' generating capacity ratio
Controllable risk	Accident risk	Load reduction ratio of double and above circuit lines trip on the same tower (N-2 fault)
		Load reduction ratio of single HVDC bipolar latch (N-2 fault)
	Investment risk	Dynamic payback period
		Internal rate of return(IRR)
	Ability to withstand risks	Ability to withstand natural disasters
		Ability to withstand other risks (human or external damage)
Social benefits	New energy efficiency	Coal amount of reduced fossil energy consumption
		Treatment cost of reduced pollutant emissions
	Energy-saving emission re duction	CO_2 emissions reduction
		SO_2 emissions reduction

Keywords: distribution network; planning alternatives; comprehensive evaluation; index system.

Abstract. In order to identify weaknesses in distribution network planning alternatives, providing a scientific basis for grid investment decisions, effective and comprehensive evaluation is needed. According to the related principles and objectives, this paper establishes a comprehensive evaluation index system based on hierarchy. This system is guided by the long-term development strategy of China southern power grid, including six strategic layer indices as safety and reliability, economic efficiency, coordination and flexible, smart and green, controllable risk and social benefits. The meaning and classification of every index is listed in details. According to different technical characteristics of every index different fuzzy membership functions are structured. Furthermore, in accordance with the relevant guidelines and specifications, this paper gives specific values of the membership function parameters to achieve standardization of indexes of different dimensions, laying the foundation for a comprehensive assessment.

Introduction

Located on the load side, the distribution network is an important part of distributing electric energy to the users. According to incomplete statistics, more than 80% of power failure is due to a fault caused by the distribution network therefore distribution network has the greatest impact on the users [1]. Distribution network planning alternatives can directly affect various aspects of the power grid construction such as reliability and economy.

Smart Grid is currently competing in the world to carry out, countries combining its own reality have been carrying out a comprehensive development and evaluation of grid to deal with the development of clean energy, climate changes and the need to control the risk of the power grid, on the basis of ensuring safety and economy. At present, the proposal of China's power grid construction projects and the priority of projects rely on experts' experience, therefore, the decision-making level is low and is with great blindness. This is not only a waste of limited investment, but also brings a lot of problems after rebuilding. The above situation is due to the lack of comprehensive knowledge and understanding of a network planning and a lack of clear quantitative criteria. Given the above situation, there is an urgent need to establish a more comprehensive, a wider range of multi-level evaluation system and to define a reasonable and scientific criterion.

About assessing indexes, extensive literature studies has found that the traditional power grid assessments mainly focus on individual assessment such as reliability[2-4], security[5] and the capacity of power supply[6-8]. Lacking a comprehensive evaluation system of technical and economic, these works don't have a strong direct guidance to the planning and construction of the power grid. Reference [9] establishes a comprehensive evaluation index system based on hierarchy, but it gives no consideration to the economic efficiency and environmental protection of the power grid.

About the index criteria, reference [10] invites many power experts to select evaluation criterion and scoring criteria to score the index, which is subjective and less practical. Reference [11] divides index into three basic types: cost type, benefit type and moderate type, giving each type a membership function, but it doesn't specify the value of the function parameters and gives no specific evaluation criteria, leaving the indicators rating lack of scientific basis.

Focus on the above problems, this paper takes a distribution network planning alternatives of a certain city from Guangdong Province for example. Guided by the long-term development strategy of China southern power grid, this paper establishes a comprehensive evaluation index system based on hierarchy, and the core of the system is safety, reliability, economy and coordination, besides it also takes the risk control and intelligent green into consideration. The system should fully reflect and guide the coordinated development among power grid, power source, society, and environment and so on. Meanwhile based on fuzzy theory and combined with relevant standards and regulations, the appropriate membership functions standardize different dimension indicators and objectively reflect the characteristics of each individual index, laying the foundation for the comprehensive assessment.

The Principles and Procedures of Establishing an Index System

The Basic Principles of Index System. The purpose of constructing the index system is to reflect the object of study comprehensively and profoundly, but it does not mean the more indexes, the better, it means increase the index which can provide useful information. So the establishment of comprehensive evaluation system needs to meet certain principles: (1) Consistency with the evaluation objectives; (2) Do not repeat and do not miss; (3) Availability; (4) A combination of qualitative and quantitative

The Procedures of Index System The purpose of the evaluation is to assess whether the index meets the planning guidelines constraint requirements before implementation of the project. Identifying weaknesses in planning alternatives to make adjustment in time, providing a scientific basis for grid investment decisions, the comprehensive assessment helps to make optimal allocation of power resources. Combining the front principles and purpose, the procedure of the construction of index system are as the following three steps:

Step one: Guided by the long-term development strategy of China southern power grid and closely integrated with the strategic objectives of network planning to get strategic layer indices.

Step Two: Target layer indices can be built on the basis of using analysis of hierarchical decomposition and combining with the purpose and effect of the evaluation.

Step three: Operating layer indices can be determined on the basis of absorbing domestic and foreign research results and adhering to related principles to screen indexes.

A Comprehensive Evaluation Index System Based on Hierarchy

The Hierarchy of Index System. The analysis of economical efficiency, reliability and security is requested in distribution network planning guidelines.On the basis of distribution network planning guidelines, coordination and flexible, smart and green, risk control and social benefits are considered in this paper. Meanwhile, hierarchy analysis model of technical and economic analysis are built. The result is shown in Table 1.

Two situations should be considered when judging whether power supply is safety or not. One is that grid occurs accident; the other one is that grid may occur accident. Two factors should be taken into account as follows: 1) whether the grid can guarantee the security of system or not when some equipments out of operation. 2) To what the extent can the power grid structure ensure system security.

The reliability of the distribution network can be measured by setting a series of index.Considering a large number of reliability indexes and simplify of state planning reliability evaluation, in this paper, reliability assessment only focus on the calculation of customer average interruption time and the

evaluation of power supply reliability rate. Meanwhile, reliability assessment of grid can be measured from the perspective of equipment by setting available modulus index and cable rate index.

Series of content should be considered when measuring the distribution network economy, such as long network planning projects duration cycle, different life of investment projects, expenses and incomes of grid construction and operation. Consequently, in order to evaluate the economics of the grid completer, Life-cycle-cost (referred to as LCC) management theory is introduced in this paper to evaluate the whole life cycle of power system.

Power system is an inseparable whole concept, generation side, transmission and the load side must be closely coordinate to ensure the safety and reliability of the grid. The grid coordination talking about here mainly refers to coordination development between grid and load and coordination development between different voltage levels.

In the process of assessing network planning project, power companies will confront many uncertainties, which will lead to risk. The existence of risk means loss, reducing risks and losses can be done through the identification and evaluation of risks. In the past, the evaluation of risk assessment is often overlooked for the grid assessment. According to the relevant guidelines[13, 14], this paper measures the controllable risk by three angles: accident risk, investment risk, ability to withstand risks.

Preliminary Research on the Index System According to the related principles and procedures, this paper establishes a comprehensive evaluation index system based on hierarchy, including 6 strategic layer indices, 15 target layer indices and 46 operating layer indices, which is listed in details in table 1.

Table 1 Comprehensive evaluation index system

Strategic layer	Target layer	Operating layer	Index Meaning	Index Classification
Safety and reliability	Power grid security	N-1 passing rate	Check the ability of power system to keep stable operating after any element out of operation	benefit type
		Ratio of single line and single transformer in high voltage distribution network	The ratio of a single into line and single main transformer substation, the larger the indicator, the poorer the security	cost type
		Interconnection ratio of medium voltage distribution lines	The ratio of lines met the interconnection structure, evaluating transferring ability and reliability of system after fault	benefit type
		Average number of transformer hooked into pubic line	Average number of transformer hooked into pubic line, the bigger the indicator, the more complicated the network ,the less the safety of the system	interval type
		Average transformer capacity hooked into pubic lines	Average transformer capacity hooked into pubic lines, the bigger the indicator, indicating the higher load rate, the less the safety of system	interval type
		Supply radius of high voltage distribution network	Evaluate the average power supply theoretical radius of substation of certain voltage level	interval type
		Average length of medium voltage distribution public lines	The ratio of the total length of main public lines and the number of the lines, reflecting the medium voltage distribution network power supply radius	interval type
		Typical connection ratio in high voltage distribution network	The percentage of number of lines meeting the typical connection mode and the total number of lines	benefit type
	Power grid reliability	Average interruption hours of customer	Average outage time for power users during statistics time (generally unit for years)	benefit type
		Electric reliability	The ratio of effective power supply hours regardless of planning outage and total statistics hours	benefit type

		Availability factor of transformer, circuit breaker, overhead line	Evaluate the accessibility of Transformer, circuit breaker, overhead line, reflecting the supply reliability of power grid	benefit type
		Cable rates	The ratio of length of cable lines and total lines, the bigger the indicator, the more reliable the system	benefit type
Economic efficiency	Equipment utilization efficiency	Maximum distribution line load rate of each voltage level	The ratio of maximum line operating current and long-term allowed current carrying capacity.	benefit type
		The distribution of Maximum distribution line voltage load rate	The distribution of Maximum distribution line voltage load rate, count according to below 50%, 50%~70% and above 70%.	benefit type
		Maximum distribution transformer load rate of each voltage level	The maximum annual load rate of each main transformer, access main transformer utilization of different voltage levels.	benefit type
		The distribution of distribution transformer load rate	The distribution of distribution transformer load rate, count according to below 50%, 50%~70% and above 70%.	benefit type
	Investment efficiency	Unit cost of distribution capacity	The ratio of power grid project total investment during accounting period and increased distribution capacity.	cost type
		Unit cost of line length	The ratio of total new transmission line investment and increased line length, access the construction cost of distribution lines.	cost type
		Distribution line loss rate	The ratio of system loss and grid electricity supply, evaluate the distribution operating economy.	cost type
		Annual cost of unit load	Calculate annual investment cost and operation and maintenance cost of grid unit load under different circumstances, guide the power grid planning construction and transformation economy.	cost type
Coordination and flexible	Coordinated development between grid and load	Ratio of substation capacity's growth rate and load's growth rate	The ratio of substation capacity's growth rate and the maximum load's growth rate	interval type
		Ratio of line length increment and load increment	The ratio of line length increment and load increment	interval type
		Ratio of distribution capacity increment and load increment	The ratio of distribution capacity increment and load increment	interval type
	Coordinated development between different voltage level	Ratio of substation number between different voltage level	Number of single higher voltage level substation supports lower voltage level substation	interval type
		Ratio of substation capacity between different voltage level	The ratio of substation capacity between different voltage level	interval type
		Ratio of line length between different voltage level	The ratio of line length between different voltage level	interval type
	Grid flexibility	Ability of transfer power supply	The ratio of the number of transferable line and the number of non-transferable line	benefit type
		Substation expansion margin	Statistics the ratio of substation expansion capacity and the total capacity	interval type
		Line interval margin	The ratio of the number of unused line interval and the total number of existing line interval and future expansion line interval	interval type
Smart and green	Intelligence level of	Proportion of smart distribution network	Statistics the ratio of smart distribution network capacity and the total distribution network	benefit type

	distribution network	capacity	capacity	
		The number of "plug and play" charging stations of end-use equipment	Statistics the number of "plug and play" charging stations of end-use equipment in the area	benefit type
		Proportion of smart meters	The ratio of smart meters and total meters in the area	benefit type
	Supply capacity of Distributed Energy	Capacity of Distributed Energy accessed to the system	Distributed Energy capacity	interval type
		Utilization ratio of Distributed Energy	The ratio of Distributed Energy average power and Distributed Energy capacity accessed to the system	benefit type
	Energy-saving emission reduction	CO_2 emission reduction	Calculate CO_2 emission reduction by converting the capacity of Distributed Energy accessed to the system	benefit type
		SO_2 emission reduction	Calculate SO_2 emission reduction by converting the capacity of Distributed Energy accessed to the system	benefit type
Controll-able risk	Accident risk	Load reduction ratio in N-1 faults	The ratio of load reduction in N-1 accident	interval type
		Load reduction ratio in N-1-1 faults	The ratio of load reduction in N-1-1 accident	cost type
	Investment risk	Dynamic investment pay-back period	Time that net earing of project consumes to counter the all investment, the smaller the indicator, the smaller the finance risk of the system investment	cost type
		Internal rate of return	Discount rate that makes the cash flow NPV of the series income and expenditure zero, the bigger the indicator, the stronger the system ability to resist economy risk	benefit type
	Ability to withstand risks	Ability to withstand natural disasters	Ability to withstand nature disaster in different nature disaster situation, including the design standard of important equipment, disaster protection and Repair resilience ability, etc.	qualitative index
		Ability to against other risk (human or external force damage)	Ability to withstand man-made or external damage(e.g., electric equipment damage, theft, etc. caused by line construction), important power plants, substations and equipment security, the secondary protection measures, etc.	qualitative index
Social benefits	The degree of popularity of rural electricity	Rural household energized rates	Count the proportion of electrical rural residents to the total number of residents	benefit type
		Each household each ammeter rate	Count the proportion of the number of rural residents achieved each household each ammeter to the total number of residents	benefit type
	The harmony power supply	Customer Evaluation Satisfaction	Measure the degree of customer satisfaction reduction caused by power failure	benefit type
		Comprehensive distribution voltage qualification rate	Measure qualified distribution voltage level comprehensively	interval type

A Comprehensive Evaluation Index System Based on Hierarchy

Previously described various quantitative and qualitative indicators reflect the technical and economic characteristics of different aspects in the distribution planning schemes, however there is no uniform measure standards, direct results' comprehensive assessment of indicators cannot be achieved. Quantitative indicators can be normalized by directly scoring method, there are many indicators scoring methods, currently the most widely used is fuzzy membership method, using the

membership function to reflect the membership degree of the investigated fuzzy object, that is to create a mapping from domain (all being investigated objects) to [0,1]. In practical applications, indicators can usually be divided into the cost, benefit and interval categories. Based on the characteristics of each index evaluation attributes, combined with expert recommendations for program simulation, get the membership function closest to the real situation. Qualitative indicators are normalized by fuzzy comprehensive evaluation method. Following, different categories of indicators are introduced combined with specific guidelines and constraints. Other indicators can refer to such methods to get.

Interval Type Indicator Interval type indicator refers to indicator of which values within a range of interval. Membership function is as Eq. (1):

$$Z_{ij}=\begin{cases} 1-\dfrac{q_{1j}-y_{1j}}{\max\left\{\left|y_{ij}-y_j^{''}\right|\right\}}, & y_{ij}<q_{1j} \\ 1, & y_{ij}\in[q_{1j},q_{2j}] \\ 1-\dfrac{y_{ij}-q_{2j}}{\max\left\{\left|q_{1j}-y_j^{\min}\right|,\left|y_j^{\max}-q_{2j}\right|\right\}}, & y_{ij}>q_{2j} \end{cases} \tag{1}$$

i=1,2,⋯,n; $j\in\Omega_4$. Where $[q_{1j}, q_{2j}]$ is the best stable range of indicator, y_j^{min}, y_j^{max} are the indicator's minimum and maximum values.

Taking "Average transformer capacity hooked into pubic lines" for example, when evaluate the indicator, although there is no clear guidance or constraints, according to relevant guidelines [15], considering 50% line load rate of various line types, the line load range is [4.11,5.27](MW). Consider the case: transformer capacity-load ratio is 100%, the reasonable range of indicator is [4.11,5.27] (MW), which is also consistent with the planning data.

Benefit and Cost Type Indicator Benefit indicator refers to indicator of which values the bigger the better, cost indicator refers to indicator of which values the smaller the better. Sine and cosine distribution membership function are used respectively, the mathematical expression are as Eq. (2,3):

$$\mu=\begin{cases} \sin\left(\dfrac{\pi}{2}\cdot\dfrac{x-x_0}{1-x_0}\right), & x_0\le x\le 100 \\ 0, & x<x_0 \end{cases} \tag{2}$$

$$\mu=\begin{cases} \cos\left(\dfrac{\pi}{2}\cdot\dfrac{y}{y_0}\right), & 0\le t\le t_0 \\ 0, & t>t_0 \end{cases} \tag{3}$$

Such as "electric reliability" is benefit type indicator, " average interruption hours of customer"is cost type indicators. where x_0 is the system minimum average rate of power supply reliability; y_0 is the maximum customer average interruption time, specific values can be selected under the relevant guidelines and specification[15]. Different load density regions are judged according to different standards.

Treatment to qualitative indicators The indicators of ability to withstand risks are qualitative indicators, which need assessment results given by relevant experts according to the power grid plan and design, and it can be divided to very high (1 point), high (0.75 points), medium (0.5 points), low (0.25 points), very low (0 points) five levels. In this paper, fuzzy comprehensive evaluation method is used to deal with such indicators, changing the qualitative indicators to quantitative to treat with.

Conclusions

Traditional comprehensive evaluation index system mainly focuses on evaluation of the status of the grid, this paper proposes a comprehensive evaluation index system suitable for planning grid. Compared with the traditional grid evaluation, this paper combines the characteristics of planning grid, simplifying some of the indicators which are not readily available in the planning grid programs,

such as the traditional "user interruption frequency" index is simplified as "cable rate" index, measuring the reliability of network planning from the perspective of the device. Guided by the long-term development strategy of China southern power grid, this paper proposes some new indicators in accordance with relevant standards and regulations, what's more this paper gives specific values of the membership function parameters to standardize index of different dimensions, laying the foundation for the comprehensive assessment.

Keywords: Electrical Power grid; Grid Security, Grid Efficiency; Grid Adequacy; Incidence Relationship; Power system evaluation.

Abstract: In order to study out the incidence relationship among security, efficiency and adequacy of Electrical Power Grid, a novel analyze model considering grid evolution and a relationship evaluation method is proposed in this paper. The model incorporates in fast dynamic and slow evolution. The former is based on an improved OPA model with low frequency load shedding control and the outage risk calculation. The latter is consists of increasing load, up-grading and constructing equipments including power plants, transformers and transmission lines, Using the model simulation the power grid development process. Based on the model, the customer outage risk caused by cascading failure is obtained in several times, the efficiency index and grid scale index are solved at the same times, these data are the basic data for analyze the incidence relationship among the security, efficiency and adequacy of electrical power grid. In this paper, the power grid of Kaifeng City in Henan Province, of China is used to simulate the evolution. The results show that the relationship among the security, efficiency and adequacy of grid is as exponential function, and a reasonable range of efficiency and adequacy of grid are proposed.

Introduction

At present, the electrical power becomes the lifeline of the national economy, which plays an extremely important role in social and economic development. At first, with the economic growing rapidly and living standard of the people enhancing quickly, the requirement of electricity power has been more and more, as a result, the construction of power system which include in power plant, transmission line, electrical transformer, ancillary facility and so on also has been constructed and put into operation more and more, the development of power grid should be ahead of the demand of power, on the other word, the power scale have to keep appropriate development margin. Secondly the security of power grid was becoming the highest priority-first matters because the grid security closely concerned the security of the economy, society people life and future. Thirdly, the power grid enterprise and the department of assets management request that the equipments must be effective.

Form the above three points, the power grid have to be secure, efficient and abundant. However, it is well known that the three aspects are conflicting opposing reciprocally. Study on the incidence relationship of the grid security, grid efficiency and grid adequacy become a important matter for government, electrical business, power enterprise and academia, it makes total sense to study a optimizing and coordinating developing way of power grid.

In this paper, a novel analyze model considering grid evolution and a relationship evaluation method is used to study on the relationship, and the key index of three aspects are proposed, the power grid of Kaifeng City in Henan Province of China is used to simulate the evolution. The results shows

that the relationship between the security and efficiency is increase exponential one, but the relationship between the security and adequacy is decrease exponential one.

Novel Evaluation Models

The power grid is continuous and quickly developing in China for match the requirements of power transfer, in order to calculate the data of the security, efficiency and adequacy of grid realistically, the process of grid development in long term is simulated in this paper. The upgrade of power grid in a long term has been studied by many academias, and different evolvement models have been proposed. Cao Y J and his colleges simulated the evolution based on a local-world evolving net-work model[1-2]; Mei S W and Ni X P did the same work based on BA scale free network model and compared the results with the real power grid through some indicators[4], such as clustering coefficient. However, the grid upgrade in the models above is quite different from the real one. For example, the upgrade of transmission lines only leads to larger capacity and smaller impedance, and N-1 criterion is not considered. So the evolution models cannot be used to estimate incidence relationship among the security, efficiency and adequacy of electrical power grid.

As we known, the proportion of satisfied N-1 criterion equipment and entire one of grid is necessary to achieve 100% in plan and operation. As a result, the proportion cannot measure the security of grid. Many blackout models are proposed to analyze power outage risks and grid safety [5-8], because blackout risk cannot be ignored [9-11]. Power outage risks caused by cascading failures are used to represent the security of grid in this paper.

The efficiency reflects the use ratio of electrical equipment, the transformer utilization efficiency (is average load ratio) and power line utilization efficiency is used to assess the efficiency of grid. The transformer utilization efficiency is related to power line load ratio in power grid with normal structure and function, therefore, The transformer utilization efficiency are used to represent the efficiency of grid in this paper.

The adequacy reflects the development of margin of the power grid, in other words, it shows that how much the newly increased electricity demand can be meet by the power grid. The transformer capacity-load ratio of power grid in an area is widely used to evaluate the adequacy and to guide the power system planning and construction. To accommodate the transformer utilization efficiency, the transformer capacity-load ratios are used to represent the efficiency of grid in this paper.

Based on the existing works about evolution simulation and risk analysis of cascading failure, this paper constructs a blackout model with evolution, which is driven by the N-1 criterion and load increasing. And power outage risks the security, efficiency and adequacy of electrical power grid will be obtained and the relationships are analyzed.

The Novel Evaluation Models inclued three parts, the frist is the strategy of evolution in slow dynamic, the second is the blackout model with evolution, the third is analyze the relationship based on the each stage data by simulation process . Then the power grid of Kaifeng city in Henan Province of China was used as an example to make analysis. Finally, the results show that the relationship among the security, efficiency and adequacy of grid is as exponential and some conclusions are given.

2.1 Evolution in slow dynamic

The development of power grid is driven by many factors. Among those factors, load growth is the essential incentive. When the load level is so high that power grid cannot meet the security needs of users, the system needs to be construct and upgrade. This construct and upgrade includes not only enhancing power generation capacity in the power supply side, but also increasing the transmission and capacity, under such condition, the power grid need keep high security in transmission of more enormous energy. The upgrade of generator, transformer and transmission line is particularly triggered by the three conditions: power reserve, load ratio and N-1 criterion. When there is a lack of power reserve in systems, generators will be built according to the distribution of resources to meet the power needs; In addition, in order to ensure the security, the components of system will be upgraded when it works with high load rate or the N-1 criterion is not satisfied. In order to complete

the upgrade of generators, transformers and transmission lines, a number of factors need to be considered, such as equipment capacity, voltage level, the access to network, etc. In this paper, we use a simplified strategy which is based on the actual situation of the grid's upgrade. The detail evolution strategy has been introduced clearly in before paper [12].

2.2 Black model with evolution in fast dynamic

Black model is used to simulate the process of cascading failure with initial faults and give assessment to blackout risk. This fast dynamic is based on the improved OPA model in this paper, and it is able to analyze low frequency load shedding [13]. The combination process of the fast dynamic and the slow dynamic is shown in Fig. 1. The slow dynamic is used to simulate the evolution of power grid in a long time frame, and the fast dynamic is used to calculate the power outage risks, the transformer utilization efficiency and the transformer capacity-load ratios.

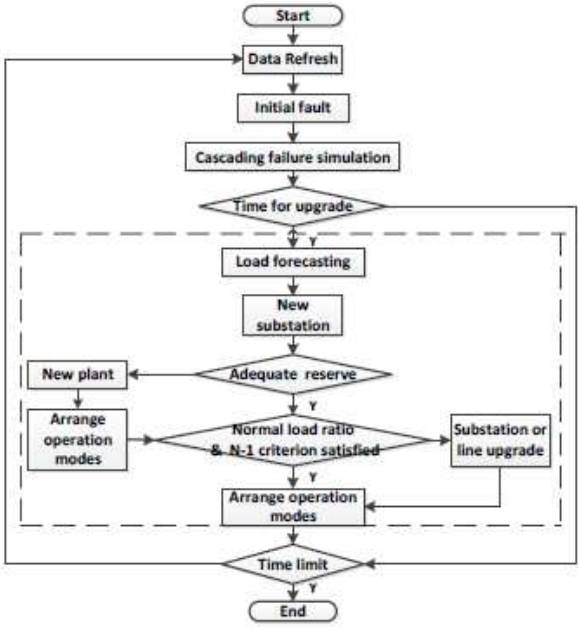

Fig. 1 Flow chart of blackout model

2.3 The relationship analysis method

The relationships of the three targets which represent the three aspects are analyzed by statistics, matching, regression analysis based on data from every time fast dynamic calculations. The equation of regression is utilized to study the reasonable range under acceptable power outage risks.

Empirical Analysis and discussions

The power grid of Kaifeng city in Henan Province of China was used as an example to make analysis in this paper. The power grid mainly contains 220kV and 500kV grade equipments, Power grid of Kaifeng city in Henan Province of China is shown in Fig. 2.

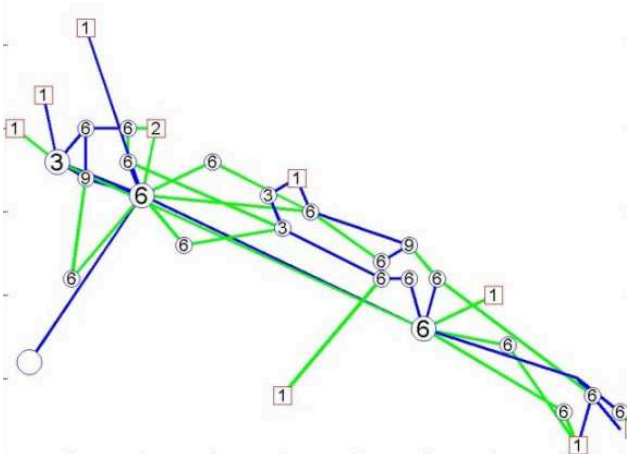

Fig. 2 Power grid of Kaifeng city in Henan Province of China

Two hundred times fast dynamic and tem times slow dynamic are calculated in simulations with power demand growth rate 6%, therefore, there are two hundred data arrays of the three targets are obtained to analyze the relationship. The relationship between the power outage risks and transformer utilization efficiency is shown in Fig. 3. With the transformer utilization efficiency increasing, the power outage risks increases correspondingly. There was an exponential relationship between the power outage risks and transformer utilization efficiency though regression analysis. The exponential equation is shown as Eq.1, with the variance is 0.7364. In equation, y is power outage risks, and x is transformer utilization efficiency.

$$y=0.0061e^{33.602x} \tag{1}$$

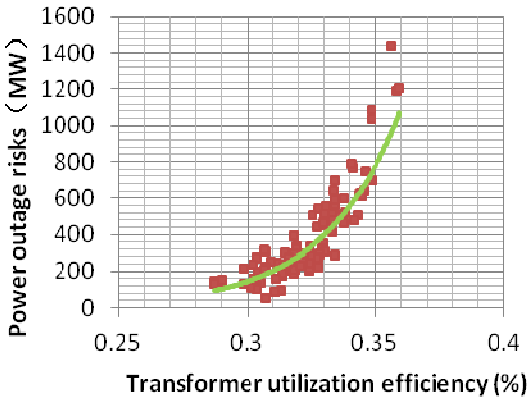

Fig. 3 The relationship between power outage risks and transformer utilization efficiency

The relationship between the power outage risks and the transformer capacity-load ratios is shown in Fig. 4. With the transformer capacity-load ratios increasing, the power outage risks decreases correspondingly. There was an exponential relationship between the power outage risks and transformer capacity-load ratios though regression analysis. The exponential equation is Eq. 2, with the variance is 0.6991. In equation, y is power outage risks, and z is transformer capacity-load ratios.

$$y=10^{6}e^{-1.8178z} \tag{2}$$

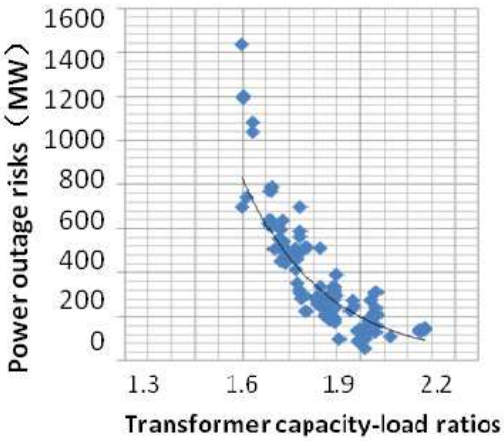

Fig. 4 The relationship between power outage risks and the transformer capacity-load ratios

We utilized the novel evaluation method simulating the power grid evolution. With the transformer utilization efficiency increasing, the power outage risks exponential increase, and with the transformer capacity-load ratios increasing, the power outage risks exponential decrease, those are reasonable as the common. As exponential equation, the independently variable *x, z* change a little, the dependent variable *y* will change greatly. Therefore, we consider controlling the power outage risks within certain limits, the independently variable *x, z* should limited in the value which avoid the power outage risks increasing greatly. Form the Fig.3, the power outage risks increasing sharply when the transformer utilization efficiency is greater than 35%. From Fig.4, the power outage risks increasing sharply when the transformer capacity-load ratios is less than 1.6, and the power outage risks increasing slowly when the transformer capacity-load ratios is more than 2.2, in other words, putting more cost to develop the power grid and increase transformer capacity-load ratios would do not assist to reduce the power outage risks and improve security of grid. Under that conditions, we can figure out that the reasonable transformer utilization efficiency is about 35% for the power grid, the reasonable transformer capacity-load ratios is range from 1.6 to 2.2.

Conclusions

Novel evaluation method which contained fast dynamic and slow dynamic was used to simulate the development process of the power grid. The power grid of Kaifeng city in Henan Province of China was used as an example to study the relationship among the security, efficiency and grid scale of electrical power grid., the calculation results were regressed as equation as exponential. And the reasonable transformer utilization efficiency is about 35% for the power grid, the reasonable transformer capacity-load ratios is range from 1.6 to 2.2 were concluded from the exponential function. The relationship among the security, efficiency and adequacy of electrical power grid are expression in quantitative equation to a certain extent.

Keywords: Power system ; Safe and stable operation ; Smart grid ; Intelligent scheduling

Abstract. The Internet and the gradual implementation of the continuous power grid market in recent years make the power system more complex under different operating environment. Safe and stable operation of power grids have become increasingly important . With the rapidf development of the grid and constant innovation, safe and stable operation also has a new requirement , because the rapid development of the power system brings more This paper analyzes the causes of blackouts and reviews security of the power system stability problems related to measures on the security and stability of the power system operation .

Introduction

In recent years, a wide range of power outages have occurred several times in the international community , causing huge losses to the economy of these countries , and seriously affect the social life. It is highly concerned by both governments and society . These incidents can be attributed to the damage events of the stability in the form of a variety of power system accidents , which are major disasters of the power system . Due to the complexity of the grid , once stable damage accidents occur , they tend to be in fast developments and the situation is more complex in the development process. There may be some automatic device failure, at which point the power grid control center is in a very nervous state among dispatchers ,it takes some time to ascertain the correct response to the accident. Therefore, it is difficult to find enough time to do the timely and correct treatment ,which is likely to disturb the control of the system , and to further expand the system collapse with serious consequences.

Blackout Analysis

By analyzing the major international incidents of the grid[1-7] , it can be concluded that the deep-seated causes of Blackouts are as follows :

Lack of overall planning of grid construction. Power grid structure is irrational , such as 345kV and 138kV lines high and low voltage lines operating in ring networks , lack of disconnecting methods between the low voltage side and high voltage side of the line of measures, untimely important information exchange between the regional power grid. Due to the hierarchy of dispatching system,the regional dispatcher can not the whole picture of the large system. Lack of unified management and coordination between the various power companies scheduling is another potential threat.

Problems in China's Power Grid

China's power grid is in a stage of rapid development. Although a lot of spectacular results has yielded , there still exists developing deficiencies. The foreign operating experiences provide good,

we have summarized the problems encountered in the development of the grid based on the current research results [8-10].

The characteristics of large interconnected power system and effectiveness of security and stability measures remain to be deeply studied ;

Unified planning and coordination of the power system during the power system (in particular, plants and networks) ;

The relationship between the grid margin and investment ; capacity issues under the electricity market ;

What is the condition of separating interconnected grid ;

The ratio of receiving power from the outside power grid and voltage support problems in the end of systems ;

Large power grids and emergency warning judgment method; Monitoring security and stability , evaluation and in-depth study of control theory ;Comprehensive assessment techniques

Power system of multiple data sources and cross- network real-time access to information issues ;

Configuration of protection relay devices and coordination of set value and level difference .

Measures to Ensure Safe and Stable Operation of the Power Grid

Three defense of security

"Guide on Security and Stability" (Chinese Standard for Power System, DL 755-2001)provides general rules of the security and stability of the power system to withstand disturbances ,where capacity is divided into the following three levels:

First-class standards : maintain stable operation and normal power grid ;

Second-class standards : maintain stable operation , but allow part load losses ;

Third-level standard : When the system can not maintain a stable operation , it is necessary to prevent system collapse and minimize loss of load .

To facilitate the analysis , we divided the state power system operation into normal, alert, emergency, extreme urgency (loss of synchronism) state and restoring state. Corresponding to the appropriate state, we set up three lines of defense to ensure that the power system in the face of various security incidents can stay stable operation :

The first line of defense : the rapid removal of faulty components with protection devices ,which is the most direct and effective way to ensure the power system transient stability ;

The second line of defense : The stability control system , cutting machine and generator , load shedding and other measures to ensure the stability of the power system in the event of large disturbances ;

The third line of defense : When the power system stability rans across multiple serious destroyed failures, relying step splitting device step- column grid solution by emergency frequency and voltage control device to maintain a balance of two parts after splitting power grid to prevent the accident and prevent blackouts .

Smart Grid

Strong smart grid is based on UHV power grid as the backbone[11-13] ,which calls for strong and coordinated development of grid power at all levels as the basis for communication and information platform for the support.It is with information technology, automation, interactive features , including power system generation, transmission, substation, distribution , consumption and scheduling of the six areas. The goal is to achieve a high degree of integration of integration covering all voltage levels , "power flow, information flow, business flow" , with a strong and reliable , cost-efficient , environmentally clean , transparent, open and friendly interactive connotation of modern grid.

Strong and smart are two basic development requirements of modern power grid. Strong are based on smart is the key. Strong emphasis is laid on highly integrated intelligent grid based on holistic, systematic approach to objectively describe the basic features of modern power grid development.

In terms of the optimal power source structure, strengthen coordination of plants and networks, smart grid is able to improve the safe operation of different power level and strengthen power system safety. Implementation of energy generation scheduling , the smart grid technology can be used to promote energy conservation . China now relies on the national wind power , solar power research and development (experimental) center to accelerate clean energy technology research and network operation and control , and to promote large-scale scientific and rational utilization of clean energy[14-16]. On the basis of national scenery storage demonstration projects, the modern clean energy technologies provide technical support and engineering potential of large-scale utilization of clean energy and flexible network operation . In order to promote the popularization and application of high-capacity storage technology it is important to adapt current guidelines to meet the needs of the rapid development of clean energy .

In terms of transmission on the basis of UHV power grid as the backbone[16] ,the development aims at the coordinated development of power at all levels of the strong grid with integrated application of new technologies, new materials , new processes to achieve the investigation digital, modular design, operation status , information standardization and application network. Full implementation of the transmission line, state-based maintenance and entire-life-cycle management.

Promoting the transformation of end-user energy use patterns is to improve energy efficiency by 2020 and strive to achieve final energy consumption in electricity accounted for more than 26.2% of the target[16] .

Intelligent scheduling

Today, large power grid to grid scheduling brings new challenges[17][18] , safe and stable operation of large power grids requires intelligent scheduling to provide technical support. National energy policy needs to access large-scale renewable energy and optimal allocation of resources , which is scheduled to run and control the grid presents new challenges. Constructed with Chinese characteristics strong smart grid . Smart Scheduling is an important part of the brain center of the smart grid . Comparing to non-adaptive scheduling , we need to build intelligent scheduling.

The overall technical route is to adhere to independent innovation , development and standardization and to carry out intensive management , research and development of intelligent scheduling technology support system as the core, around three main building and four categories applications[16] . The implementation of schedule management is through the integration of homogenization scheduling jobs . Around three main means ,sharing platform supporting is the integration of distributed , multi-dimensional coordinate security and defense and fine -optimized scheduling. Construction of four major categories of applications is the real-time monitoring and early warning applications with security check application , the application program scheduling and dispatch management applications.

Summary

Continuing to strengthen the construction of three lines of defense supporting while improving the stability control devices and a variety of automatic safety device is key to preventing a chain reaction of accidents and preventing serious damages to the master device and to avoid blackouts and ensure the rapid development of the national security, social stability and national economy.

Keywords: galloping region, transmission line, frequency method, coefficient method, meteorological-geographical method.

Abstract. Transmission line galloping is self-excited vibration of iced conductor with low frequency and large amplitude, the countries almost all over the world have occurred transmission line galloping, which caused a great economic loss. Drawing the effective distribution map for galloping plays an important role in guiding the anti-galloping design, the key of this work is to establish a scientific method for galloping region division. In this paper, several methods for galloping region division were introduced: frequency method, coefficient method and meteorological-geographical method. This paper also compared the applicability of various methods and their advantages and disadvantages. It shows that the meteorological-geographical method is the best choice for us to divide galloping region at the present time. However, in the practical application, we should take all the applicability of the three methods into consideration to get a reasonable division for galloping region.

Introduction

Galloping region division is a complex work, which is based on the statistical data of galloping, the meteorology factor that affect galloping and the topographical data where the galloping occur [1-3]. After detailed analysis of the whole data above, determine a set of principle to describe the galloping strength, and then divide the galloping region according to this principle. At present, there are mainly three methods using to divide galloping region in China, which are: frequency method, coefficient method and the meteorological-geographical method.

To divide galloping region of transmission line, we must first clarify what is *galloping region*. Obviously, the so-called *galloping region* refers to the galloping prone areas of transmission lines, these areas are usually glaze prone areas. Lines are easily iced in winter when it is glaze and strong wind, if the angle between line direction and wind direction is larger (generally greater than 45 degrees), a self-excited vibration with low frequency and large amplitude will occur, that is conductor galloping. The probability and strength of galloping may vary greatly due to the weather and terrain conditions are different, especially there are micro-topography and micro-meteorological region at the same area, thus it is necessary to divide the galloping region rationally according to its strength level. The standard of classification for galloping region is not unified in the world at present. According to China's specific situation, it is divided into four grades, namely: strong galloping region (level 3), medium galloping region (level 2), weak galloping region (Level 1) and non-galloping region (level 0).

Frequency Method

On the basis of statistical analysis in some areas, galloping region was divided into different grades according to the strength and frequency galloping occurred, this can be referred to as: frequency method [4-5]. "Frequency" here means the average number of galloping occurred in a certain length of time. This method is influenced by the size and the number of lines, it is more appropriate to the areas which have a large number of lines in use. However, for the other areas which have no lines yet, it is not applicable or too rough. In addition, it is easy to underestimate the possibility of galloping with

frequency method because galloping not frequently occurs. The principles of classification are as follows.

*Strong(Level 3)*The area which galloping has occurred 5 times and above in recent 10 years; and galloping might occur much easily according to the comprehensive meteorological and geographical factors, such as the open areas which have a higher frequency of freezing weather.

*Medium(Level 2)*The area which galloping has occurred 3 to 4 times in recent 10 years; and galloping might occur easily according to the comprehensive meteorological and geographical factors, such as the open areas which have high frequency of freezing weather.

*Weak(Level 1)*The area which galloping has occurred 1 to 2 times in recent 10 years; and galloping is not easy to occur according to the comprehensive meteorological and geographical factors.

None (Level 0) The area where galloping has never occurred in recent 10 years; and galloping will never occur according to the comprehensive meteorological and geographical factors.

After the classification of galloping region, we can draw a distribution map of galloping region for a certain area. Fig. 1shows a distribution map of galloping region for Liaoning province in China.

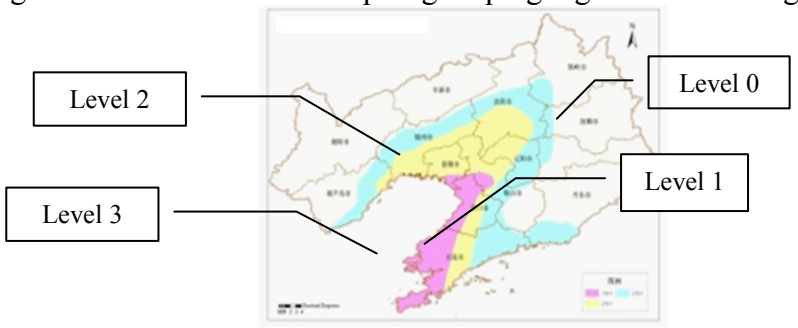

Fig.1 Galloping distribution map of Liaoning province

Coefficient Method

Based on the analysis of meteorological, geographical data when galloping occurs, use a certain coefficient to express galloping strength of different regions in a same area, this method was called coefficient method [6]. This method is relatively complicated, for it needs to estimate the galloping coefficients. The advantage of this method is that the galloping strength can be reflected more directly, and also has an instruction function to the areas which have no lines yet.

According to the analysis of the statistical data, the two parameters, thickness of ice and velocity of wind in galloping region, can be expressed by normal distribution function. The function expressions of these two parameters are shown in Eq. 1 and Eq. 2.

Ice thickness $X \sim N(\mu_X, \sigma_X^2) = N(14, 4^2)$, mm . (1)

Wind speed $Y \sim N(\mu_Y, \sigma_Y^2) = N(15, 3^2)$, m/s . (2)

The effect of topography for galloping can be represented as coefficient ξ, which ranges from 0~1, for the flat open areas, ξ values for 0.7~1, for the small part of flat areas in the mountain, ξ values 0.3~0.7, for hilly or mountain areas, ξ values below 0.3. These values are changeable; ξ can be revalued according to the actual situation in applications.

Transmission line galloping affected by ice thickness, wind speed and terrain together, and these three factors are independent of each other, then the probability of occurrence for galloping can be defined as Eq. 3.

$$P(\xi XY) = \frac{\xi}{24\pi} \iint e^{-\left(\frac{(X-14)^2}{32} + \frac{(Y-15)^2}{18}\right)} dXdY \quad (3)$$

Ice thickness of generic structure in an area was represented with x, and wind speed in winter was represented with y, according to many years'(generally not less than 20 years) statistics, these two parameters can be regarded as normal distribution, the expressions are: $x \sim N(\mu_x, \sigma_x^2)$, $y \sim N(\mu_y, \sigma_y^2)$.

According to the 3σ rule of normal distribution function, we can draw the following four intervals (Eq. 4 to Eq. 7).

3σ interval of ice thickness in galloping region,

$$X \in [\mu_X - 3\sigma_X, \mu_X + 3\sigma_X] = [2,26], \text{mm} . \quad (4)$$

3σ interval of wind speed in galloping region

$$Y \in [\mu_Y - 3\sigma_Y, \mu_Y + 3\sigma_Y] = [6,24], \text{m/s} . \quad (5)$$

3σ interval of annum ice thickness in a certain area

$$x \in [\mu_x - 3\sigma_x, \mu_x + 3\sigma_x], \text{mm} . \quad (6)$$

3σ interval of annum wind speed in a certain area

$$y \in [\mu_y - 3\sigma_y, \mu_y + 3\sigma_y], \text{m/s} . \quad (7)$$

Through the analysis of the statistical data, we can see that the annum ice thickness and wind speed intervals calculated according to the 3σ rule are often greater than the actual data intervals, therefore, the actual data (include ice thickness and wind speed) intervals should be considered in the application, the $[x_1, x_2]$ and $[y_1, y_2]$ are defined as the actual ice thickness interval and the actual wind speed interval respectively.

Intersect three intervals of ice thickness (3σ interval of ice thickness in galloping region, 3σ interval of annum ice thickness in a certain area and the actual interval of ice thickness), and then we can get a final interval of ice thickness which will be used in calculating the galloping coefficient. In the same way, a final interval of wind speed will also be obtained. They are shown in Eq. 8 and Eq. 9.

$$[2,26] \cap [\mu_x - 3\sigma_x, \mu_x + 3\sigma_x] \cap [x_1, x_2] = [\underline{X}, \overline{X}] . \quad (8)$$

$$[6,24] \cap [\mu_y - 3\sigma_y, \mu_y + 3\sigma_y] \cap [y_1, y_2] = [\underline{Y}, \overline{Y}] . \quad (9)$$

Then we can calculate the galloping coefficient η, which was shown in Eq. 10.

$$\eta = \frac{\xi}{24\pi} \int_{\underline{X}}^{\overline{X}} \int_{\underline{Y}}^{\overline{Y}} e^{-\left(\frac{(X-14)^2}{32} + \frac{(Y-15)^2}{18}\right)} dXdY . \quad (10)$$

According to the analysis above, galloping region can be classified as Table 1shows:

Table 1 Relationship between galloping strength and the coefficient

Strength of Galloping	Principles of classification
Strong (Level 3)	$\eta \geq 0.6$
Medium (Level 2)	$0.2 \leq \eta < 0.6$
Weak (Level 1)	$0.1 \leq \eta < 0.2$
None (Level 0)	$0 < \eta < 0.1$

Meteorological-geographical Method

It is easy to know that the meteorological-geographical method is to divide galloping region by analyzing meteorology and geography data. The first step is to get galloping meteorological days in 10 years through analyzing the historical meteorology data, second is to obtain galloping revising days in 10 years after studying on topographic feature, and then verify the result by experiences gathered from operating lines.

Concept involved in meteorological and geographical method.

Galloping days The day when transmission line galloping occur.

Daily minimum temperature The lowest temperature observed in 24 hours (Beijing time 08 am to 08 am of the next day)

Daily average relative humidity The average value of relative humidity observed in 24 hours (Beijing time 08 am to 08 am of the next day).

Daily maximum wind speed and corresponding direction The maximum wind speed and corresponding direction observed in 24 hours (Beijing time 08 am to 08 am of the next day).

Topographic prominence The difference between the highest and lowest altitude in a specific region.

Galloping meteorological days in 10 years Converting in 10 years period, the days that match the meteorological conditions for galloping.

Galloping revising days in 10 years Revised Galloping meteorological days in 10 years by terrain data.

Division of galloping region. To divide the galloping region by meteorological-geographical method, we must first determine which meteorology factors are intimately associated with galloping. After analysis and screening, four kinds of meteorology factors, the dominant wind direction, the maximum wind speed in the dominant wind direction, average relative humidity and daily minimum temperature, were selected as parameters for the model to decide galloping or not. Table 2 shows the threshold of the four meteorology parameters. If the weather satisfies the sum of these four threshold intervals in some day, transmission line galloping will probably occur, and this day will be regarded as a galloping meteorological day.

Table 2 Meteorological parameter threshold interval *

Parameters	Threshold interval
Dominate wind direction	north
Daily maximum wind speed in dominate wind direction (m/s)	4～15
Average relative humidity (%)	70～100
Daily minimum temperature(℃)	-5～3

*Note: The threshold interval above is just an example, the valuesare different in various areas, and they are determined by actual situation in a certain place.

The determination of meteorological days in 10 years. Collect the meteorological data in recent 10 years or more, calculate the number of days satisfying the four parameter thresholds in Table 2 at the same time, and convert them into meteorological days in 10 years (the sum of days *10/ total number of years). Using this method to do the calculation work for each meteorological station, and then get all the meteorological days in 10 years in a certain region by interpolation.

The revision work by topographic prominence. Take the digital elevation model (DEM) as background and 2000m as radius to calculate the topographic prominence, and then draw its distribution map. When the topographic prominence is larger than 100m, fit the meteorological days in 10 years and the topographic prominence, according to the function relationship between them, the meteorological days in 10 years will be revised. If the topographic prominence is less than 100m, it is not necessary to revise the meteorological days in 10 years.

The division of galloping region. Table 3shows the division result for galloping region using meteorological and geographical method.

Table 3 The division results for galloping region using meteorological and geographical method.

Strength of Galloping	Galloping revising days in 10 years
Strong (Level 3)	≥140
Medium (Level 2)	[90,140）
Weak (Level 1)	[50,90）
None (Level 0)	[0,50）

Summary

(1) The advantages of frequency method is simple and objective, it is applicable for the area which has detailed galloping observation data. For the areas which have no lines or lack of galloping observation data, frequency method is not applicable, because it will underestimate the possibility of the occurrence of galloping.

(2)The coefficient method is realized by probability and statistics, and it cannot be influenced by the transmission lines. Thus it is applicable for the areas which are lack of galloping observation data. However, it is difficult to obtain meteorological parameters which this method requires, and it is too theoretical to be popularization and application.

(3) Meteorological and geographical method is extended from coefficient method. The advantage is that this method is not affected by the transmission lines. And the meteorological and geographical data it requires is easy to obtain. So this method is applicable to all areas that no matter lines has been built or not. This method has been widely used in power system of China.
These three methods of galloping regional division have their own advantages and disadvantages respectively. In practical application, we should take all the applicability of the three methods into consideration to get a reasonable division for galloping.

Key words: electric power data center; SDN; OpenFlow; a multi-domain collaboration model

Abstract: In order to meet the developing demand of the new generation of data center, and to better satisfy the need of the smart grid, we introduce the OpenFlow-based SDN technology to electric power data center. Because there are many switches in electric power data center, it requires the use of a distributed multi-controller to manage, however there is currently no mechanism for these controllers to cooperate with the each other. Based on these questions this paper presents a collaborative model for multi-domains OpenFlow networks, which allows different network domains to collaborate with each other in an efficient way.

Introduction

Currently, electric power data center added more than 5000 thousand data records everyday. Especially with the access of renewable energy and distributed power, the amount of data in electric power data center will surge. This will propose higher demands for storage and process of massive smart grid information. However, the traditional data center network with scattered resources, limited bandwidth, low routing efficiency and other shortcomings; it is difficult to meet the power company's highly scalable, high robustness, flexible topology and other needs.

Due to the proposed of software defined network (SDN) technology and successfully applied in Google data center, a new solution has been provided to solve the bottleneck problem of electric power data center. SDN using OpenFlow protocol constitutes a control/forwarding separated networks to meet the intensive server requires centralized management in data center. This paper will research on applying OpenFlow-based SDN technology to electric power data center, to achieve efficient addressing, load balancing and other functions in data center.

OpenFlow-based SDN technology

In traditional internet, control and data forwarding are tightly coupled on network equipments, which result the management of control plane in network complicated and make the new technologies deploying on existing networks difficult. The core idea of SDN is decoupling traditional network architecture into the application layer, control layer, forwarding layer separated architecture and adopt standardization to achieve centralized management of network and make the network applications programmable [1].OpenFlow realizes the idea of SDN and represents the realization of a prototype and deploy instances of SDN technology. OpenFlow network consists of OpenFlow switches, FlowVisor and controller.

OpenFlow switch. OpenFlow switch is the core of the OpenFlow network, which mainly responsible for the data forwarding, representing the data forwarding plan. The structure is shown in Fig. 1. Each flow table in the OpenFlow switch contains a set of flow entries; each flow entry performs packet look-ups and forwarding. Data packets enter the switch to obtain the corresponding operation by querying the flow table. A secure channel is an interface between OpenFlow switch and controller .Controllers will configure and manage OpenFlow switches according to OpenFlow protocol through the interface.

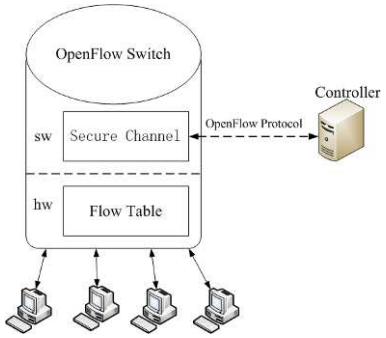

Fig.1 Structure of OpenFlow switch

FlowVisor. FlowVisor between controller and OpenFlow switch is used to realize the virtual layer of OpenFlow network. FlowVisor allows multiple controllers in an OpenFlow network but its mechanism is to slice the network into separate slices and let each slice managed by a controller.

Controller. Controller implements its functions through global topology view, and its control logic represents control plan. Controller controls the flow table in OpenFlow switches through OpenFlow protocol, in order to enable centralized control of the entire network.

In OpenFlow-based SDN, the underlying network devices are abstracted from the upper layer control and applications. So it may provide high performance, flexible management and granular traffic control for multiple vendors' network devices.

Analysis of characteristics and problems in electric power data center

Characteristics and problems in current electric power data center are as follows:

(1)Large data flow and many network devices. Data center is the core part of the smart grid. It achieves the distribution of data in production, scale, finance and other critical business. While the number of network devices is large and the management of the devices is difficult. Superposition of multiple application requirements led power information network requires higher performance.

(2)Network protocol to be improved. A typical electric power data center network topology is divided into core layer, import layer and access layer. All equipments are redundant cross-connect resulting multi-level network and complicated link [2].In data center, extensive of Transmission Control Protocol (TCP) is used. While the original TCP protocol is for the Internet, does not consider the low latency and high bandwidth characteristics in data center network.

(3)Due to strong smart grid construction needs, some information systems have been developed in order to guarantee the stable operation of the smart grid. These information systems need a strong network that almost uninterrupted. However, the current network still relies on Spanning Tree Protocol (STP) to protect link redundancy on layer 2 and Virtual Router Redundancy Protocol (VRRP) to protect equipment redundancy on layer 3. The fastest switching time is seconds or more, the network can't support the needs of the sensitivity of the information network of the smart grid.

Applying SDN technology to electric power data center

With the development of the cloud computing and SDN technology, applying OpenFlow-based SDN technology to data center has become a hot topic. Paper [3] first proposed applying OpenFlow technology into the data center. Paper [4] evaluated the usability of OpenFlow in different data center environments, such as $PRV2_1$, $PRV2_2$and EDU1. Based on the above researches, this paper proposes applying OpenFlow-based SDN technology to electric power data center.

The early design of OpenFlow implemented network management and control functions only through a single controller. Obviously, a single controller can't meet the need of large-scale electric power data center. This requires the use of multi-controller solutions. Paper [5] presented a distributed event-based control plane for OpenFlow, which allows network operators deploy any number of controllers in their networks. Paper [6] proposed two heuristic algorithms for the area

partitioning problem in a multi-controller controls. But there is no mechanism for cooperation between the controllers. When the controller received a cross-domain packet request but it didn't know the best transmission path, the controller used the flooding mechanism to route the data packets. This causes the controller can't deal with cross-domain data packets effectively. This paper proposes a collaborative model to build a multi-domain OpenFlow network, allowing for mutual cooperation through effective manner between different network domains.

Construction of the collaborative model for multi-domains OpenFlow networks

Each switch is connected to a nearest controller and directly controlled by the controller, so that each switch and the connected controller together compose a small OpenFlow network domain. Outside the network domains, a separate global controller is set and a communication channel between the controllers and the global controller is established, using a simple protocol to handle the exchange of specific information between the parties. The model is shown in Figure 2. Global controller maintains global topology view and has the global routing app, controlling the entire network on the basis of the overall. Main components of the model are shown in Fig.3.

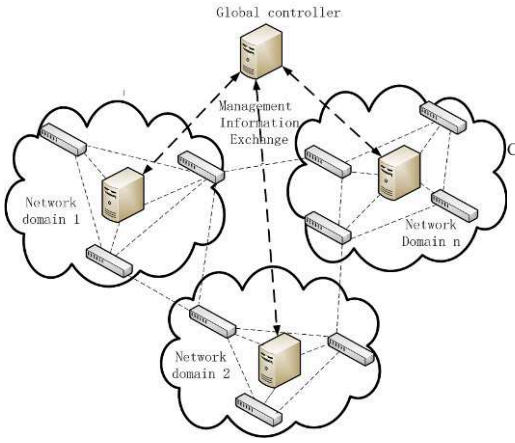

Fig.2 The collaborative model

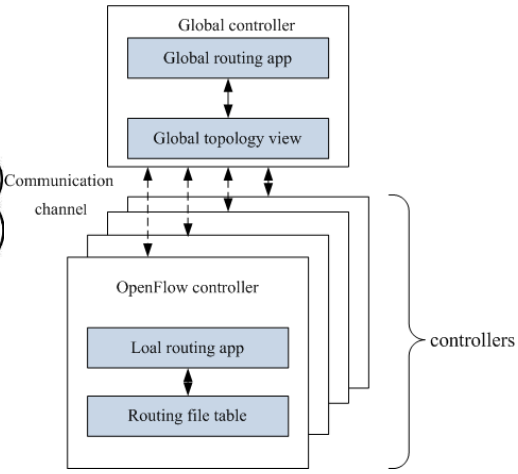

Fig. 3 Main components of the model.

Global topology view. Global topology view holds all the cross-domain routing network information and the estimated routing cost of the routing path between cross-domain switches in a network domain.

(1) Cross-domain connection table

A cross-domain connection is a link between two OpenFlow switches belonging to two different network domains. The fields contained in cross-domain connection table are shown in Table 1.As the role of source switch and destination switch in a cross-domain are equal, each cross-domain connection will be presented by only one entry in the table.

Table 1 Cross-domain connection table

Source Controller ID	Source Switch ID	Source port	Destination port	Destination Switch ID	Destination Controller ID

(2) Estimated routing cost table

In a network domain can be seen as two different types of switches: cross-domain OpenFlow switches which have a cross-domain connection; normal OpenFlow switches which have connection only in a domain. An estimated routing cost refers to the shortest routing path between cross-domain switches in a network domain. The shortest routing cost is calculated by the controller of that domain. The fields are shown in Table 2.

Table 2 Estimated routing cost table

Controller ID	Source Switch ID	Destination Switch ID	Estimated Routing Cost

All cross-domain switches and computed routing costs between these switches form each network domain together constitute the global topology view. The global topology view looks like a "weighted graph" as shown in Fig.4.In the "weighted graph", cross-domain switches are nodes(some normal switches in each network domain are not shown);connections between cross-domain switches are edges and the estimated costs between cross-domain switches are weights .

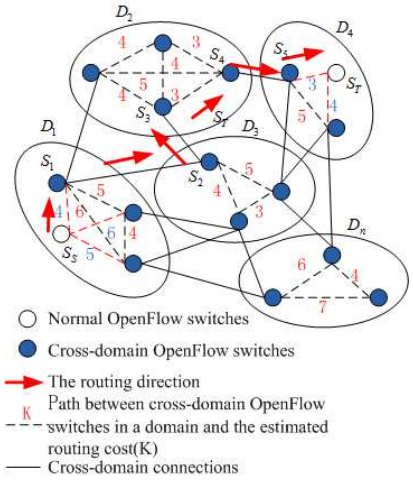

Fig.4 An image of the Global Topology View seen from Global controller

Routing file table. Each controller in the collaborative model has a learning routing file table. Each table entry is calculated on a global level. The fields are shown in Table 3. With the information, he controller can forward cross-domain data packets effectively rather than simply flood, greatly improving the efficiency.

Table 3 Routing file table

Local source switch ID	Terminal destination address	Terminal destination switch ID	Terminal destination controller ID	Local destination switch ID	Local destination output port	Estimated routing cost

Local destination switch ID, output port: In local domain, the ID of switch which the controller needs to route the packet to and the outgoing port number of the switch.

Estimated routing cost: The total estimated routing cost from the local source switch to packet's destination address.

Local routing app and global routing app. Local routing app placed in the controller side is responsible for discovering cross-domain connections in its domain and calculating the estimated routing cost between them. The information will transmit to the gable controller through the communication channel. It is also responsible for adding or deleting entries in the routing file, finding matches in the routing file to forward cross-domain packets. Global routing app placed in the global controller is responsible for building global topology view according to the collected topology information form each controller and using the shortest path algorithm to calculate cross-domain packets routing path.

Works of collaborative model for multi-domains OpenFlow networks

When the controller receives a packet request from one of OpenFlow switches it manages, extracts the destination address in packet header first. If the destination address of the packet within the network domain of the controller, the controller will process it according to OpenFlow1.3 specification [7].If there is no destination address information in the controller (that means destination address of the packet is outside the current controller domain), the controller sends the packet to the local routing app. The application will lookup in the routing file table. If a match is found, the application forwards the packet according to the instructions of the information. If no match is found, local routing app sends a routing instructions request to the global controller.

First, the controller calculates the routing cost between source OpenFlow switch (switch Ss shown in Fig. 4) and all cross-domain OpenFlow switches in the domain. Then the controller sent that information along with the destination address of the packet to the global controller. In global controller, the global routing app sends a route request of destination address to all domains addition to the domain which sending the request. Global controller will know the destination address (switch S_T shown in Fig. 4) according to the controller response and calculate the shortest path using the shortest path algorithm (as the path shown in Fig.4: Ss-S_1-S_2-S_3-S_4-S_5-S_T). Global controller sends routing instructions to the associated controller, these instructions helps to transmit cross-domain data packets effectively.

Conclusions

By analyzing the characteristics and problems the paper proposes applying OpenFlow-based SDN technology to electric power data center. A collaborative model in multi-domains OpenFlow networks is build. The model allows multiple controllers located in different network domains associate with each other so that it can deal with cross-domain data packets effectively. By analyzing the global topology view and adopt effective path computation methods to improve the performance of information exchange between multi-domain networks to provide a new solution for OpenFlow network scalability.

The next work we should do is test the efficiency, performance and scalability of this model. Then we should apply the model to electric power data center; improve the program in the practical application.

Keywords: Smart Grid, SCADA Systems, Cyber Security, Optimal Power Flow, Power Flow Tracing, Risk Assessment

Abstract. This paper aims to identify and clarify the cyber security risks and their interaction with the power system in Smart Grid. The SCADA system and other communication networks interact with the power system on a real time basis, so it is important to understand the interaction between two layers to protect the power system from potential cyber threats. In this study, the optimal power flow (OPF) and Power Flow Tracing are used to assess the interaction between the SCADA network and the power system. Through OPF and Power Flow Tracing based analysis, the physical and economic impacts from potential cyber threats are assessed, and thereby the quantitative risks are measured in a monetary unit.

Introduction

Presently power industry is facing diverse environmental changes internally and externally. The smart grid, one of them, is a core assignment promoted as a leading project of low-carbon green growth and a new power system for applying to environmental changes of power industry and enhancing the efficiency of energy use. But, power system needs real-time characteristics strongly and high-level availability (low failure frequency and fast restoration). These become factors making cyber threats of the power system more complicated and fatal than the IT system.

Therefore, this paper has the purposes in clearly defining more and more increasing problems in the security aspect of the smart grid and specifying connectivity with the power system. That is, through specific modeling on the information control system like SCADA and interaction with the power system, a methodology evaluating dangers was proposed, and specialized security measures that the smart grid could be operated stably were established.

Quantitative Methodology for Cyber Risk Assessment of SCADA in the Smart grid

In this section, problems of superficially stayed cyber risks of the smart grid are specified being connected with the physical power system, and the quantification methodology that those problems can be calculated in quantitative numerical values was suggested. Generally, cyber dangers in IT parts are defined as possible risks in occurrence actually from the mixture of vulnerability, threat, and assets.

Like Fig. 1, Vulnerability can be recognized as a parameter defining the relation between threats and assets. Threats mean cyber attacks and can be recognized as an independent variable. Lastly, assets mean a damage scale in case of the outbreak of threats from vulnerability. Namely, assets can be seen as a dependent variable.

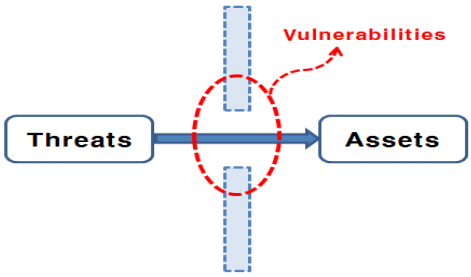

Fig. 1 Concept of Vulnerabilities

From this viewpoint, risks are defined as the possibility of real occurrence from being mixed with threats, vulnerability, and assets. That is, it can be expressed as Eq. l about R (risks) if we define T for threat, V for vulnerability and A for asset. The Eq. 1 means really credible damage scales in the power system.

$$R = T \times V \times A \tag{1}$$

Based on the above Eq. 1, by defining each element in detail, a system to quantify risks can be established. Among them, threats (T) and vulnerability (V) were defined as elements of an information layer and quantified on the basis of advanced study data [1]. In case of assets (A), it was quantified in an aspect of the power system.

Finally, to connect cyber risks with a reliability viewpoint of the power system organically, this paper proposed an evaluation method of synthetic reliability by quantitatively analyzing physical and economical effects which have on the power system based on Optimal Power Flow (OPF) and Power Flow Tracing as core technologies in operation of the power system.

2.1 Quantitative Modeling of the Information layer

In this paragraph, threats and vulnerability as elements of the information layer were quantified. In case of accidents and damage cases due to cyber attacks, because the information does not be opened well and each system has diverse cases and contexts, the quantification is not easy.

Hence, the quantification methodology referred to advanced studies [2,3]. The analysis result of the advanced studies defined attacks mostly through attack graphs in order to quantify cyber threats and vulnerability in the smart grid and tried to measure riskiness by applying generable probability by type of the pertinent attack.

For the quantification methodology of the information layer, some of the courses of AHP (Analytic Hierarchy Process) as one of quantitative methods considering multi-attributes which are often used in social science based on data of advanced studies were introduced in this study.

2.1.1 Quantification of Vulnerability (V)

According to the definition of SANA about the security vulnerability, vulnerability is like a passage to make external threats flow into systems [4]. In other words, vulnerability can be defined as security holes and plays a role of a parameter defining the relation of threats and assets.

This study selected 15 kinds of cyber threats and quantified the vulnerability in accordance with causal relationship between components of the power system and each individual cyber threat. Since the components of the power system are normally run through the control of the SCADA system, they were defined as components (EMS server, SCADA server, communication network, and RTU) of the SCADA system. In the info control system which was previously defined, based on the causal relationship between cyber threats and the components of the SCADA system, the vulnerability was arranged like Table 1.

Table 1 Vulnerablilty analysis of SCADA System

Types of threats \ Components		EMS server	SCADA server	Communication Network		RTU
				TCP/IP	Serial	
Confidentiality	Eavesdropping	V	V	V	V	V
	Traffic Analysis	0	0	V	V	0
	EM/RF Interception	0	0	0	0	V
	Indiscretions by Personnel	V	V	0	0	0
	Media Scavenging	V	V	0	0	0
mixed (Confidentiality +Integrity)	Trojan Horse	V	V	0	0	V
	Trapdoor(Backdoor)	V	V	0	0	V
	Service Spoofing	V	V	0	0	V
Integrity	Masquerade	0	0	0	0	V
	Bypassing Controls	0	0	0	0	V
	Authorization Violations	V	V	0	0	V
	Physical Intrusion	V	V	V	V	V
	Replay	0	0	0	0	V
	Theft &Illegitimate Use	0	0	0	0	V
Availability	Denial of Service	V	V	V	0	0

The shaded part (V) in Table 1 means that substantial risks occur by the relevant vulnerability. Probability of real occurrence and estimated numerable values by statistics are applied to it. Reversely, the non-shaded part (0) means rarity in the possibility of cyber threats. That is to say, because vulnerability can be said to be a probability concept that threats are realized against assets, it comes to have the value of $0 \leq$ vulnerability (V) ≤ 1. In here, 1 means that threats are passed and linked to assets according to Fig. 1. Since vulnerability cannot be defined absolutely, three predictions were made.

First, in case of the absence of the past data, probability of threats is 50%.

Second, because security strength is different according to the components of the SCADA system, after the order by each element is decided, 50% vulnerability is applied. Namely, it can be thought that as servers become stronger and the components are lower, the security strength is lower. Hence, vulnerability was defined as the level of server groups (EMS and SCADA) < TCP/IP section < Serial section < RTU.

Third, there is no differentiation by threat.

Based on already analyzed vulnerability, if an assumption is applied, quantitative numerical values can be calculated like the Table 2.

Table 2 Normalization of Vulnerability

	EMS sever	SCADA sever	TCP/IP	Serial	RTU
Vulnerability	0.057	0.057	0.051	0.057	0.278

2.1.2 Quantification of the Threat (T)

For quantitative numerical values against threats, based on the already analyzed vulnerability, about horizontal axis (by component of the SCADA) and vertical axis (cyber threats), according to latent damage capacity depending on each axis, relative ranking was given. About each axis that the order was given, normalization work was conducted. In here, the meaning of normalization means that if each individual threat exists and the size of threats is assumed to be 1, threat levels are given differentially to each element of the SCADA system.

Above all, as the components of the SCADA system of the horizontal axis, for server groups (EMS and SCADA), TCP/IP communication, Serial communication, and RTU, relative order like 4, 3, 2, and 1 was given according to the latent damage capacity.

The calculation standard of ranking is like the next. In case that server groups are breached by threats, since the latent damages are big, 4 is given. In case of RTU, because it is the lowest thing, the lowest 1 is given relatively. Also, based on the vulnerability analysis table (Table 1), in case that there is no relevance in the components of the SCADA system, 0 is given. Lastly, on the basis of the horizontal axis, assuming that the size of the pertinent threat is 1, normalization is applied. Table 3 is the result of normalization in accordance with potential damages by component of the SCADA.

Table 3 Normalization after Weights according to The Potential Damage Scale on The Horizontal axis

Components / Types of threats	EMS server	SCADA server	Communication Network		RTU	Normalization
			TCP/IP	Serial		
Eavesdropping	0.29	0.29	0.21	0.14	0.07	1
Traffic Analysis	0.00	0.00	0.67	0.33	0.00	1
EM/RF Interception	0.00	0.00	0.00	0.00	1.00	1
Indiscretions by Personnel	0.50	0.50	0.00	0.00	0.00	1
Media Scavenging	0.50	0.50	0.00	0.00	0.00	1
Trojan Horse	0.40	0.40	0.00	0.00	0.20	1
Trapdoor(Backdoor)	0.40	0.40	0.00	0.00	0.20	1
Service Spoofing	0.40	0.40	0.00	0.00	0.20	1
Masquerade	0.00	0.00	0.00	0.00	1.00	1
Bypassing Controls	0.00	0.00	0.00	0.00	1.00	1
Authorization Violations	0.40	0.40	0.00	0.00	0.20	1
Physical Intrusion	0.29	0.29	0.21	0.14	0.07	1
Replay	0.00	0.00	0.00	0.00	1.00	1
Theft & Illegitimate Use	0.00	0.00	0.00	0.00	1.00	1
Denial of Service	0.40	0.40	0.20	0.00	0.00	1

In a similar way, about each kind of threats, relative order was given according to vulnerable degrees. First, about 15 kinds of threats, they were divided into 4 areas such as confidentiality), mixture (confidentiality + integrity), integrity, and availability. Each threat was classified into the pertinent area.

In the purpose of the classification, because kinds of cyber threats are endless, there is somewhat hardness on the normalization. So, in this paper, by applying the concept of CIA as three elements of info security, threats were classified. In addition, regardless of same threats, according to IT and control systems, degrees of threats are different. This is because the capacity of lots of threats has the character of being filtered or amplified in the course of passing over through vulnerability.

This paper applied the security threat level of a control system, not the security threat level in accordance with the IT system. Normally, the power system is operated based on the control system. Therefore, on the control system, since the order of availability > integrity > mixture > confidentiality

is important; the relative order of 4, 3, 2, and 1 was given to each area orderly. Also, on the basis of the vulnerability analysis table (Table 1), in case that they are not applicable to the components of the SCADA system, 0 was given. The size of each individual threat level is assumed to be 1, they were normalized. Here, 1 means the level of a risk that each threat has. Table 4 is a result that the risk degree by each kind of threats was normalized.

Table 4 Normalization after Weights according to The Risk Scale on The Vertical axis

Components / Types of threats	EMS server	SCADA server	Communication Network		RTU
			TCP/IP	Serial	
Eavesdropping	0.04	0.04	0.13	0.20	0.04
Traffic Analysis	0.00	0.00	0.00	0.00	0.00
EM/RF Interception	0.00	0.00	0.00	0.00	0.04
Indiscretions by Personnel	0.04	0.04	0.00	0.00	0.00
Media Scavenging	0.04	0.04	0.00	0.00	0.00
Trojan Horse	0.08	0.08	0.00	0.00	0.08
Trapdoor(Backdoor)	0.08	0.08	0.00	0.00	0.08
Service Spoofing	0.08	0.08	0.00	0.00	0.08
Masquerade	0.00	0.00	0.00	0.00	0.12
Bypassing Controls	0.00	0.00	0.00	0.00	0.12
Authorization Violations	0.12	0.12	0.25	0.40	0.12
Physical Intrusion	0.12	0.12	0.25	0.40	0.12
Replay	0.12	0.12	0.00	0.00	0.12
Theft & Illegitimate Use	0.12	0.12	0.00	0.00	0.12
Denial of Service	0.16	0.16	0.38	0.00	0.00
Normalization	1	1	1	1	1

According to each axis, from executing normalization depending on potential damages and the risk degree, Table 3 and Table 4 were calculated.

If we define, potential damage effect by the system composition elements(horizontal axis) as I_T and risk level by the types of risk(vertical axis) as D_T, the final matrix equation on threat(T) can be expressed as the multiplication ($T = D_T \times I_T$) between the matrix elements of I_T and D_T.

2.2 Quantification of Assets (A)

Based on the concept of the smart grid, if assets are calculated, assets of the IT system and assets of the power system all come to be considered. The assets of IT system are commonly called tangible assets including network equipment and intangible assets like software and knowledge information, and so on. On the other hand, assets of the power system mean worth of all elements for constructing the SCADA system.

In this paragraph, to quantify the worth of assets, credible expected outage costs when loss value of communication facilities and pertinent facilities are exposed to threats was only considered.

$$A_n = \sum_{k=1}^{P}\left(LV_n^k(P) + OC_n^k(P)\right) \cdots LV_n^k + OC_n^k \approx OC_n^k \quad = \sum_{k=1}^{P}\left(OC_n^k(P)\right) \tag{2}$$

Here,
P : Power [MW]
k : Lower level compositions of nth SCADA system
A_n : Asset value of n number of SCADA system compositions
LV_n^k : Loss value of communication facilities [KRW]
OC_n^k : Outage cost [KRW]

In quantification of worth of assets defined above, communication facilities and economical worth of expected outage costs are calculated from combining them, normally, because the money of outage damage expenses is overwhelmingly higher than the worth of communication facilities, Eq. 2 presented the approximation into expected outage cost.

Related with quantitative numerical values of expected outage cost, a recently executed 2011 research report of Korea Electrotechnology Research Institute was referred [5].

Table 5 One hour Outage Cost according to the purpose

Region	Residential	Commercial	Industrial
Outage cost [KRW/kW]	2,800	32,365	127,420

2.3 Quantification of Modeling of the Power System

In this paragraph, to analyze the effect that special cyber threats have on the power system, based on optimal power flow calculation as core technology in operation of the power system, using the power flow tracing method, the power system was modeled quantitatively.

Due to physical features of electricity, in the power flow, how much the generation quantity of a special generator flows into a special load cannot be apprehended. Hence, to grasp it, using the optimal power flow calculation, net generation and power flow about a random system was calculated. About already calculated data, using the power flow tracing method, correlation of generation terminals and load terminals was grasped.

2.3.1 Formulation of the Optimal Power Flow (OPF)

The general OPF concept means economic dispatch plans under the technical, physical, and environmental restriction conditions. And conceptually, it is to conduct economic dispatch plans and power flow calculation simultaneously. Using this, the net generation and the power flow can be calculated. These calculated data are essential data to figure out correlation of generation terminals and load terminals. The formulation of OPF used in this paper is like the following.

Objective function $\underset{X_{i,g}}{\text{MINMIZE}} \sum_i \sum_g Cost_{i,g} \cdot X_{i,g}$ (3)

Constraints
$\sum_i Load_i = \sum_i \sum_g X_{i,g}$ (4)
$PF_{i,j,l} = \frac{\delta_i - \delta_j}{x_l}$ (5)
$X_{i,g} \leq CAP_g$ (6)
$PF_{i,j,l} \leq LTmax_l$ (7)

Here,

i, j	: Bus
l	: Transmission line
δ	: Phase angle
x_l	: Reactance of transmission line
$Cost_{i,g}$	: Generation cost
CAP_g	: Capacity of nth generator
Load	: Load of nth bus
LTmax	: Capacity of transmission line
$X_{i,g}$	: Generation of generator
PF	: Power flow

The objective function of Eq. 3 is the function of cost minimization. The constraint condition of Eq. 4 means supply-demand balances of systems. The constraint condition of Eq. 5 means the equation of electric supply-demand in each bus bar. Because of using the DC optimal power flow calculation, the power flow is directly proportional to phase difference and inversely proportional to the reactance of lines. The constraint condition of Eq. 6 is the restriction of generator capacity, and Eq. 7 means the restriction of line capacity.

2.3.2 Power Flow Tracing Method

The concept of power flow tracing is to grasp correlations of each individual generator and load terminals based on power flows linked between generation terminals and load terminals. By this, because how much each individual generator contributes to special loads can be apprehended, in case of disturbance occurrence in the power system, the capacity and damage of a latent outage can be predicted.

About the power flow tracing method, though there are lots of methods, this paper applied the method designed by Felix F. Wu and two people [6]. The power flow tracing method used in this paper was based on a graph theory. The graph theory is proper to solve controversial points on a system topology and can calculate contributiveness effectively between generation terminals and load terminals in the power flow.

Case Study

3.1 A Scenario and Diagram of SCADA System in the Smart Grid

In this study, the power system is composed of three generators and six bus bars. Also, loads are for commerce, industry, and residence. They have different attributes one another. The track capacity was assumed to be same of 100[MW]. This assumption was schematized like Fig. 2.

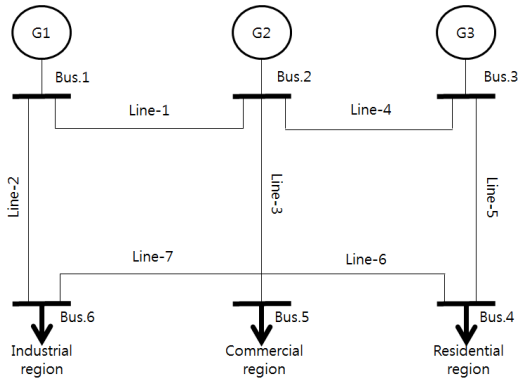

Fig. 2 6-bus power systems

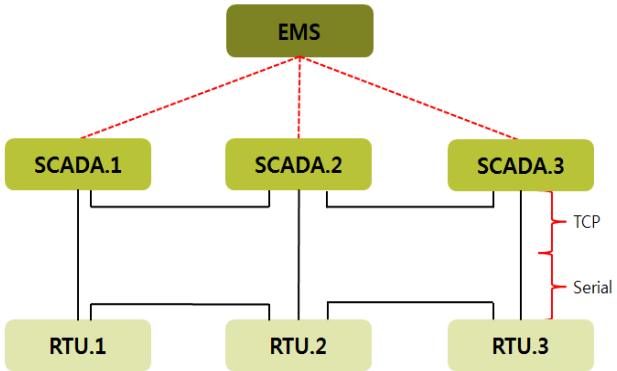

Fig. 3 Diagram of SCADA system in smart grid

On the basis of the simulated power system of six bus, hypothetical networks of the smart grid were modeled. In Fig. 3, the construction of a SCADA system model based on the simulated power system of six bus was schematized.

Table 6 Capacity and Cost of Generator

	Capacity[MW]	Cost[KRW/kW]
G1	100	8
G2	100	10
G3	100	15

Table 7 Load of Regions

	Load[MW]
Residential	50
Commercial	80
Industrial	100

3.2 Analysis of Case Study

Based on the above modeling and data, the result of the optimal power flow calculation is like the next. The red arrow in Fig. 4 means the direction of the power flow.

	OPF
	Net generation[MW]
G1	100
G2	100
G3	30
	Power Flow[MW]
1	6
2	94
3	82
4	24
5	54
6	4
7	6

Fig. 4 Result of Optimal Power Flow

On the basis of the result of the above optimal power flow calculation, if the power flow tracing method is used, generation quantity which each generator supplies can be calculated. The result is like Table 8.

Table 8 Result of Power Flow Tracing

	Residential	Commercial	Industrial
G1[MW]	1.257862	4.411292	94.33085
G2[MW]	20.96436	73.52152	5.514114
G3[MW]	27.77778	2.067183	0.155039

Based on one hour outage cost, in expected outage expenses (Table 5) defined by attribute of each load, the arranged result from adding generation quantities (Table 8) supplied by each region is like the following.

Table 9 Outage Cost according to SCADA Components and Regions

	EMS	SCADA.1	SCADA.2	SCADA.3	RTU.1	RTU.2	RTU.3
	Total	Industrial	Commercial	Residential	Industrial	Commercial	Residential
Outage cost	15,871	12,188	3,508	175	12,742	2,989	140
	L_TCP.1	L_TCP.2	L_TCP.3	L_TCP.4	L_TCP.5	L_TCP.6	L_TCP.7
	Commercial	Industrial	Commercial	Residential	Residential	Commercial	Residential
Outage cost	224	11,977	3,064	67	151	149	765
	L_Serial.1	L_Serial.2	L_Serial.3	L_Serial.4	L_Serial.5	L_Serial.6	L_Serial.7
	Commercial	Industrial	Commercial	Residential	Residential	Commercial	Residential
Outage cost	224	11,977	3,064	67	151	149	765
Outage cost : [1millon KRW]							

In Table 9, since EMS normally controls the whole region, outage expenses of all SCADA servers were calculated. Also, because transmission lines are composed of communication facilities (TCP and Serial), power flow values calculated from the optimal power flow calculation were added to elements of communication facilities. In conclusion, Table 9 means worth of assets in sample systems. The worth means only failure by direct cyber attacks. Lastly, the size due to cyber threats was calculated by the combination of threat (T) × vulnerability (V) × asset (A).

Table 10 Result of Risk

	EMS	SCADA.1	SCADA.2	SCADA.3	RTU.1	RTU.2	RTU.3
Threat(T)	0.29	0.29	0.29	0.29	0.58	0.58	0.58
vulnerability (V)	0.057	0.057	0.057	0.057	0.27	0.27	0.27
Asset (A)	15,871	12,188	3,508	175	12,742	2,989	140
Risk(R)	266	204	59	3	2,055	482	23
	L_TCP.1	L_TCP.2	L_TCP.3	L_TCP.4	L_TCP.5	L_TCP.6	L_TCP.7
Threat (T)	0.16	0.16	0.16	0.16	0.16	0.16	0.16
vulnerability (V)	0.051	0.051	0.051	0.051	0.051	0.051	0.051
Asset (A)	224	11,977	3,064	67	151	149	765
Risk (R)	2	95	24	0.53	1	1	6
	L_Serial.1	L_Serial.2	L_Serial.3	L_Serial.4	L_Serial.5	L_Serial.6	L_Serial.7
Threat (T)	0.09	0.09	0.09	0.09	0.09	0.09	0.09
vulnerability (V)	0.057	0.057	0.057	0.057	0.057	0.057	0.057
Asset(A)	224	11,977	3,064	67	151	149	765
Risk (R)	1	59	15	0.33	1	1	4
Unit of asset(A) : [1millon KRW] Unit of risk(R) : [1millon KRW]							

Table 10 is a result of a monetary unit of risks calculated finally based on data of this case study. The above table (Table 10) is represented. In the size of risks, RTU was represented to be the highest. Among them, it can be known that RTU in industrial regions is the most dangerous.

In the meanwhile, although the worth of assets of EMS and SCADA is high, since quantificational numerical values of threats and vulnerability are low, the risk capacity was calculated low relatively. As interpreted in a physical aspect, in case that cyber threats happen, it means that the possibility to be exposed to threats is low regardless of occurrence of great damages. On the other hand, in case of communication lines, it is shown that risk degrees are different according to power flows.

Conclusion

This paper established security evaluation items about an individual system element which is divided physically. About cyber security problems, the paper conducted interaction modeling between SCADA, power system, and power economy. The result of the above case study was proved to apprehend an index of security strength about the power system of future smart grids and also comprehend expected damage degrees in case of existence of cyber threats.

Namely, by evaluating cyber security risks, power system facilities were planned in the synthetic reliability viewpoint of a physical cyber aspect, and a framework to make an optimized decision economically in the pertinent course was provided.

This study is a start stage for quantifying cyber risk. So, by correctly defining and classifying security vulnerability of the smart grid which was not analyzed and perceived specifically, the study meaning is in preparing the foundation to develop future security measures and solutions.

Keywords: ESS Introduction, Load leveling, RPS, REC market, LCCA, REC weighting value

Abstract. The governments of US, Japan, Europe are planning overall change of electrical power system by adapting Smart Grid as a solution of increasing demand of electricity every year. Especially, ESS have been actively studied to plan efficient use of electrical power and grid-connected. Korea government have been proceeding not only plan of renewable energy but also spread of smart grid. At the same time they have been discussing introduction of ESS which is effective solution of demand response and new growth power. In this study, according to K-ESS policy which is governmental policy of popularizing ESS. we suggest REC weighting value control among the a lot of supporting method that if renewable Genco apply ESS system they would not suffer from lose. It is meaningful because it could be referred to the way of offering governmental incentive for the purpose of decrease peak level and enhance the contribution level of peak.

Introduction

1.1 Research background and necessity

ESS can play a role of demand-side management resource through load leveling by using electricity at the point in time the peak occurs after storing electricity in the light load, and can reduce facility investment such as power plant construction cost and power transmission line construction cost through peak shaving and frequency regulation. In addition, electric power system can be effectively operated at the point in time of peak load of electricity in the winter, summer by securing electric power reserve. And it can play a role of emergency power supply also in case blackout occurs.

However, it is hard to push ESS enforcement considering current condition. First it is very difficult to induce investment of GENCO because of its high initial facility cost expense. Second of all, it's not profitable because current low electric charges make SMP difference between ESS charging and discharging. therefore, the government is required to build basement of ESS to popularize ESS.

This study is intended to present a method of giving aid to initial investment expenditure through a method of adjusting REC weight in case of installing ESS, which is a scheme of grafting RPS onto ESS as one of those. It is the objective of this study to calculate the unit cost recovery in consideration of initial installation cost of ESS and to find out at what level of REC weight the power producer at least doesn't suffer a loss through analysis.

1.2 The related research trends

1.2.1 Overseas trends

<Fig. 1> shows a prospect for the world ESS market size. The whole ESS market is at the level of 7.5 billion dollar as of 2013, and will be at the level of approximately 43.8 billion dollar as of 2020. And consumer and renewable energy-related demand is expected to account for 70% of total demand. And ESS market of 2~10-hour capacity is expected to form the mainstream.

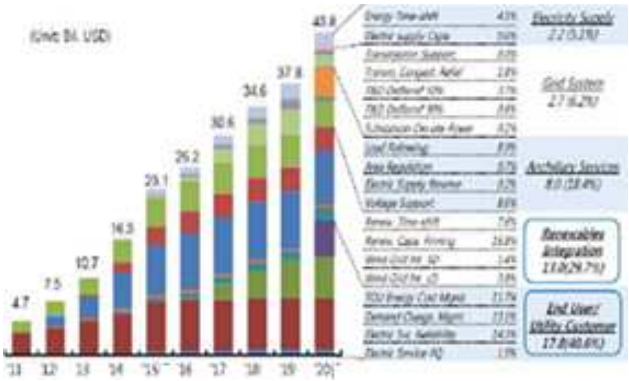

Figure.1 ESS market forecast

Japan pushes forward with a spread project in order to solve the problem of power shortage and in order to develop lithium-ion battery industry. The reason can be considered to be that ESS demand rapidly increased as household emergency power supply after Fukushima Nuclear Power Plant accident. Japan introduced the critical peak pricing with peak price difference of 5 times etc. on the basis of electric charges that are approximately 3 times as expensive as those of Korea. Therefore, the economical efficiency of ESS for consumer is relatively good in comparison with other countries.

U.S. is at the stage of carrying out commercial operation with frequency regulation and wind power ancillary resource, and is a country that first enforces mandatory ESS installation system in the world. A study on the introduction of ESS for frequency regulation is actively in progress in the areas under the jurisdiction of PJM, NYISO, CAISO, and MISO around the mainland of U.S.

In case of Germany among European countries, the purpose of pushing forward with spreading ESS is the same as that of other countries. A subsidy is granted to photovoltaic at the level of 30% in case of being connected with ESS, among main renewable energy resources.

1.2.2 Korean trends

Because Korea lacks production of renewable energy in comparison with advanced countries, there isn't sufficient motive of installing ESS. Therefore, Korean market is being slowly created. At present, it is mainly utilized for the purpose of load leveling at the transmission. distribution end, and consumer end, and is utilized as ancillary resource that compensate the output of wind power generation.

Korea focuses on preoccupying initial market. On the other hand, it is actively pushing forward with making inroads into foreign market such as U.S., Europe, and Japan. However, when considered in the aspect of technical level and demonstration experience of ESS, Korea shows inferiority in comparison with other countries. Because Lithium-ion batteries have reached the world's best level, these have been being exported overseas. On the other hand, it is the actual condition that the fundamental part and material technology of ESS is generally insufficient. The following <Table 2> shows the present technical level of Korean companies.

Table 1 ESS tecknology development status and compare technological level

	The world's best companies	Korea Companies	R&D Level	Technological level (The world's best, 100)		
				Sources	Materials	Manufacture
Li-ion	Mitsubishi	Samsung SDI, LG Chem	Apply	55	70	95
NaS	NGK	POSCO	Initial	35	35	30
Redox flow	Prudent Energy	LS. IS	Initial	40	40	45
Super capacitor	Panasonic	Nesscap, LS. Mtron	Apply	50	55	80
flywheel	Boeing	KEPRI	Product	70	60	70
CAES	PG & E	Samsung	Inicial	50	70	55

A scheme of assessing REC weight

This chapter would minutely explain a method of assessing REC weight in case of introducing ESS, which was presented as a method of the government giving aid to the initial investment expenditure of ESS, as already explained.

First of all, peak time slot is grasped through the analysis of system load pattern. And power generation pattern is analyzed according to each renewable energy resource. Through this, energy source having economical efficiency in installing ESS is selected. And scenario of each period is assessed. Peak time is fixed according to each assessed scenario. And a method of calculating REC weight at that time is explained in detail.

2.1 System load and power generation pattern analysis

2.1.1 System load pattern analysis

First of all, it is necessary to decide what time slot is regarded as peak by grasping the system load pattern. This will be more minutely explained in the case study. Load pattern analysis is meaningful in the respect that it is possible to find out the point in time of applying REC weight because peak period can be grasped.

2.1.2 Renewable energy source power generation pattern analysis

Economical power supply in introducing ESS means a energy source that has a lot of electric energy which can be stored owing to the relatively much energy generated in case of light load, and can obtain an incentive by discharging electricity in the peak time slot. Besides, in case of renewable energy source which has irregular output, the ability to respond to load change according to the demand variation increases. In other words, this means that the output of renewable energy source showing intermittent output can be changed into a high-quality energy source where the output of renewable energy source can be controlled.

2.1.3 Pattern analysis results

The pattern was analyzed on the basis of demand record and the generated energy in 2010~2012. The power generation pattern of renewable energy source was analyzed for 3 types such as wind power, photovoltaic, and fuel cell of which the output was judged to be irregular.

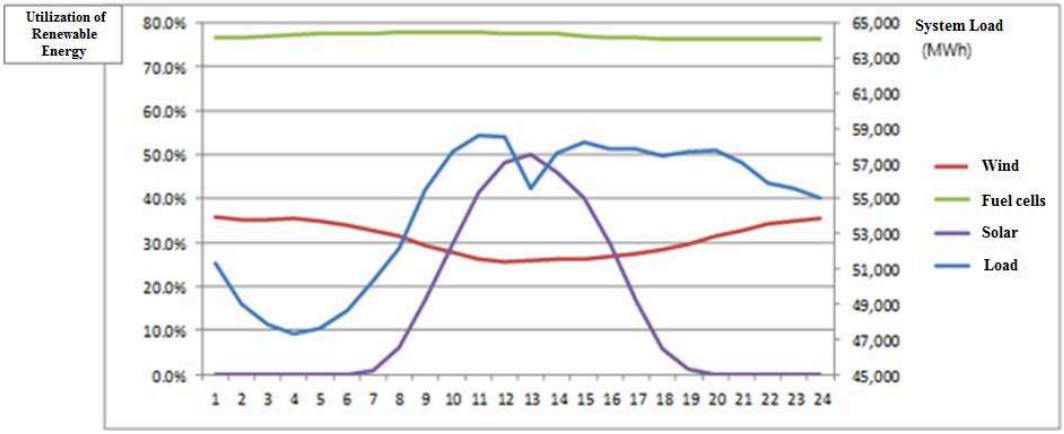

Figure.2 System load and generation pattern for renewable energy('10~'12)

Photovoltaic shows power generation pattern similar to average load curve. Therefore, we judge that there is no power to store in case of light load. Besides, fuel cell generates power on the basis of LNG and thermal power generation. Accordingly, it shows uniform power generation pattern regardless of demand curve. Therefore, it can be thought that the two power supplies under consideration don't have great effect on the mitigation of electricity demand. On the other hand, wind power generation has a characteristic that wind quantity increases owing to the difference in specific heat between land

and sea after sunset. Therefore, it is thought that the effect of ESS installation is excellent in the aspect of peak coincident factor because its share of power generation in light load is high.

2.2 REC weight assessment equation derivation

2.2.1 Renewable power producer profit calculation

The profit calculation method of renewable power producer was used in order to assess REC weight in case of introducing ESS.

$$P_t = X_t(SMP_t + REC \times w) \quad (1)$$

Where,
- t : Period
- P_t : Profit during period t
- X_t : Generation during period t (kWh)
- SMP_t : Average SMP during period t (KRW/kWh)
- REC : REC price (KRW/kWh)
- w : REC weight

The profit of renewable power producer is expressed in the form of the product of settlement part for SMP and settlement part for REC in the above Eq.1. Therefore those can be expressed, putting those together as follows. Dividing this equation by the generated energy X_t, it is changed into the equation for calculating a profit per kWh.

$$U_t = SMP_t + REC \times w \quad (2)$$

U_t : Profit per 1kWh during period t

2.2.2 ESS life cycle cost analysis

This study selected life cycle cost analysis as the method for calculating the initial installation cost of ESS. Life Cycle Cost (LCC) means total cost required in the total lifespan of specific asset or system. And it is useful for the evaluation of economical efficiency according to the change of capacity or size in the same system. There are many conventional economical efficiency analysis methods. However, the following method was selected because it is easy to consider electric charges, electricity consumption, interest rate, etc. for the corresponding period, assume that ESS life is regarded to b approximately 10 years at this point in time.

The following equation is an equation for calculating the life cycle cost of ESS.

$$LCC_{ESS} = \sum_{n=1}^{Life}\left[\left(EC^n + OM^n - OP^n_{benefit}\right)\left(\frac{1}{(1+r)^{n-1}}\right)\right] + C_0 \quad (3)$$

Where,
- n : Year
- r : Interest rates
- LCC_{ESS} : Life Cycle Cost
- EC^n : SMP
- OM^n : O&M Cost
- $OP^n_{benefit}$: Benefit due to Blackout Prevention
- C_0 : The initial construction cost
- $Life$: ESS life

Input data for calculating the cost incurred during ESS installation period is composed of SMP change, operation and maintenance cost, profit for blackout prevention, and initial investment expenditure.

2.2.3 REC weight derivation equation in case of introducing ESS

Putting the equations that have been already explained together, an equation for assessing weight in case of introducing ESS can be expressed as follows.

$$U_{t.ESS} = SMP_t + \Delta SMP_t + REC \times W \quad (4)$$

Where, $U_{t.ESS}$: Life cycle cost per kWh
ΔSMP_t : Difference between SMP
W : REC weight when ESS introduced

ΔSMP_t shows a difference between SMP and standard price according to the discharge of electricity stored in the ESS through power generation in light load. ESS life cycle cost calculated through LCC analysis is applied after being converted into kWh unit. And proper weight in case of introducing ESS is expressed in variable W, and then an equation for deriving final REC weight can be expressed as follows.

$$W = \frac{U_{t.ESS} - SMP_t - \Delta SMP_t}{REC} \quad (5)$$

Case study

Case study is carried out for onshore wind power generation equipment judged to be economically effective through the previous pattern analysis. Scenario is differently applied, being subdivided according to each season of which the heavy load continuance time slot is different.

Table 2 Estimate REC weighting value scenarios

*** Period	Note
Spring(March, April, May)	Period of '10~'12 data
Summer(June, July, August)	
Fall(September, October, November)	
Winter(December, January, February)	

3.1 System load pattern and power generation pattern analysis according to each scenario

First of all, the results of carrying out pattern analysis for deciding on peak time slot according to each scenario are as follows.

Table 3 Demand pattern & Wind generation pattern

	Demand pattern & wind generation pattern	Peak time
Scenario 1 Spring		2~6p.m (4h)
Scenario 2 Summer		1~5p.m (4h)
Scenario 3 Fall		1~5p.m (4h)
Scenario 4 Winter		8~12a.m (4h)

3.2 Input data for carrying out case study

A chart of input data for carrying out REC weight analysis in the already selected peak time slot can be made as follows.

Table 4 Input data(SMP)

	SMP (24h, KRW/kWh)	On peak SMP (4h, KRW/kWh)	Difference: ΔSMP (KRW/kWh)
Spring	162.04	169.22	7.18
Summer	174.75	185.28	10.53
Fall	141.15	147.85	6.70
Winter	157.76	168.79	11.03

The following table 14 shows the main assumptions of ESS for the analysis of LCC. With regard to the items of ESS installation cost, when the life of wind power generation equipment is approximately 20 years in this point in time, the life of ESS is approximately 10 years, a half of wind power generation equipment life. As a result, it became necessary to install ESS 2 times during the life of wind power generation equipment. Therefore, KRW 500 million was reflected in the input data for the additional installation cost of ESS after 10 years.

Table 5 Initial condition for LCCA

	Input Data
ESS Life Span	10 yrs
ESS installation cost	1billion 5hundred million KRW/MWh 5hundred million KRW/MWh ()
Operation retention rate	2.5%
C-rate	90% fixed
SMP	'10~'12 years trend of SMP
REC Price	40,000KRW

3.3 Calculation result derivation according to each scenario

Calculation results of life cycle cost (LCC) in case of installing ESS are as follows.

Table 6 LCCA results

	$U_{t.ESS}$ (KRW/kWh)	(W × REC) (KRW/kWh)
Scenario 1	239.19	69.97
Scenario 2	257.95	72.67
Scenario 3	208.35	60.51
Scenario 4	232.86	64.08

Table 7 Estimated REC weighting value for ESS introduction

	Current sytem	Off peak (20h)	On peak (4h)
Scenario 1	1.75	1.47	3.06
Scenario 2	1.81	1.53	3.17
Scenario 3	1.51	1.27	2.65
Scenario 4	1.73	1.45	3.02

Table 7 expresses the final result values of REC weight assessment in case of introducing ESS. Here, the current system means weight in case of giving the same weight, not setting the preferential level of peak time slot. Calculation result values were marked, where the current system was divided into simultaneous equations for peak time slot of 4 hours and off-peak time slot of 20 hours. Application of different weight to peak time slot is meaningful in the respect that it is a factor that can motivate the renewable power producers to use ESS, and can be utilized as baseline data of incentive

provision method of government that aims at peak reduction and the peak coincident factor improvement of renewable energy source.

Conclusion

This study proposed a method of grafting the REC market of the currently enforced RPS system onto ESS, regarding ESS as one of renewable energy sources, which is a scheme of compensating for high initial investment expenditure as a scheme of laying the foundations of spreading ESS.

A method of adjusting REC weight in case of installing ESS was presented as a scheme of grafting RPS system onto ESS. And a method of giving aid to initial investment expenditure through this was explained. Peak time slot was determined through system load pattern and renewable power generation pattern analysis, and was utilized as input data for assessing REC weight through life cycle cost analysis according to each assessed scenario.

REC weight assessment is meaningful in the respect that it is a factor that can motivate the renewable power producers to use ESS, and can be utilized as baseline data of incentive provision method of government that aims at peak reduction and the peak coincident factor improvement of renewable energy sources.

We judge that a study on the application of ESS to other renewable energy sources is necessary as the future research. Besides, it is possible to carry out a study on REC weight quantification through the work of making more elaborate one for various ESS equipment.

Key words: steam turbine overhaul; dynamic simulation; 3-D model; visualization; the human-computer interaction

Abstract：With the rapid development of the power industry, there has been more and more large thermal power unit which is more than or equal to 600MW , steam turbine equipment gradually tend to be high parameter, large capacity, complicated, the overhaul maintenance to steam turbine is the main content of the power plant production activities, it directly affects the reliability of the coal-fired power plant production safety. Aimed at the complexity of thermal steam turbine overhaul, by the use of advanced interactive devices on the visual, do an auditory perception of the virtual environment for something, which is helpful to improve practical operation skills. This paper examines the necessity and superiority of this system applied in education and training. Taking 3-D dynamic simulation system of building as an example, this paper discussed how to utilize the SolidWorks2012 and VRP - SDK to build a virtual training system, realized the combination with virtual reality and education training ,also greatly promoted science and technology progress， equipment of the steam turbine overhaul industry.

Introduction

As of June 2012, China's thermal power installed capacity reached 787.44 million kilowatts, an increase of 7.3%. To 2015, national thermal power installed capacity will reach 990 million kilowatts [1]. With the increase of installed capacity , an increase in the number of large units , structures and more complex, making maintenance more difficult, the growth cycle maintenance , project management personnel for the entire overhaul is difficult to conduct an overall grasp of the construction progress from the macro . In the course of the entire power plant maintenance, overhaul the highest technical requirements of the turbine, the most difficult, the longest period. Turbine overhaul can be completed faster and better is a direct result of the safe operation of the plant.

In the repair process, the construction program tends to have diversity, variability and complexity, including a number of professional and technical standards, the repair process involves thermal, steam turbines, metal and management, standardize huge number. In this context, how to identify a

reasonable construction organization science, improve construction efficiency and training of qualified personnel and a high level of maintenance repair station become the goal.

In this paper, a genuine overhaul of domestic 600MW ultra-supercritical coal-fired power plant turbines for example. The three-dimensional simulation technology in turbine power plant maintenance construction, namely the use of three-dimensional visual simulation technology to simulate animation turbine power plant maintenance process. The construction involved in the construction process , technical standards and safety measures in the form of dynamic simulation to reflect, a true representation of the thermal power plant construction site maintenance , personnel training and maintenance of the power plant site construction and promote industry standardization has important significance.

Thermal steam turbine maintenance problems and needs

Problems. Through field research visits to the repair , overhaul process stage steam turbine power plant discovered the existence of the following main issues :

1) repair process guidance methods behind: Currently the main reference site maintenance programs and procedures to guide the construction drawings, this method is not intuitive, the impact of construction efficiency.

2) Maintenance standardization system is imperfect: turbine overhaul process, multi- certified cross-operation, maintenance personnel should reference multiple professional construction standards and specifications. There is no complete specification of the system [4].

3) maintenance technician training methods behind: Now turbine maintenance technician training is a combination of on-site inspection photographs and drawings, using on-site apprenticeship way, long approach this training period, and the risk is high.

Requirements Analysis

Through the above analysis of the problem , power plant maintenance needs are as follows :

1) the actual repair process for the host power plant simulation object, utilizing a three-dimensional moving images with pictures, text, sound and other multimedia scene mode for the entire site overhaul and repair processes and technology for three-dimensional visual simulation.

2) to establish a three-dimensional virtual engineering environment, maintenance technician for three-dimensional dynamic simulation training, so that by the trainers, without touching scene understanding overhaul the entire process.

3) the actual repair process in a 600MW domestic ultra-supercritical coal-fired power plant generating units is based on a large number of standards, norms carve professional categories other host repair process related standards, norms systematic collation, compilation, utilize three-dimensional pictorial expression dynamically.

Simulation system design and development

Three-dimensional dynamic simulation using three-dimensional computer software and programming languages , through the key elements of simulation construction job site equipment, environmental, construction methods and technology to create simulation scenarios, and as a platform to perform the job site intuitive layout, standardized deduction operating instructions for implementation. Meanwhile, the system can be invoked as specialized training, guidance on-site construction, shorten cycle time and improve corporate training staff efficiency.

Summary of design

System Design. The overall design of the system shown in Figure 2-1 :

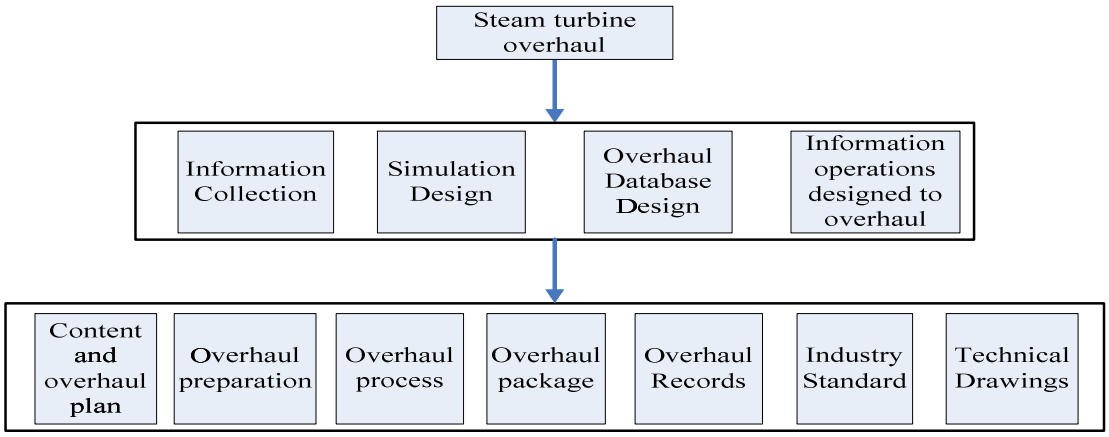

Figure 2-1 overall system design

System design framework. System design framework centered coding device, the device information, data measurement points, the technological transformation of data, maintenance data, equal to three-dimensional drawings related to the construction association model to achieve a three-dimensional model of the operation of the data. To provide users with an intuitive and vivid mode of operation. System framework design is shown in Figure 2-2:

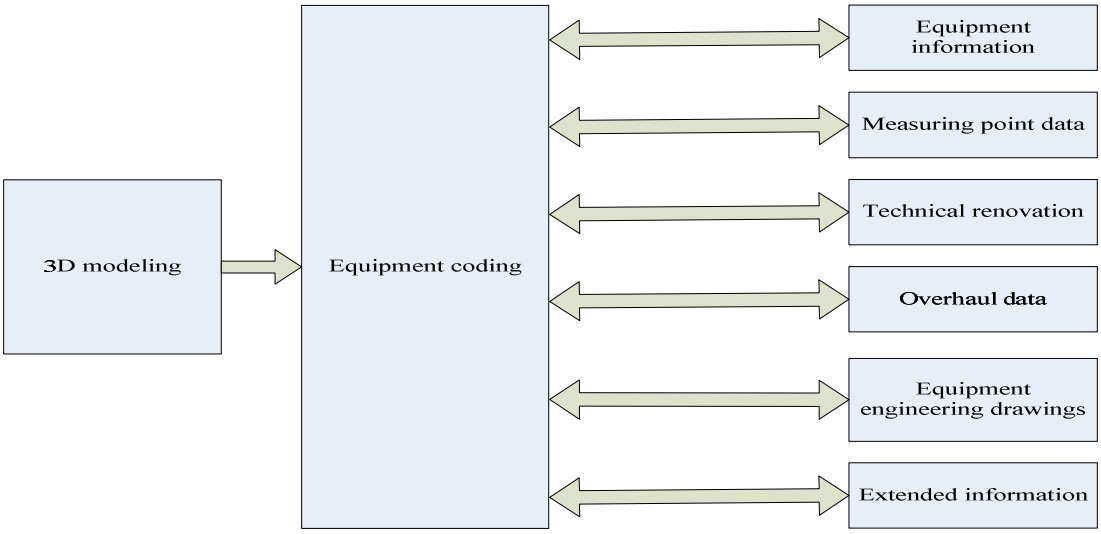

Figure 2-2 Simulation System Design Principles

System Design Principles. The system design should follow the following principles :

1)The system is a three-dimensional simulation system ;

2)To achieve a three-dimensional simulation of the real crew reproduction ;

3)Facilitate the training of operation and maintenance personnel ;

System development platforms and software selection

1)modeling software ;

The system uses SolidWorks2012 software for modeling, SolidWorks2012 modeling is characterised by simple operation, accurate modeling, dynamic simulation and image can be transmitted.

2) Plat

The system uses C # net as the system interface development software, which is easy to use, full-featured, is a painterly, object-oriented and event- driven approach structured high-level programming language;. VRP-SDK as a secondary development toolkit for scene roaming.

3)Other software

Access: database development tools ;

Photoshop: image editing tools ;

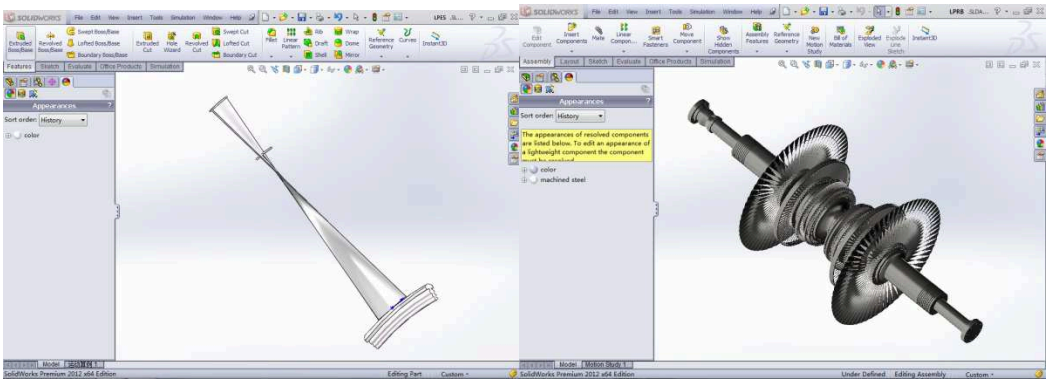
UleadVideoStudio: the simulation of dynamic simulation , sound files and subtitle files synthesis ;

Virtual reality platform editing tool system ;: VRP Builder

Coyote: audio processing tools.

Realization of three-dimensional dynamic simulation 2.3

The three-dimensional model. Turbine use SolidWorks2012 software for accurate modeling, modeling steps: select the drawing plane, according to the drawing sketch after sketch is completed, the feature to edit the generated three-dimensional models. All parts of the model generated by the above method turbine. A typical three-dimensional model of turbine parts shown in Figure 2-3:



Low-pressure end stage Low-pressure rotor blades

Figure 2-3 Last stage low pressure and low rotor blades

Turbine virtual assembly. Virtual assembly is based on a computer assembly , that is a good three-dimensional part model has been painted by SolidWorks software to assemble it by drawing up, due to the complex structure of the turbine , a large number of parts required to assemble the model in the light of , but also to its interference checking, according to interfere with the results of the model changes, and re- assembly [6] . Assembly process is shown in Figure 3-4:

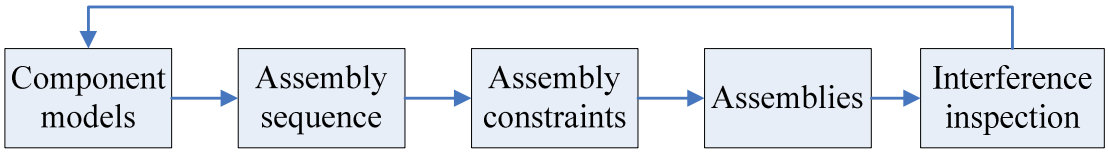


Figure 2-4 Flowchart assembly

Dynamic simulation overhaul. Dynamic simulation of a major overhaul, including maintenance processes and maintenance process demonstration. In this paper, a power plant 600MW steam turbine overhaul domestic ultra-supercritical coal-fired generating units , for example, includes eight parts : Turbine exposing large cap ; cylinder and sliding pin system overhaul ; separators and steam seal overhaul ; cylinder bolts and the center of the rotor inspection ; bearing and oil gear overhaul ; rotor blade reinforcement and repair ; deduction turbine large cap ; rotor shaft to find center.

Synthesis simulation animation, dubbing and subtitling files. The three-dimensional simulation system using Corel VideoStudio Pro X5 simulation animation, dubbing and subtitling files for synthesis. With this software, three-dimensional simulation animation, subtitles, voice synthesis, from a complete overhaul animated simulation, and finally into the system.

Systems to achieve human-computer interaction

The system requires a graphical form of human-computer interaction in the virtual dismantling, in the user interface of the three-dimensional scene model can move, rotate, hide and translucent display operation. As a consequence, users do not get too deep knowledge of computer knowledge can easily manipulate the model of the scene, to achieve the purpose of training. In the three-dimensional scene , trainees can have an intuitive understanding of the scene , in order to make trainees principles and processes for overhaul to better understand and grasp , but also the virtual scene HCI combination of three-dimensional animation and maintenance , so you can receive to good training and teaching effectiveness . Therefore, the system utilizes a three-dimensional program VRP-SDK interface to a three-dimensional scene and three-dimensional animation control. In a simulated environment, the user can utilise the mouse, keyboard, human-computer interaction. The human-computer interaction system is shown in Figure 2-5:

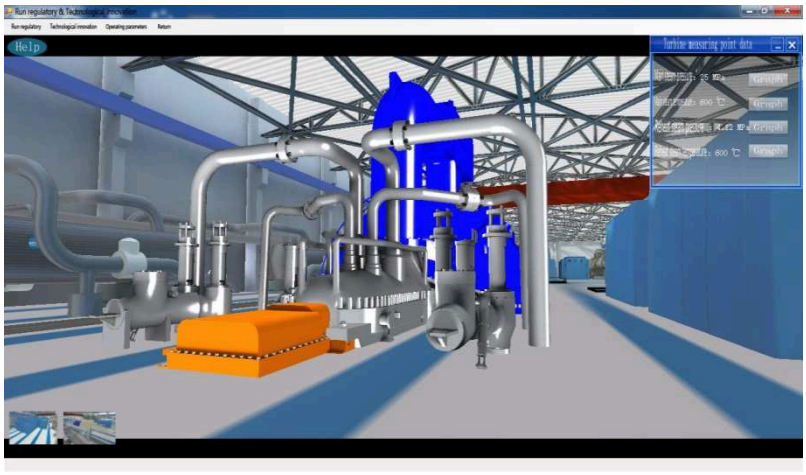

Figure 2-5 Demonstrates the human-computer interaction systems

Turbine repair industry to promote the role of science and technology

The completion of the system greatly facilitated the steam turbine overhaul the industry and technological progress, the power plant steam turbine overhaul significance of the following three aspects.

1) resolve a huge number of power plant steam turbine parts repair process three-dimensional model of light, system integration and other key technologies, reducing the demand for computer hardware, thereby reducing costs.

2) For the power plant steam turbine overhaul determine a reasonable construction organization plan, scientific construction methods to improve construction efficiency and promote technological advancement has enormous significance.

3) to assist the industry to develop high-quality turbine maintenance personnel, to promote electric power construction industry standardization process, reduce training costs, and improve the competitiveness of enterprises and promote the modernization of the plant maintenance industry.

Conclusions

This system will be applied to three-dimensional dynamic simulation technology turbine power plant maintenance process , to overcome the accurate modeling of three-dimensional simulation of the process , the system lighter , software integration and other technical problems, the first time the power plant turbine overhaul the entire process of three-dimensional visualization of dynamic simulation . Plan to build a standardized system of steam turbine power plant maintenance process will process the repair and overhaul of the standard three-dimensional dynamic simulation approach to reflect , to solve the two-dimensional display of complex environments and other security measures to analyze the situation and the danger point of reaction is not comprehensive questions , for the development of maintenance programs , security measures, layout, personnel division arrangements to provide a realistic simulation of the scene, while shortening the training cycle. The three-dimensional dynamic simulation technology used in power plant steam turbine overhaul, repair turbine power plant to promote the standardization process, digitization is important.
