Preface

It is our pleasure to welcome you to the 2014 International Conference on Energy Research and Power Engineering (ERPE'14) in Dalian, China. ERPE’14 is the first conference dedicated to issues related to Advanced Materials Science, Chemical Engineering and Technologies, Power System and Energy Engineering, Its Applications, Environmental Engineering and Resource Development, Industrial, Mechanical and Manufacturing Engineering, Mechatronics, Automation and Control, Computation Methods and Algorithms for Modeling, Simulation and Optimization, Data Mining and Data Processing, Measurement and Instrumentation, Monitoring, Testing, Detection and Identification Technologies, Power and Electric Research, Electronics and Microelectronics, Embedded and Integrated Systems, Communication, Signal and Image Processing, Information Technologies, WEB and Networks Engineering, Information Security and Software Application, Construction Materials, Architecture Science and Civil Engineering, Modern Tendency in Area of Management, Logistics, Economics, Education, Traffic and Urban Engineering.

A major goal and feature of it is to bring academic scientists, engineers, industry researchers together to exchange and share their experiences and research results, and discuss the practical challenges encountered and the solutions adopted.

We hope you will have a technically rewarding experience, and use this occasion to meet old friends and make many new ones. Don’t miss the opportunity to explore in Dalian, China. And don’t forget to take a sample of the many and diverse attractions in the rest of the China.

ERPE’14 promises to be both stimulating and informative with a wonderful array of keynote and invited speakers from all over the world. Delegates will have a wide range of sessions to choose from and will have a difficult decision in deciding which sessions to attend.

We would like to thank the organization staff, the members of the program committees and reviewers. They have worked very hard in reviewing papers and making valuable suggestions for the authors to improve their work. We also would like to express our gratitude to the external reviewers, for providing extra helps in the review process, and the authors for contributing their research result to the conference. Special thanks go to TTP Publisher.

We wish all attendees of the ERPE’14 an enjoyable scientific gathering in Dalian, China. We look forward to seeing all of you next year at the conference.

Organizing Committee

Table of Contents

Chapter 2: Power System and Energy Engineering, its Applications

Chapter 3: Environmental Engineering and Resource Development in Energy Industry

Chapter 4: Design and Research of Components and Mechanisms of Energy Equipment and Installations

Chapter 5: Electrical Machines, Mechatronics, Automation and Control

Chapter 6: Computation Methods and Algorithms for Modeling, Simulation and Optimization

Chapter 7: Measurement and Instrumentation, Monitoring, Testing, Detection and Identification Technologies

Chapter 8: Power and Electric Research, Electronics and Microelectronics, Embedded and Integrated Systems and Applications

Chapter 9: Communication

Chapter 10: Information Technologies

CHAPTER 1:

Semiconductors, Materials and Processing Technologies in Energy and Power Industry

Keywords: perfectly matched layer (PML), meta-material, finite-difference time-domain (FDTD), Z-transform method

Abstract. Efficient Z-transform implementa- tion of the complex frequency-shifted perfectly matched layer (CFS-PML) based on the stretched coordinate PML (SC-PML) formulations and the D-B formulations is proposed for truncating meta-material finite- difference time-domain (FDTD) lattices. In the proposed PML formulations, the Z- transform method is incorporated into the CFS-PML FDTD implementation. The main advantage of the proposed formulations can allow direct FDTD implementation of the Maxwell's equations in the PML regions. A numerical test has been carried out in a three dimensions (3-D) FDTD domain to validate the proposed formulations. It is shown that the proposed formulations with CFS scheme are efficient in holding good absorbing performances.

Introduction

Meta-materials are specifically referred to as a class of artificial materials that have simultaneous negative electric permittivity and magnetic permeability [1] and are also known as left-handed materials (LHMs). In recent years, Meta-materials have been received much attention due to their unusual electromagnetic properties. Meta-materials have been realized by using different models such as the Drude medium and the Lorentzian medium models and so on. Recently, the finite-difference time- domain (FDTD) method [2] has been used successfully in simulating electromagnetic wave propagation in domains that have meta-material properties [3,4,5].

When the FDTD method is used for modelling open region meta-material domains, the abso- rbing boundary conditions (ABCs), such as the stretched coordinate perfectly matched layer (SC-PML), are needed to truncate the computational domain. The SC-PML [6] has been shown to be one of the most effective FDTD ABCs. Recently, different PML formulations have been successfully introduced for truncating meta-material FDTD computati- onal domains [7,8]. In [7,8], the proposed PML formulations have been incorporated into the FDTD implementation of the meta-materials.

In this letter, a novel *Z*-transform algorithm of the CFS -PML is proposed based on SC-PML. Owing to the frequency dependency of the meta-materials, the transformation of the proposed formulations to time domain will lead to convolutions. However, because the convolution in the time domain is just a multiplication in the Z-domain [9], therefore, in the proposed PML formulations, *Z*-transform theory [10] is incorporated into the FDTD implementation of the meta-materials. A numerical test carried out in three dimensional (3-D) domains composed entirely of Lorentzian type meta-material is given to validate the proposed formulations.

Formulation

In 3-D regions, the normalized SC-PML frequency-domain modified Maxwell's curl equations can be written as

$$j\omega \mathrm{D}(\omega)=c_0 \nabla_s \times \mathrm{H}(\omega)\,. \tag{1}$$

$$j\omega \mathrm{B}(\omega)=-c_0 \nabla_s \times \mathrm{E}(\omega)\,. \tag{2}$$

where D and B are given by

$$\mathrm{D}(\omega) = \varepsilon_r(\omega)\mathrm{E}(\omega) . \tag{3}$$

$$\mathrm{B}(\omega) = \mu_r(\omega)\mathrm{H}(\omega) . \tag{4}$$

where c_0 is the speed of light in free space, $\varepsilon_r(\omega)$ and $\mu_r(\omega)$ are, respectively, the relative permittivity and permeability of the meta-materials and the operator ∇_s is expressed as

$$\nabla_s = \hat{x} S_x^{-1} \partial_x + \hat{y} S_y^{-1} \partial_y + \hat{z} S_z^{-1} \partial_z . \tag{5}$$

where $S_\eta, (\eta = x, y, z)$, is the complex stretched coordinate metrics, which was originally proposed [7] to be

$$S_\eta = 1 + \frac{\sigma_\eta}{j\omega\varepsilon_0\varepsilon_r(\omega)} . \tag{6}$$

With the CFS scheme and S_η is defined as

$$S_\eta = \kappa_\eta + \frac{\sigma_\eta}{\alpha_\eta + j\omega\varepsilon_0\varepsilon_r(\omega)} . \tag{7}$$

where σ_η and α_η are assumed to be positive real and κ_η is real and ≥ 1. $\varepsilon_r(\omega)$ is the meta-material permittivity which is assumed to be identical and realized with a Lorentz medium model [3] given by the following expression:

$$\varepsilon_r(\omega) = \mu_r(\omega) = 1 + \frac{\omega_p^2}{\omega_0^2 - \omega^2 + j\omega\Gamma} . \tag{8}$$

where $\mu_r(\omega)$ is the meta-material permeability, ω_p is the plasma frequency, ω_0 is the resonance frequency, and Γ is the absorbtion parameter of the medium.

As an instance, considering the discretization of the z component of (1) in the edges regions, we obtain

$$\frac{(1 - z^{-1})D_z}{c_0\Delta t} = \frac{1}{S_x(z)}\frac{\partial H_y}{\partial x} - \frac{1}{S_y(z)}\frac{\partial H_x}{\partial y} . \tag{9}$$

where Δt is time step and $S_\eta(z)$, $(\eta = x, \text{or } y)$, can be obtained by using the relation $j\omega \rightarrow (2/\Delta t)(1 - z^{-1})/(1 + z^{-1})$ [9].

$$S_\eta(z) = w_\eta \frac{(1 + u_\eta z^{-1} + \theta_\eta z^{-2} + f_\eta z^{-3})}{(1 + v_\eta z^{-1} + \varphi_\eta z^{-2} + \gamma_\eta z^{-3})} . \tag{10}$$

where

$$w_\eta = \frac{a_0\Delta t^3 + a_1\Delta t^2 + a_2\Delta t + a_3}{b_0\Delta t^3 + b_1\Delta t^2 + b_2\Delta t + b_3} .$$

$$u_\eta = \frac{3a_0\Delta t^3 + a_1\Delta t^2 - a_2\Delta t - 3a_3}{a_0\Delta t^3 + a_1\Delta t^2 + a_2\Delta t + a_3} .$$

$$v_\eta = \frac{3b_0\Delta t^3 + b_1\Delta t^2 - b_2\Delta t - 3b_3}{b_0\Delta t^3 + b_1\Delta t^2 + b_2\Delta t + b_3} .$$

$$\theta_\eta = \frac{3a_0\Delta t^3 - a_1\Delta t^2 - a_2\Delta t + 3a_3}{a_0\Delta t^3 + a_1\Delta t^2 + a_2\Delta t + a_3} .$$

$$\varphi_\eta = \frac{3b_0\Delta t^3 - b_1\Delta t^2 - b_2\Delta t + 3b_3}{b_0\Delta t^3 + b_1\Delta t^2 + b_2\Delta t + b_3} .$$

$$f_\eta = \frac{a_0\Delta t^3 - a_1\Delta t^2 + a_2\Delta t - a_3}{a_0\Delta t^3 + a_1\Delta t^2 + a_2\Delta t + a_3}.$$

$$\gamma_\eta = \frac{b_0\Delta t^3 - b_1\Delta t^2 + b_2\Delta t - b_3}{b_0\Delta t^3 + b_1\Delta t^2 + b_2\Delta t + b_3}.$$

where

$a_0 = (\alpha_\eta + \sigma_\eta)\omega_0^2$, $b_0 = \alpha_\eta\omega_0^2$,

$a_1 = (\alpha_\eta + \sigma_\eta)\Gamma + \varepsilon_0(\omega_0^2 + \omega_p^2)$, $b_1 = \alpha_\eta\Gamma + \varepsilon_0(\omega_0^2 + \omega_p^2)$,

$a_2 = \kappa_\eta(\alpha_\eta + \varepsilon_0\Gamma) + \sigma_\eta$, $b_2 = \alpha_\eta + \varepsilon_0\Gamma$,

$a_3 = \kappa_\eta\varepsilon_0$, $b_3 = \varepsilon_0$.

Substituting (10) into (9), we obtain

$$\frac{(1-z^{-1})D_z}{c_0\Delta t} = \frac{1}{w_x}\frac{(1+v_x z^{-1}+\varphi_x z^{-2}+\gamma_x z^{-3})}{(1+u_x z^{-1}+\theta_x z^{-2}+f_x z^{-3})}\frac{\partial H_y}{\partial x} - \frac{1}{w_y}\frac{(1+v_y z^{-1}+\varphi_y z^{-2}+\gamma_y z^{-3})}{(1+u_y z^{-1}+\theta_y z^{-2}+f_y z^{-3})}\frac{\partial H_x}{\partial y}. \quad (11)$$

Introducing two auxiliary variables ϕ_{zx} and ϕ_{zy}

$$\begin{aligned}\phi_{zx} &= \frac{1}{w_x}\frac{1}{(1+u_x z^{-1}+\theta_x z^{-2}+f_x z^{-3})}\frac{\partial H_y}{\partial x} \\ &= -u_x z^{-1}\phi_{zx} - \theta_x z^{-2}\phi_{zx} - f_x z^{-3}\phi_{zx} + \frac{1}{w_x}\frac{\partial H_y}{\partial x}\end{aligned}. \quad (12)$$

$$\begin{aligned}\phi_{zy} &= \frac{1}{w_y}\frac{1}{(1+u_y z^{-1}+\theta_y z^{-2}+f_y z^{-3})}\frac{\partial H_x}{\partial y} \\ &= -u_y z^{-1}\phi_{zy} - \theta_y z^{-2}\phi_{zy} - f_y z^{-3}\phi_{zy} + \frac{1}{w_y}\frac{\partial H_x}{\partial y}\end{aligned}. \quad (13)$$

Considering the time shifting property of the *Z*-transform [9], i.e. if $f^n \overset{z}{\longleftrightarrow} F(z)$ then $f^{n-m} \overset{z}{\longleftrightarrow} z^{-m}F(z)$, (12) – (13) can be written directly in the FDTD form, respectively, as (14) – (15),

$$\phi_{zx}^{n+1} = -u_x\phi_{zx}^n - \theta_x\phi_{zx}^{n-1} - f_x\phi_{zx}^{n-2} + \frac{1}{w_x}\frac{\partial H_y^{n+1/2}}{\partial x}. \quad (14)$$

$$\phi_{zy}^{n+1} = -u_y\phi_{zy}^n - \theta_y\phi_{zy}^{n-1} - f_y\phi_{zy}^{n-2} + \frac{1}{w_y}\frac{\partial H_x^{n+1/2}}{\partial y}. \quad (15)$$

Equation (11) can be written as

$$D_z^{n+1} = D_z^n + c_0\Delta t[(\phi_{zx}^{n+1} + v_x\phi_{zx}^n + \varphi_x\phi_{zx}^{n-1} + \gamma_x\phi_{zx}^{n-2}) - (\phi_{zy}^{n+1} + v_y\phi_{zy}^n + \varphi_y\phi_{zy}^{n-1} + \gamma_y\phi_{zy}^{n-2})]. \quad (16)$$

Finally, E can be obtained from D using (3) (and H from B using (4)), which is available in [10]. A similar method can be used for other regions of the PML.

Numerical Result

To show the validity of the proposed formulations, a numerical test carried out in 3-D FDTD computational domain is provided. A Gaussian pulse, with a central radial frequency equals to $\omega_c = 5.0\times10^9 rad/s$, is excited at the center of 3-D computational domain composed of the meta-material realized with a Lorentz model [3] with the parameters of $\omega_0 = 1.0\times10^9 rad/s$, $\omega_p = 6.9282\times10^9 rad/s$ and Γ=0. With these choices, $\varepsilon_r(\omega)$ and $\mu_r(\omega)$ are equal to –1 at the peak of the incident spectrum ω_c. The size of FDTD computational domain is $50\times50\times50$ grid with the time step Δt = 5.56ps and the

space steps $\Delta x = \Delta y = \Delta z$ =5mm. The meta-material FDTD computational domain is terminated by 8 additional PML layers. Assuming that the origin is at the corner of FDTD grid, a vertically polarized point source locates at (33, 33, 33). The relative reflection error of CFS-PML is first computed over 1200 time iterations for $\kappa_{\max}$ =7, α_η =0.003. This same example is repeated with SC-PML ($\kappa_{\max}$ =11, α_η =0). These optimum parameters are chosen empirically to obtain the lowest reflection. The PML parameters are chosen as PML [8, 2, 0.001%]. The relative reflection error (in decibels) versus time steps is computed at an observation point located at (57, 57, 57) using $R_{dB}(t)=20\log_{10}(|E_z^R(t)-E_z^T(t)|/|E_{z\_\max}^R|)$, where $E_z^T(t)$ is the field computed using the test domain, and $E_z^R(t)$ is the reference field computed by using FDTD computational larger domain truncated by the PML [16, 4, 0.001%].

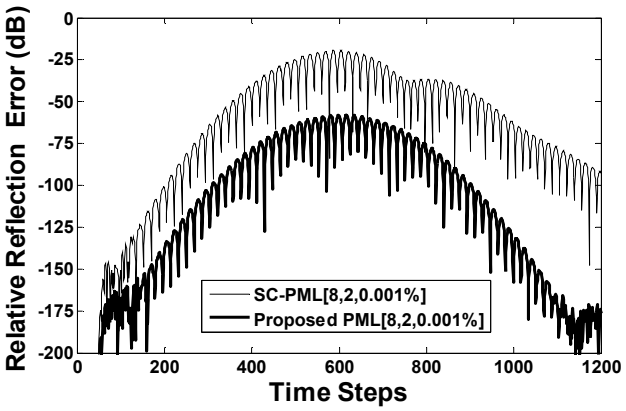

Fig. 1. Relative reflection error versus Time Steps: SC-PML ($\kappa_{\max}$ =11, α_η =0.); Proposed PML ($\kappa_{\max}$ =7, α_η =0.003).

To measure the reflection performance of the proposed PML formulations, Fig.1 shows the relative reflection error of the proposed PML formulations and conventional SC-PML formulations at observation point. The maximum relative errors of the conventional SC-PML and the proposed PML are -20dB and -58dB, respectively. It can be clearly concluded in terms of the maximum relative errors illustrated in Fig.1 that the absorbing performance of the proposed PML formulations has 38dB improvement as compared with the conventional SC-PML formulations. Finally, the reflection performance of the proposed PML formulations as function of frequency is studied. The relative reflection coefficient versus frequency is computed at an observation point located at (57, 57, 57) using $R_{dB}(f)=20\log_{10}(FT\{E_z^R(t)-E_z^T(t)\}\ /FT\{E_z^R(t)\})$. where FT {.} is the Fourier transform operation. Fig.2 shows the relative reflection coefficient for two different PML implementations as well as the frequency spectrum of the incident pulse. The proposed PML formulations hold better absorbing performance than SC-PML over the frequency range of interest, as shown in Fig.2.

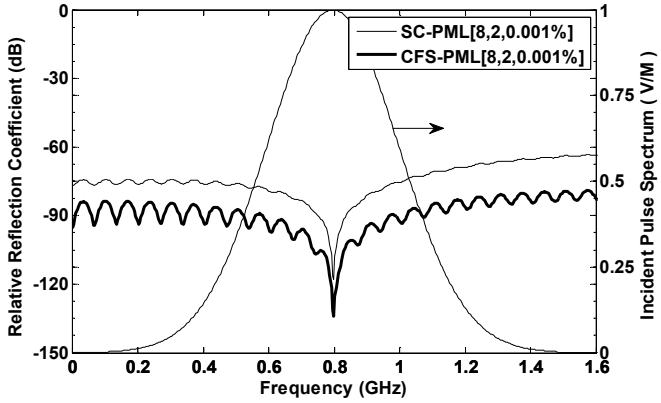

Fig. 2. Relative reflection coefficient versus Frequency: SC-PML ($\kappa_{\max}$ =11, α_η =0.); Proposed PML ($\kappa_{\max}$ =7, α_η =0.003).

Conclusion

The CFS-PML formulations are presented for truncating 3-D meta-material FDTD computati- onal domains. In the proposed CFS-PML formulations, the frequency dependence of the meta-materials has been implemented in the FDTD algorithm by using the *Z*-transform method. A numerical test carried out in 3-D FDTD computational domain shows that the proposed formulation holds comparatively good absorbing performance.

Abstract. A double-mesa hetero-junction bipolar structure of NPN type microwave power device is used. The Si is chosen for emitter and collector, and $Si_{1-x}Ge_x$ alloy is for base. Based on some experiment data, a numerical method is used to get an equation about forbidden band E_g via the variety composition of Ge at 300K using MATLAB, which is more precise than linearization. We also calculate the collector current density J_C via the variety of V_{BE} and the obtained equation is consistent with the experiment result. An optimum Ge composition value was found. It has practical significance for the device design and simulation.

Introduction

With the rapid development of semiconductor material and technology, the microwave power device has grown with higher frequency and larger output power. The design of the microwave power device is transferred from 'doping project' into 'band project'. Thus, heterogeneous form microwave Power Device Based on Si/Si_{1-x}/Si is more appealing with following advantages [1]: higher output power, Si having better performance on conducting heat which improves the overall performance of the device, $Si_{1-x}Ge_x$ alloy used for base area having higher migration rate which improves the microwave performance, and most importantly, the produce process of the device is perfectly compatible to the Si technology which lowers the costs. However, owing to the different Ge constitution, physical parameter and characteristics of $Si_{1-x}Ge_x$ alloy, the feature of device differs with the change of Ge constitution. Linearization method is usually adopted in the emulation towards the forbidden band width of $Si_{1-x}Ge_x$ alloy varying with the x value [2], making the numerical calculation coarser. Through the extraction of the result of the experiment data, we use mathematical methods of interpolation method and fitting method to achieve two better expressions than linear ones. And according to a series of obtained mathematical equations, it can be easily to implement a optimization design and simulation.

Current Density Equation Of Collector Area

As a power device, the fever of the device mainly is concentrated in the collector that we must determine the collector current. The current equation of hetero junction bipolar transistor (HBT) and that of bipolar junction transistor (BJT) differ from each other. In favor of numerical calculation and simulation, make sure in a case of a large current gain to assume that the current density of emission current density and the collector area is equal, namely, JE=JC. Here, we ignore buffer layer parasitic conduction band potential barrier, and thus yielding a current density equation with concise collector area [3]:

$$J_C = J_{C0} \cdot \exp(qV_{BE}/kT) \tag{1}$$

J_{C0} is the collector area saturation current density.

$$J_{C0} = \frac{qD_{n\_SiGe}}{G_{B\_SiGe}} \cdot \frac{(N_C N_V)_{SiGe}}{(N_C N_V)_{Si}} \cdot n^2_{i\_Si} \exp(\Delta E_{Geff}/kT) \tag{2}$$

In the equation (2), D_{n_SiGe} is the minority carrier mobility of SiGe; G_{B_SiGe} is the Gummel number; $(N_CN_V)_{SiGe}$ and $(N_CN_V)_{Si}$ are respectively the conduction band and valence band concentration product of SiGe and Si; n_{iSi} is the intrinsic carrier concentration of Si with its value equal to 1.6×10^{10} c m^{-3}; E_{Geff} is the base forbidden band width change. The parameters above for J_C must be separately obtained.

The Calculation And Determination Of The Parameters Of Model

The determination of base area minority carrier diffusion coefficient

As for SiGe HBT [4]:

$$D_{n\_SiGe} = \frac{D'_n}{1+|E|D'_n/V_T\upsilon_s} \tag{3}$$

$$N_n = \frac{D_{n0}}{1+[N_B(y)/N_m]^m} \tag{4}$$

E is the electric field intensity; υ_s is the saturation drift velocity of the electrons in SiGe and is a number between Si and Ge's saturation drift velocity that decreases gradually with the increase of the components of Ge, and according to its physical properties, we made linear calculation.

$$\upsilon_s = \upsilon_{s\_Si}\cdot(1-x)+\upsilon_{s\_Ge}\cdot x \tag{5}$$

υ_{s_Si} and υ_{s_Ge} are respectively the electronic saturation drift velocity of Si and Ge, the value of which are 8.5×10^{6} and 6×10^{6}. N_B (Y) is the base doping concentration distribution; $N_m=1.14\times10^{4}$c m^{-3} ， m= 0.29.

The number of Gummel number

According to semiconductor physics, the calculating formula for Gummel number is:

$$G_{B\_SiGe} = \int_0^{W_B} N_B(y)\,dy \tag{6}$$

W_B is the base width with base region wide effect decreasing with the increase of the V_{CE}.

Determination of the conduction band and the valence band concentration ratio of SiGe and Si

Although the sensitivity of conduction band and valence band concentration ratio of SiGe and Si towards temperature is very low, the precise value is still hard to be calculated. So the empirical formulas given in the paper [3] are not suitable for parameter simulation calculation to the device. We take advantage of the two groups of data of conduction band and valence band concentration ratio of SiGe and Si presented in the literature.

Use 0.6 (x=0.07), 0.3 (x=0.27) to combine with the conduction band and valence band concentration ratio of Si - Si (x = 0) equaling to 1, and one of Ge-S i (x=1) equaling to 1.3013×10-6 to interpolate. And then through mathematical methods fitting through the comparison, as shown in figure 1, fitting effect of six times is found to be the best.

$$\frac{(N_CN_V)_{SiGe}}{(N_CN_V)_{Si}} = P_1x^6+P_2x^5+P_3x^4+P_4x^3+P_5x^2+P_6x+P_7 \tag{7}$$

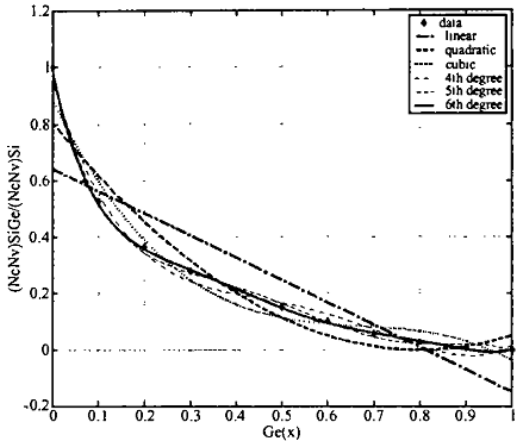

Figure.1 The conduction band and valence band concentration ratio of SiGe and Si along with the change of Ge component

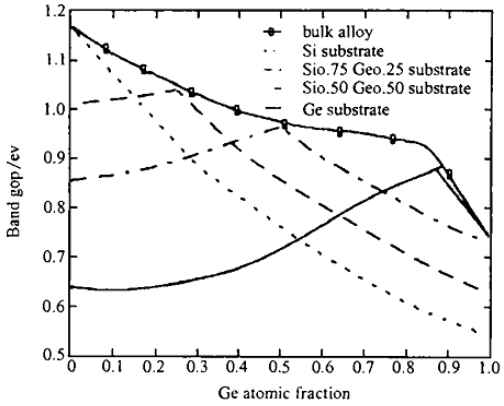

Figure.2 SiGe alloy forbidden band width Eg figure Change with Ge component x experimental data

Therein, P_1=31.374，P_2=109.22，P_3= -150.33，P_4= -103.73，P_5=37.932 ，P_6= -7.674，P_7=1.

SiGe forbidden band width and ΔE_{Geff} calculation mathematical model

The materials forbidden band width must be a precise parameter number in heterojunction devices, for the forbidden band width of Si here with the ready-made data is 1.17eV [5]. Based on reference [3], the SiGe alloy's forbidden band width Eg changes with Ge component which is x in the experimental data graph (as shown in figure 2), a set of data of Si 1-xGex alloy's forbidden band width Eg change with Ge component x can be extracted:

x/Ge	0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8
Eg/eV	1.17143	1.10714	1.06786	1.02857	0.99643	0.97500	0.96017	0.95357	0.93929

As the Si and Ge have as much as 4.17% lattice adaptation, the value of Ge component x should be less than 0.4, and the characteristics of the SiGe alloy's band gap structure is similar to the one of Si [6] when x < 0.85, so we took only the value of x to 0.8. , and by using mathematical fitting method of numerical simulation software MATLAB, we get a three fitting equation of Eg and x:

$$E_g(x) = A_1x^3 + A_2x^2 + A_3x + A_4 \quad (0 \le x \le 0.80) \tag{8}$$

Therein, Al, A2, A3 and A4 respectively equal to -0.24652, 0.65423,- 0.65233 and 1.1703. Through the two-dimensional graphic of the fitting, it is obvious that the fitting of three times is better than that of the linear approximation is shown in figure 3 below.

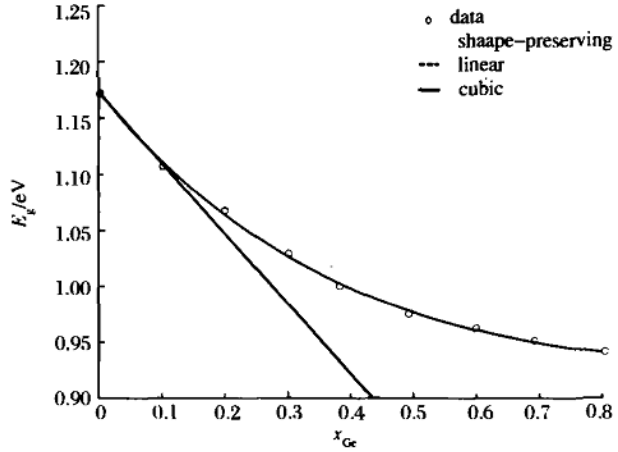

Figure.3 SiGe alloy forbidden band width Eg changes with Ge components fitting

The straight line of what the linearity equation [7] $E_g(x) = 1.17 - 0.63x$ yields is the linear results, while the curve represents the nonlinear fitting result. Linear equation can better reflect the change of Eg(x) when x≤0.2. But when x≥0.2, the error coefficient will be more and more large. At

the following calculation process, the error can reach nearly 0.5 eV. On the contrary, the nonlinear curve can well express the change of the Eg within the whole range.

Due to the base heavy doping, the band is narrowed, and the variation of forbidden band width change ΔE_{g_dop} becomes part of ΔE_{Geff}. According to the empirical formula in literature [3], when the base doping N_B>1018c m-3:

$$\Delta E_{g\text{-}dop} = A + B \cdot \lg\left(\frac{N_B}{10^{18}}\right) \tag{9}$$

A=0.0286 B=0.0274

The variation Ge introduces into the base area of the forbidden band is:

$$\Delta E_{g\text{-}Ge}(x) = 1.17 - E_g(x) \tag{10}$$

So the total variation is:

$$\Delta E_{Geff} = |\Delta E_{g\text{-}Ge}(x)| + |\Delta E_{g\text{-}dop}| \tag{11}$$

Substitute equation (8) (9) (10) into (11), yielding:

$$\Delta E_{Geff} = 0.65233x - 0.65423x^2 + 0.24652x^3 + 0.0286 + 0.0274\lg\left(\frac{N_B}{10^{18}}\right)$$

The Results Of Calculation And Verification

When designing the device, as long as the base area of the doping concentration distribution device and the base components of Ge x as well as the effective width are set, by the above parametric equations can be used to calculate the collector area of the current density of the device (here base extraneous component uniform distribution N_B=2×1019cm-3; ignoring the base region wide change effect; set the base width W_b=20nm and base region Ge components linear distribution x=0～0.4). The Gummel number $G_{B\_SiGe} = W_b N_B$. The field strength of the base area $E = \Delta E_{g\_grade} / q \cdot W_b$. ΔE_{g_grade} is the difference of forbidden band narrow amount caused by Ge constituents between the base on the emitter side and on the collector side. When working on $J_C - V_{BE} - x$ relation, ΔE_{Geff} can be yielded by equation (12) and the conduction band and valence band concentration ratio of SiGe and Si by equation (7). The $J_C - V_{BE} - x$ relationship is shown in Figure 4.

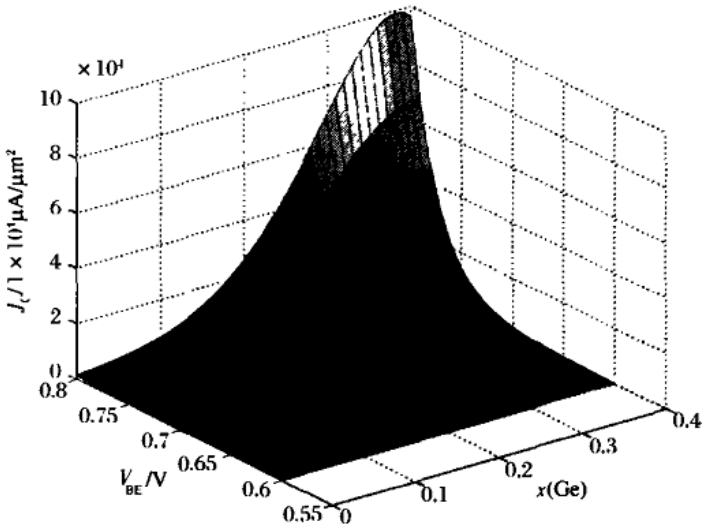

Figure.4 $J_C - V_{BE} - x$ relationship curve

Through numerical simulation, to obtain the maximum J_C when Ge constituents x =0.38. Compared to result of literature [3], [7] and [8], the parameter calculation equation inducing the model results is completely consistent to the numerical method. In addition, previous studies have shown that when Ge constituents have a value between 35% ~ 40%, the base carrier can achieve maximum mobility that verifies the parameter model is accurate and feasible. Conclusion

Based on the analysis of the mechanical theory as the foundation, designed the soccer robot pick the ball institutions optimal design process, found aim function, select design variables and the corresponding optimization algorithm to optimize a complete set of institutions. At last through the test, the final performance parameters of the institution can be achieved. Experiments show that the system has higher accuracy and stability, the new optimize pick the ball have design basic requirements, and achieved good ideal control effect.

Conclusion

According to the experimental parameters, combined with physical characteristics of SiGe alloy, and using numerical simulation software MATLAB, mathematical equations of SiGe alloy's forbidden band width and the conduction band and valence band concentration ratio of SiGe and Si varying with the change of Ge constituents can be determined. And testing and verifying the DC equation of HBT device based on Si/SiGe/Si J_C varying with the change of V_{BE}, to obtain the Ge constituents with maximum current density, confirming the correctness of the equation which has certain guiding role to the design simulation of devices.

Key words:Separation; Activated carbon fiber; Carbon dioxide; Methane

Abstract. In this paper, activated carbon fibers were modified by different chemical reagents. The modified adsorbents were used to investigate adsorption and separation performance of CO_2/CH_4 gases mixture, and then it could get the best modified adsorbent. The experimental results show that amine can't great grafting on activated carbon fiber. Compared with blank activated carbon fibers, the adsorption property of CO_2 did not have much influence on the activated carbon fiber modified by amine. However, it can increase the nitrogen functional groups and the specific surface area on the surface of activated carbon fiber that were modified with nitric acid and ammonia. The above two points were conductive to the adsorption and separation of CO_2/CH_4 mixture gases.

Introduction

With increasing seriousness of environmental problems and the lacking of fossil energy, Energy crisis is becoming more and more grievous. How to develop and utilize clean energy to reduce energy consumption and reduce pollution, has become the urgent task today. Therefore many scientific workers are working on clean energy, such as biogas and natural gas, which can replace fossil fuels[1]. However, CO_2 exists in these new energy, and it is directly affected by the combustion efficiency of methane. Therefore, separation CO_2 from CH_4 mixture is very important.

Adsorption separation technology is more and more applied in the separation of CO_2/CH_4. Adsorption separation is a method which using the adsorbent of having stronger ability to remove material[2]. Activated carbon fiber(ACF) has the congenital advantage of benefiting for modification. ACF has developed specific surface area and abundant microporous which contain a series of functional groups[3,4]. So, ACF was used as catalyst carrier is not only beneficial to adsorption and disperse of metal but also itself has adsorption active site. There are study has reported[5]that ACF which was modified by alkaline metal ion is used to removal COS and H_2S , and it was found that modified ACF has promote role for CO_2 adsorption. In addition, organic amine and CO_2 molecular can react to form relatively strong chemical bonds, and amino modification has become a way to increase adsorption selectivity[6,7].

In this experiment, we compared the effect of ACF which was loaded different kinds of chemical reagents applied in adsorption and separation of carbon dioxide and methane. To provide theoretical basis of efficient purification for natural and biogas.

Experiment

Gas and reagent. CO_2 and CH_4 were obtained from Foshan Kodi Gas Chemical industry Co.Ltd. N_2 was obtained from Meisaier Gas company. Adsorbate purities were 99.99%, 99.99% and 99.99% (wt.%) for CO_2 , CH_4, and N_2. Experimental drugs are listed as below: Potassium chloride, Barium chloride, Calcium chloride, Lithium chloride, Ammonium hydroxide(25%～28%), Nitric acidetc (65%)， Ethylene diamine, Triethylamine. These reagents were obtained from Kaimeishente Chemical company and chemical purity level of all experimental drugs are analytically pure.

Experimental process. Kinetics experiment system is described as below. Gases from each cylinder inpour into the mixing tank after go through each flowmeters. The mixing Gases enter into the fixed bed that was placed in Temperature controller to maintain a constant temperature, and then react with adsorbents. Gas chromatographic detector was used as testing instrument. The dynamic adsorption experiments were carried out in a fixed bed reactor using 1.0g of samples at 298K. The volumetric flow rate of the gas was kept at 25mL/min. Concentration for CO_2, CH_4 and N_2 were 15%, 25% and 60%(v%) , respectively.

Adsorption preparation. Firstly, ACF which were washed with distilled water were cut into 1cm × 1cm squares. And then samples were dried at 110 ℃ to remove adsorbed water.

ACF modified by nitric acid: ACF were boiled with nitric acid for 2 hours at 80℃, and then the ACF were washed with distilled water to neutral. Finally, samples were dried at 110 ℃ for 8 hours.

ACF modified by ammonia: Taking a certain amount of ACF into the beaker, and then concentrated ammonia was added into the beaker rapidly with stirring with a glass rod. Finally, putting the adsorbent in adsorption bed quickly.

ACF modified by organic amine: A sample of 1.0g of ACF was placed in a beaker with 100mL solution of ethyl alcohol. Add a certain amount of ethylene diamine into the beaker, and then reflow stirring for 24 hours under the condition of 78℃. Finally, drying at 100 ℃.

ACF modified by metal ion: In this article, impregnation was used in the experiment. A sample of 1.0g of each of the ACF was placed in contact with 17ml of solutions of 0.3mol/L concentrations of metal salts for 30min in Ultrasonic machine. Then he solutions were impregnated on ACF at ambient temperature for 1 hour. Afterwards, impregnated samples were dried at 110℃ to remove adsorbed water. Sequentially, the impregnated samples were calcined at 500℃ for 60min under a N_2(high purity, 99.99%) flow. The samples of the modified ACF were denoted as M-ACFs.

Result and analysis

Screening of activated carbon fiber types. In this study, the polypropylene fine based activated carbon fibers(PAN-ACF) and glue base activated carbon fiber (VACF) were selected to comparative adsorption and separation ability of CO_2/CH_4. The experimental results are shown in Fig.1.

As can be seen from Fig.1, it has not very big difference for adsorption of CO_2 on PAN-ACF and VACF. But VACF is more conductive to adsorption of CO_2. The adsorption capacity of CH_4 on two kinds of substrate has no obvious difference. So, VACF is more conductive to the separation of the mixture gas. VACF is adopted as adsorption material.

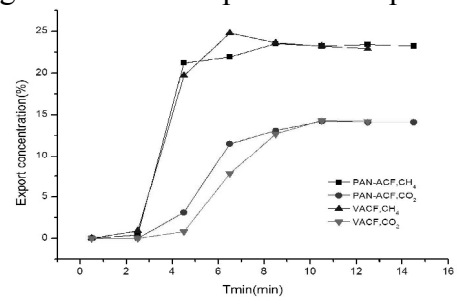

Fig. 1 The breakthrough curve of two kinds of activated carbon fiber(ACF)

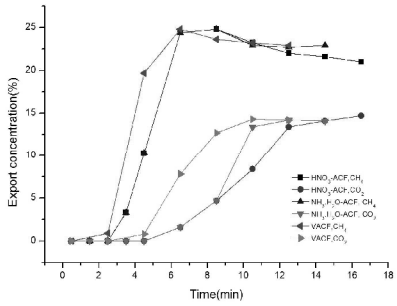

Fig.2 The breakthrough curve of two adsorbents modified by ammonia and nitrate

The study of adsorbent modified by ammonia and nitrate. Adsorption and separation of CO_2/CH_4 on modified adsorbents at 25℃ is shown in Fig.2. The capture capacities and separation factors of carbon dioxide and methane are shown in Tab.1.

Tab.1 The adsorption capacity and the separation factor of CO_2 and CH_4

Adsorbents	Adsorption capacity (mmol/g)		Separation factor α_{CO_2/CH_4}
	CO_2	CH_4	
VACF	1.43	1.37	1.69
HNO_3-ACF	1.58	1.44	1.83
$NH_3.H_2O$-ACFCF	1.54	1.43	1.79

From the Fig.2, it can be seen that adsorption performance of carbon dioxide and methane on ACF that were modified by ammonia and nitrate caused an little higher than that of on blank VACF. Studies have reported that adsorbents which were treated with nitric acid and ammonia could increase nitrogen functional groups on surface[8]. This is benefit for adsorption of CO_2. In addition, from Tab.3, it indicated that adsorption capacity of CO_2 on HNO_3-ACF is better than that of on $NH_3.H_2O$-ACF. This is because that using nitric acid to modify ACF could enlarge pore size and then increase the specific surface area[9]. It also shows that the adsorbing capacity of CH_4 is a little bigger on ACF that were treated with nitric acid than that of on blank ACF. But amplitude of variation is not higher then that of CO_2. Therefore, the separation factor of CO_2/ CH_4 is improved on pretreated ACF. So, the following activated carbon fibers could pretreated with nitric acid.

The study of adsorbent modified by organic amine. The results are shown in Fig.3 and Tab.2.

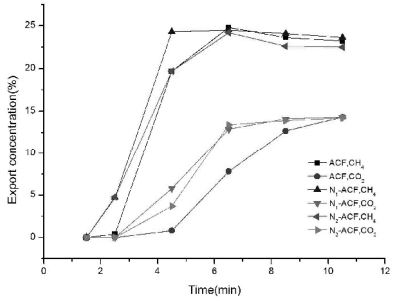

Fig.3 The breakthrough curve of CH_4 and CO_2 on N_1-ACF and N_2-ACF

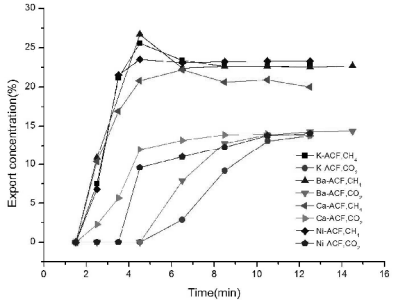

Fig.4 The breakthrough curve of CH_4 and CO_2 on adsorbents modified by metal ions

Tab.2The adsorption capacity and the separation factor of CO_2 and CH_4

adsorbents	adsorption capacity (mmol/g)		separation factor α_{CO_2/CH_4}
	CO_2	CH_4	
VACF	1.43	1.37	1.69
N_1-ACF	1.40	1.34	1.74
N_2-ACF	1.42	1.35	1.75

There are studies have reported that adsorbents modified with organic amine can promote CO_2 adsorption[10,11]. Fig.3 and Tab.2 indicate that ACF were modified by two kinds of organic amine don't promote separation performance of CO_2/CH_4. The reason may be that only a small amount of hydroxyl groups on ACF surface can react with amino functional groups. So, it had a little organic amino functional groups which is conductive to CO_2 adsorption on the surface of ACF. It shows that the method of using organic amine to modify ACF does not apply to separation of mixture.

The study of adsorbent modified by metal ions. Adsorption breakthrough curve of CO_2 and CH_4 on ACF were modified by metal ions as shown in Fig.4 and Tab.3.

Tab. 3 The adsorption capacity and the separation factor of CO_2 and CH_4

Adsorbents	Adsorption capacity (mmol/g)		Separation factor α_{CO_2/CH_4}
	CO_2	CH_4	
K-ACF	1.61	1.30	2.06
Ba-ACF	1.54	1.29	1.99
Ca-ACF	1.42	1.29	1.84
Ni-ACF	1.46	1.31	1.85

As can be seen from the Tab.3, under the same metal loads, the samples for CO_2 adsorption capacity decreased as following: $K^+ > Ba^{2+} > Ni^+ > Ca^{2+}$. Because CO_2 is acidic gas, the introduction of the alkaline earth metal ions and alkaline metal ions would improve the adsorption capacity of CO_2. The more strong of metallic, the more adsorption active site on surface of ACF. So, adsorption performance of CO_2/CH_4 on adsorbent that loaded K ions is stronger than that of on other adsorbents. In addition, Ba^{2+} is divalent metal ions, which has high charge density and polarizability. Its polarization effect is better than other metals. So, Ba^{2+} easily induced deformation of electron cloud of CO_2[12]. Adsorption and separation ability of CO_2/CH_4 on K-ACF is stronger than that of on Ni-ACF and Ca-ACF. To sum up, the adsorption and separation capacity of CO_2/CH_4 on ACF modified with K^+ than that of on adsorbents which were modified with other metal ions.

Conclusion

This article studied that the adsorption and separation properties of CO_2/CH_4 on activated carbon fiber that was modified with different types of chemical reagent. The results show that the activated carbon fibers modified by ammonia and nitrate are good for the separation of CO_2/CH_4 mixture. And loading K ion on adsorbent is more conductive to adsorption and separation of CO_2/CH_4 than loading other metal ions. However, grafting organic amine on activated carbon fiber can not promote the research of adsorption and separation for CO_2 / CH_4. So, it can continue research from two aspects to improve separation capacity of CO_2/CH_4 in the future study. One is adding the amount of nitrogen functional groups on surface of activated carbon fiber. Another is loading different kinds of potassium on activated carbon fiber.

Keywords: cryogenic engineering; cold insulation materials; thermal conductivity;

Abstract. The pipe heat transfer models were constructed, respectively, to simulate the cryogenic insulated structure, nonlinear partial differential equations was obtained considering the temperature-dependent variation in thermal conductivity of insulation materials. In order to get the temperature profile of insulation layer, Kirchhoff integral method was introduced to process, program, and iteratively calculate the simplified energy equations. The influence of heat-transfer process related to the thermal conductivities of four cold insulators was analyzed. Results indicate that phenolic foam, hydrophobic perlite, and RPUR have superior low-temperature insulation at cryogenic environment, while foam glass has better low-temperature insulation at normal temperature. The thickness of inner cryogenic-insulation layer can be reduced largely by using a multicomponent cold insulator in the discharge pipe of LNG stations, which can save both materials and costs. Meanwhile, it offers a new method to solve variable thermal conductivities.

Introduction

In recent years, with rapid development of LNG stations, there are many new insulation structures of cryogenic pipeline for long distance transportation, and the most popular way to approach the insulation goal economically by accumulative insulation method is though improve the thermal conductivity, water absorptivity, and heat capacity of insulation material. The most often used cryogenic accumulative insulation materials are expanded perlite, foam glass, phenolic foam, aerogels, nitrile rubber and diene foam , polyurethane foam and its upgrade series etc. [1].

Currently, there are two most popular methods to process thermal conductivity of cold insulator: use the average thermal conductivity of the overall period of insulation layer or divide cold insulators into multilayer[2], which use ATCM to calculate the temperature of whole cold insulator, and then find the average thermal conductivity for each layer. These two approaches either have accuracy problem or become too complicated to calculate. To solve this problem, we tried several popular cold insulators as examples to show how to build and calculate the models. The effect of thermal conductivity in cryogenic insulation calculation of pipe is also included in our results.

1 Modeling

1.1 Thermal conductivity of cold insulator

The pipeline cryogenic insulation structures in LNG station usually consists of cold insulate layer, vapor barrier layer and protective layer. As cold insulators continuously booming and updating, water adsorption of material is now significantly low, neglect the vapor barrier layer. The protective layer is constructed by metal foil strip with thickness between 0.25~1mm. Take LNG pipeline as an example, meanly focus on the effect of the varying thermal conductivity in heat transfer calculation, in another

word, only consider the cold insulate layer. The temperature-dependent thermal conductivities of some common cold insulators were figured in literature [2]. Chose some characteristic materials including foam glass, RPUR, phenolic foam, hydrophobic perlite and give simulated profile. The thermal conductivity functions for simulations are summarized in Table 1.

Table 1 Cold insulators thermal conductivity vs. temperature

Cold insulators	λ/(W/m·)	Average λ (W/m·)	Normal temperature λ(W/m·)	Temperature range t/
Foam glass	$-8.611\times10^{-8}t^3-4.535\times10^{-5}t^2-0.007542t-0.3373$	0.055	0.0631	[-163，-100]
	$0.001147e^{-0.02788t}+0.05431e^{0.005647t}$			(-100，40]
	0.0685			(40，60)
RPUR	0.0001148t+0.03082	0.021	0.0211	[-163，-98]
	$-1.656\times10^{-6}t^2-0.0001962t+0.01627$			(-98，-24]
	$-3.357\times10^{-8}t^3+2.871\times10^{-6}t^2+3.594\times10^{-5}t+0.01891$			(-24，50]
Phenolic foam	0.0001084t+0.0344	0.0272	0.0371	[-163,45]
Hydrophobic perlite	0.0001933t+0.06675	0.054	0.0716	[-163，45]

1. Average thermal conductivity λ is determined by the average thermal conductivity between -160 to 25 ;
2. Normal temperature λ is thermal conductivity at 25

1.2 Pipe heat transfer model of cryogenic insulation

Heat transfer problem with cold insulation material involve the Fourier law and energy equation. The energy equation can be approached using general control equation [3]. The cylinder pipe heat transfer can compare with the solution of hot oil transportation pipeline in soil to solve the energy equation with varying thermal conductivity [4, 5], which is required to change coordinate system to simplify equations with average thermal conductivity in temperature range. Establish the following cylinder coordinate as the pipe heat transfer model, shows in fig. 1.

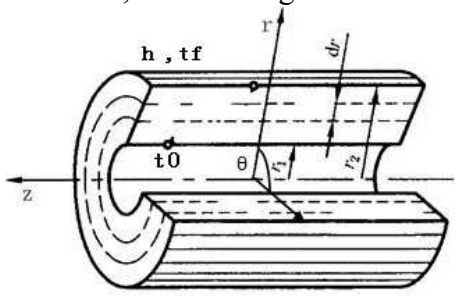

Fig. 1 Pipe model in cylinder coordinate

Because of symmetry, fix one angular θ to discuss heat transfer in roz surface. Similarly, consider the system is steady state and neglect the inner heat source, then can transform this three dimensional question into two dimension. Since λ(T) is a function of T which will make the diffusion term nonlinear, using common method to solve this problem is complicated.

2 Cryogenic insulation calculation and result analysis

In order to eliminate the nonlinear diffusion term in heat transfer equation, cite Kirchhoff integral to define scalar U.

$$U=\frac{1}{\lambda_0}\int_{T_0}^{T}\lambda dT \quad \lambda_0=\lambda\ (T_0 \tag{1}$$

Considering heat convection boundary conditions in pipe model and using Kirchhoff integral scalar U, we can deduce the non-linear equation. Using parameters of discharge pipe in a coastal LNG station to make the result more value in engineering. The outside diameter of pipe is 1016mm, cryogenic insulation layer thickness equal to 230 mm (including metal protective layer and vapor barrier layer etc.), the inner surface of pipe maintain at -160℃, outside surface follows heat convection boundary condition with heat transfer coefficient $h=11.6+7.0v^{0.5}$ W/m$^2\cdot$℃. wind speed v is equal to local highest ten mines wind speed 25m/s, atmosphere temperature t_f is equal to the highest monthly temperature in summer 35℃, and the axis length in x direction of pipe, use unit length 1. Discrete equation with central difference format, and take convergence accuracy of 10^{-3}, though control the step length of Δx, Δt to obtain convergence solution. During tuning program the upper boundary condition have large influence on converge process. When the coefficient $\frac{\Delta t \cdot h}{\lambda_0}$ is smaller, the result can be easier to converge. Similarly, after achieve the converged field U (i, j), it is easy to get the related temperature distribution of each point T (i, j). fig. 2 shows temperature fields of four different cold insulators.

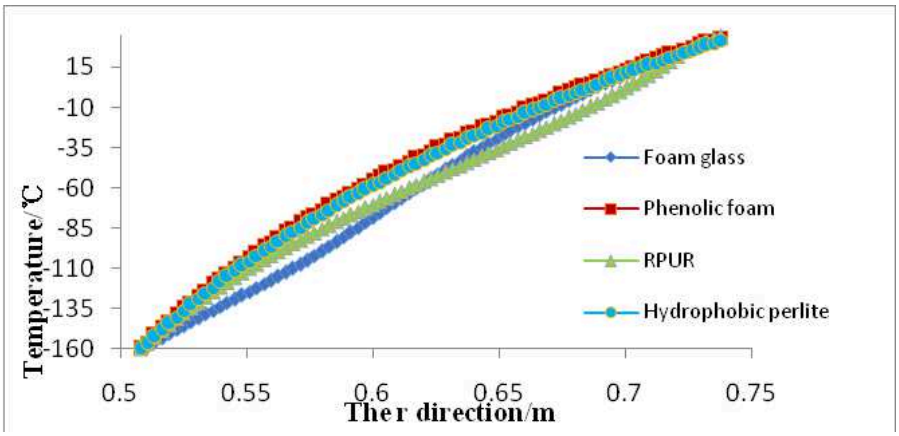

Figure 2 Temperature distribution profiles of insulation materials in radial direction

Under same boundary conditions, phenolic foam and hydrophobic perlite have similar temperature profile between -160~25℃, and they are both convex function. RPUR and foam glass have different convexity around -58℃. Below -58℃, RPUR have greater temperature gradient than foam glass; above -58℃, foam glass have greater temperature gradient than RPUR. In a conclusion, could combine the properties of different cold insulators together. When temperature range is between -160~-58℃, should use RPUR in the inner layer, above -58℃, should chose foam glass. For phenolic foam and hydrophobic perlite have higher temperature in the overall temperature range using either ATCM or VTCM, should consider this in pipe insulation design to efficiently using material. Heat loss and flux of four kinds of cold insulators calculated by three different methods shows in Table 2.

Table 2: Heat loss and heat flux in pipe heat transfer under different thermal conductivity

Cold insulators	ATCM		NTCM		VTCM	
	Heat loss/W	Heat flux/(W/m^2)	Heat loss/W	Heat flux/(W/m^2)	Heat loss/W	Heat flux/(W/m^2)
Foam glass	180.65	38.99	207.13	44.67	179.31	38.67
RPUR	69.15	14.91	69.48	14.98	60.20	12.98
Phenolic foam	89.53	19.31	122.02	26.09	90.72	19.39
Hydrophobic perlite	177.38	38.25	234.88	50.65	179.06	38.62

The outside environment also have great effect to its insulation performance, phenolic foam and hydrophobic perlite shows more obvious difference of convexity in temperature profile, which means heat transfer in pipe is more sensible about thermal conductivity. And especially cryogenic temperature area, these two materials have better insulation property. According to correlated standards [6], the maximum heat flux is 25W/m^2 if we apply the limited-unit-length- heat-loss-method

to design the insulation layer thickness. Under this condition, the LNG discharge pipeline should use phenolic foam and RPUR rather than foam glass and hydrophobic perlite. According to our survey, LNG stations often use the combination of both foam glass and RPUR as their cold insulators. From fig.2, it can be concluded that this method not only takes full advantage of the combined insulation materials' properties in both low and high temperature ranges, but also reduces the cost of insulation materials. Though verification, considering the change of thermal conductivities, the thickness of the combined cold insulators in LNG station can be further optimized. Comparing to the ATCM and VTCM, the NTCM will cause a much higher heat flux of the four materials. Furthermore, this method is too conservative, which will waste materials, and cannot be used in cold insulation verification.

3 Conclusions

The pipe heat transfer models were constructed and simplified to analyze the effects of variable thermal conductivities on cryogenic insulation layers. By applying the Kirchhoff integral factor to solve the nonlinear terms in control equations, the temperature profiles were obtained by programming and iterative calculation, and an innovative way to solve variable thermal conductivity problems was established. All of the four materials have distinct insulation performances in low and high temperature ranges. For cryogenic insulation design, multiple insulation materials can be combined according to their temperature distribution profiles to save materials and reduce costs. Both ATCM and NTCM are too conservative in insulation design and NTCM is not suitable for verification.

Furthermore, when equipment has restrict insulation property requirement and wide operation temperature range, the design of layer thickness and properties verification should consider the variation of thermal conductivities in insulation layers.

Nomenclature

RPUR: Rigid polyurethane foam
ATCM: Average thermal conductivity method
NTCM: Normal temperature thermal conductivity method
VTCM: Variable thermal conductivity method
T_0: Random reference temperature,℃
λ : Thermal conductivity of cold insulators, W/m·℃
λ_0: Thermal conductivity of certain temperature T_0, W/m·℃
Δx: Width of control volume in the x direction, m
Δt: Width of control volume in the t direction, m

Application of Hall Effect in Semiconductor Material

Shuai Kang

Zunyi Normal College , 563002, Zunyi, China

Keywords: Hall Effect, Semiconductor characteristics, semiconductor material

Abstract. As the unique properties of semiconductor material, it is made of many semiconductor Hall devices. Semiconductor Hall device has the advantages of simple structure, small volume, long service life, sensitive to magnetic field induction, strong frequency response and large variable voltage output. Hall Effect of semiconductor material is one kind of electromagnetic effects, which has practical significance. It is widely used in measurement technology, electronic technology, automation technology and so on.

Introduction

Semiconductor material has many special properties. It is doping, heat sensitive, photosensitive, rectifying. These characteristics do bring revolutionary, rapid development to science and technology, and also a lot of benefits to our life and work. For example, voice activated switch, light control switch etc. At the same time, magnetoresistive effect, photomagnetic effect, Thomson effect and Hall Effect are also very important special effect is in semiconductor. Especially the Hall Effect, which is a kind of electromagnetic effects, many materials is studied based on it, such as Hall potentiometer, linear Hall sensor. Now Hall Effect has been applied widely in many scientific fields (measurement technology, electronic technology, automation technology and so on). Therefore, Hall Effect of semiconductor materials and its application are discussed in this paper.

Characteristics of semiconductor and semiconductor materials[1-3]

Characteristics of the semiconductor

The resistivity of semiconductor usually is $10^{-5}\Omega.\bullet m \sim 10^{6}\Omega \bullet m$ at room temperature. At the same time, it is doped, heat- sensitive, photosensitive and rectifying.

Doping: Impurities are artificially doped to semiconductor to control the relative conductivity. And its characteristics are also varied with different impurities. For example, when trivalent Boron is doped to pure Silicon crystal to replace silicon atom, P type semiconductor is formed; when pentavalent Phosphorus is doped, N type semiconductor is formed.

Heat sensitive: After doped, a doped semiconductor is formed, in which the density of majority and minority carrier will vary. Since minority carrier is produced by intrinsic excitation, it is sensitive to temperature, and the conductivity decreases with the increase of temperature.

Photosensitive: The resistance of some semiconductor changes with illumination, and greatly reduces under some light, such as laboratory photoelectric switch, daily light controlled switch, etc.
Rectifier: when a positive voltage is applied on a semiconductor, it is conductive; when a negative voltage is applied, it is no longer conductive, i.e. it is selectively conductive, the typical device of which is rectifier tube.

Characteristics of semiconductor materials

After impurities doped in high purity P type and N type semiconductor, they are made to the same silicon piece side by side through corresponding techniques. In the contact area, the electron (or hole) diffuses from higher density to lower density because of density difference. Then, a PN

junction is formed. It has a characteristic of unilateral conductivity because of the diffusion direction. Semiconductor devices with different functions are manufactured using this characteristic, such as diodes, transistors, and so on. In addition, using its photosensitive and heat sensitive, various sensitive elements can be made for information exchange.

Semiconductor has many characteristics, and they are reflected with characteristic parameters, such as forbidden bandwidth, resistivity, non-equilibrium carrier lifetime and mobility. Forbidden bandwidth reflects an excited energy, which excites valence electron from bound state to free state. Conductivity of semiconductor material is represented by carrier mobility. Non-equilibrium carrier lifetime reflects relaxation characteristic of semiconductor materials, transition from non-equilibrium to equilibrium, under the action of external factors. Characteristic parameter of semiconductor is not only an important basis for differing from non semiconductor materials, but also reflects amount difference between different semiconductor materials, even the same material in different states.

Hall Effect of semiconductor materials and application

Hall Effect of semiconductor materials

A semiconductor with current is placed in the magnetic field. Direction x is the direction of the electric field, E_x is the electric field strength, whose direction is perpendicular to magnetic field direction, and along direction z, magnetic induction is B_z. A transverse electric field E_y will be produced in direction y, perpendicular to the direction of electric field and magnetic field, which is called Hall Effect. Hall field E_y, magnetic field strength B_z and current density J_x are in proportional, i.e.

$$E_y = K_H J_x B_z \tag{1}$$

Proportional coefficient K_H is called Hall coefficient.

$$K_H = \frac{E_y}{J_x B_z} \tag{2}$$

Application of Hall Effect of semiconductor materials[4-5]

One of important methods to study semiconductor is through Hall Effect. Using it, carrier density can be determined, then semiconductor type can be judged, and Hall devices can be manufactured.
Now suppose that the sample temperature is uniform, all the carrier velocity is the same. For P type material, when electric field E_x is applied along with the direction +x, hole drift velocity is v_x, current density $J_x = qpv_x$. Under the action of vertical magnetic field B_z, the Lorentz force applied on hole is $q\vec{v}\times\vec{B}$, whose direction is along direction -y, and the value is qv_xB_z. holes deflect to direction -y under Lorentz force, which causes holes accumulated in direction –y. An transverse electric field is produced in direction +y. When action of transverse electric field and Lorentz force cancel each other out, to be stable, Hall field meet following equation.

$$qE_y = qv_xB_z \tag{3}$$

i.e.

$$E_y = v_x B_z = \frac{J_x}{pq} B_z \tag{4}$$

Compared with $K_H = \frac{E_y}{J_x B_z}$

$$R_H = \frac{1}{pq} > 0 \tag{5}$$

It's unit is m^3/C.

The Hall coefficient of N type semiconductor can be got using the same method.

$$R_H = -\frac{1}{nq} < 0 \tag{6}$$

Seen from formula (5) and (6), Hall field of N type and P type are in the opposite direction, through which the conductive type can be judged. Under the corresponding assumption conditions, the Hall coefficient of N type semiconductor is less than zero; on the contrary, the Hall coefficient of P type semiconductor is greater than zero.

Semiconductor Hall device has the advantages of simple structure, small volume and long service life. More importantly, it is sensitive to magnetic field induction, has strong frequency response and large variable voltage output. It is often applied in many fields, such as measurement of semiconductor characteristics, magnetic fluid power generation, electromagnetic nondestructive testing, as well as Hall sensor.

Concerned Hall devices, integrated circuits, components of Hall sensor are made according to the principle of Hall Effect. According to the principle of Hall Effect, certain variables can be measured through controlling other variables. For example, if the current is constant, AC or DC magnetic induction and magnetic field strength can be measured. If the magnitude and direction of magnetic field strength are unchanged, DC or AC voltage and current can be measured.

Hall sensor has a very wide range of applications both in life and industry. The majority of household electrical appliances in life use the Hall sensor, such as drum motor of video tape recorder, tape commutator of sound recorder, and washing machine, which is essential in our life. The speed measurement of its motor is realized through Hall sensors, which detect and control the motor commutation and variable speed.

In industry, the application of Hall sensor is also very extensive. One is the Hall motor, main characteristics of which are relatively stable speed, low noise and long service life. Hall devices detect the relative position change between stator and rotor. The motor uses these signals to change Hall voltage, and then to adjust the drive voltage. This motor is usually applied in DVD player and other electrical appliances production. In the car, Hall devices are widely used, such as automobile brake system ABS and speed detection, because of the advantages of high reliability, good temperature stability, high sensitivity, strong anti magnetic interference ability and so on. At the same time, they are also widely used in the aerospace and military weapons.

In addition, magnetic nondestructive testing of Hall Effect is a common flaw detection method. The steel frame structure of Main Stadium of Beijing Olympic Games, bird nest, has high

requirements for materials. The steel cables for bridge also need material not hurt. There will be a leakage magnetic field in the bug, which can be detected for the high permeability of ferromagnetic materials. This method is reliable, safe, practical, and with high accuracy.

Conclusions

Semiconductor material is a kind of important materials, and Hall Effect is a kind of electromagnetic effect of practical significance. Hall Effect of semiconductor material has been widely developed and applied in many advanced fields.

With the accelerating pace of life, most electronic products cannot be made without semiconductor materials. Based on it, the research and development technology of semiconductor materials will be increasingly high, while more and more semiconductor materials will be developed by Hall Effect. It will have a broad application prospect whether in life or industry.

Keywords: Cassava; starch accumulation; Cell wall invertase; Promoter; *Cis*-acting elements

Abstract. In order to gain insight into the specific function of the cassava cell wall invertase 6 (*MeCWINV6*), the promoter sequence of *MeCWINV6* gene was cloned using the PCR amplification approach. 118 bp CDS sequence and 1042 bp potential promoter sequence of *MeCWINV6* gene were obtained. PlantCARE analyzed the putative *cis*-elements in silico revealed that these elements can be grouped into five classes: basic transcription elements (CAAT box and TATA box), light responsive elements (ACE, AE-box, ATCT-motif, AT1-motif, Box 4, GAG-motif, GT1-motif and Sp1), phytohormone responsive motifs (GARE-motif, TATC-box, TGACG-motif and TCA-element), defense and stress responsive element (TC-rich repeats and HSE), wounding and pathogen responsive elements (W-box and WUN-motif). This data demonstrate that it might be associated to regulate the cell wall invertase gene function in source-sink relations of cassava starch accumulation and response to internal and environmental stimuli.

Introduction

Cassava (*Manihot esculenta* Crantz) is a widely cultivated tuber crop of the *Euphorbiaceae* family. The starchy storage roots of cassava provide a major calorie source for more than 500 million people in tropical and subtropical regions of Africa, Asia and Latin America [1]. In addition, cassava starch mainly provides raw materials to produce industrial materials and biofuels. Cassava is a typical C3 plant, but has the characteristics of C4 plants photosynthesis. The rate of CO_2 fixation and sucrose synthesis in cassava leaves (source organ) is highest. However, the amount of photosynthate produced by leaves transfers to the roots for strach accumulation is less than 1/5 [2]. So it is meaningful to improve the energy transferring rate from source tissues leaves to sink tissues roots.

In higher plants, sucrose is the major transport form of carbohydrates which synthesized in photosynthetically active source tissues and exported to photosynthetically less active sink tissues via the phloem stream [3]. Cell wall invertases irreversibly hydrolyze sucrose into glucose and fructose, are the key sucrose-metabolizing enzymes transfer photosynthate from leaves to roots [4][5]. They play important roles in phloem unloading during assimilate partitioning by creating a steep sucrose gradient between the phloem and the surrounding sink apoplast to drive phloem unloading, then regulate source-sink relations and promote plant growth [6][7]. The expression of cell wall invertases has been shown to be regulated by a mass of internal and environmental stimuli that affect source-sink relations, including temperature [8], sugar levels [9], light [9], plant hormones, abiotic stress [10], wounding, and pathogen infection [10].

In cassava, the family of cell wall invertases is consisted of six enzymes MeCWINV1-6. In our previous research, we found that the different genes that encode these enzymes exhibit differential expression patterns in the various tissues of cassava at the different growth stages, which implies that each individual isoform has a specific function. In order to gain more insight into the specific function of the *MeCWINV6* gene, we cloned the promoter of *MeCWINV6* gene and analyzed the putative *cis*-elements in silico. Many light response and adversity *cis*-acting elements binding sites were found in the promoter. This will be scientific fundation for researching on the role of cassava invertase in cassava starch accumulation from leaves to roots.

Materials and Methods

Plant material

The cassava cultivar, *Manihot esculenta* SC8 tissue cultured seedlings cultured on MS medium for 45 days, were obtained from the Tropical Crops Genetic Resources Institute, CATAS.

Genomic DNA extraction

The cassava genomic DNA was isolated by the CTAB methods according to the manufacturer's instructions.

Isolation of the *MeCWINV6* promoter region

The 5'-flanking sequence of the cassava cell wall invertase gene *MeCWINV6* was cloned from genomic DNA of the *Manihot esculenta* SC8 tissue cultured seedlings via PCR. The forward primer (5'-AGGATGTGTCCGTTATTGAT-3') was designed according to the predictable 5' UTR region DNA sequences of *MeCWINV6* gene from the Phytozome plant genome database (http://www.phytozome.net/cassava). The reverse primer (5'-TAACCTTGACAGCTTTGACG-3') was designed according to the known coding region sequences of *MeCWINV6* gene (GenBank accession No JX339930) to confirm the product specificity. The PCR reaction (20 μl) contained 1μl genomic DNA, 1 μl primers (10 μM), 0.2 μl *LA* Taq (*TaKaRa*, Dalian, China), 3.2 μl dNTP mixture (2.5 mM), 2 μl 10x buffer and 11.6 μl H_2O. The PCR reaction consisted of 32 cycles of 94 °C, 30 s; 58 °C, 30 s; 72 °C, 2 min. The PCR products were gel-purified and cloned into the pMD19-T vector (*TaKaRa*, Dalian, China) for sequencing (Songon Biotech Ltd, Shanghai, China).

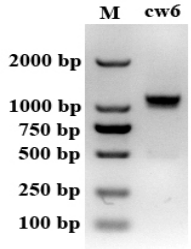
Bioinformatic analysis of the *MeCWINV6* promoter sequences

Analysis of the sequence identity was undertaken using DNAMAN against the known coding region sequences in NCBI GenBank database and the predictable promoter sequences in the Phytozome plant genome database. *Cis*-element search program PlantCARE [11], was used to identify cis-acting elements in the obtained promoter sequence.

Results and Disscusion

PCR-amplified cassava *MeCWINV6* gene promoter regions

According to the predictable DNA sequences of the promoter and the known coding region sequences of *MeCWINV6* gene (GenBank accession No JX339930), we designed the forward primer and reverse primer. The 5'-flanking sequence of *MeCWINV6* gene was cloned from cassava *Manihot esculenta* SC8 genomic DNA using semi-specific PCR method. A special DNA fragment was amplified (Fig. 1).



M: DL 2000 marker; cw6: the fragment of *MeCWINV6* promoter

Fig.1. The fragment of *MeCWINV6* promoter PCR amplified

Sequence analysis of promoter regions

Sequencing result showed that a 1160 bp gene fragment was obtained. It consists of 118 bp *MeCWINV6* gene coding region sequence and 1042 bp potential promoter and 5' UTR sequence, as shown in Fig.2. Compared with the predictable promoter sequences in the Phytozome plant genome database and the known coding region sequences of *MeCWINV6* gene, there was 100% sequence identity. Obviously, we isolated *MeCWINV6* gene promoter sequence successfully.

Bioinformatic analysis of promoter *cis*-acting regulatory elements

To study the elements of the *MeCWINV6* gene promoter, the 1042 bp-length potential promoter was analysed using web database PlantCARE [11]. As shown in Table 1, the putative cis-acting regulatory elements can be grouped into five classes: basic transcription elements, light responsive elements, phytohormone responsive motifs, defense and stress responsive element, wounding and pathogen responsive elements. The highly conserved transcriptional regulatory motif TATA box and the universal enhancer element CAAT box were present in the *MeCWINV6* promoter. Light responsive elements ACE, AE-box, ATCT-motif, AT1-motif, Box 4, GAG-motif, GT1-motif and Sp1, which are essential for light-regulated transcriptional activation, were found in the promoter. *Cis*-acting elements responding to phytohormoneswere also revealed in the promoter, such as gibberellins-responsive elements GARE-motif and TATC-box, salicylic acid-responsive element TCA-element and MeJA-responsive elements TGACG-motif and CGTCA-motif. Some potential *cis*-regulatory elements were stress-induced regulatory elements, primarily including defense and stress responsive element TC-rich repeats, heat stress response element HSE, wounding and pathogen responsive elements W-box and WUN-motif. The analysis of *MeCWINV6* promoter *cis*-acting regulatory elements indicates that the *MeCWINV6* promoter is likely functional in situ and *MeCWINV6* gene is expressed in response to the stimuli of light, hormones and abiotic and biotic stresses in the cassava developmental processes.

Conclusion

In this study, we report cloning and characterization of the cassava cell wall invertase gene *MeCWINV6* promoter. 1160 bp fragment contains 118 bp CDS sequence and 1042 bp potential promoter sequence of *MeCWINV6* gene were isolated. A number of *cis*-regulatory elements previously reported to be involved in light responses, phytohormone responses, abiotic and biotic

stress transcription elements were present in the *MeCWINV6* promoter. This is consisted with the function of cell wall invertase in the cassava starch formation, suggesting that it might be associated to regulate the cell wall invertase gene function in source-sink relations of cassava starch accumulation and response to internal and environmental stimuli.

Keywords: Bio-oil; Model compound mixture; Ethanol; Co-cracking; Bio-gasoline

Abstract. Since the composition of crude bio-oil was complex, model compounds were usually used in the study of cracking to simulate the actual bio-oil. However, the cracking of pure model compound mixture generated an inferior oil phase which had a high content of oxygenated byproducts. When ethanol was adopted as the co-reactant, the reactant conversion, yield and quality of oil phase were obviously improved. The conversions of the reactants were 100% and the selectivity of the oil phase was 31.5wt% when the concentration of model compound mixture in the feed reached 30%. Meanwhile, the oil phase also had a superior quality which was entirely composed of aliphatic and aromatic hydrocarbons.

Introduction

The bio-oil from biomass fast pyrolysis, which is regarded as a promising substitute for fossil fuel, is widely studied by researchers. However, crude bio-oil is complex, unstable and corrosive, and it has a low heating value. Therefore, some researchers used catalytic cracking to transform bio-oil to high-quality oil. Williams et al. [1] found that there are mainly two pathways for cracking: the bio-oil was cracked to olefin by zeolite and then the olefin was aromatized, or the oxygenated compounds in bio-oil were deoxygenated to aromatic compounds directly.

Because crude bio-oil had a complex of composition, rich in acids, aldehydes, ketones, alcohols, phenols, esters, ethers and sugars, researchers used model compounds (compounds with typical functional groups) to simplify the cracking reaction, and the proposed reaction mechanism of model compounds could help to understand the cracking pathways of real bio-oil. Gayubo et al. [2,3] carried out a series of cracking experiments of model compounds. The conversions of alcohols were found to be similar to methanol and ethanol, which mainly produced hydrocarbons, and the catalyst coking rate was low. The conversions of ketones and acetic acid mainly involved decarboxylation, decarbonylation, and dehydration to a less extent.

In consideration of the possible influence of oxygen content and unsaturated degree on cracking characteristics, the concept of an effective hydrogen to carbon ratio ($(H/C)_{eff}$) was introduced, as shown in Eq. (1) [4,5]. Mentzel et al. [5] found that the catalysts during the cracking of model compounds with low $(H/C)_{eff}$ ratios were easy to be deactivated.

$$(H/C)_{eff} = \frac{H - 2\cdot O - 3\cdot N - 2\cdot S}{C} \quad (1)$$

The crude bio-oil has a very low $(H/C)_{eff}$ ratio, so the catalyst is easily deactivated by coking during the cracking. Researchers tried to mix the crude bio-oil with compounds with a high $(H/C)_{eff}$ ratio to improve the stability of the cracking process. Ethanol, with a relatively high $(H/C)_{eff}$ ratio of 2, is regarded as a good co-reactant for the cracking of bio-oil, which can effectively improve the yield and quality of the hydrocarbons and extend the lifetime of catalyst. Moreover, compared with the conversion of ethanol to gasoline, the mixture of bio-oil and ethanol is more economical [6].

Hydroxypropanone, cyclopentanone and acetic acid are the typical ketones and carboxylic acids in bio-oil. In the study of co-cracking behavior of the model compound mixture and ethanol, the most suitable ethanol blending amount can be obtained by comparing the reactant conversion and the selectivity and composition of liquid and gaseous products.

Experimental section

Catalyst and materials. The catalyst used was HZSM-5 catalyst (Si/Al=25, purchased from the Catalyst Plant of Nankai University). The catalyst was calcined in the air for the activation at 550 °C for 6 h (the heating rate was 5 °C/h) and then naturally cooled and sieved to 40–60 mesh.

These bio-oil model compounds were mixed according to the component distribution of the bio-oil distilled fraction, and the weight ratio of HPO, CPO and HAc was set as 6:1:5 [7].

Catalytic test. The experimental system was discussed in detail in our previous study [7].The conditions of experiments are presented in Table 1.

Table 1 Conditions of experiments

Reactants	Temperature [°C]	Pressure [MPa]	WHSV [h^{-1}]
100%EtOH	400	2	3
15%HPO+2.5%CPO+12.5%HAc+70%EtOH	400	2	3
25%HPO+4.2%CPO+20.8%HAc+50%EtOH	400	2	3
35%HPO+5.8%CPO+29.2%HAc+30%EtOH	400	2	3
50%HPO+8.3%CPO+41.7%HAc	400	2	3

Results and discussion

Conversion of reactants and Selectivity of liquid products. The influence of EtOH addition on reactant conversion is shown in Fig.1. Ethanol made a contribution to the conversion of model compounds. Only HPO was converted completely during the cracking of pure model compound mixture, while the conversion of CPO and HAc were 89.6% and 80.3%, respectively. When the concentration of model compound mixture decreased to 70% and 50%, the CPO was also converted completely, and the conversion of acetic acid increased to 86.4% and 89.8%, respectively. When the concentration of model compound mixture was 30%, the conversion of all reactants reached 100%.

Fig.2 presents the influence of ethanol addition on liquid product selectivity. The oil phase selectivity was only 18.4wt% during the cracking of pure model compound mixture. The selectivity of oil phase increased with the increasing of ethanol concentration, while the aqueous phase selectivity was opposite. The selectivity of oil phase reached 31.5wt% under the condition of 30% model compound mixture, which was even higher than the oil phase selectivity in the cracking of pure ethanol.

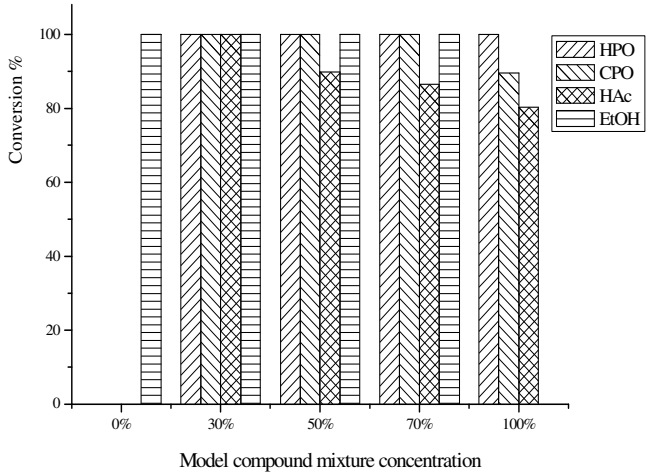

Fig.1. Conversion of reactants

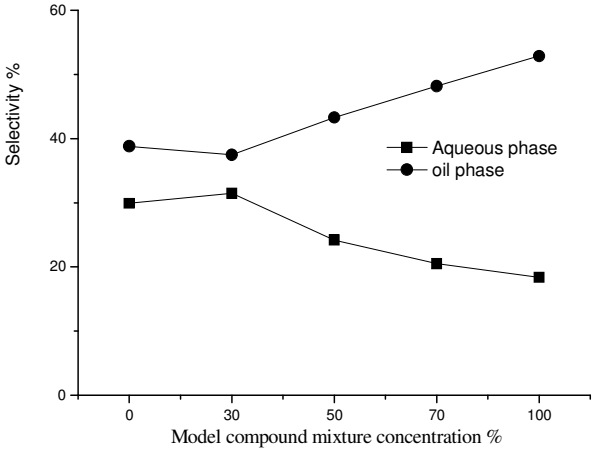

Fig.2. Selectivity of liquid products

Composition of the oil phase. Oil phases were analyzed by GC–MS, and the composition of oil phase under different conditions is presented in Fig.3.

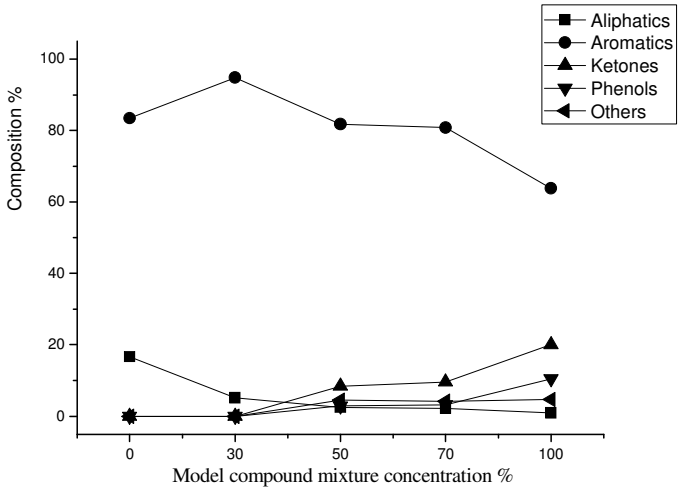

Fig.3. Composition of the oil phases

When the concentration of model compound mixture was 30%, the oil phase was completely composed of hydrocarbons, in which the contents of aliphatic hydrocarbons and aromatic hydrocarbons reached 5.2% and% and 94.8%, respectively. Compared with that from the cracking with higher concentrations of model compound mixture, the quality of this oil phase was much higher. When the model compound concentration was 50%, the contents of aliphatic hydrocarbons and aromatic hydrocarbons were 2.5% and 81.7% respectively, and there were some oxygenated compounds in the oil phase, such as 8.4% ketones and 2.9% phenols. This result showed 50% ethanol could not support the high-efficiency conversion of all the model compounds into hydrocarbons, and a part of model compounds occurred side reactions and formed ketones and phenols. When the model compound mixture concentration reached 70%, the quality of oil phase further declined, the aliphatic and aromatic hydrocarbon contents were 2.2% and 80.8% respectively, with the ketone and phenol contents of 9.6% and 3.2%. Moreover, the contents of ketones and phenols reached 20.0% and 10.5% when cracking pure model compound mixture. The cracking of pure ethanol also generated an oil phase with complete hydrocarbons, but the content of aromatic hydrocarbons was lower than co-cracking of model compound mixture and ethanol, due to the different $(H/C)_{eff}$ ratios in feed. The $(H/C)_{eff}$ ratio of 30% model compound mixture and 70% ethanol was 1.46, so compared with pure ethanol with a high $(H/C)_{eff}$ of 2, it was easier to produce aromatic liquid products ($1 \leq (H/C)_{eff} < 2$) during cracking, which was in agreement with the higher selectivity of oil phase as mentioned before. Therefore, it could be concluded that ethanol could restrain the side reactions of model compounds and thus improve the yield and quality of oil phase.

Composition of vent gas. Table 2 presents the composition of vent gas. The general distribution of gaseous products showed the vent gas under conditions with high oil phase selectivity and quality also had high contents of C_3H_8, which might be released during the aromatization of light olefins into aromatics with high degrees of unsaturation. With the increase of model compound mixture concentration, CO_x was likely to be released because of the carbonyl and carboxyl groups in the model compounds. Since C_2H_4 is regarded as the important intermediate during cracking, its massive release implies that the intensity of aromatization was weaker. The concentrations of C_2H_4 were up to 30.9% and 16.0% under the conditions of 70% and pure model compound mixture.

Table 2 Composition of vent gas under different contents of mixture of model compounds.

Conditions	Relative contents of gaseous products (%)								
	CO	CO_2	CH_4	C_2H_4	C_2H_6	C_3H_6	C_3H_8	C_4H_8	C_4H_{10}
100EtOH	5.1	1.7	5.9	0.6	14.8	0.6	53.6	12.6	5.1
70EtOH	16.4	15.3	1.8	3.4	8.5	1.8	40.5	10.1	2.2
50EtOH	23.9	25.0	2.0	1.4	8.1	1.0	26.8	8.7	3.1
30EtOH	22.3	27.7	1.9	30.9	3.4	2.8	8.7	2.1	0.3
0EtOH	24.8	51.8	1.0	16.0	0.6	0.3	4.2	1.4	0.0

Conclusions

In the co-cracking study of bio-oil model compound mixture and ethanol with different blending ratios, the introduction of ethanol was found to improve the yield and quality of the oil phase. At 400 °C and 2 MPa, when the concentrations of model compound mixture and ethanol in feed were 30% and 70%, the reactants were converted completely and a high selectivity of 31.5wt% for the oil phase was obtained, which was entirely composed of hydrocarbons.

Keywords: Lithium-ion batteries; Safety; Electrolyte additive; LiDFOB

Abstract: A new composite electrolyte for lithium-ion batteries (LIB_S) was prepared by combining N-methyl-N-propylpyrrolidinium bis(trifluoromethanesulfonyl)imide ($PYR_{13}TFSI$), N-methyl-N-propylpiperidinium bis(trifluoromethanesulfonyl)imide ($PP_{13}TFSI$) and lithium difluoro(oxalate) borate (LiDFOB). Graphite electrode was tested in the LiDFOB-containing electrolyte, exhibiting higher reversible charge/discharge capacity and better cyclic stability. An initial charge capacity of 351.5 $mAh \cdot g^{-1}$ is obtained and a stable capacity of above 332.8 $mAh \cdot g^{-1}$ is retained after 30 cycles. The coulombic efficiency remains high above 99.3%. The outstanding cell performance was associated with the formation of stable solid electrolyte interface (SEI) film on the surface of electrodes derived from LiDFOB.

1. Introduction

LIB_S is considered to be the most promising battery technology in the field of hybrid electric vehicles (HEVs) and electric vehicles (EVs) [1]. However, the thermal runaway of LIBs has caused several severe accidents in HEVs and EVs. The increase in improvement of safety is a key point for commercialization of LIB_S. Recently, ionic liquids (ILs) have been studied as potential safe electrolytes owing to their wide liquid range, a wide electrochemical stability window, negligible volatility, non-flammability, etc [2]. Pyrrolidine (PY) and piperidine (PP)-based ILs attract people′s interest due to their electrochemistry window is higher than 5 V [3]. However Graphite anode is not compatible with this ILs due to the intercalation of the organic cations such as PYR_{13}^+ and PP_{13}^+ between the graphene layers. Another disadvantages of neat ILs are high viscosity and low ionic conductivity lead to poor cyclic stability and rate performance. Several modification methods, such as mixing organic solvents and additives to assist in forming stable solid electrolyte interface (SEI) films [4]. LiDFOB was investigated as an electrolyte additive, with the advantages of both $LiBF_4$ and lithium bisoxalatoborate (LiBOB) and was found to favor a stable SEI film with thinner thickness and much lower interfacial resistance to form on the anodes [5]. In this study, a new composite electrolyte based on ILs with the additive LiDFOB and organic solvents is explored and provided LIB_S with the level of safety. In addition, the effect of LiDFOB on the electrochemical properties of Graphite anode is further investigated.

2. Experimental

2.1 The synthesis of ionic liquids, the preparation of electrolytes and the half cell

The method of preparation is based on a two-step synthesis, N-methyl-N-propylpyrrolidinium bromide($PYR_{13}Br$) was synthesized by heating 1-bromopropane (Alfa Aesar, >99%) with N-methyl pyrrolidinium (Acros, >98%) in ethyl acetate. $PYR_{13}TFSI$ was synthesized by the metathesis reaction of $PYR_{13}Br$ with excess lithium bis(trifluoromethanesulfonyl)imide (LiTFSI, Acros, >99%) in aqueous solution. The resulting $PYR_{13}TFSI$ phase was washed with deionized water until the bromide cannot be detected by 0.1 M $AgNO_3$ solution and then dried in vacuum at 110 ℃ for 48 h to remove the residual water. $PP_{13}TFSI$ was prepared by the same method. The ionic liquid/organic carbonate mixed electrolytes were obtained by adding 0.3 $mol \cdot L^{-1}$LiTFSI and 23 wt% ethylene carbonate (EC) and dimethyl carbonate (DMC)(1:1, w/w) in 70 wt%$PYR_{13}TFSI$/$PP_{13}TFSI$(1:1, v/v) and the additive LiDFOB was added at 0.25 wt%.

The performance of the electrolytes was measured with 2032 type coin cells. The active material, graphite was mixed with carbon black and poly(vinylidene difluoride) (PVDF) at a ratio of 8:1:1 in N-methyl-2-pyrrolidone (NMP). The slurry was casted on Cu foil with a diameter of 14 mm (1.54 cm^2) and dried at 110 ℃ for 12 h under vacuum. All the electrodes were dried in vacuum at 110℃ for at least 12 h prior to use.

2.2 Characterization

Thermogravimetric analysis was carried out using a TA Q50 instrument. The samples were heated from room temperature to 640 ℃ with a heating rate of 5 ℃·min^{-1} using nitrogen as purgegas (40 cm^3·min^{-1}). The charge–discharge experiments of Li/graphite cells were performed galvanostatically at 0.1 C rates in the voltage range of 0.01–2.0 V on battery testers (Land CT2001A). All the potentials throughout the work are in reference to Li/Li^+ couple unless specified otherwise. Cyclic voltammetry (CV) of the cells were measured by electrochemical workstation (14 70E Cell Test System, England) at a scan rate of 0.1 mV·s^{-1} in range of 0.01-2.0 V. The graphite electrode was used as working electrode, and lithium foil as both counter and reference electrode. The morphology of electrode washed with DMC and dried in vacuum was observed with scanning electron microscopy (S-3400N(II), Hitachi Limited).

3. Results and discussion

3.1. Thermal properties

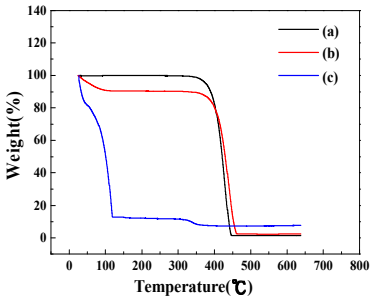

Fig. 1. TGA plots of binary ionic liquid (a), ILs-based electrolyte (b) and of 305 electrolyte (c).

The thermal property of electrolytes is the most important factor for battery safety. Fig. 1 reports the TGA plots of the binary ILs ($PYR_{13}TFSI/PP_{13}TFSI$ (1:1, v/v)), the commercial organic solvent electrolyte (305) and of the ILs-based electrolyte (0.3 M LiTFSI/70 wt%$PYR_{13}TFSI$/ $PP_{13}TFSI$ (1:1, v/v) + 23 wt%EC/DMC (1:1, w/w) + 0.25 wt%LiDFOB). There was almost no weight loss for the binary ionic liquids up to 340 ℃, and less than 0.77 wt% loss was measured at 340 ℃, confirming the high thermal stability of this ILs. In contrast, the weight loss is 17.17% when the 305 electrolyte is heated from 25 to 45 ℃, and 87.3% loss at 120 ℃. When heated from 25 to 120 ℃, ILs-base electrolyte show 9.5% weight losses which is ascribed to the evaporation of organic solvents (EC/DMC), indicating that the evaporation of organic solvents were greedy reduced duo to the intermolecular force among ILs and organic solvents. Another single-step at rather high temperatures of 350–450 ℃, can be attributed to the decomposition of the ILs and the lithium salt (LiTFSI/LiDFOB). This experiment revealed that the high thermal stability of composite electrolyte could be enhanced by adding a certain number of ILs.

3.2. Cyclic voltammetry on Graphite anode

Fig. 2 shows the CV curves of Graphite electrode in 0.3 M LiTFSI/70 wt%$PYR_{13}TFSI/PP_{13}$ TFSI (1:1, v/v) + 23 wt%EC/DMC (1:1, w/w) mixture electrolyte with or without LiDFOB. Fig. 2a show two broad cathodic peak between 0.7 and 0.3 V can be attributed to the intercalation of PP_{13}^+ and PYR_{13}^+ cations into the graphite structure. This process is partially reversible, as there is a small anodic peak detectable at ca. 0.9 V [2]. When LiDFOB was used as an electrolyte additive, the behavior of the graphite electrode was different (Fig. 2b). The irreversible reduction occurred in the

potential region from 1.0 to 0.2 V. In the second and consequent cycles, no electrochemical reduction was visible any more, indicated the irreversible decomposition of LiDFOB in the first cycle and the decomposition is inhibited by the stable interphase film.

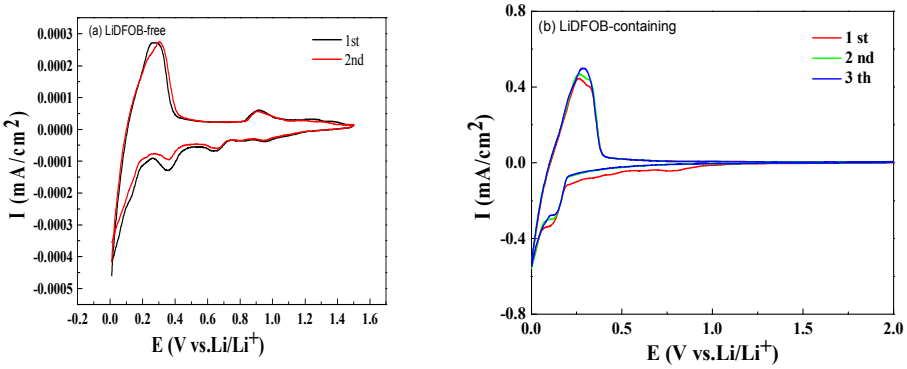

Fig. 2. CV curves of Graphite electrode in two electrolyte. (a) LiDFOB-free and (b) LiDFOB-containing.

3.3. Galvanostatic measurements in Li/Graphite half-cells

The cyclic performances are compared in Fig. 3 for Graphite electrode in 305 electrolyte and 0.3 M LiTFSI/70 wt% $PYR_{13}TFSI/PP_{13}TFSI$ (1:1, v/v) + 23 wt%EC/DMC (1:1, w/w) mixture electrolyte with or without LiDFOB. It is clear from this figure, in the absence of LiDFOB, the cell loses about 38.5% of its initial capacity after 30 cycles. However, in the presence of LiDFOB, the capacity retention was greatly improved to more than 94% after 30 cycles, and the coulombic efficiency is nearly 100%. The results indicate that the addition of LiDFOB to ILs-based electrolyte greatly improves the cyclic stability of the test cells and exhibits excellent performance which can be matched the commercial organic solvent electrolyte (305).

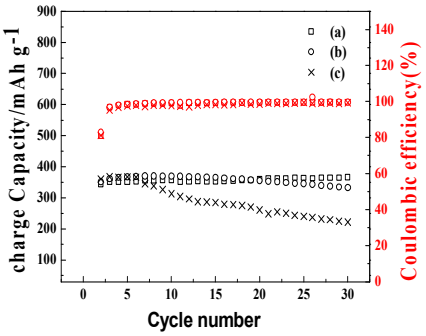

Fig. 3. Cycle performance of Li/Graphite half-cells with three different electrolytes. (a) 305, (b) LiDFOB-containing and (c) LiDFOB-free

3.4 SEM

Fig. 4 shows SEM images of Graphite electrode surfaces after 30 cycles in different electrolytes. The surface morphology of LiDFOB-free electrode is still homogeneous. However, in the present of LiDFOB, the surface of the electrode is covered with the compact film. This show that the addition of LiDFOB can favor stable SEI film to form on the graphite electrode.

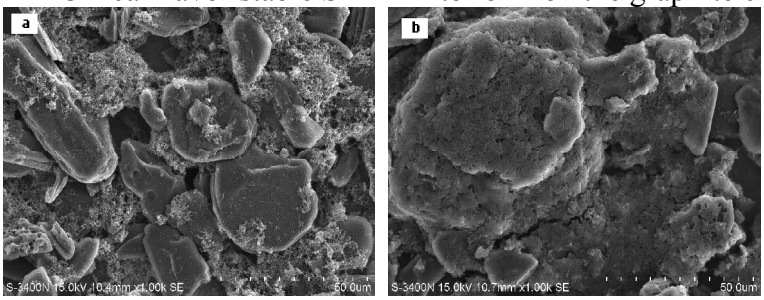

Fig. 4. SEM images of Graphite electrode surface with: (a) LiDFOB-free, (b) LiDFOB-containing mixed electrolytes after 30 cycles.

4. Conclusions

A new electrolyte component was obtained through mixing LiDFOB, $PP_{13}TFSI/PYR_{13}TFSI$ and organic solvents. The results of TGA tests indicate that ILs-based electrolyte exhibits a high thermal stability (up to 340 ℃). Electrochemical measurements demonstrate that the graphite electrode shows good cycling performance in ILs-based electrolyte with LiDFOB. The cell delivers high reversible capacity (332.8 $mAh \cdot g^{-1}$) with coulomb efficiency close to 100% after 30 cycles, due to the addition of LiDFOB can favor stable SEI film to form on the graphite electrode. The film can prevent further co-intercalation and decomposition of PP_{13}^{+} and PYR_{13}^{+} cations. The results suggest that ILs-based electrolytes with LiDFOB could be a promising electrolyte for Graphite anode in terms of high thermal stability and better electrochemical performance.

Keywords: Copper Phthalocyanine film, transfer pressure, Monomolecular Layer.

Abstract. Systematic research on monomolecular layer of symmetrically substituted copper (α) phthalocyanine (CuPc) derivatives bas been done. An attention is focused upon final determination of the transfer pressure in an ordered nano assembly film of CuPc by comparing different methods about surface pressure-area (π-A) isotherm, morphology observation and thickness measurement by transmission electron microscopy (TEM) . The present study and improvement methods provide new insight into the choice of transfer pressure for mono molecule layer .

Introduction

Since phthalocyanine (Pc) derivatives have the possibility of application in many aspects such as photoconductor, semiconductor materials, solar cells, gas-sensors, nonlinear optical material and molecular electronic devices, systematic research on their monomolecular layer, nanometer assembly film was attracted to scientists for the past decade[1-2]. In order to understand copper (Ⅱ) phthalocyanine (CuPc) nanometer assembly films and to design new film structure based on CuPc, it is very important to study the transfer pressure by means of Langmuir-Blogdett (LB) technique. In this paper attention is focused upon the determination of the film transfer pressure of CuPc. The selection of optimum transfer pressure of CuPc by comparing different direct and indirect justing methods such as surface pressure-area (π-A) isotherm, the cross-sectional area difference (ΔA) method （ or Compression-Recompression Isotherms ） , transfer ratios result, surface pressure(π))-TEM thickness isotherm and π-volume (Vol.) isotherm in which is involved in morphology observation and thickness measurement, was investigated .

Experiments and Preparation of the film

To improve properties of the ordered film the symmetrically substituted CuPc were synthesized according to the procedures reported by Snow et al [3] and they are shown as in Table 1. Details of the preparation and characterization were described elsewhere [4]. KSV-5000 Langmuir trough (Finland) with a Wilhelmy balance and domestic LB trough were employed for the π-A measurements and the monomolecular layer fabrication.

Discussions and Determination of the transfer pressure

Generally, a π-A isotherm is used for determination of the collapse pressure and transfer pressure. The π-A isotherm of CuPc[bpsp]4 and CuPc[dtpp]4 is shown as in Fig.1. The traditional collapse pressure is generally considered about 60 mNm^{-1} for CuPc[bpsp]4 , and the choice of transfer pressure of LB film is flexible in the range of 30-50 mNm^{-1}. In experiment we derive following just methods from further analysis and value the collapse pressure and transfer pressure.

Table 1. Schematic structure of symmetrically substituted CuPc

CuPc (-O-  -SO_2-  -OCH_2- )$_4$	⟶ CuPc[bpsp]$_4$
CuPc (-$COOCH_2CH_2OCH_3$)$_4$	⟶ CuPc[mec]$_4$
CuPc (-$COOCH_2CH_2OCH_2CH_2CH_2CH_3$)$_4$	⟶ CuPc[bec]$_4$
CuPc (-O-  -C_5H_{11})$_4$	⟶ CuPc[dtpp]$_4$

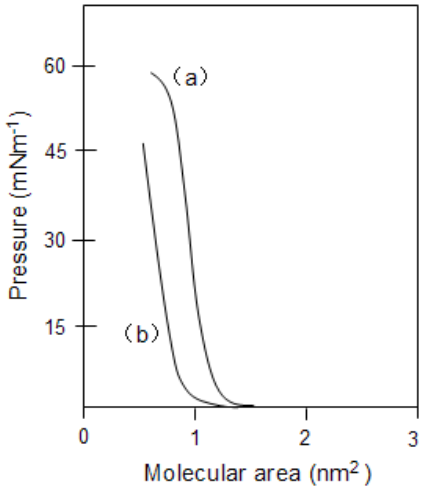

Fig. 1 A normal surface pressure-area (π-A) isotherm of Pc； (a) CuPc[bpsp]4, (b) CuPc[dtpp]4

A cross-sectional area difference (ΔA) method and Transfer ratios

A cross-sectional area difference (Δ A) method, which has relation with hysteresis phenomenon, is to identify the collapse of monolayers at the air-water interface and describe the collapse behavior of monolayer. It can be used to determine a bettter transfer pressure. For examples, two cycle isotherms of CuPc[bpsp]$_4$ were obtained by four sweeps: compression from zero to target pressure--expansion from target pressure to zero-- second compression to target pressure--second expansion to zero pressure, which are shown in Fig. 2. So we can also call it Compression-Recompression Isotherms method. The cross-sectional areas A_f and A_s per molecule at target pressure for first cycle (curve 1) and for second cycle (curve 2) respectively were recorded, and their difference $\Delta A = A_f - A_s$ was calculated. Here "f" stands for the first cycle and "s" for the second cycle. Fig.3 is the bar graph of Δ A versus target pressures. The results show that Δ A is dependent on the target pressure. For target pressures below 40 mNm^{-1}, Δ A is less than 0.01 nm^2 mol^{-1} and almost constant. For target pressure in the range 40-52 mNm^{-1} , Δ A increases gradually. For target pressures higher than 52 mNm^{-1}, A increases drastically. These results indicate that the monolayer structure may have undergone some irrecoverable changes for pressures higher than 40 mNm^{-1}. However, according to the traditional pressure-area isotherm (compression curve of "f" cycle), the Pc monolayer collapses at 52 mNm^{-1} and should be fairly good films in the linear region from 40 mNm^{-1} to 52 mNm^{-1}, We propose that the bar graph of Δ A versus target pressures be more clearly than the traditional pressure-area isotherm in identifying the collapse in this region. This point of view was supported by following transfer ratios results.

Discussion of transfer ratios

As we know, good transfer ratio of the monolayer is the key under the LB film fabrication. Here the measurement of transfer ratio was done and the result shows that it is wrong that the 52 mNm^{-1} in

the first cycle (Fig.1) is considered as the traditional collapse pressure. Transfer ratio of $CuPc[bpsp]_4$ monolayer at different pressures were recorded. The satisfactory transfer ratios are above 0.856 for pressures lower than 30 mNm^{-1}. The transfer ratios is 0.759 for pressures at 40 mNm^{-1} and begin clearly poor. It is because the partial collapse of the monolayer may account for the poor transfer ratios.

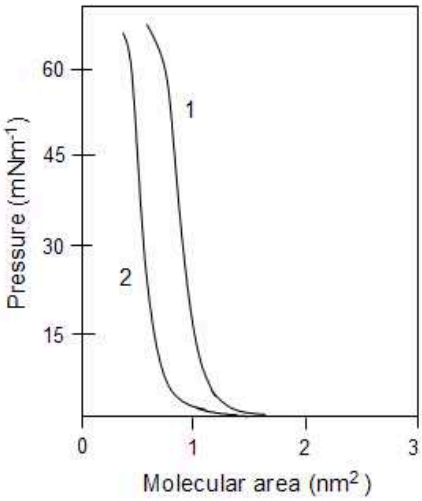

Fig. 2 Two cycle isotherms of $CuPc[bpsp]_4$

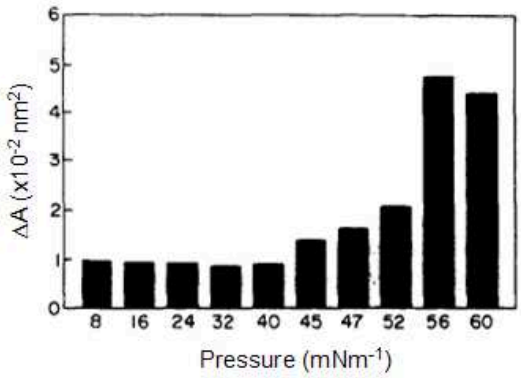

Fig. 3 the bar graph of ΔA versus target pressures for $CuPc[bpsp]_4$

Surface pressure(π)-TEM thickness isotherm and π-Vol. isotherm

The samples for transmission electron microscopy (TEM) were prepared by floating-folding method. Detail of the operation and the thickness measurement was described elsewhere[5-6]. The characterization of CuPc[mec]4, CuPc[bec]4 and CuPc[dtpp]4 in the process of LB film forming has been studied by TEM. Fig. 4 exhibits the relationship curves between surface pressure and monolayer thickness from the TEM measurement. The measured thickness of a monolayer is rather thinner at 10 mNm^{-1} surface pressure and the thickness at 35 mNm^{-1} is far greater than that of low surface pressure in Fig.4. The probable reason is no evident border between the adjacent molecules and between monolayers; that is, some molecules in the monolayer present protrusions and there are multilayer forming at the air-water interface. The molecules on the interlayer present a certain cross-arrangement. Any way, we can conclude the best deposited pressure should be below 25 mNm^{-1} rather than above 25 mNm^{-1} like the traditional transfer pressure from π-A isotherm. This conclusion is agreement with following statement derived from the pioneer work[7-8]. The surface morphology of the LB films obtained at 5, 10, 20, 25 and 35 mNm^{-1} demonstrated that the CuPc film deposited at 5 mNm^{-1} pressure are not composed of domains of a certain size. This is reflected at a low surface pressure, e.g. 10 mNm^{-1} , the floating monolayer is in an expanded 'liquid' phase, and the molecular interval is larger. It is obvious that the surface morphology is not homogeneous, fine and close enough. The CuPc film deposited at 20~25 mNm^{-1} pressure is composed of domains of a certain size which is about 70 nm, possessed a homogeneous surface morphology and is considered as the best molecular arrangement. The CuPc films deposited at 35 mNm^{-1}appears striped protrusions, which apparently is the late collapse condition. Fig. 4 shows that it is wrong that generally the 35 mNm^{-1} is thought the traditional collapse pressure for CuPc[mec]4 , because the pressure 25 mNm^{-1} is turning-point of the change in which collapse of the monolayer begin.

Combined Fig.4 and Fig. 5 (π-A isotherm), another easy figure may be drawn and it can exhibit a relationship of the volume(Vol.) occupied per molecule and the surface pressure (π-Vol. isotherm). It will show that the molecular arrangement is loosely dispersive at a low pressure. The molecules arrange tidiness and the volume occupied per molecule become smaller little by little while the pressure of film is increased.

In addition, CuPc[mec]4 arrangement in LB film is easier to begin collapsing than CuPc[bec]4 , as shown in Fig.4. We can explain as following. Through these two CuPc have the same ether bond (R.O.R), which is of a certain flex, the CuPc[mec]4 's chain is shorter than CuPc[bec]4 's, so the former's ability of tangle, lengthening and shortening is smaller. Of course , the reaction of intermolecule is also smaller than that of CuPc[bec]4 . All above make a part of the CuPc[mec]4 protrusive from the monolayer easily. Hence, CuPc[mec]4 ' s turning point is sharp apparently.

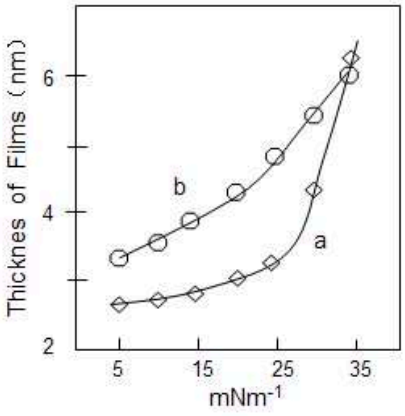

Fig. 4 The relationship of thickness and surface pressure; curve a- CuPc[mec]4, curve b-CuPc[bec]4.

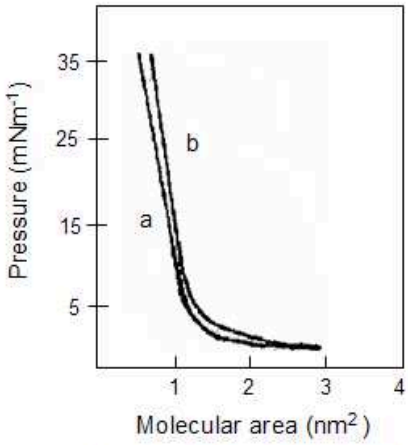

Fig. 5 π-A isotherm of the CuPc on water. curve a- CuPc[mec]4, curve b-CuPc[bec]4

Above results and conclusions were also obtained for samples of other symmetrically and asymmetrically substituted CuPc—CuPc[dtpp]$_4$ and CuPc-n[dtpp]$_3$, et al.

Keywords: Optical constants, Reflectance spectrum, Transmission spectrum, Ga_2O_3 film

Abstract: Transmission spectrum and reflectance spectrum have long been used to characterize gap semiconductor. Transmission spectrum can be measured very directly, but the influence of substrate absorption is often unavoidable. However, when using the reflectance spectrum measurement, the absorption of thin film, substrate absorption, and coherent interference will make the reflectance spectrum much more complicated. In this paper, Considering the absorption of thin film, substrate absorption, and coherent interference, we use the envelope curves algorithm to achieve the calculation formula of refractive index deduced from the reflectance spectrum. Through the analysis of the reflectance spectrum of Ga_2O_3 film, we achieved thickness of the film, refractive index, extinction and absorption coefficient and dispersion constant.

Introduction

β-Ga_2O_3 exhibits the largest band gap among transparent conductive oxides(TCOs), about 4.8 eV[1]. The research value of wide-band gap semiconductor gallium oxide is growing, how to obtain the optical constants of its thin film easily and accurately is of great significance to its production and application.

For decades, there have been many methods for the determination of optical constants and thickness of thin film. For example, Abeles[2], Thickness interferometry[3], Elliptic polarization measurement method[4], Heterodyne interferometry[5], Phase shifting interferometry[6], Photometric method[7], Reflection spectroscopy[8,9], Transmission spectra method[10], Prism coupling method and so on. However, today the most common approach is spectral analysis. Spectral analysis can provide precision measurement of thickness and refraction of thin film, which is based on the reflectance or transmission spectrum of thin film.

Experimental procedures

1)Experimental details: Gallium oxide (Ga_2O_3) thin films were deposited on Si substrates by radio-frequency magnetron sputtering. The conditions are as follows: the substrate temperature is 750℃; vacuum degree of growth chamber is 9×10^{-5} Pa; sputtering time is two hours. The samples are annealed in oxygen or nitrogen for 1 hour at 900℃. Label the six groups samples with F01, F02, F03(The corresponding proportion of argon and oxygen is 2: 1, 3: 1, 4: 1 respectively, annealing in oxygen) and F11, F12, F13(The corresponding proportion of argon and oxygen is 2: 1, 3: 1, 4: 1 respectively, annealing in nitrogen).

2)Determination of the optical constants of Gallium oxide films

Theoretical model. As show in Fig. 1, consider a thin film with an average thickness d, and a complex refractive index $\tilde{n}_2 = n_2 - jk_2$. The thin film is on an absorbing substrate with a complex refractive index $\tilde{n}_3 = n_3 - jk_3$. The film-substrate system is immersed in air with refractive index n_1=1. The complex amplitude of reflection of reflection from the film-substrate system can be expressed as[11,12]:

$$r = \frac{E_{0r}}{E_{0i}} = \frac{r_{12} + r_{23}e^{-i\delta}}{1 + r_{12}r_{23}e^{-i\delta}} \tag{1}$$

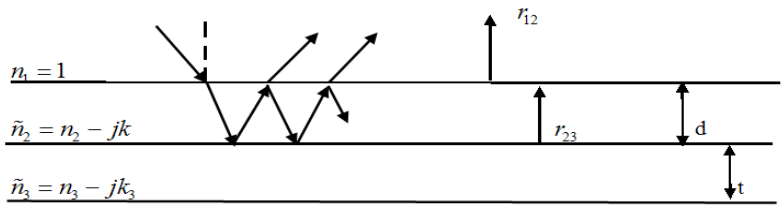

Fig. 1 Reflection on the thin film

Where $\delta = 2\pi\Delta/\lambda = 4\pi\tilde{n}_2 d/\lambda$ is the phase difference term inside the film. r_{12}, r_{23} are the reflectance amplitudes at the interfaces between air-film, and film-substrate.

$$r_{12} = \frac{(\tilde{n}_1 - \tilde{n}_2)}{(\tilde{n}_1 + \tilde{n}_2)} = \frac{1-(n_2 - jk_2)}{1+(n_2 - jk_2)} \tag{2}$$

$$r_{23} = \frac{(\tilde{n}_2 - \tilde{n}_3)}{(\tilde{n}_2 + \tilde{n}_3)} = \frac{(n_2 - jk_2)-(n_3 - jk_3)}{(n_2 - jk_2)+(n_2 - jk_3)} \tag{3}$$

The magnitudes that we can effectively measure are the reflectance R=r r*(r* is the complex conjugate of r). We have, from Eqs.(1) , Eqs.(2) and Eqs.(3),

$$R = \left|\frac{E_{0r}}{E_{0i}}\right|^2 = rr* = \frac{r_{12}^{\ 2} + \alpha^2 + 2r_{12}\alpha\cos(\delta + \phi_{12} - \phi_{23})}{1 + r_{12}^{\ 2}\alpha^2 + 2r_{12}\alpha\cos(\delta - \phi_{12} - \phi_{23})} \tag{4}$$

$\alpha = r_{23}e^{(-4\pi k_2 d/\lambda)}$, $\delta = 4\pi n_2 d/\lambda$, $\phi_{12} = \arctan(\frac{2k_2}{1 - n_2^{\ 2} - k_2^{\ 2}})$, $\phi_{23} = \arctan(\frac{2(n_2 k_3 - n_3 k_2)}{n_2^{\ 2} - n_3^{\ 2} + k_2^{\ 2} - k_3^{\ 2}})$

The condition of maximum or minimum reflectance is $\cos(\delta \pm \phi_{12} - \phi_{23}) = 1$ (5)

Substituting from Eq.(5) in Eq.(4) we get the upper envelope (lower envelope) for maximum (minimum) reflectance R_{max} (R_{min}) such that:

$$R_{max} = \frac{(r_{12} + \alpha)^2}{(1 + r_{12}\alpha)^2} \tag{6}$$

$$R_{min} = \frac{(r_{12} - \alpha)^2}{(1 - r_{12}\alpha)^2} \tag{7}$$

When the thin film absorption is small, namely $\alpha > r_{12}$, from Eqs.(6), (7), [13]

$$r_{12} = \frac{1 - \sqrt{R_{max}R_{min}} - \sqrt{(\sqrt{R_{max}R_{min}} - 1)^2 - (\sqrt{R_{max}} - \sqrt{R_{min}})^2}}{(\sqrt{R_{max}} - \sqrt{R_{min}})} \tag{8}$$

$$\alpha = \frac{1 + \sqrt{R_{max}R_{min}} - \sqrt{(\sqrt{R_{max}R_{min}} + 1)^2 - (\sqrt{R_{max}} + \sqrt{R_{min}})^2}}{(\sqrt{R_{max}} + \sqrt{R_{min}})} \tag{9}$$

Optical constants. Determination of approximate values for the films index

In this paper the absorption of Gallium oxide thin films is small, Therefore, according to the Eqs.(2) and Eqs. (8) we can calculate the refractive index of a thin film. The test results of reflection spectrum of Ga_2O_3 film is showed in Fig. 2.

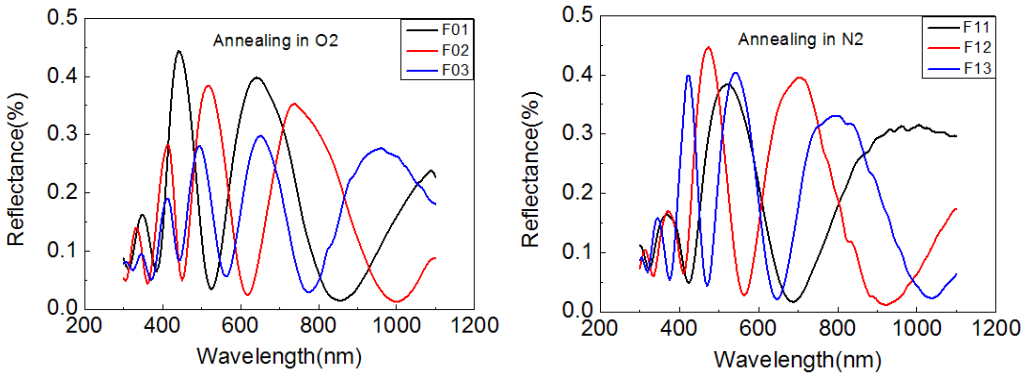

Fig. 2 Measured reflection spectrum for Ga_2O_3 film on Si (111) substrate

Put k_2=0 in Eq. (2) and solving for n_2 to get an approximate initial value for the film refractive index n_{20}: $n_{20} \approx \frac{1+r_{12}}{1-r_{12}}$ $(n_2 > 1)$ (10)

Determination of the film thickness

Using the above-obtained approximate values of n_{20} from Eq.(10), the interference order P can be determined as follows:

$$d_0 = \frac{\lambda_1 \lambda_2}{4(n_2\lambda_1 - n_1\lambda_2)} \tag{11}$$

Film thickness can be given by Eq.(11), where n_1 and n_2 are the refractive index at two adjacent extreme point at λ_1 and λ_2. Using the above-obtained approximate values of n_{20} with the values of $\overline{d}_0$ to get P for each extreme wavelength from the equation:

$$2nd = P\lambda \tag{12}$$

P is rounded to the nearest integer or half-integer. The value of the film thickness(d) is calculated from Eq.(12) for each extreme wavelength. Then the average final value of $\overline{d}$ is calculated for all wavelengths. The film refractive index n is also calculated from Eq.(12) for each wavelength using the obtained values of P and $\overline{d}$.

Determination of the extinction coefficient and absorption coefficient

r_{23} can be determined using Eq.(13) after calculating the real and imaginary parts of the refractive index for the Si substrate alone (n_3, k_3) from its reflectance and transmittance spectra using the method reported in reference[14].

$$r_{23} = [\frac{(n_3 - n_2)^2 + (k_3 - k_2)^2}{(n_2 + n_3)^2 + (k_2 + k_3)^2}]^2 \tag{13}$$

The extinction coefficient(k_2) and absorption coefficient(α_2) of the film can be determined as follows:

$$\ln(\alpha) = -\frac{4\pi k_2 d}{\lambda} + \ln(r_{23}) \quad (\text{where } \alpha_2 = \frac{4\pi k_2}{\lambda} = -\frac{1}{d}\ln(\frac{\alpha}{r_{23}})) \tag{14}$$

Table 1 shows the results of F03, it is obvious that the average approximated film thickness $\overline{d}_0$ is (1287.6±3053)nm(237.1%), while the average final thickness $\overline{d}$ is (1265.9±42.1)nm(3.32%).

Result and discussion

Fig.3 shows the refractive index of the six groups samples between 300nm and 1100nm wavelength range, which is close to the refractive index reported[15,16]. In near ultraviolet band(≤400nm), refractive index increases as increasing the wavelength; In visible light region, refractive index first increased and then decreased as increasing the wavelength; In near infrared region (700nm-1100nm), refractive index towards stability. The calculation results of extinction coefficient k_2 is showed in Fig.4, in 300nm-1100nm band Ga_2O_3 film has low light absorption.

Optical energy band gap Eg can not only give the basic absorption edge of film material, but also reflect the energy band structure of film. Band gap and absorption

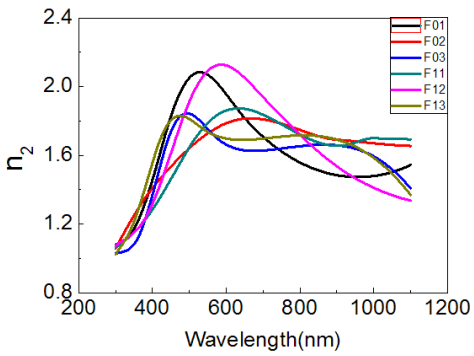

Fig. 3 Refractive index(n)

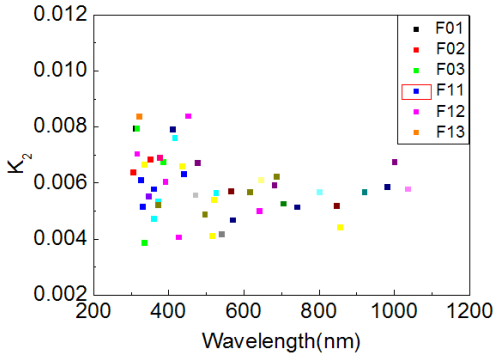

Fig. 4 Extinction co-efficient (k) spectra

coefficient have the following relations[17]: $\alpha hv=A(hv-E_g)^{1/2}$, so energy band gap Eg can be obtained by the relationship diagram $(\alpha hv)^2$ between and hv. Fig.5(left) is the relationship diagram $(\alpha hv)^2$ between and hv, which shows a steep absorption edge in the ultraviolet region.

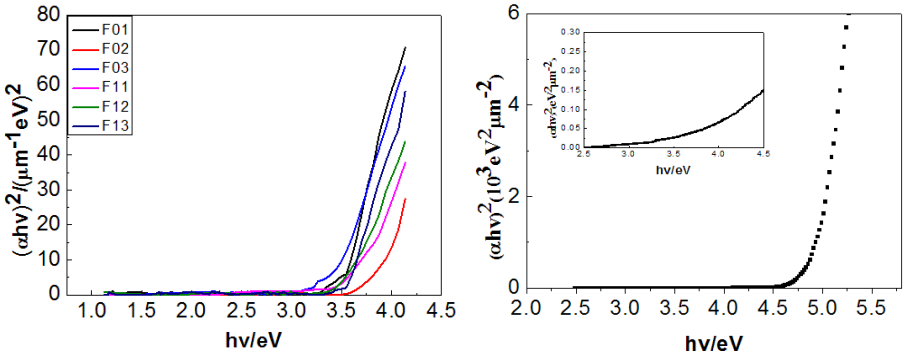

Fig. 5 $(\alpha hv)^2$ versus hv spectrum for the Gallium oxide films on Si (111) substrate

Thin film materials under different generating conditions have different absorption edge. As we can see from Table 2, when the ratio between argon and oxygen is 3:1, absorption edge is minimum, other proportions will appear a certain redshift. Fig.5(right) is the energy band gap diagram (inset in Fig.5(right) is magnification) which is consistent with the experimental data. As we didn't measure the reflectance spectrum in 200nm-300nm band range, so we can not get energy band gap Eg according to Fig.5(left).

Under different conditions, the optical constants and their limit errors were obtained using the method described in this paper. We can see from Table 2 that when the ratio between argon and oxygen is 3:1, the optical performances of film samples are best.

Table 2 Optical constants of Gallium oxide films

Conclusions

Gallium oxide films were synthesized on silicon substrate by magnetron sputtering. According to the reflectance spectrum, adopting the method described in this article, we calculated the refractive index, extinction coefficient, thickness and energy band gap of Ga_2O_3 film samples fairly accurately in 300nm-1100nm band. By the results of the energy band gap, we know that by adjusting growth conditions of films can realize the control of energy band gap, which is the prerequisite for preparing optoelectronic devices. Our work is useful for continued perfection of characterizing optical properties and guiding the preparation and application of Ga_2O_3 films.

Keywords: ZnS films; different radios; optical properties; structure; chemical bath deposition.

Abstract. ZnS thin films were deposited at three different radios of $V(NH_3 \cdot H_2O)/V(N_2H_4)$ on glass substrates by chemical bath deposition (CBD) method without stirring the deposition bath during the deposition process. The structural and optical properties were analyzed by X-ray diffraction (XRD) and UV-VIS spectrophotometer. The results showed that ZnS thin film deposited at the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:15 is higher than that of the other two different solutions. With the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$ decreasing from 15:5 to 15:15, homogenous precipitation of $Zn(OH)_2$ easily forms in the bath, but ZnS precipitation first become suppressed and then easily forms in solution. It means that the concentration of OH^- ion increases with the volume of N_2H_4 increasing, which accelerates the formation of $Zn(OH)_2$. However, when the volume of N_2H_4 increases to 15mL, relatively high concentration of OH^- ion not only accelerates the formation of $Zn(OH)_2$, but also be used to the hydrolysis of thiourea. The average transmissions of all the ZnS films from three different solutions ($V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:5, 15:10 and 15:15) are greater than 90% for wavelength values in visible region. The direct band gaps range from 3.80 to 4.0eV. The ZnS film deposited for 2.5h with the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:15 has the cubic structure only after single deposition.

Introduction

ZnS is a wide, direct band gap, Ⅱ-Ⅵ semiconductor and because of its good transmittance in visible range [1], ZnS materials have been widely used in photoelectric and solar cells area. Various techniques have been employed to prepare ZnS thin films, such as molecular beam epitaxy (MBE) [2], sputtering [3], and chemical bath deposition (CBD) [4-7] and so on. Among these methods, the CBD technique is actually the principal method used in buffer layers deposition of $Cu(In, Ga)Se_2$ (CIGS) solar cells[8] and has demonstrated be the most suitable method for depositing uniform and adherent thin films in a large area.

In recent years, CBD have attracted more and more interest because it does not require vacuum system and other expensive equipments; the low temperature required in CBD process avoids oxidation and corrosion of metallic substrates, furthermore a chemical etching of the surface of the absorber can be done during the CBD process [9]. Over the past two decades, almost all research groups focused on the reaction mechanisms, new complexing agents and different reaction systems. However, few literatures discussed the effect of different radios of two or more complexes on structural and optical properties of ZnS films. In this paper, ZnS thin films had been deposited by CBD method onto glass substrates in alkaline liquor with $NH_3 \cdot H_2O$-N_2H_4 system. The different volume radios of two complexes ($V(NH_3 \cdot H_2O)/V(N_2H_4)$) on optical and structural properties of ZnS thin films were discussed.

Experimental. The concentrations of reactants and the volume radios of $V(NH_3 \cdot H_2O)/V(N_2H_4)$ were given in Table 1. The ZnS thin films were grown on commercial glass substrates ($76 \times 25 \times 1 mm^3$) which were consecutively ultrasonically cleaned with detergent, degreased with acetone, followed by ethanol, and then washed by distilled water. A calculated amount of reagent was added to the deionized water for a final solution of 150mL in a beaker. The cleaned glass slides were immersed vertically in the deposition bath. The bath solutions were maintained at 80℃ for 2 hours or 2.5 hours.

After the deposition, the glass substrates were taken out of the beaker, washed with deionized water and dried with hairdryer.

Table 1 The concentrations (M) of reactants and the volume radios of $V(NH_3 \cdot H_2O)/V(N_2H_4)$

	$Zn(CH_3COO)_2$	$SC(NH_2)_2$	$V(NH_3 \cdot H_2O) : V(N_2H_4)$
Solution A	0.050	0.070	15 : 5
Solution B	0.050	0.070	15 : 10
Solution C	0.050	0.070	15 : 15

Results and discussion. The thicknesses of the ZnS films deposited for 2h and 2.5h were given in Table 2. It is clear from the Table 2 that the ZnS films from solution C were thicker than that from the other solutions with the same deposition time. This result indicates that with the decrease of the volume radios of $V(NH_3 \cdot H_2O)/V(N_2H_4)$, the growth rate of ZnS films increases, in other words, the increasing of the amount of N_2H_4 promotes the formation of heterogeneous ZnS thin films.

Table 2 The thicknesses (nm) of the ZnS films deposited for 2h and 2.5h from different solutions

	Deposited for 2 h	Deposited for 2.5 h
Solution A	76	88
Solution B	71	82
Solution C	80	91

As can be seen from the Fig.1, all the transmissions of ZnS films deposited for 2h and 2.5h from three different solutions were over 90% in visible range. It is noteworthy that the transmittances of ZnS films have shifted towards long wavelengths with the increase of the volume of N_2H_4.

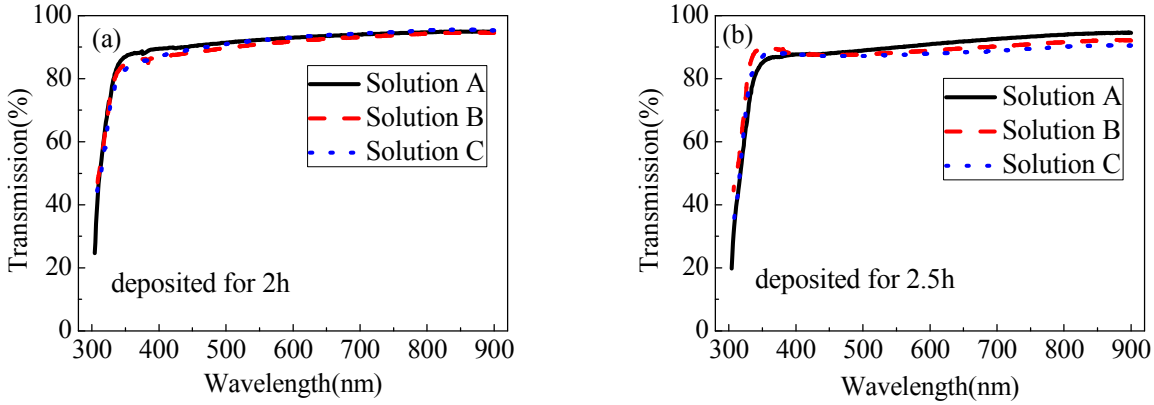

Fig.1 Transmission spectra of ZnS films deposited for different deposition time: (a) deposited for 2h; (b) deposited for 2.5h

For obtaining the optical band gap values of the film, the absorption coefficient (α), which was calculated from the transmittance, was analyzed. From the Beer-Lambert law, we could get the function of absorption coefficient and transmittance as follows: $\alpha = -\ln T/d$ where d is the thickness of the ZnS film. Then, α is used to obtain the following expression for near-edge optical absorption of semiconductors: $(\alpha h\nu)^2 = A(h\nu - E_g)$ where A is a constant, E_g is the separation between the valence and conduction bands. By this equation, the band gap value is determined from the intercept of the straight-line portion of the $(\alpha h\nu)^2$ against the graph on the $h\nu$-axis. Fig.2 shows the plot of $(\alpha h\nu)^2$ versus the incident radiation energy $h\nu$ (eV). The band-gap values of all films are higher than that of bulk ZnS (3.7eV) [10], ranging from 3.8eV to 4.0eV. The E_g values are large and have obviously shifted towards shorter wavelengths due to the quantum size effect of confinement of electrons. It is noteworthy that with the decreasing of the radios of $V(NH_3 \cdot H_2O)/V(N_2H_4)$, band gaps of ZnS thin film first decreased and then increased. This result indicates that when the volume of N_2H_4 increases from 5mL to 10mL, the grain growth of thin film becomes easy, which results in E_g decrease. However, when the volume of N_2H_4 increases to 15mL, the higher concentration of N_2H_4 increases the number of nucleation points on the substrate and decreases the single grain growth rate.

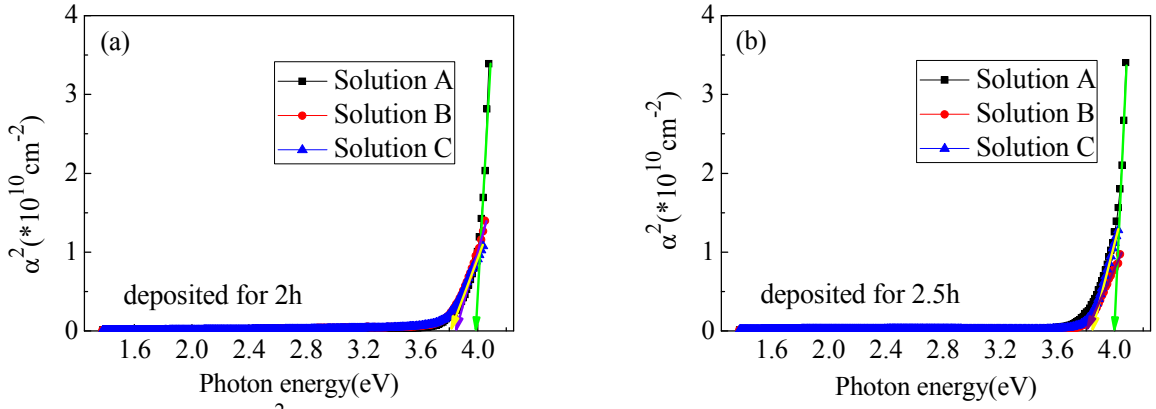

Fig.2 The plots of $(\alpha h\nu)^2$ versus hν of ZnS films deposited for different deposition time: (a) deposited for 2h; (b) deposited for 2.5h

Fig.3(a) shows the XRD patterns of ZnS films deposited for 2.5h from three different solutions. As is showed in Fig.3 (a), the ZnS thin film from solution C has one significant peak at about 2θ=29.16° which can be assigned to the (111) reflection of the sphalerite structure, while the ZnS thin films from the other two solutions have no obvious peaks. It means that the crystallinity of ZnS thin film is improved when the volume of N_2H_4 increases to 15mL, this probably because the ZnS film from solution C is thicker than that from the other two solutions, which agrees well with the figures in Table 2. Fig.3(b) shows the XRD patterns of homogeneous precipitations deposited for 2.5h from three different solutions. As can be seen from the Fig.3(b), the homogeneous precipitations deposited for 2.5h from three different solutions consist of ZnS and $Zn(OH)_2$. With the increase of the volume of N_2H_4, the $Zn(OH)_2$ peaks intensity increases, but the cubic ZnS peaks intensity of (111), (220) and (311) first decreases, and then increases. It means that when the volume of N_2H_4 increases from 5mL to 10mL, the concentration of OH^- ion increases, which accelerates the formation of $Zn(OH)_2$. However, when the volume of N_2H_4 increases to 15mL, relatively high concentration of OH^- ion not only accelerates the formation of $Zn(OH)_2$, but also be used to the hydrolysis of thiourea.

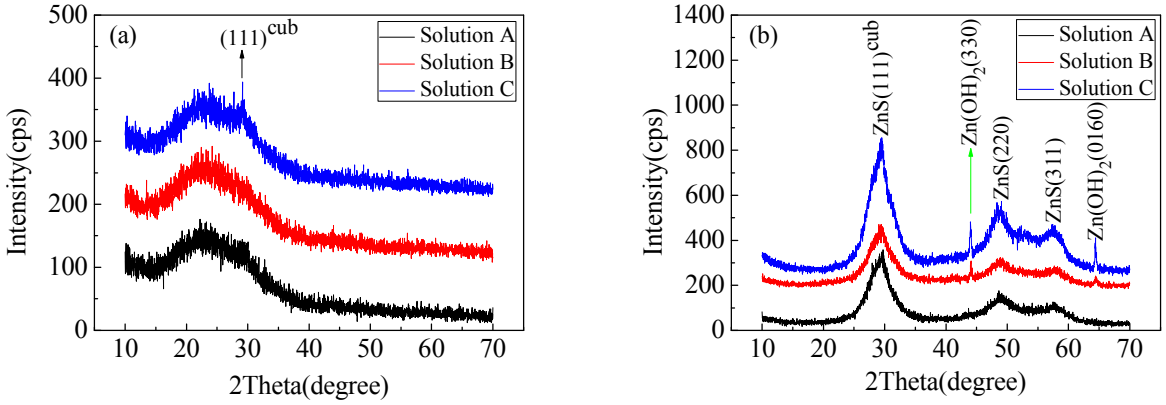

Fig.3 XRD spectrum of the samples deposited for 2.5h from three different solutions and XRD of homogenous precipitations (2.5h) collected from the reaction bath: (a) ZnS thin films; (b) homogenous precipitations

Summary

Comparing with those deposited at the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:5 and 15:10, the growth rate of ZnS thin film deposited at the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:15 is highest. With the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$ decreasing from 15:5 to 15:15, homogenous precipitation of $Zn(OH)_2$ easily forms in the bath, but ZnS precipitation first become suppressed and then easily forms in solution. It means that the concentration of OH^- ion increases with the volume of N_2H_4 increasing, which accelerates the formation of $Zn(OH)_2$. However, when the volume of N_2H_4 increases to 15mL, relatively high concentration of OH^- ion not only accelerates the formation of $Zn(OH)_2$, but also be

used to the hydrolysis of thiourea. The average transmissions of all the ZnS films from three different solutions ($V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:5, 15:10 and 15:15) are greater than 90% for wavelength values in visible region. The direct band gap energy varies from 3.80 to 4.0eV. XRD results show that ZnS film with low thickness deposited for 2.5h at the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:15 has the cubic structure only after single deposition, while the ZnS films deposited for 2.5h at the radio of $V(NH_3 \cdot H_2O)/V(N_2H_4)$=15:5 and 15:10 are amorphous.

Effect of the concentrations of the reactants on electrochemical performance of composite cathode material $LiFePO_4$/C

Xiaoling Ma , Youxiang Zhang

College of Life Science and Chemistry, Wuhan Donghu University,
Wuhan, 430212,China
Email address: 240200025@qq.com

Keywords: cathode material, lithium-ion batteries, $LiFePO_4$/C, concentration.

Abstract: $FePO_4 \cdot 2H_2O$ nanoplates are synthesized by a hydrothermal method, using Fe(III) compound as the iron source and are lithiated to $LiFePO_4$/C by a simple rheological phase mathod. The structure, morphology and electrochemical properties of the $FePO_4 \cdot 2H_2O$ nanoplates and $LiFePO_4$/C composites synthesized by changing the concentration of the reactants were characterized in detail by X-ray(XRD), scanning electron microscope(SEM), high-resolution transmission electron microscope and electrochemical measurement. The $LiFePO_4$/C nanoparticles lithiated from the $FePO_4 \cdot 2H_2O$ nanoplates when there were about 10 mmol Fe^{3+} in 20 ml water solution demonstrates excellent cyclic performance.

Introduction

With high capacity and power, lithium-ion battery has been considered to be one of the beat energy conversion and storage systems [1-2]. The $LiFePO_4$ is an attractive electrode material for the rechargeable lithium-ion batteries due to nontoxicity, environmental friendliness, and low cost. Although $LiFePO_4$ possesses many advantages, it has suffered from poor electronic conductivity and Li-ion diffusion coefficient. To overcome the problem, the $LiFePO_4$ particles are reduced to the nanometre scale to shorten the diffusion length for electrons and lithium ions and increase the effective reaction areas[3].

Herein, we synthesized nanscale $FePO_4 \cdot 2H_2O$ using a hydrothermal method and are lithiated to $LiFePO_4$/C with the same structures by a simple rheological phase method. The $LiFePO_4$/C nanoparticles show excellent electrochemical performance and long-term cyclability as the cathode in lithium-ion battery, with the specific capacities 151mAh/g.

Experimental

The $FePO_4 \cdot 2H_2O$ were synthesized using the same formulas as literature [4]. $FeCl_3$ was dissolved in water to give a 0.05mol/L Fe^{3+} precursor as sample FP-1 and $FeCl_3$ was dissolved in water to give a 0.50mol/L Fe^{3+} precursor as sample FP-2 . In a typical synthesis, The CTAB surfactant was added to distilled water and stirred for 30 min. Then, $FeCl_3$ was added and stirred. After that, H_3PO_4 was dropped to the solution and stirred. Then the solution was aged for 24h in waterbath and dried at 100℃ for 4h.

A simple rheological phase method was employed to synthesize $LiFePO_4$/C composite[5]. The $FePO_4 \cdot 2H_2O$ nanoplates, $LiOH \cdot H_2O$, PEG and appropriate amount of water were mixed, then ground for several to get a rheological. After several time, the rheological body was calcined at 600℃, and then the $LiFePO_4$/C composite was obtained. The composite LFP-1 was using the sample FP-1 precursor as sources for both the Fe and P in the materials. The composite LFP-2 was using the sample FP-2 precursor as sources for both the Fe and P in the materials.

The phase purity of the products was examined by powder X-Ray Diffraction on a Bruker D8 Advance X-ray diffractometer using Cu Kα radiation (λ = 1.54056 Å). The crystal size and morphology of the products were examined with a scanning electron microscope(SEM, QUANTA 200, Holland).

Electrochemical measurements were carried out using two-electrode cells with lithium metal as the counter electrode. The working electrode was fabricated by compressing a mixture of the

$LiFePO_4$/C composite/acetylene black/polyvinylidene fluoride (PVdF) with a weight ratio 65/30/5. The weight of active materials varied between 2.0 and 3.0 mg. The electrolyte was a 1 M $LiPF_6$ in a 1:1 mixture of ethylene carbonate (EC)/diethyl carbonate (DEC) and the separator was Celgard 2500. The cell was assembled in a glove box filled with high purity argon gas. The galvanostatic charge/discharge experiment was performed between 2.0 and 4.4 V at 1C current density with each experiment repeated at least 5 times. The experiments produced reproducible results.

Results and Discussion

The X-ray diffraction (XRD) results for the $LiFePO_4$/C are presented in Figure 1. The diffraction peaks are in good agreement with the standard values for $LiFePO_4$ (JCPDS 81-1173), which shows the high-purity of the as-synthesized samples.

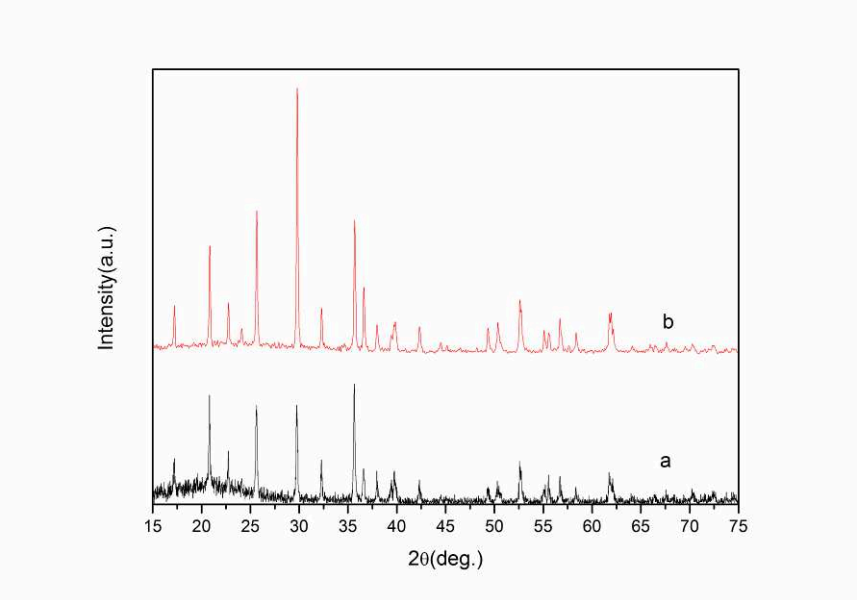

Fig. 1 XRD patterns of the as-synthesized $LiFePO_4$/C. (a) LFP-1 (b)LFP-2

Figure 2 shows the scanning electron microscope (SEM) image of the as-synthesized $LiFePO_4$/C. The nanoparticles are of morphology with very small sizes (30~ 80nm). The measurement is in agreement with the crystallite size deduced from XRD analysis.

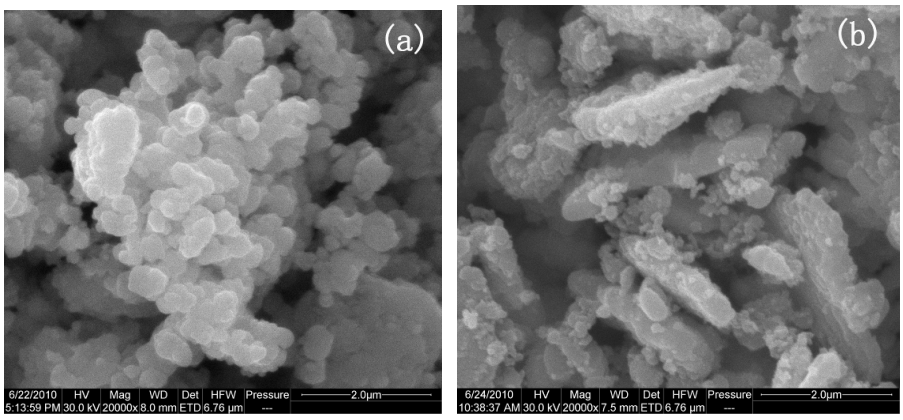

Fig. 2 SEM images of the as-synthesized $LiFePO_4$/C. (a) LFP-1 (b) LFP-2

The discharge-charge cycling of the $LiFePO_4$/C was carried out in the voltage window 2.0 and 4.4 V (vs. Li^+/Li) at a current density of 1C at room temperature. The LFP-1 sample delivers a discharge capacity of 151.3 $mAh \cdot g^{-1}$ and The LFP-2 sample delivers a discharge capacity of 131.5

$mAh \cdot g^{-1}$. Fig. 4 demonstrate that the $LiFePO_4/C$ also exhibit an excellent cycling performance. While the discharge specific capacity of the LFP-1 sample can stabilize at about150 $mAh \cdot g^{-1}$, the discharge specific capacity of the LFP-1 sample can stabilize at about130 $mAh \cdot g^{-1}$ at this current density of 1C.

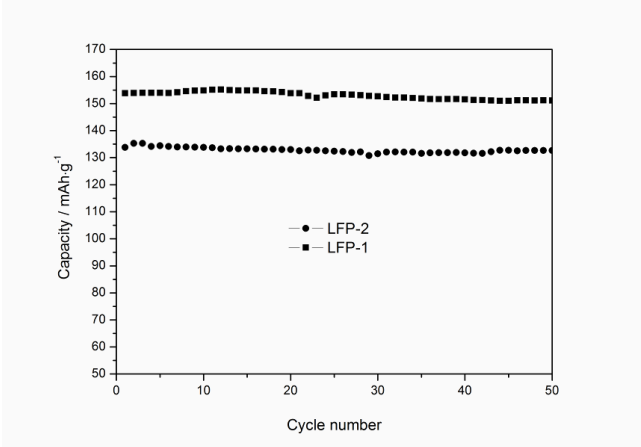

Fig. 4 The discharge capacities of the as-synthesized $LiFePO_4/C$ for the first 50 cycles.

Conclusions

In summary, nanscale $FePO_4 \cdot 2H_2O$ are synthesized using a hydrothermal method and lithiated to $LiFePO_4/C$ by a simple rheological phase method. The sample can deliver a better discharge capacity by changing the concentrations of the reactants. When $FeCl_3$ was dissolved in water to give a 0.05mol/L Fe^{3+} precursor as sample can deliver a better discharge capacity of 151.3 $mAh \cdot g^{-1}$. The nanoscale $LiFePO_4/C$ show excellent electrochemical performance and long-term cyclability.

Keywords: HTV-silicon rubber; humidity ; UV radiation; aging; FTIR;

Abstract. Along with our country " west-east electricity transmission " project and UHV projects,HTV-silicon rubber has been more and more widely used in the western regions of China,such as xining, Lhasa, hami and other regions, has strong solar radiation, long sunshine time, but the region environment humidity conditions are different. Therefore, it is necessary to study the Effect of UV Radiation on HTV-Silicon Rubber under different humidity. In this paper, the extraction of relative humidity variable, under different humidity conditions,HTV silicone rubber material taken for artificial ultraviolet aging experiment, to explore under different humidity conditions,HTV silicone rubber material's ultraviolet aging properties. Experimental samples of artificial ultraviolet aging experiment taken in static contact angle test, hardness test, fourier transform infrared spectroscopy (FTIR) analysis, then integrate the test data and make theoretical analysis.The experimental results show that both samples hardness are larger, the flexibility are reduced; their both surface static contact angle are decreased, the hydrophobic are part of the loss; their both surface roughness are bigger,and a part of filler is leaked; FTIR of peak area of Si-CH_3 and Si-O-Si keys absorption peak are reduced, shows a portion of the Si-CH_3 and Si-O-Si keys is interrupted into free radicals; UV radiation has a certain influnce on HTV silicone rubber.Humidity variable has two contray sides influence on ultraviolet aging characteristics of HTV silicone rubber material,its process is complicated.

Introduction

Compared with ceramic and glass insulators, HTV-silicon rubber composite insulator has strong resistance ability of pollution flashover, light weight, easy maintenance, etc. Therefore it has been widely used in electric power system [1–3] .In these strong UV radiation region, humidity is different, moisture variables influence on UV aging characteristic of composite insulation materials also has not been studied.In the western region of China, the UV radiation strong, composite insulator aging problem is more not allow to ignore.

Experiment

A. Experimental setup

The average annual sunshine of strong ultraviolet region amount in more than 2500h, but the relative humidity conditions vary widely, such as kunming average relative humidity is 74%, Lhasa dry season average humidity is only 15%. Soset up relative humidity variable two extreme cases are 5% and 80% respectively. Two groups of experiment is carried out .HTV silicone rubber are performed for irradiation ageing. the experiment are for 1000h respectively.1000h later the radiation is about 2015 ~ 3149 MJ/m^2 ,is equivalent to 7 ~ 11 months ultraviolet radiation in strong ultraviolet area.

B. Sample preparation

Take HTV silicone rubber materials cut into 50 mmx50mmx2mm (length x width x thickness) size, each experiment of the samples is 10 pieces, according to the preprocessing of DL/T 810-2002 [10] .

C.Test equipment and measuring instrument

Experiment equipment adopts Beijing Lihui company production of SN-66 xenon lamp aging box.Measuring instrument uses the American kono industrial company in the production of SL200A/B type contact Angle measuring instrument and the analysis software to do the sample surface hydrophobic measurement is shown in Fig.1.This paper adopts the ThermoFisher scientific company in production of Nicolet Is5 type Fourier transform infrared spectrometer, application of total reflection accessories, spectrometer is shown in Fig.2.

Fig.1 Contact angle meter

Fig.2 FTIR instrument

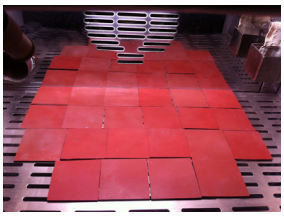

Fig.3 Xenon lamp aging box

D. Experimental scheme

According to the two relative humidity variable set, compared the two groups of HTV silicone rubber sample artificial accelerated ultraviolet aging test, as shown in figure 3, specific test plan is as follows:

Test a: 10 specimens placed in xenon lamp aging test box, set the board temperature is 65^{o} C, the specimen surface temperature of (65±5)^{o} C, relative humidity is 5% (aging experiment box has been modified). In order to ensure the consistency of the test specimen surface irradiance, after every 48h samples position has been adjusted. Take out every 100h two kind of sample each 1 piece of hydrophobic testing, hardness testing, FTIR testing, the total test time of 1000h.

Test b: The preparation of sample has another 10 specimens placed in same conditions set same xenon lamp aging test box, only relative humidity to 80%. In order to ensure the consistency of the test specimen surface irradiance, after every 48h samples position has been adjusted. Take out every 100h two kind of sample each 1 piece of hydrophobic testing, hardness testing, FTIR testing, the total time of 1000h.

Experimental results and discussions

A. Static contact angle

As shown in figure 4, the sample of hydrophobic are lower, but in the early stage of the radiation time under the condition of 80% relative humidity hydrophobic inferior to the sample under the condition of 5% relative humidity of hydrophobic, but with the increase of irradiation time, begin to appear in 300h specimen under the condition of 80% relative humidity of hydrophobic gradually is better than that of the sample under the condition of 5% relative humidity of hydrophobic trend.

B.Hardness change

As shown in figure 5, the hardness of sample are bigger, but the change of the specimen hardness change and hydrophobic have the same trend, turning point at 300h.

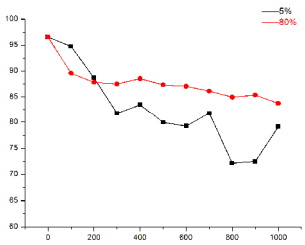

Fig.4 Sample surface static contact angle change

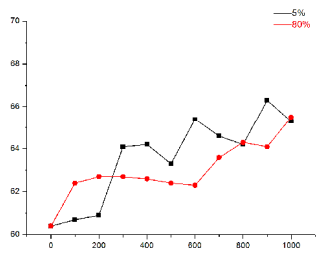

Fig.5 Sample hardness change

C.Infrared spectrum analysis

As shown in Fig. 6 and Fig. 7, Sample groups in peak area is smaller, the early stage of the test of time, relative humidity of 5% of the peak area significantly greater than 80% relative humidity of reactive peak area, but with the increase of irradiation time, relative humidity 5% began to appear in the 600h peak area gradually less than 80% relative humidity of the reactive peak area ofthe trend.

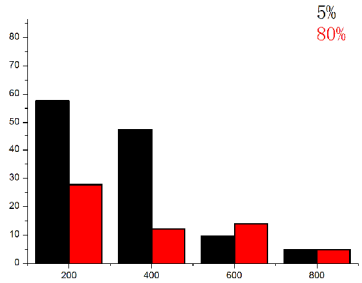

Fig.7 Si-0-Si peak area percentage

Discussions

Water molecules in the ultraviolet aging test of HTV silicone rubber, the two opposite effect:

1) on the one hand under the radiation of ultraviolet light, water molecules involved in ultraviolet aging chemical reactions inside the silicone rubber. Due to the residual catalyst in silicone rubber, silicone rubber inside the inorganic salt content increases, the residue of inorganic salt in addition to the easy absorption of water be affected with damp be affected with damp to lower the resistance to water, also make the silica in the silicone rubber chain rupture, accelerate damage vulcanizates mesh structure, an enormous influence on characteristics of silicon rubber ultraviolet aging.

2) on the other hand, the water molecules will be distributed on the surface of silicone rubber, and the sample is combined with a variety of filler particles precipitate Si particles, and have enough oxygen plays a role of medium, small changes in the molecular structure of silicon rubber outer surface, namely a kind of organic low molecular polymer silica, gradually spread evenly throughout the outer surface, a thin layer of protection, the thin layer will protect silicone rubber is no longer a further by UV light.

Conclusion

The experimental results show that:

a. Both samples hardness are larger, the flexibility are reduced.

b. Their both surface static contact angle are decreased, the hydrophobic are part of the loss.

c. Their both surface roughness are bigger,and a part of filler is leaked.

d. FTIR of peak area of Si-CH_3 and Si-O-Si keys absorption peak are reduced, shows a portion of the Si-CH_3 and Si-O-Si keys is interrupted into free radicals.

e. Humidity variable has two contray sides influence on ultraviolet aging chara-cteristics of HTV silicone rubber material,its process is complicated.

Keywords: Pt-Ag ratio; cathode catalysts; hydrogen peroxide; electro-reduction

Abstract. In this paper the different proportional Pt/Ag on XC-72 carbon are studied to serve as the electro-catalysts of H_2O_2 in acid media. All catalysts are prepared by impregnation reduction method and characterized by XRD and TEM. The electrochemical performance tests are examined by cyclic voltammetry (CV) at 25°C and 30°C, respectively. The results suggest that the peak current density increases with increasing the Ag content in Pt-Ag/C. Attributed to the temperature factor, the electro-catalytic activity of all catalysts at 30°C is better than that of 25°C.

Introduction

Direct $NaBH_4$ -H_2O_2fuel cell (DBHFC) is attractive as a new, clean alternative power source for portable electronic devices due to their high energy density, raw materials are easier to store and transport [1] [2] . In DBHFC, sodium borohydride is oxidized at anode based on following reactions of

$$BH_4^- + 8OH^- + 8e^- \rightarrow BO_2^- + 6H_2O \qquad E^0 = -1.24Vvs.SHE \tag{1}$$

Hydrogen peroxide is restored at cathode according to following reactions of

$$4H_2O_2 + 8H^+ + 8e^- \rightarrow 8H_2O \qquad E^0 = 1.77Vvs.SHE \tag{2}$$

Accordingly, the net cell reaction in DBHFC is

$$BH_4^- + 4H_2O_2 \rightarrow BO_2^- + 6H_2O \tag{3}$$

The theoretical fuel cell potential and specific energy of DBHFC are 3.01V and 17.06KWh/kg, respectively

Now, for this type of fuel cell, carbon supported Pt is widely used as cathode catalyst [3-6]. But the limited resources and higher cost of Pt greatly limit the development of DBHFC. Finding a new type of catalyst, which can not only reduce the amount of Pt but also maintain the high catalytic activity to H_2O_2 electro-reduction, is important for promoting the DBHFC technology and commercial process.

Catalyst Ag/C has higher catalytic activity to H_2O_2 electro-reduction [7]. In this paper, we prepare different ratio of Pt/Ag of Pt-Ag/C catalysts by impregnation-reduction method [8-11]. The Pt is 4% and Ag is x% (X=10, 15, 20, 25, 30, 36). In order to examined their electro-catalytic performance, we compared the reductive peak currents of catalysts at temperature25°C and30°C, respectively.

Preparation of electro-catalysts

10% Ag/C catalysts was prepared by impregnation-reduction method. In brief, 90mg XC-72Carbon and 100ml deionized water were ultrasound dispersed for 1h. 15.7 mg $AgNO_3$ and 80 mg sodium citrate, which are mixed in 20ml deionized water, was added to above suspension and ultrasound dispersed 1.5h, the PH was adjusted to alkali with ammonia solution. 10ml (0.1M) $NaBH_4$ was added to that mixture slowly and magnetic stir continually for 1h at room temperature. The mixture solution was separated by vacuum filtration, washed with distilled water, and dried at 80°C for 24h. The 15%, 20%, 25%, 30%, 36%Ag/C catalysts were got with the same procedure above.

There was a same procedure to prepare $Pt_{4\%}$-Ag $_{x\%}$/C(X=10, 15, 20, 25, 30, 36) . In brief, 96mg Ag $_{x\%}$/C(X=10, 15, 20, 25, 30, 36), 100ml deionized water and 0.4ml(0.01g/ml) H_2PtCl_6 were ultrasound dispersed for 1.5h, the PH was adjusted to alkali with ammonia solution, and excessive $NaBH_4$ solution was added in slowly. The sample was stirred continually for 3 h at80-90°C, filtered, washed, dried in vacuum for 24h at constant temperature 80°C. Finally, we got $Pt_{4\%}$-Ag $_{x\%}$/C(X=10, 15, 20, 25, 30, 36)catalysts.

Preparation of working electrode

Generally, our working electrode area is 0.5cm^2 with 2mg/cm^2 loading of catalysts. The method of preparing working electrode is as follows: firstly, a 5mg catalyst sample prepared above and a small amount of 0.5% nafion solution were ultrasonic dispersed a few minutes until a uniform ink-like formed. Secondly, the catalyst ink was coat on one side of the carbon paper, and then was put in a 40°C oven for 30 minutes.

Electrochemical test

The electrochemical performance tests of these six catalysts were examined by CV. The Pt gauze and saturated calomel electrode (SCE) were used as the counter electrode and reference electrode. The working electrode prepared above and the Pt gauze, SCE electrode worked together to complete the circuit in0.5mol/L H_2SO_4 and 0.05mol/L H_2O_2. Before testing, we need pour high purity nitrogen to the solution about 20 minutes to exclude oxygen.

Results and discussion

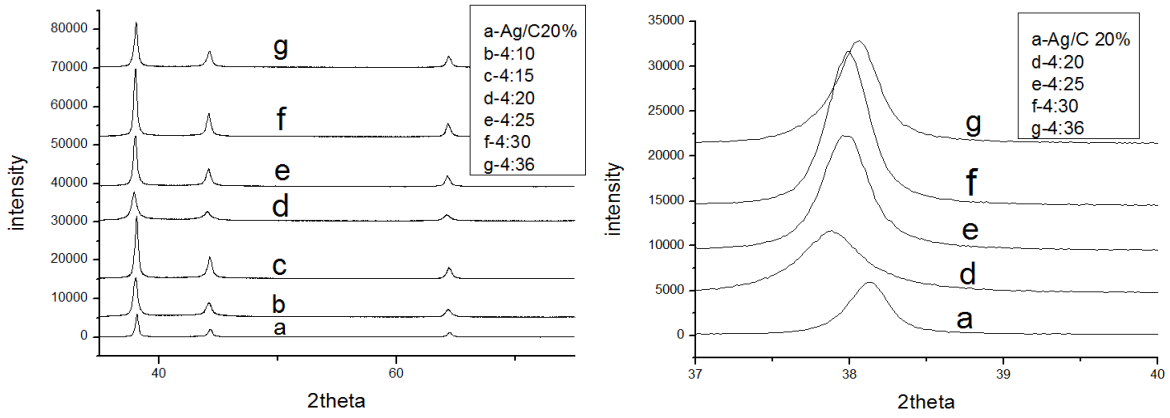

Fig.1. The XRD spectra of six catalysts

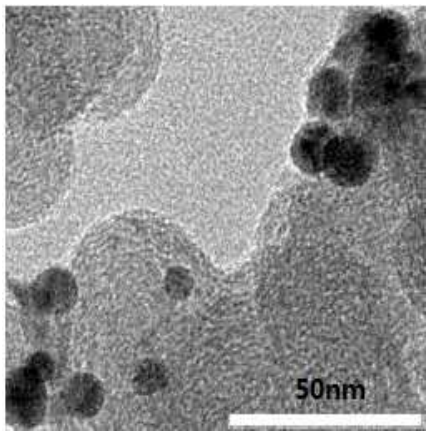

Fig.2.TEM of Pt-Ag/C catalyst

Fig.1 is the XRD spectra of six catalysts. We can know that there is a little change in peak position with the increasing content of Ag in Figure1. The angle of 2θ = 38.1°(111), 44.3°(200),

64.4°(220) are the characteristic peaks of purely metallic Ag particles. In contrast, $Pt_{4\%}$-$Ag_{20\%}$/C showed diffractions at 2θangles significantly lower than that of $Ag_{20\%}$/C, and with the increasing content of Ag, the 2θangles are more higher based on the same content of Pt4%. While the peaks at 2θ value of 38.6°, 44.9°, 65.5°are well matched for (111),(200),(220) planes of Pt, respectively. These observations may suggest that Ag and Pt are all in face-centered cubic structure but they are not fully alloyed [12]. Fig.2 shows us that Ag-Pt particles with diameters from 6 to 14 nm were uniformly dispersed on the support.

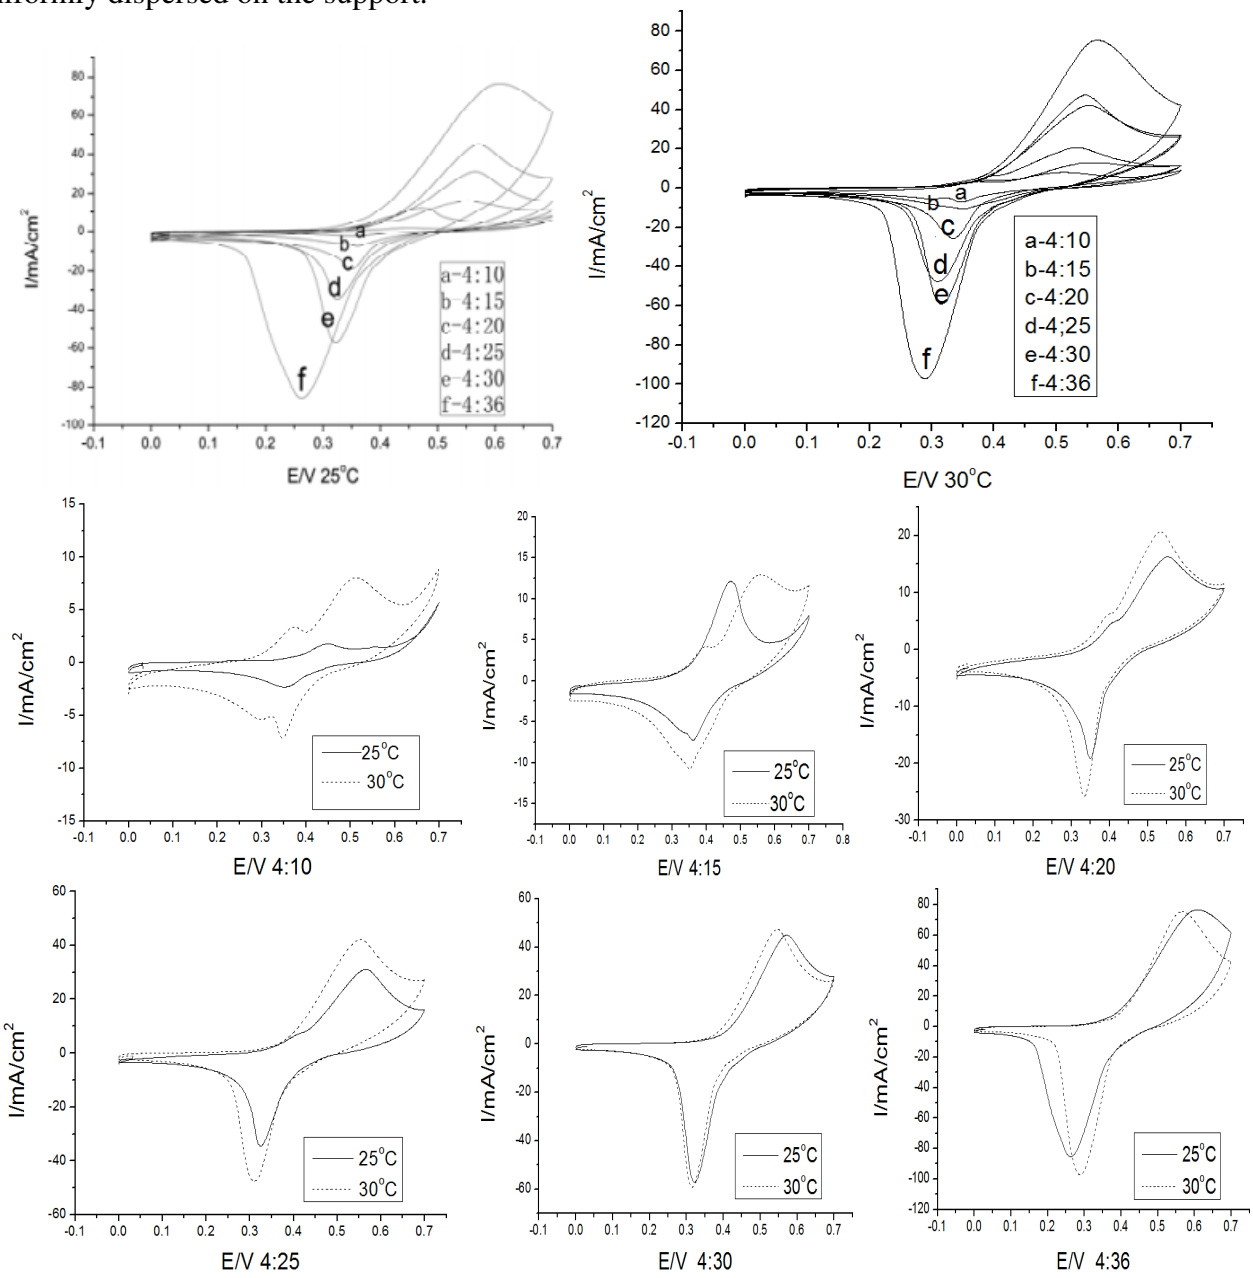

Fig.3. CV of Pt-Ag/C catalysts with different Pt/Ag ratio at 25°Cand30°C in 0.5 M H_2SO_4+0.05M H_2O_2 solution.

The electrochemical performance test results are shown in Fig.3. From Fig.3, we can know that, based on the same proportion of 4% Pt, the peak current densities increases with increasing Ag content both at 25°C and 30°C. At the same time, the six catalysts have the same change trend: the catalytic activities are higher at 30°C than that at 25°C. The data tell us that elevating temperature and increasing the proportion of Ag can contribute to improving the catalytic activity of Pt-Ag/C catalysts.

Conclusions

Six catalysts with different atomic Pt/Ag ratio were prepared by impregnation-reduction method. The XRD results indicate that six catalysts are all in face-centered cubic structure. The average particle size of the Pt-Ag nanoparticles was about 10nm. CV results indicate that elevating temperature and increasing the proportion of Ag are helpful for electrochemical reduction of H_2O_2.

Keywords: electrodeposition; ZnO films; modified surface of the polymer-PEN; pentagonal flake structure; Energy Dispersive X-ray Spectroscopy (EDX); photoluminescences.

Abstract. Since transparent conducting oxides can be as a buttom layer of complex film electrodes, electrodeposition technique may produce ZnO films depending on variety conditions and modified surface layers of substrates in electrochemical procedures. Here we invested the structure and morphologies of ZnO films by using modified surface of the substrate-ZnO/ITO/polymer-PEN and ZnO doped Ga/ ITO/polymer-PEN.

Introduction

Zinc oxide (ZnO) is one of the most promising materials for the fabrication of optoelectronic devices operating in the blue and ultraviolet (UV) region, owing to a direct wide band gap and a large exciton binding energy. It has been shown that ZnO thin films can be deposited electrochemically and that the films produced are of high structural quality [1]. ZnO layer made by electrodeposition method is for potential application of grade material and semiconductor junction devices. As we know, control of morphology and structures of oxides are of great importance for above applications and their implementation on technological devices. Zinc oxides had be obtained in different structures such as Pentagonal ZnO nanorods, hexagonal ZnO collunms , sheet nano-zinc oxide crystals with a hexagonal, pentagonal, rectangular or an irregular form etc.[2]. Different temperatures, solute and post-annealing for fabrication and characterations of ZnO films were systematically investigated by authors. In this paper, We will focus the structure of ZnO films, especially pentagonal flake structure, relation of morphologies and the surface of substrates.

Experimental Details

In the electrodeposition procedure of ZnO films a three electrode electrochemical cell is needed. It contains a aqueous solution with 5 mM $ZnCl_2$ and 100 mM KCl as supporting electrolyte and dissolved oxygen at 90 ^{0}C [3]. The conducting substrate was set up as a working electrode and was located near the referential cathode at approximately 1cm. A potentio galvanostat was used to keep a constant potential (a variant potential from -0.50 to -0.80 V) during the deposition. During the electrodeposition process four main growth variables- molarity ratios of solution, concentration of the solution, potential and modified surface of substrates have been controlled at a fixed time and temperature. The modified surface layer of one substrate used is high density ZnO film made by reactive magnetron sputtering on ITO/polymer-PEN.

Scanning electron microscopy (SEM) images and quantitative elemental analysis were obtained by a JSM 6300. The content ratio of elements in the film was obtained by means of Energy Dispersive X-ray Spectroscopy (EDX). For structural characterization it has been measured by an high-resolution X-ray diffraction (XRD) in the Θ-2Θ configuration with a copper anticathode (CuKα, 1.54 Å). Optical properties were monitored by transmittance using a Xe lamp and in association with

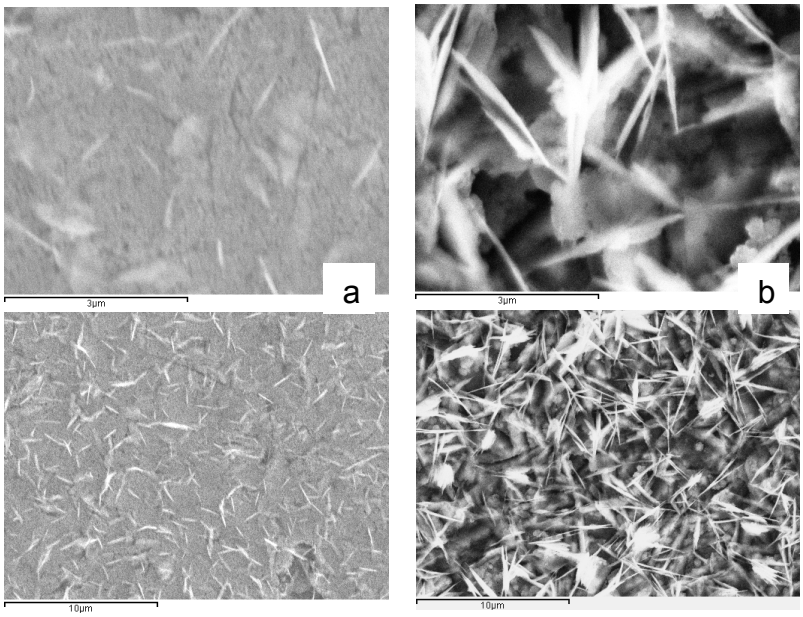
a 500 mm Yvon–Jobin HR460 spectrophotometer using back-thinned CCD detector optimized for the UV–VIS range. Photoluminescences (PL) measurements were carried out at 6k-300k temperature using a He-Cd Laser as a light source at an excitation wavelength of 325 nm.

Discussion on morphology and structures of ZnO films

Generally electrochemical procedures permit the synthesis of ZnO films on different morphologies depending on the solute, concentrations of the solutions, temperature, PH value, and electrical potential ,etc. Until now， these have been systematically investigated. In order to know that the variant morphologies of synthesised ZnO films depending on the surface of substrate, here the different modified surfaces of substrates has been used in the electrochemical method. We found a regularity of the film growth about the effect of the substrate mainly.

Fig.1 and Fig.2 show some SEM images of these kinds of ZnO films on the substrate-ZnO/ITO/polymer-PEN and ZnO doped Ga/ITO/polymer-PEN respectively. SEM reveals an aggregation of flat pentagonal flake which looks like ZnO quasi-3D structures consisted of quasi-nanowalls. These pentagonal flakes that grew up on the surface of the first basic ZnO layer do not exhibit ordered pattern.All flat pentagonal flake were predominantly normal to the substrate. Up images of Fig 1 are zoom of bottom photos of Fig 1(a)-(d).The thickness of the flakes or walls is approximately 160 nm and one edge size of a pentagonal flake is about 3.16 μm in Fig 1. and Fig.2. In case of Fig.2 above similar micro structure,an aggregation of flat pentagonal flake was not found. This could be deduced that ZnO doped Ga on surface of polymer-PEN did not form good conductive layer and suitable structure of ZnO.

EDS analysis was selected in the photo of SEM and its spectrum is shown in Fig.3. In its spectrum atomic percentage of O and Zn is 59.77% and 23.32% respectively. It indicates that there is larger intrinsic – Zinc vacancy (Vzn, Acceptors). The reason is possibly the initial formation of an hydroxides in the solution, which would slowly dehydrates. In fact zinc hydroxide forms at room temperature by precipitation of Zn^{2+} by OH^- addition [4] , and it means and suggests that the film is $Zn(OH)_2$. This is why finally the zinc oxide film with Vzn forms and grows.



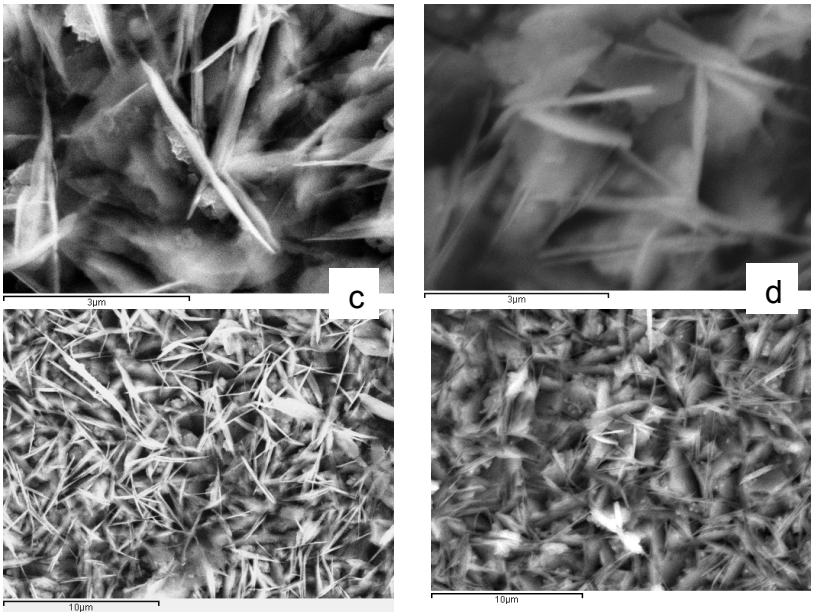


Fig.1 SEM images of ZnO film prepared in different deposition time on ZnO/ITO/polymer-PEN substrates. (a) 130s (Q= -0.1C); (b) 690s (Q=-0.4C); (c) 1500s; (d) 2800s. SEM: x20000 (up, scale : 3 micrometers), × 5000 (buttom, scale : 10 micrometers).

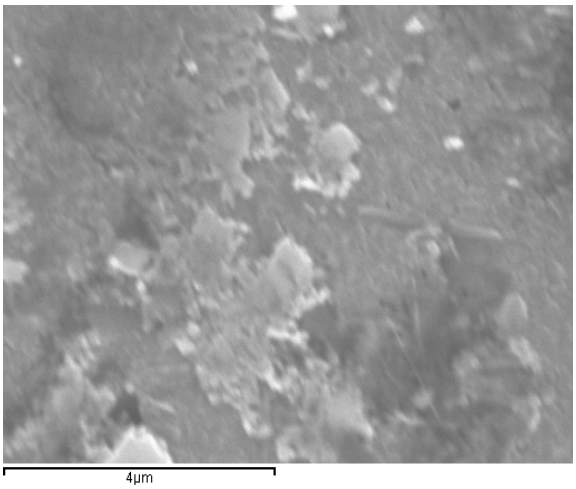

Fig.2 SEM images of ZnO film prepared in 690s (Q=-0.4C) deposition time on ZnO doped Ga/ITO/polymer-PENsubstrates. x15000, scale : 4 micrometers .

Generally it is realized that micro structure of ZnO film is of more functional and PL may gives much information about relation of the structure. There are various models being proposed to explain the complex PL band of ZnO materials. A strong PL emission peak at 370 nm is the intrinsic PL emission of ZnO crystallites due to the near band-edge emission (NBE) . It had mostly been attributed to the radiative transition between electron (in conduction band) and hole (in valence band) recombination process, of course it corresponds to the bound exciton (BE). PL spectra of the ZnO thin films from the temperature of 6 k to 300 k were measured. Two broadening PL emissions at 350-440 nm and 471-770 nm, which belong to broader NBE and deep level emission (DLE) respectively, are observed. Comparing previous results of PL band of ZnO, it is deduced that the broad NBE band shows two components—one band centred around 370 nm (3.351 eV) and another one centred around 420 nm in the range.

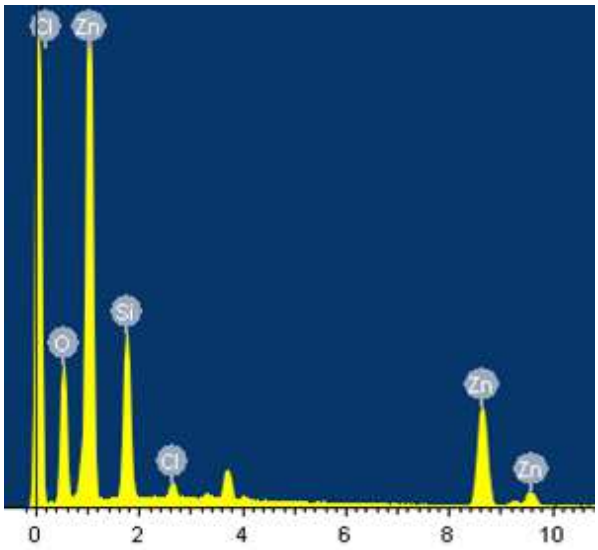

Fig.3 Discussion on morphology and structures of ZnO

Conclusion

The ZnO on modified surfaces of substrates such as ZnO/ITO/polymer-PEN and ZnO doped Ga/ITO/polymer-PEN were prepared by the electrochemical method. We carried out the experiments by adjusting concentration of the solution, potential, substrate and deposition time. The combination of the effect of solution and potential on the growth of the film, the controlled pentagonal flake structure of ZnO is obtained by us.

Keywords: oxyfuel combustion; sulfur; SO_2; SO_3; thermodynamic equilibrium

Abstract: To study migration and transformation of sulfur species in oxyfuel combustion, the study attempts to analyze distribution of sulfur compounds with thermodynamic equilibrium. Results show that sulfur-containing gases predominantly are SO_2 and SO_3, the maximum thermodynamic equilibrium concentration of those in oxyfuel combustion respectively increase by 3.4 and 4.5 times compared with the conventional combustion. Furthermore, SO_2 gas formation rate decreases while SO_3 increases under oxyfuel combustion. Sulfur-containing gases are generally more sensitive to temperature and excess air coefficient. The amount of sulfur compounds significantly increases in oxyfuel combustion.

Introduction

Oxyfuel combustion is one of the promising technologies for capturing CO_2 from power plant. Concentrations of SO_2 and H_2O increase rapidly. Sulfur species change and SO_3 concentration is improved significantly because of flue circulation[1]. Hao Liu et al [2] presents that SO_2 concentration is 6 times for oxyfuel combustion as large as that for traditional combustion and content of H_2O in flue gas varies from 10% to 40%. Daniel Fleig et al[3] indicates that SO_3 concentration in oxyfuel combustion is 4 times as large as that in traditional combustion. Existing forms of sulfur is not only related to the oxygen content in flue gas, but also to temperature and mineral composition of coals.

Measurement for sulfur existing forms is comparatively complicated because of the interference between SO_2 and SO_3[4], whereas thermodynamic equilibrium is proposed as a guidance for analysis. Through thermodynamic equilibrium calculation, the distribution of sulfur species for traditional combustion and oxyfuel combustion are predicted. Rules of sulfur's migration and transformation are revealed.

Computation method

Thermodynamic equilibrium calculation is based on the minimum free energy of Gibbs principle. Amount of sulfur element is set to 1mol in coal sample. Mole fractions of other components will be converted accordingly. The data for components of bituminous coal and the components of bituminous coal ash are shown in Table.1 and Table.2 respectively.

Table.1 Components of bituminous coal[%]

C_{ar}	H_{ar}	O_{ar}	N_{ar}	S_{ar}	M_{ar}	A_{ar}
48.51	2.57	3.78	0.77	0.64	6.78	36.95

As for oxyfuel combustion, oxidizing agent consists of circulated flue gas and pure oxygen. In consideration of simplification, flue gas is regarded as theoretical flue gas. In terms of converted mole fractions of all components, the components of theoretical flue gas are deduced by iterative computation in oxyfuel combustion. O2 concentration in oxidizing agent required by the combustion of bituminous coal is set to 29%. Accordingly the compositions of oxidizing agent are presented. Converted mole fractions of all components for bituminous coal and the amount of oxidizing agent for different combustion methods were entered into the software for thermal equilibrium calculation. Components of theoretical flue with wet flue circulation under oxyfuel combustion are shown in Table.3.

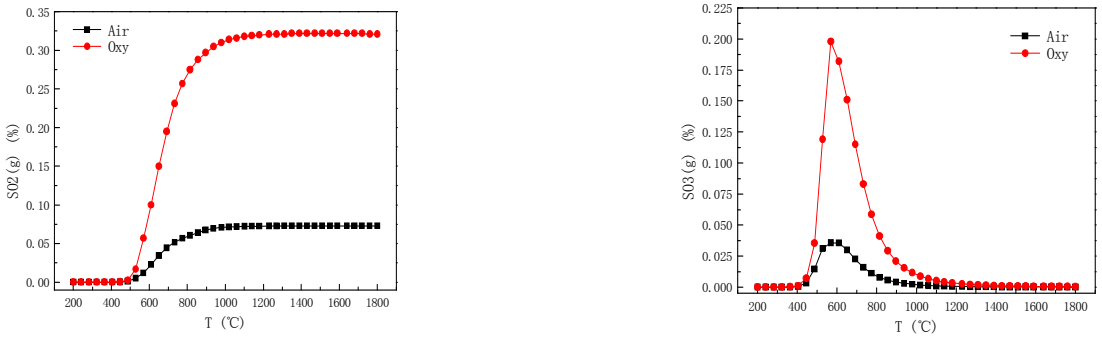
Computational result analysis

Temperature. The objective of present work is to research the impact of temperature on existing forms of sulfur in power station boiler. All initial conditions are as follows: excess air coefficient is 1.2, air pressure is 0.999atm and the range of temperature is from 200˚C to 1800˚C. The results of calculation are presented in Figure.1 and Figure.2.

For oxyfuel combustion in pulverized coal fired boiler, the sulfur-containing gases are predominantly SO_2 and SO_3. The distribution of SO_2 is shown in Figure.1(a). From 487˚C, thermodynamic equilibrium concentration of SO_2 increases rapidly with the raise of temperature. For traditional combustion, the concentration of SO_2 is basically stable around 900˚C, while the concentration of SO_2 is not stable for oxyfuel combustion until the temperature is about 1103˚C and the highest concentration of SO_2 is 0.322%, which is 4.4 times compared with traditional combustion. SO_2 is the predominantly existing form of sulfur at high temperature.



(a)Volume concentration of SO_2 (b)Volume concentration of SO_3

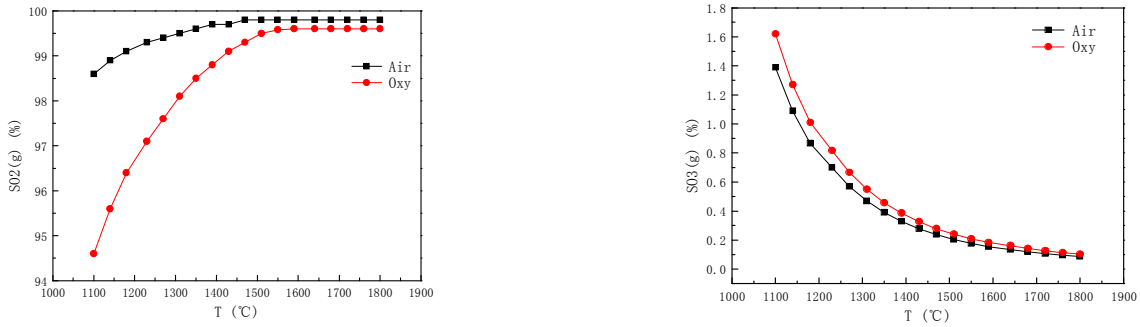
Figure.1 The distribution of sulfur-containing gases

Figure.1(b) indicates the distribution of SO_3 concentration. As the rise of temperature, thermodynamic equilibrium concentration of SO_3 first increases and then declines. SO_3 combines with steam to generate sulfuric acid steam at low temperature. However, SO_2 is more stable than SO_3 at high temperature. For traditional combustion, the concentration of SO_3 reaches a peak of 0.036% at 585˚C, while for oxyfuel combustion, the concentration of SO_3 peaks at 580˚C, which is 0.199% and it is 5.5 times than that of traditional combustion.

Actually, the resistance time of flue gas is pretty short in pulverized coal furnace. The formation rate of SO_3 is small at low temperature while it is big at high temperature. Therefore, the actual

concentration of SO_3 in pulverized coal furnace is near the thermodynamic equilibrium concentration of SO_3 at high temperature, but it is far below the thermodynamic equilibrium concentration of SO_3 at low temperature. D. Fleig [5] estimates the time required by SO_3 in the flue gas to reach 90% of thermodynamic equilibrium concentration of SO_3, when temperature is higher than 1400K, required time within 1 second, and it increases steeply with the fall of temperature, for instance, it requires 20 hours to reach 90% of thermodynamic equilibrium concentration of SO_3 when temperature drops to 800K.

The concentrations of sulfur-containing gases in oxyfuel combustion raise rapidly compared with traditional combustion, two main factors are as follows: one is that the concentration of oxidizing agent is higher than that of traditional combustion, and after air staging N_2 is not fed, which makes the decrease of flue gas. When oxygen concentration of oxidizing agent is 29%, the amount of flue gas decreases 27.3%, which leads to higher concentration of sulfur-containing gases; another reason is that approximately 70% flue gas recycling in oxyfuel combustion, leading to accumulation of moisture and sulfur-containing gases in flue gas, as a result, the concentrations of SO_2 and SO_3 are higher than that of traditional combustion.



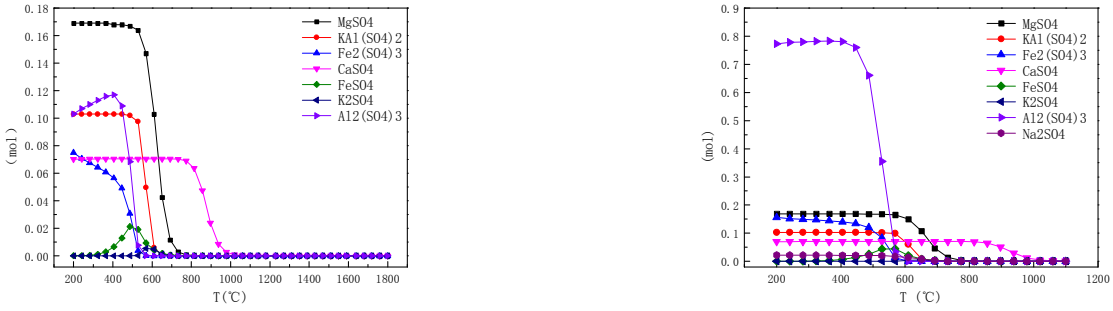
(a)Conversion for S to SO_2 in fuels (b)Conversion rate for SO_2 to SO_3

Figure.2 Conversion rate for existing forms of sulfur.

Figure.2 indicates the relation between temperature and conversion rate of sulfur-containing gases, as the raise of temperature, the formation rate of SO_2 increases with the decrease of conversion rate for SO_2 to SO_3. Compared with traditional combustion, the formation rate of SO_2 is lower and the formation rate of SO_3 is higher in oxyfuel combustion. At the temperature of 1100˚C, formation rate of SO_2 for oxyfuel combustion is only 94.59%, which is 3.9% lower than that of traditional combustion, while in 1550˚C the formation rate of SO_2 for oxyfuel combustion is merely 0.21% lower. At a temperature of 1100˚C conversion rate for SO_2 to SO_3 in oxyfuel combustion is merely 1.63%, 0.25% higher than that of traditional combustion, and at 1550˚C the conversion rate for oxyfuel combustion is only 0.02% higher than traditional combustion. With the same excess air coefficient in thermodynamic equilibrium, the content of O_2 for oxyfuel combustion is higher than that of traditional combustion, which leads to a considerable improvement of SO_3 formation rate. Hence, the ratio of sulfur in the form of sulfates increases, and it results in a decline for the formation rate of SO_2, since it is hard for sulfates existing in high temperature, the formation rate of SO_2 and SO_3 for two combustion methods are closer to each other as temperature rising.

Solid sulfur compounds. Figure.3 shows the solid sulfur compounds in thermodynamic equilibrium for different combustion methods. Sulfates commonly exist below 1000˚C and the amount of sulfates increase as the decline of temperature. As for discussed coal in this paper, aluminum sulfate takes the maximum amount in the oxyfuel combustion, whereas for traditional combustion,

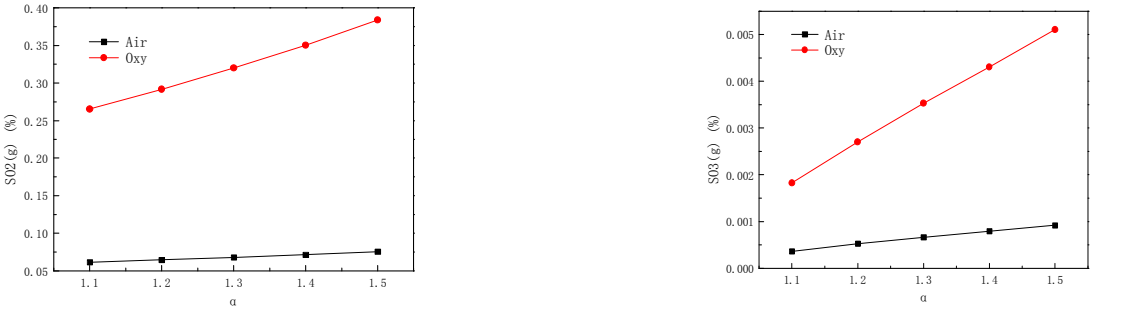
magnesium sulfate has the largest amount. Furthermore, $CaSO_4$ would not form until temperature drops to 1000˚C or below and $MgSO_4$ generates only when temperature is 750˚C or below. Consequently, Ca performs best in sulfur immobilization, Mg comes next. Their ability of sulfur immobilization is better than most other alkali metals. Monckert P etc[7] presents that capture of sulfur happens in convection section of boiler over the range of temperature from 450˚C to 1100˚C, in an agreement with the range of sulfates formation temperature. Thus, during the cooling process of flue gas, gaseous sulfur first reacts with Ca to generate $CaSO_4$, when the content of gaseous sulfur is large enough and also Ca is depleted completely, gaseous sulfur starts to react with Mg to generate $CaSO_4$ when temperature is below 750˚C. Theoretically, as long as the coal contains enough alkali metals, all the sulfur can be immobilized. The concentration of gaseous sulfur increases by a large margin in the oxyfuel combustion, leading to much more powerful sulfation ability in boiler, and Al in the ash is taken and depleted to generate more $Al_2(SO_4)_3$[7].



(a)Traditional combustion (b)Oxyfuel combustion

Figure.3 The distribution of solid sulfur compounds.

Excess air coefficient. In order to discuss the impact of excess air coefficient on sulfur existing forms, initial parameters are set as follows: temperature is 1200˚C, air pressure is 0.999atm and excess air coefficient varies from 1.1 to 1.5, and according to the 6% oxygen content, concentrations of sulfur-containing gases are converted.



(a)Volume concentration of SO_2 (b)Volume concentration of SO_3

Figure.4 The distribution of SO_2 and SO_3 under different excess air coefficient.

Figure.4 indicates the distribution of SO_2 and SO_3 with different excess air coefficients. The concentrations of SO_2 and SO_3 increase correspondingly as the increase of excess air coefficient, The SO_2 and SO_3 concentrations are more sensitive to excess air coefficient in oxyfuel combustion. When the excessive air coefficient increases 0.1, SO_2 concentration increased by 0.0298%. SO_3 concentration increases by 0.00082% in oxyfuel combustion, while the SO_2 concentration changes only 0.0035%, the SO_3 concentration changes only 0.00014% in traditional combustion. The O_2 concentration increases with the increase of excess air coefficient in traditional combustion, which

promotes the generation of SO_2 and SO_3, however, the increase of excess air coefficient contributes to the increase of O_2 concentration as well as the amount of circulated flue gas in oxyfuel combustion. This leads to the increase of SO_2 brought by circulated flue gas in the boiler, since SO_3 formation is promoted, as the result, the concentration of SO_3 increases.

Conclusion

(1) The main sulfur-containing gases are SO_2 and SO_3. Compared with the traditional combustion, the maximum thermodynamic equilibrium concentration of SO_2 and SO_3 respectively increases by 3.4 and 4.5 times in oxyfuel combustion.

(2)The solid sulfur compounds are primarily alkali metal sulfates in oxidative atmosphere, which exist steadily at low temperature and decompose at high temperature. Ca performs best in sulfur immobilization, Mg comes next. The alkali metal sulfation is stronger in oxyfuel combustion.

(3) The formation rate of SO_2 is lower and SO_3 is higher in oxyfuel combustion than in traditional combustion. In addition, the sulfur-containing gases are generally more sensitive to temperature and excess air coefficient.

Experimental Investigation of Chemical Looping Combustion of CO with Fe-based Oxygen Carrier

Qu Li[1], Changfeng Lin[1], Junjiao Zhang[1], Weiliang Cheng[2], Wu Qin[1]

[1.] National Engineering Laboratory for Biomass Power Generation Equipment, North China Electric Power University, Beijing 102206, China

Keywords: Chemical-looping combustion; Fe-based oxygen carrier; CO; CO_2-enrichment.

Abstract. Reaction activities of Ni-doped and Cu-doped Fe_2O_3 oxygen carriers (OCs) with CO were investigated using thermo gravimetric (TG-DTG).The structures of the prepared OC were characterized by X-ray diffract meter (XRD).TG-DTG investigations indicated that rational Ni and Cu doping could efficiently enhance the reactivity of Fe-base oxygen carrier for oxidizing CO under different conditions. And Fe-based OC doped with 20 wt. % Ni can realize the highest reactivity.

Introduction

Climate system warming caused by the greenhouse gas, especially CO_2 emission is gaining increasing nowadays [1].Chemical-looping combustion (CLC) has been revealed as an efficient and low costly process to achieve easier CO_2 capture [2].Compared with the traditional combustion, the dominating advantage of CLC is that it can achieve high concentration CO_2 only by condensing the exhaust gas without any extra energy penalty. In addition, CLC can minimize formation of NOx [3].

Development of efficient OCs is essential to improve the efficiency of CLC. Generally oxides of iron, nickel, and copper have been selected as the most promising candidates for CLC process [4]. Among them, because of the low cost and environmental compatibility, Fe based OC is considered an attractive option for CLC applications [5].NiO has shown very high reactivity and good performance working at the high temperatures(900-1100℃), except its toxicity [6]. CuO has not received significant attention due to the low melting point of Cu and high cost ,despite its highly reactivity in manifold cycle [7]. Based on the above, Fe-based OCs which introduced inert support Al_2O_3 doped Ni and Cu were studied. This paper focuses mainly on the reaction of Fe_2O_3 OCs with CO by TG-DTG, the structure of the prepared oxygen carriers were characterized by X-ray diffraction (XRD). The study tried to reveal the reaction mechanism of Cu-Fe_2O_3/Al_2O_3 and Ni-Fe_2O_3/Al_2O_3 with CO, and make a preparation for large-scale industrial applications in the future.

Experimental

Preparation of Oxygen Carrier. Fe-based OCs were prepared by the co-precipitation method. A certain amount of the compounds（$FeCl_3$・$6H_2O$, $CuCl_2$・$6H_2O$ or $NiCl_2$・$6H_2O$,NaCl） were dissolved in deionized water, polyethylene glycol (PEG) as dispersant. Then the solution was gradually heated to 120℃. Na_2CO_3 (0.2mol/L) was added to the solution at 120℃.The precipitate was filtered, dried in a vacuum at 50℃ for 6h. To increase the mechanical strength and eliminate the microstructure interference when heating at the TGA, oxygen carrier precursors were at calcined at 800℃ for 2h. Finally five Fe-based OCs were prepared (shown in Table 1).

Characterization of Oxygen Carrier. The solid product components were measured by XRD using Rigaku X-ray diffractometer Company (TTR Ⅲ). From the Fig.1, Fe_2O_3 patterns were very stable and had good crystallization. With the increase of Ni and Cu doped amount, the grain became larger and had higher crystallinity degree.

Table 1 The Fe-based doped Cu and Ni oxygen carrier on different proportions

Sample	Mass rate	Component
FeAl	50%:50%	Fe_2O_3,Al_2O_3
Ni5FeAl	5%:50%:50%	NiO,Fe_2O_3,Al_2O_3
Ni20FeAl	20%:50%:50%	NiO,Fe_2O_3,Al_2O_3
Cu5FeAl	5%:50%:50%	CuO,Fe_2O_3,Al_2O_3
Cu20FeAl	20%:50%:50%	CuO,Fe_2O_3,Al_2O_3

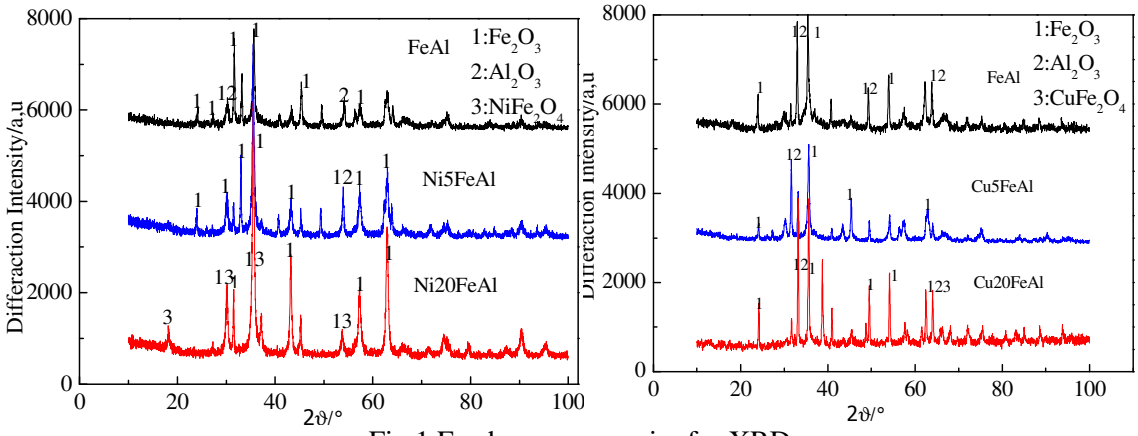

Fig.1 Fresh oxygen carrier for XRD

Experiment method. The reaction of OCs with CO were performed in TGA (STA6000, PerkinElmer Instruments, US). The experiment processes can be described as flows: firstly, N_2 was passed through for 5 min before the experiment to purge air and gas impurities. And approximately 10mg sample were heated from 30℃ to 850℃ in N_2 at 40℃/min at TGA, then CO was introduced and kept 50min at 850℃. After the reduction, oxidizing gas, air was fed for 20 min. The total gas flow rate was fixed at 40ml/min.

The general reactions for the Fe-based oxygen carrier reduction in the fuel-reactor were as following:

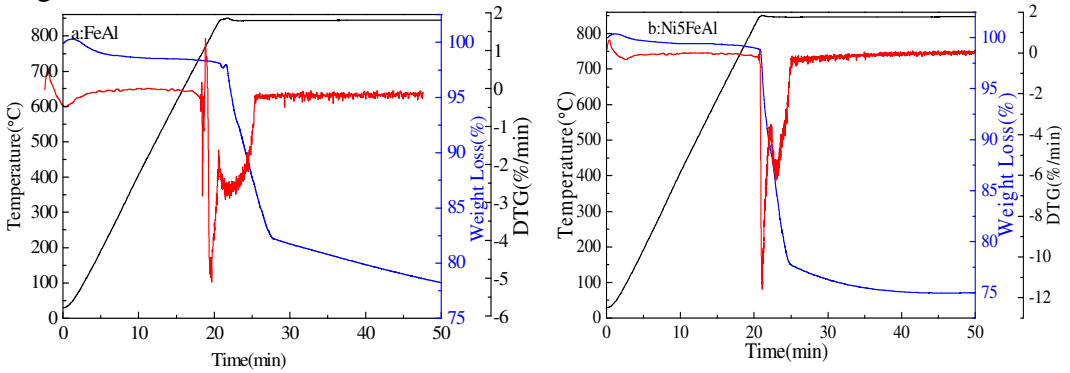
$$CO+3Fe_2O_3 \rightarrow 2Fe_3O_4+CO_2,\quad CO+Fe_3O_4 \rightarrow 3FeO+CO_2, CO+FeO \rightarrow Fe+CO_2,$$
$$CO+NiO \rightarrow Ni+CO_2, CO+CuO \rightarrow Cu+CO_2.$$

The conversion x of the oxygen carrier is defined as Eq.1, $$x=\frac{m_{ox}-m(t)}{m_{ox}-m_{re}} \quad (1)$$

where m(t) is the instantaneous mass and the denominator is the maximum oxygen transport between the fully oxidized, m_{ox}, and reduced, m_{re}, oxygen carrier .

Results and Discussion

The conversion rate analysis. In this part, the Fe-based OCs' reaction with CO were carried out in the TGA. The results of weight loss (TG) and the corresponding weight loss rate (DTG) were shown in Fig.2.



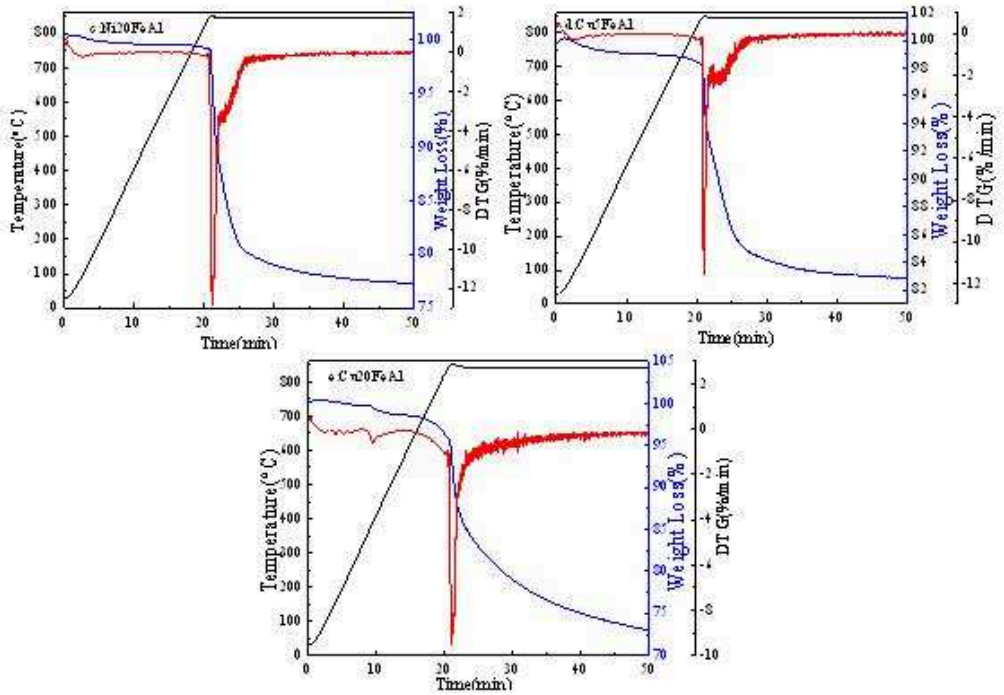


Fig.2 The TG/DTG curves for different oxygen carrier at 850℃ (a) FeAl (b) Ni5FeAl (c)Ni20FeAl (d) Cu5FeAl and (e) Cu20FeAl

From the Fig.2, the total reaction time was held for 50min. The five DTG curves all had sharp weight loss peak at 21min, and weight loss rate were 4.64, 10.2, 11.9, 11.4 and 8.7%/min. It can be concluded that the reaction rate of Ni20FeAl was faster than others, and the second was Cu5FeAl at the beginning reaction. The activity of OCs doped Ni and Cu were higher than Fe_2O_3/Al_2O_3.and the doped amount order was Ni (20 wt. %)> Cu (5 wt. %)> Ni (5 wt. %)> Cu (20 wt. %)> Fe_2O_3. From the TG curve, it can be seen that the reaction rapidly completed in 10min at 850℃. The weight losses were 78.2%, 74.9%, 77.3%, 82.9% and 74.6% corresponding to Fig.2 (a) (b) (c) (d) and (e) at 50min.The curve declined gentle without carbon deposition phenomenon.

The conversion of three oxygen carrier was calculated using Eq.1, shown in Fig.3.The finial conversion was 97.5%, 76.8%, 52.1% in 3min corresponding to 20 wt. % Ni, 20 wt. % Cu and FeAl. It was further confirmed that the Fe-based OC doped 20 wt. % Ni was the best. The images (a) and (b) were at high magnification (5000×). The particles of residues after reaction were much larger than the fresh OC, and the latter was uniformity. It was distinct from the images that there were little agglomeration.

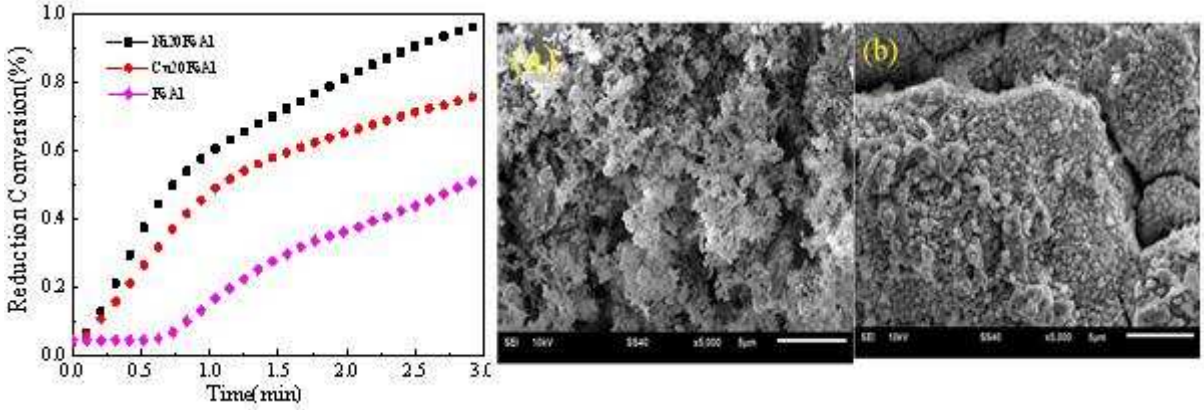

Fig.3 The conversion curves for different oxygen carrier at 850℃ and the SEM images of (a) fresh Ni20FeAl and (b) the mixture after reaction

Conclusion

Reactions between Fe-based OCs with CO were performed in a TGA, and then further investigated by XRD, SEM. It was found that the activity of oxygen carrier doped Ni and Cu were higher than Fe_2O_3/Al_2O_3, and the reactivity order corresponding to doped amount was Ni (20 wt. %) > Cu (5 wt. %)> Ni (5 wt. %)> Cu (20 wt. %)> Fe_2O_3. The final conversion of Ni20FeAl for CLC reached 97.5% and had little agglomeration occurred during CLC of CO.

Keywords: Ferrous sulfide; corrosion; trial; influencing factors

Abstract. Now steam stimulation gradually become one of the major thermal recovery methods, and hydrogen sulfide appears in the well casing. With the increase of the thermal recovery time and the application of SAGD technology, the number of wells containing hydrogen sulfide increased, and concentration of hydrogen sulfide are also rising,Producing corrosion products - ferrous sulfide. Ferrous sulfide has pyrophoric. When ferrous sulfide in contact with oxygen in the air can cause spontaneous combustion at room temperature. In order to avoid the occurrence of spontaneous combustion of ferrous sulfide we had an in-depth study of the spontaneous combustion of ferrous sulfide. Through laboratory tests we found the following points. At room temperature,sulfurization reaction of H_2S gas and iron oxides occurs more easily in a dry environment. Temperature, H_2S humidity, various iron oxides,have important effects on the generation of iron sulfide.

Introduction

According to statistics, China's annual growth rate of total oil consumption is 4%. Annual growth rate of domestic crude oil was less than 1%. Shortage of crude oil is imported to supplement. However, the sulfur content of imported crude oil is relatively high, especially in the Middle East ,are greater than 1%, up to 3.09%. When processing high sulfur crude oil is not only a threat to the environment making it very difficult to guarantee the quality of products, but also the sulfur can cause spontaneous combustion. So how to prevent and avoid the generation of sulfide become a top priority for crude oil processing, and it is important for the development of oil field.

Experimental Purpose

With the application of a series of mining technology,in the case of the control measures are not taken, the content of hydrogen sulfide in the tank will increase,and the interaction between hydrogen sulfide and tank will also increase. In order to prevent spontaneous combustion of ferrous sulfide in tank, it is necessary to analyze the factors affecting ferrous sulfide.

Several aspects were identified through the experiment. Different H_2S humidity and temperature, different iron oxides and different water content of iron oxides have different effects on iron sulfide formation

Experimental Equipment

（1）H_2S gas bag.（2）Film pump.（3）Cushion airbags.（4）Drying tower.（5）Capillary flow meter.（6）Quartz sample tube.

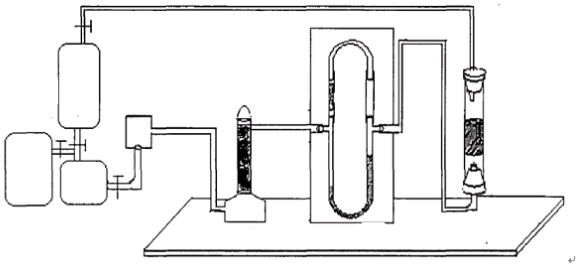

Fig .1 Set-up diagram

Experimental Process

Before the experiment weighed 4g dry iron oxide：Fe_2O_3 and Fe_3O_4. Then weigh 10g of dried iron oxide and add some deionized water making the water content of the iron oxide be 0.5%, 10%, 15%, 20% and 30%. Put them into the quartz sample tube, cover the rubber plug and connect the experimental device.

When the experiment starts, extracting some of the thin film of high-purity nitrogen gas to pump the air out of the system, and then extracting hydrogen sulfide gas. To remove water vapor, hydrogen sulfide gas flows through the airbag cushion into drying tower, Then flows through a capillary flowmeter into the quartz sample tube. The unreacted hydrogen sulfide gas may return to the gas bag.

We set the flow rate of hydrogen sulfide gas to 220mL/min.After completion of the sulfurization reaction when cooled to room temperature for the oxidation reaction experiments, when the air flow is controlled to 220mL/min, the temperature is recorded every minute.

Analysis of experimental results

（1）The temperature change of the product that produced by dried H_2S and Fe_3O_4

When the temperature is 25 ℃, dry hydrogen sulfide gas and dry Fe_3O_4 had vulcanization reaction , the temperature curve of their product was shown in Figure 2.

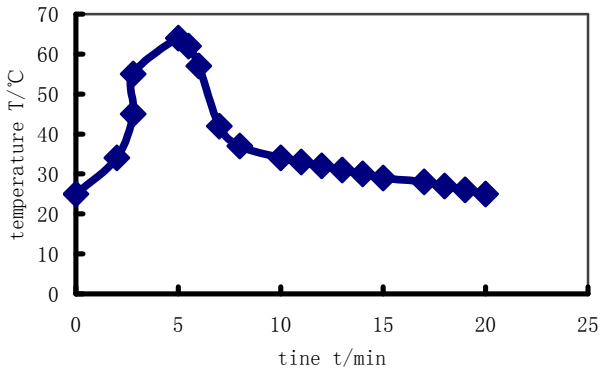

Fig .2 The temperature change of the product produced by dry H_2S and Fe_3O_4

As can be seen from the chart, the reaction temperature rises faster at the beginning stage of the reaction,and the temperature has reached the highest 64℃ in 5 minutes. However, the temperature quickly dropped 5 minutes later. This shows that at room temperature, dry hydrogen sulfide gas and the dry Fe_3O_4 can have sulfurization reaction, and their curing products have high self-ignitability. This also shows that their relatively slow curing reaction rate.

（2）The temperature change of the product produced by dry H_2S and Fe_2O_3 under two temperatures

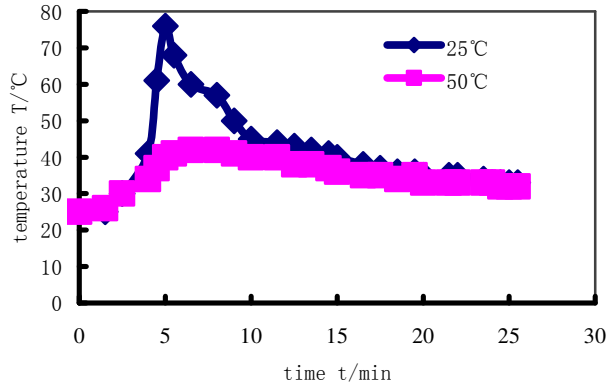

Fig .3 The temperature change of the product produced by dry H_2S and Fe_2O_3

At a temperature of 25 ℃ and 50 ℃ dry hydrogen sulfide gas and dry Fe_2O_3 had vulcanization reaction , the temperature curve of their product was shown in Figure 3. Their oxidation temperature curve is not the same. In the initial oxidation reaction,the temperature of hydrogen sulfide and Fe_2O_3 increased in varying degrees, indicating that it has a high spontaneous combustion. When the curing temperature is 50 ℃, the oxidation temperature is significantly higher than that of the curing temperature of 25 ℃, indicating that it is easier to spontaneous combustion.

At low temperature, dry hydrogen sulfide gas can react with dry Fe_2O_3, and the temperature is rising, which indicates that vulcanized product is high pyrophoric and more dangerous.

（3）The temperature change of the product produced by Fe_2O_3 that has different moisture content

Under anaerobic conditions,make Fe_2O_3 and H_2S have curing reaction.Make sure that Fe_2O_3 has different water content ,and H_2S is saturated humidity. After the end of the curing reaction cool it to room temperature, then some of the humidified air was put in so that oxidation reaction was conducted.

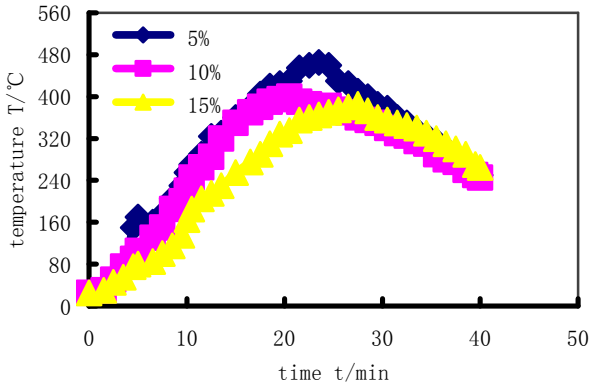

Fig .4 The temperature change of the product produced by Fe_2O_3

From the above chart we can see that the more it has water the more slowly it reaches the maximum temperature,and that the maximum temperature is more and more low.

（4）The temperature change of the product produced by Fe_3O_4 that has different moisture content

When the temperature is 25℃, make sure that the environment is anaerobic. Make Fe_3O_4 and H_2S have curing reaction.Make sure that Fe_3O_4 has different water content ,and H_2S is saturated humidity. After the end of the curing reaction cool it to room temperature, then some of the humidified air was put in so that oxidation reaction was conducted.

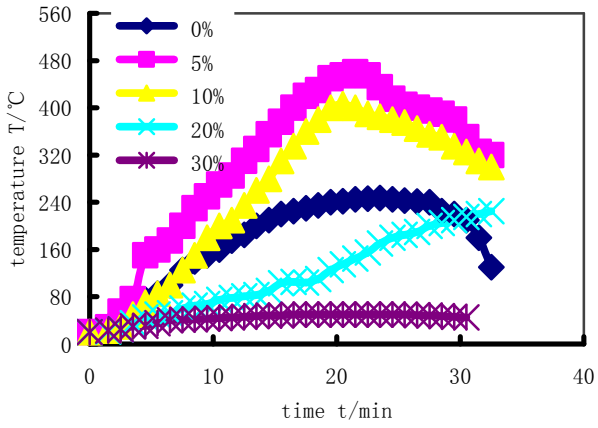

Fig .5 The temperature change of the product produced by Fe_3O_4

The figure shows that the temperature within ten minutes is more than 250℃. When the water content is between 5% and 10%,vulcanized product has a high self-ignitability. When the moisture content of the sample continued to increase, pyrophoric sulfide product decreases. When the moisture content of the sample is 30%, the curing reaction of the product of the oxidation hardly occurs at room temperature.

Summary

（1）At room temperature, sulfurization reaction of dry H_2S gas and iron oxide is more likely to occur. Product of their effects has a high spontaneous combustion.

（2）When the curing temperature increases, spontaneous combustion of vulcanized products are also increasing. Due to the presence of water vapor, H_2S gas increases the spontaneous combustion of products.

（3）Within a certain range ,water can promote the generation of ferrous sulfide However, beyond this range, the curing reaction rate is reduced.

Keywords: electrolyte; Fluoroethylene carbonate; low temperature

Abstract. N-methyl-N-allylpyrrolidinium bis(trifluoromethanesulfonyl)imide ($PYR_{1A}TFSI$) with substantial supercooling behavior is synthesized to develop low temperature electrolyte for lithium-ion batteries. Additive fluoroethylene carbonate (FEC) in LiTFSI/$PYR_{1A}TFSI$/EC/PC/EMC is found that it can reduce the freezing point. $LiFePO_4$/Li coin cells with the FEC-$PYR_{1A}TFSI$ electrolyte exhibit good capacity retention, reversible cycling behavior at low temperatures. The good performance can be attributed to the decrease in the freezing point and the polarization of the composite electrolyte.

1. Introduction

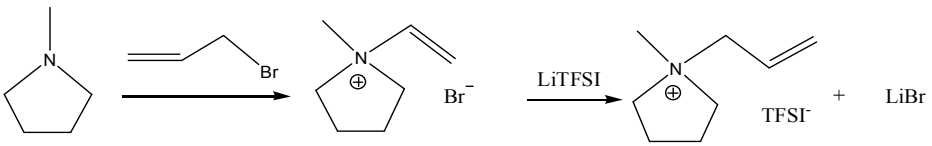
Current Li-ion technology typically employs carbonate-based electrolytes that have a temperature range of approximately -20 to 40 ℃[1]. Energy and capacity of lithium-ion batteries (LIBs) are sharply reduced at -20℃. But at present a usable temperature range of -60 to 60℃ is desirable for the electrolytes on military and space applications[2]. So it's significant for ionic liquids to apply in the research of low temperature performance of lithium-ion batteries in view of its excellent properties. Also it was found that the $LiFePO_4$ electrode, which was cycled in electrolyte containing 2 v% FEC, exhibited higher discharge capacity and better rate performance at low temperature than that without FEC [3]. So in this work, our main target was to synthesize a new ionic liquid and prepare composite electrolytes for lithium-ion batteries at lower temperature, and to characterize the effect of FEC on the capacity of $LiFePO_4$/Li at lower temperatures.

2. Experimental

Ionic liquid $Pyr_{1A}TFSI$ was synthesized according to scheme 1. The freezing point was tested by the DSC (differential scanning calorimeter), scanning from 60℃ to -60℃ at 5℃/min^{-1} [4]. In an argon-filled glove box (water content: <0.1ppm, oxygen content: <0.1ppm), the blank electrolyte with a composition of 0.5mol/L LiTFSI 1:3:7(v%) EC/PC/EMC solution (composite electrolyte I), and the electrolyte with content FEC (2v%) (composite electrolyte II) in above blank solution were prepared[5]. Then the freezing point and viscosity were tested by DSC and rheometer.

$LiFePO_4$/Li coin half-cells were assembled using lithium as the anode, $LiFePO_4$ as the cathode, Celgard polypropylene as the separator and filling with different composite electrolyte I and II [3] . The charge/discharge performance of $LiFePO_4$/Li half cells was evaluated at a constant current density of C/10 rate on a land charge/discharge instrument, China, at -30℃. A high-low temperature test-chamber (TEMI880,China) was used to provide a constant temperature environment for test. And then the $LiFePO_4$/Li half-cells were cycled at room temperatures to check whether they can reach the original and theory capacity. After the low temperature charge/discharge test, the SEM

(scanning electron microscope) test was used to observe the surface morphology of the $LiFePO_4$ electrode. CV(cyclic voltammetry) was carried out on the electrochemical workstation(1470E Cell Test System, Britain) at a scan rate of 0.1 mV/s in range of 2.6-4.2 V. The $LiFePO_4$ electrode was used as working electrode, and lithium foil as both counter and reference electrode.



Scheme 1. Scheme of synthesis procedure followed in this work for the preparation of the $ILPyr_{1A}TFSI$.

3. Results and discussion

3.1 The physical properties of the pure $Pyr_{1A}TFSI$ and composite electrolytes

From table.1, the viscosity of the pure $Pyr_{1A}TFSI$ was 0.01898Pa.s which is much higher than the composite electrolytes. It can demonstrate that the addition of the organic and FEC can significant reduced the viscosity and enhance the low temperature performance. According to the DSC, the exothermic peak moves from -8℃ to -13 ℃ when instead free-FEC electrolyte of the FEC one. It proves that FEC can reduce the freezing point and increase the ionic mobility.

Table.1. The consequences of viscosity and DSC in different electrolytes

electrolyte	$Pyr_{1A}TFSI$	Ⅰ	Ⅱ
Viscosity	0.01898Pa.s	5.59E-03Pa.s	6.14E-03Pa.s
Exothermic peak	4.1℃	-8℃	-15℃

3.2 Discharge capacity of $LiFePO_4$/Li half cells at -30℃

The discharge curves of $LiFePO_4$ electrode in the composite electrolyte with and without FEC were shown in Fig.1 at -30℃ in the rate of 0.1C. The capacity of the half cell without FEC was 63.5mAh/g, and the one with FEC was 73.5mAh/g. The capacity retention at -30℃ (155mAh/g related to the capacity at 25℃) are 41% and 47.5%. Compared with the capacity 63.5mAh/g of the free-FEC cell, the FEC-containing cell exhibits higher reversible capacity. So by adding the FEC addition, the low temperature properties can be significant improved. According to the Fig.2, the capacity of each electrolyte half cells can finally return back to about 155mAh/g(the capacity at 25℃) after cycled at -30℃. It certified that the cycles of the half cells at low temperature don't destroy the structure of the whole cells including the electrode, electrolytes and separator.

3.3 The effect of FEC on surface morphology at -30℃

SEM images for $LiFePO_4$ electrode in the composite electrolyte without and with FEC after having cycled at -30℃ was shown on Fig.3.The particles of the $LiFePO_4$ of the FEC-free cells are larger and more inhomogenous, and also the cracks between the particles are broader than FEC-containing cells. The $LiFePO_4$ electrode with FEC show smooth and uniform morphology, which is attributed to the weaker polarization of the electrode due to the formation of the SEI film. These can explain why the FEC can improve the capacity of the half cells at low temperatures.

3.4 The cyclic voltammograms of the half cells

The CV for $LiFePO_4$ electrodes in the 0.5mol/L LiTFSI composite electrolyte with and without FEC at 25℃ were shown on Fig.4. Compared with the electrolyte with FEC (b) which show a sym-

metric peak, similar area and relatively low peak potential differences 0.625V, the electrolyte without FEC(a) display more asymmetric peak and wider peak potential differences. Also the peak intensity of the $LiFePO_4$ electrode in FEC-electrolyte is dramatically higher than the FEC- free one. In conclusion, again it can prove that the addition of the FEC can weak the polarization of the $LiFePO_4$ electrode no matter at room or low temperatures.

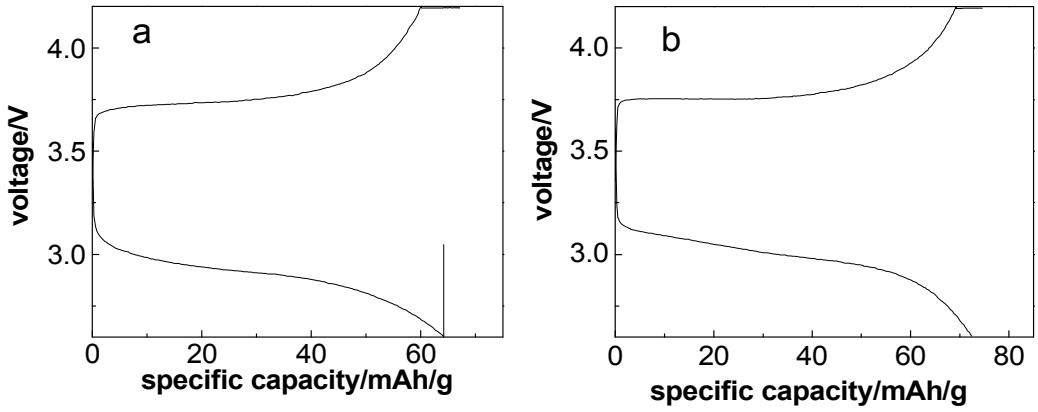


Fig.1. Charge and discharge curve of $LiFePO_4$ electrode in the composite electrolyte without FEC (a) and with FEC (b) at -30

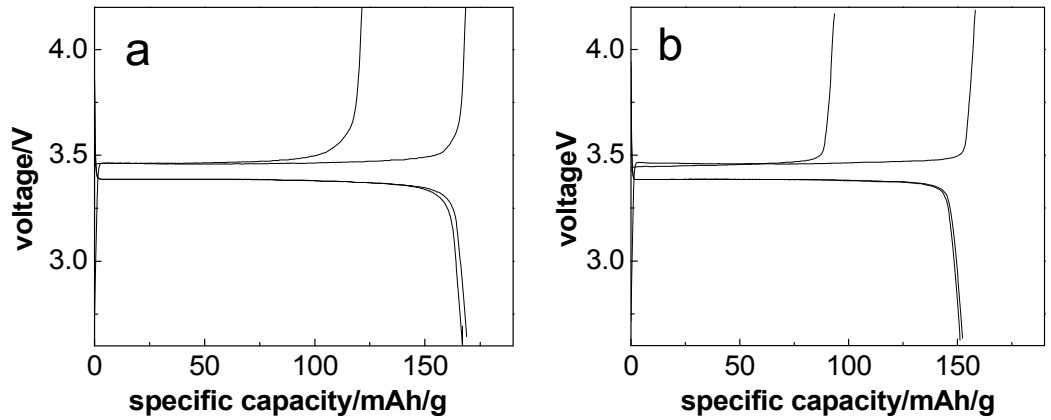

Fig.2. Charge and discharge curve of $LiFePO_4$ electrode in the composite electrolyte without FEC (a) and with FEC (b) at 25 after cycled at -30

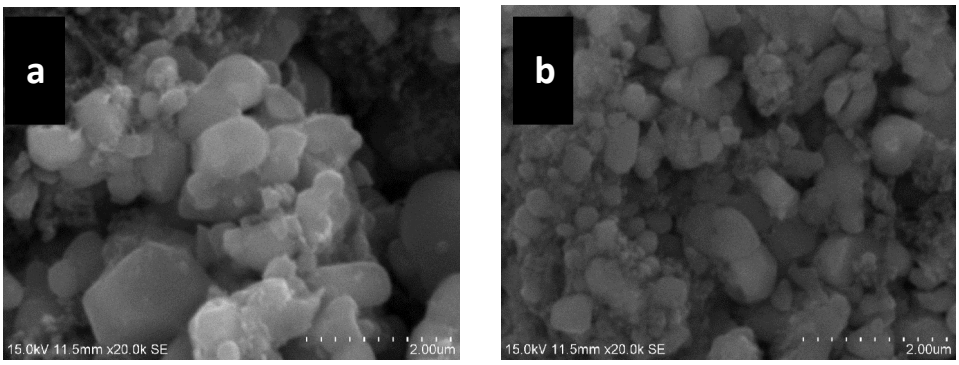

Fig.3. SEM images for $LiFePO_4$ electrode in the composite electrolyte without FEC (a) and with FEC (b) after having cycled at -30

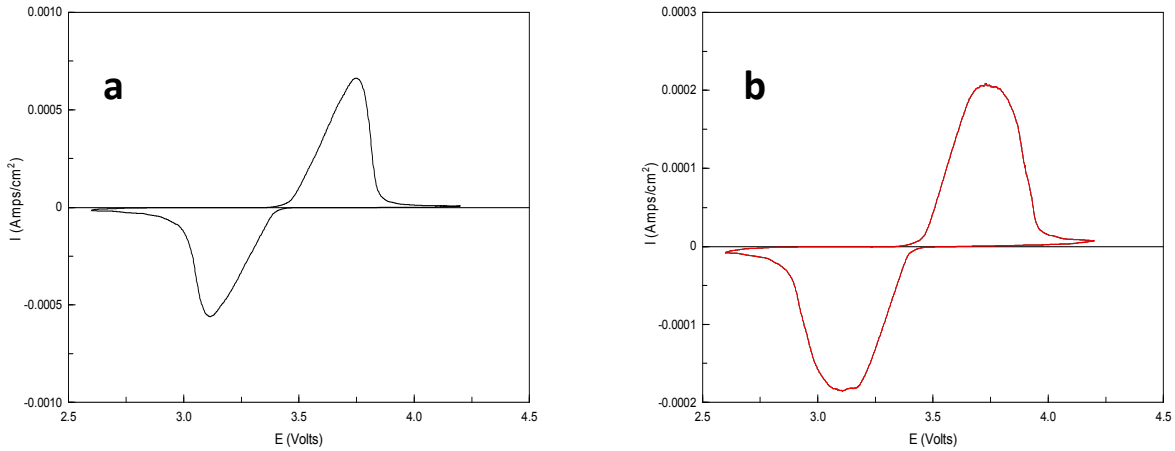

Fig.4. The cyclic voltammograms of $LiFePO_4$ electrode in the composite electrolyte without FEC (a) and with FEC (b) at 25

4. Conclusions

Addition of FEC to LiTFSI/PYR_{1A}TFSI/EC/PC/EMC electrolyte can reduce the freezing point and improve the performance of the composite electrolytes at the low temperature. FEC can dramatically increase the specific capacity at low temperatures and help the $LiFePO_4$ electrode to form more smooth and uniform surface morphology. It's attributed to the weak polarization of the $LiFePO_4$ electrode and excellent electrode/electrolyte interfacial properties. All above results demonstrated that FEC in LiTFSI-Pyr1ATFSI ionic liquid electrolyte can dramatically improve low temperature performance of lithium-ion batteries.

Keywords: Graphene oxide, Ultrasonic, Chemical oxidation, Fluorescence

Abstract. Graphene oxide (GO) was prepared via ultrasonic assisted chemical oxidation method. Contrasting with modified hummers method, GO prepared by ultrasonic assisted chemical oxidation method showed thinner flakes, the interlayer spacing increases. The emission spectra of the GO showed a similar excitation-dependent feature with the strongest peak (552 nm) excited at 477 nm.

Introduction

Graphene is a new type of two-dimensional nano materials which was discovered in 2004[1]. It has rich and novel physical properties because of special single atomic layer structure, thus received great attention and extensive research in the past few years. In the research and application of graphene, it is necessary for effective modification and surface functionalization of graphene to give full play to its excellent properties and improve its processability, therefore GO has emerged as a precursor offering the potential of cost-effective, large-scale production of graphene-based materials[2].

GO is consided as a single-layer of graphite oxide, it is usually produced by the chemical treatment of graphite through oxidation to obtain subsequent dispersion and exfoliation in water or suitable organic solvents[3,4]. In general, GO is usually synthesized by either the Brodie [5], Staudenmaier[6], or Hummers method[7]. All three methods involve oxidation of graphite to several levels. Brodie and Staudenmaier use potassium chlorate ($KClO_3$) with nitric acid (HNO_3) to oxidize graphite, while the Hummers method involves the oxidation treatment of graphite with potassium perman-ganate ($KMnO_4$) and sulfuric acid (H_2SO_4). Graphite salts made by intercalating graphite with strong acids such as H_2SO_4, HNO_3 or $HC1O_4$ have also been used for the subsequent oxidation to GO[8].Hummers method has advantage of simple synthesis, short time, high safety and less pollution to the environment, it has become the most common method used for preparing GO.

In this paper, we prepared GO via ultrasonic assisted chemical oxidation，ultrasonic auxiliary operation started in the medium and high temperature reaction stages of modified hummers method. In the process of preparing, an interesting phenomena of GO with fluorescence luminous performance was found, so we conducted a preliminary research.

Experimental

In this paper, the preparation of GO was divided into three stages. Oxidant potassium permanganate and acid(concentrated sulfuric acid and nitric acid) was added in low temperature reaction stage, oxide intercalated between the layers, temperature was controlled to 0~5 ℃. The second reaction stage started with ultrasonic, the reaction was warmed to 35~38 ℃, at which time deep oxidation was happened, and the graphite layers exfoliation were speed up under the action of ultrasonic. Ultrasonic was continued in high temperature, raise the reaction temperature to 82~85℃, at which time deionized water was added slowly for hydrolysis reaction of interlayer compounds. In order to research the ultrasonic effect in the process of GO preparation，modified hummers method was conducted as a contrast test.

Results and Discussion

Structure analysis. Fig. 1 is the XRD spectra of GO prepared by ultrasonic assisted chemical oxidation and chemical oxidation, respectively. The (001) crystal plane diffraction peak of two samples were both appeared，and diffraction peak of GO prepared by ultrasonic assisted chemical oxidation inclined left. According to the Prague equation $2d\sin\theta=\lambda$, calculations predicted that the interlayer spacing of the material is 7.3Å, larger than 6.9 Å that of GO prepared by chemical oxidation, indicating that ultrasonic contributes to the exfoliation of graphite layers.

FTIR-ATR spectra (Fig. 2) were recorded, and the following functional groups were identified in samples, the peak shape of two samples are in basic agreement. Both of the samples have a wide strong absorption band at 3200~3500cm^{-1}, corresponding to -OH stretching vibrations. In addition, the remaining water molecules also have an effect on the absorption peak. The absorption peaks in the 1735cm^{-1}, 1399cm^{-1}, 1093cm^{-1} belong to C=O, C-O-C, and C-OH stretching vibrations, respectively. The absorption peak of 1618cm^{-1} belongs to the -OH bending vibration of water molecules, indicating that the GO remains water molecules. The existence of a large number of oxygen functional groups indicated that graphite layers were inserted into a large amount of oxygen-containing groups after potassium permanganate and acid treatment.

a) Ultrasonic assisted chemical oxidation b) Chemical oxidation

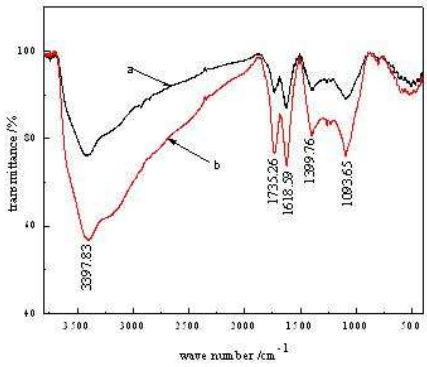

Fig. 2 FTIR-ATR spectra of GO
a) Ultrasonic assisted chemical oxidation b) Chemical oxidation

Morphology analysis. Transmission electron microscopy (TEM) photographs of the products are shown in Fig. 3. It is apparent that GO prepared by ultrasonic assisted chemical oxidation has a different morphology from that by chemical oxidation, the thickness of GO in Fig.3a is obviously thiner than that in Fig.3b, and folding in surface.The appearance is due to the effect of ultrasonic leads to the exfoliation of graphite layers,which is conform with the analysis result of Fig. 1.

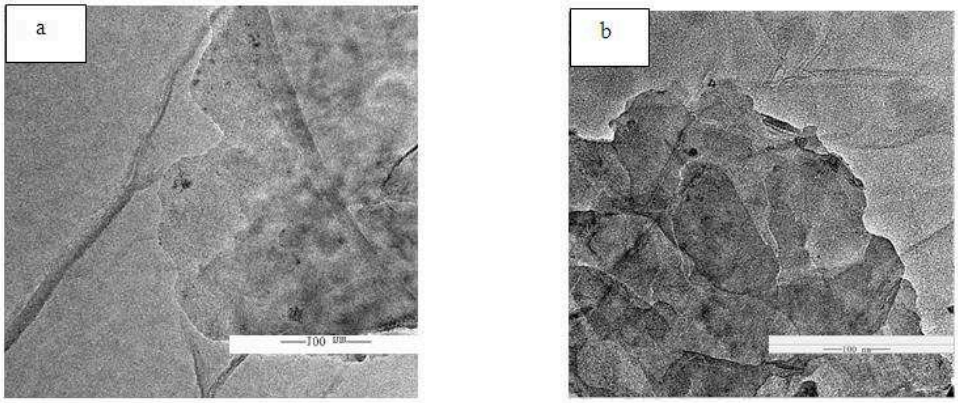

Fig. 3 TEM images of GO
a) Ultrasonic assisted chemical oxidation b) Chemical oxidation

Performance analysis. We have found an interesting phenomena that GO prepared by ultrasonic assisted chemical oxidation performs a certain degree of fluorescence property, thus we carried out a series of fluorescent light spectrum analyses of GO which prepared by two methods. Fig. 4, 5 are PL spectra and normalized PL spectra of GO at different excitation wavelengths. The emission spectra of the GO show a similar excitation-dependent feature with the strongest peak (552 nm,547 nm) excited at 477 nm and 470 nm, respectively. In addition, when the excitation wavelength changed to longer , the PL peak shifts to longer wavelengths at the same time, and its intensity first increased to the maximum(552 nm,547 nm), then decreased. GO prepared by ultrasonic assisted chemical oxidation showed more severe degree of shift. The reason is that oxygen-containing groups of graphite layers increased the number of defects, leading to fracture if external mechanical stress applied, the size of graphite layers then decreased to nanoscale and showed the similar to the quantum confined effect, fluorescence properties was then appeared. This property is closed to the fluorescence property of graphene quantum dots (GQDs)[9]. This may give a helpful advice for synthesis of GQDs.

Summary

GO prepared by ultrasonic assisted chemical oxidation shows thinner, smaller size. Ultrasound can promote the separation between the graphite layers, increasing the interlayer spacing of graphite. The oxygen containing functional groups of GO which prepared by chemical oxidation produce a number of surface defects. The use of ultrasound provides external stress, which increases the chance of graphene sheet fracture, leading to smaller size. when the size reduces to a certain extent, quantum confinement effect occurs and exhibits fluorescence property.

Keywords: Magnesium hydride, Hydrogen storage, Kinetics, Mechanical milling

Abstract. We report on the preparation and hydrogen desorption/absorption kinetics of nanocrystalline magnesium hydride (MgH_2) added commercial TiO_2 by high-energy ball milling. The phase and composition of the as-milled powders are characterized by X-ray diffraction(XRD). The results show that the milled sample contained MgH_2 phase, small amount of Mg and various phases of TiO_2 such as tetragonal and orthorhombic structure. The effect of the milling time (10, 20 and 30 h) on the hydrogen desorption property of MgH_2 has been investigated and found that the milling time of 20 h has excellent dehydrogenation properties, which can release 3.3 wt% H_2 within 60 min at 300 ^oC, which indicates that the kinetics of hydrogen desorption of MgH_2-TiO_2 composite has been greatly enhanced compared to the pure MgH_2. Moreover, hydrogen absorption kinetics of the sample milled 20 h has been studied and the hydrogen content is 0.7, 0.8 and 1.2 wt% H_2 at 250, 280 and 300 ^oC within 60 min, respectively.

Introduction

In Magnesium hydride (MgH_2) has been considered as a promising hydrogen storage material due to its high hydrogen capacity (gravimetric 7.6 wt% hydrogen and volumetric 110 kg H_2 m^{-3}) of hydrogen theoretically. And also it is cheap and abundant in the earth's crust[1]. However, MgH_2 is too stable and both dehydrogenation/ absorption kinetics are very slow and require high temperature, which creates a burden for the industrial-scale applications[2, 3]. To overcome these drawbacks, tremendous efforts have been devoted to catalysis[4, 5], alloying[6, 7] and nano-structuring[8, 9] in the past two decades, and signicant progress has been made to enhance the dehydrogenation/ absorption properties, in particular the hydrogen release kinetics.

It is advantageous to manufacturing nanocrystalline powder by high-energy ball milling. The nanocrystalline hydrides synthesized by high-energy ball milling showed very fast absorption and desorption kinetics due to faster diffusion of hydrogen along grain boundaries, as well as the high number of heterogeneous nucleation sites of the hydride on absorption[10]. Moreover, one of the most notable studies is on the addition of transition-metal oxides such as Nb_2O_5[11-15], Cr_2O_3[16, 17], CeO_2[18, 19], La_2O_3[19] and TiO_2[16, 20-22] that have been proven to ameliorate signicantly the hydrogen sorption kinetics of MgH_2. Among them, TiO_2 possesses many interesting characteristics, and has attracted much attention as an important catalyst in several typical hydrogen storage systems. For example, Schober[2] reported that dissolving hydrogen by TiO_2 after dissociation of hydrogen molecules could provide an effective path for hydrogen penetration of TiFe–TiO_2 composite systems. Wang et al.[22] prepared the nanostructured composite Mg–TiO_2 (rutile) by reaction ball milling (RBM). The addition of TiO_2 resulted in a markedly improved hydrogenation performance of Mg, such as rapid kinetics and low working temperature. Jung et al.[21] showed that the kinetics of hydrogen sorption was greatly enhanced by magnesium hydride doped with nano-sized TiO_2.

However, in spite of many researches carried out on the Mg–TiO_2 system, it is hard to enhance hydrogen desorption/ absorption kinetics simultaneously. Motivated by this, we performed a

systematic investigation on the hydrogen desorption/ absorption kinetics of MgH_2 catalyzed with various TiO_2, which was synthesized by the high-energy ball milling method.

Experimental procedures

Synthesis. The starting material MgH_2 (purity of 95%) and TiO_2 (purity of 99.8%) were purchased from Sigma–Aldrich and were used as received. The samples of MgH_2 containing TiO_2 (8 mol%) were prepared by the high-energy ball milling under argon atmosphere for 10, 20 and 30 h at a disc revolution speed of 400 rpm. The weight ratio between the ball and powder is 40:1. All material handing (including weighing and loading) was carried out in a glove box under an inert pure argon (99.999%) atmosphere so as to minimize the contamination effect of oxygen and water on the sample.
Characterization. The Powder X-ray diffraction (XRD) patterns were taken on a D/Max-RB X-ray diffractometer using Cu Kα radiation (λ=1.54178Å) to determine the phase composition of the as-milled powders. The X-ray intensity was measured over a diffraction angle from 20° to 80°. The pressure- composition-temperature (P-C-T) curves for hydrogen absorption and desorption kinetics were determined by using a computer controlled Gas Reaction Controller apparatus (PCTPro 2000).

Results and discussion

XRD analyses. Fig. 1 shows a series of powder X-ray diffraction (XRD) patterns of the pure MgH_2 and as-milled samples obtained at different milling time. It can be seen that the phase composition does not significantly change after ball milling. By inspecting the XRD pattern of MgH_2+TiO_2 mixture at different milling time, the peak intensity ascribed to MgH_2 decreases obviously after ball milling. Especially, when the milling time is 20 h, the peak ascribed to MgH_2 broadens distinctly, and this broadening can be attributed to a reduction in crystallite size and/or amorphization. So, it could conclude that the particle size of MgH_2 is smaller than the size of as-milled samples after 10 and 30 h. The milling finally results in the presence of tetragonal and orthorhombic phase TiO_2 (Joint Committee on Powder Diffraction Standards (JCPDS) No. 65-1119 and 65-2448, respectively).

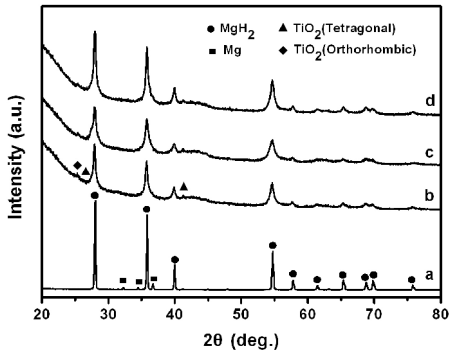

Fig. 1 Powder XRD patterns of pure MgH_2 (a) and MgH_2+TiO_2 mixture as a function of milling time: (b) 0 h, (c) 20 h and (d) 60 h, respectively.

Hydrogen desorption of MgH_2+TiO_2 composite. To determine the hydrogen desorption kinetics of the as-prepared MgH_2+TiO_2 mixture for different milling time of 10, 20, and 30 h, Fig. 2 gives the typical hydrogen desorption curves at 300 °C. It is demonstrated that the sample milled 20 h exhibits much higher kinetics than that of the others. As shown in Fig.2, the sample milled 20 h releases 3.3 wt% H_2 in 60 minutes at 300 °C. In contrast, the sample milled 10 and 30 h release 1.0 and 3.0 wt% H_2 under the same conditions. For prolonged milling (such as 30 h), it should be noted that there is no further enhancement of the dehydrogenation kinetics properties. The reason may be the larger particle sizes compared with the sample milled 20 h. The XRD curve for the dehydrogenated MgH_2+TiO_2 has been showed in Fig. 3, and it can be seen that the final product is composed of TiO_2, Mg and some residual MgO.

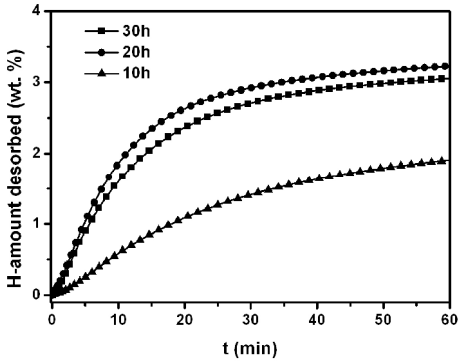

Fig. 2 Dehydrogenation curves of the as-prepared MgH_2+TiO_2 mixture for different milling time of 10, 20, and 30 h at 300 °C.

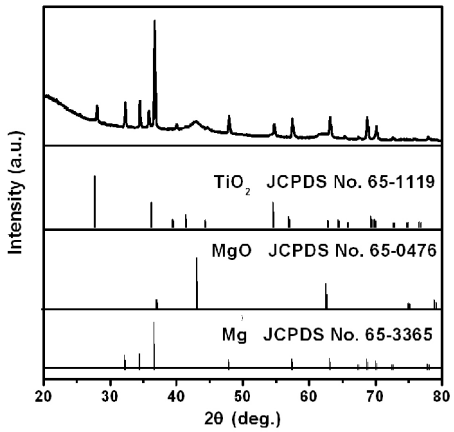

Fig. 3 The XRD curve for the dehydrogenated MgH_2+TiO_2 mixture milled 20 h.

Hydrogen absorption of MgH_2+TiO_2 composite. Besides the improvement in the dehydrogenation kinetics, the hydrogen absorption kinetics of the as-prepared MgH_2+TiO_2 milled 20 h is also shown in Fig.3a for different temperatures of 250, 280 and 300 °C. It can be seen that the sample releases 0.7, 0.8 and 1.2 wt% H_2 in 15 minutes at 250, 280 and 300 °C , respectively, while the pure MgH_2 sample can not release any hydrogen below 300 °C. It can be found that the hydrogen absorption kinetics of MgH_2 is significantly improved by the adding of TiO_2.

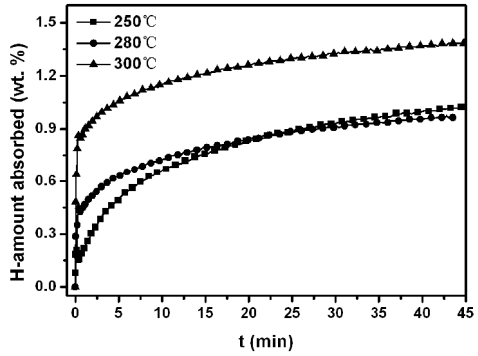

Fig. 4 The hydrogen absorption kinetics of the as-prepared MgH_2+TiO_2 milled 20 h for different temperatures of 250, 280 and 300 °C.

Conclusion

In summary, we have prepared nanocrystalline magnesium hydride (MgH_2) added commercial TiO_2 by high-energy ball milling. The results of XRD tests show that the milled sample contained MgH_2 phase, small amount of Mg and various phases of TiO_2 such as tetragonal and orthorhombic structure. The effect of the milling time (10, 20 and 30 h) on the hydrogen desorption property of MgH_2 has been investigated and found that the milling time of 20 h has excellent dehydrogenation properties,

which can release 3.3 wt% H_2 within 60 min at 300 ^oC, which indicates that the kinetics of hydrogen desorption of MgH_2-TiO_2 composite has been greatly enhanced compared to the pure MgH_2. The final product is composed of TiO_2, Mg and some residual MgO. Moreover, hydrogen absorption kinetics of the sample milled 20 h has been studied and the hydrogen content is 0.7, 0.8 and 1.2 wt% H_2 at 250, 280 and 300 ^oC within 15 min, respectively.

Keywords: flue gas desulfurization system; gas-gas heater; water balance; flue temperature

Abstract: Material balance calculation was adopted to a wet flue gas desulfurization (WFGD) system for exploring impacts of gas-gas heater (GGH). Effects of GGH on flue and water consumption were analyzed. Results showed that inlet flue temperature of desulfurization tower reduced by 3.4 ℃ at 100% load after installation of GGH. Exhausted gas temperature of system increased by 34.9℃. The heat release of original flue in desulfurization tower reduced by 43.72%. Plume rise height was significantly improved. Water evaporation in desulfurization tower declined by 42.07%.Amount of addendum water reduced by 39.06%, and water vapor carried by flue decreased by 19.78% at the outlet of WFGD. Therefore, operation condition of flue emission is improved and water consumption decreases with GGH.

1. Background

Wet flue gas desulfurization was widely applied in thermal power plant due to mature technology and high desulfurization efficiency. Gas-gas heater(GGH) was the key equipment of WFGD system. The original and net flue gas desulfurized exchanged heat at GGH, original flue gas temperature reduced and net flue gas temperature increased. Since the operation was not standardized and the purge process was unreasonable, heat storage components of GGH was prone to be choked up by scaling, causing the system pressure increased and booster fan stalled when seriously, leading to the entire unit outage finally[1,2]. Therefore, GGH were tend to be canceled in existing WFGD systems. However, the original flue gas temperature and evaporation of process water in desulfurization tower could be reduced with GGH, aiming at water conservation, which has practical significance for thermal power plants in arid regions of the Midwest. Net flue gas discharge temperature was enhanced with GGH, flue gas and acid dew point was reduced as well as flue gas carrying water, smoke plume discharge height was uplifted and corrosion of chimneys was on the decrease together with plaster rain phenomenon[3,4,5]. In this paper, the impact of GGH on important parameters of WFGD was analyzed for a 600MW unit to provide a reference for the optimization of desulfurization system.

Fig.1 Wet flue gas desulfurization with Jet bubble reactor

2. Methods

A WFGD system of 600MW unit was analyzed using a mass balance calculation in desulfurization system, influence of GGH on exhaust gas temperature and water consumption was analyzed. Flue gas balance, energy balance, solid balance, water balance and chlorine balance were included in material balance of WFGD systems as sub-modules[6]. The exhaust gas temperature of desulfurization system was obtained by energy balance calculations, water consumption of system by Water balance calculation, and volume of wastewater was determined by chlorine balancing. First, assuming exit gas temperature of desulfurization tower and GGH exports temperature of net flue gas side, evaporation of water at hypothetical temperature was determined with energy balance calculation. Making the net flue gas water vapor pressure the same as saturated steam at hypothetical temperature by iterative calculation, then hypothetical temperature of GGH was checked. All material balance data of desulfurization system was finally obtained[7]. Calculation for acid dew point was executed with A.G.Okkes acid dew point formula, and plume rise height was calculated with thermal power plant air pollutant emission standards (GB13223-2003) at 100% load, the detailed process see ref[8].

3. Results and analysis

3.1 Effect on flue gas emissions

Energy release of WFGD system major covered heat release of the original flue gas (dry basis), original smoke carrying steam, chemical reactions and oxidation air cooled. Energy balance calculations showed that heat release of the original flue gas (dry basis) accounted 87.3% of the system energy taking into the desulfurization, which was the biggest heat source dragged-in. While after GGH installed, heat release of the original flue gas in desulfurization tower reduced by 43.72% by transmitting heat of 97947.8MJ / h to net flue gas. Simultaneously, heat release of water vapor of absorber in original the flue gas reduced 9149.4MJ / h, accounted 43.57%. Energy absorbing embraced heat process water(maintain the level), gypsum slurry circulating water and limestone slurry assimilated along with heat taking away by evaporation of water. Heat absorption of water evaporation in tower was the largest term, accounted for 94.0% of the total. Calculations showed that heat absorption of water evaporation in desulfurization tower decreased by 41.89% with GGH, corresponding to 101023.9MJ / h. Meanwhile, 5356.6MJ / h for reduction of addendum water heat absorption, accounted by 49.92%, 186.2MJ/h for limestone slurry, equivalently 22.65%. So energy brought into the desulfurization tower and water evaporation heat absorption reduced with GGH.

Tab. 1 Influence of GGH on exhausted gas temperature of WFGD systems [℃]

GGH	GGH imports raw flue gas temperature	Import gas temperature of desulfurization tower	flue gas temperature spray desuperheated	Net flue gas outlet temperature of desulfurization tower	Net gas exports temperature of GGH
with	132	95	47.8	47.6	84.9
without	-	132	51.2	50.8	-

Table 1 showed influence of GGH on flue gas temperature in desulfurization system. Flue gas temperature reduced by about 37 ℃ after the original flue gas flowing through GGH with installation of GGH in desulfurization system. Compared to conditions without GGH, temperature of original flue gas spray desuperheated lowered by 3.4 ℃ and desulfurization reactor outlet flue gas temperature increased by 3.2 ℃ at working conditions installed GGH. In this case, chimney flue temperatures added to 84.9 ℃, and only 50.8℃ for conditions without GGH.

SO2 oxidation rate in flue gas was taken for 1%, dew point and acid dew point of the desulfurization system outlet flue gas were calculated. Chimney flue gas inlet dew point temperature was 46.95 ℃ and acid dew point was 122.39 ℃ without GGH, in the opposite condition, dew point was 41.84 ℃ and acid dew point was 120.67℃, 5.11℃and 1.72℃ respectively lower than the former. The reason was that the saturation temperature of desulfurization system flue gas outlet was reduced with installation of GGH, thereby moisture content of net flue gas was reduced together with dew point temperature. Simultaneously, water vapor partial pressure at the system outlet of the net flue gas was also decreased, so that net flue gas acid dew point temperature dropped. Therefore, GGH will reduce dew point and acid dew point temperature of chimney imports flue gas, thus working environment of backpass improved.

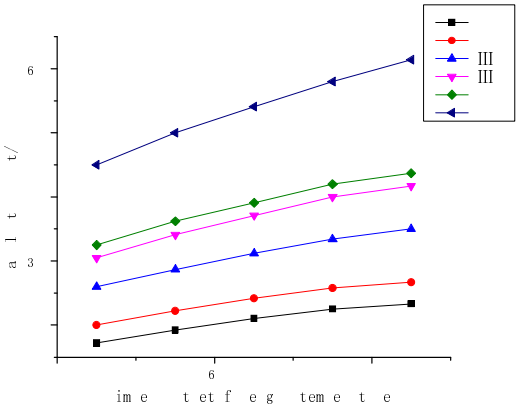

Fig.2 Influence of flue temperature on gas lift height

Plume rise height was calculated taking chimney height as 180m, wind speed at chimney ten meters as 2m/s, and exhaust gas temperature distributed at 45 ~ 85 ℃. Relationship between plume rise height and exhaust gas temperature for different atmospheric stability has shown in Figure 2. Gas lift height increased directly with atmospheric stability, similarly with chimney flue gas outlet temperature. When atmospheric stability was at level V, gas lift height was almost above 450m, which will increase 130m as the flue gas temperature rising from 45 ℃ to 75 ℃, traditional chimney gas lift height can reach to 614m corresponding to exhaust gas temperature. While I level, gas lift height was almost below 250m, which was only 172m as the flue gas temperature was 45 ℃.Different atmospheric stability and flue gas emission temperatures corresponded to 442m gap in plume rise height. Because of low WFGD system exhaust gas temperature, corresponding chimney gas lift height was low, which was less than 200m in the low atmospheric stability, resulting that smoke flowed back to the ground in the vicinity of the power plant and produced gypsum rain phenomena. Moreover, the exhaust gas temperature could be upgraded to 85 ℃ by GGH, and plume rise height was increased, phenomenon above would relieve.

3.2 Impact on the water balance

Desulfurizer water, raw flue gas carrying steam and addendum water (including equipment wash water, cooling water, gas cooling water, desulfurizer prepared water) constituted inflow item of WFGD system water balance. In which raw flue gas carrying steam was major source of system influent water, accounted more than 54% of the total. Effluent items included gypsum carrying water, net smoke carrying steam, net smoke carrying liquid and desulphurization wastewater, in which net smoke carrying steam was the most and accounted more than 95%.

Impact of GGH in WFGD system on water balance has shown in Table 2. Addendum water declined of 39.06%, net smoke carrying steam of 19.78% and desulfurization wastewater reduced by 11.53% with GGH. Decrease of net smoke carrying steam was in favor of alleviating wet flue gas emissions. Known from energy balance calculations, flue gas temperature entering the desulfurization tower reduced 3.4 ℃ and original flue gas heat in desulfurization tower reduced by 43.72% after installation of GGH. Water balance calculations indicated that evaporation in tower decreased from 101.32t / h down to 58.69t / h, reduced by 42.07%. Total evaporation of water in tower reduced with GGH, resulting in decrease of addendum water consumption, while variation in net smoke carrying steam, net smoke carrying liquid and gypsum water was small. Addendum water reduced by GGH, which leading to decrease of chloride ions brought into the desulfurization system, thus desulfurization waste water reduced, therefore desulfurization waste water was closely related to addendum water. In conclusion, energy into the tower reduced by GGH, significantly similar with evaporation of water tower, desulfurization wastewater and net smoke carrying steam, thus the consumption of process water and flue gas humidity were effectively reduced.

Tab.2 Influence of GGH on water balance

GGH	Inflow Item				Effluent Item		
	Original flue carrying steam	Chemical reaction water	Addendum water	Net flue Carrying steam	Net flue Carrying water droplets	Gypsum water	Desulfurization wastewater
with	130.55	0.63	68.36	189.24	0.17	0.41	8.59
without	134.59	0.65	112.18	235.91	0.17	0.42	9.71

4. Conclusion

（1） Because of the presence of GGH, water evaporation heat in absorption tower reduced along with flue gas carrying heat into the absorption tower. Flue gas dew point and acid dew point temperature also reduced as the flue gas absorption tower imports temperature. Therefore, plume rise height raised along with system exhaust gas temperature improving.

（2） Water evaporation in tower and the desulfurization wastewater greatly reduced with GGH, resulting process water consumption and flue gas humidity effectively reduced.

Keyword: Planar solid oxide fuel cell stack, Flow distribution, Investigation, Geometric parameters.

Abstract. In this paper, a realistic 3D numerical model is established to investigate the flow distribution of a 10-cells short planar SOFC stack. The effect of the basic geometric parameters, such as the sub-manifold radii (R_s) and the single channel width (W_{ch}), on the stack flow uniformity is examined. And the results and discusses are presented in this paper. This investigation for the SOFC stack holds great significance for the SOFC stack commercialization.

Introduction

The planar solid oxide fuel cell (SOFC) is regarded as one of the most promising technology for electrical power generation because of its great advantages such as cleaning, high efficiency and easy to manufacture [1, 2]. A typical planar solid oxide fuel cell stack with a co-flow distribution pattern has been reported by Jean [3].

One of the most emergency technology problems in the design of the planar SOFC stack is how to get a better stack performance [4]. Therefore, the aim of this work is investigating the air flow distribution in the SOFC stack and optimizing the flow uniformity as much as possible.

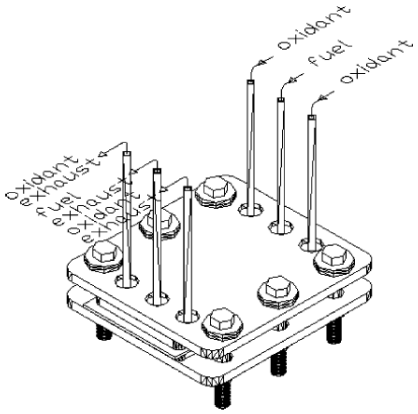

Fig. 1 The planar solid oxide fuel cell stack reported by Jean [3]

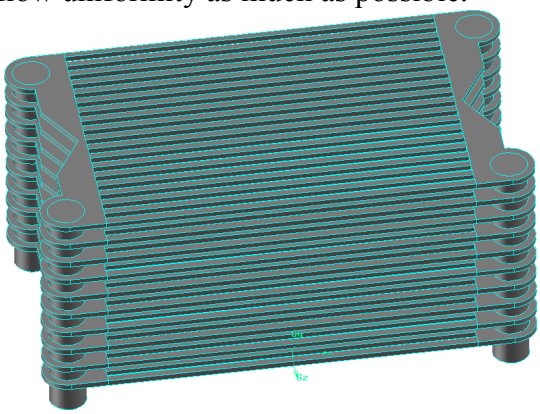

Fig. 2 The 10-cells short planar SOFC stack air flow model

The 3D realistic air flow model and CFD Calculation

This paper establishes a realistic 10-cells short planar SOFC stack air flow model with the MEA areas of 75 mm×100 mm, shown in Fig. 2, and the air flow model in a unit cell is illustrated in Fig. 3.

Commercial software, FLUENT 6.3 based on the finite volume method is adopted in our CFD calculation[5]. The governing equations including the continuity equation, the momentum equation should be calculated in this model [6]. Other relevant parameters are listed in Table 1 [7].

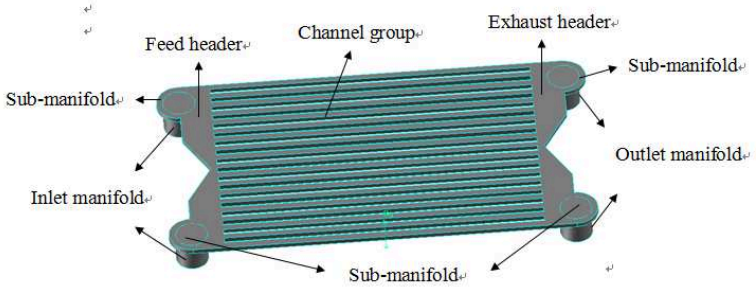

Fig. 3 The air flow model within a unit cell

Table 1. Relevant parameters should be set in FLUENT 6.3

Operation temperature	1073 [K]
Average current density	7000 [A/m2]
Oxygen utilization	0.3
Oxygen mole fraction	0.21
Density of air	0.329[kg/m3]
mole mass of air	0.029 [kg/mol]
Viscosity of air	$4.31\times10\text{-}5\ [\mathrm{kg/(m\cdot s)}]$
Inlet velocity	12.1 [m/s]

The investigation of the sub-manifold radii R_s

Fig.4 compares the flow rates of the 10 unit cells by varying the sub-manifold radii. The stack flow uniformity index U is analyzed and optimized to get better stack performance.

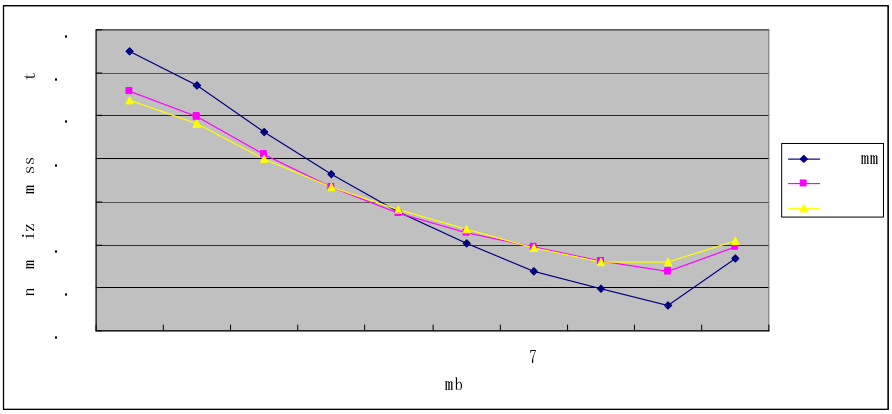

Fig. 4 The stack flow uniformity index when R_s=6 mm, 8 mm, 10 mm.

As can be seen in Fig. 4, for R_s=6 mm, 8 mm, 10 mm, the stack flow uniformity index is calculated to be 0.878, 0.879, 0.93. So the stack flow uniformity index has a certain degree of improvement with the increase of the sub-manifold radius. This may be interpreted that the flow rate can be reduced around the sub-manifold through expanding the sub-manifold radii, which helps to reduce the disorder of the gas flow from the inlet manifold. This interpretation also can be verified by Fig. 5(a-b), from this figure we can know that the 10-th unit cell velocity in the stack with R_s = 8 mm is a little larger than which in the stack with R_s=10 mm.

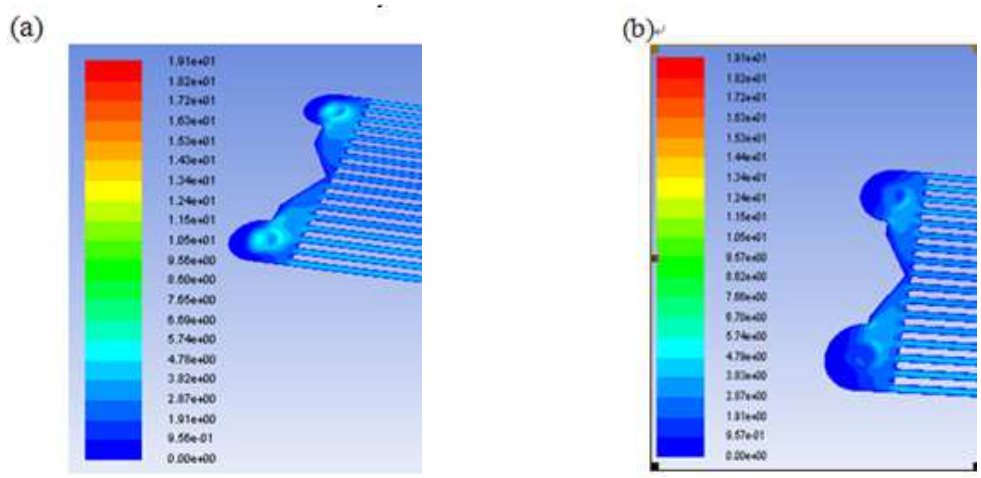

Fig. 5 The velocity diagram around the manifold of the 10-th unit cell (a) the stack with R_s =8 mm; (b) the stack with R_s =10 mm.

The investigation of the single channel width W_{ch}

In this simulation, the total interconnect plane is limited in the region between 73 mm and 75 mm. So the channel number changes along with the single channel width change.

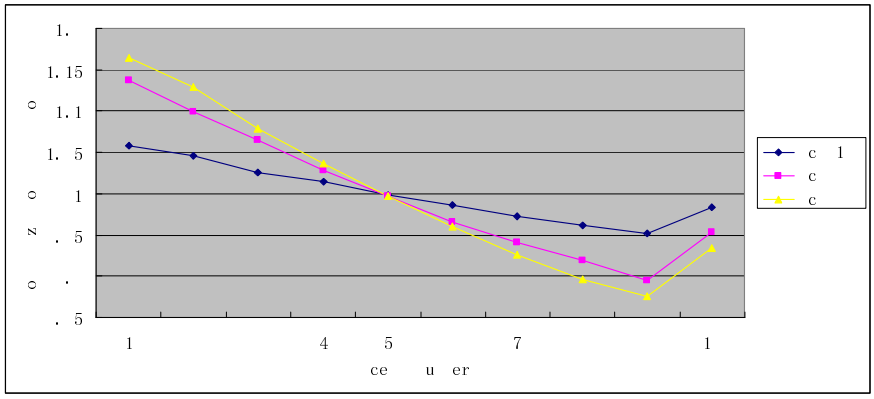

Fig. 6 The stack flow uniformity index for W_{ch} =3 mm, 2 mm and 1mm

A rang of 1mm-3mm is considered for the single channel width in the stack with R_s =8mm to examine the effect of single channel width on the flow distribution. As shown in fig.6, the flow distribution expresses better uniformity when W_{ch} =1 mm.

This phenomenon may be reasonable explained in Fig.7(a-b) , The static pressure drop shown in Fig.7(a) (the static pressure drop is about 300 pa) is much larger than which shown in Fig.7(b) (the static pressure drop is about 100 pa), which leads to better uniformity of the stack with W_{ch} =1 mm.

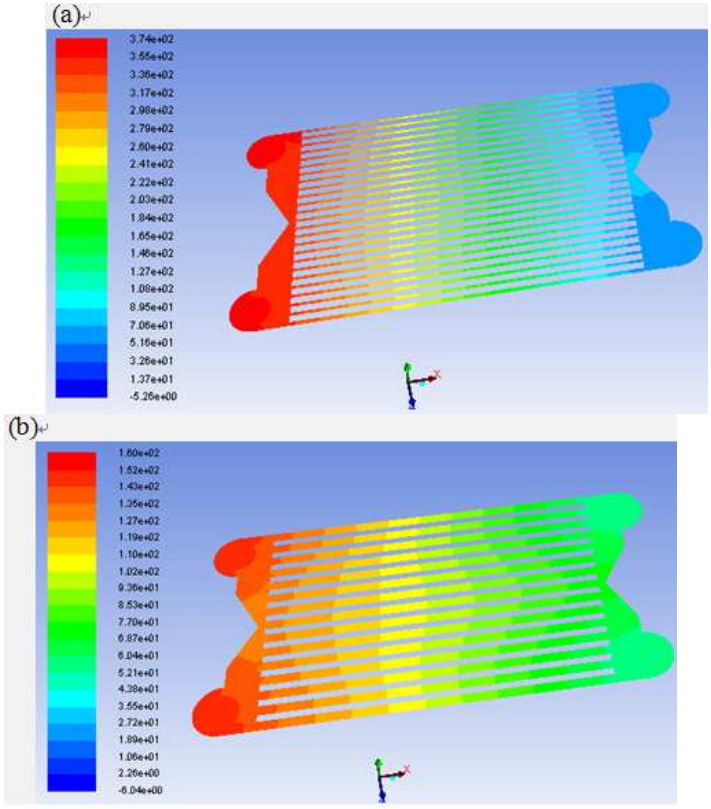

Fig. 7 The static pressure distribution of the 6-th unit cell, (a) the stack with W_{ch}=1 mm, (b) the stack with W_{ch}=3mm.

Conclusion

Realistic 3D 10-cells short planar SOFC stacks are built and investigated through CFD method using the commercial software Gambit and FLUID 6.3. The result shows that increasing the sub-manifold radii properly and decreasing the single channel width can improve the stack performance. However, the improvement of the stack performance through optimizing the channel dimension is under the expense of consuming more materials. All these analytic models and conclusions are useful and robust for the further development and commercialization of the planar SOFC stack.

Keywords: Sodium methoxide, sodium hyrdoxide, reaction coupling with separation model

Abstract. Preparing sodium methoxide by reacting sodium hydroxide with methanol was investigated. The chemical equilibrium constant was small. Removing water out of the reaction phase could drive the reaction to produce more sodium methoxide. The experiments were carried out at different temperatures and 1 atm in semi-batch reactor by liquid evaporating to remove water. The effects of initial sodium hydroxide concentration and liquid evaporating speed were discussed. A mathematical model coupling reaction with separation processes was built and the predicted results by the model were in good agreement with experiment results. The model provides useful information for industrial simulation.

Introduction

Recent years, sodium methoxide(CH_3ONa) is being extensively investigated as an efficient catalyst for biodiesel production, aiming to lower the reaction temperature, reduce the reaction time and increase biodiesel yields[1]. One method to prepare CH_3ONa is reacting metallic sodium with methanol, because of the high cost of metallic sodium and hydrogen release in the process[2], another preparation method by sodium hydroxide and methanol is more widely used in continuous production. It is usually carried out in a reactive distillation column with large amount of gaseous anhydrous methanol fed into bottom of the column. Gaseous methanol contacts countercurrent with sodium hydroxide-methanol solution, removes water from the reaction phase and increases the production of CH_3ONa [3]. The chemical reaction can be represented as follows:

$$CH_3OH + NaOH \leftrightarrow CH_3ONa + H_2O \quad (1)$$

To reduce energy consumption and improve the product purity, it is of great value to simulate and optimize this reactive distillation process. The purpose of this paper is to conduct experiments to obtain kinetic equation of the reaction. Since the chemical equilibrium constant is small[4], it is difficult to determin the amount of CH_3ONa and H_2O accurately only by homogenenous reaction method. A semi-batch experiment method coupling reaction with seperation processes was employed, removing water by liquid evaporating. The effects of initial NaOH concentration and liquid evaporation speed on the decresing rate of NaOH concentration in reaction phase were investigated. A mathematic model was built to simulate the reaction coupling separation processes.

Experiment

Chemicals. The sodium hydroxide (96.0 mass %), anhydrous methanol (99.5 mass %) and Karl Fischer reagent were purchased from Sinopharm Chemical Reagent Co. Ltd.. The water content in the methanol did not exceed 0.05 mass %. The hydrochloric acid solution (36.0～38.0 mass %) was obtained from Hangzhou Chemical Reagent Co. Ltd..

Experimental procedures. Mixtures consisting of methanol and sodium hydroxide were prepared gravimetrically using analytical balance. For each experiment, appropriate amount of sodium hydroxide-methanol solution with various concentrations of sodium hydroxide was charged

into a three-necked round-bottom flask (500 mL) equipped with a separating funnel, a condenser and a thermometer. The flask was placed in an electric heating tank. When the solution was heated to evaporate, it was set as the start-point of the reaction. The liquid evaporating speed was kept stable by controlling electrical heating power. The vapor was condensed and collected in a conical beaker. Fresh anhydrous methanol liquid was added into the flask continuously through the separating funnel to maintain the liquid level nearly the same. The samples of the liquid mixtures in flask and conical beaker were taken through micro syringe at an interval of about 15 minutes.

Initial concentration of sodium hydroxide in methanol solution was determined by weighing the sodium hydroxide and methanol and varied from (1.25 to 5) mol/L. Sodium hydroxide and methoxide were regarded as nonvolatile components. The total concentration of sodium hydroxide and water in liquid of the flask and the water in liquid of conical beaker could be determined by Karl Fischer titration[5]. The molar fraction of methanol in liquid was close to 1, so the salt effect of sodium hydroxide and sodium methoxide on vapor-liquid equilibrium (VLE) of methanol-water system could be neglected according to literatures[6]. The concentration of water in liquid of the flask could be deduced based on the VLE of methanol-water binary system and the water in vapor could be regarded as equal to the water concentration in the liquid of conical beaker. The total concentration of sodium hydroxide and sodium methoxide in liquid was determined by titration using hydrochloric acid solution, and the concentration of sodium methoxide could be calculated.

Kinetic model

The general reaction rate expression in homogeneous phase can be written as:

$$-r_{NaOH} = k_1 C_{CH_3OH} C_{NaOH} - k_2 C_{CH_3ONa} C_{H_2O}. \quad (2)$$

where r and C represent the reaction rate (calculated based on NaOH concentration) and molar concentration respectively, and k_1, k_2 are the apparent rate constants. The concentration of methanol is great and can be regarded as a constant, so the equation can be simplified as Eq.3. k_1' is a developed apparent rate constant.

$$-r_{NaOH} = k_1' C_{NaOH} - k_2 C_{CH_3ONa} C_{H_2O}. \quad (3)$$

Because the chemical equilibrium constant is very small, the concentration of CH_3ONa and H_2O in homogeneous reaction phase is difficult to be analyzed accurately. By liquid evaporating to remove water, the reaction was driven to the right. The experimental results showed the decreasing rate of NaOH concentration in reaction phase was related to both the reaction rate in reaction phase and the liquid evaporating speed. A mathematic model coupling reaction with separation processes was built and the decreasing rate of NaOH concentration can be written as:

$$-\frac{\mathrm{d}C_{NaOH}}{\mathrm{d}t} = v \cdot (k_1' C_{NaOH} - k_2 C_{CH_3ONa} C_{H_2O}). \quad (4)$$

Where v represents the liquid evaporating speed per unit of liquid volume, t is the reaction time. v can be determined by the amount of condensed liquid collected in conical beaker over a period time. k_1' and k_2 are related to temperature of the reaction phase. The concentrations of NaOH, CH_3ONa and H_2O were determined directly or calculated from the experiment results and regressed to obtain the parameters of the model.

Results and Discussion

Effect of initial concentration of NaOH. In order to study the effect of initial concentration of NaOH, a series of experiments were carried out where the initial NaOH concentration was set at (1.25, 2.25, 3.75, 4.38 and 5.00) mol/L respectively. It is difficult to determine the composition accurately when the initial concentration is too low or more than 5.00 mol/L. Relationship between

the boiling point of the solution and initial concentration of sodium hydroxide is shown in Fig.1. It indicates that the boiling point increases with the rising initial concentration of NaOH, because the salt effect of NaOH and CH_3ONa decreases the saturated vapor pressure of methanol and increases the boiling point of the solution[6,7]. When initial NaOH concentration was held the same, the reaction temperature nearly remains unchanged during the whole process. It can be deduced that NaOH converting to CH_3ONa has little effect on the reaction temperature.

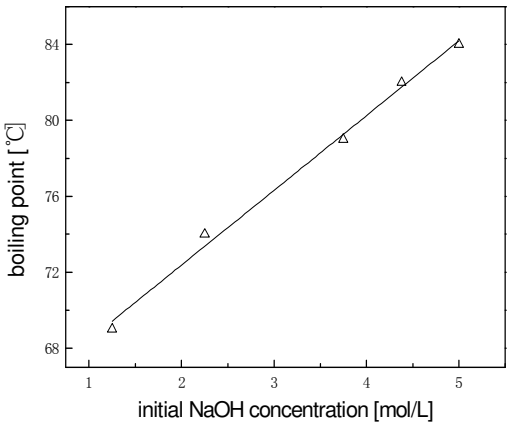

Fig. 1 Effect of initial NaOH concentration on boiling point of methanol solution

When the initial NaOH concentration varied from (1.25 to 5.00) mol/L, the liquid evaporating speed was held the same. The variation of NaOH concentration in reaction phase depending on reaction time is shown in Fig.2, represented as points in different shape. It shows that the increasing of initial NaOH concentration can enhance the decreasing rate of NaOH concentration in reaction phase. The variation of water concentration in reaction phase depending on reaction time is also shown in Fig.3.

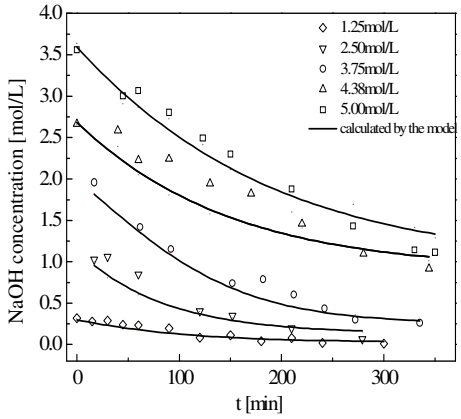

Fig. 2 Variation of NaOH concentration versus reaction time with different initial NaOH concentration

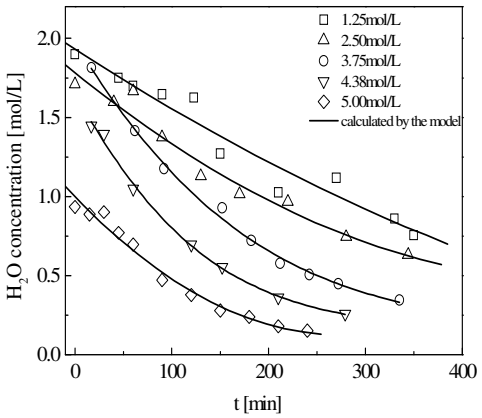

Fig. 3 Variation of H_2O concentration versus reaction time with different initial NaOH concentration

Effect of liquid evaporating speed. The liquid evaporating speed can be changed by controlling the electronic heating power. The experimental results showed that at the same reaction temperature, the decreasing rate of NaOH concentration in reaction phase gets faster with a rising liquid evaporating speed. When the liquid evaporating speed increases, more water can be removed from reaction phase into vapor phase and the reaction is driven to the right. Fig.4 shows the the variation of NaOH concentration in reaction phase depending on reaction time with different liquid evaporating speed, v, in g/(min • L), and the initial NaOH concentration fixed at 3.75 mol/L. The

experimental data is represented as points in different shape. The variation of water concentration in reaction phase depending on reaction time is also shown in Fig.5.

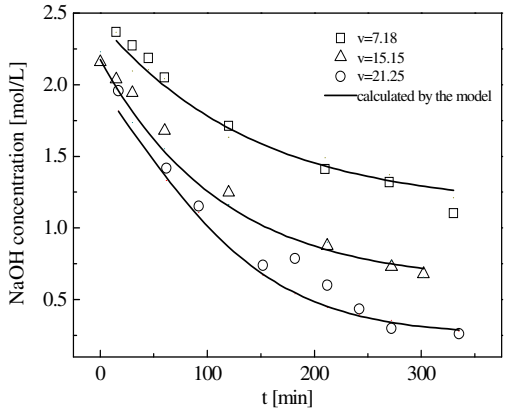

Fig. 4 NaOH concentration versus reaction time with different liquid evaporating speed

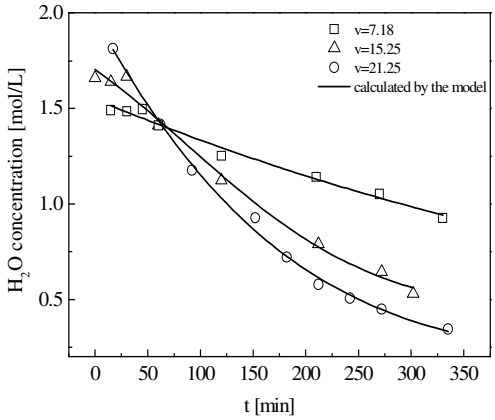

Fig. 5 H_2O concentration versus reaction time with different liquid evaporating speed

Regressed model parameters. The experimental results were fitted with multiple linear regression function to obtain the values of k_1' and k_2 in model (Eq.4) at different temperatures, and the results show that k_1' and k_2 increase with the rising temperature. According to Fig.6 and Fig.7, $\ln k_1'$ and $\ln k_2$ are linearly associated with the reciprocal of temperature.

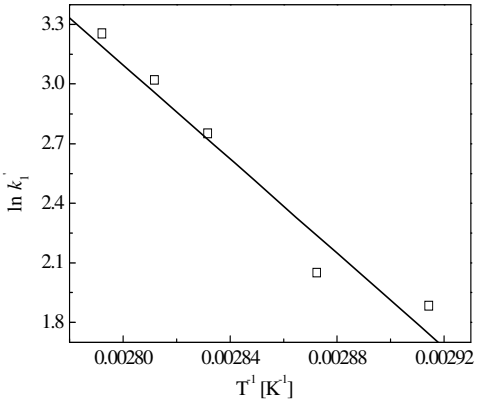

Fig. 6 Relationship between ln k_1' and 1/T

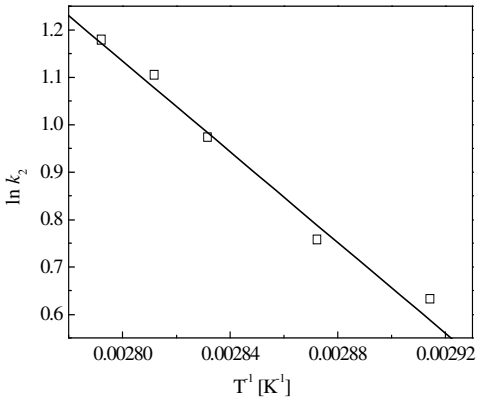

Fig. 7 Relationship between ln k_2 and 1/T

The equations between k_1', k_2 and temperature are as follows:

$$k_1' = 5.59 \times 10^{15} \exp(-\frac{11844.72}{T}). \quad (5)$$

$$k_2 = 2.06 \times 10^{6} \exp(-\frac{4787.67}{T}). \quad (6)$$

The contrasts between the predicted concentrations of sodium hydroxide and water in reaction phase by the mathematic model (Eq.4) and the experimental data are obviously shown in Fig.2, Fig.3, Fig.4 and Fig.5, the predicted results are represented as solid lines. As shown in these figures, the predicted results were in good agreement with the experimetal results. A rigorous statistical analysis was conducted on predicted results by the model and the experimental data[8]. The total sum of squares, regression sum of squares and residual sum of squares were calculated and shown in table 1. The correlation coefficient ρ^2 was found to be 0.95, and variance test value, F, was more than ten times of rejection region, $F_{0.01}$. It was concluded that when the confidence coefficient was set at 99%, the model predicted the experimental data appropriately. The model coupling reaction with separation processes can provide basic information for reactive distillation simulation.

Table 1 Statistical test of the predicted and experimental results

Statistical Index	Computing Method	Value
Experiment point, N	—	64
Independent variables, M	—	5
Total sum of squares, L	$L=\sum_{i=1}^{N}(x_i-\bar{x})^2$	54.82
Regression sum of squares, U	$U=\sum_{i=1}^{N}(\hat{x}_i-\bar{x})^2$	45.84
Residual sum of squares, Q	$Q=\sum_{i=1}^{N}(x_i-\hat{x}_i)^2$	2.75
Correlation coefficient, ρ^2	$\rho^2=1-Q/L$	0.95
Variance test value, F	$F=\frac{U/M}{Q/(N-M-1)}$	193.45
Rejection region, $F_{0.01}$	—	3.34

Conclusions

It has been demonstrated that the boiling point of methanol solution becomes higher as the initial NaOH concentration increases. Rising initial NaOH concentration and liquid evaporating speed can improve the decreasing rate of NaOH concentration in reaction phase and the degree of the reversible reaction. A mathematical model was obtained by regressing the results of experiments coupling reaction with separation processes, and it was found from the model that temperature, concentration of each component and liquid evaporating speed had great effect on the decreasing rate of NaOH concentration in reaction phase. The predicted results were in good agreement with the experimental data. The model could be used for further simulation and process optimization.

Keywords: HTV SIR; Corona; Aging; FTIR; volume resistivity-temperature character

Abstract. The HTV SIR provided the superior hydrophobicity for the composite insulator. But it faces the aging problem more than the inorganics. Corona, as an inevitable influence factor in insulator's operation, its effect to the material could not be ignored. The paper developed a multi needles to plate corona aging equipment, 1000 hours' corona aging to the HTV SIR was done. The duration of corona aging effect was study by FTIR, SEM and volume resistivity-temperature character testing. Three testing methods from the aspect of material's chemical, physical and electrical characters to evaluate the aging effect with time went on. It had good consistency in all three methods for HTV SIR's corona aging evaluation.

Introduction

The superior hydrophobicity and the mobility of hydrophobicity have highly improved the insulator's pollution flashover ability[1]. The high temperature vulcanizing silicone (HTV SIR) provided its excellent ability. Contrast with the porcelain the HTV SIR is the organic material, the aging problem become more serious. The resistance of corona and ozone are one of the twelve performance index for outdoor high voltage polymer insulator, which is recommended by CIGRE Working Group D1.14[2]. And the effect way to study corona's affect is use the artificial corona[3].

The paper developed a multi needles to plate corona aging equipment for HTV SIR's corona aging. The FTIR, SEM[4] and volume resistivity-temperature testing[5] were done after the aging. The comprehensive assessments were done in the aspects of the chemical character, physical character and the electric character.

Testing

2.1 The artificial corona aging testing equipment

The traditional single needle to plate corona aging equipment is with small effect area. And contrast with plate to plate corona aging equipment, the multi needles to plate is easier in control the bloom. Several schemes had been made in electrostatic simulation software. The scheme showed in figure 1 was selected. 12 needles were placed in two concentric annuluses with the diameter of 13.5mm and 27mm. The figure 2 showed the electrostatic simulation results when the gap between needles to plate is 6mm. The experimental circuit was showed in figure 3. The longest corona aging time was set to 1000 hours. 100 hours, 300 hours, 500 hours, 700 hours corona aging samples were selected in order to research the change with the aging time.

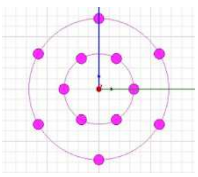

Fig. 1 The needles arranged planform

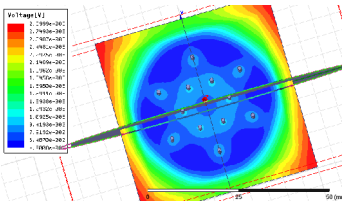

Fig. 2 Simulation of static electric field

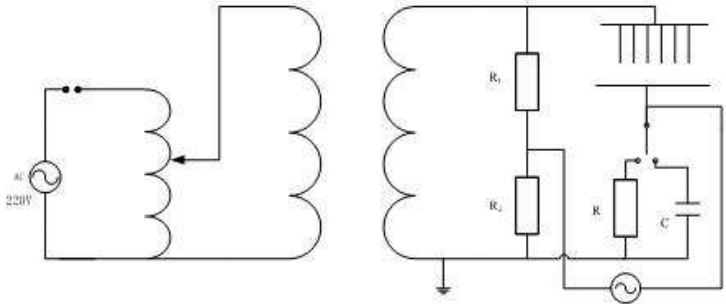

Fig. 3 Testing circuit

2.2 Testing results

The figure 4 showed the samples after different aging time. As corona aging time gain, the surface suffered more. After 100 hours corona effect, the black product come out and the affect area showed a radial effect right under the needles. The inner area was suppressed by outside needles. After 300 hours of corona aging the white product occurred and the black product became deepened.

Fig. 4 Samples after corona aging

Analysis

The material's electric character, physical character and chemical character would change under corona aging. The corona aging effect assessment was done in those three aspects.

3.1 FTIR testing

The FTIR testing was done by Nicolet Is6 Fourier transform infrared spectrometer. Based on FTIR spectrogram, the main chain Si-O-Si and side chain $Si-CH_3$ were selected to do the quantitative analysis. The original surface testing results after corona aging were showed in figure 5. Table 1 listed out the percent of each absorption peak area against the new one's. The absorption peak decreased sharply. The C-H absorption peak diminished to zero. The $Si-CH_3$ and Si-O-Si absorption peak went down largely. After 100 hours aging effect, the three –OH absorption peaks became one widely absorption peak. But as aging time gained, the absorption peak diminished. One thing should be mention was that the original surface showed the Si-O-Si absorption peak moved from $1007.624cm^{-1}$ to $1041.372cm^{-1}$, the second peak $1073.192cm^{-1}$ stayed invariability. The study figured out the absorption peak's shifting due to the long polymer chain break into short chain. After one time's FTIR testing, the product on surface fell off. So we clean the surface with alcohol and then the test to be done again. The figure 6 showed the testing results. The absorption peak compared between new and the cleaned surface had been done in Table 1 too. After cleaned the surface, the Si-O-Si absorption peak shifted to the original position and the area improved. It proved that the corona aging effect the surface more than the inner. The –OH absorption peak diminished after 100 hours' corona aging. The $Si-CH_3$ absorption peak went down slowly. After 500 hours' corona aging, the Si-O-Si absorption peak didn't show an obvious decreased. The area of absorption peak exceed to the new samples. After 700 hours' aging, the Si-O-Si absorption peak went down. Take a close look at absorption peak in $1100\sim1000cm^{-1}$, the low polymer chain in $1073cm^{-1}$ went up. It showed that the long Si-O-Si chain break into small molecule.

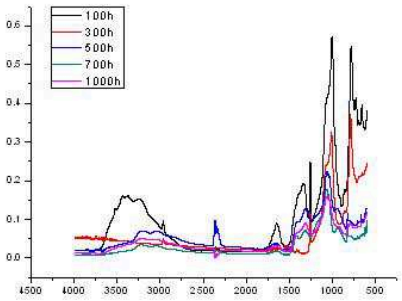

Fig. 5 Original surface's FTIR

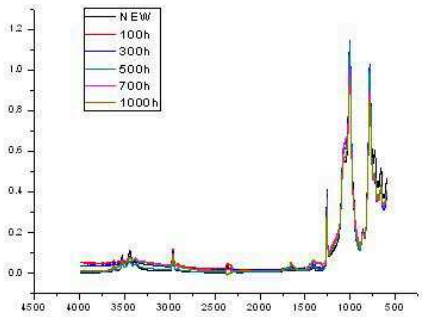

Fig. 6 Cleaned surface's FTIR

Table 1. Percentage of absorption peaks

	Si-O	Si-CH_3	C-H	-OH
100h	61.95%	73.86%	30.98%	352.05%
300h	31.52%	17.71%	16.70%	0.00%
500h	24.62%	23.19%	0.00%	4.86%
700h	22.69%	2.89%	0.00%	8.36%
1kh	18.67%	16.97%	0.00%	28.73%
C 100h	103.36%	95.16%	88.79%	34.20%
C 200h	104.80%	90.15%	83.58%	50.39%
C 300h	102.51%	91.08%	85.29%	49.11%
C 500h	103.63%	81.58%	81.33%	46.49%
C 700h	97.76%	57.77%	62.47%	51.26%
C 1kh	87.09%	69.27%	63.98%	52.29%

3.2 SEM testing

The product came out after corona was removable, so the contrast between original surface and cleaned surface had been done. The image of 500 magnified times were chosen(Figure 7). From the image, the surface of new sample was smooth and compact. As the corona aging time went on, the floccule came out and the floccule's density enhanced. The cleaned surface could not see obvious change in visual(Figure 8). But the image of 500 magnified times showed that as time went on, the hole appeared and became deeper and larger. It showed that the corona had chemical corrosion and mechanical erosion to the material.

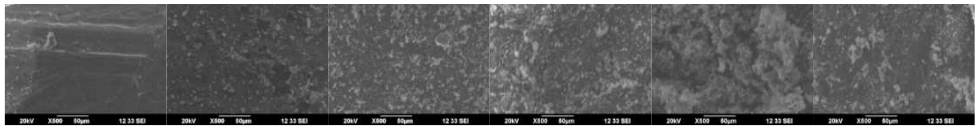

Fig. 7 The original surface

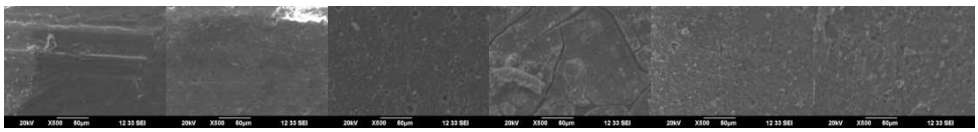

Fig. 8 The cleaned surface

3.3 Volume resistivity-temperature testing

The volume resistivity-temperature testing was done by self-made three electrode testing experiment, Which was made based on paper.

In 293K, the volume resistivity didn't show the law with the corona aging time went by. But once the linear fitting to be done from 293K to 343K, the R-Squared declined as the corona aging time gained. 500 hours and more time's aging effect, the linear had complete broke down. Take a close look at the curve; the linear first broke under temperature from 293K to 313K. The linear in 313K to 343K still kept.

Table 2. The results of volume resistivity-temperature testing

$10^{14}\Omega \cdot cm$	20	30	40	50	60	70
New	3.43	2.66	2.12	1.58	1.08	0.67
100h	2.76	2.52	1.82	1.03	0.57	0.43
300h	3.60	3.07	2.89	2.48	1.67	1.27
500h	3.10	2.85	2.16	2.04	1.33	0.87
700h	6.08	9.87	3.98	3.11	1.48	0.89
1000h	0.85	1.12	1.72	1.31	0.97	0.61

Conclusion

The multi needles to plate corona aging equipment were developed. It would get a more corona aging area and it could be average. One manufacture's HTV SIR was used. 1000 hours' corona aging was done. The duration of corona aging effect was studied by different corona aging samples. The FTIR, which reflected the chemical character, showed that the high polymer chain broke down obvious on surface. It also influenced the inner area but less obvious than the surface. The SEM testing showed that as time went on, the hole appeared and with serious erosion. The crack would appear in the serious condition. The material volume resistivity has a linear correlation with the temperature change in range 293K to 343K. As corona aging time went on, the linearity broken. And the linearity broke first in lower temperature's volume resistivity. It showed that the corona aging influence the material's chemical, physical and electric characters. All of three instruments showed a uniform in reflect the corona aging for the HTV SIR.

Abstract. The paper describes synthesis and evaluation of polymeric additives for improving the flow properties of lubricating oils. The polymer (AAV) was prepared by the free-radical initiated polymerization of methacryl esters (A_{14}) with acrylamide and vinyl acetate. A_{14} and AAV were characterized by infrared spectroscopy (IR). Three lubricating oils were selected as the test oil samples and the effect of solidification point depressant (ΔSP) with different mass fractions and other physicochemical characteristics of the samples with and without AAV added were investigated. In order to analyze the effect of AAV on the viscosity of lubricating oils, viscosity-temperature curves were plotted. The results showed that AAV not only had a good effect on dropping solidifying point for Yanshan lubricating oils, but also had a good effect on dropping viscosity; what's more, other physicochemical characteristics of lubricating oil have little changes before and after AAV added.

Introduction

Lubricating oil has been widely treated with chemical additives (pour point depressants) to improve its flow properties at low temperature. Using flow improvers is often the most economic and effective solution for the lubricating oil flow problems [1]. These additives change the size and shape of wax crystals in such a manner as to allow the oil to remain fluid at lower temperature [2].

Recently, many kinds of polymers have been developed and used as pour point depressant (PPD) to influence the behavior of n-paraffin wax formation [3] [4], such as ethylen-vinyl acetate-propylene polymers[3], styrene-maleic anhydride (methoxypolyethylene glycols) copolymers [5], maleic anhydride-vinyl acetate copolymer amides [6], maleic anhydride-hexadecene-vinyl acetate terpolymers [7], methyl methacrylate-alkyl methacrylate copolymers [8], Poly-acrylic acid derivatives [9], and so on. In recent years, increasing attention has been paid to Methyl acrylate polymers, which not only were used to improving the low temperature flow performance of lubricating oils, but also had effects on temperature-viscosity properties [10].

In the present work, methacryl esters-acrylamide-vinyl acetate copolymer (AAV) was synthesized, and the chemical structures of the polymer prepared were studied by means of IR. Kinematic viscosity, flash point, neutralization number, oxidation stability etc. are the vital properties to affect the abilities of lubricating oil, however, to date, little work has been focused on the research of these characteristics with and without AAV.

Experimental

Materials. Copolymer AAV was synthesized and purified in the laboratory. Methacrylic acid (purity≥99.5%) and Tetradecyl alcohol (A. R.) were provided by Tianjin Guangfu Fine Chemical Research Institute. Acrylamide (A. R.) was obtained from the Tianjin Fuchen Chemical Reagent Company. Vinyl acetate (purity≥99.5%) was obtained from the Fine Chemistry Trial Plant of Nankai

University. Methylenzene (purity≥99%) and Ethanol (A. R.) were provided by the Beijing Chemical Reagent Company.

In the experiment, A, B and C lubricating oils samples were 150SN, 350SN and 500SN, respectively, which obtained from Yanshan Petrochemical Corporation.

Esterification. Methacrylic acid ester was prepared by the reaction of 1.2mol methacrylic acid and 1mol tetradecyl alcohol in a round bottom flask equipped with a Dean-Stark apparatus to remove the water of reaction azeotropica as it was formed. The reaction took place in the presence of toluene (100mL) as solvent, hydroquinone (0.9%, mass fraction) as polymerization inhibitor and paratoluenesulfonic acid (0.8%, mass fraction) as catalyst. After the completion of the reaction, the toluene was removed through distillation at reduced pressure, and the crude product was neutralized using Na_2CO_3 solution and distilled water to remove the catalyst and unreacted acid, then dried over anhydrous $CaCl_2$ for 8h. Eventually, the first monomer was obtained.

Polymerization. The copolymers were prepared by reacting 0.6 mol tetradecyl acrylate with 0.1mol acrylamide and 0.3mol vinyl acetate in toluene solvent using benzoyl peroxide (0.8% by wt) as initiator. The copolymerization was conducted at 75 °C for 4 h with constant stirring and nitrogen atmosphere. Afterward, removing the solvent by reduced pressure distillation, and purifying the copolymer in ethanol and vacuum dried at 50 °C for 12h, then the polymer was prepared.

The process of the reaction is as Fig. 1:

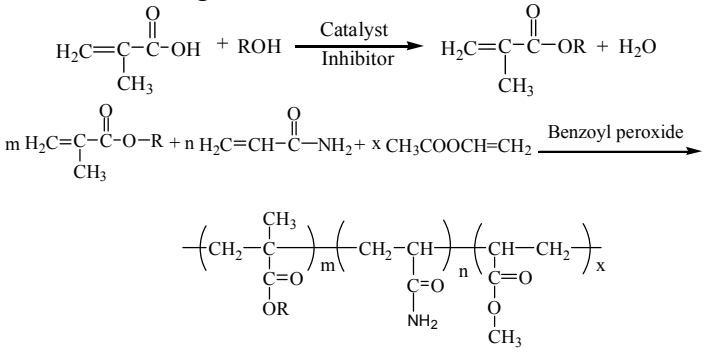

Fig. 1 The process of the reaction

Solidification point measurement. The cold flow performance, solid point depression (ΔSP) of the tested lubricating oils samples were determined according to GB/T 510 standard methods. The solid point depression was determined by SWXK-402D multi-functional tester for petroleum product made in Shanghai Pengpu Refrigeration Corporation. The lubricating oil samples, either containing additive or not, was warmed in a water bath up to (50±2) °C and cooled to (35±5) °C, then transferred to the solidification point tube kept in cooling bath, After each 2 °C interval the tube was taken out and tilted to see the behavior of the oil sample. Until the movement of the sample did not occur, the corresponding temperature was noted as the SP of the samples.

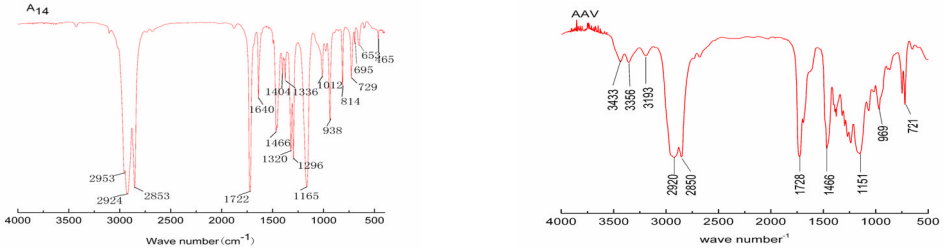
Viscosity measurement. The viscosity measurement was determined according to the national standard GN/T265-1988 "Viscosity petroleum products - Determination of kinematic viscosity and calculation of dynamic viscosity", by American Brookfield company's DV-I+ digital display viscometer. The America Brookfield company production of rotary viscometer is viscosity determination of world standard.

Results and Discussions

Characterization of chemical structures of copolymers and Methacrylic acid ester. The chemical structures of the first monomer and copolymer AAV were studied by means of infrared spectrometry in chloroform solution. MAGNA-IR 560 was used for IR spectral determination. The scanning range was from 4000 to 400 cm^{-1}, the differentiating rate was 0.35cm^{-1}, and the signal-to-noise ratio was 30,000:1.

It can be clearly seen from the Fig. 2(a) that the stretching peaks of the fatty alcohol hydroxyl (3200~3300cm^{-1}) characteristic absorption peak has gone, the stretching peaks of the characteristic -C=O of unsaturated ester is at 1722cm^{-1}, and the absorption peak of the character C-O-C is at 1165cm^{-1}. The results indicated that the A_{14} monomer was obtained.

By comparing Fig. 2(b) with Fig. 2(a), it can be seen that the stretching vibration peak of characteristic C=O of amide are at 1680cm^{-1}, the typical swing absorption peaks of character -CH_2- of long-chain alkyl is at 721cm^{-1}. However, the stretching vibration peak (1640 cm^{-1}) of C=C and in-plane rocking vibration peak (938cm^{-1} and 814cm^{-1}) of =CH_2 has disappeared. The results showed that the copolymer AAV was obtained.



(a) (b)

Fig. 2 FT-IR spectra of A_{14} and AAV: (a) A_{14}; (b) AAV

Evaluation of the cold flow performance. The cold flow performance of the tested lubricating oils was evaluated by the addition of AAV at different dosages. The results were described in Table 1.

Table 1 Influence of different dosage on pour point for different lubricating oil

w (AAV) (%)	Solidification point depression (ΔSP) (°C)		
	A	B	C
0.25	8	8	4
0.50	17	16	13
0.75	30	26	23
1.00	28	29	29
1.25	28	28	26

The mechanism of pour point depression has been well explained [6] [11]. The PPD when present in the lubricating oil, changes the wax crystal sharps from thin extensively interlocking plates to more compact crystals by co-crystallizing with the wax. The performance of the flow improver depends on the total wax content. 150SN, 350SN and 500SN were distinguished by Saybolt viscosity at 40 °C. 150SN, for example, means the Saybolt viscosity is about 150 at 40 °C, so do the 350SN and 500SN. The higher the number, the greater the viscosity, correspondingly, the higher mass fraction of wax will be. According to the figure in the table, the pour point of 150SN could be reduced by 30 °C with 0.75% of the additive, and 350SN and 500SN were reduced by 29 °C, 29 °C with 1% of the additives, respectively. On the basis of this conclusion and theoretical analysis, the pour point of sample A would be dropped easily than B and C, as the wax crystal of A was less.

Comparison of other physicochemical characteristics of the tested oils without and with AAV added. Kinematic viscosity, flash point, neutralization number aniline point, extrinsic feature, density and oxidation stability are the physicochemical characteristics related to the applications of the lubricating oil. To evaluate the effect of AAV copolymer on these physicochemical characteristics, the three base oils were selected as the tested samples. The physicochemical characteristics of the three samples before and after 0.75% (mass fraction) AAV added were furnished in Table 2.

It can be noted from the Table 2 that the kinematic viscosity at low temperature were reduced more than half compared with the samples without AAV. To evaluate the effect of AAV copolymer on the viscosity characteristic, the viscosity-temperature curves of sample A and B with and without AAV had been given as Fig. 3.

The results given in Fig. 3 showed that there were obvious drops in kinematic viscosity from -5 °C to 40 °C. What's more, compared with the blank sample, the viscosity-temperature curve of oil with 0.75% AAV becomes relatively smooth. It can be concluded that AAV additives performs well at the

viscosity-temperature properties. What' more, see Table 2, the flash point of tested oils with AAV added were reduced 2 °C to 3 °C, meaning that the AAV additive raised the vapor pressure of the oil sample. Compared with the flash point, there were no obvious changes in the extrinsic feature, neutralization number, density, aniline point and Oxidation stability.

Table 2 Influence of AAV on the physicochemical characteristics of tested oils

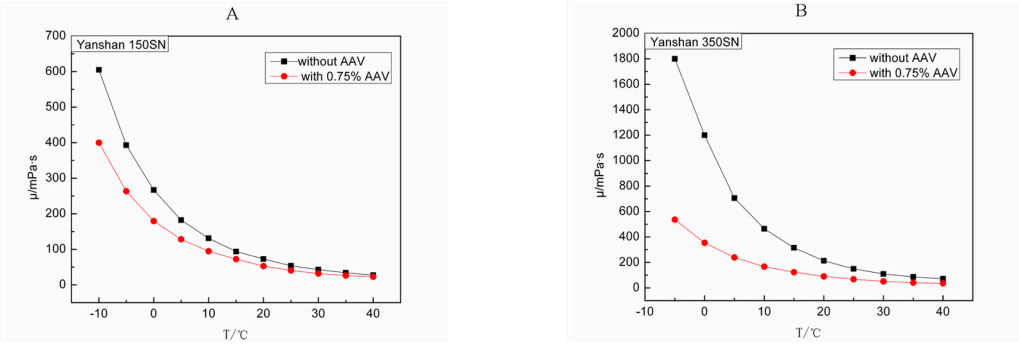

Fig. 3 Viscosity-temperature curve of Sample A and B with and without AAV

Summary

The polymer (AAV) was prepared by polymerization of methacryl esters (A_{14}) with acrylamide and vinyl acetate. When the dosage of improver AAV was 7500 μg/g, the ΔSP of the Sample A, B and C lubricating oils were lowered by 30 °C, 26 °C and 23 °C respectively. The copolymer not only had a good effect on the pour point depressant, but also had a good effect on the viscosity-temperature properties, while the other physicochemical characteristics of lubricating oil can not be significantly changed after AAV added.

Keywords: Insulation, discharge, field emission, partial arc

Abstract. A flat plate model are employed to investigate the development mechanism of the initial electrons along the insulation surface in this paper, and the field emission properties of pollutant (NaCl) and water (H_2O) adsorbed on the copper electrode are studied. The voltage when partial arc occurs is computed and a flat plate experiment is carried out to validate the computing results. Results indicate that pollutant and water have an important impact on the field emission, where pollutant is more significant than water. Meanwhile, the pollutant and water can increase the probability to form the partial arc.

Introduction

The discharge along the polluted surface of insulator is a major problem in power transmission system all the time, and it remains a hot subject in high voltage insulation field and receives much concern [1]. Many methods have been developed to deal with the polluted flashover of insulator, and a great progress has been achieved in engineering application [2-6]. Recently, the basis of selecting the parameters and their characteristics in early models are studied [7], and the calculation model is optimized too. However, there is no perfect model exists.

It is well known that the problem is more severe for HVDC lines where DC insulators are found to collect more pollutants and also flashover more readily than AC units under otherwise identical conditions [8]. Although the early scholars have already discussed some aspects about the mechanism of polluted surface discharge and learned that the pollutant can enhance field emission and aggravate the discharge along the insulation surface [9,10], the discharge reason in a profound physical meaning is still not clear. So it needs to research the discharge from the generation of initial electrons to the formation of partial arc.

In order to analyze the polluted surface discharge mechanism better, in this paper, a flat plate model is employed. The effect of field emission characteristics in dry band caused by pollutant and water are emphatically studied based on the first-principle.Then the voltage when partial arc appeared is computed and an experiment.

Physical model

For actual suspension insulators are difficult to analyze theoretically since they have a complex shape, it is more convenient to use a simpler shape for calculation and experiment. In the paper, a flat glass plate model with size of 60cm×20cm×1cm and two column electrodes with the radius of 5cm are employed, as shown in Fig.1.

Under the humid condition, the pollutant layer on the insulator surface became a conductive film, and the leakage current increased. The area where current density or layer resistance is larger produced more heat and dried much faster. A dry band formed here first, and then it became a high-resistance area without ionic conductivity.

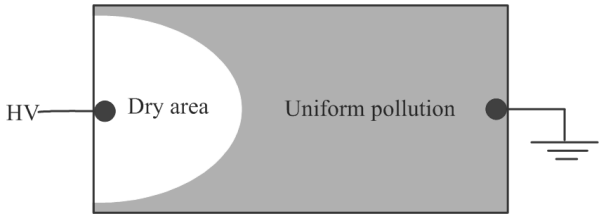

Fig.1 Flat plate model of the polluted insulator

Arc voltage calculation

Although the Malter effect, the defects, and the polarization of dielectric are different in the discharge, they can be equivalent to the field emission. The field emission current density [11] can be expressed as follows:

$$J_f = CE^2 \exp(-\frac{D}{E})$$

$$C = \frac{e^2\Phi_m^2}{2\pi h(\Phi+\Phi_m)\Phi^{1/2}} = \frac{6.16\times10^{-6}}{\Phi_b}\sqrt{\frac{\Phi_m}{\Phi}}$$

$$D = \frac{8\pi}{3h}(2me)^{\frac{1}{2}}\Phi^{\frac{3}{2}} = 6.83\times10^9\Phi^{\frac{3}{2}}$$

$$E = \frac{U}{R}$$

where Φ is the work function of metal; Φ_{m} is the potential band of metal; U is the applied voltage; R is the electrode burr tip curvature radius; and N is the electron density per cubic meter in metal. Thus, the equation J_f can be rewritten:

$$J_f = 6.16\times10^{-6}\frac{1}{\Phi_b}\sqrt{\frac{\Phi_m}{\Phi}}\times(\frac{U}{R})^2\exp(-\frac{6.83\times10^9\Phi^{\frac{3}{2}}R}{U})$$

Based on the equations [12] as follows:

$$r = \sqrt{\frac{I}{14500\pi}}$$

$$I = \pi r^2 J_f$$

the current density acquired when the partial arc occurs can be obtained:

$$J_f = 14500$$

Suppose that the arc is formed by field emission, and the current density of arc equals to the field emission current density. For the copper electrode, Φ=4.65eV, Φ_m=7eV. The surface roughness of the electrode used is R=0.5μm. The voltage calculated is $U\approx$6.01 kV when the partial arc occurs.

Tests and analysis

Tests. A DC high voltage of up to 200 kV is supplied by a cascade rectifying circuit controlled by the thyristor voltage – current feedback system, which ensured a dynamic voltage drop of less than 5% when the load current is 0.5 A. The test power supply meets the requirements commended by the IEEE Standard-4-1995 and IEC 61245 – 1993 [13-14].

The same size specimens mentioned in Section 2 are used. Referring to [14-16], the test procedures in this paper are as follows. Before the tests, all specimens are carefully cleaned. All traces of dirt and grease are removed, and dried naturally. A positive polarity-applied voltage generally results in higher flashover voltage than the negative polarity; therefore, negative DC voltages are introduced in the present paper. Every specimen is subjected to 10 tests; the average value is taken as the trial value.

Analysis.

The Field Emission Characteristics. Three kinds of electrodes were prepared: one clean, one with water, and one with pollutant. The glass surface was kept clean during the preparation of specimens. After the preparation, DC voltage was applied to the specimens and increased until flashover occurs. Fig. 2, 3, and 4 is the microdischarge of different systems before flashover (T_f), respectively.

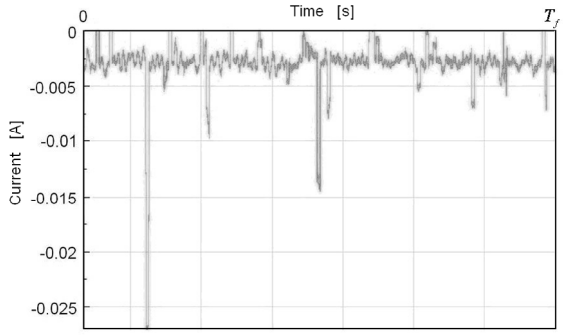

Fig.2 Micro-discharge of clean electrode

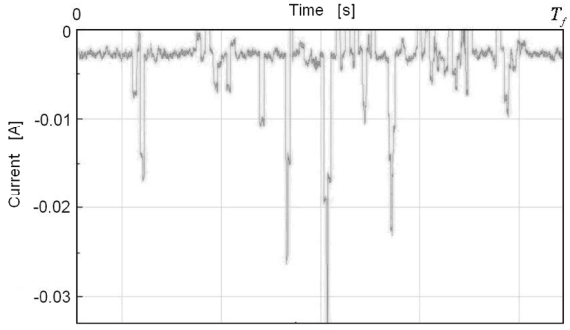

Fig.3 Micro-discharge of electrode with water

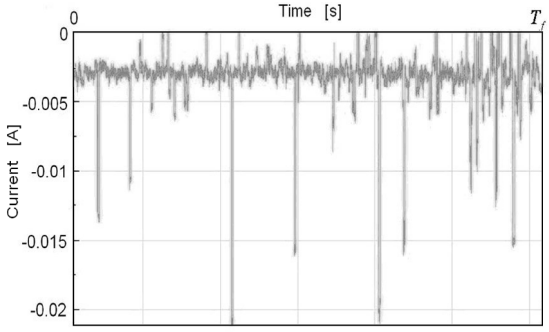

Fig.4 Micro-discharge of electrode with contamination

Figs. 2, 3 and 4 present that pollutant and water can enhance field emission, aggravate the discharge along the insulation surface, and increase the number of micro-discharge pulses. The effect of pollutant is more significant than that of water, which is consistent with the conclusion from molecular simulation. Thus, the existence of pollutant can not only reduce the flashover voltage under wet conditions, but also deeply influence the development of discharge at the beginning of applied voltage.

Table.1 The total current and times of strong discharge under different conditions

	clean	water	pollutant
Total current [A]	0.1043	0.1715	0.2358
Times of strong discharge [I>0.01A]	3	7	10

Table 1 shows the statistics of the total current and the number of strong discharge before flashover. When pollutant and water are present, the total current is 1.6 times and 2.3 times larger than that of the clean electrode, respectively, whereas the number of strong discharge is 2.3 times and 3.3 times

larger than that of the clean electrode, respectively. The effects of water and pollutant not only increase the discharge strength, but also increase the probability to form the partial arc.

Effect on the Partial Arc Voltage. One hour after the aforementioned preparation, the solid-layer method was applied to the pollution layer on the specimens where sodium chloride and kaolin were electric and inert materials, respectively [17]. The equivalent salt deposit density (ESDD, mg/cm^2) has been widely used to characterize the severity of outdoor pollution. In the present work, the authors prepared ESDD of 0.03, 0.05, 0.1, and 0.2 mg/cm^2 in four kinds of pollution grade glass flats. The pollution layer on the flat was wetted completely; in this process, the temperature was controlled to be lower than 35°C.

The relationship between voltage and ESDD is shown in Fig. 5. The blue and red curves indicate that with the increment of ESDD, the critical flashover voltage and the voltage when the partial arc appeared are all reduced exponentially. The voltages reduced 45.95% and 37.62% from clean to the pollution grade of 0.2 mg/cm^2, respectively. The black curve is the theoretical value of the appearance of the partial arc, which is always larger than experiment value when pollutants exist; the more severe the pollution is, the lower the voltage of the partial arc will be. The factors influencing discharge include pollutant particles, ambient temperature, humidity, pressure, and ray irradiation, all of which benefit discharge. The trial value at clean condition is larger than the theoretical value because the air molecule has a barrier, thereby requiring an adsorption effect and a higher voltage to maintain discharge. The green curve is the voltage difference of the critical flashover and the appearance of the partial arc, which is also reduced exponentially with the ESDD. The existence of pollutant not only reduces the critical flashover voltage under wet conditions, but also influences the development of discharge at the beginning of applied voltage deeply.

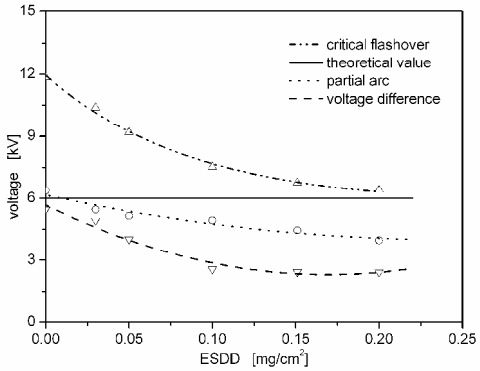

Figure.5 Relationship between voltage and ESDD

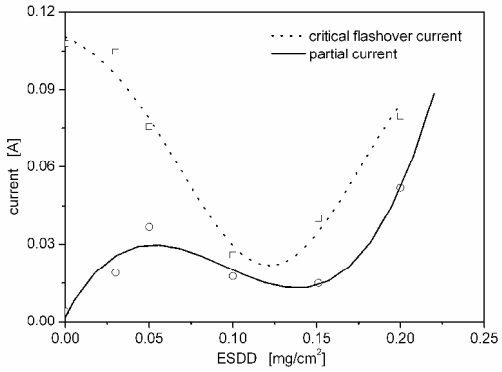

Figure.6 Relationship between the current and ESDD

The critical flashover current and the current when the partial arc appeared are compared in Fig. 6. The black curve indicates that the critical flashover current initially decreases and then increases, and has a parabolic relationship with ESDD. The red curve indicates that the current when the partial arc appeared initially decreases increases, and then increases even further. The main reason for the change in the black curve is that although conductivity is small at a low pollution grade, the high applied voltage can generate a high field that is beneficial to field emission. The residual polluted layer conductivity is high when it is at a high pollution grade. Nearly all the voltage is applied on the dry band, leading to a strong field that is also beneficial to field emission. From the two conditions

above, the current measured is high. The main reason for the change in the red curve is that the air molecule has a barrier and an adsorption effect, resulting in a weak current at clean condition. The curve shows that, up to the moderate pollution grade, the current increases because of the field emission of the pollutant particle at a strong field. When the pollution grade increases, the surface conductivity increases; thus, the voltage distributed on the electrode vicinity produces a low field and weakens the field emission, leading to a low current. The residual polluted layer conductivity is large when it is at a high pollution grade. Nearly all the voltage is applied on the dry band, leading to a strong field that is also beneficial to field emission.

Although the ESDD of a moderate pollution grade ranges from 0.1 to 0.17 mg/cm^2, little difference is found between the critical flashover current and the current when the partial arc appeared. However, the interval between the appearance of the partial arc and the flashover is very short at close quarters; it can be considered as occurring simultaneously, which is consistent with experimental observation.

Conclusion

The voltage when partial arc occurs is computed and a flat plate experiment is carried out to validate the computing results. The results indicate that the pollutant and the water promoted the field emission effectively and the effect of the pollutant is more serious than that of water, which increased the probability to form the partial arc and reduced the critical flashover voltage too.

Keywords: Grid alloys;Mixing Paste and Curing Process;The Negative Additive;The Combination of the Positive and Negative Plates

Abstract. By describing the main affecting factors of the small electric vehicles cycle life for the lead-acid batteries,then studying the main technical measures that how to improve the deep cycle performance of the batteries to prolong its life.When the methods of the combination of grid alloys ,mixing paste and curing process parameters control, the selection of the negative organic additives and the sets mode of the positive and negative plates were used,the battery performance and the cycle life greatly improved and the failure rate decreased.

Introduction

Electric bicycle is a green traffic tool which has already formed the new industry in the recent years. the representative small electric vehicles of the golf carts, sightseeing vehicle and warehouse forklift trucks are rapidly developing, and which cause the market demands of the lead-acid battery continue expanding,so that it was paid well attention to the industry peers.The battery is the key component of electric vehicle,the battery palaced space of the vehicle is limited and the battery energy requirements are higher, so the battery of the small electric vehicles are usually using the pasted positive and negative electrode. The rated voltage is 6V and the rated capacityis170 - 210Ah (5h ratio) of the golf car is the representative products of the battery (hereinafter referred to the power battery). The key indicators of this battery is the deep circulation discharge life which the cycle numbers should be no less than 400 under the condition of 80% DOD, by this way could ensure the actual use life of the battery will more than reach to 1.5-2 years. This paper mainly introduces the main factors which influencing power battery life, and studies the main measures of improving the the deep circulation performance and service life.

The Main Influence Factors of the Power Battery Life

The Corrosion Deformation of the Positive Plate

When the battery is in the long deep discharge cycle,the positive plate will suffer corrosion, grid size will linearly increase, which resulted to ribs and border elongation deformation or fracture even occurs short circuit.Anatomizing the end life battery, the deformation and fracture,the irregular fracture penetration separator plate can be seen on both sides of the plate, the upper plate expansion to the bus and cause cell short-circuit phenomenon.Theory and Practice has proved that grid corrosion and deformation is one of the important causes of deep cycle battery life shortened,so the electrochemical properties of the power battery plate should be smaller corrosion rate and non intergranular corrosion,and also should have the appropriate hardness,strength and creep resistance on the mechanical properties.

The Softening and Shedding of the Positive Active Material

In the charge- discharge cycle, PbO2 and PbSO4 will mutual transform,the volume of the active material will change and increase the change volume with the incasement of the cycle numbers.In the living plate 4BS plays an important role for the electrode plate active material strength,if mixing paste and curing process is out of control, when the 4BS content is lower than 60%,the plate active material intensity will be poor,easy soften and shed, and reduce the use life of the battery.

The Precipitation of the Negative Additive

In fasting charge and overcharge state, the battery temperature reaches above 60℃,the negative electrode plate in the high temperature electrolyte will early precipice because of the soluble of the organic expander.In the battery liquid injection hole the redness electrolyte will obviously be observed.The negative plate in the high temperature of the electrolyte, the organic expansion agent soluble, to the early from the negative precipitation, is observed in , the loss of the organic additive makes the performance of the negative electrode deteriorate.

Research of Prolonging the Cycle Life of the Battery

The Selection of the Grid Alloy

The selection of the deep cycle battery grid alloys have been many reported in the literature,the major combinations were shown in the table 1.

Table 1 The Combination Of Positive And Negative Grid Alloy

Alloy code	The alloy composite of the positive plate	The alloy composite of the negative plate	Water loss
A	$Pb{\cdot}Ca{\cdot}Sn{\cdot}Ai$（four alloy composite）	$Pb{\cdot}Ca{\cdot}Ai$（three alloy composite）	1.2-2.5
B	$Pb{\cdot}Sb$（2-2.5%）$\cdot As{\cdot}Sn{\cdot}Se{\cdot}Cu$（six alloy composite）	$Pb{\cdot}Ca{\cdot}Ai$（three alloy composite）	3.0-5.0
C	$Pb{\cdot}Sb$（2-2.5%）$\cdot As{\cdot}Sn{\cdot}Se{\cdot}Cu$（six alloy composite）	$Pb{\cdot}Sb$（2-2.5%）$\cdot As{\cdot}Sn{\cdot}Se{\cdot}Cu$（six alloy composite）	5.0-7.0

The combination of the above three grid alloy which were the grid material of the power battery, the cycle life of the merits tendency is C> B> A. A kind of combination is generally believed that the use of Pb-Ca positive grid that the active material interface layer of the corrosion resistance of purified large insulating film.To prevent the generation of the purification, the general method is to add the Sn,that is, high Sn and low Ca alloy,so the alloys are used in the positive plate of poor water VRLA battery which the water loss is a minimum and its test data is 1.5-2.5g/Ah.but the mechanical strength,creep resistance and deep charge and discharge performance (no effect in the presence of antimony) of Pb-Ca alloy is still below the Pb-Sb alloy.The small electric vehicle batteries use flooded design that it could regularly pay replenishment and maintenance,so Pb-Sb multi-alloy should be the best selection.B alloy is the best combination which can effectively improve performance while maintaining deep cycle relative reduction of water loss purposes.The alloy components are:

Positive plate alloy : Pb+Sb(1.8-2%)+As(0.1-0.2)+Sn(0.2-0.5)+Se(0.02-0.04)+Cu(0.03-0.04),

Negative plate alloy : Pb+Ca(0.06-0.1)+Ai(0.02-0.04%).

In addition,Pb-Sb alloy contains a certain amount of Cu according to relevant literatures which has an important influence on the size and composition of the alloy grain.If the alloy was aging treated at a temperature,then could obtain the recrystallized grains which without grain crystalline grains,the grain structure would be more favorable to reduce the creep rate.Many test results show that if the six Pb-Sb alloy positive plates heat treatment at temperatures of 80±5℃ for 10-12 hours, and then at room temperature for 3-5 days in a state of natural aging,its have a significant effect for the improvement of the positive plate formation and crack,meanwhile improving the battery life.

Mixing Paste and Curing Process Control

The mixing paste temperature control and raw plate curing conditions have an important role in the life on deep cycle battery life,so it must be given adequate attention.It is well known that the main ingredients of raw plate are 3BS and 4BS.The content of 3BS is high with the thinner skeleton structure ,after curing that the content of β-PbO2 in living material is high and the initial capacity of the battery is good,but the strength of the active material is poor.The 4BS with coarse skeleton structure after curing which could transform into α-PbO2 with high strength, so it plays the role of "reinforced concrete".So we could control the process to improve the content of 4BS and enhance the strength and prolong the service life of the positive plate.Theory analysis and practice research have proved that,the mixing paste temperature has an important influence on the lead paste structure under the same conditions of the positive lead paste formula and acid content.If the positive lead

paste was prepared at the highest temperature 80℃,it would mainly compose of 4BS;If the positive lead paste was prepared at less than 65℃,it would mainly compose of 3BS.When the temperature is 65℃-85℃,the highest temperature was controlled at 65℃, 70℃, 75℃, 80℃, 85℃ were divided into five groups by preparing paste which could adjust by the automatic adding acid device to control acid speed;the smear process could act as the same above process and make the rapid surface after drying and curing.Making up the positive lead paste needing Barton lead powder which must be cured at high temperature,so it could obtain a satisfactory quality.According to the characteristics of the original Barton oxide and curing process,the curing temperature was controlled at 72℃-78℃,the humidity was more than 95%, then using a multi-stage temperature and humidity control to cur the test plate and make it format and dry.The five plates with each assembly of 2 6V190Ah (5h rate) to install in the golf cart battery.The capacity and life test of small electric vehicle lead-acid battery could be carry out by the Japanese industrial standard SBA S 0802-1996 test method.The test data was shown in the table 2(each group of data are the mean values of 2 battery test data).

Table 2 The mixing paste test data at different temperatures

Mixing paste temperature control (℃)	Curing conditions	the appearance and strength of the positive plate	the initial capacity of the battery (%)	the maximum capacity of the battery (%)	cycles
65	Temperature :72 ℃ -78 ℃ ; humidity: ≥95%	If the surface was pale yellow,the strength would be poor.	106.75	118	292
70		If the surface was yellow,the strength would be plain.	97.98	119	373
75		If the surface was yellowish,the strength would be plain.	94.12	107	433
80		If the surface was orange, the strength would be good.	86.86	103	457
85		If the surface was dark orange，the strength would be good.	84.11	94	382

Seen from the table 2,if the maximum temperature of the mixing paste could control at the range of 75℃-80℃,the capacity and cycle life of the battery would better improve.

The Negative Expander Selection

The negative organic additives of the deep cycle discharge battery are not suitable for using alone lignin.The three organic expanders of the deep cycle battery negative plate are lignin,lignin+humic acid and humic acid which stability sequence is humic acid,lignin+humic acid and lignin.If using the humic acid or lignin+humic to replace alone using lignin that could get the better charge acceptance and deep cycle life performance;but it noted that the dosage should be slightly lower the car battery negative organic expanders in order to avoid the excessive expansion of the negative electrode active material plates under the deep cycle state.It should also be appropriately increased the carbon black and barium sulfate content of the negative inorganic additives,generally added 1.2-1.5 times than the organic expanders,by this way can effectively improve the performance of deep cycle batteries.

Improved Methods of Battery Design

The Design Method of Positive Plate More Than Negative Plate

Power batteries are generally run in the low- rate discharge status which mainly be controlled by the positive plate.After dissecting the life test batteries,most of them were the positive grid corrosion caused by an internal short circuit of the deformation of live material softening off, while the negative plate was normal.The improved measure is using the combination of the positive plate more than the negative plate to replace the traditional polar groups of the negative plate more than the positive plate.

Under the same charging and discharging conditions,the positive plates increased, so the relative surface area was increased that the unit area carrying current of positive plate would reduce and the corrosion and deformation of the positive plate would decrease.Take 6V 190Ah (5h rate) golf cart

batteries for an example,if changing the original monomer +9, -10 to +10, -9, that is, the battery pack of the positive plate assembled the negative plate.The performance testing showed that the method has significantly improved the performance, the capacity increased 3-5% in five hours,the cycle life improved 13% , the material consumption only increased 1.2%.

The Improved Method of the Plate Outlines

Power batteries generally use the bag separator plate with the materials of PE+fiberglass or plastic and glass fiber composite,the tight assembly of the positive plate could effectively prevent the short circuit of the battery bottom which caused by the plate living material fall away with the electric vehicle bumping and vibration.The solution of the problem is to use a unequal design of the positive and negative plate.Namely,the positive plate dimensions remain unchanged,the width of the negative plate needs reducing 4-5mm and other dimensions are unchanged,so the positive and negative plates of the assembly monomers make each side maintain a certain distance.Thus even if at both sides of the partition edge cracks that it also could effectively prevent short circuit fault of the polar group side.

The test data of the improved assembly 6V 190Ah battery(5h rate) were shown in the table 3.

Table 3 The Improved Test Data

serial number	Inspection items	Inspection standard	Standard requirements	Unit	The measured data	
					The first group	The second group
1	Capacity	SAE J537-2000	≥100	%	102.4	101.3
2	The large current discharge	SAE J537-2000	≥30	Min	36.23	37.58
3	75A discharge	SAE J537-2000	≥105	Min	117	114
4	The storage characteristics	SAE J537-2000	≥85	%	95.12	91.87
5	life	SAE J537-2000	≥400	times	455	473

Conclusion

（1）The alloy complex of the positive Pb-Sb and the negative Pb-Ca was used appropriate heat treatment,so it helps to improve the deep cycle life of small flooded power battery and could be achieved low maintenance performance.

（2）The mixing paste and curing process at high temperature and high humidity conditions can significantly increase the strength of the positive plate, although the initial capacity of the battery is low, but the cycle life is significantly extended.

（3）The organic additive of the negative uses the high purity lignin+humic acid and humic acid, it is more favorable for deep cycle discharge.

（4）The design method of positive plate more than negative plate and the plate outlines which can effectively improve the battery performance and reduce the failure rate.

Key words: PEM; fuel cell; membrane

Abstract: The proton exchange membrane (PEM) plays a key role on performance of PEM fuel cell. This paper reviewed recent developments of perfluorinated and partially fluorinated PEMs for PEM fuel cells.Comparative analysis of various PEM parameters was presented. Perfluorinated sulfonic PEMs with better technology have the issues of complicated preparation process and high cost.Partially fluorinated PEMs have lower price,but performance is not good enough.

Introduction

PEM is the key technical material of fuel cell[1].What's more,it's the heart of the cell,whose performance directly affects the performance of fuel cell operation.Aiming at the characteristics of PEM,this paper reviews the basic properties and research progress.

1 The basic properties of proton exchange membrane

The proton exchange membrane(PEM) is the key part of PEM fuel cell. The PEM includes perflourinated membrane,partially fluorinated membrane,non-fluorinated membrane and composite membrane.The classification of membranes based on materials are shown in Figure1.

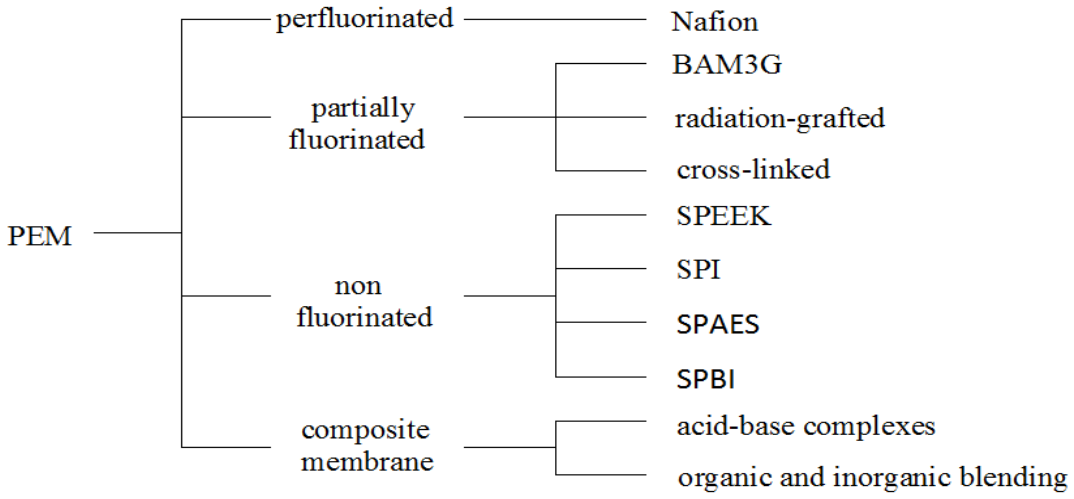

Fig.1 The classification of membranes

The performance of PEM can not only affect cell performance directly,but also be vitally important to reduce the cost and internal resistance of the cell, and improve the energy conversion efficiency[2].Therefore,PEM should meet the following conditions[3]:(1) high proton conductivity,(2) low electron conductivity,(3) low permeability to fuel and oxidant,(4) thermal, chemical, oxidative, and hydrolytic stability,(5) desirable mechanical properties in both the dry and hydrated states,(6) cost, and(7) capability for fabrication into membrane electrode assemblies (MEAs).

In this paper,the perfluorinated membrane and partially fluorinated membrane will be studied in detail.

2 Perfluorinated proton exchange membrane

Perfluorinated sulfonic proton exchange membrane(PFSA) is currently the only widely used proton exchange membrane in PEM fuel cell,and the most representative one is the Nafion membrane which is developed by Dupont in the late 1960s.After that,several other similar proton exchange membranes come into appearance in succession: DuPont's Nafion, Asahi Glass's Flemion, Asahi Chemical's Aciplex, Dow Chemical membrane, etc[4].

At present, DuPont's Nafion is the most widely used membrane both at home and abroad.It shows excellent chemical stability as well as high proton conductivity at moderate temperature and high relative humidity[5].While it also has some shortcomings.As the high temperature will cause the decrease of electrical conductivity and chemical degradation,the preparation is difficult,high cost; the waste is refractory.It may be inclined to methanol leaking when used in methanol fuel cell.

It functions only in a highly hydrated state and therefore it is limited to operation at relatively low temperatures of around 80℃ under ambient pressure in order to maintain a high water content in themembrane[6].The major factors hindering the development of PFSA are higher prices,complex production engineering and high risk.Consequently,their wider applications are limited.To overcome the disadvantages of PFSA, new proton exchange membranes have appeared.

3 Partially fluorinated proton exchange membrane

3.1 Polytrifluorostyrene membrane

Early Polytrifluorostyrene sulfonic acid membrane cannot meet the requirements of the long-term use of fuel cells,because of poor mechanical strength and chemical stability.The most prominent representatives of modified proton exchange membrane is BAM3G membrane developed by Ballad company.The life of BAM3G membrane can be increased, up to 15000h.Cost is also lower than the Nafion membrane and the Dow membrane,that is much more easily accepted[7].Due to the differences in structure, BAM3G has good thermal stability, chemical stability and mechanical strength.What's more prominent is the quality with a lower capacity (EW) and high water content, its performance is better than the Dow and Nafion117 membrane[8].

3.2 Radiation-grafted proton exchange membrane

Radiation-grafted polymer film is synthetized through copolymerization on the selected basal membrane such as polytetrafluoroethylene,polyvinylidene fluoride, copolymerization of tetrafluoroethylene,perfluoropropylene and so on.Then Ion exchange groups will be mixed by sulfonationreaction[9].This technique allows introducing ion conducting (electrolytes) regions directly into polymer films,which have excellent thermal and mechanical properties[10]. Especially, radiation grafting, a powerful method for the introduction of the proton conducting ability into commercial films has been widely utilized to prepare PEM[11].

E.E. Abdel-Hady et al. prepared the membrane in this way.The membranes achieve better water uptake, ion exchange capacity, AC electrical conductivity and tensile strength compared to that of Nafion-112[12].

3.3 Cross-linked membrane

Cross-linking can hinder the mobility of the polymer chains and efficiently enhance the mechanical strength by limiting the high degree of water uptake[13].The cross-linked membranes displayed somewhat lower proton conductivities than the corresponding uncross-linked ones

because of the reduced IECs of the former. Nevertheless, the proton conductivities of the cross-linked membranes were still at reasonably high level.

J. Ren et al. fabricate the cross-linking Am-SPAES/SiO2 hybrid membranes,and the performance of the hybrid membranes containing cross-linking network structure was considerably improved[14].Luo et al. prepare a double cross-linked membrane.The second cross-linking significantly decreased the water uptake of the membrane. The performance of direct methanol fuel cell was slightly improved as compared to Nafion 117 due to its low methanol permeability[15].

3.4 Comparative analysis of various membrane parameters

Through the in-depth study of the proton exchange membrane,all kinds of partially fluorinated and non-fluorinated proton exchange membrane come into being.This paper focuses on the characteristics of perfluorinated and partially fluorinated PEMs.The performance compared with Nafion is shown in the Table1.

It can be seen from Table 1,these partial fluorizated membranes will be superior to the Nafion membrane in the mechanical strength, thermal stability, proton conductivity and methanol permeability,as well as the prices.However, many properties is not optimal due to materials limitations.

Table 1 Performance reference table of partially fluorinated membrane

	BAM3G	Radiation grafted	Crosslinked
Thermal stability	good	good	low
Chemistry stability	good	good	good
Mechanical strength	good	good	enhance
Methanol permeability		low	low
Proton conductivity	improve limited	equal	decreace
Oxidation stability		worse	

4 Conclusion

Perfluorosulfonic acid membranes with better performance have the issues of complicated preparation process and high cost.Besides,the poor alcohol resistance restricts its application. Partially fluorinated proton exchange membranes have been developed,whose performance is better than perfluorinated membranes,and the price is much lower.However,overall performance is not good enough.It is not suitable for wider application.Therefore,it is significant to prepare novel proton exchange membranes to improve the performance of fuel cell.

Keywords: Lignite Dewatering; Coal Quality; Oxygen Adsorption; Spontaneous Combustion

Abstract. The drying experiments of three typical kinds of Inner Mongolia lignite were conducted on a self-designed apparatus. The proximate analyses and oxygen adsorbing capacities of all the samples were analyzed on an industrial analyzer and a coal spontaneous combustion tendency tester. The results show that the treated samples show no apparent changes in their properties compared to the original lignite and no pyrolysis or combustion phenomenon occurs in the drying process. It is also observed that the oxygen adsorbing capacity of the dewatered sample is lower than that of the original lignite. Especially the oxygen adsorbing capacity of the lignite sample undergoing high-temperature drying process decreases significantly. Considering the amount of adsorbed oxygen can reflect the spontaneous combustion tendency of coal to a certain extent, the spontaneous combustion tendency of the treated lignite decreases.

Introduction

China is rich in lignite. Lignite is a kind of cheap fuel, while its utilization is considerable limited for its characteristics. So far, the coal has been mainly used for electricity generation in the pulverized coal boiler of pithead power plants [1][2]. A large amount of dust discharged with flue gas during the direct combustion process, which will cause serious environmental pollution and thermal inefficiency use of lignite. Hence, it is necessary to improve the quality of lignite before application.

At present, the upgrading technologies of coal include washing, drying and topping process. The drying upgrading technology is mainly studied in the work. For the defect of high cost of drying medium in traditional drying technology, high-temperature flue gas drying technology was introduced and the properties of the samples treated under different drying temperature were investigated.

During the drying process, while the moisture content of the lignite decreasing, some small molecular compounds and volatile matters will emit from the coal particles under the high temperature and long residence time. So it is more likely to spontaneous combustion or explosion after the drying process. Generally, the dewatered coal will adsorb oxygen in the air. With oxygen binding interactions, the dewatered coal may generate heat through oxidation reaction. When the accumulation of the heat is enough, the spontaneous combustion will be caused [3][4]. Therefore, it is really useful to study that the changes of the spontaneous combustion characteristics and properties of the coal after the drying process. Moreover, the chromatographic method of fluid oxygen adsorption was applied to determine the spontaneous combustion tendency of the coal [5].

Experimental

Coal samples

Xilingol lignite, Yimin lignite, Datang five rooms lignite before and after drying process were chosen as the samples for the investigation. After the samples were milled, the lignite particle

passing through 80 mesh sieve were placed in weighing bottles for the following experiments. The effects of drying temperature and coal type were investigated in the experiments. The specific conditions for the preparation of the samples were introduced as follows.

(1) Effects of temperature

Table 1
Experimental temperature

	Gas temperature /K	Residence time
High temperature drying process	1073	30s
	973	30s
	873	30s
Low temperature drying process	463	10min
	413	10min

(2) Effects of coal type

The three lignites with the particle size of 3~25mm were selected as the experimental samples. The samples were dried in a simulated flue gas (7% O_2) flow with the rate of 0.5cm/s. The relevant experimental conditions were given in Table 2.

Table 2
Experimental coal type

	Coal type	Gas temperature /K	Residence time
High temperature drying	XLGL	1073	30s
	YM	1073	30s
	DT	1073	30s
Low temperature drying	XLGL	463	10min
	YM	463	10min
	DT	463	10min

Note: XLGL = Xilingol lignite; YM = Yimin lignite; DT = Datang five rooms lignite.

Experimental equipments

The experimental equipment used in this paper is self-designed for the drying process with high temperature flue gas. The structure of self-designed drying apparatus is shown in Figure 1. The bench with the function of temperature programming can be heated up to 1273K. A 5E-MAC III industrial analyzer (Changsha Kaiyuan Instruments Co. Ltd.) and a coal spontaneous combustion tendency analyzer of ZRJ-2000 (Beijing Star Hengtong Technology Co. Ltd.) were used to determine the properties of the lignite samples.

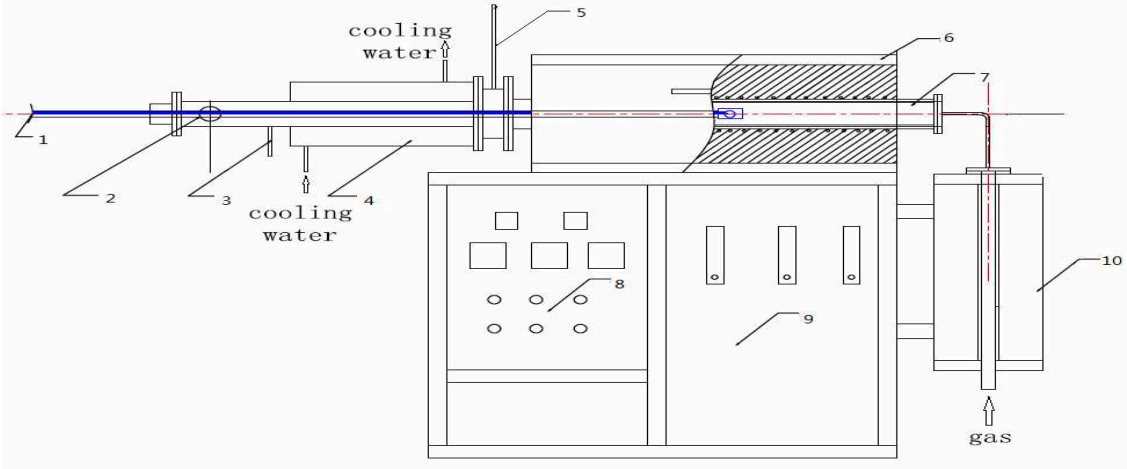

Fig.1. Self-designed drying apparatus

1-push rod with coal loading basket, thermocouples and nitrogen inlet; 2-operating hole; 3-cooling nitrogen inlet; 4-water-cooling jacket; 5-nitrogen outlet; 6-electric heater; 7-dryer; 8-controller; 9-panel with flowmeters; 10-preheater

Experimental procedure

The original lignite with particle size of 3~25mm was selected as the experimental samples. The industrial analyses and oxygen adsorption of the raw coal and the samples obtained on the

self-designed drying apparatus under different drying processes were measured. The Industrial analysis was analyzed according to GB/T212-2008, and the capacity of oxygen adsorption was measured by coal spontaneous combustion tendency tester according to GB/T20104-2006.

Results and Discussion

The results and discussion of Industrial analysis

The results of the industrial analyses of the original and partially dried samples are shown in Table 3. The drying time at high and low temperature is 30 seconds and 10 minutes, respectively.

Note: 1 = before drying; 2 = after drying; M_t = total moisture; 413K, 463K, 873K, 973K, 1073K mean the temperature of drying medium during drying process; ad = air dried basis; d = dried basis; daf = dry ash free; t = total; G = Gas.

Table 3 shows that during low temperature drying process, the total moisture removal at 463K is much greater than at 413K. Moreover, the internal moisture content of the sample dried at 463K decreases obviously. It can infer that the rise in drying temperature may help to remove the moisture from the lignite, especially for the internal moisture. Compared with Xilingol lignite, the moisture removal degree of the other coals is lower under the low-temperature drying conditions, which may be due to the different moisture content of the coals. Therefore it needs different amount of heat to obtain the equal moisture removal degree. The same drying temperature and residence time can provide the equal amount of heat, so the different samples have different moisture removal degrees. For example, the raw coal with higher moisture content shows a lower moisture removal degree.

According to industrial analyzing data of Xilingol lignite before and after drying process, the moisture removal degree of the sample dried at high temperature with the same residence time increase. Compared with the drying process at low temperature, the moisture removal degree of the sample at the high temperature drying process exceeds 50% in only 30 seconds. The result means that the drying process at higher temperature has a better efficiency. In addition, the volatile or ash yields of the samples before and after the drying process change a little and the properties of the coal does not change a lot. Obviously, no pyrolysis or combustion occurs during the high temperature drying process. When dried in the simulated flue gas with 1073K, the moisture removal degree varies for the different lignite samples with different internal and external water content and different pore structures [6][7].

Results and discussions about oxygen adsorption measured

The samples were dried at different temperature. The results are listed in Table 4.

According to the dates shown in Table 4, the original sample has the highest amount of adsorbed oxygen. After a short period of drying at high temperature, the amount of adsorbed oxygen is significantly lower than that treated under low-temperature drying. Obviously, drying temperature has a great impact on the amount of adsorbed oxygen of lignite [8][9]. As the oxygen adsorption can reflect the tendency of spontaneous combustion of coal partly and a higher oxygen adsorption may lead to an easier spontaneous combustion, so the spontaneous combustion tendency of the

lignite decreases after drying. The lignite has the dewatering degree of above 70% in a short time after high-temperature drying process with simulated flue gas as drying media. The oxygen absorption capacity of the dewatered lignite decreases a lot. Therefore, high-temperature drying process with flue gas is suitable for lignite dewatering.

Table 4
Oxygen adsorption of XLGL lignite before and after drying

Samples	Oxygen adsorption cm3/g·Dry coal	Level of spontaneous combustion tendency
XLGL-Raw	0.97	I class (Easy)
XLGL-463-Gas	0.93	I class (Easy)
XLGL-1073-Gas	0.74	I class (Easy)

Note: Easy = easy to spontaneous combustion.

Conclusion

The experimental results demonstrate that the moisture removal degree of the lignite increases with the increasing temperature during the high-temperature drying process. The moisture removal degree of the lignite varies to the kinds of coal. The properties of the lignite before and after drying process change a little and no pyrolysis or combustion reaction occurs during the drying process. Compared with the low-temperature drying process, the high-temperature drying process has a higher efficiency. The dewatered lignite, especially the coal treated after high temperature drying process, has a lower amount of adsorbed oxygen than the raw coal, which means the spontaneous combustion tendency of the dried lignite decreases.

Keywords: Strain; Electron; Model

Abstract. Nowadays, the strained-Si technology has been used to maintain the momentum of semiconductor scaling due to its enhancement performance result from the higher mobility. In this paper, the influence of ionizing impurity scattering, acoustic phonon scattering and intervalley scattering to strained-Si(101) material is discussed.In addition, a calculation of the electron mobility in Strained-Si(101) material is made using the average momentum relaxation time method described in Ref[1]. The results show that the electron mobility increases gradually for both [001] and [100] orientations while for [010] orientation increases rapidly with the increasing Ge fraction x.[1]

Introduction

Strained-Si technology, expected to set a new technology roadmap for the CMOS industry, is more and more popular due to its enhancement of mobility.Lots of studies have been done about inversion layer of strained-Si MOS[2-5], however, the study of the mobility in strained-Si material is seldom reported which is of great importance.

The structure in this paper is organized as below: In Section Ⅱ, the influence of ionizing impurity scattering, acoustic phonon scattering and intervalley scattering to strained-Si(101) material are discussed. We have also calculated the electron mobility in strained-Si(101) material as a function of strain and orientations using K·P theory and the average momentum relaxation time method described in Ref[1]. In section III, an analysis of variation of the mobility with the increasing Ge fraction x as well as Ni for [001], [100] and [010] orientations is made. The last section gives the summary of this paper.

Calculation Process

The scattering is one of the essential factors that influence the mobility. During the calculation of Electron Mobility for Strained-Si(101), ionizing impurity scattering, acoustic phonon scattering and intervalley scattering are under consideration. Their models are listed below:

$$\frac{1}{\tau_i}=\frac{N_i q^4}{16\pi(2m^*)^{1/2}(\varepsilon_o\varepsilon_{Si})^2E^{3/2}}\ln(\frac{12m^*k_B^2T^2\varepsilon_o\varepsilon}{q^2\hbar^2n_i}) \tag{1}$$

$$\frac{1}{\tau_a}=\frac{m^{*3/2}\Xi^2K_BT(2E)^{1/2}}{\pi\hbar^4c_L} \tag{2}$$

$$\frac{1}{\tau_{in}}=\frac{D_i^2(m^*)^{3/2}Z_f}{2^{1/2}\pi\hbar^3\rho\omega_i}(M_i+\frac{1}{2}\mp\frac{1}{2})(E\pm\hbar\omega_i-\Delta E_{fi})^{1/2} \tag{3}$$

τ_i, τ_a, τ_{in} represents the rate of ionizing impurity scattering, acoustic phonon scattering and intervalley scattering respectively, and by substituting those parameters into the formula (4) could we obtain the scattering rate.

m^*, the density-of-states effective mass of the strained-Si(101), is needed to calculate the scattering rate. We are not going to discuss this parameter in this paper since this work was already done in Ref[6].

The average momentum relaxation time of the scatterings mentioned above is decided according to the method in Ref[1]. As all of the three types scattering exist at any time, the total scattering rate of the strained-Si(101) can be figured out by formula (4).

$$\frac{1}{<\tau>}=\frac{1}{<\tau_i>}+\frac{1}{<\tau_a>}+\frac{1}{<\tau_{in}>} \tag{4}$$

Here, $<\tau_i>$, $<\tau_a>$, $<\tau_{in}>$ are average value of τ_i, τ_a, τ_{in} respectively.

Meanwhile, we use K·P theory to obtain the conduction band E-k relation and the conductivity effective mass m_c of the strained-Si, which can be obtained in Ref[7].

It shows that the conductivity effective mass m_c for [100] and [001] orientations increases with the increasing Ge fraction x, and approximately equals to 0.318 m_0. The conductivity effective mass m_c for [010] orientation decreases with the increasing Ge fraction x, and approximately equals to 0.19 m_0 when x is larger than 0.2.

$$\mu=\frac{q<\tau>}{m_c} \tag{5}$$

By substituting the scattering rate and the conductivity effective mass mentioned above into formula (5), we can obtain electron mobility of the strained-Si(101).

Table 1. Scattering Parameters Used in This Paper

Parameters	Symbols	Units	Value
deformation potential constant	Ξ	(eV)	5.0
longitudinal elastic constant	c_L	(kg/(m.s^2))	1.903×10^{11}
energy difference between initial and final valleys	ΔEfi	(eV)	0.443x(f),0(g)[8,9]
thermodynamics temperature	T	(K)	300
Boltzmann constant	K_B	(J/K)	1.380×10^{-23}

Results and Discussions

The calculation results of the rates of ionizing impurity scattering, acoustic phonon scattering and intervalley scattering are given as follows (figure1~figure5), and figure3~figure5 represents f2 type, f3 type and g3 type intervalley scattering respectively. It should be noted that the P in the figures below represents scattering probability, and equals to 1/τ.

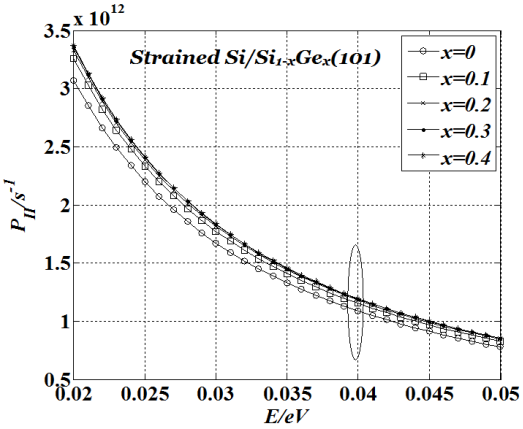

Fig.1 Ionizing impurity scattering probability of the strained- Si(101) versus with E and Ge fraction x.

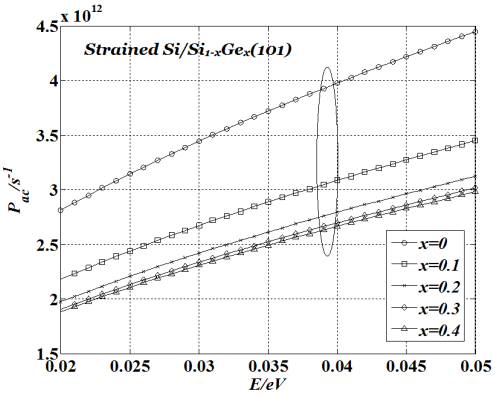

Fig. 2 Acoustic phonon scattering probability of the strained- Si(101) versus with E and Ge fraction x.

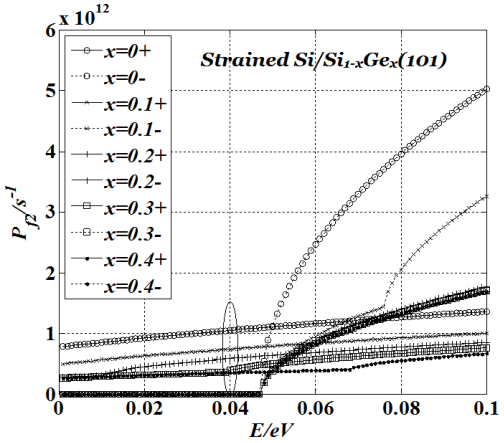

Fig. 3 f2 type intervalley scattering probability of the strained- Si(101) versus with E and Ge fraction x.

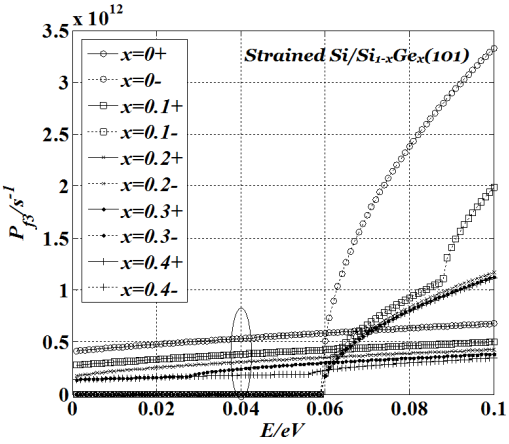

Fig. 4 f3 type intervalley scattering probability of the strained- Si(101) versus with E and Ge fraction x.

It is shown in figure1 that the ionizing impurity scattering probability of the strained-Si(101) decreases with the increasing energy, and increases with the increasing Ge fraction x when the energy is 40meV (the average energy of electron carry). Figure2 shows that the acoustic phonon scattering probability of the strained-Si(101) increases with the increasing energy, and decreases with the increasing Ge fraction x when the energy is 40meV. And from figure3, figure4 and figure5 we can find the intervalley scattering probability of the strained-Si(101) decreases with the increasing Ge fraction x when the energy is 40meV.

The electron mobility for [001], [100] and [010] orientations are showed in figure6 and figure7.It shows in figure6 that electron mobilities for [001]/[100] orientations in strained-Si(101) material versus N_i and Ge fraction x are identical.

According to figure6 and figure7, the electron mobility decreases with the increasing N_i (density of ionized impurity). It should be noted that the electron mobility get a sharp decline when N_i is larger than 10^{16}. This variation can be explained by formula (1) : the ionizing impurity scattering probability is proportional to N_i. The increasing N_i leads to an increasing ionizing impurity scattering probability thus results in a risen of the total scattering rate and a reducement of the mobility.

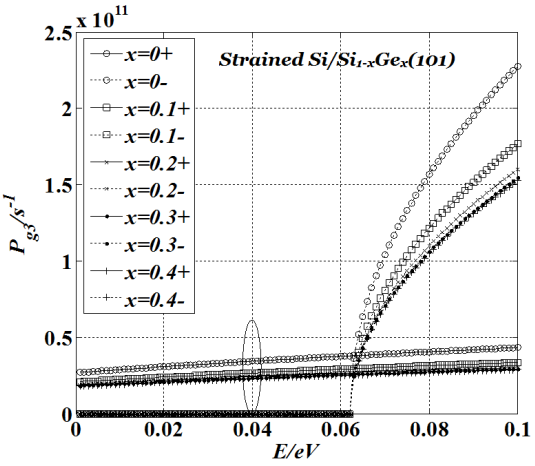

Fig. 5 g3 type intervalley scattering probability of the strained- Si(101) versus with E and Ge fraction x.

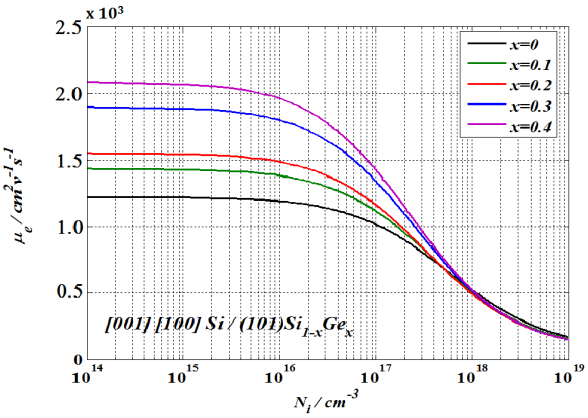

Fig. 6 Electron mobility for [001], [100] orientations in strained-Si(101) material versus Ni and Ge fraction x.

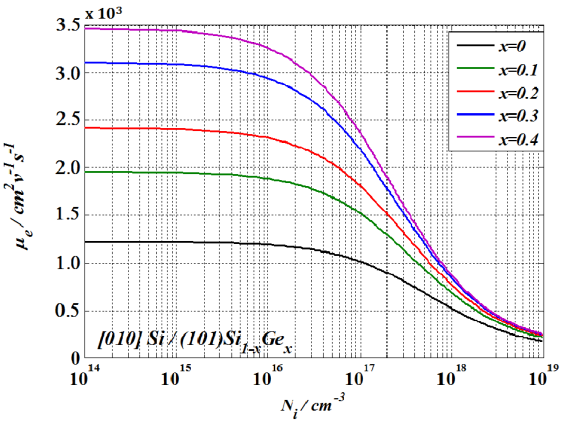

Fig. 7 Electron mobility for [010] orientations in strained-Si(101) material versus Ni and Ge fraction x.

Then we are trying to figure out how the mobility varies with Ge fraction x. For [001] and [100] orientations, the maximum mobility of the Strained-Si is about 1.68 times that of the relaxed Si material. But for [010] orientation, the electron mobility increases much more rapidly compared to other orientations and its maximum value is approximately 2.8 times that of the relaxed Si.

This phenomenon of the electron mobility of the strained-Si(101) material for different orientations can be explained as follows. The conductivity effective mass m_c for [100] and [001] orientations increases with increasing Ge fraction x, and is approximately equals to 0.318 m_0, while the conductivity effective mass m_c for [010] orientation decreases with increasing Ge fraction x, and approximately equals to 0.19 m_0 when x is larger than 0.2. Besides, the tensile strain splits the six-fold degenerate Si conduction band minimum into a two-fold (Δ_2) and a four-fold (Δ_4) degenerate band. For strained-Si(101), the four-fold degenerate band is lower in energy, so electrons prefer to occupy the Δ_4 band. The energy difference ΔE between the Δ_2 and the Δ_4 bands is proportional to the Ge fraction x [11], the Δ_4 population increases and the intervalley scattering decreases with increasing Ge fraction x，as is shown in figure3~figure5. With increasing Ge fraction x, the electron mobility for [001] and [100] orientations increase gradually while the mobility for [010] orientation get a higher increasing rate, because of the suppression of scattering and the reduction of conductivity effective mass.

Summary

In this paper, based on the analysis of the scattering in Strained-Si(101) material, the calculation of the electron mobility in strained-Si(101) material as a function of strain and orientation is made using K·P theory and the average momentum relaxation time method described in Ref[7]. The results show that the electron mobility decreases with N_i. Besides, the electron mobility for [001] and [100] orientations increase gradually with increasing Ge fraction x, while for [010] orientation, the electron mobility increases rapidly with increasing Ge fraction x, and its maximum can reach a value approximately 2.8 times that of the relaxed Si material. This result is valuable and can be used as a reference to the design of strained-Si devices.

Keywords: AC electroosmosis, double layer capacitor (DLC), electric double layers (EDL)

Abstract. Previously researchers considered ions in electric double layers (EDL) to analyze the phenomenon of alternating current electroosmosis (ACEO). However, they did not give a deep interpretation about the formation mechanism of ACEO and their theories cannot explain some experimentally observed phenomena. In this paper, we propose a physical model to analyze the formation mechanism of ACEO by considering ions both in EDL and in solution. It is found that the ions in solution play an important role in ACEO, and by considering the effect of ions both in EDL and in solution, we can reasonably explain some phenomena, including flow reversal at high frequency (typically 10-100 kHz) and inapplicability of ACEO at high salt concentration (above 30 μM), which existing theories cannot give convincing explanations. We also use Navier-Stokes equation to theoretically analyze the ACEO and it is found that the flow reversal can be predicted by our concepts in certain conditions.

Introduction

Electroosmosis (EO) is the phenomenon of movement of uncharged liquid in a channel charged by an externally applied electric field [1]. EO is inherent to the fact that many solid materials obtain surface charges at the solid-liquid interface when contact with liquids, and an electric field is established to attract the charges in the liquid with the same polarity and repulse the charges with opposite polarity, inducing EDL. The EDL contains high concentration charges with polarity opposite to the surface charges of the solids, enabling a direct current (DC) voltage applied in parallel to the channels to force the ions in the EDL to move and to generate a motion of the bulk fluid by dragging the liquid as a result of the viscosity, so-called DCEO. This EDL model for DCEO, established by Helmholtz and improved by Smoluchowski, has since served as the basis for interpretations of electrokinetic behaviors at liquid-solid interfaces.

Alternating current electroosmosis (ACEO) refers to driving fluids using the principle of EO at AC voltage. As a method to drive microfluids, ACEO only needs very low voltage (several volts) and has no moving parts, thus it can effectively prevent Faradaic reaction and can meet the requirements of limited voltage with the increasingly stringent demand of device size and long lifetime. ACEO has been employed as a potential tool for pumping fluid [1]-[3], mixing liquid [4], and manipulating biomolecules like DNA [5]. Different electrodes have been developed for ACEO, such as symmetry planar electrodes [6][7], asymmetry planar electrodes 0-[10], and three dimensional electrodes [2][3]. The symmetry planar electrodes cannot generate net flow due to that the forces produced on electrodes cancel each other out. However, when AC voltage is applied to an array of asymmetric electrodes, the difference between electrodes will produce asymmetric electric fields and this will impose dissimilar forces on microfluids, finally inducing a unidirectional fluid flow.

Similar to DCEO, ACEO has been interpreted as the action of the electric field on the induced charges in the EDL between the electrolyte and the electrode [6], [7], [10]-[13]. For example, it is believed that electric field normal to electrodes induces the EDL and electric field tangential to the electrodes drives ions in EDL to move [10]. However, this theory cannot account for several

experimental observations such as the flow reversal at high frequency [14][15] and low salt concentration limitation [16].

To address these phenomena, theoretical efforts have been devoted. Storey et al. explained the flow reversal by considering steric effects [14]. They suggested a maximum capacitance near a critical voltage across the EDL which will be influenced by power supply frequency. After the critical frequency, EDL capacitance will fall and narrow electrodes' charging time will decrease, and thus the narrow electrodes have sufficient time to charge and have more time to drive ions in fluid. This eventually causes the flow reversal. However, this explanation did not consider the forces produced by the ions beyond the Debye length [17], which could be important to the pumping mechanisms. Lastochkin et al. studied the influence of Faradaic reaction on fluid flow [18][19]. This effect only happens at low frequency and high power supply voltage, thus it cannot explain the flow reversal which only happens at high frequency. There are also some existing theories about induced-charge electroosmosis (ICEO) [20]-[22], which consider inducing EDL on electrodes by applying outside electric potential and are different from ACEO that electric potential is applied directly on electrodes.

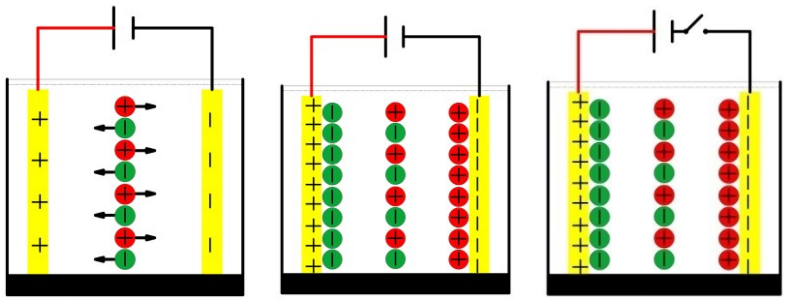
Another inconsistency between ACEO theories and experiments is the unpredictable strong decay of the flow with increasing salt concentration of the solution. The flow effectively vanishes above a bulk salt concentration of above 10 mM salt concentration, so all experiments in the literature have used few electrolytes with concentration of an order lower than most biological solutions, such as very dilute solutions (mostly KCl) or de-ionized water. To address this phenomenon, new explanations of the EDL at large voltages, such as a dramatic increase in the diffuse-layer viscosity upon ion crowding, has been proposed [16].

Understanding the inconsistency between the theory and the experiments is of great importance from both fundamental and practical points of view. However, until now, the theories about ACEO are not convincing enough and cannot explain all the experimentally observed phenomena. In this paper, we put forward our own understandings about ACEO, and try to explain some experimental results using the proposed operation mechanism. Theoretical deduction based on the Navier-Stokes equation and our proposed mechanism is presented to theoretically predict the flow reversal.

Proposed Mechanism of ACEO

With an AC electric field, the ions in solution respond to the charge on the electrode at each half-cycle, retarded by their frictional drag through the medium. The EDL then becomes sensitive to the frequency of the alternating electric field, since electrode charge oscillating faster/slower than the ions can/cannot respond and lead to incomplete/complete formation of the EDL. Considering that ACEO produces flow by charging and discharging the electrodes, which is similar to the charging and discharging process in a double layer capacitor (DLC) [23]-[25], we propose to use the DLC process to analyze ACEO.

Figure. 1 schematically shows the charging process of a DLC. When voltage applies to electrodes in aqueous solution, it will result in the collection of ions near the electrodes and form EDL. The EDL is equivalent to a capacitor of which the distance between the two "plates" is shorter than 1 nm [25], thus DLC has a capacitance thousands of times larger than ordinary plate capacitors that have the same structure but without aqueous solution.



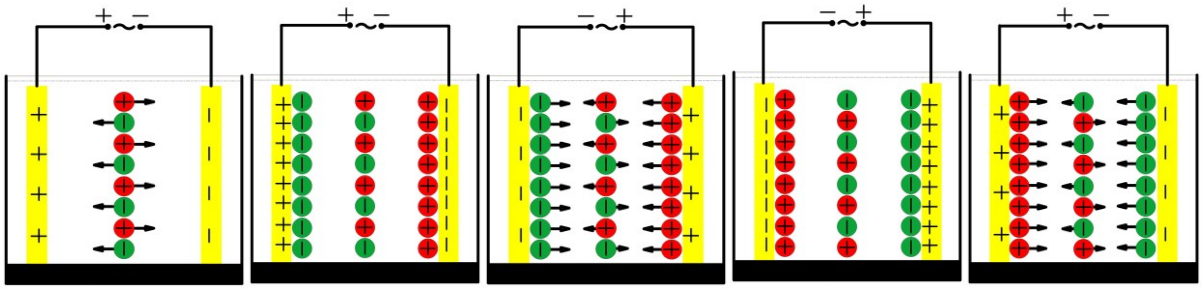
(a) (b) (c)

Figure. 1 Schematic diagram of DLC's charging process (a) start, (b) end, (c) after removing power source. (Red circles represent positive ions and green ones represent negative ions)

If there is no voltage applied to electrodes, there will be no forces exerted on ions in aqueous solution and the ions are uniformly distributed in the solution. At the beginning when applied with voltage, the ions in solution will be forced to move towards the electrodes by the electric potential, as shown in Figure. 1 (a). As long as the supply voltage is smaller than the decomposition voltage of aqueous solution, there will be no faradaic reaction in the contact interface [25].

During this charging process, fluid flow is generated by the dragging force of ions as a result of fluid viscosity. After the DLC is fully charged, there will be no electric field left in aqueous solution because the electric field caused by the DLC electrodes cancels that caused by the EDL, and thus the aqueous solution can be regarded as an equipotential body, as shown in Figure. 1 (b). Therefore, there is no force imposed on the ions in solution and they can move only through inertia, which will stop very quickly under the action of fluid resistance. Thus, only in the charging process there the ions in solution experience driving forces; after EDL is completely formed, there is no force exerted on the ions. After removing the applied voltage, the EDL can sustain a long time, as illustrated in Figure. 1 (c).

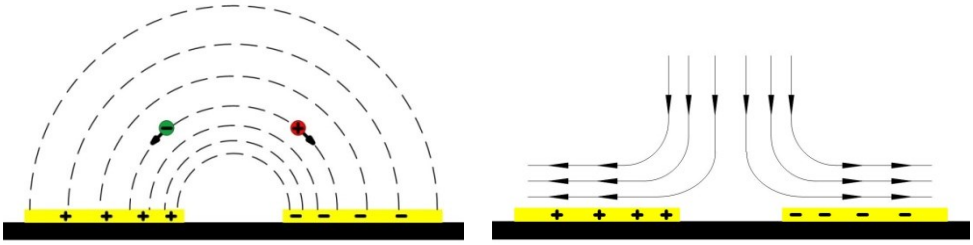
Under AC voltage conditions, the DLC has both charging and discharging processes. If the voltage frequency is smaller than the system's relaxation frequency, there will be enough time for the electrodes to be fully charged. On this occasion, the EDL will charge and discharge in the order of Figure. 2 (a)→ (b), (c), (d), (e) → (b), (c), (d), (e) →…. At the beginning there is no EDL originally, and the ions are forced to form the EDL just after the voltage applies. This charging process is identical to Figure. 1. When the electric voltage reverses, the electrodes reverse instantly due to that the charges on the electrodes are neutralized by the power and thus is extremely fast, as shown in Figure. 2 (c). Meanwhile, since there is no enough time for the ions in the EDL to move because of the resistance of solution, the ions in the EDL remain almost their original positions just after the electric voltage reverse, leading to the electric field in the solution to be a superposition of that of the electric voltage and that of the EDL. With the movement of ions in EDL, a new EDL is formed and the ions in the solution reach a new steady-state, as shown in Figure. 2 (d). In this process, ions in EDL move to aqueous solution and ions in aqueous solution move to electrodes simultaneously, and they combine to driving fluids. Therefore, when there is EDL on the electrodes, the charging and discharging process will be in the order of Figure. 2 (b), (c), (d), (e) → (b), (c), (d), (e).



(a) (b) (c) (d) (e)

Figure. 2 (a) electrodes charging begins, no EDL originally, (b) charging ends, EDL completely formed (c) electric potential reverses, (d) EDL discharging and charging ends, (e) electric potential reverses.

As the charging and discharging processes in ACEO are the same as they are in DLC, ACEO can be reasonably explained below using the principle of DLC. In ACEO, if there is no EDL originally, the movement of ions in aqueous solution will be like the charging process of DLC, just as illustrated in Figure. 3(a). The electrodes are separately charged and fringe electric field will be formed in aqueous solution. The electric field forces ions in aqueous solution to move to the electrodes and form EDL. In this process, the movement of ions will drive nearby fluids to move, as shown in Figure. 3(b).



(a) (b)

Figure. 3 The mechanism of ACEO, (a) charging begins without EDL originally (b) fluid streamline

It can be seen that in the proposed mechanism the fluid movement will be affected by ions in both the EDL and in the aqueous solution if there is EDL on electrodes. After the electric potential reverses, electric charges on electrodes is rapidly be neutralized and therefore become opposite instantly. However, ions in EDL and aqueous solution move more slowly correspondingly because they should overcome more resistance in liquid.

There are mainly three kinds of forces exerted on ions in EDL after electric potential reverses. The first force F_e is from the electric field which is produced by the charges on the DLC electrodes. After electric potential reverses, the charges on electrodes will have the same polarity with the ions in nearby EDL, thus the ions in EDL will be exerted with repulsive force. Ions in solution will also suffer this force.

The second force F_i is from the interaction of ions between EDL on relative electrodes. From the analysis above it is clear that if charging time is longer than system's relaxation time, there will be no electric field left in aqueous solution because the electric fields produced by the ions in EDL have the same magnitude but the opposite directions. Immediately after electric potential reverses, electric field produced by ions in EDL will not change as quickly as electric field produced by electric charges on electrodes, leading to the ions in EDL to experience attractive force from the relative EDL. If the DLC has been fully charged, the amount of charges in EDL is far more than ordinary plate capacitors. Thus the electric field produced by the EDL will be much larger than ordinary plate capacitors. This electric field will have a great influence on ions' movement in EDL and it will soon disappear due to the ions' movement in EDL. This force will exert on ions in solution too.

The third force F_{Diff} is from the diffusion of ions in EDL. The ions concentration in EDL is much higher than that in aqueous solution, thus ions in EDL will diffuse from EDL to aqueous solution.

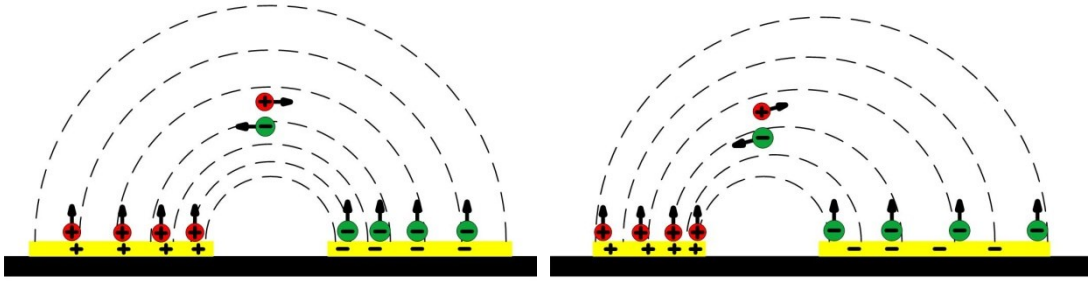
Explanations for experimental results

1. Direction of streamlines

Using existing theories, the streamlines of ACEO are expected to be downwards along the middle of two adjacent electrodes to the electrode surface [7][26]. If the streamline of fluid flow on symmetry electrodes is like this, it can be reasonably inferred that flow direction on asymmetry electrodes is from wide electrodes to nearby narrow electrodes because electric field is stronger nearby the narrow electrodes than the wide electrodes. However, almost all experimental results showed that the flow direction in ACEO on asymmetry electrodes was from the narrow electrode to the nearby wide electrode except at high frequency. Thus the existing theories must have missed something in explaining ACEO fluid flow. Brown et al. revised this defect by introducing a fluidic cycle to reverse the flow direction 0[10]. However, no forces can be found to reverse the fluid flow.

Streamlines of ACEO will be analyzed using our proposed mechanism. The direction of forces imposed on ions in EDL and in soluion of symmetry and asymmetry electrodes are illustrated in Figure. 4. From analysis in section 2, it is clear that the force produced by ions in EDL will be dominant at relatively low frequency. Ions in EDL are forced to move from the electrodes to the gap between the two electrodes. Ions density in EDL and electric charges density on symmetry

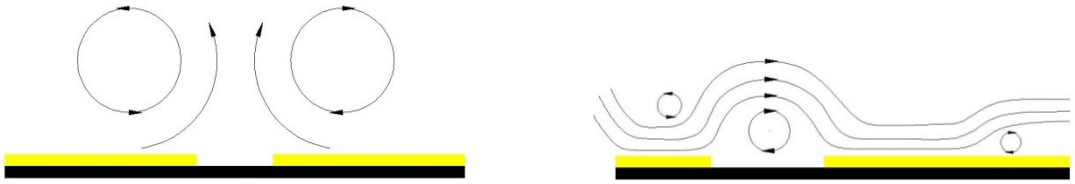
electrodes are the same, thus the ions' movement in EDL and solution will have same forces on fluid. When fluids from symmetry electrodes encounter each other in the middle of the gap between electrodes, streamline will be like in Figure 5 (a).



(a) (b)

Figure. 4 Forces exerted on ions in EDL of (a) symmetry and (b) asymmetry electrodes

For asymmetry planar electrodes, ions density in EDL of the narrow electrodes is larger than the wide ones due to the reason that the amount of ions in each electrode is the same if ions in each EDL have the same valence [14]. The larger ions density in EDL will form a stronger electric field after electric potential reverses. Furthermore, electric charges on the narrow electrodes will also produce a greater electric field than wide electrodes due to electric charges' density difference. Therefore the forces on fluid from narrow electrodes will be larger than the ones from wide electrodes, and streamline will be like in Figure. 5 (b).



(a) (b)

Figure. 5 Fluid flow streamlines of (a) symmetry electrodes and (b) asymmetry electrodes

2. Flow reversal

Flow reversal at high frequency is the most puzzling phenomenon which the existing theories cannot explain. From the aforementioned analysis, the fluid flow is due to the interaction between the ions in both EDL and in aqueous solution. It is clear that the electrodes of ACEO need a RC time to charge. As long as the charging time is longer than the RC time, i.e., the power supply frequency of ACEO is smaller than the system's relaxation frequency, there will be no electric force exerted on ions in aqueous solution after the EDL have been fully charged. On this occasion, fluid will not be successively driven by ions. With the increase of power supply frequency, though forces exerted on ions do not change, the time during which there is no electric field force on ions will be shorter. Thus the average driving force and thus the fluid velocity will get higher. If the power supply frequency equals to the system's relaxation frequency, the fluid velocity will be the highest.

When the power supply frequency increases further, there will not be enough time to form EDL and the effect of ions in EDL will weaken. This implies that if the charging time is shorter than the RC time, the ion amount in EDL and the contribution of the ions in EDL to pumping will decrease with the increase in frequency. With further increase in the power frequency to a threshold value, the force produced by the ions in EDL will be so weak that the force produced by the ions in aqueous solution becomes dominant. For example, if the frequency of power supply voltage is 100 times of the system's relaxation frequency, i.e., the charging time is 1% of RC time, the amount of ions in EDL will decrease to about 1% of that being completely charged according to the rudimentary charging equation which follows exponential relation with charging time

$$V_t = V[1-\exp(-t/RC)] \quad (1)$$

Considering the analysis in Figure 3, it is clear that the forces produced by ions in solution will have the direction in Figure. 6. In this situation, the resulted force will have the direction from wide electrodes to the nearby narrow electrodes because of the stronger electric field above the narrow electrode than the wide electrode. This change will finally result in flow reversal. The tendency is consistent with the experimental results given in previous report [15].

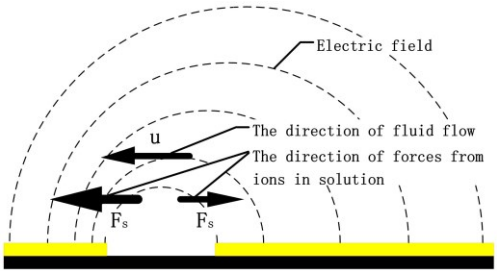


Figure. 6 Flow direction in high frequency (u represents velocity and F_s represents the force produced by ions in solution. The thickness of the arrows represents the magnitude of the force)

3. Flow decay in high concentration solution

The second phenomenon which the existing theories cannot explain is that only low concentration aqueous solution can be driven in ACEO. Experimental results show that fluid flow velocity decreases above 1 mM and if the concentration is above 30 mM it is difficult to observe fluid flow [16]. We try to explain this phenomenon using the proposed ACEO mechanism. As the capacitance of EDL is determined by the product of the capacitor and the applied voltage, the ion density of EDL will not change with the variation in the solution concentration when the electrodes are fully charged, and therefore the force magnitude generated by the ions in the EDL will not vary with solution concentration.

With the increase in the solution concentration, the ions in the solution in the vicinity of the electrodes are sufficient to fully charge the EDL, and it is not necessary for the ions in far solution (the middle of the channel) to move to the electrode surface to charge the EDL. Therefore, the EDL can be fully charged more quickly than in lower concentration because of the avoidance of ion movement through a long distance. This leads to the movement duration and movement distance of the ions in the EDL becomes shorter, so the driving force and the fluid flow arising from the ions in the EDL decrease.

Once the EDL is fully charged, the resultant electric field in the far solution is zero as a result of the superposition of the electric fields caused by the electrode and the opposite electric fields caused by the EDL. Thus, with the continuous increase in the solution concentration, the movement duration of the ions in the far solution, which equals to the duration of EDL establishment in a half cycle, will be shorter and shorter, leading to the ions in solution experience smaller and smaller forces. Finally, the fluid flow vanishes because both the ions in the EDL and the ions in the solution experience zero force.

Theoretical analysis about ACEO and prediction for flow reversal

Navier-Stokes equation is the governing equation for electrokinetics driven fluidics,

$$\rho\frac{\partial\vec{u}}{\partial t}+\rho\vec{u}\cdot\nabla\vec{u}=-\nabla p+\eta\nabla^2\vec{u}+\rho_E\cdot\vec{E} \tag{2}$$

where ρ is the space charge density, u is the fluid flow velocity, p is the pressure, η is the dynamic viscosity of the solution and E is the electric field. The left side of the formula stands for the system's momentum change rate and the right side stands for the resultant of body force and surface force on the boundary. The fluid flow velocity does not change if the voltage and frequency of the power supply remain the same, thus the system's momentum change rate is zero. By considering the adjacent narrow electrode and wide electrode, Eq. (2) can be written as

$$\eta\nabla^2\vec{u}+\rho_E\cdot\vec{E}=0 \tag{1}$$

In ACEO, ions in the EDL and solution will both be driven by electric field. However, the electric field differs with locations. Thus ions in different locations suffer different forces. Specifically, the electric field near the narrow electrodes is larger than that near the wide electrodes, thus ions near the narrow electrodes will suffer a greater force. Though the direction of electric field alternates frequently, the forces produced by ions in EDL and solution will not change, as illustrated in Figure. 7. We only consider the forces along the pipeline direction and use F_{DL} and F_S to represent the forces suffered by ions in EDL and solution, respectively.

From the analysis above it is clear that resultant of ions in EDL and solution has an opposite direction. Eq. (3)can be written as:

$$\eta\nabla^2 u + \rho_{DL} \cdot E_{DL} - \rho_S \cdot E_S = 0 \tag{2}$$

where ρ_{DL} and ρ_s stand for the space charge density of ions in EDL and solution, respectively, and E_{DL} and E_s separately stand for the electric filed suffered by ions in EDL and solution.

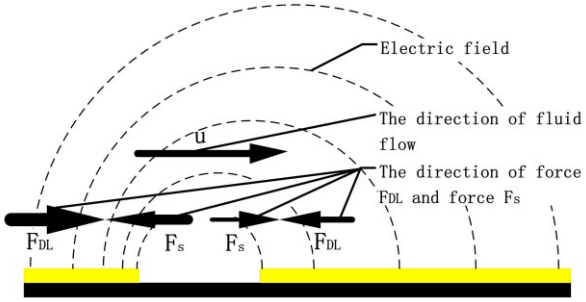

Figure. 7 The direction of forces in ACEO. (The thickness of the arrows represents the magnitude of the force)

At low frequency, there is enough time for the EDL to charge, thus the number of ions in EDL reaches its maximum. This maximum number is determined by the electrode capacitance and the supply voltage. Though the numbers of ions in EDL on adjacent narrow and wide electrode are the same, these ions suffer different electric fields due to the electrode asymmetry. As a result, the resultant produced by ions in EDL will have the direction from narrow electrode to the nearby wide electrode. Resultants suffered by ions in EDL in per unit volume can be deduced from Eq. (1)

$$F_{DL} = \rho_{DL} \cdot E_{DL} = C\tilde{V}[1 - \exp(-\frac{1}{2fRC})] \tag{3}$$

where $C\tilde{V}$ is the maximum space charge density of ions in EDL, f is frequency and RC is the system's relaxation time. EDL can be regard as the average electric field exerted on ions in EDL. In half a power period, $t = 1/2f$, the exponent part stands for the relationship between ion space charge density in EDL and power supply frequency. It shows that ions in EDL will decrease with the frequency's increase (which means the charging time will decrease).

There are both positive and negative ions in the solution, which is different from ions in EDL. It can be assumed that the space charge density of the ions in solution equals to the maximum space charge density of the ions in EDL, and formula can be written as:

$$F_S = \rho_S \cdot E_S = C\tilde{V} \cdot E_{S\max} \cdot \exp(-\frac{t}{RC}) \tag{4}$$

where t stands for time in half a period circle, $E_{S\max}$ can be regard as the maximum average electric field exerted on ions in solution. It can be assumed that space charge density of ions in solution does not change with frequency and time because solution concentration is constant. Formula (1) stands for the relationship between voltage and time on electrode, thus the potential drop in solution can be calculated by subtracting voltage on electrode from power supply voltage.

Then formula (4) can be written as:

$$\eta\nabla^2 u + C\tilde{V}[1 - \exp(-\frac{1}{2fRC})] \cdot E_{DL} - C\tilde{V} E_{S\max} \cdot \exp(-\frac{t}{RC}) = 0 \tag{5}$$

Here it can be assumed that the acting times of ions in EDL and solution are the same. If power supply's half a period is longer than the charging time, it can be assumed that forces suffered by ions in EDL and solution both become zero. Thus we can postulate that when $t > 3RC$, formula (7) becomes:

$$\eta \nabla^2 u = 0 \tag{6}$$

Figure. 8 The dimension and schematic diagram of pipeline

Figure. 8 shows the dimension of the pipeline and b represents half the pipeline height. By integrating formulae (7) and (8) we get:

$$\begin{cases} u = \dfrac{1}{2\eta}\left(b^2 - y^2\right) \cdot \left\{ C\tilde{V}[1 - \exp(-\dfrac{1}{2fRC})] \cdot E_{DL} - C\tilde{V} E_{S\max} \cdot \exp(-\dfrac{t}{RC}) \right\}, t \le 3RC \\ u = 0, t > 3RC \end{cases} \tag{7}$$

The average velocity can be calculated by integrating the velocity in half a period and then dividing the integration by time. When frequency is low, namely $T = \dfrac{1}{2} f > 3RC$, the average velocity is:

$$\begin{aligned} u &= \frac{1}{2\eta}\left(b^2 - y^2\right) C\tilde{V} \cdot \frac{\int_0^{3RC} \left[[1 - \exp(-\frac{1}{2fRC})] \cdot E_{DL} - E_{S\max} \exp(-\frac{t}{RC}) \right] dt + \int_{3RC}^{T} 0 dt}{T} \\ &= \frac{1}{2\eta}\left(b^2 - y^2\right) C\tilde{V} \cdot 2fRC \left\{ 3\left[1 - \exp\left(-\frac{1}{2fRC} \right) \right] \cdot E_{DL} - E_{S\max}\left(1 - e^{-3}\right) \right\}, 0 < 2fRC < \frac{1}{3} \end{aligned} \tag{8}$$

If the frequency is large enough, that is to say $T = \dfrac{1}{2} f \le 3RC$, the integration of the velocity is:

$$\begin{aligned} u &= \frac{1}{2\eta}\left(b^2 - y^2\right) C\tilde{V} \cdot \frac{1}{T} \int_0^T \left[[1 - \exp(-\frac{1}{2fRC})] \cdot E_{DL} - E_{S\max} \exp(-\frac{t}{RC}) \right] dt \\ &= \frac{1}{2\eta}\left(b^2 - y^2\right) C\tilde{V} \cdot \left\{ \left[1 - \exp\left(-\frac{1}{2fRC} \right) \right] \cdot E_{DL} - E_{S\max} \cdot 2fRC \left[1 - \exp\left(-\frac{1}{2fRC} \right) \right] \right\}, 2fRC \ge \frac{1}{3} \end{aligned} \tag{9}$$

In ACEO, if the solution concentration remains unchanged, the RC time will be constant. Thus for the convenience of analysis, let $x = 2fRC$ and $E_{DL} = 2E_{S\max}$. If we do not consider the coefficient of formulae (10) and (11), the two formulas can be rewritten as:

$$\begin{cases} y = x\left\{ 6\left[1 - \exp\left(-\dfrac{1}{x} \right) \right] - \left(1 - e^{-3} \right) \right\}, 0 < x < \dfrac{1}{3} \\ y = 2\left[1 - \exp\left(-\dfrac{1}{x} \right) \right] - x\left[1 - \exp\left(-\dfrac{1}{x} \right) \right], x \ge \dfrac{1}{3} \end{cases} \tag{10}$$

Figure. 9 is the curve drawn using Matlab which shows the relationship between x and y, and it can reveal the relationship between frequency f and velocity u. With the increase in x, y increases but decrease after a specific value. Flow reversal can be observed in this figure. By comparing Figure. 9 with experimental results reported in [15], it is clear that their tendencies are consistent.

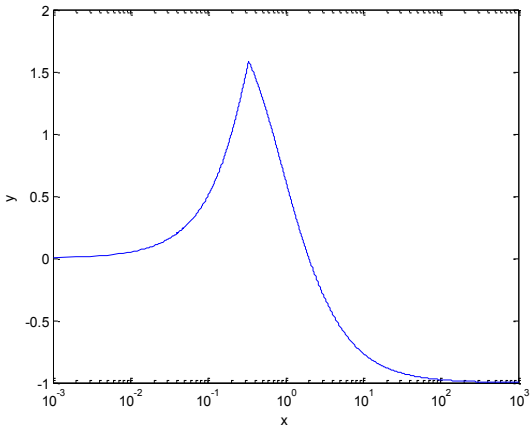

Figure. 9 The changes of y versus x. The flow changes and flow reversal can be observed.

In the simplification above, we let $E_{DL} = 2E_{S\max}$ because ions in EDL suffer a larger average electric field compared with ions in solution. Ions in EDL concentrate on the surface of the electrodes and separately suffer the maximum and minimum electric field, thus the average electric field exerted on ions in EDL will be larger than electric field suffered by ions in solution. The electrodes size and the gap between wide electrodes and narrow electrodes will both influence this ratio.

Conclusion

ACEO is like a DLC and its fluid flow is influenced both by ions in aqueous solution and EDL. In this paper, we first give an introduction about ions movement mechanism in ACEO, and then analyze two kinds of experimental phenomena that the existing theories cannot explain by using our own concepts. Furthermore, we give formulas about fluid flow velocity in section 4 and its calculated velocity tendency is consistent with experimental results. Therefore, it is clear that our understandings can reasonably explain the ACEO phenomena.

Keywords: Viscosity; Watered Fuel Oil; Oil temperature; Water Content; Agitation Speed;

Abstract. Viscosity of Watered fuel oil, which was prepared by a self-made mechanical micro-mixing device, was measured with rotation viscosimeter. The effects of oil temperature, agitation speed and water content on viscosity were investigated in this research. The experimental results showed that: viscosity of watered fuel oil decreases with the increasing of oil temperature between 60-80 ℃ and water contents in 2.0-8.0 %, but increases with the accelerating agitation speed at 1000-1300 r/min.

Introduction

Under the situation of oil resource shortage and serious environment pollutions, the emulsified fuel oil which is due to both economic and environmental advantages has become one of technologies on energy saving and emission reduction with the prospect of application [1].

Viscosity is one of the most important physicochemical characteristics to watered fuel oil. Viscosity could influence watered fuel oil on aspects of transfer, preparation and spray quality. The viscosity of heavy oil is usually high at normal temperature, so it is quite important to understand how to get over the harmful effect from high viscosity oil in the course of watered fuel oil preparing. And it is benefit for improving the produce quality of watered fuel oil preparing by knowing the variation law of viscosity, which could affect the combustion of watered fuel oil [2]. Although there is a key relationship between combustion effects and law of property changes, the researches on influence factors of oil property changes after emulsification were few. Therefore, for making sure watered fuel oil could play a better role in energy saving and emission reduction, this research has studied on the measurement of viscosity influence and effect factors of watered fuel oil, which could provide the theoretical basis and foundation for technology application of watered fuel oil.

Materials and method

Devices used to prepare watered fuel oil

Figure 1 is a self-made device which is used to prepare watered fuel oil. It is made from mechanical micro-mixing central part, metering pump, rotary pump, mixing motor (0-1400 r/min adjustable), water tank, fuel oil tank, watered fuel oil tank and electrical system. The main part is connected to water way and oil way respectively by fast joints. There are three stage zones of mixing inside mechanical micro-mixing central part. The first stage is a cylindrical rotor, the second and third stages are interlocking gear wheels. And the entrance at a micron magnitude width is in the middle of the first and second mixing zones. Rotational speed of gear wheels and entrance width are both adjustable. Fuel oil and water are injected into mechanical micro-mixing central part at about 3 atm (standard atmosphere) and 2 atm, respectively, according to a certain proportion from different angels. Then water-in-oil (W/O) of water droplet size at the micron magnitude is prepared by combined actions which are impulse force, shear stress, friction and surface tension.

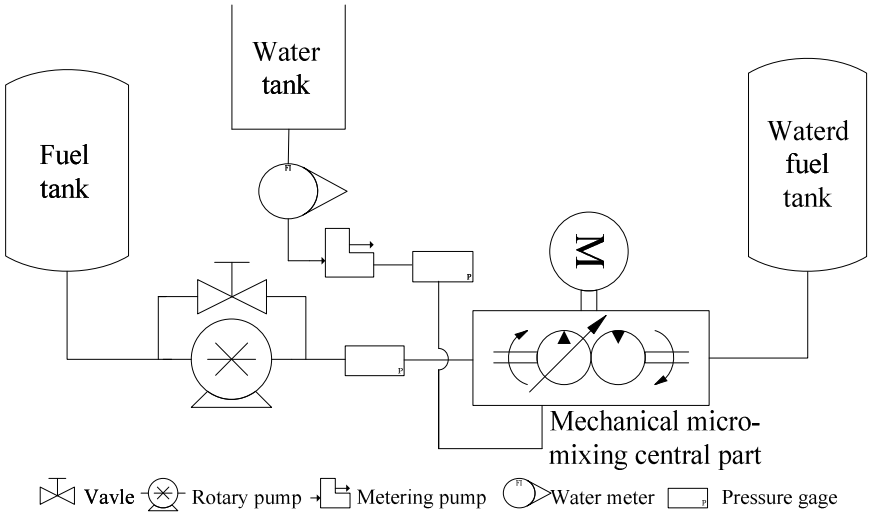

Figure 1 Flow chart of experiment

Parameters control

Watered fuel oil was prepared with mixed fuel oil from oil field and water as raw materials. Fuel oil temperature (T, ℃) in oil tank was controlled by electric heating and temperature transmitter. Agitation speed (v, r/min) was adjusted by changing rotational speed of gear wheels with the frequency transformer. Water content in watered fuel oil was adjusted by accurately controlling flow of water and oil. Sampling point was set at oil outlet of mechanical micro-mixing central part. Then viscosity was measured by using rotation viscosimeter (BROOKFIELD DV-Ⅱ+Pro). We used the thermal constant temperature extraction method to determine water volume in emulsified samples after static separation and to figure out the water content (ρ_w, %).

Results and discussion

The effects of oil temperature on viscosity

Viscosity of heavy fuel oil is high at the normal temperature. Considering the poor fluidity of oil, it needs preheat before been used. Previous studies shows the fuel oil possesses certain fluidity at the oil temperature above 50 ℃, and keeps stability well at the temperature 80 ℃, but the oil and water soon separates once the temperature exceeding 90 ℃. So we chose 60-80 ℃ as the temperature range in this research.

When agitation speeds were 1000, 1100, 1200, 1300 r/min, viscosities of watered fuel oil were measured at different temperatures 50, 60, 70, 80 ℃. As figure 2 showed, the viscosity decreased with the increasing of oil temperature at the same agitation speed. Viscosities of 4 kinds of agitation speed all reached all minimal at temperature 80 ℃, and all maximum at temperature 50 ℃. Then temperature elevated to 70 ℃, the decline of viscosity was certain. When the temperature increased from 70 to 80 ℃, the viscosity decreased significantly, and the average reduce rate was 35.3 %.

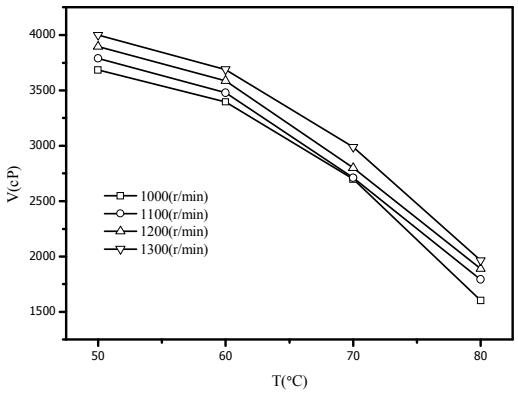

Figure 2 Viscosities of watered fuel oil at different preheating temperatures

The experiment showed, the higher temperature made viscosity of watered fuel oil lower. The reason is that high temperature causes molecules thermal motion strenuous, intermolecular interactions weaken [4], and then agitation resistance reduce, so the viscosity decreased. Fluid viscosity mainly comes from intermolecular interactions. In low temperature conditions, relatively, molecules orderly arrange, regularly move, and then intermolecular interactions are great. When temperature increasing, molecules thermal motion strengthens, next, intermolecular distances increase and inner friction reduces, as the result, viscosity decreases. From the energy point of view, thermal energy transforms into kinetic energy of molecules, and then intermolecular interactions weaken so viscosity decrease. Xiao et al researched on viscosity of emulsified oil, the results were similar with this experiment [2]. From the analysis above, increasing temperature is the effective method to decrease viscosity of watered fuel oil.

The effects of agitation speed on viscosity

Previous studies indicated, if agitation speed was lower than 1000 r/min, emulsification effect of watered fuel oil was bad. The max agitation speed of the device in this research was 1400 r/min, for the sustained and steady agitation, the next experiment chose the range of agitation speed 1000-1300 r/min.

Viscosities of watered fuel oil were measured at different agitation speeds (1000, 1100, 1200, 1300 r/min) when preheating temperatures were 50, 60, 70 and 80 ℃.As shown in figure 3, the viscosity of watered fuel oil increased with the increase of agitation speed at the same temperature. But the increase extent was small; each adding 100 r/min could increase about viscosity 110 cP. When agitation speed was 1000 r/min, viscosities of 4 kinds of temperatures were all minimal and maximum at agitation speeds 1000 and 1300 r/min, respectively. The viscosities increased 7.9-18.4 % as agitation speeds from 1000 r/min to 1300 r/min.

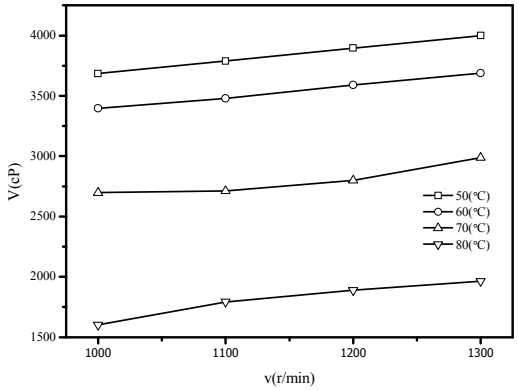

Figure 3 Viscosities of watered fuel oil at different agitation speeds

The experiment results showed, viscosity of watered fuel oil could increase slightly by adding agitation speed from 1000 r/min to 1300 r/min. The main reason is that high agitation speed makes particles of dispersed phase more and smaller, and then the viscosity increased in certain degree. In addition, fluid viscosity comes from fluid inner friction between adjacent fluidity layers. The impulse, shear and friction force can effect from different angels at mechanical agitation, which makes inner layers of watered fuel oil moved by vary speed, as the result, friction produced. High agitation speed causes adjacent fluidity layers speed difference adding, and then viscosity increases. Some researcher provided the same conclude as this experiment that increasing agitation speed could make the viscosity of emulsified oil increase [2] [5]. Though adding agitation speed can increase the viscosity of watered fuel oil, it is benefit to water droplet of dispersed phase smaller [6] [7], and improving combustion effect [8]. Therefore, it needs overall consideration to choose agitation speed in the course of preparing watered fuel oil.

The effects of water content on viscosity

Water content of emulsified oil should control in certain range. Too much water content is not good for stability of watered fuel oil, and could cause dispersed particles big, even oil-water separated. On the contrast, too little water content would limit effect of microexplosion, oil saving and pollution reducing. So the range of water content controlled from 2.0 % to 8.0 %.

Figure 4 showed viscosities of watered fuel oil at vary water content (2.0, 3.5, 5.0, 6.7 and 8.0 %) when oil temperatures were 60, 65, 70, 80 ℃ and agitation speed was 1300 r/min. From figure 4, viscosities of watered fuel oil increased with water content increasing at the same oil temperatures and agitation speed. When water content was 2.0 %, viscosities of watered fuel oil at 4 kinds of temperatures were all minimal. If increasing water content to 8.0 %, viscosities were all maximum. When water content increased from 2.0 % to 5.0 % and temperature was 80 ℃, viscosity increased 4.8 % which was the most.

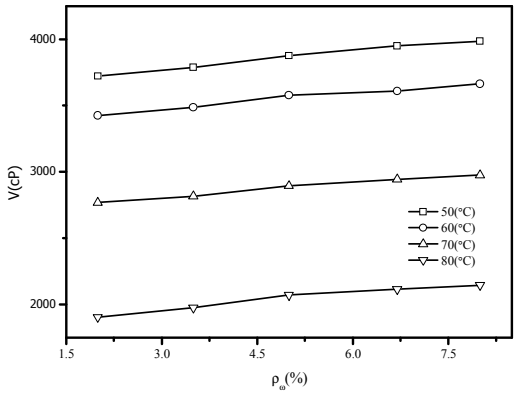

Figure 4 Viscosities of watered heavy oil at different water content

Experiment results indicated, at the range of water content 2.0-8.0 %, the more water content was, and the more viscosity was. Because the effect of water content on viscosity is closely related to the structure of water molecule. A molecule of water is made up of two atoms of hydrogen and one atom of oxygen, and three atoms are formed an isosceles triangle with two hydrogen atoms as the bottom and oxygen atom as the top. Positive and negative charge centre of molecule does not coincide, and dipole moment is quite great with very strong polarity. Because shared electron in H-O sharply deflects the side of O, H that atomic nucleus bared combine closely other atoms of strong electronegativity, short atomic radius and lone electron pair. At a certain external condition, H_2O molecule playing the double roles of the donor and acceptor of hydrogen bonding could form the stable emulsion with fuel oil depending on intermolecular and intramolecular hydrogen bonding. High water content causes much hydrocarbon combination, then increasing viscosity [6].

Conclusion

By preparing watered fuel oil using mechanical micro-mixing method without surfactant, the following conclusions can be made to this research:

(1) Viscosity of watered fuel oil decreased with increasing oil temperature. However, this applies before the oil temperature is too high to cause oil-water separation.

(2) Viscosity of watered fuel oil increased slightly with increasing agitation speed.

(3) Viscosity of watered fuel oil increased with increasing water content.

Keywords flue gas desulfurization system water balance water consumption gas-gas heater

Abstract Material balance calculation was adopted to a bubbling desulfurization system of 600MW unit for water-saving measures. Analysis was made on main factors affecting water consumption. Results showed that heat release of desulfurization reaction and water evaporation went up with sulfur content increasing; Free water and bound water in gypsum increased rapidly with calcium improved; When sulfur content enhanced from 0.5% to 3.5%, water evaporation of reactor increased by 28.9% and waste water increased by 7.8%; With inlet flue temperature of WFGD raised from 120℃ to 200℃, waste water increased by 25.3% and evaporation of water increased by 102.35%; Once gas-gas heater (GGH) was installed, heat release of original flue gas decreased by 43.72% and the total water consumption decreased by 39.06%. Therefore, with sulfur content and temperature of inlet flue increasing, water consumption raises. Installation of gas-gas heater(GGH) can effectively reduce water consumption of WFGD system.

1 Background

Sulfur dioxide (SO2), generated mainly from large-scale coal utilization, causing environmental problems such as acid rain when discharged to the atmosphere. Wet flue gas desulfurization system （WFGD）is widely applied in our country with advantages of high desulfurization efficiency, mature technology and low operating cost[1,2]. Large amounts of water was consumed by WFGD, making water conservation urgently required due to shortage of water resources in western dry areas of China.

Study of mass balance has been always basis of desulfurization system design and optimization. Mass balance import and export items of the desulfurization system was calculated, selection of desulfurization system individual devices could be determined and the system design could be further optimized[3,4]. NIE Pengfei et al[5] calculated process water consumption of a 600MW unit WFGD system, conclusion displayed water evaporation inside the absorber occupied total system water consumption by more than 90%, therefore, water-saving measures to reduce inlet flue gas temperature with low-temperature economizer were proposed. The water consumption of calcium-based wet and semi-dry flue gas desulfurization process scheme was compared by Tong Huiling et al[6] Studies have shown that water consumed of semi-dry desulfurization was larger, and the amount of water vapor carried by net flue gas after desulfurization significantly increased with exhaust gas temperature rising. LV Ming et al[7] analyzed variation of water vapor temperature in WFGD system, and found that process water evaporation in absorber effectively reduced by lowering the original flue gas temperature after calculation of water consumption before and after reducing inlet flue gas temperature, thus water consumption in desulfurization system decreased. Water balance is a very important part of material balance in desulfurization system.

A bubbling bed desulfurization system of 600MW unit was analyzed in this paper, calculation table of material balance listed below. Research provided theoretical support for selection and optimization of desulfurization process with analysis of the main factors affecting water consumption.

2 Calculation Method

Material balance of WFGD system consists of flue gas, energy, solid, water and chlorine balance modules. Volume and mass flow of inlet flue dry and wet in desulfurization system were computed by a given coal, energy balance calculation for evaporation of water in desulfurization tower, and solid balance calculation for in or out solid material items, thereby calculation of the energy and water balance partly completed. Wastewater discharge was determined by the chlorine balance in desulfurization system[8,9]. Material balance calculations for a bubble column WFGD systems of 600MW unit was performed with operation at rated load, desulfurization efficiency was 95%, ratio of calcium to sulfur was 1.05, O / S was 2.5 , moisture content of free water for dehydration gypsum was 7%, and rinse water consumption was 0.5t / t gypsum. Other parameters used in the calculation listed in literature[10].At first, outlet flue gas temperature of jet bubbling reactor and GGH net gas side were assumed, the evaporation of water was determined at assuming temperature with energy balance calculations. Next step was checking the assuming temperature of GGH, according to an iterative calculation to make net flue water vapor pressure the same as saturated vapor pressure under the assumption. All material balance data in desulfurization system finally obtained[11].

3 Results and Analysis

3.1 Effects of Sulfur Content

Water balance proceeds of WFGD mainly consist of water vapor carried by original flue and air oxidation, water carried by desulfurizer (dry) and addendum water (equipment wash water and cooling water). Expenses include net flue carrying steam and liquid, gypsum bound water, free water and desulfurization wastewater. In which amount of net flue carrying water vapor depended on evaporation of water in tower[12].

Tab.1 Influence of sulfur content on input and output of water balance

Coal Sulfur Content [%]	Expense of Water Balance[t/h]					Proceeds of Water Balance[t/h]		
	Evapora-tion of water	Net flue liquid	Gypsum free water	Gypsum bound water	Desulfuri-zation wastewater	Chemical reaction water	Gypsum wash water	Addendum water
0.5	58.69	0.16	0.41	1.17	8.59	0.63	2.94	65.45
1	61.57	0.17	0.81	2.33	8.70	1.23	5.77	66.58
1.5	64.41	0.17	1.20	3.50	8.82	1.83	8.59	67.68
2	67.36	0.17	1.60	4.66	8.94	2.42	11.42	68.89
2.5	70.11	0.17	2.00	5.83	9.06	3.02	14.24	69.9
3	72.82	0.17	2.39	7.00	9.17	3.61	17.07	70.86
3.5	75.68	0.17	2.79	8.16	9.29	4.21	19.89	71.98

Effects of different sulfur content on the water balance listed in Table 1. With coal sulfur content increasing, the evaporation of water and desulfurization wastewater increased, gypsum combined and free water increased dramatically. When coal sulfur content added from 0.5% to 3.5%, water evaporated into the flue gas increased by 28.9%, and 7.8% for desulfurization wastewater, free water of plaster increased from 0.41t/h to 2.79t / h, gypsum bound water was from 1.17t/h to 8.16t/h. The rate of increasing was consistent with the magnitude of sulfur content variation. Addition of sulfur content in coal and desulfurizer respectively resulted in elevation of SO2 concentrations in the flue gas and increasing of gypsum carrying water, the desulfurization efficiency was ensured. Increasing of desulfurization reaction heat led to increasing of total water evaporation in tower. Therefore, gypsum carrying water and chemical reaction of water were roughly proportional to

generation of gypsum with increasing of sulfur, increasing of sulphur caused significant increasing of the evaporation of water in flue.

Fluctuations of water consumption were caused by changes of sulfur inevitably, water was mainly consumed by the way of evaporation of water in tower, net flue gas carrying liquid, free and bound water in the gypsum and desulfurization wastewater. When sulfur content changed from 0.5% to 3.5%, the proportion of evaporation of water in tower reduced from 85.03% to 78.76%, and net flue liquid was from 0.23% to 0.18%, desulfurization wastewater from 12.45% to 9.67%. While proportion of free water in plaster rose from 0.59% to 2.90%, 1.70% to 8.49% for bound water. Therefore, evaporation of water accounted the highest for total water consumption, desulfurization wastewater followed. Proportion of evaporation of water, net flue liquid and desulfurization wastewater decreased, gypsum free and bound water increased with sulfur content increasing.

3.2 The impact of import of flue gas temperature

Changing in boiler operation led that import temperature of flue gas changed, sequentially caused affects on desulfurization efficiency and mass balance, in which water consumption was particularly affected. Take desulphurization system without GGH for example, desuperheating water before desulfurization tower and outlet temperature of net flue varied with import flue gas temperature of WFGD varying. Calculations showed import flue gas temperature of FGD increased from 120℃ to 200℃, flue gas temperature would increased by 6.1℃ and reached to 56.2℃ after spray, equally 6℃ for outlet flue temperature of desulfurization tower and made it reached to 55.8℃. Flue temperature spray desuperheated and JBR outlet would rose 0.75 ℃ once average import flue gas temperature elevated by 10℃. Raising the temperature of flue gas in desulfurization tower would inevitably lead to increasing in water consumption.

The impact of import flue gas temperature of desulfurization system on water balance listed in Table 2. When the temperature increased from 120 ℃ to 200 ℃, wastewater in desulfurization system increased by 25.3%. Desuperheating water increased rapidly and growth rate reached to 106.84% as the flue gas temperature increased. Simultaneously, carrying heat increased with flue gas temperature, and total evaporation of water increased by 102.35% in desulfurization tower. Eventually, the process water consumption in desulfurization system increased by 95.29%.

Tab.2 Influnce of Flue Temperature on water consumption

Flue gas temperature [℃]	Wastewater [t/h]	Evaporation water in tower[t/h]	Desuperheating water [t/h]	Process water consumption [t/h]
120	9.36	88.00	84.85	98.50
130	9.65	98.99	95.95	109.78
140	9.94	110.14	107.19	121.22
150	10.23	121.30	118.45	132.68
160	10.53	132.62	129.72	144.30
170	10.83	143.81	141.02	155.79
180	11.13	155.17	152.45	167.44
190	11.42	166.53	163.90	179.11
200	11.73	178.07	175.50	190.95

When the inlet flue gas temperature increased from 120 ℃ to 200 ℃, Desuperheating and total evaporation water had nearly doubled, there is also a small increase for amount of wastewater. Variation of process water consumption mainly based on water evaporation in tower, and desuperheating water was main supplement. Therefore, water balance affected greatly by inlet temperature of the flue gas in desulfurization system. The higher import flue gas temperature, the more energy taken into the desulfurization system, thereby the more water was consumed.

3.3 Impact of GGH

Temperature of inlet and outlet flue gas in desulfurization system would be influenced by GGH, water balance of the system was changed as variation in flue gas carrying heat in desulfurization system. Installation of GGH in desulfurization system caused a series of changes, followed by temperature of inlet and outlet net flue gas, energy balance in desulfurization reactor and water balance. Heat release of the original gas in desulfurization tower decreased by 43.72% with GGH，43.71% for water vapor, 49.92% for heat absorption of addendum water, and 22.65% for limestone slurry. The heat taken away by evaporation of water in desulfurizing reactor reduced by 41.89% with GGH, so that the heat required evaporation of water taking away significantly reduced.

Calculations showed that the original flue gas temperature lowered to 95 ℃ with GGH, and it further reduced to 47.8 ℃ after spray desuperheater. Net flue gas temperature after desulfurization increased to 84.9 ℃ by GGH heat absorption. Without the installation of GGH, original flue gas of 132℃ entered escape system, then decreased to 51.2 ℃ after spray desuperheating, net flue gas temperature out of desulfurization tower reached to 50.8 ℃. Reduction of 37 ℃ for original flue gas and improvement of 26.1 ℃ for exports net flue gas was achieved with GGH.

The total process supplemental water reduced by 39.06%, and desulfurization wastewater volume had a decline of 11.53% with application of GGH. The reason was that GGH reduced the amount of energy carrying into desulfurization reactor with original flue gas, thereby the temperature in desulfurization reactor and the total evaporation of water reduced. There is a certain air leakage coefficient for GGH, resulted in part of the original flue gas leakage into the net flue gas, and amount of water vapor carried by original flue gas decreased. The net flue gas carrying liquid and plaster surface carrying water were changed lightly due to changes in total flow of net flue gas and gypsum production. Total desulfurization wastewater was closely related to addendum water. The increase in total addendum water inevitably led that more chloride ions were taken into the desulfurization system. Total amount of addendum water decreased with GGH, leading to reduction of chloride ions, and amount of desulfurization waste water also reduced. Therefore, the consumption of process water effectively decreased because of water evaporation in desulfurization tower and the desulfurization wastewater significant reduced with GGH.

Conclusion

（1）Heat release of desulfurization reaction in tower and the amount of water evaporated increased directly with sulfur content of coal. Since more calcium was plunged in, free and bound water in gypsum rapidly increased.

（2）Flue gas inlet temperature of desulfurization tower raised with that of desulfurization systems, variation of water consumption was mainly caused by increasing of water evaporation in tower.

（3）Heat release of original flue gas in desulfurization tower decreased with GGH, resulting in decline of water evaporation, which was the main reason for saving water with GGH.

Keywords: Optical materials; Luminescence; Optical properties

Abstract: The serials of blue phosphors, $CaAl_2Si_2O_8$: Eu^{2+} doped with different content Sr^{2+} and Mg^{2+} ions, were prepared by solid-state reaction at high temperature. And their structure and photo-luminescent properties were investigated. In $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.70, 0.90) system, for $y \leqq 0.03$, all the compositions crystallize in triclinic structure of $CaAl_2Si_2O_8$, and on further increase of y, the system undergoes a compositionally induced phase transition from triclinic to monoclinic structure. For $Ca_{0.96-y}Mg_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.70, 0.90) system, for $z \leqq 0.03$, all the compositions are of triclinic structure of $CaAl_2Si_2O_8$. With the further increase of z, other phase appears. The emission spectra of these phosphors show blue shift with the introduction of Sr^{2+} ions, and red shift with Mg^{2+} ions. The reason may be due to the difference ionic radii of Mg^{2+}, Ca^{2+}, Sr^{2+}. These phosphors show excellent blue emission and broad excitation band in near-UV (ultraviolet) range. They may be potential phosphors for near-UV light-emitting diodes (LEDs).

Introduction

In recent years, the semiconductor white-light-emitting diodes (W-LEDs) attract more and more attention, since they have many advantages, such as high efficiency, energy saving and environmental-friendly characteristics[1,2]. A higher efficiency white LED with an appropriate color temperature and a higher color-rendering index can be obtained by using near-ultraviolet (nr-UV) InGaN-based LED chip coated with blue/green/red tricolor phosphors[3]. The commonly used blue-emitting phosphor for nr-UV InGaN-based white LEDs is $BaMgAl_{10}O_{17}$: Eu^{2+} (BAM: Eu^{2+})[4], which is used as commercial blue phosphor in fluorescent lamps[5]. However the excitation intensity around nr-UV range is weak, so it is interesting to find new blue phosphors with the intense excitation and emission for the near-UV LED chips.

The excitation band of Eu^{2+} in phosphors is a broad band, which is due to the 4*f*- 5*d* transitions. It can exhibit intense emission from violet to red light region in the different hosts with different crystal filed[6,7]. So the excitation and emission bands of Eu^{2+} can be controlled by changing the crystal filed. The different cations with different radii in the host compound would induce some change in the sub-lattice structure around the luminescent center ions[8], hence the crystal filed will be changed, which leads to different photo-luminescent properties.

Recently, $CaAl_2Si_2O_8$ doped with the luminescent centre ion were investigated, and it shows excellent blue emission with broad band in near-UV range, which can match the excitation of the near-UV GaInN chip[9,10]. Anorthite ($CaAl_2Si_2O_8$) in a triclinic crystal system was reported by Angel in 1988[11]. In the crystal lattice, one type of Ca^{2+} ion occupies an octahedral site with six oxygen atoms, and other Ca^{2+} ions occupy three kinds of polyhedral sites with seven coordinated oxygen atoms. Al and Si atoms both occupy tetrahedral sites with four coordinated oxygen atoms.

Ca^{2+}, Sr^{2+} and Mg^{2+} ions are alkaline earth metal ions with the same charge. The sub-lattice structure of $CaAl_2Si_2O_8$ will be changed by replacing part of Ca^{2+} with Sr^{2+} and Mg^{2+}. And the photo-luminescent properties of will be different $CaAl_2Si_2O_8$: Eu^{2+} by introducing Sr^{2+} and Mg^{2+} ions. So in this article, the phosphors $CaAl_2Si_2O_8$: Eu^{2+} doped with different content Sr^{2+} and Mg^{2+} were prepared by solid state reaction and their luminescent properties were investigated.

Experimental

The polycrystalline samples $CaAl_2Si_2O_8$:Eu doped with different content Sr^{2+} and Mg^{2+} were prepared by solid-state technique at high temperature. The stoichiometric mixtures of $CaCO_3$ (A.R. grade), Al_2O_3 (A.R. grade), SiO_2 (A.R. grade), $SrCO_3$ (A.R. grade), MgO (A.R. grade), and Eu_2O_3 (99.99 % purity) were first ground and heated at 1400 ºC in CO atmosphere for 6 h.

The structure of the final products was examined by X-ray powder diffraction (XRD) using Cu K_α radiation on RIGAKU D/max 2200 vpc X-Ray Diffractometer. The excitation and emission spectra were recorded on a JOBIN YVON FL3-21 spectrofluorometer at room temperature and a 450 W xenon lamp was used as excitation source.

Results and discussion

$Ca_{1-x}Al_2Si_2O_8$: xEu^{2+}

The XRD pattern of $Ca_{0.96}Al_2Si_2O_8$:$0.04Eu^{2+}$ is shown in Fig. 1. It is close to the JCPDS card 41-1486 [$CaAl_2Si_2O_8$]. Little other can be found in this pattern. This indicates that the phosphor $Ca_{0.96}Al_2Si_2O_8$:$0.04Eu^{2+}$ shares the similar phase with $CaAl_2Si_2O_8$. The ionic radius of Eu^{2+} (117 pm, CN = 6) is close to that of Ca^{2+} (100 pm, CN = 6), so the little doping of Eu^{2+} does not change the crystal structure, and Eu^{2+} ions occupy the site of Eu^{2+} ions in this crystal lattice.

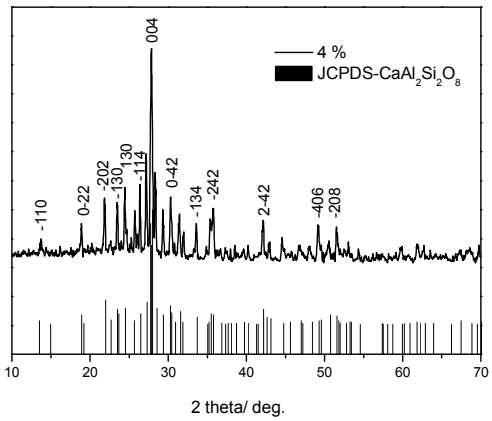

Fig. 1 The XRD pattern of $CaAl_2Si_2O_8$:$0.04Eu^{2+}$

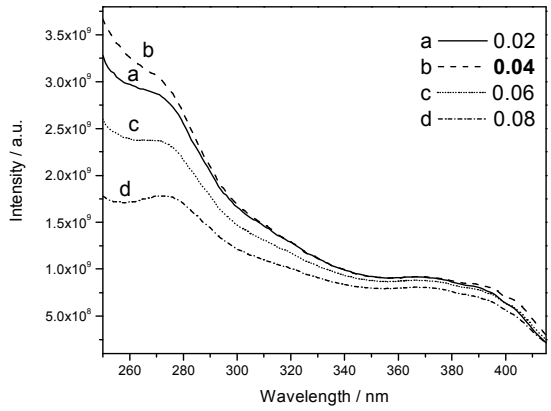

Fig.2 The excitation spectra of $CaAl_2Si_2O_8$: xEu^{2+} by monitoring emission at 435 nm

Fig.2 is the excitation spectra of the phosphors $Ca_{1-x}Al_2Si_2O_8$: xEu^{2+} (x = 0.02, 0.0.04, 0.06 and 0.08) by monitoring emission at 435 nm. The broad excitation band from 250 nm to 415 nm is due to the $4f - 5d$ transitions of Eu^{2+}. The excitation bands from 360 to 400 nm show a flatform, this is useful to find application on near-UV-LED chips. When the content of Eu^{2+} is 0.04, the excitation intensity is the strongest.

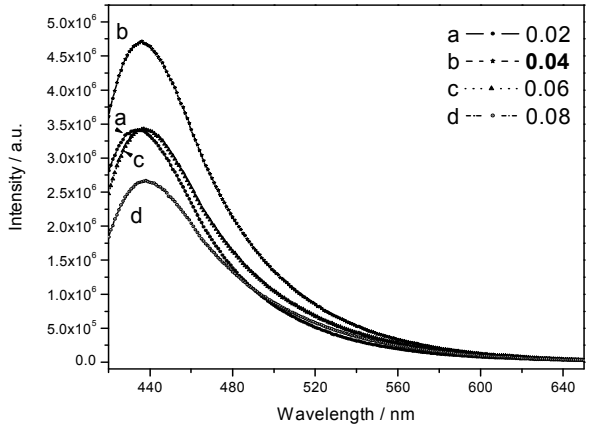

Fig.3 The emission spectra of $CaAl_2Si_2O_8$: xEu^{2+} under 400 nm excitation

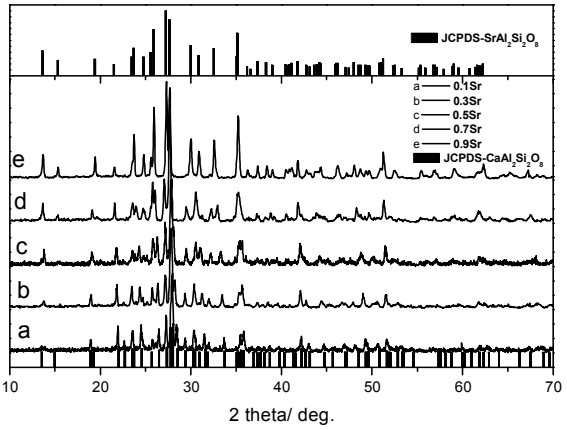

Fig.4 The XRD patterns of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.70, 0.90)

Our aim is to investigate the blue phosphor for near-UV LED chips ($\lambda_{em} \approx 400$ nm), then the emission spectra of $Ca_{1-x}Al_2Si_2O_8$: xEu^{2+} (for x = 0.02, 0.0.04, 0.06 and 0.08) under 400 nm excitation are shown in Fig.3. The broad blue emission is due to the $5d - 4f$ transitions of Eu^{2+}. It is observed that the emission bands of the phosphors show some red shifts with an increase of Eu^{2+} concentration. J. Qiu. et al.[12] had reported that the probability of an energy transfer among Eu^{2+} ions. When the content of Eu^{2+} becomes larger, the distance between Eu^{2+} ions becomes less, and the probability of energy transfer among Eu^{2+} ions is improved. In other words, the energy transfer of Eu^{2+} ions from the higher $5d$ levels to the lower $5d$ levels of Eu^{2+} ions is increased. Hence the $4f - 5d$ transitions of Eu^{2+} show the red shift with higher Eu^{2+} concentration. The sample $Ca_{0.96}Al_2Si_2O_8$: $0.04Eu^{2+}$ shows the strongest emission with appropriate CIE chromaticity coordinates ($x = 0.163$, $y = 0.112$).

$Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$

The serials of samples $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10-0.90) were prepared. As examples, the XRD patterns of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.70, 0.90) are shown in Fig.4. In this system, for $y \leqq 0.03$, all the compositions crystallize in triclinic structure of $CaAl_2Si_2O_8$ and on further increase of y, the system undergoes a compositionally induced phase transition from triclinic to monoclinic structure. The phase transformation is due to the distinct ionic radii between Ca^{2+} (100 pm, CN = 6) and Sr^{2+} (118 pm, CN = 6).

Fig.5 is the excitation spectra of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.90) by monitoring emission at 435 nm. The broad excitation band from 300 nm to 415 nm is due to the $4f - 5d$ transitions of Eu^{2+}. The phosphor $Ca_{0.66}Sr_{0.30}Al_2Si_2O_8$: $0.04Eu^{2+}$ shows the strongest excitation intensity in near-UV range (seeing the inset figure in Fig. 5).

The emission spectra of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ (y = 0.10, 0.30, 0.50, 0.90) are shown in Fig. 6. The emission band shifts to a shorter wavelength with an increase in Sr^{2+} concentration. It is well known that the ionic radius of Sr^{2+} is bigger than that of Ca^{2+}. In the triclinic structure of $CaAl_2Si_2O_8$, the length of the c axis increases by replacing part of the Ca^{2+} by Sr^{2+} ions, the effect of preferential orientation of a d-orbital in the chain direction decreases, so that the Eu^{2+} emission shifts to shorter wavelength[13]. The sample $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ shares the intense emission, and its CIE chromaticity coordinates are calculated to be $x = 0.165$, $y = 0.123$.

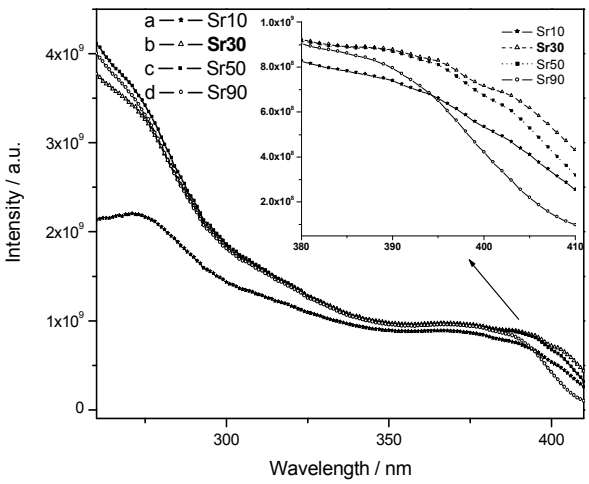

Fig.5 The excitation spectra of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ by monitoring emission at 435 nm

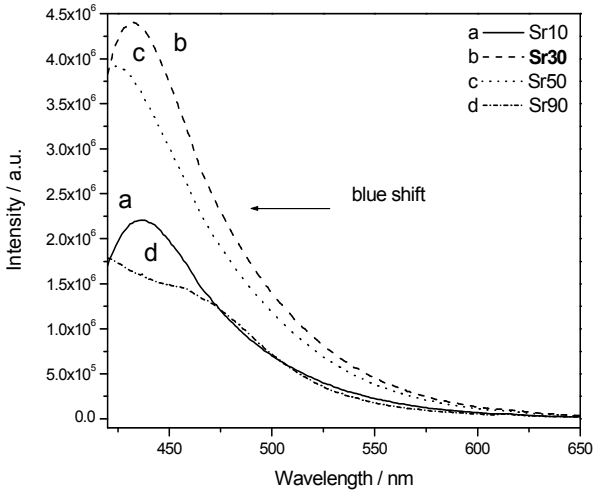

Fig.6 The emission spectra of $Ca_{0.96-y}Sr_yAl_2Si_2O_8$: $0.04Eu^{2+}$ under 400 nm excitation

$Ca_{0.96-z}Mg_zAl_2Si_2O_8$: $0.04Eu^{2+}$

Fig.7 is the excitation spectra of $Ca_{0.96-z}Mg_zAl_2Si_2O_8$: $0.04Eu^{2+}$ (z = 0.10, 0.30, 0.50) by monitoring emission at 435 nm. These three curves share similar sharp. When the z is 0.30, the sample shows the strongest excitation. The emission spectra of are exhibited in Fig.8. The emission band shows red shift with an increase in Mg^{2+} concentration. The reason may be due to the difference between ionic radius of Mg^{2+} and ionic radius of Ca^{2+}. In the triclinic structure of

$CaAl_2Si_2O_8$, the length of the *c* axis increases by replacing part of the Ca^{2+} by Mg^{2+} ions, the effect of preferential orientation of a *d*-orbital in the chain direction increases, so that the Eu^{2+} emission shifts to longer wavelength[13]. The phosphor exhibits the strongest emission with appropriate CIE chromaticity coordinates ($x = 0.166$, $y = 0.125$).

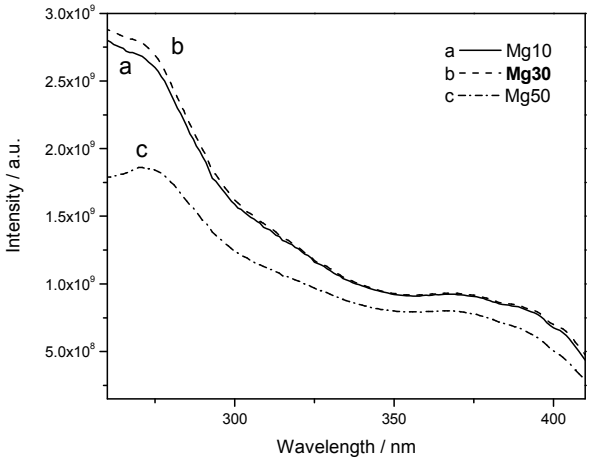

Fig.7 The XRD patterns of $Ca_{0.96-z}Mg_zAl_2Si_2O_8$: $0.04Eu^{2+}$ ($z = 0.10, 0.30, 0.50, 0.70, 1.0$)

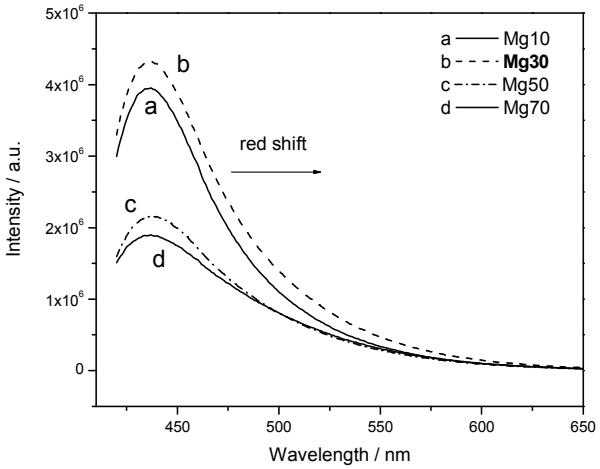

Fig.8 The excitation spectra of $Ca_{0.96-z}Mg_zAl_2Si_2O_8$: $0.04Eu^{2+}$ by monitoring emission at 435 nm

Conclusion

We have prepared blue phosphors, $CaAl_2Si_2O_8$: Eu^{2+} doped with different content Sr^{2+} and Mg^{2+}, and investigated their photo-luminescent properties. The emission spectra show blue shift with the introduction of Sr^{2+}, and red shift with Mg^{2+}. This is due to the ionic radius difference of Ca^{2+}, Sr^{2+} and Mg^{2+}. These phosphors show intense blue emission with broad excitation in near-UV range, which maybe find application in near-UV InGaN-based LED.

Keywords: GaN, metal-semiconductor-metal, photodetector, homoepitaxy

Abstract. We report the demonstration of a GaN-based planar metal-semiconductor-metal (MSM) ultraviolet photodetector (PD). The MSM PD with semitransparent interdigitated Schottky electrodes is fabricated on low-defect-density GaN homoepitaxial layer grown on bulk GaN substrate by metal-organic chemical vapor deposition. The dislocation density of the GaN homo-epilayer characterized by cathodoluminescence mapping technique is ~5×10^{6} cm^{-2}. The PD exhibits a low dark current density of ~4.1×10^{-10} A/cm^{2} and a high UV-to-visible rejection ratio up to 5 orders of magnitude at room temperature under 10 V bias. Even at a high temperature of 425 K, the dark current of the PD at 10 V is still <1×10^{-9} A/cm^{2} with a reasonable UV-to-visible rejection ratio more than 3×10^{4}, indicating that such kind of PDs are suitable for high temperature operation.

Introduction

GaN-based semiconductor material system is one of the best choices for ultraviolet (UV) photon detection due to its wide direct band gap energy, superior radiation hardness and high temperature resistance. Such UV photodetectors (PDs) are important components in a variety of military and commercial applications, such as flame detection, environmental monitoring, chemical/biological agent detection, and space communications [1]. To achieve a high-performance metal-semiconductor-metal (MSM) type UV PDs, it is important to reduce dark current of the device which determines the lowest detectable optical signal strength. Although detailed reverse leakage mechanism of GaN-based Schottky contacts is still under debate, it is well accepted that structural defects, especially dislocations, within GaN epilayer play an important role in determining junction leakage [2]. However, GaN layers grown on foreign substrate like sapphire typically have threading dislocation densities on the order of >10^{8} cm^{-2}, increasing device leakage and resulting in a premature device breakdown. In order to develop a higher signal-to-noise ratio and more reliable GaN-based PD, one should first obtain the availability of a low-dislocation GaN substrate technology.

Recently, significant improvements in material quality and device performance are expected using homoepitaxially grown GaN. With very low impurity and dislocation density, high performance GaN-based light-emitting diodes [3], high electron-mobility transistors [4], and Schottky rectifier [5] on bulk GaN substrate by employing homoepitaxial growth technique is reported. However, in spite of the excellent device performance reference above, there have been limited published reports regarding the UV PDs fabricated on bulk substrates.

In this work, we report the fabrication and characterization of a MSM PD based on low-defect-density homoepitaxial GaN layer. The PD shows low dark current and high UV-to-visible rejection ratio.

Experiment

The freestanding conductive bulk GaN substrate used in this work is prepared by hydride vapor phase epitaxy with a thickness of 320 μm and a room-temperature resistivity of ~0.01 Ω·cm. The device structure is grown by metal-organic chemical vapor deposition with optimized growth conditions, consisting of a 1 μm silicon-doped n^+-GaN (~3×10^{18} cm^{-3}) transition layer and a 3 μm n-GaN active layer (~3×10^{16} cm^{-3}). The homoepitaxial GaN is characterized by using cathodoluminescence (CL) mapping technique, high-resolution x-ray diffraction (XRD) and atomic force microscopy (AFM) respectively. In fabrication of the MSM PDs, standard photolithography and lift-off techniques are used to define the interdigitated Schottky contact electrodes, which are based on semitransparent Ni/Au (5 nm/5 nm) metal stack. The fingers of the contact electrodes are 5 μm wide and 400 μm long with a spacing of 5 μm. Finally, a 200 nm Ti/Au bi-layer is evaporated and patterned to serve as the contact pads. Figure 1 shows a schematic and a topview image of one finishied PD with an effective device area of 400×400 μm^2.

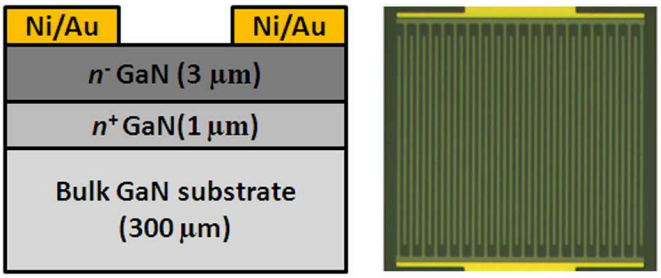

Fig.1 (a) Schematic of the device structure and (b) top wiew image of one fabricated PD with an effective device area of 400×400 μm^2.

Results and discussions

The dislocation density of the device structure on bulk GaN substrate is measured by a CL mapping technique which has been confirmed to be a reliable method to count dislocations in low-defect-density GaN [6]. Figure 2(a) shows a typical panchromatic CL mapping image of the homoepitaxial GaN layer examined over a large surface area, in which each dislocation is represented by a small dark spot resulting from strong local non-radiative recombinations. The dislocation density of the homoepitaxial GaN layer is estimated to be ~5×10^6 cm^{-2} in average, which is about 2-3 orders lower than that of the control sample grown on sapphire substrate (see Fig. 2(b), dislocation density>10^8 cm^{-2}). The corresponding full width at half maximum of the GaN (0002) XRD rocking curve is 80-100 arcsec, which agrees with the low dislocation density determined by CL mapping. The surface roughness of the GaN homo-epilayer measured by AFM over a 5×5 μm^2 area is ~0.5 nm. The above analysis indicates that low-dislocation-density GaN epilayer with reasonable surface morphology has been obtained through the homoepitaxial growth process.

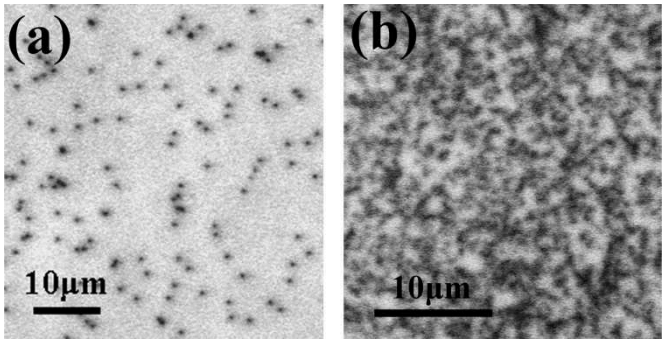

Fig. 2 (a) Typical CL mapping image of homoepitaxial GaN layer grown on bulk GaN substrate. (b) CL mapping image of the control GaN layer grown on sapphire.

The dark and photo-current curves of the MSM PD are shown in Fig. 3, in which the optical power density of the 365 nm UV illumination is ~6.5 μW/mm^2. The PD exhibits a low RT dark current of less than 1 pA at 10 V bias, which can be attributed to the low dislocation density within the homoepitaxial GaN layer. Even at a high temperature of 425 K, the dark current at 10 V is still below 5 pA, suggesting that the device is suitable for high temperature applications. The decrease of photocurrent with increasing temperature can be explained by thermal activation of trapped holes at the semiconductor/metal interface, which will be discussed later. In addition, enhanced recombination loss at high temperature can also reduce the photocurrent.

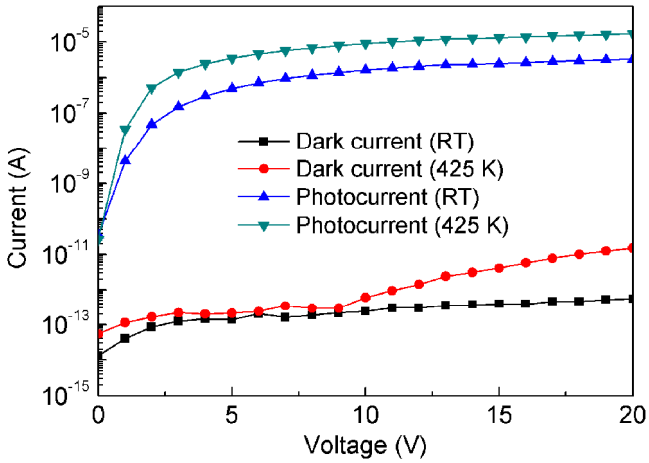

Fig.3 I-V characteristics of the PD measured under dark and under 365 nm light illumination at RT and 425 K, respectively.

Figure 4 show the spectral response characteristics of the PD at RT and at 425 K respectively. A sharp cutoff in the photo-response curves occurs at approximately 365 nm, which corresponds to the bandgap energy of GaN. At 10 V bias, the UV-to-visible rejection ratio of the PD could be as high as 1×10^5 at RT, and is still higher than 3×10^4 even at a high temperature of 425 K. Here, the UV-to-visible rejection ratio is defined as the responsivity measured at 360 nm divided by that measured at 500 nm. It can be seen clearly that the measured responsivity of PD is >1 A/W at 10 V bias, the corresponding PD quantum efficiency could well exceed 100%, indicating that an internal gain mechanism exists within the device.

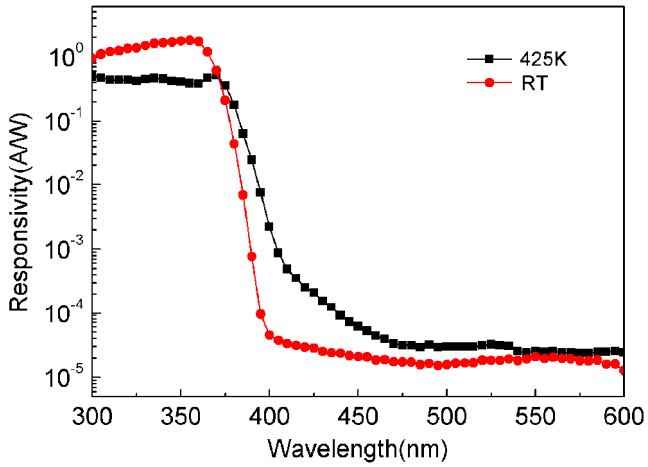

Fig.4 Spectral response of the GaN MSM PD measured at RT and 425K, respectively.

Photocurrent gain has been widely observed in various MSM PDs, which is desirable for applications requiring high responsivity but could limit the detector bandwidth simultaneously. It

seems that the internal gain is not necessarily linked to the crystalline quality of the semiconductor, as it could also present in MSM PDs based on much maturer semiconductors like GaAs [7]. Several theories have been suggested to explain the gain mechanism, such as photoconductive gain, avalanche carrier multiplication, and trapping of photo-carriers at semiconductor/metal interface. In addition, image force lowering of Schottky barrier height should happen more or less in most Schottky-based PDs at high applied bias.

Summary

We have reported the demonstration of a high performance MSM PD fabricated on low-dislocation-density homoepitaxial GaN layer on bulk GaN substrate. The PD exhibits low dark-current and high UV-to-visible rejection ratio both at RT as well as at 425 K, suggesting that the device is suitable for high temperature applications. An internal gain is observed within the PD which is explained by lowering of Schottky barrier due to photo-generated holes trapped at semiconductor/metal interface as well as image-force lowering near the contact edge of cathode electrodes where electric field is particularly high.

Keywords: Phase-shifting transformer step-down rectifier, Energy storage system, DC microgrid, Electrical appliance, Equivalent efficiency

Abstract. To increase the energy efficiency and reduce the cost, the DC-Microgrids will have a very promising future in the power supply systems. In this paper, two power supply patterns for modern appliances, the central rectifier pattern and the distributed rectifier pattern, are investigated and compared. A concept of equivalent efficiency of diode bridge rectifier for DC-powered appliances is introduced and then it is applied in the model simplification. A Curved-Load model is constructed which is based on the specific efficiency characteristics of diode bridge rectifier in a particular current range and the statistics for appliance's energy consumption as a percentage of the total. Using the Curved-Load model, the comparison of two microgrid system models was conducted with the help of simulations using Ansoft Simplorer 9.0 aiming to examine the conversion efficiency of rectifier patterns.

Introduction

The usage of renewable energy is escalating and more modern electric appliances being pro to DC power supply, and energy storage system such as vanadium-redox flow battery energy storage system [1, 2] is required to couple with the renewable energy resources to remove the intermittent manner. It is high time to reconsider employing DC grids for power distribution [3]. The concept of DC Microgrid is a subset of distributed generation which is still in its nascent stage. Microgrids are brought into picture to improve the reliability and to bring down the dependence on the main grid [4, 5]. DC microgrid is a promising microgrid adaptation which not only offers an effective way to link up renewable resources such as solar PV panels or wind turbines with DC/DC converters, but also increases the overall energy transmission efficiency from AC grid to end-user electrical appliances [6]. With the development of power electronics, many modern domestic electrical appliances are evolving—their inbuilt power supply has transformed from Alternating Current (AC) into Direct Current (DC). As a known fact, the present grid architecture in AC based and for these devices to operate, a converter arrangement is needed for AC/DC conversion. Each of these appliances uses an individual arrangement (usually is a diode bridge rectifier) as a gateway for the power inlet.

Several questions such as the amount of power loss in this power supply pattern or the presence of efficient alternatives for the conventional system arise at this stage. To answer these questions, one of the available ways is to construct the power supply system models for each pattern and then to examine them by means of simulation.

Being one of the prominent electric energy resources for DC microgrids, AC grid supplies the main share of electricity demand in the system. With the great global efforts in the development of next generation alternative energy resources such as the advanced nuclear energy systems discussed in [7-9], it can be expected that the AC power sources will continue to play a key role in the whole energy package in the future. So devising a methodology to efficiently convert the power from AC grid to the consumers in DC microgrid is an important issue for consideration in the construction of DC microgrids [10-12]. The distributed rectifier pattern based power supply scheme in Fig. 1(a) shows the typical power supply structure for modern domestic appliances, which can be called as the distributed rectifier pattern as each appliance has an individual rectifier inside. While the central

rectifier pattern based power supply scheme in Fig. 1(a) is the other model where all of the appliances in the DC microgrid use a single rectifier—the thyristor bridge rectifier in the phase-shifting transformer step-down rectifier. Before implementing the comparison of simulations, firstly it is needed to specify the main blocks as well as their relevant parameter settings in both of the system models.

Both systems are microgrid models with a capacity of 500 KW and connected to a 22 KV transmission line of AC grid by transformers. The phase-shifting transformer (PST) in the DC microgrid system model is nothing more than a conventional transformer with multiple secondary legs and with specific parameter settings. According to the comparison of simulation results (shown in Fig. 1 (b)), the performance of the PST is as good as or better than the performance of its counterpart—the conventional transformer in the AC microgrid system model. So comparing the impact of the two transformers has no significant effect on the comparison of the two rectifier patterns.

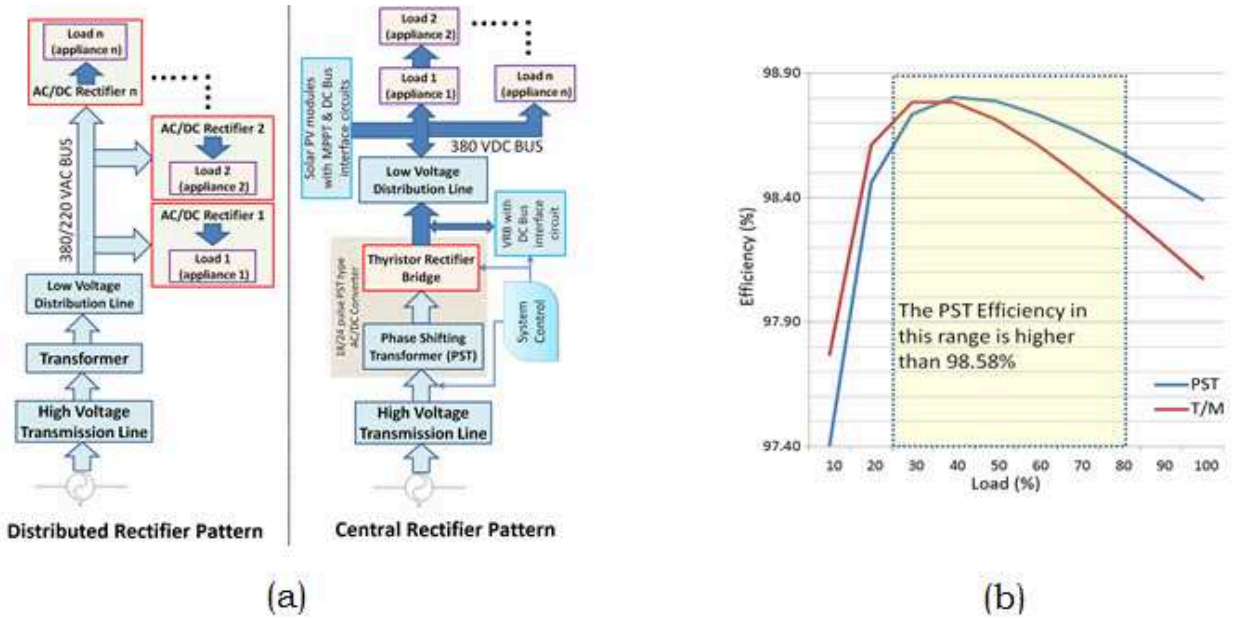

Fig. 1. (a) Block diagram of the two power supply schemes (b) Efficiency comparison between the 2 models

To make the two microgrid system models being comparable, the bus voltage of the DC microgrid is set to 380 VDC, which is equal to the RMS value of the line voltage of the AC microgrid. Therefore the low voltage distribution lines' effects on the comparison of the two rectifier patterns are also omissible. Regarding the other blocks in the DC microgrid, they have no effect on the comparison of the two rectifier patterns too. In fact, the other blocks in the DC microgrid system model are only used in assisting the optimized operation of the DC microgrid. Therefore, it is meaningful to examine the power supply patterns only by comparing the performance of the rectifier stage in the two microgrid system models.

Efficiency analysis of the diode bridge rectifier in modern domestic electrical appliances

There is a plethora of various kinds of electrical appliances in AC microgrid. So it is not practical to construct an AC microgrid system model with specific models for all the electrical appliances. The appliance models can be simplified according to the statistics on all kinds of domestic electrical appliances as well as their relevant load curves. The simplified model is constructed based on the following assumption. Since the aim of the simulation is focused on comparison of the conversion efficiency in the rectifier stage of the two power supply patterns, the model simplification effects on other components in the microgrid system models can be omitted if they satisfy the following conditions:

1. The effect is insignificant on simulation results.

2. The effect is not favorable for the DC microgrid system model (since the aim of the comparison simulation is to examine the advantages of central rectifier pattern).

The concept of equivalent efficiency of diode bridge rectifier will be introduced in the following paragraphs.

A. The efficiency characteristic of diode bridge rectifiers

The efficiency characteristic of a diode bridge rectifier varies with specific parameters. However, the basic efficiency characteristic of diode bridge rectifiers follows the typical efficiency characteristic curve. When the working current is above 10% of the rated current, the efficiency curve is almost a horizontal line; whereas the efficiency is not so good if its working current is below 10% of the rated current, and it even drops down to below 80% when the working current is lower than 1% of the rated current.

Usually, the normal working current of electrical appliances is above 10% of its rated current. Therefore, it is reasonable to use a constant, which equals to the average efficiency in the normal operation range, to represent the efficiency rating of the diode bridge rectifier of the appliance. On the other side, as the standby current and leakage current of the electrical appliances is much below 10% of its rated current, the efficiency of the diode bridge rectifier of the appliance in standby state and off state is very sensitive to the current value.

B. Equivalent efficiency of diode bridge rectifier for appliances

The equivalent efficiency of diode bridge rectifier for specific electrical appliances is used to represent their efficiency in the electrical appliances' model simplification. It is calculated based on the statistics and the specific efficiency characteristic of the diode bridge rectifier in a current range. This includes the rated efficiency, efficiency in standby as well as leakage current loss on average, for that kind of electrical appliances. The procedure for calculation is as follows:

1. Select an appliance for which the efficiency has to be calculated and identify its rated current and voltage. Based on these values, calculate the minimum requirements of the diode bridge parameters that are needed.
2. Look up for the datasheet of the diode that suits the parameter requirements. The diode parameters needed for simulation are obtained from the respective datasheets.
3. Apply the parameters of the diode bridge rectifier in the simulation circuit and extract the efficiency data from the simulation for rated current, standby current and leakage current.
4. Use the weighted average method to calculate the equivalent efficiency of diode rectifier bridge, i.e.

$$EE = AC*\eta_{AC} + SB*\eta_{SB} + LK*\eta_{LK} \quad (1)$$

Where, EE— equivalent efficiency, AC—share of the energy consumption in normal working state, η_{AC}— efficiency in normal working state, SB—share of the energy consumption in standby state, η_{SB}— efficiency in standby state, LK—share of the energy consumption in leakage current state, η_{LK}— efficiency in leakage current state.

C. Overall equivalent efficiency of diode bridge rectifiers of all electrical appliances and Curved-Load model

Further, using the weighted average method, a more accessible model simplification for electrical appliances, Curved-Load model, can be obtained. Firstly, the Curved-Load model actually is the equivalent model for all electrical appliances; therefore its load follows the typical residential (or commercial) load curve, instead of a specific load curve for each electrical appliance type. This is a very useful feature for the simulation. Secondly, the Curved-Load itself can yield a power loss that is proportional to the momentary load value. The proportional coefficient is just the overall equivalent efficiency of diode bridge rectifiers of all electrical appliances, which can be calculated as follows:

$$OEE = \sum EE_I * I_{SHARE} \quad (2)$$

Where, OEE—the overall equivalent efficiency of diode bridge rectifiers of all electrical appliances, EE_I—the equivalent efficiency of the kind of the electrical appliance I, I_{SHARE}—the percentage share of the energy consumption of the kind of the electrical appliances I in total energy

consumption. Again notice that the overall equivalent efficiency is calculated by means of weighted average of energy consumption in a large amount of this kind of electrical appliances, so that the deviation is small enough to omit the effect of the model simplification on energy conversion efficiency calculation.

Comparison of two microgrid system models' simulation and the discussion on the results

The Curved-Load model uses the typical load curve to simulate the process of analysis, which simplifies the computation process and facilitates easier operational methodologies. The two microgrid system models are constructed with the following considerations.

1. All of the models as well as their parameter setting are in the same value or as near as possible.
2. If there is any insignificant effect on examining rectifier patterns in conversion efficiency, the effect should be equitable to both system models, or at least should not favor the DC microgrid system model.
3. The models of electrical appliances are reduced to 6 Curved-Load models in each microgrid system model, whose loads vary according to the pre-setting load curve;

A. Comparisons based on Simulation results

As a model simplification measure, all of the rectifier models do not take the inductance-capacitance loss in account (this measure is equitable to both system models) and the solar PV (mentioned in Fig. 1(a)) is not considered in this model. Table I shows the comparison of transformers and rectifiers used in AC and DC microgrids. The conventional transformer used in the AC grid is denoted as T/M and the phase shifting transformer in DC microgrid is denoted as PST. It can be clearly seen from the table that the results of the transformers in both are comparable. In the rectifier stage efficiency comparison, the DC microgrid using a central PST based thyristor rectifier has an advantage of about 2.67% increase in efficiency.

TABLE I
EFFICIENCY COMPARISON IN TRANSFORMER AND RECTIFIER STAGE

Load	Transformer Efficiency			Rectifier Stage Efficiency		
	T/M	PST	Δ	AC	DC	Δ
10%	97.77%	97.08%	-0.69%	96.74%	99.41%	**2.67%**
20%	98.61%	98.34%	-0.27%	96.74%	99.41%	**2.67%**
30%	98.78%	98.71%	-0.07%	96.74%	99.41%	**2.67%**
40%	98.78%	98.86%	0.08%	96.74%	99.42%	**2.68%**
50%	98.71%	98.90%	0.19%	96.74%	99.42%	**2.68%**
60%	98.61%	98.89%	0.28%	96.74%	99.42%	**2.68%**
70%	98.49%	98.85%	0.36%	96.74%	99.42%	**2.68%**
80%	98.36%	98.81%	0.45%	96.74%	99.42%	**2.68%**
90%	98.22%	98.74%	0.52%	96.74%	99.41%	**2.67%**
100%	98.07%	98.67%	0.60%	96.74%	99.40%	**2.66%**

B. Discussion on the simulation results comparison

1. The comparison of simulation results shows that the central rectifier pattern is comprehensively superiors to the distributed rectifier pattern. For instance, only in rectifier stage, the conversion efficiency improves from 96.74% to 99.41% based on simulation results.
2. The overall equivalent efficiency of diode rectifier bridges for all of electrical appliances would more likely be lower in tropical countries like Singapore. The reason is that there are fewer non-DC powered electrical appliances (such as space heating does not need for Direct Current power supply) in use today at these places. Therefore, the conversion efficiency improvement margin would be even larger.
3. Moreover, the overall equivalent efficiency of the diode rectifier bridges for all the electrical appliances would more likely be lower with more and more DC powered appliances getting popular. This is because the power-output controllability of DC powered electrical appliances is better than that of non-DC powered electrical appliances, DC powered electrical appliances can efficiently work in a wide power-output range.

Conclusion

Introducing the concept of equivalent efficiency of diode bridge rectifier for appliances is a creative idea for model simplification, which allows us to evaluate the two power supply patterns for modern appliances—the central rectifier pattern and the distributed rectifier pattern—in a quantitative manner by means of simulation. Considering the drawbacks in the present scheme, the proposed methodology has a very good scope in reducing the losses. In the proposed method, the AC/DC conversion is centrally done and the need to use separate converter for each DC appliance is avoided. As the percentage of appliances using DC power has an upward slope, the use of DC as the primary supply becomes inevitable and the techniques discussed in this paper are in coherence with the expected future DC grid architecture.

The advantages of the central rectifier pattern over the distributed rectifier pattern are not only limited in the rectifier stage but also profound in all aspects of microgrid development. Especially for green buildings which are equipped with considerable capacity of solar PV modules and other renewable energy sources, its importance would be double.

Keywords: power system, oscillation center positioning, $U\cos\varphi$, splitting, compound criterion

Abstract. In this paper, an oscillation center fast positioning method and the criterion $U\cos\phi$ that determines whether a system is out-of-step are combined together to put forward a compound oscillation center positioning and splitting criterion with predicting function. Simulation of a classical numerical example of four-machine system in two regions and an actual example of central China-north China power grid proves that this method can pre-locate lines where oscillation center lies after out-of-step operation of the system when the system is oscillating intensely but still keeps synchronized.

Introduction

With haze problem aggravating, social demand for transporting capacity of new energy power is increasing. Therefore our country speeds up the construction pace of ultra-high voltage and large power grid, and is gradually forming a super large power system interconnected by major regional power grids. Thus, out-of-step oscillation between generator groups and areas has brought unprecedented challenges to the safe operation of power grid. To deal with out-of-step oscillation, we need to locate oscillation center quickly, and even take extreme measures like splitting to avoid blackouts[1][2].

In the early development of accidents, transmission lines and sections where oscillation center will appear must be timely and accurately predicted to block fault zone and narrow the blackout area[3]. Basing on the improved oscillation center positioning method and splitting criterion $U\cos\varphi$, a kind of compound splitting criterion with the function of predicting oscillation center is put forward. It is of great significance for power system security analysis and taking necessary control strategies[4].

Principle and Implementation Method of the Compound Criterion

2.1 Principle

An oscillation center positioning algorithm is shown as Eq. 1 below:

$$\left.\begin{aligned} L_{center}&=0 \quad ,U_2\cos\theta_{12}>U_1 \\ L_{center}&=1 \quad ,U_1\cos\theta_{12}>U_2 \end{aligned}\right\}\theta_{12}\le\theta_{set}$$
$$L_{center}=\frac{P_1R+Q_1X}{I^2(R^2+X^2)},\quad \theta_{12}>\theta_{set} \qquad (1)$$

Where, electric parameters P_1, Q_1, I can be measured by measurement units. R and X is circuit natural parameters, and voltage phase angle difference on both ends is $\theta_{12}=\theta_1-\theta_2$. When these quantities are known, it can accurately locate out-of-step oscillation center when the system is in synchronous oscillation state[5]. Combined with rapid and reliable splitting criterion, we can achieve fast, reliable out-of-step splitting control[6].

Therefore, combining oscillation center positioning algorithm and oscillation center voltage criterion $U\cos\phi$, a compound criterion with predicting function can be constructed. The compound criterion can timely predict the out-of-step runtime oscillation center line, determine the weak section when the system is in synchronous oscillation or subsynchronous resonance(SSR). It provides a valuable reference to take measures to ensure the system operate stably. When the system runs into the state of out-of-step oscillation, the criterion can quickly locate oscillation center line, and judge whether out-of-step center falls in the oscillation center circuit, and provides a best splitting position for the system.

2.2 Implementation of the method

Concrete steps to implement the criterion with predicting function are as follows :

(1) Output the needed electricity parameters：bus voltage amplitude and phase angle, active power and reactive power of transmission line, circuit impedance read from flower file.

(2) Substitute the electric parameters in step one into oscillation center positioning algorithm showed in Eq. 1.Calculate oscillation center position and get the transmission lines where the predicted oscillation center lies.

(3)Judge whether out-of-step center is in the predicted transmission line where oscillation center lies with oscillation center voltage, namely to determine whether the system is in asynchronous state.

2.3 Two-region four-machine example simulation

Fig. 1 is the schematic of the system used for simulation. The simulation system with two similar regions are connected by a weak tie. Each area has two coupling generators, with rated voltage of 20 kV and rated capacity of 900 MVA. Generator parameters in per unit value (under rated voltage and rated capacity) are shown in Table 1.

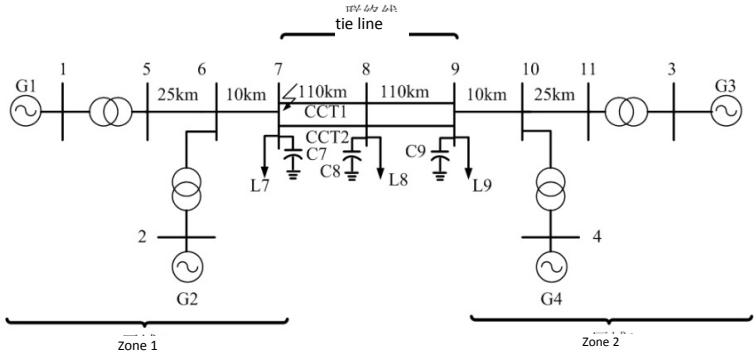

Figure 1. Two-region four-machine system with load on node 8

Table 1. Generator parameters list [p.u]

Symbol	Value	Symbol	Value	Symbol	Value	Symbol	Value
X_d	1.8	X_q	1.7	X_l	0.2	X'_d	0.3
X'_q	0.55	X''_d	0.25	X''_q	0.25	R_a	0.0025
T'_{d0}	8.0	T'_{q0}	4.0	T''_{d0}	0.03	T''_{q0}	0.05
A_{sat}	0.015	B_{sat}	9.6	ψ_{T1}	0.9	H_1	6.5
H_2	6.5	H_3	6.175	H_4	6.175	K_D	0

Under the benchmark of 20/230 kV and 900 MVA, each transformer has the change ratio 1.0, impedance $0+j0.15pu$. Transmission network voltage is rated at 230 kV. Line length is shown in Fig. 2. Circuit parameters in per unit value (capacity benchmark is 100 MVA, voltage benchmark is 230 kV) are as follows:

R_L=0.0001pu/km X_L=0.001pu/km B_C=0.00175pu/km

The generator output values are shown in Table 2.

Table 2. Generator output values

	G 1	G 2	G 3	G 4
Generator active power [MW]	700.0	700.0	712.8	700.0
Generator reactive power [MVar]	145.877	140.307	126.240	85.902

Load and reactive power compensation value as shown in Table 3.

Table 3. Load and reactive power compensation value

	Node7	Node 8	Node 9
active load [MW]	900	100	173
reactive load [MVar]	100	100	100
reactive power compensation [MVar]	200	200	350

In transient simulation, we use the six order model for generators and constant impedance model for load. When the system is in stable operation to 2.9 seconds, CCT1 transmission line of node 7 and 8 occurred three-phase short-circuit fault. CCT1 jumped in 0.1 seconds after fault, and the system eventually entered a state of asynchronous operation. Figure 2-3 and 2-4 are respectively the curves of oscillation center position and $U\cos\phi$ get from node 7.

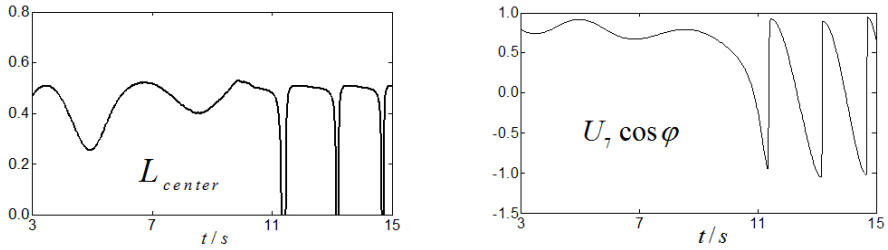

Figure 2. Oscillation center and $U\cos\varphi$ curve of node 7

Fig 2. oscillation center curve shows that before the system entered into asynchronous operation state, the oscillation center positioning method can predict that oscillation center will appear in CCT2 between node 7 and 8 after the system goes into asynchronous operation. Figure 2-4 shows that after the system goes into out-of-step operation, oscillation center appeared on line CCT2. Thus proves that the composite criterion with prediction is accurate and effective. The trajectory of criterion $U\cos\phi$ provides an important basis for splitting at the same time.

Implementation and Application in PSD - BPA Software

3.1 Implementation method in PSD - BPA

In the process of PSD - BPA electromechanical transient simulation, each simulation step contains a large amount of data. these data have important value in the analysis of stability of power grid[7]. After a simulation step, bus voltage, phase angle, active power and reactive power of transmission line, generator output, angle difference and so on are used to locate oscillation center in a system. After oscillation center positioning, judge whether the oscillation center is out of step according to the criterion$U\cos\phi$. Concrete steps are as follows:

(1) Before the start of PSD - BPA transient simulation, establish an underlying database on the basis of flow file and stable file with all transformer and circuit parameters concerned.

(2) Calculate the oscillation center position for all the transmission lines in the network. If the results is between 0~1, and is changing constantly, then the transmission lines is the one where oscillation center lies. Store all the electric parameters of oscillation center lines.

(3) Calculate all the oscillation center lines whose information have been stored according to the criterion $U\cos\phi$, and determine whether the system is out of step.

3.2 Simulation results of implementation in central China-north China power grid

We use central China – north China power grid data in 2012 for simulation.

(1) Fault scenario 1: Three-phase fault on Honggou side of transmission line Honggou-Banqiao, disconnect double circuit line. The position and voltage of Honggou-Banqiao fault oscillation center are shown in Fig.3.

(2)Fault scenario 3: Short-circuit fault in Lang-Bazhou 51 bus. After 4.5 cycles disconnect all lines connected to bus 51 on Lang-Bazhou side. Five cycles later, the other side of all lines connected to bus 51 are disconnected. The position and voltage curve of Lang-Bazhou fault oscillation center are shown in Fig.4.

(3) Fault scenario 2: Three-phase fault on Fengzhen side of transmission line Fengzhen-Wanquan. Disconnect double-circuit line. The position and voltage of Fengzhen-Wanquan fault oscillation center are shown in figure Fig.5.

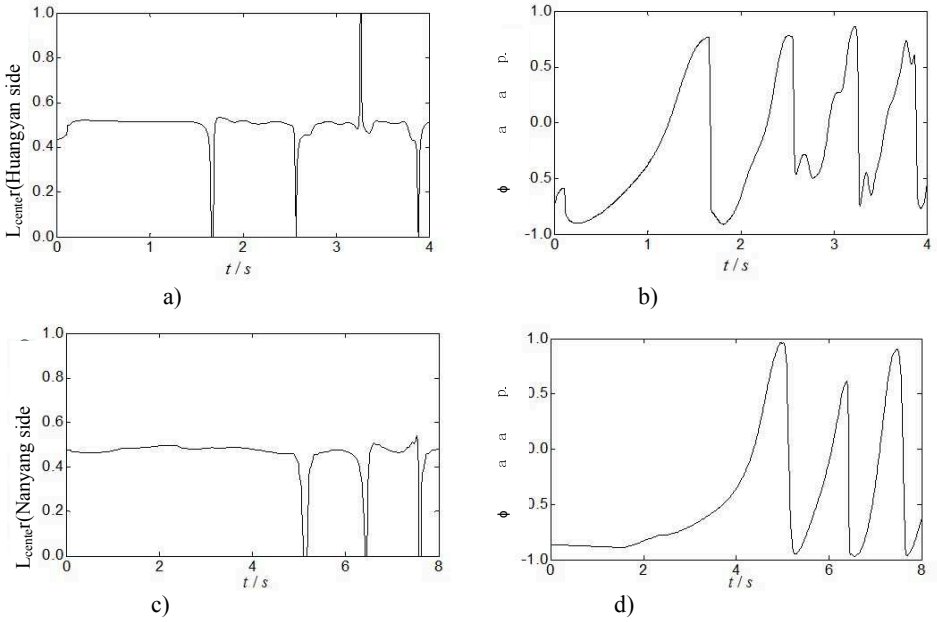

Figure 3. Oscillation center position and voltage curve corresponding to Honggou-Banqiao fault

a) Oscillation center position curve of Huangyan side b) $U\cos\varphi$ curve of Huangyan side

c) Oscillation center position curve of Nanyang side d) $U\cos\varphi$ curve of Nanyang side

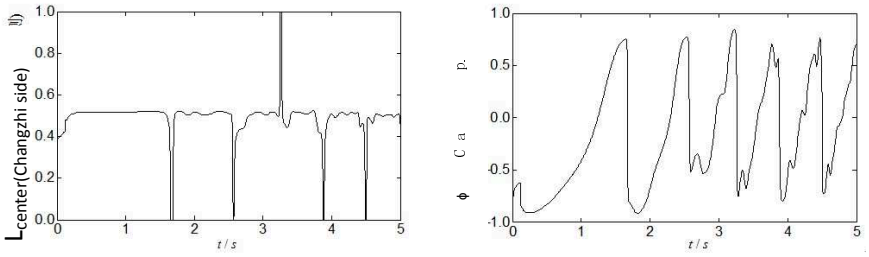

Figure 4. Oscillation center position and voltage curve corresponding to Lang-Bazhou bus 51 fault

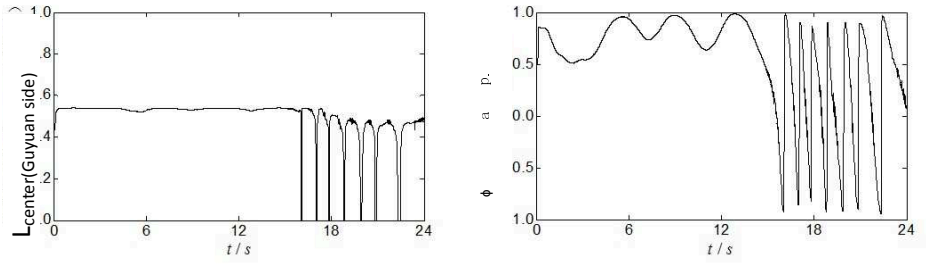
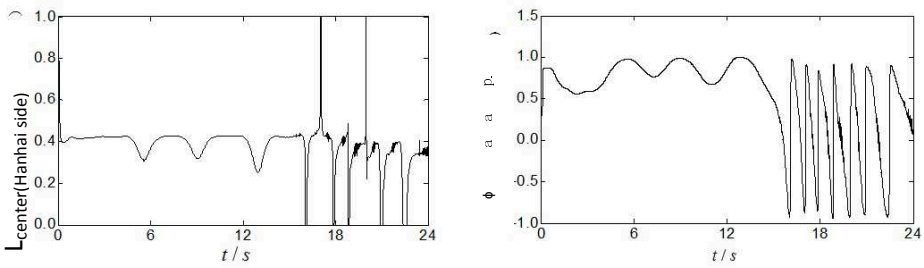
a) Oscillation center position curve of Changzhi side b) $U\cos\phi$curve of Changzhi side





c) d)

Figure 5. Oscillation center position and voltage curve corresponding to Fengzhen-Wanquan fault
a) Oscillation center position curve of Guyuan side b) $U\cos\phi$ curve of Guyuan side
c) Oscillation center position curve of Hanhai side d) $U\cos\phi$ curve of Hanhai side

Results of Fig 3.Fig 4. and Fig 5. are summarized in Table 4.

Table 4. Simulation results

Fault scenario	Predicted location of oscillation center	Actual location of oscillation center
Honggou-Banqiao fault	Huangyan -Wanxian& Nanyang-Jingmen	Huangyan -Wanxian&Nanyang-Jingmen
Lang-Bazhou bus 51 fault	Changzhi- Nanyang	Changzhi- Nanyang
Fengzhen-Wanquan fault	Hanhai-Guyuan&Guyuan -Taiping	Hanhai-Guyuan&Guyuan-Taiping

Table 3-1 shows that in these three fault scenarios, compound criterion with prediction can correctly predict on which line the oscillation center will appear before the system runs out of step. The criterion can also provide a reference for a beat splitting position.

Conclusion

Simulation on two-region four-machine system and central China-north China power grid proves that this method has the ability to predict oscillation center of the line before the system is out-of-step. Compared with traditional splitting criterion, this criterion has the advantage that it can accurately predict transmission lines where oscillation center lies before the system is out-of-step after disturbance. It can also locate weak sections of transmission lines, being an important basis to take measures to improve system stable level. Once timely discover the system is running in poor stability state, take certain measures can reduce the possibility of blackouts causing by system running from poor stability into out-of-step operation state.

A Costal Wave Energy Power Station Equipment

TONG Junjie[1,a]

[1] Guangdong Ocean University of Technology, School of Engineering, Zhanjiang 524006, China

[a]jjtong9311@163.com

Keywords: dual channel, wave energy, costal wave

Abstract. This paper introduced a coastal wave energy power generation and its unique dual channel structure, in which two–way coastal current was transformed into single direction rotation of the impeller. Also according to coastal wave energy characteristics, the paper analyzed relationship between inshore sea water kinetic energy and the wave amplitude away from the coast. In addition, the water velocity and flow area of equipment through power generation equipment are studied.

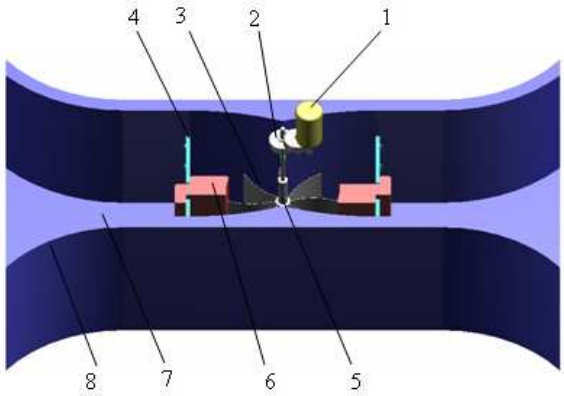
Introduction

Ocean wave energy is the most widely distributed renewable energy which accounted up to 50%[1,2]. In recent years, wave energy has represented the development of marine energy. Compare to more studies on using of wave energy in deep sea region [3~6], there were few study on using of wave energy in costal region.

Wave energy of deep sea region shows potential energy while costal wave energy shows kinetic energy, which performances two-way flow of sea water. This paper described a costal wave energy power generation equipment of unique dual-channel structure, in which was transformed into single direction rotation of the impeller and stability of the output power was improved. Also this paper analyzed the relationship between inshore sea water kinetic energy and the wave amplitude away from the coast. In addition, the seawater velocity and flow area of equipment through power generation equipment are studied.

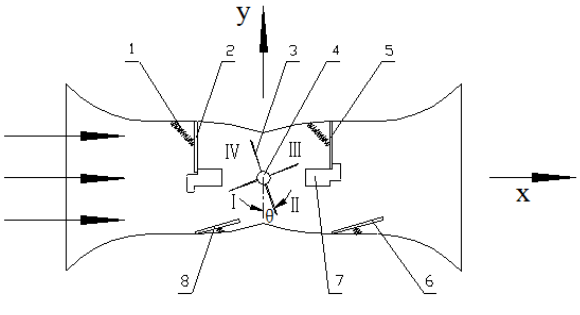
1. The dual-channel structure power generation equipment and its working principle

The dual-channel structure power generation equipment developed by the author's research team is composed of transmission, impeller, generators and valves. The structure and its working principle are shown as Figure 1 and Figure 2 respectively.



1-generator 2-transmisson 3-impeller 4-valve 5-axle 6-baffle; 7-floor board 8-side board

Fig. 1 The structure of dual channel electric power equipment (removing roof)



1-reposition spring 2-valve 1 3-blade 4- impeller axle 5-valve 2 6-valve 3 7-baffle 8-valve 4

Fig.2 Dual channel power generation equipment works

As shown in Figure 1, The dual-channel structure power generation equipment is composed of valves, baffles, floor board, side boards, transmission and generators. The combination of valves open or close decides that water flow right or left. Sea water promotes impeller rotation and drive generator running through transmission.

As shown in Figure 2, when sea water flows to right or to left the flow channel is formed as follows:

When sea water flow into the generation equipment from its left inlet, the valve 1 and the valve 2 are closed at the baffle position, simultaneously the valve 3 and the valve 4 are turned right and open. Sea water flow to right and promote impeller rotating counterclockwise.

Similarly when sea water flow into the power generation equipment from its right inlet, the valve 3 and the valve 4 are closed at the baffle position, simultaneously the valve 1 and the valve 2 are turned left and open. Sea water flow to left and promote impeller rotating counterclockwise.

Costal wave energy shows kinetic energy, which performances two-way flow of sea water. The impeller is promoted in the same direction whether sea water flow to left or to right. Thus the instability of energy output is reduced.

The inlet and outlet of the power generation equipment are designed as reduction-shaped which increase energy input.

2. Analysis of costal wave

Costal wave energy shows kinetic energy and costal wave energy is analyzed as follow.

(1)Without considering the effect of wind on the kinetic energy of the inshore water, inshore sea water kinetic energy is mainly transformed by potential energy of wave away from the shore.

(2)The energy loss of wave breaking is ignored.

(3)The kinetic energy loss of inshore sea water is caused mainly from resistance of shore.

(4)Due to little resistance of the sea floor, the kinetic energy of the sea water flow to shore reaches the maximum at the position where a certain distance from shore. The kinetic energy is mainly transformed by the potential energy of the wave away from shore.

(5) The kinetic energy of the sea water flows to the shore is more than the kinetic energy of the sea water reflows from the shore at the certain position that mentioned above as analysis (4).

According to the above analysis, when the power generation equipment is set at the position mentioned as above analysis (4), the kinetic energy will be taken advantage of to the maximum. Based on the above analysis and the Bernoulli equation, the follow equation can be obtained:

$$N = (Z_1 + \frac{p_1}{\gamma} + \frac{\alpha_1 U_1^2}{2g}) = (Z_2 + \frac{p_2}{\gamma} + \frac{\alpha_2 U_2^2}{2g}) + h_{12} \quad (1)$$

Z_1, p_1, U_1 and α_1 represent the wave amplitude, the water pressure, the water velocity and kinetic energy correction factor in the region away from the coast respectively. In contrast, Z2, p2, U2 and α_2 represent the amplitude, pressure, velocity and Kinetic energy correction factor of the water at the position mentioned above as analysis (4) respectively.

N, g, γ and h_{12} are the total pressure, gravitational acceleration, bulk density and resistance loss respectively..

For the dual-channel structure power generation equipment, utilizing the water kinetic energy is near sea surface and the kinetic energy loss is neglected. The equation 1 can be simplified to:

$$H_W = Z_1 - Z_2 = \frac{U_2^2}{2g} \tag{2}$$

The relationship between H_W and U_2 are shown as Fig 3 when the gravitation acceleration g is assumed 9.81m^2/s.

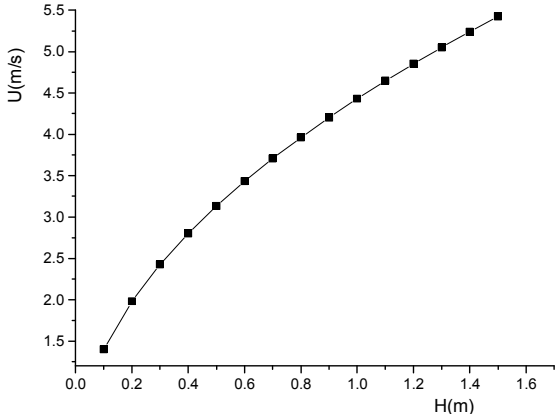


Fig.3 Fluid flow velocity and flow area through the device

As shown in Fig.3, in the process of wave energy transformation in the costal region, when the potential energy of the wave away from the shore increases the velocity of the water at the position mentioned above as analysis (4) increases correspondingly.

3. The seawater flow and flow area of the generation equipment.

When the sea water flow through the generation equipment the follow equation can be obtained based on the Bernoulli equation[7]

$$H_{io} = (Z_i + \frac{p_i}{\gamma} + \frac{\alpha_i U_i^2}{2g}) - (Z_o + \frac{p_o}{\gamma} + \frac{\alpha_o U_o^2}{2g}) \tag{3}$$

Z_i, p_i, U_i and α_i represent the amplitude, the pressure, the velocity and the kinetic energy correction factor of the sea water in the generation equipment inlet respectively. In contrast, Z_i, p_i, U_i and α_i represent the amplitude, the pressure, the velocity and the kinetic energy correction factor of the sea water in the generation equipment inlet respectively.

Due to the structural symmetry and seawater incompressible, the equations can be obtained as follows

$$U=U_i=U_o <= U_2 \tag{4}$$

$$Z_i=Z_o \tag{5}$$

$$H_{io} = \frac{p_i}{\gamma} - \frac{p_o}{\gamma} <= H_w \tag{6}$$

$$P = \gamma\, Q H_{io} \eta \tag{7}$$

Q is the seawater flow; η is the power conversion efficiency for the equipment.

The relationships for seawater velocity U , flow area of equipment and the available pressure head H_{io} are shown as Fig 4.

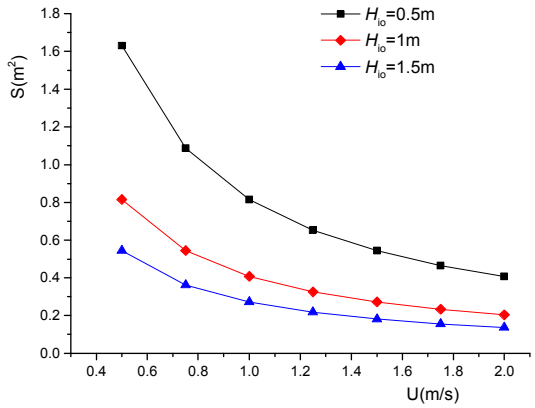

Fig.4 Fluid flow velocity and flow area through the device

4. Conclusions

(1) This paper introduced a coastal wave energy power generation and its unique dual channel structure, in which two–way coastal current was transformed into single direction rotation of the impeller. Thus the instability of energy output is reduced.

(2) The kinetic energy of the sea water flow to shore reaches the maximum at the position where a certain distance from shore. The kinetic energy is mainly transformed by the potential energy of the wave away from shore.

(3)The generation equipment output power W is determined mainly by the available pressure head Hio and seawater flow Q

(4)When generation equipment output power W is kept constant, lower seawater velocity U require larger flow area S that affects device compactness.

(5)In this paper, the costal wave and the dual-channel structure power generation equipment are analyzed without considering effects of wave breaking and wind. Thus effects on costal wave by wave breaking and winding need further research

A Energy Optimization Management Method of the Microgrid Based on Priority Ranking

Qin-Zheng Yu[1, a], Dong-Mei Zhao[1]

[1] North China Electric Power University, Changping District, Beijing 102206, China;

[a]cau_fisch@163.com

Keywords: microgrid; energy optimization management; priority raking; particle swarm optimization

Abstract. Energy optimization management can realize optimal operation of the microgrid, to meet the requirements of economic operation, power supply reliability and environmental benefit, etcetera. Artificial intelligent algorithms are most widely used to solve this problem currently. In order to avoid the weaknesses of intelligent algorithms, this paper puts forward a simple and practical method based on priority ranking. A energy optimization management model of a grid-connected microgrid is established. Using the priority ranking method, optimal operation schemes under different optimization strategies are figured out. The analysis and discussion of optimal operation schemes and the comparison with the optimization result of particle swarm optimization (PSO) indicate that the method based on priority ranking is simple, effective and practical.

Introduction

In order to make full use of the distributed generation (DG), the concept of the microgrid was proposed at the beginning of this century. As an important part of the microgrid research, energy optimization management can realize optimal operation of the microgrid, so as to meet the requirements of economic operation, power supply reliability and environmental benefit, etcetera.

Artificial intelligent optimization algorithms, including genetic algorithms (GA)[1-3], particle swarm optimization (PSO)[4,5], ant colony optimization (ACO)[6,7] and immune algorithm (IA)[8], have been applied in the energy optimization management problem of the microgrid. The algorithms mentioned above are well-adapted to different problems and are able to obtain the global optimum. However, it brings many difficulties, when using intelligent algorithms. Firstly, the optimization results are usually uncertain, and easy to fall into local optimum. Secondly it takes long time to compute. Lastly it is difficult to solve DGs start-stop unit commitment problem, because the number of dimensions is too large.

Therefore, in order to avoid the difficulties caused by intelligent algorithms, this paper proposes a energy optimization management method of the microgrid based on priority ranking, which is simple, effective and practical.

the Energy Optimization Management Model of a Grid-connected Microgrid

Typically, a microgrid is connected with the main grid, and gets frequency and voltage support from the bulk grid. Pointing at a grid-connected microgrid, this paper establishes a energy optimization management model, which contains various types of DGs, and takes a battery as the energy storage. In the interval Δt between two adjacent operation instructions, assumptions are made as following: the load demand, the output power of each DG and battery, the interaction power between the microgrid and the main grid and the electricity price maintain constant.

Objective Function

In this paper, the objective function of this optimization model is the minimum operation cost, considering feul costs, maintenance costs and interaction power costs, as Eq. 1.

$$\min C_{OPE} = \int_0^T \left[\sum_i^N \left[C_{i,t_k}^{fuel} + C_{i,t_k}^{M} \right] + C_{t_k}^{PE} \right] dt = \int_0^T \left[\sum_i^N \left[f^{fuel}\left(P_{i,t_k}\right) + K_i^M P_{i,t_k} \right] + c_{t_k}^{pe} P_{grid,t_k} \Delta t \right] dt \qquad (1)$$

Where T stands for the optimization period, here is 24 hours; t_k stands for a optimal operation time; N stands for the amount of DGs in this system; i is the DG number; C_{OPE} stands for the operation cost; C_{i,t_k}^{fuel} and C_{i,t_k}^{M} stand for the fuel cost and maintenance cost of the i-th DG at time t_k; $C_{t_k}^{PE}$ stands for the interaction power cost at time t_k; P_{i,t_k} and P_{grid,t_k} stand for the output power of the i-th DG and the interaction power at time t_k; $c_{t_k}^{pe}$ stands for the electricity price at time t_k.

Constraint Condition

●Power balance constraint: $\sum_{i}^{N} P_{i,t_k} + P_{bat,t_k} + P_{grid,t_k} - P_{\text{load},t_k} = 0, k = 1, 2, \cdots, num$ (2)

Where $num = T / \Delta t$; P_{bat,t_k} and P_{load,t_k} stand for the charge or discharge power of the battery and the load at time t_k.

●Upper and lower output limit of DGs: $P_{\text{i}}^{\min} \le P_{i,t_k} \le P_{\text{i}}^{\max}$ (3)

Where, $P_{\text{i}}^{\min}$ and $P_{\text{i}}^{\max}$ stand for the minimum and maximum output power of the i-th DG.

●State of charge (SOC) constraint of the battery: $SOC_{\min} \le SOC_{t_k} \le SOC_{\max}$ (4)

Where SOC_{t_k} stands for the SOC of the battery at time t_k; $SOC_{\min}$ and $SOC_{\max}$ stand for the minimum and maximum SOC of the battery.

●The start and end state of SOC constraint in the optimization period: $SOC_{t_1} = SOC_{t_{num}}$ (5)

Considering the involvement of the battery in the optimization process, the SOC in the beginning and in the end should be equal. The battery completes a charge-discharge cycle.

●The charge and discharge power constraint of the battery:

$SOC_{t_k} - P_{bat,t_k} \Delta t / BAT_{cap} = SOC_{t_{k+1}}, k = 1, 2, \cdots, num$ (6)

$P_{bat}^{\min} \le P_{bat,t_k} \le P_{bat}^{\max}$ (7)

Where $P_{bat}^{\min} < 0$ and $P_{bat}^{\max} > 0$ stand for the maximum charge and discharge power; BAT_{cap} stands for the battery capacity.

●Upper and lower limit of the interaction power: $P_{grid}^{\min} \le P_{grid,t_k} \le P_{grid}^{\max}$ (8)

Where $P_{grid}^{\max}$ and $P_{grid}^{\min}$ stand for the minimum and maximum interaction power between the microgrid and the main grid.

Optimization Strategy

As the renewable energy, wind and photovoltaic power are not controllable; produce less pollution, without fuel consumption; cost less operation cost; start to work quickly; changes the output rapidly. Due to the advantages mentioned above, the optimization strategy gives top priority to the use of wind and photovoltaic power; make they work in the maximum power point tracking (MPPT) mode.

And then, according to the main grid whether to involve in the optimization process and the exchange mode of the interaction power between the microgrid and the main grid, the optimization strategies of a grid-connected microgrid can be generally divided into the following 3 types.

Strategy 1: In order to make full use of DGs, firstly DGs are utilized to meet the load demand, and the main grid is taken as a supplement. Interactive power is unidirectional, which means the microgrid can absorb power from the main grid, but can not deliver power to the main grid.

Strategy 2: From the economic point of view, considering the influence of peak-valley electricity price, both the DGs and the main grid take part in optimization process. when the electricity price of the main grid is lower than the power generation cost of DGs, it takes precedence that the microgrid absorbs power from the main grid. The exchange mode of the interaction power is the same with Strategy 1.

Strategy 3: Both the DGs and the main grid take part in optimization process. Interactive power is bidirectional, which means the microgird can not only absorb power from the main grid, but also deliver power to the main grid.

the Energy Management Optimization Method of the Microgrid Based On Priority Ranking

The principle of the priority ranking method is that according to the objective function and optimization strategy on which researchers focus, sort the output of DGs and the main grid in the specified order; when load changes, adjust the state (work or stop) of DGs and arrangements the output of DGs and the main grid, based on the given output priority level. This method includes the following steps:

Step 1: establish a "output of DGs and the main grid-optimization objective" curve

Through the statistical analysis and calculation of the related data, establish a "output of DGs and the main grid-optimization objective" curve. For the energy optimization problem, the optimization objective can be operation cost, environmental benefit, depreciation cost and comprehensive cost etc.

The optimization objective in this paper is operation cost. The operation cost of DGs can be fitted by a quadratic function of output power[9-11], which is similar to a linear function. The operation cost of the main grid is proportional to the electricity price.

Step 2: make the output priority level of DGs and the main grid

According to different optimization strategies, under different load demands, sort the output of DGs and the main grid in a specified order, based on the curve given by Step1.

Step 3: calculate the curve of the net load

The net load represents the load which subtracts the output of wind and photovoltaic power, as $P_{\text{net},t_k} = P_{\text{load},t_k} - P_{\text{PV},t_k} - P_{\text{WT},t_k}$ shows. Where P_{net,t_k}, P_{PV,t_k} and P_{WT,t_k} stand for the net load, the output of wind and photovoltaic power at time t_k.

Step 4: figure out a charge and discharge plan of the battery in the optimization period

In a grid-connected microgrid, the active effect of a battery is that: 1) The battery can be used in peak load shifting to inhibit the fluctuation of the tie line power; 2) The battery can draw energy from the main grid, when load demand is low and electricity is cheap. Contrary, the battery discharges to reduce peak power demand, when electricity is expensive. Therefore, the economic benefit is improved.

When all the constraints of the battery are met, according to the net load curve obtained in Step 3, figure out the output of the battery at each moment, to make the battery complete a charge-discharge cycle in the optimization period and play a role described above.

Step 5: calculate the actual load demand

On the one hand wind and photovoltaic power generate electricity preferentially, on the other hand, a charge and discharge plan of the battery has been determined. Therefore, we can calculate the actual load demand which is met by the DGs and the main gird, as $P_{\text{real\_load},t_k} = P_{\text{load},t_k} - P_{\text{PV},t_k} - P_{\text{WT},t_k} - P_{bat,t_k}$ shows. Where $P_{\text{real\_load,tk}}$ stands for the actual load demand which is met by the DG and the main gird.

Step 6: figure out the optimal operation scheme

According to the optimization objective and strategy, arrangement the output of DGs and the main grid, based on the output priority level given by Step 2 and the actual load demand given by Step 5.

Step 7: fine-tune the optimal operation scheme

Through the above steps, the output of DGs may not satisfy the constraints. It is necessary to fine tune the scheme.

Example Analysis

Example Data

The calculation example of the microgrid considered in this paper consists of Wind Turbine(WT)，Photovoltaic(PV), Diesel Engine(DE), Fuel Cell(FC), Micro-Turbine(MT) and the battery. This microgrid system operates in the grid-connected mode. The prediction power of WT, PV and the load demand in the next day and the electricity price is shown in Fig.1.

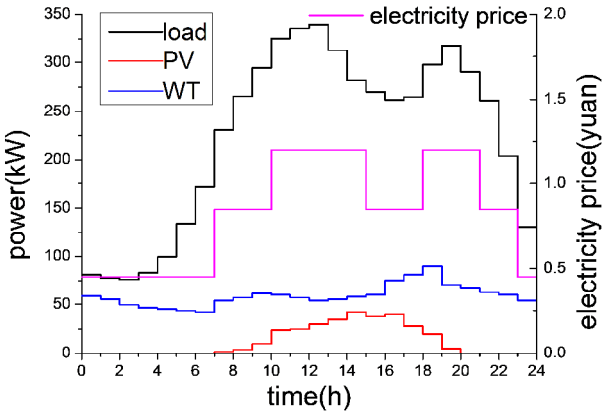

Fig.1 Prediction power and electricity price

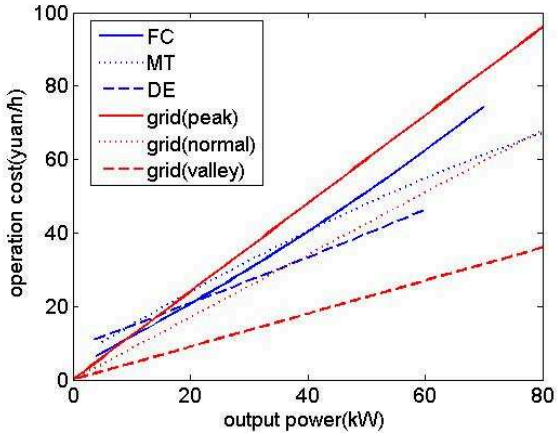

Fig.2 Output-operation cost curve

In this microgrid system, the upper and lower output limit of FC, DE and MT is 4~70kW, 3~60kW and 5~80kW respectively. Fuel costs of DGs can be fitted with a quadratic function. As shown in Fig.2[10,12], in this paper, the fuel and maintenance cost of each DG is taken as a whole (objective, the operation cost) to consider. Fig.2 also shows the operation cost of the main grid. The maximum charge and discharge power of the battery is 40kW, and its capacity is 200kWh. In order to prevent excessive charge and discharge, the operating range of SOC is set to 0.3~0.9pu, and its initial state in a optimization period is set to 0.4pu. The interactive power is limited to ±50kW.

Figure out the Output Priority Level

Through the statistical analysis and calculation of the related data, the "output-operation cost" curve is shown in Fig.2, which provide a sorting information for priority ranking. According to Fig.2, in order to reduce the operation cost to the minimum, Table 1 gives out the priority level of DGs and the main grid, under different optimization strategies and different load demands.

Table 1 The priority level of DGs under different optimization strategies

optimization strategy			the priority level of DGs and the main grid under different load demand					
Strategy 1	load demand [kW, the same below]		0-21	21-60	60-100	100-140	140-210	210-260
	priority level		FC	DE	DE, FC	DE, MT	DE, MT, FC	DE, MT, FC, grid
Strategy 2	peak	load demand	……	69-100	100-140	140-149	149-210	210-260
		priority level	……	DE, FC	DE, MT	DE, MT, grid	DE, MT, FC	DE, MT, FC, grid
	valley	load demand	0-50	50-71	71-110	110-150	150-190	190-260
		priority level	grid	grid, FC	grid, DE	grid, DE, FC	grid, DE, MT	grid, DE, MT, FC
	normal	load demand	0-38	38-60	60-110	110-137	137-190	190-260
		priority level	grid	DE	DE, grid	DE, grid, FC	DE, MT, grid	DE, MT, grid, FC
Strategy 3	peak	load demand	……	140-210		210-260		
		priority level	……	DE, MT, FC(-)		DE, MT, FC, grid		
	valley	load demand	0-50	50-71	71-110	110-150	150-190	190-260
		priority level	grid	grid, FC	grid DE	grid, DE, FC	grid, DE, MT	grid, DE, MT, FC
	normal	load demand	10-60	60-87	87-140	140-190	190-260	
		priority level	DE(-)	DE, grid	DE, MT(-)	DE, MT, grid	DE, MT, grid, FC	

Notes: DE(-), FC(-) and MT(-) mean that DE, FC, MT generate the most power, and deliver the surplus power to the main gird, when the limit of the interaction power is met.

Analysis of the Optimal Operation Scheme

According to the net load curve in Fig.3 and Step 4 of this method described in section 3, the actual load demand curve which is met by DGs and the main grid can be obtained, as Fig.3 shows. The battery charges during 0:00-4:00, when load demand is low, and discharges at peak period 10:00-13:00 and 19:00-20:00.

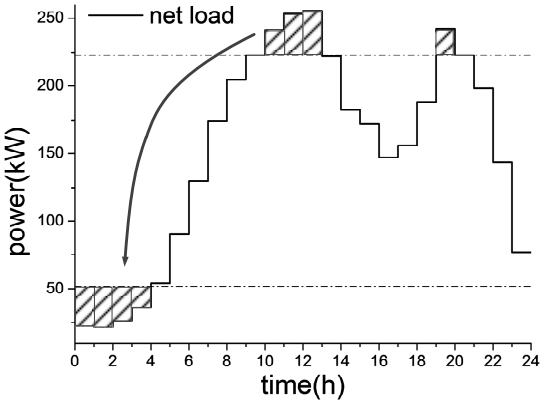

Fig.3 A charge and discharge plan of the battery

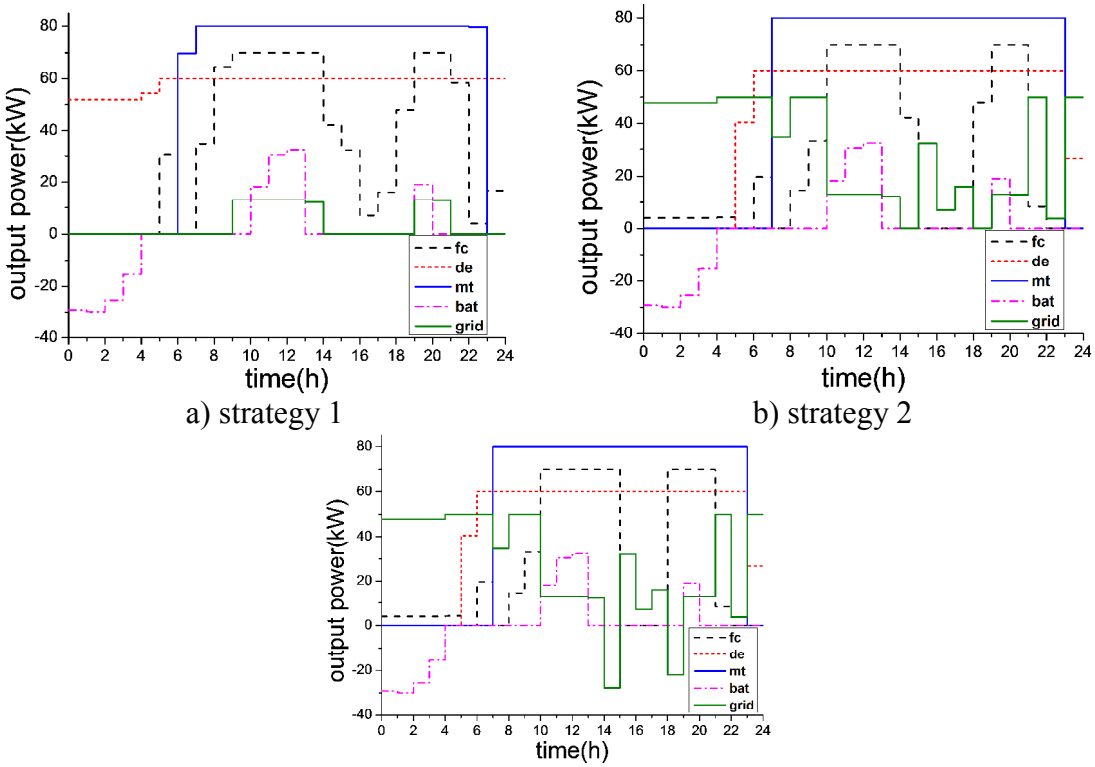
Based on the output priority level in Table 1 and the actual load demand in Fig.3, optimal operation schemes under different optimization strategies are figured out, which take the operation coat as the objective, as Fig.4.



a) strategy 1 b) strategy 2

c) strategy 3

Fig.4 Optimal operation schemes under different optimization strategies

As can be seen from Fig.4: 1)When this microgrid system uses Strategy 1, DGs generate power in the order from the lowest operation cost to the highest. The microgird draws power from the main grid, when all the DGs can not meet the load demand. 2) When using Strategy 2, both the DGs and the main grid take part in optimization process. The DG or the main grid which possesses lower operation cost have priority to generate power. The interactive power is also unidirectional. 3) When using Strategy 3, the DGs deliver power to the main grid to gain profit at peak period. The economic benefits of strategy 1, 2 and 3 are gradually improved, as shown in Table 2.

To verify the optimization accuracy by using the priority ranking method, PSO algorithm is used to calculate the same example. The result of PSO algorithm can be regarded as the global optimum. The optimization results of two methods and the errors are shown in Table 2.

Table 2 The operation cost [yuan]

	The priority ranking method	PSO	error
Strategy 1	3216.00	3216.00	0%
Strategy 2	3049.31	3049.13	<0.1%
Strategy 3	3046.76	3046.53	<0.1%

As can be seen from Table 2: Compared with the intelligent algorithm, the priority ranking method also possesses a high accuracy. The optimization results of two methods have little difference. However the priority ranking method costs less time to compute.

Conclusion

This paper establishes a energy optimization management model of a grid-connected microgrid, which consists of various types of DGs and a battery. Using the priority ranking method, optimal operation schemes under different optimization strategies are obtained. Through the analysis and discussion of the optimization schemes and the comparison with the optimization result of PSO, it indicates that using the priority ranking method can not only guarantee the calculation accuracy, and greatly reduce the computational time, but also avoid the weaknesses, when using intelligent algorithms. Therefore, this energy optimization management method of the microgrid based on priority ranking is simple, effective, easy to use, fast to compute and worthy to be used in engineering practice.

Keywords: High penetration; Distributed generation; Monte-Carlo method; Reliability analysis

Abstract. With high penetration of distributed generation connected to the grid, distribution system will have some huge impacts, and system reliability calculation models and assessment methods are changing. Based on Monte-Carlo method, a heuristic reliability analysis method for distribution system with distributed generations was proposed in the paper, which focuses on the mode of distributed generation in parallel to system power supply. Functional role of distributed generation in the power distribution system failure and distributed power adapter with load strategies were analyzed in this method. Cases simulation analysis was used to verify its effectiveness.

Introduction

With the use and development of clean and renewable energy, numerous Distributed Generations (DG) are connected to the distribution system, resulting in the changes of traditional distribution network and operation modes. The penetration rate is defined as the ratio of DG system's capacity accounting for the distribution system capacity, which is considered high when it reaches 70% generally [1]. Currently, DG system has formed a high penetration in some area distribution system.

The traditional distribution network is usually supplied radiantly by a single point generation and the model is single-supply as well. When any feeder of the grid falls in a fault, all the loads behind the fault point will lose power. However, with the installation of DG, the distribution system becomes a network with multiple power supply. The loads can avoid losing power in a fault with the help of DGs behind the fault point [2]. As the output of DG (like wind and solar) is uncertain and uncontrollable, in the case of high penetration, reliability evaluation models and methods for distribution system are different from traditional ones, and reliability analysis method also becomes complicated[3].

In [4], the uncertain factors of system components and load parameters are studied, and some impacts for different installation positions on distribution system were given by calculating the range reliability indices before and after the installation of DG. In [5], the authors proposed a reliability analysis strategy based on the Network Equivalent Method of minimum cut set. This strategy can separate distribution system into sections properly, which is suitable for the dividing of distribution system with scattered DG. An island partitioning algorithm was proposed in [6] to divide the distribution system with DG. The algorithm analyzes the reliability according to the power balance features of island operation and different requirements for power reliability. In [7], the authors equaled the DG as a distribution device, and took samples with Monte-Carlo method to analyze the power supply ability of distribution system with DG.

Currently, some results have been achieved in reliability evaluation and distributed generation technique, but the supply turning strategies for DG in a fault and the analysis methods for impact on distribution system reliability need further study. Based on Monte-Carlo Method, a reliability analysis method for distribution system with high penetration of DG was proposed in this paper, which focuses on the mode of DG in parallel to system power supply. Functional role of DG in the distribution system failure and distributed power adapter with load strategies were considered here.

Reliability Analysis of Distribution Network with DG

Operation Modes for DG. Different operation modes for DG have different impacts on the power supply reliability of distribution network system [8], mainly including three cases: 1) DG acts as the standby power for the system; 2) System power acts as the standby power for the DG; and 3) DG supports the load points in parallel to system power.

The distribution system has become a multiple power network and customers can gain power from different power supply. Thus, system power and the DG prepare for each other to improve the reliability of distribution system. However, if the control measures of disintegration are improper, system may face a problem of unsynchronized power islands. Even the stability of system will be affected when it's critical. Considering the efficiency and stability in the distribution system with DG of high penetration, the mode of DG in parallel to system power will be the mainstream [9]. This paper studies the mode of DG in parallel to system power and the same analysis method is also suitable for other modes.

Grouping Strategy for DGs and Loads. There is a circuit breaker on each line and the line is divided into forward region, middle region and backward region in a fault. As the existence of DG, the strategies of breaker tripping and the island operation of DG need to be considered. And the impacts of fault on forward region and backward region may be different, so the loads in forward and backward regions need to be divided into groups differently according to breaker tripping strategy.

Some load can turn to a DG directly without any switch operation after breaker acts. In this way, the forward and backward regions are divided into four groups: same and different groups in forward region, same and different groups in backward region. When there is more than one DG in forward or backward regions, different DGs are allowed to be in more than one same branch-group. Some load points can't turn to any DG for power and they are included in different branch-group with those in the traditional distribution network.

Distributed Power adapter with Load Strategies. In the failure of distribution system, DG carries a part of the loads in forward and backward regions directly or through quick operation. And the strategy is: the DG meets the important load in the same branch-group preferentially, and if some extra power is available, supplies the rest load in the group. If there is still more power, load in the different branch-group from the DG can also be supplied. This is for the decrease of switches operation quantity and power loss.

For backward region, even though a fault occurs, the DG will continue running because of the protection of breaker tripping strategies, so the load points in the same branch-group as DG may not lose power. It depends on the sizing comparison between DG's output and load. If the output of DG is big enough to supply all load points in the same branch-group, they will not lose power, and the extra power can be used to support the load points in different branch-groups. Or, only important load can be meted, and a rank of load points is necessary.

For forward region, when breaker acts to separate a fault, several islands with DG will be formed. The load points and DGs in forward region need to be divided into groups. For some load points, they may not lose power because of the existence of DG, but it depends on the sizing comparison between DG's output and load. If the output of DG is big enough to supply all load points in the same branch-group, they will not lose power. Or, only important load can be meted, and a rank of load points is necessary.

Interruption Indices. The purpose for reliability analysis of distribution system is to obtain the quantifiable indices of reliability. For the analysis of distribution network with DG, this paper selects the *LOLP* (Loss of Load Probability) and *AAID* (Annual Average Interruption Duration) indices.

LOLP presents the probability of load power failure in the distribution system, calculated using:

$$LOLP = \frac{1}{N}\sum_{i=1}^{n} F_{LOLP}\left(\overline{X_i}\right) \tag{1}$$

In the type: N stands for the number of randomly sampled system status; F_{LOLP} stands for possible load-shedding situations when system stays in the status $\overline{X_i}$, defined as:

$$F_{LOLP}\left(\overline{X_i}\right)=\begin{cases}0 & \text{No load-shedding in the state of } \overline{X_i}\\ 1 & \text{Load-sheeding in the state of } \overline{X_i}\end{cases}$$

AAID presents the annual average interruption duration (in hours) observed at a load point in the distribution system, and it is calculated using:

$$AAID=\frac{\sum_{i\in NS} F_{AAID}\left(\overline{X_i}\right)}{NS} \tag{2}$$

In the type, $F_{AAID}\left(\overline{X_i}\right)$ stands for the interruption duration of the observed load point every time the system stays in the sampled state $\overline{X_i}$; *NS* stands for the quantity of loads at that node.

A Heuristic Reliability Analysis Algorithm of Distribution System

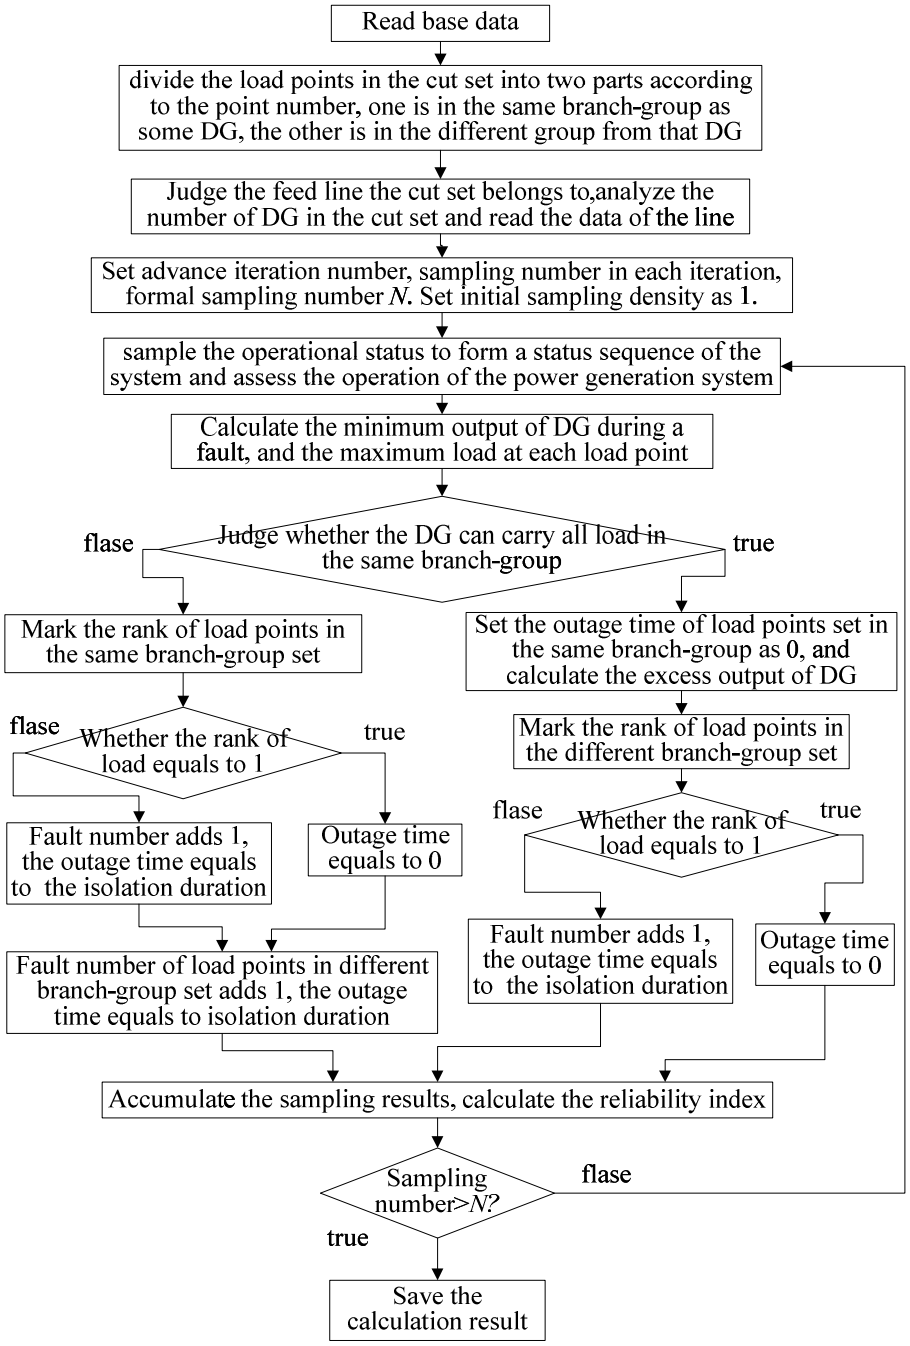

Fig.1 Distribution system reliability analysis flow chart for considering DG

Assumptions. After more and more DGs, like solar and wind, connect to the distribution system, the intermittency and uncontrollability will increase the difficulty of reliability analysis [10]. To simplify the analysis in this paper, switching devices, like breakers, are assumed no misoperations or refusing actions in the premise of computation accuracy. Thus, it is considered that the modes between connection to grid and islands can always transform to each other quickly and successfully.

Algorithm Flow. To analyze a distribution system, different kinds of fault need to be assembled at different nodes and in different timing sequence. The computation will be massive, so the fault status is sampled by Monte-Carlo Method for analysis in this paper.

First, divide the load points in the cut set into two parts according to the point number, one part is the same branch-group as some DG, the other is the different branch-group from that DG. Then, based on the judgment of feeder the cut set belongs to, analyze the quantity of DG in the cut set and read the data of corresponding line. After that, use the Monte-Carlo Method to sample the operational status to form a state sequence of the system and assess the operation of the power generation system. For a fault on the line, analyze the load restoration according to the comparison between the sizing of DG and the amount of planned loads as well as the importance of load in forward and backward regions. Last, get the reliability index of distribution system. The algorithm flow is shown in Fig. 1.

Using this method, the intermittence and uncontrollability of solar and wind due to climate changing need to be considered. In the reliability analysis, the climate factor affects the distribution system reliability a lot. It can be solved by multiplying the device reliability in different time and different climatic situations by a weight coefficient, and the weight coefficient is used to simulate different climatic status also.

Simulations and results

The proposed algorithm is applied on the IEEE-RBTS BUS6 distribution system and its specific parameters can be found in literature [11]. In Fig. 2, two DGs are connected to the buses 22 and 29 with small-capacity power storage devices. In a fault, the loads 14 to 18 and 19 to 23 can be supplied by network that works independently.

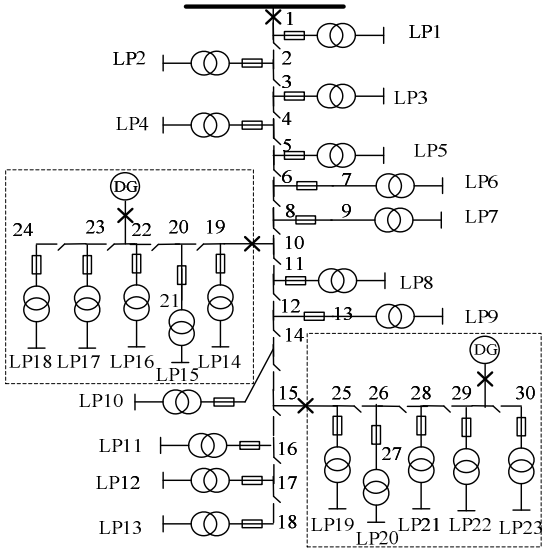

Fig. 2 Case study of IEEE-RBTS BUS6

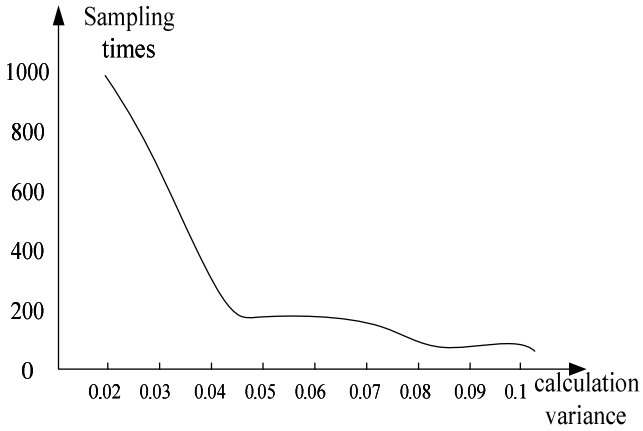

Fig. 3 Sampling occasions curve with Monte Carlo sampling calculation accuracy

Tab. 1 Monte Carlo sampling occasions and assessment results

Sampling times *N*	*LOLP*	Variance of *LOLP*	*AAID* [h]	Variance of *AAID*
200	0.0255	0.0731	4.0261	0.1243
500	0.0262	0.0460	4.1856	0.0611
1000	0.0255	0.0124	4.0197	0.0164
2000	0.0254	0.0103	4.0182	0.0139

The computation example analyzes the convergence and accuracy of this algorithm. Table 1 shows that, with the increase of sampling, the values of *LOLP* and *AAID* respectively converge to 2.54% and 4.01 hours. And the results are of high convergence. By the simulations and analysis, it can be found that the sampling times and accuracy follow inverse relationship as what is seen in Fig.3. In order to make sure the variance of reliability index is small enough, a lot of sampling times are needed.

Although the DG and inverters may increase the probability of system failures due to their own faults, the faults of DG usually don't lead to power interruption of corresponding load. In a fault, as the feeders with DG can work as an island, the probability of power failure on that line becomes lower.

Conclusion

DG has the feature of diversity, intermittent and uncontrollability. What affect the reliability are the type of DG, the modes of connection and control, the climate situation and the automation level of distribution system. For optimal effects, the proposed reliability analysis method for distribution system with DG based on Monte-Carlo Method needs to consider various factors.

Keywords: fixed series compensation(FSC); power flow control in power systems; loss reduction on grids

Abstract. Series compensation can improve the line efficiency significantly, reduce line loss and raise line voltage obviously. The paper introduces the basic principles of series compensation, and studies the influence of series compensation's installation position on compensation effect, the loss reduction effect of series compensation as well as the influence of series compensation on power flow control.

Introduction

Using series compensation in power systems can reduce line impedance, improve reactive equilibrium, enhance the transmission capacity of electric transmission lines, increase the transient stability limit, and improve the load distribution among parallel lines, so as to reduce the loss of lines, make full use of existing power system resources, and promote electric power development. Adopting the capacitors of series compensation can avoid the heavy investment on new-built lines to some extent, so as to obtain a relatively high input-output ratio. Under the circumstance that it becomes more difficult to get a line corridor at present, series compensation will be widely used further.

The Basic Principles of Series Compensation

Applying Series Compensation to Improve the Transient Stability of System

Improving the transient stability of system is one of main reasons for a power system to add series compensation, and its basic principle is to offset the inductive reactance through the capacitive reactance of series capacitor, so as to improve system stability. The schematic diagram of improve system stability is shown as follows:

Figure 2-1

A Two-machine Power System Where System S1 Transmits Power to System S2 Through Long Distance Transmission Lines

The transmitting power of transmission lines between System S1 and System S2 is:

$$P = \frac{E_1 E_2}{X_1} \sin \delta_{12} \tag{2-1}$$

After the devices of series compensation are installed in those lines, the transmitting power of lines changes to:

$$P = \frac{E_1 E_2}{X_1 - X_c} s\text{in}\,\delta_{12} \tag{2-2}$$

For the given node voltage, the transmitting power is in inverse proportion to the line reactance when the phase angle difference is constant, because series compensation reduce the reactance of compensated lines, so as to improve the stability of lines.

Applying Series Compensation to Raise Line Voltage and Reduce Line Loss

Series compensation also can improve the operating voltage of power systems, and reduce line loss. Its principle is shown as follows:

For the π equivalent circuit of lines:

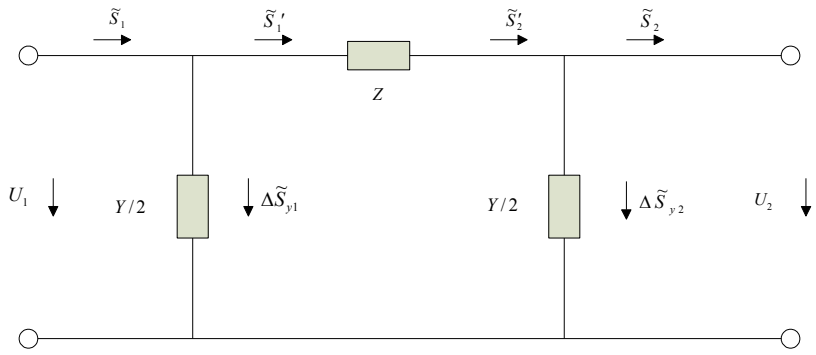

Figure 2-2

The active power loss on the Line Z is

$$\Delta P_z = \frac{P_2'^2 + Q_2'^2}{U_2'^2} R \tag{2-3}$$

The voltage loss is

$$\Delta U = \frac{P_2' R + Q_2' X}{U_2} \tag{2-4}$$

When a series compensation capacitor is added in lines, the inductive reactance of lines will be offset, so its equivalent reactance decreases. Based on the Equation 2-4, it can be found that the voltage loss on lines decreases and the voltage at the terminal of lines raises.

Through analyzing Equation 2-3, it can be found that the active power loss is in inverse proportion to the voltage at the terminal of lines, because the voltage at the terminal of lines goes up, and the active power loss on Line Z goes down with it.

The Control of Series Compensation for Power System Flow

Series compensation controls the flow of power lines through changing the series reactance of transmission lines. The application of series compensation provides people with the approach for optimizing the power flow on specific lines through changing the degree of series compensation, which is also one of considerations when people design series compensation on lines.

We can control power flow through changing the compensation degree of series compensation, so as to minimize the compensation degree of entire system.

See Figure 3-1. Line 1 is an existing line, Line 2 is a new-built line, and the minimum active power loss can be realized through controlling the compensation degree of Line 2.

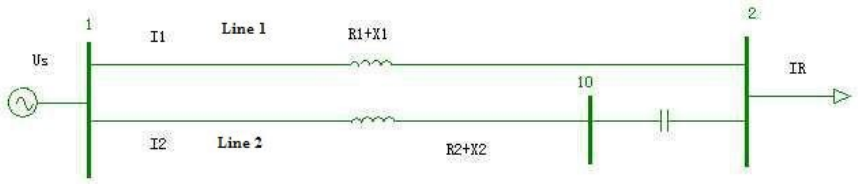

Figure 3-1

The current of two parallel branches is:

$$I_1 = \frac{Z_2}{Z_1 + Z_2} I_R$$
$$I_2 = \frac{Z_1}{Z_1 + Z_2} I_R \tag{3-1}$$

As the function of current at the terminal, the current of Line 1 can be shown as follows:

$$I_1 = \frac{R_2 + jX_2}{(R_1 + R_2) + j(X_1 + X_2)} I_R$$
$$= \frac{[R_2(R_1 + R_2) + X_2(X_1 + X_2)] + j[X_2(R_1 + R_2) - R_2(X_1 + X_2)]}{(R_1 + R_2)^2 + (X_1 + X_2)^2} I_R \tag{3-2}$$

Similarly, the similar result also can be obtained for Line 2.

The total loss of those two lines is:

$$P_L = R_1 I_1^2 + R_2 I_2^2$$
$$= \frac{R_1(R_2^2 + X_2^2) + R_2(R_1^2 + X_1^2)}{(R_1 + R_2)^2 + (X_1 + X_2)^2} I_R^2 \tag{3-3}$$

In order to work out the minimum loss, the equation above is used to take the derivative of Line 2, and then the result is set to zero. The degree of series compensation is not unique, so the reactance is a variable.

$$\frac{dP_L}{dX_L}$$
$$= \frac{2R_1X_2[(R_1 + R_2)^2 + (X_1 + X_2)^2] - 2(X_1 + X_2)[(R_1(R_2^2 + X_2^2) + R_2(R_1^2 + X_1^2)]}{[(R_1 + R_2)^2 + (X_1 + X_2)^2]^2} I_R^2$$
$$= 0 \tag{3-4}$$

The formula is expended and simplified to obtain:

$$\frac{X_2}{R_2} = \frac{X_1}{R_1} \tag{3-5}$$

Therefore, the loss of entire system will be minimum if the two values of impedance are equal, regardless of the resistance of Line 2. Therefore, for the given value, the degree of series compensation can be adjusted to make it match with the original line, so as to guarantee the minimum loss of entire system.

Keywords: peak load regulation mode; nuclear power plant(NPP); coordinated operation

Abstract: Based on extensive research, introduced the peak load regulation characteristics and capacity of different nuclear power plant (NPP) in this paper. The running mode of NPP participating in peak load regulation of power system, combined operation tactics of NPP with other peaking power source and synergistic scheduling of an integrated power generation system with wind, photovoltaic, energy storage unit and NPP were summarized, technology development trend of NPP participating in peak load regulation of power system was analyzed and forecasted.

I. Introduction

The power grid urgently needs a new economic and efficient energy to join. Because of wind power, solar power, tidal power and all kinds of new energy have the problem of large-scale power generation and economy, so accelerate the development of nuclear power has become an inevitable choice to solve the problem of China's power supply. According to the national "long-term nuclear power development plan", the new 30-million-kilowatt nuclear power plant, the total installed capacity of nuclear power reach 58 million kilowatts and 30 million kilowatts under construction in 2020. In the future, nuclear power will become a main power supply and will occupy more and more proportion.

In recent years, the rapid growth of China's electric power load and the gradual wideness of peak -valley difference have brought greater pressure to the power network construction and operation. Due to the growth of the proportion of nuclear power in electric network, power system demands for nuclear power participate in power grid peak shaving is growing. Nuclear power can participate peaking operation, nuclear power peaking operation involved in what manner, the balance of power peaking will be what kind of impact has become a problem requires a high degree of concern. While the new energy in the grid and the rapid growth of network capacity, joint operations and coordination between the various power controls has become a key issue in modern grid operation. Nuclear power plants with other power peak load regulating operation for the joint in the system, the coordination of joint store nuclear power generation system scheduling and intelligent control is the future of NPP to participate in the operation of the technology development direction.

Firstly, the various types of nuclear power load characteristics and load capacity of the unit were introduced in this paper. Secondly, the NPP's operation tactics combined with other peaking power source and synergistic scheduling of an integrated power generation system with wind, photovoltaic, energy storage unit and NPP were summarized. Finally, technology development trend of NPP participating in peak load regulation of power system was analyzed and forecasted.

II. The Situation of NPP Peak Load Regulation

Countries around the world especially focus on the peak load regulation of power grid, since the 1970s, the United States, Germany, France, Japan and other countries have implemented load tracking test and practical operation of pressurized water reactor (PWR), boiling water reactor and the improved thermal reactor nuclear power reactor type [1-5]. Pressurized water reactor more than 40 years of daily load tracking operation experience showed that daily or weekly load tracking has

no adverse effect the performance of the fuel, the circuit of the coolant radioactive concentration not rise, verify the reliability and feasibility of daily load-following operation of PWR [6-9].

Foreign peaking running instance was shown in Tab.1.

Tab.1 Foreign peaking running instance

countries	Type of reactor	summary	Output rate of change in a minute
The US	Pressurized water reactor Boiling water reactor	often implement between 50% to 100% load operation of the output range every day	Around 0.25%-1%
French	Pressurized water reactor	often implement between 40% to 100% load operation of the output range every day	Highest 5%， Usually 3%
Germany	Pressurized water reactor Boiling water reactor	often implement between 50% to 100% load operation of the output range every day	5%-10%

Our country existing nuclear power plants are built in the eastern or southern coastal developed areas, near the load center. Because of east and south China power grid capacity great, nuclear power installed capacity for a small proportion, local power shortage perennial, plan to maximize the power plant unit annual utilization hours, take maximum economic benefit of nuclear power construction, also based on the various consideration of nuclear power plant and power grid safe operation, at present, in addition to the first phase of Qinshan, Dayawan and the first phase of Lingao nuclear power plants in the past two years the Spring Festival, National Day and other special load days down load operation to peak load regulation, other nuclear power plants in any heap shape and size, are not to participate in power grid peak load regulation.

However, as the growth of NPP and increase of peak-valley difference, wind, photovoltaic and other renewable energy, electric power system load situation more and more serious, the domestic many units have been conducted on the feasibility study of nuclear power to participate in power grid peak load regulation [10-12], growing demand for nuclear power plants in power grid peak load regulation.

III. Peak Load Regulation Mode of NPP

Once nuclear power are required to participate in peak shaving, Not only for the safe operation of NPP challenges, but also will have great influence on its economy [8], [13,14]. To alleviate the pressure of the system load, nuclear power plants are usually adopting the following three ways to participate in peak load regulation:

(1) Reasonable arrange the refueling outage time

After running a power generation cycle, nuclear power plants will be offline and the new fuel component replaced spent fuel components. During the refueling time, Nuclear power plants refuel overhaul of plant in order to maintain and improve equipment operating characteristics, to ensure the safety stability of the unit in the next cycle operation. Refueling overhaul of the plants in the winter can improve the operation rate of thermal power plants, the corresponding adjustable power ratio and the load capacity of the system. In this way, nuclear power participation in the system peaking makes its economy influence down to the minimum and easily to implement. It is a commonly used of current scheduling winter peak load regulation.

(2) Load following peaking

① Modern pressurized water reactor could be designed for a larger negative temperature coefficient. When the load increases, the core cools down will automatically increase the power, run and maintain the power levels, improve the ability of nuclear track to unit load, reducing the demand for reactor power regulating system, such as accuracy, etc.;

② In response to the transient changes increase unit margin, on the design of unit, load linear change plus or minus 5% plus or minus 10% Pn/min or step change of Pn cases, one, two loop

safety protection device is not action, rely on the automatic adjustment to keep the unit stable operation;

③ The use of advanced control system and improve nuclear track load capacity. Using reactor and coordinated control of the steam turbine unit make a change, in the secondary circuit working condition, and large disturbance in cases such as the main process parameters of smaller, higher safety margin, fully digital instrument control system, which makes nuclear power units to load change of the parameters in the process of quality control is more ideal.

(3) Compression load operation in special day

In the case of system adjustable power supply dwindling, with power system peak-valley difference increasing, the load demand is more and more serious. If NPP can't peak load regulation, it needs to compression load operation to improve the boot capacity of hydropower and thermal power adjustable power supply in special load day, increase the peak load regulation capacity of the system.

IV. Combined Operation Tactics of NPP and Other Power Source

There are various modern power grid, and it is complementarily between the power on operating characteristics. Based on operating characteristics various power supply, considering the security constraints and system operating constraints of various power supply, order to safe and economic operation of the grid, we can combine to determine the power peaking mode of operation and coordinated control strategy through optimization methods.

A. NPP Directly Involved in the Daily Load Peaking Regulation

Modern Nuclear power plant have a excellent load following capability, but considering the safety of nuclear power itself and peaking speed and depth limit of NPP, the PWR nuclear power plant generally take "12-3-6-3" mode of power regulation, as shown in fig.1.

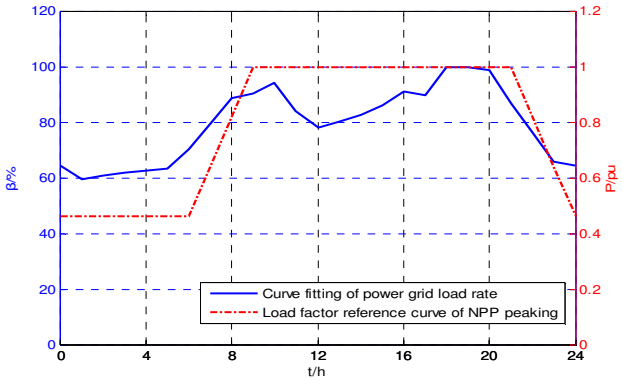

Fig.1 Mode of NPP participating in peak load regulation of power grid

The mode of power regulation of NPP in fig.1 can meet the requirements of peak load following, more in line with the trend of power grid load, the depth and speed of power regulation meet the constraints of NPP, actually it should order to the actual operation of NPP as a reference to determine the depth and speed of peak load regulation.

B. Combined Operation of NPP, Hydropower and Thermal Power

Hydropower, thermal power coordination and joint optimization of operation of nuclear power is a hot issue at home and abroad in recent years. The traditional short-term optimal operation of hydro-thermal model of the joint is usually simple to system operating costs a minimum of the objective function, to determine a certain period of time hydropower, thermal power joint power generation plan of the unit. However, a variety of joint supply planning to introduce nuclear energy structure after it is transformed into a high dimension, nonlinear, multi-constraint multi-objective optimization problem, it consider more factors, system load demand, spinning reserve, the unit output nonlinear characteristics, unit start-stop frequency and duration, flow, output and storage

constraints, the views of experts and decision-makers, and so generally include, It is a large-scale, mixed integer optimization problems.

NPP, hydropower and thermal power combined operation reasonable load distribution shall be: First let's hydropower bring the peak load of the power system, NPP bring the base-load, thermal power balance the load-left, if thermal power does not meet the speed range of the motor group climbing, we will change the power regulation mode of NPP based on thermal power ramp rate and the remaining load characteristics, determine the depth and mode of nuclear power peak load regulation. This will not only avoid abandoned water peaking of hydropower, but also ensures that the thermal power run the optimal regulation.

C. Combined Operation of NPP and New Energy Unit

(1) Combined operation of NPP and Pumped storage power plant

Pumped-storage plant has two major characteristics [15, 16]: Flexibility to switch between power generation and consumption for power system reduces the gap between peaks and troughs and double peaking capacity; the plant starts fast, flexible, reliable and able to respond quickly to changes in network load. It can assume the grid frequency, phase modulation, emergency reserve, black start and so on.

The paper [17] has analyzed the issue of nuclear power and pumped storage plants participating in jointly power peaking. According to the operating characteristics of pumped storage plants, three models of nuclear power and pumped storage power joint peaking were presented: complete tracking mode, three sections of the system tracking mode and incomplete tracking mode. Through simulation analysis proved that nuclear power and pumped storage plants jointly run power peaking can satisfy the requirements, and ensured the safe operation of nuclear power plants with base-load, with high economy.

(2) Combined operation of NPP, wind power, photovoltaic and energy storage unit

Currently, there are many studies on wind power, photovoltaic power generation and energy storage technologies [18-20], unlike conventional power, wind power and photovoltaic power generation has random, volatility and intermittent characteristics. In addition, the technical bottleneck of forecasts, scheduling and control made it different from conventional power in independent source of power generation characteristics and network coordination compared with. When wind power, photovoltaic power generation and other large-scale renewable energy power system access to power system, the traditional plant’s ramp rate often do not meet the requirements of dramatically and power fluctuations of short duration caused by renewable energy. Joint operation of wind, photovoltaic, energy storage plants and NPP can effectively weaken the fluctuations caused by wind power and photovoltaic power generation with alleviated stress of power peaking.

For example, a region’s power system contained nuclear power, wind power, photovoltaic power generation and energy storage power station. The four forms Combined to track grid load. During the day the wind power generating capacity is usually small, and the large amount of photovoltaic power generation. To ensure the operation of photovoltaic full generation power with base-load，the nuclear power should be adjusted according to changes of photovoltaic. When photovoltaic generation in large, the nuclear power will properly reduce operating. Energy storage units store energy in the load trough. Photovoltaic power plants do not generate electricity at night, but wind power is sufficient and volatile. The nuclear power should be adjusted according to changes of wind power. Storage or generation of energy storage power station needs to be based on load conditions.

V. Conclusion

Nuclear power load for optimizing the power structure, speed up the non-fossil energy alternatives to fossil energy has the effect that cannot replace. NPP has larger peak shaving depth and load capacity, can assist to complete the grid load demand. the peak shaving benefits include:

(1) To improve the safety margin of the power system operation and scheduling flexibility, better adapt to all kinds of uncertainty factors;

(2) To reduce the thermal power load pressure; Drop the thermal power key; Bring down the high cost of fuel gas and fuel power generate operation cost;

(3) To improve clean energy such as wind power and photovoltaic power generation access scale and efficiency.

Based on the analyze of all kinds of nuclear power peaking capacity and regulating mode , the NPP's operation with other peaking power source and synergistic scheduling of an integrated power generation system with wind, photovoltaic, energy storage unit were summarized. Provides a reference for future nuclear power peaking. Joint operations and coordination between various power control is to ensure grid security, stability and economic operation.

An Empirical Analysis on Guangdong's FDI, Energy Intensity and Industrialization

Xin-lin Liao

School of Economics and Management, Wuhan University, Wuhan, China

2602882823@qq.com

Keywords: FDI, energy Intensity, industrialization, Guangdong

Abstract. Energy is the base of modern industrial economy. Basing on the data of cities and industries in Guangdong from 2000 to 2013, this paper analyzes the relationship of energy intensity, FDI and industrialization by regression model. The results show that the industrialization levels of the cities in Guangdong are in accordance with their energy consumption and economic conditions, and Guangdong should focus on the development of "win-win" industries which both increasing industrial output and reducing energy efficiency.

Introduction

Guangdong's industrialization has made great progress and its energy industry has also witnessed rapid growth since the reform and opening-up policy was introduced. With the rapid industrialization and urbanization, the high energy-intensive industries has accounted for a big proportion in Guangdong.

Many scholars have given sustained attention to China and Guangdong's energy and industrialization, a brief literature review as follows. He and Zhang(2005) insisted that the main reason for the rise of energy intensity in recent years in China was the rapidly development of industry, especially heavy chemical industry, which leading to massive increase in industry energy consumption[1]. Fisher-Vanden(2006) found that production structure changes was one of the major factors for the decline of energy efficiency in China[2]. Hu and Wang(2006) analyzed the energy efficiencies of 29 administrative regions in China for the period 1995–2002. By the data envelopment analysis (DEA), they tried to find energy input of each region in China, and insisted that the energy efficiency in China would eventually improve [3].

Yu(2007)pointed out that Guangdong was the lowest province of unit GDP energy consumption in China, and the main driving force for the decrease of Guangdong's energy intensity comes from the improvement of industry energy efficiency. He suggested that Guangdong should move on to adjust and optimize the industrial structure, raise the energy-saving technological and improve the industrial energy efficiency [4]. Zhang(2010) employed the panel data of 30 provinces, cities and autonomous regions in China and by the SFA method to compare the energy efficiency, industrial structure and development gap of them from 1990 to 2008. The conclusion was that the energy efficiency of the eastern region is the first, the middle region is the second, and the western region is the third. He insisted that more attention should be paid to optimize the industrial structure [5]. Zhu, Cao and Luo(2013) suggested that the evolution of the industrial structure is one of the important factors to affect energy efficiency, and China economy would rely on extensive and high energy consumption in a long time[6].

Empirical Analysis

Set of Model. The empirical analysis of this paper bases on the panel data of the 21 Guangdong cities' industries from 2000 to 2013. First, I divide the Guangdong 21 cities into four economic regions, named the Pearl River Delta, the east wing, the west wing and the mountain area. Among them, the Pearl River Delta includes Guangzhou, Shenzhen, Zhuhai, Jiangmen, Dongguan, Foshan, Zhongshan, Huizhou and Zhao Qing; the east wing includes Shantou, Shanwei, Chaozhou and

Jieyang; the west wing includes Zhanjiang, Maoming and Yangjiang and the mountain area includes Shaoguan, Heyuan, Meizhou, Qingyuan and Yunfu.

Then I select 36 representative industrial sub-sectors which as follows: universal equipment manufacturing industry, oil and gas mining industry, transportation equipment manufacturing industry, tobacco manufacturing industry, recycling and disposal of waste industry, instrumentation and culture, electrical machinery and equipment manufacturing industry, office equipment manufacturing industry, pharmaceuticals manufacturing industry, garments, shoes, special equipment manufacturing industry, caps manufacturing industry, beverage manufacturing industry, leather, furs, feathers manufacturing industry, food manufacturing industry, handicrafts Manufacturing industry, nonferrous metals mining industry, ferrous metals mining and extraction industry, furniture manufacturing industry, printing and copying industry, sporting articles manufacturing industry, metal products industry, chemical raw materials manufacturing industry, nonmetal mineral mining and extraction industry, plastic products industry, nonferrous metals smelting and rolling processing industry, agro-food processing industry, wood, bamboo, timber processing industry, rubber products industry, chemical fiber manufacturing industry, water processing and supplying industry, hot power producing and supplying industry, papermaking and paper products industry, oil processing, textiles industry, electric power, coking and nuclear fuel processing industry, nonmetal mineral products industry, gas producing and supplying industry, ferrous metals smelting and rolling processing industry.

In terms of analysis method, first is the test and regression of the four economic regions, then to synthetically study the regression results. The data come from the Guangdong Statistical Yearbook, all the analysis will be done with the help of Eviews6.0.

I established a logarithmic model which taking energy intensity as dependent variable, FDI and industrialization index as independent variables.

$$\ln EI_{it} = \alpha_i + \beta_i \ln FDI_{it} + \gamma_i \ln IND_{it} + \delta_i \ln ING_{it} + \varepsilon_{it} \quad (1)$$

Among them, EI, FDI and IND respectively represent the energy intensity, the foreign direct investment and the industrial coefficient, in which the unit GDP energy consumption indicates the EI, the value-added of foreign-funded industrial enterprises above designated size indicates the FDI and the per capita GDP indicates the IND. In addition, I take the industrial structure variable as control variables. The industrial structure represented by the proportion of industrial added value and GDP (ING). The subscript *i* and *t* respectively represent the city and the time, *e* as a random disturbance term.

Type and Test of Model. First is the Hausman test. The Hausman test can be used to determine that, the fixed effect model and random effect model, which should be employed. The Hausman test results show that all the test coefficients of the four regions were less than 0.05 probability, therefore, the null hypothesis were rejected at 5% significance level, so I may conclude that the fixed effects model is better than the random effect model in this paper and the fixed effects model should be adopted. In econometrics and statistics, a fixed effects model is a statistical model that represents the observed quantities in terms of explanatory variables that are treated as if the quantities were non-random. Then with the help of the F test, I can determine which kind of the fixed effect models should be adopted. Take the Pearl River delta as example.

$$F=\frac{(SSE_r - SSE_u)/(N-1)}{SSE_u/(NT-N-1)}=\frac{(16.52565-0.318422)/(9-1)}{0.318422/(9\times 9-9-1)}=452.21 \quad (2)$$

Because $F=452.21 > F_{0.05}(8,71)=2.08$, therefore, reject the null hypothesis, an individual fixed effects model should be established. With the same method, I get the F values (19.76, 275.96 and 83.24) of the other three regions. Such results tell us that all the null hypothesis of the four regions should be refused, and the fixed effects model should be adopted.

The unit root test is the standard method of statistical sequence equilibrium. In order to avoid the negative effects of the unit root test method and its test results, the unit root test of this paper will use three kinds of methods, named LLC, Fisher-ADF and Fisher-PP. The test results of the Pearl River Delta region show that lnEI, lnFDI, lnIND and lnING not reject the null hypothesis of unit root, all of

them are random processes of unit root. Adopting the same method of unit root test to the other three regions, I find the results are same. The result of unit root tests in Table 1. The cointegration test results of the four regions show that their residual series are stable, and reject the null hypothesis of no cointegration relationship.

Table 1 The results of unit root test

Variables	Level value			Variables	Second order differential value		
	LLC test	MW test	PP test		LLC test	MW test	PP test
lnEI	-39.392 (0.000)*	59.094 (0.041)**	88.549 (0.000)*	lnEI	-452.815 (0.000)*	174.410 (0.000)*	172.936 (0.000)*

Regress Results. The regress results of the four regions of Guangdong in Table 2. As shown in Table 2, all the estimated values of all coefficients belong to the state of significant in the level of 1%, 5% or 10%, and the T values pass the test. The fitting is high, and the explanatory ability of the model is strong. In a word, there is the long-term relationship between the variables of the model.

Conclusion

Table 2 shows that, to the four regions in Guangdong, all the regress coefficients of industrialization index variables are negative, what suggesting that their industrialization index were inversely proportional to their energy intensity, and their energy intensity constantly lower with the progress of industrialization. The regress coefficients of the industrial added value proportion and the FDI are positive, what means that the energy intensity would increase with the increase of the proportion and the total volume. The Pearl River Delta region, for example, has the highest industrial index regression coefficient and the lowest industrial added value proportion regression coefficient, which indicating that its energy utilization efficiency is the highest across Guangdong. The regress result tell us that, as the most developed region in Guangdong, the industrial structure of the Pearl River Delta is also the most conducive to reducing energy intensity.

At the same time, the FDI regress coefficient of the Pearl River Delta is the highest, what means that its foreign-funded industrial enterprises above designated size have relied too much on high energy consumption industries and products. According to the regress coefficients of the other three regions, their industrialization levels in accordance with their resource endowment and economic conditions. In the aspect of reducing energy intensity, the Pearl River Delta and the other three regions have theirs relative merits, should learn from each other.

Keywords: power load classification; subtractive clustering; fuzzy C-means algorithm(FCM).

Abstract：FCM is used in many power load classification currently, but it also has some shortcomings. This paper give an algorithm based on Subtractive Clustering and improved Fuzzy C-means Clustering (SUB-FCM) to solve this problem. This algorithm use subtractive clustering to initialize the cluster center matrix, solve the random initialization of FCM, and improve the global search ability, avoid falling into local optima. Experimental analysis found this algorithm also could accelerate the convergence speed, and has better clustering results. It can be applied to power load classification effectively.

Introduction

With the deepening of the electric power system reform and the economics of electric power development, the trend of the future is to establish a categorized time-of-use(TOU) power price. It will help to develop the peak shaving capability of the user[1], and optimize the configuration of the electric power resource. Categorized TOU power price means to develop different TOU power price for different load characteristics of power users[2], so it has to classify the load characteristics. The so-called load characteristic classification is merge consolidated load in the same power network which have similar load characteristics into one class. And the key is the choice of load characteristics and the classification method[3].

In the early 1990s, british scholars began to study the load classification problem to develop a reasonable pricing scheme[4].Since then, the study of load

classification method is more and more deeply, and the clustering analysis method occupy the dominant position. Compared with system clustering, K-means clustering algorithm[5], clustering algorithm using the SOM neural network[6], clustering analysis based on ant colony optimization algorithm[7], fuzzy C-means clustering(FCM)[8] introduced a membership function for dividing the data softly. The method can reflect the clustering results more objectively, therefore, it is widely used in electric power load characteristics category. Literature [9] study the real power data classification using FCM and clustering validity function. But FCM is a local search algorithm, it is sensitive to initial value, easy to get the local optimal solution, and the clustering number is difficult to be identified. In order to solve this problem, literature [10] took the hypothesis testing method to determine the clustering number, but this method is very tedious and the calculation speed is very slow. Literature [11] put forward a simulated annealing genetic algorithm based fuzzy C-means (SAGA-FCM) to improve the global search ability, but it still failed to select the initial parameters. Literature [12] proposed an improved algorithm based on differential evolution (DE) adaptive optimization to reduce the dependence on initial value.

In view of this, the paper put forward an improved FCM algorithm based on subtractive clustering (SUB-FCM)[13] to application for load classification under the background of the smart grid. Subtraction clustering provides a new way to solve the problem of the FCM initial value. Find the initial clustering center with subtraction clustering before using FCM, can avoid falling into local optimal solution, improve the clustering speed, and generate a better clustering number automatically.

Algorithm description and improvement strategy

FCM Algorithm. In 1981, Jim Bezdek proposed FCM, the core idea is to determine the extent of each data point belongs to a cluster with membership[14]. Randomly selected a cluster center number first, and then calculate the optimal cluster center by iteration, make the weighted squared error function from each sample to each cluster center in a class reaches a minimum.

FCM divides the n data vectors $x_i(i = 1,2,\dots,n)$ into c fuzzy groups, if sample sets for U, cluster center for V, so the objective function can be expressed as:

$$\min J_m(U,V) = \sum_{k=1}^{n}\sum_{i=1}^{c}(u_{ik})^m (d_{ik})^2 \tag{1}$$

where m is the fuzzy factor which is used to control the degree of sharing between fuzzy classes. u_{ik} is the degree of membership about the kth data in the ith cluster and it satisfied: $d_{ik} = \|x_k - v_i\|$ is the distance about the kth data to the ith cluster center v_i.

Update the iterative center and membership according to the formula (3) and (4) after the end of each iteration process.

$$v_i^{(r+1)} = \frac{\sum_{k=1}^{n}(u_{ik}^{(r)})^m x_k}{\sum_{k=1}^{n}(u_{ik}^{(r)})^m}, \quad u_{ik}^{(r+1)} = \frac{1}{\sum_{j=1}^{c}(d_{ik}^{(r)}/d_{jk}^{(r)})^{\frac{2}{m-1}}} \tag{2}$$

where r is the iterations number; For a given threshold ρ, if $\left|J^{(r+1)} - J^{(r)}\right| < \rho$, then stop the clustering process. Otherwise, continue iterating until the stop condition is met.

Subtractive Clustering Algorithm. Subtractive clustering method put all sample data as the candidate cluster center point, it's more quick and independent. It is a simple linear relationship with the calculation amount and the number of sample data, and has nothing to do with the dimensions of the problem under consideration[13].

Consider the n data points $x_i(i = 1,2,\dots,n)$ in M dimensional space, then the steps[15] are as follows:

(1)Calculate the density of all data points x_i:

$$D_i = \sum_{j}^{n} exp\left[-\frac{\|x_i - x_j\|^2}{(0.5r_a)^2}\right] \tag{3}$$

where r_a is a positive number which defines the point's radius, and the contribution of the data points outside the radius to the density index is very small, take $ra = \frac{1}{2}\min_k\left\{\max_i\left\{\|x_i - x_k\|\right\}\right\}$. Choose the data point with the highest density as the first cluster center, make x_{c1} for the selected points, D_{c1} for its density index.

(2)Fixed the density indicator of each data point according to the kth cluster center:

$$D_i = D_i - D_{ck} exp\left[-\frac{\|x_j - x_{ck}\|^2}{(0.5r_b)^2}\right] \tag{4}$$

where r_b is a positive number, defines a area its density index function reduced significantly. In order to avoid cluster centers are too close, take $r_b = 1.2r_a$.Choose the data point x_{ck+1} with the highest density as a new cluster center.

(3)Exit condition:

$$\frac{D_{ck+1}}{D_{c1}} < \delta \tag{5}$$

if the condition is not hold, then go to step (2). Where $\delta < 1$ is a given parameter that determines the final number of initialized cluster center, smaller δ cause more cluster number.

An Improved FCM Algorithm Based on Subtractive Clustering. Subtractive clustering can select cluster center according to the density index directly. Subtractive clustering and FCM

combines in this paper, use the result of subtractive clustering as the initial cluster center of FCM, ensure that the final result is a global optimal clustering solution.

Using subtractive clustering, the order of the cluster center is determined by the density index, the data point with the higher density will appear earlier, and it will be more likely the reasonable improved initial cluster center. Therefore, when the cluster number is c, just use former cluster center generated by subtractive clustering as the new initial center, thus improve the efficiency of clustering. Flowchart of SUB-FCM is as follows:

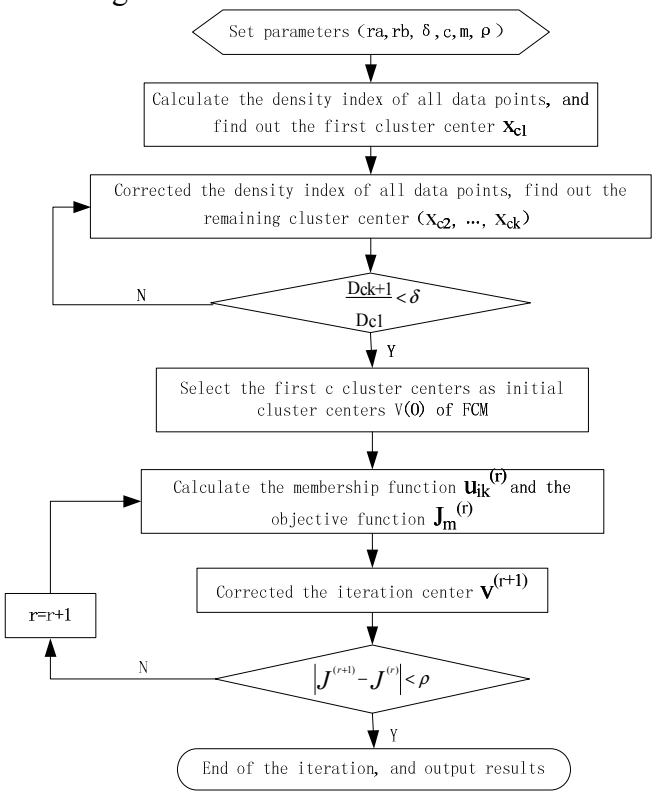

Fig 1. Flowchart of SUB-FCM

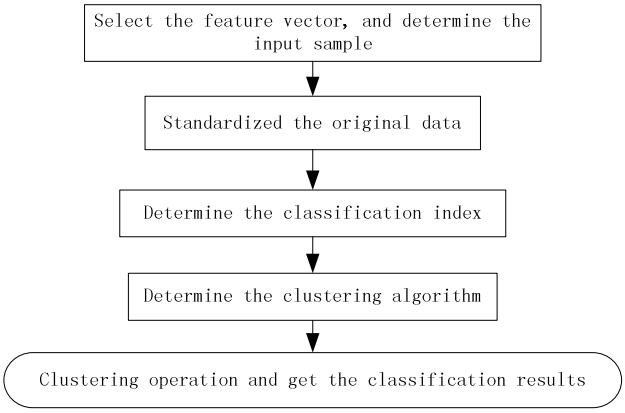

Fig 2. Model of load characteristics classification

Power load classification based on SUB-FCM

Model of Power Load Characteristics Classification. Load characteristics classification is that analysis the same or similar load samples in essentially, it is the basis of the power system planning, peak management, TOU electricity price and load forecasting. Its model is shown as Figure 2.

In order to get a good classification results, the selection of feature vector in the model should be able to reflect the essential characteristics of an object. In engineering practice, generally use run or time feature vector. In addition, raw data should be standardized before clustering calculation, in order to avoid the impact of different units and magnitude of the original data. Generally, range normalization method can be dealed with it. And the main classification indicators are description, comparison and curve. Finally, choose a suitable clustering algorithm to classify.

The Practical Problems of SUB-FCM.

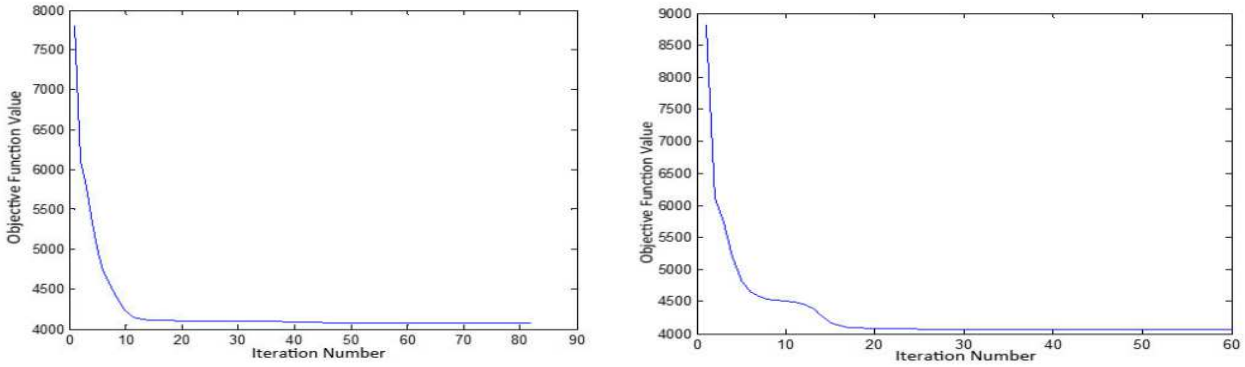
(1) c is the clustering number, namely the cluster validity problem. The optimal clustering number can be determined through effective calculation, to ensure the minimal compactness and the maximum separation.

(2)The determination of other parameters. The selection of the best fuzzy weighted index m is lack of theoretical guidance currently. The larger m lead to more fuzzy result, so the value of m should not be too large. So this paper take $m = 2$, and the neighborhood $r_a = 0.5, r_b = 0.6$ cause the larger r_a, r_b lead to less clustering number. And proportion parameter $\delta = 0.5$, allow the minimum error $\rho = 1e-5$, the maximum iteration number is 100.

Analysis of examples

The paper take consolidated load characteristic data of substations in a grid somewhere to carry out the analysis of examples, and the results were compared with the traditional FCM. The original data from six major industries which are electricity typical users of, and it has been standardized. The optimal clustering number is known as $c = 7$ [11].

Search Strategy Comparison.



(a)FCM (b)SUB-FCM

Fig 3. Evolution curve of objective function values

Comparing figure 3(a) and (b), it can be seen that the evolution curve of objective function value of the traditional FCM is smoother, it means its easy to fall into local optimal solution. And the evolution curve of SUB-FCM appeared obvious repeated, which can avoid local minimum convergence result effectively.

From the search speed, the FCM have the final result after iteration 83 times, while the SUB-FCM only need 60 times. It shows that SUB-FCM requires less iterations, and can improve the search speed.

In addition, the objective function value of FCM eventually converge to 4098.5162, and the SUB-FCM converge to 4068.3601. The optimal solution of SUB-FCM is less than FCM, shows that the SUB-FCM has better clustering results.

Clustering Effect Comparison. Cluster validity problem is about whether the fuzzy clustering results are reasonable, and now many functions have been proposed for testing the clustering validity. A good classification requires smaller intra-class compactness and larger between-class separability.

Using cluster validity function v_{XB} [17] proposed by Xie and Beni, and v_{FP} [18] proposed by Fan Jiulun which is based on the probability distribution to test the validity of the results. Under the same clustering number, the value of v_{XB} and v_{FP} should as small as possible.

Table 1. Results of validity assessment

Algorithm	v_{XB}	v_{FP}
FCM	0.2991	0.0018
SUB-FCM	0.1551	0.0014

As can be seen from Tab.1, both v_{XB} and v_{FP} of SUB-FCM are smaller than FCM. It means that SUB-FCM is better than FCM in the same clustering number.

Performance Analysis of Algorithms When *c* Changes. Clustering number c has a great influence on the clustering results. Generally, FCM needs to determine the optimal clustering number by validity functions in advance. The optimal clustering number is $c = 7$ in this paper, and SUB-FCM with subtraction clustering determines $c = 17$ automatically.

Analysis the performance of algorithms by comparing the objective function values and iteration numbers under different value of c. Considering the random initialization of FCM, the following experiments using the average of 10 simulation results for FCM.

When the clustering number is close to the optimal clustering number, the result of two algorithms are basically the same in the case of FCM does not fall into local convergence. With the increase of clustering number, the objective function value of SUB-FCM is smaller than FCM, and it shows that SUB-FCM has better results. Cause the optimal clustering number is unknown in most cases, so use SUB-FCM can get the clustering number directly, and better clustering results.

The iteration numbers of SUB-FCM is always less than FCM, no matter how the clustering number changes. When dealing with complex issues and large amount of calculation, SUB-FCM can improve the computing speed effectively.

Epilogue

This paper apply an algorithm based on Subtractive Clustering and improved Fuzzy C-means Clustering (SUB-FCM) to the power load classification. The algorithm use subtractive clustering to find the initial clustering center, and solve the random initialization of FCM effectively. In addition, the experiment shows that the algorithm can avoid falling into local optima, improve the convergence speed, and has better clustering results.

Keywords: Energy Management; Eco-industrial Symbiosis Network; Cooperation Performance; Structural Equation Modeling

Abstract. With the rapid development of economy and technology, enterprises in eco-industrial symbiosis network (EISN) are facing enormous challenges. However, the emergence and development of EISN is closely tied with the energy management in eco-industrial park (EIP). This paper takes institution construction, allocation and new technology of energy management, cooperation performance and long-term cooperation relationship into research and develops a theoretical model of energy management accordingly. We conduct statistical analysis and Structural Equation Modeling using SPSS17.0 and AMOS17.0 based on 241 valid questionnaires from the EISN enterprise managers. The findings indicate institution, allocation and new technology are significantly positively related to cooperation performance, and cooperation performance has positive significant influence on long-term cooperation relationship. Based on the above results, the relative strategies and suggestions of strengthening energy management to enhance cooperation performance are given.

Introduction

At present, to deal with environment pollution, nations around the world are actively promoting Eco-industrial Park (EIP). Eco-industrial symbiosis network (EISN) as the core organization of EIP discards the higher consumption and waste in traditional way, achieves material recycling, reduces the energy consumption and obtains both economic and environmental benefit [1]. Eco-industrial symbiosis network (EISN) is a special organization of industry. It arouses scholars' research interests, and they explain the competitive advantages of EISN from economic, social and environmental aspects[2, 3, 4]. However, the emergence and development of EISN is closely tied with the energy management in eco-industrial park (EIP).

Wang[5] thinks the level of energy management and energy efficiency is important for the development of enterprises. AN[6] puts out that Study on global energy management system by its mode and feature is helpful to accelerate China's energy reform and to optimize laws, policies, and organizations and function division. Taking this as point, we conduct statistical analysis and develop a theoretical model of energy management. Based on the above results, we put forward the relative strategies and suggestions of enhancing energy management to achieve long-term corporation and play full competition advantages of the whole EIP.

Literature References and Empirical Research

The institution construction is the important basis and safeguard to establish the stable cooperation relation[7]. Between the cooperative enterprises establishing the stable restriction and incentives can limit the cooperation into eligible scope and effectively reduce the energy waste, finally achieve the expected performance of cooperation.

To sum up, this paper generates following hypothesis:

H1: The institution construction of energy management has a positive effect on cooperation performance.

The companies in network points conduct energy allocation by information and technology interaction. The more equal allocation in interaction, the better benefit and cooperation companies can get. To sum up, this paper generates following hypothesis:

H2: The allocation of energy management has a positive effect on cooperation performance.

New technology brings new impetus for enterprises, decrease energy consumption, reduce the cost of cooperation and achieve the desired performance. To sum up, this paper generates following hypothesis:

H3: The new technology of energy management has a positive effect on cooperation performance.

Cooperation is a forecast of the future, there is a big uncertainty. Reasonable energy management makes their relations more closely. The more effective energy management is, the less the conflict exists in cooperation and the higher satisfaction it has, finally, the cooperation will be more effective. To sum up, this paper generates following hypothesis:

H4: The cooperation performance has a positive effect on long-term cooperation relationship.

Based on the above, the theoretical model is shown in Figure 1:

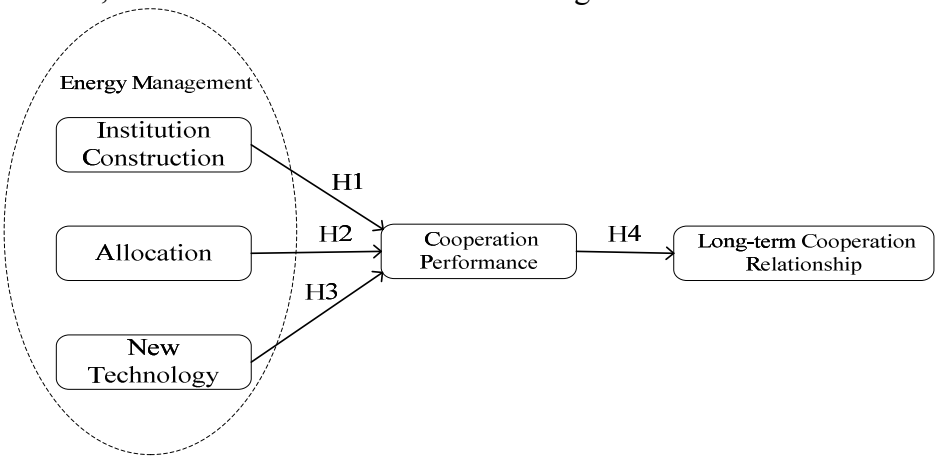

Figure 1 Theoretical Model

This paper uses the questionnaire method and measurement scale should try to come from the improved ones. Finally it has 7 items about institution construction, 9 items about allocation, 5 items about new technology, 4 items about cooperation performance and 4 items about long-term cooperation relationship. It uses Likert-type scale with the score 1 to 5 which represents "perfectly unfitted" to "perfectly fitted". In this paper, the questionnaires get recovered by direct distribution and Email which sends 300 questionnaires and totally retrieve s 172 questionnaires and effective questionnaire returns-ratio is 85.3%. Finally, excluding the incomplete ones, there were 241 valid questionnaires. The sample statistics information of valid questionnaires is shown in Table.1:

Table 1 Sample Statistics Information

	Variable	Frequency /Person	Percentage/%
Gender	Male	116	0.48
	Female	125	0.52
Age	Under 20	0	0
	20-30	99	0.41
	30-40	51	0.21
	40-50	43	0.18
	50-60	48	0.20
	Over 60	0	0
Unit Property	Private Companies	77	0.32
	State-owned Companies	65	0.27
	Colleges	77	0.32
	Other	22	0.09

Cronbach's alpha, exploratory factor analysis and confirmatory factor analysis were performed by SPSS17.0 during the study to test the reliability and validity of the scale, and Cronbach's alpha is shown in Table.2.

Table 2 Cronbach's Alpha

Variable	Number	Cronbach's Alpha
Institution Construction	7	0.819
Allocation	9	0.866
New Technology	5	0.760
Cooperation Performance	4	0.872
Long-term Cooperation Relationship	4	0.755

The analysis showed that every Cronbach's alpha was greater than 0.7, which indicated a higher reliability of the scale, and the reliability could be accepted.

To test the validity of questionnaire, we measured goodness-of-fit of relevant data using AOMS17.0. The relevant indicators, ideal values and acceptable values are shown in Table.3. It can be seen from the table that X^2/df, GFI, AGFI, CFI, NFI, RMSEA and RMR are in an acceptable range, illustrating the higher degree of fitting between the model and data and the better convergence of variables in the model.

Table 3 Fit Results of Validity

	Ideal Level	Acceptable Level	Institution Construction	Allocation	New Technology	Cooperation Performance	Long-term Cooperation Relationship
X^2/df	≤2.00	≤3.00	1.425	1.815	1.850	3.073	1.280
GFI	≥0.90	≥0.80	0.978	0.966	0.982	0.994	0.992
AGFI	≥0.90	≥0.80	0.932	0.903	0.934	0.937	0.960
CFI	≥0.90	≥0.80	0.992	0.977	0.977	0.996	0.999
NFI	≥0.90	≥0.80	0.974	0.952	0.953	0.931	0.994
RMR	≤0.05	≤0.08	0.024	0.025	0.027	0.008	0.015
RMSEA	≤0.05	≤0.08	0.052	0.072	0.073	0.093	0.042

For more in-depth analysis of the relationships between variables in research model, we gave the model further analysis and comparison, and got the model's path coefficients table and the latent variables' path coefficients table by using AMOS software. In this paper, the path coefficients are standardized, and the larger the coefficient is, the more important variable of the path relationship becomes.

Table 4 Path Coefficient between Latent Variable

Path Coefficient	Path coefficient	P value	Result
Institution Construction→Cooperation Performance	0.190	**	H1 Tenable
Allocation→Cooperation Performance	0.336	***	H2 Tenable
New Technology→Cooperation Performance	0.016	***	H3 Tenable
Cooperation Performance→Long-term Cooperation Relationship	0.464	***	H4 Tenable

*p 0.05 ** p 0.01 *** p 0.001

From the Table.4, institution construction, allocation and new technology are significantly positively related to cooperation performance, which means H1, H2 and H3 are tenable. And cooperation performance has positive significant influence on long-term cooperation relationship, which means H4 is H4. However, the path coefficient between new technology and cooperation performance is just 0.016, which indicates that this factor has negligible impact on cooperation performance.

Summary

This paper, from the view point of institution construction, allocation and new technology about energy management, discusses its facilitating roles to promote the cooperation performance in EISN. It can be used as a reference for the management in EISN; in the meantime, we have some experience to following:

(1) Correctly handle the energy management relationship between institution construction, allocation and new technology.

Firstly, institution construction is the basis and assurance in setting up collaboration between EISN companies. But, because of the complex in EISN, too much institution can hinder cooperation activities. Only with the better energy management between allocation and new technology, it can get satisfactory results.

(2) Pay careful attention to energy management, because cooperative relations in EISN is episodic.

The managers in EISN enterprises should do a good job for preventing and eliminating the undesirable energy management that might appear. In a poorly mismanaged energy, it is impossible to produce high quality cooperation performance and long-term cooperation intention between EISN enterprises, and is unlikely to get any success from development. Therefore, the terrible energy management in EISN is the key barrier to interrupt enterprises cooperation activities.

Keywords: insulation breakdown, arc suppression coil, oil chromatography, infrared detection

Abstract. Through the analysis of 66kV arc suppression coil smoke accident in Fushun Zhong Zhai 220kV substation,scientifically pointed out that the accident was due to leave hidden trouble in the process of design and manufacture of cause.This paper introduces the working principle of arc suppression coil and use value, and cites several reasons can cause arc suppression coil accidents.This paper introduces in detail the whole process of hoisting core checks after the accident in Liao Ning Yongtai Transformer Manufacturing Co., Ltd,and carefully check the chromatography test data and the operation report before and after the accident, proveing the results of the analysis of the accident is correct.

Introduction

In the 66kV system,due to large capacitive current ,if the neutral is not grounded,when the single-phase grounding fault happens, will cause throughout the whole system of arc grounding overvoltage, also known as intermittent arc grounding overvoltage.If measures are not taken, will pose a great threat to low insulation equipment and insulation weakness in the system.In the current 66kV systerm,in order to reduce the grounding current,most of the neutral point grounding by arc suppression coil[1-3].

Arc suppression coil is actually a adjustable inductance L ,which is equipped with air gap iron core.Arc suppression coil is connected between the neutral point and the ground.When single-phase grounding happened , the arc suppression coil can produce inductive current offset fault current(or capacitive current).This current can greatly reduce the single-phase grounding current,and it can avoid the arc grounding over voltage [4,5].

The reason of arc suppression coil accident

The arc suppression coil accident has a very close relationship with the faults or abnormal operating condition in the system.When the grid is normal,the voltage effect on arc suppression coil only a low displacement voltage of neutral point.So,only a small current through the arc suppression coil.Only when the single phase to ground fault occurs in the system,or the serious asymmetry,arc suppression coil will generate a larger compensation current.Therefore,arc suppression coil is generally only in the system grounding, disconnection and three-phase asymmetry, a larger current long time through, could have serious internal fault.The reasons of arc suppression coil accident are following:a,resonance overvoltage;b,overcurrent;c,the lack of oil;d,design and manufacturing processes that do not meet the requirements.

The analysis of 66kV arc suppression coil smoke accident in Fushun Zhong Zhai 220kV substation.

(1) The accident survey

On October 22,6:50,the monitoring system display the occurrence of C phase grounding fault.A three-sect currentt protection of Qingliu line of Qingyuan 66kV substation tripped immediately,distance protection and reclosing no action(third segment protection tripped,locking

the reclosing;the phase to phase fault was derived from the single-phase grounding fault through the transition resistance,the large ground transition resistance beyond the scope of protection of the three-step distance relays,the protection device was not acted,after the inspection results show that action was right),the grounding systerm was disappered.Er Daogou 66kV substation,Liu huatie 66kV substation,Gao Jiajie 66kV substation and Xia Jiapu 66kV substation,this four substations in the Qingliu line were power cut.Through inspection ,the equipments in Qingyuan substation were all right.The dispatcher ordered operated the 66 kV Qingliu line.The Qingliu line was operated successfully at 07:02,and the Zhong Zhai substation 66kVsysterm C phase ground signalling was displayed,34 seconds later,the three-sect currentt protection of Qingliu line tripped again.7:04,the light, heavy gas protection signal of Zhong Zhai substation 66kV arc suppression coil was displayed.At 7:30,the Zhong Zhai operation team reported that the arc suppression coil was smoking.7:34,dispatcher ordered power down the 66kV arc suppression coil .

(2) Operation before the accident

Zhong Zhai substation No.2 main transformer was operating ,and leading the Qingyuan substation, Nanzamu substation and Hongtoushan substation etc.19 substations which belonged to Fushun power supply company,3 user substations,3 power plants,the No.1 main transformer backup.Before Failure,the load was 86MW.Through calculation,the Zhongzhai net capacitive current was 85.68 A.When put into use the two arc suppression coils,Zhongzhai used 100A,Qingyuan used 25A.All of them were manual mode, compensation degree was 45.9%.

(3) Returned for hanging core inspection after the accident

The 66kV arc suppression coil smoke accident in Fushun Zhong Zhai 220kV substation was put into operation on May 12, 2010 ,which made by an electric incorporated company,the date was 2008 December.Manufacturing load switch manufactured by Shanghai Huaming Electric Power Equipment Co., Ltd,whose production date wass 2008 November.After the accident,the arc suppression coil was transfered to a repaire shop for hanging core inspection.The damaged condition of arc suppression coil following Figure 1.

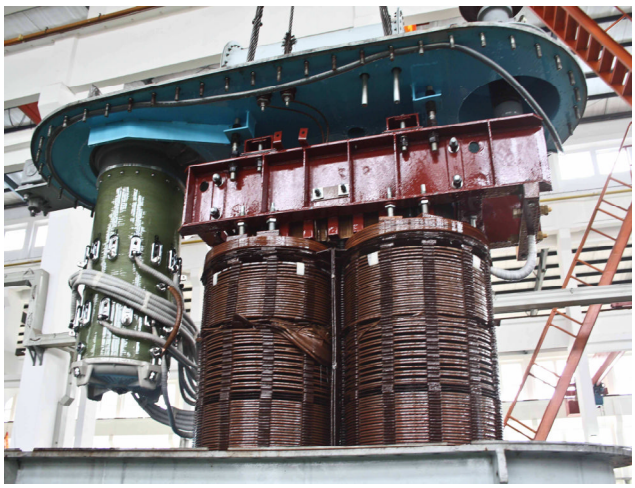

Fig. 1 The core in the middle 22.23.24 layers was twisted seriously

The first, the tail section of core was normal, but in the middle 22.23.24 layers, the core was twisted seriously, the coil plate, meter coil wire and rod insulation was cracked.

On load switch, moving contact discharger he upper portion of the switch along strapping.The contactor and the moving contact of insulation cylinder only has few arc mark,as shown in Fig. 2:

Fig. 2 The contactor in the On-load voltage regulating switch barrel and the switch

Analysis of the causes of the accident

Firstly, let us examine the experimental data before and after the accident, as shown in Table 1.

Table 1 The experimental data of the arc suppression coil

Component Data	Content μl/L							
	H2	CO	CO2	CH4	C2H6	C2H4	C2H2	C1+C2
2010.04.28	20	53	453	4.21	0.22	0.65	0.11	5.19
2011.07.15 oil injection	35	132	1959	3.79	1.15	0.67	0.07	5.68
2012.07.05	14	139	2522	4.02	1.9	1.76	0.79	8.47
2012.07.06 test again	8	125	2270	4.06	1.59	1.64	0.76	8.05
2012.10.22 oil injection	901	501	2044	151.9	3.95	222.3	672.18	1050.33

July 15, 2011.In the later operation, the content of C2H2 was growing. It proved that the discharge phenomena were happened in the arc suppression coil.

Secondly, from these waveforms out of fault wave record instrument, system resonance did not occur when twice grounding, and a smooth transition.

When Zhongzhai 66kV system C-phase was grounded, the displacement - voltage ruled in arc suppression coil was escalated and remained at about 31kV after 5 frequencies. The arc suppression coil can operate fewer 2 hours in this voltage, but the gas protection was acted when only operated 1 minute and 28 seconds. So, it can be sure that insulation of on - load - tap - changing switch. From the experimental data showed in table 1, there would be discharge phenomena once the arc suppression coil launched.

Therefore, the accident was due to the hidden trouble in the process of design, manufacture. when single-phase grounding appears in the system, impulse over voltage generated instantly would cause a voltage oscillations in the winding. With the voltage oscillation, the potential to further expand, internal insulation was further damaged, eventually caused the winding deformation fracture.

The commissioning test and operation requirements

In order to ensure the safe operation of arc suppression coil, it needs to meet the following conditions:

(1) The requirement of experiment technique.

At present, test items as follows: 1) DC resistance of windings and casings; 2) The insulation resistance and the absorption ratio of windings and casings; 3) The dielectric loss tangent of oil immersed type arc suppression coil and casings; 4) Insulation oil test.

Handover testing project should be complete, must increase the following test, if do not have test conditions, it can be appointed manufacturer for test.1) arc suppression coil volt-ampere characteristics. 2) DC leakage current of oil immersed type arc suppression coil and casings.3) AC

withstand voltage test me on DC resistance of windings and casings.4) Impact closing test under rated voltage.

(2) The operation requirements of the unit.

1) The current and voltage of arc suppression coil should be accessed to fault wave record system.

2) Increase the infrared imager on substation professional investment, strengthen the infrared detection technology training, and improve the infrared detection ability of operators

3) If the grounding fault lasts 15 min is not eliminated, related personnel should immediately sent to check the arc suppression coil body, the upper temperature should be normal, there should be no smoke injection phenomena, casing should be no traces of discharge, joints should be no heating phenomenon, and every 20 min check once a. When the oil temperature exceeds 95 ℃, continuous running time exceeds the specified value, should apply to dispatcher on duty for disabling the arc suppression coil.

Conclusion

When procuring arc suppression coil, should choosing the authority of the State Department identified, test and inspection within the period of validity and the arc suppression coil needs experience. For a long time, because of the problem of part manufacturing plant, leading to the design and manufacturing process of product problems. In the anti resonant and anti short circuit ability is poor. The quality problem of the tap-changer also exists. It is because of these problems, which leads to the arc suppression coil smoke occurred, fuel injection, sound abnormal accidents often start in. Because of the manufacturing process of the arc suppression coil needs large amount of manual operation, the process control difficult and larger dispersion. We must send professionals to the manufacturing process of supervision, and the test report and inspection report as the original data file.

Keywords: Energy industry; Industry structure; Energy saving; Optimal path

Abstract. The industrial structure optimization based on energy saving is different from the traditional industrial structure optimization. It relays on the supply and demand of industrial structure. It takes low carbon cycle, energy conservation and environmental protection as guiding principles and maximization of the use of resource and minimization of production from environmental pollution as the goals. Innovation of technology has also be taken as a means to help industry be sustainable, healthy and orderly and to shape an industrial optimization model that economy, society, nature are harmoniously existed. In this paper, we have an analysis of the energy industry structure to point out the shortages of the structure, technology, policy, talent and so on in energy industry. Then based on these shortages we explored the optimal path of industrial structure for energy saving.

Introduction

The rapid development of industry satisfied the material and cultural needs of people. But it follows with the problems of excessive of resource and the growth of natural ecological environment load and so on. And people are becoming pay attention on construction of ecological civilization. In year of 2007, to build ecological civilization has been put forward at the report of the 17th Communist Party Congress. In year of 2008, to promote ecological civilization has been stressed at the 18th Communist Party Congress. As a pattern of economy development, industry structure is the core problem of ecological civilization[1].So we should to find shortages of industry structure in ecological civilization and explore the optimum paths of industrial structure to help save energy.

The shortages existed in the energy industry structure

In traditional industrial structure theory, the process of optimizing the industrial structure is to adjust the supply and needy structure which has influence on the change of industry structure. By doing this we can realize the resource optimal allocation and configuration to promote the rationally and highly development of industry structure[2]. The industrial structure optimization based on energy saving is different from the traditional industrial structure optimization. It not stresses on the quantity growth and quality improvement ,but also stresses on being sustainable, healthy and orderly. It shapes an industrial optimization model that economy, society, nature can existed harmonious by optimizing the structure of industry. It demands structure status and trend of change could comply with the concept of ecological civilization. And the direction of the industrial structure optimization could promote energy conservation, industrial ecology transformation, the self-organizing ability of industrial structure and the sustainable development ability improvement. Nowadays, the industrial structure based on energy saving has much space on optimizing the configuration, technology and policy of industry structure. It has to be adjusted and innovated constantly in to be more rationally, more empirically and more efficient. So the self-organizing ability and sustainability of the industry structure can be improved.

The first, development of traditional energy industry is not harmonious, and it mainly depends on material resources. Industry structure optimization concentrating on promoting energy conservation requires economy, society and environment coordinated developed, maximizing the utilization rate of natural resource and minimizing the damage to environment[3]. From the development of energy industry in our country, first of all, the development of regional economy and energy industry are uncoordinated. The disparity between east and west, north and south are really obviously. The advantages and characteristics of the local energy industry have not be validly used, which have much bad influence in healthy development of the energy industry. Secondly, the economic growth mode of energy industry in China is too extensive, mainly depends on material resources, the rate of configuration and use are low as well as the huge cost during developing of energy industry. However, material resources are scarcely and it will be short when economic development arrives at a certain stage and it also will pose a threat to the long-term development of the energy industry.

The second, traditional energy industry technology innovation level needs to be improved. Because the industrial construction starts late in our country, so there is a big gap on the technical innovation between the developed countries and China[4]. The gap mainly shows in the backward production technology and smaller innovation strength, the lack of pollution control and treatment technology and immature of green energy saving technology. What's more, research level of China's energy industry lags behind, the cooperation with universities, scientific research institutes and other research institutions is insufficient. Industrial technology innovation system that integrating research, development and production has not been formed, this has a big influence on the improvement of the energy industry technology innovation level in China.

Thirdly, the energy industry administrative policy need to be improved. Laws, regulations and economic policies are two main policy tools the government used for optimizing the structure of the relevant industries. The execution of them are mandatory and they are important measures of optimizing the structure of energy industry in our country[5]. However, it ignores the regional differences in the development of energy industry, the characteristics of the regional advantage can not get to play due to the similar regional energy industry policy, this limits the development of the regional energy industry. In addition, today's energy industry policy emphasizes too much performance requirements and performance evaluation on GDP growth and ignores environmental protection and other important factors. However, the environmental protection sells at a discount in the effect of guiding the upgrading of the industry.

The fourth, talents of energy industry are pool and efficient talent introduction and cultivation mechanism has not be formed. For now, the trend of talent proportion of China's high technology and new strategy emerging energy industry is gradually rising, but the amount is still insufficient. Most of the high-quality talents are in traditional energy industries, which has be a bottleneck of in the process of advancing the energy industry structure optimization in our country. What's more, because of the lack of talent introduction and cultivation mechanism, high-level, shortage of talents are still in a state of loss and unable to meet demand of leading industry.

The path of industry structure optimization to facilitate energy saving.

The industry structure optimization based on energy saving must under target of coordinated development of economy, society and environment. It also should be guided by scientific development concept and economic cycle theory, so it can radically solve problems such as high pollution, high consumption but poor efficiency in the model of economic development. What's more, the optimization can explore the energy industry structure of saving resource and environmentally-friendly energy industry structure from aspects such as structural transformation, technology innovation and policy changing.

Transformation of the industry structure optimization to facilitate energy saving. Because of insufficiency in the structure of energy industry, industry structure optimization should pay attention to economy of each region , especially the coordinated development of services and

manufacturing industry in three traditional industry. Industry structure optimization also should strengthen the support on service industry. It should adjusts the first industry according to the principles of re-use and recycling. It should optimize the second industry by principles of low consumption, pollution but high efficiency. It should strengthen the third industry by the principles of raising proportion and added-value. It should introduce the zero industry (i.e., natural resources industry) and high industry (i.e., environmental industry and high technology industry) [6] to the industrial structure, and make it to be the leader industry in industry optimization and upgrading. We also should give full play to the resource advantage, optimize the allocation of resources, adjust the energy structure, reducing the use of traditional energy, increase use new clean energy development and utilization. Furthermore, energy industry should be guided by knowledge resources. It can take advantages of features such as sharing, limitless and green of the knowledge resources to make the energy industry structure changing from relying on material resources to relying on knowledge resources.

Push energy industry technology innovation in all sides. Due to rapid development of modern information technology, energy industry structure should be adjusted to focus on integration between industrialization, informatization and achieving “tri-networks integration” in order to deal with the impact from information industry to traditional industry. Moreover, we should aggressively develop the energy-saving and technology innovation system which is leaded by the group of enterprises, colleges and research institutes. We also should increase the capability of independent innovation of the energy industry, pushing energy industry technology innovation in all sides. On side of production, enterprises can take benefits from the rapid development of modern information technology, and then broaden use of information technology in production. We should upgrade high-tech, environmental protection technology in traditional energy industry, We should eliminate the outdated technology, bring advanced critical equipments from foreign countries and domestic market, motivate enthusiasm of the enterprises to create. So development direction of industry can be leaded from environment-damage to environment-friendly. On side of pollution management and treatment, enterprises should go for energy conservation and emissions reduction. They should take low-carbon cycle production mode as dominate role and develop the low damage and environmentally eco-industry system to improve the efficiency of resource utilization. Enterprises can strengthen the contact with universities and social scientific research institutions, deepen the pollution management research, investing more funding into the energy-saving research and development, and making the pollution management be used in reality. On side of green-energy-saving, enterprises should enhance investment of new strategic industry. They should not only import new technology or upgrade technology, but also need to invest more funds in the research projects.

Complete the policy-guide mechanism to change the policy from enforced to induced. In order to reduce negative influence caused by regional differences and performance requirements, implementation of energy conservation policy should change from been enforced to be induced as the following aspects:

(1) Develop regional characteristic industry based on the local condition. Apply a flexible guiding policy according to the regional characteristics of the environment. Limit haphazard investment and redundant construction.

(2) Improve the assessment of government. Reform the assessment criteria based on GDP, take resource use, energy conservation and emissions reduction, environmental management, development of new energy into the evaluation system. Emphasize the government's environmental responsibility and the important of coordinated development between economic growth and environment protection.

(3) Encourage and cultivate the development of emerging strategic industries. The new strategic industries like new energy industry, green environmental protection industry and bioengineering and pharmaceutical industry, the policy can trend to cultivate by funds and scientific research service.

(4) Legislate ecological compensation mechanism. It requires the enterprises to handle pollution after they developed, and it asks enterprises to take responsibility for the environment management. Otherwise, the negative effects from environment will turn to be a cost onto enterprise.

(5) Improve the enterprises credit evaluation system. Environmental protection behaviors benefit the enterprises, so enterprises should pay attention on environmental protection, clean, energy-saving and emission reduction. At present, our country enterprise credit evaluation system in the pilot stage, the system needs to be improved.

Increase the talent pool of emerging energy industry to promote the formation and nurturing talent introduction mechanism. Integration of talents and industries is an important condition to promote talent agglomeration. Technology innovation and structural adjustment should be dominated by talents. The coordinate relationship of talent, industry and technology innovation can be ensured by the relationship between human, social and environmental, so we can strive to build talent support system to promote energy conservation[7]. Talent strategy development, the first is the construction industry talent base, through industrial projects to attract and gather talent to play a leading role, while focusing on core talent training of existing personnel. Optimize energy industry base supporting measures, provide a good environment for industry professionals. Second, to promote industrial innovation and talent training mode to enterprises, universities, research institutes as the main combination of research. Strengthen cooperation with universities and research institutes to promote use of resources. Take university as the main talent transport platform to meet the talents need of the industrial structure optimization. So enterprises, talents and technological innovation can develop mutual integrated and common developed.

Summary

In this paper, we have an analysis of the energy industry structure to point out the shortages of the structure, technology, policies, talent and so on. Then based on these shortages we explored the optimum paths of industrial structure to help saving energy. First, change the industry structure optimization to promote energy saving. Second, push energy industry technology innovation in all sides. Third, complete the policy-guide mechanism to change the policy from enforced to induced. Forth, increase the talent pool of emerging energy industry to promote the formation and to nurture talent introduction mechanism.

Keywords: Double-circuit Transmission Lines; Line Parameters; Symmetry

Abstract. Double-circuit transmission lines parameters symmetry would affect the normal operation of the transmission lines and relay protection actions directly. This paper analyzes the impacts of three different phase sequence arrangements on parameters symmetry of conventional un-transposed double-circuit lines, and requirements can be met by the parameters symmetry for double-circuit transmission lines with different types and different length. Took practical engineering requirements into consideration, a simple and admissible suggestion on phase sequence arrangements and the transposition modes is given. The research results provide useful guidance and reference for future designs of double-circuit lines, especially for the compact one.

Introduction

Double-circuit transmission lines parameters would affect the normal operation of the transmission lines and relay protection actions directly [1-2]. Numerous conductors in double-circuit transmission lines make it difficult to achieve complete transposition. Diverse operation conditions, close proximity between each loop, serious electromagnetic and electrostatic coupling would cause severe parameter asymmetry.

Conventional calculation method of the transmission line parameters simplified the circuit model to make it easy for analysis, such as the literature [5] assumed that three-phase conductors transposed completely, literature [6] assumed that the parameters were symmetrical. But these assumptions are not applied in double-circuit transmission lines especially when a conventional method is used to calculate paralleled double-circuit line parameters. As loop-loop distance is greater than phase-phase distance, it ignored coupling effects between positive sequence and negative sequence [7]. While in double-circuit transmission lines, electromagnetism is strong in two lines, coupling effects between positive sequence and negative sequence cannot be ignored.

By analyzing the effects of transposition on double-circuit transmission lines parameters symmetry, this page adopts the appropriate phase sequence arrangement and combines easily realized transposition mode in a practical project to improve double-circuit transmission lines parameters symmetry. It is of great significance for the standardization of the design of transmission lines, and the improvement of the quality of power supply.

Analysis of Key Factors Affecting Double-circuit Transmission Lines Parameters

(1) Double-circuit Transmission Lines Parameters

According to the single circuit parameters calculation method, and the double-circuit transmission lines model shown in Fig.1.

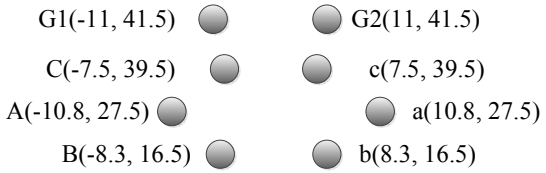

Fig.1. Transmission lines arrangement of 500kV double-circuit

Assuming that the lines do not transpose completely, double-circuit lines parameters can be calculated after the influence of the ground considered. Details can be shown in type (1).

$$\begin{bmatrix} \dot{U}_{\mathrm{IA}} \\ \dot{U}_{\mathrm{IB}} \\ \dot{U}_{\mathrm{IC}} \\ \dot{U}_{\mathrm{IIA}} \\ \dot{U}_{\mathrm{IIB}} \\ \dot{U}_{\mathrm{IIC}} \end{bmatrix} = \begin{bmatrix} Z_{\mathrm{IAIA}} & Z_{\mathrm{IAIB}} & Z_{\mathrm{IAIC}} & Z_{\mathrm{IAIIA}} & Z_{\mathrm{IAIIB}} & Z_{\mathrm{IAIIC}} \\ Z_{\mathrm{IBIA}} & Z_{\mathrm{IBIB}} & Z_{\mathrm{IBIC}} & Z_{\mathrm{IBIIA}} & Z_{\mathrm{IBIIB}} & Z_{\mathrm{IBIIC}} \\ Z_{\mathrm{ICIA}} & Z_{\mathrm{ICIB}} & Z_{\mathrm{ICIC}} & Z_{\mathrm{ICIIA}} & Z_{\mathrm{ICIIB}} & Z_{\mathrm{ICIIC}} \\ Z_{\mathrm{IIAIA}} & Z_{\mathrm{IIAIB}} & Z_{\mathrm{IIAIC}} & Z_{\mathrm{IIAIIA}} & Z_{\mathrm{IIAIIB}} & Z_{\mathrm{IIAIIC}} \\ Z_{\mathrm{IIBIA}} & Z_{\mathrm{IIBIB}} & Z_{\mathrm{IIBIC}} & Z_{\mathrm{IIBIIA}} & Z_{\mathrm{IIBIIB}} & Z_{\mathrm{IIBIIC}} \\ Z_{\mathrm{IICIA}} & Z_{\mathrm{IICIB}} & Z_{\mathrm{IICIC}} & Z_{\mathrm{IICIIA}} & Z_{\mathrm{IICIIB}} & Z_{\mathrm{IICIIC}} \end{bmatrix} \begin{bmatrix} \dot{I}_{\mathrm{IA}} \\ \dot{I}_{\mathrm{IB}} \\ \dot{I}_{\mathrm{IC}} \\ \dot{I}_{\mathrm{IIA}} \\ \dot{I}_{\mathrm{IIB}} \\ \dot{I}_{\mathrm{IIC}} \end{bmatrix} \tag{1}$$

Represented by matrix vector

$$\dot{\boldsymbol{U}}_{\mathrm{I\text{-}II}} = \boldsymbol{Z}\dot{\boldsymbol{I}}_{\mathrm{I\text{-}II}} \tag{2}$$

In order to get each sequence parameters in each line, the two loops of voltage and current phasor are transformed into two groups of symmetrical components, by the sequence component transformation, the following types can be obtained.

$$U_{1201'2'0'} = SZS^{-1}I_{1201'2'0'} = Z_{SD}I_{1201'2'0'} \tag{3}$$

$$Z_{SD} = SZS^{-1} \tag{4}$$

For the lines with completely symmetric parameters, after symmetrical component transformation, each sequence parameters are completely independent. So the circuit parameters symmetry can be represented by the transformed independence of sequence. Thus, this page simultaneously adds positive sequence voltage in two loops, and then calculates sequence current of each loop, according to type (3). If the larger proportion positive sequence current accounts and the smaller proportion negative sequence and zero sequence current accounts then the independence between each sequence are better, that is to say, the symmetry of the circuit parameters is better.

(2) Phase sequence arrangements effects on double-circuit transmission lines parameters

Compared to the compact double-circuit lines, the conventional double-circuit transmission lines phase distance is larger within each loop, the typical arrangement are same phase sequence, inverse phase sequence and heterogeneous sequence arrangement, as shown in Fig.2.

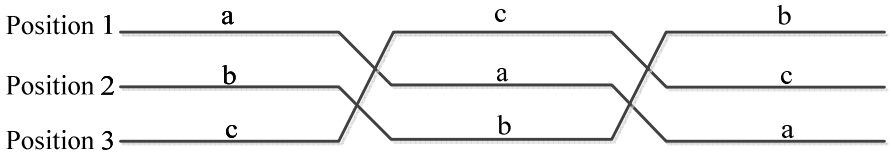

Fig.2. Sketch map of transposition in transmission lines

Here taking Fig.1 for an example, the lines parameters under same phase sequence, inverse phase sequence and heterogeneous sequence arrangements were calculated and analyzed respectively. According to type (3), Z_{SC} the impedance matrix of different kinds of phase sequence arrangements was firstly calculated, then, assuming that 500kV positive sequence line voltage was added up to two loops. Based on type (2), each sequence current under different phase sequence arrangements can be calculated. The results are listed in Table 1.

As it can be seen from Table1, under the same phase sequence, the ratio of the negative sequence current and positive sequence current is 16%, and the ratio of the zero sequence current and positive sequence current is 0.69%.Under inverse phase sequence, the ratio of the negative sequence current and positive sequence current is 3.72%, and the ratio of the zero sequence current and positive sequence current is 1.31%. Under heterogeneous sequence, the ratio of the negative sequence current and positive sequence current is 8.54%, and the ratio of the zero sequence current and positive sequence current is 4.5%.

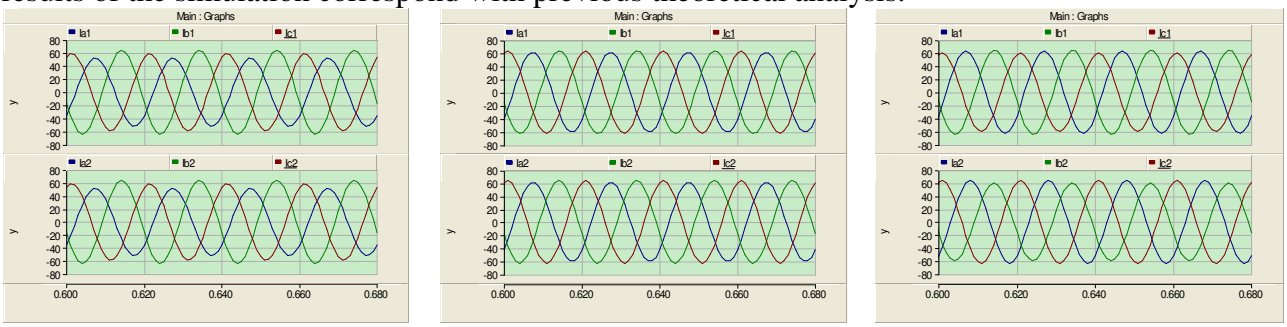
	I'_2	7.476+j3.913	8.4391	1.3337+1.7667j	2.2136	-4.9134+0.3406j	4.9252
	I'_0	0.3599-j0.1314	0.3831	0.0866-0.6813j	0.6868	-2.4596-0.9180j	2.6253

In the table 1: I_P stands for current pharos; I_M stands for current amplitude; I_1 stands for positive sequence current; I_2 stands for negative-sequence current; I_0 stands for zero sequence current.

When the lines are under inverse phase sequence, the ratio of negative sequence current and positive sequence current and the ratio of the zero sequence current and positive sequence current are small. So under this arrangement the symmetry of the line parameters is the best.

A digital simulation model shown in Fig.1 can also be built by PSCAD software, which is used to prove the accuracy of the analysis above. In the simulation, 500 kV line voltages were added in the head of line, three phases was shorted grounding in the terminal. At this time, each phase current waveform of the double-circuit lines under different phase sequence arrangements can be got in Fig.3. By contrast of each sequence current waveform, we can see intuitively when the lines are under inverse phase sequence arrangements, the symmetry of the parameters is the best. The results of the simulation correspond with previous theoretical analysis.



(a) (b) (c)

Fig.3. The contrast of each phase current of conventional double-circuit transmission lines under (a) same phase sequence, (b) inverse phase sequence and (c) heterogeneous sequence

According to the analysis above, for conventional un-transposed double-circuit lines, when two lines are all in operation, different phase sequence arrangements have apparent effects on the parameters symmetry. Among them, using inverse phase sequence the lines parameters symmetry is the best. It should be noted that when one line is not in operation, the case is the same as the single-circuit, different phase sequence arrangements have no effect on parameters symmetry, the lines parameters symmetry mainly depend on its transposition mode. Further analysis and calculation indicate that as the transposition is needed in a long double-circuit transmission lines, inverse phase sequence arrangement should be adopted to coordinate separate transposition of two loops. But after the transposition, each lines arrangement should be guaranteed to still be the inverse phase sequence. By this time, the lines parameters symmetry can be ensured well.

Double-circuit Transmission Lines Phase sequence arrangements and transposition schemes

Combined with previous analysis, this section focus on different type of double-circuit transmission lines under various conditions, and provides phase sequence arrangements and transposition schemes.

1) For short distance conventional un-transposed lines in practical, it is recommend adopting inverse phase sequence arrangement.

2) For long distance conventional un-transposed lines, two lines transpose respectively. After the transposition, inverse phase sequence arrangement is recommend adopting.

3) For the compact double-circuit lines, its parameters symmetry is superior to the conventional double-circuit lines and still be affected by phase sequence arrangements. It is also recommended adopting inverse phase sequence arrangement, and the parameters symmetry can be ensured though the lines without transposition.

Conclusion

This paper analyzes the effects of three different phase sequence arrangements on the parameters symmetry of conventional un-transposed double-circuit lines. Results indicate that different phase sequence arrangements have great influences on the lines parameters symmetry and requirements can be met by the parameters symmetry for double-circuit transmission lines with different types and different length. Combined with practical engineering requirements, a simple and admissible suggestion on phase sequence arrangements and the transposition modes is given. The research results provide useful guidance and reference for future designs of double-circuit lines, especially for the compact one.

Keywords: 750kV double circuit transmission line; altitude correction; live working; safety distance; combined gap

Abstract. In order to determine the required live working safety distance for 750kV double circuit transmission line in different altitude areas of China, by using the test data of 750kV double circuit transmission line in the low altitude areas, and combining the common altitude correction methods, the live working safety distances of different altitude correction methods are obtained. By comparing and analyzing the results of different analysis methods, the required minimum approach distances and minimum combined gap distances of live working are recommended under different working conditions in the altitude of 1000m ~ 5000m areas. The results could provide technical reference for 750kV double circuit transmission line in different altitude areas.

Introduction

With the 750kV transmission lines becoming the backbone of the Northwest power grid gradually, on one hand, the layout of 750kV double circuit transmission line could improve the transmission capacity, reduce the line corridor areas; On the other hand, the increasing of 750kV transmission line leads to many transmission lines passing through the high altitude areas, and the altitude of some lines are over 3000m, or even approaching 5000m. Live working has an important significance to guarantee the reliability and security of the transmission lines. Research of live working on 750kV double circuit transmission line in the altitude of less than 3000m areas had been performed by some research institutes, and appropriate standards and guidelines were formulated. But for the areas more than 3000m altitude, there is no corresponding provision.

The best way to study on live working is to carry out the relative live working test in high altitude areas, which could determine the live working safety distance reasonably. Currently, due to the absence of live working test data of high altitude, the analysis combining the test data of low altitude areas with the existing altitude correction methods is also an effective method for the determination of the live working safety distance in high altitude areas.

By using common altitude correction methods, and combining the test data of 750kV double circuit transmission line in the low altitude areas, the required live working minimum approach distances (MAD) of 750kV double circuit transmission line are recommended under different working conditions in the altitude of 1000m ~ 5000m areas.

Analysis of altitude correction factor k_a

For the high altitude correction of air gap discharge voltage, the current domestic and international standards mainly include: GB/T16927.1-2011, IEC 60071-2-1996, DL/T620-1997 and GB311-2012, among these correction methods, the method in GB/T16927.1-2011 is only applicable to the altitude of 2000m and requires the actual atmospheric conditions, which leads not to be considered in the article; the method in GB311-2012 has been adopted the formulas and curves given in IEC60071-2, therefore only the altitude correction methods of IEC 60071-2 and DL/T620-1997 are considered for analysis in this paper.

The recommended formula of altitude correction factor k_a in IEC 60071-2 is:

$$K_a = e^{m(H/8150)}. \quad (1)$$

In the formula, H is the altitude, m

m is the correction factor.

For SI, m is relative to the voltage amplitude, in the article, m is selected as 0.59 by checking the curve in the IEC 60071-2.

Altitude correction method in IEC60071-2 only applies to the altitude of 2000m and lower areas, by extending the application scope to the altitude of 5000m, k_a of different altitude are obtained in Table 1.

Tab. 1 Altitude correction factors k_a according to IEC 60071-2

Altitude(m)	1000	2000	3000	4000	5000
k_a	1.08	1.16	1.24	1.34	1.44

For weather conditions correction method of external insulation discharge voltage in DL/T 620-1997, the meteorological parameters of altitude 0m~3500m given in DL/T 620-1997 are extended to the altitude of 5000m areas firstly, which could be used to calculate k_a of air gap distances ranging between 3.0m and 7.0m according to the altitude correction method recommended in DL/T 620-1997, as are shown in Table 2.

Tab. 2 Altitude correction factors k_a of switching voltage according to DL/T620-1997

k_a		Altitude (m)				
		1000	2000	3000	4000	5000
Gap distance(m)	3	1.10	1.20	1.31	1.46	1.60
	4	1.08	1.17	1.26	1.38	1.49
	5	1.07	1.13	1.20	1.30	1.38
	6	1.05	1.10	1.15	1.22	1.28
	7	1.05	1.10	1.15	1.22	1.28

Analysis of live working safety distance

According to the provisions of *working regulations of power safety*, for a typical 750kV transmission lines, the overvoltage is selected as 1.80p.u..The live working risk ratio can be calculated by formula 2.

$$R_0 = \frac{1}{2}\int_0^{\infty} p_0(U)p_d(U)dU. \quad (2)$$

In the formula, $P_0\ (u)$ is the probability density function of switching over-voltage amplitude;

$P_d\ (U)$ is the air gap breakdown probability distribution function under the condition that the switching over-voltage is U.

The typical live working positions of 750kV double circuit transmission line are in Figure 1.

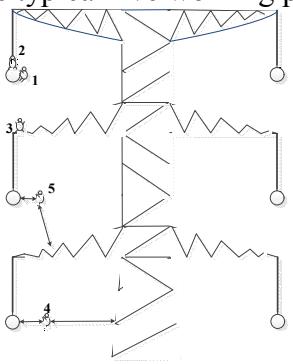

Fig.1 Schematic diagram of live working in different positions

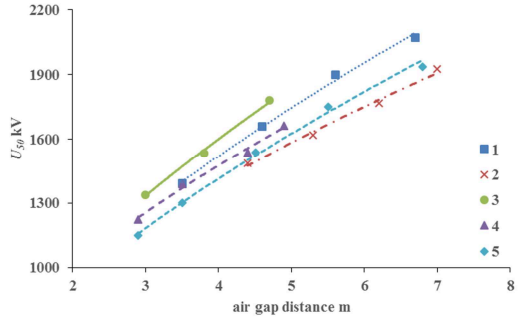

Fig.2 Live working clearance discharge characteristics curves of 750kV double circuit transmission line in different positions

In Figure 1, position 1 represents *equal potential worker to the tower body*, position 2 represents *equal potential worker to the cross arm*, position 3 represents *middle phase cross arm ground potential worker to the upper phase conductor*, Position 4 represents *lower phase conductor- workers - the tower body*, position 5 represents *middle phase conductor - workers - lower phase cross arm*.

Under the standard meteorological conditions, the live working clearance discharge characteristics curves of 750kV double circuit transmission line in different positions are shown in Figure 2.

According to k_a calculated by the methods in IEC60071-2, DL/T620-1997, and combining with the discharge characteristics curves when the worker in different positions of Figure 2, the required MAD are obtained under different working positions and different k_a in the altitude of 1000m ~ 5000m areas. As is shown in Table 4.

Tab.4 The required MAD are obtained under different working positions and different k_a in the altitude of 1000m ~ 5000m areas

Position \ Altitude (m)		0	1000	2000	3000	4000	5000
1	IEC60071-2	3.7	4.1	4.6	5.2	5.8	6.6
	DL/T 620	3.7	4.2	4.6	5.0	5.4	5.8
2	IEC60071-2	4.2	4.8	5.5	6.2	7.1	8.1
	DL/T 620	4.2	4.8	5.3	5.7	6.2	6.6
3	IEC60071-2	3.4	3.8	4.3	4.8	5.4	6.0
	DL/T 620	3.4	3.9	4.3	4.6	5.1	5.4
4	IEC60071-2	3.8	4.4	5.0	5.6	6.4	7.3
	DL/T 620	3.8	4.4	4.8	5.3	5.8	6.1
5	IEC60071-2	4.1	4.6	5.2	5.8	6.6	7.4
	DL/T 620	4.1	4.6	5.0	5.4	5.9	6.3

Remark: the range of human activity is not considered in the table.

As can be seen from Table 4: For the altitude of 1000m ~ 2000m areas, when workers are situated in different positions, the MAD obtained by the two correction methods are almost the same, however, for the altitude of 3000m areas and above, with the altitude increasing, the difference of the results obtained by the two altitude correction methods is getting bigger. At the altitude of 5000m, the results obtained by the IEC60071-2 is 1.04m larger than those of DL/T 620.

In the altitude of 1000m ~ 3000m areas, the calculation results of positions 1 and 4 compared with the provision values in DL/T 1060-2007, as are shown in Figure 3 and Figure 4.

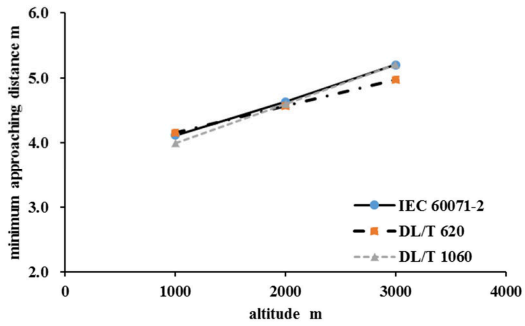

Fig.3 Results comparison of different analysis methods in position 1

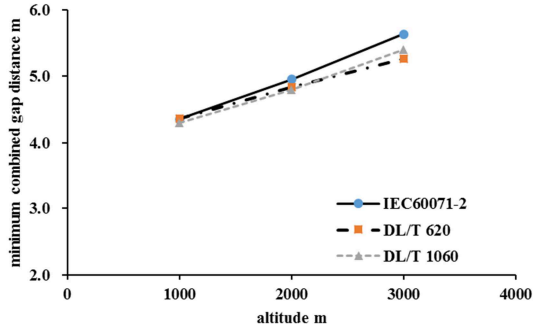

Fig.4 Results comparison of different analysis methods in position 4

As can be seen from Figure 3 and Figure 4, in the altitude of 1000m ~ 3000m areas, when workers are situated in position 1 and position 4, the MAD obtained by three analysis methods are almost consistent, and the difference is not more than 0.2m, therefore, for other working positions, the recommended the MAD obtained by the altitude correction methods have the rationality.

For security consideration, the MAD of different working positions in the altitude of 1000m ~ 5000m areas are recommended by the larger result obtained by the two altitude correction methods, as are shown in Table 5.

Tab.5 Recommended MAD in different working positions at the altitude of 1000m ~ 5000m

Working position	Altitude (m)				
	1000	2000	3000	4000	5000
equal potential worker to the tower body	4.2	4.6	5.2	5.8	6.6
equal potential worker to the cross arm	4.8	5.5	6.2	7.1	8.1
middle phase cross arm ground potential worker to the upper phase conductor	3.9	4.3	4.8	5.4	6.0
lower phase conductor- workers - the tower body	4.4	5.0	5.6	6.4	7.3
middle phase conductor - workers - lower phase cross arm	4.6	5.2	5.8	6.6	7.4

Remark: the range of human activity is not considered in the table.

In addition, the test data of low altitude areas is not under the condition of standard SI wave form (250μs/2500μs), instead, it is under the condition that the front time of the SI wave form is 740μs. The relationship between rod-plate air gap switching impulse breakdown voltage and front time in the literature [7] shows that the breakdown voltage of the air gap will increase when the front time is increasing, so the gap distance values recommended in this paper may be conservative.

Conclusion

1) Based on the test data of 750kV double circuit transmission line in the typical live working positions at low altitude, k_a of 1000m ~ 5000m altitude areas are obtained by two altitude correction methods in IEC60071-2 and DL/T620-1997. For the altitude correction method in IEC60071-2, with the increasing of the altitude, k_a also increase, and the growth rate is even; but for the altitude method in DL/T620-1997, whose k_a is relative to the air gap distance and the altitude, with the increasing of the gap distance, k_a at the same altitude is decreasing, in addition, with the increasing of the altitude, k_a under the same gap distance is also increasing.

2) According to the obtained k_a, and by calculation, comparison and analysis, the MAD of 750kV double circuit transmission line different working positions in the altitude of 1000m ~ 5000m areas are recommended. In general, the MADs in different working positions from the altitude of 1000m to 5000m are increasing, for different working positions, the position which requires the maximum MAD is *equal potential worker to the cross arm*, the position which requires the minimum MAD is *middle phase cross arm ground potential worker to the upper phase conductor*.

3) The results are based on the low altitude live working experimental data of 750kV double circuit transmission line and the altitude correction methods, which could be a reference for 750kV double circuit transmission line live working at high altitude. If the test conditions at high altitude are appropriate, it is recommended to carry out verification tests on 750kV real size tower head at high altitudes.

Keywords: Passive Residual Heat Removal System, Station Blackout, RELAP5

Abstract. This paper regarded CNP1000 power plant system as the research object, which is the second-generation half Nuclear Reactor System in our country, and tried to set Westinghouse AP1000 passive residual heat removal system to the primary circuit of CNP1000. Then set up a simulation model based on RELAP5/MOD3.2 program to calculate and analyze the response and operating characteristic of passive residual heat removal system on assumption that Station Blackout occurs. The calculation has the following conclusions: natural circulation was quickly established after accident, which removes core residual heat effectively and keep the core safe. The residual heat can be quickly removed, and during this process the actual temperature was lower than saturation temperature in reactor core.

Introduction

AP1000 is the representative of the third generation nuclear technology, the design and application of its passive safety system are focused on by scholars in many countries. Now, in our country, AP1000 nuclear power plant has been imported by State Nuclear Power Technology Corporation. However, the response of passive residual heat removal system under accident conditions was not known clearly. Based on the familiarity of AP1000 passive residual heat removal system, this paper set the passive system to the primary circuit of CNP1000. Then the simulation model is built by RELAP5/MOD3.2 program to analyze the ability of removing residual heat when Station Blackout Occurs. The conclusions could inform the improvement of the second-generation half Nuclear Reactor System in our country.

System Overview

There are three coolant loops in CNP1000 power plant system, and each coolant loop has one steam generator, one coolant pump, one hot leg and one cold leg. The pressurizer is connected with the hot leg of one coolant loop. By contrast, the AP1000 power plant system only has two coolant loops, and the structure is also different form CNP1000. But the changes of residual heat in reactor core are similar, because these two power plant system have the same output rating. So the study of heat transfer performance of the AP1000 passive residual heat removal system based on the primary circuit of CNP1000 was reasonable.

The AP1000 passive residual heat removal system was drove by natural force, and the valves follow the fail-safe standards. When the power supply lost or the guard signal reached, the valves would be triggered automatically, and then passive residual heat removal system would be put in to operation. The function of passive residual heat removal system is removing residual heat in reactor core by the usage of natural circulation under the design basis accidents. The heat exchanger of this system was made up of C-type tubes and put into the refueling water tank. The schematic diagram of passive residual heat removal system is shown below [1-3].

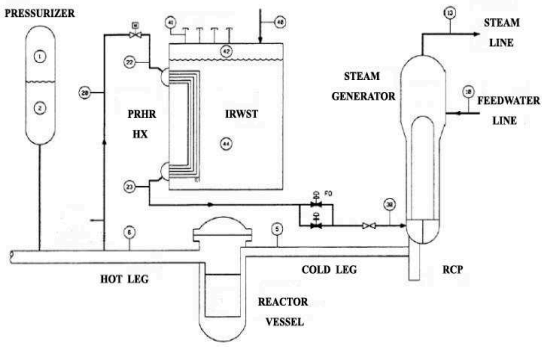

Fig.1. Schematic diagram of passive residual heat removal system

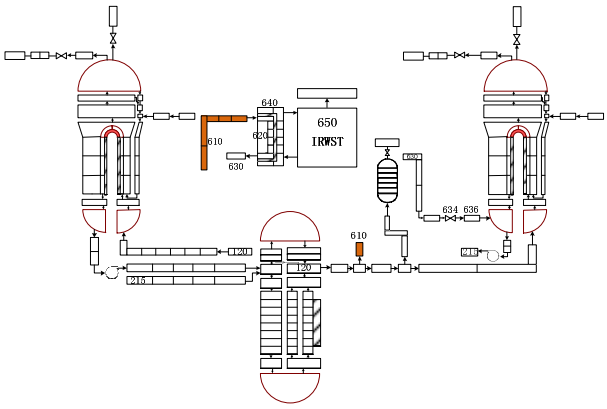

Fig.2. Control volumes of the system

The inlet pipe of the heat exchanger was connected with the hot leg of reactor coolant system. And the outlet pipe was connected with the cold chamber of steam generator's channel head. On the outlet pipe, there was a normally closed valve that would be open when air pressure lost or control signal triggered. These said equipment and pipes construct a loop associated with the pipes of reactor coolant system. When the passive residual heat removal system was put in to operation, the natural circulation would be built, and the residual heat could be removed by the coolant.

System Model

Based on RELAP5/MOD3.2 program, the model of CNP1000 reactor coolant system was built, in which the passive residual heat removal system was used. And then, the transient response of the whole system was analyzed when station blackout occurs. The key equipment include reactor vessel, coolant pipe, pressurizer, reactor coolant pump, steam generator, passive heat exchanger, refueling water tank, the relevant pipe and valves. To simplify the system model, the secondary side pipes of steam generator were set as boundaries, because this main analytical thesis being the transient response of passive residual heat removal system.

After setting the AP1000 passive residual heat removal system to the primary circuit of CNP1000, the graph of control volumes for this whole system is shown below. It should be noted that, to illustrate expediently, the loop on left side in the graph represents the two loops that have no connection with pressurizer in CNP1000 reactor coolant system.

The up-leg of passive residual heat removal system is connected with the hot leg on the main system, through which the coolant flows into the heat exchanger, whose control volume number is 620. Out of the heat exchanger the cooled fluid flows into the cold chamber of steam generator's channel head. On the outlet pipe the control volume, whose number is 634, simulated the normally closed valve that would be open when steam generator level was low. In consideration of the increase in heat transfer by natural convection, control volumes of No.650 and No. 640 were used to simulate this phenomenon [4].

Result of Calculation and Analysis

After station blackout occurred, the low speed signal of reactor coolant pump would close the reactor, and then the turbine would drop out. The feed water of steam generator would be lost, so the pressure and temperature in the secondary side would go up. When the pressure reached the setting value, drain valve would be open and the steam was discharged to air. At this time, steam generator level became lower and lower, finally the normally closed valve on the outlet pipe was tripped to open, and the passive residual heat removal system was put in to operation [5].

Tab.1 shows the design parameters of passive residual heat removal system and refueling water tank respectively [3].

Tab.1. Main design parameters of passive residual heat removal system

Design flow	2.28×10^5 Kg/h
Inlet temperature	570.35K
Outlet temperature	365.95K
Design pressure	17.1 Mpa
Design temperature	616.45K
Number of heat transfer tubes	689
External diameter of heat transfer tubes	0.0017m
Total area of heat transfer tubes	$286.9m^2$
Material of heat transfer tubes	Alloy Inconel 690

Let the system stabilize and introduce station blackout accident in 500 seconds. Then the coolant pumps began to run down, and the main feed water stopped, the low speed signal of reactor coolant pump would close the reactor. At that time, the core power began to decay form the 7 percent of the rated value and the point-reactor model was used to simulate the variety of power. 150 seconds after station blackout occurred, the coolant pumps stopped, and the level of steam generator became lower and lower, finally the passive residual heat removal system was put in to operation by low water level signal of steam generator. The key events after accident were shown in table 2.

Table 2 Key events after accident

Key events	Time(s)
Station blackout	500
Reactor shutdown	504
Pressurizer safety valve open	505
Pressurizer safety valve closed	511
Passive residual heat removal system start	554
Coolant pump stop running	650

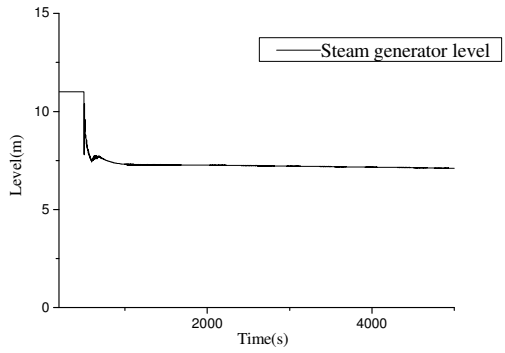

Fig.3. Level of steam generator

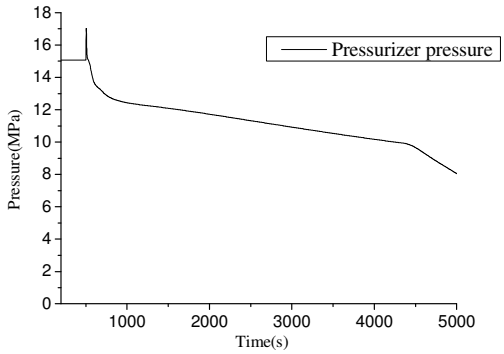

Fig.4. Pressurizer pressure varying with time

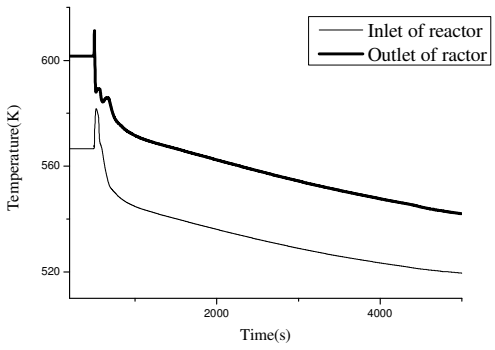

Fig.5. Inlet and outlet temperature of reactor

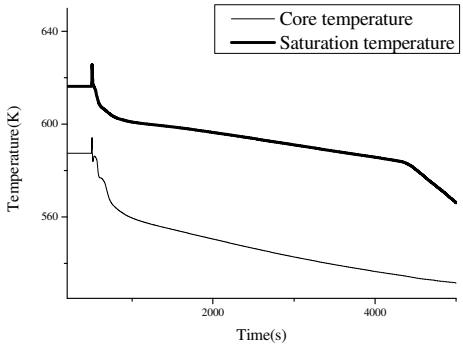

Fig.6. Core's temperature and saturation temperature under corresponding pressure

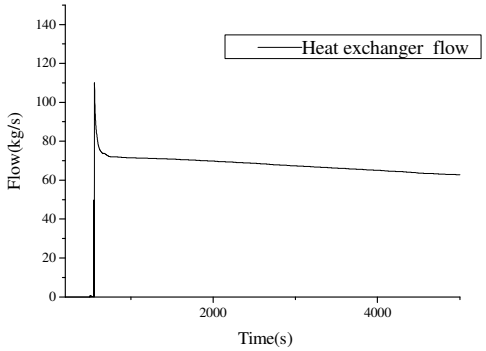

Fig.7. Flow of heat exchanger varying with time

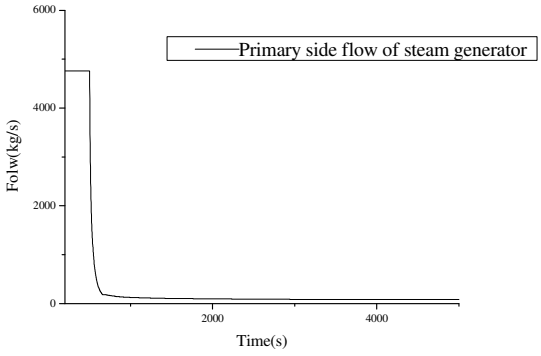

Fig.8. Primary side flow of steam generator

Before the passive residual heat removal system put in to operation, the pressure and temperature of the primary loop increased sharply, and the pressurizer safety valve was triggered to open. However after the normally closed valve became open, the residual heat of the core was quickly removed. The pressure and temperature, shown in Fig.4 and Fig5, dropped considerably. During the whole process, the core temperature was lower than the saturation temperature, shown in Fig.6, and the departure from nucleate boiling (DNB) didn't occur. Because of the gravity head of natural circulation, the coolant flow was about 60 kg/s in the passive residual heat exchanger, shown in Fig.7, and 84 kg/s in the steam generator, shown in Fig.8. It means that the gravity head of natural circulation can remove the core residual heat effectively. When the passive residual heat removal system operated steadily, the steam generator has already lost the function of hot trap. However in the steam generator heat was removed from the secondary side to the primary side. Thus it can be seen that the capacity of passive residual heat removal system can fully meet design requirements.

Calculations show that, at blackout accident, operating passive residual heat removal system can make the temperature and pressure dropped quickly. Setting the Westinghouse AP1000 passive residual heat removal system to the primary circuit of CNP1000 could ensure the security of the whole system when station blackout occurs. Testified by RELAP5 program, this scheme is feasible. After designing the passive residual heat removal system reasonably, the residual heat can be removed effectively and chronically, the core would be safe at blackout accident.

Conclusion

The aim of this paper is to set Westinghouse AP1000 passive residual heat removal system on the primary circuit of CNP1000 and use RELAP5/MOD3.2 program to calculate and analyze the response and operating characteristic of passive residual heat removal system on assumption that Station Blackout occurs. The calculation model could simulate the steady state accurately. And calculations show that, natural circulation was quickly established after accident, and residual heat can be quickly removed, and during this process the actual temperature was lower than the saturation temperature in reactor core.

Abstract: For the simulation of wind turbine, the wind speed is extremely important parameters and indicators to measure the output power of the unit is the wind load. Therefore, in the airflow dynamics and simulation of wind loads before establishing an accurate wind speed model is crucial. At present, the application for wind turbines COMSOL fan, fan blades and wind load simulation field, the extremely important wind speed model is not perfect, most of the research is confined to a single constant wind speed, wind speed virtually ignored the magnitude and direction of change, on changes over time and space at the same time is one of the few studies of wind, so find a way to accurately describe the range of wind speeds, and can be combined well with COMSOL method can greatly improve the aerodynamic performance of wind turbines the overall level of .

Introduction

COMSOL was able to get a very wide range of applications, in addition to highlighting meshing capabilities, rich physical models and advanced algorithm for solving the border issue dynamic variable grid technology, but also has an easy user-defined program secondary development interface[1] . This article is based wind turbine simulation analysis to achieve the specifications in the wind load model and simulation data and theoretical calculations through comparison proved the feasibility and accuracy of the method.

Vertical Wind Shear Model

Wind shear associated with the change of wind speed, wind turbine cycle is the main source of alternating load one[2] . Velocity shear wind speed amplitude model refers to the different spatial positions with changed circumstances, including horizontal shear and vertical shear types, this study is the vertical velocity shear. Reaction vertical wind shear wind profile v (z) is the average wind speed anywhere but highly Z varies as a function, for the standard requirements of the wind turbine wind load performance simulation and load calculations, fan wind profilers meet the following power exponential equation:

$$v(z) = v_{hub}(\frac{z}{z_{hub}})^{a} \quad (1)$$

z_{hub} — Hub height, previously established through the whole wind field model shows that Z_{hub} =80m;

a — Wind profile index is used to determine the surface through the rotor swept when the average wind shear, a= 0.2;

v_{hub} — The average hub height wind speed, vg=10m/s:

z — Height from the ground, is a function of the independent variable.

Each parameter value into equation (1), wind profiler function becomes formula (2):

$$v(z) = 10(\frac{z}{80})^{0.2} \quad (2)$$

As a non-integer, resulting in the COMSOL power exponential function and can not be called directly, this introduces a power series expansion method to simplify the formulas[3] . Elementary

functions in power series expansion binomial series is ideal for wind profiler function unfolds, binomial series as formula (3) below.

$$(1+x)^a = 1+ax+\frac{a(a-1)}{2!}x^2+\cdots+\frac{a(a-1)\cdots(a-n+1)}{n!}x^n+\cdots \quad (3)$$

COMSOL into predefined macro access to the grid coordinates of the center of the height x[l], the wind field model considering the position of the origin of coordinates, of the formula (2) in the independent variables from the original Z represents a height from the ground center height direction with grid coordinates expression m = z = x [1] +80, so that y = m/80, the wind profile function becomes formula (4)[4] :

$$v(z) = 10(1+(y-1))^{0.2} \quad (4)$$

Gust Model

On the standard scale wind turbine, wind turbine design requirements repetition period of N years gust amplitude hub height by the following formula (5) Calculation:

$$V_{gustN} = \beta(\sigma_1 / (1+0.1D/\Lambda_1)) \quad (5)$$

V_{gustN} — amplitude of the gust;

σ_1 — turbulent wind standard deviation of longitudinal component;

Λ_1 — Hub height of the vertical turbulence scale parameter;

D — wind wheel diameter, D=77m；

B — repeat cycle with constant related, β=4.8 for N=l, β=6.4 for N=50.

To repeat the cycle of N = l example, a case study was to select the level of wind turbines Grade I_a, Richard extremes reference to the average wind speed V_{ref} = 50m / s, the average wind speed v_{are} = 10m / s, turbulence intensity characteristic values I_{15} = 0.18, slope parameter a = 2: wheel hub height of 80 meters from the ground, thereby determining the longitudinal turbulence scale parameter Λ_1 = 21m; selection conditions for the average wind speed at hub height V_{hub} = 10m / s, thus calculate the standard deviation σ_1[5] :

$$\sigma_1 = 0.18(15+2\times10)/(2+1)m/s = 2.1m/s \quad (6)$$

Simulation of Aerodynamic Characteristics of Wind Turbines

In the full establishment of the whole wind field model, accurately describe the vertical velocity shear and other wind model, a reasonable set solvers and turbulence models and other parameters correctly determine wind convergence conditions, the fan performance simulation. Primary authentication of the wind speed constant, and the blade is highly integrated speed 13m / s and a vertical gust two tangential velocity of the working conditions of detailed calculations obtained wind pressure, wind velocity and wind loads, such as simulation junctions.

Build wind turbine wind field model for 10m/s, 11.5m/s and 13m/s three kinds of constant wind speed, rotor speed for a variety of conditions of the simulation analysis. Figure 1 is left with the wind speed and wind wheel torque relationship between speed curve is calculated by the formula right out of the wind turbine output power curve. As can be seen from the figure, the wind wheel starts from rest, by the action of wind generated after the initial torque, but speed is zero so that the output power is zero; the torque under the action of the wind wheel begins to accelerate, starts to output power; for different stream wind velocity, wind turbine output power reaches a maximum when they correspond to different optimum speed. For proper operation of the wind turbine, the programmable system will adjust the size of wind rotor speed, making the process of change in wind speed wheel stroke can maximize the output power.

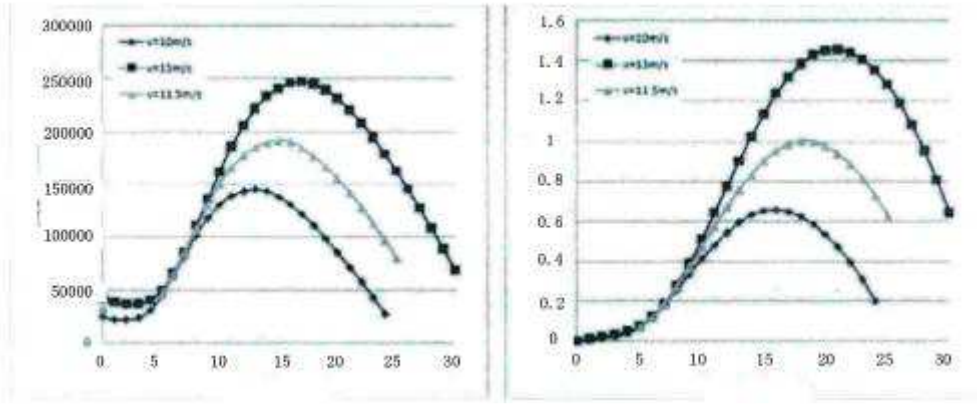

Fig.1 Relationship of torque, speed and power

In the height direction is established at Y =-20m horizontal section, the two wind conditions do not read a lot of time to the cloud static pressure distribution in the cross section shown in Figure 2, where the left is the initialization phase, the right vertical velocity shear conditions.

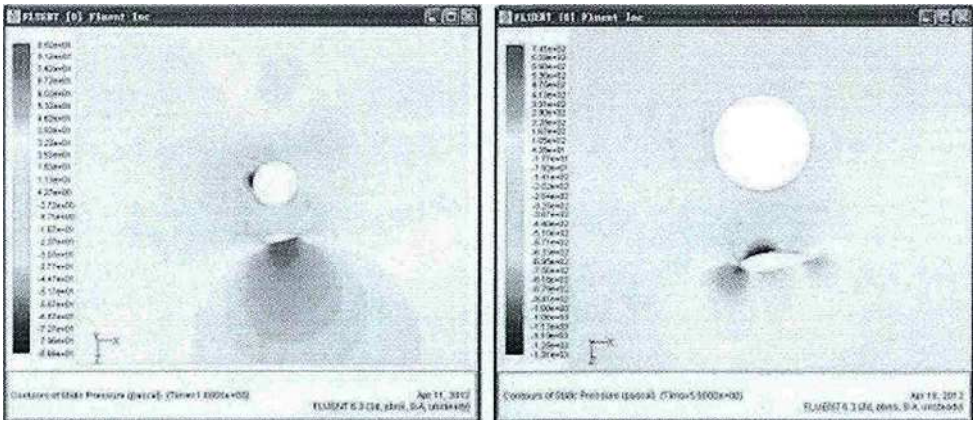

Fig.2 Pressure distribution of initialization and wind shear conditions Y =-20m

Figure 3 is a wind wheel left stationary initialization phase Y =-20m sectional velocity vector in the direction of the velocity windward surface substantially perpendicular to the blade, encounter obstacles to the right and left sides of flow, bypassing the flow of the wind tower field behind the tower between the blade and the blade trailing edge and the rear tower have formed a disaster flow; shear air damper position is right at t = 5.9s time Y =-20m sectional velocity vector cloud, then blade substantially in the tower in front of the wind wheel with 18.6rpm angular velocity in the tower is not formed between the blade cylinder and the swirling disaster, but rather from the leading edge to the rear edge of the air presence in the tower and the blade trailing edge is the same forming a vortex.

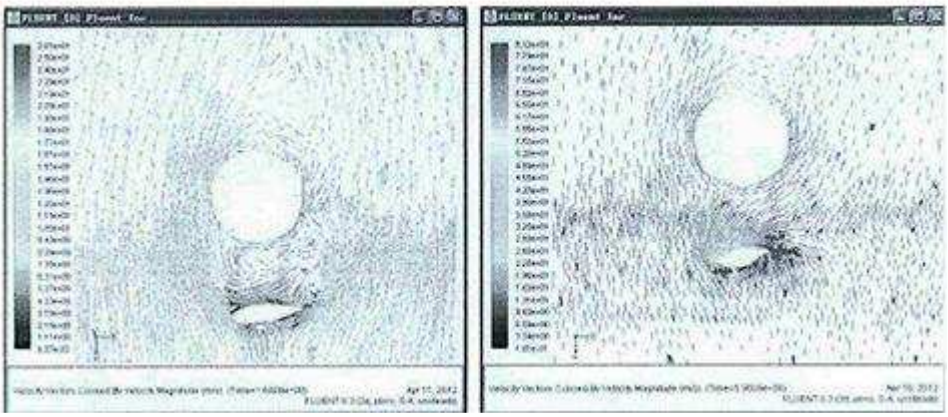

Fig.3 Y =-20m sectional velocity vector

This paper chooses the average wind speed at hub height of 10m/s, the wind wheel speed 18.6rpm, pitch angle of zero degrees vertical wind shear changes and random time-varying wind conditions for wind turbines two global model simulation, the simulation time exceeds a wind wheel rotation cycles, where the tangential wheel power condition shown in Figure 4, the calculated power is 1.32MW, 79.8% of the standard value. Torque coefficient curve shown in Figure 5.

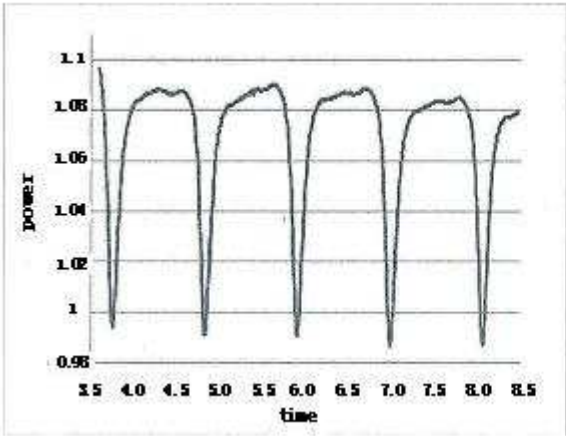

Fig.4 Wind shear conditions of the power curve

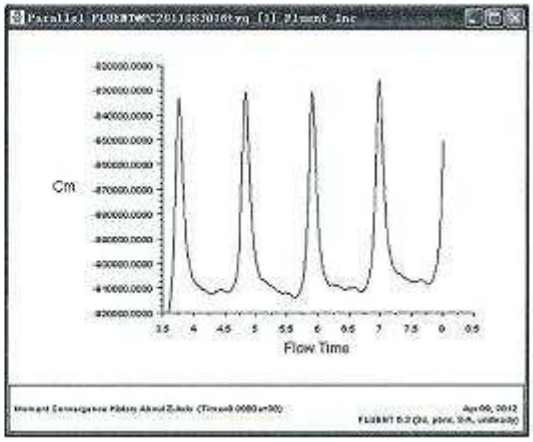

Fig.5 Wind shear conditions of the torque coefficient curve

Conclusion

This chapter of the fan operating characteristics of the simulation results were analyzed, the first step of 0.06s in the premise of the eight working conditions of constant wind power simulation verification, the basic calculation error less than 13%, reducing the simulation time step after the calculation accuracy has greatly improved, 0.02s step error is reduced to 12.3% while, thus proving COMSOL accuracy of the method, and reduces simulation step can further improve the accuracy, on the basis of analysis of the results of the other; through wind pressure and wind velocity of the gas stream with the discussion of the interaction of the blade mechanism was studied; vertical tangential wind conditions change, for example, the calculated torque and the rotor blades with three-time curve of the load, via the torque and power variation found negative effects of tower shadow effect; the particular location during rotation of the blade aerodynamic loads, to give the waving direction and the bending moment in array, and standards were compared limit load.

Analysis on capacity of transmission line based on thermal rating

Yang Bo,Wu Kuihua,Wang Yiqun,Yang Shenquan

Economic & Technology Research Institute, State Grid Shandong Electric Power Company, Shandong Jinan 250021

Keywords: Transmission capacity; Static thermal rating; Real-time static thermal rating

Abstract. The rapid growth of power grid load put forward higher requirements on the transmission capacity of line, with the growing tension of line corridors, building new transmission lines is becoming more and more difficult. Therefore, it is of realistic significance to analyze the transmission capacity of existing transmission line and fully tap the existing power grid transmission capacity. On the basis of previous studies, and consulting a large number of references, this paper summarizes and expounds the methods of improving transmission capacity by using the thermal rating analysis, introducing static thermal rating and real-time static thermal rating. Also, this paper verifies applications of the above methods in actual running environment.

1 Introduction

As an important component of power system, transmission line is the carrier of connecting power generation side and power demand side, and its transmission capacity will directly affect the level of the power generation side and electricity side, which have important influence on the development economic and social. Especially the rapid growth of social power load in recent years, how to improve the transmission capacity of power grid has becoming a hot spot of research.

On the issue of improving grid transmission capacity, on one hand, strengthening the construction of power grid and new power transmission and transformation projects, optimizing the existing network structure, to improve the power transmission capacity; on the other hand renovating the existing grid technical to improve the transmission capacity of the existing grid. For the transmission lines in power network, the transmission capacity is determined by the conductor itself limited factors. When current through conductor, temperature of the conductor rises and stress and sag of the conductor increases, which are the main factors of limiting transmission capacity. The transmission capacity of conductor is determined by the temperature of the conductor, tension and sag, which is restrained at first, in practice, temperature is usually used to express uniformly. So methods of improving the transmission capacity of existing transmission grid can mainly considering from two aspects: one method is to improve the conductor operating temperature, without changing the circuit structure to improve the transmission capacity, the permission of the allowed operating temperature is higher, the conveying capacity is greater. The other is based on the operating conditions of a transmission line changing, through real-time online measurement information (such as temperature, light intensity, etc.), through the mathematical model calculation to calculate and determine the real-time operation condition of line, on the basis of meeting the safety running to play the actual transmission capacity of line as much as possible. In the actual operation environment, power grid transmission capacity is mainly affected by transient stability, voltage and the thermal stability the three constraints, with the grid is becoming stronger and stronger, and the application of FACT technology, transient stability and voltage constraints are no longer the main factor of restricting the transmission capacity, thermal stability has gradually become the bottleneck of limiting transmission capacity[1]. Therefore, to develop thermal load capacity of the existing grid has important research value. On the basis of previous studies, this paper summarizes two analysis methods of thermal load capacity of transmission line.

2 Thermal fixed value analysis method

2.1 Static thermal rating of conductor

Static thermal rating is the maximum allowable current carrying value which is calculated according to conductor allowable temperature from the thermal equilibrium equation under stable operation condition. Now many countries and organizations put forward the solving and modeling method of static thermal constant value of transmission lines, of which the more representative is the IEEE standard, CIGRE standard calculation method[2-3]. The calculation basis of these methods are basically the same, all based on the thermal balance equation of the transmission line, which is thermal balance according to the wire in a variety of heating and cooling factors in the process of operation, to calculate the maximum allowable current carrying value, only the factors in the process of calculation is different, but difference between the results is small. Following is the analysis and calculation to the IEEE standard.

When the heat generated by the conductor itself and absorbed from the outside world is equal to the quantity of heat lost to the world, the conductor runs in the thermal equilibrium state. Assume the transmission line is a uniform conductor, the heat balance equation of conductor expressed by the IEEE standards is:

$$q_l + q_s = q_c + q_r \tag{1.1}$$

q_l on behalf of the heat generated by conductor caused by current, and q_s for the heat of conductor absorbed from sun; q_c on behalf of convection heat of conductor, and q_r means the radiation heat of conductors. In CIGRE standard, in addition to the above four factors, the evaporative heat loss and the corona loss are also taken into account, but because of the changes in the quantity of heat balance caused by those is small and has strong randomness, CIGRE standard did not give specific calculation expression.

In the range of allowable operating temperature, the approximate expression of the calorific value caused by conductor current according to IEEE standard is:

$$q_l = I_{ac}^2 R(T_c) \tag{1.2}$$

I_{ac} on behalf of the AC current, $R(T_c)$ is the AC resistance when the temperature of conductor is T_c, and

$$R(T_c) = \left[\frac{R(T_{High}) - R(T_{Low})}{T_{High} - T_{Low}}\right] \cdot (T_c - T_{Low}) + R(T_{Low}),$$

$R(T_{High})$ and $R(T_{Low})$ respectively represent the AC current resistance under the known high temperature T_{High} and low temperature T_{Low}.

For the other three factors in the heat balance equation, the IEEE standard also gives the corresponding calculation method and calculation model, no longer will we say here.

Various factors affecting the transmission line in actual operation are considered in equation (1.1), including heating and cooling factors, and the equation really reflects the relationship between conductor current and temperature in a certain operation environment. Static thermal rating of transmission line is solved according to the heat balance equation through setting conservative boundary conditions (such as high temperature, strong light, small wind speed, etc.). Therefore, the calculated difference between static thermal constant values is relatively large when using different boundary conditions. For example, some nations have their own rules to the allowable operating temperature, Japan and the United States taking the temperature of wire heating allowed is 90℃, Germany, the Netherlands, Switzerland is 80℃. Our country in the original design procedure is 70℃(large span is 90℃) referring to the standard of the former Soviet union, due to restriction of wires allow temperature, the line transport capacity is also limited. In 2010, the latest issued national standard increased the allowing temperature of conductor heating to 80℃, according to the experience, carrying capacity can be increased by 24% - 27% if wire allowing temperature from 70℃ to 80℃. Therefore, the carrying capacity can further increase if we can improve the allowing temperature of wire heating, further improving the transmission capacity of existing grid, namely

without changing conductor structure to increase transmission capacity. In order to improve the transmission capacity of the line, further researches are needed in material of transmission line to improve the allowing temperature of line in the long running time.

Static thermal rating converted the limit of the allowing temperature of conductor to the limit of the allowing current, which is convenient for the use of engineering. But because of its conservative boundary conditions, its real transmission capacity is limited in most time. In order to solve this problem, on the basis of the static thermal rating, some countries and regions began to try to calculate multiple static thermal rating under different conditions, for guiding operation scheduling and control of the system. Such as setting multiple fixed values one year or a day, some places enact normal situation, short-term situation, an emergency of the thermal constant value, etc. By setting different static thermal rating under different condition, line transmission ability can be improved in a certain extent, which is conducive to play real transmission capacity of the line as much as possible [4].

2.2 Real-time static thermal rating of conductor

When designing the line, the setting limit value of the line is a kind of static value, in order to prevent line fault if the transmission capacity more than the allowed conveying capacity, it is assuming the line running on the basis of harsh weather conditions, and determining a conservative static limited capacity. But in the actual operation conditions, such bad weather conditions is rare, so the line can't effectively play its transmission capacity and waste a portion of the resources in the vast majority of cases. Therefore, considering the combination of line heat balance equation, and the line in the actual operating conditions of a variety of circumstances (such as the weather temperature, wind speed, etc.), to consider improving transmission line transmission capacity.

With the continuous development of modern measuring technology, the environment temperature, wind speed, sag, tension, and light and other related measuring technology is mature, making it is possible to determine the load capacity of conductor environment according to the actual measurement, which is the real-time static thermal rating. Davis, in 1977, first put forward the concept of real-time static thermal constant value, is on the basis of the theory of the extension of the SCADA system, which include the meteorological data (sunshine intensity, wind speed, wind direction, environment temperature, etc.) and the conductor temperature. The system has made many times experiments study[5], combined with the thermal equilibrium equation and the actual operation environment parameter data of line, real-time static thermal rating can be further excavated the real transmission capacity of conductor, slows down the demand for construction and expansion of the line, save investment, and improve the reliability of system.

Taking LGJ - 300 overhead line used commonly for example, to demonstrate the theory that based on the actual operating conditions of real-time static thermal constant value can significantly improve the line thermal load ability, combined with the region's environmental parameters, analysis the real-time static thermal constant value of lines, and compared with its static thermal constant value (safety current).

Combining circuit parameters, and through the calculation of the heat balance equation, the static thermal constant value of LGJ - 300 transmission lines (safety current) is 710A. Through collecting meteorological data in the region (sunshine intensity, wind speed, wind direction, environment temperature, etc.), calculate and obtain real-time static thermal rating of the transmission line based on the actual running environment in a few selected time period, as is shown in Fig.1.1.

The selected three moment in Fig.1.1 respectively is on August 8, October 8, and December 28, in which August 8 represents the region appeared typical moment of maximum temperature throughout the year, and December 28th annual minimum temperature for the region of typical moment throughout the year.

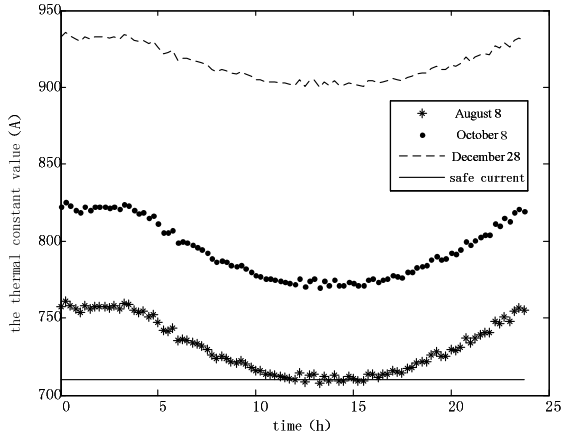

Fig.1.1 Real-time static thermal rating of LGJ - 300 transmission lines (safety current)

According to the curve in Fig.1.1, because August is the highest temperature in the region, so, in August 8, most of the time real-time static thermal constant value are higher than the safety current value, only in the moment 1, 2 PM due to environment temperature reach the highest temperature during the day, it is likely to appear the real-time static thermal constant value is lower than the safety current situation, but as the environment temperature is the extreme maximum temperature in the region; and October 8, the environment temperature is reduced, the current real-time static thermal constant value are higher than the safety current value; By December 28, the environment temperature is far lower than the temperature in August and October, so at this time the real-time static thermal constant value is much higher than current value.

Therefore, the calculated real-time static thermal rating is basically greater than the safety current value, in most of the time even far higher than the safety current value, this can also prove safety current value, namely the setting of static thermal constant is conservative, is not conducive to transmission lines to give full play real load capacity, also verify the analysis method of real-time static thermal constant value can better play to the line of actual transmission capacity.

3 Conclusion

On the basis of precious study, this paper summarized methods of researching and improving the thermal load capacity of transmission line. Combined with the heat balance equation of the transmission line, first elaborated thermal constant value analysis method based on the heat balance equation of transmission line, including static rating and real-time static thermal rating analysis methods. The paper also analyses the application of both in improving the transmission capacity of transmission line combined with the actual running environment.

Keywords: Peak regulation; Capacity of wind power; Power balance.

Abstract. Among all the factors influencing the capacity of wind power, peak regulation capability is commonly regarded as one of the most important constraint factors. From the perspective of peak regulation, the maximum peak-load regulating adequacy revised by the wind power characteristic coefficient is the limitation of the capacity of wind power. This paper proposes an assessment system on capacity of wind power integration into grid based on power balance. First of all, this assessment system takes the impact of wind power integration on the reserve capacity of the power system into consideration. Then calculate the reserve capacity based on power generation reliability index. Finally, evaluate the capacity of wind power based on the peak regulation capability of the units during the low load period. This paper analyses the capacity of wind power integration into Liaoning power grid based on power supply characteristics, load characteristics and peak-valley difference, and points out that the phenomenon of the "wind curtailment" is unavoidable. According to the specific situation of wind power limitation, this paper proposes measures to maximize the capacity of wind power.

Introduction

Wind power generation, as a fully-developed renewable energy power generation technology has developed rapidly in China in recent years. While different degrees of phenomenon of the "wind curtailment" appears in different areas, which leads to heat discussions and wide researches on the capacity of wind power integration into power grid. The capacity of wind power integration into power grid is limited and affected by aspects of safe and reliable operation of the power system, such as, the limitation of frequency regulation and peak regulation, the limitation of steady state power flow, the limitation of transient stability and the limitation of reactive power and voltage. Among these limitations, the capacity of peak regulation which has a significant influence on safe and reliable operation of the power system and is widely considered as the key factor to limit the capacity of wind power relates to the economic cost in system operation, the accurate prediction of wind power output and the component ratio and features of power.

[1] and [2] made a detailed research on the characteristics of wind power output in Jiuquan wind power base and concluded that the problem of frequency regulation the system are facing after large scale wind power integration is not obvious due to the complementarity of wind power output within a short time. Peak regulation of the system faces great pressure within a long time because of the correlation of wind power output. Usually the wind power integration into power system in a large scale requires deep spinning reserve of conventional thermal power units or the cold stand-by of hydroelectric unit to deal with the intermittent fluctuations of wind power. A large amount of reserve capacity required for the operation of wind power is the root of great pressure the system are facing after large scale integration of wind power. In order to provide support for the reasonable arrangement of the local wind power planning and scheduling strategy [3-4], based on the wind power clustering effect [5], this paper concludes the capacity of wind power integration into power grid through the analysis on the characteristics of the power supply and the load of Liaoning power grid.

The Assessment System on Capacity of Wind Power

The characteristic indexes on capacity of wind power. Because the capacity of wind power integration into power grid is not directly determined by characteristic indexes of wind power and power grid, they influence and control each other and are indirectly determined by the coordinated operation of large power grid. This paper proposes the characteristic indexes on capacity of wind power from the aspects of wind power characteristics and power grid characteristics.

Characteristic indexes of power grid mainly include the power supply characteristics, structure characteristics, load characteristics and safety reliability. Characteristic indexes of wind power include simultaneity rate, power change rate, peak-shaving capability, power prediction, credible capacity, wind power curtailment ratio and utilization rate of wind energy. Fig.1 shows the assessment system of the capacity of wind power.

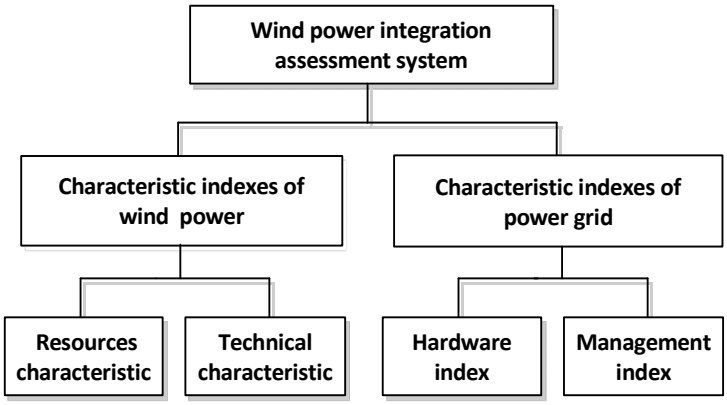

Fig. 1. The hierarchy of wind power integration assessment system

The method of evaluation on wind power integration capacity. The capacity of wind power during the low load period determines the capacity of the wind power integration into power grid. The analysis on power supply and lowest load is the main aspect of the assessment system. Power supply arrangement should consider enough spinning reserve when thermal power units and hydroelectric units are in peak load period, besides, generation power of thermal power units can reduce to the lowest output according to the deep-regulation, and the output of hydroelectric units are able to reduce to zero, but it is better to consider some unit-operating capacity of system. The capacity of wind power during the low load period equals the difference between the lowest load and the lowest output of all units in operation. The capacity during the low load period is converted to the capacity of wind power integration into power grid according to simultaneity rate [6-7].

Evaluation procedures on capacity of wind power integration into grid based on power balance as follows：

1) The overall analysis of power source composition， load characteristics, peak-valley difference, reserve capacity and fluctuation of wind power.

2) Calculate the reserve capacity according to system reliability.

3) Calculate non-dispatchable output, the capacity of heating units, tie line power and the capacity of pumped storage unit P_{pump}.

4) The maximum output $P_{g\,max}$ and the minimum output $P_{g\,min}$ inside the power system as follows

$$P_{g\,max} = P_{load\,max} - P_{tie}. \quad (1)$$

$$P_{g\,min} = P_{load\,min} + P_{pump} - \lambda_1 P_{tie}. \quad (2)$$

Where $P_{load\,max}$ is the peak load, P_{tie} is tie line power, $P_{load\,min}$ is the valley load, λ_1 stands for regulation rate of tie line power.

5) The output of peak regulation unit during peak load period $P_{reg\,max}$ and low load period $P_{reg\,min}$ as follows

$$P_{reg\,max} = P_{load\,max} - P_{con} - \lambda_2 P_{thermal}. \quad (3)$$

$$P_{\text{reg min}} = P_{\text{load min}} - P_{\text{con}} - \lambda_2 P_{\text{thermal}} . \quad (4)$$

Where P_{con} is the non-dispatchable output, λ_2 and $P_{thermal}$ stand for peak regulating rate of heat supply unit and capacity of heat supply unit.

6) The unit-operating capacity of peak regulation unit $P_{commit\ max}$ and the minimum output $P_{commitmin}$ as follows, where γ stands for regulation rate of peak regulation unit.

$$P_{\text{commit max}} = P_{\text{reg max}} + P_{\text{reserve}} . \quad (5)$$

$$P_{\text{commit min}} = \gamma P_{\text{commit max}} . \quad (6)$$

7) The capacity of wind power integration into power grid P_{wind} as follows, where β is simultaneity rate of wind power.

$$P_{\text{wind}} = \frac{P_{\text{reg min}} - P_{\text{commit min}}}{\beta} . \quad (7)$$

Analysis of Power Supply Characteristics and Load Characteristics in Liaoning Power Gird

Table 1 presents the components of power supply in Liaoning by the end of 2012, with thermal power being the major component and heat supply unit taking a relatively large portion. So the peak regulation capacity of power supply is low.

Table 1 The development of power supply and load in Liaoning Province

Category	2007	2008	2009	2010	2011	2012	annual rate of growth [%]
Peak load [MW]	19330	19450	22100	24650	24960	27750	7.50
Installed capacity of power supply [MW]	21310	22010	25550	32275	34004	38070	12.30
Tie line power [MW]	6000	6050	6800	6800	9000	9620	9.44
Installed capacity of wind power [MW]	346.7	833.6	1733.2	3084.4	4023.3	4755.9	68.83

Wind power develops quickly in Liaoning power grid and it has become the second largest power, ranking the fourth in the system of State Grid Corporation. The daily average load of Liaoning power grid in winter, 2012 is presented in figure 2. The maximal difference between peak and valley load is presented in figure 3.

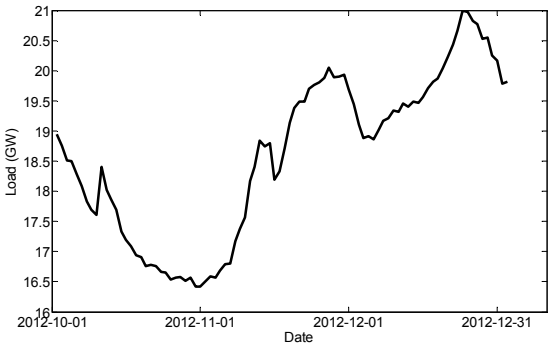

Fig.2 Daily average load of Liaoning power grid in winter

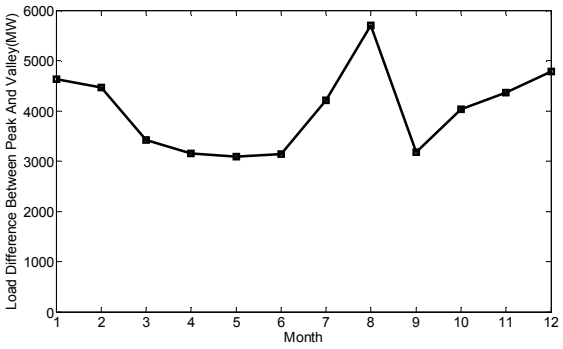

Fig.3 Maximal difference between peak and valley load

The above analysis shows that the peak-valley difference mainly appears in summer and winter which is contradictory with the distribution of wind power output, thus it leads to reverse peak regulation of wind power.

The analysis of wind power capacity in Liaoning power grid

Start-up mode is determined in the mode of winter peak time, spring festival, summer peak time and May 1st every year. Start-up principle is that power supply in peak hours must guarantee enough Spinning reserve capacity, not too much as well. Generation power of thermal power units can reduce to the lowest output according to the deep-regulation, and the output of hydroelectric units are able to reduce to zero.

The following is the illustration of calculation on capacity of wind power integration into power grid by taking winter peak time as an example. Installed capacity is 22129MW, and tie line power is 9600MW. According to statistics of wind power in 2012, the highest load demand in Dec, 24th is 23581MW and the lowest load demand is 18050MW. λ_1 is 0.7, λ_2 is 0.78, γ is 0.6, simultaneity rate is 0.7, and preserve capacity is 764MW.

Through the analysis and calculation, P_{gmax} is 13981MW according to historical data provided by Liaoning power grid. P_{gmin} is 11330MW, $P_{reg\ max}$ and $P_{reg\ min}$ are 12871MW and 10220MW respectively. So the capacity of wind power is 2914MW. The installed capacity of wind power in Liaoning power grid is 4756MW in 2012. So, when the wind power output is larger than the limitation, the phenomenon of "wind curtailment" is unavoidable. Table 2 presents the Generating capacity and wind power curtailment monthly in Liaoning Province.

Table 2 Generating capacity and wind power curtailment monthly in 2012

Category	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Installed capacity of wind power [MW]	4100	4170	4340	4390	4420	4420	4560	4560	4660	4710	4710	4760
Generating capacity [Million KWH]	306	662	783	1100	685	631	535	407	632	770	624	743
Wind power curtailment [Million KWH]	119	200	164	156	19	10	15	31	15	51	198	152
Curtailment proportion [%]	38.89	30.21	20.95	14.18	2.77	1.58	2.80	7.62	2.37	6.62	31.73	20.46
Utilization hours	75	159	186	255	154	142	116	86	135	156	132	156

Summary

The evaluation system of wind power capacity based on system reserve and peak-regulation capacity is proposed in this article. By the overall analysis of power source composition, load characteristic, reserve capacity, tie line power and peak-regulation capacity of thermal power unit, taking Liaoning power grid as an example, the result of evaluation shows that the phenomenon of "wind curtailment" exists in the low load hours during winter heating period.

Keywords: CCHP; gas engines; gas turbines; economics

Abstract. In this paper, case of hotel in Shanghai was studied, and three kinds of CCHP import solutions are discussed by this algorithm based on real working condition parameters of thermoelectric load. Then, put forward the relative conclusions based on comparison of each scheme and calculation of power supply benefits and heating benefits, from the point of power supply economics and heating economics. So it has certain realistic meaning for the application of CCHP system in city hotel buildings.

Introduction

It is well known that the present energy structure does great harm to our environment, and delayed the implementation of sustainable development. At present, the important issues are Energy Price, the stability of the electric power grid, environmental pollutions and global climate change, and how to save energy and protect the environment have become an imminent. To resolve the above problems, it is necessary to adjust the energy resources structure and the extensive development of clean energy resources including nature gas. As a kind of distributed energy systems, systems of combined cold, heat and power driven nature gas has become a trend in the world. And it can realize the project of the synthetic of saving energy, environment protection, increasing electricity servicing, dealing with the air pollution and enhancing the energy’ s synthetic utilization ratio[1,2].

Due to the special business position, hotel has large demand of power, heating and cooling. CCHP can make full use of waste heat from power generation to supply heating and cooling for users, by using waste heat recovery equipment. In this way, the primary energy utilization ratio of the system can be improved; the comprehensively cascaded utilization of energy can be enhanced[3]. And it can also supply power as energy complementary which increasing the economy income and efficiency of the entire system[4,5].

Overview of the case

The case chosen for this article is a hotel in Shanghai which covers an area of 34,700 m^2, with a total floorage of 59,320 m^2 and 500 guest rooms. Relevant information shows that hotel can be divided into big, medium and small hotel, according to the scale of the hotel (number of guest rooms in the hotel). The big hotel more than 600 guest rooms; small hotel has 300 guest rooms or less; medium hotel has 300 to 600 guest rooms. Therefore, hotel chosen in this case belong to medium-scale hotel. Before importing CCHP, three traditional sets of CJHS-G713 fuel steam boilers in original heating system of hotel. Electricity supplied by 2 sets of 2500kVA transformers. In the winter, The minimum power load is 649.59kW, maximum load is 1791.58kW, The minimum heat

load is $1288.79kW$, maximum load is $3525.15kW$. The minimum cool load is $0kW$, maximum load is $227.679kW$.

CCHP introduction plans

CCHP Introduction Model. A salient feature of Building Cooling Heating Power is multi-energy output, and it is mainly in different heat-electricity proportion. Different output proportion will greatly degrades the efficiency of the system. Combined Cooling Heating and Power system has two traditional operating modes: “fixing power based on heat" and "fixing heat based on power", “fixing power based on heat" is to determine the power output according to the heating load or cooling load[6,7]. However "fixing heat based on power" is to determine the heating output or cooling output according to the power load. Only when ratio of heat to power in actual energy consumption is approximate to that in CCHP system, the CCHP system can get good economic benefits. Capacitance of CCHP system is determined by the annual minimum power demand, and it can ensure grid-connected operation without power injection. Meanwhile, In this model, heat is generated by system much more annual heating demand, and the heat generated by system is 100% utilization, and the system will bring in great economic benefits (contribute a lot to economic profit).so, in this paper, "fixing heat based on power" is selected as the operating mode in CCHP system. Shortage of electric power could be supplied by power grid, and shortage of heating could be solved by supplementary fuel layout. And three $1.46t/h$ of gas turbine boilers are selected as supplementary equipment[8].

Introduction Plans. Considering the constraint of energy-saving potentials, this paper discusses four methods.

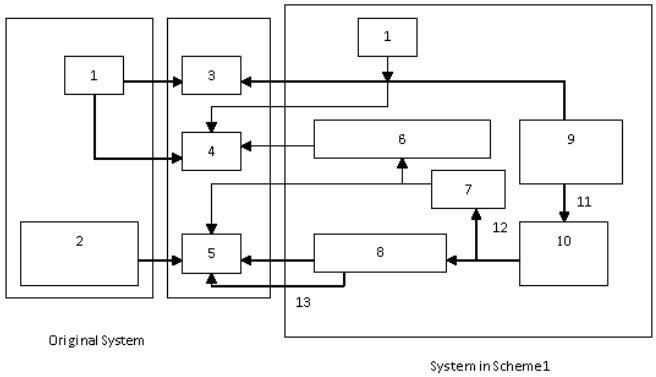
The first scheme: Yanmar EP350G gas internal combustion turbines and 0.188T / h HRSG;

The second scheme: Wilson PG475B gas turbine cogeneration units;

The third scheme: Caterpillar 500F/C15 diesel generator sets;

The forth scheme: United Technologies Corporation PureCell-400 fuel cells.

The first scheme. Internal combustion engine generator as one part of power plant, can combined with heat recovery steam generator highly efficient to recover waste heat, to enhances the efficiency of the whole system. Considering the limitation of energy-saving potentials, power load can be supplied by urban power network and gas internal combustion engine, and the Yanmar EP350G internal combustion engine generator set was selected as power plant.

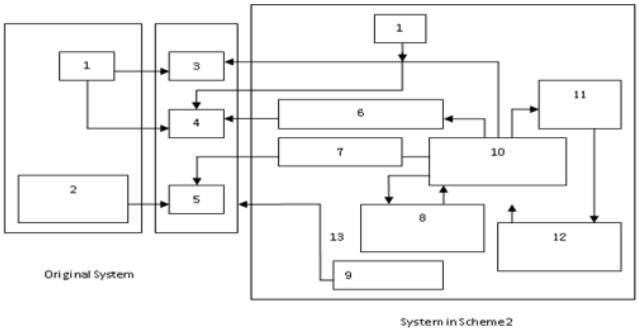


1-Commercial Power; 2-CJHS-G713 Oil-Fired Steam Boiler; 3-Power Supply; 4-Cool Supply; 5-Heat Supply; 6-Lithium Bromide Absorption Refrigerating Machine; 7-Boiler Cylinder; 8-Tubular Gas-Fired Boiler; 9-Gas Engine; 10-Afterheat Steam Evaporator; 11-High-Temperature Flue Gas;12-Steam; 13-Supplemental Combustion

Fig. 1 Flowchart of Yanmar EP350G gas turbine program

As Fig. 1 shows that, power load can be Time-Interval supplied by urban power network and internal combustion engine, the high temperature exhaust gas from the turbine is used to recovery steam generator for steam generation, and connected into gas-distributing cylinder in boiler room, which was combine by three 2t/h one-through gas boiler and one 7T/h old boiler, which can provide with heat for shower, cooking and drying. Shortage of heating could be solved by tubular gas boiler, and cooling can be achieved by the steam lithium bromide absorption chiller.

The second scheme. Gas Turbine suitable to the model of gas turbine and heat driven absorption chiller/ heater, the high temperature exhaust gas from the turbine is fully used to produce heating, and it can increase fuel efficiency. Wilson PG475B gas turbine cogeneration units was selected, for it is a high-efficiency set of solutions designed for CCHP by Wilson, with high reliability and utilization of flue gas for hotels transformation.

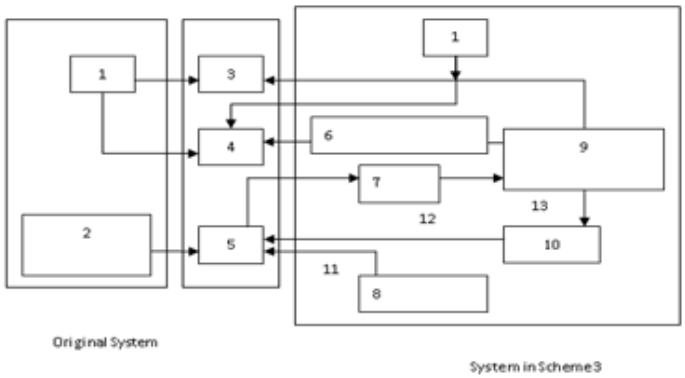


1-Commercial Power; 2-CJHS-G713 Oil-Fired Steam Boiler; 3-Power Supply; 4-Cool Supply; 5-Heat Supply; 6-Lithium Bromide Absorption Refrigerating Machine;7-Waste Gas Heat Recovery Furnace; 8-Inner-Cooling Cooling Water System and Remote Radiator; 9-Tubular Gas-Fired Boiler; 10-Wilson PG475B Gas Turbine; 11-Primary Heat Exchanger; 12-Jacket Cooling Water System and Remote Radiator; 13-Supplemental Combustion

Fig. 2 Flowchart of Wilson PG475B gas turbine cogeneration program

As Fig. 2 shows that, power load can be Time-Interval supplied by urban power network and internal combustion engine. When gas turbine is working, waste gas recovered by Waste Gas Treatment and Heat Recovery Equipment, there is a maneuvering directional valve at the inlet of equipment. The water recovers the heat of cylinder water by the primary heat exchanger and exhaust heat recovery device to further improve the temperature of water.

The third scheme. Today, research on the use of heat of diesel generators plays a less important role than gas turbines and internal combustion engines. In fact, the temperature of the exhaust gas of diesel generators is up to five-six degrees Celsius, with a high energy value in use. Considering the hotel's transformation space limitations and discharge exhaust temperature, the final choice is 500F/C15 Caterpillar diesel generator sets.



1-Commercial Power; 2-CJHS-G713 Oil-Fired Steam Boiler; 3-Power Supply; 4-Cool Supply; 5-Heat Supply; 6-Exhaust Gas Adsorption Refrigeration System; 7-Feed Water Pump; 8-Tubular Gas-Fired Boiler; 9-Caterpillar 500F/C15 Diesel Generating Set; 10-Cooler; 11-Supplemental Combustion; 12-Hot Water; 13-Exhaust

Fig. 3 Flowchart of Caterpillar 500F/C15 diesel generator program

As fig. 3 shows that, power was supplied by the market and diesel generator together. Diesel generator exhaust gas through a heat exchanger to get hot water, then hot water piped to each user, which can be adsorption refrigeration in the summer and gain heat by directly using hot water in the winter. You can also install a valve for 24-hour hot water supply.

Economy Analysis on Power Supply

The following table shows the price of electricity in Shanghai 2013.

Table 1 Price of electricity in Shanghai 2013(commercial and industrial category)

	Time (Non-Summer)	duration (h)	Price (￥/kWh)
Low valley	22:00-6:00	8	0.350
Peak	8:00-11:00 18:00-21:00	6	1.167
average	6:00-8:00 11:00-18:00 21:00-22:00	10	0.714
	time (Summer)	duration (h)	Price (￥/kWh)
Low valley	22:00-6:00	8	0.285
Peak	8:00-11:00 13:00-15:00 18:00-21:00	8	1.202
average	6:00-8:00 11:00-13:00 15:00-18:00 21:00-22:00	8	0.749

The first scheme. Based on the data obtained recently, we know that the price of natural gas used for the generator in Shanghai is 2.43 Yuan/m^3. The consumption of gas engine of Yanmar EP350G is 90m^3/h. Then we can calculate the cost of power generation is $0.625 Yuan/kWh$.

Program 2. The unit consumption of Wilson PG475B gas turbine cogeneration is 126.2m^3/h. The unit cost of power generation is $0.807 Yuan/kWh$.

Program 3. According to some information, the unit price of diesel is about $7 Yuan/L$. The unit consumption of Caterpillar 500F/C15 diesel generator is $116.5 L/h$, so we can calculate the unit cost of power generation is $2.24 Yuan/kWh$.

Conclusion

Finally, based on the conclusions and experience, following recommendations about the application of Gas CCHP System to Hotel Buildings in Shanghai are given in this paper:

(1) With CCHP, heating benefit is much higher than electrical power benefit, and the former is 4 to 5 times of the latter by calculating;

(2) Gas internal combustion engines and gas turbines will be better choice with higher economy, when selecting CCHP power plant.

(3) When selecting the specific brand and model of the unit, unit generation cost should be focus on, in order to increase the time of power generation as much as possible, and get more heat energy. Then, much more revenue can be derived, for higher market price of steam and the huge demand of heating in the hotel.

(4) If cost of self-electric power generation is not too much exceeding to market price, CCHP system can be used to self-electric power generation. Though power benefit decrease, heating benefit can make up for the loss of power benefit, for increasing of heating benefit.

Benefits Analysis of Energy Tax Reform

Ma Jian Song Yang [a]Ji Liuhe

Shenyang University, Shenyang 110044

[a]yang_wenlin@163.com

Keywords: Energy Tax, Benefit, consumer surplus, producer surplus

Abstract: Sustainable economic growth of a country needs support from energy industry. The limitation and environmental problems caused by energy makes the governments to re-examine their energy strategies. As an important tool for national macro-control, tax policy has an irreplaceable role on the promotion of conventional energy conservation, sustainable use and introduction of new energy sources. More and more theories and practices have proved that the energy tax is beneficial to conservation and utilization of energy. At present, China has yet to levy a special energy tax. There are many problems in energy taxes, so we have to reform our current energy taxes. Evaluation of the effect of the reforms can be judged in many ways. In this article, we will analyze it from a social welfare perspective, trying to build an optimization of the energy tax system in order to achieve social welfare maximization.

Introduction

The limitation and environmental problems caused by energy makes the national governments to re-examine its energy strategy. There are two orientations among countries: the first one is saving energies and committing to the development of energy-saving technologies and energy-efficient products; the second is developing new energies which can replace conventional energy sources. It can lead energy consumption structure to the direction of efficient, clean, renewable, low-carbon direction or carbon nuclear, solar and wind energy. As an important tool for national macro-control, tax policy has an irreplaceable role on the promotion of conventional energy conservation, sustainable use and introduction of new energy sources. More and more theories and practices have proved that the energy tax is beneficial to conservation and utilization of energy. At present, China has yet to levy a special energy tax. There are many problems existing in energy taxes, so we will reform current energy tax.

For the tax system, people want to be able to take into account not only fair but also to efficiency, and achieve the balance between these two and a tax optimal results. However, under the influence of a variety of factors in reality, it is difficult to achieve optimal results. So, in academia, their researches are more about how to make the tax system as close as the optimization. Through analysis of the tax system, the objective of tax system optimization is to reform and adjust itself to maximize its compliance with current environmental conditions and the choice of the parties of economic entities, and then maximize the social welfare. Only setting tax rate scientifically and rationally, guiding the behavior of businesses and consumers, can really achieve the effect of saving energy and protect the environment. In order to achieve the desired results, there must be a scientific and reasonable tax rates. If the interest rate is too high,it will hit some sectors and get opposition. So the tax can not be successfully implemented, and can not achieve the intended effect; but if tax rate is too low, it will not stimulate and guide consumer behavior. Therefore, scientific and reasonable tax rate is very important for its succes, so is energy tax. The significance of this article lies in the attempts to establish an optimization of the energy tax system to achieve the desired goal of social welfare maximization. The following is my analysis of the benefits of energy tax policy.

Differentiated price optimization model based on the objective of maximizing the benefits

According to "Ramsey rule ", for taxing different commodities with minimal loss of economy overall efficiency, the rate of different commodities should inversely relate to its demand elasticity, we should take the optimal tax rate for residents of differentiated tax as Ramsey's solution. Therefore, the implementation of differentiated tax rate based on the consumption amount is in conformity with sub-groups of incomes tax principles. The core idea is to maximize social welfare under the constraints of balanced budgets (to meet the monopoly break-even). Ramsey model takes into account both the producer's costs, and the consumer's willingness to pay. it has been seen as the model which meets the requirements of social welfare and has important guiding significance for the design of differential tax rates.

It's cost function is $C(q)$, The marginal cost is $c(q)$. Diversity of consumer demand can be represented by $\theta \in [\underline{\theta}, \overline{\theta}]$ (it mainly refers to the needs of different consumers in different income level). Assuming parameter θ only relates to income. People'needs increase as the income increase. So, the demand function for each resident can be expressed as follows.

$$q = q(p, \theta) \tag{1}$$

Where, q-- quantity residents use; p-- price, yuan / liter.

The total cost can be expressed as

$$P = F + q(p, \theta) \times p(q, \theta) \tag{2}$$

Where F-- is the fixed part in cost; $p(q, \theta)$-- marginal price related with q, yuan / liter.

The objective of resident differentiated tax rate is the maximization of social welfare, namely, the maximization of consumer and producer surplus and the welfare equilibrium between residents and businesses. The social welfare is maximized at this time.

We we use $q_{\min}$ to represent the minimum amount, $q_{\max}$ to represent the maximum amount. Total consumer surplus is represented by the following formula:

$$CS = \int_{q_{\min}}^{q_{\max}} Q(P(q), p(q), q)dq + \int_{p_{\min}}^{\infty} Q(F, 0, q_{\min})dF \tag{3}$$

Producer surplus is represented by the formula:

$$PS = \int_{q_{\min}}^{q_{\max}} Q(P(q), p(q), q)[p(q) - c(q)]dq + Q(p_{\min}, 0, q_{\min})[P_{\min} - C(q_{\min})] \tag{4}$$

Welfare maximization is represented by the formula

$$\begin{aligned} &\max_{p(q), q_{\min} P_{\min}} \int_{p_{\min}}^{\infty} Q(F, 0, q_{\min})dF + \int_{q_{\min}}^{q_{\max}} Q(P(q), p(q), q)dq \\ &+ \int_{q_{\min}}^{q_{\max}} Q(P(q), p(q), q)[p(q) - C(q)]dq \\ &+ [Q(P_{\min}, 0, q_{\min})[p_{\min} - C(q_{\min})] \end{aligned} \tag{5}$$

We get:

$$\frac{p(q) - c(q)}{p(q)} = -\frac{\alpha}{\varepsilon_p^q(q)} \tag{6}$$

In the above formula, $\varepsilon_p^q(q)$-- Price elasticity of residents'demand. From the formulas' results, the solution depends on the elasticity of demand and the marginal cost of production. The commodities demand functions for different people is different, so is the price strategy .

Calculation model of social welfare under the differentiated price

Using Marshall consumer surplus to calculate the variation of consumer welfare of different residents(based on the income). The definition of consumer surplus variation (CSV) is: the possible money saved for each resident after changing current energy price to hypothesized price. The definition of producer surplus variation (PSV) is: the possible producer loss after change current energy price to hypothesized price. Definition of social change welfare (WV) is: For society as a

whole (general consumers and supply companies), the average income of each individual (or losses). In relative terms, changes in welfare is the average energy consumption of the general population changes apart from changes in consumer surplus and producer surplus.

Consider a typical resident. The type of this resident is θ. the price structure is $p = \{n, p_i\}$, n is the number of grades of differentiated prices residents, pi is the i-th grade marginal price.

This resident's consumer surplus was represented as below

$$U(p,\theta) = \sum_{i-1}^{n-1} \int_{p_i}^{p_i+1} q(p,\theta)dp + \int_{p_n}^{\infty} q(p,\theta)dp \tag{7}$$

Where $q(p_i,\theta)$ is the Marshall linear demand function of each grade.For each price system, the average price in different range is calculated as $(p - \sum_{i-1}^{n-1} b_i p_i)$, which bi is the percentage ith takes in total expenditure.

For current residents price, these ratios can be drawn from the data observation. Residents features θ can be used to calculate the optimal resident price, it is represented by the following formula:

$$P[q(\overline{p},\theta) \le \overline{x}] \Leftrightarrow P[\theta \le \frac{1}{\beta_2}(\overline{x} + \beta_1 \overline{p} - \beta_0)] \tag{8}$$

Where $q(\overline{p},\theta)$ --the current total demand's functional prediction in definition; $\overline{x}$ --upper levels of different intervals.

Reduced consumers surplus of typical residential is represented by the following formula:

$$U(\overline{p},\theta) = \int_{\overline{p}}^{\infty} q(p,\theta)dp \tag{9}$$

Changes in consumer surplus is represented by the following formula:

$$CSV = \int_{p_0}^{p_i} q(p,\theta)dp \tag{10}$$

In the formula, p_0 --Current prices; p_1 --The value of the resident price ladder programs.

The producer surplus obtained by producer who facing residents of type θ and price structure $p = \{m, p_i\}$ is represented by following:

$$PS = (p,\theta) = \sum_{i-1}^{m} [p_i - c(q)]q(p_i,\theta) \tag{11}$$

Where $c(q)$ --marginal cost when the producer's supply is $q(p_i,\theta)$

The remaining production is expressed as the following formula:

$$PS(p,\theta) = q(p_0,\theta)[p - c(q)] \tag{12}$$

The surplus changes in production are expressed as the following formula:

$$PSV = q(p_1,\theta)[p_1 - c(q)] - q(p_0,\theta)[p_0,\theta)[p_0 - c(q)] \tag{13}$$

Finally, the total welfare changes are expressed as the following formula:

$$WV = CSV + PSV \tag{14}$$

Empirical analysis of energy tax reform benefits

Benefit calculation was gotten by setting research objects as a whole, which use empirical distribution that based on subjects and proportion of consumer distributed into different price zone. Here, we take oil tax as research objects calculating the consumer and producer surplus. For products like oil, the amount of each resident use can not be measured like water and electricity. So it can not be taxed based on amount. However, by measuring the oil consumption amount of different income group, we can know what tax rate we should use for different income group. We can subsidize different income group to reflect the differentiated tax rate. Detailed empirical analysis is as follows:

Table 1 Transportation cost effects function and demand function of five grades urban households.

Income Quintile	Consumption demand function
Low income households	$x_1 = 1342.5 / p_1$
Second quintile income households	$x_1 = 1150.15 / p_1$
Middle-income households	$x_1 = 1762.25 / p_1$
Fourth quintile income households	$x_1 = 2647.88 / p_1$
The highest income households	$x_1 = 10875.68 / p_1$

Elasticity of demand was drawn from table1 and get residents differentiated oil program according to formula 6.

Then we can get residents social welfare changes according to Equation 14.

Table 2 Changes in the social welfare of residents

Residents Type	Welfare changes
Low-income	-5.26 -5.26
Middle-income	15.1 15.1
High income	6.35 6.35
Total	16.19 16.19

As can be seen from the results, after implementing differentiated oil price according to the amount consumption, the welfare of the society increased. For low-income residents, changes in oil prices program will reduce social welfare. This is due to we reduced oil price in the frist and second grade in the simulation program. We ensure the needs of low-income residents and improve the consumer surplus. But then, the marginal cost of producer is higher than the price, so the producer surplus was reduced. So for the consumption amount in the first and second grades, they correspond to low income group, the total welfare changes are negative, that means the total welfare was reduced. The last two grades is aimed to middle and high income residents. The simulation price is increasing gradually and even higher than current price, then the consumer surplus decreases, producer surplus increase and social welfare changes turn to positive, that means the total welfare is increasing. Finally, the sum of each group's welfare is the social total welfare,which means the increase of social welfare. Therefore, the differentiated tax rate will lead to the differentiated price which increase the social welfare effectively.

Summary

Through the analysis of the energy tax benefits. We can see that the setting of energy tax should take into account its energy production, consumption characteristics and the level of economic development. Developing differentiated tax rate according to region and time. Meanwhile we can take full advantage of preferential tax policy to subsidize different energy products, producers and consumers to achieve the maximization of social welfare. You can take advantage of tax incentives and subsidies for different energy products, businesses and consumers in order to maximize social welfare.

BIPV with On-grid Tariff Policy in China

Rong Guo

RM208, Gaoceng Building,NO.13,Yanta Road,Xian city,Shanxi province,710000China

guorong1114@126.com

Keywords: BIPV; On-grid tariff; Sustainable Development

Abstract. Building integrated photovoltaic (BIPV) is an important direction of the green building. BIPV has developed rapidly in many developed countries and effectively saved resources. It owes to the government's effective promotion policy. The implementation of the on-grid tariff policy is a new stage of BIPV development. BIPV on-grid tariff pricing is a key point of BIPV promotion. Whether on-grid tariff is reasonable and applicable or not will directly affect the implementation effect of BIPV on-grid tariff policy. The current international common standard cost method is used to calculate on-grid tariff. Many countries implement unified on-grid tariff standard in their country, and often ignores the differences between different projects and areas. Based on the average on-grid tariff with standard cost method ,combined with the influence factors of BIPV on-grid tariff this paper build a corresponding on-grid tariff adjustment coefficient system with the current study method. Three methods used to get this goal are given and analyzed in this paper, the Delphi method， fuzzy mathematics method and neural network. This paper uses the Delphi method to build the on-grid tariff adjustment coefficient system model and choose three main factors, annual effective utilization hours, combination mode and PV system capacity, to build the on-gird tariff coefficient adjustment system model. This paper provides a reference basis of BIPV promotion policies and on-grid tariff pricing model for many countries.

GENERAL INSTRUCTION

With the world's growing demand, the contradictions between energy supply and demand further strengthened. The vigorous development of renewable energy can contribute to the world economy to achieve sustainable development. Construction is one of the top three energy consumption industry. Building energy efficiency get more and more national attention. Building energy consumption is almost 1/3 in China's total energy consumption [1]. Construction combined with Renewable energy has become an important development direction of building energy efficiency. Renewable energy sources include solar, wind, geothermal etc. With its advantage of abundance, clean, universality, solar energy has become widely accepted in building energy efficiency.

Solar energy on building applications include BAPV and BIPV. BAPV is Building Attached Photovoltaic, and BIPV is Building Integrated Photovoltaic. BIPV is a new direction of solar system combined with the construction[2]. Now, photovoltaic technology has gradually matured after years' development. The Chinese government has also proposed a series of policies to promote the development of BIPV, but the scale of BIPV is still a very small proportion in Chinese market. BIPV development is still in its infancy in China. To a certain scale, the government needs to formulate incentives policy to increase developer initiative to develop photovoltaic building and increase consumers' awareness of consume BIPV products.

Many foreign countries in promoting BIPV have made an notable achievement, and also accumulated abundant experience. Germany issued the "On-grid Tariff Act." Its effectiveness, scientific and operability was quickly confirmed. Many European countries followed Germany and issued On-grid Tariff policy. They also got a certain success[3].

This article will focus on China status to establish a BIPV average on-grid tariff model. Because there are many factors affect in on-grid tariff, this article will establish a factor regulation system model with Delphi Method on the base of the average on-grid tariff, in order to increase the scientific

tariff calculation and practicality. The model will make the Chinese on-grid tariff more scientific and practical.

THE METHOD OF BIPV ON-GRID TARIFF ADJUSTMENT COEFFICIENT SUSTEM

BIPV average on-grid tariff model

Standard cost method, an important part of management accounting in the West, is a method based on prepared cost criteria, with comparing standard cost with actual cost, accounting and analyzing cost diversity. Calculating on-grid tariff with standard cost method is one of the most scientific tariff calculation methods currently [4]. In this paper the annual sunshine coefficient is Chinese average coefficient and letter "U" stands for the current Chinese BIPV systems' annual generation capacity, and "pe" stands for system efficiency[5]. On these conditions, on-grid tariff calculation mode can be built with this method [6]. Currently generally widely accepted PV tariff calculation model with standard cost method is :

$$P=\left[(1-p_a)\cdot R_e\cdot C+\frac{p_a C}{n}+\sum_{i=1}^{n}\left(1-\frac{i}{n}\right)p_a\cdot C\cdot R_i+\frac{p_0 C}{n}+p_1C_0+p_2C+p_3C\right]\div p_e U$$

p-the PV tariff

Pa-The loan proportion of the initial investment

Re- Annual return rate of capita

C-Initial investment

n- Loan Term

Ri-Annual interest rate

P0-the proportion of fixed asset investment accounted for initial investment

P1-the Operation and maintenance fee rates

C0-Fixed Asset Investment

P2-the Salaries and benefits rates

P3-the Equipment upgrades and overhaul costs rates

Pe-the PV System efficiency

U-Annual generation capacity of PV system

BIPV on-grid tariff adjustment coefficient system model with Delphi method

(1)Choosing experts

Choosing experts is the first step on the Delphi method, Expert decide whether the results is objective and accurate or not with Delphi method .The experts must be familiar with the Chinese BIPV on-grid's characteristics and the basic characteristics of BIPV in each area and the factors of BIPV on-grid tariff. They must have a profound professional theory, rich experience and forecast ability. Their academic viewpoints must be authoritative and representative. They must be interested in Chinese BIPV on-grid tariff adjustment coefficient system model and can attend all along. The expert should include BIPV and related industries economic experts who accord with fore-mentioned conditions, a certain percentage of the professional personnel, management experts, technical experts and senior decision makers. The experts' number is also very important. The number should be appropriate and it can be confirmed based on the expert accords with fore-mentioned conditions. It usually should be at least 9 and not more than 25 people. Too small number it doesn't guarantee the representation of the experts and in this situation the veracity and rationality of the result isn't guaranteed. If the number is too large, the workload is too much and the time is too long and also their opinions are not unified.

(2)Design consultation table

Before design the table, extensively research work should be done, combined with factors which influence the BIPV on-grid tariff, and the main factors can be drew up as comprehensively as possible so that experts can synthetically evaluate and make choice. Consultation table's content must be comprehensive. Each part in the table will be closely linked to BIPV on-grid tariff adjustment goal. These factors must be what experts are familiar with and care about. Many factors have an effect on

BIPV on-grid tariff. Three main factors have been chosen in this paper's consultation table， capacity of， PV systems ,the combination ways of photovoltaic system and building, the effective utilization hours in different area. They are shown in table 1.Then some explanatory notes such as regional background, the meaning of each factor, must be prepared. These materials and consultation table shall be mailed or delivered directly to experts, so that the experts accurately express their evaluation opinions. Experts independently give their evaluation in consult table and write comments, and then send or retrieve on schedule. This process involves on-grid tariff influence factors for determination, consult information, statistical information, information feedback and the second consult and statistics and feedback to consult again.

Table1. Factors' adjustment coefficient.

NO.	1			2			3	
Factors	Annual effective utilization hours			Annual generation			Binding mode	
	1200	1200-1400	1400-	0-0.5U	0.5U-2U	2U-	Attached	Integrated
Adjustment coefficient	$\overline{X}$	$\overline{X}$	$\overline{X}$	$\overline{X}$	$\overline{X}$	$\overline{X}$		
Note	The calculation of national average tariff is based on the annual Effective utilization hours is 1250,the annual generation is U. The binding mode is attached							

(3)Consulting and feedback

The consultation table and the relevant information sent directly to each selected experts. The experts independently give their written opinions without meeting each other and any psychological impact of the situation, and they must send them back in time. This process includes consultation tariff factors , each factor's assessment, consult statistical information collation, feedback and consulting again, and then re-statistics and feedback again. According to the importance degree and the degree of dispersion of expert opinion, the progress can be carried on 2times to 5times.

(4)Statistical processing of the data

After each round of consultation, expert advice will be counted and distinguished correctness. Then they are been quantitative statistics and evaluated by statistical methods and mean ,standard deviation and r variance of he weight of each factor score given by experts are calculated. Finely they are summarized in the corresponding tabular form.

Mean ($\overline{X}$) is the arithmetic mean of the scores given to each factor by experts, and is calculated as:

$$\overline{X} = \frac{X + X + \ldots + X}{n} = \frac{}{n}\sum X$$

Range(R) is the different value of the maximum and minimum. Formula is as follows:

$$R_j = X_{j\max} - X_{\mathrm{jmin}}$$

Standard deviation(σ) represents the extent of expert opinion. Formula is as follows:

$$\sigma_j = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(X_{ji} - \overline{X_j}\right)^2}$$

Variance(σ2), standard deviation squared :

$$\sigma_j = \frac{1}{n}\sum\left(X_j - \overline{X_j}\right)$$

Based on mean, range and the standard deviation, you can observe and learn about the trends spread of expert advice in each survey round, to determine whether consultation results is useful. If the next round of consultation activities is needed, the results will be fed back to the experts as valuable reference material of the next round of consultation to get accurate final result. In the next round of consultation, the experts compare their own opinion with other experts advice based on the measured statistics of the last round of the regional factors mean, range and variance, and amend their own opinions appropriately. Then, the mean approaches the final result, and make smaller range and

variance. Thus, the difference advice of experts is less. After several rounds of determination, until the experts give their fixed judgment and evaluate opinions, the results are not change any more.

(5)Determine the results

After several rounds of consultation, the experts' advice is relatively stable. Finely, you can permutate and combine the different values of each factors by statistical methods. There is a power project. The annual effective utilization hours is below 1100.The annual generation is below 0.5U.The binding mode is dependent mode. The project tariff adjustment factor should be $\overline{X} \cdot \overline{X} \cdot \overline{X}$. With this method, BIPV tariff adjustment system table (Table2) can be made.

Table2. Adjustment factor value of BIPV tariff model.

		Annual effective utilization hours			Binding mode
		1200	1200-1400	1400-1600	
Annual effective utilization hours	0.5	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	Attachment
	0.5-2	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	
	2	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	
	0.5	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	Integrated
	0.5-2	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	
	2	$\overline{X_1}\,\overline{X_6}\,\overline{X_8}$	$\overline{X}\ \overline{X}\ \overline{X}$	$\overline{X}\ \overline{X}\ \overline{X}$	

SUMMARY

BIPV tariff policy can effectively promote the development of photovoltaic building. Chinese government should perform reasonable BIPV tariff and establish a related policies adjustment systems. Many methods can be used to establish this adjustment system, such as Fuzzy Math, Neural network. When formulating Policy Chinese government can also use these method to establish corresponding policy to promote the development of photovoltaic building .

Keywords: Energy, offshore wind power project, navigation safety, evaluation.

Abstract. This paper introduce the necessity of the construction of offshore wind power projects, analysis of the impact on the marine transport of offshore wind power project after completion, and then use the fuzzy comprehensive evaluation method to carry out a comprehensive assessment of offshore wind power projects, by identifying risk assessment index system, establish model for risk assessment, the final task is use the model to evaluate the navigation safety of an offshore wind power project.

Introduction

Energy is an important material basis for economic and social development; China is rich in offshore wind resources, with conditions development of offshore wind power resources.

When offshore wind power projects are completed which have influence on the navigable waters nearby. Therefore, the use of a safety assessment model for navigation safety of offshore wind farms comprehensive evaluation is very important. This paper used the comprehensive evaluation method for quantitative safety demonstration. By introducing an ample, paper proves the practicality of this model.

Integrated assessment model

Build process assessment model. Navigation safety assessment of offshore wind farm projects is a complex system, influenced by many factors, and the degree of influence are quite different, are the result of decisions directly and accurately measure the difficulty of the problem. Therefore, the mathematical model is more suitable for the method of fuzzy mathematics and analytic hierarchy process combining methods, namely multi-level comprehensive evaluation model, the establishment of multi-level comprehensive evaluation model steps are as follows:

1) Assessment index system established;
2) Each evaluation index weights established;
3) The assessment index membership to determine:
4) Establishment and application of integrated assessment model.

Establishment of evaluation index system. Through expert advice and comprehensive surveys and research scholars in this field, selected assessment evaluation factors can affect the overall response of offshore wind power projects in the navigation safety.

Through seek the opinion of experts, this paper identifies six factors for level indicators and identifies eight factors as two evaluation indicators; according to affiliation assessment criteria and indicators, carried on the lower orders, as shown in Fig.1 form factor set U.

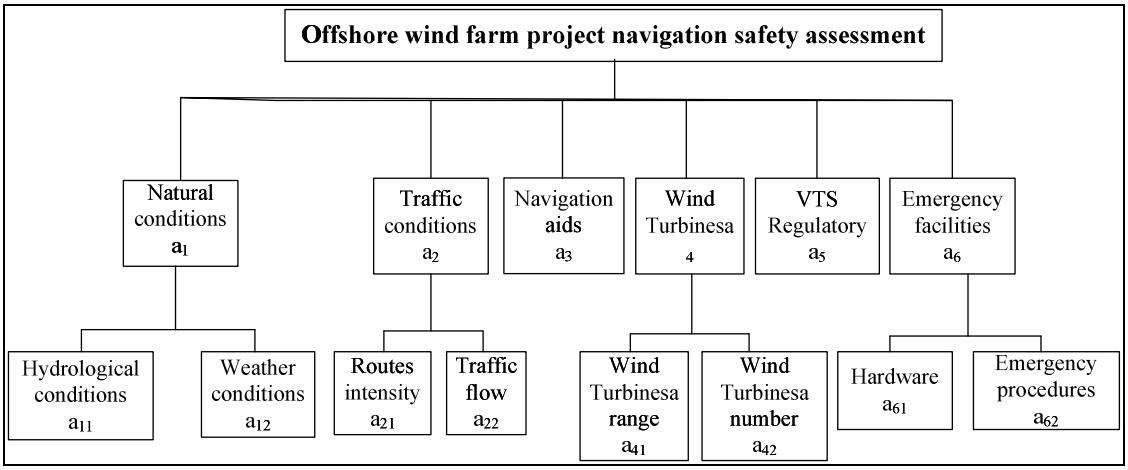

Fig. 1 The hierarchy structure of the evaluation

The evaluation index weights determined. Using questionnaires, investigators including wind farm managers, maritime experts and senior high-grade officers from Maritime Universities. Evaluation of the relative importance given judgment, and these judgments by introducing an appropriate scale (in numerical representation), generates judgment matrix. Details of the assessment index weight *W* in Table 1.

Table 1 The weight of the index

Indicators	α_1	α_2	α_3	α_4	α_5	α_6		
Weights	0.11	0.25	0.18	0.19	0.13	0.14		
Indicators	α_{11}	α_{12}	α_{21}	α_{22}	α_{41}	α_{42}	α_{61}	α_{62}
Weights	0.51	0.49	0.45	0.55	0.59	0.41	0.61	0.39

Determine the degree of membership of each evaluation index. In this paper, the evaluation grade is divided into five levels, that is V = { good, better, fair, poor, worse}, the corresponding value set is F = {5,4,3,2, 1}, As shown in Table 2.

Table.2 The evaluation grade

5	good
4	better
3	fair
2	foor
1	worse

The establishment of multi-level integrated assessment model. Through the above three steps, get the index set offshore wind farm project U {u_1, u_2, u_3, ... u_n}, offshore wind farm project safety assessment set V {v_1, v_2, v_3, ... v_n}, assessment indicators weight W {w_1, w_2, w_3, ... w_n} and evaluation matrix R. Through assessment indicators weight W and evaluation matrix R, we can get matrix B, the equation can be expressed as:

$$B = W \times R$$

For the B anti-blur, he may have a layer of navigation safety evaluation index value or the value of navigation safety assessment. Anti-blur method to calculate the center of gravity of this paper, which is calculated as follows:

$$b = \frac{\sum_{i=1}^{5} b_i \times v_i}{\sum_{i=1}^{5} b_i}$$

Multi-level Comprehensive Evaluation

Expert scores on the index. According to the article，we have established offshore wind farm projects navigation safety evaluation model, there are 20 experts carried out according to the actual situation in this article to establish offshore wind farm project evaluation, this paper summarized the results of the evaluation, the expert appraisal results table below:

Tab. 3 A navigable waters offshore wind farm project security expert appraisal result

Index Name	Select the index number of the appropriate level of the standard(Total 20 people)				
	Good (5)	Better (4)	Fair (3)	Poor (2)	Worse (1)
Hydrological conditions	0	4	5	11	0
Weather conditions	7	11	2	0	0
Routes intensity	0	10	7	3	0
Traffic flow	8	6	6	0	0
Navigation aids	2	6	10	2	0
Wind turbine range	6	11	3	0	0
Wind turbine number	0	4	12	4	0
VTS regulatory	10	8	2	0	0
Hardware	2	15	2	1	0
Emergency procedures	1	9	10	0	0

Single-factor fuzzy comprehensive evaluation. We deal with each results from experts about navigation safety indicators, you can get its single factor evaluation matrix:

(1) For natural conditions A1 and traffic situation A2 single factor evaluation matrix:

$$R_1=\begin{bmatrix} 0 & 0.2 & 0.25 & 0.55 & 0 \\ 0.35 & 0.55 & 0.1 & 0 & 0 \end{bmatrix} \qquad R_2=\begin{bmatrix} 0 & 0.5 & 0.35 & 0.15 & 0 \\ 0.4 & 0.3 & 0.3 & 0 & 0 \end{bmatrix}$$

(2) For wind turbine facilities A4 and emergency facilities A6 single factor evaluation matrix:

$$R_4=\begin{bmatrix} 0.3 & 0.55 & 0.15 & 0 & 0 \\ 0 & 0.2 & 0.6 & 0.2 & 0 \end{bmatrix} \qquad R_6=\begin{bmatrix} 0.1 & 0.75 & 0.1 & 0.05 & 0 \\ 0.05 & 0.45 & 0.5 & 0 & 0 \end{bmatrix}$$

From the above give natural conditions A1, traffic conditions A2, wind turbine facilities A4 and emergency facilities A6 univariate weights, we can get index weights:

$$W_1=(0.51,0.49), W_2=(0.45,0.55)\ , W_4=(0.59,0.41), W_5=(0.61,0.39)$$

We use synthetic operation can get comprehensive evaluation about A1, A2, A4, A6, which is calculated as follows:

$$B_1=W_1.R_1=(0.17,0.37,0.18,0.28,0); \quad B_2=W_2.R_2=(0.22,0.39,0.32,0.067,0)$$

$$B_4=W_4.R_4=(0.18,0.41,0.34,0.82,0); \quad B_6=W_6.R_6=(0.08,0.63,0.26,0.03,0)$$

Multilevel Comprehensive Evaluation. Calculated by the above we get B1, B2, B4 and B6, and A3 and A5 can be obtained by the factor score results:

$$B_3=(0.1,0.3,0.5,0.1,0); \quad B_5=(0.5,0.4,0.1,0,0)$$

We can construct a single-level comprehensive evaluation matrix R based on two factors that determine the result of the judgment:

$$R=\begin{bmatrix} 0.17 & 0.37 & 0.18 & 0.28 & 0 \\ 0.22 & 0.39 & 0.32 & 0.067 & 0 \\ 0.1 & 0.3 & 0.5 & 0.1 & 0 \\ 0.18 & 0.41 & 0.34 & 0.82 & 0 \\ 0.5 & 0.4 & 0.1 & 0 & 0 \\ 0.08 & 0.63 & 0.26 & 0.03 & 0 \end{bmatrix}$$

Right from the above evaluation level weight can be given:

$W = (0.11, 0.25, 0.18, 0.19, 0.13, 0.14)$

So comprehensive evaluation result is:

$B = A \bullet R = (0.202, 0.410\text{v}0.304, 0.226, 0)$

Multi-level fuzzy comprehensive evaluation of the results of the anti. Anti-blur method to calculate the center of gravity of this paper, which is calculated as follows:

$$b = \frac{\sum_{i=1}^{5} b_i \times v_i}{\sum_{i=1}^{5} b_i} = \frac{0.202\times5 + 0.410\times4 + 0.304\times3 + 0.226\times2 + 0\times1}{0.202 + 0.410 + 0.304 + 0.226 + 0} = 3.515$$

It can be seen that the navigable waters of the offshore wind farm project safety evaluation results between "fair" and "better".

Conclusion

Offshore wind power project as a new energy industry, application prospects, but as offshore installations, and its impact on marine transportation cannot be ignored, and therefore its impact on navigation safety research is necessary. The fuzzy comprehensive evaluation method can optimize the siting and design of offshore wind power project, for the construction of wind power projects currently play a certain specifications and guidance.

Keywords：transmission planning；the Same Tower；Monte Carlo simulation

Abstract. Electricity market reform has brought new challenges to transmission grid planning, the traditional only considers a future scenarios of transmission grid planning, this method can't meet the actual needs. In this paper, the uncertainty factors of market environment is analyzed, based on the relaxation factor and the way of wiring ,the transmission grid planning model is established. The security not only takes the N-1 breaking cases into account, but also includes the same tower Multiple-loop breaking at the same time. The model is solved using the methods based on Monte Carlo simulation and hierarchical genetic algorithm, ultimately the resulting meets reliability requirements and minimum total cost of transmission planning programmes under the future uncertainty environment. To build the simulation model, simulating the different methods of wiring way impacts on the investment and risk of the grid planning.

0 Introduction

Under the traditional vertical integration system, Transmission grid planning is based on load forecasting and power planning, it usually only considers one of the most likely future scenario, and the N or N-1 static security conditions must be met, so it generally uses penalty function method to deal with the static security constraint requirement, not taking the various kinds of uncertainty factors into account.[1~3] During the course of practice, due to the emergence of uncertainty factors, it may lead to that the mathematically rigorous optimal scheme requires a lot of compensation investment. In addition, the competitive market will cause the cooperation and competition among market participants, and lead to the uncertainty of unit power output changing. The presence of these elements has brought new challenges to the transmission planning. [4]

At present, with the rapid growth of power load, the newly built power plant capacity is bigger and bigger, the number of outgoing circuits also increased accordingly. Construction of ultra-high voltage with multiple-loop towers, due to the less land, saving line corridors and increasing the transmission capacity of per unit area and reducing the overall investment etc, has begun to favor by planning department. [5] While setting up double circuit lines on the same tower reduce the cost of investment , but also improve the security risk of system operation, how to consider the impact is a question which is worthy of study in the early stages of planning. This article puts the wiring way into single-loop and multiple-loop on the same tower, From the perspective of the wiring way, we have the grid planning. In the early stages of planning, we consider multiple-loop wiring on the same tower. The impact of the difference wiring way on the grid investment and operation risk is discussed, can help planners saving investment in the face with the erection of double-loop towers and given the quantitative indicators when the game risk increased, to facilitate decision making.

1 An uncertain power injection vector

The capacity and load of power plant in the future is uncertain, so they are random variables, probability density function we can use probability density function to describe them.

During the planning period, the new capacity of node I generally obey a discrete probability distribution:

$$P_r\{P_{G.i} = P_{G.i}^k\} = p_i^k \quad (k=1, 2,\ldots M) \tag{1}$$

where, $0 \le p_i^k \le 1$, $\sum_{k=1}^{M} p_i^k = 1$。

The active load $P_{D.i}$ of node I generally obey the normal distribution $N(\mu_i, \sigma_i^2)$ where ui is the expected value of the load and σ_i is the standard deviation of the load.

Therefore, the injection power of random vectors is recorded as ξ. According to node i's active injection power $P_i = P_{G.i} - P_{D.i}$ According to the probability distribution function of each the power source and load injected power, We are random sampling Using the monte-carlo simulation method, We can get M injection power vectors $\boldsymbol{P} = \{\xi_1, \xi_2, \xi_3 \ldots \xi_M\}$.

2 the transmission grid planning model

Power source construction and the load increase in the market environment and each generator node power output change due to the bidding behavior of power plant such as the uncertainty factors can be said as the uncertainty of system node active injection power.

Accordingly, we give the optimal the transmission grid planning model which meets the minimum comprehensive cost of the system and the requirements of operation reliability.

$$\min C = \sum_{ij \in NI} U_{ij} I_{ij} L_{ij} + \sum_{ij \in NL} V_{ij} B_{ij} L_{ij} + \alpha Z_1 \tag{2}$$

$$Z_1 = \sum_{k \in M} C_k^s + \sum_{k \in M} C_k^d \tag{3}$$

st.

$$\left.\begin{aligned} &\boldsymbol{B\theta} = \xi_k \\ &\boldsymbol{P}_b = \boldsymbol{B}_b \boldsymbol{q}_b \\ &|\boldsymbol{P}_b| \le \boldsymbol{P}_{b.max} \end{aligned}\right\} \tag{4}$$

$$\left.\begin{aligned} &\boldsymbol{B}_b^l \boldsymbol{\theta}_b^l = \xi_k \\ &\boldsymbol{P}_b^l = \boldsymbol{B}_b^l \boldsymbol{\theta}_b^l \\ &r \le \delta \end{aligned}\right\} \tag{5}$$

$$I_{ij} = \begin{cases} 0 \\ 1 \end{cases}$$

$$0 \le B_{ij} \le B_{ij}^{max}$$

In formula (2) C represents investment construction costs, including line construction costs and expenses of cutting load.

NI, NL respectively represents single loop line and multiple loop lines waiting for the selection; U_i represents unit construction investment cost of the single loop line; I_i represents 0-1 decision variables of line i, line i joins the grid $I_i = 1$,otherwise $I_i = 0$;

B_j represents decision variables of circuit number on the same tower, $B_j \in (0,1,2,3 \ldots n)$, V_j represents unit investment cost of multiple loop lines waiting for the selection,Its value varies with B_j , $V_j \in (V_{j1}, V_{j2}, V_{j3} \ldots V_{jn})$; L_i and L_j represent line length.

Z1 represents minimum load-shedding in the system,Including the N-1 minimum breaking load-shedding under M injection power vectors and the minimum breaking load-shedding of multiple circuit lines on the same tower,Thereinto, C_k^s and C_k^d respectively represents the N-1 breaking load-shedding under the K-th injection power vector and load-shedding of multiple circuit lines cutting load at the same time on the same tower, α represents unit load-shedding punishment costs.

formula (4) is the security constraints to the normal operation;formula (5) is N-1 static security constraint. ξ_k is the K-th injection power vector, $\boldsymbol{B}$ and $\boldsymbol{B}^l$ are the node admittance matrix which

correspond to the non-breaking ways and branch L breaking way, vector θ and θ^{l} are the voltages phase angle under above two mode, P_b and P_b^{l} are the corresponding branch power flow, θ_b and θ_b^{l} are the phase angle difference at both ends of branch, B_b and B_b^{l} are the diagonal matrix consisting of each branch admittance, $P_{b.\max}$ is the heat capacity limitation of branch, δ is the given risk factor threshold.

3 the example simulation

This article uses the "18-node system example in reference 7,Because there is no feasible scheme under the static security of the N-1 criterion, so we make the line transmission capacity limit increase to 3000MW.Its unit investment costs 600,000 yuan/km. Original system node values are the same with reference ,Node 11, 14, 16, 18 are new power source nodes that may appear, the probability distribution function obeys two-point distribution, the load of new added nodes satisfy the normal distribution, specific parameters of the probability distribution function can be found in reference 7.

In this paper, the simulation model was constructed as follows, to validate the proposed model and algorithm in this paper, we simulate the influence of the risk factor, the wiring way and the load-shedding punishment on the transmission grid planning result. As chart 1

Table 1 Simulation model

solution	risk factors	wiring way	punishment of cutting load (ten thousand yuan /MW)
1	δ=0.1	single loop/ multiple loop	8
2	δ=0	single loop/ multiple loop	8
3	δ=0.1	single loop/ multiple loop	80
4	δ=0	single loop/ multiple loop	80

Table 2 The simulation optimization wiring scheme

solutions	planning scheme
1	1-11, 4-16, 5-11, 5-12, 6-14（2）, 7-8, 7-13, 7-15, 8-9（2）, 9-10（2）, 9-16, 10-18, 12-13, 14-15（2）, 16-17（2）, 17-18（2）
2	1-11, 4-7, 4-16（2）, 5-11（2）, 6-14（2）, 7-8, 7-13（2）, 7-15, 8-9（2）, 9-10（2）, 10-18, 11-12（2）, 12-13, 14-15（2）, 16-17（2）, 17-18（2）
3	1-11, 4-16（2）, 5-11, 5-12, 6-13, 6-14（2）, 7-8（2）, 7-13, 7-15, 8-9（2）, 9-10（2）, 9-16（2）, 10-18, 11-12, 12-13, 14-15（2）, 16-17（2）, 17-18（2）
4	1-11, 4-16（2）, 5-11（2）, 5-12, 6-13, 6-14（2）, 7-8（2）, 7-13, 7-15（2）, 8-9（2）, 9-10（2）, 9-16（2）, 10-18, 11-12, 12-13, 14-15（2）, 16-17（2）, 17-18（2）

table 2 the number behind two nodes in parentheses is the increasing number of loop

Table 3 Simulation optimization results

solutions	investment costs of single loop/multi-loop (ten thousand yuan)	investment costs of single loop/multi-loop (ten thousand yuan)	investment costs of single loop/multi-loop (ten thousand yuan)
1	200320/172120	8650/25360	208880/197480
2	229920/187320	0/22240	229920/209596
3	245120/200920	800/121600	245920/322930
4	264160/210440	0/113600	264160/324040

From the comparison between scheme 1 and scheme 2 we can obtain that, in the same way of wiring and cutting load punishment cases, with the decrease of the risk factor δ, planning solution need to meet more operation mode, planning cost also increasing. From table 3 planning results, analyzed and obtained that the investment costs of multi-loop mode significantly lower than the single loop, cutting load is significantly higher than the single loop way. Considering both comprehensive cost, according to different punishment of cutting load, the comprehensive cost difference is bigger, when punishment of cutting load is small, the integrated cost of single loop

mode is bigger, on the contrary, the integrated cost of multi-loop mode is bigger. Therefore, in practice, wiring way can be choose according to the actual situation.

This paper also carried simulation of the punishment of cutting load influence on planning solution. Plan 1, 2, 3 and 4 were compared, in the same risk factor, with the increasing of the punishment of cutting load, the more the expansion of the line number is, the greater the investment cost is, reduced the cutting load.

4 Conclusion

This paper, by using monte-carlo simulation method to deal with the uncertainty of the future market environment, under the condition of risk factor constraints further consider the double-loop tower circuit open or shut down at the same time conditions, transmission grid planning model considering the double-loop towers is established, making the grid planning can consider the erection of double-loop towers at the beginning of the planning, can help planners saving investment in the face with the erection of double-loop towers and given the quantitative indicators when the game risk increased, to facilitate decision making.

The intervention of risk factor constraints, can make the planning scheme on the basis of further meet the requirements of a certain reliability consider the erection of the double-loop circuit tower open and shut down at the same time, making the model solution hierarchy more stronger, the planning scheme can satisfy the requirements of reliability of the global optimal solution.

Using hierarchical genetic algorithm for the grid planning model , through the underlying genetic algorithm can get the optimal solution, on the basis of the optimal solution high genetic algorithm can be well to obtain the global optimal solution. Hierarchical genetic algorithm improved the speed and efficiency of iteration, the example calculation shows that it is an effective method of solving complex grid planning

Keywords: countermeasure, new energy, automobile industry chain

Abstract. As the international energy supply remains tense, international oil price continues rising and calls for global environmental protection becomes higher, people attach more and more importance to the research and development of new energy automotive technology, and the industrialization development. Rapid industrialization led to heavy pollution, increasing greenhouse gas emission, which makes the development of new energy automobile have practical significance.

Automobile industry is an important mainstay in national economy, its industrial chain is long, correlation degree is high and the consumption pursuing is big. New energy automobile based on the gradual development of low carbon economy is a systemic revolution to the transportation that our society uses and the way of using energy, which will bring to the technical revolution of automobile industry.

1.Brief introduction.

1.1New energy automobile.

New energy automobile refers to other energy automobiles except those automobiles use gasoline and diesel engine, mainly refers to the fuel cell vehicles, hybrid vehicles, pure power cars and solar cars, etc. The development of new energy automobile industry has great importance to sustaining economic growth, expanding domestic demand, optimizing industrial structure, strengthening independent innovation ability and promoting industrial upgrading in the current situation.

1.2New energy automobile industry chain.

New energy automobile industry chain is extended on the basis of traditional automobile industry chain. It adds battery, motor, electric system and automatic transmission parts etc. Battery is the key in new energy automobile industry chain, the most core part.

And among all the new components in the new energy automobiles, battery system accounts for the highest percentage and costs the most. Among the cost composition in pure electric automobiles, power battery is as high as 60%. We can see from the analysis of each link of the traditional automobile industry chain and the new energy automotive industry chain, the new energy automobile industry chain has different characteristics in power source, basic facilities and related professional and technical talents. Facing with the needs of the low carbon economy, prominent energy problem and the trend of the upgrading of the automobile industry, the development of new energy automobile industry chain is extremely urgent. At present, it is all recognized that hybrid car is the most suitable new energy automobile for industrialization with the most mature technology.

2.The structure of new energy automobile industry chain.

Any of the industry chain can be divided into three parts: upstream, midstream and downstream. The new energy automobile industry chain can also be such divided. Upstream mainly includes the purchasing and production of components; midstream mainly includes the manufacturing of all the parts of automobile; downstream mainly includes sales and providing relevant after-sales services.

2.1Key nodes and their mutual relations of new energy automobile industry chain.

We can know from the analysis of new energy automobile industry chain that each node mainly includs whole automobile manufacturers, components manufacturers, sales manufacturers and after-sales service providers.

In recent years, along with the development of the automobile industry, sales profits gradually shift from manufacturing and sales to after-sales service providers. The improvement of the facilities, generality of charging pile and so on are all that needed to strengthen in order to make the after-sales service more perfect. So, with the development of new energy automobile industry chain, its downstream profit will be gradually increased, which will directly decide its future development.

2.2Analysis of main raw material.

Battery resources: in the next few years, our country will focus on the development of pure electric automobile. And the main battery is nickel metal hydride battery and lithium ion power battery.

Motor resources: new energy motor as a source of new energy automobile, auto motor changes electric energy into kinetic energy to drive the car. And if we see from the development of present and the demand in the future, then permanent magnet motor will become the main drive motor.

2.3Analysis of new energy automobile industry chain.

At present, the hybrid technology is relatively mature. It dose not have high requirement to battery and don not reached the requirements of pure electric vehicles, so we see from chart 1 that the nickel metal hydride batteries can meet their requirements. However, hybrid automobile can't solve energy and environmental problem very well due to engine, is only considered as a transition fro traditional automobile industry to new energy automobile industry.

In the next few years, therefore, the key is to strengthen the perfection of pure electric automobile technology and the development of fuel cell. Lithium ion battery mainly contains four parts: the cathode materials, anode materials, electrolytes, other auxiliary materials such as diaphragm and ultra-thin copper foil aluminium foil etc. Positive electrode materials and electrolyte and the diaphragm is the three core kinds of materials, which directly determine the battery safety, capacity, and account for more than 70% of the cost of lithium ion power battery.

kinds	nickel metal hydride battery	Lithium ion battery
Voltage V	1.2	3.7
Weight/energy Wh/Kg	60-80	110-190
Volume/energy Wh/L	150-200	250-500
Specific power W/kg	160-230	400-1300
Cyle life times	500-1000	1000-2000
Self discharge	30-35%	<5%
Harmful substance	no	no

Chart 1: Battery performance comparison

3.Characteristics of new energy automobile industry chain.

3.1Different power source.

New energy automobiles adopt different fuel as their power sources (or use different normal fuel but adopting new on-board power plant). Power control and drive of the vehicles have advanced technology, technical theory and new structure.

New energy automobile mainly includes fuel cell vehicles, hybrid vehicles, pure power cars and solar cars, etc. Hybrid vehicles have no external power supply and the motor assists combustion with starting, acceleration and climbing; or hybrid vehicles have external power supply which drives cars alone when battery has enough electricity and starts the combustion enter into HEV working style. Pure power cars rely on its own battery as their power source which dependents on external power supply to charge.

3.2Different facilities.

For now, there are three kinds of mature technology of electric charging stations: one kind is inserted filling pattern, charging by vehicles staying at the stations for a long time; the second one is changeable battery, changing battery by equipment automatically; the last one is quick filling pattern, recover most of the electricity in several minutes. However, the last one does much damage to the battery, so we mainly adopt the first two for the time being.

3.3More technical talents.

The promotion and application of the new energy automobiles needs a large quantity of professional people. They should have not only experience on the automobile services but also the ability of communication, analysis and learning. Some jobs even have higher requirements such as the motor drive, application of electric material, control technique of automotive motor and the control of hybrid power etc. These jobs need both good foreign language ability and skilled computer operation.

4.Optomization countermeasures.

4.1Gathering parts manufactures.

Enforcing regional gathering of parts manufactures can solve the problem of innovation and accomplish scale effect. Regional government should purchase and directly invest the industry; give them tax subsidy or tax credit; bring in high-technology professions.

4.2Perfection of battery and motor.

The main problem in battery and motor is the technology is not enough advanced and the lack of key technology. So, in the regional innovation system, the key is improving the technology on battery and motor. Regional government should give priority to the self-dependent innovation products and buy innovation products in order to stimulate the their innovation enthusiasm; accomplish motor industry gathering in the region and improving innovation by giving tax preference or tax credit; the key to battery and motor innovation is profession policy and technology policy, government can provide accommodation and welfare to them to accomplish the bringing in professions. Besides these, company should improve their quality of after-sales service.

Summary.

Because of gradual and continuous climbing of the oil price, and the increasing emission of greenhouse and the rising of temperature, and pollution, we implement a new development strategy that is new energy automobile industry chain which is the vehicle developing destination in the future. There are many countermeasures for new energy automobile industry chain optimization, such as give priority to purchasing the innovation product, tax preference, promote technology of battery and motor etc. The development of new energy automobile industry chain has much practical significance.

Keywords: Demand Side Management; Demand Side Response; Resources Investigation and Evaluation; Energy-saving Potential; Evaluation of Integrated Energy Efficiency; Power Users

Abstract. More and more deep integrated resource planning methods and demand side management (DSM) technologies have been studied and applied in China. Using technological and economic means of DSM, exploiting energy-saving potentialities from demand side, balancing load, easing contradictions of power structure, improving energy utilization rate, etc. have been important tasks in electric power enterprises. Based on this background, the paper designed and developed resources investigation and evaluation system of electric power DSM, which could investigate electricity resources of DSM of China, and implement energy-saving potential evaluation and energy efficiency analysis. From aspects of technology, economy, management, etc. suggestions were proposed for DSM, trying to be more rational and effective to allocate and use electricity resources, seeking satisfaction of power demands to the greatest degree, thus promote sustainable development of electric power enterprises effectively.

Introduction

Electric power is essential element of life in modern society, when economy of China is developing in a high speed, the contradiction is still sharp in power industry, and not solved essentially; resources of power industry are not in reasonable configuration, and energy utilization remains tense [1][2][3][4][5]. Based on this, it is necessary to establish management evaluation indicator system considering the whole process of infrastructure to promote the development of DSM projects and direct the planning for DSM projects management [6], and reference [6] analyzed the key factors of each stage influencing DSM projects with the whole process theory, and proposed an indicator system for DSM projects management evaluation; reference [7] introduced the status of power supply enterprise DSM at the county level, and from the administrative, technical, economic and other aspects, it put forward measures and methods to improve the capacity utilization efficiency of distribution transformers and electricity power factor, reduce line losses, eliminate harmonic to improve power quality, guide the users to change and optimize power consumption, improve the efficiency of electricity end-users, improve economic efficiency of power supply enterprises; in reference [8], it designed the main function modules of DSM decision supporting system, and constructed a DSM decision supporting system of B/S structure according with J2EE architecture, and the system realized ten functions, including energy efficiency assessment, DSM program design, DSM project management, DSM electricity savings analysis, electric load analysis and forecast, peak load shifting management, DSM policy modeling, DSM project comprehensive evaluation, DSM case management and DSM prime data management, this DSM decision supporting system can provide a unified decision sup-porting platform with universal functions for participants in DSM work; and in wind power integration management work in China, the implementation modes of demand side response in the initial stage, transition stage and mature stage of electricity market, are put forward respectively on the background of large-scale wind power integration, aiming to provide an useful reference in China [9].

In this paper, the management technology of DSM was studied, a resources investigation and evaluation system of electric power DSM was designed and developed, which implemented investigation aimed at electricity resources of China, developed electric power projects scientifically and reasonably, configure power resources effectively, etc. thus can greatly improve the electricity utilization rate of users. Especially for the data collection precision of DSM terminal, the methods proposed in reference [10] were adopted, and for hardware design, in reference [11], a validated design method of a power synthesized parameters monitor was presented which includes the user's demand. The design method involves analog signal regulation module, synchronous detection circuit, GPRS communication module, and the corresponding software. The monitor can measure power parameters accurately such as electric power quality, quantity and temperature. The high precision, powerful operation and reliability of monitor can be demonstrated on the experiments. Based on the hardware principle used in reference [11], the hardware was developed in this paper, and its structure scheme was given, the hardware was used to collect data of distribution system of electricity users, and the collected data supplied fundamental electricity utilization information for the upper analysis software.; In this paper, based on the technology and methods of DSM system in smart grid field [12], the resources investigation and evaluation system of electric power DSM was developed to make the power grid corporations have the ability to completely grasp potential energy-saving service opportunities of consumers from each aspect, such as the area, industry, enterprise, and electric equipment, thus will play a significant supporting role in finishing DSM work targets responsibility stipulated by national power grid corporations.

Resources definition of power demand side

The potential electricity-saving resource of power users is called "power demand side resource", which is realize by DSM, including reduced power consumption by improving electricity utilization rate, decreasing electricity demand by changing utilization mode, and the saving electric power and electricity amount through alternative energy, interruptible load of contract agreement, improving the electrical environment, etc. The power demand side resource can be classified permanent and temporary electricity saving resource according to electricity-saving time. Specific contents are shown in Fig.1 below.

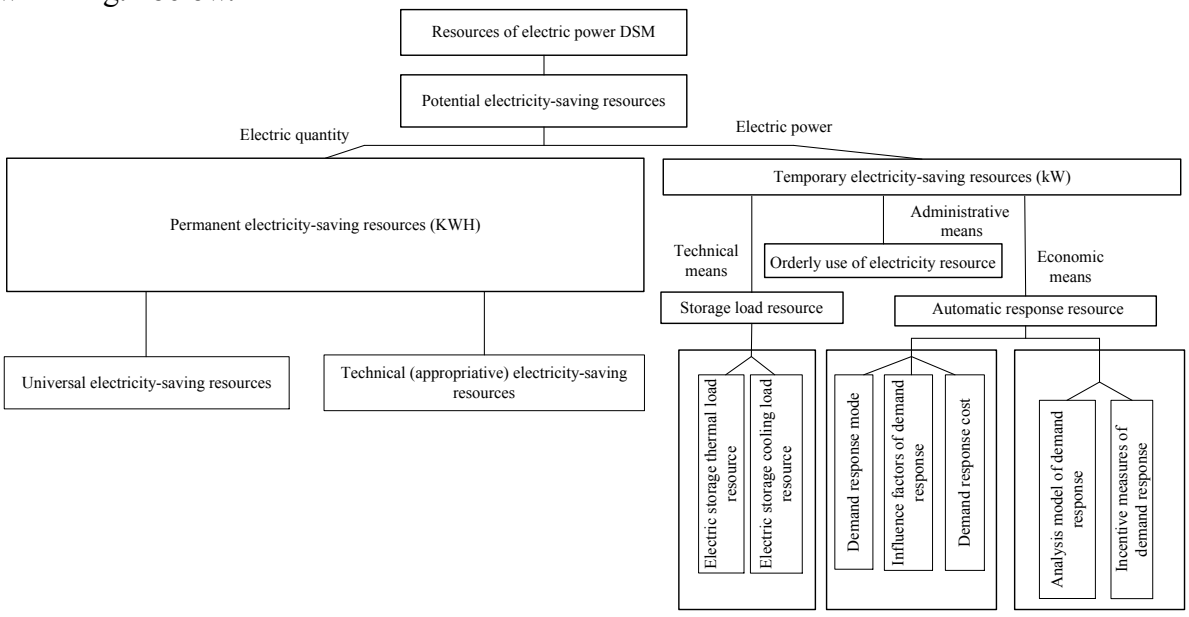

Fig.1 Resource classification of DSM

Hardware subsystem

According to the diagram of hardware subsystem structure which is shown in Fig.2, the hardware configuration of total system is composed of signal sampling unit, signal conditioning

unit, synchronous signal sampling unit, A/D converting unit, DSP core processing unit, CPLD and its peripheral human-computer interaction unit, external interface unit and so on. The device get in the signal of special users' power lines through signal sampling unit, and invert voltages and currents by voltage / current transformer, so as to acquire three-phase voltages, three-phase currents signal of special users' testing lines; then signals are transmitted into signal conditioning unit and in which the signals are treated with filtering and magnifying, A/V converting, sample-and-hold, data buffering and so on, thus these manipulated signals enter into A/D sampling unit with 8 bit analog signal (they are Ua,Ub,Uc,Un,Ia,Ib,Ic,In), during which the DSP core processing unit controls it's A/D converting process.

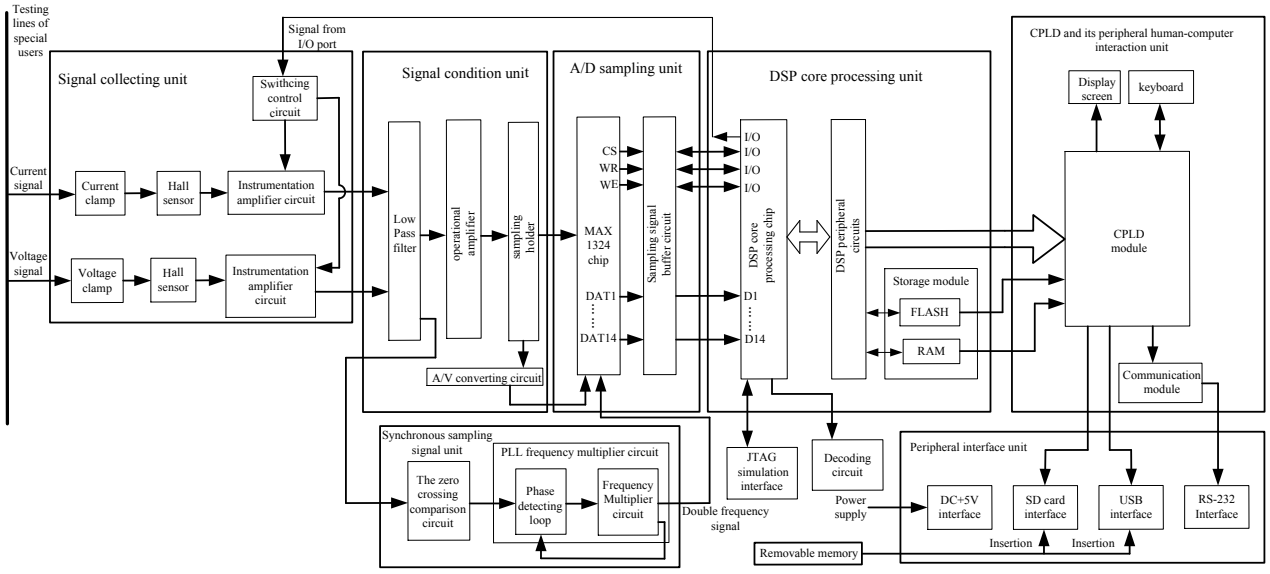

Fig.2 Hardware subsystem principle and structure block diagram

Software subsystem

The software subsystem utilizes building block design, the programs of which uses C++ language, and its main functions are to complete A/D conversion, digital filter, FFT processing, data insert, energy analysis, results display, generate data format file etc. Fig.3 shows the DSP main program chart of energy saving diagnosis operation, DSP main program is core hardware processing program in the detector, and its main functions is data filtering and FFT analyzing; Fig.4 shows Signal sampling and data analysis flow chart, at the end of the figure, through FFT analyzing and other analyzing of DSP, we get the energy consumption data files of users , which conclued various functional parameters detected and recorded by DSP chip and they are very significant for the final generation of users energy-saving audit analysis report. Fig.5 shows the user-friendly and supporting software interface of energy saving diagnosis and analysis, which concludes 6 parts: DSP chip initization, enable interrupt, start samping, sample completed, Data proceess, display results impoert data.

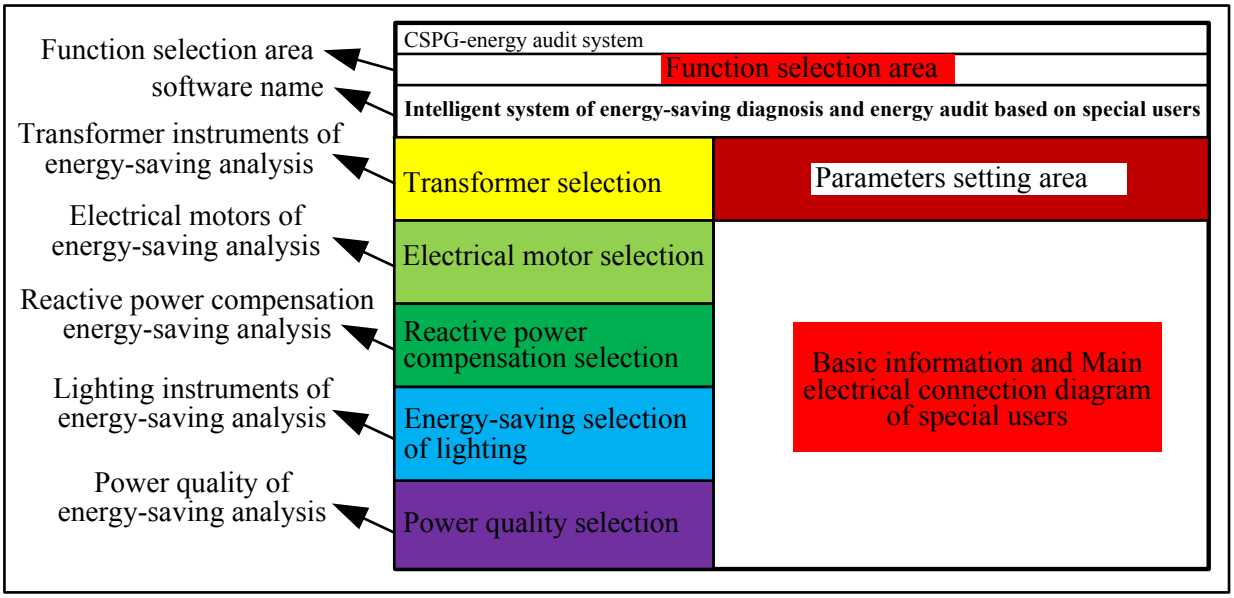

Fig. 5 The software interface of energy saving diagnosis and analysis

Test results

Utilizing the special users' energy saving potential intelligent diagnosis instrument developed in this paper to implement diagnosis and analysis of energy-saving and power quality detection in a medium-size cement factory in Guizhou province. The 35 kV Zhongyin line and Liangyin line as inlet wires of this cement factory, whose voltage reduce to 6 kV through 2 sets of S7-8000/35 main transformers. Among them, the raw mill, coal mill, and cement mill and so on, they use 6kV power source directly, at the same time, a 6 kV regional is transported to the mine substation. The voltage of I segment, II segment 6kV line reduce to 380/220 V through two fractions changed buck, which provides supply for low voltage electrical equipment. The electrical equipment were continuously measured and recorded 24 hours with using of the intelligent diagnosis instrument developed in this paper, and we record the measurement point of the main wiring diagram in detail, which is shown in Fig.6.

（1）Energy-saving diagnosis

1#electromotor (Mill), whose energy efficiency limit value is 94%, doesn't meet the limit value of require according to the GB18613—2012, and only partly operates in the economic operation area. The following table shows the energy-saving diagnosis parameters of 1#electromotor. Overall, this electromotor doesn't operate economically. The energy-saving diagnosis result of 1# electromotor is shown in Tab. 1 below.

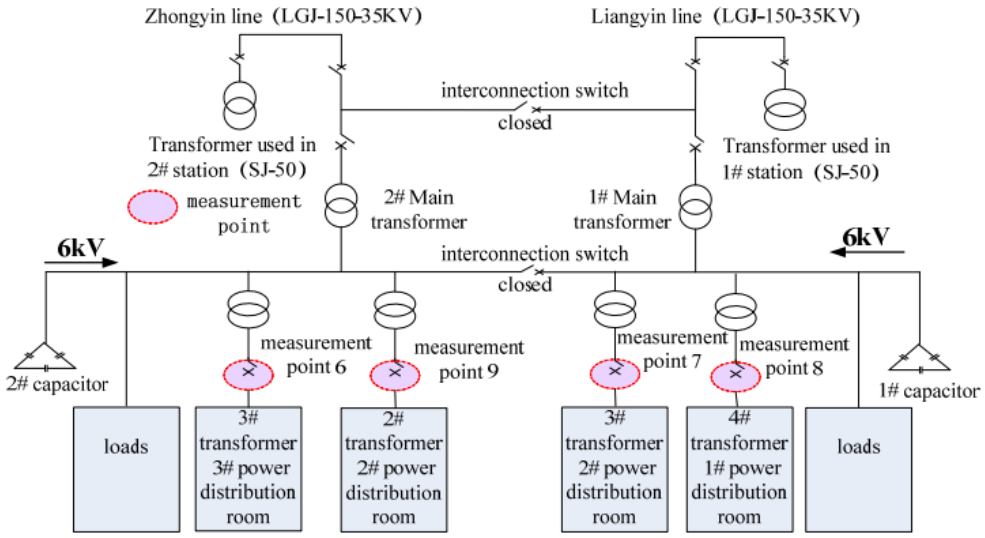

Fig.6 Measuring point of the main wiring diagram

Fig.6 Measuring point of the main wiring diagram

Tab.1 Energy-saving diagnosis result of 1# electromotor

Motor number	Motor name	Rated power (kW)	Average loss (kWh)	Efficiency	Economical probability	Economical running
1#	Mill	1000	66.7577	92.96%	31.83%	No

（2）Energy-saving solutions

Solution 1: using variable-frequency technique. While using the variable-frequency technique, the power saving rate ranges between 30% and 50%, for an electromotor with 1000 kW rated power, thus, its input power is about 11000 kW, so, its energy-saving ability is about 330-550 kW, at the same time, we assume this electromotor runs 7200 hour per year, thus, its energy-saving potential is shown in Tab. 2.

Tab.2 Energy saving potential of 1# electric motor

Annual operating time (h)	7200
Annual savings of electricity	3168000
Equivalent standard coal (t)	1279.87
Equivalent carbon dioxide emissions (t)	3353.26
Energy benefit (ten thousand RMB)	145.73

Solution 2: replacement of high efficiency electromotor. In order to achieve the purpose of energy conservation and loss reduction, it is important to replace those energy-saving motors in high efficiency.

Looking for the least loss motor in the database automatically, which could be a suggestion to choose the motor, meanwhile calculate the energy saving amount as well as the energy saving benefit and investment payback period. We can also customize a motor as a replacement of the motor by ourselves and then judge whether the effect of energy saving is well; moreover we can calculate its energy efficiency at the same time. The below Tab.3 shows the effect of energy saving by replacing energy-saving motors.

Tab.3 Energy saving potential analysis of 1# electric motor under case 2

	Current motor	Proposed motor	Optional motor
Motor type	Y1000-10/1430	YR6302-10	YR1000-12/1430
Power loss under the rated conditions (kW)	67.279	40.171	107.313
Annual energy-saving (kWh)	—	245621.3	More than the current motor
Equivalent standard coal (t)	—	95.19	—

Equivalent CO2 emissions (t)	—	249.4	—
Energy benefit(million RMB)	—	11.84	—
Estimated investment (million .RMB)	—	100	—
Investment recovery period(year)	—	7.5	—

（3）Power quality analysis

Harmonic analysis.Through monitoring power quality of the transformer, the voltage and current measured is respectively made into FFT calculation, then can get 1~25 times of harmonic content and harmonic total content, and which are compared with the national standard. According to GBT24337-2009 " Power Quality Public Power Grid harmonic", we can determine that the voltage, current harmonic content are both in a limited range. Due to harmonics, annual loss is about 82700 kWh, and the specific harmonic waveform is shown in Fig.7.

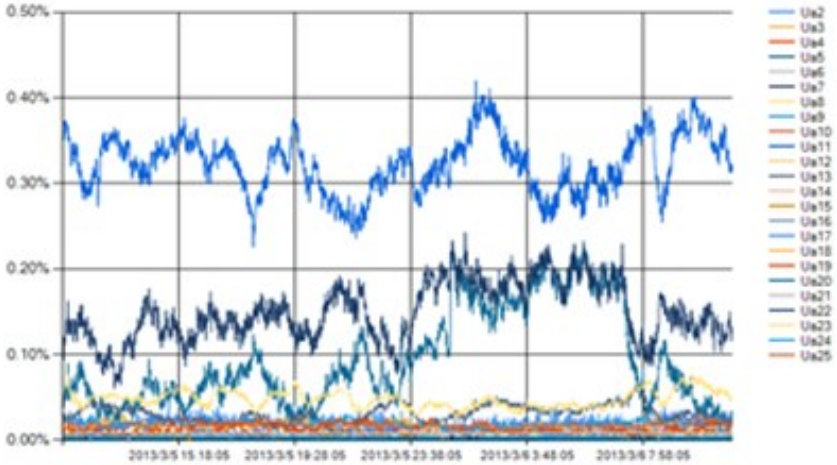

Fig.7 Harmonic analysis

According to the results of harmonic analysis, the software system will produce harmonic control scheme automatically, which shows that we can use the passive power filter (PPF) and active power filter (APF) as scheme. Because of fast response and high controllability of APF, for each times of harmonic, can be compensated effectively, and has adaptive function and is not subject to the system impedance. The use of filter is recommended as APF, which the type can be matched automatically by the software system, and that is APF-100-3L, considering other factors, the users can also choose other types of filter from the database.

（4）three-phase unbalance

The three-phase voltage and current unbalance waveform will be got through the comparision between the three-phase voltage and current monitoring data and its rated value. The average and maximum vlaue of voltage unbalance, current unbalance and power unbalance will be calculated respectively, and then they will be compared with the rated value, among them, the limited value of voltage and current unbalance is both 2, and the calculatino results are shown in Tab.4 below.

Tab.4 Unbalanced calculation

	Voltage unbalance		Current unbalance	
	Average value (%)	Maximum value (%)	Average value (%)	Maximum value (%)
Measurement value	3.797	6.838	0.096	0.177

According to the standard, voltage unbalance exceeds the requirements of limited value. Through calculation, the annual loss due to three-phase unbalance is 1396.57 kWh. The upper software will automatically produce the three-phase unbalance control scheme, that is, use cross phase conversion and other methods to make asymmetric load distribute to each phase reasonably, thus try to keep it in balance; also can choose proper compensation device, to achieve three-phase unbalance compensation. There are two kinds of compensation methods, one is to adopt TSC static

compensation device for compensation, and another is to adpot TSC+TCR mixed type of static compensation device.

（5）Energy efficiency assessement

This paper utilizes analytic hierarchy process to calculate the index weight, firstly, adopt comprehensive understanding of experts for the cement enterprise power efficiency evaluation index importance, after the corresponding mathematical calculation (results retained 3 decimal places), can get the weight of each index are as follows: the total industrial output value 0.991; economic added value 1.844; ten thousand RMB value of energy consumption 1.844; power saveing rate 3.432; each phase power factor 2.795; over load cumulative time 2.795; unqualified voltage cumulative time 5.078; unbalanced current cumulative time 5.078; harmonic content 9.227; electricity loss amount 9.227; reactive power compensation 9.246; transformer 16.014; motor 26.933; lighting device 5.498 (unit: %). Adopt recursive comprehensive evaluation method to make comprehensive energy efficiency evaluation for electricity users, thus can get energy efficiency and total efficiency level of second index. Refer to industry standard, and base on this evaluation results, then aim at the weak link of enterprise efficiency, take effective measures to make scientific energy-saving scheme, thus can fully tap the potential of energy-saving.

Conclusions

This paper aims at the problem of high energy consumption of special users and which is becoming increasingly prominent, the paper designed and developed special users' energy-saving potential online automatic diagnosis intelligent detector and based on DSP2812 and resource investigation and evaluation system of power DSM based on Visual Stidio 2012. The results shows that:

(1) This detector utilizes advanced digital signal processing technology and high accuracy technology, meanwhile, concludes high accuracy, multi channel sampling A/D converter. Through inserting data processed and recorded by detector into the internal energy-saving analysis software, thus, special users obtain the energy consumption data files and energy audit report, which provide reasonable energy-saving measures and suggestions with special users so that improve their potential ability and maximize their energy-saving production;

(2) This detector is of great practical significance in engineering, and is an urgent need for power grid enterprises to implement energy-saving and emission reduction work. Through the actual running test, indicating that the detector has a good performance of diagnosis, thus, this detector can greatly improve the efficiency, the degree of information and automation in electrical energy audit work;

(3) Technically, this detector has higher innovation. If it vigorously promotes in the energy market, the direct economic benefits and social benefits will be very significant;

(4) The resource investigation and evaluation system of power DSM is the system of investigating, evaluating and analyzing resource of DSM, and which is a DSM system of comprehensive data acquisition, storage, analysis and report. The system has friendly interface, complete function, rights management and support for multiple users, thus realize complete analysis and evaluation of DSM from downward and upward, and it can be used to study and can also for actual program of DSM, so as to provide reference for DSM planning;

(5) Through practical engineering application, the DSM resource investigation and evaluation system can achieve data acquisition and management, energy-saving analysis of demand side resource and automation and scientific of DSM decision-making analysis, then will provide convenient information service of actual load analysis work and DSM work, thus can greatly improve the work efficiency.

Keywords: photovoltaic generation, wind turbine, capacity optimization, meteorological data, reliability, economics

Abstract. Sufficient and economical power supply is important for an islanded operation mode with renewable energy. This paper deals with the problem of optimizing photovoltaic (PV) and wind turbine (WT) capacities from the point of view of power supply reliability as well as economics. Meteorological data is analyzed, and then PV and WT capacities are optimized to supply the load reliably. The optimization is also discussed when the load profile is changes. Short-term power system operation is also analyzed. Several different cities in China with different climate features are simulated.

1. Introduction

Photovoltaic solar energy and wind energy conversion systems have been widely used for electric power supply in isolated locations far from the distribution network. Since solar energy and wind energy fluctuate depending on the climate [1], [2], it is difficult to operate or plan the system. However, solar energy and wind energy are complementary. Solar energy is rich in day time and none at night, but the wind energy may be richer at night time than in the day time. In the long term, solar energy is usually richer in summer than in winter, but wind energy may be richer in winter and spring than in summer. The meteorological feature is also different in different areas.

Some reference studied reliability of hybrid WT/PV systems and explored optimization of economics and reliability of power supply from a hybrid WT/PV system [3],[4]. Many papers focus on stand-alone photovoltaic or wind turbine system. In[5], a new probabilistic model that took into account the random nature of solar irradiance and load is developed. In[6], various solar radiation prediction methods along with hourly mean solar radiation (HMSR) method are compared, it is found that reliability indices, additional load hours (ALH) and additional power (AP) exponentially decrease with an increase in load. Fuel saving is also investigated. A probabilistic technique to evaluate the distribution system reliability utilizing the segmentation concept and a novel constrained Grey predictor technique for wind speed profile estimation is presented in [7]. In[8] an approach to evaluate the contribution of wind power to the load carrying capability of a power generating system is presented in an operating scenario. In [9] the reliability effects on a composite generation and transmission system associated with the addition of large-scale wind energy conversion systems is investigated using the state sampling Monte Carlo simulation technique.

Some research work is concentrated on the PV/WT hybrid system. the solar arrays and the composition of the solar-wind change. System reliability and fuel savings are analyzed in[10]. Several combinations of WT and PV capacity are compared by several reliability indexes in [11]. The probabilistic method is employed to analyze the optimization. These are only several possible kinds of combinations that be considered. In[12], leveled cost of energy and loss of power supply probability are employed to optimize the configuration of solar-wind system, but the optimization is not global optimization, but only different capacity combinations. A hybrid (wind/photovoltaic) system sizing optimization procedure is proposed in[13], but the capacity of PV and WT is in terms of the number of rated power units, the load models are constant or simply different between night time and day time.

Much work has been done to analyze the economic and reliability features of PV/WT hybrid systems, most only discuss the proportion of PV/WT capacity simply changes or when the capacity is the number of per unit capacity. The solar radiation calculated with altitude, solar declination or wind speed simulated with Weibull distribution is not so accurate, especially for solar energy, it is interrelated with radiation intensity and sunshine hours. The load model is often considered as constant.

This paper investigates the least cost installation of PV/WT hybrid system considering the reliability index energy supplied rate (ESR) to the load, and from the economic point of view that PV/WT power is greater than load: additional power (AP) is evaluated after optimization. Practical meteorological data is analyzed and used to evaluate the optimal capacity of PV and WT in the hybrid system. Different cities in China with different climatic features are simulated to test the proposed method.

3. Theoretical Formulation

The power output deduction of solar cell and wind turbine according to the meteorological data is as follows.

A. PV Output

If the peak radiation hour d_i is known, the output energy by installed peak power of PV module can be calculated as equation (1). Peak radiation hour is the hour which the PV cell temperature is $25°C$ and air mass is 1.5 and the sunshine radiation is $1000W/m^2$, its unit is hour.

$$W_{PV} = P_{PV} \times \eta \times d_i \times 10^{-3} \tag{1}$$

Where P_{PV} is installed PV peak power (W). The unit of $W_{PV}(t)$ is kWh. η is efficiency of installed PV which is a total efficiency of PV and other components in PV arrays. η is about 0.6 to 0.9, in this paper η is considered to be 0.75. The peak sunshine hour is converted from sunshine radiation in equation (2)

$$d_i = H \times 0.0116(h) \tag{2}$$

Where H is real sunshine radiation on the earth surface, and 0.0116 is the conversion coefficient between the sunshine radiation and peak sunshine hour, its unit is $h \cdot cm^2/cal$. H is formulated as equation (3) when daily sunshine hour S in meteorological data is known.

$$H = H_L(a + b\frac{S}{S_L}) \tag{3}$$

Where a,b is constant coefficient. S_L is day time hour which is calculated by equation (4). H_L is sunshine radiation passed through atmosphere in sunny day calculated in equation(5).

$$S_L = (2/15)W_S \tag{4}$$

$$H_L = \tau \times H_0 \tag{5}$$

Where W_S is hour angle. H_0 is sunshine radiation outside the atmosphere as equation. W_S and H_0 are calculated with equation (6) and (7). τ is the transmittance coefficient of the atmosphere[14], when the day is clear with sunshine, τ is about 0.4 to 0.8 depending on the atmosphere and some other conditions.

$$W_S = \cos^{-1}(-\tan\Phi \times \tan\delta) \tag{6}$$

$$\begin{aligned} H_0 = (1/\pi) \times G_{SC} \times E_0 \times (&\cos\Phi \times \cos\delta \times \sin W_S \\ &+ (\pi/180) \times \sin\Phi \times \sin\delta \times W_S) \end{aligned} \tag{7}$$

Where Φ is latitude, δ is solar declination. $G_{SC} = 1.367W/m^2$ is the solar constant which is the solar radiation before enters the earth's atmosphere, E_0 is adjusted factor of earth orbit eccentricity.

$$\delta = c_0 - c_1\cos\Gamma + c_2\sin\Gamma - c_3\cos 2\Gamma + c_4\sin 2\Gamma - c_5\cos 3\Gamma + c_6\sin 3\Gamma \quad (8)$$

$$E_0 = e_0 + e_1\cos\Gamma + e_2\sin\Gamma + e_3\cos 2\Gamma + e_4\sin 2\Gamma \quad (9)$$

Where Γ is year angle. $\Gamma = 2\pi(l-1)/L$， l is day number, for example the day number of Jan. 1 is 1. in leap year, L=366， and non-leap year, L=365。

B. WT output

WT power is decided by wind speed. The total energy output by WT during time t is:

$$W_{WT} = \int_0^t P_{(v)}dt \quad (10)$$

Where $P_{(v)}$ is the power output by WT at the wind speed of v. The wind turbine generation can be approximately expressed mathematically as follows:

$$P(v) = \begin{cases} 0 & v < v_{in}, v > v_{out} \\ \dfrac{v - v_{in}}{v_r - v_{in}} P_{WT} & v_{in} \le v \le v_r \\ P_{WT} & v_r < v \le v_{out} \end{cases} \quad (11)$$

Where P_{WT} is rate power of installed wind turbine. v_{in}, v_r, v_{out} are respectively the cut-in speed, the rated speed, the cut-out speed.

The wind speed from national meteorological center is obtained from an anemoscope 10m above the ground. When the type of wind turbine is selected, the wind speed v_0 should be transformed to the height of the hub v. The increase of wind speed with height is known as wind shear. Exponential function is applied to the wind shear transforming in equation (12).

$$v = v_0\left(\frac{Z}{Z_0}\right)^{\alpha} \quad (12)$$

Where Z is the height of the hub, Z_0 is the reference height of anemoscope, α is roughness of the ground; it is 1/7 for the open area.

With equation (11)-(12) daily WT output energy can be computed.

C. Month Average Energy by Hybrid PT/WT System

From section II and part A and B in this section, month average daily peak radiation hour and wind speed can be calculated. If the installed PV module is P_{PV}, the PV output power of ith month can be calculated by equation (13) which is equation (1) multiplied by the day number m_i of month i. If the installed rated WT power is P_{WT}. $P_{(v)i}$ is WT output power(kW) according to the month average daily wind speed v. The WT energy output in a whole day is $24\times P_{(v)i}$, and the month WT output energy is multiplied by the day number of month i: m_i, as equation(14).

$$W_{PVi} = m_i \times P_{PV} \times \eta \times d_i \times 10^{-3}(kW\cdot h) \quad (13)$$

$$W_{WTi} = m_i \times 24 \times P_{(V)i}(kW\cdot h) \quad (14)$$

4. the mathematical model

A. The Indices of Energy Sufficient Rate and Additional Power

Using equation (18) the energy sufficient rate (ESR) of the *ith* month is formulated:

$$ESR_i = \frac{W_{PVi} + W_{WTi}}{E_{Li}} \tag{15}$$

Where ESR_i is monthly energy sufficient rate form January to December W_{PVi} is PV output energy in month i, W_{WTi} is WT output energy in month i, E_{Li} is total load in month i. From the view of economic, AP is expected to be a relatively small value. AP and the rate of additional power (RAP) are defined as equation (16), (17) respectively:

$$AP = \sum_{i=1}^{12} W_{PVi} + \sum_{i=1}^{12} W_{WTi} - \sum_{i=1}^{12} E_{Li} \tag{16}$$

$$RAP = AP / \sum_{i=1}^{12} E_{Li} \tag{17}$$

B. Optimization Model

To find the economist fixed cost capacity of PV and WT, the objective function is:

$$\min(C_{PV} + C_{WT}) \tag{18}$$

Subject to:

$$ESR_i > \lambda (i = 1, 2 \cdots 12) \tag{19}$$

Where C_{PV} is fixed cost of PV, $C_{PV} = P_{PV} \times C_{0PV}$, C_{0PV} is per peak power cost of PV fixed cost. C_{WT} is fixed cost of WT. $C_{WT} = P_{WT} \times C_{0WT}$, C_{0WT} is per unit cost of rated WT power. $ESR_i > \lambda$ means ESR of each month should be greater than threshold. The simple combination searching method is employed to WT/PV capacity optimization.

5. Simulation Result

A. The Simulation Station Information and Load Model

The life of WT and PV array is about 15 to 25 years. In this paper 20 years is assumed as the life time of PV and WT. The fixed cost includes equipment cost, control system cost, transport cost, installation cost etc. In this paper the PV per unit fixed cost is about 25000￥/kW, and the WT per unit fixed cost is about 8000￥/kW. Based on the recent ten years meteorological, several cities are selected to simulate the model. The station information is shown in table 1. In this paper, v_{in} is 3m/s, v_r is 12m/s, v_{out} is 25m/s. the hub is assumed to be 40m. In order to evaluate the long term plan of PV/WT hybrid capacity, two cases of load model is listed in table 2. It is the month average daily load power of every month, with the unit in kW・h.

TABLE 1 STATION INFORMATION

Station number	City name	Latitude(degree)
53399	Zhang Bei	41.15
51463	Wu Lu Mu Qi	43.47
50873	Jia Mu Si	46.49
58467	Ci Xi	30.16

TABLE 2 MONTH AVERAGE DAILY LOAD

Month	1	2	3	4	5	6	7	8	9	10	11	12
Case1	75	60	55	50	45	60	85	95	80	55	60	70
Case 2	50	70	80	90	100	100	100	95	80	55	60	50

B. The Optimization Result by Case 1 Load Model

For the station 53399 when the load model is as case 1. When the ESR of each month is not less than 0.9, the optimization result is 26 kW PV and 15kW WT installed, the least cost is 770,000￥.

The month average daily load is the blue column shown in Fig 1. Since the wind and solar energy is sufficient in April and May while the load is relatively low, more energy exceeds the load level.

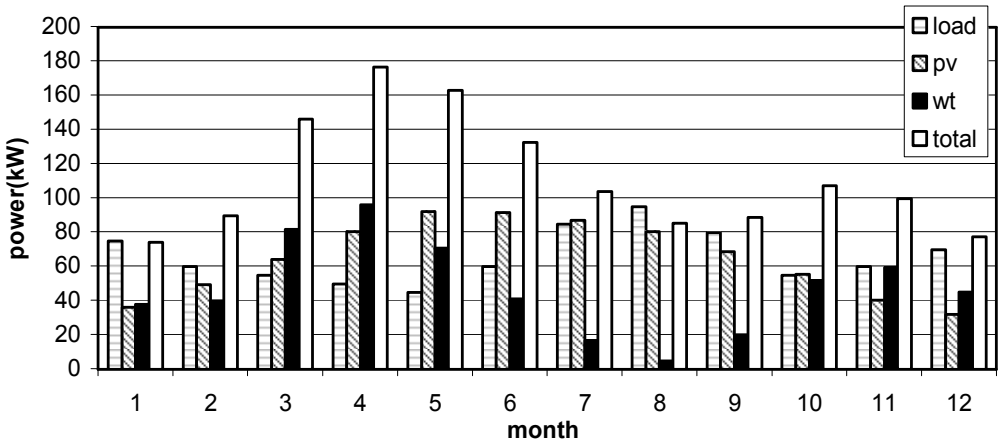

Fig. 1 Optimized power output and load level of case 1 in station 53399

Optimization of other stations with the same load model of case 1 with the constraint ESR of every month no less than 0.9 is shown in table 3. The cost of only PV or WT with the same constraint is also listed to compare with the hybrid system. For the same load model, the optimization result is very different. The proportion of the PV capacity and WT capacity is different and the economic fixed cost is very different from one city to another. Normally the hybrid system is more economical than a single PV or WT. But in the station 51463(Wu Lu Mu Qi city), for the same load level, the optimization result is that PV is the most economic way to satisfy the load. It is attributed that the wind speed is relatively smaller than the solar radiation, especially in January and December, when the month average daily wind speed is less then 3m/s, below the wind turbine cut-in speed.

TABLE 3 OPTIMIZATION RESULT WITH ESR OF EACH MONTH NOT LESS THAN 0.9

Station	Cost or capacity	PV+WT	Only PV	Only WT
Zhang Bei	Total cost(10000)	77	127.5	202.4
	PV capacity(kW)	26	51	0
	WT capacity(kW)	15	0	253
Wu Lu Mu Qi	Total cost(10000)	220	220	It can't be satisfied only by WT
	PV capacity (kW)	88	88	
	WT capacity (kW)	0	0	
Jia Mu Si	Total cost(10000)	77.7	192.5	83.2
	PV capacity (kW)	17	77	0
	WT capacity (kW)	44	0	104
Ci Xi	Total cost(10000)	124.8	127.5	140.8
	PV capacity (kW)	48	51	0
	WT capacity (kW)	6	0	176

For the same load level of case 1, when ESR changes the optimization is different too. As seen from Fig 2, the optimized total cost will increase when the ESR becomes larger in each station, though different places get different optimization results.

C. The Optimization Result Contrast with Case 2 Load Model

When load model of every month changes to case 2, the optimization result is 27 kW PV and 6 kW WT in station 53399, while the fixed cost is 723,000￥. It can be seen that less energy is wasted in such a load level from Fig. 3.

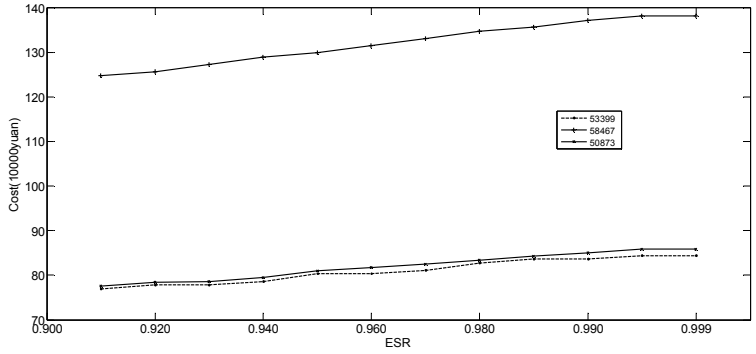

Fig. 2 The economic cost of different ESR

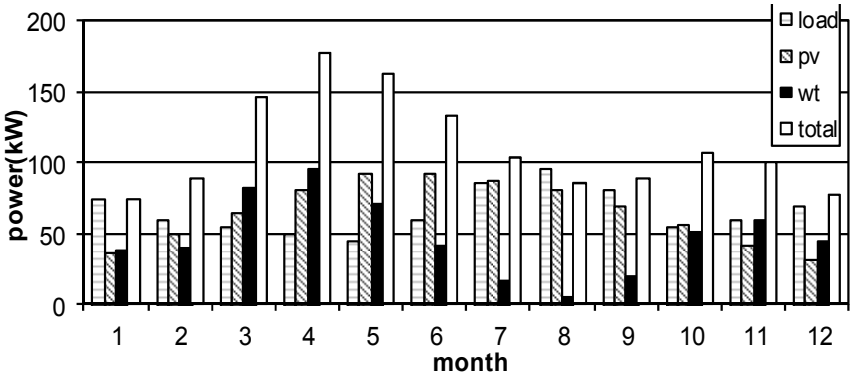

Fig. 3 Case 2 month average daily load level and optimized total output power in station 53399

D. The ESR and RAP evaluated by daily power balance

In this paper, a long term plan of the PV/WT hybrid system is optimized which is logical and meets the power supply sufficient demand in the long term.

Daily output of PV and WT is simulated by optimal installed capacity with load model case 2 with ESR greater than 0.9. Table 4 is the year ESR and RAP from 2001 to 2004 of the stations. Seen from the power supply reliability, each station in each year ESR is about 0.9, while seen from the economic aspect, RAP is about from 50% to 150%. RAP is smallest in station 58674, station 53399 has a relatively larger RAP, and station 50873 has the largest RAP. It is attributed to the proportion of wind turbine capacity in the hybrid system. Proportion of PV/WT in station 58467 is the highest while that in station 50873 is the lowest. Wind energy contributes to the unstable operation of the island system. Solar energy is relatively more stable than wind energy.

TABLE 4 EENS AND RAP IN DIFFERENT YEARS TO DIFFERENT STATIONS

year	53399(PV:26,WT:15)		50873(PV:17,WT:44)		58467(PV:48,WT:6)	
	ESR	RAP	ESR	RAP	ESR	RAP
2001	92.8%	78.96%	80.8%	150.24%	91.84%	60.48%
2002	89.68%	60.72%	79.23%	126.8%	87.76%	48.48%
2003	87.52%	47.04%	72.1%	91.23%	90.88%	60.96%
2004	91.84%	60.7%	73.3%	108.7%	91.12%	61.68%

6. Conclusion and Discussion

This paper proposes the optimization model of PV/WT hybrid system to decide the most economical capacity dispatch between PV and WT. the main attribute is: 1) economic aspect of hybrid PV/WT system is analyzed in many papers, but the best optimization capacity decision is not mentioned. The optimization capacity is obtained in this paper. The optimization model is proven to be feasible with the optimal system that the yearly ESR and RAP are meet the requirement. The optimization method is very simple and the plan capacity could be got fast and easy. 2) the optimization model is based on actual meteorological data, which is more instructive than generate

wind speed or solar radiation by some simulation software. In particular, the solar energy is evaluated by the number of sunshine hours which is more accurate than by astronomical solar radiation. 3) different circumstances are compared during the long term run plan of deciding PV and WT capacity, such as load level change and ESR change.

Keywords: FLISR, Distributed Generation, Distribution Automation

Abstract. The key distribution automation (DA) application for implementing a self-healing smart distribution network is the fault location isolation and service restoration (FLISR) application. With DGs introduce significantly more variability into distribution system power flows, it has a great impact to FLISR. Based on summarizing the existing FLISR scheme, this paper analyses the influence of fault detection and service restoration with large-scale DGs.

Introduction

One of the important characteristics of the smart grid is its ability to "self-heal". The key distribution automation (DA) application for implementing a self-healing network is the fault location isolation and service restoration (FLISR) application. FLISR creates a switching plan for re-energizing portions of a distribution circuit that have been de-energized as a result of a permanent feeder fault. Once the switching plan is created, FLISR can automatically execute the plan to restore service where possible, usually in less than one minute following the initial fault occurrence.

Around the world, conventional power system is facing the problems of gradual depletion of fossil fuel resources, poor energy efficiency and environmental pollution. These problems have led to a new trend of generating power locally at distribution voltage level by using non-conventional renewable energy sources like natural gas, wind power, solar photovoltaic cells, fuel cells, combined heat and power (CHP) systems etc. This type of power generation is termed as distributed generation (DG) [1].

DGs are connected to the low- or medium-voltage distribution system, where traditionally only consumption has been connected. So distribution lines are from single source to multi-source, which brings to impacts to fault detection and service restoration algorithm[2][3][4]. Based on summarizing the existing FLISR scheme, this paper analyses the influence of fault detection and service restoration with large-scale DGs.

FLISR Application function

The FLISR application function automatically detects that a fault has occurred, locates the fault (between two switches), sends control commands to open the switches that bound the faulty area to isolate the faulty section of the feeder, and then closes other switches (where possible) to restore service to healthy sections of the feeder. The key steps are detailed below:

(1)Fault Detection: FLISR should only operate following a short circuit (fault) on the feeder itself or in the facilities that normally supply the feeder. To meet this requirement, one or more fault detectors are needed to trigger FLISR operation when fault-level currents are detected. Common practice is to use a protective relay intelligent electronic device (IED) in the substation and feeder terminal units (FTUs) on feeder line to determine that a fault occurred in the distribution feeder protection zone and then provide a signal to trigger FLISR operation.

(2)Fault Location: The second step is to determine the "section" of the feeder that contains the fault. FLISR "sections" are portions of the feeder that are bounded by remotely controlled switches. By use the information of FTUs, FLISR algorithm determines what section is faulted. The faulted section is bounded by one FTU that has a fault indication and one or more FTUs that did not "see" the fault.

(3)Fault Isolation: FLISR then sends control commands to open the switches needed to completely isolate the faulty section. It is common practice for FLISR to defer these control actions until the standard automatic reclosing sequence has been completed. This ensures that feeder reconfiguration by FLISR is only performed following a permanent fault (should not reconfigure the feeder if fault is a self-clearing "temporary" fault).

(4)Service Restoration: Once the faulty section of the feeder is isolated, FLISR attempts to restore service to as many "healthy" sections of the feeder as possible via the available sources. Available sources include the normal source of supply to the feeder as well as any available backup sources that are connected to the faulted feeder via normally-open, remotely controlled tie switches that have spare capacity to carry additional load.

FLISR process is as figure 1 below.

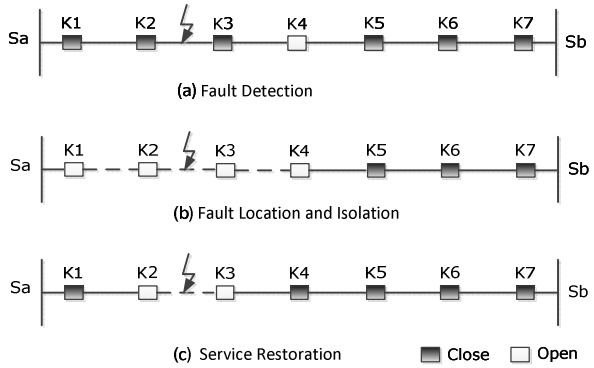

Fig.1 FLISR Process

FLISR Scheme

For each utility, the FLISR implementation process will look a little different, depending on its unique needs. FLISR applications can use either decentralized, substation, or control-center intelligence and that each has advantages and drawbacks.

Local-intelligence Scheme

Local-intelligent schemes are rudimentary applications where automatic functions occur without any communication with other devices. The schemes do sequential reclosing control by using recloser and section switch, realize the fault isolation and restore power. Due to multiple reclosing on permanent fault, it will result in stress to the system, overloads, and additional outages. This local-intelligent scheme is limited in that the breakers will simply trip and close based on breaker position, thus it has many drawbacks. A more intelligent scheme is therefore required.

Centralized Scheme

By the master control center to handle all FTU information to detect faults and fault location, remote control FTU to operate switches to achieve fault isolation and service restoration. The central intelligence remains with the system operator and the DA benefit is basically to reduce the time to manually isolate the faulted section and perform the load transfers. The system operator can utilize various SCADA data inputs from remote devices to make switching decisions in order to reconfigure the system. Reliable communications for the inputs can include open/close status points, current, voltage, and other quantities in order to ensure timely system data is transmitted to the operator. The system operator may also have the tools to make sure that the transfer will not overload the substation or the back-up circuit.

Decentralized Scheme

Distributed intelligence applies communication and software to localized sectionalizing and fault-interrupting devices to provide automated control that can vary from a simple circuit segment

to a region where multiple circuits interconnect numerous substations. While these devices are primarily controlled at the installed location, rather than from a central location, the shared software and communication distribute the data pertaining to the event or condition among the devices to effect the required circuit reconfigurations.

This solution is based on communication between FTUs, to achieve cooperative control, to improve the control response speed. Since the scheme does not depend on the master station, fault isolation and service restoration can be completed within seconds. FTUs needs peer communication network and smart control, so FTU requires a high degree of intelligence and investment is more than the other scheme.

Integrity DG in distribution system

The connection point of an energy source to the grid is usually referred to as the point of connection (PCC)[5]. Its definition depends on the ownership and utility interconnect requirements. Two different possible definitions are shown in Figure 2, where typically the interconnection relay (protection) is installed at the PCC. It will be assumed here that the PCC is the connection point before the interconnection transformer. PCC can be connected directly or as a branch line connected to the feeder line and substation bus.

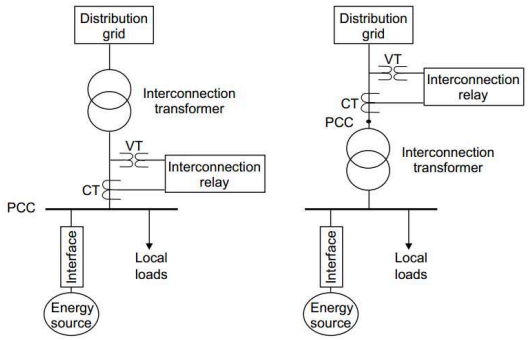

Fig.2 Two possible definitions of PCC

Impacts on Fault Detection, Location and Isolation

Most existing distribution networks were designed for one-directional flow, where power flows from the grid substation to end-users at lower voltages, and were not intended to accommodate distributed generation. Traditionally, distribution networks are designed as passive systems and ring structure but open loop operates. With DG introduces significantly more variability into distribution system power flows, it has a great impact to FLISR.

Bi-directional power flow and changes in network voltage profile caused important impact on the operation of conventional feeder fault detection schemes that are originally designed based on radial network operation assumption. Some impacts are due to an increase in fault current because of the generator. Other impacts occur because the fault current contribution from a generator is too small.

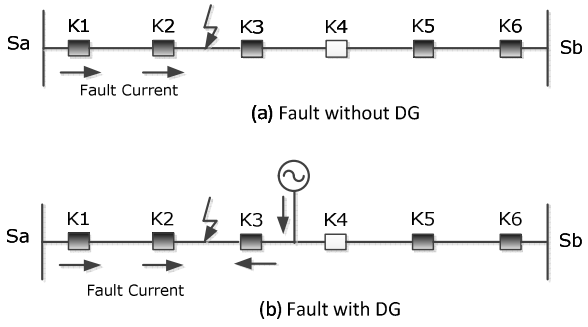

Fig. 3 Impacts on fault current with DGs

The impact of distributed generation on protection strongly depends on the fault current contribution and thus on both the size and type of the interface. Synchronous generators deliver a continuous short-circuit current; induction generators contribute during one or two cycles in case of a three-phase fault and longer in case of a non-symmetrical fault. Units with power electronics interface have none or a very limited contribution to the fault current.

Protection theory of a distribution network, in the vast majority of cases, is based on overcurrent protection. This can be definite-time or inverse-time overcurrent protection. Adding a generator to a distribution feeder will change the fault currents and thus increase the risk of a protection failure.

The following protection failures could occur due to distributed generation:

(1) The fault current contribution from the generator could result in a total fault current exceeding the rating of some equipment.

(2) The presence of a generator along a feeder will reduce the fault current at the start of the feeder, for a fault beyond the generator. When the fault current for a fault at the end of the feeder drops below the overcurrent setting of the relay at the start of the feeder, a failure to operate may occur.

(3) The fault current by the generator, for a fault on another feeder, could result in unwanted opening of the breaker at the start of the feeder.

(4) When using fast reclosing for fuse saving, the coordination between the fuse and the recloser is endangered by the presence of distributed generation along the feeder.

(5) The fault current contribution of some generators is not big enough for the overcurrent protection to detect the fault. A failure to operate could result from this. This is especially a concern for small generators and any generator equipped with a power electronics interface.

(6) The presence of a generator on a distribution feeder could result in the incorrect operation of fault current indicators. These are commonly used in underground cable networks to facilitate the location of the faulted section and to reduce the duration of an interruption of the supply for the customers.

(7) Single-phase reclosing or single-phase fuse clearing can result in ferroresonance conditions with distributed generation. Therefore, fuses and single-phase breakers should be avoided between a three-phase generator and the next upstream three-phase breaker.

For questions listed above, there have been many studies currently in progress to resolve.

Impacts on Service Restoration

Service restoration needs reconfiguration of a power distribution system, that is an operation to alter the topological structure of distribution feeders by changing open/closed status of sectionalizing and tie switches. Configuration management operation involves the restoration of service to as many customers as possible during a restorative state following a fault.

When carrying out the net reconfiguration, the operations that are executed should guarantee that the system satisfies some conditions [9][10][11][12], such as:

(1) The capacity of current of the transformers and lines should be within specified limits;

(2) The voltage drop should stay inside an established margin;

(3) System should continue being radial;

(4) The Number of operations of the equipment show be reduced as much as possible;

(5) Important customers should be given priority;

(6) System must be balanced in the best possible way;

(7) The coordination of the protection must be maintained.

With DGs introduce, systems can increase capacity to restore priority and non-priority load. But the addition of DGs significantly increases circuit reconfiguration algorithm complexity.

Circuit reconfiguration can vary based upon the system need. Reconfigured lines bring about changes in load current, available fault currents, and voltage drop. The new circuit configuration may alter protective device coordination. The load of the new circuit configuration may also exceed the existing trip settings of the protective devices.

Conclusion

The impacts with introduction of generating sources into the distribution system could be positive or negative depending on the system operating condition, distributed generation characteristic, location and sizing. FLISR scheme needs as much as possible to use advantages of DG, to avoid problems that DGs introduced. Whether existing FLISR scheme to meet requirements need to be carefully assess. Implement new FLISR scheme, information model should comply IEC61850/61970/61968 standards.

Doubly-Fed Wind Farm Engineering Aggregation Model Used for Planning

Meng Dai[1, a]

[1]Tsinghua University, Beijing 100084, China;

[a]daimeng83@126.com

Keywords: electrical calculation in wind power integration planning; doubly-fed wind farms; engineered aggregation model

Abstract. Establishing an appropriate aggregation model of wind farm is the first step of the electrical computation in wind power integration planning. This paper first summarizes the technical requirements of wind farm model from the viewpoint of engineering, then proposes an aggregation DFIG model of wind farm. Because of the lack of measured data in the planning stage, the single equivalent model is used in this paper, and be improved by considering the equivalent collection lines model. The accuracy of the aggregation model in different electrical calculation, such as power flow, transient stability and shortcut current simulation, is verified through a sample system in DIgSILENT.

Introduction

The development of wind power is fast in recent years[1, 2], so it's necessary to consider the influence of wind power at the stage of power grid planning. As the detailed model of one wind turbine is already very complex[3], the detailed model of a wind farm consisting of dozens of wind turbines is too complex to be used for the electrical calculation in wind power integration planning. As a result, it's necessary to build an equivalent model of wind farm specially for the wind power integration planning, which can simplify the calculation at the same time of ensuring the accuracy.

The existing equivalent models of wind farm still have their disadvantages when using for planning. The literatures [4, 5] introduce the method of parameter identification to build the equivalent model. This method needs the operating data of the wind farm which can't be gotten at the stage of planning. So the method of parameter identification is unsuitable for planning. The literatures [6, 7] introduce the reduced-order equivalent method to build the wind farm model. This method simplifies the differential equations of the wind turbines so that the model of the wind farm is simplified. However, the wind power integration planning is often carried out in some fixed software such as DIgSILENT and BPA. The model of the wind turbine is fixed in the software. We can't change the turbine's model easily, so the method of reduced-order is not suitable for planning.

To solve the problems mentioned above, this paper build a kind of aggregation model of wind farm, which can be used in existing software directly and simplify the calculation in planning. Then the effectiveness and accuracy of the built aggregation model are checked through building a simulation example.

Technical Requirements to the Aggregation Model Used for the Wind Power Integration Planning.

The calculation process of the wind power integration planning can be described as the fig.1 shows. There are three kinds of calculation in the process of wind power integration planning. They are power flow calculation, transient calculation and short-circuit current calculation. Each of the calculations has its requirements to the wind farm aggregation model.

Power Flow Calculation. It's required to calculate the load of the lines and the bus voltage in power flow calculation. So the wind farm aggregation model is required to give the similar terminal voltage and output active power compared with the detailed model of the wind farm.

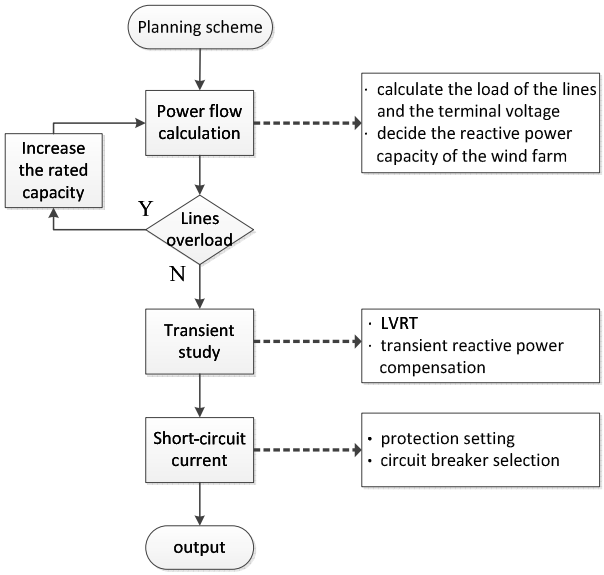

Fig. 1 The process of calculation in wind power integration planning

Transient Calculation. Transient calculation requires the model to give exact transient variables such as the drop value and recovery time.

Short-circuit Current. Short-circuit current calculation requires the model to give the exact peak value of the short-circuit current.

Table 1 Technical requirements to the equivalent model used for planning calculation

calculation	Key requirements
all	Can be used in existing software
Power flow	keep the 35kv terminal
	Give exact terminal voltage
	Give exact output active power
Transient calculation	Exact drop value and recovery time of terminal voltage
	Exact drop value and recovery time of acitive power output
	Exact drop value and recovery time of reactive power output
Short-circuit	The peak value of the short-circuit current

Aggregation Model of the Doubly-Fed Wind Farm

As the doubly-fed wind turbine is the most widely used turbine, this paper takes the doubly-fed wind farm as example to build the aggregation model. The aggregation model of the wind farm consists of two part: the aggregation model of the wind turbines and the aggregation model of the collector lines.

Aggregation Model of the wind turbines. The aggregation model of the wind turbines can be described as follows.

$$S_{eq} = mS \tag{1}$$

$$\begin{cases} X_{m\_eq} = \dfrac{X_m}{m}, X_{s\_eq} = \dfrac{X_s}{m}, X_{r\_eq} = \dfrac{X_r}{m} \\ R_{s\_eq} = \dfrac{R_s}{m}, R_{r\_eq} = \dfrac{R_r}{m} \end{cases} \tag{2}$$

$$\begin{cases} H_{gen\_eq} = mH_{gen}, H_{WTR\_eq} = mH_{WTR} \\ k_{sh\_eq} = mk_{sh}, c_{sh} = mc_{sh} \end{cases} \tag{3}$$

In these equations, S is the capacity of one turbine. m is the number of turbines in the wind farm. Subscript eq represents the equivalent aggregation model. The second equation describes the aggregation of the generator's parameters. X is the reactance and R is the resistance. The third equation describes the aggregation of the shaft. H is the time constant. k is the stiffness coefficient of the shaft.

Aggregation Model of the Collector Lines. There are two kinds of collector lines in wind farms. One of that is called route type. The turbines are linked by collector lines one by one. The aggregation model is as follows.

$$Z_{eq} = \frac{\sum_{i=1}^{n}\left(\sum_{k=1}^{i}\left(Z_k\sum_{j=k}^{n}P_j\right)P_i\right)}{\left(\sum_{i=1}^{n}P_i\right)^2} \tag{4}$$

The other is called radial type. The turbines are linked to one terminal separately. The aggregation model is as follows.

$$Z_{eq} = \frac{\sum_{i=1}^{n}\left(Z_i P_i^2\right)}{\left(\sum_{i=1}^{n}P_i\right)^2} \tag{5}$$

P is the active power output of one turbine. The subscript represents the number of the turbine.

Simulation and Verification

As the software DIgSILENT is the accepted software of electrical calculation with wind power, this paper makes use of DIgSILENT to check the accuracy of the aggregation model. Firstly a wind farm example is built as follows. The aggregation model is built through the method mentioned above.

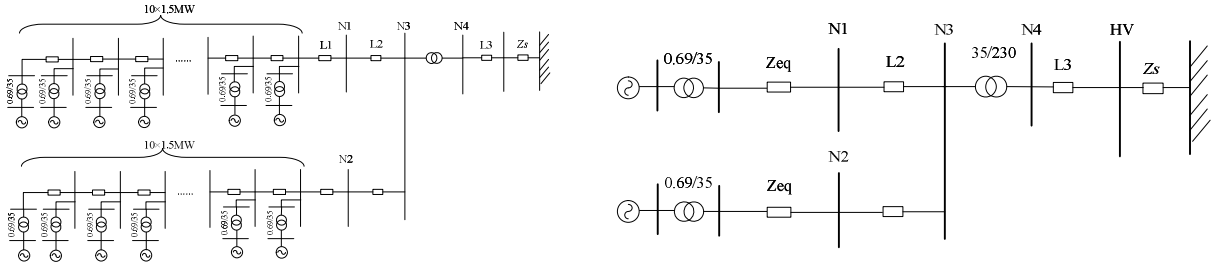

Figure 2 Detailed and aggregation model of the example

Accuracy Check of Power Flow. Calculate the terminal voltage and active power output of the wind farm. The results of the detailed model and the aggregation model are compared as follows.

Table 2 Results of power flow(voltage)

	amplitude/p.u.		Phase angle/°	
	detailed	aggregation	detailed	aggregation
N1	1.02	1.02	25.92	25.91
N3	1.02	1.02	25.54	25.53
N4	1.01	1.01	7.13	7.13
HV	1.01	1.01	6.82	6.83

Table 3 Results of power flow(active power)

	Active power/MW	
line	detailed	aggregation
N1-N3	14.9134	14.9271
N2-N3	14.9134	14.9271
N4-HV	29.4338	29.4610

It is concluded that the power flow results are similar between detailed model and aggregation model. It can be inferred that the equivalent model is suitable for the power flow calculation in planning.

Accuracy Check of Transient Calculation. Firstly the transient fault is set to be three-phase short circuit in the transformer high-voltage bus for 0.2 seconds. The terminal voltage of the wind turbine, the active power and reactive power output of the wind farm are simulated. The results are as fig. 3, fig. 4 and fig. 5 shows.

The key indexes of each figure are analyzed, which is shown in table 4. The transient results are also similar between detailed and aggregation model. It can be inferred that the equivalent model is suitable for the transient calculation in planning.

Accuracy Check of Short-circuit Current Calculation. The short-circuit fault is set the same as that in transient calculation. The short-circuit current is simulated as fig. 6 shows.

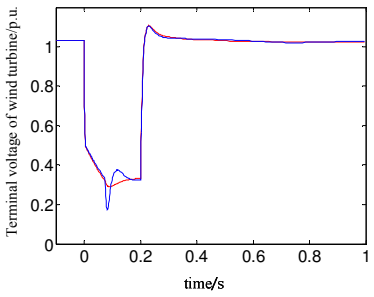

Figure 3 Voltage

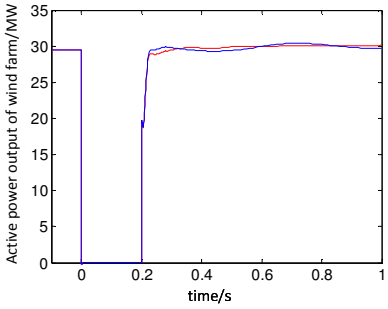

Figure 4 Active power

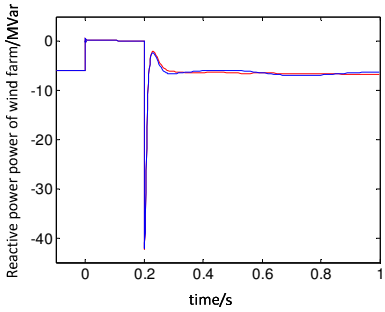

Figure 5 Reactive power

Table 4 Key indexes of the transient simulation

	Drop value		Recovery time/s	
	detailed	aggregation	detailed	aggregation
voltage/p.u.	0.1723	0.2896	0.0127	0.0128
Active power/MW	0.0230	0.0230	0.0210	0.0188
Reactive power/Mvar	-42.2346	-42.2777	0.0173	0.0173

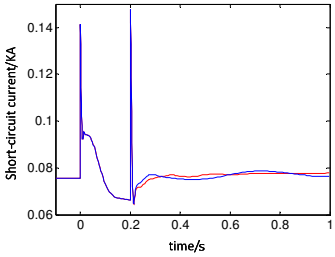

Figure 6 Short-circuit current simulation

It is inferred that the equivalent model is suitable for the short-circuit current calculation in planning.

Summary

This paper concludes the requirements to the wind farm aggregation model of planning. Based on the requirement, a method of building aggregation model is proposed. Then a simulation example is built, which verifies that the proposed aggregation model is suitable for electrical calculation in planning.

Evaluation of China's energy strategy

WANG Shuai

School of Management, Tianjin University of Technology, Tianjin300384, China

E-mail: ysp08wangshuai@163.com

Keywords: Energy strategy; Evaluation of energy; Sustainable development

Abstract: The energy problem is a matter of human survival and development of a global issue. With the deepening of the new industrialization, energy resources, climate change, environmental problems to human challenge is becoming more and more serious. In the development of China's energy consumption, energy consumption structure and the world in general there are many differences between the consumption structure, rational utilization of domestic coal resources, improve efficiency, promote the reform of energy-using way, will become China's energy industry development in the future be solved the problem. To build China's energy security system is not only the need of China's economic and social development, but also to enhance our voice and influence in the global energy affairs.

Introduction

For a long time, pursuing the growth of GDP has seen as the goal and motivation of national economic development, and the demand and consumption for resources play the center role on the choice of growth model in many countries. Under the domination of development concept, the economy in the pursuit of maximum economic benefits, many countries destroy the resources and environment for the maximum economic benefits without hesitate. As a result, the resource have been weakening, degradation and depletion. Meanwhile, the ecological environment has been wracked[1]. Since the 1990s, sustainable development has gradually become the center goal and guiding principle of national resources and environment policy. Obviously, the traditional energy evaluation already couldn't adapt to the requirements of sustainable development. It have mainly focused on the project level of energy development activity so that often fail to take the influence impact by macroeconomic factors such as political, legal, economy, technology and social cultural on regional energy strategic targets and strategic choice into account. Therefore, the research on the energy strategy evaluation which can reveal the internal mechanism between energy strategy and regional sustainable development has become a necessity.

Different from the traditional energy evaluation, energy strategy evaluation gives policymakers strategic, accumulated, indirect and induced resources environment influence as well as the information of social and economic meaning. The evaluation content tend to be more focused on the economic, social and environmental benefits of resources development and utilization strategy. The essence of energy strategy evaluation is the evaluation of sustainable utilization of energy, one of the major differences is social evaluation, economic evaluation and environmental evaluation are included. Combining the resources and environment problem with the social economy, and give the qualitative, macro conclusions guidance. In the review process, energy strategy evaluation has more uncertainty compared with traditional energy evaluation; on the evaluation methods, energy strategy evaluation has such features: need more data and information, span long time, contains more projects, effect widely files, strong comprehensive and poor accuracy. The difference between the energy strategy evaluation and general energy evaluation can been see in the table 1

Table 1The contrast of Evaluation of energy strategy and Traditional energy strategy evaluation

Compare the projec	Evaluation of energy strategy	Traditional energy strategy evaluation
object	Energy policy and planning	Specific energy development projects
Affect the situation	Indirectly, strategy	directly
Geographical scope	Global and regional	Local and regional
The evaluation conclusion	qualitative	quantitative
Time scale	Early and long-term	In the late
composition	Strategic component	The direction of the project

Energy strategy evaluation system

Energy evaluation refers to through the analysis of the construction project, calculation of the project of various energy consumption structure and consumption, accounting major energy-using equipment utilization of energy, analyzed the effect of all kinds of energy saving measures, the accounting unit of the project products and energy efficiency index and economic index per unit of output, evaluation of the project can use rationality and sophistication of a kind of evaluation method. Key of energy strategy evaluation is through revealing the internal mechanism of interaction between the energy strategy and sustainable development, realize the coordinated development of regional economy and energy[2]. In the process of implement the strategy of regional sustainable development, comprehensive coordination control objects include: energy strategy in human production and all-round development as the center of the first production process again and again; In order to meet the consumer demand of the development of the human existence in material production as the center of the reproduction process; In order to protect the resources sustainable use and ecological environment recovering well into the center of the third reproduction process.Between three types of reproduction process, the first serious lead reproduction process, the second category of serious distortion of the process of reproduction and the lag of the third class reproduction process, caused the energy strategy and collaborative mismatch between regional sustainable development and the main reason leading to the invalid energy strategy, the key point of energy strategy coordinated control[3]. Therefore need to press the following train of thought to strengthen positive interaction between collaborative forces.

1) We should be examined from a strategic height and try to reverse the process of reproduction in three broad categories of disorder and to reverse the process of interaction between In use energy strategy means to control the negative influence of the first and second process of reproduction and bad process at the same time, should establish and strengthen the third reproduction process as soon as possible, efforts to narrow the range of the synergy between three types of process dislocation, gradually form a positive interaction force of synergy, to overcome or the amount in the condition of synergy appear a series of negative effect, increase the efficiency of the energy strategy in collaborative work.

2) The key is to ensure that form a positive interaction between the three types of reproduction process, one is to control the population, improve population quality, promoting scientific and moderate consumption and meet the requirements of the modern civilization life style; 2 it is the second reproduction process must be taken to meet the requirements of the sustainable development of economic growth mode, i.e., according to the efficient and low consumption, less pollution intensive economic growth mode instead of extensive economic growth mode in the past; Three is to establish and implement inventory for energy and flow and its wealth value for scientific metrology and incorporated into the national economic accounting system for the center content of energy accounting system and the system of environmental economic loss compensation; Four is to advocate big coordinating economics under the guidance of multi-dimensional statistical method, and statistical ecology, environment, resource, population, economy, society and multidimensional data and their mutual influence factors, statistical result not only, also the statistical damage, to help people develop continuously to overcome the loss of energy planning.

3) But in the three types of reproduction process under the condition of synthetic together, mutual coordination to form a positive and orderly interaction between them, and create synergy resonance between the three, only constantly in collaborative resonance can also gradually realize the total energy consumption and the relative balance of resources and environment carrying capacity, Mr PRED coordinated development and the social sustainable development strategy. In such a coordination mechanism under the action of energy strategy evaluation is helpful to realize the sustainable use of energy.

China's energy consumption structure is not reasonable

In China's energy consumption structure, coal accounts for absolute advantage, far below the level of developed countries, the proportion of oil and gas is almost 38% lower than the world average (see chart 2). From the point of industry, the total energy consumption in the top five are: black metal smelting and rolling processing industry, chemical raw materials and products manufacturing, non-metallic mineral products supply hot water, electricity, steam production industry, oil processing and coking industry[4]. China's energy consumption structure irrationality is particularly prominent in the world.

Table2 The world's major national energy consumption

Total Energy Consumption in 2012						
Country	Total Energy Consumption (One million tons of oil equivalent)	The proportion of total consumption				
		Natural gas	Oil	Coal	Nuclear power	Hydropower
World	8755.6	28.6	50.8	37.9	10.9	3.5
United States	2243.8	27.4	46.7	26.9	10.2	2.5
Russia	683.5	62.7	25.1	19.5	6.1	3.2
Britain	253.4	38.6	34.9	18.3	12.8	0.5
France	275.9	16.5	40.3	6.3	48.5	3.2
Japan	543.8	14.3	58.6	20.3	17.2	1.8
Germany	342.8	25.6	45.2	24.3	14.3	0.8
Canada	278.2	29.2	38.8	8.6	8.6	1.6
India	305.4	8.6	38.6	57.6	1.3	2.4
South Africa	143.7	-	23.5	78.3	3.4	0.5
Korea	189.7	8.7	56.1	21.6	15.2	0.7
China	783.5	3.6	28.5	70.2	0.8	2.9

China's energy strategy thinking

1)China is a coal power, coal resources to reach 5.57 trillion tons, can support the development of Chinese economy in 100. The world's energy supply is restricted by many factors such as economic, political, China to achieve industrialization must be based on national conditions, make full use of domestic energy resources, carry out clean coal utilization, energy resources structure of disadvantage into advantage in the development of the economy.

2)Healthy and orderly development of the energy industry is closely related to the government's strong support, the Chinese government shall, according to the country and social development needs, constantly improve energy policy, to ensure security of energy supply to the promotion of the competitiveness of the energy companies[5].

3)Facing the intricate international political and economic relations and geopolitical risk threat, to build the safety of China's energy security system, we must vigorously develop the oil and gas trade, through active participation in global trade in oil and gas, enhance the voice.

4) Social and ecological environment must be at the same time as the important measure of the best scheme of energy development and utilization. Regional development is a very comprehensive multi-dimensional concept, is both economic growth and economic structure, including social development and people, and to improve the quality of the ecological environment improvement, from the aspects such as multivariate multilevel progress process, so the scheme of energy

development and utilization and the final selection must be at the same time with length scales, social progress and ecological environment dimension to an equal measure.

Keywords: 330kV composite insulator; Pollution flashover; Electric field measurement

Abstract. 330kV transmission line in the northwest region of China is much complex while pollution flashover is a major threat to the safe operation of the system. In this paper, experimental study on effect of contamination on electric field distribution of 330kV composite insulator is presented. High voltage test system of 330kV composite insulator is established according to the ratio of 1:1. Surface electric field and potential of the insulator is measured using GDC-100 optical fiber voltage electric field measuring instrument. Potential, electric field distribution of the two kinds of 330kV composite insulator are tested in different environment of clean, dry and uniform pollution layer. The test and simulation result is also compared.

Introduction

They were a lot of work on the line overvoltage and potential distribution of tower insulator at home and abroad based on which design differentiation of line insulation were take, that investment can be saved and flashover can effectively reduce. But research data on the long distance transmission line in high altitude area was scarce. Complete and effective technical measures to prevent insulator flashover of transmission line have not been put forward up to now. There are significant security risks in the operation of transmission line. Because there is a close relationship between transmission line flashover and geographical environment, climatic conditions and pollution, the characteristics of each flashover are not identical. In this paper, effect of contamination on electric field distribution of 330kV composite insulator is studied and compared with simulation result.

The Building of Test Platform

The test was taken in High-voltage test hall of State Grid Gansu Electric Power Research Institute, of which electrical wiring diagram is show in Fig.1. Rated voltage and rated capacity of Test transformer is 1000kV and 2000kVA. During the test, terminal voltage of the insulator is measured by AC capacitor divider. High voltage arm capacitor value of the divider is 458pF while low voltage arm 4581nF. The physical map is show in Fig.2.

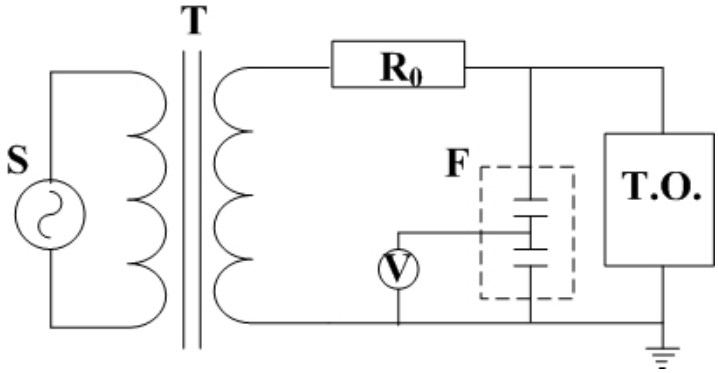

Fig.1. Electrical wiring diagram of the test

Fig.2. Physical map of the test

Arrangement of experimental tower: Simulation tower is built according to the ratio of 1:1. Double split wire is 40m long. Insulator is suspended just agreement with the actual, show in Fig.3.

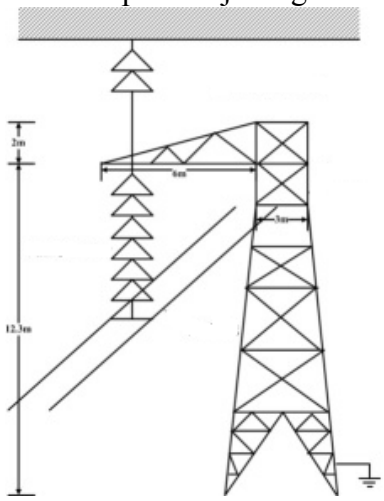

Fig.3. Arrangement of experimental tower

Stain and Humectation of the Insulator

Quantitative brushing method is taken according to GB/T 4585. Stained insulator was suspended in a cool and dry place for 24 hours. Deionized water was sprayed on the surface contamination layer of the insulator evenly. The distance between nozzle and insulator is not less than 1m, so that the spray along the insulator is in uniform. While surface pollution of the insulator layer is fully moisture, the test voltage was added later.

Determine of the test voltage

Tab.1. Total creepage distance and the minimum value of applied voltage of different insulator

	#1 organic composite insulator	#2 organic composite insulator
Total creepage distance(m)	8.42	11.89
The minimum value of applied voltage of different insulator(kV)	5.89	8.32

To avoid serious error caused by heating and drying of dirty layer during the test, voltage on the two end of insulator must to minimize. To eliminate the effect of test voltage on the electric field around the insulator, voltage on the insulator should more than 700V per meter in total creepage distance according to IEC60507. Total creepage distance and the minimum value of applied voltage of different insulator is show in tab.1.

The test results

The electric field distribution of organic composite insulator in clean and dry state: the model of the organic composite insulator in this paper is FXBW-330/100. #1 insulator has 66 sections of sheath. The measured surface electric field intensity of the sheaths in clean and dry environment is show in Tab.3

Tab.3 Measured surface electric field intensity of the sheaths in clean and dry environment

Serial number	Surface electric field(V/cm)	Serial number	Surface electric field(V/cm)
1	104	57	15.4
2	67.8	58	17.3
3	63.8	59	17.3
4	62.2	60	20.1
5	63.3	61	20.3
6	57.2	62	20.3
7	52.5	63	22.5
8	49.9	64	25.3
9	42.5	65	22.2
10	104	66	27.7
Voltage across the insulator string:6.78kV Average electric field intensity of the insulator:24.44V/cm			

The measured surface electric field intensity of the sheaths covered with a homogeneous conducting contamination layer is show in Tab.4.

Tab.4 Measured surface electric field intensity of the sheaths covered with a homogeneous conducting contamination layer

Serial number	Surface electric field(V/cm)	Serial number	Surface electric field(V/cm)
1	17.1	57	15

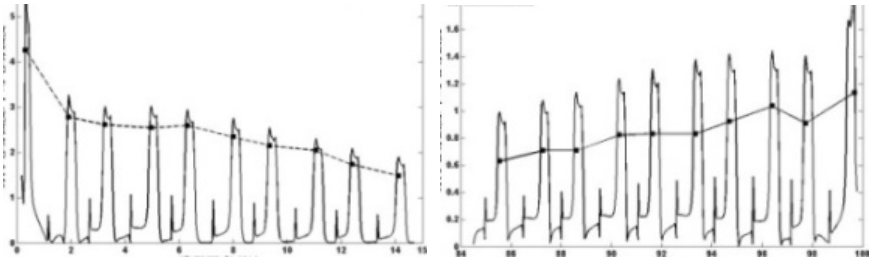
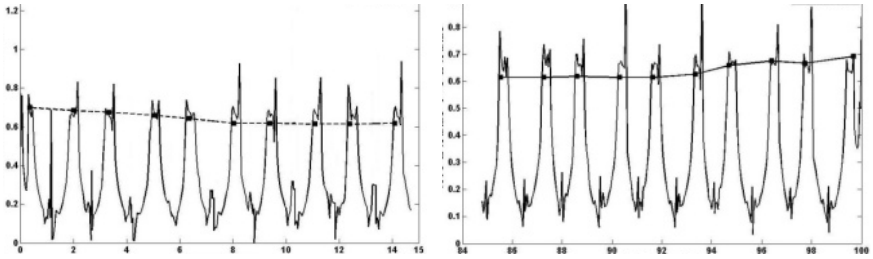
Comparison of simulation and test

Fig.4 shows the comparison of simulation and test of the organic composite insulator in clean and dry environment, while Fig.5 covered with a homogeneous conducting contamination layer.



（a）1-10 （b）57-66

Fig.4 Comparison of simulation and test of the organic composite insulator in clean and dry environment



（a）1-10 （b）57-66

Fig.5 Comparison of simulation and test of the organic composite insulator covered with a homogeneous conducting contamination layer

Conclusion

It can be judged from the simulation and test results that in the situation that organic composite insulator covered with a homogeneous conducting contamination layer, there is high normal electric field intensity at the edge of the insulator. With the increase of the conductivity of the pollution layer, normal electric field gradually increases. Corona will appear at the edge of the insulator with the increase of applied voltage. There is high tangential electric field intensity in the sheath of the insulator in the situation that organic composite insulator covered with a homogeneous conducting contamination layer. Partial electric arc will appear in the surface of the sheath near the high end fittings. To improve the anti pollution flashover ability and potential distribution of insulator, the structure must be optimized, hydrophobic must be improved.

Keywords: thermal stability limit, fast evaluation, DC power flow

Abstract. Enhanced grid structure makes the system thermal stability problems increasingly prominent. The thermal stability of grid section is deduced by use of DC power flow method in typical equivalent system, furthermore, the effect of section N-1 breaking on active power flow in operating equipment is analyzed. Based on the principle of active power flow distribution to meet the impedance proportional relationship, thermal stability limit section assessment methods and processes are presented, which can achieve fast assessment on thermal stability limits and restriction faults. Finally, the summer maximum loads mode of Henan Power Grid in 2014 is taken as example, and the thermal stability limit in northern sections is evaluated. The simulation results prove the feasibility of the proposed method. The research results can provide references for dispatchers and related software developers.

1. Introduction

With the continuous developments of power grid in China, the main power system grid is growing enhanced. In order to promote the reliability and flexibility of operation, the characteristics of main power system grid made up of UHV AC/DC lines are more prominent [1-3]. In the process of development and change of grid structure, the main contradiction and focus of grid stability problems gradually is changed from stability problem in the early development to thermal stability problem limited by power capacity of the device itself [4-8]. Therefore, research of the grid thermal stability problem and its solution, especially thermal stability limit of power grid cross-section has become an inevitable important subject in practical production of power grid.

With respect to the evaluation method on thermal stability limit of power grid cross-section, a lot of research such as linear/quadratic programming method, continuous power flow method, genetic algorithm and monte carlo simulation method has been carried out. These methods are far different from the actual way of adjustment taken by the dispatchers and are not conducive to the popularization and application in actual power grid. In actual calculation work, in order to determine the limiting value and the constraint fault of power grid cross-section thermal stability, offline power flow adjustment for many times combined with transient stability calculation simulation is still used. With the rapid development of power grid, especially the acceleration of UHV grid construction, rapid and profound changes spring up in the external boundaries of the existing 500 kV power grid section. What's more, the evaluation on thermal stability limit of power grid cross-section becomes more frequently as the expansion in transmission capacity and transformation of original lines. The old method, that adjusting power flow many times to approach the limiting value, is behind the actual work needs.

Based on the equivalent system of n AC lines, and the impedance distribution principle of section power flow, combined with the DC power flow model, an evaluation method on thermal stability limit of power grid cross-section is proposed in this paper. The evaluation on thermal stability limit of

power grid cross-section and the accurate selection of constraint fault can be realized through a N-1scan.

For checking the accuracy of the proposed method, the north of Henan Henan Power Grid is taken as an example. Fast evaluation results on thermal stability limit is approached and compared with the results of PSD-BPA time-domain simulation. It is confirmed that the results of fast evaluation method proposed in this article are basically identical with time-domain simulation method. The fast evaluation errors for result are analyzed, and the method of reducing the errors is proposed.

2. Fast evaluation method on thermal stability limit of power grid cross-section

The typical two equivalent system of n AC lines is shown in Fig. 1, where l_i is the nth line, $i \in [1,n]$, x_i is the reactance of the ith line, $\boldsymbol{V_s}$ and $\boldsymbol{V_r}$ are the voltages of buses of sending-end and receiving-end section, δ_{sr} is the voltage phase angle difference of buses of sending-end and receiving-end section. The line resistance and susceptance were ignored. Adopting the method of DC power flow for calculation in order to make the fast evaluation based on the maintenance of the calculation results accuracy.

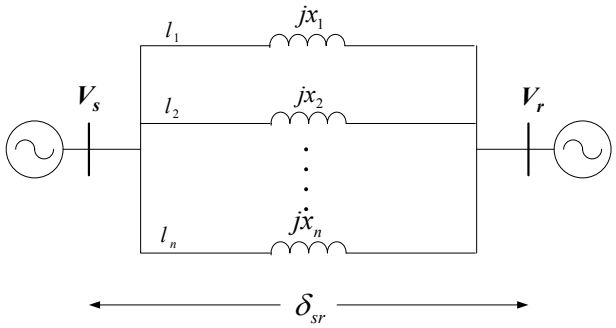

Fig. 1 Two equivalent system with cross-section

When calculating the power of line thermal stability limit, the thermal stability limit current of device is usually converted into current active power flow, and the influence of environment temperature is taken into consideration, as shown below:

$$\begin{aligned} P_t &= \sqrt{3} U I_{\max} \cos\varphi \\ I_{\max} &= K I_s \end{aligned} \tag{1}$$

where $I_{\max}$ is the thermal stability limit current, I_s is the safe current under the environment temperature of 25℃, K is the temperature correction coefficient , the power factor $\cos\varphi$ is usually 0.95, P_t is the power of line thermal stability limit.

The active power flow of two equivalent system can be calculated as Eq. 2

$$\begin{aligned} P_i &= \frac{V_s V_r \sin\delta_{sr}}{x_i} \\ P_\Sigma &= V_s V_r \sin\delta_{sr} \sum_{i=1}^{n} \frac{1}{x_i} \\ i &= 1 \ldots n \end{aligned} \tag{2}$$

As shown in Eq. 2, the power flow is proportional to each reactance of each line, that is $P_{i1} / P_{i2} = x_{i2} / x_{i1}$.

If line l_j is disconnected, the total active power flow of the section will remain unchanged because there is no change in the active power flow supply and demand in the section on both sides of the

system. The active power flow of the line l_j will be transferred to other lines in the section. The active power flow $\bar{P}_{kj}$ of line l_k after line l_j is disconnected is shown in Eq. 3

$$\bar{P}_{kj} = \frac{V_s V_r}{x_k} \sin \bar{\delta}_{srj} \tag{1}$$

Therefore, the active power flow increment of line l_k is shown in Eq. 4

$$\Delta P_{kj} = \bar{P}_{kj} - P_k = \frac{V_s V_r}{x_k} \left(\sin \bar{\delta}_{srj} - \sin \delta_{sr} \right) \tag{2}$$

where P_j is the sum of active power flow increment each line, as shown in Eq. 5

$$P_j = \sum_{k=1}^{n} \Delta P_{kj} = V_s V_r \left(\sin \bar{\delta}_{srj} - \sin \delta_{sr} \right) \sum_{k=1}^{n} \frac{1}{x_k} \tag{3}$$

where $k \neq j$.

According to Eq. 4~ Eq. 5, active power flow transfer ratio η_{kj} of line l_k after line l_j is disconnected, as shown in Eq. 6

$$\eta_{kj} = \frac{\Delta P_{kj}}{P_j} = \frac{\sum_{k=1}^{n} \frac{1}{x_k}}{x_k} \tag{4}$$

$$k \neq j$$

It can be seen that P_j will be transferred to the rest of lines according to the relationship of reactance proportion.

Till then, the definition of active power flow transfer ratio λ_{kj} of line l_k caused by the outage of line l_j can be given as Eq. 7

$$\lambda_{kj} = \frac{\Delta P_{kj}}{P_k} = \frac{\eta_{kj} P_j}{P_k} = \eta_{kj} \frac{x_k}{x_j} \tag{5}$$

λ_{kj} reflects the active power flow influence on line l_k caused by the outage of line l_j. It can be seen in Eq. 7 that λ_{kj} is a determined value associated with the section line parameters. According to Eq. 7, if $k = j$, $\Delta P_{kk} = P_k$ and $\lambda_{kk} = 1.0$.

Based on the meaning of λ_{kj}, the static power flow N-1 can be used in the disconnection simulation in section shown in Fig. 1, so is the transient N- 1. The reason is that steady state power flow of each line in section follows the reactance proportion relationship. Based on the initial power flow, a series of values λ_{kj} can be obtained after a round of disconnection simulation in section shown in Fig. 1, and relevant matrix are defined as follows:

$$\boldsymbol{\lambda} = \begin{bmatrix} 1 & \lambda_{12} & \cdots & \cdots \\ \lambda_{21} & 1 & \cdots & \cdots \\ \vdots & \vdots & \vdots & \vdots \\ \lambda_{k1} & \lambda_{k2} & \cdots & \cdots \\ \vdots & \vdots & \vdots & \vdots \\ \lambda_{n1} & \lambda_{n2} & \cdots & \cdots \end{bmatrix} \tag{6}$$

According to Eq. 7, if the section shown in Fig. 1 is in the thermal stability limit condition, one of the lines l_j will be disconnected, resulting in at least one line l_k reach the thermal stability limit condition. Therefore, active power flow of line l_k before the outage of line l_j can be obtained as follows:

$$\begin{aligned} \lambda_{kj} &= \frac{P_{kt} - P_{kj}}{P_{kj}} \\ P_{kj} &= \frac{P_{kt}}{1+\lambda_{kj}} \qquad k \neq j \end{aligned} \tag{7}$$

where P_{kt} is the power of line thermal stability limit. According to Eq. 8~ Eq. 9, active power flow matrix of section $\boldsymbol{P_T}$ in the thermal stability limit condition can be obtained as shown in Eq. 10

$$\boldsymbol{P_T} = \begin{bmatrix} P_1 & P_{12} & \cdots & \cdots \\ P_{21} & P_2 & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ P_{k1} & P_{k2} & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ P_{n1} & P_{n2} & \cdots & \cdots \end{bmatrix} \tag{8}$$

where the diagonal elements of the matrix P_j is shown in Eq. 11

$$P_j = \sum_{\substack{k=1 \\ k\neq j}}^{n} \Delta P_{kj} = \sum_{\substack{k=1 \\ k\neq j}}^{n} \left(P_{kt} - P_{kj} \right) \tag{9}$$

Till then, all the elements in matrix P_j are obtained. Corresponding to the j th column of the matrix P_j is the active power flow of each line before the outage of line l_j. The matrix P_j reflects situation of the power flow distribution before the outage of each element. The operation power flow of the section before the outage of line l_j by summing up all the elements in each column in matrix P_j. The minimum of the sums is the thermal stability limit evaluation result $P_{\Sigma t}$ on section as shown in Eq. 12

$$P_{\Sigma t} = \min \left(P_j + \sum_{\substack{k=1 \\ k\neq j}}^{n} P_{kj} \right) \qquad j = 1, \cdots \tag{10}$$

The value j, corresponding to the minimum value in Eq. 12, is the constraint outage fault of the thermal stability limit. Based on the result of evaluation result, fast reaching the thermal stability limit can be realized by operation mode adjustment of power system. The above process of obtaining the thermal stability limit is shown in Fig. 2:

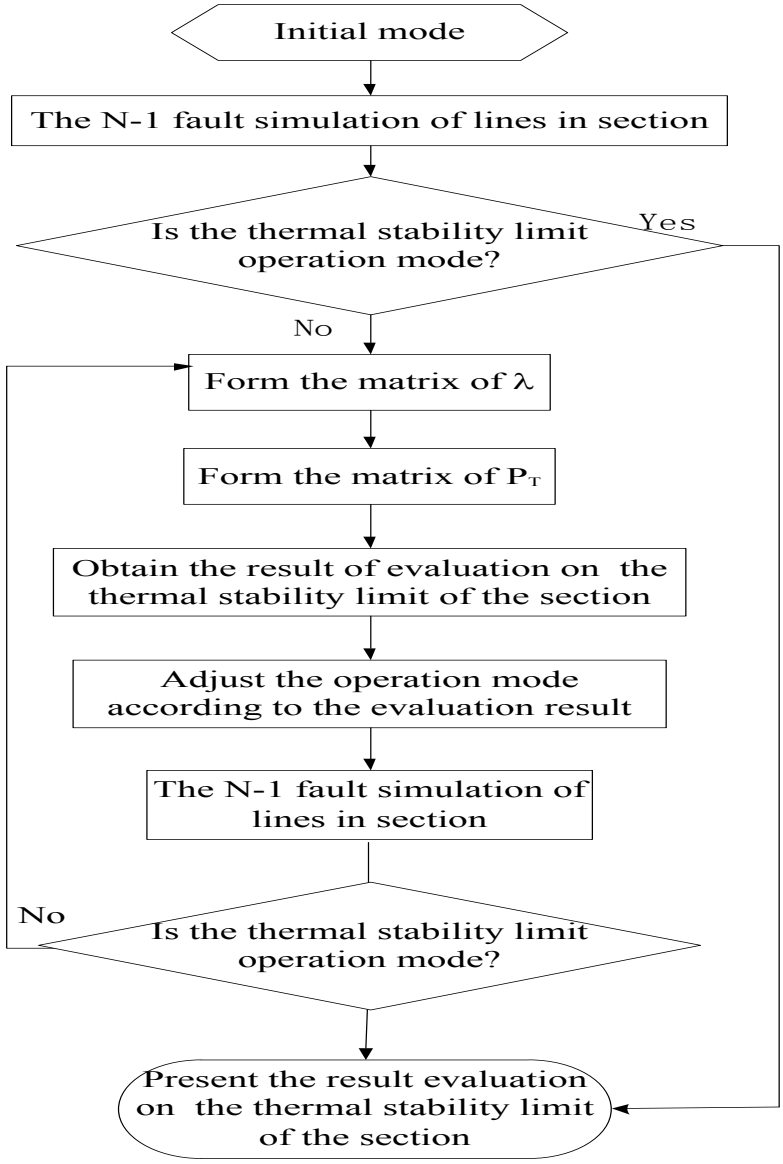

Fig. 2 Evaluation procedure of thermal stability limit in cross-section

In the evaluation process is shown in figure 2, the criteria, by which to determine whether the section is under the thermal stability limit operation mode, is that: whether the steady state power flow after line outage reaches the power of thermal stability limit P_t. Different from the existing offline method that contains times of power flow adjustment, the result of evaluation on the thermal stability limit can be obtained by each round of evaluation with proposed method. And with the target of the result, the operating generation units output can be adjusted, thereby the evaluation on thermal stability limit of power grid cross-section and the constraint fault can be realized.

3. Simulation and verification

Taking the power flow of Henan Power Grid under summer heavy load as an example, evaluate the transmission north section of Henan Power Grid with the method proposed in this article. The structure of the transmission section is shown in Fig. 3, made up of double-circuit lines HH and single-circuit line TC.

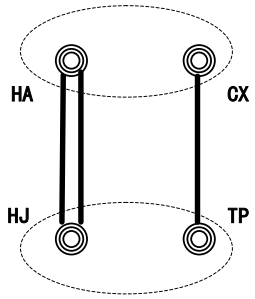

Fig. 3 Primary connection diagram on north cross-section of Henan Power Grid

The initial power flow and the thermal stability limit power flow of north section of Henan Power Grid are shown in Table 1.

Table 1 The initial power flow and the thermal stability limit in north section of Henan Power Grid

	HH I line	HH II line	TC line
initial power flow[MW]	595.8	595.8	644.9
the thermal stability limit[MW]	2056	2056	1655

After a round of Transient N-1fault simulation, the matrixes of λ and P_T can be obtained as shown in Table 2 with method proposed in this article.

Table 2 Evaluation on thermal stability in north cross-section of Henan Power Grid

		HH I line N-1	HH II line N-1	TC N-1
Power flow after outage	HH I line	——	990	918
	HH II line	990	——	918
	TC	850	850	——
Transferred power	HH I line	——	394.2	322.2
	HH II line	394.2	——	322.2
	TC	205.1	205.1	——
λ	HH I line	1	0.662	0.541
	HH II line	0.662	1	0.541
	TC	0.318	0.318	1
The thermal stability limit poewr	HH I line	1218	1237.3	1237.3
	HH II line	1237.3	1218	1334.3
	TC	1255.7	1255.7	1443.2

According to the active power flow results in the thermal stability limit condition shown in Table 2 and the judgment method in Eq. 12, the thermal stability limit of north section of Henan Power Grid is 3711MW, while the constraint fault is N-1 outage of HH lines.

Adjust the operation mode according to the results and after 4 times of adjustments, the north section of Henan Power Grid is adjusted to reach the thermal stability limit. The final result of the thermal stability limit of north section of Henan Power Grid is 3534MW. It can be seen that the result error of the first evaluation is 5%. But after adjusting for several times according to the evaluation results, the error can quickly be reduced and close to the final real results.

The source of the error of this evaluation method includes two aspects: 1) Approximate treatment on voltages of both sides of the system, thinking that the voltages of both sides of the system are 1.0 p.u. when adjusting the operation mode. 2) In practical system, it is often that a certain line first reach the thermal stability limit rather than all the lines in the section. This is the main reason for bigger

error of the thermal stability limit of north section of Henan Power Grid. However, the operation mode can be made to approach the thermal stability limit by adjusting for several times, the error can quickly be reduced.

4. Conclusion

Based on the derivation of section power flow of typical interconnected system, fast evaluation method on thermal stability limit of power grid cross-section is proposed. This paper takes the power flow of Henan Power Grid under summer heavy load as an example. The simulation and verification of the thermal stability limit of north section of Henan Power Grid is made. The following conclusions can be obtained, as follows:

The estimated value of thermal stability limit and the constraint fault can be evaluated at the same time by the proposed method in this paper. According to the evaluation results, the accurate value of thermal stability limit can be determined quickly by power grid operation mode adjustments in few times, which is convenient for dispatchers to analyze.

The errors of the proposed fast evaluation method can be controlled, and can be ignored when the power grid operation mode is approaching the thermal stability limit of cross-section.

The proposed method and process of the fast evaluation can be important references to intelligent simulation software development of power system.

Keywords: Power grid emergency logistics system (PG-ELS); Fault-tree analysis; Interval number

Abstract. Power grid, one of the critical infrastructures, is a vital component of the world's energy supply. Once large-scale natural disaster occurs, it is inevitable to meet unexpected faults on emergency logistic. Fault-tree analysis (FTA) is a risk estimation tool to describe and model causal interactions and logical relationships between undesired events in a system Taking uncertain situation and response failure into consideration, this paper proposed a fault-tree analysis on PG-ELS with fuzzy probabilistic confidence. The most critical failure mode is identified using the ranking method based on interval number.

Introduction

Critical infrastructure such as power grid is national basic support of society and economy. Once large-scale natural disaster occurs, it is bound to generate a large number of emergency logistics demand like the snow disaster in southern China, 2008. As an emerging research issue, emergency logistics management attracts more and more attention [1]. With the frequent occurrence of crisis, the existing emergency logistics system has emerged lots of defects. From the fault-perspective, it is leisured to deal with unexpected events which reduce the vulnerability instead of promoting the reliability for emergency logistics for power grid. FTA has been widely used for providing logical functional relationship among components and subsystems of a system and identifying the root causes of the undesired events in a system failure [2]. Many studies on emergency management focus on the response failure [3,4,5]. In most real applications, the probability of response failure does not assess as exactly as mechanical system. Hideo Tanaka firstly proposed the processing method of uncertain probability based on fuzzy set theory for FTA [6]. Taking into consider imprecise failure probability, many studies has introduced relevant uncertain theory. Unascertained number is employed to represent failure data combined with grey theory [3], intuitionistic fuzzy sets theory is applied to FTA on the emergency shutdown system [7] and also put into use [8].

Unfortunately, only very less paper takes into account the response failure on ELS. In this paper, to complete the FTA of PG-ELS under uncertain situation, interval number is employed to represent the failure rate. The most critical component is found to determine vulnerability and reveal parts where key improvement must be made.

Power grid emergency logistics system (PG-ELS)

Logistics support of power grid is one of the major response activities that deliver commodities such as electrical components, materials, repair equipment from warehouse to the affected area effectively [1]. It is a process that aims to pursue the greatest time benefit and the least loss. Emergency logistics may meet faults which cause delay or breakdown under various constraints.

The most important requirement is to ensure the rapidness of preparation, coordination and transportation. Components of function follow as: 1) Emergency supplies preparation (ESP) means emergency supplies reserve includes warehouses and signed production reserve; 2) Emergency supplies coordination (ESC) refers to content collaborative allocation for delivering power grid materials; 3) Emergency supplies transportation (EST) needs select the optimal or more convenient route without traffic jam or damage.

Fault-tree diagram for PG-ELS

Fault-tree analysis intuitively analyzes potential danger including qualitative description of system failures and quantitative operation. The detailed procedure for constructing the fault-tree can be known from references [1,5]. Prior to the expression of the PG-ELS fault-tree, it is necessary to have an in-depth understanding of the relationship between each section of PG-ELS. In this paper, three assumptions are essential to be clarified: 1) all basic events are independent; 2) all the events only have two states namely occurrence and nonoccurrence; 3) large-scale natural disaster can give rise to the lack of storage that enables production reserve. Thus, the FTA of the PG-ELS is developed in Fig.1, and the description of basic events is listed in Table 1.

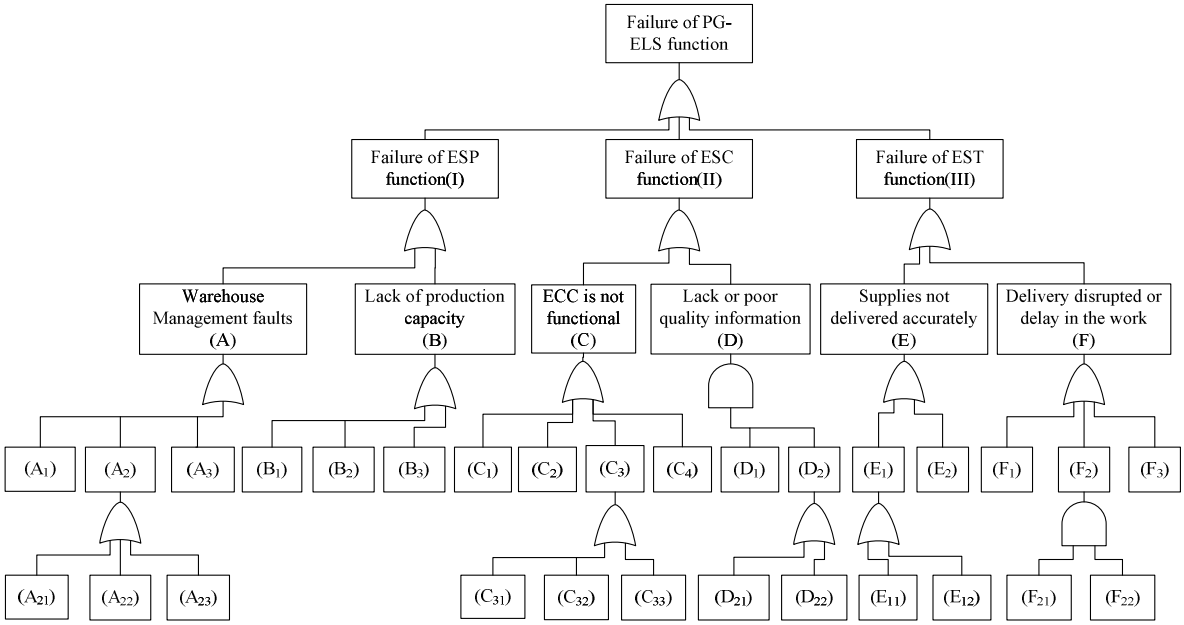

Figure 1 The fault-tree of emergency logistics system (PG-ELS)[1]

Table 1 The descriptions of the basic events of ELS system fault

Code	Details of basic event (BE)	Code	Details of basic event (BE)
A_1	Major supplies damaged or overdue	C_{33}	Communication misunderstand
A_{21}	Inventory records incorrect	C_4	Necessary ECC staff unavailable
A_{22}	No inventory management system	D_1	Loss contact to responders on site
A_{23}	Inventory management system not used	D_{21}	Incident out of sensors detection range
A_3	No resources found in appointed warehouse	D_{22}	Sensors damaged failure
B_1	Time-consuming on production	E_{11}	Command failure on destination
B_2	Workshop damaged by catastrophe	E_{12}	Go to the wrong routes
B_3	Less materials on production	E_2	Ignore some of logistics orders
C_1	Critical facilities disrupted by incident	F_1	Transportation infrastructure damaged
C_2	Operation plans not followed	F_{21}	Most of vehicles damaged by catastrophe
C_{31}	Insufficient capacity of staff	F_{22}	No third party logistics support
C_{32}	Inadequate critical facilities	F_3	Meet traffic jam or accident

After building fault-tree, we must fully understand the PG-ELS under large-scale natural disaster. More importantly, expertise and knowledge on PG-ELS operation should be required to assess the risk of each part. In the fault-tree of PG-ELS, there are 24 basic events(BE) and 22 minimal cut sets. Minimal cut set means the minimal failure set which can make the emergency logistics system failed. It is worth mentioning that there are still some critical faults have not been found out for the uncertain situation, Fig.1 only shows the key faults. On the basis of the fault-tree diagram, the failure probability operation of "and" and "or" is (f_i refers to ith event with probability of p_i):

$$f_1 \cap f_2 \cap \ldots \cap f_i = p_1 \cdot p_2 \cdot \ldots \cdot p_i \quad (1)$$

$$f_1 \cup f_2 \cup \ldots \cup f_i = 1-(1-p_1)(1-p_2)\ldots(1-p_i) \quad (2)$$

[1] A_2: "inventory management system faults"; C_3: "ECC (emergency command center) duties and setup not executed effectively", D_2: "Sensors don't work well", E_1: "Supplies delivered to incorrect location", F_2: "Insufficient transportation vehicles".

Proposed method

In order to express the uncertain situation and fuzzy probability of failure, interval number is used to represent the result. Interval number a is defined as $a=[a^L,a^U]=\{x|a^L\le x\le a^U\}$, if $a^L=a^U$, then a degenerates a crisp number [9], and the arithmetic operations can also see the reference [9]. Let $a=[a^L,a^U]$, and $b=[b^L,b^U]$ be two interval numbers, $l_a=a^U-a^L$, $l_b=b^U-b^L$, $p(a>b)\in[0,1]$ means the possibility degree of a>b, then:

$$p(a>b)=\frac{\min\{l_a+l_b,\max(a^U-b^L,0)\}}{l_a+l_b} \tag{3}$$

The fuzzy sensitivity analysis is therefore applied to identify the weakest part of the PG-ELS. P_{TE} denotes the probability of top event assumed all basic events occur, P_{TEi} represents that P_{TE} is not include the i^{th} probability of basic event. So, the fuzzy importance measure (FIM) is:

$$FIM_i=[\frac{P_{TE}-P_{TEi}}{P_{TE}}]\times 100\% \tag{4}$$

The probability important degree (PID) of event i means the extent of system unreliability changes due to the change of component i, where f_s and f_i represents the unreliability of top event and event i. The PID (I_{Pri}) is:

$$I_{PRi}=\lim_{\Delta fi\to 0}\frac{\Delta f_s}{\Delta f_i}=\frac{\partial f_s}{\partial f_i} \tag{5}$$

Case study

Shenzhen power gird is oversize urban power network with the largest power load density, advanced reliability of power supply and provincial power grid scale in China. In order to analyze the possible key faults emerged on PG-ELS, we need to use the proposed method for risk analysis. The collected data of probabilities are listed in Table 2. The bound and range of value are obtained from local power grid department and emergency office. Especially it is very difficult to estimate failure probability of manual operation failure can be estimated by expert's semantic evaluation.

Table 2 The interval probabilities of each basic event

BE	Prob.	BE	Prob.	BE	Prob.	BE	Prob.
A_1	$[1.2,1.4]\times10^{-2}$	B_2	$[4.5,5.1]\times10^{-3}$	C_{33}	$[4.5,7.2]\times10^{-3}$	E_{12}	$[6.6,7.5]\times10^{-5}$
A_{21}	$[4.5,4.7]\times10^{-3}$	B_3	$[8.8,9.4]\times10^{-3}$	C_4	$[8.4,9.2]\times10^{-5}$	E_2	$[2.5,3.2]\times10^{-3}$
A_{22}	$[8.5,8.6]\times10^{-3}$	C_1	$[3.5,4.2]\times10^{-3}$	D_1	$[3.5,4.2]\times10^{-2}$	F_1	$[2.7,3.1]\times10^{-2}$
A_{23}	$[1.2,1.4]\times10^{-3}$	C_2	$[5.4,6.0]\times10^{-4}$	D_{21}	$[1.5,2.1]\times10^{-3}$	F_{21}	$[5.8,6.4]\times10^{-3}$
A_3	$[2.4,2.6]\times10^{-2}$	C_{31}	$[7.5,7.8]\times10^{-4}$	D_{22}	$[1.4,2.0]\times10^{-2}$	F_{22}	$[1.0,1.4]\times10^{-2}$
B_1	$[3.1,3.9]\times10^{-2}$	C_{32}	$[6.4,7.2]\times10^{-5}$	E_{11}	$[4.8,5.6]\times10^{-4}$	F_3	$[1.8,2.2]\times10^{-2}$

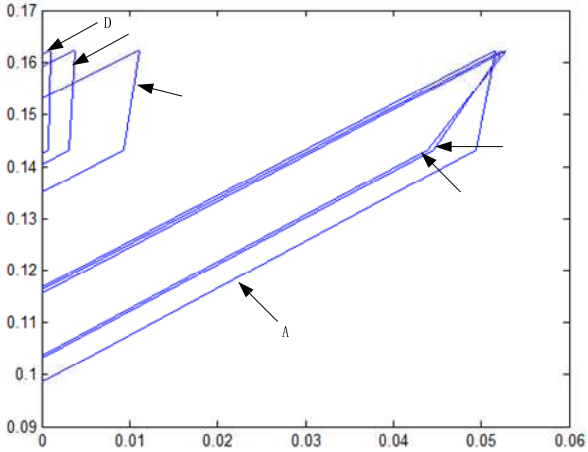

Figure 2 The interval graph of fuzzy sensitivity of event A-F

Firstly, according to Eq.(1)-(2), the probabilities of three parts I, II and III of PG-ELS are [0.0911,0.1019], [0.0102,0.0122], [0.0475, 0.0560]. Furthermore, the top event failure probability is [0.1431,0.1625]. It means that the success rate of PG-ELS is about 85.3 percent under large-scale natural disaster. The P_{TEi}, $FIM_{i\ and}$ I_{PRi} can be calculated by Eq.(4)-(5) shown in Table 3.

According to Eq.(3), the result is $p(FIM_F > FIM_B)=0.5018$, $p(FIM_A > FIM_F)=0.5259$, $p(I_{PRF} > I_{PRB})=0.5040$, $p(I_{PRA} > I_{PRF})=0.5623$ and the upper bound of A is maximal. So, the rank of criticality is A>F≈B>C>E>D. Furthermore, the fuzzy sensitivity interval graph (sensitivity function line represented by interval number) is shown in Fig.2. Obviously, the FIM of A, B, F is higher than C, D, E, and A, B, F all has certainly lots of room for improvement.

Table 3 Probabilities of key faults A-F

Key fault	Lower bound	Upper bound	P_{TEi}	FIM_i	I_{PRi}
A	$4.94x10^{-2}$	$5.17x10^{-2}$	[0.0986,0.1168]	[16.18%,44.65%]	[0.8832,0.9014]
B	$4.39x10^{-2}$	$5.29x10^{-2}$	[0.1038,0.1157]	[16.86%,41.02%]	[0.8843,0.8962]
C	$9.41x10^{-3}$	$1.11x10^{-2}$	[0.1350,0.1531]	[0,19.22%]	[0.8469,0.8650]
D	$7.53x10^{-4}$	$1.09x10^{-3}$	[0.1424,0.1616]	[0,14.05%]	[0.8384,0.8576]
E	$3.05x10^{-3}$	$3.83x10^{-3}$	[0.1405,0.1593]	[0,15.58%]	[0.8407,0.8595]
F	$4.46x10^{-2}$	$5.24x10^{-2}$	[0.1031,0.1162]	[16.55%,41.51%]	[0.8838,0.8969]

Conclusions

In this paper, we obtained expert's knowledge on PG-ELS and integrated the interval number operation on FTA. To identify the key component that is most useful to improve the performance of PG-ELS. The result is that the most critical event is A "warehouse management faults". It also needs to pay attention to B "lack of production capacity" and F "delivery disrupted or delay in the work". Warehouse management should tend to be continuous improvement for avoiding faults.

Keywords: SMR, modular, Versatile, NPP

Abstract. In recent years, advanced small nuclear power reactors, namely small modular reactors (SMRs), gained widespread attention. In areas where energy can't be provided by large scale reactors and the nuclear power plants with large scale reactors can't compete with the non-nuclear power plant technology, SMRs, as a versatile distributed integrated energy source, which result in expanding peaceful applications of nuclear energy, have enormous potential. This article describes the characteristics and analyzes prospects and challenges of SMRs.

Introduction

In recent years, advanced small nuclear reactors have attracted worldwide attention. Advanced small nuclear reactors are also called small modular reactors(SMRs, <300MW), which were designed to achieve modular construction, short construction period and passive safety, nuclear proliferation prevention, financial risk reduction and other characteristics[1]. These features encourage and allow many developing countries, with limited budget and grid capacity, to construct nuclear power plants.

Although, compared with large scale reactors, SMRs have higher specific capital cost, but also have economic advantage because of short construction period, quick learning effects[2], multi-module sharing site and infrastructure, simplified design and layout flexibility. In those areas where traditional large scale nuclear power plant can not be deployed, SMR is a option for peaceful use of nuclear energy. It can be expected that, in the future, SMRs would be widely used for urban heating supply, desalination, industrial steam supply and marine resources, and so on.

The characteristics of SMRs

SMRs have became another focus of nuclear engineering research, due to its diversity of functional application. In the future, nuclear energy will inevitably trend towards two directions, large scale nuclear power plants which can supply electrical power more than 1000MW, and SMRs with power less than 300MW. However, compared with large scale nuclear power plants, SMRs have the following features:

(1) Small size. Since smaller "size" of SMRs, compared to the large scale reactors, the total individual unit initial investment was significantly lower than large reactors. So the SMRs' investment cycle is short and with less investment risk. And then, each module can easily be transported by truck or rail to sites, while SMRs' facilities are also greatly simplified, compact plant layout, and more environmental- friendly.

(2) Modular design and construction. Modular design allows multiple units to share some systems, so the number of systems could be reduced. Modules' production and assembly can be carried out in factory, which greatly shorten construction period (24~36 months). And construction cost can also be effectively reduced, while schedule risk can be reduced. Modules can be separated and removed easily, which makes decommissioning work simplified.

"Small" and "modular" are the main characteristics of SMRs. From the sketch of SMRs designed by NuScale and Westinghouse showed in Fig.2, SMRs' characteristics can directly be caught in the picture [3].

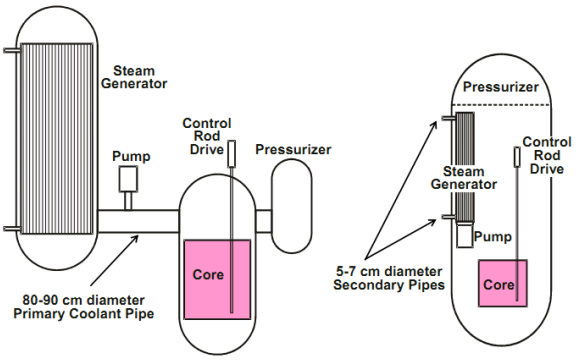

Fig.1 Comparison chart of integration PWR (right) and current (left) PWR

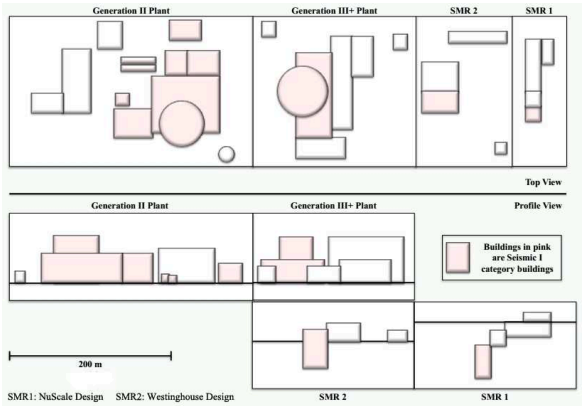

Fig.2 Comparison of the whole plant layout with SMR and large NPP

(3) Low power level, less source items. Due to low power level, SMRs can match grid which with limited power generation capacity. Meanwhile, source terms are less than large scale reactors.

(4) Simplified design to improve safety. Advanced Pressurized Water Reactor type SMRs would arrange primary systems in pressure vessel, use of passive safety systems extensively to minimize numerous pipelines, valves and other equipments. Compared with the current PWRs' loop type reactor systems, integrated small modular pressurized water reactor (iPWR) layout[4], for example, is showed in Fig.1.

(5) Long refueling cycle. Advanced SMRs(except HTR, AHWR) are usually designed as long refueling cycle, and some SMRs can even design as a whole life cycle operation without refueling. So load factor would be large, and fuel transport expense would be low.

(6) Configuration flexibility and easy to increase capacity. More modules can be added as energy demand increases. SMRs can be easily grouped together to form a larger nuclear power plant.

(7) Siting flexibility and adaptability. SMRs can be built in those remote areas where lack of energy, or in those areas with harsh environment. So it needs no long-distance transmission lines so as to avoid energy losses and to save the cost of long-distance transmission facilities.

(8) Versatile. SMRs can be designed to provide heat, supply steam, desalinate water, and product hydrogen, etc.

(9) Nonproliferation. SMRs' reactor module can be designed with lower degree of enrichment of uranium and constructed in underground location. So, it reduces the risk of proliferation.

Meanwhile, Some SMRs could be designed to arrange in a pool, making further improvement safer[5], as shown in Figure 3.

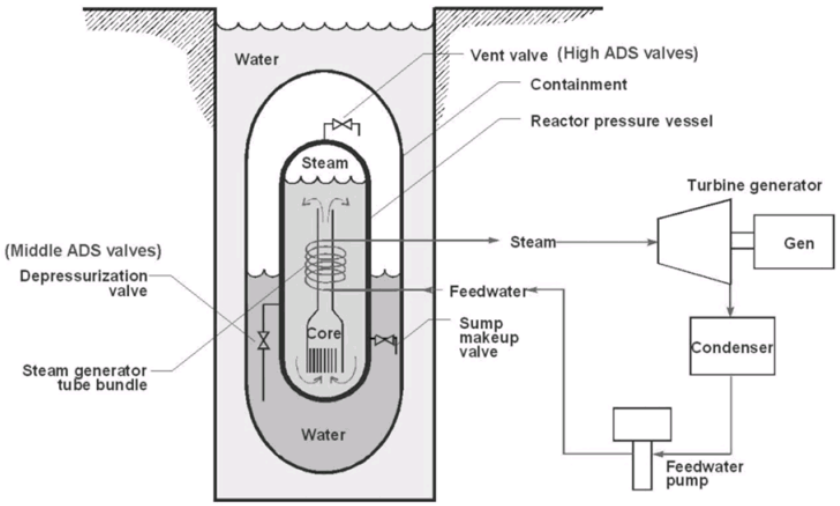

Fig.3 Design concepts of LWR type SMR

International R & D Status of SMRs

SMRs' development can be traced back to 1950s, and was mainly used for military purposes. American Navigant Research's report in June 2013 predicted that there would be 18.2GW of SMRs in operation by 2030[6]. University of Chicago predicts that SMRs would occupy 1/4 nuclear power capacity by 2050. Figure 4 shows Ux Cosulting Company's prediction of international SMRs capacity in the next 25 years[7].

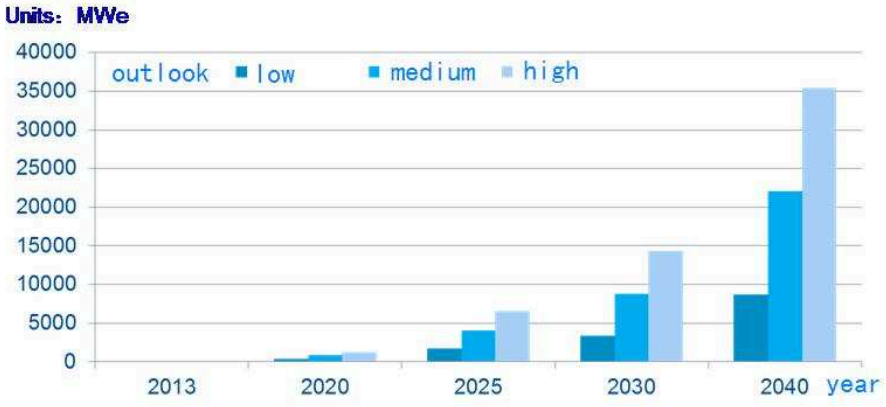

Fig.4 UxC forecasts global SMR's capacity over the next 25 years

Currently, United States, Russia, France, South Korea, Argentina and other countries are motive in the development of advanced commercial SMRs. Table 1 shows the current 22 kinds of SMRs development in brief.

Tab 1 Introduction of foreign advanced SMR development

Name	Type	Designer	P(MWe)	Country	Status
mPower	PWR	Babcock & Wilcox	125	USA	Began pre-application interactions in July 2009. Design certification application expected 3rd quarter of calendar year 2014[8]

PBMR	HTR	ESKOM	165	South Africa	Licensing of a demonstration plant in South Africa is being reconsidered. Agreement with Chinese for cooperation in development[12]

Development of China's SMRs

In present, China National Nuclear Corporation, China General Nuclear Power Group, China Nuclear Engineering and Construction Corporation, China Power Investment Group, the State Nuclear Power Technology Co., Tsinghua University, all have groups working on research and development of SMRs. National Energy Board also launched a national energy application technology research and engineering demonstration project - "small modular reactor demonstration of key technology research and application.". Meanwhile, National Nuclear Safety Administration also started research in regulations and standards, safety requirements for the design. Table 2 summarizes several advanced SMRs design.

Tab 2 Introduction of advanced SMR designs in China

Name	Type	Designer	P(MWe)	Status	Application
ACP100	PWR	CNNC	100	Detailed engineering phase	Land-based NPP & barge-mounted or floating Nuclear power station; supply heating/ electricity/ demineralized water/steam[13]
ACPR100	PWR	CGN	130	Preliminary design phase	Land-based NPP; supply heating/ demineralized water/steam[14]

CAP150	PWR	SNPTC	150	Conceptual Design Stage	Land-based NPP & floating Nuclear power station; supply electricity/ demineralized water
HTR-PB	HTR	Tsinghua University & China Hua	212	Under construction	Land-based NPP; can supply heating/electricity/demineralized water, also for Nuclear hydrogen

		Neng Group Corporation			production and refrigeration
NHR200-Ⅰ/Ⅱ	LWR	CNECC & Tsinghua University	200*	The preliminary design have been completed	Type Ⅰ for Urban heating and Thermal-desalination/ Type Ⅱ for providing industrial steam and hybrid desalination with MSF/RO

* Here is thermal power

The prospects and challenges of SMRs

In the areas where energy can not be provided by traditional large nuclear power plants, SMRs have huge potential in peaceful application of nuclear energy. IAEA predicted that in the next 20 years 50% energy consumption would be heat supply (urban district heating, industrial process heating, desalination, etc.). The demand for clean energy will increase rapidly, therefore, various SMRs designs are leading to non-electricity production application modules. So, in the near future SMRs would be designed for heating and industrial steam supply, water desalination, and marine power.

Application Prospects

Domestic Market

According to China's energy development "12th Five-Year Plan"[14], in the future, SMRs' potential onshore application can be seen in Table 3. The potential market for SMRs' offshore application is shown in Table 4.

Tab 3 SMR onshore market prospect of China's future

Potential market	Application	Current market size	Forecast the future size of the market 2015	2020
Distributed electricity market	Distributed generation	3 436 GW	6 400 GW	15 400 GW
Heating market	Industrial steam supply	10.60 Mt/h	13.35 Mt/h	—
	Urban heating	4.7 Gm^2	—	7.4 Gm^2
	CHP	127 GW	250 GW	—
Desalination water market	Desalination	750 kt/d	2 200 kt/d	2 500~3 000 kt/d
	Inland brackish water desalination	2.96 Mt/d	—	—

Tab 4 SMR offshore platform market prospect of China's future

Potential market	Application	Current market size	Forecast the future size of the market
Offshore oil and gas exploration	Energy supply	51.85 Mt/200 units*	60 Mt/231 units*(2015)
		—	150 Mt/579 units*(2030)
Island power supply	Electricity generation	3 122MW	3 835MW(2015)

* represents the number of offshore oil and gas platforms

It concludes that the future applications of SMRs would be in China's western regions where power grid are small, heat supply, water desalination, or used for supplying high temperature steam, marine power and other aspects.

Overseas Market

SMRs commercial operating experience in Russia, Canada, Bulgaria, Hungary, Ukraine, Slovakia and Switzerland and other countries have nearly 500 reactor-years with 18 reactors for heat supply. In Unites States, Japan, Kazakhstan, there are over 100 reactor-years of operating experience of nuclear desalination. Canada, Germany and Switzerland have experienced nuclear supply heating for industry with about 100 reactor-years.

According to the capital investment, national grid capacity, infrastructure and human resources, drinking water needs, as well as other aspects, we can draw SMRs overseas potential market[15], shown in Figure 5:

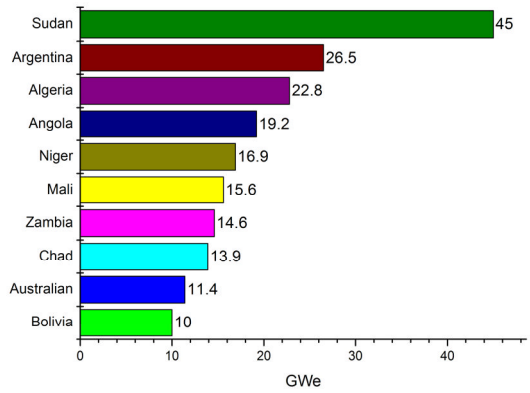

Fig.5 SMR potential overseas markets (potential deployment capacity of the top ten countries)

Challenges of SMR

There will be challenges from the technical aspects and the institutional aspects in development of SMRs.

(1)Integrated design causes SMRs to use some novel technical features and non-standard components. These technical features and components, such as steam generators in pressure vessel and compact containment designs, will make difficult in periodic in-service inspection. Many advanced SMRs are designed to achieve simplify operation and maintenance, while simplifying operation and maintenance requirements will bring challenges to instrumentation reliability,.

(2)Some of SMRs designed as off-site refueling mode. Refueling cycle would be 5 to 30 years. Although the design of fuel burn-up does not exceed the value of the same typical design, in terms of all the advanced reactor technology, the key issue is structural materials. Therefore, materials, structures and components must be Verification and Validation in design.

(3)Some of SMRs are design to be half-buried or buried underground, it causes a problem, the vulnerability of natural flood. So how to eliminate the problem becomes another issue. An if flood accident occurs, emergency activities would be more difficult, because arrive and stay in the deeply buried nuclear reactor module may be more difficult.

(4)SMRs widely adopted passive safety design. The concept of passive safety design is considered as an improvement of overall safety. However, this improvement is based on reduction of the possibility of failures in the active safety system functions, in other words, in some case it also needs highly reliable of active backup systems and I&C systems.

(5)SMRs would be design as multi-modules operating in the same time, so the control room design and operator staffing would be another issue.

(6)Based on a small source term, the SMRs' designs are all referred to simplify off-site emergency planning zone, some designers even declare there are no need of off-site emergency. So, how to simplify the off-site emergency planning zone must be scientific appraised and technical proved. And if SMRs was deployed close to the user, there would be impact on the public acceptability inevitably.

In short, SMRs can extend clean and abundant nuclear power to a wider range of energy demands. The development of SMRs is an effective way to solve the issues of air pollution and carbon dioxide emissions. But the application of SMRs would bring some challenges. Those challenges, which are not only technical but also institutional, must be addressed and demonstrated. The solution of these challenges will determine the application prospect of SMRs.

Conclusion

In present, China over relies on unsustainable fossil energy, while emissions caused the environmental pollution increasingly serious. Development of nuclear energy becomes an effective way to guarantee sufficient energy supply, pollution reduction. In some fields, SMRs have some advantages than large scale nuclear power plants and also have some disadvantages. It provides an option for China's nuclear power development. Therefore, China should be fully prepared for advanced SMRs' application in two aspects:

(1) Safety is the prerequisite for development of SMRs. Strengthen nuclear safety policies, regulations, standards, to build the foundation for safety development of small nuclear power reactors.

(2) R&D organizations and supervision departments should strengthen cooperation to promote safety and economy in the development of SMRs. Strengthen cooperation, not only to optimize the design of advanced small nuclear power reactors, but also to coordinate the safety and economy of SMRs.

Keywords: grid, power market, price bidding, Agent

Abstract. Grid technology can provide electricity market bidding to achieve the ability to provide large-scale computing. Agent technology has the autonomy, interoperability, and self-learning, can effectively solve the grid resource discovery and management, computing task allocation and scheduling problems, shared grid environment of heterogeneous computing resources. Introduction grid technology related content, Agent technology and proposes a use of Agent technology in the electricity market bidding model grid environment. Bidding able to provide the technology platform the parties a fair trade.

Introduction

With the gradual development of China's market reforms and the deep power, the power industry is gradually moving towards a fair and competitive electricity market in which bidding is a very critical issue. Generation side and user side open market, how to effectively get different regional electricity market generation and user quotes. Implementation mechanism of bidding. Become one of the problems to achieve. Since some services offer a great amount of data and distributed in different locations. Different variety of data representation, the operating system is different, therefore, to achieve efficient access to these data, the need for new technology [1].

To overcome these difficulties, you can take advantage of grid technology, accreditation and to provide users with a user interface through the mesh portal, user-submitted information and a quote; via grid middleware to manage and deal with these pricing information, computing and optimal coordination quotes portfolio, which is based on the user computing tasks can be divided into multiple tasks in parallel, when a larger number of users. Calculation of the local server to bear large, you need to use other computer resources[2]. In a grid environment, the grid middleware can find free computer resources available, assign tasks to the computer is idle, and the results returned to the user.

But to achieve grid technology, there are still many problems, such as heterogeneity, scalability and dynamic adaptability, autonomy and Agent technology, interoperability and ability to learn is an intelligent technology that can better grid computing to solve the problem. Compared with object-based expert system. Agent technology can achieve through self-learning to adapt to environmental changes, can take the initiative to interact with other Agent, more complex problems. If conflict expert systems can be used to ask for coordination among multi-agent to solve. This paper introduces the grid technology, Agent technology, and then discusses the auction model based on functional grid environment under the Multi-Agent technology and the modules and implementation processes.

Grid technology

Grid computing is an integrated environment and resources, computing resources can be fully absorbed and transformed them into a readily available, reliable, standard or economy while computing power. Grid-based problem solving is grid computing [4].

Grid computing is an emerging technology, with grid computing technology. It had nothing to servers, storage systems and networks can be combined together to form a larger system. For the end-user or application, the grid looks like a huge virtual computing systems.

Grid is divided according to a certain hierarchy, where the grid is the most critical core middleware layer, which is responsible for the distribution of resources for effective management, providing efficient, safe, reliable service [5] for the entire grid. Hierarchy shown in Figure 1.

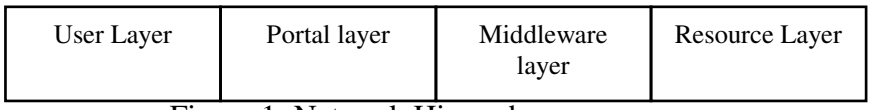

Figure 1: Network Hierarchy

Agent Technology

Was first developed by the Massachusetts Institute of Technology, part of the computer and artificial intelligence areas. Generally, Agent should have knowledge, goals and abilities. Knowledge is the solution of environmental problems and requires a certain Agent at its description by the user, the other Agent (in Multi-Agent System) or to get their own learning; goal is Agent required solutions for problems and tasks; capacity is Agent methodologies and tools can solve the problem.

Usually considered an Agent all or part of the following characteristics:

- Autonomy: Agent able to complete most of its functions in the absence of human intervention or other Agent, to control its internal state.
- Social competence: Agent can actively interact with other Agent or persons, in order to achieve their goals.
- Passive response capabilities: Agent can sense changes in the surrounding environment and the generation of real-time response meantime.
- Active response capabilities: Agent can be based on their own goals and beliefs of activities actively.
- Time Continuity: Agent process is continuous, rather than just the general procedure again on the end of that period.
- Adaptability: Agent can adapt to changes in the environment, which is often achieved through learning mechanism.
- Mobility: Agent can carry data and instructions to move to other environments and where the instruction is executed.

The electricity market bidding

Over the years, we have implemented a national network; vertically integrated factory system is not conducive to the development of the power industry in a market economy situation. Therefore, to introduce competition mechanism in the power industry and achieve a real sense of Changwangfenkai mechanism of bidding. With the deepening of reform and development, the power industry is gradually implementing the electricity market, breaking the monopoly, to a fair and competitive. Due to the existing administrative relationship between power companies and grid companies no longer exist, the formation of equitable economic relations, power companies cannot be issued executive orders to independent generating companies directly. Only be resolved by contract, agreement, "bidding" must be within the maximum range of resources to optimize the configuration of the target, to ensure safe and stable operation of the power grid, based on the minimal cost of purchasing electricity to meet the load demand [6].

Electricity market bidding is more complex , and tariff policy under state control , a variety of factors such as market pattern , the weather changes , the system unit's technical structure and ownership structure, fuel prices, rainfall , environmental standards, power suppliers bidding strategies influence ; single Agent functionality is limited, which requires an appropriate architecture through the multiple Agent tissue to form multi-Agent System (MAs), come together to complete the task of bidding , and the ability of MAS is much larger than a single Agent , not only does it have the resources to share with the general distributed systems , easy expansion , reliability, flexibility, and good real-time performance , and asked each Agent to achieve through coordinated scheduling of resources, management [7] . Agent cooperation between the various task -sharing and solved using a combination of the results of the shared task sharing refers to a complex problem into several sub-problems , each sub-problem solving respectively, by a sub- Agent to solve the problem by the Management Agent is responsible for managing each execution and results of the sub- task processing ; sharing is the result of each individual Agent work together to solve a complex problem , shared results of the Agent to each other by the Agent in charge of coordinating the results of organic integrated to form a complete answer [8] .

Participants in the electricity market transactions, including the generation side and user side, it is the physical basis of the grid, in order to achieve a balance between supply and demand for the dispatch center under the supervision of the management department. Each individual component of the electricity market are subject to the overall coordination of independent autonomy. Therefore, it is suitable for Multi-Agent Systems for problem solving. In the multi-Agent system. Adopt a distributed collection of learning methods, the use of contract negotiations between each network protocol method.

Electricity market bidding system can be divided into three parts, power generation, management section, purchase parts, each realized by the Multi-Agent Systems in a grid environment, the whole system is built on a grid platform in the grid environment bidding resources needed to get the work completed bid selection, management. Such a model can provide electricity for the power generation side and bid fair and square platform more successful scheduling, it can effectively deal with different market environments, offer different regions and rapid processing and computational problem solving large-scale data. The following section describes in detail the function of each part of the model module and bid process.

BIDDING specific model

(1) Web Module

Web module for visitors to provide a unified interface; mainly responsible for user authentication, use the grid to determine the user's permission. Part and the part of the purchase of electricity generation only after certification by the Web interface to manage part of the bids submitted to, and the result is also informed by it, that is, the specific choice of the market for the purchase of electricity generators and suppliers to the user is shielded, users can only wonder if his bid is accepted, but not about this process. Thus avoiding violations speculation and other secret operations occur.

Workflow: power generation companies, the electricity supplier first log in the web interface registration, Web Agent to verify eligibility for certification; After successful authentication, the bids submitted through the Web interface to manage part; management section the results published to the Web interface, and notify the user. Web module certification after registration center, also issued a request to the mobile library, mobile Agent will perform their respective tasks [9].

(2) Grid Environment

In this model, the system is the provision of a grid computing power. Its existence can become an open bidding system that provides computing and data into a regional internal bidding, you can also solve the problem of communication between different regions. In addition, access to different resources, different market environments can bid for market and related management.

Library Mobile Agent: Mobile Agent can move the grid node can autonomously move to a different address space to perform, during the transfer of its execution state is maintained after the transfer to the implementation of the objectives is ongoing; complete computing tasks can be carried needed for code and data as well as running the Agent between different hosts on the grid migration and complete the action. Move into task execution Agent, Mobile Agent and resources to move the query Agent. Mobile Agent responsible for calculating the task execution of specific tasks, assign tasks to carry a given grid node migration step to ask, will return the results to calculate the results of the General Agent. Query Mobile Agent in the registry after certification to the Resource Center to find the resources to meet user needs, and returns the query results to the appropriate Agent; resources to get and Mobile Agent is responsible for providing the resources required to calculate and scheduling (free to acquire, purchase, lease etc.). In order to facilitate the management, these three types of mobile Agent in Mobile Agent library.

Computing centers: the actual computing platform, different nodes in grid environment, in accordance with the principles of low priority and users real-time quote size selection generation bids. Specific computing market clearing price, handling the auction and related issues under different market conditions.

Resource Center: Provides resource sharing, publishing platform, a variety of data required to manage part of the algorithm, knowledge, models, patterns and other resources transactions can get from here. Some of the resources and power generation companies are also required to purchase electricity supplier from the Resource Center.

Summary

Grid technology is to solve large-scale data processing and distributed computing a powerful tool. Agent-based grid technology can better address some of the problems inherent in grid technology, its application to the electricity auction trading, distribution and help solve the problem of heterogeneous multi-regional multi-level electricity market, can quickly for large-scale data processing and computing, the entire bidding process for the realization of an important role.

Keywords: solid grounding, zero-sequenced reactance, grounding-fault protection, restricted grounding fault protection, back-up grounding fault protection

Abstract. This paper focuses on *proper grounding practices* and *grounding fault protection* for low voltage generators in island mode. The paper presents the fundamentals of power system grounding and requirements of IEEE with respect to grounding, the need for low voltage ground fault protection and implement is execution.

The paper outlines the solid grounding method is used and necessary grounding fault protection for multiple generators in low voltage system.

Introduction:

The more than one generator with sharing a common load is rapidly increasing. This system can provide the more reliable electrical power where there is no external power grid. Generators are essential part of the system. The safety of plant personnel and the reliability of the equipment are highly dependent on the type of system grounding selected and the type of grounding-fault protection selected.

In the low voltage system (below 600V or less), the solidly-grounded system is the most common system because it will support three-phase and single-phase loads. However, parallel generators that are directly connected to bus share common loads, care must be taken account into neutral circulating current considering selection of grounding method.

Electrical faults in low voltage system, estimated to be over 90% are grounding fault. Since a grounding fault is a common and potentially dangerous fault for stator windings, it must be detected and tripped as soon as possible. Special attention must be given to generator grounding fault protection.

Grounding system in low voltage network: In offshore oil & gas piping project, the multiple-isolated generator application consists of several units operating in parallel without connection to any electric utility supply system.

The main goals of system grounding are to minimize voltage and thermal stresses on equipment, provide personnel safety, reduce communications system interference, and give assistance in rapid detection and elimination of ground faults.

There are several grounding methods typically used in low voltage power system. These include undergrounded, solid grounded and impedance grounded. Source grounding may be accomplished by the grounding of the generators. However, the solid grounding is common arrangement in case of low voltage generator system.

In solid grounding, grounding conductor is connected to the ground with no intentional added impedance in the circuits. The following advantages and disadvantages of solid grounding are briefly listed.

Advantages:

- The neutral is effectively held at earth potential.
- When there is an earth fault on any phase of the system, transient over-voltage is eliminated. That permits to insulate the equipment for phase voltage. Therefore, there is a saving in the cost of equipment.

- It becomes easier to protect the system from earth faults which frequently occur on the system. When there is an earth fault on any phase of the system, large fault current flows between the fault point and the grounded neutral. This permits the easy operation of earth-fault relay.

Disadvantages:

- Since most of the faults are phase to earth faults, the system has to bear a large number of severe shocks. This causes the system to become unstable.
- The solid grounding results in heavy earth fault currents. Since the fault has to be cleared by the circuit breakers, the heavy earth fault currents may cause the arcing of circuit breaker contacts.
- The increased earth fault current results in greater interference in the neighbouring communication lines.

There are two different practical implementations of solid grounding in multiple generators:

a) Each generator grounded (Fig 1): where all multiple generators must be solidly grounded individually, it prevents circulating 3rd harmonic current. But it has cumulative effect on ground fault current.
b) Each source neutral connected to a common neutral bus, which is then grounded(Fig 2) : Where sources are in close proximity, or where the system is four wire, the common neutral or ground bus should be used. In a four-wire system the sources would not be considered as separately derived. And collecting neutrals and solidly grounding them collectively creates a path for excessive 3^{rd}.

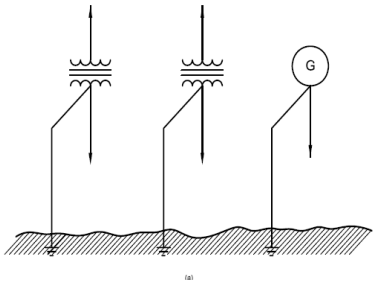

Fig. 1 Solidly grounded individually

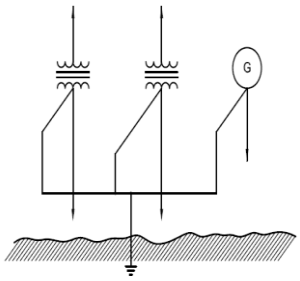

Fig 2 Common neutral bus grounded

In general, it is recommended that source one point grounded (Fig 2) for the generators with two-third pitch winding operated in parallel which have negligible circulating currents.

In order to limit the disadvantages of recommended grounded method, care about selected generator and ground fault protection method shall be taken.

Industrial low voltage generator characteristics: Generator construction will compatible with the common neutral bus grounding.

For generator, the zero-sequenced reactance has the lowest value in comparison to positive-sequence. Thus, the generator will usually have higher initial ground-fault current than a three-phase fault current in case of solid neutral grounding. However, the low voltage generator typically appears to have sufficient bracing for solid grounding.

A generator can develop a significant third-harmonic voltage when loaded. A solidly neutral grounded and lack of external impedance to circulating currents are flow of the third-harmonic current, whose value may approach rated current. However, this third-harmonic voltage will be suppressed for the generator with two-thirds pitch. Thus, generator with two-thirds pitch is best way for most electric loads that require a three phases, four wire system.

The load sharing method is important for multiple generators in parallel. The unbalance load sharing will result in 3th circulating current. Intelligent controller of generator based on digital isochronous sharing are produced to ensure that active and reactive load sharing are balanced properly.

Furthermore, it is best way that multiple generators are the same design (i.e. controller) and pitch (i.e. two-thirds pitch).

Grounding fault protection of generator: Generator is the heart of power system in island mode. The grounding fault is common for generator. It should be noted that the method of grounding fault protection is directly related to the method of system grounding used. In solid grounding, the protection can trip as soon as possible.

Range rated power of low voltage generator is less than 2500KVA. Grounding protection of generator includes the following internal and external ground fault.

- Overcurrent relay with voltage restrained (51 V)
- Stator grounding fault current (51 G)
- Restricted grounding fault (64REF)

In general, the 64REF is not too popular in small low voltage generator protection because sensitive grounding fault protection can be achieved by 51 G. But where large low voltage generator is used as prime power, the 64REF is recommended to provide more sensitive grounding.

The typical scheme of protection relay is shown on Fig 3.

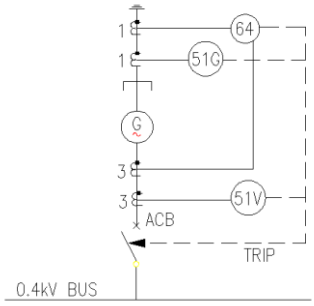

Fig3 Protection device for 64REF

A restricted grounding fault (REF) means the grounding fault from a restricted/localized zone of a circuit. In case of an internal grounding fault within the stator windings, the stator earth fault relay (i.e.64REF) will initiate and disconnect the defective generator to reduce damage. 64REF as "unit protection" applied to star windings of generator. 64REF relay is normally instantaneous operating protection and provided in neutral grounding circuit where current flows only if there is fault only involving ground/earth fault. Hence there is no great need for time discrimination.

64REF responds to only ground fault within the protected zone, while REF does not respond to phase-phase fault either within the protected zone or outside the protected zone.

The star-point connection to ground is provided with a current transformer and a sensitive relay. The Relay (5I G) is of inverse time delay type so that it can be graded as back-up protection to earth fault relays at downstream feeders and consumers. This device is based in a current transformer that surrounds the generator phases and the neutral. This configuration permits to measure the grounding current coming from the generator and the system and in this way, grounding faults are detected. The figure 4 shows the connection of generator.

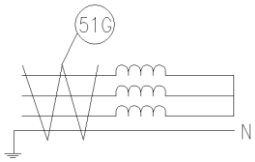

Fig 4 Connection of 51G

A standard overcurrent relay does not have a characteristic that can give a fast enough response once the initial decay has taken place. To overcome this effect the change in terminal voltage at the generator is used to measure the severity of the fault. Voltage Restrained Overcurrent Relay (51 V) as

back-up protection is produced to provide protection for fault outside of the generator zone of protection. Fig 5 show 51V connection via generator terminal connected current transformer.

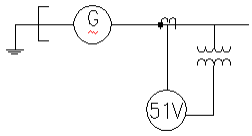

Fig 5 Connection of 51V

Summary. In the paper, the common neutral bus grounding is employed for low voltage multiple generators application. However, compatibility between system and generators shall be considered to ensure reduce the circulating currents at limited level. At the same time, it is important to select proper grounding protection for generator, which can ensure low voltage system is reliable and stable.

Keywords: 750kV Transmission Line; Power Frequency Overvoltage; Series Compensation

Abstract. The overvoltage calculation of 750kV transmission line with series compensation has great significance on the design, insulation coordination and protection of the line. In this paper, a transient model of 750kV power transmission system with series compensation is established. Effects of different capacity on no-load capacitive rise overvoltage, single-phase grounding overvoltage, two-phase grounding overvoltage are calculated. Secondary arc current and recovery voltage of different series compensation capacity in single-phase grounding is also calculated.

Introduction

Series compensation technology is the key to solve the contradiction of urgency and expensive of ultra high voltage long distance power transmission. The installing of series compensation can offset inductive reactance of the line, that transmission distance, power transfer limit and transmission efficiency increases effectively. In addition, subsynchronous oscillation can be suppressed with the application of FACTS in TCSC. Transient component can be effectively damped.

To analysis the impact of series compensation on power frequency overvoltage of 750kV ultra high voltage power system, working conditions of a transmission line with series compensation is calculated and analyzed. Simplified equivalent circuit is show in Fig.1. Centralized compensation is installed in the end of the line. The degree of compensation is 30%,40%,50%,60% and 70%. Short circuit fault occurred in the head, middle and end of the line, 0km, 186km and 372km to B.

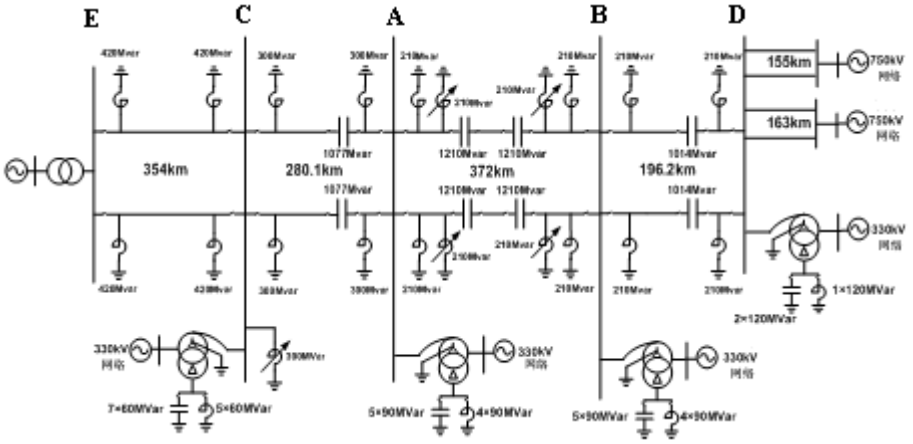

Fig.1. Simplified equivalent circuit

Research Methods

By ATP-EMTP, operation mode and parameters are calculated according to Fig.1. Overvoltage, secondary arc current and recovery voltage is also calculated. Serial number of calculation is show in Tab.1.

During calculation, Ⅱloop is in operation. The degree of compensation vary when Ⅰloop is light load. The value of compensation degree: 30%,40%,50%,60% and 70%. Transmission power of C-A: 3380MVA, B-D:4188MVA.

The reference value of calculation: $1.0 p.u. = 800/\sqrt{3} = 461.89 kV$

Tab.1. Serial number of calculation

Number of Series capacitor	Number
Ⅰloop A side	1#
Ⅰloop B side	2#
Ⅱloop A side	3#
Ⅱloop B side	4#

No-load Capacitive Rise Overvoltage

No load line can be seen as composition of countless series circuit of L and C. In power frequency voltage, the capacitive reactance of the line is far outweighed than inductive reactance. So, each point voltage is higher than the first end of the line. For double loop transmission system, there is a certain relationship between overvoltage amplitude of the end side of no load line and voltage, equivalent impedance of power side and operation of the other loop. Affected by the transmission capacity, equivalent impedance of the supply side depends on the open site.

Take C phase as an example, Tab.2 and Tab.3 is the power frequency overvoltage and the series compensating capacitor of the line when the degree of compensation varies from 30% to 70%.

Tab.2. Power frequency overvoltage of A-B transmission line in different series compensation degree

Node	Compensation degree				
	30%	40%	50%	60%	70%
Midpoint of Ⅰloop C phase	0.961	0.957	0.953	0.949	0.946
Midpoint of Ⅱloop C phase	0.959	0.957	0.955	0.955	0.955
Left of Ⅰloop C phase	0.956	0.952	0.948	0.944	0.941
Left of Ⅱloop C phase	0.949	0.946	0.943	0.940	0.937
Right of Ⅰloop C phase	0.956	0.952	0.948	0.944	0.941
Right of Ⅱloop C phase	0.941	0.940	0.941	0.946	0.958
No load side of Ⅰloop C phase	0.955	0.954	0.953	0.953	0.952

Tab.3. Overvoltage on series capacitor of A-B transmission line in different series compensation degree

Node	Compensation degree				
	30%	40%	50%	60%	70%
C phase of 1# capacitor	0.093	0.093	0.092	0.091	0.091
C phase of 2# capacitor	0.082	0.082	0.082	0.082	0.082
C phase of 3# capacitor	0.424	0.481	0.555	0.658	0.808
C phase of 4# capacitor	0.419	0.473	0.545	0.644	0.789

According to calculation, the variety of A-B transmission compensation degree line from 30% to 70% almost has no effect on the overvoltage of the high voltage bus, but has influence on overvoltage of node on line itself. With the increase of compensation degree, capacitive overvoltage monotone decrease, the maximum reduction is 3.104%. Series compensation capacitor voltage of

Ⅰloop monotone decrease with the increase of compensation degree, the maximum reduction is 3.261%. Series compensation capacitor voltage of Ⅱloop monotone increase with the decrease of compensation degree, the maximum elevation is 90.566%.

Single-phase grounding fault

When transmission line is no load, the voltage of other phase will rise during single-phase grounding fault. Because it is a common that single-phase grounding happen, the analysis of overvoltage of other phase should be take. Since the maximum voltage difference is no more than 1.5% during three single phase failures, one phase could be taken as example.

Tab.4 to Tab.5 is the power frequency overvoltage of each nod and the series compensation device during single phase fault in B phase of Ⅰloop B side when Ⅱloop in normal operation.

Tab.4. Overvoltage of the line when single-phase grounding occurred in B side

Overvoltage of Node	Compensation degree					
	0%	30%	40%	50%	60%	70%
A phase in fault point	1.261	1.246	1.242	1.238	1.234	1.230
B phase in fault point	0.029	0.006	0.006	0.006	0.006	0.006
C phase in fault point	1.169	1.157	1.151	1.150	1.146	1.143

Tab.5. Overvoltage of the line when single-phase grounding occurred in middle

Overvoltage of Node	Compensation degree					
	0%	30%	40%	50%	60%	70%
A phase in fault point	1.246	1.225	1.218	1.212	1.205	1.199
B phase in fault point	0.055	0.055	0.055	0.055	0.055	0.056
C phase in fault point	1.201	1.190	1.184	1.179	1.174	1.170

According to calculation, the variety of A-B transmission compensation degree line from 30% to 70% almost has no effect on the overvoltage of the Ⅱloop, but has influence on overvoltage of node on Ⅰloop itself. With the increase of compensation degree, capacitive overvoltage monotone decrease, the maximum reduction is 3.7%. Series compensation capacitor voltage monotone increase with the increase of compensation degree, the maximum elevation is 95.27%.

Two-phase grounding fault

When transmission line is no load, the voltage of other phase will rise during two-phase grounding fault. Lightning arrestor and fast discharge gap protection is in parallel with series compensation capacitor. When short fault occur, Fast discharge gap discharge after 1ms of the fault.

According to calculation, the influence of compensation degree to node voltage is tiny when the fault happened in the middle of the line. With the increase of the compensation degree, node voltage slight decrease, series compensation capacitor voltage monotone increase with the increase of compensation degree.

Secondary arc current and recovery voltage

Take the grounding resistance as 5Ω, Tab 6 and Tab 7 show the secondary arc current and recovery voltage of the A-B transmission line when single-phase grounding occurred in B side and middle side of the line.

The calculation results show that: the compensation degree of series compensation device has influence on the secondary arc current and recovery voltage in the fault point. With the increase of

compensation degree, secondary arc current and recovery voltage monotone increase. When compensation degree increase from 0% to 70%, secondary arc current add 22.56% , while recovery voltage add 23.74%. In addition, secondary arc current and recovery voltage is much higher when the fault happens in the middle of the A-B transmission line than the fault happens in the end of the line.

Tab.6. Secondary arc current and recovery voltage of the line when single-phase grounding occurred in B side

Node	Compensation degree					
	0%	30%	40%	50%	60%	70%
Secondary arc current in short point (A)	20.239	21.831	22.500	23.236	24.255	25.509
Recovery voltage in short point (kV)	135.338	146.469	151.127	156.257	163.304	171.967

Tab.7. Secondary arc current and recovery voltage of the line when single-phase grounding occurred in middle

Node	Compensation degree					
	0%	30%	40%	50%	60%	70%
Secondary arc current in short point (A)	21.723	23.180	23.801	24.536	25.443	26.624
Recovery voltage in short point (kV)	203.716	218.254	224.394	231.644	240.547	252.081

Conclusion

The variety of A-B transmission series compensation degree from 30% to 70% almost has no effect on the overvoltage of the two buses. It has influence on the overvoltage of node on the line itself. With the increase of the compensation degree, capacitive increase overvoltage monotone decrease. The influence of compensation degree to node voltage is tiny when the fault happened in the middle of the line. The compensation degree of series compensation device has influence on the secondary arc current and recovery voltage in the fault point.

Keywords: nuclear safety; nuclear safety culture; nuclear safety climate; index system; assessment system

Abstract. The nuclear safety became the more important after the Fukushima accident. The development of nuclear safety culture is one of the most effective methods to improve the safety. Also the assessment shows the level of the nuclear safety culture. The nuclear safety assessment model is described. The assessment model was described from its time and space, and it was also discussed from macro and micro levels. The internal and external environment parameters are considered and the assessment of different levels of safety culture is described. According to established principles of nuclear safety culture, the selection rules of the different levels evaluation indicators of nuclear safety culture are discussed too. And it is pointed that the assessment of nuclear safety culture is a long time project and an integrated system.

Introduction

With the development of the nuclear power, the safety culture was more and more important. After Three Mile Island and Chernobyl, the safety culture of the nuclear power plant (NPP) was widely attention. In 1992, the International Atomic Energy Agency (IAEA) clarified the definition of nuclear safety culture in NO.75-INSAG-4. The safety culture is that assembly of characteristics and attitudes in organizations and individuals which establishes that, as an overriding priority, nuclear plant safety issues receive the attention warranted by their significance [1]. After Fukushima, the safety culture is more and more important with the development of the nuclear power.

The nuclear safety will be extended into the research, development and application of the nuclear technology. And the nuclear safety was also combined with the design, construction and operation of NPP. Also, the nuclear safety is not only an industry security, but also a radiation safety [12]. But the nuclear safety is needed more professional, comprehensive, effective and sustainable to assessment the nuclear safety culture. The nuclear safety culture belongs to management culture. It is a kind of cultural and divided into the spiritual culture, institutional culture, behavior culture and material culture [2-5].The nuclear safety culture covers the human and physical. It is contacted with the ideas, the environment, and behavior patterns.

It is important that to assess the safety culture with the scientific model. From the quantitative assessment, the safety culture levels and weak points will be shown. The development roadmap and trend of the safety culture also will be discussed from the assessment. That information will be provided as reasons to improve the work and regulation. Between the assessment, the model and the index system will be one of the most important steps and the basic of the assessment.

The Assessment of Nuclear Safety Culture

From assessment of nuclear safety culture, the overall situation of nuclear safety culture is shown from the different perspective and levels. The general recognition is clear [6]. The main objectives were to identify specific problems in the nuclear safety culture, and analysis its causes and improvement methods. The improvement and regulation will be guided by analysis results.

The assessment process of the nuclear safety culture must be away from the benefit. And it should be ensure that the assessment results are objective reality. The assessments should be done by the third party position. The successful assessment system of nuclear safety culture should be scientific, comprehensiveness, comparability, feasibility and stability.

The assessment range should be clearly. In assessing steps, the scope should be identified, and the nuclear safety is the mainstay of the scope. As the same time, the nuclear safety-related factors of external environment indirectly impact must be considered, such as the laws and regulations, the government regulation, the industry specifications and the families of employees.

In general, the assessment the safety culture should be in the mature and stable period. This kind of assessment could reflect the real condition of the culture.

The Object of Nuclear Safety Culture Assessment

The safety culture is composed of two general parts. Firstly, it is the necessary framework within an organization and the responsibility of different management level. The second is the attitude of staff at all levels in responding to and benefiting from the framework. Based on the responsibility of different level, the safety culture is component into policy level, managers and individuals. Also the responsibility of different level is made clearly (Fig1) [1].

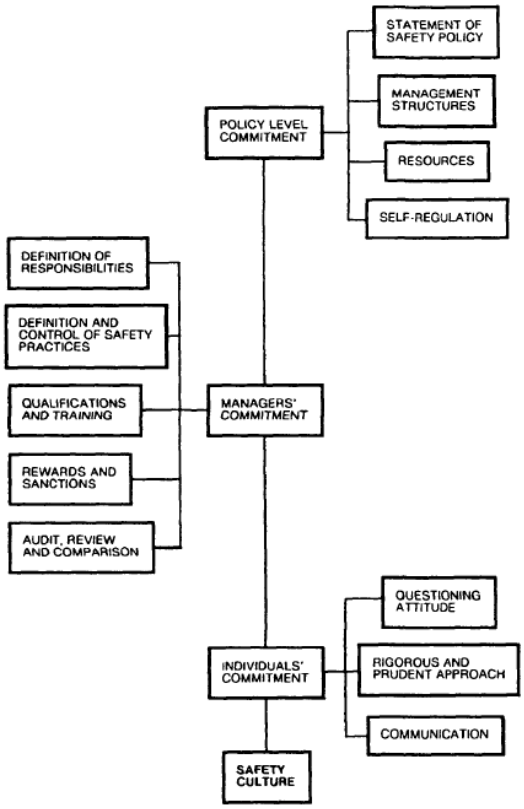

Fig.1. The Levels of Safety Culture

The policy level is the highest level of the system. This level has its permission to utilize the variety of resources and have a decisive influence. The highest level affecting nuclear plant safety is the legislative level, at which the national basis for safety culture is set. When the highest level was assessed, we focused on the emphasis and understanding of the implementation the concepts, mechanisms and measures. The management level is in the middle level of system functions, and connects the policy level and individuals. The assessment of management level should focused on the management, implementation and monitoring. Their knowledge and the implementation of training will also be assessed. The communications with employees are attention too. The individuals are the operational level. Their activities directly affected to nuclear safety level, and they affect and change the nuclear safety status at any time. So the individuals are key factors in state of nuclear safety. The assessment of individuals should focus on the responsibilities, establishment of a long-term mechanism of nuclear safety training and awareness of safety culture.

The Process and Methods of Assessment

Figure 2 shows the nuclear safety culture assessment process [6, 12]. In the really assessment, the process always more than one stage at the same time or staggered. Sometimes, the process is a circulation until get the active results. In general, before the nuclear safety culture assessment, the assessment method has been defined. The most important steps are selection the indicator system and method.

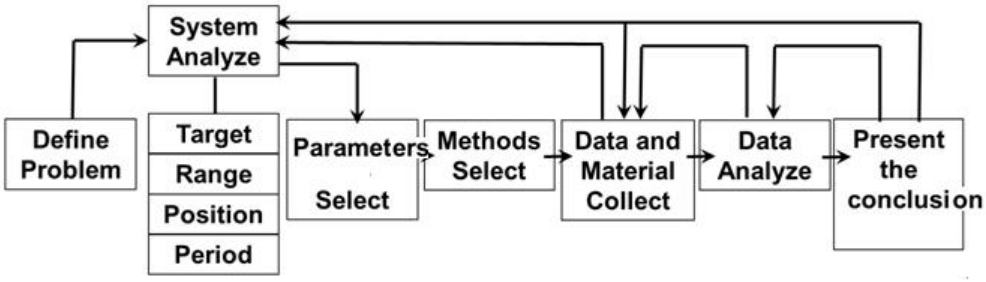

Fig.2. The Steps of Safety Culture Assessment

In the assessment process, a clear target of the assessment will be clearly, and the evaluation criteria are defined base on that target. Secondly, we will collect the quantitative data which is based on the evaluation criteria. Finally, the assessment results will be analysis and compare with the environment and background of the evaluation object to get the suggestion with reference value.

The Nuclear Safety Assessment Model

The main evaluation targets of the assessment model are the policy level, managers and individuals [1, 9], and the model is persistently and stability which are the characteristics of the culture. The external and internal environmental factors of the independent organization are also considered in the assessment index system. Those factors will focus on analysis of external manifestations, such as behaviors, risk perception and pressure.

The SMART standard [7] is the principle to design of evaluation index system of nuclear safety culture. SMART is composed of five initial in the words, and they are specific, measurable, attainable, relevant and trackable.

There are three levels of the index. The first level is designed by considered the external and internal environmental factors. Then, the evaluated objects' level in the system and the functions and roles of the objects will be considered to construct the second-level and third-level indicators. At the same time, there are three key points are considered as the following: the macro-scale and micro-scale factors, the point in time and a particular length of time influence, and the indirect effects of government regulators and employee families

The nuclear safety assessment model and its index system consists two parts. The first part reflects the long-term and relatively stable system of nuclear safety culture, and it includes the macro-scale, a length of time features and the external environmental factors. The second part reflects the atmosphere of the nuclear safety culture in the real time status. And it includes the micro-scale, the point in time and internal working environment [6]. Because of the relation between the factors, the parameters of the nuclear safety culture assessment are divided into four levels, which are the objectives, criteria, indicators and programme.

The detailed assessment model is shown in Table 1.

Table.1. The Assessment Model of Nuclear Safety Culture

Classify		Explain	Substance
Nuclear Safety Culture	macro-scale	Focus on the integrity system and concept culture	(1) The concept culture reflects nuclear safety philosophy, values, safety awareness and attitudes. (2) The institutional culture reflects the commitment, management system and the institution of rewards and punishments.

	Time View: the particular length of time	With persistence, stability and continuity the same as a “video”	(1) Production in the activities process of evaluated object, (2) With the relative stability indicators, (3) The indirectly factors which reflect characteristics.
	Space View: the external environmental	the external environmental and external environmental status relatively stable	(1) The standards and regulations on nuclear safety and the policy; (2) The government’s supervision and management of the nuclear safety; (3) Nuclear safety atmosphere of the industry; (4) The environment of the locale.
Nuclear Safety Atmosphere	micro-scale	the environmental factors and factors of individual cognition and consciousness	(1) To show the nuclear safeguards, nuclear safety supervision and the working environment, and attention on the status of nuclear safety and the internal environmental factors. (2) To show the staffs' risk perceptions, competencies, expertise and pressure of work, those are the factor of the individual awareness of nuclear safety.
	Time View: the point in time	the cognitive within the specific moment, the reflection of real-time status; a "photograph" of evaluation	Time changing with the time, people and environments, the parameters dependence on the state of nuclear safety and the working environment.
	Space View: Internal environment	the internal working environment; the internal working environment state is variable.	(1) The safety and advanced of the equipment and the public order; (2) Compliance with the nuclear safety regulations, and employees wear the safety protective; (3) The conditions of intermittent resting places are supplied for employees in the worksite.

The Selection of Nuclear Safety Culture Assessment Parameters

The parameters should focus on the macro level and micro level, and the particular length of time and the point in time. The internal and external factors should be considered too. The policy level, managers and individuals are the mainly object. The persistence and identity of the system should be included. The external manifestations are the key points to be assessed and analyzed.

For the policy level, the macro level will focus on the values, beliefs and policies of nuclear safety. But the micro levels will take attention on the supports and the implementation of the nuclear safety atmosphere creating [12]. For the managers, the assessment focuses on the supervision, communication and their awareness and attitudes. It is also very important that their knowledge of nuclear safety and the training mechanism of the nuclear safety culture. For the individuals, the long term training mechanism for nuclear safety culture will be the most important.

There are exchanging massages and communication between the system and the external, so the external environmental must be considered. At the same time, the real time of nuclear safety will be directly affected by the internal environmental, so it also must be focused on. Those are measurements of the openness of the system. As the culture’s characteristic, there is persistence, stability and continuity. Therefore, it is considered that the values, beliefs and attitudes are formed for a long time. This is the persistence of the culture.

Summary

The nuclear safety culture is the method and culture of management from top to bottom. The assessment of it should also take top to bottom, and it is an effective and sustainable mechanism for all departments. The policy level, managers and individuals are the mainly object, and the persistence and openness are considered. The assessment will be focused on the external manifestations such as the behaviors, risk perception and working pressure. The parameters can be divided into safety culture and safety atmosphere system. Those influences are considered which are the macro and micro scale, the particular length of time and the point in time, the external and internal environmental.

The assessment of nuclear safety culture is a long time project and need an integrated system. Base on the assessment and analysis, the trend of safety culture's development will be shown and the improved points will be presented.

Keywords: wind energy integration; wind power usage; power peaking; wind energy storage

Abstract. For the actual situation in Liaoning Power Grid, analyzed the problems the wind power interconnection brought. Involving power quality, power fluctuations, power peaking, power delivery and so on. Proposed related coping strategies. Strengthen wind power connection management, plan the power structure scientifically and rationally, carry out multi-channel consumer of wind power actively, improve the security and stability level of the power grid.

Introduction

With energy and environmental issues have become increasingly prominent,in recent years the world are increasing the size of the development and utilization of wind energy. China's wind power installed capacity is in explosive growth in recent years [1]. Since 2005,China's wind power installed capacity to double growth for five consecutive years. 2010,China's total wind power installed capacity surpassed the United States, ranking first in the world. After years of rapid growth, China wind power market is entering a period of steady development.

Due to the volatility of wind power is difficult to accurately prospective, when wind power interconnection reached a certain level, the adverse effects caused to the grid in turn restricts the size of its access to the grid [2, 3]. At present, China's wind power development has become a trend of large-scale access to the grid,in order to take full advantage of the resources of wind farms which have been built,how to improve the performance of network operation of wind power is the key to ensuring the sustainable development of wind power,is currently the key research project [4, 5].

The outstanding problems of grid-connected wind power operation in Liaoning

As of March 2013, the Liaoning power grid wind power capacity grew to 4.959 million kilowatts, compared with 2007's 347,000 kilowatts, an increase of 14.29 times in six years. Although the domestic wind power development slowed down, but the Liaoning power grid wind power will continue to be an annual rate of around one million kilowatts increase. The rapid development of wind power in Liaoning brings power quality, power fluctuations, power peaking, and power sending a series of questions to the grid, posed a great challenge for the safe and stable operation of the grid.

Power structure is irrational,hinder the development of wind power

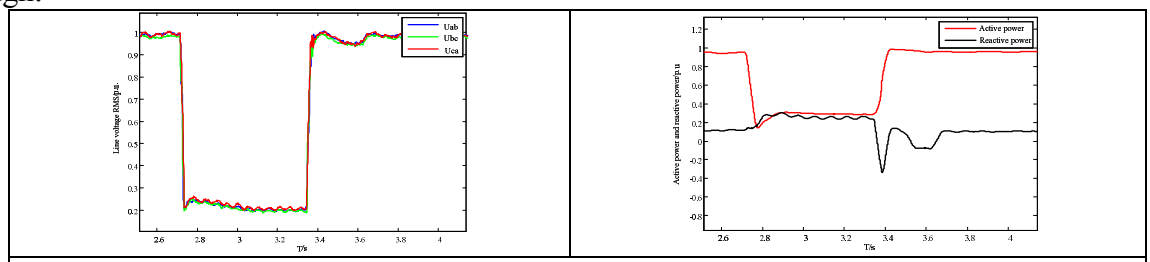
Liaoning Power Grid primary energy structure can basically be summed up as: more coal, windy, less water, less gas. As of the end of 2012, Liaoning Power Grid thermal power accounted for 80.33% of the total installed capacity,hydropower 7.15%,wind power 12.49%. Because of the special structure of power in Northeast, resulting in insufficient system peaking capacity, a serious impediment to the development of wind power in Liaoning Power Grid.

Liaoning Power Grid is mainly coal-fired thermal power grid, and its hydropower units is less, and no gas, oil and other generators, the grid quickly peaking capacity is relatively weak. Meanwhile, thermal power affecting output due to equipment defects and poor coal quality will always exist, bring enormous pressure to low power peaking. Moreover, Liaoning Power Grid heating units are more, in the winter heating period, they need to determine power generation by heat, which limited adjustable output range. Thus, the winter is the most difficult period of power peaking in Liaoning

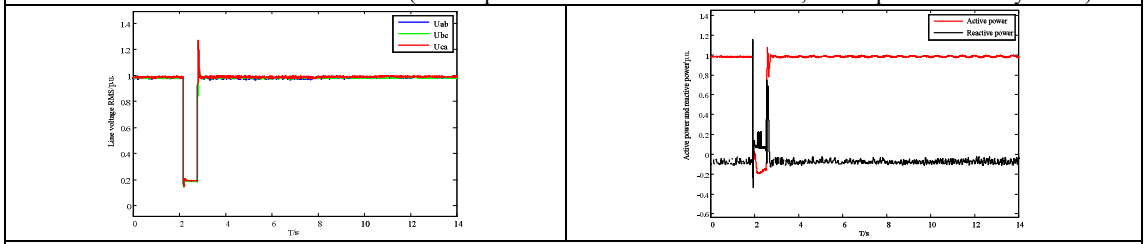
Province, coupled with anti-wind power output peaking characteristics presented in the winter, brings more power peaking difficulty.

Wind turbine skill levels uneven, wind power to run in security risk

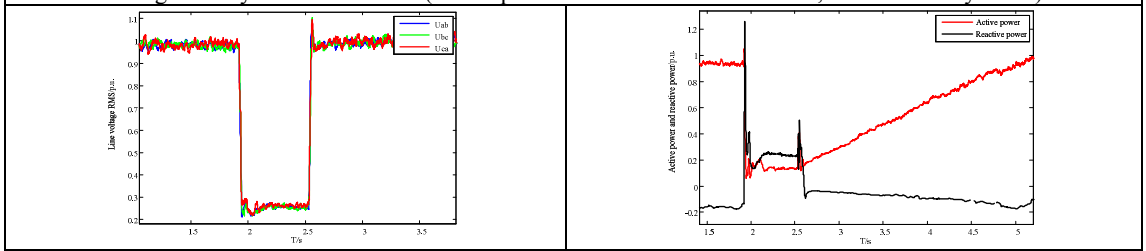
When the grid fails, the wind turbines tend to protect the unit automatically removed, so that the grid troubleshooting more difficult, may cause the accident to expand and even the grid voltage instability, cause a serious threat to the safe operation of the grid, the problem of low voltage ride through of wind turbine for the current run maximum security risks for wind power [6]. Liaoning Province strengthened wind turbine low voltage ride through capability requirements, most wind turbines have possessed low-voltage ride-through capability. As the national standards set requirements is not very specific for wind turbine response capability in the process of low voltage ride through, lead to the ability of grid-connected wind turbine low voltage ride through showing a large difference. Figure 1 shows the responsiveness of different wind turbines at low voltage ride through:



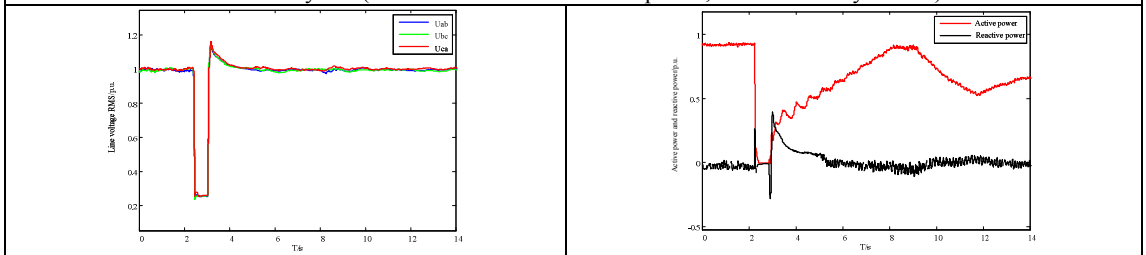
Domestic direct-drive wind turbines (failure process can emit reactive current, active power recovery faster)



Foreign doubly-fed wind turbine (failure process can emit reactive current, active recovery faster)



Domestic doubly-fed (1 can emit a certain reactive power, active recovery slower) CRE



Domestic doubly-fed (2 can transmit a certain reactive power, active power recovery process have greater volatility) Sinovel

Figure 1 Wind Turbine responsiveness at low voltage ride through

It's visible that WTG reactive power and voltage output , power recovery, terminal voltage fluctuations exist big difference at low voltage ride through, which has brought great uncertainty and security risks to the safe operation of the power grid and even the wind farm during power failures.

Wind power Influence grid voltage stability

Wind power with random fluctuations and intermittent inherent properties, so that large-scale wind power connects to grid will affect the stability of the power system. Since the majority of wind farms located in the peripheral grid, power grid construction is relatively weak, more likely to cause the grid voltage stability problems. Liaoning EPRI carried out more than 20 wind farms operating

characteristics and network testing in Liaoning Province, during the test, found that wind farms absorb reactive power from the grid, active power fluctuations exceeding the national standards, voltage fluctuations, these phenomena will all bring great security risks to wind farms and outlets voltage stability. Figure 2 shows wind farms absorb reactive power from the grid and the power change rate during the test.

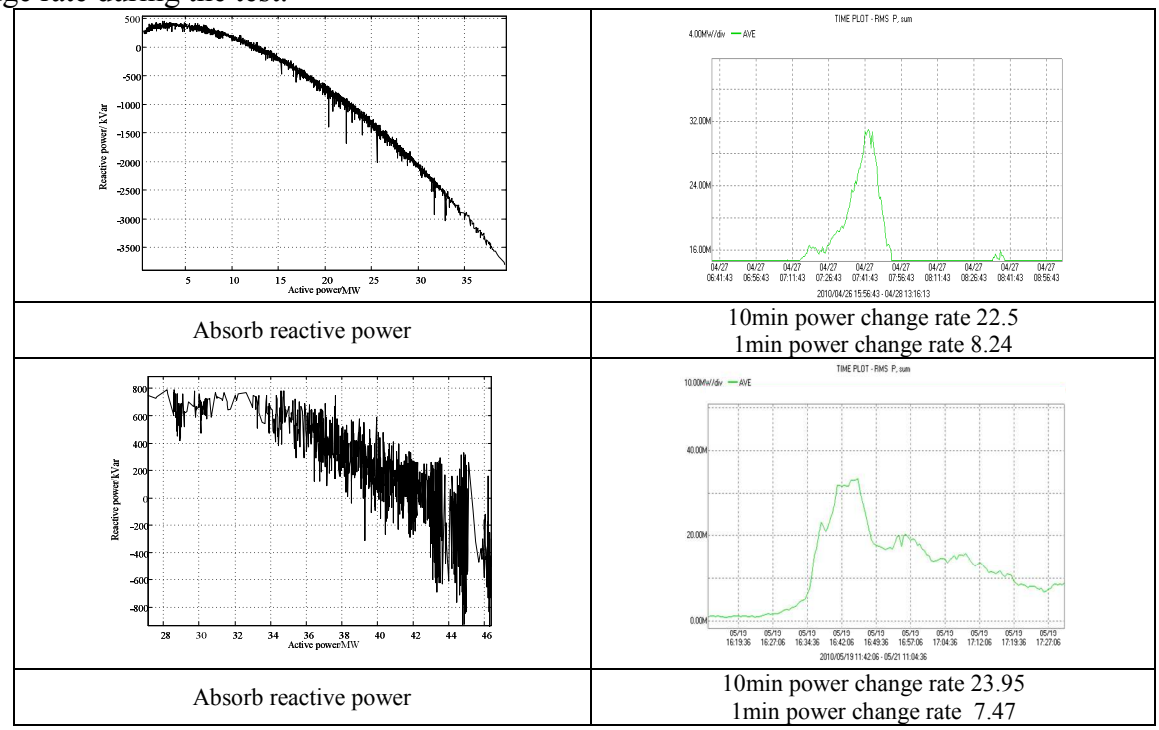


Figure 2 Wind Farm absorb reactive power from the grid and power change rate

Wind power bring critical challenge to power peaking

The power output of wind power is random fluctuations and uncontrollable, the prediction accuracy is poor, large-scale wind power generation connected to the grid make it difficult to formulate generation plan, need to increase system spare capacity, this increases the economic costs of the system operation; It put forward new demands to both the power mode operation plan and system spare capacity, especially thermal power peaking-based Liaoning grid facing enormous issue.

With the rapid development of wind power, wind power usage problem gradually emerged. Beginning in 2010, wind power usage capacity shortage emerged in portion period, wind power abandoned 110 million kWh 2010,which increased to 1.129 billion kWh 2012, an increase of nearly 9.26 times.(2012 abandoned wind power 773 million kWh in the cause of peaking, accounted for 68.47% of total abandon wind power, 356 million kWh in the cause of grid constraint, accounted for 31.53% of total abandon wind power.) Limited power ratio increased from 2.34% in 2010 to 14.33% in 2012. Table 1.1 shows 2007 to 2012 wind power limited power situation in Liaoning power grid.

Table 1 2007 to 2012 wind power limited power and generation situation in Liaoning power grid

Year	2007	2008	2009	2010	2011	2012
Limited power （hundred million kWh）	--	--	--	1.1	5.62	11.29
Limited power generation ratio（%）	--	--	--	2.34	8.51	14.33
Power utilization hours	1388	1764	2025	2033	1934	1761

Liaoning Power Grid the heating period and strong winds period are at the same time, and there is a big difference between peak and off-peak load in winter heating period. Affected by heating, thermal power peaking capacity decreased, absorptive capacity of wind power is serious shortage. Spring, autumn and summer peak and off-peak load difference decreases, and thermal power peaking capacity enhancement, wind power usage capacity has increased significantly. Table 2 shows the month of 2012 wind power generation and wind power abandoned, Figure 3 shows the past three years limited power generation ratio.

Table 2 The month of 2012 wind power generation and wind power abandoned

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sept	Oct	Nov	Dec
Wind power capacity Ten thousand kilowatts	410	417	434	439	442	442	456	456	466	471	471	476
Wind power generation hundred million kWh	3.06	6.62	7.83	11	6.85	6.31	5.35	4.07	6.32	7.7	6.24	7.43
Abandoned wind power hundred million kWh	1.19	2	1.64	1.56	0.19	0.1	0.15	0.31	0.15	0.51	1.98	1.52
Limited power ratio %	38.89	30.21	20.95	14.18	2.77	1.58	2.80	7.62	2.37	6.62	31.73	20.46
Power utilization hours	75	159	186	255	154	142	116	86	135	156	132	156

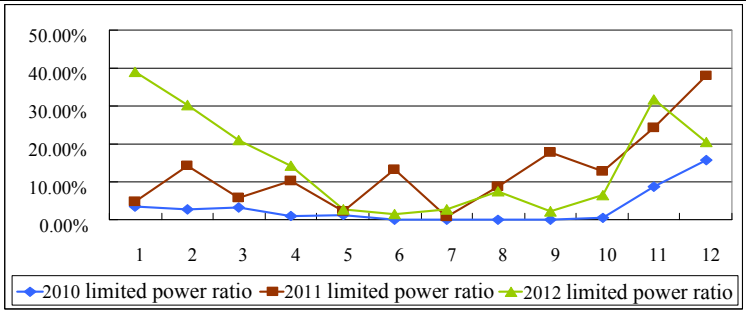

Figure 3 The past three years limited power ratio

According to wind power data analysis of nearly three years, spring and autumn (Mar-May, Oct-Nov) are the windy months, followed by winter (Dec- Feb the following year), summer (Jun-Sept) is minimal. Shortage acceptance of wind power capacity mainly from November to April the following year, 989 million kWh of wind power abandoned, account for 87.5% of total abandon wind power. Monthly wind power limited power ratio more than 10%. Which in addition to April, the rest are heating period, wind power generation power rationing more than 20%. Windy months centralized heating period, resulting in Shortage acceptance of Liaoning grid wind power capacity.

Measures on the impact of Liaoning Power Grid wind energy integration

Strengthen wind power connection management, Improve the technical level of wind energy integration

For the status of wind power manufacturing level of technological uneven, the need to actively promote wind power testing. By grid-connected testing can urge manufacturers to improve their production technology level, so as to ensure that the wind farm grid-connected security. Currently, Liaoning Power Grid has developed a comprehensive wind power detection system, and established a wind energy integration management system with wind power detection as the core, which include wind energy pre-integration technical supervision, wind energy integration security management, wind energy integration testing and evaluation. Ensure the Liaoning Power Grid wind energy integration technology at a high level.

Plan the power structure scientifically and rationally, promote wind power development and its economic intensive use

Northeast power grid is currently facing structure is irrational, the rapid development of wind power, winter heating units' capacity is large and long-running and other problems, thus bring great pressure to power peaking and frequency regulation. In this situation, accelerate the development of the power grid to adjust and optimize the power structure of the Northeast, ensure the safe, economic and stable development of the grid, has become a problem which power regulators, grid operators, power generation companies and research institutions in all aspects are extremely concerned and need to take urgent measures to solve.

Liaoning EPRI carried out a special study on the power structure influence acceptance of wind power capacity, study showed in the 2020 an increase in Liaoning different pumped storage power generation capacity, the amount of wind power abandoned fell to 0.03 percent from 2.07 percent, it can effectively improve the situation of abandoned wind power.

Table 3 Abandoned wind conditions in increased different pumped storage power generation at 2020

Increase Pumped Storage （Ten thousand kW）	0	30	50	60
Abandoned wind power （Ten thousand kW）	13151	4319	976	198
Days of abandoned wind power	80	68	16	10
Abandoned wind power/Wind power generation	2.07%	0.68%	0.15%	0.03%

Excavate thermal power peaking capacity and improve the ability of wind power consumption

Abandoned for wind power operating mode, through the analysis of peaking power technology research at home and abroad, According to the characteristics of the Northeast power grid, determine the technical route of this subject. Under the conditions of other peaking power is difficult for large-scale applications, carry out experimental research of various types of thermal power units operating characteristics at low load, as well as economic research. On the basis of the existing power peaking, proposed technology and policy to improve the ability of in depth peak load cycling of thermal power, As well as various types of units approved recommendations of load under deep cyclic operation. On this basis, use less oil combustion technology to improve the ability of in depth peak load cycling. Use unconventional peaking, develop technology of generating units under deep cyclic operation, and maximize the power grid acceptance of clean energy.

According to the characteristics of the northeast power grid, make full use of large-capacity thermal power characteristics, enhance the ability of in depth peak load cycling, use unconventional peaking, to solve a large number of wind power abandoned. On the ability of in depth peak load, Liaoning EPRI carried out research in the following areas：

1）Experimental study on the minimum stable combustion boiler load

2）Research on coal characteristics effect on peaking capacity of generating units

3）Study on various boiler operating characteristics under low load

4）Determine power generation by heat system technology research

5）Thermal automation adaptability research

6）Experimental research of various types of thermal power the ability of in depth peak load cycling

7）Deep cyclic economy research on generating units

The study results, involve Northeast and Mondon power grid all types of power units, and its range is wide, its technical factors is complicated. Northeast power peaking is extremely difficult at present, and it is often under curtailment operation, wasted a lot of wind power. Improve the thermal power peaking capacity, make full use of wind energy resources is essential, is technically feasible. Use thermal power deep cyclic technology, optimize energy configuration by grid, maximize the use of renewable energy, save Primary energy, and achieve energy conservation. According to calculation, after the realization of the deep cyclic operation, economic, environmental and social benefits are huge. Thermal power deep cyclic technology can greatly improve the power peaking capacity and it can be an effective solution to the problem of wind curtailment. The technology has great value for solving grid acceptance clean energy, energy conservation.

Conduct performance analysis of energy storage systems connected grid, promoting coordinated development of wind energy storage

2011, Liaoning Electric Power Co. declared a national 863 project "key technologies of energy storage system improve the ability of intermittent power connected to the grid research and development", aims to build large-capacity storage system to improve intermittent power connected to the grid method system. Focus on research and development of configure, manage, control and other aspects of technology about energy storage system, to improve the ability of intermittent power

supply connected to the grid, breakthrough Intermittent power scale development bottlenecks in the grid and source coordination.

May 2013, Liaoning EPRI completed energy storage power station performance test acceptance. The next step will be to carry out a series of thematic studies, including storage devices improve power quality and the capacity connected to grid, the role of energy storage device for smooth power output, feasibility of energy storage devices to run in the case of reactive output, the role of energy storage device for improving the wind farm ability of low voltage ride through, energy storage device as a black start power feasibility, energy storage device islanding capability. Use energy storage devices scientifically and rationally.

Develop coordination of a variety of new energy development, develop and utilize of wind power thermal storage technology, promote the application of wind power heating technology in the conditions suitable areas, replace the existing coal-fired boiler heating, local or remote consumptive rich wind power.

Conclusions

Liaoning power grid increasing proportion of wind power, triggering a series of wind power connected to grid issues. Need to strengthen management, implement grid-connected technology requirements strictly, plan the power structure scientifically and rationally, excavate thermal power peaking capacity, improve the capacity of wind power consumptive, while continuing to carry out a variety of new energy coordinated development, develop wind power thermal storage and other new technologies, multi-channel consumptive wind power.

Keywords: power transmission and transformation project, typical gap, lighting impulse, correction

Abstract: External insulation design of UHV power project is important. The lightning impulse (LI) voltage is one of the main factors that determine the air gap distance. Based on existing LI voltage results of power project typical gap, impact of gap structure and distance on LI discharge correction is analyzed. And from a theoretical aspect, existing LI discharge correction methods are summarized. Furthermore, by the use of common correction methods, LI voltage correction factors of rod - plane were calculated and analyzed. Results show no significant impact of gap type or gap distance on LI voltage correction is found out. Average atmospheric conditions are effective when atmospheric parameters method is used for LI voltage correction. DL/T 620, IEC 60060-1 and IEC 60071-2 can be used for LI voltage correction at areas with altitudes of 1000-5000m. While GB311.3-improvement method can be used for LI voltage correction at areas with altitudes blow 4000m.

Introduction

Dielectric strength of air is affected by humidity, temperature and pressure. Thus, during insulation design or test, it is necessary to correct air- gap discharge voltages. From the 1950s to now, scholars has carried out a number of studies about air gap discharge and has made a lot of achievements [1].

LI breakdown voltage is one of the main factors that determine air gap distance. A variety of methods which can be used for power project typical gap LI correction are recommended in current standards [2-5]. While different methods may lead to different results. In this paper, based on the existing LI voltage results of power project typical gap, impact of gap structure and distance on LI discharge correction is analyzed. And from a theoretical aspect, existing LI voltage correction methods are summarized. Furthermore, by use of these methods, LI voltage correction factors of rod - plane were calculated and analyzed.

Influencing Factors of LI Voltage Correction for Power Project Typical Gap

Effect of gap structure on LI voltage correction

To study whether gap structure affects LI voltage correction, gaps of soft bus to architecture column (which can be referred to as "soft bus to ground"), grading ring to architecture column (which can be referred to as "grading ring to ground") and rod-plane are selected as comparison objects.

Test sites of soft bus to ground and grading ring to ground are Wuhan outdoor test site (elevation 23m) and Dawu town, in Qinghai province (elevation 3727m) respectively in reference[6]. The soft bus is two split phase-changing soft bus. The distance of centerline of simulated cross arm to the ground 16m and the distance of soft bus to ground is 12m. By moving hanging point, the distance of bus to architecture column is adjusted and LI discharge test at different gap distances was carried out. Grading ring is lightning arrester grading ring and the distance of it to ground is 5.7m. By moving the insulation pillar air gap distance was adjusted and LI discharge test at different gap distances was carried out. For rod-plane, LI voltage are test results in Dawu town. Italian scholars Paris L and other people gives a relationship formula between LI voltage and rod-plane air gap distance at zero altitude areas [7], which is:

$$U = 537d \quad (1)$$

Where: U is LI discharge voltage , kV; d is the gap distance , m.

LI discharge voltage results of the three gap structure are shown in Figure 1. Soft bus to ground and grading ring to ground LI discharge voltages in Wuhan has been corrected to standard atmospheric conditions at zero altitude .

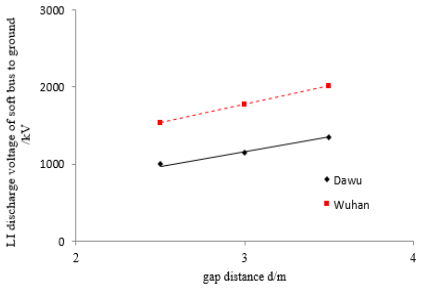

Fig.1(a) LI discharge characteristics of soft bus to ground

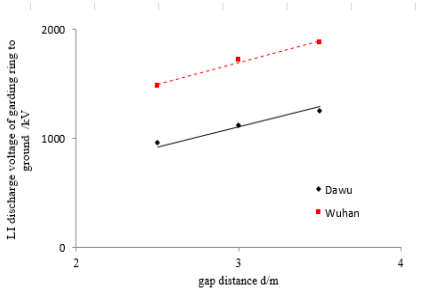

Fig.1(b) LI discharge characteristics of grading ring to ground

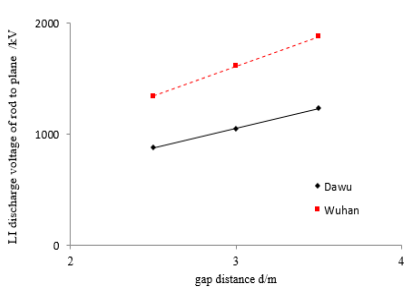

Fig.1(c) LI discharge characteristics of rod - plane

According to above results, LI voltage correction coefficients of different gap structures are obtained, as shown in Table 1.

Table 1 LI voltage correction coefficients of different gap structures

Air gap type	Soft bus to ground	Grading ring to ground	rod - plane
correction coefficients	1.52	1.53	1.53

As can be seen from Table 1, the LI voltage correction coefficients under three types of gaps are 1.53,1.52,1.53. No significant impact of gap type on LI voltage correction is found out.

Effect of gap distance on LI voltage correction

In order to study the effect of gap distance on LI voltage correction, LI voltage correction coefficient with gap distance of 2.5-3.5m and 4.0-8 .0 are compared. LI voltages with gap distance of 2.5-3.5m are rod - plane gap test results in the above chapter while those of 4.0 - 8.0 m are of test results in reference [8]. LI discharge characteristics curve of DC v-shaped string tower head in Tibet and Beijing are shown in Fig.2, where LI discharge voltages in Beijing has been corrected to standard atmospheric conditions at zero altitude.

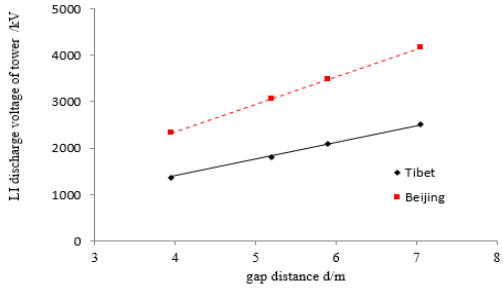

Fig.2 LI discharge characteristics curve of DC v-shaped string tower head

According to LI discharge characteristics curve at zero altitude and high altitude areas, LI discharge characteristics curves at areas with altitudes of 1000m, 2000m, 3000m, 4000m and 5000m can be obtained by linear interpolation, respectively, which is shown in Fig. 3 and Fig.4

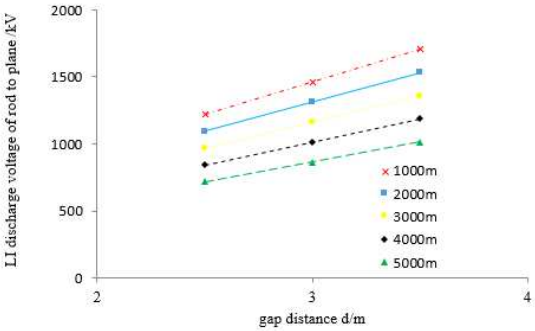

Fig.3 LI voltage of 2.5-3.5m gap distance at different areas

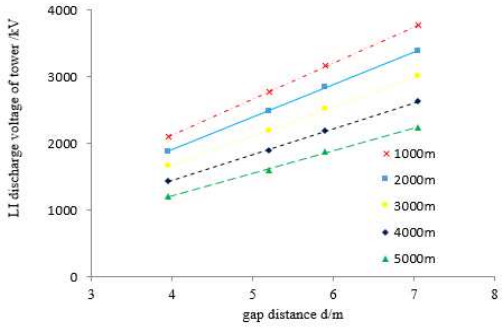

Fig.4 LI voltage of 4.0-8.0m gap distance at different areas

LI voltage correction coefficients of different gap distances are obtained, as shown in Table 2.

Table 2 LI voltage correction coefficients of different gap distances

Air gap / correction coefficients	2.5-3.5m	4.0-8.0m
1000m	1.10	1.11
2000m	1.23	1.24
3000m	1.38	1.39
4000m	1.59	1.60
5000m	1.86	1.89

As can be seen from Table 2, the maximum error of LI voltage correction coefficients of gap distance of 2.5-3.5m and 4.0-8.0m at same altitude is 1.6%. No significant impact of gap type on LI voltage correction is found out.

Analysis of Commonly Used LI Voltage Correction Methods

There are several methods can be referred to correcting LI voltage. According to theory basis, they are classified by atmospheric parameters method and altitude method. Atmospheric parameters method requires the meteorological conditions of project site, which is relatively accurate, but it is often difficult to acquire weather data. As for altitude method, it only need altitude values. This method is simple and practical, but relatively coarse. Because even in the same altitudes, meteorological conditions may still be different.

Atmospheric parameters correction method

In DL/T 620-1997[4], outer insulation discharge voltage correction method is given. The discharge voltage is corrected by the formula (1):

$$K_a = \delta^n / H^n \tag{1}$$

Where: δ is the relative air dentist; H is air humidity correction factor; n is corrected index. For LI voltage, H is decided by $1+0.009(11-h)$. h is absolute air humidity, g/m^3.For LI, n = 1.The Standard also recommend relative air dentist and absolute air humidity values under different altitudes.

In IEC 60060-1 (2010) [3], discharge voltage is corrected by the following formula:

$$U = U_0 \cdot K_t \tag{3}$$

Where: U_0 is the discharge voltage under standard atmospheric conditions, kV; U is the actual discharge voltage, kV; K_t is atmospheric correction factor, which is product of air density correction factor K_1 and air humidity correction factor K_2. K_1 depends on the relative air density δ. That is $K_1 = \delta^m$. As for K_2, it is $K_2 = K^w$.

Where K depends on the type of the test voltage. For LI discharge, formula (4) is used:

$$K = 1 + 0.010(h/\delta - 11) \tag{4}$$

m and W are corrected index , which are decided by parameter g.

Altitude correction method

In IEC 60071-2 (1996), atmospheric correction factor K_a should be calculated as follows [3]:

$$K_a = e^{m(H/8150)} \tag{5}$$

Where: H is the height over sea level, m; m is correction factor. For LI voltage, m = 1.

Based on GB311.1 (1997), Wuhan High Voltage Research Institute proposed a method [5]. Altitude correction factor K_a should be calculated with the following formula (6):

$$K_a = 1/(1.0 - mH/10000) \tag{6}$$

H is the height over sea level, m For LI voltage, m = 1.

Comparison of current LI voltage correction methods

According to test data of rod-plane, LI voltage correction methods, DL/T 620, IEC 60060-1, IEC 60071-2 and GB 311.1-improvement are compared. Because atmospheric parameters are not given at

4000m and 5000m areas in DL/T 620, they are obtained by fitting atmospheric data at areas with altitude from 500m to 3500m. As for IEC 60060-1, atmospheric conditions are obtained by the same approach of DL/T 620. Correction coefficients are shown in Table 3.

Table 3 LI voltage correction coefficients under different methods

Correciton mehtods		Atmospheric paramater mcorrection		Altitude correction		Test result
		DL/T 620	IEC 60060-1	IEC 60071-2	GB311.1-improvement	
1000m	Correction coefficients	1.13	1.13	1.13	1.11	1.10
	Correction errors	2.73%	2.73%	2.73%	0.91%	--
2000m	Correction coefficients	1.28	1.27	1.28	1.25	1.23
	Correction errors	4.07%	3.25%	4.07%	1.63%	--
3000m	Correction coefficients	1.43	1.43	1.44	1.43	1.38
	Correction errors	3.62%	3.62%	4.35%	3.62%	--
4000m	Correction coefficients	1.62	1.63	1.63	1.67	1.59
	Correction errors	1.89%	2.52%	2.52%	5.03%	--
5000m	Correction coefficients	1.86	1.91	1.85	2.00	1.86
	Correction errors	0.00%	2.69%	-0.54%	7.53%	--

At areas with altitudes of from 1000 to 5000m, absolute values of correction error obtained by DL/T 620, IEC 60060-1 and IEC 60071-2 are less than 5%, which means they apply to voltage correction in high altitude areas. Absolute values of correction errors obtained by GB311.1 -improvement are less than 5% at areas with altitudes below 4000m while are more than 5% at areas with altitudes of 4000m or above. When taking average atmospheric conditions at a certain area, atmospheric parameters method give basically the same correction coefficients with experimental results. With comprehensive comparison of the above correction methods for simplicity and accuracy of calculation, method IEC 60071-2 is recommended for engineering design of LI voltage correction.

Summary

By correcting LI voltages of air gaps for soft bus to ground, grading ring to ground, and DC v-shaped tower head and rod-plane at different areas, no significant impact of gap type or gap distance on LI voltage correction is found out. Average atmospheric conditions are effective when atmospheric parameters method is used for LI voltage correction. DL/T 620, IEC 60060-1 and IEC 60071-2 can be used for LI voltage correction at areas with altitudes of 1000-5000m. While GB311.3-improvement method can be used for LI voltage correction at areas with altitudes blow 4000m.

Keywords: entropy weight expert weight cascading failures vulnerability assessment

Abstract. To study the mechanism of cascading failures in a power grid and find out the key vulnerable lines propagating cascading failures, entropy theory and analysis hierarchy process were applied in entropy-weighted fuzzy comprehensive evaluation model, and information of objective data and the subjective opinion of experts were combined in the model to implement effective evaluation and sorting of line vulnerability. The article builds a index system that contains voltage deviation, power flow coefficient and electric betweenness in considering the network structure and real-time running state of the system, and then the lines vulnerability assessment method is proposed .This method can be used to help power grid designers and operators spot the lines prone to black-out. Numerical example results show that the proposed indicators can overcome the deficiency of existing indicators not taking the state of the grid structure and operation into account which proves the assessment method is feasible.

Introduction

In recent years, several large-scale power system blackouts occured domestic and international[1]. Research shows that these blackouts are mostly caused by the initial failure of a chain of accidents[2-3]. Very few of which have long-range connections line play a role in fueling[4-5], if we can identify these key lines and take appropriate measures to protect the control is bound to reduce the probability of cascading failures and thus reduce the likelihood of accidents blackout. Therefore, how to judge these fragile lines, has important theoretical and applied research value.

To the problem of comprehensive evaluation is very important to determine the weighing, values of weights change will directly affect the scientific rationality of the comprehensive evaluation results. some scholars of vulnerability assessment is discussed for transmission lines [5-10], but most of the literature didn't explore the methods of determine the weighing values, only using single subjectively or objectively, such as the literature [6] when determining weights depend entirely on the entropy weight method, the multi-target the relative importance of the order of the target can't reflect, literature [7] when determining weights depend entirely on expert experience, subjectivity is too strong. the existing analysis method of Line vulnerability assessment, many from the angle of the grid structure with the knowledge of the complex network theory to analyze the line vulnerability [5,8-10], not considering the actual power flow operation, evaluation results are likely to appear unreasonable.

1 theory basis of combination weighting evaluation

1.1 entropy weight method

Entropy weight method is a mathematical method to calculate the comprehensive index. According to the size of information of each index is passed to the decision makers to determine its weight, the greater the entropy weight, the smaller the variance of the information provided. With

index can be used to represent different objects to distinguish between degrees of entropy method.To calculate the objective weight steps are as follows:

(1) Develop initial evaluation index matrix；

(2) Positive and dimensionless processing of data.This is a process of various indexes can be converted to relatively unified dimension, divided into the index data type as good cost index and the bigger the better efficiency index. considering indexes for efficiency index was proposed in this paper, formula for its standardization;

(3) The calculation of entropy and entropy weight.

1.2 Analytic Hierarchy Process

Indicators of entropy reflects the objective data of lines, namely the difference degree between the grid lines, do not reflect the index to the importance of the practical problems, expert need to make decisions according to the actual situation own preferences. This article uses the nine expert decision scale method to decision.Steps are as follows:

(1) establish a class hierarchy,put the evaluation target hierarchical.

(2) building judgment matrix, after the construction of the target hierarchy, the subordinate relations between the level indicator is determined, on the same level indicators, two comparison and the comparison results in nine scaling expression [11] .

(3) verify consistency to ensure data reliability, calculated by the judgment matrix elements are being compared relative weight, calculate the combination weight of each element.

1.3 Line vulnerability evaluation index combined weights

Considering the entropy weight method can't reflect the multi-index of target sorting the relative important degree, and the analytic hierarchy process lack of objective basis, which requires the combination of subjective and objective weight, get a set of objective and subjective comprehensive weights, to overcome the disadvantages of the above two methods.

2 Line vulnerability evaluation index

To the problem of the transmission line vulnerability, if the probability of line fault sorting as the total target, influence factors as the criterion, establish the hierarchical structure of the model as shown in figure 1:

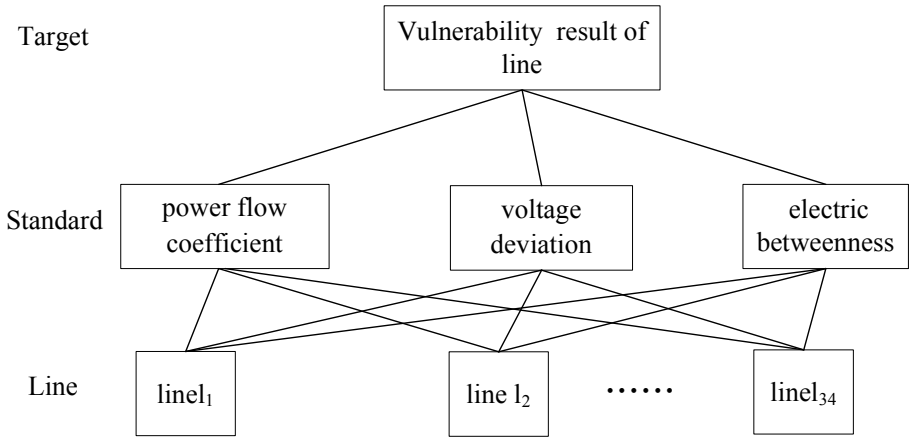

Fig.1 Architecture of AHP

This article selects three kinds of vulnerability assessment index build index set, the index definition is given below:

(1)the electric betweenness of line(m,n) as follow：

$$B_{\mathrm{e}}(m,n)=\sum_{\substack{i \\ \mathrm{j}}}^{\substack{G \\ \mathrm{L}}}\sqrt{\mathrm{W_i}W_j}\left|I^{ij}(m,n)\right| \tag{1}$$

(2)the voltage deviation of node as follow:

$$D_{\mathrm{u}} = \sum_{s \quad S\ 1)} \left| U_{\mathrm{s}} - U_{so} \right| \tag{2}$$

(3) the power flow coefficient of line as follow:

$$C_{\mathrm{i}} = \left| \frac{P_{io}}{S_L} \right| \sum_{j=1}^{L-1} \left| \frac{\Delta F_j}{F_{jo}} \right| \tag{3}$$

3 Power grid vulnerable line evaluation methods

process of vulnerability line identification consider the following factors:

(1) the analytic hierarchy process (AHP) and entropy weight method to the calculation of equal status to participate in the comprehensive weight

(2) a is 0.02, which only consider the voltage offset value greater than or equal to 0.02 per unit. According to section 2 the proposed index by using the method of section 1 figure 2 processes to calculate

4 simulated analysis

This section uses the New England 39 node system as a test system, New England 39 node system [5]have a total of 10 generator, 19 load and 34 lines (regardless of the transformer branch), system wiring diagram is shown in figure 3. PSD – BPA used as simulation calculation tool which developed by The China electric power research institute.

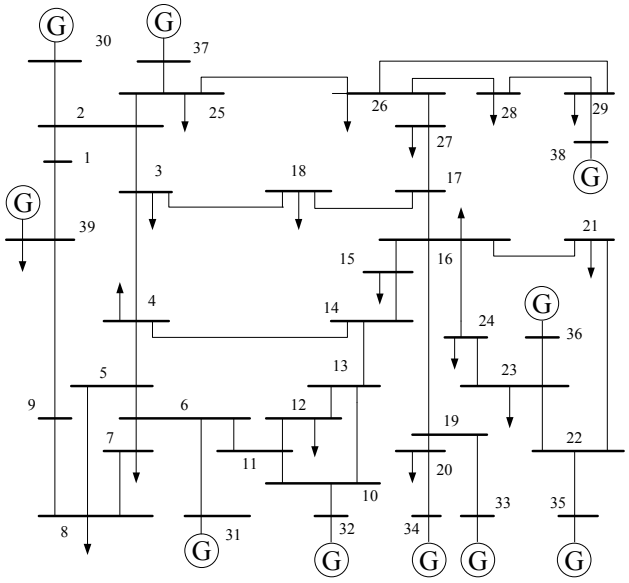

Fig.3 Connection diagram of IEEE 39-bus system

First, after every line fault the vulnerability index are calculated separately, the entropy weight line vulnerability index is obtained, as shown in table 1:

Tab.1 Entropy weights of the indices

indicator type	Power flow coefficient	voltage deviation	electric betweenness
Entropy	0.8059	0.5713	0.9140
Entropy weights	0.2738	0.6048	0.1214

Can be seen from table 1, the relationship between entropy and entropy weight is inversely, the greater the entropy, the entropy weight is smaller. Entropy weight of voltage offset is the largest which shows that important degree is high of the index in the sense of competition compare to power flow coefficient and electrical betweenness.

To build judgment matrix based on nine scaling criterion layer, as shown in table 2:

Tab.2 Judgment matrix

judgment matrix	Power flow coefficient	voltage deviation	electric betweenness
Power flow coefficient	1	2	3
voltage deviation	1/2	1	2
electric betweenness	1/3	1/2	1

Validated by the consistency index, the weight of Power flow coefficient voltage offset and electrical betweenness are: 0.5396, 0.297, 0.1634.

According to network structure to calculate the electrical betweenness, judgment matrix is given by electrical betweenness according to ways provided by table 3, thereby calculating 34 lines index weight of electrical betweenness.

Tab. 3 Expert scoring table of electric betweenness

electric betweenness	0.5-1	1-1.5	1.5-2.0	2.0-2.5	2.5-3.0
Expert score	1	2	3	4	5

Regardless of system with intermittent operation of the power grid, disconnect does not exist any line overload in test system, isolated net running system appear when disconnect the line 16-19, so the line 16-19 is the most vulnerable line The rest of the line comprehensive vulnerability index from big to small order as shown in table 4:

Tab.4 Vulnerability identification result of line

line	Power flow coefficient	rank	voltage deviation	rank	electric betweenness	rank	combination weighting
22-21	3.1	3	14	1	1.135	24	0.183
16-15	1.9	5	8	2	2.08	2	0.114
26-27	1.655	8	5.9	3	1.805	7	0.087
2-3	3.067	4	3.1	6	1.69	9	0.081
10-11	4.43	1	—	/	1.175	22	0.067
25-2	1.727	7	—	/	1.93	5	0.054
10-13	3.3	2	—	/	1.21	21	0.051
29-28	0.229	17	4.5	4	0.75	34	0.045
24-16	0.015	30	4.2	5	1.16	23	0.044
6-7	0.77	14	2.6	7	0.94	26	0.038

Summarize the foregoing analysis and calculation results:

As you can see sorting of lines on fragility , relative to the electrical betweenness, Line vulnerability in maintaining the structural vulnerability identification, take the operating conditions including voltage offset and power flow coefficient into consideration, to make evaluation results more reliable Comprehensive, so as to improve the recognition effect and accuracy, for example, electrical betweenness of Line (22-21) is not high, but through the lines of the deviation of the tidal current and voltage amplification effectively, making it a fragile degrees higher line.

Summary

two aspects of power system vulnerability is considered In this paper: the structure state of vulnerability and running state vulnerability, assessment of structural vulnerability uses the electrical betweenness to judge vulnerability, electrical betweenness is the inherent nature of grid structure to describe the vulnerability degree of power grid, the operation of the power system uses the combination of local and global indicators evaluated the grid vulnerability on the other hand, consideration of the above factors, vulnerability assessment method is proposed on the basis of comprehensive vulnerability index. From the structure vulnerability and the open circuit state balance voltage deviation to evaluate the influence of grid function in the process takes the intermittent power grid-connected operation impact on line vulnerability into consideration. The method can effectively

consider the various factors influencing the system vulnerability, and according to the system operating conditions, adjust the weights of affecting factors.

[2.] Key Laboratory of Smart Grid of Ministry of Education, Tianjin University, Tianjin 300072, China

Keywords mid-long term load forecasting; interval arithmetic; Taylor model; Monte Carlo method; reliable computing

Abstract. For long time span, the impact of many factors, uncertainties and other characteristics of mid-long term load forecasting, as well as the over-estimation of interval arithmetic, a mid-long term load forecasting method based on interval Taylor model algorithm was presented. In order to avoid misjudgment of the relationship between variables, reducing over-estimation problem, a global variable named Taylor model ID was presented to identify the independent variables and the dependent variable. The same independent variables construct the interval Taylor model only once. Use Maclaurin formula to derive the interval Taylor model of correlation function formula, and then get a quadratic exponential smoothing method based on interval the Taylor model. The proposed method has been tested on a provincial calculation. The results demonstrated the effectiveness and practical value of the approach by comparing with the results of Monte Carlo simulation and interval method.

Introduction

Power system mid-long term load changes are subject to system operating characteristics, natural conditions, social impact, and many other factors. How to consider these uncertainties and determine their effect on the original data is very critical issue. Over the past few decades, a variety of mathematical methods such as expert systems theory, genetic programming, neural networks and the system dynamics are introduced to load forecasting field[1-6].

For the above analysis, this paper introduces theinterval Taylor model algorithm to deal with the uncertainty in mid-long term load forecasting of power system, uses the Taylor model to describe uncertainty ofparameters, proposes and implements mid-long term load forecastingbased on interval Taylor model algorithm. Finally, examples are given to verify and demonstrate the results.

Interval Taylor model arithmetic

Interval Taylor model arithmetic is a kind of “Reliable Computing” arithmetic. “Reliable Computing” is first designed to avoid errors of floating point algorithm, improve the reliability of calculation results and effectively avoid the uncertainty of calculation caused by uncertainty of the parameters[7-13].

Interval Taylor model algorithm’s principle is using polynomial to represent function approximately, quantitatively estimating the size of the error.

Although the interval Taylor model algorithm is the development of the interval algorithm, , the basic data types are no longer interval number, but the interval Taylor model in interval Taylor model algorithm. An interval Taylor model $_{\alpha,}$ can be represented by the sum of a Taylor polynomial $_{\alpha,}$ and a remainder term $I_{\alpha,f}$ on bounded interval:

$$_{\alpha,} = _{\alpha,} + I_{\alpha,} \tag{1}$$

In the formula， α is the parameter of the Taylor polynomial, including order n, reference point $\vec{x}_0$,domain$[\vec{a},\vec{b}]$. That is：

$$\alpha = (n, \vec{x}_0, [\vec{a},\vec{b}]) \tag{2}$$

$P_{a,f}$ complies with polynomial algorithm, while $I_{\alpha,f}$ and polynomial parts whose order is higher than ncomply with the algorithm of interval arithmetic.

Interval algorithm can't distinguish independent variables from dependent variables. When the same variable appears many times, the interval algorithm regards them as different variables. Interval Taylor model algorithm can reduce over-estimation problem of relative variables, but has some difficulty to distinguish independent variables from dependent variables. If only distinguish by parameter α, it may cause misjudgment.

Therefore, this paper distinguishes the independent variables from dependent variables by setting a global variable—Taylor model ID. The same independent interval variables construct Taylor model only once. New independent variables mainly come from two aspects:

1) The introduction of the new independent interval variables.

2) New interval variables are generated by operation of two or more independent interval variables.

Example of interval Taylor model computing is shown in Table1:

Tab. 1 Example of interval Taylor model computing

item	ID	interval value	Interval Taylor model values	Taylor polynomial coefficients				Remainder Term
				power0	power1	power2	power3	
X	1	[2,4]	[2,4]	3	1	0	0	[0,0]

Quadratic exponential smoothing method based on the interval Taylor model.

2.1Quadratic exponential smoothing method based on the interval Taylor model.

In order to reduce over-estimation problem of interval Taylor model, this paper adopts the deformation formula of quadratic exponential smoothing methoddemonstrated in literature[14].

Single exponential smoothingdeformation formula:

$$S_t^{(1)} = \alpha \sum_{i=0}^{t-1} (1-\alpha)^i x_{t-i} + (1-\alpha)^t S_0^{(1)} \tag{3}$$

Linear intercept deformationpredicting formula:

$$\begin{aligned} \hat{a}_t = & \sum_{i=1}^{t} (2 - i\alpha)(1-\alpha)^{i-1} \alpha x_{t+1-i} \\ & + (2 - t\alpha)(1-\alpha)^t S_0^{(1)} - (1-\alpha)^t S_0^{(2)} \end{aligned} \tag{4}$$

Linear slope deformation predicting formula:

$$\begin{aligned} \hat{b}_t = & \sum_{i=1}^{t} \alpha^2 (1-\alpha)^{(t-i-1)} [1 - (t-i+1)\alpha] x_i \\ & + \alpha(1-t\alpha)(1-\alpha)^{t-1} S_0^{(1)} - \alpha(1-\alpha)^{t-1} S_0^{(2)} \end{aligned} \tag{5}$$

In formula (3)—(5)，interval Taylor model operatorsinclude elementary arithmetic and power function. Arithmetic formula of Taylor model can be found in Literature [11], power function formula derivation can be seen in formula (6)—(7).

Assuming the interval Taylor model of function f is $T_{\alpha,f} = (P_{\alpha,f}, I_{\alpha,f})$.The constant part of function f that depends on $\vec{x}_0$ is recorded as $c_{\alpha,f}$. It is equal to the constant part of the Taylor polynomial $P_{\alpha,f}$, the non-constant part of its rest is recorded as $\bar{f}$.

That is:

$$f(\vec{x}) = c_{\alpha,f} + \bar{f}(\vec{x}) \tag{6}$$

Using Maclaurin formula:

$$\begin{aligned}\left(f(\vec{x})\right)^m &= \left(c_{\alpha,f}+\overline{f}(\vec{x})\right)^m \\ &= c_{\alpha,f}^m\left(1+\frac{\overline{f}(\vec{x})}{c_{\alpha,f}}\right)^m \\ &= c_{\alpha,f}^m\cdot 1+\left\{\frac{m\,\overline{f}(\vec{x})}{c_{\alpha,f}}+\frac{m(m-1)\,\left(\overline{f}(\vec{x})\right)^2}{2!\,c_{\alpha,f}^2}\right. \\ &\qquad \left.+\cdots+\frac{m!\,\left(\overline{f}(\vec{x})\right)^k}{(m-k)!\,k!\,c_{\alpha,f}^k}\right\} \\ &\quad +c_{\alpha,f}^m\cdot\frac{m!\,\left(\overline{f}(\vec{x})\right)^{k+1}}{(m-k-1)!\,(k+1)!\,c_{\alpha,f}^{k+1}} \\ &\quad \cdot\left(1+\theta\cdot\overline{f}(\vec{x})/c_{\alpha,f}\right)^{m-k-1}\end{aligned} \tag{7}$$

Example and Analysis

This paper based on the maximum load data of a province between 1991 and 2009 forecasts the maximum load to 2012.

Assume that the actual value of power load is uncertain, its value is interval number[x_t×0.99, x_t×1.01].

Respectively use Monte Carlo method (simulation times are 500000, random numbers are uniformly distributed within the agv), interval algorithm, and the interval Taylor modelalgorithm to predict power load values of a province covering 1991 ~ 2012.The results are shown in Table 2.

Tab. 2 The load forecasting from 1991 to 2012

2012	[48919,53099]	[45012,57020]	[46083,56009]

Note：MC[$\hat{x}_t$]is load prediction using Monte Carlo method, IA[$\hat{x}_t$]is load prediction using interval arithmetic, TM[$\hat{x}_t$]is load prediction using interval Taylor model arithmetic.

Result in Table 2：the load forecasting results using interval Taylor model algorithmcontain the resultsusing Monte Carlo method and are obviously less than the width of results gained from interval algorithm. It shows the effectiveness of the interval Taylormodel algorithm.

Conclusions

The power load forecast especially mid-long term load forecastisaffected by many factors that are uncertain and difficult to be measured accurately by numerical methods.

This paper introduces interval Taylor model algorithm to deal with the uncertainty of data in mid-long term load forecast.A global variable named Taylor model ID is presented to identify the independent variables and the dependent variable, avoiding misjudgment of the relationship between variables. It derives the interval Taylor model of correlation function formula, and then gets a quadratic exponential smoothing method based on interval the Taylor model.

The results demonstrated the effectiveness and practical value of the approach by comparing with the results of Monte Carlo simulation and interval method.

Keywords: Receiving-end power grid; DC Location selection; Multi-attribute decision making

Abstract. For Receiving-end AC system, DC location selection depends on its role in supporting the DC system and economy. This paper proposes a method based on multi-attribute decision making of receiving-end power grid DC location selection. First, the balance of power DC location selected by region; then select the optimal placement through multi-attribute decision making; finally checked by calculating the feasibility of the selected placement. Zha Lute DC Shandong receiving-end power grid placement choice proved the effectiveness of the proposed method.

Introduction

HVDC transmission has a transmission capacity, low loss, effectively limit the short circuit current, applicable to inter-regional networking features, grid development in China has been more widely used [1-4]. For the receiving-end power grid is concerned, DC location choice for the protection grid security and stability, reduce network losses has very important significance (here's DC location selection refers 500kV HVDC converter station AC bus of choice, the same below).

DC Location selection needs to consider the stability and economy of the grid , a typical Multi-attribute decision making problem. Currently, most of the literature study of AC and DC systems are selected after DC Location interaction , DC Location selection aspects of research literature is not much. [5] proposed a balance of stability and economy of DC Location selection method , consider Effective Short Circuit Ratio (ESCR), the static voltage stability index and active power loss (ΔP) three factors by linear weighting method to select optimal placement . DC Location selection methods described in the literature the following three questions: First, for a DC transmission projects, there is an inherent link between the ESCR and static voltage stability indicators are reflecting the receiving-end power grid voltage DC project support capacity ; Second, the DC Location selection problems in network planning is often balancing selection in the largest regional power shortfall of electricity as DC Location by region, mainly for local load power , and then choose the right node by comparing the technical and economic as DC Location; Third Location not selected to determine its feasibility by the trend, shorts and checked.

In this paper, the power balance is selected by the appropriate DC location, select the ESCR and ΔP two indicators through multi-attribute decision making to select the optimal placement; facts show that the method has certain feasibility and effectiveness.

Method of Receiving-end Power Grid DC Location Selection

location selection. Receiving-end power grid for partitioning power balance, choose the largest power gap partition as DC location selection areas.

Select of location bus. Suppose there are N nodes can share 500kV location selection, specific selection method is as follows.

1) Effective Short Circuit Ratio

The formula for ESCR:

$$ESCR = (S_{ac} - Q_{cN}) / P_{dN} \tag{1}$$

Where:

S_{ac} In other short-circuit capacity of the AC bus station; Q_{cN} Rated voltage, reactive power generated by the equipment; P_{dN} DC rated power delivery.

SCR reaction by the end of the AC system for DC system support capabilities, mainly voltage support capability, for the purposes of HVDC system, based on the theoretical research and practical experience, the strength of the system is divided as follows: ESCR>5 high; ESCR = 3~5 medium; ESCR = 2~3 lower; ESCR<2 low.

For N nodes location areas respectively ESCR calculated the corresponding value.

2) Calculate active power loss

AC active power loss calculation system is:

$$P_{loss} = \sum_{k=1}^{N_k} G_k(i,j)\left[V_i^2 + V_j^2 + 2V_iV_j\cos(\theta_i - \theta_j)\right] \tag{2}$$

Where:

N_k —Number of branches; $G_k(i,j)$ —Branch conductance;

V_i , V_j , θ_i , θ_j —Amplitude and phase angle of each node voltages.

3) Select the target function

Firstly establish DC location selection based on linear weighted objective function and method. Set up two goals $f_i(x)\,(i=1,2)$, corresponding to ESCR and ΔP, ideal placement ESCR corresponding maximum and minimum ΔP. Assuming the weighting coefficients $\omega_i\ (i=1,2)$, the new objective function is:

$$F(x) = \omega_1 f_1(x) + \omega_2 f_2(x) \to \min \tag{3}$$

When the minimum value of the objective function, the nodes corresponding to the optimal location. To determine the appropriate DC location should solve two problems: First, a number of attributes normalized, the second is to find a suitable weighting factor.

4) Normalization process

Since the active power loss ESCR receiving-end communication system and is not an order of magnitude, and in practice the better ESCR hope, reactive power losses as small as possible, direct linear weighting of these indicators is likely to cause an unreasonable result, it is necessary the first of these two indicators normalized.

The larger the system, the more stable though ESCR, but when ESCR to a certain value after its numerical size may in itself is not very important for the stability, and therefore need to introduce thresholds $ESCR_{margin}$, so that the normalization process more reasonable.

Press formula for ESCR and active power loss of these two indicators normalized.

$$\begin{cases} f_1(x) = ESCR' = \max\left\{ \dfrac{ESCR_{\max} - ESCR}{ESCR_{\max} - ESCR_{\min}} , \dfrac{ESCR_{\max} - ESCR_{margin}}{ESCR_{\max} - ESCR_{\min}} \right\} \\ f_2(x) = \Delta P' = \dfrac{\Delta P - \Delta P_{\min}}{\Delta P_{\max} - \Delta P_{\min}} \end{cases} \tag{4}$$

Where:

ESCRmax, ESCRmin—The maximum and minimum ESCR,

Δ pmax, Δ Pmin—Maximum and minimum active power loss.

5) Set the weighting factor

Empowering method using relatively weighting coefficients determined, As shown in Table 1:

Table 1 ESCR and ΔP score sheet

	ESCR	ΔP
ESCR	0.5	1
ΔP	0	0.5

In the table, the first column i and the row j of the i-line attribute value represents the relative importance of the attributes of the first column j, the weighting factor is set as follows.

$$\lambda_{ij} = \begin{cases} 1 & x_i \text{ more important than } x_j \\ 0.5 & x_i \text{ and } x_j \text{ are equally important} \\ 0 & x_j \text{ more important than } x_i \end{cases} \tag{5}$$

Finally, the right weight values were normalized to give a weight different properties as follows:

$$w' = \left[\frac{w_1}{w_1 + w_2}, \quad \frac{w_2}{w_1 + w_2} \right] = [0.75, 0.25] \tag{6}$$

Case Study

Zha Lute DC project in Shandong power grid location selection, for example, to prove the effectiveness of this method. According to the plan, in 2018 Zha Lute HVDC project location Shandong power grid, engineering rated voltage ± 660kV, rated capacity of 8,000,000 kilowatts delivery.

Region Selection. According to the balance of power in 2018, located in the southern region of Shandong Linyi largest active shortfall. This is mainly due to the rapid economic development in recent years, resulting in Linyi region increased demand for electricity, and restrict their energy and environmental factors makes the slow construction of local power, electricity supply and demand is growing. Therefore, considering the placement of Linyi, Shandong Engineering Zha Lute DC area.

Select bus.

1) Calculation of ESCR

Linyi 500kV sites within the region is calculated to give each node ESCR DC location, as shown in Table 2.

Table 2 Each computing node ESCR

Node Name	ESCR
Yi Meng	4.93
Lan Ling	4.79
Zhi Sheng	4.90
Lv Nan	4.60

2) Active power loss calculation

The Zha Lute direct placement on the Linyi region were different 500 kV bus, obtained by calculating the size of active power loss under different circumstances, Shandong province, and the results are shown in Table 3.

Table 3 Shandong Province, the size of the power loss

Node Name	ΔP（MW）
Lan Ling	1512.70
Zhi Sheng	1512.40
Lv Nan	1500.70
Yi Meng	1531.20

3) Normalization process

By normalization, the results shown in Table 4.

Table 4 Results normalized

Node Name	ESCR’	ΔP’
Lan Ling	0.4242	0.3836
Zhi Sheng	0.0909	0.3836
Lv Nan	1.0000	0.0000
Yi Meng	0.0000	1.0000

4) Priority calculation

After addition of the weight coefficient, the value of the objective function is calculated for each node, as shown in Table 5.

Table 5 The objective function values calculated

Node Name	Function value
Zhi Sheng	0.1641
Yi Meng	0.2500
Lan Ling	0.4141
Lv Nan	0.7500

The smaller the value of the objective function, then the higher the DC Location priority. From Table 5, the objective function value of 0.1641 Zhisheng station, the smallest in all the nodes, it should be considered Zha Lute DC Location Zhisheng station to ease the power shortage situation in Linyi region.

location feasibility check. Zha Lute DC project for placement Zhisheng tide stations respectively, short circuit, and stability check. The results show that the trend of a reasonable distribution of the site, each busbar short-circuit current in the circuit breaker are within the current range, there is no stability problems under N-1 fault conditions, the placement by checking feasible.

Conclusion

This paper proposes a method based on multi-attribute decision making of receiving-end power grid DC location selection, can fully consider the power grid stability and economy, Zha Lute DC project by the end of Shandong power grid placement choice proved the effectiveness of this method. In the rapid development of China's current project today, healthy and stable development of the method for DC receiving-end power grid has an important role in guiding.

Keywords micro-grid; relay protection; transient characteristics; control mode

Abstract. Micro grid can minish the impact from fluctuation of distributed generator by control and management system as a new type of power system. But micro-grid also brings disadvantages on power attemperation, function and relay protection. Firstly the inverter's electric model is built and the fault transient is simulated. Inverter interfaced distributed generator shows evident non-linear characteristic for the limits on power and current from control system. In this paper, according to the fault transient simulation results, analysis of the problems faced by the existing relay protection and corresponding solutions is given respectively.

Introduction

Clean energy such as wind power, photovoltaic power generation, as a clean, efficient, easy to get, no energy consumption of renewable energy, has become an important part of smart grid. New energy sources such as wind power, photovoltaic mostly in the form of distributed power supply connected to the electricity grid to facilitate centralized coordination management operation, so the micro grid change arises at the historic moment. Micro-grid is composed of all kinds of DG with various load distributed energy, system capacity generally between a few kW to a few MW, the voltage level is low or medium pressure. The traditional power transmission and distribution have been unified planning, current flow to one side of the distribution network. Because of the micro grid access of distributed power supply, current flow is no longer a one-way [1][2][[3].

Micro-grid allows distribution network rendering multiple power features, making the distribution network does not work based on three-current protection current amplitude. For micro-grid, the bidirectional trend makes micro-grid protection selectivity is difficult to do, interconnection and island operation is facing a large difference of short circuit fault current. Aiming at 10kV voltage level microgrid, including wind power, photovoltaic and turbine power generation system, in parallel operation mode failure cases, the article simulates and analysis transient fault features, to illustrate problems of the micro network relay protection, and put forward ideas.

Micro-grid model and parameters

A micro-grid model builded in PSCAD is shown in Figure 1[4][5][6]. In the model photovoltaic systems, wind power systems and turbine generator systems are rectified by step-up transformer inverter then by 0.4/10kV access to micro-grid, respectively. Micro-grid internal transmission line is a short distance transmission, the length of the transmission line as shown in the figure 1 with resistance of 0.1209 Ω / km and with positive sequence reactance of 0.386Ω/ km.

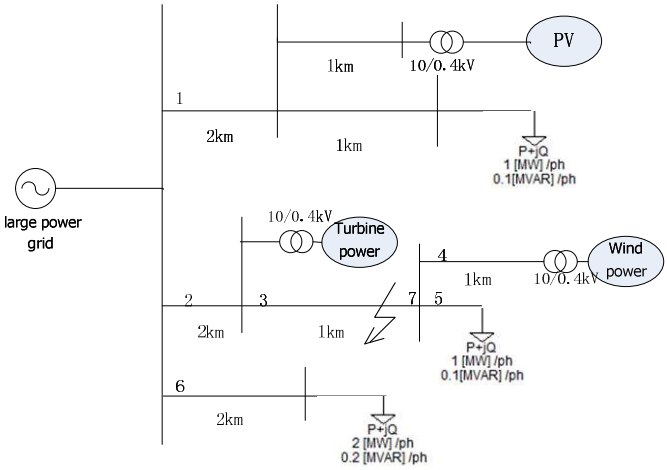

Figure 1 Micro grid model structure

Wind power system inverter adopts constant dc voltage control method, as shown in figure 2. Filter is using RLC filter. PV system inverter control method use fixed DC voltage and the filter circuit use RLC filter. Turbine power generation system inverter side uses PQ control and the control structure is shown in figure 3.

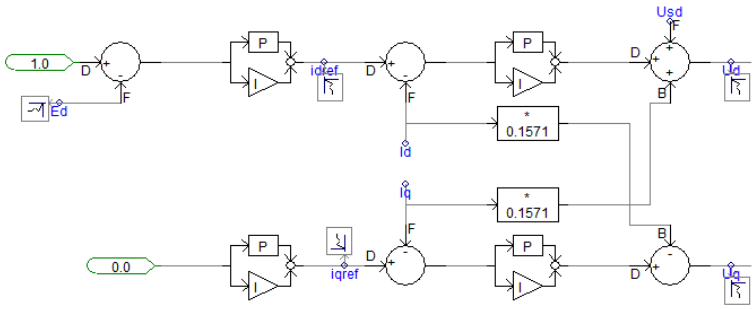

Figure 2 Dc voltage control mode

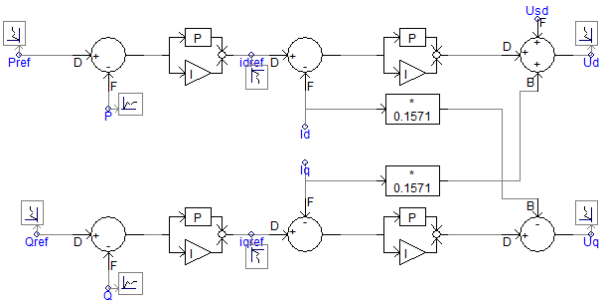

Figure 3 PQ control mode

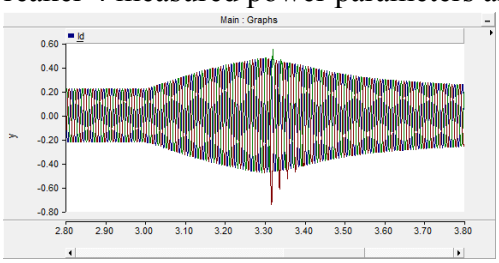
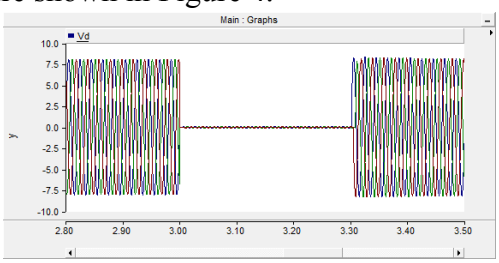
Micro -grid fault features

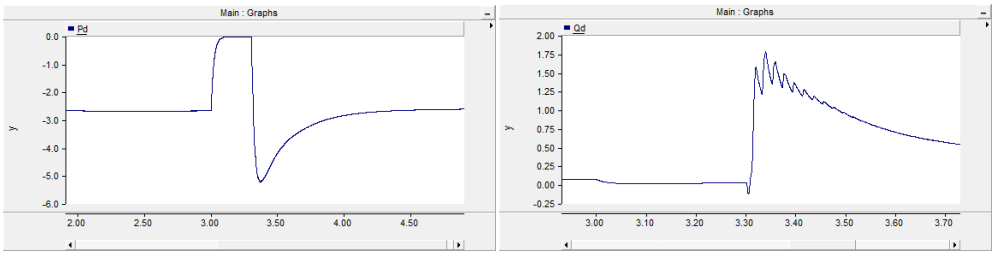
In figure 1 fault location in 3.0 s set three phase fault, and the fault for 0.3 s. For power flow direction is by grid outflow for the positive direction. For motor taking out is for the positive direction. Breaker 4 measured power parameters are shown in Figure 4.



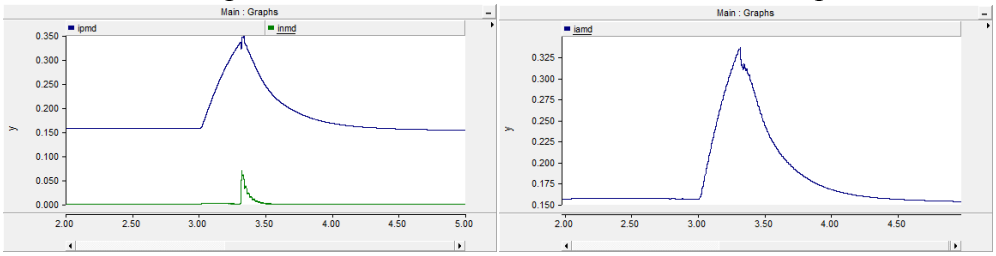
a）current



b）voltage



c） active power d） reactive power

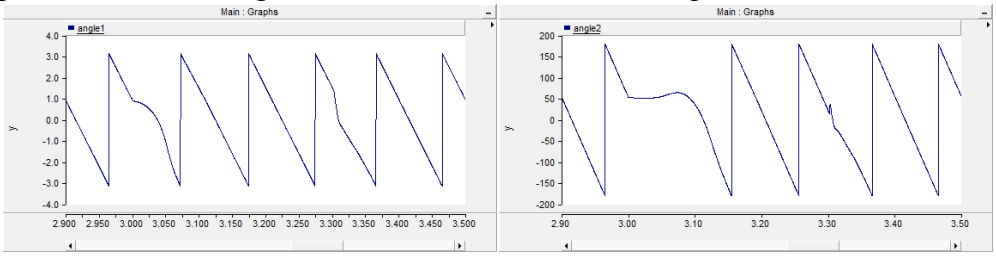


e） Positive sequence and negative sequence current f） A phase current amplitude

Figure 4 Breaker 4 measured parameters

The path of the wind power generation system, although the current increases, the voltage decreases, but the large amount of power flow change, so it will not malfunction. (Overcurrent protection may malfunction, and the following as long as it comes to the direction of current discrimination, over-current protection not apply.)

In the position shown in figure 1 circuit breaker 7 measured parameters is as shown in figure 5.



a） current phase Angle at 3 position b） current phase Angle at 7 position

Figure 5 Breaker 7 measured parameters

Close to the power grid side (circuit breaker 3) the phase angle is no more than 4^{o}. Close to the wind power system the phase angle reaches 178^{o}. For the longitudinal differential protection, 180^{o} -178^{o} $=2^{o}$, so the ends of the angle difference is not large. This demonstrates that longitudinal current differential protection can run in the micro grid.

For micro power grid protection strategy

When fault occurs within the micro-grid, only faulty equipment should be removed to ensure the power range minimum; When the primary network failure, The micro network should splitting with the main grid and continue to run in an island state with load; when failure occurs in the micro grid, the relay protection should identify the fault location and remove fault element reliably.

For over-current protection, Micro-grid has distributed power grid access, which makes the distribution network based on the current amplitude of the over-current protection not work properly. Two-way flow make the selective of micro-network protection difficult to achieve selective. Distributed power supply smaller short-circuit current may cause over-current tripping.

For distance protection, distance protection is based on the measured impedance to reflect the distance from the point of failure to protect the installation, and according to the distances to determine the action time. The micro-grid contain distributed power with power electronic devices, which makes the fault current distributed power provided is generally several times the rated current,

so the tradition distance protection can not accurately measure distance in accordance with fault voltage and fault current. The fault current is reduced as provided, distance protection cannot guarantee sensitivity.

For pilot protection, longitudinal protection can be divided into longitudinal differential protection, comparative longitudinal direction and distance protection pilot protection categories. Longitudinal differential protection equipment price is higher, to determine the fault location and movement, but requires simultaneous sampling. Comparative longitudinal direction of protection does not require synchronous sampling, there is literature to be applied to the proposed micro-grid line protection. The longitudinal distance protection problems like distance protection are that the access of the micro-power makes fault impedance measurement deviations.

Conclusions

The article simulates and analysis transient fault features, to illustrate problems of the micro network relay protection. In wind power system, the application of power electronic control device makes the wind power system to provide only 2 ~ 3 times of the rated short circuit current, so the application of relay protection method should be able to meet the characteristics of fault current. Longitudinal current differential protection can run in the micro grid.

Keywords: PV plants; MPPT; PSCAD; converter and control system.

Abstract. In order to investigate the impacts of large scale PV power plants on the stability of power system, dynamic PV models are of particular interest to the industry for simulating large-scale power systems. The transient model of large scale grid-connected PV generation system was given based on the model of each component of PV generation system. Response of the model was simulated respectively when the illumination changes. The methods proposed could be applied to the power grid with photovoltaic generation integration.

Introduction

In recent years, as the technology of PV is increasing steadily, large-scale grid-connected PV plants have broad prospects [1] ,However, large-scale PV power stations also exists a large number of technical issues needing to improve and perfect [2]. Considering the random fluctuation power, more issues may also appear in large-scale PV power plants, such as the harmonics, power quality and stability problems. With the increasing penetration of PV power plants, in order to investigate the impacts of large scale PV power plants on the stability of power system, dynamic PV models are of particular interest to the industry for simulating large-scale power system. The model which reflects the inherent mechanism and external mathematical characteristic of PV plants is required [3-6].

Basic composition of MW level PV plants

Large-scale photovoltaic power plants are generally composed of one or more of the basic units shown in Fig.1, where each unit is about 1MW. For example, one 10MW PV plant, it has twenty 500kW basic units. Among them, the large area of PV array component makes the photoelectric conversion and assigns the DC through the convergence device to the inverter part, and then the inverter and the filtering device convert the DC to AC that meets the quality requirements of the grid. In order to reduce the transmission loss, the transformer is required to raise its secondary voltage level (to 10/35kV). The inverter or the first stage integrated DC/DC converter also adjusts the PV output voltage for maximum power point tracing (MPPT).

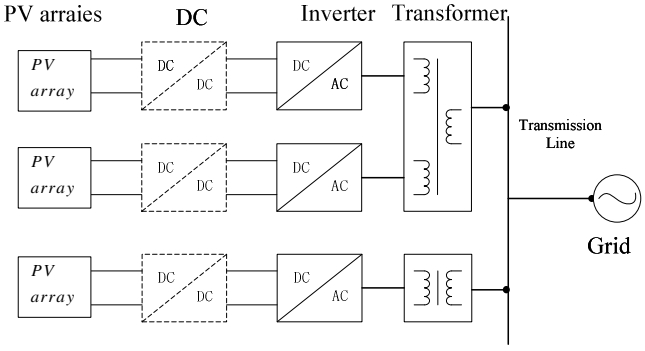

Fig.1 Topology of large-scale PV plants

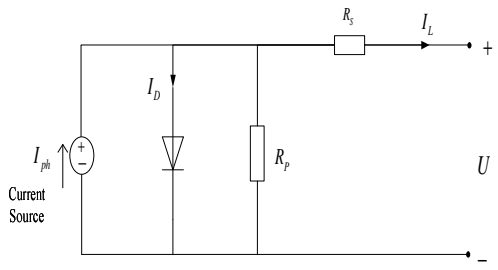

Fig 2 PV cell current-voltage characteristics

Modeling of PV array

Choose the simplification model which is used by project, the input and output characteristics of the photovoltaic battery can be expressed by the following formula:

$$I_L = I_{SC}[1 - C_1(\exp\frac{V}{C_2 V_{OC}} - 1)] \tag{1}$$

Whereby: $$C_1 = (1 - \frac{I_m}{I_{SC}})\exp(-\frac{V_m}{V_{OC}}), C_2 = (\frac{V_m}{V_{OC}} - 1)[\ln((1 - \frac{I_m}{I_{SC}})]^{-1} \tag{2}$$

Note:The four parameter is the test result on the condition of standard cell temperature $T_{ref} = 25^0$ and standard light intensity $S_{ref} = 1000W/m^2$ provided by the PV cell producer, so it must be amended by the actual temperature and light intensity, that is:

$$\Delta T = T - T_{ref}, \Delta S = \frac{S}{S_{ref}} - 1 \tag{3}$$

$$I_{scc} = I_{sc}\frac{S}{S_{STC}}(1 + \alpha\Delta T), I_{mm} = I_m\frac{S}{S_{ref}}(1 + \alpha\Delta T) \tag{4}$$

$$U_{occ} = U_{oc}(1 - \gamma\Delta T)\ln(e + \beta\Delta S), U_{mm} = U_m(1 - \gamma\Delta T)\ln(e + \beta\Delta S)$$

Among it, I_{scc}, U_{occ}, I_{mm}, U_{mm} is the short current, open voltage, peak power current, peak power voltage; T is the cell temperature; S is the light intensity; α, β, γ is the constant coefficient, experience value is $\alpha = 0.0025$; $\beta = 0.5$, $\gamma = 0.0028$.

Maximum Power Point Tracking techniques (MPPT)

It is also noticeable that the P-V curves present a unique maximum power point (MPPT) under given atmospheric conditions. The MPPT varies under different atmospheric conditions, thus I_{PV} or V_{PV} should be adjusted in an adequate way to track the MPP under these varying conditions.

The perturbation and observation method has been widely used because of its simple feedback structure and fewer measured parameters. The schematic diagram perturbation and observation method is shown in Fig. 3. It is based on the following criterion: if the operating voltage of the PV array is perturbed in a given direction and if the power drawn from the PV array increases, this means that the operating point has moved toward the MPP, therefore, the operating voltage must be further perturbed in the same direction. Otherwise, if the power drawn from the PV array decreases, the operating point has moved away from the MPP and, therefore, the direction of the operating voltage perturbation must be reversed.

Modeling of the control strategy for converters

The inverter control, which its aims is to control the active injected into the grid; control the reactive power; control voltage at PCC; control the DC bus voltage; ensure high quality of the injected power; Grid synchronization.

It can be get the converter and the transient mechanical and electrical mode of inner control system，as the fig 4 shown, where u_d ,u_q and i_d , i_q are the d- and q- axis components of the three phase inverter's output voltages and currents respectively; u_{gd} and u_{gq} are the d-and q- axis components of the grid voltage. Then all the AC current variables are all converted to the DC current ones; the active and reactive powers can be decoupled with each other. So, it is beneficial to achieve good close-loop control performance by PI controllers. Use voltage current double closed loop vector control strategy based on two phase synchronization *dq* coordinatesystem to control Photovoltaic Grid-connected generation system.

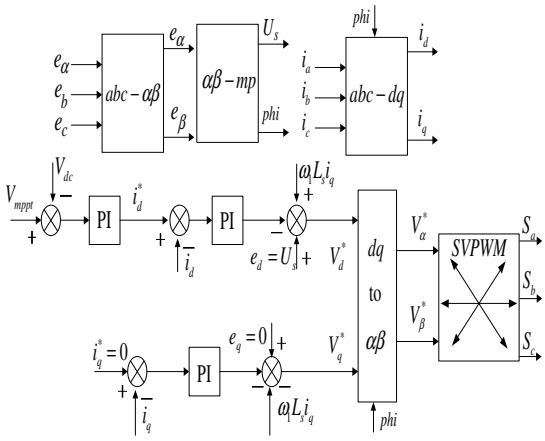

Fig.4 Main circuit of PV converter and control

Case Study

Modeling and simulation of a PV plant

A 10MW photovoltaic power plant is taken as an example for modeling. The PV plant consists of 10 unit structures shown in Fig.1. Each unit is 1MW and consists of two 500kW inverters that are connected to the1.2MVA transformer with two sets of three-phase primary windings. The inverter's output AC voltage is 270V. The three-winding transformer raises the voltage to 10kV, and connected to the terminal of distribution grid. Electromechanical modeling of large-scale grid-connected photovoltaic systems are developed on PSCAD/EMTDC.

Considering that the irradiance is equal to the whole PV array, but varies from 500W/m^2 to 1000W/m^2 at 2s, the power injected to grid, the waveforms of grid current in single inverter, the capacitor voltage and the MPPT voltage, are shown in fig5 respectively. The temperature is 25^{0}C in the simulation. From fig.5, it can be found that the PV plant is under unit power factor operation. The output power and grid current vary with the irradiance. The inverters can track the new maximum power point and maintain stable current output when the irradiance changes.

Summary

Based on the composition, inherent characteristic and mechanism of large-scale MW level PV plants, the model of PV array, inverter and its control system , and the grid interface are set up.The operation of a real MW-level PV plant is investigated by simulation in detail. Main results are summarized below:

(1) Large area PV array may have a multi-peak output character, and the proposed overall MPPT strategy is effective;

(2) The provided model represents the operation mechanism of large-scale MW level PV plants and is also suit for further researches, such as the impact of PV plants on the grid;

(3) Simulations validate the modeling. All these work make a foundation to the further research on electromechanical simulation of large-scale photovoltaic system connected in practical power grids.

Keywords: Battery energy storage system (BESS), model predictive control (MPC), renewable energy resources (RER), optimal control

Abstract. This paper discusses using the battery energy storage system (BESS) to mitigate intermittency and sustain stability of distribution system integrating high penetration level of renewable energy resources (RER). The goal of the control is to have the BESS provide as much smoothing as possible, so that the RER power can be dispatchable in some kind and reliable. The effectiveness of model predictive control (MPC) based approach proposed in this paper have been tested by detail case study, also compared with the day ahead control strategy, load following strategy , and normal situation without energy storage which are usually used before. The result shows that the proposed MPC based approach is more practical, and more robust.

Introduction

Renewable energy resources (RER) such as solar and wind are environment friendly to reduce pollutants produced by conventional fossil power plants, and energy purchasing cost associated with rising fuel price. Many governments such as Germany, France, U.S. and China have recognized the advantages of RER, providing much favorable legislation to incent RER installations [1] and using. In the near future, some places will have a high penetration level of renewable generation, such as California will have 33% of its total electric generation from RER by 2030 [2], Yancheng district of Jiangsu province will have 34% of its total electric generation from RER by 2017, and electricity generation from RER have exceeded the conventional sources in some districts even now [3], [4].

As the penetration level of RER into the grid, it poses new challenges to the electricity market and grid operators, in that RER power outputs are intermittent, which may larger the deviations in frequency and voltage on the grid than before. If there is no suitable control and power management to these intermittent sources with high grid penetration, negative impact to the grid performance will give [5]. Since a large-scale BESS is an expensive option for power system operator, adopting a control strategy for optimal use of the BESS becomes a critical issue. Various studies for sizing and adaptive control of BESS to accommodate RER exist the literature, including BESS sizing problems such as maximizing the price arbitrate and improve renewable energy integration in distribution networks by forward dynamic programming [6], minimizing costs of BESS by stochastic linear programming [7], maximizing the service life-time/ unit cost index of BESS as mixed line programming [8], minimizing cost of an off-grid hybrid PV–Wind–Diesel system by genetic algorithm [9]. Other studies concerning control approaches of BESS not sizing such as using MPC to track battery state of charge (SOC) and to smooth wind power output [10]-[12], a rule-based two-threshold policy BESS charging and discharging control to maximize the benefit in an infinite horizon [13]. This paper focus on the control strategy of BESS to smooth the fluctuation and mitigate intermittency of RER power output, so that the RER may be dispatchable like conventional power plant in some kind. The MPC based control strategy proposed in this paper will be used to control the charge and discharge of BESS to smooth the RER power output as much as possible, and compensate

the forecast errors. This paper will discuss the sizing of BESS for mitigating RER fluctuation and intermittency, also analysis the sensitivity of control algorithm with different forecast errors. Case study results shows that the MPC based control strategy is more effective in smoothing RER fluctuation and more robust to forecast errors, a smaller BESS capacity will achieve the same performance by MPC based control strategy.

The remainder of the paper is organized as follows: Section Ⅱ describes the model used in this paper, Section Ⅲpresents the mathematical models of the strategies, a detail case study and analyses are given in Section Ⅳ, and conclusions are presented in Section Ⅴ.

Modeling and System Configuration

Assuming a distribution system are consisted of a lot of micro-grids, therefore, if every controller of microgrid can mitigate the fluctuation and intermittence automatically and cooperate with the supervisory controller, the power system will be sustain reliability and stability, and the RER will be dispatchable in some kind. The configuration of microgrid as Fig. 1 shows.

A microgrid consists of a local controller, local consumers (e.g. large cooling house), renewable generators (e.g., wind turbine or/and solar) and storage facilities (e.g., BESS), and connected with the external grid.

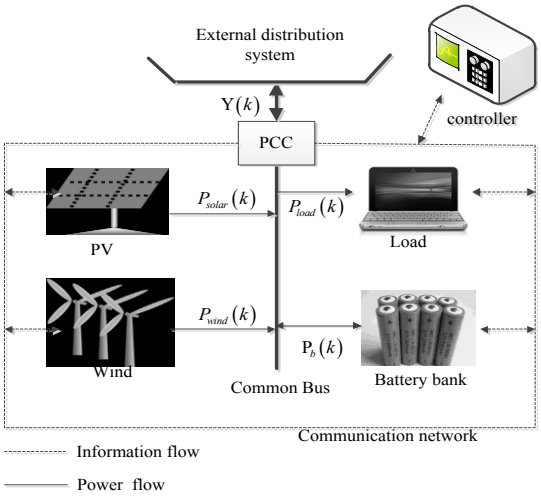

Fig. 1: Microgrid architecture

Fig. 1 precisely shows the interactions between the independent components in microgrid, the power transmitted into BESS at time period k is represented by $P_b(k)$, where $P_b(k) > 0$, indicates that BESS charge energy, which can be from RER or/also from the external grid, and $P_b(k) < 0$ $P_b(k) < 0$ indicates that BESS exports energy to compensate forecast errors or/and smooth the RER power output. Power generated by wind and solar at time period k is represented by $P_{wind}(k)$ and $P_{solar}(k)$ respectively. Load demand at time period k is represented by $P_{load}(k)$. Net power injected into or supplied from the external grid is represented by $Y(k)$, similar to BESS, if $Y(k) > 0$ $Y(k) > 0$, the microgrid transmitted extra energy to the external grid, in the opposite, the external grid transmits energy to the microgrid to keep power balance. The main objective should be reached in this paper and constraints should be met can be formulated as follows:

Objective:

$$Var = \left\{ (1/NM) \sum_{d=1}^{M} \sum_{k=1}^{N} \left[Y(k) - (1/N) \cdot \sum_{i=1}^{N} Y(k) \right]^2 \right\}^{\wedge(1/2)} \quad (1)$$

Where M represents the whole simulation horizon (e.g. one year), and N represents one finite receding horizon (e.g. one day). The main objective is to smooth the power flow in the microgrid and shafting peak power, which resulted in sustaining the microgrid reliable and stable as much as possible and (1) must subject to the following constraints.

Constrains:

(1) Energy balance constraints: The load demand at time interval t should be equal to the energy supplied by RER, BESS and the external electric network over the whole scheduling time range. That is

$$Y(k) = P_{wind}(k) + P_{solar}(k) - P_{load}(k) - \eta P_b(k) \quad (2)$$

(2) BESS operation constraints: The energy stored in BESS and power charged or discharged at any time interval k should be subject to:

$$SOC_{bmin} \le SOC_b(k) \le SOC_{bmax} \quad (3)$$

$$D_{max} \le P_b(k) \le C_{max} \quad (4)$$

$$SOC_b(k) = SOC_b(k-1) + (\eta P_b(k)\Delta t)/Q \quad (5)$$

D_{max} represents the maximum discharge power of BESS, and C_{max} represents the maximum charge power of BESS, they both are constant. $SOC_b(k)$ represents the state of charge at the end of each period, η represents the BESS discharge and charge efficiency, Δt represents the time interval of each period, and Q denotes the capacity of the BESS.

(3) Available RER and load demand constraints. Including each renewable energy generator has its maximum and minimum generation limit, and the energy supplied by them should not excess the limit.

$$0 \le P_{wind}(k) \le P_{wind}max \quad (6)$$

$$0 \le P_{solar}(k) \le P_{solar}max \quad (7)$$

$$0 \le P_{load}(k) \le P_{load}max \quad (8)$$

The utilized RER power is equal to or less than the available RER power. Extra RER energy will be curtailed.

(4) Power grid congestion constraints.

$$0 \le P_{grid}(k) \le P_{grid}max \quad (9)$$

The power transmitted into or from the external electric network cannot excess the limit of the transformer.

BESS Control Strategies

Many new infrastructure and technologies are put into for better integration RER, by taking advantage of the communication network, rich data and information can be sent and received from each component of microgrid in a timely fashion, as shown in Fig. 2. Study results have shown that RER power output (e.g. wind and solar) and load demand can be modeled effectively using autoregressive (AR) processes or machine learning or other methods in short term prediction. As communication network and forecast methods are not the focus of this paper, the communication network and forecast information are assumed to be given.

The operation of BESS is very flexible and behaves very different, which can be operated to as generation, load, or simply standby according the needs of distribution system operator or local operator. How BESS is operated has a major impact on microgrid reliability and economic benefits. In this section, BESS control strategy of day-ahead programming [14], MPC based programming and load following control strategy [15] are presented. Approach for microgrid power fluctuation smoothing of these strategies is discussed.

Strategy 1: MPC based BESS control strategy. MPC is widely used in control community (e.g. transportation network, and power plants unit commitment) to manage systems with high dynamic characteristics and uncertainties, due to its ability to use a prediction of system evolution to establish an updated control response.

MPC based operation control is a real-time strategy, the detail control strategy operated at period k can implemented as follows:

(1) Obtain the actual RER power output and load demand in current period i.

(2) Select a receding optimization horizon N periods (e.g. one day), then use forecast model of RER power output and demand to obtain the most updated information of them for the period $i+1$ to $i+\mathrm{N}$.

(3) Solve the real-time energy shifting problem, formulated as

$$\min\left\{(1/N)\cdot\sum_{k=i+1}^{i+N}\left[\mathrm{Y}(k)-(1/N)\sum_{k=i+1}^{i+N}\mathrm{Y}(k)\right]^2\right\}^{\wedge(1/2)} \tag{10}$$

Subject to constraints (2)-(9), and $k=i+1,i+2,\cdots,i+\mathrm{N}$.

(4) Implement the first period operation of the above optimization problem, which is BESS should be operated at time interval $i+1$.

(5) Update the BESS state, move to the next period and then repeat form 1) to 5) in the whole simulation horizon.

Strategy 2: Day ahead programming strategy. Optimize the BESS operation day-ahead with the day-ahead microgrid state and forecast information of the next day, and then implement the plan in real-time. The objective function is

$$\min\left\{(1/N)\sum_{k=1}^{N}\left[\mathrm{Y}(k)-(1/N)\sum_{i=1}^{N}\mathrm{Y}(k)\right]^2\right\}^{\wedge(1/2)} \tag{11}$$

Subject to constraints (2)-(9), and $k=1,2,\cdots,\mathrm{N}$. The microgrid controller will schedule the BESS operation of the next day, and will operate BESS according to the schedule strictly. To the next day will repeat this algorithm of (11).

Strategy 3: Load following strategy. No forecast information is needed to this strategy; the operation under this strategy is based on real-time microgrid information. In real-time operation, BESS will charge as much as possible unless reaching operation limits if not fully charged and is positive, then inject the surplus energy into the external grid [15]. In the opposite case, BESS will discharge as much as possible unless reaching operation limits if there is enough energy stored in the BESS, if cannot compensate the mismatched energy yet, will absorb additional energy from the external grid.

Case Study and Results

In this section, we will study the performance of mitigating fluctuation of the microgrid of the all above strategies though a series of case, and discussion the relationships referred.

The time interval $\Delta t=1hour$, which means $\mathrm{N}=24$, and $\mathrm{M}=365$ the profiles of RER power output and load demand are extracted from the website of "elia" [16] and simplified the data, and the BESS capacity constraints are soft constraints as in Fig. 3 in order to avoid system infeasibility in case of high forecast errors. BESS charge and discharge bounds are $SOC_{bmax}=2700kwh$, and $SOC_{bmin}=300kwh$ the BESS charge variation bounds $\mathrm{D}_{\max}=-800kw$, $\mathrm{C}_{\max}=800kw$ (merely19.2% of the peak demand power), η=0.95.

Next, Fig. 2 shows the solar power $P_{solar}(k)$ output, wind power $P_{wind}(k)$ output, load demand $P_{load}(k)$, and net generation from top to down, respectively.

For case study, the forecast error is needed. According to the research work on RER forecast and load demand forecast, a simplified real-time net generation forecast error is used instead to represent the forecast errors. This was formulated as follows:

$$Y_{real}(k)=Y_{real}(k)\cdot\left(1+E_{P,max}\cdot R_P\right) \tag{12}$$

Where $Y_{real}(k)$ is the forecast value of net generation power for the microgrid at future period k, $Y_{real}(k)$ is the real-time net generation of microgrid at period k, $E_{P,max}$ is random number with a Gaussian distribution, with mean value 0 and variation 1, R_P is the maximum forecast error percentage for future period k.

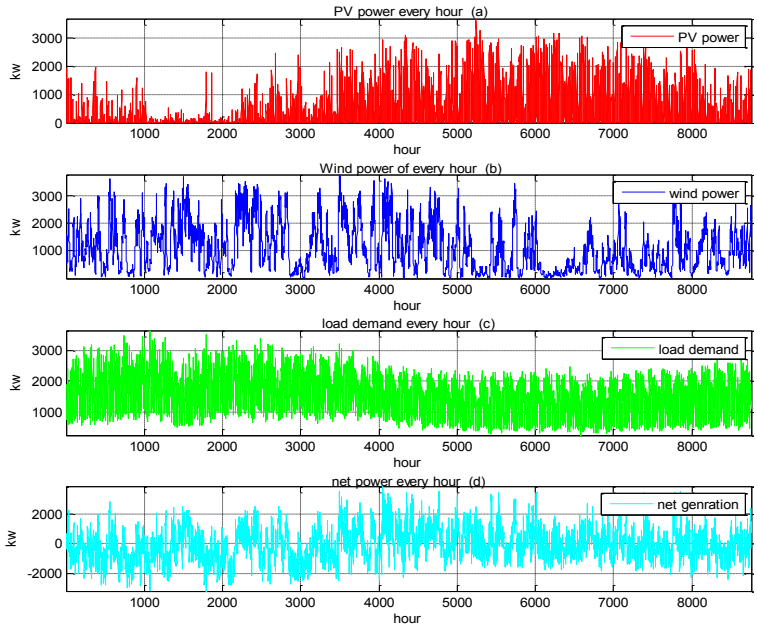

Fig. 2 Power generation and load demand of the grid-connected HES day ahead forecasted

First, for better understanding the performance of each strategy, a simple case with two typical days will be studied first. The performance of all strategies in mitigating fluctuation of the net-generation power flow in microgrid of the two days is shown in table Ⅰ,and Fig. 3.

Table I. Performance of alleviating fluctuation of the net-generation on the whole horizon period (two days)

index	Dispatch strategy			
	Strategy 1	Strategy 2	Strategy 3	Normal situation
Var	526.3576	534.445	623.0287	771.9786

Indicator of *Var* represents the standard deviation power flowed in the common bus of microgrid, which is the main index to evaluate the performance of each strategy in mitigating fluctuation of power flow in microgrid. Indicator of peak power P_{peak} is used to evaluate the performance of each strategy in power leveling in microgrid.

The values of table Ⅰ are obtained from the net generation uncertainty of 15%. From the values in table Ⅰ and two day case results in Fig. 3, we could find that MPC based approach have the best performance in mitigating power fluctuation of microgrid, day-ahead programming cannot deal with forecast errors effectively in real-time. And we could find BESS under load following strategy have no independence, all operation was determined by net generation $Y(k)$ and BESS constraints.

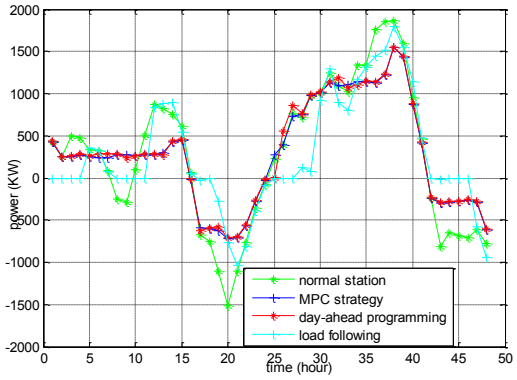

Fig. 3: Performance of alleviating fluctuation of the net-generation about all strategies (two days case)

Next, the impaction of mitigating fluctuation performance of all strategies presented in this paper will be discussed with different forecast error level in whole horizon. The net generation uncertainty of $E_{P,max}$ is assumed 0%, 5%, 10%, 15%, 20%, and 25% respectively. For saving space, we shorted forecast uncertainty as FOU. The results of robust study are shown as follows:

Table Ⅱ. Performance of all the strategies in mitigating fluctuation of RER and progressing power quality of one year

index		Dispatch strategy			
		Strategy 1	Strategy 2	Strategy3	Normal situation
Var	FOU (0%)	412.545	412.545	584.7724	685.5841
	FOU (5%)	410.187	407.005	586.8724	696.2485
	FOU (10%)	416.622	417.037	593.7003	707.9431
	FOU (15%)	424.525	434.191	613.8278	720.0404
	FOU (20%)	445.322	462.445	638.2989	739.655
	FOU (25%)	463.188	503.374	683.8895	751.7926

Table Ⅱ shows the standard deviation of power flowed in microgrid facing 6 different levels of forecast uncertainties.

Discussion and Conclusion

This paper proposes using MPC based approach to control the charge and discharge of BESS for mitigating and smoothing power flow in a microgrid. A detail case study implanted for evaluating the performance of the proposed BESS control strategy and three other strategies, the simulating results show that MPC based BESS control strategy can achieve both more smooth power flow of microgrid and robust performance, which means to cover the same performance of RER power output fluctuation and microgrid power flow the strategy of MPC based approach needs deploy less BESS than the other strategies, namely, more economic.

Future work will be focused on: 1) optimal operation management analysis of grid-connected or isolated microgrid; 2) more sophisticated BESS model to analysis of all the strategies; 3) economic analysis will be included.

Keywords: second order loss-reactive power sensitivity matrix; sensitivity analysis; hierarchical clustering; location of capacitors; distribution system

Abstract. Heuristic methods by first order sensitivity analysis are often used to determine location of capacitors of distribution power system. The selected nodes by first order sensitivity analysis often have virtual high by first order sensitivities, which could not obtain the optimal results. This paper presents an effective method to optimally determine the location and capacities of capacitors of distribution systems, based on an innovative approach by the second order sensitivity analysis and hierarchical clustering. The approach determines the location by the second order sensitivity analysis. Comparing with the traditional method, the new method considers the nonlinear factor of power flow equation and the impact of the latter selected compensation nodes on the previously selected compensation location. This method is tested on a 28-bus distribution system. Digital simulation results show that the reactive power optimization plan with the proposed method is more economic while maintaining the same level of effectiveness.

Introduction

In the radial distribution systems, capacitors must be installed in order to compensate the reactive power of the loads to reduce energy losses, to improve the voltage magnitude profile. Optimal capacitor placement (OCP) problem as a significant and vital issue has been investigated widely.

Optimal capacitor placement is a mixed integer non-linear programming problem, which consists in determining the optimal locations and sizes. The solution techniques for the OCP problem can be classified into four categories [1]: analytical, numerical programming, heuristic, and artificial intelligence-based (AI-Based).

Analytical methods were based on unrealistic assumptions of a feeder with a constant conductor size and uniform loading [2]. Numerical programming methods require more time than for analytical methods [3]. Heuristic methods pinpoint the sensitive node by sensitivity analysis in that section having the greatest effect on the system loss reduction to decrease the exhaustive search space for large distribution systems [4]. AI methods have demonstrated fine capabilities for capacitor placement, but the computational burden is nevertheless heavy, especially for large distribution systems. And they suffer from the inability to escape local optimal solutions and encounter non-convergence problems which can be troublesome to rectify [5-9].

To overcome this issue, the OCP problem of distribution system can be divided to two problems, first determining the locations of capacitors by heuristic methods and then identifying the sizes of capacitors by AI methods. It can effectively reduce the computation burden and the size of search space to avoid local optimal solutions [10]. So determining the locations of capacitors is important.

Heuristic methods often use sensitivity analysis to calculate static first order sensitivity of power loss to node reactive power under primary distribution system before installing capacitors to select the candidate buses of capacitors [11-13]. In a feeder line maybe there are several nodes with higher sensitivity. However there is one node with really high sensitivity. Other nodes that are near the node

and have high sensitivity may have not real high sensitivity. When the node with real high sensitivity has installed capacitors, other nodes with higher sensitivity have significantly decreased lower sensitivity, which is called virtual high sensitivity node. It is caused by nonlinear of power flow equations. Especial when location of capacitors is much in the whole buses, the nonlinear of power flow equations could not be neglected. Obviously, first order sensitivity analysis ignores the nonlinear of power flow, which could be a big barrier to reach the maximum efficiency. And the numbers of OCP could not be determined by first order sensitivity.

To consider nonlinear of OCP problem, this paper proposes a novel method using dynamic second order power loss sensitivity analysis and hierarchical clustering to select optimal candidate location of capacitors for distribution systems and determine optimal capacities by improved genetic algorithms. Dynamic second order power loss sensitivity analysis and hierarchical clustering can consider nonlinear of OCP problem to avoid virtual high sensitivity node to be selected as candidate nodes. Improved genetic algorithms determine the upper and lower limit by heuristic methods and regulate the sufficiency by hierarchical clustering. Computer program to implement the proposed method is written in C++. Simulations with a 28-node test system are implemented. The test results validate the proposed method.

The contents of the paper are as follows. In Section 2 second section the second order loss-reactive power sensitivity matrix is build. In Section 3 hierarchical cluster for nodes of each distribution feeder is introduced. In Section 4 the method of the optimal candidate location and capacitors using second order loss analysis and hierarchical cluster is proposed. In Section 5 Capacity of capacitors could be determined by improved genetic algorithm. In the last section the simulation results with a 28-node test system are shown.

Second order loss-reactive power sensitivity matrix (SOLPSM) calculation

Suppose there are *n* nodes in a distribution system, then the active power loss is calculated as:

$$P_{\mathrm{L}} = \sum_{i=1}^{n}\sum_{j=1}^{n} U_i U_j (G_{ij}\cos\delta_{ij} + B_{ij}\sin\delta_{ij}\} \tag{1}$$

So, the first order loss-reactive power absolute sensitivity can be calculated using equation (2):

$$\frac{\partial P_{\mathrm{L}}}{\partial \boldsymbol{u}} = (\boldsymbol{J}^{\mathrm{T}})^{-1}\frac{\partial P_{\mathrm{L}}}{\partial \boldsymbol{x}} \tag{2}$$

Where x is voltage variable matrix $\boldsymbol{x} = \begin{bmatrix} \boldsymbol{\delta} \\ \boldsymbol{U} \end{bmatrix}$; u is node input power matrix $\boldsymbol{u} = \begin{bmatrix} \boldsymbol{P} \\ \boldsymbol{Q} \end{bmatrix}$; $\boldsymbol{J}$ is Jacobian matrix.

Because of the nonlinearity of distribution system, the first order loss-reactive power sensitivity has bigger error when there are many reactive power compensation locations.

In this paper, the second loss-reactive power sensitivity is derived in equation (3).

$$\begin{aligned} \frac{\partial^2 P_{\mathrm{L}}}{\partial \mathbf{u}\partial \mathbf{u}} &= \partial\left(\frac{\partial P_{\mathrm{L}}}{\partial \mathbf{x}}\cdot\frac{\partial \mathbf{x}}{\partial \mathbf{u}}\right)/\partial \mathbf{u} \\ &= \frac{\partial P_{\mathrm{L}}}{\partial \mathbf{x}}\cdot\left(-\mathbf{J}^{-1}\cdot\sum_{j=1}^{n}\frac{\partial \mathbf{J}}{\partial x_{\mathrm{j}}}\frac{\partial x_{\mathrm{j}}}{\partial \mathbf{u}}\cdot\mathbf{J}^{-1}\right) + \left(\sum_{j=1}^{n}\frac{\partial^2 P_{\mathrm{L}}}{\partial \mathbf{x}\partial x_{\mathrm{j}}}\frac{\partial x_{\mathrm{j}}}{\partial \mathbf{u}}\right)\cdot\mathbf{J}^{-1} \end{aligned} \tag{3}$$

Second loss-reactive power sensitivity can show the coupling between different reactive power equipment nodes.

According to Taylor series expansion,

$$\Delta P_{\mathrm{L}} = \frac{\partial P_{\mathrm{L}}}{\partial \boldsymbol{u}}\Delta \boldsymbol{u} + \frac{1}{2}\Delta \boldsymbol{u}^{\mathrm{T}}\cdot\frac{\partial^2 P_{\mathrm{L}}}{\partial \boldsymbol{u}\partial \boldsymbol{u}}\cdot\Delta \boldsymbol{u} \tag{4}$$

In equation (4), ΔP_L is called loss-reactive power revised sensitivity when first order sensitivities and second order sensitivity matrices are calculated and $\Delta u \ \Delta u$ is set as the one percent of total reactive power. If $\Delta u \ \Delta u$ equals the node reactive power increment, then the second loss increment of distribution system can be obtained. If the second order items are ignored in equation (4), the first loss increment can be obtained.

$$\Delta P_L = \frac{\partial P_L}{\partial \boldsymbol{u}} \Delta \boldsymbol{u} \tag{5}$$

Hierarchical clustering

Nodes of each distribution feeder are hierarchical cluster in this paper. The main steps are as follows:

1) *n* nodes of each distribution feeder if firstly divided to *n* cluster.
2) Node distance is set as $\frac{\partial^2 P_L}{\partial Q_i \partial Q_j}$, which can reflect node mutual interaction.
3) Find the minimum distance of nodes, and the two nodes is combined to one cluster. Cluster distance is set as minimum distance between nodes in one cluster and nodes in another cluster.
4) When the cluster distance is more than the cluster threshold value, clustering stop. Otherwise turn to (2).

Determination of the optimal candidate locations of capacitors by SOLPSM **and hierarchical clustering**

The candidate locations of capacitors of distribution system can be determined using the second order sensitivity matrix, revised sensitivity and hierarchical clustering. The main steps are as follows:

(1) The first order loss-reactive power sensitivity is calculated by (2).

(2) The second order loss-reactive power sensitivity matrix is calculated by (3).

(3) The candidate nodes set is null at first. Then the unit reactive power increment is added nodes that are not in the candidate nodes set respectively. Finally the revised loss-reactive power sensitivities of the nodes that are not in candidate nodes set are calculated. From equation (3), the revised loss-reactive power sensitivity reflects the mutual effect between nodes and nonlinear factor of distribution system.

(4) By sorting the revised loss-reactive power sensitivities of nodes that are not in reactive power compensation node set, the node with maximum revised loss-reactive power sensitivity can be found. If the node is not the same cluster with the nodes, then the node is added to candidate nodes set. The nodes with virtual high sensitivities can be avoided to be selected by hierarchical clustering.

(5) By exhaustive searching, the trial compensation capacity of the selected node is determined. The capacity is installed in the node, by checking if power loss decrement is more than node investment charge.

If power loss decrement is more than node investment charge, then the selected node is selected in the candidate nodes set and then return to the first step. If not, then exit program. So with the method virtual high sensitivity nodes can be excluded and the number of capacitors can be determined.

Although the trial compensation capacity of nodes when selecting nodes is not the optimal value, they are near optimal value by the method.

(6) Install the trial capacity at the nodes within the candidate node set (except the just selected node), calculate revised sensitivity, and check if it's more than the revised sensitivity of the previously selected node. If true, then take the node out of the candidate nodes set. In doing so, the previously

selected nodes can be taken out if they are not good for power loss when latter selected nodes install relevant reactive power capacity.

(7) Following the procedures of (1)-(6), all optimal candidate nodes can be determined.

Improved genetic algorithms

Capacity of capacitors could be determined by improved genetic algorithm. The improved genetic algorithm proposes some modification to genetic algorithms. The main steps are as follows:

1) Coding. Real coded substring exists for new capacitor locations. Upper and lower limit value are set as the trial compensation capacity when determination of the optimal location of capacitors by SOLPSM and hierarchical clustering in order to reduce search space of genetic algorithm.
2) Selection. Remainder stochastic sampling is the selection scheme used. And by hierarchical clustering the fitness of the strings in the same clustering is adjusted to escape local optimal solutions as far as possible. If the fitness is large then the fitness is adjusted larger.

Case Study

A distribution system with 28 nodes and parameters are shown in reference 14.

Hierarchical clustering results of branches of 28 node system by second order sensitivity matrix are shown in Fig.1.

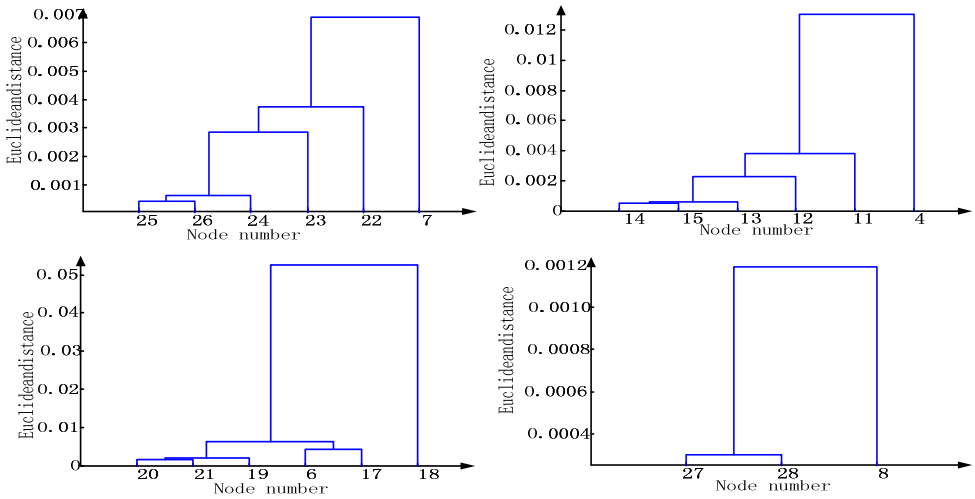

Fig.1 Hierarchical clustering result of branches of 28 node system

From Fig.1, branch {7, 22, 23, 24, 25, 26}have lesser distance than other branches. When the threshold value is set, clusters of each branch would be determined. If the threshold value is set as 0.002, it means that {24, 25, 26} is belong to the same cluster in branch {7, 22, 23, 24, 25, 26}, {13, 14, 15}is belong to the same cluster in branch {4,11,12,13,14,15},{8, 27, 28} is belong to the same cluster in branch {8, 27, 28}.When the candidate nodes are selected by second order revised sensitivity, the nodes in the same cluster are only selected one.

The node selection results by first order sensitivity and second order sensitivity are shown in Table 1.

Table.1 Loss with many locations by different sensitivity analysis method

	Node selection by first order sensitivity	Node selection by second order sensitivity
Reactive power compensation nodes	24,11,28,26,20,8,15	25,28,22,20,14,6,11
Power loss before compensation (kW)	86.48	86.48

Power loss after compensation (kW)	40.51	40.25
Lowest voltage before and after compensation	0.8921/0.9485	0.8921/0.9489
Total benifit rmb）	10.79	10.85
Total compensation capacity (kvar)	630	610

From Table 1, the selected nodes of the reactive power compensation by second order power loss based sensitivity analysis and genetic algorithm are different from the selected nodes of the reactive power compensation by first order power loss based sensitivity analysis. And the power loss decrement and total benefit by second order power loss based sensitivity analysis are more than that by first order power loss based sensitivity analysis. It shows that optimal capacitors replacement method by second order power loss based sensitivity analysis, hierarchical clustering and improved genetic algorithm is valid.

Summary

This paper presents an effective method to optimally determine the location and capacities of capacitors for distribution system, based on an innovative approach by the second order sensitivity analysis, hierarchical clustering and improved genetic algorithm. Comparing with the traditional methods, the new method considers the nonlinear factor of power flow equation and the impact of the latter selected nodes on the previously selected location. This method is tested on a 28-bus distribution system. Digital simulation results show that the capacitors replacement by the proposed method is more economic while maintaining the same level of effectiveness.

Keywords: STATCOM; enterprise grid; configuration strategy; power quality

Abstract. Considering different kind of external grid failures, this paper gives analysis of voltage fluctuation and flicker of large petrochemical enterprise grid. Trajectory-based time-domain dynamic simulation method is used to analyze problems of transient voltage security. A strategy for the application of STATCOM is proposed in order to improving electric power quality. The total loss of motor load of the whole system is counted and buses are sorted according to sensitivity analysis to ascertain installing sites of STATCOM. Then the optimal capacity of STATCOM can be gained by the way of solving linear programming model, which is suitable for transient voltage security under multi-faults. Test simulations show very encouraging result.

Introduction

With the development of power system and constant improvement of the level of industrial automation, power consumers have increasing requirements for electrical power quality and reliability. Recently, some measures have been taken to meet the requirements of power quality. However, it is still an important issue that whether the power grid could maintain its stability while it is disturbed. As a new kind of dynamic reactive power compensation device, STATCOM could be applied to improve system power factor and suppress system voltage fluctuation and flicker.

1. Modeling for Enterprise Grid

Qingdao Petrochemical Enterprises grid is used as an example. This power grid is linked to Haihe 220kV transformer substation of external power grid by two 110kV lines. It is divided into two parts by two 110kV transformer substation and each of them contains seven 35kV transformer substations. Fig. 1 shows the structure of this power grid. The influence of external grid failure should be taken into account in order to give analysis of voltage changes and motor load losses of the power system in this enterprise. Fig. 2 shows the structure of external power grid.

2. Problem of Voltage Stability in Enterprise Grid

2.1 Normal operation mode of external grid

There are two generators in this enterprise grid. Typically only one of them is operational while the other one is closed. A reasonable simulation is established to assess power system reactive voltage level. The analysis shows that all of nodal voltages are within the specified range.

2.2 Enterprise grid voltage perturbation analysis under external grid faults

Despite a certain reactive power reserve has been applied to ensure system voltage stability (generators and low voltage capacitors, etc.), but loss of motor loads will happen under several specified failures of external grid that are shown in Table 1.

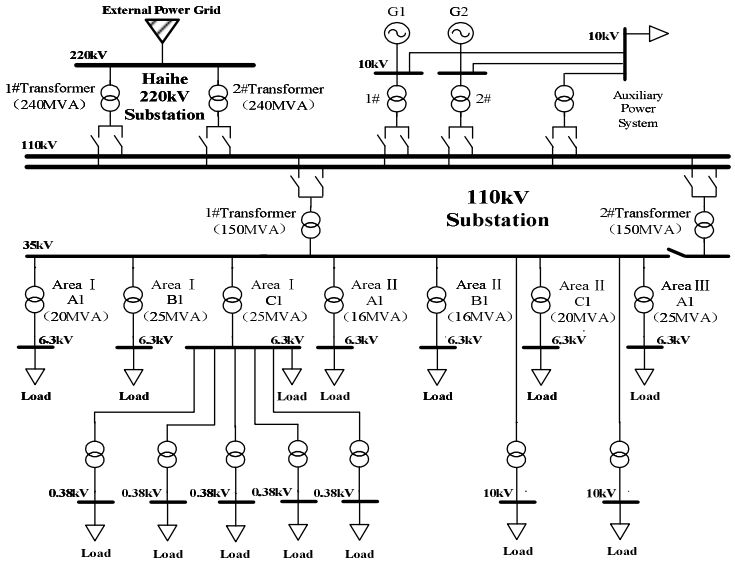

Fig. 1 Structure of Qingdao Petrochemical Enterprises grid

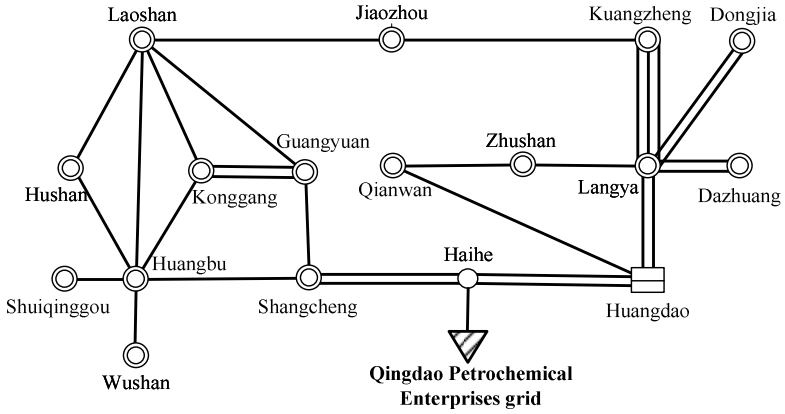

Fig. 2 Structure of external power grid

Tab.1 Loss of motor loads due to corresponding three-phase short-circuit faults

Fault Type	Fault Position	Loss of motor loads[MW]
Line	Haihe～Shangcheng	58.69
	Haihe～Huangdao	58.69
	Shangcheng～Huangbu	41.07
	Shangcheng～Guangyuan	41.07
	Huangdao～Qianwan	58.69
	Qianwan～Zhushan	*7.59
	Guangyuan～Laoshn	*7.59
	Guangyuan～Konggang	*7.59
	Jiaozhou～Kuangzheng	0
	Huangdao～Langya	0
	Laoshan～Hushan	0
Transformer	Haihe Substation 1#Transformer	14.42
Generator	Huangdao G1	65.69
Operation Mode Variation	Low voltage capacitors of Haihe Substation	0
	Load variation near Haihe Substation	0
	Output volatility of Huangdao G3	0

Voltage stability of the enterprise grid will be severely affected by three-phase short-circuit faults on external power lines near Haihe Substation. Bus voltage drops sharply after faults as is shown in Fig.3. The total loss of motor load of the whole system will be a large number.

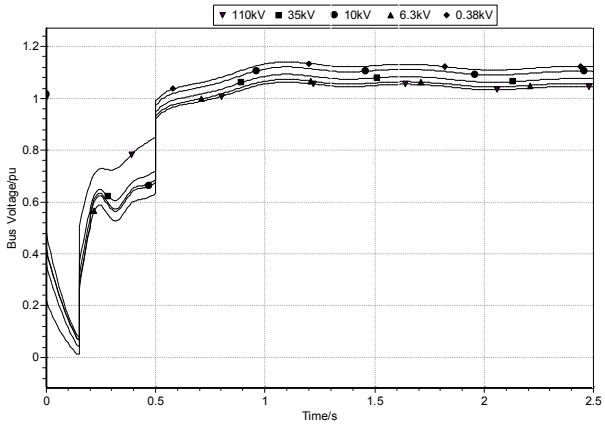

Fig. 3 Bus voltage recovery curve after Haihe~Shangcheng 220kV line fault

3. Analysis on Influences of STATCOM on Voltage Stability of Enterprise Grid

3.1 Comparison between STATCOM and SVC

STATCOM and SVC are two typical type of controllable reactive power generator. STATCOM is more effective and more rapid than SVC regarding to V-I characteristic, V-Q characteristic, transient stability and response time[1-4]. STATCOM's output is adjusted continuously to inject or absorb the reactive current. It can be treated as a shunt-connected synchronous voltage source. Comparison results between SVC and STATCOM is shown in Tab. 2.

Tab.2 Comparison between SVC & STATCOM

Items	SVC	STATCOM
Continuity of control	Discontinuous	Continuous
Control	Phase control	PWM Control
Phase delay (max.)	0.5 ~ 1 cycle	Very few
Low-order harmonics	Much	Small
Installation space	Large.	Small
Size of reactive components	Bigger	Small
Loss	Bigger	Very small
Response speed	Slow	Very fast

3.2 Analysis of allocation position of STATCOM

By the time that the voltage magnitude of system recovers to normal, sensitive buses can be ascertained. Then these sensitive buses are sorted according to sensitivity analysis. Both sensitive buses and region balance of system should be taken into account in order to ascertain installing sites of STATCOM. Based on the above analysis, two schemes of reactive power compensation are proposed that install STATCOM in low-voltage side of the transformer: Concentrated installation scheme (STATCOMs are installed in 35kV low-voltage side of the transformer in 110kV transformer substation.) and Decentralized installation scheme (each 6kV low-voltage side of the transformer in 35kV transformer substation will be installed a STATCOM device.)

3.3 Determination of optimal Capacity of STATCOM

The appropriate capacity of STATCOM should be determined to meet the requirements of voltage regulation which is suitable for transient voltage security under multi-faults. We treat the minimum of total capacity of STATCOM as objective function. By calculating the trajectory sensitivity of the magnitude of bus voltages to the capacity of each STATCOM, the transient voltage security constraints are transformed into linear inequality constraints of the capacity of STATCOM[5,6].

$$\min \sum_{i=1}^{n} S_{ci} \tag{1}$$

$$\text{s.t.} \begin{cases} \sum_{i=1}^{n} \left.\frac{\partial U}{\partial S_{ci}}\right|_{t=t_c+t_{\lim}} (S_{ci} - S_{ci}^{'}) + U_{(t_c+t_{\lim})} \geq U_{\lim} \\ \sum_{i=1}^{n} \left.\frac{\partial U}{\partial S_{ci}}\right|_{t=t_c+t_s} (S_{ci} - S_{ci}^{'}) + U_{(t_c+t_s)} \leq U_s \\ S_{ci\,\min} \leq S_{ci} \leq S_{ci\,\max} \end{cases}$$

The allocation capacity of STATCOM will influence the loss of motor loads. Take the concentrated installation scheme for example. The specific loss in different capacity will be analyzed by iterative calculation as is shown in Table 3. Finally, two 50 Mvar STATCOMs are installed (A total of 100 Mvar). A reasonable simulation experiment by BPA software is established to test and verify the above scheme. Test results show very encouraging result. All motor loads operate normally and no loss will happen after these failures that mentioned in Tab.1.

Tab.3 The specific loss in different capacity of STATCOM

Capacity of STATCOM[Mvar]	Loss of motor loads[MW]
0	51.1
10×2	51.1
20×2	33.48
30×2	32.04
40×2	20.4
45×2	9.77
50×2	0

Similarly, we can determine the optimal capacity of STATCOM of the decentralized installation scheme: each low-voltage side of the transformer in 35kV transformer substation will be assigned a 7 Mvar STATCOM device sequentially.

3.4 Simulation of applying STATCOM to enterprise grid

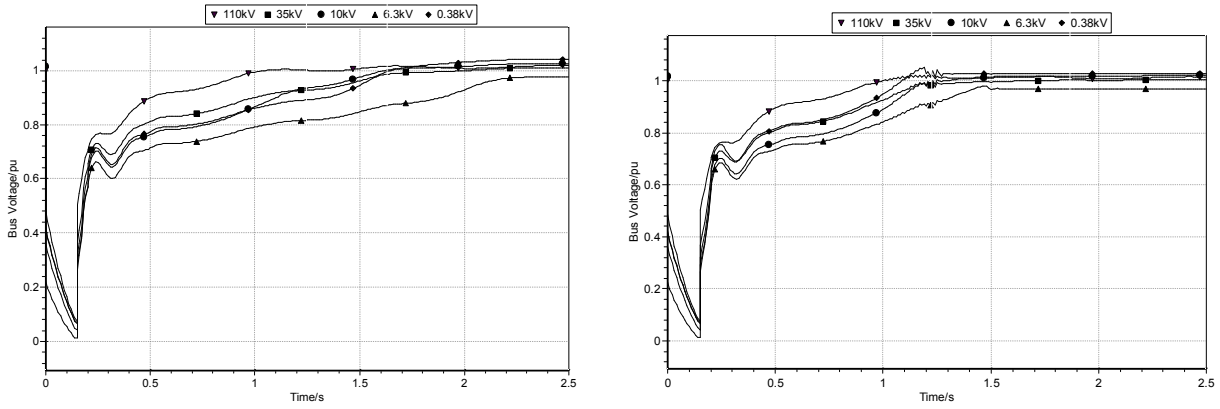
3.4.1 Determination of allocation position and optimal capacity of STATCOM

The dynamic reactive power response capabilities of reactive power compensation devices during the transient process are utilized to dynamically provide reactive power to the grid to mitigate voltage drop in real time. Fig. 4 shows the comparison curve of bus voltage recovery between concentrated installation scheme and decentralized installation scheme.

As can be seen from Fig. 4, decentralized scheme can help generator improve the reactive power responding speed effectively, consequently the transient voltage can be recovered faster than concentrated scheme.

3.4.2 Comparison on effectiveness between SVC and STATCOM

A comparison on effectiveness between SVC and STATCOM can be made. Take scheme I for example, a selected 35kV bus voltage changes curve with the same capacity of SVC or STATCOM (50×2 Mvar) is shown in Fig. 5. Obviously, the bus has a faster rate of voltage recovery by installing STATCOM than SVC.



a) concentrated scheme b) decentralized scheme

Fig. 4 Comparison curve of bus voltage recovery between concentrated scheme and decentralized scheme.

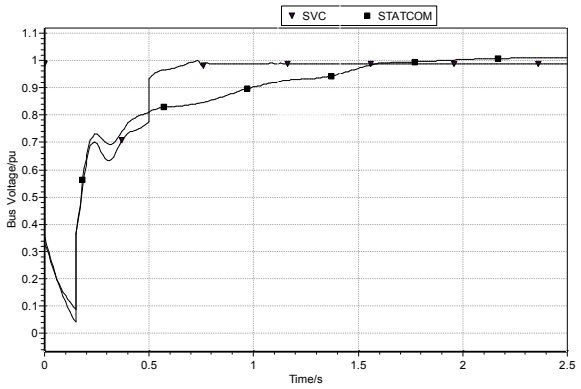


Fig. 5 35kV bus voltage recovery curve with the same installed capacity of SVC or STATCOM

4. Conclusion

STATCOM is a more effective and more rapid compensator than SVC. As a new kind of dynamic reactive power compensation device, STATCOM could be applied to improve system power factor and suppress system voltage fluctuation and flicker. This paper takes a large petrochemical enterprise grid as an example to make simulations of the grid voltage recovery caused by the external faults. A strategy for the application of STATCOM is proposed in order to improving electric power quality. Test simulations show very encouraging result.

Keywords: Virtual Power Plant; Distributed Generation; Energy management system;Optimal Energy Management;

Abstract. Virtual Power Plant (VPP) technology can take advantage of interactive communication a nd energy management system to optimize and coordinate the control of distributed generation, cont rollable load, energy storage device, so as to integrate them and participate in the energy exchange o f the grid and the quote trading of power market. This paper is devoted to study the energy manage ment system in virtual power plant. Under the day-ahead market， this project puts forward the ma ximum profit model, analyzes the operation condition of various elements in virtual power plant, an d set restrictions for its operation and energy storage; According to the randomness of the energy res ources such as wind and light in actual operation as well as the price in power market, the change of power grid load and electricity demand, and the fluctuations in the retail price of electricity, this pa per adopts the proposed model of optimal allocation to coordinate and optimize the configuration of the elements in virtual power plant.

Introduction

For aggregating Distributed Energy Resources (DER), aims to overcome the capacity limits of single DER and the intermitted natural characteristics of renewable energy sources, the autonomy of distributed generation is emphasized in microgrid that make DGs overcome technical contradictions to coordinate well with power grid[1]. However, the main control target of microgrid is to achieve on-site balance between DGs and customers which is limited by geographical area, the effective utilizing of many areas, large-scale DGs and scale benefits in the electricity market has certain limitations[2] [3]. Virtual power plant provides methods to solve these problems[4] [5].

Virtual power plant (VPP) is collection of distributed generations and flexible loads connected and operated by communication network and advanced power management system[6]. As smooth transition between a conventional distribution network and smart power grid, based on the centralized control of distributed generations and load, intelligent management of power flow is able to be achieved[7] [8].

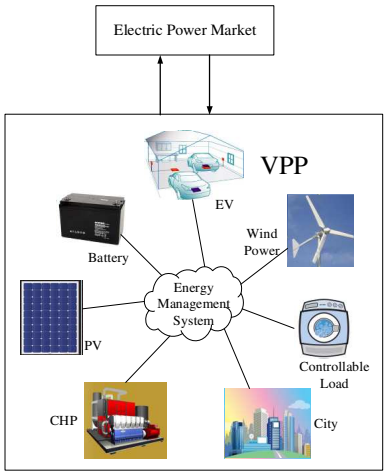

Fig.1. The structure of VPP

In Figure1, this paper sets up a VPP system consists of distributed generations (photovoltaic, wind generators), controllable load, electric vehicles stations, and energy storage units. The VPP emphasizes the external characteristics of power plant, so the implementation of diverse DER aggregation control in VPP is particularly important research content. This main work is to put forward the relevant constraints under maximal profit targets, besides, by solving the optimization algorithm will be solved and determine reasonable DER allocation to ensure the quality of electric and improve power generation efficiency.

Optimal Energy Management

The objective of VPP optimal dispatch in energy and reserve markets is to maximize comprehensive income . It regulate the output power of PV , WTG and other renewable units, exchanges power with the power market, supplies heat and power to resident, charges and discharges power to battery and electric vehicle ,and flexibly controls interruptible load[9]. Based on the above explanation, the objective function of the optimal energy management for the VPP can be expressed as

(1) Objective function:

$$\begin{aligned}\text{profit}=&\sum_{t=1}^{24}\rho_{\mathrm{e},t}\times E_t+\sum_{t=1}^{24}\rho_{\mathrm{r},t}\times R_t+\sum_{t=1}^{24}\rho_{\mathrm{l},t}\times L_t+\sum_{t=1}^{24}\rho_{\mathrm{h},t}\times H_t-\\&\sum_{\substack{t=1\\ i\in S_{DG}}}^{24}\left(C_{DG,i,t}\times P_{DG,i,t}+ST_{i,\mathrm{t}}+SH_{i,t}\right)-\sum_{\substack{t=1\\ i\in S_{CL}}}^{24}\left(C_{\mathrm{IL},i,t}\times IL_{i,t}\right)-\sum_{\substack{t=1\\ i\in S_{CHP}}}^{24}\left(C_{CHP,i,t}\times P_{\mathrm{CHP},i,t}\right)\end{aligned}\tag{1}$$

Where : S_{DG}, S_{CL} , S_{CHP} :sets of distributed generation , controllable load and combined heat and power ; $\rho_{\mathrm{e},t}$, $\rho_{\mathrm{r},t}$, $\rho_{\mathrm{l},t}$, $\rho_{\mathrm{h},t}$:the rate of electricity market, heat energy market,electricity retail to consumer and heat retail to consumer; E_t : bid of VPP to electricity market (positive and negative values indicate purchasing and selling from/to the electricity market respectively ; R_t : bid of VPP to heat energy market ; L_t : sell electricity to consumers , H_t : sell heat to consumers ,

C_{DG} : generation costs of DG units, P_{DG} : generation of DG ;ST : start up cost of DG unit ;SH :shut down cost of DG unit ; C_{IL} : cost of an interruptible consumer to curtail its load : IL the curtailment value of dispatchable load ; C_{CHP} : generation costs of CHP units: IL : heat and electricity generation of CHP ;

(2) Constraints.

A. network security[10]:

$$P_i - P_j = |V_i||V_j||Y_{ij}|\cos(\theta_{ij} + \delta_i - \delta_j) \quad (2)$$

$$Q_i - Q_j = |V_i||V_j||Y_{ij}|\sin(\theta_{ij} + \delta_i - \delta_j) \quad (3)$$

$$V_{min} < V < V_{max} \quad (4)$$

Where $P_i, P_j \ Q_i, Q_j \ V_i, V_j \ \delta_i, \delta_j$:active power,voltage and angle of two terminal in bus ; θ_{ij} : angles of complex Y-bus matrix elements (rad) ; Y_{ij} : magnitude of admittance matrix element ; V_{min}, V_{max} minimum and maximum limits on bus voltages ;

B. DG constraints : The DG constraints include Output capacity limit- Equations (5) ; Ramp limit [6] [11]-Equations (6) to (7) ; Minimum-up and down time constraint [12]-Equations (8) to (9) .

$$P_{DG.min} \le P_{DG} \le P_{DG.max} \quad (5)$$

$$P_{DG,i,t+1} - P_{DG,i,t} \le R_{DG.max} \quad (6)$$

$$P_{DG,i,t-1} - P_{DG,i,t} \le R_{DG.min} \quad (7)$$

$$\left[T_{i,t-1}^{on} - MUT_i\right] \times \left[I_{i,t-1} - I_{i,t}\right] \ge 0 \quad (8)$$

$$\left[T_{i,t-1}^{off} - MDT_i\right] \times \left[I_{i,t-1} - I_{i,t}\right] \ge 0 \quad (9)$$

Where $P_{DG.min}, P_{DG.max}$:minimum and maximum DG capacity limit for active power .

$R_{DG.min}, R_{DG.max}$:ramp-down and ramp-up limit for DG unit

MDT, MUT :minimum down time minimum up time and limit for DG unit

T^{off}, T^{on} :Number of hours for which DG unit has been on/off controllable load constraints :

C. Energy balance: electric balance and heat balance

$$E_t + SE_{dischage} + \sum P_{DG} + \alpha \sum P_{CHP} = SE_{chage} + L_t$$

$$R_t + SH_{dischage} + \beta \sum P_{CHP} = SH_{chage} + H_t \quad (10)$$

Where α, β :the scale factor of electric and heat generation in CHP ; SE, SH : battery to store electricity and boiler to store heat

D. Storage constraints :

$$SE_{min} \le SE \le SE_{max} \quad (11)$$

$$SH_{min} \le SH \le SH_{max} \quad (12)$$

Where SE_{max}, SE_{min} :maximum charge and discharge rate of electrochemical storage ; SH_{max}, SH_{min} :maximum charge and discharge rate of heat storage ;

E. Controllable load constraints :

$$IL \le IL_{max} \quad (13)$$

Where IL_{max} :Upper limit for curtailing on interruptible load.

Examples of application

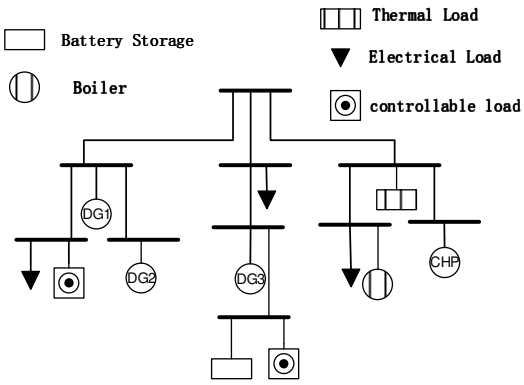

Fig.2. The Case of VPP

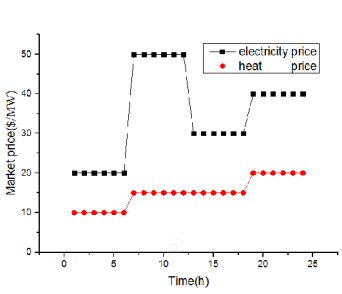
The procedure has been tested on different configurations of distribution systems with embedded generation, part of which aggregated into a VPP, and it has demonstrated the ability to give consistent and reliable results in compliance with all the network physical constraints and bounds. In the following, a case study example carried out on the system depicted in Figure. 2 is presented. The DG1 is PV (photovoltaic) power plant, the DG2 is WPP (wind power plant), the DG3 is micro gad turbine.The grid consists of three electical loads ,a thermal load and a conrollable load. The battery to storage electricity and the the boiler to storage heat .The CHP produce electricity and heat , it focus on the heat in case.VPP can buy or sell power from the power market accroting to the electricity price and domestic supply and demand. The details of elements is show as Table .1

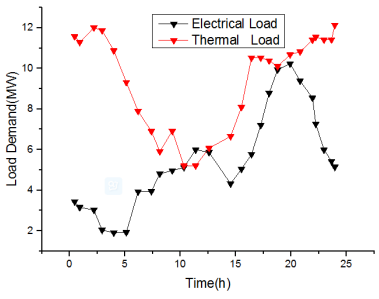
Table .1 Maximum and minimum capacity

	Pmin	Pmax
DG1	0	3
DG2	0	4
DG3	0	4
Battery	0.2	2
Boiler	0.2	2
CHP	0	3

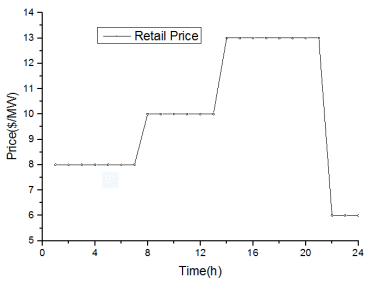
The total load of the VPP is according to Figure. 3(a). The price of wholesale energy market and the capacity price of heat market are indicated in Figure. 3(b). The retail price is shown in Figure. 3(c).



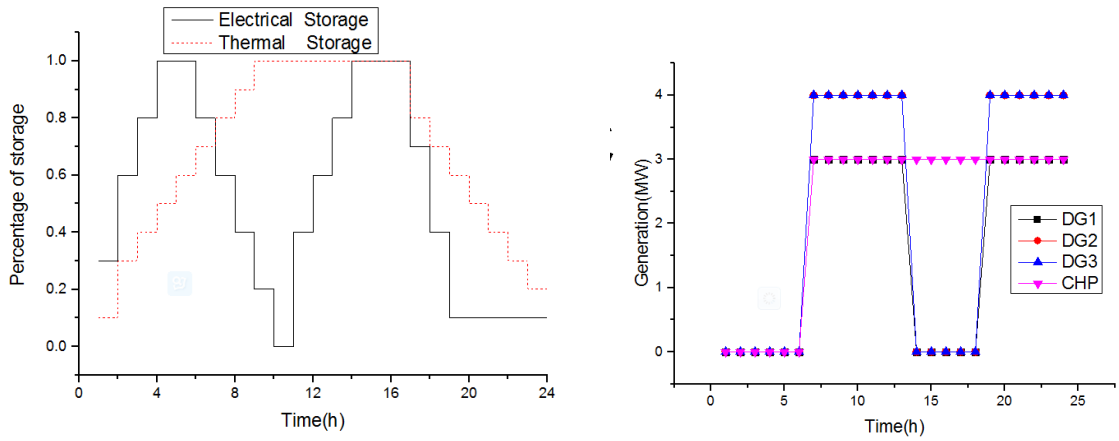
(a) The market price curves



(b) The load curves



(a) The retail price curves



(a) The storage curves (b) The generation curves

Fig.4. The experimental results

It Uses genetic algorithm to solve the optimal control problem in the study case .The results of solving the bidding problem are shown in Fig. 4(a)–(b). In the time period between hours 1 to 6, the prices of electrity and heat maket are lower than the expence of DG,so the VPP tends to buy energy from the market, meanwhile the electrical storage and themal storage begin chage untill the it is fully charged.

During the hours 7 to 11, the prices of electrity is higher than expence of DG, The VPP change consumer role to prodeucer, DG1 ,DG2,DG3 work in max capacity to achive generation as much as possible. The prices of heat is higher than expence of CHP, The CHP produces heat energy which was stored in boiler and sold to market and themal load. The electrical storage begins dischage to gets more economic benefits.

However,the electicity price goes down at 12 :00, VPP turns off expensive units including DG1 and DG3.On the contrary, the thermal price goes up ,so CHP would better not cut production capacity.During the time between the hours 19 and24, the VPP is providing energy for the market and tends to sell its surplus energy to the network.The electrical storage and themal storage begins dischage to meet the load demand.

Conclusion

In this paper,according to the technical and economic constraints, by adopting genetic optimization algorithm, optimal energy management strategy will be designed to maximize the utilization of renewable DER and achieve optimal power flow. The optimal energy management strategy have be simulated and applied in a study case. The experimental results show that the proposed optimization management strategy provides high quality solutions while meets constraints.

Keywords: Global reactive optimization, Magnetic control reactor (MCR), Immunity genetic algorithm, Inductive reactive power compensation.

Abstract. Along with the increasing use of cables in power grid and the increasing ration of distributed power sources' synchronization, such as small hydropower's synchronization, increasing the reactive power transmission on the line, make it difficult to achieve the balance of reactive hierarchical partition. Take a certain region's power grid for actual examples, after the installation of magnetic control reactor (MCR), using immune genetic algorithm (IGA) to coordinate the capacity of magnetic control reactor and the existing reactive power resources, the results show that the magnetic control reactor does much good to absorb the system's excessive reactive power and limit the voltage's increasing.

Introduction

Voltage is an important indicator to the characterization of power quality [1-2], and reactive power to ensure that the system power quality, reduce the damage and to maintain system security and stability is crucial. The trend of power system dynamic change and influence each other. In the distributed control mode [3-4], various power plants and the transformer substation all take own bus voltage as the regulative goals, but cannot coordinate each factory from the overall situation angle to stand the reactive power assignment. Therefore, that the introduction of network voltage reactive power optimization [5] coordinates the compensation in the regional power grid between multiple substations and the different voltage rank.

Immune genetic algorithm (IGA) is a recently developed multi-objective heuristic search algorithm [6-7]. IGA treats the solution of the actual problem objective function, the multi-constraint condition and the invasion life body antigen corresponds, while the feasible solution and the antibodies produced by immune system correspond. The size of affinity is measured to the merits of the candidate solution of the problem.

Based on the actual situation of a substation, the reactors and capacitors are paralleled in transformer side for voltage active power compensation. From the perspective of global optimization, established minimum net loss, the qualified node voltage, and the generator reactive power is not overstepped as the augmentation objective function optimization mathematical model. According to the characteristic of voltage reactive power optimization problem and the applicability of the immune genetic algorithm in solving global optimization problems, this article applies the immune genetic algorithm for voltage reactive power optimization system.

The working principle of MCR

Figure 1 is a schematic structure of magnetically controlled reactor (MCR) [8-9]. When the MCR is parallel operation, the two silicon-controlled rectifiers T_1, T_2 both have induced voltage on both ends,

and its size is only about 1% of the power grid voltage. Triggers the break-over silicon-controlled rectifier T_1 and T_2 in turn in the supply voltage plus and minus half period, which can produce a DC control current controlling current $i_1^{'}$ and $i_2^{'}$ in the reactor return route, then causes the reactor work iron core magnetism valve to be at the saturated condition. The size of the MCR output current is related to the size of the DC control current, namely is related to the conduction angle of silicon controlled rectifier.

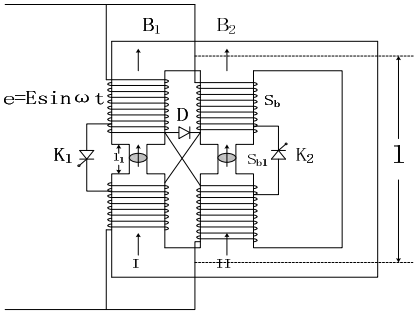

Fig. 1 MCR diagram

Regional power grid perceptual reactive power compensation points and the determination of capacity

From a particular region of the actual grid as an example for analysis, the region grid hydropower proportion is larger, power grid operation mode large changes with the seasons, and voltage level with wet and dry seasons exist different voltage adjustment problems. The optimal allocation of reactive power compensation device is to determine the installation location, equipment type and capacity in order to obtain the maximum economic efficiency and the security benefit under some constraint conditions [10-11].

As follows, the table 1 shows in the area the magnetic control reactor's installation site, voltage rank and capacity size.

Tab.1 Magnetic reactor installed capacity

installation site	voltage rank (kV)	capacity size (MVar)
2	110	30
8	35	10
17	35	10

Mathematical model and algorithm steps

Mathematical model. This paper from the perspective of safety and economy, the optimization goal is to the total net loss of the whole network minimum when each node in the grid voltage is not over limit and generator reactive power output does not exceed the limit values. The objective function is constructed in the form of penalty function, as follows:

$$\begin{cases} \min F = P_{Loss} + \lambda_V \sum \left(\dfrac{V_i - V_{il}}{V_{i\max} - V_{i\min}} \right)^2 + \lambda_Q \sum \left(\dfrac{Q_{Gi} - Q_{Gil}}{Q_{Gi\max} - Q_{Gi\min}} \right)^2 \\ V_{il} = \begin{cases} V_{i\max}, & V_i > V_{i\max} \\ V_i, & V_{i\min} \le V_i \le V_{i\max} \\ V_{i\min}, & V_i < V_{i\min} \end{cases} \\ Q_{Gil} = \begin{cases} Q_{Gi\max}, & Q_{Gi} > Q_{Gi\max} \\ Q_{Gi}, & Q_{Gi\min} \le Q_{Gi} \le Q_{Gi\max} \\ Q_{Gi\min}, & Q_{Gi} < Q_{Gi\min} \end{cases} \end{cases} \tag{1}$$

In the objective function 2nd item and the 3rd item respectively is the penalty item for the system PQ node voltage exceeding the limit and the penalty item for PV node source reactive power output

exceeding the limit. λ_V and λ_Q are the corresponding penalty coefficients, whose value can be determined by the experience and experimental observation.

Equality constraints are the power flow constraints. The inequality constraints take into account the control variable constraints of the system and the state variable constraints. Generator terminal voltage V_{Gi}, the ratio of on-load voltage regulating transformer k_{Ti} and the output of reactive power compensation device Q_{Ci} are the control variables; and the state variable constraints include node voltage and generator reactive power output constraints, as follows:

$$X_{\min} \le X \le X_{\max} \tag{2}$$

Among them, X is the variable.

Algorithm steps. The implementation steps of immune genetic algorithm in reactive power optimization of power system voltage are as follows:

(1) Input the original data. The original data include electrical network parameters and parameters of immune genetic algorithm.

(2) Generate the initial antibody population. Randomly generate initial antibody population in the solution space of voltage reactive power optimization problem, the number of iterations is set to 1.

(3) Power flow calculation. Decode the control variable condition corresponding to each antibody and calculate the power flow, and then obtain system loss, node voltage and PQ node generator reactive power output over-limit condition, and then calculate the objective function value.

(4) Calculate the antibody affinity. Calculate affinity of each antibody in the population, according to the objective function value from power flow calculation.

(5) Calculate the concentration of antibody.

(6) Antibody promotion and inhibition. According to the affinity of antibody and antibody concentration, calculate the immune selection probabilities of antibodies and then based on this probability value, select genes from the parent population to the next generation of antibody.

(7) Produce the new generation of antibody. Carry out a series of genetic crossover and mutation operations to the individuals selected out based on immune selection function, and obtain a new generation of antibody population.

(8) Evolution termination check. Check whether meet the termination conditions of evolution, if so, stop the iteration and output the final result of the optimization; and if not, iterate the number of times to add 1 and go to step (3) to start the next iteration.

Calculation and analysis of optimization of voltage and reactive power in regional power network

Before the calculation of voltage reactive power optimization in local power network, the network parameters on the regional power grid is firstly counted, then the calculation program via IGA is optimized and calculations of voltage and reactive power optimization on global scope for four kinds of typical operation modes, including wet season under heavy load and light load and dry season under heavy load and light load, are made in the region respectively. In both cases of MCR's installation and not, the optimization is calculated and the two results are compared.

Pretreatment of network parameters. As is shown in Figure 2, this is the grid structure diagrams in this region. There are totally 32 nodes, including 8 power source nodes and 5 shunt capacitor compensation nodes. And there are totally 35 branches, including 10 on-load voltage-regulating transformers (including four sets of three winding transformers, 6 double winding transformers).

For the convenience of calculation, the form of per unit value is used to indicate the region's power grid network parameters. In case of conversion, let the base capacity be S_B=100 (MVA), and the base voltage be U_B=U_{av}, besides, convert all of the parameters to the high-pressure side uniformly.

There are 26 Reactive power control variables ,including 8 voltage parameters of power source nodes, 5 compensation susceptance parameters of shunt capacitor compensation nodes,10 transformation ratio parameters of on-load voltage regulating transformers and 3 equivalent

susceptance parameters of Parallel magnetic control reactor nodes. The algorithms of parameter values are set as follows:

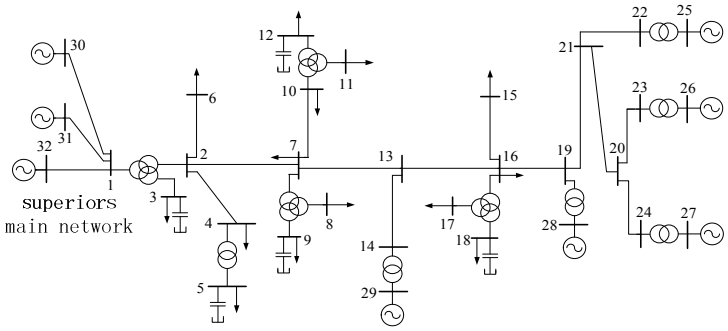

Fig.2 A regional power grid structure diagrams

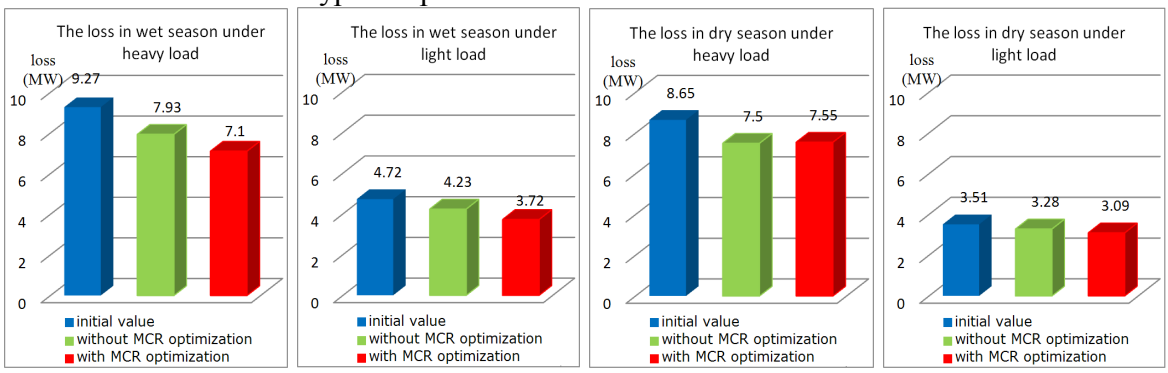
Let the population size N be 100 and the maximum evolution algebra T be 200,the crossover probability of genes between real and integer section in chromosome Pc1and Pc2 be 0.6, the reality section gene variation probability Pm1 to be 0.15, the integer section gene variation probability Pm2 be 0.15, the objective function coefficient penalty λ_V=6, λ_Q = 4 .

Since the IGA is a global probability random search algorithm, each time of optimization result in optimization calculation varies, for each operation mode, the optimization algorithm are calculated for 20 times, and the results of each optimization are finally counted.

Analysis of loss data. As is shown in figure 3, the loss's comparison diagrams before and after optimization in the 4 kinds of typical operation modes are drawn.



(a) (b) (c) (d)

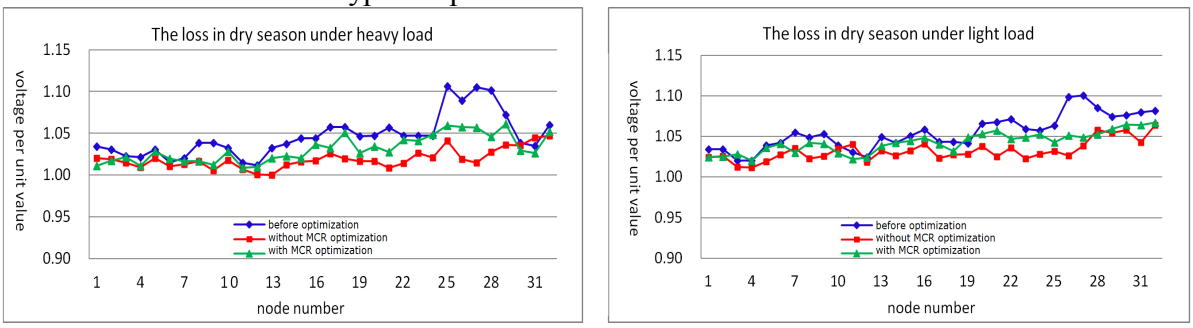
Fig.3 Before and after optimization Web damage Comparison Chart

From the comparison, it can be seen that the loss after optimization has reduced significantly, the optimized effect is obvious.

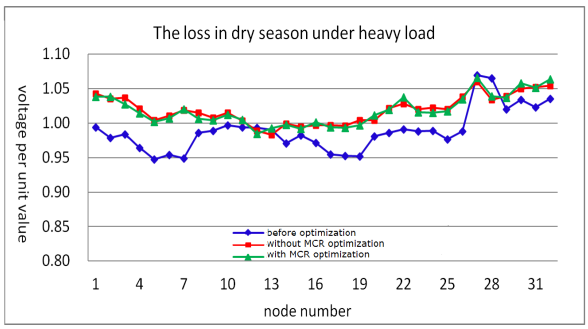
(1)During the wet season, the loss has reduced significantly when the magnetic control reactor is added, the effect of the reactor's compensation is obvious.

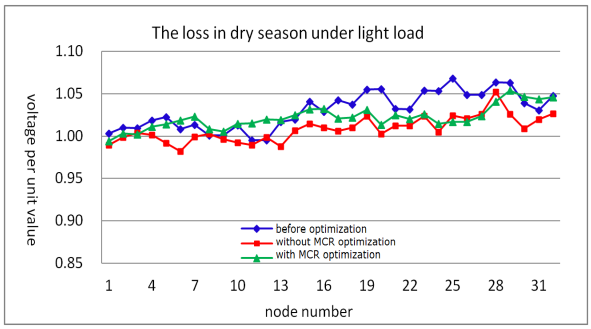
(2)During the dry season, the loss has reduced when the magnetic control reactor is added, but is higher than the wet season period.

Voltage limiting effect analysis. Figure 4 has shown the voltage distribution curve before and after optimization in the 4 kinds of typical operation modes.



(a) wet season under heavy load (b) wet season under light load





(c) dry season under heavy load (d) dry season under light load

Fig.4 Before and after optimization node voltage distribution

From the picture, it can be concluded that:

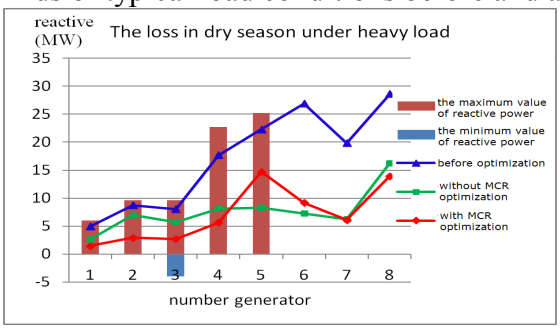
(1)During the wet season under heavy load season, it can be seen that MCR has a significant impact on the region's voltage in this operation mode and the effect of voltage limiting is obvious.

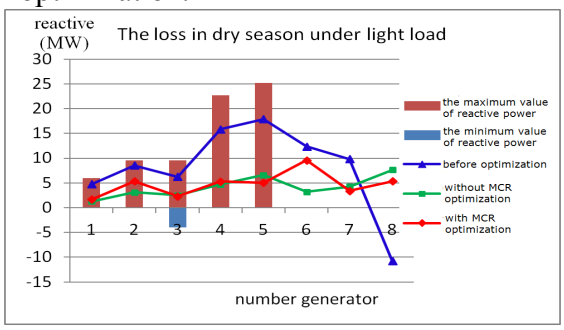
(2)During the wet season under light load season, after the use of MCR, the node voltage is limited to the allowed value.

(3)During the dry season under heavy load, the reactive power has small or no surplus, the magnetic control reactor has little affect and even run out of operation.

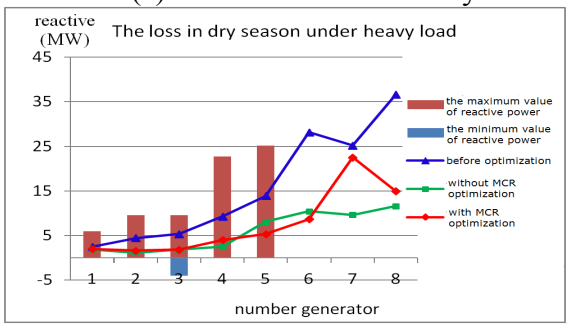
(4) During the dry season under light load, MCR has a significant impact on the region's voltage in this operation mode and the effect of voltage limiting is obvious.

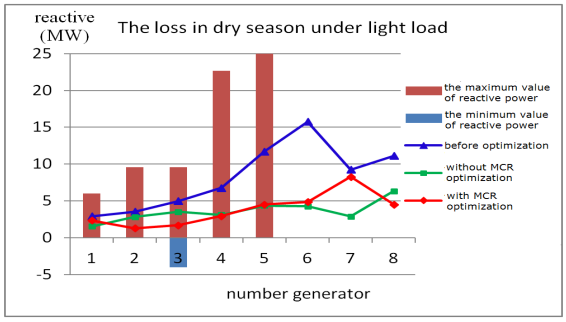
Reactive power output analysis. Figure 4 indicates the output of reactive power of generator nodes in 4 kinds of typical load conditions before and after optimization.





(a) wet season under heavy load (b) wet season under light load





(c) dry season under heavy load (d) dry season under light load

Fig.4 Before and after optimization generator reactive contribution

Comparing the output of generators, it can see that with the shunt capacitors or inactive power compensation of shunt reactor, combined with on-load voltage regulating tap effect on reactive power flow distribution, the output of the reactive power has a different degree of decrease after optimization. Especially during the wet season under light load season, the output of 500kV superior network equivalent power source's reactive power is negative, that is to say, the regional grid network delivers massively reactive power to the system, after the optimization calculation ,the equivalent source node pours smaller reactive power into regional grid network and has avoided the reactive power's traversing between different voltage levels as well as massive long-distance transmission thought lines, thus achieving the balance of the hierarchical partitioning of reactive power, and can also do good to reduce system network loss.

Summaries

Applying IGA optimization program based on MCR, for the four kinds of typical operation modes of the region, and carrying on voltage reactive power optimization within the global scope. The impact of the magnetic control reactor into the regional power network voltage and network losses is analyzed, and then the conclusions are as follows:

(1) Installing magnetic control reactor in the area and with the various existing reactive voltage and reactive power regulation equipment in the area for the regional power grid optimization, the regional power grid reactive power and voltage regulation level can be greatly improved, and the voltage will greatly increase compared with the pass rate.

(2)The reactive power optimization of regional power grid will make relevant hydropower's output of reactive power to be rationalized and reduce the reactive power flow between the various voltage levels, but also reduces the reactive power string action, thus reducing losses and greatly saving power.

[3.] State Grid Zhangqiu Power Supply Company, Jinan 250001, China)

Keywords: pricing model; electric vehicle; charging price

Abstract. First, behavior models of the station operator and consumer are established considering all the main factors. Second, an optimized EV charging pricing method using Game Theory is introduced based on benefit-cost analysis. The calculation of government subsidies is also proposed in order to reach an equilibrium charging price. Finally, actual data of Hebei is used and results are shown to give supports to local government and charging station operator's decision making.

Introduction

Electric Vehicle Charging mode includes ac slow charging and dc fast charging, both of them are the consumers purchasing the vehicle and the charging stations providing the charging services. Literature [1]discusses promoting the development of electric vehicles should adopt to the market mechanism, like conventional charging station performs commercial time-sharing electricity price, emergency charging stations accords the commercial electricity charge in the rush hour, but do not make a concrete analysis of each specific question of the electricity price. Literature[2] discusses the charge of electricity of the interests of all parties involved, the operators should be considered to ensure that they can recovery cost of the charging station and gain profit, but consumers should consider car consumption costs and the choice of charging ways. Literature [3] considering, because the charge electricity price is a matter of each side with conflicting of interest, the charge electricity price formulation is determined through the game analysis, on the basis of the sensitivity model is set up respectively by the electricity suppliers, station operators and consumers charging tariff, Through analyzing the government, the charging party (composed of power suppliers and charging station operators) and consumers tripartite of static game analysis, concluding that the three parties are acceptable range of floating charge of electricity.

This paper assumes that charging station operators in time-sharing electricity price to buy electricity, then using charge of electricity. Starting from the charge carriers and consumer benefits, and the time value of money, operators and consumers all can realize relative profit for the principle, discussing the charge of electricity of formulation and government subsidies.at last, empirical data of Heibei province is used to calculate the specific subsidies for the electric vehicle charging business.

Benefit model established

1.1 Operators benefit model

Charging station operator efficiency can be represented as follows:

$$Y_1(t) = Q_c \cdot \pi_c - (Q_c \cdot \pi_p / \eta + S_r \quad (1)$$

, of which, Q_c is the charging stations in charge capacity; π_c is the charging for electricity price; π_p is the grid electricity price ; η is the charging efficiency; S_r is the site operation cost respectively.

1.2 Consumers benefit model

Because the economy is the important factors that affect consumers to choose the car type[4] generally, only when the electric car use cost is lower than the traditional fuel cars, consumers

would choose electric cars. As a result, this paper will regard consumers to use electric cars as an investment, using the expense of the electric vehicle is equal to the cash outflows, the cash inflows are expressed as a fuel car use, then establish a consumer relative efficiency model, see type（2）.

$$Y_2(t) = (\Delta C_v + C_f + B_{r,t}) - (B_{s,t} + C_c + B_m) \quad (2)$$

Type: Y_2 is the consumers of relative efficiency; ΔC_v is the fuel cars and electric cars naked car purchase price; C_f is the fuel costs; C_c , B_m is respectively of charging, battery maintenance fee; $B_{r,t}$ is the battery recycling income; $t = 8,16,\cdots$, is effective; $B_{s,t}$ is the battery costs; $t = 0,8,16,\cdots$, is effective.

Charging tariff design

2.1 Based on the charge of electricity of absolute economic benefit index

This paper adopts the method of cost-benefit make charge of electricity, using the economic benefit index shown in table 1 for examining basis. Type（1）and type（2）give the cash inflow and outflow of charging station operators and consumers, above all, the economic benefit index calculation can be performed, and then determine an acceptable charging power for operators and consumers. The specific method is as follows: Bring type (1) and (2) into the calculation formula of each index in the table 1.For both parties of charging electricity price range, the upper is consumers can accept the highest prices, the lower is the minimum charge of electricity for operators.

Tab.1 Table of absolute economic benefit indices

Indicators	Mathematical Expression	Characteristic	Judgment Criteria
NPV	$NPV = \sum_{t=0} (CI - CO)_t (1+i_0)^{-t}$	profitability indicators.	$NPV \geq 0$
IRR	$\sum_{t=0} (CI - CO)_t (1+IRR)^{-t} = 0$	profitability indicators.	$IRR \geq i_0$

Note： i_0 is the benchmark yield, in this paper, taking 5%.

2.2 Analyze the method of the government subsidies

By the analysis of related data, the electric car battery market's supply and demand both sides cannot achieve common profit, therefore needs the government fiscal subsidies, in order to form a benign operation of the market environment. The calculation method of fiscal subsidies is:

First of all, make determine charge level of electricity to consumers' acceptable π_c;

Second, regard which both sides can accept charge of electricity of price difference as government subsidies, let the operator gain profit. Every year the government subsidies are looked as the non-business income [5] CI_{gov} , as type（3）. And converting it to the initial years in accordance with the benchmark yield, to get general government subsidies to project life cycle CI_g , as type（4）.

$$CI_{gov} = \Delta\pi_c \cdot Q_c \quad (3)$$

$$CI_g = \sum_{t=0}^{T} CI_{gov_t} (1+i_0)^{-t} \quad (4)$$

Finally, use type（5）fixing operators cash inflow, then do the calculation method for measuring according to section 2.1, government subsidies for charge of electricity can be obtained.

$$CI = CI_1 + CI_{gov} \quad (5)$$

Empirical Analysis

3.1 Basic Data

This paper bases on a charging station data for empirical analysis in Hebei province.Grid electricity price regards the TOU price in Hebei of the industry and commerce as the criterion, shown in the table 2. according to the probability distribution of the charging time can get

equivalent power tariff of a bus and passenger car equivalent power tariff π_{p2}, π_{p3} are 0.34yuan /kWh and 0.78yuan/kWh respectively.

Tab.2 Time of use power price of Heibei province and probability of different kinds of EV's charging behaviors

Time Frame	Time	Grid electricity price/yuan/*kWh*	Vehicle type	Charging time	Charging probability of each time frame
Time of valley	23:00—7:00	0.32	Bus	10:00-16:30	0.5
Time of plant	7:00—8:30 11:30—18:00	0.80		23:00-5:30	0.5
Time of top	8:30—10:30 18:00—19:00 21:00—23:00	1.28	Car	7:30-17:00 19:00-7:00	0.2 0.7

3.2 Calculation of charge electricity price that operators can accept

When the power grid equivalent electricity price is 0.78 yuan/kWh, each index of operators under different charge electricity price are shown in table 3. When all economic indicators of project reach profitable level, charging price just take 2.18 yuan/kWh. That is when $\pi_c \geq$2.18 yuan/kWh, charging station with operators investment can realize profits.

Tab.3 Economic benefit indices analysis of operator

π_c /yuan/*kWh*	T_s / year	T_d /year	*IRR*	*NPV*/ten thousand
2.15	15	>T	4%	-109.9
2.18	14	23	5%	35
2.23	13	21	6%	179.9

3.3 Calculation of charge electricity price of consumers

In order to promote widely use of the electric car, the subsidies of the government are needed to provide. Purchase subsidies of current policy for a car are 60000 yuan, the index calculation is shown in table 4. As you can see, charge electricity price of consumers can accept is 1.14 yuan/kWh.

Tab.4 Dynamic economic analysis of consumer

π_c /yuan/*kWh*	*IRR*	*NPV*/ ten thousand
1.20	5%	-0.02
1.14	6%	0.12
1.10	6%	0.27
0.95	8%	0.56

3.4 Win-win charge electricity price

As we can see, considering the existing purchase subsidy policy of electric car, there is not a win-win charging electricity price range charging station operators and consumers can achieve.

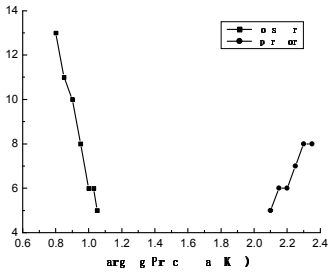

Fig.1 Comparison of IRR between operator and consumer under different charging prices

3.5 Influence of government subsidies on the charge electricity price

By the previous analysis, the role of government subsidies is to make up for the cost loss of the electric car operation and use, and in this case government subsidies of charging station operators should be greater than 1.04 (namely 2.18-1.14) yuan/kWh, when it is taken as 1.1 yuan/kWh, CI_g is $30.357 million, at this time there is a win-win charge electricity price. The influence of government subsidies on the charge electricity price is as shown in figure 2, whose lower limit reduces with the increase of subsidies level.

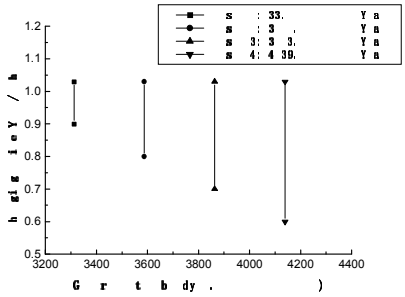

Fig.2 Effect of government subsidies on charging price

Conclusion

This paper concludes that: (1) under the current conditions, building the power tariff and charging station site cost are more higher, we cannot find the acceptable charge of electricity between operators and consumers; (2)after considering time-sharing electricity price and the charging behavior of different models, with the equivalent power tariff of charging stations become low, the operators will enhance the profitability and accept a lower charge of electricity;(3)government subsidies can effectively improve the profitability of charge carriers, it is sure closely related to the calculation of charge of electricity. In this paper, the results of the calculation of concrete examples for subsidies at least 1.04 yuan per kilowatt-hour.

Keywords: Over frequency generator tripping measure;overspeed protection;islanding operation; optimizing allocation

Abstract. Through the summary of typical accident, the problem between the over speed protection device of thermal power unit steam turbine and over frequency generator tripping measure is analyzed in island operation of sending ends of regional grid. The optimizing allocation principle between over frequency generator tripping measure and over speed protection equipment is put forward. By a variety of program analysis and comparison, the optimizing scheme is given. Finally, the typical models of thermal power unit steam turbine over speed protection are established in software. Based on a practical power system as an example, the whole process of islanding is simulated. Checking the coordination with existing over frequency generator tripping measure and the relay setting related to power network in the islanding operation, the validity and practicability of the optimal scheme and principle are analyzed. With the method, the regional grid will remain safe and stable.

Introduction

In recent years, with large scale renovation and construction of China's power girds, the 500kV grid has been formed. The reliability is greatly improved. With the development of the untying electromagnetic loop network in 500kV/220kV gird, the fault of the local power grid, the local power grid fault, extreme weather, geological disasters and man-made error, all may contribute to the regional power grid islanding operation parting from the main grid. Especially for the sending ends of regional gird, when the power is large, it may result in the frequency rising rapidly. If the control measures are not properly, large area blackout may appear. It will bring great economic loss.

At present, the accident of over frequently often occurs in the sending ends of gird when running in the islanding operation[1-5], such as: Guizhou South grid "7.7" accident, "6.25" accident in Henan power grid and "2.24" accident in Kunming power grid. Although the evolution process and cause of accident are not the same, from the accident analysis and accident simulation, it has been found that over frequency generator tripping measure and OPC, primary frequency modulation function and OPC, even under frequency load shedding and over frequency generator tripping measure mismatch. Especially, when the setting value of OPC is set properly, resulting in the generator repeatedly opened and closed. With the power of large oscillation in the isolated grid, the frequency of the grid gets instability, eventually the whole network gets outage. Finding the characteristics of OPC and identifying the reason of the power oscillation have become research hotspots that many experts and scholars concern on.

In this paper, the typical model and parameters of domestic thermal power unit steam turbine overspeed protection have been collected through the investigation. Combined with the configuration status of the OPC in China, it reveals that there will remain improper between the OPC, over frequency generator tripping measure and under frequency load shedding strategy in the end of regional isolated power grid. By the typical OPC model established in PSD-BPA, and taking actual

area grid for example, the coordination scheme between the over frequency generator tripping measure and OPC is checked. It ensures the regional gird safe and stable.

1 Generator protection related to the grid in the regional gird of high frequency

1.1 High frequency protection of the generator

The generator will result in damage, when it run in high frequency, even resulting in t collapse of the grid. According to the national standard(DL/T 1040-2007《Power Grid Operation Criterion》), the island grid frequency should be control in the area that high frequency protection of generator allowable and frequency limits of the turbine. It is shown in table 1:

In this paper, the typical model and parameters of domestic thermal power unit steam turbine The generator will result in damage, when it run in high frequency, even resulting in t collapse of the grid. According to the national standard(DL/T 1040-2007《Power Grid Operation Criterion》)[6], the island grid frequency should be control in the range that high frequency protection of generator allowable and frequency limits of the turbine. It is shown in table 1:

Tab. 1 Operation time of Turbo-generator allowed when the frequency exception

Frequency range/Hz	The allowable operating time	
	Sum（min）	Single（sec）
51.0～51.5	>30	>30
50.5～51.0	>180	>180
48.5～50.5	inadmissibility	
48.5～48.0	>300	>300
48.0～47.5	>60	>60
47.5～47.0	>10	>20
47.0～46.5	>2	>5

1.2 The over speed protection controller of turbine

The over speed protection controller is an important function module of the steam turbine control system in power plant. It can inhibit the turbine over speed, preventing the emergency protector action leading to excision of steam turbine. Thereby it will short the time that the generators reconnect to the grid. When the generator reaches the fixed value, OPC will turn the adjustment of the corresponding valve in accordance with the establish logic, preventing further increase of speed. When the rotor over speed, OPC will quickly control the regulation system, forcing valve short closed. After certain delay, regulating system recovery control turbine speed, thus it effectively inhibit generator over speed. OPC typical action logic is shown in figure1[7], there are three typical function in the OPC:

(1)103% turbine over speed protection;

(2) 110% turbine over speed protection;

(3) load drop prediction function.

The OPC action is related to the control logic and its setting value. OPC control method is different in different manufacturers. And the OPC operation mode is related to the grid state and the control measures for islanding stability.

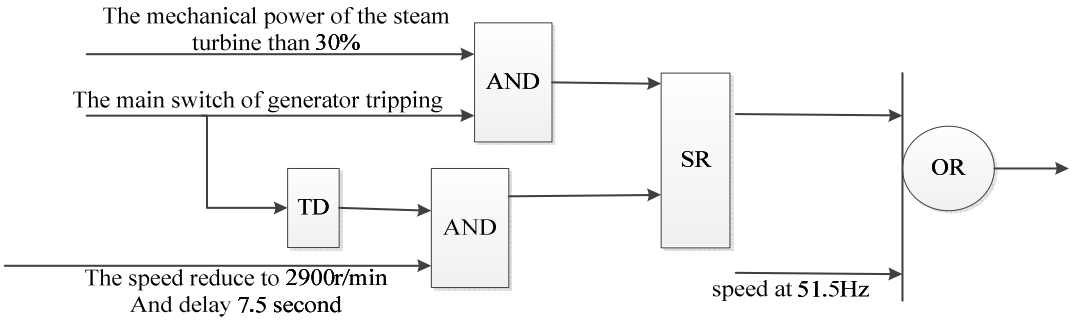

Fig. 1 OPC typical action logic

2 Optimizing scheme of over frequency generator tripping measure and OPC

2.1 Current problems between the over frequency generator tripping measure and OPC

At present, the over frequency generator tripping measure is not matching with the OPC value in the actual grid. When making the over frequency generator tripping measure, the makers mostly consider the coupling relation between the unit commitment, load and transmission power which exits in the island grid. They main ignore the effect of the OPC action to the isolated grid, and the effect to the over frequency generator tripping measure. In the OPC setting process of the power plant, it is completely on the unit itself safe operation, ignoring the interaction between the OPC and grid. The setting values are often selected according to the operation experience and suggestion. Therefore, it causes the mismatch, when the island occurred, OPC will lead to preemptive action or disoperation, and over frequency generator tripping measure will miscut or loss of cutting unit. It will directly lead to the regional power network unstable.

2.2 The principle of optimal allocation

This paper focuses on the relationship between coordination over frequency generator tripping measure and OPC. In order to solve the problem the high frequency in the isolated gird, the basic principles for all levels of measures are shown by definition:

1) To remaining the grid safe and stable, over frequency generator tripping measure of the generators should be set, as the backup measure when the chain measures are reject action.

2) When making the over frequency generator tripping measure, the generator of small capacity should be cut priority, remaining the generator of large the over frequency generator tripping measure capacity in the grid. The method will ensure the efficiency and economy of generators. And one unit should be retained in the plant, avoiding the blackout.

3) The value of the over frequency generator tripping measure is should be set in higher frequency than the OPC value, in order to minimize the isolated network under excess power impact.

4) The coordination scheme between the over frequency generator tripping measure and OPC should ensure that the island frequency can be controlled at a reasonable level, not leading the action of the underfrequency load shedding. And the scheme will avoid loss of cutting units and resulting in high frequency operation state of power grid.

5) The over frequency generator tripping measure should be configured to meet a variety of isolated network operation mode. It should have adaptability that can adapt to large load, small load and other power supply ways.

6） The fixed value of the OPC should be proper that can ensure the island frequency within the reasonable range. If it can not guarantee the island frequency controlled, the value should be set to try to ensure unit own safety.

7) The coordinated scheme should avoid repeated action of OPC and resulting collapse of the isolated grid.

2.3 The optimized allocation scheme

In order to coordinate the over frequency generator tripping measure and OPC scheme in the regional isolated gird, solving the problem of high frequency existed and maintaining stable operation, there are three options.

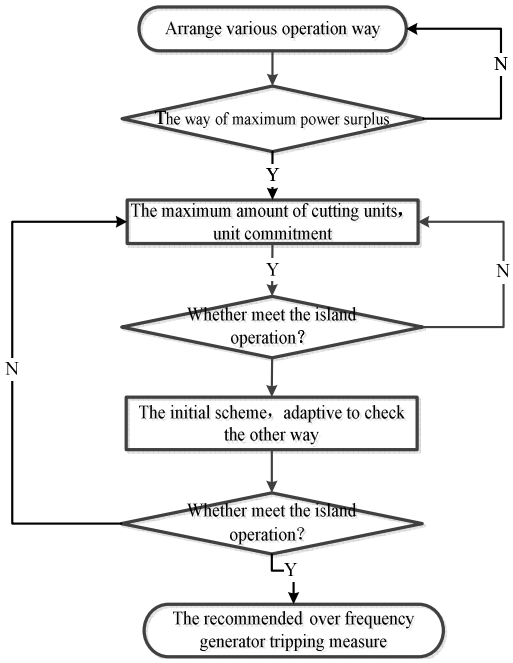

Fig. 2 The flow chart of program one

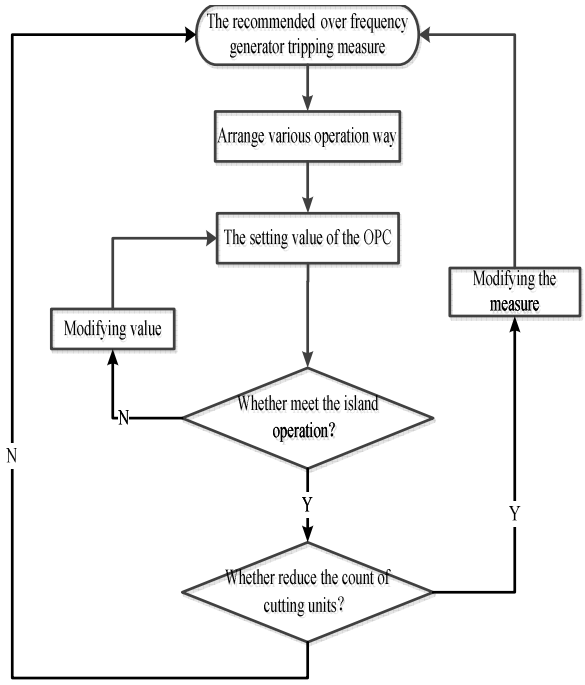

Fig. 3 The flow chart of program three

1) The first plan: the value of the over frequency generator tripping measure is lower than the OPC setting value. The over frequency generator tripping measure act first, controlling the frequency at a reasonable level without the action of the OPC.

2) The Second plan: The OPC setting value is lower than the over frequency generator tripping measure. The OPC scheme acts first, controlling the frequency at a reasonable level without the action of the over frequency generator tripping measure.

3) The Third plan: Considering the optimization of the OPC and he over frequency generator tripping measure，it will be evaluated that the OPC access may reduce the count of cutting units.

3 The analysis of the example

Taking Jiang Zhongzhu grid for example, it mainly consists of three areas: Zhong Shan grid, Zhong Zhu grid and Zhuhai power grid. The installed capacity of the regional grid is 8590MW. And the maximum load is 6635.8MW; it belongs to the typical sending end of the grid.

Through the analysis of the Jiang Zhongzhu grid, taking the waist load way for research, then the rationality of high load way and low load way will be checked.

3.1 The frequency controlling scheme of Jiang Zhongzhu grid at present

From the investigation and analysis on the OPC value and the over frequency generator tripping measure, it can be found as bellow:

1) At present, not all value of the turbine OPC is configured. The OPC principle is different, and its fixed value is also different. The existing OPC scheme is more complex, irregular. Beginning from the 51.0Hz, the generators are divided into six rounds by step of 0.5Hz. Each round of OPC starting value, closing time, and restarting value are not the same.

2) The value of over frequency generator tripping measure is set from the 51.0Hz, divided into five rounds by step of 0.5Hz. The generators' starting values and delay setting of each round are not the same. The capacity of first, second, third, fourth and fifth round are respectively 665,845, 3200,

1900, 700MW. Most of generators are involved in the high frequency controlling, but their starting values and delaying parameters need to check through the actual power network simulation.

3.2 The existing problem in the gird

Taking the waist load way for example, the external lines have the three-phase short circuit accident at the 0.2 second, and at the 0.3 second all the accident is cleared and all the tie lines are disconnected with the external grid. It will lead the Jiang Zhongzhu grid to become isolated network. Without considering the over frequency generator tripping measure and OPC, the frequency of the grid will control in about 50.7Hz, and the highest value is not more than 51.52Hz during the action, depending on the governor itself. The frequency change is shown as follow:

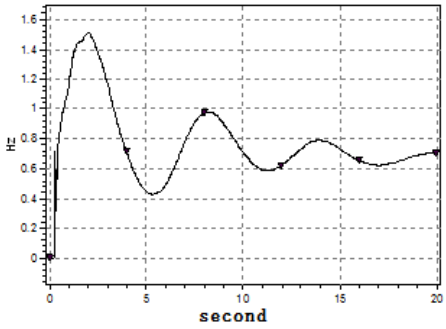

Fig. 4 The frequency curve of the grid (without OPC and over frequency generator tripping measure)

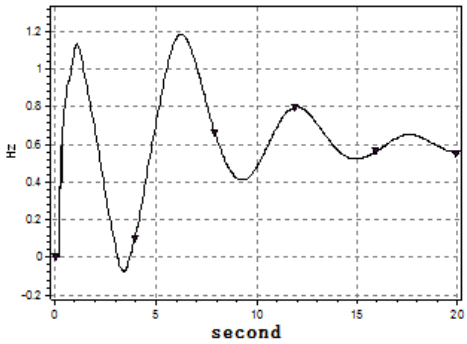

Fig. 5 The frequency curve of the grid (with OPC and over frequency generator tripping measure existing)

Considering the over frequency generator tripping measure and OPC existed, the frequency will be controlled at about 50.6Hz, the highest frequency is about 51.6Hz in the process. The frequency change is shown as follow:

From the table two, it can be seen that a total of 485MW generators are cut in the process. But the frequency of the grid cannot recovery to 50±0.5Hz. More generators need to be cut for eliminating the power surplus. The Heng Men #2 value of the over frequency generator tripping is 51.1Hz, its delay time is 10cycle, and its OPC value is 51.0Hz. So they may act at the same time. In the process, Heng Men #2 generator's OPC acts two times. At the last time, while the OPC closed the valve, Heng Men #2 was cut by the over frequency generator tripping. The over frequency generator tripping cannot act correctly.

Through the above analysis, without considering the OPC and over frequency generator tripping measure, the isolated grid is hard to maintain stability. While considering the OPC and over frequency generator tripping measure, the frequency condition is better, but it still cannot return to a reasonable range. Therefore, the scheme of OPC and over frequency generator tripping measure must be optimized.

Considering the over frequency generator tripping measure and OPC existed, the frequency will be controlled at about 50.6Hz, the highest frequency is about 51.6Hz in the process. The frequency change is shown as follow:

From the table two, it can be seen that a total of 485MW generators are cut in the process. But the frequency of the grid cannot recovery to 50±0.5Hz. More generators need to be cut for eliminating the power surplus. The Heng Men #2 value of the over frequency generator tripping is 51.1Hz, its delay time is 10cycle, and its OPC value is 51.0Hz. So they may act at the same time. In the process, Heng Men #2 generator's OPC acts two times. At the last time, while the OPC closed the valve, Heng Men #2 was cut by the over frequency generator tripping. The over frequency generator tripping cannot act correctly.

Through the above analysis, without considering the OPC and over frequency generator tripping measure, the isolated grid is hard to maintain stability. While considering the OPC and over frequency generator tripping measure, the frequency condition is better, but it still cannot return to a reasonable range. Therefore, the scheme of OPC and over frequency generator tripping measure must be optimized.

Tab. 2 Action of the over frequency generator tripping measure and OPC in the grid

Order	Time(s)	Incident
1	0.26	Zhu Hai#1, #2， ΔMW reaches to the triggering value，OPC triggered, high pressure and medium-pressure valve closed
2	0.54	The speed of the Heng Men #2 reaches 3060r/min (51.0Hz), OPC triggered，high pressure and medium-pressure valve closed
3	1.06	The speed of the Shuang Shui #5, #6 reach 51.1Hz,the generators are cut
4	1.07	The speed of the Nan Lang #4 reaches 51.0Hz,the generatos is cut
5	3.06	The frequency got down to 50 Hz, the OPC of Heng Men #2，Zhu Hai #1 and Zhu Hai#2 are triggered, all of the valve are opened.
6	5.54	The speed of the Heng Men #2 reaches 3060r/min (51.0Hz), OPC triggered，high pressure and medium-pressure valve closed
7	5.99	The speed of the Heng Men #2 reaches 51.1Hz,the generator is cut

3.3The optimized allocation scheme

On the basis of 2.3 chapter, there are three kinds of scheme existing.The analysis process is as follows:

(1) Using scheme 1: depending on the over frequency generator tripping measure entirely, the final configuration as shown in table three:

Tab. 3 The scheme of the over frequency generator tripping measure

Round	Starting Frequency（Hz）	Delay (Cycle)	Unit commitment
1	50.8	10	Heng Men #2,Nang Lang #3,Heng Men #2,Shuang Shui #5
2	50.8	35	Zhu Hai#3
3	51.0	15	Tong Gu#3
4	51.5	15	Nang Lang #1,Heng Men #1,Nang Lang #4
5	51.8	10	Zhu Hai#1,Shuang Shui # 6,Zhu Hai #4,Tong Gu#4
6	52.0	10	Zhu Hai #2,Tong Gu #5
7	52.5	15	Tong Gu #6, Tong Gu #7

(2) Using scheme 2: By changing the OPC value, the valves of some turbine will repeatedly open and close. Because of the fluctuation of output power, the frequency of the grid will lose stability, even getting to oscillation.

(3) Using scheme 3: Considering the output is much lower than the initial state after the OPC action, so the OPC action will help to eliminate some excess power, it will reduce the capacity of the cutting generators and will help the system recovery.

Compared with the scheme1, the frequency will be better in the isolated network by using the OPC configuration set. The excess power will be eliminated by the OPC action.

While sending power in 2000MW to 2600MW, it will reduce a round generator cutting by using optimized scheme. The generator of the third round will not be cut. The frequency of the grid can also remain stability. The final grid frequency will maintained within 50.5Hz.

While sending power in 1200MW to 1300MW, the frequency of the grid will remain at about 50.5Hz, only by governor of generators and the OPC of Zhu Hai #1 \#2. Compared with scheme 1, it will reduce the amount of generator cutting.

The optimized scheme has better adaptability from large load way and small load way checking.

Tab. 4 The optimized scheme of the over frequency generator tripping measure

Round	Starting Frequency（Hz）	Delay (Cycle)	Unit commitment
1	50.8	10	Heng Men #2,Nang Lang #3,Heng Men #2,Shuang Shui #5
2	50.8	35	Zhu Hai#3
3	51.0	15	Tong Gu#3
4	51.2	20	Zhu Hai#2
5	51.5	15	Nang Lang #1,Heng Men #1,Nang Lang #4
6	51.8	10	Zhu Hai#1,Shuang Shui # 6, Zhu Hai #4,Tong Gu#4
7	52.0	10	Tong Gu #5
8	52.5	15	Tong Gu #6, Tong Gu #7

Tab. 5 The optimized scheme of the OPC

Round	Starting Frequency（Hz）	Delay（Cycle）	OPC
1	——	——	Zhu Hai#1, Zhu Hai#2
2	51.0	150	Shuang Shui#5,Heng Men#2
3	51.8	100	Tong Gu#3
4	52.0	25	Zhu Hai#3
5	52.1~52.5	10	Heng Men#1（52.1）,Shuang Shui#6（52.2）,Nan Lang #4(52.3）, Tong Gu#5（52.5）
6	52.6~53.0	15	Nan Lang #2（52.6）, Zhu Hai#4(52.7), Tong Gu#4(53.0)

Summary

Through the investigation of the development of process of OPC, combined with the status of turbine, the typical OPC model has been established. By the typical OPC model established in PSD-BPA, and taking Jiang Zhongzhu grid for example, the over frequency generator tripping measure and OPC scheme is optimized. The reasonable proposals are put forward, and it will ensure the safe and stable of the gird operation. With proper OPC method, it can reduce the amount of generator cutting and improve the restoring of frequency

Keywords: Small Hydropower Stations; Microgrid; Power Control

Abstract. In China, some remote areas with rich small hydropower stations suffer from a tradeoff between water surplus and off-limit voltage in the grid during wet seasons. The microgrid of new energy sources provides a new way of solving this problem. Under the background of the microgrid proposed in somewhere of Jiangxi Province, this paper firstly carries out simplified model on the actual system. Output models of PV and small hydropower stations are established. Then with Minimizing transmission losses of microgrid system and the amount of all small hydropower abandoned waters as the optimization objective, and considering the output constraints of each micro power source, power balance constraints and voltage constraints. A micro-power output optimization model is established and then solved by improved particle swarm optimization algorithm. By comparing the micro-power output and system line loss before and after the optimization, it verifies that the proposed power control method can prevent the off-limit voltage effectively and reduce transmission losses of the system.

Introductions

Small hydropower stations has become an important part of China's hydropower stations; by 2010, our country has built 45,000 small hydropower stations, with the installed capacity of more than 54 million kW and the annual generating capacity of over 160 billion kWh[1]. However, small hydropower is often built at the end of the distribution network in remote rural areas, concentrated along the river, which output is greatly influenced by climatic season. When the total installed capacity of several small hydropower stations reaches a certain scale, it may have a greater impact on the operation of regional power grid, which may endanger the normal safe operation of the power grid. Especially in small hydropower-rich regions, the output of the small hydropower in wet period is much larger than the load capacity within the area, and most of the small hydropower has no ability to regulate the storage capacity, resulting in prominent voltage out-of-limit problem of the distribution grid [2-3].

In recent years, the rapid development of smart microgrid provides a new way to deal with the problems of microgrid in the area with rich small hydropower stations. Microgrid combines the distributed generation, load and energy storage devices, the control devices together to form an independently controllable power supply system. Smart Microgrid is used to accept the distributed new energy power generation, including small hydropower, and it can realize the optimal allocation of energy, improve the power quality and power consuming efficiency, so as to promote energy conservation and emission reduction. Scholars at home and aboard conducted extensive research [3-7] for the energy management and optimization of operational control of new energy microgrid, proposing a variety of control strategies under different technical objectives and economic objectives. At present, most of the researches for small hydropower operation optimization are in the aspect of voltage quality control. Optimization and improvement of the voltage quality by controlling the online power factor of small hydropower is proposed in [8]; a multi-objective mathematical model on voltage bias, voltage optimization investment and grid loss, etc. are established in [9] and [10], and the voltage optimization control research on the distribution grid with rich small hydropower is conducted by using an improved adaptive genetic algorithm. But currently, there are few researches over the world, working on the optimized control of small hydro-rich new energy Microgrid.

This paper mainly studies the problem of optimization control of new energy microgrid with rich small hydropower stations. Under the premise of meeting the system safe operation constraints, optimize the output of various distributed power supplies, to minimize the total transmission losses of the system and the abandoned water quantity for all small hydropower stations.

Microgrid system with rich small hydropower stations

The examples in this paper are based on a practical microgrid system which is prepared in a county of Jiangxi Province; the microgrid has four small hydropower stations, a small-scale PV power station, and a small amount of residents load. The actual system is simplified into a system with 26 nodes, with the system frequency of 50Hz and the reference voltage of 10kV. The equivalent parameters of each feeder are shown in Figure 1. The total load distribution capacity of the entire system is 1216kVA. Furthermore, the system also has a photovoltaic power generation of 10kW.

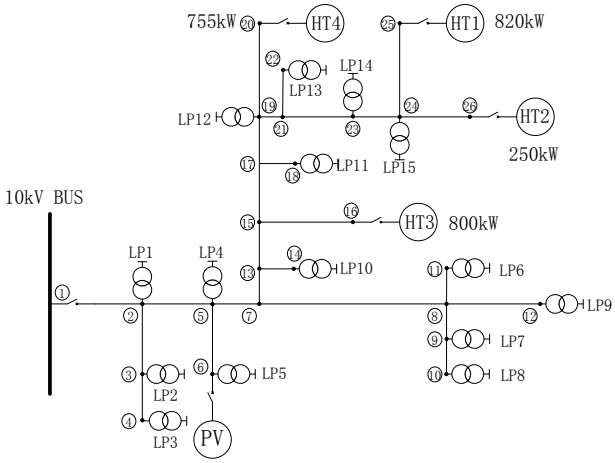

Fig.1.Simplified model of the microgrid with new energy and rich small hydropower stations

The rated power of each small hydropower is shown in Table 1, and the transmission line parameters are shown in Table 2.

In the system, the small hydropower stations are all run-off-river hydropower stations without reservoir regulation ability; during the actual operation, the electricity is generated as much as possible based on the runoff conditions. In wet period, the station is running with full output, while in dry period, limited by the runoff conditions, the generating capacity is low, even sometimes zero.

Local grid companies require that the power factor of small hydropower should be no less than 0.95.

The national standards stipulate that the voltage fluctuations of the line with 10kV should not exceed 7% of the rated voltage. Currently, in the actual operation, in wet period, the output of small hydropower has no any regulation and control; the voltages of five key nodes are detected exceeding the upper limit of the rated value, and the problem of high voltage is very prominent, as shown in Table 3. Therefore, it is quite necessary to control the power of the microgrid with rich small hydropower.

Table.3. The voltage of the key nodes in wet period without optimization

Load rate	Node 2 (p.u.)	Voltage of node 5 (p.u.)	Voltage of node 8 (p.u.)	Voltage of node 15 (p.u.)	Voltage of node 19 (p.u.)
10%	1.095	1.096	1.096	1.112	1.123
40%	1.088	1.09	1.089	1.105	1.115
70%	1.082	1.083	1.082	1.098	1.107

Output power model of micro power supply

Separate output models are built for the photovoltaic module and the small hydropower in the microgrid system with new energy.

The photovoltaic power generation system uses the MPPT control strategies to obtain the largest active power[11]; and the active power of the small-scale photovoltaic power station can be estimated according to the following formula

$$P_{PV} = P_{STC}(\frac{G_T}{G_{T,STC}})[1+\alpha_P(T_c - T_{c,STC})] \quad (1)$$

where, P_{PV} represents the active power of small-scale photovoltaic power station; P_{STC} represents the rated output active power of the photovoltaic array under standard rating conditions, with the actual value of 10kW; G_T represents irradiance intensity; $G_{T,\mathrm{STC}}$ represents the irradiance intensity of the light source under the standard test conditions, with the value of 1000w/m2; α_P represents photovoltaic battery power temperature coefficient and it's related to the types of photovoltaic battery and materials, and in fact, the photovoltaic battery power temperature coefficient α_P of the mainstream polycrystalline silicon photovoltaic battery used in the market is -0.5; $T_{c,\mathrm{STC}}$ represents photovoltaic battery operating temperature under standard test conditions, with the value of 25℃; T_c represents the operating temperature of photovoltaic battery in photovoltaic power generation system. According to local natural conditions, the photovoltaic output power can be calculated according to the Formula (1). During optimization, regard the photovoltaic as "Negative" load for treatment.

For small hydropower stations, the local power grid requires its power factor above 0.95. For simplicity, assuming that all small hydropower stations are running under constant power factor mode and the power factor is always 0.95, then its active power output is the system optimization variable.

Optimized mathematical model of small hydropower output

Take the small hydropower output as an optimization variable and setthe optimal scheduling cycle of the microgrid as 1 h.And take the microgrid composed by the small hydropower, photovoltaic and energy storage devices and the interconnected distribution grid as an infinite power supply, then set the constant voltage at the grid connection point as 10.5kV.

Objective function

The optimization objective of this paper is under the premise of meeting a variety of operating constraints of the system, to

(1) Minimize the line loss of the system

(2) Minimize the abandoned water quantity,that is maximizing the output power of each small hydropower station in the system to achieve a better economic benefit.

Optimization objective function is:

$$\min F = \min C \cdot P_{Loss} + \sum_{i=1}^{N_G} (P_{GNi} - P_{Gi}) \tag{2}$$

Where, F represents the optimization objective which is the composite function of system line loss and small hydropower generating capacity; C represents the weight coefficients of system line loss; P_{Loss} represents the total line loss of system, which is obtained through load flow calculation; N_G represents the total number of small hydropower; P_{Gi} represents the output power of the ith small hydropower station, P_{GNi} represents the rated output power of the ith small hydropower station.

Constraints

Constraints of the system include micro-power output constraints, the system power balance constraints and bus voltage constraints.

(1) Micro-power output constraint:

$$P_{Gi,\min} \le P_{Gi} \le P_{Gi,\max} \tag{3}$$

Where, P_{Gi} represents the output power of the i[th] small hydropower, $P_{Gi,\min}$ represents the lower limit of the output power of the i[th] small hydropower, $P_{Gi,\max}$ represents the upper limit of the output power of the i[th] small hydropower.

(2) System power balance constraint:

$$\sum_{i=1}^{N_G} P_{Gi} + P_{PCC} = \sum_{j=1}^{N_{load}} P_{load} + P_{Loss} \tag{4}$$

Where, N_G represents the total number of small hydropower; P_{Gi} represents the output power of the i[th] small hydropower; P_{PCC} represents the active power that the large power grid inputted to microgrid at the connection point of microgrid; P_{Loss} represents the total line loss of system, which is obtained through load flow calculation.

(3) Constraint of voltage without out-of-limit:

The national standards stipulate that the line voltage of 10kV should not exceed $\pm 7\%$ of the rated voltage, therefore,

$$0.93Un_i \le U_i \le 1.07Un_i \tag{5}$$

Particle Swarm Optimization (PSO)

Particle swarm optimization was put forward by James Kennedy and Russell Eberhart in 1997 for the first time, which belongs to evolutionary algorithms, with advantages such as easy to program, less empirical parameters need to be set and fast to convergence, etc.. In this paper, the particle swarm optimization with inertia weight was used to accelerate the convergence speed [12, 13]

When conducting practical programming, selecting active power of four small hydropower stations $P_{Gi}(i = 1,2,3,4)$ as the optimization variables, therefore, each particle has four dimensions as $[P_{G1}, P_{G2}, P_{G3}, P_{G4}]$. For the constraints given by Formula (3), exterior penalty function method is introduced, to reckon the constraints into the objective function in the form of a penalty term of penalty function, with the value of penalty factor of 100, as shown in Formula (6):

$$\min F'(x)=\begin{cases} F(x)+\sigma\left\{\sum(U_i-1.07U_{ni})^2\right\} & \text{if } U_i>1.07U_{ni} \\ F(x)+\sigma\left\{\sum(U_i-0.93U_{ni})^2\right\} & \text{if } U_i<0.93U_{ni} \\ F(x) & \text{else} \end{cases} \quad (6)$$

Optimization results

According to natural lighting data of the microgrid area, using Formula (1) to calculate the output of small-scale photovoltaic power stations as shown in Figure 2.

Typical daily load factor curve of the microgrid area is shown in Figure 3.

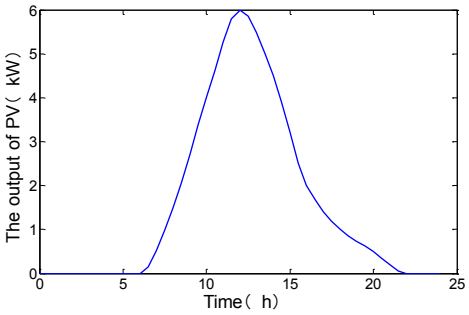

Fig.2. The output power of photovoltaic power generation

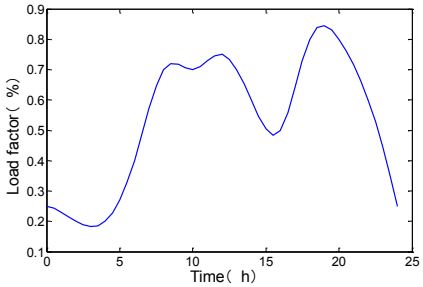

Fig.3. Typical daily load factor curve of the microgrid area

According to the above model and data, using MATLAB to conduct optimal calculations, use MATPOWER flow calculation program and particle swarm optimization, and then the optimized active power output of four small hydropower stations will be obtained, as shown in Figure 4.

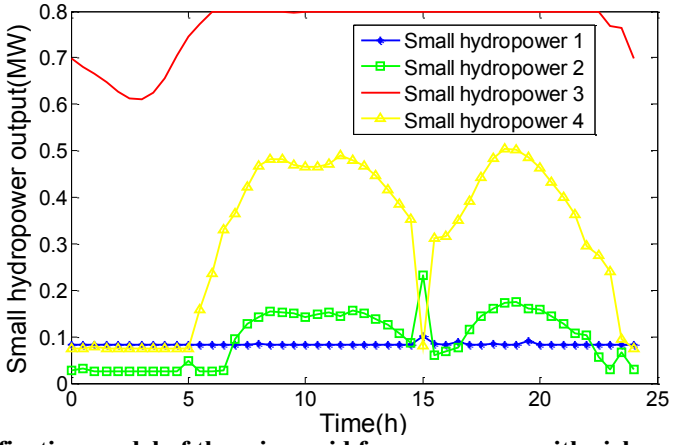

Fig.4. Simplification model of the microgrid for new energy with rich small hydropower

Figure 4 shows that, the output power of small hydropower 3 remains higher after optimization and it keeps in full load at high load; while the output power of small hydropower 1 and small hydropower 2 are significantly restricted. Compared to the system model shown in Figure 1, we can find that, it is because small hydropower 1 and 2 are at the tail end of power grid that their output power give a great impact on the voltage of the tail end of the line. The output must be restricted to prevent bus voltage of microgrid out-of-limit,.

Voltages of each node of small hydropower output before and after optimization are shown in Table 4. It can be seen that the voltage of each node are all qualified after optimization. The comparison of line loss of the system before and after optimization is shown in Table 5; we can see that the system line losses have a significant reduction as well after optimization.

Table.4. Comparison of the voltage of the key nodes before and after optimization.

	Node 2 (p.u.)	Voltage of node 5 (p.u.)	Voltage of node 8 (p.u.)	Voltage of node 15 (p.u.)	Voltage of node 19 (p.u.)
Without optimization	1.092	1.093	1.093	1.109	1.120
After optimization	1.042	1.043	1.043	1.059	1.069

Table.5. The comparison of transmission losses of the system before and after optimization

Time (h)	0	2	4	6	8	10	12

Line losses of the system after optimization (MW)	0.06	0.063	0.057	0.057	0.06	0.069	

Conclusions

This paper studies the optimization problem of each micro power supply of microgrid with small hydropower. Under the premise of meeting all constraints of system operation, take output power of each small hydropower in microgrid as optimization variables to make transmission losses of the system as small as possible and the abandoned water quantity of small hydropower as little as possible. Take the real system somewhere in Jiangxi as examples, and then adopt particle swarm optimization to conduct numerical simulation. The calculating result verifies the validity of the optimization algorithm mentioned in the paper, and provides a meaningful reference for further study of economic operation of new energy microgrid with small hydropower.

Keywords: Chemical Industry Park; Power Supply and Distribution system; Fuzzy Comprehensive Evaluation; Subjective and Objective Comprehensive Weight; AHP; Standard Deviation

Abstract. The plan for power supply and distribution system in the Chemical Industry Park is complex. The evaluation method must be easy and truly show the site conditions in order to maintain the proper function of the system. Thus the fuzzy comprehensive evaluation method was chosen and applied in this paper. As for the weight calculation, Analytic hierarchy process (AHP) was used to compute the subjective weight; on the purpose of avoiding strong effect of subjective factors, the standard deviation for each index was calculated, and then the subjective weight was integrated to build the subjective and objective comprehensive weight model. Lastly fuzzy comprehensive evaluation method was applied into the model for assessing the power supply and distribution system in the Chemical Industry Park.

Introduction

Planning and configuration of the power supply and the distribution system in the chemical industry park is complicated. The topology, load, power source and distribution unit are different from those in high-voltage transmission systems [1]. According to statistics, the percentage of power outage caused by faults of distribution units exceeded 90% [2]. The evaluation method must be easy and truly show the site conditions in order to maintain the proper function of the system. Fuzzy comprehensive evaluation, which integrates the qualitative and quantitative analyses, has been widely used in the areas of engineering technology and management evaluation [3] [4]. The first key point for utilizing this method is the selection of membership function, and the second one is the determination of the index weight [5].

Subjective and Objective Comprehensive Weight

In this paper, the target layer A is set as a single element; the criteria layer B contains p elements; the index layer C contains m elements. Referring to the index weight for the target layer A and the criterion layer B, the importance of each index in the criteria layer is compared using the AHP classical method [3]. The following judgment matrix was built:

$\mathbf{A}$ - $\mathbf{B_i}$	$\mathbf{B}_1$	$\mathbf{B}_2$	…	$\mathbf{B}_p$
$\mathbf{B}_1$	b_{11}	b_{12}	…	b_{1p}
$\mathbf{B}_2$	b_{21}	b_{22}	…	b_{2p}
…	…	…	…	…
$\mathbf{B}_p$	b_{p1}	b_{p2}	…	b_{pp}

The judgment matrix $A-B_i=\left(b_{ij}\right)_{p\times p}$ has the following nature: ① $b_{ij}>0$ ② $b_{ji}=1/b_{ij}$ ③ $b_{ii}=1$ .Among which, b_{ij} is the importance degree for b_i compared to b_j . The rating scale method, 1-9, is generally used[4].

The judgment matrix shows the importance degree between two elements, and the result is ${W_B}^A = \left({w_{B_1}}^A, {w_{B_2}}^A, \cdots, {w_{B_p}}^A \right)$. In order to maintain consistency of importance degree for all elements in a layer, consistence check needs to be performed, and the eigenvalue method is generally used. The calculation method for the weight of index layer-criterion layer ${w_{C_j}}^{B_k} = \left({w_{c_1}}^{B_k}, {w_{c_2}}^{B_k}, \cdots, {w_{c_m}}^{B_k} \right), j \in (1,2,\cdots,m), k \in (1,2,\cdots,p)$ is the same as that for the weight of criterion layer-target layer. It is noted when index C_j and B_k in the index layer are not related, the value of ${w_{C_j}}^{B_k}$ is 0 [5].

The number of p weight between the criterion layer B and the target layer A is ${w_B}^A$. The number of m weight between the index layer C and index B_j in the criterion layer is ${w_{C_j}}^{B_k}$. The sequence for element C in the index layer to the target layer is as follows:

$$ {w_{C_j}}^A = \sum_{j=1}^{m} {w_{B_k}}^A \cdot {w_{C_j}}^{B_k} \tag{1} $$

If n experts evaluate a system including m indexes, the score matrix is F.

$$ F = \begin{bmatrix} F_{11} & F_{12} & \cdots & F_{1m} \\ F_{21} & F_{22} & \cdots & F_{2m} \\ \vdots & \vdots & & \vdots \\ F_{n1} & F_{n2} & \cdots & F_{nm} \end{bmatrix} $$

Expectation μ_j of unified j attribute and standard deviation σ_j are as follows:

$$ \mu_j = \frac{1}{n} \cdot \sum_{i=1}^{n} F_{ij} $$

$$ \sigma_j = \sqrt{\frac{1}{n-1} \cdot \sum_{i=1}^{n} \left(F_{ij} - \mu_j \right)^2} \tag{2} $$

Based on the standard deviation σ_j, its standard deviation weight w_j is calculated as follows:

$$ w_{obj} = \frac{\sigma_j}{\sum_{j=1}^{m} \sigma_j} \tag{3} $$

If ε_j is the subjective and objective index of index j, the subjective and objective comprehensive weight is as follows:

$$ w_j = \frac{\varepsilon_j}{\sum_{j=1}^{m} \varepsilon_j} = \frac{{w_{C_j}}^A \cdot \sigma_j}{\sum_{j=1}^{m} \left({w_{C_j}}^A \cdot \sigma_j \right)} \tag{4} $$

Fuzzy Synthetic Evaluation Model

The factor gather is set to $U = (u_1, u_2, \cdots, u_s)$, and the assessment set is $V = (v_1, v_2, \cdots, v_m)$. If the evaluation result of the i expert among n experts is fuzzified by membership function, then the fuzzy relationship matrix is described as R_i.

Based on the calculations of the subjective and objective comprehensive weight w and the evaluation matrix R_i, the mathematical model for fuzzy comprehensive evaluation is $B = R_i \times w$. The common form of this model in the paper is:

$$ B_i = R_i \cdot w \tag{5} $$

B_i is unified to $\overline{B}_i$, and the comprehensive evaluation result of the i expert is as follows:

$$G_i = \overline{B}_i \cdot V^T \tag{6}$$

Based on the previous sequence, perform the calculations and integrate evaluations of n experts, so the vector $G = [G_1, G_2, \cdots, G_n]$.

Case Analysis

Fig.1 shows the index evaluation system for the power supply and distribution system in a chemical industry park, in which the operating status was evaluated using the fuzzy comprehensive evaluation method.

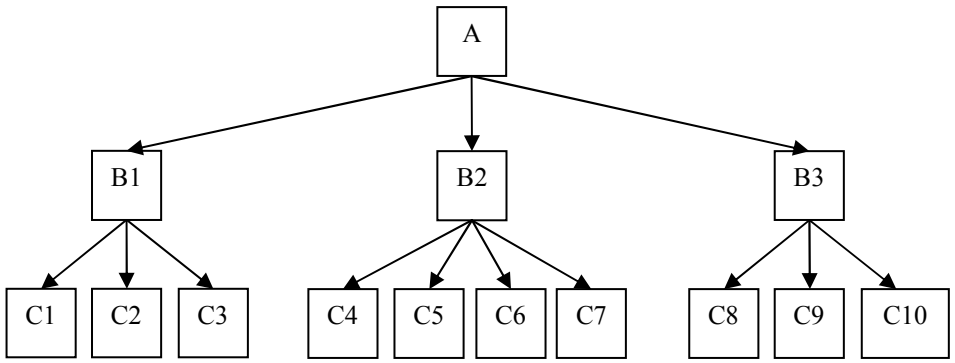

Fig.1. Index Evaluation System for Power Distribution System in Chemical Industry Park

Note: **A: overall performance; B1: economical efficiency;** C1: operating economical efficiency; C2: construction economical efficiency; C3: annual cost; **B2: reliability;** C4: average duration for system power outage; C5: average frequency for system power outage; C6: average system power supply availability; C7: costs of power outage; **B3: coordination;** C8: coordination of power supply capability for medium voltage distribution network; C9: coordination of power supply capability for high voltage distribution network; C10: matching degree of various level power transformation capacity.

The 5 scales conservative trapezoidal membership functions are utilized, as shown in Fig2-1. The score scale is defined as: 50-100, 100-90, optimum; 80-90, suboptimum; 70-80, good; 60-70, worse; 50-60, worst. Eight experts marked 10 indexes, and the result matrix F is shown as follows:

$$F = \begin{bmatrix} 78.0, 78.0, 91.0, 75.0, 93.0, 83.0, 82.0, 85.0, 80.0, 82.0 \\ 70.0, 68.0, 80.0, 73.0, 88.0, 92.0, 75.0, 71.0, 77.0, 77.0 \\ 71.0, 87.0, 87.0, 77.0, 91.0, 87.0, 78.0, 79.0, 78.0, 94.0 \\ 67.0, 83.0, 89.0, 83.0, 89.0, 80.0, 76.0, 77.0, 82.0, 68.0 \\ 65.0, 87.0, 88.0, 79.0, 90.0, 84.0, 77.0, 76.0, 80.0, 81.0 \\ 67.0, 79.0, 89.0, 81.0, 93.0, 90.0, 88.0, 85.0, 87.0, 65.0 \\ 77.0, 91.0, 90.0, 88.0, 89.0, 82.0, 84.0, 77.0, 81.0, 89.0 \\ 78.0, 88.0, 85.0, 76.0, 91.0, 89.0, 84.0, 83.0, 75.0, 84.0 \end{bmatrix}$$

According to the contents of first section, the results are $w_B{}^A = [0.54, 0.30, 0.16]$ and $w_C{}^B = [0.14, 0.29, 0.57, 0.15, 0.50, 0.27, 0.08, 0.12, 0.32, 0.56]$. The subjective and objective comprehensive weight is $w_C{}^A = [0.08, 0.15, 0.31, 0.05, 0.15, 0.08, 0.02, 0.02, 0.05, 0.09]$ according to Eq.1.

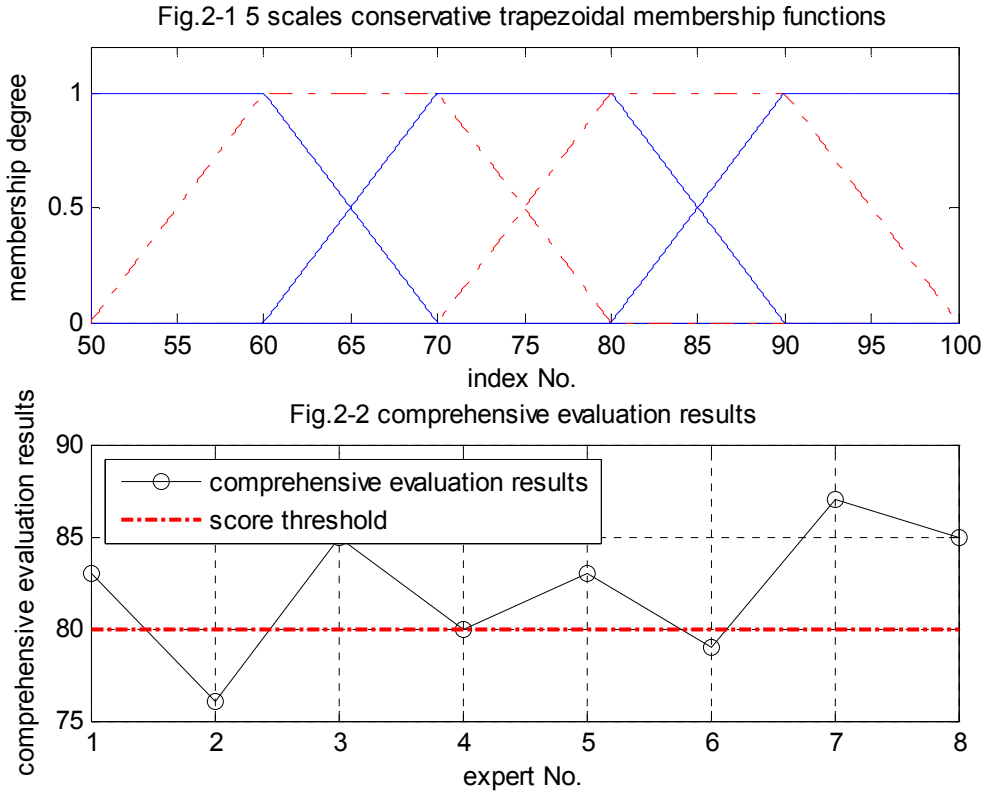

Fig.2. Membership functions and comprehensive evaluation results

The standard deviation for indexes F is $\sigma=[5.34,7.42,3.50,4.87,1.85,4.26,4.66,4.91,3.63,9.83]$, and the standard deviation weight for indexes F is $w_{obj}=[0.11,0.15,0.07,0.10,0.04,0.08,0.09,0.10,0.07,0.20]$, according to the Eq. 2 and Eq. 3; the subjective and comprehensive parameter is $\varepsilon=[0.41,1.14,1.08,0.22,0.27,0.34,0.11,0.10,0.19,0.90]$, according to formula 4; the subjective and objective comprehensive weight is $w=[0.09,0.24,0.23,0.05,0.06,0.07,0.02,0.02,0.04,0.19]$, as shown in Fig. 3.

The assessment $V=(50,65,75,85,95)$. The score threshold in the thesis is 80, and the threshold for number of people is 80%. The vector for eight experts' evaluation scores is $G=[83,76,85,80,83,79,87,85]$ according to formula Eq. 5 and formulae. 6, so 7 people pass the score threshold, as shown in Fig2-2. So the requirements for threshold for number of people is met, which mean the power supply and distribution system in the chemical industry park passes the evaluation.

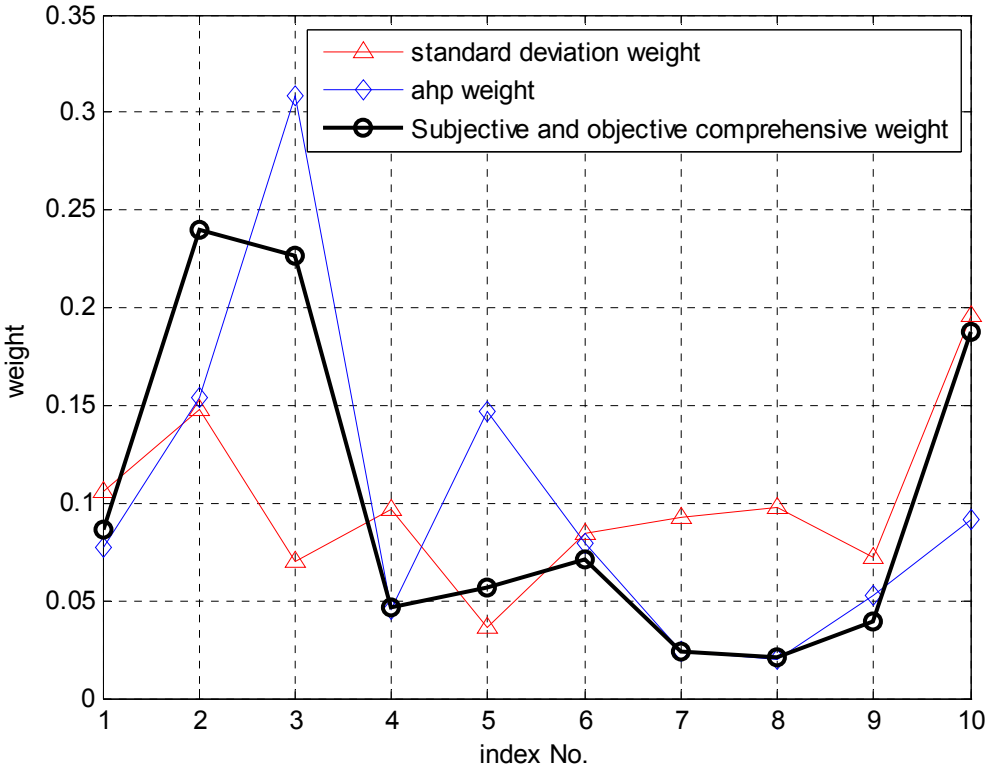

Fig.3. The three weights comparison chart

Conclusion

In this paper, we set the standard deviation weight as the objective weight, which is more constant. AHP weight is set as the subjective weight, which is more volatile. Subjective and objective comprehensive weight is as far as we can see in Fig. 3, which combines the advantages of both standard deviation weight and AHP weight, so that the comprehensive weight is even more moderate. . In the model being assessed, the evaluation result is consistent with the actual situation of the power distribution system.

Keywords: Power System Planning, Simulation, Contingency Analysis

Abstract. The objective of power system planning is to meet the requirements of the customers of the power supply bureau in a region. In addition, a good system planning is helpful to the construction, operation and power supply of a power system. Using a simulation tool is much more convenient than relying on experience or the pure analysis in theory for power system planning. In this paper a method of system planning by simulation is discussed through a certain case. Based on the results of experiments, it is shown that this is an efficient way to make a power system plan.

Introduction

Power system planning is not only an important part of the development of economy and society of a region, but also a fundamental basis of the long-term growth of the power system. The objective of power system planning is to meet the need of its users. Moreover, a good system planning is helpful to the construction, operation and power supply of power networks [1].

In order to make a perfect plan, a simple and convenient method is used in this paper. Rather than relying on experience or the pure analysis in theory [2] [3], using a simulation tool may promote power system planning. With the development of power system, it is significant to make power system planning by simulation.

The Design of a power system planning by simulation

The design of a power system planning is as follows. First, initial power flow is to be analyzed to make sure the security situation of a certain power system. Generally the assessment indicators are the bus voltage and line load by the results of simulation. Second, use the contingency analysis function of the simulator to make N-1 fault analysis. Finally the most secure and economical expanding plan is determined on the base of the load added to the original power system.

There are 3 schemes designed according to the given condition of the certain case. By the comparing of both technical and economical aspects, the final program is decided. The calculation formula of the cost is as follows:

The total cost of reconstruction = the additional construction cost – the saving cost after reconstruction.

A simulator named Power World Simulator (PWS) is used. PWS is a kind of visual software of power system [4]. It consists of 5 modules: power flow function, fault analysis, sensitivity analysis, OPF analysis, and malfunction analysis [5] [6].And the modules of power flow function and fault function are used here.

In a word, with the increasing of the load and the complexity of power system, it is significant and practical to use the method of simulation for power system planning.

A case about application on power system planning by simulation

The given conditions are as follows: A large enterprise will build a new plant in the city. To meet the additional load, a new substation served at 69kV will be constructed at this location.

The peak load of the substation is 45MW and 100Mvar. Because the production is very sensitive to blackouts, this new plant requests that at least two separate lines to the new substation are provided. The new substation is required to be large enough to accommodate a 138/69-kV transformer as well.

Now, the goal is to design a new substation on the least cost way. At the same time, it is an opportunity to fix some existing contingency problems. Specifically, the task is to make recommendations for the best transmission system besides reinforce the power system. The secure system operation requires that no lines or transformers are loaded higher than 100% of their ratings and that all bus voltage magnitudes are between 0.95 and 1.08 per unit.

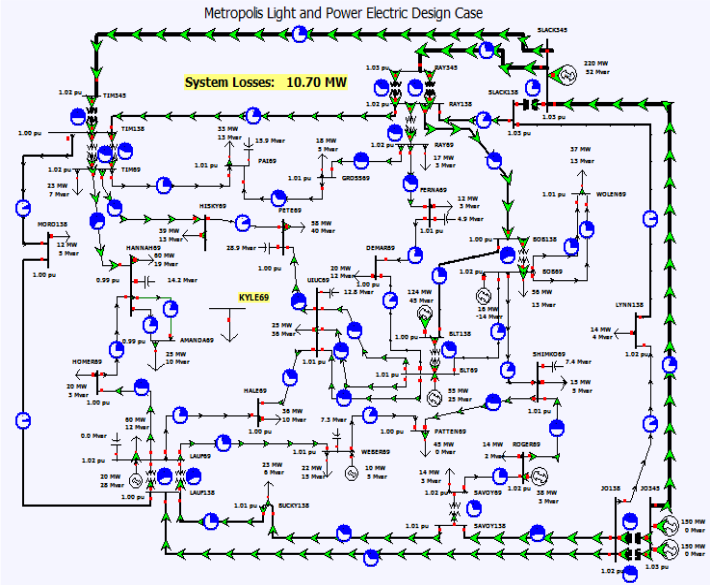

Figure 1 Initial power system of the case

Design procedures are as follows:

(1)Use Power World Simulator to make a one-line draw. Examine the operation situation of power system without new load by demonstrating original power flow. Make sure that all the line flows and bus voltage magnitudes are within certain limits.

(2)Make contingency analysis which means to considerate N-1 fault analysis under any outage of transmission line or transformer.

(3)Use the given parameters and costs of transmission line to determine the least expensive system addition so that the base case and all the contingences results in secure operation points with the new KYLE69 load(in Fig. 1). The definition of the total cost of an addition is equal to the construction cost plus the cost from changes in system losses over in the next five years.

According to the request, build simulating model and make power flow calculation by using PWS. The calculation results are shown in Fig. 1.

It is shown that all the buses and circuits are in good condition in the original power system. None of the electric parameter goes beyond the limits.

Then a contingency analysis on the original power system is conducted. That is N-1 fault analysis. And the results are shown in Fig. 2.

The results shows that although the power flows don't go beyond the limits while the original power system is operating normally, some hided weaknesses can be exposed by contingency analysis simulation.

So the corresponding solution is put forward: some reactive power compensation equipments are used to make voltage regulation according to the phenomenon of low voltage. And the design of the new economic program relates to the security of the power system.

The given conditions are as follows:

Transmission lines (69KV and 138KV): new transmission lines include a fixed cost and a variable cost. The fixed cost is for purchase or installation of the 3-phase circuit breakers, associated relays, and changes to the bus structure in the substation. The variable costs depend on the type of conductor and the length of the line. Transformer (138KV/69KV): Transformer costs include associated circuit breakers, relaying and installation.

Figure 2 Results of contingency fault analysis to the initial system

According to the request there are three additional proposals as shown in Fig. 3, 4 and 5 respectively. The project requests that the new load should be provided power by two lines for the reason of reliability.

(1)Proposal 1:select 2 from 7 69-kV buses discretionarily and connecting them to KYLE69.（Fig.3）

(2)Proposal 2: select 2 from 3 138-kV buses discretionarily and connecting them to KYLE69 by 2 138/69kV additional transformers respectively. （Fig.4）

(3)Proposal 3: discretionarily select 1 from 7 69-kV buses connected to KYLE69 right and 1 from 3 138-kV buses connected to KYLE69 by a 138/69kV additional transformer. （Fig.5）

(4)

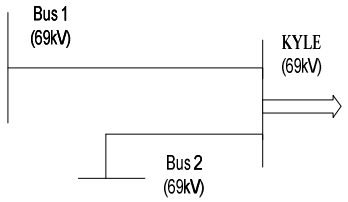

Fig. 3 Diagram for Proposal 1

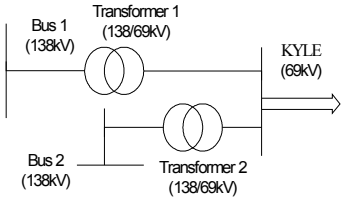

Fig. 4 Diagram for Proposal 2

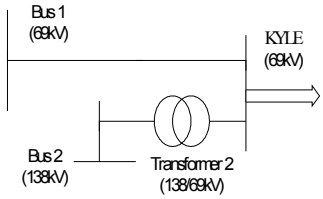

Fig.5 Diagram for Proposal 3

The analysis of the proposals simulation and calculation of new cost is as follows.

Among 3 proposals if proposal 1 is chosen, the power system can't be in normal operation and has more problems in contingency analysis. The initial power system is frailer in the region of additional load. Additional load is much larger than other load in this region. So the power system may be over loaded easily when additional load is connected. What's more, problems of low bus voltage and line overload may become more serious in original power system while N-1 fault happens.

If proposal 2 is chosen, by PWS simulation to the additional load program, power system can be in stable and normal operation. And the problem of contingency can be well solved by a potential transformer. But high cost should be considered.

If proposal 3 is chosen, power system can be in stable operation and normal situation. The problem of contingency can be well solved by an additional transformer. The highest loss is 12MW if MORO138 and AMANDA69 are chosen to be connected to KYLE69.And there is 1.2MW more than the initial loss. But from the total cost of rebuilding comparison, the cost of connecting MORO138 and AMANDA69 to KYLE69 is much lower than any connecting way of the other two.

Test results

The calculation formula of the cost is as follows:

The total cost of rebuilding = the additional building cost – the saving cost after rebuilding

Make the cost calculation of other connection methods in the same way as Table 1.

Three proposals are designed aimed at the request of additional load based on initial power system. Connecting additional load to KYLE 69 may lead to the power system breakdown or malfunctions during N-1 faults according to proposal 1. Proposal 2 and 3 can both meet the request of the project, but proposal 2 has to increase a very large cost for adding another potential transformers. The most economic method is to connect MORO138 and AMANDA69 to KYLE69. The total price of rebuilding is $3610200 which is the lowest. And power system can be in stable and secure operation if N-1 faults happen.

Table 1 Comparison of the cost from several ways of connection

Location	HISKY	AMANDA	PETE	TIM	LAUF	UIUC	HOMER
Addition Cost /$10^4$$	579.52	361.02	559.36	649.11	601.36	628.48	583.00

Conclusion

This paper mainly introduces the application of simulation in power system planning. The power flow analysis and contingency analysis to initial power system are made firstly. And more attention to comparing those proposals in both security and economy aspects after connecting new load is paid. Then the most reasonable method of connection is developed.

The practical result to design power system by simulation is drawn in this paper. With the development of power system, the method of using simulation software to design and plan power system has become the tendency.

Keywords: Load; Forecasting; Decision; Tree Step Regression

Abstract. This paper presents the results of a study regarding the relationship between temperature and power load of the electric power system. Weather-influenced load part is picked up from original load series data with the conclusion that the lagged effect of temperature on load is within 12 hours. Furthermore, decision tree and step regression methods are employed to get a group of decision trees and corresponding regression equations which are able to quantitatively describe the relationship between load and temperature. A short-term load forecasting algorithm is then developed and its practical implementation shows this quatitative analysis method could reliably reflect the influence of the temperature changes on the load and effectively improve the accuracy of short-term load forecasting.

Introduction

Short-term load forecasting, defined as the estimation of the load in future day , is an important daily work of power system operation department. The accuracy of load forecasting has a great impact on the economic profit of power generation and distribution companies.

Short-term load forecasting is influenced by many factors such as weather condition and holidays. Among these factors, the weather factors, especially the temperature, are the most important factors on accuracy of short-term load forecasting. So the consideration of weather condition is involved in short-term load forecasting in recent years.

Some methods are developed to deal with weather factors in short-term forecasting:

(1) Simple model for load forecast[1][2]. Single piece of weather information and the load of forecasted day are fitted to get the function relationship between load and weather factor.

(2)Similar days Method[3]. The method obtains the similarity of the day forecasted and days in history via cluster analysis on related factors which have influence on load. The load could be forecasted by weighted processing of the loads of days that are similar to forecasted day.

(3) Artificial neural network[4][5]. The neutral network is trained by adopting history data of weather and load. Then the neutral network approaching of non-linear function between load and related factors such as weather can be obtained.

However, these methods still have some disadvantages. In simple model for load forecasting, the randomness of selecting weather information and the form of function make it difficult for load forecasting. The similar days method takes insufficient consideration of long-term load growth. The artificial neural network method is a black box model and operators could not get the quantitative relationship between load and weather factors. These methods do not analyse load and weather factors quantitatively. For load forecasters, the quantitative relationship between load and weather factors is the basis of accurate forecasting.

In this paper, a new method of load forecasting is proposed. The method classifies the load based on weather and other factors. Progressively regression is then performed to get the relationship between load and weather factors in particular type of load. The method could obtain the quantitative relationship between load and different weather conditions. That helps to improve the

accuracy of load forecasting. Because of the weak influence on load forecasting and the inconvience of quantitative analysis, this paper ignores some weather factors such as barometric pressure and humidity. Only temperature is taken into account in the process of quantitative analysis.

Weather-influenced Load Part

Load series could be decomposed into four parts[6]. The load at moment k is shown as followed:

$$Y(k) = N(k) + W(k) + S(k) + r(k) \quad (1)$$

In the equation(1):*Y(k)* is total load; *N(k)* is base load; *W(k)* is weather-influenced load part; *S(k)* is load of special events; *r(k)* is random load part.

As special events have great impacts on load but not representative, the impact should be declined to the bottom to analyse the influence of weather factors on load. *S(k)* should be removed.

The increase of distance between crest and trough and the increase of base load would lead to the increase of total load. The average growth rate of load at different moment should be calculated before analysing the effect of long-term increase load part. The average growth rate of load is shown as Fig.1:

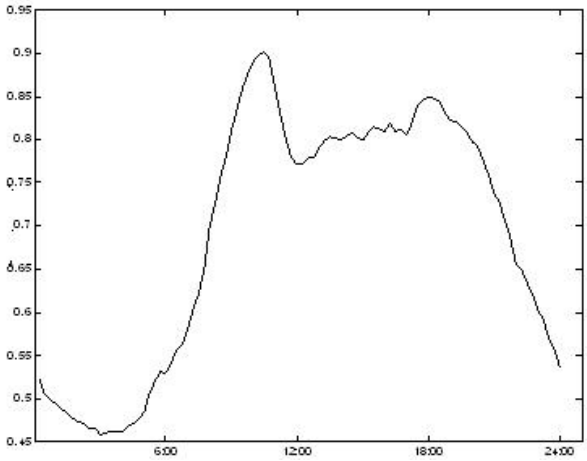

Fig 1 Load growth rate of different moment

The base load, long-term growth load and the load in special events are removed, the load at moment k could be presented as followed equation:

$$Y'(k) = W(k) + r(k) \quad (2)$$

In the equation(2): the definitions of $Y'(k)$, $W(k)$ and $S(k)$ are the same as that in equation(1). Since the random load obeys normal distribution with zero mean and constant variance, the random load would be neglected in the following analysis. This implies the character of load series $Y'(t)$ reflects that of weather-influenced load series $W(t)$.

Analysis of Lagged Effect on Load Caused by Temperature

The effect on load caused by temperature is inevitable because the effect is the response to weather change made by users and the effect is lagged.

As $Y'(t)$ is in day and month periodicity and the data of temperature is also in day periodicity, the article analyses the lagged effect in splited periods.

Because the temperature at close time has the same trend, the conclusion that the load varies with the change of temperature could not be reached. This article obtains the lagged effect of load caused by temperature by calculating the correlation coefficient between load and temperature each moment.

The correlation coefficients of the power load temperature are shown in Table 1 and Table 2. The numbers in bold indicate bigger correlation coefficients. The temperature at corresponding moment is considered to have the most impact on power load. The lagged effect of power load after midnight is obvious and the users who work before midnight react to the change of temperature rapidly.

Then the conclusion could be drawn that the lagged effect of temperature on load changes by time but generally the effect is within 12 hours.

Quantitative Analysis of the Impact of Temperature on Power Load

The relationship between weather factors and power load is multi-variable and non-inear It is so complicated that it can not be expressed by simple model. With decision tree, this article analyses the power load at different periods and temperatures before the studied period. Then the tree-constructed relationship between power load and temperature is obtained. Practically, the data of power load is classified by weather factors at the same time. The classified power load changes within a small range of weather. The relationship between the same type of power load and temperature could be considered linear approximately. With the step regression analysis of every type of load and temperature, the model of the temperature effect on power load could be expressed as decision tree with a set of regression equations. The regression equations represent the quantitative relationship between power load and the temperature belongs to the leaf node of decision tree.

Decision tree is one of the main algorithms of data mining and it is a widely used statistical process. The algorithm of decision tree could be simply described as followed optimization problem: the minimum of $p_e(T, F, d)$ could be obtained in limited training example space. In $p_e(T, F, d)$, P_e is total error rate; T is the structure of tree; F is the test property of inner node; d is the decision rule of inner node.

Because of the day periodicity of $Y'(t)$ and the difference of temperature lagged effect on load at different moment, this article gets 24 decision trees by modeling on load at 1 to 24 o'clock.

Based on the analysis, this article chooses the temperature data at 8 o'clock on the forecasted day and the day before as the property parameters of the decision trees. Taking the week periodicity of $Y'(t)$ into account, the article also chooses the type of forecasted day(non-holiday and holiday) as the property parameters. Then there are 17 property parameters in the test property of final decision trees.

Take the load at 14 o'clock as an example and the forming process of decision trees could be described as followed.

The decision tree has 147 nodes including 67 leaf nodes after fully growing. The best tree with minimum cost complexity could be picked up by cross verificating decision tree in the test collection.

Cut the branches of the best tree based on optimal tree scale and the decision tree after cutting branches is shown as Fig.2:

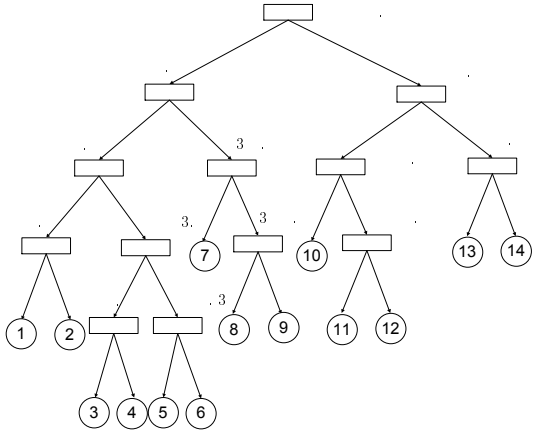

Fig.2 The decision-tree by non-holiday 14 o'clock data

X1 to X16 in Fig.2 are the temperature data at 8 o'clock on the forecasted day and the day before. X17 is the type of forecasted day with the range of 1 to 7 which means Monday to Sunday.

The power loads at 14 o'clock each day could be classified as 14 types which are on behalf of different weather conditions and types of non-holiday. Take the fourteenth leaf node as example and only the nodes which fit the following requirement could be considered as a part of node 14:

1 The temperature at 5 o'clock on forecasted day has to be bigger than 24.15;

2 The forecasted day has to be Saturday or Monday.

3 The load at 20 o'clock the day before has to be more than 24.75 kW • h.

As can be seen, node 14 stands for the condition of holiday with higher temperature which happens in summer especially in July and August. There are 19 data points which could be classified as load type like node 14 in practice data. Similarly, 14 nodes means 14 sets of different types of weather conditions.

After formulating decision trees, this article fits the relationship between weather and load at the same node with stepwise regression. Node 14 is still taken as an example of this process.

The regression equation of node 14 after backward step regression is shown in (3):

$$load = -264.86 + 505.86 * temp(10) \tag{3}$$

The test value F is 19.13, which means the regression effect is good.

In the data of all nodes, the number of rest values is less than two and the notable effect could be ensured at the confidence interval of 95%.

Test Result

To check the correctness of the relationship between weather and power load obtained in the article, the load data from January to August is forecasted by the method developed in this article. The data received by the method is compared with that received by traditional BP neural network and the result is shown as Table 3:

Table3 Comparison of the result with mentioned method and BP method

Month	Day Everage RMSE of Months	
	Method in this article	BP neural network
January	3.06%	3.43%
February	3.29%	4.65%
March	2.95%	3.52%
April	2.37%	2.89%
May	2.54%	2.65%
June	2.62%	2.73%
July	2.96%	3.81%
August	3.43%	4.53%

It could be seen from Table 3 that the method developed in this article is better than traditional BP neural network especially in winter and summer with a large amount of weather-influenced load part. The accuracy of the model gets improved because the quantitative relationship between temperature and power load could reflect the character of weather-influenced load part. The algorithm adopted in this article could avoid the influence of long-term increased load part on the forecasting accuracy in the forecasting process.

Conclusion

The relationship between temperature and load is complicated and nonlinear. It has lagged effect so the quantitative relationship between temperature and load could not be expressed by common functions. However, the quantitative analysis of weather factors and load are the base of accurate load forecasting. This article analyses the power load and weather data recent years. Then the data is classified based on the relationship between load and temperature at different moments with decision tree technique. This article also shows the regression expression about the effect of temperature data on power load. The quantitative relationship between temperature and power load in different weather conditions is then obtained. In addition, the article develops a new short-term load forecasting algorithm. The verification of the new algorithm based on practical system shows that the algorithm could handle different kinds of influence on load and reflects the time-series character of load. The new algorithm helps to improve the accuracy of short-term load forecasting.

Reactive compensation research of HVAC cables for offshore wind farms

Dui Xiaowei, Zhu Guiping

National key laboratory of power system, department of electrical engineering, Tsinghua University, Beijing, 100084

Keywords: HVAC submarine cable; Reactive compensation; Maximum transmission capacity

Abstract. This paper proposes a reactive compensation optimization method for HVAC cables of offshore wind farms, establishing the optimization model of reactive compensation capacity of HVAC submarine cables with cable current-carrying capacity as the main constraints. The maximum transmission power and transmission distance of HVAC submarine cables are calculated, considering the constraints including power factor, line loss and reactive compensation cost. Using minimum average annual cost as the objective function compensation capacity of both cable ends and corresponding average annual cost is obtained are optimized.

Introduction

With the rapid development of wind power industry in our country, China began to explore offshore wind power construction and operation in southeast coastal areas. Compared to the terrestrial environment, offshore wind resource is more abundant and stable, which is suitable for the development of wind power generation. However, offshore wind farms transmit power to onshore grid through HVAC or HVDC submarine cable which is more difficult comparing with power transmission of onshore wind farms. HVAC submarine cable transmission is more suitable for the power transmission of offshore wind farms close to shore. According to domestic and overseas project experience, when the transmission distance is less than 50km, HVAC submarine cable will be more economic. Due to the large unit capacitance of HVAC submarine cable, long-distance power transmission will produce higher charging power, thus affecting transmission capacity of their HVAC submarine cable and leading to a certain of line loss[1]. Therefore, charging power of HVAC submarine cable is one of the key issues to be solved in offshore wind farm. Reactive compensation is the preferred solution for HVAC submarine cable, namely, compensating the charging power of HVAC submarine cable through establishing reactive compensation equipment in wind farms or onshore substation. In recent years, the researches on the reactive compensation problem of HVAC submarine mainly focus on reactive compensation optimization scheme and economics. The literature [2, 3] discusses the differences between single-end and both-end compensation as well as compensation effects of different compensation capacities; the literature [4] compares the economics of reactive compensation scheme and HVDC submarine transmission, drawing a conclusion that reactive compensation is more economical when the transmission distance is less than 50km.

In this paper, a distributed circuit model of HVAC submarine cable is established for researching the relations among transmission capacity, transmission distance and reactive compensation capacity of the HVAC submarine cable. And the differences of compensation effect between compensation at wind farm and compensation at onshore substation are compared, drawing a conclusion that compensation at wind farm can improve the transmission capacity of HVAC submarine cable by balancing current distribution along HVAC submarine cable while compensation at onshore substation cannot. However, better power factor at the grid connection point and less line loss can be achieved by compensation at onshore substation. At the end of the paper, taking the optimal economics within service life of offshore wind farm power transmission system as objective, the reactive compensation capacity of both ends of HVAC submarine cable are optimized, considering the cost of reactive compensation and line losses of the submarine cable.

Optimization results have some reference value for the planning and design of reactive compensation in offshore wind farms.

Theoretical analysis of reactive compensation of HVAC submarine cable

Distributed circuit model of HVAC submarine cable

Represent HVAC submarine cable single-phase model as Π equivalent circuit shown in Figure 1, and its transmission characteristics are as shown in Formula 1.

$$\begin{bmatrix} \dot{U}_1 \\ \dot{I}_1 \end{bmatrix} = \begin{bmatrix} \cosh \gamma l & Z_c \sinh \gamma l \\ \dfrac{\sinh \gamma l}{Z_c} & \cosh \gamma l \end{bmatrix} \begin{bmatrix} \dot{U}_2 \\ \dot{I}_2 \end{bmatrix} \tag{1}$$

Where, γ represents propagation constant, Z_c represents characteristic impedance and l represents line length. Π Equivalent circuit parameters are as follows:

$$Z_{\Pi} = Z_c \sinh \gamma l, Y_{\Pi} = \frac{\cosh \gamma l - 1}{Z_c \sinh \gamma l}$$

To compensate for the capacitor charging power of the HVAC submarine cable, inductive reactive compensation can be installed at both ends. Due to frequent fluctuation in wind farm output power, SVC or STATCOM is usually adopted to guarantee the compensation effect. After the installation of reactive compensation, the HVAC submarine cable single-phase model is shown in Figure 2.

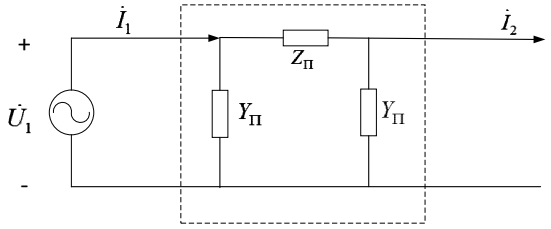

Figure 1 Schematic diagram of HVAC submarine cable model

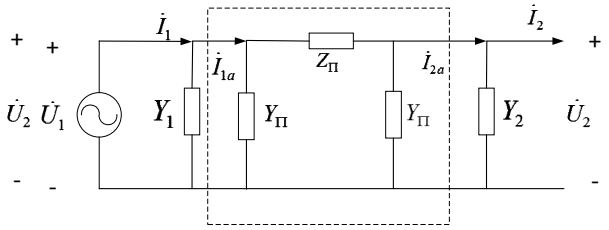

Figure 2 Schematic diagram of HVAC submarine cable reactive compensation model

Where, Y_1 represents the equivalent admittance of offshore end compensation, Y_2 represents the equivalent admittance of onshore substation compensation, in this case its transmission characteristics of its ports is shown in Formula (2):

$$\begin{bmatrix} \dot{U}_1 \\ \dot{I}_1 \end{bmatrix} = \begin{bmatrix} \cosh \gamma l + Z_c Y_2 \sinh \gamma l & Z_c \sinh \gamma l \\ (\dfrac{1}{Z_c} + Z_c Y_1 Y_2) \sinh \gamma l + (Y_1 + Y_2) \cosh \gamma l & \cosh \gamma l + Z_c Y_1 \sinh \gamma l \end{bmatrix} \begin{bmatrix} \dot{U}_2 \\ \dot{I}_2 \end{bmatrix}$$

The maximum transmission power of HVAC submarine cable

The maximum transmission power of HVAC submarine cable is constrained by a variety of conditions, of which the electrical factors mainly include current-carrying capacity and voltage deviation. Excessive current in the cable will raise cable temperature, and thus restricting the transmission capacity of the cable, meanwhile high temperature will have a negative impact on the power transmission security and cable life. Consequently current-carrying capacity is the major factor limiting power transmission capacity of the HVAC submarine cable. The range of allowable voltage deviation shall be determined according to the corresponding standard. In china, the standard *Technical Rule for Connecting Wind Farm to Power System* [5] specifies that the voltage deviation at grid connection point of wind farm should be between -3% and +7% of the nominal voltage. Usually, when the current-carrying capacity constraint is satisfied, the voltage deviation constraint can also be satisfied [1].

The maximum current occurs at either end of HVAC submarine cable, thus the constraints of current-carrying capacity is that the currents just after offshore compensation point and just before onshore compensation point should be below the upper limit of current-carrying capacity.

（1） Calculating the current before onshore end compensation point

Generally the power factor of wind turbine is close to 1, which can be considered that the output current and voltage of wind farm are in same phase. Assuming that the phase angles of $\dot{U}_1$ and $\dot{I}_1$ are both 0, the output voltage $\dot{U}_1$ is 1.05p.u. , and the length l of HVAC submarine cable is known, solve the onshore end current according to Formula (2). As onshore end compensation has no effect on the current distribution along HVAC submarine cable, it can be calculated in accordance with Y2 = 0, therefore

$$\dot{I}_2=\frac{\dot{U}_1-(\dot{I}_1-\dot{U}_1Y_1)Z_c/\tanh\gamma l}{Z_c(\sinh\gamma l-\cosh\gamma l/\tanh\gamma l)}$$

（2） Calculating the current after the offshore end compensation point

The current after the offshore end compensation point can be calculated as:

$$\dot{I}_{1a}=\dot{I}_1-\dot{U}_1Y_1$$

（3）Solving the maximum transmission power

The maximum transmission power of the offshore end equals the maximum output power of wind farm which is calculated as P_1= $3U_1I_1$. According to current-carrying capacity constraints and the foregoing calculation, assuming that the offshore end compensation capacity is Q_a, and the upper limit of current-carrying capacity is I_m, and solve the optimization problem:

$$\max \quad P_1$$

$$\begin{cases} \dot{I}_2=\dfrac{\dot{U}_1-(\dot{I}_1-\dot{U}_1Y_1)Z_c/\tanh\gamma l}{Z_c(\sinh\gamma l-\cosh\gamma l/\tanh\gamma l)} \\ \dot{I}_{1a}=\dot{I}_1-\dot{U}_1Y_1 \\ Y_1=-jQ_a/U_1^2 \\ \left|\dot{I}_2(I_1)\right|\le I_m \\ \left|\dot{I}_{1a}(I_1)\right|\le I_m \\ P_1=3U_1I_1 \end{cases}$$

The onshore end compensation capacity of HVAC submarine cable

Technical Rule for Connecting Wind Farm to Power System stipulates that, for the wind farm connecting to public grid through wind power collection system with 220kV voltage or higher, its inductive reactive compensation equipment should be able to compensate for all the charging power of HVAC submarine cable. Generally the power factor at the outlet of wind turbine is 1, therefore, the power factor of onshore end of the HVAC submarine cable (grid connection point) is also approximately equal to 1, after calculating the offshore end compensation capacity, and the onshore end compensation capacity can be calculated in accordance with the onshore end power factor, namely:

$$Q_b=3\,\mathrm{Im}(U_2I_2)$$

Where, Q_b is the onshore end compensation capacity.

Optimization of HVAC submarine cable reactive compensation

HVAC submarine cable reactive compensation is mainly for improving the transmission capacity, reducing line losses and improving grid power factor; correspondingly, reactive compensation optimization is to maximize transmission capacity, minimize economics and satisfies power factor standards.

As the largest output of wind farm is less than the maximum transmission power of HVAC submarine cable, in the optimization of reactive compensation, it needs to recalculate the economically optimized offshore end compensation capacity. Take offshore end compensation capacity as the independent variable and calculate line loss and reactive compensation cost. Then set the average annual cost as the objective to calculate the required onshore end compensation capacity. The average annual cost proposed in this paper includes economic losses caused by line losses and reactive compensation costs.

（1） Calculation of line loss

Since the onshore end compensation has no impact on the current distribution on HVAC submarine cable, line losses are only related to the offshore end compensation capacity. After calculating the offshore end compensation capacity corresponding to maximum transmission power in accordance with the foregoing method, the economic losses caused by the line losses of HVAC submarine cables are calculated as:

$$C_L = PTp = (P_1 - P_2)Tp$$

Where, C_L represents economic losses of line losses, $\triangle P$ represents loss of active power, T represents converted operation time under maximum power, which is indicated to be the operating time of the wind farm when transmission power is maximized after conversion, and p represents the gird purchase prices.

（2） Annual conversion costs of reactive compensation

Reactive compensation equipment belongs to one-time investment, which should be converted into annual costs within the service life for calculate. For simplicity, this paper share the total cost equally on an annual basis,

$$C_{ca} = C_{ct} / T_L = (kQ_a + Q_b)p_c / T_L$$

Where, C_{ca} represents annual conversion cost of reactive compensation, C_{ct} represents initial total investment cost of compensation equipment, T_L represents design service life of compensation equipment, k represents the offshore cost coefficient, indicating that the unit capacity cost of offshore end compensation equipment is k times of onshore end compensation equipment, p_c represents unit capacity cost of the onshore end compensation equipment.

Considering the constraints of line loss and reactive compensation cost, taking minimum average annual conversion cost of HVAC submarine cable transmission system as the objective, establish reactive compensation optimization model of HVAC submarine cable as follows:

$$\min \quad C$$

$$\begin{cases} Q_b = 3\,\mathrm{Im}(U_2 I_2) \\ Q_a \le Q_{a\max} \\ C_{ca} = (kQ_a + Q_b)p_c / T_L \\ C_L = (P_1 - P_2)Tp \\ C = C_{ca} + C_L \end{cases}$$

Where, $Q_{a\max}$ represents the required offshore end compensation capacity for maximum transmission power when the line length is *l*.

Examples

Use ZS-YJQF41 HVAC submarine cable for calculation example of which main parameters associated with the calculation are shown in Table 1.

Table 1 Main parameters of ZS-YJQF41

Rated voltage (kV)	Capacitance (μF/km)	Inductance (mH/km)	Resistance (Ω/km)	Current-carrying capacity (A)
127/220	0.116	0.437	0.0615	569

Calculate relations between the maximum transmission power and the transmission distance, and the result is shown in Figure 2.

Figure 2 shows that the maximum transmission distance of this model cable is 118km without compensation, and the maximum transmission distance increases to 168km after installing 100MVar compensation at offshore end. It can be seen that the offshore end compensation can increase the transmission distance of HVAC submarine cable. However, excessive compensation capacity will increase current of offshore end, leading to a slight decrease of maximum transmission power of HVAC submarine cable in reason of the limits of offshore end current-carrying capacity constraints. Therefore, the curves in Figure 3 are started from a straight line.

Calculate the offshore end compensation capacity based on the length of HVAC submarine cable to make the HVAC submarine cable reach the maximum transmission power. The relation between the offshore end compensation capacity and the transmission distance is shown in Figure 4.

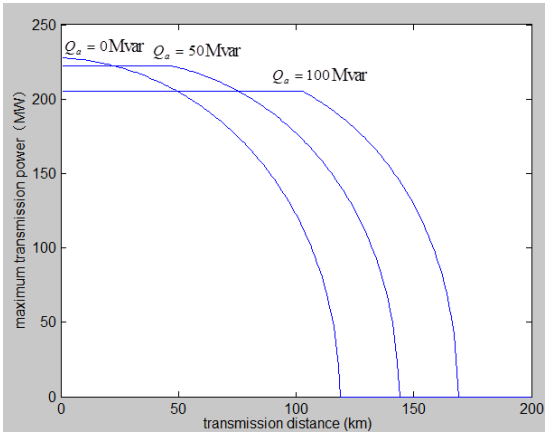

Figure 3 The relations between the maximum transmission power and the transmission distance of HVAC submarine cable

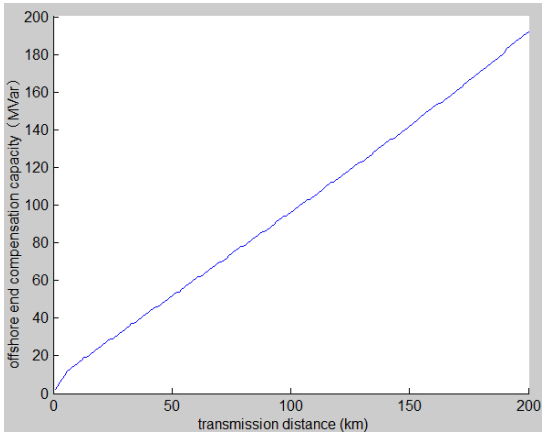

Figure 4 The relations between the offshore end compensation capacity and the transmission distance of the HVAC submarine cable

Figure 4 shows that there is basically a linear proportional relation between the offshore end compensation capacity and the transmission distance. With the increase of the offshore end compensation capacity, the transmission distance will increase accordingly.

The power transmission distance of offshore wind farm is generally less than 50km. Thus take the power transmission distance of $l = 30\text{km}$ and the offshore end transmission power of 100MW to calculate the current distribution and line losses ΔP of the HVAC submarine cable when the offshore end compensation capacity is respectively 0Mvar, 25Mvar and 50Mvar. The results are shown in Figure 5.

Figure 5 shows that, when the compensation capacity is low, the current at the onshore end of the HVAC submarine cable is relative high, and when the compensation capacity is relative high, the current at the offshore end is high. A reasonable compensation should be able to minimize the difference between onshore end and offshore end current magnitude to reach the least line loss.

Optimize the compensation capacity at both end and corresponding average annual conversion cost, using calculating parameters shown in Table 2. Optimization results are shown in Figure 6.

Table 2 Calculating parameters

Unit compensation cost (Yuan/Mvar)	Offshore cost coefficient	Service life (year)	Sales price to network (Yuan/kWh)	Transmission distance (km)	Output power of wind farm (MW)	Onshore end power factor constraint
200,000	1.5	20	0.97	30	100	$\cos\varphi = 1$

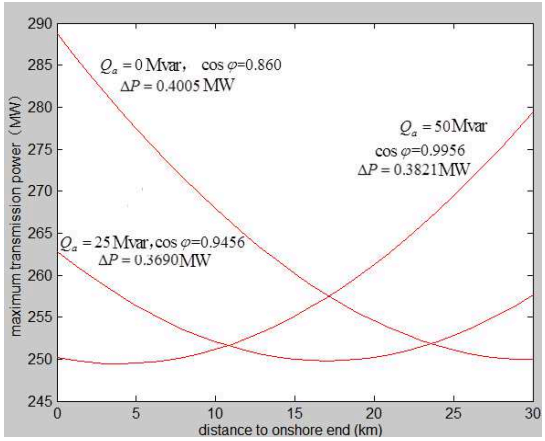

Figure 5 Schematic diagram of current distribution along HVAC submarine cable

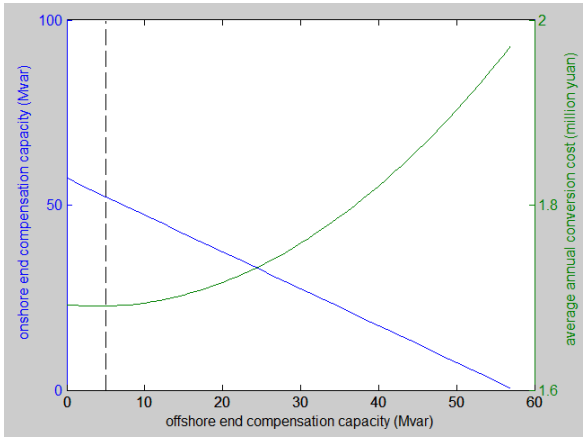

Figure 6 The relations between the compensation capacity of both head end and tail end and average annual conversion cost

When the offshore end compensation capacity is 5Mvar and the onshore end compensation capacity is 52Mvar, the average annual cost is the lowest with 1.691 million Yuan, among which, the conversion cost of reactive compensation equipment is 1.093 million Yuan, the loss caused by line losses is 598,000 Yuan. Obviously, the reactive compensation cost is the main part of the average annual cost, and the economic losses caused by line loss is relatively low, therefore the optimization results tend to reduce the compensation capacity.

Conclusions

In this paper, the reactive compensation of HVAC submarine cable in offshore wind farm has been researched in-depth; the main conclusions are as follows:

（1）The current-carrying capacity constraint is the main factor restraining the power transmission capacity of HVAC submarine cable. This paper deduced the maximum transmission power and the calculation method for the offshore end compensation capacity according to the offshore end and onshore end current-carrying capacity constraints of the HVAC submarine cable.

（2）Considering the factors including requirement of grid connection power factor, line loss of submarine cable and reactive compensation cost, etc., it carries out optimization on both end compensation capacity of HVAC submarine cable taking the minimum value of annual average conversion cost of HVAC submarine cable including reactive compensation equipment as the optimization objective and obtains the economically optimized reactive compensation configuration method.

（3）Through analysis of examples, maximum transmission power and both end compensation capacity have been calculated by using actual cable parameters. From analysis, the offshore end compensation can improve the current distribution, power factor and reduce the line loss of HVAC submarine cable, however, the cost is higher. The onshore end compensation cannot improve the current distribution along HVAC submarine cable, however, it can improve the power factor and reduce line loss with a lower cost comparing with offshore end compensation.

Keywords: FMEA; the different distribution ways; 10 kV radial lines; reliability assessment

Abstract. The 10kV feeder typical configuration is divided into two categories of no standby power and standby power in the paper, and subdivided into different configurations, then we use FMEA to analyze the power supply reliability of 10 kV radial lines under the different configurations, at last we compare and analyze the reliable indexes of the different equipment configuration schemes, such as the reliable rate RS-1, the system average interruption frequency AITC-1 etc. The research results show that space truss structure and switch configuration directly affect the power supply reliability of the distribution network. In the conditions of reserved auto-switch-on device and section switches automatically isolating faults, the power supply reliability rate is the highest, and the average interruption frequency and outage time are the lowest.

Introduction

Distribution power system is in the end of power system, which connects directly to the users. Once the equipment or line fails, it would lead to the interruption of power supply. According to incomplete statistics, more than 80% user power failures are caused by the failures of distribution system, and 10kV feeders are in the end of distribution system, therefore, we urgently need to evaluate reliability of 10kV feeders. A study on reliability of 10 kV typical configuration feeders is conducive to improve the power supply reliability of distribution network, and also has the instruction function to the planning, construction, expansion and reconstruction of power distribution system. Statistics, analysis, evaluation of the reliability indexes and the application of the statistical analysis results have guiding significance to the present system and equipment from the design to manufacture, installation, maintenance and repair [1].

At present, the entire distribution network is as the object of study in the distribution network reliability analysis of domestic and international. The experts set the reliability statistical methods of distribution network fully in detail; developed the software of reliability assessment of distribution system, then established the management mechanism related to distribution system reliability, so that the power supply reliability of the distribution network is researched and managed in China. In other countries, the experts established and perfected the power supply reliability evaluation indexes system, and their research results mainly focused on the reliability evaluation models and algorithms of distribution system.

In this paper, we analyze the reliability of the 10kV feeders in different configuration schemes, basing on the emanate wiring. We combine closely with domestic 10kV feeder typical configuration, and consider mainly that the trunk line installed subsection switches; the first of branch line installed fuses; a standby power supply etc. 10kV feeder has a variety of configuration schemes, and all schemes will be evaluated by using FMEA in the paper. The assessment results will help the electrical technical personnel to choose reasonable configuration schemes, according to the actual situation, which has strong practice and guiding significance.

10kV Feeder Typical Equipment Configuration

We use a typical 10kV domestic emanate feeder as the basis. It is divided into both having standby power and no standby power, and then subdivided into several different configurations. Device configuration classifications are as follows: ① the head of branch lines have not been installed the fuses; ②the head of branch lines have been installed the fuses; ③ the main line has not been installed section switches; ④ the main line has been installed manual section switches; ⑤the main line has been installed automatic section switches; ⑥standby power manual control; ⑦ standby power automatic control. All the cases have been arranged and combined to form different configurations, see table1.

The Power Supply Reliability Indexes and FMEA

Common Indexes of Distribution Network Reliability Evaluation. Distribution system reliability indexes include the load point reliability indexes and system reliability indexes [2]. The reliability indexes of system basing on the load point reliability indexes are quantitative assessment of the distribution network reliability level [3].

Load Point Reliability Indexes. Load point reliability indexes include [4]: failure outage rate λ (time / year); the average outage duration r (hours/time); the annual average outage time U (hours / year).

System Reliability Indexes. System reliability indexes are as follows. AITC-1: the average Interruption times of customer, it refers to the power customer average interruption time in the statistical period, unit: time/ household.

AIHC-1: the average interruption hours of Customer, it refers to the customer average interruption hours in the statistical period, unit: hour/ household.

CAIDI: customer average interruption duration index, it refers to the average interruption duration, which the users without electricity endure at per unit of time. The index is a ratio that the sum of users' interruption duration divided by the total interruption times of users in a year.

RS-1: reliability on service in total, it is a ratio that the total hours during the effective power supply time to users divided by the number of hours in statistical period. The general statistical time is one year, which has 8760 hours in non-leap years and 8784 hours in leap year.

ENS: the electricity shortage index, it refers to the electricity shortage provided to users due to component failure in one year, which is the sum that average load power of every load point multiplied by the load point average interruption duration.

AENS: average energy shortage index, it is electricity expectations of relative power losses of each user caused by the insufficient power supply in distribution system [5].

FMEA. The paper uses FMEA to analyze all possible fault events or component failure, and determine the influence of the load point, then list the failure mode and effects analysis table, at last, obtain the reliability indexes basing on the table. FMEA can calculate three kinds of reliability indexes used grid commonly: load point reliability index, system reliability index, and reliability index related to the load and energy, which can reflect the reliability degree to different aspects [6].

When a fault occurs, the circuit breaker and section switch trip, and we look up the fault segment, then the fault section is isolated in order to troubleshoot. When the circuit breakers and switches close, the loads before fault segment restore power by bus. When the rest loads can be transferred to other line, their outage time is equal to operating time of contact switch, or its outage time is equal to the component troubleshooting time.

4 Reliability Analysis Examples under10 kV Typical Configuration Feeder

A 10kV feeder within the scope of substation jurisdiction work as an example in the paper, and its reliability is analyzed by failure effects analysis method under several kinds of typical configuration schemes. We consider that the power failure of repairing, without considering the equipment periodic maintenance test，construction and expansion, effect of user application, external effect factors, ignoring the effect of bad weather, the power shortage and scheduled interruption. All the branches failure and repairs are independent events. Combining switch configuration, network structure, the main factors that influence the reliability of distribution network are concluded.

According to the data of the wiring, equipment and loads provided by a power substation, it is concluded that the data of reliability assessment we need.

1) The loads concentrate at three places, such as load1, load2, load3 and the loads power are 123.5kW, 171kW, 152kW separately.

2) The main component failure rates and repair time

Failure rates and recovery time of circuit breaker, isolating switches, fuses, switches, trunk line and branch lines are based on amounts of data provided by certain substation. The data include operating records, dispatching logs, planned outage applications, records of switch accident trip in five years.

Reliability Analysis of Different Schemes. 1) No standby power

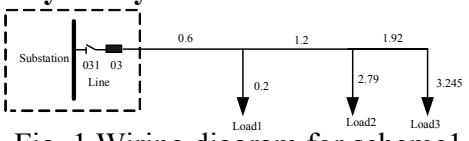

Fig. 1 Wiring diagram for scheme1

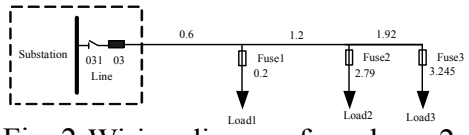

Fig. 2 Wiring diagram for scheme2

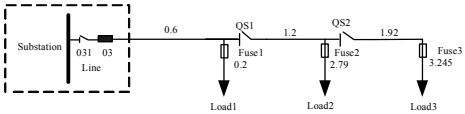

Fig. 3 Wiring diagram for scheme3

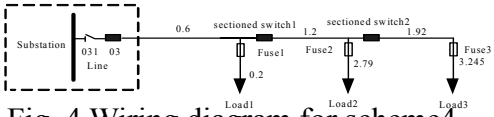

Fig. 4 Wiring diagram for scheme4

Scheme 1: The branch lines have no fuses, the trunk line is not segmented, and no standby power supply, see figure 1. There are not the sectioned switches or disconnector to segment the trunk line in scheme 1. When a trunk line or branch line faults, it will cause the main breaker to trip. There is no breakpoint to isolate system, so it is necessary to exclude each fault before the breaker reclosing. As long as any line encounters fault, it will lead to the all lines outage, each load point has the same failure rate.

Scheme 2: The branch lines have fuses, the trunk line is not segmented, and no standby power supply, see figure 2. The fuses installed in the initial of branch line in scheme2 are a kind of protective measures used usually in the actual power distribution system, namely the branch line protection. T points in each branch line install a fuse, once the branch line faults, the fuse will burn out, so it does not affect other load points and the trunk line.

Scheme 3: The branch lines have fuses, the trunk line is segmented, fault manual isolation, and no standby power supply, see figure 3. The trunk line has been mounted disconnectors in scheme 3. When a fault occurs on the trunk line, the circuit breaker 01 trips, and open disconnector, which can isolate the fault section. The loads in front of fault segment have not been influenced, and their fault outage duration time equals to operation time of disconnector.

Scheme 4: The branch lines have fuses, the trunk line is segmented, fault automatic isolation, and no standby power supply, see figure 4. The disconnectors have been changed into sectioned switches in the trunk line, which can make the load in non faulty line segment be freed from the effect of faulty line segment.

2) Supplied by the standby power

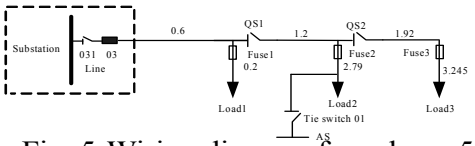

Fig. 5 Wiring diagram for scheme5

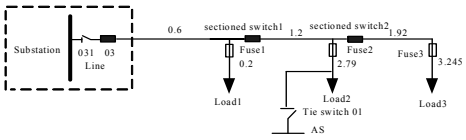

Fig. 6 Wiring diagram for scheme6

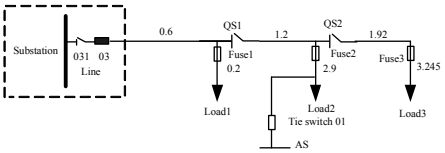

Fig. 7 Wiring diagram for scheme7

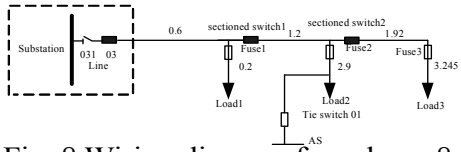

Fig. 8 Wiring diagram for scheme8

Scheme 5: The branch lines have fuses, the trunk line is segmented, fault manual isolation, and a standby power supply (manual control), see figure 5. The standby power connects to the trunk line by the tie switch01, which reduces the power cut off range in scheme 5. When the line that 0.6km long gets a breakdown, load2 and load3 are supplied by standby power. When the line that 1.2km long gets a breakdown, load1 can restore power by main power supply, but load 2, 3 are not supplied by the standby power, and this line section is not charged because of troubleshooting. When the line that 1.92km long gets a breakdown, load1and load2 supplied by the main power, but the load 3 is not supplied until the line has been repaired.

Scheme 6: The branch lines have fuses, the trunk line is segmented, fault automatic isolation, and a standby power supply (manual control), see figure 6. The disconnectors have been changed into sectioned switches in the trunk line, which can make the load in non faulty line segment be freed from the effect of faulty line segment.

Scheme 7: The branch lines have fuses, the trunk line is segmented, fault manual isolation, and a standby power source automatic switch device, see figure 7. Compared with the scheme 6, switching time of standby power decreases, which can reduce the loads' outage time greatly.

Scheme 8: The branch lines have fuses, the trunk line is segmented, fault automatic isolation, and a standby power source automatic switch device, see figure 8. The disconnectors have been changed into sectioned switches in the trunk line.

Reliability Evaluation Procedure and Results Analysis. The calculation steps are as follows:

1) According to the characteristics of FMEA method, the wiring used in distribution network are equivalent, transformers are equivalent to load points.

2) We select the suitable fault criterions, and accord the criterions to analyze all possible failure events, and then determine its impact on the load point, at last list the FMEA table.

3) According to the load reliability indexes in second step and the number of users in the corresponding line, calculate the system reliability indexes related to system.

4) According to the load reliability indexes in second step and the loads data in the corresponding line, calculate the system reliability indexes related to the load and energy [6].

Reliability indexes of the schemes are seen table2.

Table 2. Summary table of system reliability indexes of each scheme

Index / schemes		AITC-1 [Time/ (use year)]	AIHC-1 [(Hour/ (user year)]	CAIDI [Hour/ time]	RS-1	ENS [kWh/ year]	AENS [kWh/ (user year)]
no standby power supply	1	1.641222	2.658944	1.6201	0.999697	1165.636	129.5151
	2	1.413667	2.085667	1.47536	0.999763	922.849	102.5388
	3	1.7803333	2.619	1.4710728	0.9997018	1100.803	122.31144
	4	1.25833	2.16367	1.71947	0.99975	920.797	102.311
a standby power supply	5	1.7803333	1.7583333	0.9876428	0.9997998	729.334	81.037111
	6	1.258333	1.371911	1.09026	0.999844	577.9458	64.2162
	7	1.7803333	1.5113333	0.8489047	0.9998279	622.5445	69.171611
	8	1.25833	1.18091	0.93847	0.99987	494.412	54.9347

The reliability rate RS-1 is the lowest and the wiring is the simplest in scheme1. In scheme8, it has the highest reliability. In scheme2, the reliability is higher than that in scheme 1, because the head of branch lines have been installed the fuses. When any branch line encounters fault, it has no influence on the other loads, which can reduce the scope of fault influence. System average interruption frequency AITC-1 is the same in the scheme3, scheme5 and scheme7. This is to say, system average interruption frequency with radial distribution system installed a backup power is the same as that with single power supply distribution system, which shows that there is no effect on AITC-1 neither the system has standby power supply or not, but the load average interruption duration and the system average outage duration get shortened.

By comparing scheme4 with scheme3, scheme6 with scheme5, scheme8 with scheme7, we can change the disconnector to section switch, so the main breaker in the head of the trunk line does not trip. When any section of line encounters fault, the reliability could improve, because that the section switch isolated fault automatically, and it no longer affects the supply of other loads. Comparing the scheme5 with scheme7, scheme6 with scheme8, we can see that the fault rates of all load point are the same in radial distribution system with standby power, either the standby power supply for manual or automatic, so the average interruption frequency of the system is the same.

In short, the head of branch lines have installed fuses, so the fault line is separated from the trunk line automatically by fuse. When the branch line encounters fault, it does not make the main breaker trip, and does not affect other branches line power supply, so the power outage range reduces [7]. The trunk line has been installed section switches, in the first place, the fault line and the trunk line have been isolated without affecting other loads power supply interruption; in the second place, the non fault line that between the power and the section switch can continue to supply power, which is not affected by the fault line; in the third place, the non fault line that between standby power source point and section switch can restore power by switching operation, which reduces the fault influence scope and the load interruption duration. Through the analysis, standby power can reduce the load average interruption duration, and not affect the failure rate of load, which can reduce the average outage duration AIHC-1 under the unchanged number of users. Thereby BZT is more obvious effect than the manual operation device, which shortens the outage time.

5 Conclusions and Prospect

In the paper, we can see the 8 kinds' schemes in power distribution and their reliability analysis basing on a typical substation 10kV feeder, then we get some conclusions: the reliability of power supply directly affected by device configuration. In scheme1, the reliability is the lowest and the system average interruption duration AIHC-1 is the longest, which due to have not sectioned switches, branch line protection devices and standby power. In scheme8, the reliability is the highest, the system average interruption duration AIHC-1 is the shortest and the ENS is the lowest, which due to the trunk line section, the branch line fuse protection and BZT. Thus it can be seen that sectioned

switch, fuses and standby power play a positive role in the power supply reliability of distribution network.

In order to improve the reliability of power supply, it needs to add sectioned switches, branch line protection devices, the standby power supply and reasonable measures according to the actual situation of power grid. The economic investment question is not considered in the paper, so the problem of economic and reliability coordination is going to be next research direction.

Research and Simulation of Reasonable Distribution of Energy Saving Design Model in Rural Residential

WANG Ying-quan

Sichuan College of Architectural Technology, Sichuan,Deyang 618000,China

KEYWORDS: Residence; Reasonable distribution; Energy saving design

ABSTRACT: In today's society, resources and energy are short. In order to promote our country to build a conservation-oriented society and to achieve sustainable development in the construction industry, the demand for modern residential energy conservation is also growing. Studying and designing of energy-efficient rural residential are one of the key work of energy-saving building. In this paper, the design of residential land use planning, building envelope, outside doors and windows, roof and interior supporting facilities are described for equitable distribution of energy-saving design in rural residential, so as to achieve the design of energy-saving rural residential purposes.

1 Introduction

Currently, the energy shortage has become a constraining bottleneck of China's economic and social development, and building energy consumption accounts for a sizeable proportion of all energy consumption in the country [1-3]. Do best to the work of building energy saving is the key to energy saving [4]. In terms of the construction industry, construction of energy-efficient buildings and reducing building energy consumption have been urgent affairs [5]. The purpose of Building energy efficiency design is through certain building construction practices, choosing the right materials, to achieve the purposes of reducing energy consumption and heat, cold, electricity, fuel and others, but also to guarantee a certain level of comfort. Many energy-saving elements in rural residential, which has great potential, including several aspects of land planning design, building envelope design, external doors and windows design, roof design and interior supporting facilities design.

2 Energy saving design model

2.1 The main content of reasonable distribution of energy saving design in rural residential

Rural residential energy saving design is a systematic project, including planning, design, construction, maintenance and operation management. Its influence factors are complex, to emphasize one aspects separately is very difficult to achieve a comprehensive residential energy saving goals. Rural residential buildings should be arranged in the villages of the best natural conditions and health conditions, and should avoid the pollution of air and water, and bad location, there should be a certain amount of public green space and basic health facilities. Residential orientation has a great impact on its lighting and natural ventilation, so the choice of residential in the "Best orientation" should be based on geographical conditions and climatic conditions. North-south residential arrangement can guarantee residential obtaining adequate sunshine and gables facing the west can effectively avoid exposure to sunlight.

2.2 Achievement of reasonable distribution of lighting energy-saving design in rural residential

In the process of reasonable distribution of energy-saving design in rural residential, the lighting distribution design is a core step, which can select a reasonable lighting modes for reasonable distribution of energy saving design in rural residential. Moreover, the use of rural residential lighting control model can convert the lighting pattern. The procedure describes as follows:

Assuming the rural residential lighting device's voltage parameter is U_j, current sensing coefficient is l, capacitance parameter is d, and lighting duration is T, the following equation can describe the low light illumination model:

$$\begin{cases} U_j = U_l \\ U_l = l \cdot \dfrac{dj_l}{dT} \end{cases} \tag{1}$$

The use of following equation can describe the change of the voltage in process of lighting mode conversion:

$$\Delta U_l^+ = \int_0^{T_1} \frac{U_l}{l} dT = \frac{U_j}{l} T_1 \tag{2}$$

When using a medium brightness lighting mode, the input voltage of the illumination device is cut off, it needed to use the saved voltage to supply power, so it is possible to use the following equation to describe the medium brightness lighting mode.

$$\begin{cases} U_l + U_0 = 0 \\ U_l = l \cdot \dfrac{dj_l}{dT} \end{cases} \tag{3}$$

The use of following equation can describe the change of the voltage in process of lighting mode conversion:

$$\Delta U_l^- = \int_{T_1}^{T_2} \frac{-U_0}{l} dT = \frac{-U_0}{l} \cdot (T_2 - T_1) \tag{4}$$

The following equation can describe high brightness lighting mode:

$$\begin{cases} U_j - U_l = U_0 \\ U_l = l \cdot \dfrac{dj_l}{dT} \end{cases} \tag{5}$$

The following equation can describe the change of the voltage in process of lighting mode conversion:

$$\Delta U_l^- = \int_{T_1}^{T_2} \frac{U_j - U_0}{l} du = \frac{U_j - U_0}{l} (T_2 - T_1) \tag{6}$$

2.3 The evaluation of reasonable distribution of energy saving design methods in rural residential

Using five-point scale to determine the weight function. According to the importance coefficient of each function W_i, it can get the function's average of importance coefficient W, i.e. weights.

$$W = \frac{\sum_{i=1}^{k} W_i}{k} \tag{7}$$

In the equation, K is a function item of participating in evaluation.

The value coefficient is calculated according to the function coefficients and cost coefficients of each program. The equation is $V_i=F_i/C_i$.

Using the data calculated by the equation to get the C to A's comprehensive weight vector that is $N=D^T$.

D=(0.037，0.217，0.097，0.037，0.232，0.046，0.083，0.028，0.129，0.042，0.049，0.036，0.014)

The judgment matrix is $\begin{bmatrix} 1 & 1/3 & 1/5 & 1/7 \\ 3 & 1 & 3/5 & 3/7 \\ 5 & 5/3 & 1 & 5/7 \\ 7 & 7/3 & 7/5 & 1 \end{bmatrix}$, and its eigenvalue of maximum is 4, the consistency ratio CR=0<0.1, passing the one-time test.

Similarly, it can also get the other indicators weights of project X layer to C layer.

$$M=\begin{bmatrix} 0.32 & 0.26 & 0.33 & 0.31 & 0.17 & 0.20 & 0.31 & 0.25 \\ 0.37 & 0.35 & 0.40 & 0.38 & 0.25 & 0.30 & 0.54 & 0.25 \\ 0.26 & 0.30 & 0.20 & 0.23 & 0.33 & 0.30 & 0.08 & 0.25 \\ 0.05 & 0.09 & 0.07 & 0.08 & 0.25 & 0.20 & 0.08 & 0.25 \end{bmatrix} \quad (8)$$

Then it gets:

$$M \times N = \begin{bmatrix} 0.261 & 4 \\ 0.347 & 5 \\ 0.277 & 0 \\ 0.162 & 2 \end{bmatrix} \quad (9)$$

Thus it gets to know that X2's weight is the highest.

3 Calculation and analysis of energy saving effect of reasonable distribution of energy saving design in rural residential

Calculated as shown in Table 1, for example, the effect of rural residential reasonable distribution of energy saving design is analyzed. Through various energy-saving measures, the calculated values and reduction rate of energy consumption can be drawn from the residential reasonable distribution of energy saving, as shown.

In terms of residential reasonable distribution of energy saving, it can also take advantage of the rural ecological advantages, including straw, firewood, making fermentation to produce gas in biogas digester and other energy sources, which can save a lot of coal, electricity and fuel, and improve sanitation in rural areas, as well as can improve manure fertilizer, expanding fertilizer sources, so as to realize recycling of energy, have good economic and social environmental benefits.

Table 1 Calculation and analysis of the effect of residential reasonable distribution of energy saving design

Energy use	Calculation method	Design value /GJ	Standard value /GJ	Energy consumption reduction rate /%
Heating	11.8×0.55×0.9×0.6	3.5	12.8	73
Air condition	2.3×0.8×0.53×0.6	0.55	2.4	77
Aeration	4.6×0.6	2.7	4.7	43
Hot water Supply	23.5×0.5	11.7	24.5	52
lighting	10.4×0.94×0.6	5.87	10.7	45
Household appliances	22.8×0.6	13.7	23.7	42
Other		4.4	4.4	0
Total		44.2	83.2	47

Energy consumption reduction rate = (1 - energy consumption design value of residential energy saving / standard value of energy consumption)

Calculated as shown in Table1, for example, the effect of rural residential reasonable distribution of energy saving design is analyzed. Through various energy-saving measures, the calculated values and reduction rate of energy consumption can be drawn from the residential reasonable distribution of energy saving, as shown.

In terms of residential reasonable distribution of energy saving, it can also take advantage of the rural ecological advantages, including straw, firewood, making fermentation to produce gas in

biogas digester and other energy sources, which can save a lot of coal, electricity and fuel, and improve sanitation in rural areas, as well as can improve manure fertilizer, expanding fertilizer sources, so as to realize recycling of energy, have good economic and social environmental benefits.

4 Conclusion

After 20 years of efforts, China's rural residential energy saving has made tremendous progress, but compared with developed countries, the gap is still large. Developed countries continue to improve building's energy saving level, China must make more efforts to narrow the gap with the developed countries. Due to rural residential energy saving is a comprehensive and systematic project, involving architectural design, building science technology, materials, structure, construction, heating ventilation air conditioning, property management, policies and regulations and other aspects, the reasonable distribution of rural residential energy saving design work need strengthen cooperation and joint effort of each professional department to be well done.

Keywords: Island, smart micro-grid, renewable energy sources, optimal operation

Abstract. The paper introduces the advantage of the application of new energy generation, and then describes the structure of a smart micro-grid system built on an island which includes wind, solar, tidal-wave energy system. The method of day-ahead optimal operation was applied to smart micro-grid system on the island to minimize the operation cost by using genetic algorithm. Taking actual datum of Shanghai Electric Group's micro-grid for case study, the dynamic economic dispatch is compared with traditional dispatch strategy. The results verify the effectiveness of the dynamic economic.

Introduction

It is difficult for the electricity company to power consumer on the island because most of islands is far from the mainland. There are abundance of wave, solar and wind energy on the island. It is significant to develop smart micro-grid project on the island.

The literature [1] described the tidal power generation projects and scale in South Korea. But the micro-grid did not establish an effective optimal operation model and the generation system was uneconomical. The literature [2] put forward a scheduling model which takes the difference between the beginning and end of the state of charge of battery as objective function. But in actual operation, the state of charge of battery should be consistent, the scheduling was uneconomical. The optimal operation model and strategy of smart-grid on the island has not been established at present. In this paper, according to the characteristics of the micro-grid on the island, the island smart micro-grid was built. All kinds of distributed generation units of each model was established, the various economic performance factors to the micro-grid on the island was fully taken into account, and the generation plan of micro-grid on the island was developed.

Mathematical model of distributed generation units

Tidal-waves generator output power model :

$$P_{wa}(t)=\frac{0.145\rho g}{\pi}\lambda^2 A^2\omega\cos^2(\omega t-\alpha)$$

Where λ=wave length of wave; A=wave height; ω= wave angular speed; ρ = seawater density; g =acceleration of gravity; α =the initial phase Angle of wave.

Photovoltaic cells output power model:

$$P_{PV}=P_{STC}\frac{G_{ING}}{G_{STC}}(1+k(T_c-T_r))$$

Where P_{PV} = The actual output power of photovoltaic cells; G_{ING} = actual solar radiation intensity; G_{STC} = solar radiation intensity in standard test condition; P_{STC} = The maximum output power of photovoltaic cells in standard test condition; k =temperature power coefficient; T_r =photovoltaic cell rated temperature; T_c = photovoltaic cell actual temperature.

$$P_{WT}=\begin{cases}0 & v<v_i \quad or \quad v>v_0\\ k_2v^2+k_1v+k_0 & v_i\le v<v_r\\ P_r & v_r\le v<v_0\end{cases}$$

Wind generator output power model:

Where k_0 , k_1 and k_2 are Wind turbine power curve parameters; v_i =cut-in wind speed of wind generator; v_r =rated wind speed of wind generator; v_0 = cut-out wind speed of wind generator; P_r =rated power of wind generator.

Mathematical model of optimal operation

Objective function. Optimal operation was to minimize operating cost. Objective function of operation cost: $\min M_{ope}=\sum_{i=1}^{24}[C_{OM}(P_{wt-i})+C_{OM}(P_{pv-i})+C_{OM}(P_{gt-i})+C_{OM}(P_{wa-i})]+\sum_{i=1}^{24}(s\cdot P_{gt-i})$

Where $C_{OM}(P_i)=K_{OM}\cdot P_i$; M_{ope} = operating cost of micro-grid; $\min M_{ope}$ = minimum of operating cost; P_{wt-i} = wind generator output power at the time i; P_{pv-i} = PV output power at the time i; P_{gt-i} =gas turbine output power at the time i; P_{wa-i} =tidal-waves generator output power at the time i; s = gas turbine fuel cost in a hour; $C_{OM}(P_i)$ = operation cost of DG; K_{OM} = coefficient of DG operation cost, literature [3] provided coefficient of each DG.

Constraint conditions. The main constraint conditions are described and analyzed as following:

1. Load balance: $P_{pv-i}+P_{wa-i}+P_{bat-i}+P_{gt-i}=P_{load-i}$
2. Gas turbine constraint: $P_{gt-i}>0$
3. Starting SOC must be same with terminal SOC: $SOC_0=SOC_{24}$
4. SOC constraint: $SOC_{\min}\le SOC_i\le SOC_{\max}$

Where $SOC_{\max}$ =maximum of SOC； $SOC_{\min}$ =minimum of SOC. Battery can't over-charging and over-discharging to prolong the lifetime of the battery.

5. Generating capacity constraint: $P_{i\text{-}\min}\le P_i\le P_{i-\max}$

Variables. The output power of tidal-wave generator, wind generator and PV cell can't be Variables. Because their output power are uncontrollable, while, gas turbine output power can be controlled. Gas turbine output power from the first hour to the 24th hour in a day was decided to variables. $P_{gt\text{-}1},P_{gt\text{-}2},\cdots,P_{gt\text{-}i},\cdots,P_{gt-23},P_{gt-24}$

Battery output power from the first hour to the 24th hour in a day also was decided to variables. $P_{bat-1},P_{bat-2},\cdots,P_{bat-i},\cdots,P_{bat-23},P_{bat-24}$

Case study

The island micro-grid system model of Shanghai Electric Group can be seen in Fig.1. It consists of gas turbine system (rated power 7 MW), PV system (rated power 1000 KW), wind generation system (rated power 4 * 1500 KW), tidal waves generation system (rated power 5 MW), battery (rated power 1000 KW) and the load.

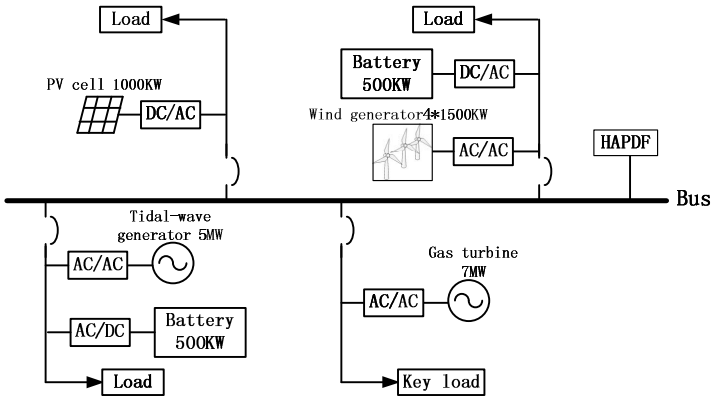

Fig.2. Chat of island micro-grid system model

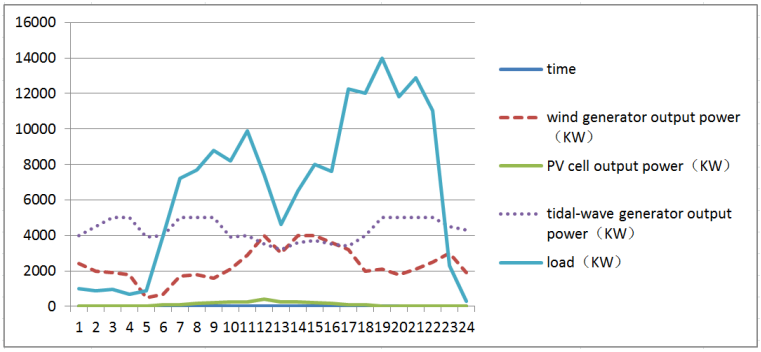

Fig.3. Chat of power prediction

Table.1 Table of DG operation coefficient

Type	Gas turbine	PV	Wind generator	Tidal-wave generator
Operation coefficient KOM RMB/KW• h)	0.0401	0.0096	0.0296	0.0315

Simulation parameters and strategy are limited: Battery initial SOC is 80%; Gas turbine keep running all day and its minimum output power is 100KW; Battery was charged and discharged on the rated voltage. The electricity generated by tidal waves, solar and wind turbine priority supply to load. The redundant electricity is used for battery charging. Battery output power was set 0 and gas turbine output power is 100KW when the battery is full and DG output power can meet load. Optimal operation of micro-grid is a typical multi-variable nonlinear optimization problem and it needs to be solved using genetic algorithm. System is simulated based on MATLAB. The simulation results can been seen in Fig.4. Random operation curve was shown in Fig.5. to comparison.

Simulation results

M_{ope} is 14572 when we apply optimal operation to island micro-grid while M_{ope} is 14972 when we apply random operation to island micro-grid. Operating cost of optimal operation was lower than before.

The battery after optimal operation charge and discharge twice in 24 hours and the gas turbine output power in night and noon from the view of optimal operation curve. When lack of electricity, battery output power first and the insufficient added by the gas turbine. Because the gas turbine operation consume fuel and its operating maintenance cost is too high from the view of objective function. Gas turbine supplied power to load on the optimal operation curve in 20th hour. While, gas turbine supplied power to load and battery on the random operation curve in 20th hour which increase operation cost. Obviously, the random operation is not economic.

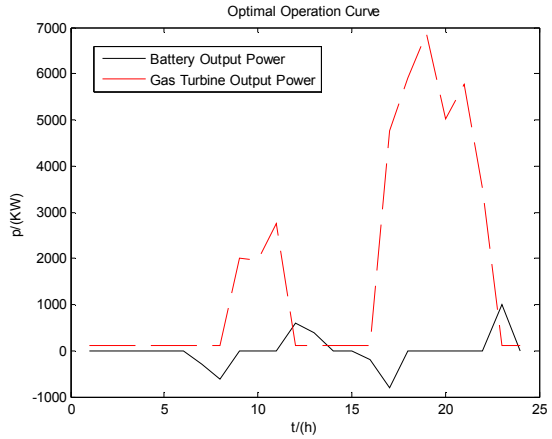

Fig.4. Optimal operation curve

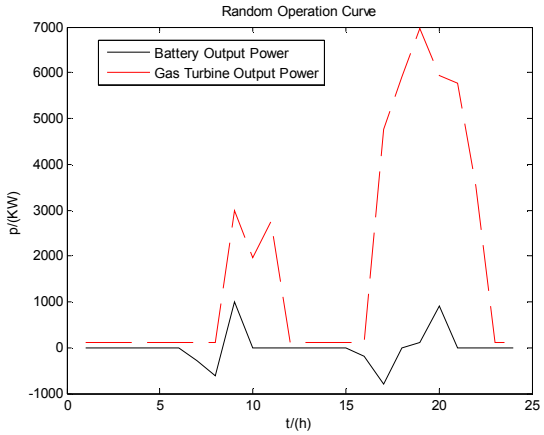

Fig.5. Random operation curve

Conclusion

Optimal operation of Shanghai Electric Group's island micro-grid was planned. It can make its operational cost minimized. Genetic algorithm was used to solve this problem. The results verify the effectiveness of the optimal operation. The paper provided a reference for other island micro-grid's optimal operation.

Keywords: Large Power Grid; Adaptability; Evaluation Content; Evaluation Index

Abstract. With the deepening of the electricity market reform and the development of community economy, as well as the increasing of grid scale, researching and establishing the adaptability evaluation theory and method of power grid construction not only is a realistic demand, but also has great influence on improving the evaluation theory system of power grid planning. In this paper, the adaptability evaluation content for large power grid construction consists of the adaptability of the national economy, the energy structure adaptability, grid structure adaptability and the adaptability of technology development. The paper also discusses the constructing theory and practice basis of the evaluation contents, in addition, the evaluation indexes of adaptability are presented in the paper.

Introduction

With the deepening of the electricity market reform and the increasing of the external environment constraints, the coordinated development between the grid and the external environment has become an increasingly important problem [1][2]. Under the new situation of high speed development of social economy, electricity market reform and the connection of national grid, the traditional grid planning thinking which mainly considers the evaluation indexes of security and power grid's economy [3][4][5], little considers the adaptability between grid and the external environment, such as energy resources, social economic development and environmental protection, will make it not coordinated between the development of the grid and power source, social economy. The incoordination has negatively impacted on the development of social economy, therefore, to put forward the evaluation contents and evaluation indexes of power grid construction adaptability, and to build a whole adaptability evaluation theory system is the reality demand. The evaluation content system is put forward for large power grid construction in this paper based on the analysis of the influencing factors of grid, which is shown in figure 1.

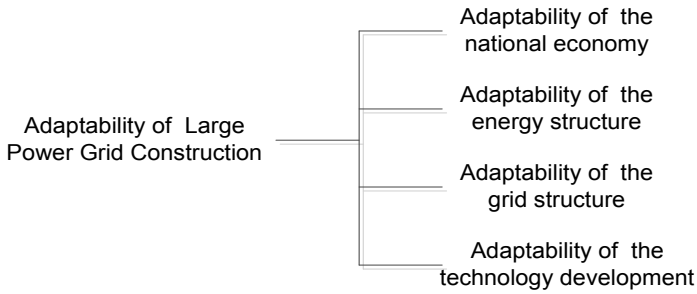

Fig.1. Adaptability evaluation content system for large power grid construction

Construction Foundation of the Evaluation Contents

(1). The need for development of national economy. Electric power industry is the foundation of the national economic construction and development, on one hand, if the development of power grid behind that of load, it will seriously restricts the development of national economy. On the other hand, the development of the national economy also has great impact on the construction of power grid. It was mentioned in literature [6][7] that power demand and national economy has

strong positive correlation, the correlation coefficient of more than 0.98, thus, both of them should develop harmonically to ensure the national economy developing well and healthily. Hence, adaptability of the national economy should be included in the adaptability evaluation system for large power grid construction.

(2). The need for optimizing the distribution of resources. It is known that energy resources and load demand is reverse distribution in China. As is shown in figure 2, power resources are mainly distributed in the west, and the load are mainly distributed in the eastern coast. In order to improve the efficiency of energy utilization, ensure national energy security, we need to build a suitable grid to realize the optimal allocation of power energy across the country [8][9].

Fig.2. Energy resources and load distribution in China

(3). The need for environmental protection, energy saving and emission reduction. With the increasing requirements for environmental protection, environmental protection and energy-saving emission reduction must be considered in the construction of power grid in future. At present, the thermal power accounts for the dominant position in China, and the environmental pollution caused by coal-fired power has become increasingly prominent. Vigorously developing solar, wind and other clean energy sources in the power structure could solve the serious polluted problems. The distribution and development of clean energy such as solar energy, wind energy, plays a very important role in the construction of large power grid.

Consolidated (2) and (3), the adaptability of the energy structure should be included in the adaptability evaluation system of the large-scale power grid.

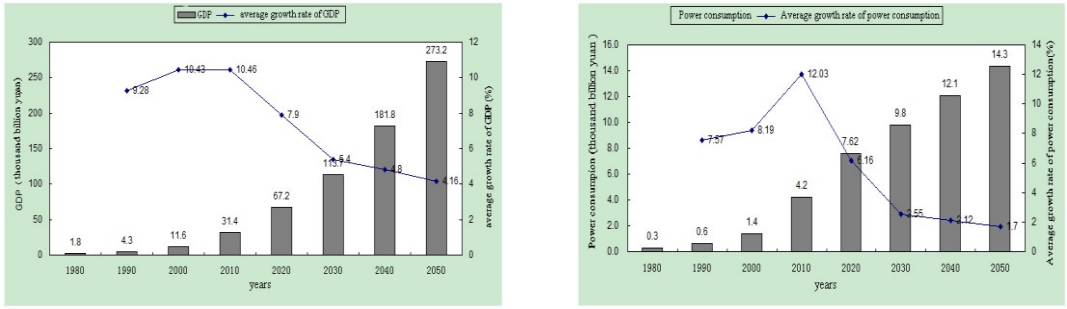
(4). The need for the development of power grid. According to the characteristics of energy distribution in China and the trend of energy development in future, most of new power plants will be located in western and northern China; on the contrary, the main power load is likely to appear in eastern China, resulting in a further increase of the distance and demand to satisfy with the power transmission of the scale cross-flow. There is needed to build a strong, flexible and adaptive primary network to solve the overload of transmission and excessive levels of short circuit, which caused by the overweight of power flow. Therefore, the adaptability of grid structure is one of the issues which should be considered in the construction of power grid.

In addition, in the history of power grid, science and technology plays a supporting role in the construction of power grid which profoundly influenced by the development of technology. Consequently the construction of large grid needs to adapt with the current science and technology, otherwise there would be not built safe, reliable and flexible power grid. Therefore, the adaptability of technology development is one of the important contents of the adaptability evaluation for large power grids.

Adaptability Evaluation Indexes for Large Power Grid Construction

Evaluation indexes of national economy adaptability

From 1980 to 2050, the growth trend of China's GDP and electricity demand shown in Figure 3 [10], the growth rate trend of GDP is consistent with the electricity that of consumption. In addition, the increasing of power load would affect directly the substation’s capacity in the construction of larger power grid. Thus the adaptability evaluation indexes of the National Economic includes Electricity balance coefficient, the elastic coefficient of electricity production and capacity load ratio, as shown in table 1.



(a) (b)

Fig.3. Change trend of economy, power consumption and their growth rate of China
(a) the change trend of economy and its growth rate
(b) the change trend of power consumption and its growth rate

Among them, the electricity balance coefficient is the ratio of the power supply to power demand, which represents if the electricity supply is adapt to the demand, and if there is an phenomena of overload or supply surplus; the elastic coefficient of electricity production refers to the ratio of the average growth rate of electricity production to the average growth rate of GDP, which represents the adaptation of the speed of power grid construction to the speed of economy development; capacity load ratio is the ratio of the transformer capacity(kVA) to the total load(kW) in the specific region and voltage level, which refers to the matching degree between the capacity and the load of the electrical. Capacity growth rate refers to the ratio of the growth rate of transformer capacity to the growth rate of load in specific voltage level during the development of power grid, which reflect the relationship of relative speed between the average annual growth rate of main transformer capacity and load average annual growth rate, and can reflect the coordination of substation capacity and load growth to a certain extent.

Table 1. Evaluation indexes of national economy adaptability

Level indicators	The adaptability of the national economy			
Secondary indicators	electricity balance coefficient	elastic coefficient of electricity production	capacity load ratio	Capacity growth rate

Evaluation indexes of energy structure adaptability

One of the major consideration contents in constructing a large grid is to achieve the optimal allocation of national resources. According to the national energy development strategy, new energy sources such as wind power and solar energy will be vigorously developed. However, thermal power will still act as the main energy in our country [8], which calls for the optimal allocation of coal to achieve the goal of efficient, clean and optimized utilization of coal resources. Meanwhile, the environmental impact on large power grid construction is mainly that thermal power plant discharges the atmospheric pollutants such as sulfur dioxide. The permissible discharge of environment becomes the constraint of thermal plant construction in cities caused by the differences in environment capacity and the cost variations in environmental management, which leads to a certain impact on the structure of power source in cities [11]]12]. Thus the evaluation indexes of energy structure adaptability are shown in Table 2.

Table 2. Evaluation indexes of energy structure adaptability

Level indicators	The adaptability of energy structure adaptability		
Secondary indicators	permissible discharge of environment	utilization efficiency of coal	ability to accept new energy

Here we need to point out the index that the permissible discharge of environment, which determines the maximum capacity of the region's new power plant, means the maximum limit of pollutant emissions in a regional environment.

It was mentioned in literature [13][14][15] that coal resources in west and north can be used in the middle eastern load area by train or by truck, thus the plants can be built near the load area. Also,

large coal and electricity bases can be built in western and northern areas, and then transit the energy to the middle and eastern areas by UHV. In addition, the evaluation index of the coal utilization efficiency should be considered into the adaptability evaluation index system of power grid and energy structure, for that the optimal allocation in a wide range and the utilization efficiency can not be achieved by rail-based transport of coal.

The ability to accept new energy [16][17] is the installed capacity to admit new energy which means the largest installed capacity to admit new energy when all the sources, including the new energy, keep balance with the load, all the operation power supply are reasonable in peak shaving, and the demand of safe and reliable operation of power grids, under overloaded of transformers and lines is meet.

Evaluation indexes of grid structure adaptability

The grid structure adaptability concludes three aspects of coordinating development between the power grid and power supply, the different levels of voltage, the load and power supply. Among them, the adaptability between the grid structure and power supply can be described as: a grid structure is able to meet the access of the power supply and to transmit electric power. The adaptability of the internal grid mainly means that the different voltage levels can be coordinated and adapted each other. The abilities of power transformation among different voltage levels matched together in order to alleviate the load pressure, which is conducive to the sustainable development of power grid. The adaptability between the grid structure and the load can be manifested that the power grid is able to provide high-quality, reliable electricity for users as much as it can. Meanwhile it can also adapt to the load fluctuation in different periods, specific indicators are shown in Table 3.

Table 3. Evaluation indexes of grid structure adaptability

Level indicators	The adaptability of grid structure adaptability				
Secondary indicators	variable machine ratio	line machine ratio	adaptability of power supply ratio	average losing power ratio	the peak-valley difference of grid withstanding

Variable machine ratio means the ratio between the public step-down substation capacity of any voltage level and the installed capacity of the centralized dispatching power. The line machine ratio means the ratio between the length of transmission line of any voltage level and the installed capacity of the same voltage level. These two ratios reflect the harmonious degree between power grid and power source.

The adaptability among different voltage levels can be reflected by the adaptability of power supply ratio among various voltage levels. The power supply ratio refers to the rate of total real transformer capacities between the upper and lower substations [18].

Power grid interconnection is an important aspect for large power grid construction, and its reliability can be reflected by average losing power ratio. The losing power ratio refers to the ratio of load that can't be transferred and the total load which is provided by the substation, when the substation breaks down. The ratio can reflect the ability to transfer load of the grid, and it also reflects the degree of interconnection and adaptation.

With the rapid growth of air conditioners and other electrical equipment, the peak-valley difference of load is increasing quickly, power grid need to improve the adaptive ability to adapt to the load changing so that it can withstand the peak-valley difference of load in different conditions. The more prominent the peak-valley difference of load that the grid can withstand, means that the stronger the flexibility of the grid, and the stronger the ability of grid to adapt to load fluctuations.

Evaluation indexes of technology development adaptability

The development of large power grid is closely related to the innovation of science and technology, which can improve the proportion of new energy power for optimizing the energy structure, and promote the power energy-saving emission reduction. Furthermore, the power grid will be more reliable and stable strong, and the operation capability of grid will be further enhanced. So the innovation of science and technology closely interrelated the large grid is significant to the

security of national energy and the steady and rapid development of economy. The adaptability evaluation index of technology development is shown in table 4.

Table 4. Evaluation indexes of technology development adaptability

Level indicators	The adaptability of technology development adaptability		
Secondary indicators	permissible discharge of environment	utilization efficiency of coal	ability to accept new energy

Conclusion

1) In the situation of social economy rapid development, conventional energy draining, and interconnection of power grid, improving safety evaluation indexes, Expanding economic evaluation indexes, and proposing adaptability evaluation indexes, are the practical needs for large power grid construction. In adaptability evaluation, we take the adaptability of the national economy, the energy structure adaptability, grid structure adaptability and the adaptability of technology development as the adaptability evaluation contents for large power grid construction. The contents put forward in the paper improve the evaluation contents for large power grid construction.

2) The paper also discusses the constructing theory and practice basis of the evaluation content, and puts forward sixteen evaluation indexes which constitute the adaptability evaluation system for large power grid construction, such as electricity balance coefficient, elastic coefficient of electricity production. In addition, the paper proposes the calculation methods of the indexes.

3) In the field of electric power planning, this paper pays as much attention to the adaptability evaluation for large power grid construction as the economic and safety evaluation. Only a part of indexes have been presented in this paper. Establishing adaptability evaluation theory and evaluation method for the large grid construction is of great academic significance and practical value, more work need to do as the theory and algorithm of the adaptability evaluation for large power grid construction involves many theories, such as energy and electrical power systems, economics and sociology.

Keywords: Power cables, Partial discharges, Defect models, Statistical operators

Abstract. Six models of typical insulation defects are designed and lab-simulated system used for partial discharge (PD) detection of cables and accessories has been constructed to study PD characteristics of internal insulation defects in 110 kV XLPE cable system. By employing CPDM, a kind of on-line PD detector, test data of various models including related PD diagrams are obtained for our research. Based on these characteristic parameters, discharge characteristic analyses of a single PD pulse are presented and statistical operators can be obtained by numerical calculation. The experimental results show that CPDM on-line detecting method is effective for detecting PD signals from internal defects of cable accessories. In addition, there are significant differences in the some statistical parameters (e.g. discharge phase, discharge repetition rate, etc) and characteristic parameters of time-domain PD waveform which can be used as reference points for PD patterns identification in future research.

Introduction

Partial discharge (PD) is the main performance of early cable and its accessories fault. It is not only the main cause of insulation aging, but also the key parameter indexing insulation situation [1]. Power cable failures/defects statistics show that more than 70% cable faults are caused by the accessories under the condition of disregarding the external force damage [2-3]. Moreover, affected by widely distributed of laying path, complex and varied operating conditions, XLPE cable lines are susceptible to external damage, weak product quality, uneven accessory installation quality and other factors, so certain operational risk and danger consist in cable line operation.

Numerous researches on internal partial discharge mechanism, detection methods, discharge characteristics and other aspects of the XLPE cable and its accessories have been paid attentions widespread in the world [4-8]. A lot of study on the typical PD models have been done as well, but these research basically emphasize simulation of metal tip and the air gap defects in a variety of partial discharge test models that doesn't conform to the actual situation and cannot be a true reflection of representative typical defect properties, characteristics and discharge mechanism of cable accessories exposed during the manufacturing, installation, operation process.

For the actual operating cable lines, especially for the cables soaked in the water under the ground, research on detection and analyzes of the potential insulation defects and diagnosis of the insulation healthy level are nearly empty. The insufficiency in relevant experience and data conduce impossibility to reach the requirements of detecting abnormality in advance or fault predicting and promptly maintenance by the operation and maintenance unit. Thus it hinders the development and application of defect detection and diagnosis technique under complicated operation conditions of XLPE cable insulation.

Based on this, we closely combine PD detection and diagnosis technology with the high voltage XLPE cable state detection and maintenance. According to the research on partial discharge detection and diagnosis technology, along with investigation about nationwide high voltage, ultra high voltage cable typical faults and defects especially in the high water level environment, the defective cable and its accessories specimens with various types and different degradation degree were established and simulated in laboratory. Then, time domain waveforms, spectrum distribution, frequency spectrum characteristics of discharge signals are collected to construct PD fingerprinting database for identifying different defects types. It lays a foundation for PD live detection and condition diagnosis of HV cable.

Modeling of typical defects of high voltage XLPE power cable

According to the previous collection of relevant literature, historical data, statistics and analysis of HV cable fault types, probability distribution and fault cause, the weakness of cable insulation and frequently failure location have been summarized. The main technical reasons and key factors of operation failure of high voltage cables have been studied. We discuss the typical defects of cable and its accessories during laying, construction, installation, operation and other links. In order to make the basic research to guide practice, considering the comprehensive representative and defect types of defects, eventually the following 6 types of representative defects were formed which are shown in the following table:

Table 1 Type and Main Physical Parameters of Representative Defects

NO.	Defect Type	Main Physical Parameters	The Images of Defect Models
1	Soaking joint	Cable inside joint was soaked in water for 24h,and water was injected during installation	
2	Incision on cable	Breadth and depth of incision is 10 cm and 2mm.Length of outer shielding lay wound is 5cm;	3	Puncture on cable	Diameter and depth of puncture are 3 cm and 4mm.	4	Sharp insulation screen on outer semiconductive layer	Two sharps are isosceles triangles which bottom edge is 4mm,height is 1cm, spacing is 8mm.	
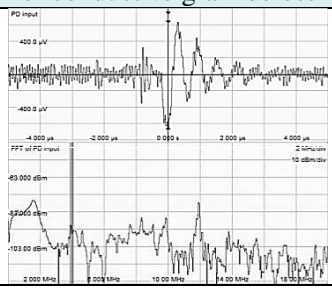
5	Conductive grain on the interface of composite insulation	Area of conductive grain is about 5cm×7.5cm	
6	Prefabricated unit offset	Stress cone is 5mm away from standard location.	

Experiments design

The lab-simulated system is composed of 110kV XLPE cable, compound insulation termination, prefabricated joint, water-insulated cable test termination and related auxiliary, according to typical defects in Table 1, adopting CPDM, experiment was conducted to study the performance of PD in the laboratory. Parts of representative spectrum diagrams are given as follows:

Table2 Pulse and frequency spectrum of typical defects

The spectrum of soaking joint defect	The spectrum of incision defect
	The spectrum of puncture defect	**The spectrum of sharp insulation screen defect**
	The spectrum of conductive grain defect	**The spectrum of prefabricated unit offset defect**
	


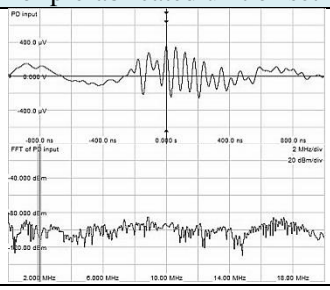


Table3 Q-Φ spectra of typical defects

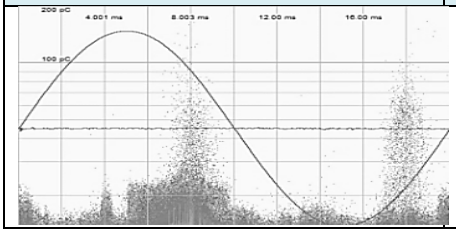
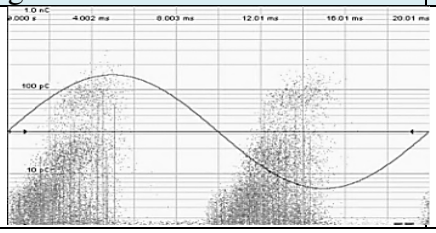
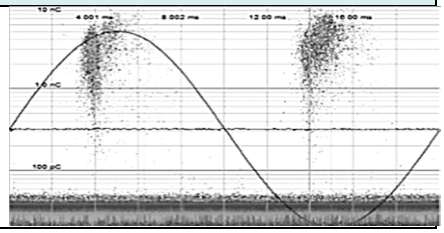
The spectra of soaking joint defect	The spectra of incision defect	The spectra of puncture defect
		The spectra of sharp insulation screen defect	**The spectra of conductive grain defect**	**The spectra of refabricated unit offset defect**
		






In this section, the characteristic spectrum diagrams of typical defects have been concluded, discharge signals in 6 samples of typical defects were acquired by CPDM in the pure electromagnetic laboratory, typical discharge signal samples were achieved in time domain, frequency domain, and corresponding Q-Φ spectra, it could achieve the obvious differences in the statistics table of various defect characteristics and it is laying foundations on identification database. All these partial discharge data will be discussed in detail later.

Experiments results analysis

Based on the experimental results, it's able to be found that all these partial discharge features are distinct and complex. Various feature extraction methods were extensively applied to pattern recognition and insulation condition diagnosis of partial discharge. However, most of these analysis methods drop or ignore some original partial discharge characteristics in calculating process more or less. In our work, whole natural parameters were collected and statistical estimators are used to compare the PD pulse pattern shapes. These statistical estimators are kurtosis, skewness, Cross Correlation, charge asymmetry; these are defined by the following expressions [9]:

$$S_k = \sum_{i=1}^{N}(x_i - \mu)^3 f(x_i)/[\sigma^3 \sum_{i=1}^{N} f(x_i)] \quad (1)$$

Where

x_i : sample value of the distribution

μ : mean value

N: number of samples

σ:standard deviation

Skewness describes the asymmetry aspect with respect to the normal distribution.

$$K_u = \sum_{i=1}^{N}(x_i - \mu)^4 f(x_i)/[\sigma^4 \sum_{i=1}^{N} f(x_i)] - 3 \quad (2)$$

Kurtosis represents sharpness with respect to the normal distribution.

$$Cc = \frac{\sum_{i=1}^{W} x_i^+ x_i^- - (\sum_{i=1}^{W} x_i^+ \sum_{i=1}^{W} x_i^-)/W}{\sqrt{[\sum_{i=1}^{W}(x_i^+)^2 - \sum_{i=1}^{W}(x_i^+)^2/W][\sum_{i=1}^{W}(x_i^-)^2 - \sum_{i=1}^{W}(x_i^{\pm})^2/W]}} \quad (3)$$

Where

x_i^+ and x_i^- sample value of the distribution at the corresponding phase φ_i and $\varphi_i + \pi$ respectively.

W number of samples of the wave period

Asymmetry represents the charge transfer differences in the positive and negative polarity discharge events; this feature has the following expression:

$$A_{sy} = N_2 \sum_{i=1}^{N_2} x_i^- / N_1 \sum_{i=1}^{N_1} x_i^+ \quad (4)$$

Where

N_1 and N_2 are number of sampling intervals in the positive and negative half-wave period.

Parts of selected representative characteristic parameters are presented in following table.

Table 2 Representative characteristic parameters of various defects

	Soaking joint defect	Cable incision defect	Cable puncture defect	Sharp screen defect	Conductive grain defect	Cutting into main insulation
Phase range of discharge	10º~100º 200º~280º	0 ° ~60 ° 180 ° ~230 °	0º~90º 180º~270º	100º~180º 220º~300º	50º~150º 220º~270º	20º~120º 190º~300º
Phase of peak	92º and 268º	31 ° and 204 °	36 ° and 207 °	89º and 253º	96º and 272º	95º and 266º
Discharge magnitude	982 pC	3.5 pC	12.4 pC	172 pC	102 pC	9 nC
Repetition rate	81 PDs⁄s	48 PDs⁄s	66 PDs⁄s	30 PDs⁄s	32 PDs⁄s	35 PDs⁄s
Rise time	21ns	33ns	227ns	143ns	279ns	18ns

Fall time	36ns	85ns	485n	189ns	364ns	35ns
Skewness	1.021(+) 1.153(-)	0.598(+) 0.526(-)	1.4244(+) 1.5029(-)	-1.717(+) -1.565(-)	1.253(+) 1.463(-)	0.847(+) 0.614(-)
Kurtosis	-0.798(+) 1.02(-)	-0.337(+) -0.382(-)	-0.7411(+) -0.6458(-)	1.266(+) 2.195(-)	0.491(+) 0.422(-)	2.267(+) 2.829(-)
Cross Correlation	0.316	0.905	0.7869	0.95	0.543	0.858
Asymmetry	1.642	1.033	0.807	0.696	0.717	0.914

In the table, rise time and fall time refer to the PD pulse waveform in time domain, phase of peak means the phase of PD maximum point. Besides, Skewness and Kurtosis were calculated in positive and negative semi-cycle respectively.

Conclusion

Based on statistical analysis of power cable faults by the State Grid Corporation, 6 kinds of typical defects have been constructed in the actual 110 kV cable which can effectively reflect the nature of the defects, characteristics and discharge mechanism in the manufacture, installation, operation process.

The analysis of typical defect types of cable and its accessories was conducted in this paper, lab-simulated system was constructed. And, the representative PD characteristics collection of 6 typical cable defects was obtained. All these fingerprint characteristics constitute our PD fingerprint database to conduct PD patterns recognition and troubleshooting. Meanwhile, in view of our research, references to work of PD identification have been proposed as follow:

A. The partial discharge signals are gathered in two clusters, the phase difference is nearly 180 º.
B. The partial discharge pulse repetition rate is higher than 30 n/s.
C. Employing adaptive filtering and anti-interference measures, partial discharge can be clearly distinguished from the noise signals.
D. After eliminate interference, partial discharge should repeat in relative long period.
E. Peaks of partial discharge spectrum may appear in multiple frequency bands
F. In time domain, single partial discharge pulse duration should be ns level.
G. For partial discharge signals, rise time should be less than fall time.

Keywords: nuclear power plant, combined peak load regulation, operation mode

Abstract: Base on Nuclear Power Plant (NPP) participating in peak load regulation of power grid, this paper studies the operation mode of hydropower, thermal power and NPP in Combined Peak Load Regulation. The optimization model for Peaking depth of NPP was set up. The case based on actual power grid were calculated and analyzed, results of the research show that in combined peak load regulation of hydropower, thermal power and NPP, a reasonable peaking depth of NPP will effectively alleviate the peaking pressure of power grid, avoid start-stop of thermal power and abandoned water of hydropower, while ensuring the hydroelectric generating capacity in the low load periods, and ensure thermal power output smooth, it further reduce the operating costs, verify the effectiveness of the model.

I. Introduction

In recent years, with the increase of the gap between peak load and valley load in power system, proportion of nuclear power in the grid, and grid connection capacity of the new energy such wind and light power, only rely on traditional load such as hydropower, thermal power will not be able to meet the demand of power system load in the future. Grid security, stability and economic operation threatened the power system needs of the nuclear power plant to participate in the growing power peaking. For grid peak shaving and optimization with the nuclear power has a great significance. Hydropower, thermal power and NPP peak load regulating operation for coordination scheduling and the joint will be necessary in order to ensure the healthy development of the future power grid security and effective measures.

Since the 1970s, the United States, Germany, France, Japan and other countries have implemented a PWR/BWR, improved thermal neutron reactors and other nuclear power reactor type load following tests and the actual operation [1-5]. During 40 years , daily load-following operation experience of PWR has shown that there is no adverse effects of daily or weekly load following on fuel performance and radioactive concentration of the coolant will not rise because of load following. The feasibility of PWR and reliability of daily load-following operation were both verified [6-9]. Considering the safety of nuclear power itself and peaking speed and depth limit of NPP, the PWR nuclear power plant generally take "12-3-6-3" mode and maximum 50% of peaking depth participate in peak load regulation of power grid [10].

Based on the NPP involved in the daily load-following operation, research the allocation of output within a day of each period of hydropower, thermal power and NPP in this paper. Through the judgment of nuclear power participates in peaking, determine the operating position of NPP. The method of hydropower, thermal power and NPP load distribution were presented. Analysis and gives the optimization model of NPP peaking at the depth of the load. The validity of the model has been verified by numerical examples

II. Output Assignment of Combined Peak Load Regulation

If NPP need to participate in peak load regulation, hydroelectric, thermal power and NPP need to re-adjust the operation mode, rational distribution of load, ensure peak regulation capacity balance of power system and operation the lowest cost. To achieve peak regulation cost minimization, it

should be based on various types of investment instruments peak regulation order, decision the best combined peak load regulation scheme.

Combined with the literature [11-12], operation cost of hydroelectric, thermal power and NPP is shown in Table 1, NPP peak load regulation cost is less then start-stop of thermal power and abandoned water of hydropower, so we need to invoke NPP peak load regulation capacity first. To avoid start-stop of thermal power and abandoned water of hydropower, we need reasonable arrangements the depth of NPP peak load regulation, the specific optimization method is described in detail in the next section. If still remaining output when invoke maximum peak load regulation of NPP, start-stop of thermal power and abandoned water of hydropower will be considered.

Tab.1 Operation cost of peak load regulation

Peak load Shaving schemes	deep peak regulation	NPP peak regulation	start-stop of thermal power	abandoned water of hydropower
Operation cost (Yuan/MW·h)	40	71	167	250

III. Optimization of NPP Peaking Depth

In combined peak load regulation of hydroelectric, thermal power and NPP, NPP peaking will let it loss of marginal costs and benefits of clean energy, and by the security, economic and other constraints, therefore NPP peaking need to be judged.

Consider only hydropower, thermal power and NPP in power grid, and without start-stop of thermal power and abandoned water of hydropower, power capacity balanced and peak regulation capacity balanced of power grid as follows:

$$\begin{cases} D=P_{H\max}+P_{T\max}+P_{N\max}-P_{L\max}-P_R \\ T=P_{L\min}-P_{T\min}-P_{F\min}-P_{N\max}-P_{R'} \end{cases} \quad (1)$$

Wherein: D is surplus capacity of the power system; T is lowered peak surpluses capacity of the power system; $P_{L\,max}$ and $P_{L\,min}$ are minimum and maximum power load of planned date; $P_{H\,max}$ and $P_{H\ min}$ are planned date the whole system adjustable maximum and minimum output of all conventional hydroelectric generating in load peaks and troughs; $P_{T\,max}$ and $P_{T\,min}$ are planned date the whole system adjustable maximum and minimum output of thermal power in load peaks and troughs; $P_{N\,max}$ is rated output of NPP planned date whole system; P_R and $P_{R'}$ are the positive and negative spinning reserve capacity.

while meeting $D \geq 0$ and $T \geq 0$, NPP don't need to participate in peak load regulation.

In the case of reasonable arrangement of hydroelectric, thermal power output mode, if T <0, means that cut peak load capacity is insufficient when the load trough, NPP need to participate in peak load regulation. Criterion is:

$$P_{L\min} < P_{H\min} + P_{T\min} + P_{N\max} + P_{R'} \quad (2)$$

The average depth of NPP participating in peak load regulation is set up for λ, then NPP output when the load trough is:

$$P_{N\ min}=(1-\lambda)P_{N\ max} \quad (3)$$

After determining need NPP peaking, the depth of the NPP peaking will be optimized base on proportion of hydroelectric, thermal power and NPP and their operating characteristics, in order to achieve the goal of peaking capacity balance and operating costs to a minimum.

Optimized unit output goal is to the lowest operating costs, including coal consumption and peak shaving costs. When established optimization model needs to meet the maximum output peaking of hydropower, thermal power output duration as long as possible and the maximum output rate of nuclear power load trough period. For such general solving multi-objective, multi-objective solving equations can be established, or simply goals into constraints to be solved. The second method was taken to solve it in this paper.

The largest output model of NPP in power grid load trough:

$$J = \max \sum_{t=0}^{6} \sum_{i=1}^{m} P_{Ni\min} \tag{4}$$

Wherein $P_{Ni\min}$ is the *i*-th NPP's output in power grid load trough, the number of NPPs is m.

Formula (4) was subject to system constraints, independent water system constraints, thermal power constraints and NPP safety constraints.

(a) System constraints

To simplify the calculation, where only consider the system peaking capacity balance constraints in low load periods:

$$P_{L\min} - P_{H\min} - P_{T\min} - P_{N\min} - P_{R'} \geq 0 \tag{5}$$

(b) Independent water system constraints

①Daily water balance conditions:

$$\sum_{i=1}^{n} (\mathrm{q}_{it} + \mathrm{w}_{it}) + spl_t = Q_t \tag{6}$$

Total hydropower is n.

②Hydropower output constraints:

$$P_{Hi,\min} \leq P_{Hi,t} \leq P_{Hi,\max} \tag{7}$$

③Hydropower generation flow constraints:

$$Q_{i,\min} \leq Q_{i,t} \leq Q_{i,\max} \tag{8}$$

④Reservoir water level constraints:

$$Z_{i,\min} \leq Z_{i,t} \leq Z_{i,\max} \tag{9}$$

⑤Hydro no abandoned water conditions:

$$K = \max \sum_{t=1}^{T} \sum_{i=1}^{n} N_t^i(\mathrm{Q}_t^i) \tag{10}$$

Where in $\mathrm{N}_t^i(\mathrm{Q}_t^i)$ is the output value by the *i*-th hydropower flow stations in the time *t*, *K* maximum means no abandoned water.

(c) Thermal power constraints

①Thermal power ramp rate constraints:

$$\left| P_{L,t+1} - P_{L,t} \right| \leq S_t \cdot t \tag{11}$$

Where in $S_t = \sum_{i=1}^{z} S_{i,t}, i = 1, 2.....z$, S_t represents a climbing speed thermal power. $S_{i,t}$ is climbing speed of i-th thermal power.

②The minimum period of continuous thermal power output:

$$\begin{cases} \left| \partial P_T \right| = 0, 0 \leq \left| t \right| \leq T_{\min} \\ \left| \partial P_T \right| \geq 0, \left| t \right| > T_{\min} \end{cases} \tag{12}$$

(d) NPP safety constraints

①Nuclear power peaking Constraints:

By the characteristics of its own, NPP can only be tracked by the shape like "12-3-6-3" output mode. In this paper, nuclear power output in accordance with this running.

②NPP peaking depth constraints:

$$\eta_i \leq \eta_{\max} \tag{13}$$

Where in, η_i represents peaking depth of the i-th nuclear power generating units. Its value was determined by the performance requirements of their own nuclear power plants, safety factors and expert advice decisions.

③NPP peaking speed constraints:

$$\rho_{\min} \le \rho_i \le \rho_{\max} \tag{14}$$

ρ_i is the *i*-th NPP's speed of change power.

IV. Example Analysis

Set up a regional power grid containing water, fire and nuclear power peaking three categories. Nuclear power capacity 1280MW and rated at 1090MW accounting for about 10% of the total installed capacity. Hydropower installed capacity of 1700 MW. Thermal power peaking capacity load of 2400 MW. Grid daily load curve shown in Figure 1, according to the power grid, load characteristic and power source structure, list the following 3 kinds of load plan.

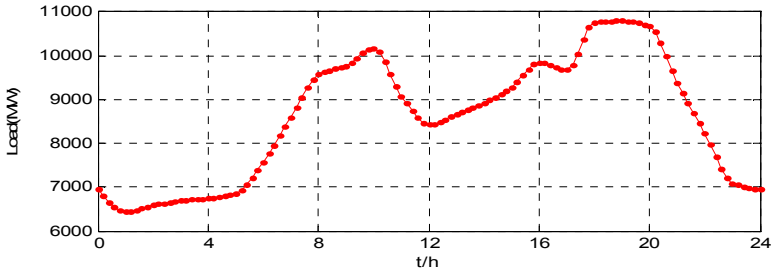

Fig.1 The daily load curve of a grid

Case 1: Hydropower peaking+ thermal power deep peak shaving + NPP peaking with smaller depth. Take NPP peak shaving depth of 20%.

Case 2: Hydropower peaking+ thermal power deep peak shaving + NPP peaking with largest depth. Take NPP peak shaving depth of 50%.

Case 3: Hydropower peaking+ thermal power deep peak shaving + NPP peaking with proper depth. Take NPP shaving depth of 40%.

Assuming that when the depth of the nuclear power peaking take 40%, hydropower peaking its daily output is just equal to the amount of water can be adjusted for maximum power. It can effectively prevent the emergence of disposable water peaking situation. In the low load periods, hydropower output help thermal power climbing and make its output steady, reaching the lowest operating costs of the system. NPP peaking insufficient depth in case 1, will result in low load periods shutting down small thermal power units, even abandoned water peaking. Accordingly, lead to a waste of resources and higher costs peaking. Case 2 NPP peaking depth is too large, did not make full use of the capacity of thermal power peaking resulting increase in coal consumption and waste of nuclear energy, increasing the cost of the peaking. In the case 3, NPP was operated based on "12-3-6-3" output mode. The actual load power curve, the curve of NPP peaking, and equivalent daily load curve are shown in Figure 2.

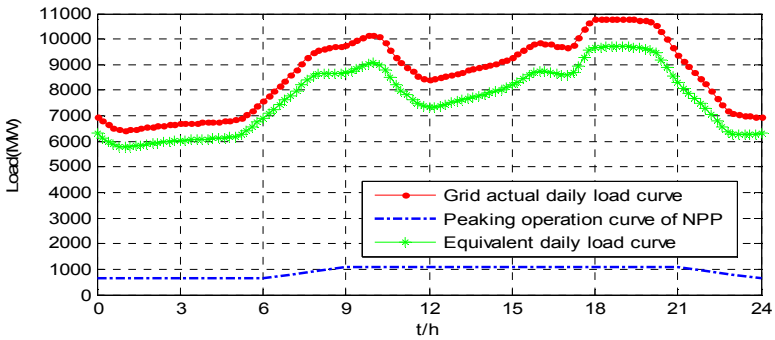

Fig.2 The actual daily load and equivalent daily load

Figure 4 shows that the equivalent daily load compared with the actual date, the trend is consistent. During 6:00-9:00 and 21:00-24:00 when nuclear power output was adjusted, the rate of change is equivalent to the daily load decreases. Occurrence of load peaks and valleys of the same, but the difference between peak load is reduced by 436MW. Therefore, the equivalent daily load

peaking effectively alleviate the pressure of peaking .It more suitable for hydropower and thermal power peaking. By optimizing depth of peaking involved in nuclear power peaking, effectively avoiding start-stop of thermal power and abandoned water of hydropower. Ensuring the smooth thermal power output and decreasing the costs of peaking, it contributes to the security, stability and economy of the power system.

V. Conclusion

In this paper, the combined peaking hydropower, thermal power and nuclear power as a starting point, nuclear with arrangements "12-3-6-3" model participate in hydropower and thermal power peaking. Through the judgment of NPP participation in power peaking, the location of NPP to run were analyzed and determined, then the hydropower, thermal power and NPP load distribution were offered. Optimization model NPP peaking at the depth of the trough load was presented. Obtained by a numerical example, in the united peaking hydropower, thermal power and NPP, NPP peaking take reasonable depth of power will effectively ease the grid pressure. It's effectively avoid start-stop of thermal power and abandoned water of hydropower, while the hydroelectric generating capacity at the time of low load, thus ensuring a smooth thermal power output and reduced the running costs. The validity of the model has been verified.

Keywords: PSR model; BP neural network; economic security; coal cities

Abstract. According to the pressure-state-response model, building an evaluation index system, evaluating the level of economic security of 21 coal cities by back propagation (BP) neural network theory and means of MATLAB. The results show that the level of economic security of coal cities in China is not ideal and must be improved. The level of economic security shows regional differences.

Introduction

With the rapid development of China economy, the demand for energy is increasing, while the pollution and damage to the environment is more and more serious. PM2.5 and haze become the focus at one's leisure talk. Whether the city economic development is safe and sustainable have attracted the attention of many researchers. However, most of them are limited to concept of study, selection of indicators, as well as individual city practice research. And for a certain class of city, especially in resource dependent city group (such as coal city), there is not much research. The predatory exploitation of coal resources has a direct relationship with the deteriorating environment, therefore, research on coal city economic security is of great practical significance and important.

To coal cities, the ecological security and sustainability is of vital importance to the economic development. Based on the results of previous studies, using the index system of ecological security of classic international framework of PSR model, using artificial neural network to study China coal city economic security system, we get China coal city economic security evaluation and provide scientific basis for the evaluation and management of city economic security decision.

The western developed countries study on coal city resources cities were relatively early and the theoretical basis are the adjustment of the economic structure theory and the theory of labor market segmentation. The representatives are Bradbury, Hayter, and Barnes. They point out, cyclical mining industry has a strong influence on mining city migration, economic development and community development.

Study on coal city in China lag behind the rapid development the coal city on the whole. Early research mainly focused on industrial development and planning. After 90 years of the last century, research has begun to pay attention to the comprehensive adjustment of industrial structure and sustainable development.

Determine of the Evaluation System and Index

The coal city has not a strict definition so far. Most believe that the coal city is formed and developed as a result of development of local coal resources, and the coal industry occupies an important position in the city industrial structure in the city. This paper studies the coal city with city level dependency: Mines are mainly in the city's urban and suburban areas, and the mining industry is the city's main pillar industry. The total of such cities are 21, respectively is: Datong, Jincheng, Yangquan, Shuozhou, Qitaihe, Hegang, Jixi, Shuangyashan, Zibo, Zaozhuang, Fushun, Huainan, Huaibei, Jiaozuo, Pingdingshan, the new port, Pingxiang, Hebi, Shizuishan, Liupanshui, Tongchuan [1].

Economic security is generalized on economic security, which includes economic, also includes the natural environment, resources, social security. From the concept of speaking, ecological security is economic security. The coal city economic security can be understood that the economic system of the coal city has the ability of facing the threat of recovery, and can make the natural resources in the population, economy, ecological conditions stable, coordinated, orderly and sustainable utilization.

PSR (Pressure-State-Response), namely pressure, state, response, is a common evaluation model of the environmental quality assessment of ecosystem health evaluation sub disciplines which was, originally proposed by the Canadian statistician David J.Rapport and Tony Friend, then developed as framework system on environmental problems by the organization for economic cooperation and development (OECD) and the United Nations Environment Program (UNEP) in later twentieth Century.

On the basis of existing research, system of coal city economic security evaluation index of four level 16 indexes by using the PSR model. See table 1.

Table 1 Coal city economic security evaluation index system

Target layer	Project level	Factor level	Index layer
Comprehensive index of economic security	Pressure on the economic environment	Population pressure	Population density (/km2)
			The natural growth of population rate（‰）
		Resource pressure	The public green area per capita（m2）
			Road area per capita（m2）
			Housing area per capita（m2）
		pressure on the social and economic	Per capita GDP（yuan）
			Every million people have the bus (car)
			Every ten thousand people owned hospital beds
	Economic systems state	Resource state	Green coverage rate in developed area (%)
			Compliance rate of centralized drinking water source water quality (%)
		Environment state	Volume of industrial waste water emissions (ten thousand tons)
			Volume of industrial soot emissions (t)
			Volume of industrial so2 emissions (t)
	Economic system response	Social response	People have a volume of books (book)
		Economic response	Education investment accounted for the proportion of GDP (%)
			The third industry accounted for the proportion of GDP (%)

According to the established evaluation system, the indicators data collected 21 cities. 16 indicators of original data are from China city statistical yearbook 2010 and part of the provincial statistical yearbook [2]. Raw data is slightly.

According to the frame of the assessment index system of city ecological security of the building, according to the following principles for determining the sign of each single index value: (1) where the existing national standards or international standards index, as far as possible the specified flag value.(2) referring to the current situation of foreign has good characteristics of city value.(3) referring to the current situation of domestic city value trend extrapolation, determine the sign value.(4) based on the existing environment and society, economy coordinated development theory, to a flag value quantification.(5) the current statistical data is not very complete, but there is a very important index in the index system, the lack of relevant statistical data index, use similar index instead of [3].

Artificial Neural Network Model

Research on neural network field background work began in late nineteenth Century and early twentieth Century, and its essence is a nonlinear dynamic system, has the strong association, self learning, recognition function, subject to artificial intelligence and systems engineering science. As a large-scale parallel processing of nonlinear dynamic systems, artificial neural networks have been widely used in economic analysis, optimization, forecasting and other fields in recent years, has obtained the good effect of [4].

Method of grading according to various index at home and abroad, the design of a determined coal city economic security classification table, so that to evaluate Chinese coal city from the overall economic security [5]. Specific classification in table 2.

Table2 Coal city economic safety criteria

Each index	Unsafe	Not safe	A security	Very safe
Population density (/km2)	4500	4000.00	3500.00	3000.00
The natural population growth rate （‰）	1	0.90	0.80	0.70
The public green area per capita （m2）	16	17.00	18.00	19.00
Road area per capita（m2）	28	29.00	30.00	31.00
The per capita housing area（m2）	14	15.00	16.00	17.00
Industrial wastewater emissions (tons)	450	400	322	300
Volume of Industrial Soot Emission (ton)	3500	3000	2574	2000
Industrial SO2 emission (ton)	9500	9000	8366	8000
Per capita GDP (yuan)	10000	15000	20000	25000
Every million people have the bus (car)	85	90.00	100.00	110.00
Every million people have hospital beds (Zhang)	85	90.00	92.48	95.00
Coverage rate of the developed area (%)	35	40	45	50
Compliance rate of centralized drinking water source water quality (%)	90	95.00	100.00	100.00
People have a volume of books (Books)	25000	30000.00	35000.00	40000.00
Education investment accounted for the proportion of GDP (%)	5	6	7	8
The third industry accounted for the proportion of GDP (%)	40	45	50	55

Test results

In order to eliminate the dimension of economic security, need to be graded standard coal city. After the network training, it is need to test network. By training the network, test network. The practical simulation output network is shown in table 3.

Table 3 The actual network simulation output

Datong	Jincheng	Yangquan	Suzhou	Qitaihe	Hegang	Jixi
Unsafe	Not safe	Unsafe	Unsafe	Very unsafe	Very unsafe	Very unsafe
Shuangyashan	Zibo	Zaozhuang	Fushun	Huainan	Huaibei	Buxin
Unsafe	Not safe	Not safe	Not safe	Unsafe	Unsafe	Unsafe
Jiaozuo	Pingdingshan	Pingxiang	Hebi	Shizuishan	Liupan	Tongchuan
Not safe	Unsafe	Unsafe	Unsafe	Unsafe	Very unsafe	Unsafe

From the table we can see, on the whole Chinese coal city economic security level is relatively low, this and they serve as resources mining city has the very big relations, and also with the criteria for the selection of the most for the relationship between the excellent city construction indicators. In addition, the economic security level showing geographical features. The two cities of Shandong Province, Anhui Huaibei, Henan Jiaozuo, Liaoning Fushun and Shanxi Tongchuan than any other city in Shanxi province is good, poor, Heilongjiang province is not the most ideal.

Conclusion

Based on the analysis of the city economic security theory as the foundation, we find that city economic security relates to resource, environment, economy, social aspects, reflect these factors should be comprehensive, but not too much. This article take the system of city ecological security assessment index of PSR model, it is still difficult to avoid subjectivity and bias. From the BP network operation result, the overall recognition rate is higher, the selection of network parameters and relationships, between complexity and economic safety evaluation. In addition, although the standard mostly adopts excellent city standard, but the standard itself and the extrapolation process or with certain subjective elements.

Keywords: Economic structure; Electricity load characteristics; Industries' structure; Three industries and residents' life; Electricity load structure

Abstract. In recent years, strategic adjustment of economic structure is as the main direction of accelerating transformation of economic development mode in Sichuan province of China. Electricity load characteristics and its development trend could reflect industries' structure of Sichuan province. The ways of typical day selection and load curve calculation are discussed. Electricity load of typical trades of three industries and residents' life is analyzed, whose load curves of everyday as well as the four seasons are obtained. As a result, relationship between electricity load structure and industrial structure is get.

Introduction

Electricity load characteristics and its development trend is the base of electricity plans, electricity programs and production operation. Recently, speed of world economic recovery becomes lower obviously, and China is under pressure of economy downlink. Strategic adjustment of economic structure is as the main direction of accelerating transformation of economic development mode in Sichuan. The purpose is to upgrade the level and core competitiveness of industry, and to promote the coordinated development of three industries[1]. Electric power industry, as the barometer of national economy, has great adjustment and dependence for adjustment of industrial structure[2].

Based on previous researchers' work[3-5], historical load-controlled electricity data for large customers was collected, superposed and checked. Electricity load curves for typical trade of three industries and residents' life were obtained in Sichuan. Electricity load characteristics and its law of development were studied. The largest load of three industries was estimated. Structure of power consumption for the whole society was analyzed. Relationship between load structure change and industrial structure adjustment was investigated. As a result, it provides a scientific basis for electricity grid development planning and market development.

Estimation of load curve

(1) Selection of typical day

For different climatic conditions, months corresponding four seasons are different for different places. Normally, the spring, summer, autumn and winter is from March to May, from June to August, from September to November and from December to next February respectively. At present, there is no uniform regulation but mainly three methods for selection of typical day.

Method 1: Daily load curve without abnormal distortion, whose daily load rate is most approaching to average daily load rate of a period (a season or a month), is as the typical day load curve of this period (a season or a month).

① Average daily load curve of working day for this month:

$$L(h)=\frac{1}{N}\sum_{d=1}^{N}L(d,h) \qquad h=0,1,2,3...23 \tag{1}$$

L(h) is average value of working day load curve of this month, in other words, average daily load curve; L(d,h) is load curve of any working day; h are 24 integral points everyday; N is the number of working day for this month.

② Daily load curve L(d,h) of working day for this month, which is most approaching to above average daily load curve L(h), is as the typical day load curve L(d*,h) of this month.

Approaching means that the distance following is smallest:

$$\sum_{h=0}^{23}\left|L(d^*,h)-L(h)\right|^2=\min_{1\le d\le N}\sum_{h=0}^{23}\left|L(d,h)-L(h)\right|^2 \tag{2}$$

Method 2: A fixed working day (e.g. the 3rd working day of 3rd week of a month) of a period (a season or a month) is as typical day.

Method 3: The day of largest load is as typical day.

(2) Calculation of load curve

Firstly is to select typical day according to above method. Secondly is to obtain typical day load curve of large customers for typical trade through load-controlled collection. Thirdly, L_1, which is electricity load curve superposition of large customers, could show the load curve shape of typical trade of this place. The total electricity consumption C_1 of these customers that day could be gained through L_1. Fourthly, daily electricity consumption C equals to electricity consumption of the customers for this month divided by days. Fifthly, M equals to C divided by C_1. That is the proportion of consumption for the customers to that for the typical trade. Finally, typical day load curve is M times of load for all the points L_1.

Investigation of electricity load characteristic

(1) Load characteristic analysis of typical trade for primary industry

Research object for primary industry is irrigation trade, as shown in Figure 1(a). There is no morning peak in spring, where it appears from 6 to 7 o'clock in summer, autumn and winter. The noon peak appears from 11 to 12 o'clock in spring and winter, where it appears from 12 to 13o'clock in summer and autumn. The evening peak appears from 20 to 21 o'clock in spring, where it appears from 21 to 22 o'clock in summer, as well as it appears from 19 to 20 o'clock in autumn and winter.

Typical day load rate is relatively large in summer, and relatively small in autumn. It shows obvious downtrend year by year. The smallest load rate of typical day is relatively large in summer, and relatively small in spring. It shows obvious downtrend year by year. The typical day peak-valley difference rate is relatively large in summer, and relatively small in summer. It shows obvious rising trend year by year.

Research object for secondary industry is chemical fiber trade, as shown in Figure 1(b). The morning peak appears from 5 to 6 o'clock in spring, where it appears from 6 to 7 o'clock in autumn, as well as it appears from 7 to 8 o'clock in summer and winter. The noon peak appears from 14 to 15 o'clock in spring, where it appears from 11 to 12 o'clock in summer, as well as it appears from 10 to 11 o'clock in autumn and winter. The evening peak appears from 21 to 22 o'clock in spring, where it appears from 17 to 18 o'clock in summer, as well as it appears from 18 to 19 o'clock in autumn and winter.

The largest load of typical day for this trade increases year by year. Typical day load rate is relatively large in winter, and relatively small in summer. It shows obvious rising trend year by year. The smallest load rate of typical day is relatively large in winter, and relatively small in spring. It shows obvious rising trend year by year. The typical day peak-valley difference rate is relatively large in spring, and relatively small in winter. It shows obvious downtrend year by year. Affected by the international financial crisis, traditional industries of labor-intensive, as well as great consumption of energy and resources, which were located in eastern China before, were relocated to the west. Because the cost of these traditional industries rose, and production could not be sustained. As a result, some enterprises with high energy consumption develop too fast is some places of Sichuan.

Research object for tertiary industry is hotel and catering trade, as shown in Figure 1(c).There is no morning peak in summer. The morning peak appears from 7 to 8 o'clock in spring, where it appears from 8 to 9 o'clock in autumn, as well as it appears from 6 to 7 o'clock in winter. The noon

peak appears from 11 to 12 o'clock in spring and winter, where it appears from 16 to 17 o'clock in summer, as well as it appears from 12 to 13 o'clock in autumn. The evening peak appears from 20 to 21 o'clock in spring, where it appears from 22 to 23 o'clock in summer, as well as it appears from 21 to 22 o'clock in autumn and winter.

The largest load of typical day for this trade increases year by year. Typical day load rate and the smallest load rate of typical day are both relatively large in summer, and both relatively small in spring. Both of them show obvious rising trend year by year. The typical day peak-valley difference rate is relatively large in spring, and relatively small in summer. It shows obvious downtrend year by year.

(2) Load characteristic of residents' life

Electricity load of resident are mainly composed by basic load and seasonal load. Basic load are mainly consumed by refrigerators, electric cookers and lights. seasonal load are consumed for cooling (including air conditionings and fans, etc) and heating (including air conditionings and heaters).

Residents' life load in Sichuan has obvious seasonal characteristic. Typical day load curve of four seasons for residents' life in Sichuan is as shown in Figure 1(d). There is no morning peak in summer and winter. The morning peak normally appears from 6 to 7 o'clock in spring, where it appears from 7 to 8 o'clock in autumn. The noon peak appears from 11 to 12 o'clock in spring and autumn, where it appears from 15 to 16 o'clock in summer, as well as it appears from 12 to 13 o'clock in winter. The evening peak appears from 18 to 19 o'clock in spring, autumn and winter, where it appears from 22 to 23 o'clock in summer, as well as it appears from 21 to 22 o'clock in summer.

The largest load of typical day for t residents' life increases year by year. Typical day load rate and the smallest load rate of typical day are both relatively large in summer, and both relatively small in autumn. Both of them show obvious downtrend year by year. The typical day peak-valley difference rate is relatively large in winter, and relatively small in summer. It shows obvious rising trend year by year.

Fig.1. Typical day load curve of four seasons in Sichuan

Investigation of electricity load structure

(1) Analysis of electricity load structure

Table 1 shown the load structure of three industries in Sichuan from 2010 to 2012.

Proportion of electricity load of primary industry is small. Irrigation is representative trade of electricity consumption trades for primary industry in Sichuan. According to relationship of electricity consumption between primary industry and irrigation, the approximate load curve of primary industry can be obtained. As spring for example, the largest load of primary industry is about 255 thousands kW in Sichuan of 2012, which is reduced by 1.16% compared to last year.

Proportion of electricity load of secondary industry is relatively large. Manufacturing of iron and steel, chlor-alkali, chemical fiber, cement manufacturing, fertilizer manufacturing and phosphorus are representative trades of electricity consumption trades for secondary industry in Sichuan. According to actual electricity consumption of typical large customers, the approximate load curve of secondary industry can be obtained. As spring for example, the largest load of secondary industry is about 21.49 millions kW in Sichuan of 2012, which is only increased by 1.56% compared to last year.

Tab.1. Load structure of three industries in Sichuan from 2010 to 2012

year	Season	date	the largest load of primary industry/1.0E+4kW	the largest load of secondary industry/1.0E+4kW	the largest load of tertiary industry /1.0E+4kW	the largest load of residents' life/1.0E+4kW
2010	spring	4/21	33.0	1718	448	467
	summer	8/18	18.9	1722	431	440
	Autumn	10/20	20.8	1825	390	519
	winter	12/15	24.0	1665	410	472
2011	spring	4/20	25.8	2116	537	515
	summer	8/17	18.7	2214	494	460
	Autumn	10/19	27.5	2110	465	574
	winter	12/21	24.8	2040	467	508
2012	spring	4/18	25.5	2149	578	543
	summer	8/15	21.1	2279	555	531
	Autumn	10/17	25.2	2175	514	571
	winter	12/19	24.9	2157	563	608

Electricity load of tertiary industry develops rapidly. Hotel and catering are representative trade of electricity consumption trades for tertiary industry in Sichuan. In similar way above, the approximate load curve of tertiary industry can be obtained. As spring for example, the largest load of primary industry is about 5.78 millions kW in Sichuan of 2012, which is reduced by 7.64% compared to last year. With fast development of tertiary industry and continuous improved quality of residents' life, compared to years before, increasing rate of load for tertiary industry and residents' life load were rising year by year. To some extent, load rate of the whole electric grid is reduced.

(2) Adjustment of industries' structure and its influence

Since 11th five-year, proportion of three industries in Sichuan adjusts from 20.1:41.5:38.4 in 2005 to 14.4:50.5:35.1 in 2010, 14.2:52.4:33.4 in 2011 and 13.8:52.8:33.4 in 2012 respectively, as shown in Figure 5. Trend of industrial structure in Sichuan is that proportion of primary industry reduced gently, while proportion of secondary industry increased greatly, and proportion of tertiary industry nearly kept the same. The largest load growth of primary and tertiary industry is lower than that of secondary industry. To some extent, development of tertiary industry increased peak-valley difference of load, and it reduced the largest load utilization hours of the whole society.

New industry is adhered in Sichuan. Industry structure will be adjusted in expanding the increment, and mode will be changed in accelerating development. Industrial efficiency would be taken the lead in the nation. A industrialization way of innovation-driven, green and low carbon, high-end trades introduced, open and cooperative, accelerating of progress will be explored.

From the point of secondary industry total to analyze its electricity consumption. In 2012, electricity consumption proportion of secondary industry was about 70.3%. Electricity load proportion of secondary industry was relatively high. Since 11th 5-year, as adjustment of three industries' structure, proportion of secondary industry total to GDP was from 34.2% to 42.0%. Secondary industry total kept fast increasing, and the largest load of secondary industry rose continuously.

From the point of secondary industry structure to analyze its electricity consumption. In 2012, heavy industry total grew by 16.0%, while light industry total grew by 16.4%, and the ratio of heavy industry total to light one is 66.8:33.2. Since 2005, the ratio of heavy industry total to light one present increasing trend. As new industry is being adhered and secondary industry structure is being adjusted in Sichuan, some enterprises with high electricity consumption and heavy pollution

would be suppressed. As a result, its electricity load growth would decrease. Load of new trades (including IT, electronic information, new materials, new energy, etc) would increase steadily year by year.

In 2015, the ratio of three industries total would be from 14.4:50.5:35.1 of 11th five-year adjusted to 10.2:50.8:39. The second industry would continue to be a "locomotive", but its power forward are mainly from innovation and technology upgrading.

Conclusions

(1)There is no morning peak of load in spring for irrigation trade. Typical day load rate is relatively large in summer, and relatively small in autumn. There is nearly no change of load curve of chemical fiber trade in winter. Typical day load rate is relatively large in winter, and relatively small in summer. There is no morning peak in summer for hotel and catering trade. Typical day load rate is relatively large in summer, and relatively small in spring.

(2)There is no morning peak of residents' life load in summer and winter in Sichuan. Typical day load rate and the smallest load rate of typical day are both relatively large in summer, and both relatively small in autumn. Both of them show obvious downtrend year by year. The typical day peak-valley difference rate is relatively large in winter, and relatively small in summer. It shows obvious rising trend year by year.

(3)Proportion of electricity load of primary industry is small in Sichuan. Proportion of secondary industry is relatively large. With fast development of tertiary industry and continuous improved quality of residents' life, to some extent, load rate of the whole electric grid is reduced.

Keywords: Energy logistics; Sustainable development; Service quality

Abstract: Analyzed about the present situation of energy logistics service quality, and combined with related literature at home and abroad, select “energy logistics tracking information timeliness”, “accuracy of energy logistics tracking information”, ”energy delivery time accuracy”, “energy distribution accuracy “, “energy integrity “, “error handling” six elements as a measure factors of the energy logistics service quality, establish research model. Through questionnaire investigation and quantitative analysis verify this research model. The Conclusions: energy distribution of accuracy have significant positive effects on sustainable development, and influence degree; Energy delivery time accuracy, integrity have significant positive effects on sustainable development, but the impact is relatively small; While energy logistics tracking information timeliness, accuracy and error of energy logistics tracking information treatment had no significant influence to the sustainable development of economy and society. Energy logistics is an important part of the logistics industry, also is an important support of economic society and people's life. Improve the quality of energy logistics service, to play an important role in promoting sustainable development.

Introduction

At present, our country's energy consumption dominant energy products mostly belong to the non-renewable energy, such as coal, oil, natural gas and so on. In terms of the logistics industry, not only to solve the problem of logistics cost, research on logistics service quality to energy saving and sustainable development has the important theory value and practical significance. Energy logistics has a very high requirement about energy geographic distribution, place of origin, off ground, quantity of flow, the timeliness. Strengthen energy logistics service quality is the important way to save energy and to realize the sustainable development.

In recent years, many scholars studied the energy logistics at home and abroad. Energy logistics service system is not a separate system, and it goes with the energy supply chain upstream and downstream production and downstream consumption link closely [1]. With the development of Internet technology and application, the RFID technology, wireless sensor technology gradually in-depth in the energy exploitation and transportation enterprises [2]. E-commerce is booming, especially in the energy and steel areas in our country, but the development is far from imaginary faster and better, which logistics capability is an important reason for the lag [3]. Hei from the point of view of the negative external economic adverse effect on the construction of urban logistics system planning process caused by the West and proposed countermeasures [4]. The energy characteristics of production, circulation and consumption, which determine the effective implementation of energy logistics service, provided energy in all aspects of information sharing must be able to effectively convey and share [5].

With different contents of the study, the paper from the point of view of energy logistics service quality, gives an empirical research about energy development status, which has guiding significance for the development of energy companies, a great significance to achieve sustainable development.

Research model and hypotheses

Logistics is an integral part of the energy transaction process, the paper based on the view of energy companies to explore the impact of logistics service quality to achieving sustainable development, combined with related literature at home and abroad, select “energy logistics tracking information timeliness”, “accuracy of energy logistics tracking information”, ”energy delivery time accuracy”, “energy distribution accuracy “, “energy integrity “, “error handling” six elements as a measure factors of the energy logistics service quality, establish research model(Fig.2.1).

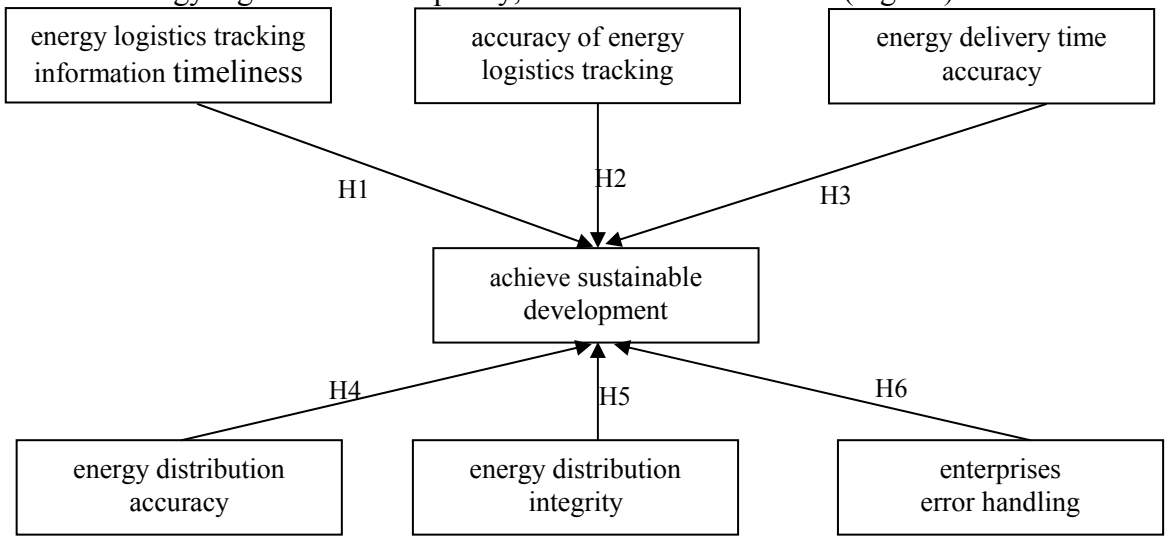

Fig.2.1 Energy logistics service quality impact model for sustainable development

Hypotheses:

H1： Energy logistics tracking information timeliness has a significant positive relationship to sustainable development

H2： Accuracy of energy logistics tracking information has a significant positive relationship to sustainable development

H3： Energy delivery time accuracy has a significant positive relationship to sustainable development

H4： Energy distribution accuracy has a significant positive relationship to sustainable development

H5： Energy integrity has a significant positive relationship to sustainable development

H6： Error handling has a significant positive relationship to sustainable development

Summary

Energy is the important guarantee of economic development. Due to large amount of energy flowing, send area wide, need to pay the huge logistics cost, so to strengthen the energy of logistics management, guarantee with minimal logistics cost, meet people's production and living energy demand, is our country national economy and social development of major issues. Through this study, the establishment of public logistics information platform, realize the department and the enterprise information sharing, coordination, improve the quality of energy logistics service, need the cooperation of government and enterprises, finally, achieve economic and social sustainable development.

Keywords: wind power;flow; reactive; voltage

Abstract. In this paper, the flow calculation problem of wind power connected to the grid was researched and the corresponding models were put forward.According to the relationship between the node voltage and reactive power of wind farms, modified the jacobian matrix.Implement and trend of the expression for calculating and according to the relationship between the node voltage and reactive power of wind farms, to modify the traditional methods of jacobian matrix and axle and consistency.Finally through the IEEE - 14 standard system, to verify this model and algorithm in this paper, satisfactory effect was obtained ,also laid the foundation for the further research.

Introduction

Wind energy is cheap and renewable.The power technology which based on wind has been paid close attention to,and now this technology has made breakthrough progress. Its performance and price more and more towards the good direction. Thus the current wind power has become a way of generating renewable energy with the fastest developing speed in, also very promising[2].

In this paper, with the help of wind turbines involved active and reactive power relations, the flow calculation problem of wind power connected to the grid compared with the traditional power flow calculation is consistent. This model considers characteristics of asynchronous generator itself, the active and are expressed as the function of wind speed, the power characteristic of induction generator can be expressed as a power and voltage and slip function.To correct the traditional wind Jacobian associated node elements, achieve simple and easy, the performance which consistent with traditional power flow calculation was researched.This idea is also convenient to other issues (such as optimal power flow ,control, etc.) processing, also accord with the actual needs.

1.The description of the association between active and reactive power of fan

1.1Active expression of the fan

Generating capacity of wind turbines affected by many factors, primarily wind speed, the blade wind area of wind turbine , etc.Mechanical power generated can be expressed as[3]:

$$P_m = 0.5 C_p \rho S V^3 \qquad (1)$$

In the formula: S is the fan blade swept area, m^2； ρ is the air density, kg/m^3; V is the wind speed, m/s ; C_p is the power coefficient of wind turbine,It is a function of tip speed ratio λ ,Among them, $\lambda = \omega r / V$ ， ω is the angular velocity of the wind wheel, rad/s ； r is wind wheel radius, m .

From the formula (1) we can see,Mechanical power of wind generator and wind area and the three times square wind speed is directly proportional relationship,as long as we know the wind the theoretical power output of wind turbine can be get.

1.2 The association between active and reactive power of fan

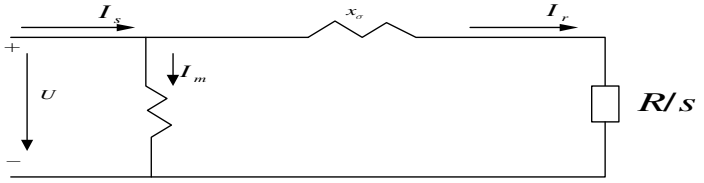

Chart 1 Equivalent circuit of induction generator

The chart 1 is the equivalent circuit of induction generator,where a is the terminal voltage of induction generator. I_s is stator current, I_m is exciting current , I_r is rotor current, x_m is exciting reactance, R is mechanical load equivalent resistance, x_σ is the value of the stator leakage reactance and rotor leakage reactance, s is slip ratio.

Form the chart 1 the electromagnetic power and power factor output by induction generator can be derived as following expression.

$$P_e = \frac{sRU^2}{s^2 x_\sigma^2 + R^2} \tag{2}$$

The power factor is

$$tg\Phi = \frac{R^2 + x_\sigma(x_\sigma + x_m)s^2}{sRx_m} \tag{3}$$

At the same time, asynchronous generator slip ratio can be expressed as:

$$s = \frac{R(U^2 - \sqrt{U^4 - 4x_\sigma^2 p_e^2})}{2p_e x_\sigma^2} \tag{4}$$

Similarly, asynchronous generator output reactive power can be expressed as:

$$Q = \frac{[R^2 + x_\sigma(x_m + x_\sigma)s^2]P_e}{sRx_m} \tag{5}$$

By formula (4) and (5) we can see that the induction generator reactive power has been transformed into a function, and this function has associated with active and voltage, and active power (ignoring losses) is the wind speed function.

Therefore, if the wind speed is determined, we can make use of the formula (1) to obtain the active power output of the wind turbine, and then by means of the formula (4) and (5) of the wind turbines needed to absorb reactive power，and then through the type (4) and (5) get the reactive power which wind turbines need to absorb.

2 The correction of traditional fashion model

Correction equations when solve traditional flow equations can be expressed as [3]:

$$\begin{bmatrix} \Delta P \\ \Delta Q \end{bmatrix} = \begin{bmatrix} H & N \\ L & J \end{bmatrix} \begin{bmatrix} \Delta\theta \\ \Delta V / V \end{bmatrix} \tag{6}$$

According to the association between active and reactive power of fan, when calculating the trend which contains wind power system, we need to modify the traditional flow correction equation.Because the function of wind farm node becomes the node voltage when it injected reactive power,therefore, when the formation of Jacobian need to supplement wind farm nodes inject reactive derivative terms of voltage to modify the Jacobi matrix related items of J .

From the formula (4), (5) and the formula (1), can get：

$$Q_e = \frac{2P_e^2 x_\sigma^2}{r_2(-U^2R+\sqrt{U^4R^2-4P_e^2R^2x_\sigma^2})x_m}\cdot \\ [-R^2-\frac{(-U^2R+\sqrt{U^4R^2-4P_e^2R^2x_\sigma^2})^2(x_\sigma+x_m)}{4P_e^2x_\sigma^3}] \tag{7}$$

Further derivation can get：

$$\frac{\partial Q}{\partial U} = -\frac{x_\sigma+x_m}{Rx_mx_\sigma}(-2UR+\frac{2U^3R^2}{\sqrt{U^4R^2-4P_e^2R^2x_\sigma^2}})- \\ \frac{2P_e^2x_\sigma^2}{Rx_m}[-2UR+2U^3R^2(U^4R^2-4P_e^2R^2x_\sigma^2)^{-\frac{1}{2}}]\cdot \\ (-U^2R+\sqrt{U^4R^2-4P_e^2R^2x_\sigma^2})^{-2}\cdot \\ [-R^2-\frac{x_\sigma+x_m}{4P_e^2x_\sigma^3}(-U^2R+\sqrt{U^4R^2-4P_e^2R^2x_\sigma^2})^2] \tag{8}$$

Visible. in the Jacobi matrix. Simply accumulated in the derivative of wind farm node reactive power to the voltage of it,the remaining elements of the Jacobi matrix unchanged.

3 The calculation of process

On the basis of the last section,The steps of power system load flow calculation and the traditional power flow calculation are consistent,except that the wind farm node into active and inactive calculation,and the modified Jacobi matrix of the nodes corresponding to the wind farm.Specific calculation process shown in Figure 2.

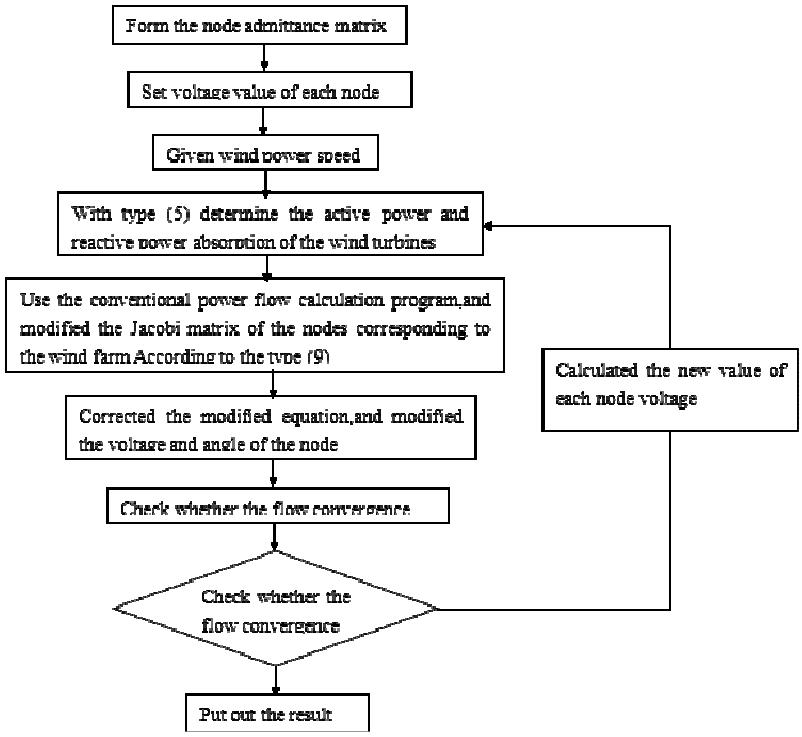

Figure 2.Wind power system flow calculation flow chart

4 An example and its analysis

The background of validation example constructed in this article described as follows: Assuming wind farm connected to the 14 node[2]of IEEE14 system(see Figure 3) through the 110KV line.Transmission impedance of accessible wind power system is:3.14963+j6.23997Ω.The capacity of wind farm is:20 × 800KW,Stator leakage reactance is:0.07620Ω,Rotor resistance is:0.00759+j0.18289Ω.Excitation reactance is:3.44979Ω. The cut-in speed, rated wind speed, excised wind speed of the wind turbine are:3m/s, 14m/s , 25m/s.After access the wind farm.,The load of 14 node increases 16MW based on the original.

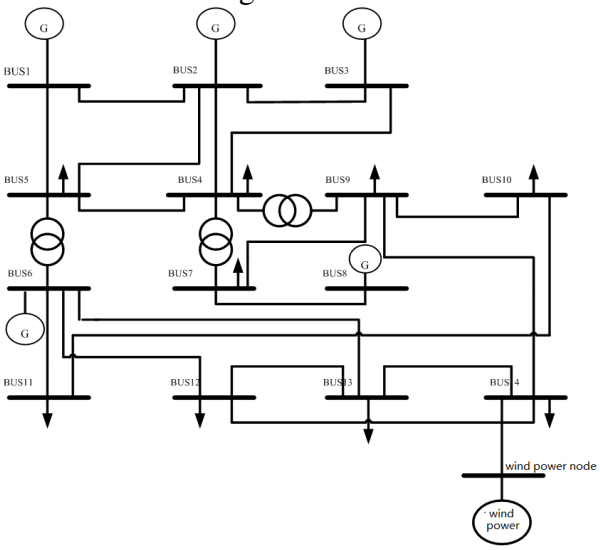

Figure 3.The system diagram of wind farm integrated

Calculated for this case with the proposed model and algorithm, and given analysis .

Table 1 is the result of wind farm node which under different wind speeds, active power, reactive power and voltage node.

Table 1:The active,reactive and node voltage of wind farm node which under different wind speed

Wind speed/m/s	Active power/pu	Reactive power/pu	Node voltage/pu
4	0.01072	-0.028067	1.0027878
6	0.03444	-0.0311064	1.0050965
8	0.0612	-0.0383134	1.0066221
10	0.091	-0.0517204	1.0067961
12	0.12384	-0.0752712	1.0044994
14	0.16	-0.129509	0.99596703

As seen in Table 1,Increasing with the wind speed,the active power output by the wind farm is gradually increased, while the absorption of reactive power also increases gradually, and the node voltage is first increased and then decreased.

When the wind speed reaches 14m/s, wind turbine operation at rated condition,at that time we compare the voltage of the 14 node of system with no wind power.As shown in table 2.

Table 2.The comparison of the ourteen node voltage when wind turbine access and non access

Node number	The model result/p.u	The results missed wind power system/p.u	Percentage deviation
1	1.06	1.0600	0
2	1.045	1.0450	0
3	1.01	1.0100	0
4	1.0192573	1.020652	0.137%
5	1.0211453	1.0220971	0.09%
6	1.07	1.07	0
7	1.0496667	1.0540368	0.39%
8	1.09	1.0900	0
9	1.0306246	1.0392594	0.83%
10	1.0302193	1.0373848	0.69%
11	1.0465128	1.0501854	0.35%
12	1.0533493	1.0558563	0.24%
13	1.0424381	1.0484186	0.57%
14	0.9981851	1.0250826	2.6%

From table 2 we can see,the node voltage amplitude changes in a small range, when the access of wind power,this phenomenon is consistent with the actual requirements, verify the correctness of the model.In the wind power access node,the voltage of the 14 node with maximum deviation. With the active power from wind turbines increaseing, at the same time the need of absorb reactive power also increaseing.As wind power and network.14 nodes need to support the wind turbine provides with reactive,so the node voltage decreases.

Table 3.The comparison of the access point of the voltage and not access point voltage,when wind farm connected to different nodes.

The node number of wind power integration	After accessing the node voltage/pu	Before accessing the node voltage/pu	Percentage deviation
4	1.015567	1.020652	0.50%
5	1.0168799	1.0220971	0.51%
7	1.0444124	1.0540368	0.91%
9	1.027298	1.0392594	1.15%
10	1.0250185	1.0373848	1.19%
11	1.0424299	1.0501854	0.74%
12	1.0562332	1.0558563	0.04%
13	1.0421935	1.0484186	0.59%
14	0.9981851	1.0250826	2.6%

From table 3 we can see. When the wind power access to 9, 10, 14 node, the voltage effect on the access point is larger. When the wind power access to 4, 5, 12, 13 node, has little effect on the access point voltage.This also shows that the connection of nodes 10, 14 with the entire system is weak,and other nodes they connect are not able to provide enough PV nodes which support with reactive,and they are no reactive compensation device.So when these nodes access wind power the effect of voltage on them is larger.

When the wind power access to these nodes of 4, 5, 12, 13 ,voltage has little influence on the access point,this is because these nodes and other nodes in the system is closely related to,on the other hand ,it also because all the nodes which connect with those nodes have PV node,with the increaseing of active output from power wind ,the reactive power absorbed by it will increase,although the access point itself without reactive power compensation device,but it is closely associated with the system, and it is also linked with PV nodes which has the ability to provide reactive power,Thereby ensuring the node voltage is not too much lower.

We can see,wind at different access points, the effect is different from the access point.If the access point is closely associated with the system, or it itself has no power compensation capabilities, it is less affected by wind power access.With the gradual increaseing in wind power capacity, in order to ensure access point voltage is not more limited,we conduct a reasonable choice of the access point and reactive compensation in the access point is very necessary.

5 Conclusion

(1)Throught the association between active and reactive power of fan,based on neglecting the mechanical loss power,we just need to correcte on the traditional trend slightly,flow calculation of wind power can be done.

(2)Computational analysis showed. When access to different nodes of wind power, its influence is different,it has a close relationship with system support conditions of reactive voltage.This idea in this paper provides a good foundation for studying the effect of wind power to power grid.

Research on New Energy Industrial Upgrading in Tianjin Based on SWOT Analysis

Qi-qi YANG[a], Fang-xu HAN[b]

School of Management, Tianjin University of Technology, Tianjin 300384, China

[a]yqq17791@163.com, [b]fangxu_han@163.com

Keywords: SWOT analysis; new energy; new energy industry; industrial upgrading

Abstract: The development of new energy industry is one of the important breakthroughs to solve energy and environmental issues and fulfill commitment to the international community for China. SWOT analysis was used to study the new energy industrial upgrading in Tianjin in this paper. By analyzing the strengths, weaknesses, opportunities and threats of the development of new energy industry in Tianjin, the current situations and problems were summarized, in order to provide reference for the practice of new energy industrial upgrading in Tianjin.

Introduction

The aggravation of energy crisis and environmental pollution promotes national economy to develop in the direction of environmental protection, low carbon and sustainable development. The new energy industry which takes renewable energy as the core is the innovation point of the world economic growth, and has significance to industrial restructuring and transformation of economic growth mode[1]. Our country has made the development of new energy industry rise to national strategic level.

Concepts of new energy and new energy industry

New energy is directly or indirectly from the sun or the earth's interior heat. It has various forms, in addition to solar energy, wind energy, biomass energy, geothermal energy, nuclear energy and hydropower, biofuels and hydrogen derived from renewable energy involved[2].

New energy industry refers to a low carbon, environmental protection and green industry which has the wide resources endowment, complex technology, less pollution to the environment and sustainable regeneration[3].

SWOT analysis of new energy industrial upgrading in Tianjin

SWOT analysis is a kind of strategic planning research technology, mainly on the strengths, weaknesses, opportunities and threats factors analysis[4]. Summarizing the actuality and existent problem by studying the external and internal factors that influence the development of new energy industry in Tianjin is of great significance.

Strength analysis

Application and industrial development of new energy have become a global consensus.

At present, new energy industry has become an important basis to measure the level of high and new technology development of countries and regions. It's also the strategy for a new round of international competition. Europe and the United States and other developed countries have taken the development of new energy industry as the main means against the financial crisis, and a series of policies to promote its development have rolled out. Major consumption of energy in China is coal and oil, so applying new energy and developing new energy industry are important means to change structure of energy consumption, ensure energy security and achieve sustainable development.

Tianjin has formed a complete new energy industry chain and industry cluster.

Now Tianjin new energy industry has four principal parts: energy storage battery, solar cell, fuel cell and wind power generation. An area of 6.6 km^2 in Binhai High-tech Zone has planned and constructed as the new energy industry base[5]. Nearly 10 large new energy companies such as Haitai group, Lishen Battery, Lantian Power, Jinneng Battery and Bamo Technology are gathered there, and develop a batch of products with strong domestic and international market competitiveness. Both the number and output value of the new energy companies here account for more than half of the city. It has formed the new energy industry cluster with the most complete product categories and highest technical level in China. Lishen company, for example, through independent research and development projects, has formed a scale that annual production capacity is 100 million pieces of lithium ion battery, and become the nation's largest lithium ion power battery production base.

Government provides support in terms of funds, policy and technology.

Tianjin municipal committee and municipal government attach great importance to the development of new energy industry that they have recognized it as one of the key hi-new-tech industries. A number of preferential policies are issued to keep the average growth rate of new energy industry more than 40%. First of all, financial investment has increased. A total of 200 million yuan a year to support new energy enterprises listing, merger, implementing major science and technology industrialization projects, developing the international market, introducing and developing related enterprises, etc.; Second, the management approach has been issued to encourage scientific and technological talents to innovate and carve out. Third, efforts have been made to construct the system of new energy industry science and technology innovation. The municipal committee and municipal government have formed the Binhai institute of new energy industry, the productivity promotion center, the public technology platform of green energy, the national industrialization base of new energy high technology, technology and product innovation centre, and the demonstration center of application of new energy products. Supporting all kinds of innovation platform has speed up the new energy industry transformation of scientific and technological achievements into realistic productivity. A good policy environment has become one of the core competitiveness of Tianjin new energy industry.

New energy products of Tianjin have high market share and huge market prospects.

In recent years, new energy industry of Tianjin has formed a batch of competitive large enterprises. 24 of them earn more than 100 million yuan and 8 enterprises earn more than 1 billion yuan, that guarantee Tianjin the dominance in the national new energy industry, and the market share of wind power equipments, lithium ion batteries and nickel metal hydride batteries among the top. Tianjin new energy industry in market share, market recognition and the future development potential has a strong core competitiveness.

Weakness analysis

The investment in human resources, capital is still inadequate.

With the rapid development of new energy industry and the implementation of related personnel policy and financial support policy in Tianjin, though a batch of high-level innovative talents of science and technology have been introduced and cultivated, and a group of domestic and foreign large-scale new energy enterprises have been attracted, that make the city's new energy industry personnel quantity and investment reach a certain scale, it’s still inadequate in terms of the demand of talents and funds. Compared to Beijing, Shanghai, the pearl river delta and Yangtze river delta region, the income level of professional and technical personnel in Tianjin is obviously on the low side, and the government guidance funds are more limited.

Opportunity analysis

International situation brings opportunities for new energy industrial upgrading.

Currently, the fossil energy consumption accounts for more than 90% of total energy consumption. There is a prominent contradiction between serious environmental pollution and the continued rapid growth in energy demand, which brings a rare opportunity for energy restructuring

and new energy development. In response to environmental pollution, international developed countries generally carried out the "Energy New Deal" to reform the energy industry. There is no exception in China. China invested 522×10^8 dollars for the development of renewable energy in 2011, an increase of 17%, accounting for 58.5% of the total annual investment in developing countries. China announced to join the International Renewable Energy Agency officially in 2013.

The development of low carbon economy speeds up the new energy industrial upgrading.

The energy development and utilization in Chain is faced with energy dwindling, sustained and rapid growth in energy demand and serious environmental pollution. Reportedly, in the first half of 2013, the annual averages of PM2.5 in Beijing, Tianjin and Hebei haven't reached the standard. Moreover, days that air quality exceeds the severe-pollution level in Beijing-Tianjin- Hebei region accounted for 21.2% in June[6]. Represented by wind and solar energy, the new energy is characterized by being abundant, clean and renewable, and meets the requirements for promoting circular economy. It is a significant way to solve the resource shortage and environmental pollution efficiently.

The energy policy in Tianjin is advantageous to the new energy industrial upgrading.

Tianjin is rich in natural resources and the development of new energy industry has begun to take shape. Accompanying with "the twelfth five-year plan of new energy and new materials industry development of Tianjin" rolled out, the government pointed out the direction and priorities of new energy industry development from green battery, wind power, photovoltaic power generation, nuclear power and biomass energy.

Threat analysis

The consumption scope of new energy products is narrow.

The new energy products sales in the domestic market are limited to the development needs of national hard targets and enterprises utilize. Individual consumers lack confidence in it that the personal consumption market of new energy products has not been formed, and domestic new energy and renewable energy account for less than 10%. Chinese new energy products which take foreign countries as the main application market are affected by photovoltaic industry expansion and the financial crisis. Spain and Germany reduced subsidies for solar energy photovoltaic industry, then the European clean energy market was shrinking, the export of new energy products suffered restriction.

New energy enterprises lack of innovation ability.

New energy is a technology-intensive industry, product development and technology innovation are key factors to improve the core competitiveness and ensure the development of new energy industry. In the new energy industry in Tianjin, except the fields of green battery, photovoltaic power generation and wind power develop leadingly, independent technology innovation ability of most new energy industry is weak, which increases the transformation difficulty of new energy technologies into practical products, reduces the reliability and economy of new energy products, and influences the sustainable development and market competitiveness of new energy industry Directly.

The supporting service system of new energy is not vigorous.

The new energy industry is a new industry that has broad prospects for development and good social benefits. It needs not only strong support of national policy, but also the supporting service system. At present, the information on new energy industry development, technological innovation, the mechanisms of talents training, mobility and introduction are not vigorous, and the financing guarantees, technical standards, professional consulting, talents training, mobility and introduction mechanisms that associate with the new energy industry are also not established. To some extent, both of them restrict the development of new energy industries.

Summary

Through the SWOT analysis of new energy industrial upgrading in Tianjin, we find that the biggest strength of new energy industry development is the solid new energy industry base and

strong supports from the government; the biggest weakness is the lack of talents and funds required; the biggest opportunity is the promotion from the development of low carbon economy on new energy industrial upgrading; the biggest threat is the lack of innovation ability and the narrow consumption scope of new energy products. On the whole, the prospects of new energy industry development are very broad, and Tianjin has a unique advantage. However, funds, technology and effective measures are still needed to realize the new energy industrial upgrading.

Keywords: Demand Response; Interruptible Load; Economic Dispatch; Fluctuant Wind Power; Monte Carlo; Interior Point Method

Abstract. Interruptible load was an important measure for demand response which can effectively implement the interaction between grid side and demand side. It's also the important feature and component of smart grid. This paper established a stochastic economic dispatch model which brought both interruptible load and stochastic wind generation models into scheduling, and took the active and reactive power constraint of generator, the adjustable capacity constraint of interruptible load and the constraint of branch power flow into account. On the basis of Monte Carlo simulation and modified interior point method, a comprehensive optimization algorithm is proposed to tackle the above stochastic economic dispatch model. The result of IEEE 118-bus system illustrated that the proposed method can effectively curtail system's operational cost and, to some extent, boost grid's adaptability to wind power.

Introduction

Traditional dispatching model in power system which only considers resource in generation side cannot meet requirements for the rapid development of smart-grid. Load can participate in power Economic Dispatch (ED) by advanced technologies based on modern network, which can implement the interaction between information on feed side and demand side. Demand response (DR) regarding Advanced Metering Infrastructure (AMI) as the core is important resource in smart grid [1], which can be divided into two types: Price-based DR and Incentive-based DR. Interruptible load (IL) is a kind of incentive-based DR that plays a crucial role in power dispatching as a virtual power plant, and enhances elasticity of demand.

In paper [2], the comprehensive analysis of characteristics on various kinds of DR is constructed, and put forward that the IL is an available approach that realizes exchange between information and electrical power. Paper [3] summarizes technical structure of five actual smart grid companies in the world, in which load control participate in system regulator including demand side bidding and strategy. Paper [4] regards IL as reserve, and optimizes IL reserve and generation side reserve coordinately based on time-of-use power price. Above research has proved the preferable economic efficiency and feasibility of IL, but it is only treated as a kind of ancillary services, the effect of IL on generation cost and renewable energy is overlooked.

In this paper, an ED model considering both of stochastic wind generation and IL is established. On the basis of Monte Carlo simulation and modified interior point method, the comprehensive optimization algorithm is proposed. Based on a modified IEEE 118-bus system, the numerical results illustrate the effectiveness of the ED method and optimum algorithm.

Interruptible Load Model

The form of IL participating in system dispatch as a kind of interactive resource can be determined through an IL contract between grid companies and IL customers. Ordinarily, consumers declare the interruptible capacity and compensative payment according to the price published by grid companies. The optimal generation scheduling is presented based on the condition of both demand and generation side. Then the contract will be signed which includes the

interruptible capacity, compensation mode and price. Finally, the ultimate compensation can be built up according to the situation which the customers are actually called upon [5].

The specific compensation cost includes two components, capacity cost and an additional activation energy cost which is actually called by grid operator. Capacity compensation is fixed cost in accordance with the contract based on different abilities of maximize interruption capability, it can't be changed whether IL is interrupted or not practically. Energy compensation is generated for the interrupted load after participate in actual operation, the optimal interrupted power is calculated by ED. Compensation cost model within a certain dispatch period of time t is as follows:

$$f_{DR,j}=C_{cap,j}Cap_{DR,j}+C_{power,j}P_{DR,j} \tag{1}$$

Where $f_{DR,j}$ is the total compensation for the jth IL customer, it is composed of both capacity cost and energy cost; $C_{Cap,j}$ and $Cap_{DR,j}$ are the capacity compensation price and the maximum ability (capacity) for the jth customer respectively; $C_{power,j}$ and $P_{DR,j}$ are the jth customer's interruptible price for unit energy and the actual interrupted power, $P_{DR,j}$=0 represents the IL is inactive.

Output Power Model of Wind

The stochastic volatility of wind power can be represented by a probabilistic model. In this paper, a model of wind output in which the actual output power is expressed as the sum of wind power prediction and the deviation value will be utilized as follows [6]:

The deviation of wind power is normal distribution of a given variance within a certain dispatch period of time t:

$$P_{W,\Delta} \sim N(\mu_W, \sigma_W^2) \tag{2}$$

$$\mu_W = 0, \quad \sigma_W = P_{Wy}/\alpha + W_{wind}/\beta \tag{3}$$

Where μ_W and σ_W are the expectation and variance of this distribution respectively; P_{Wy} presents the prediction of wind power at time t; W_{wind} is wind total installed capacity; α and β are calculation parameters of standard deviation; Actual output power of wind at time t is as follows:

$$P_W = P_{Wy} + P_{W,\Delta} \tag{4}$$

In the type: P_W is actual output power. A collection of wind power fluctuations can be obtained through random sampling which can simulate a variety of situations of wind power fluctuation, and then the collection of actual output can be got as follow, where N_M is the total number of samples.

$$\{P_W(1), P_W(2), \cdots, P_W(N_M)\} \tag{5}$$

Stochastic Economic Dispatch Model Considering IL and Wind Power

Taking the IL and wind models into dispatch, optimizing demand side resource and conventional unit output comprehensively, an ED model at time t is set up as follows:

1) Objective function:

$$Minf(P_{G,i}, P_{DR,j}) = Min(\sum_{i=1}^{N_G} f_{G,i} + \sum_{j=1}^{N_{DR}} f_{DR,j}), \quad f_{G,i} = a_i P_{G,i}^2 + b_i P_{G,i} + c_i \tag{6}$$

Where $P_{G,i}$ is the active power of the ith unit; N_G and N_{DR} are the total numbers of generators and IL customers respectively; $f_{G,i}$ is the operation cost function of the ith unit, and a_i, b_i, c_i are it's correlation coefficients.

2) Constraints:

$$\begin{cases} \sum_{i\in k} P_{G,i} + \sum_{m\in k} P_{W,m} - \left(P_{L,k} - \sum_{j\in k} P_{DR,j} \right) - V_k \sum_{l=1}^{N} V_l \left(G_{kl}\cos\theta_{kl} + B_{kl}\sin\theta_{kl} \right) = 0 \\ \sum_{i\in k} Q_{G,i} - \left(Q_{L,k} - \sum_{j\in k} Q_{DR,j} \right) - V_k \sum_{l=1}^{N} V_l \left(G_{kl}\cos\theta_{kl} - B_{kl}\sin\theta_{kl} \right) = 0 \end{cases}, \quad k = 1, 2, \cdots, N \tag{7}$$

Formulation (7) is node power balance constraint. Where $Q_{G,i}$ is the reactive power of the ith unit; $P_{L,k}$ and $Q_{L,k}$ are the active and reactive load of the kth bus; V_k and V_l are the voltage magnitude of

the kth and lth bus; G_{kl} and B_{kl} are used to represent the conductance and susceptance of branch kl; θ_{kl} is the phase angle between bus k and l; N is the system bus numbers. The inequality constraints of the model are as follows:

$$\begin{cases} V_{k.\min} \le V_k \le V_{k.\max} & ,k = 1,2,\cdots,N \\ P_{G,i.\min} \le P_{G,i} \le P_{G,i.\max} & ,i = 1,2,\cdots,N_G \\ Q_{G,i.\min} \le Q_{G,i} \le Q_{G,i.\max} & ,i = 1,2,\cdots,N_G \\ P_{DR,j.\min} \le P_{DR,j} \le P_{DR,j.\max} & ,j = 1,2,\cdots,N_{DR} \\ |L_l| \le |L_{l.\max}| & ,l = 1,2,\cdots,N_L \end{cases} \tag{8}$$

In the type (8): the inequality constraints represent the voltage constraint, the active and reactive power constraint of generator, the adjustable capacity constraint of IL and the power flow constraint of branch successively; Where L_l is the current through the lth branch; N_l is the branch numbers.

In this paper, Monte Carlo method is used to simulate the fluctuation of wind power. On the basis of this, this paper optimizes and calculates the above models through Interior Point method to get the optimal scheduling scheme; The expectation, maximum and standard deviation of the results can be used to evaluate the effectiveness of the method proposed by this paper. The calculation flow charts are as follows:

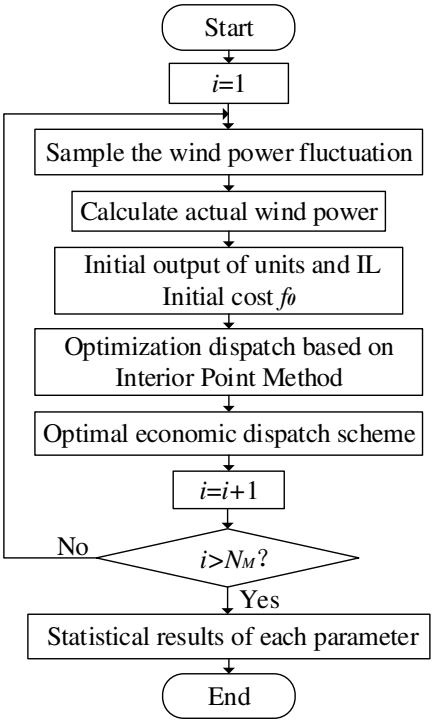

Fig.1. Calculation flow chart

Tab.1. Wind power generation parameters

Wind farm	Bus	Prediction power (MW)	Installed capacity (MW)
1	63	40	100
2	102	60	100
3	117	100	200

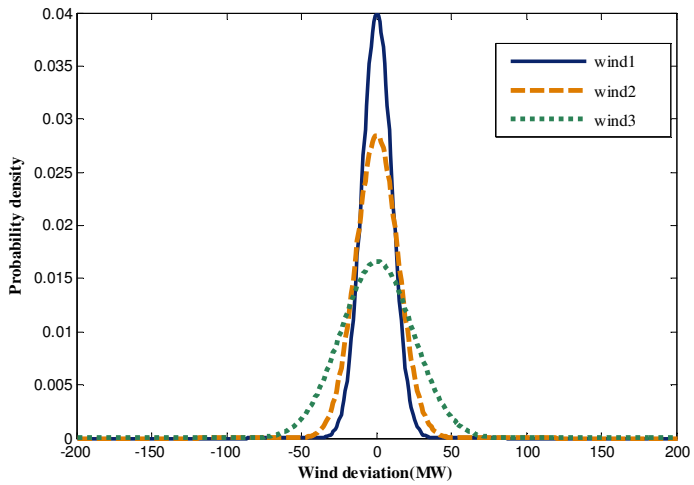

Fig.2. Probability distribution of wind generation deviation

Simulation results

A modified IEEE 118-bus system is used to clarify the proposed stochastic ED method, the system data and unit parameters reference [7]. Three wind farms with total installed capacity of 400MW which account for 10% of the total capacity of system are installed at bus 63, 102 and 117 respectively. The dispatch cycle is set to be 1 hour. The installed capacity and prediction of each wind farm at time t is shown in Table1. Using Monte Carlo method to simulate the fluctuation, the actual fluctuant wind output is obtained, α and β are set to be 5 and 50 respectively [8]. Figure2 demonstrates the probability distribution of wind generation deviation.

To facilitate the presentation, the load is set to basic level (total load is 4000MW) and heavy load level (150% of basic), which describes two scenarios with different load level. 30% of load buses are set to be IL bus, the maximum interruptible capacity is set to 50% of each total active load. Assume that the power factor remains during the process of interruption. The price of IL capacity and interrupt energy can reference [3-4]. Table2 indicates the parameters of each IL.

Tab.2. Interruptible load parameters

IL bus	11	15	18	27	32	34	40	42	49	54	55
Max. capacity (MW)	35	45	30	35	30	30	33	48	44	50	30
Capacity price ($/MW)	0.5	0.8	0.5	0.5	0.5	0.5	0.5	1.3	0.8	1.3	0.5
Energy price ($/MWh)	12.89	14.47	12.89	12.89	12.89	12.89	12.89	17.15	14.47	17.15	12.89
IL bus	56	59	60	62	76	78	80	90	92	112	116
Max. capacity (MW)	42	50	39	39	34	35	50	50	33	34	50
Capacity price ($/MW)	0.8	0.8	0.8	0.8	0.5	0.5	1.3	1.3	0.5	0.5	1.3
Energy price ($/MWh)	14.7	17.15	14.47	14.47	12.89	12.89	17.15	17.15	12.89	12.89	17.15

According to the above settings and the dispatching model in this paper, the simulation results with a wind power sample of 1000 cases are illustrated as follows. Table3 compares optimal results between two scenarios with or without IL participate in generation scheduling. The following conclusions can be obtained:

Tab.3. Comparison of Economic Dispatch results

Scenario	IL	Avg. cost ($)	Max. cost ($)	Actual IL (MW)	Total units Generation(MW)		
					Avg.	Max.	SD
1	No	62835.70	68533.97	_	3994.03	4160.27	78.0287
	Yes	61117.87	65474.03	423.85	3560.95	3634.98	47.4966
2	No	110509.01	117755.81	_	6150.81	6231.67	84.6578
	Yes	105957.19	111762.53	783.20	5343.45	5476.93	52.0627

(1) Both the average and maximum values of the total cost of the optimal dispatch results are effectively reduced after considering IL in two scenarios. In Scenario1, the average cost with IL participate in is 1700$ less than the condition without IL, while the maximum cost decreased much more, around 3000$. It indicated that the ED model considering IL can reduce the generating cost, especially for the maximum cost.

(2) The current through branch30-38 is 1.19kA in Scenario1, approach to its limit 1.26kA. When the load increases, the closely related high-cost units G15, G18 and G19 will give an additional 96.52MW output if IL not participate in. Compared with the model including IL, the increased power is only 57.68MW and the cost of dispatching high-cost units is effectively decreased. The comparison between Scenario1 and 2 shows when the load level is increasing, output of some low-cost units is limited due to the constraints of the transmission capacity and generation capacity, which give rise to an additional generation of some high-cost units in the condition without IL to meet the demand of load, that leads to the decrease of system economic efficiency. The actual interrupt amount of IL in Scenario2 is much more than that in Scenario1, which is part of substitution of high-cost units' generation. The system cost is reduced by 4.5% and the diseconomy caused by the transmission and generation capacity constraints has been improved.

(3) The generators have to change within a certain range to balance the power fluctuation due to wind generation, which make the dispatch scheme present certain randomness. The ensemble volatility in both conditions shown in Table3 presented that with IL, the standard deviation of the generation is much reduced in both of two scenarios. IL shows a more flexible adjustment ability to balance the influence of wind fluctuation than conventional unit. Unit generation fluctuate range can be decreased by dispatching IL. For further clarification of the IL ability to adjust the undulation of single unit, part of the units' maximum changes in generation that may occur during the simulation are shown in Table4.

In Scenario1 without IL, the output of unit G12 changes from 109.78MW to 182.45MW for the influence of wind fluctuation, the maximum possible variation is 73MW. This is improved to

Tab.4. Unit fluctuation in Scenario1

IL	Max. variation of units generation			
	G12	G62	G80	G89
No	72	41	69	54
Yes	26	12	23	16

26MW after considering IL dispatch. It can be perceived that the unit generation changes can be improved much smoother through IL participate.

Conclusion

This paper established a stochastic economic dispatch model which took both interruptible load and stochastic wind generation models into account. This model considered conventional unit output and demand side resource comprehensively, and was constructed with IL interaction and wind power interconnection. The comprehensive optimization algorithm based on Monte Carlo simulation and modified interior point method was used to obtain the optimal scheme. The results demonstrated the proposed method reduced the output of high-cost units and also curtailed system's operational cost. In the meanwhile, it dampened the fluctuation of units' generation due to wind variation, therefore dampened the adverse effects from wind integration, and boosted the security and economy of grid.

Keywords: renewable energy; system dynamics; economical operation

Abstract. The integration of renewable energy resources(RERs) not only shows significant environmental effect, social effect and economic effect, but also brings many challenges to grid planning and economic operation of power grid. Based on systematic dynamics, from the perspective of changes of cost and benefit of grid enterprises caused by the integration of RERs, the effect of the integration of RERs on economical operation of power grid is studied. Finally, a simulation of effect trend based on empirical data of one province demonstrates the validity of the model proposed in this paper.

Introduction

Because the installed percentage of renewable energy capacity has risen steadily, the influence of which on power grids the economic operation are increasingly highlighted. Renewable energy sources generation technologies such as wind power, photovoltaic power have their own power features, which have brought about great challenges for power grid economic operation after integration of renewable energy [2]. Research on the influence of integration renewable energy source on grid economic operation, especially on electric power loss and the economic dispatch, etc, has great significance on choosing grid economic operation mode scientifically and rationally and improving the management efficiency of the power grid company.

There are some documents that made a research on the influence of integration of renewable energy grid on power grid at present. These research, from different perspective angle, will study the impact of the renewable energy source integration on a segment of power system, but not from other segments such as power generation, transmission and electricity sales to make comprehensive analysis for the influence of the renewable energy source integration on the economic operation of power grids and power grid overall management. Therefore, this paper uses the method of system dynamics, by constructing the grid economic operation system flow chart, from angles of changes of the power grid enterprise operating costs and benefits caused by renewable energy combined to the grid to study the influence of the renewable energy grid integration on the economic operation of power grids, and uses the real data of the province over the next decade to simulate the influence trend of renewable energy grid integration on economic operation of power grids .

Impact analysis of renewable energy grid integration to economic operation of power grids

Renewable energy power generation technology has achieved rapid development in recent years, whose costs have reduced continually, but a large amount of renewable energy access generated a large impact on the structure of the distribution system and power grid economic operation [1]. Mainly manifested in the following two aspects:

(1) Impact on loss of power grid

After access of power distribution network to renewable energy power generation system, the load distribution of whole distribution network will change, which can lead to the increase of network loss, and it depends on factors such as the location of the renewable energy access, the size of access capacity and the network topology structure,etc.

(2) Impact on the line power flow

Because wind power and photovoltaic power generation force are highly affected by the weather and so on, they have intermittent and uncertainty, which will directly result in randomness of system trend, and the traditional trend algorithm will be no longer suitable to use. In addition, the renewable energy grid integration will also produce certain effect on the economic dispatch operation, which main perform difficult power prediction and bad generation electricity planning, bringing about a challenge to the ways of the grid scheduling and real-time monitoring .

And the influence of renewable energy grid integration on power grid enterprise operation cost has following several aspects:

(1) Power generation side. Renewable energy grid integration can share the partial load of the traditional thermal power and hydroelectric generating set , greatly reducing the consumption of fossil fuels, and reducing the operation costs of the power generation side.

(2) Power grid side. Due to characteristics as intermittent, uncertainty, and so on, renewable energy grid integration will affect system stability, reliability and power quality, increasing the power auxiliary service cost such as frequency control, reserve capacity, reactive power and voltage regulation, etc.

(3) Electricity side. Electricity power grid enterprises accepted the renewable energy power generation, at the same time, countries offered certain subsidy for sales power price , to a certain extent, reducing the cost of the power grid enterprise.

Model description

Based on the above analysis of the influence of renewable energy grid integration on economic operation of power grids, this part plans to adopt the system dynamics, to establish system dynamics model of renewable energy grid generation to economic operation of power grids.

In this paper, the model mainly includes three parts: First is the amount of renewable energy power generation; Second is power grid enterprises operating costs; Third is to power grid enterprise benefits.

(1) Amount of renewable energy power generation. It mainly researches the renewable energy electricity gross generation in a given area by the support technological progress and government policies, .

(2) Power grid enterprise running cost. It mainly researches considerance of the cost of line loss and auxiliary service cost that the renewable energy grid-connected power grid enterprise need to bear, on the basis of ensuring grid security operation and quality of power supply level, and meeting the demand of power supply.

(3) Power grid enterprise income. It mainly researches selling electricity income of power grid enterprise in the case of renewable energy grid-connected. Thereinto electricity selling price of renewable energy considered electricity price subsidies of the renewable energy power generation.

Based on the above analysis, this article selects the core index such as the power grid enterprise operation efficiency and renewable energy power generation, and correlation indicators affecting the core indexes. Using system dynamics software vensim, it has combed the qualitative relations between the various indicators, and constructed the grid economic operation system flow diagram, as shown in figure 1:

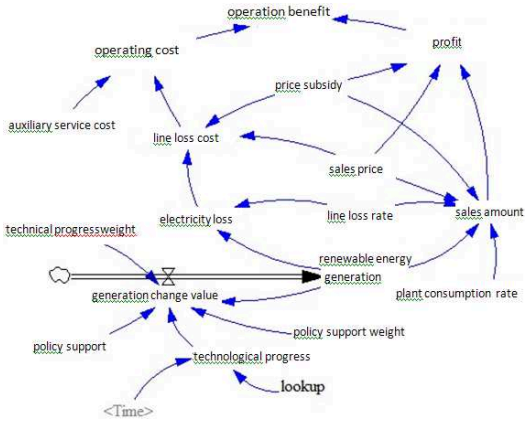

Figure 1 System Flow Chart of Economical Operation of Power Grid

Table 1 Related Factors of Economical Operation of Power Grid and their Meanings

Influence factors	The meaning of the influence factors
Electricity sales amount	Amount of renewable energy power power grid enterprise providing for the end users.
Selling electricity tariff	Renewable energy power generation electricity price electricity power grid enterprise selling to the end users.According to different renewable energy power generation technology, the price is also different , which includes wind power, solar power generating electricity price and biomass power generation electricity price, etc.
Electricity price subsidies	To encourage renewable energy grid-connected power generation, the country provides grid electricity price subsidies for grid companies in its development and promotion period.Power generation technology is different, and there are different electricity price subsidies.
Line loss cost	Loss of the cost value of renewable energy power in the process of transmission .
Auxiliary service cost	It includes three parts such as peaking and frequency modulation and spinning reserve cost renewable energy bringing about due to power generation output volatility and instability.
Amount of power wastage	Loss of electric energy renewable energy generating in the process of transmission of electricity.
Rate of waste	Power losses in the process of transmission accounts for the proportion of the total electricity transmission.

On the basis of building the system flow chart, the relationships between each index of the flow chart are e analyzed quantificationally, and system dynamics equations are presented.

(1)State equation:

$$Q_{renew}(t) = Q_{renew}(0) + \int_0^t q_{renew}(t)dt \tag{1}$$

In the formula,

$Q_{renew}(t)$ ——Renewable energy sources energy production,kWh;

$Q_{renew}(0)$ ——Renewable energy sources initial energy production,kWh;

$q_{renew}(t)$ ——Renewable energy sources power change value,kWh/year。

(2)Rate equation:

$$q_{renew}(t) = \frac{TECH(t)*TECHW(t)+POLICY(t)*POLICYW(t)}{TECHW(t)+POLICYW(t)} * Q_{renew}(t-1) \tag{2}$$

where,

$TECH(t)$ ——Technical progress factor;

$TECHW(t)$ ——Technical progress weight;

$POLICY(t)$ ——Policy support factor;

$POLICYW(t)$ ——Policy support the weight.

(3)Auxiliary equation:

A.Power grid enterprise operation cost

$$C_{grid}(t) = C_{auxi}(t) + C_{loss}(t) \tag{3}$$

$$C_{loss}(t) = Q_{loss}(t) * p_{grid}(t) \tag{4}$$

$$Q_{loss}(t) = Q_{renew}(t) * \vartheta \tag{5}$$

where,

$C_{grid}(t)$——Power grid enterprise operation cost, yuan;

$C_{loss}(t)$——Line loss cost, yuan.

$Q_{loss}(t)$——power wastage, kWh;

ϑ——Rate of waste;

$p_{grid}(t)$——Selling electricity tariff,yuan/kWh。

B.Power grid enterprise income

$$B_{grid}(t) = Q_{grid}(t) * \left(p_{grid}(t) + p_{subs}(t) \right) \tag{6}$$

$$Q_{grid}(t) = Q_{renew}(t) * (1 - \vartheta - \zeta) * \left(\frac{\alpha * p_{subs}(t)}{\beta * p_{grid}(t)} \right) \tag{7}$$

where,

$B_{grid}(t)$——Power grid enterprise income, yuan;

$Q_{grid}(t)$——Power grid enterprise electricity sales amount, yuan;

$p_{subs}(t)$——Subsidy electricity price, yuan/kWh;

α——Subsidy electricity price influence coefficient, shows the effects of subsidy electricity price on electricity sales amount, which is proportional to the electricity sales amount;

β——Selling electricity price influence coefficient, shows the effects of selling electricity price on electricity sales amount, which is inversely proportional to the electricity sales amount.

C.Power grid enterprise operation efficiency

$$E_{grid}(t) = B_{grid}(t) - C_{grid}(t) \tag{8}$$

In the formula, $E_{grid}(t)$ expresses power grid enterprise operation efficiency, yuan.

Examples analysis

This part, taking province renewable energy grid integration as an example, has simulated and run for 10 consecutive years with the time interval for 1 year, simulating and analyzing , the influence of the renewable energy grid integration on economic operation of power grids from 2011 to 2020. (1)To assignment constant in the model, as shown in the table below:

Table 2 Values of parameters in SD model

Variable quantity	Assignment	Unit
Unit length operation and maintenance cost	0.05	Ten million yuan/km
Unit length investment cost	1200	Ten million yuan/km
Unit capacity operation and maintenance cost	50	Million yuan/kvA
Unit capacity investment cost	33	Million yuan/kvA
Renewable energy grid integration proportion	0.07	1
Factor 2	7.5	1

(2) Given the technology continuous advances in renewable energy power generation, interconnection and scheduling aspects, this section will set "technical progress" as function, and its function image is shown in figure 2.

(3) Along with the advance of renewable energy power generation technology, using Vensim software simulates the model, then the operation efficiency of power grid enterprises trend diagram about renewable energy grid (figure 3) can be obtained:

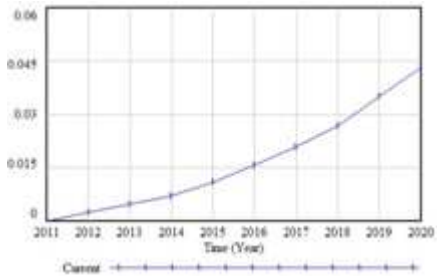

Figure 2 The Graph of Technical Progress Function

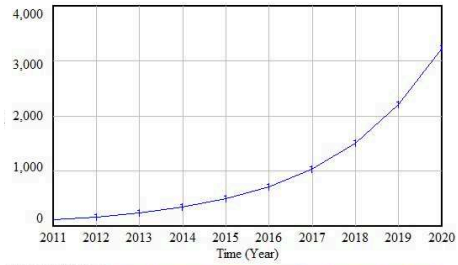

Figure 3 The Simulation Graph of Operation Benefit of Grid Enterprises

From above trend diagram, you can see in the next 10 years, with the development of technology, renewable energy power generation will increase constantly, and power grid enterprises income will gradually be improved, so renewable energy grid integration will promote economic operation of power grid.

Conclusion

This paper uses the method of system dynamics, by constructing the grid economic operation system flow chart, from angles of changes of the power grid enterprise operating costs and benefits caused by renewable energy combined to the grid to study the influence of the renewable energy grid integration on the economic operation of power grids, and uses the real data of the province over the next decade to simulate the influence trend of renewable energy grid integration on economic operation of power grids .Simulation results show that generating capacity will increase continuously with the development of renewable energy power generation technology and a complete set of power transmission technology, and the grid economic operation will get constant optimization, at the same time for the benefit of the power grid enterprise is also increasingly prominent. As a result, from the point of long-term development, the province should continue to increase the intensity of renewable energy, based on technology and management, constantly promote the progress and development of renewable energy grid integration correlation technology, improving the proportion of renewable energy installation, further optimizing economic operation ways of power grid.

Research on Thermal Power Industrial Security Issues Based on Sustainable Energy Development

LI Chunyan[1, a]

[1]China Center for Industrial Security Research, Beijing Jiaotong University, No.3 Shangyuancun, Xizhimenwai, Beijing, China

[a]lichy1973@163.com

Keywords: Energy, Sustainable development, Thermal power, Industrial security, Issues.

Abstract. China is faced with significant challenges in the energy sector such as energy shortage, environmental pollution, greenhouse gas emission, and energy supply in rural areas, which severely restrict its sustainable development. In this paper, the current status and trends of thermal power industrial security issues based on sustainable energy development in China are elaborated. The strategies of sustainable energy in China are brought forward accordingly, such as efficient thermal power industry, green thermal power industry. The corresponding implementations of sustainable energy development in China are expounded as well. In the end, this paper concludes that China must set a step-by-step unified national energy plan to promote the construction of a sustainable energy system, which will be economically, environmentally, and socially viable, and, thus, China would play an important role to promote global sustainable development.

Introduction

Energy has been the life-blood for continuing progress of human civilization. Since the beginning of industrial development around two centuries ago, the global energy consumption has increased by leaps and bounds to accelerate the human living standard [1]. China has been going through a rapid progress of industrialization and urbanization since the 1980s, with an annual gross domestic product (GDP) growth rate of approximately 16 percent from 1980 to 2008, and this fast developing trend is projected to continue in the foreseeable future [2]. To maintain the economic development, a corresponding increase in the primary energy consumption is also expected.

Thermal power industry energy security and sustainable development are closely related in China. Since the reform and opening up in 1978, China's industrial growth rate has remained at around 10%. Based on its GDP, China's economy has multiplied more than eight times, while is illustrated in Fig.1. However, industrial growth is mainly focused on highly energy-intensive industries, which brings the expansion of industrial scale [3]. The energy production has been unable to meet the needs of consumption. China's power shortage has been occurred in 2003, which leads to the shortage of the coal and diesel supply [4]. To solve this problem, a serious challenge to the thermal power industry needs to be faced in China.

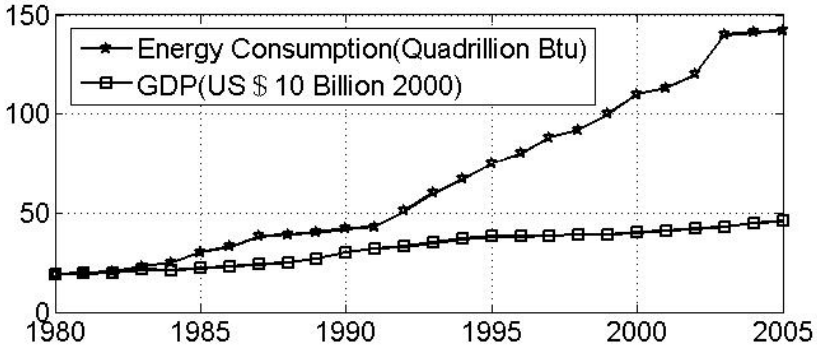

Fig.1. GDP and energy consumption

Economic growth mainly depends on the consumption of energy. China's energy consumption of 1,386 Mtoe (million tons of oil equivalents) ranks second in the world. In the past two decades,

China has been enjoying a 9.7% average annual GDP growth while limiting its annual incensement of energy usage to only 4.6%. This means that its efficiency in energy utilization has improved. Its energy intensity, as defined in terms of energy consumption per dollar of GDP, has gone through a significant 70% reduction. In other words, to produce the same amount of economic output, it is now using only 30% of the energy which had been consumed before.

Current Status of the Thermal Power Industry

Energy industry is an infrastructure sector. China is not only a large energy producing country, but also a large energy consuming country. Sustainable energy resources are most often regarded as including all renewable sources, such as wind power, solar power, biomass, geothermal power, tidal and wave power [5]. It usually also includes technologies that improve energy efficiency. China is the world's most populous nations, the world's fastest economy growth, and one of the world's biggest coal producer and consumer. Coal plays a very important role in the primary energy consumption structure and it will remain for a long time. Energy resource in China is complete in variety, rich in deposits, but uneven in distribution. Among the total electricity generation, mostly is coal-fired. Evidently, power plants will become the biggest coal consumer.

The installed generation capacities of coal, hydro, nuclear, and wind power generation from 2005 to 2008 are tabulated in Table 1. The total installed power generation capacity in China was 517.18 GW in 2005, 622 GW in 2006, 713.29 GW in 2007, and 792.53 GW in 2008 [6], and it will reach about 1600 GW by 2020. Note that coal has been playing a dominant role in the energy mix in China, which is around 75% of the total installed capacity [7]. As can be foreseen, the required coal depletion would be unbearable considering the substantial growth of total installed power generation capacity based on the current energy mix. Therefore, effective changes of energy structure must be made in the future so as to promote China's sustainable development.

Table 1 Installed power generation capacity (2005-2008) in China

Capacity (GW) / Energy	2005	2006	2007	2008
Coal	391.38	484.05	554.42	601.32
Hydro	117.39	128.57	145.26	171.52
Nuclear	6.84	6.85	8.85	9.1
Wind	1.06	1.87	4.03	8.94
Others	0.51	0.66	0.73	1.65
Total	517.18	622	713.29	792.53

As the second largest energy consumer in the world, China has a significant impact on global energy supplies. In the past two decades, China has been enjoying a 9.7% average annual GDP growth while limiting its annual incensement of energy usage to only 4.6% [8]. However, driven by industrialization and urbanization, China requires a dramatic increase of energy supply in the coming decades. The future energy supply would not be sustainable unless significant changes can be made in the power production and consumption patterns. Hence, China's overall energy strategy is striving to shift its coal based energy.

Environmental Problems

China's heavy dependence on coal is the root of its environmental problem. The environmental impacts of coal, from extraction to end use, encompass land disturbance, water usage, groundwater

contamination, and air pollution. Coal contributes to 90% of the total sulfur dioxide (SO_2) emission in the atmosphere, 65% of nitrogen oxides (NO_x) emission, 70% of particulates, and 80% of carbon dioxide (CO_2) emission in China. Oil also contributes to NOx, particulates, and to SO_2 to a lesser extent. All fossil fuels contribute to CO_2 emission.

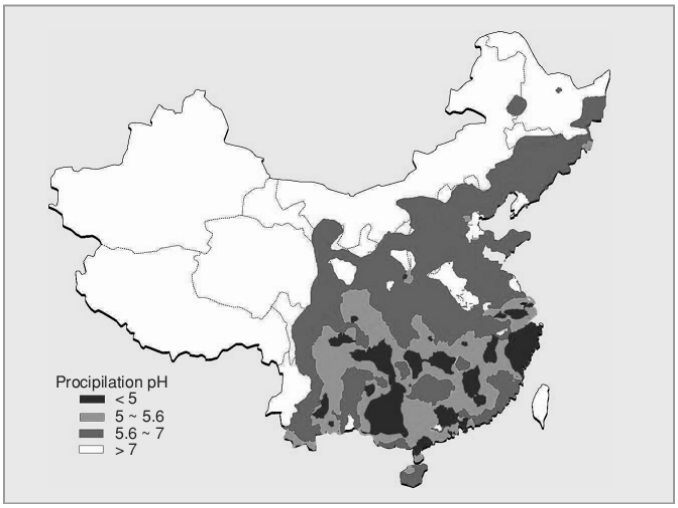

Fig.2. Geographical distribution of the pH value of depositions (2001)

Emissions of SO_2, NOx, and solid particulates have detrimental implications for air quality and health. SO_2 and NOx may travel hundreds of miles, causing acid depositions made from sulfur and nitrogen oxides mixed with rain (acid rain) over a large region. Acid rain results in damage to trees and crops and sometimes extends to the acidification of streams and lakes, resulting in the destruction of aquatic ecosystems. It also leads to the corrosion, erosion, and discoloration of buildings and monuments. In China, the affected area by acid rain has expanded to more than 1,000,000m^2 since the 1990s. Moreover, one-third of China has a pH value of less than 5.6. The graph of the geographical distribution of the pH value of depositions is presented in Fig. 2**.**

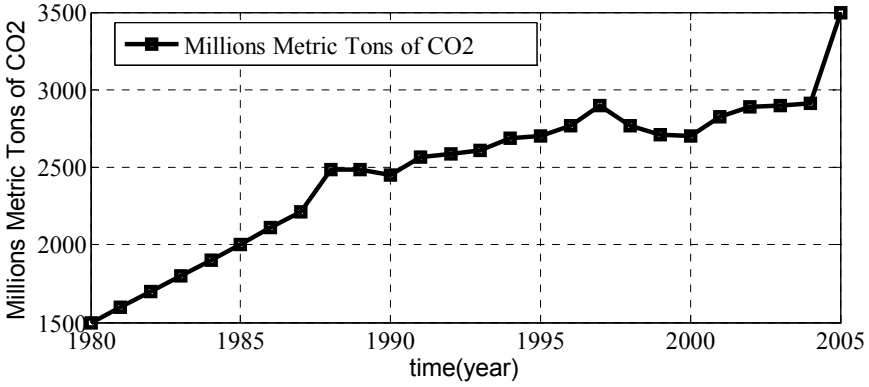

Fig.3. CO_2 emission evolution

Carbon dioxide is the major cause of greenhouse gases that contribute to global climate change. The other major greenhouse gas is methane. These gases have a long residence time. The accumulation of man-made greenhouse gases due to the burning of fossil fuels has occurred since the industrial revolution, and it is believed to have reached the maximum point of the atmosphere's carrying capacity, trapping radiated heat from the sun, and leading to higher long-term atmospheric temperature. The effect of climate change is long term, and it is global. Notably, the CO_2 emission in China has more than doubled in the last 20 years, as shown in Fig. 3. In addition, it ranks second worldwide in CO_2 emission. Fig. 4 compares the total emission of China with that of the United States, Japan, and Germany. On a per capita basis, however, China's CO_2 emission is only 14% of that produced by the United States, 29% of Japan, and 68% of the world average.

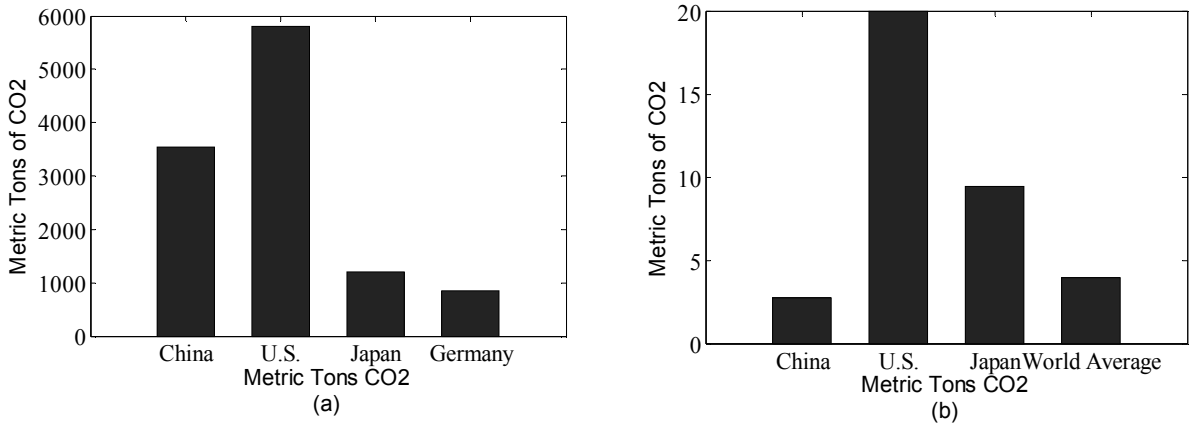

Fig.4. CO_2 emission in 2001: (a) total amount and (b) per capita

In summary, except for oil, China is basically self-sufficient and will remain so in terms of energy supply. It is heavily dependent on coal, and almost every energy and environmental problem China is currently facing, such as large quantity, low efficiency, and high emissions, can be traced back to coal.

Summary

This contribution illustrates China's current status of the energy sustainable development and thermal power industry security issues. Because of the burning of fossil fuels, environmental problems are also discussed in this paper. On all accounts, China must boost renewable energy development rapidly in the future. At the same time, China needs to attach great importance to enhancing energy saving and conservation**,** accelerating nuclear power development, and further promoting the economy.

Keywords: power system, transmission section, cascading failure, search algorithm

Abstract. This paper introduces the current research status of quick search for transmission section. Firstly, the definition of transmission section is introduced. Secondly, search algorithm for transmission section is presented. Thirdly, the safety protection measures that can prevent cascading failure are introduced. Finally, outlook on quick search for transmission section is proposed.

1 Introduction

With the enlargement in area and the increase in capacity of the interconnected power system, on the one hand, the use of resources can be rational which can bring considerable economic benefits and social benefits. On the other hand, catastrophic blackout caused by cascading failure can result in disastrous impact upon society and dairy life. According to reports about some blackouts in the world[1~3], in the early stages of the development of blackout, cascading failure often occurs in a set of lines whose safety margin is small but electrical contact is close. This set of lines can be called transmission section. Blackout can be prevented by focusing on monitoring certain transmission section rather than monitoring the entire power grid, which can save more manpower and material resources. Quickness and integrity are two main problems of search for transmission section.

2 Definition of Transmission Section

As with the definition of transmission section, a set of lines whose direction of power flow are the same and electric distance is near, under a certain base power flow, is called transmission section in literature [4]. Two other related definitions are also often involved, namely parallel transmission section and key transmission section. Transmission section with the same power supply area and load area with the overloaded line, under a certain base power flow, is defined as parallel transmission section in literature [4]. Normal transmission section which is closest to transmission limit state under a certain operation mode is defined as key transmission section or vulnerable transmission section of the system in literature [5]. In literature [6], three concepts are proposed. Initial transmission section is defined as minimum cut set of grid. Transmission section is defined as initial transmission section which has the same power flow direction and bigger LODF (line outage distribution factor). Key transmission section is defined as transmission section which has less safety margin but big influence on grid safety. The relationship of those definitions above is shown in Fig. 1.

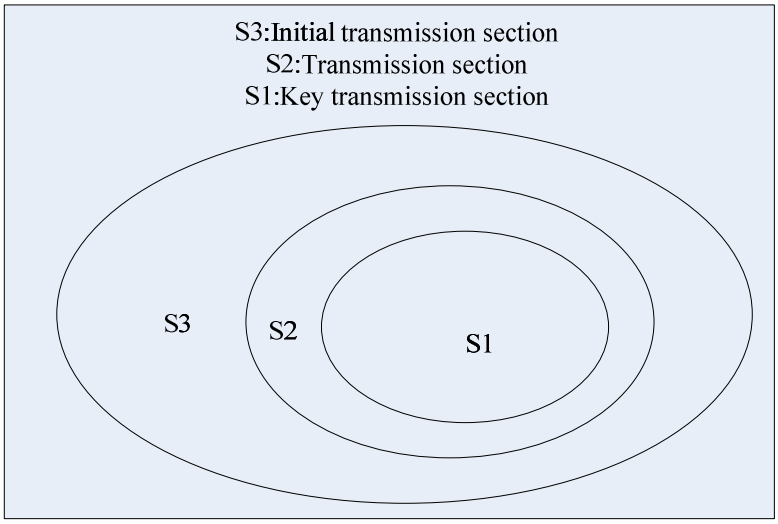

Fig. 1 Relationship of three definitions

In conclusion, there are many definitions of transmission section. But some factors should be taken into consideration such as power flow direction, topological connection and electrical connection.

3 Search Algorithms for Transmission Section

The principle of quick should be followed when search the transmission section, then a certain transmission section can be determined after an accident occurred. So related emergency control measures can be taken in order to prevent the blackout. Many algorithms have been proposed in order to search transmission section quickly.

A quick search algorithm for transmission section based on graph theory is proposed in literature [7]. The essence relationship between search for transmission section and identification of network topology .Firstly, the original network should be simplified. Secondly, the concept of "region" is defined and the system state diagram is established. Finally, parallel transmission section corresponding to an overloaded transmission line can be determined through the calculation of adjacency matrix and path matrix. As partition and simplification of the initial network are only associated with the network topology structure of power system, so the first step can be taken in advance and the second step can be taken periodic. Only the third step should be taken when a transmission line is overloaded. This algorithm is convenient for online real-time control because the calculation is fast. However topological parameters are not taken into considerations and some key transmission lines can't be searched because they are in the "region" which corresponding solution can't be found in literature [7].

A quick search algorithm for transmission section based on minimal basic circuit set is proposed in literature [8]. A conclusion is obtained by qualitative analysis. When an overloaded line is removed, the power of the removed line flows into lines whose direction of power flow is opposite to the overloaded one in the loop calculated by the ring sum of the minimal basic circuit sets. The minimal basic circuit set can be generated online based on graph theory according to network topology structure, physical parameters of component and the power flower distribution. When a transmission line is overloaded, through comparing the directions of lines in the loop that contain the overloaded line, expanding the search scope by the ring sum and calculating the active current distribution coefficient, then the transmission section can be determined. This algorithm has the feature of less amount of calculation which can save real-time analysis time.

A risk value is proposed in literature [9], after the transmission section is determined through graph theory, this risk value can reflect the mutual influence and cumulative effect between accidents. High risk line set can be filtered through comparing the risk value. The scope of lines needed to be analyzed, monitored and controlled in power system can be narrowed. However, this algorithm may have a lot of calculation.

A new search algorithm for transmission section based on K shortest paths is proposed in literature [10]. By analyzing the features of flow transferring caused by overload removal, the conception of flow transferring factor (FTF) is introduced, a new definition of transmission section based on FTF is given. By simplifying the real-time power network into a topology, based on dynamic programming theory, the K shortest paths between the two nodes of the overload line in a subgraph with overload line as its center can be fast found. Finally transmission section suffered greatly from power flow transferring can be determined. The security analysis of the whole system is reduced to the analysis of a transmission section; the workload of further analysis is greatly reduced, so it's very beneficial to avoid cascading failures.

A new search algorithm for transmission section based on deviation path is proposed in literature [11]. After analyzing the features of power flow transferring after switching off overloaded branches, it was pointed out that the branches greatly affected by power flow transferring were concentrated on the range electrically adjacent to the switched off branches. A new algorithm to rapid search lines related to the overloaded branches was given to turn real-time power network into topological graph. The k shortest paths based on deviation path was adopted to rapidly search out the lines greatly affected by power flow transferring, thus the situation of miss-searching of partial branches due to too narrow searching scope under the single path-based search could be avoided and the integrality of transmission section could be ensured. When overload occurred, the affection of overload on the security of the whole power network could be rapidly assessed by means of analyzing the influences of overload trips on lines related to the transmission section. Thus the calculation amount could be greatly reduced and it was favorable to prevent the occurrence of cascading failures.

A fast search algorithm of power flow transfers based on the concept of active power increase factor is proposed in literature [12]. When line outage failure occurs in power system, transmission section can be fast identified through searching transmission lines in upper and lower classes connected to both ends of the outage line by using graph theory and computing their active power increase factors. The transmission section is composed of transmission lines whose active power is increased evidently. According to the proposed concept of active power increase factor, it can be ensured that those lines, whose active power is increased and the directions of power flow is reversed，will not be missed．This algorithm does not need to search for the whole network topology and does not contain any large mass matrix calculation, which ensures online real-time calculation.

In conclusion, there are many algorithms proposed to search transmission section. However, quickness and integrity are two main factors needed to be taken into consideration because they can ensure the requirements of instantaneity and safety. Quickness and integrity are two contradictory factors, how to coordinate them is the key problem of designing algorithm.

4 Safety Protection Measure

The safety protection measure is defined as the measure that needed to be taken in order to avoid cascading failure after an accident occurred.

A new wide area backup protection strategy based on WAMS (Wide Area Measurement System) to identify the flow transfer is proposed in literature [13]. A new concept of flow transfer relativity factor (FTRF) is proposed to estimate the flow distribution after flow transfer occurred, and the strict definition and calculation method are presented. A new concept of PMC (Protection and Monitoring Center) is proposed to identify the power flow transfer by cooperating with the distributed protection device, and the protection device is blocked in order to avoid cascading failures. WAMS is firstly introduced in the protection strategy proposed to identify power flow transfer.

A security correction strategy combined with opposite equal quantity adjustment is proposed to find out the controlling node in literature [14]. When a transmission line is overload, generator output adjustment should be taken to alleviate overload of transmission lines and tie line groups rather than load shedding. Units can be grouped by sensitivity calculation. Each generator with positive sensitivity can be matched with a generator with negative sensitivity. Each group of generators is adjusted with opposite equal quantity in order to obtain a strategy with a balanced active power and minimum adjustment value.

In literature [15], the principal component analysis (PCA) combined importance weight is used to evaluate control nodes' comprehensive capability to alleviate overload on the transmission section, and determine the operation sequence of control nodes. AC power flow calculation is not needed in this strategy because the choice of controlling node and its quantity can ensure that normal branch won't overload and the power flow of overload branch won't arise.

A virtual branch control method is proposed to alleviate the overloaded lines in literature [16]. By adding a virtual branch to the overloaded branch, the original current of the overloaded branch can be reduced to the target level of branch current. The admittance of the virtual branch can be obtained by target shunting coefficient, and then the virtual branch can be replaced by a parameterized virtual power source. The remove of the virtual branch can be turned into injection power increase problem on the two buses of the overloaded lines. Based on sensitivity of the apparent power of the branch with respect to bus injection power, the minimum cost control strategy for overloaded branch can be obtained.

A new power flow tracing algorithm combined with superposition theorem and the principle of proportional distribution is proposed in literature [17]. This algorithm can be applied in emergency control of overloaded lines. Using the proposed algorithm, occupation coefficients of each line by each generator and each load can be calculated. Then the generator output reduction is proportional to the amount of load shedding. Then the overloaded situation can be eliminated under the principle that the amount of shedding load should be as few as possible.

In conclusion, there are many safety protection measures which can avoid cascading failures. Protection device block, generator output adjustment and load shedding are the main measures that need to be taken into consideration. However, how to optimize the sequence of the measures and determine the amount of adjustment or shedding is still worthy studying.

5 Summary and outlook

Different definitions of transmission section are introduced in section 2, and the main factors of transmission section are also summarized.

The typical search algorithms are presented in section 3. The basic problem of quick search for transmission section belongs to the problem of network identification. Therefore, the application of graph theory can effectively solve the problem. The grid topology, power grid real-time power flow (magnitude and direction) can be easily obtained due to the introduction of WAMS technology. Combining with the parameters of each route, the real-time status of the system can be reflected effectively and quickly.

The main safety protection measures are introduced in section 4. The main safety protection measures of transmission section are protection device block, generator output adjustment and load shedding. The sequence and amount of the measures are also determined according to the reference factor (risk coefficient, line outage distribution factor, etc.).

In conclusion, those literatures listed above are some typical analysis methods of quick search for transmission section. However, it is worthy thinking that whether there is a new theory or a better algorithm that can be used to analyze quick search for transmission section.

Keywords: ISM model, risk analysis, grid operational performance

Abstract. The ISM model is applied to the influencing factors risk analysis of grid operational performance. The research constructed multilevel hierarchical structure diagram by the association between various factors and reflected the hierarchical relationship of the index intuitively. Select a large driving force factors as the core influencing factors and develop a risk prediction radar diagram to provide a theoretical basis for grid operational performance improving. A provincial power grid company provides the data for empirical analysis to explore the applicability of the model.

Introduction

Grid Company is a natural monopoly industry. The business scope and the resources allocation of enterprises are controlled strictly by state. The company's business practices should be subordinated to the government's goals and plans; Grid Company is a company with strong scale effect but the sales price is under control, and the economic efficiency and profit margins are largely determined by the state. It belongs to the public utility with public characteristics and undertaken by the public service functions. Its behavioral targets are diverse.

In the process of deepening power system, implementing "separation of generation and transmission, using bidding price", building separation of government functions from enterprise management, fair competition, open and ordered, healthy development of the electricity market system, new situation and tasks bring the new opportunities to the grid enterprises as well as presenting the new challenges and giving a new mission. In this situation, the study of relationship of grid operational performance affecting factors has great significance to improve grid operational efficiency. This research identifies the relationship between grid operational influencing factors by means of Interpretative structure model and indicated the relationship between them by multilevel hierarchical structure visually, thus providing theoretical suggestions for improving the performance of the grid operation.

The establishment of ISM model

Determination of Grid operational performance influencing factors

This model select 32 operational performance related factors by the principle of optimal in accordance with national grid operational analysis model namely: “a strong three excellent” objective programming. Among them, there are eight indicators in the core resources system, such as: total assets (S1), total liabilities (S2), Line length per capita (S3), Total staff (S4), net value of fixed assets (S5), Total income (S6), The proportion of skilled talents(S7), Net income Per capita (S8); Customers market system contains eight indicators: Tariff recovery rate(S9), market share(S10), The average difference between purchase and sale price(S11), Electricity sales(S12), Customer satisfaction rate(S13),Power supply population(S14), CO_2 emission reduction through generating rights trading(S15), Province purchase (sale) electricity contract execution equalization rate(S16); Internal operation system contains eight indicators: Power supply reliability rate(S17), Comprehensive line loss rate(S18), Voltage qualification rate(S19), Loading rate(S20), Inventory

Turnover (S21), Power system failure outage rate (S22), Inventory idle rate (S23), New energy and power generation capacity (S24); Asset-liability ratio(S25), per capita profit (S26), Economic Value Added (S27), Industrial added value (S28), Total owners' equity (S29), ROE (S30), transmission and distribution costs (S31) , network maintenance operation costs (S32).

In order to analyze the impact of these factors and determine the relationship of their mutual influence (influence directionality), ISM model always uses V, A, X, O four symbols to indicate the direction of mutual influences between factors, shown in Table 1. Table 1 is called factor relation binary matrix .V is that the row factor has effects on the column factor; A is that the column factor has effects on row factor; X is that the row and column factors have mutually influence; O is that the two factors have no effects on each other.

The establishment of the adjacency matrix

In order to establish the ISM model systematically, we should set up an adjacency matrix A which expressing the relationship between each factors firstly. The elements of adjacency matrix A can be calculated by converting the corresponding elements in Table 2. The conversion rule is: If a_{ij} is corresponding to V in Table 2, so $a_{ij}=1$,and $a_{ji}=0$;If a_{ij} is corresponding to A in Table 2, so $a_{ij}=0$, and $a_{ji}=1$; If a_{ij} is corresponding to X in Table 2, $a_{ij}=a_{ji}=1$; If a_{ij} is corresponding to O in Table 2, so $a_{ij}=a_{ji}=0$ .Therefore, we can obtain the adjacency matrix A.

$$A_1=\begin{bmatrix}0&1&0&1&1&0&1&0\\0&0&0&0&0&1&1&0\\0&0&0&1&1&0&0&0\\0&0&0&0&1&1&0&0\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&1&0\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&0&0\end{bmatrix}\quad A_2=\begin{bmatrix}0&1&1&1&1&1&0&1\\0&0&1&1&1&1&0&1\\0&0&0&1&1&1&0&1\\0&0&0&0&1&1&0&1\\0&0&0&0&0&1&0&1\\0&0&0&0&0&0&0&1\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&0&0\end{bmatrix}\quad A_3=\begin{bmatrix}0&1&1&0&1&1&0&1\\0&0&1&0&0&1&0&1\\0&0&0&0&0&1&0&1\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&1&0\\0&0&0&0&0&0&0&1\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&0&0\end{bmatrix}\quad A_4=\begin{bmatrix}0&0&0&1&0&0&0&0\\0&0&0&0&1&0&1&0\\0&0&0&1&0&0&0&1\\0&0&0&0&0&0&0&1\\0&0&0&0&0&0&1&0\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&0&0\\0&0&0&0&0&0&0&0\end{bmatrix}$$

Among them, A_1 is for the adjacency matrix of core resource influencing factors relationship, A_2 is for the adjacency matrix of customer market influencing factors relationship, A_3 is for the adjacency matrix of internal operational influencing factors relationship, A_4 is for the adjacency matrix of operational results influencing factors relationship.

The establishment of reachable matrix

Reachable matrix means that using matrix form to describe that after a certain length of path, the level reached between each node in the directed connection diagram. It is calculated as: the Boolean algebra rules. Therefore, each influencing factors' reachable matrix are as below tables:

Table 5 The reachable matrix of core resource influencing factors

	S1	S2	S3	S4	S5	S6	S7	S8	Driving force

dependency	1	1	1	3	2	1	3	4	

Reachable matrix reordering

According to the study, the greater the driving force the more the important is. So, this research selected the largest twelve driving force as key factors. And the influencing factors should be reordered according to the extent of driving force to get all the factors Interpretive Structural Modeling. According to the reordering reachable matrix, the factors with same driving force can be considered as the same hierarchical structure factor; then, use arrow to connect the related factors box. We can get the Interpretive Structural Modeling chart shown in Figure 1.

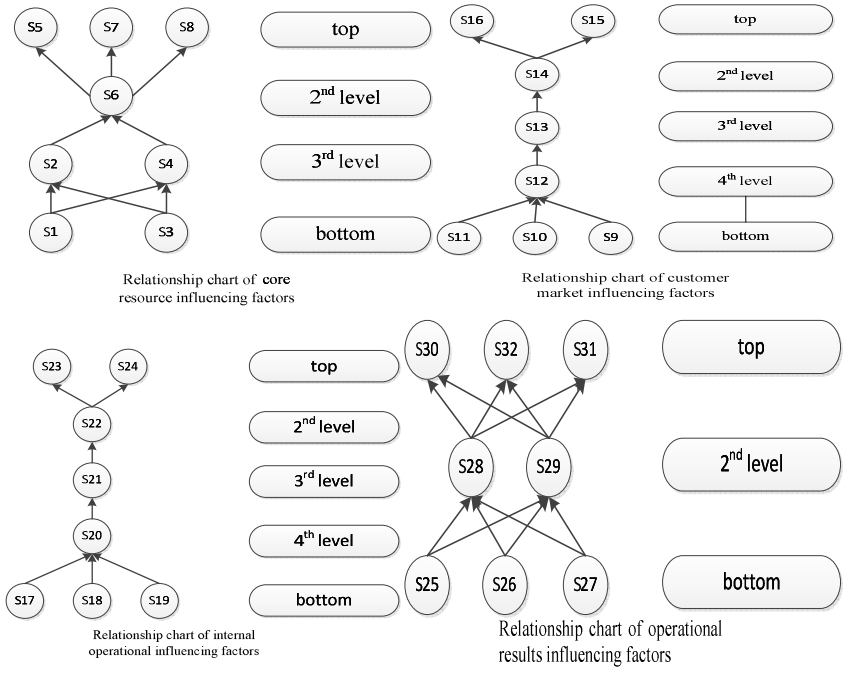

Fig1 All factors Interpretive Structural Modeling chart

Influencing factors classification

We can confirm the biggest driving force factor and the factor at the bottom by Interpretive Structural Modeling chart. The specific selection factor is as follows:

Table 9 Key factors categorized in all kinds of index system

Core resource	Customer market	Internal operation	Operational results
Total assets	Tariff recovery rate	Power supply reliability rate	Asset-liability ratio
Total liabilities	Market share	Comprehensive line loss rate	Per capita profit
Line length per capita	The average difference between purchase and sale price	Voltage qualification rate	Economic Value Added

ISM model analysis

The ISM model established above, the driving force and dependency distribution diagram visually show that the relationship between influencing factors of grid operational performance and their own attributes. The model will contribute to the grid administrator to find out the factors and deal with them.

Through the Interpretive Structural Modeling, we can see that the implementation of the twelve key factors is the largest factor to control the grid operational performance development. Therefore, the project manager should be fully aware of the importance of the grid operational performance development control and focus on the control of strong driving force factor in specific project management. So the grid enterprises can get the excellent results in operational performance.

Conclusions and Suggestions

With the social economic development and social environment changes, the uncertain factors which having effect on the development of power grid enterprises are increasing. In order to reduce the probability of risk occurrence, we need to identify sources of risk of grid operational performance and take detailed analysis. This research confirms 32 main influencing factors which impacting on the grid operational performance through statistical survey. Establish a clear hierarchical structure system and risk transfer chain of grid operational performance risk by ISM model. On this basis, we built a risk analysis model of grid operational performance based on ISM model. This method can effectively improve the prediction level of the grid operational performance risk factors and provide a basis for decisions.

The initial establishment model in this research based on ISM grid operational performance risk analysis model, considering the uncertain risk factors affecting the grid operational performance, should be discussed deeply on the transfer characteristics of risk transfer chain of grid operational performance and the effects in the future.

Safeguard Mechanism Research for Effective Implementation of Energy Tax Policy Reform

Wang Mingyou Song Yang [a]Ji Liuhe

Shenyang University, Shenyang 110044

[a]yang_wenlin@163.com

Keywords: Energy tax, Local government, Tax game analysis

Abstract: Energy tax policy has an irreplaceable role in promoting conventional energy conservation, sustainable use and promotion of new energy sources. But China's current energy taxes still has many problems and needs an energy tax reforms. The effective implementation of the energy tax policy reform must have relevant supporting mechanisms to ensure implementation of the policy. Thus we need analyze the behavioral characteristics and trade-offs involved in policy-related aspects to achieve the establishment of appropriate safeguards.

Introduction

In general, there is long-term equilibrium relationship between energy and economic growth. Sustainable economic growth needs sustainable energy output for support. However, the limited quantity and environmental problems caused by coal, oil, natural gas and other fossil fuels makes the country's governments re-examine their energy strategy. There are two guides in countries energy strategy: the first one is saving energy and committing to the development of energy-saving technologies and products. The second is to develop and utilize new energy as alternatives to conventional energy sources and make energy consumption structure to go to energy consumption structure which makes efficient, clean, renewable, low-carbon or non-carbon nuclear, solar and wind energy. As an important tool for national macro-control, the tax policy has an irreplaceable role in promotion of conventional energy conservation, sustainable use and introduction of new energy sources. More and more theories and practices have proved that the energy tax benefit the conservation and use of energy. At present, China has yet to levy a special energy tax. There are many problems in current energy taxes so we need reform. The effective implementation of the energy tax policy reform must have relevant supporting mechanisms. Thus we need analyze the behavioral characteristics and trade-offs involved in policy-related aspects to achieve the establishment of appropriate safeguards.

Status of the tax allocation structure

After the tax reform, China's tax revenue allocation structure is composed of three parts: central tax, local taxes and shared taxes. Among them, the central taxes include: customs duties, excise duty and VAT levied by the customs, excise duty, central corporate income tax; local banks, foreign banks and non-bank financial corporate income tax; Sales tax, income, profits, and city maintenance and construction tax, vehicle purchase tax paid by the railway sector, the banks head office of insurance company etc. Local tax is a kind of tax managed and used by local government.

These include: sales tax (excluding the sales tax paid by railway sector, the banks head office and insurance companies), local corporate income tax (excluding the above-mentioned local and foreign banks and non-bank financial corporate income tax), personal income tax, urban land use tax, fixed asset investment direction adjustment tax, urban maintenance and construction tax (excluding the parts paid by railway sector, the banks head office and insurance companies), property tax, vehicle tax, stamp duty, slaughter fees, agricultural tax, agricultural tax levied on the income of agricultural specialty (referred to special agricultural product tax), farmland occupation tax, deed tax, land value-added tax. There are three shared taxes: VAT, resources tax and securities transaction tax. Among them, the central share of 75% VAT, the local share of 25%. Resources taxes are divided by

varieties of different resources. Part of the resources taxes are local income. Offshore oil resources are the central income tax. Central and local share 50 percent of securities transaction tax separately. But in fact, share tax also include business tax, corporate income tax and urban maintenance tax(because these three taxes are local fixed income, but local and foreign banks and non-bank financial enterprises income tax, railway departments, bank headquarters, the insurance Corporation and other centralized payment of sales tax, income tax, urban maintenance and construction tax are collected to the central government). In our country, the current value added tax is a shared tax, the local gets 25%.

Taking VAT revenue in 1994, before tax reform, as a base, central will return the parts exceed 30%, so the local get 47.5% directly and indirectly. 1994 tax reform established the basic pattern of the existing central and local fiscal decentralization. Hereafter, the local is constantly adjusting. In 1997,the stamp duty on securities transactions increased from sharing ratio that central and local each get 50% to center share 80%,local 20%. center get 97% local 3% since 2002; income tax change from according to the enterprise subordinate relations such as division of the central and the local income tax to according to the proportional sharing between the central government and local government. After 2003, the share percentage is the central gets 60%, local 40%; export tax rebate from the original central bear all to the central bears 75%,local 25% since 2004. In addition, the intergovernmental transfer payment system also continue getting improved.

Analysis of local governments behavioral characteristics of Chinese-style fiscal decentralization.

Public choice theory holds that people's political behavior and economic behavior is the same, both are dominated by selfish motivation. Everyone participates politics for their own interests, not the good and beauty. It is because that we conceive the person as seeking to maximize their own interests that we need design incentive and restraint systems of human behavior in order to enable people to meet public interest objectives in accordance with the direction of behavior. As a government, it is a complex entity with multiple attributes. Although the government has essentially public nature and it is representing the public interest, in the actual process of operation, the government's behavior is heavily influenced by the will and preferences of the ruler. The ruler is the "economic man" who uses the government as an organization form to pursue and achieve their effectiveness, strive to minimize the cost and get the maximum benefits. In economic aspect, the rulers take maximizing revenue as their goal, trying to improve the efficiency of resource allocation, accelerate economic growth and thereby maximizing revenue. "Economic man" paradigm provides us with unified basis for analyzing the local governments. From the "economic man" perspective to exam local governments, local government has its own characteristics. Essentially they are rational "economic man", they need to maximize their own interests. Their actions do not necessarily represent the public interests in accordance with the needs, but under certain constraints, by rational cost - calculated benefits, decide their own actions. After taking into account the characteristics of the local government itself, The designed tax system which takes local governments as a part of the game has more real operability.

Western theory of fiscal decentralization, generally base on the rational allocation of revenue and expenditure authority and responsibility, thus contributing to all levels of government to provide public goods and services more effectively and achieve social welfare maximization. Especially for local governments, most of theory state that local governments has advantages on information and incentives to provide public goods, thus has a higher efficiency. Different from western fiscal decentralization, China's fiscal decentralization plays a role on incentive local government economic behavior. That decentralization of the central government to local governments property rights means independent interests status of local governments was confirmed by the central government. Local government can pursue their own interests through the central government-approved way. Meanwhile, the local governments as rational economic men have clear expectations--maximize their own interests. The better local economic development, the higher financial revenue, the more money the local governments share. Local governments began to have

"surplus profits", so the interest consciousness of local governments are awakened. Local governments began to seek their own interests. After Decentralization, local government will be more and more like business. Seeking to maximize their own interests becomes its main objective. For local government, reasonable decentralization can make local government clear their rights and responsibilities and improve the efficiency of the use of financial resources. Thus, local governments will compete with each other so that the whole community will achieve welfare maximization.

Game analysis between taxpayers and tax authorities

Design and implementation of specific tax subsidy policies will affect the interests of the tax authorities and consumer behavior choices. Next, we will analyze benefits of tax authorities and taxpayers after imposing energy tax. Tax authorities are subjects who implementing taxes and subsidies provider. consumers are both taxpayers and subsidy beneficiaries. Assuming P is the price of refined oil program, the current price of oil products is P1 .When the size of P in the range of [P-N，P+N] (N is a changing constant, varies with the amount) we can assume consumers do not pay taxes;if P1> P+N and P1; P> P1, we can assume the consumption is low. At this time, the tax department needs to subsidize: when consumers pay taxes, assuming that the tax department after adjusting for the tax effect (P - P 1) (T - t) - C, taxpayer's utility is [(PN)-P] (Tt), namely -N(Tt), reflecting the loss of the tax deduction of subsidies; when tax department subsidies and taxpayers do not pay taxes,the tax department utility is 0-C,which reflects as net loss of subsidies. The taxpayer's utility is 0, so the tax authorities do not need to make tax adjustments.

When tax authorities do not subsidize and taxpayers pay taxes: P 1 will be less than (P - N), the tax department utility is （P1-P）（T-t） which reflects in the net income tax. The taxpayers's utility is [（ PN）-P1]（Tt) which reflects tax net loss; when tax authorities do not subsidize and taxpayers do not pay taxes. Tax department utility is 0, the tax payer's utility is also 0.

Strategy portfolio's payoff matrix of tax authorities and taxpayers is as follows:

		Tax department	
Taxpayer		investigated	Not investigated
	Pay taxes	（P-P1）(T-t)-C，[（P-N)-P] (T-t)	（P1-P)(T-t)，[(P-N)-P1] (T-t)
	Do not pay taxes	-C,0	0,0

First, given a, the expected benefits when tax authorities choose subsidies (θ = 1) and choose not to subsidize (θ=0) the expected benefits :

$$\pi(1,a) = [(P - P_1)(T - t) - C]a + (-C)(1 - a) = (P - P_1)(T - t)a - C \quad (1)$$

$$\pi(0,a) = [(P_1 - P)(T - t)]a + 0 \cdot (1 - a) = (P_1 - P)(T - t)a \quad (2)$$

In the above formula, π represents the expected benefits, a and 1-a is the probability that the taxpayers pay taxes and do not pay taxes, used as weights, and 0≤a≤1. Set equal the expected return of two options, π(1, a) =π(0, a), Optimal probability of tax and non-tax game equilibrium when the taxpayer is taxable $a^* = \frac{C}{2}(P_1 - P)(T - t)a$

When a> a *, the optimal choice of the tax department is to subsidize;
When a <a *, the optimal choice of the tax department is not to subsidize;
When a = a *, the tax department randomly selected subsidies or no subsidies.

Second, given θ, the the expected benefits when taxpayers choose the to pay the tax (a = 1) and choose not to pay taxes (a = 0), respectively,are as follows:

$$\pi(\theta,1) = [(P-N)-P](T-t)\theta + [P-N)-P_1)](T-t)(1-\theta)$$
$$= -N(T-t)\theta + (P-N-P_1)(T-t)(1-\theta)$$
$$= -(P-P_1)(T-t)\theta + (P-N-P_1)(T-t) \quad (3)$$
$$\pi(\theta,0) = 0\cdot(1-a) + 0\cdot a = 0 \quad (4)$$

In the above formula, π represents expected income, θ and 1-θ is subsidized and non-subsidized probability of the tax department, representing weights here, and $0 \le \theta \le 1$. Set equal the expected benefits of the two options, namely π (θ, 1) = π (θ, 0). Optimal probability of tax and non-tax game equilibrium when the tax payer's taxable :

When θ<θ *, the optimal choice for taxpayers is to pay taxes;

When θ>θ *, the optimal choice of the taxpayer is not to pay the tax;

When θ =θ *, the taxpayer may be randomly selected pay the tax or not.

Summary

Summarizes the characteristics of the entire model, we can see that (1) the greater the price change constant N, the smaller tax department subsidies probability θ*. Differences in tax rates affect the motivation of government subsidies decisions, whether subsidize some group or not and the subsidies amount; (2) level of subsidy plays an important role on whether the taxpayer will pay the tax; (3) the price difference (P-P1) or (P1-P) determines the taxpayer's choice. When price differences is large, the probability that the taxpayer will pay taxes is low.The size of the rate difference determine the price difference, thereby setting rate differences has a great influence on consumer consumption amount choice.

When evaluating the effectiveness of the proposed energy tax reform, we must consider the relevant supporting mechanisms to ensure the effectiveness of policy implementation. By analyzing the behavioral characteristics of Chinese-style local government under fiscal decentralization, we propose that there should be a reasonable division of property rights between the central and local government. Forming a benign interaction in the energy tax issues between central government and local government to ensure the motives of energy tax reform. Through building the game model of the tax authorities and the taxpayer (the consumers) game analysis, we know the design of tax rate will affect the revenue of tax authorities, consumption behavior of taxpayers and authorities'subsidies to taxpayers to ensure that the energy tax reform was carried out in the interests of all parties on the balanced basis, so that the reform is running effectively.

Keywords: Load Forecasting; Neural Network; Genetic Algorithm; GA-Elman; Error

Abstract. Elman Neural Network is a typical neural-network which shares the characteristics of multiple-layer and dynamic recurrent, and it's more suitable than BP Neural Network when it's applied to forecast the short-term load with periodicity and similarity. To solve the problem that Elman Neural Network lacks learning efficiency, GA-Elman model is established by optimizing the weights and thresholds using Genetic Algorithm. An example is then given to prove the effectiveness of GA-Elman model, using the load data of a certain region. Relative error and MSE have been considered as criterions to analyze the results of load forecasting. By comparing the results calculated by BP, Elman and GA-Elman model, the effectiveness of GA-Elman model is verified, which will improve the accuracy of short-term load forecasting.

Introduction

Electric power can't be stored largely, and its supply and demand should be always in a balance. So load forecasting becomes the fundamental job in power system planning, designing as well as safe, stable operation. To arrange generation plan and solve economic dispatch problems more reasonably, load forecasting (including short-term forecasting) algorithms should be improved.

A great number of theories and methods have been provided, such as Time Series Theory, Fuzzy Theory, and BP Neural Network. Reference [1] forecasts the load by Time Series Theory. Reference [2] and [3] present the utilization of Fuzzy Theory and BP Neural Network respectively.

Elman Neural Network, a typical neural-network which shares the features of multiple-layer and dynamic recurrent, carries out the basic structure of BP Neural Network. By storing the internal states, Elman model gets a dynamic mapping feature, which gets the system ready to different changes [4]. Elman Neural Network, a feedback neural network, has a strong non-linear approach capability at arbitrary precision and the input of it has a time-delay. Traditional Elman model is suitable to predict short-term load with periodicity and similarity, however, slow learning speed, slow arithmetic speed and the local minimum value it often leads to really discourage the prediction accuracy. GA-Elman model which combines Genetic Algorithms and Elman Neural Network is established. GA is used to optimize and determine initial thresholds of the network and weights of each layer. Then the optimized thresholds and weights will be assigned to Elman model. In the end, an example is provided to verify the effectiveness of GA-Elman model.

GA-Elman Model

The decision of weights and thresholds of the network will have great influences on prediction accuracy and training time. With the back propagation of error during learning and training period, Elman model revises the weights and thresholds by Gradient Descent Algorithm. The learning speed of Gradient Descent Algorithm is slow, and it would easily lead to local minimum value.

While Genetic Algorithm shares the features of efficient and heuristic search, parallel computing, great global optimization ability, etc. As a consequence, GA-Elman model which combines GA and Elman Neural Network is established in this paper. Elman model optimized by Genetic Algorithm can help to improve the precision of calculation. Figure 1 shows how this model works.

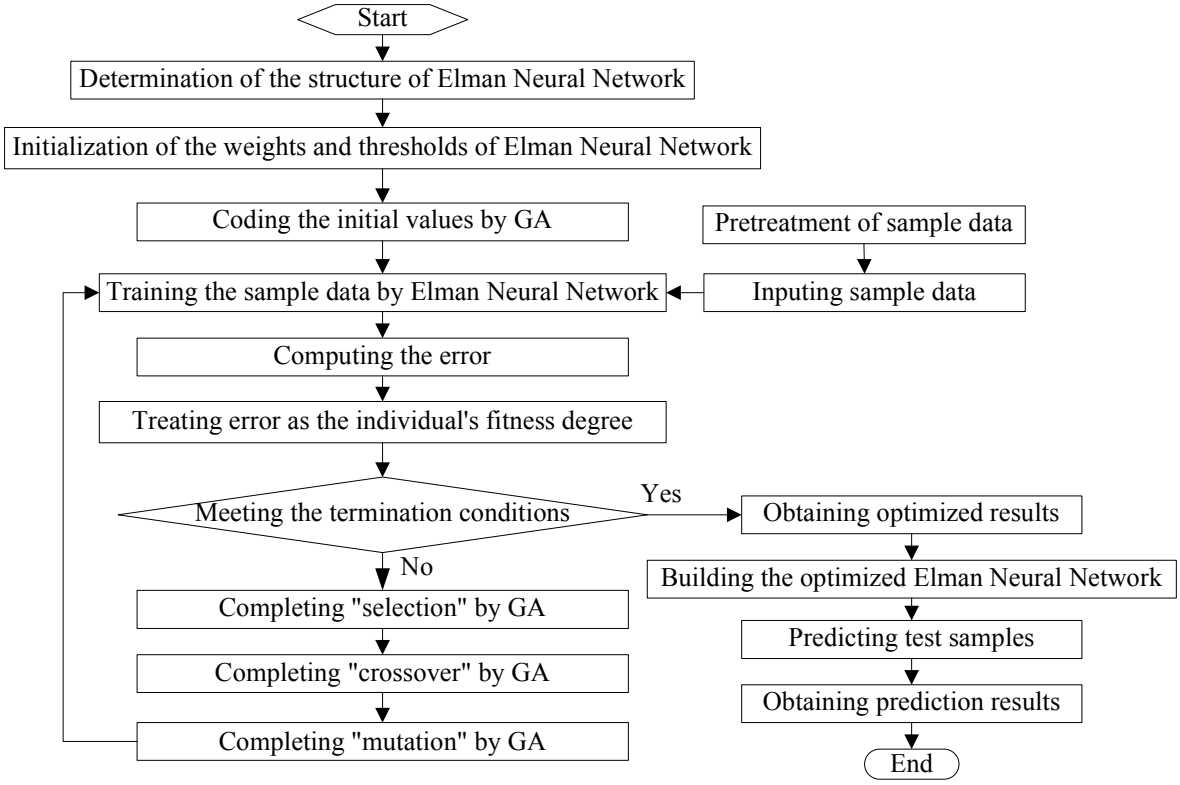

Fig.1. Algorithm flow of GA-Elman Model

In this algorithm, the structure and initial network parameters would be decided in the first place. Then selection operator, crossover operator and mutation operator in Genetic Algorithm are used to optimize the network parameters. In the end, the optimized parameters are made use of to establish a new Elman Neural Network and finish calculation with the test data. There are 5 basic elements to be noted in Genetic Algorithm procedures: parameter coding, determination of initial population, design of fitness degree function, setting of control parameters (preferably refer to population size and probability of genetic manipulation mainly), and design of heredity operation.

Application Principle of GA-Elman Model in Load Forecasting

The short-term load is constantly in a random variation, and it's hard to be described by a function, but the overall load data shows an obvious periodicity and similarity, including the regular pattern in the same hours during different days and the same day during different weeks.

GA-Elman model works well on short-term load forecasting when choosing the input and output variables, network structure as well as Genetic Algorithm parameters correctly. In GA-Elman model, each individual in the population contains all the weights and thresholds of the whole network. Treat the weights and thresholds of each individual as a chromosome, and assign real coding as coding method for chromosomes. The absolute sum of difference value between the output of network and the expected output of sample can be regarded as the fitness degree for individuals. Smaller fitness degree is better, and the probability of being selected for each individual is inversely proportional to the fitness degree of each individual. As a consequence, before selecting an individual, take the reciprocal of its fitness degree first, and randomly select two individuals to pair them up. Then let them share information in intersections which are randomly decided between the two paired individuals. In this way, a new generation is formed. Pick an individual from the new generation, and mutate the chromosome of it, for making the newly-produced individual better.

The terminal conditions for GA-Elman model is that the fitness should be less than a given value, or the difference of the optimal fitness degree between two successive generations should be less than a given value. Then pick out the individual that has the best fitness degree, and get the most optimized weights and thresholds for the Neural Network from it.

GA-Elman model can make fully use of the advantages of both Genetic Algorithm and Elman Neural Network, and it would be a better choice when dealing with short-term load forecasting.

Example Analysis

Pretreatment of Sample Data

The sample load data may be interfered by SCADA and the collected data may become abnormal. As a consequence, in order to improve the precision of load forecasting, effective cleaning needs to be done to the historical load [5]. In this procedure, saturation phenomenon needs to be avoided and the dimensions of different input samples need to be unified. As a result, equation (1) can be used to complete normalized operation for data in input layer, and equation (2) can be used to complete reverse normalized operation for data in output layer.

$$y = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \tag{1}$$

$$x = x_{\min} + (x_{\max} - x_{\min}) * y \tag{2}$$

where $x_{\max}$ and $x_{\min}$ are the largest load value and the smallest load value.

The Selection of Input value

The data which has been used to verify the effectiveness of GA-Elman model is the 24-hour (on the hour) historical load data from Aug. 1st, 2012 to Mar. 31st, 2013 from a certain region. When choosing the input of a neural network, the issues below should be taken into consideration.

a) The load has its periodic peaks and valleys in each day. A great number of references indicate that the load value is relative to the type of date. Let's assume the 7 days in a week as 7 types, and number them as 1, 2, … , 7.
b) Since cumulative effect influences temperature, the load of a day is influenced by the current local weather, and the local weather of the day before that day. The maximum temperature and minimum temperature of these two days are all regarded as the input values for the weather part.
c) The load variation is more dependent on the days more recently, so the load of the day before prediction day is regarded as the input values for the load part.

The Analysis of The Result

Choose a day in the sample data as test day. Then the historical data of the whole 3 months before the test day are regarded as the training sample. After that, build the model according to the method mentioned in this paper. Relative error e and MSE have been considered as criterions to analyze the results of load forecasting [6], the equations (3) and (4) are below.

$$e = \frac{Y - \widetilde{Y}}{Y} \times 100\% \tag{3}$$

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(Y_i - \widetilde{Y}_i)^2 \tag{4}$$

where Y and $\widetilde{Y}$ represent the actual value and predictive value, Y_i and $\widetilde{Y}_i$ are noted as the i-th actual load and predictive load, e and MSE are relative error and mean square error.

Table 1 shows the actual load on the hour of Mar. 20th, 2013. The prediction results as well as their relative errors by BP, Elman and GA-Elman model are also presented in Table 1.

If relative error which is no larger than 3% could be treated as up to standard, we can make the conclusion that less than 50% of the results by BP Neural Network are qualified. Meanwhile, about 63% of the results by Elman Neural Network and 80% of the results by GA-Elman model are eligible. Obtained by calculation, MSE of the results by GA-Elman model is the smallest of these models. Above all, GA-Elman model is better than BP and Elman Neural Network.

Table1. Forecasting results of different forecasting models

24:00	1097.182	1017.930	7.223	1026.710	6.423	1069.026	2.566

Conclusion

GA-Elman model which combines Genetic Algorithms and Elman Neural Network is established in this paper. The optimized thresholds and weights used in load forecasting really help. In the example showed in part 3, GA-Elman model avoid the local minimum value, and has better accuracy than BP and Elman Neural Network. The example verified the effectiveness of GA-Elman model in short-term load forecasting problems, which may be helpful in power market.

Keywords: wind power; dynamic prediction; genetic algorithm; BP neural network

Abstract. This paper proposes a short-term wind power dynamic prediction model based on GA-BP neural network. Different from conventional prediction models, the proposed approach incorporates a prediction error adjusting strategy into neural network based prediction model to realize the function of model parameters self-adjusting, thus increase the prediction accuracy. Genetic algorithm is used to optimize the parameters of BP neural network. The wind power prediction results from different models with and without error adjusting strategy are compared. The comparative results show that the proposed dynamic prediction approach can provide more accurate wind power forecasting.

Introduction

Wind power as one of the most widely available renewable energy resources, has been recognized as the main promising form of clean energy. With the development of mature technology and low cost, wind power has been listed as priority development strategy of the national energy in many countries [1]. However, due to the inherent intermittence and volatility of wind power, it is imperative to accurately predict wind power hours even days ahead to enhance the flexibility of the operation and control of real-time power systems including power and load dispatch. Short-term wind power prediction has attracted a lot of attention in recent years [2-3]; quite a few short-term wind power prediction systems have been successfully developed.

At home and abroad [4], most wind power prediction is using time series method based on the historical data. With the time going by, the operating condition is changing. Without considering weak correlation between the training data and real-time measurement data, the existing training models have not adapted to the present stage forecast work.

This paper proposed a dynamic model for the short-term prediction of GA-BP neural network wind farm output power. Using genetic algorithm to optimize the BP neural network algorithm, the proposed method is able to realize the dynamic prediction of wind power by discriminant function and dynamic adjustment model.

Wind power prediction

Genetic algorithm to optimize the BP neural network

BP neural network , which is a kind of effective self-learning network, has the ability of self-organizing, self-learning and distributed storage and parallel processing of information, therefore BP neural network has been widely used. However, BP neural network uses the root-mean-square error and gradient descent algorithm to realize the correction of the network connection weight, it is inevitable to exist the following problems, such as falling into local minimum value, slow convergence speed, over-fitting and so on[5].

Genetic algorithm (GA) [6] is a kind of intelligent generation process simulation, through the selection, crossover and mutation of genetic process to retain good individual fitness value, eliminate the poor individual fitness value, according to the above conditions for repeated cycle until meeting the convergence condition. Genetic algorithm, which has the characteristics of parallelism, global

optimization, stability and good robustness, is widely used in function optimization, combinatorial optimization and production scheduling, etc.

In order to overcome the shortcoming of the low sensitivity of BP network and the local minimum, the weights and thresholds of BP neural network are optimized by genetic algorithm [6]. Compared with the original BP neural network algorithm, the BP neural network, which is improved by the genetic algorithm, has higher calculation accuracy.

Discriminant error function

Mean absolute error (MAE) [7] is the average of the absolute value of the deviation between all of the individual observations and arithmetical mean. MAE is defined as shown in the following type, the index is able to evaluate the average amplitude of the prediction error.

$$e_{MAE} = \frac{\sum \left| y_i - y_i^{'} \right|}{nP} \tag{1}$$

Where, y_i is the measured data sequence，y'_i is the predicted data sequence n is the number of prediction validation data, P is the rated power of wind farm.

There is no offset problem about the mean absolute error, which can reflect the actual situation of the prediction error. Using MAR as an error discriminant function, this paper dynamically adjusts the model training set.

Wind power dynamic prediction model

Wind power, which is difficult to be predicted, has the characteristics of strong randomness. The research results show that based on the historic data to establish the prediction model, the prediction error will gradually increase with the passage of time. due to the weak correlation between the current data and the training data in the period of modeling, the existing prediction models is not able to track the data, the existing methods is no longer suitable for the prediction work at the present stage. Therefore, a dynamic adjustment strategy, which has higher prediction precision, is proposed in this paper, according to the prediction error, the prediction error adaptively adjusts the model parameters, so the prediction error is improved due to the weak correlation between the training data and real-time measurement data. Dynamic prediction model is shown in figure 1

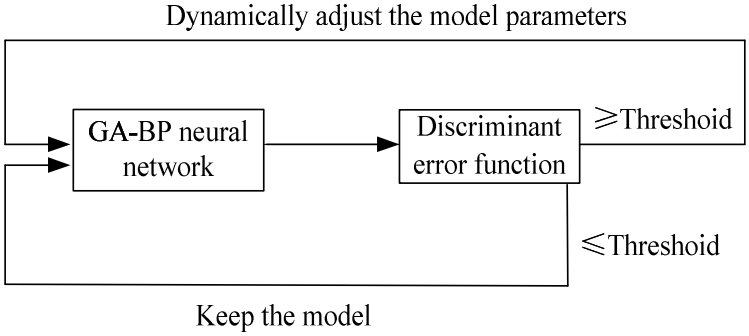

Fig 1. Dynamic prediction model

Wind speed and air temperature are the main influence factors of wind power [8]. The historic data of wind power can be provided by the energy management system of the micro-grid, and the meteorological data can be provided by the supervisory control and data acquisition (SCADA), such as wind speed, temperature, etc. The dynamic prediction model of wind power is shown figure 2.

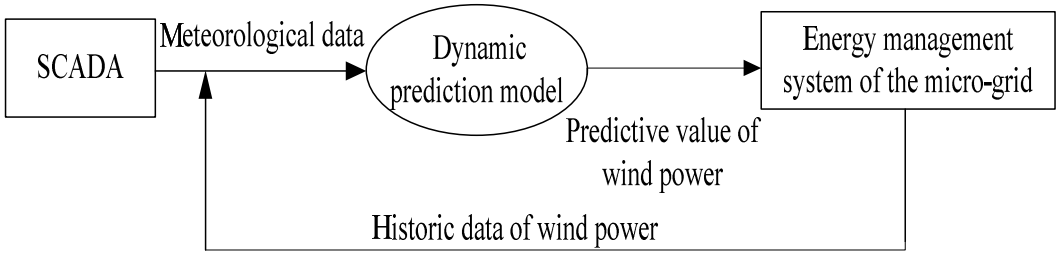

Fig 2. The dynamic prediction model of wind power

The specific steps of the dynamic prediction model of wind farms output power based on GA-BP neural network as follows:

(1) Use the traditional GA-BP neural network to train the model parameters;
(2) Input test sample to predict wind power by the prediction model;
(3) Judge whether the output of the prediction model to achieve the precision threshold by the error discriminant function;
(4) If the prediction error is less than the precision threshold, return to step (2), continue to predict the next data, on the contrary, if the prediction error is larger than the precision threshold, go to step (5);
(5) Using the suitable data as the training set, dynamically adjust the model parameters, repeat step (1) to train the model parameters.

Case study

Data from a month of a wind farm is used for analysis, modeling and prediction in this case, including the actual power and the meteorological data, such as wind speed and temperature, etc. The data sampling period for 10 minutes at a time, rated capacity of the wind turbine is 850kW. Using the 100 groups of data as the training samples and 200 groups of data as the test samples, dynamic model and static model are used to predict short-term output power of wind farm respectively. The root-mean-square error (RMSE) and the relative error (RE) are selected as the error discriminant function in this paper.

The threshold of the discriminat function

When the threshold of MAE is larger than the precision error, the prediction model cannot achieve effective dynamic adjustment and reach to the expected accuracy requirement. When the threshold of MAE is too small, the model will be unnecessary to adjust. In addition, the threshold of the discriminant function has a certain influence on the final prediction accuracy of wind power.

Using the genetic algorithm to optimize the BP neural network model, the prediction result is shown in figure 4. The result of figure 4 shows that most of the MAE of the prediction power by traditional static GA-BP model is less than 0.02, a few time point of the MAE value is too larger; the highest amount to 0.07, the average value is 0.0161 by calculating. On the basis of ensuring the prediction precision, aiming at the least number of the dynamic adjustment, the precision threshold is selected.

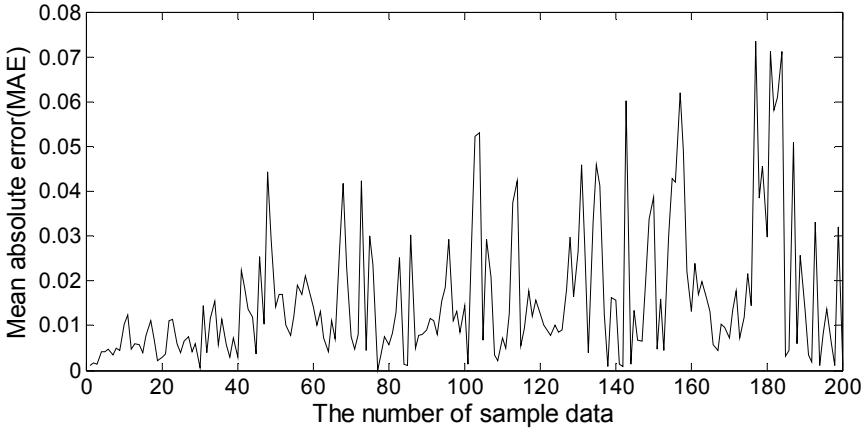

Fig3. The mean absolute error of the static GA-BP neural network output power

Tab.1 The MAE and dynamic adjustment number of the different precision threshold

Precision threshold	MAE%	The number of the dynamic adjustment	Precision threshold	MAE%	The number of the dynamic adjustment
0.01	0.9273	43	0.016	1.154	20
0.011	0.9743	37	0.017	1.179	17
0.012	1.012	33	0.018	1.194	15
0.013	1.074	28	0.019	1.218	13
0.014	1.104	25	0.020	1.249	12
0.015	1.148	22	0.021	1.302	11

The threshold, which gradually increases to 0.021 of the step length of 0.001, is set to 0.010 at first. In order to find the best accuracy threshold, the simulation of this paper uses the dynamic GA-BP neural network model to predict the 200 sets of data. According to table 1,it will be the ideal prediction effect when the Precision threshold is 0.016.

Result analysis

The prediction power of the dynamic and static GA-BP neural network model and the corresponding actual power are shown in figure 4. The mean absolute errors of the dynamic and static model are also shown in figure 4. It can be seen from the figure 5 that the prediction power of the dynamic model is closer to the actual power, compared to the static model, the dynamic model has better prediction effect.

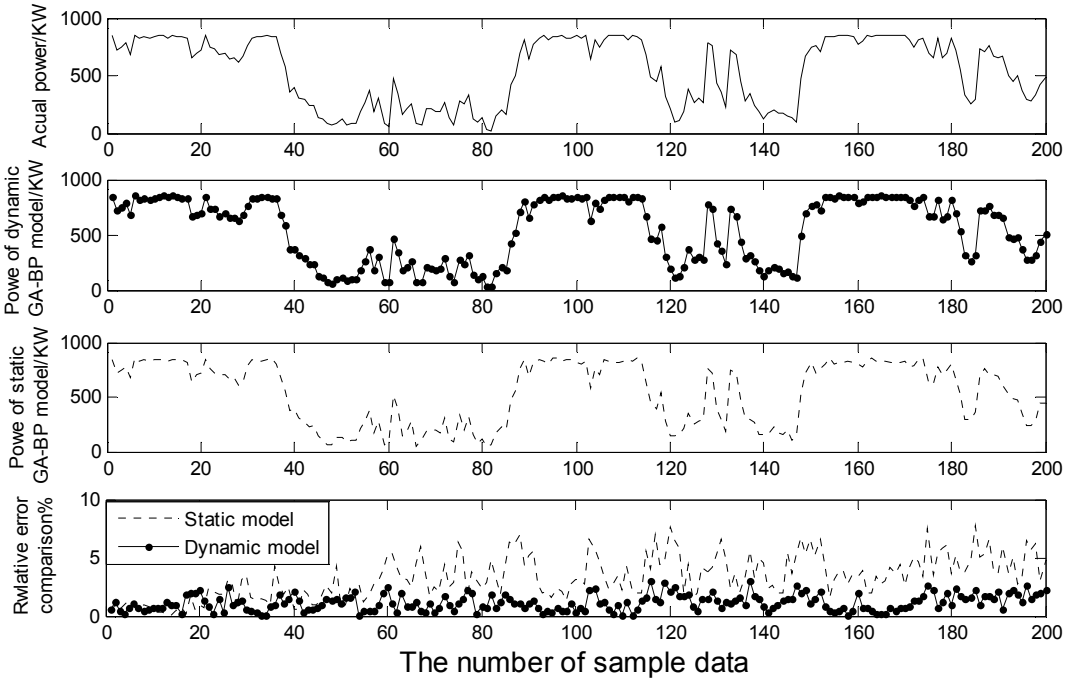

Fig.4 The wind power prediction result

The result of errors is shown in table 2. After using the dynamic model, the mean value and the maximum value of the prediction relative error decline 59.15% and 60.98% respectively. In addition, after introducing the dynamic adjustment strategy, the mean square error of the prediction power declines 57.49%.

Tab.2 The wind power prediction error

	Relative error		Mean square error kW
	Average	Maximum	
Dynamic model	0.0116	0.0302	11.50
Static model	0.0284	0.0774	27.05
Improved situation	59.15%	60.98%	57.49%

In the process of the dynamic model simulation, the dynamic adjustment situations and the prediction time of the each set of sample data need to be recorded. According to the results, the average prediction time of the each set of sample data is 0.0465s without dynamic adjustment, the average prediction time of the each set of sample data is 0.503s with dynamic adjustment. Every 91

minutes the prediction model need to be dynamically adjusted at a once, and the number of the dynamic adjustment is 22, it takes 19.34 in total.

Combined with figure 4 and table 2, it can be seen that the prediction precision of wind power has a considerate improvement after introducing the dynamic adjustment strategy. The dynamic model, which is used for a period of time after completing the each dynamic adjustment, has the characteristic of sustainability. Compared with the time of the prediction sample, the dynamic adjustment time is negligible. Therefore, the dynamic model has a certain practicability.

Conclusion

In view of the traditional static wind power prediction model has a series of problems about the weak correlation between the current data and the training data, a short-term dynamic prediction model of wind farm output power based on the GA-BP neural network is proposed in this paper, according to the mean absolute error, the dynamic prediction model adaptively adjusts model parameters. At first, the best precision threshold of the discriminant function is determined. Then, this paper analyzes the prediction performance before and after introducing the dynamic adjustment strategy. In general, the relative error and root-mean-square error of the dynamic prediction model are greatly improved; the dynamic prediction has higher prediction precision.

Keywords: wind power integration; multi-objective reactive power optimization; genetic algorithm; adaptive weight

Abstract: Aiming at problems which were brought by large-scale wind power integration, and the problem of multi-objective reactive power optimization considering the coexistence of discrete variables and continuous variables, a method of simulation based on genetic algorithm with adaptive weight is brought out. A solving thinking presents that capacitor switching and transformer tap adjusting and other discrete equipments are first, and the action sequence of generator and dynamic reactive power compensation (DRPC) devices and other continuous equipments setting follows, which is presented that optimization problem is decomposed into continuous variable optimization and discrete variable optimization, then they are solved respectively and cross iteration until convergence. In view of the optimization complexity and the coexistence of discrete variables and continuous variables, genetic algorithm with adaptive weight is presented for finding global optimal solution. Case studies show that the proposed thinking and algorithm for solving multi-objective reactive power optimization are reasonable.

Introduction

Wind power is developing at large pace in the need of energy and environmental sustainability nowadays. Large-scale wind power bases of China in plan are gradually carrying out the construction, the areas of wind power integration are most weak in grid, and the base load there is always small, as a result a large number of wind power needs to be transmitted out[1]. And in the process of transmission, the random changes in wind power output will have a great impact on the grid nearby. There might have the risks of Imbalances in the distribution of reactive power and unbalanced voltage fluctuations, and might cause problems such as voltage instability which are more serious[2]. The problem of multi-objective reactive power optimization of wind power integration on optimization of power loss, voltage quality and voltage stability after wind power integration needs to be solved. There are always DRPC devices and other continuous equipments in wind power base, and mechanical capacitors and transformer tap and other discrete devices in the grid nearby, and there are also thermal generator, hydro generator and other conventional generator, so the their terminal bus voltage can be controlled continuously. As a result, the study on multi-objective reactive power optimization of wind power integration with discrete variables and continuous variables has important theoretical and practical significance of engineering.

The difficulty of multi-objective reactive power optimization is the coexistence of discrete and continuous variables and the optimization complexity, the optimization is multi-objective. Much research has been done on this problem. Paper [3] uses the novel quadratic penalty function to handle with discrete variables for Newton optimal power flow. Paper [4] discusses in detail about the theory of penalty function dealing with discrete variables and how to bind to Primal-dual

interior point method directly and presents a new method to solve the problem of reactive power optimization in large-scale power systems with discrete variables. The disadvantage of methods above is that it's hard to achieve to the best optimal solution within an acceptable time. And Modern optimization techniques such as the simulated annealing algorithm, the tabu search method and the genetic algorithm(GA) and other strategies of randomly optimization[5], can guarantee to achieve to the best optimal solution within an acceptable time in principle, and are easy to deal with discrete variables. And among them the genetic algorithm(GA) on reactive power optimization is quite attractive. Though certain achievements have been made on the study of multi-objective reactive power optimization considering the coexistence of discrete variables and continuous variables, more research and investigation should be made to solve the problem better[6].

A method of multi-objective reactive power optimization of wind power integration based on genetic algorithm with adaptive weight is presented. Case studies show that the proposed model, thinking and algorithm are reasonable.

Simulation of Wind Power Integration

Most wind farms in Jiuquan wind power base are connected to the grid via two step-up transformers-0.69kV/35kV, 35kV/330kV, and are sent out vie the long passage: Dunhuang-Jiuquan-Hexi-Wusheng 750kV, such as 1st,2ed,3rd wind farm in Ganxi, 1st,2ed,3rd wind farm in Gandong, 1st,2ed,3rd wind farm in Qiaoxi, 1st,2ed,3rd wind farm in Qiaodong. Every wind farm has the installed capacity of about 200MW. The fluctuant wind power is sent out via the long transmission passage, which will have an impact on the reactive power balance of the passage and will bring the problem of increasing power loss, voltage fluctuation and voltage instability.

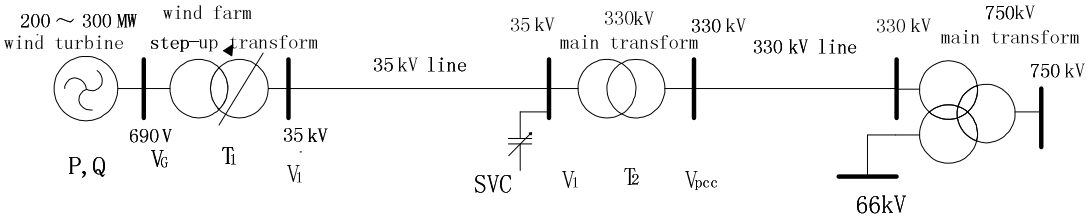

Fig.1 Typical wiring and location of dynamic reactive power compensation diagram

As Fig.1 says, DRPC devices are set at the side of 35kV of the step-up transformer of every wind farm, which are in control of the 330KV bus voltage of the high-voltage side of the step-up transformer. That means the control bus of the DRPC devices is the bus of 330kV[13]. The numbers of DRPC devices are twelve. The capacitive capacity of the DRPC devices of every wind farm in Jiuquan wind power base is 20% of the installed capacity of wind farm, and the inductance capacity is 30% of the capacitive capacity.

The algorithmic routine about this study is written by C++ , and Tab.1 gives out the power loss, voltage quality and load margin before optimization.

Tab.1 VALUE of objectives before optimization

objectives	calculated value(p.u.)
power loss(p-loss)	0.0634
voltage quality(v-quality)	0.01983
load margin(l-margin)	7.28874

Solve the continuous variable optimization and discrete variable optimization respectively, and put into cross iteration until convergence and get the optimal control solution. Tab.2 gives out the coding of continuous variables and discrete variables:

Tab.2 Coding of control variables

	adjustable step	lower (p.u.)	upper (p.u.)	coding length of unit	total length (unit length×device number)
generator	0.01	0.90	1.10	5	5×6=30
DRPC	0.01	0.90	1.10	5	5×12=60
transformer	0.02	0.90	1.10	4	4×4=16
capacitor	0.01	0.00	0.20	5	5×4=20
coding length of continuous variable	90				
coding length of discrete variable	36				

After operation for many times, the better set parameter of searching performance of genetic algorithm is get. The population scale is 60, the selectivity rate is 0.6, the retention rate is 0.05~0.1, the cross rate and mutation rate are given adaptively as mentioned earlier. Tab.3 gives out the information of time consuming and iteration number of genetic solution algorithm.

Tab.3 Statistic for time consuming and iteration number of genetic solution algorithm

time consuming of continuous variable optimization (1time)	12(m)
time consuming of discrete variable optimization (1 time)	10(m)
iteration number	5 times
total time consuming	22×5=110(m)

After 5 times' iteration optimization of discrete variable and continuous variable, and get the optimal solution after convergence, and Tab.4 gives out the optimal solution of control variables:

Tab.4-1 Optimal solution of control variables

generator	terminal bus voltage	substation	transformer tap ratio	substation	capacitor susceptance
Jiure#1	1.04	Dunhuang	1.00	Dunhuang	0.20
Jiure#2	1.04	Jiuquan	1.02	Jiuquan	0.12
Zhangye#1	1.02	Hexi	0.96	Hexi	0.08
Zhangye#2	1.02	Wusheng	0.94	Wusheng	0.06
Jinchang#1	1.08				
Jinchang#2	1.08				

Tab.4-2 Optimal solution of control variables

DRPC	controlled bus voltage	DRPC	controlled bus voltage
Ganxi#1	1.06	**Gandong#1**	1.08
Ganxi#2		**Gandong#2**	
Ganxi#3		**Gandong#3**	
DRPC	**controlled bus voltage**	**DRPC**	**controlled bus voltage**

Qiaoxi#1	1.05	**Qiaodong#1**	1.04
Qiaoxi#2		**Qiaodong#2**	
Qiaoxi#3		**Qiaodong#3**	

Every optimal objectives after optimization has greatly improved comparing with every optimal objectives before optimization, as Tab.5:

Tab.5 VALUE of objective after optimization

objectives	calculated value (p.u.)
power loss(p-loss)	0.0609
voltage quality(v-quality)	0.00645
load margin(l-margin)	7.45082

Conclusion

This paper aims at the problems which were brought by large-scale wind power integration, considering the coexistence of DRPC devices, the terminal bus voltage of conventional generators and other continuous equipments, and the coexistence of mechanical low-voltage compensation devices, adjustable transformer tap ratio and other discrete equipments, and creates the model of multi-objective reactive power optimization of power loss, voltage quality and voltage stability, gives out a thinking of solving model of multi-objective reactive power optimization based on genetic algorithm with adaptive weight. The study gives out the strategy of coordinative optimization of discrete variables and continuous variables, and the operation strategy of the coding of genetic algorithm, cross and variation, and adaptive determined method of multi-objective weight in the process of genetic algorithm, writes an algorithm program using C++, gives the simulation of multi-objective reactive power optimization based on the large-scale wind power base integration in Gansu Jiuquan of China and confirms the certainty of this model.

Smart Grid and Its Application

Yuwei Li

School of Electrical & Electronic Engineering,
North China Electric Power University, Beijing 102206, China
E-mail: 1162062263@qq.com

Keywords: Smart grid; Distributed generation; Energy market; Distribution automation

Abstract: Smart grid could meet the electricity demand against the rapid development of economy and society. The idea to implement smart grid is fully in accordance with the energy developing strategy and it will exert far-reaching impact on the adjustment of energy structure, the sustainable development of society as well as low-carbon economy. Currently, smart grid has attracted wide attention around the world and major countries in the world have been carrying out related researches. This paper describes the background and basic concepts of the smart grid, and takes the United States, European Union and China for example to introduce the development characteristics and typical projects. Besides, this paper analyzes and compares the smart grid in U.S., E.U. and China and gives related suggestions on the key issues of the development of smart grid in China.

Introduction

Due to energy crisis and increasing concerns about environment, strict environmental supervision is needed around the world. The proportion of generation based on renewable energy is required to increase in energy policies. In North America, European Union, Japan, Australia and other countries, powerful research groups have been formed to carry out IntelliGrid / self-healing grid (SHG) / modern power/smart grid study[1-3]. These words have similar meaning and “Smart Grid” is more used at present.

Concept of the Smart Grid

Research objects of Smart grid include various aspects of electric power systems such as power generation, transmission, distribution and consumption. Studies on research and development of new power control technology, information technology and management technology, achieves the intelligent communication of information in all aspects of electricity from power generation to consumption, and optimizes systematically the whole process of power production, transmission, distribution and consumption. Represented by developed countries in American and European, the European Commission, U.S. Department of Energy and the various types of power enterprises and organizations have invested considerable manpower, materials and financial resources, trying to make substantial breakthroughs as soon as possible.

However, there is no uniform definition for smart grid. Given studies of smart grid at home and abroad, the definition of smart grid can be considered that: the smart grid is a fully automated power network, where each customer and node have been real-time monitored and it is ensured that information of every point between the power plant to electrical of the client is bidirectional flowing [4-5]. By widely used smart devices, broadband communications and automatic control system integration, it can ensure the real-time of market transactions and seamless connections and real-time interaction among members in the power grid online.

Fig. 1 is schematic diagram of the smart grid operation. It can be seen from the figure that through the trade center smart grid links organically the energy market, control system of transmission system and power distribution system, combined cooling heating and power system (CCHP), distributed generation,

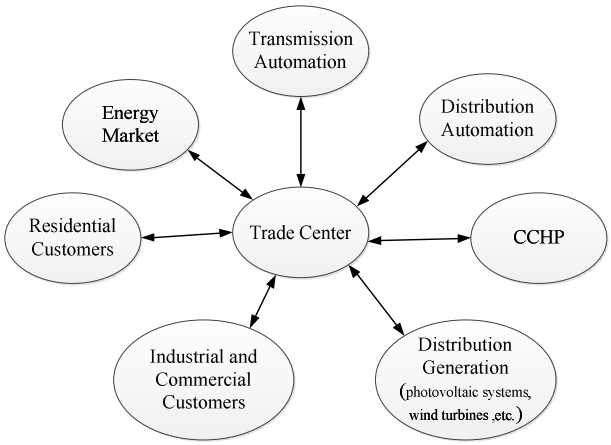

Fig. 1 Sketch map of smart grid operation

industrial and commercial customers, residential customers and so on. In terms of the power system, the smart grid is an intelligent network which is gotten from the combination of the power system and advanced communications and computer technology, power electronics technology, which can predict and self-heal before the system losses control during system failure and has higher flexibility. In terms of customers, power provided by smart grid has greater reliability and security and energy consumption is lower. The smart grid can provide better service with a low cost.

Smart Grid Implementation

(1)The Smart Grid In U.S.

1) Research situation of the smart grid in U.S.

EPRI of U.S. firstly proposed the concept of smart grid in 2001.And the U.S. government proposed planning of "Grid 2030" in February 2003, which officially launched the research and development of smart grid. Subsequently, UCA, SISCO, Lucent, EnerNex, Hypertek and other companies took part in an international scientific cooperation project aiming at studying on the architecture of power system in the future, which was created by the EPRI and run by GE. In the 18 months from early 2003 to 2004, the project firstly completed the IECSA (integrated energy and communication system architecture), followed by an extension study on the architecture of smart grid. Smart Grid of EPRI mainly emphasizes features such as safety, self-healing, coordination, integration, interaction, forecasting, and optimization, etc. In October 2008, a smart grid working group was established in the United States and the working group cooperated with NIST (National Institute of Standards and Technology) and EPRI for smart grid standards development and working on smart grid appliances which were adapted to new smart grid technologies. In 2009, the U.S. government formulated a series of development and implementation plans of smart grid and invested to accelerate the intelligent process of power grid.

2) Smart grid demonstration projects in U.S.

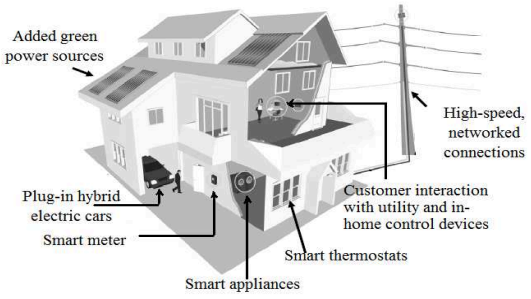

Fig. 2 The smart home

Main functions of smart home are: to achieve two-way communication and interaction with the supply network, priority use of the wind, solar and other clean energy sources intuitively based on real-time information, monitoring and interaction for home by telephone, mobile and remote

networks, management of energy consumption and reduction of energy costs, reasonable distribution of power in substation through the collection of every household's electricity consumption.

Currently, there are other Smart Grid projects in the United States, such as Pacific Northwest Smart Grid project, San Diego Smart Grid project, construction of California Smart Grid and miniature Smart Grid project in coastal city.

(2) The Smart Grid in China

According to characteristics that Chinese geographical distribution of energy and imbalance of load demand, in May 2009 the State Grid Corporation of China announced a plan to build a unified, strong and smart grid for the first time. In addition, the Ministry of Science and Technology deployed "Smart Grid Research and Development of Key Technologies (one-stage)" major projects in the field of advanced energy technologies of the "863" plan, focusing on key technologies to overcome and form a standard system, building demonstration projects and carrying out its application.

The first batch of State Grid Corporation smart grid pilot project is Shanghai World Expo smart grid comprehensive demonstration project. It is in accordance with the core content of smart grid and displays smart grid from there aspects, green energy, strong smart grid and rational use of electricity. Sino-Singapore Tianjin Eco-city comprehensive smart grid demonstration project is the second batch of State Grid Corporation smart grid pilot projects. Its purpose is to promote breakthroughs and application of key technologies of all aspects of strong smart grid in urban construction, to achieve the harmonious development of grid and the natural environment.

Besides, in 2009 China had built UHV 1000 kV Southeastern Shanxi - Nanyang - Jingmen demonstration project, ± 800 kV HVDC Xiangjiaba - Shanghai demonstration project, and planned to construct "three vertical three horizontal" ultra-high voltage grid during the "12th Five-year". In March 2011, State Grid Corporation claimed that China's strong smart grid would be into the all-round construction stage and would build 67 smart substations, seven-fold electric vehicle charging facilities, 11 smart grid demonstration projects and 88 smart grid standards. China will basically complete the smart grid in 2020.

Analysis and Comparison on Smart Grid in U.S., E.U. and China

There are different features in several aspects because of different comprehension of smart grid and different situation of power system in U.S., E.U., Japan and China.The focus of the development of smart grid in U.S. is to update the basic infrastructure of power grid and establish the intelligent distribution network based on informatization. Meanwhile, it emphasized developments in the basic services fields such as information technology, customer service, policies and regulations, labor support and fund guarantee. The construction of a "Unified National Smart Grid" proposed by United States is a combination of scattered smart grids in order to form a national network system aiming at building an intelligent, stable, efficient and reliable power grid.The focuses of European smart grid development are connecting renewable energy into the power grid, the construction of system based on distributed energy and integration and large-scale use of renewable energy, so that it will combine the wide area power transmission network with smart grid to become a wide area intelligent network.

China's smart grid features are: ultra-high voltage power grid as the backbone, the coordinated development of power at all levels, to achieve a strong physical power; solving planning, forecasting, monitoring, analysis, operation and control problems of distributed energy and renewable energy connected to grid; solving safe and stable operation problems of large grid, and improving abilities of making scientific decision and management, to achieve intelligent dispatch; building efficient, flexible and rational distribution grid architecture; building intelligent electricity service system, to carry out two-way interactive electricity services. Compared with other countries, the unique challenge of the development of smart grid in China is to protect the special large-scale, ultra-high voltage, large capacity transmission grid clean, safe, self-healing, economic, and interactive operation.

Thinking of Strengthening Smart Grid Construction with Chinese Characteristics

Compared to the level of research in developed countries, China still has many weaknesses in smart grid construction although China has had lots of achievements recent years. Several suggestions for China to carry out Smart grid are as follows:

1) To enhance government energy assurance capabilities and plan for smart grid resiliency. A clear and supported pricing mechanism for active and reactive power components exchange must be developed. Besides, raise power investment and construction efficiency on the premise of continuously supporting the national economic growth.

2) The concept of smart grid greatly expanded, and attention should be closely paid to domestic and foreign smart grid technology research and development trends. Key equipment is still lack, such as mass storage devices, smart energy meters, unified power flow controller, etc. So that it can't meet the technical demand of a unity strong smart grid. It needs to increased research efforts.

4) To strengthen the research and development of smart grid technical standards and communication standard architecture. Currently, there are many kinds of technical standards and communication standards, and their compatibility are poor and there are a lot of proprietary protocols, making the power system of information sharing difficult, unable to meet the smart home, the smart meters and other new requirements.

Conclusion

Smart grid will be the next generation power grid tend. It has been approved by a number of international energy policy-making departments and power companies. But because of different national conditions, starting points and cognition, the development and implementation of smart grid are distinctive among all the world countries. The paper describes the background and basic concepts of the smart grid, studies on technical application and characteristics of smart grid in world's major countries and areas and gives related suggestions on the key issues of the development of smart grid in China.

Smart Grid in China

Shi Wei

China Petroleum Pipeline Engineering Corporation(CPPE)

Heping Road No.146, LangFang, Hebei province, China

cppeshiwei@cnpc.com.cn

Keywords: Smart Grid, China, Execution, Prospect

Abstract: The concept of Smart Grid is created this century, with the focus of whole world. With the social development, the requirement of power security is growing fast. China, as a great power towards to industrialized country, its requirement is more intense. This paper introduces the generation of the concept ‘smart grid’, as well as the inevitable trend of future development, plans of China for smart grid construction and some achievements, finally explains the advantages of China's smart grid development and prospects of the future.

Smart Grid comes from U.S.

"Smart Grid (IntelliGrid)" was first proposed by the U.S. Electric Power Research Institute (EPRI) in 2001. They proposed further research framework of smart grid in 2003. Subsequently, the U.S. Department of Energy released the "Grid2030" to promote construction and development of the smart grid. In 2009, U.S. government announced planning to invest $ 4 billion to promote smart grid construction. In the same year, U.S. government promulgated the ‘American Clean Energy and Security Act’ (ACES), emphasizing the importance of the smart grid in increasing the power transmission efficiency. In May 18, 2009, U.S. Secretary of Commerce Luo Jiahui (Gary Faye Locke) and Secretary of Energy Zhu Diwen (Steven Chu) announced the first batch of standards for smart grid construction, marking the U.S. smart grid construction officially started[1]. U.S. Institute of Electrical and Electronics Engineers (IEEE) and National Institute of Standards and Technology (NIST) also developed standards and principles for interactive smart grid (IEEE2030) in 2009. Then many countries formulate the development plan of smart grid according to their own reality.

Smart Grid is the Future

The electric power industry is basic industry related to people's livelihood and the important guarantee for economic and social development. Electrical power grid has been the basic and important part of industrialization, information technology and social development. At the same time, power grid constantly absorbs achievements of industrialization and information technology, so that many advanced technologies have been integrated in the power grid, which greatly enhance the power system functions.

(1) Smart grid technology is the inevitable trend for the technology development. Recently, Telecommunication, Computer, Automation and other technologies in the power grid has been extensively and organic integrated with traditional power technology, the integration greatly improves the intelligence level of the power grid. The application of Sensor & Information technology in power grid provides technical supports for system analysis and decision-making, and makes grid self-recovery to be possible. Mature development of scheduling technology, automation technology and flexible transmission technology provide basic guarantees for the development and utilization of renewable energy and distributed power source. Improvement of communication network and popularization of user information collection technology, promote two-way interaction between power grid and the user. With the further development and application of new technologies and highly integrated with physical grid, smart grid came into being.

(2) Developing smart grid is the inevitable choice of social & economic development. To achieve the development, transportation, and consumption of clean energy, the power grid must improve its flexibility and compatibility. To counter the increasing of natural disasters and external interference, the power grid must rely on smart grid to continuously improve its security and defense capability

and self-recovery capabilities. To reduce operating costs and promote energy conservation and pollution reduction, power grid must be more economic and effective, and intelligent in controlling equipments to minimize power consumption. The rapid development of distributed power generation, energy storage technologies, and electric vehicles has changed the traditional mode of power supply, and prompt the power flow, information flow and business flow integration, in order to meet increasingly diverse requirements of users.

The smart grid will be the core of future power industry. It is not only structural upgrade of the modern power grid, but also profound change for the global power industry.

Plan and Execution of China

Smart grid represents the new direction of power grid transformation. At present, many countries are actively planning to promote smart grid. State Grid Corporation of China for the first time public the "smart grid development plan" and preliminary construction schedule on May 21, 2009, which marks that the Chinese smart grid construction was officially put on the agenda. We are gradually building our smart grid:

The first stage is plan and experiment phase (2009 - 2010): Focus on smart grid development planning, drafting technical standards and management practices, researching and developing key technologies and equipments, carrying out all aspects of the experimental work.

Table -1 The first group 22 core standards for smart grid recommended by State Grid Corporation[2]

No.	Title	
1	DL755—2001 Guide on security and stability for power system	
2	Terminology and Methodology of Smart Grid	Reference IEC/PAS 62559 IntelliGrid Methodology for Developing Requirements for Energy Systems
3	Q/GDW 392—2009 Technical Rule for connecting wind farm into power grid	
4	Technical Rule for connecting wind farm into power grid	
5	DL/T 837—2012 Reliability evaluation code for transmission and distribution installation	
6	overhead transmission line monitoring device standards	Including Q/GDW242～Q/GDW245
7	Q/GDW383—2009 Technical guide for smart substation	
8	DL/T860 Communication networks and systems in substations	Equal IEC61850 Substation communication networks and systems
9	Q/GDW382—2009 Technical Guide for Distribution Automation	Equal IEC61968 Application integration at electric utilities--System

		interfaces for distribution management
10	DL/T1080 Application integration at electric utilities-System interfaces for distribution management	
11	Open Geodata Interoperability Specification	Equal Open Geodata Interoperability Specification，OpenGIS
12	Q/GDW480—2010 Technical rule for distributed resources connected to power grid	
13	Intelligent power meter standards	Including Q/GDW1354～Q/GDW1365
14	Electric vehicles standards	Including GB/T 18487(Equal IEC61851), Q/GDW233～Q/GDW 238, Q/GDW Z423, Q/GDW397～Q/GDW400
15	DL/T890 Energy management system application program interface(EMS-API)	Equal IEC61970 Energy management system application program interface (EMS-API)
16	GB/T18700.5 Telecontrol equipment and systems	Equal IEC60870−5
17	GB/T22239—2008 Information security technology—Baseline for classified protection of information system	
18	IEC62351 Power System Control and Associated Communications-Data and Communication Security	
19	IEC62357 Power System Control and Associated Communications Reference Architecture for Object Models, Services and Protocols	
20	GB/T 22080~22081—2008《Information technology—Security techniques》	Equal ISO/IEC27000 Information security management system fundamentals and

		vocabulary
21	GB/T 18336—2008 Information technology - Security techniques - Evaluation criteria for IT security	Equal ISO/IEC15408 Information technology – Security techniques -- Evaluation criteria for IT security
22	GB/T 20279—2006 Information security technology Security techniques requirements of separation components of network and terminal equipment	

The second phase is the comprehensive construction phase (2011 to 2015): Accelerate construction for UHV power grid and distribution network in urban and rural, Initially Forming the smart grid operation and interactive service system, key technologies and equipments achieve breakthrough and be widely used.

On June 26, 2010, the first ±800kV / 4750A UHVDC converter valve in the world developed by China EPRI successfully passed all type tests in State Grid Corp's power electronics laboratory[3]

On July 8, 2010, ±800kV UHVDC SiChuan~ShangHai Line as a main artery of West-East electricity transmission project successfully put into operation. SiChuan~ShangHai Line has the maximum voltage (±800kV), the maximum transmission capacity (6.4GW), the maximum distance (1907kM), the most advanced technology. It bears the task of sending out clean energy from Jinsha River hydropower base[4].

The third stage is the leading and ascension phase (2016 to 2020): Basically complete the smart grid, the grid resource allocation capability, safety, efficiency, and the interaction between power grid, power source, and the users could significantly increase.

These three phases are the overall arrangements for the implementation of smart grid construction and cannot be completely separated. Technology research, equipment development, testing, standard perfecting and popularizing work will be throughout.

Our Advantage and Prospect in China

Over the years, China's power industry vigorously strengthen power grid infrastructure, while paying close attention to the international power technology development, emphasis on research and innovation and integration of various new technologies, enhance independent innovation capability quickly, good condition for the construction of smart grid has been created.

1) In power grid construction, China continue to strengthen and improve the network structure, fully mastered the core technology of UHV power transmission, UHV AC pilot project and HVDC demonstration project are stable in operation, lay the solid foundation for grid development.

2) In large power grid operation control, China has the advantages of "unified management" system and rich operation experience, technology and equipment of scheduling are international advanced; dispatching automation systems and relay protection devices which independent researched are widely used.

3) In the construction of communication and information platform, many power communication nets have been finished; it forms the communication network structure in which optical fiber, microwave, carrier and other means coexists.

4) In the aspect of test detection means, China has set up large-scale wind power, solar power and electricity technology testing center according to the needs of development of smart grid.

5) In the development of smart grid pilot practice, each link has been fully carried out, the smart grid dispatching technical support system, intelligent substation, electric information

acquisition system, electric vehicle charging infrastructure, FTTH pilot projects progress smoothly.

6) In the field of electric vehicle charging and discharging, China carried out a large number of accesses, in charging and discharging facility monitoring and billing and so on, and has completed the electric vehicle charging operation site on a part of cities.

7) In the aspect of power grid development mechanism, business scope of Chinese power enterprise covers each link from the generation, transmission, distribution to substation; there are obvious advantages in unified planning, unified standards, and fast forward.

Smart grid has become the direction of future development; the core of smart grid is a comprehensive, dynamic integration of user side resources, including relevant information of load and electricity use. Therefore, the demand side management is one of the most important parts of smart grid. Although the demand side management framework of smart grid has good development opportunity, China must learn experiences of foreign countries in the concrete implementation process and combine with the actual situation, actively carry out innovation. While smart grid promote bidirectional interactive information to bring convenience for the development of demand side management, it also brings the risk of information security; for information acquisition security (sensor), communication and data security work, we should attach great importance, in order to prevent hackers and virus attacks; China shall actively prevent investment risk when paying attention to increase supports of the construction of smart grid, demand side management, and because it is a system engineering, conspicuous gains will be achieved piecemeal.

Keywords: spatial load forecasting,least square support vector machine,matlab simulation

Abstract. This paper proposes a new spatial load forecasting method for distribution network based on least squares support vector machine. The method adopt data, the characteristic of which is similar with forecast sample, to training in order to obtain the regression coefficients and bias, which we need to do the forecasting.Atthe same time,compare with artificial neural network model,The least squares support vector machine transforms quadratic programming problems into linear equations, thus avoiding the insensitive loss function, greatly reducing the computational complexity and further improving the accuracy of the prediction model. Finally, the effectiveness and practicality are verified by examples.

Introduction

1980s American H. L. Willis made on the basis of spatial power distribution network load forecasting (Spatial Load Forecasting, SLF) this concept [1-2] . Spatial load forecasting not only need to load forecasting , spatial information needed to predict the load . Domestic space in line with forecasts , there are four main methods : trend method , multivariate methods , land use simulation method [3-7] . As the trend of law are many and difficult to choose a template , multivariate methods of data overload and prone to large errors , these two methods have gradually been eliminated. Currently, most of the land is to use simulation to predict method, which is divided by the cell , the law of the land in order to analyze the development of predictive models for simulation, get a load of the total amount of space , the average amount allocated to give each cell load distribution , this method has higher accuracy.

Literature [8-9] proposed the use of fuzzy logic for spatial load forecasting , however, the choice of model for the membership functions with obvious subjectivity. Literature [10-11] , fuzzy logic and rough set theory, spatial load forecasting, but this method ignores the uncertainty in the data itself . [12] proposed a method based on ant colony algorithm to predict the load space , the method of slow convergence and easy to fall into local optimum . [13] is the spatial load forecasting based on cellular automata , although the method can describe the relevant factors affecting the development of spatial load from many angles , but the relevant rules and parameters still need improvement. The characteristics of the grid for distribution , we propose a method based on least squares support vector machine room load forecasting method to construct least squares support vector machine model , and then predict the target year , and in Taiwan , for example, to verify superiority.

Spatial load forecasting basic steps

Spatial load forecasting prediction by following these steps .

(1) Prepare data load , the total load prediction

Historical data extracted from the GIS and other loads . The total load cell is carried out by combined forecasting model to predict the total . Each of the prediction model according to the information useful to combine the organic , the load prediction accuracy is greatly improved.

(2)classification and classification load forecast

Through the different needs of users of the land use classification of the load is divided into industrial , residential , commercial, administrative and educational four categories. Load has certain synthetic load density.

(3) cell division

Spatial load forecasting is the most important cell division , in order to be able to predict a good position to increase the load on the distribution network planning to provide useful information that will be tested area is divided into a plurality of cells . The concept of the cell as the smallest geographic unit for spatial load forecasting . In order to simplify the steps of spatial load forecasting and improve forecast accuracy , a reasonable division of the cell . After analysis , the predicted three layers , the total layer , the acquisition layer and the data layer of the simulation , the model can effectively control the interval of data collection work , while ensuring the accuracy and resolution of land classification.

(4) land use simulation

Simulation is a lot of land for the extraction of spatial information. The first step is a multi-partition, a city that is divided into several layers , such as industrial level , school level , transport layer , residential layer. By dividing each of the smallest unit cell computing and industrial areas, schools , residential areas, commercial areas , such as the shortest distance . According to the data , analyze each cell salable area of land available , and can be used in the future to develop the land area . The introduction of GIS spatial load forecasting , can reduce high spatial information collection effort , which is valid for spatial load forecasting is extremely important .

(5) the use of least squares support vector machine load space

① Select the kernel function.Mercer Theorem is the kernel function interpreted as the product of tectonic kernel feature space technology can be found in many papers. Select a Gaussian radial basis (RBF) function as kernel function, as shown in Equation(1) as shown in this article.

$$K(X, x_i) = exp\{-\|x - x_i\|^2/2\sigma^2\} \quad (1)$$

② data preprocessing.In order to meet network requirements for input and output , according to the model before training

$$X_i = (X_i - X_{min})/(X_{max} - X_{min}) \quad (2)$$

The batch data after linear normalization processing transformed data values between 0-1.

③ set parameters , using the training sample data , build the model. With trainlssvm () to achieve the network training , the regression coefficients and bias, thereby obtaining predictive models. Predict the trained model, and predictions by the anti- normalization restored.

④ error checking to obtain the predicted results.

Cases considered

In order to verify the least squares support vector machine algorithm proposed text on the effectiveness of long-term power load forecasting , the choice of Taiwan from 1981 to 2000, a total of 20 years of electricity load data for validation. In forecasting process to 1981-1995 annual load data as two -dimensional input vector data , training samples after the establishment of appropriate mathematical model to predict back five years or even longer in electricity load . We put Taiwan geographically divided into four parts , namely, northern, central , eastern and southern .

Uses need to set the width δ^2 kernel function parameters to establish calibration model based on radial basis function (RBF) kernel function method of least squares support vector machine .

Caution should be taken to determine the model parameters.Least squares support vector machine σ^2 has a great influence on the performance of the algorithm.Regularization parameter σ^2 is proportional to the sample data punishment,the training error and generalization ability compared with the inverse algorithm ; regularization parameter values $\omega^t\omega$ right on the relative weight of the inverse algorithm generalization ability will worse.So,we passed the test method to obtain the optimal solution.

To measure the mean difference model to predict the effect of the expression

$$E_{A.D} = \left(\frac{\frac{\Sigma |y_{pre} - \hat{y_{pre}}|}{n_{pre}}}{y_{pre}} \right) * 100\% \quad (3)$$

Corrected sample y_{pre} dependent variable $\hat{y_{pre}}$ measured values , n_{pre} number of samples for the calibration data set.

According to a good tune model parameters , get the final predictions . Select $\gamma = 1 \sim 100$, $\sigma^2 = 0.01$, according matlab calculation to get the predicted load of the load them with the actual amount of contrast, to obtain comparative diagram in Figure 1.

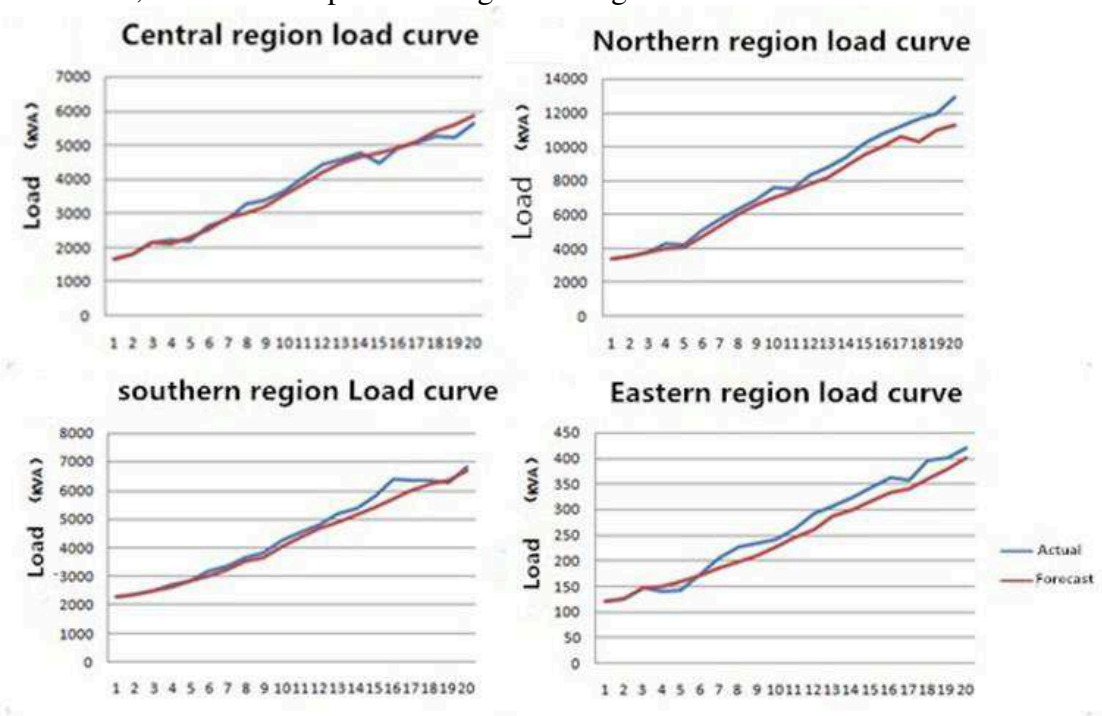

Fig.1 Taiwan's actual load compared with predicted annual load

In the above figures , the blue is the actual annual load curve , red is forecast load curve .

Charts available in the method of least squares support vector machine , the error can be controlled within a narrow range , with some accuracy.

The mean difference in various regions shown in Table 1:

Tab.1 The mean difference in Taiwan

Parameter	Northern	Central	Southern	East	Taiwan
The mean difference (%)	5.67	6.03	6.75	5.98	6.14

Conclusion

This paper focuses on the method of least squares support vector machines , and related models proposed derivation . Through practical examples and analysis , to overcome the past to predict the results of subjective poor results due to quantization , get vector machines have the advantage of least squares support , small sample needed , a small error range, and enhanced versatility , high accuracy . To strike spatial load forecasting provides a new thinking and new methods.

Keywords: wind power generation; harmonic; voltage fluctuation and flicker; assessment method.

Abstract. The grid-connected wind farms bring power quality problems to power system due to the volatility and random of wind power generation. Analysis and calculation are carried out in this paper for the main influence factors of wind power harmonics, voltage fluctuations and flicker, and the assessment methods of the above power quality problems. For a certain wind farm, the corresponding power quality index limits can be calculated. Assessment conclusions can also be given by comparing the calculated power quality index values and the index limits.

Introduction

Recently, more and more attentions are paid to the power quality problems of grid-connected wind farms. The stochastic volatility of wind power and the use of power electronic devices may cause voltage fluctuation and flicker [1, 2], harmonic [3] and other power quality problems. According to the characteristics of wind power generation, reference [4] established a wind farm simulation platform in Matlab and analyzed the influence of voltage fluctuation and flicker. Reference [5] studied the voltage flicker issue at the point of common coupling (PCC) by reference to IEC 61400-21[6]. Reference [7] analyzed harmonic problems in wind farms, but the evaluation methods of voltage fluctuation and flicker is not given. In addition, there are some other references studied the assessment method of the grid-connected wind farm power quality [8, 9, 10].

Wind farm harmonic problem

Harmonic current analysis

Reference [11] fundamentally regulates harmonic current limits on different voltage levels. For specific wind farm, the limit value should be determined according to the actual short-circuit capacity of PCC, as it is shown in Eq. 1.

$$I_h = \frac{S_{SC}}{S_{k1}} I_{hp} \tag{1}$$

where S_{SC} is minimum short-circuit capacity of PCC, MVA, S_{k1} is benchmark short-circuit capacity, MVA, I_{hp} is the h harmonic current limit value, A, I_h is the h harmonic current limit value corresponds to S_{SC}, A.

For each wind farm connected to the same PCC, harmonic current allowable value can be calculated by Eq. 2.

$$I_{hi} = \left(S_i / S_t\right)^{\frac{1}{\alpha}} I_h \tag{2}$$

where I_{hi} is the i wind farm's h harmonic current limit value, A, S_i is the i wind farm's agreement electricity capacity, MVA, S_t is power devices capacity of PCC, MVA, α is phase superposition coefficient.

The total wind farm harmonics injected into PCC can be superposition calculate by Eq. 3, in which coefficient K_h selection reference to Table 1.

$$I_h = \sqrt{{I_{h1}}^2 + {I_{h2}}^2 + K_h I_{h1} I_{h2}} \tag{3}$$

Table 1 Value of coefficient K_h

h	3	5	7	11	13	9	>13	even
K_h	1.62	1.28	0.72	0.18	0.08		0	

After calculating the superposition harmonic current of all turbines, it's necessary to convert the superposition value into the PCC side, and then judge whether they exceed or not by comparing the calculated value with the limited value.

Harmonic voltage analysis

The *h* harmonic voltage ratio HRU_h in PCC can be calculated by Eq. 4.

$$HRU_h = \frac{\sqrt{3} U_N h I_h}{10 S_k} \tag{4}$$

where, U_N is nominal voltage of power grid, kV, S_k is PCC short-circuit capacity, MVA.

Eq. 5 calculates the total harmonic voltage distortion THD_u.

$$THD_u = \sqrt{\sum_{h=2}^{\infty} (HRU_h)^2} \times 100 \tag{5}$$

Assessment and exceed judgment of harmonic voltage can be made by HRU_h, THD_u and limit value.

Wind farm voltage fluctuation and flicker

Voltage fluctuation analysis

Relative voltage fluctuation by single turbine switching operation can be measured according to Eq.6.

$$d = 100 \cdot \varphi_u \cdot \frac{S_n}{S_k} \tag{6}$$

where, d is relative voltage fluctuation, %, φ_u is voltage fluctuation of grid connecting point, S_n is single turbine rated apparent power, MVA.

When limit start-up and shut down number of wind turbines, voltage fluctuation is calculated by Eq. 7.

$$d \approx \frac{\Delta S_i}{S_{SC}} \times 100\% \tag{7}$$

where, ΔS_i is three-phase load change value, MVA.

Voltage flicker analysis

As for wind power generation, user's load, agreement electricity capacity, and system voltage should be considered in voltage flicker limit configuration. Comparing with the standard limit [12, 13], we should first measure the total PCC voltage flicker G caused by all turbines.

$$G = \sqrt[3]{L_P^3 - T^3 L_H^3} \tag{8}$$

where, L_P is long time voltage flicker limit, L_H is long time voltage flicker limit for a higher voltage level, T is voltage flicker transfer coefficient.

Voltage flicker limit E_i is,

$$E_i = G \sqrt[3]{\frac{S_i}{S_t} \cdot \frac{1}{F}} \tag{9}$$

where, F is simultaneous factor for fluctuating load, the typical value F=0.2~0.3(But $S_i / F \le S_t$ must meet).

Voltage flicker for wind turbine is,

a. Continuous operation

When wind turbines works in continuous operation state, the total voltage flicker value they generate is calculated by Eq. 10.

$$P_{lt\Sigma} = \frac{1}{S_k}\sqrt{\sum_{i=1}^{I}\left(\varphi_C \cdot S_n\right)^2} \tag{10}$$

where, φ_C is flicker coefficient of a single unit, I is the number of wind turbines connected to the grid.

b. Switching operation

The total flicker value produced by several units switching operation is,

$$P_{lt\Sigma} = \frac{8}{S_k}\left[\sum_{i=1}^{I} k_{120,a}\left(\varphi_S \cdot S_n\right)^{3.2}\right]^{0.31} \tag{11}$$

where, φ_S is flicker step coefficient of a single unit, $k_{120,a}$ is switching time for wind turbines in 120min.

The system bus flicker value that comes from wind turbines outlet is get by wind turbine flicker multiply transfer coefficient, as it is shown in Eq. 12 and Eq. 13.

$$P_{ltA} = T_{BA} \cdot P_{ltB} \tag{12}$$

$$T_{BA} = \frac{S'_{lcA}}{S_{lcA} - S'_{lcB}} \tag{13}$$

where, T_{BA} is transfer coefficient, P_{ltA} is node A long time voltage flicker value caused by node B, P_{ltB} is node B long time voltage flicker value, S'_{lcA} is short-circuit capacity that node A transfer to node B, S_{lcA} is node A short-circuit capacity, S'_{lcB} is short-circuit capacity that node B transfer to node A.

Assessment case

To analyze the problem, this paper takes a typical 49.5MW wind farm case as an example, using 1.5MW GW82/1500 wind turbines, 1.6MVA S9-1600 box-type transformers and LGJ-400 transmission line to access to the grid. Fig. 1 shows the wind farm equivalent wiring diagram, assemble line short-circuit capacity is 900MVA, PCC minimum short-circuit capacity is 3030MVA, PCC power devices capacity account by planning capacity 1410MVA.

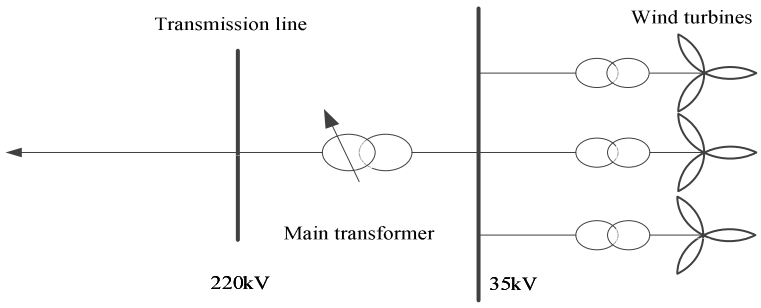

Fig.1 Equivalent wiring diagram of wind farm

According to the test data of the assess wind farm, each harmonic current histogram is shown in Fig. 2.

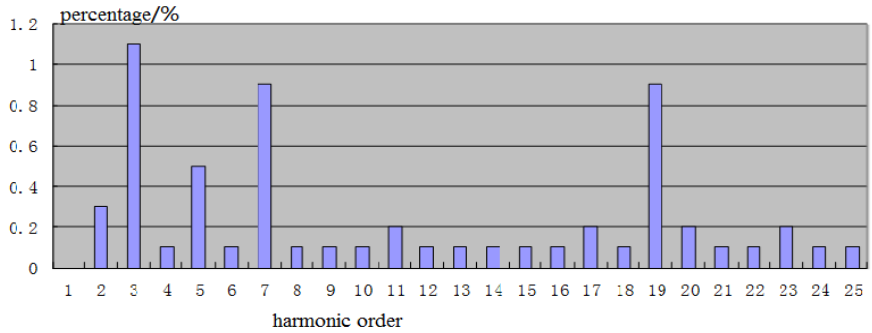

Fig. 2 Harmonic current histogram of a single wind turbine

Evaluating harmonic current according to the above method, the results is shown in Table 2.

Table 2 Assessment result for harmonic current

Harmonic order	PCC harmonic current limit /A	Harmonic current value /A	Conclusion
2	0.92	0.07	qualified
3	0.19	1.27	unqualified
4	0.46	0.03	qualified
5	0.24	0.47	unqualified
6	0.31	0.03	qualified
7	0.54	0.54	unqualified
8	0.23	0.03	qualified
9	0.24	0.03	qualified
10	0.18	0.03	qualified
11	0.27	0.06	qualified
12	0.15	0.03	qualified
13	0.26	0.03	qualified

Total injection harmonic is mainly affected by the single turbine harmonic current value, as can be seen from Fig. 2, the 3rd, 5th and 7th harmonic current of this case is larger. Among them, the 3rd harmonic current even exceeds the rated current 1%, which is one of the important factors affecting wind farm. Besides, PCC short-circuit capacity is small, while the access capacity is large, which makes user's assigned limit value smaller and more rigorous.

Table 3 shows the comparison result of total harmonic voltage distortion and PCC harmonic voltage limit.

Table 3 Assessment result for harmonic voltage

Total harmonic voltage distortion /%	PCC harmonic voltage limit /%	Percentage/%	Conclusion
0.36	2.0	18	qualified

According to the calculation result, the harmonic voltage caused by harmonic current injection is lower than the standard limit, which is qualified.

Table 4 analyses the voltage fluctuation value caused by several wind turbines. In the process of field-testing, the biggest voltage change value is about 1.35%, which matches the theoretical analysis result, and did not exceed the standard limit at all.

Table 4 Calculation data of voltage fluctuate

Number	Calculated value/%	Standard limit/%	Conclusion
1	0.0105	1.5	qualified
33	1.3434	1.5	qualified

For voltage flicker analysis, continuous operation and switching operation state are different. Take continuous operation as an example, flicker coefficient is shown in Table 5, voltage flicker comparison result is shown in Table 6.

The wind farm voltage flicker transfer to PCC is 0.27, less than PCC allowed value 0.31, voltage flicker is qualified, but close to the limit. It's advised that the wind farm should take some corresponding measures, in order to reduce operation voltage flicker.

Table 5 Value of flicker coefficient

Impedance angle	30°	50°	70°	85°
Annual average wind speed	Flicker coefficient			
6.0	2.71	2.57	2.50	2.50
7.5	2.60	2.48	2.38	2.37
8.5	2.58	2.44	2.33	2.30

Table 6 Voltage flicker assessment for PCC

PCC voltage flicker /%	Voltage flicker limit/%	Percentage/%	Conclusion
0.27	0.31	87	qualified

Summary

As to the increasing numbers of the problem of the poor power quality influenced by grid-connected wind farms, this paper studies the main influence factors of wind farm harmonic, voltage fluctuation and flicker, as well as their calculation and assessment methods. Harmonic is mainly affected by the types of wind turbines. As for the voltage fluctuation and flicker, the influence factors mainly include wind conditions, wind turbines types, control strategy, system conditions and etc. Furthermore, a wind farm case validates the feasibility of the above assessment method.

Study in the application of PSIM software in the teaching of curriculums related to the new energy power generation

Hongwei Li[a], Gui Chen[b]

School of electrical information, Southwest Petroleum University, Chengdu, 610500, P.R.C.

[a]lhwmail@126.com, [b]chengui@swpu.edu.cn

Keywords: Teaching, PSIM software, wind power system, Permanent magnet synchronous generator (PMSG), full power converter.

Abstract. In view of the teaching requirements of the new curriculums about new energy power generation technology in electrical engineering field, this paper has proposed and designed a rated 3kW wind power system under the environment of PSIM9.0 software. Through systematically analyzing the mathematics and theory knowledge of the small and medium sized permanent-magnet direct-drive wind power system (PDWPS for short), the wind power system model has been built and the back-to-back double-PWM control circuit has been designed. Then the whole PDWPS has been established based on PSIM. The simulation results show that, when the wind speed changes, the output power of the generator is stable and the DC voltage of the inverter is constant. The results prove that the control strategy is correct and valid. As a powerful auxiliary teaching tool, PSIM can be used to strengthen student's understanding of theoretical knowledge and improve the students' learning interest and enthusiasm. The contents in this paper provide a new method to the teaching and practice in electrical engineering courses.

Introduction

Smart grid has a very wide range of content and the integration of renewable energy is its one important feature. In recent years, a lot of ordinary colleges and universities have opened the courses such as "distributed generation", "new energy power generation and interconnection", "wind and photovoltaic power generation" and other courses about new energy power. But those curriculums need wide knowledge base, the concepts are relatively abstract, and all of them are strong theoretical and practical comprehensive courses. In order to improve the teaching effectiveness, the experiment teaching is necessary. But now, the ordinary colleges and universities are lack of corresponding experiment equipment, the teaching time is cut down and teaching content increases. All these questions result in poor teaching effectiveness. The introduction of the simulation software maybe can solve those problems well.

At present, there are many power electronics and power system simulation tools used in the commercial and educational power system [1-4]. The PSIM is a kind of simulation software packages used in the field of power electronics and motor control. PSIM has simple user interface and is easy to learn and use. And it also has fast simulation speed and clear simulation waveform. Moreover, compared with the MATLAB simulation tools, PSIM has the properties of very small setup capacity (less than 100M bytes), fast operation speed and good expansibility and transplantation (even it can run directly without setup process)[4].Especially, PSIM9.0 and later version add new energy power generation models such as solar cell and wind power generation. So, PSIM provides an excellent platform for its application in the development of new energy power generation or distributed generation virtual experiments.

Currently, the small and medium-sized independent wind power generation found strong support from the national policies. They are mainly used in remote areas, where lack of electricity but lack not of wind energy, and in parts of the self-supply power plants, such as remote mountains, border posts, lonely islands large oil fields, etc. [5] Small and medium-sized wind turbine system is an important content of "distributed generation", and the permanent-magnet direct-drive wind power generation

system (PDWPS for short) is an investigative hot spot in recent years. Through the simulation and modeling of PDWPS, this paper described the application of PSIM in the above mentioned courses teaching.

Overview of PDWPS

PDWPS, whose basic structure are shown in Fig.1, is mainly composed of four modules: wind turbine, PMSG, converter and control system. Unlike traditional asynchronous wind power generator system, PDWPS saves heavy speed-increasing gearbox, and this increases the utilization efficiency of wind power and improves the unit operation reliability. Moreover, PDWPS does not consume reactive power from the main grid, and the power converter can improve the low voltage ride-through of the system. All those provide a strong guarantee for the wind power to meet increasingly stringent interconnection requirements. PDWPS has the following main characteristics [6]: 1) smaller size and lighter weight for generator; 2) smaller electromagnetic interference and good EMC performance; 3) simple structure, good reliability, long service life; 4) high efficiency, obvious energy saving; 5) better adaptation even under the bad environment; 6) good voltage waveform and strong adaptive capacity to variation of load.

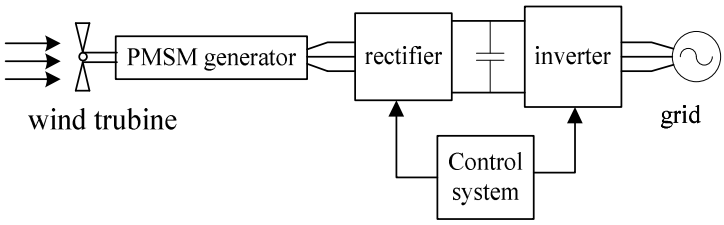

Fig.1 Diagram of basic structure for PDWPS

Mathematical model of PDWPS

3.1 power characteristics for wind turbine

As a key component of the wind power generation system, the main function of wind turbine is to intercept wind energy and convert the wind energy to the mechanical kinetic energy efficiently. So, the wind turbine not only affects the effectiveness and stability of the output of the wind power generation system, but also directly decides whether the system can run normally.

According to the hydrodynamics knowledge, the input power of the wind turbine equals to the kinetic energy produced by flow of air. The expression is,

$$E = mv^2 / 2 = \rho S v^2 / 2 \tag{1}$$

Based on Betz limit theorem [5], the theoretical maximum output power of wind turbine is,

$$P_{\max} = EC_{\max} = \rho S v^2 C_{\max} / 2 \tag{2}$$

Where, m is the intercepted air quality, S is the swept area by wind leaf, v is wind speed, ρ is air density. And $C_{\max}$ is the maximum power conversion coefficient, its theoretical value is 0.593, but the actual value is about 0.4 because it is impossible to achieve the theoretical value in the actual operation.

The output torque formula of the wind turbine is,

$$T_m = P / \omega = \rho S v^2 C_p / 2\omega \tag{3}$$

Where, P is the output active power, C_p is the power conversion coefficient, ω is the blades rotating angular velocity of wind turbine.

3.2 The model of PMSG

During the running process of PMSG, the electromagnetic relations are very complex, so it is hard to establish its accurate mathematical model. For the sake of analysis, it is usual to make the following assumptions: 1) Y type connection for the stator winding; 2) the back EMF be sine-wave and do not consider the effect of space harmonic and magnetic circuit saturation; 3) do not consider the losses of eddy current and hysteresis; 4) no dynamic response process for excitation current.

In d-q axis rotation coordinates, the mathematical relationships for PMSG voltage and electromagnetic torque are as following [6].

Voltage equations are,

$$\begin{cases} U_d = -\omega_c \psi_q + (R_s + pL_d) i_d \\ U_q = \omega_c \psi_d + (R_s + pL_q) i_q \end{cases} \tag{4}$$

Flux linkage equations are,

$$\begin{cases} \psi_d = L_d i_d + \psi_f \\ \psi_q = L_q i_q \end{cases} \tag{5}$$

Electromagnetic torque equation is,

$$T_e = 3n_p[\psi_f i_q + (L_d - L_q) i_q i_d]/2 \tag{6}$$

Where, ψ_q and ψ_d are the d-axis and q-axis flux linkages respectively, L_d and L_q are the d-axis and q-axis self-inductances for stator windings, R_s is the stator resistance, i_d and i_q are the d-axis and q-axis armature currents, ω_c is the rotor angular velocity, p is the differential operator symbol, n_p is the poles pares of PMSG, ψ_f is the flux linkage of permanent magnets and is constant.

Modeling and control strategies

Back-to-back double PWM converter consists of the generator side rectifier, DC bus and the grid side inverter. The rectifier accepts the active power from the generator then converts them to DC power, and then through the DC bus, the inverter converts the DC power to AC power and injects AC power into the grid. Due to wind speed and generator speed continuously changing, the generator output voltage and frequency change with them. In order to meet the interconnection requirements of voltage and frequency, the control method and strategy of the dual PWM converter are very critical.

4.1 Modeling and control strategy in generator side

The control objective of rectifier in generator side is to achieve the maximum power point tracking (MPPT) by adjusting the speed and torque of PMSG when the wind speed changes. Under the rotating coordinates, the equation (6) shows that the torque is only related to q-axis armature current when $L_d = L_q$, so the torque control is the current control. In short, the rectifier adopts current-speed double closed loop control. The speed and torque depend on the space vector currents. It can achieve control objectives by making i_d and i_q track the given signals i_d^* and i_q^*. The control models and diagram are shown in Fig. 2 based on PSIM.

4.2 Modeling and control strategy in grid side

The control objective of inverter in grid side is to make the DC bus voltage more stable and the grid run under unit power factor. In order to overcome the drawbacks of the single current control method in traditional small and medium-sized wind power system, this paper adopts double closed loop voltage oriented vector control method [7-8]. Voltage oriented vector control method include indirect control and direct control. Here, the direct current control method has been adopted for it uses the current closed-loop control and has better dynamic performance and good robustness [9]. In the method, the outer loop voltage signal was controlled by the given DC voltage U_{dc}^* and the actual feedback DC voltage U_{dc}, and the inner loop current signal was controlled by the currents in grid side and the output of outer loop. The control models and diagram are shown in Fig.3 based on PSIM.

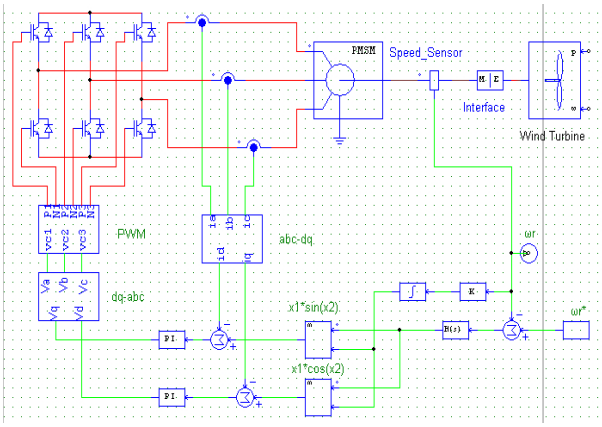

Fig.2 Control system model of PMSG side rectifier

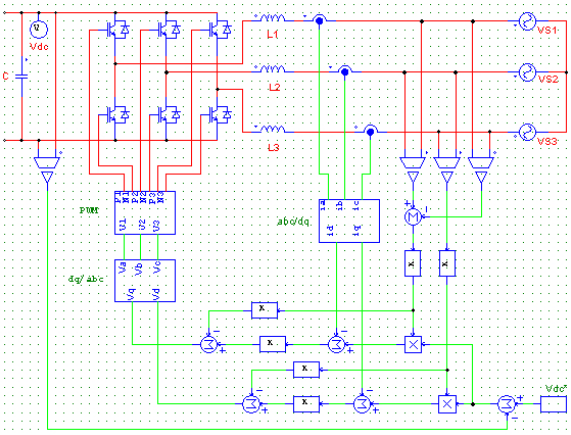

Fig.3 Control system model of Grid side inverter

Simulation and results analysis

In order to verify the feasibility of the small and medium-sized permanent-magnet wind power system, this paper, based on PSIM, design a system with the rated power of 3 kW whose main parameters are shown in table 1. To verify the stability of proposed system, the wind speed has a sudden change from the rated speed 12m/s to 9m/s (shown in Fig.4) during the simulation. After the simulation, the speed and torque of PMSG are shown in Fig. 5, the output active power of PMSG is shown in Fig. 6, the DC bus voltage is shown in Fig. 7 and the output currents of inverter is shown in Fig. 8.

It can be seen from Fig.5~8, when the wind speed has a sudden change, the system has a fast dynamic response and very small overshoot. When the system runs below the rated wind speed, the DC bus voltage is almost constant 400 V and the inverter output voltage frequency is the same as the grid voltage frequency. The simulation results show that the model was correct, the system was stable and the control strategies were feasible and valid.

Table 1 Parameters of the complete system

item	parameter	item	parameter
Air density	1.2kg/m3	Grid frequency	50Hz
Radius of the blades	2m	Dc bus voltage	400V
Rated wind speed	12m/s	Dc bus capacitance value	1.9mF
Rated power	3kW	Converter switching frequency	10kHZ
Phase voltage	180V

Conclusion

This paper discusses the modeling and simulation of the small and medium-sized permanent magnet wind power system based on PSIM9.0. The simulation results are in agreement with the theoretical calculation values. Compared with PSIM, although PSCAD and MATLAB/Simulink software is so powerful and can realize the simulation of complex system, they launch slowly and have long running time and software transplantation is relatively difficult.

In the teaching, the working principles of the system are analyzed first, and then the system are modeled based on PSIM. The parameter correction designs need to be done based on the requirement of engineering design before running the simulation system. Finally, the simulation system is used to verify whether the designs and the models are correct or not. By introducing PSIM into the classes to develop corresponding virtual experiments, it can solve the problem of insufficient experimental time, provide students with a good platform for integration of theory with practice, grasp the corresponding professional theoretical knowledge better and enrich the teaching content, method and means. Moreover, it also can stimulate students' interest in learning, train students comprehensive and scientific research, practice and innovation ability.

Keywords: Electric vehicle, Charging market, Supply chain, Cooperative games, Shapley distribution model.

Abstract. This thesis applies the thought of cooperative game and studies on the best mode of cooperation and benefit distribution in the charging market in supply chain. Firstly by researching the relationship between the unit cost and the number of charging pile construction, the thesis concludes that grid, gas station and car park three party will participate at the same time. Then, with the data of Beijing charging market, it makes specific accounting of five unions of profit model, and finds out the best program in which the three-party union could be established. Finally, it uses classic Shapley method, getting the distribution models of enterprise union.

Introduction.

As the best choice for the low-carbon economy, electric vehicles contain huge market potential. The construction of charging facilities is the vital basis of its extensive promotion. Commonly used electric vehicle charging way are slow filling and fast filling.But now, the application of electric vehicles is also in the testing and demonstration phase, and the construction of charging stations and operation mode select are still in exploration. It has become an urgently important task of research to find out the kind of cooperation and allocation mechanisms, which the parties of supply chain should establish to maximize the benefits and fair and reasonable.

Introduction to Supply Chain Cooperative Game and Shapley Value Method.

Supply Chain Cooperative Game.

Supply Chain Cooperation. Supply chain cooperation is supply, production, sales, mutual cooperation between two or more nodes on the supply chain enterprises in order to achieve the common goal, obtaining the biggest value with the minimum cost.

Mathematical Model. N={1, 2, 3,... , n}, S, any subset of the N, is called union. V (S) is the corresponding characteristic function, indicating participators of union S can get the maximum utility in mutual cooperation, namely:

$$v(s_1 \cup s_2) \geq v(s_1) + v(s_2), \quad s_1 \cap s_2 = \emptyset \qquad (1)$$

Shapley Distribution Model.

Shapley value of cooperative game theory method are widely used in the supply chain cooperation profit distribution problem. The Shapley value of game (N, v) will apportion major league benefit v (N) according to the following formula:

$$\emptyset_i(v) = \sum_{S \subseteq S_i} \frac{(n-|s|)!(|s|-1)!}{n!}(v(S) - v(S\backslash i) \qquad (2)$$

$$v(\emptyset)=0$$

Research Hypothesis.

Hypothesis 1. In a certain area, fast charging price P_k and slow charging price P_m were determined.

Hypothesis 2. In a certain area, total number of charging pile M is determined, the corresponding total charge amount Q is also determined.

Hypothesis 3. After charging market actual formation, there exist fast and slow filling charging methods at the same time, relations between the number of two kinds charging piles is established in proportion, the corresponding annual charging amount also have fixed relation.

Hypothesis 4. Grid companies provide quick charging service, while charging station provide slow filling services.

Charging cooperation models.

Analysis of market participants. According to the existing optional way of charging, there are three possible participants in the market: the grid companies A_1, gas station A_2 and a parking lot A_3.Assuming that a certain area in the specified period, the number of fast charging piles and slow charging piles is M_k and M_m respectively, corresponding charging amount is Q_k, Q_m. It is set that the number of fast and slow charging piles A_1built is m_1 and m_2, the number of A_2 is$(M_k - m_1)$, the number of A_3 is $(M_m - m_2)$. $m_1 \in [0, M_k]$, $m_2 \in [0, M_m]$.

General income of all participants is:

$$Y(S) = \sum_{i=k,m} P_i \times Q_i \qquad (3)$$

Cooperation Pattern Analysis. For all the possible coalition, there are five kinds of possibilities, Hj , j=1,2,3,4,5, as shown in table.1.

Table.1 Cooperation Pattern

	Fives Cooperation Pattern
H_1	{1}，{2}，{3}
H_2	{1，3}，{2}
H_3	{1，2}，{3}
H_4	{1}，{2，3}
H_5	{1，2，3}

Income Analysis. Benefit analysis of all kinds of cooperation mode.

Mode 1. 1,2,3 operate independent respectively, namely {1}，{2}，{3}.

$$Y(1) = P_k Q_{k1} + P_m Q_{m1} + P_{b1} Q_{k2} + P_{b2} Q_{m2}$$

$$Y(2) = P_k Q_{k2}$$

$$Y(3) = P_m Q_{m2}$$

$$C(1) = P_c(Q_{k1} + Q_{m1}) + C_{k1} + C_{m1} + C_{rm} + C_{rk} + C_{ek} + C_{em}$$

$$C(2) = P_{b1} Q_{k2} + C_{k2} + C_{r2}$$

$$C(3) = P_{b2} Q_{m2} + C_{m3} + C_{r3}$$

$$V(1) = P_k Q_{k1} + P_m Q_{m1} + P_{b1} Q_{k2} + P_{b2} Q_{m2} - (P_c(Q_{k1} + Q_{m1}) + C_{k1} + C_{m1} + C_{rm} + C_{rk} + C_{ek} + C_{em})$$

$$V(2) = P_k Q_{k2} - P_{b1} Q_{k2} + C_{k2} + C_{r2}$$

$V(3) = P_m Q_{m2} - P_{b2} Q_{m2} + C_{m3} + C_{r3}$

Mode 2. 2 operate by oneself, 1, 3 cooperate with each other, namely {1,3},{2}. In this opinion, Union may establish. It is the same with Mode 3 and Mode 4.

Mode 5. 1,2,3cooperate with each other, namely{1， 2， 3}, establishing league union.

$$Y(1,2,3) = P_k(Q_{k1} + Q_{k2}) + P_m(Q_{m1} + Q_{m2})$$
$$= P_k Q_{k1} + P_m Q_{m1} + P_k Q_{k2} + P_m Q_{m2}$$

$C(1,2,3) =$

$P_c(Q_{k1} + Q_{m1} + Q_{k2} + Q_{m2}) + C_{k1} + C_{m1} + C_{rm} + C_{rk} + C_{k2} + C_{r2} + C_{m3} + C_{r3})$

$$V(1,2,3) = (P_k Q_{k1} + P_m Q_{m1} + P_k Q_{k2} + P_m Q_{m2}) -$$
$$(P_c(Q_{k1} + Q_{m1} + Q_{k2} + Q_{m2}) + C_{k1} + C_{m1} + C_{rm} +$$
$$C_{rk} + C_{k2} + C_{r2} + C_{m3} + C_{r3})$$
$$\Delta V_{5a} = V(1,2,3) - \big(V(1,2) + V(3)\big) = \Delta C_{em} + \Delta C_{q5} > 0$$
$$\Delta V_{5b} = V(1,2,3) - \big(V(1,3) + V(2)\big) > 0$$
$$\Delta V_{5c} = V(1,2,3) - \big(V(2,3) + V(1)\big) > 0$$

Through the model test, researcher can get Mode 5 is one of the best cooperation mode.

Shapley Value Method in Profit Distribution. Shapley value of (N,v) will distribute benefit v(N) according to Eq.4:

$$\emptyset_i(v) = \sum_{S \subseteq S_i} \frac{(n-|s|)!(|s|-1)!}{n!} (v(S) - v(S \backslash i)) \quad (4)$$

In this equation, $v(\emptyset) = 0$, $w(|s|) = \frac{(n-|s|)!(|s|-1)!}{n!}$ can be taken as the weighting factor, S_i is the subset of all contains members of N collection, |s| is the number of elements in subset S.

Conclusions. This paper discuss five kinds of electric vehicle charging market operation mode, using Shapley value method to calculate the charging market profit distribution situation of the parties. Results and conclusions are as follows:

League Alliance. Power grid companies, gas stations and parking lots will be participating at the same time in the market, when the tripartite cooperation, alliance assembly will be greatly reduced, and the enthusiasm is higher. Establishing the operation mode is the most appropriate.

Necessity of Cooperation. Shapley value method is used to undertake three parties profit allocation, further verifying the necessity of the big leagues.

Additional Recommendations. When the participants actual profits is inconsistent with Shapley value distribution, government can adjust the price participants purchase electric power. If the expected income gap is still big, government should subside to solve the problem.

Keywords: Solar Generation; Power Grid; Power Fluctuation; Solar Utilization Factor; Solar Electricity Share

Abstract. The climate change and the shortage of energy have made the solar energy as the priority renewable energy in many countries, and solar energy is under the fast development. Since the solar energy has the intrinsic intermittence and fluctuation, its integration into the power grid will lead to the power fluctuations. The paper proposes a method of deploying the photovoltaic generation which is the main solar generation technology in China to meet the load demand in order to reduce the storage investment. The analysis shows that there is a strong correlation between daytime solar generation fluctuations and grid load fluctuations, and it is able to use solar plant instead of some peek-load regulating generator units. Therefore, solar generation technology also has great potential of integration ability even without the use of energy storage, and the purpose of solar generation is to increase the share of solar electriciy at the lowest unit cost rather than to guarantee 100% utilization factor.

Introduction

The climate change and the shortage of energy have made the solar energy as one of the promising renewable energy resources in many countries. Solar energy does not require fuel costs and can be used in any sunshine place. At present, solar generation mainly includes two technologies: photovoltaic generation and solar thermal power generation. Photovoltaic generation technology has been used worldwide popularly, and currently there are more than 200,000,000 running solar cell matrixes [1]. Solar thermal power generation is an important project for the use of solar energy by heating the fluid to drive the steam or warm air turbine, and it can be broadly divided into three categories: concentrating solar power systems, solar pond technology and solar chimney power generation [2-4]. Compared with the photovoltaic generation, solar thermal power generation has lower investment costs but has not yet implemented wide commercial applications.

Nowadays, solar energy industry is under the fast development. In China, the large-scale solar power plants which use photovoltaic technology have been built and connected to the power grid. Since the solar energy has the intrinsic intermittence and fluctuation, its integration into the power grid will lead to the power fluctuations. The traditional grid is designed for the centralized production, dispatch and distribution of electricity. When the share of solar energy is small, the traditional generation can compensate the power fluctuation of the solar generation by itself. However, with the increase in the share of solar generation, the power fluctuation may go beyond the adjusting limitation, adding difficulties to the system operation and making the integration of solar energy limited.

Thus to the grid, the crucial issue of solar energy integration is to maintain the balance between the generation and the demand. The solar power and the grid demand are all fluctuating and they add the complexity of the grid planning and operating [5, 6]. The objective of solar energy is to maintain the power balance with an acceptable cost and maximize the utilization of the solar energy. Based on the correlation between the solar irradiation and the grid load fluctuations, the paper proposes a method of deploying the photovoltaic generation which is the main solar generation technology in China to meet the load demand in order to reduce the storage investment. It is proved that the share of solar electricity can increase remarkably by reducing the solar utilization rate slightly while keeping the cost stable.

Power grid load and supply configuration

The main task of grid scheduling is scheduling generators to meet changes in the load demand. Normally, the grid load can be decomposed into two parts of fixed component (base load) and changed component (peak load). Seen from the load structure, part of the base load demand is from the continuous operation of electrical equipment, and the rest is from the intermittent load. When the intermittent loads are demanded at different times, it will smooth the overall load fluctuations. However, the overall fluctuations will increase when the intermittent loads with certain synchronicity which related to the season, the weather, the daily routine and habits. In some power grids, the daytime maximum load demand is about 40%~70% higher than the demand at night, and the average daytime demand in summer is about 30% higher than the daytime demand in winter. Since the load volatility exists in the grid, the grid requires peek-load regulating generator units else to meet the load demand in real time except the stable base generator units. Base generator units usually include nuclear power plants, coal-fired power plants and some large gas-fired power plants which have the relatively low cost of power generation and stable operation throughout the year. In contrast with the base generator unit, the peak-load regulating generator units only start in the case of meeting the load fluctuations with short and random running time in minutes or few hours. Obviously, the base units have higher utilization of equipment than the peek-load regulating units. Although the base units provide the most power required by the grid, it is often about 50% of the total installed capacity in the grid to meet load fluctuations.

For the characteristics of power grid mentioned as above and the actual situation of solar generation in China, the paper argues that solar generation has a great potential of supplying peak power to the grid. The solar plants can take the place of peek-load generator units for the reasons as follow:

1) Compared with the base generator units, the solar generation has higher Levelized Energy Costs (LECs) which are closer to those of peek-load regulating generator units;

2) Since the daytime load is always higher than the load at night, the peek-load regulating generator units most operate in the day, and the solar generation just conforms to this characteristic.

The characteristics of solar generation

With the movement of the sun in a day, the received radiation power of solar plant related directly to the solar electricity also constantly changes, as shown in Fig. 1. Different day conditions have a direct impact on the cost of solar generation. Besides, purchase of equipment, conversion efficiency and useful time must be considered to estimate the cost [7, 8]. The better day conditions, the higher conversion efficiency and the longer useful time can reduce the unit cost of solar generation.

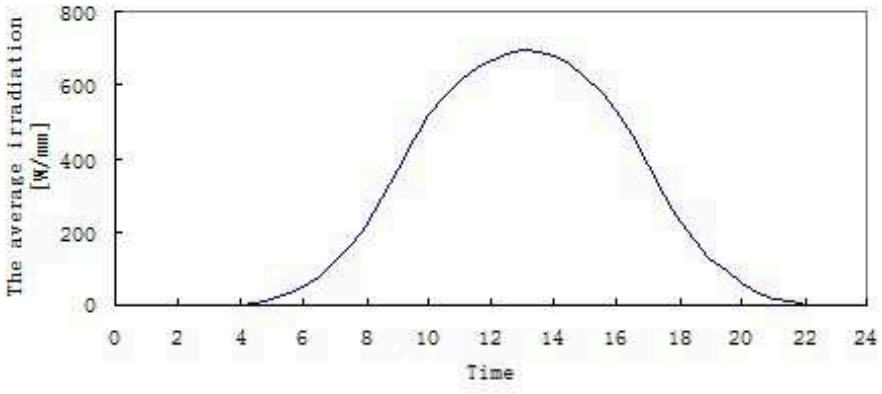

Fig.1 The diurnal irradiation curve

Analysis and discussion

In the paper, the hourly load data of a regional grid and the local annual solar radiation are used to calculate the grid acceptance of solar generation, and to analyze the relationship among utilization factor, solar electricity share and unit cost with the increase in capacity of solar generation.

Daily load curve of the grid has seasonal differences, as shown in Fig.2 [9]. According to the data curves in Fig.1 and Fig.2, it is obvious that the visible grid load fluctuations and solar generation have a significant correlation which is conductive to solar energy integration into the power grid. Basically, the increase or decrease in the load is the same as solar power generation in a day, especially from 12:00 to 14:00 which is the period of the maximum load coinciding with the maximum solar electricity. Similarly, the grid load in summer is higher than the load in winter, and the solar utilization factor is also higher than the utilization factor in winter. The consistency of curves is just to meet the needs of the peek-load regulating.

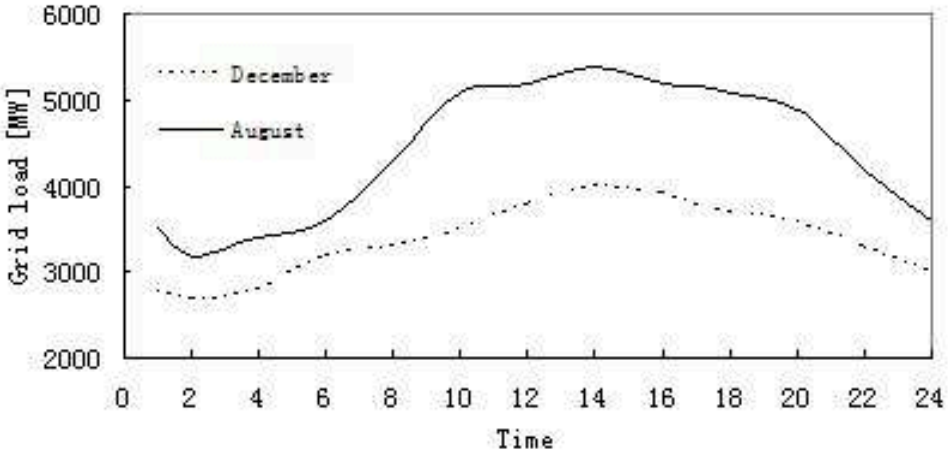

Fig.2 The average grid load curve

The paper defines the solar utilization factor is the ratio of solar power to the grid and maximum solar power, and the solar electricity share is the ratio of solar power to the grid and grid load. In theory, it can be found out directly that solar unit cost will reduce with the improvement of solar utilization factor, but the relationship between solar electricity share and utilization factor is not clear. Fig.3 shows the simulation results that the grid is able to accept all solar generation power when solar electricity share is lower than 2.5%. With the increased installed capacity of solar generation, the power grid starts to abandon the solar generation power and the unit cost of solar electricity rises.

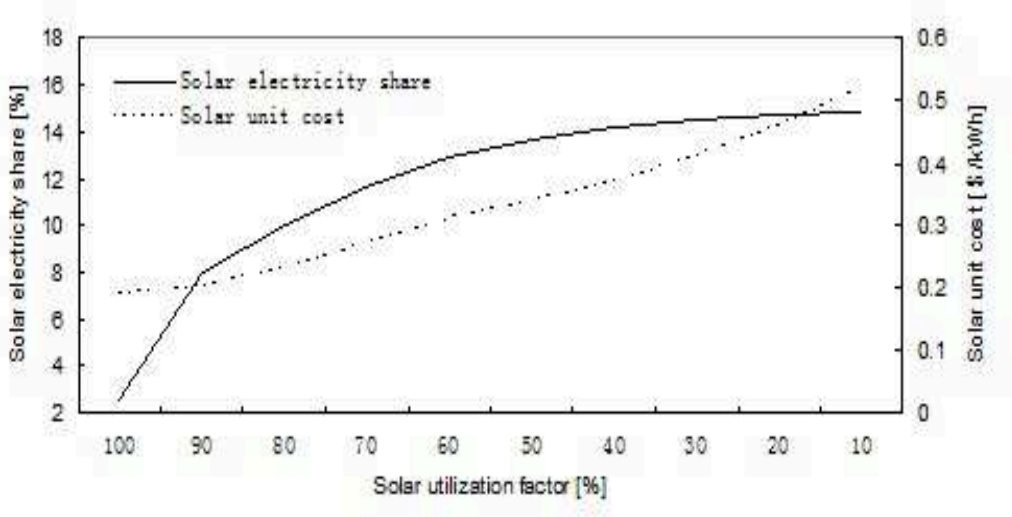

Fig.3 The relationship among utilization factor, solar electricity share and unit cost

It is worth noting that, when the utilization factor decreases from 100% to 90%, the unit cost increases from 0.19$/kW·h to 0.20$/kW·h. At this stage, the unit cost basically does not change, while the share of solar electricity is accounted for 2.5% to 8% with an increase by 220% which means better effective use of renewable energy. By increasing solar installed capacity continuously, the unit cost continues to increase, but the increase in the share of solar electricity is significantly weakened.

Conclusions

Based on the analysis in the paper, there is a strong correlation between daytime solar generation fluctuations and grid load fluctuations, and it is able to use solar plant instead of some peek-load regulating generator units. Therefore, solar generation technology also has great potential of integration ability even without the use of energy storage. Simulation results show that the utilization factor decreases from 100% to 90%, as well as the unit cost increases to 0.20$/kW·h from 0.19$/kW·h. At this stage, the unit cost basically does not change, while the share of solar electricity is accounted for 2.5% to 8% with an increase by 220%. It means the purpose of solar generation is to increase the share of solar electricity at the lowest unit cost rather than to guarantee 100% utilization factor.

Keywords: dose equivalent I-131; fission product; primary coolant source term; release source term;

Abstract. The problems occurring in the fission product source term calculations for M310/CPR1000, EPR and AP1000 are briefly analyzed, based on the related regulations and standards, as well as operational feedback, review experiences and recent research achievements for nuclear power plants in China. The framework of fission product source term proper to China has been first studied and proposed in perspective of the purpose of source terms. The calculation processes of fission product source term are rearranged and the requirements for deferent reactor types are specified. The proposed framework can be taken as a foundation for solution of the long-standing problems in the calculation of fission product source term and provide reference for source term calculation.

Introduction

The reactor types of nuclear power plants (NPPs) that will be constructed in China mainly include CPR1000, EPR and AP1000. The CPR1000 originated from the M310, which are GWe-level NPP introduced from French, while EPR and AP1000 are advanced Generation-Ⅲ NPPs, with the power output of 1.75GWe and 1.25GWe, respectively. The designs of these three reactor types have evolved for several decades and the safety, reliability and economy have been enhanced greatly. Although some improvements have been made in their source term calculation, problems still exist which would lead to the incoherence between the designs and realistic operation, influence the radioactive waste minimization, release optimization and environmental impact assessment, and even limit the development of the nuclear power industry.

The problems occurring in the fission product source term estimations for M310/CPR1000, EPR and AP1000 are briefly analyzed, based on the related regulations and standards, as well as operational feedback, review experiences and recent research achievements for nuclear power plants in China. The calculation framework of fission product source term proper to China has been firstly studied and proposed in perspective of the purpose of source terms. The calculation processes of fission product source term are rearranged and the requirements for deferent reactor types are specified. The proposed calculation framework can be taken as a foundation for solution of the long-standing problems in the calculation of fission product source term and provide reference for source term calculation.

The problems existing in the fission product source term calculations

Introduction of the fission product source term

The source terms for NPPs under normal operation include the radwaste management source term (RMST) and the radiation shielding design source term. The former is mainly used for environmental impact assessment while the latter is used for radiation protection management. The RMST can be divided as core inventories, primary coolant source terms and release source terms following the calculating processes, and be divided as fission products, activated corrosion products, tritium and carbon-14, according to their origins.

Radioactive materials are generated from the fission of heavy nuclides and the activation of corrosion products within the core. The information such as the total activities and concentrations of the fluid in various systems and effluent, as well as the concentration of solid waste during the normal operation should be precisely estimated for radiation protection management, radwaste management, environmental impact assessment and environmental monitoring.

The fission products in pressed water reactors (PWR) are generated within the fuel, its source term is named as core inventories. A small part of the fission products are transferred into the primary coolant during the normal operation and then transported to the other systems. The majority of these nuclides are finally solidified into the solid wastes, with a tiny amount released into the environment by the means of gaseous and liquid effluent. Therefore, the fission product source terms includes the core inventories, primary coolant source term, gaseous and liquid effluent source term, among which the core inventories are the origin, the second one is used for radwaste management and radiation protection management, and the last one aimed for effluent discharge control, environmental impact assessment and monitoring.

The primary coolant source term consists of activated corrosion products, tritium, and carbon-14 besides the fission products. The fission product source term in the primary coolant is influenced by several factors, such as the fuel defect rate, escape rate coefficient etc. It can be lowered by updating the core design and improving fuel cladding materials so as to reduce the fuel defects. Tritium is chiefly produced by the ternary fission of uranium and the neutron activation of boron, lithium and deuterium. The principal ways of carbon-14 production are neutron reaction with oxygen-17, nitrogen-14 and carbon-13. This article is focusing on the calculation framework of fission product source term.

The Problems in Fission Product Source Term for M310/CRP1000

The source terms of M310, provided by Electricite De France (EDF) in 1980s, generally reflected the operation level and design requirements at that time, which was rational as it met the regulations and standards then.

The realistic and conservative primary coolant source terms have been provided by M310, which are calculated employing PROFIP code. The calculation of realistic source term is based on 0.55GBq/t dose equivalent I-131, which is the average concentration of iodine activity at the end of the cycle of nearly 200 unit·years (except the 2^{nd} and 8^{th} cycles of Bugey unit 2) of 900MW French PWRs in 1980s. The conservative source, which assumes 0.25% fuel defects and is normalized to 37GBq/t dose equivalent I-131, is consistent with the technical specification limits.

The term dose equivalent I-131 is the concentration of I-131that alone would produce the same thyroid dose as the quantity and isotopic mixture of I-131, I-132, I-133, I-134, andI-135 actually present.

Two release source terms of M310, case A and case B, are based on different assumptions of the concentration of primary coolant radionuclide. In Case A, the dose equivalent I-131 in the primary coolant is assumed to be 0.55GBq/t during the whole cycle, while for the case B, a mixture of 0.55 GBq/t for the initial 1/4 cycle, 4.44 GBq/t for the intermediate 1/2 cycle and 37 GBq/t for the last 1/4 cycle is assumed, the average of which is 11.6GBq/t. These two sources are calculated using the REJGAS and REJLIQ code developed by EDF.

Several problems have been found in the subsequent CPR1000 design and review[1]. For example, there is no scientific basis for the calculation method of the technical specification source term, including the parameters used to describe the nuclide transportation from the fuel to the coolant and the combination used in the primary coolant source calculation. And the assumptions of the source calculation are on controversial as well. Therefore, the issues of source terms were listed as the common problems in the M310 review in 2008. Plenty of investigations on the rate and size of fuel failure, the sensitivity analysis on the defects distribution, the contribution of the uranium contamination on the cladding surface and differences of the core inventories given by ORIGEN-S and PROFIP5.1 were launched since then. The method for calculating the technical specification of primary coolant source term has been determined based on the present research achievements.

However, the basic assumptions of the primary coolant activity in the release source terms calculation for case A and case B still have not reached consensus.

In spite of the recalculation of the radwaste management source term for the newly constructed CPR1000 such as Hongyanhe NPP[2], has been done, its design ideas and calculation processes are generally the same with that of M310. Consequently it inherits the source problems from M310.

The recent feedback from NPPs shows that the fuel defects under normal operation has been dramatically reduced profiting from the improvement of the core design, fuel design and fabrication, and the dose equivalent I-131 in primary coolant is thus significantly lower than the value in 1980s. Therefore, the basic assumption of 0.55GBq/t dose equivalent I-131 in Case A seems too conservative. Thus, the fission product source would be overestimated while the corrosion product source be under-evaluated. On the other hand, the combination of three different dose equivalent I-131 values for Case B has not been justified. The recently revised national standards, GB6249-2011 and GB14587-2011, provide the discharge limits of radionuclide activities at the outlet (1000Bq/L for coastal NPPs while 100Bq/L for inland NPPs) and bring stricter requirements on the design of liquid waste systems and the calculation of release source term.

The irrational basic assumptions of the release source term affect the veracity of the estimation and corrupt the rationality of environmental impact assessment source term. It would also cause the incoherence between the designs and realistic operations, and interfere the optimization of the emission application and pertinence of the environmental impact assessment. The determination of environmental impact assessment source term is still controversial. For example, the Case A+Case B or 2Case B model are widely accepted in the environmental impact assessment during the stages of sitting, designing and first fuel loading for double units site while various combinations of case A and case B are used for multi units site. The source term used for critical nuclide, group, and exposure pathway analyses is not unified yet. All these problems are related with the irrational basic assumptions and the indistinct destination of release source terms.

The Problems in Fission Product Source Term for EPR

The EPR is designed following the European utility requirement document and based on the French N4 series and the German KONVOI plants and meets. Three sets of source terms for the primary coolant have been provided: realistic, design and technical specification source term[3], of which the last two are identical. Two suits of release source terms, expected source and the maximum source are provided for EPR.

The realistic source term for primary coolant, based on total 244 unit·years operational experience feedback of 1300MW plants and N4 series in French, is estimated to about 0.2 GBq/t dose equivalent I-131. The fuel defect of 0.25% is assumed for the technical specification source term. In the calculation, the core inventories are established with the ORIGEN-S code, and the radionuclide concentrations in the primary coolant are estimated by considering the escape rate from the fuel defects, letdown flow, purification and radioactive decay. This source term is about 23GBq/t dose equivalent I-131and is the same with the design basis and shielding design source terms.

The release source term of EPR encompasses the experience feedback from the 1300MWe units in 8 operating French NPPs during 2001-2003, with the improvements of materials, coolant chemistry, radwaste system. The expected release source term represents the average values of the experience feedback, while the maximum one takes all situations under the normal operations (including the shutdown transients) into account. The emission data from 900MW, 1300MW and the N4 NPPs in Franch during 2001-2003 are provided by EDF to support the conservativity of the design release source term.

The EPR source terms are derived from the experience feedback, and the maximum release source term was used for environmental impact assessment during the stages of sitting, designing and first fuel loading. However, the issues such as the sufficiency of the data and the rationality of the radioactive measurements, data statistics and processes etc. became the focuses of the reviews and the investigations. Therefore, the theoretical calculation of the release source term is queried by the authorities to reconfirm its conservativity, and the issues of which were listed as the

construction permit conditions in the ongoing review of Taishan NPP primary safety analysis reports.

The Problems in Fission Product Source Term for AP1000

AP1000 is a Generation-Ⅲ reactor type designed by Westinghouse Electric Company LLC. It provides two sources for the primary coolant, including the realistic source term which is 3.0 GBq/t dose equivalent I-131 approximately and the conservative, or design basis, source term which is about 37GBq/t dose equivalent I-131[4]. The latter assumes 0.25% fuel defects and employs ORIGEN-S code in the calculation.

Only one release source, called operational release source term, is provided by AP1000. It is calculated using the PWR-GALE code[5] based on the basis of realistic source term in primary coolant, thus it is not related with the technical specifications. The realistic source term for the primary coolant is determined by applying the reference plant values, which is derived from the data obtained from the experience of 26 units in 20 operating US PWRs such as H.B, Rohbinson, Arkansas, D. C. Cook etc. during 1971-1979, and the adjustment factors provided in ANSI-18.1-1984[6].

Although this source has been used for environmental impact assessment, site capacity assessment, and critical nuclide, group, and exposure pathway analyses during the stages of sitting, designing and first fuel loading, it has not been authorized by the reviewer yet because of its low conservativity for a design basis release source term. The Westinghouse compared the calculated effluent concentrations in the case of 0.25% fuel defects with it to justify that the effluent release satisfies the appendix B of 10CFR20[7], implying that it was not been regarded as a conservative source. On the other hand, this source is too stringent to be the realistic release source term. The reference data collected about four decades ago are out of date to a certain extent to effectively guide the design and operation management of nowadays NPPs, because the fuel defect rate has been significantly lowered since 1970s with the development of nuclear industry, profiting from the improvement of the levels of core design, fuel design and manufacture and operation management.

In the situation that the problems in AP1000 source terms have not been resolved and the applicability of different versions of ANSI/ANS-18.1 continues to be controversial, they were put on the list of construction permit conditions in the ongoing review of Sanmen and Haiyang NPP primary safety analysis reports.

Study on the Framework of Fission Product Source Term

As analyzed above, problems still exist in the fission product source term calculations for the three reactor types. For example, the design requirements and purpose of the release source term are not clear, and the assumptions about the primary coolant are irrational as well. Based on the national codes and standards and operational experiences from both domestic and international NPPs, this article dedicates to resolve the existing problems in source estimation, rationalize the calculation processes, normalize the calculation method for different reactor types and finally establish a calculation framework of fission product source term for Chinese NPPs, which will lay the foundation for the formulation of the standard review plan of radwaste management source term.

The Requirements of the Codes and Standards

As shown in Table-1, the main authorities referenced in the radwaste management source design and the safety analysis report reviews of Chinese NPPs, GB6249-2011 and GB14587-2011 give the discharge control values of gaseous and liquid effluent for a single unit and for the whole site, the radioactivity concentration limits of liquid effluent except H-3 and C-14 and the requirements of release management as well. However, the calculation method of design release source term is not involved. The design requirements and calculation methods are prescribed in ANSI/ANS-18.1-1984, NUREG-0017(Rev.1985) and GB13976-2008, which referenced the first two, but they are not applicable for M310/CPR1000 and EPR types. For Ap1000, although these

standards are principally appropriate, the disputes on the applicability of the two different versions of ANSI/ANS-18.1, 1984 and 1999, are not ended yet notwithstanding their principal appropriation.

In respect that the standards guiding the radwaste management source calculations are not consummate and systematic yet, the problems existed in the source terms for the three reactor types have not been resolved. The diversity of the reactor types in China, and accordingly of the calculation methods, increases the difficulty of standards setting. The standard review plan is presently in preparation and it will be helpful to resolve the problems.

Table-1 Requirements of the relative standards.

Serial Number	Title	Main requirements
GB6249-2011	Regulations for environmental radiation protection of nuclear power plant	● Provides the concentration limits of radionuclide in liquid effluents, except H-3 and C-14; ● Provides the control values of gaseous and liquid effluents discharge quantity; ● The personal equivalent dose for public caused by the radioactive materials emitted from all nuclear power reactors in the site should be less than 0.25mSv/a.
GB14587-2011	Technical requirements for discharge of radioactive liquid effluents from nuclear power plant	● Environmental impact assessment should be made according to the design discharge quantity of the reference plant at the stage of siting, and principally design value and applied value of discharge quantity at the stages of designing and first fuel loading, respectively; ● Provides the concentration limits of radionuclide in the liquid effluents, except H-3 and C-14.
GB13976-2008	Radioactive source term of PWR nuclear power plant for operational states	● Provides the requirements of release source term for normally operational NPPs; ● This standard mainly referenced ANSI/ANS-18.1-1984 and NUREG-0017(Rev.1985).
SRP11	NRC Standard review plan，Chapter11	● Radioactive effluents discharge of NPPs should meet the principle of ALARA; ● Other requirements in the standard are the same with ANSI/ANS-18.1-1984 and NUREG-0017(Rev.1985).

Operational Data of Primary Coolant Activities

As the primary coolant source terms are the basic assumption and initial condition for the release source term calculation, the collection and analysis of relative operational data, which is a very tough task, are crucial for the primary coolant source term optimization. A mass of relative investigations were carried out in recent years. The collected data of dose equivalent I-131 in primary coolant from some French, American and Chinese NPPs is listed in Table-2.

It is obviously shown that the fuel defects were continuously reducing due to the improvement of the core design, fuel design and fabrication, which caused the dose equivalent I-131 a trend of decline. The average value of French and Chinese NPPs in recent twenty years is less than 0.1GBq/t, and the maximum of French NPPs is 4.44 GBq/t.

Table 2 Collected data of dose equivalent I-131 in primary coolant

State	Dose equivalent I-131 [GBq/t]	Time	Notes
China	0.06	2000s	The average value of 23 cycles of Daya Bay Nuclear Power Base (including the cycles with fuel defects)[8]
France	0.07	1990s-2000s	The average value of 44 unit·years data from the French N4 series (including the cycles with fuel defects)
	0.10	1990s	The average value of 200 unit·years data from 1300MW NPPs in French (including the cycles with fuel defects)
	0.55	1980s	The average value of 200 unit·years data from French NPPs (including the cycles with fuel defects)
	4.44	1980s	The maximum value of the data from 900MW NPPs in French (the cycle with fuel defects)
USA	0.36	1980s-1990s	The average value of the data from American NPPs (including the cycles with fuel defects)
	3.0	1970s	The average value of the data from American NPPs (including the cycles with fuel defects)
China	0.55	/	The realistic source term of the primary coolant for M310/CPR1000
France	0.2	/	The realistic source term of the primary coolant for EPR
USA	3.0	/	The realistic source term of the primary coolant for AP1000

To estimate the expectation and the maximum of risk caused to the public, the basic assumptions of realistic source terms should be realistic, while that of conservative source terms moderately conservative. Taking M310/CRP1000 as an example, 0.1GBq/t dose equivalent I-131 in the primary coolant will be a rational assumption for the realistic release source term, while the present used assumption, 0.55GBq/t, is a bit conservative and affects the radiation shielding optimization and the radwaste minimization. According to the technical specification, the reactor should be shutdown in two months if the average dose equivalent I-131 is more than 2.2GBq/t, and it should be shutdown in 6hours if the transient value exceeds 37GBq/t. Therefore, the basic assumption of 5GBq/t is more rational than the present used 11.6GBq/t, which is over-conservative.

The fuel defects mainly depend on the fuel design and the cladding materials, whereas have little relations with the reactor type. Since the cladding materials of all the three types are Zr-Nb alloy and the improvements on the fuel design are similar, the basic assumption of the primary coolant source term for M310/CPR1000 are valuable reference for EPR and AP1000.

Framework of Fission Product Source Term

The framework of fission product source term calculation, encompassing a considerable amount of investigation achievements, is demonstrated in Figure1. It is oriented to the purposes of release source term estimation, and combines the experience feedback with theoretical calculation.

The design of the radiation shielding and radwaste management should meet the requirements of normal operation (including the anticipated operational occurrences), and the radwaste minimization and radiation shielding optimization are closely related with the practical operations. Therefore, the source terms are divided into two sets: design basis and realistic.

It is clarified in the framework that the limits of the technical specification (such as 37GBq/t dose equivalent for M310/CPR1000) make the boundary between the normal operations and

accidents, the radiation shielding and the radwaste management under normal operation are considered within the range under the limits, and the parameters describing the rate and the size of fuel defects are used as a part of the basic assumptions of the calculation. The clarification of the basic assumptions of design basis source term will definitely benefit the normalization of the design of radiation shielding and radwaste management.

The design requirements and purposes of the release source term for the three reactor types are specified in the framework. Three sets of release source terms, including design basis, operational and realistic, are required so as to accurately evaluate and monitor the public risks. These sources also contribute to assess the feasibility of the sitting and program the effluent monitoring and environmental monitoring.

The issue of the irrational assumptions in the release source term calculations has also been resolved within the framework. The dose equivalent I-131 in primary coolant of the realistic and the design basis release sources are assumed to 0.1GBq/t and 5GBq/t, respectively, and that of operational release source can be deduced on the basis of the optimization of the latter.

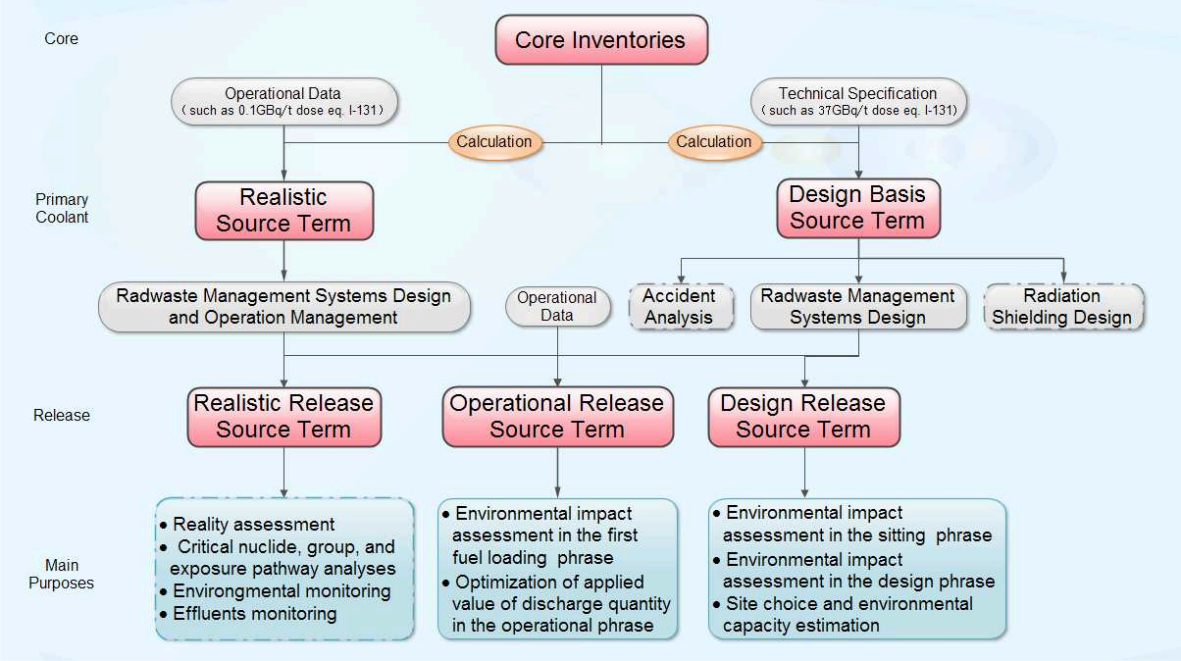

Figure1. The framework of fission product source termfor NPPs

This framework is applicable to the fission product source term calculations for CPR1000, EPR and AP1000, and can be referenced for WWER, HTGR and HWR as well. The basic ideas of the framework can not only guide the source estimation of fission products, but also be used for activated corrosion products, tritium and carbon-14.

Being a part of the complicated works of product source term calculations, this article is focusing on the construction of the framework and the formulation of the processes. Further investigations are needed on the calculation methods, basic assumptions and parameters used in the source estimation for different reactor types.

Conclusions and Suggestions

The problems in the fission product source terms for M310/CPR1000, EPR and AP1000 are analyzed,based on the codes and standards, operational feedback, review experiences and research achievements. The framework, which is applicable to the fission product source term calculation for Chinese NPPs, is established for the first time, oriented to the purposes of these sources. It provides the processes and requirements of product source term estimation, and lays the foundation for resolving the relative existing problems, and can be referenced in future calculations.

The primary coolant source terms include the design basis source and realistic source, as shown in Figure1. It is clarified in the framework that the limits of the technical specification make the boundary between the normal operations and accidents, the radiation shielding and the radwaste

management under normal operation are considered within the range under the limits, and the parameters such as the rate and the size of fuel defects are used as a part of the basic assumptions of calculation. The clarification of the basic assumptions of design basis source term will definitely benefit the normalization of the design of radiation shielding and radwaste management.

Three sets of release source terms, including design basis, operational and realistic, are required according to the framework so as to accuratelyevaluate and monitor the maximum and the realistic public risks. These sources also contribute to assess the feasibility of the sitting and program the effluent monitoring and environmental monitoring.

It is suggested thatdomestic NPPs accumulate data to support the source term estimations. Further investigations on the calculation methods and recalculations of sources for the NPPs, including newly constructed, on-building and operational ones, should be made as soon as possible to lay the foundation for the radiation shielding design, radwaste management, environmental impact assessment and environmental monitoring of NPPs under normal operation.

Keywords: power system, simulation model, error evaluation, index classification

Abstract. The integrity, objectivity and science of the evaluation index system will be directly related to the accuracy of the evaluation results. However, studies on the quantitative assessment of the effectiveness of the simulation model are not still perfect, comprehensive, and links between relevant literatures are not close enough. The main thing is the lack of systematic summary of the theoretical literatures. Therefore, this paper is summarized in three aspects, the research results, indices classification and their respective advantages and disadvantages, the applicable range of indicators.

Introduction

Power system dynamic simulation plays an increasingly important role in the operation of the system, the credibility of the simulation results directly affect security and economy of system operation [1]. Improving the credibility of the dynamic simulation is only based on ensuring the effectiveness of the model and the parameters involved in the simulation [2], with the increasing complexity of modeling and simulation, the validity and reliability of the simulation model are paid more and more attention.

Currently, there are a number of domestic and foreign literatures for the quantitative assessment of the simulation model error indicators conducted in-depth study [3], and achieved certain results. In [4], it marks the arrival of an accurate simulation of the times, which is a landmark article. In [5], in order to find error sources and validate effectiveness of the model, measurement data based on WAMS (wide-area measurement system) were used to simulate the grid block. But the number of components in each sub-block is still large, how to further confirm the validity of the model is still difficult. In [6], the method of spectral analysis were used to verify simulation model validation, but spectral estimation, which need zero mean and smooth processing for sequence, changed the original information of the timing, and the problem of the algorithm‘s order was not solved. In [7], the frequency, damping, energy and other characteristics were extracted by Prony transformation method. In [8], the similarity principle, which calculated numerical similarity of measurement and simulation sequence, was exploited to quantitatively analyze simulation accuracy. In [9], a method of evaluating the model effectiveness considering the numerical similarity and the shape similarity was proposed, this method applied specification coefficient method, landmark boundary method and correlation analysis to calculate shape similarity. In [10], the types of residual analysis and Theil coefficient were introduced in detail, a dynamic simulation method based on residual analysis for the load model was proposed. In [11], a simulation evaluation method based on fuzzy analytic hierarchy process was raised, and error sources backtracking theory based on PMU measurement data block was proposed. In [12], in order to make a quantitative assessment of the confidence level for simulation system, the system identification method combining similarity was used to measure the similarity between actual model and simulation model.

As can be seen from the above literature review, studies on the accuracy of the power system simulation model are mostly in its infancy. The relevant literatures are very little, mostly confined to a detail study, or lacked a solid theoretical foundation.

Classification of Error Indices

At present, there is no systematic theory specifically for dynamic simulation model error within the power discipline [13]. But from the literature review, some experts use some error methods in dealing with the specific research topic, Integrated into two types: qualitative analysis and quantitative analysis.

The qualitative error indicators include mainly visual and graphic error method etc [14]. Qualitative indicators errors under certain circumstances, is intuitive and effective, but it is largely constrained by the subjective will of the analysts, and it is difficult to accurately assess the accuracy of the model, so there is no more introduced in detail.

Currently, researches on the quantitative error evaluation method are mainly concentrated in the numerical analysis, eigenvalue analysis, correlation-based analysis and pattern recognition analysis [15]. In this paper, take the generator model as an example, according to mechanism and application of several quantitative analyses, error indicators are classified, summarized in Table 1.

Table 1 List of several error indicators

Indices Type Name	Indices name		Objective function	Advantages and disadvantages
Numerical Indices	Residual analysis	Error sum of squares (SSE)	$\mathrm{SSE}=\sum_{i=1}^{n} w_i(y_i-\hat{y}_i)^2$	Numeric indices method: simple, easy to calculate, ignoring the parallel drift, noise and other factors, not effectively reflect the dynamic characteristics of time sequence [16]; AE and MSE: reflect the average error; SSE: absolute error accumulation, high requirements for sampling points; REE: true and reliable results, physical information-rich, strong guidance.
		Mean absolute error (MAE)	$\mathrm{MAE}=\frac{1}{n}\sum_{i=1}^{n}\lvert y_i-\hat{y}_i\rvert$	
		Mean square error (MSE)	$\mathrm{MSE}=\frac{1}{n}\sqrt{\sum_{i=1}^{n}(y_i-\hat{y}_i)^2}$	
		Mean absolute percentage error (MAPE)	$\mathrm{MAPE}=\frac{1}{n}\sum_{i=1}^{n}\left\lvert\frac{y_i-\hat{y}_i}{y_i}\right\rvert$	
		Mean square percentage error (MSPE)	$\mathrm{MSPE}=\frac{1}{n}\sqrt{\sum_{i=1}^{n}(\frac{y_i-\hat{y}_i}{y_i})^2}$	
		Average error(AE)	$\mathrm{AE}=\frac{1}{4}(\mathrm{MAE}+\mathrm{MSE}+\mathrm{MAPE}+\mathrm{MSPE})$	
	Ratio of error energy(REE)		$\mathrm{REE}=\frac{\sum_{i=1}^{n}(y_s(i)-y_m(i))^2}{\sum_{i=1}^{n}(y_m(i)-y_{stab})^2}$	
Eigenvalue Type Indices	Frequency similarity(FS)		$\varphi_t=\sum_{i=1}^{n_s}(\gamma_i\delta_i)$ Value close to 1 description error is smaller.	FS and DS can measure the dynamic variable mode [17]. Prony can give characteristic quantities of dynamic response variables in each oscillation mode, such as damping, frequency, amplitude, phase, and energy, etc. Sensitive to the noise signal, Must avoid the strong non-linear [18,19]. FSAE: Relative value form,
	Damping similarity(DS)		$\varphi_\zeta=\sum_{i=1}^{n_s}(\gamma_i\eta_i)$ Value close to 1 description error is smaller.	

	The first swing characteristic Indices	The first swing amplitude error (FSAE)	$FSAE = \frac{M_S - M_m}{M_m}$ Value close to 0 description error is smaller.	reflecting the impact of the size of the fault.
		The first swing error energy ratio (FSEE)	$FSEE = \frac{\sum_{i=1}^{n}(y_s(i) - y_m(i))^2}{\sum_{i=1}^{n}(y_m(i) - y_{stab})^2}$ The indices share similar physical meaning with REE	
Related Type Indices	Correlation coefficient shape similarity(CCSS)		$CCSS = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}}$ Value is larger, the higher the trajectory similarity	Correlation coefficien Can effectively measure the shape similarity of two time series [20]. DGI: Principle is simple, easy to master, easy to calculate, sort clear. TIC: Easing the requirements for data sequence does not require independence and normality.
	Degree of grey incidence(DGI)		$DGI = \frac{1}{n}\sum_{k=1}^{n}\gamma(x_0(k), x_i(k))$ If greater than the given values, that satisfy the accuracy requirements	
	Theil's inequality coefficients(TIC)		$TIC = \frac{\sqrt{\sum_{i=1}^{n}(y - \hat{y})^2}}{\sqrt{\sum_{i=1}^{n} y^2} + \sqrt{\sum_{i=1}^{n} \hat{y}^2}}$ Value close to 0 description error is smaller.	
Pattern Recognition Indices (PRI)	Statistical pattern recognition method(SPRM)		---	PRI can analyze complex signals and image, dependent samples and expert scoring, complex calculation process.
	Structural pattern recognition method(SPRM)			

The alphabet notes are as follows:

n: Dynamic response variable sampling points; $y_i, \hat{y}_i$: Sampled values of the measurement and simulation dynamic response variables at the i point; w_i: Weights; $y_s(i)$: simulation Variables; $y_m(i)$: Measurement Variables; y_{stab}: Measurement value of the variable before oscillation occur; n_3: The number of signal processing decomposition; $\gamma_i = \frac{\lambda_i'}{\sum_{j=1}^{n}\lambda_j'}$: Signal Weights ($\lambda_i'$: signal energy); $\delta_i = 1 - |\frac{f_{mi}' - f_{si}'}{f_{mi}'}|$: Frequency similarity ($f_{mi}'$、$f_{si}'$ frequency of measurement and simulation); $\eta_i = \begin{cases} 1 - \left|\frac{\zeta_{mi}' - \zeta_{si}'}{\zeta_{mi}'}\right| & \zeta_{si}' > 0 \\ 0 & \zeta_{mi}'\zeta_{si}' < 0 \end{cases}$: Damping similarity ($\zeta_{mi}'$、$\zeta_{si}'$: Damping of measurement and simulation Variables);

M_S: Measurement variable value of the first swing; M_m: Simulation variable value of the first swing.

The scope of application

The each method of above has its own merits. When selecting the error calculation methods, the selected indices must reflect the characteristics of dynamic variables, and can provide enough information to find the source of error.

Curves that represent the dynamic characteristics of the system include the swing curves, power curves and voltage curves in studies on the dynamic characteristics of the power system [21]. Those curves will be taken for example to illustrate the scope of the above several error indices' application in table 2.

Table 2: The scope of the above several error indices' application

Error evaluation indices		Swing curve	Power curve	Voltage curve
Numerical Indices	Error sum of squares(SSE)	✓	✓	✓
	Mean absolute error(MAE)	✓	✓	✓
	Mean square error(MSE)	✓	✓	✓
	Mean absolute percentage error(MAPE)	✓	✓	✓
	Mean square percentage error(MSPE)	✓	✓	✓
	Average error(AE)	✓	✓	✓
	Ratio of error energy(REE)	✓	✓	✓
Eigenvalue type Indices	Frequency similarity(FS)	✓	✓	×
	Damping similarity(DS)	✓	✓	×
	The first swing amplitude error(FSAE)	✓	✓	×
	The first swing error energy ratio(FSEE)	✓	✓	×
Related type indices	Correlation coefficient shape similarity(CCSS)	✓	✓	×
	Degree of grey incidence(DGI)	✓	✓	✓
	Theil's inequality coefficients(TIC)	✓	✓	✓
Pattern Recognition indices	Statistical pattern recognition method(SPRM)	✓	✓	✓
	Structural pattern recognition method(SPRM)	✓	✓	✓

Comment：✓: Applicable; ×: Inapplicable.

As can be seen from the table, most of the error indices in these three curves can all be used. The specific method of selecting the error indices should depend on the specific circumstances and information of elements.

Conclusion and Outlook

This paper have done a more detailed collate and summarize about studies on the error evaluation indices in the field of power system, divided error evaluation indices of simulation model into four categories, provided a method reference for the study on error evaluation, and had certain guiding significance for analyzing and selecting a different indices system.

Study on model error evaluation of power system dynamic simulation still need to dig deeper dynamic characteristics, and error evaluation indices that can reflect dynamics characteristics well should be put forward dynamic performance good to guide research.

Keywords: Sustained overvoltage; Power system restoration; Sensitivity and safety margin

Abstract. Changeable sensitivity and safety margin are proposed in this paper, which can avoid the voltage violation according to the operation of the current situation. A simulation test is presented to demonstrate the proposed method can decrease adjusting amounts and restoration time efficiently.

Introduction

In order to speed up the process of power system restoration (PSR), it's necessary to energy some high and extra-high voltage transmission lines during the early stages. Most of these transmission lines are unloaded or lightly loaded, which will cause sustained power frequency overvoltage because of the serious reactive power imbalance.

Reference [1] presented a simple and approximate approach for evaluating sustained and transient voltages, which can provide approximate solutions. Reference [2] presented sensitivity analysis and Efficiency Coefficients method to determine the most efficient control variables for the correction of voltage violations. Reference [3] compared PSR with normal system, applied expert system technique and nonlinear programming to provide the control scheme.

However, the methods mentioned above are static optimization without considering the whole process of PSR and global optimization. This paper takes sensitivity analysis and safety margin into consideration, adjusts the coefficient properly according to the PSR process, which can coordinate the voltage safety and the PSR time preferably.

Problem Formulation

Compared with the normal condition of power system, during the early stages of restoration, most of the control devices and loads are out of service. Adjusting these new control variables uses less time than readjusting those already in-service control variables, so these new control variables take the higher priority. It's preferable to find a solution which has less adjusting amounts of control variables and enough safety margin to cope with the subsequent operations.

Objective Function. The proposed object is to minimize the adjusting amounts of control variables and the voltage deviation, which can be formulated as follows

$$\min \ f = \sum_{i \in N} \left(V_i - 1.0\right)^2 + \sum_{j \in K} C_j \Delta u_j^{\ 2}, \tag{1}$$

where N is the number of bus; K is the number of control variables; V_i is the bus voltage; C_j is the coefficient decided by the reciprocal of sensitivity; Δu_j is the deviation of control variables.

Constraints. During PSR, the objective function is subjected to the power flow equations and the operating limits like voltage, power limits and device limits, which can be written as

$$\begin{aligned} &\mathrm{F}(u, x) = 0 \\ &\mathrm{G}(u, x) \le 0 \end{aligned}, \tag{2}$$

where x is bus voltage; u is control variable.

Sustained Overvoltage Control Strategy

Sensitivity Analysis Based on Adjoint Network Method[4]**.** The power flow equation can be expressed as

$$E_M^* Y_T V_M = S_M^*, \tag{3}$$

where E_M is a diagonal matrix with node voltage of each elements; Y_T is the nodal admittance matrix; V_M is the nodal voltage matrix ; S_M is the nodal injection power matrix.

The follow equation can be obtained from adjoint network,

$$\begin{bmatrix} K^T & (\overline{K}^*)^T \\ \overline{K}^T & (K^*)^T \end{bmatrix} \begin{bmatrix} \hat{\dot{V}} \\ \hat{\dot{V}}^* \end{bmatrix} = \begin{bmatrix} \hat{\mu} \\ \hat{\mu}^* \end{bmatrix}, \tag{4}$$

where $\hat{\mu} = \dfrac{\partial f}{\partial \dot{V}_M}$; $\hat{\dot{V}}$ is the adjoint voltage; K and $\overline{K}$ is decided by the type of node.

If defining $d = \delta S_M^* - \dot{E}_M^* \delta Y_T \dot{V}_M$, Where δS_M^* , δY_T are the first order change of S_M^* , Y_T , respectively, then the first order change of f can be expressed as

$$\delta f = [(\hat{\dot{V}})^T \quad (\hat{\dot{V}}^*)^T] \begin{bmatrix} d \\ d^* \end{bmatrix} + \delta f_P, \tag{5}$$

take the adjoint voltage into the above function can get the first order change of f and sensitivity.

The Value of Coefficient C. When sustained overvoltage occurred during PSR, adjusting the control variables according to the sensitivity can decrease the adjusting amounts efficiently. If the bus voltage is higher than safety limits, switching the control variables can lower the bus voltage level in the whole system, however it can also cause bigger deviation to the bus whose voltage is lower than safety limits, vice versa.

Suppose the voltage of bus *i* is the highest and greater than 1.0 p.u. , the voltage of bus *j* is the lowest and less than 1.0 p.u. ; the sensitivities of the voltage at bus *i* to the all control variables is S_i , where S_i={ $S_{n1,i}$, $S_{n2,i}$, … , $S_{nk,i}$ }, the sensitivities of the voltage at bus *j* to the all control variables is S_j , where S_j={ $S_{n1,j}$, $S_{n2,j}$,… , $S_{nk,j}$ }. Defining the sensitivities of all control variables to the system is S, where $S = S_i - S_j$, S={ S_{n1}, S_{n2}, … , S_{nk}}.

As mentioned above, switching unadjusted device uses less time than readjusting already switched device. If there are D control variables unadjusted under the present condition, the sensitivities of these variables is S_{new} = {S_{i1}, S_{i2}, … , S_{id} }, then it can be redefined as

$$S'_{id} = 10 * S_{max} * \frac{S_{id}}{S_{idmax}}, \tag{6}$$

where S_{max} is the max sensitivity of all control variables, S_{idmax} is the max sensitivity of unadjusted control variables.

Define C_i=1/ S'_{ni}, then C_i can have the similar function as unit adjustment cost used in optimal reactive power dispatch, which will get the minimum adjusting amounts.

During the PSR, if adjust the bus voltage according to the sensitivity of voltage alone, the bus voltage may stay near the safety limits. When restore next element, it is very likely to cause new voltage violation. So it's reasonable to adjust the control variables as less as possible, and meanwhile, leave appropriate safety margin to keep the voltage safe in the following steps.

Solving Method

PSO is adopted to solve this reactive/voltage control problem. The position of particle is corresponding to the control variables, including the voltage of generator bus, the tap position of reactive compensator and transformer, this paper only take the generator bus voltage and tap position of reactive compensator into consideration, so the x_{id} can be expressed as

$$x_{id} = [V_{G1}, ..., V_{GN_G}, Q_{C1}, ..., Q_{CN_C}]. \tag{7}$$

The position of each iteration is shown as follows

$$\begin{aligned} v_{id}^{k+1} &= \omega v_{id}^{k} + c_1 r_1 (p_{id}^{k} - x_{id}^{k}) + c_2 r_2 (p_{gd}^{k} - x_{id}^{k}) \\ x_{id}^{k+1} &= x_{id}^{k} + v_{id}^{k+1} \end{aligned}, \quad (8)$$

where ω is the weight; v_{id} is velocity of particle; c_1 and c_2 are positive constants; r_1 and r_2 are random numbers between [0,1]; p_{id} and p_{gd} are the best position of individual and particle swarm, respectively.

Simulation Study

IEEE 39-bus system is used to evaluate the proposed model, as shown in Fig1, where including ten generators, and four reactive compensators at bus 2,13,22,26, the capacity is 6*-0.2 respectively.

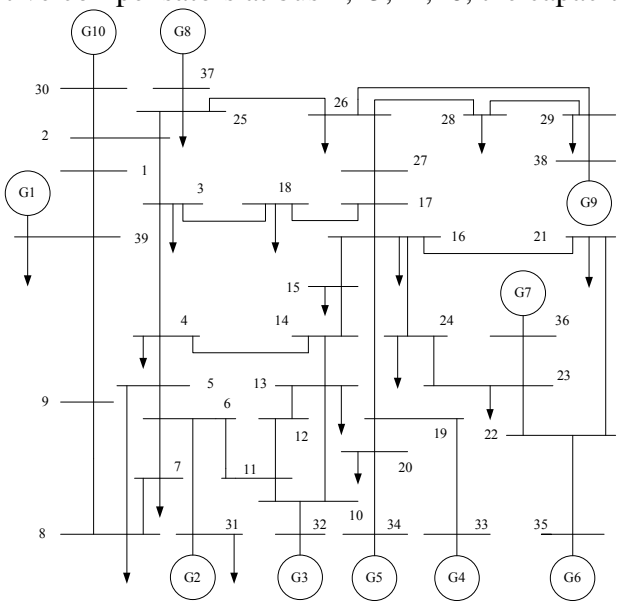

Fig.1. IEEE 39-bus New England test system

According to restoration plan in [5], the system is restored from bus30 using G10 as BSU. The steps before cranking a NBSU are shown in Table 1, the voltage limitation is [0.95, 1.05], and if the voltage adjustment of generator bus is less than 0.001 p.u., it is regarded as unchanged.

Table 1 Comparison of the result for different methods

	The method in this paper		Consider sensitivity alone	
	Voltage violation	Adjusted variable	Voltage violation	Adjusted variable
Bus 2	No	None	No	None
Bus 25	No	None	No	None
Bus 1	No	None	No	None
Bus 3	No	None	No	None
Bus 37	No	None	No	None
Bus 39	Yes	G10, C2	Yes	G10
Bus 26	No	None	Yes	G10
Bus 4	No	None	Yes	G10
Bus18	No	None	Yes	G10
Bus27	No	None	No	None
Bus5	No	None	Yes	G10,C2
Bus14	Yes	G10,C26	Yes	G10,C2
Bus17	No	None	Yes	G10
Bus6	No	None	Yes	G10

As the data shown in Table1, the method proposed in this paper has less adjusting amounts. Also the control variables adjusted firstly in the method are unadjusted or new devices, which means this method uses less time than considering sensitivity alone.

Summary

This paper presents a new method for sustained overvoltage control during PSR, in which the safety margin and changeable sensitivity according to the current situation are considered. Simulation test demonstrates that the proposed method can decrease adjusting amounts and restoration time of the PSR process efficiently.

Abstract. This paper focuses on the application of cluster analysis algorithm in the indicators comparison of power industry. The provincial power companies are classified by the power supply quality indicator with K-means clustering algorithm to identify the standard companies and to verify the feasibility and effectiveness of the algorithm. The results show that the cluster analysis enable the power companies to accurately identify the gap between the enterprise and the benchmark of industry, so as to continuously improve the level of management and benefit.

CLC number：TM715

Introduction

With the development of power industry benchmarking activities, benchmarking enterprises continue to increase, the benchmarking index system has been improved.In order to quickly find out the potential distribution of indicators from the index data where a large number of irregular in,it is necessary to conduct a reasonable division to the standard enterprise,cluster analysis is a very effective method. Common modeling methods including K-means algorithm, fuzzy C-means algorithm and improved neural network algorithm.

This paper will select the index data of 24 provincial power companies,By K-means algorithm cluster analyzed the supply quality indicators of provincial company.and benchmarking Enterprise elected from each of the power companies in the index,through the analysis of the gap between benchmarking enterprise. identify their own deficiencies, and enhance the management level.

K-means algorithm

1.1 Data processing

Because of the complexity of the benchmarking index system and the diversity of the data,we need to process the data comparability before performing indicators cluster analysis,it mainly includes forward processing and the dimensionless processing two aspects.

（1） Forward processing

The evaluation standard of the benchmarking index the benchmarking index are not the same, some index value bigger is better,these index values are called the forward index, such as the rate of return on total assets, the tariff rate etc;Some index value smaller is better,these index values are called the reverse index, such as the line loss rate etc;Some index value need to reach a certain standard, these index values are called appropriate index,such as asset-liability ratio etc.In order to facilitate a comprehensive evaluation of the indexes.we need to do forward processing for the indexes, for the reverse index we can take it's opposite number,for appropriate index can take it's absolute value of the difference between the actual value and the standard.

（2）Dimensionless processing

Statistical unit is different between different indexes. Statistical unit in different grid enterprises of the same index may be different. Therefore, we need to do dimensionless processing for the original data of the indexes.Dimensionless method includes the following.

①Extreme value method

Through the calculation of the index which between its actual value and extreme value (Maxima or minima),we can do dimensionless processing for the indexes:

$$v_i' = \frac{v_i}{\max v_i} \quad (1)$$

②Standard deviation method

Using the standard deviation of index, we also can do dimensionless processing for the indexes,But this method is more reasonable when the original data of index in a normal distribution , and the processing method as follows:

$$v_i' = \frac{v_i - \overline{v_i}}{s} = \frac{v_i - \overline{v_i}}{\sqrt{\frac{1}{n}\sum (v_i - \overline{v_i})^2}} \quad (2)$$

In which, v_i is the actual value of a index, v_i' is the dimensionless value of this index and s is the standard deviation of it.

These two dimensionless methods assume that the actual value of index and the dimensionless value is linear relationship,however, in practice the two are not necessarily proportional change,therefore, the dimensionless processing needs concrete analysis according to the actual situation.

1.2 K- means Algorithm process

The basic idea of the K-means algorithm is firstly selected K points as the initial cluster centers, and then calculated the distance that each sample to the cluster center , the sample was attributed to the location which is nearest to the cluster center of class.Calculate of the clustering center of new class after the adjustment,If the clustering center adjacent two times without any changes,it shows that the sample have adjusted, clustering criterion function J_c convergence.After finishing the adjustment of the whole sample, modified the cluster center, go to the next iteration[1-3].The results of K-means algorithm depends on the choice of the initial cluster centers. Accurate selection of the initial centers will greatly reduce the iterative steps.Specific steps as the following:

Step1:given *n* sample dates,at the same time select *K* clustering centers C_j, $j = 1,2,...,K$

Step2:Calculate the distance $d(v_i, C_j)$ $i = 1,2,...,n;$ $j = 1,2,...,K$ of each sample data and the *K* clustering centers, if the distance satisfied $d(v_i, C_b) = \min\{d(v_i, C_j), i = 1,2,...,n\}$

if the distance satisfied $d(v_i, C_b) = \min\{d(v_i, C_j), i = 1,2,...,n\}$ the sample data should be categorized as the *b* clustering center.

Step 3:Recalculate the clustering center $C_j(i+1)$ and the clustering criterion function *Jc*

$$C_j(i+1) = \frac{1}{n_j}\sum_{i=1}^{n_j} v_i^{(j)}, j = 1,2,...,K \quad (3)$$

$$J_c(i+1) = \sum_{j=1}^{K}\sum_{b=1}^{n_j}\left\| v_b^{(j)} - C_j(i)\right\|^2 \quad (4)$$

Among them, n_j is the number of sample data in section *j* clustering , $v_i^{(j)}$as the sample data of the section *j* clustering.

Step 4:If $|J_c(i+1) - J_c(i)| < \varepsilon$,then the algorithm end,else let *i=i+1,*back to the step2 to reclassify.

1.3 The application of K- means algorithm

In the electric power enterprise benchmarking process,determining the benchmark enterprise is a very important content .Cluster analyzed the electric power enterprise benchmarking with K-means algorithm ,which can be divided into the following steps.

(1)Data processing

The good or bad of data processing will determine the efficiency, the accuracy and effectiveness of the final result of the clustering analysis.Therefore, we should do pretreatment for the original data of each index benchmarking ,using the formula (1) or (2) do the forward processing and dimensionless processing for the data, which can be directly carried out cluster analysis.

(2)Choose clustering index

Because the electric power enterprise benchmarking index system is more complex, the data which need to collect is complex,therefore, in the selection of cluster index, only need to cluster the core of index data.

(3)Using K-means algorithm for clustering analysis

K-means algorithm is a key step in clustering analysis.When using K-means algorithm, the determining of the K value will directly affect the clustering results, thus affect the evaluation of the index.Therefore, the selection of clustering center should be clearly reflected the gap between enterprises.

(4)Enterprise classification

According to the results of clustering index data we can classify the enterprise ,choose the benchmarking enterprises and determine the actual development level and the gap between benchmarking enterprises of each enterprise ,thus promote the enterprises to put the benchmarking enterprise as goal, continue to improve the ability of sustainable development and competitive ability of enterprises.

The analysis of example

Power quality has an important impact on the industrial and the safety in production, economic and living of utility users,it is not only reflected in the planning, design, construction, construction, operation and management level of electric power enterprise, is also an important indicator of the domestic and foreign various power enterprises .Therefore, this paper will use the K-means algorithm, clustering analyzed the power quality index of 24 provincial power company, established benchmarking enterprises and provided guidance and decision support for power supply quality of benchmarking management .

Assessment of China's power supply quality indicators enterprise mainly through four indicators,such as the qualified rate of city comprehensive supply voltage, the qualified rate of rural comprehensive power supply voltage, city and rural power supply reliability rate etc.Power quality related indicators of provincial power corporation in 2011 as shown in table 1.

Tab.1 Data of the power supply quality indicators of provincial power corporation in 2011

enterprise	The qualified rate of city comprehensive supply voltage %	The qualified rate of rural comprehensive supply voltage %	City power supply reliability rate %	Rural power supply reliability rate %
enterprise1	99.86	99.62	99.9813	99.9303

enterprise3	97.16	97.16	99.9105	99.7653
enterprise4	99.48	98.81	99.9712	99.9401
enterprise5	99.805	98.921	99.9702	99.9066
enterprise6	96.5	96.403	99.9535	99.8085
enterprise7	99.689	99.6	99.9249	99.6262
enterprise8	99.301	94.88	99.8936	99.761
enterprise9	99.954	99.826	99.9526	99.8785
enterprise10	99.953	99.864	99.9729	99.8062
enterprise11	96.68	96.65	99.9473	99.7692
enterprise12	99.811	97.456	99.9832	99.9404
enterprise13	99.791	97.1	99.9379	99.7387
enterprise14	99.731	96.888	99.9562	99.8567
enterprise15	99.822	97.826	99.945	99.7678
enterprise16	98.24	96.567	99.943	99.7809
enterprise17	99.708	99.776	99.9403	99.6842
enterprise18	99.876	97.312	99.9182	99.7901
enterprise19	99.94	96.98	99.9286	99.7445
enterprise20	98.93	98.29	99.9287	99.8869
enterprise21	99.281	99.832	99.9209	99.6086
enterprise22	98.075	98.2638	99.8559	99.6194
enterprise23	99.656	98.35	99.9427	99.8183
enterprise24	98.98	98.56	99.8766	99.7418

Because these four indicators of power supply are positive indicators of quality, therefore it does not need to be pretreated, we can directly use K-means clustering.Can be seen from table 1.The qualified rate of city and rural comprehensive supply voltage ,city and rural power supply reliability rate all wave in three levels.In order to reflect the true difference between the various power companies,distinguish excellent, good and poor among enterprises,in this paper, K the number of clusters is determined as 3,and uses SPSS software to clustering analyze.Assuming when the clustering criterion function $J_c < \varepsilon = 0.05$, the algorithm end,the results of cluster analysis and the cluster centers are as shown in table 2 and table 3.

Tab.2 The output table of cluster analysis

enterprise	K-means algorithm		enterprise	K-means algorithm

Tab.3 The clustering center table of K-means algorithm

Clustering categories	center of clustering		
	1	2	3
Qualified rate of city comprehensive supply voltage	99.5622	99.7531	97.3310
Qualified rate of rural comprehensive supply voltage	99.1297	96.9203	97.0088
City power supply reliability rate	99.9428	99.9375	99.9220
Rural power supply reliability rate	99.7991	99.7999	99.7487

From table 2 and 3 we can see, the first class enterprises including 12 electric power enterprises, these enterprises' performance on the four indicators are good, and the indicators show a relatively balanced;the second class enterprises including 7 electric power enterprises,these enterprises' indicators of 'qualified rate of city comprehensive supply voltage' and ' rural power supply reliability rate ' is better than the first class,but the other two indicators is worse, especially 'qualified rate of rural comprehensive supply voltage' ;The third class enterprises only includes five electric power enterprises,these enterprises' performance on the 'qualified rate of rural comprehensive supply voltage'is better than the second class,but the other three indicators is worse.In summary, we can choose first class as the benchmark companies of the power supply quality benchmarking.

Considering the in the power enterprises which participate in benchmarking, first class enterprises accounted for a larger proportion, so we can choose the clustering center of the first class enterprise as a reference index value of the first type of electric power enterprise benchmarking .By comparing the gap between the first class power companies's indicators and cluster centers indicators, The power supply quality benchmarking management of the first class power company can be get more in-depth and meticulous guidance. Those enterprises which index

value is not reached the reference index value through analyzing the lagging indicator corresponding, and give some suggestions of improvement, to further strengthen the backward index management level.Those enterprises which index value reaches or exceeds the standard data, on one hand should summarize advanced experience, improve the management level of the enterprise, on the other hand, should be aimed at enterprise index more advanced, and further enhance the quality of power supply to enterprise level.

For the second and third class enterprises,they should identify the gaps with the first class enterprises, strengthen grid security management, improve the overall quality of power supply.Among them, the "Qualified rate of rural comprehensive supply voltage" is the short board of the second class enterprise , it affected the power supply quality comprehensive evaluation results of this kind enterprises .Therefore, this seven power companies should pay more attention to "rural power supply voltage integrated pass rate" indicator assessment, comparing and referring to the rural power supply management measures of the first class , dig the reason why the "Qualified rate of rural comprehensive supply voltage" behind ,then explore targeted measures and improvement programs,to achieve a balanced improvement of enterprise power quality level .

By K-means algorithm cluster analyzed the supply quality indicators of power enterprise.On the one hand, the development level of all power enterprises power quality indexes can be clear, help enterprises to put benchmark enterprises as the target to continuously improve their own deficiencies, and enhance their competitiveness;On the other hand, by clustering analysis the various indicators not only to conduct a comprehensive analysis and comparison of power enterprise quality management, and can accurately identify the root causes of the the quality of power supply gap between power enterprises.

Conclusion

In this paper, through combine the K-means algorithm with the theory and practice of electric power enterprise benchmarking , to provide decision support for electric benchmarking. Based on the basic principle of K-means algorithm, this paper studies the application of this algorithm on the power quality index in 24 provincial power company benchmarking.As can be seen from the results of cluster analysis, K-means algorithm for power enterprises peer benchmarking has a positive effect,through indicator cluster we can not only achieve a evaluation of comprehensive index, but also correctly classify the enterprise, establish business models to achieve contrast and catch up between the enterprises.

This paper is the preliminary attempt application of K-means algorithm in the electric power enterprise benchmarking.Committed to explore and verify k-means algorithm’s viability in power peer benchmarking ,there is still a lack in the establishment of analysis of electric power enterprise benchmarking.The example of this paper does not consider the impact of different power enterprise location and other objective factors, so the results lack of certain practical significance, and the k-means algorithm itself has some limitations. When the power enterprises using K-means algorithm to benchmark,the electric power enterprises need to combine their own actual situation, at the same time effectively combine with other methods such as discriminant analysis, principal component analysis etc, so as to achieve better calibration effect, provide more reliable decision support for the further development of electric power enterprises.

Keywords: Series Compensation, Fast Switching, Voltage Quality

Abstract. This paper analyzes the voltage quality problems on transmission line of 10kv distribution network, and then introduces a series compensation device, which is based on fast switching and can effectively solve the above problem. Furthermore, this paper calculates the voltage under a actual situation, which fits the expected results.

Introduction

Currently, with the development of economic and rapid growth of electricity load, the majority of the most remote regions grid extends to areas without electricity. Due to the length of the radius of the transmission line, the quality of power supply has become increasingly prominent in the remote rural areas and low-voltage of 10kv distribution network, which is embodied in the low voltage and voltage fluctuation rate and results that the load side of the supply voltage goes far beyond the quality standards prescribed by the state and affects the production and people life. To overcome the deficiencies of existing technology described above, this paper provides a series compensated equipment based on fast switching， which can improve the terminal voltage and effectively solve the voltage quality problem so that we can make full use of energy.

The principle of series compensation device structure

This series compensation device is composed of the series capacitor, metal oxide（ZnO）, fast switching, current limiting resistors and other components. Among them, the series capacitor fits to compensate for line inductance drop and improve voltage quality. The metal oxide fits to limit the voltage across the capacitor to prevent from burning capacitor under short circuit. Fast switching fits to short-circuit capacitors and metal oxide to protect them. Limiting resistor is to prevent that the line current gets too high when switch is closed. The diagram of the device structure principle is shown below:

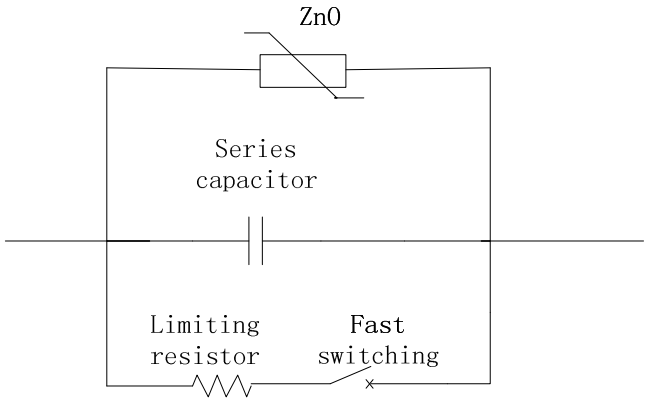

Fig.1. Series compensation device structure

When the series compensation device works properly, the capacitor is seriesed connected in line. Fast switch is open and the metal oxide is in a non-conducting state. Once the short-circuit fault occurs, the voltage across the metal oxide increases rapidly. When the voltage across the capacitor reaches the level of ZnO protection, the current through the ZnO increased rapidly. ZnO will limit the voltage added to the capacitor connected in series, and then immediately put capacitor into effect with the fault current gone.

The fast switching

The device uses a quick series of vacuum circuit breaker with fast eddy drive technology as a control executive compensation capacitor switching components. It will close in about 10ms and open less than 5ms. Combined with the rapid recognition of short circuit fault, rapid vacuum circuit breaker can be accomplished short series capacitor in about 15ms after a short-circuit fault occurs. It can significantly shorten the duration of the over-voltage so that the required energy capacity of ZnO components can be greatly reduced.

Instead of the traditional use of spark gap and 10kv circuit breakers, fast switching greatly simplifies the structure of device, improve the reliability of the device, reduce the volume and lower the cost.

Examples of simulation

Line information and operating data is shown in Table.1.

Line Information	Line length	27km	
	Taps number	33	
	Main/branch linear	LGJ-120/ LGJ-50	
Operating Data	Required data	Maximum load	Average load
	Head of the line voltage (kv)	10.49	10.51
	End of the line voltage (kv)	8.8	9.9
	Head bus current	118	83
	Head bus Power Factor	0.93	0.98

In order to improve the terminal voltage, a series capacitor is put in the middle of the line where the location voltage is 9.6kv.The capacitance values 7.15 ohms and the degree of compensation is 1.55. The compensation effect is shown in Fig.2 and Fig.3.

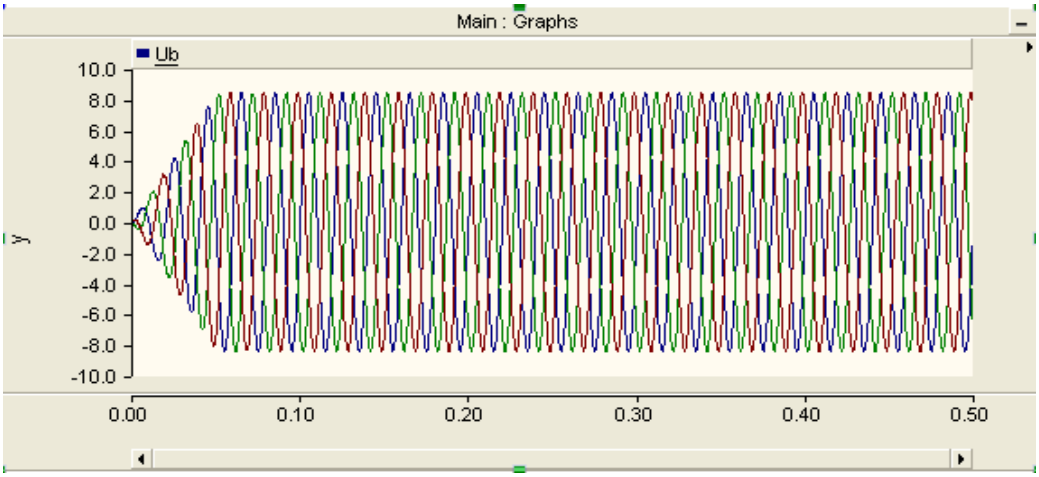

Fig.2 The end of the voltage when not compensated

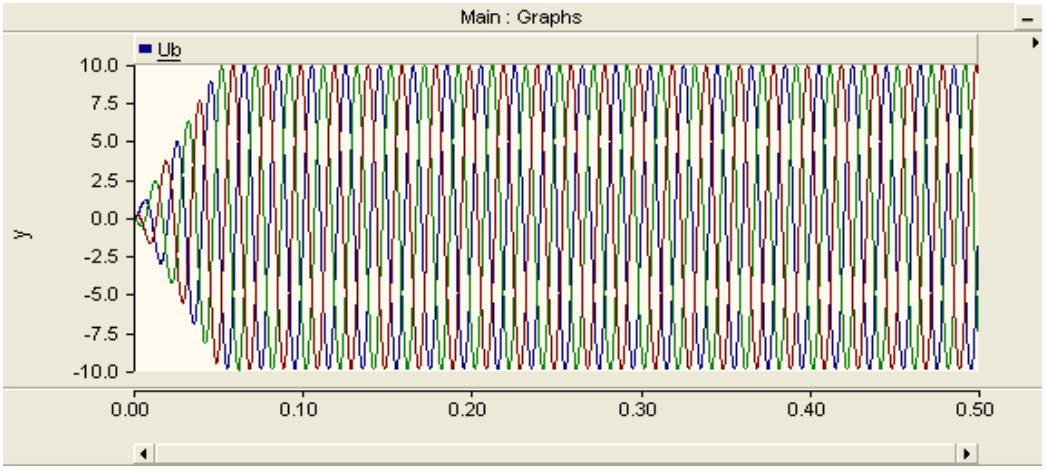

Fig.3 The end of the voltage when compensated

The compensation data under different conditions is shown in Table.2.

		Not Compensated	Compensated	Voltage Increase
End of the line voltage	Maximum load	8.8kv	9.6kv	0.8kv
	Average load	9.9kv	10.5kv	0.6kv

Visible seen from the above table, the adding series compensation not only along make the voltage meet the requirements, but also not cause excessive voltage under the average load operating conditions. The effect to improve voltage quality is apparent.

Conclusion

This paper proposed a series compensation device based on fast switching. On one hand, the fast switching can quickly short capacitance when fault is coming. On the other hand, the series compensation device makes a perfect effect on improving voltage quality.

The Criticality Safety Analysis of the Spent Fuel Storage Pool Area I in Small Modular Reactor

Xiangzhen HAN[a], Guoshun YOU[b]

Nuclear and Radiation Safety Center, Beijing, 100082, China

[a] email: nearly119@sina.com, [b] email:gsyou77@yahoo.com

Keywords: Criticality Safety; Spent Fuel Pool; Storage Rack

Abstract. Based on the Monte Carlo calculation method, geometric model of spent fuel storage pool Area I of small modular reactor is established, assuming infinite 6×6 type storage racks. Calculation results show that the reactivity is maximal when the water density is 1.0g/cm3. The value of k_{eff} is 0.8729 in normal storage condition. The spacing of storage racks in spent fuel pool would change in an earthquake accident condition. The values of reactivity of spent fuel pool in the assumed earthquake accident condition are also calculated. The values of k_{eff} are between 0.872 and 0.876. Both in normal condition and assumed earthquake accident condition, the values of k_{eff} are less than 0.95, to meet nuclear safety regulatory requirements.

Introduction

Maintaining sub-criticality of the fuel should be fulfilled at all times to the fuel handling and storage systems. It is 24 months fuel management program in small modular reactor. Spent fuel storage pool of small modular reactor is designed to partition layout, which is divided into storage area I and storage area II. Area I is used for the storage of new fuel assemblies before loaded into the reactor, the assemblies which are unloaded out of the core during unplanned shutdown, and the spent fuel assemblies which don't meet burn-up limit and are not allowed stored in Area II. The design of the storage racks in Area II uses burn-up credit. Area II is used for storage of spent fuel assemblies which reach a predetermined burn-up limit. Burn-up credit means taking into account the reactivity reduced of fuel irradiated in the criticality safety analysis of spent fuel storage pool. This can increase the number of storage spent fuel assemblies and the storage economy of spent fuel. In this paper, we study the criticality safety analysis of spent fuel storage pool in small modular reactor.

Calculation Code

The code used in our study is MCNP, which is a general-purpose Monte Carlo N–Particle code that can be used for neutron, photon, electron, or coupled neutron/photon/electron transport, including the capability to calculate eigenvalues for critical systems. The code treats an arbitrary three-dimensional configuration of materials in geometric cells bounded by first- and second-degree surfaces and fourth-degree elliptical tori. Pointwise cross-section data are used in MCNP. For neutrons, all reactions given in a particular cross-section evaluation (such as ENDF/B-VI) are accounted for. Thermal neutrons are described by both the free gas and S (α, β) models. Important standard features that make MCNP very versatile and easy to use include a powerful general source, criticality source, and surface source; both geometry and output tally plotters; a rich collection of variance reduction techniques; a flexible tally structure; and an extensive collection of cross-section data. MCNP code is widely used in the evaluation of criticality safety for nuclear facilities [1].

Regulations and Standards

The following are regulations and standards which are adopted and referenced in criticality safety analysis of nuclear safety review:

HAF102 "Nuclear Power Plant Design and Safety Requirements," 2004[2];

HAD102/15 "Nuclear Power Plant Fuel Handling and Storage Systems," 2007[3];

GB15146.1-2008 Nuclear criticality safety of fissile materials outside reactors - Part 1: Administrative practices for nuclear criticality safety [4];

GB15146.2-2008 Nuclear criticality safety of fissile materials outside reactors - Part 2: Basic technical practices and subcritical limits for handling, processing and operations with fissile materials [4];

GB15146.3-2008 Nuclear criticality safety of fissile materials outside reactors - Part 3: Requirements for nuclear criticality safety in the storage of fissile materials [4];

GB15146.8-2008 Nuclear criticality safety of fissile materials outside reactors - Part 8:Criticality safety criteria for the handling, storage, and transportation of LWR fuel outside reactors [4];

RCC-P "Design and Construction Rules for System Design of 900 MW PWR Nuclear Power Plants", 1991. (Amended in 1995) [5].

Critical Safety Standards

During criticality safety analysis of spent fuel storage pool Area I of small modular reactor, the enrichment of spent fuel assemblies is considered as newwith the maximal expected enrichment. It means that the enrichment of spent fuel assemblies is taken 4.2%. The design of Area I racks of spent fuel storage pool should be ensure that: At the maximal design capacity of spent fuel storage pool and the maximal acceptable new fuel enrichment of fuel asseblies, considering various uncertainties, normal and credible accident conditions, the value of keff should not be exceeded 0.95.

Geometric Model

Fuel Assemblies

Each fuel assembly contains a 17×17 rod array composed nominally of 264 fuel rods, 24 rod cluster control thimbles, and an in-core instrumentation thimble. Figure 1 shows a cross-sectional view of a 17×17 fuel assembly and the related rod cluster control guide thimble locations. The fuel rods are fabricated from cylindrical tubes made lf zirconium based alloy(s) containing uranium dioxide fuel pellets. Area I of spent fuel storage pool is used for the storage of new fuel assemblies and spent fuel assemblies which has not been reached burn-up limit. When calculating the criticality safety of spent fuel storage pool, the enrichment of fuel assemblies is assumed to 4.2% for considering conservative.

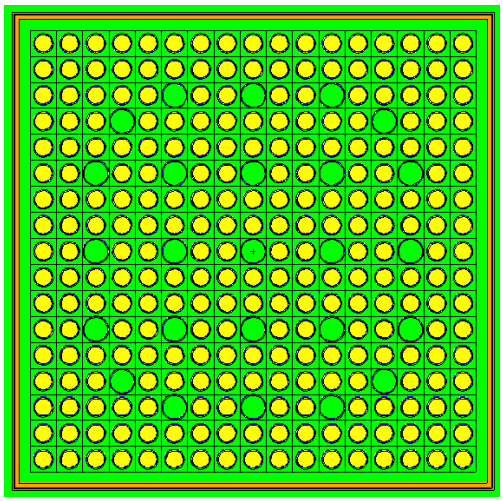

Fig.1. Fuel assembly diagram

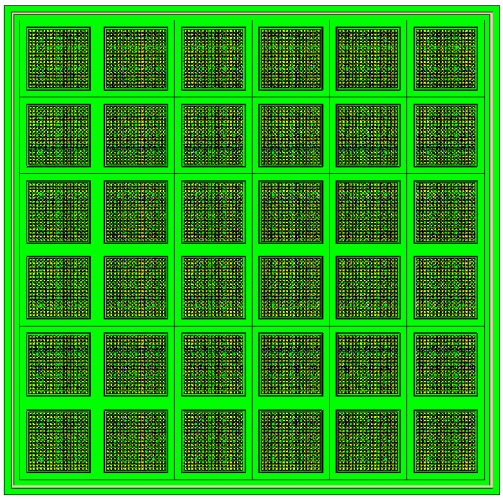

Fig.2. Storage rack model diagram

Storage Racks

New fuel is stored in a high density rack which includes integral neutron absorbing material which is cadmium to maintain the required degree of sub-criticality. The rack is designed to store fuel of the maximum design basis enrichment. Each fuel assembly is stored in stainless steel sleeve

in which cadmium panels insert. (Figure 1) The rack array center-to-center spacing of 28cm provides a minimum separation between adjacent fuel assemblies sufficient with neutron absorbing material to maintain a subcritical array.

Boundary Conditions

During criticality safety analysis of Area I of spent fuel storage pool, we analyze the relatively of 6×6 type spent fuel storage racks which are dense stored in the pool. The new fuel rack includes storage locations for 36 fuel assemblies. The rack layout and array center-to-center spacing is shown in Figure 2. There is water reflection layer of 30cm thick set on the rack. And another water reflection layer is set under the rack. For considering conservative, the boundary condition surrounded the rack of the calculation model is assumed to specular reflection. The physical meaning of the model is infinite 6×6 type storage rack arranged. The water in spent fuel storage pool is assumed to be pure, without considering the effects of neutron absorbing of boron.

Calculated Results

A calculation model of infinite storage racks arranged in space is established to calculate the reactivity in normal storage condition. This is conservative for criticality safety analysis in normal condition. In order to determine the effect of the pool reactivity on the water density caused by water temperature change, we analyze the pool k_{eff} on the influence of water temperature. The calculated results are shown in Figure 3.

It is clearly that the value of k_{eff} is lower with reduced density of water in the pool which is fulfilled with 4.2% enrichment fuel assemblies. According to Figure 3, the calculated assumed 1.0 g/cm^3 as the density of water is conserved in both conditions of normal storage and incident of criticality safety analysis.

Data in Table 1 show that the spent fuel pool k_{eff} is the maximum of 0.8729 when the density of water is assumed 1.0g/cm^3 at normal storage condition. At 95% confidence level, the values of k_{eff} are in the range from 0.87209 to 0.87372, which are all less than 0.95 and meet nuclear safety regulatory requirements.

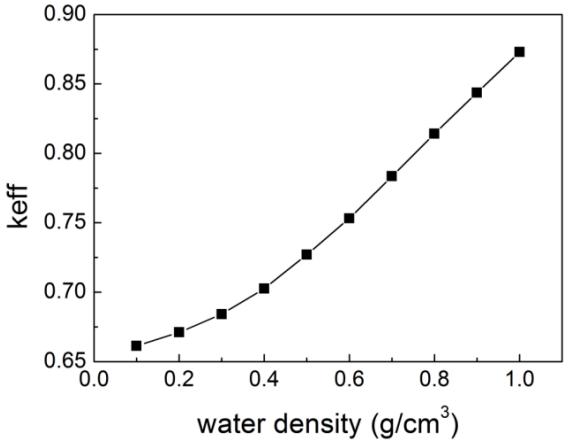

Fig.3. The function of k_{eff} with water density

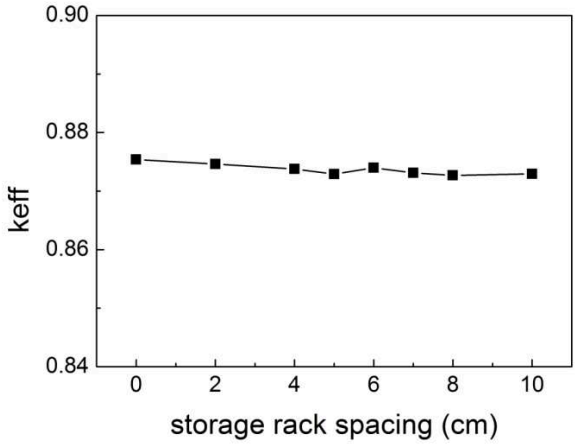

Fig.4. The function of k_{eff} with racks spacing

Accident Analysis

In this paper, we analyze the accident safety in the earthquake, and study the effect of criticality safety of spent fuel storage pool on storage racks spacing caused by the earthquake. Figure 4 shows the earthquake accident analysis results. The spacing of normal conditions between adjacent storage racks is 5cm. The calculation model simulates the effect of reactivity when rack is close to or away from each other. Figure 4 shows that the reactivity change is not obvious when the storage racks spacing change. This is due to the spacing of fuel assemblies which are in adjacent racks is maintained a certain distance when the storage racks are close to each other. So the reactivity insertion is not obvious when the spacing of storage racks change, and the value of k_{eff} is nearly the calculated value of k_{eff} of normal condition.

Conclusion

Based on the Monte Carlo calculation method, geometric model of spent fuel storage pool Area I of small modular reactor is established, assuming infinite 6×6 type storage racks. As the pool temperature will affect the moderator density, the reactivity of spent fuel pool is calculated with different water density. Calculation results show that the reactivity is maximal when the water density is 1.0g/cm^3. For considering conservative, the value of density of moderator in the pool is assumed to 1.0g/cm^3. The value of k_{eff} is 0.8729 in normal storage condition. The spacing of storage racks in spent fuel pool would change in an earthquake accident condition. The values of reactivity of spent fuel pool in the assumed earthquake accident condition are also calculated. The values of k_{eff} are between 0.872 and 0.876. Both in normal condition and assumed earthquake accident condition, the values of k_{eff} are less than 0.95, to meet nuclear safety regulatory requirements.

Keywords: Nuclear power Plant; AEC; Data Planning（DP）; Business Model; Data Model

Abstract. Data plays more and more important roles in the AEC field, especially in Nuclear power plant constructing and engineering. In this paper, except introduce the basic DP theory and methodology, we analyzed the key points while doing the DP in nuclear power plant. Based on the analyzed results, which is an actuality of Nuclear power engineering, the paper proposed the ways to improve the data integration solution to standardize the data of project data, reduce the redundant data in the database and improve the system integration efficiency.

A. Foreword

"Development of Nuclear Power in a safe and efficient way" has been listed as a part of the "125"state planning. The development of Nuclear power now is a part of the country's energy development plan and state strategies, which has very important significance to the supply and insurance of energy usage, environment protection, structure optimization of energy chain, sustainable development strategy as well as promoting the economic and technical competitive force. But meanwhile, there are lots of challenges have been detected in nuclear power development, including the technical difficulties, large-scale construction, long-time construction period and big team collaboration, etc.

To overcome these challenges, IT technology as the backend of the business is very important as well. With the investigation and analyzation of the business process and the related data of EPCS in the whole lifecycle of nuclear plant construction, the team tried to figure out how to build up the stander of the data to improve the data quality and dig the value to serve the entire business. In our DP project, we also analyzed the data from project perspective, and focused on project planning, cost control, security, quality, experience learning. With the work above, we were trying to mitigate the islands of redundant and inconsistent data during the information system development and build up a stander to unify the way of data creating and sharing, so that the overall quality of the data can be improved to serve the business efficiently.

B. Enterprise Data Planning Overview

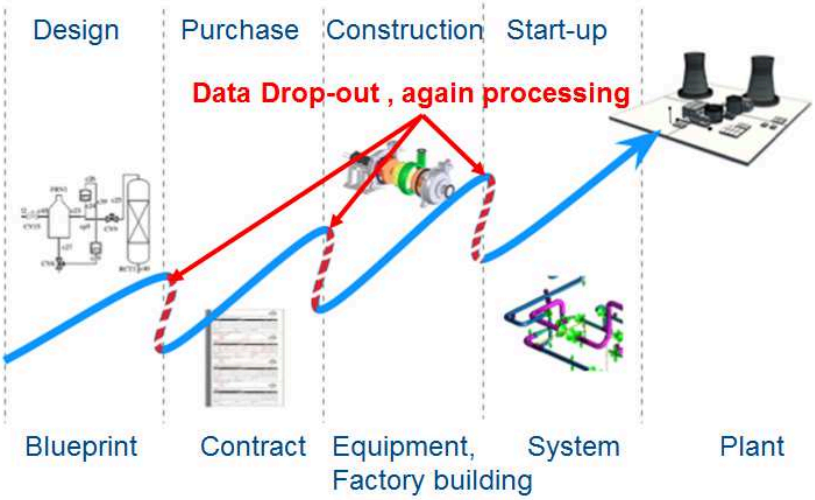
a) About Enterprise data planning

Data Planning is a branch of enterprise resource planning, which is focusing on the particular segment of enterprise business data model development. The so-called data planning means to follow the basic rule of database, investigate the business information and information access, and design to create a practical business oriented database model, which is used to ensure the accuracy, consistency and security of data. With the using of the data model, the information sharing will be improved, meanwhile, the core value of the enterprise business will be enhanced by leverage the value of data.

To serve the nuclear power plant building process, business process data and management information are included in data planning. And it can work as an overall blue print for the information system development during the engineering process. Understanding the business requirements and build an information data stander to close the gap during the business collaboration is one of the main purpose of data planning. With data planning implemented, the isolated data island can be mitigate, and the maturity level of system development can be improved as well. While working in the qualified information data environment, the technical and efficiency of nuclear engineering will be ultimately improved as well.

b) The Necessity of Data Planning Project

During the development of enterprises informaization, same as the other resources, like people, money, properties, etc., data resources are as important as they are, which play a more and more role to the entire company. Therefore, it should be managed like managing the other important assets. Data resources are one of the core assets of the company, and it is the core objects for data planning as well. So to establish a high-end enterprise information environment, data planning should have a global viewpoint, holistic strategy and uniform standards. The data planning project can not only serve a single department adjustment or reform, but also may related to most of the other departments. It's an enterprise-level strategic planning.



In the nuclear power engineering process, no matter the plant design, materials and equipment procurement, or the construction, installation commissioning business will generate mass of data. In order to improve the collaboration of the department and data sharing amount the complex business units, we need to ensure the quality of data flow, which not only satisfy the management's requirements, but also can serve the leadership's decision making. Without the enterprise level data planning, it's will impossible to achieve the goal.

C. The Methodology in Data Planning project

The fundamental goal of data planning is to build the business and data model to reflect the business activities. Meanwhile, with the in-depth and meticulous analysis of the business model, master data will be recognized and the relationship between the master data will be figured out as well. The master data is the core framework, and we need to setup the standard for data and data table, which can be a foundation for the database application system.

In our data planning for nuclear power engineering, while build the data model, the flexibility for the end user should be considered, so that we can encourage the business user to implement the data model during the information system development; in the other aspect, the certain rules should be applied, so that it can guide the different system development to keep the data on the same page, which can mitigate the gap and improve the data sharing efficiency amount the different system.

a) Establish the Project Team

Data planning is fundamental and core part of the enterprise resources planning. Therefore, the support and involvement of leadership are vital important for the success of the project. Meanwhile, to ensure the success of the project, the project team needs to have a clear responsibilities and rights for each team member who are involved in it. The data planning project team is directly under the lead of the senior leadership, and we also have a project manager to manager the detail action plan of the team. At the same time, some of the senior business experts and professionals were involved.

It is also worth noting that all the members involved should be have the commitment of the time. If there are too much time conflict while running the projects, we would recommend to stop until the time can be committed.

b) Business tackling and Modeling

Business and data analysis are the second step for the data planning project. The goal of the analysis is to understand the enterprise requirements deeply in a systematically way, which is also known as “business tackling”. During the business tackling, business function domain, business process and business activity are the critical part we need to take care of.

Business function domain is an abstract for the major business activities. Define the domain is the first step. After getting the domain list, project team will setup various group to take charge of the domain area. Each group will start to dig into the domain, and analyze the business function domain. We will find the domain can be made up by number of business process, and in each business process will have number of business activities. So the business model can be described by three tiers structure, which is “Business function domain – Business process – Business Activities”.

For example, during nuclear power engineering, the major business domains are usually have design, procurement (including manufacture and supervision), construction (including building and deployment) and System commission & delivery; the major management domains are usually have project plan, finance, security & quality assurance, human resource, and risk control. And the procurement domain is consisted by some procurement related processes, such as procurement planning and implementation, contract execution and implementation, equipment manufacture and supervision, and Delivery etc. In procurement planning and implementation is consisted by procurement plan, procurement request, technical specification, supplier selection, ordering, etc. Similarly, in system commission and delivery business domain, commission preparation, commission execution, system commission delivery and commission support are the main business process; and TOB, TOM, TOTO, FW, OT are the main business activity in the process of system commission delivery.

Meanwhile, while learning the business model, the interface of the domains, process and activities should be analyzed as well. For example, the procurement implementation in procurement domain and system commission preparation in system commission domain are related to the domain of project plan domain.

c) Data Analyzing and Modeling

Data analyzing and modeling are based on the business tackling and modeling. The process is to generate the data model, which including extract the data from the user view to master database, from data flow to ER diagram, from data entities to data table. According to the business process and activities, we need to extract the entities in these business, and group them to a specific group, which is called master data. We can also create the relationship of the master data, to map it back on the domain, process as well as activities. This can help us to double check the data and make it more reasonable.

The purpose of data modeling is to determine the relationship between the data and business and create a corresponding data structure to represent the business. Generally, the steps are listed as below:

Firstly, identify and define the business domain based on the user view, and then create the Conceptual Data Model.

Secondly, analyze the entity, and standardize the data structure, then build up the Logical Data Model.

Thirdly, standardize the data elements, and implement the data and coding standard in the database table, which is also called Physical Data Model.

With the help of data analyzing and modeling, we can build a more robust information recourse management structure. The model can serve as a system development guide line at the top level, and it's a foundation work for the high-end data environment.

D. Conclusion

To mitigate or clear the redundancy data in the enterprise, which has been accumulated for years of system development, is the essential goal of data planning. With the success of the project, it can help the enterprise to setup the basic data standard, reduce the isolated date island and improve the quality of the data. In a data environment with chaos, it not only a west a money during the system development, but also a bottleneck for the entire company to move the next step. Now is the time to take all the data and business to consideration, learning the experience and transform the way of thinking for our strategy of system and information development.

The energy management of Chinese tourist hotel under the background of low-carbon economy

Feilong Liu

School of Economics and Management Hunan Institute of Science and Technology, 414006,Yueyang, Hunan, China

E-mail:liufeilong12@126.com

Keywords: Low carbon economy; China; Tourist hotel; Energy management

Abstract. Tourist hotel is a “high energy consumption high emission high pollution” industry. So it is of great realistic significance of strengthening Chinese tourist hotel energy management under the background of low carbon economy. Aiming at the main problems of energy management of Chinese tourist hotel, we should begin from the following several aspects: First,To establish a scientific concept of hotel energy management and combine energy management training and assessment closely;The second is to build and improve energy management system and strengthen scientific and effective implement;The third is to establish a sound mechanism of hotel computer remote monitoring system to achieve hotel energy management information and automation.

In contemporary society, the change of energy environment and climate has become the focus of world attention, "low carbon economy" which based on low energy consumption, low emission, low pollution is becoming a global focus. The influence of low carbon economy on the development of hotel industry is very profound. Green hotel construction has made some useful attempts in the development of low-carbon economy. Under the background of low carbon economy, we can understand it is the hotel that is constructed and operated by the core value concept of low carbon economy, low carbon economy development mode and low-carbon science and technology. In fact, the hotel industry is " a high energy consumption, high emissions, high pollution" industry, coupled with the global energy demand is growing, resources shortage problem has become increasingly prominent, naturally led to rising energy prices. At the same time the hotel energy costs accounted for the proportion of expenditure for operating expenses showed a trend of rising. Therefore, in the condition of low carbon economic development, to strengthen the hotel energy management, and reduce energy consumption and operation cost of the hotel is an important research task in the China Hotel industry.[1]

The hotel energy management has an extremely important meaning

The so-called hotel energy management means that the hotel uses the modern scientific management methods and the advanced and mature technology and experience to give a comprehensive, multifunctional management to the hotel energy use. It also can say the hotel energy management is a scientific and effective management through the use of equipment and the consumption energy used by all people on the equipment using. Energy management under the background of low carbon economy is in line with the modern hotel development trend and the green hotel construction idea is come down in one continuous line. Green hotel was born in the last century 80's, the developed countries in Europe and America, and it’s proposed and initiated by a green sign organization of Germany, it is only an academic research at first. Late in twentieth Century 90 years, the White Swan ,Canadian maple leaf, German blue angel environmental labeling system organization and the nation of Israel ,American, Britain and other hotel management organization and green environmental protection agencies start to develop and publish the national or regional green hotel standards. For example in the Nordic (Sweden, Norway, Finland, Denmark) White Swan environmental labeling promulgated by the system of organization in the green hotel standards, It provides detailed energy-saving, water-saving, limited use of cleaning and chemicals

standard. Also provides the method and index of consumer goods reduction, classification of waste disposal, indoor facilities to encourage the use of environmentally friendly products and file management. The European and American countries Green Hotel growth rate is annually at a rate of 18.2%. According to the relevant data shows, the developed countries generally green hotel can reduce energy consumption by 5% to 10%, saving 10% to 20%, with great economic value. Now the developed countries have gone through the concept of "Green Hotel" into the popularization and application of substantive universal stage. So for energy management the important link of the construction of the green hotel, on the basis of the advanced management experience of European and American countries on how science works more effective, undoubtedly has become a tourist hotel industry in China need to complete a very urgent task. [2]

After joining WTO, foreign capital hotel as well as foreign hotel group gets into the China hotel market is in the accelerating speed, so the competition of the hotel industry will be more intense. If China hotel want to gain a firm foothold in the fierce market competition, it must work along both lines, not only to improve market share and operation revenue constantly, but also control costs, however the hotel energy management is an important part of the cost control of hotel. Therefore, to strengthen energy management of Tourist Hotel under the background of low carbon economy has very important practical significance.

The major problems of China Tourist Hotel energy management

So far, China tourism Star Hotel has reached about 15000, there are many times non star hotel more than the Star hotel Tourist Hotel, which is a large energy consumption ranks. From the actual operation of China Tourist Hotel, to control hotel hydropower oil and gas energy has always been a priority among priorities of its energy saving. But the internal cost control of many restaurants is often on the publicity and education and other flexible mode, the effect is not obvious. Energy management is not only the engineering work but involves all departments of the hotel. Many restaurants do not establish strict internal assessment system, which makes the hotel energy management difficult to implement. Generally speaking, the hotel energy management is mainly related to the hotel power supply system, drainage system, heating system, cooling system, central air conditioning system and so on. Energy consumption of the operation of the hotel equipment becomes an important part of the hotel product which is diverse, widely distributed, concealed installation and advanced technology. However, the equipment management of the hotel, especially the repair usually belongs to the engineering department, which resulted in the separation of duty use and maintenance. While energy consumption to produce concrete data cost also tend to stay in the financial department, resulting in consumption and pay for separation of duty. So, it will inevitably lead to many problems of energy management of tourist Hotel. To sum up, mainly in the following areas:

The tourist hotel energy management is not active

Strengthening the hotel energy management is exactly how to maximize the energy saving work in hotel in the guarantee of the normal operation of the hotel .According to "the people's Republic of China energy conservation law", energy-saving means to strengthen energy management and take technically feasible, economically rational and socially and environmentally acceptable measures to reduce the various segments of the loss and waste from energy production to consumption, and make more effectively and rational use of energy. Therefore, in the understanding of the concept, we must turn the simple "energy conservation" to "energy efficiency"; in the energy-saving ideas, we should turn the "want me to save energy "to I want energy-saving". However, in the fierce market competition, Chinese tourist Hotel industry has been in the stage of the hotel product pile up in excess of requirement. In order to gain more market share and revenue, hotel operators and managers have to take a variety of ways, such as price, to develop new products, to provide personalized service. They often focus on improving the hotel sales and market share, but the repeatability and long-term energy management is difficult to in-depth, Tourist Hotel management personnel many still remain in the "want me to energy-saving" passive stage. [3]

The tourist hotel energy management lack training and strict appraisal mechanism

In the era of green hotels, restaurants usually propagate green consumption to the guests, such as room will not changed daily disposable goods any longer. Replacement of the sheets, towels is also on the basis of the needs of customers. Many hotels placed that the card called "if you need to change the sheets, please put the cards on your pillow" in the room to cultivate the green consciousness and consumption of the spiritual. However, in actual operation, the hotel staff energy-saving awareness is weak. They often forget to turn off the lights. The daylight lamp, incandescent light is very common. Hotel staff training is a very important work, which should be involved in all aspects of the hotel management services. such as from the hotel new employees training to the fire protection knowledge training to service skills training to the reception of foreign language training etc. However, from the actual operation of the hotel, the hotel equipment often lacks the proper use and maintenance training and energy management training. From the aspects of appraisal system, hotel appraisal of department managers still focus on sales most, while the appraisal of employees, focus on attendance, service attitude and service skills, etc. Neither the hotel management nor general staff are lack of energy management system review. This situation is bound to cause the hotel's energy consumption will appear "everyone to use, no one is responsible for" phenomenon when using hotel facilities.

Tourist Hotel energy management is lack of scientific and rational technology and method

Hotel energy management involves all aspects of the hotel; the demand for both technical and hotel management level are high. From the developing trend of China's tourist hotel, the hotel industry in the future will pay more attention to the development of coordination with the balance of ecological environment and saving energy. But the actual situation is that most hotel energy management is very simple, especially lack of modern scientific management methods and advanced or mature energy management technology and experience to the comprehensive and multi-functional management of the hotel energy using. Of course, its reason is in many ways. First, from the point of environment, hotel energy conservation of China starts late, and don't have much experience. Second，due to the current status of development of the hotel, most of its engineering technology strength relatively weak restrict the implement and carry out energy saving work of the hotel. Third，modern science and technology changes every day, energy-saving new technologies, new methods constantly emerging, how to choose the most suitable technology and method for the hotel energy saving as soon as possible is also the problem.[4]

The measures and countermeasures of strengthening Chinese tourist hotel energy management

Establish scientific concept of hotel energy management, combining energy management training and examination closely

There are three conceptual change of subject that is the general hotel management, hotel staff and guests of the restaurant. To shift their concept of hotel managers' energy saving should be determined by the "energy-saving" want me to "I want to" energy saving, energy and the hotel management concept from "reduce cost" to "internal revenue", must be closely combined with the immediate interests of the hotel managers. Changing the hotel's general staff energy-saving idea, we must require the hotel full participation, also should closely combine with their vital interests, enabling them to consciously start from their own, thus eliminating daylight lamp and incandescent light, to promote the energy saving everyone good atmosphere. The idea of hotel staff transformed, improve the environmental consciousness, will also improve work quality, and, in turn, can affect the employee's family and the next generation, resulting in a huge social benefits. Changing attitudes of hotel guests, focuses on the cultivation of the green consumption spirit, from the perspective of the guests, should focus on guides them to strengthen the consciousness of energy conservation and environmental protection, and the pursuit of the civilized way of life.[5]In readjusting the tourist hotel will be the basis of scientific concept of energy management energy management training and examination of organic combine to form a complete and effective system.

To establish and improve hotel energy management system and strengthen scientific and effective implementation

In order to make the hotel energy management more scientific and institutionalized, must establish and improve a casing can, can use, energy saving regulations, clear the hotel energy management organization and management of division of labor and job responsibility, the hotel energy management departments in the work of the relationship as well as to the production and use of energy, such as saving requirements of each part. The hotel's energy management system to establish and perfect work should focus on the following several aspects:

First，the hotel management system for economic operation of the equipment. Economic operation management is mainly for energy dissipation (or capacity) equipment (system) how to improve the efficiency of management. The operation and management system, the provisions of the post responsibility system, each operation to make each device system, there is someone who's in charge of, according to the actual need to start or stop. Hotel equipment and economic operation management system including the management of economic operation of the boiler, central air conditioning system and the management of the economic operation and management and lighting electricity.

Second, the hotel use energy management system including water, electricity, oil, gas and other transport, use, energy saving index as well as the inspection and appraisal.

Third，the hotel departments of energy management system. Each department shall, according to the actual situation of unit energy consumption for the energy management system. The basis of energy management and hotel job mainly includes two aspects, namely, to establish complete system of energy measurement and energy consumption statistical work that is to emphasize on the hotel's energy consumption digital management.

To Establish and improve the hotel computer remote monitoring system in order to achieve the hotel energy management information and automation

By establishing and improving the computer remote monitoring system of the hotel, we can analysis the hotel energy usage scientifically during the operation and find and solve problems timely so as to realize the information and automation of the hotel energy management. The system should include hotels energy resource assessment, energy cost analysis, financial budget, real-time management of energy consumption, financial analysis of energy project, dynamic monitoring of energy-saving equipment, the accurately confirmation of the amount of energy-saving etc. we can realize scientific management and effective application of terminal equipment by taking advantage of the remote computer monitoring technology, scheduling energy load reasonably ,using the equipment in the long-term optimal energy state and the principle of " needs is the supply" .The hotel management personnel should make use of computer remote monitoring technology comprehensively and communicate about the problems and results of computer remote monitoring information system timely to share Information to accumulate the hotel staff energy-saving experience.

Keywords: PSD-BPA; Offshore Wind Power (OWP); Simulation; Detailed Model

Abstract. For the power load centers in china coast, large-scale development of new energy(such as offshore wind power and onshore wind power) is not only an effective means of control the bad weather(such as fog and haze), but also the practical requirements of coastal power shortage. In this paper, according to actual situation of China's large-scale wind power accessing to the coastal load centers centrally, also the characteristics of onshore and offshore wind farm models is considered, The voltage variation in the centralized model and detailed model is analyzed based on the platform of PSD-BPA, and the characteristic of each model is obtained. Research results have a certain reference value for China's coastal onshore and offshore wind power development.

Introduction

Currently, compared to other renewable energy resources, the industry foundation and application technology of wind power are relatively mature, so it is very suitable for commercial development of new energy power generation. As onshore quality wind resource is drained, more and more coastal countries are focusing attention on offshore wind power. Recently, the report of "2013 China's wind power installed capacity statistics" released by Chinese Wind Energy Association shows that, by the end of 2013, the totally installed capacity of offshore wind power projects is only 428.8 MW, which is far from the target of cumulative installed capacity of 5000MW by the end of "Twelfth Five-Year plan".

Modeling of wind farms has gone through two phases: in the early development of wind power, the capacity of wind farm is small, people are more concerned about the detailed model of single wind turbine, they consider that the composition of wind farm is a large number of small-capacity generators, boosting transformers and connecting lines; With the expansion of grid and wind farm scale, the way of detailed modeling appears poor convergence, long simulation time and other issues. So the centralization (equivalents) model, which studies the interaction between whole wind farm and power system, has been proposed [1]. As a large number of offshore wind farm planning, construction and operation, the proportion of offshore wind power in wind power industry will gradually expand. However considering the differences between offshore wind power and onshore wind power, for example, the unit capacity and the system characteristics [2], it is really a question whether the traditional land-based centralization model is suitable for offshore wind farms.

Based on the above analysis, and combine the research findings of offshore wind power at home and abroad, in this paper, a detailed model of offshore wind farm is built including the equipment models of wind turbine, package transformer, submarine cable and transformer, etc. So local grid voltage change and fluctuation rule is studied under different wind power output, the conclusions of this paper have reference value to depth research the characteristics of wind power model and offshore wind power.

Modeling of Wind Farm and its Influence on the Static Voltage

Onshore Wind Farm. The applied technology of onshore wind power is quite mature, each field of land wind power (such as site selection, wind resource assessment, collection system design, LVRT

capability and so on) has an associated normative guideline. Therefore, the classic model will be referenced in the detailed model of onshore wind power, specific methods will not repeat.

Offshore Wind Farm. The difference between offshore wind power and onshore wind power is embodied in the following points: 1) larger unit capacity, the wind turbine around 5MW has been the mainstream turbine at present; 2) a great influence of submarine cable on the reactive voltage, the submarine cable must be used to collect or transmit electrical energy in the field of OWP, AC cable will bring a lot of charging current. It not only limits the transmission distance and capacity, but also raise the voltage of OWF bus; 3) more choices of integration mode (HVAC, LCC-HVDC, VSC-HVDC and so on), by the requirement of transmission capacity and system stability, VSC-HVDC using in offshore wind power will be the future development trend.

For studying the static voltage level, we pay close attention on the effects of submarine cables and collector system architecture on static voltage level in offshore wind farm modeling. The structure of a detailed OWF model is shown in Figure 1 after referred the offshore wind projects (Donghai Bridge offshore wind farms, etc.) and wind farm design and integration standards.

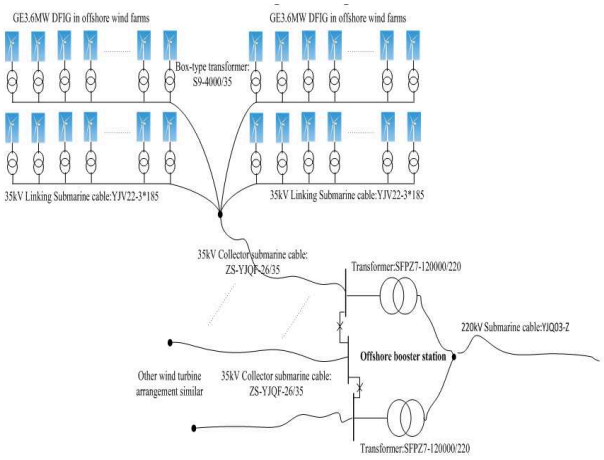

Figure 1

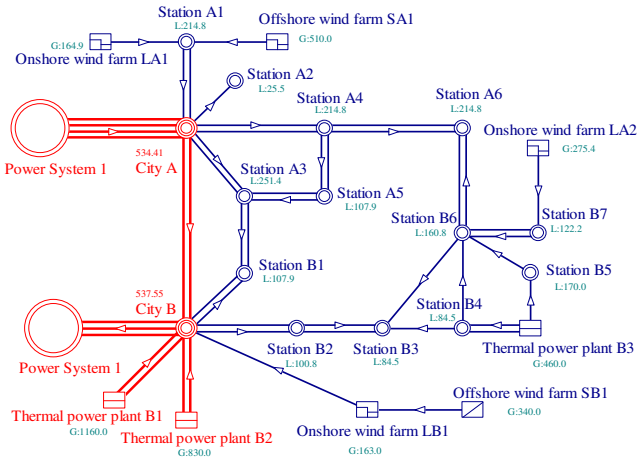

Figure 2

The Impact of Wind Farm on Static Voltage Levels. Due to the intermittent and random of wind power, large-scale wind power connecting to grid will have more and more obvious influence on grid structure design, operation scheduling scheme, reactive compensation measure and power quality[4]. For wind farms have been built, the impact of wind farm on grid voltage is mainly reflected in the WTG characteristics and reactive power compensation.

Active power output from WTG mainly depends on the wind speed; in terms of reactive power, constant speed wind turbine absorbs reactive power influenced by the active power, the fluctuation of reactive power is less for DFIG generally using constant power factor control mode. During the process of grid-connected wind turbine operation, the output of wind turbine will be influenced by tower shadow, yaw error and other factors, and the fluctuation is changed with turbulent intensity [5]. In addition, wind turbine in the process of starting, stopping and switching will produce voltage fluctuations and flicker [6].

The integration operation of wind power farm will consume some reactive power and have a negative impact on the voltage quality. This effect comes from the reactive power losses of wind turbine, collection system and boosting transformer. Existing reactive power compensation device can basically meet the system requirements of reactive power, but it has the drawback of slow adjustment and discrete adjustment. SVC can achieve quickly compensate and smooth adjustment, provide dynamic voltage support and improve the operating performance because it has introduced power electronic components into the traditional static reactive power compensation device. In addition to compensating to the wind farm, SVC can also improve the voltage quality and system stability [7].

Simulation Analysis

System Outline. In this paper, the research object is a power system of China's eastern coast. It plans to build five wind power farms (total installed capacity of 1711MW, and total output of 1454MW) in this region, including two offshore wind farms (SA1 and SB1, output respectively 510MW and 340MW). Considering the limited scale of OWP at this stage, two offshore wind farms have been accessed into the 220kV region power grid. Schematic diagram of the system is shown in Figure 2.

The Influence of Wind Farm Model on System Voltage level. In this paper, 1.5MW and 3.6MW double-fed wind turbine models produced by GE Corporation are used in onshore and offshore wind farms respectively, and the maximum output is considered as 85 percent of the installed capacity of wind farm. Also wind turbines run at constant power factor control mode (power factor of 1.0) and the wind farms consider the role of reactive power compensation device (SVC).

A coastal power system in eastern China is studied here. The voltage fluctuation is analyzed respectively in condition of centralized model, detailed model of onshore wind power and detailed model of onshore and offshore wind power. The system prerequisites of reactive power compensation, other generator status and terminal voltage remain unchanged during the change process of wind power output. In above conditions, the voltage fluctuation results are shown in Table 1 and Table 2.

Table 1 The impact of centralized model and detailed model on static voltage level under the minimum and maximum output of wind farm

Bus Station	Centralized model(kV)		Detailed model of onshore wind power(kV)		Detailed model of onshore and offshore wind power(kV)	
	Min (0%)	Max (85%)	Min (0%)	Max (85%)	Min (0%)	Max (85%)
SA1	241.8	238.4	241.9	239.2	241.7	237.9
LA1	237.7	235.2	237.9	235.9	237.6	235.3
A1	237.4	234.8	237.6	235.5	237.3	234.9
City AL	237.2	235.0	237.4	235.7	237.1	235.1
A4	236.2	233.9	236.4	234.6	236.0	234.1
A6	235.3	233.4	235.5	234.0	235.1	233.5
B6	235.5	233.8	235.7	234.3	235.4	233.9
B3	235.8	233.9	236.1	234.4	235.7	234.0
B2	236.2	233.9	236.5	234.6	235.9	234.1

SB1	241.7	239.5	243.5	240.1	242.0	239.8
B7	236.2	234.4	236.5	234.9	236.1	234.5
LA2	238.0	235.9	238.3	236.4	237.9	236.0

Table 2 The impact of wind power output change on voltage fluctuation ratio under different models

Bus Station	Rated voltage (kV)	Centralized model	Detailed model of onshore wind power	Detailed model of onshore and offshore wind power
SA1	220	1.55%	1.23%	1.73%
LA1	220	1.14%	0.91%	1.05%
A1	220	1.18%	0.95%	1.09%
City AL	220	1.00%	0.77%	0.91%
A4	220	1.05%	0.82%	0.86%
A6	220	0.86%	0.68%	0.73%
B6	220	0.77%	0.64%	0.68%
B3	220	0.86%	0.77%	0.77%
B2	220	1.05%	0.86%	0.82%
City BL	220	1.09%	0.91%	0.82%
LB1	220	1.77%	1.95%	1.18%
SB1	220	1.00%	1.55%	1.00%
B7	220	0.82%	0.73%	0.73%
LA2	220	0.95%	0.86%	0.86%
City B	500	0.56%	0.30%	0.38%
B1	220	1.09%	0.82%	0.86%
A3	220	1.05%	0.82%	0.91%
City A	500	0.40%	0.18%	0.28%
Plant B3	220	0.55%	0.41%	0.45%

According to Table 1, the distribution curve of static voltage level can be drawn under the six operation case, specifically as shown in Figure 3. According to Table 2, the distribution ratio curve of static voltage can be drawn under three models, specifically as shown in Figure 4.

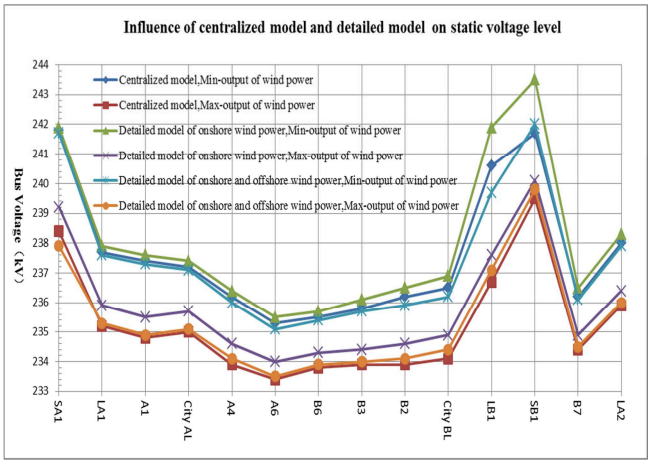

Figure 3

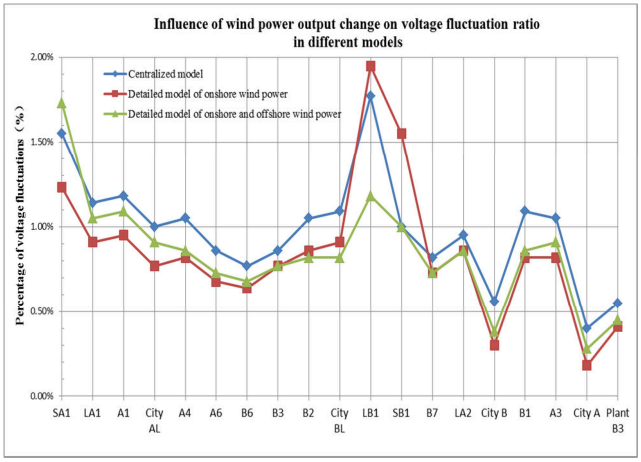

Figure 4

The following conclusions can be obtained from Table 1 and Figure 3: 1) in the models of centralized model, detailed model of onshore and detailed model of onshore and offshore, the changing trend of static voltage is consistent, so the three models are effective and realistic; 2) Stations of the highest voltage appear in bus SA1 and bus SB1, higher than the adjacent bus about 4kV and 2.4kV respectively. This fully confirms that the charging power produced by submarine cable can make the related bus voltage higher than others; 3) The bus voltage in intermediate area of the three wind farm groups is lower generally, the lowest voltage appears in station A6. So it should pay attention on station A6, for example, the reactive power compensation device should be installed in case of voltage collapse problem; 4) From the three models, the voltage level of minimum output of wind power is higher than the maximum output of wind power. The voltage level of detailed model of onshore is the highest in minimum output of wind power, and the lowest is the centralized model in maximum output of wind power. The voltage level of considering a detailed model of offshore wind power is very close to the voltage level of centralized model, but it has a gap with voltage level of detailed model of onshore wind power.

The following conclusions can be obtained from Table 2 and Figure 4: Among the simulation results, the maximum percentage of voltage fluctuation appears in centralized model, and the minimum - appears in detailed model of onshore wind power. But the rule does not be complied in the buses of SA1 and SB1, the voltage fluctuation percentage of SA1 and SB1 in detailed onshore model is higher than other models significantly, but the bus of LB1 is lower. This phenomenon is mainly caused by the charging power of OWP submarine cable.

Summary

Network architectures and integration characteristics of OWP have a large difference compared with onshore wind power. As can be seen from the simulation result, the outlet port voltage of offshore wind farms have been raised significantly, and even raised voltage of the nearby area. So necessary measures should be taken to inhibit the phenomenon, for example, it shows that compensating the charging power of the submarine cable through high voltage reactors can effectively weaken the capacitance effect of the line when the power factor is set to -0.98 [8]. In addition, it can be seen by comparing three models that the static voltage fluctuation trend is consistent, but there are some differences in voltage level and complexity of the models. Therefore, this paper suggests that the researchers can choose the right model to simplify difficulty based on research accuracy, research subject and voltage fluctuation, etc. From the research status home and abroad, the OWP development has been focusing attention on large-scale offshore wind farms. The research of China's OWP is still in the exploratory stage, in the future, the theoretical research of OWP should focus on internal wind farm and integration characteristics.

Keywords: wind power integration, power system, small disturbance stability

Abstract. Setting up a practical power system containing wind farm small disturbance stability mathematical model, and the linearized equation of wind turbines and original equations of linear system, power system containing wind turbines augmented state formation matrix, turn the inverse iteration with PSASP software Rayleigh (Rayleigh quotient iterative algorithm and sparse matrix technique for large state matrix eigenvalues. In this paper, the Inner Mongolia power grid, wind power access to power system oscillation mode and the influence of the oscillation characteristics and meet the requirements of small disturbance stability of wind scale and operation control scheme. The influence of the wind farm is proposed for power system damping characteristics will not greater than the same capacity of synchronous generator's point of view.

Introduction

Small disturbance stability refers to the power system under small disturbance in sync operation ability, in math, it said in a running point near the stability of the system equations are linearized embodied.

For small disturbance stability analysis is presented in this paper the mathematical model of wind turbine for power system containing wind farm small disturbance stability calculation, combined with the actual power grid, the large capacity of wind power grid for power system oscillation mode and the influence of the damping characteristics.

Doubly-fed wind turbine mathematical model small disturbance

Doubly-fed wind turbine model writing form as follows:

$$\begin{aligned} \dot{y}_{\mathrm{g}} &= f_1(y_g, u_g) \\ \dot{y}_{\mathrm{e}} &= f_2(y_e, u_e) \\ \dot{y}_t &= f_3(y_t, u_t) \\ 0 &= g_1(y_g, u_g) \\ 0 &= g_2(y_e, u_e) \\ 0 &= g_3(y_t, u_t) \end{aligned} \tag{1}$$

Including, $\mathrm{f} = [\mathrm{f}_1^{\mathrm{T}}, \mathrm{f}_2^{\mathrm{T}}, \mathrm{f}_3^{\mathrm{T}}]^{\mathrm{T}}$ and $\mathrm{g} = [\mathrm{g}_1^{\mathrm{T}}, \mathrm{g}_2^{\mathrm{T}}, \mathrm{g}_3^{\mathrm{T}}]^{\mathrm{T}}$ are for doubly-fed wind turbine model of the dynamic equation and algebraic equation, $\mathrm{f}_1, \mathrm{g}_1$ are parts of the dynamic equation and algebraic equation for generator, $\mathrm{f}_2, \mathrm{g}_2$ for the inverter electrical control parts of the dynamic equation and algebraic equation, $\mathrm{f}_3, \mathrm{g}_3$ for the wind machine and control system parts of the dynamic equation and algebraic equation;

$\mathrm{y} = \left[y_g^T, y_e^T, y_t^T\right]^T$ and $\mathrm{u} = \left[u_g^T, u_e^T, u_t^T\right]^T$ are for the doubly-fed wind power generator sets of state variables and input variables, y_g, u_g are for generator part states variables and input variables, y_e, u_e are for the inverter electrical control parts state variables and input variables, y_t, u_t are for the wind machine and control system parts state variables and input variables.

For the stability of small disturbance linearization, available:

$$\Delta \mathrm{y} = \left[\Delta y_g^T, \Delta y_e^T, \Delta y_t^T\right]^T \tag{2}$$

The corresponding state after linearization matrix, input matrix and output matrix and feedforward matrix, respectively:

$$A_2 = \begin{bmatrix} \frac{\partial f_1}{\partial y_g} & \frac{\partial f_1}{\partial y_e} & \frac{\partial f_1}{\partial y_t} \\ \frac{\partial f_2}{\partial y_g} & \frac{\partial f_2}{\partial y_e} & \frac{\partial f_2}{\partial y_t} \\ \frac{\partial f_3}{\partial y_g} & \frac{\partial f_3}{\partial y_e} & \frac{\partial f_3}{\partial y_t} \end{bmatrix} \tag{3}$$

$$B_2 = \begin{bmatrix} \frac{\partial f_1}{\partial u_g} & \frac{\partial f_1}{\partial u_e} & \frac{\partial f_1}{\partial u_t} \\ \frac{\partial f_2}{\partial u_g} & \frac{\partial f_2}{\partial u_e} & \frac{\partial f_2}{\partial u_t} \\ \frac{\partial f_3}{\partial u_g} & \frac{\partial f_3}{\partial u_e} & \frac{\partial f_3}{\partial u_t} \end{bmatrix} \tag{4}$$

$$C_2 = \begin{bmatrix} \frac{\partial g_1}{\partial y_g} & \frac{\partial g_1}{\partial y_e} & \frac{\partial g_1}{\partial y_t} \\ \frac{\partial g_2}{\partial y_g} & \frac{\partial g_2}{\partial y_e} & \frac{\partial g_2}{\partial y_t} \\ \frac{\partial g_3}{\partial y_g} & \frac{\partial g_3}{\partial y_e} & \frac{\partial g_3}{\partial y_t} \end{bmatrix} \tag{5}$$

$$D_2 = \begin{bmatrix} \frac{\partial g_1}{\partial u_g} & \frac{\partial g_1}{\partial u_e} & \frac{\partial g_1}{\partial u_t} \\ \frac{\partial g_2}{\partial u_g} & \frac{\partial g_2}{\partial u_e} & \frac{\partial g_2}{\partial u_t} \\ \frac{\partial g_3}{\partial u_g} & \frac{\partial g_3}{\partial u_e} & \frac{\partial g_3}{\partial u_t} \end{bmatrix} \tag{6}$$

After the linearization with the system and the equation of wind turbine components and the equations of linear network, the system can be augmented state matrixA', can be obtained by solving the characteristic value of small disturbance stability of all kinds of information system. Based on integrated power system analysis program (PSASP) the small disturbance stability analysis software, realizes the wind linearized equation and original of simultaneous linear equation system, using the software of the inverse iteration to Rayleigh and sparse matrix technology (Rayleigh) quotient iteration method to calculate large state matrix eigenvalue, and implements the power grid containing wind farm small disturbance stability calculation function.

Wind power grid in Inner Mongolia power grid after small disturbance stability analysis

Calculation Conditions

Calculation used in wind turbines and control system parameters are as follows:

A single asynchronous wind turbine parameters (unit capacity standard MAO value): $P_g = 0.7\text{MW}$, $U_g = 690\text{V}$, V_r=15/ms, $V_{cr} = 4\text{m/s}$, $V_{co} = 25\text{m/s}$, r_r=0.01718p.u, x_r=0.124p.u, $x_s = 0.11\text{p.u}$, $T'_{do} = 47\text{s}$, $T_j = 6\text{s}$, $\tau_s = 1s$.

A single main parameters doubly-fed wind power generator (unit capacity standard MAO value): $P_g = 1.5\text{MW}$, $U_\text{g} = 690\text{V}$, $\text{V}_r = 11.8\text{m/s}$, $V_\text{ci} = 3\text{m/s}$, $V_{co} = 25\text{m/s}$, $X^{''} = 0.55\text{p.u}$, $\text{R} = 35.2\text{m}$, $T_\text{t} = 7.64\text{s}$, $T_g = 1.14\text{s}$, $K_{tg} = 1.246\text{p.u.torque/rad}$, $D_{tg} = 1.5\text{p.u.torque/p.u.speed}$, $\text{w}_d = 125.66\text{rad/s}$, $\theta_{max} = 27\text{deg}$, $\theta_{min} = 0deg$, $P_{max} = 1.12\text{p.u.}$, $P_{min} = 0.1\text{p.u.}$, $Q_{max} = 0.312\text{p.u.}$, $Q_{min} = -0.436\text{p.u.}$.

Through calculation, the wind power grid power grid in Inner Mongolia area oscillation mode comparison between before and after.

Wind power grid power grid in Inner Mongolia area oscillation mode comparison between before and after verified through the calculation of small disturbance stability of Inner Mongolia power grid, related to the power grid in Inner Mongolia mainly have six regional oscillation mode, respectively is: (1) cylinder unit area on the system oscillation mode; (2) Inner Mongolia, Shanxi unit of north China provides oscillation mode; (3) Inner Mongolia units of Shanxi units oscillation mode.

Table 1 to table 3, respectively, as well as the characteristics of wind power grid before and after the oscillation mode, the comparison, among them, Z, f, alpha, beta, respectively is oscillation mode corresponding characteristic value, frequency, damping ratio and the related mechanical and electrical circuits.

Analysis of the above calculation results can get the following conclusion:

(1) Larger capacity of wind, both asynchronous wind power generator and doubly-fed wind power generator, related to the power grid in Inner Mongolia regional oscillation pattern has not changed, and two kinds of models of the calculation results are basically identical.

(2) Inner Mongolia, Shanxi unit of north China provides oscillation of Shanxi, Inner Mongolia unit model in wind turbines characteristics after the access to the root distribution, there was no big change, damping ratio decreased but not by much.

(3) Cylinder area through a 430km, 500kv line contact with the main system is weak, the wind generator in the region have no access, cylinder unit area the main oscillation mode damping ratio 3.65; Access to a larger capacity of wind power units (500mw), the oscillation mode damping characteristics have fallen sharply, even became negative damping, the unstable operation of the system of the actual working condition.

Conclusion

This paper sets up a small disturbance stability power system containing wind farm mathematical model. By small disturbance stability calculation of Inner Mongolia power grid, and analyses the influence of large-scale wind power system oscillation mode and the influence of the oscillation characteristics, this paper discusses the weak power grid wind that could satisfy the requirement of small disturbance stability operation scale and system operation control measures.

Key words: Iced conductor; Uniform; Non-uniform ; Jumping off the ice

Abstract: This paper introduces several kinds of icing and ice-off simulation method: the equivalent load method, quality method, Támás model method and cell death method. With a large span cross section as an example, using finite element method, established the finite element model of single span icing wire, analyzed the non-uniform ice-off and the even ice-off,the results show that: Non-uniform ice-off dynamic tension is significantly smaller than even ice-off dynamic tension,the smallest dynamic tension is closely related to wire jump amplitude, the greater jump amplitude leads to the smaller dynamic tension，the essence of which is determined by the conductor slack.

Introduction

When weather conditions change, wind load and the external mechanical forces, then the icing lines will happen various forms of ice-off. At home and abroad, for overhead lines ice-off bouncing, the research focuses on the ice thickness, ice-off mode and wind load analysis, but the research of simulating icing and ice-off is tiny little. This article start from the simulation method of icing and ice-off, carefully clarify the mechanism and applicability of these methods, and employ the finite element method for a large span wire, numerically simulate the non-uniform and uniform ice-off.

Simulation method of the ice- off

The equivalent load method

When research on icing, the usual method is look it as the circle model which locates at the outside of the wire. The equivalent load method, in short, is dispersing icing load to some points on wire, and the method can be divided into concentrated load and uniformly distributed load.the reference [1] has been validated: Using the former method for lines icing and ice-off jumping off to simulate, found that the tension of line and the jumping height are conformity with the actual, so this method is feasible.

The quality method

When dynamic and static analysis of lines, only take the own weight of the icing into consideration, without considering the other influence. In finite element model, directly simulate the icing as the quality block of the unit node or the equivalent increasing density of the wire. At the time of simulation to ice-off, accordingly unload the equivalent mass block or reduce wire density. The method's principle is simple, the quality block commonly uses Mass21 to simulate, and program design is more concise[2].

Támás model

The quality method and the equivalent load method only take the own weight of the ice into consideration, without considering the other influences, but in fact, the icing has some mechanical properties. The icing has the other capacity, such as tensile, compression, torsion, shear. In order to consider the mechanical properties of the ice wires, Támás used beam element instead of stem cell, and used the finite element method to study the single line, analyzed this model's dynamic response of ice-off machine[3].

This method need to set up two models in finite element modeling, the first step is to simulate the wire with cable or stick, then the second step is to simulate icing with beam at the same node with stem cell.

Birth and death element method

When research on a model, sometimes need one or some unit do not exist, use the birth and death element method to study these problems will be a good choice at this time. The birth and death element method's essence is the element stiffness settings. When some unit is needed, they can exist like other units. Otherwise, can set it inexistence. The principle is that use a small formulas to decrease the stiffness matrix, and the other parameters are set to zero[4].

For the characteristics of the birth and death element method, in the simulation of overhead line ice-off, can simulate deicing with the element's birth and death. For the entity model which's ice locates on the outside of the line, the method can conveniently simulate ice-off.

The above analyzed several ice and deice method, and then the paper will give a simulation ice-off example using the first kind of simulation method.

The example analysis

Wire and the icing parameters

Set a single wire horizontal span L=1000m, wire model is LGJ-400 / 35,, two suspension points have no height difference., the wire cross area S is 435 $mm2$. Modulus of elasticity E=6.5×10 ^{10}Pa, Unit mass m=1.349kg / m , Poisson's ratio=0.3. In a weather condition, the ice thickness is 12 mm . Density is 900kg / m^3 , the wire horizontal stress σ =58.27 MPa ,the wire material damping ratio is 0.02.

Build the finite element model

With the finite element software ANSYS, selects the LINK10 to establish the finite element model with dividing line into 1000 units.

The wire shape finding

Wire self-weight shape finding

With the ANSYS, in the study of the single suspension cable, can adopt direct iterative method or the shape finding analysis. This paper use the direct iteration method to analyze the line self-weight shape finding. The basic principle: When the finite element modeling, can first built a straight line, at the meshing stage, use the LINK10 to transform it into a sufficient number of units. Restrict on the two endpoints and set the real material parameters , then set initial dependent variable into enough small, then add the acceleration of gravity and set the suspension cable tension as the convergence conditions, through a series of iterative update model, finally complete self-weight shape finding[5].

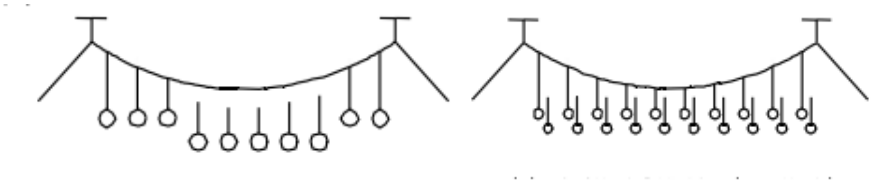
Icing wire shape finding

After wire covered by ice, the shape finding is called the second shape finding, which applying ice shape based on self-weight shape finding, this step use the load step in ANSYS. Using the equivalent load method to simulate the ice, when icing shape finding, with the form of load step, it's easy to determine the shape of wire in the end. As shown in Figure 1, shape finding is completed.

Figure1-1 The final shape of the wire after shape finding

Simulate non-uniform ice jump off of the iced wire

In fact, wire's ice-off is a complex process, uniform ice-off and uneven ice-off are all exist, and the randomness is strong. In order to simulate non-uniform ice-off, this paper take the simulation method that shown in the figure to simulate non-uniform ice-off and uniform ice-off.



(a) Non-uniform off the ice simulation (b) Even off the ice simulation

Figure1-2 Iced wire uniform and non-uniform ice-off simulating method

For the same example to simulate the wire's uneven ice-off.(50% ice-off)

Choose the nodes of middle-span, left of middle-span and right of middle-span, to plot the S-t graph of ice-off process. The Figure 1-3 show the Y-direction S-t graph of middle-span 500 node.

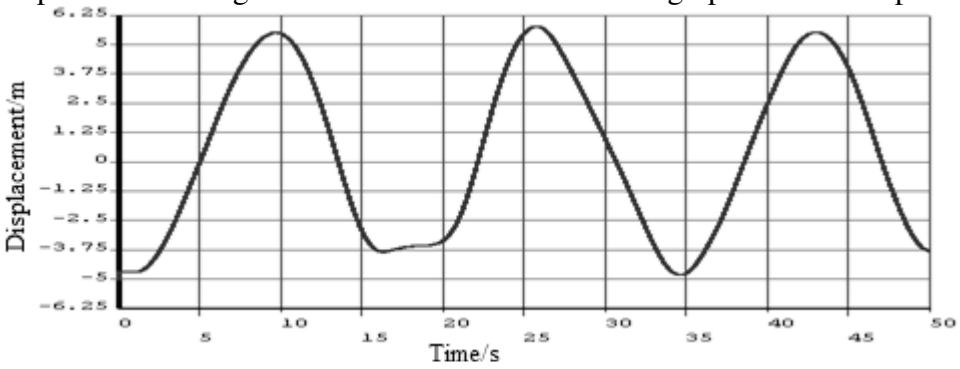


Figure1-3 Y-direction S-t graph of middle-span 500 node

Chart1-1 The maximum displacement of each node jumping

Node number	Y negative displacement	Y forward displacement
500	-5.030m	+5.765m
250	-3.770m	-1.849m
750	-3.810m	-2.054m

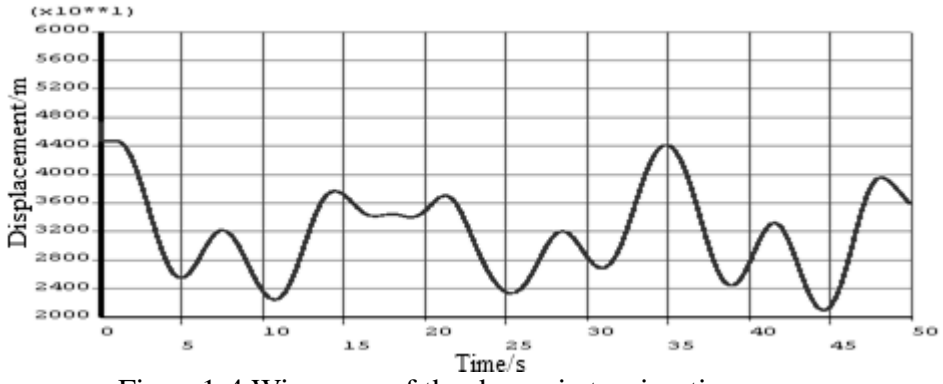

Figure1-4 Wire span of the dynamic tension time curve

The above is the rule about the wire ice-off displacement changed with time. The figure1-4 show the ice-off span dynamic tension variation.

Chart1-2 Ice-off conditions of wire tension control table

wire tension kN	100% ice-off	50% non-uniform ice-off	50% uniform ice-off
The initial tension	25.345	25.345	25.345
Iced wire tension	48.319	48.319	48.319
The maximum dynamic tension	37.815	43.738	40.378
The minimum dynamic tension	8.327	21.002	15.673

Through the wire tension comparison table, it can be seen that the tension increase obviously after the wire icing. The wires ice-off is either 100% or 50%.After ice-off, middle-span's tension is small than icing, on the three kinds of work condition, 50% non-uniform ice-off dynamic tension is maximum, 100% ice-off dynamic tension is minimum. At the same time, minimum wire dynamic tension is closely linked with jump height, and more wire jump height will lead dynamic tension to decrease, its essence is due to the wire relaxation degree.

Conclusion

To simulation of overhead line jumping, the key step is the simulation of icing and ice-off, which is less researched in the past. This paper introduces several kinds of icing and ice-off simulation method: the equivalent load method, quality method, Támás model method and cell death method. With a large span cross section as an example, using finite element method, analyzed the non-uniform ice-off and the even ice-off, the conclusion are:

When the lines ice-off jumping, middle span's amplitude is largest. The inappropriate design will lead the interphase flashover, so the line design need to be care, especially at heavy ice area, large span, and bad meteorological condition.

Either 100% or 50% ice-off jumping, middle-span's tension is small than icing line tension, on the three kinds of work condition, 50% non-uniform ice-off dynamic tension is maximum, 100% ice-off dynamic tension is minimum, at the same time, minimum wire dynamic tension is closely linked with line's jump height, and more wire jump height will lead dynamic tension to decrease, its essence is due to the wire relaxation degree.

After 100% ice-off, middle span's tension will be less then icing, which is due to line's slack, the great harm of 100% ice-off is not due to tension's increase, but wire's oscillate up and down repeatedly. In a short time, the tension's sudden change will lead the line to be damaged seriously. The suspension points need more address.

Keywords: Changing Meteorological Conditions; Photovoltaic; SC; Charge and Discharge Control; Optimal Energy Storage Capacity Configuration

Abstract. In the paper, energy storage system and charge and discharge control strategy for large-scale photovoltaic generation are designed. The optimal energy storage capacity is configurated for PV array. The energy storage system and control module for PV generation are built in MATLAB-Simulink platform. Supercapacitor (SC) is the energy storage element. Considering the insolation and temperature under the changing meteorological conditions, the output power would be fluctuant. By controlling MOSFET switches based on power signal, SC will charge when the lighting is adequate and discharge in the instance of lack of light to keep DC bus voltage in constant. Configuring the optimal energy storage capacity by simulation, the result proves that the control strategy is feasible and the configuration is optimal.

Introduction

With the rapid development of large-scale photovoltaic generation, energy storage control strategy develops fast since the storage system is the obbligato link. The energy storage system has a very important function on promoting the quality of photovoltaic generation. The solar energy is fluctuant and stochastic, thus the output power of PV array is not constant. Charging or discharging of SC balance the fluctuant output power caused by adequate and scarce sunlight. The process is implemented by controlling SC in PV generation with energy storage system.

SC is widely used as storage element in electric power system. The main contribution of paper [1] is to propose an SC control strategy for a bidirectional DC/DC converter in an micro grid ESS based on SCs. The primary objective of paper [2] is to solve above problems and improve the performance of the isolated symmetry half-bridge bidirectional DC/DC converter, novel design guidelines, novel modeling of the converter and novel control strategy are proposed by analyzing the principle of the converter and the characteristics of SC module. Paper [3] analyzed the working mode of DC/DC converter when the SC is charging, and designed the closed loop control parameters.

In this paper, a control strategy of energy storage system including PV array and SC is proposed to smooth the output power of DC bus for the grid-connected PV generation. The proposed charging and discharging control method reduces the fluctuant of output power caused by the changing meteorological conditions and configurates the optimal energy storage capacity by simulation for the PV generation system. This paper is organized as followed. In section of 'SC Energy Storage Structure of PV Generation', PV characteristics and mathematical model are analyzed, and the main parameters' formula derivations of the circuit are given. In section of 'The Optimal Energy Storage Capacity Configuration', SC charge and discharge control module based on power signal is given. The control strategy keeps the DC bus voltage in constant before the PV generation connects to grid. In section of 'Simulate Results', the SC energy storage control system of PV generation is built, which includes PV array module and charging and discharging control strategy module in MATLAB-Simulink. And the waveform of SC input and output power caused by changing meteorological conditions is showed.

SC Energy Storage Structure of PV Generation

Fig.1 shows the SC energy storage structure of PV generation. It consists of a PV array, a SC connected by a boost-buck DC/DC convertor and a boost DC/DC converter.

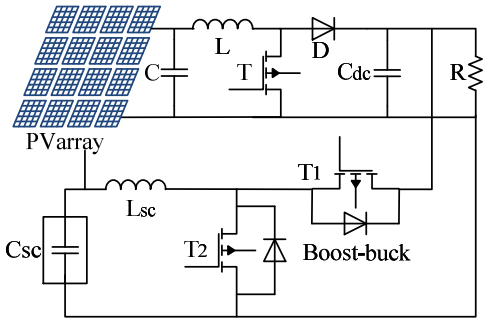

Fig.1. SC energy storage structure of PV generation

In fig.1, C is filter capacitor which makes the output power of PV array continuous. It will lead to a big amplitude ripple wave if its value is relatively small. Also, C will cause the response time to increase if its value is too big. Inductance L is chosen in the continuous mode. According to the volt-second balance theory, the integral for voltage of both ends of L is zero, which is expressed as:

$$U_{pv}DT_S + \left(U_{pv} - U_{dc}\right)\left(1 - DT_S\right) = 0 \tag{1}$$

In equation (1): U_{pv} is the output voltage of PV array; U_{dc} is the voltage of DC bus; D is the duty ratio of MOSFET, T_S is switching period, we can divide both sides of the equation, then the relationship of U_{pv}, U_{dc} and D is expressed as follows:

$$\frac{U_{dc}}{U_{pv}} = \frac{1}{1-D} \tag{2}$$

In the condition of no loss, input power equals to output power $P_{pv} = P_{dc}$, which is equivalents to $U_{pv} I_{pv} = U_{dc} I_{dc}$. The relationship between current and duty ratio is $I_{dc} / I_{pv} = 1\text{-}D$. Because the inductance current equals to PV output current, $I_{dc}/I_L = 1\text{-}D$. Considering $U_L = L*di/dt$, the ripple current of the inductance is expressed as:

$$\Delta i_L = \frac{U_{pv}DT_S}{L} \tag{3}$$

In equation (3): Δi_L can be expressed as $\Delta i_L = \eta_I / i_L$, in which η_I is ripple factor of the ripple current of the inductance. Based on equations (1) (2) (3), the calculation formula of inductance L could be expressed as equation (4). Seeking the extreme L by taking derivative with D, L is obtained the maximum with D =1/3 and the computational formula of the maximal L is expressed as:

$$L = \frac{U_{dc}{}^2\left(1-D\right)^2 DT_S}{\eta_l P_{dc}} \xrightarrow{D=\frac{1}{3}} L_{\max} = \frac{4U_{dc}^2 T_S}{27\eta_l P_{dc}} \tag{4}$$

The DC bus capacitor C_{dc}, the capacitor of DC-link, is the key link between PV array, SC energy storage system and grid-connected invertor. When choosing the capacity of C_{dc}, the circuit has to working under the condition of continuous mode. The quantity of electric charge or discharge ΔQ causes a voltage ripple of DC bus, which can be expressed as:

$$\Delta U_{dc} = \frac{\Delta Q}{C_{dc}} = \frac{I_{dc}DT_S}{C_{dc}} = \frac{P_{dc}DT_S}{U_{dc}C_{dc}} \tag{5}$$

In equation (5): ΔU_{dc} can be expressed as $\Delta U_{dc} = \eta_U U_{dc}$, in which η_U is the ripple factor of the ripple voltage. Add η_U into equation (5), the DC bus voltage C_{dc} is expressed as:

$$C_{dc} = \frac{P_{dc}DT_S}{\eta_U U_{dc}^2} \tag{6}$$

The formula of the SC inductance L_{SC} is the same as L_{max} showed in equation (5).

The Optimal Energy Storage Capacity Configuration

The control objective of energy storage is to stabilize the fluctuation caused by meteorological condition. Charge and discharge control of SC keeps the DC bus voltage in constant before the PV generation connects to grid. In the SC energy storage system, power signal is used as a switch signal to control MOSFET M_1 and M_2. Fig.2 shows the SC charge and discharge control module.

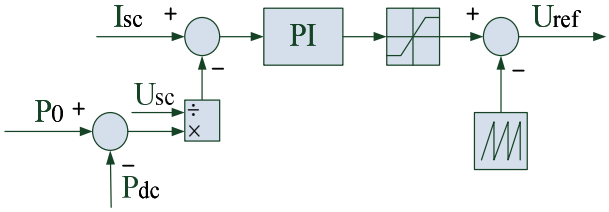

Fig.2. SC charge and discharge control module

In fig.2, P_0 is the reference power. The fluctuating power is the difference between reference power and output power, which serves as control signal to control the state of the MOSFET M_1 and M_2. When the output power is much bigger than the reference power P_0, the fluctuating power difference value is negative and M_1 is on by PWM signal of PI control of the electric current loop. On the contrary, M_2 is on. The switching table is showed as followed:

TABLE 1 Switching table of SC boost-buck circuit

$P_0 < P_{dc}$	SC charging	M_1 is on, M_2 is off
$P_0 > P_{dc}$	SC discharging	M_1 is off, M_2 is on

For large-scale PV generation, generating capacity is high so it is arduous task for SC energy storage system when weather changes. Larger capacity energy has a better storage capacity. But considering the economic efficiency, the optimal storage capacity is configurated for the requirements of large-scale PV generation.

$$C_{SC} = \frac{\Delta Q}{U_{SC}} = \frac{I \cdot t}{U_{SC}} = \frac{\Delta P_{SC} \cdot t}{U_{sc}^2} \tag{7}$$

Equation (7) is the computational formula of SC. By calculating the output power under large carving illumination and low light intensity, the ΔP could be obtained which equals to ΔP_{SC}. The capacity of SC could be calculated by equation (7).

Simulate Results

This paper builds the SC energy storage control system of PV generation, which includes PV array module and charging and discharging control strategy module in MATLAB-Simulink. The parameters of the simulation are followed: Set the initial voltage of SC to 160V, the capacity of SC to 6F, set the reference voltage U_0 to 600V. The variable illuminations are 800-600-800-1000-800 kW/m^2 in each 0.1 second showed in fig.3. The simulation time is 0.5s, and the simulation arithmetic is ode23tb. The simulation waveform of SC is showed in fig.4.

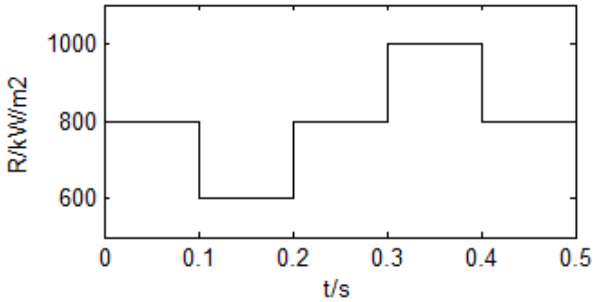

Fig.3. Variable illuminations

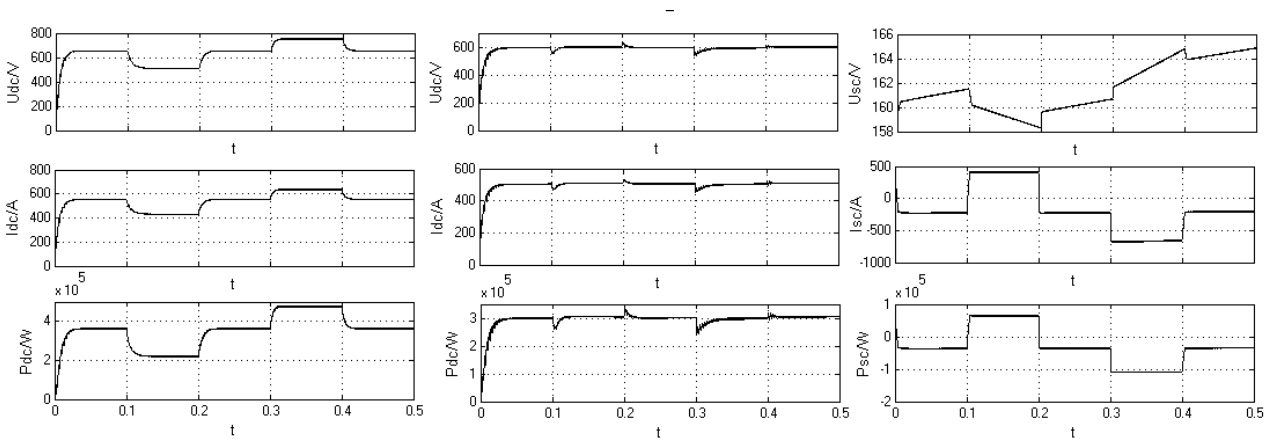

(a) U_{dc}, I_{dc}, P_{dc} without SC (b) U_{dc}, I_{dc}, P_{dc} with SC (C) U_{dc}, I_{dc}, P_{dc} of SC

Fig.4. Output voltage, current, power of DC bus and SC

In fig.4 (a), output power fluctuates as the variable illumination. The minimum output power is 220kW when illumination is 600 kW/m^2 while the maximum output power is 490kW when illumination is 1000 kW/m^2. The capacity of SC is 5.27F after calculation. In fig.4 (b), SC is used to store energy to keep the DC bus voltage in constant. Fig.4 (c) shows that when the fluctuating power is bigger than reference power, SC charged and on the contrary, SC discharged. The simulation result proves that the capacity of SC equal 6F is reasonable.

Conclusion

In this paper, the correct parameters of the PV generation system with SC are chosen. Based on the analysis of the SC boost-buck circuit, a switching table of the MOSFET is constructed to control the SC to charge and reduce the DC bus voltage or to discharge and increase the DC bus voltage. Considering both of the capacity requirement and economic efficiency, an exact capacity of SC is chosen to keep the DC bus voltage in constant. And the simulation result proves it reasonable.

Abstract. This paper briefly introduces the characteristics of wind power technology and its development process, Through data comparison, demonstrate the superiority of the variable speed wind turbine operation. In keeping the best tip speed ratio, the variable speed constant frequency control for the biggest wind power.

Introduction

Due to the worldwide coal, petroleum and other non-renewable energy is reduced,and coal as the main energy of the electric power industry brings the serious problems of environmental pollution,all countries in the world to focus shifted to renewable and clean energy research, development and utilization.For the use of renewable and clean energy, the most mature is wind power technology[1].

In recent years, the rapid development of wind power technology.Capacity of constantly improve, commercially available megawatt wind power unit;The variable pitch wind turbine power regulation replaced the fixed pitch adjustment, the generator of variable speed constant frequency operation replaced the traditional constant speed constant frequency operation, further improve the system efficiency;Implements the wind farm in real-time monitoring, remote controlling and computer group control, improve the stability of distribution or parallel operation and power quality.

Wind power generation technology

Wind power technology is the aerodynamics, electrical machinery, materials science, mechanical transmission, automatic control, power electronics technology and other multi-disciplinary comprehensive technology. Although wind power development has been about 100 years, but it wasn't until the 1970 s brought to the attention of the people gradually, domestic and foreign existing wind power technology has failed to fully show the advantage of wind power, wind power technology and larger development space. Large wind power generators to large capacity, good power quality, improve material utilization, reduce noise, reduce cost and improve efficiency of direction[2].

Unit capacity increase

In the early 1980 s, commercialization of the stand-alone capacity of wind turbines is given priority to with 55 kW, the middle 1980s to the early 1990s to give priority to with 100 ~ 450 kW, 90 s to 500 kW ~ 1 MW.At present, large and medium-sized units connected to the grid, has become the main form of wind energy.To reduce the cost of unit kw, save the using area of wind farm, speed up the construction of wind farms, improve the economic benefits of wind power, many wind power manufacturers committed to improve the capacity of producing capacity is greater than 1 MW commodity unit,see table 1[3-4].

Power regulation mode

Power control is one of the key technology of wind power generators.Wind generating set in more than the rated wind speed (generally for 12 ~ 16 m/s), due to the mechanical strength and

physical properties such as generators, power electronics capacity constraints, have to reduce the energy capture of wind turbines, to keep the power output near the rating, at the same time reduce the load and the whole wind turbine blade have been hit, to ensure wind turbine.Power regulation ways mainly have a fixed pitch stall adjustment, variable pitch adjustment, take the initiative to stall adjustment three ways [3].

Table 1. Megawatt wind turbine

Manufacturers/wind turbine model	Rated power/kW	Wind turbines control	Speed control	The rotor diameter/m
DeWind	1250	Variable pitch	Variable speed	70
AN BONUS	1500	Take the initiative to stall	Constant speed	80
Enron EW1.5s	2000	Variable pitch	Variable speed	70
Enron EW3.6	1800	Variable pitch	Variable speed	90
Pro&Pro MD70	1250	Variable pitch	Variable speed	70
Vestas V80	1500	Variable pitch	Variable speed	80
Nordex N80	2250	Variable pitch	Variable speed	80
Enercon E-66	1500	Variable pitch	Variable speed	90

Variable speed operation

The output power of the wind turbine mainly by three factors: the available wind power, generator power curve and generator's ability to response changes in wind speed.The fan to power from wind energy capture for:

$$P_r = \frac{1}{2} C_P(\beta, \lambda) \rho \pi R^2 V_\omega \tag{1}$$

$$\lambda = \frac{\omega R}{V_\omega} \tag{2}$$

P_r: Turbine power absorption（W）, ρ: Air density（kg/m^3）,R:The rotor radius（m）, λ: Tip speed ratio，ω: Rotor speed（rad/s）. $C_P(\beta, \lambda)$:Wind energy utilization coefficient，The maximum is Bates limit of 59.3%， C_P Curve [5] as shown in figure 1.

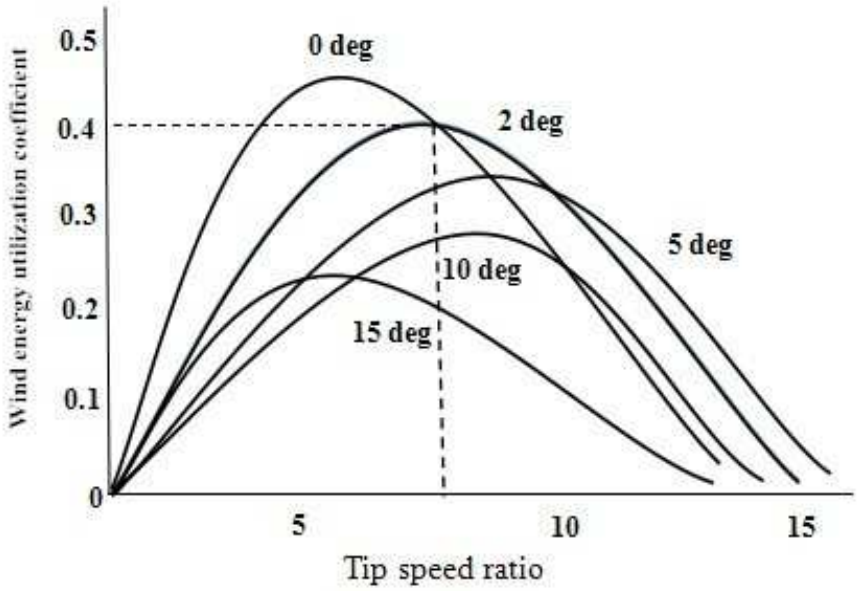

Fig.1 C_P -Curve

If they remain β constant, A curve can be used to describe the performance of it as λ.According to the figure 1,as long as you make the rotor blade tip speed ratio $\lambda = \lambda_{opt}$,can keep the unit running under $C_{p,\max}$ .Variable speed control make the wind turbines to follow the change of

wind speed change the rotation speed and maintain optimal tip speed ratio of basic constant λ_{opt} ,Relative to the constant speed operation, speed system has the following advantages:

①Have a higher efficiency, can make the pitch adjusting simplification.Variable speed operation to relax the requirement of pitch control response speed and reduce the complexity of the control system of pitch, reducing peak power demand.Low wind speed, pitch Angle is fixed, the high wind speed, adjust the pitch Angle limit maximum output power.

②Can absorb wind energy, the energy stored in the moment of inertia of rotor machinery, reduce wind fatigue damage incurred by the impact of wind generating set, reduce mechanical stress and torque ripple, extend the life of the unit.When the wind speed dropped, high-speed rotor kinetic energy is released into electricity to power grid.

③System with high efficiency.Variable speed running fan run at optimal tip speed ratio, maximum power point, improve the efficiency of wind turbine, compared to constant speed constant frequency wind power system, power generating capacity can increase more than 10% in general.

④To improve power quality.Because of the flexibility of the rotor system to reduce the torque ripple, thereby reducing the output power fluctuations.

⑤Reduce the running noise.Low wind speed, wind turbines at a low speed running state, the lower the noise.

Summary

To improve the efficiency of wind power, reduce costs, improve power quality, reduce noise, stable and reliable running, wind power technology will continue to large capacity, brushless, intelligence and control of variable speed constant frequency direction.

Abstract. As a kind of renewable clean energy, the constant access of wind power to power grids is bound to have a great impact on the power system. Based on the grid structure in Fuxin, this paper will state the difficulty of peak regulation and the matter of wasting wind power caused by the large-scale wind power integration and put forward some reasonable methods for using the wasting wind power in the heating in winter. The relevant results indicate that capacity of local consumption of wasting wind power can be improved. Under the circumstances, it can be conductive to solve the problem of wasting wind power results from the difficulty of peak regulation as well as inspire the power system planners.

Introduction

Clean energy refers to the energy that does not emit pollutants, which includes nuclear energy, hydropower, wind power, solar energy, biological energy (biogas), and tidal energy. From the Fukushima nuclear explosion we can see that compared with the wind power, nuclear energy has lower security, hydropower and solar energy have higher construction cost, the location of biological energy and tidal energy is less flexible, so the wind power has become the main force in the clean energy.

In 2012, China issued the *Five-year Development Program of Wind Power*, which clearly expounded the grand goal of future development of wind power: by 2015 the installed wind turbine capacity of wind power integration will reach 100,000,000KWH and by 2020 it will reach 200,000,000KWH. Although our wind power industry has been rapid developed in recent years, the speed of power grid construction is relatively lagging behind and the wind power consumption need to be further improved. The difficulty of peak regulation in the power system caused by the large-scale wind power integration is becoming more and more serious and the wasting wind power has also become an important factor restricting the development of wind power.

The situation of wasting wind power in China

At present, China owns the most installed wind turbines throughout the world, which accounts for 26% of all countries. However, compared with Germany, Denmark and other European countries, the percentage of wind power in China's overall energy structure is very low. As such it has a huge space for development.

In April 2013, the *Notice about Dealing Well with the Related Work of Wind Power Integration and Consumption in 2013* (hereinafter referred to as the *Notice*) showed that Northeast has become the "hardest-hit area" of wasting wind power and power rationing ,which accounted for half of that in China , that is 10 billion KWH. In 2012 the national wasting wind power is about 20 billion KWH, which is double of that in 2011. Calculate to the current state of coal consumption of generating power, 20 billion KWHs of electricity is equivalent to burning about 6,000,000 tons of coal. According to the electricity price, the direct economic loss is more than10 billion yuan.

In April 2014, the National Energy Administration issued the *Notice about Dealing Well with the Related Work of Wind Power Integration and Consumption in 2014*. *Notice* pointed out that in 2013, the using time of national wind power rose by an average of 180 hours and the wasting wind power

declined by about 5 billion KWH. The matter of wasting wind power and power rationing, however, has not been fundamentally solved, so regional wasting of wind power still restricts the development of wind power industry in China.

From the consecutive two-year notices about the work of wind power integration and consumption released by the National Energy Administration, we can see that the wasting wind power problem has been eased and the overall data is not bad, but due to the increasing load and the limit of wind power access to power grids, in China, there is still a big problem in the context of the development of wind power industry. The problem of wasting wind power not only restricted the development of wind power, but also not contributed to the overall healthy development of China's renewable energy industry due to the huge waste of investment and energy caused by the direct consequence of wasting wind power led by the difficulty of peak regulation.

Fuxin is located in west of Liaoning province in Northeast China and cogeneration is to be used for heating in winter, at the same time it will produce electricity, which has been largely enough for local electricity load of winter. Because of this most of the wind power and wind turbines must be stopped, which will inevitably cause a large amount of wasting wind power, namely northeast has particularly acute problem of wasting wind power in China. Fuxin, as the area of available wind resource, has typical problem of wasting wind power and its consumption in the process of wind power development. This paper will study the problem of wasting wind power and its consumption based on the actual data of 66 KV wind farm in Fuxin.

The situation of wasting wind power in Fuxin (2013)

Form 1 Five Wind Farms of 66 KV in Fuxin（Administrated by area)

No.	Name of Wind Farm	installed wind turbines capacity GW
1	Huadian Jinshan ZhangWu Wind Farm	24.65
2	Huadian Jinshan Kangping Wind Farm	24.65
3	Huarun Guben Wind Farm	99
4	Huaneng Gaoshanzi Wind Farm	100.5
5	Datang International Shijingao Wind Farm	49.5

The form above shows that grids have been incorporated in Fuxin area and the capacity of installed wind turbines of 66 KV is 298.3 GW in 2013.

Form 2 Statistical Form of Power Rationing in 66 KV Wind Farms of Fuxin in 2013

Statistical Form of Power Rationing in Local Wind Farms					
Name of Wind Farm	Month	Reason of Power Rationing	Times of Power Rationing	Accumulated electric quantity MWH）	Accumulated hours H）
Gaoshanzi Wind Farm	1	Difficulty of peak regulation	15	3046	80.94
	2	Difficulty of peak reguation	24	6809	218.91
	3	Difficulty of peak regulation	8	2651	56.61

	12	Difficulty of peak regulation	12	239.785	60
	In total		63	1383.809	298
Kangping Wind Farm	1	Difficulty of peak regulation	6	571	12.98
	2	Difficulty of peak regulation	14	126	194.74
	3	Difficulty of peak regulation	12	637	25.33
	4	Difficulty of peak regulation	1	10	1.4
	5	Difficulty of peak regulation	10	181	22.74
	6	Difficulty of peak regulation	2	14	10.57
	7	No power rationing	0	0	0
	8	No power rationing	0	0	0
	9	Difficulty of peak regulation	1	4.9	0.7
	10	No power rationing	0	0	0
	11	Difficulty of peak regulation	4	19.85	18.68
	12	Difficulty of peak regulation	14	359	22.55
	In total		64	1922.75	309.69
Totally			465	78233.16	2684.36

We can know from the above form, there are 5 online wind farms of 66KV administrated by Fuxin area in the whole year of 2013, in which the times of power rationing in Gaoshanzi Wind Farm are 116 times, the time are 727.4 hours, accumulative total of 22476.3 MWH, the times of power rationing in ShiJingao Wind Farm are 121 times throughout the year, 664.98 hours, accumulative total of 18482.98 MWH, the times of power rationing in Guben Wind Farm are 101 times throughout the year, the time are 308.25 hours, accumulative total of 33967.33 MWH, the times of power rationing in ZhangWu Wind Farm are 63 times throughout the year, the time are 122.38 hours, accumulative total of 1383.809 MWH, the times of power rationing in Kangping Wind Farm are 64 times throughout the year, the time are 309.69 hours, accumulative total of 1922.75 MWh. Due to the difficulty of peak regulation, the total times of 5 wind farms of 66 KV are 465 times, the total time are 2684 hours and the total power 78233.16 MWH.

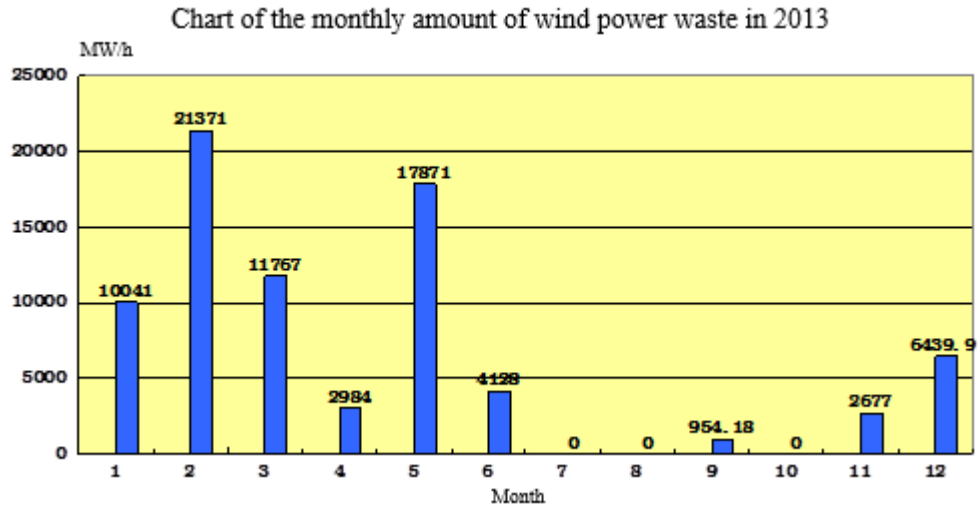

Figure 1 The monthly wasting wind power in 66KV wind farms of Fuxin in 2013

From the Figure 1 we can see that, the phenomenon of wasting wind power occurs mainly in the first five months and November to December, that is the winter heating period with off-peak load (the Fuxin's wind is heavy in May 2013, so the wasting wind power is higher).The wasting wind power is 52280 MWH in heating period, which accounted for 66.83% of the whole year's wind power; The wasting wind power of the off-peak heating period accounts for a great proportion. In winter heating period, the proportion of Fuxin coal heating increased, the crowding out the online space of wind power, therefore the difficulty of peak regulation led to the wasting wind power.

Set the Guben Wind Farm of 66 KV as an example (the curves are from the OPEN3000 system of Fuxin Power Supply Company):

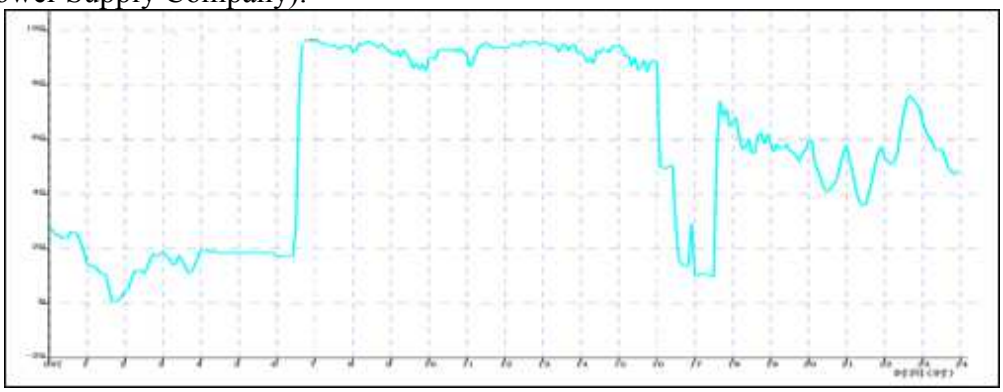

Figure 2 The curve of actual active power output on 3rd in January 2013 of 66KV wind farm

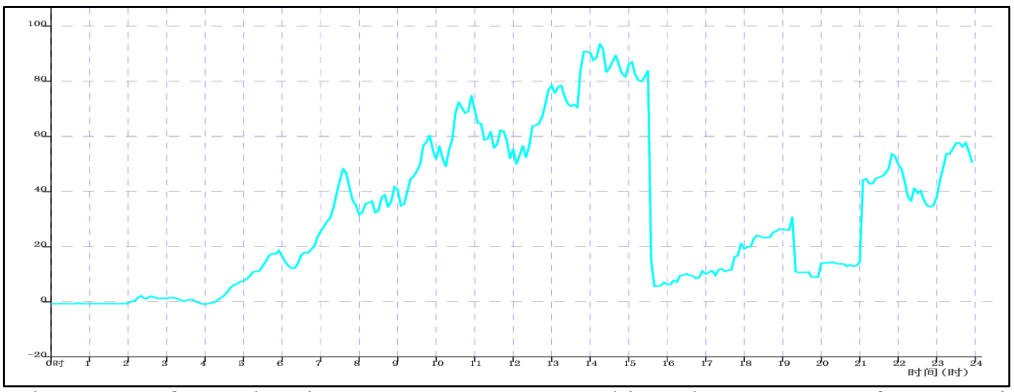

Figure3 The curve of actual active power output on 2nd in February 2013 of 66KV wind farm

In the field of power, especially of new energy, wind power is one of the fastest growing fields in the past a few years. Fuxin plans to build a super wind power demonstration base (including 220 KV wind farm), whose installed size will be over million kilowatt, so the development of the mass

concentration model is bound to make the consumption of wind power become the biggest problem. According to the present situation, the phenomenon of wasting wind power is inevitable.

Analyze the reasons of the difficulty of peak regulation

Affected by the weather, the wind power is not so stable that the wind can't completely replace thermal power, but to mutually combine and complement. Wind power development is too fast to be consumed by the local power grid. As electricity cannot be stored, and users' demand for electric power has a real-time change, the electricity is generated according to the demand. So there are much more wind power, there are less thermal power and others and vice versa. Therefore, where there are more installed wind turbines, there are more difficulties of peak regulation.

Fuxin is an area of available wind, but the wind resource and load is reverse. The fast speed of wind often occurs at night, while the load of night is low. According to the present level of wind power prediction and development of power grid, peak regulation is doubtlessly difficult and the wasting wind power is now inevitable.

The quality of wind power in winter is very good, but winter temperatures in Fuxin is very low and the heating of people's daily life need to be ensured. In order to reduce the scattered heating supply of small boilers, Fuxin supplies heating by using cogeneration, which is decided by thermal electricity. Because the heating can't be stopped, the thermal electricity, which could have to give way to wind power, cannot do that. Therefore only can the wind power stop. That is why Fuxin could have more wind power in recent years and the phenomenon of wasting of wind power increased.

Methods for improving potential of consumption

Implement of *Heating by Using the Wasting Wind Power*

Heating by Using the Wasting Wind Power is mainly to solve the difficulties of peak regulation caused by cogeneration in winter.

Concept

Heating by Using the Wasting Wind Power refers to make full use of wasting wind power, one part of which is for heating, and the other part is for storing heat that is to guarantee the supply of heating in the period without wind. Compared with the storage of electricity, storing heating is much easier. Any objects has the function of absorbing, storing and releasing heat, so as long as we find the object of storing heat, the electricity can be transformed into heat to solve the problem of supplying heating in the period without wind.

Economic problem

In terms of current technology, Heating by Using the Wasting Wind Power can be achieved completely. Its advantage lies in that the power transmission has less lose than the thermal transmission, which not only can supply heating centrally, but also can supply heating dispersedly and even to neighborhood or a single family. But the reason that so convenient way of supplying heating can't be promoted today is the price of electricity. Compared with the cost of heating transmitted by electricity, waste heat of thermal and power unit costs lower and the price is also low. Because of the electricity price, even if the families have the condition of using the heating transmitted by electricity will choose the waste heat. So the reasonable electricity price is the root cause of changing the cost gap of waste heat and electric heating.

1)The introduction of the concept of the electric price of regional wasting wind power

In November 2010, the six ministries such as the National Development and Reform Commission and the State Electricity Regulatory Commission jointly issued the "Side Measures for the Management of Power Demand ". It has put forward 16 qualitative or quantitative managerial and incentive measures for the electric power demand, in which they mentioned that they would promote and improve the system of peak price and encourage off-peak energy storage". But compared with the cost of waste heat, the cost of off-peak electricity price is still slightly higher

This paper put forward the concept of the electric price of regional wasting wind power, namely the price of some wind farm's wind power that should be stopped bought by the grid in some certain area and time. Due to the different proportion of wind power in different areas, electricity price of wasting wind power should also be slightly different. For example, the wind power in Fuxin is much richer, through analyzing the proportion of wasting wind power and adopting the method of electricity price bidding to get online for wasting wind power, they will choose the wind field whose electricity price is lower to generate electricity as a priority. So in Fuxin, electricity price of wasting wind power is lower than other regions, the scheme can be implemented more likely. Hereinafter referred to as the "the price of wasting wind power".

2)Orientation of the electricity price of wasting wind power

The waste heat cost of the residents in Fuxin is $26 /㎡, every year the heating time is from November 1 to March 31, about 150 days in total. Its average temperature in winter is from- 12 ℃ to 0 ℃. The general electric heaters, for example, an electric heater of 1000w is big enough for 10-square-meter room in winter.

Set the electric heaters occupy heating for a 10-square-meter room in continuous 8 hours as an example:

Waste heat cost of the residents: 26yuan /㎡* 10 ㎡= 260yuan

Power consumption of electric heaters in winter: 1KW * 8 hours/day *150 days = 1200 KWH

∴ Residents' reasonable electricity price of wasting wind power is less than or equals to 260yuan / 1200 KWH, is about 0.22yuan/KWH

Because of some actual reasons, such as the electric heaters can't be used in continuous full 8 hours, the space of a room can't be make full use and the area need to pay heating fee includes the shared area, the above standard price of wasting wind power: 0.22yuan/KWH is lower, so it can be appropriately increased

The environmental cost in a heating of cogeneration costs can't be ignored, and the clean energy like wind power will not impact on the environment, and it can reduce the cost of government to beautify the environment, so the government can give a wind farm proper green subsidies.

Selection of the heating places

In 2013, the wasting wind power in Fuxin during the heating period is 78233.16MWH, which can, theoretically, supply heat for 650,000-square space. In Fuxin, the actual heating area is 26,450,000 ㎡ in 2013, 2.4% of which can consume the present wasting wind power. The heating places should be chosen at the edge of waste heat radiation web with the users whose heating effect is poorer, and the selection principle should be considered as the real heating demand of users.

Operative method of electricity price

According to the price of wasting wind power, the grid company purchases the wasting wind power, and users buy the electricity from the grid company. In the ideal model, only the price of electricity used during the period of the wasting wind power can be settled accounts according to electricity price of wasting wind power, but it is difficult to be strictly divided by time, so we need to take some new marketing modes.

1)The mode of charging by two kinds of electricity price

To charge power fee by proportion and based on user's property area, for example, daily use is 0.8 KWH per square meter and the area of the house is 100 square meters, for example, the wasting wind power for about a month is: 100 * 0.8 * 30 = 2400KWH

The electricity used by a 100 - square - meter house during the winter is about 200KWH to 300KWH , in order to facilitate understanding and calculation, we take 266KWH, or the ratio of wasting wind power and the normal power is 9:1, so finally the charge standard of the user is that 90% of power is charged by 0.22yuan/KWH, and the rest 10% is charged by 0.50yuan/KWH.

2)The mode of ladder electricity price

Still set the above user as an example:

First stage: the first 266 KWH will charge according to 0.50yuan/KWH;

Second stage: 266 KWH to 3000 KWH will charge according to 0.22yuan/KWH;

Third stage: above 3000 KWHs above will charge according to 0.50yuan/KWH.

3)The mode of charging by different periods

Assume the average time of stopping the wind power is from 08:00 to 19:00 of the next day in winter:

Still set the above user as an example, During the time of using the wasting wind power, the electricity fee will be charged according to 0.22yuan/KWH, but the cap is 2400KWH, exceeding part will be charged by 0.50yuan/KWH, also in other time. In addition, in order to ensure the wasting wind power can be really consumed and avoid phenomenon of only using the wasting wind power, they should do the assessment on the users of using wasting wind power and establish a long-term relations of cooperation with a large number and stable electricity users.

The calculation method of electricity consumption

Because the output power can't be regarded as wasting wind power, which is hard to define, so adopting the following methods:

According to fit the related data of the wind power generation growth curve, wasting wind power curve and the regional increasing load curve, you can calculate the theoretical wasting wind power during the heating period of the year, issue the target generating electricity, and settle amounts of trading fee of electricity by the wasting wind power.

Based on the planed electricity generation of a wind farm, we make the coefficient of wasting wind power and generate electricity according to the agreement. In a whole year, a big part of electricity belongs to the wasting wind power, which will be charged by the price of wasting wind power.

Conclusion

As the world's most promising new energy technology, wind power has got a rapid development in China. In the wave of the wind power, China is facing a serious problem of wasting wind power caused by the introduction of large-scale wind power, so the study of the wasting wind power and its methods of consumption is very significant in the reality. This article has carried on the preliminary research, mainly including:

1) Fuxin belongs to the typical area of cogeneration, this paper analyzes, under the influence of this power supply, the reasons of wasting wind power caused by the difficulties of peak regulation.

2) Based on the marketing mode of electricity, this paper put forward the new concept of regional electricity price of wasting wind power, the system of heating by using the wasting wind power and the methods of managing the electricity price.

3) In terms of the heating by using the wasting wind power and comparing the costs of different ways of heating, this paper figures out the electricity price of wasting wind power that is suitable for Fuxin in details.

4) This paper gives us three modes of electricity price, they are charging by two kinds of electricity price, ladder electricity price and charging by different periods. And it also gives us a primary mode of figuring out he electricity.

5) From the proportion of heating by using the wasting wind power accounts for only 2% of heating in Fuxin area we can see when large-scale wind power is introduced into grid of Fuxin region, the above mode also can be used and further to develop the potential of the regional wasting wind power consumption in the area of Three-North regions relying on heating.

6) The concept of "regional electricity price of wasting wind power" not only can be used in the problems of local consumption during the heating period, and even can be extended to the mode of prices during the period without heating supply to further complement and improve the electricity price leverage led by the price during the peak period—restrain the rapid growth of the peak power consumption during peak period and improve the low electricity consumption during the off-peak period, so as to improve the efficiency of the whole society and further regulate the balance between supply and demand.

Keywords: distribution network, Monte Carlo simulation, forward/backward power flow

Abstract. This paper presents a theoretical line loss calculation of distribution network containing an uncertainty power of wind turbine. First, this paper establishes the theoretical line loss mathematical model considering wind turbine power constraint within the sampling period. Then this paper gets multi group wind turbine output data satisfied the power constraints through Monte Carlo simulation. By combining with the first power coefficient method and Monte Carlo simulation technique, this paper also generates multi groups load pseudo measurement test of non real time. By combining the real-time measurement of power flow calculation, a group of simulated data with minimum error between the power flow results and the real time measurement are selected. Finally based on the selected pseudo measurement, the theoretical line loss within the given time period based on periodic accumulative calculation of real-time measurement are calculated. 14 nodes example is given to verify the accuracy and practicality of the algorithm.

Introduction

Due to be influenced by the speed of wind, the wind output is random and the change is big. It cannot be simply considered as the hourly constant load to calculate the theoretical line loss. But it is rarely considered the influence of the distributed power supply in traditional theoretical line loss calculation [1-14].

Therefore, reference [15] put forward a kind of calculation method for distribution network line loss based on the theory of power flow calculation. It preferably solved the line loss change issues caused by the trend reverse flow which is induced by the distributed power in interval time. But it is assumed that the active power and reactive power of intermittent distributed power per hour is constant. Due to the distribution of intermittent power supply, such as wind turbine output affected by wind speed, this paper assumes that influenced the accuracy of line loss calculation. Reference [16] studies the influence of distribution network in different location, capacity, and operation mode after the intermittent distributed power accessed distribution network. But it does not take into account the theoretical line loss calculation problem under the condition of uncertainty of intermittent distributed power outputs.

The above methods do not consider the theoretical line loss calculation problem caused by the intermittent randomness of output capacity of distributed power supply. This paper proposes a theoretical line loss calculation model under the condition of the randomness of intermittent distributed power output.

Theoretical line loss calculation model with wind turbine

Theoretical line loss calculation model of distribution network is as follows:

$$E_T = P_{loss} \times \Delta t \tag{1}$$

Where: E_T is line loss in cycle calculation; Δt is sampling time interval in Real-time measurement data; P_{loss} is theoretical line loss in the period Δt .

Because the wind turbine power exports usually exist active and reactive power electrical degrees at every hour. The time interval of real time measurement Δt are usually less than 1 hour, so it is need to transfer wind turbine output of integral point into the wind turbine output of time interval of Δt, and wind turbine output multiplied by the sum of time is equal to the wind turbine capacity per hour, which is satisfied by the following conditions:

$$\begin{aligned} E_w^P &= \sum_{i=1}^{n} P_{w,i} \times \Delta t_i \\ E_w^Q &= \sum_{i=1}^{n} Q_{w,i} \times \Delta t_i \end{aligned} \tag{2}$$

Where: E_w^P, E_w^Q are represent the active and reactive power of wind turbine export for one hour, respectively; $P_{w,i}, Q_{w,i}$ are the pseudo measurement of wind turbine active and reactive power output for the period of Δt_i; n is the number contained Δt for one hour.

Estimation of Pseudo measurement for non-measured nodes. In the semi-automatic distribution network, here were plenty of non real-time measurement nodes; the head end power method [4] could generate pseudo measurement for non measurement nodes by the hour as the unit. The precision are low. Reference [4-7] with matching trend technology effectively enhanced the precision of pseudo measurement, but only use the measurement of the first node of the feeder. They do not make full use of the measurement of other section switches, impacted the calculation accuracy for the trend, and then reduced the theoretical line loss calculation accuracy

The Monte Carlo simulation of non measurement data. The load power of non measured load node usually obeys the normal distribution, considered the pseudo measurement of the head end power method as the average power, and also considered the electricity per hour for the active and reactive power of the wind turbine output as the average pseudo measurement, under the condition of a given variance, now gave below in the period of time Δt_i, the probability density function of active and reactive power for measurement node j is as follows:

$$\begin{cases} f_{\Delta t_i,P}(P_{\Delta t_i,j}) = \dfrac{1}{\delta_{P_{\Delta t_i,j}}\sqrt{2\pi}} \exp[-\dfrac{(P_{\Delta t_i,j} - P_{\Delta t_i,j}^{real})}{2\delta_{p_{\Delta t,j}}^2}] \\ f_{\Delta t_i,Q}(Q_{\Delta t_i,j}) = \dfrac{1}{\delta_{Q_{\Delta t_i,j}}\sqrt{2\pi}} \exp[-\dfrac{(Q_{\Delta t_i,j} - Q_{\Delta t_i,j}^{real})}{2\delta_{Q_{\Delta t_i,j}}^2}] \end{cases} \tag{3}$$

Where: $f_{\Delta t_i,P}$ and $f_{\Delta t_i,Q}$ are the probability density function obeyed the normal distribution of active and reactive power; $\delta_{P_{\Delta t_i,j}}$ and $\delta_{Q_{\Delta t_i,j}}$ are the given variances of the active power and reactive power; $P_{\Delta t_i,j}^{real}$ and $Q_{\Delta t_i,j}^{real}$ are the average active power and reactive power determined by the head end power coefficient method.

Based on the probability density function of the active and reactive load, under the condition of a given variance, if processing Monte Carlo simulation for all the non measurement load nodes of feeder and the active and reactive power output of the wind turbine, there will produce multiple sets of data. Take a set of data satisfied the constraints (2) for wind turbine, if the non real-time measurement nodes with historical electricity data have the statistical power by the hour, the Monte Carlo simulation results also need to satisfy the constraints of similar type (2).

Ensure the pseudo measurement based on the least square method. We can be forward sweep power flow to calculate each node voltage and power of branch and branch current value, if the error between these values and the measured values is smaller, that illustrates that it is more possible for estimating the pseudo measurement accuracy.

Below using the weighted least square method, we can get the mathematical model aiming at minimum error, which stands for the error between the real-time measurement and the pseudo measurement flow calculation results of measured nodes and wind turbine output.

$$\min \varepsilon_{\Delta t_i} = \sum_{i=1}^{n_V} w_{V,i} \mid V_{i,w} - V_i \mid + \sum_{ij=1}^{n_I} w_{I,ij} \mid I_{ij,w} - I_{ij} \mid + \sum_{ij=1}^{n_P} w_{p,ij} \mid P_{ij,w} - P_{ij} \mid + \sum_{ij=1}^{n_Q} w_{Q,ij} \mid Q_{ij,w} - Q_{ij} \mid \quad (4)$$

Where: $w_{V,i}, w_{I,ij}, w_{P,ij}, w_{Q,ij}$ are respectively represented measurement node voltage amplitude, branch current amplitude, the weight of branch active power and reactive power. n_V, n_I, n_P, n_Q are the number of variables of real-time measuring for the node voltage amplitude, branch current amplitude, branch active power and reactive power. $V_{i,w}, V_i$ are the power flow calculation values of node voltage amplitude for node i and the real-time measurement. $I_{ij,w}, I_{ij}$ are the power flow calculation of branch current amplitude and real-time measurement values for node i and j. $P_{ij,w}, P_{ij}$ are the branch of active power flow calculation and live measured values for node i and j. $Q_{ij,w}, Q_{ij}$ are the branch of reactive power for power flow calculation and real-time measurement values for node i and j.

By type (4), the more the real-time measurement nodes, the more accurate of the pseudo measurement's estimate results. The introduction of distributed power supply, may result in the changes of the trend direction, if there are a section switch on the branch of trend changes and real-time measurement, in this case, if only use the head end power measurement matching trend to estimate pseudo measurement, it cannot use the measurement section switch, can't consider the direction of the trend of change, and affects the accuracy of evaluation of pseudo measurement.

The whole algorithm process. Here are calculation steps of theoretical line loss based on the forward sweep trend:

1) Put in network structure parameters, power with the real-time measurement of load node in the calculation time within of each time interval Δt_i, the electricity per hour of wind turbine in computing time cycle, electricity of power load node with historical electricity and the parameters of power distribution transformer, make $i = 1$;

2) For the period of time Δt_i, construct the probability density function according to type (3) for all the measured load node and the active and reactive power of the wind turbine;

3) according to the probability density function of step 2), we can get multiple sets of the measured load node and the pseudo measurement data of the wind turbine through monte carlo simulation;

4) if the difference between more groups of pseudo measurement data from wind turbine simulation and the hourly power were greater than the given value, transfer to step 3). Otherwise, for the satisfied group of pseudo measurement data, calculate out the branch power, node voltage and load current according to the forward sweep power flow calculation;

5) according to the type 4), take a group of minimum error ε of non measurement nodes and pseudo measurement data of wind turbine as the result, calculate the losses in period of Δt_i forward sweep power flow calculation;

Examples and analysis.

As is shown in figure 1, there is a circuit of 11 nodes system[17], of which distribution transferred rated voltage is 10 kV, and average bus voltage is 10.5 kV, adds a wind turbine of which capacity is 800 kW respectively in the node of i and j, assumes that the wind turbine keeps the power factor as 0.95, the wind power characteristics and parameters can be found in the literature [18].

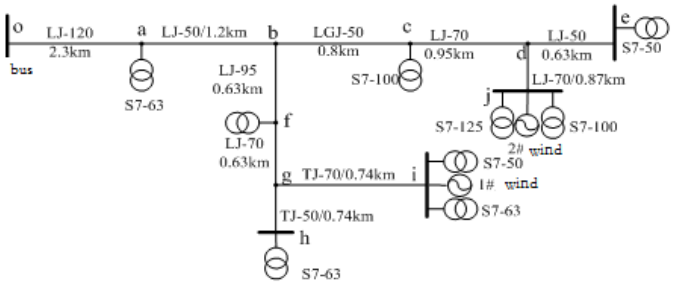

Figure 1. 11 nodes distribution network structure contains the wind turbine

Assume that the head power of branch $o-a$ and $b-c$ have real-time measurement values, wind turbine record export capacity per hour, real-time data sampling interval is 10 minutes, table 1 shows the history data for one hour one day, the wind speed change of the wind turbine is not very big, but the calculation of output power changes is very big, and has great volatility

Table 1. Historical data

Measurement amount	Time					
	00:00	00:10	00:20	00:30	00:40	00:50
1# wind turbine speed (m/s)	5.1	5.2	5.4	5.6	6	6
1# wind turbine active power (kW)	59	63	72	81	99	99
1# wind turbine reactive power (kvar)	19.5	20.8	23.8	26.7	32.7	32.7
2# wind turbine speed (m/s)	6.8	6.7	6.2	6.5	6.6	6.2
2# wind turbine active power (kW)	160	153	115	138	145	115
2# wind turbine reactive power (kvar)	52.8	50.5	38	45.5	47.9	38
Active power of branch o-a head (kW)	332.7	335.7	364.6	332.7	307.7	337.7
Reactive power of branch o-a head(kvar)	149.1	150.1	159.7	149.2	140.8	150.7
Current of branch o-a head (A)	3.645	3.677	3.98	3.646	3.38	3.697
Voltage of node o (kV)	10.5					
Active power of branch b-c head (kW)	137.2	144.2	181.8	159.1	152.2	181.9
Reactive power of branch b-c head (kW)	66.9	69.2	81.6	74.2	71.8	81.67
Current of branch b-c head (A)	1.535	1.607	2	1.764	1.69	2
Voltage of node b (kV)	10.44	10.44	10.44	10.45	10.45	10.4
1# wind turbine (kW ·h)	80					
1# wind turbine (kvar·h)	26					
2# wind turbine (kW ·h)	138					
2# wind turbine (kvar·h)	46					

Due to the changes of load power in one hour is small, assume that the pseudo measurement of every load calculating through the head end power coefficient method is maintained constant in one hour, so the case only aim at type (4) to calculate the pseudo measurement of output capacity of 1 # and 2 # wind turbine , and satisfy the wind turbine power constraints of type (2), the calculation results are shown in table 2.

Table 2. Simulated data of wind turbine

Measurement amount	Time					
	00:00	00:10	00:20	00:30	00:40	00:50
1# wind turbine analog wind speed(m/s)	5.06	5.24	5.37	5.65	6.04	5.97
1# wind turbine active power (kW)	57	65	71.5	83	102	97
1# wind turbine reactive power (kvar)	18.8	21.5	23.5	27.4	33.7	32.1
2# wind turbine simulated wind speed (m/s)	6.75	6.74	6.16	6.55	6.66	6.18
2# wind turbine active power (kW)	157	156	112	142	149	113
2# wind turbine reactive power (kvar)	51.8	51.5	37	46.9	49.2	37.3

Contrast to the Reference [4-7] using only the measurement value of the branch $o-a$, the above example also takes advantage of the measurement of the branch $b-c$ to improve the estimation accuracy of the wind turbine output power.

Table 3 shows the contrast results of the example for network loss calculation in one hour.

Table 3. The calculation result of line loss

Output result	Branch loss	Iron loss of transform	Copper loss of transform	Total losses
Reference value	1.71135	2.21666	10.6333	14.566
document[] method	1.6857	2.2221	10.6373	14.452
This paper method	1.70373	2.22208	10.6405	14.563

The table 3 shows that contrasting to literature [7], this algorithm considered the randomness of the output of the wind turbine, so it not only matched the measurement of root node branch $o-a$ in the process of power flow calculation, but also matched the measurement of branch $b-c$, and also improved the accuracy of the power flow calculation, made the calculation results more close to the real value.

Conclusions

This paper put forward to the distribution network line loss calculation method theory using of all the real time measurement and considering the uncertainty of wind turbine output, it can accurately simulate the uncertainty of wind turbine output through Monte Carlo simulation method. The example results show that, compared with the existing literature, this paper considers the theoretical line loss calculation under the condition of the uncertainty of wind turbine output, and improves the precision of theoretical line loss calculation.

Transient stability of wind power system with DFIG

Guo li-sa

College of Electrical Engineering,GuiZhou University,Guiyang 550003,China

email: 373196924@qq.com

Keywords: Wind power, Transient stability , DFIG

Abstract. Analyzed mathematical model of wind power which consist doubly-fed wind turbine (DFIG).Strategies for pitch angle control were developed.Used MATLAB to establish equivalent model contain infinite power system concluding DFIG ,The results showed that wind power with DFIG have good transient stability.

Introduction

Wind power is the new research field in the power system study.Wind power is gradually to the scale and industrialization. The international wind power technology research hot spot is coming from Small capacity of stand-alone wind power generation technology to the large capacity system,coming from studying the steady state behavior of the large capacity of wind farm to studying the dynamic transient behavior after the access to the grid[1].Because the DFIG using the conventional synchronous generator technology. The transient characteristics have great difference with traditional synchronous generator when fault takes place in network[2].

Wind power application has long history.Wind power development began in the 19th century.Until the nineteen-eighties century wind farms to enter the modern electric power system[3]. China have rich wind energy resources in the world.The utilization wind energy about 250 million kW[4].

Double-Fed Induction generation(DFIG) consist wound-rotor induction generator that connection to the grid and Insulated Gate Bipolar Transistor (IGBT) that installed in the rotor winding by back to back[5].Normal operation, the stator side accesses to the three phase power frequency grid, the rotor gains low frequency through current frequency converter.When the DFIG is operated in super-synchronous speeds, energy is transferred to the grid through the stator side and the rotor side.

The Models of wind turbine

Wind turbine is made up of blade,hub,gearbox and coupling.Wind energy is the third power of wind speed,shown as followers:

$$P_m = \frac{1}{2} C_p \rho S V_0^3 \tag{1}$$

In the type:P_m is wind turbine output of wind power;C_p is rotor power coefficient,the maximum C_p can not exceed 0.59[6];ρ is air density;S is the rotor swept area;V_0 is wind speed before into wind turbine.

The mathematical model of transmission

Therefore, the performance of mechanical properties,wind turbine blades and hub have a big inertia, The speed of wind turbine output mechanical power lag behind the wind conditions change.The models of transmission machine is represented by equation:

$$\frac{dT_M}{dt} = \frac{1}{\tau_w}(T_w - T_M) \tag{2}$$

In the type:$T_w$is the output torque of wind turbine; T_M is the input torque of generator;$\tau_w$is the inertia time constant of wind turbine.

The models of DFIG

The electromagnetic torque of doubly-fed induction generator is as follows:

$$T_e = \frac{P_s - sP_s}{\omega_r} = \frac{(1-s)P_s}{\omega_r} \approx \frac{3}{2}(i_{sq}\psi_{sd} - i_{sd}\psi_{sq}) \quad (3)$$

Same as the derivation of induction generator, electromagnetic power is as followers:

$$P_{em} = \frac{P_r}{s} - \frac{P_{cu2}}{s} \quad (4)$$

$$sP_{em} = P_r - P_{cu2} \quad (5)$$

$$P_{mech} = P_{em}(1-s) \quad (6)$$

The energy transfer of doubly-fed induction generator in connection with the state of the generator, when it produce electricity, $P_{mech} \rangle 0$.

The control system of DFIG:

Wind turbine generator system is a complex,multivariable,and nonlinear system.The control system of DFIG include pitch angle control model,max power point track method and converter control. The control system of DFIG plays an important role.

Doubly-fed wind power generator module is vector control in MATLAB. Only consider positive-sequence component of the stator voltage, the variable pitch blades are rigid,the wind speed is invariant.When the wind turbines in less than rated speed,Pitch Angle remains 0° .When the wind turbines in less than rated speed,use the strategies for pitch angle control to limit the maximum output active power.The control system is as follows:

$$\frac{d\beta}{dt} = \frac{1}{\tau_\beta}(\beta_r - \beta) \quad (7)$$

Energy flow between the rotor and power grid is depend on the running state of the generator.Transducer is bidirectional power flow in the variable speed constant frequency wind turbine. RSC and GSC are connected in the voltage source conversion by back to back[7].

Control strategy of the grid side converter is vector control. The current of frequency converter resolve into two current component that are mutually perpendicular.There are active current that located in the direct axis and reactive current that located in the quadrature axis. Reactive power of grid side converter is related to the reactive current that located in the quadrature axis[8]. Control objectives of the rotor-side converter is active power changes with reference value,at the same time,the power factor is constant.

Power electronic element of frequency converter is sensitive to transient disturbance. Frequency converter need to configure relay protection equipment.Breaker with fixed switching on-off time can avoid the influence of transient current and recover frequency converter quickly.It is advantageous to transient stability.

The simulation of power system with wind power

Synchronous generators stability is one of the basic conditions to ensure safe power system operation. Load distribution and interaction effect between component are not included in this study.In the power simulation system,using of DFIG instead of the whole power station[9].

In order to make the simulation comparable,Two simulation system are established, there are power system with DFIG and only synchronous generator(SG).The diagram is as followers:

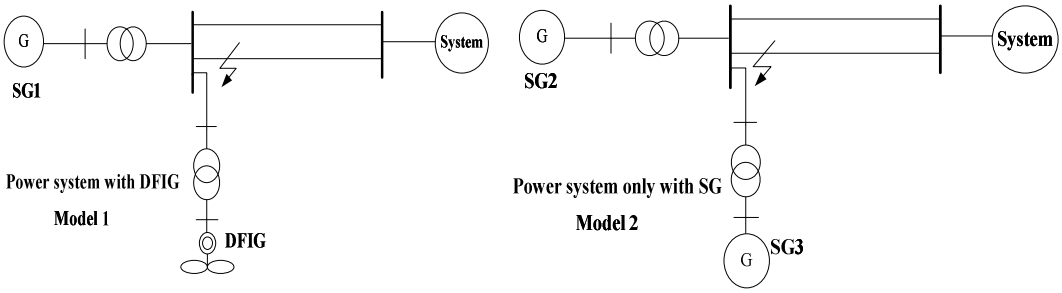

Figure 1.Simulation model diagram

Power system transient stability when three-phase short circuit occurs

Run time is 8s,step-size is 0.03ms.when t=5s,three-phase short circuit occurs in double-circuit transmission lines(as shown in figure 1).After 0.1s,the fault is removed. As shown in figure 2,the active power curve of SG in the same location is made a comparison.Curve of SG1 tend to the balance point smoothly,the recovery speed of SG2 is slower than SG1.The power wind with DFIG have a better transient stability.In Figure2,orizontal axis is time(t/s);vertical axis is power curve(P/Kw).

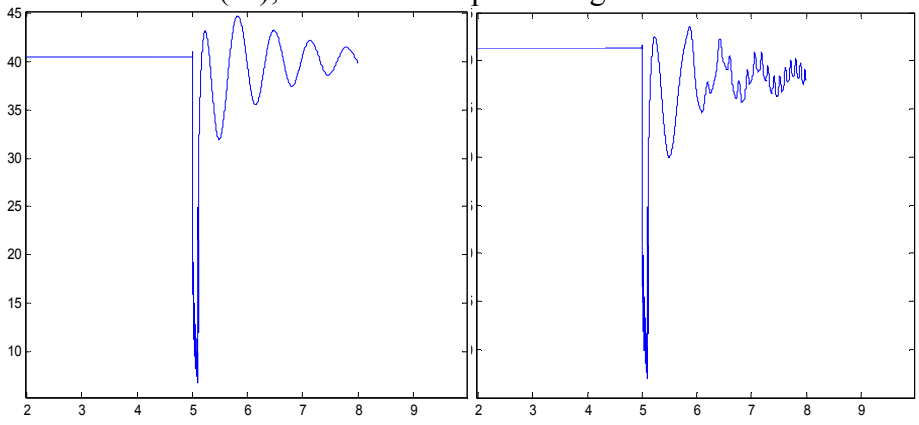
Figure 2.Diagram of active power

As shown in figure 3,the power angle characteristics of SG in the same location is made a comparison.Orizontal axis is time(t/s);vertical axis is power angle.



SG1 of Model1 SG2 of Model 2

Figure 3.Diagram of power angle characteristics

After cutting off the fault,power angle characteristics of SG1 is more fluctuant than SG2, The results show damping of Model 1 is smaller than SG.But curve of SG1 tend to the balance point smoothly and quickly.The power wind with DFIG have a better transient stability.

Chang the time of duration of three-phase shortcircuit.In the model 2,three-phase shortcircuit happen in 5s.If fault duration is 258ms in model 2,the system will loss the stability.If fault duration is 265ms in model 1,the system will loss the stability.The critical clearing time of system with DFIG

is longer than the system only with SG.The power wind with DFIG have a better transient stability than system only with SG.

Conclusion

Based on the control system of DFIG,the models of transmission machine and the models of DFIG,a simple power system with DFIG is studied by simulation using MATLAB. Three-phase short circuit occurs in the power system with DFIG and the system only with SG,depend on the active of power curve,angle characteristics and critical clearing time,The power wind with DFIG have a better transient stability.

Keywords: transmission planning; electricity market; N-2

Abstract. Traditional Transmission Network Planning scheme only considers N and N-1 security , with little regard for safety of N-2 system. This paper introduces the relaxation factor establishing Transmission Network Planning model, and further considers the N-2 secure of double-circuit transmission line on the basis of relaxation on the N-1 constraints. A hierarchical genetic algorithm(HGA) Model is proposed to solve the model.The final Transmission Network Planning scheme meets the reliability requirements under uncertain environment and has the minimum overall cost.A simulation model to simulate the impact of construction of the same tower line on the investment and security of transmission network planning is builded.

0 Introduction

Large scale blackout many times at home and abroad show that with the increase in the complexity of the grid interconnection,a small perturbation of the system is likely to occur cascading failure, bringing huge economic losses to the power system and the whole society when the system is in a state of emergency after a single failure.At the same time, the existence of the power system planning maintenance also makes the power grid only meet N - 1 safety criterion not enough.Therefore, considering the N-2 security of system from planning level has important practical significance[1-2].But considering all the lines N-2 breaking not only computes intensively and for a long time, but also makes the plan too conservative, leading to excessive investment and impacting the power company benefits. [3]

1 Power Transmission System Model

Uncertain market environment factors mentioned above, can be expressed as M power injection vectors $\boldsymbol{P}=\{\xi_1,\xi_2,\xi_3...\xi_M\}$, ξ_k is the k-th power injection vector.

Transmission network planning model further considering the security when same tower double circuits are simultaneously breaking and investment savings on the basis of N-1 security constraint shows as follows.

$$\min C = \sum_{ij\in S} U_{ij} I_{ij} L_{ij} + \sum_{ij\in D} V_{ij}(B_{ij}) B_{ij} L_{ij} + \alpha Z_1 \tag{1}$$

$$Z_1 = \sum_{k\in M} C_k^s + \sum_{k\in M} C_k^d \tag{2}$$

st.

$$\left.\begin{aligned} \boldsymbol{B\theta} &= \xi_k \\ P_b &= B_b \theta_b \\ |P_b| &\le P_{b.max} \end{aligned}\right\} \tag{3}$$

$$\left.\begin{aligned} \boldsymbol{B}_b^l \boldsymbol{\theta}_b^l &= \xi_k \\ \boldsymbol{P}_b^l &= \boldsymbol{B}_b^l \theta_b^l \\ r &\le \delta \end{aligned}\right\} \tag{4}$$

$$I_{ij} = \begin{cases} 0 \\ 1 \end{cases} \quad (5)$$

$$0 \le B_{ij} \le 2 \quad (6)$$

In formula (1), C is the investment and construction costs, including the cost of building the line and load shedding costs; S, D are single loop to be chosen and double-circuit lines on the same tower set; U_{ij} is branch ij unit invetistment costs; I_{ij} is 0-1 decision variables of branch ij; B_{ij} is double-circuit on the same tower decision variables of branch ij, V_{ij} is the unit investment costs of dual-circuit branches ij to be selected, its value varies with B_{ij}; L_{ij} is line length. Z_1 is the minimum shed load of the system, including the minimum shed load of N-1 breaking and double-circuit breaking at the same time under M power injection vectors. C_k^s and C_k^d are shed loadscaused by N-1 breaking and double-circuit breaking at the same time under the k-th power injection vector, α is unit load sheddingpenaltyfee.

Formular(3) is security constraints for normal operation; Formular (4) is the relax N-1 static security constraints. ξ_k is the k-th power injection vector. $\boldsymbol{B}$ and ^{l} are Node admittance matrix, corresponding to the non-breaking way and breaking way of branch I. θ and θ^l are node voltage phase angles of the above two ways . $\boldsymbol{P}_b$ and $\boldsymbol{P}_b^l$ are the corresponding branch current, and are phase angle difference on both ends of the branch. and $\boldsymbol{B}$ are diagonal matrix consisted by each branch admittance. $\boldsymbol{P}_{b.\max}$ are heat capacity limit of the branch, δ is given relaxation factor threshold value.

1.1 Description and calculation of the relaxation factor

The uncertainty of node power injection can lead to the diversity of power grid operation mode. Power transmission system determined by the power grid planning X. There may be N – 1 overload risk under the various operation modes. In this paper, the relaxation factor is introduced to quantitatively measure the relaxation. the relaxation factor is defined as follows,

$$r = \frac{\sum_{l=1}^{N} q^l P_r^l \left\{ \left(\left| P_b^l(\xi_k) \right| > P_{b.\max} \right) / X \right\}}{\sum_{l=1}^{N} q^l} \quad (7)$$

q^l is the probability of only branch x failure breaking, P_b^l is the branch wave vector which corresponds to branch l failure breaking way. ℓ represents the probability the event E established in conditions of F.So $P_r^l\left\{\left(\left|P_b^l(\xi_k)\right| > P_{b.\max}\right)/X\right\}$ is the system overload probability after line I failure breaking. Overload probability of all N-1 failure breaking $\sum_{l=1}^{N} q^l P_r^l \left\{ \left(\left| P_b^l(\xi_k) \right| > P_{b.\max} \right) / X \right\}$,r∈[0,1]since $0 \le \sum_{l=1}^{N} q^l P_r^l \left\{ \left(\left| P_b^l(\xi_k) \right| > P_{b.\max} \right) / X \right\} \le \sum_{l=1}^{N} q^l$. value the greater the r is, the higher risk of overload the N-1 breaking will have. through the set, the transmission grid planners can set r values based on the development stage of the grid and risk appetite.

2 Simulation result

This example uses the"18 nodes system" in reference [4]. Because there is no feasible plan under N – 1 standards of static safety can increase the limit of the line transport capacity to 3000 mw. Because all line corridors of the"18 nodes system" are no more than 3, a double loop is set up as multi-circuit transmission line in this paper. For easy calculation, we assume all single-circuit line investment cost is 800000 yuan/km and the same tower double-circuit single-circuit line unit construction cost is 600000 yuan/km. When two lines appears in the designated same tower double circuit line of the planning scheme, select the double-circuit lines installed on same tower ; if only one line, select the single circuit line. The original node load values are the same as those in reference [4]. Node 11,14,16,18 are new power source nodes that may occur whose probability distribution functions follow the two-point distribution, new load node loads obey the law of normal distribution. Specific parameters of each probability distribution functions can be seen in reference [5].

This paper constructs the following simulation models. Simulation 1: single loop is applied to all lines; Simulation 2:designate some line sets $ij \in \{(4,16),(5,11),(6,14),(7,13),(9,16),(16,17)\}$ as double circuit lines installed on same tower to be chosen;Simulation3: designate all multi-circuits lines as double circuit lines on same tower. In addition, the simulation 4 and 5 simulate relaxation factor and cutting load punishment's influence on grid planning, as shown in Table1:

Table 1. Emulational modal

simulation	Relaxation factor threshold value	Wiring way	Load-shedding punishment Ten thousand yuan /MW
1	$\delta=0$	All multi-circuit lines are single-circuit line	8
2	$\delta=0$	Some multi-circuit lines are on same tower	8
3	$\delta=0$	All multi-circuit lines are on same tower	8
4	$\delta=0.1$	All multi-circuit lines are on same tower	8
5	$\delta=0.1$	All multi-circuit lines are on same tower	80

Solve the above five situations using the hierarchical genetic algorithm.The planning scheme is shown in Table 2 as the number of underlying iteration and high-level iteration are all 100.

Table 2. Planning scheme of emulational modal

scheme	Planning scheme
1	1-11, 4-7, 4-16 2）, 5-11, 6-13, 6-14 2）, 7-9, 7-13, 7-15, 8-9, 9-10 2）, 10-18, 11-12, 12-13, 14-15 2）, 16-17 2）, 17-18 2）
2	1-11, 4-7, 4-16 2）, 5-11, 6-14 2）, 7-9, 7-13 2）, 7-15, 8-9, 9-10 2）, 10-18, 11-12, 12-13, 14-15 2）, 16-17 2）, 17-18 2）
3	Same to 2
4	1-11, 4-16, 5-11, 5-12, 6-14 2）, 7-9, 7-13, 7-15, 8-9, 9-10 2）, 9-16, 10-18, 12-13, 14-15 2）, 16-17 2）, 17-18 2）
5	1-11, 4-16 2）, 5-11, 5-12, 6-13, 6-14 2）, 7-8, 7-9, 7-13, 7-15, 8-9, 9-10 2）, 9-16 2）, 10-18, 11-12, 12-13, 14-15 2）, 16-17 2）, 17-18 2）

In Table 2,the number in the bracket behind two nodes indicates an increase in the number of lines as 4-16 (2) means toextend two 4-16lines.

Table 3. Planning scheme comparison

scheme	investment cost Ten thousand yuan）	load-shedding cost Ten thousand yuan）	comprehensive cost Ten thousand yuan）
1	221120	0	221120
2	199920	4800	204720
3	182902	23680	206582
4	172120	25360	197480
5	200920	121600	322520

Scheme 2 increases 7-1 and decreases 6-13 comparing scheme 1 with 2.Double circuit lines installed on same tower are constructed to save costs by increasing 7-13 which is designated by scheme 2 as double circuit lines and save more than load-shedding costs of connecting and disconnecting at the same time. The planning schemes of plan 2 and 3 are the same. From the perspective of the investment cost, because Scheme 3 specifies that all loops are built as same-tower double-circuit lines, saving a lot of investment costs while increasing the load-shedding cost of the system, comprehensive cost increases. Line 9 and 10 in Scheme 3 are in the same tower, saving line investment costs 80 million yuan while increasing the load-shedding cost to 182.4 million yuan, therefore, line 9-10 should not be built as double-circuit lines installed on the same tower. In the actual process of planning, construction of lines installed on the same tower should be based on quantitative analysis. The scheme has minimum comprehensive cost 1 2 3 analysis often sets up double-circuit lines installed on same tower.

In scheme 3 and 4, in the same way of stringing and load-shedding punishment, the planning scheme needs to meet more operation mode, and the cost of investment increase with the decrease of the threshold value of the risk factor δ.Comparing Scheme 3 and 4,line 9-16 replaces line 4-7, line 4-16, 11-12 are decreased, and line 5-12 are increased. Line 9-16makes it easier to increase relaxation factor than Line 4-7, but reduces the shed loads in the system. Therefore, no 9-16occurresin Simulation 1, 2, 3 where the threshold value of relaxation factor is 0 while 9-16 occurs to reduce the load-shedding costs in Simulation 4 where the relaxation factor is larger.

By plan 4 and 5, with the increase of load-shedding punishment, planning scheme needs to expand more lines to eliminate overload ,which makes investment costs increase and shed load reduce, but increases load-shedding costs due to the increase in load punishment.

3 Conclusions

This paper describes the uncertainty of market environment using uncertain power injection, further considers the situation of double-circuit lines installed on same tower connecting and disconnecting at the same time under the condition of relaxation N-1 constraint, and gives the quantitative indicators of double-circuit lines, providing decision basis for planners at the beginning of the planning.

The intervention of relaxation factor constraints can make the planning scheme further consider N-2 security when the same tower lines connect and disconnect simultaneously, bringing the model solution with flexibility and hierarchy.

Solving speed and iteration efficiency are improved using hierarchical genetic algorithm for the grid planning model. Flexible setup of the feasible region makes the model solution more convenient and flexible. The example demonstrates that it is an effective method of solving complex grid planning problems.

Transmission Section Search for Vulnerable Line Based on Power Transfer Distribution Factor

Junjiao Wei, Jianwen Ren

North China Electric Power University, Baoding, Hebei, 071003, China

Wjj903239@163.com

Keywords: power transfer distribution factor; integrative electrical betweenness; vulnerable line; transmission section; Coefficient of difference

Abstract: For the purpose of considering characteristics of transmission line in the round, with utilization of related knowledge in complex network, Integrative Electrical Betweenness has been put forward. The proposed index, on one hand, over comes shortcoming of assuming power only transmit along the shortest path existed in previous indexes. On the other hand, ability of transferring power when other lines removal is considered. In order to further facility to grid security control, a novel method is proposed to search key transmission section of vulnerable line. The algorithm only needs simple calculation, there is no large-scale computation. The proposed algorithm has been tested on New England IEEE 39-bus system to validate its efficacy.

Introduction

Frequent blackouts, which happen in recent years, has brought new challenges to security and stability control work in power systems. The upsurge of transmission section research emerges as time requires. Through deep analysis of several typical blackouts, it's knowable that cascading failure caused by outage of individual line, plays a vital role on the occurrence of blackout. Based on this reason, in order to prevent blackouts happening again, Scholars carry on embed researches at the following two aspects：searching individual lines that cause cascading failure[1] , identify the set of lines[3,4,5].

Through analysis of previous literature, it's obvious that current research on these two aspects exist problems of caring for this and losing that. For the first aspect, the scholars put forward corresponding index to characterize vulnerability lines, in accordance with different study focus, as a result, it cannot fully reflect comprehensive transfer contribution of line. As for the latter, when finding transmission section, current researches are mostly based on the overload / heavy-load line. However, it's known that the impact of vulnerable line outage on the grid is far more serious than overload line. At the same time, previous section search methods mostly need matrix calculation or other large-scale computation, which limits its application in large scale power network.

This paper considers not only normal operating conditions, but also the status after some rest lines out of service. Then combined with PTDF, Integrative Electrical Betweenness (B_{ie}) is proposed to identify vulnerable line. The index takes both distribution network topological structure and current operation into account, creatively consider the transmission line's capability to transfer power after some fault occur. What is more, a new method is proposed to find out transmission section of specific vulnerable line，the algorithm only needs some simple calculations.

Identification of Vulnerable Line Based on Integrative Electrical Betweenness.

Betweenness(B_0). In complex network, B_0 is applied to glass concrete role of line plays in the communication process of information. With hypothesis that information of two nodes is only transmit through the shortest path, B_0 of given line l is identified as the ratio of shortest paths between node pairs (s,t) (resp. (s,t)) which through line l ($\delta_{st}(l)$) and total shortest paths between (s,t) (δ_{st}), as follows:

$$B_0(l) = \sum_{s \neq t \in V} \frac{\delta_{st}(l)}{\delta_{st}} \tag{1}$$

Integrative Electrical Betweenness. As a transmission lines, there is no doubt that it's first and foremost task is transfer power. From the definition of B_0, we know that it exist limitation to reflect the effect of transmission line by using B_0 directly. The fundamental reason is that power transmission system not only has common feature of transmission network, but also has its own 'characteristic', power transfer, not only along the shortest path, but also in all possible transmission path.

Owing to the inevitable problem of B_0, and considering transmission characteristics of power system itself, this paper puts forward Integrative Electrical Betweenness(B_{ie}) of line l to indicate its transmission contribution during electricity transmission. $B_{ie}(l)$ is defined as follows:

$$B_{ie}(l) = \sum_{s \in G, t \in L} \sqrt{R_s * R_t} * T_{st}(l) + \sum_{s \in G, t \in L} \sqrt{R_s * R_t} * A_{st}(l) * \frac{P^{\max}(l) - P^0(l)}{P^{\max}(l)} \tag{2}$$

$$T_{st}(l) = \frac{\Delta P_{ij}}{\Delta P_{st}} = \frac{X_{is} - X_{js} - X_{it} + X_{jt}}{x_{ij}} \tag{3}$$

$$A_{st}(l) = \begin{cases} 0 & , T_{st}(l) \leq 0.8 \\ \dfrac{1}{T_{st}(l)} & T_{st}(l) > 0.8 \end{cases} \tag{4}$$

Where R_s, R_t are power capacity of node s and node t respectively; Q_{st} reflects weight of different (s,t); $P^0(l)$, $P^{\max}(l)$ separately reflect current power and maximum transmission power of line l; $T_{st}(l)$ is PTDF of line l as to (s,t),it means that ,when power transaction volume between s to t has an augment of ΔP_{st} , there has a variation of ΔP_{ij} of line l connected between bus i and bus j; X_{is} is the corresponding elements of is th elements in node impedance matrix; means of X_{js}, X_{it}, X_{jt} are similar to X_{is}; x_{ij} means self-reactance of line l.

From (2), it is not difficult to find out that B_{ie} is composed of two parts:

1. $\sum_{s \in G, t \in L} Q_{st} * T_{st}(l)$, which illustrates the total transmission contribution of line l to all node pair. Its magnitude means whether an important role or not that line l plays.

2. $\sum_{s \in G, t \in L} Q_{st} * A_{st}(l) * \frac{P^{\max}(l) - P^0(l)}{P^{\max}(l)}$ reflects remain transmission capability of line l. We explain the prime reason of define $A_{st}(l)$ as (4) here: firstly without considering value of $T_{st}(l)$, the remain transmission capacity can be expressed as $\sum_{s \in G, t \in L} Q_{st} * \frac{P^{\max}(l) - P^0(l)}{T_{st}(l) * P^{\max}(l)}$.However, a potential problem will emerge, under the condition that $T_{st}(l)$ is rather small. On account of $\sum_{s \in G, t \in L} Q_{st} * \frac{P^{\max}(l) - P^0(l)}{T_{st}(l) * P^{\max}(l)}$, remain transmission capacity of line l is extraordinary large. However, the real fact is that, when $T_{st}(l)$ is small, it implies that line l is insensitive to the transmission power about (s,t), in other words, the contribution of line l on power transmission is tiny. In order to solve this issue, (4) is adopted in this paper, assumed that only when the magnitude of $T_{st}(l)$ is greater than a certain threshold value (0.8), line l use its surplus capacity to transfer power from (s,t).

B_{ie} ,proposed in this paper, not only reflects the real transmission contribution under present conditions of transmission network, but also innovatively take the ability of line l about taking shift power when a fault(such as one line outage) occurs in power system into account . With greater

value of $B_{ie}(l)$, line l has the greater degree of fragile, thus its outage is likely to affect the entire network. As a result, security analysis work should be focus on these vulnerable lines.

Transmission Section Search Based on PTDF

In order to prevent occurrence of cascading failure, and for the purpose of reducing supervision range of security and stability control, it's necessary to search transmission section of vulnerable line l, and carry online safety monitor on it.

With the common sense that parallel transmission lines are main components of transmission section. Therefore, before introduce the proposed search algorithm, this paper, firstly, analyses the relationship of parallel transmission line in the aspect of PTDF.

1. line l and line k are two parallel lines of power supply source s to load t, as shown in Fig. 1:

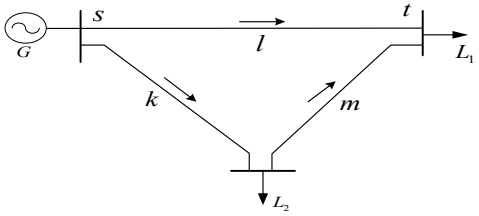

Fig.1 Schematic diagram of same source power to loads

According to the definition of PTDF, it's knowable that line l and line k take all incremental power of (s,t). Therefore, $T_{st}(l)$ of line l and $T_{st}(k)$ of line k satisfy the following equation:

$$T_{st}(l)+T_{st}(k)=1 \tag{5}$$

2. When line l, line k and line m are transmission lines for different power bus to the same load t, as shown in Fig. 2:

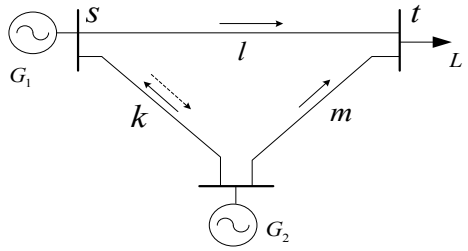

Fig.2 Schematic diagram of sources to same load

As shown in Figure 2, when transmittal power from source node s to node t increases a unit, power flow on line k will 'reverse', it forms another path to transmit power for (s,t), with line m, except path l. Then in solving process of PTDF, it need to exchange first node and end node of line k, namely $T_{st}(k)^{*}=-T_{st}(k)$ ($T_{st}(k)$ is the former PTDF of line k before exchange of node), so $T_{st}(l)$, $T_{st}(k)$ and $T_{st}(m)$ meet the following relationship:

$$T_{st}(l)+T_{st}(m)=1 \tag{6}$$

$$T_{st}(l)-T_{st}(k)=1 \tag{7}$$

$$T_{st}(k)=-T_{st}(m) \tag{8}$$

Equations (5) ~ (7) are equivalent to (9):

$$\left|T_{st}(l)\right|+\left|T_{st}(k)\right|=1 \tag{9}$$

Based on the mentioned relationship of PTDF between parallel transmission lines, a novel search method $T_{st}(k)$ is proposed. The basic principle of this algorithm is as follows:

Computing Coefficient of Difference of PTDF Between Vulnerable Line l and Line k . First of all, corresponding measures as (11) are taken when PTDF satisfy (9) and (10) ,then coefficient of difference($D(l,k)$) is quantified as (12).

$$d_{st}=\begin{cases}\left(T_{st}(l)+T_{st}(k)\right)^2, & -\varepsilon \le T_{st}(l)-T_{st}(k)\le \varepsilon \\ \left(\left|T_{st}(l)\right|+\left|T_{st}(k)\right|-1\right)^2, & -\varepsilon \le \left|T_{st}(l)\right|+\left|T_{st}(k)\right|-1\le \varepsilon \\ \left(T_{st}(l)-T_{st}(k)\right)^2, & else\end{cases} \quad (11)$$

$$D(l,k)=\sum_{s\in G,t\in L} d_{st} \quad (12)$$

Where ε is a small positive number. Thought (11) ~ (12), it shows that two line are likely to be parallel transmission lines under the conditions that $D(l,k)$ of these two lines is small.

Determine Key Transmission Section of Vulnerable Line l **.**Through calculation of $D(l,k)$, the sort $P(l)$ of $D(l,k)$ about line l and the rest lines in power system is achieved. It is knowable that lines, which have large growth of active power when line l outage, make up key transmission section of line l. Therefore, , this paper utilize relationship of size between Branch Outage Distribution Coefficient $\lambda(l,k)$ and the threshold $\lambda_{set}(l,k)$($\lambda_{set}(l,k)$ in this paper is 0.2), to ascertain whether line k belongs to key transmission section of line l When $\lambda(l,k)<\lambda_{set}(l,k)$ takes place for the first time, the search ends, then key transmission section of line l is obtained.

Example Analysis

In order to verify its validity, the proposed algorithm has been tested on IEEE39-bus system, which has 10 generators, 39 nodes, 34 lines.

Results of Identify Vulnerable Line. As a matter of fact, it's effect on the whole network, when vulnerable line l out of operation, is manifested by the total amount of changed transfer flow in entire lines to a large extent .Therefore, in this paper, identification results of vulnerable line is compared with entire change rate of active power of remaining lines under the condition that vulnerable line l out of operation (resp. C_r) and B_0, as shown in Table 1.

Tab.1 Comparison table of some line indicators sort of IEEE39 bus-system

line		B_{ie}	sort	B_0	sort	C_r	sort	load[MW]	sort
first node	end node								
16	17	39233.20	1	12	1	9.42	4	201.1	18
16	19	30049.75	2	6	5	9.53	2	451.3	3
19	20	27318.58	3	1	29	10.2	1	174.7	22
16	15	23559.18	4	3	15	9.45	3	292.6	13
17	27	22584.22	5	3	15	8.51	9	13.1	33

From Table 1, although load rate of line $l_{16\text{-}17}$ is too small to rank $18th$, however it ranks top, not only in the aspect of B_{ie}, but also in B_0. It is able to obtain ,because of $l_{16\text{-}17}$ is the only way must be passed ,when centralized supply areas transmit power to load zone, its outage will cause transmission path of generation nodes, such as 33, 34, 35 and36 get snagged without doubt. Furthermore, transmission section of load nodes such as node 3, 18 and 27 reduce to a great degree. Similarly, outage of $l_{16\text{-}19}$ and $l_{19\text{-}20}$, will directly cause the issue that power of generation node 33 and 34 cannot delivery and require of large capacity load 20 cannot be satisfied.

Analysis of Transmission Section Search Results. For the purpose of verifying effectiveness and feasibility of proposed method, transmission section of vulnerable line $l_{16\text{-}17}$ was searched, the search result is compared with outcome of Power World Simulation Software, as shown in Table 2. From Table 2, it is know that the proposed method can search out all lines whose flow change in a large degree, when line $l_{16\text{-}17}$ outage. In addition, the proposed method can effectively line, whose

power is reversed and increased ($l_{3\text{-}4}$, $l_{18\text{-}3}$, l_{17-27} , $l_{14\text{-}15}$).It can reduce leakage problem, because of power reverse. Undeniable, the proposed method has few leakage lines, investigating its fundamental reason, PTDF obtained by DC model, lake of considering load effect. But $\lambda(l,k)$ of leakage line is only 0.22, and its load is 29/34 (77.1MW), as a result, its active margin is too large to transfer increased power, without being overload, when $l_{16\text{-}17}$ is outage.

Tab.2 Search results for key transmission section of line $l_{16\text{-}17}$

	line		$D\ l,k$ of $l_{16\text{-}17}$	sort	$\lambda\ l\ k$	results of AC
	first node	end node				
search result	16	15	0.1075372	1	0.9921	increase
	14	4	0.1129526	2	0.7121	increases
	3	4	0.1238404	3	-0.8359	increase ∪ reverse
	18	3	0.5272180	4	-0.7812	increase ∪ reverse
	17	18	1.1906396	5	-0.7812	reduce ∪ reverse

	10	11	1.3509434	7	0.2511	increases
	26	27	1.4168168	8	0.2193	increases
	17	27	1.5644251	9	-0.2178	increase ∪ reverse
	14	15	1.5739188	10	-0.9901	increase ∪ reverse
boundary line	6	5	1.6027826	11	0.1919	increases
leakage line	25	26	1.8930206	12	0.2202	increases

Summary

In this paper, on the basis of analyzing the influence factors of transmission line contribution in electric power system all-around, Integrative Electrical Betweenness B_{ie} is putted forward to identify the weak links of power grid - vulnerable line correctly and reliably. On this basis, using coefficient of difference of PTDF to obtain key transmission section, thus further reduce monitoring range of grid security and stability control on this account.

Using Fuzzy Synthetic Evaluation Model to assess technical risk of China's alternative fuel vehicle industry

Jinfeng Lin

School of Economics & Management, Harbin Engineering University, Harbin 150001, China

linjinfeng2006@163.com

Keywords: Industry technical risk, China's alternative fuel vehicle industry, Fuzzy Synthetic Evaluation Model

Abstract. The energy, which has a close bearing on the national economy and the people's livelihood, is always a world-wide attention issues. To promote the development of alternative fuel vehicle, we have to break through many technical difficulties, at the same time, as one of strategic emerging industry, China's alternative fuel vehicle industry future development has a high degree of uncertainty, will face a lot of risks. In this paper, we set up an evaluation index system of those risks and use AHP method and Fuzzy Synthetic Evaluation Model to assess technical risk of China's alternative fuel vehicle industry.

Introduction

After nearly a century with the internal combustion engine dominating the personal transportation sector, it now appears that the alternative fuel vehicle is on the verge of experiencing rapid growth in both developed and developing vehicle markets(see table1). [1-2]

The rapid growth of vehicles has resulted in continuing growth in China's oil demand. since 2009, China's automobile production and sales has been ranked first in the world, data prediction of the NDRC Energy Research Institute shows that the number of China's automobile on the road will reach 1.5 billion by 2020, the rapid growth of automobile will result in oil consumption exceeding 2.5 billion tons, accounting for the country's total oil demand in 57%, will further aggravate the carbon emissions and environmental problems, increasing difficulty of realization of China's carbon emission reduction targets [3]. In this context, to accelerate the development of alternative fuel vehicle industry becomes the inevitable choice to break this plight.

Table 1 Some countries alternative fuel vehicle sales from 2010—2012 [4]

	2010		2011		2012	
	EV	Plug-in	EV	Plug-in	EV	Plug-in
American	37	326	10144	7671	14592	38585
Japan	2361	—	13449	—	15943	7241
China	63	417	5576	613	11375	1416
France	57	—	4012	36	8880	225
Germany	—	—	1800	241	2976	863

Alternative fuel vehicle belongs to the emerging industry, using the new technology or developing technology, technology plays the most important role in development of alternative fuel vehicle industry, but the reality is that, there are many uncertainties on alternative fuel vehicle technology, such as associated with the technical level, technology is mature or not? Whether the technology is advanced, technology is facing risk being replaced? Associated with the technical social & environment adaptability， such as technology policy is effective or not? What about the complementary technology development, etc.. So, scientific assess alternative fuel vehicle technology risk has the important significance.

Technical risk is a kind of non clear concept; the causes leading to the risk of are complex, multifaceted. Many risk factors not only the relationship between perplexing, and the risk factors and

external factors permeate each other alternately, the levels of the risk no clear extension. At the risk of between "big" or "small" exists a gradual change and transition, namely technology with fuzzy attribute of "sensory risk" [5].

In this paper, we set up an evaluation index system of those risks and use AHP method and Fuzzy Synthetic Evaluation Model to assess technical risk of China's alternative fuel vehicle industry.

Establishment of technical risk evaluation indexes set and weights determination

According to related literatures, this paper constructs the technical risk evaluation index system as shown in table 2 [6-8].

Table 2 The alternative fuel vehicle technical risk evaluation index

Target layer	Index layers	Weights	Sub index layers	Weights
Technical risk factors (U)	Technical level (U_1)	0.5000	Technology Independence (X_{11})	0.2701
			Technology Advancement (X_{12})	0.2122
			Competition and Barrier (such as patents, licensing etc.) (X_{13})	0.2412
			Technology Replacement (X_{14})	0.1334
			Technology readiness level (X_{15})	0.0900
			Technology endowment (X_{16})	0.0531
	Technical social & environment adaptability (U_2)	0.5000	Technology policy (X_{21})	0.4576
			Raw material supply ability (X_{22})	0.2203
			The Improvement and stability of technical standards (X_{23})	0.1525
			The development of complementary technologies (X_{24})	0.1695

The index weight is determined by AHP and Delphi method.

Evaluation grades determination

Evaluation grade is the criteria for evaluation, evaluation grade set is $V=(v_1,v_2,\cdots v_k)$, this paper select 5 grades, i.e. {very low, low, medium, high, very high}.

Fuzzy evaluation matrix constructions

After determining the evaluation grades, sub index layers of alternative fuel vehicle risk were evaluated respectively, use membership grades to represent sub index's membership to evaluation grade, and then get the fuzzy relation matrix(see equation 1), wherein $j=(1,2,\cdots m)$.

$$R_i=\begin{bmatrix} r_{i11} & r_{i12} & \cdots & r_{i1k} \\ r_{i21} & r_{i22} & \ddots & r_{i2k} \\ \cdots & \cdots & \cdots & \cdots \\ r_{im1} & r_{im2} & r_{im2} & r_{imk} \end{bmatrix} \quad (1)$$

Usually, on the basis of the questionnaire, r_{ijk} determined by the following equation:

$$r_{ijk}=\frac{d_{ijk}}{d} \quad (2)$$

Wherein d is the total number of experts, d_{ijk} is the number of experts made comments on k grade to the index ij .

This study invited 10 experts to give evaluation to index layers, through data processing, the two evaluation matrixes are:

$$R_1 = \begin{bmatrix} 0 & 0 & 0.20 & 0.30 & 0.50 \\ 0 & 0.20 & 0.30 & 0.30 & 0.20 \\ 0 & 0.10 & 0.30 & 0.60 & 0 \\ 0 & 0.30 & 0.50 & 0.20 & 0 \\ 0 & 0 & 0.20 & 0.70 & 0.10 \\ 0 & 0.20 & 0.30 & 0.40 & 0.10 \end{bmatrix}; \quad R_2 = \begin{bmatrix} 0 & 0.10 & 0.20 & 0.40 & 0.30 \\ 0 & 0.30 & 0.40 & 0.20 & 0.10 \\ 0 & 0.10 & 0.30 & 0.50 & 0.10 \\ 0 & 0.20 & 0.20 & 0.30 & 0.30 \end{bmatrix}$$

Evaluation vector

Use following equation calculating the evaluation vector:

$$E_i = W_i R_i = (w_{i1}, w_{i2}, \cdots, w_{im}) \begin{bmatrix} r_{i11} & r_{i12} & \cdots & r_{i1k} \\ r_{i21} & r_{i22} & \ddots & r_{i2k} \\ \cdots & \cdots & \cdots & \cdots \\ r_{im1} & r_{im2} & r_{im2} & r_{imk} \end{bmatrix} \tag{3}$$

$$E_1 = \begin{bmatrix} 0.2701 \\ 0.2122 \\ 0.2412 \\ 0.1334 \\ 0.900 \\ 0.0531 \end{bmatrix}^T \begin{bmatrix} 0 & 0 & 0.20 & 0.30 & 0.50 \\ 0 & 0.20 & 0.30 & 0.30 & 0.20 \\ 0 & 0.10 & 0.30 & 0.60 & 0 \\ 0 & 0.30 & 0.50 & 0.20 & 0 \\ 0 & 0 & 0.20 & 0.70 & 0.10 \\ 0 & 0.20 & 0.30 & 0.40 & 0.10 \end{bmatrix} = \begin{bmatrix} 0.0000 \\ 0.1172 \\ 0.2907 \\ 0.4003 \\ 0.1918 \end{bmatrix}^T$$

$$E_2 = \begin{bmatrix} 0.4576 \\ 0.2203 \\ 0.1525 \\ 0.1695 \end{bmatrix}^T \begin{bmatrix} 0 & 0.10 & 0.20 & 0.40 & 0.30 \\ 0 & 0.30 & 0.40 & 0.20 & 0.10 \\ 0 & 0.10 & 0.30 & 0.50 & 0.10 \\ 0 & 0.20 & 0.20 & 0.30 & 0.30 \end{bmatrix} = \begin{bmatrix} 0.0000 \\ 0.1610 \\ 0.2593 \\ 0.3542 \\ 0.2254 \end{bmatrix}^T$$

Evaluation vector E_1 and E_2 can present the index layers risk levels respectively.

Comprehensive evaluation of technical risk as a result of:

$$B = WR = 0.5 \begin{bmatrix} 0.0000 \\ 0.1172 \\ 0.2907 \\ 0.4003 \\ 0.1918 \end{bmatrix}^T + 0.5 \begin{bmatrix} 0.0000 \\ 0.1610 \\ 0.2593 \\ 0.3542 \\ 0.2254 \end{bmatrix}^T = \begin{bmatrix} 0.0000 \\ 0.1391 \\ 0.2750 \\ 0.3773 \\ 0.2086 \end{bmatrix}^T$$

B is showing the degree of technical risk level belonging to each grade. In order to make the evaluation result more specific, we can introduce the membership degree vector K, as shown in table3.

Table3 Evaluation grade set and corresponding intervals and median

Grade	Very low	Low	Medium,	High	Very high
Intervals	0-20	20-40	40-60	60-80	80-100
Median	10	30	50	70	90

Use medians to constitute the membership vector, i.e. $K = (10,30,50,70,90)$.Then the comprehensive evaluation results can be expressed as:

$$R = KB = (10,30,50,70,90)\begin{bmatrix} 0.0000 \\ 0.1391 \\ 0.2750 \\ 0.3773 \\ 0.2086 \end{bmatrix} = 63.1080$$

This shows that China's alternative fuel vehicle industry technical risk is at a high level.

Keywords: Distribution Network; Vulnerability Assessment; Transient Energy Function; Monte-Carlo Simulation; Risk Indices; Brittleness of System;

Abstract. This article is based on the concept of vulnerability for power system, and focuses on vulnerable source of distribution network and summarizes the characteristics of vulnerability assessment methodologies and inadequate for the distribution network.And pointed out that domestic and international research for distribution network vulnerability is still in the initial stages,evaluation of existing methods are accessible only from one side distribution system's security status,the vulnerability assessment methodology of distribution network can be more fully reflected the global distribution network of security that will be researched in the future.

Introduction

In recent years,power system Blackouts occur frequently all over the world,experts from various countries come to realize that traditional security analysis has been insufficient..In the Past,power system security only contains stability and reliability,most of the safety analysis is set up on the basis of screening and storting on expect accidents,which can't reflect the change from one or more of the operating parameters in the system on impact of the trend and stability margin change.The future development direction of power system safety analysis should be run fast accurate analysis of status and trends on the basis of avoiding the occurrence of major accidents, guarantee safe operation of power system.For this reason, some literature to expand conventional power system safety, vulnerability theory is a theory developed by this one.This article summarizes the distribution network vulnerability assessment , analysis and research the different kind of theories and methods, aims to establish a distribution network vulnerability assessment method and index system for reference.

Vulnerability for Distribution Network and its Definition

The vulnerability for distribution caused by human intervention, calculation errors, communication failures, factors such as internal elements and protection systems and for the potential of large scope blackout risk.Such hidden dangers fault is only exposed when the accident occurred, which performance the ability for the power grid remain normal and stable supply of electricity to users.Distribution network vulnerability assessment includes the following 4 aspects :event recognition, risk calculation, network analysis and decision analysis.At this point, vulnerability for distribution network can be defined as extension of the safety and stability of power distribution network.

vulnerable source of distribution network

Categorize and summarize the vulnerable sources in distribution networks, can be divided into external and internal sources.

1 External Source.External sources can be summed up in two aspects.1.Force majeure such as natural disasters and weather conditions.Mainly includes:Earthquakes and typhoons, storms, high temperatures, hail, thunderstorms, flooding, forest fires, as well as plants and animals triggered failures;2.Artificial fault.Include the misuse of the system operator, controls and protection system error , vandalism,etc.

2 Internal Source.Mainly includes:1.Main components of fault in distribution networks;2. Protection and control systems failure;3.Information and communication system failures;4.Distribution system is unstable;5.Distribution network modeling and assessment is inadequate;6.Electricity market competition leads to vulnerability;7.Unable to access, integrate and use of reliable information;8.Some criminals have used high-tech data intrusion and tampering.All of the above are major vulnerable source of distribution network.

Method for Distribution Network Vulnerability Assessment

Summary

Now,Vulnerability assessment method for power system has no recognized and unified analysis standards.Vulnerability assessment for distribution network is an aspect of vulnerability assessment in power system and its assessment methods need to be improved and summarized as appropriate.At present, methods could be applied to assessment vulnerability for distribution network can broken down into the following three categories

1 Assessment methods based on brittleness of system.

2 Assessment methods based on probability theory,which include assessment methods based on risk theory and Monte-Carlo simulation.

3 Assessment methods based on transient stability analysis,which include assessment methods based on transient energy function.

Assessment methods based on brittleness of system

Brittleness analysis is an theory that attempt to explain and analysis a cascading failures in the system.[3] based on the mechanisms of cellular automata, elaborates specific modeling steps for vulnerability assessment model,defining brittleness risk function based on probabilistic risk method,quantitative analysis of probability of brittleness risk.Proposed power grid is a self-organized critical system and the brittleness inspired because of the system is self-organized criticality.

This paper study components due to failure to quit running based on self-organized criticality of power system,other elements of a system overload because of the current redistribution,caused by breaking one after another, eventually caused the system to crash.Because it does not take into account other aspects such as voltage stability and transient stability of system,which do not work for complex power system in today.

Assessment methods based on probability theory

Assessment methods based on risk theory

Risk theory study the possibility and severity of disaster.Use risk indicators to quantitatively grasp the possibility and severity of an accident , so as to more fully reflect the impact of accidents on power system.Risk is defined as the product of the probability and the consequences of the accident.Risk indicators calculated as follow

$$R(C/Y_t)=\sum P(E_i/Y_t)\times S(C/E_i) \tag{1}$$

In this formula,i:The collection of normal operating elements;Yt:The running state before failure;Ei:Uncertain accident in future moment t;P(Ei/Yt):The probability of accidents Ei in case Yt;S(C/Ei):After the accident Ei, the severity of the consequences;R(C/Yt): vulnerable indicators of system in accident Ei.Calculation of risk indicators for distribution network requires the probability and consequences of accidents caused by two important parameters.The probability of Power system accidents largely satisfies the Poisson distribution

$$P(E_i)=(1-e^{-\lambda_i})\times e^{-\sum_{j\neq i}\lambda_j} \tag{2}$$

The severity of consequences of the accident impact on power system security.Define the appropriate severity link to specific systems, specific requirements as well as the risks types.

Risk calculation of decoupling,which calculated separately each incident or each category of security issues, each component.Therefore, you can rewrite the formula(1),according to security assessments, calculate different kinds of vulnerability indicators , reflect the overall vulnerability of different power system problems.Finally, the combined vulnerability indicators can be integrated to reflect your overall system vulnerability risk index.

Theory of risk-based assessment methodology is merely a response to an aspect of the system or any part of the security problem, not reaction system-global security

Assessment methods based on Monte-Carlo simulation

Monte Carlo simulation is for solving the problems associated with a certain degree of probability model to obtain the approximate solution of the problem.[7] noted that indicators of vulnerability analysis of power system based on Monte Carlo method can be summarized as:Using random probability sampling to determine the System State,study on dynamic and static characteristics,indicators of risk through statistical analysis computing system outages.These can be divided into three parts1.State selection;2.State estimation;3.Index calculation.The advantage of this method is 1.This is a statistical testing method, easy to understand and master;2.This method can discover unexpected accidents, easier to deal with its random variation;3.Easy to handle system for operations in chronological order;4.Ideal for intensive low-reliability components, and multiple failures affect systems that cannot be ignored.Its shortage is mainly calculated time and calculated accuracy is closely related to, in order to achieve high precision reliability index, often takes a long time.

[7] serious blackout occurred in the simulation system of probability is defined as the vulnerability of the system.Its formula is

$$V = \sum \left[F(i) / N \right] \tag{3}$$

Among them, V is vulnerability of system.;I is loss of total load is greater than the threshold to take emergency control still unstable after a simulation. F (i) = 1;N is the total number of system simulation.

Computation not scale or level of complexity of the system affected, ideally suited to handle a variety of complex factors.In a certain precision and study all decrease the variance in skills is the key to improve the convergence speed of Monte-Carlo method.

Assessment methods based on transient stability analysis

Assessment methods based on transient energy function

Evaluation method based on transient stability analysis,[8] taking into account the expected probability of accidents and use potential energy boundary method for solving critical energy and fault removal of energy, composition the vulnerability indicators of system.In the literature,The absolute indicators is definite as vulnerability indicators for the contingency of i .

$$P_i^J = P_i e^{-V^i{}_{critical}} \tag{4}$$

In this formula,Pi is Probability in accident of i;Vicritical is critical energy of the contingency of i.According to the critical energy of contingency and transient energy within the time of fault clearing defined the relative indices of contingency of i.

$$P_i^X = P_i e^{V^i{}_{clear} - V^i{}_{critical}} \tag{5}$$

In the formula,V^i_{clear} is critical energy of the time of Contingency i removal .

A combination of these two indicators could get the integrated indicators of vulnerability:

$$P_S = \frac{1}{2}\left(\frac{1}{N} \left\| I_s \right\|_1 + \left\| I_s \right\|_\infty \right) \tag{6}$$

In this formula,I is integrated indicators of vulnerability within Contingency.

Set S is an acceptable benchmark thresholds and assess the system's security status.System's vulnerability mainly depends on the assessment of vulnerability index is greater than or less than the specified threshold value of S.

Conclusion

This article is based on the concept of vulnerability as well as sources of vulnerability for distribution network, Summed up vulnerability assessment method for distribution network in different literature at home and abroad.However evaluation methods mentioned in this article are available only from some aspect of power systems to assess the vulnerability index,combining multiple assessment indicators to establish comprehensive assessment indicators is research direction of distribution network vulnerability assessments need to focus.

Abstract. At present most of the research is aimed at the end of the central air conditioning equipment, not considering the inner link between each component of the central air conditioning. In order to achieve economic operation of equipment and systems, to maximize energy saving of central air conditioning, we designed and implemented a monitoring system analysis which considered in the system more equipments linkage, multi parameter coupling, and a variety of factor. It collected energy consumption data of each device, to get the system running in typical operating conditions of the system by simulating the optimal process parameters and guide debugging critical control equipment.

Introduction

With China's rapid economic development, energy issues become increasingly prominent. Energy has become an important factor in the healthy and sustainable development of our national economy. According to incomplete statistics, China's building energy consumption has accounted for 30% of the total social energy. With the advancement of China's urbanization process, the continuous improvement of people's living standard, Experts predict if not timely solve the problems existing in the aspects of building energy consumption, this proportion will rise rapidly to about 40%. Building energy has enormous social and economic benefits. Energy consumption is one of the central air conditioning system, and heating, air conditioning, ventilation energy consumption accounts for about two-thirds of the total energy consumption. Related data show that the building of central air conditioning in operation load rate is low. Generally less than 50% of the design load running time accounts for more than 70%. So building energy-saving central air conditioning system has great potential and significance. Moreover, according to the predict calculation, if not take effective energy saving measures, China's energy consumption of building will grow by more than three times the current building energy consumption by 2020. Thus, the building energy problem is imminent. Therefore, we have developed a comprehensive analysis of the monitoring system in this situation which considered in the system more equipment linkage, multi parameter coupling, and a variety of factor. It collected energy consumption data of each device, to get the system running in typical operating conditions of the system by simulating the optimal process parameters and guide debugging critical control equipment. It implements the economical operation of equipment and systems and saves the energy consumption of central air conditioner to the maximum [1].

System Design

The system adopts the technology of the Internet of things, and realizes the date collection of monitoring and saving energy control in building central air conditioning system through the wireless and IP network. Building central air monitoring data collection includes the chiller, chilled water pump motors, cooling water pump motors, air conditioning blower motor, cooling tower fan related parameters as well as the indoor environment. Meanwhile, it is not suitable adopting the way of the cable for the part of the data collection such as indoor temperature, humidity and other

micro-meteorological environmental data. Because if deployed conventional devices, the data output in the form of cable, data lines must be deployed to the installation of the interior of each point and each device, and it is bound to cause the refrigeration circuit messy and complicated installation, therefore, we adopt wireless way. Moreover, adopting the way of wireless in the central air conditioning system has been running can avoid the transformation of the existing air conditioning and avoid wiring [2]. Figure 1 is the overall scheme of the system.

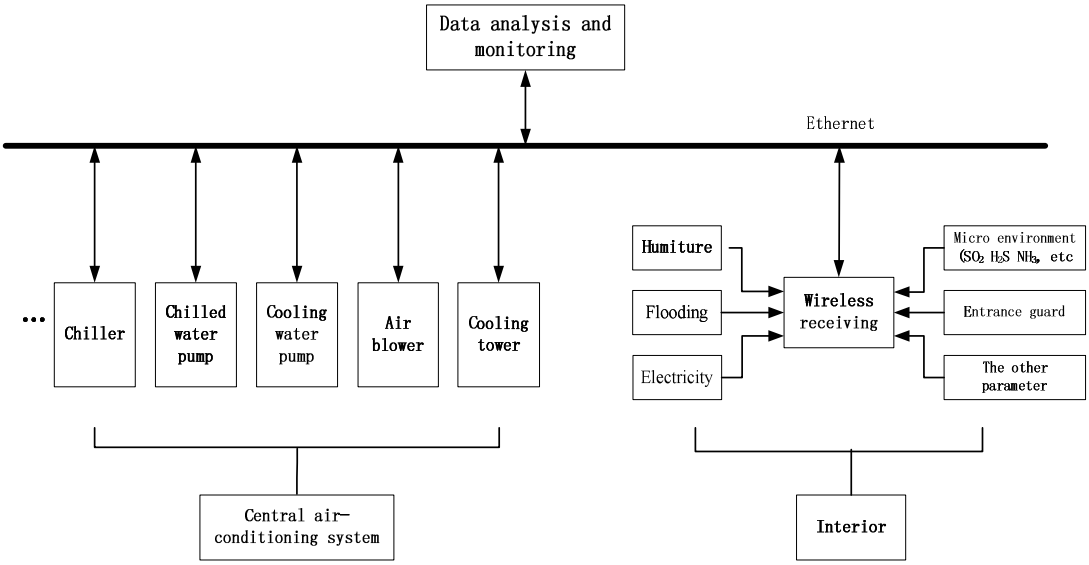

Fig.1. The overall scheme of the figure system

Central Air-conditioning System

Capacity of the central air conditioning system is selected by the maximum design load of the building, and have left margin. According to the American Air-Conditioning and Refrigeration Institute statistics, the central air conditioning equipment in 90% time runs at rated load under 70%. Due to the change of the season, day and night, and the user load, the actual air conditioning of heat load in the most time is lower than the design load. Central air conditioner can automatically adjust its operating power according to the heat load, but its circulating pump system working under a fixed maximum flow for a long time all the year which makes the system most of the time in a large flow of low temperature condition. Most of the circulating pump energy becomes pipeline transportation losses, meanwhile results in the decrease of efficiency of the host [3].

Table 1. The annual distribution imbalance of air conditioning load

Load rate	75 100	50 75	25 50	25
Percentage of the total running time	10	50	30	10

From table 1 can be seen that the distribution of the air conditioning load, within a year is not balanced. Design load accounts for about 6%～8% of the total run time, the running time of load rate is more than 75 accounts for only 10%, the running time of load rate is 50% to 75% accounts for 50%, the running time of load rate is below 50% reaches up to 40%. Therefore, for central air conditioning reasonable running, we can refer to the following:

(1) Operation and stop of the device. Analysis of overheating too cold case continues to operate and preheat pre cooling operation and as far as possible to increase the stop time.

(2) Air volume control. In the operation of the blower, the air flow control method to control the damper manually is very poor. Since the shaft power of blower and air volume are proportional to the size, so according to the heat load to control the air volume can greatly save power.

(3) Flow control. Requirements of cooling water, hot water, cold water are different with of heat load, water supply and water drainage difference in temperature. Therefore, we should control the

flow according to the above conditions. Pump power and the flow rate are proportional to the size, so the flow control can save energy significantly.

(4) The temperature and humidity control. Determining the operating state of air conditioner such as running, stop, for air conditioning should be according to the indoor temperature. Thermostatic control can prevent the waste caused by extreme cold or heat. There are a function of humidity and temperature, relative humidity decreased by 5%, equivalent to a temperature decrease 1 ℃.

The host is a major component of the air conditioning system and energy saving of host should be considered in combination with frozen water pump, cooling water pump, cooling towers, air conditioner, fan and other equipment. Therefore, we need to find the best system device configuration in co-operation between all the devices, and not just in a single device performance analysis to replace the energy-saving operation analysis of entire air conditioning system.

Inner environment

(1) Sensor

Temperature and humidity sensors used in solution are designed by Shandong Computing Science Center and which are low-power wireless sensors. Wireless communication frequency of sensors is 2.4 GHz, and which can ensure that the wireless communication distance is more than 300 meters. Temperature measuring range of sensors is -40 ℃～+125 ℃ and temperature measurement accuracy is between ± 0.3 ℃～± 2.5%. Relative humidity measurement range is 0.5% RH～100% RH and the relative humidity measurement accuracy is between ±1.8% RH ± 20%. More prominent advantages for this sensor it that electronic battery it built-in the sensor and current average is less than 7μA. Furthermore, it can work for 6 consecutive years without replacing the battery.

Other micro-environmental sensors used are all are independent designed by Shandong Computer Science Center. The current output signal of probe in detecting is very weak and need to develop special processing signal extraction circuit. Meanwhile circuit design requirements to prevent the circuit reverse connection, high voltage and high current. The signal communicates with the host through the circuit module using RS485 serial port or RF and transmits data in a wireless way.

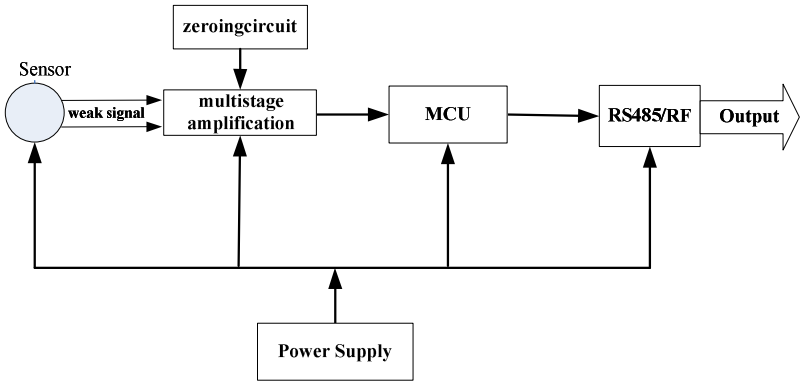

Fig.2. Circuit schematic diagram

Figure 2 is the schematic diagram of the sensor circuit. Detection circuit module receives the weak current signal which is produced by the electrochemical reaction of some parameters microenvironment. The current signal needs to make further amplification processing before A/D conversion. The signal input of the first amplifier stage must be able to pick up weak current output signal from sensor and the amplified signal is output to the amplifier. In the signal amplification process, the effective signal is amplified, noise is filtered out. Therefore, in this session we chose the small signal precision amplifiers produced by TI. The amplified signal needs to do the A/D conversion, that is converting analog signals into digital signals and after further processed, the signal output through RS485/RF. Taking into account the signal can be easily connected to an

external circuit after AD conversion, where the choice of chips are with low power consumption, small size, stability, development and simple. The transformed signal chip acquisition ultimately converted into RS485 or into the RF signal to ensure the longest transmission distance.

(2) Acquisition

Timing acquisition. Specific feature is that users can choose the type of equipment acquisition and flexible set timing acquisition time. The system can automatically collect data timed according to the user setting.

Real-time acquisition. The specific function is user generated commands to the device through the interface of data acquisition, the system responds by calling the data acquisition interface devices to obtain data. Real time data acquisition can be collected by a key, and can also select the type of device for separate collection.

Remote Control. The system processes and analyzes the data collected to get the system running in typical operating conditions of the system by simulating the optimal process parameters, and then sent the instructions in manual or automated form controlling the central air-conditioning of the building to reach the scientific operation.

At present, most of the building air conditioning system is running at part load conditions in most of the time. For the air-conditioning operation control department, they can formulate corresponding operation strategy according to the technical characteristics of building, equipment, collection and analysis of the external environment temperature inside the building and other technical parameters in all kinds of weather conditions as the basic data [4].

Conclusion

This design has reached the expected target, and achieved the desired function and which considered in the system more equipment linkage, multi parameter coupling, and a variety of factors. It collected energy consumption data of each device, to get the system running in typical operating conditions of the system by simulating the optimal process parameters and finally implemented the operation instruction of the central air conditioning. Meanwhile, this system not only can be used with the construction of the central air-conditioning energy saving, but also can be applied to the computer data center energy efficiency and other similar applications, so the potential is tremendous [5].

Keywords: Small islands; Renewable Resource; NO-Energy-Storage; Direct development and utilization

Abstract: Aiming at small islands location limits and the established power grid characteristics, the paper analyses some practical problems to be dealt with when renewable resource is utilized. Combined with the characteristics of small islands, the paper puts forward the new mode without energy storage devices, and designs a renewable resource application system driven directly by photovoltaic devices, emphatically analyses the key technology of no energy storage mode. The new mode effectively resolves the battle neck problem of traditional off-net mode.

Introductions

Renewable resource Utilization on small islands is an effective way to improve the energy supply mode of the islands; but there are still many problems, such as small islands often lacking of large power grid and renewable energy application often being off-net mode. Actually the cost factors and lifespan of the indispensable energy storage battery component are their natural defects in off-net mode. Meanwhile the extremely corrosive conditions on small islands are often beyond the technical conditions of routine renewable energy use, which makes the renewable energy utilization on small islands is still at a very low level. Combined with the engineering test, the paper discusses some practical problems to solve, and gives a typical design of no-energy-storage application system being suitable for small island features system.

1 Questions analysis of renewable resource development and utilization on small islands

At present, the renewable energy technology has been used in various forms even with super large scale in china. At the same time China's photovoltaic power generation capacity and installed wind power capacity are first in the world. But there are still many problems to be solved when these mature technologies are applied on small islands.

1.1 Discuss on the utilization mode

There are two basic forms in development and utilization of renewable energy application, one is grid-connected model, another form is Off-grid model. In grid-connected model, the outside power grid are indispensable, the power generated by renewable energy is transferred to large power grid through modulation to reduce the other energy needs of electric power. In off-grid model, without external power grid the energy generated by renewable resource must be stored and converted, and then provided to the necessary loads. On many small islands diesel generators or gas turbines supply power for load, the capacity of generators and scale of grid all can not meet the large disturbance requirements of renewable resource power connected to grid. The cost and life span of energy storage batteries, the stringent requirements for loads and converting efficiency limit the application scale of off-grid model. So the renewable resource utilization on small islands is still decorative such as street lighting etc.

1.2 About environment corrosion characteristics and equipment protection problem on small islands

More harsh application environment conditions are considered when renewable resource utilization is performed. However usually when temperature is considered, the environmental temperature limit and working temperature limit are focused on. About the corrosion condition, mainly considering the oxidation corrosion of metal, which is mainly considered moisture and oxygen in the air. About equipments protection grade I level, dust and sands are emphasis. But the

characteristics of environmental corrosion on small islands are manifested in the following aspects, the main consideration of environmental temperature is the seasonal temperature difference, the temperature difference between day and night or in a short time is very small. In addition to oxidation corrosion of high humidity, salt ion corrosion and salt spray are extremely serious. About the dust protection, the main protective object on small islands is salt spray and constantly high humidity. Practical experience shows that the life span is about 1/3 if environment corrosion characteristics and equipment protection have not been considered.

2 Probe on the utilization model of renewable resource on small islands

In the case of lacking of large power grid relying on, reasonable optimization of renewable energy exploitation patterns is an effective way to improve the independent ability of small islands. Aiming at the defect of the common off-grid patterns, we proposed a zero-energy-storage renewable energy application model as follow. The system principle is shown in figure 1.

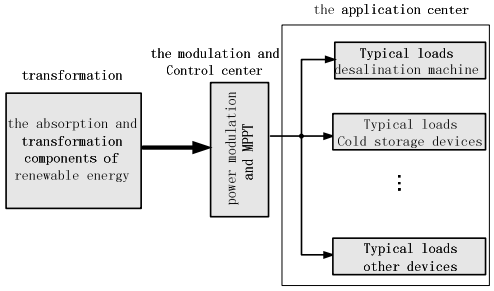

Fig.1 No-energy-storage model of renewable resource

The basic idea of the zero-energy-storage model is that energy converted by renewable resource is consumed instantaneously to the greatest degree of the conversion. The model consists of three parts. One is the absorption and transformation component of renewable energy, which coverts the most richly existing renewable resource on small islands into other forms of energy-usually electrical energy. Two is the control and modulating component. It should at least meet three requirements. First is the power modulation, which modulates the irregular electrical energy to the regular electrical energy which can meet the application center load directly; Second is the maximum power tracking, which demands the converted energy consuming at possibly high efficiency; Third is the loads regulation at application center, such as loads preferred starting right and optimal load working state, in order to make the whole system coordinated working. Three are the loads at application center, which should have enough flexibility. The flexibility here means not only that the loads can be starting or stopping according to the orders from the control components but also that the working states of the loads can be adjusted according to the power supplying from energy converting components.

3 A classical design of the zero-energy-storage model

The No-energy-storage application model is structured aiming at the problems of electrical power storage. According to the current technology level, the cost of storage 1KWH electricity is about 3000￥ or more, while the storage cost of 1 tons of water only a few yuan. On small islands, freshwater, cold and heat energy are fast consumable essential, the problems of electrical power storage will be resolved easily if using the energy converted from renewable resource directly. Based on the idea that water storage is better electricity storage, we give a classical design of solar desalination system driven directly by PV.

3.1 The whole consist of the system

Through the control of intelligent management unit, the energy from the solar photovoltaic components makes the reverse osmosis desalination machine dynamically adjusting its working state, so that the dynamic consumption instantaneously is less than or equal to the PV maximum output power, which ensure the whole system balance. The designed Peak power of the system is eight thousand warts, consisting of 48 pieces of photovoltaic components connected by 16 series connection and 3 parallel connections. All these components collected by lightning protection

confluence box supply energy to seawater desalination devices directly by intelligent management unit without energy storage devices. The minimum operating frequency and the minimum operating power is 20Hz and 600warts.The best operating frequency and power is 50Hz and 4000warts. It produces 5t fresh water daily under normal lighting circumstances. The framework of the system is as shown in figure 2.

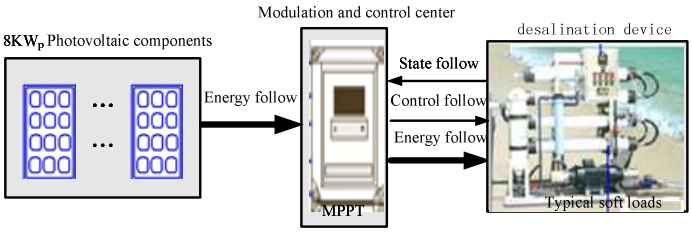

Fig.2 The frame of the photovoltaic desalination device

3.2 Analysis of the critical technology

Knowing from the typical application diagram of no-energy-storage model, the key parts of the whole system are intelligent management or conversion control units, which basic function is the energy conversion and management. Though the photovoltaic components can converts light energy into DC power which varies whit light intensity, however the electricity driving the desalination devices must three-phase alternating current. All these require intelligent management unit can not only complete the energy conversion, and according to the real-time solar illumination intensity, make desalination device stability and maximum use of the PV module converting electrical energy. Another main function is realizing the starting and stopping control automatically according to the external light. The hardware design of the system is simple relatively. Now we discuss the software programming.

The software design of the system mainly embodies the programming of power tracking unit, which mainly includes system start determining, maximum power point tracking method and the transition process of weather transients. The starting delay time is critical. Too short waiting time makes the pump starting frequently within a short time, which can not work continuously, and also shorten the life of the devices. Too long waiting time decreases the efficiency of the whole system. The starting flow of the system is shown in figure 3.

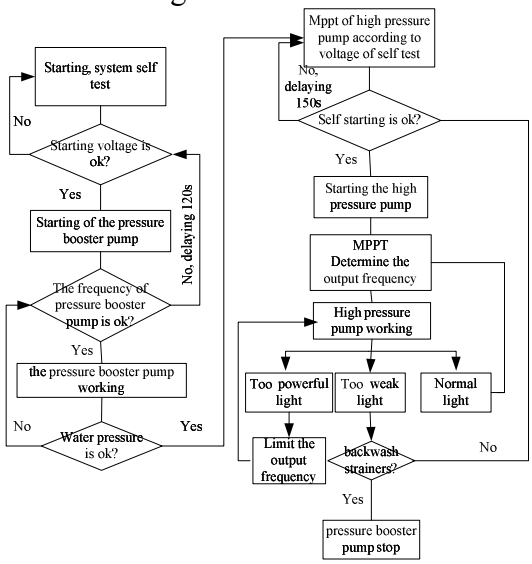

Fig.3 Flow chart of intelligent PV control unit

4 Conclusions

According to application model brought out in this paper, we established application on a small island in 2009. It has worked more five years placidly. The experiment practice of the no-energy-storage model shows that the new application model well resolved the problems of traditional model. It can improve the existing ability of the small islands greatly.
