Abstract. Firstly, this paper briefly introduces Panzhihua City's location, climatic conditions and hours of sunshine. Secondly, it proposes alternative solution of integrating the heat collector with high-rise residential building's facades. Thirdly, several equations on heat collector's area, row distance, and azimuth are explained and discussed.

Introduction

With the rapid growth in energy demand, resulting in increasingly serious environmental pollution, China is facing the dual pressures and challenges of unprecedented energy and the environment. Since the beginning of the 20th century, 90 years, China has increased the research and application of solar energy and building integration, but now China has nearly 2 billion m^2 building completed about 70% of the residential annually, the proportion of high-rise residential is also increasing large year by year, while 99% of these buildings are high energy consumers, urban water supply in order to meet more and more high-density high-rise buildings do not affect the appearance of building facades, solar collectors how to more effectively together and building facades [1]. The author quote Panzhihua City an example of high-rise residential solar panels and exterior design integrated exploration, hoping to promote and facilitate the application of solar collectors in high-rise buildings, faster realization of our energy reduction targets.

Panzhihua City high-rise residential buildings selection analysis

More and more modern high-rise residential buildings in the city appeared an important part of the overall image of the city (Figure 1). Due to the important influence of its huge scale and massing of city landscape, we require high-rise residential buildings not only to meet the general residence requirements. Also requires a certain aesthetic value and ornamental. Panzhihua is located in the Southwest, Northwest, Southwest belongs to the city, mainly in the following three high-rise residential style forms:

Figure1 Panzhihua City building close-up view

1. Modernism. In the form of binding function, the overall style is simple, crisp. Focus on stress points, lines, composition principles plane. Simple and elegant facade colors, no frills (Figure 2 (a)).

2. Neoclassicism. Emphasize the relevance of history in the design practices; refine the language of classical architecture and innovation, the use of a large number of modern materials, reflecting the overall atmosphere, elegant architectural style (Figure 2 (b)).

3. Art Deco. It is currently one of the more popular styles of high-rise residential buildings. It is enough of a new classicism to modernism style transition, showing the characteristics of modern elegance, emphasizing vertical lines and abstract decorative pattern (Figure 2 (c)).

（a）modernism （b）Neoclassicism （c）Art Deco

Functional solar collector design parameters

A solar collector installation location

In building surface choose a suitable installation location is the key to ensuring a solar hot water system functional requirements, installation location is the most ideal building roof, followed by building facades, such as walls, balconies and other parts (due to the mounting angle of the collector limit the amount of radiation to get affected by certain impacts) should be avoided in the bottom of the building facade, surrounded by green areas or building block recess shape of the installation.

Solar collector area calculations.

① design average daily water consumption

Design Day Average water consumption: from December 1, 2010 implementation of the "civil-saving design standards" (GB50555-2010), the provisions of the average daily water consumption of residential hot water, specifically for solar water heating systems and hot water mining quota selection. The average daily water consumption rise residential Panzhihua value should be in accordance with Table 1.

Table 1 Residential average daily water consumption quota of hot water

Hot water supply and equipment	average water quota (L)	Unit
owned heating water supply and bath equipment	20 60	L / person · d
central Heating water supply and bath equipment	25 70	

②Solar system guaranteed rate

Solar fraction F is the total load in the percentage of solar water heating system consists of solar burden is an important parameter to determine the solar collector area of the key factors also affect the economic performance of the system, which is calculated as follows:

$$F = Q / L \qquad (1)$$

In the formula, Q is the system effective heat gain from the sun; L is the system total load.

③ collector area calculation

"Civil solar water heating system technical specifications" in accordance with the different types of solar water heating systems heat the solar collector area calculation is divided into two cases:

The first is a direct system collector area calculation: total collector area of direct system according to the daily water consumption and water temperature to determine the user, calculated as follows:

$$A_C = \frac{Q_W C_W (t_{end} - t_i) f \rho}{J_T \eta_{cd} (1 - \eta_L)} \qquad (2)$$

In the formula, A_c is the collector system for the direct total area, m^2; Q_W is the average daily water consumption, L; C_w is the water specific heat capacity, 4.187kJ / (kg.℃); t_{end} is the design temperature of the water storage tank,℃, usually take 60℃; t_i is the initial water temperature,℃; ρ is the density of water, 1.0kg / L; Annual average daily amount of solar radiation collector J_T is

local lighting up, kJ/m^2, Panzhihua City's average amount of radiation can press the summer months and winter months, respectively, where the surface of the collector lighting calculations; f is the solar fraction,%, based on the life of the solar irradiation system, economic system and user requirements and other factors after considering identified, should be 30% to 80%; η_{cd} is annual average thermal efficiency of the collector, the value should be based on the experience of 0.25 to 0.50; η_L is the rate of heat loss from the storage tank and piping, the value should be based on the experience of 0.20 ~ 0.30.

The second is indirect area of the collector system: the system to be considered an indirect heat exchanger factor, so compared to the direct system, to obtain the same quantity of water, which requires relatively large area, the collector the area is calculated as follows:

$$A_{IN} = A_C \left(1 + \frac{F_R U_L \cdot A_C}{U_{hx} \cdot A_{hx}} \right) \qquad (3)$$

In the formula, the total collector area of indirect systems, m^2; collector system for the direct total area, m^2; total loss coefficient for the collector, W/m^2.℃, for flat plate collectors, should take 4~6 W/m^2.℃. For vacuum tube collectors, should take1~2W/m^2.℃, the specific values should be based on actual test data collector products may be; as heat transfer coefficient, W/m^2.℃; Ripe for the change called the plot's heat, m^2.

Azimuth solar collectors

According to the solar radiation Panzhihua typical local weather parameters, the collector angle is set to 60° and 30° change in azimuth 0°~90° range of azimuth calculation under different circumstances change the size of the received solar radiation on the surface of the inclined . Known horizontal surface daily average direct sun radiation (H_{bH}) and monthly average daily diffuse radiation (H_{dH}) per month, according to Klein derivation formula R_b direct radiation factor and Liu-Jordan derivation of scattered radiation factor Rd, the horizontal solar radiation is converted to an inclined surface solar radiation (H_β):

$$H_\beta = H_{bH} R_b + H_{dH} R_d \qquad (4)$$

Collector row spacing

When the collector is installed, it is should avoid blocking the surrounding shade or collectors. The length of buildings' shadow which is a minimum level of clearance of collectors from the shade, It is the collector row spacing. Calculated according to the following formula (Figure 3):

$$D = H \cdot \cos X_S \qquad (5)$$

In the formula, D is the horizontal distance from the collector minimum spacing (m) shade or between front and rear; H is the vertical height (m) the highest point of the shade light collector surface between the lowest point; X_s is building location solstice 10:00 sun elevation angle (year-round use) (°) (in order to ensure that no less than any time in the sunshine of the winter solstice on the collector 4 hours).

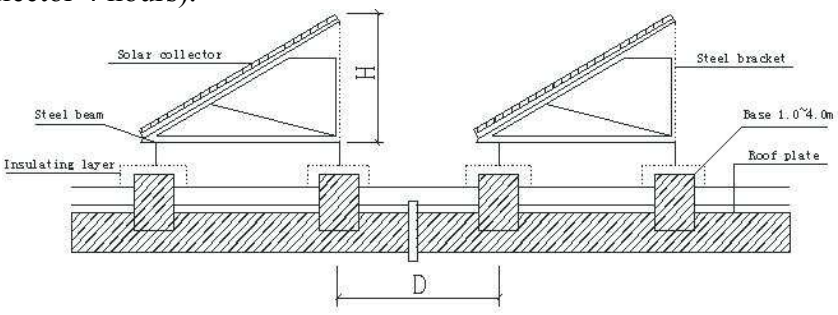

Figure 3 Schematic cross-sections of solar collectors

Solar collectors and residential facades specific binding mode

Combined with flat roofs

Installation of solar collectors on flat roofs is the most simple and feasible way for residential and collector toward no special requirements, and sufficient solar radiation. It should be noted collectors front row spacing, to avoid blocking. Through the bracket and solar collectors on the roof base with fixed, neatly arranged in a certain inclination, embedded base, good waterproofing measures pipeline through the floor, should not affect the existing roof waterproofing, insulation and drainage structures. Since the height of high-rise residential and the roof-mounted solar collectors are not in the normal field view, as long as the organized arrangement, there is no significant impact on the building exterior.

(a) Flat roof solar cell - Tube Products

(b) the cell demonstration projects - Flat-plate collector products

Figure 5 Examples of collectors installed on flat roofs

Combined with the sloping roof

The solar collectors mounted on the south to the top of the hill, and the roof slope consistent with the inclination, better reflects the collector and architecture combined effect (Figure 6). Different forms of roof material texture add richness, especially textured glass roof flat plate collector surface to form skylight effect. But if it uses high-rise residential pitched roof shape, roof area is smaller than the flat roof and pitched roof due to the various changes in the body, so that the effective available area is also smaller, generally only a few households to meet top hot water load requirements. Installation technology is more complex to avoid impact on the roofing, insulation, bois, and drainage. According to the relationship between the collector and the roof points, there is overhead, style and down slope embedded surface covered three installation methods.

Figure 6 The sloping roof-mounted solar collector heat instance

Combined with metope

In conjunction with the wall solar collectors and wall combination can reduce the length of the pipeline, but also solve the high-rise buildings due to limited roof area and cannot put collectors' problem. First, the analysis should be carried out when the sun collectors and wall combination. For Panzhihua City, but also to the south wall sunshine is good, but more balconies, bay windows, the walls are divided into smaller areas, collectors can choose between the installation location window walls, the window wall. Something, which is may be a large area of the wall installation that using union tube form.

In conjunction with balcony

Flat-plate collector plate appearance and balcony railing similar to the vacuum tube and the grid-like texture is similar to the balcony railing. The collector and balcony bar coordination, increasing the market for color, texture, form a sense of rhythm, is more suited to the combination

of high-rise residential. In consideration of the aesthetics, the solar collectors in general and balcony railings (board) parallel or install a larger inclination. The solar radiation collector would be less acceptable to some, should be considered in the design of this adverse effect (Figure 7)

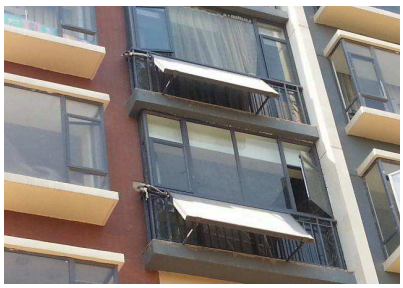

Figure 7 Examples of a district collector balcony

In conjunction with grill

Tend to be reserved for high-rise residential air conditioner outdoor unit design position and cover with a wooden or metal grille. Vacuum tubes and grille texture similar architectural design can leave the position of a collector tube installed in the vicinity of the air conditioner bit. Decorative grille and air integration does not increase the amount of facade elements (Figure 8).

In conjunction with floating panels, decorative frame

Vacuum tube solar collector combined to form an array of floating panels, frame mounting, forming a strong sense of rhythm, solar collectors play a shading effect, but also form a rich shade variations, roof trusses overhead space can become a resident of activities. (Figure 9).

Figure 8 Examples of grille with

Figure 9 Demonstration and application of a plot

Conclusion

When accelerate the process of high-rise residential solar panels with integrated design applications, there are two main issues restricting the development of solar collectors and high-rise residential appearance of the integrated design. On the one hand, the solar collectors on the market, this is poor fitting with the architectural appearance [3]. On the other hand, the importance of the architect solar hot water system has not been designed to understand the existing solar hot water system products is still lacking. Therefore, architects need to gradually increase the emphasis on subjective solar hot water system, which was used as one of the elements of architectural design[4]; addition, the development of solar collector products not only pay attention to improve product performance, but also the architectural requirements should be changed type and new product development.

Keywords: Sustainable development, optimization model, coal industry

Abstract. China's increasing demand for energy, the energy development and utilization patterns of traditional high exploitation, high emission and low use, not only caused a serious waste of resources and environmental damage, but also is difficult to meet the needs of economic development and facing the industry crisis of survival. Entered a new period of development, the coal industry how to get out of a resource conservation and production intensive road of sustainable development becomes an important strategic task. In this paper, by constructing and using efficiency of coal resources optimal allocation model and path analysis for the sustainable development of coal industry, circular economy, as a kind of advanced development model to promote the coordinated development of resources, environment and economy, becomes the inevitable choice of the coal industry to explore a new road to industrialization.

Introduction

According to the related statistics data, expected by 2030, fossil energy including oil, natural gas and coal still occupies the mainstream energy status in the world. Especially for coal resources, the total amount of coal resources that at the present stage of China possession is among the world top, and it belong to the world's largest producer and consumer of coal resources supported by the current technical conditions[1-2]. From the perspective of one-time energy consumption structure, the coal resources consumption proportion in primary energy sources in total consumption always control the proportion of over 70%, and this trend will not change in a certain period of development. In order to ensure the sustainable development of the modern economic society, except for making full use of clean and renewable energy, it is also very important that based on the circulation economic perspective to explore the sustainable application of primary energy sources in measures. Combining with the development of coal industry, model and strategic analysis should be build for the sustainable development of the coal industry under the circular economy[3-4].

The necessity of the coal industry to develop circular economy

The coal industry to develop recycling economy is to realize the sustainable development strategy. The opening of the UN climate change conference in Copenhagen, it marks a green, low carbon economy as the theme of the new development mode is sweeping the globe. China's economy accounts for about 7% of the world economy. However, the yearly consumption of coal accounts for 40% of the world and CO2 emissions account for 18% of the global total. China is already one of the world's largest emitter of carbon. That's a tall order for China, which puts forward to 2020 carbon dioxide emissions per unit of GDP than in 2005 decreased by 40% to 45% and the primary energy consumption of non fossil energy ratio reaches 15%. China’s "Twelfth Five Year Plan" clearly pointed out the need to accelerate the construction of resource-saving and environment-friendly society, save energy, reduce greenhouse gas emissions intensity, the development of circular economy, promote low-carbon technologies, actively respond to climate change, promote economic and social development in harmony with the population resources environment, and walk the road of

sustainable development. Coal as the important basic energy in China, we must change the mode of development, control the total quantity of coal, vigorously develop circular economy, accelerate the clean production and utilization of coal, promote the coal industry to achieve "green development". That's China's strategy development direction according to optimize energy structure, fulfill commitment on carbon emission reduction and actively respond to climate change.

The development of circular economy of coal industry is the fundamental way outof environmental pollution. For a long time, the serious ecological problems brought by large-scale and high strength development of coal resources and energy production-consumption structure based coal coke thermal power. First of all, coal annually produces a lot of poisonous gases methane and coal direct combustion emissions, as well as some gangue spontaneous combustion caused serious air pollution. Second, the surface subsidence caused by underground mining area already amounted to 4.0 * 1010 m^2, resulting in a large number of farmland abandoned, village forced relocation, seriously affecting the development of mining economic and regional economy. In addition, coal mining serious damage to water resources. Ever year, the national coal mine water is discharged about 2.2 * 109 m^3, which utilization rate is less than 30%. However, the coal mining area of the underground water level falling, causing parts of human and animal drinking water spare hard, severely affected agricultural production. Also, the annual production of coal gangue is 1.5 × 108 t, which occupy land more than 1.2 x 108m^2 and increase the rate at 2 × 106 ~ 3 × 106 m^2 every year[5].

In order to change this situation, development and utilization of coal resources must be based on the core of circular economy, promoting clean coal production, circulation efficiency and energy-saving emission reduction, the exploitation and utilization of the demand for natural resources and ecological environment will reduce to the lowest degree with minimal resource consumption.

The development of circular economy is an important measure to improve the economic efficiency of coal enterprises. Coal resources as the exhaustible resources, once be exploited, the physical form will be permanently lost resources. Non-renewable characteristics determines the scarcity of coal resources; nevertheless, circular economy is a powerful weapon to solve the scarcity of resources. To the recycling of resources as the basic form of circular economy, it changes the traditional "resources-products-pollution discharge" as the process of economic form, through the progress of science and technology to fully explore the added value of coal products, coal gangue, coal bed methane generated in the traditional coal production and mine water "waste". It forms a new economic growth point that waste to treasure.

In recent years, China has been accelerating the reform of the coal market, creating a good development environment to coal industry and promoting increased economic benefits of trade[6]. However, to improve the economic benefits of the current coal are heavily dependent on coal production capacity expansion and the coal price promotion. Therefore, endogenous growth momentum is insufficient. So, the development of circular economy in coal enterprise, change from the exploitation of resources and primary processing to the resources development, deep processing, has become an important guarantee for improving the economic efficiency and market competitiveness.

System optimization model for sustainable development of coal industry

Based on the concept of sustainable development system of the coal industry and to maximize the net effect by using the value of coal resources, coal industry is the important way of sustainable development. Therefore, construction and utilization of coal resources and optimal allocation model has important realistic value.

Within a certain time T, to maximize the net benefit value to get the discount with the resources use, and to meet the constraints of sustainability, namely the final make production possibility set a collection at the beginning of all productive. Belongs to the non-renewable resources of coal resources, considering the intergenerational equilibrium using non-renewable resources, mining rate of non-renewable resources should not be greater than its development reserves growth rate, or less

than to seek alternative renewable resources replacement rate. Non-renewable resources in the net benefits for t years of exploitation are as follows:

$$E_t = P_t Y_t - c_t(Y_t,\ X_t) - W_t Y_t \tag{1}$$

Refer with: E_t. Net benefit value, P_t. Resource unit price, X_t. Resources exploitation for t years, $c_t(Y_t,\ X_t)$. Resources exploitation cost for t years, W_t. Resources exploitation quantity change unit rents and royalties.

Non-renewable resources of the optimal model for mining system as follows:

$$\max E = \int_0^T E_t e^{-\rho t} dt \tag{2}$$
$$\text{s.t } setZ_0(k_0,\ L_0,\ X_0) \subset setZ_T(k_T,\ L_T,\ X_T)$$
$$Y_t \le X_t \le Q_t$$

Refer with: ρ. Discount rate, $Z_0(k_0,\ L_0,\ X_0)$. Initial production possibility set, $Z_T(k_T,\ L_T,\ X_T)$. Final production possibility set, L. Labor capital, K. Material capital, Q .Available amount of substitution for non-renewable resources.

The optimal mining mathematical model of non-renewable resource can be used to describe the general nature of sustainable utilization of non-renewable resources[7]. The pursuit of the rational use for non-renewable resources, so that it make the net benefit maximization of resources. With the finite time instead of the maximization of the infinite time, model achieves the sustainable development of coal resources by principle of precession rolling forward or dynamic methods.

Path analysis for sustainable development of coal industry

(1)The aid of the relevant laws and regulations of the repairs, ensure the sustainable development of the coal industry under the Perspective of circular economy can always be in a good policy and legal environment to support them:

First, for the coal industry needs to be revised policies and regulations, improve the audit system to maximize of coal production and operation permit, the reasonable control of enterprise access. At the same time, related to coal enterprises involved in the process of production and operation of coal resource consumption and pollutant emissions issues should be implemented to the specific legal provisions and standards, and clearly the appropriate liability regime. On this basis also need the help of integrated applications on a variety of new technology, new materials and new technology, the progressive realization of the optimization and upgrading of the entire coal industry.

Second, the need to combine our corporate social functions related to the separation of policy and requirements for coal companies to do the separation process of social functions performed significantly advance its purpose is reasonable to reduce the production and management of coal enterprises in the process undertaken by the social and historical burden problem.

Third, the need to build the cumulative of aging converting coal industry funding system, which is part of the application should be implemented in special funds to take over the work of the development of the coal industry among, for the development of coal resources depleted mines, through the construction of infrastructure and the implementation of the fostering of fiscal transfer payment policy in application, to accelerate its economic restructuring efforts and the process of economic transformation and development.

(2)With the aid of to give full play to economic leverage, full development based on the coal industry chain of circular economy.

First, formulate preferential fiscal and tax policies. For our country, by the presence of a long and continuing influence on policy under low background of the planned economy, the vast majority of coal enterprises with limited sources of development funding, to ensure that this part of the business cycle in the process of developing sustainable economic development able to have adequate sources

of funding should be based on financial regulation and taxation as a means of control, to ensure the effectiveness of the tax treatment through price subsidies, financial discount, pre-tax loan loss allowance and a variety of ways.

Second, it should be combined with coal production and management enterprise actual situation, to be effective against the coal companies to improve and perfect the existing cost accounting system, by effectively increasing the environmental costs through cost-effective handling of the price mechanism, with coal enterprises environmental awareness effectively strengthened, to ensure sustainable development of coal enterprises with economic development and ecological environment.

Third, by the reasonable control of emissions from waste coal companies to ensure that the drainage plan and pollution indexes were able to get effective implementation to ensure that the cost of coal enterprises themselves sewage pollution has been effectively implemented.

Conclusion

As we all know, energy is the human society to stabilize the foundation of survival and development. Under the process of global economic integration and growing urbanization continues to expand the scale of the background action, communication and exchange of energy issues for many aspects of economic, political, military and cultural world between the various countries and regions attention is only to rise in. In the background of this development, the development of circular economy and promote the process of the national economic and social development can be said to be the key measures and strategy to achieve conservation of resources both in technical and economic basis of reasonable and feasible and the environment protection purposes, the key for the development of disposable resources such as coal energy is undoubtedly a class is crucial. In conclusion, the article for the sustainable development path issues related to the coal industry and made a brief analysis of the model and description, hoping to provide some help for future reference and to carry out related research and practice work.

Keywords: Aluminum potroom; Natural Ventilation; Workshop Structure; CFD

Abstract. This paper aims to eliminate the danger of high temperature in the aluminum potroom by natural ventilation. According to the history of aluminum potroom, two different workshop structures are proposed to improve the natural ventilation effect. The first structure is called the inner-partition potroom, which contains blind grilles located at certain distance from the two sides of electrolytic cell. The second structure, called the large-opening potroom, directly set up a large opening on the outer wall of aluminum potroom. Two structures are compared with the aid of CFD simulation, and the physical model is established based on the field measurement. The velocity and temperature fields are simulated under three different outdoor conditions. By the comparative analysis of temperatures on the electrolytic cell and operating area, this paper indicates the large-opening potroom has better performance on high temperature condition.

Introduction

The main equipments in the aluminum potroom includes the electrolytic cell and other auxiliary equipments, which equipments as heat source release constantly heat and pollutants into surroundings environment[1]. The superfluous heat and pollutants enter into working area will cause heat dissipation problem of electrolytic cell and severe working environment, which make a negative effect on product quality and work efficiency [2]. In China, the hot potroom usually uses natural ventilation to eliminate superfluous heat and pollutants and provide fresh air [3]. The workshop structure directly affects natural ventilation performance. The current structure that contains blind grilles located at certain distance from the two sides of electrolytic cell, shown in Figure 1, is called inner-partition potroom in this paper.

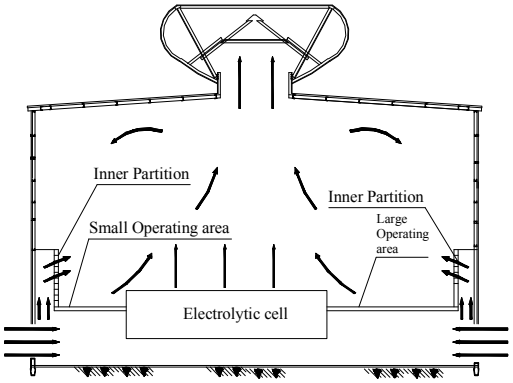

Fig.1. The inner-partition aluminum potroom

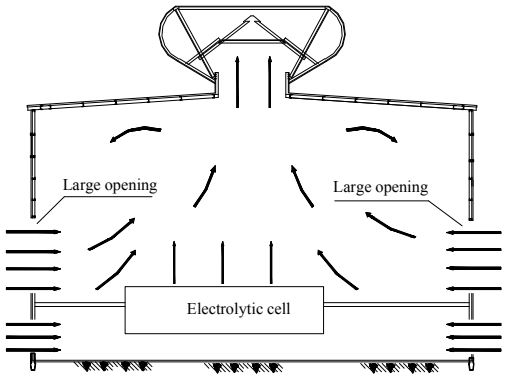

Fig.2. The large-opening aluminum potroom

When fresh air enter the potroom from the opening at the bottom of outdoor, most fresh air flows through the surfaces of electrolytic cell by the way of fixed grilles and take away superfluous heat and pollutants discharged by skylight. The rest fresh air enter workshop through the inner partition. This kind of structure can effectively reduce the surface temperature of cell and improve the product quality [4]. But, in some hot region, this structure may make high temperature operating area where workers must stay some time. So this paper proposes the large-opening potroom shown

in Figure 2, which leads more outdoor air into the operating area by enlarging the opening of second floor. In the paper, CFD method is used to analyze ventilation effects in two kinds of workshop structures.

Simulation model

Since the aluminum potroom has complicate structure and many kinds of equipment, it is necessary to simplify the physical model properly [5]. This paper constructs the physical model about 300KA electrolytic cell based on the field measurement in the aluminum factory of shanxi qingjian. The details of objects in the model are shown in Table 1, which displays all the sizes and parameters. For the large-opening potroom, the opening on outer wall is from the ground of first floor to the elevation 8 meters, which will not affect the normal operation of crane. In a practical application, the large opening on the second floor can be considered installing the electric blind or shutter on it to keep the workshop from rainwater.

Table 1. The sizes and parameters for all the objects

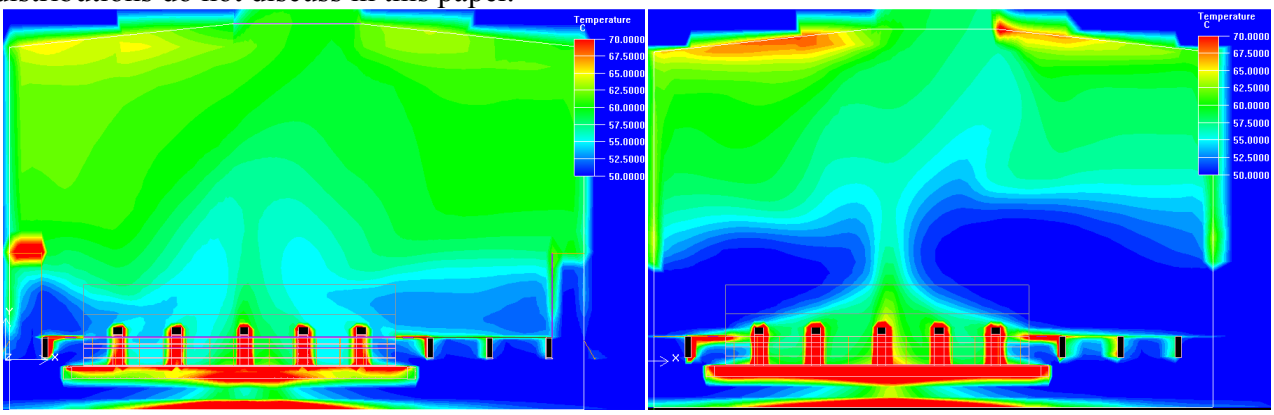
Object	Name	x (m)	y (m)	z (m)	Parameter
Wall	Workshop	27	18.21	6.2	
Blocks	Beam	0.25	0.6	6.2	
	Oblique bus	0.46	1.6	1.6	
	Upright bus	0.46	1.5	0.38	
	Level bus	15.78	0.534	0.38	
	Feed box	13.28	1.4	0.45	
	Tip	0	1.334	2.015	Heat:4570.14W
	Electrolyte layer	14.65	0.3	2.015	Heat:29611.46W
	Aluminum layer	14.65	0.2	2.015	Heat:15410.05W
	Carbon layer	14.65	0.45	2.015	Heat:40791.30W
	Insulating layer	14.65	0.384	2.015	Heat:2417.26W
Opening	Air inlet	4.8	0	6.2	
Partitions	shield plate	14.65	1.1	1.1	
	Small operating area	3.48	0	6.2	
	Large operating area	8.87	0	6.2	
	Rib plate	0	1.334	0.38	
Resistances	Grille of cells	14.65	0	1.41	ξ=0.5
	Inlet window	0	2.4	6.2	ξ=2.37
	Outlet window	2.7	0	6.2	ξ=1.42

In simulation, standard k-ε turbulent model and discrete ordinate radiation model are chosen to predict the velocity and temperature fields in the workshop [6] [7]. To consider the potroom locates in hot region, the outdoor air temperature selects a extreme value 50℃ as the high temperature condition. The outdoor wind speed chooses 0, 2m/s and 4m/s representing real outdoor conditions named Condition Ⅰ, Condition Ⅱ, and Condition Ⅲ, and the wind direction always keeps perpendicular with the large operating area side of potroom.

Simulation results and analysis

According to the above simulation model, the velocity and temperature fields in two workshop structures are obtained. The temperature distributions under Condition Ⅰ are shown in Figure 2. The results display the thermals appear in two structures, which cause the obvious temperature gradient in the whole workshop. By comparison, the temperatures in small and large operating area

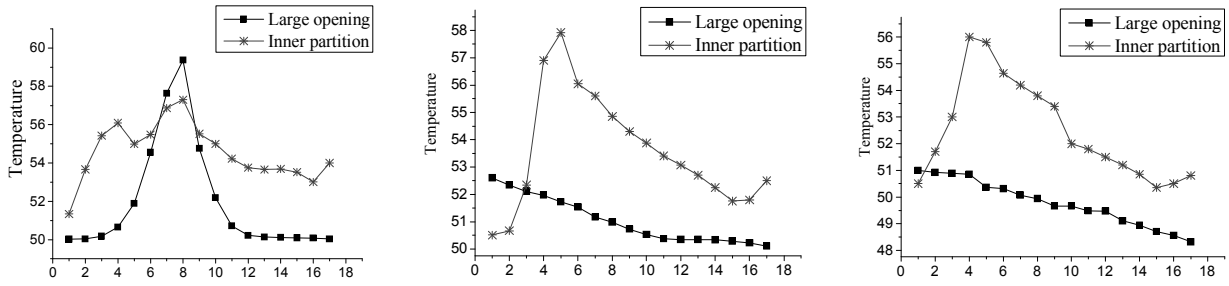
in the large-opening potroom are lower than in the inner-partition potroom, because more fresh air flows into the workshop without the resistance of inner partition. But because of the resistance of inner partition, more fresh air enter in the first floor of inner-partition potroom and then flow through the surfaces of electrolytic cell to take more heat away by thermal. So the temperatures on the cell surfaces in the inner-partition potroom are lower than in the large-opening potroom. Meanwhile, the temperature distribution in the inner-partition potroom is more uniform in that the interference from fresh air is less. Owing to space constraints, the other temperature and velocity distributions do not discuss in this paper.



(a) The inner-partition potroom (b) The large-opening potroon

Fig.2. Temperature distribution in the potroom

The operating area worker must stay some time, includes small operating area, large operating area and the operating area between electrolytic cells. To fully describe the temperatures of operating area, the paper gives the air temperatures on the middle section between cells by selecting 17 data points about 0.5m apart from 1.8 meters above the operating area, which are shown in Figure 3. Figure 3(a) indicates that the temperatures in small and large operating area with large opening are lower than with inner partition because of more fresh air, but the temperatures in the middle part are higher since hot airflow intensely passes the middle region into the upper workshop. Figure 3(b) shows that the temperatures in the large-opening potroom are mainly lower than in the inner-partition potroom because outdoor fresh air through the passage between cells takes more heat away. At the same time, the highest temperature in the inner-partition potroom appears the region deviating leeward side due to the outdoor wind interference. Figure 3(c) has the same tendency with Figure 3(b), but only the highest-temperature region in the inner-partition potroom is closer to leeward side and the temperature decline in the large-opening potroom is greater on account of more wind speed. Comprehensively, all the air temperatures of operating area in two kinds of structures decrease with the increasing of outdoor wind speed.



(a) Condition Ⅰ (b) Condition Ⅱ (c) Condition Ⅲ

Fig.3. Comparison of air temperatures of operating area

Table 2 displays the temperatures on the surfaces of electrolytic cell. According to the results for Condition Ⅰ, the temperatures on cell surfaces in the large-opening potroom is slightly below them in the inner-partition potroom, and the reason is that fresh air cooling the cell enter the first floor less without the resistance of inner partition. For Condition Ⅱ, the temperatures on the Aluminum, Electrolyte and Carbon layers with the large opening is higher than with the inner partition, but

those on the other objects is lower. The cause for this is that the Aluminum, Electrolyte and Carbon layers are mainly cooled by thermal from the first floor which is destroyed by outdoor wind, and the other objects can be directly cooled by the transverse airflow from the second floor wind. As outdoor wind speed increases, which results in strong transverse airflow in all floors, only the Aluminum layer has higher temperature in the large-opening potroom according to Condition Ⅲ. On the whole, the temperatures on the cell surfaces in large-opening potroom is higher when outdoor wind has small speed, but the highest temperature is also below 400℃ the limit on the electrolytic cell.

Table 2. Temperatures on the electrolytic cell surfaces Unit: ℃

Condition	Structure	Position	Layer				Equipment	
		Object	Aluminum	Electrolyte	Carbon	Insulating	Shield plate	Feed box
Ⅱ	Inner partition	Highest	344.214	317.926	366.953	286.754	366.953	125.939
		Average	292.543	247.562	238.641	118.591	142.714	85.4628
	Large opening	Highest	337.058	380.873	321.183	292.089	380.873	124.288
		Average	299.740	269.085	259.298	127.914	149.122	85.4708
	Inner partition	Highest	343.621	352.791	319.484	301.878	352.791	142.934
		Average	285.860	224.197	241.435	115.944	132.707	84.9818
	Large opening	Highest	396.040	390.791	340.279	230.027	230.027	138.738
		Average	299.278	255.460	249.800	112.653	127.658	82.5246
	Inner partition	Highest	393.784	389.588	317.237	264.464	389.588	149.180
		Average	283.486	227.943	235.811	105.784	137.925	84.6380
	Large opening	Highest	362.910	373.015	316.891	207.590	373.015	128.736
		Average	274.633	236.553	224.416	97.2570	110.531	81.3031

Conclusion

Based on the analysis of the simulation results under three conditions, the potroom with large opening on the outer wall generally has lower temperature in the operating area. Although the temperatures on the electrolytic cell surfaces are higher than them in the inner-partition potroom, the highest temperature is also below the limit 400℃. At the same time, the cooling effect for electrolytic cell will better in the large-opening potroom with the increasing of outdoor wind speed. In conclusion, the workshop structure of aluminum potroom on high temperature condition should be designed as the larger opening on the outer wall to improve natural ventilation.

Keywords: Transmission tower icing; The dynamic Characteristic: seismic performance

Abstract. Southwest area of china is the zone of the transmission lines which often happens icing disaster. It is also an earthquake-prone area, also influenced by the interaction between ice and earthquake. This article uses the finite element method (fem), establishing three-dimensional model for steel towers in southwest china, to analyze the dynamic performance of the ice condition and the analysis of seismic action. The aim is to get internal forces for steel towers under the action of earthquake and deformation law along with the change of ice thickness.

Introduction

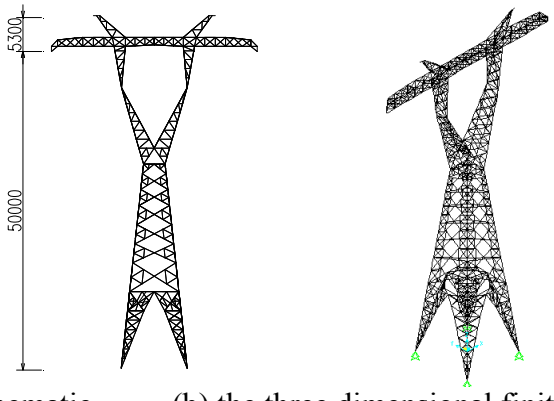
High voltage grade of transmission lines is the lifeline engineering of the national project. China is an earthquake-prone country. The southwest of china, which located on the earthquake fault zone, its power transmission facilities should be considered more on its safe operation. Only in Yunnan province from 1993 to 2003, the losses of electric power facilities in all previous earthquakes are more than 218 million [3]. The earthquake in Wenchuan brings 185lines to rest [4].With the power grid construction is going to have large capacity, high pressure, the tower of the seismic performance should take enough attention to research and design.

In addition, the congelation or frequent climate region in southwest China easily makes the tower and conductor frozen in winter. Only in Guizhou province in 2008, 184875 towers collapsed [5].Tower, under the condition of icing, its dynamic characteristics of the great changes have been taken place [1].

This paper takes a type glass tower in southwest China as an example, with the help of finite element method, established a three-dimensional finite element analysis model for iron tower, using the equivalent density method considering ice tower, seismic response analysis of structure, discussed the influence of ice thickness on the structural seismic performance.

Engineering background

In this paper, we choose a 500kV transmission line tower which has been built in the west high altitude localities as an example to analyze. The height of the tower is 55.3 m, and the practical height is 50m. the schematic is shown in figure 1(a).



(a) Plane schematic (b) the three dimensional finite element model

Fig.1 The diagram of the transmission tower

The tower, assembled by Q235 angle steel could be separated to three parts: the first tower, the tower and the tower legs. There are three main types of materials which can constitute a tower bar: advocate material, oblique materials and auxiliary materials, respectively, the Angle steel models could be adopt by ∟160 x 12, ∟80 x 6 and ∟45 x 4. There is a bolt between rods and bars; the finite element model is shown in figure 1(b).

Calculation model

Establish the three-dimensional finite element analysis model of the tower by using SAP2000 as finite element analysis tool to. According to the connection characteristics of tower structure, advocate material, oblique materials and auxiliary materials used space beam element. The auxiliary material bar bending moment has been put in the end. In addition to both computational efficiency and computational accuracy requirements, we should divide the stab about 1 m into the unit. Steel [6], [7] ice calculation parameters are shown in table 1:

Table 1 The physical properties of the material indicators

material	E (N/m2)	υ	α(cent degree)	ρ(kg/m3)
steel	2.06×10^{11}	0.3	1.2×10^{-5}	7850
Yu Song ice	5.2×109	0.3	—	900

We do not consider the tower icing contribution to the structural stiffness [1] in the analysis .The ice is calculated by using the equivalent density method for structural dynamic characteristics. The influence of equivalent density could be calculated according to the equation(1).

$$\rho_o = \frac{A_i\rho_i + A_s\rho_s}{A_s + A_i} \tag{1}$$

ρ_o is the equivalent density，kg/m^3 ；

A_s , A_i is the area of the steel bar and ice, m^2；

ρ_s , ρ_i is the density of the steel bar and ice, kg/m^3 .

Adopting finite element analysis software SAP2000, establishing the three-dimensional truss model, using the subspace iteration method, the dynamic characteristics analysis and using the mode superposition to response spectrum method, seismic response analysis of structure.

Dynamic characteristic analysis

Dynamic characteristic analysis is the basement of the dynamic analysis. Before the seismic performance, power transmission tower's dynamic characteristic analysis should be first. Particularly, to calculate tower's dynamic characteristic, we could ignore the weight of ground wire. Its weight could be put into the load only.

Table 2 The top 3 order natural frequency of vibration Hz

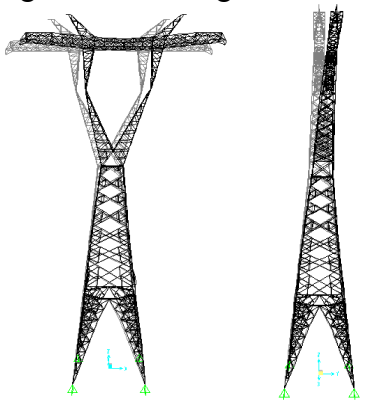
frequent	ice free	5mm	10mm	15mm	20mm	25mm	30mm
X	1.2329	1.1218	1.0313	0.9559	0.8919	0.8367	0.7886
Y	1.2937	1.1776	1.0829	1.0041	0.9370	0.8792	0.8287
Torsion	1.6100	1.4591	1.3373	1.2365	1.1513	1.0782	1.0146

It can be seen from figure 2，, the structure of the first three order vibration frequency of the vibration mode include X to translation, Y to translation and torsional as a whole. With the increase of ice thickness structure, the corresponding frequencies decrease.

Spectrum analysis

Mode-superposition response spectrum method is used for tower analysis under the action of the more severe earthquake internal force and deformation. Assuming that the region seismic fortification intensity of 7 degrees, design earthquake acceleration of 0.1 g. A maximum horizontal earthquake influence coefficient is 0.08.The second field, earthquake are grouped into the second group, site characteristic period of 0.4 s. Analyze the tower structure to seismic action in X and Y to

the earthquake under the action of displacement value and the counteracting force. X to the earthquake under the action of overall structure deformation as shown in figure 2 (a), Y to the deformation of the structure under seismic loading are shown in figure 2 (b) .Displacement value trends along with the change of ice thickness as shown in figure 3.



(a) (b)

Fig.2 Seismic deformation

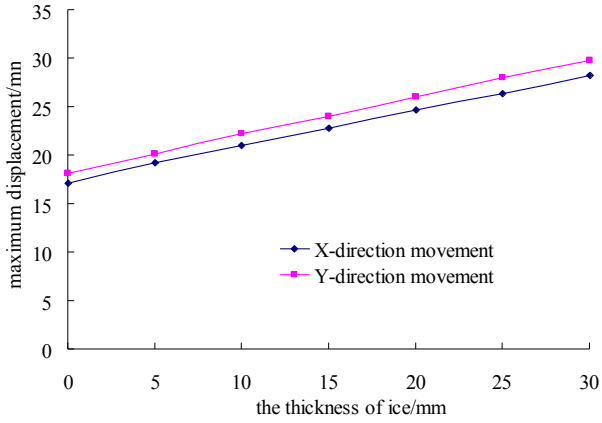


Fig.3 The value of seismic deformation

It can be seen from the figure 2, under the action of earthquake, the structure of each position displacement size associated with the height from the ground. The greater the height from the ground, the greater the displacement value is. It can be seen from the figure 3, Y to the displacement value is slightly greater than X to the displacement, Y to the stiffness is larger than X to the stiffness. With the increase of ice thickness, the maximum of tower displacement increases, and it approximately equals to linear relationship.

For tower, marked four bearing Numbers for A, B, C, D, as shown in figure 4.And statistics when ice thickness is not at the same time, each bearing in X and Y to the earthquake in all directions under the action of reactions, as shown in table 3.

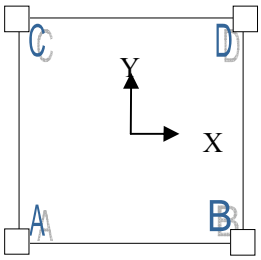

Fig.4 The support of tower

Table 3 Force of support

Bearing Serial number	The earthquake direction	direction	The thickness of the ice/mm						
			0	5	10	15	20	25	30
A	seismic action(X)	X	4.747	5.685	6.659	7.714	8.850	10.104	11.477
		Y	3.620	4.207	4.786	5.404	6.055	6.716	7.435
		Z	26.640	30.616	34.456	38.561	42.879	47.167	51.096
	seismic action(Y)	X	4.127	4.714	5.336	5.971	6.681	7.407	8.159
		Y	4.765	5.554	6.436	7.343	8.374	9.659	10.962
		Z	28.956	32.678	36.618	40.446	44.841	49.315	53.776
B	seismic action(X)	X	3.890	4.576	5.269	5.985	6.763	7.559	8.429
		Y	3.311	3.794	4.247	4.719	5.204	5.697	6.258
		Z	24.830	28.187	31.272	34.481	37.821	41.064	44.687
	seismic action(Y)	X	3.481	3.998	4.536	5.078	5.658	6.229	6.817
		Y	4.575	5.381	6.239	7.129	8.104	9.325	10.566
		Z	27.240	30.834	34.558	38.024	41.990	46.041	49.993

C	seismic action(X)	X	4.949	5.938	6.957	8.035	9.203	10.471	11.863
		Y	3.815	4.449	5.079	5.739	6.433	7.138	7.893
		Z	27.399	31.588	35.622	39.881	44.359	48.853	53.785
	seismic action(Y)	X	3.457	3.935	3.708	4.884	5.382	5.896	6.431
		Y	3.586	4.167	4.568	5.351	6.022	6.698	7.422
		Z	25.616	28.742	31.663	34.735	38.007	41.181	44.222
D	seismic action(X)	X	3.461	4.071	4.686	5.336	6.021	6.724	7.479
		Y	2.788	3.154	3.489	3.842	4.209	4.561	4.956
		Z	2.351	26.589	29.386	32.321	35.356	38.206	41.413
	seismic action(Y)	X	2.982	3.343	3.709	4.044	4.431	4.807	5.173
		Y	3.452	3.987	4.568	5.157	5.810	6.478	7.166
		Z	25.544	28.558	31.663	34.475	37.757	40.910	43.922

It can be seen from table 3, X to the earthquake, the support to the reaction force is less than X to Y reaction, as the change of ice thickness, the ratio showed a trend of expansion. X under the action of earthquake, bearing A and C that X to the reaction force is greater than B C support that X to the reaction; Y to the earthquake, the A and B bearing Y to the bearing reaction force is larger than C D that Y to reaction. The reasons for this phenomenon are limited by the response spectrum method. Overall, with the increase of ice thickness, the bearing under the action of earthquake reaction are also increasing.

Conclusion

Through the analysis, we can get the following conclusion:

1, the tower in the first three order vibration mode respectively characterized by X to translation, Y to translational and torsional. With the increase of thickness of ice, each order frequency is on the decline.

2, under the effect of more severe earthquake, the displacement in the Y to the displacement value is slightly greater than X value that is slightly greater than X Y to the stiffness of the stiffness.

3, with the increase of ice thickness, tower under seismic action of reactions are also increasing.

Research on the dynamic characteristics of strain tower in heavy icing area based on SAP2000

Shilong WANG[1],Qixiang LIN[2],Ying Qian[3]

[1,2]College of Electrical Engineering & New Energy of China Three Gorges University

[3]State Grid of Hubei Xianning Power Supply Company,Xianning,437000,China

email: ctgulin@sina.com

Keywords: heavy icing area; strain tower; SAP2000; Dynamic analysis;

Abstract. This paper is a further analysis of the strain tower on 1YD - JC4.After making a static analysis of 1YD - JC4 strain tower,we select the best offset point and make a dynamic analysis of it.Based on the finite element analysis software SAP2000, we set up a three-dimensional model of 1YD - JC4 strain tower of 110kv about heavy icing area,and then obtain the first six modal frequencies after making a dynamic analysis . We then draw the response spectrum curve.in the end, we select the safe and economic value of damping according to the curve.

Introduction

The ice disaster damage to the line is mainly to damage the tower , such as tower collapsing, deformation, insulator off. The ice disaster has caused enormous loss to the power grid in the year of 2008. After that,State Grid Corporation of China has promulgated new codes and specifications in which we improve the safety level of the important lines,strengthen the vertical strength of lines from external load and internal force calculation conditions , and improve safety coefficient of the tower,[1].Because of this,Yichang Electric Power Survey and Design Institute of Electric Power Co., Ltd has specially designed tower-1YD series which are used in heavy icing area.For the high-rise structures under the control of deformation.We should adapt the appropriate vibration control technology to reduce the deformation and acceleration of the structure[2]. The real tower test is usually needed to do to ensure the safety and accuracy though the really tower test is expensive.So this paper simulate and analyze 110kv 1YD - JC4 strain tower based on the finite element analysis software SAP2000,which has proved reference for the Subsequent transmission tower test simulation, tower optimization and the simulation of disaster prevention.

calculation model and analysis methods

1.1 calculation model

The 1YD series tower is specially designed by Yichang Electric Power Survey and Design Institute Co.,Ltd. according to the actual conditions of Shennongjia heavy icing area. The practical height is 30.0 m,the total height is 37.5m,the weight of the tower is 20.4 t,the horizontal span is 400m and the vertical span is 900m.We take Q345 steel for the main member of tower body and we take Q235 steel for the auxiliary member .the icing thickness is set as 30mm.We set up A three-dimensional model of the 1YD-JC4 tower in the finite element analysis software SAP2000 and all the rods piece use the space bar element. See chart 1.

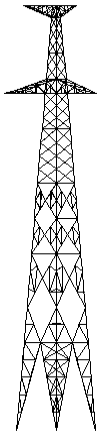

Fig.1 Dimensional model of the 1YD tower

1.2 The load on the tower

The loads of pole tower are generally divided into the vertical loads(The direction perpendiculars to the ground), the transverse horizontal loads(parallel plane along the horizontal direction)and the longitudinal horizontal loads(The vertical plane which is vertical horizontal direction).The vertical loads include the gravity loads of wire, ground wire,insulator strings and fittings,tower self weight loads and the vertical loads in installation and maintenance of which include the gravity loads of workers, tools and accessories and so on.The transverse horizontal loads include the wind pressure of wire ,ground wire ,insulator strings and fittings,the wind loads of tower and tower body and the angel force of the wire and the ground wire on the angle tower . The longitudinal horizontal loads include the unbalanced tension of wire and ground wire(the direction of unbalanced tension of no corner tower is along the line, and the unbalanced tension of corner tower perpendicular the cross arm of the tower),the tension of broken wire and broken ground wire ,the support of the normal force from the ground wire to the tower when the wire breaks and the tight line tension when installing wire[3].

The Circuit parameters :①The wire model is LGJ-240/55,and the ground wire model is JLBIA-120.②The weight of the insulator tension string of wire and ground wire are 500N, 100 N.③The spacer weights 30 N.

(1)Condition 1—The stiuation of the operation situation.The strain tower load combination consists of the minimum temperature, no wind, ice free,and not breaking load （$v=0, T=-20^0C, b=0$）. Ground gravity GB=7246 N ,wire gravity GD=10 310 N, wire pressure PD=3 140 N.

(2)Condition 2—The stiuation of the broken wire situation.Load combination for ice free, calm, off any two phases.Random phase wires broken will produce two kinds of deformation because there are upper, middle and lower three-phase conducting wires.The breakage of random phase wires,upper wire and a lower or two lower wires.The gravity of ground wire GB=7246 N ,not broken wire gravity GD=10313 N.The broken phase wire gravity GD=5422 N,and the wire gravity TD=14294 N.

(3)Condition 3—The stiuation of the broken ground wire situation.Load combination consists of ice free, calm, not broken wires , broken in any one ground wire.wire gravity GD=10310N,Ground wire gravity GB=3723 N,Ground wire tension TD=10593N.

(4)Condition 4— The stiuation of the installation I situation.Lifting the upper wire.And the load combination for a corresponding wind, ice free.（V=15 m/s, T=-10℃，b=0）.Ground wire gravity GB=7 248 N,ground wire pressure PB=900 N,Wire gravity GD=10 310 N,wire pressure PD=1 413 N.When hanging the wire,wire gravity GD=27 955 N,wire pressure PD=6 284 N.

(5)Condition 5—The stiuation of the installation II situation.Lifting the lower wire.The load combination is the same to the condition 4.Ground wire gravity GB=7 248N,ground wire pressure PB=900N,wire gravity GD=10310N,wire pressure PD=1 413N.When lifting the lower wire,the lower crossarm total gravity GD=14841 N,wire pressure PD=1413N.

We apply the calculated tower load to the 3D model operation to analysis.

1.3 analysis methods

The structural vibration instability of tower under dynamic loading is an important factor of causing tower collapse accident.Therefore, in order to avoid huge economic loss brought by tower collapse accident,it is necessary to grasp the dynamic response of tower unde the effect of the wind loads and the impact loads caused by the earthquake or other reasons and the influence of those dynamic on tower strength based on taking tower strength into consideration in the process of the design[4].

Time-history analysis is a dynamic analysis hose structure is more realistic.Linear time-history analysis is essentially based on the basic to solute dynamic differential equations (1) ,and then obtain the basic size of structural response under the action of dynamic load[5].

$$M\ddot{u}_a(t)+C\dot{u}_a(t)+Ku_a(t)=F(t) \tag{1}$$

In the formula: M—The mass matrix

C—A viscous damping matrix

K—Static structural element system stiffness matrix

$\ddot{u}_a(\mathrm{t})$, $\dot{u}_a(\mathrm{t})$, $u_a(\mathrm{t})$ are the absolute displacement, velocity and acceleration of the nodes, and they are all vector related to time.

A typical modality equation is :

$$\ddot{y}(t)_n+2\xi_n\omega_n\dot{y}(t)_n=\overline{f}(t)_n \tag{2}$$

$\overline{f}(\mathrm{t})_n$ is the modality load

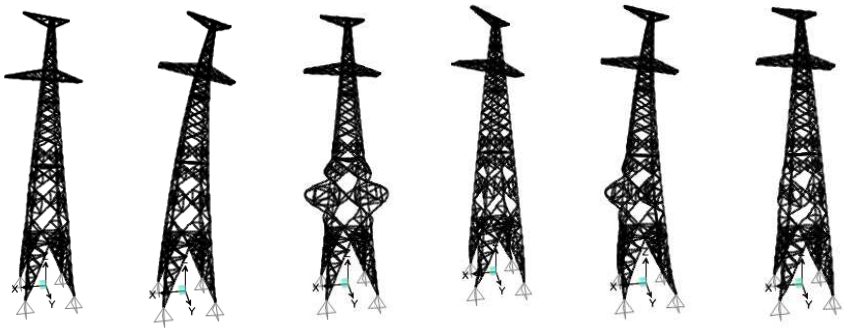
According to the method of solving the differential equation of arbitrary loading solution, we can obtain the approximate solution of load in smaller time increments using the polynomial.

$$\ddot{y}(t)_n+2\xi_n\omega_n\dot{y}(t)_n+\omega_n^2y(t)=R_{i-1}+t\dot{R}_{i-1}+t^2\ddot{R}_{i-1}+\frac{t^3}{6}\dddot{R}_{i-1} \tag{3}$$

Dynamics analysis

When the structure suffers earthquake action,even if the main structural component structure remains elastic deformation,the permanent deformation of secondary structure will dissipate some energy.However ,this part of the energy is difficult to estimate in theory.In the dynamic analysis of structures, the energy dissipation is defined and implemented by damping[5].

The structural damping should be taken into consideration when doing the structure Time-history analysis. In general,Structural damping is defined by the modality damping ratio,and it is the ratio of the modality damping and critical damping.



Modality1 Modality 2 Modality 3 Modality 4 Modality 5 Modality 6

Fig 2.1～6 Modality figures

Since we have done the static analysis to the model, we find that the point of 250 is the largest offset.Consequently,we choose the point 250 to do linear dynamic analysis.After running the software,The first six modality graphs(Fig 2) and frequencies can be calculated and they are shown in the following table.

Table 1 The first six frequencies of strain tower

	Modality 1	Modality 2	Modality 3	Modality 4	Modality 5	Modality 6
Frequency(f)	4.11	4.11	7.39	7.72	8.23	8.39

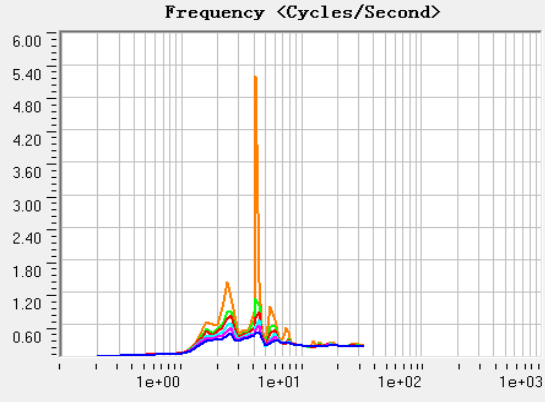


Fig 3.The response spectrum curve

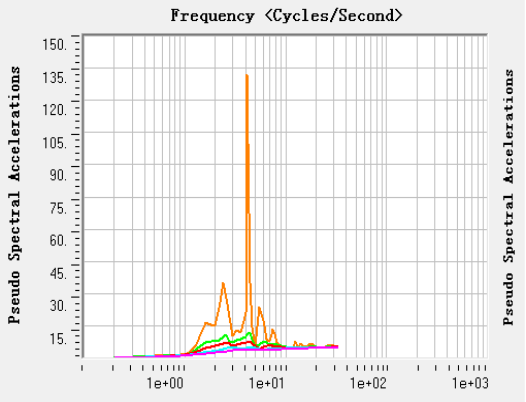

Fig 4. The response spectrum curve

In Fig. 3, the abscissa represents the frequency,and the ordinate shows pseudo acceleration.The software can generate a corresponding response spectrum curve for each value of damping. From the figure,We can see that when the damping value is assigned as 0,the acceleration is the maximum and the curve volatility is very extreme.While the damping values are 0.02, 0.03, 0.05, 0.07, 0.10,the acceleration decreased gradually, and the curve is more gentle.If the damping value is 0.2, 0.4, 0.6,The curves gradually tend to be straightas shown in Fig 4.However,at this time, the anti elastic ability of the structure is very high, and the economic investment is very large.Therefor, the most economical way is that the structure vibration in safe condition.In conclusion,taking economic and security into consideration,the modality damping ratio of steel structure is generally selected as 0.02.And the attenuation ratio which shows vibration between two adjacent maximum is 0.88[5].

Conclusion

On the basis of the static analysis,We do a further analysis of the strain tower in heavy icing area based on SAP2000 .We can obtain the response spectrum curves of damping value of 0, 0.02, 0.03, 0.05, 0.07, 0.10, 0.2, 0.4 and 0.6.In the end,we select the damping ratio of tension tower as 0.02 considering the two factors of economic and security .

Keywords: wind field; wind energy; building roofs; wind turbine installation; built environment;

Abstract: Wind energy utilization in the building environment has the advantage that it can avoid transporting effectively, especially it has important significance for residents without electricity. This paper mainly analyzed the basic situation of three-dimensional wind field around the buildings with the theoretical analysis and CFD numerical simulation method. By simulating the wind with different directions and different speeds, the characteristics of the wind field around single flat and pitched roof building are analyzed.

Introduction

With the large number of fossil energy used, the shortages of energy have become increasingly prominent; meanwhile, using fossil fuels can also cause many negative effects to the natural environment[1]. Wind energy development is one important way to solve the energy shortage and environmental pollution. But the wind field around the building is relatively complex, and because of the buildings' block, the wind velocities in different areas around the building vary greatly[2]. This paper presented the wind flow condition around the flat roof building and pitched roof building by Computational Fluid Dynamic (CFD) technique, including the wind energy on building roof. And then this paper discussed the suitable installation site of wind turbines on the building roof from the analysis results of wind velocity and turbulence intensity.

1 wind field analysis around single flat roof building

The building model is designed two-story high, which is 10m length, 8m wide and 8m height. It is used Gambit to generate meshes and simulated by Fluent. The inlet velocity was specified by constant wind velocity because the building is low. Turbulence condition is set by turbulence intensity I and hydraulic diameter L. equations are as following[3]:

$$I=0.16Re\text{^}(-1/8) \quad (1)$$

$$Re=vd\rho/\eta \quad (2)$$

$$L=4A/P \quad (3)$$

Where: Re- Reynolds number; v-average velocity; d-flow diameter; ρ-medium density; η-medium power coefficient of viscosity; A-Inflow surface area; P- Inflow surface perimeter.

In this simulation turbulent flow equation adopted *standard k-e* model. Second order wind schemes should be used for solving the algebraic equations in convective term. The fluid adopted Newtonian fluid and steady flow. Medium is air which is low-speed and incompressible. The scaled residuals should be in the range of 10^{-3} which mean the calculation reach steady state[4,5].

For the building, 9 points at the front, middle and back of the building top are selected as the reference site for installing a turbine to analyze wind energy aggregation. Meanwhile, in order to study the effect of wind speed and direction to buildings, wind velocity is designed 5m/s, and wind direction(α) is 0°and 45°as shown in Fig. 1. The computed normalized, U/Ue, measure the wind energy effect of building roof.

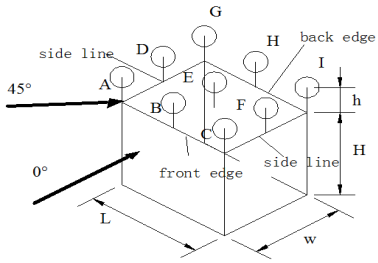

Fig.1 Flat roof building model

1.1 wind flow around flat roof building under wind direction α=0°

Fig.2 show the wind speed contour and turbulence intensity contour of building middle vertical section(x=0). From Fig.2 (a), wind velocities is generally improved on the top of the roof when wind flow through the building. But turbulence intensity is also improved around building shown in Fig.2 (b).

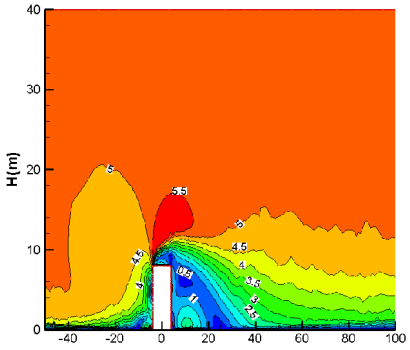

Fig.2 (a) Velocity contours at x=0

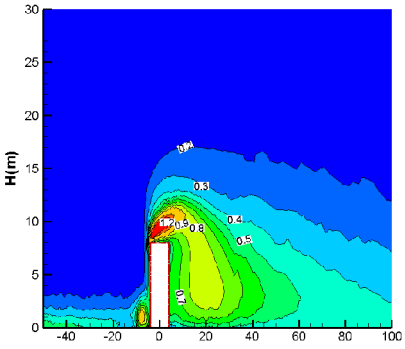

Fig.2 (b) Turbulence intensity contours at x=0

In order to make full use of space to install wind turbines, this section focused on analysis the changes of wind speed and turbulence intensity in the roof top. Fig. 3 shows the changes of wind velocity ratio and turbulence intensity at each reference point as the change of the height (h) above roof. From fig. 3(a), the wind velocity ratio of point B achieved highest when h=0.5m, and gradually stabilized at 1.18 with *h* increasing, that wind speed of 5.59m/s. Wind velocity ratio of point E reached maximum when h=3m, and stabilized at 1.2 with h increasing, that wind speed of 6m / s. And when h=4.5m, wind velocity ratio of point H achieved highest and gradually stabilized at 1.1 with *h* increasing.

Wind turbulence intensity of the wind turbine installation location is usually lower than 25%, and not more than 30%[4]. The changes of turbulence intensity can be found in Fig.3(b). Turbulence intensity of point A, point B and point C is lower than 30% when h=3m; when h=3m, turbulence intensity of point D, point E and point F is lower than 30%; and turbulence intensity of point G, point H and point I is lower than 30% as h=6m.

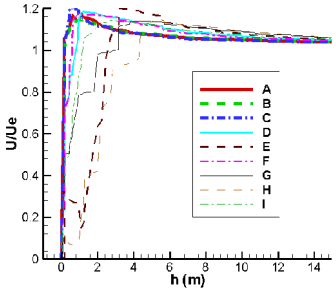

Fig.3(a) Wind velocity ratio for *α=0°*

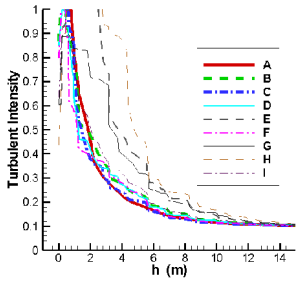

Fig.3(b) Turbulence intensity for *α=0°*

1.2 wind flow around flat roof building under wind direction α=45°

Fig.4 shows the changes of and turbulence intensity at each reference point as the change of the height (h) above roof. From Fig. 4(a), wind velocity ratio of each point is more than 1, which means that wind velocities of roof points are improved. Fig.4(b) shows the changes of turbulence

intensity with h changing. Turbulence intensity of point A and point D is lower than 20% when h=2m, other points are becoming stationary when h=4m.

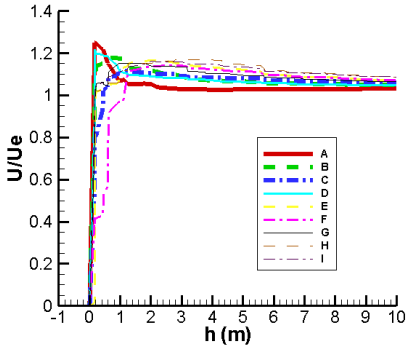

Fig. 4(a) Wind velocity ratio for α=45°

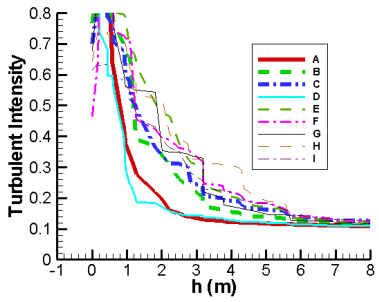

Fig. 4(b) Turbulence intensity for α=45°

It can be seen from the changes of wind velocity ratio and turbulence intensity under wind direction α=0° and α=45°: there are no obvious changes about the heights above the roof reference points, this shows that different wind directions have little influences to the heights above roof which are suitable to install wind turbines. Therefore the heights of each reference point suitable for installation of wind turbines on the rooftop not only reducing wind turbine installation height appropriately, but also satisfying the installation requirements of wind turbine. Fig. 5 shows the uniform wind turbine installation heights under different wind direction for U=5m/s.

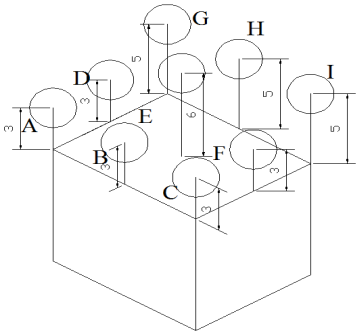

Fig. 5 Suitable installation height of each reference point

2 wind field analysis around pitched roof building

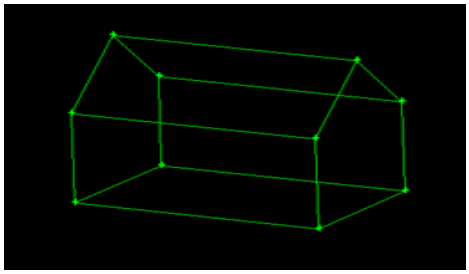

Fig. 6(a) patched roof building model

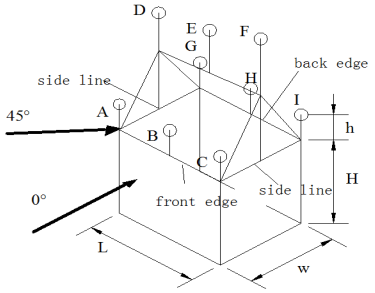

Fig.6 (b) Reference points of patched roof

Relative to the roof, pitched roof is also a very common typical roof. The sizes of pitched roof building are: L=10m, W=10m and H=12m which contain pitched height is 4m, the reference points are shown by Fig.6.

Fig.7 shows the changes of velocity and turbulence intensity at each reference point as the change of the height (H) above ground under wind direction α=0°. From Fig.7(a), the velocity of each point is over 5m/s and the highest wind velocity reached 6.5m/s because of the building. But points G,H,I of back edge appear low velocity areas because the pitched roof resisted, and then the velocity sharp increase. Fig.7(b) presents that when the wind is just connected the building, the turbulent intensity is low, which shows the turbulent intensity of points A ,B ,C can low than 20% as H=14m. But turbulent intensity become higher because the building obstructs, and the turbulent intensity of back edge can reach 20% as H =17m.

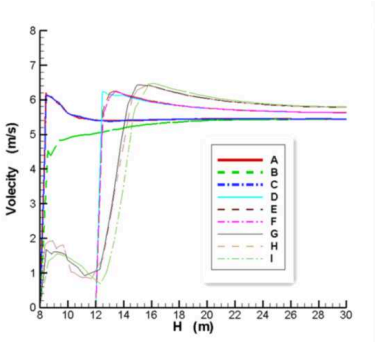

Fig.7(a) Wind velocity ratio for $\alpha=0°$

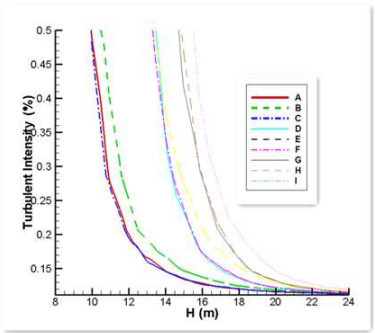

Fig.7(b) Turbulence intensity for $\alpha=0°$

3 Conclusions

CFD simulations for the cuboids buildings have been performed, and analyzed the wind energy of building rooftop at different roofs and different wind directions. Some conclusions are as follows:

1) The flat roofs of cuboids building have gather effects for wind energy, and the wind velocity above roof can increase more than 20%.

2) Under the same wind velocity, the wind turbine suitable installation heights at building front edge are lower than heights at building back edge, but the heights of building middle areas should be higher because the turbulence intensity is much large at the middle areas of building roof. Therefore, if the building is wide enough, wind turbines can be installed with height differences at the building roof, which can increase the installation quantities of wind turbine and then increase the total generating capacity.

Keywords: wind farm; medium-and-long term; wind speed distribution; parameter estimation

Abstract: The main objective of this paper is to review some models of medium-and-long-term wind speed distribution in wind farms, for example Gamma distribution, Log-normal distribution, Weibull distribution, Rayleigh distribution and Burr distribution. On the base of the Weibull distribution, some kinds of parameter estimation approaches are introduced. Meanwhile, the advantages and the disadvantages of various algorithms are analyzed and compared. The prospects of this research are put forward at the end of this paper.

I. Introduction

Recently, generation power technology of renewable energies has been paid more and more attention because most countries in the world have focused on environmental protection and sustainable development. Wind energy, as a non-polluted renewable energy, has been used to generate power aiming to improve energy structure and protect ecologic environment in many countries. However, wind power has random, undulated and intermittent property, which makes output wind power fluctuate larger. In addition, the safety of power network will be influenced seriously if penetration power reaches an extreme value [1-2]. Therefore, it is necessary to study distribution characteristic of wind speed for optimizing dispatching, reducing reserved capacity, enhancing penetration limit and satisfying business needs of power market.

The probability distribution of wind speed can describe statistics character of wind power. According to the difference of time scale, there are short-term, medium-term and long-term wind speed distributions. However, the majority of researches involve medium-and-long term wind speed distributions [3]. The aim of this paper is to sum up statistical characteristics of current wind speed distributions. As an example of Weibull model, some common methods of parameter estimation are intruduced. Finally, some suggestions are presented for wind power exploitation and utilizing in China.

II. Probability distribution models of wind speed

Nowadays, there are several probability density functions (pdf) and their cumulative distribution functions (cdf) that can be used to model wind speed, such as Gamma function, Log-normal function, Weibull function, Rayleigh function and Burr function, in which two-parameter Weibull function has been generalised. Then the pdf, cdf and their characteristics are introduced as follows.

A. Gamma distribution

In development and utilization of wind energy, the earliest model was Gamma distribution, which represented the sum of exponentially distributed random variables. Gamma distribution nearly can imitate all of circumstances in Europe continent [4]. Its pdf was given by [1]:

$$f(v)=\frac{v^{k-1}}{c^{k}\Gamma(k)}\exp\left(-\frac{v}{c}\right) \tag{1}$$

where v is wind speed. k is the dimensionless shape parameter and c is the scale parameter. Γ is the gamma function. The relationship between the mean or expected value μ, variance σ^2 and parameters of the Gamma distribution are respectively shown:

$$\mu=ck \quad \text{and} \quad \sigma^2=c^2k \tag{2}$$

Its cdf was defined in [4]

$$F(v)=\frac{\Gamma_{v/c}(k)}{\Gamma(k)} \tag{3}$$

where $\Gamma_{v/c}$ is an incompletable gamma function.

B. Log-normal distribution

Excepted for Gamma distribution, the log-normal distribution often was used to describe wind speed frequency distribution. The pdf of a log-normal distribution was [5]:

$$f(v)=\frac{1}{vk\sqrt{2\pi}}\exp\left[\frac{-(\ln v-c)^2}{2k^2}\right] \quad (4)$$

The mean μ and variance σ^2 of Log-normal distribution are found to be:

$$\mu=\exp\left(c+k^2/2\right) \quad \text{and} \quad \sigma^2=\exp\left(2c+k^2\right)\left[\exp\left(k^2\right)-1\right] \quad (5)$$

Its cdf was shown in [6]:

$$F(v)=\frac{1}{\sqrt{2\pi}k}\int_0^v\frac{1}{x}\exp[-\frac{(\ln x-c)^2}{2k^2}]\mathrm{d}x=\Phi\left(\frac{\ln v-c}{k}\right) \quad (6)$$

As the Log-normal distribution could't be used well to imitate the instances of low or high wind speed, it hasn't be advocated to apply now [7].

C. Weilbull distribution

In wind studies, the Weibull pdf has been widely adopted. The general form of the Weibull distribution, which has two parameters, was given by [6]:

$$f(v)=\frac{k}{c}\left(\frac{v}{c}\right)^{k-1}\exp\left[-\left(\frac{v}{c}\right)^k\right] \quad (7)$$

where $f(v)$ is the probability function of wind speed v, k is the dimensionless shape parameter and c is the scale parameter, which has a reference value in the units of wind speed.

The mean μ and variance σ^2 of the Weibull distribution can then be calculated from

$$\mu=c\Gamma(1+1/k) \quad \text{and} \quad \sigma^2=c^2\Gamma(1+2/k)-\mu^2 \quad (8)$$

The corresponding cdf of the Weibull distribution was [8]:

$$F(V)=P(v\le V)=1-\exp\left[-\left(\frac{V}{c}\right)^k\right] \quad (9)$$

where V is known usually.

In general, k ranges from 1.5 to 3 at most conditions. c shows the average speed of wind farm. When c is equal to 1, it is named by the standard Weibull distribution. Note that the Weibull function can't model some extreme wind speed distribution [9].

D. Rayleigh distribution

The Rayleigh distribution is a special case of the Weibull distribution in which the shape parameter is taken as 2.0, and it has only one parameter namely the average wind speed, that makes it simpler to use. When wind data in one year or several years were obtained at certain site, the Rayleigh distribution can depict accurately wind speed. But the result is relatively worse when the average wind speed is less than 4.5 m/s. when the average wind speed is less than 3.6 m/s, the Rayleigh distribution can't be completely suitable to use. The Rayleigh pdf was [6]:

$$f(v)=\frac{v}{c^2}\exp\left(-\frac{v^2}{2c^2}\right) \quad (10)$$

The mean μ and variance σ^2 of the Rayleigh distribution can then be obtained from

$$\mu=c\sqrt{\frac{\pi}{2}}\approx 1.253c \quad \text{and} \quad \sigma^2=c^2(2-\pi/2)\approx 0.429c^2 \quad (11)$$

its cdf was given by [10]:

$$F(v)=1-\exp\left(-\frac{v^2}{2c^2}\right) \quad (12)$$

Generally speaking, the results of Rayleigh distribution exist to 10% errors. When there isn't better wind data, we can use them to estimate wind speed, but this function can't be used to model wind speed at any sites.

E. Burr distribution

In recent years, Burr distribution has been gradually applied to simulate wind speed. It had better effect [11-12], but it has slowly calculated speed. The pdf of Burr distribution was [11]:

$$f(v)=\frac{\alpha k\left(\frac{v}{\beta}\right)^{\alpha-1}}{\beta\left[1+\left(\frac{v}{\beta}\right)^{\alpha}\right]^{k+1}} \tag{13}$$

where α is the scale parameter, β and k *are* the shape parameters. The mean μ and variance σ^2 of the Burr distribution can then be calculated from

$$\mu=\frac{\beta\Gamma\left(1+\frac{1}{\alpha}\right)\Gamma\left(k-\frac{1}{\alpha}\right)}{\Gamma(k)} \quad \text{and} \quad \sigma^2=\frac{\Gamma\left(1+\frac{1}{\alpha}\right)\Gamma\left(k-\frac{2}{\alpha}\right)}{\Gamma(k)}-\mu^2 \tag{14}$$

The corresponding cdf of the Burr distribution was:

$$F(v)=1-\left(1+\left(\frac{v}{\beta}\right)^{\alpha}\right)^{-k} \tag{15}$$

In a word, note that select the distribution model according to the real condition of wind resource at some area. If geography climates are different, the distributed rules of wind speeds are different.

III. Parameter estimation methods

In the above-mentioned distribution models, as long as the related parameters are gained, the form of distribution can be determined. At present, there are some parameter evaluated approaches, for instance graphic method, maximum likelihood method, and moment method. Then they will be introduced separately for example of Weibull distribution.

A. Graphic method

Graphic method is derived by using cdf. Take twice the logarithm of Eq. 9.

$$\ln[-\ln[1-F(V)]]=k\ln V-k\ln c \tag{16}$$

We obtain $y=ax+b$ form respect to ln[-ln[1-$F(V)$]] and ln$V$ and also k is the slope of the straight line. Using cdf, we evaluate (lnV_i,ln[-ln[1-$F(V_i)$]]) pairs and then we solve linear least squares problem to obtain coefficients of straight line *a, b*. Hence

$$k=a \tag{17}$$

$$c=\exp(-b/a) \tag{18}$$

Implementation of this method consists of three stages such that: (i) using wind speed data, calculate cumulative frequency distribution or first evaluate frequency distribution, which requires sorting wind speed data into bins, and then using frequency distribution, obtain cumulative frequency distribution, (ii) calculate (lnV_i,ln[-ln[1-$F(V_i)$]]) pairs and (iii) solve linear least squares problem and find scale and shape parameters using Eq. 17 and Eq. 18.

B. Maximum likelihood method

Maximum likelihood method is an approach suggested by Stevens and Smulders [13], details on the development of this method can be found in [14]. Maximum likelihood method requires extensive iterative calculations. Shape and scale parameters of Weibull distribution are estimated by these two equations

$$k=\left(\frac{\sum_{i=1}^{n}v_i^k\ln(v_i)}{\sum_{i=1}^{n}v_i^k}-\frac{\sum_{i=1}^{n}\ln(v_i)}{n}\right)^{-1} \tag{19}$$

$$c=\left(\frac{1}{n}\sum_{i=1}^{n}v_i^k\right)^{\frac{1}{k}} \tag{20}$$

where v_i is the wind speed and n is the number of nonzero wind speeds.

This method is implemented in two stages such that: (i) using wind speed data, calculate summations in Eq. 19 and Eq. 20 with taking care of zero wind speeds which make logarithm indefinite and then calculate shape parameter with Eq. 20 and (ii) find scale parameter using a numerical technique in order to find the root of Eq. 19 around $k = 2$.

C. Moment method

This method is suggested by Justus et al. [15]. When the mean wind speed $\overline{V}$ and standard deviation are available, shape and scale parameters can be estimated with this method using

$$k = \left(\frac{\sigma}{\overline{V}}\right)^{-1.086} \quad 1 \le k \le 10 \tag{21}$$

$$c = \frac{\overline{v}}{\Gamma(1+1/k))} \tag{22}$$

Also mean wind speed is calculated by

$$\overline{V} = \frac{1}{n}\sum_{i=1}^{n} v_i \tag{23}$$

and standard deviation is calculated by

$$\sigma = \left[\frac{1}{n-1}\sum_{i=1}^{n}(v_i - \overline{V})^2\right]^{0.5} \tag{24}$$

This method also requires two stages such that: (i) using wind speed data, calculate summations in Eq. 23 and Eq. 24, calculate mean wind speed $\overline{V}$ and standard deviation σ and (ii) find scale parameter k and shape parameter c using Eq. 21 and Eq. 22.

The advantages or disadvantages of parameter estimated methods aforementioned are shown in Table 1. The graphic method is the method of choice because it could be performed by hand with minimal computation. But the maximum likelihood method and the moment method are the more accuracy and more appropriate computer-based method.

Tab.1 Comparison of parameter estimated methods

method	character
Graphic method	It is simple and easy to realize, but it is less accurate and less robust.
Maximum likelihood method	It has high accuracy, but complex transcendental equations must be calculated and results are sensitive to initial values.
Moment method	It is simple and has higher precision, but it cannot use the whole sample information.

IV. Conclusions and prospects

Studies showed that the two-parameter Weilbull function can well imitate medium-and-long-term wind speed, but it cannot describe accurately the situation of two peaks or even three peaks existing in the short-term wind speed distribution when sudden climates change [12]. Therefore, the author suggests that the next emphasis in study will be the feature research of short-term wind speed. For example, we can make better by applying to some combined approaches, builting multiple parameter Weibull distribution, increasing calculated speed and accuracy of parameter estimation, simplifying complicated distributed models, and so on. In general, it is very important to accurately model wind speed for pre-judging the change trend of wind, enhancing accepted capacity, and promoting massive exploitation and utilizing of wind power.

Modeling and Uncertainty Estimation of Wind Power Curve Based on Recorded Field Data

Peng Lin[a], Shu-qiang Zhao[b]

State Key Laboratory of Alternate Electric Power System with Renewable Energy Sources, North China Electric Power University, Beijing, 102206, China

[a]jamiedsg@163.com, [b]shuqiang_zhao@163.com

Keywords: method of bins; measured wind power curve; uncertainty estimation; non-parametric interval estimation; confidence interval.

Abstract. Wind power curve of wind turbine has great importance in the prediction of wind power. The measured wind power curve is drawn by method of bins based on recorded field data; the uncertainty factors of the wind power curve is analyzed, and a non-parametric confidence interval estimation method is proposed based on analyzing the statistical characteristics of the data distribution. By means of the method, a probability density function model for wind power in each wind speed level is established, and the uncertainty estimation confidence interval of wind power curve is obtained on the basis of deterministic estimation. The example analysis proves the efficiency and feasibility of the method proposed in this paper.

Introduction

Wind power resources, widely distributed, is a kind of clean and cheap renewable green energy. Because the wind randomness and volatility has a negative effect on the economic operation, security and stability of power grids, the research on wind power prediction is deepening fast. Wind power curve is the key to wind power prediction. Wind power curve is influenced by many factors, and the wind power is not only related to wind speed, but also other factors such as air density , the swept area and fan mechanical conditions, so wind power curve itself exists great uncertainty. Wind power curve is one of the major curves reflecting the wind turbine output performance [1]. The existing research on wind power curve is almost deterministic analysis, which gives the corresponding point value of output under a certain wind speed, while there is a big risk [2]. In this paper, the uncertainty method proposed enriches the information of wind power curve and improves the reliability of the estimation results.

Modeling of the wind power curve

In accordance with the international electrotechnical commission (IEC) standard of IEC61400-12, wind power curve of wind turbines represents the relationship between the average wind speed and power for 10 min [3,4], and it should be obtained by the measured way, different from the standard wind power curve provided by manufacturer [5]. Because wind speed and power is not a one-to-one correspondence, so the measured data should be modeled and analyzed. Method of bins is used in this paper [6,7,8].

Wind speed is equally divided into M intervals according to the method of bins, which is called wind speed bin. For an example, take 0.5 m/s for a small bin. Then calculate the average wind speed and power of each bean respectively to receive M (V_{imean}, P_{imean}) data:

$$V_{imean} = \frac{1}{n_i}\sum_{j=1}^{n_i} V_{ij} \ . \tag{1}$$

$$P_{imean} = \frac{1}{n_i}\sum_{j=1}^{n_i} P_{ij} \ . \tag{2}$$

Finally use spline interpolation method to synthesize a smooth curve with M (V_{imean}, P_{imean}) point, namely the wind power curve by method of bins. This method involves all the measured data in the model, so the error of the wind power curve obtained is small, the smoothness is good, and the model is stable.

Uncertainty estimation

Probability density function estimation problem is to estimate the probability density function through the samples, containing parametric, semi-parametric and non-parametric estimation method [9, 10].

Non-parametric method doesn't need to give any priori assumptions of the distribution so it is more in line with the actual distribution. Compared to the parametric method, the functional form and parameters of non-parametric estimation method are unknown [11]. Its advantage is: when doing overall estimate, the form of function is freedom and doesn't rely on the distribution of the sample; it is suitable for nonlinear, inhomogeneous data and the data of which the overall distribution is unknown. For the distribution of the measured wind power curve, there is not a specific form to carry on the accurate description. Therefore, in this paper, the non-parametric estimation method is adopted to establish the probability density function of wind power curve.

Kernel function regression is one of the non-parameters estimation methods. It mainly adopts kernel density estimation. Kernel density estimation function is:

$$f(x)=\frac{1}{nh}\sum_{i=1}^{n}K\left(\frac{x-X_i}{h}\right). \tag{3}$$

Gaussian kernel function $K=\frac{1}{\sqrt{2\pi}}e^{-\frac{u^2}{2}}$ is used in this paper.

Interval estimation

Interval estimation is a method describing the uncertainty of estimator [12]. Based on the deterministic point estimation, interval estimation gets probability density function by wind power curve error measurement, and uses the theory of probability to calculate estimate interval under a given confidence level.

ξ is a random variable, and $F(\xi)$ is the probability distribution function, the non-parametric estimation technique is adopted to establish the $1-\alpha$ estimate interval $\left[G(\alpha_1),G(\alpha_2)\right]$ ($\alpha_2-\alpha_1=1-\alpha$). Take symmetric probability interval, this is to say, $\alpha_1=\alpha/2$ $\alpha_2=1-\alpha/2$. The probability confidence interval is:

$$\left[G(\alpha_1),G(\alpha_2)\right]=\left[G\left(\frac{\alpha}{2}\right),G\left(1-\frac{\alpha}{2}\right)\right]. \tag{4}$$

$G(q)$ is the inverse function of $F(\xi)$, so $\Pr\{\xi\le G(q)\}=q$ through which estimate interval boundary value can be obtained under the given confidence level.

The error of wind power curve is associated with a variety of factors such as wind speed and air density. Data analysis shows that when the wind speed is different, the power probability density distribution function varies greatly. As a result, in this paper, wind speed considered as the main influencing factors of wind power curve error, is divided into 50 levels by 0.5 m/s (under normal circumstances, wind speed at wind farms is under 25 m/s). Respectively, set up different power probability distribution.

According to the deterministic estimate of wind power curve and probability density function, estimate interval under a given confidence level can be received, so as to reflect the range of output.

Example analysis

Select the recorded field data of a wind turbine from Colorado as an example for analysis. The data contains the actual wind speed and power output from 0:00 on January 1, 2006 to 23:50 on December 31, 2006 every ten minutes.

Figure.1 depicts scattered data points and the measured wind power curve drawn by method of bins. The measured data points are evenly distributed on both sides of the wind power curve, and the curve is smooth.

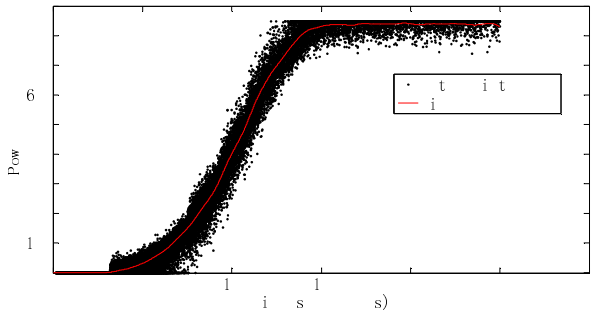

Fig.1 Measured wind power curve drawn by method of bins

Figure.2 shows wind power probability density curve of the 10th wind speed level and it is shaped like the double-peak normal distribution. Figure.3 shows wind power probability density curve of the 25th wind speed level and it is shaped like the normal distribution. The different results illustrate that power output distribution varies. That is to say, the classification method proposed in this paper is feasible and can well describe the power output distribution at different wind speed levels.

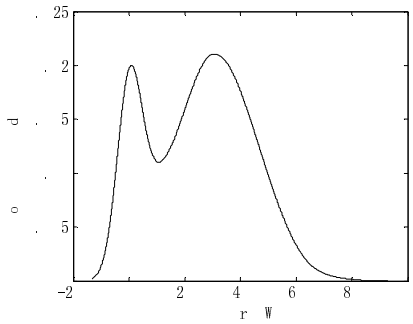

Fig.2 Wind power probability density curve of the 10th level

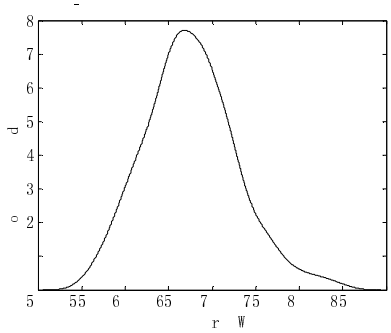

Fig.3 Wind power probability density curve of the 25th level

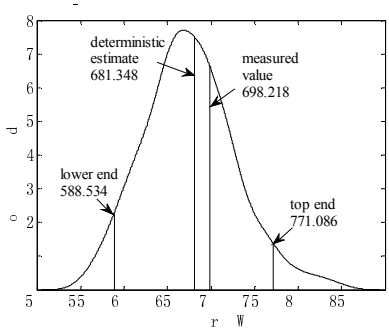

Fig.4 Wind power probability density curve of the 10th level and the 90% confidence interval

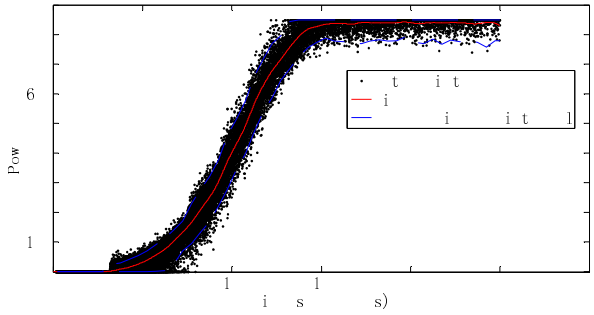

Fig.5 The 90% confidence interval of wind power curve

Figure.4 depicts the power probability density curve of the 22380th data of 09:50 on June 5, 2006 and the 90% confidence interval. Its deterministic estimate value is 681.348 kW, and the 90% confidence interval is [588.534, 771.086] kW. The measured value is 698.218 kW included in the range of the confidence interval. The result proves that the non-parametric interval estimation method is feasible and effective.

Using the same method, confidence interval of each wind speed level can be obtained. Connect the boundaries of all the confidence intervals then two envelopes can be formed up and down on the wind power curve. Figure.5 shows the result of 90% interval estimation.

Summary

Method of bins is proposed to build the measured wind power curve, which reflects the actual operation of wind turbine. Furthermore, method of non-parametric kernel density interval estimation based on the deterministic estimation is adopted to calculate the uncertainty estimation interval of output under a given confidence level. The approach improves the reliability of the estimation results. In this paper, the proposed approach extends the traditional deterministic research on wind power curve, gives the uncertainty range of wind power curve estimation and provides technical support for wind power prediction and power grid dispatch.

Keywords: feed-water heating allocation; nuclear power secondary loop; PSO; optimal design

Abstract. Based on theoretical deduction, according to the characteristics of nuclear power unit, a universal heat economic framework for PWR nuclear power plant heat regenerative system was established. And on this basis, the cycle thermal efficiency was chosen as the optimization goal, the extraction steam pressures were chosen as optimization variables, a universal nuclear power unit regenerative system optimization model was established. A 900 MW nuclear power unit was taken for example, it's the first time that AWPSO was applied to optimize the regenerative heat system of nuclear power unit. The result shows that the convergence ability and search performance of PSO are superior to other methods and the original design scheme. A new and convenient design is provided for PWR nuclear power plant heat regenerative system in this paper.

Introduction

The regenerative feed-water heating system is the core of whole thermodynamic cycle in thermal power plants. It plays a decisive role for the thermo-economy of a steam turbine unit [1]. Therefore, many experts and scholars at home and abroad carried out a lot of research in order to get the best allocation scheme of feed-water enthalpy rise and produced important results in this field. In fact, some traditional methods have been attempting to solve the feed-water heating allocation problems, such as average allocation, enthalpy drop allocation, geometric series allocation, etc. [2-4]. The systems are all further simplified by these allocation schemes, and it leads to fall short of result and facts. Some scholars optimized by direct optimization method, such as dynamic programming, the simplex method, the nonlinear optimization method, etc. [5], but the calculation processes of these methods are very tedious and the versatility and accuracy are not high, so they're difficult to popularize. In recent years, simulated natural ecosystem mechanism is introduced to optimize the regenerative heating system by some scholars, and some certain achievements are obtained, such as genetic algorithm (GA) and simulated annealing algorithm, but these algorithms have some shortcomings such as easy to bring immature convergence, poor stability, and etc.

In this paper, adaptive weight particle swarm optimization (AWPSO) was applied to solve the feed-water heating allocation problem of nuclear power units for the first time. The calculation result demonstrates that AWPSO is superior to other methods and the original design scheme. A new and convenient design was provides for PWR nuclear power plant heat regenerative system.

Mathematical model

General regenerative system of nuclear power unit is shown in Figure 1. Different from conventional thermal power unit, the high pressure cylinder exhaust steam of nuclear power unit is separated by steam separator (after separation, the "steam" is used as reheat steam, the "water" is fed into the deaerator). And the new steam and extraction steam of the first stage of high pressure cylinder are used as reheating source, the drain is fed into one high pressure heater. On the other hand, one pipe of reheated steam is used as the steam source of feed-water pump usually in nuclear power unit, which is also different from general thermal power unit. These factors make steam circulation system very complex, increase the calculation difficulty, and the ever optimized methods

for thermal power unit are no longer suitable for nuclear power unit. It is need to establish a new optimization model, which is suitable for nuclear power unit.

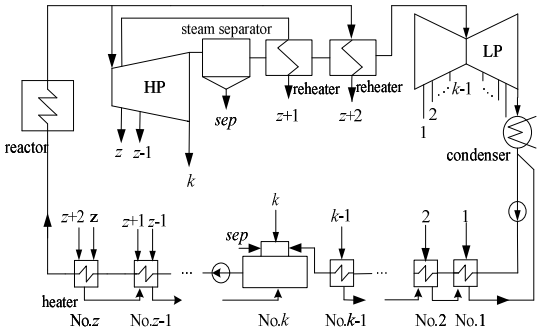

Fig.1 Thermodynamic system of nuclear power unit

Construction of steam-water distribution equation

According to the divided steam-water system, considering the energy balance and mass balance, steam-water distribution equation of unclear power unit secondary loop can be written as follow:

$$[A][\alpha_j]+[A_\tau][\alpha_\tau]+[A_f][\alpha_f]+[\Delta q]=[B][\tau] \tag{1}$$

The significance and composition rules of each element of the matrix are as follows:

1) $[A][\alpha_j]$ represents the main steam-water. $[\alpha_j]=[\alpha_1,\alpha_2\cdots\alpha_{z+2}]^{\mathrm{T}}$ are the shares of each extration steam of heaters and reheaters; $[A]$ is $z+2$ factorial square matrix, constituted as follow:

$$A=\begin{pmatrix}
q_1 & \gamma_1 & \gamma_1 & \cdots & \gamma_1 & \beta\tau_1 & \beta\tau_1 & & \cdots & & \beta\tau_1 \\
0 & q_2 & \gamma_2 & \cdots & \gamma_2 & \beta\tau_2 & \beta\tau_2 & & \cdots & & \beta\tau_2 \\
0 & 0 & \ddots & \ddots & \vdots & \vdots & & & & & \\
 & & & q_{k-1} & \gamma_{k-1} & \beta\tau_{k-1} & \beta\tau_{k-1} & & \cdots & & \beta\tau_{k-1} \\
 & & & & q_k & \gamma_k & \gamma_k & & \cdots & & \gamma_k \\
\vdots & \vdots & \ddots & & \ddots & q_{k+1} & \gamma_{k+1} & & \cdots & & \gamma_{k+1} \\
 & & & & & & \ddots & \ddots & \ddots & & \vdots \\
 & & & & & & & q_{z-1} & \gamma_{z-1} & \gamma_{z-1} & \gamma_{z-1} \\
0 & 0 & & & \cdots & & & 0 & q_z & 0 & \gamma_{z+2} \\
0 & 0 & \cdots & 0 & \beta\tau_{z+1} & \beta\tau_{z+1} & \cdots & & \beta\tau_{z+1} & q_{z+1} & \beta\tau_{z+1} \\
0 & 0 & \cdots & 0 & \beta\tau_{z+2} & \beta\tau_{z+2} & \cdots & & & \beta\tau_{z+2} & q_{z+2}
\end{pmatrix}$$

where q is the heat of steam, τ is the enthalpy rise of feed-water in each heater, γ is heat of the drain water, β is the flow coefficient in steam-water separator.

2) $[\alpha_\tau]$ represents the share of auxiliary water ; $[\alpha_f]$ represents the share of auxiliary steam; $[A_\tau]$ and $[A_f]$ are $z+2$ factorial square matrix, whose composition rule and determine method are identical to matrix $[A]$.

3) $\Delta q=[\Delta q_1,\Delta q_2,\cdots\Delta q_{z+2}]^{\mathrm{T}}$ represents the pure heat that in and out of the system. $\Delta q_i\neq 0$ means that Δq_i pure heat is let into the i^{th} heater. For ease in writing, the drain water heat of the steam separator in deaerator and the pump power of the feed- water pump are classed as this category. Thus, Δq_k contains $\alpha_{sep}\gamma_{sep}$ and τ_b.

4) $[\tau]$ represents the feed-water enthalpy rise of each heater and the reheat steam enthalpy rise in the reheaters. $[B]$ is a $z+2$ factorial diagonal matrix, constituted as follow:

$$B=diag[\underbrace{\beta(1-\alpha_p),\beta(1-\alpha_p),\cdots\beta(1-\alpha_p)}_{k-1\text{项}},\underbrace{1,1,\cdots 1}_{z+1-k\text{项}},\ \beta,\ \beta]$$

Transforming formula (1), combining the definition of q, τ and γ, α_j can be expressed by p_j as follow:

$$\alpha_j=f^j_{p\to\alpha}(p_1,p_2,\cdots p_z) \tag{2}$$

Establish the optimal model

Thus, the cycle thermal efficiency of the unit can be calculated as follow:

$$\eta_i = \frac{w}{\bar{q}} = [(1-\alpha_{z+2})(h_0 - h_k) - (\alpha_z + \alpha_{z+1})(h_z - h_k) + \alpha_{rh}(h_{rh} - h_c) - \sum_{j=k}^{z-1}\alpha_j(h_j - h_k) - \sum_{j=1}^{k-1}\alpha_j(h_j - h_c) - \Pi]/(h_0 - h_{fw}) \quad (3)$$

where α_{rh} represents the share of the reheat steam; h_c represents exhaust enthalpy; h_{fw} represents the feed-water enthalpy; Π is the power losses caused by steam leakage of the shaft gland, gateway and etc.

Combining the formula (2) and formula (3), the cycle thermal efficiency η_i can be expressed by extraction steam pressure p_j as follow:

$$\eta_i = f(p_1, p_2, \cdots, p_z) \quad (4)$$

Considering some constraints, the optimal mathematical model of nuclear power unit thermal system can be described as follows:

$$\begin{cases} \max \eta_i \\ s.t \quad G_j(\vec{x}) \geq 0, j = 1,2,\cdots z \end{cases}, \quad \text{where } G_j(\vec{x}) = \begin{cases} G_1(\vec{x}) = p_1 - p_c; G_2(\vec{x}) = p_2 - p_1; \\ \cdots; G_z(\vec{x}) = p_z - p_{z\text{-}1}; G_{z+1}(\vec{x}) = p_0 - p_z \end{cases} \quad (5)$$

The example calculation and the result analysis

A certain 900 MW pressurized water reactor nuclear power unit thermodynamic system as shown in Figure 2. The terminal temperature difference of feed-water heaters and pipe extraction pressure losses are shown in Tab.1

Tab.1Entropy extraction efficiency of all levels, pressure drop and temperature difference of heaters

items	symbols	units	H5	H4	H3	H2	H1	SEP	RH
Extraction pressure loss	Δp_j	%	5	5	5	5	5	2	2.6
outlet terminmal difference	θ_j	◦C	3	0	2.5	2.5	2.5	0	13.4
inlet terminmal difference	φ_j	◦C	8	-	5	5	-	-	-

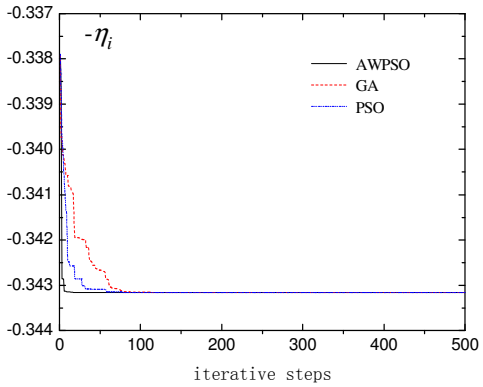

Fig.3. The evolution curves of AWPSO, PSO and GA

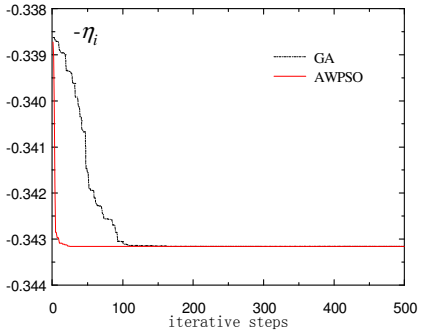

Fig.4. The evolution curves of AWPS0 and GA in population of 10

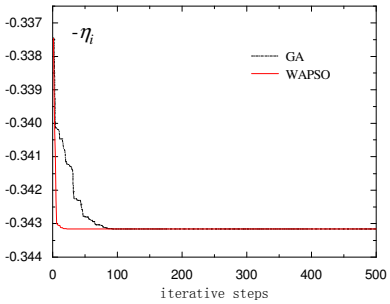

Fig.5. The evolution curves of AWPS0 and GA in population of 30

Due to PSO is usually to find the minimum value of fitness function, so when optimize the regenerative heating system, combining the formula (5), the fitness function is constructed as $F = -\eta_i$. Parameter Settings: Population size is 20; Learning factors c1=c2=2; Inertia weigh w_{max}=0.9, w_{min}=0.5; Iteration steps t=500. Compare the optimization result with the original design value, the average distribution method, GA and standard PSO, as shown in Table 2. Fig.3-Fig.5 are the evolution curves of different methods under different population sizes.

The Table 2 shows that result of AWPSO compared with the original design is relatively increased about 0.051%. If the annual utilization hours are 7000, extra generating capacity will be made by one unit each year. If the average power produce fuel consumption is 320 KW/h in the country, 1028.613 tons of standard coal will be saved by one unit, which gives considerable economic benefit.

Tab.2 The optimization results of all programs

items	Original design	Average divide	GA	standard PSO	AWPSO
p_1	0.0244	0.0393	0.0267	0.0273	0.0267
p_2	0.0898	0.1295	0.1053	0.1028	0.1056
p_3	0.3531	0.3242	0.3489	0.3417	0.3487

α_2	0.0381076	0.0381067	0.0410939	0.0397166	0.0410312
α_3	0.0536341	0.0375159	0.0479189	0.0477821	0.0479573
α_4	0.0854198	0.0898916	0.0860544	0.0871591	0.0861064
α_5	0.0696247	0.0696948	0.0696346	0.0696519	0.0696129
α_{rh}	0.6907854	0.6874193	0.6902595	0.6889778	0.6902452
$\alpha_{0,\ rh}$	0.0743967	0.0739969	0.0743496	0.0742412	0.0743348
η_i	0.342986	0.342905	0.343158	0.343157	0.343161

Note: α_{rh} represents the share of reheat steam; $\alpha_{0,\ rh}$ represents the share of the new steam that used to heat the reheat steam.

Conclusion

According to the characteristics of the secondary loop system of nuclear power unit, a universal heat economic framework for PWR nuclear power plant heat regenerative system was established based on theoretical deduction. The cycle thermal efficiency was chosen as the optimization goal, the extraction steam pressures were chosen as optimization variables, a universal nuclear power unit regenerative system optimization model was established. PSO was applied to optimize the thermal system of nuclear power units for the first time. The practical calculation shows that the AWPSO can achieve or approximate the optimal value, with high efficiency and good stability, and it's easy to master and apply in the practical work for the simple procedure and less operations. An effective way is provided to analyzing and solving the problem of nuclear power unit thermal system optimization.

Calculation of Capacitance and Inductance Parameters of Transformer Winding under Very Fast Transient Overvoltage

Yan Li, Yang Li, Yinjun Guan, Tianyuan Li

Research Institute of Special Electrical Machines, Shenyang University of Technology, China

Email: tlly0808@yeah.net

Keywords: Transformer, VFTO, Capacitance, Inductance, FEM

Abstract. The distributed parameters of transformer windings are indispensable in analyzing the transients particularly caused by the very fast transients which occur at the time of disconnecting switch operations in GIS. Winding insulation structure and the safe and stable operation of the transformer are determined by the accuracy of the calculation. In this paper, finite element method(FEM) is used to model and simulate the electromagnetic field calculation of winding capacitance and inductance parameters. The simulation calculation results are consistent with the experimental measurements on a transformer model, which verifies this method is feasible.

Introduction

Disconnect switch restriking causes very fast transient overvoltage (VFTO) in gas insulated substations (GIS) which can damage power equipment, especially inductance devices in the substations[1][2]. The very fast transient overvoltage has a steep wave front of time, the main oscillation frequency depends on the length of the GIS, general is 1 ~ 40 MHz. The directly invading of Very Fast Transient Overvoltage caused by the switching operation in GIS to transformer windings may severely damage their longitudinal insulation. Research in transformer windings under VFTO wave process of transformer insulation design and protection has significance meanings [3][4].

The transformer windings can be regard as a complex networks composed by capacitance, inductance, resistance and conductance, under very fast transient overvoltage. During the process of transient response of transformer windings to impulse waves, transformer winding can be seen as a lumped parameter network [5]. During the process of transient response of transformer windings to impulse waves, the initial voltage distribution along transformer winding due to a step voltage input was determined by the capacitances within the winding. The final voltage distribution along transformer winding was determined by the inductance of the winding [6][7][8]. Therefore, to obtain a more accurate result, it is necessary to improve the method of the analytical formula or to find a new method other than analytical formulation method in calculating the parameters of capacitance and inductance [9][10].

This paper presents a finite element method by using Ansoft software to calculate the parameters of capacitance and inductance of different kind of winding forms in the high-voltage transformer. In order to validate the correctness of this method, the parameters of one practical transformer is taken for analyzing, and the results are read by the self-compiling software to realize the analysis of the wave process under VFTO.

Calculation of Inductance Parameter

In the process of impact, when the impulse waves' equivalent frequency is low enough, the effect of impulse waves on the winding is completely determined by the inductance. For the infinite without iron yoke core model, simulate the magnetic field distribution, to improve the accuracy of the inductance calculation. The calculation of distributing inductance is based on the magnetic static. By applying the boundary conditions the infinite long core will be better simulated, and the distribution of magnetic field around windings will be more close to the actual situation. Consequently the accuracy of the calculation of inductance will be improved significantly.

Calculation method and procedure of Inductance is based on a three-phase double-winding without on-load tap-changer 400MVA/500kV power transformer. The finite element method calculation model is shown in Fig.1.

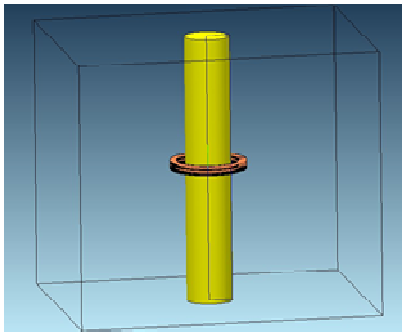

Fig.1.Inductance model of disk to disk

Inductance consists of two parts, hollow inductance component and core inductive component. Self-inductance is calculated by planar coil inductance formula, the structure as shown in Fig.2.

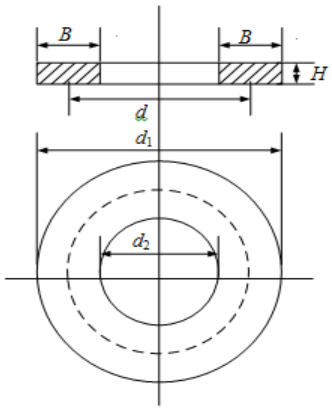

Fig.2 Structure size of plane coil

The calculation of self-inductance is given by

$$L = \frac{\mu_0}{8\pi} d \psi w^2 \quad (1)$$

Where μ_0 is the permeability of vacuum, d is the average diameter of disk, w is the number of turns per disk, Ψ is a function of associated with ρ=B/d.

Mutual inductance is obtained by the coupling coefficient method.The calculation of mutual inductance is given by

$$M_{ij}=L_i q^{|i-j|}, \quad i \neq j \quad (2)$$

Where L_i is the self-induction of the unit i, q=0.97~0.99 is coupling coefficient.

The results of mutual inductance calculated are shown in the Table 1.

Table 1. Inductance value of the first disk with the top 6 cake（μH）

Numbering	Finite element method	Analytical method
$M_{1,1}$	1052.9	1101.4
$M_{1,2}$	1022.4	1071.5
$M_{1,3}$	1003.2	1038.8
$M_{1,4}$	981.1	1015.9
$M_{1,5}$	1023.5	1073.7
$M_{1,6}$	1012.7	1053.5

It can be seen from the Table 1, the difference of the result calculated by the both methods is not significant which shows the correctness of the new method. The main reason of causing difference is that, analytical method has been simplified and not considered the entire structure.

Calculation of Capacitance Parameter

Electric field analysis is the basis for calculating the capacitance of the transformer, the finite element method of electric field analysis is most close to the actual situation of the transformer, reduce the assumptions, the calculation results can be obtained with high accuracy. The capacitance is calculated using the finite element software of electrostatic field. Through a series of electrostatic simulation, the capacitance matrix will be calculated. In every simulation process, one conductor was set to 1V voltage, other conductors was set to be grounding.

The capacitance C of conductors i and j is calculated by energy formula. The capacitance C of conductors i and j is given by

$$C = \frac{2W_{ij}}{U^2} = \int_{\Omega} D_i \cdot E_j \, \mathrm{d}\Omega \tag{3}$$

Where W_{ij} is the electrostatic energy stored in the volume between the conductors i and j, D_i is the electric flux density of conductor i, E_j is the electric field intensity of conductor j. U is the voltage difference between i and j.

Calculation method of capacitance is similar to the process of inductance. The calculation of capacitance is based on the 400MVA/500KV mentioned above, the calculation model built by a disk as a unit is shown in Fig.3. To verify the results, the analytical formula is used to calculate capacitance of the winding. The calculation of disk to disk capacitance is given by

$$C_s = \frac{\varepsilon_{de} d_a B}{4 a_d} \times 0.11 \tag{4}$$

Where ε_{de} is the permittivity of compound insulation, d_a is the average diameter of one disk, B is the radial width of one disk, a_d is the insulation wide between disks.

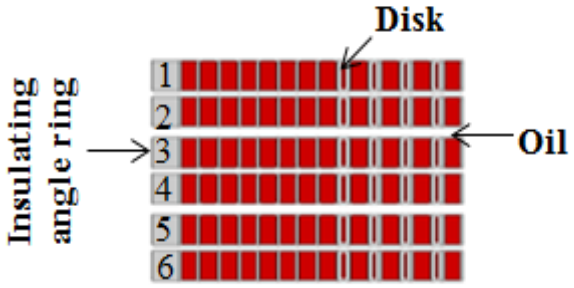

Fig.3. Disk winding model

The results of capacitance calculated are shown in the Table 2.

Table 2. The capacitance of disk to disk (F)

Numbering	Finite element method	Analytical method
$C_{s1,2}$	$3.32e^{-9}$	$3.16e^{-9}$
$C_{s2,3}$	$1.97e^{-9}$	$1.86e^{-9}$
$C_{s3,4}$	$3.28e^{-9}$	$3.16e^{-9}$
$C_{s4,5}$	$1.97e^{-9}$	$1.86e^{-9}$
$C_{s5,6}$	$3.32e^{-9}$	$3.16e^{-9}$

From the data comparison of Table 2, the results calculate by the finite element method is slightly larger than analytic method, that illustrate the validity of the finite element method. The difference mainly comes from the approximate calculation as the analytic formula cannot figure out the actual condition that electric field distribution influences the capacitance.

Conclusion

A finite element method is presented in this paper to calculate the electric and magnetic fields of transformer and then figure out the distributed capacitance and inductance parameters of windings. The calculation of disk-to-disk parameters of capacitance and inductance in a high voltage transformer compared with result of analytical method is similar. That means this method is feasible and accurate.

Keywords：Settling Technique of Compound Flow; Desulphurization Precipitator; Surface Load, impact

Abstract：In order to discuss the treatment performance of wastewater from desulphurization precipitator by settling technique of compound flow, the field test rendered the effluents of integrated desulfurization precipitator as the handing objects. The results show that the critical load of the sediment separator is 4mm/s. When the surface load is less than or equal to 4 mm / s, the turbidity of effluent is less then 10 degrees and the maximum is less then 18.2 degrees. The effect of hydraulic load impact on the water treatment system is greater than that of pH and SS of inlet. The treatment efficiency of field test is equivalent that of laboratory simulation.

The main source of the pollutants of industrial coal-fired boiler desulfurization dust catcher in the wastewater is coal combustion in boiler flue gas from coal-fired industrial boilers. In China, desulfurization precipitator for supporting the use of coal-fired industrial boiler can be divided into two generations and three categories. The second generation of desulfurization precipitator has the function of simultaneous desulfurization and dust removal with high efficiency. Industrial boiler desulfurization dust catcher is the core producer of waste water, property of flue gas, working fluid (water) and precipitator itself is the three basic ways of influencing wastewater quality. The coal quality, combustion and furnace of boiler, boiler load, structure and operation management of boiler, the types and performance of dust catcher, supply mode and property of working fluid influence the wastewater quality through their own way, SS of wastewater changes during the operation. At present, the industrial boiler in China have treatment technology of wastewater recovery in desulfurization precipitator like coagulating sedimentation [1-3], alkaline medium deep filtering technology [4], microporous ceramic surface filtering technology [5] and neutralization treatment technology of alkaline industrial wastewater [6]. Precipitation technology is widely used in the field of water treatment because of its economy and effectiveness. Advection sedimentation, inclined plate sedimentation and inclined tube sedimentation is the most traditional precipitation technology. The development of new high efficiency and widely suitable precipitation technology is the most active research direction [7]. The common characteristics of Industrial boiler desulfurization precipitator wastewater quality is high SS, high Al^{3+}, high Fe^{3+}, and low pH [8].

1 Experiment Device

As it is shown Chart 1, the treatment processing system includes inflow lifting system, coagulant medication system, pH value adjustment system, mixture flocculation unit, the composite sedimentation processing unit and flocculation by swirling flocculation column, with 2 types, which are type I D×h = 153mm×2080mm = 38.2L and type II D×h = 250mm×1733mm = 85.0L. Composite flow inclined plate settler are all single composite precipitator for the downward flow and upward flow.

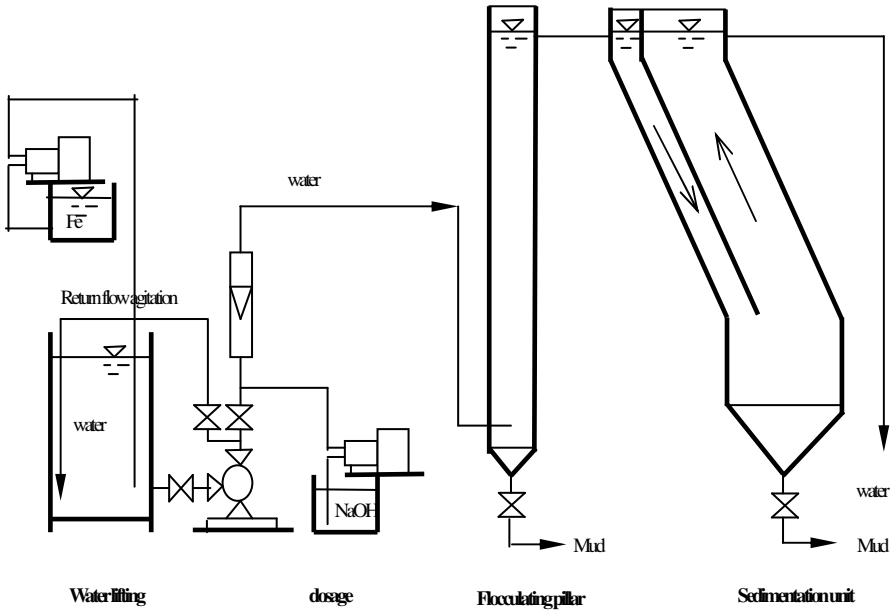

Chart 1: Process of Experiment

2 Experiment Water Sample

Experiments were carried out in an industrial boiler flue gas desulphurization and dust removal area, with waste water from integrated desulfurization precipitator, with SS 1596mg/L, 320 FTU of turbidity, total solids 2590mg/L, pH value 3.1, the average temperature 18.1 ℃. Using $FeCl_3$ and NaOH combined medication dosing method. Add $FeCl_3$ in the pump suction mouth, dosage of 10mg/L; Add NaOH in anterior pipeline of the measuring equipment, dosage of 20-40mg/L.

3 Experiment Equipment and Methods

3.1 Main Analytical Instrument and Equipment

Turbidity Measurement: By using phototurbidometry, we determined the value of extinction through type 721 Spectrophotometer made by Shanghai Second Analytical Instrument Factory. The testing sample is compounded with diatomaceous and the regression equation of standard curve as follows:

When turbidity between 3-10FTU：Y=110.57X-0.4936

When turbidity between 10-100FTU：Y=168.32X-7.1054.

pH Measurement: By the pHS-2 acidity meter made by Shanghai Second Analytical Instrument Factory, the method to measure pH is glass electrode method.

3.2 Experiment Content and Method

Steady running performance test uses the experiment method of inflow gradually to increase the load step by step. Table 1 is shown all the system performance of all experiment working condition. In the working condition 3 includes 2 different flocculation times.

The impact resistance performance experiment can change the water load, the inflow water quality (SS and pH) with the basis of certain running result to observe the impact resistance performance.

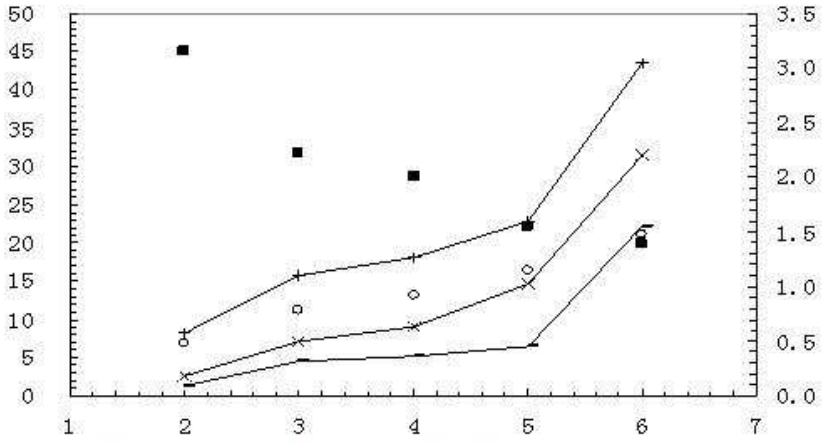

Chart 2: Effluent Turbidity-Net Surface

Table 1: Test Experiment Conditions of Working Condition

Experiment Working Condition	1	2	3-I	3-Ⅱ	4	5
Water Quality of Inflow Water						
pH Value	3.1	4.2	3.0	2.8	3.5	2.9
Turbidity Degree	325	365	330	310	310	345
Flocculation conditions						
Flocculation column No.	Ⅰ#	Ⅰ#	Ⅰ#	Ⅱ#	Ⅱ#	Ⅱ#
Flocculation time/min	7.1	4.7	3.5	7.9	6.3	5.2
Precipitation Surface Unit Load /mm/s	2	3	4	4	5	6

4 Experiment Result and Discussion

Steady Running Treatment Performance

Chart 2 displays the relationship that the effluent turbidity and removal rate are changing with surface load convert. In this table, the data of working condition 3 comes from 3-II operation status. The water quality fluctuation coefficient is the ratio of the max value of the effluent turbidity and the average value when $K_{\max}$ is running at the certain working condition. ΔC_{max} means the water quality fluctuation is poor.

Chart 2 shows that the effluent turbidity is increasing with the rise of sedimentation unit surface load. When $u_0 \leqslant 4$mm/s, the effluent turbidity is increasing slowly; When $u_0 > 4$mm/s, the effluent turbidity is increasing fast. Thus, from the experiment we find the critical value of the surface load is 4mm/s. The gradually decrease of $K_{\max}$ indicate the range of the relative volatility of effluent turbidity becomes smaller, and the rapid increasing of $\Delta C_{\max}$ indicate Absolute amplitude is on the increase. When the surface load is $u_0 \leqslant 4$mm/s, the average of effluent turbidity is <10FTU, the max value is <18.2FTU; When $u_0 \leqslant 5$mm/s, the average value of the effluent turbidity is <15FTU, the max value is $\leqslant$22.8FTU; When $u_0 \leqslant 6$mm/s, the average of effluent turbidity <32FTU and the max value is <43.5FTU.

Comparing with the traditional precipitation technique, duplicate confluence precipitation technology does not only achieve the same level of removal rate but it also has better adaptability of the inflow water quality as well as concentrating function.

5 Conclusions

1) Duplicate confluence precipitation technology processing desulphurization dust removal actual waste water has the reliable performance, with simple technology, combining the sediment and concentration together.
2) When the surface loading is $u_0 \leq 4$mm/s, the average value of effluent turbidity is <10FTU and the maximum value <18.2FTU. With the rise of surface loading, the effluent turbidity is increasing but the relative fluctuation range is lower with rise of absolute rangeability.
3) In the three elements of water load including water load, inflow SS and pH, the water load impact has the largest impact to the system treatment effect, when the water impact level reach to 1.2, the turbidity responsibility reach to 1.2.
4）Treatment processing performance of boiler desulfurization precipitator and laboratory prepared samples are basically the same, but affected raw water quality fluctuation in the field test, the effluent turbidity is more volatile.

Keywords: uranium tailings impoundment, nuclide migration, static experiment, partitioning coefficient, numerical simulation

Abstract. As acid rain getting more and more serious, increasing attention is given to environmental effect assessment of uranium tailings under the condition of acid rain. In the paper, influence of acid rain to partitioning coefficient (Kd) of U(Ⅵ) in soil was studied, and migration of radionuclide uranium in soil was simulated by computer. The static experiment results showed that the Kd value of U(Ⅵ) in soil reaches minimum value when pH is 2.0. When 2.0＜pH＜3.5, the Kd showed a rising tendency； The Kd in soil reaches maximum value when pH is 3.5. And when 3.5＜pH＜8.0, the Kd showed a decreasing tendency. This paper has taken a large uranium tailings impoundment in South China as an example studied by VisualModflow. After setting up models of groundwater movement and radionuclide migration in the study area, migration tendency of radionuclide U(Ⅵ) was simulated and pollution of radionuclide to environment was predicted. The results of simulation show that the migration of uranium speed to be the slowest when pH = 2.0, and the figure to be the fastest when pH = 3.5. Furthermore, maximum speed is about 1.24 times of minimum speed.

Introduction

Since the early 1950s，our country has already started to uranium geology work. China is a big mining country, the capacity of tailings in China is more than one hundred million tons [1-3].Uranium slag is a product of uranium hydrometallurgical processes, which is usually stored in the uranium tailings. Uranium tailings contain depleted ore that have extracted uranium and various contaminants produced during the process of mining, also includes not recycled uranium and all decay daughters of uranium series [4-6]. It is usually open-air stacking in the tailings area. Due to the effect of leaching of the atmospheric precipitation, heavy metal in the tailings and radionuclide are easy to enter the shallow groundwater, which have serious impact on the ecological environment of the uranium tailings and its surroundings[7-8]. Therefore, the development on simulation research of radionuclide migration in uranium tailings may well make sense to analysis the groundwater pollution that uranium tailings could produce and offer some solutions to this problem.

The studies about transport dispersion law of pollutant in ground water adopted more and more frequently over these years [9]. With the development of computer simulation technology on groundwater movement and pollutant diffusion, we have got surprising evolvement in quantitative description of pollutant migration. Computer simulation study of nuclide migration refers to predicting the activity and distribution of radionuclide in geological environment of tailings area and it's surrounding in hundreds, thousands or even millions of years. To finish the work, we need analysis a large number of hydro geological data, experimental data and technical information from relevant experiment. Meanwhile, we must combine with the related discipline theory model for computer simulation and calculation [10-11].

The research subject of uranium tailings is located in southern China, with abundant precipitation, but also a large acid rain region. Acid rain has an influence on the pH of the mining area. pH mainly

bring effects on the existence form of uranium in soil and the adsorption characteristics on the surface of soil particles, it also change the soil absorbability of uranium [12]. The main parameter reflects the soil on the absorption ability of the metal is the partitioning coefficient (Kd). A small Kd means metal ions mainly dissolved in the liquid phase, when Various chemical reactions occur easily. A large Kd shows that the soil absorbability of metal ions is strong [13].

This paper proposed adopts the method of experiments combined with simulation, study the effect of pH on the partitioning coefficient of U(VI) in the soil by static experiment firstly, then use groundwater numerical simulation software Visual MODFLOW to simulate the migration of U(VI) with different partitioning coefficient. These may provide the necessary theoretical base for comprehensive control of uranium tailings. Visual MODFLOW is a three-dimensional visualization professional software which is the most popular software in the international field of assessment and forecast of groundwater [14-15].

Solute movement equation

Migration partial differential equation in three dimensions of homogeneous chemical compositions was established in this study, considering the groundwater convection, dispersion, and fluid sink/source term, equilibrium adsorption, first-order irreversible reaction

$$\theta R\frac{\partial C}{\partial t}=\frac{\partial}{\partial x_i}\left(\theta D_{ij}\frac{\partial C}{\partial x_i}\right)-\frac{\partial}{\partial x_i}(q_i C)+q_s C_s-\lambda_1\theta C-\lambda_2\rho_b\overline{C} \tag{1}$$

Retardation factor is defined as:

$$R=1+\frac{\rho_b}{\theta}\frac{\partial\overline{C}}{\partial C} \tag{2}$$

In this formula, C is the dissolving concentration (ML-3); $\overline{C}$ is adsorption concentration (MM-1), which is the function of dissolving concentration C according to the adsorption isotherm relationship; q_i is Darcy velocity (LT-1); D_{ij} is diffusion coefficient tensor (L2T-1); q_s is flow of aquifer per unit volume in source/sink(T-1); C_s is concentration in source/sink (ML-3); λ_1 is reaction rate constant of dissolved phase (T-1); λ_2 is reaction rate constant of adsorbed phase (T-1); θ is porosity (dimension is 1); ρ_b is bulk density of medium in gap (ML-3)。

Materials and methods

Collection soil in field

Soil used in this paper is undisturbed soil, which is unpolluted and able to represent the main characteristics of the research region undisturbed soil. The physical structure of the soil should not be destroyed if there is a possibility when collecting.

The influence of different pH on the adsorption test

In this experiment, ten 250mL Erlenmeyer flasks were divided into two groups, A and B, each group has five Erlenmeyer flasks. Then added 1g mining soil sample which sifted by a No. 35 sieve to group A; and added 1g soil sample around the area which sifted by a No. 35 sieve to group B. Next, added equivalent dose of U3O8 solution which CU(VI)=5mg/L into group A and B. then adjusted pH value to 2.0, 3.5, 5.0, 6.5, 8.0 using sodium hydroxide solution and nitric acid(error was plus or minus 0.05). At the same time, kept the water-soil ratio was 100: 1(mass). Shook the sample solution for 2 hours then let it stand for 24 hours, centrifuged the sample solution in the end. After centrifugation, the uranium content of supernatant was measured.

Method of analysis

This paper measured the uranium content of solution using GB6768-86-spectrophotometry.

Results analysis on static adsorption experiment

According to data measured by static adsorption experiment, the partitioning coefficient (Kd) were calculated by using the following formula: $\mathrm{Kd} = \frac{\mathrm{V}}{W}\left(\frac{C_0}{C} - 1\right)$

In this formula,

Kd ——partitioning coefficient (mL/g);

V ——volume of the soil solution (mL);

W ——mass of the soil sample (g);

C_0 ——initial concentration of heavy metal ions in the liquid phase (mg/L);

C ——initial concentration of heavy metal ions in the liquid phase after the soil adsorption (mg/L).

Curves of partitioning coefficient affected by different pH in soil were graphed after calculating (figure 1).

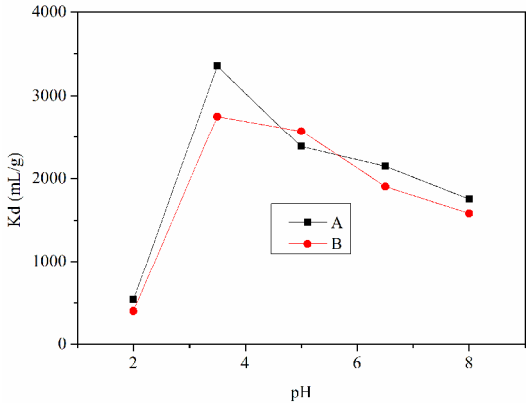

Fig. 1 The effect of pH on Kd of uranium in the soil

Transport and transform simulation of U(Ⅵ) in uranium tailing site

Boundary conditions

The east and west sides of the uranium tailing are surrounded by rivers, and the north side is a mountain range that sort of run east-west. Set the north side as water boundary, and set east, west, south sides as constant head boundary after comprehensive analysis of hydrogeology geological conditions in the study area. Moreover, set the entire ground surface in the study area as rainfall infiltration.

Set the aquifer as unconfined aquifer which is a same thickness and homogenization single layer according to the hydrogeology geological conditions in the study area. Assumed the flow state was steady flow at the same time. Set the entire tailing as an equivalent water head distribution surface, and infiltration of the tailing was simplified into uniform infiltration. The entire ground surface in tailing was supposed to equivalent concentrations surface.

Subdivision model

The area of simulating region was about 80 square kilometers. The plan of whole region was divided into 100 rows and 80 columns, and the length and width of each grid was 100 meters. In order to make the simulation results in more reliable, and the distance and direction of nuclides migration exactly, the plan of Uranium Tailing was divided into 200 rows and 160 columns. Then the accuracy of grid was doubled. The model was subdivided into two layers in vertical direction. The first layer was phreatic aquifer and the second layer was aquiclude. The elevation of simulating region was about 30 meters. Phreatic aquifer was set as 15 meters in this study.

Determine the model parameters

According to the hydrogeology geological conditions in the study area, the percolation coefficient of aquiclude in simulating region was divided into three different parts. And percolation coefficient, specific yield, porosity, etc were assigned respectively in each area.

The mock object was radioactive nuclides of uranium in this study. Concentration in simulating region except for uranium tailing was zero. Infiltration supplement of the uranium tailing was generalized into uniform infiltration, and concentration boundary was supposed to uniform. According to the maximization principle of pollution damage, set the average concentration of U(VI) before the uranium tailing operate as initial concentration in simulation.

Correct the model

In order to accurately describe the characteristics of the aquifer, each parameter such as percolation coefficient was adjusted for several times. Thus, head by simulation corresponds closely to the measurements by drilling, and the modeling result would be exact.

Percolation coefficient, dispersion coefficient, specific yield in each part was listed in table 1.

Table 1 Values of parameters involved in model

parameter	1	2	3
percolation coefficient K(m/d)	30	6.5	4.0
specific yield	0.014	0.009	0.007

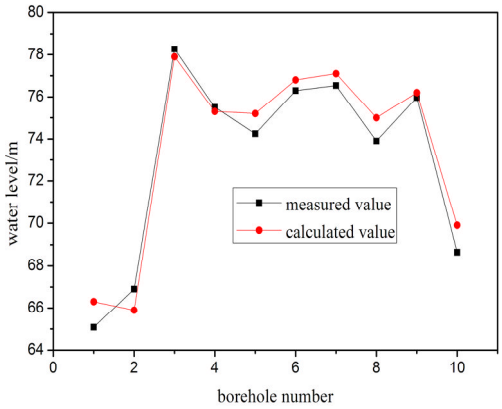

Fig.2 Water level fitting of observation boreholes

The simulated heads were compared with the drilling ones (as shown in figure 2), and a good agreement was obtained, which indicated the model founded was reasonable and reliable. Therefore, the model founded was used to simulate the migration of U(VI) in uranium tailing.

Analyses on migration simulation results

Basing upon the experimental data, three groups of partitioning coefficient (pH=2.0, 3.5, 8.0) were input the model. Following results were listed after running the model.

(1) pH=2.0, Kd_1= 398mL/g (partitioning coefficient in uranium tailing); Kd_2 = 532 mL/g (partitioning coefficient around the mining area), concentration distribution of U(VI) in groundwater after a year as shown in figure 3:

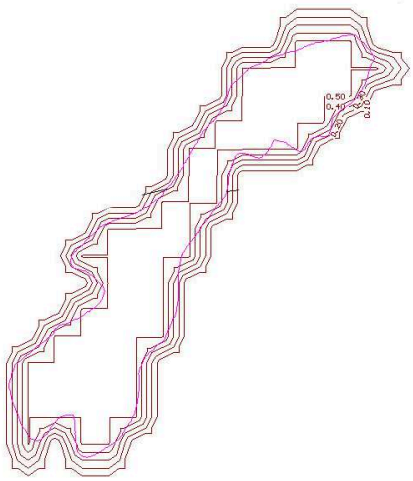

Fig.3 Contour map of the uranium mass concentration in the groundwater in 1 year (pH=2.0)

(2) pH=3.5, Kd_1= 2754mL/g (partitioning coefficient in uranium tailing); Kd_2 = 3357 mL/g (partitioning coefficient around the mining area), concentration distribution of U(VI) in groundwater after a year as shown in figure 4:

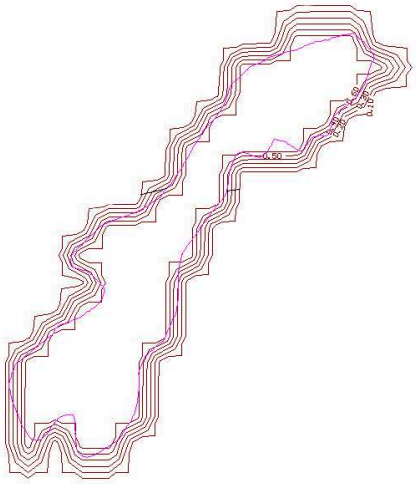

Fig.4 Contour map of the uranium mass concentration in the groundwater in 1 year (pH=3.5)

(3) pH=8.0, Kd_1= 1582mL/g (partitioning coefficient in uranium tailing); Kd_2 = 1751mL/g (partitioning coefficient around the mining area), concentration distribution of U(VI) in groundwater after a year as shown in figure 5:

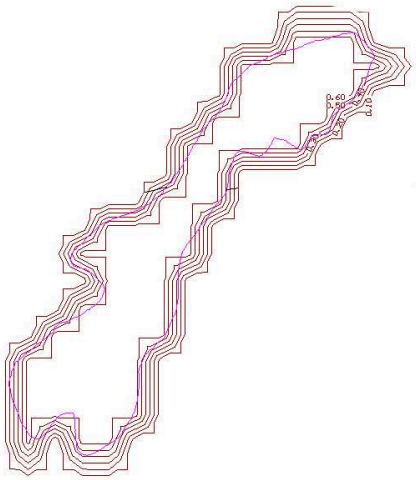

Fig.5 Contour map of the uranium mass concentration in the groundwater in 1 year (pH=8.0)

As can be seen from these three figures, the variation of pH value had definite influence on migration of U(VI) under the same conditions. The migration of uranium speed to be the slowest when pH = 2.0 and the figure to be the fastest when pH = 3.5. Furthermore, maximum speed is about 1.24 times of minimum speed. Therefore, control of the pH value in uranium tailings has certain actual significance in prevention and control of radioactive pollution.

Conclusions

1) From the results of numerical simulation, the migration of U(VI) in aquifer is relatively slow, surface water isn't polluted so far. But since long half-life of uranium, it is necessary to take long-term monitoring to it.

2) The pH value has impact on partitioning coefficient, thus affecting the migration of U(VI) in groundwater. So, control of the pH value in uranium tailings and acid rain management has much practical significance in prediction and controlling the pollution problem in uranium tailings.

Keywords: Hot Dry rock, petrology, geochronology, geochemistry, geothermal application

Abstract. In the past forty years, the investigation on Hot Dry Rock (HDR) geothermal resource has been a hot topic. A great number of investigations confirm that electricity power generated from HDR is feasible and propose that a right HDR site is composed of basement rock and its overlying cover. In the present study, we explore the petrology, geochronology and geochemistry features of the HDR basement rocks with the aim to further optimize HDR siting conditions. Combined analyses show that young S-type or crustally-derived granites with high U, Th and K contents have great potential to develop HDR geothermal resources.

Introduction

The concept of HDR, which is defined as the deep hot crystalline rock, has firstly been proposed by American scientists at early 1970s during the first oil crisis [1]. Subsequently, American and other seven countries have carried out HDR experiments at several different locations like Fenton Hill (American), Soultz-sous-Forêts (France), and so on [2] [3] [4]. Generally, a suitable HDR site should be composed of "basement" rocks (i.e., the deep crystallization rocks) and their overlying "cover" [5]. A large number of HDR experiments and numerical simulations indicate that electricity power generated from HDR is feasible and also suggest that HDR geothermal resource is a kind of renewable and local energy resources with great potential [3]. In this regard, many other countries including developed and developing ones will plan to develop HDR geothermal resources in the near future. However, in order to reduce the cost and skill risks, we should select the most possible HDR extraction sites for geothermal applications [5]. In the present contribution, we explore the possible constraints from petrology, geochronology and geochemistry data for basement rocks with the aim to further optimize HDR siting conditions.

Petrology constraints

In theory, any position on the Earth has potential for developing HDR geothermal applications because the temperature becomes higher from surface to bottom. However, due to the skill, cost and other factors, the site should be located in some special locations. Voluminous investigations exhibit that the most suitable rock types for HDR geothermal applications are S-type or crustally-derived granites including K-feldspar granites, mica- or biotite-bearing granites, monzogranites, leucogranites, syenogranites, and so on [4]. Petrologically, the main composition minerals for these granites are K-feldspar, mica (biotite or muscovite), plagioclase, quartz with minor accessory and secondary minerals like zircon and chlorite [5] [6]. Most of the major minerals belong to felsic or leucocratic minerals [6]. In contrast to the metamorphic rocks, basic rocks and A-type granites, the above-mentioned granites are predominantly sourced from remelting or differentiation of pre-existing crustal materials with minor or no involvement of mantle-derived materials [4]. Analytical results also indicate that the S-type or crustally-derived granites have relatively higher

volumetric heat production rates than those of gneisses, schists, amphibolites, quartzites, ultrabasites and basalts [5] [6]. Thus, the major rock types for HDR basement rocks are S-type or crustally-derived granites.

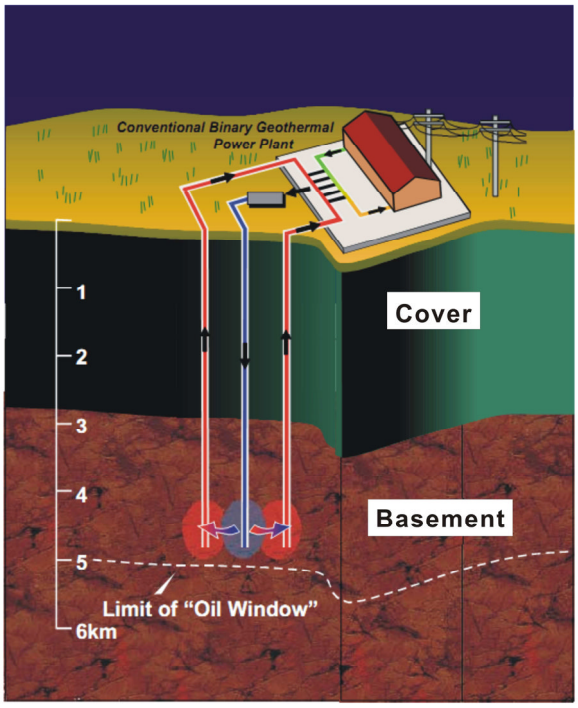

Figure 1. A carton diagram showing that a HDR site is composed of basement rocks and cover sedimentary rocks (modified from [7])

Geochronology constraints

The formation or emplacement timing of the basement rocks is also vital for developing HDR geothermal resources. Voluminous surface heat flow data show that the Precambrian continental crust or landmass like shield displays low heat flow value but relatively younger terrains exhibit high heat flow, implying that the ancient shield is cold and the HDR sites should be located in the younger terranes [8]. Elemental determination results suggest that ancient basement rocks are easily exposed and eroded, which result in the loss of mobile radioactive elements U, Th and K. Therefore, the Precambrian basement rocks generally display low volumetric heat production rate and geothermic gradient. As an example, the Sweden Fjällbacka HDR project is located in the Precambrian (about 920Ma) crystalline bedrock with low heat flow density of 35-65 mW/m^2 and temperature gradients of 10-18 °C/km [9]. Based on these conditions, we suggest that Fjällbacka HDR project is not suitable for generating electric power. In fact, the Sweden government has ended it in 1989.

Geochemistry constraints

The heat sources of HDR are predominantly stemmed from the long half-life radioactive elements U, Th and K, which are incompatible and easily concentrated in continental crust. In this regard, the mantle-derived rocks are generally depleted in U, Th and K, while crustally-remelting granites are commonly enriched in U, Th and K [4]. It is noted here that not all but a small proportion of crustally-remelting granites can be used to abstract HDR geothermal sources. Generally, the right HDR basement rocks display high K_2O/Na_2O ratios larger than 1.0 belonging to the K-rich granites, and show U, Th and K peaks in the primitive-mantle normalized trace element diagrams. The thermal ability of basement rocks can be evaluated by volumetric heat production rate. On the basis of previous data, it is proposed in the present study that the granites can be used to develop HDR geothermal resources when their volumetric heat production rates are equal to or larger than 5.0 μW/m^3 [5].

Conclusion

Coupled analyses from petrology, geochronology and geochemistry for HDR basement rocks suggest that young or Phanerozoic especially Mesozoic and Cenozoic S-type or crustally-derived granites with high U, Th and K contents have great potential to develop HDR geothermal resources. However, as is stated above, a right HDR site should be composed of basement rocks and cover sedimentary rocks or sediments. The feature of cover sedimentary rocks or sediments is another subject in the next study.

Keywords: FuYu oil layer; Yang DaChengZi reservoir; reservoir pore space; reservoir permeability; diagenic metamorphism of reservoir.

Abstract. Using a large number of core, logging and seismic data, on the basis of sequence stratigraphy, reservoir geology, sedimentology, such as theory, the San Zhao peripheral zone were studied. FuYu reservoir is studied and Yang DaChengZi reservoir structure of reservoir. Based on coring well cores observation and rock thin section, casting thin sections and scanning electron microscopy (sem) analysis techniques, such as the SQ3–Y1 a sedimentary period main sedimentary, main lithological types, and different oil reservoir is studied.

Regional Geology Overview

San Zhao surrounding the zone through years of exploration, the principal part of the construction of a total of exploratory well, evaluation Wells and development Wells, seismic exploration degree is higher, the basic is covered by 3 d seismic.The main purpose of the study area layer to help Yang oil layer. Fu Yang oil reservoir pore types as follows: primary intergranular pore, narrow primary intergranular pore, dissolution to expand intergranular pore and intragranular dissolved pore, mold holes and cracks.Various pore types, Fu Yang oil reservoirs are mainly composed of secondary pores.

Reservoir petrology characteristics

Reservoir petrology characteristics mainly reflect reservoir sandstone of compositional maturity and structural maturity, is to control the reservoir physical property of original sedimentary conditions and evaluation index, at the same time affect the reservoir in the late diagenesis and diagenetic evolution.

2.1 Fuyu oil layer

FuYu reservoir rock types in the delta plain sedimentary grey lithic feldspar sandstone (powder), a small amount of transition to feldspathic lithic sandstone .The feldspar content is 25%~45%;Quartz content is 12%~42%;Cuttings content is 16%~62%, the Yang DaChengZi reservoir rock debris content increased slightly, the average is about 32%. Lithic types are mainly acidic extrusive rock cuttings and metamorphic rock cuttings. Through the casting thin sections, rock thin sections and scanning electron microscopy (sem) analysis shows that the rock-good sorting, rounded way round - edge is given priority to. Cement and mixed base content and features similar to Yang DaChengZi reservoir. Overall, FuYu reservoir sandstone rock particle size, structure and composition of medium-low maturity of petrology characteristics.

2.2 Yang DaChengZi reservoir

Through core observation and microscopic microscopic analysis showed that Yang DaChengZi reservoir rock types in fluvial facies sedimentary grey lithic feldspar sandstone (fine) quality is given priority to, a small amount of transition to feldspathic lithic sandstone .The feldspar content is 27%~47%; Quartz content is 24% ~36%; Cuttings content is 22%~48%, lithic types are mainly acidic extrusive rock cuttings, followed by metamorphic rock cuttings. Rock-good sorting, rounded way round-edge is given priority to. Calcite and argillaceous cement development, content is generally greater than 10%;Impurity content of the base is less, generally less than 5%.In general, Yang DaChengZi reservoir sandstone of rock fine granularity, structure and component maturity middle-class petrology characteristics.

Reservoir diagenesis and diagenetic sequence

3.1 Diagenesis

Diagenesis is one of the main factors affecting reservoir physical properties. Ro value is between 0.5%~1.3%, and in the study area is in A rock up phase.

3.1.1 Compaction

In the study area, sandstone reservoir, shallow buried depth overall, general distribution in the range 1200 m to 2400 m depth, compaction degree is weak, grain contact relationship to a point-line contact is given priority to, residual intergranular pore is development. With the increase of buried depth, occasional line contact, concave and convex contact, plastic debris was compaction deformation and the plastic debris is compaction are false mixed base. As compaction gradually increases, characterized by primary intergranular pore, grain contact relationship closer, rock density increases.

3.1.2 Dissolution

Dissolution is mineral type and volume conversion process. Accompany the feldspar dissolution of authigenic minerals such as kaolinite and quartz are precipitated. In the study area, acidic water may come from compaction of argillaceous rock.

3.2 Diagenetic stages and diagenetic sequence

By Ro data and the microscopic analysis of characteristics of mineral, springs for A period of Three to Yao in the study area is at A rock into A subage. The main diagenetic events can be described as: The medium intensity compaction: point - line contact, a small amount of concave and convex contact; The plastic debris compaction deformation; Primary pores gradually reduce, compaction residual intergranular pore. Late calcite cementation development: rich calcium ions under CO_2 involved in the formation water in occur between pore precipitation, precipitation of calcite.

In conclusion, early diagenetic sequence can be summarized as follows: compaction-calcite cementation-feldspar dissolution-calcite replacement of silica particles-occasional lysis pressure-a small amount of quartz overgrowth and surrounding particles of illite and chlorite envelope.

3.3 The reservoir pore type and pore evolution

Based on key Wells in the study area the casting thin sections and scanning electron microscope, spring for a period of three to Yao sandstone reservoir space types of the reservoir is given priority to with residual intergranular pore and dissolution pore, microfracture rare.

Overall, the changes of pore types in the study area from top to bottom is: the primary pore is given priority to, mixed pore, secondary dissolution pore. Transformation of influencing pore types and diagenesis are: the damage of calcite cementation, compaction, clay mineral formation and transformation; Improve the role of feldspar dissolution.

3.4 Reservoir control factors analysis and evaluation

Through the study of a mere 273 Wells in the core physical property data analysis, reservoir quality differences between different reservoir is obvious.

Table 1-1 Reservoir classification evaluation standard

Reservoir classification	Porosity (%)	Permeability (mD)	Reservoir space	Exploration results	Evaluation
	>12	>0.5	Intergranular pore,intragranular pore,fracture	Found oil gas fields	good
Ⅱ	8~12	0.1~0.5	Intergranular pore,intragranular pore,fracture	Found oil and gas fields	preferably
	5~8	0.01~0.1	Intergranular pore and fracture	Oil and gas showsgood	general
Ⅳ	<5	<0.01	Intergranular pore and fracture	Trace gas show	poor

3.4.1 Fuyu oil layer

FuYu reservoir buried depth is mainly for the 1600 m to 2000 m, is under FuYang DaChengZi reservoir significantly. Porosity is mainly distributed between 5% ~ 20%, average 12.1%.Permeability is generally less than $10\times10^{-3}\mu m^2$, with a mean of $13.82\times10^{-3}\mu m^2$. Strongly the cementation of FuYu oil reservoir property significantly lower than the overlying putaohua oil layer, and Yang DaChengZi reservoir.

By studying FuYu oil layer thickness of single sand body statistical histogram can be seen, FuYu oil layer thickness of single sand bodies are mainly distributed in 1~2 m, about 41%, the second is less than 1 m single sand body, accounted for 36%, on the whole the thin sand body dominant, but these sand body vertical superimposed each other and accumulated considerable thickness.

3.4.2 Yang DaChengZi reservoir

Yang DaChengZi reservoir porosity is mainly distributed between 5% ~ 15%, the average of 10.8%.Permeability is generally less than $10\times10^{-3}\mu m^2$, with a mean of $1.8\times10^{-3}\mu m^2$.

By carbonate content and depth of diagram analysis shows that in the 1900 m and 2200 m or so, appear unusually high value with two carbonate content corresponding to the porosity and permeability of low-value belt, with dense calcite cementation. Carbonate content and porosity is very good relationship, shows that the decrease of porosity in the study area is closely related with calcite cementation.

Conclusion

(1) FuYu oil layer due to the intense calcite cementation have a poor reservoir property, and the underlying Yang DaChengZi reservoir reservoir property.

(2)The physical properties of the reservoir in the study area are mainly controlled Yu Changshi selective dissolution and compaction.

(3)The feldspar dissolution and calcite cement difficult soluble or insoluble;Kept good for weak compaction, primary pore and the late acid dissolution in water easily into the rock.

(4)Use of FuYu reservoir strata slice technology can obtain the key layer of shallow water delta sand body distribution characteristics and Yang DaChengZi reservoir river sedimentary sand body distribution characteristics.

(5)In the shallow water delta distributary channel, underwater distributary channel sand body and fluvial channel sand body distribution range is wide, vertically superimposed each other, on the transverse fault fold shall, constitute a favorable oil and gas reservoir.

Keywords: Coal's green mining; Technology roadmap; Jurassic coalfield of northern Shaanxi

Abstract. Jurassic coalfield in northern Shaanxi is a typical ecologically fragile area. In recent years, with the rapid development of coal mining industry in this area, the environmental problems were caused by coal mining have become so serious that threat seriously to the sustainable development of northern Shaanxi. In this paper, the research team use multi-round expert seminar to design a coal's green mining technology roadmap(CGM-TRM) for Jurassic coalfield of northern Shaanxi, which will provide a macro guidance for related government, institutions and enterprises, and produce wide range of utility in relevant R&D activity.

Introduction

As a kind of low cost energy, coal play very important role in China's energy security and economic development, but with the continuous expansion of coal development in China, the environment destruction that caused by coal mining is highlighted, and has become serious problem that not only constrained healthy development of china's coal industry, but also seriously impact the sustainable development of coal area. So realize the green mining of coal is an important measure for scientific development of coal industry in China, also is the only route which must be passed to realize sustainable development in coal-rich regions.

There are a variety of reasons that initiate the environment destruction in the process of coal mining, among them, the technical failure (it means existing technology cannot take into account both efficient exploitation and environmental protection) is the most important one. At present, there are a lot of related research focus on the technology of coal's green mining in China, but the focus of existing research are mainly on the technology system and technology applications, for example, QIAN Ming-gao, MIAO Xie-xing, XU Jia-lin put forward the concept of coal's green mining, and analyzed the technical framework and application situation[1][2][3][4], ZhANG Guo-qiao,LI Gang analyzed the application of green mining technology coal in China[5], YU Xue-yi, HUANG Sen-lin analyzed the falling crack failure of overburden strata of shallow coal seam and its control method[6], WANG Shuang-ming, HUANG Qing-xiang, et al put forward the water protection mining technology based on the regionalization method [7], MIAO Xie-xing, ZHANG Ji-xiong, et al analyzed the waste-filling method and its application in fully-mechanized coal mining[8]. In contrast with the above research, the research on the technology foresight and R&D planning of coal's green mining is very lack in China, especially the coal's green mining technology roadmap (CGM-TRM) is still blank. Therefore, it is necessary to research and design CGM-TRM for strengthening the foreseen and planning of coal's green mining technology according with the real situation of typical mining area.

The general situation in the study area

Jurassic coalfield in northern Shaanxi, that is one of the seven major coalfield in the world, is located in the northern six counties of yulin city, namely Fugu, Shenmu, Yuyang, Hengshan, Jingbian and Dingbian, that covers an area of 27000 km^2 and buried 138.8 billion tons of proved reserves of coal resources, that accounts for about 53.5% of total amount of coal resources in

Shanxi Province. Since the turn of the century, has not yet been used 131.5 billion tons. Since the turn of the century, Jurassic coalfield of northern Shaanxi has entered into the phase of large-scale development. In 2009, China's central government set up 13 large coal base, among them, the main part of "Shaanbei" and "Shendong" base located in the Jurassic coalfield in northern Shaanxi. Up to now, the accumulative production of coal amount to 6.17 billion tons in this coalfield. In 2012, the coal output of Jurassic coalfield in northern Shaanxi amount to 300 million tons that accounting for 8.19% of the total coal production in China. This above shows that Jurassic coalfield of northern Shaanxi has become one of the most important coal base of China to support China's modernization construction, and will play an indispensable strategic role in the national energy security system.

In recent years, with a large number of coal resources was developed, the ecological environment destruction of the Jurassic coal field of northern Shaanxi is becoming more and more serious. In this coal field, Gob area is continuously expanding that cause the serious surface subsidence disaster, and destruct of the earth's surface buildings, land and other important production and living facilities. At the same time, coal mining also cause serious destruction of underground water resources, a large number of wells springs and stream dried up that lead a lot of ground vegetation to dying, and then raises the serious soil erosion and land desertification. For "Shenfu" mining area as an example, by the end of 2011, the coal mine gob area totaling 35446.57 hm^2, among them the subsidence area totaling 4410.8 hm^2, the underground water level of this area decrease from 1~2m to less than 31~50m, 4 rivers disappeared, lakes number reduced from 869 to 79. In Shenmu county, the area of soil and water loss is totaled 6700 km^2, erosion modulus is as high as 20-40 thousands t/km^2, soil and water loss amounted to nearly 100 million tons every year, land desertification is continuous expanding to the southeast at the rate of 0.5%/t. These above problems not only severely restricted the healthy development of coal industry in northern Shaanxi, but also serious threat the region's sustainable development.

Methodologies

Technology roadmap(TRM) is a kind of efficient tool for carry out technology foresight and R&D planning. It uses some simple form of graphics, tables and text to describe the step of technology innovation and logical relationship between them. It is useful to assistant the users to clear the technology development direction in specific technology areas, to identify the key technology, and to foresee the technical bottlenecks, and to choose suitable strategy for technology innovation. At present, TRM has been acknowledged as one of the basic tools of R&D management for government, institution and enterprises.

Execution flow of CGM-TRM. The research and develop of CGM-TRM of Jurassic coalfield in northern Shaanxi including four stages, it is as shown in table 1. In the first stage, the preparatory work for designing CGM-TRM was carried out by research team that including establishing expert database, formulating research plan and field investigations, etc. In the second stage, the first expert seminar was carried out to discuss the present situation and problems existing in the coal mining of the Jurassic coalfield of northern Shaanxi, and to set up the goals of CGM-TRM. In the third stage, the second expert seminar was carried out to select key technologies of CGM-TRM, and to analyze the possible bottleneck of key technologies, and then to discuss the strategies for breaking through the technology bottlenecks that including R&D project and R&D organizer, R&D schedule and R&D mode, etc. In the fourth stage, the first version of CGM-TRM was prepared by research team, and it was audited by the third expert seminar, and then according to the expert's opinions, the final CGM-TRM was formulated by the research team.

Tab 1 The Execution flow and method of designing CGM-TRM

Stage	Work Contents	Methodologies
1	Establishing expert database, formulating research plan and field investigations	Literature analysis, Questionnaire survey, Field investigation
2	Analysis of the present situation and problems, and set the targets of CGM-TRM of the Jurassic coalfield of northern Shaanxi	Expert seminar, Scenario analysis
3	Selection and analysis of key technology， and R&D strategy analysis	Questionnaire survey ,Expert seminar
4	CGM-TRM preparation, review and revision	Expert seminar

Targets setting. The target setting is the precondition for selection of key technology, thus it is the foundation for CGM-TRM designing. According to the resources occurrence and mining conditions in the study area, the research team grasps the status quo of R&D and application of related technology by literature analysis, questionnaire survey and field investigation. Based on the above works, the targets of CGM-TRM were determined by expert's opinion, that include establishing technological system of coal's green mining of Jurassic coalfield in northern Shaanxi from two aspects of feed forward prevention and environmental restoration, from 2013 to 2020 ,the subsidence damage reclamation rate reach 85%, the mine water utilization rate reach 100% and the waste rock and other solid waste utilization rate above 80%.

Key technologies analysis. Key technologies analysis, which mainly includes three contents namely key technology selection, technology bottleneck analysis and R&D project setting in this study, has been completed by the second expert seminar. According to the expert's opinion, water-preserved coal mining technology, filling mining technology and ecological restoration technology in subsidence area were selected as key technologies firstly, then the bottlenecks of every key technology were listed in detail, and then the R&D projects for breaking through the technology bottlenecks are designed respectively, the result of key technology analysis are listed in table 2.

Tab2 Key technologies analysis of coal's green mining of Jurassic coalfield in northern Shaanxi

Key technology	Technology bottlenecks	Project
Water-preserved coal mining technology	● Detailed exploration of hydrologic condition in mining area ● The influence mechanism of different mining method on water-resisting layer ● The technical specifications of water-preserved coal mining technology	◆ Detailed exploration of hydrologic condition in mining area ◆Research and design the specifications of water-preserved coal mining technology ◆ Demonstration project construction of water-preserved coal mining technology
Filling mining technology	● Low cost filling materials ● Filling equipment system that matching high-efficient coal exploitation mode	◆ Low cost filling materials ◆ High speed filling material transport system ◆ Integration hydraulic support for working face support and filling ◆ Industrial test and demonstration project construction of filling mining technology system
Ecological restoration technology in subsidence area	● Land reclamation technology in subsidence area ● Ecological reconstruction technology in subsidence area	◆ Experimental research of land reclamation and ecological reconstruction technology ◆ Comprehensive ecological restoration mode research of subsidence disasters

R&D strategies analysis. R&D strategy analysis, which also mainly includes three contents namely determining R&D organizers, designing R&D schedule and selecting R&D mode in this study, has been completed by the third expert seminar. As far as R&D organizers is concerned, there are one project should be organized by government, five projects should be organized by related university and institution, three projects should be organized by coal mine enterprises. In aspects of R&D schedule, the kind of technology R&D projects should be completed within 2-3 years, and the kind of industrial test and engineering demonstration project should be completed within 3-4 years. In the aspect of R&D mode, there are two projects should use technology introduction, three projects should use independent innovation, and four projects should use cooperative innovation. The R&D strategies are shown in the table 3.

Tab 3 R&D strategy analysis of key technology in CGM-TRM

Key technology	Project	Organizer	Schedule	Mode

Results

Based on two round expert seminar, research team draw up the first vision of CGM-TRM. After this, the third expert seminar was carried out to audit the first vision of CGM-TRM, according to the expert's opinion, research team modified the CGM-TRM correspondingly, then the final CGM-TRM were completed, it is shown in figure 1.

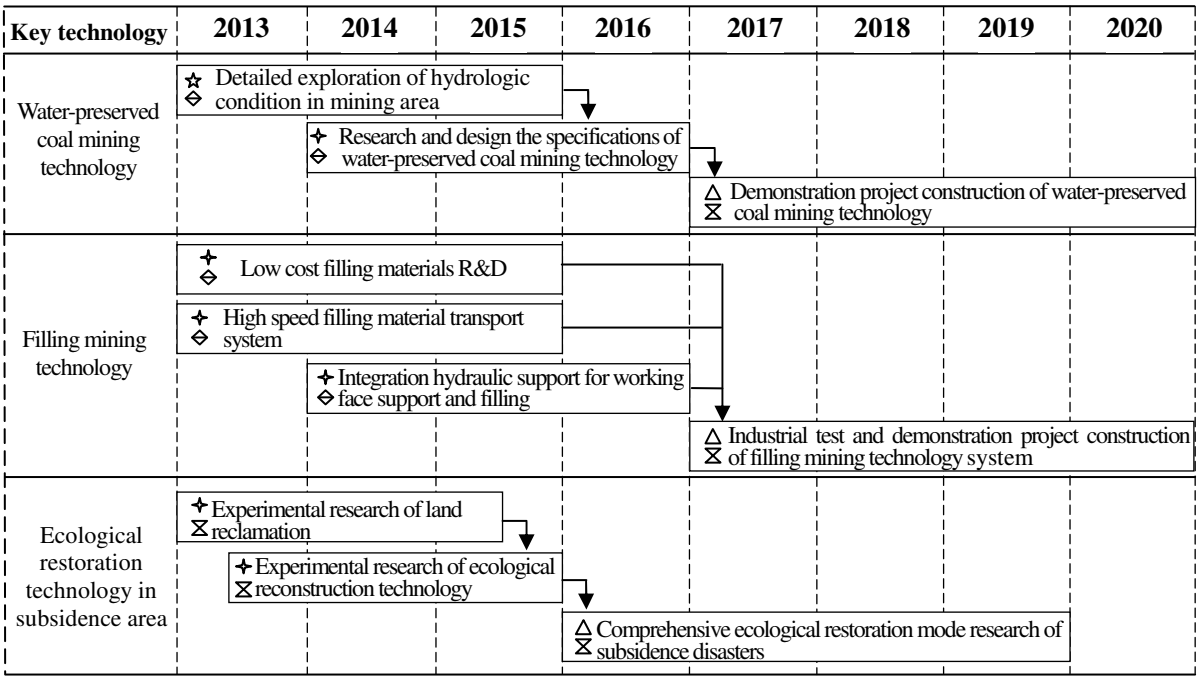

Fig 1 The CGM-TRM in Jurassic coalfield of northern Shaanxi: 2013-2010

Conclusions and Discussion

In this paper, the CGM-TRM of Jurassic coalfield in northern Shaanxi was designed by multi-round expert seminar, in which the key technologies and its R&D strategy were analyzed detailed. It will provide macro guidance for coal's green mining technology innovation, and help related governmental departments, institutions and enterprises to make clear the direction of future coal's green mining technology needs of Jurassic coalfield in northern Shaanxi, then help them to develop reasonable R&D plan accordingly for optimizing the allocation of innovation resources.

In next stage, an important work is to communicate the CGM-TRM with government departments, related institutions and enterprises, to reach a consensus in a wide range of relevant subjects. At the same time, as far as a lot of uncertain factors in the process of R&D as concerned, it is necessary to update and adjustment the CGM-TRM according with the changing conditions.

Keywords: mineral dust, disaster, dust collection, prevention and control

Abstract. With the development of modern coal mining equipment, high-yield, high efficiency, high-speed mining technology was achieved, but also a sharp increase in the amount of dust generated in the mine at the same time, it damage workers health and bring insecurity to mine production. This paper has summarized the existing domestic and international prevention and control technology of dusts, elaborated mineral dust prevention and control work from the dust control, dust generation and dust diffusion three major aspects, and noted that the current technology trends.

Introduction

Mine dust is the inevitable outcome of the mine production and construction process, is the general term for all kinds of particles, but also led to one of the main mine production disasters. Mine dust bring hazardous to workers' health workers, cause pneumoconiosis, affect work efficiency; accelerate wear of mechanical equipment, reducing the life of some of the instruments; impede vision worker increases the occurrence of accidents; even some mineral dust (such as sulfide dust, coal dust)can explosive, have a serious threat to mine production safety.

Pneumoconiosis is the most serious occupational disease in our country and the majority of patients are mine workers, but people do not have enough hazard awareness on mine dust. A large amount of mine have less investment on preventing and controlling technology of dusts. Make mine dust prevention theory and application technology research is relatively weak, and less using. So far there is no complete set of prevention and control system and adequate attention.

Dust source control

Coal dusts mainly be produced in heading and wining faces, a large number of coal dusts would float in the face, hinder the normal production and harm the operator if don't take any dust control measures, so it is need to take appropriate measures to control and reduce mine dusts in heading and wining faces.

Coal seam infusion. In the coal body in advance before playing a number of drilling in coal mining, injection pressure water into the interior of coal, increasing moisture and reduce coal dust generated during mining. Practical experience has proved that water can get to a certain coal dust suppression effect, this method is also used in many coal mines abroad. Our preliminary trials to date, coal injection devices have a theoretical and rapid changes, accumulated a lot of experience.

Factors affecting coal seam water effects are follows: wetting properties of liquids, coal gas pressure and internal gas pressure on coal, cracks and pores of the degree of development and injection parameters. Injection parameters including injection pressure, velocity, flow, time and drilling depth, spacing, etc.. Different coal corresponding to different water parameters, they can be determined in accordance with successful experience of the same coal face reality. Injection equipments consist of drilling rigs, pumps, sealing, splitters, etc., the achievements have been developed in Xi'an branch of Coal Academy can be resolved into soft coal seam drilling equipment porosity problems, Chongqing branch of Coal Academy developed the coal mine linkage hydraulic drilling rig, and so on.

Chemical inhibitors. Chemical inhibitor is an aqueous solution when the additive injection coal, the purpose is to reduce the surface tension of water, reduce the polarity of the water, and enhance the dust trapping ability of the coal to improve wetting effect and strengthen the dust. Chemical inhibitors, also known as wetting agents, it can improve the effectiveness of coal seam water injection. WANG Huibing, who at the time of injection Yaoqiao conducted tests and found that after adding a wetting agent, injection speed increased, injection pressure reduced, the moist scope of coal expanded and water incremental increased, removal rate is improved and for the more obvious effects of respirable dust[1]. Development of new chemical inhibitors has made a lot of achievements in recent years.

Mining dusting

In the mining and tunneling face, coal continue to be destroyed, a large amount of dusts in the process of fragmentation, so it is need to take measures to collect dusts. Coal mining processes mainly have blasted mining, conventional mining and mechanized mining, according to the principle of the destruction of the coal dust to arrange different measures.

Water stemming blasting. Water stemming blasting is a new technology blasting that uses a special bag filled with water instead of solid stemming explosives filled in the front and rear. When blasted, water was atomized under high temperature and pressure into water vapor and fine water droplets to spread around rapidly penetrate into the coal weight, adsorbed gases and capture dust, which can reduce the harmful gases and dust concentration, but also have the flash suppressor, a cooling effect on the gas mines[2]. Notably PVC bag may generate new harmful substances in the explosion, the harmful to the human body should to be discussed and studied further.

Spraying dust technology. Water sprayed from nozzle with the help of pressure facilities, the water is atomized into fine droplets sprayed in the air, the movement of water droplets collide with dusts and moisture they to be dust-laden water droplets and sink under gravity; adhesion dust particles fall into pieces and make it difficult flying.

Air curtain dust technology. The air curtain is a transparent wall, formed by the use of strip-shaped slit blowing air jet wind, isolating contaminants to protect the health conditions of the workspace. In life there are widely used, such as the use to prevent mosquito flying into the kitchen. Air curtain was installed at the shearer to jet air to prevent the driver from the proliferation of cutting coal dust. Air curtain isolation technology is also applied in the heading face, Mainly have two forms of air nozzles and mural chimney. Air nozzle is similar to air curtain in shearer to form air wall. The air of mural chimney generated wall attachment effect, changed the axial wind into rotating wind in the section tunnel of heading face, and built air curtain to block the dust in front of the machine driver[3].

Dust diffusion controlled

Water curtain purification technology. Water pipe in the tunnel at the top or at the side, is provided with a plurality of sprays on the water pipe, the water curtain was jet by sprays to capture mine dusts. So the sprays shall be arranged so that the water curtain covered the whole cross section of tunnel. Water curtain can be arranged in the gateways of the full-mechanized caving faces and the driving working faces and other dust generating sources. Increasing the number of water curtain can improve the cleaning efficiency. According to mine conditions, water curtain spray can use the automatic mode of photoelectric and touch.

Precipitators. High efficient dust precipitator is so large that is unsuitable to be installed directly on the shearer and tunneling machine, usually installed in the return airway and into the face. At present, The dust collector in mine commonly used with SCF series fan, MAD series air purifier, KGC series dust tunneling machine and PSCF water jet fan etc[4]. They can be divided into dry dust remover, wet scrubbers and electrostatic precipitators three categories. Dry dust removal methods are gravitational settling, inertial dust, centrifugal dust removal and filtration. It needed to clean the collectors regularly, otherwise they would be blocked by dust and reduce

efficiency. Wet dust collector consumes a large amount of water, and sewage treatment, with low operation costing mine which have lots of water. Electrostatic precipitator dust removal efficiency is high, but the installation requirements are strict, need to consider the dust properties, installation conditions and economic cost. All series of precipitators can be divided into dry precipitators, wet scrubbers and electrostatic precipitators three categories. Dry dust removal methods are gravitational settling, inertial dust, centrifugal dust removal and filtration, to be timed for the dust to clean, to prevent dust collection efficiency decreases blocked. Wet scrubber water consumption and waste water to be treated, lower operating costs and more mines in the water. Electric precipitator have high efficiency, but the installation demanding is strict. Advantages and disadvantages of three types of dust, dust to be based on the nature of the site, installation conditions, considering the economic cost options.

Ventilation dusting. Ventilation dusting is using airflow to dilute and exhaust mineral dusts of air in operating site. The main factors of affecting the efficiency of ventilation dusting are the properties of wind speed, mineral dust density, particle size and so on. According to mineral dust choose the best wind, which can maximize exclude dust without causing secondary dust flying. The maximum wind speed in heading face specified in the "Coal Mine Safety Regulations" is 4m/s. Ventilation dusting systems about heading face has far-pressing-near-absorption, far-pressing and far- absorption -near- pressing can be selected according to production status and technical conditions of the mine. Ventilation dusting and dust catcher are often used together, for example, that dust catcher installed on extraction fan can greatly reduce dust exclude gas dust content in the heading face; with series ventilation underground, dust collector can guarantee the air quality of the next face in air return laneway in the coal face. In pressure and exhaust ventilation system, the layout of fan, air duct and dust catcher should be right, and arrange the air volume between pressure and exhaust ventilation system reasonable.

Individual Protection. The individual Protection is to reduce the inhalation of dust by wearing a variety of protective equipment. Although a series of measures are taken in the dust prevention and reducing of mine, there will be a small amount of fine dust whose concentration exceeds in some places suspended in a roadway, so individual protection is indispensable as the last checkpoint that prevents dust damage. Individual protection equipment mainly include dust mask, dust respirator wind, dust cover and so on, to let the workers wearing can breathe clean air and work normally.

Dust control is also a main measure to prevent the coal dust explosion, but from the governance of the coal dust explosion condition, it is necessary that measures are taken to prevent the coal dust burned, for example, exercise strict management over possible fire. To prevent and reduce the harm of coal dust explosion, measures of reducing the explosive power and the explosion range are also taken, including, regular cleaning the dust to prevent deposition of coal dust in explosion reaction, regularly spreading some inert powder in some tunnel to increase the ash of coal dust deposition, setting the flameproof shed to quickly absorb heat, eliminate fire and reduce the impact and so on after the coal dust explosion.

The trend of mine dust hazard control

Mine dust monitoring system used in mine will realize the networked, real-time online and intelligent development, in which the performance of dust concentration sensor is improving, and the instrumentation can automatically analyze the rule the generation and movement of mine dust. Monitoring can realize remote control and intelligent control, such as the spray system and flameproof shed automatically spraying according to the monitoring data. Mine dust monitoring system will share monitoring circuit and control platform with other monitoring system to realize the resource sharing. People will continue to study the water injection technology, equipment and technology of hard in-seam water infusion to promote the existing water injection process into automation development; improve the automation and standardization of spray dusting, do research in the formula of efficient environmental chemical inhibitor and its proportion technology, automatic feeding, the technology and its equipment of water quality filter technology; strengthen the research on the process of shearer and driving machine to reduce dust generated during the

production; actively introduce and digest the domestic and foreign advanced dustproof technology and apply foam dust[5], dust cylinder, ultrasound dust, magnetic dust in the production; strengthen the management of personnel and equipment, and develop comprehensive dustproof standard specification.

Conclusion

In view of the relationship between numerous dust control technology and the physicochemical properties of dust, the paper does testing and analysis of dust around the working face before making dustproof job. It is necessary to test and analyze the nature of true density, specific surface area, dispersion, surface tension, contact Angle, the optical properties, wettability and charged, etc. Then, based on the nature, the paper chooses different dustproof technique and technology.

Keywords: SRV; CBM; natural fracture; in-situ stress; brittleness index.

Abstract. In our country there is plenty of CBM (coalbed methane), but the state of CBM itself, unique output mechanism and low saturation, low permeability, low reservoir pressure and high gas content, et al. determine the low efficiency of it, so in order to improve CBM recovery, combined with the successful experience of north American shale gas reservoir by SRV(stimulated reservoir volume), the writer summarizes the implementation of SRV, deeply analyzes effectiveness and limitations of this new technology in CBM development. The results of practical research and theoretical analysis show that SRV in the coal reservoir can achieve the desired effect on the condition that there are great quantity of natural fractures, joints and bedding, weak structure surface development in the reservoir, the rock brittleness index is greater than 40 and horizontal principal stress difference is relatively smaller. Finally, simulating a well's condition by the MEYER software, the result shows that SRV is feasible in coal reservoir, which will create important guiding significance and practical value for the exploration of CBM.

Introduction

Our country is very rich in coalbed methane, but the low permeability of itself rusults in the low efficiency and poor economic, which means most wells must take measures such as fracturing stimulation to improve the reservoir flow capacity and thus achieve better economic. At present, the most common method is the conventional stimulation hydraulic fracturing technology by forming a single symmetrical wings cracks and complex "T" type joints, etc. to improve the flow properties of the reservoir. However, its effect is so insignificant that creativereform and innovation is necessary and urgent. Recently, SRVas a new technology has made remarkable achievements in the oil and gas exploration, especially in shale gas, which will creat a good inspiration for Coalbed methane exploration and development.

This paper proposes the conditions for SRV and analyses the effectiveness and limitations of SRV in coal reservoir combined the successful exploitation of the experience in North American shale gas; finally, takes a coalbed methane well for example to conduct numerical simulation software through MEYER, which confirms that SRV is feasible in coal reservoir.

Applicability of SRV

Being different from conventional fracturing, SRV refers to reconstructing reservoir during hydraulic fracturing, communicating simultaneously natural fractures through the man-made main cracks(fig.1), therefore three-dimensional fracture networks in which natural fractures and artificial fractures intersect is made to increase SRV and improve penetration channels. In other words, the core of this technology is to achieve 3D transformation and generate large-scale reticular flowing channel.

On the basis of the results of previous studies, the author puts forward the suitable conditions from natural fractures, the mechanism of reservoir rock composition and mechanical joints network structure: ①abundant natural fractures are queite necessary for SRV. When

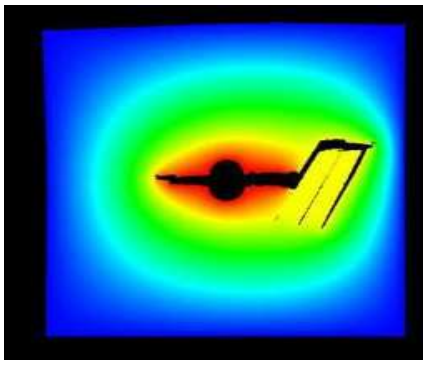

Fig.1 Seam network formation process schematic

implementing hydraulic fracturing,it can creat secondary seams as well as main cracks extending to three dimensions, which communicate natural fractures effectively.Besides, the higher the degree of development of natural fractures are, it is much easier to form complex network systems within the formation relatively. ②high content (greater than 35%) of Siliceous and high brittleness index is the material basis of SRV. In general, the higher the content of siliceous rocks are, the stronger its brittlenessis, higher consolidated Young's modulus is, the lower Poisson's ratio is, so it is far more prone to fracture failure of the reservoir. A large number of empirical data show that when the brittleness index is greater than 35, a wide crack fracture zone can be formed within reservoir; the reservoir system is easy to form a network of cracks on the condition that brittleness index is greater than 40. ③little difference betwween formation horizontal principal stresses is the basic prerequisite for SRV. It has been studied that situ-stress magnitude and orientation determines the orientation and shape of the artificial crack. As cracks always initiate and extends along the direction of maximum horizontal stress, it is easy to form a single main fracture morphology with large horizontal principal stress difference while it tends to form reticular cracks in the system.

Currently, the western has successfully develop this technology in dense shale gas, oil shale and sandstone gas and its mining efficiency has beed improved significantly, especially in the Great Basin USA 5 Fort Worth, Illinois Basin it has been close to maturity. In contrast, this technology in the domestic shale gas as well as in hypotonic, low permeability reservoirs is still at an initial stage.

Analysis on the Feasibility of SRV in coal reservoir

The characteristics of coal reservoir "three low and one high (low porosity and low permeability, low reservoir pressure and high saturation),"as well as the mode of occurrence of coalbed methane determine that fracturing process is the key of coalbed methane exploration stage.

According to the mechanism of CBM reservoir, its mining process can be summarized as Desorption-Diffusion-Seepage-Shaft output of these four stages. Among them, the flow control process is rather decisive of coalbed methane output, therefore to maximize communication between the wellbore fracture and the degree of connectivity is the most effective way to obtain high yield for single well. In addition to that, practice in field shows that low permeability in coal reservoir has dominantly limited the yield of CBM. As can be seen from the simulation results shown in Fig.2 that within the same time the larger coal reservoir permeability is, gas flows farther and corresponding the higher economic productivity is. For the reason that, in order to maximize the benefits of the exploitation of coalbed methane wells, the shortcut is to improve the flow properties of the reservoir, that is to say implementing SRV technology.

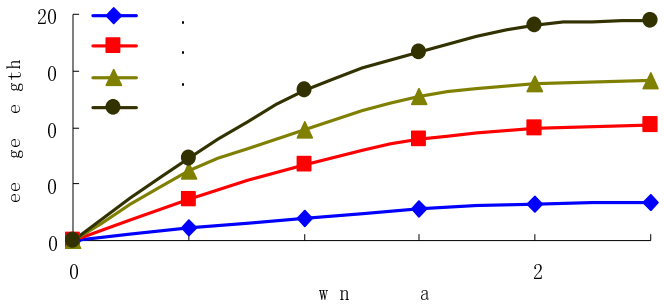

Fig.2 Different fluid flowing characteristic curves within the reservoir

Coal reservoir rock, as a feature with multiple fractures extensively develops vertical, group-based natural fractures, joints and bedding, etc, thence through SRV the produced multi-level secondary cracks cross effectively the original natural fractures, which leads to the formation of large-scale fracture network system.Apart from that, in the implementation of fracturing, coal reservoirs under high level of principal stress difference is prone to produce straight hydraulic fractures while under low stress conditions it tends to creat radial extension of the fracture network structure.

However, there are many disadvantages.At first, high content of clay minerals in the coal makes brittleness weak, whicn brings much difficulties in initiating fractures. Then, lots of cracks in reservoir makes it easier to fracturing fluid filtration, which clogs pores of the reservoir and swells the matrix. Finally, the soft texture of coal is prone to plastic deformation under external force and proppant embeds the formation of interna easily, all of which contributes to formed cracks with low conductivity capabilities.

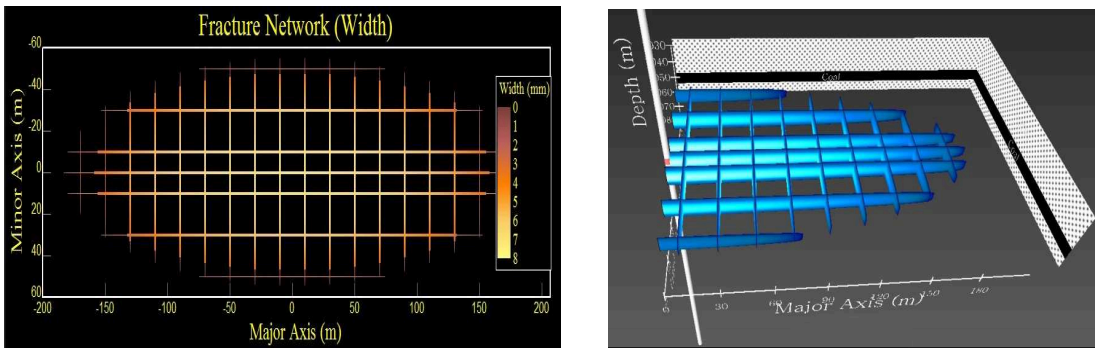
Numerical simulation

Take a coalbed methane well in Linfen City, Shanxi Province for example to carry out numerical simulation by MEYER Software. The mechanical parameters of this well is in Table 1.

Table 1 Mechanical parameters of the target layer

Depth/m	1051.55m~1058.50m	σ_v/MPa	25.5
σ_H/MPa	18	σ_h/MPa	16
p_p/MPa	10.5	σ_t/MPa	1
E/MPa	6000	υ	0.36

Simulation results from fig.5 show that three-dimensional network of complex joints in the coal reservoir is successfully formed. Based on the results of data, SRV is up to 140m^3 which is 5 to 8 times the volume of conventional hydraulic fracture; besides, the length of fracture network extends to 3564.03m and secondary sewn as the major part of the whole network system lengthen out to 3198.88m; average high of cracks is 10.33m and the average width is 3.22mm, which has already reached effective fracture conductivity standard; moreover, the surface area arrives at 36864m^2 , SRV is about 240180m^3 and the average volume fracturing efficiency reaches up to 37.113%, which basically achieves the desired effect of fracturing.



(a) **(b)**

Fig.3 Seam network plan & 3D schematic diagram

Table 2 Fracture network system parameters

	Fracture	DFN	secondary
Fracture Volume/m^3	18.395	142.567	124.169
Length/m	365.12	3564.03	3198.88
Frac Height-Avg/m	11.33	10.33	10.22
Area/m^2	4139.99	36864.27	32723.91
Avg.Hydraulic Frac Width/mm	3.7	3.22	3.16

Summary

Field practice and theoretical analysis show that the success of SRV is closely related to natural fractures' development, brittleness and horizontal stress; The higher the degree of development of natural fractures is, the greater brittleness index is, the smaller the difference between horizontal stress is, the more easily SRV forms seam network and the more significant increase the yield dose. More importantly, the numerical results indicate it is feasible to enhance CBM's production by SRV.

Keywords: Thermal discharge, phytoplankton, power plant, nuclear

Abstract. Elevated water temperatures are the major threats from thermal discharges of coastal power plants. The effects of thermal discharge from power plant on phytoplankton were reviewed. With increasing amount of nuclear power plants in China, The effects of thermal discharge from a nuclear power plant on phytoplankton were investigated. Several results and suggestions were proposed.

Introduction

There is great concern about the ecological impacts of coastal power plants on coastal waters. Elevated water temperatures and residual chlorine (anti-fouling agent) are major threats from thermal discharges of coastal power plants with the once-through cooling systems [1,2]. Thermal power plant (nuclear and fossil-fuelled) are the largest sources of waste heat, over 60% of the energy input as fuel is lost to the environment via cooling water [3]. As compared with fossil-fuelled power plants, a nuclear power plant with similar power rate discharges more waste heat, which may cause higher elevated temperature and more obvious impact on environment. With increasing amount of nuclear power plants in China, the effects of the thermal discharges from nuclear power plants on the abundance, productivity, and community composition of phytoplankton need to be studied.

Phytoplankton is the most important primary producer in the ocean ecosystem. It plays an important role in global carbon cycle, and is an important part of the marine food chain. It not only provides food for zooplankton, crustaceans, mollusks and larvae fish, but also indicates the change of sea water quality and global climate [4]. The following several important species of phytoplankton were concerned in the current studies: diatom, dinoflagellates, blue-green algae and chlorophyta.

The objectives of this study were (1) to summarize the effects of the thermal discharges from power plants on the abundance, productivity, and community composition of phytoplankton; (2) to determine the effects of the thermal discharges from a Chinese nuclear power plants on phytoplankton, and (3) to determine future work concerning effects of high water temperatures on phytoplankton.

Results and discussions

Effects of thermal discharge on community composition of phytoplankton

In the open waters, it was thought that the influence of thermal discharge on community composition of phytoplankton is limited, but when the surface temperature has a rise of more than 1.5 ^{o}C, water stratification may occur. This may affect the nutrient exchange in vertical direction, and finally affect phytoplankton and zooplankton [5]. For the closed or semi-closed waters, due to the restriction of water exchange, the higher elevated water temperatures may lead to the changes of phytoplankton community composition. In the Tampa bay (Florida), with a rise of 3 ^{o}C, blue-green algae become the dominant species of phytoplankton in seawater [6]. With the temperature increased from 0 to 10 ^{o}C, the species succession from the spring species (diatoms and dinoflagellates were the dominant species) to the summer species (autotrophic and heterotrophic flagellate as the dominant species) occurred in the south of the Baltic seawaters [7,8].

According to the study above, it was concluded that with increasing of water temperature, the dominant species of phytoplankton community were gradually changed into the species with stronger heat resistance.

Effects of thermal discharge on red tide

Phytoplankton play a key role in the assimilation of organic matter and excess nutrient inputs in the water column from farming, these primary producers are then grazed by groups higher in the trophic chain (e.g., ciliates, zooplankton, and shellfish). Nevertheless, eutrophic levels and the alteration of nutrient content composition (proportion) induce harmful algal blooms. Jiang[9] studied that in Xiangshan Bay (a subtropical, eutrophic, semi-enclosed bay), temperature elevation caused by thermal discharge associated with eutrophication resulted in a dominant species shifting from diatoms alone to dinoflagellates and diatoms. The stress-induced toxic dinoflagellate (Prorocentrum minimum) blooms in winter and the winter–spring transition appeared in this bay.

Sanmen nuclear power plant in China was situated on coast of Shanmen Bay which is near Xiangshan bay mentioned above. Therefore, there may be the similar phytoplankton community composition as Xiangshan bay. Thermal discharge of Sanmen nuclear power plant will result in the similar changes of phytoplankton community composition as Xiangshan bay, which should be given more attentions.

Tolerance temperature limit of phytoplankton

Breeman [10] pointed out that, in some species, ecotypic differentiation in thermal responses over the distribution range influenced the location of geographic boundaries. Breeman demonstrated the complexity of temperature control on the distribution of macroalgae. The differential tolerance of different life-stages as well as differential temperature requirements for processes such as reproduction was found. He states that while Amphi-Atlantic (Arctic) temperate species survived at sub-zero temperatures, southern boundaries are set by lethally high summer temperatures on both sides of the Atlantic; none of these species survived temperatures over 30^{o}C[11，12].

In the tropic areas, indian researchers studied the effects of thermal discharge from Madras nuclear power plant on plankton. The results showed that when the temperature is higher than 38.2 ^{o}C, the primary production of tropical phytoplankton was inhibited [13,14]. It was found that, tolerance temperature limits of phytoplankton in the tropics are generally below 40 ^{o}C.

Most sea areas in China are in temperate and subtropical zones, the main Chinese studies of the tolerance temperature limit of phytoplankton were described as follow. Liao et al. studied the effects of elevated temperature on the composition and the cell density of marine phytoplankton both in winter and summer. It was found that the number of phytoplankton species and the cell density were sharply reduced with experimental temperature more than 36 ^{o}C in summer (natural water temperature 28 ^{o}C) and with experimental temperature more than 34 ^{o}C in winter (natural water temperature of 12 ^{o}C) [15].

The experimental results of Zeng showed that the tolerance temperature limit of coscinodiscus jonesianus and coscinodiscus radiatus is 38 ^{o}C in summer, and only 34 ^{o}C in winter. the tolerance temperature limit of chaetoceros gracilis is 36 ^{o}C in summer, and only 32 ^{o}C in winter [8]. Yu studied the effects of elevated temperature on the growth of 10 kinds of typical phytoplankton species in the Chinese east sea. The results showed that The optimum temperature of the growth of these phytoplankton species were between 20 ^{o}C and 25 ^{o}C. When the temperature increased to 30 ^{o}C, these phytoplankton species showed very low growing rate or almost no growing [16].

According to the results above, it was concluded that the tolerance temperature limit of phytoplankton in China is mainly between 30 to 40 ^{o}C.

Effects of thermal discharge from a nuclear power plant

Daya Bay nuclear power plant is located in Shenzhen Dapeng peninsula of china. It is the second nuclear power plant built in mainland China.

Before the operation Daya Bay nuclear power plant, the water temperature of the west coast of Daya Bay was about 17.5 ^{o}C in winter and about 29 ^{o}C in summer. The annual average temperature was about 23.5 ^{o}C, water temperature distribution from the shallow coastal water to the deep water area had a decreasing trend. After the operation of the nuclear power plant in 1994, the isotherm of

17.5 ^{o}C in winter migrates to site of Dalajia. The influence of thermal discharge is more obvious in summer, the temperature of many sea areas is as high as 30 ^{o}C. The average annual temperature is increased to 23.88 ^{o}C, which has an increase of about 0.4 ^{o}C as compared with the value before the operation of nuclear power plant. The surface water temperature of the outfall of the nuclear power plant is high all the year, It is up to 35 ^{o}C in summer. The obvious difference between the surface and the bottom water temperature results in the formation of obvious thermocline. The elevated temperature zone of 4 ^{o}C is close to 2 km^2, and the elevated temperature zone of 1 ^{o}C in winter and summer are 27 km^2 and 12 km^2, respectively [17].

A large number of investigations and researches near Daya Bay nuclear power plant were performed [18-21]. It was found that the effects of thermal discharge on phytoplankton species mainly have the following three aspects: (1) In the ecological monitoring area of Daya Bay, the dominant phytoplankton was changed from warm water species of phytoplankton into a wide-temperature species of phytoplankton. The abundance of species is declining year by year. The diatoms are the dominant population throughout the year [18]; (2) In the past years, the proportion of diatom felled slightly, which was different from that of dinoflagellate. The proportion of diatom/dinoflagellates ratio was declining, which was more obvious in the summer [19]; the diversity index was significantly lower in the summer [19, 20]; (3) from 2005 to 2006, in the sporocysts of Alexandrium cysts researched the peak values in winter [21].

It was concluded that there is obvious impact of thermal discharge from Daya Bay nuclear power plant on the community structure of phytoplankton.

Conclusions and Suggestions

This paper studied the effects thermal discharge of power plant on phytoplankton. Several conclusions were proposed according to the available studies.

(1) With increasing of water temperature, the dominant species of phytoplankton community were gradually changed into the species with stronger heat resistance.

(2) The tolerance temperature limit of phytoplankton in China is mainly between 30 to 40 ^{o}C.

(3)There is obvious impact of thermal discharge from Daya Bay nuclear power plant on the community composition of phytoplankton.

(4) Thermal discharge of Sanmen nuclear power plant may result in the similar changes of phytoplankton community composition as Xiangshan bay, which should be given more attentions.

The following work need to be done in future: (1) to determiner interactive effects of high water temperatures and residual chlorine on phytoplankton productivities; (2) to compare of the effects of thermal discharge on phytoplankton and the effects of impingement and entrainment on phytoplankton.

Keywords: Nuclear power plants, radiation environment, supervision monitoring, review

Abstract. The supervision monitoring program of radiation environment around nuclear power plants is an important basis for the environmental radiation monitoring work. Key elements such as source, exposure pathway and representative person are discussed in the design of the supervision monitoring program, and technical details about the review of monitoring, evaluating and quality assurance are also given in this article. For the supervision monitoring work of radiation environment around nuclear power plants, it can provide some guidance about the review of the supervision monitoring program for nuclear safety regulators, and provide some reference about the design and revision of the supervision monitoring program for nuclear safety monitoring departments.

Introduction

The radioactive pollution monitoring system has been established in China. For the nuclear and radiation facilities, there are "dual track" managements in the radiation environmental monitoring work, the government supervision management and the operating unit management. According to article 24 of the law of the People's Republic of China on Prevention and Control of Radioactive Pollution, the competent administrative department of environmental protection under the State Council should be responsible for the supervision monitoring of important nuclear facilities such as nuclear power plants.

The supervision monitoring work of nuclear power plants consists of two parts: the external radiation environment supervision monitoring and the radioactive effluent monitoring. At present, because of absence of related technical standards of the supervision monitoring, monitoring project, point and frequency are significantly different between nuclear power plants [1-2]. While taking into account the feedback of Fukushima nuclear accident experience and combing with the actual situation of existing supervisory monitoring system in China, several important questions on the review of external radiation environmental supervision monitoring program are discussed to unify and regulate the work of supervision monitoring around nuclear power plants as far as possible. It can provide some guidance about the review of the supervision monitoring program for nuclear safety regulators, and provide some reference about the design and revision of supervision monitoring program for nuclear safety monitoring departments.

Review of design information

The design information should be reviewed firstly, including the necessity and sufficiency of the description of site environment and operation situation, as well as the rationality of the source, exposure pathway and representative person [3-4].

Site environment and operation situation. The related information of the design of site environment should contain the site location information, meteorological condition, hydrologic geology, current and future land use, land resources, aquatic resources, population distribution and other important data of site environment. In addition, the status and historical trend of radiation

environment, radionuclide type, operational limits and conditions on the operating license and other important information should be given.

Source analysis. In particular, the supervision monitoring program should be designed such that radionuclides that are significant in terms of dose to the representative person are monitored. Thus, all kinds of radioactive waste gas and waste water should be analyzed, and the most critical nuclide for the exposure should be determined in the supervision monitoring program, through giving the source, release, calculation model and other parameters.

Exposure pathway. The gaseous, liquid and other exposure pathways should be given in the supervision monitoring program. Gaseous way should at least consider air immersion external exposure, surface sediment external exposure, internal radiation of inhaled air and eating vegetables, grain, milk, and meat. Liquid way should at least consider shore sediments external exposure, water immersion external exposure, waterborne external exposure, drinking water internal radiation, internal radiation of ingestion of vegetables, grain and fruit due to contaminated water, internal radiation of ingestion of aquatic organisms, internal radiation of ingestion of animal products (meat, milk) due to contaminated crops and drinking water. Meanwhile, other exposure pathways around the site those can reach or exceed 10% contribution to individual and collective dose should also be described. Through the analysis of the gaseous, liquid and other exposure pathways, the most critical pathway should be determined.

Representative person. In the operation stage of nuclear power plants, the representative person should be described, through giving living habits, diet information, resource utilization information of living place and other important information necessary to dose estimation. The information is generally associated with ages of the representative person.

Review of main content

The scope, object, point, frequency, low limit of detection and other important elements should be given a detailed review from aspects of the feasibility, rationality and regulations compliance with the law and standard.

The scope of monitoring. Supervision monitoring of radiation environment around nuclear power plants includes measurement of environmental gamma radiation level and environmental medium radiation level, and the scope of monitoring should usually satisfy: 20 km away from the nuclear power plant for the environmental gamma radiation, 10 km for the environmental medium radiation, and 30~80 km for the control point.

Monitoring objects. Monitoring objects should include terrestrial gamma radiation, gamma cumulative dose, aerosols, gases, deposition, precipitation, surface water, groundwater, drinking water, seawater, sediment, aquatic, terrestrial plants, livestock, poultry, cattle (sheep) milk, biological indicator, soil/sediment, intertidal zone and other important objects.

Sample/monitoring points. For all monitoring objects, the number, range, distance and other information about the representativeness of sample/monitoring points should be reviewed. For example, in the case of terrestrial gamma radiation, including the instantaneous monitoring and the continuous monitoring, points of the instantaneous monitoring should be:

(1) Outside the factory ground maximum concentration;

(2) In 8 cross azimuth according to the radius of 2, 5, 10, 20 km around the factory;

(3) Increased appropriately under the direction of the wind and densely populated areas [5].

Points of the continuous monitoring should be:

(1) In the range of 10 km around nuclear power plants;

(2) In 16 azimuthal uniformly;

(3) Increased appropriately under the direction of the wind and densely populated areas [6].

Points of instantaneous monitoring should take into account the continuous monitoring points, and 20%~30% overlap is generally required for the purpose of data comparison. At the same time, the supervision monitoring program should also include pre-operational monitoring of the background

levels so that the incremental contribution from the nuclear power plant can be determined. Thus, monitoring points of the terrestrial gamma radiation should be fully taken into account the consistency of survey points of pre-operation of nuclear power plants. This is particularly important with practices that discharge NORM.

Table 1 Sampling frequencies and measurement analysis projects of the supervision monitoring of radiation environment around nuclear power plants

Object	Sampling frequency	Measurement analysis project and frequency
Terrestrial gamma radiation	Quarterly	Gamma radiation dose rate, quarterly
	Continuously	Gamma radiation dose rate, continuously
Gamma cumulative dose	Quarterly	Gamma radiation dose rate, quarterly
Aerosols	Continuously	α/β , continuously
		Gamma nuclide analysis , monthly
	Accumulatively	Total α, total β, gamma nuclide analysis , monthly
Gases	Continuously	^{131}I, ^{133}I , monthly
	Monthly	^{3}H, ^{14}C, monthly
	Quarterly	noble gas quarterly
Deposition	Accumulatively	Total α, total β, ^{90}Sr, gamma nuclide analysis , quarterly
Precipitation	The precipitation period	^{3}H, ^{90}Sr, gamma nuclide analysis
Surface water	Twice a year	^{3}H, ^{90}Sr, gamma nuclide analysis, twice a year
Groundwater	Twice a year	^{3}H, ^{90}Sr, gamma nuclide analysis, twice a year
Drinking water	Quarterly	Total α, tatal β, ^{3}H, ^{90}Sr, gamma nuclide analysis, quarterly
Seawater	Twice a year	^{3}H, ^{90}Sr, gamma nuclide analysis , twice a year
Sediment	Once a year(coastal nuclear power plant), Quarterly (inland nuclear power plant)	^{3}H, ^{90}Sr, gamma nuclide analysis, same with sampling frequencies
Aquatic	Once a year	^{90}Sr, gamma nuclide analysis, twice a year
Terrestrial plants	Each month during growing season	^{3}H, ^{90}Sr, ^{14}C, gamma nuclide analysis
Livestock/poultry	Once a year	Gamma nuclide analysis, twice a year
Cattle (sheep) milk	Twice a year	^{131}I, ^{90}Sr, twice a year
Biological indicator	Once a year	Characteristic nuclide , once a year
Soil/sediment	Once a year	^{90}Sr, gamma nuclide analysis, once a year
intertidal zone	Once a year	^{90}Sr, gamma nuclide analysis, once a year

) Recommended;

) : ^{54}Mn, ^{60}Co, ^{134}Cs , ^{137}Cs, ^{144}Ce, ^{238}U, ^{232}Th, ^{226}Ra and ^{40}K are generally suggested;

3) : ^{110m}Ag is generally required.

At least, one control point should be set in all monitoring items. Control points should be under the direction of the minimum wind frequency, or up the river receiving wastewater, or in the sea unaffected by the nuclear facilities. Environments of control points and sample/monitoring points should be as consistent as possible.

Sampling frequencies and analysis of measurement projects. The frequency of monitoring and sampling should be determined by the complexity of the environment, the significance of the doses to the representative person and the properties of radionuclides. Sampling frequencies and measurement analysis projects of supervision monitoring of radiation environment around nuclear power plants are shown in table 1. According to the natural environment in different regions, monitoring items can be adjusted.

Table 2 Typical monitoring methods and low limits of detection of main monitoring projects in the supervision monitoring of radiation environment around nuclear power plants

Object	Item	Monitoring standard/method	Typical low limit of detection
Environmental radiation	Terrestrial gamma-radiation dose rate	Norm for the measurement of environmental terrestrial gamma-radiation dose rate GB/T14583-1993	10 nGy/h
Environmental media	Gamma activity concentrations of radionuclides	Gamma spectrometry method of analysing radionuclides in soil GB/T11743-1989	10 Bq/kg
		Gamma spectrometry method of analysing radionuclides in air WS/T184-1999	5×10^{-3} Bq/m^3
		Gamma spectrometry method of analysing radionuclides in biological samples GB/T16145-1995	10 Bq/kg
		Gamma spectrometry method for analysis of radionuclides in water GB/T16140-1995	1 Bq/L
	Total α, total β	Determination of gross alpha activity in water thick source method EJ/T1075-1998	5×10^{-2} Bq/L
		Determination of total β radioactivity in water Evaporation method EJ/T900-1994	5×10^{-2} Bq/L
	^{90}Sr	Analytical method for strontium-90 in soil EJ/T1035-2011	0.5 Bq/kg
		Radiochemical analysis of Sr-90 in ash of biological samples - extraction chromatography by di- (2-ethylhexyl) phosphate GB/T11222.1-1989	0.1 Bq/kg
		Radiochemical analysis of strontium-90 in water Extraction chromatography by di-(2-ethylhexyl) phosphoric acid GB/T6766-1986	10^{-2} Bq/L
	^{3}H	Analytical method of tritium in water GB/T12375-1990	0.5 Bq/L

Monitoring methods and low limits of detection. In the review of the supervision monitoring program for radiation environment around nuclear power plants, the national standards or industry standards/method should be chose, and mature methods home and abroad should be applied for the project lack of national standards and industry standards. A detailed list of standards of sampling, monitoring, analysis method and basis of the supervision monitoring program also should be given. In addition, typical low limits of detection of main monitoring projects should be given, as shown in Table 2.

Quality assurance

A complete quality assurance system should be established for the supervision monitoring work of radiation environmental around nuclear power plants, while giving detailed quality control measures.

The quality assurance system of the supervision monitoring implements a comprehensive quality management on the whole supervision monitoring process of nuclear power plants, including all activities of supervision monitoring that ensure data accurate and reliable. It mainly includes the supervision monitoring organization guarantee, equipment calibration and maintenance, supervision monitoring method validation, supervision monitoring program, supervision monitoring personnel training and exercises, supervision monitoring evaluation and quality supervision, nuclear accident supervision monitoring and sampling, laboratory analysis, monitoring data processing and result report, as shown in Figure 1.

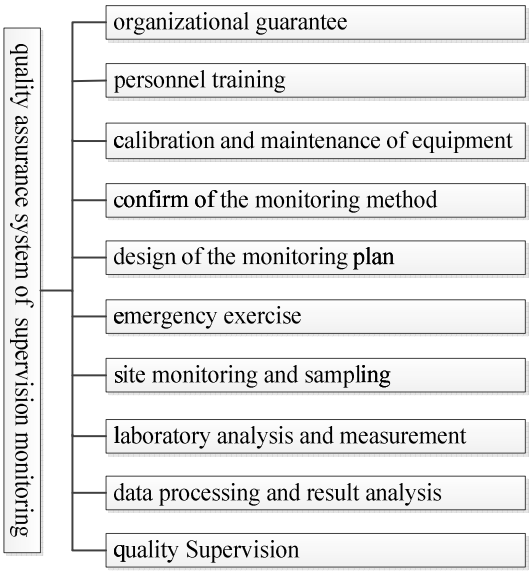

Figure1 The quality assurance system structure of the supervision monitoring in nuclear power plants

Conclusion

As an important part of supervision monitoring, through analysis of the source, exposure pathway, representative person and other key elements of the supervision monitoring program of radiation environment around nuclear power plants, technical details about the review on monitoring, evaluating and quality assurance are also given in this paper. It can provide some guidance about the review of the supervision monitoring program for nuclear safety regulators, and provide some reference about the design and revision of the supervision monitoring program for nuclear safety monitoring departments. This study will effectively promote China's nuclear power plant supervisory monitoring work around nuclear power plants and protect public health and environmental radiation safety.

Keywords: Electromagnetic environment; Substation; Transmission line; The impact analysis

Abstract. In light of the increasingly prominent environmental problems and disputes of the power transmission transformation engineering, analysis many of the environmental impact of 500 kV power transmission transformation engineering, introduce the related standards of electromagnetic environmental impact, focusing on the analogy analysis and theoretical prediction for the electromagnetic environment around typical 500 kV power transmission transformation engineering , analysis the condition of the power frequency electromagnetic field and radio interference which generated by power transmission transformation engineering effects on the environment. put forward the countermeasures and technical measures to solve and alleviate the problem of environment .

1 The environmental impact factors of 500kv power transmission transformation project

The main environmental impact factors of 500kv power transmission transformation project are power frequency electric field, power frequency magnetic field, radio interference and noise generating at project runtime. And different from general construction projects, the main characteristics of electric power construction projects is the electromagnetic impact on the environment, this paper mainly refers to the impact of the power frequency electric field, power frequency magnetic field and radio interference on the environment [1].

2 The evaluation scope and standards

2.1 The evaluation scope

The evaluation scope of power frequency electric field and power frequency magnetic field in substation is the area within 500m range outside the substation fence, focus on evaluating the area within 100m range outside the fence; The site location of radio interference is the area within 2000m range outside the fence, focus on evaluating the area within 100m range outside the fence

The evaluation scope of power frequency electric field and power frequency magnetic field on transmission line is the banded region bounded by outside the transmission line edge wire 50m, and the evaluation scope of radio interference is the banded region on both sides of the transmission lines 2000m, focus on evaluating the banded region on both sides of the edge wire 100m [2].

2.2 Evaluation standard

Power frequency electric field and power frequency magnetic induction intensity execute the requirements of 4kV/m evaluation standards and 0.1mT recommended by The Technical Specifications for the Environmental Impact Assessment of Electromagnetic Radiation of 500kV EHV Transmission Transformation Project HJ/T24-1998; The radio interference value in accordance with the provisions of The Radio Interference Limits of High Voltage AC Overhead Transmission Lines GB15707-1995, in the location of the 20m distance from edge phase conductors projection, and in the condition of test frequency of 0.5 MHz and good weather, The radio interference value of the 500kv transmission line less than the limitation requirement of 55 dB (μV/m), 500kv substation with reference to the standards.

3 The environmental impact of 500kv substation

Such as the 500kv substation constructed in plain area of Shandong province ,in which substation scale is 2×1000 MVA main transformer, and 500kv, 220kv all adopt GIS power distribution unit, can adopt the Mudu 500kV substation of Suzhou city, Jiangsu province to analogy forecast.

Monitoring section select outside the walls of outlet side of the Mudu substation high voltage power distribution unit. The monitoring points of power frequency electric field and power frequency magnetic field outside the wall to 5m as the starting point. A monitoring points is arranged every 5m and monitoring to 60m outside the wall.

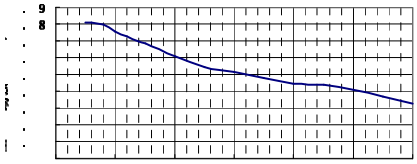

Fig1 The changing trend for the power frequency electric field intensity of Mudu 500kV substation

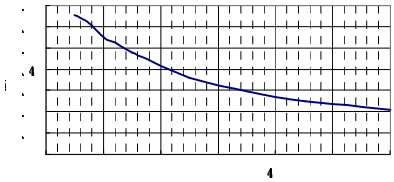

Fig2 The changing trend for the power frequency magnetic induction intensity of Mudu 500kV substation

The monitoring points of radio interference outside the wall to 1m as the starting point. A monitoring points is arranged every 2nm (n takes 0~6)and monitoring to 64m outside the wall[3].

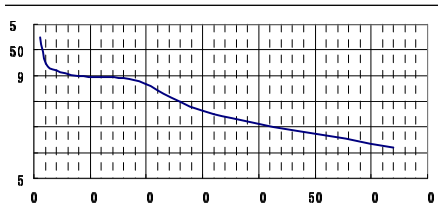

Fig3 The changing trend for the radio interference of Mudu 500kV substation

From the monitoring results of Figure 1~3 can be seen, with the increase of distance, the changes of power frequency electric field intensity and power frequency magnetic induction intensity outside the 500kV substation fence in trends were attenuated, the monitoring values outside the substation fence all can meet the evaluation standards of 4kV/m and 0.1mT. The monitoring values of radio interference outside the substation fence 20m can satisfy the limitation requirement of 55dB（μV/m）. Therefore, It generally doesn't need to take technical measures beyond design specifications outside the 500kV substation fence to satisfy the standard of environmental impact assessment.

4 The environmental impact of 500kv transmission line

Prediction calculation adopt the calculation method recommended by The Technical Specifications for the Environmental Impact Assessment of Electromagnetic Radiation of 500kV EHV Transmission&Transformation Project HT/T24-1998, in a typical design tower SZ1, for example, select the typical calculation parameters of SZ1 tower design(Figure 4) into the calculation.

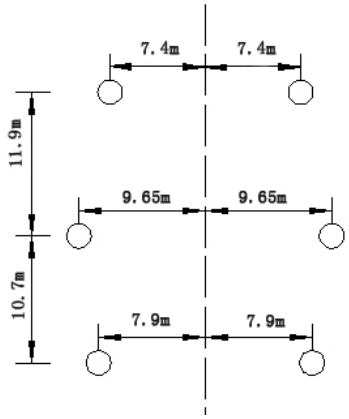

Fig 4 The parameter of SZ1 tower

The line wire is selected by 4×JL/LB20A-630/45 with wire diameter is 33.6mm and spacing split is 500mm, phase sequence alignment is considered by A-B-C and C-B-A. Consider voltage by 525kV（Go up 5% of rated voltage），and electric current by 1100A。The erection height of line is considered by wire-to-ground height with residential erection height is 14m and nonresidential erection height is 11m, calculate the power frequency electric field intensity, power frequency magnetic induction intensity and radio interference generated by its operation. The calculation results are shown in Figure 5, Figure 6, and Figure 7. In the design, power transmission transformation project often use multiple tower, and it doesn't need to calculate each tower type. Because the calculation value of power frequency electric field of the larger tower is bigger, the calculation value of radio interference of the smaller tower is larger, and the power frequency magnetic field generally doesn't become constraints, so in the theoretical calculation of the specific projects, simply select one kind of the larger and one kind of the smaller tower to calculate.

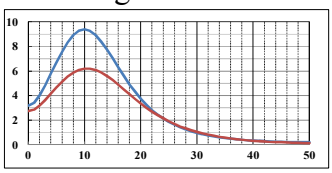

Fig5 The forecast distribution curve for the power frequency electric field intensity of 500kV tower double-circuit transmission line

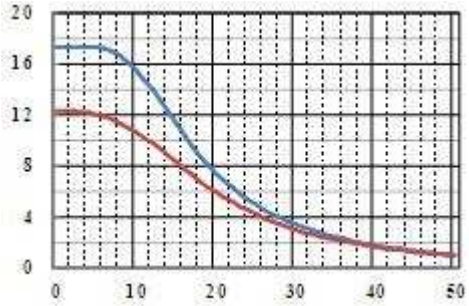

Fig6 The forecast distribution curve for the power frequency magnetic induction intensity of 500kV tower double-circuit transmission line

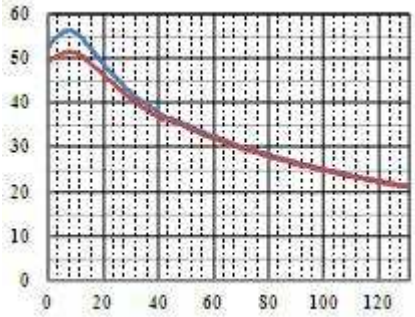

Fig7 The forecast（80%）distribution curve for the radio interference of 500kV tower double-circuit transmission line

From Figure 5 can be seen, when the line is erected in accordance with the requirements in design statutes of 14m erection height in residential area, since the demolition control requirements of 500kV transmission line project is the houses within 5m range of edge wire on both sides of the line, but the power frequency electric field intensity in the height of 1.5m from the some area ground outside 5m range outside line edge wire is more than 4kv/m, unable to meet the requirement of the evaluation standard of 4kv/m, so only according to the requirements of 500kv design procedures to execute the 500kv transmission line construction, unable to satisfy the requirements of 4kv/m environmental impact assessment standard. To 19m from the center of line (that is, 9.35m outside the edge wire), the power frequency electric field intensity in the height of 1.5m from the ground can satisfy the requirements of 4kv/m environmental impact assessment standard.

From Figure 6 and Figure 7 shows, the power frequency magnetic induction intensity of 500kv transmission transformation line is far less than 0.1mT, the radio interference at the location of 20m (that is, 29.65m from the center of line) outside line edge wire is also far less than 55dB (μV/m), the power frequency magnetic field and radio interference will not become the environmental constraints.

5 Epilogues

Through the theoretical analysis calculation and analogy monitoring for 500kv power transmission and transformation project, it generally doesn't need to take technical measures outside the design specifications to satisfy the standard of environmental impact assessment outside the 500kV substation fence. When the wires erection height of 500kv transmission line are increased to more than 17 m above residential area, after according to the circuit design rules removing the houses within 5m range of edge wire on both sides of line, the power frequency electric field, power frequency magnetic field and radio interference all can satisfy the standard of environmental impact assessment, it doesn't need to take other measures such as increasing the demolition range, and effectively reduce the civil disputes in the environmental demolition and demolition investment

Keywords: heavy metal, zero-valent iron, natural zeolite, acid mine drainage

Abstract: In this study, two different bed materials in media filter systems were examined. Natural zeolite has the ability to take up heavy metals (Cd, Zn) from acid mine drainage (AMD) as well as zero-valent iron (ZVI). The aim of the study was to estimate the ability to remove heavy metals of Natural zeolite and compare the efficiencies of the two media. A major purpose of this report was to determine which media would have a higher permeation rate after running a period of time. It was concluded that ZVI had a higher efficiency of taking up heavy metals (>96.5%) and a faster permeation rate which had a longer operating life.

Introduction

Acid mine drainage (AMD) is a form of water pollution occurring worldwide in association with mining of coal and sulfide ore deposits [1]. AMD is always harmful with low pH (3-6) and high concentrations of heavy metals and many heavy metals are known to be toxic or carcinogenic [2]. Zero-valent iron (ZVI) has been successfully applied for the treatment of wastewater and groundwater with heavy metals, arsenic, nitrate, phenol, dyes [3]. There is an increasing trend of the use of ZVI for the removal of contaminants from wastewater and groundwater [4]. During the last few years, ZVI has been reported to demonstrate effective removal of many metallic irons, including Pb^{2+},Zn^{2+},Cu^{2+},Pb^{2+},Cr(Ⅵ)[5, 6]. Natural zeolite also has the ability to take up heavy metals [7]; either for their cation exchange or molecular sieving properties. Currently, Natural Zeolite is widely used in wastewater and soil beneficiation [7, 8].

The objective of this study was to compare the removal efficiency of Zn^{2+} and Cd^{2+} from AMD between ZVI and natural zeolite, and to investigate the changes in infiltration rate of pore media, and to select economical and effective media [9, 10].

Materials and methods

The column experiment was carried out using polyvinyl chloride resin (PVC) filter columns of 50 cm height and 16 cm internal diameter. The columns had inlet and outlet connections so that waste water could flow downwards through them. The bottom of each column was closed using PVC plate. Column 1 was packed with 15% ZVI and 85% ceramsite (2-3mm in diameter) and column 2 was packed with 30% natural zeolite (2-4mm in diameter) and 70% ceramsite (2-3mm in diameter). The wastewater was constantly supplied at the top of columns with peristaltic pumps, and the level was maintained at 10 cm depth above the media surface throughout the experiment. The flow rates in two columns are 0.05cm^3s^{-1} and hydraulic residence time is 24 hours.

Effluent was collected daily and then chemical concentration was determined. The pH was measured by electrode; heavy metals were measured with flame atomic absorption spectrometry. The hydraulic conductivity (K) indicates the ability of media to conduct wastewater through it under hydraulic gradients [1]. The hydraulic conductivity of the two columns was estimated by measuring the head loss. The head loss was measured using piezometers located 15, 25, 35 cm above the bottom. The permeability of the two columns was calculated from water head and the flux which was measured by the flow rate from the outlet using Darcy's law:

$$K=\frac{Q\cdot}{A\cdot\triangle}$$

Where Q is the flow rate(L^3T^{-1}), Δ is the head loss(L), and Δ is the distance between the two points where Δ is measured(L), and A is the cross section area of the columns(L^2). The K and the concentrations of Cd^{2+} and Zn^{2+} were measured daily. The pH values were measured every half-day.

Results and discussion

The pH value of AMD was about 5, it can be seen that pH values of the two columns reach around 9.6 rapidly after running 2-3 days, then decreased to around 9.1 and fluctuated slowly. The results may be caused by dissolution of alkaline hydrolysis, and with the advance of the experiments, pH values decreased with the slower dissolution of alkaline hydrolysis. The results are shown in Fig.1.

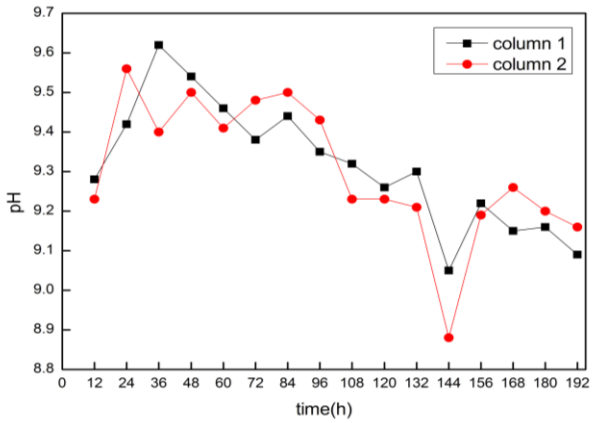

Fig.1. pH value changes during the experiment

The variations of the hydraulic conductivity during the experiment are shown in Fig.2. In the experiment, the hydraulic conductivity of column 1 decreased rapidly during the first two days, and then became smooth. At the same time the hydraulic conductivity of column 2 decreased slower than that of column 1 in the first three days. These two reductions may be due to clogging of chemical precipitation or dissolution, the mineralogical composition of the media, redox potential. The productions were adsorbed by these media which made the reductions of pore volume. The results also showed that ZVI- ceramsite mixture had a higher permeability than natural zeolite-ceramsite mixture.

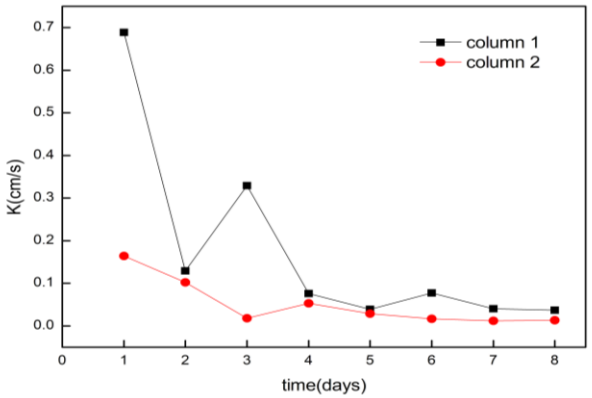

Fig.2. Permeability changes during the experiment

The removal efficiencies of Cd^{2+} and Zn^{2+} are shown in Fig.3. The results indicated that the two media can remove >94% Cd^{2+} and >99% Zn^{2+}, and ZVI had a higher removal efficiency than Natural Zeolite. It also can be seen the removal efficiencies somewhat decreased after the columns ran three to four days, but always >90%.

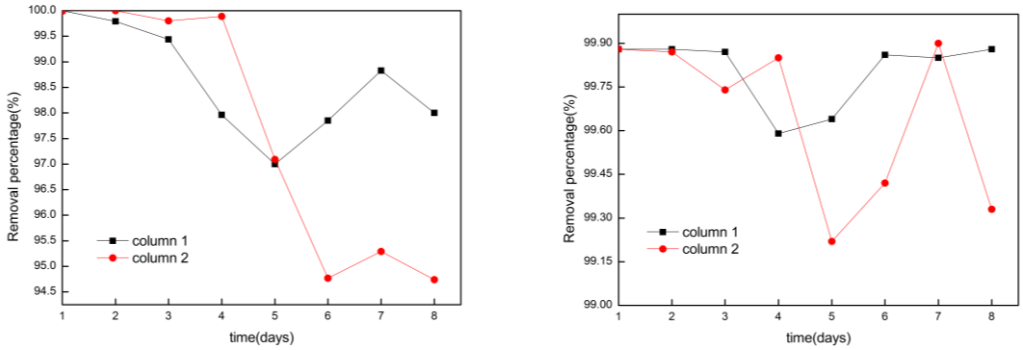

Fig.3. Removal efficiencies of Cd^{2+}, Zn^{2+}

Conclusions

The clogging of porous media is a chemical and physical phenomenon, resulting in a decrease in the capacity of permeating water and the efficiency of conducting wastewater [11]. Metals are removed as the pH increase, and the pH value is an important parameter that controls the removal of metals. Alkaline substances (ceramsite) can improve the pH of AMD, and then precipitate some heavy metals.

ZVI and natural zeolite can effectively remove heavy metals, but ZVI had a higher efficiency of removal in disposing heavy metals than natural zeolite, and a faster permeation rate [11, 12]. There is an increasing interest in the use of ZVI and artificial zeolite for the removal of contaminants from wastewater and groundwater. The two media can be combined with other media to remove many other contaminants, such as nitrate, phenol, ammonia nitrogen.

Acknowledgments

This work was supported in part by the grants from the National Natural Science Foundation of China (51274001) and the Opening Project of State Key Laboratory of Coal Recourses and Safe Mining (SKLCRSM10KFA05).Sincere gratitude is expressed to Professor Changfeng Cai for her help.

Keywords: Mercury; SCR catalyst; Oxidation; flue gas

Abstract. The application of selective catalytic reduction (SCR) system may affect mercury speciation in coal-combustion flue gas. The factors affecting mercury oxidation efficiency by SCR catalysts have been evaluated in this research. The influencing factors investigated included hydrogen chloride (HCl), sulfur dioxide (SO_2), ammonia (NH_3) injection rate and space velocity. HCl had been found to promote mercury oxidation significantly. The Eley-Rideal mechanism was proven to be suitable to explain the reaction of Hg^0 and HCl. NH_3 injection had a strong negative effect to mercury oxidation. The deactivation of aged SCR catalysts was mainly due to loss of active sites.

Introduction

In recent years, elemental mercury emission is a major environmental issue as a consequence of its persistence, long-range mobility, bioaccumulation and neurotoxicity [1]. Coal-fired power plant is one of the largest anthropogenic sources of mercury emission, accounting for about 30% of total mercury emission in the world [2]. U.S Environmental Protection Agency finalized the Mercury and Air Toxics Standards (MATS) to limit the mercury emissions from power plants in 2012 [3]. The UN Minamata Convention on Mercury was signed worldwide in 2013 to regulate the use of mercury and reduce mercury emission [4]. There are three main forms of mercury in atmosphere, i.e. elemental (Hg^0), oxidized (Hg^{2+}) and particle-bound (Hg^P) [1]. In coal-fired power plants, most of Hg^{2+} can be removed by wet flue gas desulfurization (WFGD) systems because Hg^{2+} is soluble in water. Hg^P can be collected with fly ash by particulate material control systems [1]. It is difficult to remove Hg^0 due to its water-insoluble and highly volatility. Sorbent injection is one of the most efficient technologies in Hg^0 removal [5]. However, the application of sorbent injection has been limited due to its high cost. Efficient mercury removal technology with low cost is the main concern in mercury emission control researches.

Selective catalytic reduction (SCR) is a widely commercialized technology for NO_x emission control in power plants [6]. The SCR catalysts could oxidize Hg^0 [7]. The application of SCR exhibits co-benefit of mercury catalytic oxidation and NO_x reduction. In recent years, many power plants have installed SCR and WFGD systems. The proportion of $DeNO_x$ systems installation of power plants in China is 28% on 2012 and SCR systems accounts for 98% of $DeNO_x$ systems [8]. The proportion of SCR installation will have a sustainable growth in future due to the stringent environmental limits in China [9]. SCR systems can promote Hg^0 oxidation [1] [6] [7], while the mechanism of Hg^0 catalytic oxidation by SCR was not well confirmed.

This study investigates the effects of SCR catalysts on Hg^0 oxidation under simulated coal-fired flue gases. The effects of HCl, SO_2 and NH_3 on mercury oxidation were studied. The deactivation of SCR catalysts was also investigated.

Experimental Section

Apparatus

The experimental setup for the tests is similar to our previous research [10]. The reactor system is comprised of four parts: mercury generation, simulated flue gas mixing, fixed-bed reactor and tail gas treatment. Hg^0 was generated by a PSA Mercury Generator (Cavkit 10.534) and water vapor was generated by an IAS Hovocal Gas Generator. The fixed-bed reactor was made of a 40 mm inside diameter quartz tube. The simulated flue gas was accurately controlled by Mass Flow Controllers. All the tubes, joints and valves with Hg containing gas passing through were made of either quartz or PTFE. The concentration of NO_x was monitored by FTIR gas analyzer (Nexus 670). The concentrations of Hg^0 and Hg^{2+} were continuously monitored by an online cold vapor atomic absorption spectroscopic mercury analyzer (ThermoFisher CEMS). Hg^P absorbed by the SCR catalysts was measured by Lumex RA-915M. The total system error range was previously determined as ±10% [10].

Experimental Procedure and data processing

The SCR catalyst in the quartz tube is honeycomb structure, which is the same shape as the catalyst in SCR reactor in power plants. The height of the catalyst was about 6 mm (space velocity was 17600 /h), the wall thickness was about 1 mm, and the weight was about 1 g (±0.01 g). The inlet elemental mercury concentration was set at 20 μg/Nm^3 for all the tests and the total flow rate was controlled at 2 L/min. Normally the reaction temperature was 350°C and the gas sampling line was maintained at 140°C to avoid moisture condensation and mercury adsorption. Each test normally lasts for 5 h and three replicates were done for each test.

The total Hg^0 oxidation rate has been defined as:

$$\text{Total Oxidation Rate } \eta_{oxi} = \frac{\sum_0^t c^t_{Hg^{2+}}}{c_0 \cdot t} \times 100\% \quad (1)$$

where c_0 is the inlet Hg^0 concentration, $c^t_{Hg^{2+}}$ are the outlet Hg^{2+} concentrations at the reaction time.

The NO conversion was determined by the following equation:

$$\text{NO conversion } \eta_{NO} = \frac{(c^{in}_{NO} - c^{out}_{NO})}{c^{in}_{NO}} \times 100\% \quad (2)$$

where c^{in}_{NO} and c^{out}_{NO} are the NO concentrations in the inlet and outlet streams.

Characterization of the SCR catalysts

Both the fresh and aged SCR catalyst was obtained from the same SCR reactor in a 600 MW coal-fired power plant (Taishan, China). The catalysts are in corrugate shape. The space velocity inside SCR reactor was normally 17600 /h. The catalyst which had been operated for about 26000 h was tested as the aged SCR for comparisons.

The surface area and pore size of the catalysts were measured on an automatic nitrogen adsorption analyzer (Quanta Autosorb-1-c, USA). X-ray diffraction (XRD) analyses were conducted on a diffractometer (Bruker D8, German) using Cu Kα radiation. The elemental analysis was measured by an X-ray fluorescence spectrometer (XRF, PAN alytical Axios PW4400, Netherlands).

Results and Discussion

Catalyst Characterization

The specific surface area, pore volume and average pore diameter of the catalysts are shown in Table 1. The result indicates that the specific surface area and pore volume of the catalyst decreased after the service in power plant. The reduction may be caused by blockage by fly ash particles and sintering of TiO_2 particles.

Table 1 Physical properties of the catalysts

Sample	BET Specific Surface Area(m^2/g)	Total Pore Volume (cm^3/g)	BET Averaged Pore Size(nm)
fresh SCR catalyst	59.7	2.81E-03	11.5
aged SCR catalyst	28.4	1.67E-03	14.2

Figure 1 depicts the X-ray diffraction patterns of the catalysts. The TiO_2 crystalline phase of the catalyst was anatase. There was no obvious transition of TiO_2 crystalline phase during the service indicating no sintering of TiO_2 on the surface of the catalyst. Since other components are not observed, it can be conclude that the impurities are well dispersed on the surface of used SCR catalyst.

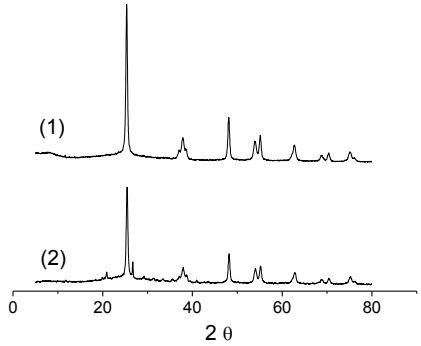

Fig. 1. X-ray diffraction patterns: (1) fresh catalyst, (2) aged catalyst

The main chemical composition of the SCR catalysts was measured by X-ray fluorescence (XRF), as shown in Table 2. The main components of the SCR catalyst are TiO_2, SiO_2, WO_3 and V_2O_5, which are widely used in commercial SCR catalysts. Compared to fresh catalyst, the content of TiO_2, WO_3 and V_2O_5 in the aged catalyst decreased and the content of K, Ca, Na, Mg, Al, S, Si, Fe increased. The mass fraction of alkali metal oxide is nearly 10% of the aged catalyst. The deactivation of aged SCR catalyst appears to be pore blocking of alkali deposition. The decrease of TiO_2 concentration was due to the deposition of fly ash constituents over the catalyst surface. The loss of active content (V, W, Ti) and fly ash deposition may cause deactivation and have negative effect to mercury oxidation.

Table 2. XRF analysis of the catalysts (w.%)

Composition	Fresh SCR	Aged SCR	Fly ash
TiO_2	67.2	55.5	1.23
SiO_2	13.7	18.2	39.6
WO_3	6.47	4.5	0.05
Al_2O_3	1.75	3.7	12.98
Fe_2O_3	0.14	1.9	9.8
CaO	2.33	3.4	9.72
P_2O_5	0.72	0.6	0.12
SO_3	0.13	2.6	17.81
V_2O_5	1.92	1.1	0.07
K_2O	0.05	0.3	1.51
MgO	0.10	0.2	0.75
Na_2O	0.05	0.3	1.53

Mercury catalytic oxidation efficiency

1) The effect of HCl

The Hg^0 oxidation activity of the SCR catalysts is greatly promoted in the presence of hydrogen chloride, and the reaction is considered to proceed as follows[11]:

$$Hg + 2HCl + 1/2\ O_2 \rightarrow HgCl_2 + H_2O \quad (3)$$

Factors that enhance surface chlorination, such as higher inlet HCl concentrations, promote Hg^0 oxidation [12]. In order to investigate the influence of HCl on the Hg^0 oxidation, tests were conducted under different HCl concentrations and the mercury speciation was shown in Figure 2. There was a trace of Hg^P on catalyst when HCl was in presence. For fresh SCR catalyst, the extent of mercury oxidation was progressively increased as the HCl concentration in the flue gas increased. The research carried out by Hocquel [13] proved that V_2O_5 could significantly promote the amount of $HgCl_2$ in the flue gas. The oxidation of mercury occurred at the active V_2O_5 sites. Mercury oxidation increased with increasing HCl content [11] [13] [14]. The Deacon process had been

suggested as the mechanism of releasing chlorine (Cl_2) via a reaction between V_2O_5 and HCl [15]. The active Cl can react with Hg^0 in the gas phase. The Eley-Rideal mechanism was suitable in explaining the reaction of Hg^0 and HCl on the catalyst, since there was no adsorbed mercury in the HCl atmosphere. However, the promotion effect on Hg^0 oxidation in the presence of high concentration HCl was limited for aged SCR, which was due to the reduced active sites on the surface of aged SCR [16]. Pore blocking of aged SCR by combined alkali and calcium sulfate deposition and growth had been proposed to explain the deactivation of SCR catalysts [17]. It had been observed that the surface was blocked and active contents were lost for the aged SCR catalyst from both SEM and XRF analyses. When all the active sites were occupied by HCl for aged SCR catalyst, the mercury oxidation efficiency would no longer increase with increasing HCl concentration.

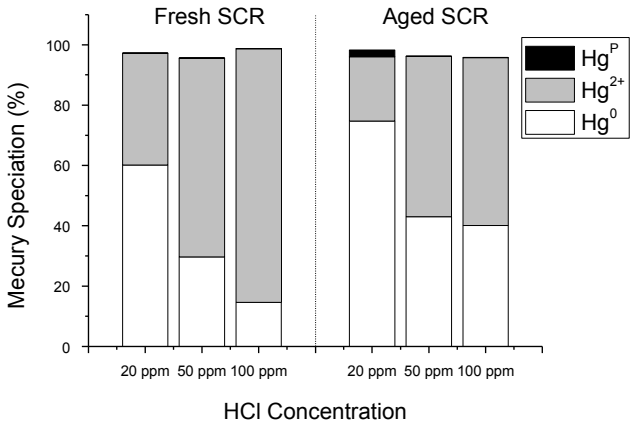

Fig. 2. The effect of HCl on mercury oxidation (6%vol. O_2,12%vol. CO_2, 5.12%vol. H_2O, 20-100 ppm HCl, 500 ppm SO_2 and 300 ppm NO balanced by N_2)

2) The effect of space velocity

The mercury oxidation rates were tested at the space velocities of 17600 /h (typical value in the boilers) and 8800 /h. The test results are illustrated in Figure 3.

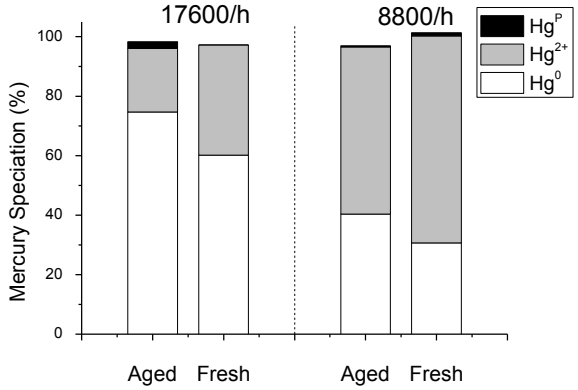

Fig.3. Mercury speciation under different space velocities(6%vol. O_2,12%vol. CO_2, 5.12%vol. H_2O, 20 ppm HCl, 500 ppm SO_2 and 300 ppm NO balanced by N_2)

As expected, Hg^0 oxidation rates increased for smaller space velocity over SCR catalysts. For the same space velocity, the extents of Hg^0 oxidation fell as the usage of the SCR catalyst. This was apparently due to the deactivation of aged SCR catalyst. When the space velocity decreases, the residence time increases. If the difference between the performances of fresh catalyst and aged catalyst is due to the disparity of the specific surface area and total pore value, the difference of Hg^0 oxidation rates between the catalysts will increase and the ratio of the Hg^0 oxidation rates will be close to the ratio of the specific areas when the space velocity decreases. However, the result is opposite. The result in Figure 3 showed that the difference of the Hg^0 oxidation rates between the catalysts decreased when the space velocity reduced to 8800 /h. This phenomenon indicates that the difference of Hg^0 oxidation rates between the catalysts is due to the decrease of active sites, which is consistent with the XRF data.

3) The effect of SO_2

Figure 4 shows the mercury speciation of fresh SCR catalyst under different SO_2 concentrations. As the SO_2 concentration in the flue gas boosted, the mercury removal process was slightly suppressed and the amount of Hg^0 increased. The result is consistent with previous research [18]. This was probably due to the adsorption active sites occupied by the high concentration SO_2. The SO_2 related chemical reactions that are of interest in coal-fired power plants include:

$$SO_2 + 1/2\ O_2 \rightarrow SO_3 \quad (4)$$

$$Hg + SO_3 + 1/2O_2 \rightarrow HgSO_4 \quad (5)$$

Further studies might be worthwhile to evaluate the active species responsible for mercury oxidation in the SO_2 simulated atmosphere.

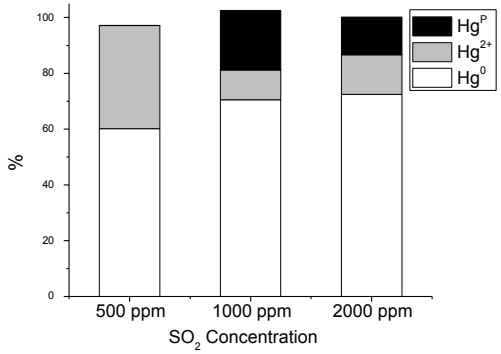

Fig.4. The effect of SO_2 on mercury speciation (6%vol. O_2,12%vol. CO_2, 5.12%vol. H_2O, 20 ppm HCl, 500-2000 ppm SO_2 and 300 ppm NO balanced by N_2)

4) The effect of NH_3 Injection

Ammonia (NH_3) has been most widely applied for NO_x reduction in the SCR process. In a SCR reactor, the reduction of NO with NH_3 proceeds according to the following reaction:

$$4NO + 4NH_3 + O_2 \rightarrow 4N_2 + 6H_2O \quad (6)$$

Figure 5 shows the Hg^0 oxidation and NO conversion over the fresh SCR catalyst as a function of NH_3/NO molar ratio. The NO conversion was almost linearly increased with NH_3/NO ratio in the presence of 50 ppm HCl, and fresh SCR catalyst exhibited good NO_x reduction catalytic activity. Hg^0 oxidation rate, on the contrary, decayed as NH_3/NO ratio rose. This interpreted that NH_3 had a strong inhibition effect on mercury oxidation. With the increase of the NH_3/NO ratios, the effect of HCl concentrations to the Hg^0 oxidation rates decreases. This indicates that the promotion effect of HCl to the Hg^0 oxidation rates was restrained when the NH_3 concentration increased. The reaction mechanism was that NH_3 competed for surface active sites against HCl, which is consistent with previous research [19]. NH_3 bound to the V_2O_5 sites on SCR catalyst as part of NO reduction process and therefore competed against Hg^0 adsorption [14]. Hg^0 contacted the chlorinated active sites from gas phase or as a weakly adsorbed species. Higher HCl concentrations promote Hg^0 oxidation.

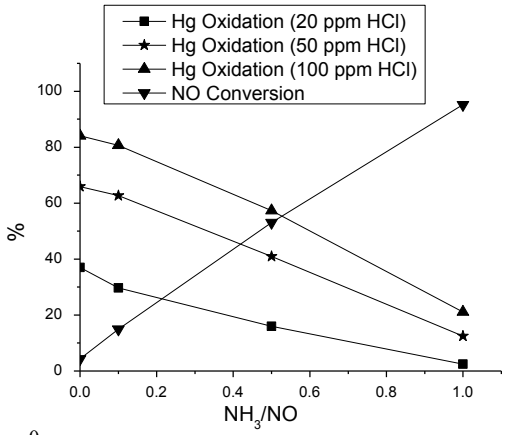

Figure 5. Dependence of Hg^0 oxidation and NO conversion on the NH_3/NO moler ratio (6%vol. O_2,12%vol. CO_2, 5.12%vol. H_2O, 20-100 ppm HCl, 500 ppm SO_2, 300 ppm NO and 0-300 ppm NH_3 balanced by N_2)

Conclusions

This study has been performed to understand the factors affecting Hg^0 oxidation rate by SCR catalyst. Tests results have indicated that SCR catalysts could oxidize elemental mercury at the temperature expected in SCR process in a variety of flue gas species. HCl was the most significant flue gas component that converted Hg^0 to Hg^{2+} under the application of SCR catalysts. NH_3 addition decreased mercury oxidation rates. Increasing the chlorine content of the flue gas could reduce the negative impact of ammonia injection. The Eley-Rideal mechanism might be appropriate to explain the reaction of Hg^0 and HCl. The deactivation of aged SCR catalysts was due to pore blocking by alkali and fly ash deposition and loss of active sites.

Abstract. In a wetted-wall column of pilot-scale sulphur dioxide removal efficiencies were measured at 20℃ and atmospheric pressure with aqueous ammonia solutions as the scrubbing liquid for different sulphur dioxide inlet concentration in the range of 1000-3000 mg/m^3. A mathematical model with the effects of a chemical enhancement factor and sulfite concentration in the liquid phase developed to interpret laboratory experiments was adapted and the calculated values were in reasonable agreement with the experimental values. It appears that this model can provide good predictions of the absorption performances of industrial columns and be helpful to design scrubbers for SO_2 abatement with aqueous ammonia solutions.

Introduction

It is well known that sulfur dioxide exist in the flue gases of power plants and industrial boilers lead to acid rain which damages buildings, vegetation and water ground cycle [1]. SO_2 is also considered to be toxic to humans by inhalation. Throughout the world, pollutant emission standards have become increasingly strict over the past ten years [2]. The most effective wet processes use sodium or calcium hydroxides [3,4], but the liquid or solid wastes that absorption produced must be treated correctly if they are not marketable.

Ammonia-based wet flue gas desulphurization has drawn increasing attention because of its higher desulphurization efficiency, useful byproducts, and lower investment in china in recent years [5, 6]. Liu Guorong [7] investigated the effects of several key factors on the efficiency of ammonia desulphurization and established a mathematical model for ammonia desulphurization based on the two-film theory in spray towers. Jia Yong[8]studied the gas-liquid mass transfer and chemical reaction process during ammonia-based flue gas desulfurization in a packed column. Gao Xiang[9] investigated the characteristics of the gas-liquid absorption reaction between sulfur dioxide and an ammonium sulfite solution in a stirred tank reactor and indicated that the absorption of sulfur dioxide is controlled by both the gas-and liquid-films when the ammonium sulfite concentration is lower than 0.05mol/L, and mainly by the gas-film at higher concentrations.

The aim of this study was to investigate the characteristics of SO_2 absorption into aqueous ammonia solutions and the influence of operating conditions on absorption efficiency in wetted-wall column at 20±0.5℃ and atmospheric pressure.

Materils and Methods

The experimental set-up is shown schematically in Fig.1.It includes a pilot-scale column and a heat exchanger and a pump resistant to acid or alkali solutions. The tower has an inside diameter of 0.1m

and is packed with ceramic tube which has an inside diameter of 8mm and outside diameter of 10mm. The number of ceramic tube is 38 and the height of the packing is 1.2m.

The gaseous mixture is made of SO_2 supplied by a high pressure cylinder and air blown by a compressor. Sample of gas at the input and the output of the column is analyzed by UV analyzer, which gives the SO_2 contents.

Efficiency of desulphurization is defined according to measured results for gas composition.

$$\eta = \frac{c_{in} - c_{out}}{c_{in}} \tag{1}$$

The column is operated co-currently with recycle of the scrubbing liquid, aqueous ammonia solution was used.

A series of absorption tests was conducted at 20 ± 0.5℃ and atmospheric pressure. Experiments were performed with gas flow rates in the range from 15m^3/h to 85m^3/h and a liquid flow rate varying between 0.05 m^3/h and 0.15 m^3/h.

Fig 1 Diagram of experimental system of ammonia desulphurization

Modeling of SO_2 absorption into aqueous ammonia solution

Based on the two-film theory of absorption with chemical reaction, a mathematical model was developed to simulate the SO_2 absorption into aqueous ammonia solutions. The model assumes the absorbed gas SO_2 undergoes a fast irreversible reaction with the liquid reactant $(NH_4)_2SO_3$, which is complete within the liquid film.

The following reactions will mainly occur during the absorption of SO_2 into aqueous solution with ammonia:

$$SO2+(NH4)2SO3+H2O \rightarrow 2NH4HSO3 \tag{2}$$

The model assumes that dissolved SO_2 undergoes a fast irreversible reaction which is completed in the liquid film. The absorption reaction is considered to be globally of second order with respect to the reactants according to:

$$r = k_2 c_{SO_2} c_{(NH_4)SO_3} \tag{3}$$

Based on the two-film model, the mass transfer equation of SO_2 into $(NH_4)_2SO_3$ solution is :

$$N_{SO_2} = k_G (p_{SO_2} - p_{SO_2,i}) = E k_L c_{SO_2,i} \tag{4}$$

The concentration of $(NH_4)_2SO_3$ in the bulk liquid being much greater than the SO_2 interfacial concentration $c_{SO2,i}$, the kinetics of the reaction becomes pseudo-first order and for large Hatta numbers:

$$E = \frac{Ha}{\tanh H} \approx Ha \tag{5}$$

Where H is Henry's coefficient of SO_2 for aqueous ammonia solution.

$$Ha = \sqrt{k_1 D_{SO_2}} / k_L = \sqrt{k_2 D_{SO_2} c_{(NH_4)_2SO_3}} / k_L \tag{6}$$

The following expression is finally used for the absorption rate.

$$N_{SO_2} = \frac{p_{SO_2,i}\sqrt{k_2 D_{SO_2} c_{(NH_4)_2SO_3}}}{H} \tag{7}$$

Experimental parameters and dimensions are listed in Table 1 and the physical parameters in Table 2

Results and discussion

Effect of $(NH_4)_2SO_3$ Concentration on the SO_2 absorption Rate

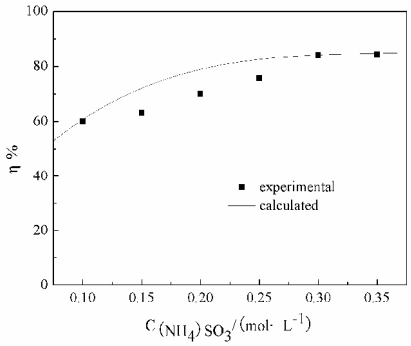

Fig 2 Relationship between absorbent concentration and desulphurization efficiency

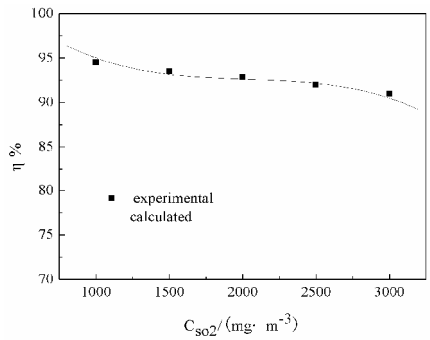

Fig 3 Effect of the SO_2 inlet concentration on desulphurizat efficiency

Fig.2 illustrates the influence of absorbent concentration and desulphurization efficiency, while the SO_2 concentration was 2500mg/m^3.The liquid flow rate was 120L/h during the runs. It appears that, for a constant acidity of the absorbent, a rise in $(NH_4)_2SO_3$ concentration involves an increasing desulphurization efficiency when $(NH_4)_2SO_3$ concentration lower than 0.3mol/L. However, the SO_2 absorption rate becomes nearly constant as the $(NH_4)_2SO_3$ concentration rises above 0.3mol/L. In the latter case, the reaction may be mainly influenced by gas-film.

Effect of Inlet Concentration on SO_2 Absorption Rate

Fig.3 shows the effect of the SO_2 inlet concentration on desulphurization efficiency. pH is 6.5 $\pm$0.1, gas flow rate is 50m^3/h and liquid flow rate is 120L/h. It reveals that desulphurization efficiency decreases with SO_2 inlet concentration increase. However, this does not imply decrease in absorption rate. In fact, the absorption rate is a simple increasing function of SO_2 inlet concentration, while the decreasing tendency of η is resulted from fast increase of SO_2 that needs to be absorbed.

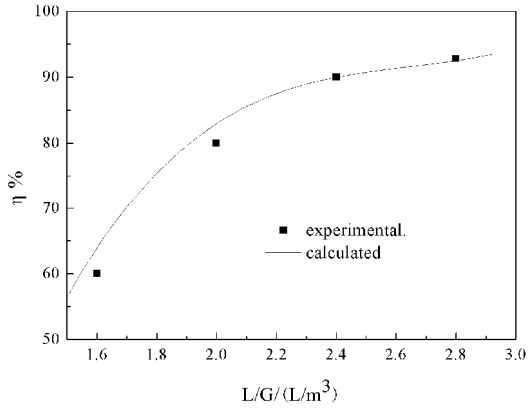

Fig 4 Effect of liquid-gas ratio on the flue gas desulphurization efficiency

Effect of Liquid-gas Ratio on the SO_2 Absorption Rate

The results of effect of liquid-gas ratio on the flue gas desulphurization efficiency are shown in fig.4.The experiments are carried at a fixed liquid flow rate, while gas flow rate is controlled according requested L/G. As can be seen from fig.7, η increases as the flow ratio increasing. When L/G is over 2.5, the change of η is smoothed. Obviously, η increases because of the increase in interface increasing. On the other hand, increase the L/G ratio leads to increased power consumption and thus operation cost.

Conclusions

On the basis of experiments with wetted-wall column it is possible to draw the following conclusions: The results demonstrate that when inlet concentration is 2500mg/m^3 the best technical parameters are 2.4 to 2.8L/m^3 for the liquid-gas ratio, 5.8 to 6.5 for the pH value of absorption. Under the best technical parameters the desulphurization rate can reach 95%. The liquid-phase and gas-phase mass transfer coefficients of the system were determined. A model with a chemical enhancement factor was developed for the prediction of the SO_2 removal efficiency. It is showed that the calculated values of the SO_2 removal efficiency are in reasonable agreement with the experimental values.

Keywords: Mechanics behavior, Gas Hydrate Sediments, Review

Abstract. The purpose of this review paper is to summarize the recent research in mechanics behavior of hydrate bearing sediments (HBS). The paper will discuss recent research of the laboratories mechanics test with analysis on HBS and numerical simulation on mechanics behavior of HBS.

Introduction

As a potential energy of 21st centuries, commercial development of gas hydrate (GH) from the permafrost and oceans is put on the list of future national energy security by some countries. The main problem of GH development is geo-mechanical stabilities due to dissociation of the solid hydrates during drilling, casing and gas production. They can degrade the structural strength of the HBS which can lead to the casualties like wellbore collapse, blow-outs and even tsunamis due to large-scale geological subsidence. So it is significant to research in the mechanics behavior of HBS.[1]

China drilled out gas hydrate onshore at Qinghai-Tibet Plateau in 2009 and offshore at South China Sea in 2007 and 2013. However, due to lack of original gas hydrate cores, the laboratories' artificial HBS is widely applied while the numerical simulation on mechanics behavior applies the laboratory's data to simulate the field condition before the gas hydrate trial production. North American onshore tests at Alaska and Mackenzie Delta at beginning of this century while Japan offshore tests at Nankai Trough in 2013 were both followed this process, laboratories data-model simulation-field test.

Laboratories Mechanics Test and Theoretical Analysis on HBS

The tri-axial compressive test with theoretical analysis is the basic approach for current research of HBS mechanics behavior. American researchers had reviewed gas hydrate research in 2011, based on their mechanics review, this review will give below.[1]

Winter et al. [2] have built an instrument, named GHASTLI - Gas Hydrate and Sediment Test Laboratory Instrument, to research on the properties of ice, pure gas hydrate and HBS from Mackenzie Dealt, Alaska Mexico and India. They analyze the mechanical properties like stress-strain relationships, strength and modulus with the HBS grain properties and distribution. The strength of sediments with GH is much larger than that without GH. Furthermore, they find out the bond effect between hydrate and sediment grains in the laboratories' artificial HBS which should be considered in the prediction model because there is no cementation effect in the field HBS. Meanwhile, they researched the acoustic property for the in situ exploration, drilling, well-test and production projects.

Hyodo et al.[3, 4] discussed the relationships between GH saturation and mechanics properties. Draw the diagrams of stress-strain in the different GH saturation with temperatures, confining pressures and shear strain rates. The bonding effect was discussed on the shear strength and deformation of HBS with GH saturation and grain size of sediments.[3] With the successful trail production of marine GH by Japan in March, 2013, a series of tests for production methods, the thermal recovery method or depressurization method, were conducted to investigate the shear strength and deformation behavior of HBS. From the laboratories' test, the results indicate that:

thermal recovery method reduces the failure strength of isotropically consolidated HBS but increases the initial stiffness and volumetric strain when compare these with the pure Toyoura sand; depressurization method will not cause the collapse of HBS during depressurization and that give little effect on the ultimate deformation of HBS, while the initial deformation rate goes up with depressurization rate up. Furthermore, the larger the reduction of pore pressure is, the larger axial strain and volumetric strain are. When the axial load is higher than the strength of HBS after dissociation, both water pressure recovery and thermal recovery method will lead to failure of HBS.[4]

Masui et al.[5-9] give a conclusion that shear strength and elastic modulus increase with saturation up while shear strength decrease with porosity down at same saturation. Additionally, in the Mohr–Coulomb criteria, cohesion increases with saturation, however there is no obvious trend to the internal friction angle and poisson's ratio. They compared the HBS properties of retrieved cores from Eastern Nankai Trough with synthetic GH samples, similar strength, but different elastic modulus due to initial porosity with grain size and distribution, and different volumetric strain because of dilatancy effect by size distribution. Interestingly, they researched on the unloading-reloading tri-compression test.[8] From the Fig. 1, the total stress-stain curve of HBS unloading-reloading is similar to conventional HBS stress-strain curve. However, the tangent of the stress-strain curve diminishes throughout the unloading-reloading process. In other words, once deformed, a specimen becomes easy to deform again in the same direction. From the Fig. 2, the deformation mechanism is two parts: (1) At the beginning of axial loading, the consolidation is a dominant deformation mechanism where the slope of unloading-reloading curve influencing elastic component of deformation has increased. Then, the dilatancy is a dominant deformation mechanism because that has decreased. (2)After the peak, the dilatancy behavior is still a dominant deformation mechanism; the irreversible strain (inelastic strain) makes more contributions than the reversible strain (elastic strain) to the deformation increase of a specimen.

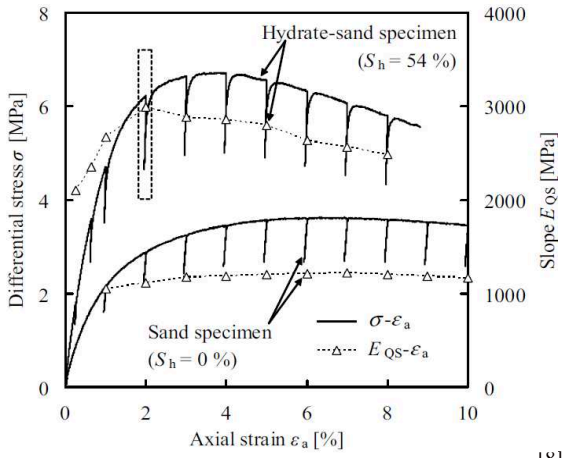

Fig.1 Differential stress-axial strain curve [8]

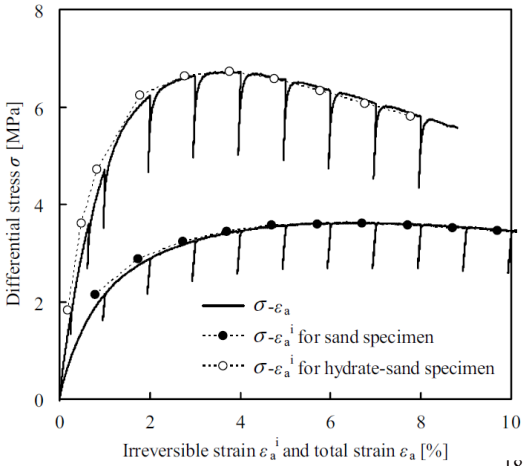

Fig. 2 Strain in unloading-reloading test [8]

The effective confining pressure σ'_3 test for the formulation of strength is given by experiment data where cohesion c and internal friction angle φ can be calculated. For the hydrate, based on the Mohr-Coulomb failure criterion, the tri-axial compressive strength $\sigma_C(S_h, \sigma'_3)$ can expand to equitation (6) [10]:

$$\sigma_C(S_h, \sigma'_3) = \frac{2\cdot\cos\varphi}{1-\sin\varphi} c(S_h = 0) + \alpha \cdot S_h^{\beta} + \frac{2\cdot\sin\varphi}{1-\sin\varphi}\sigma'_3 = \sigma_C(0,0) + \Delta\sigma_{C-sh} + \Delta\sigma_{C-cp} \quad (1)$$

(The cohesion c is a function of GH saturation S_h; the internal friction angle φ and effective normal stress σ'_3. The first, second and third terms in the right side of Eq. (1) can be explained to correspond to the apparent uniaxial compressive strength of sand specimen $\sigma_C(0,0)$, the strength increase with GH saturation $\Delta\sigma_{C-sh}$ and the strength increase with effective confining pressure $\Delta\sigma_{C-cp}$, respectively. $\Delta\sigma_{C-sh}$ can be got a equitation related to S_h from the difference of strength versus hydrate saturation chart by experiment data where α and β is coefficient and exponent for approximation of $\Delta\sigma_{C-sh}$).

The researchers from Southampton University [11-14] applied a Gas Hydrate Resonant Column (GHRC) apparatus to investigate the strength and stiffness during the hydrate formation and dissociation. In the hydrate formation, the total increase in stiffness with full hydrate formation was up to 20 times that measured when without GH was in the pore space. Furthermore, hydrate volume which affects the buckling resistance of column and effective confining stress applied to the specimen can take significant influence of stiffness during the hydrate formation.[13] For the bonding effect, the small amounts of bonding had a huge affection on the shear modulus of the sand with hydrate, and hydrate bonding had the little impact on the bulk modulus. While there was little dependence of stiffness on effective stress when above hydrate contents are enough. Hydrate-bonded sand was found to be much higher damping than the sand specimens with the same equivalent water content. A peak damping ratio was found at about 3–5% hydrate content, both in torsion and in flexure. It is suggested this should be the intrinsic damping properties of the hydrate itself.[15] In the hydrate dissociation, large decrease of specimen stiffness was detected to slight changes in hydrate saturation. Final, they give the suggestion of the nonlinear behavior will be required to more accurately model the behavior of HBS because the current model of quantifying soil strength/stiffness value for hydrate volume remaining would be overestimated.[13]

Dalian University of Technology researchers [16-19] conducted series of tri-axial compression tests on synthetic HBS cores under high confining pressures and low temperature. They take the two stages of HBS stress-strain relationship into consideration, rapid structural damage stage and complete structural damage stage, following the Duncan-Chang model. They found out the initial yield strain, initial yield strength, initial deformation modulus and ultimate deviator stress increase with the confining pressure up and temperature down while the initial yield modulus is only affected by temperature. Both cohesion and friction angle are increased with the decreased of temperature and increase of strain rate; the strength increased with decreasing porosity; the porosity has a great influence on the cohesion but not on the fraction angle. The variations of failure strength with porosity mainly were caused by the variations of cohesion.[16] Moreover, the stress-strain curves of HBS showed as a shape of hyperbola, and that deviator stress rises gradually with axial strain going upwards and eventually arrives at a constant value without significant peak value. When confining pressure over 5 MPa, the failure strength drops with confining pressure up. A new strength criterion is proposed based on the experimental results which can well reflect the failure load of HBS under high confining pressures. The Duncan–Chang model is used to describe the deformation behavior of HBS under various confining pressures, and that simulated results are well match to the experimental data.[18]

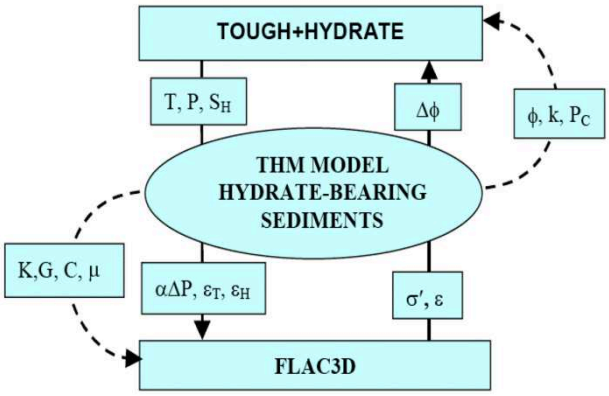
WU et al [20] established a statistical damage constitutive model of HBS. A power function is established for the damage variable which thinks about the affection of effective confining pressure based on the relationship between equivalent elastic modulus and hydrate saturation. The strength of a micro-element of HBS is described by Drucker-Prager failure criterion and the variation of the micro-element strength is assuming to follow Waybill's distribution. The statistical damage constitutive model of HBS is established.

Numerical Simulation on Mechanics Behavior of HBS

Heriot Watt University researchers [21-23] established a wellbore stability model for HBS with rock and soil mechanics software FLAC^{3D}. This model can couple the thermodynamically stability, heat transforms, porous medium flow and geo-mechanics deformation of GH.[22] Then they combined finite-element model of casing for HBS with GH simulator HWHYD with rock with soil mechanics software ABAQUS. Although this model solved the problems of fluid-solid coupling, the coupling between mechanical and thermal terms is only one-way coupling.[23]

Lawrence Berkeley National Laboratory researchers [24-27] took the numerical studies on geo-mechanical stability of HBS with hydrate simulator TOUGH2+HYDRATE (T+H) and soil mechanics software FLAC3D (F). T+H is the system hydraulic, thermal, and thermodynamic behavior in geological media containing GH. FLAC3D has built-in constitutive mechanical models suitable for soil and rocks, including various elastoplastic models for quasi-static yield and failure

analysis, and viscoplastic models for time dependent (creep) analysis, that could be used directly or modified for analysis of geo-mechanical behavior of HBS. TOUGH+HYDRATE and FLAC3D are linked through a coupled thermal/hydrological/mechanical (THM) model of the HBS (Fig. 3). In Fig. 3, the data exchanges between TOUGH+ HYDRATE and FLAC3D are illustrated with arrows going through the central THM model. The shear strength, bulk modulus, cohesion and friction angle is considered as the parameter of HBS mechanics. T+H simulator can give the results of thermodynamic parameters (such as temperature T), hydraulic parameters (such as capillary pressure Pc, intrinsic permeability k and pressure P). Then they simulated production on GH reservoir and got the stress field, strength and mechanics behavior versus time. Their simulation results indicate that gas production from oceanic deposits may affect the geo-mechanical stability of HBS. Conversely, the increased pressure caused by the weight of structures on the ocean floor increases the stability of underlying hydrates.[27, 28]



--	Direct couplings	S_H	Hydrate saturation	K	Bulk modulus	C	Cohesion
—	Indirect coupling	μ	Coefficient of friction	σ'	Effective stress	ε	Strain
T	Temperature	k	Intrinsic permeability	P	Pressure	$\emptyset$	Porosity
G	Shear modulus	P_c	Capilary pressure				

Fig. 3 Coupling of TOUGH+HYDRATE and FLAC3D for analyzing geomechnical behavior of HBS[29]

Kolditz et al.[30] developed the OpenGeoSys, a free scientific multi-platform modeling package that enables numerical simulations of individual or coupled thermo-hydro-mechanical-chemical (THMC) processes in porous and fractured media. A gas module for OpenGeoSys with coupled THMC is the subject of a study currently in progress.

Recent research of Guangzhou Institute of Energy Conversion

China's marine HBS is below 2000m water depth, much deeper than the Japan, India and North American, which the confining pressure is over 20MPa and pore pressure is about 20MPa.[1, 31] So there is not too much successful research on such high pressure in the laboratory. Recently, Guangzhou Institute of Energy Conversion built tri-axial facilities, which can apply the maximum capabilities of 250 kN for axial loading with accuracy of 0.1%/min strain-rate, 30 MPa for confining pressure and 20 MPa back pressure. The temperature inside the chamber can be controlled at the range from 243 K to 323 K with an accuracy of 0.5 K by circulating 50% ethylene alcohol solution from the refrigerator. The data of displacements, load, confining pressure, back pressure and temperature were acquired and recorded by the computer system at every 10 seconds during the test. This tri-axial facility took the advantages of laboratories mentioned above; it specially designed to simulate the high pressure condition of South China Sea.

Conclusion

In brief, it is not easy to get the mechanics data of HBS in the field, such as the permafrost and the deep marine. Thus, to get the full understanding stability of HBS for future exploitation, the laboratories test with theoretical analysis and numerical simulation have a long way to go.

Keywords: Shale gas, low-cost development, fiscal and taxation incenting policy, comparison.

Abstract. The experience of shale gas low-cost development in America provided production organization and management methods including horizontal well drilling, cluster well drilling, pad drilling, batch drilling, factory drilling, and reservoir volume fracturing. The policy of finance and taxation has played a positive role in promoting and encouraging shale gas development. The development of shale gas in China is different from America in sides of resource features, development process, the technical levels and the policy environment. We should learn from the technical means, management method and encouraging fiscal and financial policy of low-cost development strategy of America, study and formulate policy suitable to China's own characteristics, to promote low-cost development of shale gas.

Introduction

The progress of shale gas development technology in America has an important impact on the development of global energy [1]. It even changed several countries' economy and living standards. Oil companies are accelerating the adjustment of development strategies so as to meet the needs of unconventional resources, especially the development scale of shale gas [2]. Drilling equipment is in continuous improvement. On the other hand, the technology of well construction and drilling methods are in continuous improvement. Improvements in technology promote the emergence and development of more effective management modes. Well production management and operation management model have been an important way in the efficient development of shale gas.

Low-cost Development Method of Shale Gas

Horizontal well drilling. Vertical wells were the main drilling mode of shale gas development in America before 2002. With the great success of Devon Energy Corporation's seven horizontal wells' test of shale gas, the industry began to promote horizontal drilling. Horizontal drilling has been the main way of drilling in shale-gas drilling at present. The number of horizontal wells of shale gas increased rapidly after 2002. The number of Barnett's horizontal wells added up to 4960 from 2003 to 2007, which made up more than 50% of Barnett's horizontal wells. The number of drilled horizontal wells was 2219 and made up of 94% of Barnett's horizontal wells in 2007. The number of drilled horizontal wells was 13740 and even made up of 95% in 2009. The technology of horizontal well drilling can maximize the contact of the reservoir which can increase the recoverable reserves and single-well output. Especially the technology's breakthrough of multi-section fracture of horizontal wells improved the technology to a new level. Practice indicates that the contact area of horizontal wells is 20 times that of the vertical wells. In this case, horizontal wells can improve the recovery efficiency of oil and gas dramatically.

Cluster well drilling and pad drilling. Because shale gas is stored in low porosity and low permeability formation and the output decline is fast, so it needs to be through large-scale mining way to achieve considerable economic benefits. With the improvement of horizontal well drilling, cluster well drilling and pad drilling have been widely used in drilling operation in America. With the adoption of pad drilling, multiple horizontal wells can be drilled in the same well, which can improve the mining area of oil and gas so as to reduce the cost of single well [3]. This mode can save space, be easy for centralized operation, increase mining area and realize large-scale mining, so it has been one of the most popular ways in drilling.

Batch drilling. Batch drilling, in short, is the drilling method of using a drill in the same wellblock to complete the surface casing, intermediate casing or oil-string casing. In drilling practice, it is mainly used in surface drilling of cluster well. It will remove the drilling machine to the next well immediately and go on drilling the next one, if one well is completed. Special surface drilling machine has the characteristics of small size, flexible, convenient and cheap. Also, it is very fast in drilling surface. It only needs 36 hours to finish drilling the surface of 500 meters. It can save the time of waiting greatly, so as to improve the use ratio of drilling machine and reduce the cost of drilling.

Factory drilling. The road to success of America's high-efficient development is to reduce the cost of drilling and completion, ensure cementing and fracturing quality, so as to increase the single well production. One important way is factory operation, which is to design multiple wells. From drilling, perforation, fracturing, completion to production, the overall process is completed by central area, so as to give full play to the advantages of automated drilling machine.

The concept of factory drilling aims to solve the problems of frequent cross-operation and repetitive operation. It is formed to improve the operational efficiency and reduce operating costs. Its core is to implement the equipment and process standardization, and improve continuously in the process of drilling. Factory Drilling refers to the decoration of many similar wells and the use of plenty of standardized equipment or services in the same area. It is an effective and low cost operation mode which is in the form of production or assembly to conduct drilling and well completion. Factory drilling promotes the fast growth of the number and speed of horizontal wells in America and also plays a key role in the cost reduction of shale gas.

Reservoir volume fracturing. Factory operation can not only improve the drilling efficiency, but also improve the effect of reservoir reconstruction. The cost of single well of four shale gas reservoirs (Barnett, Haynesville, Fayetteville, Marcellus) in America, drilling expense and reservoir reconstruction make up more than 80% and each one accounts for a half. Low-cost strategy is the key to realize the effective development of shale gas. Reservoir volume fracturing could encourage the interaction in the process of hydraulic fracture to generate a more complex net to increase volume. Reservoir volume fracturing is the key technology to realize low-cost development.

Implementation methods:

(1) Simultaneous fracturing--Two sets of fracturing trucks fracture at the same time;

(2) Crossing fracturing--Two wells, one set of fracturing truck, perforation and some other operating types construct interactively and fracture by piece.

Tab 1 Production data and well cost of building in America

	Barnett	Marcellus	Haynesville	Fayetteville
Initial capacity of well $10^4m^3/d$	7	12	28	5.3
Decline rate of the first year %	70	75	81	68
Recovery ratio	0.74	0.75	0.82	0.62
Well cost of building 10^4\$	280	350	700	300

The great effect of factory operation can be shown from the following points:

(1) It raises the initial production and final recovery ratio;

(2) It reduces the operation time and moves of facility, so as to reduce the cost of construction;

(3) The average output can raise 21% to 55% compared with single fracturing.

The main features of organization form lie in drilling in bulk, truckload, storing containers, bulk operation and reducing the mud replacement.

The fiscal and taxation incenting policy to promote the low cost and efficient development of shale gas

The U.S. government in the late 1970s and early 1980s established the fiscal and taxation incenting policies, including price incentives and tax credits to develop the unconventional gas. The implementation of these policies played a key role in improving the economic benefits of shale gas and other unconventional gas, arousing the enthusiasm of producers, increasing the drilling of unconventional natural gas and promoting the technological progress and the development of shale gas industry. These policies are the successful implementation of the strategy for the development of shale gas at low cost.

Price incentives. America published '*Natural gas policy act*' in 1978 which was in view of the unconventional gas price incentives [4]. Shale gas, coal-bed methane, tight gas and other unconventional gas were classified as "high cost" of natural gas, which were allowed to increase the control price limit year by year. The act also removed the price controls of new wells of unconventional natural gas.

Tax credits. America published '*Crude oil windfall profits tax act*' in 1980 which stipulated that shale gas and tight gas were implemented tax deduction and exemption which were between 1979 and 1993 and after2003 [5]. '*Internal revenue code*' increased the tax credits of No. 29 which aimed at unconventional natural gas. It stipulated that tax credit was based on the production and the credit was 3 $/barrel, about 0.52$/ thousand cubic feet. Other unconventional fuel tax credits were adjusted according to the inflation rate year by year except for tight gas [6].

Statistical research suggests that America's price incentives and tax credits have significant positive correlation relationship with the number of unconventional gas wells. Policy incentives make unconventional gas drilling more active, the increase in the number of drilling promotes the technological progress and technological progress accelerates the drilling, reduces the cost of development of unconventional natural gas, increases the gas reserves and production. Unconventional gas production increased nearly 50% in the United States, while conventional gas production increased less than 10% between 1987 and 1992.

Comparison between the present situation of shale gas development between China and America

In the development of shale gas resources, it mainly exist the following differences in China and America at present.

Differences in the resource characteristics. China is similar to America in the development, quality and other aspects of organic shale, but enrichment region is located in the Sichuan mountains which was discovered at present, thus it is hard for the quick movement of drilling machines, which increases the difficulty and cost of development.

Differences in the development process. The shale gas development has formed eight production patterns in America, and it has been into the commercialization stage completely [7]. Unconventional natural gas production was 190 billion cubic meters in 2011 which made up 30% of gas production. While shale gas development in China is still in the stage of exploration and Chinese are carrying out the research experiments now.

Differences in the technological level. Lots of research input and technical progress were the main power to promote the development of America's unconventional gas, which formed high efficiency and low cost technology and technology integration promoted the exponential growth of shale gas production.

China's drilling well types and the ways of completion in the development of shale gas are fairly homogeneous, the technology of drilling and completion of slim hole is not matched and the technology which is suitable for shale gas' large displacement fracturing is still immature.

Differences in the policy environment. The early research input in shale gas which was dominated by government, policies support, commercial operation practices, perfect infrastructure and pipeline network provided a good environmental condition for America's shale gas industry.

Implications and suggestions

The successful implementation of the strategies for the development of low-cost shale gas was the result of market, technology, management, finance and tax and legal policy which provided the enlightenment to the development of shale gas industry in China. People in China should draw lessons from the example of America, combine China's own characteristics, study and formulate effective means and methods of the shale gas development, so as to promote the scientific development of the shale gas industry in China.

Using the experience of factory drilling for reference and promoting low cost and efficient development of shale gas. Low cost and efficient development of shale gas needs not only the continuous improvement of drilling technology, but also the improvement of production methods and the refinement of management. Factory operation is a technological progress and a kind of management innovation. It can effectively solve the problems of cooperation, time waste, cost control in the operations. The successful experience of unconventional oil and gas development in America is of great significance for promoting shale gas and other unconventional oil and gas development in China.

Emphasis on the accumulation of experience and preparing for technology. China should pay more attention to the accumulation of experience and technology, increase the technology and management of laboratories, accumulate experience rapidly, speed up the pace of learning and improvement, promote work in all areas by drawing upon the experience gained on key points, in order to move towards from experimental zone to large-scale application.

Related policies coming into being as soon as possible. To begin with, the business model which is dominated by large companies can widely attract the capital investment of shale gas development. China should insist on keeping the markets open and expanding the cooperation and introduce the foreign companies with unique technology boldly. China can also introduce key technology, equipment and management experience through acquisitions or foreign cooperation. Thirdly, the preferential amount should be increased and the subsidization criteria should be improved. Last but not least, China should speed up the policies of fiscal and taxation policies with aspiration and regulations.

Keywords: Coal mine roadway, rock bolt support, surrounding rock, classification

Abstract:. Classification of Surrounding rock of roadway of Coal mine bolt supporting is the basis of bolting design, To scientifically design coal roadway bolting, classification of surrounding rock of coal roadway bolting must first be carry out. in this paper, the comprehensive application of knowledge engineering, rock mechanics, we developed the surrounding rock classification system for the bolt support of coal mine roadway engineering, the surrounding rock classification system is practical easy to use, the bolt supporting of roadway surrounding rock classification results to the coal mine roadway bolt support has important significance and practical value.

Introduction

Surrounding rock classification of roadway of Coal mine bolt supporting of roadway is the basis of bolting design, To scientifically design coal roadway bolting, classification of surrounding rock of coal roadway bolting must first be carry out. Throughout the surrounding rock classification methods at home and abroad [1-5], according to the classification of surrounding rock by considering factors and adopt different index and classification method of surrounding rock can be generally summarized as the following: (1) the single factor index classification, such as rock strong coefficient f as the classification index, although this method reflects the characteristics of the rock on the one hand, but with a single index to determine the surrounding rock which is influenced by many factors is incomplete. (2) Multiple factors combined qualitative and quantitative indexes of classification, compare with a single index classification, it has the obvious progress and caught the main influence factors of the stability of surrounding rock. (3) Multifactor composite index classification, this kind of classification method consider the effect of various factors on the stability of surrounding rock, it more fully reflect the engineering properties of surrounding rock, it is a good kind of surrounding rock classification method.

The Influence factors analysis of Coal mine roadway bolting support surrounding rock classification

Due to different roadway of coal mine corresponding to different geological conditions, the bolt support may be subjected many influence factors to its surrounding rock classification, and it is the interaction, mutual influence, it can be analyzed in the large system theory decomposition-coordination analysis, as is shown in Fig.1

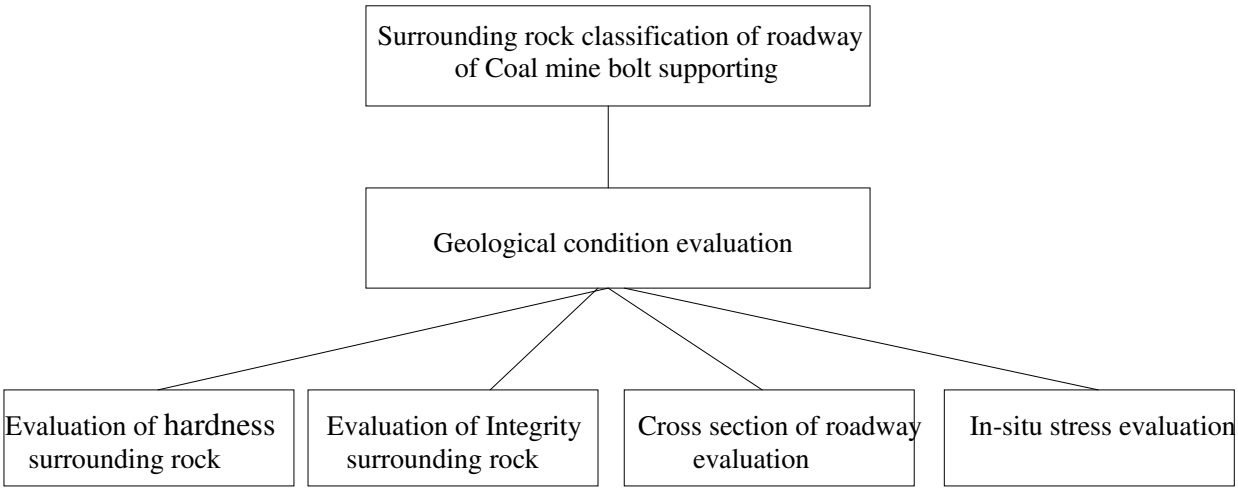

Fig.1. Factors analysis of classification of bolt support surrounding rock

Based on the experience of a large number of data and In-situ field engineering, coal mine roadway bolting surrounding rock classification should consider the following factors:

(1) Evaluation of hardness of surrounding rock

The strength of surrounding rock of roadway directly influence on the roadway stability of the roadway after excavation, the higher the strength of surrounding rock, the easier it is to support of roadway, on the other hand, supporting the more difficult. Roadway surrounding rock hardness evaluation factors is shown in Fig.2

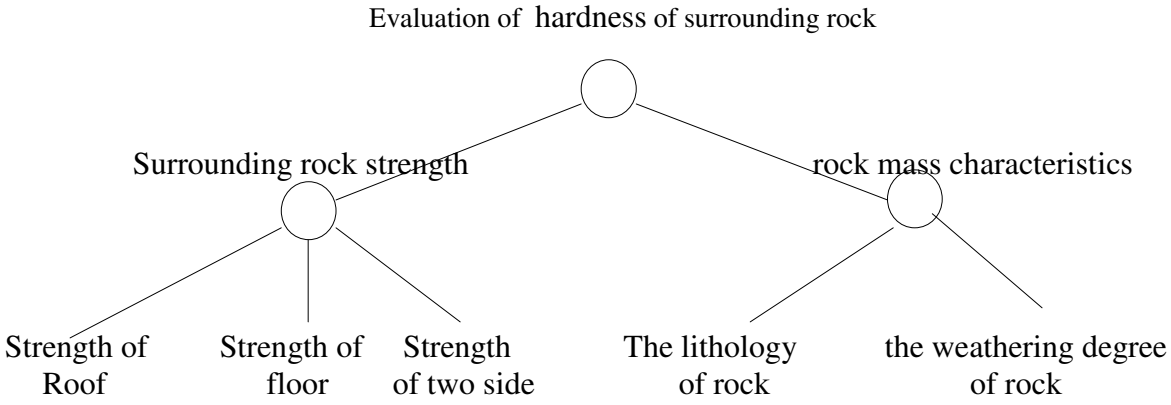

Fig.2. Evaluation factors analysis of rock hardness of roadway surrounding rock

(2) Evaluation of Integrity of surrounding rock.

Roadway surrounding rock with different geological weak surface and structural planes, such as bedding, joint and fissure, weak intercalation, the weak surface and structure surface, largely weaken the integrity of rock mass, it is weak surface and structural planes that easily lead to the unstability of the roadway, Evaluation of Integrity of surrounding rock factors analysis is shown in Fig.3

(3) Evaluation of Cross section of roadway

The cross section of roadway, the greater the balance disturbance to the surrounding rock of roadway in the greater the influence, also is not easy to support , Cross section of roadway evaluation factors analysis is shown in Fig.4

(4) In-situ stress evaluation

In-situ stress is the cause of roadway surrounding rock deformation and failure of the main force, the mining depth of roadway ground stress has a direct impact , In-situ stress evaluation factors analysis is shown in Fig.5

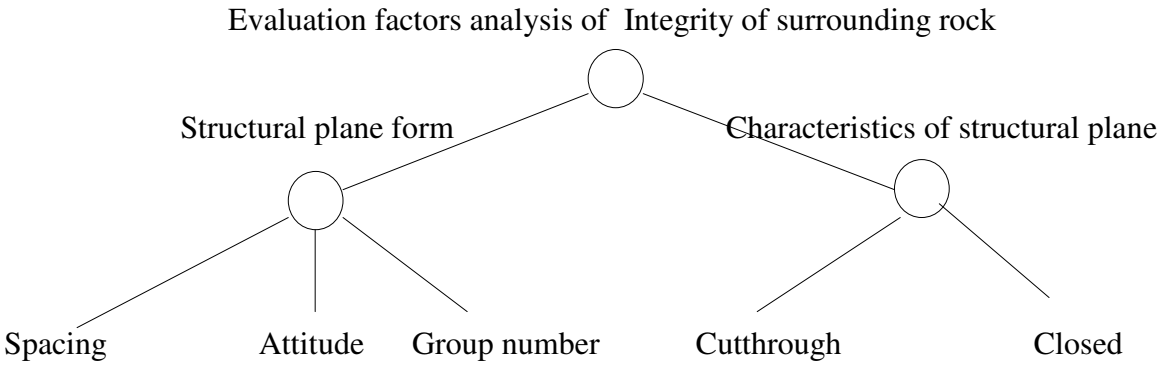

Fig.3. Evaluation factors analysis of Integrity of surrounding rock

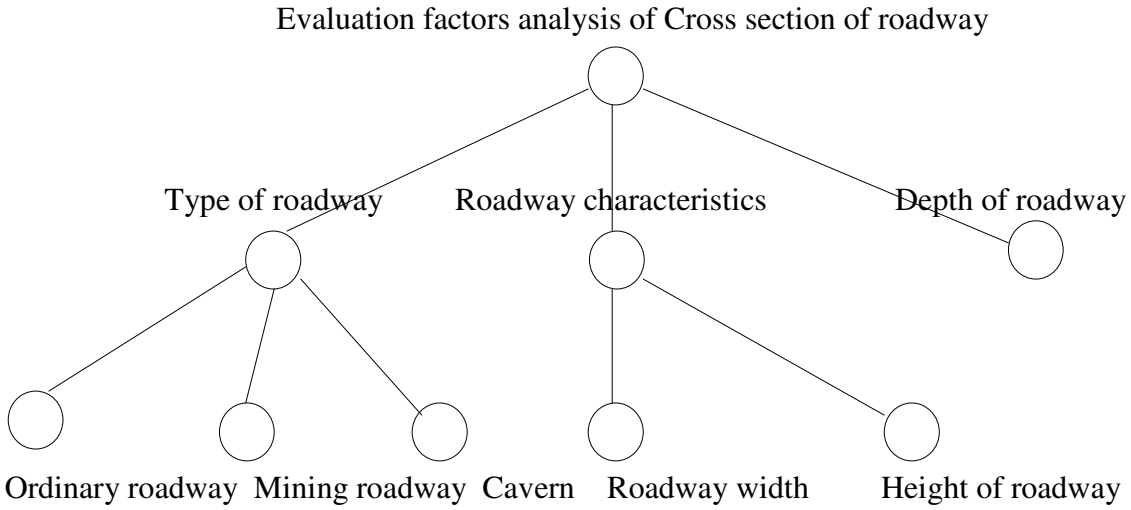

Fig.4. Evaluation factors analysis of Cross section of roadway

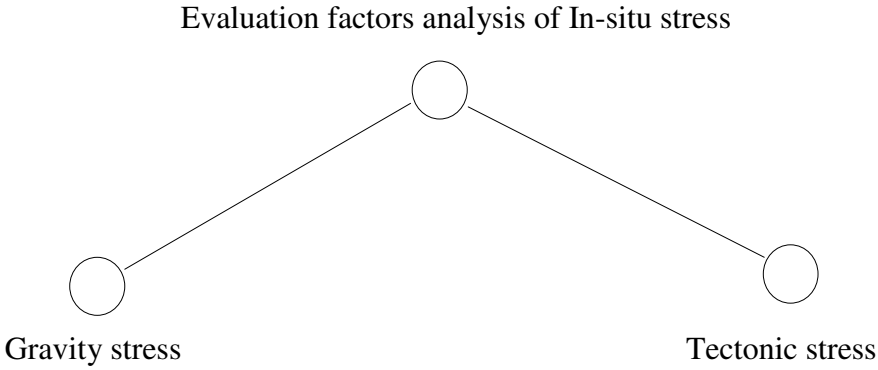

Fig.5. Evaluation factors analysis of In-situ stress

Classification of Bolt Supported Surrounding Rock in Coal Mine Roadway

Based on the experience of coal roadway bolting, Select the following coal roadway bolting surrounding rock classification indexes：（1）strength of surrounding rock of roadway σ,（2）joint influence coefficient J , (3) roadway width L, (4) mining depth H.

Classification of Bolt Supported Surrounding Rock in Coal Mine Roadway is shown in Table 1

Table 1 Classification of bolt supported of surrounding rock in coal mine roadway

Classification	Strength of surrounding rock of roadway σ / *Mpa*	Joint influence coefficient J	Roadway width L / *m*	Mining depth H / *Km*
Ⅰ	<25	<0.4	>8	>1
Ⅱ	25～40	0.4 ～ 0.6	5 ～8	0.6 ～1
Ⅲ	40～65	0.6 ～0.8	3.6～5	0.3 ～0.6

Keywords: Shale; Finite Element; Stress Anisotropy; Fracturing; Fracture

Abstract. Theoretical studies have shown that the generation of the hydraulic fractures reduces or even reverses the stress anisotropy near the fractures and results in increasing the complexity of fractures. A finite element model was established in which the pore pressure elements were used to simulate the behavior of porous media and the pore pressure cohesive elements were adopted to catch the characters of hydraulic fractures. A special fracturing manner was adopted to create complicated fracture networks by reducing or even reversing the stress anisotropy between fractures. The geometries of hydraulic fractures, strains, stresses, pore pressure distributions and fluid pressures within the fractures are obtained. The results of the model are fit well with the corresponding theoretical data. The simulation results show that the stress anisotropy is reduced by the generation of the hydraulic fractures, multiple parallel transverse fractures of horizontal well even reverse the stress anisotropy in some place of the reservoir. The simulation results validate the feasibility of the theoretical studies and the expected complex network fractures could be created by adopting special fracturing manner.

Introduction

Shale is organic-rich formation and also is the source rock as well as the reservoir. The shale gas is stored in the pore space of the reservoir, and a considerable of the shale gas is adsorbed on the organic material. The shale reservoir has low or ultra-low permeability, and it is no economic productivity except the stimulation treatments are implemented. It is important to realize that economic production in these low or ultra-low permeability reservoirs can be increased by creating fracture networks.

The typical characters of shale reservoirs are：(1) The permeability is between 0.000001 mD and 0.001 mD; (2) The thickness is between 15 m and 180 m; (3) The effective porosity is 1~5%; (4) The depth is between 300 m and 3000 m; (5) The percentage composition of quartz is 40~50%; (6) The content of organic carbon is larger than 2%, and the grade of maturity is 1.4~3%; (7) The brittleness coefficient is high, and it is easy to create fracture network; (8) Shale gas in shale reservoir is mainly in free state, adsorption state and dissolved state [1].

The Conception of Fracture Network Fracturing and Multi-fracture Fracturing

For the low and ultra-low permeability shale reservoir, the major fracture and branch fractures are created simultaneously when fracture net pressure reaches the sum of horizontal differential stresses and rock tensile strength. Multiply branch fractures and the major fracture intersect and the complex fracture network is created [2]. Figure 1 is the sketch map of ideal fracture network when volume fracturing is performed. Volume fracturing is a special hydraulic fracturing in which hydraulic fractures and natural fractures propagate simultaneously and the fracture network is

created. Multi-fracture fracturing is a special volume fracturing. Volume fracturing is not only adapt to ultra-low permeability shale reservoir, but also to tight gas reservoir and coalbed methane reservoir.

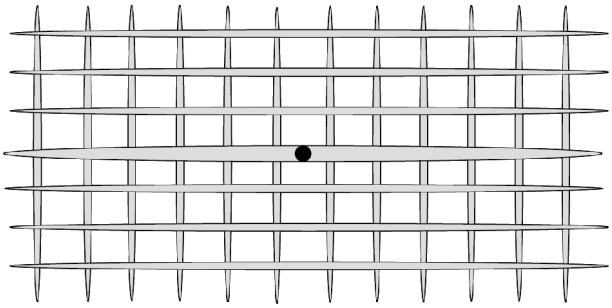

Fig.1 Sketch map of ideal fracture network

Suitable Reservoir Conditions for Fracture Network Fracturing

Stress Field of Shale Reservoir

The stress distribution in shale reservoir has a crucial effect for the generation of fracture network. For conventional reservoir, the created hydraulic fractures are perpendicular to the direction of the least principal stress. For the ultra-low permeability shale reservoir, it is need to create fracture network to maximum the conductive surface area in contact with the shale matrix. When fracture net pressure reaches the sum of horizontal differential stresses and rock tensile strength, the branch fractures initiate and propagate [2]. When the horizontal differential stresses are small, the generation of branch fractures is easy.

Modulus and Poisson's Ratio of Shale Reservoir

In the production stage, the flow conductivity of branch fractures has a considerable effect on productivity of oil gas well. The larger elastic moduli of shale reservoir results in the smaller embed distance of proppant, and the higher flow conductivity of fractures [3]. The ratio of elastic modulus to poisson's ratio represents the brittleness of rock, the larger the value, the more brittle of the rock [4]. The more brittle the shale reservoir is, the easier of creation of branch fractures and complex fracture network.

Shale Reservoir Heterogeneity

The shear fractures are easily created when shale reservoirs have many natural fractures, joints, and intercalary strata, and these discontinuity surfaces have a small angle with the horizontal maximum principal stress [5-7]. The formed shear fractures and the major fractures intersect, and the complex fracture network is generated [8].

Performance Evaluation of Shale Reservoir Fracture Network Fracturing

The Stimulated Reservoir Volume of Shale Reservoir

For the ultra-low permeability shale reservoir, it is normal to adopt the microseismic monitoring technology to estimate the stimulated reservoir volume (SRV). In the process of hydraulic fracturing, microseismic monitor technology mainly records the shear deformation which result from stress variation around fracture tip and pore pressure variation because of the leakoff of fracturing fluid. For the ultra-low permeability shale reservoir, the pore pressure variation because of the leakoff of fracturing fluid is very small, the shear deformation resulting from the pore pressure variation could be ignored, thus the signals recorded by the microseismic monitoring technology are mainly the shear deformation resulting from the stress variation around the fracture tip. The volume besieged by the boundary of all the recorded shear deformation is the stimulated reservoir volume (SRV) [9].

Fracture Spacing of Fracture Network

The stimulated reservoir volume (SRV) has no any detail about the construction of fracture network, which has considerable affect on the fracturing treatment effect. The total length of fracture network can be expressed as [9]

$$L_{ftotal} = \frac{4x_f x_n}{\Delta x_s} + 2x_f + x_n \quad (1)$$

Where: L_{ftotal} is the total length of fracture network; x_f and x_n are the half length and the width of fracture network, respectively; Δx_s is the fracture spacing of fracture network.

Form the above equation, the larger the L_{ftotal} is, the better the fracturing treatment effect, so for the same stimulated reservoir volume (SRV), the smaller the fracture spacing is, the better the fracturing treatment effect.

Petrophysical Parameters and Treatment Parameters Effect on Multi-fracture Fracturing

Properties of Fracturing Fluid

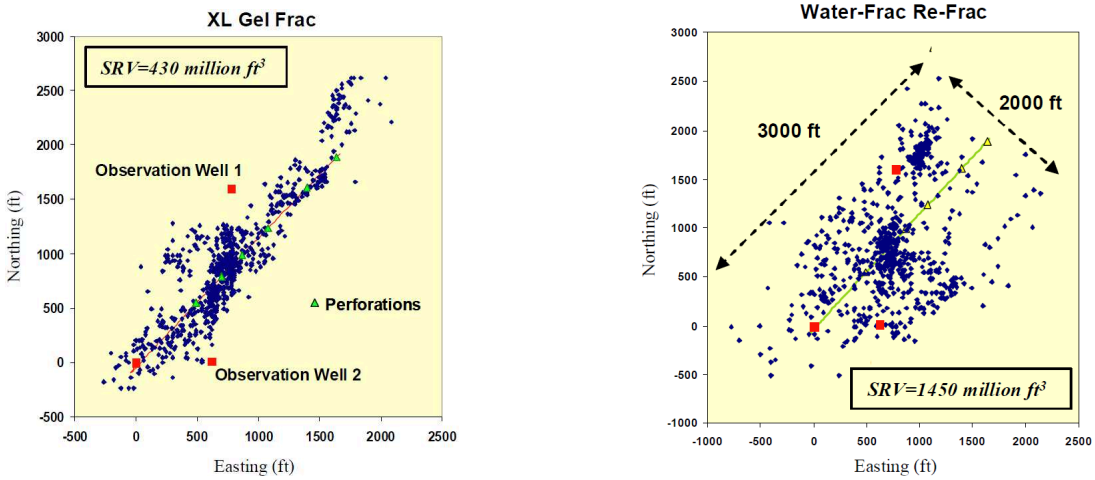
The viscosity of fracturing fluid has a considerable affect on the complexity of the fracture network. Laboratory and field experiment have verified that the complexity of fracture network near and away from the wellbore when enlarging the viscosity of fracturing fluid [3]. In the process of hydraulic fracturing, the flow distance of fracturing fluid within branch fractures can be expressed as [3, 10]

$$y = \sqrt{\frac{2k\Delta Pt}{\varphi\mu}} \quad (2)$$

Where: y is flow distance of fracturing fluid within branch fractures; k is the permeability of branch fractures; ΔP is fluid pressure gradient along the fracture; t is the opening time of fracture; φ is the porosity of fracture; μ is the viscosity of fracturing fluid.

From the above equation, the flow distance of fracturing fluid within branch fractures has a inverse ratio to the viscosity of fracturing fluid, so reducing the viscosity of fracturing fluid can increasing the complexity of fracture network.

Figure 2 is the microseismic record dots map for the same well [11]. (a) adopts the cross linked gel as the fracturing fluid, (b) employs water as fracturing fluid after (a) has been performed. The stimulated reservoir volume (SRV) in (b) is larger than (a), it can conclude that the low viscosity fracturing fluid can increase the complexity of fracture network and the stimulated reservoir volume.



(a) Cross-linked gel fracturing (b) Water-fracturing re-fracturing

Fig.2 Microseismic event cloud structure observed by microseismic fracture mapping

Properties of Proppant

For the same proppant concentration and proppant compressive strength, smaller proppant has larger superficial area and larger contact area with fracture, so it is unbreakable [3]. Smaller proppant has larger contact area with fracturing fluid, is easily been carried into the tips of fractures, can enlarge the flow conductivity of the fracture.

Treatment Flow Rate

For the volume fracturing, because of the large stimulated reservoir volume and high net pressure to create branch fractures, it needs to adopt large injection flow rate.

Change In-situ Stress and Generate Complex Fracture Network

The Effect of Obtained Fractures on Reservoir Stress Field

The reservoir stress field has a crucial effect on the fracture network [12]. The generated fractures will change the in situ stress around the fractures, and has affect on the shape and configuration of subsequent fractures.

In 1946 Sneddon proposed the plain strain model, which gives the theoretical formulae about the changed stress resulting from the generation of fractures [13]. Figure 3 is the sketch map of the plain strain model, in which σ_h and σ_H are horizontal minimum principal stress and maximum principal stress, respectively.

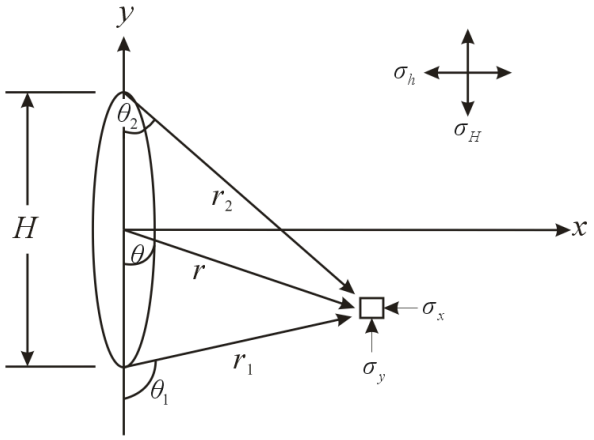


Fig.3 Sketch map of the plain strain model

The basic support is that the shale reservoir is an isotropy, homogeneous linear elastic material. Based on the plain strain model, the theoretical formulae are listed as:

$$\frac{1}{2}(\Delta\sigma_y+\Delta\sigma_x)=p_o\left\{\frac{r}{\sqrt{r_1r_2}}\cos(\theta-0.5\theta_1-0.5\theta_2)-1\right\} \tag{3}$$

$$\frac{1}{2}(\Delta\sigma_y-\Delta\sigma_x)=p_o\frac{2r\cos\theta}{H}(\frac{H}{4r_1r_2})^{3/2}\cos(\frac{3}{2}(\theta_1+\theta_2)) \tag{4}$$

$$\Delta\tau_{xy}=-p_o\frac{2r\cos\theta}{H}(\frac{H}{4r_1r_2})^{3/2}\sin(\frac{3}{2}(\theta_1+\theta_2)) \tag{5}$$

$$\Delta\sigma_z=\mu(\sigma_x+\sigma_y) \tag{6}$$

Where H is the height of fracture; p_o is the internal fluid pressure; $\Delta\sigma_x$, $\Delta\sigma_y$, and $\Delta\sigma_z$ are the induced stress in x direction, y direction and z direction, respectively; $\Delta\tau_{xy}$ is the induced shear stress in the xy plain.

The following geometry relationship could be obtained from figure 3.

$$L=\sqrt{x^2+y^2} \tag{7}$$

$$\theta=\tan^{-1}\left(-x/y\right) \tag{8}$$

$$L_1=\sqrt{x^2+(y+H/2)^2} \tag{9}$$

$$\theta_1=\tan^{-1}\left[-x/(y+H/2)\right] \tag{10}$$

$$L_2=\sqrt{x^2+(y-H/2)^2} \tag{11}$$

$$\theta_2=\tan^{-1}\left[x/(H/2-y)\right] \tag{12}$$

Basing on equations (3)~(12), Soliman obtains the relationship between the reduced stress and the distance away from the fracture [14], as depicted in figure 4. In the figure, both the vertical and the horizontal coordinates are dimensionless. The reduced stress near the fracture in the *x* direction is larger than the *y* direction, that is $\Delta\sigma_x > \Delta\sigma_y$, so the created fracture reduce of even reverse the differential stress between *x* and *y* directions, resulting in the generation of fracture network easier. In same place near the fracture where the equation $\sigma_h + \Delta\sigma_x = \sigma_H + \Delta\sigma_y$ meets, the fracture network is easiest to come into being.

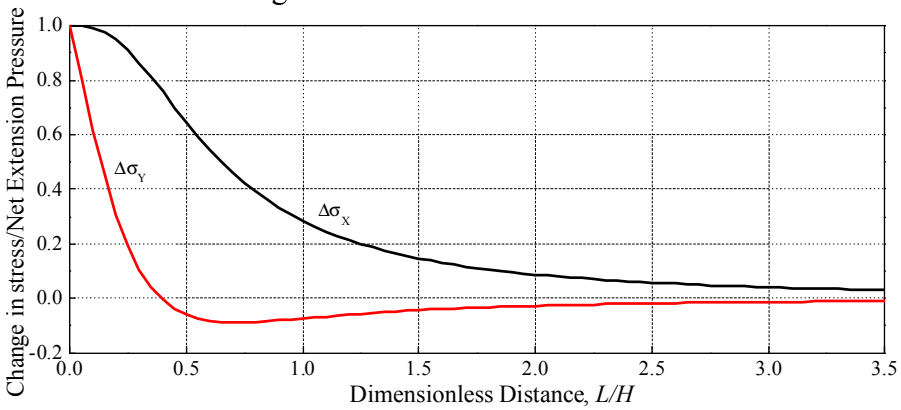

Fig.4 Reservoir stress change resulting from the presence of a plain strain fracture

Generate Fracture Network by Taking Fracturing Treatment

Shale reservoirs have a high brittleness, and are easy to create stress-relief fractures, as depicted in figure 5. Microseismic data have proved that stress-relief fractures do not intersect with the major fracture. Special fracturing treatment should be carried out to intersect stress-relief with the major fracture and to create complex fracture network.

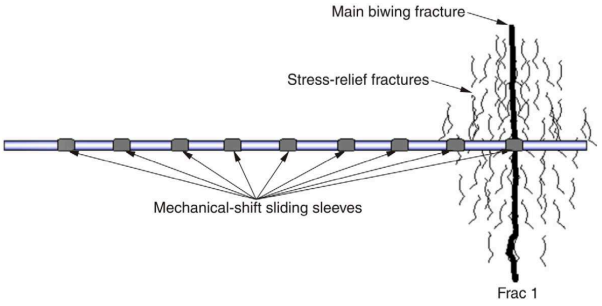

Fig.5 The generation of Fracture 1

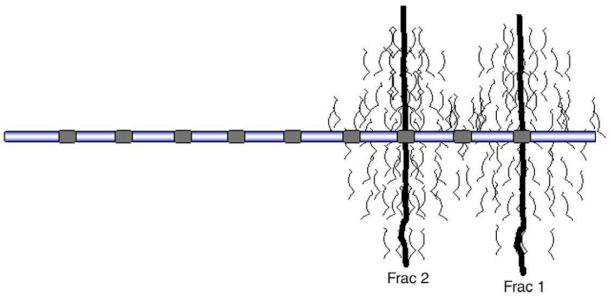

Fig.6 The generation of Fracture 2

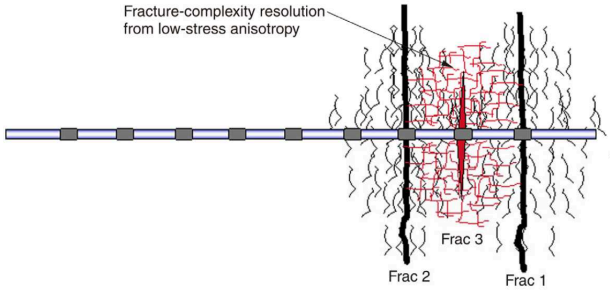

Fig.7 The generation of Fracture 3

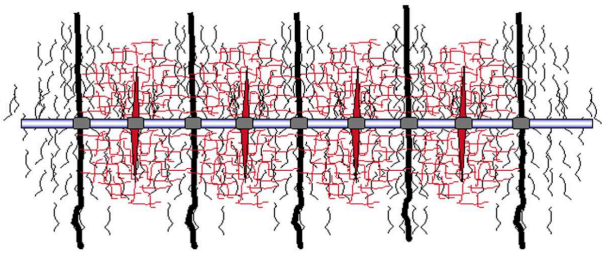

Fig.8 The final complex fracture network

The formed fracture change the stress field near the fracture, the stress anisotropy of the formation between two formed fractures is considerably reduced. Complex fracture network is easily created if hydraulic fracturing are performed in this place [15, 16]. For the horizontal well staged fracturing, it is possible to create complex fracture network by change the sequence of fractured interval. The first fracture are created at the toe of the horizontal well (Figure 5), then, moving toward the heel, a second fracture are formed (Figure 6). Then, instead of continuing toward the heel, the third fracture is generated between the two formed fractures (Figure 7). The generation of the third fracture reverses the stress field between the two formed fractures, and the

reduced stress-relief fractures intersect with the three major fractures and previous generated stress-relief fractures, and the complex fracture network are created. Following this fracturing sequence, a horizontal completion with nine fracturing intervals is illustrated in Figure 8 [17, 18].

Conclusions and Recognitions

(1) Shale reservoirs have low or ultra-low permeability. In order to get economic productivity special fracturing treatments are needed to create complex fracture network.

(2) The stimulated reservoir volume (SRV) and fracture interval of fracture network are two important parameters for evaluating the volume fracturing. Large SRV and small fracture interval could improve stimulation effect.

(3) The stress field has a crucial effect on the creation of fracture network. The fracture network is easily created when the horizontal differential stress is small. The brittleness of shale reservoirs has also important affect on the generation of fracture network.

(4) The property of fracturing fluid and proppant has considerable affect on the stimulation effect. Small viscosity of fracturing fluid can improve the complexity of fracture networks. Small particle size proppant can increase the flow conductivity of fractures.

(5) The generation of fractures can reduce the stress anisotropy around the fracture. Multiple parallel transverse fractures of horizontal well further reduce or even reverse the stress anisotropy in some place of the reservoir. Special stimulation treatment can be performed to decrease the stress anisotropy, and it is possible to create complex fracture networks by employing the special fracturing methods.

The research of energy efficiency construction design with pollution control consideration

Guohaiqing

Inner Mongolia Technical College of Construction，Hohhot, Inner Mongolia，010070

Keywords: differentiations; architectural groups; landscapes; distribution model

Abstract: Focusing on the architectural proper distribution problems with low energy consumption, this paper analyzes the architectural distribution model and builds the architectural landscape target location distribution model with pollution control consideration. According to the features of the architectural landscape pollution control, the paper analyzes the architectural landscape target location distribution model with differentiations and finds the optimal distribution with less pollution for the architectural landscapes. The Oealcle spatial is used to describe the relationship model of the vegetation objects in the landscapes in order to obtain the optimal distribution model for the architectures with differentiations. The simulation experiments illustrate the proposed model can appropriate distribute the architectural landscapes with differentiations with better pollution control effects.

1 Introduction

With the rapid economic development, China's urbanization rate is gradually improving. People have more stringent requirements for the architectural landscape distribution[1]. The architectures are not only important parts for the cities, but also reflection of the changes in the landscapes. However, the pollution from the architectures is unavoidable. To seek a reasonable way to get cleaner landscape distribution model is a hot research issue for related personnel[2,3]. The architectural landscapes with less pollution have dynamic and stochastic characteristics. The traditional two-dimensional geographic analysis method[4,5] cannot handle the uncertainty characteristics caused by architectural landscape pollution. Therefore, there are big deviations of the architectural landscape distribution results with large defects.

2 The simulation analysis of the landscape distribution model with different architectures

2.1 The establishment of the landscape objective positions distribution model

Typically, the architectural landscape distribution will be affected by the surrounding complex surfaces and their own features, such as contribution ratio between input and output of the landscape type, building density, average building height and building area ratio which are dynamic architectural landscape features. Therefore, the target position data of the architectural landscape have uncertain features. According to the central limit theorem, the initial positions of the architectural landscape targets are considered to follow two-dimensional normal distribution $N(0,\sigma_0^2)$. The center of the building distribution is the initial point which follows the independent distribution of x_0 and y_0. Assuming the initial position is the origin of the coordinates and subjects to distribution of $N(0,\sigma_0^2)$. The building the joint probability density function in the polar coordinates (R,Θ) is expressed by equation (1).

$$\varphi_0(r,\theta)=f_0(r\cos\theta,r\sin\theta)\bullet\left|\partial(x,y)/(\partial(r,\theta)x)\right|=[r/(2\pi\sigma_0^2)]e^{-r^2/(2\sigma_0^2)}((r,\theta)\in D) \quad (1)$$

In the equation, $D=\{(r,\theta)|r>0,\theta\in[0,2\pi)\}$. The probability density of R and Θ can be expressed by equation (2).

$$\begin{cases} \varphi_{R_0}(r)=\int_0^{2\pi}\varphi_0(r,\theta)d\theta=(r/\sigma_0^2)]e^{-r^2/(2\sigma_0^2)}I_{(0,+\infty)} \\ \varphi_{\Theta_0}(\theta)=\int_0^{+\infty}\varphi_0(r,\theta)dr=\dfrac{1}{2\pi}I_{[0,2\pi)} \end{cases} \quad (2)$$

In the equation, I is unit function.

Equation (1) can be transformed to the format of $\varphi_0(r,\theta)=\varphi_{R_0}(r)\varphi_{\Theta_0}(\theta),(r,\theta)\in D$. In polar coordinates, R follows Rayleigh distribution, Θ following the uniform distribution on the interval of $[0,2\pi)$, and R and Θ are independent for each other.

The architectural landscape target distribution is increasingly expanding with the initial position distribution as the center and the degrees of the position distribution expand is relative to the changing modes of the architectural landscape dynamic changing features. Therefore, the architectural landscape target positions are consisted of two parts-initial distribution and distributions determined by the uncertainty of the architectural feature elements. This paper analyzes the distribution model of the architectural landscape target position with differentiations according to the architectural landscape dynamic changing features. Because of the uncertainty and dynamics of the architectural landscape features with differentiations, the distribution model of the architectural landscape with differentiations is random distribution model. The position and direction of the unknown architectural landscape target follow uniform distribution in the interval of $[0,2\pi)$. Assuming the initial position follows uniform distribution, the distribution model of random architectural landscape target can be deduced. When the source target remain stable after time t_0, the probability density function of the position of the architectural landscape is expressed by equation (3).

$$\begin{cases} \varphi(r,\theta)=[r/(2\pi\sigma^2)]e^{-r^2/(2\sigma^2)} \\ \sigma^2=\sigma_0^2+2(\bar{v}t_0)^2/\pi \end{cases} \quad (3)$$

In the equation, $\bar{v}$ denotes the mean of the objective architectural landscape distribution function which is usually considered as a reasonable landscape distribution.

2.2 The add of pollution constrains in the model

In the procedure of architecture distribution, the costs generated by the pollution control process should be considered. The architecture distribution and pollution control information have strong relativity. When the amount of architecture meets $N(t_0)<k$ in equation (1) or close to k, the constrains should be applied.

The pollution levels generated by the architecture exceed the threshold of law penalty, it should be punished. The utility of the architecture generating pollution can be expressed by equation (4).

$$u_f-(\gamma+\Delta\gamma)\ \ u_c>0 \quad (4)$$

u_f is construction cost, u_c is the extra cost due to pollution, γ is penalty proportion, $\Delta\gamma$ is penalty compensation coefficient. By analyzing equation (3), the norms the utility should meet after breaking the constrains can be expressed by

$$u_f-\Delta\gamma u_c>\gamma u_c \quad (4)$$

The pollution behavior will be completely punished and the utility norms generated by the architecture can be expressed by

$$FU=(u_f-\Delta u_f)-(\gamma+\Delta\gamma)u_c>0 \quad (5)$$

The increase of the penalty probability and reduce of the predication efficiency will prevent the trends of some polluted architecture. The norms of the architectural distribution utility after breaking the lawful constrains can be expressed by

$$u_f-\Delta u_f-\Delta\lambda u_c>\gamma u_c \quad (6)$$

The architecture enterprises who disobey the laws will pollute the environment. The equations (2) and (4) are compared and analyzed and the critical points in equation (2) and (4) are higher than those in equation (1) which illustrate the information disclosure will inhibit the process of law-abiding behaviors of some architecture enterprises.

3 Simulation experiments

In order to verify the validity of the proposed model, simulation is necessary. The simulation experiment builds models of the 3D landscape of the architectural groups with differentiations with differentiations in some regions. The region area is 150km × 120km which contains different types of vegetation, buildings and roads. The experiments analyze the representative objects, such as trees and buildings which are imported from the two-dimensional image map in the navigation shoot. The shapes of the buildings and roads are generated by the software of 3Dmax and transformed to SDO_Geometry object format. The vegetation model is generated by fractal technology and stored as SDO_Geometry format. The experimental platform is with 2.4GHz P4 processor, 512M RAM and 32M display memory. In the experiments, the plan effects with the proposed model and traditional model with two-dimension images are described in Fig. 1.

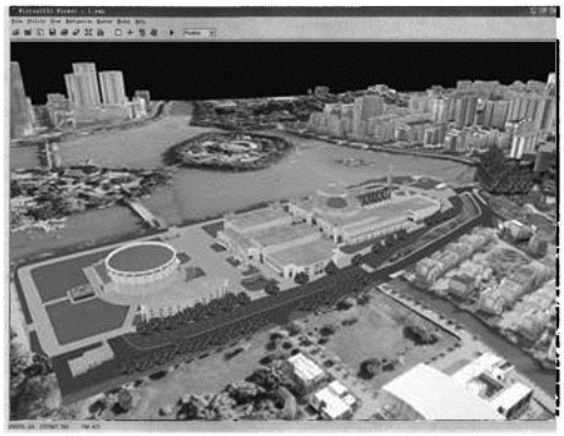

Fig.1 The architectural landscape distribution scheme with proposed model

The pollutions and energy costs caused by different layout methods are described in Table 1.

Table 1 The architectural distribution effects comparison with three algorithms

Max Energy	Mean model		Variance model		Proposed model	
	Mean costs	Mean time consuming/ms	Mean costs	Mean time consuming/ms	Mean costs	Mean time consuming/ms
200	108684.62	4.01	100558.43	1.60	99776.82	1.21
250	110694.67	3.48	101867.10	1.60	99983.74	1.22
300	108565.93	3.72	99793.46	1.61	98293.22	1.22
350	108959.22	3.82	101256.82	1.61	99939.29	1.22
400	110649.82	3.77	102124.34	1.61	99873.98	1.22
450	109466.72	3.92	100520.07	1.60	99923.87	1.21
550	108923.65	3.76	100882.76	1.61	99843.45	1.22
650	108466.23	3.46	99903.29	1.61	98329.32	1.22
750	107687.62	3.68	99035.85	1.61	98231.28	1.21
950	105827.73	3.89	102360.27	1.62	100217.62	1.22

By Fig. 1 and Table 1, the energy savings of the proposed model for the architectural landscape distribution plan are better than those in the traditional models with satisfactory results.

4 Conclusions

This paper builds the architectural landscape target location distribution model with pollution control consideration which analyzes the architectural landscape target location distribution model with differentiations and finds the optimal distribution with less pollution for the architectural landscapes. The Oealcle spatial is used to describe the relationship model of the vegetation objects in the landscapes in order to obtain the optimal distribution model for the architectures with differentiations. The simulation experiments illustrate the proposed model can appropriate distribute the architectural landscapes with differentiations with better pollution control effects.

Abstract. Paper in view of the dense medium coal preparation process control, carefully study the density of heavy medium coal preparation control system of the internal structure, main characteristics, control laws and the design method. Open field bus control structure is adopted in the system, Siemens S7-300 programmable controller is responsible for control, executing agencies responsible for enforcing the orders of the PLC to control the related parameters. Through the practice, this control system is powerful, easy to operate, reliable performance, has certain theoretical significance and practical application value.

Introduction

Coal preparation is to improve product quality in the production of coal industry indispensable link, is the comprehensive utilization of resources, an effective way to energy conservation and environmental protection, is also China's sustainable development strategy in the 21st century is an important part of the clean coal technology. High-tech input is the necessary way of high efficient coal, is the JianRen effect, reduce the processing cost, the effective measures to achieve maximum economic benefits. And heavy medium density automatic control system is one of the most important link, its height and stability of the link to the coal production process product quality and production rate plays a decisive role.

Dense medium coal preparation is the use of coal in a certain density of the liquid medium according to the density rise or fall, and the different density of material plant, China coal and gangue separation. Dense medium coal preparation is sorting according to density, in order to ensure product quality, must ensure that the medium density and stability. Medium density is too high, so high density material rise, affect the product quality, medium density is too low, can make the buoyancy material sinking, resulting in loss of buoyancy materials.

In traditional control methods of coal preparation plant, the relationship between the density control system of main equipment are implemented through hardware control circuit, the execution is more complex, the reliability is also poor. With the development of PLC technology, the application of PLC to the heavy medium coal preparation process parameters of detection, automatic control and production management functions such as set at an organic whole, constitute a separate subsystems. In density control system, the relationship can be implemented through software and hardware of the main equipment to complete the real-time control and regulation of heavy medium density accurately, thus to improve the product quality, increase the carbon yield, reduce the tons of coal, the purpose of the dielectric loss.

Process control

Dense medium coal preparation process is shown in fig.1. In density control system, artificial medium, the medium on the pump discharge pipe and a densitometer, tube above the barrels and electric door, when artificial add medium by pump cycle to determine the medium density, determination by densimeter, for medium density is achieved when stop adding interfaces; Sorting, barrel by dense medium through the corresponding pump will play to the sorting machine, medium medium density by another densitometer for measuring at this time. Such as medium density is greater than the separation density, through the control valve and water control system, in order to reduce the density, guarantee the stability of the density and meets the requirements; Below the separation density, such as medium density can be adjusted through the shunt volume to increase into the thin dielectric drum, through magnetic separation after a pause into the dense medium barrels, guarantee the density conform to the requirements of the separation. System operation process, high density medium plus quantitative circulating water, to supplement water and maintain stability of the density[1].

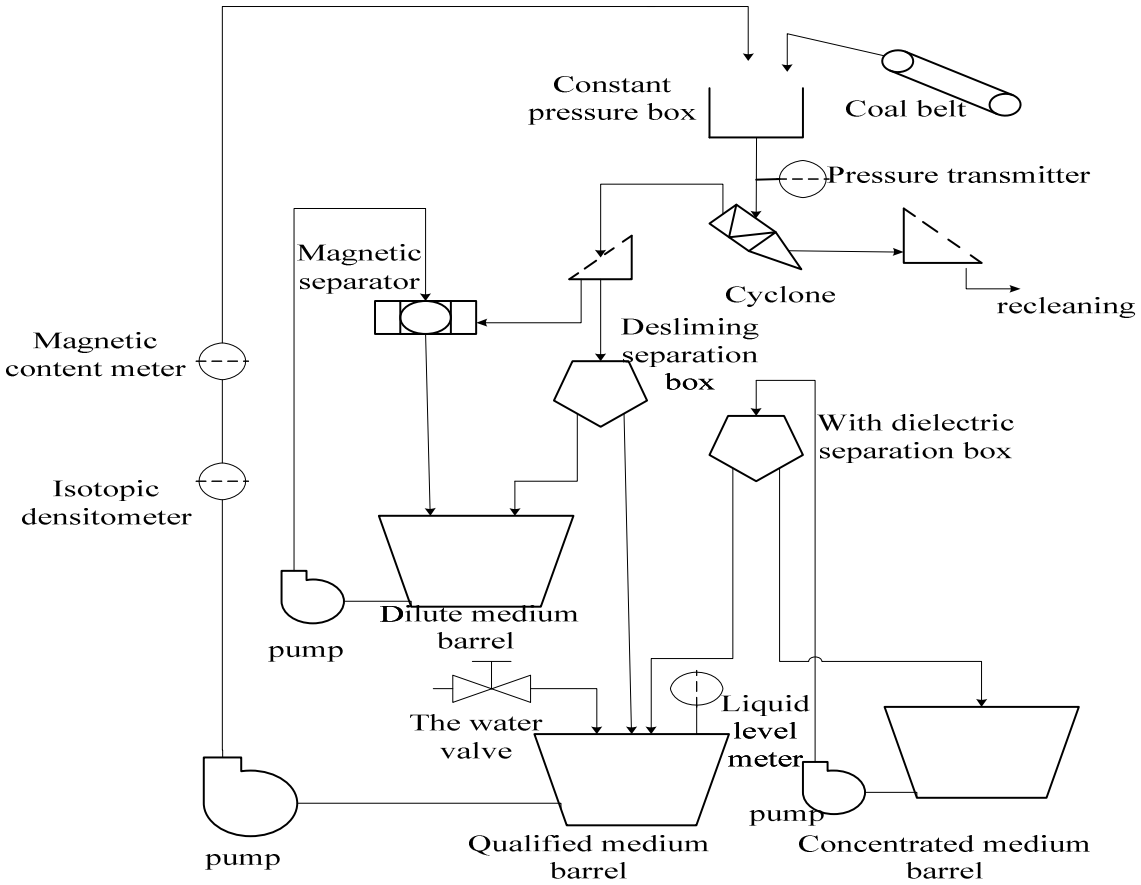

Fig.1. Diagram of dense medium coal preparation production

Density control system working principle is to use the PLC internal PID function block, analyse density gauge, level gauge, such as on-site inspection equipment of the input signal, to detect the process variables comparing with set point, through the analog output module, the output signal to drive the water regulating valve, shunt valve electric actuator, to achieve dynamic control of pressure, density, liquid level white. The PID controller parameter setting is the core content of control system design, according to the character of the charged process to determine the proportion coefficient of PID controller, the size of the integral and differential time, mainly depends on engineering experience, in the experiment of the control system[2].

Density control system set in density as the system input, feedback densitometer feedback signal as input, the PLC input to the system and feedback input count, quantification, and calculated by the algorithm, the proportional valve opening signal, through the analog output module, the output analog

signal to drive all kinds of electric actuator. Density control system principle block diagram is shown in fig.2.

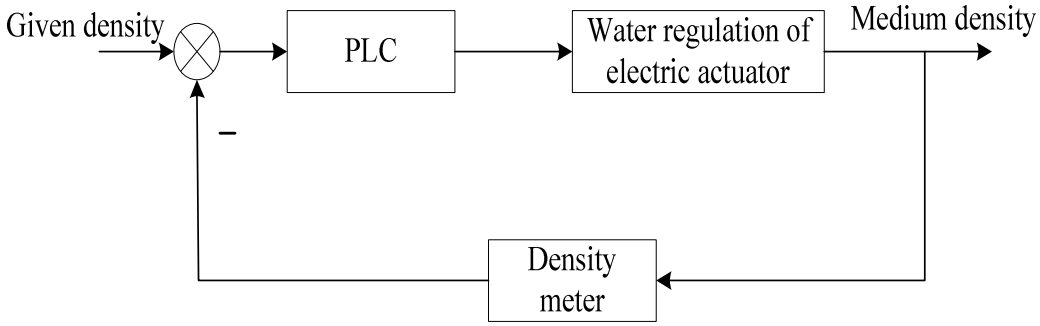

Fig.2.Block diagram of the density control system

Before the open control system, qualified medium bucket will blast first, after waiting for slurry mixing pump, circulation system implementation, the density meter in the measurement location, density signal into current signal output, transmitted to the PLC PID regulator, regulator according to the following regulation:

(1)The actual value is less than the set value, medium density is low, the dense medium cyclone separation, part of the plant into the coal system, coal into coal gangue system, reduce coal preparation efficiency. Low density, the regulator output 4 mA signal, shut off the water valve, if still can not meet the required to produce the density value density, to qualified medium barrel adding medium, in order to achieve the required density values.

(2)The actual value is greater than the set value, medium density is high, the dense medium cyclone separation, coal into the plant system, grind stone into the coal system, reduce product quality. Density is high, the regulator output 4 mA - 20 mA signal, transferred to the water regulator, add water to the qualified medium tube, gradually reduce the density, density value is equal to the set value, regulator output, add water valve is closed[3].

PLC selection

PLC has become the most important and most used in industrial automation control equipment, adopt PLC as the core and with the rotation sensor for detecting element, such as photoelectric encoder is simplified the hardware design, and improves the system reliability and stability, received the affirmation of the user. PLC selection focuses on several aspects: PLC performance, peripherals and capacity. Brand PLC has the system reliable operation, strong anti-interference ability, low failure rate, small volume, low energy consumption, abundant I / 0 interface, can be to control various devices; Through the Ethernet module can make intuitive in upper machine, equipment, stop or process display; Advanced modular structure, making it easy for users to design, combination and strong maintainability; Structure of ladder diagram, programming is easily operation.

The state in accordance with the requirements of the density control system, PLC required for various types of input/output points, such as: medium density monitoring (choose magnetic content of CE, isotopic densitometer ME); Plant ash monitoring (select ray ash gauge HE); Qualified medium level monitoring (select level gauge YE) raw coal in measuring monitoring (choose belt weigher JE); Jig water level and pressure monitoring (choose water level sensor SP1, pressure sensor SP2); Dense medium cyclone steady speed running monitoring (selection pressure transmitter PE), etc. These interfaces are analog signal, so the choice is suitable for the PLC device analog input point.

Through a comparative analysis of various aspects of PLC performance, cost-effective, and finally density control system network using S7-300 PLC and FCS field bus technology Siemens company.

S7-300 series of CPU315 2DP[4], is a stacking structure of medium-sized PLC system, instruction rich, strong function, easy to expand. PLC hardware connection diagram is shown in fig.3[5].

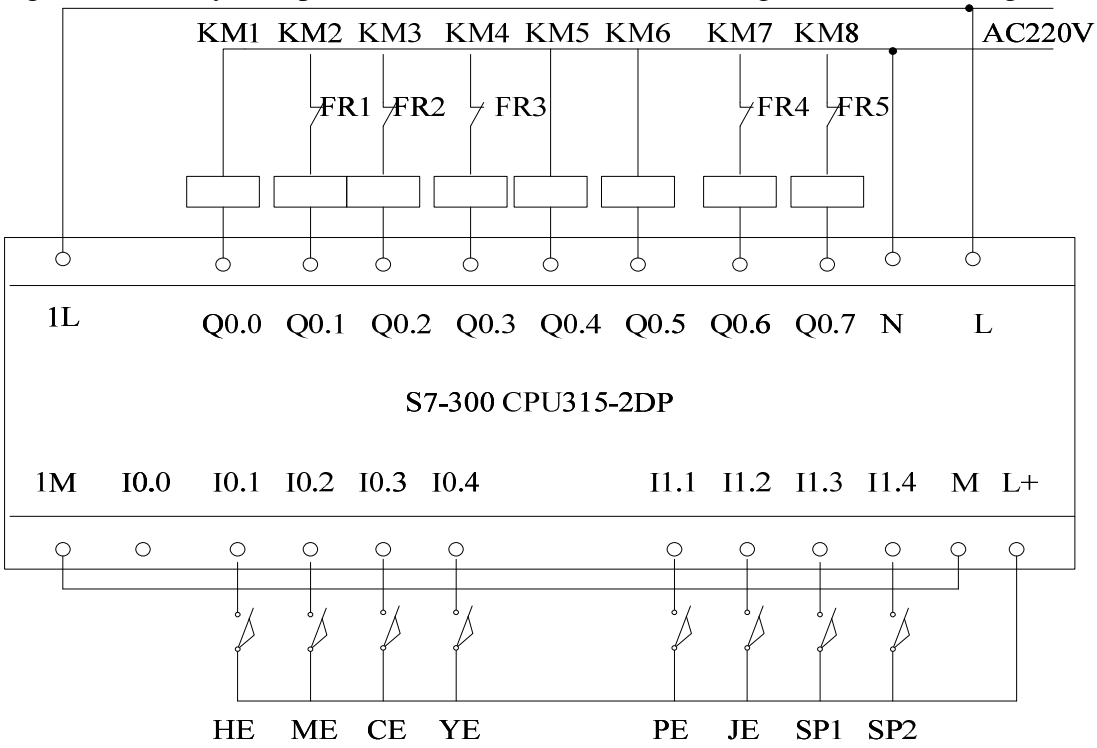

Fig.3.PLC hardware connection diagram

The system of PLC control system and communication network not only can collect and display field devices on/stop, failure state, inverter output frequency, electrical current, coal bunker coal level, liquid level, flow, medium density, such as real-time data, can also use the real-time data in systems and control, statistical main equipment operation and fault condition, asked the data sent to a more senior management, or as a reference equipment repair and related production tasks.

Conclusions

In short, dense medium density adjusting control system can complete in the process of dense medium coal preparation process of various physical parameters of display, alarm and regulating function, and a complete set of automatic detection, automatic adjustment and remote operation, process signals, etc, so as to guarantee the operation of the production process continuity, stability, reliability, and guarantee the quality of cleaned coal, increase plant yield.

Abstract. Designed a set of hydraulic experimental system for testing some performance parameters of oil drilling and production equipments and demonstrating its functions and principles. This system provided hydraulic environment for pumping unit, ESP (Electric Submersible Pump), well control devices, drilling and workover experiments, collected and analyzed experimental data, provided an important platform for the research and development of oil drilling and production equipments and experiment teaching. The functions and principles of hydraulic system's components are introduced, and some main components are selected and designed in the system.

Introduction

There are already had some experimental apparatuses, used for testing performances and studying technology of the oil drilling and production equipments in china and abroad. In the early 1990s, Northeast Petroleum University developed a "Deep well- pumping unit test device", we can observe the working conditions of fixed valve; Jianghan Petroleum Institute designed a "Horizontal wells pump test device" in 1997, to study the horizontal wells performance [1].By summarizing the relevant researches, designed a hydraulic experimental system. Its main purpose is to simulate drilling, workover, oil production and other equipment's working principles, test the main working parameters, both for scientific experiments, and serve the teaching experiments.

The structure and functions of hydraulic experimental system

Hydraulic experimental system mainly consists of high-pressure and low-pressure hydraulic system, metering system, data acquisition and control system. The relationship of hydraulic system to the subsystems of oil drilling and production equipment is shown in Figure1.

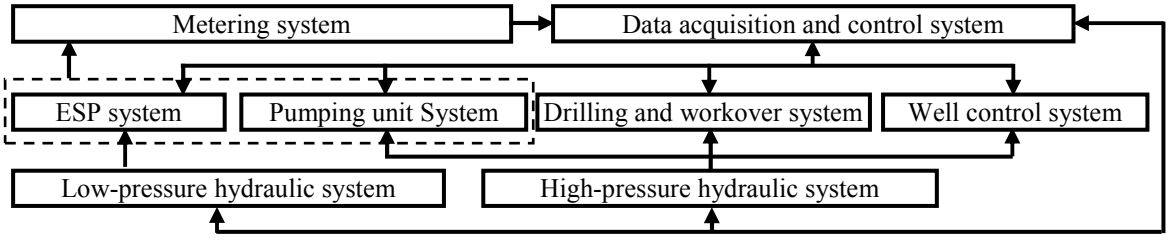

Fig.1 The relationship of hydraulic system to the subsystems of oil drilling and production equipment

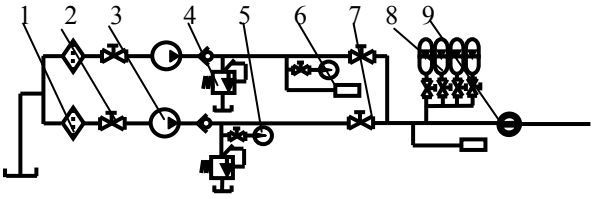
Based on the process and technology requirements of pumping unit, ESP devices, well control equipments, drilling and workover equipments, the hydraulic experimental system can test the principle and performance of drilling and production equipments, in order to analyze, evaluate study and develop them efficiently.

High-pressure hydraulic system

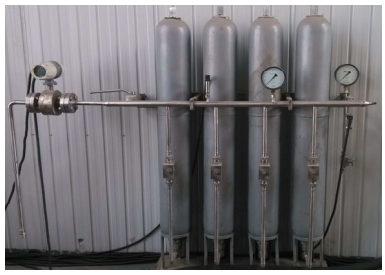
High-pressure hydraulic system is shown in Figure 2 (a). It can provide high-pressure hydraulic experimental environment, simulate the downhole pressure, water injection pressure, circulating

pressure of workover and drilling, well control pressure, so that the experimental conditions closer to the oil field environment.



1-Filter; 2-Inlet valve; 3-High pressure plunger pump; 4-Unloading valve; 5-Pressure gauge; 6-Pressure sensor; 7-High pressure valve; 8-Accumulators; 9-Flowmeter

(a)



(b)

Fig.2 (a) The schematic diagram of high pressure hydraulic system. (b) The picture of high-pressure system

High-pressure hydraulic system uses both 40MPa and 15MPa high pressure plunger pumps as power source. They can work alone, or work simultaneously. The accumulators can be used as an auxiliary or emergency power source, replenish system leaks, stabilize system working pressure, absorb pulsation of the pump and hydraulic shock, etc [2]. Pressure gauges, pressure sensors and electromagnetic flow-meter main tests discharge pressure and flow-rate values of high pressure plunger pumps.

When the accumulator as the power source, can reduce the power of engine [3], the effective volume of accumulator is the largest. In this case the accumulator volume can be calculated through the equation

$$V_0 \geq \frac{V(P_1/P_0)^{\frac{1}{n}}}{1-(P_1/P_2)^{\frac{1}{n}}}. \tag{1}$$

Where V_0 is the desired effective volume of accumulator, V is the working volume of accumulator, P_0 is its charge pressure, P_1 is the lowest working pressure, P_2 is the highest working pressure, and n is the exponent. According to the experimental requirements, the relevant calculation parameters of accumulator are shown in Table 1.

Table 1 The relevant calculation parameters of accumulator

V [m3]	P_1 [MPa]	P_2 [MPa]	P_0 [MPa]	n
0.095	16	24	14	1.4

Based on the Equation (1) and relevant parameters, the volume of accumulator is $V_0 \geq 0.149 m^3$. System uses an accumulator group consists of four 40L accumulators. Manual valves installed at the outlet of accumulators, so we can choice the number of accumulators to work, as shown in Figure 2 (b).

Low-pressure hydraulic system

Low-pressure hydraulic system is shown in Figure 3. It can provide low pressure large flow water resource for ESP experiments. The resource can meet the flow-rate requirement of ESP, which will avoid cavitations, not affect ESP's performance analysis results [4].

System uses two centrifugal pumps in parallel to provide a wider range of flow-rate for experimental system. By adjusting the flow-rate regulating valve, the low-pressure hydraulic system can provide different flow-rate of water for experiments.

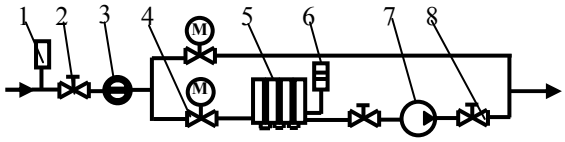
6-Flowmeter; 7-Pressure sensor; 8-Flow control valve

Fig.3 The schematic diagram of low pressure hydraulic system

Metering system

Metering system connects with the discharge port of ESP and pumping unit experimental system's Christmas tree, for adjusting the pressure and flow-rate of produced fluid, and measuring the volume of it. The schematic diagram of metering system is shown in Figure 4 (a).



1-Pressure sensor; 2-Hand operated valve;3-Flow-meter;
4-Electric valve; 5-Gauge tanks; 6-Liquidometer;
7-Line pump; 8-Ball valve

(a)

(b)

Fig.4 (a) The schamatic diagram of metering system. (b) The picture of metering system

In the whole system, the ESP's delivery capacity is the largest [5]. The flow-rate of ESP is 150m^3/d, the volume of produced water is 0.1042m^3 per minute. If each experiment last for 6 minutes, there will have 0.6252m^3 water flow into the gauge tanks. In order to adapt to a longer time experiment, the volume of the gauge tanks designed for 1m^3.

Taking into account the wall thickness, strength, installation, transportation, floor space, and other factors, we choose four gauge tanks of 250L in series for measuring. The liquidometer mounted at the top of the gauge tanks, can measure the liquid level in the gauge tanks, as shown in Figure 4 (b).

Data acquisition and control system

Date acquisition and control system can monitor the experimental status, examine and record the experimental parameters, draw experimental curves, remotely control parts of the experiments, set and modify some system parameters. It mainly consists of IPC (Industrial Personal Computer), data acquisition card, Siemens PLC (Programmable Logic Controller) and expansion modules, display instruments, buttons, etc. System's block diagram is shown in Figure 5.

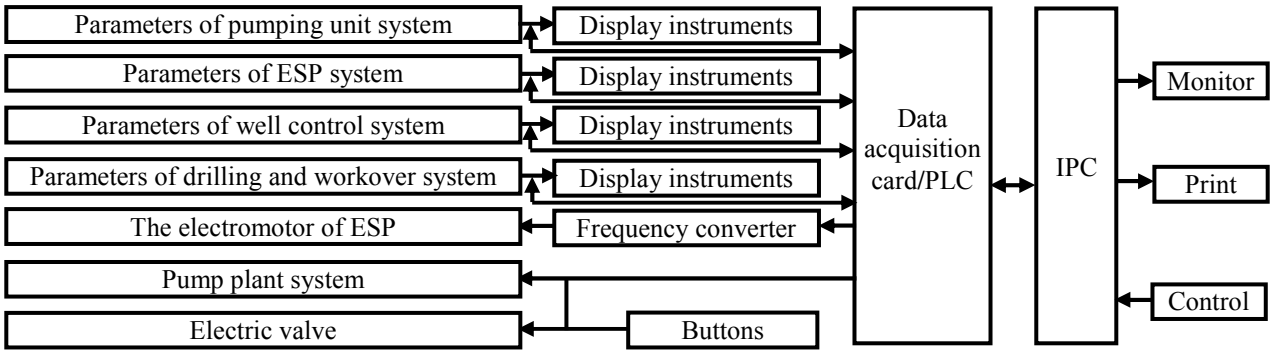


Fig.5 Block diagram of data acquisition and control system

The testing parameters of pumping unit system include the pressure of water in wellbore hole simulator, the produced water's pressure and flow-rate, and the liquid level in the gauge tanks. ESP system testing parameters, including the ESP's rotor speed and torque, the pump inlet water pressure and flow-rate, the pump outlet water pressure and flow-rate, and the fluid level in the gauge tanks. In drilling and workover system and well control system mainly tests the water pressure in the wellbore hole simulator. Pump plant system includes high-pressure plunger pump, low-pressure plunger pump, large flow-rate pump, low flow-rate pump, pipeline pump.

Experimental curves

During the experiment, some real-time curves of fluid pressure and flow-rate can be drawn by the data acquisition system, as shown in Figure 6.

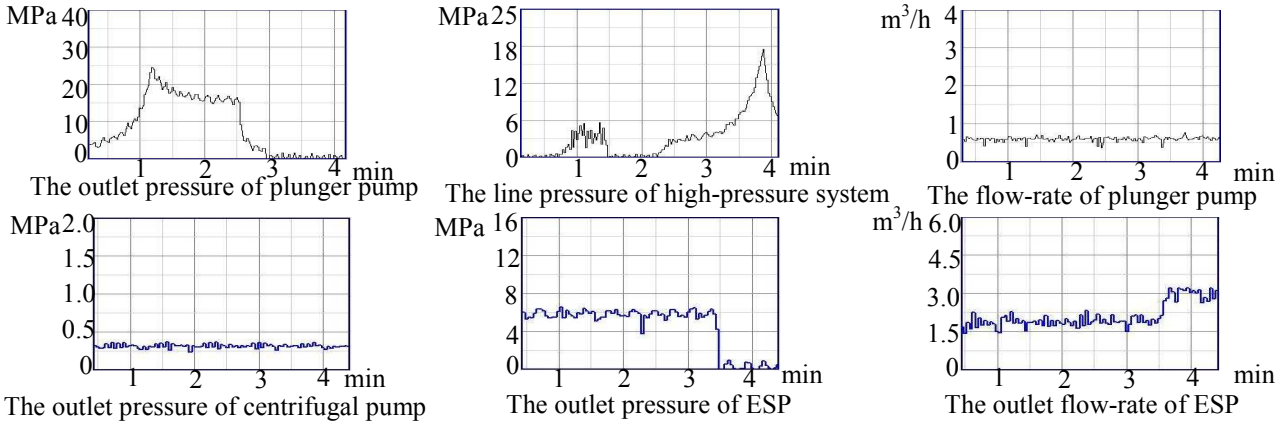

Fig.6 The experimental data curves

Conclusions

Hydraulic experimental system can provide 40MPa high pressure water resource and 50m^3/h low pressure water resource for the oil drilling-production experimental equipments. It can meet the pressure and flow-rate requirements of different tests. The data curves of pressure and flow-rate can display the performance of experimental equipments. This system can create condition for improving the standard of teaching and academic level, and cultivating innovative engineering talents with oil characteristics.

A New Purification Method for Rotor Center's Orbit by Using Ensemble Empirical Mode Decomposition

Wenbin Zhang[a], Jiaxing Zhu[b],Yasong Pu[c] and Yanping Su[d]

Engineering College, Honghe University, Mengzi 661100, Yunnan, China

Keywords: Rotor center's orbit, Purification, Ensemble empirical mode decomposition, Rotating machinery

Abstract. Aiming at the purification of rotor center's orbit, a new approach was presented by using ensemble empirical mode decomposition (EEMD). Ensemble empirical mode decomposition decomposed a complicated signal into a series of intrinsic mode functions (IMFs). Then according to prior knowledge of rotating machinery, chose some interested IMFs and reconstructed the needed signal. By doing this the noises would be eliminated successfully. At last the purification of rotor center's orbit was obtained by extracting the useful signal component. Simulation and practical results show the advantage of EEMD in noise de-noising and purification of rotor center's orbit. This method also has simple algorithm and high calculating speed; it provides a new way for purification of rotor center's orbit of rotating machinery.

Introduction

Vibration monitoring is a very important content for turbine generator unit. And the rotor center's orbit can express the vibration characteristic of generator unit. Different rotor center's orbit represents different rotor condition or fault information, such as ellipse represents unbalance fault, outer eight represents misalignment and inner eight represents oil-film whirl, et al [1]. Generally speaking, the original rotor center's orbit can't be used due to the noise interference. How to eliminate noise and to obtain the refine rotor center's orbit is the main studying content for rotor center's orbit purification.

Empirical Mode Decomposition(EMD) is an adaptive signal processing method that can be applied to nonlinear and non—stationary process perfectly [2]. It may decompose any complicated signal into a set of complete, adaptive and almost orthogonal components called Intrinsic Mode Functions (IMFs). The IMFs represent the natural oscillatory mode embedded in the signal and work as the basis functions, which are determined by the signal itself, rather than predetermined kernels. EMD method is widely applied to many project fields [3-5]. However, one of the major drawbacks of the original EMD is the frequent appearance of mode mixing, which is defined as a single IMF either consisting of signals of widely disparate scales, or a signal of a similar scale residing in different IMFs, To alleviate this drawback, Ensemble Empirical Mode Decomposition (EEMD), a substantial improvement of EMD, is presented by Zhaohua Wu and N. E. Huang [6]. EEMD is a new noise-assisted data analysis method by utilizing the full advantage of the statistical characteristics of white noise to perturb the signal in its true solution neighborhood, and to remove itself after serving its purpose.

Considering the characteristic of rotating machinery, a new purification method is proposed by using EEMD. At first, the sample data is decomposed by EEMD into a series of IMFs. Then, the interested periodical sine components are extracted. In the end, the purified rotor center's orbit could be obtained from the reconstruction of useful signal component.

Conception of EEMD

The EEMD algorithm can be stated as follows [6-7]:

(1) Initialize the ensemble number M and the amplitude of the added white noise, let M=1.

(2) Execute the mth trial for the signal added white noise.

(a) Add the white noise series with the given amplitude to the investigated signal, i.e.

$$x_m(t)=x(t)+n_m(t) \quad (1)$$

Where $n_m(t)$ represents the mth added white noise, and $x_m(t)$ indicates the noise-added signal of the mth trial.

(b) Decompose the noise-added signal $x_m(t)$ into l IMFs $c_{i,m}(i=1,2,\ldots l, m=1,2,\ldots,M)$ using the EMD method. Where $c_{i,m}$ indicates the ith IMF of the mth trial; l is the number of IMFs and M means the number of the ensemble.

(c) If $m<M$, then let $m=m+1$ and repeat the step (a) and (b) again and again until $m=M$, but with different white noise each time.

(3) Compute the ensemble mean $\bar{c}_i$ of the M trials for each IMF, and we obtain

$$\bar{c}=\frac{1}{M}\sum c \quad (2)$$

(4) Report the mean $\bar{c}_i$ ($i=1,2,\ldots,l$) of each of l IMFs as the final ith IMF.

Simulation

To verify the good performance of the EEMD method in noise de-noising, the simulation signal showed as follows:

$$f(x)=\sin(2\pi x f_1/f_s)+\sin(2\pi x f_2/fs)+i(x) \quad (3)$$

In which $i(x)$ refers to the noise interferences. Fig.1 shows waveform of the original simulation signal in time domain and its spectrum.

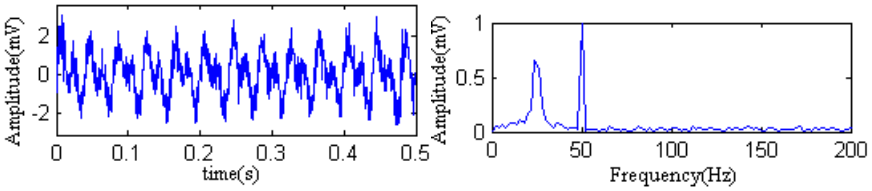

Figure 1. Original signal in time domain and frequency domain.

Take sampling frequency as f_s=2000Hz, and f_1=25Hz, f_2=50Hz. Now we use EEMD method to decompose the original signal into some IMFs. Fig.2 shows the decomposed results.

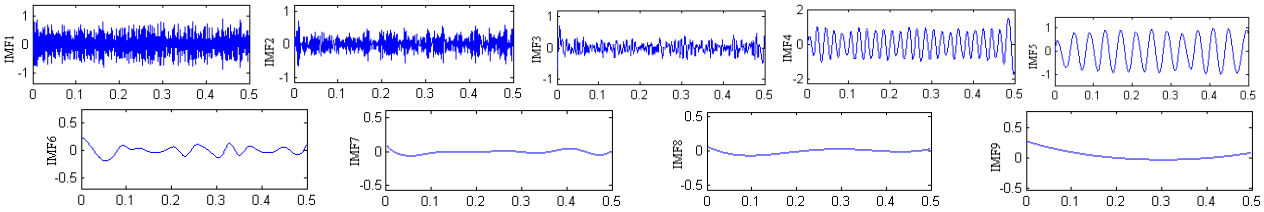

Figure 2. EEMD decomposition results of simulation signal

From Fig.2 we can see that simulation vibration signal is decomposed into a finite number of stationary intrinsic mode functions (IMFs). In Fig. 2 we can know that IMF4 and IMF5 are the periodical sine signals. Fig.3 gives the frequency spectrum of these two IMFs. We know that the periodical components of the simulation signal are extracted by EEMD respectively.

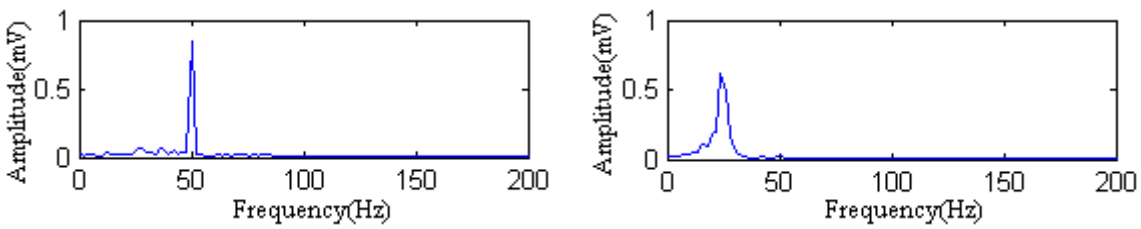

Figure 3. Frequency spectrum of IMF4 and IMF5

Purification of Practical Rotor Center's Orbit

In this section, the EEMD method is applied to purify the rotor center's orbit. The sample date comes from a practical rotor center's orbit of the turbine generator units in the power plant. The speed of the rotor is near 3000 rpm. Let the sampling frequency equal to 6400Hz. Due to the serious noise interference, the original rotor center's orbit is too disordered to get any fault information. Fig. 4 shows original two vertical vibration signals and the periodical component extracted by EEMD decomposition for them.

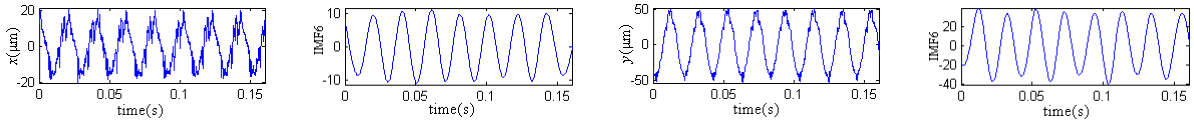

Figure 4. Two vertical signals before and after extracted by EEMD.

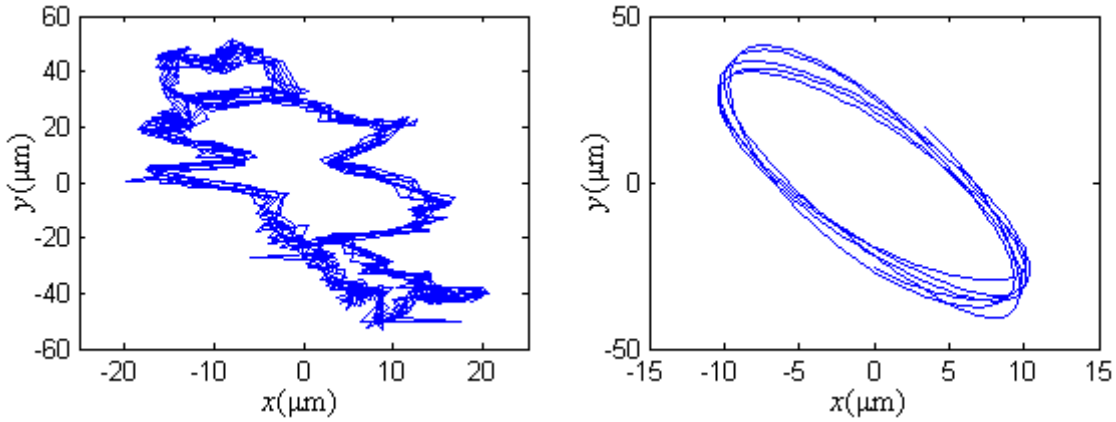

Figure 5. Original rotor center's orbit and the purified result.

Now we combine the rotor center's orbit by these two periodical components. Fig. 5 shows the purified rotor center's orbit by EEMD and the original signal. According to the common fault spectrum feature, we know that elliptical axis trace means unbalanced fault.

Conclusion

The EEMD method is proposed to purify rotor center's orbit of rotating machinery, effectively overcoming the shortcoming of the mode mixing occurring in the empirical mode decomposition method. Simulation and practical results show that this method has good advantage in rotor fault diagnosis, it will supply a new way for fault diagnosis of rotating machinery.

Keywords: wet steam; corrugated plate separator; numerical simulation; condensation.

Abstract. To provide steam of appropriate quality and to improve the efficiency of steam-water separation over corrugated plates, it is necessary to study the condensation behavior of wet steam moving over a corrugated plate separator. In this paper, classical nucleation theory and a droplet growth model are used to describe the process of wet steam condensation on corrugated plates. The CFX software water droplet condensation model was employed to simulate the process and to allow analysis of the characteristics of wet steam condensation. The results show that: (1) the nucleation rate increases gradually over time and exhibits a positive correlation with the temperature of the wet steam, (2) departure from the saturated state decreases gradually along the flow direction, leading to a concurrent decrease in the steam condensation rate and (3) the steam condensation rate is elevated with increases in the local pressure gradient.

Introduction

Wet steam has the ability to produce a large number of droplets which in turn may cause serious water erosion that reduces equipment strength and service life and can even threaten the operational safety parameters of the equipment. For these reasons, a steam-liquid separator must be used to dehumidify wet steam. At present, the corrugated plate separator is the most widely used means of final stage moisture separation and so understanding the process of wet steam condensation on a corrugated plate separator is an important step in evaluating the performance of such devices and in improving separation efficiency. Herein, a numerical model for wet steam flow over a three-dimensional corrugated plate separator is described.

The calculation model

A. The physical model

This work investigated numerical simulations of the condensation characteristics of wet steam flowing over a single channel corrugated plate, as pictured in Fig. 1. The corrugated plate length applied during modeling was 175 mm, with plate spacing of 15 mm and a wave number of three with a pitch of 42 mm and a flexion angle of 30°. The straight segment length before and after each wave plate was 14 mm.

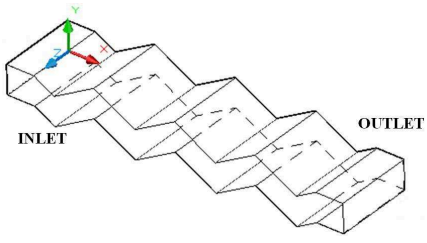

Figure1. The corrugated-plate structure

B. Condensation model

It is generally agreed that the process of spontaneous condensation can be described by a combination of classical nucleation theory and droplet growth theory.[1] To simplify calculations associated with the process of steam condensation and the modeling of droplet growth, the following was assumed[2]:

- the wet steam is homogeneous and without impurities,
- small liquid water droplets in the wet steam are spherical,
- both phases of the vapor-liquid mixture have the same velocity,
- interactions between droplets may be ignored, and

- the heat capacity of small droplets is negligible compared with the latent heat of condensation.

1) Spontaneous condensation models

In this model, the nucleation rate represents the nucleus formation rate per unit mass of mixture, denoted by J, based on the classical nucleation theory as modified by Kantrowitz and incorporating non-isothermal effects. The nucleation rate is given by[3]

$$J = q_c(2\sigma / \pi M^3)^{1/2}\ \rho_g{}^2 \exp(-4r_c^2\sigma / 3K_bT) / \rho_l(1+\Phi) \quad (1)$$

In this equation, q_c is the condensation coefficient, M is the mass of one molecule, σ is the liquid surface tension coefficient in N/m, K_b is the Boltzmann constant, Φ is a non-isothermal correction factor and r_c is the critical droplet radius which is calculated by

$$r_c = 2\sigma T_s / \rho_l h_{fg}(T_s - T) \quad (2)$$

where T_s is the saturation temperature and T denotes the droplet temperature.

2) Water droplet growth model

Based on the work of Gyarmathy,[4] Young developed a droplet growth rate expression incorporating a three layer theoretical model proposed by Langmuir.[5,6] The droplet growth rate at low pressures (0.1 to 0.3 bar) is modified to obtain better agreement between calculated and experimental values. The specific form is written as[7]

$$dr / dt = \frac{\lambda_g(T_s - T)(1 - r_c / r)}{\rho_l h_{fg} r[1/(1+2\beta K_n) + 3.78(1-\upsilon)K_n / P_{rg}]} \quad (3)$$

where λ_g is the thermal conductivity, β is the proportionality coefficient (equal to 0.75), K_n is the mean free path of the gas molecules P_{rg} is the Prandtl number and υ is an adjustable correction factor.

Determination of the computational model and mesh topology

The Reynolds number is used to calculate the flow pattern of the wet steam flow field over the wave plate. The standard k-ε model is adopted for the continuous phase, while the discrete phase is determined by means of the zero-equation model and the wall function method is used to process the region adjacent to the wall. Because of the regular geometry of the corrugated plate flow channel, a structural mesh is employed to improve the precision of calculations as well as to reduce memory occupancy, employing a total mesh number of 540,000. The resulting grid structure is shown in Figure 2.

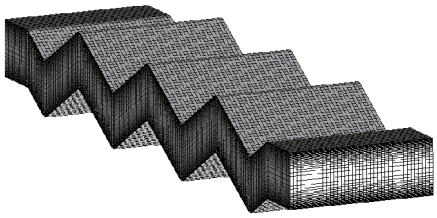

Figure2. The structure of the waveforms board

Boundary conditions and calculation methods

When modeling the condensation flow of wet steam over the corrugated plate, the Euler-Euler governing equation is employed to describe the two phase vapor-liquid characteristics. The numerical model is solved using the TVD difference method and the CFX two phase flow droplet condensation model, neglecting water droplet collisions and aggregation. The wet steam is assumed to flow as a homogeneous two-phase system at an inlet velocity of 6 m/s and 10% humidity, at a temperature of 369 K. The vapor-liquid two phase state equations were set to meet the IAPWS library conditions. The outlet relative pressure is set to 0 atm and the corrugated plate wall is assumed to be both adiabatic and non-slip. The backsplash and adsorption of droplets on the wall are not considered in the model.

Results and analysis

A. Changes in wet steam condensation characteristics over time

When modeling, the zero point of the time scale is set equal to the moment at which the flow indicated by cross section A (perpendicular to the vapor flow direction) moves past the entrance to the corrugated plate. Cross section A subsequently moves further from the entrance of the corrugated plate over time. Analysis of the area-averaged parameters of the wet steam at cross section A as the section travels to different locations is then performed, with the specific results detailed below.

Figure 3 shows that, over time, the nucleation rate gradually increases, although the rate of increase eventually slows. Based on the nucleation rate formula, an analysis of the nucleation rate variation during the process of steam condensation is performed.

In accordance with classical nucleation theory, expressions for the nucleation rate (Equation 1) and the critical radius (Equation 2) have been given. Substituting Equation 2 into 1 gives a new expression indicating that the cube of the surface tension coefficient is inversely proportional to the nucleation rate and that undercooling is proportional to the nucleation rate. Therefore reducing the value of the surface tension coefficient will produce higher nucleation rates, while a lower degree of deviation from the saturated state will lead to a lower nucleation rate. The surface tension and vapor saturation thus both have a significant effect on the nucleation rate.

The surface tension may be calculated as[8]

$$\sigma = 0.2358(1/T - T_c)^{1.256}[1 - 0.625(1 - T/T_c)] \quad (4)$$

Here T is the water temperature and T_c is the critical temperature of water (647.3 K).

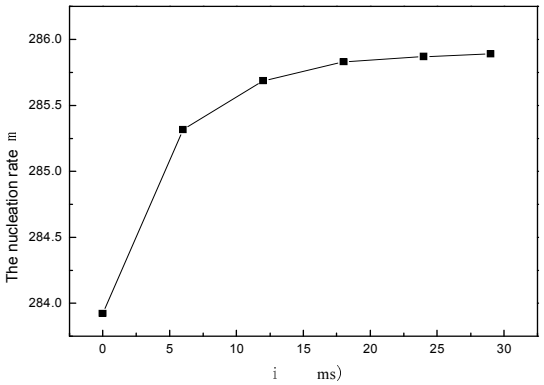

Figure3. Nucleation rate changes over time

The relationship given here between surface tension and temperature shows that higher temperatures reduce the surface tension coefficient but increase the nucleation rate. Figure 4 shows that the steam temperature increases over time and so the droplet surface tension will be reduced, leading to an increase in the nucleation rate. Because of the role of the corrugated plate as a separator of wet steam, the relative humidity of the steam also decreases and so the degree to which the steam deviates from the saturation state is lowered, which can lead to a decrease in the nucleation rate over time. The impact of such changes on the nucleation rate is small, however, relative to the effect of changes in the surface tension coefficient, and simply serves to reduce the rate of increase.

Figure 5 shows that the droplet diameter gradually increases over time until a plateau is reached, after which the diameter is relatively stable. An analysis of changes in the droplet diameter may be performed based on phase equilibrium conditions. The radius, r, of a droplet under equilibrium water vapor pressure may be incorporated into the follow expression[9]

$$P_r = P_\infty \exp(2\sigma / \rho_l R_g T_r) \quad (5)$$

In this equation, P_x is the water vapor pressure associated with water droplets of radius r, Pa is the vapor pressure at phase equilibrium and P_∞ is the water vapor saturation pressure when the droplet radius is infinity (that is, the vapor-liquid interface is infinity).

The above equation for P_x shows that P_x is larger than P_∞ and that P_x will be reduced as the droplet radius increases and thus will approach P_∞. As the vapor molecules condense into water droplets, the droplet surface area increases and the equilibrium partial pressure of the water droplets is slightly reduced. However, the water vapor pressure does not change, such that the smaller droplets will continue to grow. When the water droplets grow to a certain size the steam will attain a new thermodynamic equilibrium and no further growth will occur.

Figures 6 and 7 demonstrate that the number of drops is gradually reduced as the humidity of the steam decreases over time. The curved flow path of the wave plate occasionally changes the direction of the steam flow and thus, owing to their inertia, a portion of the water droplets deviate from the trajectory of the vapor phase as vortices are formed in the corners of the corrugated plate, leaving the droplets stranded in these locations. At each vortex site, the area over which wet steam is in contact with the wall of the corrugated plate is very large, such that the droplets inside the vortex are essentially attached to the wall and thus separated from the wet steam. As wet steam flows over the corrugated plate, therefore, the number of water droplets is gradually reduced and the humidity of the steam slowly decreases. The results also show that the wet steam traverses the first band of the corrugated plate between 6 and 12 ms from time zero and this is the time span over which the steam humidity and the number of water droplets decrease most rapidly. Thus the first band of the plate represents the most effective wet steam separator.

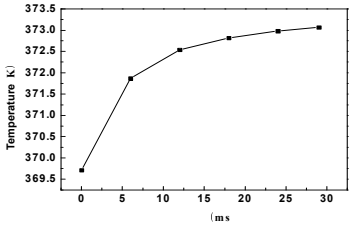

Figure4. Temperature changes over time

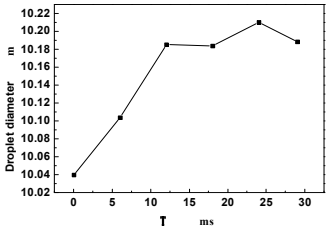

Figure5. Water droplet diameter changes over time

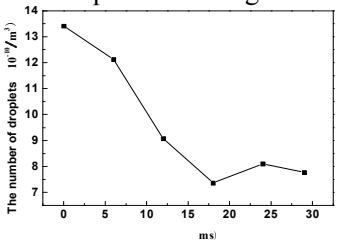

Figure6. Variations in the number of water droplets over time

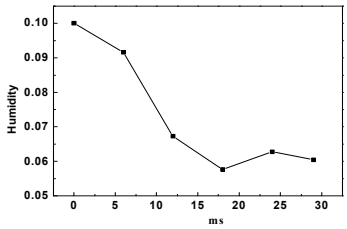

Figure7. Humidity changes over time

B. Characteristics of wet steam condensation on the waveform board at specific times

1) The effect of the saturation state of wet steam on condensation

Because of the spontaneous condensation of the wet steam and the separation effect of the wave plate, the degree of saturation of the wet steam is constantly changing, and this will have a pronounced effect on the condensation process. Cross section B, which is parallel to the direction of steam flow at Z = 20 mm is used to examine the physical parameters of the interface at any given moment and to analyze the wet steam condensation.

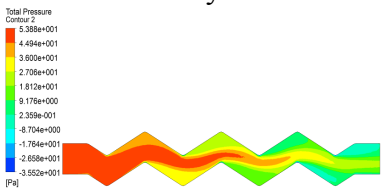

Figure8. Variations in pressure along the flow direction

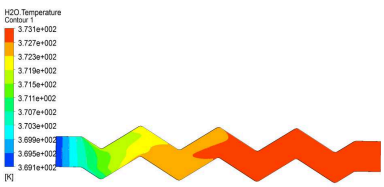

Figure9. Variations in temperature along the flow direction

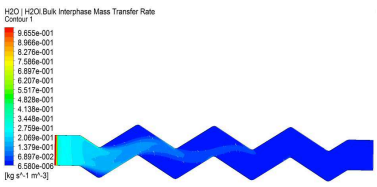

Figure10. Variations in condensation rate along the flow direction

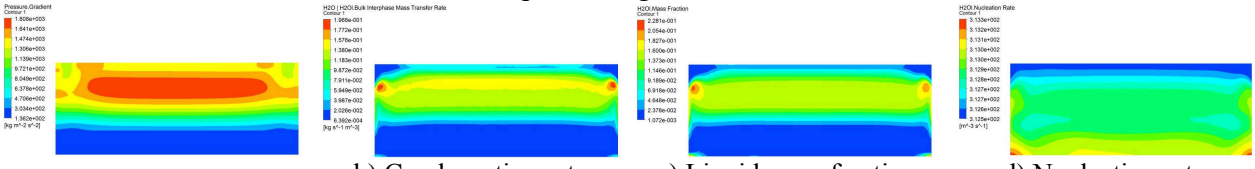
Figures 8 and 9 demonstrate that the temperature gradually increases in the direction of the flow of the wet steam, going from the initial temperature of 369 K to a value of 373 K. The wet steam pressure also gradually decreases to a relative pressure 53.8 Pa less than the initial atmospheric pressure at the entrance. With increased extent of steam flow, the deviation of the wet steam from saturation conditions is diminished. Based on what is known of wet steam condensation, the greater the extent of deviation from saturation, the greater the degree of condensation. Thus the wet steam condensation rate decreases along the flow direction, as shown in Figure 10.

2) The effect of pressure gradient on wet steam condensation

The preceding analysis showed that the first band of the corrugated plate produces the greatest amount of steam separation. The characteristics of wet steam condensation along a cross section of the corrugated plate were analyzed using a cross section, which is perpendicular to the direction of the wet steam flow on the windward side.

Figure 11 shows the location of the most extreme pressure gradient at the cross section, and also demonstrates that this zone corresponds to the greatest quantity of droplets and the highest liquid mass fraction and condensation rate. There is, however, no obvious relationship between the distribution of the nucleation rate and the pressure gradient.



a) Pressure gradient b) Condensation rate distribution c) Liquid mass fraction distribution d) Nucleation rate distribution

Figure11. The distributions of steam parameters along the cross section

Based on the equations associated with control of the liquid phase, an analysis of the relationship between various steam parameters may be performed. The equation relating the quality setting of the speed, m_j, with the steam humidity, Y, the nucleation rate, J, and the number of drops, N, is

$$m_j = 4\pi r_c^3 \rho_l (1-Y) J / 3 + 4\pi r^2 \rho_l N \frac{dr}{dt} \quad (6)$$

The first part of this equation represents the mass that undergoes phase transition due to the nucleated condensation of water droplets, while the second part expresses the phase transition mass resulting from droplet growth. An analysis of the order of magnitude of these two parts shows that the magnitude of the first part is on the order of 10^{-9}, whereas the magnitude of the second part is on the order of 10^4. Therefore the condensation rate is primarily influenced by the quantity of water droplets. Because the pressure drop plate is small, the speed of the wet steam flow is low over the corrugated plate and this reduces the spontaneous condensation of the wet steam, hence the nucleation rate has little effect on the condensation rate. Based on an analysis of the images in Figure 11, the pressure gradient has a greater effect on the water droplet growth rate and a lesser effect on the water droplet nucleation rate. As a result, increasing the pressure gradient generates a greater amount of liquid condensation.

Conclusions

(1) The nucleation rate of wet steam passing over corrugated plates gradually increases and is positively correlated with the temperature of the steam.
(2) The degree of departure from the saturated state decreases gradually along the flow direction, leading to a concurrent decrease in the rate of steam condensation.
(3) The rate of steam condensation increases as the pressure gradient is increased.

A Study on Exhaust Muffler Using Counter-phase Counteract

Ying-li Shao

Department of Statistics and Mathematics Inner Mongolia Finance and Economics College

Huhhot, P. R. China

yinglishao@163.com

Keywords: Counter-phase, Diesel engine, Muffle, Insertion loss.

Abstract. The exhaust noise, which falls into low-frequency noise, is the dominant noise source of a diesel engines and tractors. The traditional exhaust silencers, which are normally constructed by combination of expansion chamber, and perforated pipe or perforated board, are with high exhaust resistance, but poor noise reduction especially for the low-frequency band noise. For this reason, a new theory of exhaust muffler of diesel engine based on counter-phase counteracts has been proposed. The mathematical model and the corresponding experimental validation for the new exhaust muffler based on this theory were performed.

Introduction

Exhaust noise, a kind of bump, is the main noise source of diesel engines and tractors. Installing exhaust muffler is the most direct and effective method to control the exhaust noise [1]. But most of the traditional exhaust mufflers are composed of expansion chamber, and perforated pipe or perforated board [2], whose exhaust resistance is rather great and whose function of noise reduction is very poor, especially for the low frequency, which is the major part of exhaust noise [3]. Pointing at the problem in the traditional mufflers of diesel engines, the author puts forth a new theory of exhaust silencer of diesel engine based on counter-phase counteract and split-gas rushing . The dominant low-frequency noise components are controlled by counteract of two sound waves with counter-phases (180°phase difference), the other frequency-band noise is reduced by lowering the exhaust gas flow rate thus lowering exhaust noise. In addition, the author establishes a physics model of counter-phase counteract, founds a mathematics modelling on the basis of and analyses the acoustical characteristics of the above-mentioned physics model, deduces theoretical model of the transmission loss of the new muffler, and founds the relationship between its acoustic characteristics and the major parameters of framework. Thereafter, according to the new theory, taking the single-cylinder diesel engine of CG25 as the sample model machine, the author designs an exhaust muffler, and tests and verifies the new theory and the theoretical analysis.

Principle of the muffler

The principle of the new muffler is shown in Fig.1. The muffler unit is mainly composed of an outer tube and an inside tube. There are two round and opposite holes in the inside tube, and the sizes of the two holes are same, and the summation of the sectional areas of the two holes is no less than the sectional area of the entrance of the inside tube. With the help of the U-tube,the exhaust noise enters from the entrance, and counter-phase when it enters the inside tube of the muffler, along the upper passages and lower passages. In accordance with the theory of sound radiation, the author can regard the two opposite holes as the two plunger sound source, and due to the reverse oscillation, the radiation capability of the combined sound resource is reduced, so the author can reach the aim of noise reduction.

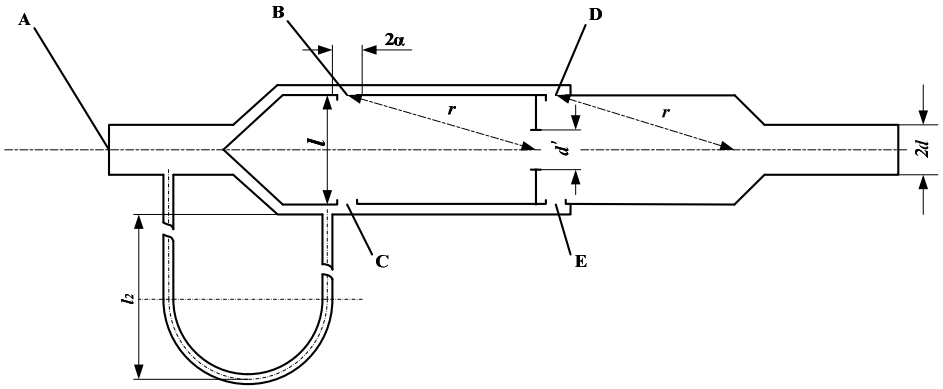

Fig. 1 Principle of the muffler using reversed-phase cancelling

Analysis to the experimental results

The theoretical formula for transmission loss of the new type muffler

$$TL=20\log\frac{2r^2}{akdl}$$

The author designs 3 series of data and name them as Muffler Type Ⅰ, Muffler Type Ⅱ and Muffler TypeⅢ, and their sizes are as the following:

Muffler Type Ⅰ: r=165mm, l=80mm;

Muffler Type Ⅱ: r=165mm, l=60mm;

Muffler TypeⅢ: r=56mm, l=80mm

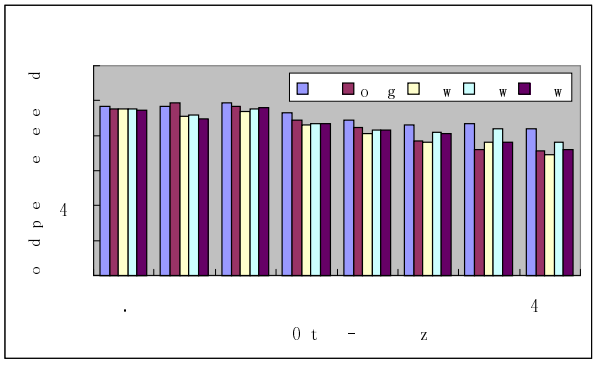

Fig. 2 The contrast on octave-band sound pressure level at 1800r/min

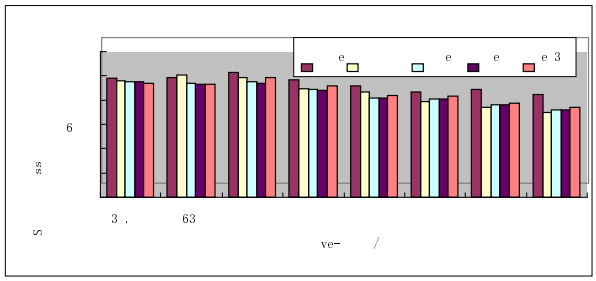

Fig. 3 The contrast on octave-band sound pressure level at 2000r/min

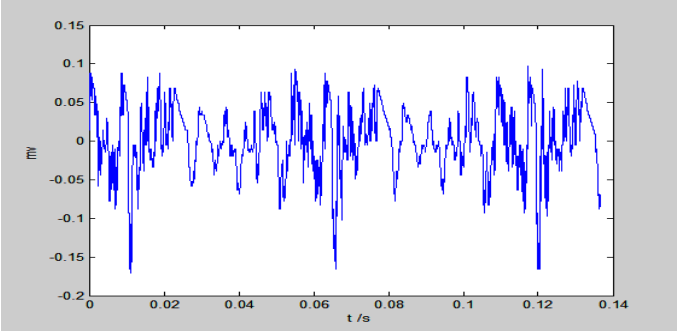

Fig. 4 The time domain signal of the new Ⅰ at 2000r/min

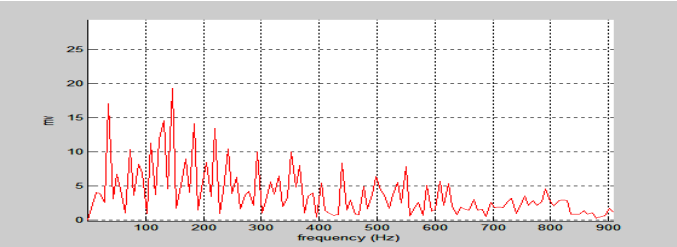

Fig. 5 The spectrum of the new Ⅰ muffler at 2200r/min

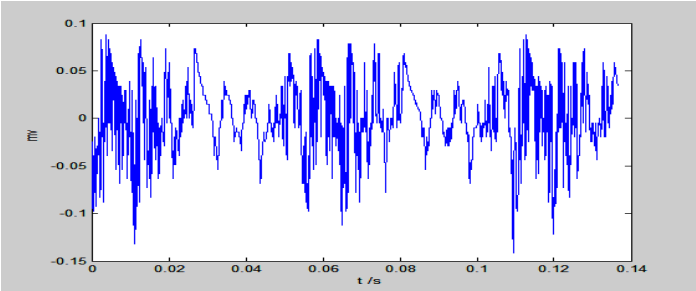

Fig. 6 The time domain signal of the new Ⅱ at 2000r/min

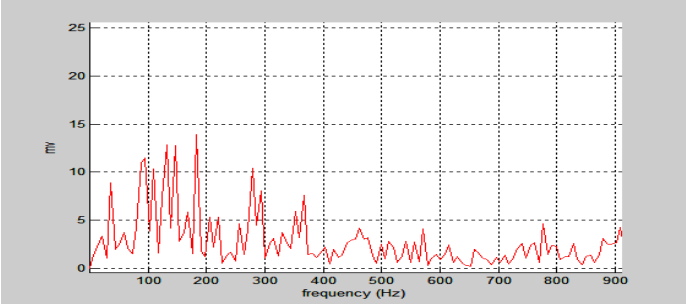

Fig. 7 The spectrum of the new Ⅱ muffler at 2200r/min

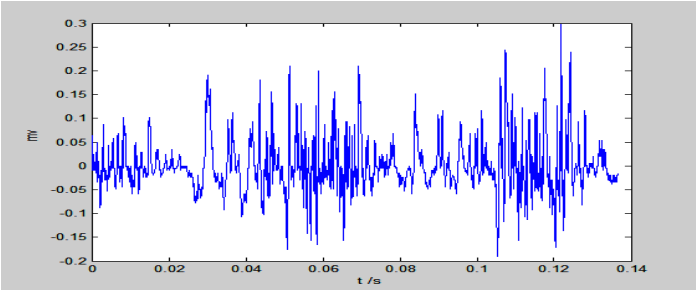

Fig. 8 The time domain signal of the newⅢat 2000r/min

The tested results show that the insertion loss of three new mufflers has all reached 7dB (A), more than 4dB (A) improved compared to original muffler. The original muffler can only reduce the high-frequency noise components, it cannot reduce, even strengthen the noise of frequency below

500 Hz, proved conventional muffler with poor capacity of lowering the low-frequency noise again. The new exhaust mufflers were obviously effective in controlling the low-frequency exhaust noise, which proved correctness of the new theory. In addition, it has been found that the new mufflers have a good effect of noise control in the whole frequency domain especially in the range of under 500 Hz. This not only proved that the new mufflers have very good performance for low-frequency noise reduction, but also proved that using split-gas rushing can lower the air flow speed thus lowering the air-regeneration noise. The counter-phase is only effective to the exhaust noise of the target frequency and its odd multiple harmonics instead of the whole frequency range, but the split-gas rushing is working to the noise in all frequency range. By comparing the results of three new mufflers, it was noticed that the new muffler type Ⅱ was the best, especially at the rated speed the effect is more pronounced, which is consistent with the theoretical model analysis, further proved the correctness of the theory.

Conclusions”

Taking the single-cylinder diesel engine CG25 as the experimental engine, the exhaust noise was measured and its spectrum was analyzed. In order to accurately extract the exhaust noise as the control target, the singular value decomposition technique was utilized for decomposition and reconstruction of the signal.

Based on this, three new mufflers with different parameters were designed and manufactured. The sound level pressure dB (A), octave-band sound pressure level as well as detailed spectrum of exhaust noise from the tested diesel engine with three new mufflers were measured and analyzed respectively at five different speeds. By comparing the results with that without muffler and with the original muffler of the engine, the new theory of muffler has been verified.

Keywords: Finned tube condenser, Test, Simulation

Abstract. In this paper, a finned tube condenser performance test platform by using hot water as heat transfer medium in the pipe was established. The air side correlations of pressure drop and heat transfer were acquired based on lots of testing datas.A segment by segment model of the finned tube condenser used in these correlations was proposed and a simulation program was developed by using Visual C++ programming tools. Experiment and simulation results show that the air side correlations of pressure drop and heat transfer are fitting well with experimental datas. The deviation between the experimental and calculated values is within ±5%.The deviation of Nu Number is within ±10% and the deviation of the pressure loss is within±15%.

Introduction

Improve the efficiency of the system in the field of refrigeration and air conditioning is an important issue. Condenser is the main component of the refrigeration and air-conditioning systems, its heat transfer performance will directly affect the entire cooling system performance. To better understand the performance characteristics of the condenser in order to improve its performance, domestic and foreign scholars have done a lot of experiments and simulation studies. 1978, McQuiston[1] presented flat fin heat exchangers general correlation in accordance with its five prototype test data . In recent years, Wang [2] summarized heat exchanger corresponding experimental correlations based on experimental data of 9 prototypes. However, the fin spacing and size of the test tube pitch are the same for these prototypes; the extended universality of correlations has not been verified. Jensen [3] established phase change heat exchanger model by using the moving boundary. Each phase moving boundary method is a distributed lumped parameter method , the refrigerant heat physical parameters in each region of the phase transformation is represented by a lumped parameter phase zone length as state variables (micro- component), making the heat exchanger zone length in the system varies with time during the simulation. Yue Ting [4] establishes a steady state simulation model of a small refrigeration unit condenser. In this simulation model , the combination of distributed parameter model and the lumped parameter model of the merits , according to the condenser refrigerant state division, district of refrigerant superheat and sub cooling zones were established distributed parameter model and experimentally validated models and the accuracy of the algorithm.

The condenser running conditions can quickly be predicted by using of the steady-state distribution parameter model to simulate finned tube condenser performance, and determine whether the parameters of the condenser meet the design requirements. Not only can avoid frequent prototype trial and experimentation, reduce costs, but also can improve design efficiency and shorten the product development cycle.

Firstly, to establish a Finned tube condenser performance test platform using hot water as heat transfer fluid, obtained heat transfer coefficient of air side and resistance characteristics parameters by experiment; then using Segment by Segment model [5], combined with the test results, to build condenser calculation model. Finally, a exchanger simulation program was compiled by using

Visual C++ programming tools. In the simulation process in the condenser is divided into three zones, namely, to solve its basic equations illustrate the impact of changes in the structural parameters of the condenser to the condenser performance.

Steady distributed parameter model

Condenser model. Condenser is using Segment-by-Segment model simulation. According to the order flow of the refrigerant tubes, each computing unit used in the calculation method for solving, calculated heat transfer process within each Segment tube inside and outside of the tube, respectively, to solve the energy conservation equation and momentum conservation equations [6]. Combined with the actual operation of the condenser, the model makes the following assumptions:

1) Air flow rate of air flowing outside the tube is regarded as one-dimensional flow patterns, regardless of its structure causes uneven distribution;
2) Using the cross-flow heat exchanger structure, but the common condenser, the refrigerant tube and the tube relative to the outer air flow to cross flow within the flow cross each calculation Segment of a distribution model;
3) Ignore tubes axial heat loss through the fins of the heat exchanger considered only in the vertical direction;
4) Assuming each Segment air flow area is one-dimensional, and air without mixing at axial direction .
5) Ignore the pressure drop at the U-tube.

The control equations within segment. Generalized thermodynamic definition of dryness in the overheated state of the super cooled state, other thermodynamic defined dryness. Segment status within the refrigerant by generalized dryness value judgments.

$$X = \frac{h - h_{bub}}{h_{dew} - h_{bub}} \tag{1}$$

For any Segment, the following equations can be established.

1) Refrigerant heat equation

Continuity equation:

$$m_r = const \tag{2}$$

Energy equation:

$$Q_r = m_r(h_{in} - h_{out}) = m_r(f(X_{in}) - f(X_{out})) = \alpha_r A_i (T_r - T_w) \tag{3}$$

Where:

Q_r —Refrigerant heat exchange capacity; m_r —Refrigerant mass; h_{in}, h_{out} —Refrigerant inlet and outlet enthalpy; α_r —Local heat transfer coefficient of refrigerant [8]; A_i —The refrigerant heat exchanger area;

T_r —Refrigerant temperature; T_w —Heat exchange tube wall temperature.

2) Air-side flow and heat transfer equations

Continuity equation:

$$m_a = const \tag{4}$$

Heat equation:

$$Q_a = m_a Cp_a \varepsilon_t (T_{a,o} - T_{a,i}) = \alpha_a A (T_w - \frac{T_{a,o} + T_{a,i}}{2}) \tag{5}$$

Where:

Q_a —Air heat exchange; Cp_a —Air specific heat capacity at constant pressure;

ε_t —Temperature efficiency; m_a —Air mass flow.

3) Tube inside and outside heat balance equation

Ignore heat loss as well as a small amount of refrigerant in the refrigeration oil influence on heat transfer from the energy conservation equation shows:

$$Q_a = Q_r \tag{6}$$

4) Calculation of the pressure loss of the refrigerant

Refrigerant pressure loss in the pipe by the static pressure loss, the pressure loss and the friction pressure loss component of acceleration, the pressure loss according to the reference [8].

5) Algorithms and processes

Figure 1 is the flow chart of the simulation process, A is a simulation flow chart for the entire condenser, B is a simulation flow chart of one segment .Said single heat exchanger simulation model based on the use of Visual C++ compiled a heat exchanger performance simulation program. In the calculation, the parameters may be parameters of the structure of the condenser and inlet and fluid parameters are set in a range of condenser simulation program according to the setting. The simulation output of the main heat load heat exchanger, the pressure loss on the air side, the air outlet temperatures.

Refrigerant properties model. In order to ensure the calculation results, the physical properties of the refrigerant used herein, is calculated using the American Institute of Standards and Technology (NIST) developed physical computing software Refprop 8.0[7], using Visual C + + for Refprop.dll encapsulation used in the simulation program to ensure that refrigerant accuracy physical properties.

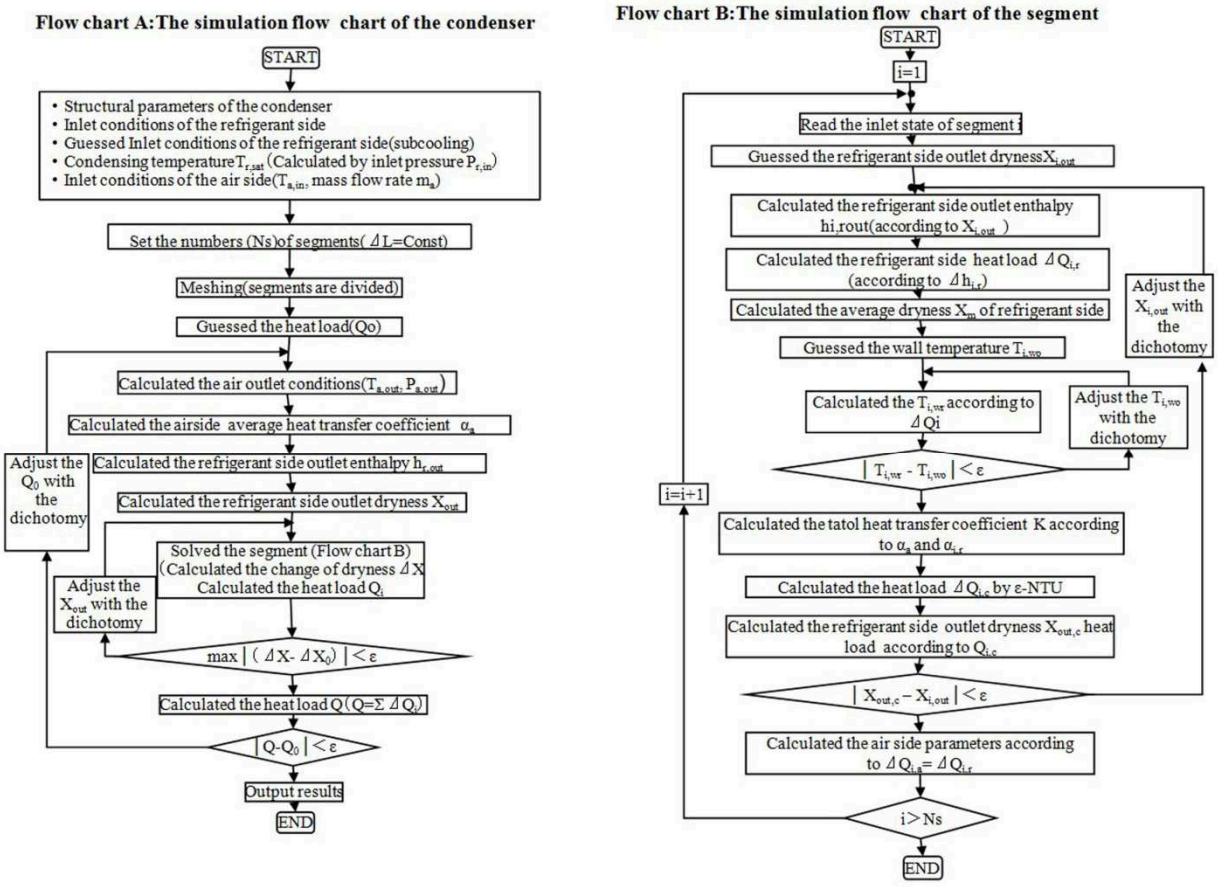

Figure 1 The Flow Chart of Simulation Calculation

Test device

Air system. Test Lab with air enthalpy-difference method for the condenser air inlet by an air handling system to control parameters; dry air side outlet of the wet bulb temperature is measured by the sampling means in the wind tunnel. The air flow through the condenser is controlled by changing the operating frequency of the induced draft fan. After the heat exchanger outlet and the nozzle are provided with static pressure measuring three points, each measuring point by the static pressure measuring hole to take four different directions, the mixture was measured by the

differential pressure transducer and the static pressure of the wind pressure nozzle before and after. The air-side heat exchanger pressure loss can calculate by the static pressure of the wind; the air temperature and humidity around the nozzle pressure and nozzle can calculate the volume of air flow through the nozzle, so you can get the air flowing through the heat exchanger and the face wind speed.

Water System. Mainly by the constant temperature water tank water system, circulating pump, a flow control device composed of a closed loop system uses a stable manner in the water flow rate and temperature were tested heat exchanger. Each in charge of road traffic through manual valve, pressure regulator and out of the water in the heat exchanger can be achieved within the water flow path for each charge is equal. Water system uses RTD sensors to measure water temperature and water temperature for each charge of the road.

Test Equipment. The RTD sensor to measure temperature, air pressure and water static pressure is measured using a differential pressure transmitter. The test datas obtained by the sensor and transmitter are transferred to the computer every 6 s.

Tests and calculations

Test results. Figure 2 shows the variation of pressure loss with tube number of columns, which can be seen, the deviation between the experimental results and the calculated results are mainly distributed within ± 15%. Figure 3 shows the variation of air side Nu number with x^*, and can be seen from the figure 3, when $x^* \le 0.3$, under the same conditions as x^*, with the increase in the number of rows, Nu number increases; while x^* relatively large , the number of columns is not significantly affected. Deviation Nu number between experimental results and the calculated results are mainly distributed within ± 10%, especially in the larger face velocity range (approximately 1.6-8m / s), the calculated and experimental values are closer fitting formula.

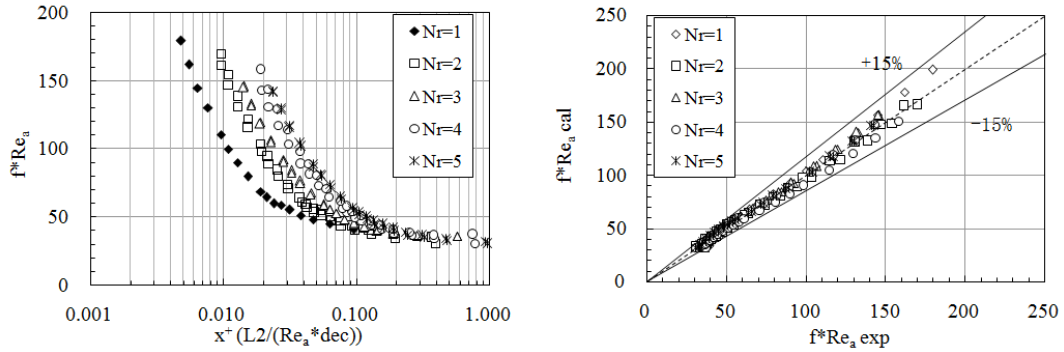

Figure 2 The relationship of the pressure loss vs. row number

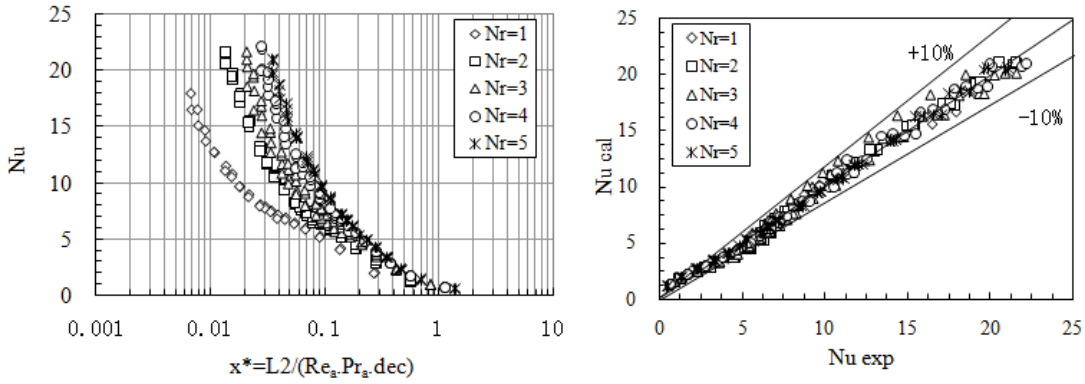

Figure 3 The relationship of the Nu number vs row number

Simulation. In order to verify the accuracy of the calculation results, a series simulation of a condenser are carried out: The air face velocity range is 1.8~2.6m/s, the step size is 0.2m/s. The data in Table 1 can be seen in the deviation between simulation results and experimental values within the allowable range (± 5%), to achieve a better description of the simulation accuracy, basically to meet the heat exchanger in the design and verification phase requirements.

Table 1 Simulation results vs test results

Heat load (kW)			Loss of air pressure(Pa)		
Experiment	Simulation	Deviation	Experiment	Simulation	Deviation
5.96	5.97	0.17%	17.22	17.78	3.40%
5.28	5.46	3.41%	25.91	24.88	-3.95%
4.85	5.02	3.51%	16.82	16.37	-2.52%
11.41	11.03	-3.33%	64.33	67.51	4.98%
4.12	4.31	4.61%	12.51	12.98	3.87%

Conclusion

In this paper, water as a medium to establish a test platform Finned tube condenser through experiments applicable to slit fin heat exchangers and pressure losses associated relational style, and apply it to the condenser of the simulation model, while preparing the condenser performance simulation program, and the condenser prototype experiment and simulation comparison. The results showed that the simulation and the experimental error can be maintained within ± 5%, a condenser designed to meet the needs. While the design cycle is shortening about 90%t, thus can greatly reducing the product development and design cycles.

Keywords: Crane; Boom; Double corrosion points; FEA

Abstract. Currently, corrosion of offshore crane booms is serious and badly affects equipment performance and working safety. Obviously, analysis of the corrosion is necessary. In this paper, as an actual case, the boom FEM of 320t pipe-laying crane is built to analyze its double points corrosion based on analysis of single point corrosion. By analyzing stress concentration and stress distribution of different distance for double corroded points, which can be axially arranged or circularly arranged, we try to obtain some affected trends.

Introduction

Corrosion of steel structure not only causes the waste of resource, but also seriously affects the equipment performance and working safety. In practical application, structure has corrosion protection. But as time goes on, corrosion cannot be avoided due to severe working environment and poor equipment maintenance [1]. When corrosion reaches to a certain level, structure is damaged and doesn't work. So, corrosion can not to be ignored.

Offshore cranes are corroded more easily than ones on land because of marine environment. These crane booms are mostly composed of trusses. As a typical example, Fig. 1 and Fig. 2 show 320t pipe-laying crane which has worked for almost 30 years, and its serious corrosion which is found recently. The corrosion's distribution is various, such as two points corrosion distribution and multi-point corrosion distribution. These corrosions can lead stress concentration and damage structure at last.

There are many scholars to research corrosion problem. Dong Shier [2], Li Zengliang [3], Hong Laifeng [4] and other scholars used ANSYS to research the effect of point corrosion defects on oil pipeline's residual strength. Wei Huazhong [5] made a detailed description of establishing reasonable model of corrosion points. Chou Chaoui B A [6] made nonlinear FEA on point corrosion pipelines. It can be seen that existing studies have more focused on corrosion analysis of transmission pipelines. But only a few studies are about the boom corrosion of offshore cranes. We can refer to the former, but they are different. Pipeline is longer and mainly subjects to internal pressure. However, the crane boom mainly subjects to axial load and bending moment when loading. So, their research methods are similar, but different. In this paper, based on single point corrosion achievement [7], two points corrosion and its influence facts are analyzed, which are the distance between two corrosive points. The analysis example is 320t pipe-laying crane's boom, whose sizes are shown in Tab. 1.

Fig. 1 320t pipe-laying crane

Fig. 2 Points corrosion of the boom

Table 1 Size and specification of the boom

Boom length (m)	Boom cross section (mm)	Chords(angle steel) (mm)	Bracings(pipe) (mm)
75	3975x2320	203.2×203.2×25.4	Φ60.3×3.9 Φ73×5.2 Φ88.9×5.5 Φ101.6×5.8

1 FEM of corroded pipe

According to Saint-Venant's principle, in order to avoid the boundary effect, the bracing of boom is selected whose sizes are 500mm length and Φ88.9 × 5.5mm. Its FEM is built by solid95 element. According to [8], corrosion point is simply built as hemispheroid, as shown in Fig.3. The model is meshed by tetrahedron and hexahedron. For lower stress gradient area, grid size is relatively sparse, and is about 10mm. For higher stress gradient area, especially around of corrosion point, grid is subdivided, and its size is as small as 1mm. The model's node is 93334 and its element is 43184.

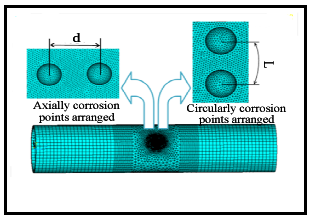

Fig. 3 Finite element model

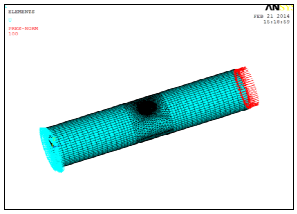

Fig. 4 Model of applying boundary conditions

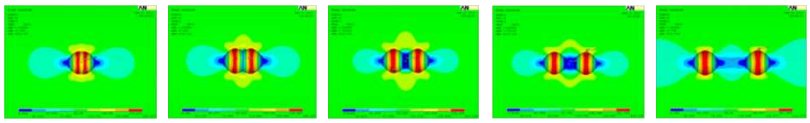
It is noted that two corrosive points can be classified in axially arrange and circularly arrange, as shown in Fig. 3. The distance of two axially arranged points is defined as linear distance d between the two corrosion points center. And the distance of two circularly arranged points is defined as arc length L between the two corrosion points center. The parameters about corrosion points are shown in Tab. 2.

For crane boom, its bracings are mainly subjected to axial load. Through analyzing boom FEM, we can obtain that bracings' max. stress is about 100MPa. So, we apply a uniform compressive stress 100MPa on the side of the bracing model and apply full displacement constraints to the other side, as shown in Fig. 4.

Tab.2 Parameters of corrosion points

Parameters	Definitions
D	Diameter of corrosion points
$\alpha=d/D$	The ratio between axial distance d and diameter D
$\beta=L/D$	The ratio between arc length L and diameter D
σ_{mid}	Von mises stress on the middle between two corrosion points' center
σ_{emax}	Max. von mises stress at the edge of corrosion points(except σ_{mid})
σ_{max}	Max.{ σ_{mid} , σ_{emax}}
$K=\sigma_{max}/100$	Factor of stress concentration
α_{lim}	Ratio α when two axially arranged corrosion points cannot affect each other
β_{lim}	Ratio β when two circularly arranged corrosion points cannot affect each other

2 FEA of two axially arranged points



(a)α=0.2 (b)α=0.6 (c)α=1.0 (d)α=1.4 (e)α=1.8

Fig. 5 Stress distribution of different α for 45% of corrosion depth ratio

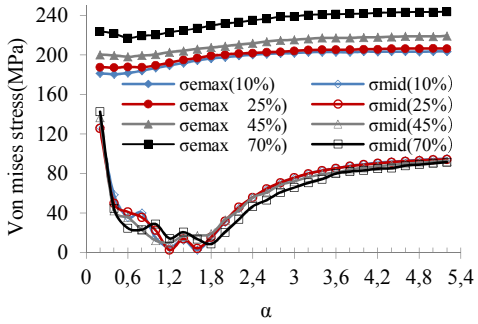


Fig. 6 Stress curves of different α

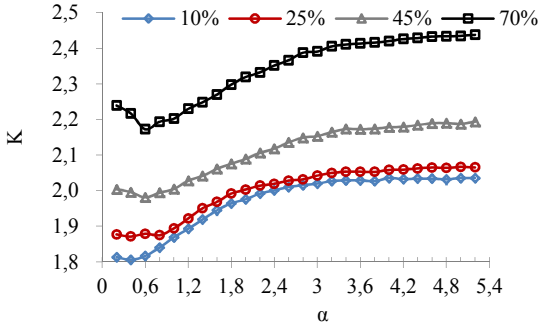

Fig. 7 K curves of different α

FEA models with different corrosion depth ratios (10%, 25%, 45%, 70%) and different d are built, in which two corrosion points are arranged axially. We can make α-σ_{mid} curves, α-σ_{emax} curves and α-K curves with different depth ratios, as shown in Fig. 5 , Fig. 6 and Fig. 7.

From these figures, different depth ratios have similar curve trend, whose max. stress occurs at the edge of the corrosion points. If α is more and more higher, σ_{emax} and σ_{mid} tend to be a stable value, and the stable values of σ_{emax} are near to their single corrosion point's max. stress. Simultaneously, the two corrosion points are unaffected, like two independent single point corrosion. Here, we can define α_{lim}. In order to uniform rule, Δ_i are calculated according to Eq. 1, and $\Delta_i < 5\%$ is as judgment rule to obtain α_{lim} [9], as shown in Tab. 3. From this table, we can show that α_{lim} is similar and between 3.0 and 3.2 with different corrosion depth ratios. So, we take α_{lim} = 3.2 as judgment if the two corrosion points are affected or not.

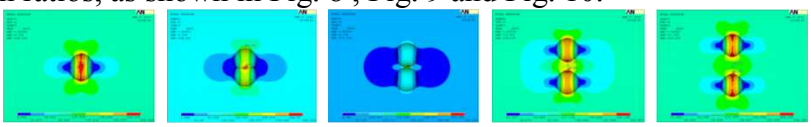
$$\Delta_i = \left| \frac{K_{i+1} - K_i}{\alpha_{i+1} - \alpha_i} \right| \times 100\% . \tag{1}$$

Tab.3 α_{lim} values with different corrosion depth ratios

Corrosion depth ratio	10%	25%	45%	70%
α_{lim}	3.0	3.0	3.2	3.2

3 FEA of two circularly arranged points

FEA models with different corrosion depth ratios (10%, 25%, 45%, 70%) and different L are built, two corrosion points are arranged axially. We can make β-σ_{mid} curves , β-σ_{emax} curves and β-K curves with different depth ratios, as shown in Fig. 8 , Fig. 9 and Fig. 10.



(a) β=0.2 (b) β=0.6 (c) β=1.0 (d) β=1.4 (e) β=1.8

Fig. 8 Stress distribution of different β for 45% of corrosion depth ratio

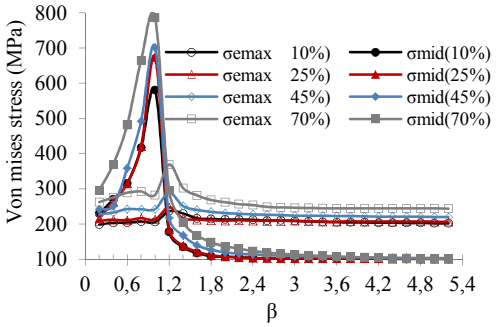


Fig. 9 Stress curves of different β

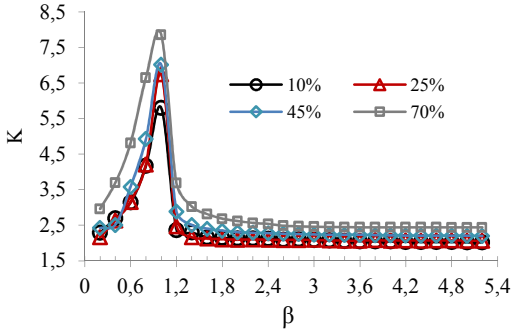

Fig. 10 K curves of different β

From these figures, different depth ratios have similar curve trend, whose cutoff point is β = 1. When β≤1, the max. stress is σ_{mid}. And when β>1, the max. stress occurs at the edge of the corrosion points. If β is more and more higher, σ_{emax} and σ_{mid} tend to be a stable value, and the stable values of

σ_{emax} are near to their single corrosion point's max. stress. Simultaneously, the two corrosion points are unaffected, like two independent single point corrosion. Here, we can define β_{lim}. Also using Eq. 1, β_{lim} of different depth ratios are shown in Tab. 4. β_{lim} is between 4.0 and 4.2. So, we take β_{lim} = 4.2 as judgment if the two corrosion points are affected or not.

Tab.4 β_{lim} values with different corrosion depth ratios

Corrosion depth ratio	10%	25%	45%	70%
β_{lim}	4.2	4.0	4.0	4.0

Conclusions

For the two-point corrosion of boom pipes, FEA model is built and analyzed and make some conclusions as follow:

(1) In the corrosion case of two axially arranged points, stress concentration is not very obvious than single point corrosion. The limitation ratio α_{lim}=3.2 can be as judgment to judge if two corrosion points affect each other or not. That is to say, when α<3.2, stress of the two corrosion points are affected. When $\alpha \geq 3.2$, the two corrosion points are unaffected, like two independent single point corrosion.

(2) In the corrosion case of two circularly arranged points, stress concentration is more obvious than single point corrosion. Also there exists limitation ratio β_{lim}=4.2 as judgment. When α<4.2, stress of the two corrosion points are affected. When $\alpha \geq 4.2$, the two corrosion points are unaffected.

(3) Stress concentration in two circularly arranged points is more serious than ones in two axially arranged points, so we should pay more attention to the formers.

Keywords: IGBT, Electrical-thermal-mechanical coupling, Thermal stress

Abstract. Reliability of IGBT power module is one of the biggest concerns regarding wind power system, which generates the non-uniform distribution of temperature and thermal stress. The effects of non-uniform distribution will cause failure of IGBT module. Therefore, analysis of thermal-mechanical stress distribution is crucially important for investigation of IGBT failure mechanism. This paper uses FEM method to establish an electrical-thermal-mechanical coupling model of IGBT power module. Firstly, thermal stress distribution of solder layer is studied under power cycling. Then, the effects of initial failure of solder layer on the characteristic of IGBT module is investigated. Experimental results indicate that the strain energy density and inelastic strain are higher which will reduce reliability and lifetime of power modules.

Introduction

Insulated Gate Bipolar Transistor (IGBT) is commonly used in wind power systems, which often surfs severe environments. Thus, reliability is of great importance for that matter[1,2]. A reliable wind power system calls for a good working condition for its wind power converter, of which IGBT is the central part. So a close study of the failure mechanism of the power module is very important to improve the reliability of converters.

In real operation, IGBT modules burden huge amount of heat which is produce by the conducting and switching state, also leading to an non-uniform temperature distribution in IGBT module, because of the multi-layer structure and the mismatching of the expansion coefficient of every layer producing thermal stress in IGBT module. At the interface of different layers, the shear stress will firstly cause crack in solder layer, and eventually accumulate into failure.

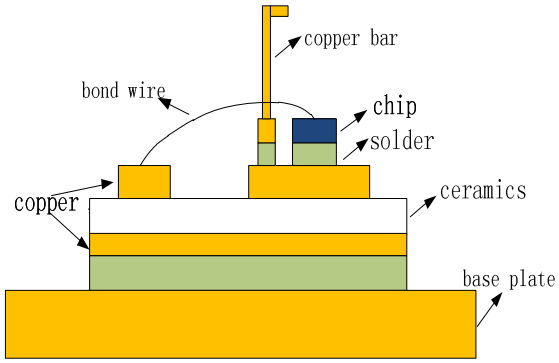
Aiming at the effects of power cycling, an electro-thermal-mechanical model is built to analyze the thermal stress characteristic, including the common used parameters for lifetime prediction. Then, the effects of center void in solder layer was discussed, impact of size of void on the junction temperature was analyzed, and effects of the corresponding of thermal stress parameters was also discussed. By analyzing the variation of thermal stress, the real operation of IGBT can help to understand the failure mechanism and improve the lifetime prediction model, overcoming the current module in which the temperature was taken into account.

IGBT Structure Module

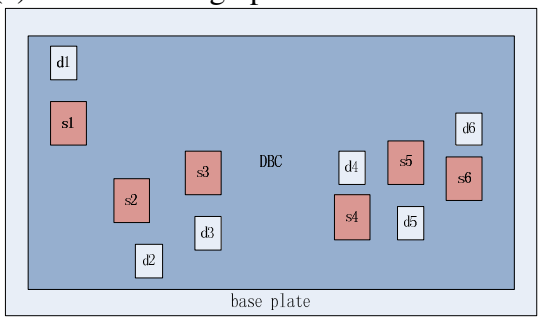
Figure 1 shows the typical structure of a IGBT power module. Fatigue and aging of solder materials can be caused by its special multilayer structure as well as the mismatching of thermal expansion coefficient among different materials. This can lead to failure of the device as a result of rupture of chip bong wires, breakage in solder layers or an increase in temperature[3-5].

In thermal aging, the solder layer has creep effects under constant stress where the layer has relatively low melting point. When building a finite element model for IGBT power module, all the

materials are assumed to be elastic, while the elastic-plastic-creep effect of layer is explained by Anand model[6].



(a)Cross-section graph of the IGBT module



(b)Top view of the IGBT module

Fig. 1 Cross-section graph and top view of the IGBT module under study

Thermal-Mechanical Stress Analysis

Power Cycling Model. In real operation, IGBT always keeps conduction and switching state, which can generate huge amount of heat, exposing the IGBT chip to constant temperature fluctuation. Together with the mismatching of thermal expanding coefficient of the inner structure of model, the temperature fluctuation gives rise to alternating thermal stress between interfaces of different materials. This leads to cracks in solder layer, which means a reduction in heat dissipation, a concentrating of heats and even more serious failure of the layer[7,8].

In this paper, the transient thermal stress distribution of the solder layer under power cycling failure model is analyzed. Because transient temperature fluctuation in switching period is negligible to the failure of a device. Therefore, by considering the aging acceleration and changing the period of loading current, we could attain the heat source variation to the pattern shown in Fig. 3. All together 3 power cycling periods are chosen to analyze the thermal-stress variation of IGBT power module in power cycling. The Von Mises stress distribution of the last moment can be seen in Figure 4.

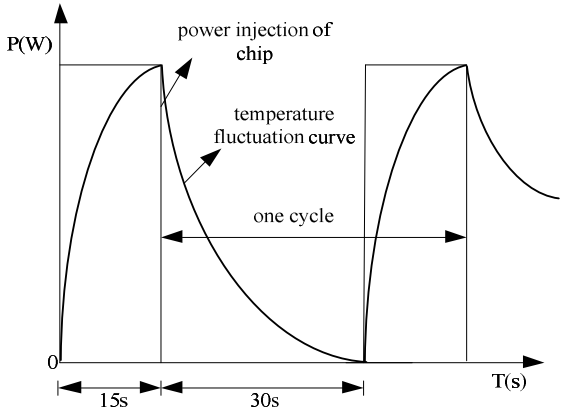


Fig. 3 Illustration of power cycling

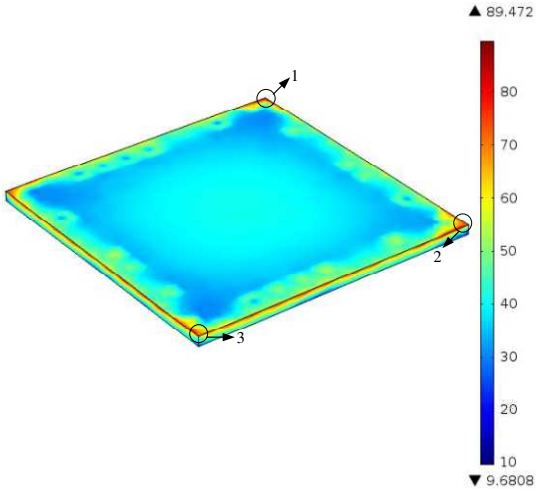

Fig. 4 Distribution of Von Mises stress for solder

It can be concluded that thermal stress mainly concentrates on the edges of the solder layer, especially on the vertexes, which agrees with former experimental findings[9]. Edges and vertexes are the most delicate parts defined as dangerous points, where cracks generally stem from here and gradually expand towards the center. In addition, more strain and strain energy appear in these areas for the reason that the thermal mismatching from CTE differences are the most serious here.

We then analyze strain energy density of solder layer in different moment. As can be seen in Figure 5, the density increases with the time in an approximately ladder-like pattern. When the circulation reaches steady state, the lifetime of a solder layer can be calculated by fluctuation amplitude and Kliman energy fatigue model.

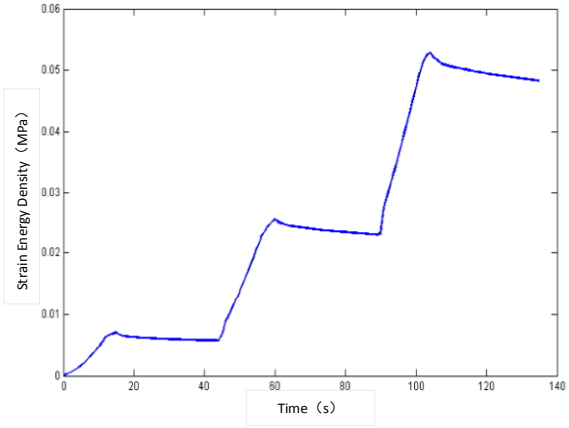

Fig. 5 Contour map of strain energy density of solder

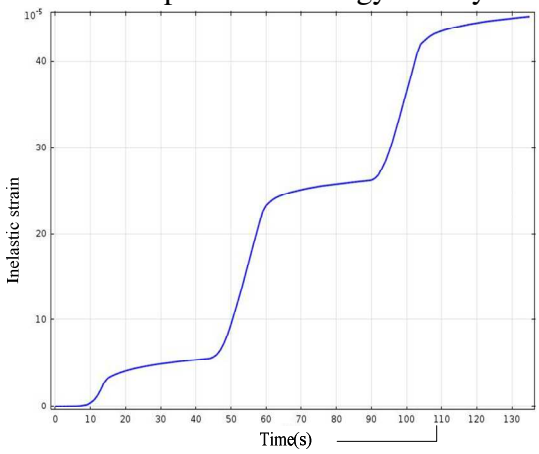

Fig. 6 Contour map of inelastic strain of solder

Fig. 6 shows the variation curve of the inelastic strain of solder layer. The inelastic strain increases with the time in a ladder-like pattern. It can also be seen that strain variation rate varies with the

heating stage. In the early stages, the rate is low because the material's elastic deformation occur. So inelastic deformation is approximately is 0 in the early stages. In this process, strain variation rates are distinct in different power cycling.

Influence of Initial Voids on the IGBT Solder Layer Failure. The solder layer of power module is vital for the properties and reliability of a device as it lies in the main course of heat and electric conduction[8]. Void can frequently be seen in solder layers as a result of technologic factors in manufacturing. Changes in temperature caused by power cycling can lead to circulating shear strain and spatial temperature gradient, causing the void to expand and the layer to crack or even stratify.

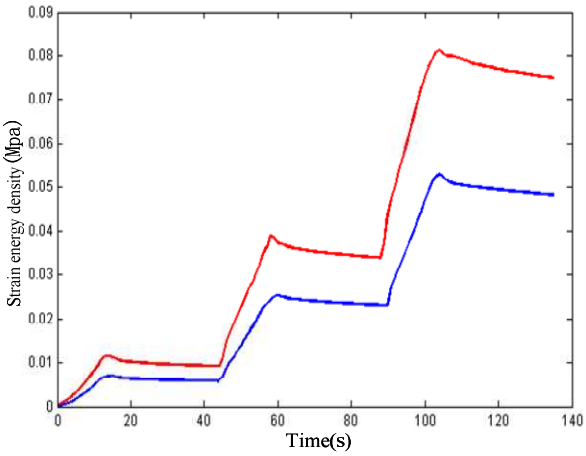

Fig. 7 Comparisons of strain energy density for danger point of solder layer

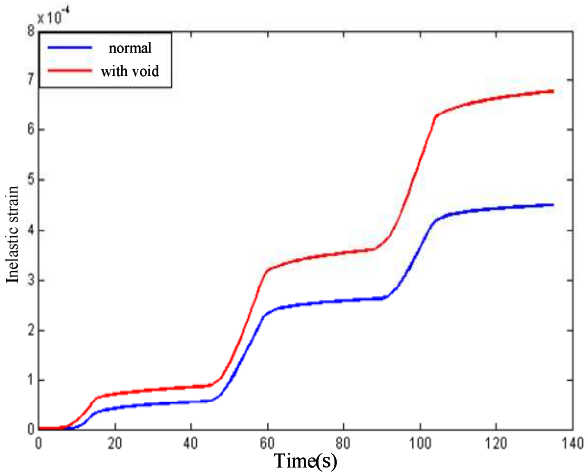

Fig. 8 Comparisons of inelastic strain for danger point of solder layer

Strain energy density and inelastic strain are two parameters to describe the lifetime of an IGBT power module. When encountering voids, the changes is shown in Fig. 7 and Fig. 8 where strain energy density increases 0.032MPa as well as inelastic strain rises $1.53e^{-4}$. Also, according to the Coffin-Mason lifetime formula and the Kliman formula, the thermal fatigue lifetime of a solder layer is in inverse relation to the strain energy density amplitude and strain amplitude. As a result, voids in solder layer leads to shorter lifetime. Layer with previous faults suffers from serious deformation when overvoltage or overcurrent. The temperature impact caused by the voltage and current may accelerate the cracking of the layer and the bonding wires lift-off, leading to the failure of the module.

Conclusions

The self-circulating heating process of the IGBT power module can bring diversity in the inner temperature and thermal stress of the module. Taking the impact of inconsistency on the aging of power module into consideration, the electro-thermal-mechanical coupling model which based on accelerate aging method is established to analyze the variation of the transient thermal stress characteristics of the IGBT power module. The result demonstrates that in such case:

1. In the power cycling, a higher frequency of dangerous point's heat exchange brings about a greater temperature gradient and greater Von Mises stress, which means more possibility in failure.

2. In the initial failure of the solder layer, the strain energy density and inelastic strain are 0.032MPa and $1.53e^{-4}$ higher. These shorten the lifetime of the solder layer which results decreasing the reliability as well as the lifetime of the module.

Keywords: Viscoelastic fluid; Velocity field; Tangential tension; Laplace transform; Modeling

Abstract. The velocity field and the associated tangential tension corresponding to the flow of the viscoelastic fluid over an infinite rigid plate are determined in this paper. The characteristic of the non-Newtonian viscoelastic fluid flow is analyzed using the Stehfest method of the numerical inversion of Laplace transform. It indicates that the flow of the viscoelastic fluid is very sensitive to the material constants. Finally, some comparative diagrams concerning the velocity and tangential tension profiles are presented.

Introduction

In recent years, due to its practical applications, non-Newtonian fluid has received much attention in some areas such as oil drilling, food industry and paper industry [1,2]. The rheological properties of these fluids are determined by their so-called constitutive equations. For a Newtonian fluid, its flow is described by the Navier-Stokes equations[3]. However, these equations are not enough to describe many real fluids, especially those of high molecular weight such as polymeric liquids, food stuffs, biological fluids, etc. Recently, one of the most popular non-Newtonian fluid model is the so-called Burger fluid model [4,5].

The velocity field and the associated tangential tension corresponding to the motion of a viscoelastic fluid over a suddenly moved flat plat are determined in present paper. The well-known solutions of this problem for an Oldroyd-B fluid, Maxwell fluid, second-grade fluid and a Newtonian fluid appear as a limiting case of our solution. Finally, some comparative diagrams concerning the velocity and tangential tension profiles are presented.

Mathematical formulation

Several kinds of fluid model have been developed to describe the flow of viscoelastic fluid [6,7]. A rate type model due to Oldroyd will be considered in the following mathematical models, in which the second convected derivative of the strain tensor is included. The model contains one retardation time and two relaxation times.

Initially, the fluid is at rest and at time t=0+ the plate is impulsively brought to the constant velocity V (at y=0). The fluid occupies the space y > 0. The x-axis is taken parallel to the flow. The differential equation for the tangential tension $\tau_y(y,t)$ is of the form

$$\tau_y(y,t) + \lambda\partial_t\tau_y(y,t) = \mu(1+\lambda_r\partial_t+\beta\partial_t^2)\partial_y v(y,t) \tag{1}$$

Where λ is relaxation time, λr and β are retardation times, μ is the dynamic viscosity of the fluid.

In the absence of a pressure gradient in the x-direction, the equation for fluid motion is

$$\partial_y \tau_y(y,t) = \rho \partial_t v(y,t) \tag{2}$$

Where ρ is the constant density of the fluid.

Eliminating $\tau_y(y,t)$ between Eq.1 and 2, we attain to the governing equation

$$\partial_t v(y,t) + \lambda \partial_t^2 v(y,t) = \gamma(1 + \lambda_r \partial_t + \beta \partial_t^2)\partial_y^2 v(y,t), \quad y,t > 0 \tag{3}$$

Where $\gamma=\mu/\rho$ is the kinematic viscosity of the fluid.

The initial conditions are

$$v(y,0) = 0, y > 0 \tag{4}$$

$$\partial_t v(y,t) \to 0 \quad \text{as } t \to 0 \tag{5}$$

The boundary conditions are

$$v(0,t) = V, t > 0 \tag{6}$$

$$v(y,t), \partial_y v(y,t) \to 0 \text{ as } y \to \infty \tag{7}$$

Solution of the problem

Calculation of velocity[8,9]

Multiplying Eq.3 by exp(-st), integrating with respect to t from 0 to ∞ and taking into account the initial conditions (4), (5), we find that

$$\lambda s^2 v_s(y,s) + s v_s(y,s) = \gamma(1 + \lambda_r s + \beta s^2)\partial_y^2 v_s(y,s) \qquad y,s>0 \tag{8}$$

Where $v_s(y,s)$ is the Laplace transform of the function $v_t(y,t)$. From the boundary conditions (6) and (7) we also get the equations:

$$\begin{aligned} &v_s(0,s) = \frac{V}{s} \\ &v_s(y,s) \to 0, \ \partial_y v_s(y,s) \to 0 \quad as \ y \to \infty \end{aligned} \tag{9}$$

The solution to Eq.8 subjected to the boundary conditions (9) is

$$v_s(y,s) = \frac{V}{s}\exp\left(-\sqrt{\frac{\lambda s^2 + s}{\gamma(1 + \lambda_r s + \beta s^2)}}\, y\right) \tag{10}$$

Calculation of the tangential tension

Having in mind the fluid being at rest up to the moment t=0, the initial condition for the tangential tension is of the form

$$\tau_y(y,0) = 0 \tag{11}$$

Multiplying Eq.(1) by exp(-st), integrating with respect to t from 0 to ∞ and taking into account the initial condition(11), we find that

$$(1+\lambda s)\tau_s(y,s) = \mu(1+\lambda_r s+\beta s^2)\partial_y v(y,s) \tag{12}$$

Where $\tau_s(y,s)$ is the Laplace transform of the function $\tau_y(y,t)$.

Substituting (10) in (12), we attain to the tangential tension $\tau_s(y,s)$:

$$\tau_s(y,s) = -\frac{V\rho}{\sqrt{\frac{\lambda s^2+s}{\gamma(1+\lambda_r s+\beta s^2)}}} e^{-\sqrt{\frac{\lambda s^2+s}{\gamma(1+\lambda_r s+\beta s^2)}}y} \tag{13}$$

Limiting cases

By letting $\beta\to 0$ in Eq.10 and 13, we attain to the Laplace space solutions corresponding to an Oldroyd-B fluid. In the special case when $\beta\to 0$ and $\lambda r\to 0$, the Eq.10 and 13 can be put into the form corresponding to a Maxwell fluid. Taking the limit of equation (10) and (13) as $\beta\to 0$ and $\lambda\to 0$, we get the velocity field and the tangential tension corresponding to a second grad fluid. Finally, as$\beta\to 0$, $\lambda\to 0$ and $\lambda r\to 0$, the equation (10) and (13) yield the Laplace space solution corresponding to a Navier-Stokes fluid .

Results and Discussion

The velocity and tangential tension profiles corresponding to the viscoelastic fluid are obtained using the Stehfest method of the numerical inversion of Laplace transform. The influence of the material constants on the viscoelastic fluid flow is studied in this part.

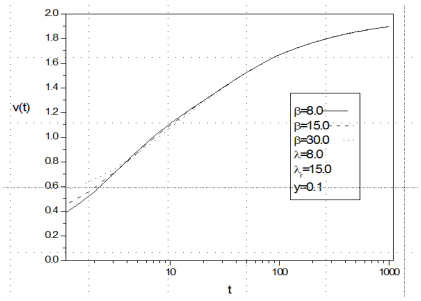

Fig.1 y=0.1, velocity profiles v (t) corresponding to a viscoelastic fluid for V=2, γ=0.0011746, λ=8.0,λr=15.0.

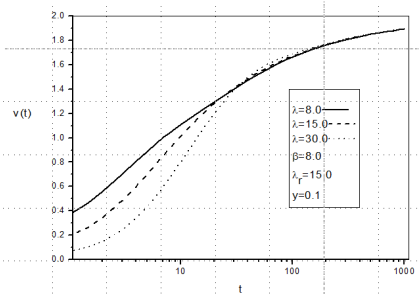

Fig. 2 y=0.1, velocity profiles v (t) corresponding to a viscoelastic fluid for V=2,γ=0.0011746, λr=15.0, β=8.0.

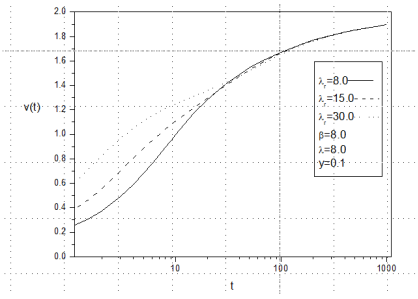

Fig.3. y=0.1, velocity profiles v (t) corresponding to a viscoelastic fluid for V=2, γ =0.0011746, β =8.0, λ =8.0.

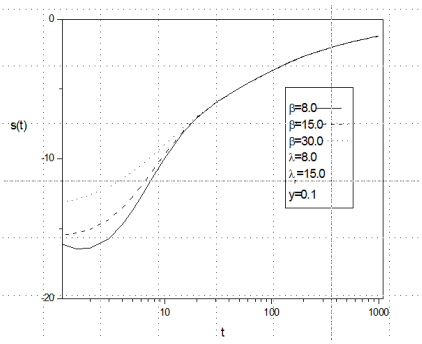

Fig.4 γ=0.1, tangential tension profiles s(t) corresponding to a viscoelastic fluid for V=2, γ=0.0011746, λ=8.0,λr=15.0.

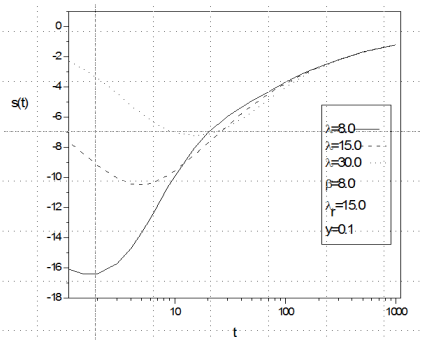

Fig.5 γ=0.1, tangential tension profiles s(t) corresponding to a viscoelastic fluid for V=2, γ=0.0011746, λr=15.0, β=8.0.

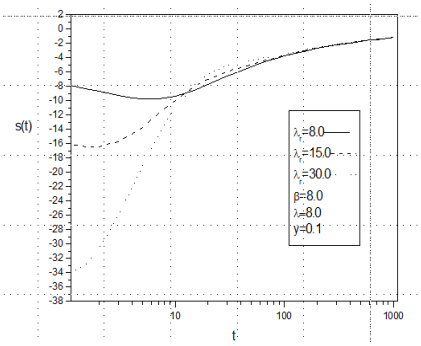

Fig.6 γ=0.1, tangential tension profiles s(t) corresponding to a viscoelastic fluid for V=2, γ=0.0011746, β=8.0, λ=8.0.

In figs. 1, 2 and 3, the variations of velocity field v(y,t) are plotted for different material constants. For different values of the retardation time β (fig. 1.) and λr (fig. 3.), the larger of its value, the velocity v(y,t) is bigger at t=0. The opposite is true for the relaxation time λ (fig. 2.). In each case the velocity is going to the initial velocity V for $t \to \infty$. Figs 4, 5 and 6 depict the effect of the relaxation time λ (fig. 5.) and the retardation time β (fig. 4.) and λr (fig. 6.) on the associated tangential tensions. In each case the tangential tension tend to zero for $t \to \infty$. The influence of the material parameters on the fluid velocity and associated tangential tensions is mainly in early stage.

Abstract. By applying the seamless data interface between SolidWorks and ADAMS, the model of the internal combustion compressor was imported. The internal combustion compressor virtual prototype model was established, the kinematics and dynamics analysis were completed, and the dynamic load on crankshaft was given. After we use finite element analysis software ANSYS, the modal analysis of crankshaft were accomplished, the modes of vibration and response frequency in the first five orders were obtained. The mixed body dynamics model was established, and the crankshaft force curves under the rigid body and flexible body morphology were obtained.

Introduction

The internal combustion air compressor is a simple, highly efficient and convenient new type air compressing device which can transform heat energy into air pressure energy. It uses a connecting rod to connect dynamic piston with compressive piston as a whole in order to move right and left, which realizes the action of air induction and air compress. This device reserves the advantages of crank and connecting rod mechanism in the traditional piston internal combustion engine, which can restrict piston motion and realize the timing of system. So it has the advantages of piston internal combustion engine, piston compressor and HFPE. The Internal Combustion Air Compressor can be the power source of all kinds of air power mechanisms in field operation[1-2].

Operational Principles and Features

Operational Principles of the internal combustion air compressor is as shown in Fig. 1.

In the operational process fuel mixed gases combust to push dynamic piston and do work. Compressive piston is in the middle of piston component which outputs air pressure energy. The internal combustion air compressor realizes the retrace of piston component by means of crank and connecting rod mechanism; meanwhile, crank and connecting rod mechanism drive the operation of the subsidiary system of internal combustion engine. In the operational process described above, the 1st operation room realizes transformation from fuel heat energy to mechanical energy of piston component, just as the theory of energy transformation of four-stroke internal combustion engine; the 2nd operation room realizes energy transformation from mechanical energy of piston component to air pressure energy.

However, because of the newly components like added compressive piston, guiding sliding chunk and connecting rod , the weight of the components in the internal combusting air compressor which moves left and right will increase, so will the inertia force of the system. Consequently, dynamic performance of the internal combustion air compressor will decrease. Studying dynamic characteristics of the internal combustion air compressor by means of building dynamics simulation model of crankshaft system in the internal combustion air compressor through combining finite element analysis technology and virtual prototyping technology and simulating crankshaft system through rigid-flexible coupling multi-body kinematics and dynamics becomes one of pressing issues in the designing process of the internal combustion air compressor.

Fig. 1 Working principle diagram

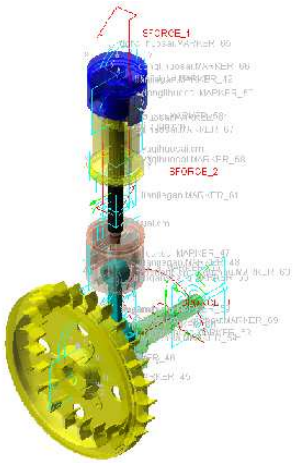

Fig. 2 Simulation model

The multi-rigid body dynamics simulation of crankshaft system

The article adopt the method of combining 3D modeling software named Solidworks and dynamics simulation software named ADAMS to build and analyze multi-rigid body dynamics simulation model of the internal combustion air compressor. Please see specific method in literature[3]. Simulation model consists of piston, connecting rod, cylinder block, compressive piston, sliding chunk, Crank and connecting rod mechanism and fly wheel. Simulation is as shown in Fig. 2.

Through the software named AVL Boost, operation pressure on the dynamic piston is obtained by simulation for the process of thermodynamics in the combustor of the internal combustion air compressor. The calculation of the force pressed on the compressive piston and the friction on the internal combustion air compressor can be seen in literature[4].

After finishing modeling and simulation under the circumstance of ADAMS/View, we can use post processor in ADAMS to obtain not only kinematics parameter curve of compressive piston component like position, velocity and acceleration but also changing force curve of both sides of connecting rod.

Fig. 3 is the stress distribution curve of the big side of the connecting rod. We can see that when the crankshaft turns around about 12 degrees, the peak value of stress will be 35000N. Afterwards, the stress of the connecting rod is relatively steady in a period, the impact force of dynamic piston on the crankshaft is relatively small.

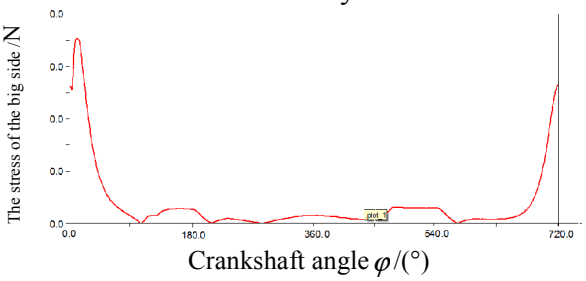

Fig. 3 The stress distribution curve of the big side of the connecting rod

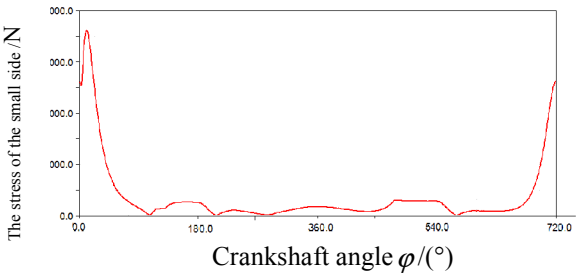

Fig. 4 The stress distribution curve of the small side of the connecting rod

Through calculating the stress between the small side of the connecting rod and the sliding block, we obtain the stress distribution curve of the small side of the connecting rod which is shown as Fig. 4. Peak value of stress is a little larger than the big side of the connecting rod, which is about 36000N. Other times the stress of the kinematics pair is relatively steady.

The stress on both sides of the connecting rod is primarily influenced by combustion pressure in different operating conditions, which is maximum when the combustion pressure is maximum.

Analysis on crankshaft mode

Firstly, we import its 3D model of parasolid into ANSYS to finish the transformation of its wireframe style. The finite element mesh generation uses tetrahedron, and mesh generation is the smart one. Crankshaft generation produces 104361 nodes and 21207 units. The finite element mode after mesh generation of the crankshaft is shown as Fig. 5:

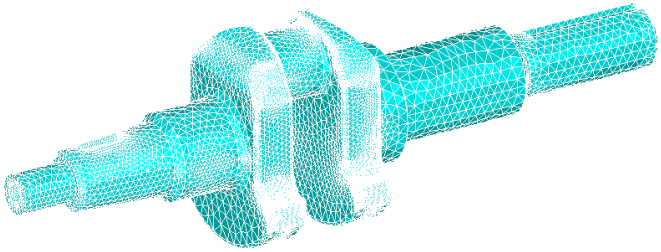

Fig. 5 Finite element model of crankshaft

The modal analysis is a technique used to define the vibration features (solid frequency and vibration modes) of designing mechanism and components. Solid frequency and vibration modes are important parameters of designing framework supporting dynamic load, which are also the key to analyze other kinematics questions.

The methods of mode analysis in ANSYS are: Subspace, Lanczos, PowerDynamics, ReducedHolder, Unsymmetic, etc[5]. We choose Lanczos in this article, in which we use eigenvector to realize iterative algorithm. The modes of vibration in the first five orders were obtained through calculation, which are as follows:

(1) The frequency of the crankshaft's first order is 1319.2HZ, and the change of the vibration mode is shown Fig. 6: its main performance is roughly along radial elastic vibration around 2 endpoints.

(2) The frequency of the crankshaft's second order is 1705.44 HZ, and the change of the vibration mode is shown Fig. 7: its main performance is slight elastic vibration along direction y around 2 endpoints.

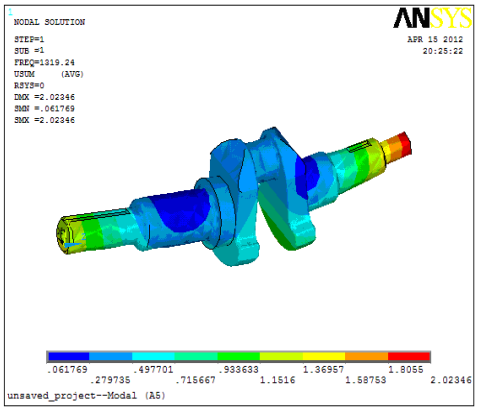

Fig. 6 The modal of the crankshaft's first order

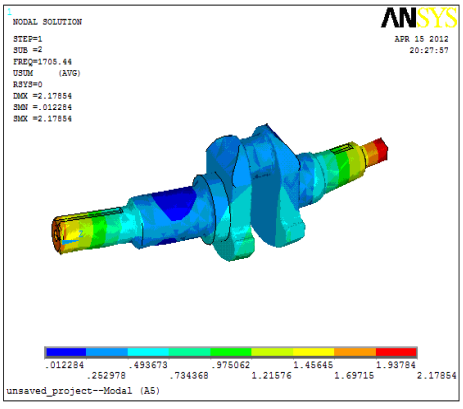

Fig. 7 The modal of the crankshaft's second order

(3) The frequency of the crankshaft's third order is 2742.04HZ, and the change of the vibration mode is shown Fig. 8: its main performance is roughly torsion around spindle direction y.

(4) The frequency of the crankshaft's fourth order is 3518.73 HZ, and the change of the vibration mode is shown Fig. 9: its main performance is that the bottom of main axle neck keeps still while wavelike vibration happens to other parts along direction y.

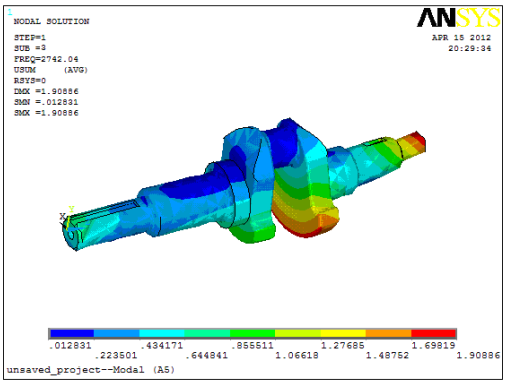

Fig. 8 The modal of the crankshaft's third order

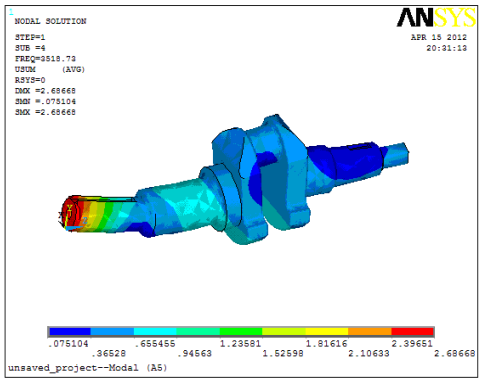

Fig. 9 The modal of the crankshaft's fourth order

(5) The frequency of the crankshaft's fifth order is 4826.53HZ, and the change of the vibration mode is shown Fig. 10: its main performance is wholely wavelike vibration along direction x.

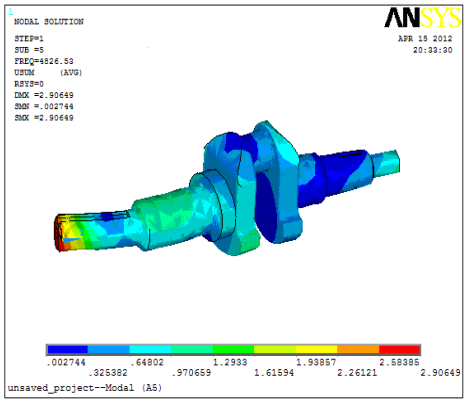

Fig. 10 The modal of the crankshaft's fifth order

Analysis on kinematics of the flexible body in the crankshaft system

After the mesh generation of modals in ANSYS, through choosing spots on the boundary, it will export CFL which can be imported into ADAMS/Flex in order to create the mixed (rigid and flexible) kinematics modals.

After the simulation, we can obtain the stress of the kinematics pair between the crankshaft flexible body and the connecting rod, and compare with the stress of the crankshaft when the rigid body is loading. The stress of the hinge in the flexible body crankshaft condition is shown as Fig. 11.

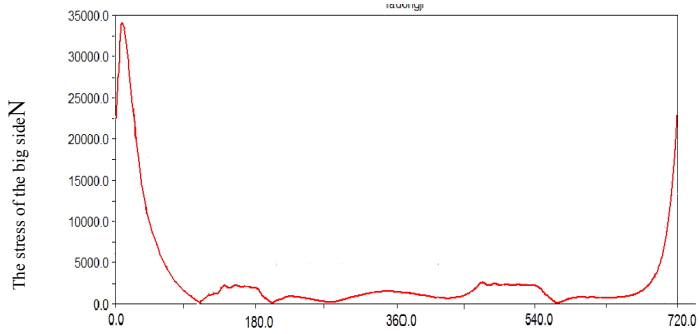

Fig. 11 The stress of the hinge in the flexible body crankshaft condition

Through comparing and analyzing it with the rigid one, we can know that when the crankshaft is loading as the flexible body, its stress curve doesn't change so much. However, the peak value declines, so it reveals that the replacement will have some influence on the kinematics features of the whole crankshaft system.

Conclusion

By applying the seamless data interface between SolidWorks and ADAMS, the model of the internal combustion compressor was imported. The internal combustion compressor virtual prototype model was established, the kinematics and dynamics analysis were completed, and the dynamic load on crankshaft was given. After we use finite element analysis software ANSYS, the modal analysis of crankshaft were accomplished, the modes of vibration and response frequency in the first five orders were obtained. After calculating and comparing the hinge stress of the rigid body and the flexible body, we know that peak values of them are 35000N and 33000N, which lays the foundation of following reliability study and optimal design.

Keywords: mechanical expanding, welding pipe, finite element method, deformation characteristic

Abstract. Mechanical expanding is widely used in production of large diameter submerged-arc welding pipes. To improve welded pipe quality, it is necessary to investigated effects of geometry parameters on mechanical expanding forming process. So, effects of geometry parameters on mechanical expanding is obtained using finite element method..

Taking the expanding of X80 steel Φ1219mm×22mm×12000mm welding pipe for instance, the mechanical expanding forming process is simulated by finite element (FE) code ABAQUS. In this paper, the simulation data is validated by experiments and a comparison showed a good agreement with experiments results. The effects of geometry parameters on mechanical expanding are discussed. Thus, the result of research provides a basis to improve welded pipe quality.

Introduction

Mechanical expanding technology is widely used in large-diameter straight seam submerged arc weld (LSAW) pipes. In the forming process. Expansion is accomplished by an internal mandrel. The mandrel consists of 8, 10, or 12 segments. Segments are chosen so that their radii are near that of the inside of the pipe. The mandrel is hydraulically actuated, and in one step it typically expands a length of one half to one diameter (depending on the wall thickness). Each step maintains some overlap between the expanded and unexpanded pipe sections. Expansion improves the roundness of the pipe and brings it to its desired final size. To achieve low ovality, the pipe is typically expanded 0.8 – 1.3% from its diameter.

Affected by the previous forming process, there have been ellipse and pouting in welded pipe before expanding. To evaluate ellipse and pouting, this paper proposed two indicators: ovality T and pouting f.

$$T = \frac{D_{\max} - D_{\min}}{D_{nor}} \times 100\%$$

Where $D_{\max}$ —Maximum diameter/mm,

$D_{\min}$ —Minimum diameter/mm,

D_{nor} —Nominal diameter/mm.

Pouting f is defined as maximum radial deviation with theory of circular arc within 75mm scope of welds.

The mechanical expanding is a very complicated procedure since it is usually influenced by many factors. It is difficult to control the forming quality. Thus there have been many researches about mechanical expanding. In early stage, the research on mechanical expanding is depended on experiments[1, 2]. Although the results are an useful to guide production， they are lack of universality and difficult to promote in further. The analytical method of analysis is based upon simplifications of

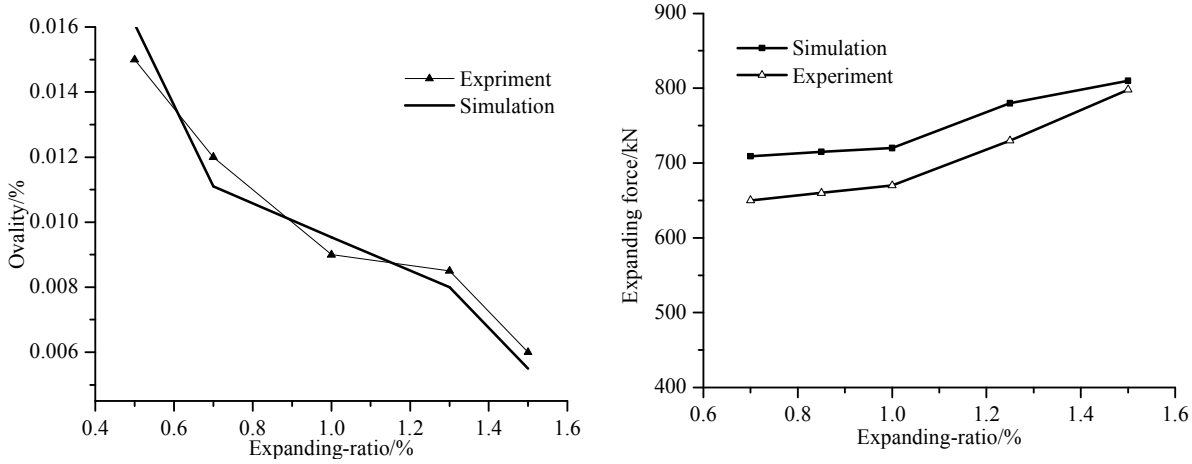
process and material behavior. The analytical method of analysis generally has to be formulated with significant simplifications of forming conditions which can considerably affect the accuracy of the results [3- 5]. With the advent of computation technology, most of research is depend on finite element methods. So many scholars analyzed the effect of mechanical expanding to the pipe quality using the finite element method respectively, such as G. Palumbo[6], M. D. Herynk[7], Guo[8], Wu[9], Liu[10], and Cai[11]. But they do not consider about the effect of front process.

The aim of this paper is to show that effects of geometry parameters of welded pipe on mechanical expanding. This research is based on commercial FEA code ABAQUS. By using FEA, the shape of welded pipe is obtained. The results of research provide a basis to guide mechanical expanding production.

Finite element analysis

FEA of expanding was carried out using the commercial code Abaqus/Standard. A 2D finite element model is established for the plane strain condition. In simulation, the mandrels are defined as analytical rigid which would not need requiring elements is divided for simple geometric shapes. In analysis process of forming, one of the most important factors is the calculation of springback. So, considering both efficiency and accuracy in the deformation process, the 2mm four-node plane strain reduced integration quadrilateral element CPE4R which had high efficiency and accuracy for calculating springback is set in deformable sheet. The sheet metal is defined as elastic–plastic. Also, simple limited slid master-slave contact algorithm in which the mould was master surface, the sheet was slave surface is selected, and the penalty function model of friction coefficient 0.1 is established to judge the contacting state. The objectives of this analysis are to investigate the deformation characteristic in expanding.

Validation experiments Experiments were carried out using a hydraulic press as a platform to develop the expanding process. An experimental mould system, where the welded pipe is set around it, was placed on the horizontal table of the hydraulic press. Inclined plane and segmented design provide expanding during the movement of the internal mandrel. The material used for the investigations corresponds to Q235A. The size of the welded pipe corresponds to Φ333mm×4.75.Displacement of segments are realized by controlling displacement of internal mandrel. Several experiments were carried out and the resulting welded pipe profiles were measured. A validation of the FE model has been carried out through the comparison between ovality and expanding force calculated through FE simulation and the experimentally measured in Fig. 1-Fig. 2. In summary about the comparison between numerical and experimental results, a proper correlation could be observed. The results are demonstrated that FEA could obtain accurately the forming process.



(a) Ovality (b) Expanding force

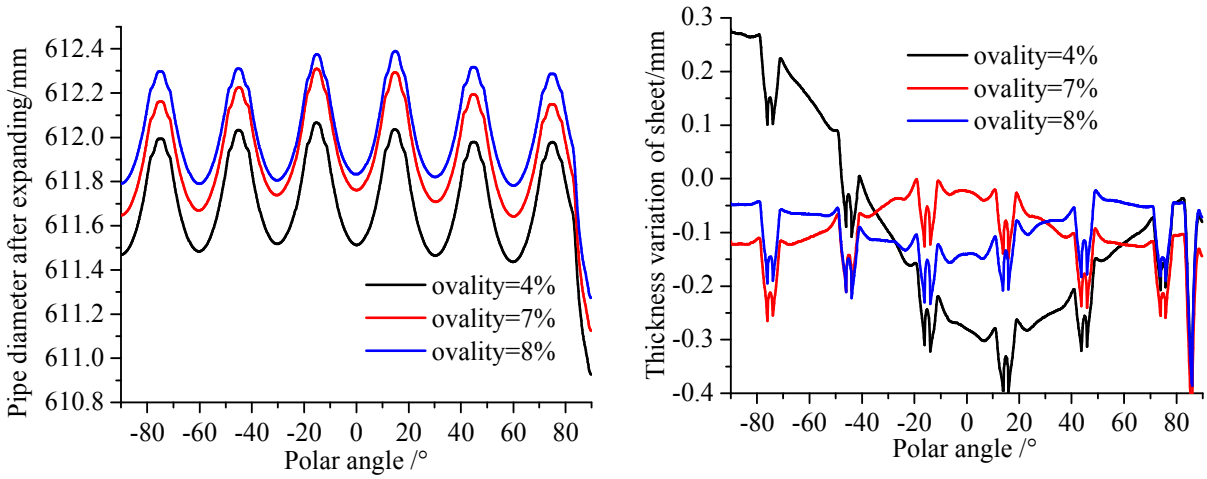
Figure 1 Comparison between simulation and production

Results and discussion

A welding pipe of Φ1219mm×22 mm×12000mm was taken as research objective. The material X80 grade pipeline steel, where is E = 245 Gpa, σ_s = 569.5 Mpa. A 2D plane model of the pipe for the expanding process was constructed from the geometry obtained from production after welding. The deformed weld pipe was obtained from the FE analysis and the effects of geometry parameters of welded pipe on mechanical expanding were investigated.

The pipe diameter and thickness of sheet for different ovality after expanding predicted from the FE analyses are shown in Figs. 3 respectively. With the changing of polar angle, the pipe diameter and thickness of sheet is cycle fluctuation change. It is indicated that the pipe diameter and thickness of sheet mainly affected with segments of mandrel. From Fig. 3a, it is observed that the larger the ovality, the greater need of expanding rate, which caused welded pipe diameter increased obviously. From Fig. 3b, it is shown that the wave shape appeared suspended parts between two segments, The thickness of sheet reduced overall, and it has the thinnest in the edge area of segments. It is demonstrated that the plastic deformation mainly occurred in suspended parts between two segments.

At the same time, small plastic deformation with small ovality (such as ovality =4%) lead to nonuniformity of thickness.



(a) Pipe diameter after expanding (b) Thickness of sheet

Figure 3 Pipe diameter and thickness of sheet for different ovality after expanding

In Fig. 3c, section geometry of welded pipe regularly changed and it is obviously observed that there is pouting in weld pipe. The results indicated that the pipe diameter increases with increase of pouting.

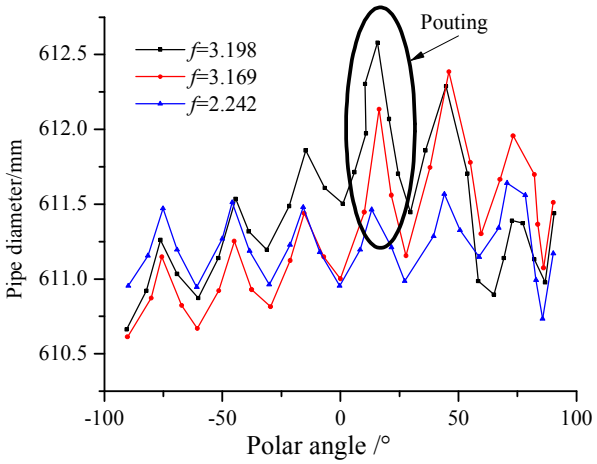


Figure 8 Pipe diameter for different pouting

In general, it can be seen that the pipe diameter and thickness of sheet regularly changed with segments of mandrel in whole pipe. Thus, the segments number of mandrel is the main factor

affecting the pipe diameter and thickness of sheet. So less segments number of mandrel is used, which can improve the residual stress distribution and quality of welded pipe.

Conclusion

The present work has been to analysis effects of geometry parameters of welded pipe on mechanical expanding for improving quality of welded pipe. In this paper, The mechanical expanding forming process is simulated using the finite element code ABAQUS. In this work, the following conclusions can be drawn:

(1)In mechanical expanding forming process, the pipe diameter, thickness of sheet and pouting mainly affected with segments of mandrel.

(2) Less segments number of mandrel will benefit to improve the residual stress distribution and quality of welded pipe.

Experimental study on emission characteristics of methanol gasoline in the GW491QE engine

Zexu WU, Yinshan WANG

School of Automotive and Transportation, Tianjin University of Technology and Education, Tianjin, China, 300222

Email:wuzexu2007@126.com

Keywords: Methanol gasoline; Experimental study; Engine emission Performance

Abstract. M10, M15, M50 methanol gasoline and 93 # gasoline engine emission performance test were researched on the engine GW491QE. Always stayed in 60 N·m torque and rotational speed increased from 1000 r/min to 3000 r/min, recorded the corresponding data, performance, emission performance curve was drawn respectively, comparison and analysis, the influencing factors of GW491QE engine emission performance were discussed, practical application on engine GW491QE suitable blending ratio of methanol gasoline was chosen. The experimental results show that: three kinds of methanol gasoline of HC emissions is lower, M15 improvement is most obvious; NOx emissions are reduced. GW491QE engine emission performance is taken into account, M15 methanol gasoline is a good proportion of the actual application.

Introduction

Methanol (CH_3OH) is a kind of similar to gasoline with the physical and chemical properties of the fuel, the molecular structure of simple, high octane number and oxygen percentage, synthesis process is simple, is regarded as one of the most promising future oil alternative fuel[1] . However, there are some problems in the methanol fuel engine in practical application, after methanol combustion such as formaldehyde, acetaldehyde produces harmful emissions[2] , and methanol cold start performance is poorer, low calorific value, burning ability is poor. And the methanol gasoline can improve the situation in some degree.

Methanol gasoline is usually marked by the content of methanol fuel mix, such as M20 mixed fuel is marking the volume fraction of 20% methanol and 80% of gasoline. Analysis of this paper mainly introduces and discusses three kinds of proportion of methanol gasoline (M10, M15 and M50) and 93 # gasoline(M0) emission performance experiment on engine GW491QE, choose to practical application in engine GW491QE suitable blending ratio of methanol gasoline.

Test fuel, equipment and methods

Test with fuel, the physical and chemical characteristics of methanol and 93 # gasoline are shown in table 1.

Table 1 Comparison of several physical and chemical properties of methanol and gasoline

Performance indicators	methanol	gasoline
Density (20 ° C) /(g·L^{-1})	810	700 ~ 800
Gasification hot /(MJ·kg^{-1})	1100	350
Theoretical air-fuel ratio	6.45	14.7
Limits on fire /(%)	6.7 ~ 36.5	1.4 ~ 7.6
Low calorific value /(MJ·kg^{-1})	19.7	42.5

This experiment with GW491QE gasoline engine, which is produced in the Great Wall internal combustion engine manufacturing co., LTD, the structure form for four-cylinder inline, four stroke, vertical, and water-cooled. Main performance parameters: 2.237 L displacement, cylinder diameter of 91 mm, compression ratio of 8.8:1, the maximum output power of 78 kW, rated power speed is 4800 $r \cdot min^{-1}$,the maximum torque of 190 N·m, minimum fuel consumption rate 270 $g \cdot (kW \cdot h)^{-1}$.

The test equipment used for the test:engine FST2E CNC system;eddy current dynamometer CW160; the engine exhaust emission analyzer AVL - 4000; the engine coolant temperature device.

Test condition requirements: the engine keep under 60 N·m torque , experiment is conducted to study the characteristics of velocity; The other engine performance parameters are no longer adjust in the test. Select five sites speed measurement to do emission test[3], accurately record test data. The four types of fuel are test three times, finally the data take 3 times of the average data, data charts are drawn.

Test results and analysis

HC emissions

On GW491QE engines M10, M15, M50 methanol gasoline and 93 # gasoline(M0) were burned ,HC emissions curve was drawn, as shown in figure 1.

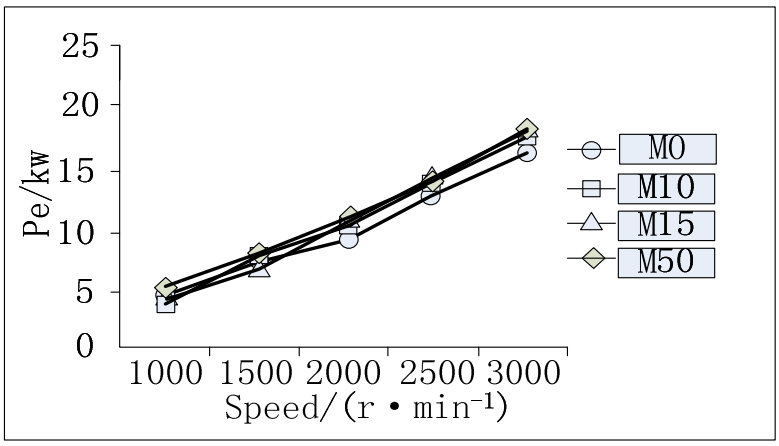

Fig.1 When 60 N • m 93 # gasoline and M10, M15, M50 HC emissions comparison

According to the shown in figure 1, 3 kinds of proportion of methanol gasoline HC emissions are less than 93 # gasoline(M0), and fell more obvious. With the increase of rotational speed, four kinds of basic same HC emissions change trend of fuel; In the three kinds of methanol gasoline, with the increase of methanol proportion, gradually reduce the HC emissions. In addition, in terms of degree of curve, while burning M15 drops fastest HC emissions curve, namely the M15 HC is most obvious.

Analysis reasons: (1) because methanol (CH_3OH) is only a carbon atom, burning with autonomous oxygen effect, which can speed up the combustion and promote complete combustion. After adding a certain proportion of methanol gasoline combustion, flame propagation speed and reduces the surface quenching effect, thus reduce the HC emissions [7]. (2) methanol can dissolve obstruction of HC emissions of carbon deposition sediments, also reduces the HC emissions.

NOx emissions

On GW491QE engines M10, M15, M50 methanol gasoline and 93 # gasoline were burned, NO*x* emissions curve was drawn, as shown in figure 2.

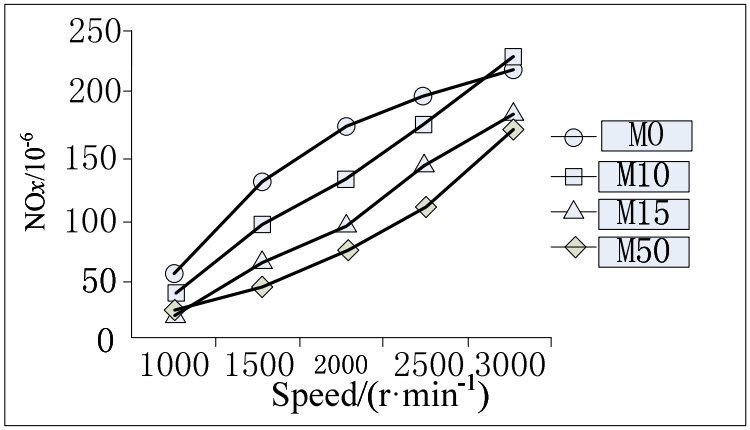

Fig. 2 The When 60 N, m 93 # gasoline and M10, M15, M50 NO*x* emissions comparison

According to figure 2, 3 kinds of methanol gasoline NO*x* emissions is less than 93 # gasoline on the whole. Analysis of reasons: NO*x* emissions increase and decrease, which depend on the temperature and concentration of oxygen in cylinder, on the one hand because of methanol as oxygen fuel and the combustion speed, promote the formation of NO*x* oxygen-rich conditions. But on the other hand, low calorific values of methanol, latent heat of vaporization is 3 times of gasoline , reduces the maximum combustion temperature and exhaust temperature, to a certain extent inhibit the formation of NO*x*, which make the methanol gasoline NO*x* emissions increase with the increase of the content of methanol.

Summary

Emissions performance was tested on the GW491QE engine , got the following conclusion:

(1) The M10, M15, M50 of HC emissions decreased obviously, and M15 improved the most obvious.

(2) Methanol gasoline NO*x* emissions were less than 93 # gasoline on the whole.

(3) GW491QE engine emission performance is taken into account, M15 methanol gasoline is a good proportion of the actual application.

Keywords: Condenser; Strength and Stiffness; Finite element analysis

Abstract: Using finite element method to simulate complex operations of the whole condenser under extreme water pressure, this paper aims at predicting the strength and stiffness of the condenser components under extreme pressure conditions. The results show that the max stress of the components is less than the allowable stress, and the max deformation is also within the permitted scope. The results will provide necessary reference for the further optimization design of condenser.

1 Introduction

The application and development of the once-through boilers and nuclear power devices in the electricity industry lead to higher requirements for condenser performance [1].To analyze the stiffness and strength of large-scale condenser by using economic and efficient methods, it is particularly important to instruct condenser optimization design and to study the mechanical operation properties of the condenser components. So far, some academics have done some important work on condenser. For example, Lanxin Zhou and Mingzhi Zhang have achieved a comprehensive assessment of condenser running performance [2]. Shuguang Gong and Guilan Xie have completed optimization design of the ultra-specification tube sheets system [3].

A typical structure of condenser from a company is applied in this paper. Considering the contact problems of condenser tube bundles with the support plates and steel beams, the contact problems of bolts and the effect of the bolt preloads on structure strength, we conduct a numerical simulation of the whole condenser under extreme water pressure. At the same time, an analysis of stiffness and strength of condenser components is made in this study and it will provide some useful theoretical reference for the optimization design of condenser.

2 Finite element analysis model of condenser

2.1 The three-dimensional model and finite element mesh of condenser

Since the number of tubes is too large, we must simplify it. Tubes are established under the rules of constant volume and equivalent elastic modulus. At the same time, the perforated area of the tube sheets is established solid boards under the rules of considering the rigid weakening coefficient [4].The whole three-dimensional condenser model is shown in Fig.1. As the condenser is a symmetrical model, half of the model is selected as the analysis object. The number of nodes is 1,720,530, and of elements are 465,461. Mesh results are shown in Fig. 2.

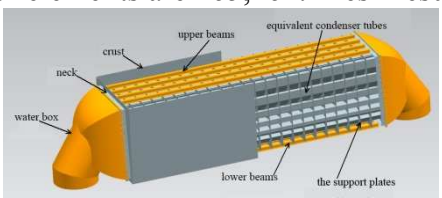

Fig.1 Model of condenser

Fig.2 Condenser grid model

2.2 Determination of the calculation conditions and boundary conditions

As for calculation condition, the max work pressure of condenser is less than 0.4MPa, so 0.4MPa is the max required hydrostatic test pressure in this study. The effects of hydrostatic pressure are also under consideration, so the pressure of unperforated area is P_1=1E-5×z+0.4, and perforated

area is P_2=(1E-5×z+0.4)×0.6575, where z-axis is the height direction of the tube sheet and the positive z-axis pointing to the bottom of the tube sheet.

In terms of loads applied, the loads include gravity, water pressure and bolt preloads. The specification of bolt in the study is 8.8 class, M27. The specific parameters are shown in Tab.1.

And for constraints imposed, the condenser is fixed by anchor bolt (M28) on the bearing through the lower beams and the constraint surfaces are shown in Fig.3.

Tab.1 Bolt preloads of M27

Bolt	M27
Preload（kN）	190.9

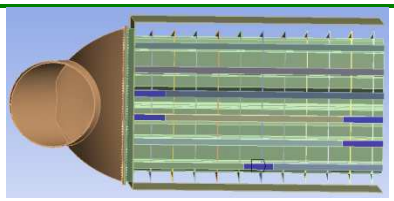

Fig 3 Constraint surfaces of condenser

The contact problems of the condenser relates to water box, tube sheets, neck, rectangular plates, the support plates, condensing tube bundles and the steel beams. Water box bolts the flange of tube sheets via plate. Since the contact area between water box, tube sheets flange and the neck is basically unchanged and contact surfaces had no relative sliding and separation either, the contact type is set bonded. The connect type of perforated area and the tubes equivalent entity is expanding and welding. With contact surfaces no relative sliding, the contact type is set bonded. Similarly, air cooling zone of the tube sheets and air-cooled equivalent entity is also set bonded.

2.3 Mechanical properties of the tube sheets materials and condensing tubes

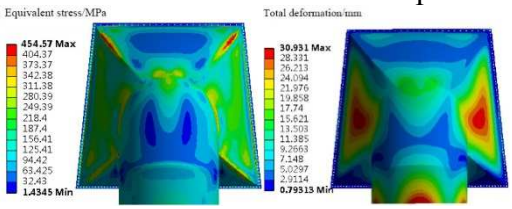
As the tube sheet is a composite of different materials, we need to calculate its equivalent results. These equivalent results of material mechanical properties in this paper are calculated according to relevant standards HEI. The specific calculation method is in bibliography [5,6] The results are shown in Tab.2.

Table2 Equivalent Mechanical performance parameters of tube sheets and tubes

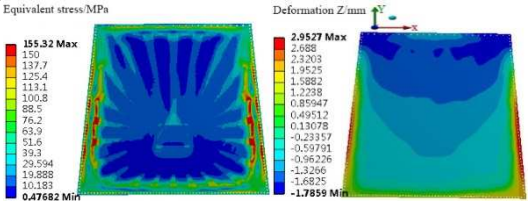
machinery performance	equivalent elastic modulus[MPa]	allowable stress S_m[MPa]
perforated area	41147.12	50.23
unperforated area	189481.43	173
equivalent condensing tubes	5080	132.7

3 Results and analysis

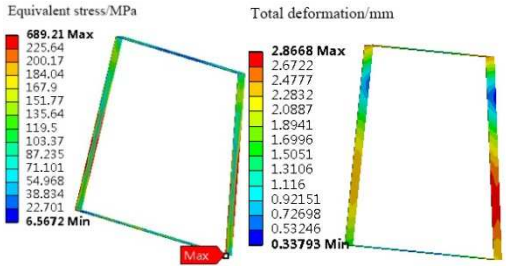
Stress and deformation are two main factors in finite element analysis.After calculation, the results of stress and deformation of condenser components are shown in Figure a~g, and the maximum equivalent stress and maximum deformation of components are shown in Tab. 3.



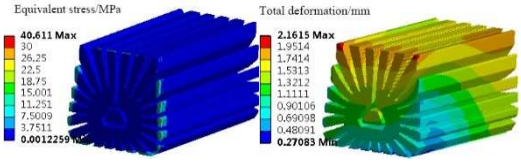
(a)Total deformation and equivalent stress of water box



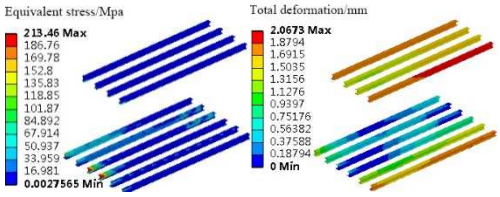
(b)Z axis deformation and equivalent stress of tube sheet



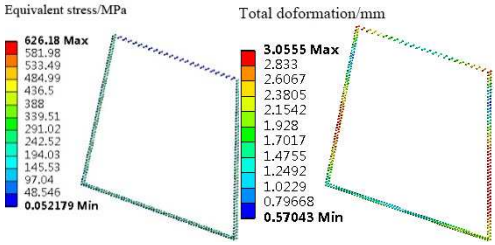
(c)Equivalent stress and total deformation of neck



(d) Equivalent stress and total deformation of condensing tubes equivalent entity



(e)Equivalent stress and total deformation of beams



(f)Equivalent stress and total deformation of bolts

Tab.3 Results of max von-misers stress and deformation of components

condenser components	max equivalent stress[MPa]	max equivalent deformation[mm]	yield strength/ allowable stress[MPa]
water box	454.73	30.635	460
neck	225.64	2.8668	285
bolt	626.18	3.0555	735
support plate	134.45	±1.78	285
H steel beams	213.46	2.067	370
perforated area	39.3	-1.7859	50.23
unperforated area	155.81	+1.9525	173
tubes equivalent entity	40.611	2.1615	132.7

As can be seen from Tab.3, the tube sheet max stress is less than allowable stress; the max stress of components is less than yield strength, so the strength requirements are met, plastic deformation of components does not occur.

Fig. a shows that the max stress of water box appears on the seal of four surfaces consist water box, the protruding edges in the seal lead to local stress concentration. The max deformation appears at the center of both sides of water box, reaching 30.6mm.The height of water box is 4,460mm and the max percentage of elongation is 30.6/4460=0.69%, but it is too small to affect the operation of the water box. Fig. b shows that max stress in perforated area concentrated on the outer region of the tube and the unperforated area concentrated on the edge of tube sheets. The support reinforcement role of the condensing tube bundles leading to the stress in perforated area is less than unperforated area, while unperforated area had larger stress for the greater torque effect transmitted from water box. However, the strength requirements are met. Deformation of the tube sheets along the z-axis is small which meets the project requirements. Fig. c shows that above 95% stress of the neck is far less than its yield strength. The two corners of the neck bottom has local

stress concentration phenomenon, which is related to the corner curvature of the neck. The deformation of the neck is small, so it is safe for them to be judged from the function. Fig. d shows that equivalent stress of condensing tubes is generally lower, because it is not the force components. In fig. e, the beams stress is generally less than 39.7MPa; the max deformation occurs on the two upper outermost beams: it reaches 2.1mm. Fig. f shows that the stress in upper bolts is smaller with its value below 56.97MPa, But the stress in left and right side and the lower portion of the bolt is larger, and the max stress area occurs on the left and right sides of the nuts, with the value of 626.18MPa, bolt safety factor of $s_2=[\sigma_b]/\sigma=835/626.18=1.33$. As for the connection of control bolt preloads, the safety factor is within the requirements: from 1.2 to 1.5[7]. Max deformation occurs in the lower region of both sides of the bolts with the value of 3.06mm, the nut length of 180mm, and the percentage of elongation of 3.06/180=1.69%, which are too small to affect the seal.

4 Conclusions

(1)The method of finite element numerical simulation is used to calculate the equivalence stress and components deformation of the condenser, as well as the max deformation and the max equivalence stress of components. The results show that the stiffness and strength of the condenser exactly meet the requirements.

(2)The results show that at the seal of different surfaces, local stress concentration exists in the water box and the bottom corner of the neck, which leads to the stress of local points suddenly increasing greatly. Therefore, transferring the corners of tube sheets rounded design and the water box corners into circle transition leads to the curvature in the seal of surfaces changes uniformly, thereby improving the stress concentration. This idea can be applied in neck corner design.

(3)The results of stress distribution of the tube sheets, bolts and neck come to a conclusion that greater stress area occurs below the center of both sides of the tube sheets flanges, and the stress here can be reduced by appropriately increasing the effective local supports.

Keywords: modeling, optimization, fluid kinematics, fluid path-lines, fluid turbulence intensity

Abstract. The HE (heat exchanger) of automotive exhaust TEG (thermoelectric generator) plays a vital role in converting thermal energy into electrical energy, therefore achieves the goal of energy conservation and emission reduction. A new regular-octagon HE is modeled and simulated in FLUENT to obtain the velocity path-lines of fluid. Through simulation results, the velocity path-line is tracked and analyzed, in order to evaluate the fluid resistance and fluid turbulence intensity. By using control variable method, a variety of HE models with different structural parameters are modeled and simulated, to optimize the structure of HE. Eventually, it is intended to design a HE with proper fluid resistance and remarkable turbulence intensity.

Introduction

Recently, it is a hot theme to do research on automotive exhaust TEG, for the sake of the growing shortage of resources and energy crisis [1]. The HE is a one of the key component in TEG, which can efficiently converts thermal energy into electrical energy [2]. Moreover, its internal structure plays an important role in the thermal performance of HE. And a relatively optimal thermal performance can be achieved by designing different internal guiding fins and setting different structural parameters of these guiding fins, and analyzing the velocity of fluid path-line. This paper mainly focused on the fluid kinematics analysis. By analyzing the shape of the fluid path-line and the velocity magnitude, a relatively optimal HE with proper fluid resistance and remarkable turbulence intensity is obtained.

Based on this idea, a new HE, whose middle structure is regular-octagon, is designed to explore its structure to the fluid kinematical characteristics. What's more, both the front part and the extreme part of this new HE are wedge cavity structures. The three-dimensional structure is shown in Fig.1.

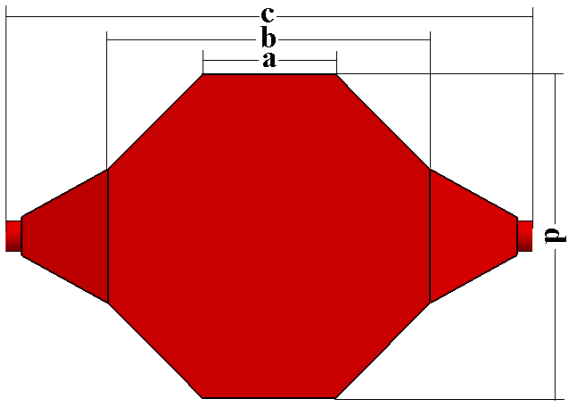

Fig.1 The three-dimensional structure of HE

As shown in Fig.1, the structural parameters are as follows: a is170mm, b is 420mm, c is 670mm, d is 420mm. In addition, both the inlet diameter and outlet diameter is 40mm, and its thickness is 4mm, and its inner cavity height is 14mm.

Modeling and Simulation of the HE

Modeling of Three-dimensional Models. At first, only half part of each HE is modeled for the sake of their axis-symmetry property on structure [3]. There are three kinds of HE models, all of their external structure is the same as the three-dimensional structure of HE shown in Fig.1. Meanwhile, inside the HE, there are a certain number of guiding fins installed on both sides of its interface. The guiding fins respectively are "fish-bone" (named model-1, shown in Fig.2 (a)), "annular" (named model-2, shown in Fig.2 (b)) and "labyrinth"(named model-3, shown in Fig.2 (c)). The thickness of the guiding fins is 4mm, and the height of those is 14mm.

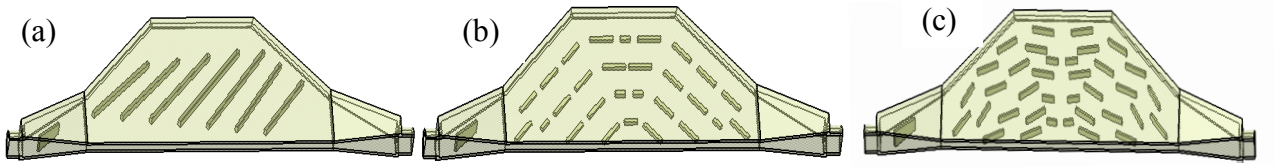

Fig.2 Three-dimensional models of HEs of model-1 (a) , model-2 (b) and model-3 (c)

Theoretical Basis of Fluid Kinematics. Basically, there are three condition equations applied in the fluid kinematics to calculate varieties of fluid kinematical problems. Which are three dimensional continuous equation, momentum equation and energy conservation equation [3, 4].

The three dimensional continuous equation is shown as below.

$$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0$$

In the equation, u v w are the velocity components on x, y and z direction.

The momentum equation is shown as below.

$$\begin{cases}\rho\left(u\dfrac{\partial u}{\partial x}+v\dfrac{\partial u}{\partial y}+w\dfrac{\partial u}{\partial z}\right)=-\dfrac{\partial p}{\partial x}+\mu\left(\dfrac{\partial^2 u}{\partial x^2}+\dfrac{\partial^2 u}{\partial y^2}+\dfrac{\partial^2 u}{\partial z^2}\right)\\ \rho\left(v\dfrac{\partial v}{\partial x}+u\dfrac{\partial v}{\partial y}+w\dfrac{\partial v}{\partial z}\right)=-\dfrac{\partial p}{\partial y}+\mu\left(\dfrac{\partial^2 v}{\partial x^2}+\dfrac{\partial^2 v}{\partial y^2}+\dfrac{\partial^2 v}{\partial z^2}\right)\\ \rho\left(u\dfrac{\partial w}{\partial x}+v\dfrac{\partial w}{\partial y}+w\dfrac{\partial w}{\partial z}\right)=-\dfrac{\partial p}{\partial z}+\mu\left(\dfrac{\partial^2 w}{\partial x^2}+\dfrac{\partial^2 w}{\partial y^2}+\dfrac{\partial^2 w}{\partial z^2}\right)\end{cases}$$

In the equation, u , v , w are the velocity components on x, y and z direction, ρ is the fluid density , μ is the dynamic viscosity coefficient of the fluid.

The energy conservation equation is shown as below.

$$\rho c_p\left(u\frac{\partial T}{\partial x}+v\frac{\partial T}{\partial y}+w\frac{\partial T}{\partial z}\right)=\lambda\left(\frac{\partial^2 T}{\partial x^2}+\frac{\partial^2 T}{\partial y^2}+\frac{\partial^2 T}{\partial z^2}\right)$$

In order to make clear the condition of fluid, some fluid kinematical parameters should be given or calculated, such as Reynolds number (Re) and turbulence intensity (I).

The Reynolds number (Re) can be calculated out through the equation as below.

$$\mathrm{Re}=\frac{\rho u d}{\mu}$$

In the equation, Re is the Reynolds number, ρ is the density of fluid, u is the average speed of fluid, d is the fluid diameter, μ is the dynamic viscosity coefficient of the fluid.

The turbulence intensity (I) can be calculated out through the equation as below.

$$I=0.16\,\mathrm{Re}^{-}\cdot$$

In the equation, Re is the Reynolds number, I is the turbulence intensity.

Boundary Condition Parameters Setting. Based on bench test data, the inlet velocity is 21 m/s, the inlet temperature is 340℃, the exhaust gas density is 0.6 kg/m³, and the dynamic viscosity coefficient is 2.96×105 Pa·s. In this condition, the exhaust gas can be regarded as incompressible air [4]. What's more, the HE is made of brass. In order to get the exact and precise result, heat conduction and heat convection are considered in the FLUENT simulation.

Based on the given parameters, Re is calculated to be 14890. For Re is a low Reynolds number, according to previous study, Wilcox $-\omega$ model is best suitable for the simulation of exhaust gas. Thus the standard $-\omega$ equation is taken to calculate the fluid mechanics [3, 4]. The boundary condition is set as velocity inlet and pressure outlet [5]. The boundary condition parameters are: inlet velocity 21 m/s, inlet temperature340℃, inlet turbulence intensity 0.05,outlet gauge pressure 0 bar, outlet turbulence intensity 0.03, inlet and outlet hydraulic diameter 40mm, convection heat transfer coefficient is 21 W/(㎡·K).

Discussion

Velocity Path-lines of Exhaust Gas with Different Guiding Fins. Taking model-1, model-2 and model-3 in to the FLUENT simulation, the velocity path-lines are shown in Fig.3. Fig.3 (a) is the velocity path-lines of model-1, Fig.3 (b) is the velocity path-lines of model-2, and Fig.3(c) is the velocity path-lines of model-3.

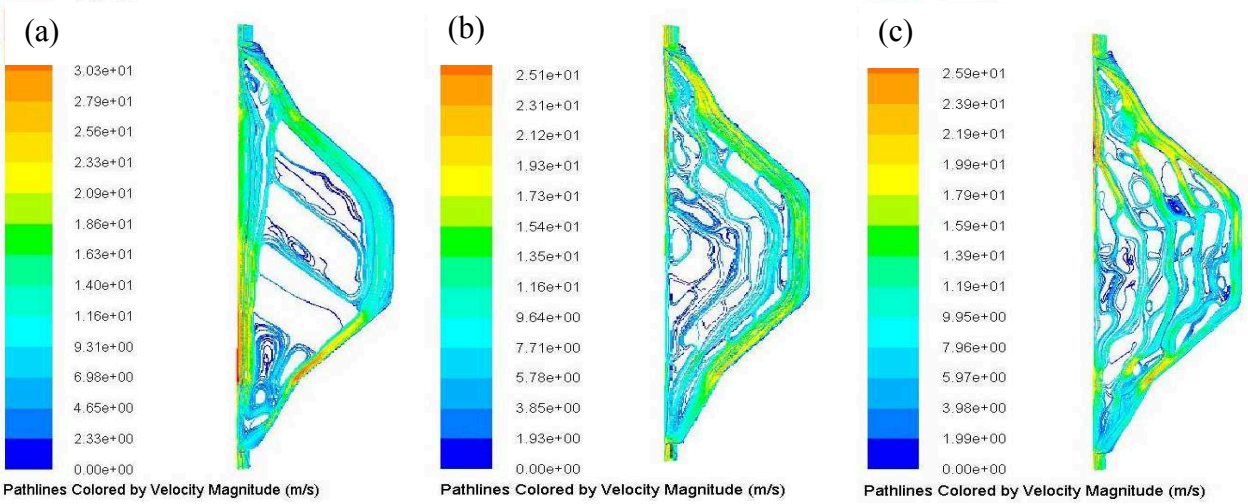

Fig.3 Velocity path-lines of exhaust gas of model-1 (a) , model-2 (b) and model-3 (c)

From the velocity path-lines simulation results, it is apparently that model-3's fluid distribution is the best among the three models. Model-1, with "fish-bone" guiding fins, contains too many zones where the fluid can't pass through directly. And its velocity ranges from 0 to 32.6m/s, the velocity difference is so huge that exhaust gas can't flow uniformly inside the HE.

Taking model-2 and model-3 into comparison, the fluid velocity difference of these two models are approximately the same, while model-3's average velocity is about 5m/s higher. Moreover, there are more turbulence flows generating inside model-3, which can enhance the heat convection.

Through the comparison, the conclusion is that, the HE with "labyrinth" guiding fins can obtain the relatively optimal fluid velocity magnitude and relatively optimal turbulence intensity of fluid.

Velocity Path-lines of Exhaust Gas with Different Thickness of "Labyrinth" Guiding Fins. Based on the previous simulation, the HE with "labyrinth" guiding fins can obtain relatively optimal fluid kinematical performance. Therefore, control variable method can be used to explore the problem, which is that how different thickness of guiding fins influences the fluid kinematical performance of exhaust gas. And then mode-4 and model-5 are modeled, in comparison with model-3. The thickness of mode-4 and model-5 respectively are 3mm and 3.5mm. Other parameters are the same with model-3. The simulation results are shown in Fig.4 (a) (velocity path-lines of model-4) and Fig.4 (b) (velocity path-lines of model-5).

Comparing model-3, model-4 and model-5, the optimal model is still model-3, whose average velocity is not too high, whose turbulence intensity is remarkable. The turbulence intensity of model-4 and model-5 is higher than model-3, however, their fluid speed is higher, most of the exhaust gas can't exchange heat energy with HE.

Velocity Path-lines of Exhaust Gas with Different Height of "Labyrinth" Guiding Fins. By using control variable method once again, model-6 and model-7 are modeled, in contrast with

model-3. The height of "labyrinth" guiding fins of model-6 and model-7 respectively are 10mm and 12mm, other parameters are the same with model-3.

Comparing model-3, model-6 and model-7, the optimal model is model-7, which owes the maximum turbulence flow and minimum velocity difference. The reason is that, model-6's fins height is too low, most of the fluid rushes through the HE without exchanging heat with HE. And the turbulence flow of model-3 is fewer than that of model-7. Therefore, the fins' height of model-7 is ideal, which promotes fluid mixes with each other [5]. Thus, the turbulence flow is remarkable.

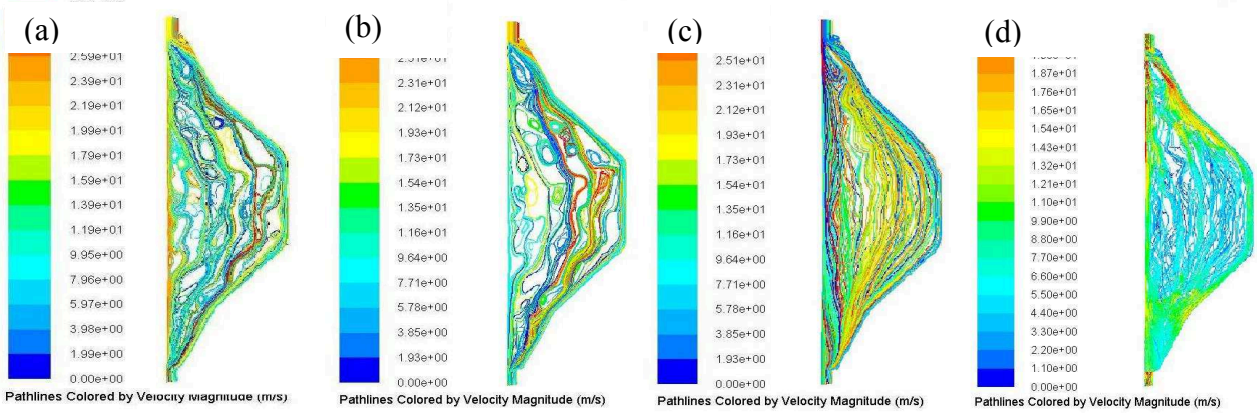

Fig.4 Velocity path-lines of exhaust gas of model-4 (a) , model-5 (b), model-6 (c) and model-7 (d)

Conclusion

This paper mainly concentrates on modeling and optimization of HE in automotive exhaust TEG, so as to obtain an optimal structure and fluid kinematical performance of HE. Therefore, the regular octagon HE is installed with "fish-bone", "annular" and "labyrinth" guiding fins one by one. Then three different models are modeled and simulated in FLUENT. By analyzing velocity magnitude, path-line and turbulence intensity, the HE with "labyrinth" guiding fins is evaluated to be the optimal one. Then the simulation models with different height and thickness of guiding fins are modeled. By using control variable method, a series of simulation results are compared one by one, thus the HE is optimized. Finally, the HE with the shape of regular octagon, with "labyrinth" guiding fins installed in the inner cavity, with the guiding fins height 12mm and thickness 4mm, is the optimal structure.

However, this study is limited to modeling and simulation in FLUENT to optimize the HE based on fluid kinematic, more research should be carried out on exploring the heat transfer mode between exhaust gas and HE. Therefore, in the future study, the research emphasis is focused on the thermal performance of HE.

Keywords: Physical parameters consistency; Refractive effects; Temperature field; Refractive index field

Abstract. We present a novel solution to accurately recover 3D dynamic flame temperature field based on physical parameters consistency. First, a new optical model is proposed to establish the relationship between the flame radiation and the radiance field, this model fully considers refractive effect caused by refraction index changing; Second, high dynamic range (HDR) cameras are used to take flame images, a lookup table is employed calculate temperature from radiance; Third, an algorithm is put forward to reconstruct the flame temperature field. Experimental results on real flame accord with physical facts, which demonstrate that our solution is validate.

Introduction

Since temperature is one of the most essential physical parameters to flame, reconstructing flame temperature field becomes the hotspot, and is significantly valuable to related industries [1].

Temperature field measurements can be divided into two categories, i.e. the intrusive measurements and the non-intrusive ones. Early methods belong to the former category. They are easy to implement, but only applicable to measure single point temperature each time. Non-intrusive measurements can be further divided into two subcategories, i.e. active methods and passive ones. Typical technologies such as acoustic thermometry [2] belong to the former one. The needs of costly facilities limit its application. Passive methods rely on the radiation of the flame. The radiation from flame is captured by sensors and shown through images. Then the temperature field is reconstructed based on those flame images. Shimoda et al [3] introduced a flame temperature field measurement method, namely two-color method, which is only suitable for two dimensional cases. Wu[4] investigated the relationship between flame image brightness and flame temperature. Wang et al[5] made an intensive study of reconstruction of flame temperature field as well as concentration field. Wang and Zhao[6] made important contribution to flame image process and 3D flame temperature field reconstruction. Wang et al[7] takes flame images with high dynamic range cameras and reconstructs the radiance field on camera band for the flame, then obtains the flame temperature field through the lookup table between radiance and temperature.

There exist two drawbacks of the passive methods mentioned above. First, all the methods ignore the refraction of the flame and assume that light rays travel through the flame along straight lines. Since flame is a kind of inhomogeneous medium, it bends the light rays internally. Second, except for the work proposed by Wang et al[7], other works do not take into account the fact that the dynamic range of the flame emission is larger than that of general industrial cameras.

Our approach belongs to the passive methods. In our work, we offer three contributions over the existing state of the art. First, a new model, which takes account refraction caused by refraction index changing, is put forward. Second, lookup table between temperature and radiance is established to effectively reduce the computational complexity. Third, an algorithm that reconstructs the

temperature field based on the consistency between temperature and refractive index is proposed. Experimental results indicate that our improvements are successful.

1. Optical model

Fire is typically defined as an oxygen-fueled chemical decompositioon that releases heat to the environment, and flame is the visible luminous reaction products of fire. When the radiation from flame arrives at the sensor (CCD or CMOS), it is converted into electrical signals by a photoelectric convertor. The electrical signals are then digitized and formed images on the image processor. Before reaching the sensor, radiant energy inevitably undergoes several kinds of attenuation, including reflection, refraction and absorption.

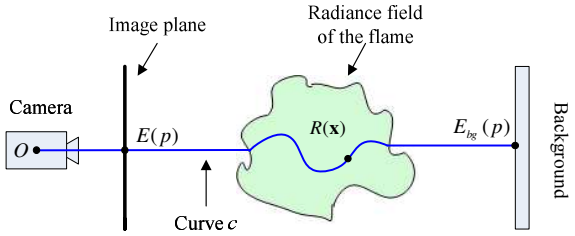

Fig.1 Optical model of flame.

The radiant energy $E(p)$, a pixel p in a flame image received, consists of two parts (as shown in Fig.1): The radiant energy emitted from flame along curve c and background's contribution $E_{bg}(p)$. Curve c is the path, which light rays travel along, before reaching pixel p. The reason why light rays travel through the flame along a curve path lies that, flame is inhomogeneous, the density of fire products varies in different areas of the flame. As a result, light rays are bent inside the flame. Thus, $E(p)$ can be expressed as

$$E(p) = \int_c \alpha(\mathbf{x})\mathbf{R}(\mathbf{x})\tau(\mathbf{x})d\mathbf{x} + E_{bg}(p) \tag{1}$$

Where $\alpha(\mathbf{x})$ is the view factor from $\mathbf{x}$, a point locating on curve c, to pixel p. $\mathbf{R}(\mathbf{x})$ is the radiance field. Here, we make an assumption on the structure of $\mathbf{R}(\mathbf{x})$, we do this by assuming that $\mathbf{R}(\mathbf{x})$ can be represented by a linear combination of base functions $R_i(\mathbf{x})$:

$$\mathbf{R}(\mathbf{x}) = \sum_i a_i R_i(\mathbf{x}) \tag{2}$$

a_i is the corresponding coefficient of $R_i(\mathbf{x})$. The choice of the base functions $R_i(\mathbf{x})$ is essential for the tractability of the model. In order to simply the calculation, we chose the box function as the base functions. $\tau(\mathbf{x})$ denotes the transmissivity of light rays travel along curve c. For simplicity, we assume that the transmissivity is only determined by path length of light rays. Particularly, if curve c is parameterized by t, t_1 is the nearest intersection to the lens between curve c and the flame bound, and $\mathbf{x}$ corresponds to t_2 on curve c, $\tau(\mathbf{x})$ can be calculated by the following formula

$$\tau(\mathbf{x}) = \exp[-\sigma\int_{t_1}^{t_2}\sqrt{1+[c'(t)]^2}\,dt] \tag{3}$$

where σ is a positive medium-dependent constant known as the extinction cross-section, and is assumed to constant throughout the flame. $E_{bg}(p)$ denotes the radiant energy contribution from background. Under certain conditions, e.g. in a completely dark room, $E_{bg}(p)$ can be neglected. If no special instructions, we let $E_{bg}(p)$ equals 0 in this paper.

With the discussion above, the radiant energy that pixel p received can be formulated as

$$E(p) = \sum_i a_i \int_c \tau(\mathbf{x})\alpha(\mathbf{x})R_i(\mathbf{x})d\mathbf{x} \tag{4}$$

Eq.(4) describes a nonlinear system of equations

$$E(\mathbf{p}) = \mathbf{Sa} \tag{5}$$

Where vector $E(\mathbf{p})=[E(p_1),\cdots,E(p_m)]^T$ represents the radiant energy that the flame image received, $\mathbf{a}=[a_1,\cdots,a_n]^T$ denotes the coefficient vector of the basic functions. The coefficient matrix $\mathbf{S}$ has the following form

$$\mathbf{S}=\begin{bmatrix} \int_{c_1}\tau(\mathbf{x})\alpha(\mathbf{x})R_1(\mathbf{x})d\mathbf{x} & \cdots & \int_{c_1}\tau(\mathbf{x})\alpha(\mathbf{x})R_n(\mathbf{x})d\mathbf{x} \\ \vdots & \vdots & \vdots \\ \int_{c_m}\tau(\mathbf{x})\alpha(\mathbf{x})R_1(\mathbf{x})d\mathbf{x} & \cdots & \int_{c_m}\tau(\mathbf{x})\alpha(\mathbf{x})R_n(\mathbf{x})d\mathbf{x} \end{bmatrix} \tag{6}$$

In the coefficient matrix $\mathbf{S}$, $c_i, i=1,\cdots,m$ is completely determined by the refractive index field $\Phi(\mathbf{x})$ of the flame.

Given the radiant energy that the flame image received as well as the refractive index field $\Phi(\mathbf{x})$, the radiance field of the flame can be solved. The radiant energy of the flame image received could be obtained by calibrating the camera response function.

According to [7], the temperature field $\mathbf{T}(\mathbf{x})$ (If no special instructions, temperature refers to Kelvin temperature) can be obtained via the lookup table after given the radiance field $\mathbf{R}(\mathbf{x})$. When no confusion happens, $\mathbf{R}(\mathbf{x})$, $R_i(\mathbf{x})$, $\Phi(\mathbf{x})$ and $\mathbf{T}(\mathbf{x})$ are denoted as $\mathbf{R}$, R_i, Φ and $\mathbf{T}$ respectively for short in the following content of this paper.

2. Temperature field reconstruction

During the flame imaging process, irradiance plays a key role. After experiencing a certain optical system, the irradiance $\hat{E}(p)$ that pixel p receives can be described as[8]

$$\hat{E}(p)=\beta\gamma\zeta^2E(p) \tag{7}$$

where β denotes the optical system's transmittance, and γ demonstrates the sensor's spectral response. The two parameters can be obtained through calibration process. ζ is the ratio of aperture radius to focal length.

The camera response function could be calculated via images taken from the same scene with different exposure times[8].

After calibrating the camera response function, we derive the linear system from Eq.(5) and Eq.(7)

$$\theta\hat{E}(\mathbf{p})=\mathbf{Sa} \tag{8}$$

with $\theta=1/(J_0\beta\lambda\zeta^2)$, $\hat{E}(\mathbf{p})=[\hat{E}(p_1),\cdots,\hat{E}(p_m)]^T$. Note that coefficient matrix $\mathbf{S}$ is completely determined by refractive index field Φ, which must be calculated before solving the linear system (8). In a least squares sense, the solution is

$$\mathbf{a}=\theta\mathbf{S}^+\hat{E}(\mathbf{p}) \tag{9}$$

Here $\mathbf{S}^+$ is the generalized inverse matrix of $\mathbf{S}$. Since coefficient vector of the base functions $\mathbf{a}$ is determined by radiance field $\mathbf{R}$, and $\mathbf{S}^+$ is determined by Φ, Eq.(9) could be rewritten as

$$\mathbf{a}(\mathbf{R})=\theta\mathbf{S}^+(\Phi)\hat{E}(\mathbf{p}) \tag{10}$$

That is to say, solving linear system (19) equals to finding a appropriate combination of radiance and refractive index field $(\hat{\mathbf{R}},\hat{\Phi})$, which satisfies Eq.(10).

Based on Wang's work [7], there is a one-to-one mapping between $\mathbf{T}$ and $\mathbf{R}$. Under the assumption that the air pressure remains unchanged during the burning process, the flame temperature T and the flame density ρ satisfy the following equation according to the ideal gas law

$$\rho=\frac{P\mu}{rT} \tag{11}$$

where μ denotes the molar mass of the flame's products, $r=8.32J/(K\cdot mol)$ is a scalar. According to Gladstone-Dale equation [9], the relationship between ρ and the flame refractive index ϕ is

$$\rho=\frac{\phi-1}{\kappa} \tag{12}$$

Here, κ represents the Gladstone-Dale constant. According to Eq.(11) and Eq.(12), we obtain the mathematical relation between T and ϕ

$$T = h(\phi) = \frac{P\mu\kappa}{r(\phi - 1)} \tag{13}$$

That is to say, there exists a one-to-one mapping $h(\cdot): \Phi \to \mathbf{T}$.

In this paper, we adopt $\Phi_0(\mathbf{x}) = \mathbf{1} \in \mathbf{R}^{m \times n}$ as the initial value of Φ. After calculating the initial coefficient matrix $\mathbf{S}_0$ according to formula (6), we obtain the coefficient vector $\mathbf{a}_0 = [a_1^0, \cdots, a_n^0]^T$ from the following OP

$$\begin{cases} \min \quad \sum_{i=1}^{m} [\mathbf{S}_i^0 \mathbf{a}_0 - \theta \hat{E}(p_i)]^2 + \eta \sum_{j=1}^{n} [\Delta A_0(\mathbf{x}_j)]^2 \\ s.t. \quad \mathbf{a}_0 \geq \mathbf{0} \end{cases} \tag{14}$$

where $\mathbf{S}_i^0$ denotes the *ith* line of $\mathbf{S}_0$. In the objective function, the first term is the data fitting term, it ensures that the solution satisfies Eq.(8-9) in a least squares sense; the second term is the smoothness term. Scalar η is used to weight the smoothness term relative to the data fitting term. $A_0(\mathbf{x}_j) = \sum_{q=1}^{n} a_q^0 R_q(\mathbf{x}_j) = a_j^0$, $\mathbf{x}_j$ denotes the center of the support region of base functions R_j. Laplace operator Δ is employed here, because if $\Delta A_0(\mathbf{x}) = 0$ holds, $A_0(\mathbf{x})$ is harmonic, and harmonic function is smooth enough. The constrain $\mathbf{a}_0 \geq \mathbf{0}$ is used to guarantee the non-negativity of the solution. Then, we can calculate the initial value of the radiance field via formula $\mathbf{R}_0 = \sum_{q=1}^{n} a_q^0 R_q$. Now, the initial value of the temperature field $\mathbf{T}_0$ can be obtained too through the lookup table between radiance and temperature.

The iteration strategy we adopt is: In step k, Φ_k denotes the refractive index field. We calculate $\mathbf{S}_k$ according to Eq.(6), and get $\mathbf{a}_k = [a_1^k, \cdots, a_n^k]^T$ via the following convex problem (CP)

$$\begin{cases} \min \quad \sum_{i=1}^{m} [\mathbf{S}_i^k \mathbf{a}_k - \theta \hat{E}(p_i)]^2 + \eta \sum_{j=1}^{n} [\Delta A_k(\mathbf{x}_j)]^2 \\ s.t. \quad \|\mathbf{a}_k - \mathbf{a}_{k-1}\| \leq \delta D_k, \quad \mathbf{a}_k \geq \mathbf{0} \end{cases} \tag{15}$$

Here, $\mathbf{S}_i^k$ denotes the *ith* line of $\mathbf{S}_k$, $A_k(\mathbf{x}_j) = \sum_{q=1}^{n} a_q^k R_q(\mathbf{x}_j) = a_j^k$. Scalar $\delta \in (0,1)$, $D_k = \|\mathbf{a}_k - \mathbf{a}_{k-1}\|$.

The smaller and smaller search radius δD_k ensures the convergence of $\{\mathbf{a}_k\}$. With $\mathbf{a}_k$, $\mathbf{R}_k$ is calculated conveniently. After obtaining $\mathbf{T}_k$ through the lookup table, Φ_{k+1} can be got too according to Eq.(14). The iteration terminates when $\|\Phi_{k+1} - \Phi_k\|$ is small enough. The terminate condition based on the fact that the temperature and the refractive index field of flame must be consistent with each other all the time. $\|\Phi_{k+1} - \Phi_k\|$ describes the consistency of the temperature and the refractive index field, i.e. the smaller $\|\Phi_{k+1} - \Phi_k\|$ is, the more consistent $\mathbf{T}$ and Φ are.

4. Results and discussion

We use two kinds of cameras to take flame images, i.e. HDR cameras and general industrial ones. HDR cameras are used to take HDR flame images for the purpose of minimizing the information loss caused by overexposure or underexposure. The other cameras are used to add views. More views of the flame will lead to more accurate visual hull. The experimental setup is shown in Fig. 2.

To guarantee the accuracy of the reconstruction results, flame images must not be polluted by ambient illumination. So our setup is placed in a totally dark room. We use the industrial 95% ethyl alcohol as the fuel, and put the fuel into an ordinary alcohol burner. We tried 8 bit, 10 bit and 12 bit flame images in our experiments, only to find trivial difference in smoothness and resolution of the reconstructing results. So the following results are all based on 8 bit flame images.

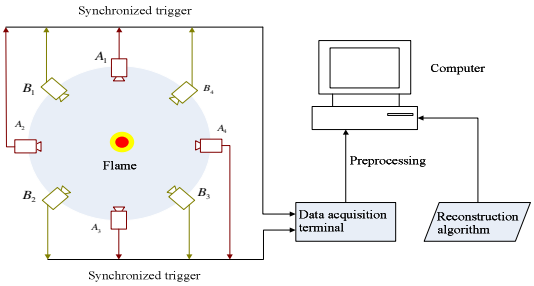

Fig.2 Schematic of the imaging system. A_1-A_4 are HDR cameras, B_1-B_4 are general industrial cameras.

Before reconstruct the flame temperature field, the support region of the base function R_i must be determined first. In our work, we calculate the flame visual hull of flame with eight viewed images, and divide the flame body inside the visual hull into voxels. The resolution of the flame body is determined by the number of effective pixels of the flame images. Here effective pixel refers to the pixel, which locating on the flame in the flame images. We take voxels of the flame body as the support region of R_i for simplicity. In this case, the number of base functions equals that of voxels.

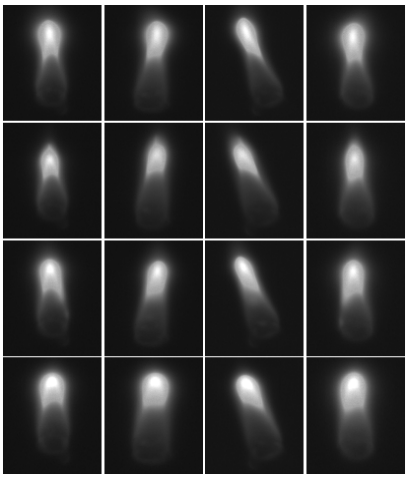

Fig.3 Multi-view HDR images of alcohol lamb flame.

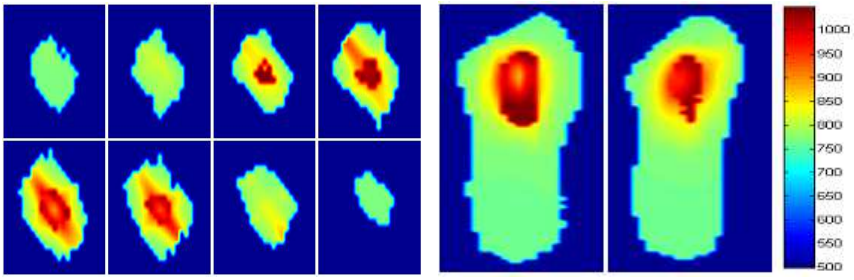
Fig.3 shows the HDR flame images of the alcohol lamb. Each line shows the images taken from four different views at the same time, and each column corresponds to four images taken from the same view. Obviously, the flame can be divided into two parts, the bright head and the rest loom part. For the loom part is ambiguous, we only reconstruct temperature field and refractive index field for the bright head. Then we generate the back-projected images for the bright head. The comparison is restricted inside the bright head. The bright head can be easily detected by threshold based methods.



(a) (b)

Fig.4 Cross- and longitudinal-section of the flame temperature field.

Fig.4 shows the cross- and longitudinal-sections of the flame temperature field from HDR images in Line 1 of Fig.3. In this figure, the dark red represents the greatest temperature level and the dark blue represents the lowest temperature level. According to the temperature distribution, the

temperature in the central region is relatively low, rises along radial direction, and drops when it reaches the outermost layer. So the flame can be divided into three levels, i.e. flame core, inner flame and outer flame. The very center of the "brain" is the flame core, the highest temperature appears in the inner flame, and the rest region belongs to the outer flame. In the flame core, the gaseous alcohol's concentration is relative high but the oxygen's is low, which makes the alcohol unable to burn completely. In inner flame, with sufficient oxygen supplied by surrounding air, the temperature rises reasonably and reaches its maximum. In the outmost layer, flowing air cools the flame, making the temperature lower than that in inner flame. The distribution of the flame temperature field agrees well with the physical law of the real world, which confirms the validity of our solution.

4. Conclusions

In this paper we present an optical model of flame imaging, this model fully considers light deflection caused by refraction index changing. To avoid solving a complex transcendental equation, we use a lookup table to effectively reduce the computational complexity. An algorithm based on the consistency between temperature and refractive index is proposed. The algorithm starts under the assumption that light rays travel along straight line inside the flame, and terminates when temperature and refractive index field physically consistent with each other. The reconstructed temperature field of alcohol flame confirms the validity of our approach.

Keywords: aero-engine bearing; reliability; small sample; Weibull distribution

Abstract: Aiming at the test of Aero-engine bearing is expensive, small sample without failure, and bearing life obeys Weibull distribution, small sample data is introduced in order to estimate the reliability of bearing with the method of Bayesian point estimation. The weighted least squares method is utilized to estimate the shape and scale parameters of Weibull distribution in the case of no failure. The bearing cumulative failure function, failure rate and average life can be gotten. Finally, the bearing experiment data is used to verify the validity of the small sample evaluation. It is proved that the method has an important value for the replacement and maintenance of Aero-engine bearing.

0. Introduction

Aero engine main bearing is a key work part, in high temperature, high speed, variable load and in poor working conditions, which results in the rolling bearings failure problems often appears in the process of aircraft engine application. According to statistics, the main bearing failure accounts for 30% of the total engine failure. So strengthening the reliability of aero engine bearing, is great of significance to shorten the development cycle of aero engine. Compared with ordinary bearing, the reliability of aero engine bearing is relatively high. Therefore, it can not do the complete test in the experiment, but it only can do truncation test regularly with small sample and short time. So the evaluation of small sample and no failure data is put forward.

1. Evaluation Methods in Small Sample Data

1.1 No Failure Data of Small Sample Censored Time

N set of samples are randomly selected to test from the product of a group (n less than or equal to 2), doing the sample's test life about timing censored test for k times[1], truncated time is (t_i,s_i) i=1,2,…k , sample number without failure is denoted as n_i before the i^{th} truncation, then n=n_i.

All samples data without failure is expressed as: (t_i,s_i) i=1,2,...,k. Where:s_i=n_1+n_2+...+n_k, it is expressed at cut-off time t_i during the k^{th} s_i sample truncation test regularly.

1.2 The Cumulative Failure Probability Analysis of p_i Multilayer Bayesian

In the condition the cumulative failure probability of p_i is known at the t_i moment, by the binomial theorem, r_i sample failure probability of s_i samples is shown as follows:

$$L(r_i / p_i) = C_{s_i}^{r_i} p_i^{r_i} (1 - p_i)^{s_i - r_i} \tag{1}$$

Where: $C_{s_i}^{r_i}$ expresses failure combination of r_i samples in s_i samples.

According to the test results of bearing which is only failure or no-failure, conjugate distribution Beta (a, b) of binomial distribution is selected to regard as the prior distribution of the cumulative failure probability p_i[2,3].

For the Beta distribution, the probability density function of the incomplete $Beta(\theta_1,\theta_2,a,b)$ distribution in the interval (θ_1,θ_2) is shown as following:

$$f(x)=\frac{(x-\theta_1)^{a-1}(\theta_2-x)^{b-1}}{B(a,b)(\theta_2-\theta_1)^{a+b-1}},\theta_1<x<\theta_2 \tag{2}$$

Combined with the test analysis of bearing, the failure probability p_i of bearing is obviously smaller. For the convenience of calculation, usually taking a=1, b>1.

1.3 The Estimation of Cumulative Failure Probability p_1, p_2, p_i

Taking $Beta(0,1,1,b)$ distribution as the prior distribution of cumulative failure probability p_1 in the interval (0,1), the multilayer prior distribution of cumulative failure probability p_1 can be obtained under the condition of the hyper parameter b obeying uniform distribution in the interval (1,u).

$$f(p_1/u)=\frac{1}{u-1}[\frac{u(1-p_1)^{u-1}}{\ln(1-p_1)}-\frac{(1-p_1)^{u-1}}{[\ln(1-p_1)]^2}-\frac{1}{\ln(1-p_1)}+\frac{1}{[(1-p_1)]^2}] \tag{3}$$

According to the Bayesian theorem, the posterior distribution of p_1 is shown as following:

$$\pi(p_1/s_1)=[f(p_1/u)L(0/p_1)]/\int_0^1 f(p_1/u)L(0/p_1)dp_1 \tag{4}$$

Because the Bayesian point estimation is the minimum in terms of risk compared with other loss functions, so $L(\hat{p},p)=(\hat{p}-p)^2$ is usually used as loss function. $L(\hat{p},p)$ is expressed the loss derived from parameter p when it is adopted decision $\hat{p}$.

$$\hat{p}_1=\int_0^1\pi(p_1/s_1)dp_1=[(1+s_1)\ln\frac{s_1+u+1}{s_1+2}-s_1\ln\frac{s_1+u}{s_1+1}]/[u-1-s_1\ln\frac{s_1+u}{s_1+1}] \tag{5}$$

Similarly the cumulative failure probability p_2 can be launched:

$$\hat{p}_2=\int_{\hat{p}_1}^1\pi(p_2/s_2)dp_2=\hat{p}_1+(1-\hat{p}_1)[(1+s_2)\ln\frac{s_2+u+1}{s_2+2}-s_2\ln\frac{s_2+u}{s_2+1}]/[u-1-s_2\ln\frac{s_2+u}{s_2+1}] \tag{6}$$

According to the derivation about the analysis of the cumulative failure probability for p_1, p_2, using inductive method, taking parameter b as uniform distribution in the interval (1, u), incomplete $Beta(\hat{p}_i,1,1,b)$ distribution is the prior distribution of cumulative failure probability p_i in the interval $(\hat{p}_{i-1},1)$, then the cumulative failure probability analysis of multilayer is shown as below:

$$f(p_i/u,\hat{p}_{i-1})=\int_1^u\frac{(1-p_i)^{b-1}}{B(1,b)(1-\hat{p}_{i-1})^b}*\frac{1}{u-1}db \tag{7}$$

The cumulative failure probability p_i formula can be derived by the Bayesian method:

$$\hat{p}_i=\int_{\hat{p}_{i-1}}^1\pi(p_i/s_i)dp_i=\hat{p}_{i-1}+(1-\hat{p}_{i-1})[(1+s_i)\ln\frac{s_i+u+1}{s_i+2}-s_i\ln\frac{s_i+u}{s_i+1}]/[u-1-s_i\ln\frac{s_i+u}{s_i+1}] \tag{8}$$

2. Analysis of Bearing Life and Reliability of the Weibull Distribution

According to a lot of experimental proof, bearing life approximately obeys Weibull distribution. Bearing life obeyed Weibull distribution with two parameters will be discussed[4]. The function of bearing reliability is shown as follow:

$$R(t)=\mathrm{e}^{[-(t/\eta)^m]} \tag{9}$$

The estimation $\hat{p}_i$ of cumulative failure probability $\hat{p}_i$ at the moment of t_i can be gotten by the Bayesian method, using the weighted least squares method to calculate the shape and scale parameters of bearing life model in the case of no failure[5].

$$p_i=p(t_i\le t)=1-e^{-(\frac{t_i}{\eta})^m} \tag{10}$$

Using the calculation $\hat{p}_i$ instead of the cumulative failure probability p_i, the shape and scale parameters will be obtained by the weighted least squares method. Taking the weight: $w_i = n_i t_i / \sum_{i=1}^{k} n_i t_i$, ($i$=1,2,..,$k$).

Order: $$Q(m,\eta) = \sum_{i=1}^{k} w_i [1 - p_i - e^{-(t_i/\eta)^m}]^2 \tag{11}$$

Derive partial derivative of the function of $Q(m,\eta)$, then the numerical number of $\hat{m}$ and $\hat{\eta}$ will be obtained. $\hat{m} = (B - A^2)/(D - A*C)$, $\hat{\eta} = e^{[(B*C - A*D)/(B - A^2)]}$

Where: $A = \sum_{i=1}^{k} w_i \ln(\ln \frac{1}{1-\hat{p}_i})$, $B = \sum_{i=1}^{k} w_i [\ln(\ln \frac{1}{1-\hat{p}_i})]^2$ $C = \sum_{i=1}^{k} w_i \ln t_i$, $D = \sum_{i=1}^{k} w_i \ln t_i \ln(\ln \frac{1}{1-\hat{p}_i})$

So it can calculate reliability, failure rate and average life of bearing:
$R(t) = e^{-(t/\hat{\eta})^{\hat{m}}}$, $\lambda(t) = (\hat{m}/\hat{\eta})/(t/\hat{\eta})^{\hat{m}-1}$, $ET = \hat{\eta}\Gamma(1+1/m)$

3. The Reliability Case of Aero-engine Bearing without Failure Data

Aiming at some type of bearing, Randomly selected 2 sets from the whole truncated life test is done regularly for five times, no failure data obtained is shown in Table 1 no failure data.

Table 1 No failure data

Truncated sequence (i)	censored data (h)	sample number n_i / a	no failure number s_i / a
1	180	2	10
2	300	2	8
3	500	2	6
4	600	2	4
5	800	2	2

According to the conclusion of reference[6], b should not be made too large, the upper limit of b is designated as u temporarily. U is selected in the interval (2, 8). Usually u is respectively selected 2, 3, 4, 5, 6, 7, 8. According to equation (5), (6), (8), (10) and (11), getting the numerical number of $\hat{m}$, $\hat{\eta}$ and R(t), whose results are shown in table 2 the cumulative failure probability and table 3 reliability.

Table 2 The cumulative failure probability

Parameters	2	3	4	5	6	7	8
P_1	0.0443	0.0432	0.0421	0.0411	0.0401	0.0391	0.0383
P_2	0.0908	0.0876	0.0862	0.0840	0.0820	0.0799	0.0782
P_3	0.1458	0.1409	0.1378	0.1340	0.1306	0.1271	0.1242
P_4	0.2045	0.1977	0.1927	0.1871	0.1821	0.1771	0.1728
P_5	0.2800	0.2699	0.2618	0.2535	0.2460	0.2388	0.2324

It can be seen from table 3, the selection of u has some influence on shape parameters $\hat{m}$ and scale parameters $\hat{\eta}$, but has little effect on the reliability estimation. For example: When the time is 60 hours, the reliability is below 0.0001; When it is 180 hours, the reliability is below 0.001; When it is 600 hours, the reliability is below 0.01. From figure 1 and figure 2, the reliability and failure rate of different shape parameters at different time can be seen, the selection of u has little effect on the change of reliability and failure rate curve. Therefore, u=5 is right in the interval (2, 8) .

Table 3 Reliability

Parameters	2	3	4	5	6	7	8
$\hat{m}$	1.4659	1.4378	1.4119	1.3921	1.3784	1.3605	1.3449
$\hat{\eta}$	1015.4631	1078.1480	1141.0452	1202.1898	1259.4117	1320.8094	1380.7747
R(60)	0.9843	0.9844	0.9845	0.9847	0.9850	0.9852	0.9854
R(180)	0.9239	0.9265	0.9290	0.9314	0.9338	0.9358	0.9374
R(300)	0.8459	0.8531	0.8593	0.8652	0.8708	0.8754	0.8796
R(500)	0.7019	0.7180	0.7321	0.7446	0.7559	0.7659	0.7748
R(600)	0.6298	0.6501	0.6680	0.6839	0.6977	0.7105	0.7218
R(800)	0.4941	0.5218	0.5457	0.5671	0.5857	0.6032	0.6188

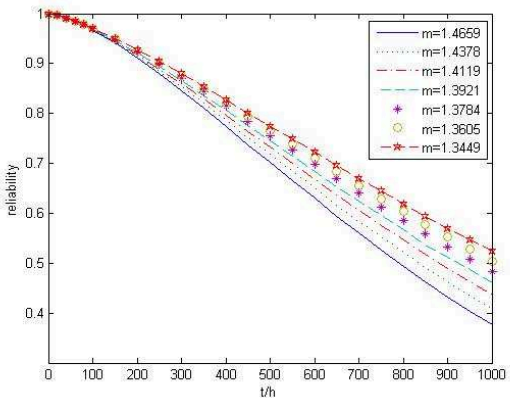

Fig. 1 Reliability curve

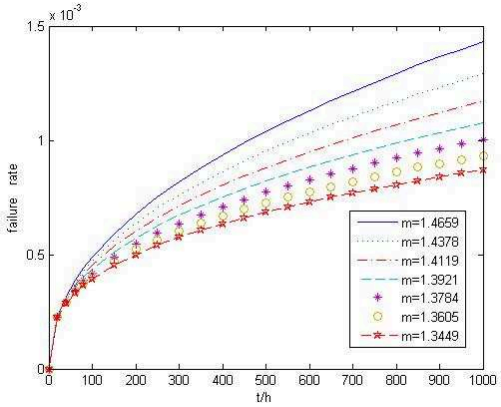

Fig. 2 Failure rate curve

When u is equal to 5, shape and scale parameters are respectively 1.3921 and 1202.1898. So the reliability, failure rate and average life can be concluded.

4. Conclusion

In this paper, conjugate distribution Beta(a,b) of binomial distribution is regarded as prior distribution of cumulative failure probability by using the Bayesian method. The model of bearing reliability evaluation can be gotten, the assessment accuracy of bearing reliability will be improved. Prior information should be continued to accumulate and collected in order to ensure reliability evaluation results more accurate.

Keywords: Hydraulic turbine, cavitation, Cordon method

Abstract. Since the first hydraulic mechanical erosion discovered in the later stage of 19th century, researchers from both abroad and home have devoted a large amount of time and energy, ranging from fluid dynamics of multiphase systems and dynamics of materials to design of impeller, processing craft and material application with multi-subject research.

Although great achievements have been acquired, some problems are still waiting to be resolved. At present, the fundamental principle of hydraulic turbine's erosion has been found out. When temperature of water is kept at a stable level and pressure of fluid's internal part decreases to a critical point, the fluid will evaporate, forming a vacant cave which will be destroyed in a short moment and cause pressure wave of hundreds of MPa to intensely vibrate hydraulic turbine and leave trails shaping like honeycomb.

However, reasons of hydraulic turbine's cavitation are extremely diverse and complicated, not only involving factors such as waterpower and mechanism, but also working conditions of hydraulic turbines, setting conditions of hydropower stations as well as working environment. Causes of hydraulic turbine cavitation in every hydropower station differ due to different factors, which undoubtedly increases the difficulty to prevent and predict cavitation.

This passage is to apply Cordon method to predict destruction volume of cavitation and compare it with the real conditions of hydropower station. In additions, both reasons and measures will also be researched in order to gain a favorable effect.

Cavitation phenomenon in hydraulic turbines

Cavitation is caused by the bursting of bubbles due to swirls, producing large pressures on the surface of the metal and ripping the surface metal. If it happens in a caustic environment, damage will be larger.

As the sites with lower pressures produce more bubbles, water in the sites with high pressures will destroy the bubbles and strike the metal in a fast speed, making the surface of the metal shaping like what is bitten by mice. Attacked by cavitation, all the notches and flaws may speed up the erosion at the surface of the metal despite of smearing the protection layer. The damage of cavitation on the materials is accumulated with each day, thus, designers are supposed to get a better understanding of cavitation and make effective measures. Figure 1 indicates the cavitation phenomenon occurring in hudraulic turbines.

Figure 1. Cavitation phenomenon in hydraulic turbines

Prediction formula of cavitation.

At present, few methods can be utilized to predict cavitation. But Cordon method is a comprehensive formula which refers to the cavitation characters of hundreds of hydraulic turbines in North America.

Weight loss W(kg) of hydraulic turbines' impellers after eight thousand hours' working can be calculated according to Formula (1).

$$W = K_1 d^2 \tag{1}$$

In the above formula, K_1 represents cavitation intensity index of hydraulic turbines, d the throat diameter（m） of wheels. Cavitation intensity index of hydraulic turbines can K_1 can be calculated referring to Formula (2):

$$K_1 = 2.178^n \tag{2}$$

$$n = 0.45v^2 b^{-0.56} + 2.3C_f - S_a - R_1 - B \tag{3}$$

n------represents the effect index of K_1;
v------average fluid speed of unit;
b------ number of wheels' impellers;
C_f------utilization index of unit loading;
S_a------drowning depth of hydraulic turbine(m);
R_1------material index of hydraulic turbine;
B------ local air pressure.

According to Formula (1), (2), (3), based on real references of power stations, the weight loss, 162.6kg for one year, can be predicted. Compared with that of 2009, the weight loss is 150kg from which we are able to draw a conclusion that the error is just 12.6kg.

Therefore, Cordon method is not only feasible, but also credible.

Causes of Cavitation

As Cordon method is able to well predict the conditions of cavitation in hydropower stations, causes of cavitation can be analyzed through decomposition of Cordon.

According to Cordon method, the main factors which influence cavitation index K_1 include average fluid speed, number of impellers, loading utilizing index, drowning depth, material index as well as local air pressure. To rule out the fixed factors like design and local air pressure, the effect factors of cavitation in the hydropower can be indicted in Chart 1:

Item	Parameter	Item	parameter
Type of wheel	HL220-LJ-380	Loading utilizing index	0.95
Fluid volume of unit(m^3/s)	112	Drowning depth of lower reach/m	-0.86
Water head/m	51	Material index of impellers	2.8
Diameter of wheel/m	3.8	Air pressure/kPa	93.8
Fluid speed/(m/s)	10.8	Weight loss of current year	162.6
Number of impellers	14	Real weight loss of current year	150

Chart 1. Prediction of weight loss for hydraulic turbine

The wheel material in this station is made from ZG45 carbon steel which is easy for forging but soft. Obviously, ZG45 carbon steel's cavitation resistance ability is worse, which is one of the most important reasons causing severe erosion in hydraulic turbine.

What's more, drowning depth of lower reach is also firmly related with cavitation. When pressure of the fluid in which hydraulic turbine works is low, cavitation will be easy to be made. The real extracting height when hydropower unit works directly influences pressure of the fluid and extracting height is largely related with the drowning height of lower reach. As investigation has indicated, the larger extracting height is, the bigger possibility of cavitation will be.

Loading utilizing index is also a vital factor affecting hydraulic turbine. It can be expressed through the ratio between full operating time of hydraulic turbine and its normal operating time of a year. As indicated in the investigation, loading utilizing index will exert negative impact on hydraulic turbine no matter it is higher or lower.

Measures dealing with cavitation.

4.1 Serious research on problems of sand discharging.

One vital step is to make feasible sand discharging plans in the hydropower station with large amounts of mud and sand to decrease the amount of sand accumulation. Hasty work without investigation of sand discharging will not only bring tremendous waste to people, but also potential catastrophes.

4.2 Basic research on hydraulic turbines' cavitation.

It is essential to found a foundation which exclusively supports the research of hydraulic turbines' cavitation and actively take part in the research of mechanism of cavitation and abrasion. The fact that old experts who research in these aspects have retired, the majority of people in middle ages have experienced career change and young people are reluctant to engage in this job should inspire more people to work hard to create an active atmosphere for the development of this research.

4.3 Making of reasonable operating plan.

Reasonable plans are supposed to be made in order to reduce extracting height. According to local hydrological conditions, based on situations of sea levels in both high and low reaches, reasonable operating plans are supposed to be made to reduce extracting height on condition that adequate amount of power is generated.

4.4 Fulfilling mending regulations.

Despite the softness of materials and bad capability of resisting erosion, wheel should not be changed directly based on economical reasons. Therefore, it is quite significant to fulfilling mending regulations. It will not only shorten mending time and prolong using lifetime, but also make more economic profits and guarantee safe operation with good use of Cordon method to predict the developing process of cavitation.

4.5 Welding of wheels.

Stainless welding bars of new type which resist cavitation and abrasion must be used in the process of further welding. To take OCr13Ni4~6Mo stainless welding bar for example, it matches the mechanical facilities whose mother material is carbon steel. Besides, it is in possession of features such as easy welding and processing as well as resistance of cavitation and crack which have been applied in a great many large-scale hydropower stations in both abroad and home.

4.6 Protection of coverage.

In order to further strengthen the resistance of cavitation, coverage protection is supposed to be implemented in hydraulic turbines. Common spraying materials include mental, alloy, pottery and plastic. Spraying craft includes surface brushing, arc spraying and electroplating. For instance, Dongchuan hydropower station applies electroplating to strengthen the ability of cavitation and achieves great effects.

Summary

China's hydropower development has a quite promising future, but a great many hydropower stations which have been established are experiencing severe cavitaion and abrasion. These damages reduce operating efficiency and intensify vibration, not only threatening the safety of hydropower stations, but also bringing troubles to the normal operation of power grid.

Although the mechanism of cavitation is simple, its causes are supposed to be analyzed from diverse respects. Measures implemented also continuously change and their effects are difficult to be predicted. Therefore, conclusion of mending experience, utilization of Cordon method, confirmation of causes of cavitation as well as good selection of resisting measures are greatly meaningful to stations' economical operation and technological transformation.

Keywords: Slurry pipeline transportation, Drag reduction technology, Micro-bubble drag reduction, Vibration drag reduction.

Abstract. The resistance of slurry pipeline transportation has greatly impact on slurry transportation system. In order to improve transportation efficiency,energy utilization rate,taking the appropriate drag reduction technology has a very important significance.This paper presents drag reduction technologies for slurry transportation applications,including micro-bubble drag reduction technology and vibration drag reduction technology.

Introduction

Slurry pipeline transportation has greatly advantages such as less investment, construction period shortly, less environmental pollution and ease of management,causing various aspects of attention.It has been used widely in many fields.With increasing depletion of energy and intensification environmental pollution,energy-saving and emission reduction have to be solved.Thus the research of drag reduction technology plays an increasingly important role.There appears a variety of drag reduction methods.For instance,soluble high molecular weight polymer,fiber material, spiral flow, changing pipe geometry,heating drag reduction and adjusting the size of particles etc.With the analysis of the theoretical knowledge and experimental data to be established,the above drag reduction technologies had been made great progress, but there are some disadvantages and some of the drag reduction technology apply in reality still for a long time.This article will discuss micro-bubble drag reduction technology and vibration drag reduction technology.

The Technology of Micro-bubble Drag Reduction

The Development of Micro-bubble Drag Reduction Technology. In 1949 Locknar and Mantinelli firstly proposed the injection of gas in the pipeline.They found, however, that the injection of gas increased the pressure gradient in the pipe.In other words, the injected gas increased transport resistance [1].Nevertheless,Heywood N.I .and Rechardson J.F. et al, through experimental studies found that gas injection drag reduction in the laminar flow was best [2].Chinese scholar Xingrong Zhang et al, in1982, Conducted a three-phase flow pipeline experimental in Qingshan power plant and got some preliminary results of this trial: drag reduction rate was up to 6.2% [5].In 1996, Chinese scholar Yonggang Zheng and other scholars,in the study of circular pipe aerated flow drag reduction,considered that circular pipeline aerated drag reduction was actually achieved lower resistance by bubbles attached in the boundary layer of pipeline as same as polymer additive [8].Under the assumption of gas-liquid stratified flow situation,they studied the theory of drag reduction pipeline aeration.In the theoretical model proposed,drag reduction rate reached 30% to 50% [7].

In 2005,Aluf Orell conducted systemic research and presented complete set of its governing equations for predicting the slug unit pressure gradient [4].In 2007,Aluf Orell first attended to proposed model for evaluating the pressure gradients for stationary and moving solid beds overlaid by three-phase slug flow.His research came to the conclusion that in critical value for slurry speed ,it could achieve better effect on reducing resistance [3].

In 2008,Chinese scholars Bo Tang, Jianyi Kong and Runsheng Rao,in the three-phase flow experiment of pipeline drag reduction,investigated many factors about the drag reduction.For example, the flow rate of the slurry, adding content of the gas, the impact of gas pressure and the movement patterns of gas in transportation pipeline and other factors of the performance of slurry.Concluded when adding gas volume fraction reached to 12%, it will obtain the minimum drag coefficient [9].

Meanwhile,in recent years in the test for the different aerated device trials,which generally considered that rotating jets spray gas device has prominent advantage.Because the design of this device can obtain abundant Micro-bubbles and achieve the size less than 1mm [10].This design can still produce a negative pressure air vortex, has the ability to self-inspiratory ,avoid the drawback of blocking phenomenon.In further studies of the nozzle device,Chinese scholars Ting Xiong, Shidong Fan and Zixuan Yang drawn that diameter of the Spiral pipe in 10mm, the mixing effect is better and the pitch in 60mm, the pressure loss is minimum [11].

Micro-bubble drag reduction technology has made great progress and theoretical research.Meanwhile it has been applied slurry transportation in short distance such as cutter suction dredgers and other fields.

The Mechanism of Micro-bubble Drag Reduction. Chinese scholars Xingrong Zhang, Shaoqiang Zhang and Lvtai Zou came to conclusion of drag reduction mechanism [5]:Under certain velocity of slurry condition , when added to a appropriate amount of gas, the gas destroyed the movement mechanism and the structure of two-phase flow in slurry pipeline ,which enhance turbulence of slurry.It made numerous small bubbles in the slurry flow evenly blended among,then result in the cross-sectional velocity and concentration of the slurry more evenly distributed.The velocity gradient and concentration gradient were reduced, so that reduced the shear force of the pipe wall , and achieved the effect of drag reduction.

In 1989,Chinese scholars Baowei Song, Jingquan Huang[6],in Northwestern Polytechnical University,studied the effects of friction in the boundary layer on the flat surface of micro-bubbles. They thought the drag reduction mechanism that properties of micro-bubbles within the boundary layer viscous and elastic in itself,a portion of the fluid shear force transits into deformation energy stored, thereby reducing the energy loss.the key was to change the density of the boundary layer, and thus got drag reduction effect.

The Mechanism of Micro-bubble drag reduction is generally summed up that at conditions of high concentrations and low flow rate, to inject the right amount of gas can get a better drag reduction result. And vice verse. The joined bubbles changed the viscous and the density of boundary layer,flow structure and velocity gradient, so that the friction coefficient of pipe wall surface reduced and the direct friction of slurry pipe wall weaken.Meantime,it destroyed the flocculation reticular of slurry flow and enhanced the internal turbulence intensity ,which made the slurry concentration more well-distributed in cross-section.In additiont,the properties of viscosity and volatility of the bubbles, it can store up the energy of fluid in contact with the pipe wall as well as play a role of lubrication , such that transmission of resistance is reduced.

The Deficiency and Prospect of Micro-bubble Drag Reduction Technology. Although micro-bubble drag reduction even relatively low cost and easy to implement, but there are shortcomings that in the long distances,micro-bubbles is unstable, prone to burst, and certainly generate more large resistance and noise.At the same time the size of the bubble is not easy to control.Small bubble drag reduction effect is not obvious, and large bubbles can influence efficiency of pipeline, so the control of the bubble size and stability which is worthwhile for us to have a further discussion and study. For example,to improve the adsorption characteristics of piping material and make the bubbles to scroll along the wall and to change the physical stability of the bubble characteristics that the bubble is not easily broken.It is also that do some changes on the inner wall of the pipeline structure shape, making the bubble more evenly distributed around the perimeter of the pipe wall.As well as try to make micro-bubble drag reduction technology and other drag reduction for joint,which find out the drag reduction effect more obvious and easy to implement method of drag reduction.

The Technology of Vibration Drag Reduction

The Development of Vibration Drag Reduction. In 1960,M.O. Kramer put forward a drag reduction method of the bionic:artificial dolphins skin.The drag reduction rate could reach to 50% [14].This method can be understood that the movement of fluid contributed to the outer membrane of volatility, making the boundary layer in fluctuation , which increase the thickness of boundary layer , so as to achieve the effect of drag reduction [12].

In 1993,Chinese scholars DeSheng Gu, Guangwen Chen[12]thought that the drag reduction method was internal, passive method of drag reduction, so that it was not easy to control.Therefore,they proposed the external force as vibration source,realizing dynamic drag reduction of drag reduction method ,which was vibrating drag reduction.

In 1995,Chinese scholar Youyuan Tan[16]proceeded the experiment of vibration drag reduction in tailing.She concluded that: the concentration and the transmission speed of slurry and vibration parameters in the process of drag reduction were the main parameters, and within the low speed and high concentration (< 72.6%) could get good drag reduction effect.

In 2001,Chinese scholars Yezhi Sun, Aixiang Wu and Jianhua Li[13]in tailing test of drag reduction vibration, also confirmed the above conclusion, at the same time analyzed the reflection and transmission of stress wave and the stability of boundary layer thickness and change, and acquainted the feasibility of drag reduction vibration.

Vibration drag reduction technology is a novel drag reduction method and its basic idea which is use wall vibration to lower the concentration gradient and the velocity gradient of the boundary layer , in order to achieve the effect of drag reduction. But the usability and stability of this method needs further study.

The Mechanism of Vibration Drag Reduction Technology. Chinese scholars Desheng Gu, Guangwen Chen[12]hold the mechanism of vibration drag reduction : There were three aspects that elaborate the mechanism of vibration drag reduction technology.First boundary layer fluctuation was caused by the external force in the pipeline, contributed to the movement of the slurry particles of the boundary layer, reduced the velocity gradient and the shear stress on the boundary layer.Moreover, vibration made the boundary layer more stability, and its thickness was also increase.Finally,vibration promoted slurry particles to easily suspended, which made the slurry concentration gradient reduced. So as to achieve the effect of drag reduction.

About the mechanism of drag reduction of vibration ,There are some else points [15]:On the one hand ,drag reduction associated with the vortex state in the spanwise direction ,which is produced by the periodic stokes layer on the vibratory pipe wall.On the other hand ,boundary layer exists the phenomenon of flow to the vortex of recycling.

The Deficiency and Prospect of Vibration Drag Reduction Technology. Due to lack of theoretical consensus of the mechanism of vibration drag reduction, so it still need further in-depth studies on theory.Moreover, when transporting slurry concentration is higher, the vibration of the pipeline could produce the phenomenon of segregation of slurry,resulting in the effect of drag reduction significantly lower. In addition, the vibration source produces the optimal amplitude and frequency which is not clear.The relationship between the velocity and concentration of slurry flow and vibration parameters far from clear. These questions need further study.

Summary

In this paper, the micro-bubble drag reduction technology and the vibration drag reduction technology are simple summarized. There applied prospects is extensive and economical.But their respective theoretical studies are not very perfect, which also should be deepened.At the same time, combined with other drag reduction technology experiment also need to be researched, thus obtain good drag reduction effect.

Keywords: GDI engine, AVL-Fire, simulation, ignition timing, particle

Abstract. In this paper, the AVL-Fire software was used to research the effects of ignition timing on homogeneous combustion and particle emission in a GDI engine. The result shows that the highest temperature and pressure reduce with the delay of ignition timing under the homogeneous charge mode in which gasoline is injected in the intake process. But the soot mass fraction decrease first and increase subsequently.

Introduction

In recent decades, how to improve the fuel economy and emissions of the internal combustion engine has been an important research direction in face of global energy crisis and strict emission regulations. Because the gasoline direct injection (GDI) in cylinder can effectively increase the engine power and fuel economy, so it has become a research hotspot. But particle emission of GDI is high in comparison to traditional gasoline engine, close to that of diesel engine. So it's necessary to study the particle emission of the GDI engine. This paper uses the AVL-Fire software to study how the ignition timing affects the particle emission under the homogeneous combustion mode in GDI engine [1-3].

The Establishment of Three-dimensional Model

The EA888 engine parameters show in table 1.

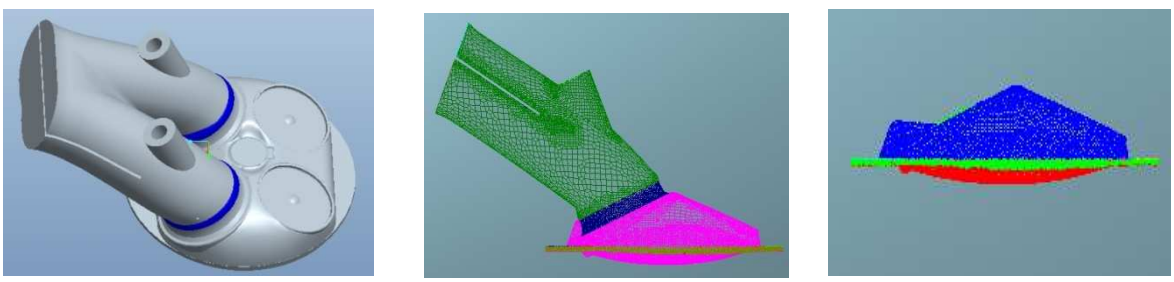
Table 1 EA888 engine parameters

Form	Four cylinders
Compression Ratio	9.6
Stroke(mm)	84.2
Cylinder Diameter(mm)	82.5
Nozzle Diameter(mm)	0.18

Table 2 Initial Conditions and Boundary Conditions

Boundary conditions	Inlet temperature(k)	330
	Combustion chamber crown(k)	550
	Cylinder wall temperature(k)	450
	Piston crown temperature (k)	600
Initial conditions	Intake port temperature(k)	333.15
	Intake port pressure(Pa)	100000
	Cylinder temperature(k)	951

The Establishment of Model. First, EA888 geometric model was built in Pro/E software. Then AVL-Fire software is used to treat the model. Dynamic grid was generated in the range of 0-540 degrees crank angle. The valve open time is 0°crank angle and the compression top dead center is 360°crank angle.



(a) Geometry model (b) 360°CA BTDC (c) 0°CA BTDC

Fig. 1 EA888 engine model

The dynamic grid is showed in Fig.1b and the model adopts hexahedral grid. In order to shorten the calculation time, the inlet and exhaust ports are removed when the inlet and outlet valves close. The largest mesh size is 2 mm and the minimum mesh size is 0.25 mm.

The Initial Conditions and Boundary Conditions. The initial conditions and boundary conditions of model show in table 2.

Model Validation

Fig.2 shows the EA888 engine bench. The engine speed is 2000r/min and the injection time is 40°CA BTDC. The fuel injection duration is 20 degrees crank angle, the fuel injection amount is 25mg and the ignition timing is 19°CA BTDC. From the Fig. 3, the model is proved correct.

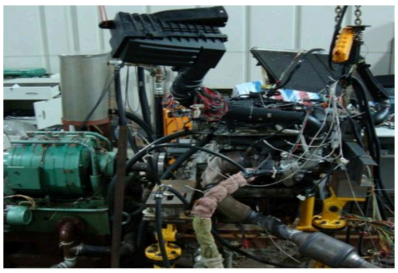


Fig.2 EA888 engine bench test

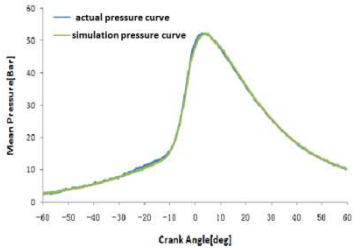

Fig.3 Model validation curve

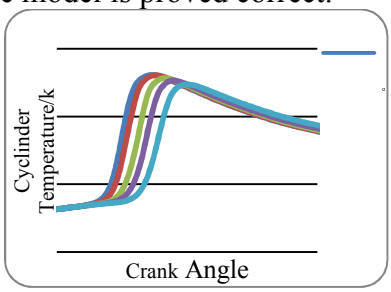

Fig. 4 Cylinder temperature curves

The Results of Numerical Simulation Analysis

This article researches how the ignition timing affects the combustion and soot emission of GDI gasoline engine under the homogeneous combustion mode. In this mode, the mixture formation time is long and relatively uniform. Thus the ignition timing has an important impact on the combustion and soot emission.

The engine speed is 2000 r/min, injection quantity is 25mg per cycle, the injection time is from 40 to 60 degrees crank angle and the ignition time is 24°CA BTDC ,21°CA BTDC,17°CA BTDC,14°CA BTDC,10°CA BTDC respectively.

Combustion Analysis. Fig.4 and Fig.5 show the temperature curve and pressure curve with different ignition timings. The highest temperature and pressure increase and the peaks are closer to the compression top dead center with the advance of ignition timing.

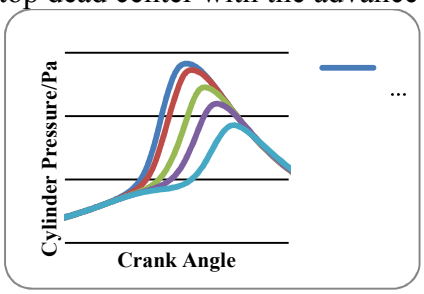

Fig.5 Cylinder pressure curves with crank angle

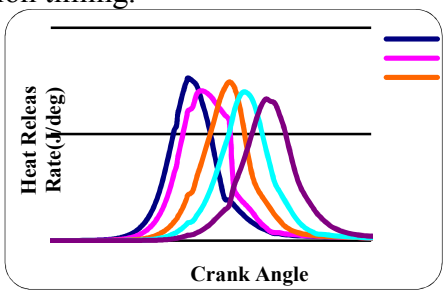

Fig.6 Heat release rate curves with crank angle

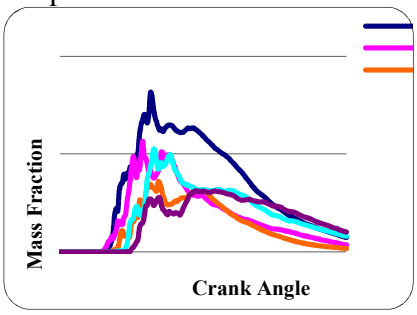
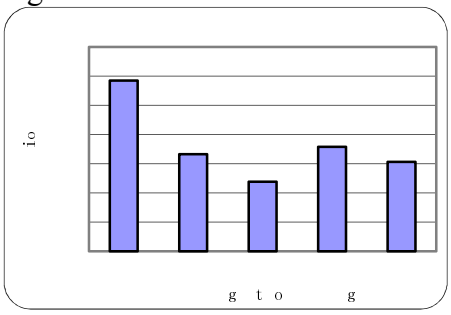


(a)Soot mass fraction curves with crank angle



(b)Soot mass fraction with different ignition timing

Fig. 7 Soot mass fraction

Emissions analysis. From fig.6, the heat release rate shows an increasing trend, but a peak at 17°CA BTDC appears. And the soot mass fraction decrease first and increase subsequently from fig.7b. There are some reasons for this phenomenon.

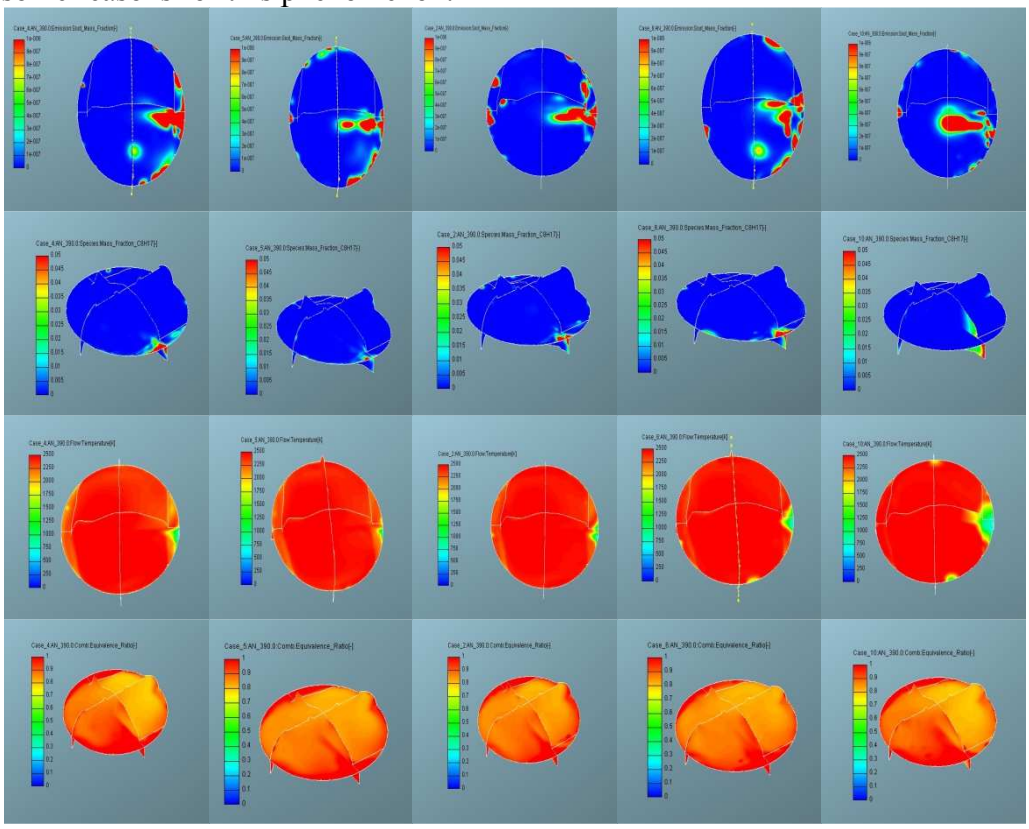


Fig. 8a SOOT, 8b HC, 8c temperature, 8d equivalent ration (20°CA ATDC)

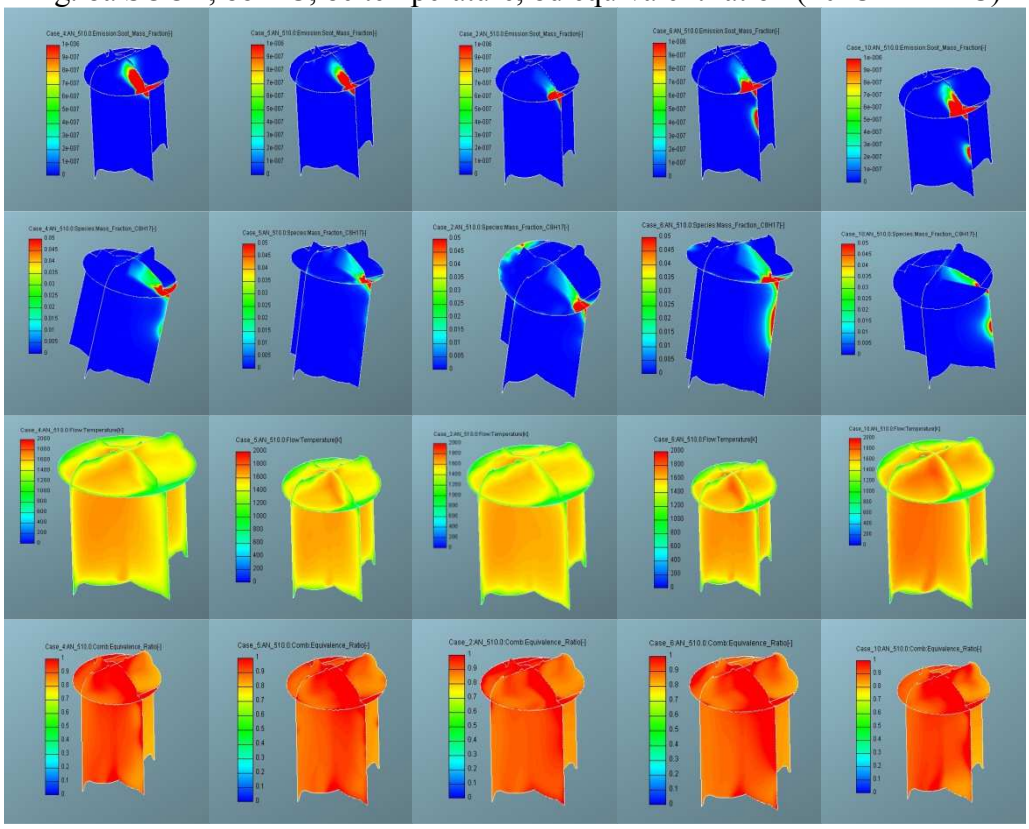

Fig. 9a SOOT, 9b HC, 9c temperature, 9d equivalent ration (150°CA ATDC)

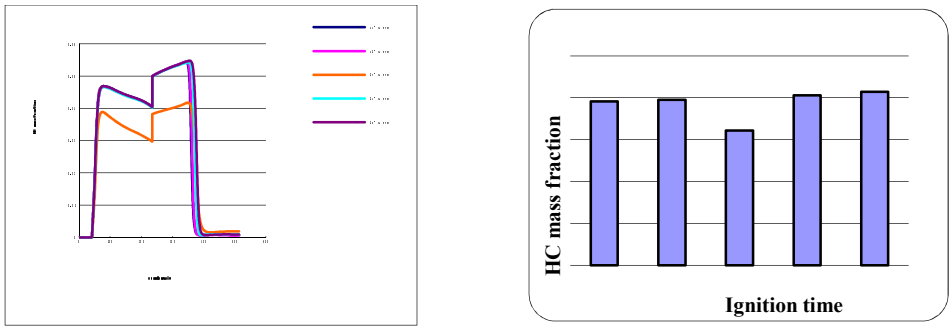

(a)HC mass fraction curves with crank angle (b)HC mass fraction with different ignition timing

Fig. 10 HC mass fraction

Soot formation condition is high temperature and oxygen, so it is necessary to analyze the cylinder temperature, equivalent ratio and HC. Because, Kleeman found that organic compounds were the main components for the gasoline engine particles [4]. Soot and HC are in the similar areas at 20°CA ATDC from fig.8a and fig.8b. From the fig.8c, the cylinder temperature is about 2500k except that a small part in cylinder is 2000 k. However, the area is the soot area when the temperature is under 2000k. (Research showed that the soot formation was between 1500k and 2400k, no matter how high the equivalence ratio was, there was almost no soot formation. And when the temperature exceeded 2400K, there was no soot[5].) And the fig.8d shows that the equivalence ratio is about 1.1 in the soot area. All of this is the best conditions for soot.

At the moment of the exhaust valve open, the combustion in cylinder is shown in fig.9. This phase is mainly for the soot oxidation. The fig.9c shows that the cylinder temperature is lower than 1800k at 150°CA ATDC. (The research showed when the temperature was below 2000k, the soot wouldn't be oxidized in the later phase[6].) So the soot will not be oxidized from 150°CA ATDC.

Conclusions

(1) Using the simulation software, the paper analyzes how the ignition timing affects the combustion. And with the delay of ignition timing, the maximum pressure and the highest temperature peak decrease.

(2) Analyze the factors how affect the particle generation, and pointed out the main soot formation area.

(3) Last, a conclusion is concluded that 17°CA BTDC is the best ignition timing in this condition.

Keywords: PNGV equivalent battery mode; SOC estimation; UKF arithmetic

Abstract: Based on PNGV (the Partnership for a New Generation of Vehicles) equivalent battery model, establishing state-space equations, discrediting them and using UKF (Unsvented Kalman Filtering) arithmetic to achieve an exact SOC estimation under the non-linear condition. According to simulation experiment, UKF estimation just has an error rate of less than 6 percent, and has a quite high use value.

Introduction

Battery management system as an important part of hybrid electric vehicle mainly responsible for collecting information, estimating SOC and enabling real time communication with the vehicle control unit. This can help to extend battery life, remind the distance per charge and insurance the traffic safety. As a result, the research of battery management system has important applications.

Battery equivalent circuit model

Typical equivalent circuit models are Rint, Thevenin and PNGV. Rint does not involve the battery internal dynamic characteristics and just be used to simulate the simple circuits but not for EV. The precision of Thevinin model is higher than that of Rint，but lower than PNGV. PNGV medal is standard battery model in PNGV Battery Test Manual in 2001, and still use in Freedom CAR Battery Test Manual in 2003. It is consisted of resistance and Capacitance and be used to formulate operating characteristics of battery. This method has clear physical meaning and can easily distinguish model parameters. Considering the temperature influence to model parameters can obtain more correct PNGV model parameters, and then it raises the battery SOC estimation accuracy. Base on such advantages, this paper chooses PNGV equivalent circuit model. As shown in the fig 1.

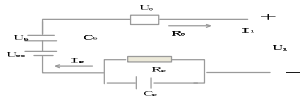

Fig.1 PNGV equivalent circuit model

In the model, U_{oc} is ideal voltage source, referring the open circuit voltage of batter; R_0 is ohmic resistance, R_p is the polarization resistance, I_p is By current of passing polarization impedance, C_p is polarization capacity, I_l is the battery load current, C_b capacitance describe the accumulative open circuit voltage changes when it loads current.

From the figure 1-1, following equations can be get:

$$U_b = U_{oc} - \frac{1}{C_b}\left[\int I_l d_t\right] - R_0 I_l - R_p I_p \tag{1}$$

state equation is shown as figure1-1:

$$\begin{cases}\begin{bmatrix}\dot{U}_b\\ \dot{U}_p\end{bmatrix}=\begin{pmatrix}0 & 0\\ 0 & -\dfrac{1}{C_pR_p}\end{pmatrix}\begin{bmatrix}U_b\\ U_p\end{bmatrix}+\begin{bmatrix}\dfrac{1}{C_b}\\ \dfrac{1}{C_p}\end{bmatrix}I_l\\ \dot{S}=-\dfrac{\eta}{Q_0}I_l\end{cases} \tag{2}$$

In this state equation, the voltage value of the capacitance of PNGV model is state variable, and the terminal voltage of battery is output variable. of which, Q_0 is battery available capacity,S is functions of SOC about current. That is:

$$S(t)=S(t_0)-\frac{1}{Q_0}\int_{t_1}^{t}\eta I_l d_t \tag{3}$$

$S(t_0)$ is initial value of SOC, η is coulomb efficiency.Following state-space equations can be obtained after the discretization of equation(1)and equation(2)

$$U_{b,\varepsilon}=F[S_\varepsilon]-\frac{1}{C_b}\left(\sum I_l\Delta t\right)_\varepsilon-I_{l,\varepsilon}R_0-I_{p,\varepsilon}R_p+V_\varepsilon \tag{4}$$

$$\begin{bmatrix}U_{b,\varepsilon+1}\\ U_{p,\varepsilon+1}\\ U_{\varepsilon+1}\end{bmatrix}=\begin{bmatrix}1 & 0 & 0\\ 0 & \exp\left(-\Delta t/\left(R_pC_p\right)\right) & 0\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}U_{b,\varepsilon}\\ U_{p,\varepsilon}\\ S_\varepsilon\end{bmatrix}+\begin{bmatrix}\Delta t/C_p\\ R_p\left[1-\exp(-\Delta t/(R_pC_p))\right]\\ -\Delta t\eta_\varepsilon/Q_0\end{bmatrix}I_{l,\varepsilon}-\begin{bmatrix}W_{1,\varepsilon}\\ W_{2,\varepsilon}\\ W_{3,\varepsilon}\end{bmatrix} \tag{5}$$

$F[S_\varepsilon]$ is functional relation of SOC and electromotive force, W_1,W_2,W_3 is system white noise, V_ε is observation noise

In Document [3], battery model has been given an accuracy test. By simulation and experiment, using HPPC test to calculate model parameters estimates SOC error rate is less than 6 percent. According to the experiment, the PNGV model parameters gained under normal temperature is reasonable, and this model has a high accuracy. Fig 2 is HPPC current schematic diagram.

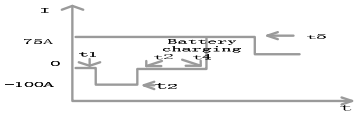

Fig 2 HPPC current schematic diagram

The UKF estimation based on PNGV

UKF filtering method dealing with noise includes extension and non-extension such two ways. In this paper, UKF filtering method of non-extension form is used, because non-extension rule can reduce the dimension of system and the number of sigma point. Filtering has a better real-time performance, so it is propitious to deal with the Gaussian Noise.

UKF filtering calculation method:

For non-linear system

$$X_k+1=f(X_k)+W_k \tag{6}$$

$$Y_k=h(X_k)+V_k \tag{7}$$

Supposing state is gaussian random vector ,statistic characteristics of process noise and measurement noise are:

$W_k \sim N(0, Q_k)$ $V_k \sim N(0, R_k)$

(1) initialization

$$\hat{X}_0 = E[X_0] \tag{8}$$

$$P_0 = E[(X_0 - \hat{X}_0)(X_0 - \hat{X}_0)^T] \tag{9}$$

(2) State estimation

(a) calculating Sigma point

$$X_{k-1}^0 = \hat{X}_{k-1} \tag{10}$$

$$X_{k-1}^1 = \hat{X}_{k-1} + (\sqrt{(n+k)P_{k-1}})_i, i = 1, 2, 3....n \tag{11}$$

$$X_{k-1}^i = \hat{X}_{k-1} + (\sqrt{(n+k)P_{k-1}})_i, i = n+1, ..., 2n \tag{12}$$

(b) time dissemination equations

$$X_{k\backslash k-1}^i = f(X_{k+1}^i) \tag{13}$$

$$X_k^1 = \sum_{i=0}^{2n} W_i^{(m)} X_{k\backslash k-1}^i \tag{14}$$

$$P_{x,k}^- = \sum_{i=0}^{2n} W_i^{(c)} [X_{k\backslash k-1}^i - \hat{X}_k^-][X_{k\backslash k-1}^i - \hat{X}_k^i]^T \tag{15}$$

$$r_{k\backslash k-1}^i = h(X_{k\backslash k-1}^i) \tag{16}$$

$$\hat{y}_k^- = \sum_{i=0}^{2n} W_i^{(m)} r_{k\backslash k-1}^i \tag{17}$$

(c) measure updating equations

$$P_{y,k} = \sum_{i=0}^{2n} W_i^{(c)} [r_{k\backslash k-1}^i - \hat{y}_k^-][r_{k\backslash k-1}^i - \hat{y}_k^-]^T + R_k \tag{18}$$

$$P_{xy,k} = \sum_{i=0}^{2n} W_i^{(c)} [X_{k\backslash k-1}^i - \hat{X}_k^-][r_{k\backslash k-1}^i - \hat{y}_k^-]^T \tag{19}$$

$$K = P_{xy,k} P_{y,k}^{-1} \tag{20}$$

$$\hat{X}_k = \hat{X}_k^- + K(Y_k - \hat{Y}_k^-) \tag{21}$$

$$P_{x,k} = P_{x,k}^- - K P_{y,k} K^T \tag{22}$$

Combine PNGV battery model equation (3), (4), (5). the UKF calculation can be used in SOC estimation of nickel-metal hydride batteries.

Experiment and the result

In order to verify The feasibility and accuracy of SOC estimation of Unsvented Kalman Filtering arithmetic based on PNGV model to the energy management system of hybrid electric vehicle, in Laboratory, by using test data and MATLAB simulation, we get SOC estimated curve as shown in the fig 3. That shows it is efficient for Unsvented Kalman Filtering arithmetic to give an online SOC estimation on nickel metal hydride battery, and can calculate SOC data rather correctly.

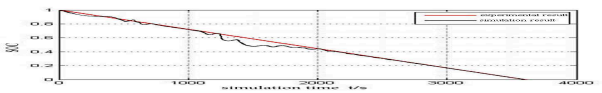

Fig.3 SOC estimation on PNGV model and UKF

Summary

This paper establishes two-dimensional state-space equations on the foundation of PNGV model, using UKF arithmetic which has two functions in non-linear filtering field to the SOC estimation of nickel metal hydride battery, and achieving good results. SOC error is within 6 percent.

However, temperature has a significant impact on characteristics of nickel metal hydride battery. PNGV model Parameter also has an evident change with temperature. So in BMS research, we must have a systematic consideration on the influence of temperature changes to battery model.

Stress Analysis and Measures Resistance to Deformation of Coal Pipeline Above Goaf

Guo KeYi

Tangshan Research Institute of coal science and Industry Group Co., Ltd.,Hebei, Tangshan,063012, China

email: tsjxgky@163.com

Keyword: coal pipeline; mining influence; force analysis; anti-deformation measure

Abstract. Based on one company's engineering of constructing underground coal pipeline above goaf, calculation analysis the influence of residual subsidence deformation and stress distribution of the coal pipeline engineering. The mining subsidence make the underground coal pipeline bearing not only the earth pressure of upper, lower and lateral, but also the result of the subsidence deformation include of vertical and horizontal in-plane bending moment. Based on this, put forward the anti-deformation technical measures to build new coal pipeline and provide scientific basis for anti-deformation design.

Basic situation

One company is planning to build the underground coal pipeline, the project covers an area of 229.09 mu, the north-south longitudinal length is 2.4 km. The cross-section of the coal pipeline is rectangular and section size is 3.9 * 2.5 m, the pipeline is all buried and is for cast-in-situ reinforced concrete structure. The amateur is in the range of the seventh coal mining belong to the PingMei group. The coal seam extracted by the seventh mine in the area has three sets of coal, WU,JI, GENG, extractive time is between 1961 to 2009, the total mining thickness is about 12.5 m, mining depth is 70 m~ 323 m, and dip Angle of coal seam is 8 ~ 10°. In addition, some small mining such as Hualian mining, Wenji mining and Xinhua mining have exploited for a long time in the nearby, Mainly exploited residual coal of JI and fault coal pillar. The area affected by faults and the small fold associated with faults, the coal seam is discontinuous across pitch and tendency, thickness change is big, coal seam is fragmentary, geological structure is relatively complex.

Condition of the surface deformation

To study the estimated surface subsidence deformation, the domestic and foreign experts put forward many methods. At present in our country the commonly used method in calculating the surface movement deformation include of probability integral method, the negative exponential function method, the Weibull function method and typical curve method. The probability integral method has the advantages of parameters are easy to determine and strong practicability, so it is widely used in the mining area and is the most commonly used method. The estimate of ground residual subsidence deformation is according to the probability integral method calculated the ground residual subsidence deformation along the longitudinal and transverse direction of the coal pipe. The selected parameters of predicting surface movement is shown in table 1.

Table 1 The selected parameters of subsidence technology

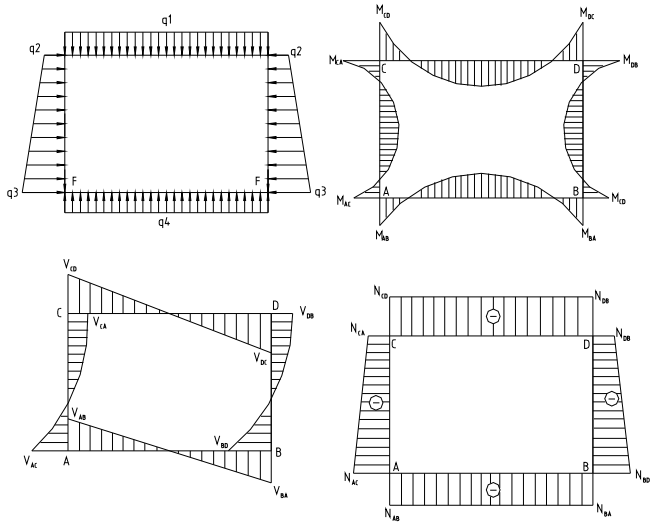
Subsidence coefficient, q	Horizontal transfer coefficient, b	the tangent of mainly affect ,tgβ	Mining influence transmission coefficient, k	Movement distance of inflection point, s/H
0.03 0.15	0.30	2.0	0.7	0.05

After calculation, can see that the maximum ground subsidence is 355 mmalong coal pipeline, the maximum deformation of slope is 5.0 mm/m along the longitudinal direction of coal pipeline, the maximum horizontal deformation is -2.1 mm/m, the maximum deformation of slope is 3.0

mm/m in transverse direction, the maximum horizontal deformation is 1.3 mm/m, so will be affected by mining Ⅱ level[1-2].

The structure stress analysis

Can know from past numerous domestic ground construction above mine mining area and the goaf, the new building above mined-out area will cause the activation of old mined-out area, the surface movement deformation will intensify. Combined with the project, under the influence of mining additional force, pipeline structure produces excessive deformation and failure. First of all, we make force analysis of the coal pipeline in the normal condition (not affected by the condition of mining underground). The pipeline bear except the uniformly distributed earth pressure, there are some tiny deformation caused by heat bilges cold shrink might be slightly friction with the soil and these basically are negligible. Based on the analysis of its stress distribution, underground coal pipeline mainly bear bending moment (M), shear force (V) and axial force (N), the stress distribution is showed in figure 1.



note:q- Uniformly distributed load,F-Concentrated load,M-Bending moment,V-Shear,N-Axial force

Fig.1 Coal piping stress analysis diagram regardless of the mining influence under the condition

Mining subsidence make underground building generating additional force mainly include three fields: First is the holding role generated by the relative motion of soil along the underground building surface caused by the earth's surface horizontal deformation, it will produce certain friction force and bending moment, make the structure failure or extrusion fracture; Followed by the earth's surface curvature distortion because of uneven subsidence, that will cause the underground building (structure) produce bending moment around a vertical in-plane, make underground building produce concentrated bending deformation and fracture; Again is the uneven level of mobile of the earth's along the transverse of underground building, that will make the underground building produce bending moment in the plane of the horizon and fracture damage [3-5].

Due to the project structure similar to surrounding rock of roadway, influenced by mining, surrounding rock stress becomes more complicated.In view of the coal pipeline cross-sectional area is not large, and the structure is simple, let's see a coal pipeline as linear geometric structure, For this structure, the main damaged deformation is the lateral deformation (tensile, compression).

Assume that underground coal pipe for a rigid rod, underground coal mining influence the overburden deformation pipeline soil shear, produce sliding friction, on the one hand can prevent soil movement, on the other hand make the coal pipe movement and deformation. Friction Fr is equal to the product of the positive pressure Fn and friction coefficient μ, that is

$$Fr=\mu Fn$$

Here in order to further simplify the force analysis, we do not consider the soil of different impact of friction coefficient and the effects of the whole channel in different depth of the underground coal, positive pressure Fn is the whole coal pipe load.

In general, regard he halfway point of the mining building as the center of gravity of the slip resistance, in this point the building movement with the soil completely, namely the relative displacement Vx is zero. Outside the scope, underground coal pipeline produce relative displacement between soil. These relative displacement make friction passing to the coal pipeline and generate additional strain. Add up the friction transmit to coal pipeline as elastic deformation force, its value increases gradually from center to the ends of buildings, as shown in figure 2.

The maximum friction force is: $Fr_{\max} = \frac{1}{2} Fr = \mu \bullet \frac{l}{2} q$

In the formula, q is uniformly distributed load generated by coal pipeline's weight.

Therefore, additional tension due to the friction increases along with the length L of coal pipeline on the direction of movement.

So, in constructing the coal underground pipelines affected by goaf, setting deformation joint to the entire coal pipeline to reduce length of the monomers is need.

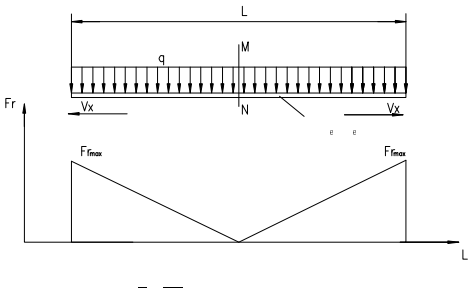


Figure 2 Coal piping stress analysis diagram consider of the mining influence under the condition

Anti-deformation protection technology

Due to underground coal pipe moves with the earth's surface (subsidence, inclination, horizontal movement), so the structural safeguard procedures applies simply to soil transformation of direct close to the mining coal pipe and additional stress transfer to coal pipeline.

The anti-deformation measures including flexible and rigid measures, Two kinds of measures can be used to prevent the destruction of the surface curvature and surface horizontal parallel effect. In general, in order to save money, the rigid of many building (structure) is not big, So when the earth's surface occur uneven movement, the building(structure) will produce deformation, And then only when the deformation exceeds a certain value, the building(structure) damage. Flexible measures allow the building(structure) to produce small deformation, in order to reduce the increased cost of rigid measures. Flexible measures generally include setting deformation joint, the excavation buffer groove, add foundation pad and sliding layer, etc.; Rigid measures generally includes as much as possible to adjust structure form and enlarging section and structure reinforcement of primary member such as foundation according to the deformation situation appropriately, etc. The new underground coal pipe is cast-in-place reinforced concrete structure, its anti-deformation technology measures including flexible measures, rigid measures and the combination of flexible measures and rigid measures, in order to make buildings can withstand different types of mining subsidence deformation without damage [6-7]. Based on past experience and calculation, the specific anti- deformation technical measures is as follows:

(1) Setting one deformation joint every 30 m, from base to top all apart, deformation joint's width is 70㎜, the body type of each monomer separated by the deformation should strive to simple.

(2) Setting sliding layer under the concrete foundation, practice: 100㎜ thick C15 concrete cushion, with cement mortar screeding, with two layers of linoleum. Compare to width of the base, 100㎜ more per side.

(3) make waterproof layer on all around and top of the outsid concrete wall' outside, make protective layer on waterproof layer and outside of the protective layer fill 200㎜ thickness of slag.

(4) increase coal pipeline' stiffness and the amount of reinforcement appropriately.

Measures of resistance to deformation is the precondition of building structural design, can refer to in the design of the new building measures of resistance to deformation and resistance to

deformation of concrete design still need to calculate according to the deformation of the concrete situation in detail.

Summary

1.The new coal pipeline engineering is a cast-in-place reinforced concrete structure and all buried, will undergo Ⅱ stage mining influence affected by the residual subsidence deformation of the seventh coal mining belong to the PingMei group.

2. The mining subsidence make the underground coal pipeline bearing not only the earth pressure of upper, lower and lateral, but also the result of the subsidence deformation include of vertical and horizontal in-plane bending moment.

3.Through comprehensive analysis of underground mining influence and stress distribution of coal pipeline, put forward the scientific and reasonable anti-deformation technical measures, providing basis for anti-deformation design.

Stress intensity factors for high aspect ratio semi-elliptical external surface cracks in cylindrical vessels

QI Hong-yu[1,2,a], GUO Peng-chao[1,b]

[1]School of Energy and Power Engineering, Beihang University, Beijing 100191, China;

[2]Collaborative Innovation Center of Advanced Aero-Engine, Beijing 100191, China;

Keywords: Aspect ratio; External longitudinal crack; Influence coefficient; Stress-intensity factors (SIFs).

Abstract. External surface cracks can occur in cylindrical vessels due to damage and propagate in the manufacturing process and during service life. Most of research focuses on stress intensity factors for surface cracks with low aspect ratios, i.e., a/c ≤1.0. Situation may well arise where the aspect ratio of cracks is larger than one. An external longitudinal surface crack is assumed to be subjected to different types of hoop stress distributions acting perpendicular to the crack faces. The stress intensity factors (SIFs) along the crack front were determined through the three-dimensional finite element method. Then these results are used to compute approximate values of SIFs in the case of complex loadings by employing both the superposition principle and the power series expansions of the actual hoop stresses. It is found that the maximum stress intensity factor for external surface cracks with high aspect ratio occurs at different point to that with low aspect ratio.

Introduction

Cylindrical vessels are widely used as pressure vessels in infrastructure engineering, for example, in the power plant and chemical industries and in the manufacturing process and during service life, semi-elliptical surface cracks may initiate on internal or external surface. These cracks can extend quickly under applied loads which may cause catastrophic failure. Therefore,accurate stress intensity factors (SIFs) for such elastic surface cracks are necessary for reliable prediction of fatigue crack growth rates of pressure vessels.

Lots of efforts has been devoted to the calculation of SIFs for the semi-elliptical surface cracks. Despite of the accuracy, analytical solutions are complex and only applicable to some simple crack configurations and boundary conditions [1]. To avoid this limitation, numerical solutions have proved to be an effective approach.Newman and Raju[2] used 3-dimensional finite-element methods （FEM）to calculate stress intensity factors for semi-elliptical surface cracks as well as Roberto Brighenti[3]. Bueckner HF [4,5]used weight function method to obtain the SIFs. Others numerical methods also have been used, boundary element method (BEM) [6, 7], and element-free method [8].

However,much focus has been (see references above) on SIFs for semi-elliptical surface cracks with aspect ratio a/c≤1. Kou and Burdekin [9] used finite element method to calculate SIFs with high aspect ratio up to 2.0 for circumferential semi-elliptical surface cracks but not longitudinal cracks. C.Q. Li and S.T. Yang[10] obtained the SIFs of longitudinal internal cracks with the aspect ratio a/c ≥1 but not the external cracks. External surface cracks can occur in cylindrical vessels due to damage and propagate, for instance, by fatigue.

The present study is to calculate the SIFs for cylindrical vessels with high aspect ratio semielliptical longitudinal external surface cracks and subjected to internal pressure (Fig.1)

Loading Conditions

Based on the principle of superposition[2], for a cylinder with an external surface crack, the stress induced by the internal pressure P_I is equal to that caused by the hoop stress P_a produced by the

internal pressure acting on the crack surface plus the stress produced by the internal pressure acting on the intact cylinder

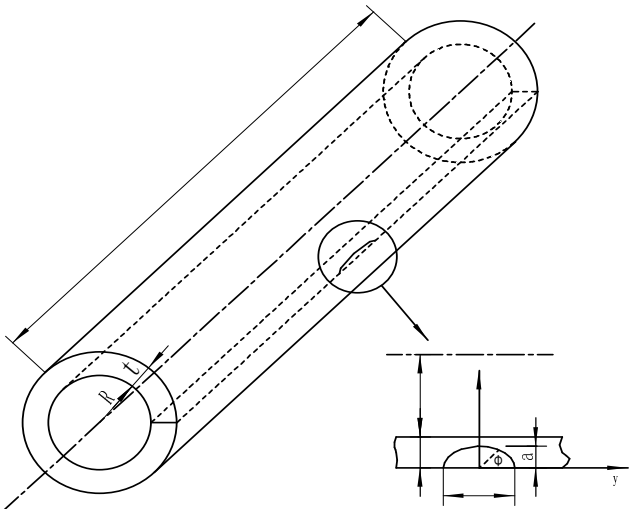

Fig.1 External longitudinal flaw in a cylinder

Such a principle can be used together with the Tylor-expand principle. The cylinder is subject to a load (p) which is applied to the surface crack with five different types of distribution, defined in a local coordinate system as shown in Fig.1 along the thickness direction (x direction). These five loading distributions are constant, linear, quadratic, cubic and quartic and can be expressed as follows:

$$p=(\frac{x}{a})^n \tag{1}$$

where n is equal to 0,1, 2,3 or 4 representing five types of load distribution. For any arbitrary load distribution at the crack face p_a, it can approximately be represented by a fourth order polynomial according to Tylor-expand principle as follows:

$$p_a=\sum_{n=0}^{4} Y_n(\frac{x}{a})^n \tag{2}$$

where $Y_n$is the coefficients that determine the form of the polynomial and will be derived in the next section. The dimensionless Mode I stress-intensity factor for the *n*th stress distribution is calculated as follows:

$$K^*_{I(n)}=\frac{K_{I(n)}}{\sigma_{ref}\sqrt{\pi a/Q}} \tag{3}$$

where $K^*_{I(n)}$ is referred to as the influence coefficient and $K_{I(n)}$ is the stress intensity factor for each given loading case p (n = 0,1, 2 ,3 or 4). σ_{ref}represents the reference stress, i.e., $\sigma_{ref}=1$.

$$Q = 1 + 1.464(\frac{a}{c})^{1.65} \text{ for } a/c\leqslant 1 \tag{4a}$$

$$Q = [1 + 1.464\left(\frac{a}{c}\right)^{1.65}](\frac{a}{c})^2 \text{ for } a/c>1 \tag{4b}$$

The given loading case p (Eq.(1)) can be replaced by an arbitrary p_a (Eq.(2)) by multiplying the term$\sum_{n=0}^{4} Y_n$. With the principle of superposition the stress intensity factor under the arbitrary load p_a, should be $\sum_{n=0}^{4} Y_n K_{I(n)}$ which can be expanded by substituting $K^*_{I(n)}$(Eq. (3)) for $K_{I(n)}$ as follows:

$$K_I=\sum_{n=0}^{4} Y_n K_{I(n)} =\sum_{n=0}^{4} Y_n K^*_{I(n)}\ \sigma_{ref}\sqrt{\pi a/Q}=$$

$$\sqrt{\frac{\pi a}{Q}}\,(Y_0K^*_{I(0)}+Y_{10}K^*_{I(1)}+Y_2K^*_{I(2)}+Y_3K^*_{I(3)}+Y_4K^*_{I(4)}) \qquad (\sigma_{ref}=1) \tag{5}$$

Application of internal pressure

Most cylinders are subjected to internal pressures.Acorrding to the above depiction, the cylinder is subjected to internal pressures P_I, then [11]

$$p_a=\frac{P_I R^2}{(R+t)^2-R^2}(\frac{(R+t)^2}{(R-x)^2}+1) \tag{6}$$

By the Tylor-expand P_I can be expanded at x=0 as follows:

$$p_a=f(x)=\sum_{n=0}^{4}\frac{x^n}{n!}f^{(n)}(0)^n$$
$$=\frac{P_I R^2}{(R+t)^2-R^2}\left(2+\frac{2}{R+t}x+\frac{3}{(R+t)^2}x^2+\frac{4}{(R+t)^3}x^3+\frac{5}{(R+t)^4}x^4\right) \quad (7)$$

Since the stress distribution is in the form of $(\frac{x}{a})^n$, (n=0, 1, 2, 3, or4), p_a can be written as

$$p_a=f(x)=\frac{P_I R^2}{(R+t)^2-R^2}\left(2+\frac{2a}{R+t}\frac{x}{a}+\frac{3a^2}{(R+t)^2}\frac{x^2}{a^2}+\frac{4a^3}{(R+t)^3}\frac{x^3}{a^3}+\frac{5a^4}{(R+t)^4}\frac{x^4}{a^4}\right) \quad (8)$$

Denoting Y_n for the coefficients in Eq. (8), then

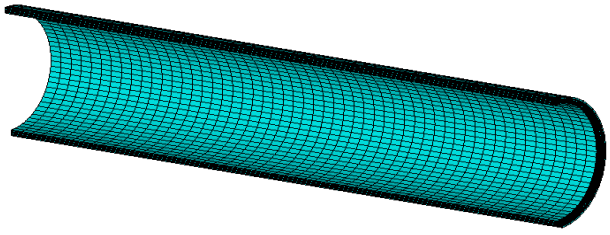
$Y_0=\frac{2P_I R^2}{(R+t)^2-R^2}$, $Y_1=\frac{2aP_I R^2}{(R+t)a[(R+t)^2-R^2]}$, $Y_3=\frac{4a^3P_I R^2}{(R+t)^3a^3[(R+t)^2-R^2]}$, $Y_4=\frac{5a^4P_I R^2}{(R+t)^4a^4[(R+t)^2-R^2]}$

Numerical Analysis

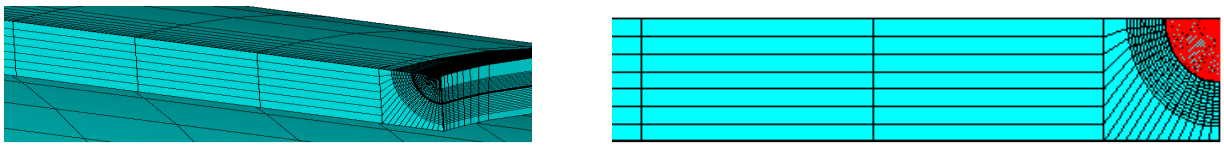
As discussed above the key obtain the stress intensity factor is to determine the influence coefficients$K^*_{I(n)}$. Before working out the influence coefficients for, it is necessary to verify the 3D finite element method proposed above. A finite element model with a quarter of cracked cylinder is used to analyze the SIFs under each of the five elementary stresses because of the symmetry (Fig.2). In the 3D FEA, wedge finite elements are created by collapsing one side of each brick element near the crack front; the mid-side nodes of the wedge elements are shifted to quarter-point positions to model the theoretical square root singularity of the stresses and strains. The quarter cylinder was then carefully partitioned with the purpose of creating desired mesh around the crack front. The influence coefficients are determined under each stress distribution respectively based on Eq. (3). The results of the influence coefficients are presented in Table 1 together with those of Raju and Newman [2]. The difference between the two for most results is within 3.0% with the maximum difference less than 6.0%.The comparison suggests that the proposed 3D FE model and method as accurate as those of Raju and Newman [2].

With the proposed 3D FE method verified, the influence coefficients for high aspect ratio semi-elliptical surface crack (a/c=1.2 or 1.5) in a cylindrical vessel subjected to constant, linear, quadratic ,cubic or quartic stress distributions have been calculated using ANSYS software. As discussed above, there are many geometric and loading factors that affect the stress intensity factor K_I among which are: a/t, a/c, t/R. And the K_I varies along the crack front. In the 3D FEA, the influence coefficients were calculated on the crack front of the elements as determined by the angle ϕ.

As shown in Fig.3-6 ,influence coefficients distribution along the crack front in terms of the angle ϕ for various values of a/c, a/t and t/R. As can be seen the influence coefficients K^*_n at the same points on the crack front considerably vary with the different type of load distribution. For example, in Fig.3,at the surface point, $\phi=0$, the influence coefficient of constant load distribution is about 52 times that of quartic load distribution. Moreover, not only the magnitude of the influence coefficient is affected by load distributions, but also the trend along the crack front is different. As can be seen in Fig.3-6, under the constant load distribution the influence coefficients mainly decrease from the surface point($\phi=0$) to the deepest point($\phi=\pi/2$).However, under the other four load distributions the influence coefficients increase from the surface point($\phi=0$) to the deepest point($\phi=\pi/2$).



a FE model of a quarter of the cylinder



b the crack face **c** the distribution of load on crack face (in red)

Fig.2 Finite element model for the cylinder

On the other hand, the ratio of wall thickness to the radius of the cylinder vessel t/R almost have no effect on influence coefficient at present study. As can be compared Fig.5 and Fig.6 with the same condition other than t/R, when the t/R from 0.1 to 0.25,the difference between the two value of influence coefficient is within 1%. However, it is found that the higher the aspect ratio of cracks the larger the stress intensity factors at the surface point when compared Fig.3 with Fig.5.

According to the Eq. (5), the SIFs of the crack front from the surface point ($\phi=0$) to the deepest point ($\phi=\pi/2$) can be obtained with the cylinder subjected to internal pressure p_I through the 3D FE model. The K_n has been shown in Fig.7, which define the p_I equal to 1, with the different of a/c.

From above results it has been shown that, the maximum stress intensity factor can occur at the deepest point ($\phi=\pi/2$) of the crack front for cracks with low aspect ratio while it may occur at the surface point ($\phi=0$) when the crack has high aspect ratio. Therefore, aspect ratio of the crack may cause different modes of failure for the cylinder vessels. These results vindicate the need for further research on cylinders with semi-elliptical surface crack for high aspect ratio (a/c＞1) even though almost all current research focuses on low aspect ratio (a/c≤1).

Conclusions

The stress intensity factors of high aspect ratio semi-elliptical longitudinal external surface cracks in metallic cylindrical vessels have been examined through employing a three-dimensional finite element model. It has been found that the maximum stress intensity factor for external surface cracks with high aspect ratio occurs at different point to that with low aspect ratio and hence may lead to different modes of failure. It has also been found that the type of loading is the most significant factor that affects the stress intensity factor. It can be concluded that the method presented in the paper can be used to determine the stress intensity factors for cylindrical vessels with surface cracks of a large range of aspect ratios. This will enable more accurate prediction of crack growth rate and shape parameter of cylindrical vessels with various longitudinal semi-elliptical surface cracks.

Keywords: Impact perforation; Pipe string ; Dynamic response; Finite element analysis

Abstract. Impact load of perforation will result in strong vibration of downhole string, string operated such as bending fracture accidents. Considering the clearance between string and casing, using space beam and spring element to solve the nonlinear contact problems between oil jacket, established the numerical model of string structure dynamic response analysis in horizontal well. Extracting downhole perforation pressure wave monitoring data, using the finite element software ANSYS, analyzed the dynamic response of the tubing under perforation of detonation shock wave impact, got the displacement of the tubing, acceleration time history. The results show that, without packer, the maximum Mises equivalent stress in the end of the string, the deformation and stress changes in deflecting section of the tubing string are bigger than in vertical Wells.

Introduction

Perforation completion is adopted widely in oilfield, The enormous detonation wave generated When perforating gun firing is released within the wellbore. This part of the detonation wave will push string strong shock vibration[1,2] upwards,may cause tubing string bend, fracture etc. Due to the horizontal well string thousands of meters long, it is very difficult to solve the process of string dynamics when perforating with analytical method . a lot of simplification is needed for the model, even without a lot of simplification can't get analytical solutions[3,4] . But this kind of problem can be solved by the finite element method,even without simplification, only need to establish a correct finite element model. This paper, using finite element method of transient dynamic problems, theoretical studied the perforating tubing string vibration problem in horizontal well.

The transient dynamics fundamental equations

The basic equation of transient dynamics analysis is:

$$[M]\{\ddot{u}\}+[C]\{\dot{u}\}+[K]\{u\}=\{F(t)\} \quad (1)$$

Where:

$[M]$=mass matrix

$[C]$=damping matrix

$[C]$=stiffness matrix

$\{\ddot{u}\}$=acceleration vector of the node

$\{\dot{u}\}$=velocity vector of the node

$\{u\}$=displacement vector of the node

At any given time t, these equations can be considered as a series of the static equilibrium equations ,which considering the inertial force and damping force.

String structure dynamic model

Select the entire string as the research object, the initial position of the string and borehole axis is a coincidence. String in the wellbore distorted under a variety of load combination such as gravity, buoyancy force, internal and external pressure, perforating impact etc,and multidirectional random contact with the inner wall of the casing will happen.

Because considering the initial clearance of the string and casing , the contact problem of string and casing is a random contact nonlinear mechanics problem, the calculation method has the certain difficulty and complexity. Each beam element string can list a unit balance equation, all the balance equation after coordinate transformation and assembled unit, the whole string of overall balance equation is obtained:

$$\{K\}\{u\} = \{P\} \tag{2}$$

Where:

$\{K\}$=global stiffness matrix

$\{u\}$=the overall displacement vector

$\{P\}$=the overall load vector

with the balance equation of beam element and spring element equilibrium equation are combined after assembling, string contact nonlinear problem of overall balance equation is obtained as follows:

$$\{K + K_T\}\{u\} = \{P\} \tag{3}$$

Where:

$\{K_T\}$=the whole stiffness matrix for all the spring element after conversion to assemble

A large number of numerical examples show that when perforating the longitudinal vibration load produced by the tubing string is much higher than on the tubing string lateral load. That is to say longitudinal vibration (axial) plays a main role[5,6], therefore the model only need apply the longitudinal vibration impact load in the end of the perforation .

Analysis of examples

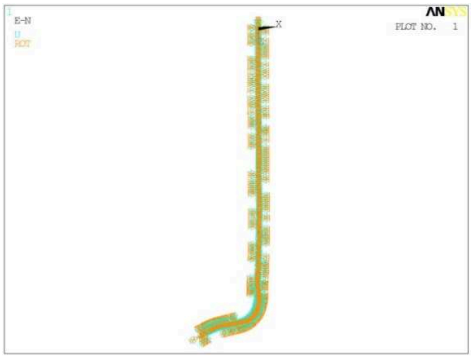
The finite element model

For example , the string in a perforation completion horizontal well, according to the survey data, established the whole interval finite element analysis model . Among them, the column diameter is 73 mm, inner diameter is 62 mm, the material is N80 steel, the density is 7846 kg/m3, poisson's ratio is 0.3, the elastic modulus is 206 GPa, yield limit is 564 mpa and shear modulus is 79.4 GPa.

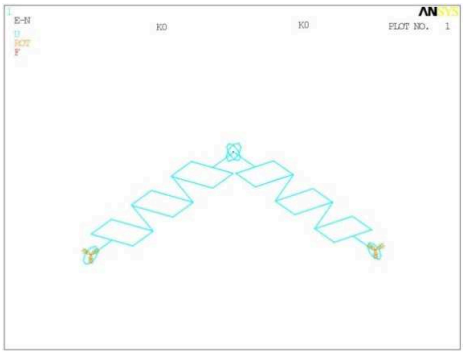
Use Beam4 and Combination14 unit established the string structure finite element model as shown in figure 1.

The boundary conditions

Imposing fixed constraints in the location of the well head, using coordinate system in the other nodes of the column, imposing the constraint of double spring element along the radial and axial direction of the column, even at the end of the spring on the column node, the other end is fixed.



(a) whole



(b) a node applied two-way spring

Figure 1.String finite element model

Column loads

Through pressure monitor we gather the distribution of wellbore pressure, and extract the data as the dynamic load of the column structure.

The simplified perforation detonation wave load as shown in figure 2, the figure shows that the longitudinal impact load increases rapidly firstly , and then fail to a certain value ,lastly flunctuate around it during the process of blasting. Lengthwise perforation impact load as shown in figure 2 is imposed to the end of horizontal pipe column.

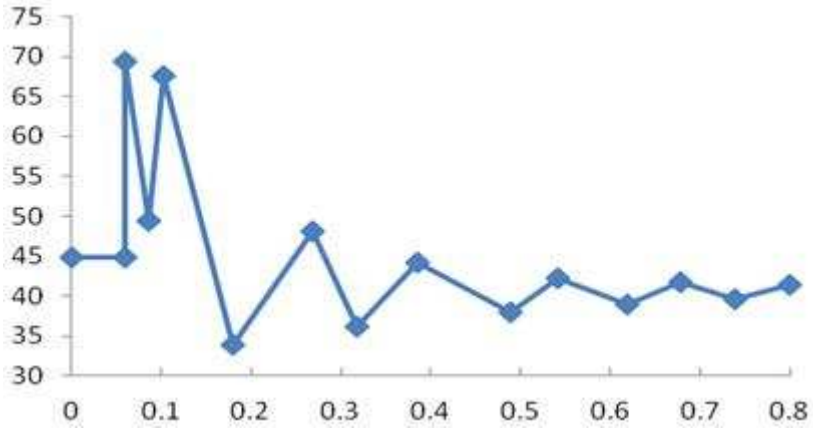


Figure 2.Perforating impact load curve

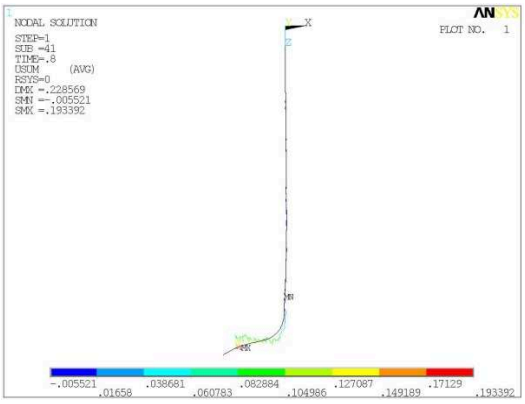
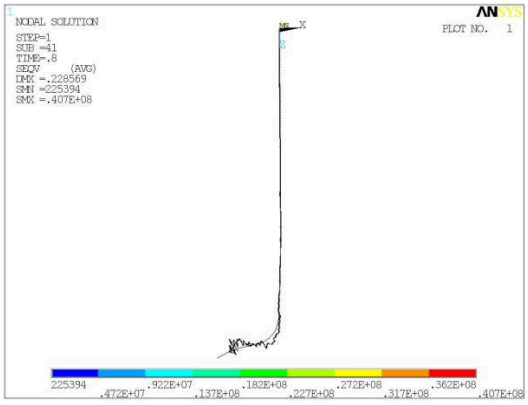
Analysis of the results

Through the numerical analysis of dynamic response of the column under the action of detonation wave by the finite element software ANASYS, we obtain the deformation and stress contours of the whole model as shown in figure 3.



(a) Model displacement nephogram



(b) Model stress nephogram

Figure 3.String structure dynamic response

By the figure, we know the maximum displacement of column node is about 0.229m, located NO.268 node, and deformation of tubing string on the deflecting section are much larger than on the vertical section. The maximum Mises stress is 40.7MP, located at the end of the column; the minimum value is 0.225MP, in the tube end of the mouth of the well.

Extract the result data of node 278, and analysis the column longitudinal vibration displacement, velocity and the time history of acceleration as shown in figure 4, 5 after perforating. As shown in the figure 2, under the action of perforation impact load, node 278 longitudinal displacement trend along with the change of time and impact load are of a similar change trend, which is rapidly increasing first, then the attenuation, the maximum value is about 0.3m. Without considering damping, the biggest vibration velocity of the column is about 2.08m/s.

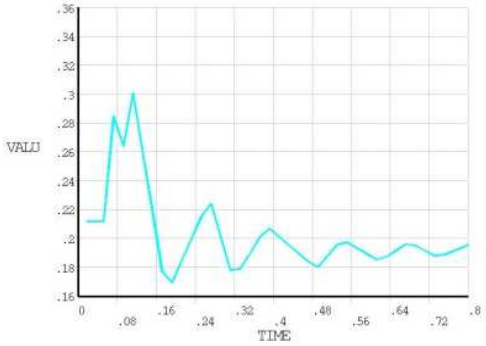


Figure 4.Displacement-Time curve

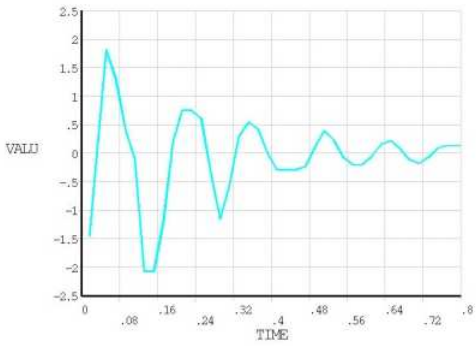

Figure 5.Speed-Time curve

Conclusions

(1)By the clearance between column and casing, the introduction of spring element model, finite element dynamic model of horizontal well tubing string, we can easily carry out the perforating dynamic analysis on the tubing column.

(2)In order to analysis the vibration mechanics problems of tubing string under the action of impact load accurately and reasonably, first we must accurately measure the relations that the perforating shock wave change along with the time, and effect on the tubing string as the transient initial dynamic load of the tubing string finite element dynamic analysis.

(3)Without arrangement of the packer, the maximum Mises equivalent stress occurred in the end of the tubing string, the stress and deformation of tubing string on the deflecting section are much larger than on the vertical section under the effect of perforating impact load.

Keywords: adsorption bed; typical weather conditions; desorption temperature

Abstract. In this paper, the desorption temperature of adsorption bed in typical weather condition is studied though the solar adsorption refrigeration experiment with conditions of different weather. The results showed that: the better the weather condition is, the higher the highest temperature of the adsorption bed is, so the better the effect of desorption is. No matter in cloudless sunny or partly cloudy sunny conditions, the desorption temperature of adsorption bed can reach 93.4℃, and the amount of desorption also will be larger; however, in cloudy weather conditions, desorption temperature can reach 88.5℃, and desorption quantity is relatively fewer than it in cloudless sunny days.

Introduction

The solar energy refrigeration way mainly includes the solar energy light hot refrigeration and the solar energy photoelectricity refrigeration. The photoelectricity refrigeration is mainly photovoltaic refrigerator; the light hot refrigeration mainly has adsorption type, absorption type, the jet type, dehumidification type, etc. Adsorption refrigeration has the advantages of a simple structure, low operating cost, the long lifetime and thermal coefficient of performance (COP) higher, etc. Therefore, the adsorption refrigeration technology is widely concerned by refrigeration field [1].

Adsorption refrigeration as a environment-friendly refrigeration way, many domestic and foreign scholars have done a lot of research from theory and experiment: Y. Zhong [2-3] study on the isothermal adsorption characteristics of barium chloride. He pointed out that the barium chloride - ammonia working pairs can be used for air conditioning and refrigeration. For the air conditioning performance, when the cooling temperature is 35℃ and refrigeration temperature is 15 ℃, system COP as high as 0.6. Shanghai Jiao tong University, Y.Z. Lu [4] applies thezeolite molecular sieve - water adsorption refrigeration in the locomotive air conditioning. The research indicated the zeolite molecular sieve - water working pairs has the very high cold storage capacity and 1 kg zeolite molecular sieve stores cold up to 600 kJ. D.M. Li[5] established a Thermodynamic calculation model of the adsorbent bed, which take into account the interactions in absorption bed temperature, pressure and the quality. By using the numerical calculation method give a reasonable explanation of equation in solar energy radiation intensity change, for further analysis of dynamic characteristics in adsorption bed laid a foundation. To reduce the adsorption bed thermal resistance, D.S. Zhu[6] has carried on the experimental study of adsorption bed and adsorbent (Polyaniline) particles on the surface of the contact thermal resistance. He analyzed the influence on the contact surface coated with conductive gel and pressurizing method on thermal contact resistance. The experiments show that this method can effectively reduce the contact heat resistance, and no influence on the mass transfer process in the adsorbent bed of adsorbent.

The weather conditions has important effect on the performance of adsorption bed, but there is still no mature theoretical analysis [7-8], and also lack of corresponding experimental research. Therefore, this paper mainly experimental research and analysis from the influence of weather condtions on the desorption temperature of adsorption bed, and provides a theoretical basis for the application of adsorption refrigeration technology.

Solar adsorption refrigeration principle

Solar adsorption refrigeration system is mainly composed of adsorbent bed, condenser, evaporator and valve, etc. As shown in Figure 1. The adsorption bed temperature increased after absorbed solar energy. When it reaches the temperature of refrigerant desorption, the refrigerant desorbed from the adsorbent. Refrigerant vapor desorbed by condenser into liquid, and stored in the evaporator. The temperature and pressure of adsorption bed decreases in the night. Desorption of refrigerant vapors in the daytime again by adsorbents. Thus the refrigerant in the evaporator evaporation heat generated cooling, in order for the refrigeration cycle [9].

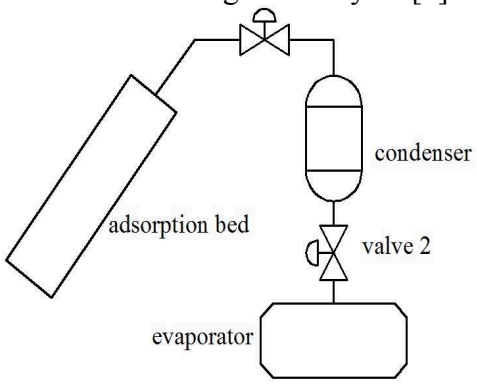

Fig. 1 Principle of adsorption refrigeration system

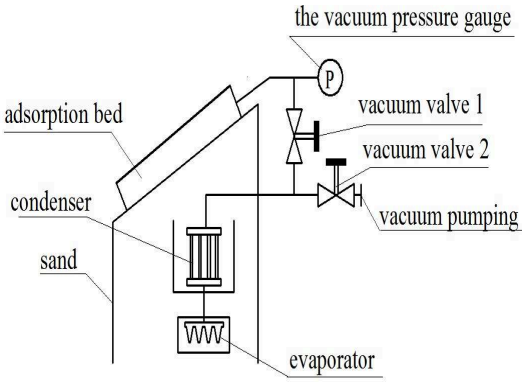

Fig. 2 Schematic diagram of adsorption refrigeration experiment

Experimental study of typical weather conditions on adsorption desorption temperature

The experiment adopts the integral fin tube as the adsorption collector bed, the effective heat collecting area of 1.5 square meters, and uses the multi tube adsorption structure of adsorbent bed and with valve control solar adsorption cooling system [10]. Refrigeration working pairs using Active carbon-methanol. Adsorption refrigeration system experiment schematic diagram is shown in Figure 2.

The effect of typical weather conditions on the temperature change of the adsorption bed

In order to accurate illustrate the effects of typical weather conditions on the desorption temperature of adsorption bed, this paper makes some research on solar adsorption refrigeration experiment under the cloudless sunny, partly clouds in the sunny, cloudy with strong solar radiation and cloudy with weak solar radiation environments, and analyses the temperature changes of adsorption bed in four typical weather conditions. The curves of temperature of adsorption bed and solar radiation under the four typical weather conditions are shown in Figure 3.

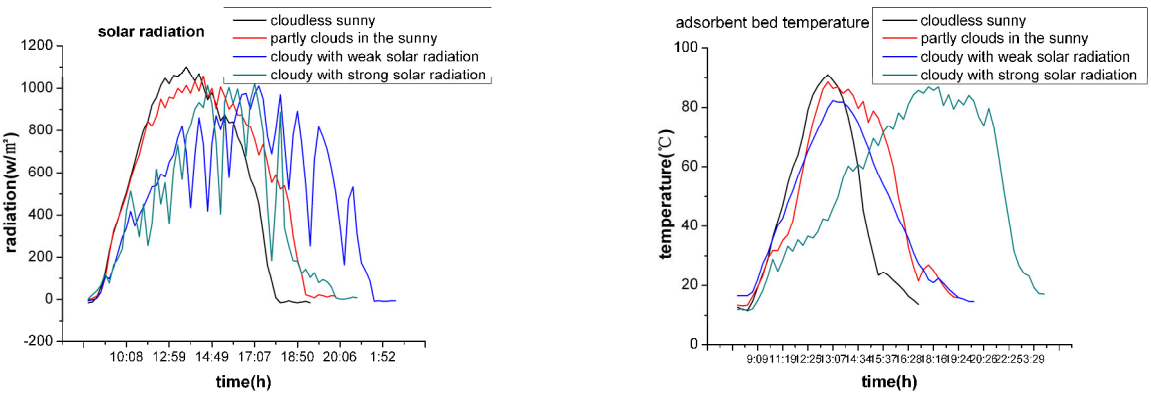

Figure.3 The curves of the temperature of adsorption bed and solar radiation

Analysis of Figure 3 indicate that the temperature of adsorbent bed mainly depends on the weather conditions. In the heating stage, the adsorption bed received solar radiation, the temperature of

adsorption bed begin to rise gently until the temperature rises to the highest point, then the temperature of adsorption bed maintains stably. In the heating stage, adsorption bed is mainly used for desorption of methanol in adsorbent. During the cooling stage, closed the valve, and the temperature of adsorption bed begins to decline until the temperature of adsorption bed tends to be stable. Then opened the valve, the pressure of adsorption bed is reduced. However, the temperature of adsorption bed will rise owing to releasing the adsorption heat that it is generated from the evaporation of methanol in evaporator. Eventually, adsorption equilibrium and adsorption bed temperature tend to be stable.

In cloudless sunny weather, the temperature of adsorption bed rises the fastest and the temperature curve is smooth. There was no significant fluctuation in temperature; in partly clouds in the sunny weather, the temperature of adsorption bed appears small fluctuations and the curves of temperature have concaves; in cloudy with strong solar radiation weather, clouds cover a long time, the temperature of adsorption bed change scope is big, and the curves of temperature has a lot of concaves; in the three kinds of weather conditions which given above, the temperature of adsorption bed in high temperature (greater than 80℃) time is greater than 3 hours, and the effect of desorption is better. In cloudy with weak solar radiation, temperature's variation of the adsorption bed is not obvious, whereas the temperature of adsorption bed maintains at above 80 ℃ less than 2 hours, and the function of desorption is poor.

The effect of typical weather conditions on the maximum desorption temperature of adsorption bed

In order to further illustrate the influence of typical weather conditions on the desorption temperature of adsorption bed, this paper studies on the highest temperature of adsorption bed. Then it compares and analysis the highest temperature of adsorption bed under the cloudless sunny day, partly clouds in the sunny and cloudy with strong solar radiation environments. Experimental data is shown in Figure 4.

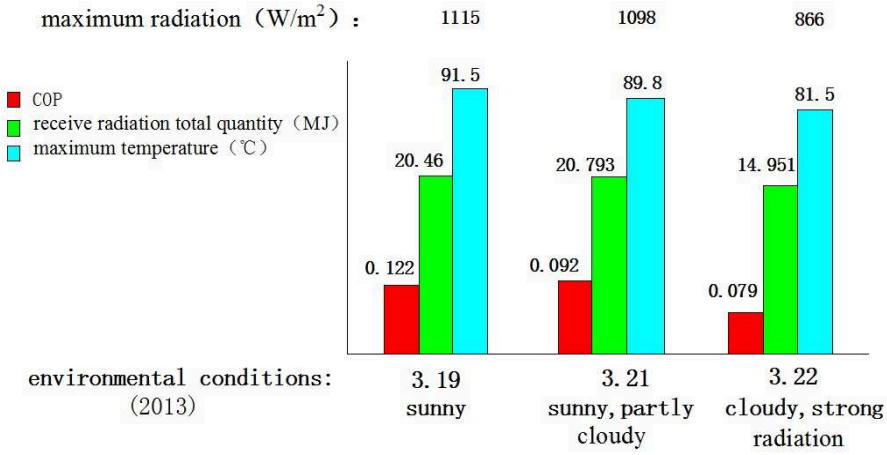

Figure.4 Typical weather conditions and the highest temperature of adsorption bed

Compared the cloudless sunny and partly clouds in the sunny weather, although the total amount of radiation received by adsorption bed in partly clouds in the sunny weather more than that in the cloudless sunny weather, however the largest amount of radiation received by adsorption bed in cloudless sunny weather is 1115 W/㎡, and it is 1098 W/㎡ in partly clouds in the sunny weather. So the highest temperature of adsorption bed in the cloudless sunny weather is 1.7℃ higher than it in partly clouds in the sunny weather. In addition, the COP is also greater than it in partly clouds in the sunny weather. The total solar radiation and the maximum amount of radiation received by adsorption bed in partly clouds in the sunny weather is greater than those in cloudy with strong radiation weather. Therefore, the maximum temperature of adsorption bed is 8.3 ℃ higher than it in cloudy with strong radiation weather. Through the above analyses, the maximum temperature of adsorption bed has very significant relation with weather conditions. The better the weather conditions are, the higher the

highest desorption temperature of adsorption bed is, and the adsorption refrigeration system has a high cooling efficiency.

Summary

In this paper, the desorption temperature of adsorption bed under typical weather conditions are studied though the solar adsorption refrigeration experiment and then drawing the following conclusions:

(1)The temperature of adsorbent bed mainly depends on the weather conditions, the better the weather conditions are , the higher the highest desorption temperature of adsorption bed is. So this state is advantageous to the adsorbent desorption and the adsorption refrigeration system has a high cooling efficiency.

(2)In cloudless weather, temperature of adsorption bed almost has no fluctuations, it maintains at high temperature for long periods of time. Hence, this state is advantageous to the adsorbent desorption; In partly clouds in the sunny, cloudy with strong solar radiation weather, the adsorbent desorption efficiency is not good; Meanwhile, in cloudy with weak solar radiation weather, the variation range of adsorption bed temperature is not obvious, and the temperature maintains at high temperature for a short time. So the adsorbent desorption condition is poor, and it has less contribution to the refrigeration system. The progress of research on new adsorbent bed

Keywords: Ruled surface blade; Deformation; Finite element simulation

Abstract. Integral impeller is the key component in aviation, aerospace and other fields, and the deformation has an important effect to the machining quality and precision of the integral impeller. Because of the complexity of the geometry and surface curvature changes for the integral impeller, and the semi suspended state during the processing, force analysis and control technology for the deformation have become the key and difficulty to realize high quality processing. In this paper, the situation about the blade machining with the finite element analysis is introduced, and the factors about the blade machining deformation is also summarized. The deformation of a single cutter location point are computed and analyzed with finite element method, and the application problems to the machining deformation with the finite element are presented.

Introduction

Impeller parts are the typical and representative parts with complex surfaces. The processing precision and quality directly determine the effectiveness of the related mechanical equipment. It is still a research spot on the tool path planning and processing technology in the field of numerical control machining for high speed and stable impeller parts. It is easy to make a deformation during blade machining, which causes the errors of parts dimension and leaf thickness non-uniformity. On the other hand, it will have a complex stress and large vibration amplitude for the blade surface during the work processing. In order to improve the efficiency of product processing, it usually works in the milling deformation limit state for the machine systems and the cutting process. Therefore, the analysis of deformation of the impeller machining process is directly related to the processing quality of impeller and its working performance in the future.

Before the work-pieces are machined, it can make a good preparation for the thin walled work-piece milling if the model is analyzed with finite element, which can know about the parameters, such as stress changes, temperature changes and yield limit. Compared to the traditional experimental methods, the finite element simulation for the surface quality analysis, tools' design, process selection and so on, can save more time. The most important is the mechanical and physical properties can be obtained from the finite element simulation results. However, it is difficult to achieve the result with the traditional experiment.

Thin blade machining situation with finite element

At present, the research direction about the finite element model can be divided into two types: only considering the work-piece deformation and considering both the work-piece and the tools deformation. Wang Zhigang [1] analyzed the milling processing deformation of Aeronautical thin-wall box parts by the finite element software, which was under the assumption that the tool was a rigid body and the feedback effect of deformation was ignored. Ratchev [2] established the surface error prediction model of the thin-walled parts round side milling using the finite element software ABAQUS. A flexible prediction model was established which included the work-piece deformation and surface error with the changes of entry angle and exit angle [3].

Kline [4] studied the milling deformation model of a rectangular thin plate. Budak [5] confirmed the instantaneous un-deformed chip thickness converged to the nominal value in the static milling

process. So only the correction value of radial cutting depth is considered, but the correction value of the instantaneous un-deformed chip thickness isn't considered during considering the deformation coupling model of the tool and work-piece deformation. The iterative algorithm would be used to analyze the coupling effects between tool and work-piece deformation and the material removal effect in the processing. Budak [6] established a tool model by using the equivalent cylindrical cantilever beam unit along the axial length. On this basis, Wan Min [7] proposed a method to discrete the structure with irregular finite element grids, which provides a general method for complex parts to discrete the grid. In addition, Zhang Zhihai [8] established a model to predict the work-piece surface error in the end milling, which considered the relationship between the milling force / torque and instantaneous un-deformed chip thickness. The deformations of the tool, work-piece and machine tools and other factors were considered in this model, but the coupling effect between the tool deformation and work-piece deformation were not considered.

At present, it is not perfect in the field of thin-walled components machining deformation by finite element analysis, but it was able to simulate the relationships among different parameters. In the model of only considering the deformation of the work-piece, it cannot reflect the characteristics of periodic fluctuation in milling processing and the distribution law of milling force along the direction of the cutting edge, and has a certain effect on the deformation prediction accuracy, because the applied milling force is the average values according to the empirical formula. In the model of considering both the deformation of the work-piece and cutter, although the deformation factors including the tool and work-piece and machine are considered, but the coupling effects of the tool and work-piece deformation are ignored, so it must have some influences on the machining simulation precision.

Deformation analysis of the blade machining

The deformation caused by the low stiffness is very important in milling thin-walled components, because it is related to the thin-walled components machining quality and precision. The elastic deformation for the thin blade will be generated due to the effects of the force. The impeller blades' deformation can not be ignored because it is in the semi suspended state during the processing, which is shown as Fig. 1. Generated parts size errors and leaf thickness non-uniformity errors will directly influence the overall performance of the impeller. However, it will be an effective method for machining the integral impeller to reduce the machining deformation by adjusting the radial depth parameters, after analysis the deformation of blade, and calculating the final deformation of thin-walled blades with the iterative algorithm.

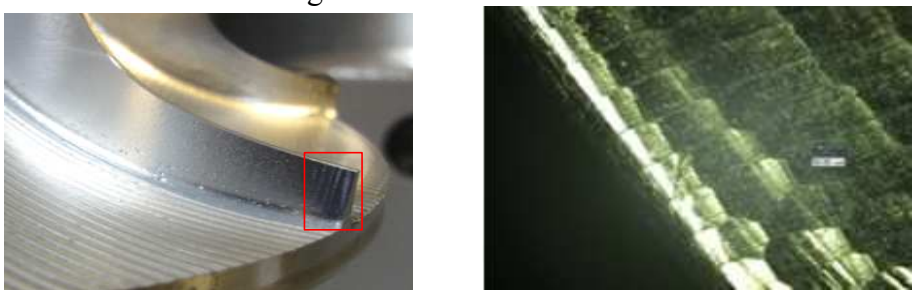

Fig. 1 High speed milling blade surface morphology

The deformation of the blade will be analyzed by ANSYS, and the studied blade machining deformation is decomposed into two directions, including the normal direction and the tangent direction. The deformation along the normal direction mainly inflects the effects on processing parameters with the work-piece deformation, while the tangential direction mainly inflects the effects on the compression tension deformation for blade. Deformation of materials in actual processing is often negligible, and blade deformation is mainly elastic deformation along the normal direction.

In the cutting process of single blade, it will have an elastic deformation generated by milling force to cause the changes of radial cutting depth. At the same time, the new milling force will generate a new deformation. It actually means the work-piece deformation has a feedback effect on

machining parameters. So it leads the radial cut depth becomes small by deformation with the milling force, and then it will make the cutting force become smaller. The smaller cutting force will generate a smaller deformation, which will make the radial cutting depth and the cutting force increase. After the cutting force increases, it will make the work-piece deformation increase. And this will result in radial cutting depth decrease, causing the milling force decrease. This repeated process will make the parameters influence each other until the convergence condition with a stable equilibrium state. It is shown as in Fig. 2. Therefore, the factors of the milling force, deformation and radial cutting depth will affect each other.

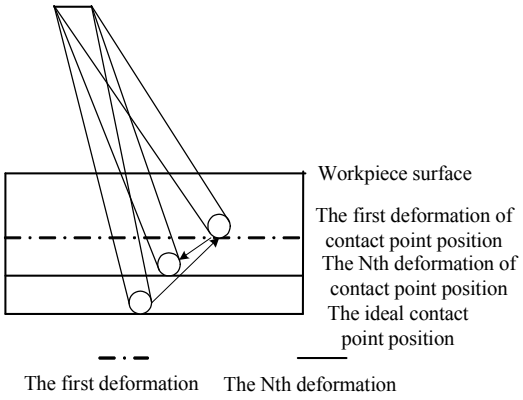

Fig. 2 Deformation iteration process

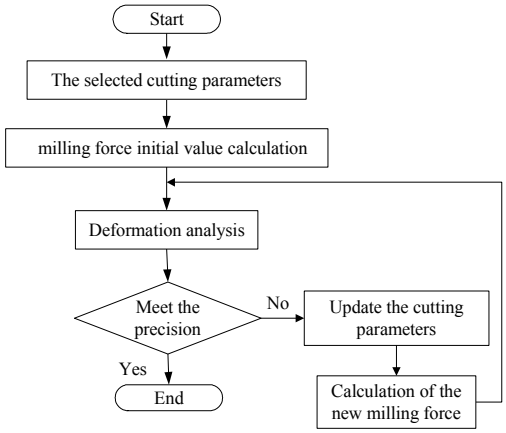

Fig. 3 Analysis flow for a single cutter location point

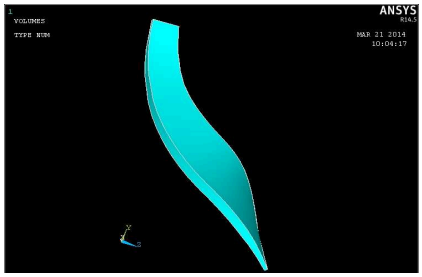
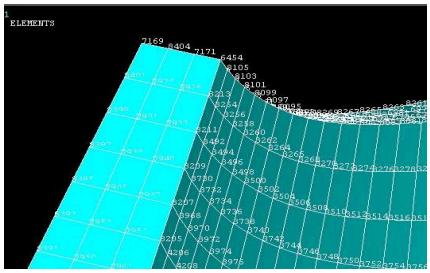
It is difficult to describe the relationship between the deformation and cutting force with two-dimensional graph, because the milling force and the deformation have a nonlinear relationship for the non-developable ruled surface blade. So the blade deformation can be obtained with the finite element technology, which is shown in Fig. 3. Then the new milling force can be computed with the new deformation, and iterate this process until the desired accuracy is realized.

Blade deformation calculation based on finite element analysis

The blade surface studied in this paper belongs to the undevelopable ruled surface, which has a complicated geometry. However, the ANSYS finite element software cannot realize blade's geometric modeling well. To solve this problem, the solid geometry model using 3D UG software to establish an impeller. In order to facilitate grid, blade model is a simple model (without blade root part connected with hub). Blade model with the blade root will lead to identify the interface wrong, and can't have meshes. Graphic conversion will be executed using the graphical interface between ANSYS and UG. The final model is saved as IGES format ANSYS can identify, and the 3D lead geometric model into ANSYS software is shown as in Fig. 4 a).

After the blade entity construction is completed, the grid division can be directly carried. Although the blade is thin part, it isn't suitable to grid in accordance with shell element because the blade thickness difference is very large. Therefore 3-D solid element division should be adopted. The 3-D solid element mainly has 4 nodes tetrahedron element and 20 node hexahedron unit. Tetrahedron mesh is relatively easy, but the grid is not regular, especially the distribution of nodes is irregular. Hexahedral nodes distribution is in each vertex and the midpoint of each edge, which is a hexahedron with 20 nodes. Because the node is located on the cutter location points, cutting force will not be applied to the cutter location accurately if the nodes distribution are irregular. This will be not conducive to the subsequent deformation analysis, and calculation accuracy will be bad compared with hexahedral tetrahedral. So the hexahedral element mesh will be used in the paper. Element type is selected as solid186, material is aluminum alloy T7075-651, elastic modulus EX is set to 71Gpa, Poisson's ratio PRXY is set to 0.33. The number of grid thickness needs to pay attention, and it must be in 2 or more than 2. Otherwise, the mesh cannot be generated. The result is shown as in Figure 4 b). It contains 3360 elements, 17962 nodes. It also can be seen that grid is regular, and the nodes numbers are sequential.





a) A blade solid model lead into ANSYS b) Grid node number

Fig. 4 A blade solid model and its mesh division

The integral impeller hub strength is greater, so the deformation is very small, and it can be neglected. So the blade root part should be constrained when adding a constraint. The blade root part can be selected using the Displacement-On Areas command, and zero can be filled in VALVE after selecting ALL DOF (full freedom constraint). It also means the displacement constraint in blade root is set as zero.

Take the numbers of 6534 single point deformation analysis for an example, the initial value of the milling force can be calculated after applying the initial milling force. Select the command of Force/Moment-On Nodes, and input node number 6534, the milling force value can be computed according to the experience formula. The results can be solved after respectively applying milling force in Fx, Fy, Fz directions. During the application process, the red milling force arrows node can be seen, then the Contour Plot-Nodal Solu command can be selected, and the deformation cloud chart can be viewed from the DOF Solution in the Nodal Solution option, which is shown as Fig. 5.

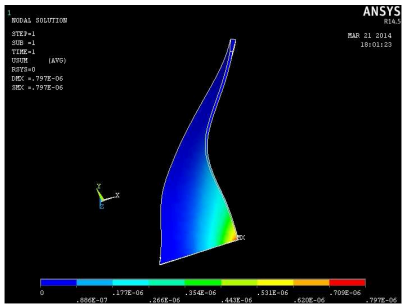


Fig. 5 Blade milling force deformation cloud chart Fig. 6 Node processing deformation

The deformation at 6534 can be observed via the command of Scalar Parameters. The total output deformation result is shown as Fig. 6.

Since the output deformations in x, y and z are not the studied result, but the total deformation is needed, and it needs to decompose the total deformation into elastic deformation along the normal direction, so as to adjust the radial cutting depth to calculate a new milling force, to calculate a new deformation until equilibrium is realized. With this process, the analysis of a single point deformation is over. Deformation calculation for the next cutter location point can go on like this.

In conclusion, the finite element analysis can be divided into three stages, including preprocessing, calculation analysis and post-processing. Preprocessing is to establish the finite element model to complete the mesh analysis. Calculation analysis can complete the computation of the force and the displacement with the relevant finite element theory. Post processing can obtain the acquired and processed results, and output it in a simple way, which is convenient for the user to quickly extract the required information.

Conclusion

The thin-walled blade deformation caused by cutting force is studied in this paper, and the calculation of single point machining deformation is analyzed by finite element method.

(1) The setting methods of blade grid and constraint conditions are shown, which is according to the geometric characteristics and the actual situation of blade machining. The finite element blade machining process analysis can be realized accurately with this method.

(2) Overall deformation size and deformation trend for individual cutter location point are calculated by finite element method, which set the foundation for deformation compensation for each cutter location point.

Keywords: diesel engine; cylinder liner; Fourier series; finite element.

Abstract. The measurement of deformation of one diesel engine water cooling cylinder liner under free condition and assembly load case is carried out by V-INCOMETER testing system. The basic principles of radial deformation for this cylinder liner are obtained through the test data Fourier transformation. And the affect principles of cylinder liner original distort, which results from mechanical machining and heat treatment process, to the cylinder liner assembly deformation are carried out.

Introduction

The liner of water-cooled internal combustion engine embedded in block body is composed of the combustion chamber with piston set, cylinder head and cylinder head gasket. While cylinder liner also plays a guiding role for the reciprocating motion of the piston. When the diesel engine is working, the inner walls of cylinder liner contact with high temperature high pressure gas in combustion chamber directly.The outer walls contact with cooling water. Thermal stress is generated due to the temperature difference between the inner and outer walls. Combustion pressure, piston side pressure and cylinder head bolt preload, make cylinder liner to become one part in the worst working environment of the entire engine. Due to manufacture processing errors, working load and other factors, cylinder liners will appear distortion which can not be completely eliminated. The excessive cylinder liner deformation causes the piston ring and cylinder liner wall not to be fit completely. So that the piston ring sealed performance degradation will increase combustion chamber leak. At the same time that also causes poor lubrication of piston ring-cylinder liner friction pair, the piston rings excessive wear, cylinder scoring and other failures in engine operating. So the cylinder liner deformation is closely related to oil consumption, friction work, the friction pair wear and exhaust emission.

Although the total deformation of cylinder liner in working state is bigger than the assembly deformation an order of magnitude or so, it is mainly radial deformation under heat loading and combustion presure based on the assembly deformation. Thermal deformation and deformation under gas presure are mainly concentric expansion deformation and the piston ring has strong adaptability for it. The testing and simulation calculations of the cylinder liner dynamic deformation are still very difficult. The test and the calculation precision of dynamic deformation can not to be guaranteed. Therefore, to carry out the test and simulation of assembly deformation and to get the basic rules and information of cylinder liner deformation in present engine development process still have important engineering application value.

In this paper, one wet cylinder liner of a certain type of diesel engine is as the research object. Fourier transform analysis of the test results of cylinder liner deformation in free state and different preload conditions were carried out. The radial deformation rules of cylinder liner in top, middle and bottom position are obtained. The influence laws of cylinder deformation by initial deformation, which caused by mechanical processing and heat treatment, are researched systematically. The study results provided the basis support to find the main reasons of cylinder liner excessive deformation in engineering practice.

Testing of cylinder liner deformation

V-Incometer form and roughness measurement system is shown in Fig.1. It can be used to make a flexible measurement of cylinder bore deformation, wear, temperature influences and dimensioning of piston rings in engine development. The measurement system is flexible and mobile due to simple adaptation of the measuring probe to different cylinder dimensions. Using the V-Incometer system, the cylinder liner radial deformations of one 6V type diesel engine were measured under three different conditions: free state, free installation state in which the cylinder liner set into block body without installing the cylinder head, assembly state in which the cylinder head fixed by four bolts with 60kN preload. And the relative deformation of cylinder liner of assembly state is obtained by removed the free installation deformation from assembly deformation. The test device was fixed from the crankshaft end and located position to the inner cylindrical surface of the inferior cylinder. The whole cylinder liner's inner surface radial deformation can be measured with high accuracy by controlling the measuring arm rotation and axial movement. The measurement system reproducibility is less than 2μm.

Fig.1 V-Incometer：Form and Roughness Measurement System

Though the deformation value of each cylinder liner in this 6V type diesel engine is different, the basic laws of deformation are identical. So in this paper only one cylinder deformation data and analysis results are provided. The section position in which deformation data extracted are shown as Fig.2. Comparison analysis of deformation between section 1, section 2 and section 3 under various load case are performed. The section 1 is the position of the first piston ring location when the piston reaches upper stopping spot. The section 2 is the position when the piston reaches maximum velocity. And the section 3 is the position of the first piston ring location when the piston reaches lower stopping spot.

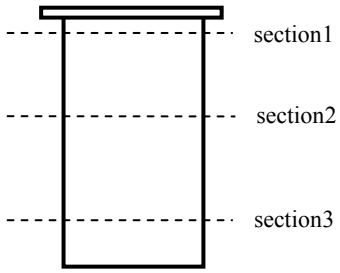

Fig.2 Sketch of deformation data extracted section position on cylinder liner

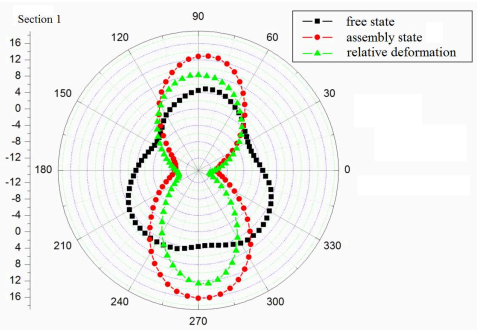
Analysis of testing results

Fig.3, Fig.5 and Fig.7 provided the testing results of radial deformation in three cylinder liner sections under various load cases. Fig.4, Fig.6 and Fig.8 gave the Fourier transformation results of above radial deformations.

Fig.3 and Fig.4 show that the cylinder liner deformations under free state in section 1, which are caused by machining and heat treatment, have obviously thrice curve characteristic. The 0 to 3 order Fourier deformation coefficient are relative bigger than others, but the deformation amplitude is small

(≤3μm). After the cylinder head bolt force preloaded, the assembly deformation and relative deformation become quadratic curve. Comparison to free state, the 2 order Fourier deformation increase obviously, which deformation amplitude reaches above 12μm. And other 0 ,3 and 4 order deformations are also increased at a certain extent. Moreover, the profiles of cylinder liner assembly and relative deformation are consistent, which shows the deformation caused by bolt preload is dominant to the final form of section 1 in cylinder liner.



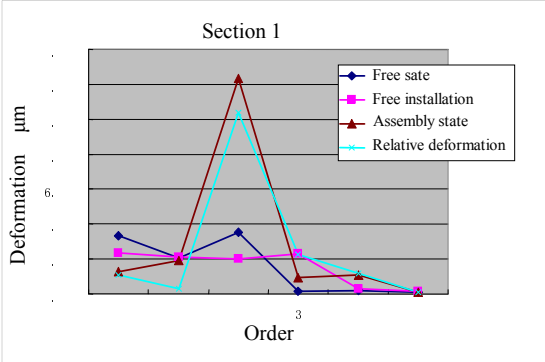


Fig.3 Radial deformation of section 1 Fig.4 Each Fourier deformation coefficients of section 1

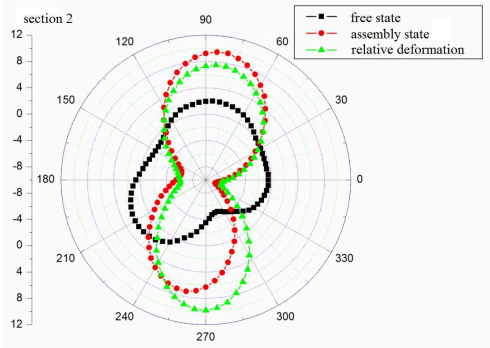
The deformation of section 2 of cylinder liner is similar with section 1. The deformation amplitude is gradually decreased with the liner section position moving down. And comparison to the section1, the Fourier deformation coefficient of 0 order is decreased obviously as shown in Fig.5 and Fig.6.



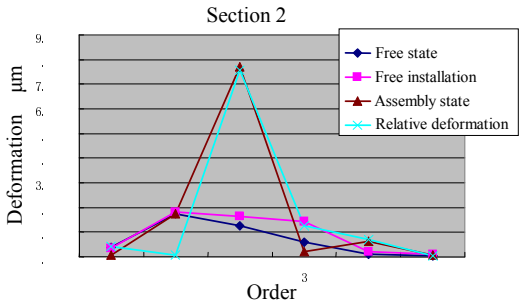


Fig.5 Radial deformation of section 2 Fig.6 Each Fourier deformation coefficients of section 2

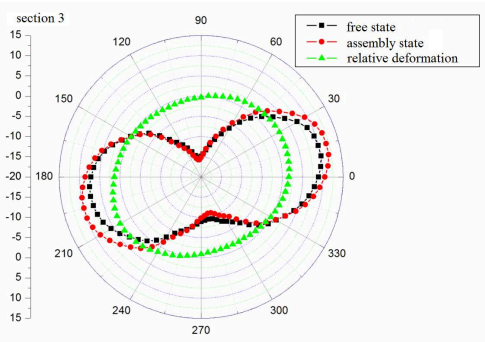
As shown in Fig.7, the profile of section 3 is changed from thrice curve to quadratic curve under free state and free installation state, and the deformation amplitude is increased greatly. From Fourier deformation transfer results shown in Fig.8, the origin deformation which caused machining and heat treatment mainly is the secondary order deformation. The deformation amplitude is up to 10μm. Nevertheless the relative deformation in section 3 is very small, which is less than 2μm. These results show that the influence of cylinder head bolt preload on cylinder liner bottom deformation is very small. The assembly deformations of liner bottom section are mainly composed of origin deformation caused by machining and heat treatment in progress of cylinder liner production.



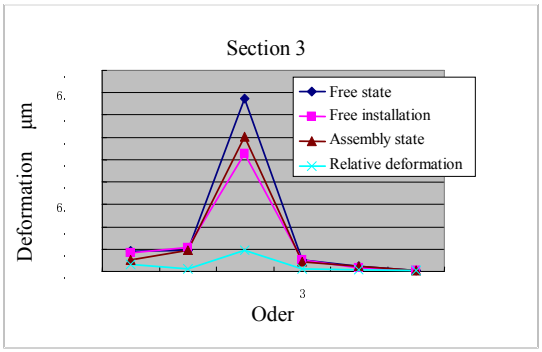


Fig.7 Radial deformation of section 3 Fig.8 Each Fourier deformation coefficients of section 3

Through synthesis analysis of the three sections deformation results and other testing results not given in this paper, the origin deformations caused from liner production are thrice curve with small

amplitude on the top liner. And with the section moved to the liner bottom, the origin radial deformations are changed to quadratic curve. Cylinder head bolt preload force has a significant effect on the deformation of upper part of cylinder liner. And bolt preload mainly affects the 2 order, 3 order and 4 order Fourier deformation coefficients, but the influence on the lower part deformation is gradually weakened.

Summary

Through a comprehensive analysis of the test results of the cylinder liner deformation, we get the following conclusions:

(1) Initial twist generated in the production process of the cylinder liner affect the final assembly deformation significantly, particularly in the lower part of the cylinder liner, the initial deformation of the cylinder liner substantially dominated the final assembly deformation.

(2) When using the finite element method to calculate deformation of the cylinder liner, it is difficult to consider the initial deformation, and therefore must be used the relative deformation of the cylinder liner to effectively correct and verify the calculate model.

(3) Deformed shape of the cylinder liners are not the same for each section. Fourier coefficients of each section of the deformation are not the same trend. The deformation profiles are closely related to particular structures form. So when the analysis and evaluation of deformation of the cylinder liner are performed, need to select a typical cross-section according to different structural forms.

Keywords: multiple practice; center axis ; coupling; calculation method.

Abstract. It is magnificent to find the center of the coupling after many calculations, test and optimization. It presents a check based on looking methods and determine the centering of this calculation method after repeatedly overhaul of a 200mw extraction condensing steam turbine adjusting center practice. The effectiveness of its application in practice can duration, and the average time and its consumption of money could be reduced to 1/3, 1/3 and 1/5of its original, illustrates the adjustment process issues which should pay attention to,and provides technical reference for the safe operation of the same type of rotating machinery .

Introduction

It is the foundation of the normal operation of the steam turbine within the prescribed scope of steam turbine shaft coupling center in the factory. Hot bolt ,setting error, uneven sedimentation, cylinder deformation, unsteady thermal expansion etc, however, will cause the shaft center measurement deviation,combined with long-term solid particle impact will led to the steam turbine cracking and corrosion [1], the repair process is very difficult [2].By repeatedly overhaul the 200MW smoke condensate steam turbine,it could be possible to find center adjustment after the practical process for multiply times,.Then,it would be no hard to achieve the minimum quantity adjustment, the easiest design and most efficient adjustment process . Generally,according to the lack of a precise systematic, streamline processes, this process is time-consuming and waste of energy.This paper deduces the a simplified calculation method based on center adjustment, among them, clearly adjust center calculation is divided into several specific part, and clearly describe the key processes of it , and applied to other analogous process of finding center.

1 Center adjustment method of the application

1.1 Initial parameters

In this example,the diameter of coupling of two rod plane table is referred to,which is D 603.00 mm, the distance of circular table to 2 # bearing center is 327.00 mm, center distance of2# bearing is 2220.00 mm,the angle of bearing adjustment block center and the shim the centerline named a=75 °, and cosa =0.28, sina= 0.92.Coupling circumference value and openings deviation as shown in Fig. 1,

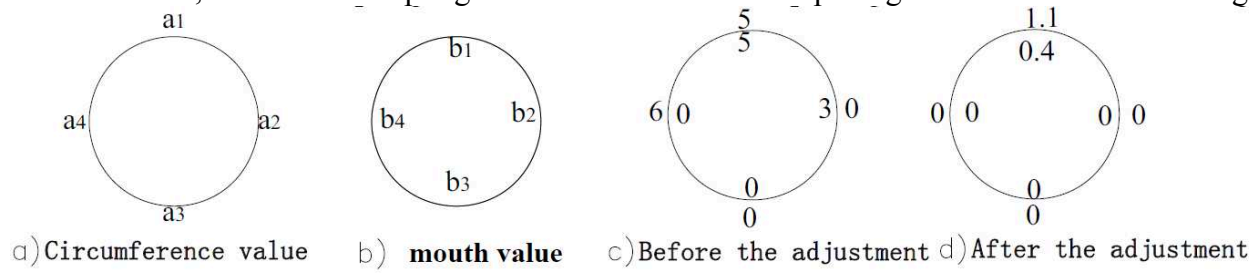

Fig. 1, Numerical coupling center before and after the adjustment

1.2 Calculation process and results

Using formula (1-6) to calculate. The specific calculation process of gasket adjustment method is shown in Tab. 1.it is necessary to increase the left side of the gasket(displacement) △ H_{2zc} = 0.0236 mm, and △ H_2 = 0.0118 mm on the right side;3 # bearing:increases gasket vertical direction t △ H_3 = 0.2022 mm, increase the left side of the gasket △ H_{3zc}= 0.2727 mm, cut right gasket △ H_{3zc} = 0.1059 mm,After adjusting the circumference the results are shown in Tab. 1.

Tab. 1, Coupling center adjustment calculation

serial number	name	symbol	Calculate formulation	Numerical unit 0.01mm	note
1	2 # bearing vertical adjustment value △ H_2 on both sides of the gasket	$\triangle H_2$	$\triangle H_{2c}=\triangle H_2\cos\alpha$	2.32	
2	2 # bearing horizontal modifier △ H_2 'on both sides of the gasket modifier	$\triangle H_2'$	$\triangle H_2'c=\triangle H_2'\sin\alpha$	1.09	
3	2 # left the gasket at the bottom of the bearing adjustment value	$\triangle H_{2zc}$	$\triangle H_{2zc}=\triangle H_2+\triangle H_2'$	2.75	Increase the gasket
3	2 # bearing right at the bottom of the gasket modifier	$\triangle H_{2yc}$	$\triangle H_{2yc}=\triangle H_2-\triangle H_2'$	1.19	Increase the gasket
5	3 # bearing vertical adjustment $\triangle H_3$ on both sides of the gasket	$\triangle H_3$	$\triangle H_{3c}=\triangle H_3\cos\alpha$	12.68	
6	3 # bearing horizontal modifier$\triangle H_3$'on both sides of the gasket modifier	$\triangle H_3'$	$\triangle H_3'_c=\triangle H_3'\sin\alpha$	22.32	
7	3 # left the gasket at the bottom of the bearing adjustment value	$\triangle H_{3zc}$	$\triangle H_{3zc}=\triangle H_3+\triangle H_3'$	26.05	Increase the gasket
8	3 # bearing right at the bottom of the gasket modifier	$\triangle H_{3yc}$	$\triangle H_{3yc}=\triangle H_3-\triangle H_3'$	-11.0262	Reduce the gasket

Calculation results are as follows: 2 # bearing: vertical increase gasket △ H_2 = 0.0519mm,

1.2 The result analyses

From 2 # and 3 # two bearing ,those in the vertical direction, the left and the right side : the adding displacement of value of the gasket can be identified by using this method, hence, this method is applicable for the same type of steam turbine shaft coupling, and, by making a systematic calculation in Tab. 1,it could accelerate corresponding calculation efficiency . The results of all the circumference of a circle and openings deviation values conform to the technical requirements for cylindrical is less than 0.02 mm, the opening is less than 0.01mm, half coupling axis eccentricity is less than 0.01 mm, other uncertain factors of differential settlement of the foundation, uneven subsidence is less than 18mm,which is superior to the standard .Not only that, due to the use of summarized recent overhaul ,the elimination amount of its openings deviation and circumference value is 2/3 and 2/3, respectively than the original average level. Applying this method could actual eliminate the error and uneven subsidence value of finding the axis of coupling than the original 1/5.The above calculation is the result of the multiple overhauls, lots of calculation statistics. With other collaborate process of adjusting coupling center, the circumference of a circle, openings deviation eccentric degree, the uneven subsidence equivalent amount can be adjusted to the corresponding result.

2 Coupling center finding method

2.1 Finding center

Finding Coupling center, is to make the rotor axis balanced into a smooth curve,which did not fold point in the middle of the rotor. The connection of rotor will have a periodic alternating on bearing force, which cause vibration and noise. The center will not affect the bearing load distribution, whether poor circular excursion or openings deviation of unbalanced load have influence on the coupling.

2.2 Finding process

(1) Establish standard adjustment: according to the former bearing shell temperature and vibration situation, considering all the factors,provide standard which affect the shaft system

adjustment and the center of the manufacturer, start solid cylinder shaft center adjustment after the establishment of standard.(2) determine the adjustment quantity: after setting major repair and overhaul of solid cylinder standard, half cylinder has to be calculated, then the reserved acceptance standard of half cylinder adjustment after overhaul has to be determined, to determine the amount of adjustment according to overhaul before half cylinder center and reserved after overhaul of half cylinder standard .(2) the adjustment steps: Main steps of measurement, calculation and adjustment of three main links of grinding bearing pad iron .

2.2 Calculation method

It has five circle center adjustment of coupling measurement by every step of the data,to record the location of the center value,namely 0 to 90 °, 180 °, 270 ° and the total average of every numerical as shown in Fig. 2(a). Considering there is circular offset and open openings deviation and its direction changes.To meet the requirements,the steam turbine rotor, generator rotor bearing center have to be adjusted, the center adjustment calculation method can be divided into the following two aspects.

2.2.1 Eliminate the circumference difference

Coupling center and 2 #, 3 # poor bearing circular adjustment quantity as shown in figure, 2 #, 3 # . It is on the left represents the center of the coupling in figure.the rail on behalf of the rotor, h on behalf of the up and down or left and right amount of translation, at the same time will be 2 #, 3 # bearing to the upper left translation h after coupling center for namely. H value calculation is as follows:

Upper and lower center panning.

$$h_{sx} = \frac{(a_{1/0.99} - a_{3/0.98})}{2}. \quad (1)$$

Left and right center panning:

$$h_{zy} = \frac{(a_{2/0.99} - a_{2/0.98})}{2}. \quad (2)$$

Type of a1, a2, a2, a3 is circumference value, h_{sx}, h_{zy} represent the displacement of vertical and horizontal direction , which have been taking comprehensive consideration of table direction and the value of a1, a2, a2, a3 and symbols.

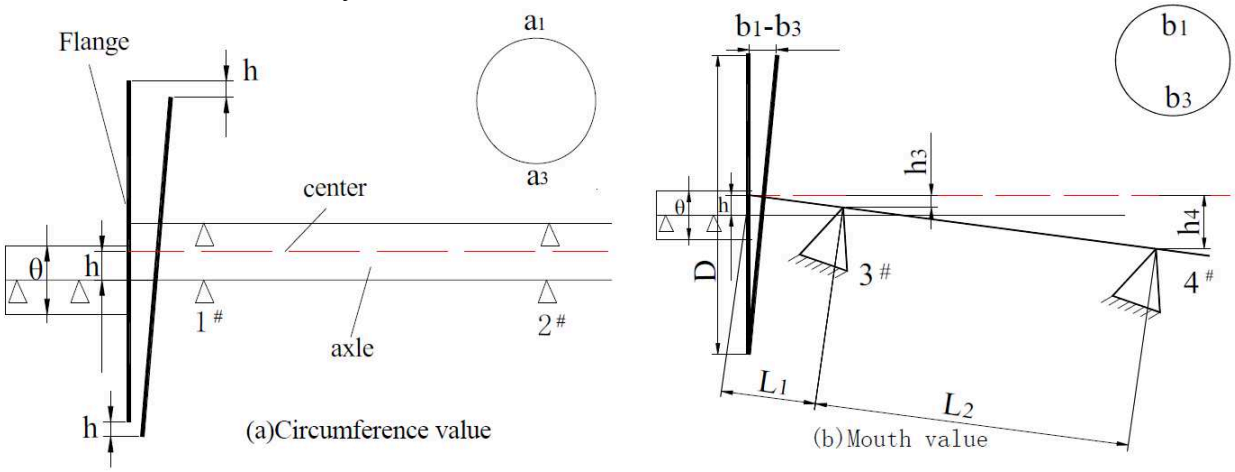

Fig. 2, Schematic of eliminate the circumferential difference(a) and illustration of the removal of coupling openings deviation(b).

2.2.2 Remove openings deviation

As shown in Fig. 2(b),coupling center and 2 #, 3 # of bearing flat openings deviation adjustment quantity is different. The bearing up of 2 # is h_2, bearing up after the of3 # is h_3,respectively. two coupling openings deviation b_1, b_2.The h_2, h_3 calculation is as follows, the calculation of eliminate the openings deviation is as follows:

$$h_2 = \frac{(b_1 - b_2) \times L_1}{D} \quad h_2' = \frac{(b_1 + b_2) \times L_1}{D} \quad . \tag{2}$$

$$h_3 = \frac{(b_1 - b_2) \times (L_1 + L_2)}{D} \quad h_3 = \frac{(b_1 + b_2) \times (L_1 + L_2)}{D} \tag{3}$$

shim adjustment numerical algebra sum of 2 #, 3 # bearing should take two parts,

$$\Delta H_2 = h + h_2 - 0.1h_2', \qquad \Delta H_3 = h + h_3 - 0.1h_3' \tag{4}$$

Type of b1, b2, b2, b3 end face, respectively, h2, h3 symbol has respectively, fixed around openings deviation instead of b1 b2 can be used to calculate the h2 respectively, b2 instead of b3 to calculate the h3;Referred to in rod coupling diameter, D - two plane table L1 - circular table to 2 # bearing center distance of measuring points and L2, 2 #, 3 # bearing center distance. Considering plane table direction, b1, b2, values and symbols and the h value, to adjust gasket to eliminate the openings deviation. Second, change the position of the upper and lower gasket at the same time, must be a corresponding change on both sides of the gasket thickness, to maintain good spherical contact.

2.2.2 Adjust volume of the gaskets.

On both sides of the gasket to adjust quantity calculation method , which takes gasket center Angle to △H_b on behalf of the vertical direction of gasket, △ Ha on behalf of the horizontal direction. When vertical direction △H_b add and subtract to lower gasket thickness and the bearing shell mobile△H_b equal on both sides of the gasket thickness at the same time, plus or minus △ $H_b$cos a;If the horizontal direction mobile △ Ha, lower gasket, on both sides of the gasket thickness respectively add (subtract) △ $H_a$sina. Each of the shim under the adjusting shim shoulds not be more than three pieces.To adjust gasket sheet steel should be adopted and phosphor copper, unfavorable use copper skin soft material such as Single chip thickness is not less than 0.02 mm, the aperture should be bigger than shim aperture of 1 ~ 2 mm; Gasket assembly, should be carefully cleaned its burring and rough edge. In the center deviation within the scope allowed the position for turbine center is higher than the generator, and lay on the above position to its openings deviation. Adjustment is within 0.1 mm gasket contact with hollow nest situation doesn't have to check. If adjustment quantity more than 0.1 mm, which should be re-examine and crapping block, after crapping again review center. Center after the adjustment to the bearing oil gear measurement, adjustment and repair, and are able to be adjusted on tile gasket to keep bearing force.

Conclusions

This method of coupling center adjustment is based on predecessors experience and practice application for many times, the adjustment process of steam turbine generator shaft system has shown in the form of chart compiled.To sum up ,it is an accurate calculation method of a calibration center. This method was applied to concrete coupling overhaul center adjustment process of turbo-generator set.It has proved in multiple practice by applying this method to adjust the unit operation, the result shows that shaft system is stable, related parameters of the bearing is superior to the requirement. The effect is good after the unit running because this method is feasible and maintenance, the time , procedure, money consuming can be reduced to 1/3 ,1/3and 1/5 of the original, In a nutshell,it can offer reference for the application of the same type unit, but for the big unit shaft system aspect application, needs further research.

Keywords: Low temperature corrosion; Acid dew point; Phase equilibrium; Fugacity equation

Abstract. Inadequacy was discussed of using acid dew point temperature (ADT) as safe low limitation of exhaust gas temperature on the background of waste heat deep utilization of flue gases. Concept of limited corrosion dew point (LCT) was presented based on corrosion property of ordinary carbon steel and binary phase equilibrium of H_2SO_4-H_2O system,. Calculation formula of LCT was solved by establishing fugacity equation of H2O with a fixed concentration and constant pressure. The results show that LCT lies during 68-84℃ when volume percentage of H_2O vapor varies from 6-12% which is in line with that of exhaust gas of boiler. The maximum relative error of the calculated data is 1.43% in contrast to reported data. Ordinary carbon steel in contact with flue gas with its surface temperature above LCT will not occur obvious corrosion and wet soot deposition through observation of experiment on site. It is available for exhaust gas temperature to decline below ADT but above LCT in process of deep utilization of waste heat of flue gas.

Introduction

Whenever fossil fuels containing sulfur are fired in heaters or boilers, sulfur dioxide, and to a small extent sulfur trioxide, are formed in addition to water vapor. The SO_3 combines with water vapor in the flue gas to form sulfuric acid and condenses on heat transfer surfaces, which could lead to corrosion and destruction of the surfaces. Significant efforts have been devoted for establishing methods to predict the sulfuric acid dew point (ADT) of flue gas [1-3]. A thermodynamic approach has been used for predicting ADT with very low sulfuric acid vapor concentration by Muller [4], based on partial pressure data of vapor-liquid phase equilibrium of H_2SO_4-H_2O derived by Abel [5-6]. Later experimental work using a SO3 condenser method confirmed Muller theoretical calculations expressed by Muller curve.

Muller curve is now the bases for evaluating various methods for measuring SO_3 and widely cited in lots of literatures [7-9]. About 1-50 ppm of H_2SO_4 vapor remains in the flue gas. The ADT varies from 117-147℃ by Muller Curve with 10% water vapor concentration by volume. It has been an important parameter for designers to determine the temperature of exhaust gas [10]. With more and more strict request for environment protection and energy saving in China, exhaust gas temperature of widely using heat recovery equipments has been reduced to 100℃, the wall temperature of metal tube is about 80-90℃, Which is obvious lower than ADT. The unacceptable corrosion and ash deposition did not occur without using special anticorrosive material. From the operation experience of the power plant, as long as the wall temperature of ARH is above 75℃, obvious corrosion will not occur [11]. As a result, in the background of deep utilization of waste heat of flue gases, it is inadequate to use ADT as safe low limitation of exhaust gas.

The ADT is only the starting temperature which could lead to sulfuric acid corrosion, but corrosion rate is not only connected with ACD but also the concentration and condensed amount of sulfuric acid. When surface temperature is below ADT, condensation occurs with high concentration of sulfuric acid and little condensed amount. Valid corrosion and sulfuric ash deposition will not happen for heat recovery system made from the ordinary carbon steel, such as

#20C, in contact with aqueous of high sulfuric acid concentration 60-90(Wt%). Some scholars proposed that temperature of available corrosion point should lie somewhere between acid dew point and water dew point and gave an experienced formula, but lacking theory bases [12].

According to theory of binary phase equilibrium and corrosion property of ordinary carbon steel, concept of limited corrosion point temperature was presented. The formula associated with single variable of water vapor partial pressure is solved by setting up water fugacity equation.

Concept of limited corrosion point temperature and its connection with thermodynamics acid dew point temperature

Concept of limited corrosion dew point temperature

The exhaust gas of boiler is a complicated and compound system including N_2, O_2, CO_X, NO_X, SO_2, SO_3, and so on. From thermodynamics point of view, the ADT can be solved by theory of multi-phase equilibrium. Due to the complex of theoretical study, it is necessary to reasonably simplify exhaust gas system. The following hypothesis are main points:

1) The exhaust gas is considered as ideal gas.

2) Gases apart from H_2SO_4 and H_2O are considered as inactive gases.

Based on these two points, the exhaust gas system is considered as a binary system of H_2SO_4-H_2O.

By Gibbs phase rule, the degree of freedom of the binary liquid-vapor system equals 2, i.e., the numbers of independent intensive variable are 2. Only two parameters are independent among T, P, X1 or Y1 (the mole fraction of liquid H_2SO_4 or H_2O), X2 or Y2 (the mole fraction of vapor phase H_2SO_4 or H_2O). If choosing P and Y2 as independent variables, thus the partial pressure of water vapor can be expressed: P1=P*Y2.

Limited corrosion point temperature is defined as a temperature value which the state point lies at equilibrium with 60% liquid weight concentration of H_2SO_4 under pressure 1 bar.

Reasons for LCP to be more valid than ADT as basis of valid corrosion temperature.

The reasons are based the following two points:

1) ADT is only the starting point of low temperature corrosion, it does not mean that at the ADT the valid corrosion and sulfuric deposition happen.

2) According to the corrosion property of ordinary steel carbon, weight concentration 60-90 percent sulfuric aqueous has a low corrosion rate(about 6 g/m2.h) in contact with ordinary steel carbon ,which is much less than the fastest corrosion rate(about 80 g/m2.h) at 56 percent weight concentration.

Connection with thermodynamic acid dew point

T-X fig of binary system of H_2SO_4-H_2O under pressure 1bar is showed in fig.1. The temperature of superheated vapor with state A falls to point B where the first liquid drop appears in the liquid-steam equilibrium state, this temperature is called the ACP. We assume that the concentration of liquid phase sulfuric acid is 80 percent (wt %). When the temperature continues falling to a point C where the concentration of liquid phase sulfuric acid is 60 percent (wt %), we call the temperature of the point C as LCP.

So both ADP and LCP are state points of liquid-vapor phase equilibrium. ADP lies in a state with fraction of liquid phase being zero, but LCP lies in a state with a few fraction of liquid phase, its value can be achieved by data of phase equilibrium.

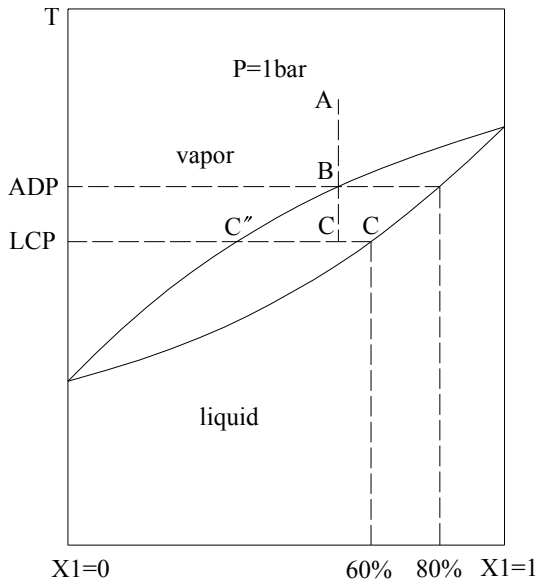

Fig.1. T-X figure of H_2SO_4-H_2O syetem

Establishment of mathematical model and derivation of LCP equation

Mathematical model establishing

The Fugacity equation as mathematical model for solving phase equilibrium of H2SO4 and H2O was first established by Abel, which was expressed by thermodynamics parameters and temperature functions through the hypothesis of ideal gases. Then displace Fugacity with partial pressure. At last, partial pressure of vapor phase of binary system was solved. Gmitro and Vermeulen used the renewed thermodynamics parameters and revised the fugacity equation [13].

Based on the hypothesis of ideal gases, the fugacity of water vapor was derived by using the latest thermodynamics parameters here. The LCP was worked out expressed by a single variable function of partial pressure of water vapor.

Derivation of LCP equation

At equilibrium, the partial mole free energy of water vapor $\Delta\bar{G}_\pi(g)$ is equal to the partial mole free energy of the liquid water $\Delta\bar{G}_\pi(l)$:

$$\bar{G}_\pi(g) = \bar{G}_\pi(l) \tag{1}$$

Suppose the vapor acts as perfect gas, we obtain:

$$G^0(g) + RT\ln p_\pi = G^0(l) + RT\ln a_\pi \tag{2}$$

$$\ln p_\pi = \frac{G^0(l) - G^0(g)}{RT} + \ln a_\pi \tag{2a}$$

$$\ln p_\pi = \frac{-\Delta G^0}{RT} + \ln a_\pi \tag{2b}$$

Equation (2b) holds at any temperature and composition. The partial pressure under consideration is given by the sum of two terms: a pure-component term $-\Delta G^0 / RT$, a function of temperature only; and an activity term $\ln a_\pi$, a function of both temperature and composition.

The derivation process can be seen from literature [13]

At last, we obtain：

$$\ln p_\pi = A\ln\frac{298}{T} + \frac{B}{T} + C + DT + ET^2$$

where

$$A=\frac{1}{R}\left[-a+\bar{c}_p(298)-298\alpha\right]$$

$$B=\frac{1}{R}\left[-\Delta H^0_{298}+298a+\frac{298^2}{2}b+\frac{298^3}{3}c+\bar{L}_{298}-298\bar{c}_p(298)+\frac{298^2}{2}\alpha\right]$$

$$C=\frac{1}{R}\left\{-\Delta S^0_{298}-a-298b-\frac{298^2}{2}c+\bar{c}_p(298)+\left[(\bar{G}_\pi(l)-G^0(l))_{298}-\bar{L}_{298}\right]\frac{1}{298}\right\}$$

$$D=\frac{1}{2R}(b-\alpha)$$

$$E=\frac{1}{6R}c$$

Strictly speaking, α is a function of temperature and composition. When the temperature is below 200℃, the influence of composition can be omitted [13].

For H_2SO4 aqueous (wt60%), the latest thermal data and the results are shown in table 1. [14]

Table1 Pure composition H_2O, H_2SO4 and H_2SO4 aqueous（wt60%） thermal data

Parameter	Unit		H2O	H2SO4
ΔH^0_{298}	kJ/mol	K	44.014	79.131
ΔS^0_{298}	J/mol	K	118.884	144.152
$\bar{L}_{298}$	J/mol	K	-4710.15	-35190.1
$\bar{c}_p(298)$	J/mol	K	68.39138	112.8343
$(\bar{G}_\pi(l)-G^0(l))_{298}$	J/mol	K	-4502.07	-29458.3
a	J/mol	K	32.838	32.908
b	J/mol	K2	2.42E-3	193.221 E-3
c	J/mol	K3	0	-10.936 E-5
α	J/mol	K2	0.0485	-0.00460
A	none		2.530	9.623
B	K		-6860.669	-15690.51
C	none		18.554	22.902
D	(K)-1		-2.77E-3	1.16E-2
E	(K)-2		0	-2.19E-6

Note: Any coefficient or subscript shown as 298 is actually computed as 298.15K (25℃); The standard state pressure is 1bar.

From above data, the partial pressure of H_2O (bar) can be solved：

$$\ln p_\pi = 2.530\ln\frac{298}{T}-\frac{6860.669}{T}+18.554-0.00277T \tag{3}$$

Contrast to thermal equilibrium data of associated literature

Flue gas moisture content of coal-fired boiler of is usually around 10%, which changes between 5% and 15%. The contrast results are shown in table 2 between thermal equilibrium data and data calculated by formula (6).

Table 2 Contrast of data

Temperature ( )	Pressure (KPa [15])	Pressure (KPa[16])	Data (KPa)	Relative error (%)
65	5.03	5	5.02	0.40
70	6.40	6.39	6.41	0.31
75	8.03	8.09	8.12	1.12
80	10.04	10.19	10.22	1.43
85	12.57	12.72	12.75	1.19
90	15.60	15.80	15.81	1.28

Note: The pressure unit is mmHg in (15), converted to KPa here; data of the third column from equation (3)

Test verification on corrosion and ash deposition on site

Test was carried out respectively in 200MW unit, 300MW unit, 600MW unit, test position is located after air pre-heater and before electric precipitation. The test material is ordinary 20# carbon steel. The aim of test is to check up corrosion and ash deposition of the surface which temperature lies between water dew point and LCP. The original data, operation parameters, and thermal data are shown in the table 3.

The process of corrosion test on site

The parameters of the test are shown in fig 2. The system is composed of constant temperature box; water tube and its accessories, including pump, flow meter, temperature measuring point, and so on; heating tube in gas duct). Due to LCP of different unit varying from 64-74℃, three constant temperature boxes with different temperature (70℃, 65℃, 40-60℃) were designed.

Table3 Original data and operation parameters

Parameter	Unit	200WM	325WM	600WM
Electrical load	WM	150-220	210-325	40-55
Flue gas temperature	℃	120-135	132-147	115-129
Flue gas velocity	m/s	8-10	7-11	7-10
$Q_{ar.net}$	KJ/kg	19000-21000	18250-19750	17500-19500
V_{daf}	%	15-19	14-18	16-22
S_{ar}	%	0.8-1.5	1.2-1.8	1.3-2.2
M_{ar}	%	6-8	6-9	6-10
Concentration by volume	%	6.0-6.6	6.3-6.9	6.8-7.6
Dew point of water		42-44	43-45	45-47
SO_2 concentration	mg/Nm3	1900-2000	2100-2300	2200-2400
SO_3 concentration	ppm	7-42	8-48	9-54
ADP		121-147	123-149	126-151
LCP		64-67	70-72	72-74

The system is divided into four sections: (1) section without water; (2) section with water temperature 70℃; (3) section with water temperature 65℃; (4) section with water temperature 40-60℃.

Heat transfer and ash deposition of the surface were recorded. The test time is about 3 months for each unit (200 MW unit, 300 MW unit, 600 MW unit)

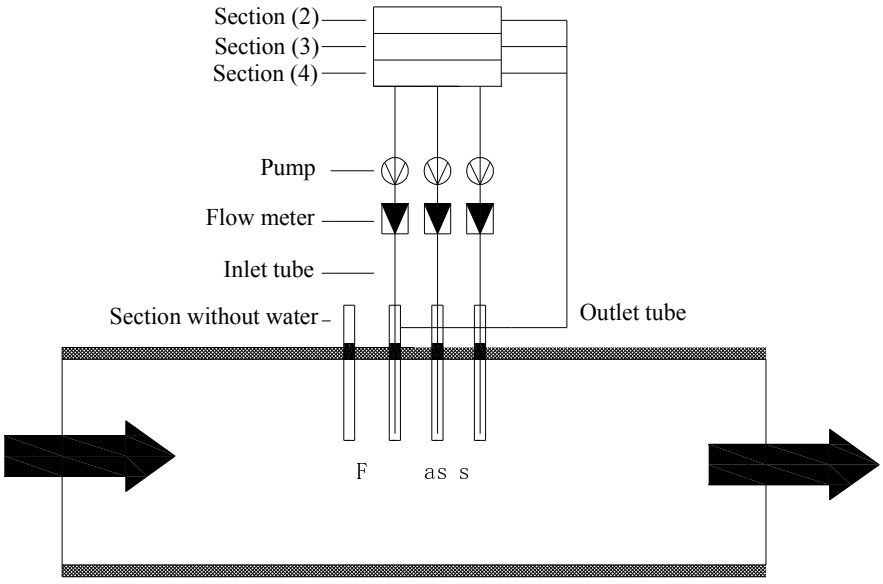

Fig. 2 Figure of the test system

Results of test

The following results are achieved by the test on site (different ash deposition on surface are shown in fig 3：

(1) No water test section: wall temperature of the steel tube is equal to that of flue gas. The upwind side is smooth and have no ash deposition, the backwind side with stable float ash, no corrosion phenomena appears.

(2) Water temperature 65℃ test section and the water temperature 70℃ test section (wall temperature is higher about 3-5℃ than the water temperature via computation), the windward side is smooth without dust, the backwind side with stable float ash, did not see the yellow sulfuric corrosion layer after the removal of the float ash layer.

(3) Test section with the water temperature 40-60℃: water temperature below 65℃, the upwind ash deposition began to accumulate, yellow sulfuric corrosion layer can be seen after the removal of the float ash layer.

(4) Water temperature below 40 ℃ is close to the water dew point, the upwind side appeared granular ash with ash layer obvious thickening and obvious corrosion.

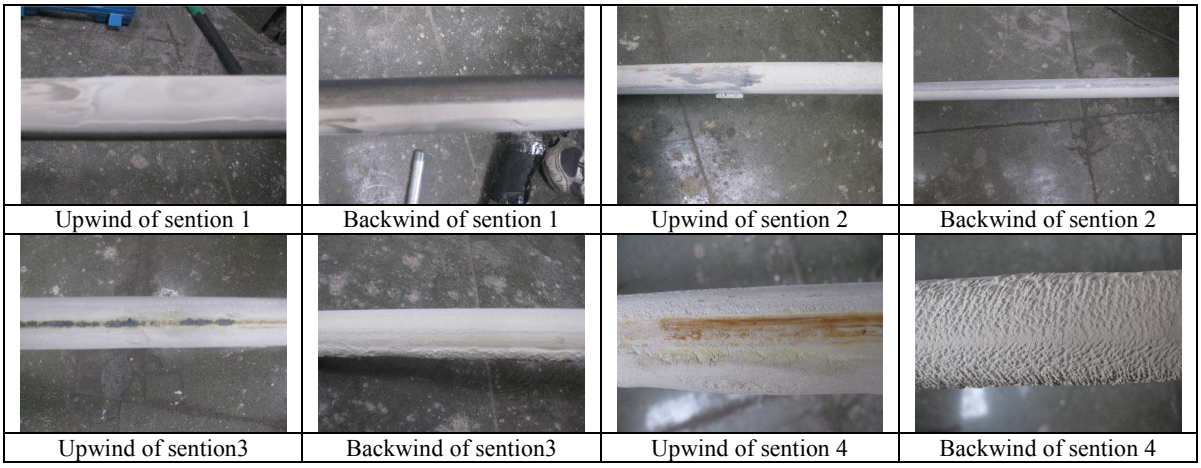

Fig. 3 Corrosion and ash depositon of different test elections

Discussion of the test

(1) Ordinary steel heat exchanger can be safe and stable operation for a long time with its wall temperature below ADP and above CLP, no valid corrosion phenomenon was observed.

(2) When the wall temperature is lower than LCP, the effective corrosion and dust deposition of windward side gradually appear, the corrosion layer thickens gradually as the temperature decreases.

(3) When the wall temperature is near the water dew point, the windward side appears a large number of granular ash, corrosion is serious.

Conclusion

The concept of limited corrosion dew point temperature was presented based on corrosion property of ordinary carbon steel and binary phase equilibrium of H2SO4-H2O. It is more valid and has a more significance in engineering practice of wasted heat utilization than ADT as the basis on low-temperature corrosion of flue gas in coal-fired boilers.

(1) The limited corrosion dew point temperature (LCT) was worked out by fugacity of H_2O, its relative error is less than 2% compared with reported data.

(2) Ordinary carbon steel in contact with flue gas with its surface temperature above LCT which is far lower than ADT will not occur obvious corrosion and wet soot deposition through observation of experiment on site.

Design and Research of offshore Drilling Platform Electric Power System

[1,a] Chen Pingliang

[1]CNPC offshore engineering co., LTD, Beijing, China, 100028

[a]chenpl.cpoe@cnpc.com.cn

Keywords: offshore Drilling Platform, Electric System, Design.

Abstract. In order to design a reasonable safe power control system and realize the automated management of offshore drilling system, this paper analyzes the electric system features and grid configuration of drilling platform; power station design and short circuit calculation; electrical power system electroplax selection. This system adopts oceanographic engineering software EDSA for construction and parameter input and conducts short-circuit calculation for modeling and simulation. The electric system design and short-circuit calculation can be examined by simulation result and real platform.

Introduction

Petroleum is the blood of economy and sufficient and stable supply of oil and gas resources is the essential conditions for economy steady development. 21 century is the is the age of energy scarcity.a lot of countries have turned their eyes on ocean and put abundant manpower and material into marine energy resource development. Self-elevating drilling platform is one of offshore drilling equipment the wildly used at present in the word, mostly operating at intertidal zone and shallow sea. In recent years, the quantity of self-elevating drilling platform is increasing. The design, construction, check and research of the offshore drilling platform of our country cry for development, especially in basic technology design. We lack of independent design and mostly rely on foreign design technology. Thus, improving the above-mentioned research work can enhance our country's offshore structure design and manufacture ability and international competitiveness, which is of great significance to the marine resource exploitation and oceanographic engineering development. offshore drilling platform is the base of marine oil gas exploitation. Electric system of the platform is a set of independent electricity generation, electricity transmission, and electricity distribution system, and real-time reliable electric monitoring system is of great significance to the offshore drilling platform.

Engineering Background

The two drilling platform is launched at China offshore oil engineering construction base dock at the west coast of Qingdao, and head for Bohai bay for mud oil. The two drilling platform is triangular-formed truss-spud-legged self-elevating drilling platform with the maximum drilling depth of 6,000 meters, which is designed and built according to the norm of American bureau of shipping and China bureau of shipping. At present, two more platforms are built at the base. The four drilling platforms will operate at the same time and same site, which is beyond example in Chinese mainland. The basic components of semi-submersible drilling platform are offshore system, drilling system and dynamic positioning system. offshore system is mainly composed by the motives providing power station, stability maintaining ballasting system, offshore control system and other systems like commination system. Drilling system is mainly composed by drilling equipment, mud system and bop system. Dynamic positioning system is mainly composed by controller, power distributor and thruster etc.

Design and Analysis of Drilling Platform Electric System

Power Grid Calculating in Power supply schema Translation: The relation between delivery and load electricity consumption of platform diesel generating set is shown in formula (1) and (2).

$$P_{G1}+P_{G2}+P_{G3}+P_{G4}+P_{G5}+P_{G6}+P_{G7}+P_{G8}=P_{\text{Network loss}}+\text{P}_{\text{Load}} \quad (1)$$

$$P_{\text{Network loss}}=5/100(P_{G1}+P_{G2}+P_{G3}+P_{G4}+P_{G5}+P_{G6}+P_{G7}+P_{G8}) \quad (2)$$

In (4.1), PG1 to PG8 separately represent the delivery of eight diesel generating sets. Load P is the electricity consumption the platform load needed. In formula (2), the loss coefficient of 5/100 is the common empirical data in current application system.

Pre-diagnostic Analysis of Power Supply Schema Translation: Power supply mode needs transmission for the drilling needs. The load, power supply and charging line of these two power supply modes differ. Thus, in the transmission, the constraint conditions and switching paths of the associated equipment require consideration. The main factors influencing power supply mode transmission mainly contains power/electricity consumption, breaker conditions and diesel generating sets conditions. In the switching process from mode two to mode one, assume that diesel generating set G6 is in breakdown maintenance and breaker P is broken. According to the task decomposition figure, detail the task to each underlying device. The loads in Mode one are thruster 1,2,3,4,5,6; main winch motor 1,2,3,4 and main top drive motor 1,2.

Partial realized program of pre-diagnostic function is shown as follows:

```
Sub a1() as bool                          // examining the feasibility of schema translation
If   Fix32.Fix.Lode.F_CV/0.95> Fix32.Fix.PL.F_CV
// Fix32.Fix.Lode.F_CV load power in model one, Fix32.Fix.PL.F_CV maximum available power of
power grid remain
       a1=false
else
a1=true
end if
end sub
Sub a2 () as bool
Dim s As Integer                          // examining how many diesel generating sets are on
      a2=false
exit sub
S=Fix32.Fix.Lode.F_CV/4896
a2=true
end sub
```

2.3. Power Supply and Power Distribution System Design of Drilling Platform Electric System

This platform selects alternator (synchronous generator). Galvanic magnet exciting coil produces structural magnetic field. Put magnet exciting coil on the rotor and put armature winding on the stator. Put two sets of power transformer in the cabin transformer room and the rated capacity is voltage: 1000kVA. The alternating–current distribution system on this platform is supplied by two parallel-operated main generators with 600v rating and 50Hz three phase insulation. The1000kVA 600/400v main transformer provides the platform with 400V power, and VFD and 2 sets of drilling motor provide with AC600V. The single line drawing of power distribution system is shown in figure 1:

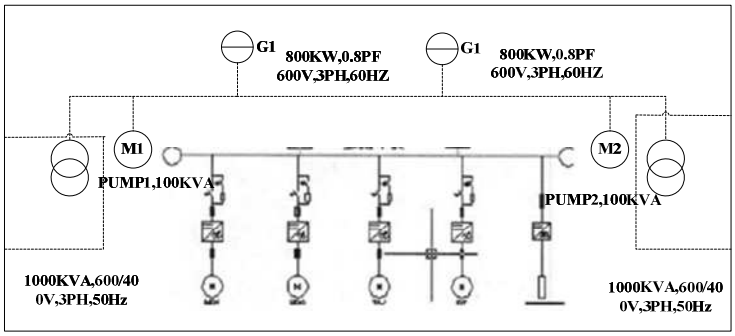

Figure 1: Single Line Drawing of power Distribution System

Variable Frequency Drive and Platform Grid Construction: We have completed the electricity distribution of drilling platform variable frequency drive system, analysis and single line drawing

design and calculating of frequency conversion system. The electricity distribution single line drawing of variable frequency drive system is shown in figure 2. In the figure, the main drilling equipment is constituted by four VFD-connected alternating current dynamos. Each dynamo contain a set of electrical machine cable and a set of controlling cable to connect air blower, air space heater, pull-rod cooling water pump, chain lubrication oil pump and safety isolating switch. The alternating current dynamo connected into the system is: one winch motor, two slush pump motors, one 600kW turntable drive motor, and one winch brake energy absorption resistance control panel.

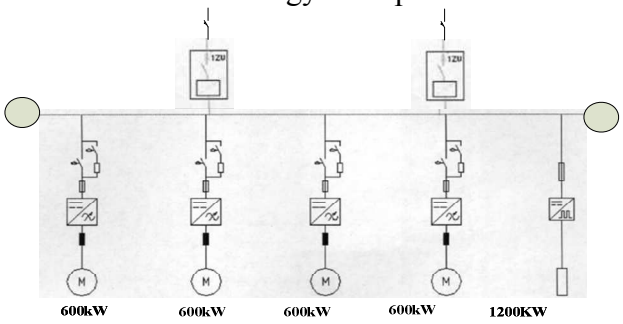

Figure2： VFD Control System

The electrical design of daily drilling drive electromechanical adopts AC variable frequency speed regulating. Full digital technical AC variable frequency speed regulating generates harmonic generation, which can be inhabited by increasing transducer pulse count.

All cables should satisfy the standard of IEEE-45, IEC33 etc. except some dedicated device adopting machine cables. Voltage class of power cable is 0.6/kV. Voltage class of instrument and controlling cable is 250V. Low-smoke, halogen-free, inflaming retarding set or fire-resistant offshore cable is with double sheath and tinned copper wire armoured, whose cable core can resist the degree of 85℃.

Electric Installation Selection of Main Distribution Board: According to power distribution system and application, this platform can be divided into 600V main distributing board, 400V switchboard. Power distribution unit structure contains switchboard protection grade, electric installation install ways, and framework and operation panel. Main switch of electric generator in offshore engineering project adopts air circuit breaker, like Terasaki AR12, Schnelder, MT, Siemens 3WL etc. the switch is selected according to formula (3) and (4) to ensure the overload protection.

$$I_{ac} = I_{acG2} + I_{acM1} \times 2 \quad (3)$$

$$i_{pc} = i_{pG2} + i_{pM1} \times 2 \quad (4)$$

Rated current should be larger than the electric generator's rated 860A current, rated 600V voltage, and rated 50Hz frequency. Rated short circuit making capacity is larger than the maximum expected peak current, namely the effective value of Iac(3.79kA). In conclusion, considering the price factors, this platform adopts Terasaki AR12 air circuit breaker (extraction type) as the main switch of the electric generator. There are many kinds of similar switches as the main switch of the load screen, like Terasaki XS, Schneider NS, Siemens 3VF, and ABB IsomaxS etc. This Platform adopts the Terasaki XS225NS moulded case circuit breaker. This platform adopts the Terasaki AR12 air circuit breaker (extraction type) as the switch of primary side of the transformer ACB6, 7, and adopts Terasaki ARZ165 air circuit breaker (extraction type) as the switch of transform vice side ACBS,9.

System Implementation

This paper adopts ESDA electrical modelling and analysis to conduct electric power design analysis. Firstly, we draw the single line drawing, and then we turn short-circuits calculation toolbar and select the different calculation standard in the standard selection menu. We adopt the IEC909 calculation basis, as shown in Figure 3.

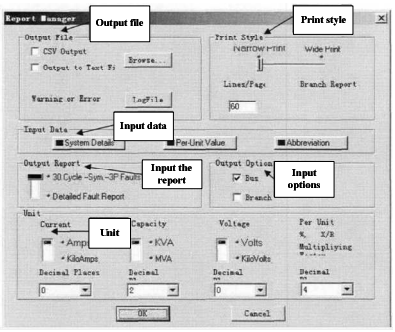

Figure3: IECgOg Standard Control Options

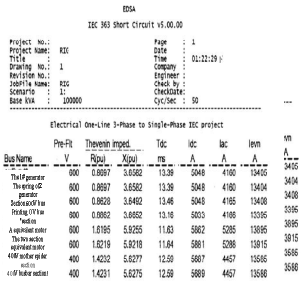

Figure4: EDSA calculation data

Short-circuit calculation adopts the computing method of IEC61363 three-phase alternating current system. Calculating software adopts EDSAZO05 (Revl), which is certificated by Sweden platform level club. Working conditions of calculation: three-phase short circuit current of two main generators in full-load operation and one main generator in full-load operation.

Summary: we can see from the EDSA calculating results that the calculating data of drilling platform power station get from EDSA is identical to the former calculation result. Hand computation lays emphasis on formula, ignoring a lot of parameters, while software relies on parameter adjustment, paying more attention to parameters. The value difference of formula computing and software computing is under 10%. Calculating result fully proves the correctness of drilling platform power station based on EDSA software and the design and short circuit calculation, which achieves the purpose of using EDSA for simulation.

Conclusion

By the drilling platform electric system design, this paper grasps the steps of platform power station design, understands comprehensively controller switching equipment like generator, switchboard etc. and gets familiar with the short-circuit current and distribution switch examination. By EDSA modelling, we compute the short-circuit current and the simulation result design is similar to the calculating result, which proves the correctness in two ways and can be the reference and of engineering significance to the development of offshore platform electric system design.

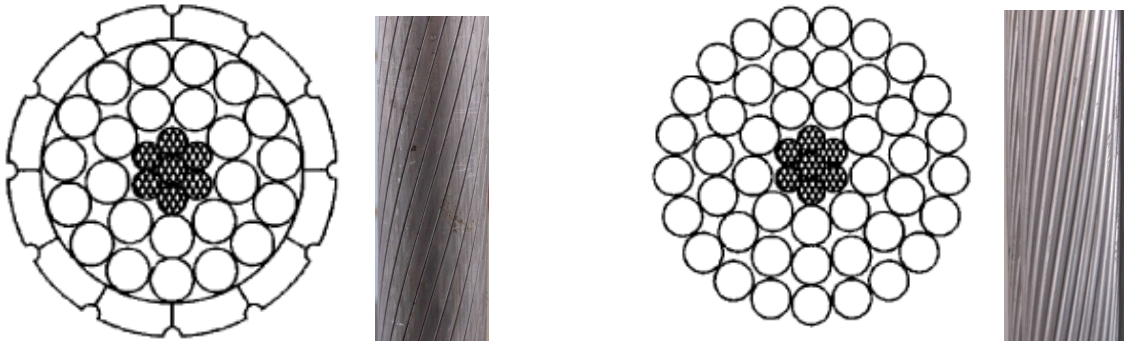
Keywords: energy-saving conductor, ice accretion characteristic, icing test

Abstract. New type of energy-saving conductor which can obviously reduce the transmission losses was recently developed in power project. However, considering ice-coating and galloping in winter, it is necessary to investigate its ice accretion characteristic compared with conventional conductor. Research was conducted by icing wind tunnel test. Ice mass and ice shape of conductor with different diameter were examined. There is no clear advantage on the ice-coating resistance capability of energy-saving conductor with small diameter, while for conductor with larger diameter, energy-saving conductor's ice-coating resistance capability is better than conventional conductor. The test result is helpful for choosing suitable type of large diameter conductor in high and ultra-high voltage transmission project.

Introduction

In recent year, a new type of conductor for transmission lines has been developed. Small semi-circular or trapezoid grooves are spirally engraved on the newly designed conductor's surface, as shown in Fig.1a. The global surface configuration of newly developed conductor is much smoother than that of a conventional conductor, shown in Fig.1b (Eguchi [1]).



(a) Recently developed conductor (b) Conventional conductor

Fig. 1 Cross-section of two types of conductors

It has been found that because of the smoother surface and smaller ruggedness, the electric property of the new type of conductor is better than that of conventional conductor. It is called energy-saving conductor for less electric loss than conventional conductor in long distance power transmission. It seems that the new conductor is more suitable for the high and ultra-high voltage transmission projects being set up in China. However, more and more transmission lines will cross valleys, rivers and micrometeorological area in mountainous regions of west and south China, ice accretion on conductor is inevitable in winter. Under certain condition, wind can induce galloping--large amplitude, low frequency self-oscillation of ice-coated conductor (Nigol [2]). Galloping can be extremely harmful to the safe operation of power transmission system. It is necessary to investigate energy-saving conductor's ice accretion characteristic by test, comparing

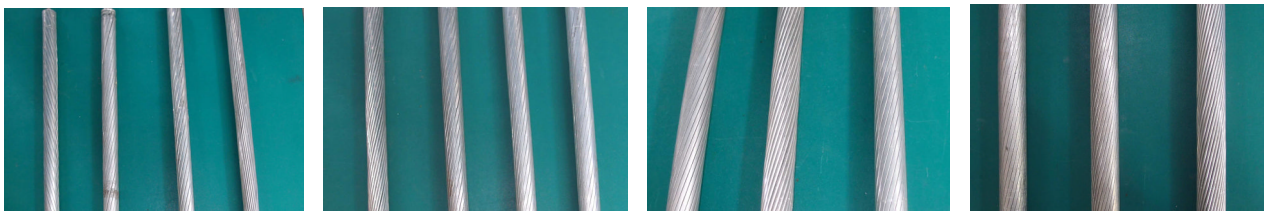
with that of conventional conductor. There are certain limits of using the current available test results, which all focus on conventional conductor (Long [3] and Fu [4]). In this research, small size ice wind tunnel was used to investigate ice accretion characteristic on 4 different diameter groups of energy-saving and conventional conductor commonly used in transmission project.

Experiment Design

Icing test was conducted in 0.3 m×0.2m ice wind tunnel at Low Speed Aerodynamics Institute of China Aerodynamics Research and Development Center (CARDC). The ice wind tunnel is a close-circuit wind tunnel with two sections in tandem. The second section where test was conducted, is 0.3m×0.2m, as shown in Fig.2. The maximum wind speed in the second section is 60m/s, the lowest temperature is -30℃. In test, the temperature was dropped to the preset value by cooling system, while water spraying device was used to generate mist. MVD was 50 μm in the test, which was comparable to the size of water droplet in natural rainy and foggy weather.

The test models are sections of real conductor. There are 14 types of conductor, which divided into 4 groups with diameter about 25mm, 30mm, 34mm and 40mm respectively, as shown in Fig.3. For every group, there are one conventional conductor, which is No.4, No.5, No.10 and No.14 respectively, and other 2~3 energy-saving conductors. Models were firmly mounted horizontally in the tunnel, the test wind speed was 8m/s and 15m/s, temperature was -6℃. After 30minutes icing, the ice mass and ice shape would be recorded and analyzed.

Fig.2 Test section of ice wind tunnel



No.01～04 No.05～08 No.09～11 No.12～14

Fig.3 4 Groups of conductors

Analysis of Ice Accretion Characteristic

Kind of Ice Shape. Ice accretion phenomena on conductors are clearly, the most common ice shapes on conductor are fan-shaped, crescent and shape similar to crescent with smoother outline. Under natural condition, the most common ice shapes on conductor are crescent and fan-shaped, which is confirmed in this study, as shown in Fig4.

Influence of Wind Speed. Some conductors with detail geometric data of ice shape at different wind speed are shownd in Fig4. The change of ice mass of all conductors is shown in Tab.1. For every conductor, there is a noticeable increase of ice mass with the increase of wind speed. There is even more than 3 times larger amount of ice mass at wind speed 15m/s than that of at 8m/s. This mainly because that over-frozen droplet in mist moves with the air flow, the larger the speed is, the

more amounts of droplets will collide directly with conductor's surface and solidifying and freezing on the surfac. From literature [5], "when temperature is mild (higher than -10℃), wind speed 15m/s is more favorable for ice accretion", considering comman climate condition in power project operation, 8m/s and 15m/s reasonably reprents conductor's ice accretion characteristic at low and high wind speed respectivly. Basically, the thickness and cross-section areas of ice shape at 15m/s is also larger. For some conductors, the increase of ice mass with the speed may even cause the ice shape change from crescent or shape similar to crescent to fan-shaped, for example, conductor No.4, which means larger aerodynamic forces on conductor. This may pose safety issues to the transmission system and should be taken into great consideration in design and operation.

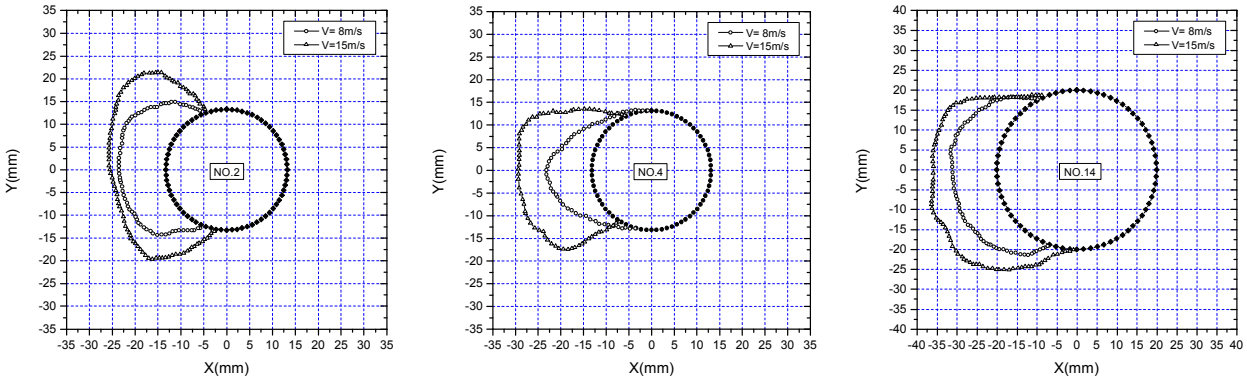


Fig.4 Geometric form of ice shapes

Table 1 Ice mass changes with types of conductors (g)

Group No.	Type No.	Ice mass V= 8m/s	Ice mass V= 15m/s	Type No.	Ice mass V= 8m/s	Ice mass V= 15m/s
1	No.1 d=25mm	93.6	152.7	No.2 d=25.2mm	98.9	193.6
	No.3 d=25.94mm	72.5	183.9	No.4 d=26.67mm	53.3	196.3
2	No.5 d=30mm	103.8	158.2	No.6 d=30.2mm	110.6	230.0
	No.7 d=30.2mm	80.2	160.8	No.8 d=30.5mm	102.7	202.6
3	No.9 d=32.4mm	129.2	229.4	No.10 d=33.75mm	64.3	98.2
	No.11 d=33.9mm	48.9	84.4	---	----	---
4	No.12 d=39.5mm	107.8	172.7	No.13 d=39.5mm	76.7	101.7
	No.14 d=39.9mm	124.8	197.0	---	---	---

Comparison of Ice-coating Resistance Capability of Two Kinds of Conductors

As shown in Tab.1, when wind speed is 8m/s, from group1 to group 4, conductor with smallest value of ice mass in each group is conventional conductor No.4, energy-saving conductor No.7, energy-saving conductor No.11, energy-saving conductor No.13 respectively. Conductor with largest value of ice mass in each group is energy-saving conductor No.2, energy-saving conductor No.6, energy-saving conductor No.9, conventional conductor No.14.

As for 15m/s, conductor with smallest value of ice mass is energy-saving conductor No.1, conventional conductor No.5, energy-saving conductor No.11, energy-saving conductor No.13. Conductor with largest value of ice mass is conventional conductor No.4, energy-saving conductor No.6, energy-saving conductor No.9, conventional conductor No.14.

It can be found that, when the diameter of conductor is less than 30.5mm, for example group 1&2, there is no clear advantage in ice-coating resistance capability for energy-saving conductor compared with conventional conductor. Sometimes, the value of ice mass of conventional conductor is the smallest. While with the increase of conductor's diameter, the advantage of energy-saving conductor becomes more and more clear. In group 3, the ice accretion characteristic of energy-saving conductor No.11 is better than conventional conductor No.10. While for the group 4 with relative larger diameter, all two types of energy-saving conductors' ice accretion characteristic are better than conventional conductor at all testing wind speed, especially No.13. This conclusion can be helpful for choosing suitable type of large diameter conductor in high and ultra-high voltage transmission project.

Ice mass and ice thickness do not increase linearly with the increase of conductor's diameter. Attention should be paid that, for the conventional conductor series, the value of ice mass of No.14 conductor with largest diameter is the largest at different testing speed, while for the energy-saving conductor series, the value of ice mass of No.9 and No.6 conductor with smaller diameter is the largest respectively. That also means that energy-saving conductor with large diameter may has the better ice accretion characteristic.

Conclusions

Ice accretion phenomena on conductors are clearly, the most common ice shapes on conductor are fan-shaped, crescent and shape similar to crescent. There is a noticeable increase of ice mass with the wind speed, 3 times larger amount of ice mass at higher speed than at lower speed was observed. The increase of ice mass with the speed may even result in the change of ice shape's type. Ice mass and ice thickness do not increase linearly with the increase of conductor's diameter. Comparing with conventional conductor, there is no clear advantage on the ice-coating resistance capability of energy-saving conductor with small diameter, while for conductor with large diameter, particular type of energy-saving conductor's ice-coating resistance capability is much better.

Keywords: New Energy, Automobile, Battery Pack, Welding

Abstract. This article presents some research of welding methods according to battery pack working requirements of new energy automotive, for meeting the battery pack processing of new energy automotive in theory , single-sided duplex parallel resistance mass spot welding process is proposed.

Introduction

Currently, the new-energy automobile industry is listed in the seven national strategic emerging industries in China and therefore, the development of new energy automobiles is the historic opportunity of China's automobile industry. With increasingly serious environmental pollution and energy shortage, the research, development and promotion of new energy automobiles have become the core concern of governments and enterprises of all countries. Hereinto, power battery is the key technology as well as the bottleneck technology in the development of electric automobile due to its significant role in handling quality, driving safety, reliability and research and development costs of electric automobile [1]. For the secondary batteries researched and developed over the past decades such as nickel-cadmium, plumbic acid, nickel metal hydride, lithium ion and zinc air battery as well as fuel cell, they all have their own characteristics. However, considering the features required by electric automobile such as safety, high capacity, high-energy density and service life, lithium ion battery is going to become the mainstream technical trend that will be developed by all electric automobile enterprises. Apart from the performance features possessed by lithium ion battery itself, using lithium ion battery as the power supply system of electric automobile in China also possesses the following advantages: the mineral resources that manufacture lithium ion battery such as lithium, manganese, iron, vanadium, etc. are abundant; the technical level and scale of lithium ion battery in China has reached the world leading level; the production and processing of lithium ion battery have formed the integrated industry chain and the annual output of battery has reached more than 1/3 of the world's total output, which promotes the electric automobile to develop toward industrialization and large scale. Striving to develop lithium ion power battery industry will promote the development of new-energy automobile industry in China effectively.

In order to meet the requirements in terms of voltage, power and energy of the whole power supply system, lithium ion battery pack generally consists of several shunt-wound lithium-ion cell monomers and the nickel plating steel sheet and lithium ion battery core are welded through resistance spot welding technique under normal conditions during mass production. The internal resistance of battery pack will be increased if the welding strength is too low and in some severe cases, the lithium ion battery core and nickel plating steel sheet will be separated because the welding is not firm and this can lead to the failure of power supply; if the welding strength is too high, then it will cause the leakage of electrolyte and the combustion or explosion of lithium ion battery pack due to short circuit [2]. Therefore, resistance spot welding becomes a significant procedure in the production process of battery pack. Welding quality has a decisive effect on quality of lithium ion battery pack and its service life. As a result, the automatic welding machine principle in series-parallel welding of Model 18650 cylinder-shaped lithium ion battery commonly used in power supply system for new energy automobiles is discussed in this paper.

Determining the Welding Method

Fig. 1 below is the real photo of lithium ion battery pack applied in power supply system of new energy automobiles. Fig. 2 is the dimensional sketch of lithium-ion cell monomer.

Fig. 1 Real Photo of Lithium Ion Battery Pack

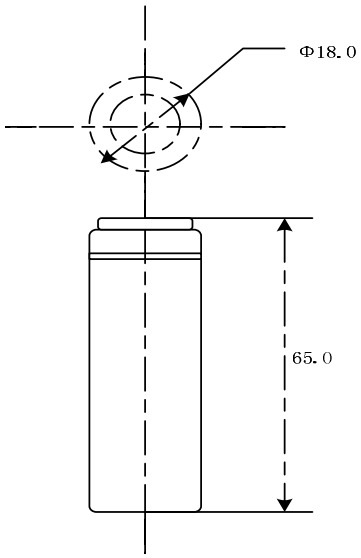

Fig.2 Dimensional Sketch of Lithium Ion Battery

The welding methods of metals can be divided into three categories according to the characteristics of technical process and they are fusion welding, pressure welding and braze welding. The welding heat sources are varied, including flame, electric arc, resistance, ultrasonic wave, friction, plasma, electron beam, laser beam, microwave, etc. Considering the welding of lithium ion battery pack is the lap welding of thin plate, pressure welding technique of resistance spot welding is adopted in this paper.

Through utilizing the resistance heat from the contact surface when the current flows through the workpiece to heat the workpiece to be welded which is pressed between electrodes to melting state and finally, the efficient and economical metal binding welding-and-forming technique is formed. This technique possesses many advantages such as concentrated heat quantity, small welding deformation, without using welding material, less auxiliary processes, low energy consumption and non-pollution, simple processing and achieving welding automation easily, etc. The operating principle is shown in Fig. 3.

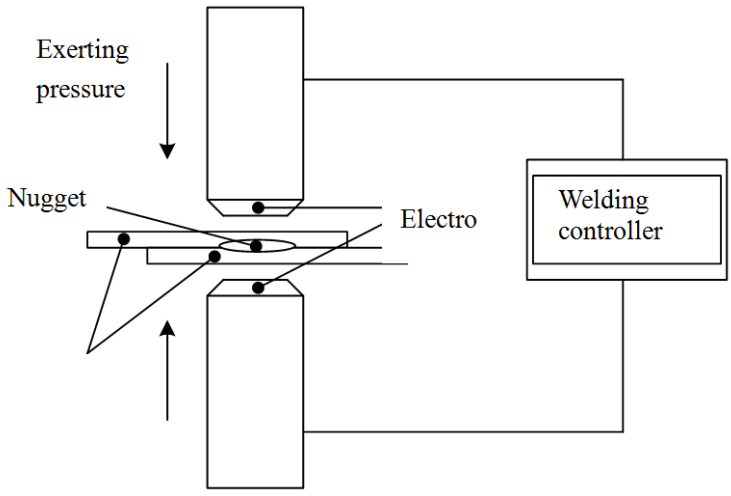

Fig. 3. Diagram for Operating Principle of Resistance Spot Welding

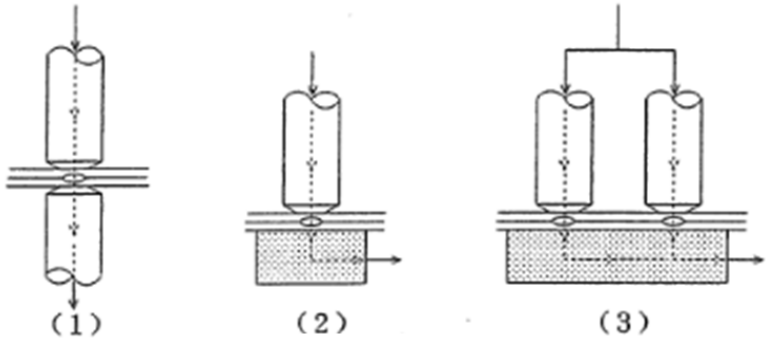
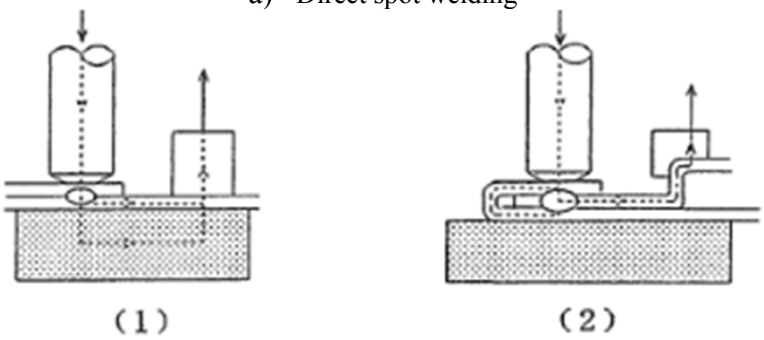
Determining the Electrification Method

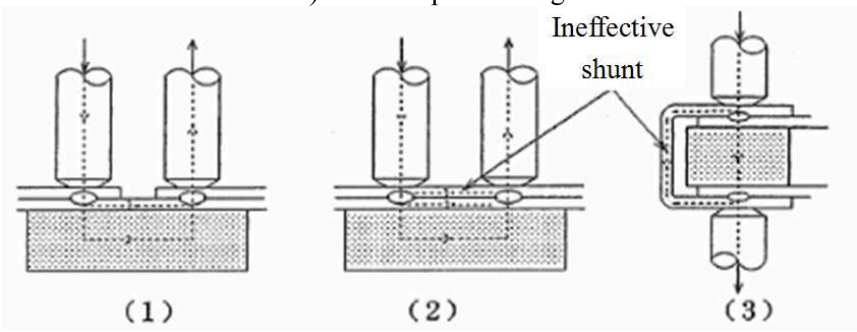
Based on the different discharge methods of electrode to workpiece to be welded, resistance spot welding mainly can be divided into four categories: direct spot welding, indirect spot welding, series spot welding and duplex spot welding. Some common electrification methods in spot welding are presented in Fig. 4.



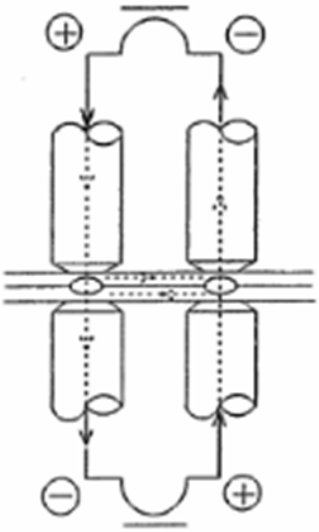
a) Direct spot welding



b) Indirect spot welding



c) Series spot welding



d) Duplex spot welding(Push-pull spot welding)

Fig. 4. Some Common Electrifying Methods in Spot Welding

In direct spot welding, a group of electrodes directly clamp the workpiece to be welded tightly through exerting pressure and the welding current flows through one of the electrode and the contact surface of workpiece to be welded to another electrode and forms conducting state; while indirect spot welding is the current of the contact surface of workpiece to be welded flows through one certain part of the workpiece from one electrode to another; series spot welding refers to the case in which the current flows through two contact regions in sequence and performs spot welding when there are two contact regions in one welding current circuit, however, in some cases, the current may be shunted and the electrode shall be increased in order to prevent the decrease of current efficiency and to guarantee the welding quality; duplex spot welding is using the welding transformer of both ends of the electrode and performing duplex spot welding simultaneously. Compared with series spot welding, this method can decrease shunt phenomena. Due to the structure and characteristics of lithium ion battery core, direct spot welding method is hard to achieve the welding between battery core and the connecting sheet. Therefore, the unilateral duplex parallel spot welding method shall be adopted.

Conclusion

Based on the practical situation of lithium ion battery pack used in the power supply system of new energy automobiles in this paper, the existing welding techniques and process are analyzed. It is believed that resistance mash spot welding technique is more reasonable and the single-sided duplex parallel spot welding method shall be adopted in terms of electrification methods. This paper only focuses on theoretical discussion currently and the next step is to conduct experimental investigation systematically in order to determine the proper welding method and corresponding technological parameters and achieve better welding effects.

Finite Element Analysis for the Collapse Accident of A 110kV Transmission Tower

Yi Zhu，Bo Li，Hao Wang，Kun Li

Economic & Technology Research Institute, State Grid Shandong Electric Power Company, Shandong Jinan 250021;

Keywords: straight-line tower ; the strong wind ; collapse ; the finite element analysis ; line tower coupling

Abstract. Put the finite element analysis of line tower coupling modeling to the collapse of a 110 kV line straight-line tower, study the effect of strong wind on transmission tower and wire. The results show that under the action of strong wind, the material specification selected by the part of the rods on the type of tower is lower, cross section is smaller, the principal material of tower will be instable and flexional under the compression, resulting in tower collapsed.

Introduction

On April 29, 2011, the rainstorm appeared in the via area of a 110kV line, gust grade is 10, local wind grade is 11. On ten past zero, April 30, the line zero-sequence I segment and distance I segment generate protective action, so that superposition is not successful. Through inspection the cause is that the tower body of the line # 11, # 12 and # 13 tower collapsed due to storm wind.

Fig.1 A case of #12 tower failure for 110 kV transmission line

Fig.2 A case of No.13 tower failure for 110 kV transmission line

Free-standing transmission tower, which is connected by Angle steel or steel pipe, is a large space hyperstatic truss structure. Many of the running transmission tower in actual lines are designed in the 1980s or even earlier, when due to the limitations of design methods and analytic means, it is difficult to make a comprehensive & detailed analysis and evaluation for the design structure, and unable to fully consider the issues of strength, stiffness and stability of each component in the structure. With frequent extreme weather in recent years, some security issues on transmission tower putting into use in earlier times become more prominent [1].

Using general finite element analysis software ANSYS, this paper aimed at the local weather conditions to establish mechanical calculation model of transmission tower, research the structure characteristics of transmission tower in line, determine the condition of tower structure strength in such extreme operating condition, to get stress state in each rod, and find out the reasons for the collapse of transmission towers.

1 The finite element modeling for transmission tower

1.1 Transmission tower structure

11 and # 12, # 13 tower are 110kv ZGU2-21 (7727) straight-line dual-circuits tower, the type of tower is designed in the late 1970s.The nominal height of the tower is 21 m, and the total height is 31 m. The root open is 4.595 m for front, and 3.214 m for side. The design for horizontal span is 350 m, vertical span is 350 m,and the actual span is 328 m.The landing leg and the main limb on body part 1 of the tower are connected by different specifications of the Q345 angle steel, and the

others are all connected by Q235 angle steel. The structure type is shown in figure 3. The model number of wire is LGJ - 240/40, the model number of ground wire is GJ - 50.

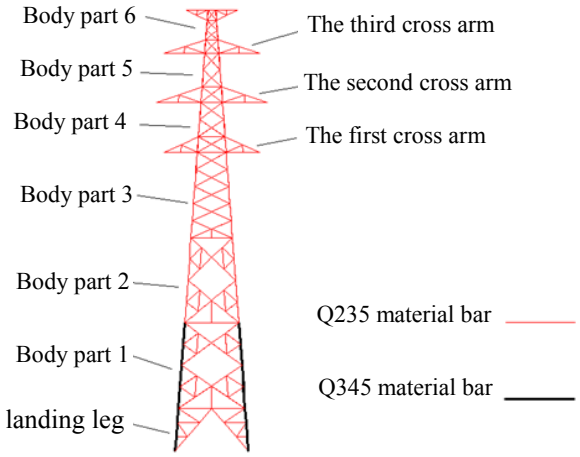

Fig.3 Subsection numbers and structures of #11-#13 straight-line towers

1.2 Finite element analysis model

Due to the interaction of the stress of wire, ground wire and transmission tower, in order to accurately simulate the stress status of tower, build a model for wire (ground wire) together with the tower, build a three-towers&four-wire finite element model. Transmission towers using beam elements Beam188 to disperse all rods, the rods are connected with each other through steel node, ignore the specific structure of the junction, only consider the quality of the connection, and regardless of the impact of the jumper wire connection and the altitude difference of the wire suspension point[2]. On the basis of the wire (ground wire)"form-finding"[3], according to the deformation and mechanical characteristics of wire (ground wire), using the rod element of LINK10 to conduct the model, when calculating the geometric nonlinear effects should be considered.

1.3 Computational load

As far as analysis for working condition, the load auctioning on transmission tower can be divided into three parts: the first part is the self-weight of transmission tower structure; the second part is the role of the wire (ground wire) to the transmission tower; the third part is the impact of wind loads. According to local meteorological conditions, use the wind of grade 11 to account in this calculation(30m/s), the wind direction with the line is 90°. Load combination considers the combined action of these three part load.

2 The assessment for structural strength of transmission tower structure

According to the specification requirements, base on the design theory of probability limit, in accordance with the requirements of The Technical Specification For 110～750kV Overhead Transmission Lines GB50545-2010[4], the transmission tower components were categorically assessed according to the nature of stress.

2.1 The strength calculation of tension components

According to the specification requirements, use the following formula to calculate the strength of tension components：

$$\sigma = \frac{N}{m \cdot A_n} \pm \frac{M}{m_M \cdot W} \le f \tag{1}$$

In this formula, N is the axial force ; An is the net sectional area of components ; m is the strength reduction factor for the axial stress components, regarding to the single limb connection angle steel components, m=0.85[5] ; mM is the stable strength reduction factor for flexural components, regarding to the single limb connection angle steel components, mM=1.0 ; M is the bending moment design value ; W is the net section resistance moment of components ; f is the strength design value of the material.

2.2 Local stability calculation of compression member

After the transmission tower structure under load, about half of the rods bear the combined action of the axial pressure and bending moment, these rods may exist the possibility of instability. Loss of overall stability of transmission tower is because of the accumulation of each rod local instability, which changes the structure into mechanism. According to the specification requirements, use the following formula to calculate the local stability of the compression member:

$$\sigma = \frac{N}{\phi \cdot m_N \cdot A} \pm \frac{M}{m_M \cdot W} \le f \qquad (2)$$

In this formula, A is gross sectional area of components ; ϕ is axial compression stability coefficient of components ; mN is the stable strength reduction factor for compressive rod, regarding to the equilateral double angle steel components, mN=1.0[5] ;W is the gross section resistance moment of components.

3 The analysis for calculation results and collapsed reasons.

3.1 The analysis for structural strength

For the same three-tower structure and the similar runtime environment, the calculation results of the three-tower are basically the same. In order o save space, this article only specifically describe the calculation of # 12 straight tower. Under the action of strong wind (wind direction is perpendicular to the line direction), the tension member of # 12 straight tower account for 48.8% of the total rods, the compression member account for 51.2%. The maximum stress and the location of bars of two kinds of material for transmission towers are shown in Table 1 and Figure 4.

Tab.1 The maximum stress and the location of bars

Rod material	The maximum tensile stress of tension member(MPa)	The maximum compressive stress of compression member(MPa)	Strength design values[6] (MPa)	The location of the maximum stress
Q345	306.6	332.2	310	The rods in leeward side of the root of landing leg
Q235	217.8	272.2	215	The rods in leeward side of the connection location of body part 1 and body part 2

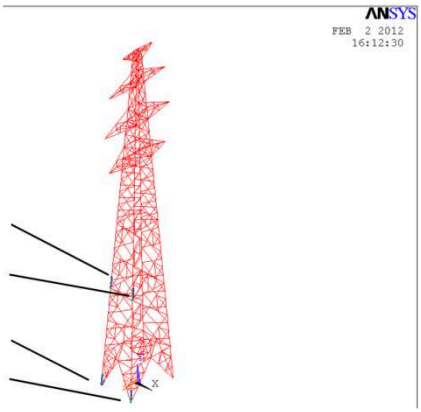

Fig.4 The location of the maximum stress of Q345 and Q235 rod members.

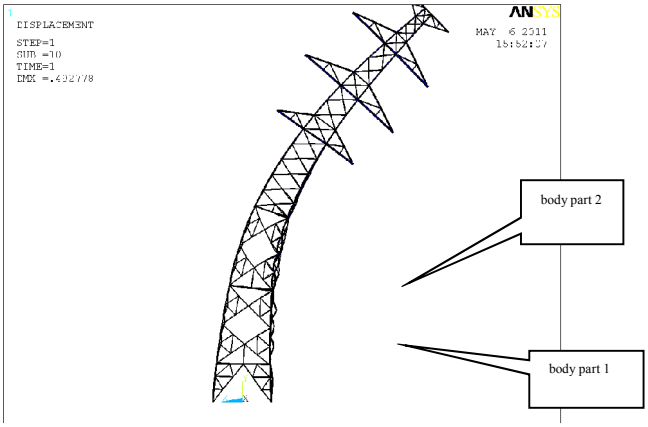

Fig.5 The deformation of tower body

3.2 The analysis for the structural deformation

Under the action of strong wind (wind direction is perpendicular to the wire), the transmission tower rods in the connection location of body part 1 and body part 2 all generate the larger deformation, as shown in Figure 5.

3.3 The analysis for collapsed reasons

Sample the principal material and auxiliary material of the collapsed #11-#13 line tower, and make the material testing analysis for the chemical composition, organizational analysis, mechanical properties, according to the test results, the tissue of the principal material and auxiliary

material are normal, element content and mechanical properties at room temperature conform to the requirements of *The Carbon Structural Steel* GB/T700-2006[11] for Q235 and Q345 structural steel.

Synthesize the calculation results of stress and displacement, and combine the design strength value of the component material, the principal material of the root of landing leg, and the rod material of the connection location etc of body part 1 and body part 2 all generated overstressing. Among them the maximum overstressing proportion of the principal material is 4%, and the maximum overstressing proportion of the rod material of the connection location of body part 1 and body part 2 is 26%. In terms of deformation, the overall structure on the location of body part 1 and body part 2 generate the maximum deformation, so under the action of strong wind (wind direction is perpendicular to the line direction), this position is the most dangerous position, which may be damaged because of the strength and the insufficient local stability, the analysis results are consistent with the the actual collapsed situation of tower, as shown in Figure 1 and Figure 2.

In view of the collapse accidents have occurred many times in the region in history (the year of 2002 and 2005), when the wind speed all exceed 30.0 m/s. So it should be appropriate to improve the design standards of wind resistance in the region, and it is suggest that the collapse of the 110kV line 7727 type tower in the region is generally surveyed. On the basis of the wind speed no less than 33m/s (wind grade is 12), again according to *The Technical Specification For 110～750kV Overhead Transmission Lines* (GB50545-2010) to check reinforcement ; In densely populated areas and tuyere areas, it is suggest that make a reinforcement processing for under 300m span transmission tower, and make a redesigned replacement for more than 300 m span transmission tower, in order to prevent the collapse accidents from happening again.

4 Conclusion

1) The reason for the collapse of the line is that under the action of the strong wind of grade 11, the connection location of tower body 1 and body 2 generate overstressing, take place larger deformation, cause the principal material of tower instability and flexion under the compression.

2) The tower type (7727) is finalized in 1977, according to The Technical Specification For 110～750kV Overhead Transmission Lines (GB50545-2010) accounting, found the body part 2 and above the main limb bar choose Q235, material specifications is lower, unable to meet the using demand of the strong wind of grade 11.

3) It is suggest that suitably improve the wind-resistant design standards in the wind prone areas in history, the old lines in such regions need a re-checking reinforcement, in order to prevent the collapse accidents from happening again.

Impacts of Diverting Potential Difference on Armored Cables in Substations

Li CHEN

Transmission and Distribution Line Training Department, Sichuan Electric Power Corporation, Skills Training Centre, Chengdu 611133, China

email: chitangyuan@163.com

Keywords: Grounding Grid; Ground Resistance; Diverting Potential Difference; Armored Cable; CDEGS

Abstract. To reduce the interference on communication equipments caused by transient electromagnetic field of switching operation, the shields of cables are connected to grounding grid on both sides in the substations grounding designs. However, when the substation is stroke by lightning or shorted, the huge potential difference called diverting potential difference between the cable core and the shield is generated, which can easily destroy insulation of cables, even producing electrical tree or dielectric breakdown in insulation material. Moreover, the large current flowing through the shield of cables will cause personnel accidents and equipment damages. In this paper, the electric model of cables is established using grounding grid simulation software—CEDGS. The way diverting potential difference changes influenced by grounding grids, soil and other parameters is analyzed. Measures to reduce diverting potential difference are proposed for providing a theoretical basis of construction in practice.

Introduction

Diverting potential [1] refers to the potential which is transferred from grounding device to the equipment with bonding conductors when the short-circuit current or the lightning current flows through the grounding device. To reduce the interference on communication equipments caused by transient electromagnetic field of switching operation, the shields of cables are connected to grounding grid on both sides in the substations grounding designs. However, when the substation is stroke by lightning or shorted, the huge potential difference called diverting potential difference between the cable core and the shield is generated, which can easily destroy insulation of cables, even producing electrical tree or dielectric breakdown in insulation material. Moreover, the large current flowing through the shield of cables will cause personnel accidents and equipment damages [2] [3].

In addition, the grounding grids in China are made from steel instead of copper because steel is much cheaper than copper. As a result, the problem of ground potential unbalance is more outstanding than that at abroad. Especially on the condition that substation is stroke by lightning which produce high-frequency current, along with the facts that permeability of steel is much larger —200 times than copper, so the gradient of grounding grid potential is much too big [4]. In order to solve the above problems, it is necessary to analysis impacts of diverting potential difference on armored cables in substations [5].

In this paper, the diverting potential caused short circuit in substations is discussed merely, because characteristics of lightning stroke in the substations are much more complex.

Cable model and grounding grid model

The current flowing through armor tier is composed of short-circuit current. Not only it's related to short-circuit current and the location where the current empties into earth, but also it's affected by the topology of the network. It's difficult to calculate the result by numerical analysis in practice [6] [7] [8]. With grounding grids simulation software—CEDGS, the rule of diverting potential influenced by grounding grids and soil can easily be obtained.

We assume that the grounding gird is a square, the length of one side is 100 meters. The distance of equalizing conductors is 10 meters. Grounding grid which is made from copper is buried 0.8 meters deep. The grounding conductors' radius is 10.1 millimeters, and the shape is cylindrical. Homogeneous soil resistivity is 500 $\Omega \bullet m$. There is a VV22 armored cable in substation transferring status signals from primary side to central control room. The length of the cable is 60 meters. This single core cable's nominal cross section area is 10 square millimeters. The material of the core is copper, and the material of the armor tier is steel. The inner diameter of armor tier is 4.9 millimeters, the external diameter is 5.0 millimeters. The armor tier is stretched over with PVC of 2 millimeters thickness. The cable's parameters are shown in Figure1.

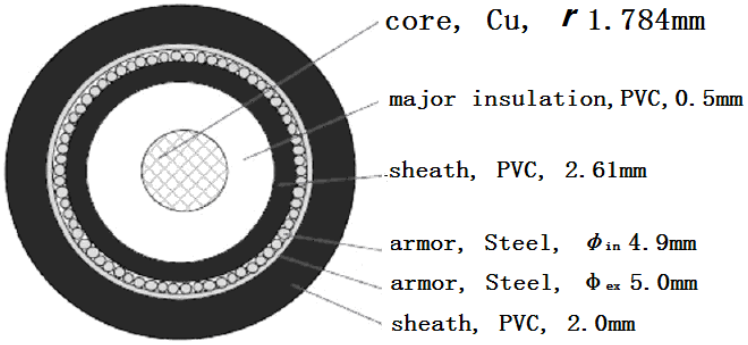

Fig.1. The armor cable—VV22

The cable is buried in 0.1 meters depth. Core conductor is connected to grounding grid through equivalent output impedance which is 300 Ω at primary side, and is connected to grounding grid through equivalent input impedance which is 1 Ω in the control room. Armored shield is connected to grounding grid at both sides by earth connecting conductors which is made from steel. The radius of earth connecting conductors is 2 millimeters. Suppose 10kA short-circuit current flows into grounding grid, the location where the current empties into earth is shown in Figure2.

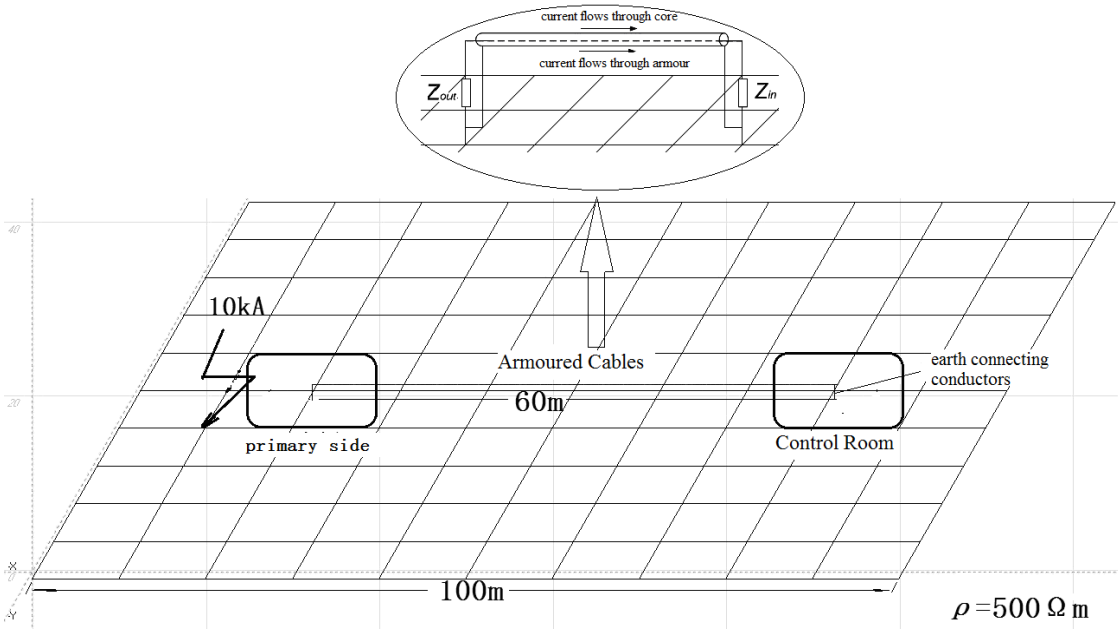

Fig.2. Simulation model of grounding grid and armored cable

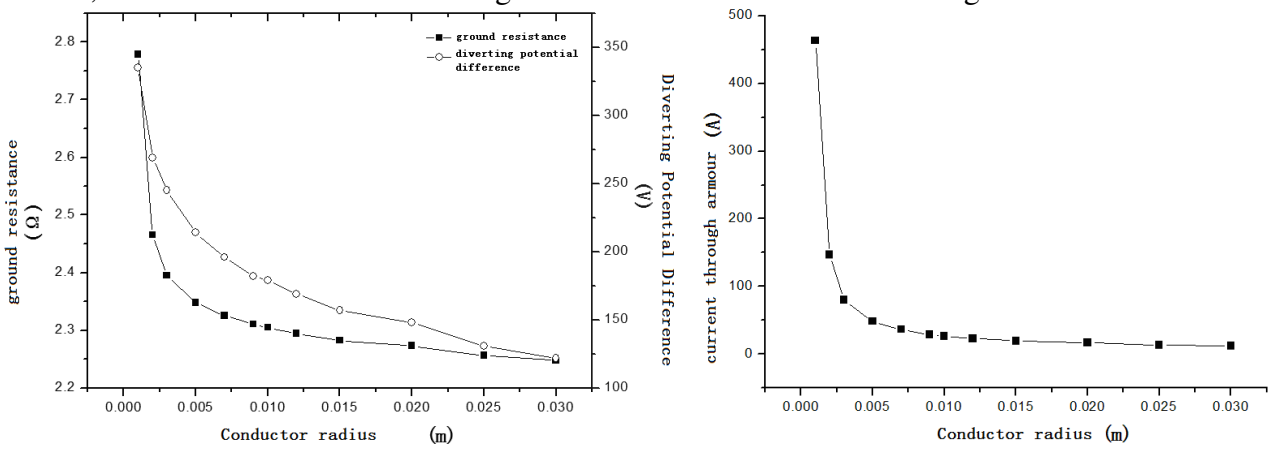
Test results of homogeneous soil model

Through the simulation of CDEGS, the biggest diverting potential difference between the core and the armor can be obtained near primary side, because the gradient of grounding grids potential is much bigger in this area [9]. Diverting potential difference discussed later in this paper refers the biggest voltage between the core and the armor.

Put the calculation parameters into CDEGS, and assume respectively the radius of grounding conductor will be 0.001m, 0.002m, 0.003m, 0.005m, 0.007m, 0.009m, 0.010m, 0.012m, 0.015m, 0.020m, 0.025m and 0.030m. The change rules can be obtained shown in Figure3.



(a) The influence on diverting potential difference (b) The influence on current through armor

Fig.3. The simulation result influenced by conductor radius

Analyzing the data, we can draw a conclusion that conductor radius is smaller, ground potential is more unbalanced, which will lead to the bigger diverting potential difference. When the radius becomes bigger, the fault current is prone to flow into earth and the potential unbalanced degree of grounding grid is declining, so the diverting potential difference and current flow through armor becomes smaller.

Keep the parameters of grounding grid and armored cable unchanged, and assume respectively homogeneous soil resistivity will be $500\,\Omega \bullet m$, $1000\,\Omega \bullet m$, $1500\,\Omega \bullet m$, $2000\,\Omega \bullet m$, $2500\,\Omega \bullet m$ and $3000\,\Omega \bullet m$. The change rules can be obtained shown in Figure4.

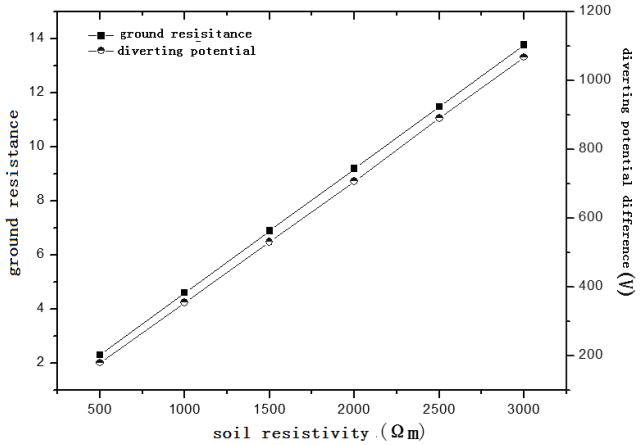


Fig.4. The simulation result influenced by soil resistivity

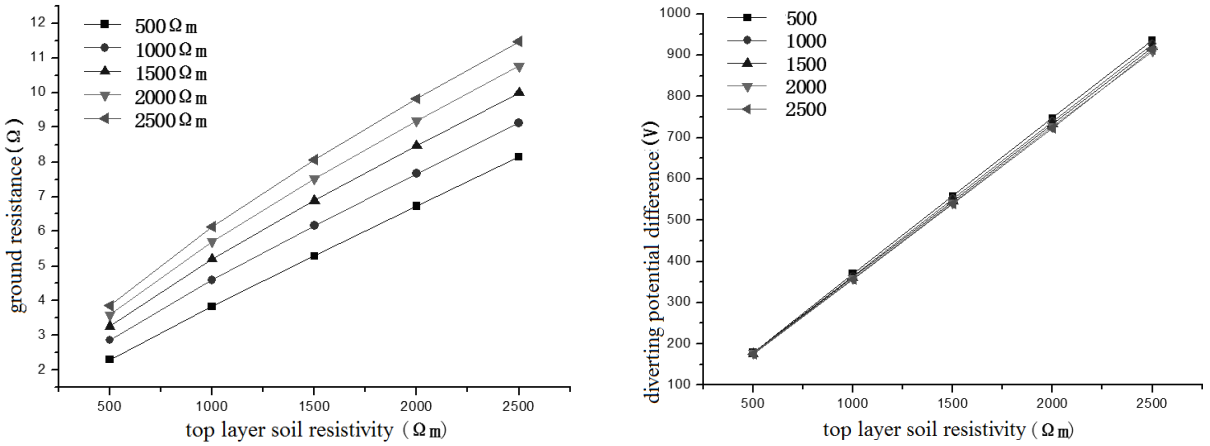
The result is obvious that soil resistivity is proportional to ground resistance and diverting potential difference. However, the current which flows through armor tier keeps no change.

It's been proved that in engineering design inductive effect of grounding grids can't be ignored for 500kV large substations or substations stroke by lightning because potential unbalanced degree becomes bigger. In this simulation, homogeneous soil resistivity doesn't affect potential unbalanced degree of the grounding grid due to current remaining unchanged, so the reason why diverting potential increase is that the potential of the whole grounding grid becomes larger. The soil resistivity is bigger, the more difficulty for current to disperse in the soil.

Test results of horizontal two layer soil model

Keep the parameters of grounding grid and armored cable unchanged, and assume the bottom layer soil resistivity is 500 $\Omega \bullet m$ which the thickness is infinite and the top layer thickness is 50 meters. Put $500\,\Omega \bullet m$, $1000\,\Omega \bullet m$, $1500\,\Omega \bullet m$, $2000\,\Omega \bullet m$ and $2500\,\Omega \bullet m$ into the top layer soil resistivity. The change rules can be obtained shown in Figure5.



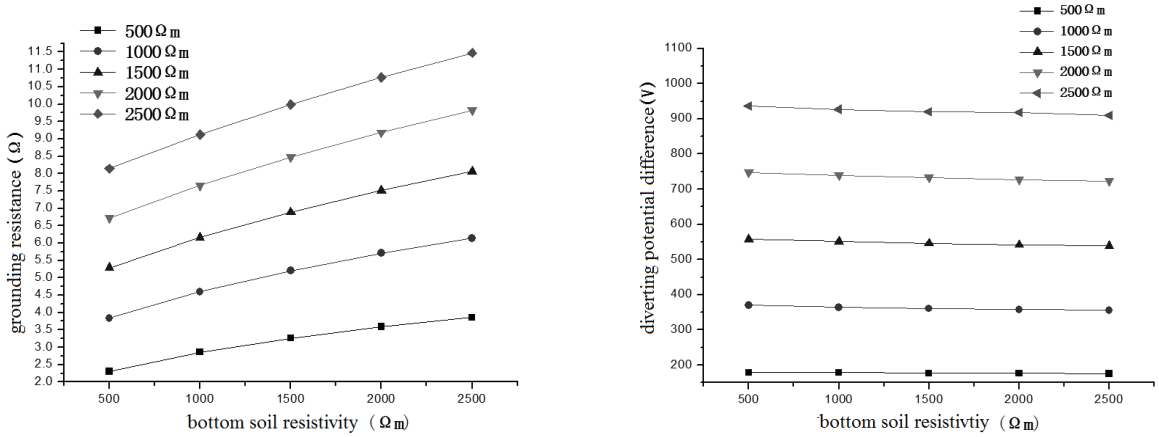
(a) The influence on ground resistance (b) The influence on diverting potential difference

Fig.5. The simulation result influenced by top layer soil resistivity

The result shows that top soil resistivity is proportional to ground resistance, diverting potential difference and current flowing through armor tier. With the increasing of soil resistivity, the ground resistance increases. As a result, diverting potential difference becomes larger due to the increasing of unbalanced degree of grounding grid.

In this simulation, the current flowing through armor tier remains unchanged. That's because the impedance of the armor loop is very large—armor tier is made from steel which have the high resistivity and the thickness of that is only 0.1mm.

Keep the parameters of grounding grid and armored cable unchanged, and assume the top layer soil resistivity is 500 $\Omega \bullet m$ and the thickness is 50 meters. Put $500\,\Omega \bullet m$, $1000\,\Omega \bullet m$, $1500\,\Omega \bullet m$, $2000\,\Omega \bullet m$ and $2500\,\Omega \bullet m$ into the bottom layer soil resistivity. The change rules can be obtained shown in Figure6.



(a) The influence on ground resistance (b) The influence on diverting potential difference

Fig.6. The simulation result influenced by bottom layer soil resistivity

The results showed that with bottom soil resistivity increasing, ground resistance increases and diverting potential difference decreases slightly, current flows through armor tier stays the same.

Analyzing the data above, it's found easily that there is no direct relationship between ground resistance and diverting potential difference. Diverting potential difference is mainly affected by the top soil rather than bottom soil. It's obvious that the unbalanced degree of grounding grid is decreasing due to the increasing of the bottom soil resistivity.

Conclusion

Based on grounding grid simulation software—CEDGS, established the model of grounding gird and armored cable, select variables to simulate and calculate. Through the simulations to get the way diverting potential difference how to change influenced by grounding grid, soil and other

parameters. Measures to reduce diverting potential difference are proposed for providing a theoretical basis of substations construction.

Modal Analysis of Vibration and its Program Development in Power Transformer Core

Fangxu Han, Yan Li, Xin Sun , Huan Wang

Research Institute of Special Electrical Machines, Shenyang University of Technology, China

email: hanfangxu021532@163.com

Keywords: Power transformer; Natural vibration frequency; Program development

Abstract. In this paper, based on the modal analysis combined with power transformer product structure, using the empirical formula calculation method and finite element simulation analysis software calculates the natural vibration frequency of power transformer core, respectively, while making the VB language as a tool to develop the calculation software of natural vibration frequency of power transformer, provides a strong support for product tenders, design and optimization.

Introduction

Power transformer is an elastic vibration system composed of kinds of structures. The system has a lot of natural vibration frequency. When transformer core, winding, fuel tanks and other structure mechanical vibration natural frequency is equal to or close to the core of silicon steel sheet of the magnetostrictive vibration fundamental frequency and integer times, will produce a resonance phenomenon, make the transformer noise significantly increased[1,2]. Therefore, according to the structural parameters of power transformer core calculating the natural frequency of vibration accurately is important for reducing the vibration noise, to avoid structure resonance and improve the quality of the product design.

Mode analysis of transformer core is the basis of the transformer body vibration noise, modal vibration mode and natural frequency can be obtained, analyzes the possibility of resonance structure, and then guide the transformer construction design, to avoid the resonance. In this paper, the application of ANSYS finite element software to modal analysis the core structure of a DSP-24650/132 type transformer, finds resonance modes, gives structure to avoid resonance rationalization proposals. At the same time, based on the empirical formula and Visual Basic language as a tool develop the power transformer core vibration frequency calculation software.

The natural vibration frequency of core empirical formula：

According to the empirical formula, the natural vibration frequency of core can use the type to calculate[3]：

$$\mathrm{F}_0 = 1.08K_c \frac{(Z+h)}{(H_0+h)^2} \times 10^5 \tag{1}$$

Definition function is: F_0 is natural vibration frequency of core, Hz ; $H_1 = H_0 + h$,cm; $M_1 = B_0 + z$,cm; K_c is and $(H_0+h)/(B_0+Z)$ related coefficient, and its relation as shown：

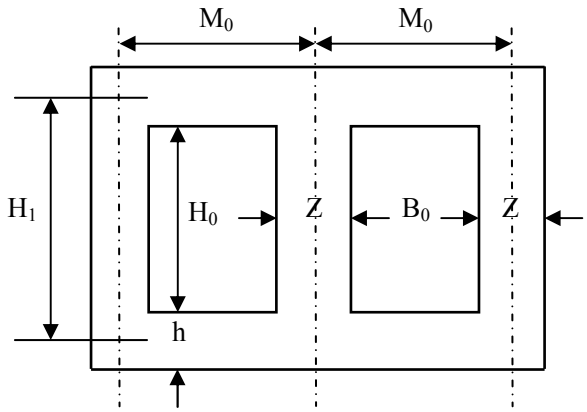
Figure 2 by the curve fitting coefficient K_c is calculated by the following formula:

$$K_c = 0.125(\frac{H_1}{M_0}) + 0.725 \quad \text{(For single phase)} \tag{2}$$

$$K_c = 0.0625(\frac{H_1}{M_0}) + 0.78125 \quad \text{(For the three phase)} \tag{3}$$

The fundamental frequency, two, three, four high frequency to 50Hz of the magnetostrictive vibration frequency is 100Hz, 200Hz, 300Hz and 400 Hz, etc, respectively. And its corresponding frequency band range usually take 75～125Hz, 175～225Hz, 275～325Hz, 375～425Hz. In order

to avoid the resonance, should make its core natural frequencies avoid the magnetostrictive vibration frequency range[4].



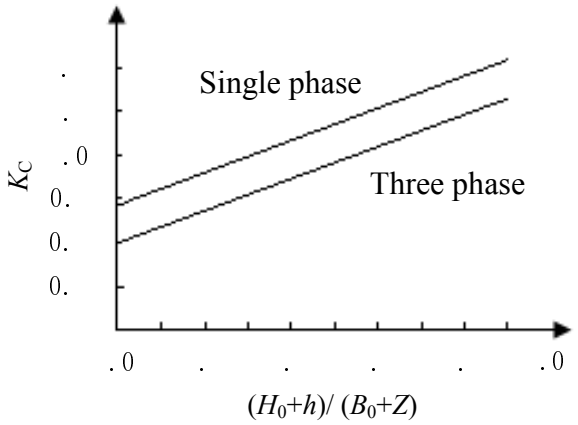


Fig.1.Natural vibration frequency variable parameters Fig.2.Relation curve of K_c and $\frac{(H_0+h)}{(B_0+Z)}$

The natural frequency of core model is about 236 which obtained by analytical formulas, the specific calculation process is as follows:

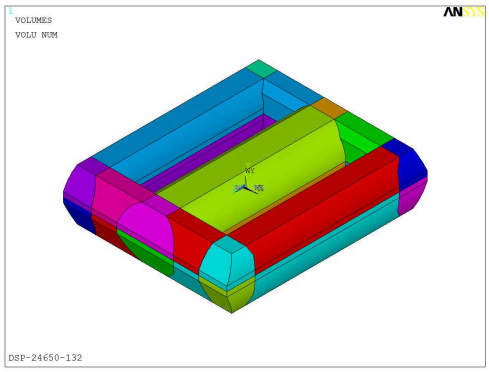
$$K_c = 0.0625(\frac{H_1}{M_0}) + 0.78125 = 0.0625 \times (\frac{212}{83.5}) + 0.78125 \approx 0.94$$

$$F_0 = 1.08K_c \frac{(Z+h)}{(H_0+h)^2} \times 10^5 = 1.08 \times 0.94 \times \frac{(70+34.5)}{(177.5+34.5)^2} \times 10^5 \approx 236$$

Core vibration modal analysis

Modal analysis is in fact to convert the vector which described in the original physical coordinate to the "modal coordinates", it can be said modal analysis is actually a form of coordinate transformation[5]. Power transformer core natural vibration frequency simulation calculation can obtain by ANSYS software, its modal analysis calculation module provides six modal extraction methods, DSP-24650/132 type transformer core, for example, the modal analysis of the specific process is as follows:

(1) Modeling and meshing: power transformer core is a complicated multi freedom degree system, its modeling necessary to simplify. Since modal calculation does not support non-linear characteristics, the calculation will be considered as a whole, ignoring the laminated structure and the joint structure between the yokes of iron. Modal analysis shall establish a three-dimensional entity model, adopt SOLID186 unit meshing core model and generate 2808 units 14660 nodes. The solid model and finite element calculation model as shown in figure 3 and 4 respectively.



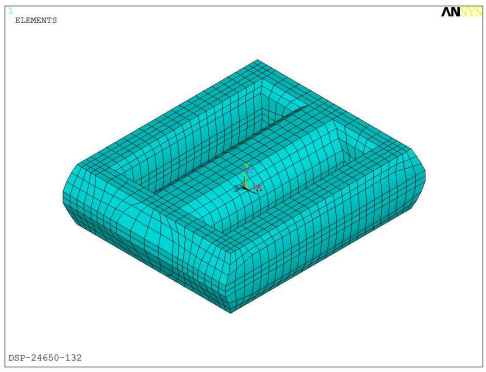


Fig.3. Core entity model Fig.4. Core modal calculation model

(2) The determination of material parameters: modal analysis to determine the material properties include: elastic modulus, poisson's ratio and density of core. The density and poisson's ratio of silicon steel sheet can be provided by the manufacturer or manual detected, because the core

is made of laminated silicon steel, the density of core should be the density of silicon steel sheet multiplied by pile coefficient, the transformer core pile coefficient is 0.95, so the density of core is 7650 * 0.95 = 7267.5. Elastic modulus accurate or not directly determine the accuracy of the results of the modal analysis, based on past papers and research results mainly has the following two kinds: $E=2.06\times10^{11}$Pa(ignoring the impact of the laminated structure); $E=1.50\times10^{11}$Pa(consider the impact of laminate structure).

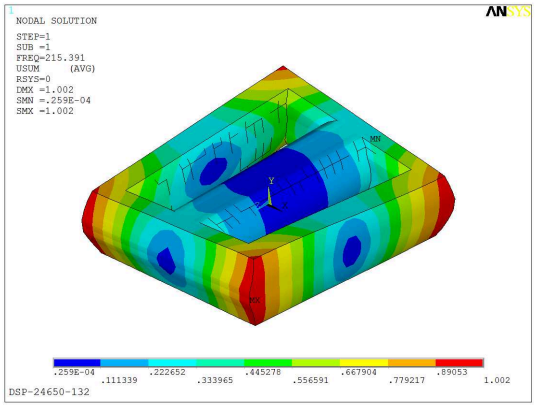
（3）Boundary conditions and loading: In modal analysis, the different boundary conditions will directly affect the core structure of the modal vibration and natural frequency. According to the actual situation of the transformer installation, at present mainly adopts two kinds of boundary conditions: bottom constraint and free boundary. Bottom constraint refers to the transformer core model at the bottom of the nodes on the x y z three directions of the degrees of freedom is defined as zero.

（4）The solution and result analysis: type select Model Analysis, modal extraction method selection Subspace, solving the frequency range is defined as 0 ~ 1000Hz. Table 1 shows the power transformer core free-bound and bottom constraint in the first 10 order natural frequency. As the calculation results can be seen in table 1, analytical value and freedom condition of 1 order simulation value match, and its error was 8.7%.

Table 1 Core inherent frequency simulation calculation results

Order number	Free constraint / Hz	Bottom constraint/ Hz
1	215.39	31.831
2	265.99	97.247
3	275.00	114.22
4	277.70	290.68
5	292.44	296.92
6	369.44	311.75
7	407.63	322.05
8	453.06	379.73
9	531.23	451.25
10	539.22	456.34

Using ANSYS finite element software objects modal analysis, can know the structure of each order natural frequency and each order natural frequency of the vibration mode. The vibration mode of the core at free boundary and bottom constraint is shown in figure 5.



First-order (freedom constraint)

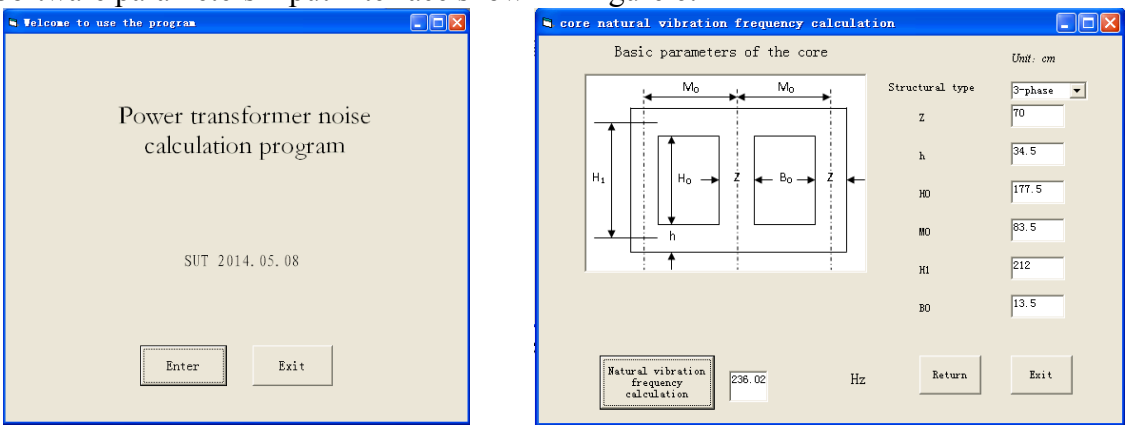
Core natural vibration frequency calculation program development

Based on the above calculation method, using VB language as a tool to design software parameter input interface, based on the input parameters obtain the natural vibration frequency of core. Software parameters input interface shown in Figure 6.



a) Login interface b) Calculate the interface

Fig.6 Core natural frequencies calculation program

Conclusion

Product design can be through the selection of reasonable core size, make its natural frequency to avoid the fundamental frequency and two, three, four high frequency band（75～125Hz, 175～225Hz, 275～325Hz, 375～425Hz）of magnetostrictive vibration, to prevent noise caused by the resonance increases effectively. Before core structure parameters selected can be calculate natural vibration frequency preliminary for the core through author design software, in order to improve the efficiency of designers. At the same time by Visual Basic language as a tool develops a power transformer core natural vibration frequency calculation procedure, for products bidding, design and optimization provides a strong support.

Keywords: Frame-shear Wall Structure, PV Panels, Numerical Analysis, Structural Analysis

Abstract. As a kind of pollution-free and sustainable energy, solar energy has received people's favor increasingly. Integration of solar power and architecture has become one of the important ways that people use solar energy. In this paper, numerical analysis of four frame-shear wall structure models on which PV panels are installed or not installed is conducted by ANSYS. The results show that integration of solar power and architecture meets the requirements of technical specification for concrete structures of tall building. But PV panels installed on the building surface will increase story displacement and produce stress and strain redistribution, which have negative effects on structural safety. This study provides a reference for the structure design of integration of solar power and architecture.

Introduction

Now the energy crisis is getting more and more nervous. As a respond to this condition, the architect have to consider how to reduce the energy consumption of the building in the process of designing architectural style[1]. Solar energy is abundant, recyclable, clean and it brings low environmental loads[2], so that integration of solar power and architecture structure[3] is becoming more and more popular with the builder. However, the builder don't consider the adverse effects generated by the PV panels when solar energy facilities are installed on the buildings. Considering this problem, numerical analysis is made under four frame-shear wall structure models on which PV panels are installed or not installed by using the finite-element software ANSYS in the paper. The results show that installing PV panels in high-rise frame-shear wall structure meets the requirements of technical specification for concrete structures of tall building[4]. But PV panels installed on the building surface will increase story displacement and produce stress and strain redistribution which have negative effects on structural safety, so that these negative effects should be valued particularly in the structure design of integration of solar power and architecture.

Establishment of Finite Element Model

Structure Parameters. The main body of calculation models is a 12-floor frame-shear wall structure. The bottom floor is 6m in height. The top floor is 3.5m in height and other standard floors are 3m. The total height of the building is 39.5m from the land surface. The section size of frame column is 500m×500m and frame beam is 300m×200m. Thickness of transition floor slab is 100mm and thickness of shear wall is 250mm. The standard floor layouts of frame-shear wall structure are shown in Fig.1.

Polycrystalline silicon photovoltaic panels which are installed on the side of structure from the second floor to the top floor are used in solar panels. In order to simplify the calculation models, the solar panels are installed on frame column with brackets. The distance of the panels and column is 200mm[5]. The size of PV panels is 265mm×265mm×25mm and its density is 2500kg/m^3. The location schematic diagram of PV panels are shown in Fig.2.

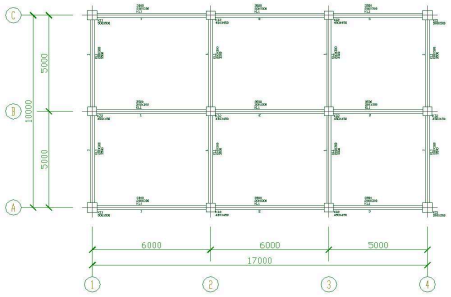

Fig.1. The standard floor layouts

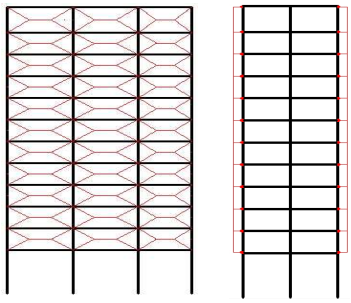

Fig.2. The location schematic diagram of PV panels

Selection of elements and modeling. The selection of material parameters and elements is based on the material texture and section shape of components, as shown in Table1.

Table1. Material parameters and elements selection[6]

Component	Material	Modulus of elasticity [N/mm^2]	Poisson ratio	Density [Kg/m^3]	element selection
Beam, Column	concrete	3.0×10^{10}	0.2	2500	Beam4
Shear wall	concrete	3.0×10^{10}	0.2	2500	Shell63
slab	concrete	3.0×10^{10}	0.2	2500	Shell63

The finite element analysis software ANSYS is used to analysis the models. The APDL command stream is used to build geometric model and Do statement is used to build model from the bottom to the top. First the key points are established according to the specific coordinates of structure, then column, beam, slab and shear wall are created by connecting the key points. The grids are meshed into the same elements. Geometric and element model is shown in Fig.3.

The unitary deformation performance and distribution of stress and strain of the structure under gravity loads and solar panel loads is analyzed in this paper.

Calculation model. Model1: under the gravity loads not being installed PV panels. Model2: PV panels being installed on the side away from the shear wall. Model3: PV panels being installed close to the side of the shear wall. Model4: PV panels being installed on both sides of the frame-shear structure.

Loading and Solving. The vertical influence of PV panels´ gravity loads is ignored when numerical simulation of the frame-shear structure is made by ANSYS. The effects on frame-shear structure from horizontal loads generated by PV panels are emphatically considered. The loading position of horizontal loads is set on beam-column joints from 2 floor to 11 floor. In the same layer, the loads on middle beam-column joints are twice times compared with the edges. Gravity loads on each node are set to the acceleration of gravity (g=9.8m/s2)[6]. Displacement and degree of freedom of all nodes on X,Y and Z directions are constrained at the bottom. Taking an example of Model4, the model loading and constraint diagram is shown in Fig.4.

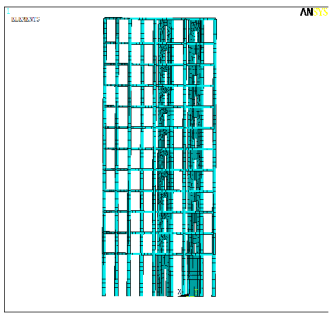

Fig.3. Geometric and element model

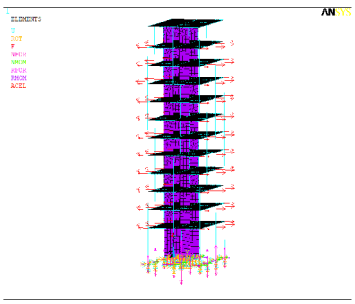

Fig.4. The model loading and constraint diagram

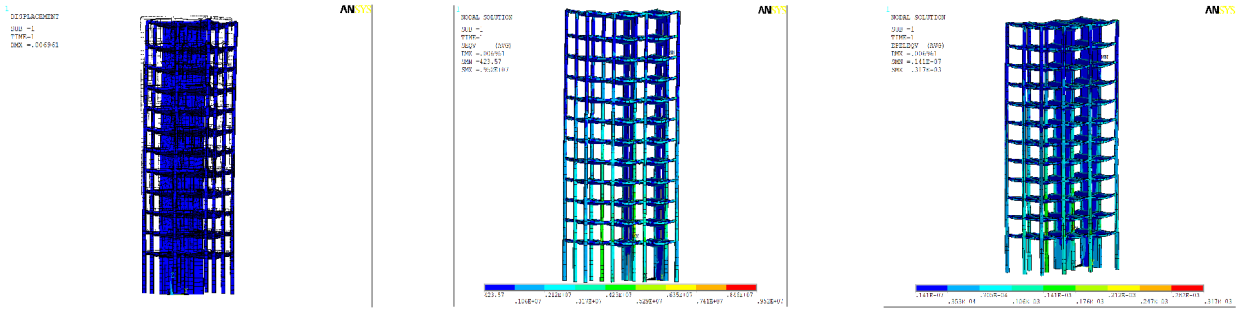
Results analysis

The deformation and distribution of stress and strain of four calculation models are obtained. And the maximum story drift, maximum stress and strain are also obtained.

Results analysis—Model1. The distribution diagram of displacement is shown in Fig.5(a). The distribution diagrams of stress and strain are shown in Fig.5(b) and Fig.5(c).

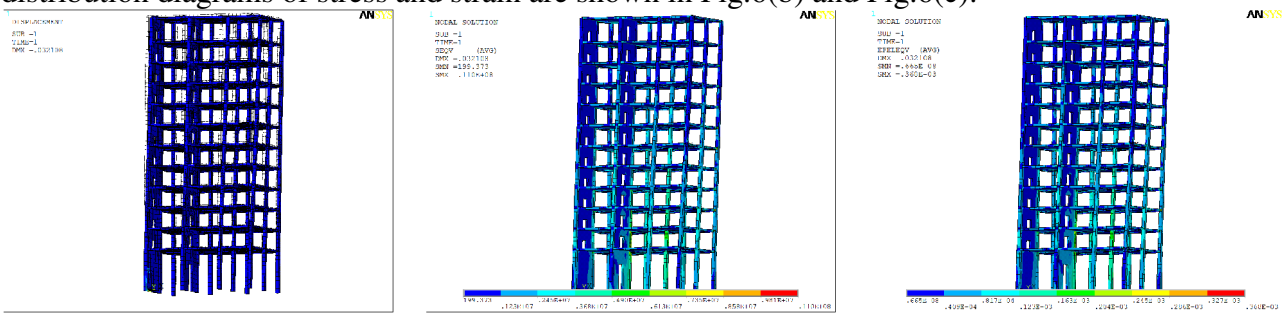


(a) (b) (c)

Fig.5: (a)The distribution diagram of displacement (b)The distribution diagrams of stress (c)The distribution diagrams of strain

According to the calculation results, when the structure bears the gravity loads, the maximum story drift of the model appears to be 6.961mm, the maximum stress is 9.52Mpa and the maximum strain is 3.17×10^{-4} . The stress and strain are mainly distributed at the bottom of column and shear wall evenly.

Results analysis—Model2. The distribution diagram of displacement is shown in Fig.6(a). The distribution diagrams of stress and strain are shown in Fig.6(b) and Fig.6(c).



(a) (b) (c)

Fig.6:(a)The distribution diagram of displacement (b)The distribution diagrams of stress (c)The distribution diagrams of strain

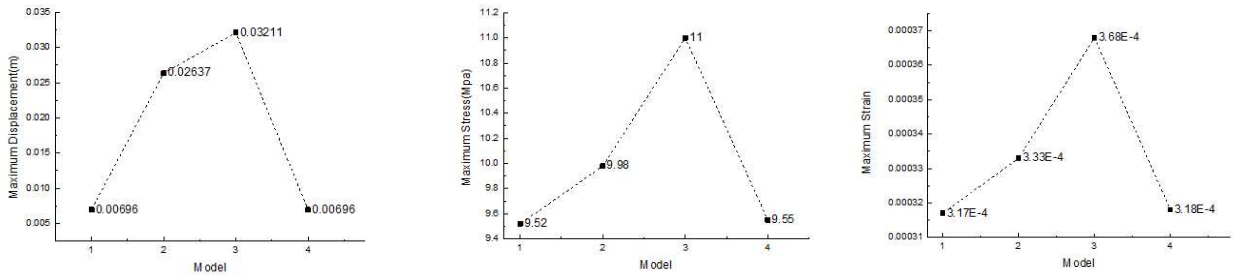
According to the calculation results, when the structure bears the gravity loads and horizontal loads closing to the side of shear wall, the maximum story drift of the model appears to be 32.108mm. It produces stress and strain redistribution and produces torque. The maximum stress is 11Mpa, the maximum strain is 3.68×10^{-4}. The maximum stress and strain are close to the side of the bottom of the column and shear wall on which PV panels have been installed.

Results analysis—Model3. The calculation results of Model3 are close to the value of Model2. The maximum story drift of the model appears to be 26.365mm, the maximum stress is 9.98Mpa and the maximum strain is 3.33×10^{-4} . The stress and strain are mainly distributed at the bottom of column and shear wall. Comparing the two models, there are less effects on structure when PV panels are installed close to the shear wall.

Results analysis—Model4. Taking no account of the vertical loads of PV panels, the calculation results of Model4 are close to the value of Model1. Because horizontal loads imposed on both sides of the structure are the same. The maximum story drift of the model appears to be 6.958mm, the maximum stress is 9.55Mpa and the maximum strain is 3.18×10^{-4} .

Analysis and Comparison

According to the calculation results, the maximum layer displacement, the maximum stress and the maximum strain of frame-shear wall structure are compared, as shown in Fig.7(a), (b) and (c).



(a) (b) (c)

Fig.7:(a)The contrast of maximum layer displacement (b)The contrast of maximum stress (c)The contrast of maximum strain

After the comparison, the results show that the maximum layer displacement of Model2 is 5 times compared with Model1 when vertical loads are not considered. As well, stress and strain redistribute and increase accordingly. There are small effects among the maximum layer displacement, the maximum stress and the maximum strain of architectural structure when PV panels are installed symmetrically on both sides of the building.

Conclusions

(1)Integration of solar power and architecture meets the requirements of technical specification for concrete structures of tall building. But PV panels installed on the building surface will increase story displacement and produce stress and strain redistribution. Horizontal loads should be valued seriously in the process of design.

(2)Solar panels should be installed in the symmetrical position to reduce the maximum structural displacement and ensure the safety of building structure.

(3)As for integration of solar power and high-rise architecture, more attention should be paid to the influence of PV panels for buildings.

Keywords: 2D finite element, isolated phase buses, short circuit electromagnetic force

Abstract. Short circuit electromagnetic forces are one of the most important factors in design and operation of buses. 2D infinite element models are set up with ANSOFT for isolated phase buses, simulating with transient method and calculating short circuit electromagnetic force taking eddy effect and proximity effect into account. The result reveals that the maximum electromagnetic force under short circuit condition is a periodic function of current phase angle.

Introduction

There phase isolated phase buses (IPBs) have been widely used in power plants to delivery power from generators to transforms, due to magnetic field density between phases and eddy current loss are reduced significantly[1]. Electromagnetic force impose on buses under short circuit condition will cause large deformation or even permanent damages, which effect safety of power delivery, therefore it is important to calculate accurately in design and operation of IPBs.

As development of simulation technique, finite element methods on multi-physics are applied in electromagnetic design. Finite element methods are used to calculate eddy current, power loss of IPB [2-3]. It also is used to compute transient electromagnetic force on other type of buses [4-5]. Finite element methods based on ANSYS are used to calculate electromagnetic force [6]. However, more efforts is still needed to investigate characteristic of short circuit electromagnetic force. In this paper, 2D finite element model taking buses size, skin effect and proximity effect into account is established. Magnetic field distribution and force imposed on conductor and shell are calculated with ANSOFT parametric method and the results provide advices and reference for design and optimization of IPBs.

IPB modeling

Physical model. IPB consists of three tubular conductors fixed in three cylindrical shaped shells. The conductor is supported by insulators made of epoxy material. The conductors and shells are made of aluminum material and welding the joints. The shells are connected together at each end by bonding plates and are grounded at one end. The cross section of IPB is shown in Fig. 1

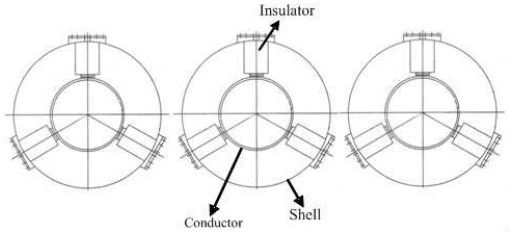

Fig 1 Cross section of IPBs

Mathematical model. The numerical calculation was processed under the ANSOFT software. In order to simplify the calculation, we proposed several hypotheses below in mathematical modeling :

A. Longitudinal dimension of bus is significantly greater then the cross section.
B. characteristics of materials are constant
C. displacements currents are neglected.

Based on the physical model and hypotheses above, the electromagnetic field control equation can be expressed as [7]:

$$\nabla\times(\upsilon\nabla\times A)=J$$

There is only Z component of current density and magnetic vector potential, that means

$$A_x=A_y=0,\quad J_x=J_y=0$$

So the control equation is expressed as

$$\frac{\partial}{\partial x}(\upsilon\frac{\partial A_z}{\partial x})+\frac{\partial}{\partial y}(\upsilon\frac{\partial A_z}{\partial y})=-J_{sz}+\sigma\frac{\partial A_z}{\partial t}$$

In the equations above, A_z is the Z component of magnetic vector potential, J_{sz} is the source current density, J_{cz} is the eddy current density of conducting region, σ is conductivity. The Coulomb gauge $\nabla\cdot A=0$ is employed to ensure the uniqueness of vector potential.

The largest electromagnetic force occurs during short circuit condition and the transient three phase short circuit currents in phase conductors are function of time as follows:

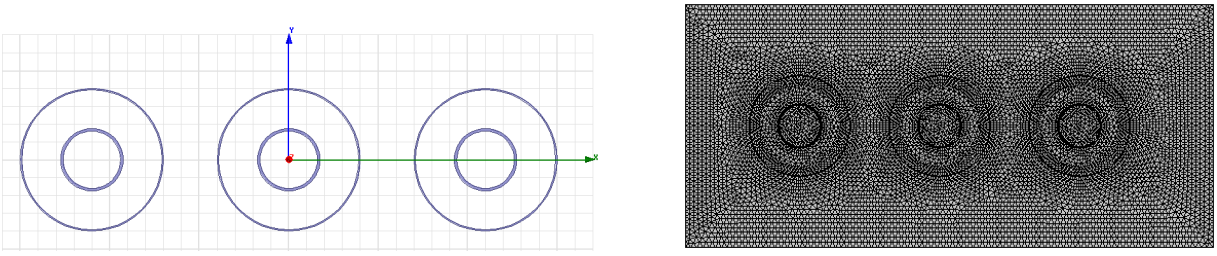
$$i_A=\sqrt{2}I_0\left[e^{-\frac{t}{T_a}}\cos a-\cos(\omega t+a)\right]$$

$$i_B=\sqrt{2}I_0\left[e^{-\frac{t}{T_a}}\cos\left(a-\frac{2\pi}{3}\right)-\cos\left(\omega t+a-\frac{2\pi}{3}\right)\right]$$

$$i_C=\sqrt{2}I_0\left[e^{-\frac{t}{T_a}}\cos\left(a+\frac{2\pi}{3}\right)-\cos\left(\omega t+a+\frac{2\pi}{3}\right)\right]$$

Where I_0, T_a, ω, A_z and a are effective short circuit current, decay constant of direct current component, angular frequency and phase angle. Value of I_0, T_a, ω and a used in simulation is 160kA, 45ms,314.15 and 30^o respectively.

Determination of physical property parameter. The model for simulation and analysis is built as Fig 2 shown. The number of elements and nodes in finite element model are 14460 and 29157.



(a) Model of IPB (b) finite element mesh

Fig 2 Analyzed models

The geometry data and physical property parameter are shown as table 1

Table.1 Geometry data and physical property

parameter / type	Material	Inner radius (mm)	Outer radius(mm)	Permeability	Resistivity($\Omega\cdot m$)
Conductor	Aluminum	320	350	1	2.6e-8
Shell	Aluminum	784	800	1	2.6e-8

Setting of rest conditions.

A. The boundary condition is $A_z=0$ on the border of air region;

B. Applied current on conductors taking eddy current into account;

C. Set simulation time $T=0.4s$ and time step $\Delta T=0.001s$

Analysis of simulation results. Parametric method of ANSOFT is use to compute electromagnetic force. The distribution of magnetic field shown as Fig 3 shown:

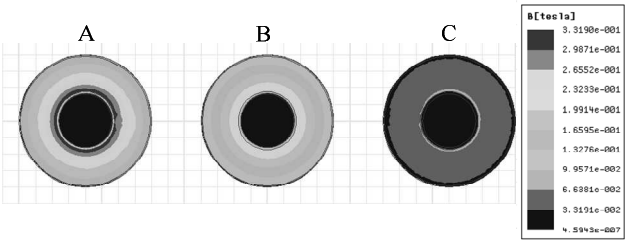


Fig 3 Distribution of magnetic field at t=0.005s

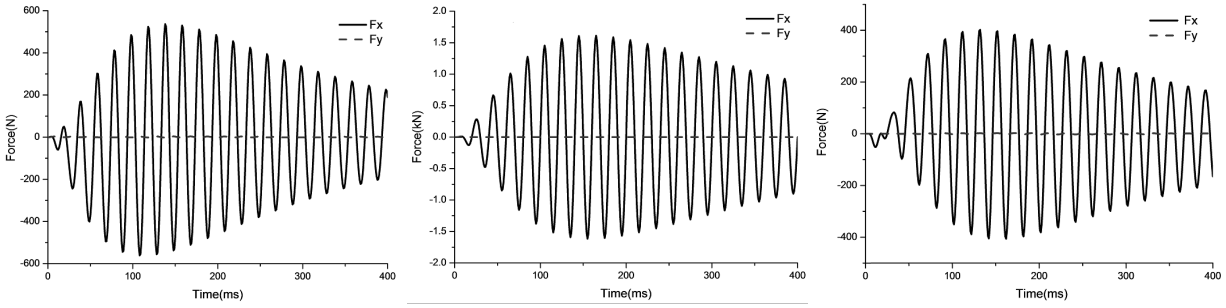
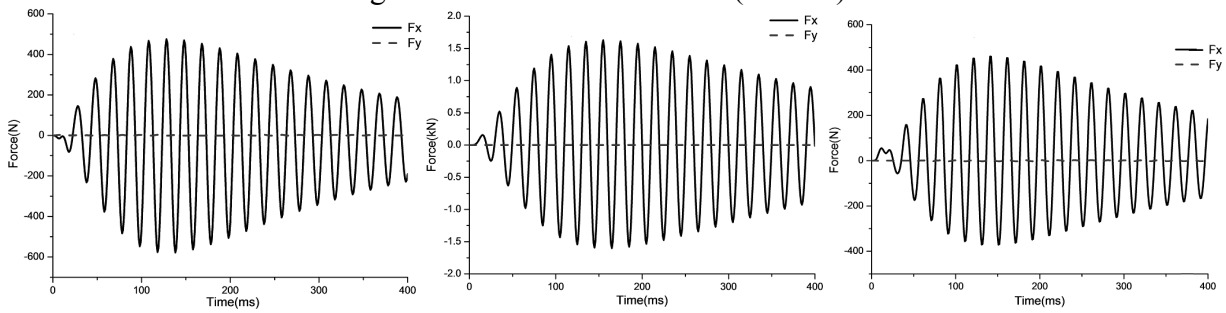
Electromagnetic force imposed on conductor and shell varies as short circuit changes. It is known form Fig 4 and Fig 5 that short circuit electromagnetic force has a large x-direction component and the y-direction component is so small that it can be neglected.



(a) Phase A (b) Phase B (c) Phase C

Fig 4 Force on the conductors ($a = 30^0$)



(a) A Phase (b) B Phase (c) C Phase

Fig 5 Force on the shells ($a = 30^0$)

Electromagnetic force on phase B is larger than other phase and the force is about 1616N per meter of IPB. The comparison of x-direction component of force at different phase angle is shown as Fig6.

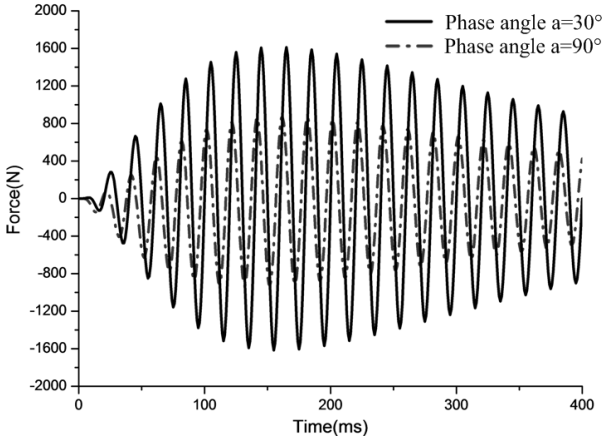


Fig6 Force on conductor B versus phase angles

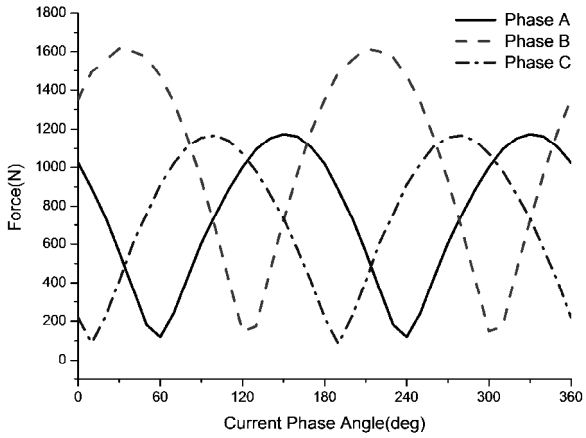

Fig7 Force on conductors versus phase angles

Regarding current phase angle as an unknown parameter, peak value of electromagnetic force is calculating by sweeping current phase angle from 0^o to 360^o with ANSOFT.

By analyzing Fig 7 we found that the peak values of short circuit electromagnetic force is a periodic function of current phase angle and the cycle is 180^o. The maximum electromagnetic force occurs when current phase angle $a = 30^o$ and minimum force as $a = 120^o$. Besides, the maximum

force of phase A and phase C almost identical, which is about 72% of phase B's peak value; what's more, the minimum force of phase A and phase C is approximately 10% of maximum force of phase B.

Conclusion

This paper built 2D finite element model of the isolated phase buses and compute magnetic field and transient electromagnetic force with ANSOFT fast and accurately. The results reveal that the middle phase conductor experience largest force, maximum short circuit electromagnetic force is a periodic function of current phase angle and the cycle is 180^o. In addition, horizontal component of force is much greater than vertical component. The result could be applied to design and optimize IPBs.

Keywords: Power Transformer; Core Column; Nonlinear Regression; Integer Programming; Optimized Design

Abstract. The progression of power transformer core is usually determined by the core diameter and the width and thickness of the silicon-steel sheet is determined by the graphing method. Therefore, coil section can't be fully utilized. To analyze the manufacturing characteristics of power transformer core columns from the performance and material savings and the nonlinear integer regression programming model is established. Taking the circumscribed circle diameter is 800mm, progression equal to 17 as an example. The optimized design of column section is solved by using the MATLAB. The results show that the optimized design can increase the cross-section fill factor by 3.8% and the diameter of the core columns larger, the optimization results better.

Introduction

The rectangular sizes at various levels of power transformer core column section is the key factor of the ultimate performance and costing, is very important to optimization and design. However, in the traditional transformer design, every diameter progression of core column is reference to the production experience. Subjectively, in consideration of achieve to certain number of stages in order to meet certain geometric cross-sectional area without exact or scientific solving process. After determining the core column diameter, the various core cross-sectional geometric dimensioning uniquely determined according to a unified national standard core design manual [1]. This will lead to progression of the core columns increasing unnecessarily, increasing the cost of power transformers and reducing the performance of the transformer. Therefore, a reasonable choice of progression power transformer core column section to determine the geometry dimensioning of all levels is a crux to improve the performance and reduce the transformer costs. With the development of computer applications and mathematics software, according to these practical problems to establish optimization model abstractly and simplified by mathematical method. Then using the computer technology to solve the problem and providing a solution.

At present the traditional methods in engineering is graphing method, but the course is very inconvenient and the deviations is large from the optimal solution. Thus, by building the nonlinear regression integer programming model about stepped rectangular cross-section dimensions at all levels and using the MATLAB to carry out standardization solving and obtain the optimization results about various types of core column section according to this optimization model [2, 3]. The main focus of this paper is optimization model establishing, the computer solving and data analysis.

Traditional methods to determine the silicon steel progression

Core section design is an important part of the column power transformer design. Power transformer core columns usually within a circular coil, in order to make full use of the space within the circular coil, the core column section is designed as a multi-stage axial symmetry and down the ladder. By properly selecting the size of each rectangle ladder in the design to strive to make the core cross-sectional geometry has a largest column. When the diameter circular of coil constant, the more core pillar progression, cross-sectional area larger, and the better the performance of the transformer, but the specifications of silicon steel be going to complicated if the progression too much, manufacturing hours increasing. So must be considered utilization factor and workmanship of core column synthetically. In the conventional transformer design, if the core diameter is

determined, the size which is the core section of the stack at all levels will be uniquely determined according to the design manual. The experience correspondence between the core column diameter and progression as shown in Table 1, which is usually on the basis of the scope of the core column diameter to determine the core columns progression.

Table 1 Selection of core column section progression

Core column diameter mm	progression
80-195	5-7
200-265	8-10
270-390	11
400-740	12-14
760-800	15-17
1000	19
1200	22

Choosing the ratio of the actual geometry cross-sectional and the area of the circumscribed circle to measure the fill factor of power transformer core column section [4], the specific formula is:

$$\eta=\frac{S_{Core}}{S_{circle}}\times 100\%=\frac{S}{\pi r^2}\times 100\% \tag{1}$$

The effective area of the core columns

The effective area of the core columns refers to the sum of all levels of silicon steel geometric cross-sectional area (excluding oil channel). Because of assuming the lamination factor is 1, the effective cross-sectional area of the core columns can be considered approximately equal to its sum of multi-level cross-sectional area of the geometry [5, 6]. Due to the axial symmetry of cross-section in a circle up and down, left and right, the theoretical calculation of the effective cross-sectional area of the core columns:

$$S=\sum_{i=1}^{n}2x_i y_i \tag{2}$$

Where the x_i is the level i width ($i=1,2,3\cdots n$), the y_i is the level i thickness ($i=1,2,3\cdots n$), S is the effective cross-sectional area of the core columns (Unit: mm^2).

$$y_i=\sqrt{r^2-x_i^2}-\sum_{k=1}^{i-1}y_k \quad (i=1,2,3\ldots,n) \tag{3}$$

In order to simplify the equation (2) into a single objective function, can be determined the relationship between x_i and y_i according to geometric relation of the each size from figure 1. In the figure 1, $x_1=OA$, $x_2=DC$, $y_1=AB$, $y_2=BC$, $OD=y_1+y_2$, $OC=OB=r$ (the r is the radius of the circle). From the Pythagorean Theorem could be obtained the $x_1^2+y_1^2=r^2$ from the $Rt\Delta OAB$, that is $y_1=\sqrt{r^2-x_1^2}$, $y_2=\sqrt{r^2-x_2^2}-y_1$. Thus obtained the relationship between x_i and y_i.

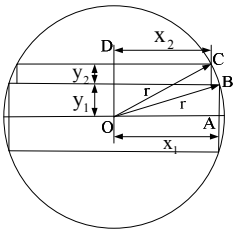

Fig.1 Schematic cross section of the core columns

The slice width mantissa dimensions at all levels is 0 or 5 generally at cross-section optimization, according to the width of each class film can be calculated from the corresponding stack thickness. Because of the actual thickness of the stack must be an integer multiple of the thickness of the silicon steel sheet, the given limiting value of the outer diameter by core can be controlled necessarily[7,8]. Width at all levels must be a multiple of w:

$$\left[\frac{x_i}{w}\right] = \frac{x_i}{w} \tag{4}$$

The level 1 must be greater than the thickness of 26mm, that is:

$$y_1 \geq 26 \tag{5}$$

The level n width greater than 20mm:

$$x_n \geq 20 \tag{6}$$

Width increasing with levels increasing:

$$x_1 \geq x_2 \geq x_3 \geq \cdots \geq x_n \tag{7}$$

The total thickness and maximum width of the silicon steel could not be greater than the diameter of the core columns circumscribed circle:

$$x_1 < d, \sum_{i=1}^{n} y_t < d \tag{8}$$

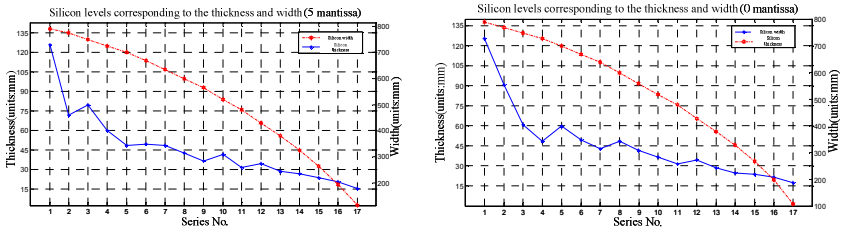
Solving and analysis of the effective area of the core columns

A. Specific examples

Take the $d = 800\text{mm}$ as an example, the core columns cross-sectional area optimization method uses the MATLAB to solve nonlinear integer programming. Using the constr function to solve the optimal solution for each unknown from the nonlinear programming objective function, but the results is decimal which need programming to adjust. Making the mantissa is 0 if the range between (0, 2.4) and (7.5, 0) and making the mantissa is 5 if the range between (2.5, 7.4) when number 5 as a multiple; Making the mantissa rounding when number 10 as a multiple. Then get the solution about the width, thickness, effective area and the filling factor of the iron core shown in Figures 2.

Figure 2 shows the corresponding levels of silicon thickness and width. When the mantissa number is 5 and 0, there is no big difference at all levels of the corresponding silicon steel sheet width and thickness. Take the level eight silicon steel as an example, the slice width is 600mm and the slice height is 43mm when the mantissa is 5; The slice width is 600mm and the slice height is 49mm when the mantissa is 0.

The fill factor of the core columns is lower according to the traditional design methods of core pillar, is 93.48%. After the above optimization, while the mantissa is 5, the fill factor is 97.24%; while the mantissa is 0, the fill factor is 97.25%. It can be seen, the fill factor of the optimized core columns were higher than the traditional core column fill factor.



(a) 5 mantissa (b) 0 mantissa

Fig.2 Silicon levels corresponding to the thickness and width

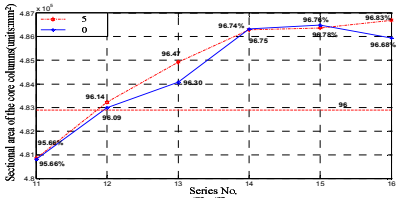


Fig.3 The effective area and fill factor of the core columns when the progression is 11-16

B. The impact of progression on the optimization results

Currently the core column design which is uniformly used by 17 level, the fill factor is lower, only 93.48%. Enhancing the fill factor to reduce the manufacturing costs of core columns and improve the performance of power transformers [9]. Figure 3 shows the effective area and fill factor of the core columns progression between 11 and 16.

Contrasted the effective area and the fill factor of the core by progression between 11 and 17 from the conclusions, the effective cross-sectional area and the fill factor of the core columns increasing with silicon steel progression increasing, when $n=17$, the effective cross-sectional area of the core columns is 488850 mm2 and the maximum value of fill factor is 97.25%. This is means the number of stages of the core columns increasing appropriately could improving the effective area and fill factor effectively.

From figure 3, if $n=12$, the fill factor of silicon is still greater than 96%. So if the choice about silicon steel is level 12, the manufacturing cost of the entire core columns will be greatly reduced.

C. The impact of diameter on the optimization results

Take the $d=800\text{mm}\ 1000\text{mm}\ 1200\text{mm}$ as an example, through the method of linear programming to calculate the indicators of different diameter core columns, and the make a compare with the traditional core columns manufacturing index. The specific results are shown in Table 2.

Table 2 Contrast between optimization results of the index and traditional manufacturing index

Core column diameter	800mm	1000mm	1200mm
circumscribed circle area	502650 mm2	785400 mm2	1131000 mm2
progression	17	19	22
Original cross-sectional area	469860 mm^2	736320 mm^2	1065440 mm^2
Now cross-sectional area	488850 mm^2	765740 mm^2	1104155 mm^2
Original fill factor	93.48%	93.75%	94.2%
Now fill factor	97.25	97.5%	97.63%

Data can be seen from Table 2, the larger of core column diameter, the greater of the circumscribed circle area, the more stages, the effective area of core column and the larger the fill factor, the better optimization results.

Conclusion

1) By nonlinear programming method for power transformer core column section to optimize the design, and in an examples which is the diameter is 800mm and the progression is 17, the cross-sectional area fill factor improved by 3.8%;

2) In the same diameter of circumscribed circle, the effective area and fill factor of the core columns will increase with the core pillar progression increases. When the design is level 12, the relative original fill factor also increased 2.5%. And for the entire transformer to reduce 10 laminated layers will greatly improve production efficiency and reduce costs;

3) The larger the diameter of the core columns, the more progression of core columns, the effective area and fill factor of the core columns greater, the optimization results better.

Keywords: Hybrid excavator, energy recovery, slewing mechanism, electric motor

Abstract. In the traditional excavator, the slewing braking energy cannot be recovered and eventually became heat. As the hybrid technology was introduced into the hydraulic excavator, it makes energy recovery possible. In this article, a new energy recovery method based on hybrid, using an electric motor instead of a hydraulic motor to drive the swing mechanism. When braking, the electric motor will enter the generator mode and the energy will be recovered and stored in super-capacitors. This method has been proved to have high energy recovery efficiency.

Introduction

The energy saving effect of hybrid hydraulic excavator has been widely recognized, and its energy-saving features focused on two main areas: 1) by improving the working conditions of the engine and down-sizing engine rated power, to achieve energy; 2) to further improve energy efficiency through energy recovery effect. Currently, researchers are mainly focused on two aspects. The fist one is to recycle the potential energy of the boom when it is dropping, the second is to recover the kinetic energy of the slewing system when it is braking. Some researchers take the measure of single motor driven single joint programs in order to achieve flexible control and energy recovery. There are also researchers those choose a hydraulic accumulator scheme to recover the kinetic energy of the rotating mechanism. Both programs would increase the system cost a lot, and they may not be used on traditional powered excavators. But it is not the case for hybrid powered exactors. Because they are already equipped with electric motor, the energy storage unit and electric controller, it is relatively a low-cost solution to drive the slewing mechanism by a electric motor / generator and recover the kinetic energy when it is braking.

Analysis on the power loss of slewing mechanism

The standard digging cycle time of a 7-Ton excavator is about 10 ~ 15senconds, and the two rotary motion of time contains about half of the total time. The rotary motion also contains a single start acceleration, constant speed (longer turnaround time), the braking of the three stages. During braking, the rotational speed of the motor abruptly changes, much heat is generated, causing a great loss of energy. According to the most commonly used devices and working conditions to estimate the rotational inertia of the platform, according to the following empirical formula using backhoe working device when estimating [4] [5]:

Rotate with full-load $$J = 128G^{\frac{5}{3}}\left(kg \cdot m^2\right) \quad (1)$$

Rotate with no load $$J_0 = 72G^{\frac{5}{3}}\left(kg \cdot m^2\right) \quad (2)$$

Where G is the mass of the excavator。

If G=7 Ton, then we can get $J = 3278.7\,kg \cdot m^2$, $J_0 = 1844.3\,kg \cdot m^2$ 。

And so ,in a digging cycle, the braking energy can be calculated as follow,

$$W = \frac{1}{2} \cdot J \cdot w^2 = \frac{1}{2} \cdot J \cdot \left(\frac{2\pi \cdot n}{60} \right)^2 + \frac{1}{2} \cdot J_0 \cdot \left(\frac{2\pi \cdot n_0}{60} \right)^2 \qquad (3)$$

Where n is the start rotate speed with full load, and here it is set to 14RPM； similarly, n_0 is the start rotate speed with no load, and here it is also set to 14RPM.

Then we get the total braking energy W=5.5KJ.

The electric motor drive strategy

In the traditional hydraulic excavator, it may cost too much to reuse the braking energy by electric method for many electric components such as battery, capacitor, electric motor and generator must be used. But in the hybrid hydraulic excavator, due to its system has a kind of electrical components, the cost can be achieved without spending too much energy recovery electric type, so the use of electric hybrid hydraulic excavator-style energy recovery is quite feasible, with the energy storage element is the direction of recovery energy recovery hybrid hydraulic excavator development [3].

As shown in fig.1, when the rotational speed of the motor torque when both positive or both negative, the motor for the generator; conversely, was the motor. When the rotation motor is initiated, the super capacitor begins to discharge with the super capacitor or SOC reaches a certain stage of the handle operator to stop the rotation shake super capacitor stops discharging, due to the inertia continues rotating platform driven rotary motor rotational power, and the to the super capacitor energy storage.

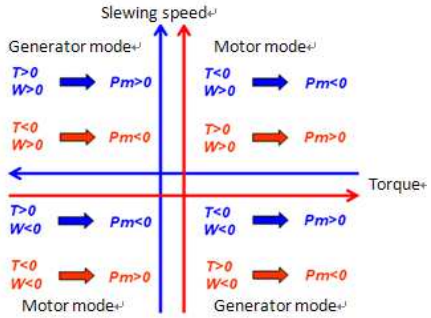

Fig.1 The work type of the electric motor

The simulation model of the slewing mechanism

The electric generator using AmeSim model motor controller model and a capacitor model, such as integrated model consisting of inertia rotary folder rotating brake simulation model is shown below, where the rotary motor parameters for the selected model TYB325-42-80's permanent magnet synchronous motor, which is rated at 5.22kw, bus rated voltage of 380V, rated speed 2400RPM, rated current o:10A, rated torque: 20.69Nm.

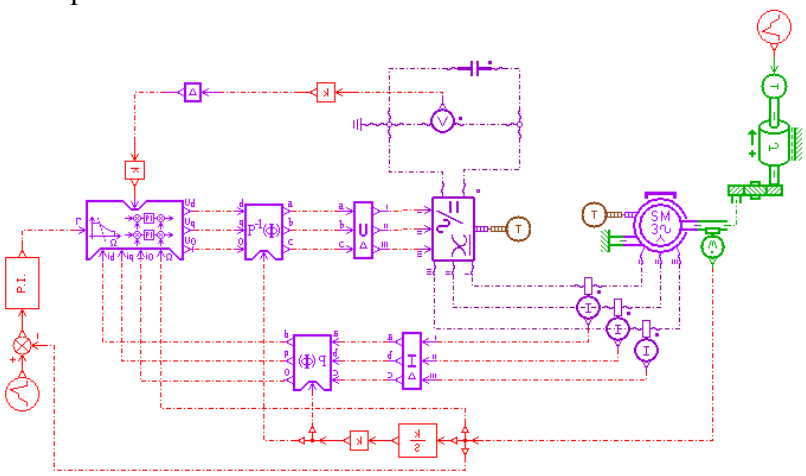

Fig.2 The Simulation based model of the slewing mechanism driven by electric motor

Simulation Result

Fig.3 and fig.4 shown the target motor speed and load torque which are the simulation inputs. In 0s ~ 0.1s stage, the motor starts to rotate, the sharp increase torque by 0Nm into-25Nm; in 0.1s ~ 1s phase motors do accelerated motion, in addition to a portion of the output torque of the motor to resist friction, wind, etc. drag torque generated, the majority of the torque is used to drive the motor to make accelerated motion, and the motor output torque of about-19Nm; in 1s ~ 2.5s phase motors do uniform motion. Then all the motor output torque to resist friction and wind resistance torque generated by the motor output torque at this time about-4.9Nm; in 2.5s ~ 3.5s phase brake motors turning into a generator, this when the output torque of the motor is not mainly rely on inertia rotary motor driven rotary platform, and the motor torque is 8.5Nm. The parameters of the electric motor are shown in fig.5- fig.7.

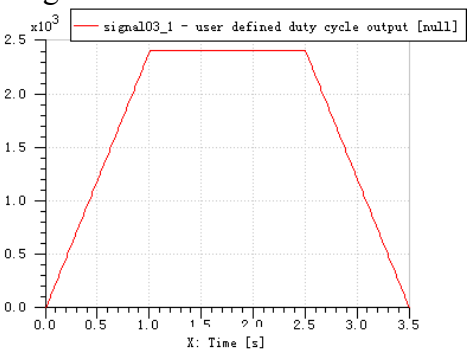

Fig.3 The target speed

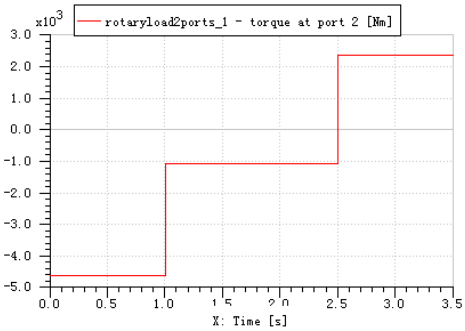

Fig.4 The load torque

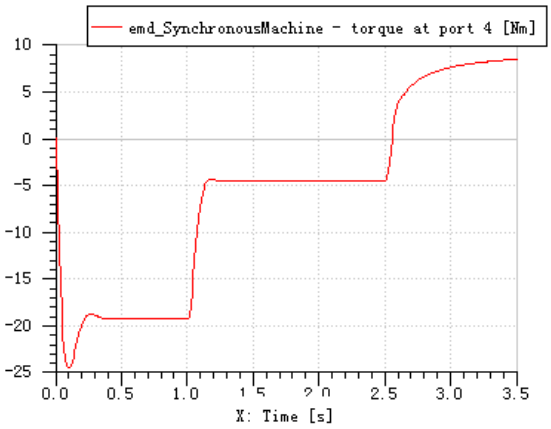

Fig.5 The output torque of the electric motor

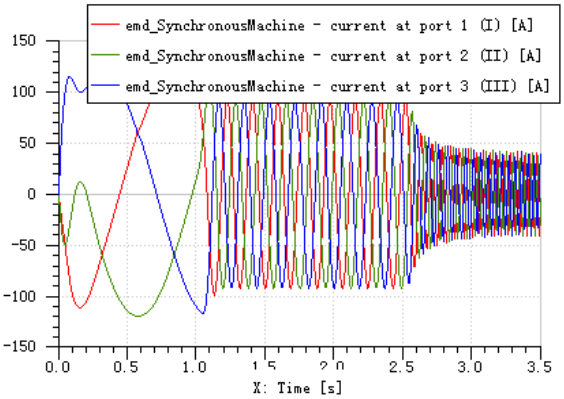

Fig.6 The current of the electric motor

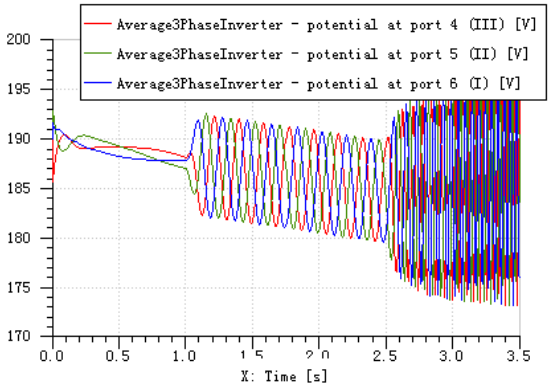

Fig.7 The voltage of DC line of the electric motor

Super-capacitor current variation shown in fig.8. From the figure difficult to find current changes corresponding to the state of the motor sport can be divided into three parts. The first part of the motor acceleration to do, then the super capacitor current sharply increases to about 1.5A, and the

fluctuation about 1.5A; motor as a second portion of uniform rotary motion, when the current is reduced to the super capacitor 1.2A; s Third part of the motor deceleration done, this time due to the motor torque is positive, the motor power, the current becomes negative, the capacitor begins to charge.

Super-capacitor voltage curve shown in fig.9. 2.5s to change the voltage dividing line is divided into two parts: the first part of the motor for the electric motor, the voltage falling capacitance falling; the latter half of the motor as a generator, the voltage starts to rise, the capacitance increases.

the SOC of the super-capacitor is：

$$SOC = \frac{0.5CV_c^2}{0.5CV_{cR}^2} = 95.42\%$$

The energy storage of the super capacitor is

$$Q = \frac{1}{2}CU^2$$

After calculation, the recovery energy for one slewing cycle is 2153J。

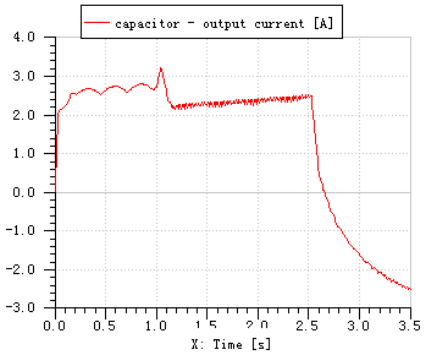

Fig.8 The current curve of the super-capacitor

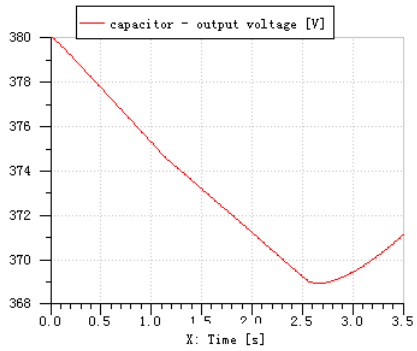

Fig.9 The voltage curve of the super-capacitor

Conclusion

Based on motor-driven rotary super-capacitor energy storage and energy recovery solutions, with high energy recovery efficiency, and does not affect the overall handling, the hybrid excavator equipped with a great value.

Keywords: wave energy, hydrodynamic performance,numerical calculation

Abstract. Under the pressure of fossil energy shortage, rational exploitation of ocean wave energy is propitious to establish an environmentally friendly society. This paper presents the results of a practical research done in a test tank, on the hydrodynamic performance of a wave energy converter with swing arms and floaters designed purposely. Fixed on a trailer, the converter was composed of two floaters, two swing arms, mechanical transmission devices and generators. The method of this research was to measure the floater's acceleration and the output voltages of the generator under the movement of waves, analysis the influence of wave height and period on floaters' movement, then compute the wave energy conversion efficiency. At last, the research findings show that the converter performed well with heaving motion performance and high energy conversion efficiency.

Introduction

As the economy and the population are growing rapidly, the traditional fossil energy resources are consumed increasingly. Under the pressure of the energy shortage, countries attach great importance to rational exploitations of traditional energy and researches on new energy. As a sort of clean marine renewable energy, wave energy has been recognized as an available choice. It has a impressive prospects with its abundant reserves and wide distribution. Hence, researches on ocean wave energy development became active in recent years[1-4].

Wave power generation is the main form for wave energy developing and utilizing. Since the first wave energy device came out in 1955, hundreds of different converter forms have been found all over the world. Generally, they consisted of three parts: wave energy capturing system, mechanical conversion system and generation system[5,6]. Among them, wave energy capturing system is used to capture wave energy. So far there has been pendulum, canard, mussels, oscillating water column type, float type and other forms. Mechanical conversion system is used to convert the captured wave energy to a particular form of mechanical energy (such as air or water pressure energy).Generation system plays the role of using turbine or mechanical transmission device to transmit mechanical energy to generator, and then, generator converts the mechanical to electric energy[7-9]. Some devices only contain wave energy capturing system and generation system while eliminating mechanical conversion system, such as direct-driven generator. Currently, researches of wave energy conversion device mainly focus on conversion efficiencies, reliability and cost issues of the three main systems. Researchers, at home and abroad, have done a lot of theoretical and experimental researches on that, and pay close attention to the oscillating water-column type and the oscillating floater type nowadays. Moreover, the oscillating floater type has been a hot research point gradually, due to its simple structure and high conversion efficiency[10].

A wave energy converter with swing arms and floaters was designed in this paper. This device capture wave energy by floaters, then convey it to generator with the help of swing arms and the mechanical transmission device. We set up model experiments under different wave height and period on floaters' movement, by measuring the vertical acceleration of floaters and average output power of the device, to research floaters' moving rules and the device's energy conversion performance, and then, to provide reference for further research on wave energy converter.

1. Test Scheme

1.1 Principle of the Wave Energy Device

The converter was composed of two floaters, two swing arms, a mechanical transmission device and generators. Among them, floaters floated on the water, and each of them fixed with one end of the swing arms. The other end of the swing arms was connected with the projecting shaft to the mechanical transmission device which was installed in a container structure. The overall structure of the model and the internal structure of the container are shown as the figure 1 respectively. Under the effect of waves, the floaters moved upward and downward, pushed the swing arms reciprocating. Then, the oscillating traverse motions of the swing arms drove the transmission device work. In addition, the transmission device contained a reversing mechanism and a speed-increasing box. The reversing mechanism converted the oscillating traverse motions of the swing arms to one-way rotation motion of the shaft, connected to the speed-increasing box through the shaft coupling to increase the rotation speed. The speed-increasing box drove the rotating generator rotate, which can convert mechanical energy into electric energy. Each floater corresponded to each generator.

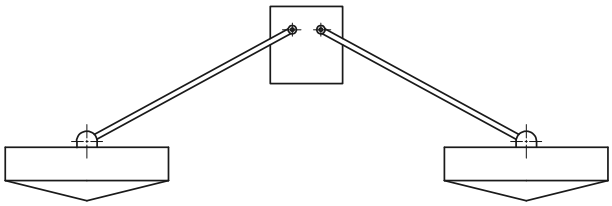

Fig.1 The overall structure of the model

1.2 Equipment and Instruments

This experiment was conducted in Harbin Engineering University's towing tank, which is 108m long, 7m wide, and 3.5m depth. The experimental equipment and instruments mainly consisted of a rocker-flap wave maker, wave shore, a trailer, Donghua DH5920 dynamic signal test and analysis system, the acceleration sensor, and the resistance box. The wave maker can produce regular wave with cycle ranges from 0.4 to 4 seconds while maximum wave height can reach at 0.4 meters, it can simulate ITTC spectrum under single and double parameters, JONSWAP spectrum, P-M spectrum, wave spectrum of the actual sampling and so on. Also, the wave maker can produce irregular wave whose significant height can reach at 0.32 meters; The signal testing and analyzing system had 16 working channels, it can sample the frequency ranging from 10 to 100kHz, with system error less than 0.5% and instability less than 0.05%.It was used to collect acceleration, force and the voltage and the current of the generator.

1.3 Method of Experiment

The purpose of this experiment was to measure the floater's acceleration and the output power of generator under the action of waves, grasp the effect laws of floater motion performance and energy conversion performance in the factors like wave height, period, damping and so on, and finally provided the experimental basis for the study of the wave energy device. The model was fixed in the trailer by a framework and the float was floating on water. The trailer was parked in towing tank and 48m far away from the wave maker (shown in figure 2). Stuck on the center of the two floaters, the acceleration sensor was connected to the dynamic signal measurement and analysis system through cable. The output terminal of the generator was connected to rheostat, which was in parallel with the dynamic signal measurement and analysis system to measure the voltage of the rheostat and finally to obtain the output power of the generator.

Fig.2 Picture of experiment

The main parameters of the experimental model are shown in Table 1. The signal sampling frequency of the dynamic signal test and analysis system was 50Hz. The wave was regular, and wave height and period are as follows:

(1) wave height: 0.125m, 0.15m, 0.175m;

⑵ period: 1.2s, 1.4s, 1.6s, 1.8s, 2.0s, 2.2s, 2.4s, 2.6s;

Table 1 Major Parameters of the model

Number	Items	Parameter	Unit
1	Diameter of floaters	750	mm
2	Shape of floaters	cone	
3	Height of floaters	265	mm
4	Length of swing arms	900	mm
5	draft	89	mm
6	Weight of swing arms	17	kg
7	Angle between swing arms and horizontal in equilibrium	24	º
8	Power rating of generator	50	W

2. Data Processing and Result Analysis

2.1 Experiment of the Floaters'Movement Performance

The floaters were arranged perpendicularly to the direction of wave, which was regular produced by the wave maker. After finishing the collection of the acceleration of the floaters under the function of the waves with the help of the acceleration transducer, we declined noise and integrated the experimental data by matlab, then we got the speed and displacement of the floaters and analyzed the movement discipline of the floaters according to the result. In addition, the changes of the waves in real time were measured by the wave height recorder. In figure 3, it was a curve of the regular wave, whose wave height was 0.15cm and period was 1.4s.

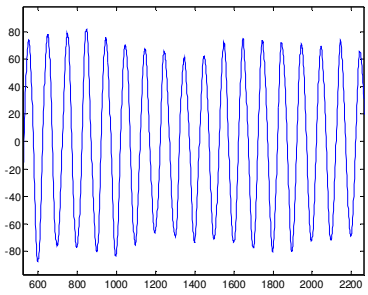

Fig.3 Wave curve

Next, the vertical accelerations of the two floaters under the same experimental condition were compared. Figure 4 was the vertical acceleration curve of the two floaters when the height of the incident wave was 0.15m and the period was 2.0s. The abscissa of the figure was the sampling number, and the ordinate was the displacement of floaters.

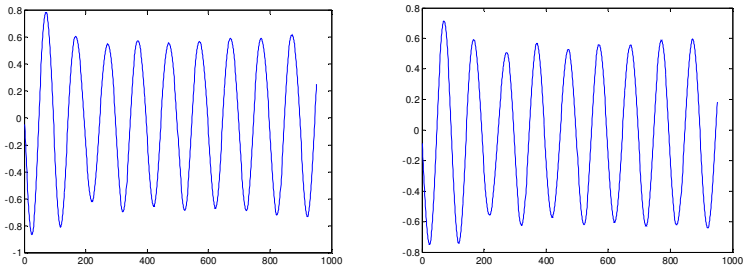

Fig.4 Acceleration curve of two floaters

Ignored the factors such as the irregularity of wave itself and measuring errors, it can be seen from the figure 4 that the motion curve of the floaters is sine curve and the vibration period of the floaters is 2.0s, just same as the wave period under the function of the regular wave. On the other hand, it can be seen from figure 4 that the vertical accelerations of the two floaters are nearly same and the average error of them is 1.2%. The error mainly were caused by mechanical transmission device and measuring instruments. Thus, the movements of the two floaters were the same under the same experimental condition. Hence, we only analyzed the energy output of one floater's movement in following discussion.

In order to analyze the connection of the vertical displacement amplitude and incident wave period of the floaters, the wave height was fixed on 0.15m. When the wave period is 1.2s, 1.4s, 1.6s, 1.8s, 2.0s, 2.2s, 2.4s, 2.6s respectively, we measure the vertical displacement of the floaters, and calculate the vertical displacement of the floaters and the ratio of its average during the calculate time and the wave height. Figure 5 was the change curve of the trend that the ratio of the average displacement amplitude and the wave height（z/h）varied in different period. The abscissa was the wave period and the ordinate was the ratio of the average displacement amplitude and the wave height.

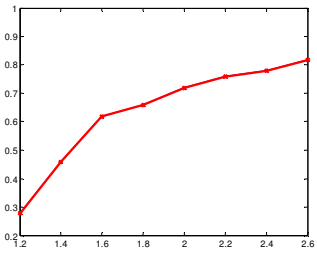

Fig.5 The change curve of the growth rate of displacement amplitude

It can be seen from the experimental result above that under the function of the regular wave which period ranged between 1.2s to 2.6s and the ratio of the displacement amplitude and the wave height between 0.2s to 0.8s, the displacement amplitude of the floaters decrease with the increasing of the wave period.

Now, comparing the relationship of the movement displacement amplitude of the floaters and the wave when wave periods were the same and wave heights were different. Preset the wave period at 1.8s and the wave height at 0,125m, 0.15m, 0.175m. In the measurement cycle, the change curve of the floater's mean displacement amplitude just as figure 6, of which, the abscissa was the wave height and the ordinate was the displacement amplitude of the floaters.

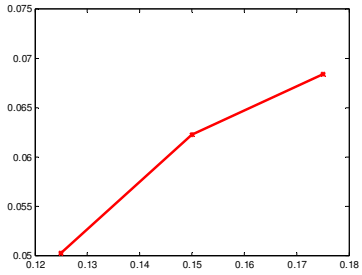

Fig.6 The change curve of the floater's mean displacement amplitude

When the wave period was 1.8s, the wave length λ was nearly 5.1m, the wave height was 0.175λ, and this curve can be seen as linear wave. It showed that the displacement amplitude of the floaters increased with the increasing of wave height. However, the connection was the non-linear damping of the mechanical actuating mechanism, not linear increment.

2.2 Energy Conversion Efficient of the Converter

For counting the energy conversion efficiency of the device, it need to count the power of the incident wave in the width of the floaters and the output power of the device separately. Meanwhile, the conversion efficiency was measured by ratio of the device's output power and the power of the incident wave in the width of the floaters.

The efficiency of the incident wave in the unit size can be counted by the eq. 1:

$$P_{\mathrm{w}} = \frac{\rho g^2}{32\pi} H^2 T \tag{1}$$

The output power of the device can be counted by the eq. 2:

$$P_{\mathrm{out}} = \frac{1}{T}\int_0^T \frac{U^2(t)}{R}\,dt \tag{2}$$

In the two formulas above, ρ is the density of the water, H is the height of the wave, T is the period of the wave, R is the external resistor of the generator, $U(t)$ is the functions that vary with the voltage across this resistor gathered by the dynamic signal analysis system, $U(t)$ is discrete function, the number of the data is N, the spacing interval is, so the eq. 2 should be counted as the following formula[11,12] in the actual calculation process[11,1 Δt 2].

$$P_{\mathrm{out}} = \frac{1}{N\times\Delta t}\sum_{k=0}^{N-1}\frac{U^2(k)}{R}\Delta t \tag{3}$$

Supposing that the diameter of the floater is D, the conversion efficient can be counted by the eq. 4.

$$\eta = \frac{P_{\mathrm{out}}}{P_{\mathrm{w}}\times D}\times 100\% \tag{4}$$

This experiment takes the voltage across this resistor gathered by the dynamic signal analysis system, and when the resistance was 100 Ω, the spacing interval was 0.02s. Then we have the result counted the energy conversion efficient under different condition according to eq. 1 to eq. 4, as table 2.

Table 2 Corresponding relation of the efficiency with wave height and period

Period(s)	Efficiency（%） of Wave height: 0.125m	Efficiency（%） of Wave height: 0.15m	Efficiency（%） of Wave height: 0.175m
1.2	12.3	16.2	18.1
1.4	18.7	23.5	25.7
1.6	22.4	27.5	30.8
1.8	28.6	31.6	33.8
2.0	21.9	25.7	29.1
2.2	12.3	16.1	20.4
2.4	7.8	10.2	13.1
2.6	5.6	6.4	8.6

From the table 2, it can be seen that, under the condition of the wave height is 0.125m, 0.15m, 0.175m, and the period ranged from 1.2s to 1.8s, the output power of the device increases with the increasing of wave period. When the wave period is 1.8s, the output power increases to the top, and then decreases with the increasing of the period. While under the same period, the higher the wave is, the higher efficiency of the device's energy conversion performances; The higher the wave is, the larger the amplitude of the floater is. And the efficiency of the mechanical transmission device and generators are the highest in that time. The experiment showed that under the condition above, the maximum efficiency of the device can reach to 33.8%.

3.Conclusion

This paper designed a wave energy converter with swing arms and floaters, and took experiment of electricity generation in test towing tank. The experiment mainly study on the hydrodynamic performance of the converter, and analyze the influence of regular wave height and period on the efficient of floaters' movement and energy conversion. The experiment results show that in the effect of regular wave, when the two floaters arranged perpendicularly to the direction of incoming wave, the movement of them are synchronous. The displacement amplitude of the floaters' vertical movement increases by degrees with the augment of the wave's period, and increasing of the wave's height, but the speed of the increment decreased; Under the same condition of the wave height, the energy conversion efficiency of the device firstly increases and then decreases with the increasing of wave period. In this converter, when the wave period is 1.8s, the efficiency is the highest. On the other hand, when the wave periods are the same, the higher the wave is, the higher the efficiency of the converter is. Synthesize the result of the experiment above, the wave energy converter possessed superior energy conversion performance.

[a]email: 173139168@qq.com

Keywords: HVDC converter station; converter transformers; spectral characteristics; noise source control; comprehensive management

Abstract. HVDC converter station noise problem is getting attention by the relevant departments. The noise of converter stations is mainly generates by the converter transformers, smoothing reactor, AC and DC filter and valve outer cooling fan equipment, on this basis, the converter station noise control must be integrated into a variety of factors. In this paper, the noise source control, noise propagation route control and protection noise receptor were studied and explored.

Introduction

Compared with AC Transmission,HVDC has many advantages ,such as large transmission capacity,small active power loss of line,reliable operation and quick speed adjustment .In the HVDC system,Converter station is the site ,which is in order to complete the DC and AC power conversion,and to achieve power system for stability and power quality.But it brings the optimal allocation of power resources ,at the same time, will also have the effect of noise on the surrounding environment,and caused widespread concern in the community.This paper analyse the converter station equipment noise and study the noise reduction measures.

The analysis of main noise sources in converter station

The main noise sources in converter station include converter transformers, smoothing reactor, AC and DC filter, valve outer cooling fan equipment and so on .Among them, converter transformers,smoothing reactor, AC and DC filter noise was generated by the electromagnetic noise,and valve outer cooling fan equipment noise was generated by the mechanical noise and aerodynamic noise.

1)The noise of converter transformers

The converter transformer is the noise source,which is of the maximum sound level ,and the noise source is divided into three parts:① electromagnetic noise: under the action of an alternating magnetic field, the core leads small changes of the transformer silicon steel sheet .called magnetostriction [1],resulting in vibration noise②The noise of the transformer and magnetic materials ,which is caused by the electromagnetic force between the coil and the coil wire[2].③The noise ,which is caused by the converter transformer cooling system fan.

Figure 1 is a converter transformer noise spectrum (Figure A-weighted noise amplitude with measurements), hereinafter,and its frequency is to 100Hz fundamental frequency and its harmonics based.As can be seen from Figure 1, the frequency of converter transformer noise distribution is very wide,and is In the low-frequency-based.The peak value is appeared in the low band center frequency of 100,200,400 HZ,and it becomes flat in the mid and high frequency flatten. the mean noise level in front of the converter transformer is 85-100 dB (A).

2)The noise of smoothing reactor

The size of the smoothing reactor noise is related to the Structure, operating power and factory model.The Smoothing reactor core is devided into oil and dry air core ,and its noise is mainly caused by that the coil vibration of the DC current and harmonic currents interaction[3].Oil core

smoothing reactor noise generation principle, sound level intensity, frequency range was similar to converter transformer.The coil of the dry smoothing reactor is made up of the one or more epoxy impregnation and sealing coil layers,and the material is the insulated aluminum.The main reason of the noise caused by the air core smoothing reactors is the coil vibration and the currents of the coil magnetic field interaction.

As can be seen from Figure 2, the frequency of smoothing reactor noise distribution is very wide,The peak value is appeared in the low band center frequency of 100,400 HZ,and the frequency components is rich in the medium and high frequency and becomes flat .At rated power,the total noise level of the oil smoothing reactor is 85~90 dB[4],the total noise level of the dry smoothing reactor is 70 dB.

3)The noise of the AC filter group

The AC filter group is made up of the filter reactor and filter capacitor,。The filter reactor often use the dry hollow reactor.The reactor coil noise is generated by the alternating electromagnetic field, causing the cyclical magnetostrictive effect ,and there is significant peak in the low frequency.The noise,producted by the bottom and top of the capacitor element,is the highest,which is the main noise source[5].and the sound level is lower than the noise producted by the converter transformer and smothing reactor.

As can be seen from Figure 3, the frequency of smoothing reactor noise distribution is very wide,The peak value is appeared in the low band center frequency of 50， 100 HZ,and it becomes flat in the medium and high frequency,the total noise level of the AC filter group reactor is 60.6~66.6 dBdB[6] .

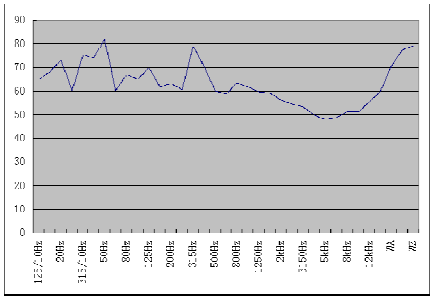

Figure 1 Converter transformer noise spectrum

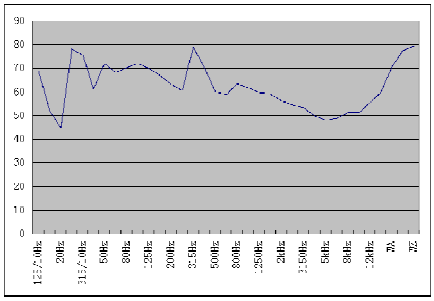

Figure 2 Smoothing reactor noise spectrum

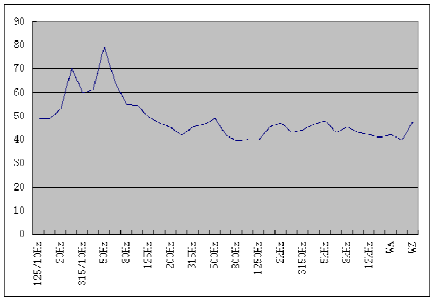

Figure 3 AC filter group noise spectrum

4)The noise of valve outer cooling fan equipment

The converter valve external cooling devices cooled units and the valve cooling tower can produce large noise.The spectral characteristics of the valve cooling tower fan noise is a typical fan noise spectrum,and the frequency of smoothing reactor noise distribution is very wide,low, medium and high band frequency components is rich and average, and have no significant peak.

The study of the noise comprehensive treatment in converter station

Noise control channels in converter station , including the following three ways: ①control the noise source; ② cut noise transmission routes; ③protection of noise receptors. Below with the actual situation of the converter station equipment were described.

1)control the noise source

Converter transformer : ①Reduce core flux density. Tests showed that each lower flux density 0.1T, the core can reduce noise 2 ~ 3dB (A) ;②Due to the size and rate of silicon steel magnetostrictive material related,magnetostrictive rate can be a small high permeability material,Such as high permeability silicon steel core noise at the same flux density reduced 2 ~ 4dB (A),however, this method costs higher.3)use low-noise fan;

Smoothing reactors :①For dry-type smoothing reactors, vibration limit the coil, adjust the structure size, spacing and mechanical support rods away from the critical frequency resonance frequency,the use of large amplitude conductor increases and other measures to reduce inertia can be reduced 5-10dB noise;②respectively, using the top and bottom of the package installation mode noise shield, the shield noise reduction of up to 15-20dB .

2)Noise control transmission route

If the above method does not significantly reduce noise,or to further reduce the high cost of equipment required for the noise,noise may be considered off main route of transmission noise reduction measures, such as insulation, silencers, acoustic and vibration isolation.

Converter station design optimization

①converter transformer valve hall and arranged face to face should be adopted;②try to control the floor, hall and converter transformer valve disposed in the central region of station site;③ AC filter and converter transformer should be arranged separately, while reducing the AC filter height,And bounded away from the station.By using noise analysis software SOUNDPLAN converter station area on the simulated noise,Figures 4 and 5, respectively, when using a face-arranged to change shape and noise distribution flow stations.

As can be seen from Figure 4 and Figure 5, when compared with a zigzag arrangement according to the valve hall and converter transformers are arranged face to face can be improved by the converter station outside noise environments.

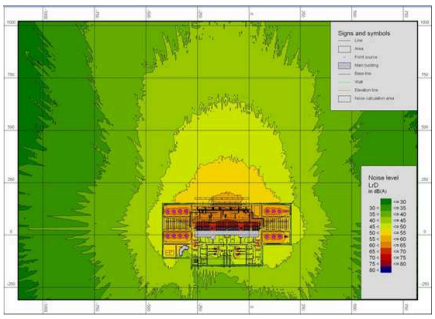

Figure 4 Valve hall an in-line converter station noise distribution

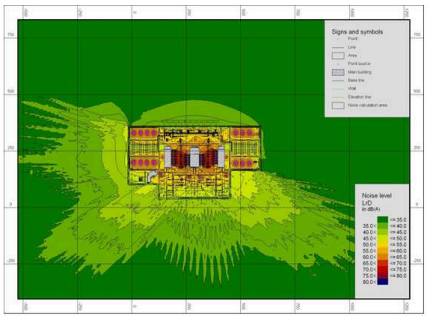

Figure 5 Valve hall-face arrangement converter station noise distribution

Set the sound barrier

①sound barrier materials are brick, steel, various types of composite structure, the insertion loss of the sound barrier (ie noise reduction) depends on the acoustic sound barrier transmission, diffraction and reflection case , the general can get 5 ~ 15dB of noise reduction②fan muffler: generally available 15 ~ 30dB (A) noise reduction.③isolation device: you can reduce the noise 1 ~ 5dB (A). Such as converter transformers and other equipment in the installation of the bottom structure damping device to reduce low frequency noise.④Acoustic enclosures: its sound effect is better than the sound barrier, the general noise reduction can reach 15 ~ 25dB (A).

Noise control effect analysis

A converter station on the main noise source noise reduction program are as follows:

Scenario 1: change sides transformer plus converter transformer sides of a firewall, surrounded by walls and ventilation plant noise reduction device settings sound barriers, sound-absorbing material posted firewall (composite absorber), and extend the length of the firewall.

Scenario 2: converter station capacitors using towers structure, thereby reducing the height of the sound source, and reduces noise transmission range.

Scenario 3: Converter Transformer BOX-IN packages noise, the converter station to minimize the noise level has been standing boundary noise level is less than 50dB.

Contrast these noise reduction program, using noise analysis using software SOUNDPLAN converter station area on noise simulation, which makes the program 1 a converter station to minimize the noise level has been, so stop the noise control community at 50 dB (A) or less, residential noise levels are controlled in the acoustic environment quality standard class II standards[7].

Conclusion

Converter transformers, smoothing reactors, AC filter group, the valve is the main source of noise outside Cooler converter station within the noise types include electromagnetic noise, mechanical noise and aerodynamic noise. Noise reduction measures should be taken to co-ordinate the planning, follow environmental standards, technical feasibility, economic rationality principle of governance.Equipment noise spectral characteristics in converter stations with a wide band characteristics, which mainly low-frequency noise, high frequency component is weak.converter station noise control should be a reasonable choice of converter station sites, followed as much as possible to reduce the number and intensity of noise sources, then consider a reasonable choice and optimization of the design, and finally consider the necessary sound insulation, noise reduction, etc. noise control measures.

Keywords: FRP; Transmission line; cross section form; wire grounding scheme; pole

Abstract. Traditional transmission line poles and towers have many problems, such as higher corrosion, heavy weight, poor durability and maintenance cost is high. Use of fiber reinforced polymer composites (FRP), based on the theory of poles and towers design, 110 kV FRP pole structure size parameters are calculated, designed the 110 kV FRP pole structure, cross section form and wire grounding scheme. Design results show that compared with traditional pole, 110 kV FRP pole has the characteristics of compact structure, small occupied line corridors.

Introduction

At present, the use of traditional transmission line towers are mainly steel tube tower, angle steel tower and concrete pole, they are exposed to the atmosphere all year round, prone to corrosion in the external factors. In addition, there is the heavy weight, poor durability, maintenance cost is high, prone to various security risks [1-2]. Fiber reinforced polymer composites (FRP) has a light weight, high strength, corrosion resistance and good insulation performance characteristics. FRP used for transmission line poles and towers, steel can be saved and easy to solve the transmission line wind deviation and the pollution flashover accident, reduce the width of line corridors, reduce the maintenance costs of transportation and operation[3-6]. In this paper, according to the characteristics of FRP to planning and design of 110 kV transmission line FRP pole, and to explore the section form and wire grounding scheme.

The characteristics of FRP

Light weight. The density of FRP is about a quarter of the steel, one tenth of the concrete. FRP transmission poles with light weight characteristics can greatly reduce transport costs, especially in traffic difficult mountain.

Good insulation properties. FRP has high insulation resistance, under the condition of wet and dirty, still has a certain insulation properties. FRP transmission poles can reduce lightning accident; reduce the gap between the conductor and the poles, reduce the width of line corridors occupied, saving scarce land resources; without insulator string, decrease the shaft height.

High strength, corrosion resisting. The strength of FRP is close to the yield value of Q235 which commonly used in transmission line towers. FRP transmission poles to corrosive medium such as acid, alkali, salt and organic solvents, corrosion resistance can be excellent, it is particularly suitable for concrete and steel with special anti-corrosion requirements of environments such as coastal areas, industrial zones and acid rain-prone areas and so on.

110kV pole design condition

Conductor selection of LGJ-300/25, earth wire selection of LGJ-95/55, span 250m. Design of meteorological conditions such as shown in Tab.1.

Calculation parameters

Calculate of conductor and ground wire Kilo Newton per cubic miter load. According to the conductor and ground wire specifications and other design conditions, calculation of conductor and ground wire Kilo Newton per cubic miter load, the results are shown in Tab. 2.

Tab. 1 Meteorological conditions

Meteorological conditions	Temperature ( )	Wind speed(m/s)	Thickness of ice (mm)
Maximum temperature	+40	0	0
Minimum temperature	-20	0	0
Maximum wind speed	-5	30	0
Icing situation	-5	10	10
Mean temperature	5	0	0
Installation situation	-15	10	0

Tab.2 Conductor and ground wire Kilo Newton per cubic miter load value (10^{-3}MPa/m)

Kilo Newton per cubic miter load	conductor	ground wire
Kilo Newton per cubic miter weight (γ_1)	31.13	45.42
Kilo Newton per cubic miter ice (γ_2)	28.08	47.18
Kilo Newton per cubic miter total vertical load (γ_3)	59.21	92.60
Kilo Newton per cubic miter wind without ice (γ_4)	33.08	53.01
Kilo Newton per cubic miter ice and wind (γ_5)	9.85	17.67
Kilo Newton per cubic miter total load without ice (γ_6)	45.42	69.80
Kilo Newton per cubic miter total load with ice and wind (γ_7)	60.03	94.27

Calculate of conductor and ground wire maximum sag. With an average annual temperature is the first state, the maximum temperature for the second state. According to the equation of state of hanging point of overhead lines:

$$\sigma_{02}-\frac{E\gamma_2^2l^2}{24\sigma_{02}^2}=\sigma_{01}-\frac{E\gamma_1^2l^2}{24\sigma_{01}^2}-\alpha E(t_2-t_1) \tag{1}$$

$$f_C=\frac{\gamma_1 l^2}{8\sigma_{02}} \tag{2}$$

By the formula 2, calculate of conductor and ground wire maximum sag. The maximum sag of conductor is 5.55m; the maximum sag of ground wire is 3.31m.

Determine of practical height. Tower cross-arm bottom edge line onto the floor of the vertical distance of the ground is called practical height; it is important to the tower safety and economy. The practical height of FRP poles calculates by formula 3.

$$H=f_{\max}+h_x+\Delta h \tag{3}$$

Where, $f_{\max}$ is maximum conductor sag, m; h_x is conductor from the ground and the across safety distance, m; h is construction margin, m. The calculated practical height is 12.5m.

Conductor arrangement

Horizontal distance between conductors. Under normal operating voltage of weather conditions, because of the action of wind load, swaying in the conductor, the middle of the span conductor swing amplitude is the largest. When the wire rolling is not synchronous, span central conductors will close to breakdown air gap between conductors, occurrence of flashover. When the span follows 1000m, the horizontal distance calculates by formula 4[7].

$$D=\frac{U}{110}+0.65\sqrt{f_{\max}} \tag{4}$$

Where, D is conductor horizontal distance; U is system nominal voltage; $f_{\max}$ is maximum conductor sag. According to the results and control the results of other studies, 110kV FRP pole horizontal distance is 3.6m.

Vertical distance between conductors. When two-phase conductors are arranged vertically, the main factors that determine the vertical line spacing is: Conductors' uneven ice or ice shedding lead the conductors jump sharply. In order to ensure the conductors galloping without collision, two

phase conductors must ensure a safe distance. The vertical distance of 110kV FRP pole between the phase conductors is not less than 3.5m [7].

Horizontal migration between conductors. Ice-shedding will make the conductors to produce vertical jump, if the upper and lower conductors of the adjacent no design level offset, it is easier to produce collision, so that occurrence of power system fault.

110kV transmission line, adjacent the upper and lower conductors' horizontal migration is not less than 0.5m [7].

Determine the pole structure size and cross section form

Because of FRP has good insulation performance, so the conductors fixed on the cross arm directly, eliminating the insulator string, also don't need to check wind deviation. According to the design parameters are calculated; take the upward-form pole as the prototype, the FRP pole structure size design as shown in Figure 1. Pole section is circular, diameter 350mm, wall thickness 10mm, adding triangular ribs, as shown in Figure 2.

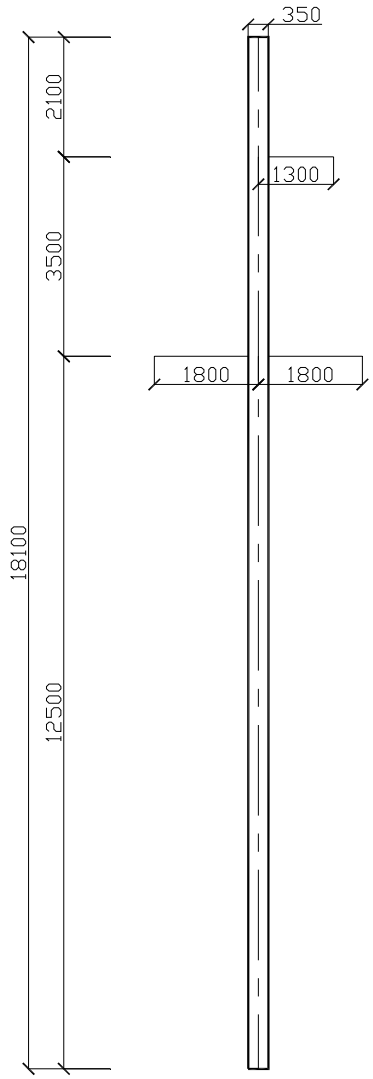

Fig.1. 110kV FRP pole structure size

Fig.2. 110kV FRP pole cross section form

Ground wire grounding scheme

Installation of ground wire in the FRP pole at the top, a ground down lead is arranged in the inner pole, set a short gap in the central of the ground down lead, so that under normal operating conditions can not be broken down, when lightning current flows, gap breakdown occurs, the ground down lead short circuit, and the lightning current smoothly discharged into the ground.

Conclusion

According to FRP itself good insulation and related specifications, designs and gives a 110 kV FRP pole structure size. Structure and size of the FRP pole is significantly less than the traditional pole with the same voltage level, more compact and smaller occupy line corridor.

Keywords: RPC pole, design and calculate,finite element analysis

Abstract. Reactive Powder Concrete（RPC） material has good performances such as great strength, good durability and good stability,Therefore it has higher application value.In this paper, We design and calculate theoretically for the transmission lines of RPC door type double pole , and use the finite element analysis software ANSYS analysis the RPC double pole. Then we compare the results of numerical calculation we have get with the theoretical calculation results .It turned out that the RPC pole in the 500 kv transmission line designed application is feasible.

Introduction

RPC (Reactive Powder Concrete) materials is the combination of DSP and fiber reinforced materials of high technology concrete materials, with high strength, high toughness, high durability and the characteristics of high density［2-4］.The material in those aspects such as raw material composition and preparation technology are great differences with high performance concrete, and the durability and compactness of its internal structure got improved significantly. At present, the main research work of RPC is focused on the material mechanical properties and micro aspects of the production process, The structure of applied research is less, much more less in the application of transmission line pole research［4］.

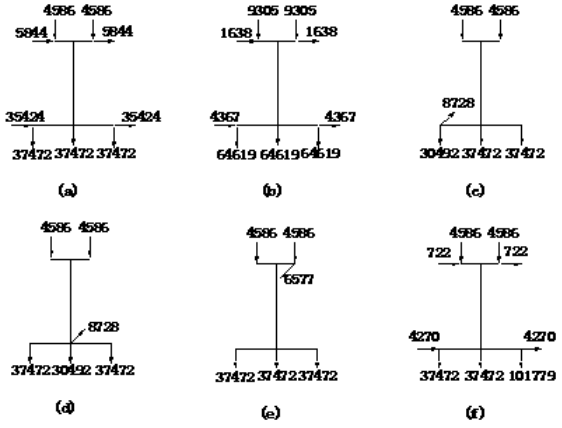
The theoretical design and calculation of 500kv transmission line RPC pole

1.1 The design parameters and load calculation of tower head

The conductor we take is LGJ - 400/35 and the ground wire is JLB4-150. The RPC pole designed according to the typical weather zone II,the horizontal span is 400 m,the vertical span is 580 m, the pole with φ 500 diameter and the wall thickness of 100mm.The RPC pole composed of six rods which section of 6m long, and each Paragraph with welded connections.Tension control stress is 700 M Pa.Suspension insulator string consists of 28 pieces XWP2-160 insulator,the String length （λd） is 4340mm.The total mass of wire insulator strings and its fittings for 218.49kg.Wire fittings length λb is 645 mm,The total mass of wire insulators and its fittings for 7.03 kg. The lightning line maximum and minimum support force are T_D=9.97kN and T_D=9.97kN .Preliminary selection of pole geometry size are:Overall length (L) is 36m,outside diameter (R) is 500 mm, inner diameter (r) is 400 mm.According to the design requirements, insulation coordination and lightning protection and so on.

Reinforcement in accordance with the constitution requirement to use of partially prestressed stell. The prestressed reinforcement with 16 high strength steels which the diameter is 12. The non-prestressed reinforcement with 12 ordinary steels which its diameter is 14［6］.

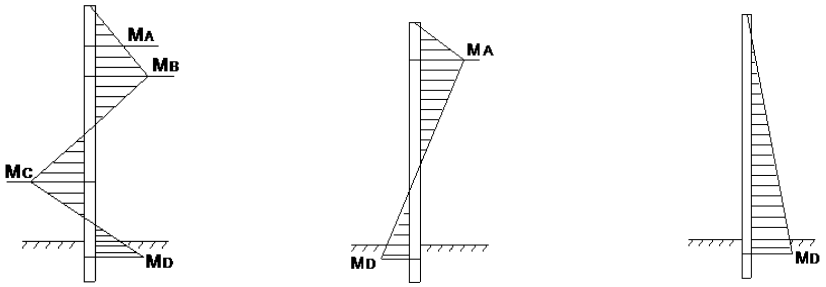
The rod head design load values calculated by the design conditions as shown in Fig 1:



(a)Operation of Ⅰ, (b) Operation of Ⅱ, (c)Off the left wire,
(d)Off the middle wire,（e）The ground uneven tension, (f)The installation situation
Fig 1.The rod head design value of load (N)

1.2 The internal force calculation

The maximum wind conditions, the wire-off side circumstances and ground of the unbalanced tension situation cause internal forces greater ,and we calculate the bending moment separately caused by operation Ⅰ (maximum wind), the wire-off side and the ground wire unbalanced tension , bending moment diagram as follows:



(a)The gale case (b)Broken edge wire (c)Ground wire unbalanced tension
Fig 2. Bending moment diagram of electric pole

The calculation results as follows: The wind: M_A=78.8kN·m, M_B=415.5kN·m, M_C=426.4kN·m, M_D=426.4kN·m ; Broken edge wire:M_A=74.8kN·m, M_D=13.7kN·m ; Ground unbalanced caused tension:M_D =175.2kN·m. From the results,we can see that everywhere of Poles'strength are controlled by the normal wind conditions.

1.3 The bending bearing capacity calculation

According to the literature 1, a new formula of calculation of bending bearing capacity, crack resistance and deflection on the basis of the original design specification. In this paper, We calculate those situations by referring to the calculation formula［1-3］.

The bearing capacity of bending is:

$$M_p = f_{cm}A(r_1+r_2)\frac{\sin\pi\alpha}{2\pi} + f_p' A_p r_p \frac{\sin\pi\alpha}{\pi} + (f_p - \sigma_{po})A_p r_p \frac{\sin\pi\alpha_1}{\pi} + f_{cy}(r_1+r_2)\frac{\sin\pi\alpha}{\pi} + f_y A_s r_s \frac{\sin\pi\alpha + \sin\pi a}{\pi}$$
$$= 460.5kN\cdot m > 426.4kN\cdot m$$

During the calculation,M_P is the bending moment design value,A is the member area, A_P is the All interface area of the prestressed reinforcement,r_1 and r_2 are the radius of circular cross section inside and outside respectively, r_p is longitudinal prestressed reinforced circle radius,$\alpha_1$is the ratio of longitudinal reinforcement sectional area and pull all longitudinal section area of steel,f_{cm} is the

design value of concrete flexural compressive,f_p and f'_p are the prestressed tensile and compressive strength design values,$\delta_{p0}$is the effective prestress of prestressed reinforcement.The bearing capacity of bending meets the design requirements.

1.4 Crack width checking

Stage allows the cracks in prestressed steel fiber reinforced concrete poles checking cross-section (normal section) cracking when subjected to bending moment is:

$$M_{cr} = \gamma f_{tk} W_d \left(1 + \beta_c \alpha_{pL} \lambda_f\right) + \sigma_{pc} W_d = 175kN \cdot m$$

During the calculation, r is the plastic influence coefficient of concrete in tension zone, f_{tk} is the matrix of concrete tensile strength standard values,W_d is the conversion section elastic resistance moment,and ,α_{PL} is the coefficient of steel fiber on the tensile strength of reactive powder concrete(When reactive powder concrete strength grade during CF35~CF45,α_{PL}=0.55;and when Steel fiber reinforced concrete strength grade is CF50~CF60,α_{PL}=0.63).

Considering the reinforcement effect of steel fiber, under the combination of short-term effects of loading,and in the using phase , the pole steel fiber prestressed concrete crack bending cross-section (normal section) is allowed the maximum crack width:

$$\delta_{f\max} = (200 + S)\frac{M_s - M_{fcr}}{A_s E_s r_s} \upsilon\left(1 - \beta_c \beta_{cw}\right) = 0.0197mm \angle 0.05mm$$

During the calculation,M_s is the moment of reactive powder concrete pole by the combination of short-term effects of load calculation of bending section (section) .S is the spiral rib spacing,V is the coefficient of associated with longitudinal reinforced surface characteristics(Ribbed bar is 0.7,high strength spiral rib steel wire is 0.6), β_{CW} is the coefficient of steel fiber reactive powder concrete effect on pole crack width(When reactive powder concrete strength grade during CF35~CF60, β_{CW}=0.5)

According to the regulation, circular crack width should less than or equal to 0.05 mm, so the crack width meets the specification requirements［5］.

1.5 The deflection calculation

The stiffness of RPC(Reactive Powder Concrete) pole after appears cracks :

$$B_s = \left[0.65 + \frac{2}{3}\left(\frac{M_{cr}}{M_s} - 0.7\right)\right] E_c I_c \left(1 + \beta_G\right) = 2.1 \times 10^{14} N \cdot mm^2$$

During the calculation,β_G is the influence coefficient of steel fiber bending stiffness of reactive powder concrete pole of the short-term(When reactive powder concrete strength grade during CF35~CF60,β_G=0.35),E_C is the elastic modulus of concrete and I_C is the moment of inertia of conversion section.Calculation method of load combination of long term effect is same to the front.

The top of the pole displacement:

$$y = \frac{K \Sigma P H^3}{3 B_s} = 172.4mm$$

$$\Sigma P = 15.2 \times 36.5 + 642 \times 2 + 126 \times 2 = 2090.8N$$

The pole under the action of horizontal force, and structural material elastically deform ,which make the peak produce the deflection as follows:

$$\omega = \frac{y}{L} = \frac{172.4}{36.5 \times 10^3} = \frac{4.71}{1000} < \frac{5}{1000}$$

Therefore the pole deflection meets specification requirements［5］.

The 500kV transmission line RPC electric poles of finite element calculation

Establishing RPC double pole finite element model , setting up the unit type, and using solid 45 unit concrete, steel and cross arm use BEAM3 element[6], then define material properties, division of grid, load and solve.After loading the finite element model and the calculation results are as follows:

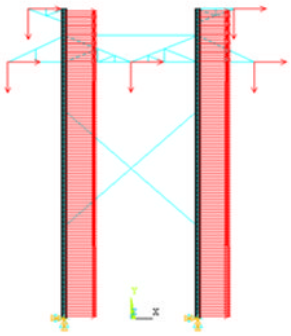


Fig3 After loading the Finite element model

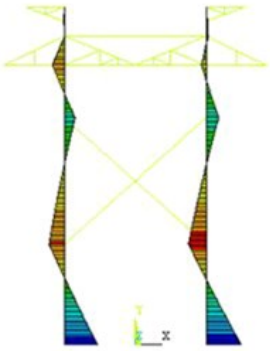

Fig4 Under the combination of long-term effects of deformation figure

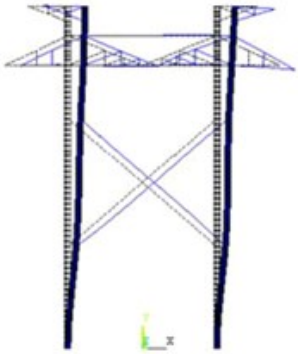

Fig 5 The bending moment diagram of structure

The maximum deflection of ANSYS simulation structure is 193.75 mm, the theoretical calculation value is 172.4 mm,and the error is 12.4%, within a reasonable range.The maximum bending moment value of ANSYS simulation structure is $4.19\times10^{8}N\cdot mm$, the theoretical calculation value is $4.26\times10^{8}N\cdot mm$,and the error is 1.6%, within a reasonable range.From the results of the analysis ,we can conclude that RPC concrete pole has higher bearing capacity, better crack resistance and anti deformation ability.

Conclusion

In this paper, We design and calculate for the pole by an example.And we use the finite element analysis software ANSYS to analyze the RPC pole, and then extract its deformation figure and deflection under the combination of long-term effects.From the analyze results,we can conclude that RPC concrete pole has broad prospective market which can be applied to the 500 kv transmission line.

Keywords: subsea production facilities; ILM; SIT; pipe line end termination; deep water;

Abstract. With the development of offshore oil and gas field enters into deep water constantly, subsea production system has become the main development mode in deep water development. Subsea Inline manifold (ILM) is common facilities in subsea production system and is used to gather oil and gas from the side subsea wells. Two subsea ILMs has been adopted in Panyu 35-1/35-2 Gas field with water depth range from 194 to 338 m in South China Sea. System integration test (SIT) is very important for the subsea production facilities. This paper states the flow chart, master equipment, purpose and precautions for each test of ILM SIT, which collects great technology for the development of subsea production system.

Introduction

With the gradual dying out of the land and shallow water petroleum energy, the oil and gas from the offshore deep water is increasing constantly. Depending on the good reliability, economy and outstanding achievements, the subsea production system has become the important model for the deep water oil field development. The water depth explored by this mode has reached 3000m[1].

Panyu 35-1/35-2 Gas field lies in South China Sea. The subsea charismas trees, PLETs(pipeline end termination), ILMs, jumpers and SUTUs(subsea umbilical termination unit)and other subsea facilities have been adopted in this subsea production system. The oil, gas and water from PY34-1/35-2/35-1 will be processed at PY34-1 central processing platform (CEP) and then transported to Liwan 3-1 natural gas central processing platform[2]. After separation, metering and pressurization, the oil and gas are transported to CNOOC Deepwater Gas Plant onshore terminal for further processing. The field layout is shown in Fig 1.

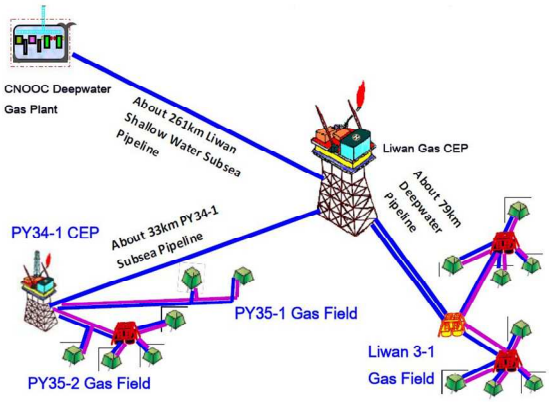

Fig.1. The schematic gas field layout of PY35-1/2

Subsea ILM is one kind of subsea manifolds which is integrated with subsea valves, hubs, bullseyes, etc. It is adopted when there are oil wells near the side of the subsea pipeline and the manifold is required to be laid together with the pipeline[3]. After the fabrication of subsea facilities, the ILM will be laid together with pipeline through the tensioner of the pipe-laying vessel. Then, jumper will be installed to connect the ILM with charismas trees under water. All the interfaces during installation and future production operations should be tested during SIT to validate the fabrication compliance with requested functionality of ILM[8]. Since there are many

interfaces, further many operations have to be carried out by remotely operated vehicle (ROV), the unknown risk is very high. If any issue happened during installation or production, the whole gas field may be affected. Therefore, the SIT is a very important test for subsea facilities.

This paper states in detail the flowchart, key equipment, purpose and precautions for each test included in SIT for subsea ILMs in PY35-1/2 project. The laying of ILMs has been completed successfully.

ILM composition

The ILM structure is designed into two parts.

1) Upper structure

The upper structure is a rigid frame which supports the valves, CAMERON vertical type connectors, jumpers and pipeline. The upper structure can be lifted using 4 padeyes and it slides on a rail system to allow to cater for thermal expansion of flow line and transfers load to mudmat.

2) Mudmat with protection frame

The mudmat is made up of single mat with skirts to increase the bearing capacity. Guiding rails sit over the mudmat to guide the upper structure during pipeline expansion and prevent lateral movement of upper structure in transverse direction [4].

6 in ILM composition is shown in Fig 2.

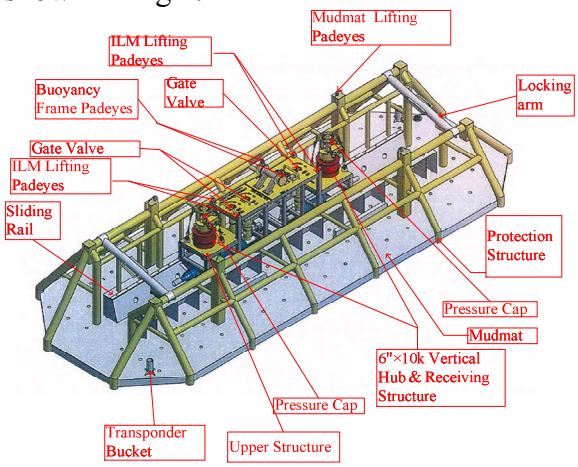

Fig.2. ILM components

Flow chart

There are 8 tests in the SIT for ILM. The test flow chart after optimization is shown in Fig.3.

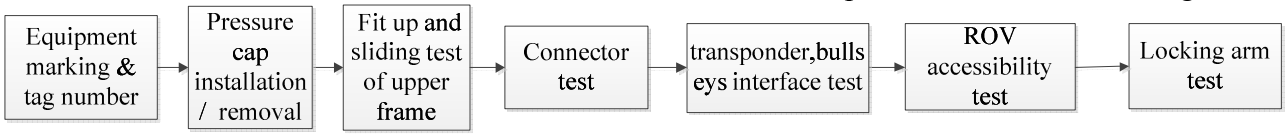

Fig.3. SIT flow chart

Master equipment list

The key equipment used in SIT for ILM is shown is table 1.

SIT

Initial status

Before carrying out any activity, the following points have to be completed [5]:

1) Before SIT carried out, the unit FAT for each component of ILM should be completed. The sequence of SIT can be changed to meet the offshore schedule if required.

2) Equipment to conduct the tests has been received on the yard and is fit for purpose, including calibration, certification, etc.

3) Specific work that has to be completed ahead of each task has been identified.

4) Specific task plan (for each major activity) has been prepared and approved.

5) Toolbox talk has been conducted with all personnel involved in the operation. Roles and responsibilities are clearly identified

6) Permits to work are in place

Lifting plans

All non-routine lifting operations shall have a lift plan supported by an analysis of the hazards and risks.

Equipment marking & tag number

1) The objective is to verify equipment marking & tag number as per related data sheets (DDS), specifications and drawings.

2) Precautions:

a) if there is inconformity between DDS and nameplates, the information should be fed back to client.

b) The number of subsea valves for opening and closing is different from the DDS, the actual turns should be followed.

Pressure cap installation/removal

1) The purpose of this test is to trial fit the Pressure caps and to verify its integrity with ILM CVC hubs. The pressure cap installation test is shown in Fig.4.

Fig.4. Pressure cap installation test

2) Precautions:
   a) Seal verification will be performed during this test if client required.
   b) The lifting force to remove the pressure should not exceed 4 ton.
   c) Levelness of the pressure should be monitored during installation and removal.

Fit up and sliding test of upper structure

1) The purpose of this test is to verify the fit-up of the ILM upper structure with the protection frame and simulate the pipeline expansion during the field production.

2) Precautions:

Two forklift should be prepared, one for ILM sliding, the other one for emergency hold back. The sliding test scheme is shown in Fig.5.

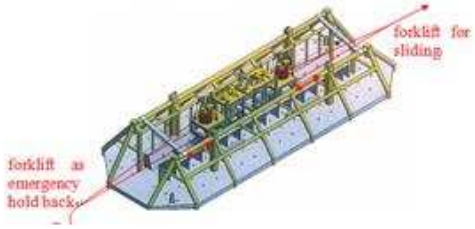

Fig.5. ILM upper structure sliding test

Connector test

1) The purpose of this test is to verify:

a) Interface between CVC hub and CVC connector

b) Interface between CVC RT and CVC connectors[6].

The on-site connector test is shown in Fig.6.

Fig.6. Connector test

Fig.7. Bullseye fit-up test

2) Precautions:

a) The Cameron operation manual for operating RT to connect the connector to the hub should be followed strictly.

b) The cleanliness of water-based hydraulic oil to operation Running Tool(RT) to connect the connector to hub should be tested. The cleanliness should be no higher than NAS 1638 class8.

c) The pressure of HPU used for driving the RT should no less than 5000psi, and the volume should be bigger than 50L.

Survey Equipment fit-up.

1) The objective of this test is to perform the fit up test for all surveying aids to be used offshore during installation. This fit-up include bullseye and transponder with the ILM[7].

2) Precautions: There is requirement for the installed direction of the bullseye. The longitudinal axis of the bullseye should be parallel to the main longitudinal axis of ILM. The installed bullseye is shown in Fig.7.

ROV accessibility test

1) The purpose of this test is to verify the ROV interface with ILM components for subsea operation[8]. The yard ROV access test is shown in Fig.8.

Fig.8. ROV access test

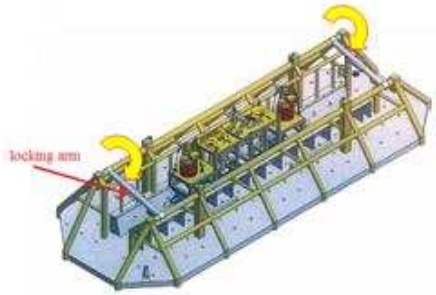

Fig.9. Locking arm swivel test

2) Precautions:

a) All the access of ROV during offshore installation and future field production should be checked.

b) The operation related to ROV should be careful in case causing the damage of ROV.

Locking arm test

1) The purpose of this test is to check the swiveling function of locking arm of ILM. The test scheme is shown in Fig.9.

2) Precautions: lubricating oil should be used in the swiveling trunnions and locking latches of ILM.

Conclusion

This paper in detail states the flow chart, master equipment, purpose and precautions for each test included in ILM SIT first time depending on PY35-1/2 subsea project. It provides technical references for other subsea facilities such as central manifold, pipeline end manifold, pipe line end termination, subsea jumper, enhancing the SIT technology further. It is very good for the development of vast unexploited deep water oil field, causing great social and economic benefit.

School of Electrical Engineering, Wuhan University, Wuhan, China

zhangyangsai@163.com,sclingwhu@163.com

Keywords: GIB, temperature distribution, multiple species

Abstract: The temperature field distribution is a most important part we pay close attention to when gas insulated bus is designed. In this paper, finite element method is employed to calculate the temperature rise of gas insulated bus based on fluid governing equation and heat conduction equation. The problem of convection heat transfer between fluid and solid is solved by multiple species transport technique which provides convenience for the calculation of convection heat transfer coefficient. The solution region includes SF_6 gas, ambient air, conduct and tank whose electrical and thermal properties are dependent of temperature. Analysis result illustrates that the thermal field distribution is symmetrical, the lowest temperature is at the bottom of the tank, while the highest temperature is on the top of the conductor.

1. Introduction

The study of gas insulated bus began in 1960s, which has the advantages of large transmission capacity, low power loss, small electromagnetic interference, low maintenance cost and long service life etc [1]. With the continuous expansion of city size and power demand, the power supply should have higher reliability. In addition, environmental factors are becoming more and more serious for the construction of power facilities. Therefore, GIB becomes one of the ideal choices to transfer power which will be possible to replace the overhead transmission line[2].

The calculation of temperature rise of GIB will couple electromagnetic field and thermal field analysis. The common calculation methods include finite element method and analytical method. The conductor and tank temperature is solved by analytical method through establishing heat balance of iterative loss equation, convection heat transfer equation and the heat radiation equation. The treatment of convection and radiation heat transfer of air and insulating gas is different in finite element methods which have been reported [3]. The convective and radiation heat transfer is equivalent to the heat conduction in GIB. However, heat transfer coefficient is often difficult to compute because of the unknown surface temperature and there is deviation of calculated results with the actual temperature distribution [4].The convective heat transfer coefficient, which is calculated by dimensionless parameters, is regarded as constant [5]. Although this method can simplify the calculation, the result is inconsistent with the actual situation.

Due to the different installation environment, the temperature of running GIB will be certainly affected by ambient temperature and operating current. Research shows that all the parameters of the fluid are the function of temperature and the convective heat transfer coefficient is not same in different surface orientation of fluid-solid heat transfer surface. Because of sophisticated temperature factors in GIB, it is difficult to study these problems only by experiments. The numerical calculation method has the advantages of low cost which can simulate any complex environment. On the basis of the analysis mentioned above, considering the nonlinear characteristics of the temperature of gas physical parameters, this paper has established GIB finite element model to calculate the temperature rise with multiple species transport technique. The technique, which avoids applying constant convective heat transfer coefficient to tank surface, reduces the computational error. Through analyzing the related factors, the paper provides a theoretical basis for the design of GIB size and temperature monitoring.

2. Steady-state mathematical model of the electromagnetic field

The simulation based on a 500KV 4600A GIB for the original model. Its structure is shown in Fig.1. As the temperature field calculation of the heat source, electromagnetic field analysis must compute GIB conductor and tank Power loss accurately. In order to facilitate the simulation, simplifying assumptions make the following four points:

1) Due to the symmetrical structure of GIB and its axial length is much larger than the outer diameter of the tank, in order to reduce the amount of computation, two-dimensional finite element analysis is used to solve the electromagnetic fields of GIB.

2) The relative permeability of conductor and tank is constant.

3) The resistivity of the conductor and tank are a function of temperature.

4) The impact of bus contact structure on temperature distribution is ignored.

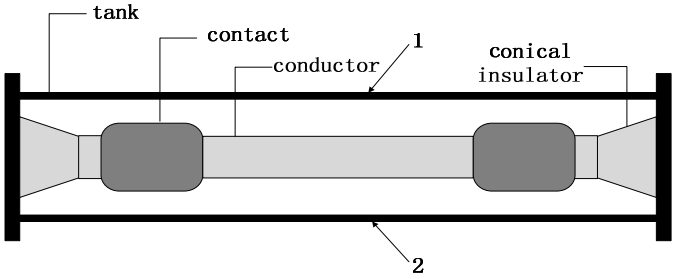

Fig. 1 Structure of the GIB and the locations of measurement points

Therefore, under the above assumptions, GIB cross section including the outside air is selected to solution region because the tank permeability is close to air. The solution region is shown in Fig.2.

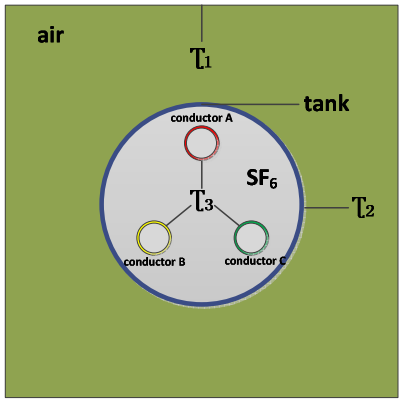

Fig. 2 Solution region of the model

Combining the specific model parameters and finite element analysis of the electromagnetic field, the 2-D current diffusion problem in a time-harmonic regime can be stated as follows :

$$\begin{cases} \Omega : \dfrac{1}{\mu}\left(\dfrac{\partial^2 A}{\partial x^2}+\dfrac{\partial^2 A}{\partial y^2}\right)=-J_z \\ \Gamma_1 : A_z = 0 \end{cases} \tag{1}$$

Where Ω is the solution region, Γ1 is the Dirichlet boundary condition, μ is the magnetic permeability, A_z is the z component of the magnetic vector potential, J_z is the total current density. Considering the change of resistivity with temperature, GIB power losses per unit length of the conductor and tank can be written as:

$$Q=\sum_{i=1}^{n} q_i^e=\sum_{i=1}^{n}\frac{J_i^e J_i^{e^*}}{\sigma(T)S_i^e} \tag{2}$$

$$\sigma(T)=\sigma_{20}/[1+0.004(T-20)] \tag{3}$$

Where n is the number of elements, q_i^e is the power losses of typical finite element, J_i^e and σ_{20} are the total current density and the electric conductivity of the element in 20℃ , respectively. S_i^e is the area of element, T is the temperature of tank.

The material and size parameters of GIB are shown in table.1.

Tab. 1 Dimensions and parameters of the GIB

parameter	conductor	tank
material	A6063-T5	A5005-0
internal diameter[mm]	140	480
external diameter[mm]	160	490

3. Mathematical model of thermal field

A. Heat transfer mechanism and the basic assumptions

The solution region of thermal field which is same with electromagnetic field is shown in Fig.2.The heat of conductor and tank is dissipated through ambient air. Conductors, insulators and tank composed of a closed cavity, which is filled with SF_6 gas. The power losses of the conductor warm the surrounding, which causes insulating gas to expand. Therefore, the heat from conductor gets into the insulating gas primarily through the natural convection heat transfer. Similar with conductor, there is a same heat exchanger manner between the tank and ambient air. The difference is that the former is a limited space within the convective and radiation heat transfer, the latter belongs to the large space of convection and radiation heat transfer.

The calculation of GIB thermal field is based on the following assumptions:

1) *GIB is in a room, thus ignoring the temperature effects caused by wind speed and solar radiation.*

2) The radiation heat transfer of SF6 gas is not considered.

3) The density, viscosity and thermal conductivity of SF_6 gas and air are related to temperature but gas specific heat are considered constant.

B. The natural convection heat transfer

In order to avoid calculating the convective heat transfer coefficient of the tank surface, ambient air is introduced to analyze the convection heat transfer of GIB. It is worth noting that there are two fluids which have different physical parameters after the introduction of ambient air. The equation is stated as:

$$\alpha_{\text{bulk}}=Y_{SF_6}\alpha_{SF_6}+Y_{air}\alpha_{air} \tag{4}$$

Where α is density, thermal conductivity or viscosity of air or SF_6, Y is mass fraction of air or SF_6 , α_{bulk} is the physical parameters of two fluid combination.

The gas density, thermal conductivity and viscosity are the function of temperature and it can be written as:

$$\rho_{\text{bulk}}(T)=\rho_0 PC_1/(TC_2) \tag{5}$$

$$\lambda_{\text{bulk}}(T)=\lambda_0(T/C_1)^{1.5}(C_1+C_2)/(T+C_2) \tag{6}$$

$$\mu_{\text{bulk}}(T)=\mu_0(T/C_1)^{1.5}(C_1+C_2)/(T+C_2) \tag{7}$$

Where ρ_0, λ_0 , μ_0 is density, thermal conductivity or viscosity of SF_6 or air respectively in environment temperature, P is gas pressure, C_1 and C_2 is constant associated with the gas physical parameters.

4. Analysis of simulation results

A. Multi-field coupling calculation method

As the resistivity of conductor and tank is relevant to temperature, therefore the power losses of them, which are used as input conditions of thermal field analysis model, can be iteratively calculated according to the initial temperature. There is a comparison of calculated and the initial value of conductor temperature to decide whether to update the initial temperature, which finally helps calculate the correct temperature distribution of GIB.

B. Analysis of simulation results

The power losses of GIB conductor and tank for different load currents are shown in Tab.2

Tab. 2 Power losses of the conductor and tank for different load currents

Current A	Conductor losses $W \cdot m^{-1}$	Tank losses $W \cdot m^{-1}$
2400	43.31	24.15
3500	73.99	41.03
4600	141.22	80.99

The load current is 4600A, environment temperature is 21.5 ℃, emission rate of tank surface is 0.9. the thermal field distribution is shown in Figure 3. By the GIB fluid thermal field simulation results that the internal temperature distribution of GIB general rule is: The thermal field of solution region is symmetrically distributed. The maximum temperature of the solution region locates at the top of conductor, whereas the temperature of ambient air is lowest. The section temperature of conductor which is approximately equal rises 40K.The differences of temperature in insulating gas are significant. The temperature of gas in bottom is lower than the top. Compared with the conductor, the temperature gradient of tank is more obvious because of the larger diameter. The maximum and minimum temperature of the tank locates at the top and button of tank respectively. The gas flowing characteristics is the main cause of the temperature distribution above.

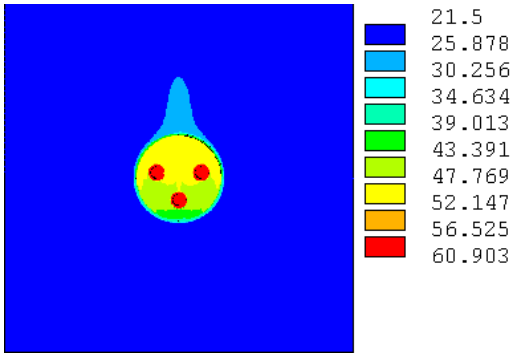

Fig. 3 Temperature profile of the GIB

The results comparison is shown in Tab.3. The measuring points are shown in Fig1.The result shows that the simulation results are consistent with the experimental results.

Tab. 3 Comparison between the calculated and tested results of temperature field

Current (A)	Test point 1		Test point 2		T_0 (°C)
	calculated value (°C)	experimental value (°C)	calculated value (°C)	experimental value (°C)	
2400	32.97	34.0	31.7	31.0	26.0
3500	34.21	35.0	32.05	31.7	22.0
4600	36.37	37.0	32.65	32.0	21.5

5. Conclusion

1) Compared with conventional finite element method, the multiple species transport technique has higher accuracy to calculate coupled fluid and thermal fields. It avoids applying the convective heat transfer boundary conditions.

2) The temperature rise of conductor is not obvious compared with the tank.

3) Convective heat transfer coefficient is not constant. So when calculating the temperature rise of GIB, the nonlinear thermophysical parameters of SF6 on the tank must be considered to reduce the computational error.

Keywords: Fast Neutron Fluence; Monte Carlo Method; verifying Calculation

Abstract. The reactor pressure vessel is an unchangeable component of the light water reactor. To some extent, the life of the pressure vessel depends on the fast neutron fluence. In addition, the fast neutron fluence is an important parameter for radiation protection. So, the fast neutron fluence is one of the main parameters which should be verifying calculated by the reviewers. The verifying calculation of the fast neutron fluence of one reactor pressure vessel is presented in this paper, and the standard deviation between the verifying and designing calculations is lower than 10%. The reasons for the deviation are discussed.

Introduction

The reactor pressure vessel is an unchangeable component of the light water reactor. The life of the nuclear power plants depends on the service life of the pressure vessel, which is under the influence of the fast neutron fluence. At present, the designed life of the reactors under operation in China is 40 years, and many of them are planning to extent to 60 years such as Qinshan nuclear power plant. The pressure vessel fast neutron fluence is an important factor to estimate whether it is actionable. And, the fast neutron fluence is one of the important parameters of radiation protection, and also included in the area of review in Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants LWR Edition (SRP) [1]. Thus, the reactor pressure vessel fast neutron fluence should be verifying calculated by the nuclear safety reviewers to determine the accuracy and reasonableness of the designing values [2][3].

The reactor pressure vessel fast neutron fluence can be calculated by the discrete ordinate (SN) method and Monte Carlo (MC) method [4][5][6]. Both methods are approved by Nuclear Regulatory Commission of USA, and widely used in designing and reviewing [7]. The SN method is based on deterministic theory with high calculation efficiency. And it could obtain the distribution of the pressure vessel fast neutron in a single calculation. In contrast, the MC method is based on the probability theory with lower efficiency. But the parameters of geometry can be described in detail with MC method, which is the disadvantage of the SN method. Besides, in recent years, both of the methods have been improved very much with the development of the computer technology. The description of geometry with SN method is more and more accurate, and the efficiency of the MC has a substantial increased.

In this paper, pressure vessel fast neutron fluence of a reactor is verifying calculated. The results of the verifying and the designing calculations are compared, and there are some reasons for the relative deviation between them. The pressure vessel fast neutron fluence of the sample reactor is designed by the SN method and verifying calculated by the MC method [8][9][10].

The theory of the verifying calculation of reactor pressure vessel fast neutron fluence

The neutrons with energy above 0.1MeV or 1MeV are called fast neutrons. In the light water reactor, the life of the pressure vessel is depends on the radiation effect of the fast neutrons fluence with energy above 0.1MeV (E>0.1MeV). And the fast neutron fluence with energy above 1MeV (E>1MeV) plays an important role in the materials embrittlement and damage under the radiation. Both kinds of the neutrons are simulated in the verifying calculation. And in this paper, the calculations are at the inner surface of the reactor pressure vessel.

There are a few simplified handlings in the process of modeling depending on some experience. There is a brief introduction at follows. Some sensitivity analysis had been done to confirm the reliability of the handlings, which is not a major task in this paper. Only the conclusions of the sensitivity analysis are described.

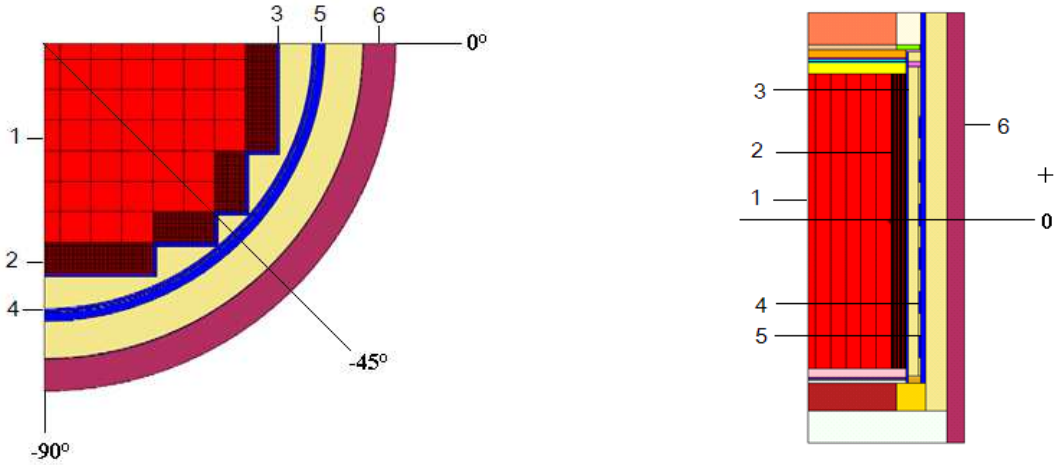
First, in the modeling, the materials like water, void and some metal supports are mixed into the fuel rods as a whole. What's more, as the influences of the outer fuel assemblies are more important to the pressure vessel fast neutron fluence than the inner ones, the fuel rods which contained in the outer fuel assemblies are modeled pin-by-pin, but the inner ones are mixed in further. The sensitivity analysis shows that if fuel rods of the inner fuel assemblies are also modeled pin-by-pin, the calculation results could converge slowly but with a few influences to the results of the fast neutron fluence.

Second, to obtain the maximum value of the fast neutron fluence at the inner surface of the reactor pressure vessel, the distribution of the fast neutrons in the circumferential direction is calculated in the first step, and there would be a maximum value in an azimuth angle. Then, the distribution in the axial direction is calculated at this azimuth angle. The maximum value obtained by the second step is considered to be the maximum value at the inner surface of the pressure vessel as an approximate. The sensitivity analysis shows that the calculation results of the maximum value at the other azimuth angle are lower than this value, only a few are higher with very small deviation.

Third, because of the symmetry of the reactor core, 1/4 of the core model is enough, and the results could be corrected to the real at last or in the process of the calculation.

In addition, to make sure the accuracy of the results, the statistical variances are controlled to be lower than 0.03 in the calculation with the Monte Carlo method. The energy of the neutron is cut at 1E-11MeV in the calculation, and it hardly affects the fast neutron fluence. The ENDF/B library is chosen as the cross section library in the calculation.

The method and discussion of the verifying calculation



(a) The model in radial cross section (b) The model in axial cross section

1-inner fuel assemble; 2-outer fuel assemble; 3-core baffle; 4-core shroud; 5-core barrel; 6-reactor pressure vessel.

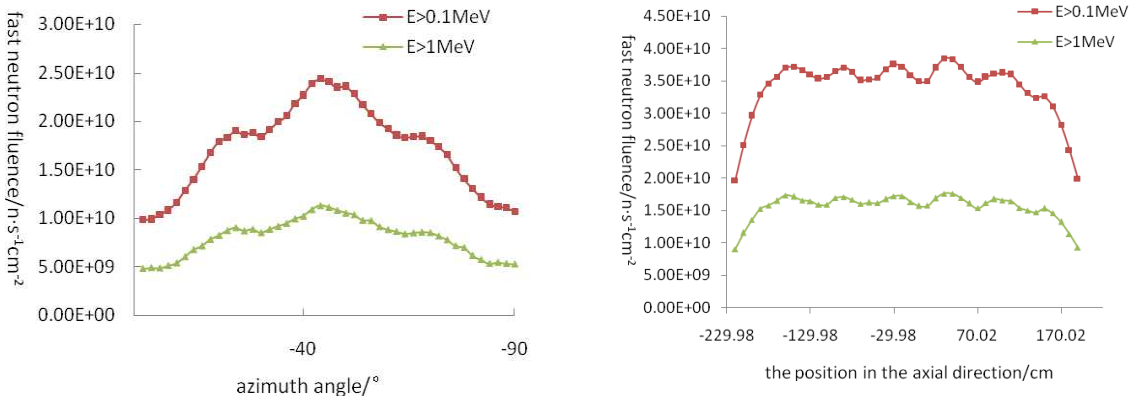
Fig.1. The geometry model of the verifying calculation

All the parameters of the reactor are provided by the designers. The geometry model is built with the MC method. The models for verifying calculation is shown in Figure 1(a) and (b), the model is shown in radial and axial cross section respectively. As it is shown in Figure 1, the origin in the radial is on the horizontal line, and the origin in the axial is on the mid-plane of the reactor core. In the geometry model, there are fuel assembles and their upper and lower support structures, the reactor internals, pressure vessel, and water between them. The reactor internals are out of the reactor core, and they are core baffle, core shrouds and core barrel from the inside out. There are 6 reactor shrouds surrounding the core baffle. Different colors in the figure stand for different

materials. In this sample, the core baffle, core shrouds, and the core barrel is made of stainless steel. The reactor pressure vessel is made of carbon steel.

The distribution of the fast neutron fluence in the circumferential direction with steps of 2° is calculated at first. As it is shown in figure 2(a), the fast neutron fluence of either E>0.1MeV or E>1MeV is low at 0° and -90°, and the maximum value is 2.45E+10n·cm^{-2}s^{-1} in the azimuth angle of -46° to -44° and 1.12E+10 n·cm^{-2}s^{-1} in the azimuth angle of -44° to -42° respectively. The obtained azimuth angles are mostly agreed with a few deviations.

Then, the distribution in the axial direction is calculated in the azimuth angle of -46° to -44°, and a step of 5cm is used in this calculation. As it is shown in figure 2(b), the maximum value of the fast neutron fluence is 3.83E+10n·cm^{-2}s^{-1} at -89.98cm to -99.98cm in the axial direction (E>0.1MeV) and 1.75E+10n·cm^{-2}s^{-1} at -9.98cm to -19.98cm in the axial direction (E>1MeV) respectively, which are the maximum values at the inner surface of the pressure vessel as an approximate.



(a) The distribution of the fast neutron fluence in the circumferential direction
(b) The distribution of the fast neutron fluence in the axial direction
Fig.2. Distribution of the fast neutron fluence

The verifying results of the maximum value at the inner surface of the pressure vessel are compared with the designing ones, and the comparison is shown in table 1. The standard deviation is within 10%. Relatively speaking, the former ones are higher, and they are more conservative than the latter. The results of both kinds of methods are up to the required standards of the SRP. (The provision in the SRP: The peak vessel wall fluence for the design life of the plant is less than 1E+20 neutrons per square centimeter (n/cm^2) for neutrons of energy greater than 1MeV.)

Tab.1. Comparison between the verifying and designing calculation of the maximum value at the inner surface of the reactor pressure vessel

Energy	Verifying Calculation (MC Method)	Designing Calculation (SN Method)	Standard Deviation
E>0.1MeV(n·cm^{-2}s^{-1})	3.83E+10	3.54E+10	-8.2%
E>1MeV (n·cm^{-2}s^{-1})	1.75E+10	1.66E+10	-5.4%

There are some reasons for the relative deviation between the verifying and designing calculation.

First, different methods are used in the verifying and the designing calculation. Either method could be used to the calculation of the fast neutron fluence. When using the same method, only systemic errors for different users would be shown. Otherwise, it may bring in some deviations depending on different methods. In this verifying calculation, a three-dimensional model is built by the Monte Carlo method, while a two-dimensional model is used in the discrete ordinate method. The latter is less detailed than the former.

Second, the methods in the simplification of the geometry are different. In the designing calculation, some reactor internals, such as core shrouds, are omitted. Hence the average value of the pressure vessel fast neutron fluence would be higher than the actual value. It could leads to a

more conservative result. However, the geometry is described more resemble real in the verifying calculation. This kind of simplification can generally be accepted by the calculation of the fast neutron fluence, because the more conservative result would lead to the less damage to the reactor pressure vessel.

Third, the methods for handling the results are different. The results of verifying calculation with the Monte Carlo method are ensured their accuracy by controlling the statistical variances, although there are some uncertainties because of the cross section of the neutrons, the geometry simplifies, and so on. Because the history of each single particle could be simulated with this method, and a statistical result could be obtained at last. However, after the calculation with the discrete ordinate method, the results should be multiplied by two factors. One is the uncertainty factor of the method and the other is the distribution factor in axial direction. The two factors are elected from experiments. In this condition, the accuracy or rationality of the factors should be evaluated.

In addition, some other different conditions are set in the designing and the verifying calculations respectively. It would bring in some influences to the results. For example, the units of the counting are surfaces and grids respectively in the verifying calculation with the Monte Carlo method and the designing calculation with the discrete ordinate method. Different sizes of the surfaces or the grids may lead to different results. In general, the smaller of the sizes, the more accurate of the results, and usually at the expense of the calculation speed.

Conclusion

The Monte Carlo method is applied to the verifying calculation of the reactor pressure vessel fast neutron fluence, which is different of the discrete ordinate method in the designing. The standard deviation between the results of the verifying and the designing calculations is within 10%. Although the verifying calculation results are more conservative than the designing calculation results, both methods are allowed to calculate the fast neutron fluence of reactor pressure vessel, and the calculation results could meet the specified requirements of SRP. The deviation between the results of the two calculation methods may result from the different calculation methods, the simplicity of the geometry, the handling of the calculation results, the conditions setting in the designing, and so on. These considerations which could lead to the deviation should be taken seriously in the verifying calculation of the reactor pressure vessel fast neutron fluence to make sure the scientific of the verifying calculation. If it is necessary, some of the accuracy or rationality of the treatment should be evaluated both in the verifying and the designing calculation.

Keywords: Biomass; Burner; Greenhouse environment; Research application

Abstract. According to the demands of greenhouse environmental conditions, this paper examines a solid fuel burning stove applied to compression molding of biomass in order to solve the issues which temperature is too low in greenhouses in winter north of China and carbon dioxide concentration is too low caused by insufficient ventilation number. The burning stove designed with big furnace, no grate and recalculated secondary air. Fuel utilization was improved in the largest degree in this design. Feed amount, feed rate and time are controlled by the PLC system which is adopted to make fuel fully burning, low pollution emissions and more automation. The temperature field and gas flow field changes is simulated by the FLUENT. The temperature of various sections and the formation of nitrogen oxides is reduced by the special design when burning. Experiment shows that sulfur dioxide concentration is about 0.41mg/m^3, nitrogen dioxide is about 0.498mg/m^3 which have no effect in growth and development of crops. This paper provides theoretic guidance for improving greenhouse conditions.

Introduction

Biomass solid fuel [1] belongs to renewable energy, it's a kind of clean energy, high-density, low pollution, low cost, easy to transport, easy to store, etc. Biomass solid fuel burner is efficient combustion equipment, stable combustion, heat output uniform [2]. Greenhouse heat mainly from solar radiation, temperature is too low in the winter north of China, low temperature is not conducive to the growth of greenhouse crops; Insufficient ventilation number result in insufficient ventilation restricted concentrations of carbon dioxide, reducing the photosynthetic rate of greenhouse crops; Additions burner equipment can be used, while heat by burning fuel to produce carbon dioxide, greenhouse environmental conditions is improved. Biomass burning stove applied in greenhouse environment conditions can change the traditional way of carbon dioxide warming and supplying viewed from energy conservation and environmental meet the need of environmental conditions of growth and development of plants required ,contribute to the growth of crops, increase production, achieve zero pollution, maintain the ecological greenhouse in the circulatory system.

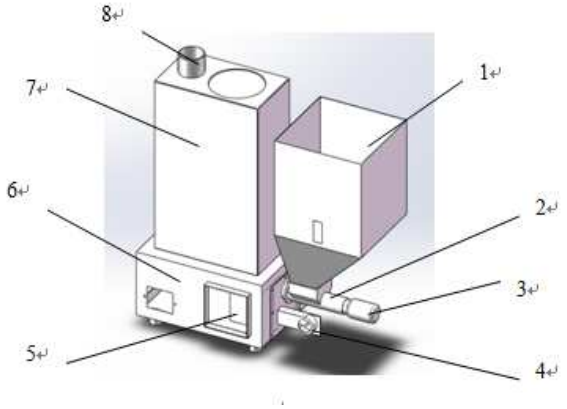
Demands of Greenhouse Environmental Conditions

Arch greenhouses are selected in this experiment, it has three sides wall and a rear wall, lighting structure is provided on the front wall, the total area of approximately 1152m^2, four townhouses, single buildings heat required about 6500W by theoretical calculations.[3]the greenhouse crops` most suitable temperature is 20~25℃, the carbon dioxide concentration of 0.11% to 0.13%. Within a certain range of concentrations, plants for sulfur dioxide, nitrogen oxides have some resistance, and some have evolved ability to absorb in a considerable degree. Research shows that plants will be damaged when the concentration of sulfur dioxide in the air reach to 0.05~10mg/L, nitrogen dioxide concentration of 2~3mg/L [5] [6].

Structural Design of Biomass Burning Stove

No grate design, batch combustion method; Feed amount, speed and time were controlled by the feeder; Combustion furnace automation degree is improved by PLC control system; Low moisture solid biomass compression molding fuel is selected, the amount of combustion air is controlled by the induced fan, fuel is complete burning, lowest the pollution emissions, meet the environmental requirements of greenhouse crops.

The specific structure of new design compression molding of biomass solid fuel burning stove [7] [8] as shown below:



1.Feed tank 2.Screw feeder 3.Motor 4.Blower 5.Combustion chamber 6.Ash chamber 7.Cooling zone 8. Exhaust port

Fig.1.Combustion furnace structure

Calculating the fuel consumption according to the formula [8]:

$$B = \frac{Q}{Q_{net,ar} \cdot \eta} \quad (1)$$

In the type: B_j is fuel consumption (kg/h); Q is heat required (kJ/h); $Q_{net,ar}$ is base low calorific value (kJ/kg); η is thermal efficiency (%).

Burning stove efficiency takes 45.5% when theoretical calculation, the fuel is corn stalk solid modeling pellet, its low calorific value is 15.75 MJ/kg, calories is about 6500 W, fuel consumption (fuel consumption rate) of biomass compression modeling solid fuel burning stove is calculated of 3.27 kg/h according to the energy balance [9].To provide enough heat and carbon dioxide for the whole greenhouse, burning stove need work continuously for 4 hours, the packing density of particle is 100 kg/m^3, so need combustion chamber volume is 0.141 m^3. Designed burning stove is mainly composed of the cooling area, ash chamber and the combustion chamber three parts, the overall volume is greater than the minimum required volume.

Screw feeder is controlled by PLC control system. Overall design of the combustor is an inverted trapezoid structure, volume is 0.0135m^3. Air distribution system is composed of induced fan, primary wind plat and secondary wind ring. Primary wind plat is composed of 135 holes that diameter is 5mm, the area is about 0.106m^2, air through the hole in the bottom space of the chamber into combustor. Secondary wind ring is composed of 20 holes that diameter is 5mm, air from the ash chamber wall through the top of wind ring into combustor. Corn stalk compression modeling solid fuel completely burn need air volume is 4.36 m^3/ kg by theoretical calculation.

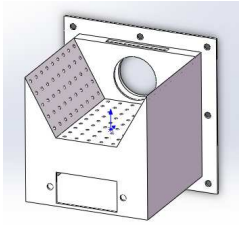

Fig.3 Combustor

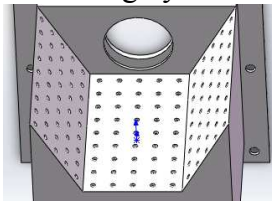

Fig.4 Primary wind plat

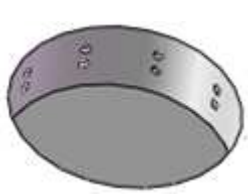

Fig.5 Secondary wind ring

Simulation Analysis and Temperature Measurement of Burning Stove

Two-dimensional compression molding of biomass solid fuel burning stove is simulated according to FLUENT software-Eddy dissipation (ED) model [9]. The simulation conditions are as follows: room temperature is 21℃, standard atmospheric pressure, the specific flow of 0.3, continue wind, the wind speed is 170.68 m^3/h, mainly set up factor is the wind, burning main composition is methane, feed speed is 3 kg/h, the ignition temperature is 343K, continuous burning,[10]. Speed scalar figure and the static temperature figure are analysis treatment results as follows . Maximum speed can be find on the primary wind plat, secondary wind ring and smoke outlet, velocity scalar presents a top-to-down trend; Static temperature figure shows that the highest temperature at the exit of fuel combustion, the cooling zone has uniform temperature decreasing changes.

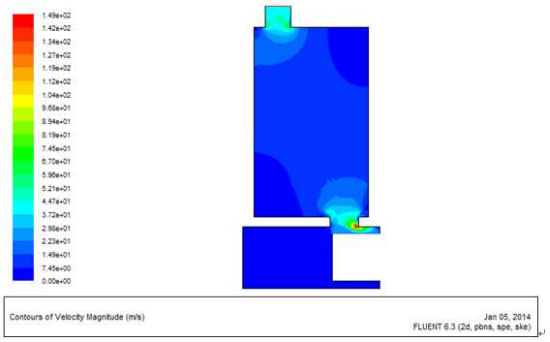

Fig.6. Velocity scalar

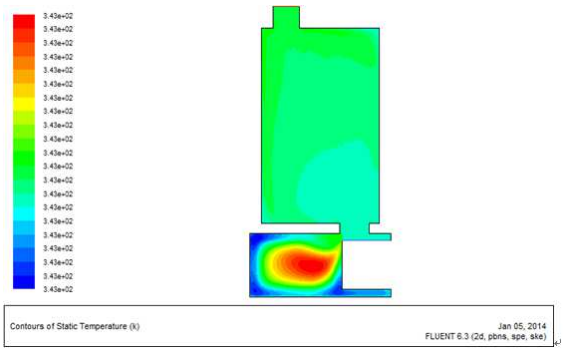

Fig.7. Static temperature

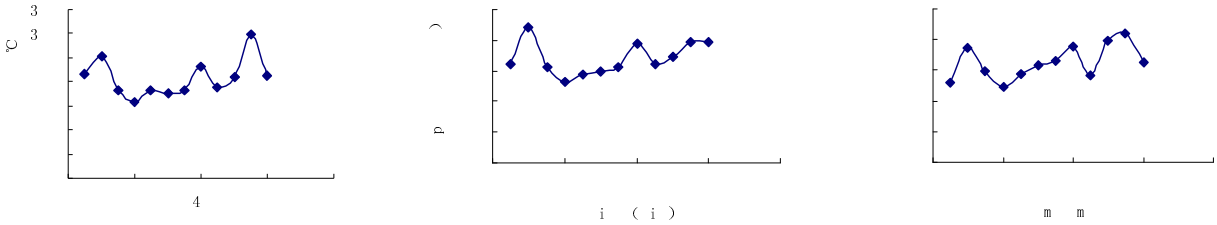
This paper finds that the wall temperature have a obviously influences on the inside temperature field during gas phase flow field simulation in burning stove This is the result of gas movement heat transfer [11] [12]. If burning stove has lower temperature, nitrogen content will be less. The changing of each part of the burning stove in the test as follows:



(a) Vent pipe wall (b) Radiation zone wall center (c) Combustion chamber wall

Fig.8 Various parts of the temperature change

The biomass compression molding solid fuel are ignited, temperatures continue to rise, due to the intermittent feed, feeding the second time before fuel fully burned, the flame by pressure, smoke temperature is reduced, when fuel burning temperature rise again, until to the end of the test. The design features of this burning stove is proved that reduce inside temperature and bring down the formation of nitrogen oxides pollution

Emissions Measurement of Sulfur Dioxide and Nitrogen Dioxide

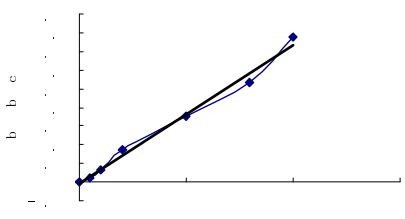


Fig.9 SO_2standard curve regression equation

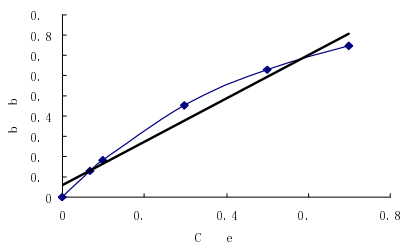

Fig.10.NO_2^-standard curve regression equation

Experimental sulfur dioxide and nitrite standard curve regression equations were Y=0.037X-0.0022, Y=1.0684X+0.0588. Ambient air was drawn through the air sampler, in the samples of the test, sulfur dioxide and reagent blank absorbance was 0.176 and 0.042; nitrite and reagent blank absorbance were 0.517 and 0.132. The contents of each pollutions which existed in the state of gases is calculated by the method of chemical analysis, sulfur dioxide and nitrogen dioxide concentrations were approximately 0.41mg/m^3 and 0.498mg/m^3,the measurement results u limited range of crops pollutant concentrations, does not affect the normal growth of greenhouse crops.

Conclusion

The result shows that with the big furnace design can dispersion heat and lower the temperature in the stove and reduce the formation of nitrogen oxides. No grate design, batch combustion method and the way which feed amount, feed rate and time controlled by the PLC control system are adopted to make fuel fully burning, lowest the pollution emissions and more automation. The air into combustor is controlled by induced fan. Primary wind plat and secondary wind ring are designed to meet the needs of primary wind and to ensure unburned volatile gases and smoke fully burn in the furnace with the secondary wind at the same time. The results provide theoretical guidance for improving greenhouse conditions and provide a certain degree of scientific basis for the application and popularization of biomass burning stove in greenhouses.

Keywords: Seismically Active Belt; Transmission Lines; Geological Hazards; Measures

Abstract. In the seismically active belt, frequent landslides, debris flow, avalanches, rock and soil creep and uneven ground subsidence and other geological disasters regularly cause risk to transmission lines, and even risk the safe operation of the power network. The main reasons of geological disasters occur are: fragile geological environment, heavy rain, the foundation defect, the destruction of vegetation, artificial spoil, unauthorized mining etc. Transmission line route optimization design, suitable use of the new technology in construction and technical innovations are effective measures to prevent geological disasters.

Introduction

The main inland seismically active belt topography is plateau and mountainous. Geological disasters in these areas has the characteristics of various kinds, caused disaster soon, frequency occurrence, wide influence, heavy damage, long term influence etc. These regional geological disasters regularly cause damage to the tower base, foundation collapse, tower deformation, tower break down, etc., which seriously risk transmission lines even the safe operation of electricity networks. This paper intends to classified analyze geological disasters occurrence of transmission lines in the seismically active belt, and combined with preventive measures of common geological disasters to exploration and research on destruction and preventive measures for geological damage on transmission lines from transmission lines management and operation and the use of new technology, etc.

Destruction and Cause Reason Analyze of Geological Disaster on Transmission Lines in the Seismically Active Belt

In the seismically active belt, transmission lines generally impact by frequent landslides, debris flow, avalanches, rock and soil creep and uneven ground subsidence and other geological disasters.

Landslide is quantities, large-scale, serious destruction, complex characteristics, but has a certain regularity natural geological disasters in the mountain deformation. It is the major representation of geological disasters in the seismically active belt which contains 90% of the total number of geological disasters risk transmission lines or more. The main destruction representation on transmission lines are the resurrection of the ancient landslide, landslides occurred within the shallow layer of loosely packed and occur along the contact surface of the cover layer and bedrock landslides and other forms of damage.

Figure 1 Impact on transmission lines by the resurrection of ancient landslides

Resurrection of ancient landslides means transmission line tower is located on the ancient landslide has occurred in the past, the latter due to the impact of natural or man-made factors, resulting in partial or whole resurrection landslide deformation, causing the tower displacement, deformation damage or even collapse. It shown in Figure 1, the resurrection of ancient landslides caused by tower shift, severe deformation, and the maximum displacement over 4m, surface cracking, tower severely deformed, and other elements to pull off.

Overburden and bedrock landslide along the contact surface also means loose deposits occur along the base layer of the top surface of the slide occurred, such relatively large landslide thickness, generally thicker than 6 meters, which has a heavy risk on the tower foundation. For example, in China the Longmen Shan fault zone, by impact of the "5.12" earthquake and "4.20 Lushan" earthquake, such landslide occurrence have increased significantly on size, distribution and frequency, resulting in a large number of transmission line towers main member bent, tower foundation subsidence settling even tower collapse and other major safety incidents. As shown in Figure 2, by the “5.12" earthquake and aftershocks impact to induce such landslides, causing serious destruction to 500kV line tower.

Figure 2 Impact of landslide for 500kV transmission line

According to years of analysis on seismically active belt geological disasters condition, fragile geological environment is an essential factor in the development of geological disasters. The hydro power transmission lines typically locate in geological fault zones. Normally, the zones along the

complex terrain conditions (deep valleys, steep terrain), slippery ground (clay stone, marl) development, covering a wide layer of loosely distributed, huge thickness, fracture structure development , much active fracture have stronger seismic activity. The rains are the major factors that induce geological disasters like: landslides, mudslides, etc. According to statistics, in recent years, China's major seismically active belts had an average annual rainfall of 900 to 1800 mm, which also increases the possibility of local geological disasters. For seasons, summer has the maximum rainfall, basically from the beginning of May to the end of October, accounting for 80% of the total annual rainfall. Regularly, concentrated rainfall, long duration is the incentive of geological disaster-prone. According to years of real transmission lines operation and management condition in the seismically active belt, the main human-cause geological disasters more regularity occurring are: the destruction of vegetation, artificial spoil, unauthorized mining etc.

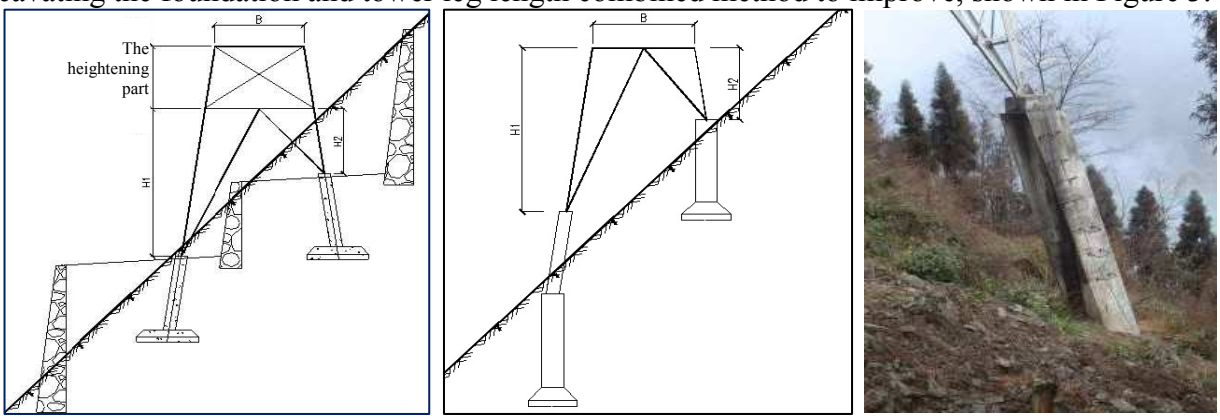
Preventive Measures of Geological Disasters Damage on Transmission Lines in the Seismically Active Belt

Choose route of transmission lines and towers location reasonably.

In the design stage of transmission lines, geological disaster-prone areas with seismic activity area characteristics should be considered. The design choices of the transmission line's geological conditions need to be full analyzed, especially on geological disasters and demonstration to avoid the range of geological disaster-prone, principally focused on disaster region. The tower located in the zones with ditches, scarp edge and slope side condition, slope stability and growth should be estimate analyzed to ensure that within a long-term trend the tower location can against collapse or landslide risks. Large instability ancient landslide should be identification timely during the survey design. The tower in this area will be arranged with the department's position shift. It cannot only pursue the route toward convenient transmission lines, while ignoring the huge losses future geological disasters.

Foundation improvements

Improvement of foundation type and construction process can be used in transmission lines construction on mountain, which excavation is too large to form a high-cut slope and generate a lot of spoil, resulting in manmade geological disasters. In the case of the tower steep slopes, it can excavation inclined inserted straight excavating the foundation for the improvement of excavating the foundation with helical column. It also can change the traditional fort-like ridge, slope protection, excavation practice small platform way, into high above the ground oblique column excavating the foundation and tower leg length combined method to improve, shown in Figure 3.



(a)Traditional (b) Improvement (c) Real photo

Figure 3 Tower foundation improvements on steep slope

When the tower located on a narrow ridge, change the traditional group and fort-like ridge practice, into not lower the foundation and straight column excavating the foundation, combine using integrated foundation with the four basic composition of the coupling beam, which can make it a frame structure to improve the stability of the foundation. If the tower is located in the scarp edge, improve traditional fort-like ridge, slope protection and excavation small platform measures, into

use full-length leg combine and high and low foundation with oblique beams, which besides improve the ability of foundation anti-overturning. These improvements not only lower the height of the tower to reduce project costs, but also as much as possible to maintain the original topography and vegetation. The amount of construction waste soil and surface wound is small, which greatly benefit landslides, collapses and other geological to prevent disasters.

Lines transitive

For such large-scale revival of ancient landslides, deep landslides and other location with huge geological risk, take general measures such as the construction of revetment effect, fort-like ridge, and anchor piles obvious lower effect, which would cause too much reconstruction. Recent seismic activity experience with regional geological disaster prevention work has proved that only way to complete solve the problem is using reconstruction, diversions and high cross-avoidance to transformation landslide and other measures to improve the technology.

Slope reinforcement and rocks anti-flying

For shallow landslides, the contact surface bedrock landslides, landslides and other geological disasters, it can use pile, anchor piles, anchor grouting etc. to reinforced slope. Anti-slide pile can use Φ600 reinforced concrete piles with 8m interval setting. Dump piles deep to bedrock surface. The main strip use four Φ40, Φ24 of four of Class II threaded steel reinforcement with a pile rib cage hoop stirrups, concrete grade 250, by way of construction of bored pile construction, concrete pouring underwater perfusion, which has good treatment effect. Prevention of geological disasters such as landslides can use SNS flexible slope protection nets. According to the terrain, it can choose passive or active protection network protection network to use.

Long-term prevention

Emphasis on fort-like ridge, slope, and drainage ditches inspections and timely repair the defects. Plant vegetation in poor geological conditions enhances the ability to resist soil erosion. In the transmission line construction, the selection of model aircraft wire-laying, avoiding the pay-channel tree felling, but also to protect the environment, minimizing the human factors of geological disasters desirable approach.

Conclusion

In recent years , the actual experience of geological disasters prevention and treatment showed that preventive measures on the foundation of the traditional emphasis during the design of geological survey work, and more to analyze the possibility of geological disasters to prevent; use of a new foundation, avoid large foundation excavation; discovered problem should be handled, select the appropriate, targeted pre-control measures can minimize the risks of geological disasters on transmission lines, and effectively ensuring the long-term safe and reliable operation of the transmission line.

Keywords: fouling; performance; the fill layer; analysis

Abstract: Based on that the film filling was simplified to the flat plate model, the heat and mass transfer of the filling zone with fouling in cooling tower were analyzed. The effect of fouling on the performance of filler was analyzed according to the dirt growth model. The work done in this paper can simply forecast changes in cooling tower performance caused by the filler fouling. It will lay a theoretical foundation for accurately calculating the performance coefficient of filler. And it is helpful to solving the problem of no the ripe empirical formula of filler performance with fouling for engineering applications.

Introduction

Cooling tower is the final equipment of low-temperature heat releasing in turbine cold junction system, within the cooling tower, the filler zone is an important zone. The temperature drop in the filler zone usually occupies about 60-70% of the total drop. So the performance of the filler zone directly affects the temperature of the outlet water. Among the many affecting factors, such as filling method, filling height, filling depth ect, the cleanliness of the filler should not be underestimated. The dirt is inevitably flocked in gap of the filling during the operating time of cooling tower. Once the filling of the cooling tower is not clean, the heat and mass transfer performance of the filling would change.

Currently, the empirical formula of heat and mass transfer coefficients given by the references are for the clean filler layer to make analysis of thermal and resistance performance. However the empirical formula with fouling has not been reported. This is mainly because the complex shapes of the filling which is more complex with fouling. But, just as previously described, the accumulation of dirt is bound to happen. It is imperative to study how fouling affects the filler's heat and mass transfer performance. Because of the limitations of the experimental conditions, it is quite difficult to get the heat and mass transfer performance from the experiments. So, one simplified approach was tried to get the heat and mass transfer performance of the filler layer with fouling in this paper. The work would be help for researching the performance changing of the cooling tower.

Heat and mass transfer model of flat plate filler

The flat plate model. There are several types of filling for cooling tower: drip, film and bit thin film.[1] Usually the film filling could provide more contact surface between water and air. It is widly used because of its high cooling efficiency. Fig1 is the schematic diagram of the film filling commonly used in engineering. According to the different surface shape, the film filling is divided into several cases. There are composite wave, S wave, sine wave, two-way wave and so on. In order to analyze heat and mass transfer mechanism of the film filler, the model B, C in Fig.1 can be simplified as the model of A, namely the flat plate model.

Although the fouling on the flat plate filler layer would change the mass and heat transfer coefficient, the filler layer with fouling still can be considered to be flat plate if the fouling is simplified to distribute on the plate evenly. The only change is that the spacing between the flat plate becomes smaller.

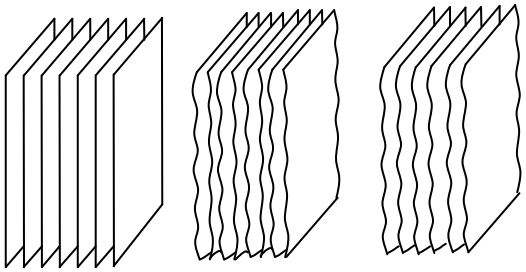

Fig.1 Schematic diagram of film filling

Heat transfer model of steam-water in the flat plate. Compared to the width and the height of the plate, the filler layer spacing is much smaller. The spacing could be usually neglected. And the change scope of the air velocity and temperature in filling zone is also small. In addition, the wind velocity of the filler and the water spray strength can be controlled in a certain range. Taking these factors, we can assume the following: firstly, the air flow is two-dimensional; secondly, the shear carrying when air sweeps over the water film can be ignored. According to physical conservation conditions,the heat transfer process of filler layer can be represented by those differential equations:

1) The mass conservation equation

$$\nabla \cdot (\rho \vec{v}) = 0 \tag{1}$$

In the formula: $\vec{v}$ is the air velocity vector; ρ is the air density, kg/m^3.

2) The momentum equation

$$\nabla \cdot (\rho \vec{v}\vec{v}) = -\nabla p + \mu \nabla \cdot \left(\nabla \cdot \vec{v} - \frac{2}{3} \nabla \cdot \vec{v} I \right) + \rho \vec{g} + S_F \tag{2}$$

In the formula: p is the air partial pressure; μ is the laminar and turbulent viscosity coefficient, kg/(m·s); I is unit tensor $\vec{g}$ is the gravity acceleration vector; $\vec{S}_F$ is the force between air and cooling water film.

3) The energy conservation equation

$$\nabla \cdot \left(\rho \vec{v} \int_{t_{ref}}^{t} c_a dt \right) = \nabla \cdot \left[\lambda \nabla t - \sum_j h_j J_j \right] + S_e \tag{3}$$

In the formula: t_{ref} is the reference temperature of enthalpy calculation, 0℃; h_i is the corresponding enthalpy of component i, J/(kg·K) , the formula is $h_i = \int_{t_{ref}}^{t} c_a dt$; λ is the thermal conductivity coefficient, W/(m·K); $\sum_j h_j J_j$ is sensible enthalpy transfer caused by component diffusion; S_e is the energy source term, W.

4) The component conservation equation

$$\nabla \cdot (\rho \vec{v} Y_V) = \nabla \cdot [\rho D_c \nabla Y_V] + S_m \tag{4}$$

D_c is the diffusion coefficient of water vapor in humid air , m^2/s; S_m is the source term, namely the cooling water evaporation quantity of per unit volume and per unit time, kg/(m^3·s).

Mass transfer model of steam-water in the flat plate. The heat transfer process is always accompanied with mass transfer in the filling layer. Water film mass transfer process of flat plate can be drawing as Fig.2 [2]. In the picture, the shadow part is flat; and the curve represents the water-air interface namely the falling surface of water film. b is the imaginary plane, infinitely closed to the actual interface. In order to simplify the calculation, when all components are water the water component is assumed to be 1. Generally, the mass percentage of water vapor in the air is usually quite small, and in this case the highest value is on the b plane. Although the temperature is high to 50 ℃ and the total pressure is 1atm, the corresponding value of the water mass percentage is only 0.077. The driving potential of vapor leaving the water-air interface is the difference of the water vapor mass percentage. Since the water vapor mass percentage of surface b and the infinity

are both small, the difference is much smaller than which between water film and b(approximately 1). So the diffusion of water vapor mainly occurs on the imaginary plane b.

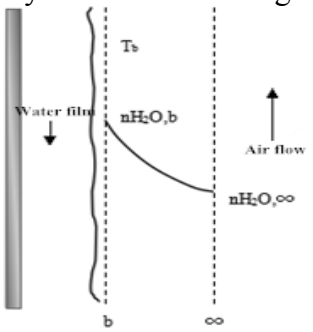

Fig.2 Schematic diagram of falling water film evaporation in air

Because the heat and mass transfer diffusion have same form in physics laws, there is a close analogy relationship between them.Based on the heat transfer diffusion model,the mass transfer diffusion could be dealt with using the analogy method. In order to make the analogy coefficient be more consistent with the model of mass transfer, the water film is idealized as follows:

1) The property of water film is constant and the surface is adiabatic.
2) The flow rate reduction caused by water evaporation is ignored；
3) The thickness of water film is uniform, no fluctuation；
4) There is no sliding on the surface;
5) The velocity of flow in water film is uniform;
6) There is no temperature gradient on the water film cross-section；
7) The thermal conduction through the flow direction is neglected；

With these assumptions, the differential equations and the boundary conditions of the mass transfer boundary layer is completely similar to the heat transfer boundary layer. So the mass transfer can be analyzed using the mathematical model of heat transfer.

Calculation of relevant parameters in the filler layer. As we all know, the flow, and the heat transfer and the mass transfer in the filling layer are associated with many parameters. Through the above analysis, these parameters (i.e. the average drag coefficient, heat transfer number Nu, mass transfer number Sh) can be calculated referencing the knowledge of flow between the two plates[3]. When the cooling tower runs, the wind speed is generally 1~3m/s. And the gap of the filler is usually between 20~30mm. Under the above conditions, the corresponding Re is greater than the critical value of laminar flow(2300). Therefore the air flow in the filler is turbulent. Calculating formulas of the related parameters are as follows：

1) The average drag coefficient

$$C_{fm}=\frac{\frac{1}{l}\int_0^l \tau_w dx}{\frac{1}{2}\rho u_\infty^2}=0.0792\ \mathrm{Re}^{-\frac{1}{4}} \qquad (10^4<\mathrm{Re}<1.2\times10^5) \tag{5}$$

In the formula: l is the plate length, m； μ_∞ is the mainstream velocity of the air , kg/(m^2·s).

2) Heat transfer number Nu

$$Nu_m=\frac{\alpha_m l}{\lambda}=0.023\ \mathrm{Re}^{\frac{4}{5}}\ \mathrm{Pr}^{\frac{2}{5}} \qquad (10^4<\mathrm{Re}<1.2\times10^5) \tag{6}$$

In the formula: α_m is the convective heat transfer coefficient of plate, W/(m^2·K)； λ is thermal conductivity of wet air molecules, W/(m·K).

3) Mass transfer number Sh

$$Sh_m=\frac{\beta_m l}{\rho D_c}=0.023\ \mathrm{Re}^{\frac{4}{5}}\ Sc^{\frac{4}{5}} \qquad (10^4<\mathrm{Re}<1.2\times10^5) \tag{7}$$

In the formula: β_m is the convective mass transfer coefficient of flat plate, kg/(m^2·s)； D_c is the water vapor diffusion coefficient, kg/m^2.

4) The volumetric mass transfer coefficient

$$\beta_{xv} = 1439(g/1000)^{0.54}(q/1000)^{0.47} \tag{8}$$

In the formula: g is mass air flow, t/(m^2·h)； q is water-spraying density, t/(m^2·h)；

5) Resistance characteristics of the filler:

$$\Delta p = \gamma_a A v^M \tag{9}$$

In the formula: ΔP is filler resistance, N/m； γ_a is air bulk density, N/m^3； v is the airflow velocity through filler, m/s；

$$A = -9.2354\times10^{-4}q^2 + 4.3290\times10^{-2}q + 0.760 \tag{10}$$

$$M = 2.1783\times10^{-4}q^2 - 9.3581\times10^{-3}q + 1.982 \tag{11}$$

The fouling growth model of filler layer.

Steam-water heat and mass transfer model of flat plate given in the last section is suitable for completely clean filler layer. Once the filler layer is fouled, the heat and mass transfer performance is affected. Since the fouling is accumulated gradually, different degree of fouling has different influences on the filler layer. Therefore, the calculation of mass and heat transfer performance of the filler layer with fouling must be matched with the growth model.

Fouling of cooling tower filler is divided into two parts. One part is the external material deposition. The other part is microbial growth (biofouling) on the surface of filler which occurs mainly in the plastic thin wall surface when water flows through. With the passage of time, the dirt accumulates and results in the decreases of filler layer spacing gradually. This will affect the water cooling, ultimately result in declining efficiency of cooling tower.

The increases of dirt thickness lead to the increases of the filling weight. Generally speaking, the dirt changes with time can be divided into linear, exponential, drop rate and asymptotic growth model. Because of different filling ways, the changes are not the same. In this paper, the asymptotic fouling growth model was selected.

For the asymptotic fouling model, Kern and Seaton[4] assumes that the dirt sedimentation velocity is constant, and the dirt denudation rate is proportional to the quality:

$$\frac{dm}{d\theta} = \dot{m}_d - \dot{m}_r = \dot{m}_d - bm \tag{12}$$

In the formular, b is denudation proportionality constant, 1/s. Integrating (12) :

$$m = m_f\left[1-\exp(-\theta/\theta_c)\right] \tag{13}$$

In the formula, $m_f = m_d/b$, it is the asymptotic deposition quality, kg/m^2； $\theta c=1/b$, it is time constant. It can be interpreted as the mean residence time for a component of fouling deposited on the surface. It can also be interpreted as the time required for the dirt growing to the asymptotic value by constant linear rate[5] (assuming $\dot{m}_r$ = O), as shown in fig.3.

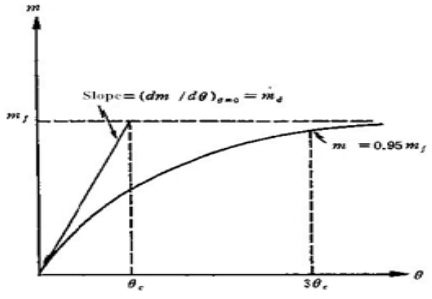

Fig.3 The meaning of θ_c

Calculation of the filling performance with fouling.

The calculation was done under the condition of taking filler (TJ-10) as an example and supposing that the dirt was evenly on the plate. According to the experimental analysis of Michel[6], dirt

growth was in accordance with the asymptotic model. The corresponding time constant is 40, and the asymptotic quality m_f is 8.5. According to the Eq.13, dirt quality can be calculated under different time. Conversely, since the uniform fouling on the flat surface leads the decreases of the spacing between the flats, the diaphragm spacing can reflect the fouling thickness. This can be used to calculate the dirt quality and the required time. Because of the complex components, the density is difficult to be determined. Therefore, in this paper, the selected dirt was simple dirt (calcium, magnesium carbonate). The density is 2.6×10^3 kg/m^3. The distance change reflects the growth of fouling, then the performance changes of the filler was analyzed.

Table 1. Filler fouling calculation data

Distance b/m	Equivalent diameter d/m	the coverage rate of dirt %	time/days	Re	C_{fm}	Nu_m	Sh_m	ΔP/Pa	ΔP reducti-on/%	β_{xv} /kg·m^{-3}·s^{-1}	B_{xv} reducti-on/%

0.024	0.048	20	99.87	9869.663	—	—	—	—	—	—	—

The filling width and filling height are both supposed to be 1m, and film distance is 30mm. Because the wind speed in filling is 3m/s, so the corresponding Re>10^4. The water spraying density is 15m^3/(m^2·h), and the air density is 1.22kg/m. The viscous coefficient is 1.78×10^{-5}kg/ (m·s), and water vapor diffusion coefficient Dc is 2.2×10^{-5}m^2/s. According to the Eq.8~9, volumetric mass transfer coefficient β_{XV} was 0.039kg/(m^3·s), and ΔP was 114.844Pa. According to Eq.5~11, relevant data could be calculated as shown in table 1.

The changes of ΔP and β_{XV} in table 1 was plotted in Fig.4. It was clear to see: with the fouling increasing, the filler layer's resistance was increased, and the volumetric mass transfer coefficient was decreased , and the heat and mass transfer performance was reduced. The trend of dirt analysis on the simplified flat plate was consistent with the experiment result. This proved the correctness of the simplified analysis and laid a theoretical foundation to accurately calculate the performance coefficient of filling dirt.

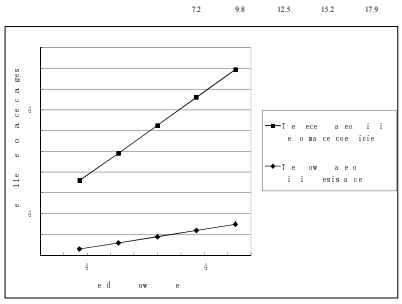

Fig.4 The relationship between filler performance and dirt growth

Conclusions

In this paper, firstly complex film filler was simplified to flat plate model, then the heat and mass transfer model of plat plate was discussed. Secondly, the asymptotic fouling growth model was explained in brief and this model was used to calculate the filling performance under different fouling. At last, compared with the experimental results, it proved that this model could simply forecast the filler performance changes due to fouling growth in cooling tower.

Keywords: Paralleled Battery Pack, Expansion Mode, Remaining Useful Life, Genetic Algorithm.

Abstract. Remaining useful life (RUL) is of great importance to energy supply systems, such as battery pack. In this paper, an optimization model of RUL for the paralleled battery pack on expansion mode is proposed based on the basic concept of RUL and the capacity fading model. genetic algorithm (GA) is adopted to solve the problem. Case study shows that the battery pack's RUL can be extended by using the optimization model and GA.

Introduction

The capacity of each battery cell is relatively small due to the restrictions on manufacture and security, resulting in a big gap between cell and load, which is usually eliminated by constructing battery pack in the connection of series and parallel. If the last step is the parallel connection, the pack could be looked as paralleled battery pack, and each paralleled circuitry could be regard as a module. The Paralleled battery pack has many advantages, e.g., the system capacity could be expanded easily by paralleling a new module.

The life of paralleled battery pack is expressed by RUL regularity, which has been researched by a group of scholars with several papers published: in order to estimate the power battery's RUL, an electrochemical impedance spectra (EIS) method for calendar ageing quantification of batteries is presented in [1], with the effects of State of Charge (SOC) and temperature (T) taken into account; the commonly used RUL prediction methods are reviewed in [2]; and reference [3] compares various RUL prediction algorithms, etc.

All the works mentioned above have made some significant progress on RUL prediction and estimation; however the optimization of RUL is ignored. In order to fulfill the optimization, a great deal of meaningful thoughts have been put forward: reference [4] improves the utilization rate and RUL of battery by using micro-controller which is driven by detected battery operation data to perform equilibrium; the life of battery pack is extended in [5] with the help of good battery operation management; the battery equalization management is discussed in detail in [6], etc. Generally, the consistency control and balance management mainly concentrate on the self-adjustment of circuit, for example using resistance to share current in order to protect the weak battery, lacking some quantitative description.

The objective of this work is to enhance the quantitative analysis in RUL extending for paralleled battery pack by the refined discharge current control of each module, which is performed with the help of the newly designed RUL optimization model and GA.

Case study shows that the battery pack's RUL could be extended by using the optimization model and GA, and some conclusions on the efficiency of optimization is given as well.

RUL and Expansion Mode

Remaining Useful Life. The service life of battery is usually expressed by the State of Health (SOH), which is defined as the ratio between current capacity detected by instrument and original capacity given by the manufacture company [7].

The SOH value of brand new battery usually equals 100%, and will decline as the cycles increase. When the SOH value is reduced to 80%, the IEEE standard 1188-1996 claims that the battery should be replaced [8]. The time before the service life ending is called RUL, which can be expressed as RUL_i, where i (i =*1*~*N*) indicates the #*i* battery and N is the scale of paralleled battery pack.

The paralleled battery pack can be regard as series system from the view point of reliability, because the pack acts as an independent power supply system. Thus the RUL of paralleled battery pack denoted as RUL_P can be achieved by Eq. 1:

$$RUL_P = \min_{i=1\sim N}\{RUL_i\}. \tag{1}$$

Expansion Mode. Due to less estimation of load demand growth rate, power supply system may need to enlarge its capacity during operation, which is called expansion mode. At the expansion point, the group of N used units which is expressed as B_N, and the another group of M fresh units is expressed as B_M.

As B_N has been used before expansion, so its RUL value is smaller than that of B_M, but the pack's RUL is limited to the minimum module according to Eq. 1, thus the expansion does nothing positive to the pack's RUL. Besides, when B_N meets its end point of life, there may be some utilizable cycles on B_M. In order to improve the pack's RUL as well as reduce the cycle waste of B_M, effective strategy should be proposed.

RUL optimization model

The RUL model of single cells. The calculation of RUL for cell i (RUL_i) is needed when optimizing the pack's RUL, which relays largely on an accurate SOH degradation model. The SOH degradation model can be transferred from capacity fading model to some extent, which has been proposed by previous research [9-11].

The literature [11] establishes an empirical model which could be used to evaluate the cycle life of battery by means of data fitting and regression based on the test data:

$$\begin{aligned} &C_r(T,I,n_c) = A(T,I)\times n_c^{B(T,I)} \\ &A(T,I) = 2674.698e^{0.734/T} - 0.155/I - 2679.913 \\ &B(T,I) = 785.460e^{-0.844/T} + 0.122I - 782.972 \end{aligned} \tag{2}$$

Eq. 2 describes the capacity fading model, where T is the environmental temperature (the absolute temperature *K*); I is the discharge current (the current rate *C*); n_c is cycled times; $C_r(T,I,n_c)$ is the capacity when the battery has been cycled n_c times with the discharge current I in the ambient temperature T.

According to the definition of SOH, the SOH degradation model can be derived from Eq. 2:

$$S(T,I,n_c) = 1 - \frac{C_r(T,I,n_c)}{100} = 1 - 0.01A(T,I)\times n_c^{B(T,I)}. \tag{3}$$

Eq. 3 describes the SOH degradation model, where $S(T,I,n_c)$ is the SOH when the battery has been cycled n_c times with the discharge current I in the ambient temperature T. Then the inverse function of n_c for Eq. 3 is available:

$$n_c(T,I,S) = \left(100(1-S)/A(T,I)\right)^{1/B(T,I)}. \tag{4}$$

Where $n_c(T,I,S)$ is the cycled times when the battery has been cycled until the SOH decreased to S with the discharge current I in the ambient temperature T, that is, the battery's "age". Therefore, $n_c(T,I,0.8)$ is the total life of the battery, so the battery's RUL can be expressed as:

$$RUL(T,I,S) = n_c(T,I,0.8) - n_c(T,I,S) \quad (5)$$

Where $RUL(T,I,S)$ is the RUL of battery with its SOH value equals S if discharging with the current of I at ambient temperature T.

The optimization model of paralleled battery pack's RUL. The RUL of paralleled battery pack (shown as Eq. 6) could be generated by the Eq. 5 and Eq. 2:

$$RUL_P(\vec{T},\vec{I},\vec{S}) = \min_{i=1\sim M+N}\{RUL(T_i,I_i,S_i)\} \quad \vec{T}=[T_1,T_2,\cdots,T_{M+N}] \quad \vec{I}=[I_1,I_2,\cdots,I_{M+N}] \quad \vec{S}=[S_1,S_2,\cdots,S_{M+N}]. \quad (6)$$

Therefore, the optimization model of paralleled battery pack's RUL can be expressed as:

$$\begin{aligned} &Object: \ max\{RUL_P(\vec{T},\vec{I},\vec{S})\} \\ &S.\ t. \ I_1+I_2+\cdots+I_{M+N}=I_{load} \\ &\quad 0\le I_i\le I_{max}, i=1\sim M+N \end{aligned} \quad (7)$$

Where $\vec{I}$ is decision variable, $\vec{T},\vec{S},I_{load},I_{max}$ are state and constraints parameters, the first constraint indicates that the output current of paralleled battery pack should meet the load current demand, the second constraint represents the limited discharge current zone of each module.

Genetic Algorithm

GA is a heuristic algorithm first proposed by John Holland in 1960s, describing a solution as an individual consisted of a string of code. In this paper, the classical genetic algorithm is adopted to solve the optimization model (Eq. 7) with several key steps newly designed.

Encoding. There are several encoding modes: binary encoding, real encoding, orderly string encoding and structured encoding, which make big difference in the performance and population diversity of genetic algorithm. In this paper, the real coding is adopted as follows:

Set the population of generation t $(t=0,1,2,\cdots)$ as $X_t=\left(x_t^1\ x_t^2\ \ldots\ x_t^n\right)^T$, where n is the number of individuals in a population; x_t^i $(i=1,2,\cdots,n)$ is the individual i, made up of m ($m=M+N$) real numbers, which can be expressed as a $1\times m$ vector $x_t^i=\left(x_t^{i(1)}\ x_t^{i(2)}\ \ldots\ x_t^{i(m)}\right)$. So the population can be expressed as a matrix:

$$X_t=\begin{bmatrix} x_t^{1(1)} & x_t^{1(2)} & \cdots & x_t^{1(m)} \\ x_t^{2(1)} & x_t^{2(2)} & \cdots & x_t^{2(m)} \\ \vdots & \vdots & \ddots & \vdots \\ x_t^{n(1)} & x_t^{n(2)} & \cdots & x_t^{n(m)} \end{bmatrix}. \quad (8)$$

Initialization. The initialization is that generating a series of random feasible solution satisfied the constraints. The following steps are implemented in this paper:

① Generate m random numbers $r_i(1\le i\le m)$, and normalize these numbers into m new numbers;

$$R_i=r_i/\sum_{j=1}^m r_j \quad (1\le i\le m). \quad (9)$$

② Get each current value $I_i(1\le i\le m)$ according to Eq. 10;

$$I_i=R_i\times I_{load} \quad (1\le i\le m) \quad (10)$$

③ Check out whether each current value $I_i(1\le i\le m)$ meets the constraints $0\le I_i\le I_{max}$ or not. If satisfied, then go to step ⑤, otherwise, go to step ④;

④ Distribute the exceeded part $I_{max}-I_i$ into $\lfloor n/2\rfloor$ batteries with smaller discharge current on average, then go to step ⑤;

⑤ Repeat the above steps n times, constituting a $n\times m$ matrix.

Selection. The purpose of selection is reserving outstanding individuals with larger fitness value to the next generation and eliminating some bad ones. This paper adopts "roulette gambling + β% elitist reserving" strategy, where β is a parameter values $[0 \sim 50]$, which is carried out as follows:

① Get the fitness value $F_i (i = 1,2,\cdots,n)$ of each individual in population X_t according to fitness function;

② Get the probability that individual i is selected according to Eq. 11;

$$P_i = F_i \Big/ \sum_{i=1}^{n} F_i \quad (i = 1,2,\cdots,n) \tag{11}$$

③ Generate the roulette wheel. Get the cumulative probability of individual i according to Eq. 12, and additionally set $CP_0 = 0$;

$$CP_i = \sum_{j=1}^{i} P_j \quad (i = 1,2,\cdots,n) \tag{12}$$

④ Roulette wheel selection. Generate a random number $r \in (0,1]$, if r locates in the interval $(CP_{i-1}, CP_i]$ $(i = 1,2,\cdots,n)$, and then select the individual i to reserve to the next generation. Repeat the roulette wheel selection n times, select n individuals to constitute population X_{t+1}.

⑤ Elitist reserving. Sort the individuals of population X_t according to the fitness value decrease, then use the β% individuals to replace the other β% individuals which were random selected from population X_{t+1}, the result is population X_{t+1}.

Crossover. Crossover refers to swapping genes of two individuals, thereby generating two new individual, which is performed in three steps:

① Choose the individual and make pairs. The probability for each individual being selected is p_c. The selected M individuals were paired in a random way, if M is odd, then an individual would be deleted or added.

② Perform crossover operation on paired individuals. There are two kinds of crossovers: discrete crossover and arithmetic crossover, this paper uses the latter one, which was described below:

x_t^i and x_t^j $(i, j = 1,2,\cdots,n)$ are two individuals in population t, the new individuals would be generated according to the crossover operation shown by Eq. 13:

$$x_{t+1}^i = \alpha x_t^j + (1-\alpha) x_t^j \qquad x_{t+1}^j = \alpha x_t^j + (1-\alpha) x_t^i \tag{13}$$

Where α is the parameter for the crossover operation valued in the interval $[0,1]$.

③ Check the new individuals whether meet the constraints or not. Firstly, if $\sum_{k=1}^{m} x_{t+1}^{i(k)} > I_{load}$ or $\sum_{k=1}^{m} x_{t+1}^{i(k)} < I_{load}$, then distribute the margin $\sum_{k=1}^{m} x_{t+1}^{i(k)} - I_{load}$ or $\sum_{k=1}^{m} x_{t+1}^{i(k)} < I_{load}$ to m modules averagely. Secondly, check the individuals again with the step ③ described in chapter 3.2.

Mutation. Mutation refers to randomly change the value of certain genes of individual by a relatively small probability p_m, with the purpose of improving the local search ability of genetic algorithm.

The mutation operation is divided into two steps, firstly individual was selected at the probability of p_m. Then the selected individuals are put into the process of mutation. There are several mutations, including uniform mutation, non-uniform mutation, normal mutation and adaptive mutation, etc. The normal mutation is adopt by this paper and described below:

If $x_t^i = (x_t^{i(1)}\ x_t^{i(2)} \ldots x_t^{i(k)} \ldots x_t^{i(m)})$ is the selected individual in population X_t, and the gene k is the mutation point, then the newly individual after mutation is $\widehat{x_t^i} = (x_t^{i(1)}\ x_t^{i(2)} \ldots \widehat{x_t^{i(k)}} \ldots x_t^{i(m)})$, where $\widehat{x_t^{i(k)}}$ is determined by Eq. 14:

$$\widehat{x_t^{i(k)}} = Normal(x_t^{i(k)}, \sigma^2) \tag{14}$$

Where $Normal(x_t^{i(k)},\sigma^2)$ is a normal distribution random number generator with the mean of $x_t^{i(k)}$ and the standard deviation of σ.

In addition, the new individual $\hat{x}_t^i$ is also need to do constraints check as step ③ shown in chapter 3.4.

The values of mutation operator p_m cannot be too large, if $p_m > 0.5$, then the genetic algorithm will degenerate into a random search.

Termination condition. The termination condition of the algorithm proposed by this paper is that the global optimal solution kept the same for N_{sd} continuously evolutionary generations.

Case study and discussion

In order to verify the validity of RUL optimization model and the effectiveness of genetic algorithm, the following case was presented and discussed.

The paralleled Li-ion battery pack's initial parallel scale is $N=7$, expansion scale is $M=3$, the SOH of pack at the expansion point is $S_P=0.88$, and all the batteries' capacity fading follows the law described by Eq. 2.

The load current requirement is 8.0 C, the maximum discharge rate is 2.0 C, the SOH value of fresh battery is 100%, the ambient temperature is room temperature and keeps constant, and the difference between each model's SOH can be ignored. To sum up, the parameter value of optimization model (Eq. 7) as shown in Table 1.

TABLE 1. THE VALUE OF OPTIMIZATION MODEL PARAMETER

Parameter	t_0	S_P	N	M	I_{load}	I_{max}
Value	318 [K]	0.88	7	3	8.00 [C]	2.00 [C]

TABLE 2. THE VALUE OF GENETIC ALGORITHM PARAMETER

Parameter	n	m	β	p_c	α	p_m	σ	N_{sd}
Value	200	10	10	0.95	0.8	0.10	0.02	400

According to Table 1, both $\vec{T}$ and $\vec{S}$ are 1×10 vectors, equal $[t_0\ t_0\ t_0\ t_0\ t_0\ t_0\ t_0\ t_0\ t_0\ t_0]$ and $[S_P\ S_P\ S_P\ S_P\ S_P\ S_P\ S_P\ 1.00\ 1.00\ 1.00]$ respectively.

For the given optimization model, the parameter of newly designed genetic algorithm is shown in Table 2.

The result of optimization model solved by GA defined in Table 2 is showed in Fig 1.

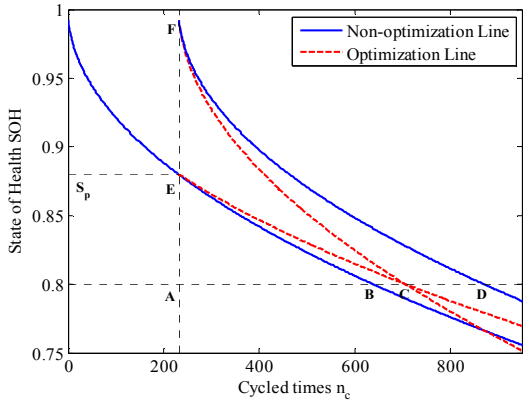

Fig. 1. The optimization Result ($S_P=0.88$)

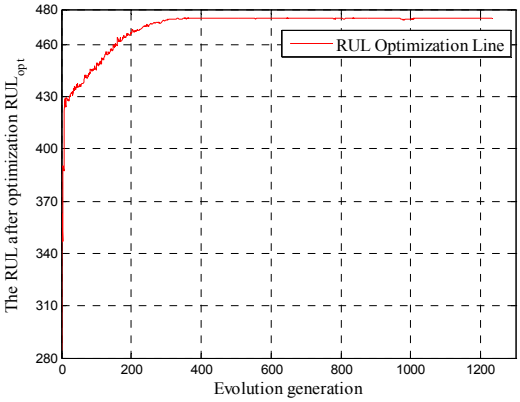

Fig. 2 The process of optimization for GA

As Fig. 1 shows, the load current is 5.6 C with each module shared 0.8 C at the beginning, and this value keeps constant before it increases to 8.0 C when the pack's SOH decreases to $S_P=0.88$ (point A). Faced with large load demand, the expansion decision is made, and the expansion scale is 3. The real line starts from point E and point F is the SOH fading line if the pack discharges in non-optimization mode, point B and point D represents the end of life point for the expanded and initial battery respectively; the dotted line starts from point E and point F is the SOH fading line if the pack discharges in optimization mode, point C indicates the end of life point for both expanded and initial battery. The discharge plan for every module in non-optimization mode is $[800\ 800\ 800\ 800\ 800\ 800\ 800\ 800\ 800\ 800]\times 10^{-3}$ C, the pack's RUL is the length of line AB, that is $RUL_{ini}=408$;

the discharge plan for every module in optimization mode is $[737\ 737\ 737\ 737\ 737\ 737\ 737\ 948\ 948\ 948]\times10^{-3}$ C, and the pack's RUL is the length of line AC, which is $RUL_{opt}=475$ (the process of optimization for GA is shown in Fig. 2); thus the increasing rate of RUL is $\Delta RUL=(475-408)/408\times100\%=16.67\%$.

In order to further discuss the optimization model, three main parameters in Table 1 S_P, M and I_{load} are adjusted, and the results are as follows:

① Set S_P vary at the step of 0.01 in $(1\ \ 0.8)$ with the others in Table 1 kept as constant, and each kind of circumstance is solved by GA with the result showed in Table 3. As Table 3 shows, the lower S_P, the higher ΔRUL, which indicates that the optimization is easily achieved for the pack with poor performance, and the main reason is that the poor pack's initial RUL is relatively small, so the growth could impact ΔRUL easily.

② Set M vary at the step of 1 in $[1\ \ 5]$ with the others in I kept as constant, the results is shown in Fig. 3. As Fig. 3 shows, the growth amount increases as M increases, indicating that increasing the expansion scale has a promoting effect on extending RUL.

③ Set I_{load} vary at the step of 1 in $[6\ \ 10]$ with the others in table I kept constant, the results is shown in Fig. 4. As Fig. 4 shows, the growth rate ΔRUL kept almost the same as I_{load} increases, indicating that ΔRUL has little relation on I_{load}.

TABLE 3. THE EFFECT OF S_P ON THE OPTIMIZATION RESULTS

S_P	RUL_{ini}	RUL_{opt}	ΔRUL	I_{low} / C	I_{high} / C
0.99	638	639	0.16%	0.800	0.801

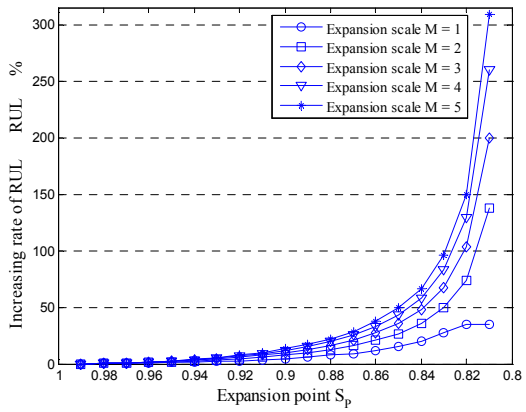

Fig. 3 The effect of expansion scale M on the optimization results

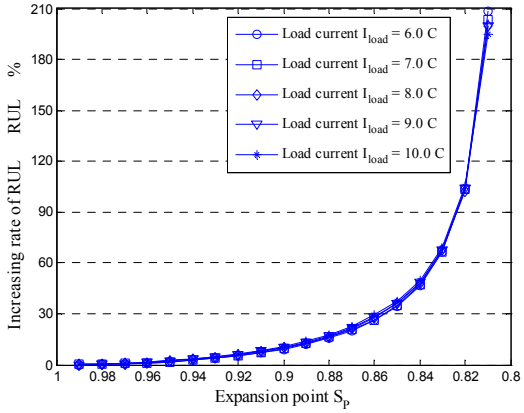

Fig. 4 The effect of load current on the optimization results

④ Parameter t_0 determines the degradation trend of SOH in Eq. 3, leaving some impact on the sensitivity of model, as literature [11] has analyzed the characteristic of parameter T in Eq. 2, this paper leaves this part out. Parameter N and I_{max} have similar effect on optimization results with parameter M and I_{load}, so this part is also omitted.

Conclusion

This paper analyzes the paralleled Li-ion battery pack's RUL under the conditions of expansion, the pack's RUL optimization model has been established based on the capacity fading model proposed in literature [11], for solving the model, the traditional genetic algorithm is improved by some special design, and finally the RUL optimization model and algorithm are analyzed and discussed in a case.

The case study proved that the pack's RUL can be extended and optimized by current distribution, and three rules are gained:

① The RUL growth amount and rate is larger if the expansion time is later (the pack's SOH value is low at the expansion point);

② The larger expansion of scale is, the higher RUL growth amount and rate are;

③ The load current is smaller, the RUL growth amount is larger, but the growth rate of RUL remains constant.

Keywords: crimping, welding pipe, finite element method, deformation Characteristic

Abstract. Crimping is widely used in production of large diameter submerged-arc welding pipes. In order to improve crimping forming quality, it is necessary to analysis deformation characteristic of crimping forming process. So, crimping is analyzed using finite element method.
Taking the crimping of X80 steel Φ1219mm×22mm×12000mm welding pipe for instance, the crimping forming process is simulated by finite element (FE) code ABAQUS. In this paper, the simulation data is validated by product and a comparison showed a good agreement with product results. The stress/strain from simulation is discussed. Thus, the results of research provides a basis to improve crimping quality.

Introduction

Crimping forming technology is widely used in large-diameter straight seam submerged arc weld (LSAW) pipes. In the forming process, both edges of sheet are bended into a certain curvature by crimping die. And the edges of sheet are made close to or reach the nominal curvature of pipe. The geometry and dimensional accuracy of final products are obtained. The peach beak and the cracking in expanding are prevented effectively by the crimping.

In the present investigation, several papers have been published dealing with these parameters and their effect on crimping quality. In early stage, the research on crimping is depended on experience in production[1, 2]. Although the results are an useful to guide production，they are lack of universality and difficult to promote in further. The analytical method of analysis is based upon simplifications of process and material behavior. There are following relevant literatures on the crimping: design parameters[3], bending moment/forming force[4], springback[5] and stress/strain[6]. With the advent of computation technology, simulation of crimping can be analyzed using finite element methods. So many scholars analyzed the effect of crimping to the pipe quality using the finite element method respectively, such as PALUMBO G [6], Liu [7], HERYNK M D[8] , TONG[9], GAO, [10] and REN[11]. Finite element analysis (FEA) is an efficient tool for researching crimping forming process. But the most significant disadvantage in the design of crimping parameters are time consuming.

The aim of this paper is to provides a basis to improve crimping quality. This research is based on the forming analysis performed by the commercial FEA code ABAQUS. By using FEA, the distribution of stress/strain before and after forming are obtained.

Finite element analysis

FEA of crimping was carried out using the commercial code Abaqus/Standard. A 2D finite element model is established for the plane strain condition. In simulation, the holders are defined as analytical rigid which would not need requiring elements is divided for simple geometric shapes. The

discrete rigid body and 2.5mm R2D2 element are defined in punch and die without considering the deformation. In analysis process of forming, one of the most important factors is the calculation of springback. So, considering both efficiency and accuracy in the deformation process, the 2mm four-node plane strain reduced integration quadrilateral element CPE4R which had high efficiency and accuracy for calculating springback is set in deformable sheet. The sheet metal is defined as elastic–plastic. Also, simple limited slid master-slave contact algorithm in which the mould was master surface, the sheet was slave surface is selected, and the penalty function model of friction coefficient 0.1 is established to judge the contacting state.

A welding pipe of X80 level Φ1219mm×22 mm×12000mm was taken as research objective. The Fig. 1 show the curve of true stress and strain X80 grade pipeline steel real, including E = 245 GPa, σ s = 569.5 MPa. In Fig. 5, finite element analysis is compared with the profile of sheet in top surface after crimping measured with a portable three-coordinate measuring system. The results are demonstrated that FEA could predict accurately the crimping profile. The crimping parameters in simulation are shown in table 1.

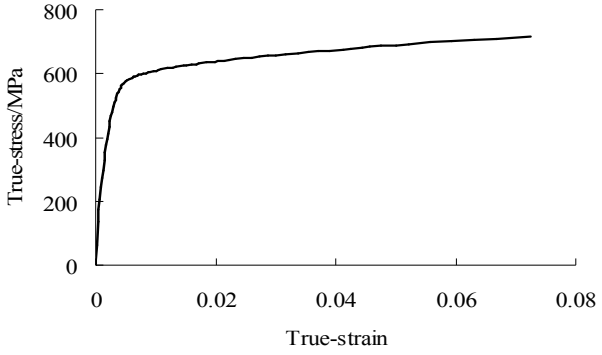

Figure 1 X80 uniaxial tension

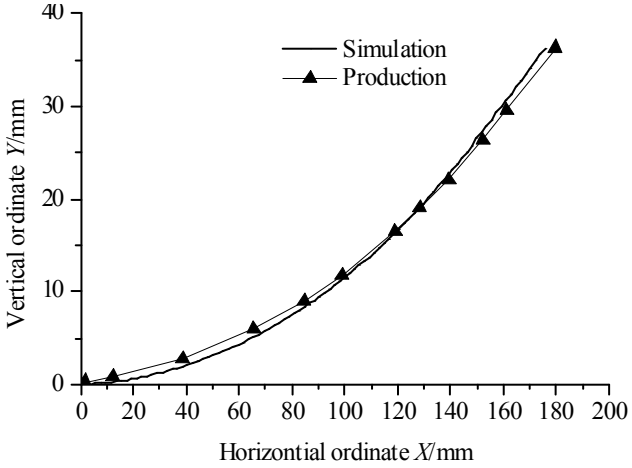

Figure 2 Comparison between simulation and production

Table 1 Parameters of the crimping simulation

Parameters	Description	Value
R_p /mm	Base radius of punch	303.20
β_p /°	Terminal angle of the punch	88
ρ_p/mm	Radius of curvature of the punch termination	465.7
R_d/mm	Base radius of die	303.20
β_d /°	Terminal angle of die	88
ρ_d/mm	Radius of curvature of the die termination	465.7
h/mm	Die displacement	42.1
B/mm	Length of crimping	190
D/mm	Horizontal distance between punch and die	80

Results and discussion

Distribution of stress Fig. 3 shows that the Mises stress is symmetrically along the sheet layer and the maximum Mises stress distributes at the top and bottom of sheet surface. The Mises stress in the tangential direction is increased with decreasing the radius of curvature gradually. Fig. 4 for geometry and residual stress distribution after unloading, from which it is known that the cloud is no stress no deformation near the edge of sheet.

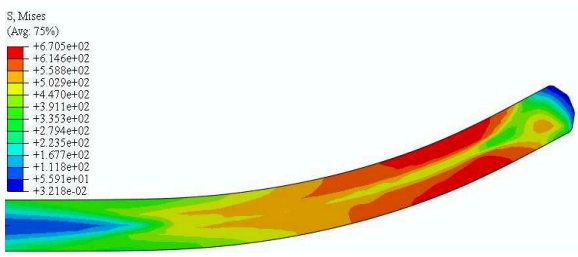

Figure 3 Mises stress of crimping in load

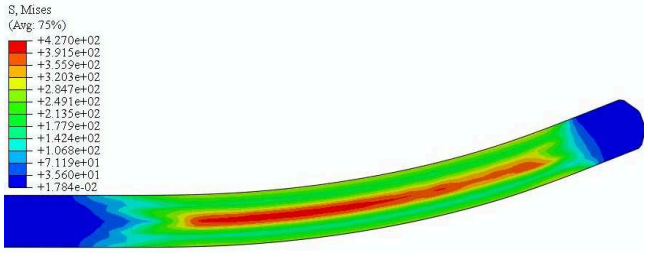

Figure 4 Mises stress of crimping after springback

Analysis of stress and strain The stress and strain value form simulation are researched in Fig. 5- Fig. 7. In Fig. 5, the Mises stress vary with horizontial ordinate which ranges from 0 mm to 190 mm. And the maximum Mises stress value $\sigma = 650MPa$ in upper surface and lower surface are at x = 130mm. From the trend of curve, it is indicated that the stress value increases with increased curvature. In Fig. 6, The curve of residual stress from surface showed that the value changes more gently and the residual stress fluctuation is less. The results indicated that after forming the stress is rearranged and the even distribution of residual stress is the main element to assure the crimping quality. In Fig. 7, The curve of plastic strain from surface can be divided into three parts: small deformation, main deformation and difficult-to-deformation. When x $45mm$, small curvature caused elastic deformation is larger than plastic deformation in small deformation part, so the plastic strain is little. When $45mm$ x $130mm$, most of the sheet material is yield and increasing of small curvature caused plastic deformation is larger than elastic deformation, so the plastic strain is maximum in main deformation part. When $x \geq 130mm$, decreases of Forming torque Increased the difficulty to occurr plastic deformation, so the plastic strain is decreases obviously.

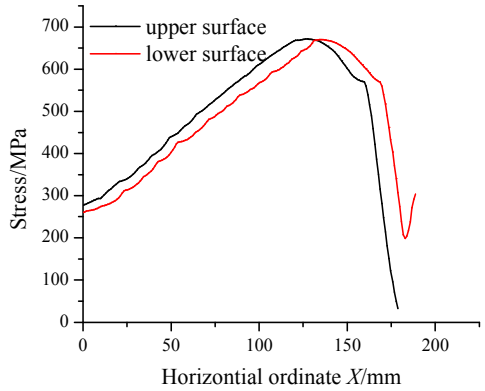

Figure 5 Curve of stress in horizontial ordinate

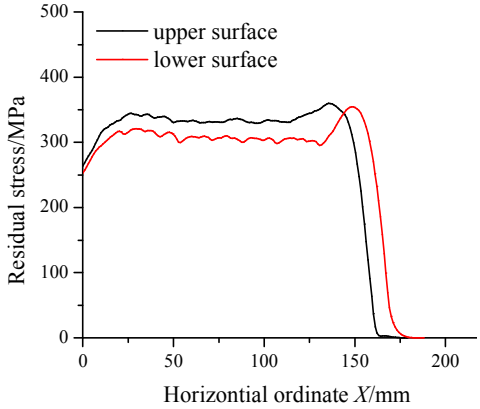

Figure 6 Curve of residual stress in horizontial ordinate

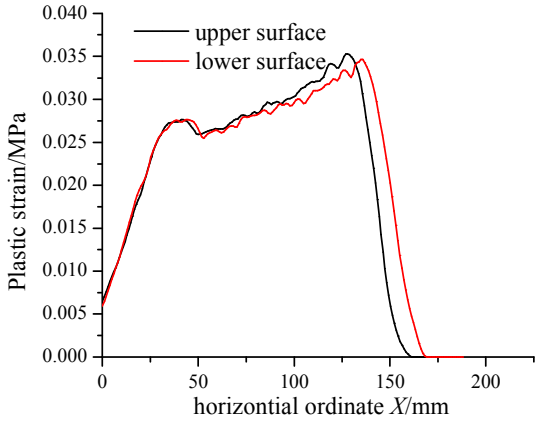

Figure 7 Curve of plastic strain in horizontial ordinate

It also can be seen that there is straight flange in the edge of sheet because of no stress and no deformation. In production, larger straight flange directly reduce the quality of welded pipe. So, it indicated that crimping forming process still needed to be improved.

Conclusion

In this paper, the following conclusions can be drawn:

(1) Crimping forming process is simulated by finite element (FE) code ABAQUS, and the simulation data is validated by product and a comparison showed a good agreement with product results.

(2) The distribution of stress and strain are investigated. Thus, the present work has been to study deformation characteristic of crimping forming for improving forming quality.

Keywords: Lithium-ion Battery Pack Thermal Characteristic, Thermo Physical Parameters, Temperature Field Simulation, Experimental Verification.

Abstract. Batteries are used the energy storage of the pure electric vehicle. When the battery pack work in the high temperature environment for a long-term, permanent damage that high temperature does to the battery cannot be restored, the battery life will be drastically reduced. When the batteries temperature reaches a relatively high value, the battery pack will caught fire. This paper firstly analyzed the characteristic of the Lithium-ion Battery by batteries experiment. On the basis of the thermal experiment ,this paper do a lot of research of the cooling method by ANSYS and verified the accuracy of the model of the thermal model.

Introduction

In recent years, because the energy crisis and environmental pollution are worsening, all countries put a lot of energy and money to accelerate the commercialization process of pure electric vehicles. As the only source of power for electric vehicle, the battery performance directly affects the use performance of electric vehicles. Because environmental temperature has a significant influence on the performance of the batteries, battery pack thermal management technology, which regards the control of the battery internal temperature range and uniformity as the goal, becomes an important research topic.

The ambient temperature is the main factor which affects the performance of lithium batteries. When the temperature is relatively high, a large current discharge causes the battery pack temperature rises too fast. Although the high temperature will cause the speed of battery pack chemical reaction become faster, but also will cause great harm to the battery pack. High temperatures cause the battery generate irreversible internal substance, which makes the battery life reduced.

Experimental study on the thermal characteristics of the battery

Noboru Sato analyzes the causes of lithium battery generating heat, summed up the heat source of lithium battery[1]. the specific heat production is calculated as shown in Formula1.

$$Q_t = Q_r + Q_p + Q_s + Q_j \tag{1}$$

Among them, Q_t is the total heat production of lithium battery, Q_r is the chemical reaction heat lithium ion and electron transfer generate in the reaction, Q_p is the heat generated from the difference between cutoff voltage and the balance voltage, which is called polarization reaction heat, Q_s is called the vice reaction heat generated by the electrolyte electrolysis in lithium battery charging and discharging process or the discharge side reaction which is called a sub-reaction, Q_j is the Joule heat generated by the internal resistance of lithium battery.

Beinad etc. see lithium battery as a uniform internal heat production[1], Base on the lithium battery internal resistance and reaction principle of entropy increase, Beinad proposed a theoretical formula to calculate the rate of heat generation of lithium battery, as specified shown in Equation2.

$$\Phi = -IT\frac{dE}{dT} + I(E-V) \tag{2}$$

$-IT\frac{dE}{dT}$ is lithium battery reversible reaction heat, I(E-V) represents the ohmic resistance or irreversible thermal reaction, I is lithium battery charge and discharge current, E is the open circuit voltage of the lithium battery, T is the inside temperature of the lithium battery, V is the voltage.

Research on the thermal Simulation of lithium batteries pack

This paper does some research on the Lithium battery temperature field by a three-dimensional thermal model. Assuming that each part of the material inside the battery properties are consistent, thermal conductivity, etc. is approximately constant in the process of charging and discharging , we can obtain lithium battery heat model[3][4]:

$$\rho C_p \frac{\partial T}{\partial t} = k_x \frac{\partial^2 T}{\partial x^2} + k_y \frac{\partial^2 T}{\partial y^2} + k_z \frac{\partial^2 T}{\partial z^2} + q \tag{3}$$

ρ represents an average density of lithium batteries ,T represents the temperature of the lithium battery, C_p is the lithium battery specific heat capacity, t represents time, respectively, K_x,K_y,K_z represents the thermal conductivity inside lithium battery.

This paper designs the battery pack cooling system, using CFD simulation software to study the effects of battery pack cooling structure on the battery pack temperature field. Firstly,this paper establish the batteries model, Natural cooling model is showed in the Fig.1.

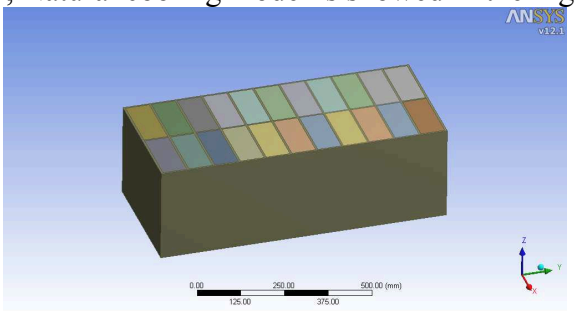

Fig.1 Natural cooling model

In the natural convection simulation , air movement of the lithium battery surface and flow field wall are selected as natural convection ,heat transfer coefficient is set as 4w/m^2.K ,air and lithium battery pack contacts are set as fluid and structure interaction. Figure2 is lithium battery use 120A discharge one hour natural cooling results. Figure3 is a lithium battery serial cooling temperature field simulation, the simulation discharge current is set as 120A, the convective heat transfer coefficient is 10w/m2.k, air is from the left into the battery pack.

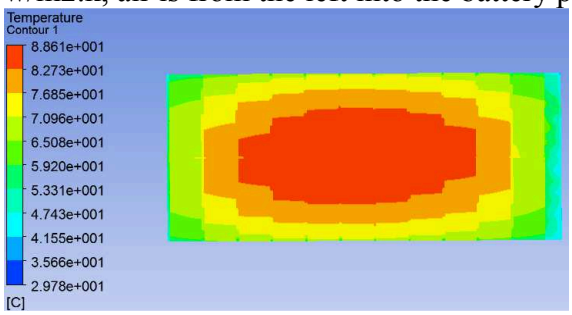

Fig.2 Natural cooling simulation result

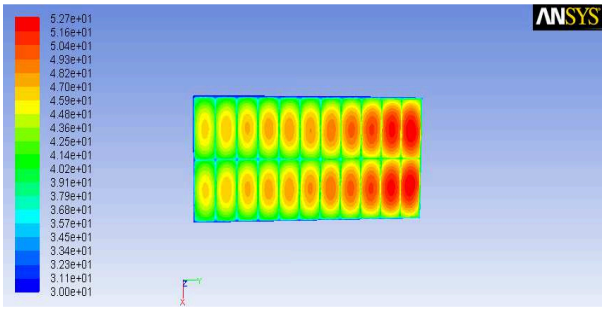

Fig.3 String-type cooling simulation result

From the results in Figure 2, when lithium battery pack use 120A discharge one hour and outside temperature is 30℃, the batteries maximum temperature reaches 88℃, which will cause serious damage to the batteries. Figure 3 is the result of battery pack serial cooling. From this result, it can be seen that the maximum temperature of the battery pack is reduced to 57℃, but the temperature uniformity of the battery pack become worse.Therefore, the battery pack must be designed thermal structure.

In order to solve the heat problem, this paper designs the following cooling structure, gray part is the battery box, blue part represents the battery pack ,the structure is shown in Fig.4.Fig.5 is Battery pack and air field simulation model.

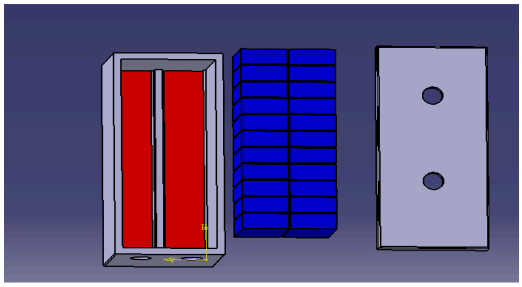

Fig.4 Arrangement relationship between batteries and battery box

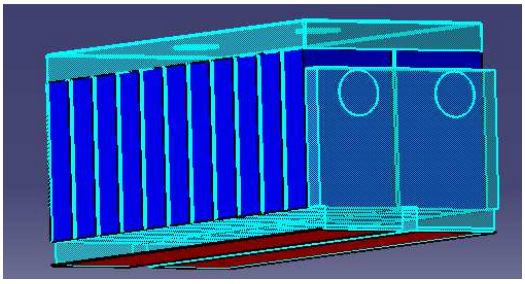

Fig.5 Battery pack and air field simulation model

This paper study temperature field of the design of the thermal structure by the CFD simulation, the simulation results show that although this structure can effectively reduce the temperature of the battery pack, but can cause the temperature dead zone of battery pack. Figure 6 is the temperature contours of the lithium battery center plane, the simulation conditions were set: time is 20min; current is 120A;the wind speed is 8m/s.

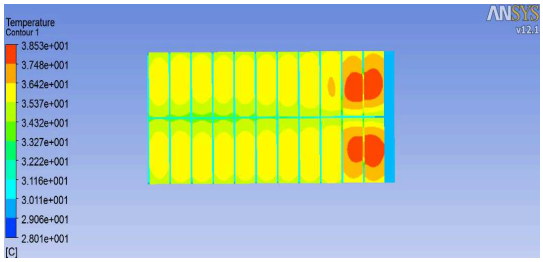

Fig.6 Battery pack and air field simulation model

In order to remove the dead zone temperature caused by heat dissipation structure, This article improves the cooling structure by installing the windshield at the bottom of battery box, Improvements are shown in the following two figure.

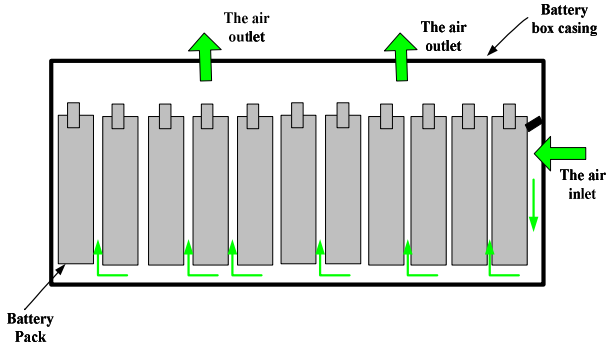

Fig.7 Air flow field before improvement

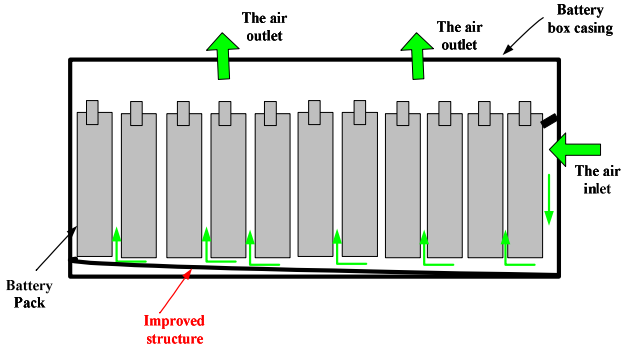

Fig.8 Air flow field after improvement

Improved structure significantly improves the battery pack cooling temperature uniformity, Fig.9 is the temperature contours of the lithium battery center plane, the simulation conditions were set: time is 20min; current is 120A;the wind speed is 8m/s.

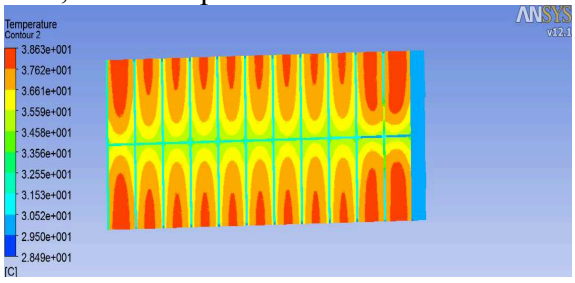

Fig.9 Battery pack and air field simulation model

Thermal model experimental verification

Figure 11 is the comparison chart of monitoring points temperature obtained by experiment and ANSYS simulation results of lithium battery pack, simulation and experiment conditions are set Consistent : discharge current is120A, time is half an hour, cooling wind speed is 5m/s. Figure 10 is the layout of the cooling test temperature sensor.

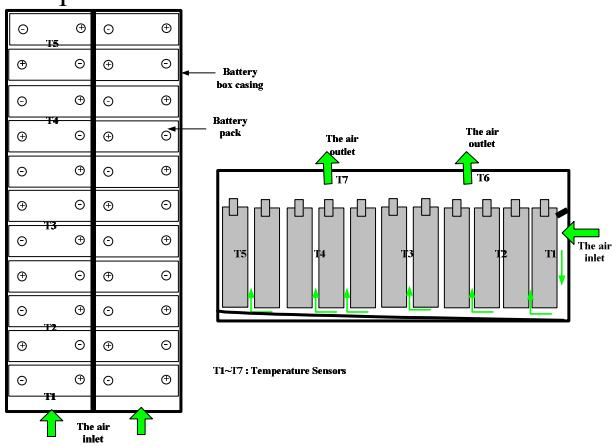

Fig.10 Cooling test temperature sensor layout

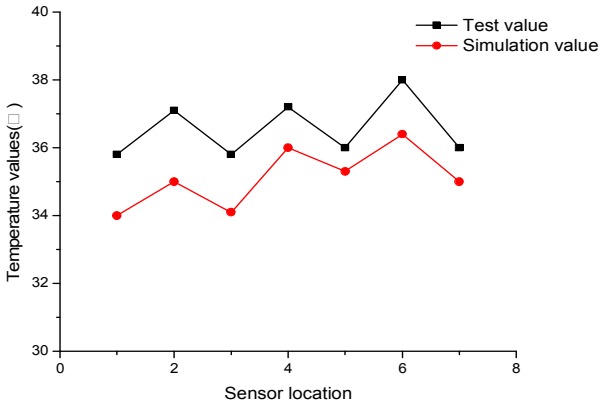

Fig.11 Cooling test temperature sensor layout

Summary

This paper do some theoretical analysis on the battery pack's internal heat production and designs a cooling structure of the battery pack, and improves and optimizes the structure, finally validates the accuracy of the cooling simulation system through experimental study.

Keywords: Nonlinear; Mechanical Analysis; Superheater; Particle swarm optimization

Abstract. In order to solve the problems of strong coupling and nonlinear parameters of superheater model, in this paper, we aimed at a 600MW subcritical drum boiler high temperature superheater as the object of study .On the basis of mechanism analysis and its dynamic characteristics I built a dynamic model of high superheater contains 9 typical working conditions .I optimized the model parameters by using field data. A continuous nonlinear model is obtained by curve fitting. The simulation results show that superheater model built by this method can better simulate the field characteristic. This model provides a reference design of automatic control system of main steam temperature .This paper aims to provide the basis for the application of advanced control algorithms in the field. Furthermore, this model can provide higher accuracy for on-site training to improve training effect.

Introduction

Summarize the existing in Superheater model as followed, Yongsheng Fan, Zhigao Xu proposed a Transfer function of the 600MW concurrent boiler to simulate the dynamic characteristics of different working conditions in 1997[1]. According to this theory provides a new idea for nonlinear models .As different working conditions of transfer function is calculated by manual work, not through the optimization parameter identification .Therefore this model may lack of precision .Pu Han in 1994 proposed an experimental method to obtain the object of Dynamic characteristics .Including the step response method with correlation analysis and identification methods [2]. Literature [3] discusses the application of genetic algorithm in thermal process identification .But did not resolve the problem of nonlinear thermal model. Literature [4] presented an automatic optimization algorithm framework parameter thermodynamic system model based on genetic algorithm and neural network .Providing a simple and practical method for the thermal power plant simulator mathematical modeling and parameter optimization .Document [5] by the research of data mining rough set reduct, using the quantum Particle swarm optimization, parametering the main steam temperature transfer function, finally get accurate results.

Superheater Mechanism Model

In order to make the model simplified making the following assumptions in this paper:

- All of the parallel tube is equivalent to a heated tube.
- The metal tube has the same temperature. Neglect the axial changes in metal temperature.
- As a medium in the pipe flow along the length direction.

These assumptions can make the model simplified maximum based on the right to reflect the main physical phenomena .The mass conservation equation (1), energy conservation equation (2), the unit length of metal heat balance equation (3) and the unit length of metal pipe medium heat equation (4) which can be used to develop the boiler.

$$\frac{\partial D}{\partial y}-(\frac{F}{v^2})(\frac{\partial v}{\partial \tau})=0 \tag{1}$$

$$Q_2=\frac{\partial(\mathrm{DH})}{\partial y}+F\frac{\partial(\rho u)}{\partial \tau} \tag{2}$$

$$Q_1-Q_2=m_j c_j\frac{\partial T_j}{\partial \tau} \tag{3}$$

$$Q_2=\alpha_2\pi d_2(T_j-T)=\alpha_2 a_2(T_j-T) \tag{4}$$

The above formula, Q_1 representative absorption of heat pipe wall; Q_2 is released to the steam heat pipe wall; a_2 is the unit length of pipe inner surface area; d_2 as the inner diameter of the pipe; T_j and T is a metal and medium temperature; α_2 is exothermic coefficient; m_j is metal mass per unit length of pipe; c_j is the metal specific heat; D is the medium flow; v as a medium specific heat capacity; F is the cross-sectional area; y as the tube length.

We can be obtained by using single phase relative variables represent the dynamic equations of heat pipe by equation (1) (2) (3) (4) linear .In order to get the expression of η enthalpy, we can use the time τ for variables on Laplasse change with the equations been linearized .Then we can get the equation (5).

$$\eta_2(s)=\frac{1}{1+T_m s}e^{-\frac{a^*}{2}\frac{shB}{B}}q_1(s)-\left\{\frac{c^*}{b^*}\left[1-e^{-\frac{a^*}{2}\left(chB+\frac{a^*}{2B}shB\right)}\right]-\frac{FP_0}{Q_0}e^{-\frac{a^*}{2}\frac{shB}{B}s}\right\}$$

$$+p(s)e^{-\frac{a^*}{2}\left(chB-\frac{a^*}{2B}shB\right)}\eta_1(s)+\frac{1+(1-n)T_m s}{1+T_m s}e^{-\frac{a^*}{2}\frac{shB}{B}}d_1(s) \tag{5}$$

Obviously equation (5) has a transcendental function in the form of the transfer function and very complex .It also needs to simplify. It can be assumed that the medium heat capacity v remain unchanged .And take an entire section of the inlet and outlet of the arithmetic mean value .So $T_a=0$ $b^*=0$ and (5) can be simplified as follows.

$$\eta_2(s)=e^{-\tau_0 s-\frac{\alpha_d T_m s}{1+T_m s}}\eta_1(s)-\frac{1+(1-n)T_m s}{T_a s(1+T_b s)}\left(1-e^{-\tau_0 s-\frac{\alpha_d T_m s}{1+T_m s}}\right)d_1(s)$$

$$+\frac{1}{T_a s(1+T_b s)}\left(1-e^{-\tau_0 s-\frac{\alpha_d T_m s}{1+T_m s}}\right)q_1(s) \tag{6}$$

By formula (6) can get the relationship between $\eta_1(s)$ and $\eta_2(s)$ for (7).

$$\frac{\eta_2(s)}{\eta_1(s)}=e^{-\tau_0 s-\frac{\alpha_d T_m s}{1+T_m s}} \tag{7}$$

From the formula can be pushed to the transfer function (8) of the superheater outlet temperature and water flow.

$$\frac{T(s)}{D_{sp}(s)}=-Ke^{-\tau_0 s-\frac{\alpha_d T_m s}{1+T_m s}} \tag{8}$$

$$K=(I_1-I_{sp})/(D\cdot C_{p2}) \tag{9}$$

The above formula, I_1 and I_{sp} as the water steam enthalpy and the enthalpy of water; C_{p2} is the link of export of specific heat at constant pressure.

Identification of Superheater Transfer Function in Different Working Points

The research object of this paper is the high temperature superheater of a 600MW subcritical boiler. Therefore we choosing 50%, 57%, 65%, 73%, 80%, 83%, 92%, 97% and 100% working condition data for research .Formula (8) can be approximated by higher-order inertia link (10).

$$G(s)=\frac{K}{(1+Ts)^n} \tag{10}$$

The transfer function of the use of particle swarm algorithm (10) identification in the MATLAB environment .We finding out the temperature transfer function of water disturbance with nine typical load point .As shown in TABLE I

TABLE I. THE DYNAMIC CHARACTERISTICS OF WATER JET DISTURBANCE IN TYPICAL WORKING CONDITION

Load	main steam flow (t/s)	Pilot area （℃/kg/s）	Inert area （℃/℃）
50%	830	$-2.2564/(1+700s)^2$	$1.1498/(1+399s)^4$
57%	961	$-1.8478/(1+626s)^2$	$1.2299/(1+368.6759s)^4$

A Nonlinear Model of Superherater

From the TABLE I we can see that the relationship between leading region gain and the main steam flow should be through 9 points. Function as shown in Figure 1 and the Function relation:

$f_1(x)=0.0662x^3-2.3442x^2+7.5809x-6.986$

Empathy can be obtained with the pilot area time constant of the main steam flow .Shown in Figure 2 and the Function relation: $f_2(x)=-162.52x^3+652.45x^2-864.62x+432.15$

Similarly we can get the relation curve of the inert region gain and the main steam flow .Shown in Figure 3 and the Function relation: $f_3(x)=-0.8296x^3+5.2721x^2-8.7861x+5.3826$

Similarly we can get the relation curve of the inert zone time constant and the main steam flow .Shown in Figure 4 and the Function: $f_4(x)=-703.1488x^3+252.93x^2-314.46x+116.91$

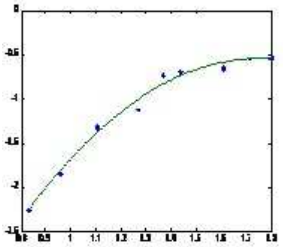

Figure 1
Pilot area gain

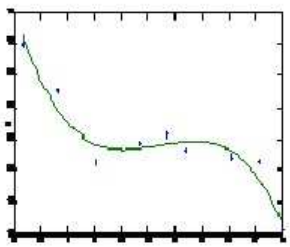

Figure 2
Pilot area time

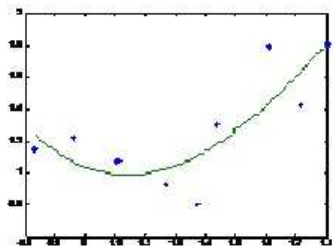

Figure 3
Inert area gain

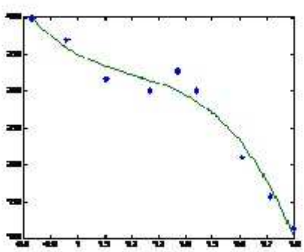

Figure 4
Inert area time

Figure 5 is a block diagram of a nonlinear model and the Fnc1 to Fnc4 corresponding $f_1(x)$ to $f_2(x)$. Getting a wider range of model because the model according to the current main steam flow to calculate the transfer function of the corresponding .The operation results in any condition of the model, as shown in Figure 6 .We can see tracking characteristic of this model is great .Because the system is not only in operation for several operating points, with the help of a new model can describe any working condition.

Model diagram

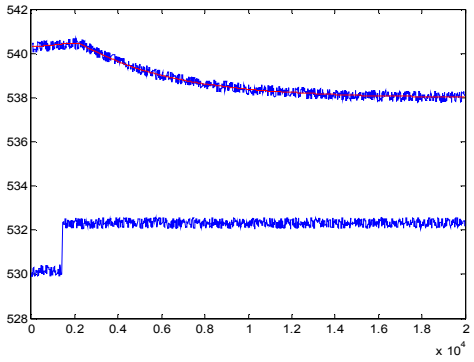

Figure 6
Simulation result

Conclusion

In this paper, with a power plant boiler superheater temperature controlled object for research background, I explored a method of modeling which can describe a class of nonlinear systems .The dynamic characteristics of the superheater temperature controlled object that can be described by a unified mathematical model .This model avoided some technical problems when using piecewise linear modeling with a plurality of transfer functions.

Keywords: middle-asia district, pipeline layout, process scheme, wall thickness selection, SNIP, ASME, design feature, difference, analyze

Abstract. According the experience of gas pipeline project in the Middle-Asia district, the writer analyzes and concludes the design feature for the pipeline route and the process scheme for the gas pipeline project in the Middle-Asia district. For the requirement of code SNIP, ASME and Chinese specification, the writer analyzes the difference and design feature on the design requirement and draws the conclusion. The pipe grade, design parameter, wall thickness selection and the process design for station are detailed described in the article, which can expand the design thought and provide the reference for the similar project.

Introduction

As the project increasing in the Middle-Asia district, the design philosophy and the code are difference with European and America districts. The SNIP code system of Russian is adopted in these districts which are difference with the code system of ASME code. So, the feature and difference are obvious in the design of route and process of gas pipeline.

Design feature and Analyze

Pipeline grade and design factor

On the choosing of pipeline grade and the design factor of pipe wall thickness, it is decided by the purpose and scope of the position and line pipe laying location in the SNIP code. In the ASME code, the location class is a geographic area along the pipeline classified according to the number and proximity of buildings intended for human occupancy and other characteristics that are considered when prescribing design factors for construction, operation pressures and methods of testing pipelines and mains located in the area and applying certain operating and maintenance requirements. For the details of SNIP code are as follows:

Table 1 Pipeline grade distribution

Pipeline grade	Factor on Strength, stability and working conditions of pipeline	Scope（for example）
B	0.60	Compressor stations, gas pressure reducing station, underground gas stations, gas stations, gas metering station；
I	0.75	Waters wear across segments, railway and road wear crossing segments, the swamp crossing segment; pigging transceiver station and 100m long pipe connected thereto; gas pipeline hub is turned on, compressor station inlet outlet pipeline
II	0.75	Pipeline block valve station and the length of 250m from the valve center to both side, crossing with the underground pipe and cable
III	0.90	Diameter of pipe is more than 1200mm, northern climate construction area, grade V road
IV	0.90	Diameter of pipe is less than 1200mm

Calculation of wall thickness

On the pipe wall thickness calculation scheme, calculated formulas between SNIP norms and ASME code system are not the same. the author calculate the wall thickness using the design parameters for the same conditions, according to a different formula to calculate and compare different diameters, can analyze the basic trends: for grade B pipe, wall thickness calculated according to SNIP norms is in the middle of result between factor of 0.4 and 0.5 by the ASME B31.8 Code; for grade I pipe sections, wall thickness calculated according to SNIP norms is in the middle of result between factor of 0.5 and 0.6 by the ASME B31.8 Code. For the details, please see the following table:

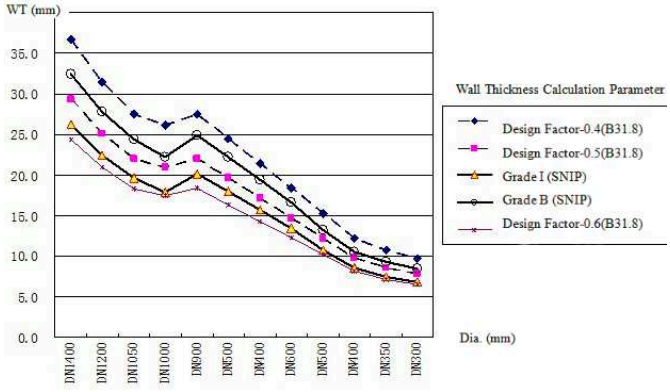

Fig.1 Calculate the wall thickness comparison chart

Block valve station

For the ordinary pipeline block valve station design, which must have an emergency shutdown automatic device or remote control function according to the SNIP standards, emergency shutdown devices should drop rate decreased by 10% to 15% within 1 to 3 minutes, the distance for the adjacent block valve stations shall be not more than 30Km. But, according to ASME standards there is no explicitly requested block valve station need to have emergency shut-off function drop rate, the distance of adjacent block valve stations is designed in accordance with the regional class, as follows: in the class I region, the distance shall be not more than 32Km, in the class II region, the distance shall be not more than 24Km, in the class III region, the distance shall be not more than 16Km, in the class IV region, the distance shall be not more than 8Km.

For the Compressor Station downstream protection valve station design, the block valve station shall be installed in the 750m of upstream and downstream of the gas pipeline to protect the compressor station and shall be remote controlled by compressor station; But, according to ASME standards there is no explicitly requested block valve station to install, only the minimum distance is not more than 8Km.

Venting pipe

In SNIP code, the distance between the venting pipe and the block vale is clearly defined: if the diameter is less than 1000mm, the distance is not less than 15m, if the diameter is more than 1000mm, the distance is not less than 50m, and the distance from other buildings or structures shall be not less than 300m. the ascertain of vent pipe diameter should meet the finish venting empty of adjacent trunk line section in the 1.5 ~ 2h, the height of venting pipe from the ground is not less than 3m. Due to security requirements from a large set of vent shorter and lower height, the torch is generally not adopted. In the ASME code, the height of venting pipe shall be not less than 10m above the natural ground.

Pig trap station

According to SNIP code, pig trap stations are separate with the compressor stations and the distance is not less than 200m.the condensate collector shall be set and the filter separating device shall be set in the compressor station. The condensate collector can use the same wall thickness pipe in the class I section, the features including venting with liquid loading, vacuum purge, clean up the bottom of the tube, sampling and level display.

According to the ASME code, pig trap station and compressor station can be set in the same yard, the cyclone separation and filtration equipment shall be set in the pig trap station.

Gas metering device

According to SNIP code, the gas flow metering station shall be set on the bypass pipe of gas pipeline. for accurate measurement requirements, Transmission Pipeline Set double valve to protect the measurement accuracy. When pigging, open Trunk line valve, but do not close the metering station and export valve. Since the pigging device does not set, some gas can not be measured during the pigging, the main solution for the calculation of time through ball and pass the ball stage based on the average output rate can be calculated pass the ball during the bypass flow. But in the ASME code, The bypass line does not allow to set and the pig trap devices must be set.

Gas purifying device

For the SNIP standards, specifications require the use of dust on the gas purification level, after three to five compressor stations for individual compressor stations, usually filter - gas separator for secondary purification. The above requirements are different setup with ASME which requires the cyclone filter and filter separator set in each compressor stations.

Lube stock

For SNIP standards, the cleaning oil tank (not less than $50m^3$) and waste oil tank (not less than $25m^3$) shall be set in the lubrication stock on compressor station, and a fuel pressure unit to supply clean oil to the fuel pump and libraries waste tank pumping waste oil pump. lubricants plant set in a separate compartment near the fuel pressure unit. ASME specification does not require oil workshop set.

Safe distance of compressor station

For SNIP standards, compressor stations and gas transmission lines need to follow the safety distance requirements for the design. for the 1000mm diameter pipeline, the pressure of the gas station and trunk spacing is not less than 225m, shift quarters and trunk spacing is not less than 300m, shift dormitory and compressor stations is not less than 700m, each compressor stations shall have a tarmac.

Summary

Listed in this article are just some of the main features and differences in line and process design encountered in practice. With the development of the CIS, the current Middle Asia countries revise their specifications in accordance with their characteristics. because its specifications system is very complex, these should be integrated in the design process analysis problems encountered and should not be applied mechanically.

Research and simulation of energy-saving hierarchical design model for differentiate architecture

Guo haiqing

Inner Mongolia Technical College of Construction，Hohhot, Inner Mongolia，010070）

Keywords: building energy-saving; energy consumption; evaluation indicator system

Abstract: Energy-saving hierarchical design model is established for differentiate architecture. From current status of China's construction, exploration research is established on energy-saving hierarchical design model of differentiate architecture to evaluate indicator system of energy-saving building. Availability of evaluation information in index system is low, so it is difficult to play the role of evaluation of building energy-efficiency. EHTV difference method is used to calculate and evaluate energy-saving design of hierarchical building, including: heat transfer indicator of building envelope targets, air conditioning and heating consumption, basis of EHTV indicators.

1 Introduction

In the background of the depletion of non-renewable energy, building energy economy accounts is about 30% (20% to 25% in our country) of the total energy consumption, which gains concern of all walks of life [1,2]. Many countries have made clear legal provisions in energy consumption and developed a variety of assessment methods and technical standards [3]. China in the early 1980s began to promulgate the relevant national and industry standards, due to the lack of necessary evaluation system of building energy consumption and effective measures to regulate building energy efficiency standards, standards in the implementation meet lots of difficulties [4]. There are terms of mature practice in developed countries on promoting building energy efficiency, such as the implementation of DSM (demand-side energy management), National Housing Energy Rating system, building energy audits, etc., but smooth implementation of these measures are based on scientific building energy assessment [5]. This article points out the necessity of establishing energy evaluation system in line with China's national conditions, and then construct hierarchical model of differentiate architecture energy for our country's current situation.

2 energy hierarchical design model for differentiate building

2.1 single building model

Ground floor heating in the building envelope gains increasing proportion. Ground floor heating is a two-dimensional or three-dimensional dynamic heat transfer process, with computational complexity and heavy calculating workload.

The basic principles of heat transfer calculation method for ground floor heating: Ignoring thermal properties changes with temperature of ground floor area, according to different influencing factors, heating of ground floor is divided into three heat transfer process: ① heat transfer process of outdoor under the influence of the earth's surface temperature; ②heat transfer process of indoor ground floor③ heat transfer of difference of temperature between adjoining room.

2.2 establish energy hierarchical design model of differentiate building

Heat transfer Q0 of building envelope structure including three parts as walls, windows and roof, can be expressed as:

$$Q_0=Q_w+Q_f+Q_r \tag{1}$$

where: Q_w : heat transfer of exterior wall,W.

$$Q_w=\sum(F_W\times K_W\times\rho_W\times\Delta_{TEQW}) \tag{2}$$

Q_f : Heat transfer of windows, W. window heat transfer includes two parts: heat from solar radiation and heat from temperature difference.

$$Q_f=\sum(F_f\times K_f\times\Delta_t)+\sum(F_f\times SC\times ESC_K\times SF) \tag{3}$$

Q_r :heat transfer of inner wall,W.

$$Q_r = \sum (F_r \times K_r \times \rho_r \times \Delta_{tEQr}) \quad (4)$$

In equation(2), (3), (4): F_w: area of exterior wall, m^2; F_f: outside area of window, m^2; Fr: roof area, m^2; Δt: difference between indoor and outdoor temperature , ℃, For air conditioning energy consumption calculation: difference between average outdoor temperature of calculated local air conditioning and designed indoor temperature (26 ℃); For the heating energy consumption calculation: difference between average outdoor temperature of calculated local heating and designed indoor temperature (18 ℃);

When carrying out energy consumption calculation of building air conditioning and heating, it needs to calculate partially heat transfer estimate of air conditioning Qoc and heating estimate

Q_{oh}: $Q_{oc} = Q_{wc} + Q_{fc} + Q_{rc}$, $Q_{oh} = Q_{wh} + Q_{fh} + Q_{rh}$ 。

Heat transfer index EHTV of building envelope structure is average of units area converted from sum energy of building envelope structure.

Corresponding heat index of air-conditioning $EHTV_c = Q_{oc}/F_0 (W/m^2)$; indicators of heat transfer $EHTV_h = Q_{oc}/F_0 (W/m^2)$ 。

wherein: F_0 : construction area, m^2 .

From above analysis, to obtain heat transfer index EHTV of building envelope, in addition to the parameters of building design, the key is to get parameters such as equivalent temperature difference between the walls and roof, shading coefficients, and radiation heat of standard window solar.

3 Simulation experiments and results

Select computing five cities such as Harbin, Guang Zhou and Wei Fang etal., as examples, some only need heating, some only need conditioning, some need both. Numerical example is a form of residential buildings, three floors, whose height is 2.5m, construction area is about 1500m2. Comparing results by calculating the effective heat transfer coefficient using traditional methods and EHTV methods are shown in Table 1.

Table1 Comparison to different examples

	Haerbin	Guangzhou	Weifang air conditioning	Weifang heating	Shanghai air conditioning	Shang Hai heating	Beiing air conditioning	Beijing heating
EHTV	-14.97	19.05	21.71	-4.30	17.85	-9.30	13.07	-10.44
Energy consumption per year	224.32	42.98	31.96	36.43	18.07	72.21	12.80	85.29
DOE	249.34	48.63	34.08	45.00	19.67	83.44	14.11	95.13
Relative errors	1.13	-0.88	6.01	-9.76	3.52	-3.43	1.89	0.69

EHTV envelope method is a simplified method of calculation of heat transfer and energy consumption structure. When EHTV method evaluates using the equivalent temperature difference parameters, simplifies calculations of transfer envelope. Meanwhile, calculating annual energy consumption for heating in air conditioning, an exponential equation is also employed, substituting consumption parameters and shape correction factor. Moreover, EHTV indicators include the effects of shape factor.

4 Conclusions

Based EHTV algorithm energy-saving hierarchical design model of differentiated building is in simulation and research. Taking Harbin, Guangzhou, Weifang and other five cities as residential samples, a specific test is carried out to obtain heating and air conditioning of the environment indicators and comparative analysis from samples of residential energy. The results show that: energy-saving building layered design is significantly better than residential energy-saving design.

Establishment of energy hierarchical design system, for the purpose of energy conservation lays a good foundation to help the healthy and sustainable development of urban construction.

Keywords: the brushless dc motor, the control strategy, the torque ripple

Abstract. Because torque ripple disturbance can be created when the brushless dc motor is communicating, In this paper, from two aspects of energy feedback and the torque ripple, H/L - PWM - ON control strategy is analyzed .And a simulation system is set up. Through the trials, it shows that H/L - PWM - ON strategy can efficiently complete the energy feedback, has small torque ripple, and fully proves the feasibility and practicability of this control strategy.

Introduction

The commonly used PWM - ON and ON - PWM, H - PWM - L – PWM [1, 2] is included in the PWM strategy of Brushless DC Motor. The existing main problem is that commutation has torque ripple when the BLDCM is running, When the ripple is solved, it is beneficial to extern the scope of motor application . In this paper, H/L - PWM modulation control strategy is presented . The paper analyses the energy flow and the commutation torque ripple when machine is stop . The following conclusion is obtained: H/L - PWM - ON strategy can quickly achieve energy feedback. It has small torque ripple. And it is Suitable for the control of the brushless dc motor.

Strategic analysis

Brushless dc motor control system is shown in figure 1. The whole circuit is supplied by the dc power . and the Three-phase half bridge inverter is a power -supply source of the brushless dc motor. The model of the motor and the number of Switch tube and diode has been shown in the figure.

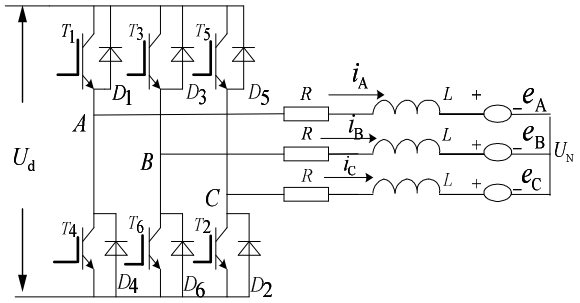

Figure 1 System circuit

This article focuses on another modulation H / L-PWM-ON mode. This modulation scheme is proposed, based on the Complementary switch tube up and down. However another one with a lower arm is reached . Its timing is shown in Figure 7.

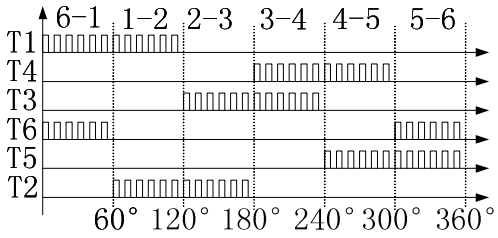

Figure 2 H_PWM-L_PWM type

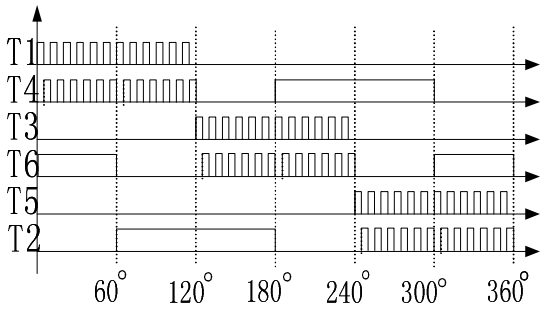

Figure 3 H/L-PWM-ON type

According to the figure 7, it is obtained that any one of the six states has three state switch work in this modulation method . This is different from the first five kands. The advantage is that when the motor is running , it is in favor of the feedback energy so that the motor stopped and reversed more quickly. Because when the motor is running, from the single-phase ,it is the current double quadrant circuit.

Such as in a moment that T4 and T1 is modulating while T6 is reached , the motot is running on a duty ratio. The circuit is as simplified as Figure 8 . In the figure , UA0 is the sum of the middle voltage U_N and the counter electromotive force

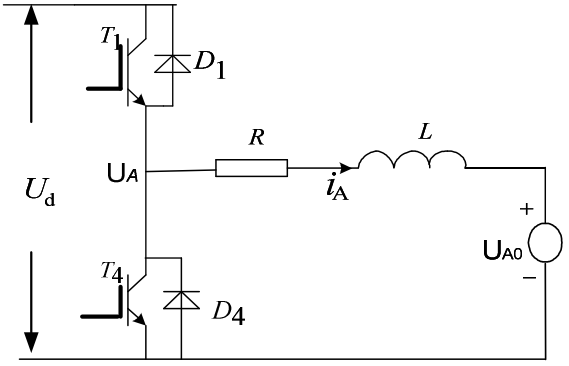

Figure 4 Current double quadrant circuits

From the positive point of current, power, T1, D4 and load are Buck circuit; When the reverse electricity is flowing, the switch T4 and D1 make up the Boost boost circuit. When the duty ratio of the motor decreases, the voltage UA will be less than UA0. When the motor is required to stop running, the same results will happen .Then the Current will reduce or even reverse. At the moment, the circuit is Boost circuit. The energy is provided from the motor to the power –supply. it can achieve the positive braking to achieve the purpose of energy-saving and fast shutdown .

In contrast, the first four modulation, because of two different phase of the switch tube, slow down or stop the process, form the Internal free-wheeling only by the corresponding lower arm freewheeling diode. But they have no corresponding the boost boost circuit for energy feedback channel so that energy efficiency is not high and the braking performance motor is poor. Because it is double polarity modulation, the feedback channel of the fifth kand of way is completed by the corresponding diodes to stream. Motor load and power always have energy exchange . But the switching loss is about two times that of other methods, which impacts its range of applications.

The torque ripple analysis

Literature [6] carefully analyzes the influence of modulation of the torque ripple. Next, it will take a look at the comparison of the effects of H / L-PWM-ON mode for torque ripple.

First Electromagnetic torque size is analyzed when the motor is running smoothly. That is to say the phase is not changed . It is supposed to be electromagnetic torque(unit N·m) which is generated by the brushless motor. Then Three-phase electromagnetic torque sum can be expressed as the follow :

$$T_e = (e_A i_A + e_B i_B + e_C i_C) / \omega$$

In this formula, ω represent the rotor mechanical angular velocity .

Since the magnetic potential of the brushless DC motor is trapezoidal wave, only the largest counter electromotive force value is conducting when the motor is running at any time . it means that when only two phases is opening up ,(If at this time A phase T1T4 is complementary to be opened, B phase T6 will be always reached) the following will be obtained :

$$\begin{cases} e_A = E \\ e_B = -E \end{cases} \qquad \begin{cases} i_A = -i_B = I_A \\ i_A + i_B + i_C = 0 \end{cases}$$

Then The total electromagnetic torque will be $T_e = 2EI_A / \omega$.

In this formula, I_A is the average a phase current in the stable operation.

Since the phrase commutation is divided into the bridge arm in phase and the lower bridge arm phase , therefore it needs to compare the current ripple up and down, respectively, when the arm commutation. First the current ripple is compared when the lower bridge arm phase is communicating.

first torque changes are analyzed during the phase commutation in the H/L - PWM - ON modulation mode. As shown in figure 1, With A phase modulation as an example, the up and down at this point, the switch from T1T4T6 switch to T1T4T2, namely the current bridge arm is from under the phase B to C arm phase under the bridge.

At present , it is existed. $\begin{cases} e_A = E \\ e_B = e_C = -E \end{cases}$

Because of the Continuity of the electric current, In an instant commutation, T6 tubes will be shutdown .But i_B will not instantly become 0 which lead to make diode conducting . so the following equation is shown:

$$\begin{cases} U_A = DU_d = Ri_A + L\dfrac{di_A}{dt} + e_A + U_N \\ U_B = U_d = Ri_B + L\dfrac{di_B}{dt} + e_B + U_N \\ U_C = 0 = Ri_C + L\dfrac{di_C}{dt} + e_C + U_N \end{cases} \tag{1}$$

The three equation is added , and the following equation is get :

$$(1+D)U_d = e_A + e_B + e_C + 3U_N = -E + 3U_N$$

Then the result can be obtained :

$$U_N = \frac{(1+D)U_d + E}{3} \tag{2}$$

Put the (2) into the (1) ,and it can be get :

$$U_A = DU_d = Ri_A + L\frac{di_A}{dt} + e_A + \frac{(1+D)U_d + E}{3}$$

resistance voltage change is ignored , then :

$$\Delta i_{A1} = \frac{(2D-1)U_d - 4E}{3L}\Delta t \tag{3}$$

Through the above analysis and comparison, the torque ripple of H/L - PWM - ON control strategy is small, and it is conducive to the smooth running of the motor. it's worth noting that this strategy has disadvantage which is that it exists risks in the direct connection ,when the guidance of the up and down tubes is conducting . And when the up and down tubes of only two different phases in the first five kinds types is conducting, direct connection won't be absolutely appeared.

Experimental result

Through the above analysis, theoretically , this way of modulation is feasible. Brushless dc motor parameters used in the experiment are as follows: Rated power is 550 W, Voltage ranges from 220 V to 240 V . Pole-pairs are 2. Rated current is 3.5 A . torque is 1.7 N · m . Rated speed is 3000 r/m .

In the experiment, 3KHZ switching frequency is used . Under the condition of duty ratio of 0.5, When the motor is under the low speed or under the light load, the waveform of A phase current and line voltage is shown in the figure 9.

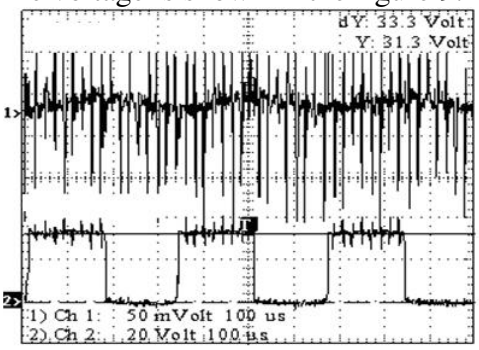

Figure 9 I_A and U_{AB}

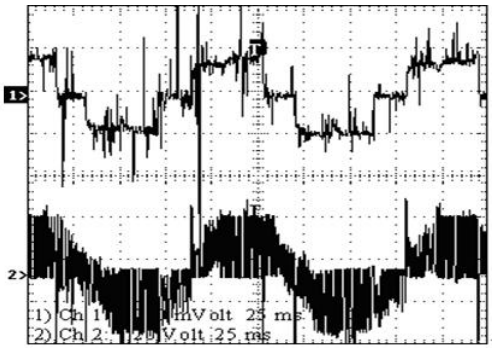

Figure 10 I_A and U_{AC}

As can be seen from the figure 9 , when T_1, T_4 are modulate up and down ,and T_6 is conducting , when the line voltage UAB is positive , A phase current is on the rise; Line voltage UAB is appositive; a phase current is on the decline.

To be sure: A complete cycle (that is, the six state), is that A phase current is negative.The waveform of A phase current and line voltage UAC when motor has load is shown in figure 10.

Conclusion

Through the theoretical analysis and experimental results, compared with other kinds of control strategy, the electromagnetic torque ripple caused by the H/L - PWM - ON this way of modulation is small. And it is conducive to the smooth running of the motor. It can realize two-way flow of energy and achieve the quick stop of the motor and energy saving.

Keywords: Island mode, brushless generator, isochronous load sharing, electronic governor, digital data communication

Abstract. This paper focuses on *selecting control of parallel generator* that ensures safety and efficiency operation in oil & gas offshore pipeline application. For island grid system, the advanced microcontroller based digital isochronous method of active load sharing is introduced. The programmable logic controller system is adapted to automatic load sharing.

Introduction:

One or more diesel generators without a connection to an electrical grid are operating in "island" mode.

Generator systems in island are rapidly increasing, particular on site in oil & gas offshore pipeline application.

The more than one generator provides the advantages of high flexibility, reliability and redundancy, thus an island generator plant will have at least two generators.

The automatic generator control is rapidly increasing to match the load demands. The intelligent controller has the following objectives:

To hold system constant frequency;

To maintain the correct interchange of power between generators

To ensure each generator unit at the most economic value;

Active load sharing of automatic generator control shall be digital isochronous sharing, which actively calculated the percentage of real load on generator sets.

Generator system. In general, the alternators installed in oil & gas offshore application shall be brushless, salient pole rotor self regulating type as Fig. 1 shows

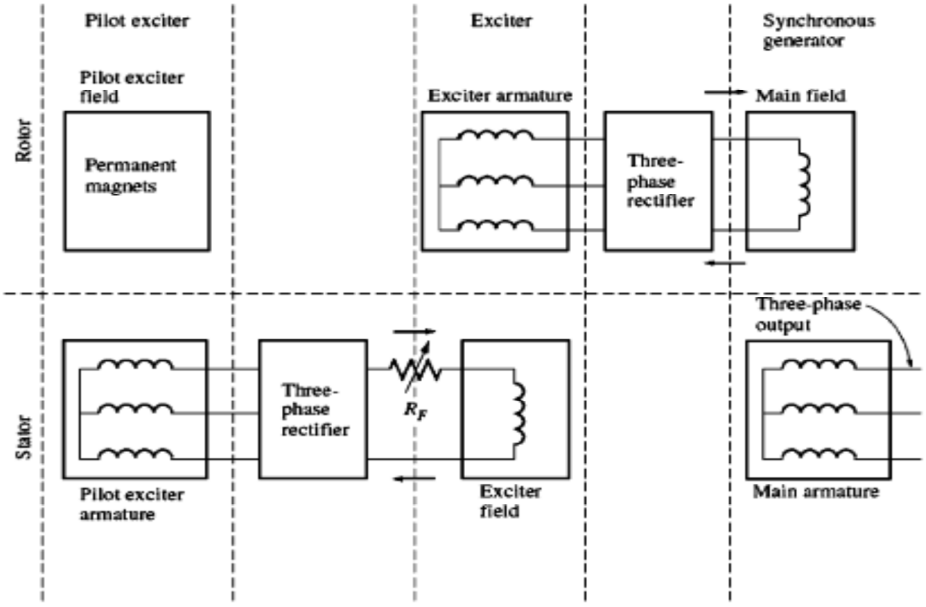

Fig. 1 Configuration of generator:

A typical configuration of parallel operating multi-generators system in oil & gas pipeline application is illustrate in Fig. 2

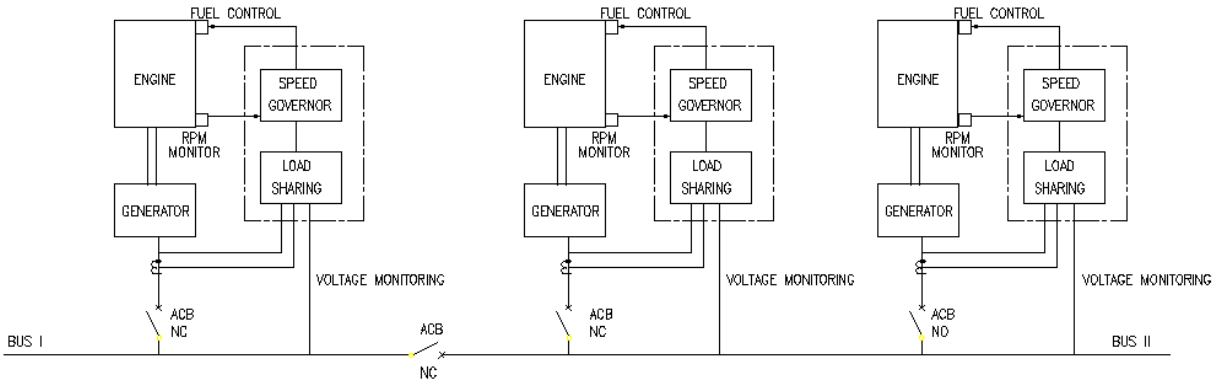

Fig. 2 Parallel operating multi-generators system

In general, electric power is generated by three diesel generators sets to supply power to loads, with operation in N+1 philosophy (2 sets running and 1 set standby), where N is the minimum number of generators required to meet the load demand. The bus bar is divided into two sections via bus couple which was in the normally closed.

Generator load sharing. Essentially, parallel running is achieve in two stages include synchronizing and load sharing. Once the Auto- synchronizing between generators to the main bus is complete, the power will be shared depending upon the generator characteristics.

There are two methods for active load sharing of the power system [1]:

1 Isochronous load sharing (constant frequency);

2 Droop load sharing(varying frequency);

The loads in offshore pipeline application mainly are continuous duty and require high quality of power supply. Frequency variation will have effects on the induction process motor. Thus, the constant frequency is required in island mode.

Generator in isochronous sharing mode can maintain the requested speed very precisely. But the generators running in parallel, it is impossible to keep load sharing stable between generators in isochronous mode [2]. Unless, communication may be employed to be increase the stability of this mode. That means digital isochronous load sharing.

The digital isochronous load sharing system shall be produced to achieve stabilize the island multiple generators operation.

Structure of load sharing. In comparison traditional generator controllers which have some different modules resulting in a lot hardwires, but intelligent generator controller can achieve the function including governor control, synchronizing and load sharing.

The digital data communication via CAN bus between generators exchanges power information (real power).

A typical schematic diagram for data communication for isochronous load sharing between generators is illustrate in Fig. 3

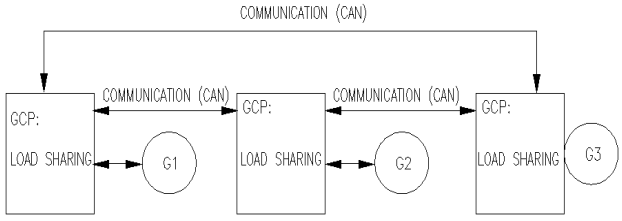

Fig. 3 Control unit communications between generators

For digital isochronous load sharing system, the key of active load sharing of island operation is mainly relaying on the generator governor and controller.

Governor. In general, governor specifically performs the speed and active power control of the engine. That is the governor applied to an engine-generator set controls engine speed to assure the driven AC generator provides the proper frequency of the AC power output. Fig 4 shows the block diagram of speed governor.

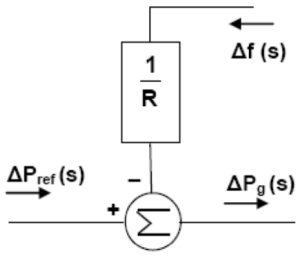

Fig. 4 Block Diagram of Speed Governor

Engine generator with electronic governor is necessary to required for digital isochronous load sharing. The electronic speed control senses actual engine speed and provides a feedback signal to the actuator, which, in turn, positions the engine throttle or fuel control to maintain a very accurate engine speed.

In general, there are two operating modes used for speed governing engine is droop and isochronous. However, the isochronous governor is used in automatic active load sharing.

Isochronous governing causes the steady state speed error to become zero, thereby producing a constant speed at the shaft and a constant frequency for the power system. Isochronous governing is also a form of 'integral control'. This method is best suited to a power system that is supplied by one generator. In multiple generators in parallel, the generators will "fight" each other in order that system is non-stable in load sharing. However, the intelligent controller is introduced to control isochronous governor in active load sharing via communication line.

Controller. The key successful of digital active load sharing is relaying on controller. Intelligent controller is automatic load sharing control functions between generators. Active load sharing is achieved by increasing/decrease fuel to engine via controller software while maintaining a fixed speed.

Fig. 5 shows the active power control block of generator, where inputs are local measurement of frequency and power output and load output, and the set points are provided by the central controller. The output is fuel demand.

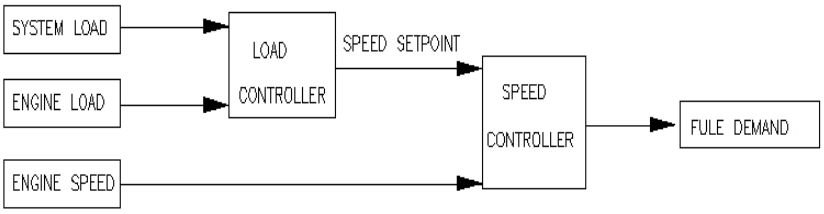

Fig. 5 Control block of generator

Controller has active control system that actively calculate the percentage of real load on a specific generator set, compare those values to the percentage of real load on the system, and then provides control to the fuel and excitation system of the generator to drive the percentage of load on the generator to the same value as the percentage of load on the system.

Communication data between generators is important to achieve isochronous active load sharing. The analogue and digital line is used. But digital line is superior to the analogue line since more data can be communicated to perform complex and accurate load sharing function. Moreover, data line can be more suitable for long distance in comparison with analogue line.

Summary. Microcontroller based on digital isochronous has been automatically achieved for the load sharing. The controller is simple and reliable. In comparison to traditional, it decrease different module and can be give easy and liable operation about load sharing.

Keywords: fractional order; permanent magnet synchronous generator; chaos control;circuit

Abstract. In this paper, the directly driven wind turbine with permanent magnet synchronous generator (D-PMSG) is investigated, the mathematical model of which is built up. Also, the chaotic behaviors or limit cycle phenomena is demonstrated under certain working conditions or the parameters of the model having a certain range of values. A novel adaptive controller is designed based on the quasi-Lyapunov stability theory for fractional-order systems. Also, electronic circuits are designed to realize the controllers using Multisim. The simulation results demonstrate the effectiveness and realizable ness of the proposed methods, besides, the research results will be provided as theoretical references for the study of improving control performance.

Introduction

At present,the energy and the environment are the pressing problem facing mankind[1][2].As the wind power is a kind of green energy,it is the widely recognized in general. The chaos is a new subject that started in the twentieth century.Under certain conditions,the brushless DC motor can generate chaotic phenomena in the literature[3].Brushless doubly-fed wind power generator is controlled in documents[4].The sliding mode variable structure control method is taken in the the D-PMSM chaotic system in documents[5], but the requirement for the sliding mode variable structure's accuracy of the mathematical model is not so high.Therefore,there may be some errors on the establishment of mathematical model. The paper of documents[6] proposes a adaptive control way of the chaos system in permanent magnet synchronous motor.The permanent magnet synchronous generator system above is not considered to establish the mathematical model of damping.But, the wind turbine system's study about damping is not much.

According to the characteristics of the permanent magnet synchronous generator,the system model is reestablished in damp conditions. Meanwhile, this paper presents a fractional order to describe D-PMSG.In this paper, an adaptive synchronization control method is designed by using the fractional Lyapunov stability theory[8][9] ,and the control strategy is tested through the circuit simulation.

The system model of D - PMSG

The basic structure of D-PMSG is as shown in fig1,which consists of a wind turbine,converter and other components.The wind turbine converts the wind energy into the mechanical energy and the generator converts the mechanical energy into the electrical energy.In addition,the converter moves the electrical energy into the grid.

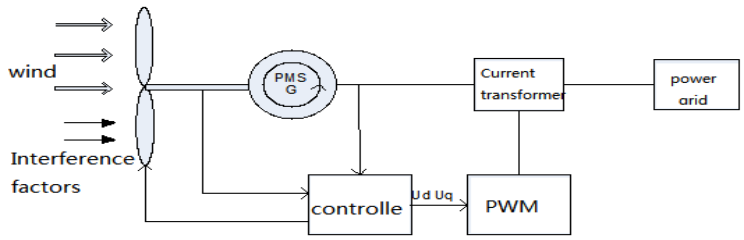

Fig.1 The basic mechanism of D- PMSG

Assuming generator has the uniform air gap and the inductance of D and Q axes are same, Considering the influence factors on the system, the system of certain properties and damping, friction and other physical quantities with fractional characteristics, it can be used for fractional differential description, rewrite rewritten dynamic mathematical model:

$$\begin{cases} D^{q_1}x_1 = -x_1 + x_2x_3 + \hat{u}_d \\ D^{q_2}x_2 = -x_2 - x_1x_3 + \sigma x_3 + \hat{u}_q \\ D^{q_3}x_3 = \gamma(x_2 - x_3) - \hat{T}_w \end{cases} \quad (1)$$

When $\hat{u}_d = 0$, $\hat{u}_q = 0, \hat{T}_w = 0$, this process can be viewed as the transient period after the wind turbine permanent magnet synchronous generator runs over. Its parameters are taken as follows: σ = 25, γ = 5.46. The formula (1) has the chaos characteristics.

Chaotic synchronization controller

According to the literature in the [6] to the motor synchronous control of chaos, we can construct the response system.

$$\begin{cases} D^{q_1}y_1 = -y_1 + y_2y_3 + k_1e_1 \\ D^{q_2}y_2 = -y_2 - y_1y_3 + \sigma y_3 + k_2e_2 \\ D^{q_3}y_3 = \gamma(y_2 - y_3) + k_3e_3 \end{cases} \quad (2)$$

Among them,it meets $e_i = y_i - x_i (i = 1,2,3)$ .Using the(1)-(2),we can obtain

$$\begin{cases} D^{q_1}e_1 = -e_1 + y_2e_3 + x_3e_2 + k_1e_1 \\ D^{q_2}e_2 = -e_2 - e_1y_3 - x_1e_3 + \sigma e_3 + k_2e_2 \\ D^{q_3}e_3 = \gamma(e_2 - e_3) + k_3e_3 \end{cases} \quad (3)$$

Therefore,we can get

$$D^q e = (B + F(x, y) + K)e \quad (4)$$

According to equation(2) ,we construct the H function

$$H = e_k^T PD^q + e_k e^T PD^q e \quad (5)$$

Expanding the formula(5),we can obtain

$$H = e^T D^q e + e_k^T ED^q e_k \quad (6)$$

From the formula(6),it can be derived the format of the text chart.

$$\max\{\tilde{k}_i\} \le -[\max\{eig(\frac{A^T + A}{2})\} + \max\{eig(\frac{F(x,y)^T + F(x,y)}{2})\}] \quad (7)$$

According to the formula(7),the value of $\tilde{k}_i$ can be obtained, which proves that the system(1) is stable .

Circuit simulation

When the system is in chaos,the minimum value of q is 0.95. According to the previous analysis,can find the value of $\widetilde{k}_i$,and write the corresponding response of the system(2).The drive system and response system are similar,so we only draw the circuit principle diagram of the system(2) .The system (2) is implemented by linear resistance, capacitance, operational amplifier LM741 and analog multiplier AD633.

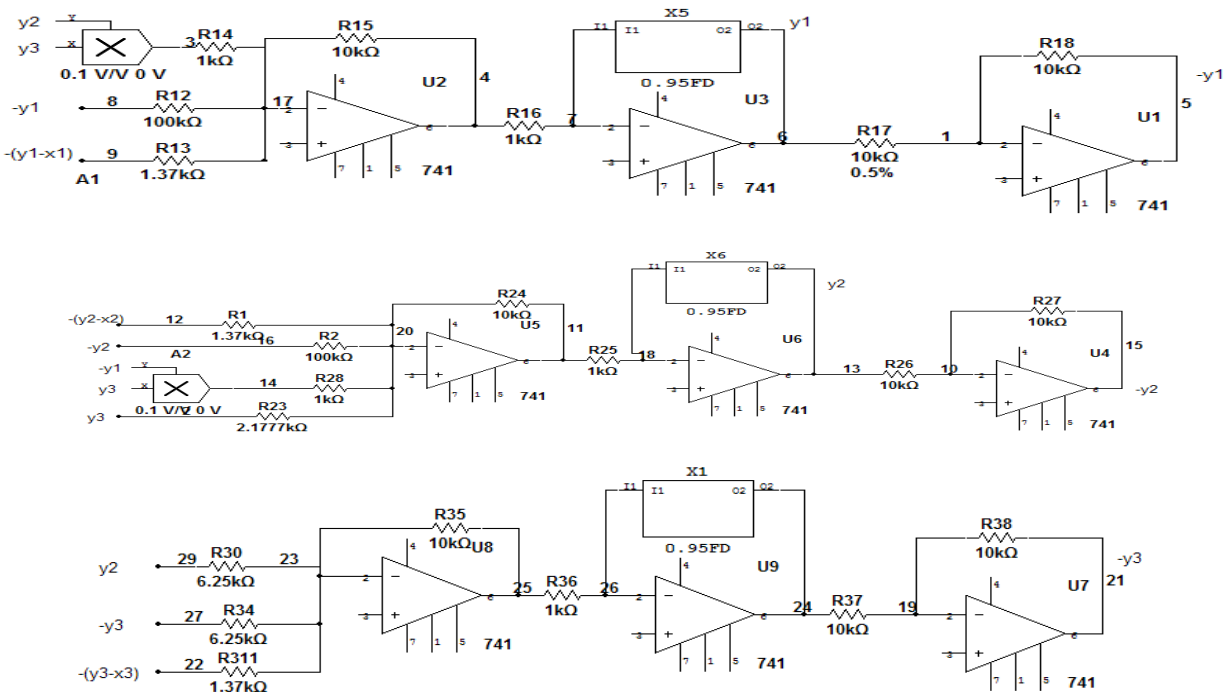

Fig. 2 The circuit principle diagram of the system(2)

Using Mutisim10 to simulate the circuit,we can get the attractor Fig.3 of the system and draw the synchronous wave form as shown in Fig.4.

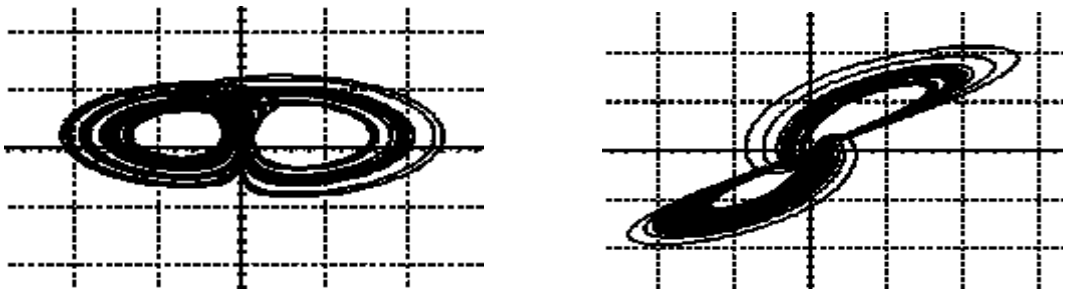

Fig. 3 Chaotic attractor of the system(1)

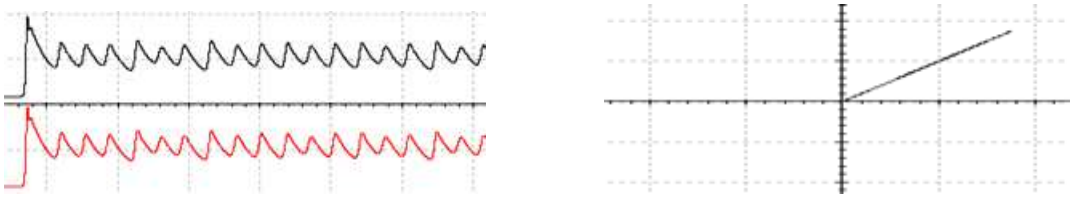

a $t-x_1, y_1$ (5V/div 5V/div) b x_1-y_1 (5V/div 5V/div)

Fig.4 Synchronous simulation results

Conclusion

In the light of the damping effect of the permanent magnet synchronous generator in the chaotic system,this paper presents a fractional order to describe the permanent magnet synchronous generator.An adaptive synchronization method is proposed.At the same time,astrict mathematical theory of this control method is proved to be given.The circuit is designed and tested by using modular design method.Furthermore,in the experiment,we receive prospective results that the experimental results is fully consistent with theoretical analysis circuit.Ultimately,the correctness and validity of the method are confirmed.

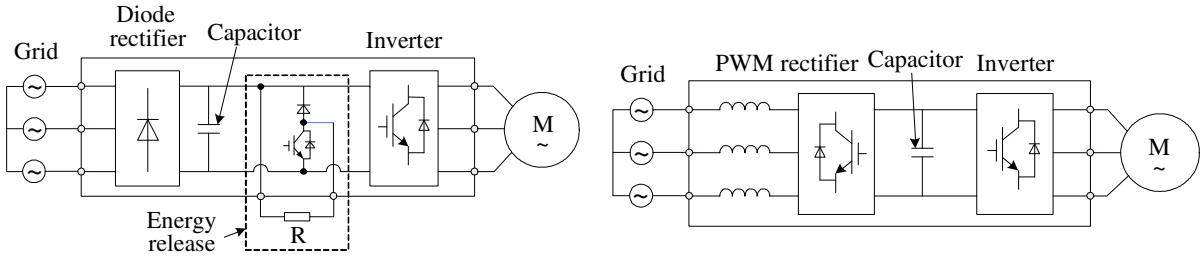
Keywords: Motor Drive System; Energy-Saving Scheme; Ultracapacitor; DC-DC Converter

Abstract. In order to prevent DC link voltage pump during braking, a paralleled release circuit composed of chopper and resistor is often employed. As a result of energy waste on the resistor, the efficiency of the motor drive system is low in the case of frequent braking. To improve the efficiency, an energy-saving scheme of motor drive systems based on ultracapacitors is proposed in this paper. An energy storage system (ESS) paralleled with the DC link of the motor drive is adopted in the scheme, which is composed of a bidirectional DC-DC converter and ultracapacitors. The ESS can realize recycling of the braking energy. Compared with PWM rectifier, this scheme can avoid various technical requirements for grid-connected inverters.

Introduction

The modern drive system has been applied in fields of industry and electric vehicles since they can improve the performance and efficiency of motors substantially. To brake the motor, resistors or the winding are often used to consume regenerative energy during braking, which results in low efficiency of the motor drive system [1] [2]. To improve the overall efficiency and performance of the motor drive system, an four-quadrant drive in which the diode rectifier is replaced by PWM rectifier is adopted, as shown in Fig.1(b) [3]-[6]. As the four-quadrant drive, since the related standards for grid-connected inverters should be complied with, the design requirement and complexity are increased.



(a) Diode rectifier-inverter topology with brake resistor (b) PWM rectifier-inverter topology

Fig.1. Typical topologies of motor drive systems

To simplify the design, an energy-saving scheme based on ESS paralleled with DC link is proposed in this paper. This scheme can be used to reform traditional motor drive systems with diode rectifiers, since it can recycle regenerative energy and improve the efficiency of motor drive systems.

Proposal of the energy-saving control scheme

The proposed energy-saving scheme for motor drive systems is shown in Fig.2. In the scheme, the energy storage and management unit paralleled with the DC link is used to recycle the braking energy. The unit is consists of a bidirectional multiple DC-DC converter and ultracapacitor group. The high level end of the converter is connected to DC link and the low level end is the ultracapacitor group.

The operation principle of the energy-saving scheme can be described as follows. When the motor brakes, the regenerative energy is fed to capacitors on DC link, and then pumps DC link voltage. The controller of energy storage units measures the DC link voltage, and when the voltage reaches a preset value U_{ch}, the DC-DC converter runs in Buck. At this moment, the energy storage unit is equivalent to a virtual load for the motor drive. By hysteretic chopping control of DC link voltage, the feedback energy from the motor can be absorbed. When the motor runs, the DC link voltage declines to U_{disch} and the DC-DC converter operates in Boost. And DC link voltage closed-loop is carried with U_{disch} as the reference. Since U_{disch} is larger than the diode-rectified voltage value, the energy required by the motor is offered by the energy storage unit prior to the rectifier. When the voltage of ultracapacitors is less than the preset value, the DC-DC converter will stop and the DC link is supported by the diode rectifier again.

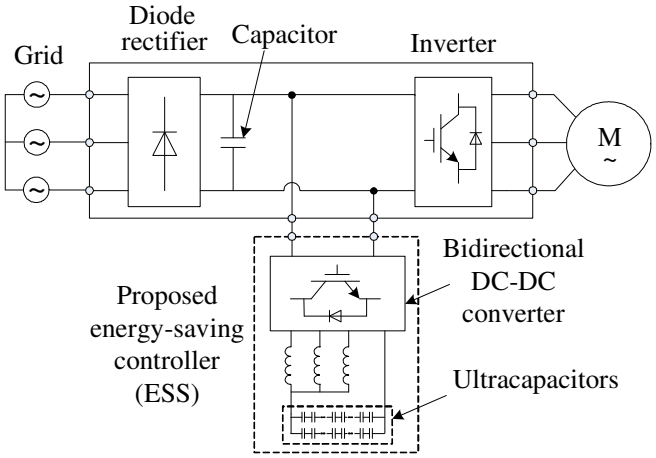


Fig.2. The proposed energy-saving scheme of motor drive systems

Design and control strategy of the energy-saving scheme

The function of the energy storage unit is to store regenerative energy of the motor, and to supply the motor with the energy again when the motor needs. Energy recycling is achieved and the overall efficiency of the system is improved. To realize the above-mentioned function, the DC-DC converter together with its control strategy and the ultracapacitor group are required to design, as shown in Fig.3. Triple structure is employed in the bidirectional DC-DC converter, in which the low level end is connected to ultracapacitors and the high level end with the DC link.

The relationship between DC voltage U_{dc} and effective value U_{ac} of the AC supply is:

$$U_{dc} \approx 1.4U_{ac} \tag{1}$$

For a system powered by three-phase 380V voltage, U_{dc} is around 530V. Taking the grid voltage fluctuation into account, the rated voltage on the high level end of the DC-DC converter is designed as 650V and 480V for the low level end.

As shown in Fig.2, the control system of the bidirectional triple DC-DC converter includes a charging controller (Buck) and a discharging controller (Boost). Both of them employ double closed-loop structure with current loop and voltage one. Regulators in both voltage loop and current loop use PI controller. Output of the voltage loop is regarded as the current reference, and output of the current loop is used for PWM modulation. In order to reduce current ripples of inductors, the carrier phase-shifted PWM is adopted.

Operation state of the controller is decided by the switch logic, as shown in Fig.3. The DC link voltage can be controlled like Fig.4 under the motor brake and electromotion. When the DC link voltage increases when the motor brakes, a hysteretic comparator is carried out between the threshold value U_{dcch} (650V) and the measured voltage U_{dc} to chopper for charging. Considering the current limitation in the closed-loop control of Buck as I_{lmax}, and duty of the chopper as D, the

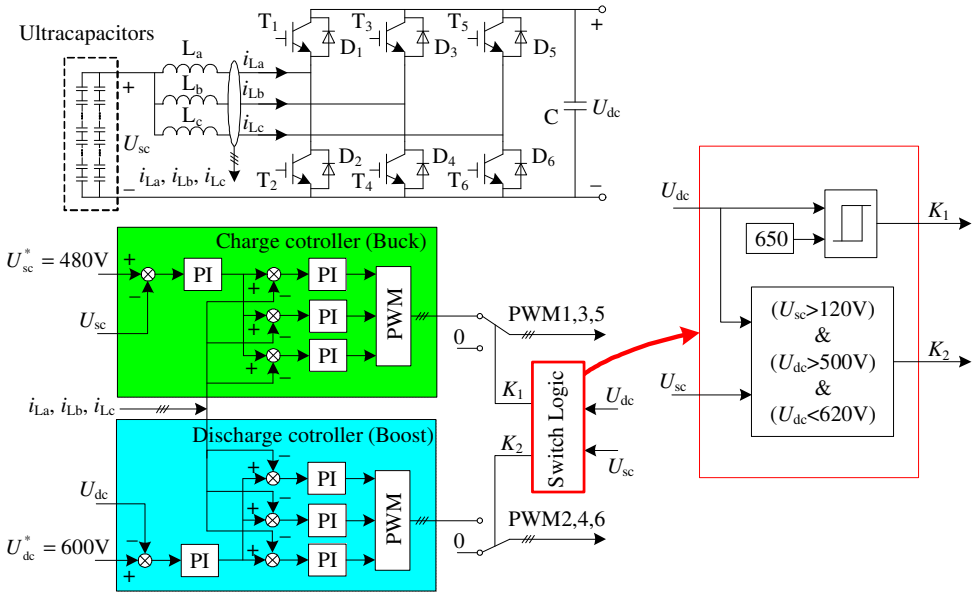

Fig.3. Topology and control strategy of the energy storage unit

DC-DC converter can be equivalent to a resistor R_{eq} for the DC link:

$$R_{eq} = \frac{U_{dc}}{3DI_{Lmax}} \tag{2}$$

And, the regenerative energy is stored into the ultracapacitor group by chopper with the hysteresis comparation between U_{dc} and U_{dcch}.

When the motor transit from brake to electromotion, the DC link voltage will decline to $U_{dcdisch}$ (620V). Then Boost control starts work, and the DC link voltage is controlled as the reference U_{dc}^{*}. Here, the energy in ultracapacitors is offered to the motor. With declining of the voltage on the ultracapacitor group, the DC-DC converter will stop when the ultracapacitor voltage declines to U_{scmin}. And then, the motor is powered by the AC supply. These threshold voltage values in the scheme meet the following relationship:

$$U_{dcrec} < U_{dc}^{*} < U_{dcdisch} < U_{dcch} \tag{3}$$

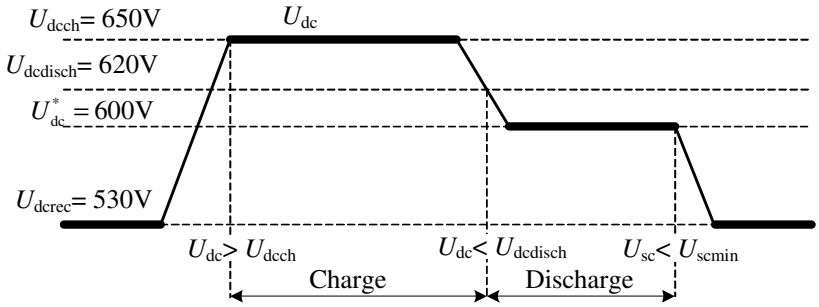

Fig.4. DC link voltage waveform during charge and discharge

Simulation results

The simulation model of the proposed energy-saving control scheme is set up by Matlab. Vector controlled three-phase permanent magnet synchronous motor is considered, the motor parameters include: rated rotate speed 2000rpm, rated current 24.5A, rated torque 27Nm, torque coefficient

1.1Nm/A and rotational inertia 89.5×10^{-4}Kgm^2. The AC supply voltage is 380V, switching frequency is 4kHz and the load is 27Nm. The initial voltage of ultracapacitor group is 100V with limited value U_{scmin} 120V. The simulation results are shown in Fig.5. The initial speed of the motor is zero, and change to –2000rpm at 0.1s and 2000rpm at 0.4s, respectively. The speed, torque and current waveforms are shown in Fig.4(a)(b). Before 0.1s, the speed is zero, motor does not need energy and the ESS does not work, which is shown in Fig.4(e)(f). At 0.1s, the speed is –2000rpm, and the motor works as a generator. At this moment, the regenerative energy is used to charge ultracapacitors through the bidirectional DC-DC converter as a Buck, shown in Fig.4(c)(d). The charge controller keeps the DC link voltage stable at 650V, as shown in Fig.4(g). At 0.4s, the speed is changed to 2000rpm, the energy that the motor needs is offered by the ESS. Meanwhile, the DC link voltage is stable at 600V. The voltage on ultracapacitors declines until to 120V, the ESS will stop and then the motor fed by the AC supply. Totally, the simulation results demonstrate that the proposed energy-saving scheme can realize recycling of regenerative energy of the motor and improve efficiency of the motor drive system.

Conclusion

An energy-saving control scheme for motor drive systems is proposed in this paper, which is in parallel with the DC link as the energy storage system composed of a bidirectional DC-DC converter and ultracapacitor group. When the motor brakes, the regenerative energy is absorbed, and when the motor runs as electromotion, the stored energy is offered to motor again. The proposed scheme can recycle the braking energy and improve efficiency of the motor drive system, which is validated by the simulation results.

Keywords: Induction Motor; Open-End Winding; Dual Inverter; SVPWM Strategy; Common-Mode Voltage

Abstract. Dual inverter fed open-end winding induction motor (OEW-IM) is a new solution for multilevel drive. Comparing with traditional multilevel converters, the dual inverter is being interested in for its more flexible current control, the absence of fluctuating neutral point, and fault-tolerant capability. This paper analyzes the potential common-mode voltage (CMV) in the open-end winding induction motor system, and proposes a new space vector PWM (SVPWM) strategy to reduce the CMV. The proposed method is validated by simulations and experiments.

Introduction

With the development of multilevel converters, a dual inverter fed open-end winding induction motor drive is proposed [1] [2]. The dual two-level inverter can produce space voltage vector locations identical to that of a three-level inverter, and avoids the undesirable fluctuating voltage on the series DC capacitors. Recently, several power converter configurations derived from the dual inverter are presented [3]-[5]. A common DC link or isolated DC sources can be adopted in the dual inverters. In the common DC-link dual inverter, the zero-sequence current is detrimental to the system performance [6]-[8]. As to the dual inverter with isolated DC sources, the zero-sequence current can be eliminated but the common-mode voltage may produce axis current and shorten longevity of the motor. In order to eliminate the CMV in the dual inverter fed by isolated DC sources, the SVPWM strategy employing these switching combinations that do not contribute to the CMV is introduced [9]. Nevertheless, the maximum amplitude of reference voltage vector by these combinations is equal to DC link voltage V_{dc}, and the maximum DC link voltage utilization can not be obtained. To increase the DC voltage utilization, a new SVPWM strategy is proposed in this paper. The proposed strategy can eliminate the CMV completely when the magnitude of reference voltage is less than V_{dc} and the CMV can be restrained when the reference is larger than V_{dc}. The realization algorithms are introduced, and the method is validated by the simulation and experimental results.

Dual Inverter Fed Open-End Winding Motor System

The open-end winding induction motor drive system fed by dual inverters is shown in Fig.1. In this configuration, neutral connection of the motor is separated and fed by the dual two-level inverter from the both ends of the winding.

In Fig.1, the dual inverter is composed of two inverters, INV1 and INV2. The voltage vectors of the two inverters can be defined as follows:

$$\begin{cases} \boldsymbol{V}_{s1} = 2(v_{a1o} + v_{b1o}e^{j2\pi/3} + v_{c1o}e^{j4\pi/3})/3 \\ \boldsymbol{V}_{s2} = 2(v_{a2o'} + v_{b2o'}e^{j2\pi/3} + v_{c2o'}e^{j4\pi/3})/3 \end{cases} \tag{1}$$

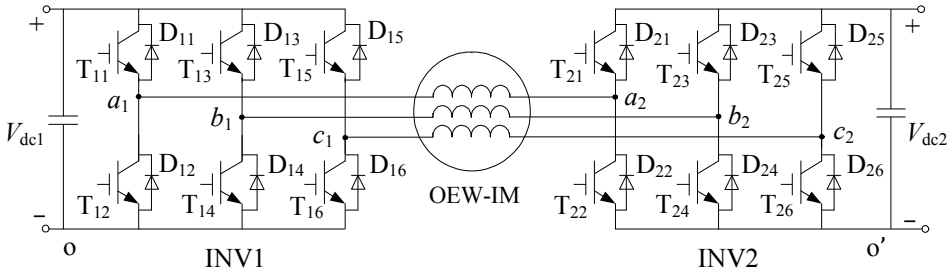

Fig.1. Open-end winding induction motor fed by dual inverter with isolated DC sources

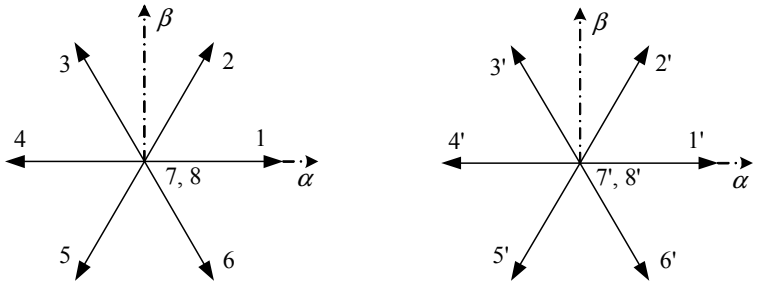
In a two-level inverter, there are six switches on three legs. Eight combinations of these switches can produce eight voltage vectors including two zero vectors. Accordingly, space distribution of the voltage vectors by a single inverter is shown in Fig.2(a) for INV1 and Fig.2(b) for INV2, respectively.



(a) INV1 (b) INV2

Fig.2. Space voltage vectors produced by INV1 and INV2

Thus, three phase voltages of the induction motor in Fig.1 are described by:

$$\begin{cases} v_{a1a2} = v_{a1o} - v_{a2o'} + v_{oo'} \\ v_{b1b2} = v_{b1o} - v_{b2o'} + v_{oo'} \\ v_{c1c2} = v_{c1o} - v_{c2o'} + v_{oo'} \end{cases} \tag{2}$$

Then, the space voltage vectors produced by the dual inverter can be solved by:

$$\boldsymbol{V}_s = 2(v_{a1a2} + v_{b1b2}e^{j2\pi/3} + v_{c1c2}e^{j4\pi/3})/3 = \boldsymbol{V}_{s1} - \boldsymbol{V}_{s2} \tag{3}$$

In other words, the output voltage vectors of the dual inverter can be combined by those from two inverters. There are 64 states totally, corresponding to 64 switching combinations, which can produce 18 non-zero space vector locations and a zero one. The distribution of these vectors in αβ reference frame is shown in Fig.3. The 19 vectors form 3 hexagons, the small hexagon ABCDEF, the middle one HJLNQS and the large one GIKMPQ respectively. According to the modulation principle of SVPWM, voltage vectors of the three hexagons can be used to synthesize the expected reference vector. Different from the two-level SVPWM, some vectors in the dual inverter may bring the CMV in the open-end induction motor drive.

SVPWM and Analysis of Common-Mode Voltage

For the system described in Fig.1, the sum of three phase currents is zero. As a result of the symmetrical back electromotive forces in the motor, the sum of three phase winding voltages is also zero, that is $u_{a1a2}+ u_{b1b2}+ u_{c1c2}=0$. Based on (2), the CMV can be obtained by:

$$u_{oo'} = -\frac{1}{3}(u_{a1o} + u_{b1o} + u_{c1o} - u_{a2o'} - u_{b2o'} - u_{c2o'}) \tag{4}$$

For a three-phase open-end winding motor, the 64 switching combinations are substituted into (4), respectively, and then their CMVs are shown in Table 1.

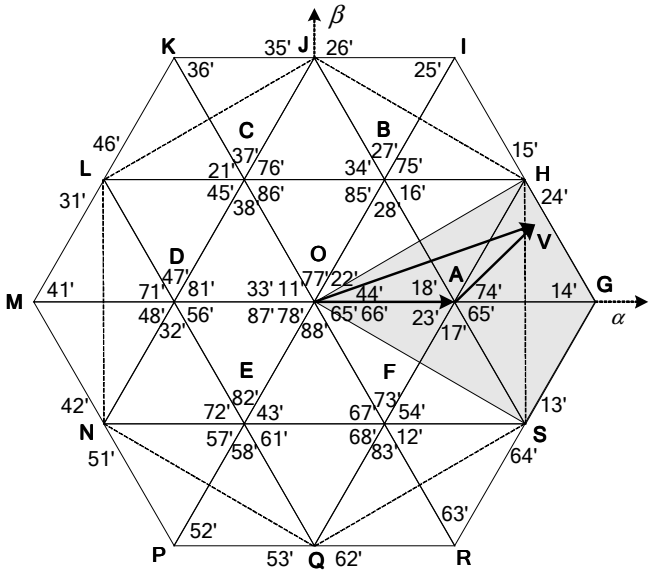


Fig.3. Distribution of space voltage vectors

Table 1 CMVs under various switching states

CMV	$-V_{dc}$	$-2V_{dc}/3$	$-V_{dc}/3$	0	$V_{dc}/3$	$2V_{dc}/3$	V_{dc}
Space voltage vectors	78’	74’, 76’, 72’, 58’, 38’, 18’	75’, 73’, 54’, 34’, 14’, 71’, 56’, 36’, 52’, 32’, 48’, 16’, 12’, 68’, 28’	88’, 77’, 66’, 55’, 44’, 33’, 22’, 11’, 53’, 35’, 15’, 51’, 13’, 31’, 46’, 64’, 24’, 42’, 26’, 62’	57’, 37,’ 45’, 43’, 41’, 17’, 65’, 63’, 25’, 23’, 84’, 61’, 21’, 86’, 82’	47’, 67’, 27’, 85’, 83’, 81’	87’

From Table 1, the CMVs produced by these voltage vectors on the middle hexagon HJLNQS are zero. Therefore, the CMVs will not be produced by employing these voltage vectors in SVPWM strategy. The traditional two-level SVPWM algorithm can be used to accomplish the modulation of the middle hexagon, but the sectors in the middle hexagon rotate 30 degree clockwise corresponding to that in the small one.

The modulation index m is defined to denote DC link voltage utilization as:

$$m = \left|\boldsymbol{V}_{\text{ref}}\right| / V_{\text{dc}} \tag{5}$$

Where, $\boldsymbol{V}_{\text{ref}}$ is the reference voltage vector. From Fig.3, the maximum linear modulation index of the dual inverter is $m_{\max}$=1.15. According to the modulation principle of SVPWM, the maximum amplitude of the synthesized reference voltage vector is V_{dc} by the middle hexagon, which is the radius of inscribed circle of the middle hexagon. Under this condition, the modulation index is one, and does not reach the maximum one obviously. Thus, when the amplitude of the reference vector is larger than V_{dc}, namely m>1, voltage vectors on the large hexagon are required to synthesize. The region of the large hexagon can be divided into 6 small hexagons, OBHGSF, OCJIHA, ODLKJB, OENMLC, OFQPND and OASRQE, which center on A, B, C, D, E and F, respectively. As shown in Fig.3, when the reference vector **OV** locates inside the shadow of the hexagon OBHGSF, it can be divided into two parts, namely **OV**=**OA**+**AV.** Moreover, **OA** can be obtained by vector 1 from INV1 (shown in Fig.2(a)), and the fixed switching state remains during one switching period. Meanwhile, **AV** can be obtained by modulating in the hexagon OBHGSF. In other words, **OV** can be achieved by making INV1 locate on vector 1 and modulating INV2. Then, **AV**=**OV**–**OA**, and the relationship for αβ components of vector **AV** and **OV** is:

$$v_{\text{AV}\alpha} = v_{\alpha} - \frac{2}{3}V_{\text{dc}};\ \ v_{\text{AV}\beta} = v_{\beta} \tag{6}$$

Similarly, when **OV** locates inside the hexagon OCJIHA, there is **OV**=**OB**+**BV**. **OB** is obtained by the vector 2 from INV2, and **BV** by modulation of INV1 in the hexagon OCJIHA. Successively, **OV** can be achieved by separating **OV** in to two parts, as **OV**=**OX**+**XV, (X**=**A**, **B**, **C**, **D**, **E**, **F)**. Here, **OX** is produced by one inverter and **XV** by the other one. To simplify the algorithm, the unified

pulse width modulation [10] is adopted to synthesize **XV** in these small hexagons. First, convert the reference vector into three phase reference frame by the inverse Clarke transformation:

$$\begin{bmatrix} v_{\mathrm{XVa}} \\ v_{\mathrm{XVb}} \\ v_{\mathrm{XVc}} \end{bmatrix} = \frac{2}{3}\begin{bmatrix} 1 & 0 \\ -1/2 & \sqrt{3}/2 \\ -1/2 & -\sqrt{3}/2 \end{bmatrix}\begin{bmatrix} v_{\mathrm{XV}\alpha} \\ v_{\mathrm{XV}\beta} \end{bmatrix} \tag{7}$$

The corresponding active times are defined as, respectively:

$$T_{\mathrm{a}} = Tv_{\mathrm{XVa}}/V_{\mathrm{dc}};\ \ T_b = Tv_{\mathrm{XVb}}/V_{\mathrm{dc}};\ \ T_{\mathrm{c}} = Tv_{\mathrm{XVc}}/V_{\mathrm{dc}} \tag{8}$$

Where, T is the switching period. The effective time T_{eff}, zero vector time T_0, and offset time T_{offset} are defined as, respectively:

$$T_{\mathrm{eff}} = T_{\max} - T_{\min};\ \ T_0 = T - T_{\mathrm{eff}};\ \ T_{\mathrm{offset}} = T_0/2 - T_{\min} \tag{9}$$

Where, $T_{\max}$ and $T_{\min}$ represent the maximum and minimum value of T_{a}, T_{b}, T_{c}, respectively. Then, conducting times of top switches in the inverter are:

$$T_{\mathrm{ga}} = T_{\mathrm{a}} + T_{\mathrm{offset}};\ \ T_{\mathrm{gb}} = T_{\mathrm{b}} + T_{\mathrm{offset}};\ \ T_{\mathrm{gc}} = T_{\mathrm{c}} + T_{\mathrm{offset}} \tag{10}$$

According to the modulation method above, the voltage vector with maximum amplitude of $2\sqrt{3}V_{\mathrm{dc}}/3$ can be achieved. However, the CMV may be produced during modulating with the large hexagon vectors. For example, when the reference vector **OV** locates inside the triangle AHG, vector 17', 14', 15', and 18' are used and the CMVs contributed by each vectors are $V_{\mathrm{dc}}/3$, $-V_{\mathrm{dc}}/3$, 0, and $-2V_{\mathrm{dc}}/3$, respectively. And their active times are $T_0/2$, T_1, T_2, and $T_0/2$. Then, the CMV during one PWM period is:

$$v_{\mathrm{oo'}} = \frac{V_{\mathrm{dc}}}{3}\times\frac{T_0}{2} + (-\frac{V_{\mathrm{dc}}}{3})\times T_1 + (-\frac{2V_{\mathrm{dc}}}{3})\times\frac{T_0}{2} = -\frac{V_{\mathrm{dc}}}{6}(T_0 + 2T_1) \neq 0 \tag{11}$$

Where, T_1, T_2 and T_0 are the active times of **AG**, **AH** and point **A**. From (11), the CMV is not zero when the modulation strategy above is adopted.

New SVPWM Strategy Suppressing Zero-Sequence Voltage

Here, how to restrain the CMV will be discussed. If one defines active time distribution factor x （0<x<1）for zero vectors, and supposes the active time of vector 17' is xT0 and that of 18' is (1-x)T0 , then the CMVs can be expressed as:

$$v_{\mathrm{oo'}} = \frac{V_{\mathrm{dc}}}{3}\times\frac{xT_0}{2} + (-\frac{V_{\mathrm{dc}}}{3})\times T_1 + (-\frac{2V_{\mathrm{dc}}}{3})\times\frac{(1-x)T_0}{2} \tag{12}$$

To restrain the CMV furthest, one can let $v_{\mathrm{oo'}}$=0 and obtain:

$$x = \frac{2}{3} + \frac{T_1}{3T_0} \tag{13}$$

By redistributing the active time for zero voltage vectors, one can obtain (14) based on (8).

$$T_{\mathrm{offset}} = \frac{1}{3}(T_0 - T_2) - T_{\min} \tag{14}$$

When vector AV locates in the shadow in Fig.3, T1=Tmid–Tmin. And based on Tmax+Tmid+Tmin=0, one can get the offset time according to (9) as:

$$T_{\mathrm{offset}} = \frac{T_0 + T_{\mathrm{eff}}}{3} = T/3 \tag{15}$$

Substituting the results into (10), the conducting times of top switches in INV2 can be achieved. The same process can be used for the situations that vector OV locates in other regions. Further analysis shows that the same result Toffset =T/3 can be obtained wherever OV locates. Thus, the modulation strategy restraining the CMV can be simplified according to the conclusion.

Based on (13), when T1=T0, x=1, and the limitation for eliminating the CMV is reached, and meanwhile |OV|=$2\sqrt{3}V_{\mathrm{dc}}/3$. When the amplitude of the reference vector OV is larger than $2\sqrt{3}V_{\mathrm{dc}}/3$, the proposed modulation strategy can not eliminate the CMV completely but retrain it to the greatest degree fortunately.

Simulation and Experimental Results

The model of a vector controlled open-end winding induction drive fed by the dual inverter is established by Matlab/Simulink. The induction motor's parameters are as follows: rated voltage 380V, rated current 6.8A, rated frequency 50Hz, stator resistance 2.375Ω, stator inductance 189.2mH, mutual inductance 181.4mH, rotor resistance 1.741Ω, rotor inductance 188.9mH, rotary inertia 0.0109 Kgm² and polepairs 2. The simulation results are shown in Fig.4. Phase-a voltage is shown in Fig.4(a), three phase currents are shown in Fig.4(b), and motor speed and torque are shown in Fig.4(c). Fig.4(d)(e) and (f) show the CMV waveforms by modulating with the middle hexagon, the large hexagon and the proposed SVPWM, respectively. From the simulation results, the CMV is almost zero when the middle hexagon is used for modulation. However there is obvious CMV when the large hexagon is adopted. When the modulation index is larger that one (m>1), the CMV can be restrained effectively by the proposed method. The experiment results for the modulation with the large hexagon and the proposed method are shown in Fig.5, respectively. The experiment results are consistent with the simulation ones, which validate the proposed SVPWM strategy.

Conclusion

The same voltage vector locations can be obtained in the open-end winding induction motor system fed by dual inverters as those in three-level inverters. Comparing with two-level inverters, the configuration can improve the DC link voltage utilization significantly. The CMV problem in dual inverters fed by isolated DC sources is discussed in this paper, and a now SVPWM modulation strategy for restraining the CMV is proposed. The proposed strategy can eliminate the CMV completely when the modulation index m<1 and restrain the CMV effectively when m>1. The simulation results as well as experimental ones validate the presented method.

Keywords: Braking Strategy; brake pedal simulator; pedal feel; vehicle test.

Abstract. Brake pedal feel is intuitive feelings for the driver and affected vehicle safety performance. Due to the participation of the motor, brake force distribution and the original pedal feel of the driver would be changed. Based on the traditional hydraulic unit of ESC, Jilin University developed a braking energy recovery system of uniaxial decoupled. A series of fixed partition coefficient control strategy was developed, coordinated control of electrical regenerative braking and hydraulic braking was carried out. Vehicle test was carried out for coordinated braking strategy, parallel strategy and traditional control strategy. Vehicle test results show that the brake pedal travel simulator and the coordinated braking strategy can improve the energy recovery, and ensure that the brake pedal feel is consistent with the traditional vehicle.

Introduction

Regenerative braking system converted the kinetic energy into other forms of energy and reused when vehicle was deceleration or braking [1]. Due to the participation of the motor, brake force distribution and the original pedal feel of the driver would be changed and vehicle safety, economy and comfort were affected. In order to improve the braking energy recovery rate and ensure the brake pedal feel, foreign car manufacturers developed many mature brake energy recovery systems[2-5], Such as the ECB system of Toyota , the EDIBS system of Nissan developed with Hitachi, the ESP-hev and HAS-hev system of BOSCH, regenerative braking system based ESC of Continental. Domestic was in infancy, some companies and universities proposed some new configuration system, and applied for a patent, but no actual product appearance. To solve the above problems and avoid the patents, Jilin University proposed a solution, that the hydraulic brake system and motor regenerative is decoupled for one axis, the pedal travel simulator was designed and developed independent [6].

System Architecture

Vehicle Introduction. In this paper, the target vehicle was a hybrid vehicle of domestic [7]. The vehicle technical parameters was shown in Table 1

Table 1 The main technical parameters

Parameter	Value
Vehicle mass	1524kg
Wheelbase	2675mm
Rolling radius	307mm
Motor rated power	20kw
Maximum motor power	40kw
Motor rated torque	130Nm
Maximum motor torque	260Nm
Battery voltage	288V
Battery capacity	6Ah
Main reduction ratio	4.313

Hardware Introduction. Jilin University brake system hardware solution was as shown in Figure 1. Normal state, the valve 1 is normally open, valve 2 is normally closed. When the vehicle was braking, valve 1 and valve 2 was energized, the valve 1 was used to cut off the hydraulic brake circuit between front axle and master cylinder. Valve 2 was used to control the work state of the simulator and simulate the pedal feel of the front axle. When the braking torque of the motor is insufficient or braking torque of demand increases, It need to be compensated by hydraulic brake, Active increase pressure was achieved by hydraulic pump of the ESC hydraulic unit and the check valve. When the pedal travel simulator fails, vehicle restored the traditional braking to ensure the safety of vehicle.

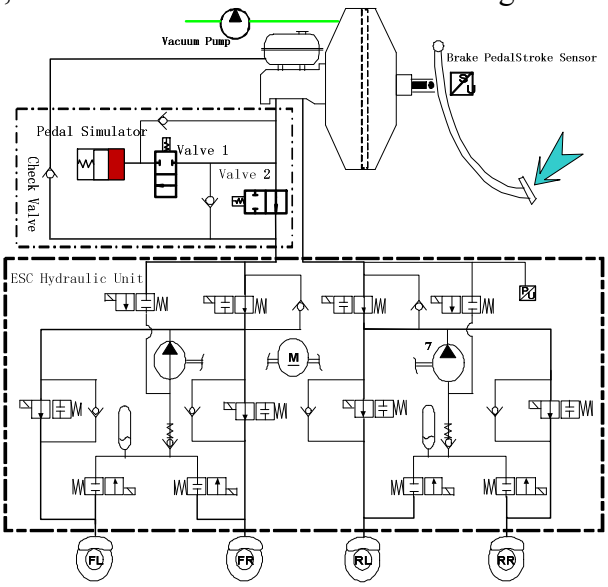

Fig 1 Hardware solutions of hydraulic braking system

Control Strategies.

In this paper, there are three control strategies: a fixed percentage of brake force distribution control strategy, parallel regenerative braking control strategies and the traditional control strategy were divided into two cases, the motor braking torque was 80Nm for parallel regenerative braking control strategy. That these four control strategies were strategy A, strategy B, and strategy C.

Strategy A: a fixed percentage of brake force distribution control strategy [8] is used as brake torque distribution for the front and rear axles based on traditional distribution vehicles , that the front axle during braking remains a traditional car brake force distribution coefficient β unchanged. As shown in Figure 2.

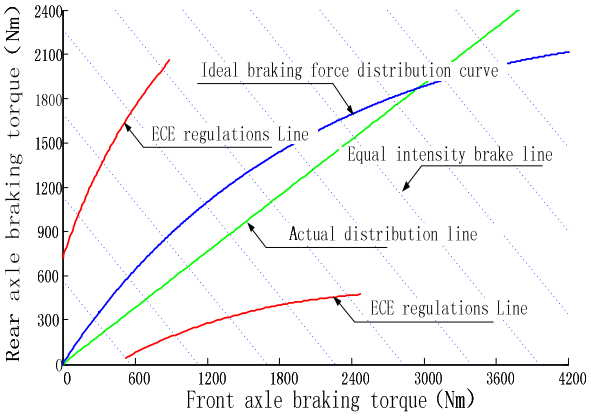

Fig2 Braking torque distribution method

Demand braking torque of front axle is described as:

$$T\_Req\_FA = \beta * T\_require \quad (1)$$

Demand braking torque of front axle is described as:

$$T\_Req\_RA = (1-\beta) * T\_require \quad (2)$$

Demand braking torque of front axle is described as:

$$T\_require = 2 * P\_RR * (C_f + C_r) \quad (3)$$

Here, T_Req_FA-demand braking torque of front axle; T_Req_RA-demand braking torque of front axle; T_require-demand braking torque of driver. P_RR-wheel cylinder pressure of right reart; C_f-brake effectiveness factor of front wheel; C_r-brake effectiveness factor of rear wheel.

Front axle braking torque could be consisted by motor torque and hydraulic braking torque. The demand braking force of front axle was the goal, to maximize the regenerative braking force of the motor, the shortfall was complemented by the hydraulic braking force of front axle. When the vehicle speed is below the minimum speed, reducing the braking force of the motor gradually and increasing front axle hydraulic braking force to ensure that the total braking force unchanged.

So the demand braking torque of motor and the demand hydraulic braking torque of the front axle were calculated as:

$$T\_Mot\_Req = \min(T\_Mot\_Max, T\_Req\_FA) \quad (4)$$

$$T\_Hyd\_FA\_Req = T\_Req\_FA - T\_Mot\_Act \quad (5)$$

Here, T_Mot_Req -demand braking torque of motor; T_Mot_max -maximum braking torque of motor; T_Hyd_FA_Req -demand hydraulic braking torque of front axle; T_Mot_Act -actual braking torque of motor.

Strategy B: Cancel simulator control, set the demand motor braking torque is 80Nm.

Strategy C: Cancel simulator control, set the demand motor braking torque is 0Nm.

Vehicle Test

Real vehicle test verification was carried out on high adhesion road, under speed 60km / h to verify the four control strategies proposed above, the brake pedal is divided into fast and slow speeds. Test results are shown in Figs.

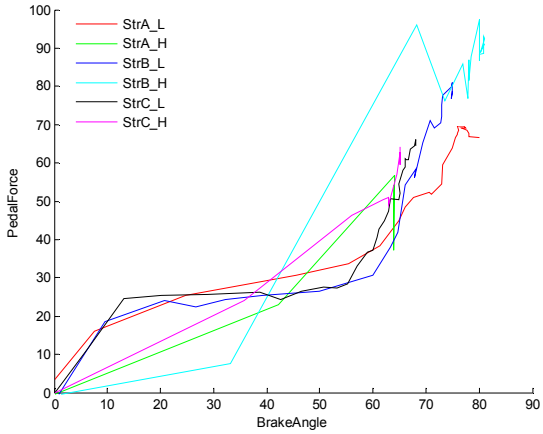

Fig3 brake pedal angle and force

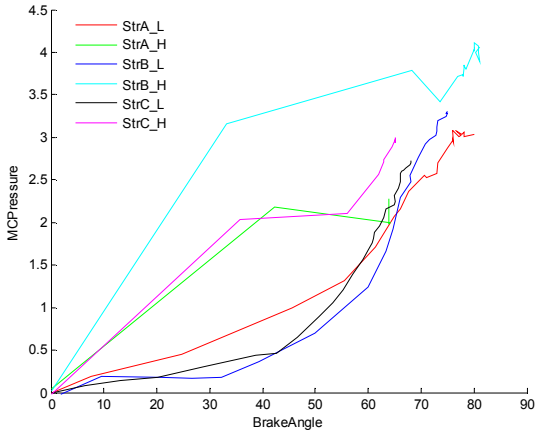

Fig4 Brake pedal angle and vehicle deceleration

StrA_L is the condition of strategy A and pedal speed is low; StrA_H is the condition of strategy A and pedal speed is high; StrB_L is the condition of strategy B and pedal speed is low; StrB_H is the condition of strategy B and pedal speed is high; StrC_L is the condition of strategy C and pedal speed is low; StrC_H is the condition of strategy C and pedal speed is high.

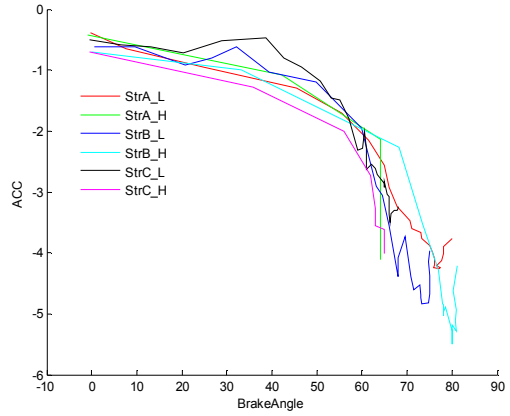

Fig5 Brake pedal angle and master pressure

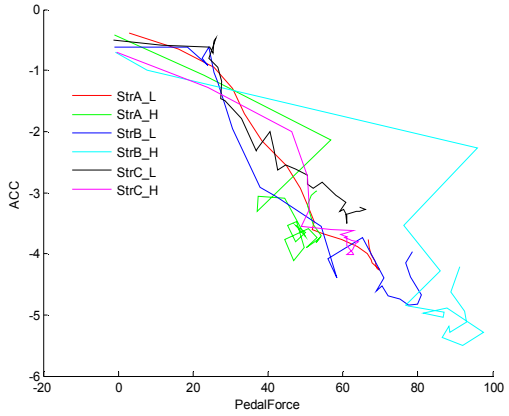

Fig6 Brake pedal force and vehicle deceleration

Pedal feel of coordinated control algorithm is basically same with the original car pedal feel , Parallel braking control strategy, due to entry and exit of the motor braking torque pedal feel changes, especially exit stage, the driver braking feeling becomes 'soft' and impacts vehicle safety.

Results

Parallel braking strategy, in order to ensure safety, motor braking torque values cannot be too large, and therefore energy recovery is finite, the driver braking feel becomes 'soft' when motor torque exits and impact vehicle safety performance. Coordinated braking strategy can use torque motor fully and ensure the pedal feel to consistency with the original vehicle.

Keywords: Fast disruption mitigation valve, Control system

Abstract. Disruptions are highly undesired events during tokamak plasma discharge, and now massive gas injection (MGI) is the most promising technique mitigating all negative consequences of a disruption. A fast disruption mitigation valve has been designed and tested for J-TEXT tokamak based on eddy-current repulsion mechanism. In order to get the key operating parameters of the valve such as voltage and gas pressure in real time and to realize remote automatic control, a control system on LabVIEW software platform based on hardwires of sensors, relays, Advantech industrial computer and NI-6221 data acquisition card has also been designed. The experimental test results show that the control system works well.

Introduction

Tokamak is the most advanced device of artificial fusion machines. The tokamak operation on several mega-ampere（MA） and thus contains an abundant source of energy. But during tokamak plasma discharge, because of plasma MHD instability, an unfavorable current distribution can lead to the creation of internal plasma modes and to enhanced losses of energy and particles or, in the worst case, to an abrupt termination of the plasma current. This process is called disruption [1].

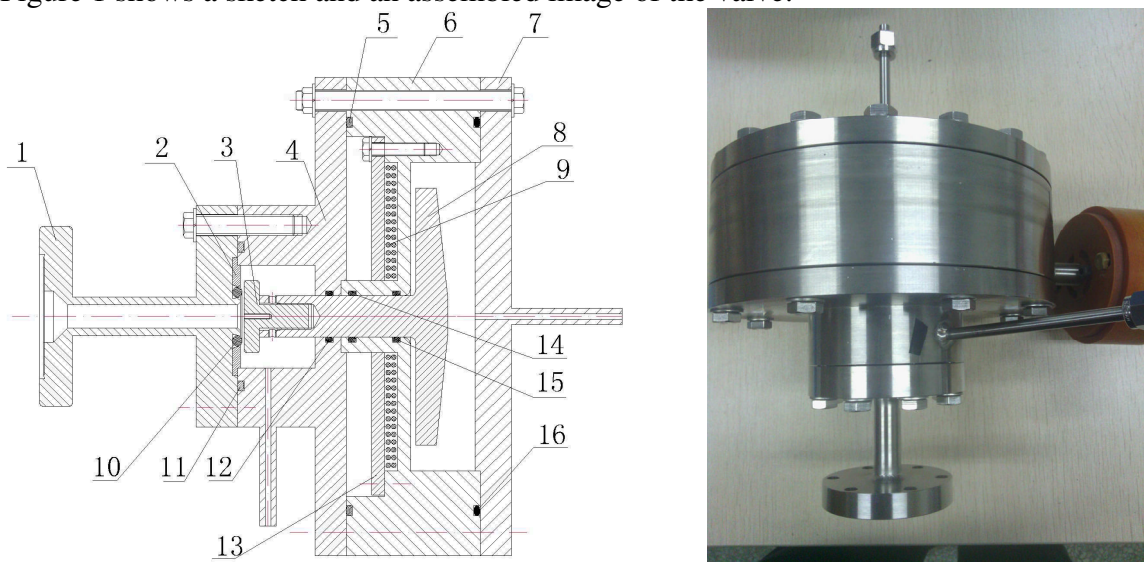
Disruptions are highly undesired events. In current large size tokamaks, they can cause significant machine damage. Major disruption during tokamak operation can cause a severe damage on tokamak, especially in the next step large devices such as ITER. During disruptions, the plasma energy would loss within 1 ms and result in a large force load on vessel components. The runaway electrons (REs) with hundreds mega-electron-volt (MeV) energy also generate due to the high electrical field. The REs could impact and damage the plasma facing components [1, 2].

In order to mitigate the negative effects of a disruption, MGI is selected because of its important advantages: the gas flows very fast and can fill the whole vessel immediately which leaving no space for the development of runaway electrons. As the warning time prior to the disruption given by MHD modes or other signatures can only amount to 100 ms or even shorter, the most important for mitigation is a very fast reaction of massive gas injection device.

A fast disruption mitigation valve has been developed on J-TEXT successfully. This paper introduces a detailed design and test of the control system for the fast disruption mitigation valve which could open 0.5 ms after a TTL trigger signal, the control system can get key operating parameters of the valve such as voltage and gas pressure in real time and realize remote automatic control. The basic construction of the valve system will be presented firstly, and then a detailed design of the valve control system based on LabVIEW will be shown, test results and summary are given at last.

Construction of the valve system

Figure 1 shows a sketch and an assembled image of the valve:



(a) (b)

FIG. 1, (a) Structure of the valve: (1) CF 35 flange; (2) washer; (3) removable piston; (4) work chamber; (5), (10), (11), (12), (14), (15), (16) o-rings; (6) back chamber; (7) cover; (8) mushroom piston; (9) coil; (13) platen, (b) image of the fast valve.

Figure 1 (a) shows structure of the valve. All the components contacted with vacuum vessel are made of stainless steel, except for the aluminum piston. To begin with its principle, the work and back chamber are filled with helium or argon, there's a strong force pressed on the mushroom piston and the o-ring (10) because of the difference of the actual areas on which the pressures are acting, when the capacitor (C=0.5 mF) is discharged through the coil an eddy current excited by a time-varying magnetic field will generate an electromagnetic force which opens the valve [2, 3]. The work chamber volume is about 30ml. The gas pressure can be selected between 1 and 50 bar but should be high enough in order to guarantee a fast gas flow into the discharge vacuum. The assembled image of the valve is shown in Fig.1. (b)

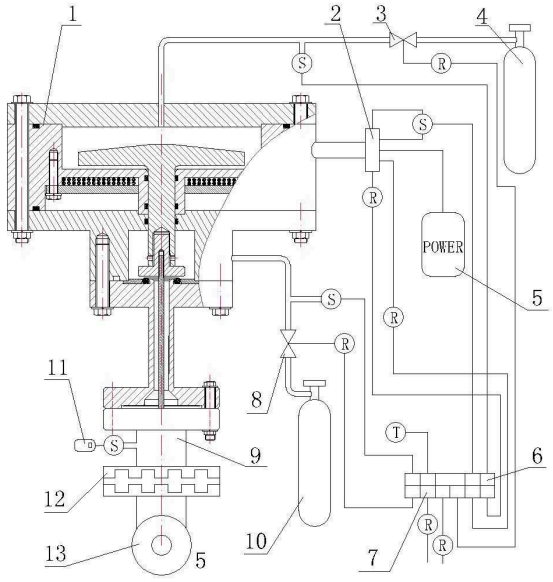


FIG. 2, Test bench (1) the valve; (2) capacitor; (3),(8) safety valves; (4),(10) gas bottles; (5) high voltage power supply of the capacitor; (6) signal input of the integrated controller; (7) signal output of the integrated controller; (9) vacuum chamber; (11) vacuum gauge; (12) flapper valve; (13) vacuum pump; S represents the sensors, T represents the trigger and R represents solid state relay.

For checking the valve and control system performance, a basic test and calibration bench system has been assembled in laboratory shown in Fig. 2 [2]. The valve system contains the disruption mitigation valve (1) assembled with a vacuum chamber (9), pressure sensors represented as S, trigger signal represented as T and solid state relays represented as R in the figure, a vacuum pump (13), a high voltage supply (5), and gas bottles (4), (10). The vacuum pump is located to pump out the injection chamber after each test. An integrated controller which contains signal input (6) and output (7) has been used.

First the safety valve (3) is opened which provides a force on the mushroom piston leading the fast valve (1) separated from the vacuum chamber (11). After that, the capacitance voltage, pressures in work chamber are changed to the desired value. The values of the capacitance voltage and pressures in both two chambers can be detected by the sensors and changed by switching the relays. At last, when the valve control system detects the trigger, it will output an open signal and the energy storage in the capacitor will be released through the coil and thus the fast valve will be opened.

Design and test of the valve control system

The main function of the control system is when a trigger signal of an intended disruption is detected, it outputs a high level TTL signal which will open the valve and thus a certain amount of gas is injected into the tokamak vacuum. The amount needed of gas injected vary on different plasma operation parameters. And during research, the mitigation effects of different capacitor voltage and different amount of the gas injected are very important. All the valve operation parameters need to be adjusted manually or automatically. In order to facilitate the experiment, two channels of A and B for charging the capacitor have been used as shown in Fig. 3(b). Channel A is used for automatic charge and B for manual. Another important consideration is keeping functions of aeration and charging the capacitor of the fast valve closed when detected the trigger signal for one second. And the fast valve opens a certain time that can be adjusted after getting the trigger signal for requirements of physical experiment.

Due to the complexity of the valve work environment (strong electromagnetic radiation), the output values of sensors have a small fluctuation which can cause repeated action of the relay. For the gas pressure and capacitance voltage is very high, the control system could have a noise tolerance ΔN, when the gas pressure or voltage exceed these settings, the control system will output a low TTL level and only when it decreases to ΔN smaller than the settings will the control system output a high TTL level (so called threshold protection).

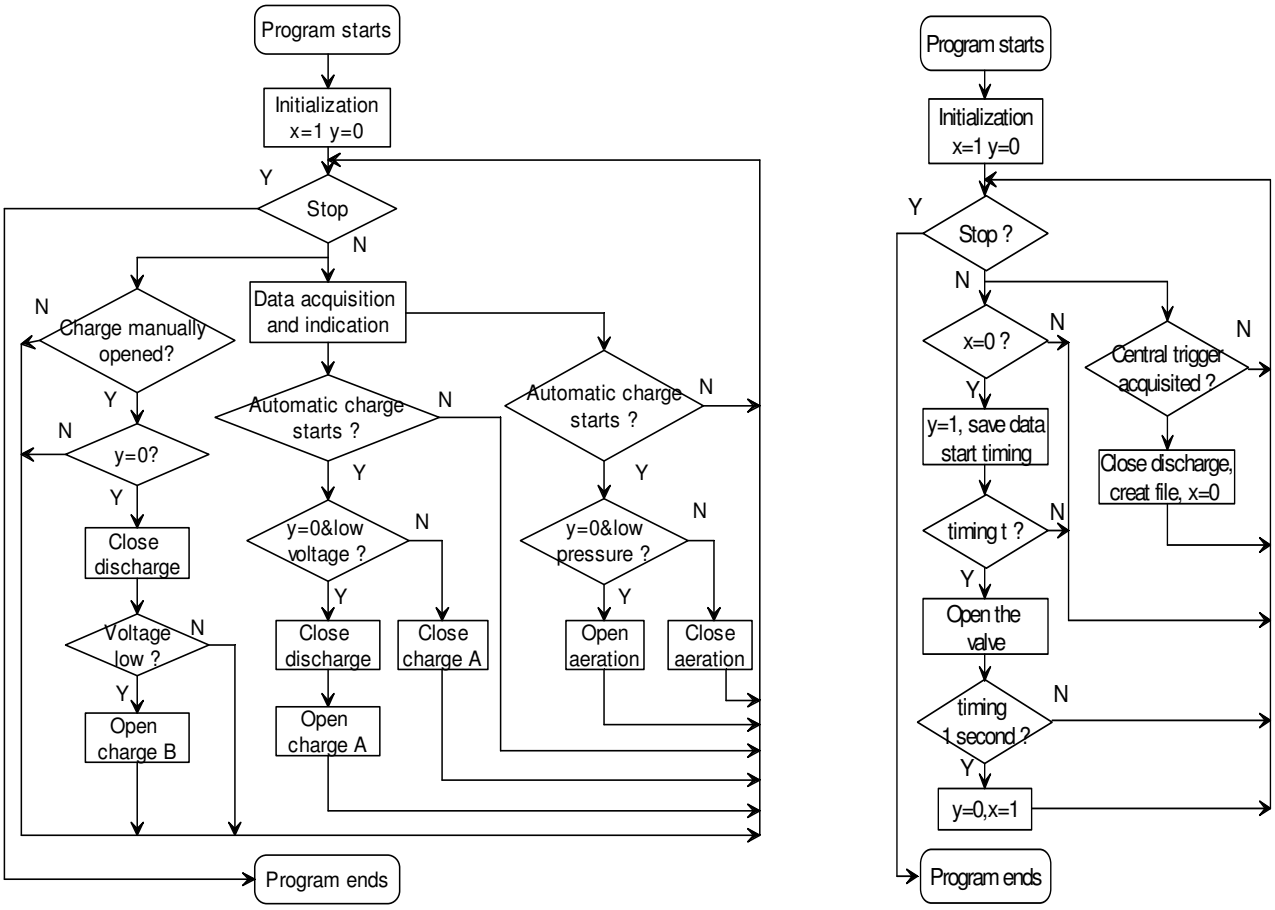
Main functions of the control system are listed below [4]:

a) Analog signal acquisition of the coil voltage and gas pressures of both work and back chamber
b) Digital signal acquisition of the trigger
c) Automatic aeration
d) Automatic and manual charging
e) Save specific data for further checking
f) Threshold protection

As shown in Fig. 2, the whole hardware bench is based on sensors, relays, Advantech industrial computer and NI-6221 data acquisition card. According to the requirements mentioned above, LabVIEW is chosen as the most suitable software development bench because of its great capabilities in the field of test, measurement and control. LabVIEW is a graphical programming language and it has a straightforward development interface which can reduce the development time of prototype design significantly and make it easier for future maintenance [4, 5].

To make the system performance better and solve contradiction between rapid trigger signal acquisition and relatively slow analog data indication, multithreading design is selected. A text file is created and the acquainted data will be saved into it when getting the trigger and data storage only lasts for one second.

The basic program flow diagrams are given below in Fig.3. [6]



(a) (b)

FIG. 3, (a) Control thread of the valve; (b) Trigger detection, timing and data storage thread

The interface of the control system is shown in Fig. 4.

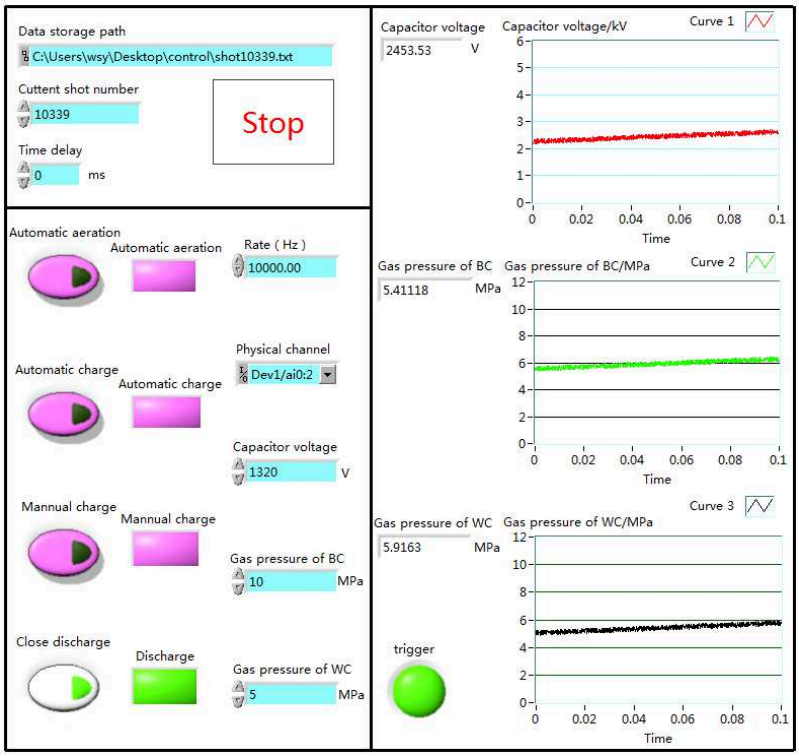


FIG. 4, Operation interface of the control system

As shown in Fig.4, the part of data acquisition and indication is on the right. And the parameters settings and control area are on the left. The software threshold protection is an important function of the control system and its realization is shown in Fig. 5. It is used as a subroutine in the system.

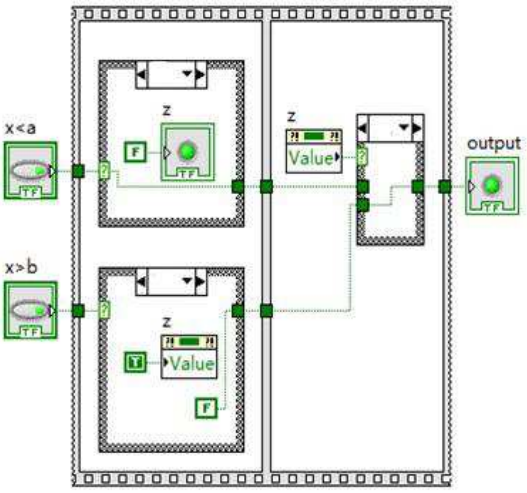

FIG. 5, Realization of the threshold protection

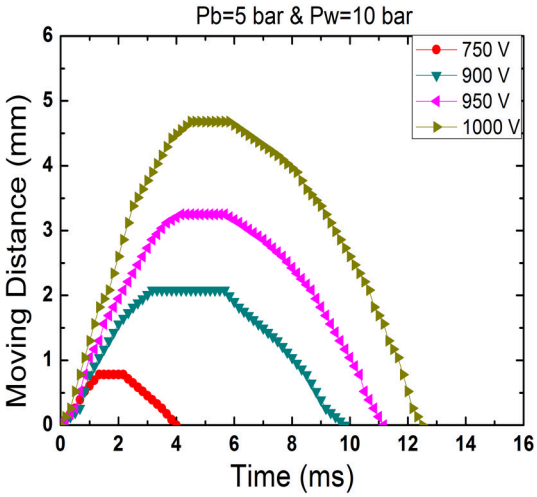

FIG. 6, Opening characteristics of the valve

Fig. 6 shows a typical waveform of the opening characteristics of the valve by a fast camera under different capacitor voltages ranging from 750V to 1000V (Pb represents gas pressure in back chamber and Pw in work chamber, both gases are argon). One can see the valve starts to open about 0.3ms after the trigger signal. After about 3ms, it is nearly completely open and 10ms later is closed again due to the high gas pressure in the back chamber when the capacitor voltage is 900V.

Summary

In this paper, a fast valve test bench and its real-time control system have been introduced. The control system can quickly get and adjust various parameters of the valve， which is very convenient for relevant physical experiments. To meet some special experimental requirements, the control system also has some particular functions such as accurate delayed trigger of the capacitor and locking functions of aeration and charge when the valve is open. The control system has a friendly interface and stable operation. During tests, it works well and will be used in the next round physical experiments on J-TEXT tokamak.

Keywords: electric vehicle; brushless dc motor; STM32; PID controller

Abstract. In view of the defects of the electric car driver motor technology, considering actual needs of the car running, relaxing the electrical power density and the limitation of the moment of inertia etc, focusing on the reliability, speed range and high efficient operation area of the motor, based on the analysis of permanent magnet brushless dc motor operation principle, this paper designed a low cost, high intelligent electric car permanent magnet brushless dc motor controller. Through the analysis, simulation, experiment and comparison, the results show that the control system has good dynamic response and steady state properties.

Introduction

With the advantages of high efficiency, high torque, easy to control, easy to cooling, maintenance costs low, long life, safe and reliable, low noise, magnetic brushless dc motor are widely used as a drive motor for electric vehicles. There are many factors restricting the development of electric vehicles, while motor controller is one of the important reasons. In general, permanent magnet brushless dc motor can be broken down into ontology, electronic commutation device and the rotor position sensor and so on three parts. The principle block diagram is shown in fig.1. in this diagram, the dc power provides power; the rotor position sensors detect the rotor position information and send signals to the electronic commutation circuit processing, then get the next position electronic switch signal conduction.

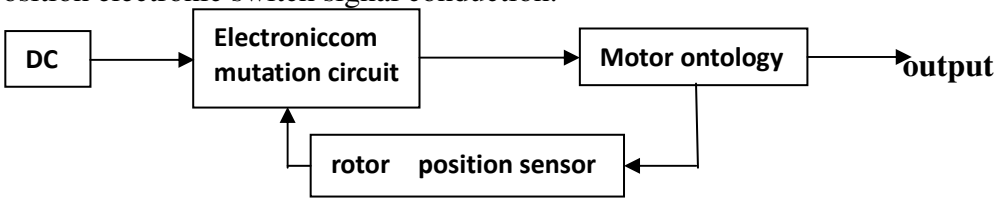

Fig.1 Brushless dc motor working principle diagram

Applied to motor control system of micro controller must be short interrupt time delay, namely good real-time response, and must have the superior control performance. Based on the above requirements, this design employ the STM32 series microcontrollers STM32F103, which is the core of the drive system. STM32F103 uses the 32-bit ARM Coaex-M3 kernel and it has the advantages of operation speed, high performance, low power consumption, high code density, etc. The kernel is specifically designed to meet the high performance, low power consumption, competitive price in the integration of embedded in the field of requirements. The traditional PID control algorithm is simple and has good robustness and reliability, so it is often used to control motor control system of position loop, current loop and speed loop.

Permanent Magnet Brushless Dc Motor Control System

The electric car driving system

In general, the electric car motor drive system include motor, sensor, control circuit and peripheral circuit, etc, as shown in Fig.2. The dc power which is provided by storage battery is

converting by IGBT power circuit for brushless dc motor, the system uses pulse width modulation to adjust the motor speed, and the current detecting circuit detects that the current signal and the torque for a given value for PID arithmetic to control the generation of PWM wave. By controlling the width of the pulse width of PWM waves to realize speed regulation; When the system is greater than the current over-current protection setting, the system produces the interruption, and interrupt handling subroutine into fault protection, blockading PWM wave output until the fault elimination.

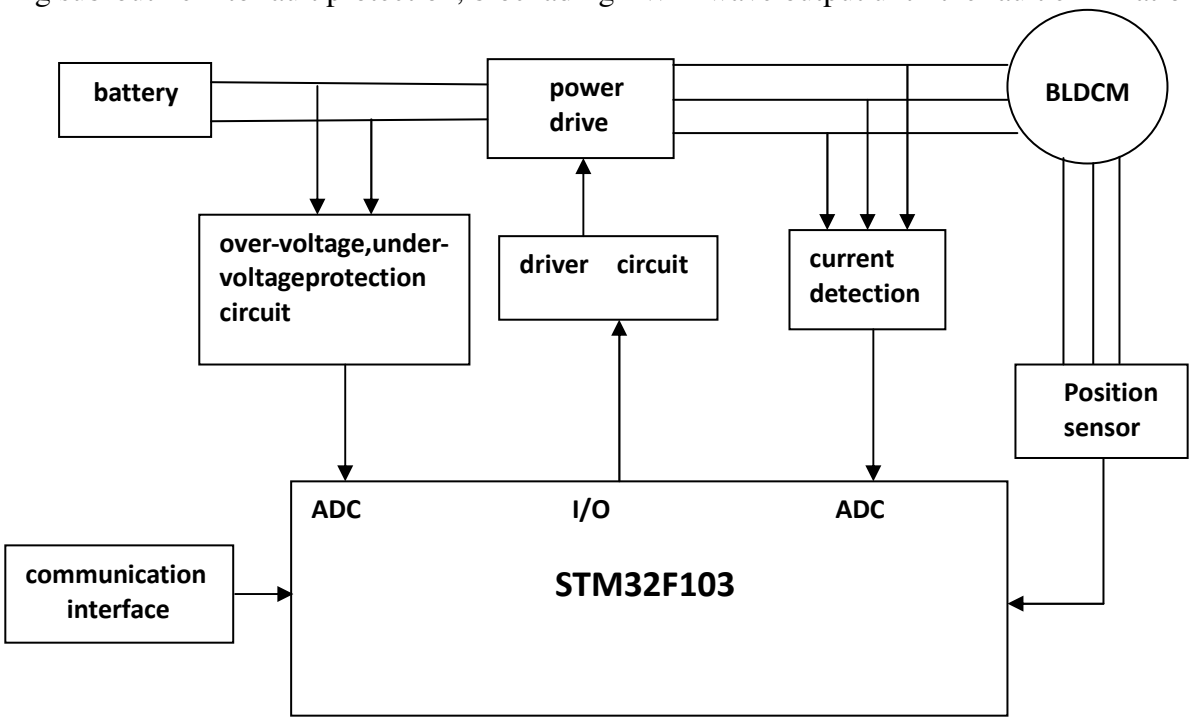

Fig.2 The hardware of control system block diagram

The Design of Controller Hardware Circuit

Controller hardware circuit is mainly composed of two parts: one is the peripheral control circuit, including the auxiliary power circuit, MOSF ET drive circuit and protection circuit and the contactor of driving circuit; Another piece is the core control circuit, the main STM32 micro-processor as the core, including two kinds of protection circuit, detection circuit, signal modulation circuit, CAN bus communication circuit, watchdog circuit and isolation of auxiliary power supply circuit.

①The Design Of The Hall Sensor Interface Circuit

The power supply for Hall sensor driver is usually 5v, so as to prevent the power against, it add a diode ,the hall sensor is open circuit output, have to be connected to a resistance, and add a low pass for hall sensor RC filter to prevent the strong magnetic fields in the brushless motors and brushless motor controller PWM carrier frequency interference.

②The Design Of The Protection Circuit

Over-current protection is the key content of the controller design, this scheme adopts the combination of hard and soft can effectively protect the security of the controller and motor load, and can play out the overload capacity of the load to reflect the intelligent control of the system. Over-current protection circuit must first solve the problems of the power circuit current sampling, this scheme adopts the hall transformer for high current sampling, can detect alternating current and direct current, even the transient peaks, which can realize power circuit and control circuit of electrical isolation; At the same time,it has good linearity, precision, fast dynamic response and superior electrical properties. In order to prevent the motor overload, controllers, temperature and battery aging damage, this scheme also designs the overvoltage protection circuit, temperature protection, low voltage protection circuit.

③The Design Of The Detection Circuit

Detection circuit system is divided into system self-check and running status detection, system self-check detect power detection module, motor, accelerator, brake state, battery voltage before the

operation the boot system, to ensure control system reliable. Running state detection detect the loop current, temperature and motor speed controller in the normal work process of the controller , through a serial port communication to transfer system parameters to the front of the instrument panel to make driving personnel's judgment convenient.

Control Strategy And Software Design

The system realizes current closed-loop PID control strategy by software, control algorithm for incremental PID is increment control algorithm. As a high intelligent degree of the controller, software is an important part of the controller. Fig.3 is the initialization program flow diagram and Fig.4 is the main program diagram.

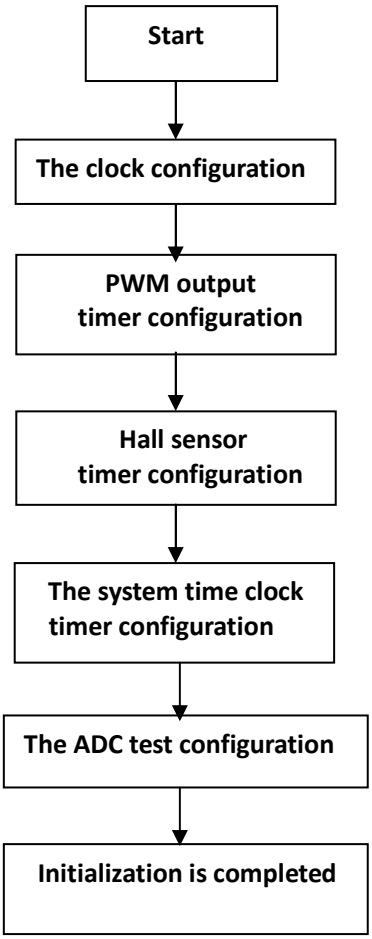

Fig.3 System initialization module block diagram

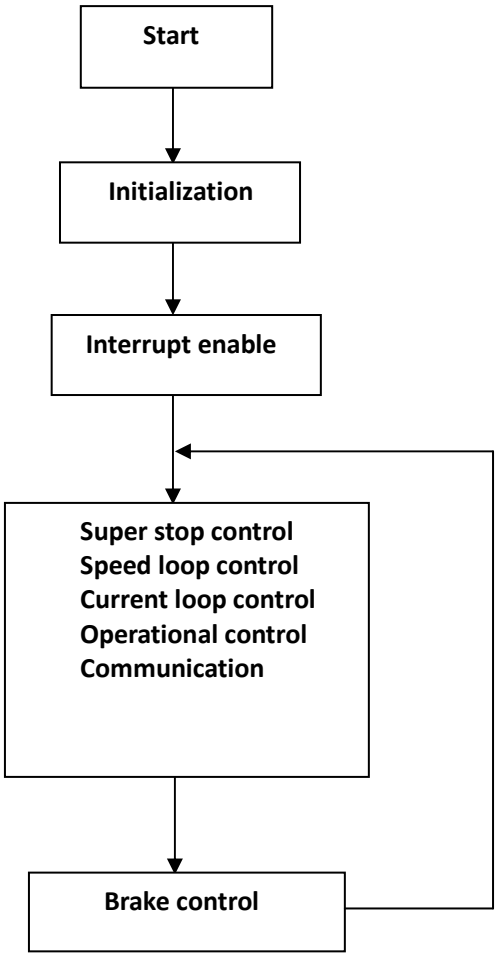

Fig.4 System main program module block diagram

The software is the embodiment of the intelligent controller software design including the generation of PWM function module, the signal detection module design, the software design overload protection, temperature protection, low voltage protection software design, communication module, software design and self-inspection process design and programmable power speed curve design. The controller for a variety of signal detection and communication processing happens in the interrupt. And in a reasonable amount of time the automatic updates occur. When the controller receives the external command it can respond immediately, so that the main loop or other modules can be read immediately when it needs to use a test of its corresponding variables, without need to wait, And read the latest data, make the main loop can focus on data processing and all kinds of exception handling. After systems reset every time, they first perform initialization program, then open another interruption, finally execute the main program.When systems have an interrupt request, they implement the interrupt service subroutine. Initialization programs include the definition of setting all kinds of system clock, interrupt vectors, initializes the I/O port initialization, the control

register setting and each function module. After the initialization is finished, the motor is started by the main programs to detect the rotor position information, and then to control the current loop speed loop, etc.

Experiment Results

The rated power in the experiment is 500w brushless direct current motor, under the condition of laboratory. The dc power supply a voltage of 72 v and the experimental results are observed by the oscilloscope. In the experiment, the motor can be safe and reliable to operation, and control effect is better, so the motor's overall experimental results are good.

Conclusions

The control design regard safety, reliability and stability as a goal, the designed controller has a more perfect protection function, self diagnosis and fault response function, and has good scalability, easy hardware upgrade ability. The controller hardware circuit is simple, low cost, easy to operation and maintenance.

Keywords: Permanent Magnet Synchronous Motor; Servo System; Vector Control

Abstract. The objective of this work is to improve the control performance by redesigning the permanent magnet synchronous motor servo system .The vector control thought is used to control the permanent magnet synchronous motor. So it is easy to realize the torque current characteristic of linear. The design of the permanent magnet synchronous motor servo system is first proposed. The hardware and software designs are realized in this paper, and it is subsequently verified experimentally. Experimental results show that the DSP controller for the permanent magnet synchronous motor servo system has extensive applicability, high reliability and high performance price ratio.

Introduction

In this paper, permanent magnet synchronous motor servo system is a researched object. And the AC permanent magnet motor is a servo drive control object. The position, speed and torque of the permanent magnet synchronous motor are controlled by the servo drive controller. In addition, the high precision, large range and constant torque speed regulation are implemented in this servo system.

The vector control technology and control strategy of permanent magnet synchronous motor are proposed in [1] by authors. Vector control is based on the direction of the magnetic field vector as axes. The size and direction of the motor current vector is represented by the instantaneous value. At the same time, the control torque problem is solved by the coordinate transformation. The size and direction of the motor current vector is represented by the instantaneous value. So the problem of the torque control is solved by coordinate transformation.

The basic idea of vector control of permanent magnet synchronous motor is as follows: The DC motor torque control law is simulated when the permanent magnet synchronous motor is controlled. And the stator current of permanent magnet synchronous motor is decomposed in the rotating coordinate axes. Then the excitation current of flux and the torque of the torque current are gotten. The amplitude and phase of the stator current are controlled. Then the excitation current and torque current are changed. Because of the excitation current and torque current is orthogonal relationship, the excitation current and torque current are controlled separately. So the Torque is controlled effectively.

Hardware Design of Permanent Magnet Synchronous Motor Servo System

The design of the DSP controller for the servo system of permanent magnet synchronous motor is proposed in this paper. The hardware design of the DSP controller for the permanent magnet synchronous motor servo system as depicted in Fig. 1 was developed in the laboratory and used to start the motor.

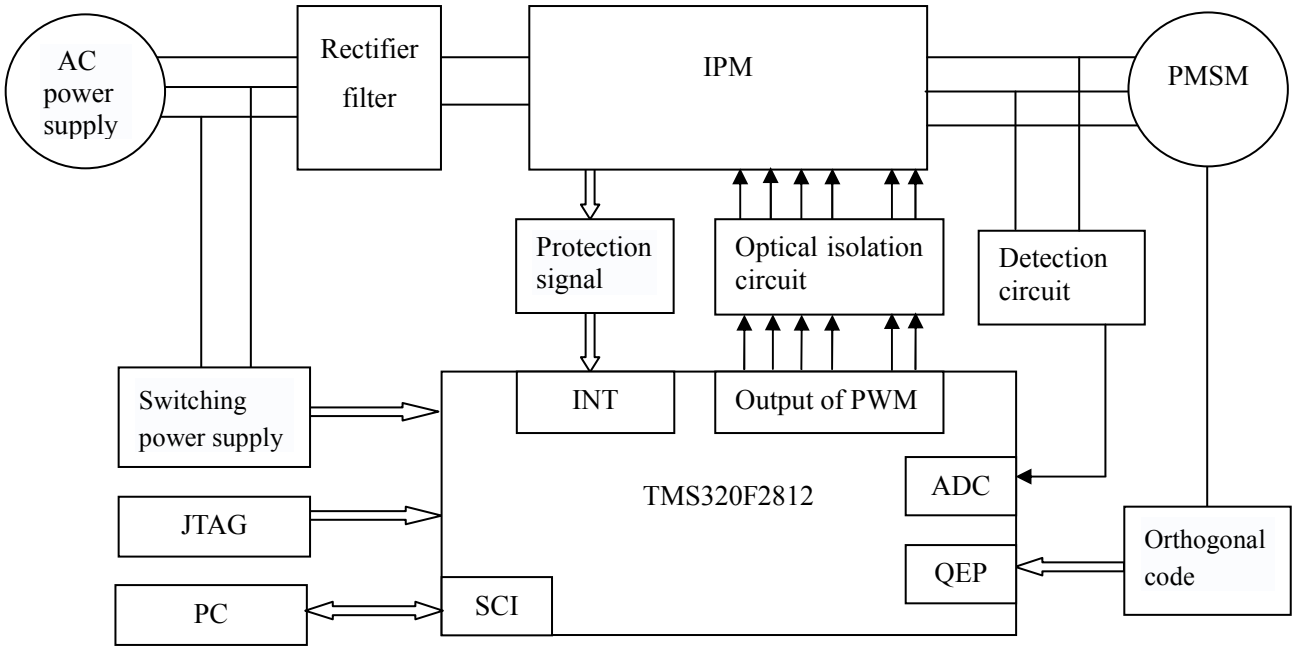

Fig.1 The hardware block diagram of the DSP controller for the PWSM servo system

The system has better dynamic and static performance in this design. The system can be realized functions, such as the change of the internal parameters, interface, communication with controller, debugging and monitoring.

This hardware mainly consists of the control circuit and the power circuit. The control circuit consists of the DSP minimum system, external input and output circuit, current and voltage detection circuit, motor speed and position detection circuit, the communication circuit and protection circuit. The power circuit consists of rectifier circuit, filter circuit and inverter circuit.

Process of the design can be divided into three important parts as follows:

Rectifier and filter circuit: The alternating current is transformed into direct the current by the rectifier circuit. The rectifier circuit is composed of the three-phase uncontrolled rectifier diode. After current is rectified by the three-phase uncontrolled rectifier bridge, the output voltage has the harmonics. In order to reduce the fluctuation of DC bus voltage, the filter circuit is designed. The rectifier and filter circuit is shown in Fig. 2.

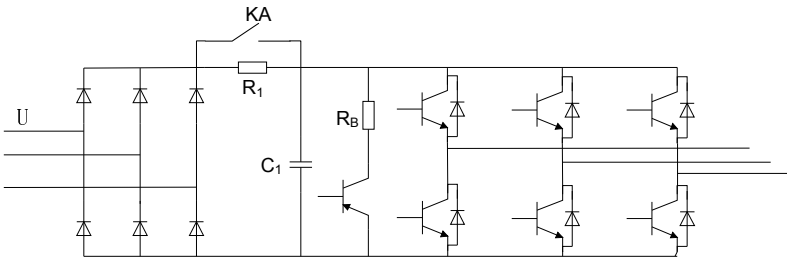

Fig.2 The rectifier and filter circuit

Optical isolation circuit: The DSP signal can't drive IGBT directly, so the optical isolation circuit is designed.

The control unit of DSP: The TMS320LF2812 DSP microprocessor DSP controller for the permanent magnet synchronous motor to achieve higher control accuracy under the conditions of external interference.

Software Design of Permanent Magnet Synchronous Motor Servo System

The modularized programming is used to design the software of DSP controller for the permanent magnet synchronous motor servo system. The procedure includes main program, timer interrupt service program, serial port interrupt program, the unusual interrupt program and so on. The software flow chart of the main procedure is shown in Fig. 3.

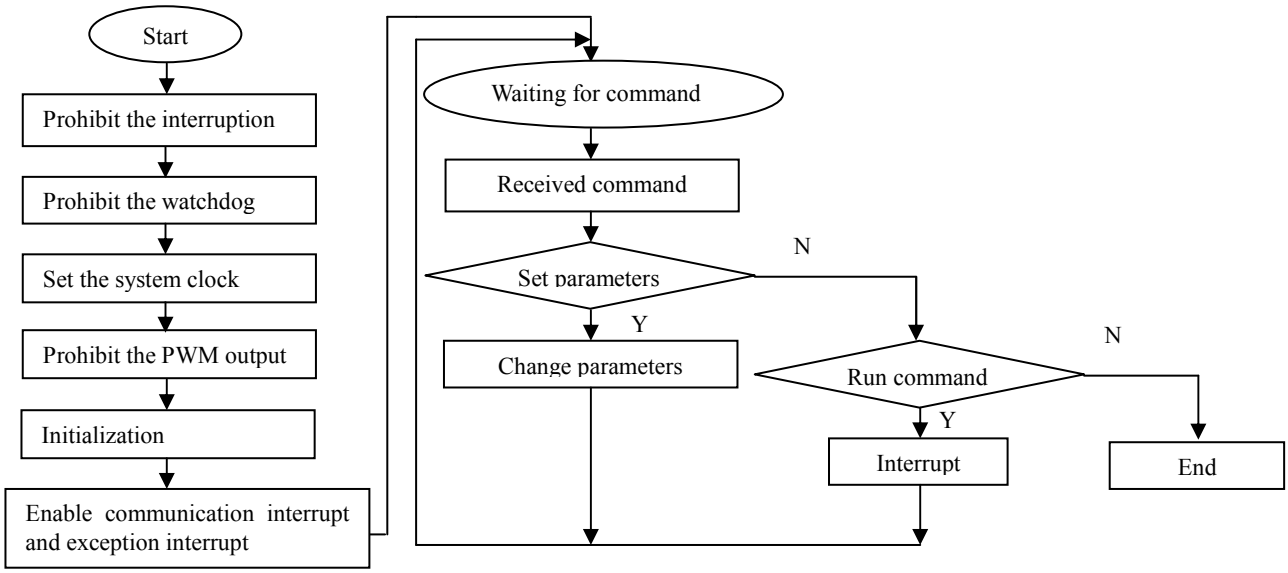

Fig.3 The software flow chart of the main procedure

The software flow chart of the main procedure is described as follows:
1) When the system start, the interruption and the watchdog are prohibited. Then the system clock is set, and then the PWM output is prohibited.
2) After the PWM output is prohibited, the system is initialization.
3) According to the different operation instructions, the system is operated by the different ways.
4) When the operation instruction is “waiting for command”, the process of the command is received. The run procedure is run as Fig. 3.
The main procedure can be divided into four steps as follows: the system clock, interrupt initialization, the register allocation on AD conversion and the initialization time management module and IO port.

Conclusion

This work has focused on the design and implementation of permanent magnet synchronous motor servo system based on DSP. The control performance of the permanent magnet synchronous motor servo system is improved. Towards this goal, the DSP controller for the permanent magnet synchronous motor servo system is first designed in the laboratory. The characteristics of this controller are described below.
1) The powerful data processing capability and high operating speed DSP is employed in this paper. The proposed DSP controller has extensive applicability, high reliability and high performance price ratio. The speed and precision of data processing, the integration and the real-time performance have all been obviously improved.
2) It is easy to realize the torque current characteristic of linear.
Overall, the successful implementation with a low cost micro controller illustrates the feasibility of the new approach in this paper.

Keywords: Shearer, STM32, CAN bus, Electrical control system

Abstract. This paper introduces a new type of electric traction shearer control device based on the STM32. This kind of device is constituted by three different function modules and some peripheral modules. The different modules are interconnected through RS-485 and CAN bus. According to this paper,we make a detailed description about the structure and hardware of the shearer electrical control system, and expound the characteristics of RS-485 and CAN network communication. This electric control system can highly improve the stability and safety of the shearer.

Introduction

China is a big country in coal production and consumption. The total output of national raw coal reached 3.33 billion tons while the consumption was about 3.62 billion tons in 2012[1]. And annual coal imports amounted to 289 million tons. Shearer is an important equipment of domestic coal mining in our country. Due to its special working environment and complex internal structure, its stability and efficiency are directly affecting the output of coal and the safety of the coal miners. Therefore, it has an important significance for the sustainable development of Chinese economy and the energy security to improve the automation level of coal winning equipment, to make the existing coal mine production more productive, efficient and safe, and reduce the dependency of external coal.

This paper introduces an electrical traction shearer control device based on embedded technology which uses the STM32F107 processor as the core, using the distributed technology to make different functional modules respectively complete data acquisition and processing, receives and sends control command, achieves a real-time display of various parameters of the system, and finally through the output relay signals control frequency converter to control each motor complete coal mining actions.

The Composition of Shearer Control System

The designing scheme of this control system is shown in Fig.1, consisting of the main control module, DAQ module, traction control module and some peripheral devices. The CPU in three function modules uses STM32F107VCT microprocessor produced by ARM's Cortex as core. The processor is based on the Cortex-M3 core, high-performance micro-controller chip, clocked at 72MHZ, its interior contains 256KB of Flash and 64KB of SRAM, the built-in resource-rich, including: SPI, I2C, UART, CAN, etc.[2], supporting JTAG online debug mode, compatible on the pin and software in the same series of different models[3]. System peripherals include RF Wireless Remote Module (intrinsically safety), LCB/RCB (intrinsically safety), gas breaker, leakage protector, LCD, etc.

Considering the implementation , maturity and economy of the practical engineering , the communication network among various modules is established by CAN bus and RS-485. The RS-485 interface consists of a balancing driver and differential receiver, which has good noise immunity and high transmission rate[4]. Its main mission is the transmission of data between modules;The CAN bus has the advantages of high information transmission stability and good real-time performance, and it has been successfully used in the automotive and other industrial fields[5]. Because the STM32F107 has two built-in integration CAN bus controller, only one more external receiver can realize the function and reduce the volume and complexity of hardware circuit. In this control system, the task of CAN bus is to receive and send the commands from the LCB/RCB and RF Wireless Remote Module.

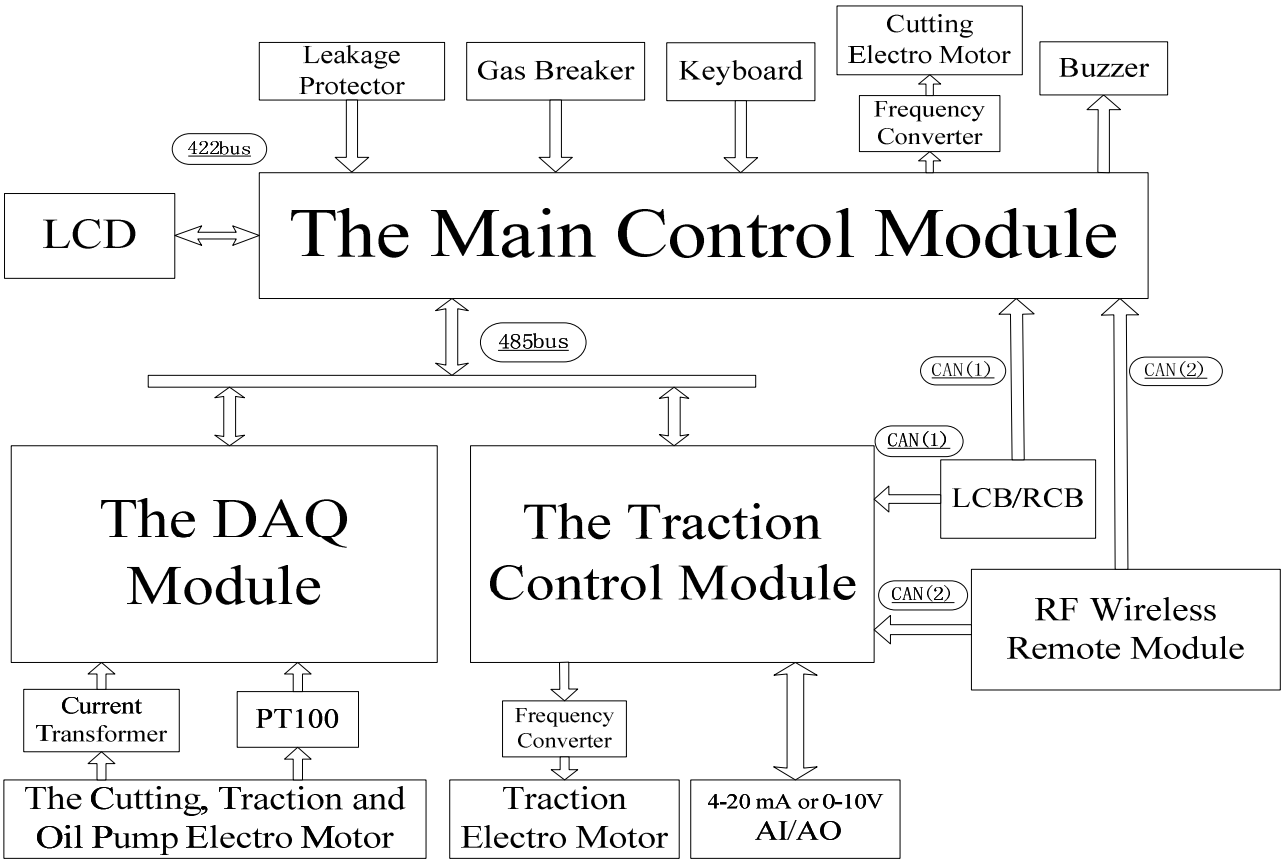

Fig.1.The structure of the control system of shearer

The LCD uses, in the GP series, 5.7 inch touch screen of PRO-FACE. This kind of LCD is widely used in industrial field with high resolution and its power is supplied by 24V DC. With the setting function, parameters can be manually set by the touch screen such as the pulling speed, alert limit of the motor temperature and current. And the screen can storage a lot of warning and fault information in order to rapidly locate the fault location and shorten the maintenance time.

The Hardware Design of Control System

The Main Control Module. As the core of the whole control system, the main control module is responsible for receiving data and commands from the DAQ module, the LCB/RCB and RF Wireless Remote Module. After calculating, processing and packaging, the data will be sent to the traction control module and LCD to complete the corresponding action and information display. In addition, the main control module also directly control the main start, stop, arm up, down, and some other high priority functions whose actions are made by the relay or solenoid valve. The hardware structure of the main control module is as shown in Fig.2.

The hardware circuit mainly consists of the CPU, reset circuit, clock circuit, storage circuit, I/O, etc. The I/O signal channels are all made of optical coupling isolation to prevent the external disturbance. It uses ULN2003 with high current gain and load ability as output driver chip. And the main control module itself still has a gas concentration in 200-1000 Hz frequency input signal interface and an Ethernet interface which can be used to upload information of shearer to the PC over telephone wire.

The DAQ Module. The DAQ module can be regarded as sensory organs of the whole control system, responsible for collecting the real-time temperature and current data of the cutting motor, traction motor and oil pump motor in the system, and sending the signals to the master control module through RS-485 bus after the analog signal acquired is converted into digital signals. The temperature sensor adopts PT100 platinum thermal resistance that is stable performance and easy to use in -50℃ to 200 ℃ temperature range and the current transformer is adopted to test the current[6]. The system uses

high-performances AD converter to complete the conversion of analog signal to digital signal and realize inverse time over current protection of all electrical circuits. All the digital signals converted are sent to the CPU through the photoelectric isolation, ensuring the integrity of the data and the stability in the process of data transmission.

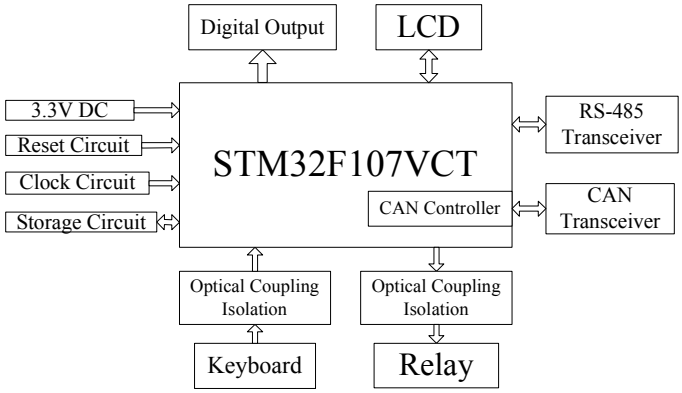

Fig.2. The hardware structure of the main control module

The Traction Control Module. The control of the traction motor is accomplished by controlling frequency converter through the output relay signals, including the control of the traction motor traction right and left, speed up and slow down, pine and brake operations. In addition to the reset circuit, clock circuit, communication circuit, traction control module also contains 2 road AO feedback contact, 2 road (0-10 V) AI, which can be directly connected to frequency controlling the acceleration and deceleration of traction motor [7]. Moreover designed CAN bus communication circuit in the traction control module can directly receive the commands from the LCB/RCB and RF Wireless Remote Module under the condition of damage in the main control module, making the system complete a simple control action in the case of downgrade. It controls the normal traction direction of coal winning machine.

Hardware Design of Power Supply Part. Control system as a whole uses 24V DC power supply, using DC-DC power modules. The module standard input voltage is 24V, and output voltage is 5V. It has the functions of short circuit protection, self-resumption, output shutdown and large isolation voltage .etc. Using tiny SIP encapsulation, it can allow more space for other devices and wiring in the limited space of each module.

In order to minimize the interference between each other and ensure the stability of the system, the communication circuit, temperature collection circuit and AD conversion circuit adopt independent power supply module power supply respectively on the hardware design of a power supply.In addition, the system keeps a special power supply module with low dropout linear regulators, which changes 5 DCV to 3.3DCV, for powering the CPU and other chips.

Hardware Design of the Communication Network. The CAN bus is mainly responsible for the reception and dispatch of the control commands in this system. Inside the STM32F107VCT processor, there are two CAN bus channels, each of them has its own transmitter TX and receiver RX, which respectively located on chip GPIO pins PD0 and PD1, PB5, and PB6 [8]. When using two CAN bus channels, it will be directly connected to the CAN bus repeater, and then hooked up to CAN bus, which can greatly simplify the complexity of hardware circuit.

ISO1050, as the transceiver of CAN bus, is conformed to the technical manual of ISO11898-2 standard, which used with isolated power supply, ISO1050 can prevent noise of the data bus or other circuit current into the local ground to interfere and damage sensitive circuits. It has some merits such as high transmission rate, strong anti-interference ability, high reliability, and provides check grade emission ability and difference within the capacity for the CAN controller of STM32F107VCT. In hardware design, CAN bus network at both ends are equipped with 120 Ω terminal resistance to prevent the signal reflection. PSM712 is the ESD. The CAN bus interface hardware construction is as shown in Fig.3.

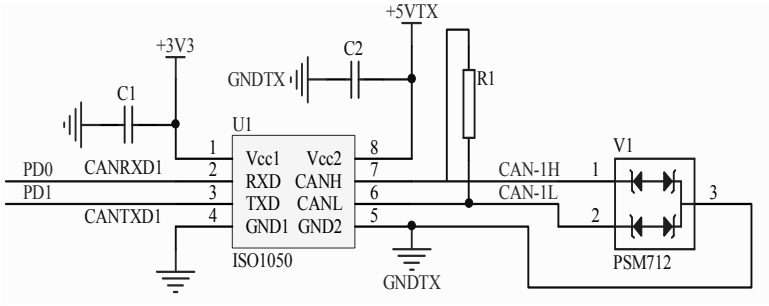

Fig.3. CAN bus interface hardware construction

RS-485 bus is mainly responsible for the communication of the main control module with the DAQ and the traction control module. Each module in the control system has a SP3485. The chip is +3.3V low power half duplex transceiver, fully meeting the required RS-485 electrical specifications of the serial protocol, and data transfer of the data transmisson rates up to 10Mbps (load), which, on the same serial bus, allows connection of up to 32 transceivers. The RS-485 interface hardware construction is as shown in Fig.4.

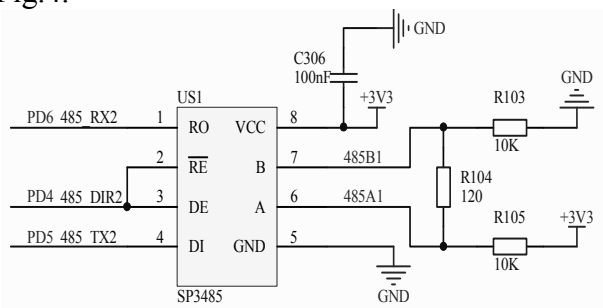

Fig.4. Hardware interface of RS-485

Software Design of the System

The software debugging work is completed based on RealView MDK development tool in the environment of Keil uVision.The software integrates with editor, compiler, emulator and debugger. The RealView MDK, a software development tool designed for all kinds of embedded processors by ARM, contains numerous case template and firmware instance. The system supports JLINK online simulation, and simplifies the program debugging process. It also can reduce the development difficulty, shorten the development cycle and can make developers more convenient in the process of debugging. Using JLINK emulator supports JTAG debug interface for online debugging [9].

Specific workflow in control system is as follow: After the system boots, initializes and then completes self-test, the DAQ module firstly tests temperature acquisition node and the integrity of and current collection node, and then enters the stage of data collection after receiving the feedback information and confirming the correct; After transforming digital signals of the electricity and the temperature signals acquired to analog signals, which packages in the data buffer, waiting for the inquiries from the main control module and eventually the data passes to it through RS - 485 bus network; The display sends the internal stored parameters to the main control module through RS-422 bus; The RF Wireless Remote Module and the LCB/RCB can send commands to the main control module through their respective CAN bus; The main control module transmits real-time parameters and control commands received of Shearer to the screen and traction control module to complete the corresponding action. Software flow chart of the control system is shown in Fig.5.

Control system adopts the design of distributed structure. The control module can effectively deal with the relevant data from other nodes, so as to determine the current working condition of coal winning machine. The control system preferentially detects the links such as the gas density and whether there is electric leakage in the shearer after the system boots, which fully guarantees shearer in a safe working environment all the time.

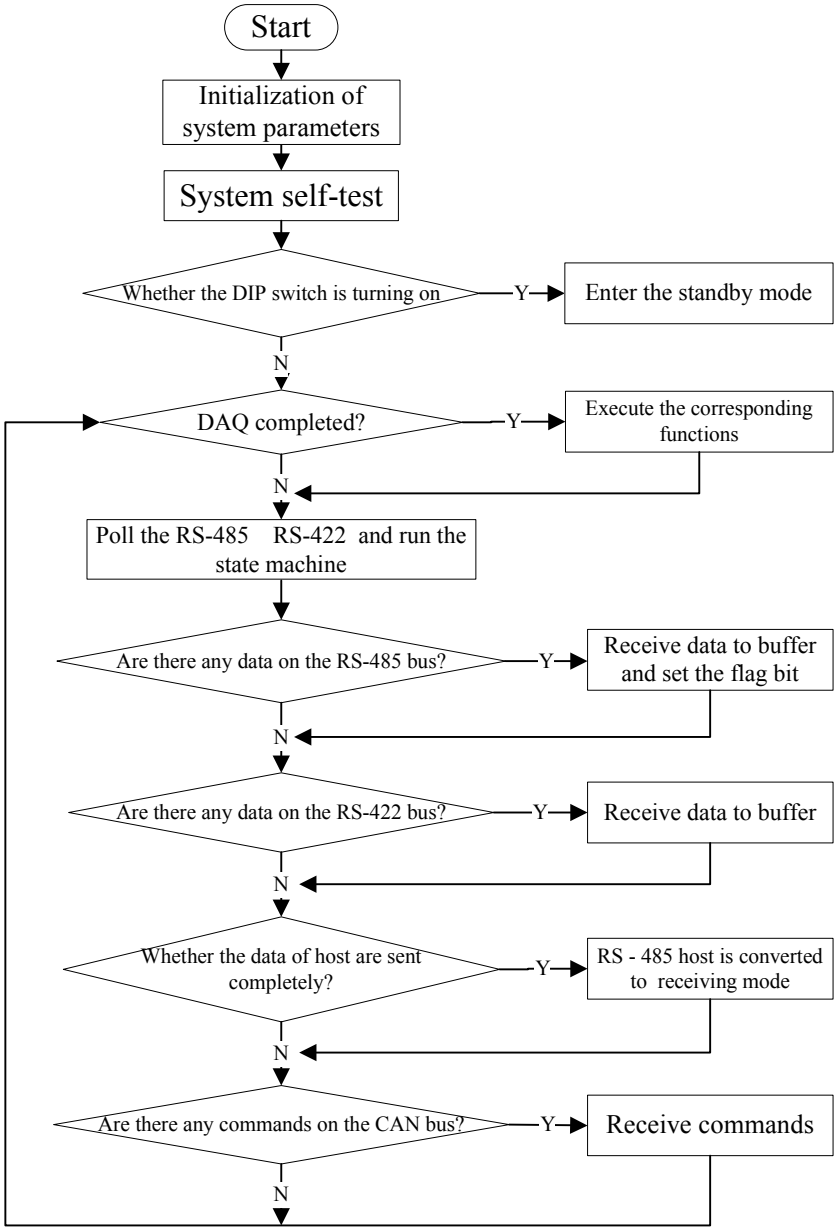

Fig.5. The system flow chart

Fault Tolerance Design of the System

Because coal mining machine need long time to adapt to the wicked underground work under harsh conditions, the safety, reliability and easy maintainability are higher required, so it is a certain fault tolerance. In this way, even if part of the shearer control system break down, it is still safe to do some basic operations. When the overall shearer breaks down, it can quickly find the cause of the problem, locate the fault module and restore system running in a short period of time. When compiling, the software program designs the multiple standby modes to maintain the basic operating functions of the system. For example, the CAN bus module setting in the traction control module can be activated by turning on the toggle switch to complete initialization when the main control module communication is damaged or completely interrupted. The traction control module through the CAN bus directly receive the commands from the LCB/RCB and the RF Wireless Remote Module, controlling the direction of coal winning machine around traction to protect the safety of underground workers. When lower communication network malfunction in the system breaks down, the shearer control system can control transducer through AO reserved 2 way switch and analog quantity to achieve control of the frequency converter operation. A large amount of redundancy is designed to improve

the reliability of coal winning machine as a whole, to reduce the probability of breaking down in control system.

Conclusions

STM32F107VCT as the core, shearer electrical control system is designed based on CAN bus and RS-485 bus, with high reliability, strong anti-jamming capability of the CAN bus interface which can realize the communication between the remote control and the main control system. Each module in the control system adopts RS - 485 bus to constitute the internal communication network, whose advantages are fast data transfer rate and strong ability to resist noise. It can monitor the real time working status of shearer by LCD and PC. Under the strong magnetic interference, through repeated tests,the system is working properly and the communication network is working steadily.It overcomes some weaknesses of traditional PLC control system such as the bad anti-jamming ability and shortcomings in real-time performance,etc. At the same time, the design of modular hardware structure has great advantage in the aspect of maintenance.

Keywords: FPGA (Field Programmable Gata Array); stepper motor; LabView

Abstract. A stepper motor control system is designed based on the stepper motor controller and EP2C5Q208C8. The control system of the host human-computer interaction interface is designed by LabView; through RS232 to communicate with the PC. According to the characteristic of the stepper motor control system , Verilog HDL language program and the software of Quartus Ⅱ are used to simulate each function modules. The analysis of simulation results and experiment show that using the method of FPGA+LabView can simplify the complexity of the system design and possess a very high stability on the running status. The motor running status can be easily observed in the PC interface.

Introduction

This paper proposes that adopting LabView to set up the host human-computer interaction interface and using FPGA as the master chip to control stepper motor through the stepper motor controller and sending data to human-computer interaction interface to display the motor running status. The design makes full use of the advantages of FPGA: it can quickly process the data; all of the control logic is high reliable and is completed by hardware. So the electrical interference with the control system has been reduced and the operation mode which is used to set up the motor running status is simplified by the interactive interface.

The Overall Program Design of the System

As is shown in Fig.1, a block diagram of a stepper motor control system mainly consists of a PC interface, a Field Programmable Gata Array (FPGA), a stepper motor controller and a motor. FPGA receive data via RS232 from PC and process the data. On the one hand, the corresponding control command and data are transmitted to the stepper motor controller in order to control the stepper motor. On the other hand, the processed data sent to the host computer through the RS232 for allowing the host computer interface to clearly see the stepper motor running.

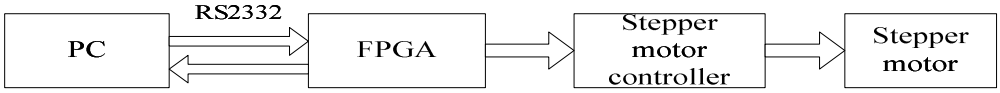

Figure1.Stepper motor control system block diagram

Hardware Design

EP2C5Q208C8, which is produced by Altera, is used as a master chip, and L298N is used in this system by stepper motor controller. L298N is a high-voltage, high current motor driver chip produced by SGS. It can be controlled by standard TTL logic level signal. FPGA can output LVTTL level. As the output range of the LVTTL level is a subset of the TTL-level input voltage range, the output port of FPGA can be connected directly with the pin of stepper motor controller. System connection diagram is shown in Fig.2.

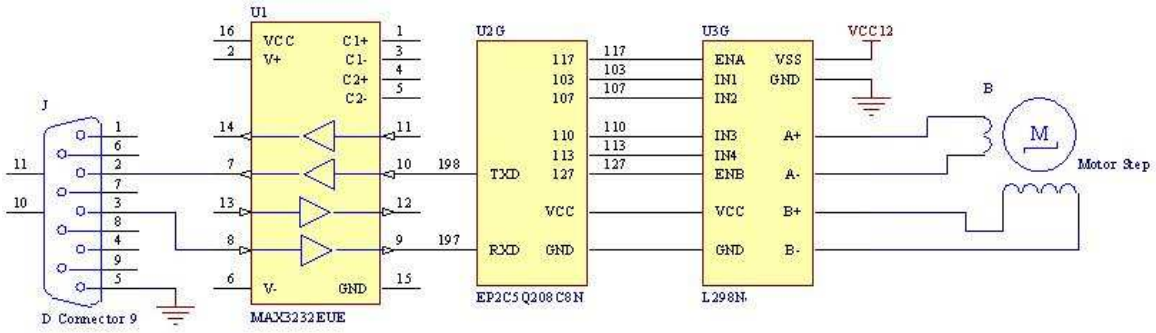

Figure2. System connection diagram

A. EP2C5Q208C8

EP2C5Q208C8 input / output power voltage is 3.3V and it has 288 logical blocks, 142 input / output lines, 208 pins and a PQFP package. It is composed of input / output unit, basic programmable logic unit, Global Clock Network & Phase-Locked Loops, embedded memory, multitrack interconnect, and embedded multipliers[2].

B. The stepper motor and stepper motor controller

Stepper motor is an open-loop control element that can transmit the electrical pulse signal to the angular or linear displacement. The motor speed and stopped position only depend on the frequency and number of pulses of the pulse signal, regardless of load changes in the case of non-overloaded, i.e. a pulse signal is sent to the motor, and the motor is rotated by one step angle[4]. Stepper motor do not have cumulative error, only periodic errors, this feature is widely used in the areas of controlling of the stepper motor speed and position control in areas.

L298N controller is selected to be stepper motor driver. Its instantaneous peak current can be up to 3A, and continuous operating current is 2A. TLP521optocoupler is used in L298N controller for optical isolation to prevent the spikes impact on FPGA generated when the controller is started and stopped.

The two-phase four-wire stepper motor is used in this system. Considering the influence of torque, smooth, noise, and other aspects, we adopt the eight-shot way of working. According to the characteristics of stepper motor control system, the system uses modular design principle; a top-down design, functional separation design and level design are all used according to the modern EDA project[5].

Software Design

The design of the program is based on Quartus Ⅱ software platform and written by the language of Verilog HDL.. The program contains three major modules: rx_module, tx_motor and data_conversion. FPGA uses EP2C5Q208C8, and the external clock is 20MHz.

A. The rx_module module

The rx_module module consists of rx_fifo_module module, rx_top_control module and rx module. Rx module also contains detect module, rx_bps module and rx_control module. Its main role is to receive the data via the serial port from PC and send the data into the FIFO buffer.

When detect module detects a start bit, it outputs a high level signal to the rx_control modules. The rx_control module controls rx_bps module to generate timing, reads the useful data received by rx_control module according to the signal output by rx_bps module and outputs the data. The rx_top_control module receives the data and sends them into the rx_fifo_module in order to cache data, wherein FIFO depth is set to 16.

B. The data_conversion module

The main role of data_conversion module is to take out the data which are located in FIFO data buffer and send them to rx_module module so that the data can be processed by the follow-up module.

C. The tx_motor module

The tx_module module consists of tx_fifo_module module, tx_top_control module, data_motor module and tx module. Data_motor module also contains data_control module and motor module. The main roles of tx_motor module, on the one hand, is to send data to PC through tx so as to display the motor's running status; on the other hand, is to transfer control module commands and data to the stepper motor driver through data_motor output to control the motor.

The data_control module is used to set the operation mode of the stepper motor based on the received serial data, including the direction of rotation, the initial velocity, acceleration and deceleration, operation mode and the number of steps. The motor module is used to set the stepper motor's running configuration, perform command according to the data_control module.

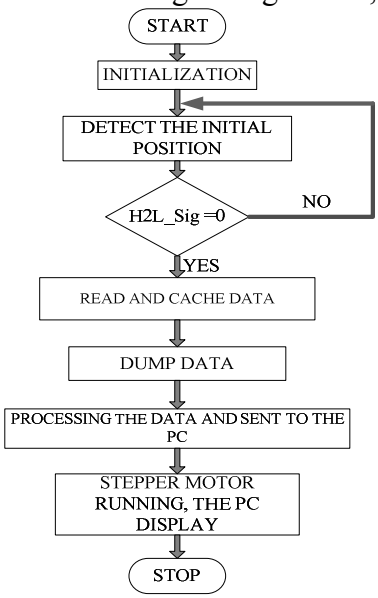

Figure 3. Software design flow chart

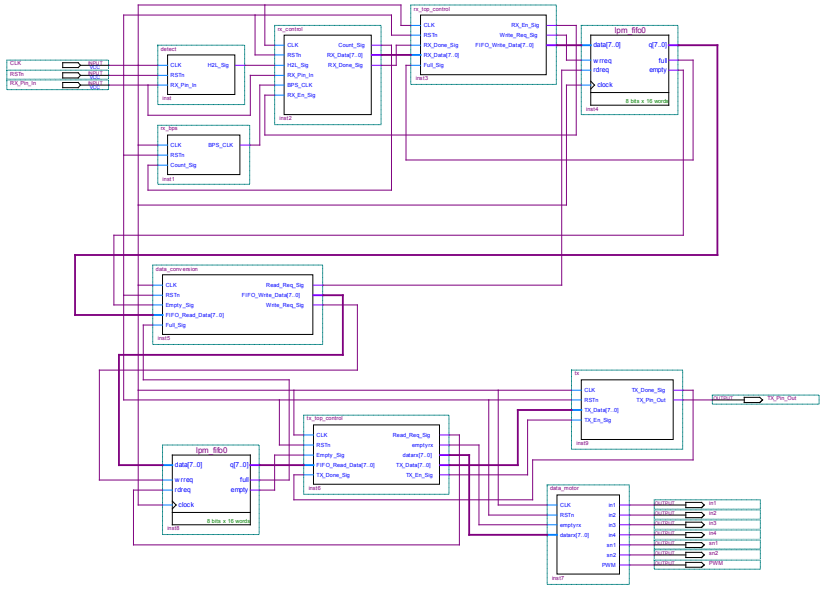

Figure 4. Module connection diagram

D.The Software Design Flow Chart and Connection Diagram

1) Software Design Flow Chart

The software design flow chart is shown in Fig.3. Firstly, system is initialized and each module signal is reset; detect module will detect the initial position. When detect module is pulled low level, the rx_module module will read the data and cache the data; after dumping the data through the data_conversion module, the tx_module module will process the data, control the stepper motor, and send the data back to the PC for display.

2) Module connection diagram

The Module connection diagram is shown in Figure 4.

E. The upper monitor

Host-computer keeps in touch with console-computer via serial communication. Using the LabVIEW platform to develop serial communication is relatively simple because the LabVIEW function template provides several serial communication subroutines. The left side of the front panel is used to initialize the serial port settings of the computer; the right side of the front panel is used to set the motor running and displaying. There are two modes of operation: continuous operation mode can be set to the motor rotation direction, speed, etc.; step by-step operation mode can also set the number of steps. After configuring the serial port parameters, we need to click the button of 'setting the parameters' to set the parameters for final confirmation. When motor state is set up, if we click the Run button, the motor will start to run. The motor running status will be shown according to the information which is sent back from the console-computer.

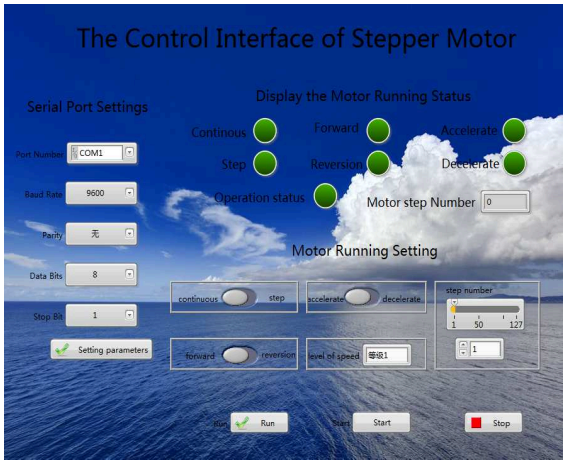

Figure 5. The front panel

Conclusion

After repeated experiments, using the method of FPGA+L298N can simplify the design's complexity and ensure the stability of the system; the motor running control and display are set by host-computer designed by LabVIEW with the advantage of simple interface, simple control and being easily observed to the motor running. LabVIEW+FPGA+L298N are used in stepper motor control system. The stepper motor now can run continuously with given number of steps, controlled speed and direction.

Keywords: Current feedback operational amplifier; bi-quad loop filter circuit; analog multiplier; voltage-controlled band-pass filter.

Abstract. This paper puts forward structure and realization method of the voltage-controlled band-pass filter based on the current feedback operational amplifier (CFA) which uses bi-quad loop filter circuit model to design the new filter circuit. Input voltage signal is input to voltage-controlled band-pass filter circuit composed by an analog multiplier AD835 and a current feedback operational amplifier AD8001 which are the core. Using the voltage signal to adjust the center frequency of the filter, the filter has wide frequency band and good high-frequency performance. This paper describes the design principles, infers the design formulas and designs the circuit of the voltage-controlled first-order and second-order band-pass filter.Through the simulation, the filter can realize the scope of the center frequency from 200KHz to 10MHz.

Introduction

In the field of signal processing, data collection and communication systems, the filter has a wide range of applications, including the voltage-controlled filter with a simple circuit structure, convenient adjustment, high accuracy, and solving the wide variations of the pending signal frequency, which plays an important role in the field of signal processing[1][2][3] .The voltage-controlled filter can achieve automatic adjustment of the filter frequency[4].The voltage-controlled filter is mainly composed by an analog multipliers and an operational amplifiers. Using the current feedback operational amplifier to design the voltage-controlled filter is common method. Compared with the voltage feedback operational amplifier[5],the current feedback operational amplifier has the high-inverting input impedance, the low-inverting input impedance, distortion, so it can achieve the high frequency filter . The basic design methods of the voltage-controlled band-pass filter based on the voltage and the current feedback operational amplifier are similar[6]. These methods include the component replacement method[7], the cascade method[8], RLC-CRD transformation method[9], and trapezoidal network simulation method[10]. The design uses a current feedback operational amplifier AD8001.While the analog multiplier uses a voltage-output four-quadrant multiplier AD835. The voltage-controlled band-pass filter based on the voltage feedback operational amplifier uses the current feedback operational amplifier to replace the voltage feedback operational amplifier [11][12], and then the adjoint network to replace the original network, by which we gain the current feedback filter. Compared the voltage-controlled filter designed in this thesis with other voltage-controlled filters, its center frequency is high, waveform is smooth, distortion is small and other features.

The design and principle of the voltage controlled band-pass filter

2.1 The design and principle of the voltage-controlled first-order band-pass filter

The voltage-controlled first-order band-pass filter based on the current feedback operational amplifier mainly uses the four-quadrant multiplier voltage output, the current feedback operational

amplifier and a few resistors and capacitors. The band-pass filter is formed by the simple high-pass and low-pass filter in series, whose sequence is bound, it must connect the high-pass filter with the low-pass filter in series and meet the condition of $f_{LP}>f_{HP}$, And when taking $f_{LP}<f_{HP}$, all the signals will be filtered out. To form a 20dB attenuation band-pass filter, it should make a first-order high-pass filter and a first-order low-pass filter connected in series; to form a 40dB attenuation band-pass filter, it should make a second-order high-pass filter and a second-order low-pass filter connected in series, and so on. Therefore, to form a voltage-controlled first-order band-pass filter, which just need to make a voltage-controlled first-order high-pass filter and a voltage-controlled first-order low-pass filter connected in series.

The voltage-controlled first-order band-pass filter circuit uses the above method to design is shown in Figure1.In the circuit, U_5, U_6, the resistors R_{10}~R_{14} and the capacitor C_2 form the voltage-controlled first-order low-pass filter. While U_1~U_4,the resistors R_1~R_9 and the capacitor C_1 form the voltage-controlled first-order high-pass filter. To connect a voltage-controlled first-order high-pass and low-pass in series forms a voltage-controlled first-order band-pass filter. The upper cut-off frequency of the voltage-controlled first-order band-pass filter is the cut-off frequency f_{HP} of the high-pass filter. The lower frequency is the cutoff frequency f_{LP} of the low-pass filter. Its bandwidth is BW=f_{LP}-f_{HP}, and the center frequency is $f_0=\sqrt{f_{LP}f_{HP}}$. By adjusting the cut-off frequency of the voltage-controlled high-pass and low-pass filter to adjust the bandwidth, thereby the center frequency of the voltage-controlled band-pass filter is adjusted. And because the cutoff frequency of the voltage-controlled high-pass and low-pass filter is adjusted by the control voltage V_f ,so the upper and lower frequency of the voltage-controlled band-pass filter is also adjusted by the control voltage V_f.

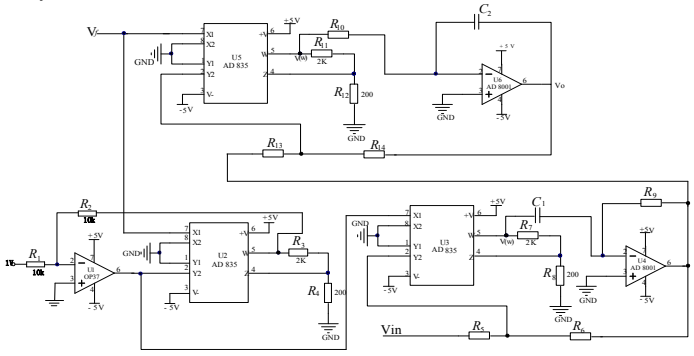

Figure 1 The voltage-controlled first-order band-pass filter

According to Kirchhoff's law and Figure1,the transfer function of the voltage-controlled first-order low-pass filter transfer function is:

$$H_{LP}(s)=-(R_{14}/R_{13})/\{s[(R_{13}+R_{14})/R_{13}]\times(R_{10}C_2/V_f)+1\} \quad (1.1)$$

Formula（1.1），it can deduced the cut-off frequency of the filter is :

$$f_{LP}=\omega_{LP}/2\pi=V_fR_{13}/[2\pi(R_{13}+R_{14})R_{10}C_2] \quad (1.2)$$

When takingR_{13}=R_{14},formula (1.2) becomes to be :

$$f_{LP}=V_f/(4\pi R_{10}C_2) \quad (1.3)$$

Similarly, the transfer function of the voltage-controlled first-order high-pass filter is:

$$H_{HP}(s)=-(sR_6/R_5)/\{s+[V_f(R_6+R_5)]/(R_5R_9C_1)\} \quad (1.4)$$

formula（1.4）,it can deduced the cutoff frequency of the filter is :

$$f_{HP}=\omega_{HP}/2\pi=V_f(R_6+R_5)/(2\pi R_5R_9C_1) \quad (1.5)$$

When taking R_5=R_6, formula (1.5) becomes to be:

$$f_{HP}=V_f/(\pi R_9C_1) \quad (1.6)$$

So the central frequency of the voltage-controlled first-order filter is:

$$f_0=\sqrt{f_{LP}f_{HP}}=\sqrt{V_f^2/(4\pi^2R_9R_{10}C_1C_2)}=V_f\sqrt{1/(R_9R_{10}C_1C_2)}/2\pi \quad (1.7)$$

In the experiment ,when taking R_5=R_6=1k,R_9=1.416k,C_1=60pF,then it can deduced f_{HP}=3.75*10^6 V_f, when taking R_{13}=R_{14}=500Ω,R_{10}=88.5Ω,C_2=30pF,then f_{LP}=3.0*10^7 V_f. When V_f taking 0.3v, 0.4v, 0.6v, 0.8v, 1.0v,the simulation results using ORCAD is shown in Figure 2.

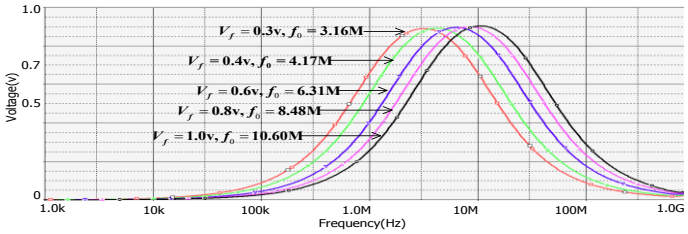

Figure 2 The amplitude-frequency characteristics simulation curve of the voltage-controlled first-order band-pass filter

After testing, when the control voltage V_f taking 0.3v,0.4v,0.6v,0.8v,1.0v,the measured and calculated values of the center frequency f_0 is shown in below Table 1.

Table 1 Comparison of the measured and theoretical values of the center frequency of the first-order band-pass filter

V_f / v	theoretical value	0.3	0.4	0.6	0.8	1.0
f_0 / *M*Hz	measured value	3.16	4.17	6.31	8.48	10.60
	Calculated	3.18	4.24	6.36	8.51	10.72
δ_f （Relative error）(%)		0.63	1.65	0.79	0.35	1.12

2.2 The design of the voltage-controlled second-order band-pass filter

The circuit of the voltage-controlled second-order band-pass filter based on the current feedback operational amplifier is shown in Figure 3. In the figure 3, U_5, R_{10}, R_9, R_8 and C_2 form a summing integrator damper, U_3, R_5, R_7 form an inverting input of the operational amplifier closed-loop, and U_4,R_6 and C_1 form an inverting integrator. The role of $U_1$is to achieve the square of the signal, which makes a linear relationship between the cut-off frequency and the input frequency. While U_2 is to realize multiplied signal to control the voltage. In the circuit, V_f is the control voltage.

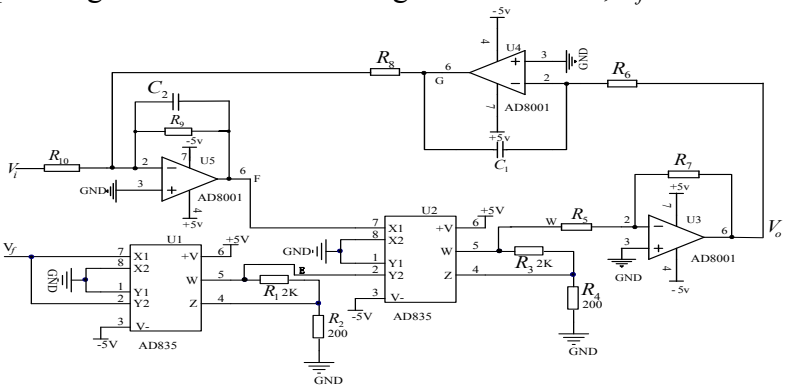

Figure 3 The voltage-controlled second-order band-pass filter

According to Kirchhoff's law：

$$V_E = 0.4V_f^2 \quad (2.1)$$

$$0.4V_E V_F = V_W \quad (2.2)$$

$$V_W / R_5 = V_Q / R_7 \quad (2.3)$$

$$V_Q / R_6 = V_G C_1 S \quad (2.4)$$

$$V_i / R_{10} = (V_F / R_9) + (V_F C_2 S) + (V_G / R_8) \quad (2.5)$$

$$V_D = 0.4V_f^2 V_O \quad (2.6)$$

$$V_Q / R_{11} = -V_D / R_{12} = -0.4V_f^2 V_O / R_{12} \quad (2.7)$$

According to the formula(2.1~2.7),it deduce the transfer function of the filter is:

$$H(s) = [R_7 s / (C_2 R_{10} R_5)] / [s^2 + s / (C_2 R_9) + V_f^2 R_7 / (C_1 C_2 R_5 R_6 R_8)] \quad (2.8)$$

formula(2.8),it can deduce the center angular frequency is

$$\omega_{BP} = V_f \sqrt{R_7} / \sqrt{C_1 C_2 R_5 R_6 R_8} \quad (2.9)$$

The gain factor is $K = R_9 R_7 / (R_{10} R_5)$ (2.10)

The quality factor is $Q_{BP} = V_f R_9 \sqrt{C_2 R_7} / \sqrt{C_1 R_5 R_6 R_8}$ (2.11)

So ,the central frequency is $f_0 = V_f \sqrt{R_7} / (2\pi \sqrt{C_1 C_2 R_5 R_6 R_8})$ (2.12)

From formula(2.10)and (2.11),it can see the quality factor Q_{BP} of filter is controlled by voltage V_f, but the gain K is not controlled by voltage V_f, When taking $C_1=C_2=C$,$R_6=R_8=R$,$R_5=R_7$,it can deduce

$$f_0 = V_f / (2\pi RC) \quad (2.13)$$

Considering the maximum input voltage of the AD835 is 1.0V, when the control voltage V_f taking 0.4v, 0.5v, 0.7v,0.9v,1.0v,the simulate results using ORCAD to is shown in Figure 4

.

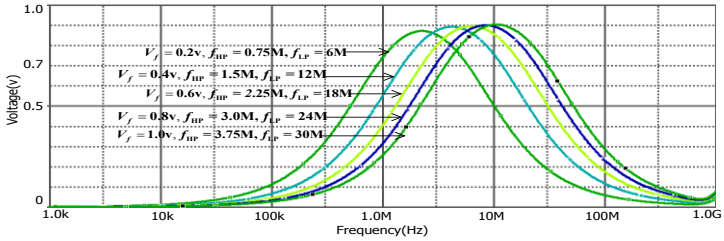

Figure 4 The amplitude-frequency characteristics simulation curve of the voltage-controlled second-order filter

After testing , when the control voltage V_f taking 0.4v,0.5v,0.7v,0.9v,1.0v,the measured and calculated values of the central frequency f_0 is shown in below Table 2.

Table2 Comparison of the measured and theoretical values of the center frequency of the second-order band-pass filter

V_f / v	heoretical value	0.4	0.5	0.7	0.9	1.0
f_0 / KHz	measured value	316.2	501.2	631.0	794.3	1000
	Calculated	318.6	502.3	632.5	795.9	1001
δ_f （Relative error）(%)		0.75	0.22	0.24	0.20	0.10

Conclusion

This paper provides a new design method and circuit of the voltage-controlled band-pass filter based on the current feedback operational amplifiers .The design uses the model of the double second-order loop filter, by making the analog multiplier and the current feedback operational amplifier to lead into the model of the double second-order loop filter to design the new filter circuit. Input voltage signal is input the voltage-controlled band-pass filter circuit constituted by an analog multiplier AD835 and a current feedback operational amplifier AD8001,through which to adjust the the center frequency of the filter to design a filter with frequency bandwidth, high-frequency filters, good performance, simple circuit structure, real-time, low cost, easy to adjust. Besides, the scope of its center frequency is 200KHz-10MHz.If adding the frequency voltage conversion circuit and other circuits to the filter circuit, it can achieve the adaptive voltage controlled band-pass filter. Therefore, the voltage-controlled band-pass filter designed in the thesis based on the current feedback operational amplifier (CFA) has good practical value and broad application prospects.

Drive Circuit Design of H-bridge Permanent-magnet DC Moment Motor Based on HIP4081 Chip

Bing Zhao

Yantai Engineering Technology College

zb6933517@163.com

Keywords: HIP4081, H-bridge, PWM, Permanent-magnet DC moment motor

Abstract. In order to achieve reliable drive for Permanent-magnet DC moment motor and high-precision control, we use special chips designed HIP4081 H-bridge PWM motor drive circuit bipolar reversible, with DSP as the controller completed a two-way rotation and permanent magnet DC motor speed control . Experiments show that the circuit is safe, reliable, environmental adaptability, good thermal conductivity, high efficiency, applicable to Permanent-magnet DC moment motor powered a variety of control systems.

Introduction

Permanent-magnet DC moment motor is a low speed, high torque motor, which can be long-term work in the stall, you can directly drive the low-load, with optical encoder or encoder can be composed of high-precision servo system, due to its regulation characteristics and mechanical characteristics, speed and torque ripple small advantages have been widely used[1].

Permanent-magnet DC moment motor is currently widely used PWM drive mode, this drive mode can achieve a wide range of speed and position control, as compared with the conventional driving method has a great advantage. Although PWM technology has made great achievements, but DC PWM control technology and associated power drive technology will continue to develop. Since the market is relatively small permanent magnet DC torque motor supporting power drive components, so for a certain type of permanent magnet DC torque motor developed a driver card. HIP4081 driver chip using the chip as NMOSFET power tube, using a digital signal processor (DSP) to generate the PWM pulse width modulated wave, the drive mode can not only drive Permanent-magnet DC moment motor[2], you can also drive other medium-power DC motors.

H-bridge PWM driving principle

PWM drive motor armature voltage polarity by way of reversible and irreversible drive into two categories, irreversible PWM motor driving one or two-quadrant operation, poor speed performance. In order to ensure permanent magnet DC torque in four quadrant operation with good speed performance, using a reversible PWM drive, reversible PWM drive can be divided into two kinds of unipolar and bipolar. Reversible PWM different main circuit structure is divided into H-type and T-type, in which the H-type widely used in the actual system[3], which is composed of four power switching elements and four-wheeling diode bridge circuit composed.

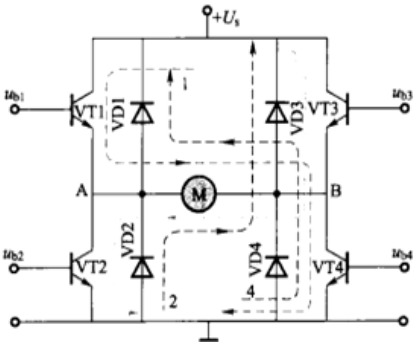

Figure1 H-bridge driver circuit bipolar PWM basic principle reversible

Four power switches driving voltage is divided into two groups, the driving voltage of opposite polarity. The driving voltage $u_{b1} = u_{b4}$ and VT1 VT4 driving power switch turned on and off simultaneously. The driving voltage $u_{b2} = u_{b3}$, and the driving power on member VT2 and V3 are simultaneously turned off. In a driving cycle, when $0 \le t \le t_{on}$, the driving voltage is positive u_{b1} and u_{b4}, and the power switch VT1 VT4 saturated conduction; the driving voltage u_{b2} and u_{b3} is negative, the power switching device off VT2 and VT3. Then the forward voltage is applied to both ends of the motor armature, the armature voltage $u_a = U_s$, and the armature voltage is greater than the inductor voltage $u_a > E_a$, forward current flows through the circuit 1. In time $t_{on} \le t \le T$, the driving voltages u_{b1} and u_{b4} is negative, and the power switching device VT1 VT4 full off; driving voltage u_{b2} and u_{b3} is positive, VT2 and VT3, but not the power switch is turned on immediately, releasing stored energy in the motor armature under the action of the motor armature current along the circuit 2 via the diode VD2, VD3 freewheeling current direction remains positive, the diode VD2, VD3 drop on the power switching device VT2, VT3 withstand back pressure, when the armature voltage $u_a = -U_s$.

Introduction HIP4081 driver chip

In the small motor applications, due to the integrated power amplifier power amplifier circuit performance parameters than ordinary electronic components higher and better overall performance, smaller volume amplifier circuit, system failure may be lower, and enhance the reliability of the system. But conventional driver IC operating current is not large, so the chip design with HIP4081 H-bridge motor drive circuit[4]. HIP4081 chip pin as shown in Figure 2.

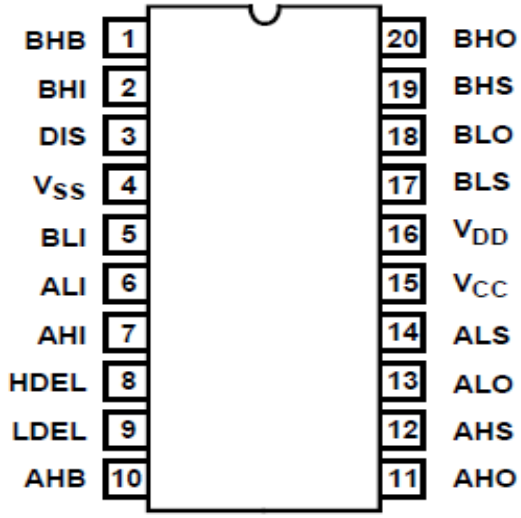

Figure 2 HIP4081 chip pin

HIP4081 chip is intersil company launched a high-frequency full-bridge driver chips, widely used in the control H bridge. This chip has a separate low and high input channels, each drive four N-channel MOS transistor; peak output current of 2.5 A; internal charge pump and chips with dead time set; suspended supply using bootstrap circuit, its high-end working voltage up to 80 V, the logic supply voltage range 6 ~ 15 V, high operating frequency up to 1 MHz; has to control all inputs ban ends, can easily form a protective circuit with external components.

Power switching component selection

With the development of electronic technology, power electronics has experienced rapid technological change. Development of IGBT, MOSFET and including intelligent components, including the power module technology has made tremendous progress[5]. This selection of enhanced NMOSFET IRF3205 HEXFET as power conversion devices, with very low on-resistance internal dynamic dv/dt rating, enhanced with a combination of high-speed switching reliability.

Drive circuit design of permanent magnet DC moment motor

PWM driver circuit shown in Figure 3:

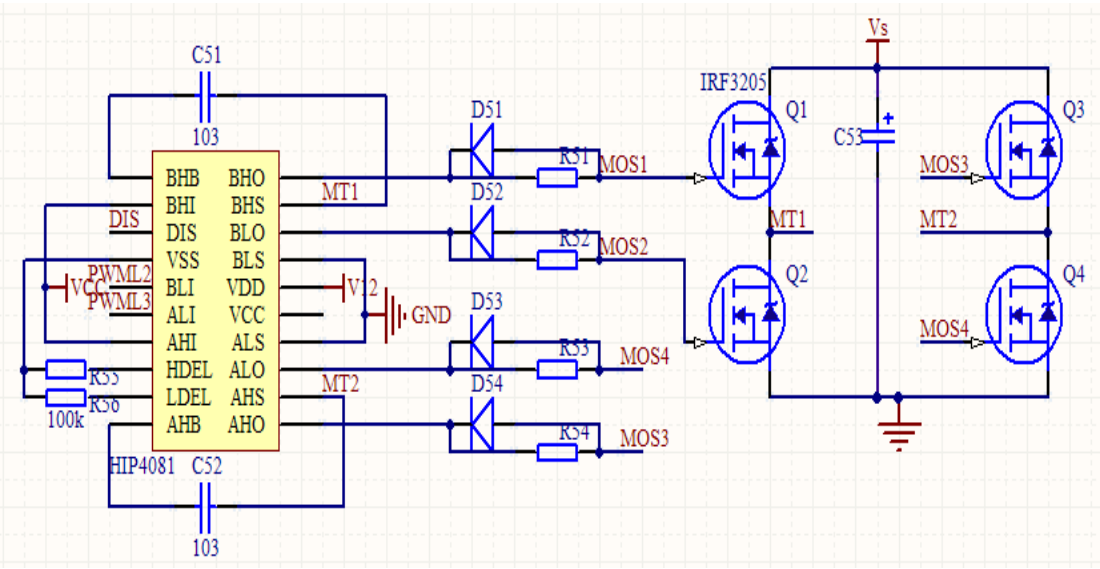

Figure 3 Permanent magnet DC torque motor drive circuit PWM

State of motion and motor work follows a logical sequence in Table 1 below[6][7]:

Table 1 Logical relationship

ALI	AHI	BLI	BHI	DIS	ALO	AHO	BLO	BHO	H-bridge state	Function
×	×	×	×	1	0	0	0	0	M1~M4 Close	Stop
1	1	0	1	0	1	0	0	1	M1,M4 Conduction	Forward
0	1	1	1	0	0	1	1	0	M2,M3 Conduction	Reversion
0	1	0	1	0	0	1	0	1	M1,M3 Conduction	Brake
1	1	1	1	0	1	0	1	0	M2,M4 Conduction	Brake

PWM input is TTL compatible PWM signal, dutycycle between 0% ~ 100%; Vs for the H-bridge power supply, MOS tube to obtain the output current from the power supply terminal. 4-quadrant mode, changing the direction controlled by dutycycle compatible with TTL level PWM signal to get. In addition, to ensure the ipsilateral H bridge two simultaneous conduction MOS tube is not very important. For Q1 and Q2 or Q3 and Q4 in the conduction time there is a delay, the dead time in the circuit. In order to increase the power density and thermal capacity of the circuit, by the thick film printing process ALN substrate and burning metal welding.

Conclusion

The practical application shows: H-bridge PWM reversible bipolar driver circuit designed in this paper is not only safe and reliable way to achieve a two-way rotation and speed permanent magnet DC torque motor, improve the reliability of the drive circuits and systems, and small product size, thermal performance well, high efficiency, safe working in harsh environments, can be applied by a permanent magnet DC torque motor as the drag of the original variety of control systems.

Modeling and Simulation of UAV Electric Servo System

Zheng Xing

Wuhan Mechanical Technology College, Wuhan 430075

zhengxcn@foxmail.com

Keywords: Electric Servo System; MATLAB; Dynamic Simulation

Abstract. With the dynamic simulation tool of MATLAB named SIMULINK, modeling and simulation are made for a certain type of UAV electric servo system. Through detailed performance analysis of simulation results, the simulation experiment is confirmed to be accuracy.

Introduction

Electric servo System is an important and indispensable part of the aerospace vehicle flight control system. it is a force application device of the controller. Electric servo system generates force and torque, manipulate control surface and boost guide mechanism in order to achieve flight attitude and trajectory control [1-2]. Therefore, the performance of servo system directly affects the performance and flight safety of the flight control system.

In this paper, the dynamic simulation tool of MATLAB named SIMULINK is used to construct simulation model of the electric servo control system [3]. From the simulation of a commonly used electric servo system example, the detailed analysis of the system performance is made and the accuracy of the results is verified.

System components and principles

Energy of the Electric servo is electric. Because of its simple structure, easy maintenance, reliable, it is widely used in UAV flight control system. A certain type UAV electric servo system is a position servo feedback system. It is mainly made up of servo amplifier, DC servo motor, reducer, position feedback potentiometer and output rack etc, as shown in Figure 1.

When the difference of the input signal u_i and the feedback potentiometer feedback signal u_f is not zero, servo amplifier amplifies the error signal e_i to make the DC servo motor rotation and the reducer makes the output rack move to the required direction. At the same time, the brush of the feedback potentiometer synchronously motion with the rack. When the rack is moved to the position where the difference between the control signal and the feedback signal is zero, the error signal e_i disappears, DC servo motor and the rack stop. The displacement and the direction of the rack are in direct ratio with the size and polarity of the control signals [4].

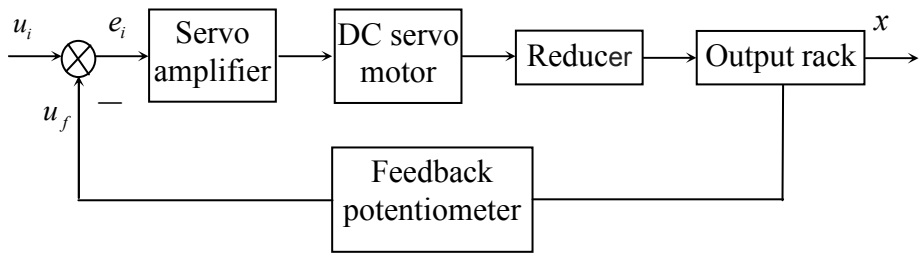

Fig.1 Block diagram of the electric servo system

The mathematical model of the system

Before the simulation, the mathematical model of the various parts of the system is established.

Servo amplifier. The error signal equation is shown as Eq. 1.

$$e_i = u_i - u_f \tag{1}$$

The Amplifier circuit equation is shown as Eq. 2.

$$u_o = Ke_i \tag{2}$$

Among them, u_i the input signal, u_f the feedback signal, e_i is an error signal, K is a magnification, u_o the amplifier output signal.

DC servo motor. The armature circuit voltage balance equation is shown as Eq. 3.

$$u_o = L_a \frac{di}{dt} + i(r_a + r_b) + E_a \tag{3}$$

The armature back EMF equation is shown as Eq. 4.

$$E_a = C_e \frac{d\theta}{dt} \tag{4}$$

The torque balance equation of the motor shaft is shown as Eq. 5.

$$J\frac{d^2\theta}{dt^2} + f\frac{d\theta}{dt} = M - M_l \tag{5}$$

The electromagnetic torque equation is shown as Eq. 6.

$$M = C_T i \tag{6}$$

Among them, L_a is the inductance of the armature winding, r_a is the resistance of the armature winding, r_b is The equivalent resistance of the servo amplifier, i is the current in the armature winding, E_a is the The back EMF, C_e is the back EMF coefficients, θ is the angular displacement of the motor shaft, J is the motor and load inertia referred to the motor shaft, f is the motor and load viscous friction coefficient referred to the motor shaft, M is the torque generated by the motor, M_l is the load torque.

Reducer. The reducer equations are shown as Eq.7 and Eq.8.

$$x = \frac{1}{n}s \tag{7}$$

$$s = r\theta \tag{8}$$

Among them, x is the output displacement of the rack, n is the reduction ratio, s is the linear displacement of the motor shaft, *and* r is the motor shaft radius.

Feedback. Potentiometer The feedback potentiometer equation is shown as Eq.9.

$$u_f = K_f x \tag{9}$$

Among them, K_f is the Feedback coefficient.

Based on the above equations, after simplification, we can establish the structure of the electric servo system, as shown in Figure 2.

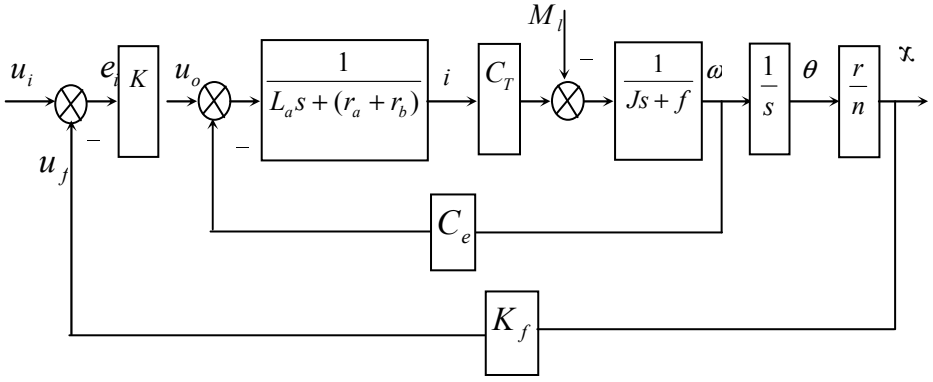

Fig.2 Structure of the electric servo system

Simulation Analyses

MATLAB/SIMULINK provides the basic function module, which is stored in the Module library of the SIMULINK. Run SIMULINK in MATLAB [5], create a Model file. Based on the system structure, don't consider the effect of load torque M_i, after substituting the corresponding parameters, a simulation example as figure3 is built.

Run the command [a,b,c,d]=linmod(fz.mdl) and step(a,b,c,d) in MATLAB, a system step response curve can be obtained, as figure 4. The figure shows that the system is stable. The rise time is 0.053s, the overshoot is 23%, and oscillation frequency is 2.5 times, regulation time is 0.35s, magnification is 5mm/1v. (The actual rise time of the system is 0.046s, the overshoot is 20%, oscillation frequency is 2.5 times, regulation time is 0.3s, magnification is 10±0.5mm/2v). Then, run bode(a,b,c,d), The amplitude frequency characteristics of system can be obtained, as figure5. The system bandwidth is about 8.7 Hz (The actual bandwidth is 10Hz). The above analysis shows that the simulation results close to the actual system, also proves the correctness of the system model.

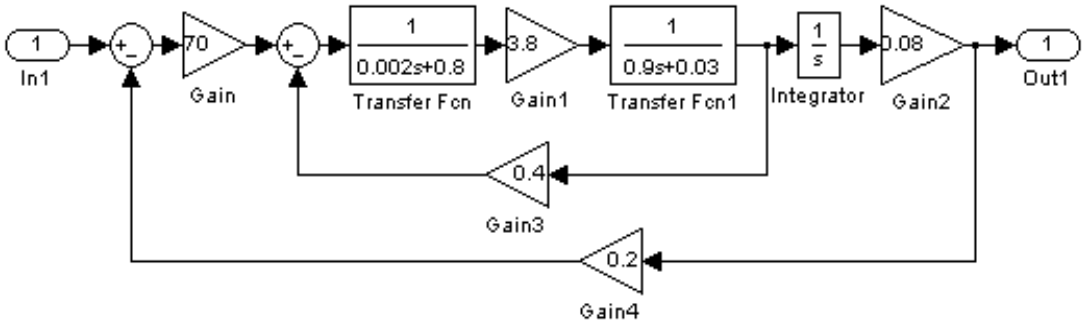

Fig.3 A System simulation example

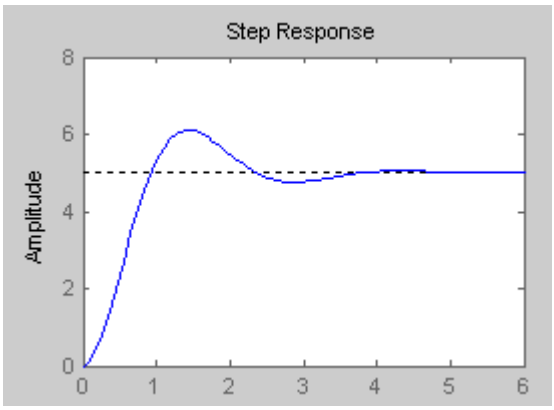

Fig.4 Step response characteristic simulation results

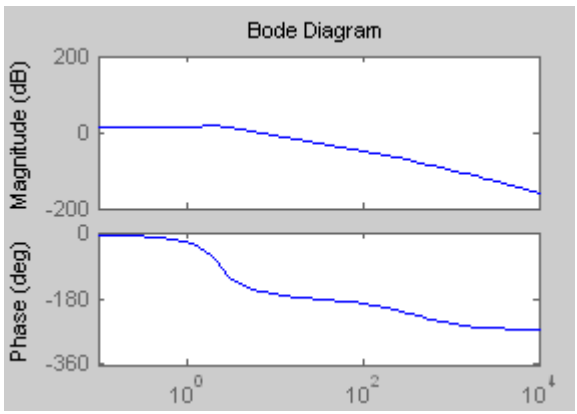

Fig.5 Amplitude-frequency characteristic simulation results

Conclusion

The established mathematical model reflect the actual situation of the system very well, the simulation result is close to the actual system. Using SIMULINK to simulate the electric servo control system, we can modify the parameters, and intuitively obtain simulation results. This method is Convenient and practical. According to the simulation model to analyze the static and dynamic performance of the electric servo system has important practical value of the electric servo system design, research and performance testing

Keywords: CVT; plug-in hybrid electric vehicle; target speed ratio; energy economy

Abstract: Taking CVT plug-in hybrid electric vehicle as the study subject, the objective function of the energy economy is created. In view of engine, motor efficiency and CVT efficiency coupled relationship; proposed reverse optimization algorithm to solve function. The target speed ratio of optimal energy economy is obtained in different SOC (State Of Charge), velocity, acceleration and slope. On the Matlab/Simulink platform, the system simulation model is built and simulated. The results shows that the target speed ration optimized control law in the case of no additional hardware cost , energy economy save about respectively 3.6% ,4.6%,6.7% in driving cycles of the NEDC,UDDS,HWFET before optimization.

Introduction

Traditional best economy control strategy of continuously variable transmission (CVT) only make the engine work in high efficient area . If plug-in hybrid electric vehicle(PHEV) adopts CVT as the transmission，its energy consumption is not only related to the engine efficiency, but also affected by CVT efficiency, motor efficiency and battery efficiency.

In this paper, the objective function of the energy consumption is set up, which is calculated by reverse calculation method. Then the best target speed ratio of CVT MAP is get under different state of charge (SOC), velocity, acceleration and grade. The PHEV model is built based on Matlab/Simulink, and the control laws of before and after optimization has carried on the simulation analysis.

Systen Configuration

The baseline vehicle studied in this paper is a parallel car with single-shaft and torque coupling as shown in Fig.1. The powertrain is composed of engine, motor, one-way clutch (C1), friction clutch (C2), CVT, differential,batteries and other parts. The role of the one-way clutch is to ensure that the speed of the one-way clutch is to ensure that the speed of the drive system is not lower than the engine speed. The friction clutch is used to start the engine and transfer engine torque.

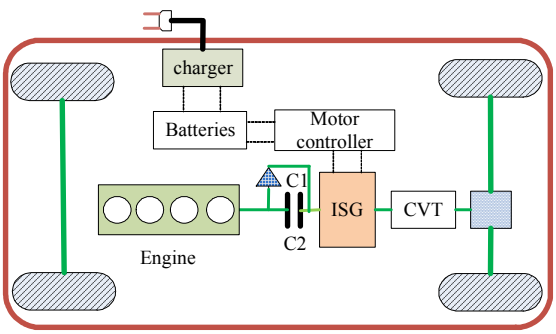

Fig.1. Drivetrain configuration of a parallel PHEV

CVT Speed Ratio Control Strategy

Influence factors.PHEV is different from ordinary sense of the hybrid electric vehicle. Part of its energy from the fuel, the other part is from the power grid. In order to unify the two energy measurement, defined in this article, the energy consumption economy function is the sum of two kinds of energy consumption of the cost.

The consumption of electricity cost can be expressed in equation (1).

$$Q_{electric} = \frac{a_{electric}\int_0^t P_m dt}{3600\eta_m\eta_{bat\_discharge}} \tag{1}$$

where $Q_{electric}$ is the consumption of electricity cost; $a_{electirc}$ is the price of power grid; P_m is the power of motor; η_m and $\eta_{bat-discharge}$ are the efficiency of motor and batteries.

The consumption of fuel cost can be expressed in equation (2).

$$Q_{fuel} = \frac{a_{fuel}\cdot g\int_0^t b_e P_e / 3600dt}{1000\gamma} \tag{2}$$

where Q_{fuel} is the consumption of fuel cost; a_{fuel} is the price of gasoline; g is the acceleration of gravity; P_e is the power of engine; b_e is the fuel consumption rate; γ is the heavy of fuel oil.

$$b_e = \frac{3.6\times10^6}{\eta_e Hu} \tag{3}$$

where η_e is the efficiency of engine; Hu is the low calorific value of gasoline.

Then the equation (3) is taken into equation (2). $$Q_{fuel} = \frac{a_{fuel}\cdot g\int_0^t P_e dt}{\gamma Hu\eta_e} \tag{4}$$

When the demand of vehicle power is P_v, the efficiency of CVT is η_{cvt}, the vehicle power from the actual need is indicated in equation（5）and（6）.

$$P_m + P_e = \frac{P_v}{\eta_{cvt}} \tag{5}$$

$$P_v = (mg\cos(\alpha)\cdot f_r + \frac{C_D A\cdot v_r^2}{21.15} + \ldots \cdots mg\sin(\alpha) + \delta ma)\cdot\frac{v}{3600\eta_{cvt}} \tag{6}$$

where m is the weight of vehicle; f_r is the rolling resistance coefficient; C_D is the drag coefficient; A is the frontal area; δ is the correction coefficient of rotating mass; v_r is the relative velocity; v is the velocity; α is the grade.

The energy consumption economy can be expressed as indicated in equation (7).

$$Q = \frac{a_{electric}\int_0^t P_m dt}{3600\eta_m\eta_{cvt}\cdot\eta_{bat\_discharge}} + \frac{a_{fuel}\cdot g\int_0^t P_e dt}{\gamma Hu\eta_e\eta_{cvt}} \tag{7}$$

By the equation (7) can be concluded that energy consumption economy is mainly affected by the efficiency of the engine, motor, batteries and CVT.

The definition of the optimization problem. According to the equation (7) can be seen that the optimization of energy consumption economy about PHEV, it comes down to the following optimization problem that seeks the best target speed ratio and the speed and torque of engine and motor under the given SOC, velocity and acceleration.

In this way, the system optimization objective function can be expressed as indicated in $\max Q$ (8).

The Analysis of Simulation Result

Based on the vehicle simulate model, a simulation for the optimization of CVT target speed ratio and the traditional economy embed the control target speed ratio are performed.

The figure 2 is the efficiency profile of motor and CVT in combined NEDC drive cycle. It can be seen that under most of the working point, the CVT efficiency and motor efficiency of after speed ratio optimization is more than before optimization.

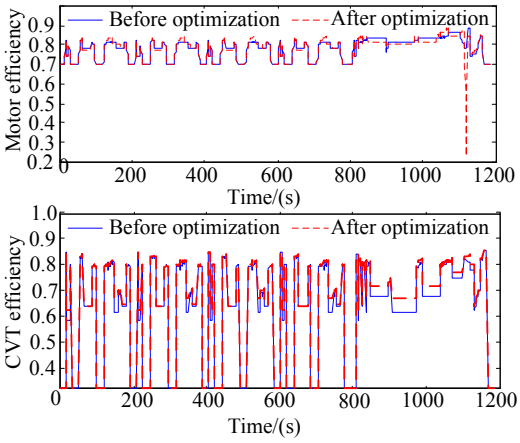

Fig.2. Simulation result in combined NEDC drive cycle

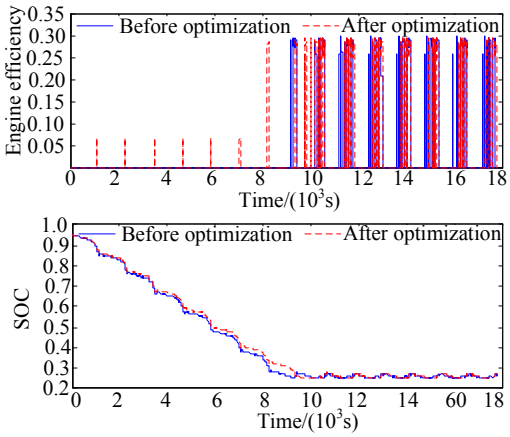

Fig.3.Simulation result in combined 15 NEDC drive cycles

The figure 3 shows the engine efficiency profile and battery SOC profile in combined 15 NEDC driving cycle. It can be seen that the engine participate in the work time is slightly different before and after speed ratio optimization; the most operations points have higher efficiency after optimization. This is because CVT better adjusts the engine working points.

Table.1.Simulation result in combined three drive cycles

Drive cycle	Q /Yuan			
	times	Before	After	Save
NEDC	1	0.88	0.86	2.27%
	10	19.57	18.57	5.11%
	15	42.73	41.2	3.58%
UDDS	1	0.88	0.85	3.41%
	10	18.48	17.34	6.17%
	15	41.64	39.87	4.25%
HWFET	1	1.54	1.47	4.55%
	5	12.47	11.02	11.63%
	10	50.14	48.15	3.97%

From the changing curve of the battery SOC, it can be seen that running time in CD mode is slightly greater than before optimization. This is because the optimized CVT speed ratio can improve the powertrain efficiency of the system. The simulation results of several drive cycles

shows in Table.1. It can be seen that the optimized target speed ratio can make the energy consumption economy save about 3.6 percent, 4.6 percent, 6.7 percent under NEDC, UDDS, HWFET, respectively.

Conclusion

In this paper, three contributions are proposed:

1) For plug-in hybrid cars can recharge the characteristics of the cost of objective function is established.

2) In view of the efficiency of CVT has coupling relationship between the efficiency of engine and motor, the reverse calculation of optimization method is designed to solve best CVT speed ratio under different SOC, velocity, acceleration and slope grade.

3) The simulation results shows that the energy consumption economy can save about 3.6 percent, 4.6 percent, 6.7 percent in NEDC, UDDS, HWFET, respectively, under the condition of without increasing hardware cost.

Keywords: PV Grid; Micro-inverter; Self-tuning PID Control; Fuzzy Control;

Abstract. This paper introduces a kind of grid-connected micro-inverter system. Photovoltaic micro-inverter system is a highly nonlinear and time-varying system. Compared to traditional linear control strategy, Fuzzy Controller has better robustness and stability in the changing or non-linear application. Matlab simulation model for current tracking PV Grid-connected Micro-inverter was completed based on the Fuzzy self-tuning PI controller and the control strategy was tested on the micro-inverter prototype. The resu1ts show that this control strategy can effectively reduce the tracking error of the net current, and improve the system's dynamic response.

Introduction

The micro inverter device can realize the maximum power tracking in panel level and support hot-plugging. The PV power generation system possesses the advantages of high power density, high conversion efficiency, high reliability, and flexible system scalability. Hence, the grid-connected micro-inverter system will be the trend of photovoltaic power generation[1-4].Photovoltaic power generation system is a multi-variable, time-varying system. In the absence of the precise mathematical model traditional linear control strategies is difficult to achieve the perfect performance[5].

In order to overcome the conventional PID controller's deficiencies and improve system performance，a certain intelligence Fuzzy reasoning will be applied to the PID parameter self-tuning in this paper. The parameters K_p,K_i of the PI controller can be tuned according to the operating status of the system. Therefore, the system can get a better dynamic and static performance.

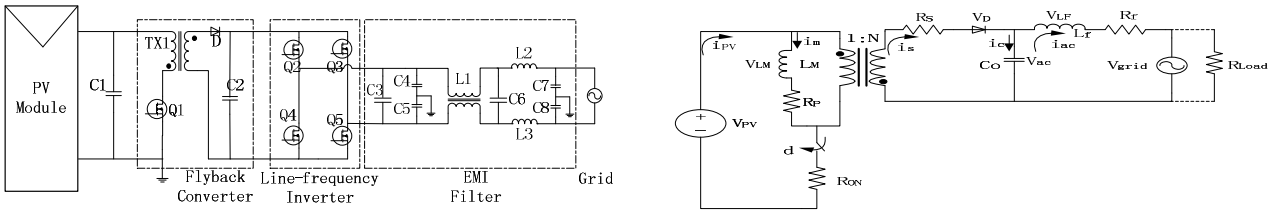
Model and Characterization

2.1 Topology Structure of Micro-inverter

In this paper the photovoltaic micro-inverter power generation system is mainly composed of PV module, micro-inverter and Grid, as shown in Fig.1 a. The micro-inverter mainly includes three parts, the DC/DC converter using flyback topology and the DC/AC converter using MOSFET full-bridge, and the filter circuit using Electro-Magnetic Interference (EMI).Functionally, the DC/DC part can achieve boost transformation, maximum power point tracking (MPPT), and it converts the DC output of the solar panels to a half-wave sinusoidal current. The output half-wave sinusoidal current is converted to be full-wave sinusoidal current by the DC/AC part, and then the current is fed to the EMI filter before the grid.

2.2 Model of Photovoltaic Grid-connected Micro-inverter

Flyback converter is the core part of the micro inverter, and its equivalent non-isolated circuit is a Buck-Boost converter. In order to facilitate analysis, the grid voltage V_{grid} is equivalent to half sine wave, and the system equivalent circuit is shown in Fig.1 b.



a Topology Structure b Equivalent circuit of micro-inverter

Fig.1 Topology Structure and Equivalent circuit of Photovoltaic Grid-connected Micro-inverter

Flyback converter has the following three states that need to be analyzed corresponding to three energy storage elements: flyback inductor current I_m, flyback output capacitor voltage V_{ac}, System output current I_{ac}. The averaged Kirchhoff's Voltage Law and Current Law (KVL and KCL) equations of the converter over one switching cycle are shown in Eqs.1-6.

$$V_{LM}=L_M\frac{d(i_m)}{d(t)}=d\cdot V_{pv}-d\cdot i_m(R_{ON}+R_P)-d'(\frac{V_{ac}+i_m\cdot R_s}{N}) \tag{1}$$

$$i_s=\frac{i_m}{N}\cdot d' \tag{2}$$

$$V_{LF}=L_f\cdot\frac{d(i_{ac})}{d(t)}=V_{ac}-i_{ac}\cdot R_f-V_{grid} \tag{3}$$

$$i_c=C_o\cdot\frac{d(V_{ac})}{d(t)}=i_s-i_{ac} \tag{4}$$

$$V_{grid}=R_{load}\cdot i_{ac} \tag{5}$$

$$i_{pv}=d\cdot i_m \tag{6}$$

Where d is the duty cycle of modulation signal, d' is the off-time (1-d), N is the turns ratio of flyback transformer. Assume X, U and Y represent the system static working point, $\tilde{x},\tilde{u}$ and $\tilde{y}$ are the perturbations over the operating point, then there are

$$x=X+\tilde{x}=[I_m\ \ I_{ac}\ V_{ac}]+[\tilde{i}_m\ \tilde{i}_{ac}\ \tilde{v}_{ac}] \tag{7}$$

$$u=U+\tilde{u}=[D\ V_{grid}\ V_{pv}]+[\tilde{d}\ \tilde{v}_{grid}\ \tilde{v}_{pv}] \tag{8}$$

$$y=Y+\tilde{y}=[I_{ac}]+[\tilde{i}_{ac}] \tag{9}$$

Substituting Eqs.7-9 into Eqs.1-6, the small signal linearized model is obtained, as shown in Eq.10 and Eq.11.

$$\begin{bmatrix}\dot{\tilde{i}}_m\\ \dot{\tilde{i}}_{ac}\\ \dot{\tilde{V}}_{ac}\end{bmatrix}=\begin{bmatrix}-\frac{R}{L_m} & 0 & -\frac{D'}{L_m\cdot N}\\ 0 & -\frac{R_f}{L_f} & \frac{1}{L_f}\\ \frac{D'}{N\cdot C_o} & -\frac{1}{C_o} & 0\end{bmatrix}\begin{bmatrix}\tilde{i}_m\\ \tilde{i}_{ac}\\ \tilde{V}_{ac}\end{bmatrix}+\begin{bmatrix}\frac{k}{L_m}\\ 0\\ -\frac{I_m}{N\cdot C_o}\end{bmatrix}[\tilde{d}]+\begin{bmatrix}\frac{D}{L_m}\\ 0\\ 0\end{bmatrix}[\tilde{V}_{pv}]+\begin{bmatrix}0\\ -\frac{1}{L_f}\\ 0\end{bmatrix}[\tilde{V}_{grid}] \tag{10}$$

$$\tilde{i}_{ac}=\begin{bmatrix}0 & 1 & 0\end{bmatrix}\begin{bmatrix}\tilde{i}_m\\ \tilde{i}_{ac}\\ \tilde{V}_{ac}\end{bmatrix} \tag{11}$$

where

$$D'=1-D$$

$$k=V_{pv}-I_m(R_{ON}+R_P)+\frac{V_{ac}+I_m\cdot R_s}{N}$$

$$R=D(R_{ON}+R_P)+\frac{D'R_s}{N}$$

In order to obtain the relationship between the micro-inverter output AC current (i_{ac}) and modulation input (d), the disturbance of other variables are not considered. Therefore, the transfer function is obtained between output AC current and modulation input, as shown in Eq.12.

$$G(s)=\frac{\frac{kD'-I_mR}{L_mN^2L_fC_o}-\frac{I_m}{L_mC_oN^2}s}{s^3+(\frac{R}{L_m}+\frac{R_f}{L_f})s^2+(\frac{RR_f}{L_mL_f}+\frac{1}{L_fC_o}+\frac{D^2}{N^2L_mC_o})s+(\frac{R}{L_mL_fC_o}+\frac{R_fD^2}{N^2L_mC_o})} \tag{12}$$

Self-tuning Fuzzy-PI Control Strategy

By Eq.12 shows that the transfer function of micro-inverter output current (i_{ac}) and PWM duty cycle (d) varies as the inductor(L_m) current (i_m). Self-tuning Fuzzy-PI control strategy is applied. The parameters (K_p, K_i)of the PI controller can be tuned according to the operating status of the system. Therefore, the system can get a better dynamic and static performance.

3.1 Fuzzy controller design

For fuzzy reasoning, take the grid-connected current deviation E and its rate of change E_c as input variables, the proportion coefficient increment ΔK_p, integral coefficient increment ΔK_i as output variables. Fuzzy subsets of the all the four variables are defined as {NB, NM, NS, O, PS, PM, PB}.

Triangular membership function is chosen in this paper. The membership functions of the current deviation E, the current deviation rate E_c, the proportional coefficient ΔK_p and the integral coefficient ΔK_i are shown in Fig.2.

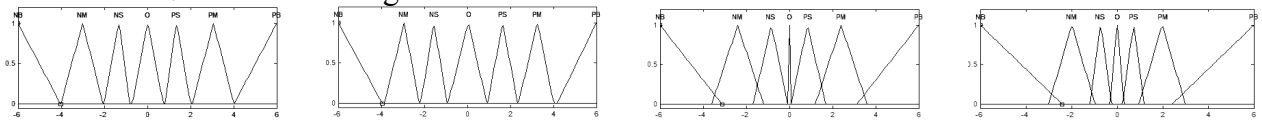


Fig.2 Membership Functions of the Input and Output variables

According to the knowledge of control theory and human control experience summary, in the design of adjustment rules to PI controller parameters, fuzzy rule tables are established , as shown in Table 1 and Table 2.

3.2 Structure of Self-tuning Fuzzy-PI

The idea of self-tuning Fuzzy-PI controller is to accommodate both the advantages of the traditional PI control and Fuzzy control. The system of the PV micro-inverter not only has a strong adaptability of Fuzzy controller, but also has a high precision of PI controller.The current deviation E and its rate of change E_c are selected as the two input variables of the two-dimensional fuzzy controller. Then, Fuzzy rules are built to make a reasonable and logical inference. The PID parameters are modified according to the Fuzzy control rules. $K_p=K'_p+\triangle K_p$, $K_i=K'_i+\triangle K_i$. The structure of self-tuning Fuzzy-PI Controller is shown in Fig.3.

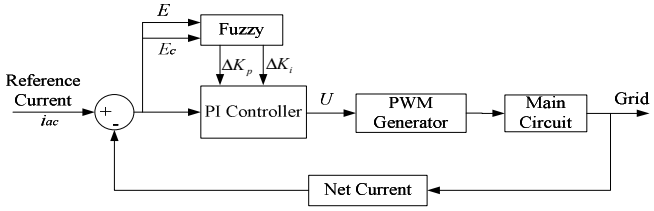

Fig.3 Structure of the Self-tuning Fuzzy-PI Controller

Simulation and Experiment

4.1 Simulation of micro-inverter system

Simulation model of the system is established using the Matlab SimElectronics component library. The Initial value of the fuzzy PI controller parameters are K_p= 0.01, K_i=500. Simulation structure of the micro-inverter system is shown in Fig.4

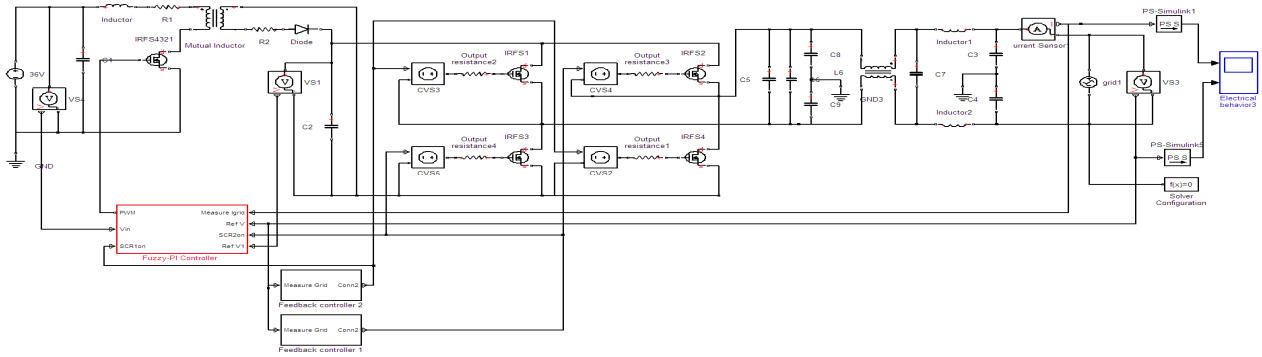

Fig 4 Simulation of micro-inverter system

Control method of fixed parameter PI controller and control method of Fuzzy-PI controller are performed respectively. Grid-connected current waveforms of the two methods are shown in Fig.5 and Fig.6. Obviously, compared with the grid-connected current obtained by fixed parameter PI controller, the grid-connected current obtained by Fuzzy-PI controller has higher sine degree and less harmonic content.

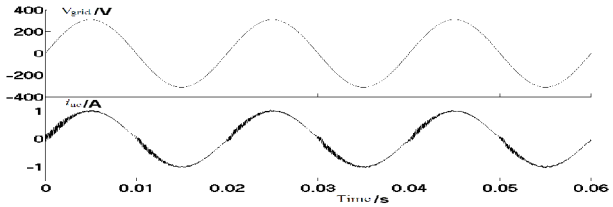

Fig.5 Simulation of fixed parameter PI controller

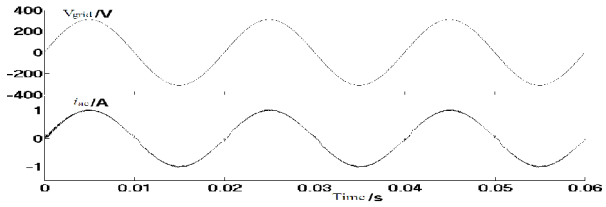

Fig.6 Simulation of Fuzzy-PI controller

4.2 Experiment of micro-inverter system

In order to verify the effectiveness of the system control method further, a 160w micro inverter prototype is completed, which is in accordance with the simulation of the system. DsPIC33 microcomputer is adopted as the main control chip, the turns ratio of the flyback transformer is 1:12, original side switch tubeQ1 is IRF3710, and switch frequency is 57 KHZ, vice side diode is C2D05120E, switch tubes Q2-Q5 of full bridge inverter part are IPB60R190C6, C1=12000 uF,C2=0.1 uF, C3=0.47uF, and L1=600 uH. The results of the experiment are shown in Fig.7 and Fig.8.

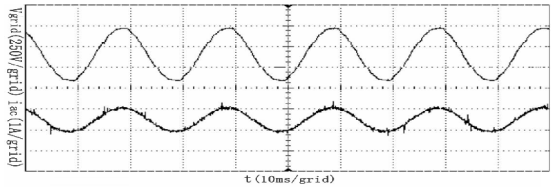

Fig.7 Experiment of fixed parameter PI controller

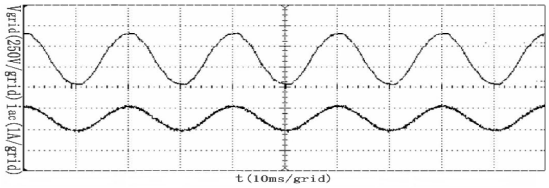

Fig.8 Experiment of Fuzzy-PI controller

Conclusion

In this paper, small signal analysis model of micro-inverter is established. As a high nonlinear and time-varying system, it is difficult to achieve good control effect using traditional PI controller. Self-tuning Fuzzy-PI control strategy is put forward for photovoltaic grid-connected micro-inverter. Simulation and experiment results show that the control strategy has the virtues of good robustness, and could reduce the harmonic content of grid-connected current. Therefore, the system gets a better dynamic and static performance.

Keywords: electro hydraulic, servo system, robust control, PID, accurate tacking.

Abstract. In recent years, electro hydraulic servo systems are more and more widely used in the aerospace, manufacturing industry and the agricultural machinery. As a result, higher requirements are put forward for the performance and application environment, including better tracking precision and respond speed. Aiming at the shortcomings of conventional PID controller, such as the large overshoot, long transfer time and poor robustness performance, a robust control scheme with dual-loop structure is proposed in this paper. Simulation results show that better performances are acquired in the novel approach in contrast with the PID control scheme and the structure of the proposed scheme is simple and easy to implement.

Introduction

Electro hydraulic servo control is an emerging science and technology, which was firstly presented in the 1950s and developed gradually to form a discipline. Especially in the late 1970s and early 1980s, great improvement and popularity of computer control technology laid the foundation of the combination of electronics and hydraulic technology, making a breakthrough in the capacity of the hydraulic servo control system used in complex systems. Electro hydraulic control system combines the advantages of both electric and hydraumatic. The tracking precision is relatively high and the whole system is fast and easy to tune. Moreover the control output power can be very large, resulting in a wide implement. It was firstly applied in military field, and latterly applied in varieties of industry areas such as mechanical manufacturing, mining, environment and electric power engineering and other automatic control of mobile devices [1-3].

In practical engineering, the most widely used control scheme is the proportional, integral and differential approach which is referred as PID control. Based on the system errors, the PID controller calculates the command by employing the proportional, integral and differential method. Owing to its simple structure, great stability and reliability, PID control scheme has remained a leading position in the industry control technologies. However, due to the nonlinear load torques and the uncertainties caused by the electro hydraulic servo system and the environment, PID parameters are inefficiently tuned which make it difficult to meet the control requirements [1]. As a result, a novel robust approach which can be applied to electro hydraulic servo system based on PID technology is studied in this paper.

Disturbance observer (DOB) [4] which is confirmed to be simple and practical ,is the most effective approach to solve the aforementioned problems. The main idea of DOB is to measure the errors between the outputs of the nominal and actual systems, and the estimated disturbance is adopted to eliminate interference. DOB holds capacity of anti-interferences and improve the system robustness against uncertainties including parameter perturbations and the disturbance of load torque [5-7]. Hence, DOB is introduced in the design of the robust controller for electro hydraulic servo system in this paper.

Problem Description

Electro hydraulic servo target is a hydraulic device composed of servo controller, power amplifier, hydraulic control component and actuators. The control component can be chosen as hydraulic valve or servo variable displacement pump and the actuators can be hydraulic cylinder or hydraulic motor.

Within a certain range, the amplifier output current i_v and the control voltage signal u are in proportion

$$i_v = K_u u \tag{1}$$

Where K_u represents the static amplification coefficient.

The linear flow equation of the control component is shown as

$$Q_f = K_Q i_v - K_C p_f \tag{2}$$

Where Q_f describes the load flow, K_Q describes the amplification coefficient and K_C represents the flow-pressure factor coefficient, after all p_f represents load pressure difference.

The continuity flow equation of the hydraulic cylinder is presented as

$$Q_f = A_t R \frac{\mathrm{d}\theta}{\mathrm{d}t} + \frac{V_t}{4E_y}\frac{\mathrm{d}p_f}{\mathrm{d}t} + C_{s1} p_f \tag{3}$$

Where A_t describes the piston area of the hydraulic cylinder, R describes the arm length, θ denotes the rotation angle correspond to the displacement of the piston, V_t is the total volume and E_y represents equivalent volume elasticity coefficient while C_{s1} indicates the total leakage coefficient.

The load torque balance equation is described as below

$$A_t R p_f = I\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2} + B_t\frac{\mathrm{d}\theta}{\mathrm{d}t} + K_t\theta + M_L \tag{4}$$

Where I denotes the total moment of inertia of the piston and load, B_t represents viscous damping coefficients, K_t describes the stiffness of the loading spring and M_L describes the load moment.

Taking Laplace transform, if there is no elastic load and the value of B_t is small, the open loop function of the electro hydraulic system is described as

$$G_P(s) = \frac{\theta(s)}{u(s)} = \frac{K_a}{s\left(\frac{s^2}{\omega_h^2} + 2\frac{\xi_h}{\omega_h}s + 1\right)} \tag{5}$$

Here $\omega_h = 2A_t R\sqrt{\frac{E_y}{IV_t}}$ represents natural frequency of the hydraulic pressure, $\xi_h = \frac{K_{ce}}{A_t R}\sqrt{\frac{E_y I}{V_t}}$ denotes the damping factor and $K_a = \frac{K_Q K_u}{A_t R}$ describes the open loop amplification coefficient.

The load torque of the electro hydraulic servo targets consist of moment of inertia M_J, moment of coulomb friction M_f, damping moment M_v, and position moment M_θ.The expressions of them are

$$\begin{cases} M_J = J\dfrac{\mathrm{d}^2\theta}{\mathrm{d}t^2} \\ M_f = M_{f0}\mathrm{sgn}\left(\dfrac{\mathrm{d}\theta}{\mathrm{d}t}\right) \\ M_v = K_v\dfrac{\mathrm{d}\theta}{\mathrm{d}t} \\ M_\theta = K_\theta\theta \end{cases} \tag{6}$$

So far, the modeling process of the electro hydraulic servo system has been completed.

Robust Control Design and Analyze

DOB based inner loop control. The basic idea of DOB is to observe the difference between the output of actual system and nominal model [4], which is caused by the external torque disturbance and the parameter perturbations, and take it into consideration in the design of control input. In other words, equivalent interference is observed and compensated in the control command. The construction of the DOB is illustrated in Fig.1:

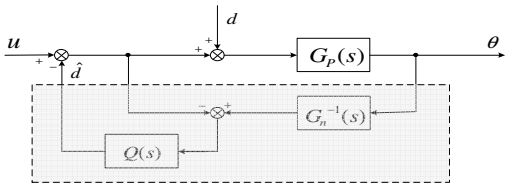

Fig.1 The construction of DOB

In Fig.1, $G_P(s)$ denotes the actual target, $G_n(s)$ is the nominal model, $Q(s)$ describes the low filter, d and $\hat{d}$ represent the equivalent interfering moment and its estimation respectively.

Consider u and d as control input and the system output is shown as

$$\theta = G_{U\theta}(s)u + G_{D\theta}(s)d \tag{7}$$

Where

$$G_{U\theta}(s) = \frac{G_P(s)G_n(s)}{G_n(s)+[G_P(s)-G_n(s)]Q(s)} \tag{8}$$

$$G_{D\theta}(s) = \frac{G_P(s)G_n(s)[1-Q(s)]}{G_n(s)+[G_P(s)-G_n(s)]Q(s)} \tag{9}$$

The frequency band of the filter $Q(s)$ is f_0, which indicates that in the low frequency, when $f \le f_0$, $Q(s) \approx 1$ .As a result, $G_{U\theta}(s) \approx G_n(s)$, $G_{D\theta}(s) \approx 0$. The results show that DOB leads the actual system be equal to the nominal model approximately, and hold strong suppression ability against various disturbance as well as parameter perturbations. Comprise between the robustness and the interference rejection capability is made by choosing appropriate $G_n(s)$ and $Q(s)$.

$G_n(s)$ is considered as unconstructed uncertainty and the simplified nominal model is established as

$$G_n(s) = \frac{K_{an}}{s\left(\dfrac{s^2}{\omega_{hn}^2} + 2\dfrac{\xi_{hn}}{\omega_{hn}}s + 1\right)} \tag{10}$$

Where K_{an} , ω_{hn} and ξ_{hn} are nominal parameters.

$Q(s)$ is a very important step in the DOB design, firstly to make $Q(s)G_n^{-1}(s)$ regular, the relative order of $Q(s)$ must be larger than that of $G_n^{-1}(s)$. For the nominal model $G_n(s)$, we can choose

$$Q(s)=\frac{4\tau s+1}{\tau^4 s^4+4\tau^3 s^3+6\tau^2 s^2+4\tau s+1} \tag{11}$$

The bandwidth design of $Q(s)$ is a comprise between the robustness and the interference rejection capability, which is decided by choosing appropriate τ.

Outer loop control based on PID. In order to achieve good tracing performance of the angular position, a PID controller using angular tracking errors based on DOB is designed in this section. The construction of the controller is shown in Fig.2

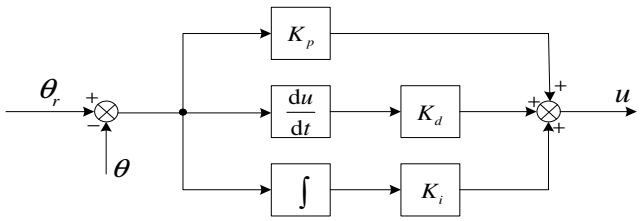

Fig.2 The construction of the PID controller of outer loop system

In Fig.2, θ_r describes the desired output of the electro hydraulic servo system, hence the output u is chosen as part of the input of the DOB.

Simulations

The parameters of the actual object are shown as $K_a=18.5$, $\omega_h=92.0$ rad/s, $\xi_h=0.32$.While the model parameters are $K_{an}=17.5$, $\omega_{hn}=94.0$ rad/s, $\xi_{hn}=0.30$.

We can conclude that model errors exist between the nominal and actual model, and the load torque coefficients are illustrated as

$J=0.00012\,\mathrm{N\cdot s^2/rad^2}$, $M_{f0}=0.55\,\mathrm{N}$, $K_v=0.0025\,\mathrm{N\cdot s/rad}$, $K_\theta=0.025\,\mathrm{N/rad}$

Considering the practice engineering, the control input of the servo controller is limited to ±10V.

The parameters of the control scheme are illustrated as

$\tau=0.0012$ s/rad, $K_p=6.0$, $K_i=0.0$, $K_d=0.25$.

While the conventional PID scheme is shown $K_p=1.2$, $K_i=2.5$, $K_d=0.065$.

The step signal is set as 10deg and the response curves under the control schemes above are shown in Fig.3.Conclusion can be made from Fig.3 that, in contrast with conventional PID control scheme, the setting time of the robust control approach in this paper is much smaller, in other words, the tracking velocity is increased and no obvious overshot emerges.

Then the desired angle signal is set as a 1Hz sine wave with amplitude of 1deg. The tracking error curves in both control approaches are shown as in Fig.4.From Fig.4, we can see that the tracking errors in the robust control method proposed in this paper are smaller than that of the traditional PID control. So far, the rationality and validity of the control scheme in this paper is demonstrated.

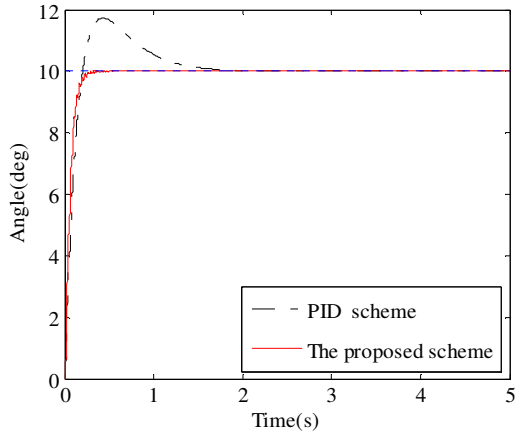

Fig.3 Curves of angle tracking under two control schemes.

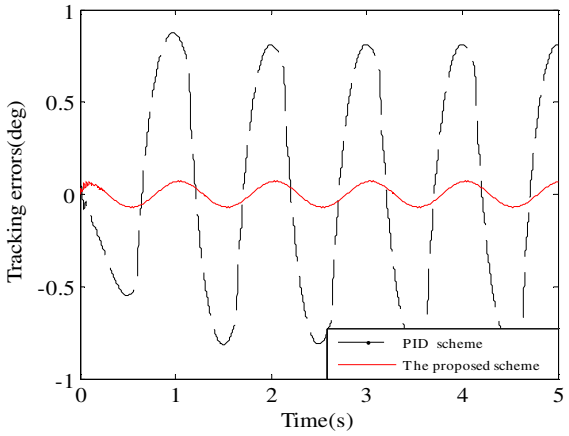

Fig.4 Curves of angle tracking error under two control schemes

Conclusion

In this paper, a novel robust control scheme using a dual-loop structure is proposed for the electro hydraulic servo systems with multi load torques. Simulations show that in contrast with conventional PID control approach, the electro hydraulic system achieves better performances under the robust control scheme with higher response speed and angular tracing precision, as well as smaller overshoot. As a result, the rationality and validity of the novel control scheme is demonstrated.

Keywords: SVG, PWM control, multilevel

Abstract. With the rapid development of control theory and microprocessor, many new rectifier control strategy has been born. In current power system, the rapid development of full-control devices, the high application of converter makes the electricity demand is higher and higher. At the same time the increase of power grid users, also bring more harmonic wave pollution, noise and other problems. Therefore, in the field of researching on inverter control has attracted more attention of more people. In order to meet the capacity of switching devices and reduce the switching frequency, often adopts multilevel topology structure [1]. This page based on the cascaded multilevel based on SVG topology structure, analysis of PWM control method and put forward a simple and feasible PWM control method and improve the utilization rate of DC side.

Introduction

According to the working principle of three-phase voltage source PWM rectifier [2-3], figure 1 is the basic unit topology of H bridge, it outputs three levels of +E,−E,0 under the different breakover combination of switching devices.

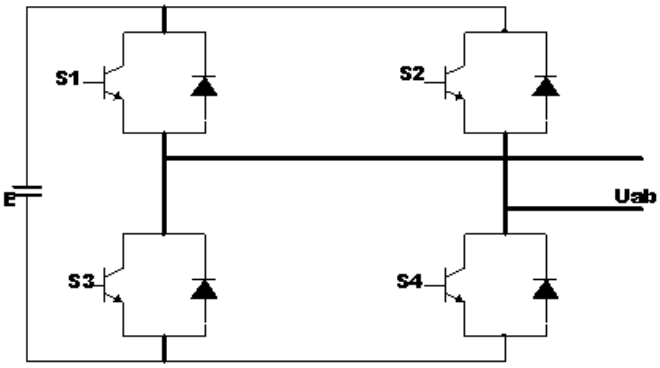

Fig. 1 The basic H-bridge topology

In order to avoid causing short because of the switching tube breakover in a common H bridge, so the IGBT of S1 and S3 do not on at the same time, and their pulse drive signals of T1 and T3 is complementary relationship [4]. In the same way, the S2 and S4 also don't on at the same time. When the IGBT of S_1 and S_4 on at the same time, H bridge output level = E, and when the IGBT of S_2 and S_3 on at the same time, H bridge output level = -E. Carrier wave use triangle wave or use sawtooth wave[5], in this paper to illustrate the optimization effect of the modulation wave, so the carrier still adopts triangle wave.

Putting the basic H bridges unit together constitute the cascaded multilevel SVG, n kind of cascaded structure of multiple units in series as a valve group, three valve form a complete set of three-phase inverter, the cascaded structure is easy to output the multilevel, figure 2 shows the main circuit structure of three-phase H bridge on multilevel SVG , the level number is 2n+1.

The Improved Control Algorithm of Cascaded Multilevel Converter

For cascaded multilevel converter PWM control, with the increase of number of level, its control strategy is also more and more complex, the triangular carrier phase shift PWM control method is only suitable for cascaded multilevel inverter, as long as the carrier ratio is high enough, it contains no

low harmonic and only contain higher harmonic which is related to carrier frequency in the PWM. To inject the zero sequence component to sine wave[6-7], the zero sequence component is a weighted average of the maximum and minimum values in three-phase transient sine wave, assume formula of a three-phase voltage are:

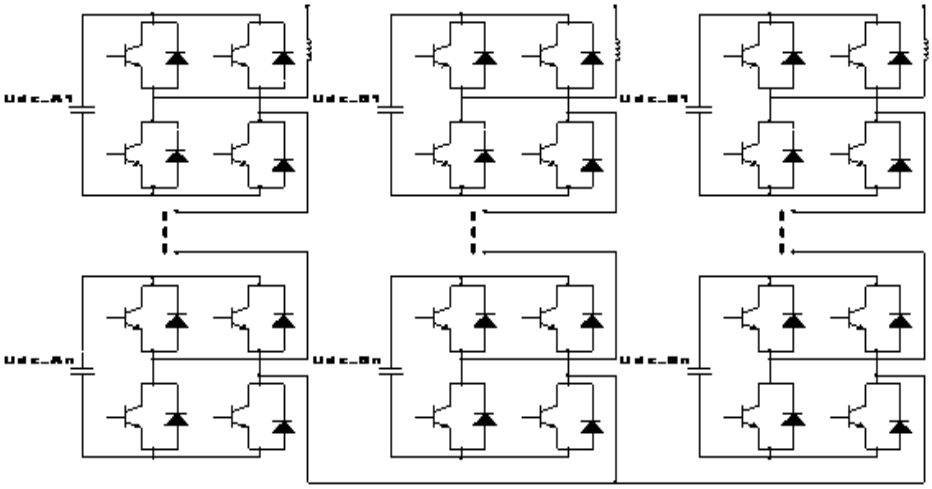

Fig. 2 Cascaded multilevel SVG topology

$$\begin{cases} U_{\alpha 1} = \mathrm{Ur}\sin(\omega t) \\ U_{\beta 1} = \mathrm{Ur}\sin(\omega t + 120°) \\ \mathrm{U}_{\gamma 1} = \mathrm{Ur}\sin(\omega t + 240°) \end{cases} \tag{1}$$

According to the above definition, the zero sequence component:

$$\mathrm{U}_0 = -\frac{\mathrm{MAX}(\mathrm{U}_{\alpha 1},\ \mathrm{U}_{\beta 1},\ \mathrm{U}_{\gamma 1}) + \mathrm{MIN}(\mathrm{U}_{\alpha 1},\ \mathrm{U}_{\beta 1},\ \mathrm{U}_{\gamma 1})}{2} \tag{2}$$

$$\begin{cases} \mathrm{U_a} = \mathrm{U}_{\alpha 1} + \mathrm{U}_0 \\ \mathrm{U_b} = \mathrm{U}_{\beta 1} + \mathrm{U}_0 \\ \mathrm{U_c} = \mathrm{U}_{\gamma 1} + \mathrm{U}_0 \end{cases} \tag{3}$$

Taking an example of seven power unit of cascaded multilevel converter, the carrier adopts triangle wave, the modulation waveform adopts the injected zero sequence component, the triangle wave sampling the sine wave and getting the step wave, the intersection point of the triangle wave and step wave controls the switching devices of conduction and shut off, so output the SPWM, the pulse width which is determined by the intersection point of the triangle wave and step wave when the triangle wave only in its vertex positions (or low) sampling sine wave, the method is only applicable to three-phase system, because of the injected zero sequence component cannot cancel each other in a single phase system, which contains three harmonics in output waveform, and this situation is not exist in the three-phase system.

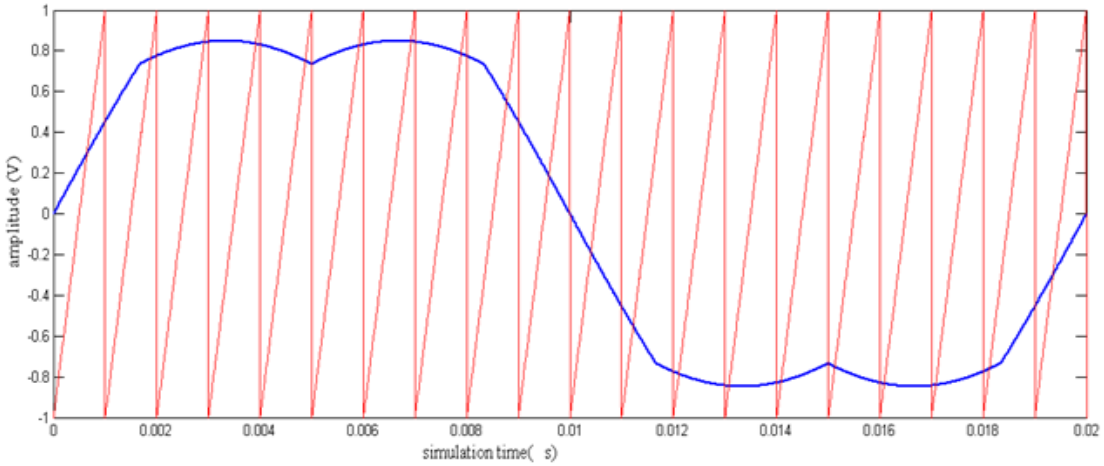

Fig. 3 The comparison of modulated wave with carrier wave

Simulated Analysis

According to the analysis above, built simulation model in the MATLAB, figure 5 is the overall structural model, figure 4 is the module of modulation wave formation after injecting zero sequence component, getting the transient value of maximum and the minimum of three phase by MAX and MIN module, and through the gain module to count its weighted average to get zero sequence component, and add the zero sequence component to sine signal to get the required waveform, out1 is the modulation waveform after injecting zero sequence component.

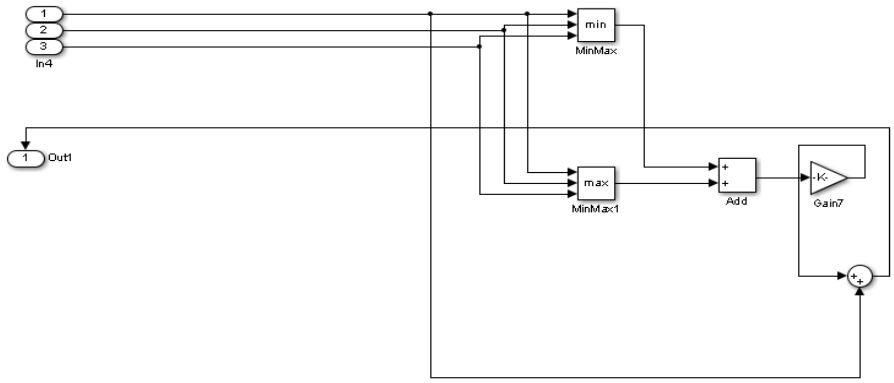

Fig.4 The module of modulated wave

Sine wave modulation frequency is 50Hz, phase difference is 120°, the triangular wave frequency is 1KHz, modulation ratio M = 0.9[8-9], the power supply of power unit is DC 700V, load is in series of resistance of 60Ω and inductance of 20mh. The picture below is the whole simulation graphics.

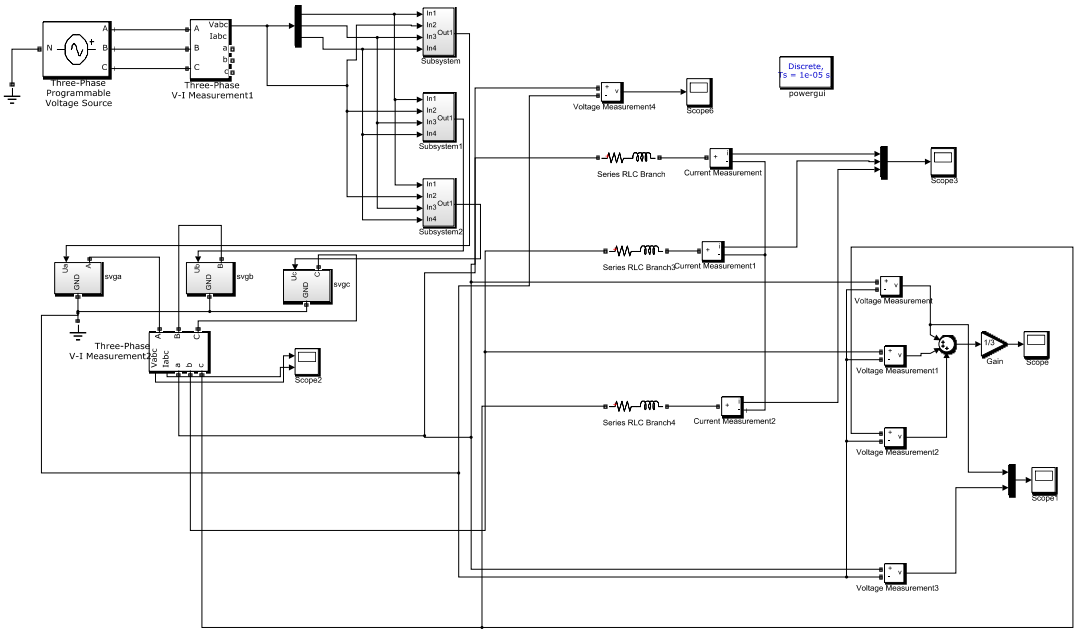

Fig. 5 Entirety simulation figure

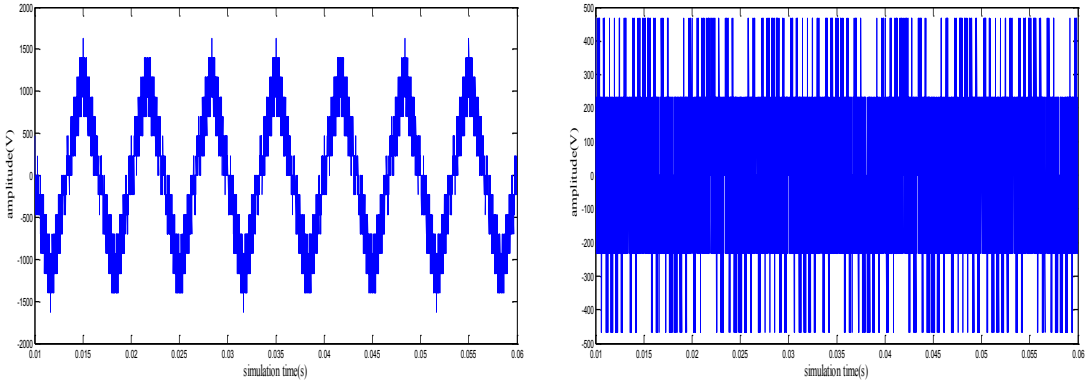

Fig. 6 The line voltage of system compare with unimproved

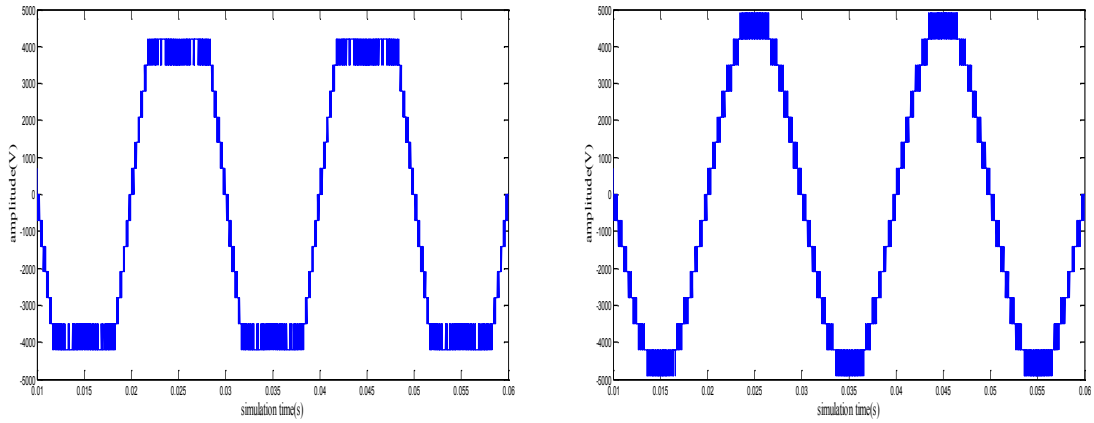

Fig. 7 The phase voltage of A-phase compare with unimproved

Conclusion

Figure 7 is A phase voltage after simulating. The system's line voltage as shown in figure 6, because of the influence of injecting zero sequence component, A phase voltage had a high time harmonic component, because of the harmonics in three-phase system offset each other, phase voltage fluctuation is serious, line voltage have a good harmonic characteristic.

From PWM control method of mechanism analysis, this paper deduced the improvement ideas of the PWM control method, an improved method of modulation wave modulation wave greatly reduces the complexity of calculation on for the high pressure of multilevel inverter control provides a simple and feasible method of PWM control, and in the MATLAB simulation to prove the validity of the theory and feasibility.

Research of direct torque control of asynchronous motor

Chunbo Gu[a, *], Zhongchu Wang, Lin Liu

University of Science and Technology Liaoning, Anshan 114000, China

[a]361047793@qq.com

Keywords: Asynchronous motor; direct torque control; Simulink

Abstract. Direct torque control (DTC) as a new type of motor control strategy, make the control system has good dynamic regulation performance. In this paper, we use the theory of direct torque control to research the speed regulation system of asynchronous motor direct torque control principle and its main component. Use Matlab/Simulink library to build the simulation model of induction motor DTC complete simulation and results show that the direct torque control run time has good control effect in asynchronous motor.

Introduction

Due to the torque control obtained the very good solve, ac motor won a wide application in industry [1]. Direct torque control is a kind of typical control theory after induction motor vector control theory. Direct torque control system is different from the vector torque control system, it static coordinates calculation and control stator flux linkage and torque of the motor directly with space vector concept by detecting the stator voltage and current and then to obtain high dynamic performance of the torque. Direct torque control has the advantage of fast dynamic response, simple control and small parameters dependence [2].

Dynamic mathematical model of asynchronous motor

The mathematical model of three -phase asynchronous motor is a high-order nonlinear and strong coupling multivariable system, in order to facilitate analysis the mathematical model of asynchronous motor, we have to idealize the motor model and make some assumptions, these assumptions are:

1.Uniform air gap, motor radial magnetic circuit isotropic, then, self-inductance of rotor winding don't changes over rotor position;

2.The rotor three-phase winding of the stator and rotor is symmetrical, the conductor space make sine distribution along the air gap effectively;

3.Ignore the harmonic magnetic field;

4.The rotor measurement are all converted to the stator side, so that the stator and rotor winding have the same number of turns;

5.Ignore the effect of magnetic saturation and the iron loss[3].

Based on the analysis of the direct torque control, we generally use the mathematical analysis method of space vector. Asynchronous motor is usually described in orthogonal stator coordinate system (α-β coordinate system), as shown in figure1 is the equivalent circuit diagram of space vector of asynchronous motor.

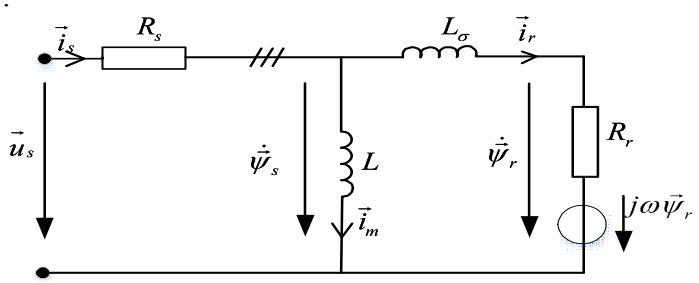

Fig.1 Space vector of asynchronous motor equivalent figure

Where $\vec{u_s}$ is the stator voltage space vector ; $\vec{i_s}$ is the stator current space vector; $\vec{\varphi_s}$ is the stator flux linkage space vector; $\vec{i_r}$ is the rotor current space vector; $\vec{\varphi_r}$: is the rotor flux space vector; ω is the electrical angular velocity.

And rules, we will be rotating space vector projection is called the alpha component on the shaft in the alpha and call the beta component in the beta axis in the orthogonal projection. By above knowable, asynchronous motor in stator coordinate system represented by the following formula:

$$u_s = R_s i_s + \dot{\varphi}_\mu \tag{1-1}$$

$$0 = R_r i_r - \dot{\varphi}_r + j\omega\varphi_r \tag{1-2}$$

It can be deduced stator and the rotor flux and electromagnetic torque equation by Eq. 1-2:

$$\vec{\varphi}_r = \vec{\varphi}_s - L_\sigma \vec{i}_r \tag{1-3}$$

$$\vec{\varphi}_s = \int (\vec{U}_s - R_s \vec{i}_s) dt \tag{1-4}$$

$$\vec{\varphi}_r + (\frac{1}{T_\sigma} - j\omega_r)\vec{\varphi}_r = \frac{1}{T_\sigma}\vec{\varphi}_s \tag{1-5}$$

$$T_e = \frac{3}{2} n_p (\varphi_{s\alpha} i_{s\beta} - \varphi_{s\beta} i_{s\alpha}) = \frac{1}{L_\sigma}\frac{3}{2}|\vec{\varphi}_s||\vec{\varphi}_r|\sin\theta \tag{1-6}$$

The formula for the rotor angular velocity, ω_r is the rotor angular velocity, θ is flux angle, $T_\sigma = L_\sigma / R_r$ is time constant of motor rotor. n actual operation of the asynchronous motor, it is necessary to keep the amplitude of the stator flux linkage as the rating, so as to make full use of the motor ferromagnetic materials; And the rotor flux linkage amplitude generally determined by the load. Because when the stator flux changing, the rotor flux vector basically remains unchanged, so as long as the change of the stator flux linkage vector space position, you can change the flux Angle theta and to change the electromagnetic torque of the motor. The rotor flux can be according to the type(1-3)by changing the rotor current. The stator flux linkage can be changed according to the type(1-4)to the integral of the stator voltage .Steady-state torque calculation can be finished according to the type(1-6)based on rotor flux and the flux Angle theta calculation.

Induction motor direct torque control theory

In recent years, the ac technique develops rapidly and gains a lot of creative achievements. Among them, Depenbrock who is a German professor put forward direct torque control(DTC)system in 1985.Direct torque is different from the vector control technology, it has its own features: simple structure, good performance, direct control means and so on. It rejected the idea of decoupling vector control and let the rotor flux orientation change of the stator flux orientation[5].In the operation of the motor, we just need to know the resistance of the motor parameters, so the direct torque control for motor parameters are lower than the dependence of vector control[6].

We analysis and control direct torque system which is based on voltage space vector. It convert the motor of sone physical quantity to vector by introducing the park transformation[7] and then using stator flux to analysis mathematical model of asynchronous motor in αβ0 coordinates. Then calculate the electromagnetic torque equation and the expression of the stator flux linkage according to u-n model [8]. After getting the electromagnetic torque and stator flux linkage, we make it and the value which has been given for hysteresis comparison. PWM inverter signal is obtained by look-up table and direct control of inverter switch state, so as to control the torque of the motor in real-time. The schematic diagram is shown in figure 2.

As we can see from the figure 2, A direct torque control system is made up collectively of motor, inverter, voltage, torque observer, flux observer, current two-thirds of converter, torque hysteresis comparator, flux hysteresis comparator, sector selection, speed regulator, switch selector and so on, it can be divided into three parts:

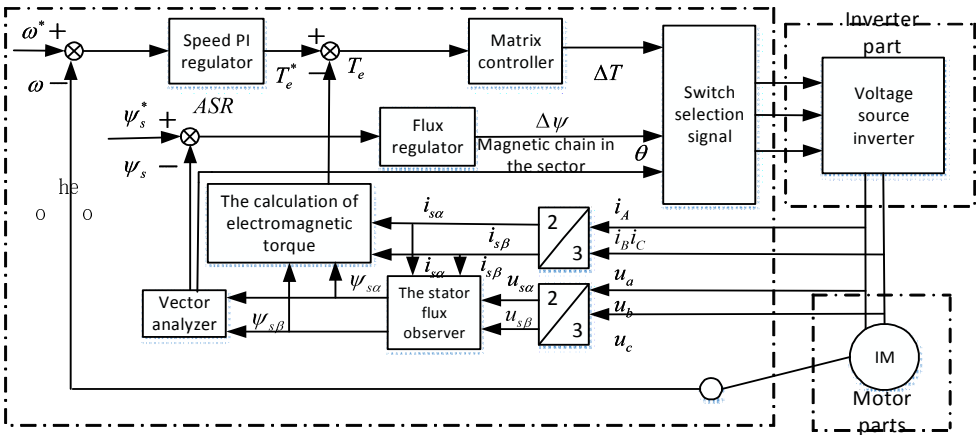

Fig.2 The basic component of direct torque control block diagram

The control part: voltage, torque observer, flux observer, current two-thirds of converter, torque hysteresis comparator, flux hysteresis comparator, sector selection, speed regulator, switch selector. This part mainly adjust torque, flux of interval judgment, stator flux linkage, it select the unit output of the inverter switching state through switch signal. Motor part: motor. Inverter part: inverter.

Among them, the flux observer and torque observer which are by sampling values of voltage and current through two-thirds change according to the asynchronous motor mathematical model to calculate the stator flux linkage and torque of the stator; Voltage state of the unit of flux position detecting should not only depend on the choice of flux linkage and torque control signal, but also on the stator flux linkage section, this unit is based on the stator flux linkage of alpha and beta component to determine the position of the stator flux linkage; Speed regulator control the speed by using of a given speed and feedback speed difference and then output a given value of torque through regulator; Flux regulator is to facilitate the control the change of the stator flux near the set value and then output flux control signal; The function of torque controller is that export torque control signal in a given output torque by using hysteresis control, thereby control the torque of the motor directly; The unit of switch state selector output appropriate switch state to control the inverter drive motor and stable operation according to the torque, stator flux linkage position and the stator flux linkage.

Direct torque control system simulation model

In this paper, the simulation based on Matlab 7.9,it is built in simulink which invokes the visualization module and combinate S function, its structure is simple,clear outline and control idea. System simulation is shown in figure 3:

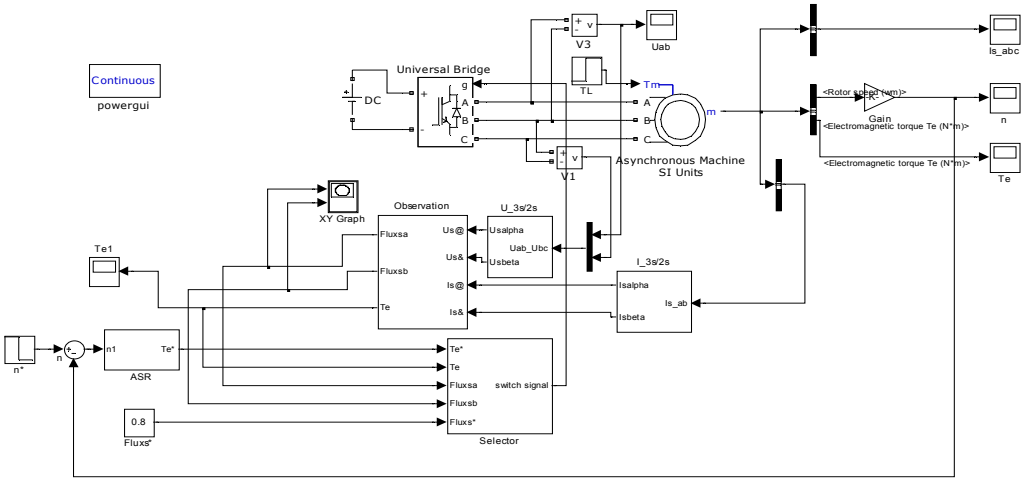

Fig.3 Induction motor direct torque control system simulation diagram

In figure 3, it use the three-phase asynchronous motor module which is provided by the Simulink Simpower systems. Its parameter selection are as follows: three-phase inter switch device IGBT power, the parallel feedback diode, IGBT buffer resistance R_s =100 $K\Omega$,buffer capacity C_s =inf. we

use asynchronous motor parameters in simulation experiments as: power rating P_N =15 KW , rated voltage U_N =400V,rated frequency f =50HZ,moment of inertia J =0.102 $kg \cdot m^2$, logarithmic n_p =2, stator resistance R_s =0.2147 Ω , stator inductance L_s =0.000991H,rotor resistance R_r =0.2205 Ω , rotor inductance L_r =0.000991H, stator mutual inductance L_m =0.06419H.System of other parameters: magnetic chain set in_flux =0.8Wb,voltage of dc side U_{dc} =490V,load torque T_L =60 $N \cdot m$, proportion coefficient of the PI controller K_p =50 and integral coefficient K_i =10,system sampling time T_s =1s,the given value of speed n_e in step 0.5s from 1420 $r/\min$ to 1200 $r/\min$,motor control method has always been a round flux control[10].All sorts of motor startup and steady-state waveform as shown in figure 4 to 7:

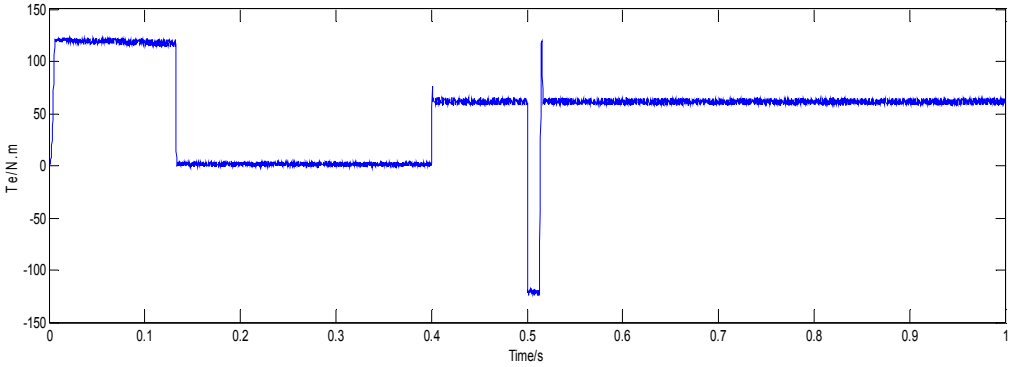

Fig.4 Electromagnetic torque waveform

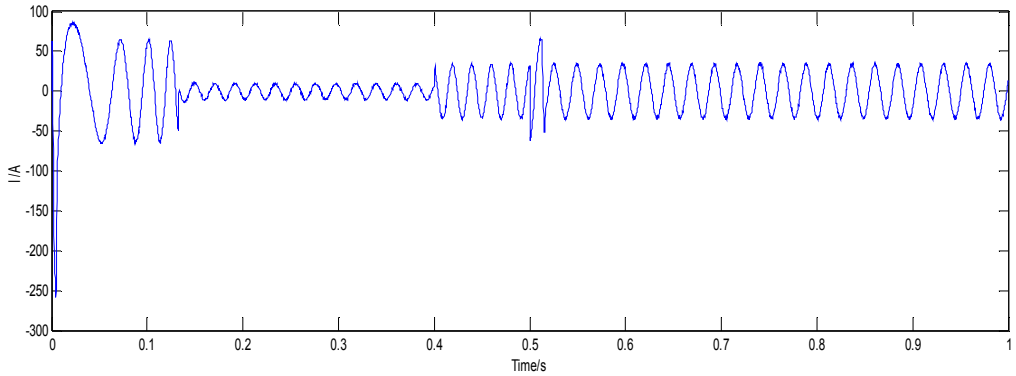

Fig.5 Motor stator current

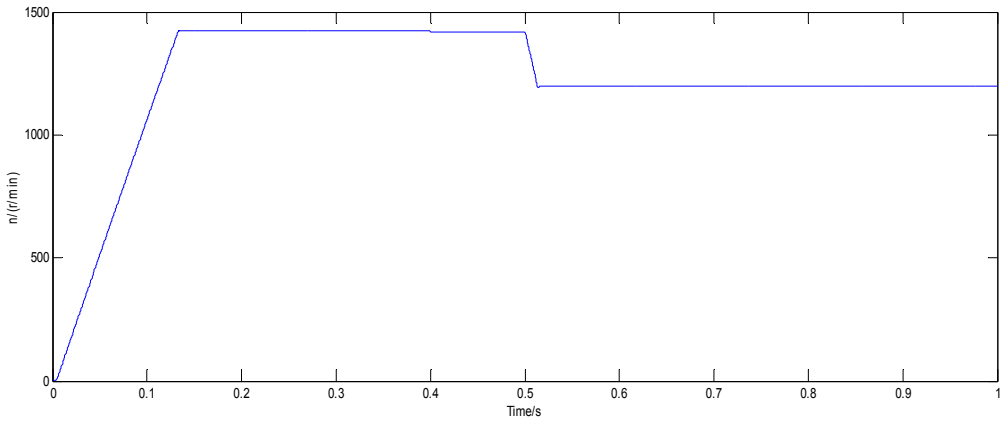

Fig.6 Motor speed waveform

Figure 4 and 5 respectively are motor electromagnetic torque waveforms and stator current waveform diagram. Figure 6 shows the waveform of motor speed, the simulation speed for a given value is 0.5s speed from 1420 $r/\min$ to 1200 $r/\min$, it can be see that speed feedback is good to follow a given that the system can meet the requirements of the speed control. Figure 7 shows the stator begin from the center, counterclockwise and amplitude increases gradually, achieve stable circle finally, it simulate the motor start-up process very well and its effect is very good. The reason is

that tolerance width of flux hysteresis regulator and the torque hysteresis regulator is smaller. If the tolerance of flux linkage and torque is large, the overall of flux is also circular but fluctuation of the circular will increase [11].

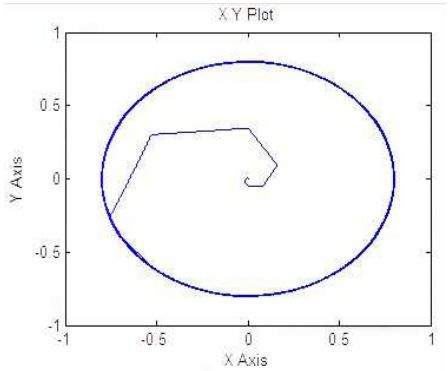

Fig.7 Stator flux linkage waveform

Conclusion

Direct torque control analysis the asynchronous motor of the mathematical model, control motor flux linkage and torque under stator coordinate system directly to make the system structure become simple and to implement more easy. It solved largely that control computation complex, features affected easily by motor parameters change and the actual performance is difficult to achieve the results of theoretical analysis and some major problems in the control of the vector.

Keywords: servo system; CNC; GISE; PID parameter tuning

Abstract. In this paper, the tricyclic control block diagram for CNC AC servo system of three phase permanent magnet synchronous motor was established. And three loop PID controller tuning was analyzed. At the same time, this paper proposed the tuning tricyclic PID parameters adopting GISE. Then take the CNC milling machine for example, simulation tuning was conducted in MATLAB using GISE. The results show that the servo system is no overshoot, fast response and good stability. So GISE is more suitable for parameter's optimization and tuning of permanent magnet synchronous motors' AC position servo system.

Introduction

With the development of power electronics technology, computer technology, control technology and sensor technology, the AC motor and DC motor control performance can become parable with good dynamic performance, so the AC drive system is widely used in CNC machine tools position servo system. Currently, the NC machine AC servo systems generally use tricyclic (current loop, velocity loop and position loop) PID regulator control technology, the traditional PID parameter tuning method has low efficiency, large errors shortcomings. In order to further improve the performance of CNC servo system; there is need for further research CNC servo system PID parameter tuning and optimization problems.

CNC AC servo system PID controller tuning tricyclic

CNC machine tools in AC Servo System uses a lot of three-phase permanent magnet synchronous servomotor(PMSM),three-phase permanent magnet synchronous servomotor with three-phase AC power supply, and its mathematical model with multi-variable, strong coupling and nonlinear characteristics, control them more complex, currently the most commonly used method is the use of vector transform method for linear motor decoupling control, getting mathematical model similar to the DC motor, the dynamic structure shown in Figure 1.

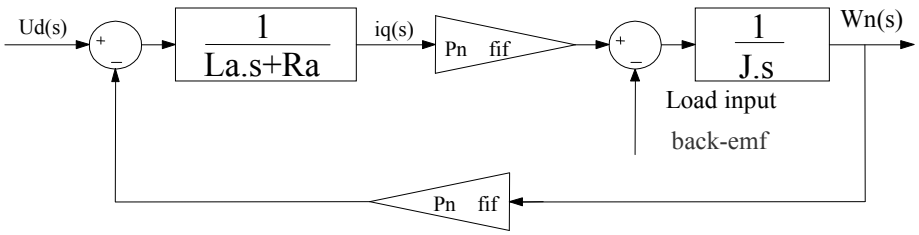

Fig.1 The block diagram of the PMSM

A. Design of the current loop tuning

In the tricyclic structure of permanent magnet synchronous servo system, high current loop is the fundamental of high performance servo system; its dynamic response is directly related to the implementation of vector control strategy or not, directly affecting the dynamic performance of the whole system. Decoupling the permanent magnet synchronous motor based on the model together with the above components, you can create permanent magnet synchronous motor current loop control block diagram shown in Figure 2.

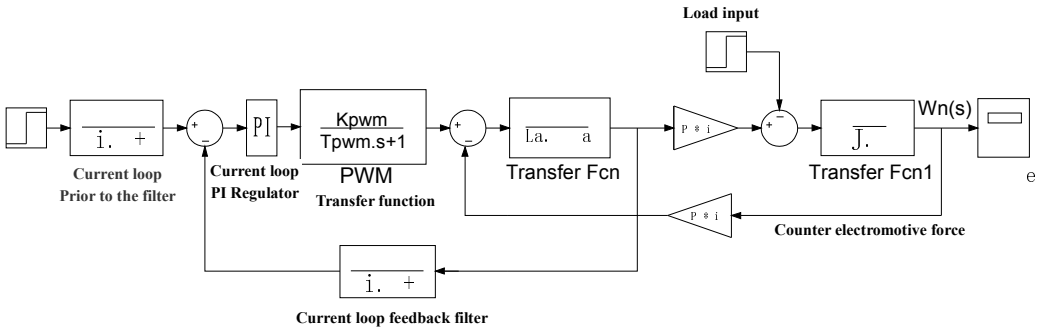

Fig.2 The block diagram of current loop

As the motor SPWM electrical time constant greater than the time constant, to offset the large inertia of the system delay, and improve the response speed of the current loop, taking the time constant equal to the motor controller electrical time constant, that is to take: adjust the current loop open after loop transfer function is:

$$G_1(s)=\frac{K_I K_{P1} K_{PWM}/R_d}{\tau_I s(T_\Sigma s+1)} \tag{1}$$

At this point, the current loop is adjusted second-order system, in accordance with order "best" system design to take:

$$\frac{K_I K_{p1} K_{PWM}}{R_a \tau_I} T_\Sigma = 0.5$$

Therefore $K_I = \frac{R_a \tau_I}{2K_{p1}K_{PWM}T_\Sigma}$, thus the current loop tuning regulator design is completed.

B. The design speed loop tuning

AC servo system speed control is an extremely important aspect. The servo control performance of its overall system performance is an important component of the speed servo control should have a high accuracy, fast response characteristics. When the design of the current loop similar to that in the speed loop in the feedback path and the low-pass filter link (filter time constant of0.01s), and after the given signal with the corresponding part of the balance filter. Speed loop control system block diagram shown in Figure 3.

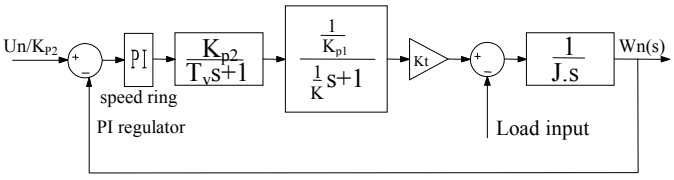

Fig.3 The simplified block diagram of speed loop

The role of the speed loop is usually resistant to load disturbances, inhibition rate fluctuations, the project will usually speed loop tuning into a type II system, so the speed loop regulator should also be designed as PI controller, the transfer function is:

$$G_{Pn}(s)=K_v\frac{\tau_v s+1}{\tau_v s} \tag{2}$$

At this point, the speed loop open-loop transfer unction is:

$$G_P(s)=K_v\frac{\tau_v s+1}{\tau_v s}\frac{K_{p2}K_t}{JK_{p1}s(T_v s+1)(\frac{1}{K}s+1)}=K_N\frac{\tau_v s+1}{s^2(T_{\Sigma v}s+1)} \tag{3}$$

Among: $K_N=\frac{K_v K_{p2} K_t}{K_{p1} J\tau_v}$, $T_{\Sigma v}=T_v+\frac{1}{K}$, Adopt $M_{r\min}$ criteria for selecting parameters, can be obtained:

$$K_N=\frac{h+1}{2h^2T_{\Sigma v}^2} \quad \tau_v=hT_{\Sigma v} \quad h=5 \tag{4}$$

Associated vertical (3) and (4) can be solved and, thus speed loop controller design tuning is completed.

C. Position loop tuning design

The main objective of the position loop is to quickly track the command value changes, the main performance indicator is the steady-state position tracking error and position loop gain. When the system processes the input after the end of the transient response, the servo system at steady operation the actual position error between the target value and the command is defined as the steady-state position tracking errors. Simplify the system structure shown in Figure 4.

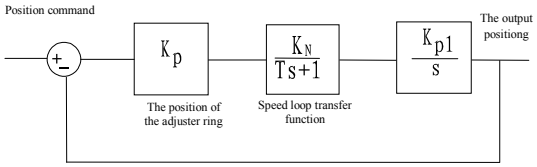

Fig.4 The simplified block diagram of position loop

CNC machine tools in the application, the general ramp input command signal to determine the location of the system tracking error, the unit ramp function input, position loop tracking error is:

$$\varepsilon = \frac{1}{K_{pp}} \tag{5}$$

Where is the position loop gain for the speed loop proportional coefficient for the speed loop gain for optical encoder detects amplification factor.

CNC milling machine servo system tricyclic setting calculation

Select Normal After transformation of NC milling machine Z-feed motor as the research object, the model for1FK6102, motor parameters are as follows:

$n_r = 3000rpm$, $I_r = 11.6A$, $M_r = 16.5Nm$, $J = 0.01215kgm^2$, $R_a = 0.15\Omega$, $T_s = 0.0022s$, $T_L = 0.0113s$, $K_{p1} = 1$, $T_v = 0.01s$, $K_E = 100V/1000rpm = 0.96V/(rad/s)$, $K_t = 1.51N \cdot m/A$, $K_{p2} = 1$, $K_{PWM} = 7.78V/A$, $T_{PWM} = 167us$, $T_i = 100us$.

The manual calculation of system parameters into the model test results of the tuning, analysis in time domain and frequency domain, the results after the setting shown in Table 1.

Table1 The quality of the corrected system

Performance	Current loop	Speed loop	Position loop
Regulation time s）	0.0025	0.2	0.4
Overshoot	2%	27%	0
Amplitude-frequency margin db）	19.5	26.8	10.6
Phase frequency margin deg）	65.6	42.2	74.2
Angular frequency amplitude-frequency shear rad/s）	1620	40.8	19.4
Phase frequency shear angular frequency rad/s）	7740	580	51.8

From the results, the position loop, velocity loop, current loop design results basically meet the needs of engineering controls. As for the speed loop overshoot, in practical applications, since the input is not a unit step, the actual overshoot to be much smaller.

AC servo system parameter optimization

As mentioned earlier, traditional AC Position Servo System parameter tuning regulator was designed to simplify all aspects of the transfer function into the corresponding typical link of frequency characteristics and root locus method regulator tuning parameters, which makes tuning parameters more complicated, and to some extent dependent on the engineer's experience, there is a certain degree of error, the system does not work in the best condition. In order to make the system optimal or sub-optimal mode of operation, experts and scholars put forward the optimal PID parameter tuning method, the optimal PID parameters self-tuning is the key performance index function selection and optimization algorithm, its direct impact to system optimization results. Common objective function includes ITAE, IST2E, GISE guidelines, criteria GIST example to do this in order to explore further.

Self-tuning PID parameter optimization criterion of GISE index function can be expressed as:

$$Q=\int_0^{\infty}\left[e(t)^2+\rho\dot{e}(t)^2\right]dt$$

Take GISE guide lines different? Valuesto optimize the system to optimize the results in Table2.

Table 2 Effect of initial value on optimum results

Initial [kp kv tsv]	optimization results [kp kv tsv]		
	?=0.001	?=0.01	?=0.05
[30 4 2]	[68.668 8.0495 0.207]	[46.666 11.491 0.544]	[16.523 9.257 2.132]

[20 1 0.01]	[71.903 13.773 0.588]	[42.625 11.429 0.049]	[16.159 9.476 0.790]

The results of the optimization objective function to the system model for the generation of the unit step response system and bode diagram shown in Figure 5 and Table 3.

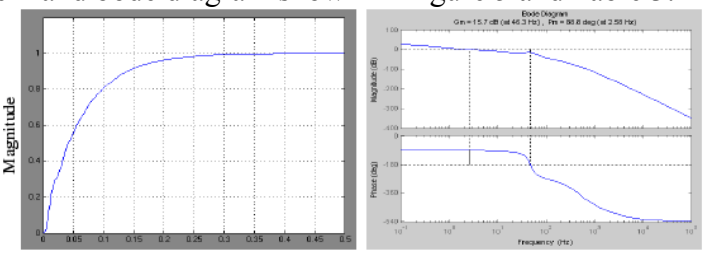

Fig.5 Optimized results of GISE rule

Table3 Effect of optimization rules on optimum results

Regulation time s）	Overshoot %）	Amplitude-frequency margin db）	Phase frequency margin deg）
0.35	0	15.7	88.8

GISE criteria optimization is the key to a reasonable selection parameter ρ, the smaller the parameter ρ take the optimized parameter valuesgreater choice in this case?=0.05, the optimized system regulation time of0.4s,no overshoot, and the transition process without oscillation.

To sum up, the generalized integral square error(GISE)as the optimization criterion, the optimized system has no overshoot, short response time(0.4s),the transition relatively stable, steady-state error characteristics of small, more suitable and permanent magnet synchronous motors AC position Servo System parameter Tuning.

Conclusion

In the traditional CNC position servo system tuning adjustment, the model simplification is bound to bring error for tuning results of PID parameters, and manual calculation is tedious and inefficient. While using MATLAB optimizing the system parameters can improve the efficiency and accuracy of the system parameter adjustment and the dynamic performance after tuning the system. The selection of optimal objective function has a great influence to the performance of the system after tuning; this research shows that it is more suitable to take GISE as the optimization criterion for permanent magnet synchronous motor.

Keywords: Micro-hydro Power;Self-excited Asynchronous Generator;Double Loop Control;Circuit Topology.

Abstract. On the existing independent operation of micro-hydro systems, a kind of circuit topology of micro hydro power based on self-excited asynchronous generator are studied. Using power electronic devices to meet power standard and reduce circuit losses. The double loop to control of inner current loop and outer voltage loop is studied, realizes the fast control of system and injected into the grid in the form of current, it's safety and high efficiency. Last,using experimental platform to verify the feasibility of the system.

Introduction

With increasing shortages for energy , people have a more deeply research on renewable energy power generation technology such as wind power , photovoltaic , micro- hydro,and distributed generation and grid technology has been known to the public. China is rich in micro- hydro resources , micro-hydro [1]have the advantages which power transmission line is simple , low cost, low maintenance costs , environmental pollution-free.etc, as one of important micro power is increasingly people's attention . From the cost analysis, if micro- hydro uses the traditional control of small and medium hydro electric power, it will have a high cost,therefore, micro-hydro use the asynchronous generator which does not control, the output power is constant. When users load changes , micro- hydro systems need to maintain a constant power outp ut for the power balance [2][3] , users load will absorb excess power through certain controls to ensure that the terminal voltage is constant. At present, micro- hydro power is used in remote mountainous areas in China , with the popularity of the grid, the grid in remote mountainous areas have been covered , but they are basically on the tip of the grid ,and have poor power quality , high electricity costs. On the basis of new energy technology on the network [4][5][6] , this paper proposes a new micro- hydro power topology and control strategy that based on the self-excited induction generator which is not control, it can be achieved a complementary between micro-hydro and electric power ,and reduce electricity cost of users.

Micro-hydro Systems Topology

When turbine drives in asynchronous generators, through the excitation and electromagnetic induction, the stator current and stator voltage are generated in the side of generator stator. The hydropower potential difference in the input side and the output load is fixed, the turbine speed is constant, the induction generator to maintain constant voltage and frequency values, so that the generator output voltage and frequency is constant, namely ,power generation devices have a constant power output.

The topology structure of micro-hydro power system as shown in Fig.1, the user load is directly connected to the asynchronous generator, the generator supply power to the local user load.The difference between the generator output power and load demand power will be backed to the grid by control circuit, thus ensuring the stability of the system. In order to avoid increasing the

harmonic to generator by the control loop, the control circuit is divided into two parts, before part adopts controllable rectifier, after part uses grid inverter, and then access LC filter circuit. The advantage of this design is the only difference power through electronic circuits, which reduces the capacity requirements of power electronic devices and equipment costs.

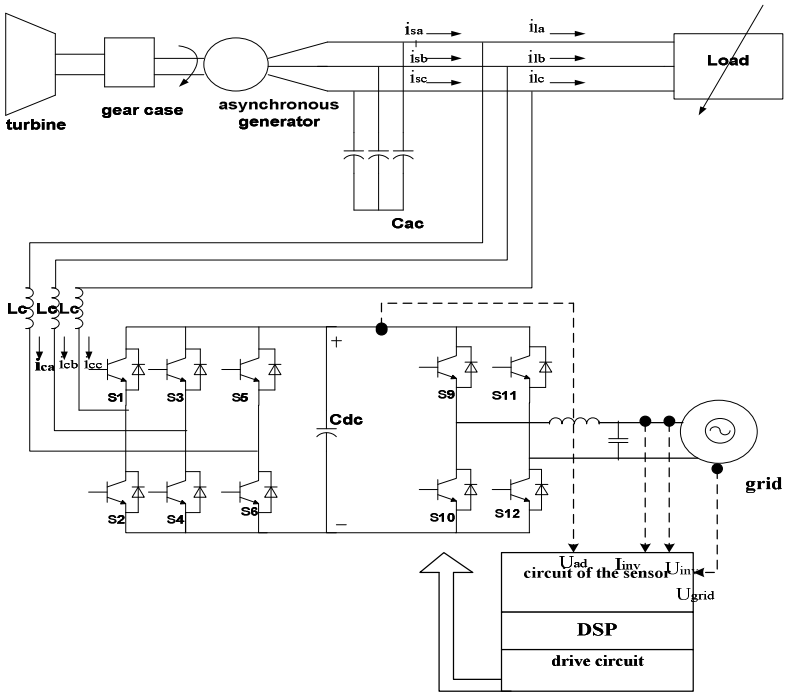

Fig.1. The grid-connected circuit topology of micro-hydro power system

The Grid-connected Control Strategy of Micro-hydro Systems

Analysis of the previous section, the no-controlled mirco-hydro output power is stability, once the users load changes, the generator voltage will also changes. In order to maintain the generator output voltage is stability, corresponding control strategy is used to calculate the difference power which depends on the load side voltage changes, then the difference power is injected into the grid in the current form, thus ensuring clients voltage is stability. In this paper, double-loop control strategy is used. Figure 2 is a block diagram of double-loop control. Current loop control and voltage loop control can be analyzed separately. In the inner current loop, including the current PI controller transfer function, the transfer function of the inverter, the filter transfer function. Its grid-connected process: given the reference current i*L, compared with the inverter side of the inductor current iL, the difference is accommodated by PI current controller, and then get modulated signal Ur through the inverter part, which will be corrected by the grid voltage, the sinusoidal current will be outputted with same frequency and phase of the grid after filtered links, system achieves grid-connected.

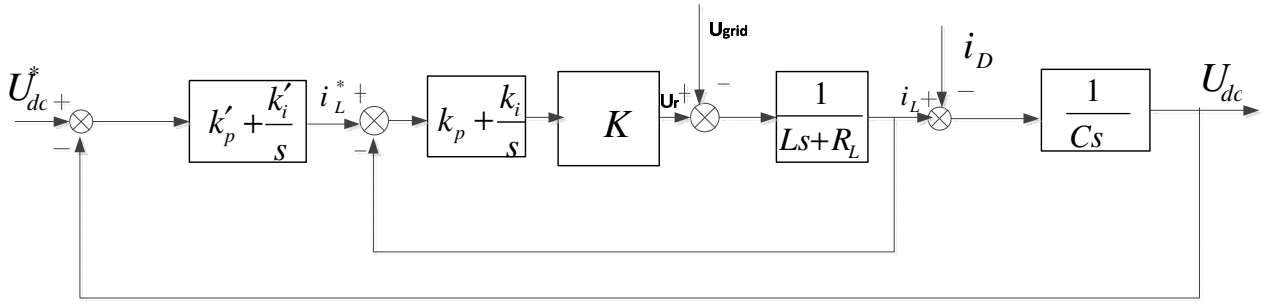

Fig.2. The block diagram of double closed loop

The inner current loop transfer function is:

$$G(s)=\frac{\frac{Kk_p}{L}s+\frac{Kk_i}{L}}{s^2+\frac{R_L+Kk_p}{L}s+\frac{Kk_i}{L}} \tag{1}$$

In Fig.2, the voltage loop control is analysised, which ignores the voltage sampling delay link, it consists of outer voltage transfer function of the PI controller, the current inner loop transfer function, the transfer function of the DC bus side. U*dc is reference voltage of DC bus, iD is the DC current perturbation, Udcis the actual DC link voltage. Its operation process is: compared the actual DC voltage with the reference voltage, the voltage difference is processed by the PI controller, it will generate reference value inner current, adjusted through the current inner loop, the actual current of the output inverter side is disturbed by disturbance current and decoupling control,so that the DC bus voltage is stability.

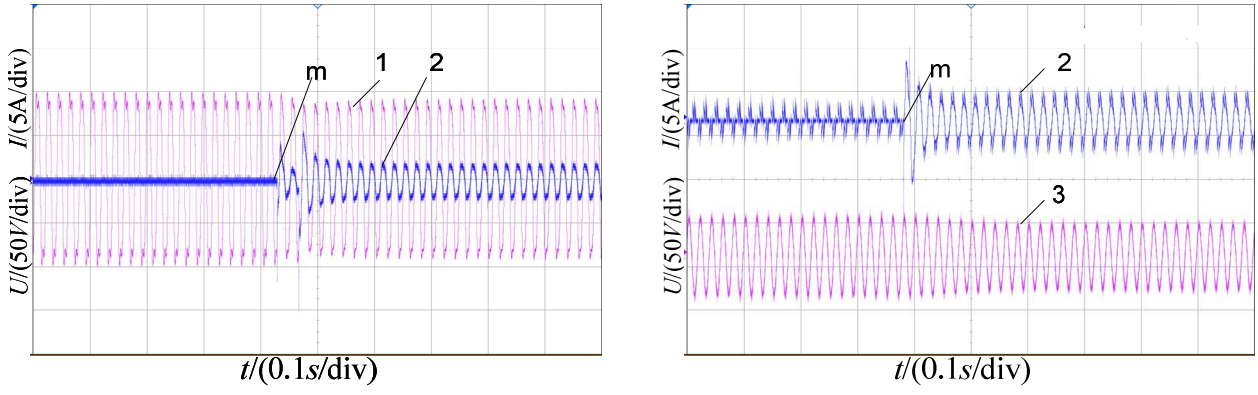
The outer voltage loop transfer function:

$$G(s)=\frac{\frac{k_p'K'}{C}+\frac{k_i'K'}{C}}{s^2+\frac{k_p'K'}{C}s+\frac{k_i'K'}{C}} \tag{2}$$

Experiment Results

In this paper, the experimental platform is builded to verify the feasibility of systems. In the experiment, using frequency converter control 2.2kW three-phase asynchronous motors that simulates micro-hydro turbine, 1.5kW three-phase squirrel cage induction motor is choosed as self-excited generator, the output side of generator connects to the variable resistive load.

Figure3(a) is the waveform of generator output voltage and output current with the load side changes, the curve 1 is output voltage of the generator, the curve 2 is load current in the user side. Figure3 (b) is the waveform of generator output current and inverter output current when the load side changes, the curve 2 is load current in the user side, the curve 3 is the output current of the inverter side. Before the point of m, when the generator is opened, as the local load power is 0W, load current in generator side is 0A, the maximum output voltage is 220V, the output maximum current of the inverter is 2.3A. When the load power increases 400W at the point of m, the load current is 1.2A, the output current of the inverter side that grid current is automatically reduced, the voltage is essentially unchanged. It illustrates that the system which uses a self-excited induction generator-controlled has a good operating performance and feasible.



(a) (b)

Fig.3 The waveform of output voltage in generator side and current of load and output current in inverter side with the load power changes

Fig.4 is the waveform of output current in the inverter side and the grid voltage, the curve 4 is the output current in inverter side, curve 5 is the grid voltage. From the Fig.4 ,as the phase and frequency of the inverter output current and grid voltage, the grid current has a good tracking variation with the grid voltage, and the output current is stable, the power factor is close to 1.

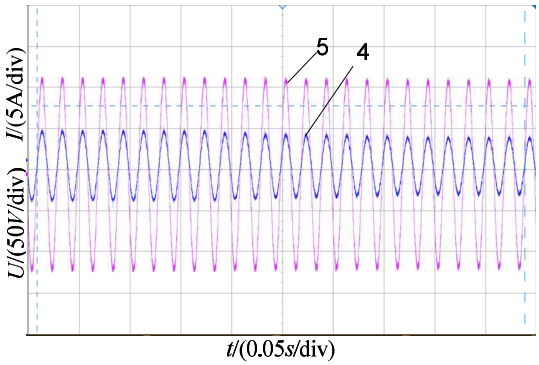


Fig.4. The waveform of output current in inverter side and grid voltage with the load power changes

Conclusion

This paper presents a novel micro-hydro system circuit topology and the corresponding control strategy. Experimental results show that when the load changes, the output voltage of the generator-side remains substantially constant, the generator-side load current increases, the output current of the inverter side decreases, that is in line with the theoretical analysis. The output current of the inverter can maintain the same frequency and phase with the grid voltage , power factor closes to 1, the system is reliable.

Abstract. In order to improve the performance of vehicle steering system and reduce the system energy consumption, the structure and operation principle of an electro-hydraulic power steering(EHPS) system with a electro-hydraulic steering pump are described, on this basis, with the function requirement of steering system, and by using vehicle design and fluid drive theory, the design method of this electro-hydraulic steering pump and its matching with the vehicle are presented. Through building electro-hydraulic steering pump test platform to test its performance parameters, the results prove the correctness and effectiveness of this kind of design method, provide the basis for subsequent development of the electronic control system.

Introduction

EHPS system is developed on the basis of the hydraulic power steering(HPS) system, the use of electric motor to drive the steering pump. EHPS system has three advantages relative to the HPS system: (1)steering light; 2 good fuel economy; (3) steering road feeling good[1-3].

Based on the vehicle design and fluid drive theory, this paper puts forward the design method of this electro-hydraulic steering pump and its matching with the vehicle. Through building electro-hydraulic steering pump test platform to test its performance parameters, it provides the basis for subsequent development of the electronic control system.

Composition and Working Principle of EHPS System

EHPS system is mainly composed of electric steering pump, electric control unit (ECU), steering wheel angle sensor, vehicle speed sensor, power steering gear, cylinder, etc, shown in Fig.1.

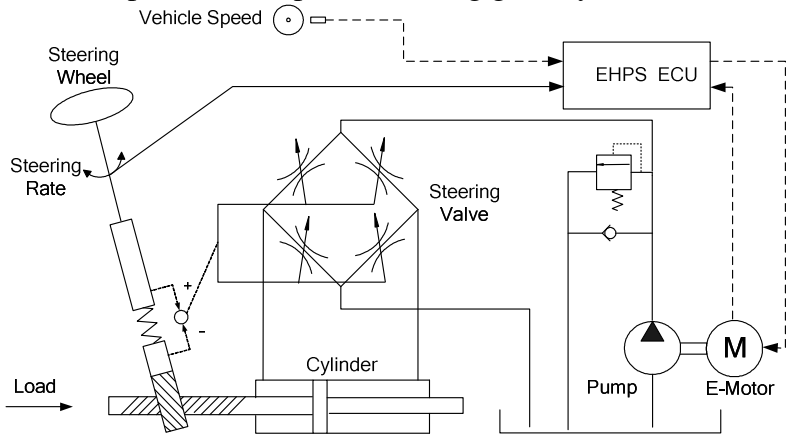

Fig.1 EHPS Working Principle

In the process of vehicle steering, according to the speed of vehicle, the steering wheel angular velocity sensor signal, the EHPS system controller output a pulse width modulation(PWM) duty ratio signal to control the speed of the motor, so as to control the steering pump output flow rate change, and to control the pressure into the power cylinder oil, to control the steering force.

Design of Steering Pump Working Parameters

In the parking steering, a steering wheel steering resistance torque T_1 can be used to estimate as follows[4,5].

$$T_1 = \frac{\mu}{3}\sqrt{\frac{G^3}{P_w}} \tag{1}$$

Where: T_1 is a steering wheel steering resistance torque at the time of the parking steering, N•m; G is acting on a tire normal load, N; μ is sliding friction coefficient between the tire and the road surface; P_w is tire pressure, Pa.

The front axle steering resistance torque T_2 of the parking steering is $2T_1$.

In the parking steering, power steering gear output torque T_3 is described as follows.

$$T_3 = P \cdot A \cdot L \cdot (\cos\theta_1 + \cos\theta_2)/\eta \tag{2}$$

Where: P is power cylinder maximum pressure, MPa; A is power cylinder piston effective area, mm^2; L is knuckle arm length, mm; θ_1,θ_2 are respectively inside and outside the maximum steering angle of the front wheels, °; η is mechanical efficiency of the transmission mechanism of the steering.

Generally approximate that T_2 and T_3 are equal, Eq.3 can be calculated by the system maximum working pressure P.

$$P = \frac{T_3 \cdot \eta}{A \cdot L \cdot (\cos\theta_1 + \cos\theta_2)} \tag{3}$$

According to the maximum pressure of the hydraulic cylinder P and loss of the system pressure $\Sigma\Delta P$ to determine the maximum working pressure P_{max} of pump.

$$P_{max} = P + \sum \Delta P \tag{4}$$

Where: P_{max} is maximum working pressure of pump, MPa; $\Sigma\Delta P$ is loss of system pressure, MPa.

Steering desired flow Q_0 is generally determined by power piston effective area A, rack & pinion steering gain G_R and steering wheel maximum rotational speed n. It can be approximated by the volume change of the power cylinder as a function of time with the leakage flow Q_2 within the steering gear.

$$Q_0 = G_R \cdot n \cdot A \times 60 \times 10^{-6} \tag{5}$$

Where: Q_0 is steering desired flow, L/min; G_R is rack & pinion steering gain, mm/r; n is steering wheel maximum rotational speed, r/min.

The actual need for the pump maximum flow Q_1 (L / min) is:

$$Q_1 = (1.5 \sim 2)Q_0 + Q_2 \tag{6}$$

Where: Q_1 is actual need for the pump maximum flow, L/min; Q_2 is leakage flow within the steering gear, L/min.

By calculating the above parameters, hydraulic power required by the system can be estimated by the Eq.7.

$$W = Q_1 \cdot P_{max}/\eta_p \tag{7}$$

Where: W is hydraulic power required by system, W; η_p is total efficiency of steering pump.

Then pump structure, the size of the pump cavity is optimized design, make it accord with common displacement values in the series. According to the calculated pressure and flow to design the steering pump.

Design of Motor Parameter

Motor is one of the important parts of EHPS system, the power of the motor is slightly bigger than steering pump power.

The output torque of the motor T_i (N, m) as follows.

$$T_i = \frac{P_{\max} \cdot q}{2\pi \cdot \eta_m} \tag{8}$$

Where: η_m is mechanical transmission efficiency between the pump and motor.

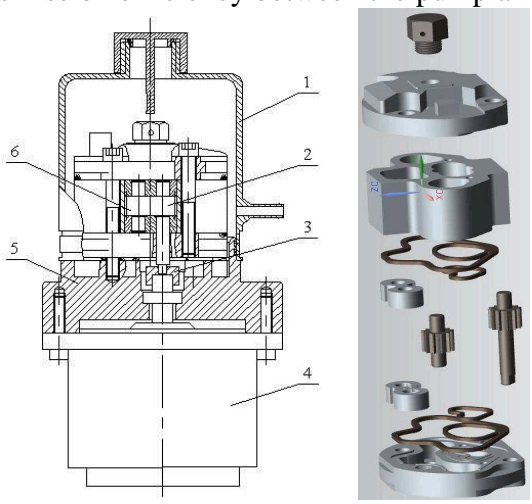

Fig.2 Electric Steering Pump Structure

5-pump and motor coupling body 6-driven gear

Experiment Research of Electric Steering Pump

Experiment principle is shown in fig.3. In the experiment, through the throttle valve 5 to adjust the size of the steering pump 2 export work pressure, adjust the speed of motor 1 to control the steering pump output flow, motor speed by rotating speed sensor 5 acquisition, acquisition the actual output flow of steering pump under different working pressure through the pressure and flow sensor group 4.

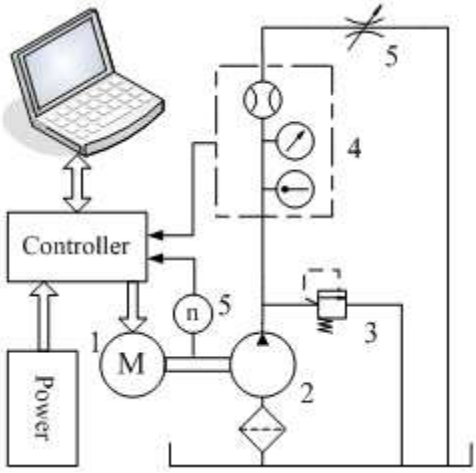

Fig.3 Principle Diagram of Electric Steering Pump Test

Flow-Pressure Characteristics of Steering Pump. Under different speed and different working pressure of steering pump output flow is measured, the output flow and pressure characteristic curve is obtained, as shown in Fig 4. Steering pump flow rate decreases with the increase of test pressure, with the increase of test speed increases.

Volumetric efficiency of Steering Pump. Under different rotation speed and in different working pressure, the volumetric efficiency of the pump features along with the change of pressure is measured.

$$\eta_v = \frac{Q}{Q_0} \tag{9}$$

Where: Q_0 is the theory flow of the pump under different rotational speed, L/min; Q is the actual flow of the pump under different pressure, L/min.

As shown in Fig.5, the volumetric efficiency of the pump decreases with the increase of test pressure, with the increase of test speed increases.

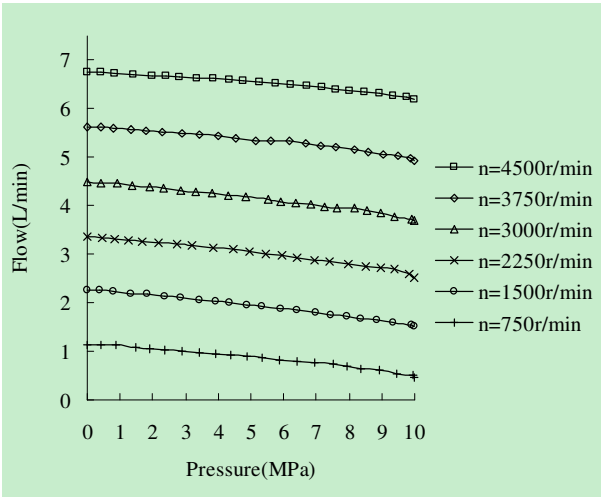

Fig.4 Flow and Pressure Characteristic Curve of Electric Steering Pump

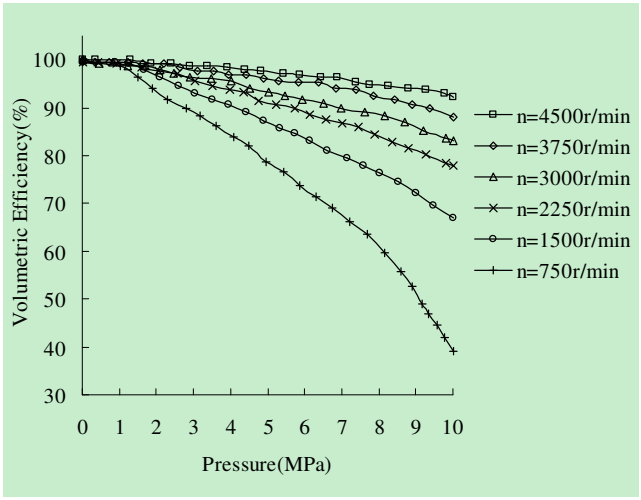

Fig.5 Volumetric Efficiency of the Steering Pump

As shown in Fig.5, with the pressure rising, the volumetric efficiency of the pump was significantly decreased trend when the rotating speed of 750 r/min, the volumetric efficiency is low; When speed up to 1500 r/min, volumetric efficiency is obvious rise, but it is still not ideal. Speed of 2250 r/min, 3000 r/min and 3750 r/min and 4500 r/min of volumetric efficiency curve were similar, the volumetric efficiency is over 80%, it is ideal.

Summary

EHPS system is new concept of vehicle steering system. At present, domestic is lack of mature design theory and method of EHPS system. In this paper, the key parts of electric hydraulic pump of EHPS system was designed, the design method is verified for the correctness and validity through experiment, and provides a theoretical basis for the research and development of the electric hydraulic pump.

Keywords: Distributed Generation; DC Micro-grid; Energy Saving; Voltage Stability;

Abstract. Distributed generation(DG) into DC micro-grid can save a lot of converter equipments compared with AC micro-grid,.So,with the popularity of DG,DC micro-grid technology also has get great development.However,the key technology of DC micro-grid is not yet mature.This paper is based on shanghai DC micro-grid demonstration project of Sate Grid Smart Grid Research Institute.Firstly,we analysis the advantages and disadvantages of AC,DC and AC/DC hybrid micro-grid.Then, after comparison and analysis of DC micro-grid topology,we put forward system scheme and corresponding control strategy.The simulation results show that, the proposed control strategy is feasible,simple,real-time and effective.This design scheme is applicable for radiant topology and would provide guidance to the development direction of DC micro-grid project later.

Introduction

Nowadays,traditional fossil fuel resources,not only generate global environmental pollution and climate change,but also has reduced gradually.This has threated the world development and human survival.At the same time, the traditional electric system intensifies the energy crisis because of its disadvantages of complex structure and big loss [1].In the threat of resources and environment, development of new energy has become an important developing direction all over the world.Thus,distributed generation(DG) can solve the problems of large electric system by saving power lines and loss of converter devices.This is a huge advantage in Environmental friendly society today.

Micro-grid is posed to make full use of large-scale DG.It scales between electric systems and DG,which not only couples electric systems and DG,but also can run independently.It can provide electricity of high power quality and security safety to loads.Articles [2-4] introduces systematically the concept of micro-grid and micro-grid research status of the United States,Europe,Japan,etc.This paper is based on shanghai DC micro-grid demonstration project.After DC micro-grid current situation study,we design system topology structure,operation modes,stability control strategy and key equipments for the project.Last,we verify The accuracy of the topology and control strategy to provide theoretical support for demonstration project.

Key Technology of DC Micro-grid

Nowadays, micro-grid structure mainly includes AC type,DC type and AC/DC hybrid type at home and abroad [5].Among them,AC type is main realization form.Distributed electric resource（DER)and energy storage devices connect to AC bus through converters.For example,solar cells, fuel cells and other DC power need inverters.But for wind power generation,gas turbine and other AC power,they need both rectifiers and inverters.To meet the requirements of power supply reliability,electric system must connect a large number of converters.This not only adds the cost of the electric system,but also increases the system complexity and failure rate.

In DC micro-grid,DER and energy storage devices connect to DC bus with less converters.For example,personal computers,workstation servers and other sensitive digital electricity equipments can connect to bus with just DC chopper.By selecting suitable DC bus voltage,DC power can connect to bus directly and AC power just need to a simple rectifier.The most obvious advantage is the introduction of large capacity battery and super capacitor as a backup.On one hand, they can be used as the power battery for electric cars.On the other hand ,they also can improve the reliability of micro system.Now,DC micro-grid technology is still in initial stage.It is only researched in some universities and used in some special application,such as aerospace and ships.There's no commercial DC micro-grid engineering examples.The shanghai DC micro-grid is the first large demonstration project in China.

In AC/DC hybrid micro-grid,AC bus provide power for AC loads and DC bus for DC loads.Compared with AC micro-grid,it can reduce converter devices and make less cost.Compared with DC micro-grid,it can simplify frequency conversion process,but it has more problems such as complex control links,difficult power supply and apparent power quality problems.Considering its transitional nature,it may become an important direction of DC micro-grid application.

Transmission power,transmission radius,line loss and load voltage are the most important factors of setting DC micro-grid voltage level.In addition,matched degreed with AC power system and practical engineering investment is in considering,too.Now,DC micro-grid voltage level has not reached consensus all over the world.But most experts tend to750V,380V,220V,110Vand 48V level [6].Considering DC micro-grid needs at home,this system sets up three voltage grades.750V bus mainly connect DER and energy storage, and maintain the whole system stability.380V high voltage directly provide DC power for lighting,air conditioning system, large electrical appliances and other DC loads.In addition,48V low voltage level is setted for small DC loads.

Shanghai DC Micro-grid Example

The structure of DC micro-grid can be divided into the ring,mesh and radiant type.For ring topology,there are two current path between any two stations [7].It would improve reliability,security and quality of power supply.But,the fault diagnosis and protection control are relatively difficult.Meanwhile,the ring type need large equipment investment.Moreover ,mesh type consists of two or more rings,which needs more complex control strategy.This type is still in the stage of theoretical research, no relevant pilot and applications.

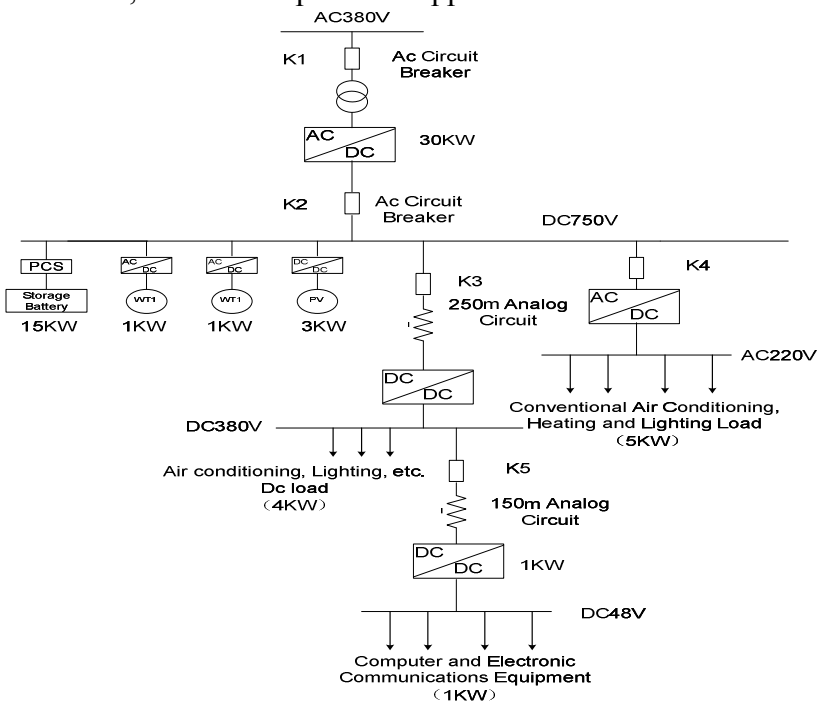

Fig.1 System Structure of Shanghai DC Micro-grid

Shanghai DC micro-grid project adopts radiant topology.Radiant topology has great advantages,such as easy flow control,simple fault protection,low line investment,etc.It's the most practical value structure currently.As shown in figure 1,the micro-grid power is 30KW,including three DC micro-grids.Electric system connect to 750V bus through isolation transformer.750V bus power flow is large ,including photovoltaic cells,wind power,energy storage devices and AC loads, etc.Small wind turbines are located in the periphery of project area,because it covers a lager area.So that,750V bus also is setted in periphery.750V bucks to 380V to,then 380V bucks to 48V.The power flow is smaller in this two DC buses,which are located in center of project area.

Meanwhile, two simulation circuit devices are setted in system to strengthen scientific research function.One simulates 250m low line between 750V and 380V.The other simulates 150m between 750V and 380V.They both can adjust continuous line length and install faults in any position.

The Control Strategy

This system adopts multi-layer control mode, dividing into total distribution network control, DC layer control and micro-grid element control.

As shown in figure 2,total distribution network control is at the top of system.On one hand, it monitors the information trend between electrical power system and micro-grid real-time.According to system energy state,it would choose point of common coupling(PCC)to control working condition of 30KW AC/DC module.At this time, micro-grid become grid connection state.When there is a grid fault in electric system,micro-grid transforms working condition from grid connection to isolated island operation.DER and energy storage equipments could safeguard important loads demand.On the other hand,the top control can adjust micro-grid operation mode according to collecting information of voltage, current and power.

DC layer control is the core of the whole control system.Its task is receiving the top command signal and controlling each part of micro-grid.When system is running normally,system takes master-slave control.Electric system act as main power supply and 30KW AC/DC module acts as main control.Meanwhile,other DER operate in PQ control mode.When a system fault occurs,control system first maks judgment on the fault rapidly,then it isolates fault zone.Thus,it can ensure normal area power supply and limit fault current in a certain extent.For example,when a short trouble occurs,DC layer control first determine fault location.If fault occurs in 220V,380V and 48V net,it would lock relevant pulses to isolate fault nets from 750V net to prevent fault expanding.If fault occurs in 750V net,it isolate 750V net from 220V and 380V net.At the same time,it blockade IGBT trigger pulse of wind turbines and photovoltaic cells to ensure DER not be affected.

Micro-grid element control is the underlying control.It mainly controls start-stop of DER,loads and energy storage devices to maintain voltage and frequency stable and provide relevant protection.With environment changing,it must monitor work condition of DER real-time.Photovoltaic battery capacity is affected by light and wind generator is affected by weather,temperature and monsoon significantly.Their generation is random and rolling.So,it need calculate power of each grid node to adjust output power,through controlling input numbers of photovoltaic battery and the proportion of wind turbine blade tip.Through load forecast and reasonable monitoring of DER,it can plan battery groups' number reasonable to optimize load demands.It is called peak clipping and valley filling.The underlying control manages photovoltaic battery,wind generator and energy storage battery.Because they act different roles in system,they adopt different control strategies.The key is that,their voltage and current instructions from controller is different.DER is in voltage and current double closed loop control at low voltage side,and energy storage battery is in voltage and current double closed loop control at high voltage side.Energy storage battery absorbs DER short-term fluctuations and maintains DC bus voltage.The control principle as shown in figure 3,voltage outer loop is to stabilize DC bus voltage,and current inner loop is to stabilize energy storage battery current.U^*_{dc} is given bus voltage,U_{dc} is measured bus voltage,I^*_{dc} is given energy storage battery current,I_{dc} is measured energy storage battery current.The difference between U^*_{dc} and U_{dc} passes PI regulator to get the required output current instantaneous value of energy storage battery I^*_{dc}.Then,the difference between I_{dc} and I^*_{dc} passes PI to get the

switch tube.With controlling IGBT, battery can achieve constant output current.However,For DER,U^*_{dc} and I^*_{dc} are given by their own value.

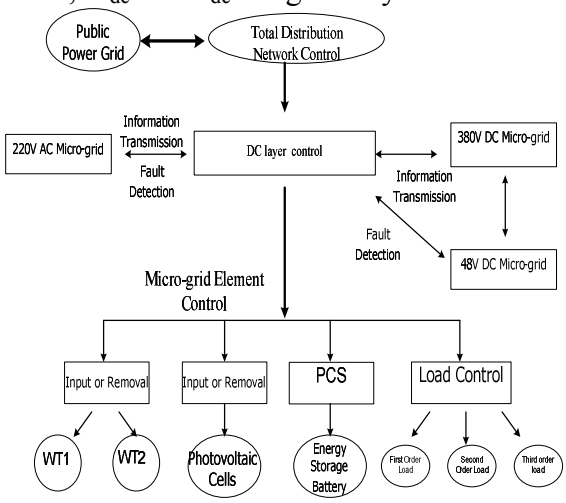

Fig.2 Multi-layer Control Mode of DC Micro-grid

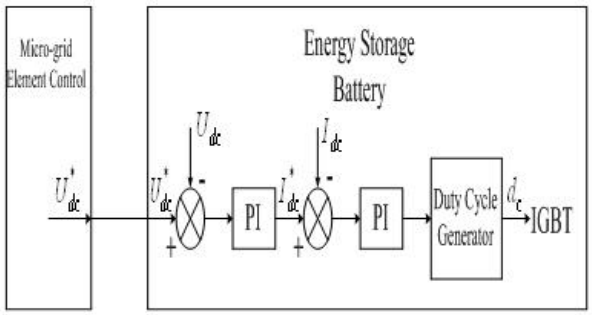

Fig.3 Battery Control Principle Diagram

Simulation Analysis

According to the figure 1, we set up corresponding PSCAD simulation model.By simulating grid connection and isolated island condition,we can further study characteristics of DC micro-grid and verify feasibility of control strategy.

When system is running normally,system takes master-slave control.30KW AC/DC module acts as main control unit.Meanwhile,other DER operate in PQ control mode.Traditional power quality problems won't happen on DC bus,so the key of DC power supply is maintaining bus voltage stable.

The simulation shows in figure 4,bus voltage fluctuate slightly at the start.Then,voltage remain stable with fluctuation less than 0.1%.

Micro system is susceptible to disturbance because of limited capacity.Distribution network nodes are so numerous that short circuit faults occur occasionally.As shown in figure 5 and figure 6,when t=1s,we simulate short circuit fault for 0.2s between 380V micro-grid and 250m power line.At that time,380V micro-grid is cut off rapidly and DC bus voltage drops to zero.when t=1.2s, voltage returns to normal working condition.Throughout the process,750V micro-grid,which is effected little, still can run normally.After a brief fluctuations less than 2.0%,DC voltage quickly return to rating.

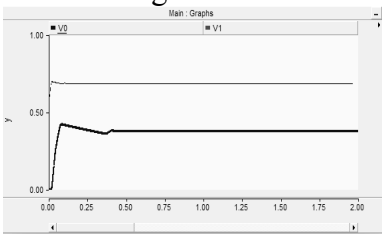

Fig.4 Normal Operation Voltage

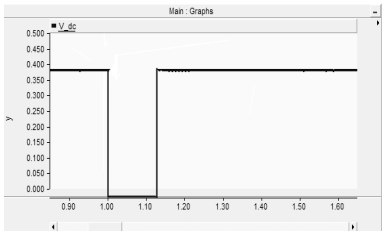

Fig.5 380V Bus Voltage

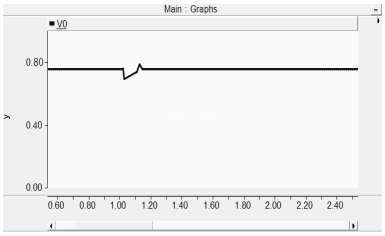

Fig.6 750V Bus Voltage

Micro-grid transforms work modes between grid connection and isolated island by PCC control.When system run in isolated island,energy storage battery converts to V/F control mode to maintain the whole system voltage stable.As shown in figure 7,we simulate inputting and removing loads to cause transient disturbance.when t=0.5s,asynchronous motor connects to micro-grid.At the same time, the bus voltage appear larger fluctuation and recover in a short time.

The size of the battery capacity is the most important factor to maintain isolated island operation.Small capacity is difficult to maintain voltage stable and large capacity would cause resources waste.The battery power output is shown in figure 8,battery increases the power output to meet the loads demand.From theoretical calculation and simulation,15KW capacity is a good choice for this system,which can provide enough power for isolated island.When DER and battery energy

can not meet loads need,bus voltage is lower than the preset threshold.The system needs to control the load shedding to ensure the continuity of important loads power supply.

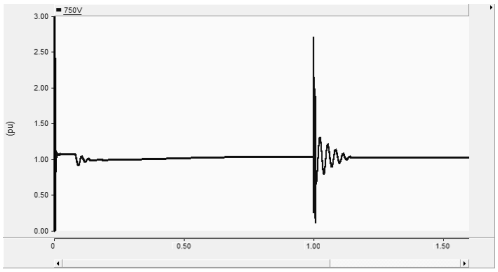

Fig.750V Bus Voltage Changes

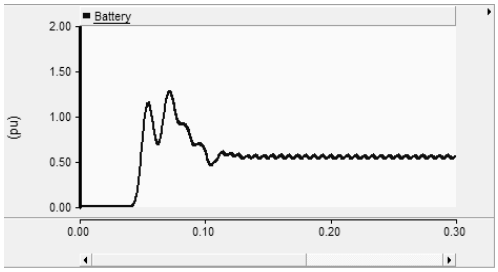

Fig.8 Battery Power Changes

Conclusion

DC micro-grid is better compatible with future renewable power supply,distributed energy storage and bidirectional current demand electric vehicle charging stations.Traditional power quality problems,such as frequency, reactive power and harmonic problems,would not happen on DC bus.DC system only prevent DC voltage from flickering or dropping,that it can get good power quality.In this paper ,we design a radiant system structure and calculate technical parameters of the relevant equipments for shanghai DC micro-grid demonstration project.On the basis,we put forward multi-layer control strategy,whose main task is to maintain DC bus voltage stable.The simulation results show that,the established strategy can ensure DC micro-grid operate normally in grid connection and isolated island condition.This paper results would provide theoretical guidance for the demonstration project.

Keywords: permanent magnet synchronous motor; vector control; sliding mode observer; Sigmoid function.

Abstract. In sensorless vector control of permanent magnet synchronous motor, it is necessary to achieve an accurate estimate of the motor speed and position of the rotor. Traditional sliding mode observer algorithm has the inherent chattering problem which reduces accuracy. The Sigmoid function was used to replace the sign function in the traditional sliding mode observer as the switching control function to cancel the filter and phase compensation links. A new sliding mode observer was designed and its stability was proved. High-speed permanent magnet synchronous motor simulation and experimental results show: the new modified sliding mode observer based on Sigmoid function can eliminate the severe buffeting of the traditional sliding mode observer, achieve the accurate estimation of the rotor speed and position for high-speed permanent magnet synchronous motor to complete a wide range of speed control; the correctness and feasibility of the sensorless control strategy based on this method is verified.

Introduction

PMSM(Permanent Magnet Synchronous Motor) has advantages of high power density, fast dynamic response and small torque ripple[1]. Combined with magnetic bearings the rated speed of high speed PMSM can reach tens of thousands or even hundreds of thousands of revolutions per minute. It can be widely used in molecular pumps, compressors, centrifuges and other high-speed drive applications. For vector control of PMSM, the accurate rotor position signals is the prerequisite. In conventional PMSM vector control system, to obtain the rotor position information we need optical encoder position sensor, etc., which not only increases the cost and complexity of the system, but also reduces the reliability of the system. Thus, in recent years the control methods without position sensors of PMSM has been a hot research field.

At present, the common position sensorless control method for PMSM is mainly divided into two categories [2]: one is the motor saliency-based methods, such as high-frequency signal injection method, these methods at zero speed and low-speed work better, but they are not suitable for high-speed applications, and is only applicable for saliency effects interior permanent magnet synchronous motor; other is based on the back-EMF or flux estimation method to estimate the rotor position, for example, the estimation method based on electromagnetic relations [3,4], the model reference adaptive method [5], extended Kalman filter method [6], sliding mode observer method [7] and so on. Estimation method based on the electromagnetic relations are mostly working in the open-loop state, so it's vulnerable to motor parameter variation; model reference adaptive method is simple, but it's also very sensitive to parameter variations; extended Kalman filter method is too large, it is difficult for high-speed situations; sliding mode observer method is simple and easy to implementation, and it has good robustness.

In order to achieve the sensorless control of PMSM, this paper selected a new switch function, Sigmoid function , to take place of the traditional switch function. At the same time, low-pass filter and phase compensation are removed. The system was simplified and the estimation accuracy was improved. Finally, experimental verification showed the correctness and effectiveness of this method.

1 Mathematical Model of the Permanent Magnet Synchronous Motor

The rotor structure of PMSM can be divided into the surface-mount and the buried. This article focused on surface mount PMSM. For the establishment of mathematical model of PMSM ,without affecting the performance of the premise, we made the following assumptions [4]:

(1) Ignore the magnetic core saturation;

(2) Exclude the impact of hysteresis and eddy current losses;

(3) Wind EMF waveform is a sine wave.

In the two-phase stationary coordinate system, the mathematical model of PMSM can be expressed as:

$$\frac{di_\alpha}{dt} = -\frac{R}{L}i_\alpha + \frac{1}{L}V_\alpha - \frac{1}{L}e_\alpha \tag{1}$$

$$\frac{di_\beta}{dt} = -\frac{R}{L}i_\beta + \frac{1}{L}V_\beta - \frac{1}{L}e_\beta \tag{2}$$

Back-EMF equation can be expressed as:

$$e_\alpha = -k_e\omega_r \sin\theta_r \tag{3}$$

$$e_\beta = k_e\omega_r \cos\theta_r \tag{4}$$

2 Modified Sliding Mode Observer

According to the mathematical model of PMSM, the sliding mode current observer equation can be constructed:

$$\frac{d\hat{i}_\alpha}{dt} = -\frac{R}{L}\hat{i}_\alpha + \frac{1}{L}V_\alpha - \frac{1}{L}u_\alpha \tag{5}$$

$$\frac{d\hat{i}_\beta}{dt} = -\frac{R}{L}\hat{i}_\beta + \frac{1}{L}V_\beta - \frac{1}{L}u_\beta \tag{6}$$

$$u_\alpha = k_{sw}sign(\hat{i}_\alpha - i_\alpha) \tag{7}$$

$$u_\beta = k_{sw}sign(\hat{i}_\beta - i_\beta) \tag{8}$$

By equation (1), (2), (5), (6) a current observer error equation is obtained:

$$\frac{d\left(\hat{i}_\alpha - i_\alpha\right)}{dt} = -\frac{R}{L}\left(\hat{i}_\alpha - i_\alpha\right) + \frac{1}{L}\left(e_\alpha - u_\alpha\right) \tag{9}$$

$$\frac{d\left(\hat{i}_\beta - i_\beta\right)}{dt} = -\frac{R}{L}\left(\hat{i}_\beta - i_\beta\right) + \frac{1}{L}\left(e_\beta - u_\beta\right) \tag{10}$$

The current difference between the estimated value and the actual current is selected as a sliding switch plane:

$$s = s(x) = \hat{i}_s - i_s \tag{11}$$

When the system is in the sliding surface movement, s = 0.The back-EMF $e_s = u_s = k_{sw}sign(\hat{i}_s - i_s)$. As can be seen, sliding switch function expression contains the information of back-EMF of the motor. Because it contains a high-frequency switching signal ,and the results must be filtered.By low-pass filter to obtain the back-EMF takes the phase delay. Therefore, the conventional sliding mode observer needs to be compensated.

The final expression for the angular position of the rotor:

$$\hat{\theta} = -\arctan(\frac{\hat{e}_\alpha}{\hat{e}_\beta}) + \Delta\theta \tag{12}$$

In conventional sliding mode observer, the introduction of a low-pass filter brought significant phase delay and it would affect the position estimation accuracy. In addition, due to the non-ideal characteristics of the switching function, we must adopt a certain angle compensation. In such a high precision high speed system, the output of the low pass filter, it is difficult to meet the requirements. It is necessary for observer to be improved. In order to obtain better observation results, this paper introduces Sigmoid function as a sliding switch function, designed a new type of sliding mode observer.

The current difference between the estimated value and the actual current is selected as a sliding switch plane. The current observer equation is established:

$$\frac{d\hat{i}_\alpha}{dt} = -\frac{R}{L}\hat{i}_\alpha + \frac{1}{L}V_\alpha - \frac{1}{L}k_{sw}H(\hat{i}_\alpha - i_\alpha) \tag{13}$$

$$\frac{d\hat{i}_\beta}{dt} = -\frac{R}{L}\hat{i}_\beta + \frac{1}{L}V_\beta - \frac{1}{L}k_{sw}H(\hat{i}_\beta - i_\beta) \tag{14}$$

The traditional sliding mode observer uses symbolic function as a switch control function, its inherent discontinuity switching characteristics result in serious chattering. To reduce this chattering, we used a new switch control function, that is Sigmoid function.

$$H(x) = \frac{2}{1+e^{-k\cdot x}} - 1 \tag{15}$$

When the system reaches the sliding surface and moves in the sliding surface, the back-EMF is expressed as:

$$\hat{e}_\alpha = k_{sw}\cdot H(\hat{i}_\alpha - i_\alpha) \tag{16}$$

$$\hat{e}_\beta = k_{sw}\cdot H(\hat{i}_\beta - i_\beta) \tag{17}$$

Combined with the back-EMF equation (3), (4), the rotor angular position and speed equation is established:

$$\hat{\theta} = -\arctan\left(\frac{\hat{e}_\alpha}{\hat{e}_\beta}\right) \tag{18}$$

$$\hat{\omega} = \frac{\sqrt{\hat{e}_\alpha{}^2 + \hat{e}_\beta{}^2}}{\psi_f} \tag{19}$$

In order to prove the stability of the new sliding mode observer, Lyapunov function can be constructed:

$$V = \frac{1}{2}S^T S \tag{20}$$

The stability condition of the new sliding mode observer is:

$$\dot{V} = S^T\dot{S} \le 0 \tag{21}$$

When the sliding gain k value is large enough, we can guarantee the existence of sliding motion and ensure that the system is asymptotically stable.

$$k \ge \max(|e_\alpha|, |e_\beta|) \tag{22}$$

3 Experimental Verification

In order to verify the feasibility of the proposed method, 4kW high-speed PMSM was used to build a motor control system experimental platform. The TMS320F28335DSP was used as the core of control system and power amplifier module is Mitsubishi PM25RLA120 IPM, the switch frequency is 10KHz. The rotor position signals of two kind of sliding mode observers were put into oscilloscope by external DA chip.

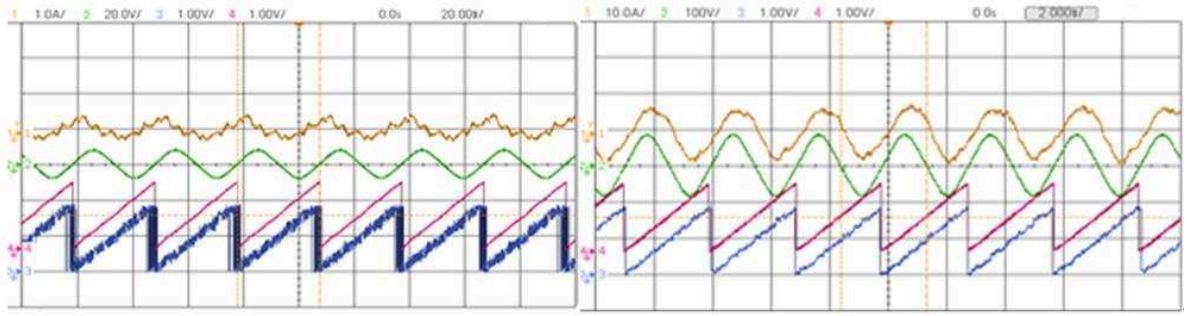

Fig. 1 Comparison of the rotor position at 2000r/min(L) and 20000r/min(R)

The third signal from top down is rotor position signal which is provided by improved sliding mode observer, and the fourth signal from top down is the rotor position signal which is provided by traditional sliding mode observer . As can be seen from the figure, the rotor position signal estimated by the traditional sliding mode observer contained severe chattering , but the method used herein significantly reduced chattering.

4 Summary

Based on the analysis of traditional sliding mode observer structure and characteristics, Sigmoid function was used to replace the traditional symbol function or saturation function as a switch control function. Phase compensation and filter link were cancelled. A new sliding mode observer was designed. Experimental results showed that: the new sliding mode observer can output more accurate estimation of the rotor position and speed to achieve position sensorless control of PMSM. The stable operation of experimental motor at high speed range (0-20000r/min), verified the correctness and feasibility of the proposed method.

Keywords: permanent magnet linear synchronous motor, Self-organizing rule and self-regulared parameter fuzzy control, speed controller, Simulation

Abstract. In view of the permanent magnet linear synchronous motor vector control system, this paper proposes a model reference adaptive speed controller gain fuzzy self-tuning neurons. The simulation results show that when a sudden load disturbance or parameter mutation, the gain of model reference adaptive fuzzy self-tuning neuron speed control has quick response, strong robustness, good dynamic and static characteristic, etc.

Introduction

In the coal Direct drive permanent magnet linear synchronous motor, because it saved the middle of the transmission link, eliminating the effects of mechanical transmission chain; and its high-performance permanent magnets with high intensity electromagnetic thrust, low loss, small electrical time constant, fast response time, etc. [1]. Compared with the traditional rotary motor, although eliminates some of the adverse effects brought by the mechanical transmission, but it increases the difficulty to control. For perturbation and uncertainties such as the impact of disturbance on the system, in this paper, the design speed loop gain of the model reference adaptive fuzzy self-tuning neuron speed controller to ensure the robustness of the system.

Permanent magnet linear synchronous motor mathematical model

Establishment of permanent magnet linear synchronous motor mathematical model is a computer simulation of the premise. In the derivation process, make the following assumptions [2]:
Ignore the core saturation;

Excluding the eddy current and hysteresis effects; On the active cell without damping windings, permanent magnets are no damping effect; Counter-electromotive force is sinusoidal.

Under the condition of field oriented vector control, PMLSM mathematical model can be described as follows [2]:

Mechanical equations of motion : $F_e = M \cdot dv/dt + Bv + F_f = K_f \cdot i_q$, $K_f = \pi \cdot \psi_f / \tau_n$

In the formula, M is the mass of the motor mover, B is a viscous friction coefficient, F_f representative of the load resistance, F_e representative of the electromagnetic thrust, τ_n representative of the permanent magnet flux effectively, v is the linear velocity of the mover, and $v = 2\tau_n f = v_s$.

In the formula, f is the frequency of the inverter output power, v_s is the motor synchronous speed, K_f is the thrust coefficient.

d-q-axis voltage and current equation. $\begin{cases} u_d = -\pi v \psi_q / \tau_n + d(\psi_f + \psi_d)/dt \\ u_q = -r_q i_q + \pi v \psi_f / \tau_n + d\psi_q / dt \end{cases}$.

In the formula: $\psi_d = L_d i_d$; $\psi_q = L_q i_q$ .In the formula, u_d, u_q denote d-axis mover, the q-axis voltage; i_d, i_q denote d-axis mover, the q-axis armature current; ψ_d, ψ_q denote move d axis, the q axis armature

current d and q axis magnetic chain; r_d, r_q denote d-axis mover, the q-axis resistance; L_d, L_q denote d-axis mover, the q-axis inductance.

According to the equivalent mathematical model of these kinds have PMLSM shown in Figure 1.

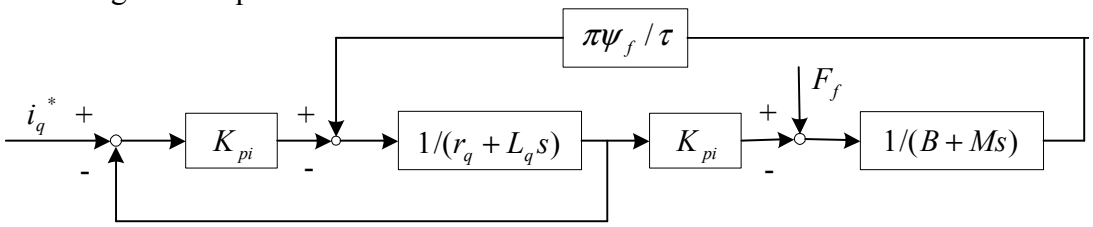

Figure 1 Vector control ($i_d = 0$) when the mathematical model of PMLSM

Model reference adaptive gain fuzzy self-tuning adaptive speed controller design

Model reference adaptive neuron adaptive control and speed control is to model neuron adaptive control with the combination of control technology, can enhance the performance of the servo system. It combines a model reference adaptive control with dual characteristics of neural control.

Reference model assumes that the selected mathematical model, the mathematical model can provide a proper reference for the desired output, the desired system response speed. Through continuous tracking the reference model output, timely correction neurons teacher value of the speed controller, which makes neural neurons speed controller supervision learning part with correct and timely signals, which ensures the weights learning convergence in the right direction. Thus, the output neuron controller is adjusted to force the output speed of the system follows the reference model output [3].

Neuron model reference adaptive speed controller shown in Figure 2.

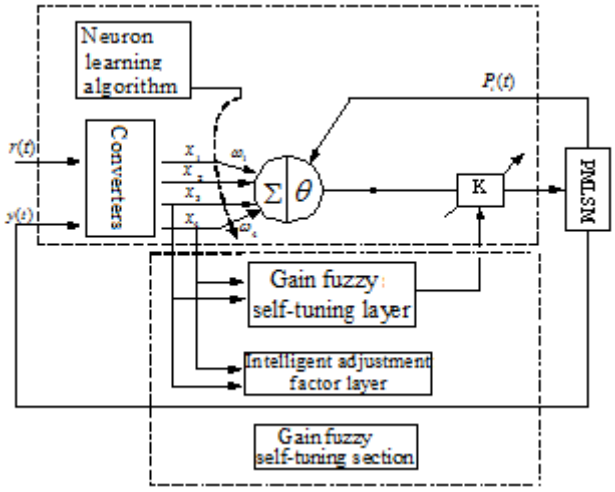

Figure 2 Adaptive neuron controller fuzzy self-tuning of gain

The choice of reference model. Reference model selection system of one-order inertial system, its transfer function is [4]: $G(s) = y(s)/u(s) = 1/(T_1 + 1)$

In the formula, u is a step input reference model, but also neurons speed controller speed command signal; y is the reference model output, $y(t) = (1 - e^{-t/T_1})u(t)$; T_1 represents the time constant, as required, by selecting the value of T_1, to obtain the desired exponential rate curve.

Neuron controller to calculate the value of the speed of teachers. To translate into time domain differential equation formula: $dy/dt = -my + mu$ .In the formula, $m = 1/T_1$. Dynamic error e is defined as the difference between output and the time lag compensator output of the reference model.

Rated motor parameters to take the case, the mechanical equations of motion have PMLSM speed differential equations can be obtained: $dv_t/dt = K_f \widetilde{I}_q^* / M_n - B_n v_t / M_n - F_n / M_n$ .In the formula, M_n, B_n respectively mover mass nominal value and the nominal value of the viscous friction coefficient, F_n is the nominal resistance value of the load, $\widetilde{I}_q^*$ load resistance is not considered representative of the disturbance, the mover mass change, viscous friction coefficient change the value of the reference section neurons teacher case calculation. Therefore, the dynamic error e is the derivative:

$$de/dt = dv_t/dt - dy/dt = K_f \widetilde{I}_q^* / M_n - (mM_n - B_n)v_t / M_n - F_n / M_n - me - mu$$

Take *L*yapunov function $V = e^2/2$, then $dV/dt = ede/dt$. Select $de/dt = -ge$ (Constant $g > 0$), then $dV/dt = -ge^2 < 0$, so that the system meets the asymptotically stable. Substituted into $de/dt = -ge$, to be launched:

$$\widetilde{I}_q^* = (m-g)/M_n e/K_f - (mM_n - B_n)v_t / K_f + F_n / K_f + mM_n u / K_f$$

$$= (m-g)M_n e/(\pi\psi_f/\tau_n) - (mM_n - B_n)v_t/(\pi\psi_f/\tau_n) + F_n/(\pi\psi_f/\tau_n) + mM_n u/(\pi\psi_f/\tau_n)$$

Formula calculated $\widetilde{I}_q^*$ is only part of the neuron controller teachers' value calculation, which includes compensation for the permanent magnet flux perturbation harmonic disturbances and time delay, is not added to the system parameters (i.e.: load resistance changes mover mass changes, changes in viscous friction coefficient) compensation for disturbance.

Also, consider the load resistance changes, the situation mover mass changes, changes in the viscous friction coefficient, and teachers value neurons compensate. Here the end effect of PMLSM's influence on the thrust can be equivalent load disturbance resistance, so as part of the load disturbance resistance to compensate [3].

Teachers value through online correction neuron controller values, and constantly to neurons on-line training speed controller, the controller of the actual output is equal to the desired current instructions.

Simulation results analysis

(1) When the load is 10kg, tuning PID parameters, the parameters fixed gain adaptive neuron controller is: K = 0.05; d = 120; initial weights were taken 10. Gain fuzzy self-tuning parameters adaptive neuron controller is: K=0.05; d = 120; initial weights were taken 10. $K_{Min} = 0.05, K_{Max} = 1.0$. The actual belt load 20kg, the response curve shown in Figure 3.

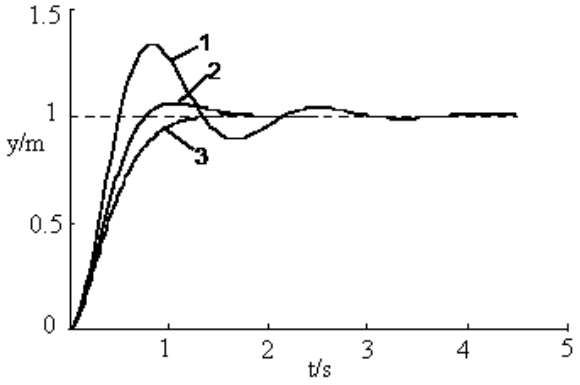

Figure 3 Effect of change in the three parameters

Curve 1 is the PID control; Curve 2 is a fixed gain of adaptive neuron controller; curve 3 to gain self-tuning adaptive fuzzy neuron controller.

Clearly, because of the PID parameter is sensitive to changes in the object, when the operating state changes PMLSM drive system, the control action is almost lost. Fixed gain adaptive neuron

controller, while having some control, but not very effective. Two gain self-tuning adaptive fuzzy neuron controllers for this case has a good control effect.

(2) Setting PID when load for 10 kg, fixed gain adaptive neuron controller does not use deviation nonlinear transformation; gain self-tuning adaptive fuzzy neuron controller uses a nonlinear transformation deviation, both still on the same parameters. 5kg perturbation added in 3.5s, shown in Figure 4.

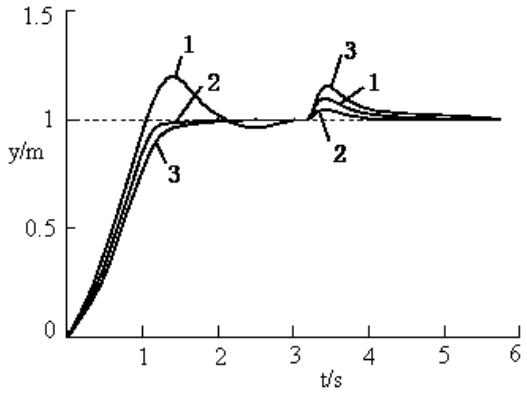

Figure 4 External disturbance control performance comparison of three

Curve 1 is the PID control; Curve 2 is a fixed gain of adaptive neuron controller; curve 3 to gain self-tuning adaptive fuzzy neuron controller.

Visible deviation neuron controller did not use non-linear transformation of the system when there is disturbance relatively large super pick, adjust the recovery time is longer, so the use of non-linear transformation deviation significantly strengthened the immunity of the controller.

From comparing these two cases, the gain of fuzzy self-tuning layer neuron controller makes adding significantly faster dynamic response, overshoot suppression capability significantly strengthened.

Conclusions

On the basis of adaptive neuron controllers joined the gain on fuzzy self-tuning layer, thereby improving the response speed controller inhibited overshoot, while exhibiting a strong and robust line model changes PMLSM servo system to adapt sex.

Abstract. In this paper,the rotor speed and the position of the SSP propulsion motor are estimated for building sensorless vector control system with speed and current double closed loops based on square root center difference Kalman filter(SR-CDKF) algorithm. This method makes use of the QR decomposition linear algebra techniques and so on, and it updates the matrix square-root of the state covariance by the Cholesky factor updating. This method can not only get the more steady results but also improve the estimation accuracy of the SSP podded propulsion system. Simulation result shows that the improved CDKF algorithm is not only more accurate but also has higher rate of convergence compared with CDKF speed controller.

Introduction

Podded propulsion is the new type of ship electrical propulsion system which has developed in recent years. It is mainly made up of stents, pod and propeller parts, the propulsion motor was placed in a 360^0 rotary podding, the propeller was directly driven on both ends of the propulsion motor, thus the many complex mechanism (such as clutch, gearbox, intermediate shaft, thrust, etc.) were simplified and it was replaced by the electric control system that has the higher reliability than mechanical system. The redundancy has been greatly improved, which can realize the quick start, quick reversals, stepless speed regulation, low speed stability and excellent control performance [1].

Square Root center difference Kalman filter (SR-CDKF) is a novel filtering method of the nonlinear systems, and it is different with the central Difference Kalman filtering (CDKF), it doesn't need to calculate the square root of the covariance matrix of state during the every time update[2]. In view of the nonlinear problem of Podded propulsion system, the CDKF covariance square array is used instead of covariance matrix iterative arithmetic in this paper, it can avoid the filter divergence effectively, and the convergence speed and stability of the filtering algorithm were improved, it can meet the mobility characteristics of Podded propulsion system.

Square Root center difference Kalman filter algorithm

The central difference was adopted to instead of the first and second order derivative of Taylor series expansion.

$$f'(\overline{x}) \approx \frac{f(\overline{x}+h\delta x)-f(\overline{x}-h\delta x)}{2h} \tag{1}$$

$$f''(\overline{x}) \approx \frac{f(\overline{x}+h\delta x)+f(\overline{x}-h\delta x)-2f(\overline{x})}{2h^2} \tag{2}$$

For state vector, Sigma points and weights according to the type (2) structure:

The number of CDKF Sigma point is 2n+1 for n state vector, and the Sigma points and weights were structured according to the type (2)

$$\chi_0 = \overline{x}\,,\ \chi_i = \overline{x} + \left(h\sqrt{P_{xx}}\right)_i, i = 1,\cdots,n$$

$$\chi_i = \overline{x} - \left(h\sqrt{P_{xx}}\right)_i, i = n+1,\cdots,2n \tag{3}$$

$$W_0 = h^2 - n/h^2 , W_i = 1/\left(2h^2\right), i = 1,\cdots,2n$$

The square-root form of the CDKF makes use of three powerful linear algebra techniques, QR decomposition, Cholesky factor updating and efficient least squares, which

QR decomposition.

The QR decomposition or factorization of a matrix $A \in \mathbb{R}^{L\times N}$ is given by, $A^T = QR$, where $Q \in \mathbb{R}^{N\times N}$ is orthogonal, $R \in \mathbb{R}^{N\times L}$ is upper triangular and N ≥ L. The upper triangular part of R , $\tilde{R}$, is the transpose of the Cholesky factor of $P = AA^T$, i.e., $\tilde{R} = S^T$,such that $\tilde{R}^T\tilde{R} = AA^T$ .We use the shorthand notation qr{•} donate a QR decomposition of a matrix where only «± is returned[3].

Cholesky factor updating.

If S is the original Cholesky factor of $P = AA^T$, then the Cholesky factor of the $P \pm \sqrt{vuu}$ is denoted as $S = cholupdate\{S, u, \pm v\}$. This algorithm (available in Matlab as cholupdate) is only $O(L^2)$ per update.

Efficient least squares.

The solution to the equation $(AA^T)x = A^Tb$ Þ also corresponds to the solution of the over determined least squares problem $Ax = b$.

The detail algorithm is obtained as follows:

Initialize with:

$$\hat{x}_0 = E[x_0] , \ S_0 = chol\left\{E[(x_0 - \hat{x}_0)(x_0 - \hat{x}_0)^T]\right\} \tag{4}$$

Where: $\hat{x}_0$ is initial value of the fixed state estimation, S_0 is the value which is initialized by calculating the matrix square-root of the state covariance via a Cholesky factorization.

$$S^-_k = \text{chol}(P_{k-1}) \tag{5}$$

For $k \geq 1$, $2n+1$ Sigma points were adopted[7]:

$$\chi_{k-1} = \left[\hat{x}_{k-1} \quad \hat{x}_{k-1} + \eta S^-_k \quad \hat{x}_{k-1} - \eta S^-_k\right] \tag{6}$$

Time update equations:

$$\chi_{k|k-1} = F[\chi_{k-1}, u_{k-1}], \ \hat{x}_k^- = \sum_{i=0}^{2L} W_i^{(m)} \chi_{i,k|k-1} \tag{7}$$

$$S_k^- = \text{qr}\left\{\left[\sqrt{W_1^{(c)}}(\chi_{1:2L,k|k-1} - \hat{x}_k^-) \quad \sqrt{Q^v}\right]\right\}, S_k^- = \text{cholupdate}\left\{S_k^-, \chi_{0,k} - \hat{x}_k^-, W_0^{(c)}\right\} \tag{8}$$

$$Z_{k|k-1} = H[\chi_{k|k-1}], \hat{z}_k^- = \sum_{i=0}^{2L} W_i^{(m)} Z_{i,k|k-1} \tag{9}$$

Measurement updates equations:

$$S_{\tilde{z}_k} = \text{qr}\left\{\left[\sqrt{W_1^{(c)}}\left[Z_{1:2L,k} - \hat{z}_k\right] \quad \sqrt{R_k^n}\right]\right\}, \ S_{\tilde{z}_k} = \text{cholupdate}\left\{S_{\tilde{z}_k}, Z_{0,k} - \hat{z}_k, W_0^{(c)}\right\} \tag{10}$$

$$P_{x_k z_k} = \sum_{i=0}^{2L} W_i^{(c)}[\chi_{i,k|k-1} - \hat{x}_k^-][Z_{i,k|k-1} - \hat{z}_k^-]^T , \kappa_k = \left(P_{x_k z_k} / S^T_{\tilde{z}_k}\right) / S_{\tilde{z}_k} \tag{11}$$

$$\hat{x}_k = \hat{x}_k^- + \kappa_k(z_k - \hat{z}_k^-), \ U = \kappa_k S_{\tilde{z}_k} , S_k = \text{cholupdate}\left\{S^-_k, U, -1\right\} \tag{12}$$

Model Analysis of Ship Electrical Propulsion Motor Control System

Electromagnetic torque of the SSP propulsion is

$$T_e = \frac{3p}{2}\frac{\psi_r^2}{R_r}\omega_s^* \tag{13}$$

Where Te is electromagnetic torque, P is the number of magnetic poles, Rr is the rotor resistance, ψr is the rotor flux valid values[4].

The friction torque of SSP propulsion system Tf is

$$T_{\mathrm{f}}=\mathrm{sign}(\omega)T_{\mathrm{s}}+k_{\omega}\omega \tag{14}$$

Where $\omega=2\pi n/60$, n is propeller speed, Ts is the static friction torque, n is the linear friction coefficient.

The motion equation of the SSP propulsion system is

$$\frac{d\omega}{dt}=\frac{1}{J}(T_{\mathrm{e}}-F\omega-T_{\mathrm{L}}),\ \frac{d\theta}{dt}=\omega \tag{15}$$

Where J is SSP moment of inertia, Tm is the load torque[5].

The dynamic model of SSP propulsion system is

$$T_{\mathrm{p}}=K_{\mathrm{T}}(J)\cdot\rho D^5 n|n| \tag{16}$$

$$F_{\mathrm{e}}=K_{\mathrm{F}}(J)\cdot\rho D^4 n|n|\cdot(1-\tau) \tag{17}$$

$$P_P=2\pi nT_{\mathrm{p}}=K_{\mathrm{T}}(J)\cdot 2\pi\rho D^5 n^3 \tag{18}$$

Where $T_{\mathrm{e}}(i_{\mathrm{a}},i_{\mathrm{b}},i_{\mathrm{c}},\theta)=P\dfrac{\partial \mathbf{W}_{\mathrm{m}}(\psi,\theta)}{\partial\theta}$, i_{a} is thrust deduction coefficient, i_{b} is wake fraction, the value can be obtained by ship's manual, Tp is propeller torque, Fe is propeller effective thrust, ρ is density of water,D is propeller diameter.During stable sailing in the sea, the ratio of propeller is a constant value, it shows that propeller will work on the speed ratio of the characteristic curve[6].

Simulation and Results

The simulation parameter of propulsion motor was based on "Taiankou", as follows: power rating= 4700kW, rated voltage=660V,rated speed=155 r/min, rated torque=1185KN·m, rotor permanent magnet flux linkage= 4.55Wb,stator resistance=1.632m,number of motor pole=8, inductance of d axis=0.25 mH,inductance of q axis=0.47 mH.

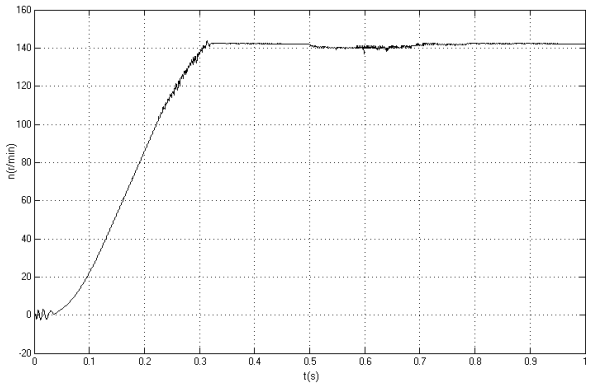

Fig.1 Speed curve based on CDKF

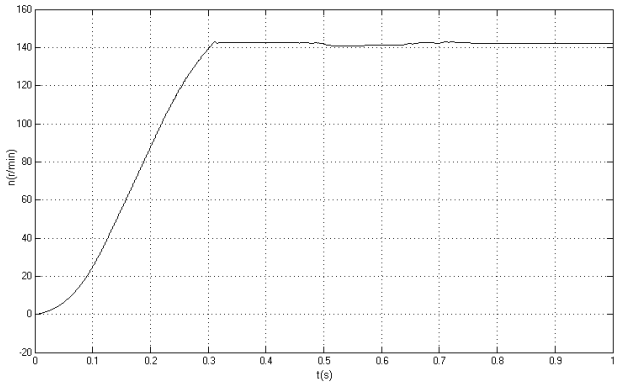

Fig.2 Speed curve based on SR-CDKF

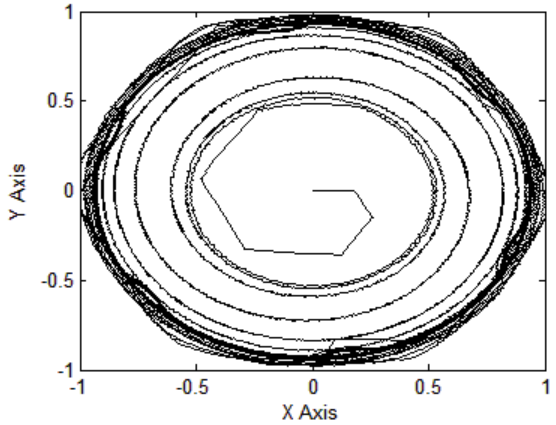

Fig.3 Stator flux based on CDKF

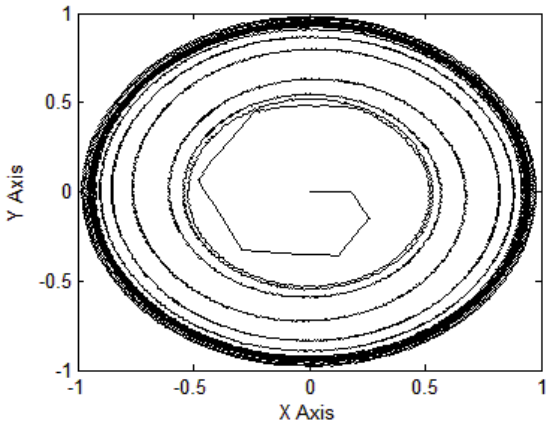

Fig.4 Stator flux based on SR-CDKF

When ship sailing in navigation at 142r/min, sea condition suddenly changes (such as the rough waves,etc.),so that the torque of the propeller load will change, the simulation analysis was carried out on this working condition. The simulation time is 1s, the initial speed is 142 r/min, at the beginning of the simulation, the motor load torque is 1100KN·m, at the time of 0.5 s propeller load torque changes to 400KN·m.The simulation results about the control method of SSP propulsion motor based on vector control with CDKF and SR-CDKF composite algorithm are shown as Fig.1-Fig.4.

The simulation results show that: When sea condition changes, under the two control modes, speed up smoothly, and the speed changes slightly after the the torque of the propeller load changes but back then. The system reaches the given speed after 0.31 s and propeller load changes in 0.5 s, the controller, torque and current have a corresponding response by the SR-CDKF. The speed oscillation of propulsion system based on SR-CDKF composite control was less than 6r/min,but the speed oscillation based on CDKF reached 15r/min, and the propulsion system based on SR-CDKF composite control can be achieved the setting speed in a short period of time, it has the faster response speed character.

Conclusions

In this paper the SR-CDKF control algorithm was introduced into the sensorless vector control of ship propulsion motor control system due to the CDKF algorithm is the optimal estimation method and the model of the propulsion motor in the process of actual operation can't be identical with the actual system, adopting PI speed controller system unavoidably affected by parameters change, but the SR-CDKF has better numerical properties and guarantees positive semi-definiteness of the underlying state covariance, it is not sensitive to external disturbance and parameter variation, it has very strong robustness. The simulation results show that the SR-CDKF propulsion motor control system can provide higher precision than the CDKF propulsion motor control system. It has the better ability to resist load disturbance, it has faster response speed, smaller dynamic overshoot and ripple, it can satisfy the maneuvering requirements under rough sea.

Abstract: To improve the speed sensorless speed control system's performance, this paper analyzes the rotor flux and speed estimation principle based on MRAS. On this basis, a new online identification method of induction motor stator resistance based on fuzzy logic is proposed. This method takes rotor flux and stator current vector as input and the stator resistance changes as the output. In the simulation environment, we compare the speed waveforms after the increase of stator resistance identification and conduct simulation to the identification effect when doubling the original value of stator resistance suddenly. The experiments show that the method has simple structure, high reliability, low computational complexity and obvious ability to identify the stator resistance changes, and besides, it can significantly improve the speed control system performance.

Introduction

If the vector control technology is widely used in the high-performance induction motor speed control system, the speed estimation accuracy and system robustness have high sensitivity to the motor parameters. Observation of the rotor flux is an important issue for vector control, and the observation precision of rotor flux directly affects the performance of vector control system. No matter what method is taken to estimate the rotor flux, it will inevitably be affected by the motor parameters. For example, when computing the rotor flux based on the voltage model, the stator resistance changes will make the flux observations inaccurate, and the control effect of vector control system will be reduced, because the stator resistance changes with the changes of current frequency, temperature and other factors and is also affected by the skin effect and flux saturation effects. In order to improve the performance of speed sensorless vector control system, online identification or compensation for the stator resistance has become a hot topic [1-4]. Many scholars have studied the identification methods of stator resistance: calculating the stator resistance by using the measured motor parameters and motor steady-state model; building the stator resistance signals based on the adaptive algorithm; and online stator resistance identification based on neural network technology [5-6]. This paper puts forward a speed sensorless vector control strategy based on fuzzy logic. It takes the rotor flux and the stator current vector as the fuzzy controller input, and the variation of stator resistance as the output. Simulation results verify the feasibility and effectiveness of this control strategy.

Rotor Flux and Speed Estimation Principle

According to the design method of MRAS, this paper selects the rotor flux voltage model as the reference model, and takes the rotor flux current model as the adjustable model, because the voltage model only uses the two signals of stator voltage and stator current without using the speed signal, and it is less affected by changes in motor parameters. Current model has a speed signal, so the rotor speed can be estimated by using the positive real dynamic system and Popov hyperstability theory to design the appropriate adaptive law. The block diagram of MRAS speed estimation based on rotor flux is as shown in Figure 1.

To realize the rotor flux speed sensorless field-oriented vector control of the induction motor, this paper needs the accurate phase position and amplitude of rotor flux ψ_r, but it is difficult to directly detect the rotor flux ψ_r in the engineering technology application, and the rotor flux vector shall be indirectly estimated by using the state observer.

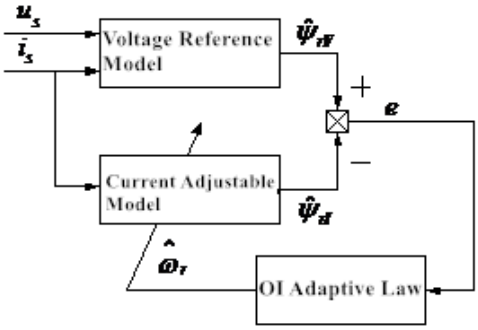

Figure 1 Block Diagram of MRAS Speed Estimation based on Rotor Flux

Equation (1) and Equation (2) are based on the stator voltage and stator current, whereas Equation (3) and Equation (4) are based on the stator current and motor speed. Equation (5) is based on MRAS speed estimation expression.

$$\psi_{r\alpha V} = \frac{L_r}{L_m}\int \left[u_{s\alpha} - (R_s + \sigma L_s P) i_{s\alpha} \right] dt \quad (1)$$

$$\psi_{r\beta V} = \frac{L_r}{L_m}\int \left[u_{s\beta} - (R_s + \sigma L_s P) i_{s\beta} \right] dt \quad (2)$$

$$\psi_{r\alpha I} = \frac{1}{1 + T_r p}\left[L_m i_{s\alpha} - T_r \psi_{r\beta} \omega_r \right] \quad (3)$$

$$\psi_{r\beta I} = \frac{1}{1 + T_r p}\left[L_m i_{s\beta} - T_r \psi_{r\alpha} \omega_r \right] \quad (4)$$

$$\hat{\omega}_r = (K_p + \frac{K_i}{s})(\hat{\psi}_{r\alpha I}\hat{\psi}_{r\beta V} - \hat{\psi}_{r\beta I}\hat{\psi}_{r\alpha V}) \quad (5)$$

Where R_s and R_r respectively represent the stator resistance and rotor resistance, L_r, L_s, L_m respectively represent the rotor inductance, stator inductance and mutual inductance, $T_r = L_r / R_r$ represents the rotor time constant, $\sigma = 1 - L_m^2 / L_s L_r$ represents the leakage inductance coefficient.

The method estimates the speed by firstly estimating the rotor flux. However, the temperature, current frequency and other factors make the stator resistance R_s change and deviate from the nominal value during operation of the motor, so the stator resistance is different from the true resistance under the actual motor operating conditions. From the above speed estimation method, in equations (1) and (2), R_s changes result in the speed estimation error. In MRAS model, the reference model is related to R_s, so that error exists when the adjustable model approaches the reference model, and finally there is a greater error between the speed estimation and the real speed. At the same time, when the system operates at low speeds, the stator resistance has obvious voltage drop effects, the measurement error submerges the counter electromotive force, and brings greater systematic errors and poor system low-speed performance, which may cause serious system instability[7].

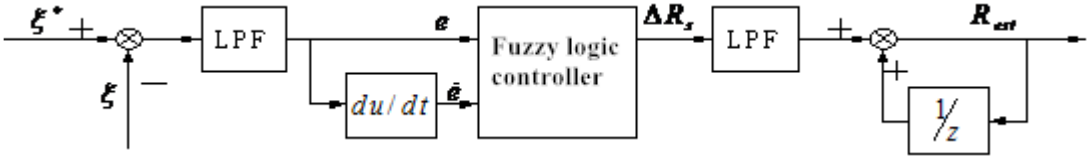

Figure 2 Block Diagram of Stator Resistance Identification based on Fuzzy Logic

Stator Resistance Identification Based on Fuzzy Logic

The block diagram of the proposed stator resistance online identification based on fuzzy logic is as shown in Figure 2. ξ^* and ξ are calculated by flux observer based on the rotor flux obtained from equations (1)-(4) and the stator current obtained from equations (6)-(7), and $i_{\alpha s}$ and $i_{\beta s}$ can be obtained by CLARKE transformation.

$$\xi^* = i_{\alpha s}\psi_{\alpha rV} + i_{\beta s}\psi_{\beta rV} \tag{6}$$

$$\xi = i_{\alpha s}\psi_{\alpha rI} + i_{\beta s}\psi_{\beta rI} \tag{7}$$

Where, $\psi_{\alpha rV}$ is the rotor flux voltage model's component on the α axis, $\psi_{\beta rV}$ is the rotor flux voltage model's component on the β axis, $\psi_{\alpha rI}$ is the rotor flux current model's component on the α axis, $\psi_{\beta rI}$ is the rotor flux current model's component on the β axis, the deviation signal e of ξ^* and ξ removes the high frequency harmonics in the signal through a low-pass filter, and then feeds the deviation signal and its differential components to the fuzzy logic controller, and the controller's output variable is the variation of stator resistance identification ΔR_s. Similarly, the variation of stator resistance identification ΔR_s obtains a smoother variation of the stator resistance through a low-pass filter.

In the design of the rule base, quantify the fuzzy controller's input signal deviation signal e and $\dot{e}$ as well as the output ΔR_s into seven fuzzy subsets, namely negative big (NB), negative medium (NM), negative small (NS), zero (ZE), positive small (PS), positive medium (PM) and positive big (PB). Where, the domain range of ΔR_s and e is [-3, 3], and the domain of $\dot{e}$ is between [-60,60]. Select the triangular membership function. Control rules are designed as:

If e is A_i and $\dot{e}$ is B_i, then ΔR_s is C_i。

Fuzzy control rule table is shown in Table 1. Fuzzy inference uses the direct product method. The weighting factor of i-th fuzzy rule is:

$$\alpha_i = \mu_{ei}(e)\cdot\mu_{\dot{e}i}(\dot{e}) \tag{8}$$

$$\mu_{\Delta R_n Rule_i}(\Delta R_s) = \sup[\alpha_i \mu_{\Delta R_n'}(\Delta R_s)] \tag{9}$$

Where, $\mu_{\Delta R_n Rule_i}(\Delta R_s)$ represents the membership of controller output ΔR_s in the i-th fuzzy rule. $\mu_{\Delta R_n'}(\Delta R_s)$ represents the membership function of fuzzy sets $\Delta R_n'$ on the controller output ΔR_s domain. The membership are shown in Figure 3, Figure 4 and Figure 5.

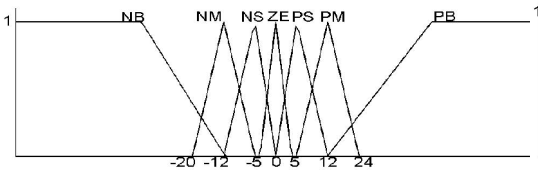

Figure 3 e Membership Function Graph

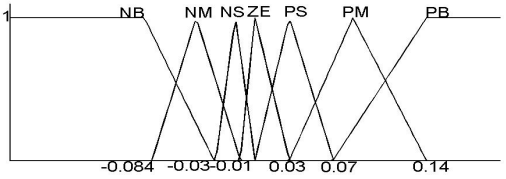

Figure 4 $\dot{e}$ Membership Function Graph

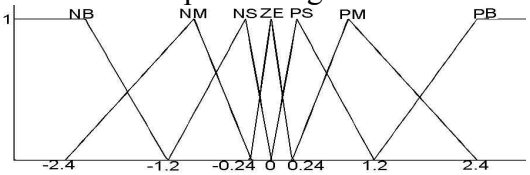

Figure 5 ΔR_s Membership Function Graph

The membership function $\mu_{\Delta R_n}$ of controller output ΔR_s is:

$$\mu_{\Delta R_n} = \max_{j=1}^{49} \mu\Delta R_n Rule_j(\Delta R_s) \tag{12}$$

Finally, this paper adopts the centroid method to solve ambiguity for the resulted fuzzy sets, and obtains the exact value. The value of output ΔR_s on the discrete domain can be obtained.

$$\Delta R_s = \frac{\sum_{j=1}^{49} \mu_{\Delta R_n}\left(\Delta R_{sj} \bullet C\left(\Delta R_{sj}\right)\right)}{\sum_{j=1}^{49} \mu_{\Delta R_n}\left(\Delta R_{sj}\right)} \tag{13}$$

Simulation Results and Analysis

This paper uses Matlab/Simulink tool to simulate the speed sensorless vector control system, the simulation selects the three-phase squirrel-cage induction motor, and its parameters are: rated power of 1.1kw, rated voltage of 380V, rated frequency of 50Hz, stator resistance $R_s = 0.93\,\Omega$, rotor resistance $R_r = 0.71\,\Omega$, stator leakage inductance $L_{\sigma r} = L_r - L_m = 0.0035$H, mutual induction $L_m = 0.082$H and friction coefficient $F = 0.006\text{N}\cdot\text{m}\cdot\text{s}$. Rotor leakage inductance $L_{\sigma s} = L_s - L_m = 0.0035$H, and the inertia coefficient is $J = 0.19\text{Kg}\cdot\text{m}^2$. In the simulation process, the system given speed is 50rad/s. Given that the motor stator resistance mutates into 2 times of the original value when it is at 2s, namely, mutating from 0.933Ω to 1.866Ω. Simulation experiments have made comparative analysis for the waveforms of stator resistance identification and no stator resistance identification. Figure 6 and Figure 7 respectively show the speed waveform of no stator resistance identification and torque simulation curve waveform of no stator resistance identification.

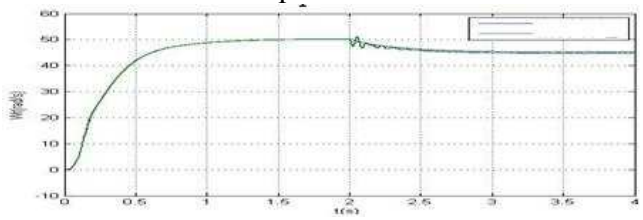

Figure 6 Speed Waveform of No Stator Resistance Identification with a given speed of 50rad/s, and stator resistance increases by 100% at 2s

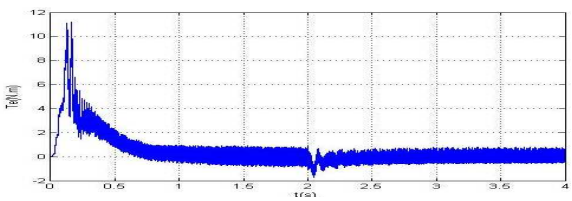

Figure 7 Torque Waveform of No Stator Resistance Identification, given the speed is 50rad/s, and stator resistance increases by 100% at 2s

Figure 6 and Figure 7 are respectively the speed and torque simulation curve waveforms of stator resistance identification. As seen in Figure 6, the speed estimation and the actual speed have significantly deviated from the given value and oscillation is generated, indicating that the changes of stator resistance have a great impact on the speed accuracy and result in a serious decline of the system performance. As seen in Figure 8, the damped oscillation occurs when the speed is at 2s, yet does not deviate from the given value, so the system is stable. As seen in Figure 7, the electromagnetic torque has a greater disturbance when the motor starts, and larger oscillation and pulsation are generated when the motor stator resistance changes. As seen in Figure 7, the oscillation and torque pulsation are relatively smaller for the torque with stator resistance identification.

According to the simulation results, under the condition of severe stator resistance mutations, the speed and torque waveforms presented in this paper are obviously better than the waveforms without stator resistance identification. Besides, the speed does not deviate from the given value, and it has good stability. Also, the torque has better smoothness and a good identification of the stator resistance dynamic changes.

Conclusions

In the speed sensorless vector control system based on MRAS method, this paper proposes a new stator resistance online identification solution based on fuzzy logic, which takes the rotor flux and the stator current vector as the input as well as the stator resistance changes as the output. Then, this paper makes a simple analysis of rotor flux and speed estimation principle, adopts new method to handle the effects of stator resistance changes, and establishes a stator resistance identification method based on fuzzy logic.

Simulation results show that the stator resistance changes have a greater influence on the speed estimation, and the proposed stator resistance identification strategy can achieve real-time estimation of the actual stator resistance. The method has simple structure, high reliability and low computational complexity. The application of stator resistance identification system can significantly improve the speed control system performance.

Study on optimal-power Ratio Optimization of Automatic Transmission

Fengping Cao

Automotive Department, Shandong Jiaotong University, Jinan, Shandong, China

cao2138@163.com

Keywords: Compound Automotive Transmission, Optimal Power, Ratio Optimization, SimulationX Software.

Abstract. Regards the compound auto transmission as the object of research, an optimal-power ratio optimization algorithm that takes into account the efficiency of CVT was presented in the paper. Firstly, the numerical models of drivetrain were established, which included the engine output torque model and the efficiency model of CVT. Then, the driving power was chosen as the dynamic target, and the optimized objective function was built. According to the requirement of shift gear, the ratio of shuttle transmission components was determined. Based on the Simulation X, the simulation car model with the compound auto transmission was design to confirm the validity and effectiveness of the proposed method.

Introduction

In recent years, cars production and ownership are increased rapidly, which brought a lot of harm to the society, such as air pollution and energy consumption. In order to improve the performance of vehicles, several measures were adopted in the world [1, 2, 3]. Among them, the matching and optimized designing of the power transmission system is largely determines the automotive dynamics and fuel economy, and is considered as an important measure to improve the automobile general performance. Regards the compound auto transmission as the research object, an optimal-power ratio optimization algorithm is presented in the paper.

Organization of the Text

The Structure and Workings of Compound Auto Transmission

The transmission composed of a metal belt CVT unit and a shuttle transmission component, and can realize continuously variable transmission and a variable transmission according to the automotive operation mode. It not only can play the advantage of gear transmission efficiency, but also overcome the shortages of low efficiency of metal belt type continuously variable transmission in high-speed and high-power [4].

Establishment the Mathematics Model of Drivetrain

The Engine Output Torque Model. Engine output torque is the function of throttle opening and engine speed, that is $T_e = f(\alpha, n_e)$. Through the engine bench test, and using interpolating fitting methods can get the steady numerical model of engine output torque, which is shown as Fig. 1.

Because of the impact of mixture concentration, the engine is usually worked under non steady state. Modified the engine output torque under steady conditions using formula (1), and take this as the engine output torque under non steady state [5].

$$T_{ed} = T_e - K \cdot W_e \tag{1}$$

Where, T_{ed} is the engine output torque under non steady state, T_e is the engine output torque under steady conditions, W_e is the angle acceleration of the Crankshaft, and k is the falling coefficient of engine torque.

The Efficiency Model of CVT. For the metal belt CVT unit, power loss is inevitable during energy transferring. In order to optimize the drivetrain, it is need to build the efficiency model of CVT. Research indicates that the efficiency model of metal belt CVT is the function of its ratio and engine torque [6]. The relational data are gained through experiment, and the efficiency model of CVT built is shown as Fig. 2.

The Model of Optimal Power Ratio Optimization for the CVT

The driving power is not just the engine power, but also the efficiency of CVT. It is need to consider the efficiency of CVT for automotive dynamics when optimizing the ratio of CVT.

For a car with the compound auto transmission, if the ratio of shuttle transmission component is determined, in order to ensure best automotive dynamics, there requires the car obtain the maximum driving power at any throttle opening and car speed. The driving power of the car can be calculated by formula (2) regardless of the main reducer efficiency.

$$P_d = P_e \eta_{cvt} \tag{2}$$

Where, P_d is the driving power, P_e is the engine power, and η_{cvt} is the efficiency of CVT.

Simulation and Analysis

According to the structure and workings of compound auto transmission, the mathematics model of drivetrain, and simplified the driving resistance to air resistance and rolling resistance, the

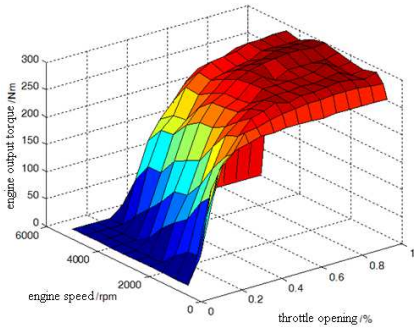

Fig. 1 The numerical model of engine output torque

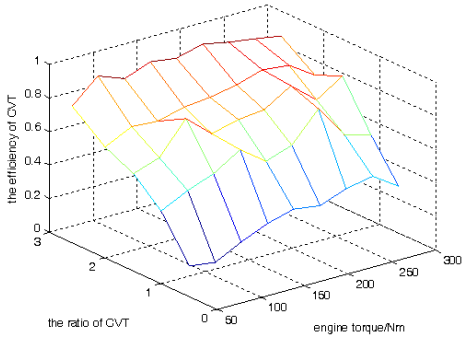

Fig. 2 The CVT efficiency numerical model

simulation model is established based on SimulationX software as Fig. 3. The ratio of shuttle transmission components is determined as 1.5, and the range of CVT ratio is set as [0.5, 2.6], and according to the transmission's radius, the original ratio of CVT is shown as Fig. 4.

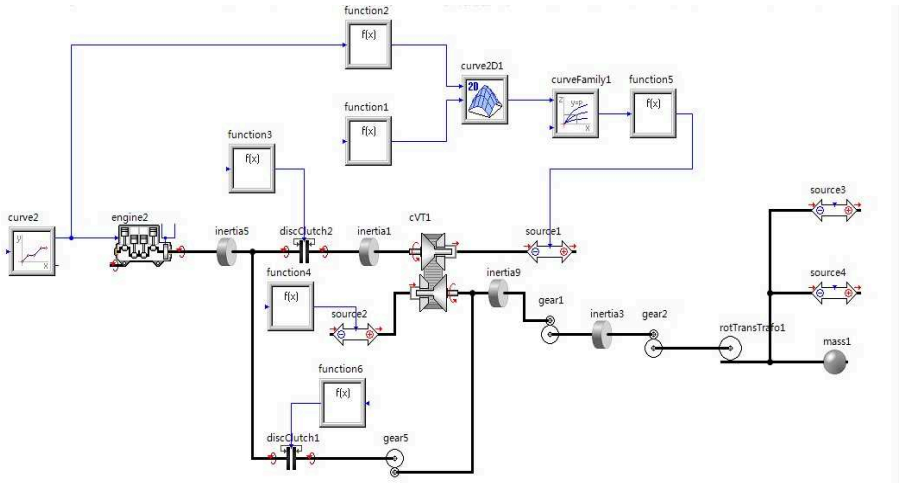

Fig. 3 Simulation model with compound auto transmission based on SimulationX

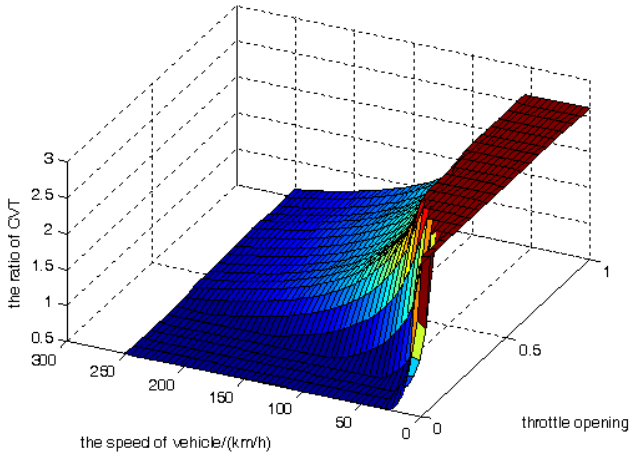

Fig. 4 The original ratio of CVT

Set the simulation time as 50s, and the simulation results of automotive speed is shown as Fig. 5.

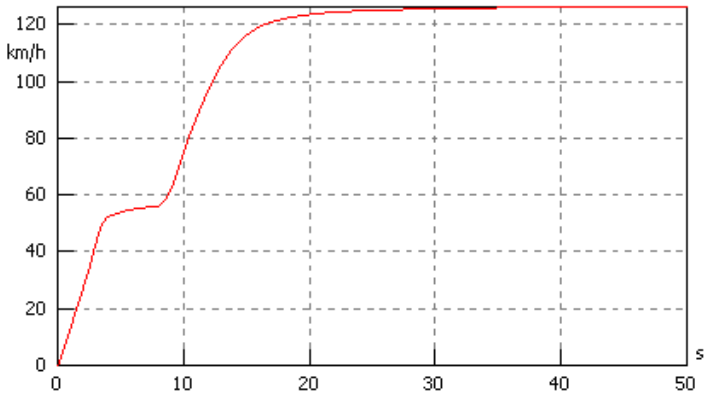

Fig. 5 The automotive speed

Using the above simulation model and the ratio optimization model, optimize the ratio of CVT. Fig. 6 is the ratio optimization result for the CVT.

For the transmission, set the ratio of CVT as the optimization results, and in this case, the automotive speed is shown as Fig.7.

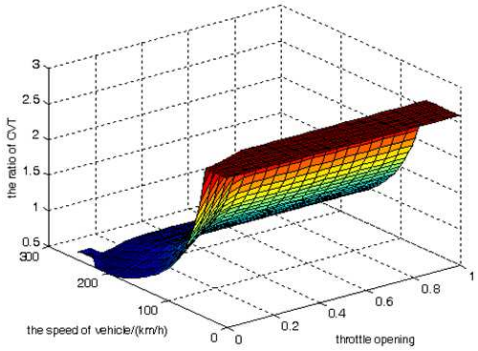

Fig. 6 The CVT ratio optimization results

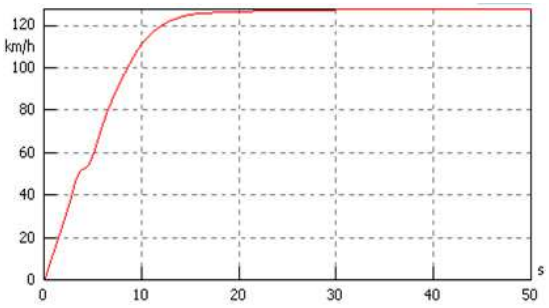

Fig. 7 The automotive speed after optimization

From Fig. 5 and Fig. 7, we can see that the 0-100km/h acceleration time before and after optimization is 12.31s and 8.58s, the acceleration time reduced 30.3%. This shows that the car's dynamic characteristic improved significantly.

Conclusions

In the paper, an optimal-power ratio optimization algorithm that takes into account the efficiency of CVT is presented.

The numerical models of drivetrain, which included the engine output torque model and the efficiency model of CVT, are established.

The optimized objective function is built, which considered the efficiency of CVT. Using the simulation car model based on the SimulationX software, the validity and effectiveness of the optimization method is confirmed.

[a]huyang_ncepu@163.com, [b]460378470@qq.com

Keywords: VSC-HVDC; Control Strategy; SIMULINK.

Abstract. With the development of high-power full-controlled power electronic devices based HVDC voltage source converter (VSC) and pulse width modulation (PWM) technology (VSC-H VDC) technology has become a reality. Currently VSC - HVDC technology in foreign countries in the theoretical study of the transition phase to the experimental system, while the domestic is just beginning, many of the basic theory and applications related to basic issues to be studied. In this paper, based on existing research, analyzes power VSC-HVDC system control strategy proposed *dq0* coordinates using a steady state model, and based on the model , designing the control program. Finally, to build a system using SIMULINK simulation model for a steady-state simulation analysis.

Introduction

As the power electronics technology developing, the use of full-controlled devices based on voltage source converter (Voltage Source Converter, VSC) in HVDC has become possible. In 1990, McGill University, Boon-Teek Ooi put forward HVDC concept with PWM control VSC, the so-called HVDC (HVDC light) [1,2]. In 1999, Gotland ,ABB put into operation in the world's first commercialization of VSC-HVDC system [3], the rated operating capacity of the system is 50MW, both ends of the VSC rated capacity of 65MW, transmission voltage is ± 80kv, transmission distance is 70km, it is the southern tip of the South Island Gothic with a wind farm 70km outside the city of Visby to link up with the existing AC lines run in parallel. In the ABB company IGBT switching devices developed for the VSC-HVDC, while Japan has also developed a switching element GTO for the VSC-HVDC interconnection and back to back, at present, CIGRE 14th meeting of the group has set up a working group for the VSC-HVDC [4,5].

In this paper, based on existing research, analyzes VSC-HVDC system rectifier and inverter power control strategy, using a steady state model proposed dq0 coordinate, and design control strategy. Finally, to build a system using SIMULINK simulation model for a steady-state analysis.

Research control strategy for steady state

For steady state, assuming symmetrical three-phase system is running, there is no zero-sequence component, the first derivative of the state variable to 0, we obtain:

$$\begin{cases} 0 = u_{cd} - Ri_d - u_{sd} + \omega L i_q \\ 0 = u_{cq} - Ri_q - u_{sq} - \omega L i_d \end{cases} \quad (1)$$

Decoupling control for the search, where the initial phase angle of voltage is 0° on AC side . Thus $u_{sd} = |u_s|$, $u_{sq} = 0$ and let ωL is the fundamental reactance , Then the formula (1) can be simplified as:

$$\begin{cases} u_{cd} = Ri_d + u_{sd} - X_T i_q \\ u_{cq} = Ri_q + X_T i_d \end{cases} \quad (2)$$

Variables research is needed into the AC system reactive power Q_s And DC side injection of active power P_c. Loss simulated by a resistor. We can get:

$$P_c = \frac{3}{2}(u_{cd}i_d + u_{cq}i_q) = \frac{3}{2}\left[u_{sd}i_d + R(i_d^2 + i_q^2)\right] \quad (3)$$

$$Q_s = \frac{3}{2}(u_{sq}i_d - u_{sd}i_q) = -\frac{3}{2}u_{sd}i_q \quad (4)$$

Formula (3) and formula (4) have a relatively clear physical meaning. Assuming AC system is strong enough, u_{sd} is a constant value, the reactive power on the AC side is obviously only the *q*-axis current proportional. The active side of the inverter consists of two parts, the first part representatives of the desired power converter, the inverter and the representative part of the reactor loss.

Therefore, the alternating current component can be decomposed into two separate i_d and i_q. Although in the formula (3) i_q is also the vatiable quantity of P_c, but the actual control process can be calculated based on the reactive value of i_q, therefore the active side of the inverter P_c can be considered only with i_d been related. So the model is active and reactive decoupled. Further, considering the normal operation active power transmission loss is much less than the value, so P_c and i_d ,Their approximate linear relationship is also very conducive to controller design.

By controlling i_d and i_q ,can reach the active and reactive power control purposes. Generally, however, the real power is the VSC-HVDC direct current or DC voltage by the control of either the AC side may be required to control the reactive power control of the AC voltage may also be required. The following can be a PI controller are designed, respectively, for controlling i_d and i_q.

A. **Active Power Controller.** A controller for controlling the active i_d in modeling, we use the DC power controller. To improve system response speed, steady-state inverse model provided by i_d reference value.

DC power controller shown in Figure 1.

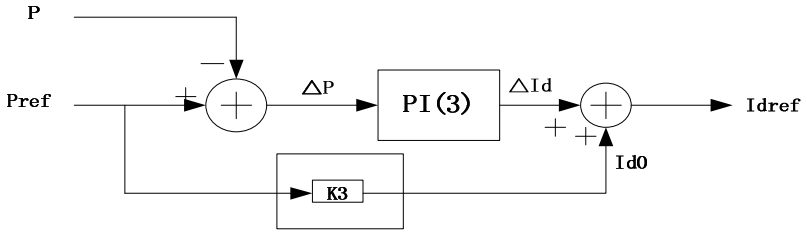

Fig. 1 DC power controller structure

B. Reactive Power Controller. A controller for controlling the reactive power i_q AC reactive power controller shown in Figure 2.

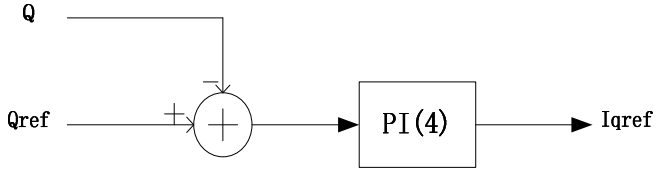

Fig. 2 AC reactive power controller structure

C. modulation wave synthesis. By the amount of control i_d and i_q VSC modulated wave can be synthesized. Synthesis of the inverter modulation wave structure shown in Figure 3. *R* is the

equivalent loss resistance of the analog; U_{cd} , U_{cq} after Park inversing become i modulated signal form, PLL links for locking phase.

MATLAB simulation-based analysis of VSC-HVDC

Using fixed-step discrete algorithms, Ts_Power = 7.407e-6; Ts_Control = 74.07e-6. To analysis steady-state and step response. Figure 4 is a system main circuit simulation model. First, in the model of three-phase programmable so that no short circuit between the power supply voltage failure without fluctuation, "Station2" and "AC System2", research VSC control system performance under normal conditions [6].

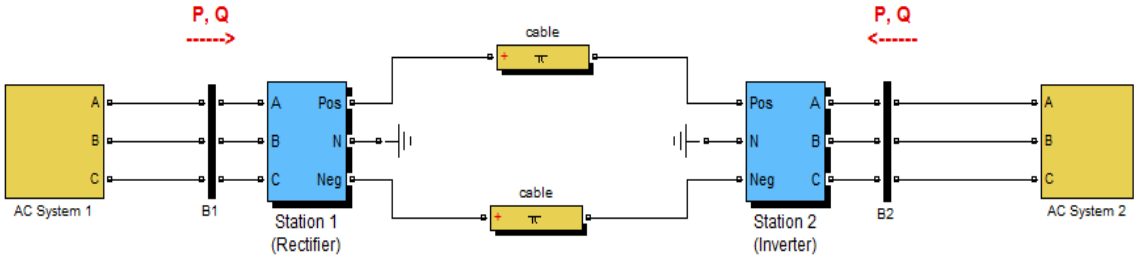

Fig. 4 System main circuit simulation model

Run the program to obtain simulation results shown in Figure 5 to Figure 6, namely "Station1" and "Station2" DC voltage, active power and reactive power.

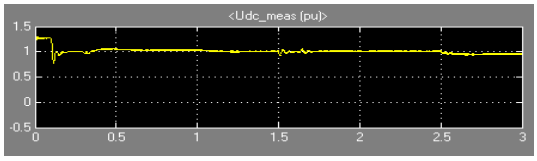

Fig. 5 (a) Station1 DC voltage waveform

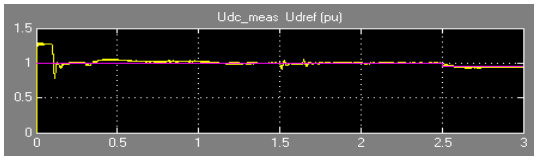

Fig. 6 (a) Station2 DC voltage waveform

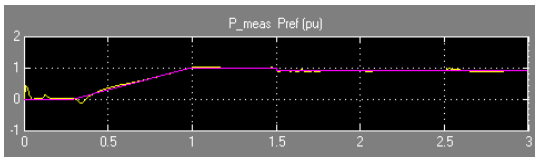

Fig. 5 (b) Station1 active waveform

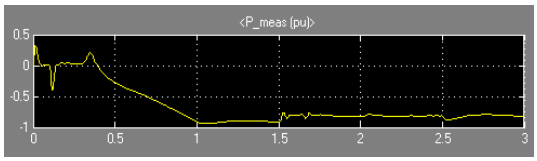

Fig. 6 (b) Station2 active waveform

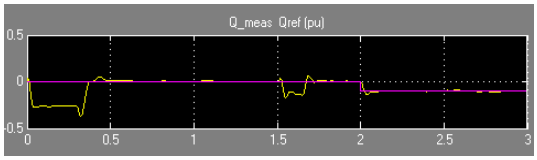

Fig. 5 (c) Station1 reactive power waveform

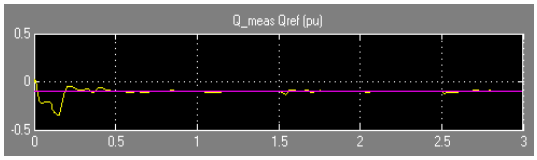

Fig. 6 (c) Station2 reactive power waveform

Seen from the waveform, in converter station 1and station 2 ,control system working with 1.3s time to reach steady state. After the steady state, the DC voltage is 1.0 p.u (200kV), steady-state power of 1.0 p.u (200MW). Reactive power rectifier side is 0, the inverter side reactive power is -0.1 p.u (20Mvar).

When 1.5s, the converter station power command a mutation, the actual active power can change quickly follow instructions to achieve stable within 0.3s, while active two converter stations also change accordingly. When 2.0s, after commutation reactive power command station a mutation, seen from Figure 5 (c) the actual reactive power corresponding change rapidly, and on the DC voltage and active power is small, a control system Good decoupling performance. When 2.5s, the DC voltage command converter station 2 mutation, a DC voltage converter station will follow changes in the short-term fluctuations in active settings quickly restored, fundamental reactive power is not affected . Active and reactive power reference value and the DC voltage changes, the system needs to re-enter the steady 0.3s time. Active and reactive power control is theoretically independent, but the visible waveform analysis, or a certain degree of interaction between the two.

Conclusion

In this paper, VSC-HVDC system control strategies were studied by using a steady state model based on dq0 coordinates. Using the SIMULINK to build the model. Simulation and analysis includ steady state of active and reactive power, voltage control. Studying the various operating conditions of the VSC-HVDC system, the model reflects the good operating performance.

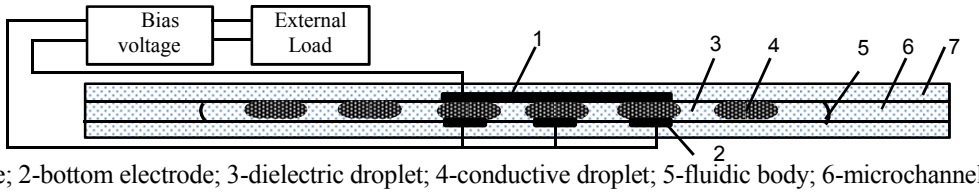
Keywords: microfluidic power generator, reverse electrowetting, mechanical-to-electrical energy conversion mechanism, influencing parameter, power output.

Abstract. The micro power generators that depend on converting the ambient energy into usable electrical energy for portable electronic devices have attracted much attention in recent years. A novel microfluidic power generator which is based on reverse electrowetting in a microchannel geometry was presented by Tom Krupenkin and J. Ashley Taylor. This generator overcomes the defects such as low output and low resource utilization of traditional energy converters. Understanding the parameters influencing output of this generator is a key to enhance the power output of it. This paper discussed the effects of factors on generator output by numerical simulation. The results show that promising performance of REWOD-based power generator can be achieved by choosing a thinner dielectric film with high dielectric constant and high break strength, and increasing the droplet oscillation frequency.

Introduction

With the rapid development of portable electronic devices, electrical batteries characteristics such as short lifespan, limited capacity, poor portability, etc. have become the critical bottleneck of its applications. Alternative power sources which overcame these limitations are thus highly desirable. More recently years efforts have been focused on ways to convert environmental energy into electrical power. Actually there exist many ways to convert ambient energy into usable electrical energy [1-4]. The general opinion from the literatures is that mechanical energy in the form of motion is particularly the most versatile and ubiquitous ambient energy source available for portable applications[5-8], but currently its use is substantially limited by low power output of energy converters. To solve this problem, Tom Krupenkin and J. Ashley Taylor developed a completely new mechanical-to-electrical energy conversion method which is based on reverse electrowetting-on-dielectric (REWOD), the approach and apparatus are introduced in the patent [9]. Fig. 1 show the schematics of microfluidic power generator based on reverse electrowetting in a microchannel geometry. The main parts of this generator are a plurality of electrodes and a fluidic body which comprise spatially separated conductive droplets and dielectric droplets. Electrodes are covered by dielectric film and the hydrophobic film, the hydrophobic film provides low-hysteresis surface for droplets motion. Fluidic body is configured to reversibly move as a whole with respect to plurality of electrodes under the influence of a mechanical force. Each cycle of alternations of the amount of electrical charge accumulated by the electrodes, whereby generating electrical current flow between electrodes.



1-top electrode; 2-bottom electrode; 3-dielectric droplet; 4-conductive droplet; 5-fluidic body; 6-microchannel; 7-substrate.

Fig. 1 Schematics of REWOD generator of microchannel geometry [9]

The microfluidic power generation based on REWOD is a novel method of mechanical-to-electrical energy conversion, which had not been previously described in the

literatures besides the mentioned in Tom Krupenkin and J. Ashley Taylor's article[10], the research about influencing parameters of the reverse electrowetting process is lacking. In this paper, we discussed the influences of dielectric film material and thickness, and droplet oscillation frequency on the REWOD-based microfluidic power generator output by numerical simulation.

Simulation

In this section, according to the mechanism of microfluidic power generator based on the reverse electrowetting which described in the patent [9], we provide a numerical simulation of finite element method to discuss the influences of factors on the generator output.

The entire apparatus of the REWOD-based power generator in a microchannel geometry is consisting of some REWOD units with the same structure, and one of the units is schematically shown in Fig. 2. In the simplest approximation, we neglect the intricacy of the wetting-dewetting process associated with the motion of liquid droplets during the REWOD process and treat each droplet simply as a variable capacitor [10] shown in Fig. 2. The value of bias voltage V_{app} is switched from zero to V_0 during the whole process is shown in Fig. 3, where T is the cycle time period of the droplet oscillation.

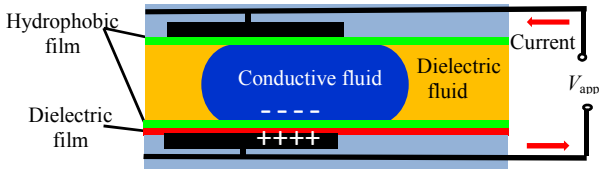


Fig. 2 Schematics of REWOD unit mechanisms

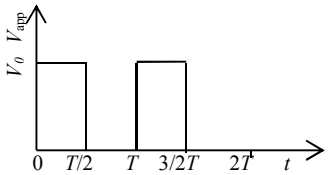

Fig. 3 Value of the V_{app} switched with time

The simplified calculation model of the REWOD unit is shown in Fig. 4, The entire simplified model size is 2.5mm×150μm, bottom electrode size is 1mm×20μm, conductive droplet length is 1mm, the gap between top and bottom electrode is 100μm. The value of parameters for the simulation are shown in Table1.

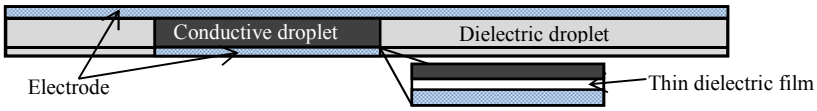

Fig. 4. The simplified calculation model of the REWOD unit

Table 1. The value of parameters for the simulation

Item	Material	Dielectric Constant	Breakdown strength
Dielectric film	Si_3N_4	9.7	1000[V/μm]
	ParyleneC	3.0	200[V/μm]
	SiO_2	4.2	100-1000[V/μm]
Dielectric fluid	Transform oil	2.36	18-20[V/μm]
Conductive fluid	Hg	Approaching infinity	–
Electrode	Cu	Approaching infinity	–

The domain of conductive droplet, dielectric droplet and the dielectric film comply with Eq. (1), where V is the electric potential, ε_d is the dielectric constant of the medium.

$$\nabla\cdot(\varepsilon_0\varepsilon_d(-\nabla V))=0 \tag{1}$$

The boundary conditions on the surface of the top and bottom electrode respectively are V=0 and V=V_{app}.The boundary conditions about the interface between the liquid-solid and liquid-liquid are as follows Eq.(2), where ρ_s is the surface charge density, $\boldsymbol{E}$ is the electric field, $\boldsymbol{D}$ is the electric displacement vector, $\boldsymbol{n}$ is the (outward) unit normal vector.

$$\boldsymbol{n}\cdot(\boldsymbol{D}_1-\boldsymbol{D}_2)=\rho_s \quad \boldsymbol{n}\times(\boldsymbol{E}_1-\boldsymbol{E}_2)=0 \tag{2}$$

The charge on the electrode plate and the net energy generated are calculated following Eq. (3), where the S is the surface of the electrode, the Q_0 is the total charge.

$$\int \rho_s \mathrm{d}S = Q_0 \quad W_t = 0.5Q_0V \tag{3}$$

The Eq. (3) showed that the energy of REWOD process generated in one cycle is equal in amount to the capacitor stored actually. Assuming that the conductive droplet moved periodically in the x direction as follows x=0.5[mm](1-cos2πft), where the f is the droplet oscillation frequency, t is time. Charge and net electrical energy generated under different conditions by the microfluidic power generator based on REWOD in a microchannel geometry are calculated in two cycles.

Dielectric Film Material. As shown in Fig. 5, for three different dielectric films with the 10μm thickness, charge are decreasing from the maximum to zero while the energy generated is increasing from zero to the maximum as the movement of the conductive droplet in a cycle. What's more, dielectric films with different dielectric constant have important influence on the net energy generated. The charge and net energy are both most for dielectric film Si_3N_4, on the contrast, which are both less for dielectric film paryleneC. This can be interpreted as the dielectric constant of Si_3N_4 and paryleneC is the largest and smallest respectively in the three kinds of films. It is concluded from the above results that the higher dielectric constant is, the more charge and net energy are.

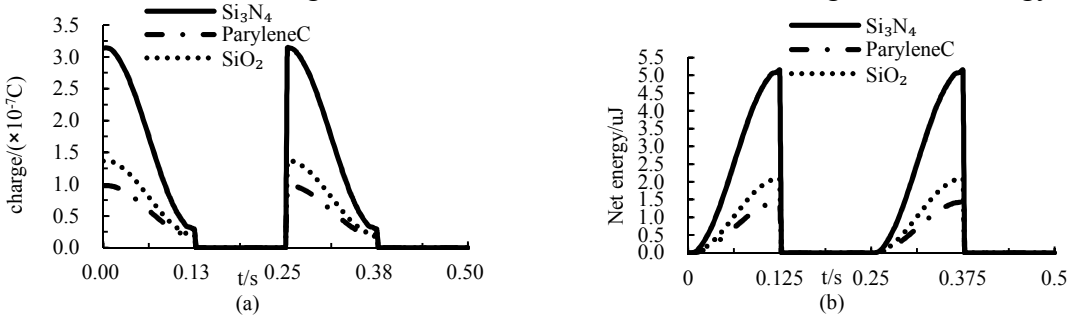

Fig. 5 The (a) variation of charge and (b) net energy generated for three different dielectric films with thickness of 10μm, bias voltage applied is 36V, and droplet oscillation frequency is 4Hz.

Dielectric Film Thickness. The plot of charge and net energy generated in two cycles for three different thickness of Si_3N_4 film was given in Fig. 6. The general trend of charge and generated net energy curves are quite similar in all three cases. Charge decreased from maximum to zero and net energy generated increased from zero to maximum along with the motion of the droplets. However, from the results one can see that the net energy of almost 10μJ is obtained for the 5μm thickness Si_3N_4 film, but only 3μJ energy generated for the 15μm case. Thus it can be seen that decreasing the thickness of the dielectric film lead to increase the energy generated effectively. But meanwhile, it brings the challenges to electric breakdown resistance of dielectric material and the technology of thin film fabrication.

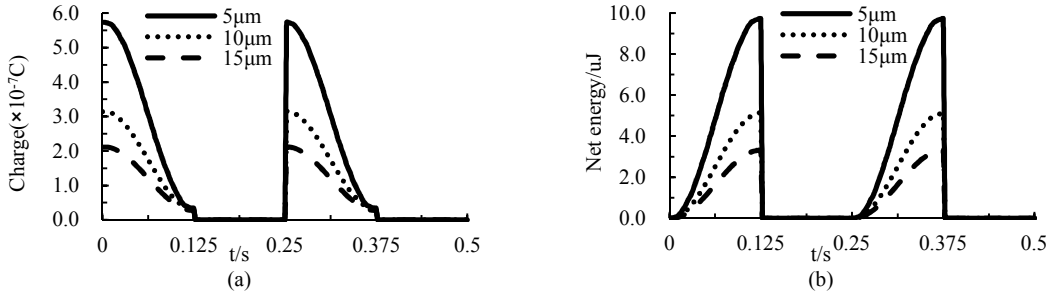

Fig. 6 The (a) variation of charge and (b) net energy generated for different thickness of Si_3N_4 film. Bias voltage applied is 36V, and droplet oscillation frequency is 4Hz.

Droplet Oscillation Frequency. Droplet oscillation frequency is another important parameter to the output of generator based on REWOD. We calculated variations of the charge and net energy for three different droplet oscillation frequencies as shown in Fig. 7. The maximum amount of charge and net energy are equivalent for three cases in per period, but the higher oscillation frequency, the shorter cycle of wetting-dewetting, net energy generated almost 52μJ in a second for oscillation frequency of 10Hz, while for low frequency of 1Hz, only 5.2μJ generated. It is obvious that more electrical charge flowed back to circuit and more energy generated per unit time for the case of higher oscillation frequency. Apparently, higher oscillation frequency can increase power output remarkably, and that the generated net energy linearly increases with droplet oscillation frequency.

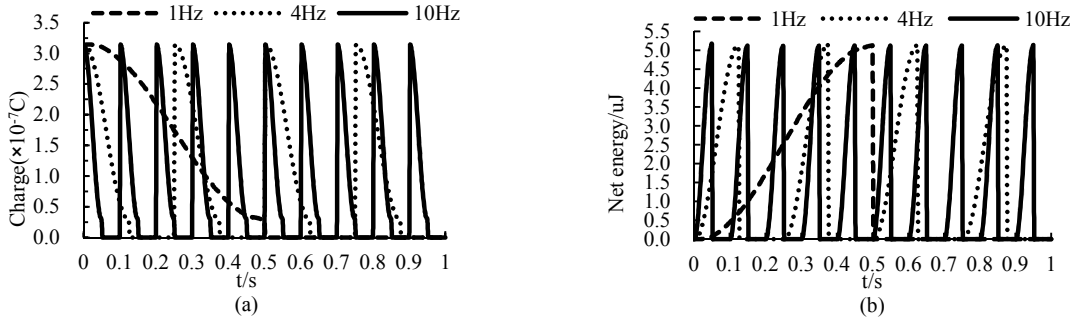

Fig. 7 The (a) variation of charge and (b) net energy generated for different droplet oscillation frequency. Dielectric film is Si_3N_4 with 10μm thickness, bias voltage applied is 36V.

Summary

In this paper, we discussed the influences of parameters on the output of the microfluidic power generator based on REWOD in a microchannel geometry by simulating this process. The results show that: (1) more net energy can be generated by using dielectric layer with high dielectric constant and high break strength such as Si_3N_4; (2) the thin film show far better performance than the thick film; (3)The generated net energy increases linearly with droplet oscillation frequency, and the net energy generated under 10Hz frequency is ten times more than the case of 1Hz within the same time.

From the above, one can conclude that the promising performance of microfluidic power generator based on REWOD in a microchannel geometry can be achieved by choosing a thinner dielectric film with high dielectric constant and high break strength, and increasing the droplet oscillation frequency.

Keywords: Smart system; Thermoelectric generator; Solar energy; Energy harvest

Abstract. This paper presents a typical application for a newly developed thermoelectric energy harvesting system. The proposed solar thermoelectric generator (TEG) operates with phase change material (PCM) day and night. An energy management system was connected with the TEG to increase the output voltage while the harvested power was used to drive a wireless transmitter. The wireless receiver controlled the switch of a water tap which functions as a smart cooler of a photovoltaic cell. This study demonstrates a way of using micro-energy to improve macro-energy production smartly.

Introduction

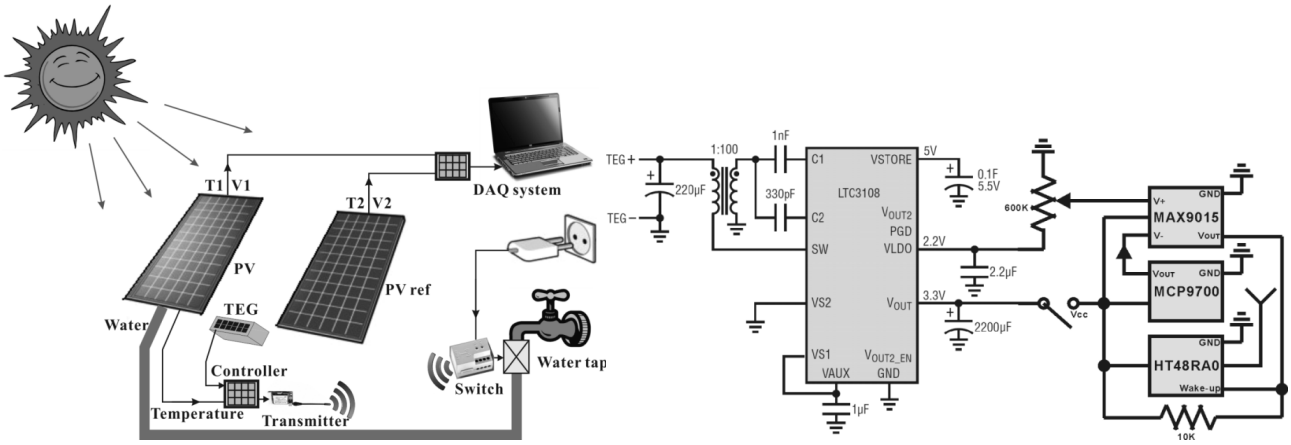
Solar micro energy harvesting has become an attractive topic in researches for a long time [1]. The most popular technology includes thermoelectric effect [2] with space variation of temperature and pyroelectric effect [3][4] with time variation of temperature. A newly developed solar thermoelectric generator uses phase change material to accompany the working process of the TEG [5-6], improving the temperature stability on its cold face during the day and extending the work time of the TEG into the night. The newly proposed TEG had been proved with a maximum power generation 17μW outside, which is insufficient with a majority of wireless application. The focus of this study is to realize a typical wireless application with this TEG, taking advantage of a group of the micro generator and impedance matching.

Constitution of the Experimental System

It is well known that the weakness of photovoltaic power is that the power generation decreases when the panels become hot. This decrease is often greatest when solar radiation is high. So our experiment uses the developed TEG group as a (self-powered) smart system in order to improve photovoltaic power generation. The proposed smart system aims to refresh the photovoltaic panel through water evaporation. The constitution of the smart system is shown in Fig.1(a) which mainly includes: (1) a TEG work unit (2) a smart controller which was powered by the TEG, it monitors the temperature in two PVs and sends out a wireless signal to activate the cooler. (3) two identical photovoltaic panels: one serves as a reference while the other is fitted with a cooling system on its shaded side where it is not irradiated by the sun. (4) a water tap which was controlled by a wireless switch. Solar radiation is measured with a cmp3 pyranometer from Kipp & Zonen company. All data were recorded with a data acquisition system (NI USB-6259 BNC).

The TEG in work unit is made of 12 pieces of TEC-12708 module which were connected in series electrically. The equivalent seebeck coefficient of each module is 30mV/°c and its internal resistance is 2.5Ω. The TEG was connected to the PCM with two heat exchangers (63730 AAVID THERMALLOY). A paraffin wax from Dupont company is used as the PCM; its melting point is 21.7°C. Between 18°C and 22°C, the heat storage capacity is 40mJ/m3. Solar radiation is the heat source and the PCM is the heat sink during the day. At night, heat from the PCM is dissipated into

the environment by convection. The TEG has two separately treated work statuses: during the day, a glass cover is used to increase the absorption of solar radiation while at night; the glass is taken off to enhance convection.



(a) The entire system (b) The controller

Fig.1. Constitution of the experimental system

A diagram of the smart controller is shown in Fig.1(b). It contains transformer, DC-DC converter, temperature sensor, comparator, micro-controller and wireless transmitter. The maximum output voltage of the TEG is 1V according to a previous test outside. It is not sufficient to power common commercial electronic devices directly. A DC-DC converter is a solution to this problem. The ultra-low voltage step-up converter (LTC3108 from Linear Technology Corporation) was adopted, allowing the system to operate with such a low TEG output voltage. A coupled inductor (LPR6235-752SML from Coilcraft INC.) with a ratio of 1:100 is used as the transformer. The main output of the converter is set to 3.3V and a 2200μF capacitor is used to temporarily store the energy. It is able to drive the temperature sensor, comparator, micro-controller and wireless transmitter at the same time. The output for the battery in the converter is connected to a 0.1F capacitor, storing energy from the TEG when the primary capacitor is fully charged. A low-power linear active thermistor (MCP9700 from Microchip Technology INC.) is used to sense the temperature on the PV panel. It is placed on the back of the panel and it transfers the temperature, giving analog output. In order to limit our test to the demonstration of the efficient use of harvested micro-energy without developing a specific wireless transmitter and electric switch receiver, we chose a commercial wireless doorbell (D403 from Friedland company) with an integrated transmitting micro-controller (ht48ra0-2 from Holtek Semiconductor INC.) working at 433MHz. The wireless switch is activated automatically when the doorbell rang. The micro-controller was put on standby most of the time when no command was sent to the transmitter. It is “woken up” by grounded triggering from the voltage comparator (MAX9015A from Maxim Integrated Products, INC.) and the doorbell rings. The inverting input of the comparator is connected to the output of the temperature sensor while the non-inverting input receives a given reference temperature from the potentiometer driven by the low drop-out linear regulator in the step-up converter.

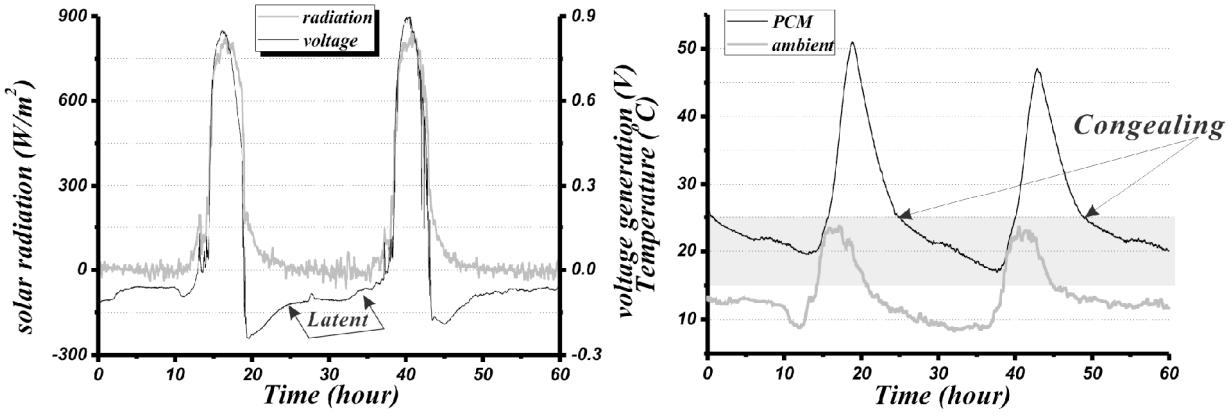
The principle of the panel cooling system is based on drying combined with solar radiation. The first layer of a water-pipe system (such as waterSmart drip line) was glued to the back of the PV panel. The drip line is associated with a tap timer in order to create an automatic drip system designed to work at low pressure without a pump. A layer of superabsorbent cloth was glued to this first layer of the water-pipe system. A second layer of drip line was added and it was covered with another layer of superabsorbent cloth. So there were then two layers of drip line and superabsorbent cloth. When the water drip line was open, the superabsorbent cloth was impregnated. Once the water supply was cut off, the PV panel was refreshed through the drying of the superabsorbent cloth.

The energy from the PV panel made the water in the cloth evaporate into the surroundings and thus refreshed the PV panel. To clearly show the possible effect of such a smart system and to guarantee the correct status of all the power consumers after the converter, we present in this paper the results for when the switch is turned on manually for ten minutes every hour.

Experimental results

The tests were performed over several autumn days in Aix-Les-Bains (France). We present the results of two consecutive days with very similar solar radiation and the same ambient thermal loads. Fig.2 shows the sunshine and ambient temperature measured on these two days. Solar radiation ranged from 0 to 900W/m^2. The relatively low ambient temperature varied between 10 and 26°C at midday and fell by around 10°C at night. The two days were windless and the convection effect was considered as natural convection. The maximum daily temperature could not be very high in our test conditions. However, these conditions are still interesting for us because if the performance of the PV is improved during the autumn, the improvement should be even more significant in the summer.

The performed test considered two PV panels: one equipped with the cooling system and the other one left in its normal working state. On the first day, the two panels worked without any special management. For the second day, the cooling system was activated at the back of one panel. The analysis of the results aims to (i) present the micro-energy harvest by TEG work unit in a real situation and (ii) demonstrate the improvement provided by the cooling system controlled by the self-powered wireless system powered by harvested micro-energy.

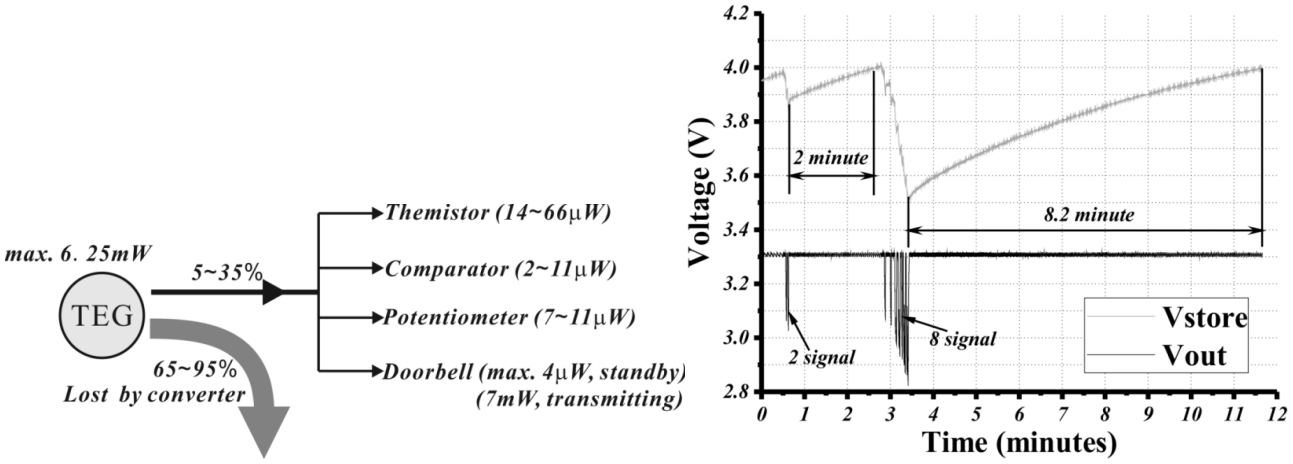


a) Recorded radiation and TEG voltage (b) Temperature in the PCM and environment

Fig.2. Experimental results of the TEG

Fig.2 shows also the recorded voltage generation on an external resistor of 40Ω with the TEG and temperature variation inside the PCM over 60 hours. Analysis of this figure lead to five comments: (i) the energy harvested was 465J over 60hours - an average power of 2.15mW. The daily maximum power reached 20mW (a power density of 2.7mW/cm^3 or 1W/m^2). Energy harvested at night by the TEG formed 10% of the total energy. This real situation test was carried out in autumn. Logically, the performance would be better in summer and not so good in winter. (ii) the voltage generated in daytime reached 0.9V for a solar radiation intensity of 900W/m^2. Although less voltage was generated at night than during the day, the absolute value was generally greater than 0.02V (more than 90% of the time). It can be regulated with the step-up converter and utilized in a some application at night. (iii) the phase change process occurred during our test. The decrease in ambient temperature was gradual from hour 21 to 27, but there was a definite change in the PCM

temperature variation at hour 25. This change of slope recurs at hour 49 at the same temperature, 25°C. As this fits with the manufacturer's stated melting point, we believe that this is the congealing point of the PCM. When the PCM releases the latent heat, the generated voltage becomes stable, as indicated in Fig.2(a). However, the latent heat in the developed prototype generator is still insufficient. Its sensible heat is utilized during the experiment. It can be expected that with more PCM or more latent heat capacity, the performance would be better. (iv) the temperature curve (Fig.2(b)) clearly shows the inertial effects of PCM in generating a temperature gradient in the TEG. There is indeed a shift in the peak ambient temperature and the peak internal temperature of the PCM. The shift of temperature, between ambient and PCM internal temperature, is favorable for maintaining a temperature gradient in the TEG. It can be noted that, in the absence of solar radiation, the temperature inside the PCM remains high. This confirms the idea of heat storage in the PCM for the generation of micro-energy at night. (v) the voltage generated by the TEG was very sensitive to solar radiation during the day. The night performance depends mainly on convection and ambient temperature. Variations in voltage generation can be used for sensing radiation during the day; this confirms the possible use of the TEG device to carry out smart control strategies in some processes.



(a) Energy balance in the controller (b) Transmitting process of temperature sensor

Fig.3. Experimental results of the controller

The characteristics of the self-powered controller depend on the power capability of the TEG, the DC-DC energy conversion efficiency and the power consumption of the electronic devices. A diagram of the energy balance in the system can be seen in Fig.3(a). The TEG system can provide a maximum power of 20mW. When the TEG is connected to the step-up converter, the output DC signal is first changed into a switched AC signal and then amplified by the transformer. The amount of energy lost in this process depends on both the transformer ratio and the input voltage to the converter. The maximum energy conversion efficiency reaches 35% in our case. Intended as the study of a typical case, one TEG module was constantly irradiated with the maximum recorded value in the environment and it generated 150 mV in an open circuit status. It was used to drive the sensing system and the performance is shown in Fig.3(b). The voltage variation in the two capacitors (V_{out} is connected to 2200μF and V_{store} to 0.1F) was recorded. When the TEG was connected to the converter, the generated voltage fell to 100mV. The calculated input power to the converter was 1.67mW. With V_{out} fully charged and V_{store} charged to 4V, two groups of doorbell commands were sent out by manual activation of the temperature sensor. The recorded pattern of voltage variation shows that V_{out} was used to drive the electronic consumers directly while V_{store} sensed the change of V_{out} and quickly recharged it. The drop in V_{store} was in relation to the power consumption of the doorbell and the increase corresponded to the major part of energy harvested from the TEG. The measured harvested power after the converter was between 0.39 and 0.47mW. The calculated energy conversion efficiency was 23-28%; this is in line with the characteristics

provided by the manufacturer. In short, the step-up converter is a good solution for a self-powered controller when the generated power from the TEG is not enough to drive the electronic devices directly. With one module of the TEG and without matched impedance, the system can send out at least one signal every two minutes. It is expected that this kind of system could work as an independent sensor node within a well-designed control strategy.

Fig.4 shows the results of the water cooling application of harvested micro-energy related to macro-energy. The two PV panels work without any special treatment during the first day. The cooling system is activated on the second day. Fig.4 (a) and (b) present the voltage generation from the PV panels and the temperature variation on their rear side. The results of the two PV panels are also compared with dimensionless values. Fig.4 (c) and (d) present the ratio of measured data. These graphs clearly show that: (i) the two PV panels have almost the same behavior on the first day, without cooling. The variation in their temperature ratios is less than 15% while that of their voltage generation is less than 3%. The temperature of the PV panels with the cooling system is a little higher when the water is not supplied because the cloth on the rear side reduces convection. (ii) when the cooling system is active at hour 39.7, as shown in Fig.4(d), significant improvements in voltage generation are achieved. The variation of their temperature ratios is more than 50%, while that of their voltage generation is 10%. It is thus seen that temperature monitoring by our self-powered wireless sensor can improve the output of PV panels by controlling a water-cooling system automatically.

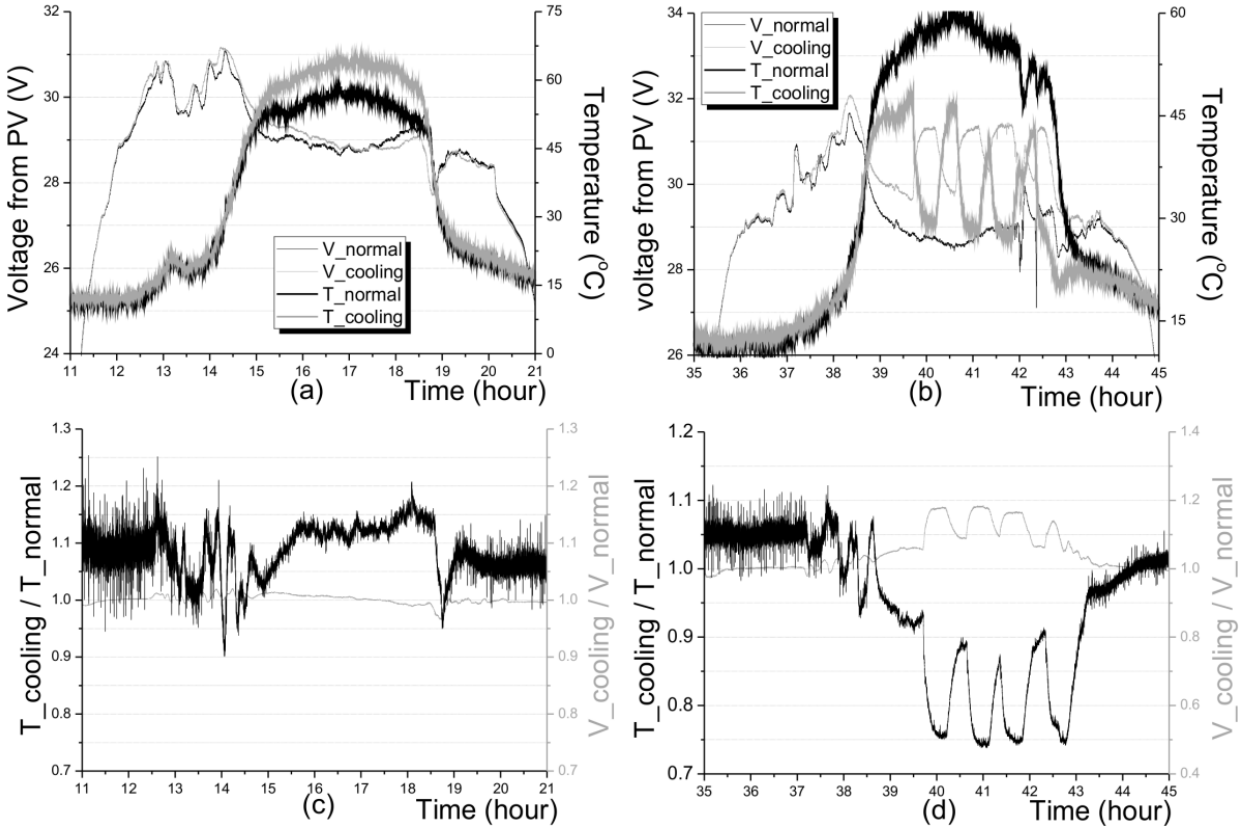


Fig. 4. Experimental results of the PVs with and without cooling: (a) and (c) are performance during the first day; (b) and (d) are performance during the second day.

Conclusion

In this study, a smart cooling system for PV panel is developed. The framework of independent wireless temperature sensor nodes was used to improve the performance of a PV panel. The feasibility of the proposed wireless application was proved step by step. The solar thermal micro-generator based on a thermoelectric device and phase change material was first tested for its

output voltage and power in outside conditions. The generated power was 2.15mw on a typical sunny autumn day, sufficient to drive both a temperature sensor and a wireless transmitter intermittently. Since the generated voltage was not sufficient to drive the electronic consumers directly, a step-up converter was adopted in the proposed power management circuit. The converter also solves the problem of the storage of electric energy, as the output of the TEG changes continually. With our prototype self-powered temperature sensing system, it can respond to the target temperature every two minutes when the input solar radiation is around 900W/m^2. The results of the autonomous temperature monitoring show that with a simple cooling system and with the harvested micro-energy, one can increase the performance of a PV panel (10% of voltage increase with ambient thermal loading in autumn).

Keywords: Weak Grid; Adaptive Notch Filter; Active Damping Control

Abstract. The LCL filter is widely applied as interface between grid-connected inverter and grid due to the preferable high frequency attenuation characteristic. Under the condition of weak grid, impedance value of grid model cannot be ignored, the existence of grid impedance results in different LCL resonant frequencies, which will arise challenges of traditional active damping control. Based on the analysis of band pass filter using active damping control strategy, an adaptive active damping control is proposed in this paper by introducing the application of active notch filter, which can adjust the position of negative resonance point adaptively so as to manage sudden grid changes. Theoretical analysis and simulation results presented on the platform of grid-connected PV inverter system indicate the effectiveness and adaptability of this active damping strategy.

Introduction

Since more and more power electronic equipments have accessed to power grid, a plenty of non-linear loads have been introduced. Additionally, long-distance transmission lines could bring a possibility of superabundant line impedance, which will harm the grid due to underlying harmonic pollution and line voltage distortion. Gird in this condition called weak-grid, according to its weak connection with power secondary equipments. Simulation model of weak-grid does no longer consist of 220V AC stabilized-voltage power but annexed with a serial RL branch instead [1].

Weak-grid can impact on the inverter, which is the interface between distributed power generator and grid, conversely. References [2] indicates that variable line impedance can challenge the inverter stability, current control strategy, parameter design of LCL filter as well as the adaptability of active damping control and so on.

This paper aims at the resonance point offset problem arisen by grid impedance variation. Applying the adaptive notch filter as a breakthrough, the paper proposes a new active damping method which can adjust the position of negative resonance point adaptively so as to manage sudden grid changes.

Adaptive Notch Filter Based Active Damping Control Strategy

Since band-reject filter can realize a complementary function of band-pass filter, which means band-pass filter can be replaced by band-reject filter to achieve the same active damping control efficiency showed in references [3]. Besides, adaptive notch filter is derived to have the equivalent transfer function of band-reject filter expressed as Eq.(1) [4].

$$\frac{\varepsilon(\mathrm{s})}{x(\mathrm{s})}=\frac{s^2+\omega_o^{\,2}}{s^2+\dfrac{\mu A^2}{\tau}s+\omega_o^{\,2}} \tag{1}$$

Without adding excess sensor, inserting the adaptive notch filter in front of the generator element of modulating wave, a new adaptive notch filter based active damping control strategy is proposed whose overall framework is demonstrated in Fig.1.

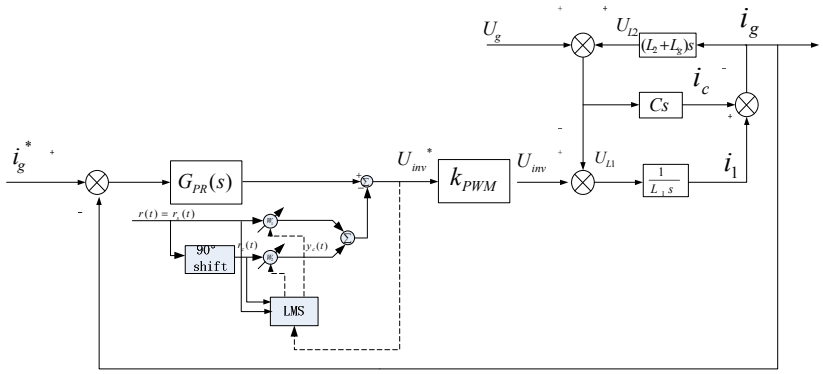

Fig.1.Framework of Adaptive notch filter based active damping control strategy

Where signal U_{inv} stands for the finally modulation wave, which comes out through a calculation of PR current regulator, is being sent into PWM generator module. A unity-negative feedback circuit is applied here by taking sampling of the grid-side current signal I_g, forming the whole control framework.

Accordingly, system open loop transfer function can be obtained as below:

$$G_o(s)=\mathrm{G}_{PR}(s)\frac{k_{pwm}G_{ANF}(s)}{L_1(L_2+L_g)Cs^3+(L_1+L_2+L_g)s} \tag{2}$$

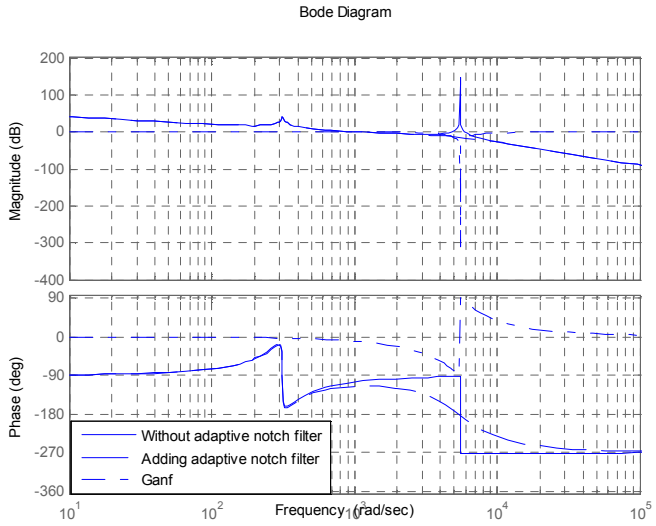
$$G_{ANF}(\mathrm{s})=\frac{\varepsilon(\mathrm{s})}{x(\mathrm{s})}=\frac{s^2+\omega_o^{\,2}}{s^2+\frac{\mu A^2}{\tau}s+\omega_o^{\,2}}$$

Where represents the transfer function of adaptive notch filter. When resonance frequency is reached, system pole - zero cancellations happen. As a result, resonance peak of old system is effectively controlled.

Eq.(2) could be written in the simplified form as follows:

$$G_o(s)=G_{PR}(s)\frac{k_{pwm}}{L_1(L_2+L_g)Cs(s^2+\frac{\mu A^2}{\tau}s+\omega_o^{\,2})} \tag{3}$$

System comparison open loop bode plot is drawn as Fig.2 for further analysis, according to Eq.(2) and Eq.(3).



$(L_1=1.2\mathrm{mH}, L_2=0.5\mathrm{mH}, C=83\mu\mathrm{F}, L_g=0.1\mathrm{mH})$

Fig.2. System Bode Plot

Comparing three curves in the figure, an obvious positive resonance peak could be found in straight line represented system, which demonstrates a potential instable factor included in the original system. At the same frequency point, band-reject filter link represented chain dotted line system shows a negative resonance peak, which can overlay with the preceding positive resonance

peak. Therefore there is no resonance peak existing in the new method introduced system, consequently unstable factor has been eliminated.

Additionally, Bode plot of high-frequency band and low-frequency band are completely unaffected by the introduction of band-reject filter, which means this active damping control strategy has no negative influence on the high-frequency attenuation efficiency of LCL filter and it also preserves the favorable tracing performance of PR controller. From the phase perspective, original system has a 180° phase mutation problem generated by conjugate poles, which is introduced by LCL filter, has been resolved to some extent.

Test results

Fig.3 and Fig.4 respectively represents the grid-connected current FFT diagrams for system before and after introducing the adaptive notch filter based active damping method. Comparing these two pictures, we can easily find a significant decrease of harmonic contents happened in Fig.4 at the resonance frequency (873Hz) and near frequency band compared to Fig.3. Meanwhile, table.2 lists the detail percent content of specific frequency point, which also reflects a remarkable harmonic attenuation characteristic around resonance frequency by this new method. Accordingly the effectiveness of this active damping method has been testified.

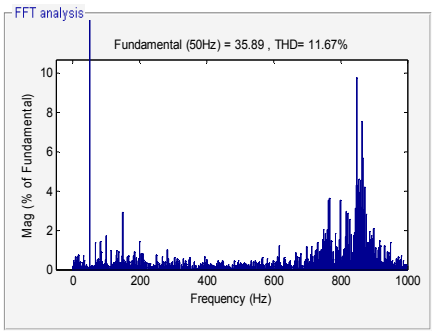


Fig.3 Grid-connected current I_g FFT (Without adopting active damping control)

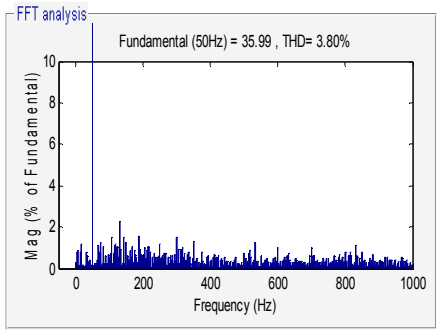

Fig.4 Grid-connected current I_g FFT (Adopting active damping control)

Table.1 Harmonic contents comparison

Frequency/Hz	contents/%(Fig.3)	Frequency/Hz	contents/%(Fig.4)
860	4.56	860	0.20
865	7.53	865	0.20
870	3.08	870	0.45
875	1.11	875	0.07
880	0.14	880	0.12
885	1.33	885	0.23
890	1.49	890	0.18

After varying the value of L_g from 0.1mH to 0.5m, the new resonance frequency changes to 748Hz. Still using resonance frequency harmonic suppression results to measure the efficiency of two control strategies shown in Fig.5 and Fig.6. In Fig.5[5], the frequency percent content around new resonance frequency shows a slightly decrease, which prove that there has no adaptability for the traditional control method under a weak-grid condition. Also Table.2 demonstrates the detail harmonic content of each frequency point.

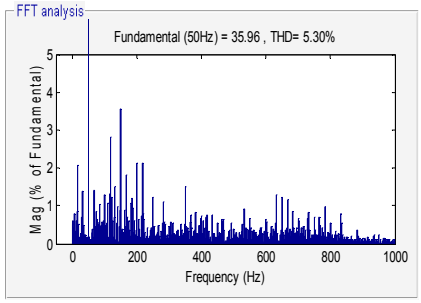

Fig.5 Traditional active damping control result

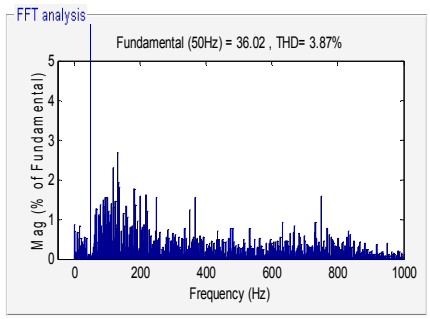

Fig.6 Adaptive active damping control result

In this group of comparison, the harmonic contents of new resonant frequency and adjacent frequency in Fig.6 is smaller than what in Fig.5, which proves that adaptive notch filter based active damping control has a better attenuation performance compared to traditional band-reject filter based active damping control.

Table.2 Harmonic contents comparison

Frequency/Hz	Content/%(Fig.5	Frequency/Hz	Content/%(Fig.6)
735	0.91	735	0.31
740	0.19	740	0.05
745	0.52	745	0.34
750	0.70	750	0.05
755	0.14	755	0.01
760	0.44	760	0.23
765	0.19	765	0.12

Although the downward trend in this comparison experiment is not as significant as the former one, when system resonance frequency shifts slightly, the new resonance frequency still can be attenuated by traditional active damping control to some extent for the reason that original system bandwidth is wide enough. However, according to the data shown in Table.2, some difference control result between the traditional active damping control and new control method still can be found by observing above data. Therefore, the adaptability of proposed method in this paper is verified also.

Conclusion

This new active damping control method needs to be implemented on a premise of accurate measurement of power grid impedance value. Although extra power grid impedance on-line measurement technology is costly, however control structure proposed in this paper is quite simple and can be easily implement, besides will not bring other harmonics. What's most important, it can bring a remarkable improvement of adaptability for adaptive damping control under weak-grid situation. Above all, adaptive notch filter based active damping control proposed in this paper has a certain application prospect and development space.

Abstract. Governments have become increasingly concerned about the development of the smart grid, and a series of smart grid demonstration projects have been started. Multi-levels common and integrated infrastructure architecture for smart grid demonstration project was proposed in the paper. The implementation and operation of its back office systems were presented, which include the design, development and deployment of network management system, meter data management system, load control systems, community level and home energy management system, and web portal. The integration between different parts and their managements were also were proposed.

Introduction

Advanced Metering Infrastructure (AMI) is recognized to be the first step for power system to move towards smart grid, which will not only support automated meter readings, customer home appliance connections, but also future distribution automation, substation automation and possibly mobile workforce management and other advanced applications [2]. Areas of AMI that cover the scope of a smart grid include the following [3-6]: (1) the end-use systems and related distributed-energy resources (e.g., building and factory loads, distributed generation, storage, electric vehicles); (2) management of the generation and delivery infrastructure at the various levels of system coordination (e.g., transmission and distribution control centers, regional reliability coordination centers, national emergency response centers); (3) the information networks themselves (e.g., remote measurement and control communications networks, inter and intra enterprise communications, public Internet), and (4) the financial and regulatory environment that fuels investment and motivates decision makers to procure, implement, and maintain all aspects of the system (e.g., stock and bond markets, government incentives, regulated or non-regulated rate-of-return on investment).

Fig.1 shows the technological development of smart grid from the conventional grid. In conventional electric grids we have only one direction of communication from the grid to the consumer. In smart grids we have two way communications between the utility and the consumers. With the help of the bi-directional communication the generation of electricity can be made dynamic. In smart grids with distributed resources a design of grid which is smart with bi-directional communication is implemented and it will most importantly include more number of renewable and eco-friendly sources of power gene ration [7].

The purpose of this paper is to present a description of advanced metering infrastructure for smart grid demonstration project of China, which is

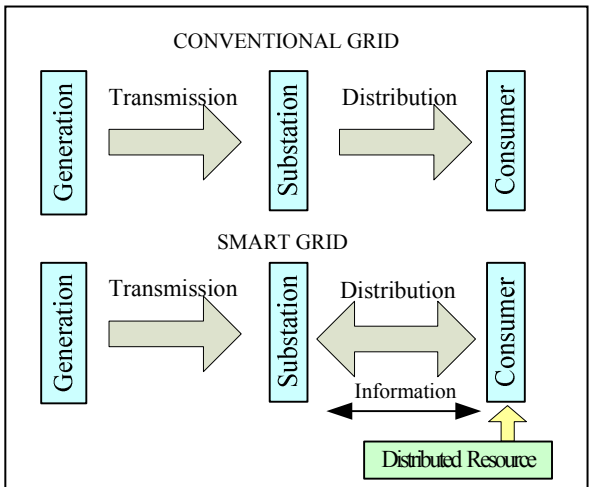

Fig. 1 Technological development of Smart Grid

aimed at improving customer understanding and efficiency of their electricity usage, making distributed power "plug and play accesses", reducing operations and maintenance costs, and so on. The project AMI and its back office architecture were promoted, which may provide a source of inspiration for the demonstration and application of other smart grid projects

Smart Grid Infrastructure Architecture

The smart grid is proposed use digital technology to improve reliability, security, and efficiency (both economic and energy) of the electric system from large generation, through the delivery systems to electricity consumers and a growing number of distributed-generation and storage resources [8]. Integrated smart gird infrastructure architecture is illustrated in Fig. 2, which contains three network levels, WAN, LAN and HAN. The communication network also serves as the control link or information link between the operational command center to different end devices for control or customer services display and alarm. These end devices can be control switches for capacitor banks or load control devices. Hence the communication system, by implication, is basically a two-way communication system and practically serves as a neural network of the system.

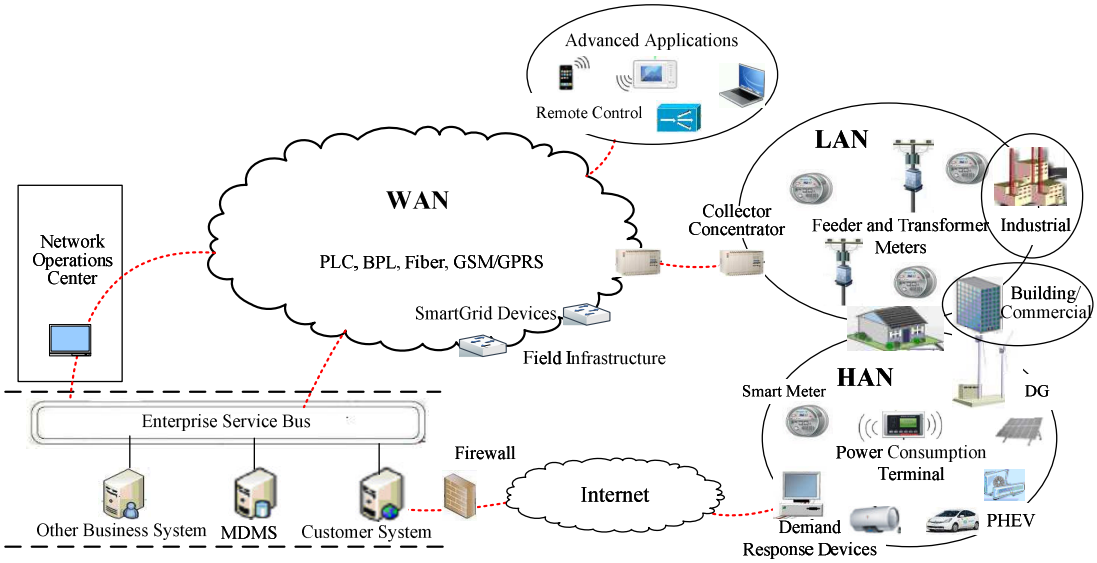

Fig. 2 Multi-level common and integrated smart gird infrastructure architecture

AMI is not a single technology, but rather an integration of many technologies that provides an intelligent connection between consumers and system operators. AMI gives consumers the information they need to make intelligent decisions, the ability to execute those decisions and a variety of choices leading to substantial benefits they do not currently enjoy. In addition, system operators are able to greatly improve consumer service by refining utility operating and asset management processes based on AMI data.

Through the integration of multiple technologies (such as smart metering, home area networks, integrated communications, data management applications, and standardized software interfaces) with existing utility operations and asset management processes, AMI provides an essential link between the grid, consumers and their loads, and generation and storage resources. Such a link is a fundamental requirement of a Modern Grid.

Back Software Architecture for Future Power System

Back Software of the AMI is responsible for managing all of the activities associated with identifying and designing the appropriate business process requirements for the information technology needs and then designing, developing, procuring and implementing the resulting automation (hardware and software) that will be required to establish two-way system communications between meter at the customer's premise and power company's back office

systems. Critical elements of these systems include the design, development and deployment of the Network Management System, Meter Data Management System (MDMS), load control systems, Community level and home Energy Management system (EMS), web portal development for energy information and program support, along with integration between these systems and other legacy systems, such as outage management.

In the back software architecture, Network Management System is the gateway, with which, all commands sent to and all data received from the smart meters and field infrastructure. The system includes three subcomponents: the head-end component to communicate with the meters; the network management console to optimize and manage the individual meters and network field infrastructure and how they work together; and the cryptographic services component to secure the data and communications of the entire network. A network operations center should be setup to oversee the operations of the AMI telecommunications network.

MDMS is the repository of the meter and event data from smart meters and variety sensors. The important system provides all of the validation, editing and estimating necessary to support customer usage calculation. As the system of record for meter data, other systems that require meter data will retrieve such data from the MDMS. Aside from meter reading and billing support functions, the MDMS also receives and routes all messages from the meter population to the appropriate systems. This includes alarms for meter failures, power outage, demand response messages, service switch operation and messages from associated HAN devices.

Load Control Systems are the management and control system to manage the smart thermostat and other new dispatchable load resources. For customers that sign up for demand response programs allowing power company to control their devices, remotely during demand response events, the Load Control Systems are responsible for dispatching the commands through the network to the devices that will ultimately respond. The information about the customer, their participation in demand response programs and the configuration of their meters and devices must be received from the MDMS and Network Management System.

With bi-directional flows of energy and coordination through communication mechanisms, a smart grid should help balance supply and demand and enhance reliability by modifying the manner in which customers use and purchase electricity. These modifications can be the result of consumer choices that motivate shifting patterns of behavior and consumption. These choices involve community level EMS and home EMS.

Distributed energy resources management is an important part of this EMS: The ability to connect distributed generation, storage, and renewable resources is becoming more standardized and cost effective. Several other concepts associated with a smart grid are in a nascent phase of deployment these include the integration of micro-grids, electric vehicles, and demand response initiatives, including grid-sensitive appliances [9]. Another important function is the capability to interface with meters for plug-in hybrids through the HAN communication interface which might allow for design of special plug-in hybrid programs. MDMS would need to be aware of the program the customer is participating in and the customer's vehicle information. This would require some additional enhancements to the MDMS and surrounding interfaces.

Web Portal will provide each customer the opportunity to view their own usage data, collected by smart meters, through the internet via the internet website. In order to accomplish this task, the MDMS system will process and send the customer's data to a web portal for access to their meter data. The system may require some analytical preparation of the data so the customer can use it as well as integration with web portal so the data may be displayed. The connection is secure so that customers only may view their own personalized data. Further development that support personalization and simplification of choice related to programs and services available, such as more robust functionality including sophisticated analytics that would relate the usage data to the customer's program and bill, is developing.

The Way to Integration of Different Parts

The relationship between the smart gird back office systems is depicted in Fig.3. The lines in between the systems represent integrations that transfer data and information between the systems that allow each system to operate and enable the proposed business processes.

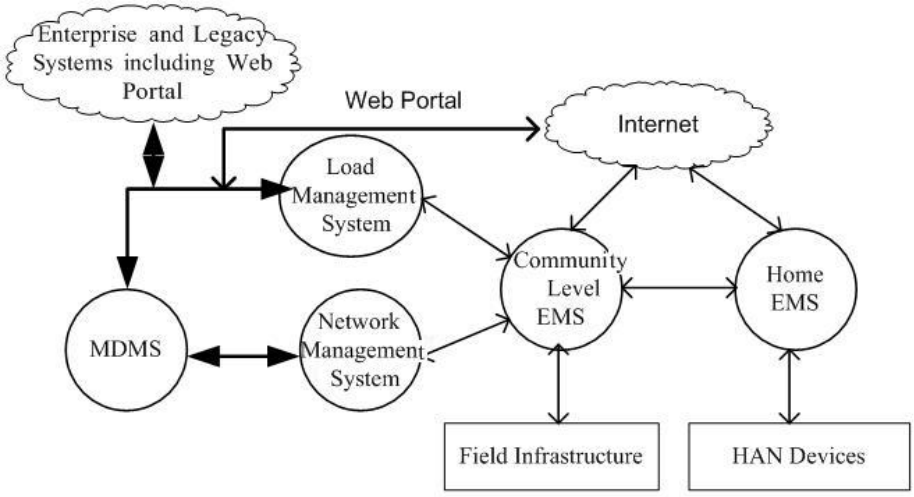

Fig. 3 Back software architecture for demand response

The integration of different parts to architecture of smart grid are shown as follow way.

A. Integrating Network Management System and MDMS

The MDMS integrates with Network Management System to facilitate two way communications between the meter at each customer's premise with MDMS, load control systems and Community level and home EMS. The first step is to identify business processes that are changed or enabled through the implementation of power company. These business processes are designed and then analyzed to identify the data and commands necessary to enable the new or changed business process. Individual interfaces are designed and developed to enable the flow of data between these two systems. The volume of the data and frequency with which each interface must run determines the software and hardware design and sizing necessary to support the integration.

B. Integrating MDMS with Load Control Systems

The Load Control systems are designed to support enabled demand response programs across distribution control area. As such, the MDMS must be aware of those customers who are on demand response rates, which demand response program each customer is enrolled in, and when a demand response event has occurred. This will allow the MDMS to calculate the customer's usage and monitor their response to the event accordingly. In turn, the billing system, through the integration described above will receive the information necessary to accurately bill the customer according to the terms of the appropriate demand response program.

C. Integrating MDMS with Community level and home EMS

Community-level and home EMS require integration with the MDMS should include time-of-use rates with a critical peak price overlay (subject to regulatory approval) and related information services in conjunction with advanced metering to encourage consumers to reduce peak demands or shift consumption from on-to off-peak periods and then to measure and validate the demand response. The capability to perform contract meter reading (gas/water meter reads) is possible.

D. Integrating MDMS with Web Portal

The MDMS integrates with web portal to provide interval usage data for each customer via the Internet. In order to accomplish this task, the MDMS system will process and send the customer's data to a web portal to provide customer to access their meter data, and it expenses include labor necessary to maintain software and hardware for integration and within the MDMS and Web Portal to provide customers access to their meter data on-line.

To ensure successful development and implementation of back office systems, structured project management oversight and governance will be utilized. Processes and tools will be put in place to manage scope, schedule, budget, and resources consistent with the Project Management Institute's Project Management Body of Knowledge. Appropriate governance will also be put in place to manage issues identification, escalation, and resolution.

Conclusion

There are various uncertainties and risks that may affect the integration and enhancements of the integrated infrastructure architecture. Risks including vendor and the integration and enhancements of the power company legacy systems should be analyzed. With the implementation of the project, Nanning, the capital city of Guangxi Province and the demonstration city of this project, is installing two-way communication AMI system, customer systems and programs to provide consumers with information, choices, and technologies to better manage their electricity costs while reducing distribution system peak demand and correlated pollution and cost impacts.

Keywords: Power Plants; Earthquake; Emergency Alarm System; Programmable Automation Controller

Abstract. To avoid or relief the fatal damage of an earthquake, a seismic automatic alarm system was put forward to meet the needs of power plant. Both a digital accelerometer AKE392B and a programmable automation controller SC200AD-1 were introduced to compose the earthquake emergency alarm system. The AKE392B converts the acceleration of ground motion into a series of digital signal, and this digital signal is transferred to the SC200AD-1 by the field bus EIA485. The PAC in the system is applied to collect the ground motion data, remove the non-seismic interrupts, access an earthquake's intensity, carry out emergency auto-handling actions by ON/OFF values, and generate emergency alarm to its parent system, power plant management system. Through theory and experiment analysis, the earthquake emergency alarm system could be easily built to measure the ground motion acceleration in accuracy, and generate the seismic emergency alarm rapidly.

Introduction

Power plant, one of the most important parts of lifeline engineering systems, maintains the functions of our modern society. Many kinds of natural disasters especially earthquake can do the greatest threats to power plants and power supply systems. These threats are not only reflected in the severe damages of the power supply system itself in an earthquake, but also in a series of serious secondary disasters, such as triggering fire and hazardous substances leaking [1] [2]. Power plant is supposed to be strong enough to survive from the attacks by an earthquake. But only by strengthening of the buildings and components is a non-commercial and time-consuming plan [3]. An earthquake early warning system could probably provide the critical alarms and information needed to protect power plants against an earthquake. Unfortunately, research on earthquake early warning system was not good enough to solve the problem completely: one reason is that there is about a 30 kilometers' blind zone on the meizoseismal area of an earthquake and another reason lies in that the false rate is still too high to impact the routines of a power plant [4]. Although earthquake early warning system does not work at present, the ground motion measurement can assessed the earthquake damage rapidly. Therefore, an earthquake emergency alarm system based on the onsite ground motion measurement might provide an easy, effective and reliable way of disaster reduction. A seismic emergency auto-handling system was put forward to protect the water supply system [5]. Considering the complexity of the power plant management system, a programmable automation controller (PAC) based earthquake emergency alarm system was proposed, which was regarded as a subsystem of the power plant management system. Comparing with the programmable logic controller (PLC), PAC is much powerful in data processing beside its openness and flexibility.

The Earthquake Emergency Alarm System's Development

As shown in Fig. 1, the earthquake emergency alarm system was composed by some distributed seismic accelerometers, a PAC, and several actuators, for example ON/OFF values. The earthquake emergency alarm system was connected by the field bus EIA-485, and performed as a subsystem of the power plant management system.

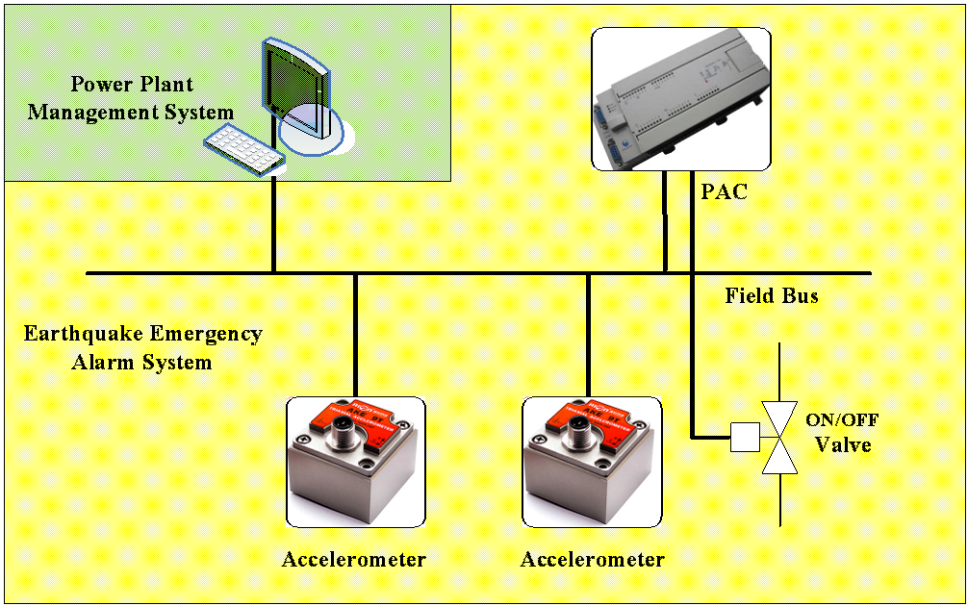

Fig.1. The block diagram of the earthquake emergency alarm system

Several three-axis accelerometers, AKE392B, were mounted around a power plant distributed to measure the acceleration of the ground motion. AKE392B's scale factor in the full range of long-term stability and the deviation are typically less than 0.1%. This specification makes AKE392B a reliable solution for the seismic acceleration measurement. In addition, due to its digital output and different address codes, several AKE392Bs were used to form a multi-point measurement system, which helped the earthquake emergency alarm system to cover a broad range and to reduce false operation.

The specifications of the AKE392B were listed below:

- Measuring Range: ±2g (X, Y, and Z axis);
- Frequency Band width: 1-80Hz;
- Nonlinearity: ±1% F. S.;
- Resolution/threshold (@1Hz): < 1mg;
- Interface: EIA-485;
- Power Supply：9-36V DC.

A PAC, SC200AD-1 was introduced to the earthquake emergency alarm system. The SC200AD-1 acted as a captain of the alarm system: collecting ground motion data from accelerometers, removing the non-seismic interrupts, accessing an earthquake's intensity, carrying out emergency auto-handling actions by ON/OFF values, and generating emergency alarm to its parent system, power plant management system. SC200AD-1, one of PAC, combined the good features of a personal computer (PC) and a PLC, which made it openness, reliability, and high-performance computing.

Software's Design

Due to the flexible interface of AKE392B and the openness of SC200AD-1, the software of the earthquake emergency alarm system was easily built. The AKE392B's acceleration data frame was shown by Fig. 2.

Identifier (1byte)	Data Length (1byte)	Address code (1byte)	Command word (1byte)	Date domain	Check sum (1byte)
0x68	0x0D	0x00	0x84	0x00 0x02 0x10 0x10 0x08 0x50 0x00 0x05 0x04	0x32

Fig.2. The acceleration data frame of AKE392B

The data domain given by hexadecimal in the example above was the acceleration values measured by AKE392B, where the acceleration on X axis was 0.210 g, the acceleration on Y axis was -0.850 g, and the acceleration on Y axis was 0.504 g.

SC200AD-1 supports the NI's Labview to develop its software. Based on the data frame given by Fig. 2, the acceleration data's collection program was built, which was shown by Fig. 3.

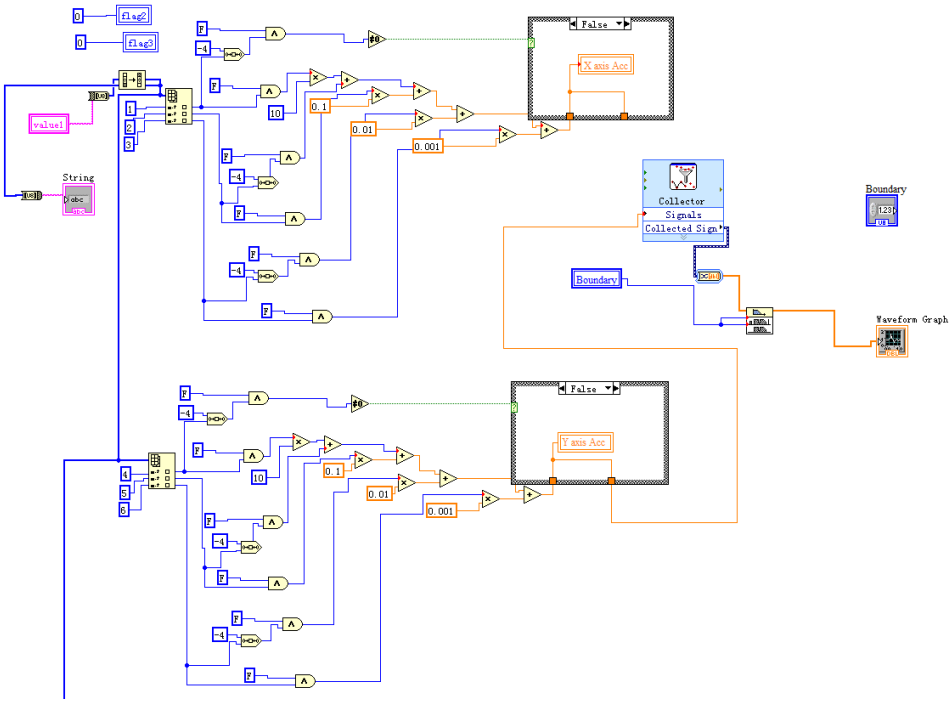

Fig.3. The program of acceleration data's collection

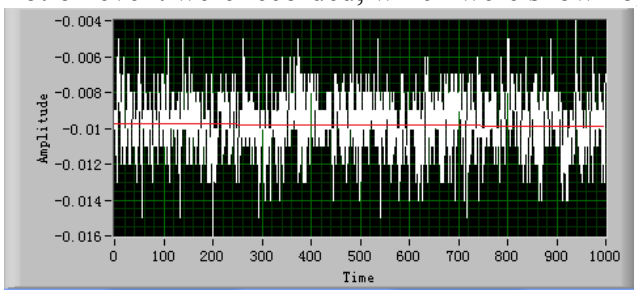
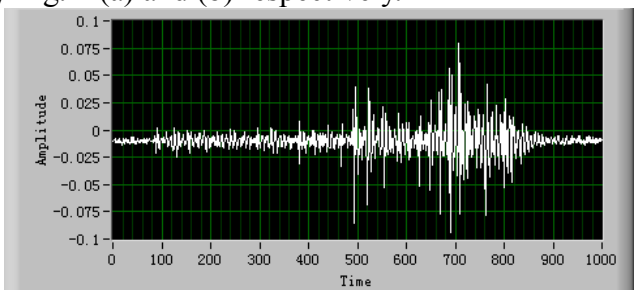
Using the program above, the back ground noise of the ground motion and a small ground motion event were recorded, which were shown by Fig. 4 (a) and (b) respectively.



(a) The back ground noise



(b) The small ground motion event

Fig.4. The acceleration data collected

There are two non-seismic interrupts: the baseline drift and the impulse noise. These interrupts not only would cut down the accuracy of the earthquake intensity's assessment, but also might cause some serious false operations for the earthquake emergency alarm system. Therefore these two noises should be removed as much as possible. And two kinds of digital filters were used to do the signal pretreatments.

One filter was a high pass filter, which was used to revise the baseline drift in long period. It could be described by the recursion Eq. (1) [6].

$$a_j = \frac{1+q}{2} \cdot (a_j^* - a_{j-1}^*) + q \cdot a_{j-1} \tag{1}$$

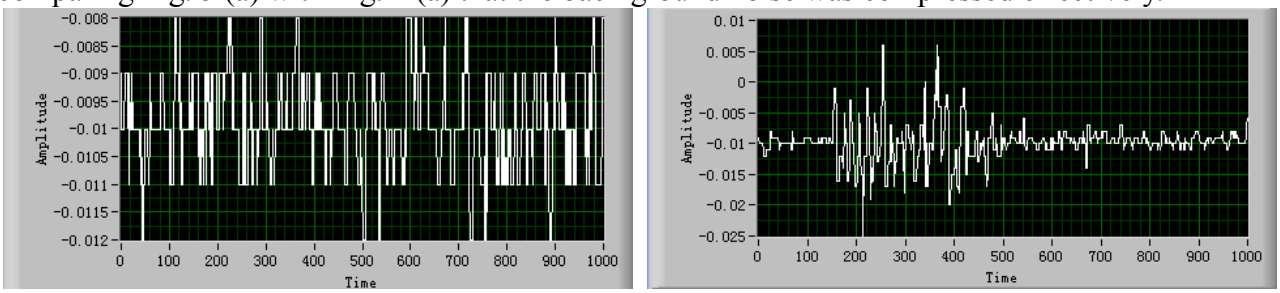
where $a_j^* (j = 1, 2, \cdots$ was the acceleration sequence before filtering, and $a_j (j = 1, 2, \cdots$ was the acceleration sequence after filtering. And q was a filter parameter. The q's value determined the cutoff frequency of the high pass filter, and it was close to 1 but less than 1. Here the q's value was set to 0.99. By applying the high pass filter the baseline was shown by the red line on Fig. 3 (a).

After high pass filter, another filter, median filter, was employed to remove the impulse noise. Median filtering is a popular method of noise removal, because its non-linear technique could effectively suppress impulse noise while preserving edge information. Specifically, the main idea of the median filter was to run through the signal entry by entry, replacing each entry with the median of neighboring entries:

$$y(i) = meadian\{x(j), j \in (i-m, i+m)\} \quad (2)$$

where $(i-m, i+m)$ represents a neighborhood centered around location i in the acceleration sequence. m was the maximum of the distance between i and j. Here m was set to 2.

By applying the median filter above the back ground noise of the ground motion and a small ground motion event were both presented by Fig. 5 (a) and (b). And it was clearly shown by comparing Fig. 5 (a) with Fig. 4 (a) that the back ground noise was compressed effectively.



(a) The back ground noise (b) The small ground motion event

Fig.5. The acceleration data filtered

Before carrying out emergency auto-handling actions or generating emergency alarm, the earthquake emergency alarm system should access the earthquake's intensity at first. Recent research showed that the misjudging rate was the smallest using spectral intensity to assess seismic intensity or the damages of the lifeline engineering system [7]. Taking this into account, the spectral intensity was employed in the alarm system, and it was obtained by:

$$SI = \int_{0.1}^{2.5} S_v(\xi, T)dt \quad (3)$$

where ξ was the damp of the single degree of freedom (SDOF), T was the period, and S_v was the SDOF's velocity response. To get the peak spectral intensity in time, some immediate processing methods in the time domain were used [8].

Experiment Analysis

The seismic accelerometers were the front end of the earthquake emergency alarm system. Their performances would affect the whole system's abilities. AKE392B's performances were tested by attached on a closed-loop control vibration system WS-Z30. The WS-Z30 exported a serial of acceleration signals with the same amplitude (0.25g). The outputs of AKE392B and the standard sensor were both recorded at different frequency points (1, 2, 5, 10, 20, 40, 60, and 80Hz). The test results were shown by Tab. 1.

Tab.1. The test results of AKE392B's performance

Frequency (Hz)	1	2	5	10	20	40	60	80
Sensitivity (V/g)	0.857	0.857	0.856	0.855	0.857	0.855	0.848	0.852
Deviation (%)	0.23	0.23	0.12	0.00	0.23	0.00	-0.82	-0.35

The test results indicated the sensor AKE392B could measure ground motion with sufficient accuracy, and their maximum of sensitivity deviations on frequency response were -0.82% and less than 1%.

Conclusion

Through the preliminary theory and experiment analysis, the earthquake emergency alarm system possessed the following features:

- The earthquake emergency alarm system could be easily built and act as a subsystem of power plant's management system;
- The PAC, SC200AD-1, made the earthquake emergency alarm system a full use of the advantages of PC and PLC;

- High pass filter and median filter were both effective to remove the non-seismic interrupts, which could improve the accuracy of the earthquake intensity's assessment and avoid some false operations unwanted;
- The accelerometer AKE392B in the earthquake emergency alarm system could measure the ground motion acceleration with adequate accuracy in real-time.

Keywords: Braking recovery, EHB, Coupling relationship, Energy flow

Abstract. The battery ability of recovering electricity plays a significant role in improving the regenerative braking performance. In this paper, a control for recovery of braking energy in Electric Vehicles (EVs) with electro hydraulic brake (EHB) is proposed, which makes the recovery transfer to the electric hydraulic pump of EHB directly, rather than being stored statically in the battery. An energy flow strategy was designed for the maximum braking energy recovery based on this control. The simulation results show higher energy recovery rate in comparison to the general recycling control.

Introduction

The amount of energy dissipated during vehicle braking is significant. The most advantageous development is to find a method to extend the mileage of EVs by recycling part of braking energy. However, the battery ability of recovering electricity is a decisive role to the process of the energy recovery. [1]

During the process of braking energy recovery in general EVs, the electric energy, transformed from kinetic energy, stores in the battery and releases when EVs starts. But the battery ability of recovering electricity hiders EVs maximize braking energy recovery. In EVs with EHB, the recovery transfers to the electric pump of EHB directly, which is utilized dynamically in the process of vehicle braking, so the battery is no longer the main energy storage unit. [2]

Control model

The actuator of EHB is a high-pressure accumulator, which power is supplied by a electric hydraulic pump. As the pressure of the accumulator will reduce during brake, the recovery can transfers to the electric pump of EHB directly to pump oil to maintain enough pressure. Excess electricity transfers to the battery if the generator is performing a power higher than the required power of EHB electric pump, otherwise, the battery to supplement electricity. That is to say, the recovery is utilized dynamically in the process of vehicle braking in the EV with EHB.

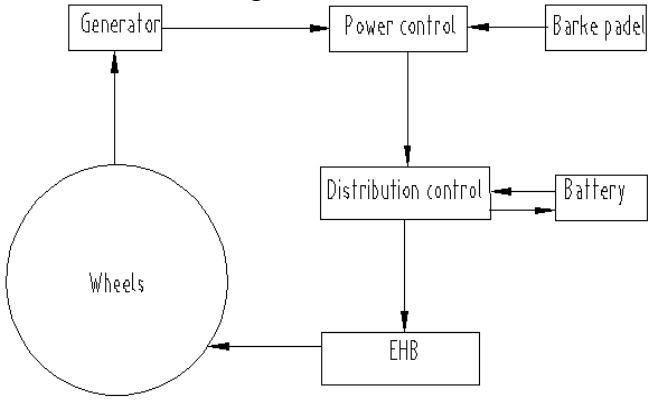

Fig 1. Model structure

Coupling between force and power

Brake Force Distribution. At the view of energy recovery, motor should supply brake force as much as possible by working as a generator during braking. As the motor is only connected to the front axle in this model, it means the actual brake force distribution curve more closing to horizontal axis in the braking force distribution diagram, more energy can be regenerated. But in order to avoid side slipping and keep the steering ability, this curve should be above the regulations limit curve declared by the ECR13. [3] The requirements are taken to design a control for brake force distribution to maximize braking energy recovery based on maintaining braking performance during braking, which does not need to take the battery ability of recovering electricity the into account.

Strategy for Braking Energy Recovery. Brake intensity, speed and the State of Charge (SOC) of battery are the key factors to the strategy for braking energy recovery, which are taken as the strategy inputs. The brake intensity can be reflected by the brake pedal position, while the actual speed can be traced by the current generated by the generator.

If the vehicle is in a state of emergency braking, regeneration doesn't work in the emergency braking in this strategy for the security.

If the EV speed is lower than a minimum vehicle speed, the charging efficiency of battery is very low to be charged. The regenerative brake force is no longer in existence at this state.

To supply sufficient brake torque and prevent overcharging, the regenerative braking should be prohibited to charge the battery when the SOC reaches the limit.

Linked with the motor characteristics between torque and speed, ultimate regenerative brake force can be calculated in various vehicle speed.

The brake force between front and rear wheels are distributed by the braking control module according to the maximal principal mentioned above. The front wheels brake force is divided into motor brake force and the front EHB brake force. All of the brake force act on EV power system to get the actual deceleration. The cooperation algorithm can be described as Fig 2.The regenerative force showed in Fig 3.

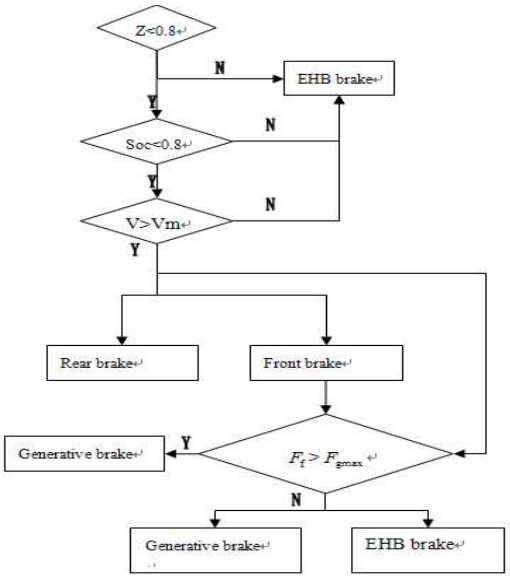

Fig 2. Brake force distribution algorithm

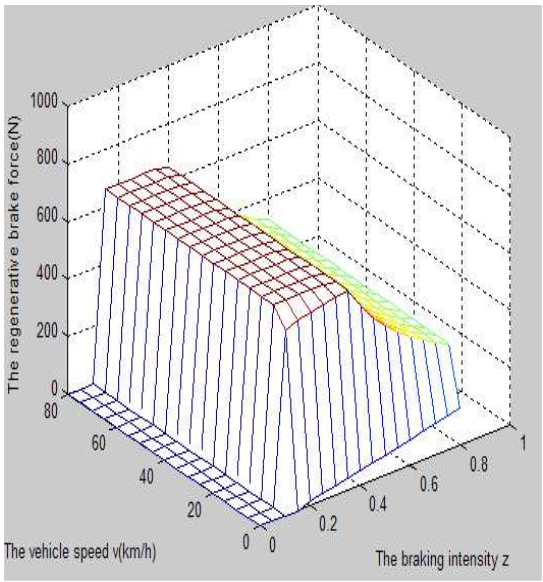

Fig 3. The regenerative brake force

The Strategy of Energy Flow. The motor is taken as a generator during brake, the output power changes with the speed, The expression between them can be got by fitting the load characteristic of the motor: I = f (n).

In the process of braking, the recovery is affected by SOC of the battery, which reflects the change of the battery capacity.

EHB with a electric hydraulic pump starts to pump after giving it the certain energy. The relationship between output flow and rotate speed is presented in Eq.1.

$$q_b = V_b \cdot S_m \frac{E}{E - (a \cdot P_{bin} + (1-\alpha) \cdot P_{bout})} \tag{1}$$

Above, V_b is the pump displacement, P_{bin}, P_{bout} are the Inlet and outlet pressure of the pump. The rotate speed of the pump can be got from the load characteristic of the pump.

The brake fluid is stored in the accumulator to establish a high pressure. The brake force of the EHB can be adjusted by using the valves to control the flow to brake cylinder. When the brake fluid drives brake pads to touch the brake disc, a relationship between the positive pressure and the relative displacement is determined, that can be obtained by Eq.2.

$$\mathrm{m}_c \frac{d^2 x_c}{dt^2} = -p_{cy1} A_p + C_{ec} \frac{dx_c}{dt} + k_{ec} x_c \tag{2}$$

Above, m_c, C_{ec}, k_{ec} are mass, damping, spring stiffness of the brake caliper. When the EHB is supplied by power, the brake force of it can be calculated by Eq.1, Eq.2.

The energy flow strategy was designed to utilize the recovery dynamically described as following Fig. 4.

The Results of the Simulation

The consumption or recovery of the battery can be calculated by the change of its voltage and current, showed in Eq.3. The energy consumption value is calculated if the current value is greater than 0. Otherwise, energy recovery value is calculated when the current value is less than 0.

$$E_0 = \int_0^{\mathrm{t}} (\mathrm{E_k} - I(\mathrm{t})R) I(t)\mathrm{dt}. \tag{3}$$

Where E_{k} is the initial voltage of battery, R is the internal resistance of battery.

EHB utilizes the regenerative current generated by generator dynamically, which power can be presented in Eq.4.

$$E_{\mathrm{m}} = \int_0^{\mathrm{t}} F_{\mathrm{m}} \mathrm{v(t)}\ \mathrm{dt} \tag{4}$$

Where F_m is the brake force of EHB.

The entire consumption of energy without the process of recovery is calculated in Eq.5.

$$E = P_{\mathrm{w}} \mathrm{tv}(F_w + F_{rr} + mzg). \tag{5}$$

Where F_{w} is air resistance, F_{rr} is rolling resistance.

The energy recovery rate, that is the ratio of regenerative energy and entire consumption of energy, is used to evaluate the design:

$$\eta = \frac{E_0 + E_{\mathrm{m}}}{E} \times 100\%. \tag{6}$$

When initial braking speed is 60km / h, the braking intensity of 0.3， was simulated. The initial SOC was selected as 0.8. Simulation results are showed in Fig. 5.

Simulation results show the SOC changes smaller than the general EVs. It means that EV with EMB has a higher energy recovery rate to the general EVs, which rate is about 30%. Another is that general EV cannot recover energy during the SOC is higher than 0.8, while EV with EHB can make the recovery transfer to the EHB.

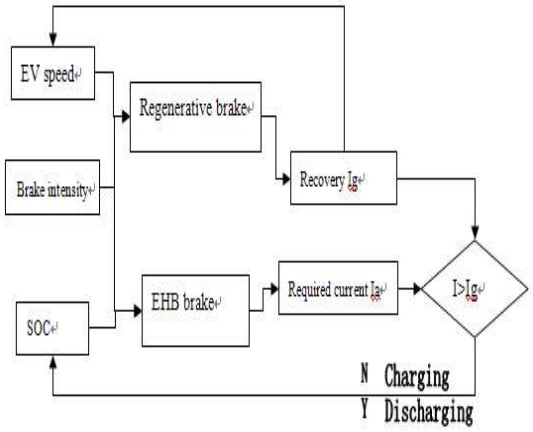

Fig 4 Energy flow strategy

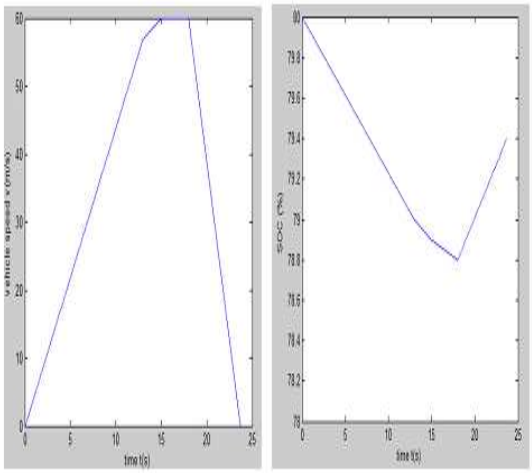

Fig 5. Simulation results

Conclusion

In this paper, a strategy to utilize the generative brake force dynamically during brake is proposed for the EV with EHB. The coupling relationship between distribution of brake force and the energy flow is pointed out. The front-drive EV with EHB has been built in the MATLAB/Simulink to simulate its energy recovery rate. The simulation results demonstrate that EHB braking and regenerative braking can work cooperatively to capture more energy than general HEV storing the recovery statically. These analytical procedures forecast that energy recovery utilized timely can provide some guidelines in terms of a method to extend the mileage of EVs.

Keywords: thermal power unit, primary frequency regulation, analysis

Abstract. With the increase of the load capacity and the development of the automation degree, the power dispatching center has a higher requirement for the primary frequency regulation function of the unit aircrew. After a certain period of time when the unit has been put into operation, the primary frequency regulation function must have the conditions to be put into operation, so that the unit can be involved in grid frequency at any time when the conditions are satisfied and the power supply quality can be fully guaranteed [1]. The regulation performance of primary frequency regulation plays a vital role in maintaining the stability of the unit aircrew and the power grid, so it is very necessary to conduct the frequency tests for the thermal power units [2]. In this paper, we describe the disturbance tests and recovery tests under different load points and different network frequencies. Through the analysis, we can draw the conclusion that the primary frequency regulation function of unit 1 can fully meet the requirement of the frequency regulation of the power grid.

Introduction

Primary frequency regulation is also known as the primary regulation for the frequency of the power grid [3]. The primary frequency regulation function refers to that when the grid frequency beyond the normal limits, the speed control system of each unit which is to participate in the grid's primary frequency regulation will automatically increase or decrease the unit power according to the changes of the grid frequency, so as to achieve a new balance and limit the grid frequency within a certain range. Primary frequency regulation is related to the structure and working principle of the speed governor and the working characteristics of the speed control system [4]. The principle of primary frequency regulation of thermal power unit is that the imbalance between the generator's input and output power results in the frequency instability of the electric power system, the mathematical formula is shown as follow:

$$\mathrm{Pm} - \mathrm{Pe} = 2\mathrm{Hs}\Delta\omega \tag{1}$$

In the formula: Pm refers to mechanical power, which is related to the generator's prime mover and governor's characteristics; Pe is the electromagnetic power, which not only is related to the generator's electromagnetic characteristics, but also depends on the load characteristics of the electric power system; Hs refers to the generator's inertia constant; $\Delta\omega$ is the speed deviation of the generator [4]. Figure 1 is the schematic diagram of primary frequency regulation of thermal power unit, which is made up by the coordinated control system (CCS), governor, steam turbine and boiler. In the mode of turbine following boiler, we regulate the opening of the turbine tones according to the changes of the main steam pressure. In this mode, the load variation rate is so slow that the unit does not have the primary frequency modulation function. Thus, we establish the model based on the coordinated control system in the mode of boiler following turbine[4].

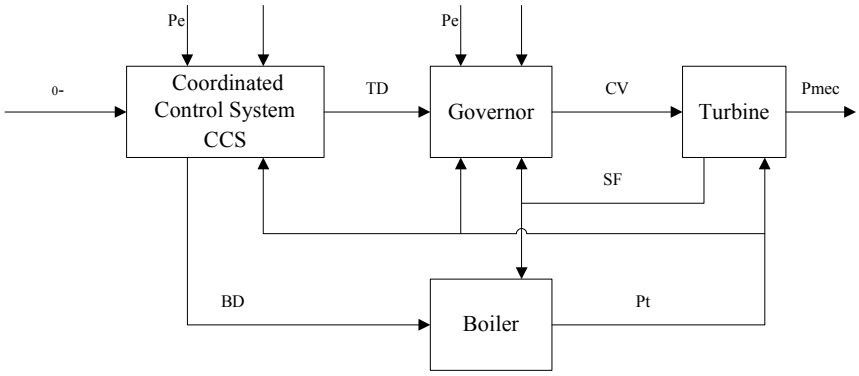

Figure 1 Schematic diagram of primary frequency regulation of thermal power unit

Major Technical Indicators of Primary Frequency Regulation

The main technical indexes of primary frequency regulation contain speed droop, dead band, power compensation, slow rate, lag time of response, stability time.

Speed droop is defined as that the unit aircrew adopt the grid connected mode in the way of differential speed regulation. When the synchronizer is in a position, this regulation system keeps the speed in the vicinity of the ratings. Meanwhile, each power (P) corresponds to a speed (N). The variation of speed following power is shown in Figure 2.

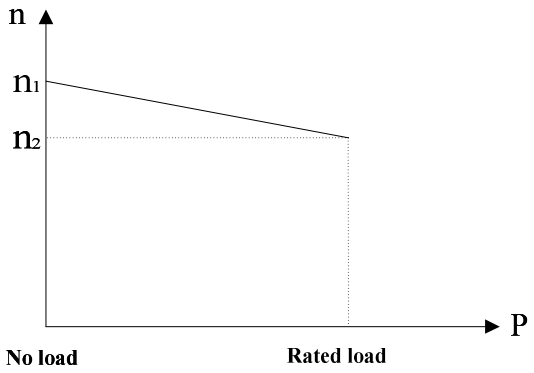

Figure 2 The variation of speed following power

Under the condition that the given value of the control system is unchanged, the ratio of the rotation speed variation rate (Δn) and the rated speed (n_0) which is corresponding to the unit power from zero to the rated speed is usually expressed in percentage [4].

$$\delta = \frac{\Delta n}{n_0} * 100\% \tag{2}$$

For the unit that undertakes basic load, the speed droop is generally a bit more, in the hope that the changes of the grid frequency have a small impact on its power, so that the unit can run a long time under the economic condition. As to the unit that bears the peak load, the speed droop is smaller, in the hope that it will undertake more varying load after the grid frequency changes.

Dead band refers to the insensitive area in the vicinity of the rated speed. The setting of the dead band is mainly to prevent the turbine tones' unnecessary frequent movement when the grid frequency fluctuates in a small scope, which is not conducive to the safe operation of the equipment. Otherwise, in order to maintain the stability, the actual frequency regulation capacity and the safety of the unit, we also need to limit the frequency regulation load, in case that the unit is in overload condition when the primary frequency regulation acts [4].

Power compensation is calculated by the speed droop (δ) and the grid frequency deviation which can be converted to the speed difference (Δn) [5]. The formula is as follow:

$$\Delta p = -\frac{\frac{\Delta n}{n_0} * 100\%}{\delta} * P_N \tag{3}$$

In the formula, n_0 is the rated speed and P_N refers to rated power.

For example, the unit which the speed droop is 5%, when the speed difference (Δn) is -6 and the grid frequency deviation (Δf) is -0.10Hz, Δp is calculated as follow:

$$\Delta p = -\left(\frac{\frac{-6}{3000}*100\%}{5\%} * P_N\right) = 0.04 * P_N = 4\%P_N \quad (4)$$

Slow rate is that due to the friction and clearance of the governor, the transmission amplification mechanism and the steam distribution mechanism component, there is a retardation phenomenon between the input and the output. This phenomenon acts on the control system so that in a certain range of the speed difference (Δn), the power remains unchanged [5]. The computational formula of slow rate (ε) is as follow:

$$\varepsilon = (\Delta n/n_0) * 100\% \quad (5)$$

In the formula, n_0 refers to the rated speed.

Lag time of response refers to the time needed from the change of the grid frequency meets the primary frequency regulation required value to the unit's load begins to change, which should be less than 3 seconds [5].

Stability time is the time the unit's load needed to reach stability in the process of primary frequency regulation after the grid frequency is stable, which should be less than 1 minute. The load instruction changes factors should be excluded, when the coordinate control system (CCS) or the automatic generation control system (AGC) is running [5].

The Implement of Primary Frequency Regulation

The primary frequency regulation function is an important means to maintain the frequency stability of the grid. The unit 1 of one power plant uses the C145/N200-130/535/535 turbine generator which is designed and manufactured by Harbin Steam Turbine Plant. We modify the turbine generator as C150/N220-12.75/535/535. The boiler is the natural circulation boiler which is produced by Beijing Babcock Willcocks and the type is B&W-670/13.7-M. After adjusting, the approval max load is 215MW. The DCS system of the unit is composited by the Beijing Hitachi HIACS5000 system, while the steam turbine electro-hydraulic control system is the Xinhua control system. When the unit load is in the range of 95MW-215MW, the primary frequency regulation should be put into use automatically. The primary frequency regulation speed change is set to 4% to meet the requirement of the grid frequency regulation.

Function Tests of Primary Frequency Regulation

Subjects and Requirements

1) Turbine generator and DEH, CCS

2) Speed variation rate is set to 4% and the speed drop of DEH-side is directly added to the turbine control valve instructions through the speed varying law setting function. We design frequency correction circuit at the CCS-side, while the corrective commands are not limited by the speed. The dead band is set to ±2r/min (±0.033Hz). For the thermal power unit which the rated load is 215MW, we limit the magnitude to 20MW. There is no load limit that is set by the operating personnel. According to the thermal power plant's safety evaluation requirements, the primary frequency regulation function and the major technical indicators after the maintenance of the unit meet the needs of the grid frequency regulation and the requirement of the national grid company's "The Guidelines of primary frequency regulation tests of Thermal power generating units".

Tests and Analysis

We conducted several primary frequency regulation tests on unit 1 on June 9, 2013, which were 0.067Hz, 0.1Hz and 0.2Hz step frequency modulation at three load points (140MW, 160MW and 190MW). Here we mainly analyze the disturbance test and the recovery test which were conducted when the load was 140MW and the high grid frequency was 0.1Hz. Other experiments' results are shown in Table 4.1.

1) The disturbance test

The grid frequency was 50Hz and the speed was 3000r/min, while the real load was 140.07MW and the actual speed stage pressure was 5.93MPa at 15:11:45 under the mode that turbine follows boiler. 3 seconds later, the grid frequency and the speed deviation were manually set to 50.1Hz and -6r/min. At that time, the calculation result of the regulation system was that the frequency difference load is -9.06MW (the rate of speed fluctuation is less than 4%) and the real load is 134.46MW. The unit actually reduced the load by 5.41MW within 3 seconds, which meets the requirement of the primary frequency regulation rules that the lag time of load response should be less than 3 seconds. 15 seconds later, the real load was 127.92MW and the speed stage pressure was 5.14MPa. The unit's load raised 12.15MW within 15 seconds since the grid frequency began to change, which meets the requirement that the load adjustment should reach 90% of the maximum theoretical load adjustment within 15 seconds.

2) The recovery test

The grid frequency was 50.1Hz and the speed was 3006r/min, while the real load was 131.71MW and the actual speed stage pressure was 5.51MPa at 15:15:04 under the mode that turbine follows boiler. 3 seconds later, the grid frequency and the speed deviation were manually set to 50Hz and 0r/min. At that time, the calculation result of the regulation system was that the frequency difference load is 0MW (the rate of speed fluctuation is less than 4%) and the real load is 136.87MW. The unit actually reduced the load by 5.16MW within 3 seconds, which meets the requirement of the primary frequency regulation rules that the lag time of load response should be less than 3 seconds. 15 seconds later, the real load was 144.38MW and the speed stage pressure was 6.24MPa. The unit's load raised 13.67MW within 15 seconds since the grid frequency began to change, which meets the requirement that the load adjustment should reach 90% of the maximum theoretical load adjustment within 15 seconds.

Conclusions

Through the tests, we can draw the conclusion that the lag time of response is less than 3 seconds, the stability time is less than 1 minute and the load adjustment reaches 90% of the maximum theoretical load adjustment within 15 seconds. It can proof that the primary frequency regulation function can fully meet the requirement of the rules and the frequency regulation indicators are better than the requirement of the national grid company's "The Guidelines of primary frequency regulation tests of Thermal power generating units".

Keywords: new generation of smart substation; special optical fiber; sensing technology; online monitoring

Abstract. The new generation of smart substation puts forward higher requirements to sensing technology. Based on the needs of these requirements, four kinds of special optical fiber sensing technology in power systems were researched: all-optical current transformer, distributed temperature sensing technology, fiber grating vibration sensing technology and fiber Bragg grating sensing technology. These kinds of optical fiber sensing technology for the new generation of smart substation to enhance its performance were analyzed. Finally, based on the fiber Bragg grating sensing technology, the online oil and winding temperature monitoring system was constructed for the new generation of smart substation.

Introduction

The smart grid is a breakthrough in the 21st century. It is also a trend of development in the field of power systems. As an important foundation for the smart grid, smart substation is the source of operational data collection and command execution units. The development of smart grid smart substation raises higher requirements for smart substation: constructing professional maintenance mode, the device status visualization technology and online monitoring techniques; developing new materials, equipments and communication technology that satisfies the greater capacity for information exchanging and processing functions [1].

Optimizing smart substation secondary system while ensuring its operational reliability is an important way to improve the economic benefits and achieve long-term development of smart substation. The new generation of smart substation proposed four main aspects of optimization for its secondary system: the automation system network; the allocation and integration of secondary equipment functions to achieve data monitoring with panoramic views; the function of smart assistance systems; the configuration of monitoring system and propose the device online monitoring optimization program [2].

Sensing system bears the inspection tasks of related parameters in smart substation. The use of online monitoring technology to monitor the operational status of smart substation is the key to guarantee its security, reliability, efficiency.

The new generation of smart substation proposes higher demands for its sensing technology in many aspects such as monitoring accuracy, fault tolerance, area covered, remote control monitoring, self-organizing, multi-hop path. However, in some high-pressure environments needed to be measured that requires better insulating properties such as online monitoring of smart switch, real-time measuring of high-voltage transformer winding temperature, current and other parameters, electrical sensing technology using in traditional smart substation is not applicable.

Special optical fiber sensing have features of electrical insulation, high temperature resistance, low energy consumption, no spark, no short circuit fault, anti-electromagnetic interference, small size and high sensitivity. Special optical fiber sensing can achieve goals of precise acquainting, accurate passing and significantly reduces the occupied area. The special optical fiber sensing technology has immeasurable prospects in the new generation of smart substation.

Special optical fiber sensing technology

Special optical fiber sensing technology has many advantages: small energy loss, stable chemical properties, small cross-section, strong anti-noise capability, anti-electromagnetic interference, no spark, no short circuit fault, high temperature resistance and so on. It is applicable in the field of electric power system to achieve the function of devices online monitoring and ensuring its operation safety and reliability.

There are four kinds of special optical fiber sensing technology being researched now.

Fiber Optical Current Transformer. Currently, the new developing fiber optical current transformer (FOCT) uses special fibers as the current sensing material. The sensing fiber ring is twined around measured current carrying wires. Based on the polarization properties of optical fibers, it measures current indirectly by measuring Faraday rotation angles in optical fibers. Each component in FOCT system is connected via fibers that welding together. It has a simple insulated structure, large dynamic range, reliable connection, no explosion, no danger of secondary circuit open, long-term stability, good consistency, mature technology and no discrete components in it. FOCT fiber sensing ring also has a light weight, small size and low cost.

The installation of FOCT is flexibility. It is suitable for traditional types of independent strut, transformer bushing or hanging. Because of its strong interference capability, it is ideally suited for gas-insulated switchgear (GIS) and other high-voltage equipment in complex electromagnetic environment without having to install the remote module. FOCT fiber ring has no heating phenomenon, thus the measurement accuracy will not be affected by increscent current. It has no saturation and anti-electromagnetic interference, thus can also be used for DC measurements.

However FOCT still has defects, affected by external magnetic and electric fields, the all-fiber current sensor inside will produce Faraday effect and optical Kerr effect, causing circular birefringence and linear birefringence. At this time, the polarization state is not only affected by the strain and temperature, but also by changes in the polarization plane of the incident light, which makes it impossible to distinguish the cause of changes in polarization state between changes in magnetic field and external disturbance.

For this problem, the influence of linear birefringence effects can be reduced or compensated mainly from the following aspects [3]: First, finding glass materials of low photoelastic coefficient to produce fiber and reducing photoelastic effect in the fiber to reduce the linear birefringence. The birefringence of ZF6 in flint glass is small, and it is little affected by temperature, makes it an ideal new material for sensing fiber in FOCT. Second, using fiber with double cladding structures can reduce the linear birefringence. Choose silicon material which has the most stable Young's modulus over a wide temperature range to be the first cladding layer. Because of its fragile mechanical properties, choose acrylate material to be the second cladding layer. Optical fiber of this structure has a good stability. Third, use new fiber processing technique to suppress birefringence: spun fiber has a good stability to environmental changes; twisted fiber can significantly reduce the linear birefringence inside; annealing to eliminate the birefringence caused by the bending of light. Last, by improving the measurement methods, like using Sagnac interferometer to achieve all-fiber current sensor program, reducing the impact of birefringence on the measurement [4].

Distributed temperature sensing. Distributed Temperature Sensing technology is suitable for the real-time measurement of space temperature distribution. Its optical fiber is the transmission medium as well as the sensing medium. Distributed Temperature Sensing technology can accomplish the task of distributed measurement of temperature field distribution along the fiber uninterrupted. It has many advantages that conventional sensors cannot match, such as anti-electromagnetic interference, high spatial resolution, flameproof, small size, long span, and little effect on the measured temperature field etc. Currently, distributed optical fiber temperature sensor mainly based on Raman scattering effect and optical time domain reflectometer (OTDR) technology to achieve continuous distributed measurement. Time domain and frequency domain optical system based on Brillouin is also a current hotspot.

Distributed Temperature Sensing technology is mainly used for inlet and outlet temperature monitoring of high-voltage cables in the new generation of smart substation. It can not only extend

the life of power cables but also improve the power transmission capacity. It can also be used for the fault warning of power system cables and power system sensing cables.

The distributed optical fiber temperature sensor detects the Raman scattered light which contains temperature information is very weak, or even submerged in noise. The noise elimination level of the anti-Stokes and Stokes backscatter is directly related to the accuracy of temperature measurement in the entire system. To improve the strength of long-distance optical transmission signal, fluorine-doped optical fiber can be used. The main task of fluorine is to reduce the refractive index of the silica. Because its Rayleigh scattering is small and the loss is also close to the theoretical minimum value, fluorine-doped optical is mainly applied for optical signal transmission over long distances.

Optical fiber interferometric vibration sensing. Optical fiber interferometric vibration sensing technology uses vibration sensing fiber as the sensing unit. When it is affected by the external disturbance, the vibration it caused changes some characteristic of the light transmitting part (wavelength, phase, attenuation, polarization, propagation time, and mode field distribution). By monitoring the optical signal, vibration interference information can be got. Using special sensing device in optical fiber monitoring changes of light characteristics, the detection of events and states (including: temperature, strain, destruction, damage, shock, sound waves, vibration load and displacement) can be achieved. This sensing technology has a high precision and a wide frequency range. It will never cause the grid resonance and has a strong immunity to electromagnetic interference outside.

Optical fiber interferometric vibration sensor can be laid along walls, fences or under the gravel, soil and turf. It can also be installed on masonry or concrete wall, the fiber perimeter monitoring system (FPMS) mounted around can monitor the system and alarm when foreign invasions are detected. At the same time, it applies to the online monitoring of iced transmission line galloping under certain wind velocity to prevent serious incidents and ensure the reliability and safety of auxiliary systems and infrastructures in the new generation of smart substation.

Optical fiber interferometric vibration sensing technology mainly uses ordinary communication optical fiber cable as transmission cable, 2-48 core fiber cable mostly, based on system requirements.

Fiber Bragg Grating Sensing. Fiber Bragg Grating (FBG) sensing technology is based on the photosensitivity of fibers. The interaction of germanium ions in the core and external incident photon causes permanent changes in the refractive index. However, the perturbations of periodic refractive index only affect a narrow section of the spectrum. When the broadband light wave transmitting inside, the incident light will be reflected on the corresponding frequency, and the remaining transmitted light waves are largely unaffected.

FBG sensing technology can directly measure the temperature and strain two basic physical quantities. It has many advantages such as anti-interference ability, simple sensing probe structure, small size, good repeatability of measurement results, etc. FBG sensing technology can be applied to current detecting, GIS system temperature measuring, pressure testing and other auxiliary facilities monitoring.

But for now, problems still exist in FBG sensing technology. That the response sensitivity of bare FBG is low is the critical one of these problems. In order to improve the sensitivity of the fiber Bragg grating, material's thermal expansion coefficients and thermo-optic coefficients can be appropriately increased. Pressure and Temperature are two main factors in improving its sensitivity: First, since the refractive index of light caused by temperature has the most significant impact on coupling wavelength, the temperature sensitivity of fiber grating can be improved by selecting the appropriate core or cladding doped materials and there density. Adding germanium and boron to optical fiber materials can increase the photosensitivity and decrease its numerical aperture. Polymer material with larger coefficient of thermal expansion like polyester fiber can also be applied to achieve embedding encapsulation. Second, in terms of the pressure factor, choose special polymer material with relatively small elastic modulus and low thermal expansion coefficient (like Polytetrafluoroethene) to achieve embedding encapsulation. Using a special cavity structure for Grating encapsulation may also increase the pressure-sensitive characteristics [5].

Transformer parameters monitoring

Transformer online monitoring is based on a variety of electrical and mechanical characteristics of the transformer to achieve the monitoring purpose of the transformer through the methods of partial discharge analysis, oil dissolved gas analysis, oil and winding temperature analysis, and transformer vibration online analysis [6]. This part mainly describes the online monitoring system of transformer oil and winding temperature based on FBG sensing technology and its installation.

Transformer burning occurs frequently due to the high oil temperature. One important reason is that the transformer overloads, its oil temperature exceeds the preset temperature. Meanwhile, oil and winding temperature directly affects the operation of the transformer cooling system. Therefore, transformer oil and winding temperature online monitoring system is of great importance to the safety and reliability of the new generation of smart substation.

Temperature of the transformer top is oil-immersed transformer's detecting temperature. In order to be easy for installation and maintenance, sensors are usually mounted on top of the transformer enclosure. The highest temperature of transformer windings situated in its upper part where is hard to measure, thus the surface temperature of the windings is often used as an alternative. Conventional temperature sensors are larger and susceptible to electromagnetic interference [7].

The temperature online monitoring system of transformer oil is based on FBG sensing technology. The system mainly consists of the temperature host, probes and connecting cables. The structure of transformer oil temperature online monitoring system is shown in Fig 1.

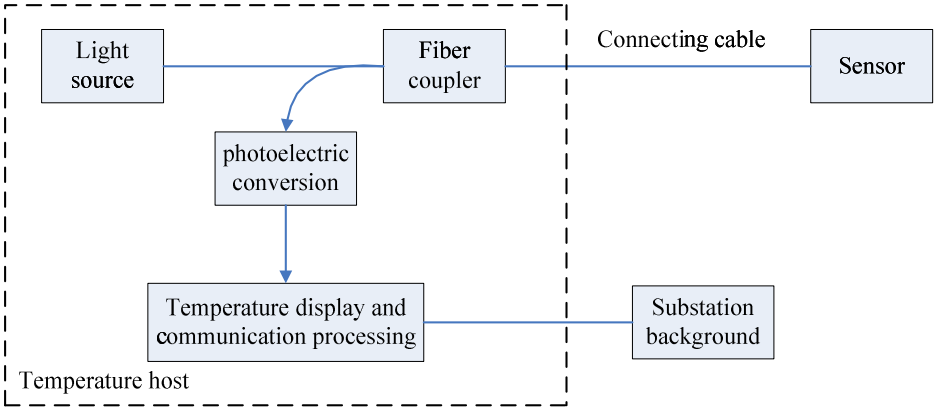

Fig.1 Structure of transformer oil temperature online monitoring system

FBG sensor is sensitive to temperature changes and of small size. After special designed， it can be embedded to the oil temperature detecting hole or pasted in a small plane on the upper surface of the windings to achieve real-time measurement. FBG sensing technology has strong anti-interference characteristics. It is very suitable for high pressure, high magnetic field environments. The probe of FBG sensor can work across a long distance without being affected. Thus, FBG sensing technology is ideal for temperature online monitoring of transformer oil and windings.

In addition, special optical fiber technologies can also achieve transformer current, partial discharge, gas dissolved in oil, transformers vibration and other aspects of online monitoring: through measuring optical radiation caused by partial discharge, FBG sensing technology can make various researches like partial discharge detection, location and analysis possible to conduct; Optical fiber interferometric vibration sensing technology can achieve the propose of online monitoring of gas dissolved in oil and transformer vibration by detecting the strain of transformer oil, transformer windings and core; the online monitoring of transformer current can be realized by FOCT sensing technology.

Conclusion

Special optical fiber sensing technology can achieve the goal of constructing transformer online monitoring system for the new generation of smart substation, effectively ensure its operating

security and reliable as well as improve its economic benefits. Therefore making it possible for the new generation of smart substation to meet the higher demands put forward by the smart grid. Based on traditional fiber sensing technology, special optical fiber sensing technologies improve and refine the materials, structure, etc. The application of special optical fiber sensing technology has broad prospects in the new generation of smart substation.

Keywords: Engine exhaust noise reduction, Active noise elimination, Acoustic interference

Abstract: In order to enhance the capacity of elimination of engine exhaust low frequency noise, a set of engine exhaust active noise control system was developed. The system was developed by using MC9S12XS128 MCU, and it is based on the theory of sound wave interference. The system can realize the voice signal acquisition, reverse phase processing and output, and can eliminate engine exhaust low frequency noise. Experimental results showed that the system has good silencing effects on the engine exhaust noise under the steady state.

Introduction

In recent years, with the vigorous development of Chinese automobile industry, car ownership in China is increasing year by year. At present, Chinese annual growth in the amount of cars is more than 20 million or more. The increasing of vehicles has brought the adverse effect for the environment, including the main part of the urban noise pollution casued by vehicles. Engine exhaust noise, which accounts for a significant proportion of the whole machine noise, is the largest noise source. The traditional method for controlling engine exhaust noise is installing a muffle. But traditional muffler may cause an increase in engine exhaust back pressure, increase the overall weight of the vehicle and have other defects. Active muffler system has been increasingly favored by the major car manufacturers because of its small size, light weight and can effectively reduce engine exhaust back pressure, etc. U.S. Bose active noise control system has been developed from research and development to advance market applications. Many other foreign examples can also prove the feasibility of its technology. China also has begun a series of research and has achieved some results in the field of active noise control. In the future, with more wide application of the active noise elimination technology, the costs will be lower. Active noise elimination technology has a broad prospect in China as a new kind of automotive noise control technology.

This article describes the development process of an engine exhaust active noise control system. The system was developed based on MC9S12XS128 single chip. The development of the system verified the feasibility of active noise elimination, put forward the idea of active noise elimination, found some problems need to be solved and pointed out the direction of the deep development of engine exhaust active noise control system.

Brief introduction to the Active Noise Control system

Active Noise Control is based on destructively interfere between two sound waves or the principle of sound radiation suppression. Acoustic radiation, which has the equal pressure and the opposite phase with the primary source, is generated by the secondary source. The two waves offset each other, so as to achieve the aim of reducing noise [1]. The basic theory of active noise control is the young's interference theory of sound wave. When the two same frequency and opposite phase columns of sound waves met in space, interference phenomenon will be produced. Its principle is shown in Figure1.

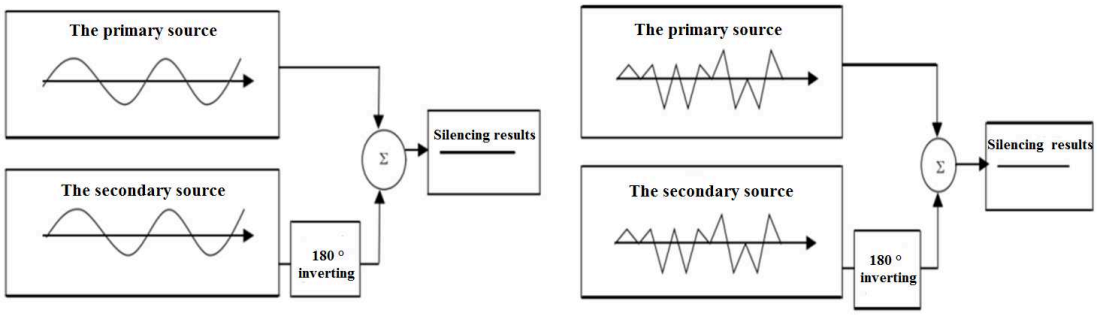

Fig.1. The principle diagram of the young's interference of sound waves

This paper describes an active noise control system for the engine tailpipe exhaust noise, so the system was designed with the particular sound field of the pipe as the research object. System structure diagram as shown in Figure2. The system picks up noise signal through the microphone installed on the upstream of the exhaust pipe. After inverse processing, then noise signal will be feed to the secondary sound source (speaker) installed on the downstream of the exhaust pipe. By adjusting the output of secondary sound source to make it have the equal amplitude and opposite phase with the original noise signal, the purpose of eliminating noise can be achieved[3].

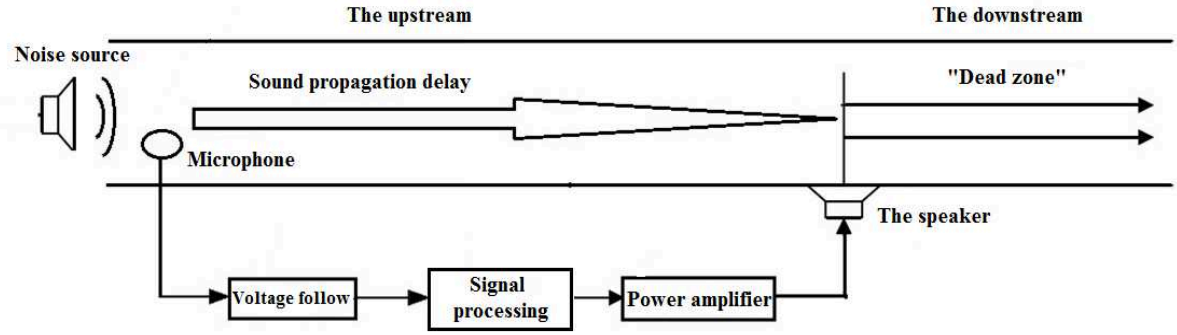

Fig. 2. System structure diagram

sound interference can be easily achieved by using audio processing software. Audio signals collected by audio processing software will be reverse phase processing. Then making the left and right sound channel output are equal in amplitude and opposite on the phase, noise elimination can be realized.Common audio processing software is Cool Edit Pro. Cool Edit Pro is a powerful multi-track recording and processing software developed by the U.S. Adobe Systems. It can handle multiple files at the same time, easy to cut and paste in several files, merging and overlapping sound operation[4].

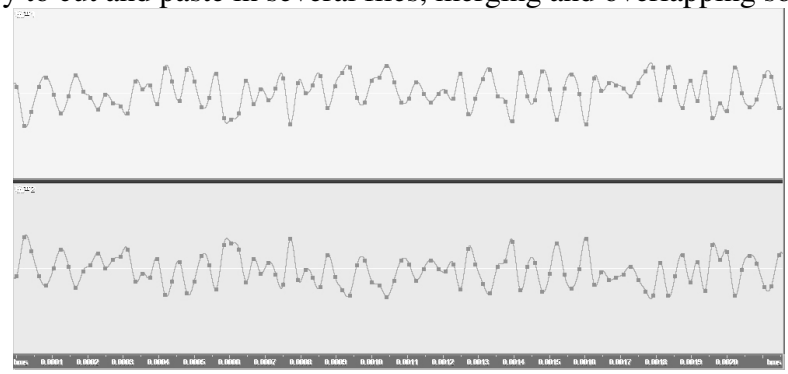

Fig.3. Diagram of noise signal waveform before and after reverse phase

This paper uses the Cool Edit Pro to Generate a random noise signal, Then we can generate a signal with opposite phase and the same frequency with the original signal. Waveform diagram before and after being Inverted is shown in Figure3. Finally, the two waveform overlap. Experimental results show that when the two waveform overlap, one can be seen as a noise source, another can be seen as the secondary sound sources in active noise control system, two sound source will produce interference phenomenon. Since the waveform is completely inverted, when excluding the impact of error factors, the noise signal is completely eliminated. The successful elimination of noise signals

showed that destructively interfering of sound waves can be used as the principle means of eliminating noise.

Active noise control system design

The controller of the active noise control system described in this article is realized by MC9S12XS128 MCU. Microcontroller is used to process signals coming from the sound sensor, adjust the control system to keep it always in the best control effect mode. System is designed in blocks, which includes three parts: single chip processing module, microphone module, speaker module. Two blocks combine with connectors, which can facilitate the future extension improvement, testing, and replacement. Hardwares included in the System are shown in Figure4, and the several modules will be introduced in the following.

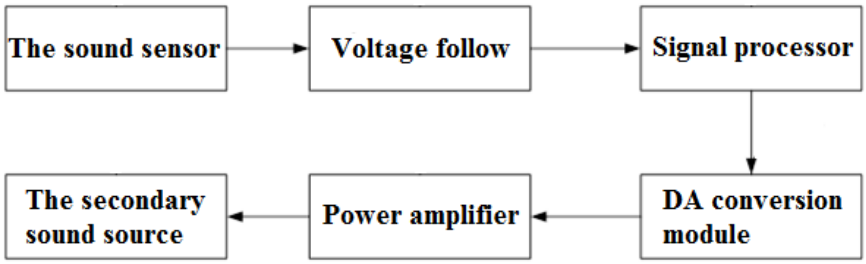

Fig.4. Hardwares included in the System

Microphone module includes sound sensor and a voltage follower circuit module. Sound sensors is used to detect the intensity of the sound on the noise source, the output can use 3.3 V and 5 V reference voltage signal which is available for the AD converter acquisition[5]; The voltage follower circuit module is connected with the sound sensor, which is used for increasing the input impedance, so that the voltage is more closer to the true value of AD module.

Signal processing module include a processor and a DA converter module. Signal processor uses MCS12XS128 MCU to process voltage signal. the AD module is used to complete the switch from the voltage signal to the digital signal. Single chip microcomputer completed the inverse processing of digital signal. Digital signal after inverse processing output to the DA conversion module. DA conversion module is connected to the signal processor, is used to switch the processed digital signals into analog voltage signal, and output to power amplifier. DA conversion module adopts TLC5615, TLC5615 is a D/A converter with serial interface, whose output is voltage type, and output voltage is double the maximum voltage reference. In this system, TLC5615 uses SPI serial transmission for single chip microcomputer CPU interface. The maximum transmission rate is 1.21 Mhz. DA conversion time is 12.5us. The conversion accuracy of TLC5615 is 10 bit, and the converted output is voltage. The maximum output voltage is VDD-0.4 V. The logic voltage input is 5 V (+ 5%). If using 5 V logic level, the maximum input voltage is 4.6 V.

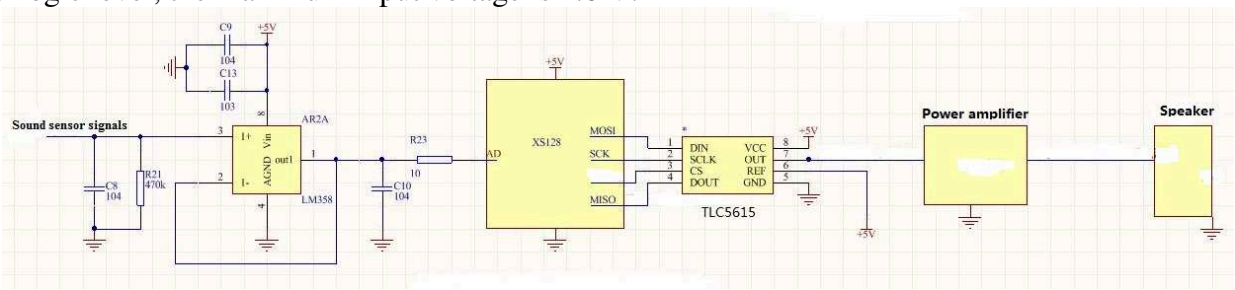

Fig.5. Schematic circuit diagram of system

Speaker module contains power amplifier and speakers. Connection with the DA conversion module, power amplifier is used to amplify the signal to meet the needs of the speaker. Power amplifier use TEA2025 amplifier integration module, which can directly amplify the output signal of the DA module. Secondary sound source module adopts full frequency electrodynamic loudspeaker to

meet the needs of the low frequency sound wave. Schematic circuit diagram of system is shown in Figure5.

Active noise control system function debugging

Combination of a signal generator and oscilloscope was used to debug the inverse function of the system.

Functional verification of inverting was completed by using dual channel oscilloscope. A certain frequency signal from a signal generator was collected. Signals after dealing with the inverse system and without inverse processing are showed at the same by using dual channel oscilloscope. During the experimental process, different frequency square wave, sawtooth wave and sine wave were generated by using signal generator, the 20 hz square wave and sine wave diagram are respectively shown in Figure6.

Experimental results of inverse function showed that for low frequency sound signal, the system has good capability of reverse phase, but with the increasing of frequency, the system will show a certain of ductility. The higher the frequency, the more obvious time delay phenomenon. By changing different signal source, we can get the same conclusion that for low frequency sound signal, the system has good inverse function; for high frequency signal, the delay phenomenon is serious, the system doesn‘t have a good ability of reverse phase. Reason analysis showed that when the frequency of the sound source signal is too high, the speed of signal transmission and DA converting can not meet the requirements, whcan lead to a voice signal processing is not timely, resulting in signal delay.

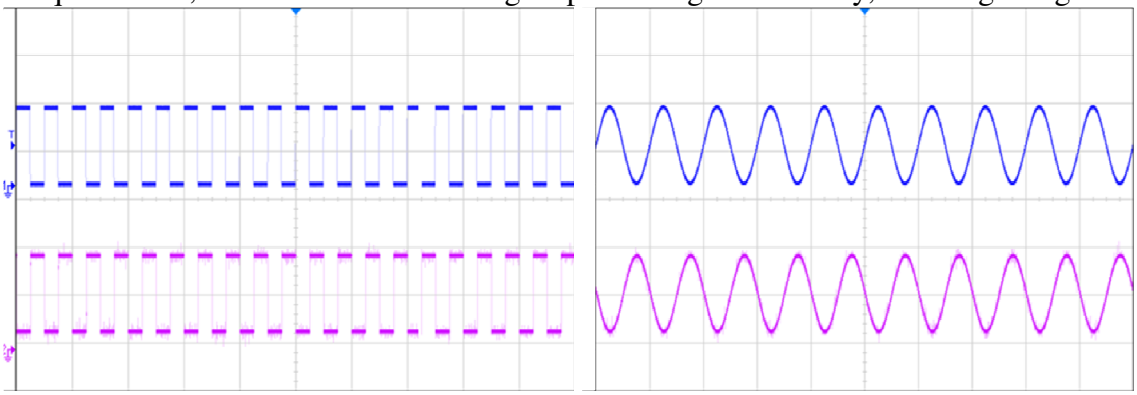

Fig.6. Diagram of the 20Hz square wave and sine wave

According to the actual measured engine exhaust noise, further inverse function of this system was debugged. The inverse function was debugged mainly for engine low frequency noise on the steady state. Figure 7 is the engine exhaust noise on a steady speed of 2500rpm (Abscissa is time, ordinate is samples values). Figure 8 is the noise spectrum of the engine exhaust noise after the Fourier transform based on external audio processing method(Abscissa is frequency, ordinate is sound pressure level).

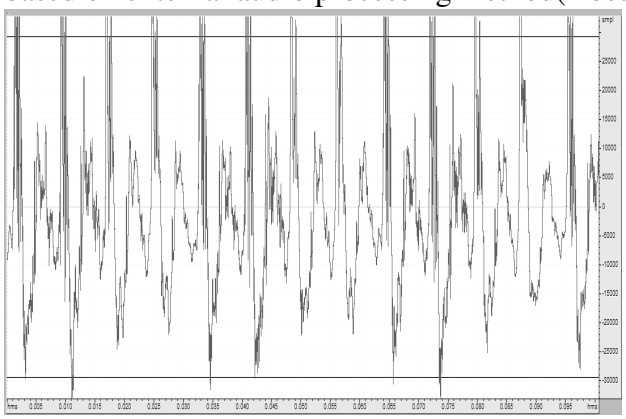

Fig. 7 Exhaust noise on speed of 2500rpm

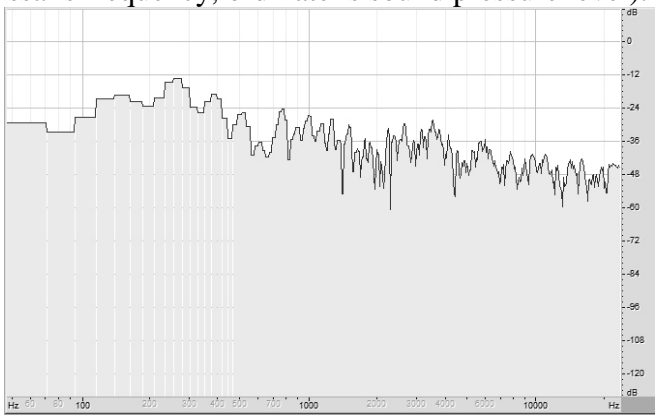

Fig.8 Spectrum obtained by Fourier transformation

According to the analysis of the noise spectrum diagram shown in figure 8, on low frequency range of engine exhaust noise, the sound pressure level on nearly 140Hz and 257Hz and 375Hz frequency

are in the peak position. By using audio processing software, we generated sine wave with the corresponding frequency and sound pressure level, and stacking output it for the system to acquire. System will output the voice signal which has been inverted. And the voice signal will eliminate the original engine exhaust noise by interference cancellation. By collecting and processing the sound signal, the spectrum diagram of processed signal can be obtained and shown in Figure9. From the figure we can see that the sound pressure decreased about 10dB in the low frequency range, particularly on the above location of the three frequencies, which means this system has good silencing effect on the elimination of engine exhaust low- frequency noise.

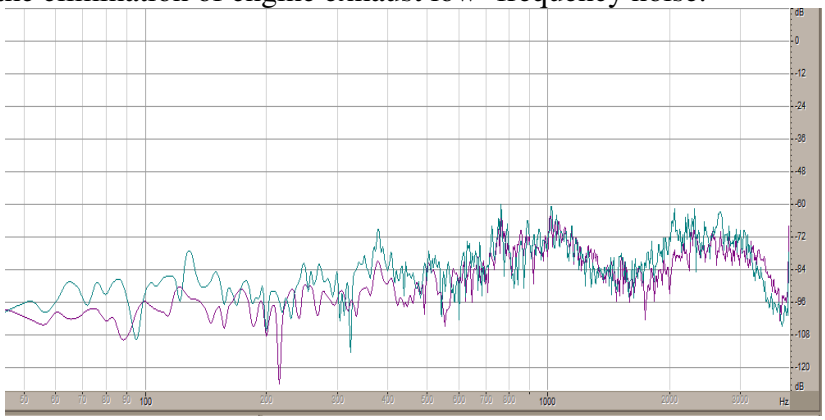

Fig. 9 Spectrum diagram of sound signal before and after interference cancellation

Conclusions

a. By using the audio processing software, the principle of active noise elimination was simulated. The Verification results showed that acoustic interference principle can achieve good silencing effect. The system has the advantages especially on the low frequency steady noise processing. Active noise elimination principle can be used as a silencer technical means to eliminate engine exhaust noise to more in-depth study.

b. Paper designed and developed a kind of engine exhaust active noise control system. The noise signal was processed and inverted by using MC9S12XS128 micro-computer. The system successfully realized processing of 140Hz, 257Hz and 375Hz exhaust noise, which were measured by the engine bench test. The actual exhaust noise in the above frequencies droped by about 10dB. The effectiveness of the system was proved.

c. System designed in this paper has a better handling capacity for stationary noise. But for transient noise, the effect is not good due to factors such as signal delay. So improvement will be continued in subsequent research.

Keywords: weak grids, frequency control; voltage control; coordinated control

Abstract: Variable-speed constant-frequency (VSCF) wind farms are gradually becoming a significant proportion of generation in weak grids with constantly increasing penetration rate, and it should certainly take responsibility of the grid frequency and voltage stability. Based on the P-Q performance curve of doubly fed induction generator (DFIG), by introducing static synchronous compensator (STATCOM), this paper presents a coordinated control strategy of active power and reactive power to deal with fault and load disturbance in weak grids. Simulation results show that the proposed coordinated control strategy can effectively improve the frequency and voltage stability of the grids.

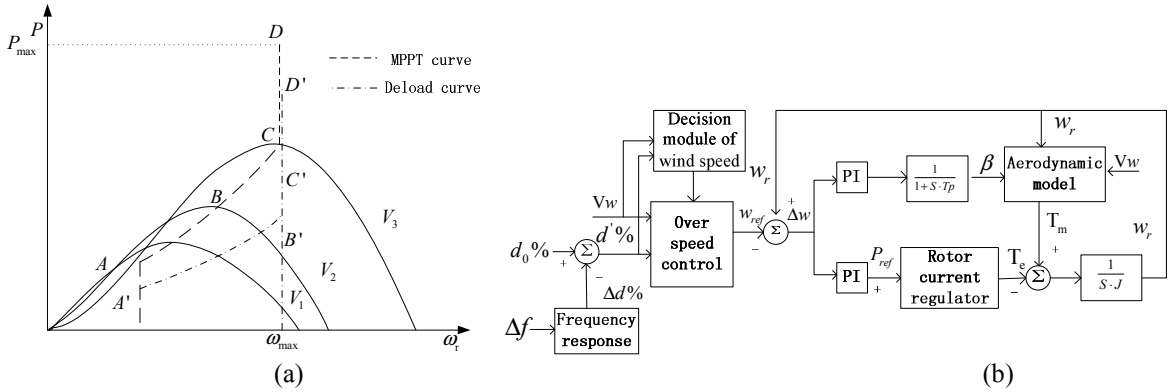
Introduction

In recent years, wind power has developed rapidly, which occupies the increasing proportion of weak grids. When fault and load fluctuation occur in weak grids, the wind farm should undertake part of the frequcency and voltage modulation tasks[1, 2]. Cooperating with STATCOM, VSCF wind turbine has the voltage adjustment ability [3] and frequency regulation ability [4, 5].

In the present paper, a coordinated control strategy based on the active power deload control and voltage compensation is proposed such that, when weak grids frequency excursion or fault occurs, wind farms change active power output and reactive power output together with STATCOM. The effectiveness of this control approach was tested in weak grids, where wind generation plays an important role.

Power Regulation Capability Analysis of DFIG Wind Turbines

To develop frequency regulation ability of DFIG, this paper proposed a coordinated control method based on pitch angle control and overspeed control. In this control approach, wind generators operate according to a deload optimum power extraction curve compared to the maximum power point tracking (MPPT), such that the active power provided by each wind turbine increases or decreases during system frequency changes, as depicted in Figure 1(a).



(a) (b)

Fig. 1. Frequency characteristics of DFIG. (a) Power-speed performance curves. (b) Frequency controller

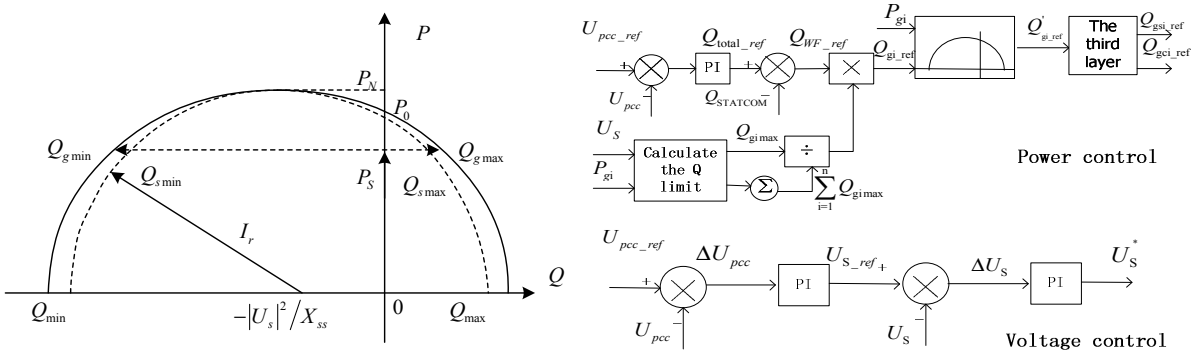
The principle of this control approch is that overspeed control is used in preference to pitch angle control to obtain a faster response speed, and pitch angle control starts when the overspeed control can not meet the demand of frequency regulation. Depending on the wind speed, control strategy is divided into three modes: low wind condition, medium wind condition, and high wind condition. Assuming reserve power of DFIG can be expressed as:

$$\Delta P_R = d\% \cdot P_{\mathrm{MPPT}} \tag{1}$$

Where, $d\%$ is deload coefficient, P_{MPPT} is value of MPPT. $d\%$ can be changed according to different circumstances needed to support. This paper proposes an improved active power control for DFIG at all regions of wind speed. The frequency regulation controller is designed as Figure 1 (b).

The input are rotor speed w_r, wind speed V_W, frequency f and the initial level of deload coefficient $d_0\%$. The output are pitch angle β and active power reference value P_w. Wind speed mode is selected first according to each input, and wind generators operate according to a deload optimum power extraction curve such that the DFIG is able to provide a proportional frequency response. When the system frequency drops, the controller will reduce the rotor speed or increase the pitch angle to increase the active output, vice versa.

Considering reactive power output of the converter, P-Q performance curve of DFIG and reactive control block are shown in Figure 2.



(a) (b)

Fig. 2. Reactive power characteristics of DFIG. (a) P-Q performance curve. (b) Reactive power control

As shown in Figure 2(a), when active output is under the given conditions, the reactive power has different operation mode; the adjusting range of reactive power is different when active power output under different conditions. As the change of wind speed, the active power output varies accordingly within $[0, P_N]$, while the reactive power output range is also changing. When the active power output is within $[P_0, P_N]$, the closer active power output to P_N, the more reactive power needed. Control block diagram of reactive power is shown in Figure 2(b), including power control and voltage control. Power control is applicable for the condition of crowbar inaction, and voltage control is applicable for the condition of crowbar action. In the power control mode, reactive power is allocated through three levels. The first is between wind farm and STATCOM; the second is between different wind turbines; the third is between rotor side converter and grid side converter.

Central Control System in Weak Grids

In order to maintain the stability of the grid voltage, a certain reactive power value is needed to inject to the weak grids. As shown in Figure 2, reactive power output is strong volatility for stochastic volatility of the active power and grid fault. This paper studies the effect of injecting optimum reacitve power using STATCOM on voltage of weak grids connected DFIG. Also, DFIG operates on deload mode to ensure that DFIG has sufficient active capacity and provides active power support for weak grids. The block diagram with proposed central control is shown in Figure 3.

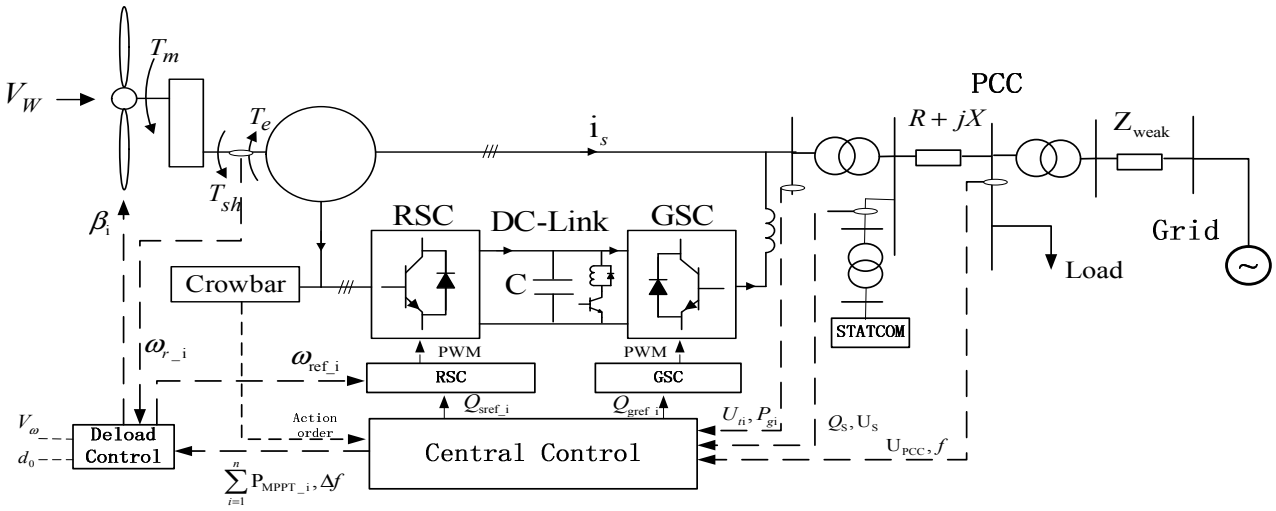


Fig. 3. Simplified block diagram with central control system

In the control diagram of Figure 3, the central control system achieves the active and reactive power balance objectives through real-time coordinated control among the wind farm, the compensation unit and grid system. The central control system contains three operational mode: power control , voltage control and frequency control. The control process is shown in Figure 4.

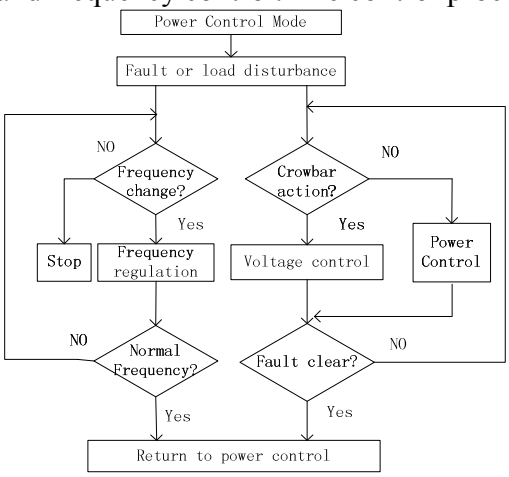

Fig. 4. Central control system flow chart

Test System and Simulation Results

The test system within PSCAD/EMTDC used for this study is shown in Figure 3. Two different cases studied on this test system are: (1) 3-phase, high impendance fault to ground, (2) sudden increase in load in the weak system.

Case 1 Three phase to ground fault

In this case, the 3-phase fault at t=0.5s is studied at PCC. The voltage drop are 20% and 50%, respectively. As shown in Figure 5(a)(c), after providing reactive power compensation by using the central control, the voltage drop during the fault has improved, and recovered to original value quickly after the clearance of fault. Figure 5(b)(d) are reactive power allocation between wind farm and STATCOM of different needs.

Fig. 6. Simulation results of frequency response. (a) Traces of frequency. (b) Wind farm's frequency response

Summary

This paper presents an active-reactive power coordinated control strategy based on the P-Q performance curve of DFIG. Center control system is established to improve the frequency and voltage stability in weak grids. The Robustness of the control system is the focus of future research.

Keywords: grid converter; three-level NPC; decoupling control; closed-loop control; power factor;

Abstract. Conergy three-level NPC topology is often used in grid connected inverter due to its high efficiency, fewer switching devices and better EMI performance. Traditional half-bridge topology can be transformed to Conergy NPC topology by adding bi-direction switches. This paper proposed a novel control strategy for Conergy three-level NPC three phase grid converter with real and reactive power closed-loop controller in the synchronous d-q rotating frame. The power control loop is based on the feed forward decoupling of d-axis and q-axis components of the output current, thus the active and reactive power can be controlled separately. Additionally a proportional-integral controller is added to enhance the robustness of the power controller. Simulation results verify the effectiveness of the proposed strategy.

Introduction

Grid converters for applications such as wind power system and photovoltaic have gained more and more attention in recent years, demanding for outstanding efficiency and relatively low cost [1]. Neutral point clamped (NPC) multi-level topology has a lower voltage rising rate, lower switching losses and higher inverter efficiency compared to the traditional two-level full-bridge circuit. As a variant of classical NPC three-level topology, Conergy NPC three-level topology is suitable for grid converters due to its high efficiency, fewer switching devices and better EMI performance [2].

Grid converters should comply with strict power quality requirements before they are allowed to be connected to the power grid. Apart from those requirements, power factor is frequently mentioned. Usually the power factor for photovoltaic inverters should be interpreted as a requirement to operate at a unit power factor [3]. In wind power generation, Grid Codes require the grid converter to behave like conventional synchronous generator and the reactive power demand can be calculated by its set point, power factor controller or voltage controller. In smart grid concept, flexible AC transmission devices such as STATCOM and UPFC are required to injected specific reactive power into the power system for local compensation or to support the AC voltage.

In this paper, a novel control strategy for Conergy NPC three-level three phase grid converter is proposed. The topology and its modulation method are first introduced. Then the mathematical model of the proposed grid converter in synchronous d-q rotating frame is studied and analyzed. Forward decoupling current control is employed to realize the separate control of real and reactive current. Then the closed-loop controller for active and reactive power is implemented, with PI controllers regulating the reference current in synchronous d-q rotating frame. Finally some simulation results are presented and conclusion made.

Topology and modulation method

A transformation from classical 2-level full bridge topology to the Conergy NPC 3-level is achieved by adding “clamping circuit”, which differs from the diode clamp three-level NPC topology. Alternate choices for the “clamping circuit” include two IGBTs connected in inverse parallel, or a single reverse blocking IGBT [4] [5].

The topology is shown in Fig. 1 (a), in addition to the buses “P” and “N” connected to the positive and negative of DC source respectively, the neutral point bus “M” is also essential. The ‘midpoint’ or ‘neutral point’ is obtained by adding capacitors of exactly the same capacity between bus P and M

and between bus N and M. Compared to the diode-clamping NPC, there is no need for additional diodes meanwhile the IGBT body diodes are used as current path. The new topology would require six additional isolated gate drives for the clamping switches.

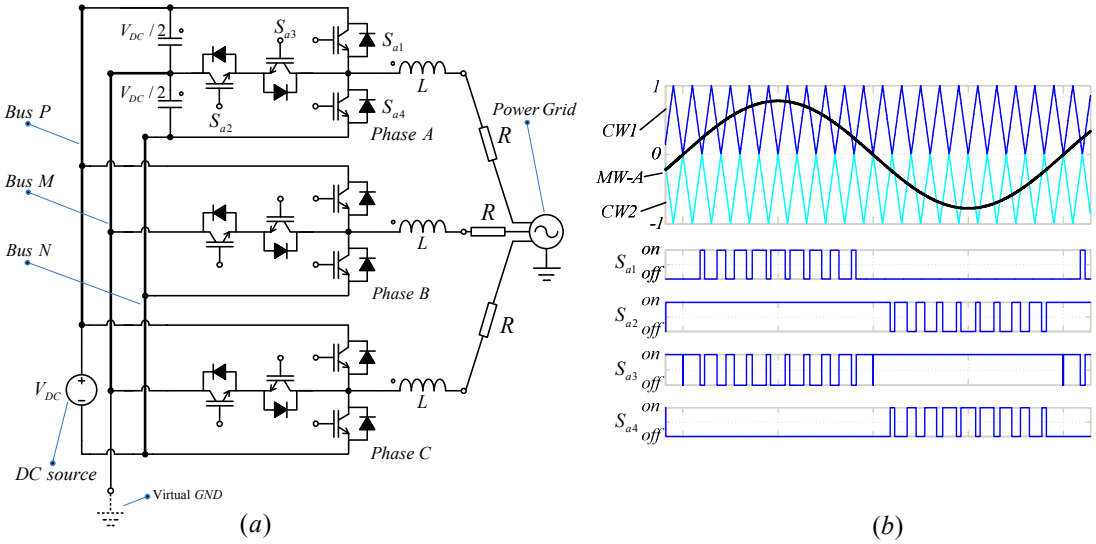

Fig. 1 (a) Schematic of the three-level Conergy NPC three-phase Grid Converter; (b) Bipolar SPWM modulation for phase A of the grid converter

In general three-phase SPWM modulation method three sinusoidal modulation signals with a phase shift of 120 degrees to each other are used to produce balanced three phase AC voltages. New pulse generation method for the proposed converter requires some modifications. Take phase A as an example, the only difference for the other two phases is the phase shift angle [6].

Apart from positive and negative states, the new method should also generate zero states for the converter. Like the bipolar SPWM modulation method, carrier are bipolar isosceles triangle waves, modulated wave is in phase with the output sine wave. The modulation method is shown in Fig .1(b). The corresponding switch states for generating positive and negative voltage is show in Table 1.

Table 1 Switch states

Voltage	Sa1	Sa2	Sa3	Sa4
Positive	on	on	off	off
0	off	on	on	off
Negative	off	off	on	on

Positive polarity carrier *cw1* and negative polarity carrier *cw2* were compared with the modulation wave *mw-A*. In the positive half cycle of the modulation sine wave, *Sa2* remains conductive and Sa4 remain off short, compare *mw-A* with *cw1* to generate two complementary drive signals for *Sa1* and *Sa3*; During the negative half cycle of the sine wave, it is similar to the positive situation.

Mathematic model

Assume the converter is connected to ideal three phase power grid through a low pass L-R filter shown in Fig. 1(a). The general mathematical model in the three phase system is first established and transformed into a d-q frame which is rotating at the angular speed omega. The mathematic model of the Grid converter in the d-q frame can be expressed Eq. 1 [7].

In equation Eq. 1 *ed* and *eq* represent components of the grid voltage. *Vd* and *Vq* are components of the equivalent output voltage of the converter. The coupling terms in the equation will affect the dynamic characteristics of the grid converter. In order to control real power and reactive power separately, some decoupling method is necessary.

$$\begin{cases} e_d = L\dfrac{di_d}{dt} + Ri_d - \omega L i_q + v_d \\ e_q = \omega L i_d + L\dfrac{di_q}{dt} + Ri_q + v_q \end{cases} \tag{1}$$

Decoupled d-q current control

Grid converter's power control is based on the instantaneous power theory and the control strategy is implemented in the d-q frame [8]. This method makes it very convenient to control real and reactive current directly, which are in proportion to the real and reactive power. The current regulator also employs the proportional-integral control method and the expression is the controller is Eq. 2.

$$\begin{cases} v_q = -(k_{iP} + \dfrac{k_{iI}}{s})(i_{q,ref} - i_q) - \omega L i_d + e_q \\ v_d = -(-k_{iP} + \dfrac{k_{iI}}{s})(i_{d,ref} - i_d) + \omega L i_q + e_d \end{cases} \tag{2}$$

kiP and *kiI* are parameters in current loop proportional integral controller. *Idref* and *iqref* are current command in d-q frame. Substituted the current controller Eq. 2 into the mathematic model Eq. 1, expression of id in Eq. 3 does not contain the variable *iq*, the decoupling is realized.

$$\begin{cases} \dfrac{di_d}{dt} = -\left[R - (k_{iP} + \dfrac{k_{iI}}{s})\dfrac{1}{L} \right] i_d - \dfrac{1}{L}(k_{iP} + \dfrac{k_{iI}}{s}) i_{d,ref} \\ \dfrac{di_q}{dt} = -\left[R - (k_{iP} + \dfrac{k_{iI}}{s})\dfrac{1}{L} \right] i_q - \dfrac{1}{L}(k_{iP} + \dfrac{k_{iI}}{s}) i_{q,ref} \end{cases} \tag{3}$$

The above results indicate that after the feed forward decoupling process, the cross effect between the d and q axis components of the output current will be eliminated. Therefore real and reactive current can be controlled separately shown in Fig. 2(a).

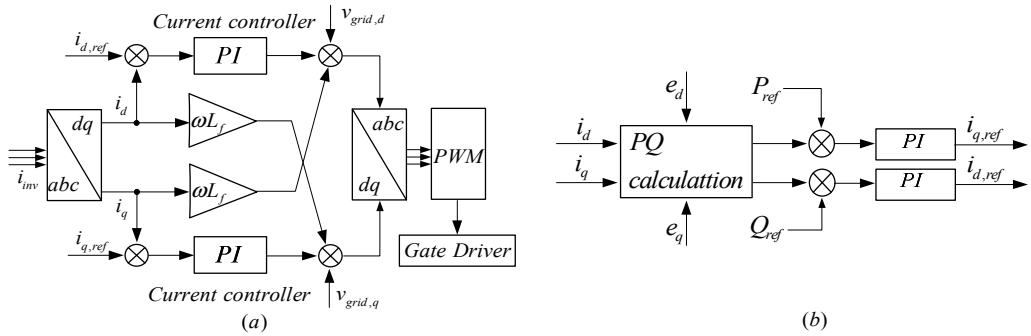

Fig. 2 (a) Decoupled current control in d-q frame; (b) Real and reactive power closed-loop control

The expression of d axis and q axis component are similar to each other and they share the same system parameters. Same controller can be applied to both d axis and q axis components, whether in the double closed-loop situation or just a single current closed-loop situation.

Power Control

In instantaneous power theory, the active and reactive power of a balanced three-phase system in the synchronous d-q frame is calculated by Eq. 4.

$$\begin{bmatrix} P \\ Q \end{bmatrix} = \begin{bmatrix} e_d & e_q \\ -e_q & e_d \end{bmatrix} \begin{bmatrix} i_d \\ i_q \end{bmatrix} \tag{4}$$

Feed-back method can be introduced to enhance this strategy. The reference real power *Pref* and reactive power *Qref* are interpreted to the reference current in d-q frame as the output of PI controller. The proposed power closed-loop controller is show in Fig. 2(b). The proportional integral power controller has the advantage to stabilize the output power when grid voltage fluctuates. Accuracy of output real and reactive power is also increased.

Simulation Results

A 5KVA simulation model for Conergy NPC 3-level 3-phase grid converter has been constructed to verify the proposed control strategy. The real and reactive power regulation command is given in the form of per unit (also known as p.u.). Base voltage is 380V and base power is 5KVA. DC bus voltage is 800V and switching frequency is 10 kHz with 2-microseconds dead time inserted. The L-R filter parameters are 4.8mH and 0.5 ohm.

Case 1: Unit power factor operation. First set the reactive power at zero and maintain unit power factor operation. Fig. 3 shows the phase voltage before L-R filter have three values: 800V, -800V and zero. The output current is sinusoidal and in phase with the grid voltage.

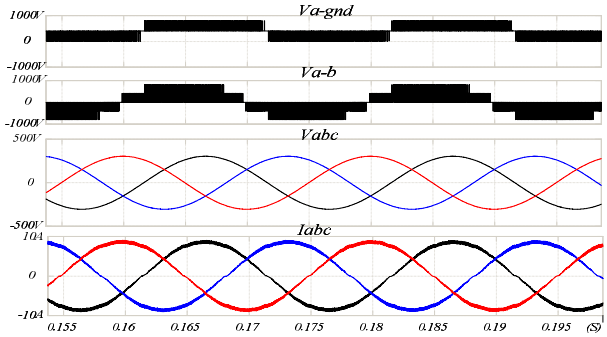

Fig. 3 Unit power factor operation

Case 2: Power command changes. Change the output real and reactive power command at 0.22s. The active power command jumps from 0.5 per unit to 0.8 per unit and the reactive power command jumps from 0 to 0.62 per unit. Power factor changes from unit to 0.627. Grid voltage, inverter current and real and reactive power is shown in Fig. 4(a) and Fig. 4(b).

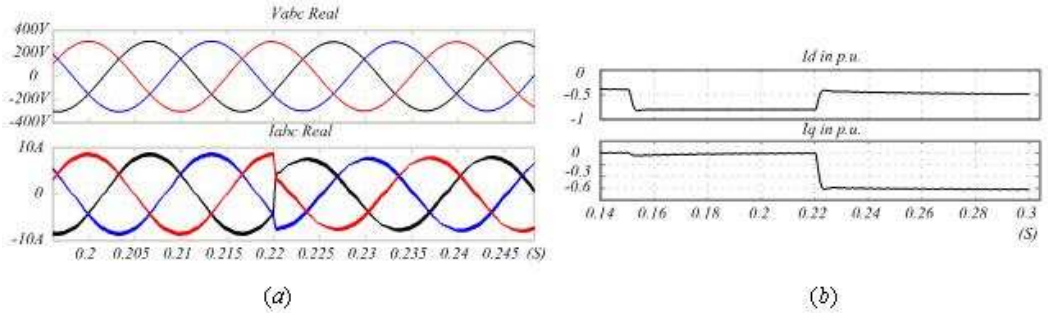

Fig. 4: (a) Grid voltage and current; (b) Real and reactive power.

Case 3: Grid voltage fluctuation. The grid voltage drops to 0.9 p.u. at 0.35s and jump back to 1.0 p.u. at 0.4s, grid voltage and inverter current is shown in Fig. 5(a). The output real power and reactive power are shown in Fig. 5(b). When grid voltage fluctuates, the output current will be adjusted to maintain the output power at its set point.

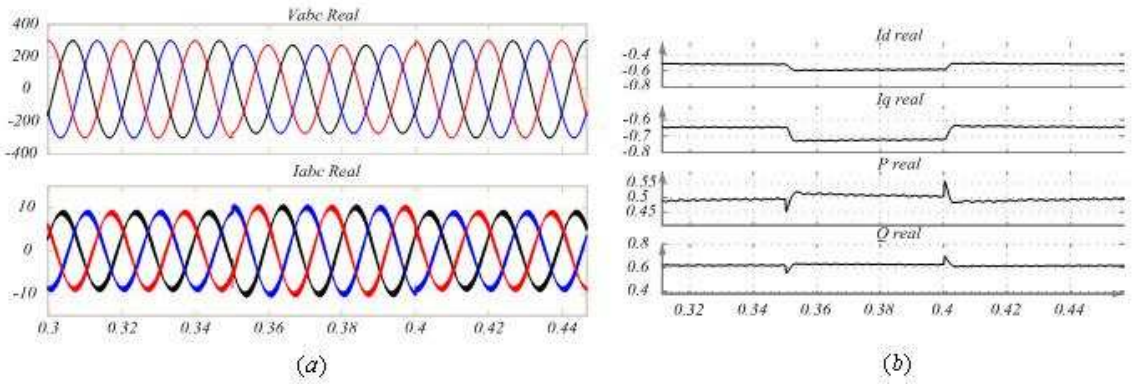

Fig. 5: (a) Grid voltage and current; (b) Real and reactive power injected into the power grid.

Conclusion

A SPWM modulation strategy for three-level Conergy NPC three-phase Grid converter with real and reactive power control based on the synchronous d-q frame is proposed. The feed forward decoupling current control loop can control the real and reactive current separately. Thus the power factor can be controlled to reach its set point. With a proportional-integral power controller, the grid converter can generate specified amount of real and reactive power. During the grid voltage fluctuation, the output power maintain constant. The proposed control strategy can enhance the robustness of the grid converter.

Keywords: Transformer; Purify in line; Breakdown Voltage; Purifier; Transformer oil

Abstract. Power transformer oil purifier described in this article is equipment that filters charged transformer oil in running transformers. Transformer oil can be filtered on line to improve performance of the transformer oil. This article analyzes the necessity of the purification and filtration on processing power transformer oil, describes the overall design ideas of oil purifier in line. Through examples, power transformer oil purifier in line is further discussed the steps and precautions in the application. By comparing the power outage transformer oil purifier and oil purifier in line, the superiority and science of oil purifier in line are clarified.

Introduction

Power transformer is the core of energy conversion and transmission, also the most important and critical equipment in grid. Currently, oil-immersed transformers have been used most widely. Transformer oil is a fractionated product of petroleum. It combined with Paraffin, Naphthenic hydrocarbon, Aromatic unsaturated hydrocarbons .ect. Commonly known as the Fang Peng oil, Light yellow transparent liquid, relative density is 0.895, Freezing point less than -45 ℃[1-3].

Mainly there are effects like insulation, thermal and protective mainly on transformer oil in transformers. With the running time increased, transformer oil will be gradually deteriorated and generate a series of harmful substances. Not only degrade the insulation of transformer oil, but also affect the cooling effect because of clogging the cooling oil circuit that drive transformer heat, the safe operation of transformer is posed a threat [4,5].

In operation, degradation of transformer oil is a process which resulting in degraded performance of liquid dielectric or physical and chemical properties gradually deteriorated due to the free discharge of the electric field, magnetic field, electric arc or corona. In order to ensure the indicators of transformer oil reaches operating procedures required, the purification is needed. The role of purifier is filter, distill the deterioration transformer oil and a series of operations, remove impurities in transformer oil (water is mainly), making the index reach close to new oil standards. Then purifier is put into use in transformers again. The purpose is to achieve energy saving[6].

Significance of purify in line

As users' increasingly demanding on voltage quality and reliable continuous power supply, development and application of power transformer oil purifier online become very important. Purifier online is to purify transformer oil in running transformers, this device is using to effectively remove free carbon, water, metal particles and its oxides in the oil under normal operating conditions, dielectric strength and service life of transformer oil is ensured, safety and reliability of running transformer is effectively improved, thereby maintenance outage is reduced, maintenance cycle is extended.

According to the "Decision on accelerating the development of strategic emerging industries" made by the State Council. "Guiding Catalogue of strategic emerging industries focused on products and services," drafting of such as the National Development and Reform Commission and the Ministry of Science, the Ministry of Finance and other relevant departments, outfits of waste oil regeneration is included in renewable resources projects. This shows filtering equipment, and other similar devices will get more attention and be more widely used.

Performance and indicators

The main structure of oil purifier in line is consisted of inlet pipe, inlet valve, prefilter, heater, thermometer, automatic valve, vacuum cylinder, nozzle, buoys, suction tubes, vacuum gauge, condensers, water Chu, vacuum pumps, oil drain pump, pressure gauge, fine filter, pump, reservoir tanks, flowlines, check valves, etc. As shown in Figure 1.

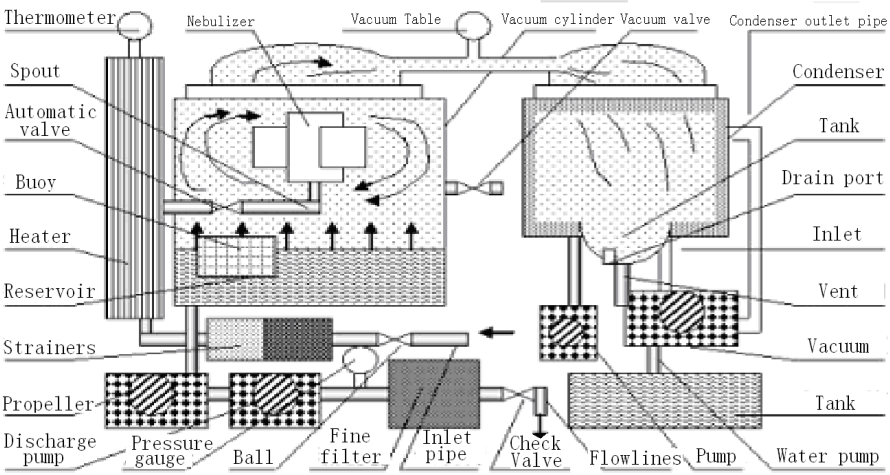

Figure 1 Technology Schematic of Oil Purifier in Line

Electrical control is another important part of the Oil Purifier in Line. The main electrical control automatically tracked by the programmable controller and inverter composed. The frequency of inverter motor kept within a certain range by electrical control, ensure that the device starts to accelerate the impact does not appear instantly. So that the whole flow stabilizes, no flow charged phenomena arises by shock, acetylene, ions flow. As shown in Figure 2.

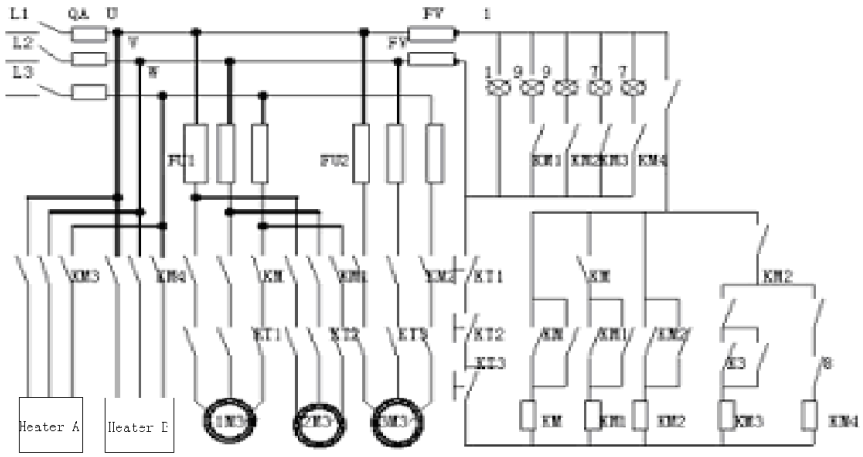

Figure 2 Electrical control of Oil Purifier in Line

Operation procedure

Two oil tank and outside-circulation line are provided, which can realize the two system trading off and subsection optimizing of change and purify oil. With filling value and outlet value are autocontrolled, synchronization effect of circulation oil flow is achieved best.Then the security of oil purifier in line is ensured. Using about one year, operating steps of oil purifier in line is tidied:

(1)Oil purifier in line should be placed on flat space (which can move, adjust direction and height), so that degassing efficiency of oil purifier in line is expressed fully.

(2)Oil purifier in line should be placed near oil level indicator, so that the accommodation of oil level can be watched.

(3) Oil purifier in line has a return value, in order to control the oil flow in operation. To avoid part of oil flow rate make too large, static friction and other disturbing factors are produced.

(4) The oil valve or reliable check valve should be installed on outlet of oil purifier in line, in order to avoid oil in storage tanks siphon back or running oil phenomenon after a temporary shutdown (such as rain), thus affecting the normal oil level in the conservator.

(5) The insertion tube of oil tanks must be inserted into the oil above 30mm.

(6) Gas in the oil escape more thorough when using oil purifier in line. Oil has a stronger intake performance, oil in the oil tank has a certain intake process and after that will produce negative pressure.

(7) The gas relay should be put into signal position before running, in order to avoid purifying gas make malfunction.

(8)Qualified oil ,about 5%～6% of all transformer oil, is prepared.

(9) Oil drain valve port at transformer bottom should be matched with the purifier tube, if not a flowline should be removed to re-weld.

(10) Regenerator in oil purifier in line must be filled with qualified oil

(11) Open the transformer oil pillow cover; the flowlines of the purifier are put into the pillow of the oil level.

(12) Inlet pipe of oil purifier in line is put into the prepared qualified oil.

(13) The oil drain valve under the transformer is opened.1%～2% of oil in the transformer is discharged.

(14) While performing step 13, oil purifier in line should be vacuumized (Not less than-0.09Mpa), and oil is synchronize supplemented into transformer oil pillow.

(15) While “Waste oil” is drained 1%～2% of all using the oil drain valve under the transformer, inlet pipe of the purifier is connected to the drain valve.

(16) At this point the purifier can work normally.

Precautions in using oil purifier on line

(1) Purifying in line must be taken in sunny day.

(2) Into and out oil of a maximum of 60L/min, with the decrease of transformer oil capacity is reduced.

(3) When purifying in line, the authenticity of oil level must be ensured and transformer oil is ensured enough.

(4) When transformer oil regenerating online, regenerating must after purifying, regenerator must be filled with qualified oil.

(5) Connections of the into-out oil tube must be carried out under the command of professionals.

(6) Before purifying in line, the purifier must be checked carefully. Oil purified performance is ensured (heating, vacuum function, filter systems) before work.

Application results of oil purifier in line

There is a S9—500/10 transformer in Li Shih Fushun Economic Development Zone, Northern Heating Co., Ltd. Because of the special requirements of electricity, the user’s power supply can not be interrupted. Otherwise it will damage the boiler and other equipment. As often running at full capacity, the phenomenon of aging comes to the transformer insulating oil. From the observation of oil pillow standard, transformer oil become black. The electrical in the plant worry about there is hidden in transformer. So they contact testing department of Power Administration test the oil sample. In accordance with national standards, breakdown voltage of transformer oil should be greater than 45kV. The test results of the transformer oil is only 19.5kV which does not meet the national standard, and also water content of 89mg/kg.According to user needs, 7th December, 2013 to 8th December,2013, “oil purifier in line” is used to the transformer purifying for 15 hours. After purifying, the results of testing the transformer oil shows that breakdown voltage reach 46kV and

water content of 41mg/kg that complying with national standards. Test results of transformer oil are shown in Table 1.Reliable protection for safe and stable operation of transformer is provided by using oil purifier in line. Potential pitfalls are solved and problems are not caused for power users.

Table 1 Test results of transformer oil

Project	Flow L/min	Moisture mg/kg	Breakdown Voltage kV
Before	---	89	19.5
After	50	41	46

Conclusion

Currently, State Grid Power Company of Fushun use oil purifier in line on transformers for 10kV and below, and obtain successful experience. The effect is also satisfactory. For 66kV and above voltage level of transformer has no courage to adopt oil purifier in line. The main consideration is when purifying in line transformer oil is pressured into the transformer by purifier. The oil may contain a lot of bubbles. These bubbles will produce free at a higher voltage. Perhaps insulation of transformer oil will be declined. In severe cases, even lead to internal discharge.

With the development of electronics, sensors, and control and other technology, carried out oil purifying on 66kV and above voltage level transformer is not only feasible, but also is the future research directions and goals.

Distributed Reactive Power-Voltage Control Method of Micro-grid

Yuwei Li

School of Electrical & Electronic Engineering,

North China Electric Power University, Beijing 102206, China

Email: 1162062263@qq.com

Keywords: Micro-grid; Distributed generation; Droop control; Distributed control.

Abstract. For micro-grid with multiple distributed power supply, a micro-grid distributed reactive power-voltage control method is proposed in this paper. By introducing active power disturbance, the load reactive power can be distributed in accordance with the distributed generation power rate, which leads to accurate distribution. At the same time, in order to ensure system voltage output stability in the rate, based on consistency and input/output linearization theory, under the distributed power multi-agent network topology, the distributed nonlinear co-droop controller is designed to make up for voltage fluctuation caused by active power disturbance. The simulation results verified the correctness and feasibility of the proposed control method.

Introduction

Micro-grid is a kind of medium or low voltage distribution power system, which assembled by a variety of forms of distributed power supplies, energy storage devices, loads, the control units and protections. In recent years, many scholars have carried out related researches on above issues: When the resistive and inductive components of micro-grid line impedance can not be ignored, paper [1-2] proposed a decoupling coordinate transformation method which based on virtual power, virtual frequency and voltage, to solve the problem of power control coupling. However, these methods can not completely eliminate the reactive power allocation errors while improving the stability of the micro-grid system, also, they need more accurate line parameters. In [3], it adopts virtual output impedance to overcome power coupling, inhibit the affection of impedance differences on the accuracy of power allocation. However, the introduction of virtue impedance makes the system voltage quality lower, and increased instability in the system at the same time. In [4-5], a method is put forward to compensate for the line impedance characteristics and distribution errors caused by local loads by introducing virtual inductance, but the droop coefficient of this method is difficult to get.

Under the distributed power multi-agent network topology, based on consistency and input/output linearization theory, the distributed nonlinear co-droop controlling is used to keep the micro-grid voltage stable. Power controller based on distributed control design is improved, which makes it can not only ensure the reasonable distribution of the load reactive power, but improve the quality of the system output voltage at the same time. In this paper, a power control method is proposed, it introduced active power disturbance to compensate for reactive power distribution error. The proposed method can not be affected by micro-grid line impedance characteristics, the influence of local loads and the influence of the topology structure, in another word, it can not only ensure the accuracy of load reactive power allocation but also maintain the stability of the system voltage.

Distributed Voltage-reactive Power Control Method

For each distributed power supply with its multi-agent, the general form of the distributed control is:

$$\boldsymbol{u}_i = \alpha_i(s_{i0}\boldsymbol{y}_0, s_{i1}\boldsymbol{y}_1, s_{i2}\boldsymbol{y}_2, \ldots, s_{in}\boldsymbol{y}_n) \quad i = 1,2,\ldots,n \tag{1}$$

where $\boldsymbol{y}_0$ represents the output of distributed control. $\boldsymbol{y}_i, i=1,2,\cdots,n$ represents the output of distributed power number i. The multi-agent network topology matrix is showed as following:

$$\boldsymbol{S}=\begin{bmatrix} s_{10}(t) & s_{11} & & \cdots & s_{1n}(t) \\ s_{20}(t) & s_{21}(t) & s_{22} & \cdots & s_{2n}(t) \\ \vdots & \vdots & & \ddots & \\ s_{n0}(t) & s_{n1}(t) & s_{n2}(t) & \cdots & s_{nn} \end{bmatrix} \in \mathbb{R}^{n\times(n+1)} \tag{2}$$

where $s_{ii}(t)=1$.when the distributed power number i can get the information of distributed power number j: $s_{ij}(t)=1$, otherwise: $s_{ij}(t)=0$. When the distributed power number i can get the information of leading agent: $s_{i0}(t)=1$, otherwise: $s_{i0}(t)=0$.

For reactive power-voltage droop control, derivative should be introduced for linearization. As following, in the distributed power multi-agent network topology, based on input/output linearization and consistency theory, the distributed nonlinear co-droop controlling is used to keep the micro-grid voltage stable.

For the nonlinear system:

$$\begin{cases} \dot{\boldsymbol{x}}_i = \boldsymbol{f}(\boldsymbol{x}_i)+g(\boldsymbol{x}_i)u_i \\ y_i = h(\boldsymbol{x}_i)+D_i u_i \end{cases} \tag{4}$$

where $\boldsymbol{x}_i$ is state variable; u_i is control input;$u_i=E_{oi}$; $\boldsymbol{\zeta}_i$ is disturbance input; y_i is the output of the system; $y_i=v_{odi}$; h_i is output function; $\boldsymbol{A}_i$, $\boldsymbol{B}_{1i}$, $\boldsymbol{B}_{2i}$, D_i are corresponding matrix; vector field $\boldsymbol{f}(\boldsymbol{x}_i)=\boldsymbol{A}_i\boldsymbol{x}_i+\boldsymbol{B}_{1i}\boldsymbol{\zeta}_i$, $g(\boldsymbol{x}_i)u_i=B_{2i}u_i$, $D_i=0$.

Due to the control input $u_i=E_{oi}$, the output of the system $y_i=v_{odi}$ is nonlinear, and it meets the equation $v_{odi}^2=E_{oi}^2-v_{oqi}^2$, by solving two differential, we can get:

$$\ddot{y}_i = L_f^2 h(\boldsymbol{x}_i)+L_g L_f h(\boldsymbol{x}_i)u_i \tag{5}$$

$$u_{vi}=\frac{-L_f^2 h(\boldsymbol{x}_i)+v_i}{L_g L_f h(\boldsymbol{x}_i)} \tag{6}$$

In that case, a system which has been accurate linearized can be got, it has new coordinate system: $\boldsymbol{z}_i=[z_{1i},z_{2i}]^{\mathrm{T}}=[v_{odi},\dot{v}_{odi}]^{\mathrm{T}}$. The linear relationship can be described as $z_{1i}=y_i$, $\dot{z}_{1i}=z_{2i}$, $\dot{z}_{2i}=v_i$; $\boldsymbol{A}$, $\boldsymbol{B}$ are the coefficient matrices of the newly established linear equation.

Assuming the distributed control law to be:

$$v_i=-\boldsymbol{\alpha}_{vi}[D_{i0}\boldsymbol{z}_{oref}+\sum_{j=1}^{n}D_{ij}\boldsymbol{z}_j-\boldsymbol{z}_i]=-\boldsymbol{\alpha}_{vi}\boldsymbol{e}_{vi} \tag{7}$$

where $\boldsymbol{\alpha}_{vi}$ represents the voltage feedback matrix, $\boldsymbol{e}_{vi}$ represents voltage error, $\boldsymbol{z}_{oref}=[v_{oref},0]^{\mathrm{T}}$.

According to the theory of optimal control for linear systems, optimal control volume meets the following conditions:

$$\begin{cases} v_i=-\boldsymbol{\alpha}_{vi}[D_{i0}\boldsymbol{z}_{oref}+\sum_{j=1}^{n}D_{ij}\boldsymbol{z}_j-\boldsymbol{z}_i] \\ \boldsymbol{\alpha}_{vi}=\boldsymbol{B}^{\mathrm{T}}\boldsymbol{P} \\ \boldsymbol{P}\boldsymbol{A}+\boldsymbol{A}^{\mathrm{T}}\boldsymbol{P}-\boldsymbol{P}\boldsymbol{B}\boldsymbol{B}^{\mathrm{T}}\boldsymbol{P}+\boldsymbol{Q}=\boldsymbol{0} \end{cases} \tag{9}$$

Improved Power Controller

Firstly, the distributed collaborative droop control make the load power an initial allocation, when a compensate signal is sent by the distributed control system, using sampling/retainer to preserver the active distribution state at this time, so a preparation for the next step can be made. Secondly, introducing the active disturbance to realize the accurate distribution of load power in improved power controller, also reactive power distribution error caused by the distributed collaborative droop control can be compensated by introducing active disturbance. The expression of the proposed improved power controller can be got as following:

$$\begin{cases} w_i = w_{oi} - (m_{Pi} \cdot P_i + K_{\mathrm{I}} \cdot n_{Qi} \cdot G \cdot Q_i) \\ E_i = E_{0i} - n_{Qi} \cdot Q_i + K_{\mathrm{C}} \cdot G \cdot \int_t Q_i \mathrm{d}t \\ E_{oi} = \dfrac{-L_f^2 h(\boldsymbol{x}_i) + \{-\boldsymbol{\alpha}_{vi}[D_{i0}\boldsymbol{z}_{oref} + \sum_{j=1}^{n} D_{ij}\boldsymbol{z}_j - \boldsymbol{z}_i]\}}{L_g L_f h(\boldsymbol{x}_i)} \end{cases} \tag{12}$$

In the equations above: G represents the soft gain compensation of the synchronization signal; K_{I}, K_{C} respectively represent the active disturbance gain and the integral control gain. All distributed generations choose the same K_{C}.

Due to the introduction of active disturbance, the voltage quality will be affected in the process of power control; the proposed distributed collaborative droop control can make the precise distribution of voltage quality in power load and improve the voltage quality at the same time through dynamic adjustment.

Simulation Analysis

In order to test and verify the correctness of the presented control method, the 380V/50Hz independent micro-grid system which is in island operation is used to make simulation experiment; the system is showed in Fig.1. In this micro-grid system, there is 5 DG and 6 loads, the line parameters are mostly with resistance, are Z_i=3.46+j1.52Ω. Load parameters of this system are: $P_{L_1} = P_{L_2} = 20k\mathrm{W}$, $Q_{L_1} = Q_{L_2} = 9.75k\mathrm{Var}$, $P_{L_3} = P_{L_4} = 6.67k\mathrm{W}$, $Q_{L_3} = Q_{L4} = 3.75k\mathrm{Var}$, $P_{L_5} = P_{L_6} = 20k\mathrm{W}$, $Q_{L_5} = Q_{L_6}$ $7.5k\mathrm{Var}$, the output impedance of each distributed generation is: Z_{g1}=0.1+j0.2Ω, Z_{g2}=0.4+j0.4Ω, Z_{g3}=0.5+j0.5Ω, Z_{g4}=0.7+j0.8Ω and Z_{g5}=1+j0.8Ω.

The droop control module is made up of power control, voltage control and current control. In the distributed collaborative control, let $\boldsymbol{Q} = diag\{6000,10\}$, voltage feedback matrix can be got by equation (9): $\boldsymbol{\alpha}_v = [77.4597 \quad 12.8421]$.

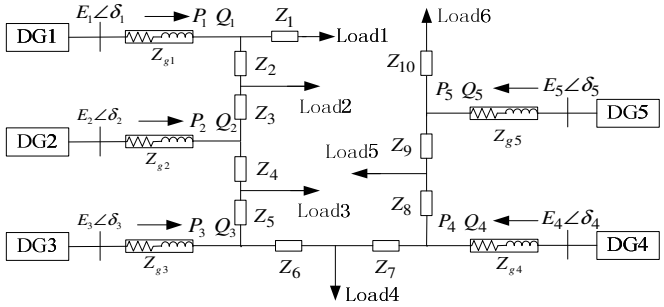

Fig. 1 Structure of simulated micro-grid system

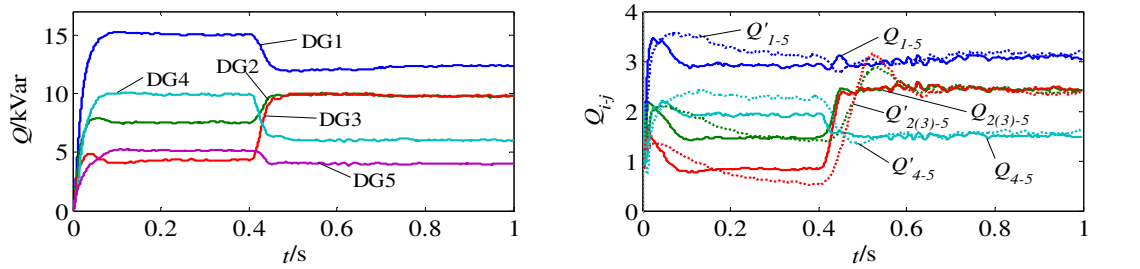
In order to make the distributed power allocate according to the proportion of the load capacity S_i^*, the droop coefficient should be inversely proportional to its capacity, where $Q_{i\text{-}j}$ represents the power sharing ratio $Q_i : Q_j$.

According to Fig.2(a-b), DG3, which has the smallest droop coefficient, takes the least reactive power, this kind of reactive power allocation is unfavorable to the stable operation of the micro-grid. After the introduction of active disturbance power controller, the distributed power can share the reactive load according to its own capacity, The ratio among the output power of the distributed power $Q_{1\text{-}5}$, $Q_{2(3)\text{-}5}$ and $Q_{4\text{-}5}$ are tending to the required power sharing ratio 3, 2.5 and 1.5.

In order to verify the effectiveness of the proposed improved control method, each distributed power droop coefficient was reduced to 1/10 of the original, and the simulation result is shown in figure 2(c) of the dotted line. The overshoot and oscillations of the dynamic response are also improved comparing to the distributed collaborative droop control.

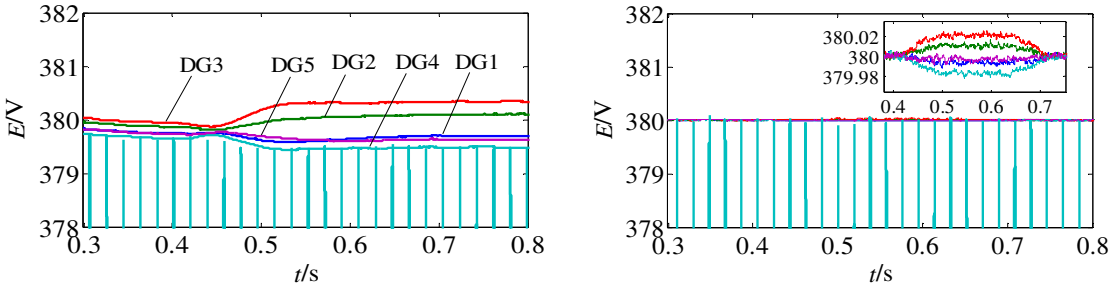
In order to get a further verification of the distributed collaborative droop control method, as it shown in Fig.3 (a-b), comparing to the traditional droop control, the distributed collaborative control can make the output of DG voltage stable in the rating or make the deviation very small. Therefore, the improved load power allocation method which based on the distributed collaborative



(a) DG reactive power distribution (b) DG reactive power ratio change among

Fig. 2 Simulation results of power sharing

droop control can ensure an accurate allocation of reactive power; also, it can make the control system with a control function of making the voltage constant.



(a) (b)

Fig. 3 DG voltage curves under different control modes (a) with traditional droop control method (b) with distributed collaborative droop control method

Conclusion

In the independent micro-grid, to solve the problem of reactive power allocation among the distributed power supplies and the voltage quality problem, in this paper, a islanded micro-grid distributed reactive power-voltage control method has been put forward, the method is based on the analysis of factors that influencing the power allocation. In the distributed generation with multi-agent, based on the theory of consistency and input/output linearization, the nonlinear distributed collaborative droop controller was designed. Furthermore, on the above basis, we introduced active power disturbance to compensate the distribute error of the load reactive power. In that cases, the reactive power can be distributed precisely, at the same time, the stability of the system voltage can be guaranteed and the system can get good dynamic and steady-state characteristics.

Marine fuel boiler system design platform

Hou Ying-ying

Zaozhuang Vocational College of Science & Technology, TengZhou , 277500

Keywords: Signal interface, analog, digital, PLC Design

Abstract. This design platform consists of a computer control, signal interface and PLC or IPC and other components. Signal interface consists of analog and digital input and output board composition, these boards are equipped with signal conditioning and terminal board, the input and output to meet industry standards, can be directly connected with the actual computer control system, this article will focus on the signal interface.

Introduction

There are a lot of marine fuel boilers and analog switches, when the boiler system simulation, it involves a lot of input and output analog switch status and size[1]. The design of the boiler simulation system made of industrial objects connected via simulation platform and actual PLC controller via analog input and digital input boards USB2832 card PCI2310 read control signal PLC controllers into the boiler simulation system , and calculate the corresponding action in the model, and then the switch state model and calculate the analog output board USB2833 and PCI2310 information to the PLC via analog controller as input PLC, constitutes hardware-in -the-loop (HIL) simulation systems. This HIL simulation platform can be used for a variety of test and validate the control system development process, but also as curriculum design, graduate design and other aspects of the control algorithm or the controlled object validation tools in teaching.

Platform structure

This design platform consists of a computer, signal interface and PLC or IPC and other controller. Signal interface consists of analog and digital input and output board composition, these boards are equipped with signal conditioning and terminal board, the input and output to meet the industry standard, you can connect directly with the actual computer control system, will be the focus of this chapter describes the signal interface[2]. To achieve the controlled object model and the controller signal via signal interface, can be composed of HIL simulation system.

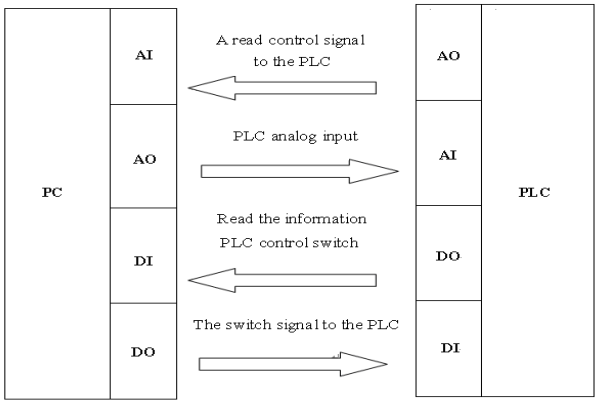

Figure1 Computer and PLC connection diagram

Figure 1, for example in marine fuel boiler, analog and digital simulation model output signal is the output signal is regarded as the boiler pressure and temperature sensors as the input signal from the controller; analog simulation model inputs and switches semaphore signals seen as a controller for the water supply valve and fuel valve.

Signal Interface

Analog input data acquisition card. USB2832 is a USB bus-based data acquisition card, the computer is directly connected to the USB interface can be achieved. Can be used in the laboratory and product testing in areas such as data acquisition, waveform analysis and processing systems. USB2832 card with AD, DA, DI, DO, and CNT timer /counter functions, where it's used in the AD analog input function, the AD has the following characteristics[3]:

1) Converter Type: AD7321
2) Input Range: ±10V, ±5V, ±2.5V, 0~10V
3) Conversion Accuracy: 13 (Bit)
4) Sampling rate: Maximum switching frequency 500KHz chip
5) Physical Channels: 32 channels, 16 channels
6) Analog input: Single-ended and double-ended analog input
7) Sampling channels: The end of the channel - the first channel +1
8) Channel switching mode: The first end of the channel in order to switch
9) Acquisition mode: Continuous acquisition
10) Clock: Board internal clock
11) Non-linear error: ±1LSB
12) System Accuracy: 0.1%
13) Operating temperature range: 0℃~+50℃

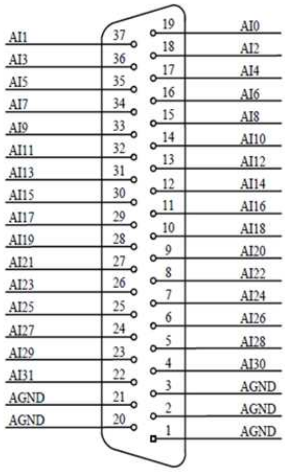

Figure2 37-pin D-type connector pin definitions Figure

Figure 2, the signal connector pin definitions: AI0 ~ AI31 as analog input pin, when a single-ended input, to 32 analog channels; When is a double-ended input, the first 16 to the positive input terminal after 16 corresponding to the negative input terminal is a terminal. AGND analog signal common ground that the analog signal input and output regarded it as a reference. Is a single-ended input channel one signal when multiple signals, they use the same ground. When the number of channels required more environmental disturbance is relatively small and can be used single-ended mode. Figure 3 is a single-ended wiring methods[4].

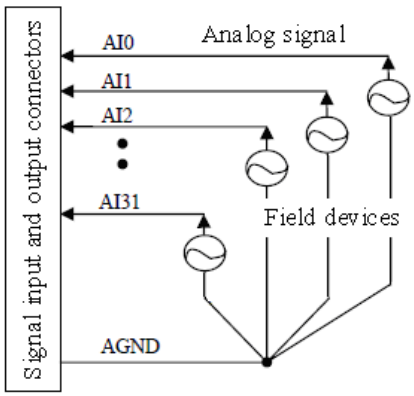

Figure3 AD single-ended input connection diagram

Analog output data acquisition card. USB2833 data acquisition card with AD, DA, DI, DO, CNT timer / counter functions used here its DA analog output function, the DA features are as follows:

1) Converter Type: AD5724
2) Output Range: 0~5V, 0~10V, 0~10.8V, ±5V, ±10V, ±10.8V
3) Conversion Accuracy: 12Bit
4) Number of channels:4
5) Setup time: 10 ms
6) Non-linear error: ±1LSB
7) Operating Temperature: 0℃~+50℃

The design of the large ones due to be greater than the analog output of 4, used a two USB2833. In order to distinguish between two USB2833, their physical ID number will be set to 0 and 1 respectively.

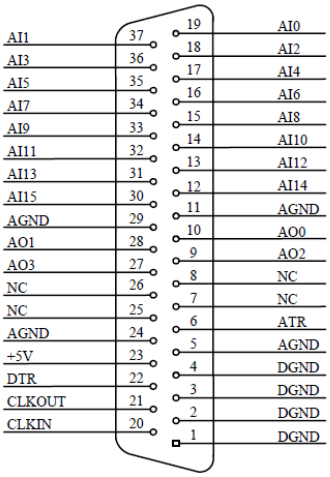

Figure4 37-pin D-type socket pins

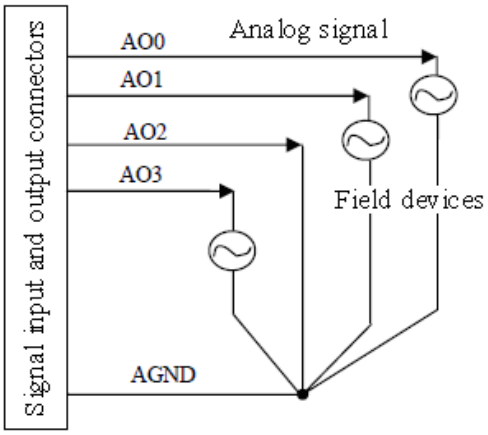

Figure5 Signal connection method DA analog output

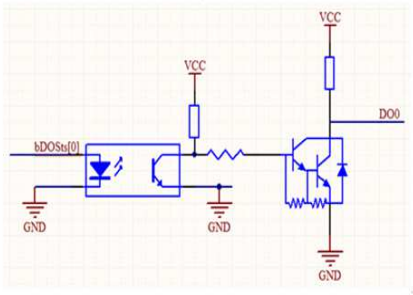
Pin defined in Figure 4, USB2833 is: AO0 ~ AO3 analog signal output pins. AGND analog signal, the input and output analog signals it as a reference. In this design does not use the rest of the pins will not repeat them. Figure 5 is a terminal connection methods.

Connected to circuit design and PLC

In order to match the PLC connection circuit in the switch input circuit and output circuits were added to the ULN2803, namely eight NPN Darlington[5]. ULN2803 internal circuit diagram is shown in Figure 11.

Figure 6 with the first switch output DO0 example, on the basis of the actual circuit of Figure 9 plus the external power supply and pull-up resistors, ULN2803 also added the external power supply and pull-up resistors. When the output bDOSts [0] is high, the transistor is turned on, the voltage at the collector within PCI2310 low, Darlington is not conducting, DO0 is high. When the output bDOSts [0] is low, transistor PCI2310 within the non-conducting, the collector voltage is high. Darlington conduction, DO0 at a low level.



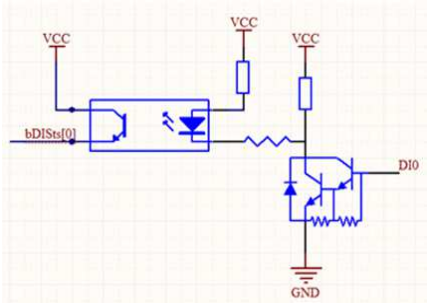


Figure6 Witch output adjustment circuit Figure7 Witch input adjustment circuit

Figure 7 with the first switch input DI0 road for example, DI0 is high Darlington conduction, the output low emitting diode conduction, and thus the transistor conduction PCI2310 inside, bDISts [0] is high. DI0 is low Darlington is not conducting, the output of the high level cannot make light-emitting diode conduction in the transistor PCI2310 have not turned on, bDISts [0] is low.

Conclusion

Industrial object simulation platform in the joint action of the hardware and software of the computer simulation model and PLC control systems to connect and communicate. Complete hardware conditions, the correct tool for the entire design is to achieve security features, and software conditions are a function of the hardware design can be achieved. In connection with the PLC controller also take into account matching of both voltage and current, load capacity issues. Constitute a virtual simulation system with the actual PLC controller connected hardware loop simulation system. When the accuracy of the computer simulation model to reach a certain requirement, this system can be developed or validation controller.

Keywords: energy matching, power equipment, robot

Abstract. To increase the flexibility performance of robot dog, dynamic performance matching of power equipment in four-footed robot dog is made. Demand for power and configure in robot dog power equipment is briefly analyzed, improved backward power match between gasoline and pump is presented, power and flow rate match between gasoline and pump is calculated, control strategy based on pump pressure feedback is applied into gasoline engine control in order to save energy. With experimental bench test, experimental results showed that energy saving matching of power equipment can meet the requirement of fast dynamic meditation for robot dog .

Introduction

Combined with many techonolgies of articulation mechanism, hydraulic pressure transmission, electronic control and intelligent control[1], robot dog used four–footed constructure motion style so that it can do work in the harsh condition, robot dog plays an important role in emergency-saving and disaster-saving and explosion-proof. In order to make rapid reaction to the change of road surface and weight, good mobility is needed for bearing burdern four-footed robot dog, power equipment with high power density and flexible control is needed, since there are some advantages of small volume, large torque and easy control for variable bump system, and small volume, easy starting for gasoline engine[2], small gasoline engine and variable bump are selected to form power equipment. When it worked, regular change load of variable bump made gasoline engine to operate in range of high fuel consumption, engine power is not reached optimal value, power match between gasoline engine and variable pump directly affected dynamic character and stabilization, there are many literatures and technology matertials published in professional periodicals, most for hydraulic prssure grab, such as, [3] presented nomal work range in max power and lower fuel consumption area when power match between gasoline engine and variable pump is made for full hydraulic prssure grab, in order to prevent large rotation speed undulation, rotation speed of gasoline engine is controlled to optimal speed range by means of digital PID using limit load. [4] used rotation speed sensoring control strategy to adjust pump input power to match output power in gasoline engine. in order to keep operation speed of gasoline engine in range of saving energy.[5] used step-motor to reform mechical throttle valve to preform electronic control, and control step motor by microprocess 68376, so that opening angle of electricity throttle valve is effectively controlled, all these literatures are focus on stable condition. According to requirement of high speed reaction to transient operation of robot dog, based on electronic controlled reforming for foreign single cylinder, improved backward match method based on bump pressure feedback is presented, calculation process of work flow rate for variable pump and savign energy match of gasoline engine is given, final match test is made to verify match validity.

1 Power Equipment

Four-footed bearing-burden robot dog is made up of power equipment, articulation structure, hydraulic pressure system, electric control system, sensoring system and top controller, as shown in figure 1.

According to overall sketch requirement, overall index for power equipment is large power, light weight, high reliability, high ratio of performance and price, its technical parameter is : power 20kW, weight 20kg , hydraulic pressure 20MPa, foreign gasoline engine with two strokes and

single cylinder is selected as power resource, electronic controlled threttle valve and electric control system are added to this gasoline engine,it performs precision control and profile mediation, power equipment arrangement is shown in figure 2, the technical parameter of gasoline engine is power 20kW, Max rotational speed 18000 r/minm, Max torque 100N m and hydraulic bump is power 14kW, Max rotational speed 4000 r/minm, Max torque 80N m. Gasoline engine provided power to robot dog, rotation of variable pump is driven by crankshaft of gasoline engine, load is input torque of variable pump, according to change of road surface and weight, flow rate is continued to mediate and to keep hydraulic pressure system in stable condition, electronic control system automatically regulated throttle valve angle to meet real power demand according to system pressure.

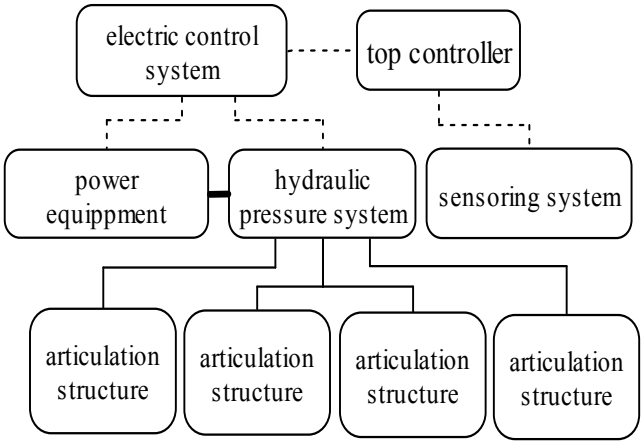

Fig.1 Basic constructure of robot dog

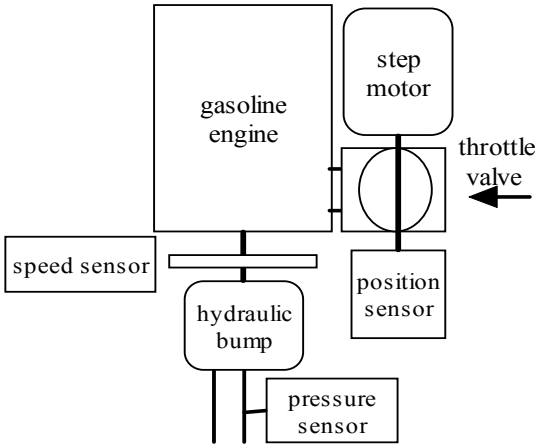

Fig.2 Arrangement of power equipment

2 Match Method

The goal of saving energy match in dynamic equipment is that rotation speed and output torque of gaoline engine can adapt to external load and continue to change, and it makes real work point of gasoline engine to optimal saving energy point: high power and lower fuel consumption. while it fullfils basic match among gasoline, variable pump and external load. Three are two kind of traditional match method: forward match and backward match, backward match method is improved to increase dynamic equipment, its principle is shown in figure 3.

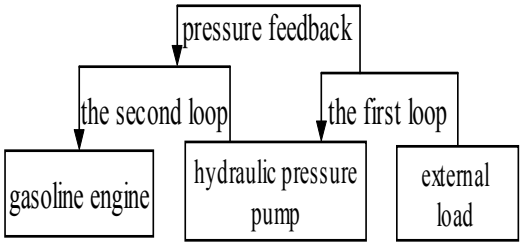

Fig.3 Match principle of backward match method

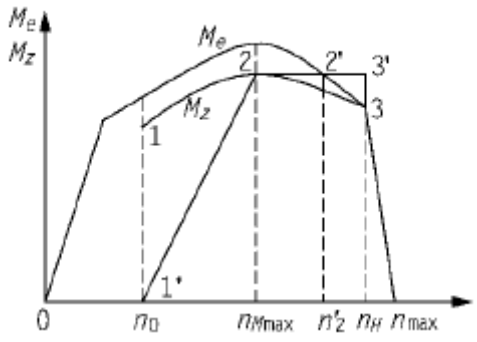

—effective engine torque z —pump load torque

Fig.4 Max engine torque character and pump target load

The first loop fullfils match between pump and external load, self–adaption control is used to adjust output flow to meet the demand of robot dog. The second loop makes match btween gasoline engine and pump, closed-loop control for throttle valve is made to gasoline engine, the third loop is a connection between first loop and second loop, hydraulic pressure is used as feedback to gasoline engine to sensor the work condition of robot dog. Since road surface makes walking posture change, in order to keep balance condition of robot dog walking, it needed to fast response change of external load to gasoline engine control, output pressure of variable pump conresponds to external load, pressure change speed is higher than rotation speed in indicating change of external load, hydraulic pressure connects the two loop, hydraulic pressure is used to predict to relative torque of gasoline engine, closed-loop control for throttle valve is made to gasoline engine

according to prediction torque, it makes gasoline engine output torque to reach target and assure pump to absorb all output power of gasoline engine

3 Match Calculation

3.1 Gasoline engine

Different performance is corresponding to different operation profile of gasoline engine. When external resistance torque is equal to near 75 precent of max torque of gasoline eneine, gasoline engine will operate in optimal saving energy point and keep high ecnomy index.When external resistance torque is near max torque of gasoline eneine, gasoline engine will operate in max power point and keep high dynamic index.

When output torque of gasoline engine $M_e \in [75\%M_{e\max}, M_{e\max}]$ resistance torque M_i is given,angle acceleration speed a, rotation speed n is shown as follow.

Angle acceleration speed a: $a = \dfrac{M_e - M_1}{j_e}$ rotation speed n_e $n_e = \dfrac{\omega_0 + \alpha t}{2\pi}$ (1)

Where, M_1 is external resistance torque, Me is output torque, J_e is running inertia.

3.2 hydraulic pressure pump

Gasoline engine connects with hydraulic pressure pump by transmission case, absorbing power N_p of hydraulic pressure pump is equal to output power N_e of gasoline engine in optimal operation point.

$$N_p = p_p q_p n_p = N_e \tag{2}$$

To keep pump to work in high efficiency point and gasoline engine in good dynamic and fuel consumption, max power of engine target load is selected as control target for hydraulic transmission, pressure difference Δp is used as sensor value, output flow rate of optimal profile in pump is followed.

$$q_p = \frac{6000 N_{e\max} \eta_{pt}}{\Delta p \cdot n} \tag{3}$$

Where, Δp is pressure difference, n is rotational speed of pump, q_p is output flow rate, $N_{e\max}$ is rating power of gasoline engine.

Relation of Max torque character in gasoline engine and target load in pump is shown in figure 4. When 90 percent of max power of gasoline engine is selected as pump power,corresponding ideal load curve MZ 1-2-3, combined real condition, ‘- - ’ line is real target curve, out put flow of pump is followed.

When $n_0 \le n \le n_{M\max}$ $q_p = \dfrac{6000 \times 0.9 N_{e\max}(n - n_0)}{n_{M\max} - n_0} \times \dfrac{\eta_{pt}}{\Delta p \cdot n}$

When $n \ge n_{M\max}$ $q = q_{p\max}$

Where, $N_{M\max}$ and $n_{M\max}$ is power and rotation speed in max torque profile respectively, n_0 is starting speed of pump, $N_{e\max}$ is rated power, $n_{\min}$ is idle speed of gasoline engine.

4 Experimental verification

4.1 Matching performance

According to operation requirement of robot dog, idle speed of gasoline engine is set to 2300r/min, stable operation speed is 12000r/min, max rotation speed is 16000r/min, torque of engine and pressure of pump is measured dynamically, when engine operated in stable speed range, parameters of pump and engine are shown in figure 5. From figure 5, pump pressure change is located in 11000-12000r/min range, this rotation speed is work range of max torque in engine, it showed that load change of pump is suited to optimal operation range of gasoline.

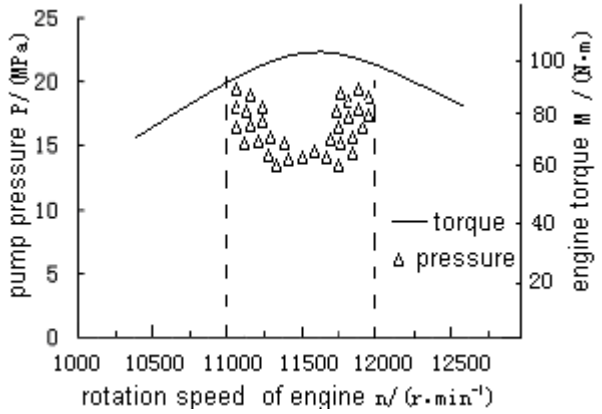

Fig.5 Parameter change of gasoline and variable pump

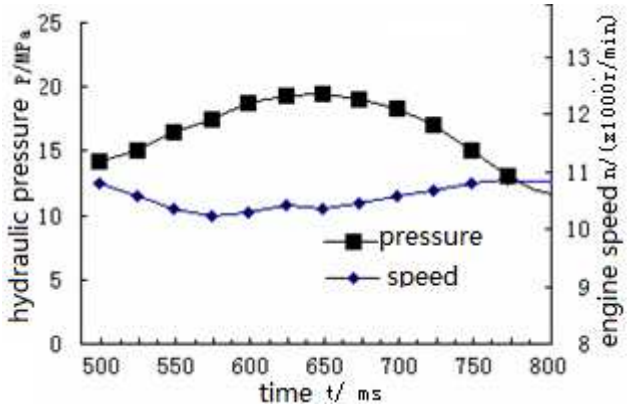

Fig.6 Rotation speed change of gasoline

4.2 Control Effect

Power equipment load is varied with walk gesture and bearing-burden condition of robot dog, in order to keep hydraulic system pressure to a fixed range, rotational speed of gasoline engine is required to control in real time by ECU and change in a given range. When hydraulic system pressure is fixed to 15-20MPa and gasoline engine rotation speed target is 10500r/min, real speed control effect under varying load is shown in figure 6. Seen from fig.6, when hydraulic system pressure is changed, real speed varied under the setting speed target, varied amplitude is about ±100r/min, and there is no oscillation speed to appear.

5 Conclusions

Acccordingto operation requirement of power equipment in robot dog, improving backward match method is presented, match calculation process of saving energy between pump and engine is provided, fast prediciton torqure by sensoring pump pressure is found for gasoline engine, saving engine in transient condition of power equipment is effectively resolved. Experimental result showed that gasoline engine can operate in high efficiency range and fast reaction meditation is achieved.

Keywords: Photovoltaic; Frequency Regulation; Power Tracking Control Strategy; Droop Control

Abstract. PV (Photovoltaic) generation output with MPPT (Maximum power point tracking) is unadjustable. In this paper, PV generation is expected to regulate grid frequency. Thus a power tracking control strategy based on feedback frequency instead of MPPT is put forward. The feedback frequency is transferred to controlling unit of DC-DC inverter. The DC bus voltage is adjusted by controlling the duty cycle of DC-DC invertor. A grid-connected PV system with a power tracking control strategy based on feedback frequency and a DC-AC inverter control module are built in MATLAB-Simulink platform. Experiment result indicates that PV generation could regulate grid frequency by the control strategy based on feedback frequency.

Introduction

Maximum power point tracking (MPPT) is widely used in Photovoltaic (PV) to make the output efficient since MPPT could achieve the max PV outputs. Nowadays with the development of large-scaled PV generation, PV generation is expected to regulate grid frequency. PV generation output with MPPT is unadjustable so that PV generation cannot participate in frequency regulation. A new control strategy is needed to take place of MPPT, which can make DC bus voltage adjustable to regulate grid frequency.

Analyzing the PV characteristic curve is the first thing to research the PV generation. In paper [1], a simulation model of PV module based on Simulink is built in accordance with PV module's physical and mathematical model. The $I \sim V$ curve of PV is determined by this physical and mathematical model. There are a lot of methods of MPPT used in PV generation, and paper [2] introduces a tracking method named P&O (Perturbation and Observation), which is the most widely applied in MPPT control for PV generation. A DC-AC inverter is the key link of the grid-connected PV generation. Paper [3] studied the deadbeat control strategy for the grid-connected current in three-phase voltage-type PV grid-connected inverter. In paper [4], the hierarchical control is applied to ac micro grids, solving the tradeoff of the droop method by implementing a secondary control loop and capable of operating in grid-connected and islanded modes.

In this paper, a power tracking control strategy based on feedback frequency is put forward. DC bus voltage is adjusted by controlling the duty cycle of DC-DC invertor. Then PV could regulate grid frequency when the frequency is fluctuating. This paper is organized as followed. In section of 'Power Tracking Control Strategy based on Feedback Frequency', PV characteristics and mathematical model are analyzed, and a new control strategy is put forward. In section of 'Control Structure of DC-AC Inverter', droop control and double loop control strategy are used in large-scale grid-connected photovoltaic inverter, which assume unbalance power of inverter. In section of 'Simulate Results', a grid-connected PV system with power tracking control strategy based on feedback frequency and a DC-AC inverter control module are built in MATLAB-Simulink platform and the waveform of DC bus voltage and active power is obtained.

Power Tracking Control Strategy based on Feedback Frequency

The solar cell equivalent model is made up of ideal current source I_s, antiparallel freewheeling diode D, series resistance R_s, and parallel resistance R_{sh}. The value of I_s is equal to the short-circuit current, which reflects the insolation and temperature of the solar cell. The I~V characteristic equation of the solar cell is shown as equation (1):

$$I = I_s - I_0 \left\{ \exp\left[\frac{q(V + R_s I)}{AKT} \right] - 1 \right\} - \frac{(V + R_s I)}{R_{sh}} \tag{1}$$

In equation (1): I is operating current of solar cell; I_s is short-circuit current; I_0 is reverse saturation current; q is charge constant; V is output voltage; A is diode P-N junction coefficient; K is Boltzmann constant; T is absolute temperature. The I~V curve will be got by equation (1). But the five coefficients including I_s, I_0, R_s, R_{sh}, A, which are related to the temperature of solar cell and insolation, and they are difficult to confirm. This model is not convenient for engineering application. Solar cells used in engineering application require several important parameters, such as I_{sc}, V_{oc}, I_m, V_m, P_m. The PV array character is equivalent to an engineering simplifying model by ignore $(V+R_sI)/R_{sh}$, and considering I=0 $I = 0$, V=V_{oc} at the condition of open circuit, while V=V_m, I=I_m at the condition of short circuit. The engineering simplified mode is showed as:

$$I = I_{sc}\left\{1 - C_1\left[\exp V/(C_2 V_{oc}) - 1\right]\right\} \tag{2}$$

$$C_1 = (1 - I_m/I_{sc})\exp\left[-V_m/(C_2 V_{oc})\right] \tag{3}$$

$$C_2 = (V_m/V_{oc} - 1)\left[\ln(1 - I_m/I_{sc})\right]^{-1} \tag{4}$$

In equations (2), (3) and (4), C_1 and C_2 can be determined by I_{sc}, V_{oc}, I_m, V_m. The I~V curve is determined by equation (2). The P~V curve is a single peak curve determined by I*V~V .

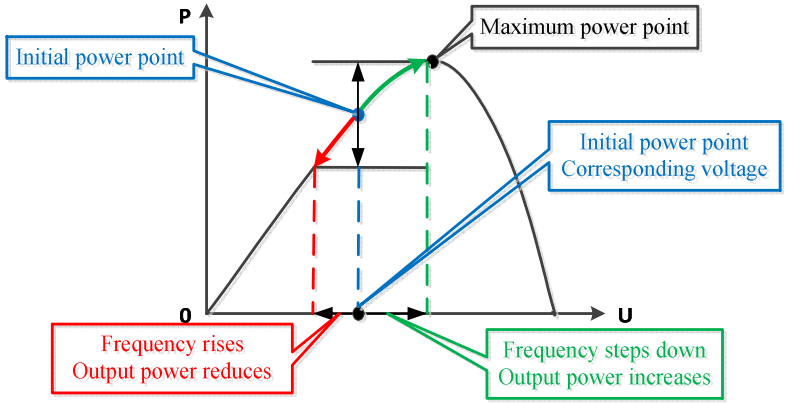

Fig.1. Power tracking control strategy on P~V curve

Fig.1 shows the theory of power tracking control strategy. In order to make the PV generation participate in regulating frequency, the output power of the DC-DC inverter control unit will not export at the maximum power point with MPPT. So the PV generation sacrifices some power. And the output voltage of DC-DC inverter is a little bit smaller than the maximum power point voltage. When the grid frequency is fluctuating, the voltage has an allowance to increase or decrease to change the duty cycle of DC-DC inverter. So the corresponding output active power is changed to regulate frequency.

TABLE 1 Adjustment of output voltage and active power based on grid frequency

		Power point on P~V curve	DC bus voltage	DC bus power
grid frequency	rise	move left	decrease	decrease
	decrease	move right	increase	increase

The power tracking control strategy is based on feedback frequency. Set the initial output power point a little bit lower than the maximum power point, in other words, the corresponding voltage is

on the left side of the maximum power point voltage. When the system frequency rises, the tracking point moves left and the output active power reduces. On the contrary, when the frequency reduces, the output active power increases. The adjustment of output voltage and active power based on grid frequency is showed in Table 1. This tracking strategy makes the PV generation output power adjustable, so the PV generation could participate in regulating frequency.

Control Structure of DC-AC Inverter

By analyzing the output characteristic of inverter, the output power is expressed as:

$$S = P + jQ = \dot{E}\dot{I}^* = \dot{E}\left(\frac{\dot{U} - \dot{E}}{\dot{Z}}\right)^* \tag{5}$$

In equation (5): E is the bus voltage of the grid side; U is the output voltage of the inverter. Suppose the angle of the grid is 0, and the power angle isφ. Z is the impedance between inverter and the grid and θ is the impedance angle with $Z\angle\theta = R + jX$. X is much bigger than R when Z is inductive by ignoring the resistance R . So Z would be considered as X, thus $\theta \approx 90°, \sin\theta \approx 1, \cos\theta \approx 0$, and then the active power and reactive power can be expressed as:

$$\begin{cases} P = \left(\dfrac{EU}{Z}\cos\phi - \dfrac{E^2}{Z}\right)\cos\theta + \dfrac{EU}{Z}\sin\phi\sin\theta \\ Q = \left(\dfrac{EU}{Z}\cos\phi - \dfrac{E^2}{Z}\right)\sin\theta - \dfrac{EU}{Z}\sin\phi\cos\theta \end{cases} \Rightarrow \begin{cases} P = \dfrac{EU}{Z}\sin\phi \\ Q = \dfrac{E}{Z}\left(U\cos\phi - E\right) \end{cases} \tag{6}$$

According equation (6), it could be obtained that P is determined byφ and Q is determined by U-E when the power angleφ is so small that it could be ignored. In this condition, P and Q could be controlled independently. Classical droop control strategy $P \sim \omega$ and $Q \sim U$ are used as the control theory of the inverter. The droop characteristic equations are expressed as:

$$\begin{cases} \omega = \omega - m_p P \\ U = U_0 - n_q Q \end{cases} \tag{7}$$

In equation (7): ω_0 and U_0 are the frequency and voltage at non-load; ω and U are the frequency and voltage in reality; m_p and n_q are the droop gain of frequency and voltage. On the basis of traditional inverter strategy, the closed-loop dynamic behavior of inverter output voltage and current control loop have to be considered. Fig.2 shows the control structure of the inverter.

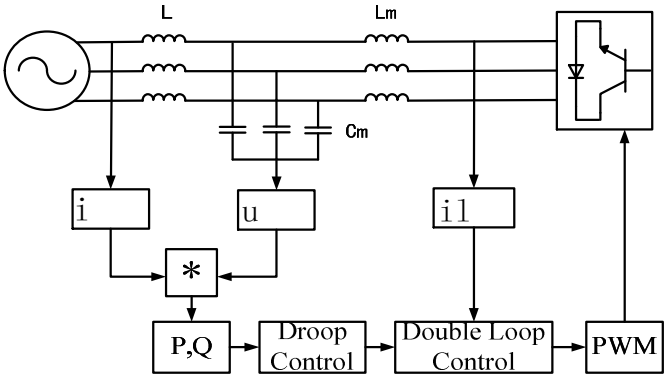

Fig.2. Control structure of the DC-AC inverter

The control structure in fig.2 includes three parts: the first part is used to calculate P and Q. The current and voltage on the AC side are transformed into the ones in dq coordinates by introducing Park's Transformation, and then P and Q could be calculated. The second part is droop control, which calculates the output voltage and frequency by PQ droop characteristic showed in equation (7). The third part is double loop control, which could reduce the high frequency interference and keep frequency stable. The double loop control structure is showed in fig.3.

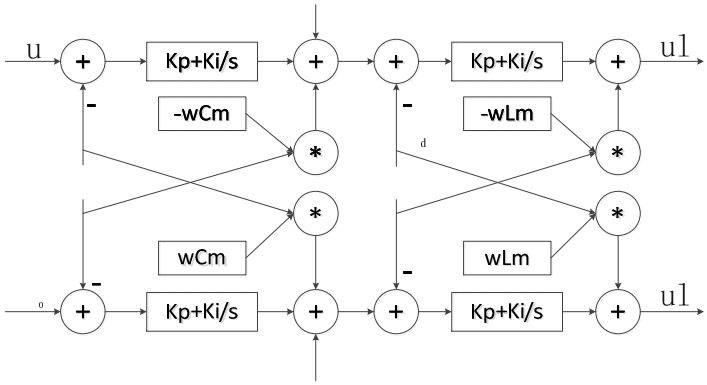

Fig.3. Double loop control structure of the inverter

Simulate Results

The grid-connected PV module is built in MATLAB-Simulink. The system simulation is showed in fig.4. Set a frequency fluctuation of the system and feed it back to DC-DC inverter control unit. According to the control of duty cycle, the DC bus output voltage and active power is adjustable. The system frequency keeps stable with PQ droop control and double loop control strategy.

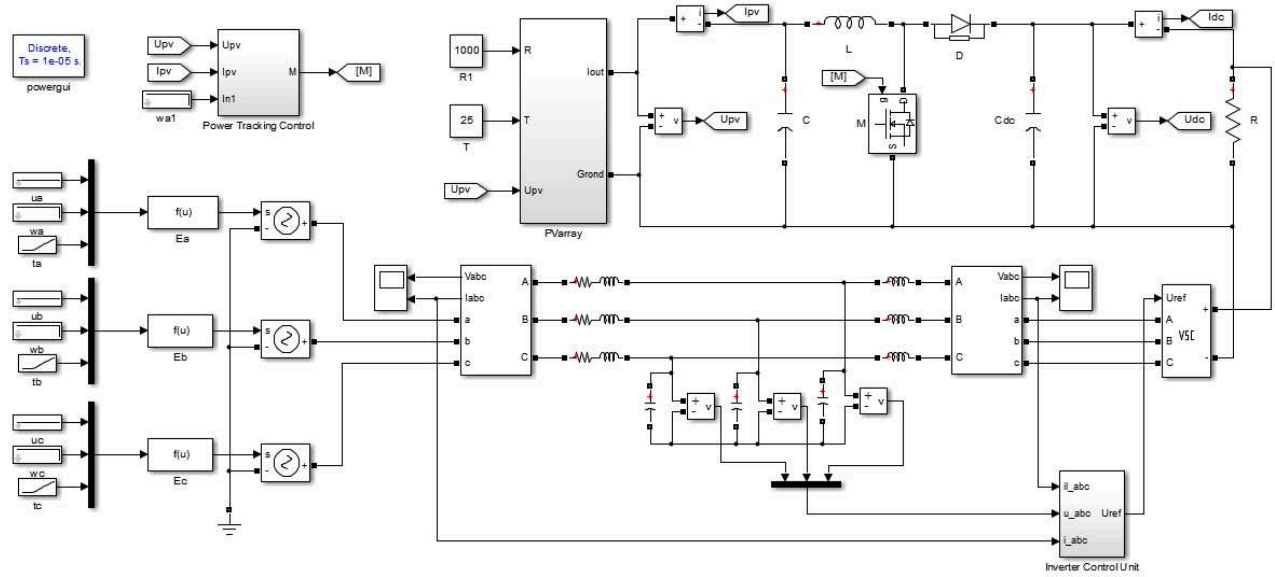

Fig.4. PV system simulation

There is a frequency fluctuation at 0.05s and the grid frequency reduces 1Hz from 50Hz to 49Hz. The tracking point on *P*~*V* curve moves to the right and the output active power increases. The duty cycle of DC-DC inverter changes to adjust the DC bus voltage. PV output power increases to regulate grid frequency. The simulation of PV output voltage and power is showed in fig.5.

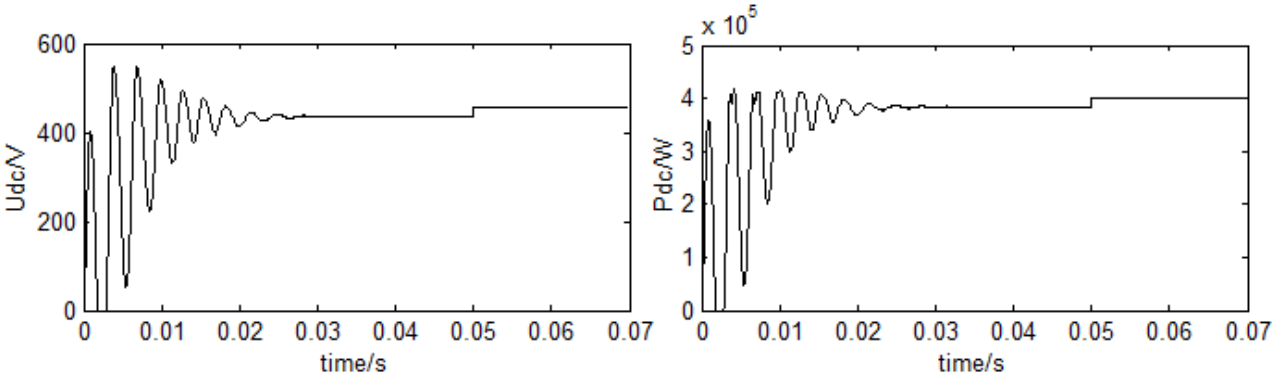

Fig.5. DC bus output voltage and power wave of the PV system simulation

When the system frequency steps down, the tracking point moves to the right then the voltage increases from 437V to 457V, and the output active power increases from 384kW to 402kW. The PV generation output adjusts quickly to adapt to the frequency and stabilize the fluctuation to keep the system frequency stable. By PQ droop control, it has a batter effect on frequency stability.

Conclusion

Based on power tracking control strategy and the control of duty cycle, the DC bus output voltage and active power are adjustable. Thus PV generation could participate in regulating frequency when the grid frequency is fluctuating. The system frequency keeps stable with PQ droop control. Double loop control could reduce the high frequency interference and keep frequency stable. The control strategy is feasible and it makes a contribution to regulate grid frequency and keep frequency constant.

Research and development of the wind power monitoring system for North China Power Grid

Li Lixing

Department of electric power engineering, North China Electric Power University, Baoding, China

Email: lilixing123123@gmail.com

Keywords: North China Power Grid, wind power, monitoring system, output characteristics

Abstract. Facing to the current environment, energy pressure and wind power development at home and abroad, combined with the actual situation of North China Power Grid, this paper analyzes the wind development in North China firstly, and then based on C# language and the Oracle database develops based on B/S mode of wind power monitoring informing system. This system includes monitoring module, wind data mining module, data management module, real-time alarm module, and the user management module, which realized the wind power in North China Grid remote monitoring and statistical analysis of the data, to ensure data consistency.

Introduction

North China Power Grid Company made response to the new national energy policy actively, active docking for planning of power grid construction and new energy development. There are abundant wind resources in north China, such as Inner Mongolia region, zhangjiakou in BTT (Beijing-Tianjin-Tangshan) region and Chengde bashang region. At the end of 2008, the BTT power grid scheduling directly under wind power installed capacity of 797 MW (megawatt), reached 1378 MW by the end of 2009, and the total installed capacity of wind has been researched 3.3 million kilowatts in the end of 2010 [1-3]. Now, Tens of millions of MW level wind power base in hebei province is planning, predicts a total installed capacity of wind electricity will be 7.5 million kilowatts in 2015 for north region of hebei. Wind power plant is developed from the situation that small-scale access to the low-voltage power grid to the other, which based on large-scale and accessed to high voltage level. With the establish of millions of wind power and wind power base level, wind power will develop at an unprecedented speed.

With the rapid development of wind power technology, the scale of wind power expanded as well. There is different from the small-scale wind power, the influence made by the large one have been expanded from a simple voltage fluctuation problem to the power adjustment control, quality of electric energy and power system stability [4]. The intensive production of Large-scale grid wind farms will make the power grid peak shaving contradictions become more prominent. Output of the wind turbine is determined by the crew size characteristics and wind speed, and the characteristics of wind speed are change uncertainty. Considering the worst case, that in the load peak situation the wind generator output is zero and in the low load the output of wind become largest [5]. In this situation, the wind power not only can not participate in peak shaving, but also increasing the difficulty of the load peak shaving and increase the requirements for the thermal power unit [6, 7].

Based on the former introduction, real-time monitoring of wind power system operation condition and reasonable scheduling wind power resource is very important. The wind monitoring system could monitoring the operation condition real time of wind farms in the scheduling area, analyze the historical accumulation of wind data and provide a Data platform for further research, such as wind software development, wind power forecast and so on.

Summary of the monitoring system

The wind monitoring system is a monitoring and control system for wind power system based on the date of scheduling system and the energy management system. Its main purpose is to realize the real-time monitoring of grid wind farm operation, DM (data mining) according to the accumulation

of basic data and understand the operation of the wind characteristics. Then provide a powerful basis for wind guiding and as a subsequent management of data platform. This system processing and analysis the collected data at the same time and realize the global monitoring and macro management. The final purpose of this system is wind power prediction function and scheduling based on the prediction.

This system is developed by three layer architecture of B/S mode. The communication principle is as follows [8]:

(1) The client browser makes a request to the server for accessing the database and the requirement in the form of HTTP.

(2) The Web server accepts the client request, transfers the request to SQL syntax, and sends it to the database server.

(3) The database server receives the request and verifies its legitimacy, then carries on data processing and return the results back to the Web server.

(4) The Web server transfers the results in the form of HTML, forwarded to the client browser and displays the results in a form of friendly Web page.

The structural model is shown in figures 1.

Fig.1 Structural model

Data sources

The data of wind power monitoring system for North China Power Grid mainly comes from the scheduling monitoring system and the energy management system [9]. They are all based on the scheduling platform of North China Power Grid Dispatching Center (NCPGD).

According to the data of different nature, wind power monitoring system data sources are different. The data mainly come from the provincial scheduling, local scheduling and the direct dispatching. Some data consist of the real-time data and historical data of monitoring system, some data consist of artificial data and statistics date of management system, and other data consist of wind power plant and scheduling center. Whatever the kinds of the data, they are all transferred by the follow ways:

(1) Using the terminal way from the site or region and the province reported data.

(2) PI (Plant Information System) database data.

(3) OMS (Open Mobile System) data.

Systematic designs

The overall structure of data mining and analying system is shown in Fig 2, and the Fig 3 shows the way of data transmission.

The system extract the data of real-time wind power by PI data interface module and the electricity data from Oracle database by OMS module. Then deposit the real-time wind power and electricity data to the Oracle database of the data mining and analysis system of North China Power Grid., and proide the synchronous storage by interpolation processing. The delayed data system needed typed in manually and realize the important function, such as wind power real-time monitoring, wind power data query, data mining analysis and WebGIS function. This function can be realized through the IE browesr for the LAN users.

The system decomposed the information processing into five parts: basic information, real-time data, alarm data, historical data and report data. Every informations are mainly processed by database.

This syetem is mainly composed by six modules: monitoring function module, data mining function module, data management module, real-time alarm module, user's system management module and help module of the system.

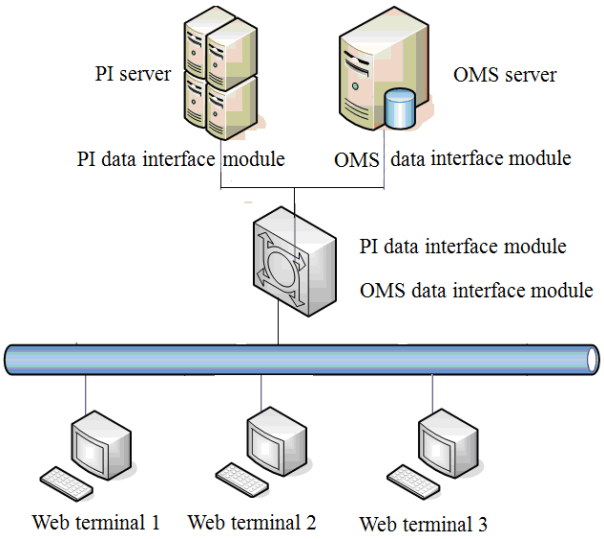

Fig.2 Overall structure of system

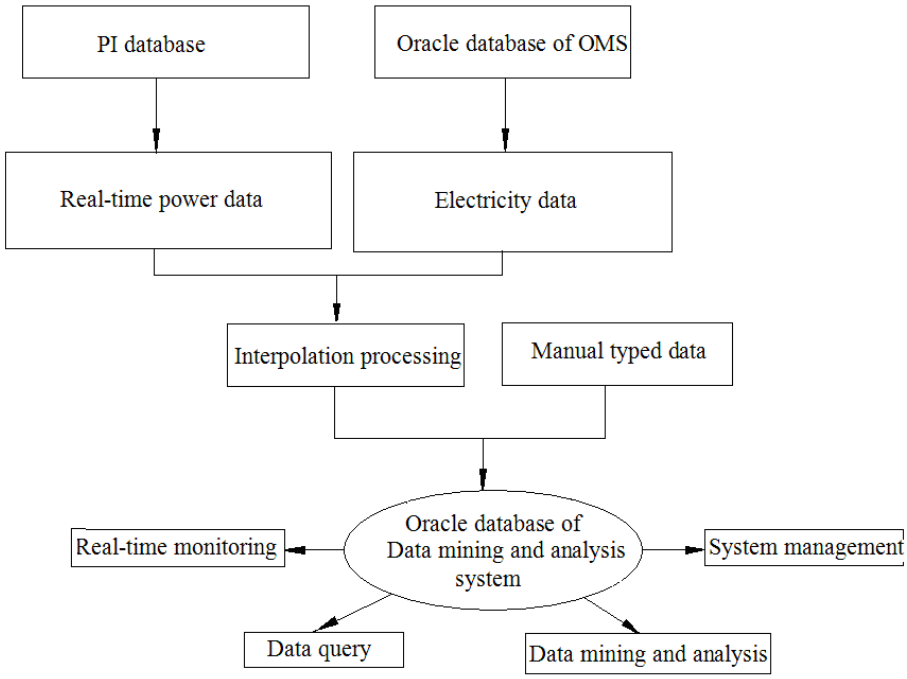

Fig.3 Data flowchart

Analysis of system function

Data mining and auxiliary decision-making function is based on the collection of real-time and historical data. This function can not only analyze all sorts of equipment running status, format related statements and analyze results according to the statement, but also evaluate the current situation of equipment operation. The evaluation is easy to adjust equipment maintenance and product selection, so as to decide whether to continue to promote a device, rather than simply reflects the current problems. The content of analysis includes the daily wind power, the difference between peak and valley, short-term fluctuations, wind power utilization hours etc.

Output sequence features of wind power

Wind power generation is the main rely on wind energy and the biggest characteristic of wind energy is uncertainty and instability. For this reason, the wind power generation also has the instability and volatility. But on the other hand, the wind power has some regularity with a day a quarter or a year. It is important to analyze the output sequence features for mastering the regular pattern of wind power output change, increasing the accuracy of the scheduling staff and improving the system security and economy.

1) Circannual output features of wind power

This system drew the monthly average output during January 2010 to January 2011 through the real-time data of wind power. The data in figures is the average values of the data in one day, which is typical day every month. The figures show in Fig 4.

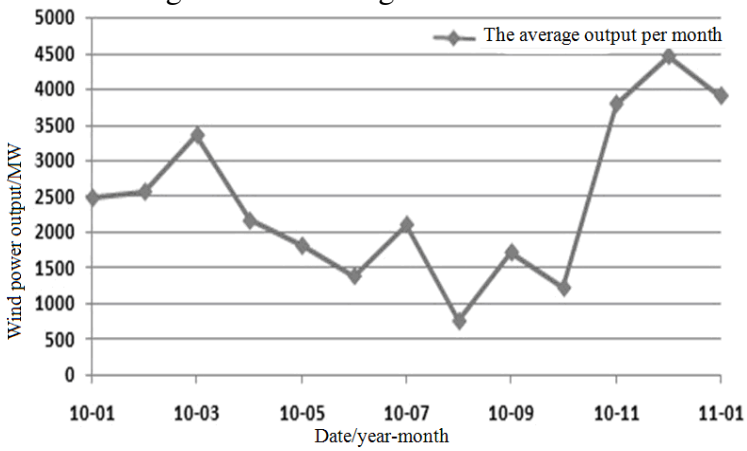

Fig.4 Monthly average wind power output

Wind power output has certain seasonal characteristics of North China Power Grid: wind power output significantly larger in spring and winter, but slightly low in summer and autumn. The maximum average output in winter is about twice the summer and fall wind power output.

2) Daily output features of wind power

Because of the obvious seasonal characteristics, this paper averaged wind power output data which exist in every season in the same time and drew the typical daily output curve of different seasons, as shown in Fig.5.

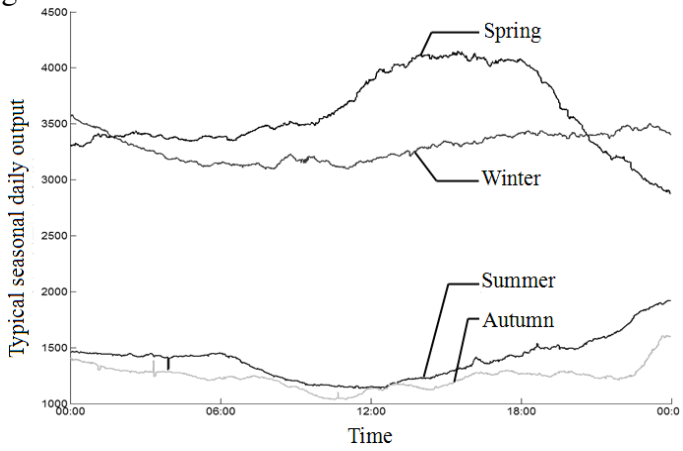

Fig.5 Typical daily curves of seasonal wind power output

Quantity of electricity

This system could display the quantity of electricity of wind power plant, such as Provinces North China Power Grid, BTT Power Grid and each straight scheduling wind farm. Taking an example of BTT Power Grid, figure 6 shows the quantity of wind electricity in 1-5 month.

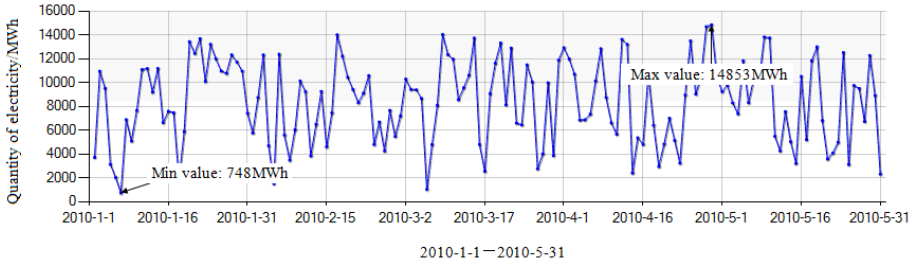

Fig.6 The quantity of wind electricity

Wind power utilization hours

Wind power utilization hours equal to using hours at full power, reflect the generated energy of wind power plant in the statistical cycle. It could visually check the wind power situation. Taking an

example of BTT Power Grid, figure 7 shows the wind power utilization hours and converted value for all the year round.

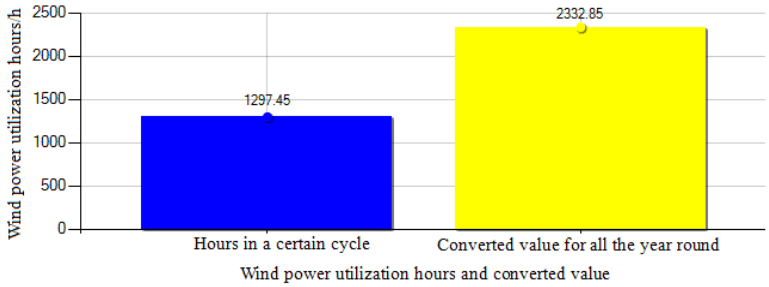

Fig.7 Wind power utilization hours

Alarm module

The wind power alarm module is necessary to monitor the wind plant. It related to normal operation of the wind farm monitoring, safety of the wind farm and even safety of the power grid. In this system, alarm module contrapose the problem of a certain wind farm, as Fan repair or closing down. If there are some problems of a wind farm, this system will display the source and flashing alarm lamp. It will eliminate when the farm become normal.

Conclusions

The wind power monitoring system real-time monitoring the North China Power Grid and the wind farm based on the real-time data. This system analyze the related statistics and data mining at the same time and provide powerful basis for guiding wind power operation.

The system is not perfect, the monitoring system should predict the wind power and wind power scheduling based on monitoring data the in the future. This monitoring system makes the analysis of the effect of wind farm on line possible, and lay a foundation for large wind power grid safe and stable operation and reasonable allocate resources.

Research and simulation on the energy-saving control model of large-scale intelligent electromechanical device

ZHANG Yun-long

BaoTou Light Industry Vocational college，Mongolia,Baotou,014035

Keywords: electromechanical device; energy-saving design; non-essential energy

Abstract: In energy-saving control process of large-scale-scale intelligent electromechanical device, it is need to consume non-essential energy. To reduce energy consumption, energy-saving design method is proposed based on adaptive linear genetic algorithms. According to theory of adaptive particle swarm optimization, optimal particle is searched in the global domain, which provides basis for energy-saving control of large-scale-scale intelligent electromechanical device. According to adaptive linear genetic theory, energy-saving control model of large-scale intelligent electromechanical device is built to complete energy-saving control. Experimental results show that algorithm can effectively reduce energy consumption and obtain satisfactory results.

1 Introduction

With worldwide energy shortage, China's energy is continually in emergency [1]. To relieve energy crisis of production and life, energy conservation measures need to be spread to different areas [2]. Therefore, energy-saving control design for large-scale intelligent electrical and mechanical devices becomes a hot issue in the field of energy research by the attention of many experts [3]. At this stage, major methods for control design of large-scale-scale intelligent electromechanical device includes energy-saving control methods based on dynamic adjustment algorithm, multi-core embedded algorithms and dynamic balance algorithms [4]. Among them, the most commonly control method is based on dynamic adjustment algorithm. Due to constantly expanding application of energy-saving control methods for large-scale intelligent electromechanical device, there is a broad space for development, as is the main subject of research in energy field [5].

2 Relevant principles of energy-saving control method for large-scale intelligent electromechanical device

2.1 Energy saving control parameters calculating

According to theory of adaptive particle swarm optimization, global optimal particle is searched to calculate energy-saving control parameters, which provides technical support of energy-saving control for large-scale intelligent electromechanical device. Specific steps are as follows:

Step1：Generate random particle populations and speed according to a given search space.

Step2：Calculate value of objective function according to objective function and all generated particles.

Step3：Calculate the global optimum.

Step4：Vary weight and learning factors according to evolutionary generation,.

Step5：Modify position and velocity of particles according to updating formula of speed and position.

Step6：Calculate objective function value by updating particles.

Step7：Determine whether objective function value is less than global optimum.

Step8：Unchange global optimum value if objective function value is large-scale; replace objective function value if global optimum is large-scale.

Step9：Determine whether to meet maximum evolutionary generation, if not go to Step 4; if is go to Step 10.

Step10：Output global optimum value and obtain global optimum variable values.

As optimizing energy-saving control system of electromechanical device, test functions employed are: in Sphere Model $f_1=\sum_{i=1}^{N}x_i^2$ function， in Schwefel's Problem 2.22 $f_2=\sum_{i=1}^{N}|x_i|+\prod_{i=1}^{N}|x_i|$ function, in Schwefel's Problem 1.2 $f_3=\sum_{i=1}^{N}(\sum_{j=1}^{i}x_i)^2$ function， in Schwefel's Problem $f_4=\max\{|x_i|\}$ function, in Schwefel's Problem 2.22 $f_2=\sum_{i=1}^{N}|x_i|+\prod_{i=1}^{N}|x_i|$ function。

For above 5 test functions, search space is the range [-100,100]. In order to simplify search process, search variable dimension is 5. To use the ability of close search, a lot of random particles are generated in search space, and then position and velocity of a particle are updated based on current best position and global best position. In the iterative process of continuous adjustment factor inertia weight and learning, all particles are gradually approaching optimal value of global energy-saving control.

2.2 energy-saving control model establishment of large-scale intelligent electromechanical

Employing adaptive linear genetic algorithm, adaptive parameter can be effectively adjusted for energy-saving control of large-scale electromechanical device, so as to reduce energy consumption. Details are described below:

Spatial location of electromechanical components and spatial position of the element as a chromosome can be expressed by following sets:

$$Y=\left[(U_1,IM_1),(U_2,IM_2)\ldots(U_k,IM_k)\ldots(U_N,IM_N)\right] \tag{1}$$

Where， U_k can be used to describe position of $k(k=1,2,\cdots,N)$ th electromechanical components, U_k can be used to describe encoding of electromechanical components,， N is the length of the chromosome.

In control process of large-scale intelligent electromechanical device energy-saving, there are many types of constraints, which can be expressed by following penalty function:

$$H_{\min}=S+\chi\times(|x_U|+|U-U_{set}|+|V-V_{set}|+load1+load2)$$
$$H_{\max}=\frac{1}{H_{\min}} \tag{2}$$

where：

$$load1=\begin{cases}\gamma & (x_k\geq x_k)\\ 0 & (w_j<\mathrm{w}_{\lim,j})\end{cases}$$
$$load2=\begin{cases}\gamma & (\frac{dc}{dv}\geq v)\\ 0 & (\frac{dc}{dv}<v)\end{cases}$$

In the above formula, c , γ and η are all corresponding penalty coefficient.

Using the following formula population conversion can be cross, in order to gain diversity of chromosome populations in control process of large-scale intelligent electromechanical device energy-saving:

$$V_{1k}^{'}=w\cdot Z_{1k}+(1-w)\cdot Z_{2k}$$
$$Z_{2k}^{'}=w\cdot Z_{2k}+(1-w)\cdot Z_{1k} \tag{3}$$

Where， $w\in(0,1)$ 。 Z_{1k} and $Z_{2k}^{'}$ are samples of chromosomes population。

3 Analysis of experimental results

In order to verify effectiveness of proposed method, an experiment is done in Visual C + +6.0 as experimental environment. Set element number of large-scale intelligent as m , necessary energy consumption as f , unnecessary energy consumption as g . Energy efficiency of energy-saving control for large-scale electromechanical device can be calculated by the following formula:

$$\omega = \frac{\sqrt{m-f}}{g^2-\varphi^2-1} \tag{4}$$

According to energy efficiency of energy saving control for these large-scale intelligent electromechanical device, effects of energy-saving control is accurately measured by different methods.

Experiments are performed by traditional energy-saving control algorithm, as obtained results are described by the following figure:

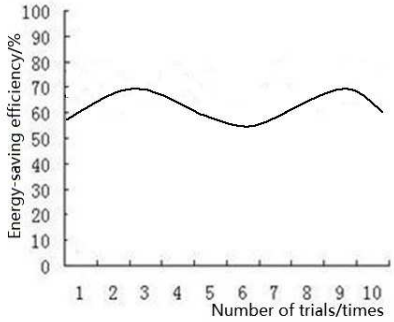

Figure1 Energy-saving control results of traditional algorithm

Experiments are performed energy-saving control algorithm in this paper to obtain results as described by the following figure:

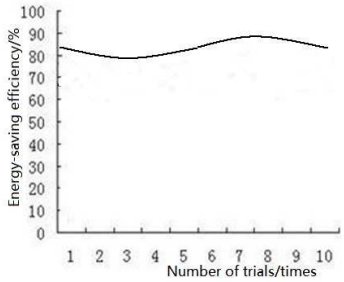

Figure2 Results of energy-saving control algorithm in this paper

Based on the above two figures, it is presented that this algorithm is employed to energy-saving control of intelligent electromechanical device; energy-saving effect is much higher than conventional algorithms.

For energy-saving control of large-scale intelligent electromechanical device by different methods, results are classified and analyzed. Table 1 can be obtained as follows:

Table1 Datasheets of energy-saving control

Algorithms	Times	Energy-saving efficiency
Traditional algorithm	10	27%
Proposed algorithm	10	46%

According to Table 1, proposed algorithm is employed for energy-saving control of intelligent electromechanical device and reduces energy effectively.

4 Conclusions

A method for energy-saving design based on adaptive linear genetic algorithm is presented in this paper. According to theory of adaptive particle swarm, optimal particle is searched in global range so as to provide the basis for energy-saving control of large-scale intelligent electromechanical device. According to adaptive linear genetic theory, energy-saving control model of large-scale intelligent electromechanical device is established and energy-saving control is completed. Experimental results show that proposed algorithm can effectively reduce the energy consumption which obtains satisfactory results.

Keywords: demand response, battery, model, ordered charging, free charging.

Abstract. Batteries have been widely used in the residential electric systems. This paper firstly analyzes the characteristics and feasibility of using the battery to participate in Demand Response (DR) programs. Secondly, the load characteristics in the two different kinds of battery systems are studied, including the power battery of electric bicycles and the battery which are used as the standby power for communication systems and computer systems. Thirdly, this paper studies the DR implementation method of reducing peak and filling valley and related impact on power grid load.

Introduction

Nowadays, the number of battery power users is growing rapidly. Battery can be used for electric bicycles (EBs), tricycles (ETs), vehicles, and also can be used for information systems such as communication systems, computer systems, automatic control systems and so on [1]. According to incomplete statistics, the number of EBs and personal notebook computers in china has reached hundreds of millions and the quantity of wireless base stations, communication rooms and data centers have reached millions. The proportion of these battery loads in residential electricity load keeps sustained growing and the load characteristics of battery have attracted the attention of Power Supply Companies and relevant departments of government. But so far the research emphases in this field still focus on the impact of electric vehicle [2] battery and energy storage battery [3] on the grid. Few articles study the relationship between DR [4-5] and battery of EBs, communication and computer systems in depth, or put forward the specific methods and effects of the battery systems participating in DR.

Based on the research of the battery's using features and charging characteristics, we know that most of equipment and systems include battery can participate in DR by changing the charge and discharge schedule. This paper presents a new approach to control the battery's charging and discharging time. We can change the behavior of the battery through DR time controller based on DR signals, to charge as much as possible at the off-peak time in order to reduce grid load and difference between peak and valley.

Strategies of battery participating in DR

Power users who want to participate in DR need the equipment include DR ability. Battery can be used as a load when charging and can be used as a power source when discharging [6]. According to related tariffs or incentives, power users change the charging and discharging behavior of battery products spontaneously, to make them discharging during the peak hours, offering energy to the load instead of the grid, and charging during the valley hours. Battery control flow is shown in Fig. 1.

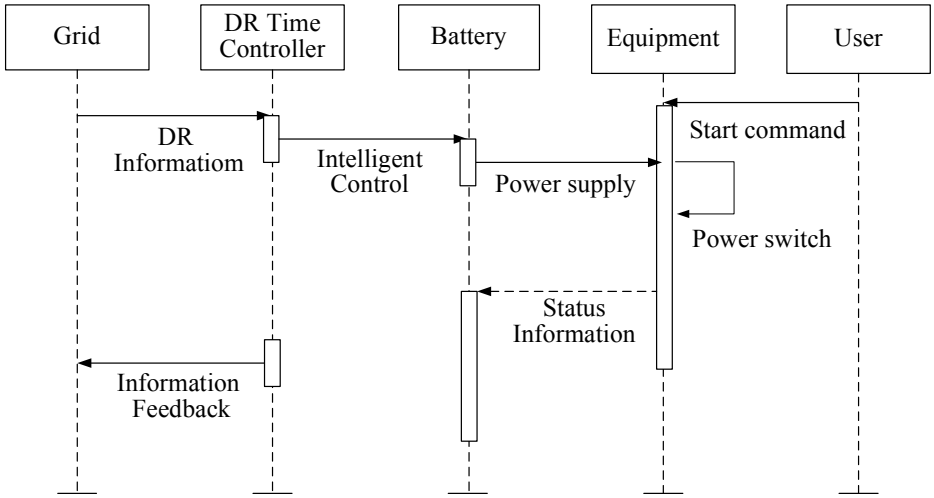

Fig. 1. Battery control flow on DR

According to their using features, the battery can be divided into two different kinds of model. One is the power battery of EBs (include ETs) whose load characteristics can be affected by the habits of the users, and the charging behavior is of randomness and intermittent which is in a disordered state of charging. The other one is the batteries which are used as the standby power of communication and computer systems. When the system is supplied by mains power, the battery has been charged fully in a floating state, and almost have no impact on the grid. In this paper, two charging models are established for these two battery systems [7], investigating the characteristics of the load of battery system and, how load affect to the grid when a certain scale of battery participate in DR.

Battery charging characteristic analysis

When battery connected to the grid, its power demand is determined by charging voltage and current. Battery charge mode can be divided into common charge and fast charge. Common charge current is 0.1C ~ 0.3C and fast charge current is 1C. Battery charging voltage is about 1.2 times of the rated voltage (U). When charging by the way of limited voltage and constant current, the battery charging power can be obtained by the charging current and charging voltage as (1).

$$P_c = U_c I_c \tag{1}$$

In the formula above, P_c represents charging power, U_c denotes charging voltage, $U_c = U \times 120\%$, I_c stands for charging current.

Battery charging time can be obtained through charging power and state-of-charge (SOC). SOC can be determined by subtracting the depth of discharge (DOD) from total capacity (C). We can get the charging time as follow (2)

$$t_c = (C - SOC) / I_c \tag{2}$$

Battery charging time can also be obtained through electricity used by battery load. If P_l represents load power, t_l represents load working time, then charging time can be estimated as follow (3).

$$t_c = P_l \times t_l / P_c \tag{3}$$

For different battery equipment, the charging time connected to the grid will be subject to certain restrictions. Different uses of batteries have different design standards which shown in Table 1.

Table 1. Standards for Different Uses of Batteries

Use of Battery	Capacity(C)	Voltage(U)	Discharge time
Electric Bicycle	10 20Ah	48V	2 4h
Electric tricycle	60 120Ah	48V	2 4h
Laptop	2 8Ah	12V	2 8h
Wireless base	500 1000Ah	48V	2 8h
Communications	2000 6000Ah	48V	2 8h

EB battery charging modeling. For EBs, we refer to the data of people's travel habits from the National Household Travel Survey (NHTS 2001) [8]. Potential interconnection hours were derived from the likely residential customer home arrival times. If it is assumed that the start time of charging is equal to end time of the last trip, the start time of charging can be considered approximately as a normal distribution model N (μ, σ2). The values of μ and σ as well as the average charging time of EBs can be estimated under certain precondition. It is generally used to take into account that EBs are charged after work, taking μ is 19 and σ is 4.

The charging load curves that a large number of EBs connected to the grid in a day can be obtained by the start time of charging, charging length, charging power and other data of every EB. Assumptions are as follows: battery capacity of EB is 20Ah and ET is 100Ah, all EBs and ETs rated charging current is 0.1C and the average depth of discharge is 50%. When the battery is fully charged, we can find the average charging time equal 5 hours, the charging power of EB is 115.2W and ET is 576W. Based on the data above, the charging load curves of 24 hours in a day can be calculated using the Monte Carlo simulation method.

Communications system load charging modeling. Standby power is to provide safe, stable and reliable power protection for reliable operation of the system. For communication base stations and communications rooms, refer to their battery capacity configuration, the equipment power of some kind of communication base station and communication room is assumed to be 2kW and 40kW and the power change is negligible. Setting N_b is the number of communication base stations, N_r is the number of communications rooms, then the system loads on the grid can be obtained as follow (4)

$$P_s = 2N_b + 40N_r \tag{4}$$

Battery resource characteristics analysis

Simulation scenario is set in Zhuji City, Zhejiang Province, China, taking the load curve of one day in the summer of 2013 for example. The number of people is about 1.2 million in Zhuji City. Assuming that ET ownership is 50,000, the number of communication base stations is 1000 and the number of communications rooms is 100. Each family has four people and one EB, EB ownership is calculated to be 300,000. When batteries do not participate in DR, the main parameters of the system, including the equipment power, charging power, charging time, discharging time, are analyzed and the daily power probability distribution of the system can be derived which shown in Fig. 2.

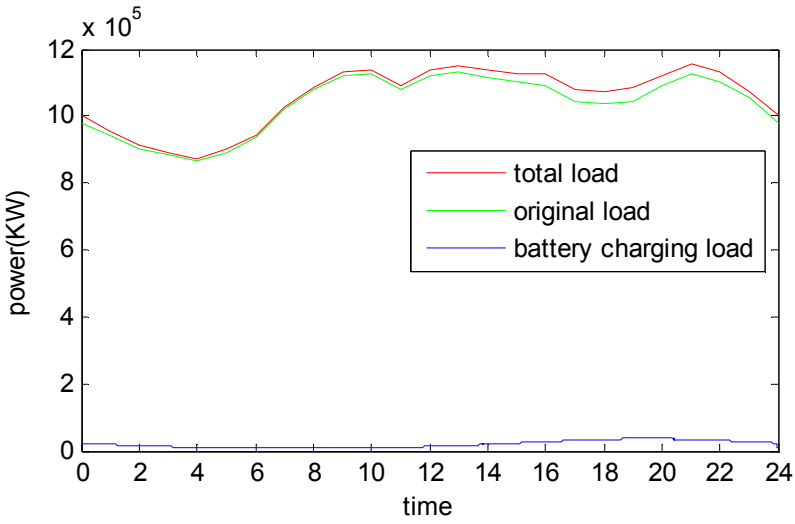

Fig. 2. Summer day load curve not participating in DR

When batteries participate in DR, a typical simulation scenario is set as follow. On the base of load curve on the grid, 24 hours was divided into three sessions in a day: Peak Hours (8:00-16:00 and 19:00-22:00）, common hours (6:00-8:00, 16:00-19:00 and 22:00-24:00) and valley hours (0:00-6:00). Price strategy of power supply companies implementing the measure is TOU. Battery obtain pricing information through DR time controller participating in DR. When participating in DR, EBs and ETs are controlled to charge as much as possible at the valley hours. 90% of the EBs (include ETs) need to participate in DR, 10% of them remain free charging. For communication base stations and communications rooms, battery DOD need to be controlled to ensure the safe operation of the system. When the system can be supplied by batteries for 10 hours, batteries are discharged 20% at the peak hours by DR time controller, i.e., two hours, and charged fully at valley hours. According to the power grid load curve, the system is supplied at 10:00-11:00 and 12:00-13:00 by batteries and then batteries are charged by the gird at 3:00-5:00.

According to the simulation of battery participating in DR, daily battery charging power probability distribution can be calculated. The change of grid load curve shown in Fig. 3.

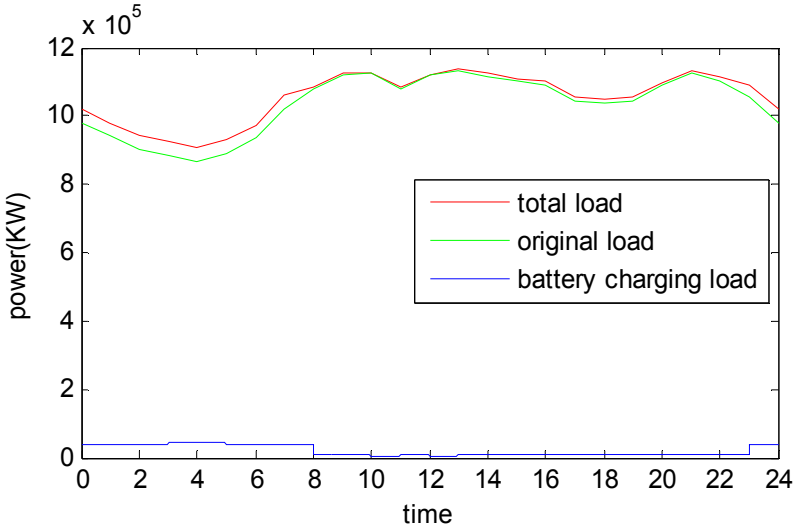

Fig. 3. Summer day load curve participating in DR

Particular targets of load characteristics shown in Table 2.

Table 2. Particular targets of grid load characteristics considering battery charging load

Mode	maximum power kW	minimum power kW	valley-to-peak kW	valley-to-peak rate
original load	1130740	865500	265240	23.4%
Free charge	1155400	874010	281390	24.4%
Ordered charge	1137892	919510	218382	19.2%

According to the simulation results, after changing battery from free charging mode to ordered charging mode, day peak value decrease by approximately 1.5%, day valley value increase 5.2%, valley-to-peak value decrease 63008kW, valley-to-peak rate decreased from 24.4% to 19.2%.

Conclusion

In this paper, we have studied two charging models which are established for the two battery systems to forecast the battery load. The simulation results have demonstrate that optimizing and controlling charging and discharging time of the battery, the operating characteristics and operational efficiency of the grid will be improved significantly, which shows the battery to participate in DR is effective.

Keywords: Intelligent Substation; Substation-area Protection; Condition Monitoring; GOOSE

Abstract. Protection equipment in intelligent substation includes Merging Unit, protection equipment and Intelligent Terminal. At present, the status of the intelligent electronic device in intelligent substation protection system is still lack of effective monitoring means. According to the characteristics that substation area protection can obtain current information of all circuits in substation through GOOSE network, a protection system conditioning monitoring relay named PSCMR is designed in this paper. Based on the principle of current differential, PSCMR can accurately identify the abnormal condition or malfunction of Merging Unit or Electronic Current Transformer and realize condition monitoring of intelligent electronic device in protection system.

Introduction

In intelligent substation, protection system contains Merging Unit, protective equipment and Intelligent Terminal [1]. At present, the intelligent electronic devices in protection system are lack of effective monitoring measures. Failure of protective equipment cannot be found in time which cannot trip for the faults in power system. And it may results in disastrous consequences [2].

In the new generation of intelligent substation, hierarchical protection system is adopted [3]. As shown in figure 1, the protection system includes local protection, Substation-area Protection and Wide-area Protection. Local protection is traditional protection, such as line protection, bus bar protection, and so on. Substation-area Protection collects voltage and current data of all circuit in substation and provide the function of backup protection, the under frequency load shedding, and so on[4-6]. Wide-area Protection installed in pivotal substation can realize backup protection, network topology analysis, power flow analysis, and so on [7-11].

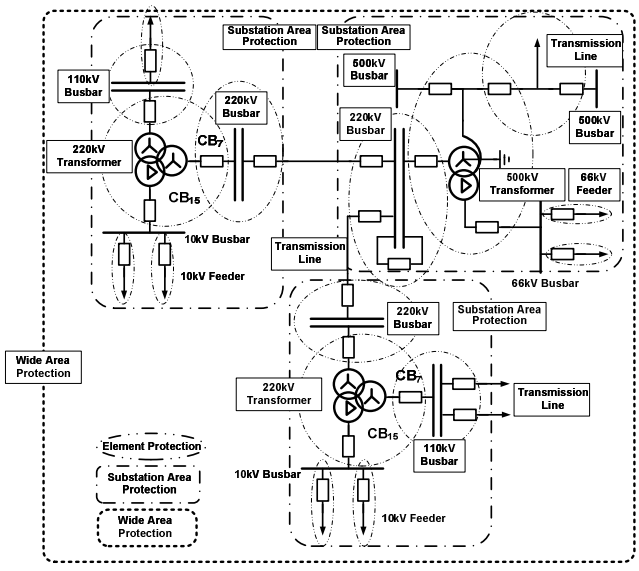

Fig.1 Function scope of hierarchical protection system

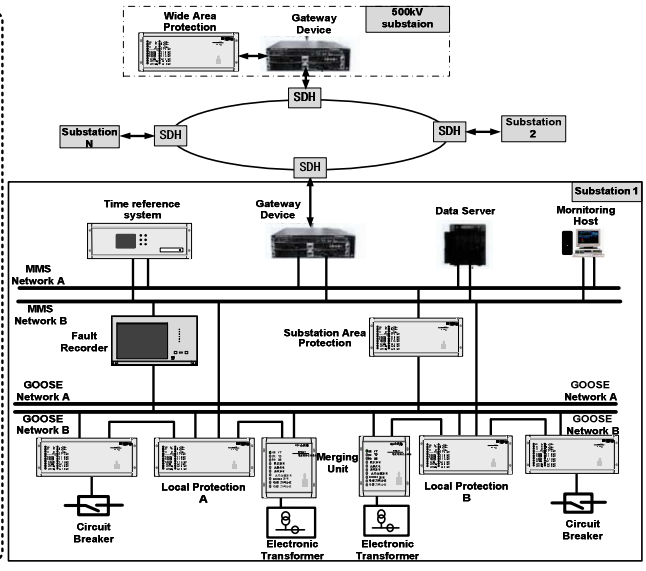

Fig.2 Framework of hierarchical protection system

As shown in figure 2，Substation-area protection can collect the data of current and voltage of every circuit in whole substation through GOOSE network. A Protection System State Supervision Relay (PSCMR) which utilizes the currents of all circuit in whole substation is designed in this paper. Through comparing the difference of substation-area protection and local protection, PSCMR can identify those faulty intelligent electronic devices and send alarm message in time. It can avoid the malfunction or refusing trip of protection system, and provide the safety of power system.

Basic Principle of PSCMR

Kirchhoff's current law based current differential protection has advantage of natural phase selection，operates very fast and is immune to power swing and widely used in power system [12].

Current differential protection based Protection System Condition Monitoring Relay has been developed in this paper. As shown in Figure 3, a typical 220kV substation is studied. 16 current differential circuits labeled as D1 ~ D16 are constructed in whole substation. As shown in Table 1, D1~D2 are current different circuits for transformers, D3~D8 are current different circuits for bus bar. D9~D16 are current different circuits for four 220kV transmission lines and four 110kV transmission lines.

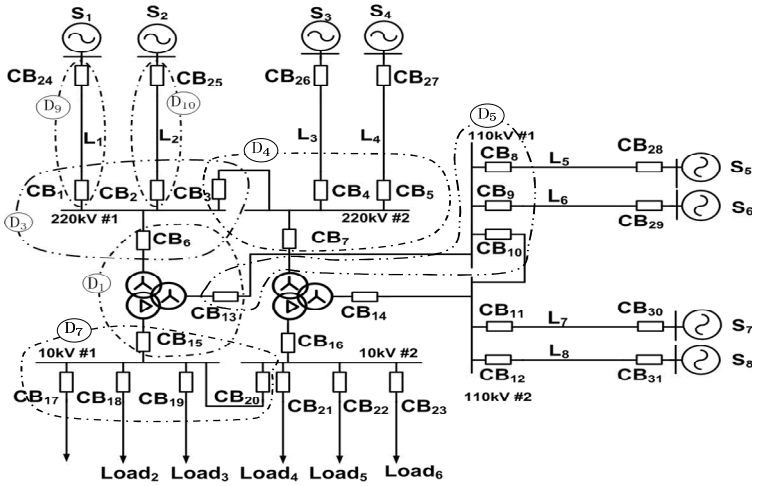

Fig.3 Electric diagram of a typical 220kV substation

PSCMR calculates the differential current for every current differential circuit in real time. Different current of D1~D16 will be zero during normal operation of protection system. As shown in figure 3, in the presence of abnormal condition of Electronic Transformer or Merge Unit will cause differential currents in at least two differential circuit circuits. By analyzing the differential current circuit, PSCMR can recognize the faulty Merging Unit or Electronic Transformer.

Tab.1 The scope of differential circuits in substation

Differential Circuit	Protected Device	Scope of Circuit Breaker	Differential Circuit	Protected Device	Scope of Circuit Breaker
D_1	Transformer T1	CB_6,CB_{13},CB_{15}	D9	Line L1	CB_1,CB_{24}
D_2	Transformer T2	CB_7,CB_{14},CB_{16}	D10	Line L2	CB_2,CB_{25}
D_3	220kV#1Busbar	CB_1,CB_2,CB_3,CB_6	D11	Line L3	CB_4,CB_{26}
D_4	220kV#2 Busbar	CB_3,CB_4,CB_5,CB_7	D12	Line L4	CB_5,CB_{27}
D_5	110kV#1 Busbar	CB_8,CB_9,CB_{10},CB_{13}	D13	Line L5	CB_8,CB_{28}
D_6	110kV#2 Busbar	CB_{10},CB_{11},CB_{12},CB_{14}	D14	Line L6	CB_9,CB_{29}
D7	10kV#1 Busbar	CB_{15},CB_{17},CB_{18},CB_{19},CB_{20}	D15	Line L7	CB_{11},CB_{30}
D8	10kV#2 Busbar	CB_{16}, CB_{20},CB_{21},CB_{22},CB_{23}	D16	Line L8	CB_{12},CB_{31}

For example, Merging Unit of CB1 has fault, differential currents will appear in D3 and D9. When PSCMR recognizing differential currents in D3，it can utilize traversal algorithm shown in figure 4 to locate the faulty intelligent electronic device.

Since differential current circuit D3 includes CB1, CB2, CB3 and CB6, PSCMR can detect whether D1 is normal firstly. If there is no differential current in D_1, PSCMR will continue to

traverse D4, So in turn, until differential current is found in D9. Thus it can determine whether Merging Unit or Electronic Transformer abnormality or failure happened in CB1.

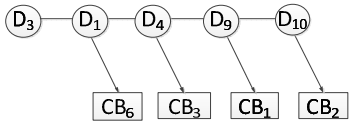

Fig.4 Differential Circuit Traversal Algorithm

Tab.2 Malfunction Identification of Differential Circuit

Circuit Breaker	Differential Circuit for Abnormal Identification	Circuit Breaker	Differential Circuit for Abnormal Identification
CB_1	D_3,D_9	CB_9	D_5,D_{14}
CB_2	D_3,D_{10}	CB_{10}	D_5,D_6
CB_3	D_3,D_4	CB_{11}	D_6,D_{15}
CB_4	D_4,D_{11}	CB_{12}	D_6,D_{16}
CB_5	D_4,D_{12}	CB_{13}	D_5,D_1
CB_6	D_3,D_1	CB_{14}	D_6,D_2
CB_7	D_4,D_2	CB_{15}	D_1,D_7
CB_8	D_5,D_{13}	CB_{16}	D_2,D_8

Algorithm of PSCMR

Phase segregated current differential protection principle is adopted in PSCMR, and its ratio-restrained characteristic[13] is shown in figure 5 and expressed in equation (1).

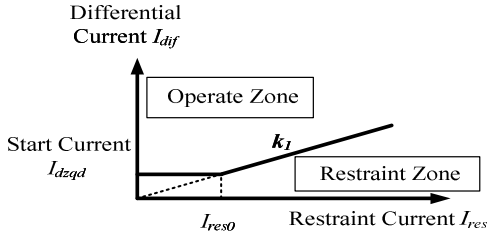

Fig.5 Ratio-restrained characteristic of differential principle

$$\begin{cases} I_{dif} > I_{dzqd} & (I_{res} < I_{res0}) \\ I_{dif} > k_1 I_{res} & (I_{res0} \le I_{res}) \end{cases} \tag{1}$$

The main function of PSCMR is monitoring whether there are faults in Merging Unit or Electronic Transformer during normal operation of power system. According to 10% Error Curve of Current Transformers, error of Current Transformer is no more than 10%. Ratio coefficient k_1 in this paper is set 0.1.

Phase A for example, differential current is the sum of vector current in each branch; resistant current is the sum of scalar current in each branch. Assumed positive direction of current is from Bus to Line.

$$I_{dif\,A} = \left| \alpha_1 \cdot \dot{I}'_{1A} + \alpha_2 \cdot \dot{I}'_{2A} + \cdots + \alpha_n \cdot \dot{I}'_{nA} \right| \tag{2}$$

$$I_{res\,A} = \alpha_1 \cdot \left| \dot{I}'_{1A} \right| + \alpha_2 \cdot \left| \dot{I}'_{2A} \right| + \cdots + \alpha_n \cdot \left| \dot{I}'_{nA} \right| \tag{3}$$

α_1, $\cdots$, α_n are factors to balance the different ratio of Current Transformer in each side of transformer.

Software Diagram of PSCMR

Shown in figure 6, PSCMR calculate differential current in D_1~D_{16} in order, and determine whether differential protection of D_1~D_{16} should act. If differential protection of D_1 act，PSCMR run into traverse subroutine of D1. First, PSCMR detect whether differential protection of D_3 acts. If

differential protection of D_3 act, it can be determined that intellectual electronic device in protection system of CB_6 have occurred abnormal situation. Otherwise，PSMCR will continue to detect differential current of D_5. If differential protection of D_5 act, it can be determined that intellectual electronic device in protection system of CB_{13} have occurred abnormal situation. Otherwise, PSMCR will continue to detect differential current of D_7. If differential protection of D_7 act, it can be determined that intellectual electronic device in protection system of CB_{15} have occurred abnormal situation, and traverse subroutine of differential circuit D_1 end，algorithm of PSCMR returns to main program, and continues to detect differential current of D_2 ~ D_{16} in sequence until the program ends.

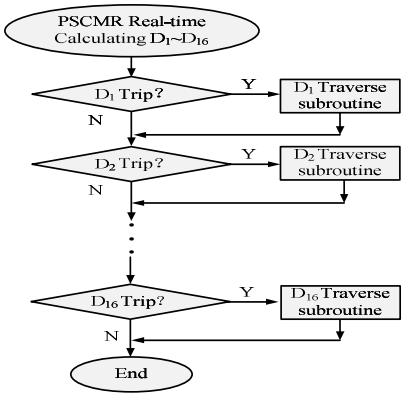

Fig.6 Main program of PSCMR software algorithm

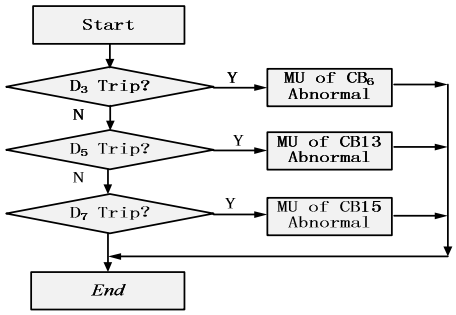

Fig.7 Traverse subroutine of differential circuit D_1

Simulation and Evaluation

A typical 220kV substation simulation model shown in Figure 3 has been established in the Alternative Transient Program (ATP), and algorithm of PSCMR is programmed in MATLAB. Data get from ATP is used to test the algorithm of PSCMR.

Normal operation conditions, abnormal operation of Merging Unit all have been simulated to test the algorithm of PSCMR in this paper. Some simulation results to abnormal operation of Merging Unit in CB1are shown in Figure 8.

It can be seen that D3 and D9 have acted. PSCMR can locate the abnormal situation in protection system of CB1 accurately and send alarm signal.

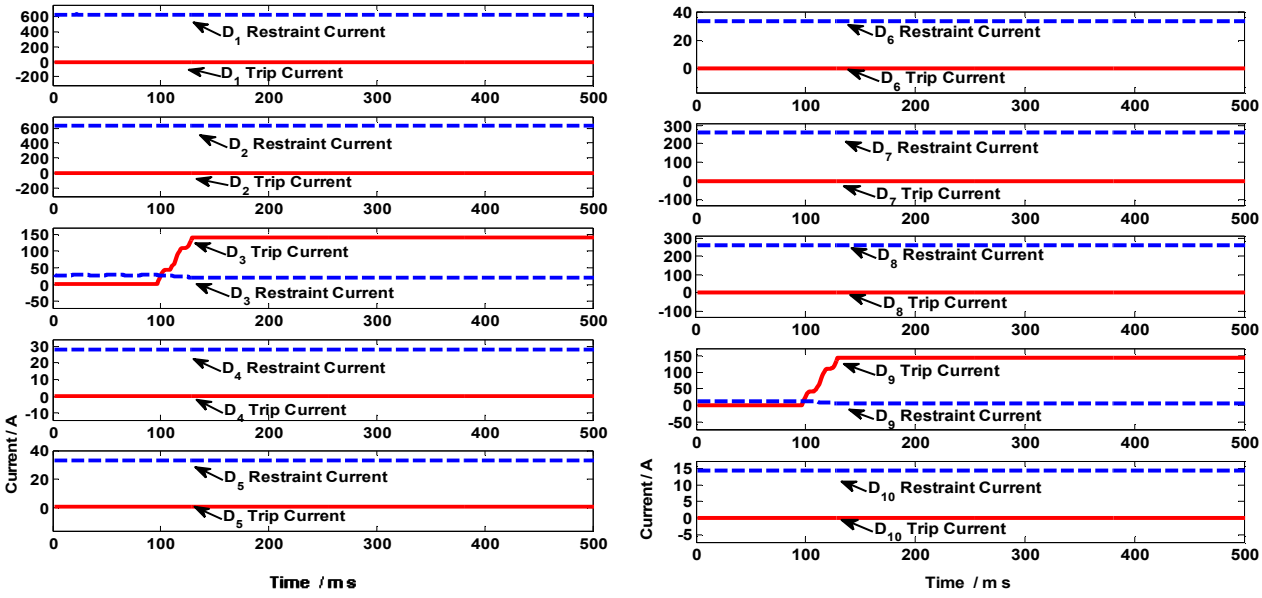

Fig.8 Currents in differential circuit caused by abnormal Merging Unit of CB1

Simulation results of ATP indicate that PSCMR can monitor the operating situation of protection system in whole substation, and can identify abnormal Merging Unit or Electronic Transformer accurately.

Patrol Function of PSCMR

PSCMR can communicate with all local protection devices and Intelligent Terminals in whole substation. It can call all local protection devices and Intelligent Terminals periodically. If any local protection device or Intelligent Terminals have no response, alarm signal will be sent by PSCMR.

Conclusion

Online condition monitoring of intelligent electronic devices in intelligent substation is very important to improve the reliability of protection system. According to the characteristics that Substation-area protection can obtain current information of all circuits in substation through GOOSE network, current differential protection based Protection System Conditioning Monitoring Relay named PSCMR is designed in this paper. PSCMR can identify the abnormal device through the action results of each differential current circuit and patrol local protection device and intelligent terminals through GOOSE network. Alarm signals will be sent out by PSCMR in the presence of abnormal conditions of intelligent electronic device. PSCMR is a valuable try of online condition monitoring of protection system, it also enrich the function of Substation-area protection.

Keywords: LabVIEW,power quality,ATT7022C,oilfield

Abstract: For the specific requirements of power quality in the process of oil exploration,this paper designs a distributed intelligent monitoring systems,including oilfield power quality monitoring center and single oil well monitoring terminal.Among them,Single well terminal hardware is composed of high precision meter chip ATT7022C and ARM9 processor, it can complete the accurate measurement of the electrical parameters.The monitoring center is designed with LabVIEW as the carrier of the power quality comprehensive platform.Using ethernet for data transmission between the terminal and monitoring center. The results show that the system is comprehensive, it can effectively detect multiple power quality parameters and harmonic variation of the grid side,and also can provide technical support for oilfield power quality monitorng automation.

0 Preface

Petroleum is an important energy in China. There are two main problems in the current oil exploitation:1.With the rectifier, inverter and switching power supply technology, new energy-saving equipment put into use in the field of oil exploitation, inevitably resulting in a frequency deviation, as well as three-phase unbalanced and harmonic problems. 2.Oilfield is composed of a plurality of single well set.In the case of a wider range monitoring, only using a single monitor of power quality monitoring system is not flexible enough, and it is difficult to analyze the overall situation.Therefore,it is necessary to establish a monitoring and control system of distributed, networked, intelligent.

1 Overall system design

Oilfield power quality monitoring system is composed of the power quality monitoring center and some monitoring terminals.Monitoring center is located at each substation, is responsible for the management and maintenance of the monitoring terminal data transmission.And the role of the monitoring terminal is to report each real-time electricity parameters of oil pumping well.Its structure is shown in figure 1.

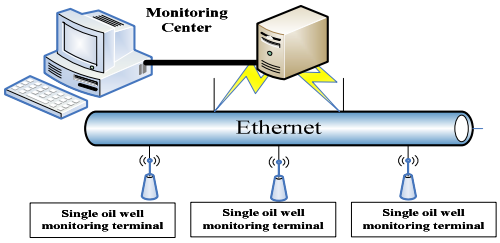

Fig.1 The overall structure of the system

2 structure and function of the single well monitoring terminal

The design of the single well monitoring terminal with high precision in the three-phase electric meter IC ATT7022C can achieve its own recuperated for electrical signal filtering, the voltage, current, frequency, reactive power detection accuracy reached 0.5%,meeting the standards at the national level of the instrument.The measurement of electrical parameters meter chip and ARM9 processor send the data to the PC machine by the Ethernet .Through the calculation of basic electrical parameters，It implements the voltage deviation, three-phase imbalance degree deviation, current steady-state power and reactive power index analysis.In this paper, windowed interpolation FFT algorithm combined with wavelet transform Mallat, thus completing the positioning harmonic measurement and transient perturbation signal.LabVIEW has powerful functions and data programming ability, can complete the programming and the realization of interface index.In figure 2, you can see its structure diagram.

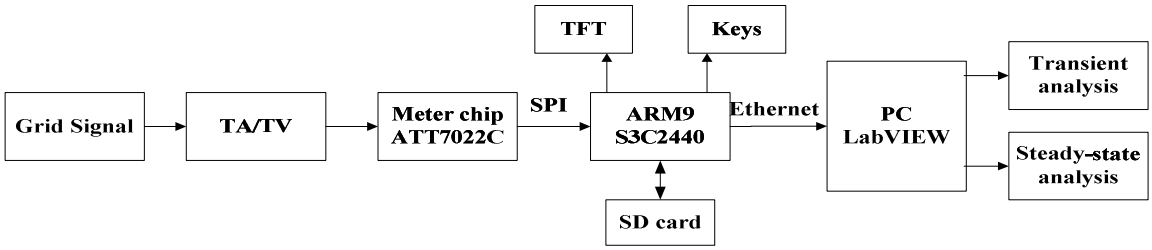

Fig.2 The overall structure of the system

Figure 2, the voltage or current transformer is in proportion to the transformation of the equipment.Its main function is to convert the high voltage and large current power grid into a standard low voltage scaling transformation (380/5V) or standard small current (10A/5mA).In order to achieve real-time transmission of data, use the check more accurate TCP protocol, using multifunctional monolithic network interface chip W5300, which integrates an10/100M Ethernet controller ， its speed can reach 80Mbps.In LabVIEW, with support for serial interface,GPIB, VXI, PXI and Ethernet standard bus data acquisition equipment VISA interface software library which could realize the communication between the upper and lower computer[2].

3 Harmonic and transient power quality parameters

3.1 Harmonic Analysis

From the IEC standards and national standard definition, harmonic frequency spectral component is defined as an integer multiple of.When the power grid is in steady state ,FFT algorithm is the most common method in Harmonic Analysis[3].Any function can be used in the form of a Fourier series launched：

$$f(t) = A_0 + \sum_{1}^{\infty} [A_n \cos(nwt + \varphi_n)] \quad (1)$$

Wherein, T represents periodic, A_n represents the corresponding amplitude, φ_n represents the initial phase angle.

Real FFT analysis of frequency spectrum leakage effect.In order to reduce leakage, need to add window fuction.Frequency-domain response function sidelobe amplitude and width of the main lobe will cause a certain process is not complete, so it should look at the performance of the frequency domain window function closest to the impact function, that is, the side lobe is small and narrow main lobe window function.In this paper, using the Hanning window.

This paper processes the signal through LabVIEW signal processing for conversion under the menu controls FFT.vi,it can be able to get HRU and THD.As shown in Figure4.

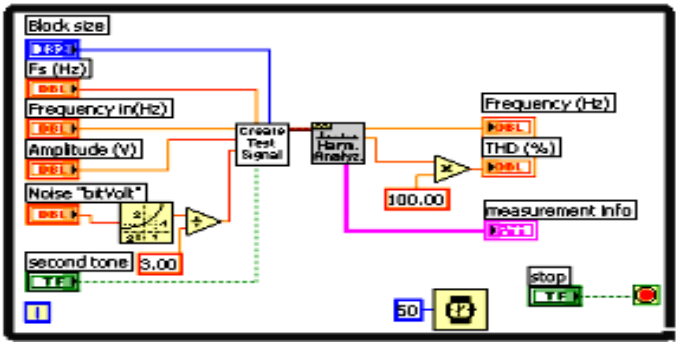

Fig. 4 Harmonic analysis program

3.2 Wavelet localization of transient disturbance parameters

Due to the high-power oil pumping unit works with a high-frequency DC-DC power conversion technology and three-phase rectifier technology, the distribution network will lead to a certain line voltage and current disturbances. However, once the state is bound to contain a mutation abnormal signal (voltage sags, swells) or high-frequency resonant interference, Fourier transform look powerless.Using an improved algorithm based on wavelet decomposition and reconstruction,it can deal with signal of high frequency and low frequency part respectively.For the high frequency component contains noise and singular information,wavelet transform is used to determine the signal mutation point time and amplitude and high frequency resonance happened[4].

Wavelet transform is a special kind of waveform with finite length, its average value is 0. Wavelet sequence defined as:

$$\Psi_{a,b}(t)=\frac{1}{\sqrt{|a|}}\Psi(\frac{t-b}{a}) \qquad a,b\in R \tag{2}$$

In the formula, a represents the frequency factor, b indicates the time shift factor.

Mallat algorithm is a fast algorithm of wavelet transform,its steps are as follows：

(1)The selection of wavelet base.This paper selects db4 wavelet,compared to other dbn wavelet, it has the most short time window, better time resolution.

(2)To determine the decomposition level.As far as possible to ensure that the fundamental frequency of the lowest subband is located in the center of the fundamental frequency component, thereby reducing the interference of the other sub bands.The formula is:

$$N=(\log_2 f_s / f)-2 \tag{3}$$

（3）Wavelet denoising[5]. Treatment of each layer of wavelet coefficients in the larger and smaller than a certain threshold model coefficients, and then the wavelet coefficients are processed and then inverse transform, reconstruction of the signal over noise, so as to achieve the purpose of denoising.

4.The experimental analysis

High-power pumping unit has voltage sag effect when it is working, and the characteristic of high frequency disturbance is obvious.We mainly use sag duration and temporary decline in value to describe voltage sags.The mathematical model of its expression is:

$$f(t)=\begin{cases}\sin(wt+\varphi_1) & t<t_1,t>t_2\\ a\sin(wt+\varphi_2) & t_1\le t\le t_2\end{cases} \quad (0.1<a<0.9) \tag{4}$$

The programmable AC power（The Chroma 61703Programmable AC Power Source） to produce a common transient power quality disturbance signals.The effective value of the fundamental signal set 220V, frequency of 50Hz,Harmonic signals were 3 harmonic 3%, 5 harmonic 2%, 7 and 9 harmonics 1%.To use this system for voltage sag real-time signal analysis, db4 wavelet is uesd as the wavelet basis in the process of experiments.The sampling frequency is 12.8kHz, the sampling length is 10 cycles.The analysis results as shown below.

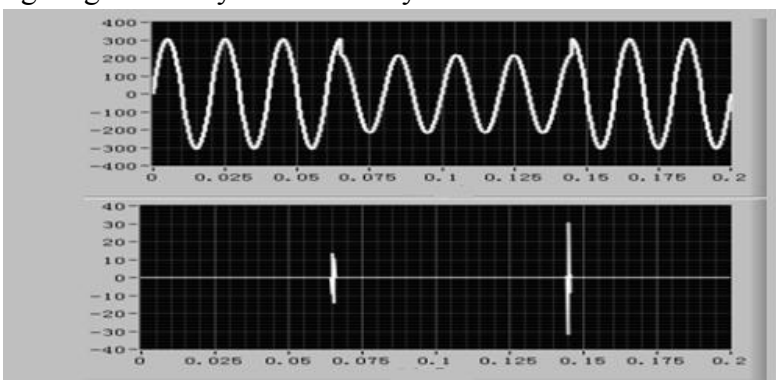

Fig.6 Detection of voltage sags by running mallat

The results can be obtained: Test duration 0.0802s, the magnitude of change was 29.8291%. The actual duration of 0.08s, the amplitude variation rate is 30%. The results show that the transient analysis module of the system has higher accuracy and amplitude in the time domain.

5 Conclusion

In this paper, the authors design a distributed power quality monitoring system of oilfield,the following conclusions can be obtained:

1) This design has realized the monitoring terminal hardware design, software design, to achieve the expected goals,and solving the oilfield network integrated wiring difficult problems caused by the dispersed.

2) Power quality monitoring platform constituted by the embedded hardware and LabVIEW,it can effectively analyze each phase harmonic distortion rate, every harmonic containing rate , transient parameter of time domain and amplitude. It also possess a good monitoring effect on the steady state phase voltage deviation, frequency deviation, three-phase unbalance degree.Its error precision instruments to meet Class A standards, which is expected to be used in practice.

Keywords: power grid failure, auxiliary decision-making, failure diagnosis

Abstract. a secure and stable operation of power grid will provide critical assurance for sustainable development of society and economy. Through power grid dispatching auxiliary decision-making system, key information could be obtained from various information sources of the control center such as energy management system, security and stability control system and safety production information system. In case that accident occurs, this intelligent auxiliary decision-making system will provide full assistance to dispatcher with dealing with accidents by starting failure diagnosis function and producing project for coping with accidents. Accelerate transformation of accident handling style from empirical style to analytical and intelligent handling style to improve technical level of sensing of power grid operation status, risks assessment, failure diagnosis and dispatching.

Introduction

When accident occur to power grid, the dispatcher should analyze accident, find out the focus problem, eliminate off-limits of the system and provide referenced scheme for recovering power-supplying in the area where accident occur with assistance of accident auxiliary decision-making system. General flow chart for regional power grid accident auxiliary decision-making system is as shown in Fig.1.

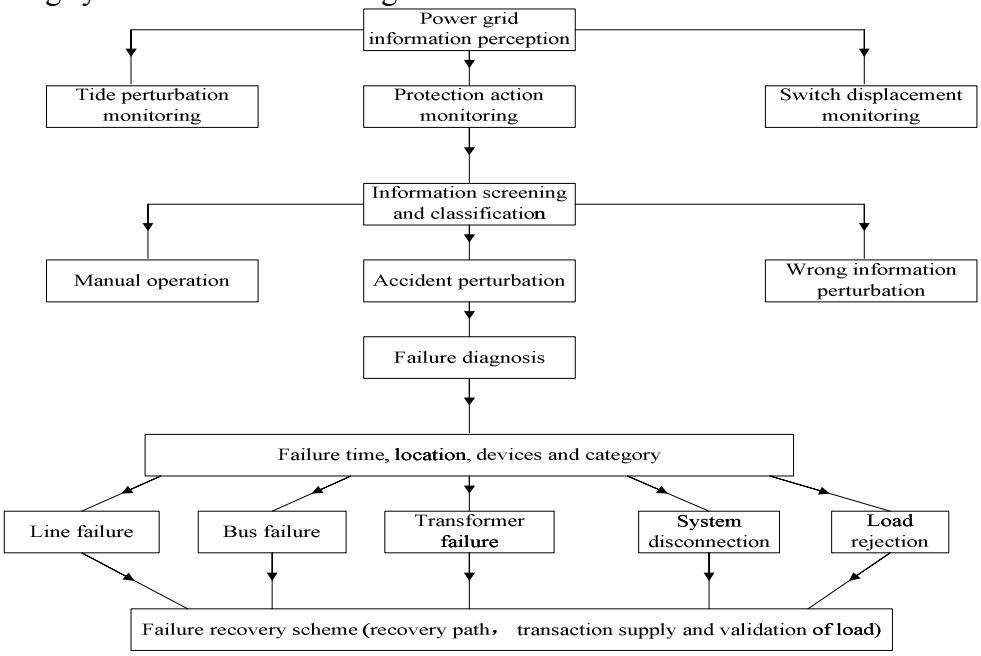

Fig.1.General process for making decision

Production of Sequential Network Topology

Replication and reproduction of the model of the whole network in scale of 1:1 provide reliable data base for power grid failure diagnosis technology which is based on network topology analysis.

The key process for carrying out analysis and recovery of system accident is to maximally restore loads in the power-losing area within the shortest time and transfer loads of over-loaded equipment and then put out reasonable plan for coping with accident.

It could be observed from this that restoration of controlling is a constraint optimized dispatching process with multiple targets which should be carried out by stages. It is of the objective to restore the maximal loads with the shortest time. Constraint conditions to be fulfilled for accident recovery control are to make sure that loads of all devices are within limit values and all node voltages are fulfilling requirements. Due to particularity of elements for electric system of discrete type in system construction, topology analysis algorithm is critical for the device search process.

Shading Network Topology Analysis

Shading method applied in network topology analysis for this system is based on accident handling auxiliary decision-making system which is basing on shading network topology analysis. Comparing with the conventional topology analysis algorithm applying stack for searching, shading network topology analysis algorithm is free from low efficiency with process rolled back during searching and it is of high speed, high efficiency and with simply designed program.

Progress for Sequential Network Topology Analysis

During normal operation, turn on a switch displacement monitoring and when a switch is shifted (regardless of manual operation or protection action), network topology module will initiate whole network topology once and topology information will be stored in a CASE when topology is completed. By one time, the system can store 30 CASE with each CASE has timing mark, activating signal and flag value. Connectivity, load, voltage and current information will also be stored together with storage of CASE. In case that failure occurs to the system, when switch is shifted, the former and the latter CASE are implying data variations before and after failures occur. Fault area and load loss could be figured out by comparing the two CASEs.

During normal operation, in case that no displacement of switch occurs, renovate all remote measurements with certain interval to update to the new CASE. By this operation, to make sure that the connectivity and operation status stored are consistent. Topology monitoring process is as shown in Fig.2.

Finally, after the power restoration program is generated, mark running load rate, load limit value of each line and transformer after expert system finishes strategic analysis to provide power constraint for further restoration scheme.

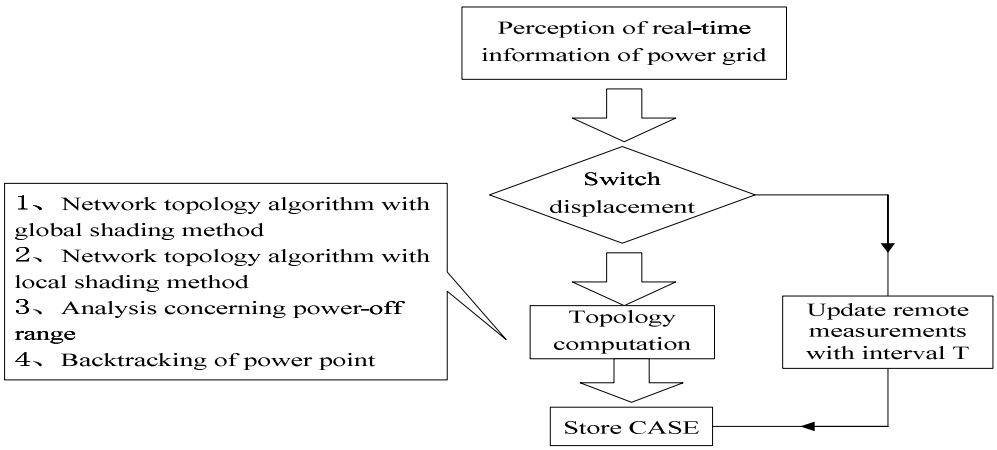

Fig.2.Sequential network topology analysis process

Power Grid Failure Diagnosis

The four most significant characteristics，also be called as the four failure elements appear after various faults occur to electric system are:

(1)Various protection action configured for components for relating electric system with simultaneous protection and being put out;

(2) Tripping of switch for connecting components of electric system;

(3) Resultant failure signal given by transformer with fault components.

(4) Electrical running parameters of components, such as current, power rate are changed,

Through the above four elements, summarize various faults and corresponding statistic features to failures of components and fulfill intelligent diagnosis of failures. An alarm could be defined by figuring out the four elements for alarming, the definition is as follows:

① Protection of general export

② A protection action

③ Displacement of a switch

④ Corresponding zero of remote measuring

①+②+③+④=fully defined failure occurred；

②+③+④=fully defined failure occurred, but general accident is not received;

①+③+④=failure occurred while failure type cannot be defined;

①+②+④=failure possibly occur, but deflection of remote communication is not received, verification should be carried out.

①+②+③=failure possibly occur, but zero of remote measuring is not received. Reclosing is possible fulfilled and record of reclosing action is required; it is possible that zero of remote measuring is not received; verification should be carried out through other methods.

Fulfill power grid failure diagnosis to figure out power-off area of power grid which could be taken as the starting condition for failure diagnosis. With support from relaying protection failure information and displacement signal of remote communication of automatic dispatching system, real-time network topology analysis will be carried out. Fault area should be defined first. Simple failures, such as the fault area with only one fault component could be directly defined as the fault component. For complicated failure (switch, protection action failure, wrong action), reliability of failure of each component in power-off area could be computerized by the system and failures will be sorted from high reliability to low reliability and then the dispatcher will determine the fault device eventually according to the inspection report results. Failure diagnosis process is as follows:

Decision-making for Recovery of Power Grid Accident

Accident recovery decision-making system of power grid will report the power-off area, station, load loosing value, area to be restored with power, off-limit of fault devices and other information after failures occur. For the area to be restored with power, power restoration path should be searched first and alternative schemes should be provided. Filter alternative schemes according to constraint conditions configured by customer and get the final optimal route recovery scheme complying with the objective function. For off-limited devices, method to eliminate off-limits should be provided basing on principle concerning sensitivity. Meanwhile, carry out risk assessment for fault power grid and figure out weak point of fault power grid and provide corresponding correcting and controlling strategy.

Conclusion

With rapid development of national economy, the power grid is continuously expanded and the electric power industry plays an increasingly important role in people's lives and work. How to eliminate failures promptly, restore power supplying within power-off areas, or to minimize the power-off area and short power-off time to minimize losses caused by power failure with presumption of a safe and stable power grid is of important and practical significance to

development of the whole electronic industry, regional power grid accident auxiliary decision-making system can solve these problems.

Keywords: intelligent substation, multicast, flooding, VLAN, GMRP

Abstract. The existence of a large number of multicast flooding data in the process level of smart substation,causes serious influence on the real-time performance and reliability of network.Through the exchange principle of Ethernet,the forwarding process of second-layer multicast in network is introduced. Combined with the application in intelligent substation and some experimental data, through in-depth analysis of the 802.1Q VLAN isolating broadcast domain,setting static multicast to change the static MAC address table ,and GMRP to change the multicast information on Ethernet switch through the interactive protocol data, the multicast flooding suppression method is illustrated. And based on the practical engineering situation, the three kinds of methods are compared from the characteristics of debugging operation and maintenance convenience and reliability of intelligent equipment,then the technology route recommendation is given.

Introduction

The intelligent substation adopt the concept of hierarchical information of automation system in substation proposed by IEC61850 ,and it is divided into three levels:the station level, bay level, process level.The process level consists mainly of two types of packets GOOSE and SV.The GOOSE packets transmitted information includes latching signal, position signal , status signal and control signal , and it has high requirement to the real-time and reliability .Sampling packet transmission information from process level to bay level,and this kind of message has high requirement to real-time.Currently SV and GOOSE messages are second-layer multicast packets in process level network.The general processing of this type of packet in industrial Ethernet switch is that ,if the port mapping corresponding to the multicast destination address is not existent in the MAC address table,the packet will forward to all the ports except the input port in the same VLAN.As the SV flow of MU is very large ,the IED in the SV network will receive a lot of irrelevant message,then the network bandwidth will be wasted,and the IED will receive serious impact ,especially in mixed network of SV and GOOSE,GOOSE message will be blocked in the absence of preferential measures,the performance of real-time can not be ensured,also the reliability and safety will be jeopardized[1-6].

The article firstly introduce the principle of multicast communication,then describe several technology of multicast flooding suppression,and the proposal is given combined with project practice.

The principle of multicast communication

The principle of switch

In smart substation,especially the process level,the IED communicate via Ethernet,and the Ethernet switch can learn the MAC address of the equipment connected to the port.The process of learning is that switch listens all the incoming packets,and examines the source MAC address,then forms a mapping of MAC address to the corresponding port,and the mappings are stored in the MAC address table in the switch.When a frame arrives at the switch,the switch determine how

to transmit the frame by the lookup of the MAC address table.If the destination address exists in the MAC address table,the frame will be forwarded to the corresponding port,otherwise the frame will be forwarded to all the ports except the source port.

The principle of multicast

Multicast technology, is a technique that allows one or more hosts to transmit a single packet to multiple hosts. The difference between multicast MAC address and unicast MAC address (physical MAC address) is that, in the six bytes of the multicast MAC address,the lowest bit of the highest byte is 1, while the bit of unicast MAC address is 0, as shown in Figure 1. GOOSE message and SV message are both multicast message.The second-layer multicast has a mapping to a group of Ethernet port in the MAC address table,when such a message arrives at Ethernet switch,the switch will analytic the destination address of the message and query the MAC address in MAC address table of the switch .If the address appears in the table , check the corresponding multicast members of the address,and the message will forward to all the member ports,else the message will forward to all the ports in the same VLAN.

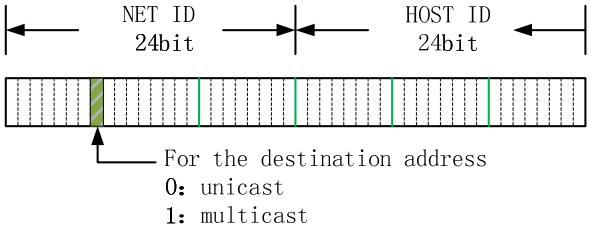

Figure 1 The MAC address of unicast and multicast

The suppression of VLAN

The concept of VLAN

VLAN is an end-to-end logical network constructed by network management software,and it can step across different segment and network.A VLAN forms a logical subnet, which is a logical broadcast domain,and it can cover multiple network devices in different geographic locations, allowingInternet users to join a logical subnet.In brief,VLAN can divide a physical network into several logical network, then it can control the broadcast domain, improve network security, simplify network management,also, it makes the construction and expansion of network more convenient.

The isolation of unknown multicast flooding by VLAN

When a multicast packet arrives at a port of the switch, the switch port will check whether the message has 802.1Q tag,if not ,the switch will insert a tag into the frame according to the default VLAN ID of this port . If the message contains the 802.1Q tag, the switch determines whether to allow the message to the port according to the VLAN the port belonging to. After the multicast packet entering the switch,it will forward to corresponding destination port by querying the multicast MAC address table.If there is no the multicast in the MAC table ,the packet will forward to all the other ports in the same VLAN. The division of VLAN has greatly reduced the scope of flooding, therefore the network system is more stable and reliable.

In order to limit the scope of multicast flooding and improve the utilization rate of network resources,some IED and multicast source will be configed into a same VLAN.In general,the substation will be divided into different logic zone according to the voltage level,such as 220kv system region, 110kv system region, 35kv system region.VLAN is set according to different bay in different voltage levels,and a VLAN is set in one bay,such as 110 kV line bay,110kv section bay, 110 kV PT control bay[7,8].

Assuming in a switch of SV network, each merging unit sends out the multicast traffic for 6Mbps,we can contrast the flooding flow between before and after VLAN config according to different amount of MU,and the experimental data:

Table 1: The comparison of SV flooding between before and after setting VLAN

The count of MU	1	2	4	6	8	10
SV flooding before VLAN setting (Mbps)	6	12	24	36	48	60
SV flooding after VLAN setting (Mbps)	0	0	0	0	0	0

If there are ten MUs connected to a Ethernet switch ,these ten MUs will send out data of 60Mbps without VLAN setting, and most of these flow is useless to the other IED connected to the same switch and will cause the tremendous impact on the IEDs.If each MU is in the independent VLAN,the SV packet will not flood to other VLAN,and the network reliability will greatly enhanced.

Suppression of static multicast

Static multicast refers to the static multicast group with manual configuration,and the multicast address will not disappear automatically when the ageing time is overtime.To add or delete multicast address entries in MAC address table staticly can realize the management of multicast group member.When a multicast packet arrives,the switch will query the multicast address table,then the packet will forward to corresponding destination ports.

In order to solve the problem of multicast flooding in intelligent substation,especially the serious impact on the IED caused by SV packet in process level,static multicast group can be created in switch according to the destination address of the packet.When the SV or GOOSE packet arrive at the switch,the the switch will query the multicast address table,then the packet will forward to corresponding destination ports,instead of forwarding all the other ports.

According to the design of network and the business needs,it can be determined that which ports will be connected to the switch by the IEDs,and the communication service among the IEDs can be confirmed.According to the destination of each multicast service on the IED,the destination IED can be confirmed ,then the switch ports will also be confirmed,after that,the mapping of the multicast to the switch ports.The static multicast group can be created through the management software of Ethernet switch,then the mapping entry will be added in the MAC address table. Then,all the other multicast group could be created,and the multicast address can be found in the MAC address table.And all the multicast packet will forward to de designated ports,and will not flood to all the ports.All the Ethernet swith in the process level will be set the same config for the multicast group.If the multicast packet will be sent out across the switch,the cascaded ports would be added to the multicast group.By creating static multicast in all the cascaded Ethernet switches,the whole process layer network can be made no multicast flooding.

The suppression of dynamic multicast

Dynamic multicast is changeable relative the static multicast,and the entry of the multicast address in the MAC address table will change when the switch receives the protocol message,so,the multicast packet may be sent out to different ports although it has the same destination address. GMRP is defined in IEEE 802.1P,and it is used to maintain the multicast registration information in the Ethernet switch.GMRP can filter the second-layer multicast,so it is suitable for SV and GOOSE message in smart substation.

The destination address of GMRP is a specific multicast MAC(01-80-C2-00-00-20),and switch or host can distinguish GMRP message from other message.When a terminal device want to join a multicast group,it will send join-in information.After receiving the message,the switch will join the port connected to the device in the multicast group,also ,the swith will broadcast the GMRP join-in information in the VLAN the port belonging to, then the multicast source in the VLAN can know the presence of new multicast members.When the multicast source send a multicast packet,the switch will query the MAC address table,then forward the packet to the corresponding ports,so as to

realize the forwarding of second-layer multicast in the VLAN.The process can be described in schematic as shown below.Also, the Ethernet switch will periodically send a GMRP querying message(LeaveAll),if the device want to stay in the multicast group,it should respond to the querying by sending join-in message,otherwise,it can send a leaving message or do not respond to the querying.If the switch can not receive a responding message or receive a leaving message ,it will delelte the corresponding port of the multicast group in the MAC address table.A device can join multiple multicast groups,and this can meet the need of that a protection may require data from more than one MU.GMRP can effectively control the multicast flooding,and it is especially suitable for information transmission of MSV9-2 and GOOSE based on the pubish/subscribe mechanism in smart substation[9-11].

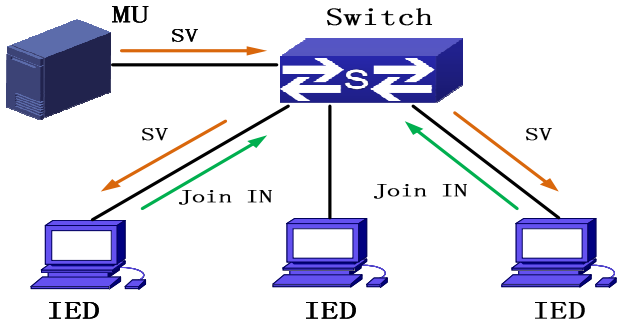

Figure 2 The description of joining in the multicast group

Conclusion

At present,VLAN technology is the most widely used isolation technology of multicast message,and the VLAN can be configured in Ethernet switch by the connection between switch ports and IED,also by the interaction relationship among the IEDs,and it does not need to do much operation at IEDs.But the function configuration of the Ethernet switch is complicated,and this will increase the difficulty of debugging and maintenance.But once configured,the correspondence between the IEDs and the Ethernet switch ports is not free to change,otherwise,the IEDs can not communicate normally.Static multicast is suitable for the situation of that the multicast group only has a small number of members,when there is a lager number of members or frequent changes,this method of static multicast is not suitable.Ethernet switch only need to open the function when the GMRP is used,also,do not need to define a specific port,so the work of configuration is greatly simplified.But,the IED should support the GMRP protocol,and this will improve the requirements of function and reliability of the IEDs.But considering the simplicity of the switch configuration and the convenience of substation expansion,the GMRP technology will become the mainstream packet filtering in process layer of intelligent substation in future.At the same time ,static multicast technology can be used as the supplement of GMRP when the IED can not support GMRP.

Keywords: Frequency Characteristics, AGC Control Strategy; Primary Frequency Regulation; AGC

Abstract. This paper introduces the current research status of primary frequency regulation and AGC control strategy. Firstly, some important parameters about primary frequency regulation are introduced. Secondly, describes the development on the theory of AGC. Thirdly, the basic concept of CPS and ACE were briefly described, and then the difference between CPS and former A1/A2 standard were compared. Finally, outlook on the coordination between AGC control strategies and primary frequency regulation.

Introduction

With the expansion of the power grid interconnection and the power market, the application of technological innovation to conventional automatic generation control (AGC) will become a hot spot. Mainly in the following areas：Research on interconnected power grid of AGC control strategy and methods； The operating with AGC and primary frequency regulation under special mode. This literature describes the factors of primary frequency regulation, development status and trends of AGC basic control strategy and outlook the operating strategy between AGC and primary frequency regulation in a special power shortage situation.

1 Analysis on Primary Frequency Regulation Parameter of Power Grid

Primary Frequency Regulation(PFR)[1] means automatic control unit of generators conditioning control system will increase or decrease active power so that the grid frequency can quickly return to the rating range when the grid frequency deviation. Literature [3] studied the following characteristics of PFR: (1) Function of PFR is shared in an interconnected power system so that bigger system is more likely to get stronger ability of PFR. (2) The response time of PFR is very short, generally not more than 15s after frequency changes. (3) Working time can be more than 15min. (4) PFR requests generators in system to retain enough reserve capacity. Below describes the parameters of PFR.

1.1 Regulation dead zone

The function of regulating dead zone contributes to stable operation, when the grid frequency is basically stable near the rating value and is not going beyond the regulation dead zone, units don't have to take regulation against the tiny fluctuation of frequency, reduce the changes of valve position and improve the stability of generator operation. On the other hand, when frequency deviation is beyond regulation dead zone, frequency regulation will be taken to meet the need of primary frequency of power system. The regulation dead zone of generators involved in primary frequency regulation domestic is generally restricted to ± 0.033 Hz. Literature [2] pointed out that in practical applications, the artificial failure zone of domestic speed control system can only be set to achieve two decimal places, the dead zone of primary frequency regulation in most power plant is

set to $\pm$0.04 Hz. Generator units of the hydroelectric power plant built in the mountains away from load center whose frequency are volatile, dead zone can properly be extended.

1.2 Regulation coefficient

Regulation coefficient δ reflects the relationship between generator output power and frequency that is the static characteristic of power - frequency; it can be approximated to a straight line, as shown in figure 1.

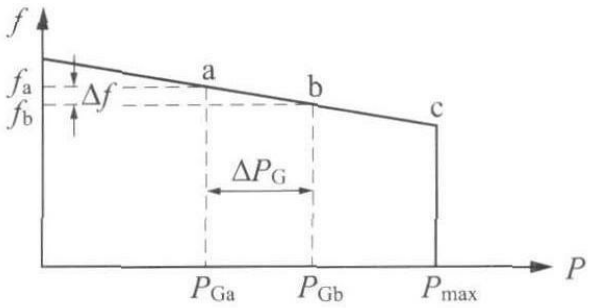

Figure1 Static characteristic of power - frequency

Regulation coefficient is defined as:

$$\delta = -\frac{f_a - f_b}{P_{Ga} - P_{Gb}} = -\frac{\Delta f}{\Delta P_G}$$

Which:

Δf —— changes of power grid frequency from f_a to f_b;

ΔP_G ——changes of generator output from P_{Ga} to P_{Gb}.

In addition, from the concept of speed regulation system, a parameter, speed unequal rate, used in larger range is put forward. Speed unequal rate and relative regulation coefficient in essence is the same, and the difference is that speed unequal rate is a parameter of the regulation system, but regulation coefficient is raised from the angle of power grid frequency regulation. Regulation coefficient is of a great influence on maintaining the stability of system frequency.

Studies in reference [2] show that regulation coefficient values in a system should be different. When system load changes, generators with smaller regulation coefficient values should undertake the load changes first, and then do the generators with larger regulation coefficient. Basing on this principle, δ of hydropower generators that take the task of peaking and frequency modulation will lager than that plants excluding the peaking and frequency modulation tasks.

1.3 Delay rate

The above static characteristic curve of regulating system is completely theoretical. It is based on the corresponding of speed and load of the unit. Once the speed of the unit has a deviation, the speed control system will immediately act, and the unit power is immediately changed. However, with the influence of factors such as friction and clearance, when the speed of the unit changes, the static characteristic curve is no longer a curve, but turns into a pair of parallel curves. It is usually referred to the delay phenomenon of the regulation system. The delay rate parameter of the unit is proposed in literature [3].

Formula is defined as follows

$$\varepsilon = \frac{\Delta n}{n_0} \times 100\% \quad ;$$

Which:

Δn ——Speed difference of the characteristic line between the speed ascent and descent;

n ——Unit rated speed.

Delay rate of turbine operation is very unfavorable, because the slow rate is higher, indicating the interval time from the turbine speed changes to the regulating valve starts operation is larger, which causing the turbine cannot be adjust the external load changes. Especially when load rejection, regulation valve closed behind caused by delay rate, make speed increases too much, causing a critical security control action. In addition, due to the presence of delay rate, in the parallel operation, the unit load swing cause the swing of the speed when stand-alone operation, that the supply frequency fluctuations. Therefore, it required delay rate the smaller the better.

1.4 Response time

Primary frequency regulation response time is the time from when the grid frequency changes by the action time of primary frequency regulation to the unit load began to change, which should be less than 3 seconds.

1.5 Setting time

Primary frequency regulation settling time is the time when unit load reach a stable line after the grid frequency stabilized, which should be less than 1 minute. It should be excluded from the load instruction changes when unit coordinated control system or automatic generation control (AGC) is running.

Literature [4] gives the related tracking unit primary frequency regulation parameters settings of China Southern Power Grid：

Table1 PFR parameter settings of China Southern Power Grid

Regulation coefficient	4%~ 5% Thermal power
	3%~ 4% Hydro
Regulation dead zone	± 0.033Hz Thermal power
	± 0.05Hz Hydro
Response time	≤ 3*s*
Setting time	< 60*s*
Delay rate	< 0.07% ~ 0.1%
Magnitude of the load	≥ ±6% ~ ±10%

2 Development on the Theory of AGC

As early as the 1950s, based on the principle of the transfer function in classical control theory, Kirchmayer proposed a mathematical model of interconnected system LFC to study the PI control method, which is widely used in AGC PI control link nowadays.

With the development of computer technology, AGC system technology has developed from the early analog systems into a digital system now. That is, from the simple, strong robustness and decentralized system control to complex, highly nonlinear and continuous variation of the power system. In 1970, Elgerd and Fosha first applied modern control theory to the interconnected system of LFC problem, but because of the centralized control, the LFC met the problem of "curse of

dimensionality" in the information delivery. Literature [5] reviewed the characteristics of the traditional AGC systems and the features of the proposed system based on modern control theory. The application of modern control theory proposed method may improve the effect of the traditional methods based on modern control theory. On the basis of a large number of practical engineering applications, Literature [6] improved AGC control cycle, control strategy, database models, unit control mode and the Area Control Error smooth handling in conventional AGC algorithm, introducing dynamic filters to remove some dead-ACE effects of high frequency noise, reducing unnecessary control commands.

According to AGC control characteristics, the model system can be described using the no-model control method, intelligent AGC is an important research direction with the development of intelligent control. Literature [7] did a pioneering work in the application of fuzzy control theory of complex multi-area interconnected power system of LFC and improved fuzzy control rules with correction factors. However, due to the normal two-dimensional fuzzy controller only set error and error change as input variables and lack of integral action, combined with the fuzzy controller specific quantization process, the conventional fuzzy control system cannot eliminate the steady state error, which limiting the accuracy requirements for steady higher process control applications. Literature [8] used a PID controller design experts for large-area interconnected load frequency control. Rules of experts are made up of two parts. One part comes from the standard analysis and practical experience of the CPS, the other part is based on the PID dynamic characteristics of the controller and the actual situation of load frequency control.

3 Research Status on AGC Strategy

Automatic generation control (AGC) regional interconnection has become the most important subject of power grid in the modern design and operation. The goal of AGC is by adjusting the power output of AGC generators with fluctuating load requirements to maintain the grid frequency constant and tie-line power close to the planning. To assess the effect of AGC control, the North American electric reliability council (NERC) has put forward several control performance assessment criterion successively. Have A1/A2 standards then CPS standards [9] in 1996 in order.

According to the character analysis of interconnected power grid in China composed by grid dispatching center and provincial dispatching center, literature [10] proposed grid/provincial dispatching center AGC hierarchical control and coordination technology based on tie-line and frequency bias control. It also put forward AGC control methods based on CPS standard. Because provincial dispatching centers adopt TBC control, it can keep balance between generators power and load in each province. The main use of AGC in grid dispatching center is monitoring. Whether if the AGC taking part in regulation and the size of regulation depend on specific conditions. CPS standard is based on the ACE value in A1/A2 standard. ACE control area is divided into 4 parts: dead zone, normal area, sub-emergency zone, emergency zone, each control zone with processing on the change of CPS index.

Literature [11] illustrated AGC control strategy under CPS and proposed the concept of CPS regulation power component. Then the concept is combined with proportional component and integral component, and constituted the region's total power regulation. More, the total regulating power of the region can be amended to further enhance the CPS indicators according to the size and direction of the area control error and frequency deviation. Finally, the paper proposed a method of dividing the AGC control area according to the total regulating power of the region rather than ACE. These control strategies helps improve the quality of grid frequency, and reflects the mutual support function between interconnected AGC control areas in emergency situations.

Literature [12] analyses the difference between CPS and A1/A2 standard, the AGC control strategy based on the CPS should be considered the relationship between ACE and the system frequency synthetically. We put forward a kind of ideal AGC control strategy based on the CPS standard, that is when the frequency deviation is big, the control objectives of the AGC is to make the ACE and the frequency deviation opposite , when the frequency deviation reduce, AGC control strategy make the ACE to minimum. Using the methods of "AGC control strategy based on frequency change", “combined primary frequency regulation with AGC coordination “and " AGC unit cluster control mode", improved the level of the AGC operation and CPS assessment effectively.

4 Summary

The interconnection and marketization of regional power grid are two important reforming directions of state grid, it is meaningful to research parameter of primary frequency regulation and set reasonable parameter values. The control of AGC based on CPS standard will be a hot spot in future. Nowadays AGC control strategies are unformed, and AGC control strategies in coordination with multiple types of generators will be carried out. And the coordination between AGC control strategies and primary frequency regulation under power shortage conditions should be more deeply researched.

Keywords: Photovoltaic, Superconducting Magnetic Energy Storage, Photovoltaic Generation;

Abstract. Photovoltaic (PV) generation is widely used to solve energy shortage and environment problem. Since the output current of the solar cell will change with the sunlight irradiation, the power of the solar cells are not stable, so there is a need of a storage equipment connected to the PV system. With the characteristics of high efficient energy storage and quick response of the power exchange, the superconducting magnetic energy storage (SMES) can be used to meet the balance between the grid and the PV. A SMES and PV subsystem are connected together with the DC bus, which have less power electronics elements and can control power quality efficiently than linked with the AC bus. This hybrid system is composed of a DC/AC converter on the grid side, a DC/DC converter with the PV arrays, and a DC chopper with the superconducting magnet. A detailed model of the hybrid system is built with MATLAB/SIMULINK. Simulation results with and without SMES connected to the grid-connected photovoltaic system are presented, compared, and analyzed. The results of simulation demonstrate that the SMES system can maintain the DC bus as a constant value which can contribute to the stability and reliability of the grid-connected PV system.

Introduction

Solar resource is an effective way to be the main alternative energy source to replace traditional ones in the future. The photovoltaic (PV) cell is an all-electrical device, which produces electrical power when exposed to sunlight and connected to a suitable load. Without any moving parts inside the PV module, the tear-and-wear is very low.

Since the output current of the solar cell will change with the sunlight irradiation, the power of the solar cells are not stable. As a result, PV cells' output cannot always meet demand power, the power mismatch should be compensated with the power from the main grid. On the other hand, they sometimes generate more power than load need, excessive power flows to the grid. It is not good to have a big influence on the grid, there is a need of energy storage equipment to make power from the grid stable. Superconducting magnetic energy storage (SMES) have lots of advantages such as high power density, long periodic life, a high speed, can be used to meet the balance between the grid and the PV.

Among the earlier work in the literature, there are some studies about SMES, such as stabilization of the power system [1][2] and the transient stability [3][4]. And it is proved that SMES is effective as an energy storage device. Also in terms of practical use of renewable energy, the PV and SMES combined system is focused on recently. In the combined system, energy storage device is essential because PV needs power management in the particular area. Many of the former study linked the SMES on the AC side of the grid. However, linked with DC bus will have less power electronics elements and can control power quality efficiently than linked with the AC bus. Study of applying SMES to the PV[5] linked with DC bus is introduced. In this manuscript, the authors focus on the power characteristic of SMES, no detailed model of the PV cells or the SMES. And the power of the system is up to only 5KW.What's more, the irradiation of the sunlight impact on the power has not been fully considered.

In this paper, each part of the hybrid system is introduced and the control strategy is clarified in section II and III. In section IV, with and without SMES are simulated on the grid-connected photovoltaic system to investigate their impacts on the dynamic performance and power flow of the PV generation system.

System Model

The main circuit of the combined system is shown in Fig. 1. The system is composed of PV cell array, PV side DC/DC converter, DC chopper, superconducting magnet and the grid side converter. In a grid-connected PV system, the energy storages equipment must have the characteristic of high energy storage efficiency and quick power response, and the energy storage capacity is also enough. So the superconducting magnet is selected as the energy storage equipment of the PV system. It is linked with the PV system with the DC bus. The DC chopper is set to manage the energy pass through the superconducting magnet by charging and discharging of the current of the superconducting magnet. With the coordinate control of converter, the power transfer between the superconducting magnet and the PV units or the power grid can be controlled effectively.

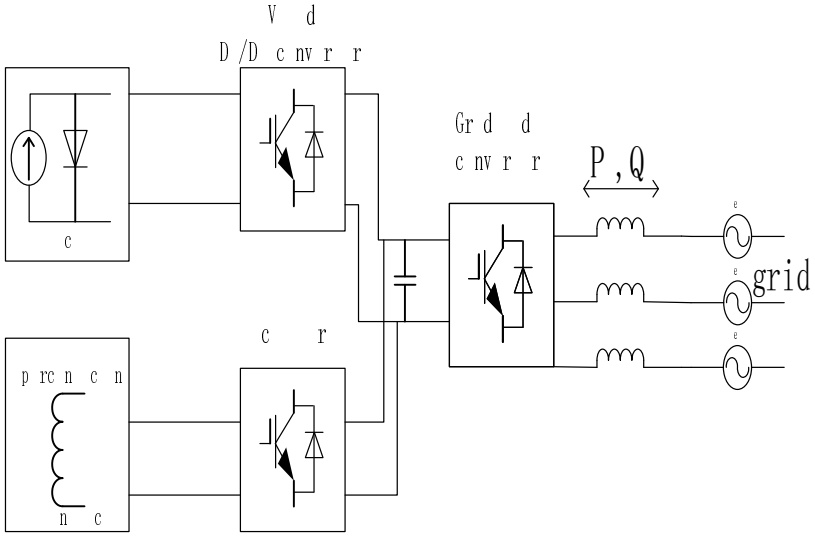

Fig. 1. The main circuit of PV with SMES.

The structure of SMES circuit is as shown in Fig 2.

It contains two main part, one is the voltage source converter (VSC), and the DC chopper. The VSC is used to control the active power P and the reactive power Q respectively, the function of the DC chopper is to control the magnitude and polarity of the current flowing through the superconducting coil (SC); the energy is stored in the SC in magnetic field.

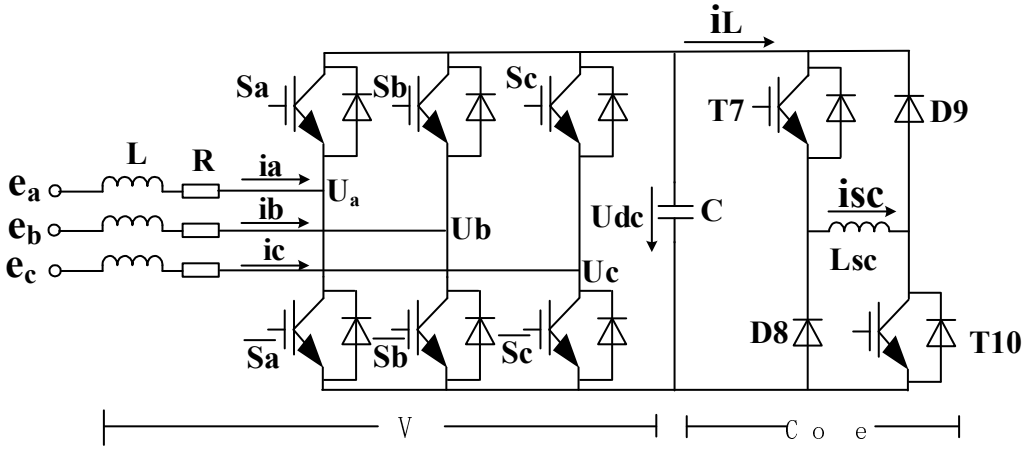

Fig. 2. The main circuit of SMES

A typical PV module is made up around 36 or 72 cells connected in series, encapsulated in a structure made of, e.g., aluminum and Tedlar®. A simplified electrical model of the PV cell is depicted in Fig. 3.

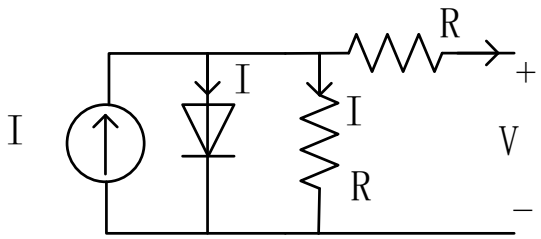

Fig. 3. The main circuit of PV.

System Control

The system level control can be divided into two conditions. In normal operation state of the grid, the PV can realize the operation of maximizing the energy capture based on Maximum PowerPoint Tracker (MPPT). In the condition of less insolation, the control objective is to make the SMES to supply the capability of the PV. This control level gives out the power demand for the SMES, which is represented in the Fig. 4.

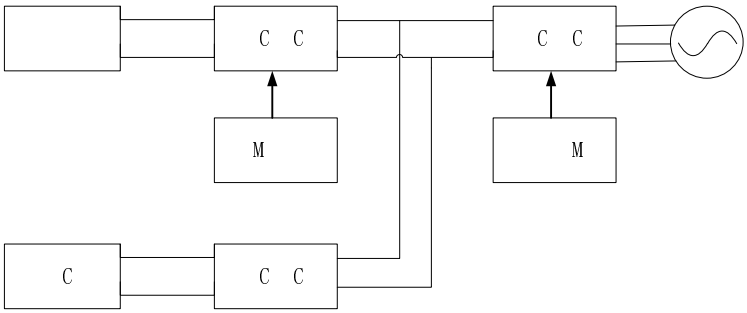

Fig.4 System control

The control of the SMES can be divided into two parts, that one is the active power current control, and the other is the reactive power. It is shown in Fig 5.

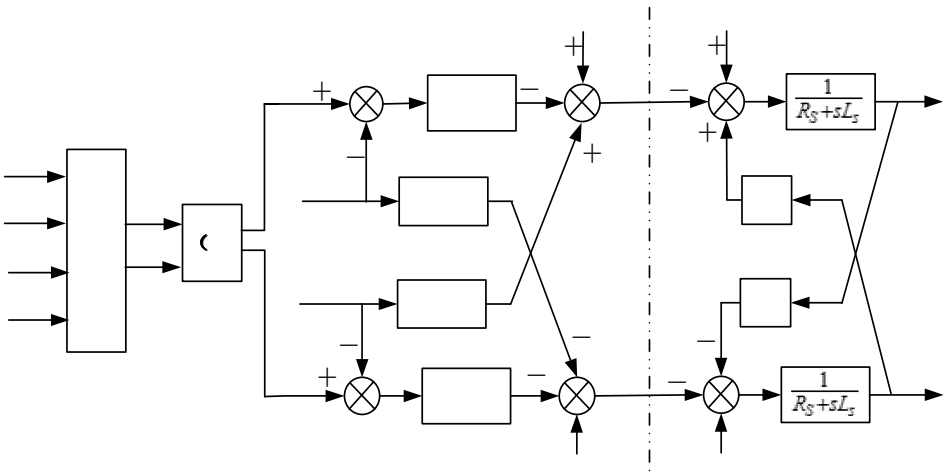

Fig.5 The control block diagram of VSC

The Perturb and observe (P&O) method operates periodically incrementing or decrementing the output terminal voltage of the PV and comparing the power obtained in the current cycle with the power of the previous cycle. If the voltage varies and the power increases, the control system changes the operating point in that direction, otherwise change the operating point opposite direction. Once the direction for the change of current is known, the current is varied at a constant rate. This rate is a parameter that should be adjusted to allow the balance between faster responses with less fluctuation in steady state.

Simulation

To evaluate the system performance, the model of the combined system is established using MATLAB /SIMULINK. The model contains a PV cell array, three power converters and associated controllers, a DC-link capacitor, a superconducting magnet, and an equivalent power grid.

According to the parameters of the SunPower SPR-305-WHT, the parameter of PV cell arrays are designed in Table I. For the grid-connected converter of the hybrid system, the capacity design should consider the power requirement for different control objective within the 50% rating power of the PV system. Considering the current carrying level of the high temperature superconducting tapes, the rating current of the magnet is selected as 160A.

TABLE I Design Parameters

Item		Parameters
PV	Rating power	45kVA
	Rating voltage	64.2V
	Rsh	0.038Ohm
Grid-side Converter	Rating power	100kVA
	Switching frequency	5kHz
	Filter inductor L	1mH
DC chopper	Rating power	100kVA
	Switching frequency	10kHz
	DC link capacitor	10000uF
	DC rating voltage	630V

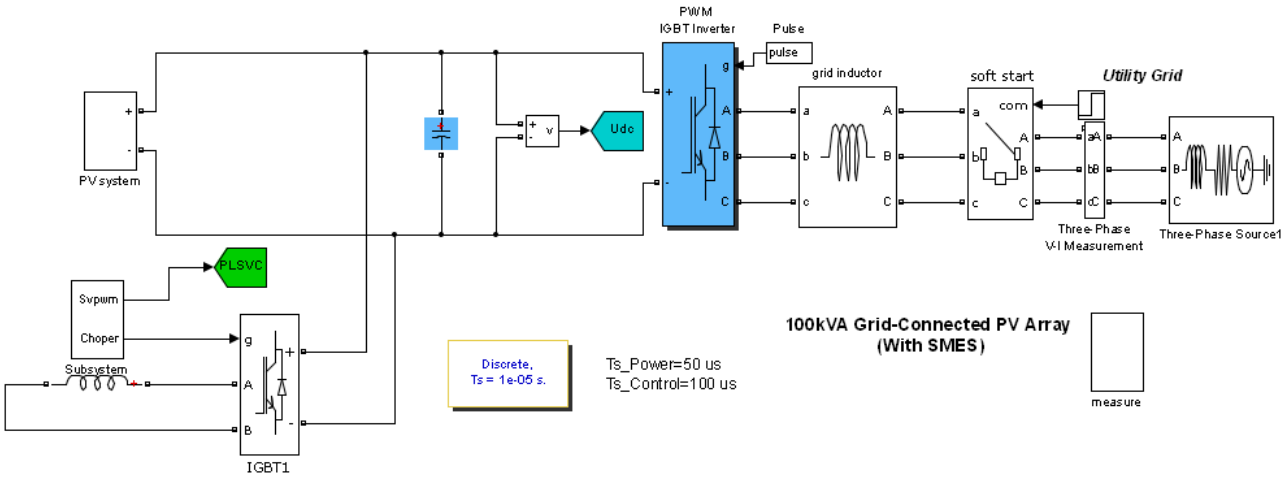

Fig.6 The simulation circuit with SMES

The simulation was set as shown in Fig.6. And then the result was given in Fig 7 and 8.

Fig. 7(a) shows the DC bus voltage dropped down from 630V to 580V without SMES. Fig. 7(b) shows the grid side current was influenced and cannot meet the stand to connect to the grid. Fig. 7(c) shows the grid side power the set power of the VSC the PV output power and the irradiation all in per-unit value. And the grid absorbs power from the PV as the line is below zero. As shown in Fig. 7(c) the PV output power can catch up with the irradiation using the MPPT. But the grid side power cannot meet the demand power. Fig. 8(a) shows the results with SMES, in which the DC bus voltage can keep as nearly a constant 630V. Fig. 8(b) shows the grid side voltage and the current is in high power factor. Fig. 8(c) shows that power of the PV can also track the maxim point and have no oscillation. The grid absorbs the exactly power as the demand. It can be seen that the SMES can smooth the power fluctuation of the PV effectively.

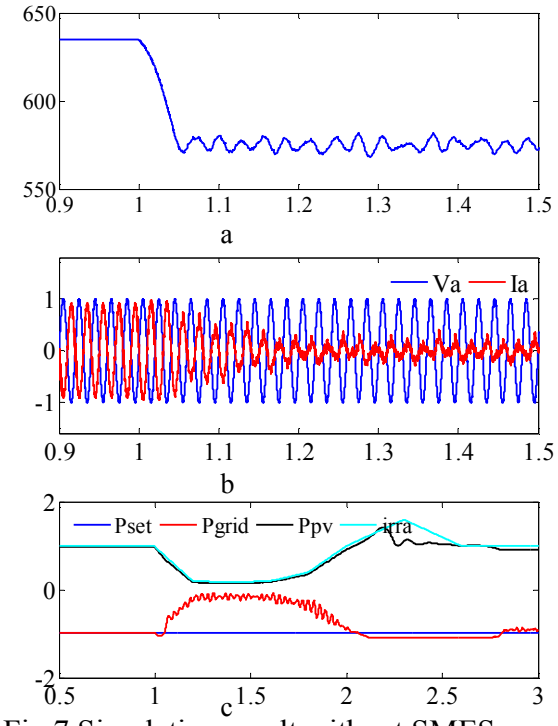

Fig.7 Simulation result without SMES

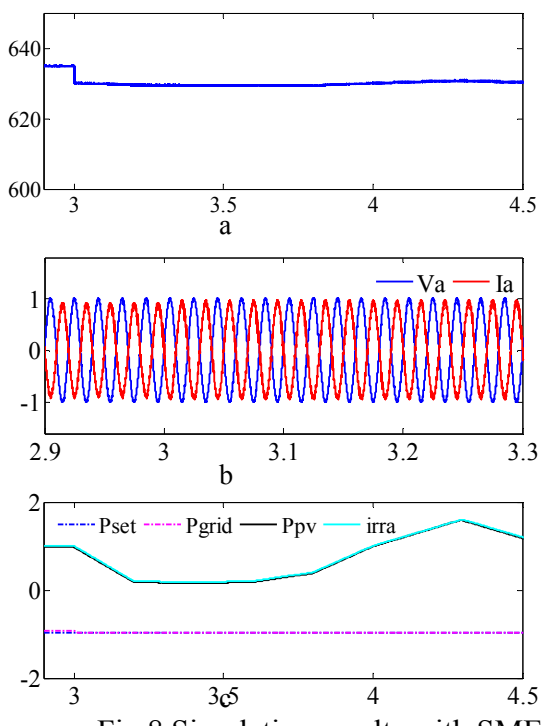

Fig.8 Simulation results with SMES

Conclusion

This paper presents a SMES based hybrid system for PV used in photovoltaic power generation. The SMES is designed to improve the stability and reliability of the grid-connected photovoltaic system. To evaluate the dynamic response of the hybrid system, simulation tests are carried out using MATLAB/SIMULINK. The results of simulation demonstrate that the SMES system can contribute to the stability and reliability of the grid-connected PV system.

email: jxlisong1@163.com

Keywords: Five-level inverter; Walsh function; Multi-band ;selected harmonic elimination

Abstract. SHEPWM technique applicable to multi-level voltage inverter via Walsh function can be solved by linear equations instead of nonlinear transcendental equations. This method don't need a large number of initial values, it's suitable for online calculation because of its advantages such as high speed calculation and high-accuracy. For the traditional SHEPWM technique based on Walsh function has modulation index restricted problem. This paper proposes a multilevel SHEPWM technique, which Combined Walsh function with multi-band modulation technique. Through the analysis of multi-level multi-band SHEPWM voltage waveform based on Fourier series transform, summarized the multi-level multi-band SHEPWM nonlinear equations when modulation index changed from 0 to 1, and solved the problem with on-line control calculating and modulation index expanding by Walsh function transform. Take five-level inverter as an example, according to the values obtained and considering some equations have several solutions under certain modulation index, using the MATLAB/SIMULINK software do simulation research. The result confirmed that the multi-level multi-band SHEPWM technique based on Walsh function transform is correct and practical.

Introduction

H type bridge cascade inverter is a kind of multilevel topology that has a good application prospect [1]. The pulse width modulation control method for multilevel inverter includes sine pulse width modulation technology [2], space vector pulse width modulation technology [3] and the selected harmonics elimination pulse width modulation technology [4]. Among these technologies the SHEPWM technology's low switching frequency and high quality output features has receive more attentions on inverter's control research. The traditional SHEPWM technology need to be solved for nonlinear equations, and can not realize online calculation, real-time control for switch angles [5]. For multilevel inverter can not calculate the nonlinear equations if take the traditional SHE control method when the modulation ratio is very low. This is also a main problem that limits the method for practical application.

The literature [6] put forward a SHEPWM technology based on Walsh function, analyzed the transformation relation between the Walsh domain and Fourier domain, convert the nonlinear transcendental equations based on Fourier domain to piecewise linear equations based on Walsh domain. The literature [7-10] improved the calculation steps of conversion process, proposed the recursive solution method between harmonic elimination switch angle and each amplitude fundamental voltage subsection. Walsh function transformation technology has low requirements for initial value of switching angles; a set of initial values can calculate each fundamental voltage amplitude piecewise. The literature [11] conclude that when the multilevel inverter under low modulation ratio control, piecewise linear system of equations can not solved based on Walsh function. On the basis of the above research results, this paper proposes a multi-band modulation scheme [12] that can broaden the multilevel inverter's modulation ratio and applied to Walsh function's transformation. The method analyzed the SHEPWM voltage waveform for multilevel inverter based on different waveband modulation mode, conclude unified SHEPWM solving model for multilevel inverter multi-band modulation when modulation ratio changes from high to low.

Through Walsh function transform the SHEPWM nonlinear equations based on unified solving model to piecewise linear system of equations.

Multi-band multilevel inverter SHEPWM harmonic elimination model

Figure 1(a) is a half-wave symmetric two-level staircase waveform; by Fourier transform can get the formula (1)

$$u(\omega t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos(n\omega t) + b_n \sin(n\omega t)) \quad n = 0,1,2,3... \tag{1}$$

Analyze the above formula can change as following general form

$$u(\omega t) = \begin{cases} b_n = 0, n \text{ is even} \\ b_n = \dfrac{4E}{n\pi} \sum_{k=1}^{N} p_k \cos(n\theta_k), n \text{ is odd} \end{cases} \tag{2}$$

In the formula, Mark b_n as the harmonic coefficient matrix, p_k at the rising edge of θ_k record +1, at the falling edge record -1.

Figure 1(b) is five-level trapezoidal modulation half cycle waveform, according to the formula (2) establish the harmonic elimination system of linear equations, eliminate 5 times harmonics, adopt the numerical algorithm to solve. When the modulation ratio is below 0.373, the equations have no solution. Aim at the above situation, this paper proposes a multi-band modulation scheme that can broaden the modulation ratio, take turns to broaden the modulation ratio by figure 1(a) and 1(b).

(a) Five-level A waveband model staircase waveform

b) Five-level B waveband model staircase waveform

Figure 1.Multi-band SHEPWM waveform for multi-level inverter

Observe the above staircase waveform, it is not hard to see that the waveform transformation rules between the different bands is take turns to downward folded the top waveform according to the dotted line. The applicable range modulation ratio for model A and B respectively is [0.373 1] and [0 0.373]. It can be see that adopt the multi-band modulation method can broaden the modulation ratio to [0 1]. When the modulation ratio is in different range can take the correspond waveband to establish the SHEPWM nonlinear equations, so you can get the different modulation ratio's correct switch angle.

The transformation of Walsh function and the establish of harmonic elimination model

The Walsh can be represented as Wal(n,t).n usually represent as the number of passing zero within time T under a certain order for Walsh function, t is the normalized time interval within time T.

Normalized the 1/4 periodic waveform figure 1(a) as figure 2 show, T (0-1) divided into 2^m equal parts, and mark c as the normalized value, the interval number for rising edge is N. Similar to Fourier expression, the above waveform by Walsh transform can get a group of Walsh function gather, as shown below

$$f(t) = a_0 Wal(0,t) + \sum_{i=1}^{N-1} a_i Wal(i,t) \tag{3}$$

$$\begin{cases} a_0 = \dfrac{2}{T}\int_0^T f(t)Wal(0,t)dt \\ a_i = \dfrac{1}{T}\int_0^T f(t)Wal(i,t)dt \end{cases} \quad \text{i} = 1,2,3... \tag{4}$$

Formula (3) simplified as follows on the basis of symmetry

$$f(t)=\sum_{i=1}^{N/2}W_{4i-3}Wal(4i-3,t) \tag{5}$$

Mark $W_{4i-3}=F^{\omega}(4i-3)$ as the Walsh coefficient of waveform f (t) that the Walsh function correspond, combined with figure 2

$$F^{\omega}(4i-3)=\frac{1}{2^{m-2}}\sum_{n=N+1}^{2^m/4}Wal(4i-3,n)+(\frac{N}{2^{m-2}}-4c)\cdot Wal(4i-3,N)\quad \text{i}=1,2,3\ldots \tag{6}$$

The simulation result

According to the data of above table draw the harmonic elimination switch angle trajectory as figure 3 show, the figure shows that modulation ratio in the range of 0 to 1 each band can get the correct switch angles. At each bands' transform place near minizone has multiple sets of switch Angle trajectory, These seemingly redundant switch angles can increase the select flexibility and control performance of switch angles when actual control.

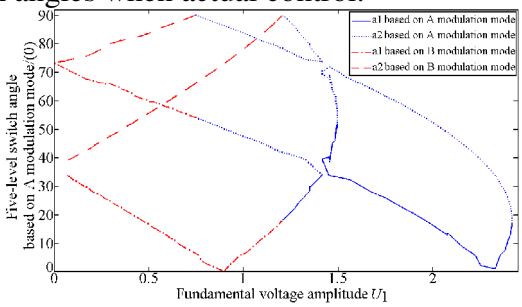

Figure 3. Switch angle trajectory for each waveband

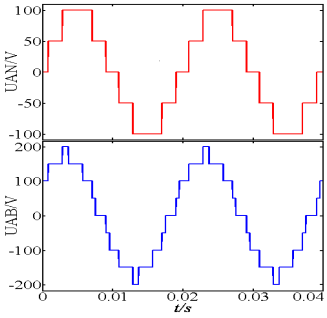
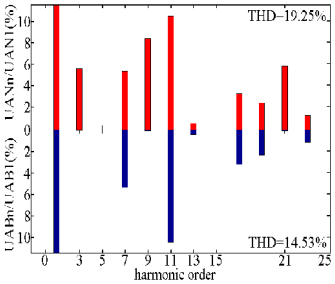
In order to validate the above theoretical analysis and the solve results, This paper use Matlab/Simulink simulation software to set up the simulation model and conduct researches for five-level inverter multi-band SHEPWM control technology based on Walsh transform. The simulation parameters: Independent dc voltage source voltage 50V; A and B band take U1 for 2.0 and 1.2 respectively when the switch angles are solved. Figure 4 and 5 give the five-level inverter output voltage waveform and spectrum distribution that the three kinds of the switch angles correspond.



(a) Phase voltage and line voltage simulation waveform



b) Phase voltage and line voltage spectrum distribution

Figure 4. A mode the simulation waveform

(b) Phase voltage and line voltage spectrum distribution

Figure 5. B mode the simulation waveform

Conclusion

This paper on the basis of analysis the multi-band multi-level inverter SHEPWM control method based on Walsh function transform, get the following conclusion:

The paper proposed the multi-band multi-level inverter SHEPWM control method based on Walsh function transform is able to expand the modulation ratio from 0 to 1 and transform the traditional SHEPWM nonlinear equations to piecewise linear system of equations to solve, Make the multi-level inverter can calculate the SHEPWM switch angles online, and able to eliminate harmonic by real-time.

The simulation results verify that 5 times harmonic of each band modulation mode is eliminated, Proved the paper that proposed linear multi-band solving method based on Walsh function is correct and practical.

Keywords: grid-tied inverter, unsymmetrical fall, P-R controller, LVPT

Abstract. In this paper, 10KW three-phase three-level photovoltaic grid-tied inverter is applied as hardware platform. Considering the insufficiency of PV arrays power output and low overall efficiency due to grid voltage falls asymmetrically, P-R current controller is used to provide unsymmetrical positive and negative sequence current to the grid so that low voltage ride through (LVPT) in photovoltaic inverter can be achieved. Through the implement of experiments, it is well proved that the requirement of LVPT when the grid voltage falls asymmetrically can be met by applying the solution proposed in this paper.

Introduction

In recent years, as the increasing of photovoltaic power penetration, especially more and more large-scale photovoltaic power stations are gradually connected to the grid, the photovoltaic inverter disconnection will arise when there is a short time grid failure occurring (such as short-circuit, component failure, launch of heavy load, etc.). Since there is a period of time before the gird recovers to normal condition, the losses of power will cause the disconnection of near inverters. Then, because of the disconnection of distributed power generation systems, energy will be accumulated at DC side to bring forth overvoltage of bus capacitor and over-current or distortion of grid-connected current. Thus, power quality will be seriously impacted. Consequently, PV grid-tied inverter is required to have the capability for LVPT.

Considering the factors that grid voltage fall unsymmetrically will result in insufficiency of PV arrays power output and low overall efficiency, comparison between decoupled dual synchronous current controller and Proportion-Resonant current controller is made. Finally Proportion-Resonant current controller is selected to achieve LVPT when the grid voltage falls unsymmetrically[1,2].

Hardware platform of low voltage ride through(LVRT)

The platform of LVRT is 10KW three-phase three-level photovoltaic grid-connected inverter, a simplified figure of the hardware topology is shown as Figure 1.

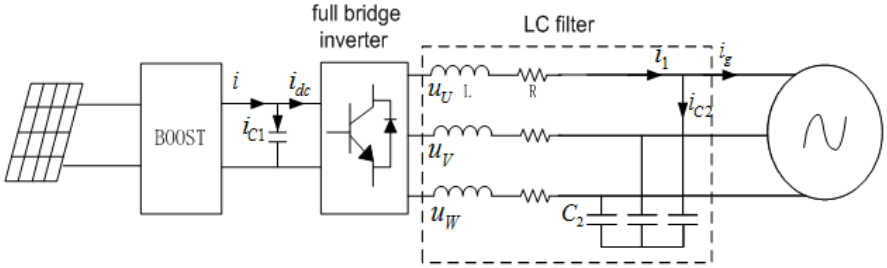

Figure1 Simplified topology of LVRT

Double Boost converter is used in the first stage in order to reduce the Boost current flowing through each channel, current pressure, switching losses and line losses of the switches of Boost circuit. Three-phase full-bridge inverter based on clamping diodes is applied as the second stage circuit to realize inverter transformation. The inverter current flows through LC filter to the grid.

Double Boost circuit is connected to two PV arrays and independent MPPT control is implemented to accommodate the power difference between two photovoltaic arrays due to hot spot effect or other elements. Film capacitance is used to connect the first stage and the second stage. On the one hand, stable bus voltage can be achieved, on the other hand, DC power of DC side and AC power of AC side can be decoupled. Usually, filters are applied to filter output current of inverter for the purpose of reducing switch losses and EMI. Considering the elements of control easiness, dynamic response, filter effects, switching loss, cost and size, LC filter is designed in the circuit. LEM sensor is applied to sample current and voltage, and then signals are transferred to control chips DSP2808 and CPLD. Multiple computation and control of the circuit are conducted in the control chip. ARM3S811 is selected as the core chip of monitoring system and standard Modbus Protocol is applied as the communication protocol. All of the inverter status are shown in the LCD256160.

Design of current controller

For single-phase systems, when grid voltage falls, the amplitude m and phase θ of voltage will change，it is easy to achieve LVPT if the PV grid-connected inverter adjusts the amplitude and phase of inverter current. Currently, current controller of three-phase system usually adopts PI controller in rotating coordinate system. When three-phase voltage falls symmetrically, traditional PI controller provides symmetrical current to the grid to achieve LVPT. However, when three-phase voltage falls asymmetrically, traditional PI controller only considers positive sequence component of inverter current, neglects the negative sequence component of inverter current, so traditional PI controller is not suitable for unsymmetrical voltage fall of three-phase system. To solve the situation mentioned above, there are two kind of current controllers can provide unsymmetrical current to the grid to achieve LVPT[3,4]

Decoupled dual synchronous current controller

Decoupled dual synchronous current controller controls positive current and negative current respectively through rotating of $\pm\omega$.

Because of PV grid-connected inverter is connected to the grid by three-phase three-wire, there is no residual current or residual voltage. When the grid has unsymmetrical malfunctions, the inverter current is shown in following formula 1

$$i = I^{+}\begin{bmatrix}\cos(\omega t+\phi^{+})\\ \cos(\omega t+\phi^{+}-\frac{2\pi}{3})\\ \cos(\omega t+\phi^{+}+\frac{2\pi}{3})\end{bmatrix}+I^{-}\begin{bmatrix}\cos(\omega t+\phi^{+})\\ \cos(\omega t+\phi^{+}+\frac{2\pi}{3})\\ \cos(\omega t+\phi^{+}-\frac{2\pi}{3})\end{bmatrix} \quad (1)$$

Current i transfer to positive current of dq axis by Park coordinate:

$$i_d^{+} = I^{+}\cos\phi^{+} + I^{-}\cos\phi^{-}\cos(2\omega t) + I^{-}\sin\phi^{-}\sin(2\omega t) \quad (2)$$

$$i_q^{+} = I^{+}\sin\phi^{+} - I^{-}\cos\phi^{-}\sin(2\omega t) + I^{-}\sin\phi^{-}\cos(2\omega t) \quad (3)$$

negative current of dq axis：

$$i_d^{-} = I^{-}\cos\phi^{-} + I^{+}\cos\phi^{+}\cos(2\omega t) - I^{+}\sin\phi^{+}\sin(2\omega t) \quad (4)$$

$$i_q^{-} = I^{-}\sin\phi^{-} + I^{+}\cos\phi^{+}\sin(2\omega t) + I^{+}\sin\phi^{+}\cos(2\omega t) \quad (5)$$

i_d^{+}, i_q^{+}, i_d^{-}, i_q^{-} are all constitute of DC component and double -frequency(2ω)alternating vibrate component，positive component i_d^{+}, i_q^{+} and negative component i_d^{-}, i_q^{-} have coupling, so it is necessary to filter alternating vibrating component, decoupling positive component and negative component.

On the base of decoupled dual synchronous current controller, a decoupling circuit and low-pass filter are applied to eliminate the need for complex designs of damping ratio and decouple the coupling of positive component and negative component. However, there are disadvantages of this method, PI controller needs tracking on DC reference values without static error. In fact, PI

controller is a time-varying function, it will generate static error while tracking DC parameters. Feed-forward net is adopted based on this problem, which means that the feed-forward negative current reference value can offset the double-frequency vibrate of positive component, the feed-forward positive current reference value offset the double-frequency vibrate of negative component. So the coupling of DC component and AC component can be relieved. The control block diagram is shown in Figure 2.

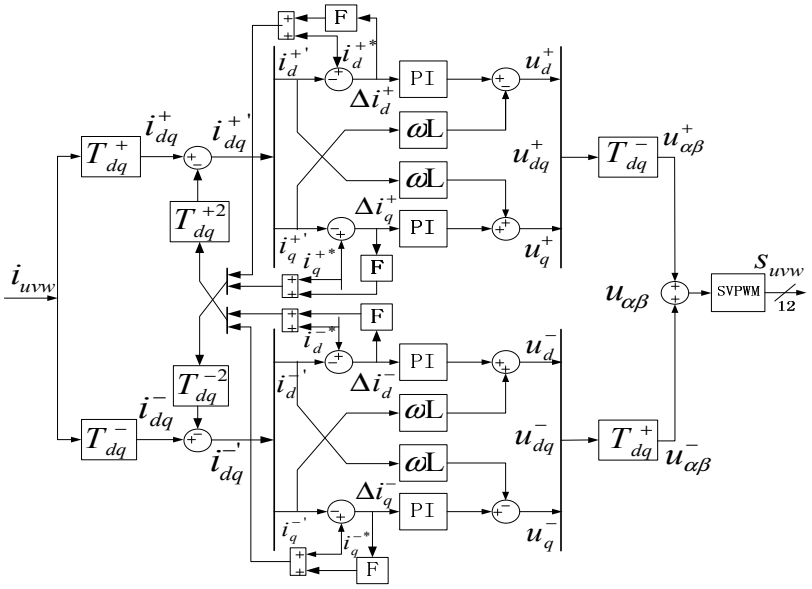

Figure2 Decoupled dual synchronous current controller based on feed-forward and low-pass filter

T_{dq}^{+}, T_{dq}^{-} are Park transform matrix, sampling current transfer to positive component and negative component of d axis and q axis, $T_{dq}^{+} = \left(T_{dq}^{-}\right)^{T} = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix}$, θ is grid phase.

Proportion-Resonant current controller

Decoupled dual synchronous current controller can provide unsymmetrical positive and negative current to the grid without static error only when DC reference values are perfectly tracked by PI controller, but it is hard to achieve in practical application. Introduction of feed-forward can compensate the double-frequency vibration, but decoupled dual synchronous current controller needs two current loops that complex algorithm and huge calculation is required. In contrast, P-R current controller works in static frame, all calculation are based on grid frequency f and only one current loop is needed to control positive and negative current. Output without static error can be achieved.[5] For the factors mentioned above, a P-R current controller is used in this paper to provide unsymmetrical positive and negative current to the grid so that the inverter can achieve LVPT when grid voltage falls asymmetrically.

The P-R current controller used in this paper consists of proportional part and second order undamped vibration part, in the transfer function, $G_{PR}(s) = K_p + \frac{K_i s}{s^2 + \omega^2}$, K_p is scaling factor, K_i is gain coefficient. The control block diagram of P-R current controller is shown as Figure 3.

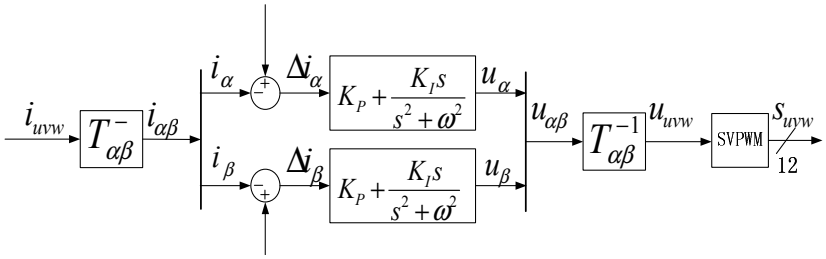

Figure3 P-R current controller based on static abc Coordinate system

$$u_\alpha = G_{PR} \cdot \Delta i_\alpha, u_\beta = G_{PR} \cdot \Delta i_\beta \quad (6)$$

From Figure 3, u_α, u_β do not interfere with each other, P-R current controller can achieve static error-free output, and Δi_α, Δi_β ripple wave are reduced, this is what PI current controller can not achieve[6,7].

Analysis of experimental results

When grid voltage falls asymmetrically, LVPT in photovoltaic inverter can be achieved by tracking positive component of the gird falling voltage fundamental wave and providing unsymmetrical positive and negative current to the grid. The result of the experiments is shown in Figure 4 and 5.

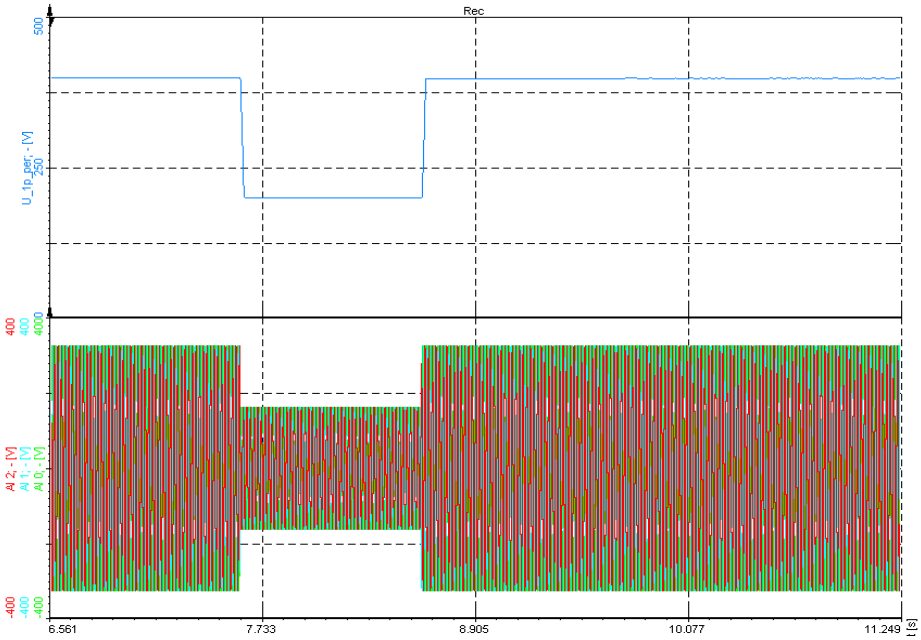

Figure 4 Three-phase voltage unsymmetrical falls and positive component track

The lower part of Figure4 indicates U and V voltage fall simultaneously. The unsymmetrical drop depth of voltage is less than 50%, downtime is about 8600-7400=1200ms, which meets the needs of LVPT: voltage unsymmetrical drop depth is between 20% and 90%, crossing time is less than 3 seconds. The upper part indicates that positive component of falling voltage fundamental wave keeps good consistency with the actual voltage drop.

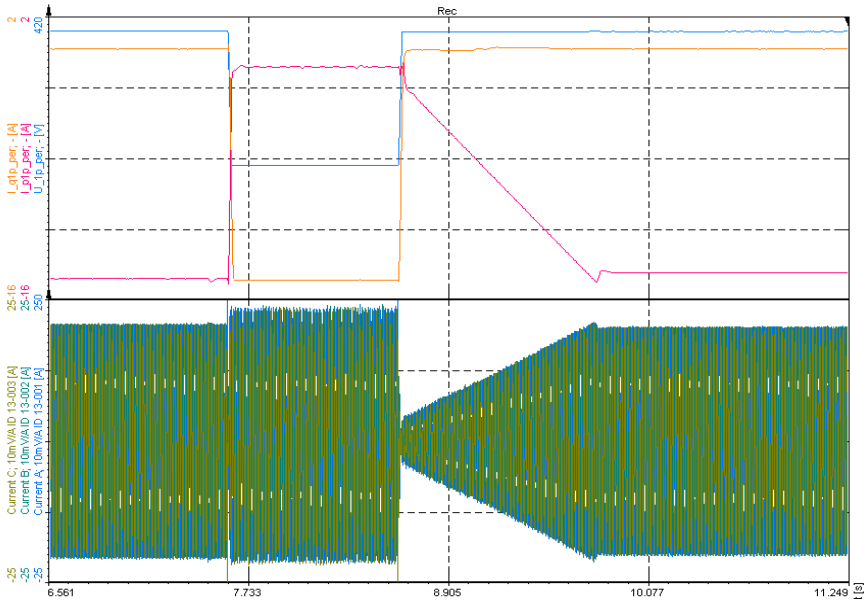

Figure 5 Unsymmetrical positive and negative current inject to the grid simultaneously to achieve LVPT

As Figure 5 shows, when the fault occurs at 7400ms, positive component of voltage fundamental wave is rapidly captured by the control loop. Thus, inverter can rapidly increase negative current input to the grid and decrease positive current input to the grid. When fault occurs, the inverter output current suddenly increases. At 8600ms，positive component of voltage fundamental wave recovers to normal level, inverter increases positive current, decreases negative current, grid current is gradually increased to the pre-fault level until 9400ms and downtime is 9400-7400=2000ms, less than 3s, which also meets the requirement of LVPT.

Conclusion

In this paper, the hardware platforms of LVPT is briefly introduced. Besides, comparison between decoupled dual synchronous current controller and P-R current controller is made and come to the solution of applying P-R current controller to provide unsymmetrical positive and negative current to the grid to achieve LVPT. Through experiments, the results shows that the proposed solution can rapidly recover to normal working status by achieving output without static error, reducing grid-tied vibration frequency and also meeting the requirements of achieving LVPT when grid voltage falls asymmetrically.

Study on control strategy of the grid-side converter on doubly-fed induction generator system

Feng Yuan [a], Zhili Tan [b]

Faculty of Mechanical & Electronic Information, China University of Geosciences, Wuhan 430074, China

[a]yuanfeng0505@163.com, [b]Tanzhili@cug.edu.com

Keywords: Double-fed induction generator, grid-side convertor, SVPWM, vector control.

Abstract. Double-fed induction generator has the characteristic that voltage signal output maintain stable with the stable rotate speed, which leads to the wide utility of double-fed induction generator in the area of distributed power generation. In this paper, the basic structure and control method of double-fed induction generator were introduced and emphasis was put on the control technique of grid-side convertor of double-fed interaction power generation system. Simplified model of grid-side convertor was given in the double-fed interaction power generation system. On this basis, the performance was analyzed and control scheme of grid-side convertor was designed. Through Matlab/Simulink, simulation of stable output of DC side voltage was realized.

Introduction

With the unceasing exploit of fossil fuel, the ecological environment problem becomes increasingly fierce. Reproducible and clean alternative energy sources are badly needed. Doubly-fed asynchronous motor can get rid of the restriction of rotate speed. With doubly-fed asynchronous motor, distributed power generation system can improve the energy transfer efficiency remarkably, which has been increasingly used in new energy power generation systems such as solar energy, wind energy, biomass energy and geothermal energy etc.

For grid side converter, many kinds of control strategy were proposed in recent years. With the control strategy of space vector pulse width modulation (SVPWM) and the grid voltage vector orientation, voltage closed loop keeps the stability of DC bus voltage. Through the two current close loop of d, q axis, active power and reactive power decoupling control is realized, and arbitrary adjustable of power factor is realized. Based on the mathematical model of the grid side converter, to its principle and steady-state characteristics is analyzed. According to the dynamic model of the synchronous rotating coordinate system, with the design method of the double closed loop system, double closed loops control system is designed, include voltage closed loop and current closed loop. The simulation of Matlab/Simulink verified the feasibility and validity of the scheme.

Basic structure and principle of double-fed induction generator

In this system, the stator of double-fed induction generator is connected to the power grid directly, the rotor proceeds AC excitation, to change the phase position, frequency and amplitude of field current. Of the field current. When the power input changes, generator rotate speed changes to control the frequency of field current, which can realize variable speed constant frequency power generation. Principle of double-fed induction generator is showed in fig.1.

From grid convertor to rotor side convertor, capacitance and rotor side convertor can be seen as load, grid convertor is a one-third phase voltage type PWM rectifier. Simplified model of three-phase voltage type PWM rectifier is in fig.2. According to the kirchhoff voltage and current law,

$$L_s \frac{di_{gk}}{dt} + R_s i_{gk} = u_{gk} - (v_{kN} + v_{No}) \qquad (k = a,b,c) \tag{1}$$

From fig.2, $v_{kn} = v_{dc} S_k$.

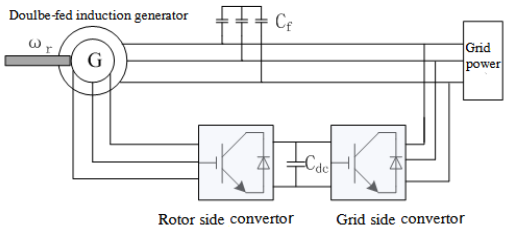

Fig.1 Structure diagram of independent double-fed power generation system

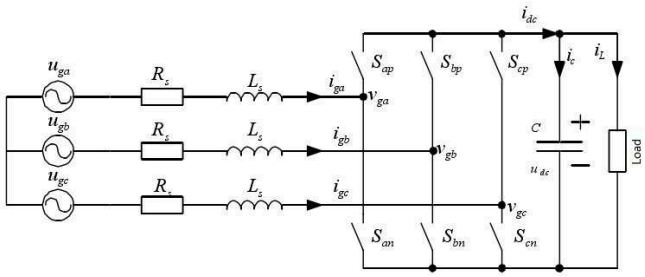

Fig.2 Simplified model of three-phase voltage type PWM rectifier

For three phase system of equilibrium state,

$$i_{ga} + i_{gb} + i_{gc} = 0 \,,\; u_{ga} + u_{gb} + u_{gc} = 0$$

We get,

$$v_{No} = -\frac{v_{dc}}{3} \sum_{k=a,b,c} S_k \tag{2}$$

Making $v_{kN} + v_{No} = v_{gk}$

From (1), (2) and capacitance current equation of direct current side, we get the mathematic model of grid side convertor of three phase in rest frame. With park transformational matrix, we get the mathematic model of grid side convertor in dq synchronous rotating reference frame.

$$\begin{cases} L_s \dfrac{di_{gd}}{dt} = -R_s i_{gd} + \omega L_s i_{gq} - v_{gd} + u_{gd} \\ L_s \dfrac{di_{gq}}{dt} = -R_s i_{gq} + \omega L_s i_{gd} - v_{gq} + u_{gq} \\ C \dfrac{du_{dc}}{dt} = S_d i_{gd} + S_q i_{gq} - i_L \end{cases} \tag{3}$$

Where, u_{gd} , u_{gq} are components of network voltage of d, q axle; i_{gd} , i_{gq} are components of current input of d,q axle; v_{gd} , v_{gq} are components of rectifier bridge voltage of d, q axle; S_d , S_q are components of switch function of d, q axle. ω is frequency of exchange network.

Control method of grid side convertor

The vector control is used in exchange network voltage control of grid side convertor. The principle is that equation above showed the mathematic model of three phase PWM rectifier in d, q synchronous rotating reference frame. If the orientation of d axle is the orientation of network voltage comprehensive vector $\vec{u}_g$, then

$$\begin{cases} u_{gd} = |\vec{u}_g| = \sqrt{\dfrac{3}{2}} U_{gm} \\ u_{gq} = 0 \end{cases} \tag{4}$$

Where, U_{gm} is phase voltage peak.

Transform (3) and get the first two equations,

$$\begin{cases} v_{gd} = -R_s i_{gd} - L_s \dfrac{di_{gd}}{dt} + \omega L_s i_{gq} + u_{gd} \\ v_{gq} = -R_s i_{gq} - L_s \dfrac{di_{gq}}{dt} - \omega L_s i_{gd} \end{cases} \tag{5}$$

The influence of electricity cross coupling items $\omega L_s i_{gd}$, $\omega L_s i_{gq}$ and network voltage u_{gd} existed. A control method is needed to relieve current coupling between d and q axis and remove network voltage disturbance. Feed forward decoupling control strategy can achieve this goal.
Transform (5) as follows:

$$\begin{bmatrix} v_{gd} \\ v_{gq} \end{bmatrix} = \begin{bmatrix} -v'_{gd} \\ -v'_{gq} \end{bmatrix} + \begin{bmatrix} \Delta v_{gd} \\ \Delta v_{gq} \end{bmatrix} + \begin{bmatrix} u_{gd} \\ 0 \end{bmatrix} \tag{6}$$

Where, v'_{gd}, v'_{gq} are first-order differential of voltage component related to i_{gd}, i_{gq}; $\Delta v_{gd}, \Delta v_{gq}$ are voltage compensation coupling term of d and q axis.

Meanwhile, 1-7 alternating current side disturbance voltage u_{gd} was used to proceed feed foreword compensation. Then, feed forward control of d and q axis is realized.

Active power and inactive power of d and q axis were as follows:

$$\begin{cases} P = u_{gd} i_{gd} + u_{gq} i_{gq} \\ Q = u_{gd} i_{gq} + u_{gq} i_{gd} \end{cases} \tag{7}$$

Where, when p>0, it means the convertor is in rectification, absorbing active power from the network; when p<0, it means the convertor is in contravariant, absorbing active power from the network.

The rectifier uses double closed loop control. The main function of outer loop, Dc voltage control loop, is Trace output voltage outer loop current instruction to realize fast current control. The specific control block diagram is in fig.3.

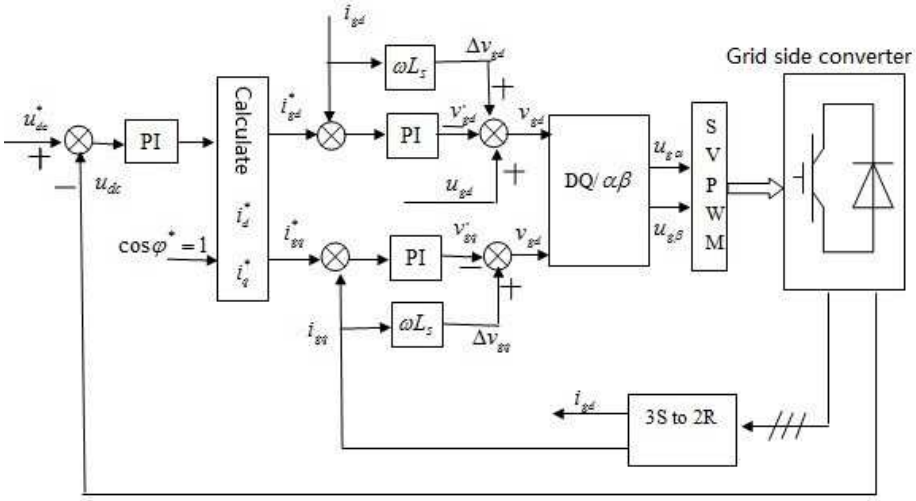

Fig.3 Diagram of grid side convertor control

In direct current link, present voltage u^*_{gd} and feedback voltage u_{gd} were compared and the error would be output through PI regulator. Power factor was set as unity power factor. i^*_{gd}, i^*_{gq} were compared with feedback current i_{gd}, i_{gq}, and the result v'_{gd}, v'_{gq} would be outputted through PI regulator. Then, v'_{gd}, v'_{gq} would be calculated with their own compensation items $\Delta v_{gd}, \Delta v_{gq}$ and power grid voltage disturbance feed-forward compensation term u_{gd}. AC side converter reference voltage v_{gd}, v_{gq} would be get. After transformation of coordinates of reference voltage, component values $v_{g\alpha}, v_{g\beta}$ of coordinate system were get. And after SVPWM modulation, driving signal appeared.

Simulation and analysis

According to the mathematic model and control diagram, Matlab was used to build the system model. network voltage 220V, frequency 50Hz, DC side stabilivolt capacitance 3300μf, AC side filter

inductance 5mH, DC side reference voltage 300V, system simulation would be normalized. SVPWM pulse modulation mode was used to strike the on/off of IGBT.

Simulated tests of unity power factor rectification and unity power factor contravariant were undertaken to test its performance in steady state. Two different conditions were simulated.

Rectification operation simulation of unity power factor.

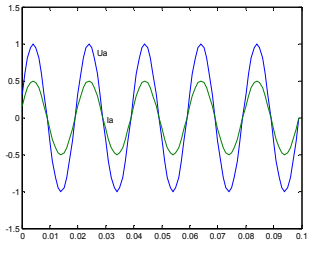

Fig.4 Phase voltage vs. phase current in rectification

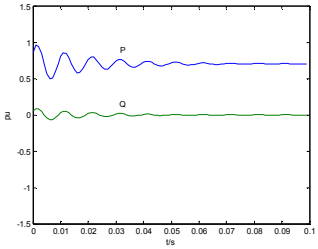

Fig.5 Active power vs. inactive power in rectification

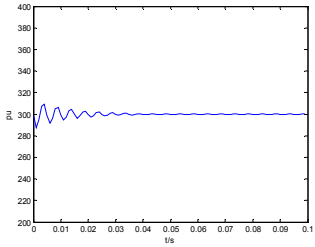

Fig.6 DC side tracking voltage waveform in rectification

In the unity power factor rectification (fig.4-6), fundamental wave of phase current is sinusoidal, keeping in phase with phase voltage. The power flows into rectifier from the network entirely. In this time, active power of the system is greater than 0, and inactive power is 0, power factor is 1, and DC side voltage is stable at a given reference voltage through regulating.

Contravariant operation simulation of unity power factor.

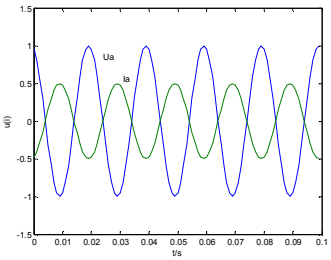

Fig.7 Waveform of phase voltage and phase current in contravariant

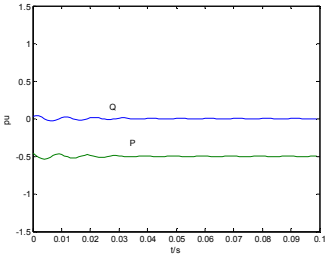

Fig.8 Active power and inactive power in contravariant

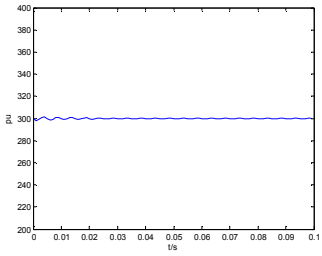

Fig.9 DC side tracking voltage waveform in contravariant

In the contravariant of unity power factor (fig.7-9), fundamental wave of phase current is sinusoidal, keeping in opposite phase with phase voltage. The power flows into the network from DC side entirely. In this time, active power of the system is less than 0, and inactive power is 0. There is no current between the network and rectifier. Power factor is 1, and DC side voltage is stable at a given reference voltage through regulating.

Conclusion

The mathematic model of grid-side convertor of double-fed interaction power generation system is established. On this basis, voltage and current double closed-loop control system was adopted. According to SVMWP, simulation and experimental study were preceded to this system. Research results showed that grid-side convertor can get sine-input current with adjustable power factor, and can maintain DC bus voltage stable, which meet the design requirement of double-fed interaction power generation system.

Keywords: Distributed Power Flow Controller; suppress oscillation; PSCAD/EMTDC; improve system stability

Abstract. In this paper, the series converters of Distributed Power Flow Controller are the main object of study. Its mechanism of suppressing power system oscillations is studied by theoretical analysis and formula derivation, which relies on a single-machine infinite-bus power system, installed the series converters. Then based on the mechanism, adopting the classic PI control and the damping controller, designed the transient stability control loop for the series converters. Finally, simulations performed by PSCAD/EMTDC, the results show that DPFC device can effectively suppress oscillation and improve system stability.

Introduction

With the characteristics of large units, ultra-high voltage, long distance and heavy load, the modern power system has become a typically strong nonlinear, high-dimension and dynamic system, along with its rapid development. As a result, it's more and more possible to cause oscillation in the power system. The essential reason of generating oscillation in power system is the absence of damping. Presently, additional controls are commonly used to provide extra damping to suppress it and control measures are generally focused on the generation and transmission parts. In the generation part, the traditional method used to increase the damping of a power system is by adding a Power System Stabilizer (PSS) in the excitation and governing system of the generator, while in the transmission part, the flexible and fast power electronic devices are mainly used on the line to provide additional control.

More current research is in the transmission part by using FACTS devices. A Phillips-Heffron model is established in literature [1-2] to analyze the mechanism of damping low frequency oscillation in power system by Thyristor Controlled Series Capacitor (TCSC), Static Var Compensator (SVC) and other FACTS devices. While, Lyapunov method is introduced in literature [3] for analyzing the damping mechanism of the Unified Power Flow Controller (UPFC). Distributed Power Flow Controller (DPFC) is the latest FACTS devices with the combined functions of series compensation and shunt compensation, however, the domestic research on it is relatively less. A single-machine infinite-bus system established with the dynamic model of the series converters of DPFC is adopted in this paper to study the mechanism of damping oscillation. Then based on the mechanism, adopting the classic PI control and the damping controller, designed the transient stability control loop for the series converters. Finally, simulations performed by PSCAD/EMTDC, the results show that DPFC device can effectively suppress oscillation and improve system stability.

The Principle of DPFC

DPFC consists of several low-power series converters and one shunt large-power converter without common dc link. The shunt converter is similar to a STATCOM; primarily used to maintain stability of the bus voltage and provide the third harmonic power the series converters are required. While the series converters employs the DSSC concept. It uses multiple low-power single-phase voltage inverters instead of a centralized large-capacity three-phase inverter in UPFC. Each converter within DPFC is independently controlled. The configuration of the DPFC is shown in shown in Fig.1.

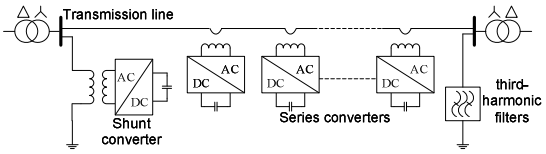

Fig.1.DPFC configuration

In order to study the function of DPFC inhibiting oscillation, a simplified equivalent model is adopted in this paper: The DPFC is accessed to a single infinite system and the shunt converter is equivalent to a third harmonic current source (derivation ignored, the simulation uses).

The Mechanism of Damping Oscillation

The output voltage is in series with the circuit via a single-phase inverter [4]. Based on the pulse width modulation (PWM), the dynamic model of the series converter can be expressed in Eq.1:

$$\begin{cases} \dot{V}_{ss} = m\dfrac{V_{dc}}{\sqrt{2}}(\sin\delta_{ss} + j\cos\delta_{ss}) \\ \dfrac{dV_{dc}}{dt} = \dfrac{3m}{2C}(I_d \sin\delta_{ss} + I_q \cos\delta_{ss}) \end{cases} \tag{1}$$

Where: m, δss are amplitude modulation ratio and phase angle of the series injected voltage; Vdc is the voltage of the series converters in DC side, Iq and Id are q-axis and d-axis current component of the series converter in AC side.

After series converter of DPFC access to system, the generator voltage equation is shown in Eq.2.

$$\begin{cases} E_q^{'} = V_{bq} + V_{ssq} + I_d x_{d\Sigma}^{'} \\ 0 = V_{bd} + V_{ssd} - I_q x_{q\Sigma}^{'} \end{cases} \tag{2}$$

Where: Xd=XL1+XL2+XT+Xss+Xd′, XqΣ=XL1 +XL2+XT+Xss+Xq, Xd is d-axis transient reactance, Xq is q-axis reactance, Vssq and Vssd are the q-axis and d-axis component of the injected voltage of series converters, Vbq and Vbd are q-axis and d-axis components of infinite bus voltage. Associated (1) and (2) yields Eq.3 for the line current. Substituted Eq.3 to nonlinear dynamic equations [5] of single-machine infinite system and linearize it at a stable operating point can obtained Eq.4.

$$\begin{cases} I_q = \dfrac{1}{x_{q\Sigma}}\left[\dfrac{mV_{dc}\sin\delta_{ss}}{\sqrt{2}} + V_{bd}\right] \\ I_d = \dfrac{1}{x_{d\Sigma}^{'}}\left[E_q^{'} - V_{bq} - \dfrac{mV_{dc}\cos\delta_{ss}}{\sqrt{2}}\right] \end{cases} \tag{3}$$

Eq.4 is the Phillips-Heffron model of single-machine infinite system installed series converters of DPFC. Phillips-Heffron model has been used in analyzing the feasibility of utilizing FACTS devices in damping oscillation and designing the corresponding controller [5-7], whose torque to the system is shown in Eq.5. Where: [Δm, Δδss]T is input signal of series converters; Kp=[Kpm, Kpδ]T, Kq=[Kqm, Kqδ]T and Ku=[Kum, Kuδ]T are definite value based on stable operating point; [Cm(jωs), Cδ(jωs)]T is the damping controller transfer function. Eq.5 shows that the torque DPFC can be provided to the system contains synchronizing torque and damping torque. Its size and negative are determined by the phase of ΔT in the plane composed of Δδ and Δω. As long as control the damping torque within a certain range can suppress system oscillation well.

$$\begin{bmatrix} \Delta\dot{\delta} \\ \Delta\dot{\omega} \\ \Delta\dot{E}'_q \\ \Delta\dot{E}_f \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ \frac{-\omega_0 K_1}{M} & \frac{-D}{M} & \frac{-\omega_0 K_2}{M} & 0 \\ \frac{-K_4}{T'_{d0}} & 0 & \frac{-K_3}{T'_{d0}} & \frac{1}{T'_{d0}} \\ \frac{-K_E K_5}{T_E} & 0 & \frac{-K_E K_6}{T_E} & \frac{-1}{T_E} \end{bmatrix} \begin{bmatrix} \Delta\delta \\ \Delta\omega \\ \Delta E'_q \\ \Delta E_f \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ \frac{-K_{pm}}{M} & \frac{-K_{q\delta}}{M} \\ \frac{-K_{qm}}{T'_{d0}} & \frac{-K_{q\delta}}{T'_{d0}} \\ \frac{-K_E K_{um}}{T_E} & \frac{-K_E K_{u\delta}}{T_E} \end{bmatrix} \begin{bmatrix} \Delta m \\ \Delta\delta_{ss} \end{bmatrix} \tag{4}$$

$$\Delta T = \left[K_{\mathrm{p}} - \frac{K_E K_2 K_q + K_2(1 + j\omega_s T_E) K_u}{(K_3 + j\omega_s T'_{d0})(1 + j\omega_s T_E) + K_6 K_E} \right] \begin{bmatrix} C_m(j\omega_s) \\ C_\delta(j\omega_s) \end{bmatrix} \begin{bmatrix} \Delta m \\ \Delta\delta_{ss} \end{bmatrix} \tag{5}$$

The Control Strategy of DPFC

Since the integrals of all the cross product of terms with different frequencies are zero and the active powers at different frequencies are independent from each other, a converter without a power source can generate active power at one frequency and absorb this power from other frequencies [8]. Based on this conclusion, the 3rd harmonic is selected to replace DC link for active power exchange in DPFC, due to the unique features of 3rd harmonic frequency components in a three-phase system. Control for shunt converter contains Three-phase voltage at the fundamental frequency and single-phase 3rd harmonic currents. Control block diagram is shown in Fig.2.

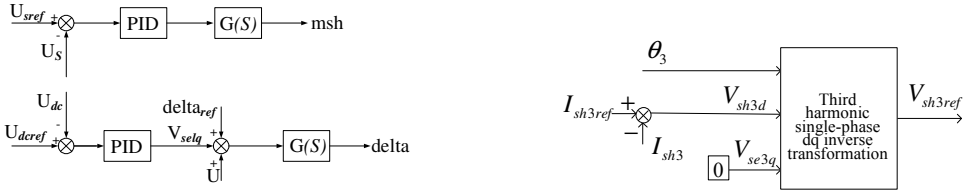

Fig.2.Control block for shunt converter

Series converters are absorbed 3rd harmonic active power and generate the fundamental frequency voltage. By injecting the voltage change the transmission characteristics of the grid. The control scheme of series converters uses the PI control and dq decoupling control. The entire control block diagram is shown in Fig.3.

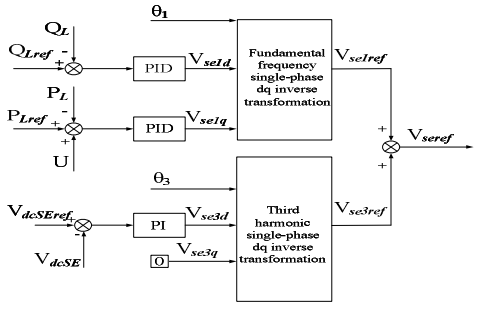

Fig.3.Control scheme of the series converter

Damping controller is used to improve the damping capacity of power system. Output parameter of damping controller is to modify the reference signal of the power flow controller. DPFC controllable parameters include voltage amplitude, phase angle of shunt converters and voltage amplitude, phase angle of series converter. All these can be used to modify the damping torque. Modulating the voltage phase angle of shunt converters or the voltage amplitude of series converters is best. In this paper, the block diagram of damping controller is shown in Fig.4.

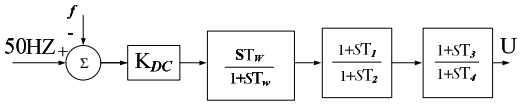

Fig.4.Block diagram of damping controller

Simulations

Simulation system of single phase diagram used in this article is shown in Fig.5, DPFC device connected to a double circuit in the network. In this graph, the valid value of line voltage of G1 is 230V, the initial phase angle is 35°, the output power is 0.65KW, and the power factor is 0.8.G2 is infinite power, the valid value is 230V, and initial phase angle is 0°. The equivalent impedance of two transmission lines L1, L2 is 1.69+j22.70. The turn ratio of transform T1, T3 is 0.23KV/0.8KV, the capacity is 15KVA, and leakage reactance is 13%, Y-△connection. The turn ratio of transform T2, T4 is 0.8KV/0.23KV; others are the same as T1, T3. Specific generator parameters are: Ta=0.125sec,Xp=0.113pu,Xd=0.56pu,Xd'=0.132pu,Tdo'=1.3323sec,Xd"=0.113pu,Tdo"=0.045sec, Xq=0.4pu,Xq"=0.135pu,Tqo"=0.034pu,W0=100π; Initial operating conditions are: Vt0=0.913pu, degv0=0.5393rad.

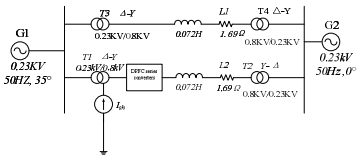

Fig.5.Simulation system wiring diagram

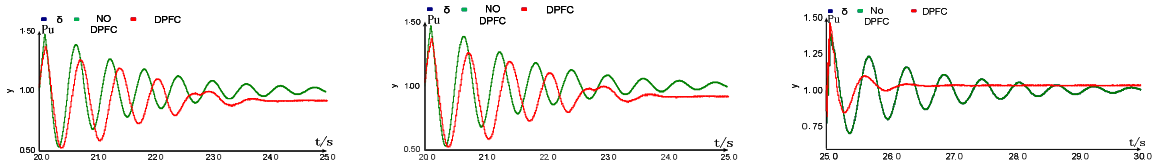
Simulation when mechanical torque mutation in 20s (shown in Fig.6.(a)), load power mutation in 20s (shown in Fig.6.(b)), three-phase fault in 25s (shown in Fig.6.(c)).



(a) (b) (c)

Fig.6.Damping simulation

To further validate the damping ability of the DPFC for inter-area oscillation, build a two-area four-machine system, installing DPFC in the two regional tie-lines. Set three-phase fault in the tie-lines in 20s, the simulation results shown in Fig.7.

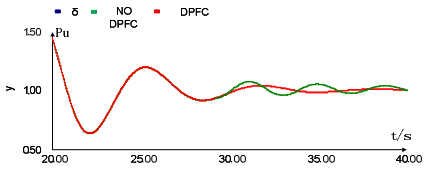


Fig.7.Damping Simulation of two-area four-machine system

As can be seen from the simulation results, the power angle of the generator can suddenly change, lose stability or even cause oscillation when mechanical torque mutation, load power mutation and three-phase fault occur. When DPFC is not connected to the system, depending on the damping ability of the system, the time to re-stabilize the system to reach a new power balance is much longer than the system access DPFC.

Conclusions

The paper derived its mechanism of damping oscillation after introduced the structure of DPFC, and then described the control strategy for the shunt converter and series converters. Adopting the classic PI control and the damping controller, designed the transient stability control loop for the series converters. Through simulation, the results show that when the system oscillation occurs, DPFC able to quickly damping oscillation of local system, allowing the system to reach a new

Keywords: New energy, High altitude area, Solar energy, Wind energy, Biomass energy, Intelligent Greenhouse

Abstract: In the high altitude, solar energy, biomass energy and wind energy are widely available and renewable energy sources. It will improve the region's living levels at high altitude and the ecological environment when developed efficiently and in low cost. Making full use of renewable natural resources is of great value and significance to sustain the development of high-altitude areas of the economy. This paper is a kind of research and study, which based on new energy and aims at making full use of solar energy, wind energy, biomass energy complementary relationship and physical changes between planting and breeding to improve the renewable energy industry, integrated, modular for the high altitude area residents gathered .

Introduction

The advanced biological modeling technology and the automatic control program will be used in the Intelligent greenhouse[1]. The comprehensive development of planting and breeding technology in intelligent greenhouse is a new try. Microcomputer will apperceive the environmental indicators by water level sensors, temperature sensors, humidity sensors, carbon dioxide concentration sensors, oxygen concentration sensors, light intensity sensors and other sensors. Microcomputer collects , analyses and process data, to control relative drip irrigation pipe system, wind power, solar power equipment, storage equipment, ventilation equipment, planting areas, breeding areas, the biogas production facilities to do the implementation of real-time monitoring. Microcomputer adjusts the concentration of different materials in the area and farming area, then simulates the most appropriate relative optimal environment. Finally, the greenhouse changes the growth environment of the plants and animals by former progresses in order to avoid the production losses due to human' factors.

Intelligent greenhouse structure

(1) General structure

Gradually, along with the decrease of traditional fossil energy, new energy came into the stage of history. It is a bold attempt to make the solar energy, wind energy, biomass energy and other new energy apply to intelligent greenhouse[2]. The new type of intelligent greenhouse is established to change the structure of the traditional intelligent greenhouse and makes full use of the material advantages of planting and breeding, and improves the production efficiently.

New intelligent greenhouse is divided into nine parts such as the tent body, breeding areas, planting areas, wind power, solar power, biogas digester, reservoir, living area, control area (following pictures in Fig. 1 and Fig. 2). Modules are independent and cooperative with each other forms the basis of the new intelligent greenhouse structure. And it is necessary for the normal running of the greenhouses to provide the protection.

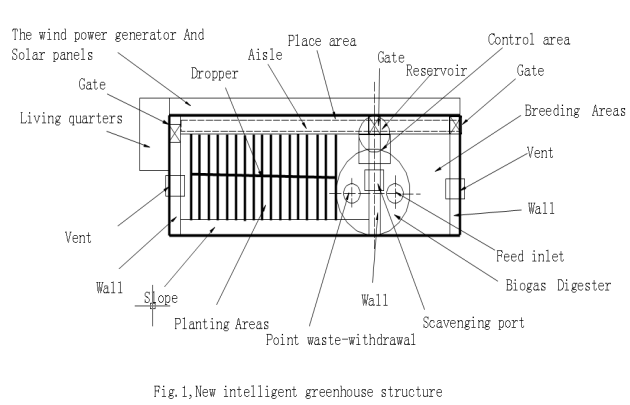

Fig. 1

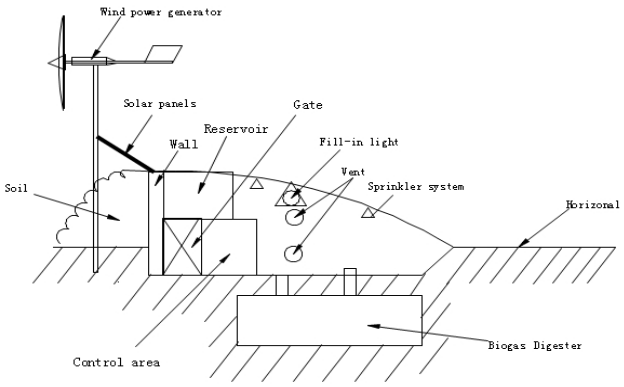

Fig. 2

(2)Tent body

The whole structure of greenhouses is covered by PE or PVC films, of which the thickness is 0.1 mm, the color is colorless and transparent. Distance between the bottom and horizontal is 1.0-1.5 m inside the greenhouse. The soil which is digged inside the greenhouse will be put on the rear of the casing body in order to form slope type for heat insulation. There is a wall between the planting areas and breeding areas to isolate them with controlled areas, biogas digester and reservoir around. On the wall , there are ventilation, adjustable gas content between the belt and farming districts.

(3)Planting areas

Planting areas is one of the main structures of the Tent body. The front of planting areas is a slope which is helpful to collect the sunlight and increase the area of shade plants. Above tent body, is the corresponding arrangement with methane and the fill light lamp. It is mainly used for plants to provide necessary light conditions during the night or cloudy day, to make plants better to do the photosynthesis to generate organic matter and release oxygen. Experiments show that use of plant growth lamp and the calefacient lamp for animals and plants can make warming lamp 15cm ground temperature inside the greenhouse increased averagely by 1.33℃, 667 m^2 cucumber yield increased by 17.4% on average, 667 m^2 production increased by 8195.4 yuan. Under the low temperature according to the weather, the average temperature increased by 1.13℃, the cucumber yield increased by 19.32%; delicious, can obviously resist the influence of low temperature according to the weather[3].Dropper pipelines which is scattered throughout ,can save the water resources,can provide the necessary water for plant growth, and achieve the goal of science with water.

(4)Breeding areas

The breeding areas is in order to carry on animal husbandry and aquaculture besides planting areas. Its demand is not so high like the planting areas. Animals will be centralized management in here. Above the tent body, there are the fill lights that will provide illumination and temperature under the right conditions for animals that needs to grow.It will help animals to avoid high altitude coldness. There is an entrance of biogas digester .The animals waste is put into biogas digester, providing the necessary raw materials for the methane production. The CO2 from the animals will become the main source in planting areas.

(5)Planting and Breeding areas

The areas is scattered with the temperature sensor, humidity sensor, the concentration sensor of carbon dioxide, the concentration sensor of oxygen, light sensor. The sensors collect the planting and breeding areas of changing parameters.

(6)Biogas Digester

It is in the middle of planting areas and breeding areas under the earth. It facilitates the original materials which produced by breeding areas for the biogas digester . Besides it provides fertilizer to Planting areas. Biogas digester generated biogas to delivery to residential areas, at the same time as a part of the planting areas sources of energy and raw materials.

(7)Reservoir

It is the main source of water demanded in the whole system. Reservoir has water level detection sensor. It provides water through the water supply pump. Water will be assigned by the control system to breeding areas as animal drinking water,as well as sealing water digester, and the area of drip irrigation system water, and source of domestic water for residential area, etc.

(8)Solar power area

Solar power area is located in the rear of the greenhouses, beneath the wind turbines, and horizontal ground into 45° .The 45° is the best accept of the solar illumination. Solar panels produced a steady stream of energy by photo-production volt phenomenon-electricity[4].

(9)Wind power area

Behind the tent body is vertical wind power device, this place is conducive to gather the maximum wind power, and avoid the influence for tent body and solar panels, light collection. When the wind comes, wind turbines will generate a steady stream of alternating current.

(10)Control area

It is the core of the whole system and it locates at the isolated wall. It is conducive to a better collect information in order to achieve better control modules. Wind power, solar energy that generated electricity will be stored here by the control system for unified management and distribution. Control system accepts all massages from each sensor. These messages through a conductor journey will be sent to the controlled area, through the modulus conversion device convert analog to digital quantity, passed to the microcomputer. The microcomputer receives the data, transform, storage, processing, reasonable judgment, deployment of resources of the whole system, establishes the whole system log, and allows all parameters of Planting and Breeding areas to meet the optimal parameters of plant and animal need.

New energy structure

When the morning's first ray of sunlight on the solar panels of new intelligent greenhouse, solar device would start preparation. With the height increase of the sun, light intensity gradually strengthened, and tens of thousands of photons will play to the panels. Enough energy photons can be in p-type silicon and n-type silicon electronic excitation from covalent bond, so that produce electronic-hole pair, produced more strikes with electronic-hole, and the Photovoltaic phenomenon is happened.This current is affected by light, it is unstable, and instantaneity. It needs us to add the charge controller between solar panels and batteries .

Compared with solar energy, wind energy is not stable. Wind power generation device is in standby state, waiting for the arrival of suitable wind. When the powerful currents of wind turbine impeller rotates, alternating current (AC) is produced. This kind of an alternating current is not stable, the amplitude and frequency of the voltage is as the size of the wind of change, is cannot be used directly. This requires DC/AC transform to produce a stable DC, which is stored in the battery.

At high altitude there is ideal lighting conditions, and wind conditions are satisfactory. Here we use the solar wind with complementary power generation that can completely meet the needs of the whole system.Solar energy, as energy of generating electricity, is not only just here ,but also the tent area heat and an important source of animal and plant grow light source[5].

High altitude air is thin and less oxygen, and farming proportion is very important in people's life.This needs the combination with the planting and breeding. We found that the biogas digester is the best device to connect the planting and breeding by data at home and abroad. The waste of breeding animals gets into the entrance of the biogas digester, after the biogas fermentation, it becomes a part of the organic matter decomposition inorganic substances, with the main combustible gas produced. These gases can be used to the life of people, burning the gas to the area to provide heat, light in the long dark night. Produced biogas fertilizer can be further used in the area of increasing crop production cost reduction.The area of organic compounds can be used to sell, at the same time also can be supplied to breeding areas, and the oxygen is indispensable to plants and animals living conditions. Thus formed an interconnected network. We know that the entire

network normal operation requires a powerful control system to adjust and various auxiliary power facilities help, like wind and solar power into the network makes the whole network interconnected interdependence[6].

Intelligent control system

According to the relative different kinds of animals and plants in different periods of temperature and humidity, concentration of carbon oxide, oxygen concentration, light intensity, temperature different needs, such as system of sensor collected data by using PID algorithm to control[7], in order to make intelligent greenhouse environment to achieve the best environment for plant and animal growth. Now we will show the main structure of control system in intelligent greenhouse in Fig. 3.

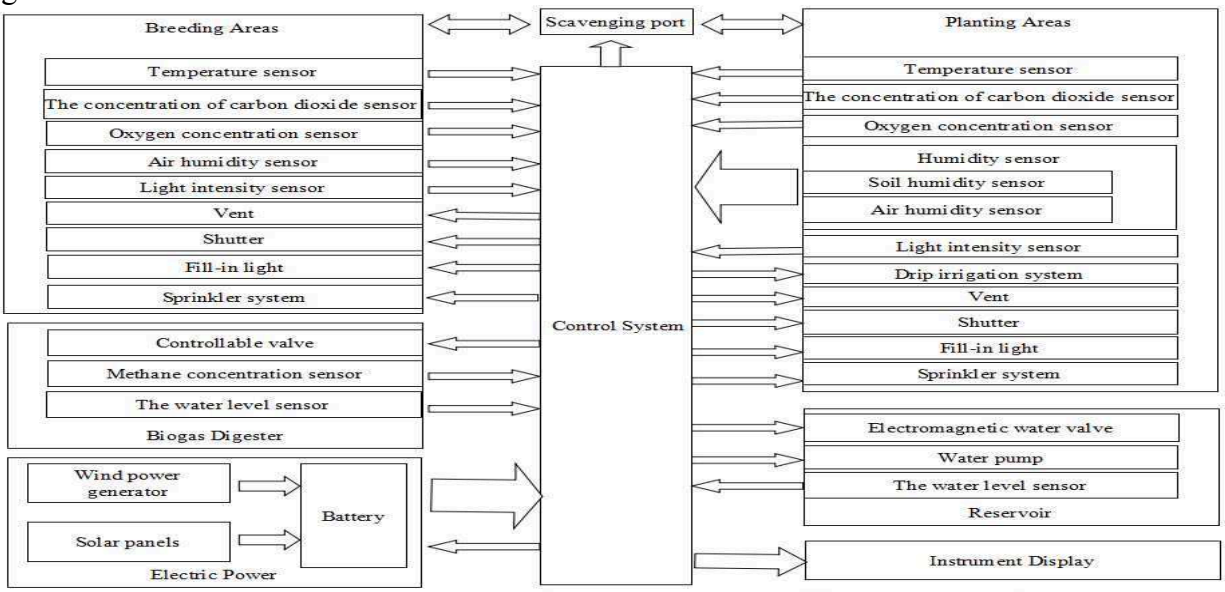

Fig. 3, the main structure of control system in intelligent greenhouse.

Main control system management is an important guarantee normal operation of the system. All process are through the control system of unified management function module.

Power system is made up of solar panels and wind turbines, as well as the battery together. Complementary wind and solar power provides a powerful source of energy to the whole system. the operation of the electric equipment provides the foundation for the entire system security. Every moment of electricity is different, but rechargeable batteries need to be better,so it still need our control system, for the power equipment of electric power monitoring and control. Make our system more stable work.

In the greenhouse,humidity in the air, temperature,light, concentration of oxygen concentration data constantly intertwined, and converged into the control system.The AD after AD collection, changes the analog quantity into digital quantity.Main control system receives and processes the data,and uses them to build a model and log to generates growth.At the same time control is gonging on.By drip irrigation control system to control the humidity of the soil, through spray system to change the planting areas and breeding areas air humidity, by controlling the air vents to change the temperature of the planting areas and breeding areas,the Control system got its aim.To change the temperature,CO_2 concentrations,and light intensity of planting areas is by Biogas lamp. Through the liquid level detection meter to change the water within the reservoir and the biogas digester, so as to better regulate the amount of water. All data will be displayed on the screen that really could easy to understand the operation of system.

Summary

This system is based on new energy which makes full use of not only complementary relationship of solar energy,wind energy and biomass energy but also adequate illumination time,

and sufficient wind in high altitude areas.It is for the normal operation of the whole system provides energy basis. Material is flowing from planting areas to breeding areas and the breeding area gains some different materials from planting areas at the same time.This process is an exchange. The intelligent greenhouse has a strong intelligent control system,so that it can reasonably adjust the needs in the process of the growth of animals and plants. It will provide a new exploration road for high altitude area to increase the economic development.

Keywords: DFIG, STATCOM, Crowbar, low voltage ride through

Abstract. When the grid voltage dips, in order to keep DFIG connected to grid and accelerate the recovery of grid voltage, reactive power compensation STATCOM is adapted to provide reactive power for grid, and crowbar circuit is installed to protect the converter of DIFG. Transient stability of power system is improved and the low voltage ride through is realized.

Introduction

In china, majority of wind farms are located in remote areas and the grid which wind power connected to is far away from the load center. This grid is relatively weak, prone to fluctuate, Even more serious is that the grid voltage greatly drop may exist, and eventually lead to wind turbines splitting, so it's a serious threat to the safe operation of power grid.

In order to protect safety of wind turbine, if the wind turbine still uses the passive split protection[1] when voltage drops, the difficulty of recovery of the whole grid will increase, the severity of the failure may be aggravated, eventually lead to all other units split from the grid. So we must take effective measures of LVRT[2] to keep the stability of grid.

This paper established the mathematic model of STATCOM, and analyzed the working principle of crowbar circuit, then established the overall implementation to realize the low voltage ride through of DFIG.

The mathematical model of STATCOM

Synchronous compensator STATCOM[3] is one of the important members of FACTS controller. It plays an important role in maintaining node voltage, suppressing the voltage flicker, preventing system oscillation, improving the system transient stability.

The device principle block of STATCOM is shown in figure1:

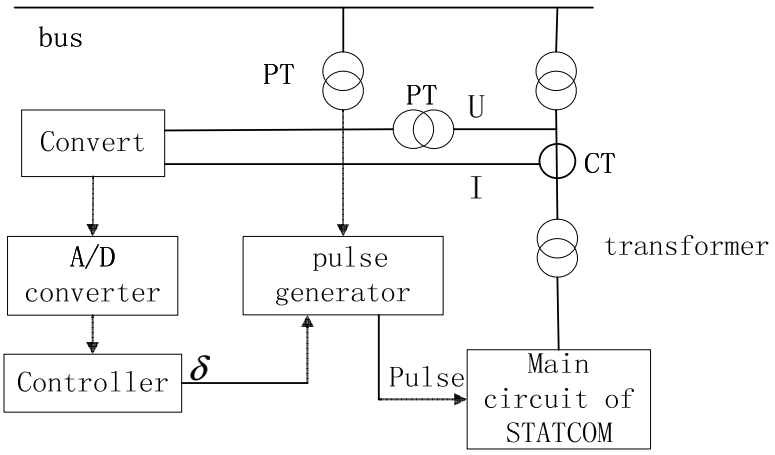

Fig. 1 The device principle block of STATCOM

In fig 1.1, PT is the voltage transformer and CT is current transformer, I_{abc} is three-phase current of system, U_{abc} is three-phase voltage of system, δ is the Angle between the output voltage of STATCOM and the system voltage.

The mathematical model of STATCOM is shown in type (1) :

$$\frac{d}{dt}\begin{bmatrix} i \\ i \\ V \end{bmatrix} = \begin{bmatrix} -\frac{R}{L} & \omega & \frac{m}{L}\cos\delta \\ -\omega & -\frac{R}{L} & \frac{m}{L}\sin\delta \\ -\frac{3m}{2C}\cos\delta & -\frac{3m}{2C}\sin\delta & 0 \end{bmatrix}\begin{bmatrix} i \\ i \\ V \end{bmatrix} - \frac{1}{L}\begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} \quad (1)$$

In the type (1), ω is the rotational angular frequency in d-q coordinate system; the same as the angular frequency of the three-phase voltage; L and R are the Connection inductance and the Equivalent resistance of STATCOM; C is the capacitor value of DC side of STATCOM; m is inverter modulation ratio of inverter; U_s is the instantaneous effective value of System voltage; V_{dc} is the DC capacitor voltage.

Block diagram of STATCOM controller structure as shown in figure 2.

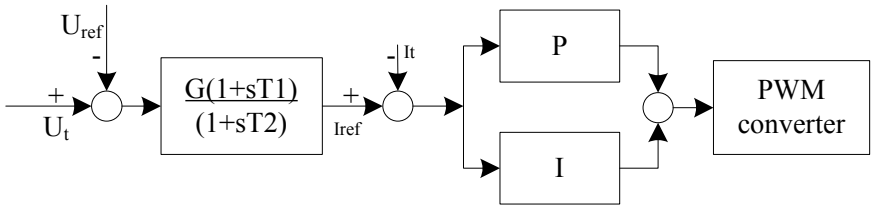

Fig. 2 The control block diagram of STATCOM

In this figure, U_t is bus voltage; U_{ref} is the expectations of bus voltage. Input the gap between the bus voltage and the expectation to the current regulator; obtain the desired current signal I_{ref}. Then compared I_{ref} with the actual output current of STATCOM, and input the resulting gap to PI regulator, obtain the phase difference δ between the output voltage of the AC side and the voltage of the Access system. Then by the PWM frequency converter, obtain the ON signal of switching devices in the main circuit of STATCOM.

Crowbar circuit

The voltage drop will cause large impulse current in the stator winding, because of the electromagnetic coupling relationship between the rotor and the stator of generator, voltage drop can also cause the overcurrent in the rotor side[4, 5], Damage the rotor side converter, and Over voltage may damage the generator rotor winding. In order to protect the rotor side converter, Crowbar circuit is installed in the rotor side, provides a bypass for the large current of rotor side.

The operation diagram of DFIG with crowbar as shown in Figure 3:

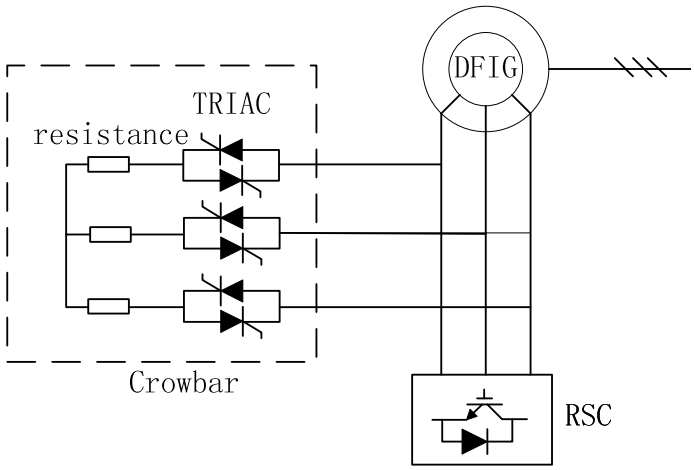

Fig. 3 The operation diagram of DFIG with crowbar

When the grid voltage dips, the rotor side converter stop working and the crowbar circuit start to work, then fault transient current will decline rapidly, and after a period of time (60ms-120ms), the pulse of bidirectional thyristor was locked. And the current gradually was gradually declined to below the thyristor holding current, at last the converter went back to work and the grid voltage recovered.

The overall implementation scheme

The overall implementation of LVRT with STATCOM and crowbar circuit as shown in figure 4:

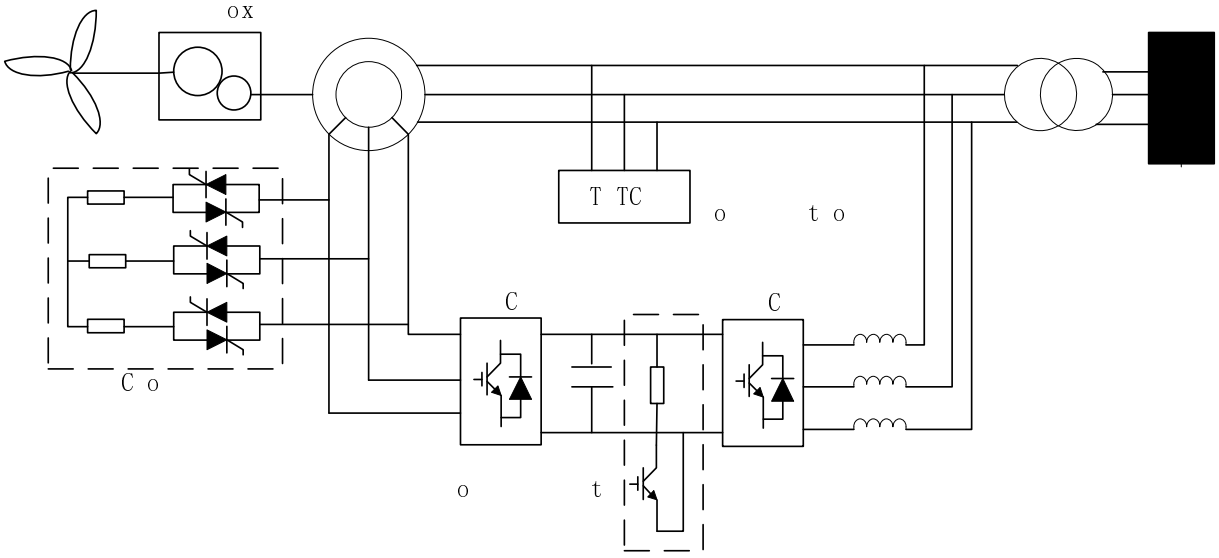

Fig. 4 The overall implementation scheme of LVRT with STATCOM and crowbar circuit

When the grid voltage dips, on the one hand, wind turbine uses the crowbar circuit to protect the equipment of wind power, and the rotor side converter can stay connected with the rotor at same time; on the other hand STATCOM is installed to compensate he reactive power for grid and Promote the recovery of grid voltage. And because STATCOM and crowbar circuit are installed, the wind turbine have the ability of Low voltage ride through. After the failure was eliminated, the crowbar circuit would exit, the power system returned to normal operation.

Conclusion

The implementation scheme of LVRT could compensate reactive power and promote the recovery of grid voltage when the grid voltage dips, and protect the converter at same time, provide a solution for integration of wind power to overcome the problem of LVRT.

Abstract. This paper proposed, with the constant speed and variable pitch wind turbine as the research object, and E-Wind Turbine software as simulation platform, S7-1200 PLC as the master controller, the system control module were optimized for selection and configuration，thereby improving system performance and reducing design costs. Finally, in the STEP7 Basic V11 the modules which had been a good selection and configuration were connected, then to complete the configuration of communication, to verify the feasibility of communication and the effectiveness of the system optimize configuration when the wind turbine implemented the simulation in the E-WT platform.

Introduction

Wind power is the main form of wind energy[1,2]. Master the operating characteristics of wind turbines, as well as by improving its control performance to improve operation efficiency is a hot point work of the science and technology personnel. The conditions of actual wind field are random and uncontrolled, and the wind turbine is large scale, complex, high risk and high cost, these factors brought inconvenience to researchers. Simulation equipment just can overcome these deficiencies, compared it to the actual wind farms, we can find its low cost, low risk operation, flexible operation, and it can according to set conditions to run. So we can learn to wind turbine operation characteristics and study the control performance by simulation equipment.

E-WT can embed PLC program be compatible control, so it can be directly used for the actual wind turbine control system, and has occupied a certain application markets; At the same time, it has a specific fan simulation interface, 3D dynamic effect is good, and that has the certain scene simulation effect, so this paper takes E-WT as the simulation platform. There are a lot of research focused on the two aspects which are the object characteristic analysis and the design of control strategy of the wind turbine. The references [3] on the aerodynamic characteristics, variable pitch and yaw characteristics of the wind turbine were carried out detailed analysis and research. The references [4] and [5] are studied the yaw control strategy and variable pitch control strategy respectively, which are the major parts of the air blower control system. In contrast, the research of the control modules selection is relatively scarce, in the references [6], it analyzed the choice of PLC and system configuration, but it is not to do the specific research for one control object.

In this paper, it will with the constant speed and variable pitch wind turbine as the research object, and E-Wind Turbine software as simulation platform，the selection and connection of the control module as the key research, to make up for the inadequacy of the wind turbine system simulation in this study. It is worth noting that large capacity and low cost are the optimization targets of the wind turbine control system configuration.

Wind turbine control structure

Wind turbine control structure includes main circuit, control circuit and sensor and interface circuit, the connection of different parts is shown in Fig.1.

The Fig.1 shows main controller through communicate with power acquisition module to get power data, these data include electrical signals which were converted by wind speed, rotational speed, liquid level analog signal, connected to power grid's electrical signals, the site of the digital signal, and Mutual transfer electrical signals between PC and control module, etc. In addition the controller module output control signals, which is used to control wind turbine yaw system, hydraulic system, etc. For wind turbine's physical structure, it passes through the transmission system which is composed by the rotor, shaft, gear box, high speed growth axis, mechanical brake and the generator, accomplish the transformation of energy ,when achieve interconnection conditions it will be made into electricity grid.

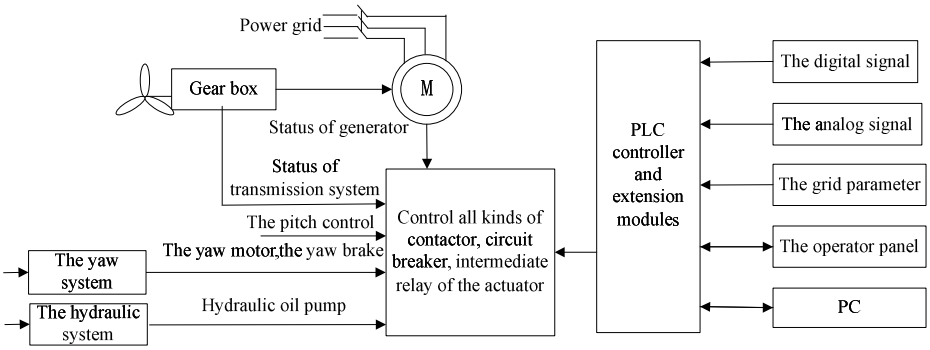

Fig.1. The control structure and the principle diagram

Wind turbine control module selection

According to the control requirements of the wind turbine operation, in order to realize the basic function to select the appropriate controller, communication equipment and power supply module, etc.

The selection of PLC. S7-1200 compared with S7-200 stronger control function, then has lower prices than S7-200, S7-300 and S7-400, and can achieve the same control effect, combined with S7-1200 controller is used flexible and powerful, can control all kinds of equipment in order to satisfy the demands of automation, and its compact design, flexible configuration and has a powerful set of instructions, so this article chooses its as the embedded controller of E - Wind Turbine platform.

The selection of I/O modules. Variable pitch and constant speed wind turbine control system with a total of 54 I/O points, including 28 digital I/O points and 26 analog I/O points. S7-1200 PLC has four kinds of CPU models, this paper selected models for CPU 1214C. CPU 1214C has 14 digital input points and 10 digital output, moreover the CPU nested a signal board, on the signal board has four digital quantity input point, it can be used as extend the digital input, and it is meet the system demand for digital I/O points.

In this case, we just need to expand analog I/O module. Wind turbine has many analog input points which is total of 22, and only has 4 analog output points. For there is a feature that the number of analog input points is far more than the number of output points, then in order to make the expansion modules can be fully utilized ,it expanded 2 SM 1231 and 2 SM 1234. SM1231 is an analog input module with 8 analog inputs on each module; SM1234 is an analog input and output module with 4 inputs and 2o outputs on each module, able to meet the system requirements for analog input and output points.

According to the above principles for the selection of I/O modules, namely on the basis of meet the requirements of input and output channels, then the maximum extent, improve the utilization rate of the module, and effectively reduce the design cost, it helps the system to achieve the optimal configuration.

The selection of communication network elements. On the basis of SIMATIC S7-1200 controller, matching using KTP600 Basic color PN, it can realize the power monitoring and the control of wind turbine real-time , and its basic protection grade is high, reaches IP65, can adapt to bad environment.

Communication module is using CSM 1277, it is a industrial Ethernet switch which is applied to the compact structure of SIMATIC S7-1200 and modular design, compared with the use of external network components, it reduced the assembly costs and installation space.

R4233A is a kind of intelligent three-phase electric parameters of the integrated data acquisition module, it can be widely used for power monitoring system in various industrial control and measurement system, and can replace transmitter or input module of measurement, which related to the current, voltage, power, etc, to reduce the system cost, convenient wiring, improve the reliability of the system.

The data is exchanged between PLC and E-WT using ProfiBus DP communication agreement. S7-1200 PLC configuration of the main communication module for CM1243-5, the ProfiBus DP slave station communication module is used PM125.

Finally, it also need to configure the power supply module which is STIOP to meet the requirement of the CPU and the extension module power supply, to ensure the normal operation of the whole system.

Based on E - WT of wind turbine control modules connection

The system hardware configuration. Based on the selection of the wind turbine control modules, get the system main hardware configuration as shown in Table 1. Other required universal devices, such as ProfiBus DP, ROFIBUS S7 bus, data acquisition card, all kinds of connecting line, etc, can follow the general principles and requirements.

Table 1. The hardware system's configuration list

	Module Type	Number(piece)	instruction
CPU	CPU 1214C DC/DC/DC	1	The controller
Frame	SIMATIC IC S7-1200	1	The fixed component of extension module
Power module	SITOP	1	——
Analog input module	SM 1231 AI 8x13 bit	2	Analog input channel
Analog input and output module	SM 1234 AI 4x13 bit AQ 2x14 bit	2	Analog input and output channels
Profibus master station	CM 1243-5	1	——
Communication module	CSM 1277	1	Communication with the operator panel
The operator interface	KTP600 Basic color PN	1	The operator panel
Signal board	DI 4*24VDC	1	Extended digital input
The power acquisition module	R4233A	1	Electric parameter acquisition
Si Bo PM125	PM125	1	Connecting the CPU with the power acquisition module

Communication configuration. STEP7 Basic V11 is used to the connection between the PLC modules, as shown in Fig.2 [7].

As shown in the Fig. 2, when the controller download the corresponding program, the CPU 1214C is responsible for the execution of the program; the two SM 1231 and the two SM 1234 on the left side are the transmission port of analog signal; CM1243-5 DP on the right side is used to implement a data exchange between PLC and E-WT. Connect the controller with other modules, forming the

communication network as shown in Fig.3. As a result of the S7-1200 with the integrated PROFINET interface, it can be a direct communication with these devices which are the programming device, HMI communication equipment and other SIMATIC controllers, and the connection between the equipment is simple. That is to say, only need a switchboard which is CSM1277 can achieve the connection. Communication configuration and the actual hardware connection is absolutely match, and after a correct communication configuration, it need a prefect fit between software and hardware, so that it can realize the information transmission between the simulation equipment and the controller, and can complete the simulation of wind turbine operation.

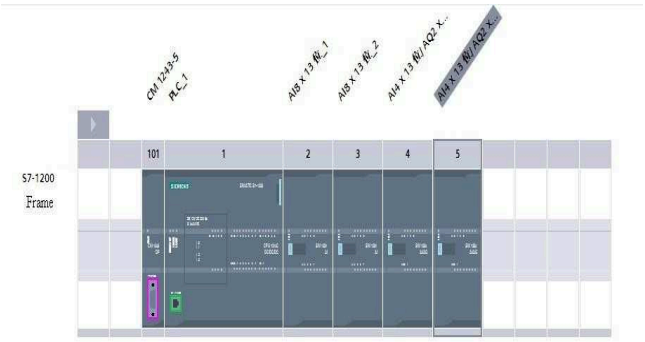

Fig.2. The connection between CPU and extension modules

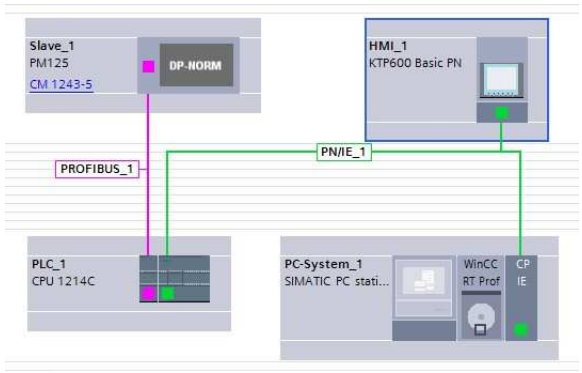

Fig.3. Communication configuration

Conclusions

In this paper, based on E-WT simulation equipment, it studied the optimal allocation of wind turbine control system, in order to make the control system to realize high performance and low cost the double optimization goals. Draw the following conclusions：

(1) The PLC S7-1200 has compact design, flexible configuration and has a powerful set of instructions, with it as the controller, can control all kinds of equipment in order to satisfy the demands of automation, and its price is low.

(2) In view the feature of the number of input and output points of control object，it used signal board as the digital quantity extension module, analog extended module choice two 1231 and two SM 1234 SM, as far as possible to reduce the number of extension module, so as to reduce the design cost.

(3) KTP600 Basic color PN with high degree of protection, so that it can improve the system performance; using CSM 1277, can reduce the difficulty of the connection between the modules in the control system, and reduce the design cost; electrical parameter acquisition module selected R4233A, using its intelligent, integrated features to reduce system cost and improve system reliability.

(4) In this paper, the optimization configuration of the control system is feasible, it plays an important role to realize simulation of wind turbine's operation .

The research of Low voltage control at Li Tang Trunk line in Li Jia Transformer substation

Liu Bo, Liu Chenyang, Cheng Pengfei, Liu Chuanbo, Wang Enlu, Zhu Bo, Xie Xinnan, Guan Ling, Bi Chuanbing, Wang Qinghao, Lin Bin

Fushun Power Supply Company, Liaoning Electric Power Company Limited, State Grid, China, wts55@126.com

Keywords: Low Voltage; MSE Power; Reactive secondary exact moment; Power Quality.

Abstract. In this paper, the rural power low-voltage of Li-Tang mains Trunk line raised the issue of secondary boost more than two groups reactive power compensation solutions, focusing on both the load power load variance method to calculate the location and placement of the regulator boost ratio, using precise moment method and reactive secondary terminal voltage rises method calculates the load side of intelligent reactive compensation on the trunk and installation location and capacity, to achieve the optimum design load tap rural power lines and intelligent var compensator configuration. The program changed in Fushun Li-Tang Trunk line in Li-Jia Transformer substation significantly after the implementation of effective, so that the end of the 31km-long line of power quality standards. Economic operation efficiency is improved.

Introduction

Li-Tang Trunk line in Li-Jia Transformer substation is a dispersed in rural area, long lines, largely load 10kV rural power grid. There is a peak period at the end of the line voltage is too low, The problem of power factor decreasing, line losing seriously which not only affect the power index, but also causing great economic losses of power supply. The effective solution to the problem of low voltage power line is important and urgen[1

The main parameters of Li-Tang Trunk line at table 1 lines which runes status and power flow calculation and analysis show that only rely on the circuit non reactive power compensation and adjustment of main transformer is not fundamentally governance Li Tang line low voltage problem. Effective way is in the middle long trunk with load ratio voltage regulator to increase at the end of the line voltage, at the same time, matching the appropriate non power compensator to compensate for the shortage of reactive power. When using intelligent load ratio voltage regulator and non power compensator combined treatment line in low voltage, according to the line structure, flow calculation, the mathematical model of equivalent rational calculation, determine the pressure regulator resettlement sites, pressure ratio, as well as to determine the capacity and with power compensator[2,3].

Table1 The parameter of Li-Tang Trunk line

length kM	The number of the transformer	The total capacity of the transformer kVA	The maximum power load kW	The maximum non reactive power load kvar
31	100	5068	2480	714

A voltage load coefficient of variance method to determine the load voltage regulating device configuration

(1) Long lines with voltage regulating transformer need to select appropriate locations, ratio and capacity, when the line is in the maximum load, The line has the best load voltage qualified rate. In order to reflect the accurate selection of voltage deviation, voltage mean variance and mean as the evaluation parameters.

The mean value of voltage:

$$U_M = \frac{\sum_{i\in\ell} U_i}{N} \tag{1}$$

Which U_i is the first load voltage, ℓ is the circuit transformer of line, N is the transformer number.

The mean variance:

$$\Delta U_s^2 = \frac{1}{N}\sum_{i\in\ell}(U_i - U_M)^2 \tag{2}$$

(2) Formula （2）describes the deviation of voltage in the mean near U_M . Because power load point does not influence the rated voltage, voltage deviation is not the same: impact load is large, so the voltage deviation should contain the load factor:

$$J = \frac{1}{N}\sum_{i\in\ell}\frac{S_i}{S_{avg}}(U_i - U_M)^2 \tag{3}$$

S_i is the node of I transformer in power, $S_{avg} = \frac{\sum_{i\in\ell} S_i}{N}$ is the node of I transformer in power, if we ignore the line loss, NS_{avg} is practical approximate to the line input end in power S_{IN} .

In the model of the first as an example, assume that line in the j rod is arranged on load voltage regulator, voltage regulator of the line is divided into 2 sections, calculation of variance were calculated Respectively also, A_j is the transformer before J , after J is the B_j transformer.

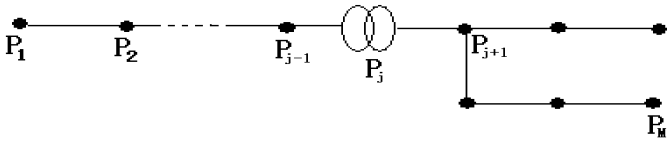

Fig.1 The distribution network line model

The boundary condition of the model:

A. Line load from the historical maximum load, the transformer's load capacity according to the distribution share.

B. Transformer active power P_i , inactive power Q_i corresponding model is equivalent to the resistance and inductance

$$\begin{cases} R_i = \dfrac{U_i^2}{P_i} \\ X_i = \dfrac{U_i^2}{Q_i} \end{cases} \tag{4}$$

U_i is the load voltage node i; R_i , X_i respectively, resistance, reactance of the node i of load, remained unchanged in the current iteration. Fig. 1 voltage variance can be expressed as:

$$\begin{cases} J_A(j) = \sum_{i\in A_j}\dfrac{S_i}{S_{IN1}}(U_i - U_{AM})^2 \\ J_B(j) = \sum_{i\in B_j}\dfrac{S_i}{S_{IN2}}(U_i - U_{BM})^2 \\ J(j) = J_A(j) + J_B(j) \end{cases} \tag{5}$$

In (5) formula, S_{IN1} is the transformer total apparent power of The A_j collection, S_{IN2} is the transformer total apparent power of The B_j collection, U_{AM} , U_{BM} by calculating.

$$\begin{cases} U_{AM} = \dfrac{\sum U_i}{N_A} \\ U_{BM} = \dfrac{\sum U_i}{N_B} \end{cases} \quad (6)$$

Which N_A is the number of A_j transformer set; N_B is the number of B_j transformer set.

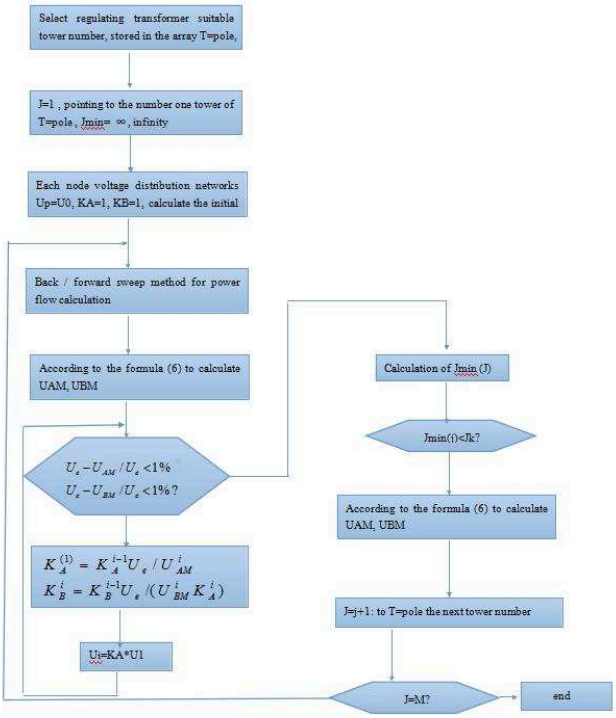

Figure 2 Load regulator position and ratio calculation flow chart

The entrance end of line voltage coefficient $k_A = \dfrac{U_1}{U_e}$, U_1 is the line entrance voltage, U_e is the rated voltage. The on load tap changer ratio is $k_B = \dfrac{U_{jout}}{U_{jin}}$, U_{jin} is the regulator input voltage, U_{jout} voltage regulator outlet voltage. U_{AM} is the regulator outlet voltage. Obviously, $U_{AM} \propto k_A$, $U_{BM} \propto k_A k_B$, in power flow calculation can be adjusted correction, correction of $U_i (i \in A)$ with k_A. Modification of U_{jout} $U_i (i \in B)$ with k_A, k_B, Calculation of the target is to make (6) in $U_{AM} = U_e$, $U_{BM} = U_e$, found for all $j \in l$ minimum $J(j)$ corresponding to k_A, k_B and J, then the regulator's capacity is determined according to the current and voltage of J.

The two tree data link back / forward sweep method based on [2], the beginning of the distribution network voltage and rated voltage, terminal load according to the transformer capacity allocation table 1 of the maximum load, the calculation flow chart shown in Figure 2, $k_A^{(i-1)}$ $k_A^{(i)}$ is the respectively I-1, I iteration of k_A , $k_B^{(i-1)}$ $k_B^{(i)}$ $U_{AM}^{(i)}$ $U_{BM}^{(i)}$ similarly explain. The calculated value of Jmin delay line distribution as shown in figure 3.

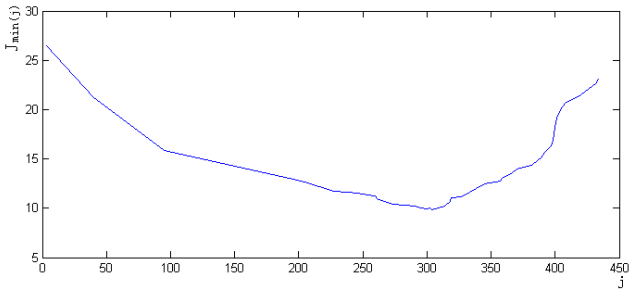

Figure 3 Dstribution of Li Tang trunks Jmin

Wattless power compensation of location and capacity

Considering Li Tang trunk line has the characteristics of too long line, wide distribution and too many transformer, in this study, the line selection on the terminal voltage boosting is a set of large nodes, the compensation In order to selection of low voltage load transformer, according to the calculation of compensation node position relative to the upper trunk load point of wattless power two times accurate moment sort. Select the value of load torque, in the low-pressure side of the local compensation.

Calculation formula of the non reactive power two precise matrix is $T_j^2 = R_{dj}(\frac{Q_{bj}^2}{U_j^2} - \sum_{s\in j}\frac{Q_{bs}^2}{U_s^2})$.Rdj means the total of j node to the source node or upstream compensation point encountered branch resistance and Qbj means the wattless power branch inflow from J node,Qbs into the node s (s is directly adjacent to the node j of wattless power). The second moment T_j^2 reflect J node has no influence on the power load on the line. Through the power flow calculation, the arrangement to each load point T_j^2, choose the maximum node as the compensation point.

In the trunk, due to long lines, the nonreactive power load is big, so we need to select more than one node important dispersion compensation. Considering the compensation capacity downstream compensation point will affect the compensation capacity current compensation node, therefore in the calculation, we should select the increasing the maximum trunk terminal voltage of a group from the same number of nodes in the selection of compensation. The amount of compensation point, depends on the non reactive power optimization on the line: the degree of compensation point is the more line reactive power, the less equipment investment, To Li Tang line as an example, its trunk nonreactive power distribution and compensation as shown in figure 4.

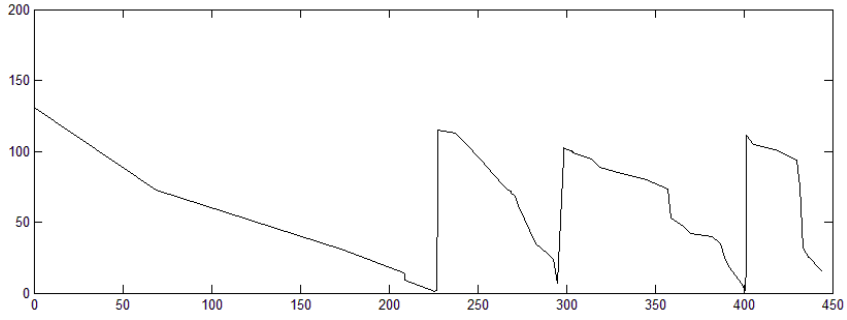

Figure 4 Trunk Li Tang trunk wattless power compensation

Calculate the Li Tang trunk line installation location of load voltage regulating transformer and nonreactive power compensator capacity, the installation location using the above method. Li Tang trunk load voltage regulating transformer capacity is 2000kVA, the location of the installation of the 300# rod, step-up ratio $k_B = 1.20$ 10kV reactive power compensator are respectively installed on the 227# rod (double verb complement 50+65kvar), 300# rod (single verb complement 100kvar), 401# rod (double verb complement 50+65kvar). The limitation of length, capacity and location related 0.4kV reactive power compensator no particular.

Governance effect

Li Tang trunk government before the 2012 January peak period of one end of the transmission line voltage is 10.3kV, the end of the lowest voltage up to 9.0kV. In 2014 January after the line control electricity peak period of one end of the transmission line voltage is 10.3kV, the terminal voltage is 9.7kV. From the operating data before and after Li Tang line low voltage government, has fundamentally solved the problem of low voltage, effectively ensure the terminal power quality standards.

Computer monitoring network based on GPRS

Intelligent load voltage regulating transformer, intelligent circuit reactive power compensator, intelligent distribution transformer voltage, current nonreactive compensator are real-time sampling at the nodes and grid operation data, operation data and equipment through GPRS network to upload sample itself.

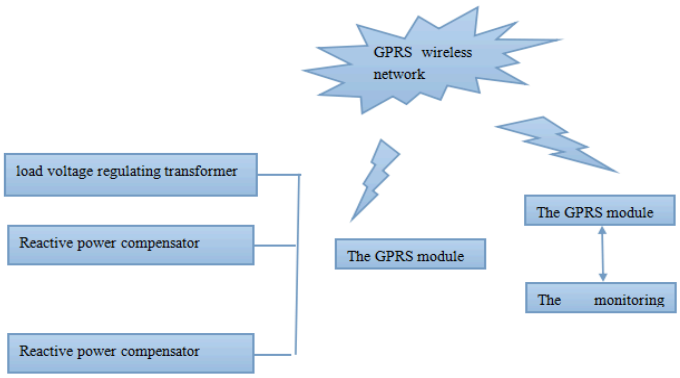

Fig. 5 The supervisory system based on GPRS

GPRS communication intelligent voltage and reactive power compensation system can timely measurement of access point voltage, current, reactive power and other data based on condition monitoring equipment, operation, and can according to the operating personnel, select the control line of non reactive compensator switching combination and the pressure regulation level, the system structure as shown in Figure 5.

The computer timing sampling measurement data of each device save for the historical data, convenient query running status line operation data and equipment. Through analysis of the historical data, summarizes the characteristics of grid voltage and reactive power without changes, through remote setting function of equipment to adjust and improve of equipment automatic operation mode.

Conclusion

In this study, in order to solve Li Tang trunk rural network line low voltage as the starting point, we use the mean of variance method using load of power on load tap changer configuration, the capacity and the site two times without power moment method to determine the load end reactive power compensator and trunk reactive power compensator, received a significant effect in Li Tang trunk line, ensure the qualification rate of the power index. Intelligent voltage and compensating device is realized by GPRS communication mode of automatic control network optimization of computer, the efficient operation of rural economic main Li Tang trunk line.

Abstract. For three-wire three-phase system load imbalance in the system when the current imbalance of power grid, The SVG control strategy which was applied in the unbalanced system was proposed by the paper, and carried on the research and analysis by MATLAB simulation function. The simulation results proved that the control strategy could achieve compensation control requirements， at the same time can effectively restrain the negative sequence current.

Introduction

In the case of active power remains the same，reactive power would be to lower the power factor,thus need to increase the capacity of power generation equipment and transmission equipment. So it will lead to increase investment, power loss, operating cost, the transmission line drop, at the same time, electric power equipment can not get full application and it is not conducive to electric power transmission and reasonable application. With the rapid development of power electronic technology,SVG has become the development trend of intelligent reactive power compensation; it also is hot spot of the world of reactive power compensation device research[1].

The research of SVG control strategy

Symmetry in the three-phase power network load balancing, only considering fundamental component,the common current inner loop decoupling control strategy is used which is based on dq transform[2][3]. But when the system load unbalanced, the AC current composed of positive sequence current and negative sequence current. Therefore we need to separately achieve the positive sequence current dq orthogonal coordinate transformation and negative sequence dq[4] [5]. In other words, the phase of d-axis is same as the grid voltage vector, which signifies the axis of active-component; while q-axis represents reactive-component axis. Taking rotation frequency ω_0 as positive sequence transformation, regarded rotation frequency $-\omega_0$ as negative sequence transformation. Through transformation we got Positive sequence dq coordinate transformation:

$$\begin{bmatrix} i_d^p \\ i_q^p \end{bmatrix} = C_{abc-dq}^p \cdot i_{sp} + C_{abc-dq}^p \cdot i_{sn} = \sqrt{\frac{2}{3}} I_{sm}^p \begin{bmatrix} \sin\phi_p \\ \cos\phi_p \end{bmatrix} + \sqrt{\frac{2}{3}} I_{smn} \begin{bmatrix} \sin(2\omega t + \phi_n) \\ \cos(2\omega t + \phi_n) \end{bmatrix} \quad (1)$$

Negative sequence dq coordinate transformation:

$$\begin{bmatrix} i_d^n \\ i_q^n \end{bmatrix} = C_{abc-dq}^n \cdot i_{sp} + C_{abc-dq}^n \cdot i_{sn} = \sqrt{\frac{2}{3}} I_{sm}^n \begin{bmatrix} -\sin(2\omega t - \phi_n) \\ \cos(2\omega t - \phi_n) \end{bmatrix} + \sqrt{\frac{2}{3}} I_{smp} \begin{bmatrix} \sin\phi_p \\ \cos\phi_p \end{bmatrix} \quad (2)$$

Through coordinate transformation， i_{dp} is positive sequence fundamental current active component and i_{qp} is reactive component, i_{dn} is negative sequence fundamental current active component and i_{qp} is reactive component, Then the positive sequence reactive current and negative sequence current control can achieve the anticipated goal. From the formula (1) it can be seen that through the positive sequence dq coordinate transformation, we get the positive sequence component. From the formula (2) it can be seen that through the negative sequence dq coordinate

transformation, we get the negative sequence component. the positive sequence and negative sequence double sequence synchronization control strategy was designed.. The article bases on dq coordinate transformation of positive sequence current inner loop decoupling control, the negative sequence transformation also uses the same control strategy.

The positive sequence current decoupling control algorithm for the inner ring could be represented as:

$$\begin{cases} u_d^{p*} = u_{sd}^p + (k_{iP}^p + \dfrac{k_{iI}^p}{s})(i_{dref}^P - i_d^p) + \omega L i_d^p \\ u_q^{p*} = u_{sq}^p + (k_{iP}^p + \dfrac{k_{iI}^p}{s})(i_{qref}^P - i_q^p) - \omega L i_q^p \end{cases} \quad (3)$$

The negative sequence current decoupling control algorithm for the inner ring could be represented as:

$$\begin{cases} u_d^{n*} = u_{sd}^n + (k_{iP}^n + \dfrac{k_{iI}^n}{s})(i_{dref}^n - i_d^n) - \omega L i_d^n \\ u_q^{n*} = u_{sq}^n + (k_{iP}^n + \dfrac{k_{iI}^n}{s})(i_{qref}^n - i_q^n) + \omega L i_q^n \end{cases} \quad (4)$$

It concluded that the structural schematic diagram of control strategy can be shown as Fig.1.

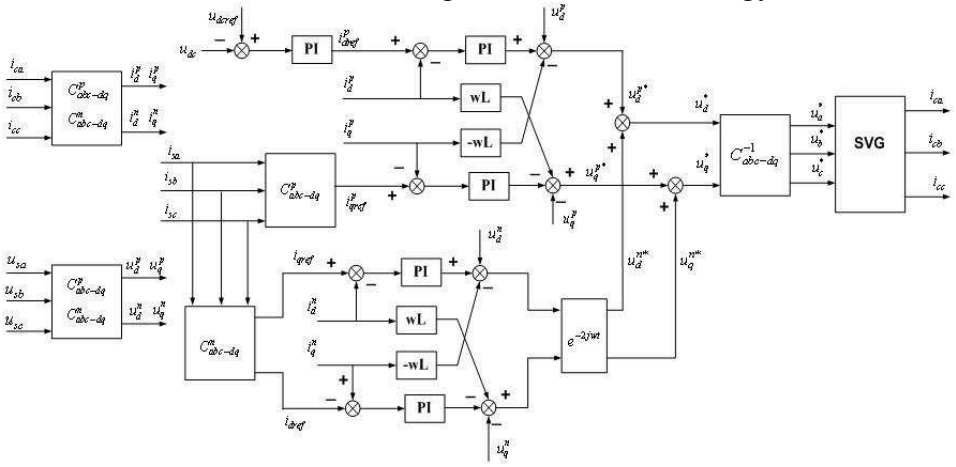

Fig.1 The diagram of based on dq coordinate transformation of positive and negative double sequence synchronization control strategy

Positive sequence adopts voltage outside loop and current inner loop decoupling control structure, The i_d^p and i_q^p are the instantaneous active and reactive power current value when SVG inverter side feedback current signal go through the positive sequence dq coordinate transformation; The i_d^n and i_q^n are instantaneous active and reactive power current value after negative sequence dq coordinate transformation; The u_d^p, u_q^p and u_d^n, u_q^n are voltage signal of the positive sequence and negative sequence active and reactive components after coordinate transformation; The subtraction between DC side voltage instantaneous value u_{dc} and reference value u_{dcref} after PI regulator operation is positive sequence active current reference value i_{dref}^p; Load side current go through positive sequence dq coordinate transformation becomes positive sequence reactive current reference value i_{qref}^p;Voltage ring ensure the SVG converter dc side voltage stability, current loop realize the decoupling control to complete the positive sequence of the reactive current in real time to follow. Through this control strategy, the systems achieve positive sequence reactive current compensation.

Negative sequence uses negative sequence current inner loop decoupling control, load side current becomes negative sequence active current reference i_{dref}^n and reactive current reference

i_{qref}^{n} through negative sequence dq coordinate transformation. Through the current inner loop decoupling control, the system realize the full compensation of negative sequence current, thus inhibiting the effects of negative sequence current to power grids due to unbalanced load of.

u_d^{p*} and u_q^{p*} are the positive sequence voltage control instruction signal through positive sequence control; u_d^{n*} and u_q^{n*} are the negative sequence voltage control instruction signal through negative sequence control. Negative sequence voltage instruction signal convert to positive sequence dq coordinate system, so that we get the input voltage instruction signal of SPWM module:

$$\begin{cases} u_d^* = u_d^{p*} + e^{-2j\omega t} u_d^{n*} \\ u_q^* = u_q^{p*} + e^{-2j\omega t} u_q^{n*} \end{cases} \quad (5)$$

The system applies the positive sequence and negative sequence synchronization independent control strategy. The detection methods of positive sequence current and negative sequence current applies the positive sequence and negative sequence synchronization test which bases on dq coordinate transformation by above-mentioned. After processing, the corresponding variables become direct component. The system uses PI controller to realize astatic control of positive sequence and negative sequence reactive current.

The simulation research of SVG control strategy

According to above analysis, with the aid of MATLAB simulation function the SVG system is set up and shown in Fig.2. The parameters of SVG system simulation are as follows: the voltage valid values Us is 690 V, the SVG connection inductance L is 1.5 mH, the device equivalent resistance R is 0.5 Ω, the inverter dc side capacitor C is 4700uF*5, the inverter dc side voltage value U_{dcref} is set to 1200 V. The system adopts SPWM pulse drive technology and the positive sequence and negative sequence synchronization control strategy which can be applied to the unbalanced system based on dq coordinate transformation.

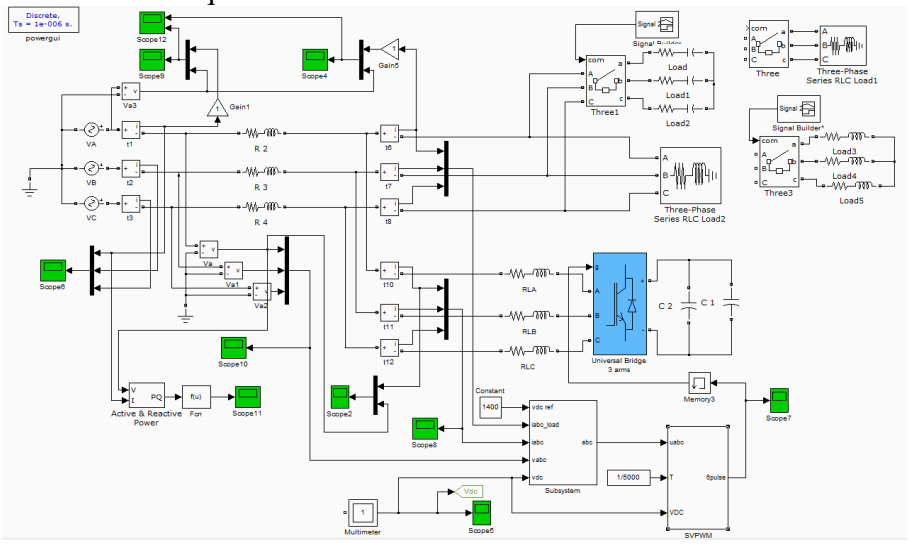

Fig2. The whole simulation model of SVG system

(1) simulation experiment with unbalanced RL load

The system simulation process is 0.6 s and it starts with power of 60 kw resistive load. When system run at 0.2 s, three-phase unbalanced load is suddenly applied: A phase load of active power is 10 kw, reactive power is 50 kvar. B phase load and C phase load is the same. Then A phase load suddenly change: active power becomes 10 kw, reactive power becomes 300 kvar. In the end, the load is removed at 0.4 s. The simulation waveform is shown in Fig. 3.

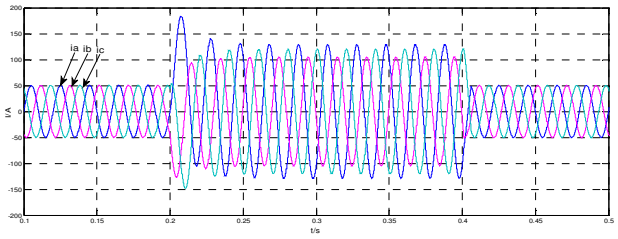

Fig.a Three phase current waveform of SVG without compensation

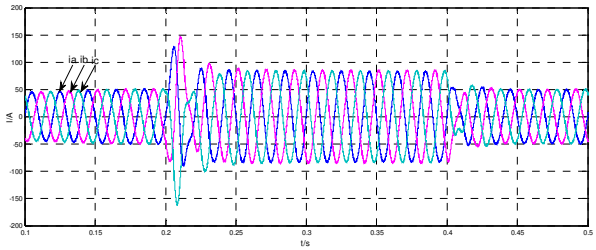

Fig.b Three phase current waveform with double sequence synchronization control strategy compensation

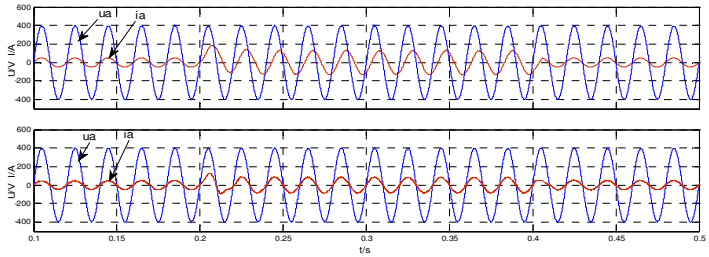

Fig.c A phase current waveform with double sequence synchronization control strategy compensation

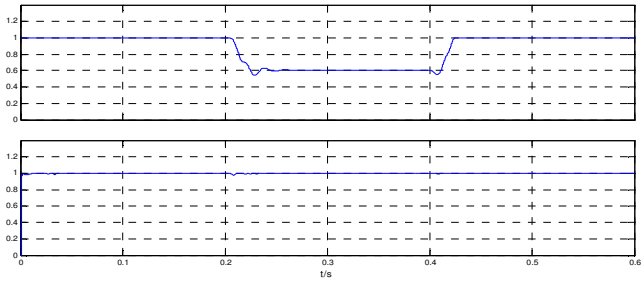

Fig.d A phase power factor before and after compensation

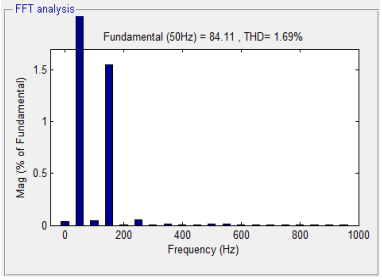

Fig.e current harmonic content with SVG compensation

Fig.3 Simulation waveform with three-phase unbalanced RL load

Through the simulation results in Fig. 3, it can be seen that when the load is unbalanced, three phase current of system is in a state of imbalance. The negative sequence current will form in three phase system. Each user of the common connection point cause that point of negative sequence voltage imbalance is not more than 2%, short time should not exceed 4%. According to the no zero sequence current unbalanced degree calculation formula:

$$\varepsilon = \sqrt{\frac{1-\sqrt{3-6L}}{1+\sqrt{3-6L}}} \times 100\% \qquad (6)$$

where $L = (i_a^4 + i_b^4 + i_c^4) / (i_a^2 + i_b^2 + i_c^2)^2$.

After load of system changing,. The unbalanced degree of three phase current without compensation is 15% in Fig.a. As shown in Fig.b, after applying single sequence of dq decoupling control strategy to compensate the inner ring, the unbalanced degree of three phase current is still 13%. When taking double sequence synchronization control strategy, three phase current wave is shown in Fig.c. By the simulation result, the unbalanced degree which is 0.05% reaches the national standard requirements. The wave of A phase power factor is shown in Fig.d. Power factor is 0.6% before compensation, after the compensation, it becomes unit power factor, system response time is less than 40 ms. The THD of AC current harmonic content is 1.69% as shown in Fig.e. The current inner loop decoupling control strategy based on positive sequence dq coordinate transformation can't realize negative sequence of reactive current compensation separately. The positive and negative sequence synchronization control strategy can realize the compensation of inductive reactive power and negative sequence current. Taking this control strategy has a good compensation effect.

(2) simulation experiment with unbalanced RC load

The system simulation process is 0.6 s and it starts with power of 60 kW resistive load. When system run at 0.2 s, three-phase capacitive unbalanced load is suddenly applied: A phase load of active power is 10 kW, reactive power is 50 kVar. B phase load and C phase load is the same. Then

A phase load suddenly change: active power adds 10 kW, reactive power becomes 300 kVar. In the end, the load is removed at 0.4 s. The simulation waveform is shown in Fig. 4.

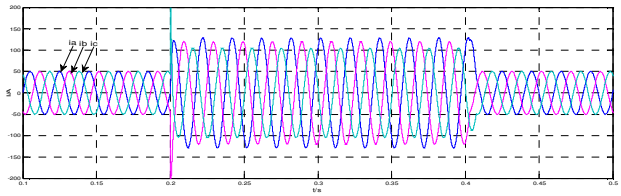

Fig.a Three phase current without compensation

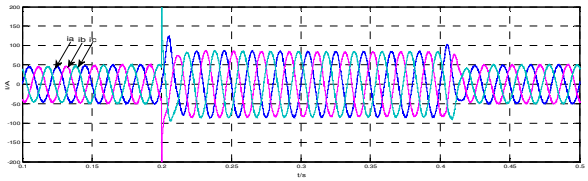

Fig.b Three phase current with compensation

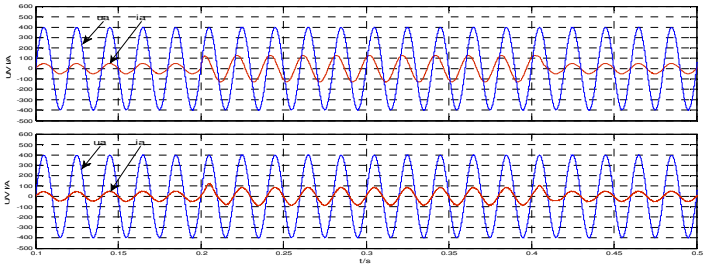

Fig.c A phase current waveform with double sequence synchronization control strategy compensation

Fig.4 Simulation waveform with three-phase unbalanced RC load

The simulation results can be seen through Fig 4. After load of system changing, three phase current includes reactive current of positive sequence current and negative sequence current. The unbalanced degree of three phase current without compensation is 15% in Fig.a. After compensation, the unbalanced degree becomes 0.045%.It achieves the national standard requirements. in the Fig.c, compare to A phase voltage, the current advances when given a sudden loading, but they are in the same phase after compensation; The power factor is 0.6 before compensation, after the compensation, it becomes unit power factor. The system response time is less than 40 ms. The THD of AC current harmonic content is 1.14%.The overshoot amount of DC side voltage is 0.32%.The control strategy of research can achieve the effect that the strategy compensates the capacitive reactive power and negative sequence current at the same time. Meanwhile, the strategy has a good compensation effect.

Conclusion

Through analysis and research, the positive sequence and negative sequence control strategy based on dq coordinate sequence synchronization has he function of the SVG reactive power compensation, at the same time it improves the ability which can inhibit negative sequence current caused by unbalanced load. In addition, system realizes compensation function of negative sequence current in simulation process. Meanwhile, the effect of reactive current signal, dynamic compensation and harmonic achieve the design requirements. And the system has good dynamic characteristics, provided a certain reference for the further application of SVG.

Keywords: STCVT, kinematics, dynamic analysis, torque-transfer

Abstract. This paper describes a new genre of Toroidal-CVT system, called the Sphere-Toroidal Continuously Variable Transmission (STCVT), which is derived from the half-toroidal traction drive (TCVT) and introduces its structure and working principle. The torque transfers from the input shaft to the cross-axle universal shaft coupling connected with the driven shaft. By discussing the difference between the torque-transfer, the paper will show the possibility of the application in the vehicle. To conclude, the system has the potential to implement infinite extension for the CVT theoretically.

Introduction

In response to global demands for environment conservation, the automobile industry is placing greater focus on the development of fuel-efficient technologies to reduce the Carbon dioxide emission [1]. Now as people are paying growing attention to driving comfort and stability, automatic transmission has been widely applied [2]. However, automatic transmission itself combines sophisticated structure with high cost, meanwhile, its maintenance cost is expensive, and all of these shortcomings hinder its development. While Continuously Variable Transmission (CVT),which has been identified as a strategic technology for improving fuel economy, as well as power performance and ride comfort of vehicles, enjoys a linear transmission ratio [3].

For decades now the half-Toroidal Continuously Variable Transmission (TCVT),which mainly consists of an input disc that is connected to the vehicle's engine, an output disc that is connected to the transmission output shaft, and the power rollers that are located between the discs has been widely studied [4,5]. But it still has many defections which restrict its development. This paper introduces a new design for the power transmission, which called Sphere-toroidal Continuously Variable Transmission (STCVT). The theoretical study has shown that STCVT has the ability to implement the change of transmission ratio continuously.

Structure and working Principle

Physical model. The half-toroidal CVT has a input toroidal disc and output toroidal disc (see Fig.1). The power is transmitted from the input disc to the output disc via a set of identical rollers regularly fitted around the discs common rotation axis. The transmission ratio change is achieved through the inclination of the roller rotation axis. The transmission ratio change is achieved through the inclination of the roller rotation axis. Inclining the pivoting roller support changes the two rollers to disc contact point positions relative to the toroidal discs common rotation axis. To force the roller to roll on the disc surfaces without slippage, all the elements are pre-loaded by introducing an axial thrust on the discs so as to push one toward the other along their common rotation axis. The housing reaction forces then press the rollers on to the disc surfaces.

The STCVT is similar to the TCVT, but remove the output disc and change the construction of the input disc (see Fig.2).

The output shaft connected with the sphere is fixed on the slider, which can move along with the slider to change the position of the sphere. Power is ultimately output through cross-axle universal

shaft coupling connected with the driven shaft. A sphere moves in the slots, accordingly, the power transmitted through the friction of the sphere and tank wall. By changing the position of the sphere, the transmission ratio changes as well.

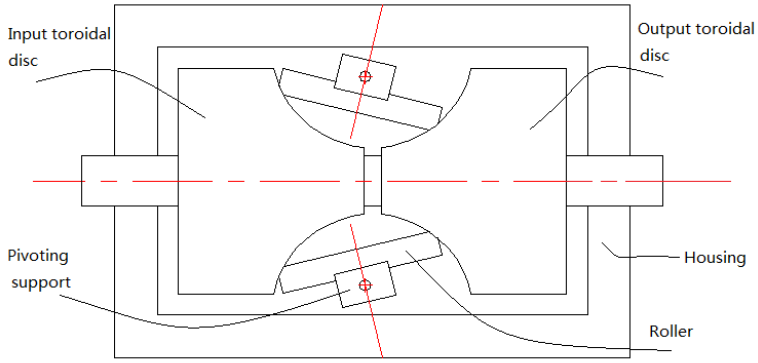

Fig.1 The construction of TCVT

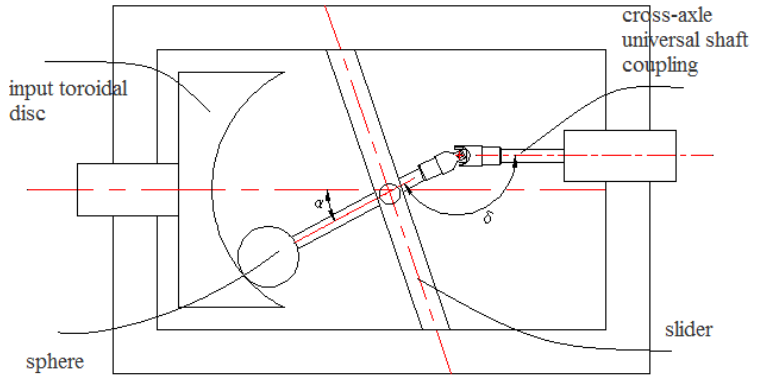

Fig.2 The construction of STCVT

Transmission ratio. As shown in Figure 3, the sphere and the input disc linear velocities at the point of tangency are equal, i.e. $v_1 = v_2$. We assume that the drive shaft angular velocity is ω_1, and active sphere driven shaft is ω_1, then we can get the following equations:

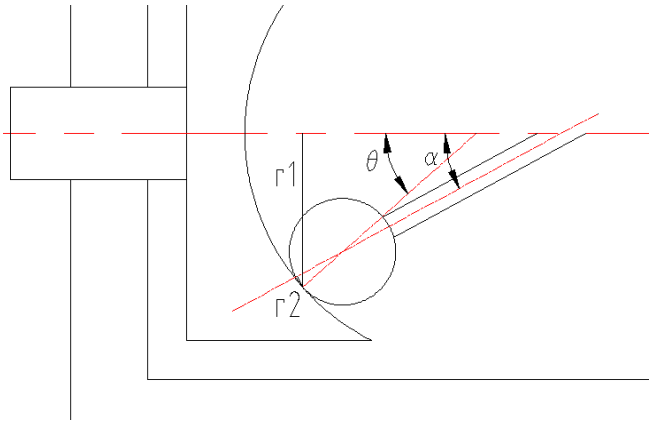

Fig.3 The transmission ratio

$$v = \omega \times r (r = R \sin \theta)$$

$$v = \omega \times r (r = r \times \sin(\theta - \alpha))$$

Among them, θ: The inclined angle between the line connecting the center of the groove and the point of tangency and horizontal direction. The two hemispheres must do remain contact α The

incline angle between the line connecting the center of the sphere and the point of tangency and horizontal direction.

So the transmission ratio can be calculated:

$$i = \frac{\omega}{\omega} = \frac{r \times \sin(\theta - \alpha)}{R \times \sin\theta}$$

The cross shaft driving mechanism motion analysis

Since the axis of the driven shaft is removable, we use the cross-axle universal shaft coupling to accomplish power take-off. As shown in the reference [6], when the axis angle of the active and driven shaft of the single cross-axle universal shaft coupling (σ is not 0), we have the equation as follows:

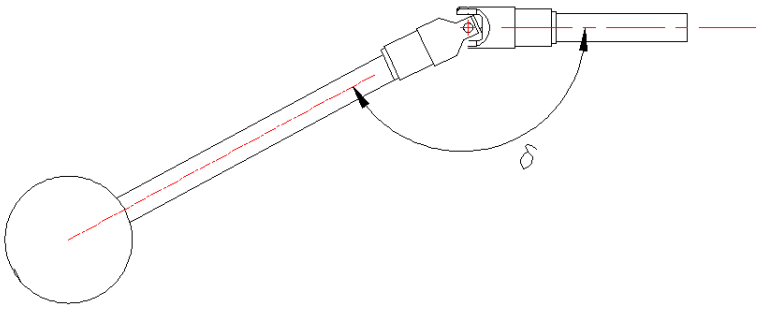

Fig.4 Diagram of the cross-axle universal shaft coupling

$$\frac{\tan\varphi}{\tan\varphi} = \cos\sigma$$

Here, φ_1, φ_2 is the rotation angle of the active and driven shaft.

We take the derivation versus time of this equation, and then get:

$$\omega = \frac{\cos\sigma}{1 - \sin\sigma\cos\varphi}\omega$$

Here, ω_1, ω_2 is the angular velocity of the active and driven shaft.

Because φ_1 remains to be 0 all the while, so

$$\omega = \frac{\omega}{\cos\sigma} = \frac{\omega}{\cos\sigma}\frac{R \times \sin\theta}{r \times \sin(\theta - \alpha)}$$

The general transmission ratio i is:

$$i = i \times i = \frac{\cos\sigma \times r \times \sin(\theta - \alpha)}{R \times \sin\theta}$$

Simulation

We choose the dynamics simulation software ADAMS to test and verify the performance of TCVT and STCVT. First of all, we build the mechanical modes in the ADAMS/VIEW and impose joint revolute constraint respectively on driving part and phantom element, and then apply contact constraint between them. Set the friction force as coulomb, and add drive motion to active part. Set the simulation time for 5s, step size for 0.05s. The result is shown in Fig.5 and Fig.6.

The result shows that the TCVT conveys larger torque. Because TCVT transfer torque through a circular arc surface, while STCVT through a point contact. The torque-transfer capability of TCVT is almost twice of that of the STCVT. The two figures show that transmission characteristic is smooth in the simulation.

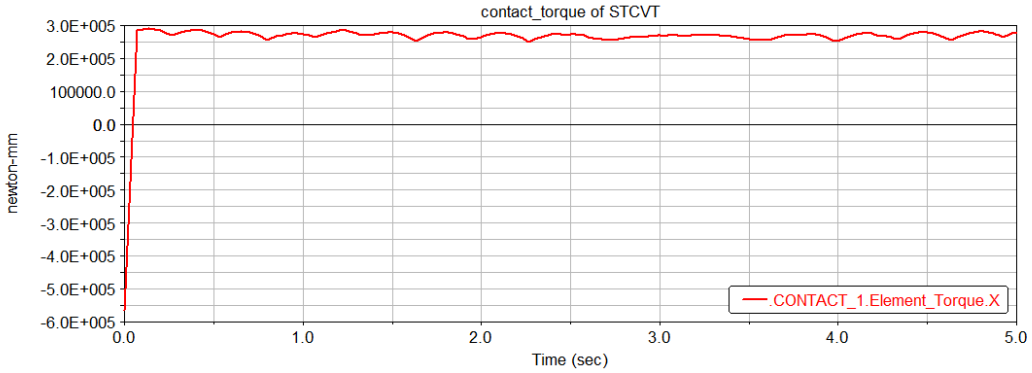

Fig.5 Contact-torque of STCVT

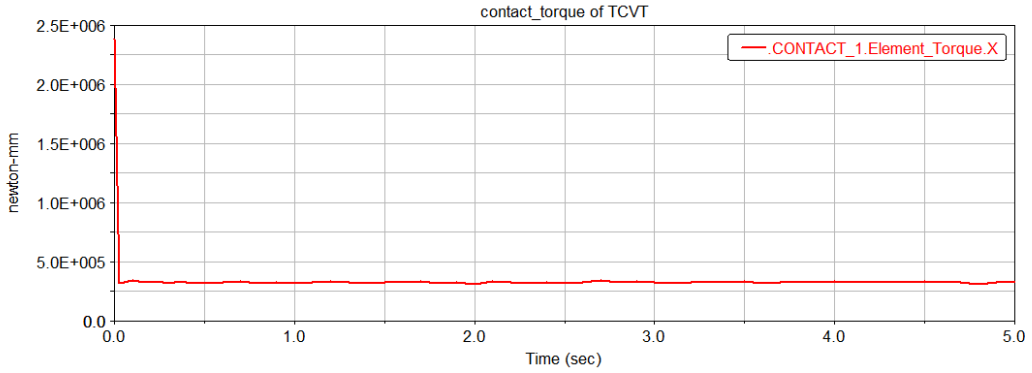

Fig.6 Contact-torque TCVT

Conclusion

Through above analysis, this paper reaches the conclusion that: The STCVT system could realize continuously change of the transmission ratio. And it has a poorer performance than the TCVT in torque transmission. But STCVT has a simple structure, and can be convenient operated, which makes it easily to cooperate with other transmission device. All in all, STCVT is an extension of the half-Toroidal CVT, and provides a profitable reference for the optimization and development of TCVT in the future.

Keywords: Pipe Production Line, S7-300, Handshake Mode, Virtual Sensor, WinCC

Abstract. Steel pipe for pipeline have to go through multiple procedure in the whole process, and steel pipe transportation problem exists between the various processes. According to the specific requirements of the workshop environment and control tasks, a new communication mode that use S7-300PLC as the control core, connect 8 DP substation, involve 1077 output and input dot was adopted in the whole system. In the automatic mode, requirements of the complex technological process were realized; shake hands work mode was adopted between the production; using the proximity switch completed the material length measurement; in the location of inconvenience sensor installation, adopted virtual sensor in positioning. The HMI software in PC was WinCC V7.0, and communicated with PLC by Ethernet.

Introduction

Advantages of pipeline in relation to other transportation for oil and gas include large amount of transportation and low cost. The control system for pipe production line is developed based on the requirement of oil and gas project.

The automatic conveyor system utilizes the modular structure with centralized management and discrete control. The infrastructure consists of computer (or HMI), console with local/remote mode selector by which operation can be performed at either control room or field. In manual mode the motors and/or valves are operated through push buttons on the console or local panel, while in automatic mode the control is modulated based on the process parameters in the system.

The system controller is Siemens S7-300 series 315-2DP CPU module. DP (decentralized peripherals) interface which consist of Profibus-DP port for the production line interfaces with eight ET200 modules.CP343-1 lean module is connected to PC through Ethernet TCP/IP for Supervisory control and data acquisition and human machine interface(HMI) is configured for future process monitoring. The total physical input/output count is 1077. The HMI software is Siemens WinCC V7.0.

Process Flow Requirement

The whole system is divided into thirteen sections and convey rollers which include A,B,C,D (interior longitudinal seam welding), E (Cited arc plate cutting), F1 (Required corrected circular steel storage), F2 (Corrected steel pipe storage), G (longitudinal seam inspection), H1 (Storage), H2(Storage), J (waste district), N (steel group girth weld) and O (inspection).Each section is part of process flow while steel pipes produced in each stage is transferred to the next by convey roller. Sections A~E are located in one factory and others are at another location. The trolleys are used to transport the steel pipes between two factories. The steel pipe length is around 1200mm~3000mm and outer diameter is in the range of 400~900mm. The control requirements for section A,B,C is stated in below sections.

Stage A - Cited Arc Plate Welded Storage. This section has 3 steps A11,A12, A13. The design requirement as: After rolling and spot welding is complete, the pipes are lifted and transported to the required position by crane. There are sensors installed in the area. In manual mode, the pipes are moved by trolleys to the required position. In automatic mode, the A11, A12 and A13 will response to the command sent from next stage B11 and consequently instruct the trolleys to load the steel pipes onto the convey rollers which will transport the pipes to the section B11.

Stage B - Exterior longitudinal seam Welding. Section B has four positions.B11 is set for pre-welding; B12, B13 and B14 is for welding. All four positions can be operated manually and automatically. In automatic mode, steel pipes are shifted from A onto the current convey roller once the LOAD button is pressed. The pipes then are transported by trolleys and are welding on the operation station.

Stage C - Emergency Buffer. Upon the status of B12, B12, B14 of sent out pipes and status of D of no incoming pipes, the trolleys will transport the pipes to the emergency buffer after system checks the enough space in the area. Once received the load demand, the trolleys will enter storage buffer, load the pipes onto the conveyor. Then system will start conveyor which transport the pipes to section D.

Hardware structure and configuration

Hardware Configuration specifies the required modules, network architecture, assigns the module parameters and addresses, etc. The graphic configuration is illustrated in Fig.1.

Siemens S7-300 controller (CPU315-2DP) has two built-in DP ports which are connected to sub-stations. The baud rate is adjusted based on the application. Lower speed would be benefit for reducing the interference. At rate of 187.5K the maximum communication distance is limited to 1000 meters. If the actual distance between the control cabinets is greater than 1000 meters, the repeater is required

Discrete inputs on the center control cabinet is used to start while discrete outputs to indicate the status of sub-stations. Each sub-station is equipped with RUN, MAINTENANCE push buttons as well as corresponding indicators.

Software implementation

Here an example is given to demonstrate section A to B11 and B11 to B12. The same consideration would be applied to the pipe transports among others.

Pipe transportation between A and B11. When A is in manual mode, the pipes can be loaded on the roller by operating the trolley through FORWARD, BACKWARD, UP and DOWN push buttons on the local console, then pipes are removed from storage racks and transferred to specified location by operating the motors to rotate roller through CLOCKWISE and COUNTERCLOCKWISE buttons. Storage racks, trolley and rollers are shown in Fig 2. The storage racks have V shapes. The sensors are installed to detect pipes inventory and the trolley backward position. When the trolley is running right under the roller, the sensor detects forward position. After the pipes are transported to the front of B11, the trolley in section B11 is run by operator to remove them from roller to the welding station.

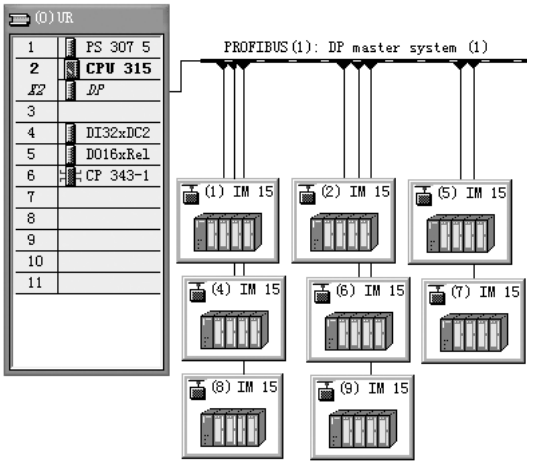

Fig. 1. Hardware configuration

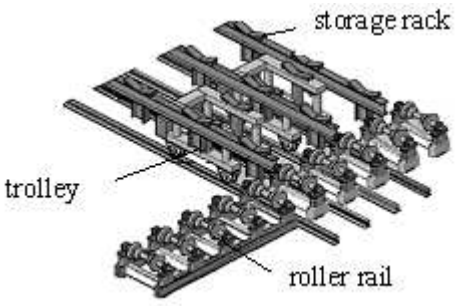

Fig. 2. Storage rack, trolley and roller rail schematic

In the automation mode the control requirements is shown in Fig3. B11 loading command is valid and there are steel pipes available in section A, the system will instruct the trolley in B11 to load the

pipes onto the conveyor and send the run command to roller so the pipes are transported to B11 forward position and are unloaded at the welding station. The B11 will go to idol mode if no pipes are available on the A storage racks after the LOAD push button at B11 is pressed.

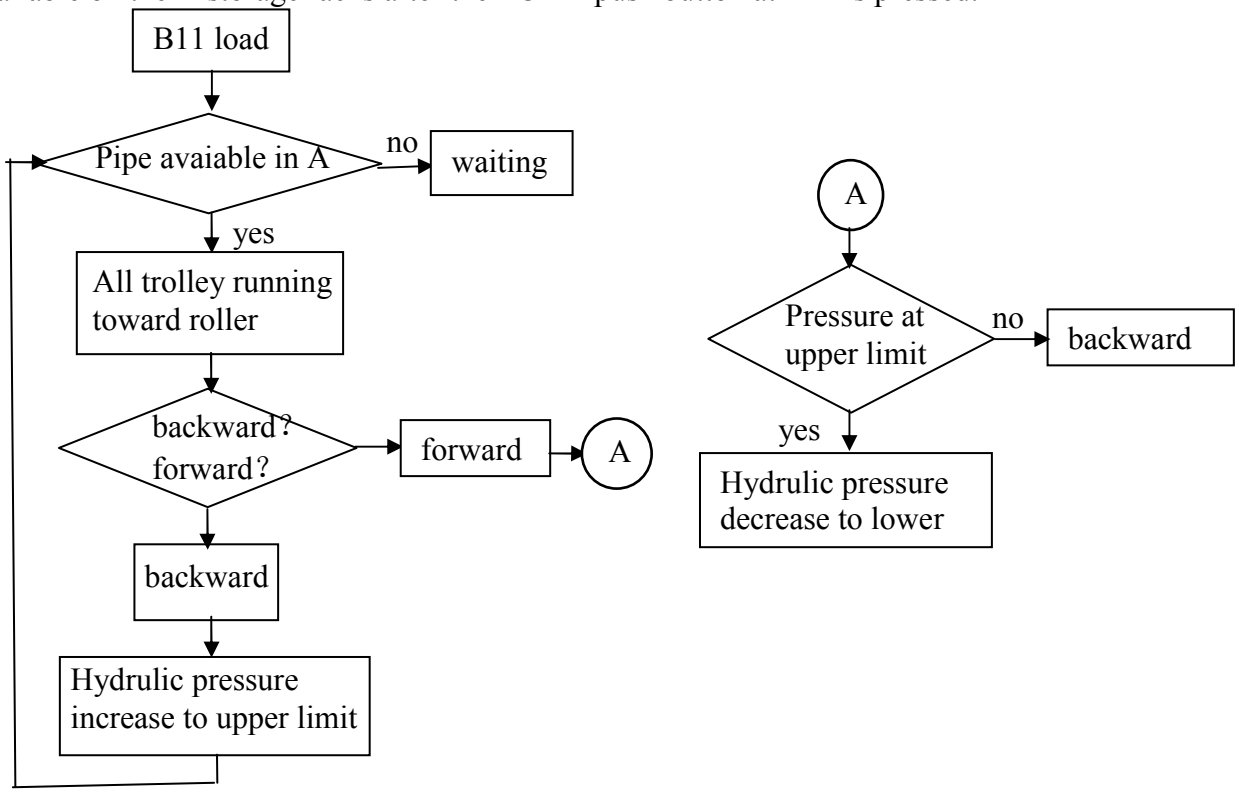

Fig. 3. Trolley of a11 control flow diagram

In the manual mode the trolley could be stopped at any position on rail. Switched to the automatic mode when trolley is at run status, the system needs to know the actual position, run direction (forward or backward) and hydraulic pressure level (upper/lower limit) before sends trolley instruction for next move. There are no upper/lower position limit sensors installed for the trolley hydraulic pressure system. The functions are achieved by timer plus SET/RESET instructions to simulate the upper/lower position. The control ladder diagram is shown in Fig.4.

Steel pipe transfer between section B11 and B12.B11 is for pre-welding and B12 is for welding. Control panel with LOAD and SENT buttons are installed in both areas. When B11 is set to auto and the LOAD button is pressed, the pipes in A should be transferred to the area automatically. After pre-welding is complete, the pipes are sent to B12, B13 or B14.If B11 is preceding the current procedure which indicates the inventory, the B11 is set to idol mode. Override by pressing the LOAD button, trolley in B11 will start movement and transfer the pipes onto the roller which transports the pipes in front of B12.consequently the trolley in B12 takes the pipes to the welding station. Simultaneously a shake hand signal is sent to confirm the SEND command from B11 and RECEIVE status of B12.If the signal is fail, both B11 and B12 will stay in idol modes. The welded pipes are transported to C storage area upon the RECEIVE command from B12.

Pipe length measurement. This section illustrates the importance of length measurement for pipe between sections A and B11. Fig.5 shows the control ladder diagram.

After the pipes are unloaded from roller and moved in front of B11, the length of pipes must be known so that they can be lifted and transported to welding station by trolley in the area. The length will be measured in B11 as well. The two values are compared and an error is calculated in the system. The error within 0.5 would ensure firm lift and transportation. A proximity switch is installed on the rail between *A* and *B11* for this purpose. When pipes are approaching the switch it starts counting, from which the length is able to be calculated. A proximity switch is required in front of B11 as well. The ladder logic for implementing length measurement is shown in figure 5: M0.0 is defined as a 100ms pulse and M1.0 is valid status set by shake hand signal between *A* and B11.

Pipe transportation between two plants. The pipes backward transportation between two plants is performed by the backward trolleys installed on the rail. The trolley power is supplied by either rail or backup battery and controlled by S7-200 controller. The control signals are sent from S7-300 discrete output module and relay to S7-200 through the rail. The flow diagram as: the backward trolley will start if it received the SEND command from E and confirmed the RECEIVE mode from F; otherwise the E will enter into WAITING mode.

Summary

After one year's installation and commissioning, the functionalities of control system are met the client's requirement. The system realizes the discrete control and centralized management. The plant-wide real time human machine interface is designed clearly, friendly and operated easily. The system design includes process flow tracking, alarms, History data storage, display and inquiry. The implementation of project improves the operation procedure which was performed by the crane. The efficiency and safety are also made better.

Keywords: power control, fault protection, temperature sensor of P-N Junction transistors, LED power supply

Abstract. Power control technology of LED is proposed, which can be adaptive to the change of temperature while online. The input power of LED will be adjusted according to the current value and its change rate of LED radiator. Reducing input power can balance the decreasing of the capacity of heat dissipation caused by the rise of ambient temperature in order to keep radiator temperature in a safe range. This avoids the vicious circle of the temperature excursion of P-N Junction caused by the rise of the temperature of LED light source characteristic of negative temperature. This, in turn, avoids damage to LED at high temperature.

Introduction

LED lamps, especially LED street lamps work under the condition of a wide temperature differential. In winter the temperature may reach to below -20℃ and in summer goes to more than 60℃. The wide temperature differential troubles the thermal design. If we design at maxium ambient temperature may raise the cost and weight of LED, which hinders its application. Otherwise, the problem of maintaining reliability performance under high temperature condition is hard to resolve.

At present, the solutions are as follows:

Overheated power-off protection method.

The implementation of this method is: install a temperature sensor in the LED lamp radiator. As the temperature exceeds maximum value, the LED drive through the hardware circuit connected with temperature sensor is shut off and the power supply is cut off in order to avoid the light emitting diode burnt down at high temperature.

Adaptive control method.

This is the improvement of the former method, which fuses modern control theory and single chip technology. The implementation of this method is as follows a temperature sensor is installed in the LED lamp radiator. Its output is linked with the single chip's (or DSP's) A/D port. Thus the analog quantity of temperature of the radiator will enter from A/D port into single chip microcomputer to realise digital monitoring of temperature. When the exceeding temperature of the radiator is detected by the single chip microcomputer, it will control the input power of the LED lights through the PWM output port to lower calorific value and get LED lamp radiator temperature back to normal.

A self-adaptive adjusting hardware control circuit is designed in this research. On the basis of the current value and its change rate of LED radiator, the input power of LED will be adjusted while online. Reducing input power can balance the decreasing of the capacity of heat dissipation caused by the rise of ambient temperature to keep radiator temperature in a safe range. This avoids the damage of LED device. And this particularly suits the condition of wide temperature differential.

The control principle of the temperature-change-adapted power

Circuit principle

The control principle of temperature-change-adapted power shown in figure 1. As is shown in the diagram, when ambient temperature rises, V_{FT} decreases because of the negative temperature characteristic of P-N Junction's temperature sensor D_1. However, with the regulation of R_1, the decreasing rate of V_1 is limited in $\Delta V_1/\Delta T \approx \delta$. And V_1 is used to control the input power of LED lamps, which means that the volume of heat dissipation of LED chips decreases following δ. On the other hand, with the rise of ambient temperature, the capacity of heat dissipation of radiator decreases. The decreasing rate is $\Delta P_D/\Delta T \approx \eta$. Because the selection of circuit components is decided on the condition of ensuring $\delta = \eta$, The capacity of heat dissipation equals to the decreasing rate of input power. In a word, the temperature of radiator will be balanced in a regulation scope no matter how the ambient changes, and this has promoted the reliability of LED working in high temperature.

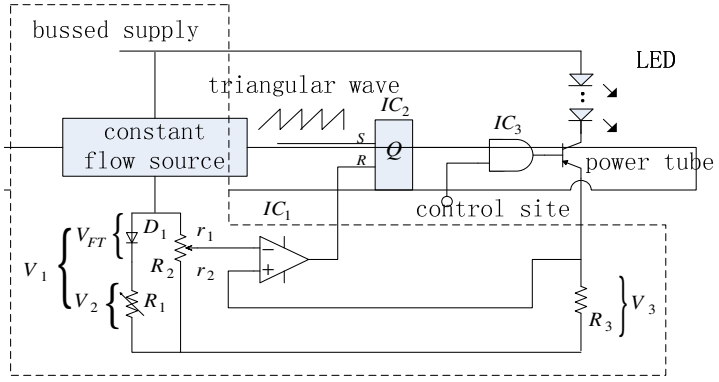

Figure. 1. The circuit principle of the LED lights temperature online adaptive adjustment

Theoretical foundation

When LED light source is working, due to the thermal resistor, the temperature of P-N Junction is[1] ,

$$T_J = T_A + R_\theta P_D \quad (1)$$

In the equation, T_J is the temperature of P-N Junction (approximately equals to the temperature of radiator), T_A is the ambient temperature, R_θ is the thermal resisitance from P-N Junction to the environment, P_D is heat dissipation. In LED, the 3%~5% of input electric power is transfered to luminous energy for output, and the rest dissipate in the device as the modality of heat, thus the heat dissipation also equals to forward voltage drop multiplied by input current, which may not cause great deviation to the experimental study[2].

The performance parameters of the effects of elevated ambient temperature are mainly reflected in two aspects. One is the monotonically decreasing of forward voltage drop V_{FT} between the two ends of LED, they can be approximated as:

$$V_{FT} = V_{F0} + K(T - T_0) \quad (2)$$

In the equation, V_{FT} is the voltage between the two ends of temperature sensor D_1 when ambient temperature is T, V_{F0} is the voltage between two ends of D_1 when ambient temperature is T_0, K is the coefficient that voltage changes with temperature, which is a negative value. For instance, the LED whose luminescent material is InGaN and substrate material is SiC, its K is: -2.66(mV/℃)[3].

And secondly, the capacity of heat dissipation of LED lamps decreases. Based on equation(1) we conclude that:

$$P_D = (T_J - T_A)/R_\theta \quad (3)$$

Obviously, as T_J, R_θ are given, when T_A rises, the power of heat dissipation P_D decreases.

It is concluded from formula(2)and (3) that: the rise of ambient temperature reduces not only the capacity of heat dissipation but also the voltage of P-N Junctions. Both of them worsen the thermal

environment of LED lamps. The measure we take in this paper is proposed to meet this need. With the change of ambient temperature, this measure adjusts the power of dissipation of P-N Junction of LED, and maintain the radiator temperature in an allowable range constantly. This avoids the vicious circle of the temperature excursion of P-N Junction caused by the rise of the temperature of LED light source, which possesses negative temperature characteristic, influenced by the rise of ambient temperature.

Technical solution

As is shown in figure 1, the method to control LED input power V_1 is as follows. In figure 1, R_1 is the gradient adjust resistor, which is used to change V_1's slope of the curve that decreases with the rise of temperature. R_2 is divider resistor(could be replaced by two constant resistors, the divider value depends on R_3 , which is the maximum of V_3 the voltage drop of R_3, R_3 is the constant current control resistor.

Selection of components and calculation of parameters[4].

①The calculation of R_1

The calculation of R_1 is the core of this paper, and it plays the role of changing V_1's slope of the curve that decreases with the rise of temperature. First of all, calculate the changing rate δ that change with the temperature:

$$V_1 = V_2 + V_{FT} = I_0 R1 + V_F T_0 + K(T - T_0) \quad (4)$$

We can deduce from formula that: $$\Delta V_1 / \Delta T \approx KT / (V_2 + V_F T_0) = \delta \quad (5)$$

In addition, with the change of ambient temperature, the dissipation rate η of radiator is regarded as: $$\Delta P_D / \Delta T = \Delta T / R_\theta = \eta \quad (6)$$

If we need to maintain radiator temperature when ambient temperature rises, we must meet: $\delta = \eta$, result in: $KT/(V_2 + V_F T_0) = \Delta T / R_\theta$, namely: $V_2 = I_0 R_1 = V_F T_0 + K R_\theta$

Thus: $$R_1 = (V_F T_0 + K R_\theta) / I_0 \quad (7)$$

In formula (7), V_F, T_0, K, R_θ, I_0 are known as quantity values.

②The calculation of R_2

Assume that: $R_2 = r_1 + r_2$, as is demanded by this patent, the selection of r_1 and r_2 must meet following requirements.

A. The requirement of bleeder

The selection of r_1, r_2 must meet: $V_1 r_1/(r_1+r_2)=I_1 R_3$, which plays the role of protecting temperature and maintaining current constant.

B. The requirement of shunt

As I_0 is constant flow source output, R_2 must be big enough to avoid it impact the precision of shunt of D_1 - R_1 branch, and the shunt of constant flow source should be as small as possible(approximately $0.02I_0$).

③The calculation of R_3

The requirements of resistors of this patent are as follows: dissipation power of R_3 should reach the minimum value, and the detected value V_3 / $I_1 R_3$ must meet the needs of voltage comparator, which includes the capacity of anti-interference and precision requirement, and in general the value ranges from decades to hundreds of million.(confirmed by the value of load current).

④the choice of the temperature sensor D_1

The temperature sensor D of the P-N Junction can be LED diode, same model to the lamps, to ensure consistency of parameters in wide temperature range. When the K value of selected LED diode cannot meet the needs when P_D decreasing. Other normal low power diode(such as 1N4148,etc) whose absolute value of K is larger also is available, but because of the impact of equivalent resistant of P-N Junction, the precision is a bit worse when other model diode in ultra-temperature is selected(T_j above 100 degrees).

The control method

As is shown in figure 1, when ambient temperature rises, V_{FT} decreases because of the negative temperature characteristic of D_1 . However, with the adjustment of R_1, the decreasing rate is limited in $\Delta V_1/\Delta T \approx \delta$. As V_1 is used to control power, we can concluded from formula 1 that the volume of heat dissipation decreases with δ . Meanwhile as temperature rises, the capacity of heat dissipation decreases in the rate of $\Delta P_D/\Delta T = \Delta T/R_\theta = \eta$. On account that the selection condition is $\delta = \eta$, the capacity of heat dissipation of radiator equals to the decreasing of input power. Thus, the temperature of radiator could be balanced in defined limits and improve the reliability of LED lamps working under high temperature, because of the ensurement that $\delta = \eta$ no matter how ambient temperature changes [6].

Examples of application

The implementation of A Power Control Technology Adapting to Temperature Change is shown in figure 2. In that, D_2(1N4148) is junction temperature sensor of P-N Junction that detects ambient temperature. R_9 is gradient adjusting resistor and R_6 is divider resistor. The calculation of these three resistors is shown in chapter Technical solution.

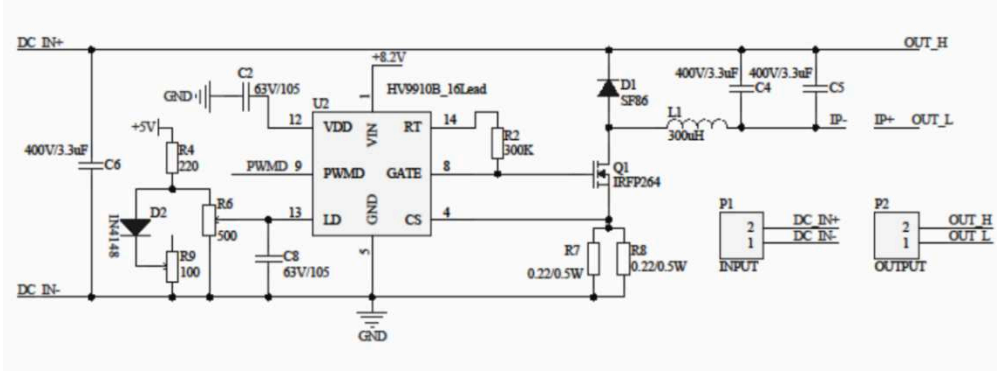

Figure .2. The Power control principle diagram of The adaptive temperature change

In figure 2, the output of Q_1 drive chip is controlled not only by the voltage drop of current-limiting resistor R_6 but also by the output voltage of R_6. In normal temperature, the voltage drop of current-limiting resistor R_7 and R_8 are lower than the output voltage of R_6 at the stage of self-adjustment, so the output power is controlled only by current-limiting resistor. Hence the output power is rated[7]. As soon as temperature rises, the output voltage of R_6 will decrease gradually due to the negative temperature characteristic of P-N Junction. When this voltage decreases to a value lower than the voltage of current limiting resistor R_7 and R_8, the drive chip of Q_1 is transfered to be controlled by self-adaptive temperature. The output power of Q_1 will be lower than the rated value. The more temperature exceeds, the lower voltage of R_6 is, the lower output power is. It makes up the decreasing of the capacity of heat dissipation of power devices caused by temperature deterioration. Since the gradient adjusts regulation resistor R_9, the power devices such as the power Q_1's capacity of heat dissipation still maintain in a safe range, the reliability of power supply working in high temperature condition.

At present, this technology has been applied to the network distributed centralized power supply system, and remarkable results have been achieved.

Conclusion

When LED lamps and lanterns are installed on road, and square where working environment temperature changes greatly, the temperature difference is often more than 80 ℃.Large temperature difference not only buys trouble to the cooling design, also brings troubles for power device selection. Tolerance selection of power devices is too big, which will further increase the cost,

leading to negative promotion of the LED light source. In this paper, the power control technology adapting to temperature changes can be used to compensate the reduction of heat dissipation and ensure the reliability of the power supply in extreme temperature environment. Moreover, the implementation cost is low, and the technology is easy to apply. In addition, due to the reduced power control within the scope of the permit, it will not impact LED light source obviously.

Magnetic Field Analysis for the Dual-stator Toroidal Motor with Hybrid Excitation

Xin LIU, Ling NIE, Shouyong ZHOU

Tianjin Key Laboratory of Modern Electromechanical Equipment Technology,

Tianjin Polytechnic University, Tianjin, 300387, China

email: liuxin@tjpu.edu.cn

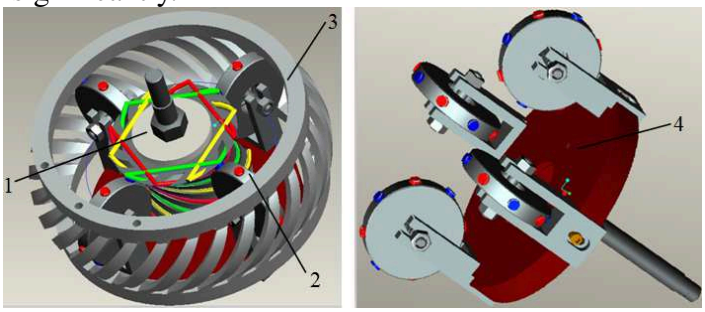
Keywords: Dual-stator; Toroidal Motor; Hybrid Excitation; Magnetic Field

Abstract. A dual-stator toroidal motor with hybrid excitation was proposed and its structure and operating principal were introduced. The spiral currents of worm armature coils were resolved into two orthogonal components. The FEM analytic models for current components were built. Distributions of static magnetic field were simulated. Air gap flux density curves were obtained. The simulation results justify the rationality of the electromagnetic parameters of the motor. The research results are useful for analyzing electromagnetic characteristics of the motor, and offer meaningful instruction for further research and practical application of the novel motor.

Introduction

Toroidal drive can transmit large torque in a small size and is suitable for fields such as aviation and space flight, etc[1-4]. As more and more electromagnetic and control techniques are utilized in engineering field, the new-type composite motors become advancing edge of electromechanical science. Thus the dual-stator toroidal motor with hybrid excitation has more expansive application prospect. The motor is a new concept spatial motor in which mechanical elements and magnetic ones are integrated[5,6]. It can be substituted for a servo system to simplify the structure of the existing electromechanical systems. Besides the fields that require compactness, the toroidal motor can be used in fields such as robots and aviation, etc, that require accurate control.

The dual-stator toroidal motor with hybrid excitation shown in Fig.1 consists of four basic elements: (1) the central worm inner stator; (2) radially positioned planets; (3) permanent magnetic outer stator; and (4) rotor which forms the output shaft upon which the planets are mounted. In the motor, the inner stator is fixed and armature coils are mounted in helical grooves of its surface. The outer stator has several helical beams made of magnetic steel or permanent magnets. The N and S polar helical permanent magnets are mounted alternately on the outer stator. And the planets have permanent magnetic teeth. In the same manner as the stator, the N and S polar permanent magnets are embedded alternately in a planet. The planets adopt permanent magnetic structure for excitation. The excitation method does not need exciting current, no armature wire with simple structure and high reliability, it can make the motor have smaller size and weight than the electromagnetic method[7,8]. Besides, the toroidal motor with the special rotor structure can realize direct drive that can improve efficiency significantly.



(a) Two stators of the motor (b) the rotor parts

Fig.1. The solid model of the toroidal motor

Operating Principal

Using techniques of motor driven and permanent magnet motor for reference, the authors develop the dual-stator toroidal motor. If a specific relation between planet pitch, number of pole-pairs and helical angle of the worm inner stator and tooth number of the outer stator is realized, N pole of the planets will correspond to S pole of the stators all along. The electromagnetic attractive forces between N and S pole of the different elements are driving forces. When the alternating voltage source is connected to the coils of the worm, a toroidal circular electromagnetic field is formed. It drives the planets to rotate about their own axes. The winding mode of the armature worm is related to planet teeth number. The worm is one excitation stator of the motor. The other outer stator is used to attract magnetic planets along a spiral trajectory as its helical steel beams. So the magnetic forces between the teeth of the planet and stators cause the rotor to rotate about its own axis. Thus, output power with a large torque at low speed is generated.

Toroidal motor can not only convert electrical energy into mechanical energy as general motors, but also can achieve deceleration function with a certain transmission ratio. The toroidal motor includes special mechanical structure and electromagnetic system. The coupled field between stators and rotor of the motor should be investigated further. However, the study for the magnetic field of the toroidal motor is quite difficult because the worm coils have toroidal shape and outer stator has helical beams. In this study, the current among worm coils is resolved into two orthogonal components. Circumferential and toroidal magnetic fields are simulated. The air gap flux density distributions of the motor are analyzed. The results are useful for further characteristic analysis for the new motor.

Electromagnetic Model

The magnetic field of the toroidal motor is an important subject that should be developed. Understanding the field distribution of the new motor is very important for analyzing its electromagnetic characteristics.

A worm in mesh with the planets is shown in Fig.2. The currents of armature coils run in the toroidal direction. For simplifying analysis, the current among some one phase coil can be resolved into two orthogonal components. Fig.2 shows the current and its two components at position in mesh. Let β denote the lead angle of the coil, i is the current intensity at the position for one phase coil, i_1 and i_2 are tangent and axial components of the current i respectively. From Fig.2, it is known

$$\begin{cases} i_1 = i\cos\beta \\ i_2 = i\sin\beta \end{cases} \tag{1}$$

$$\tan\beta = 2p/Z_2\left(a/R - \cos\alpha\right) \tag{2}$$

Where p is the pole pair number of the worm coils, Z_2 is the tooth number of the planet, a is the center distance between the planet and the worm, R is the circle radius of the planet, α is position angle in mesh.

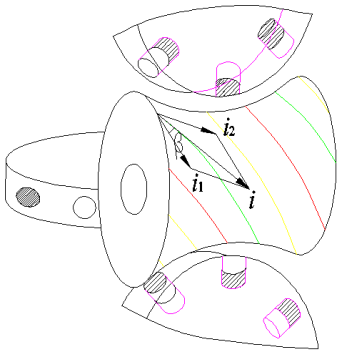


Fig.2. Current components among coil of inner stator

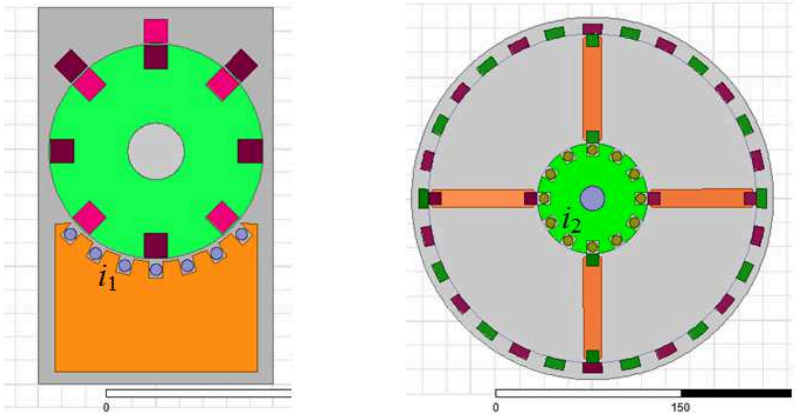
Based on the special structure and excitation mode of the toroidal motor, the FEM models are build by using the professional electromagnet simulation tool developed in a Ansoft environment. Fig.3(a) shows the 1/2 model of toroidal magnetic field caused by current i_1, teeth of outer stator in mesh and one planet. The view is the cross section of the worm and the planet perpendicular to current i_1. In the same manner, the view of Fig.3(b) is the cross section of the worm perpendicular to its axis through the position in mesh. It shows the model of circumferential magnetic field caused by current i_2, outer stator and all planets mounted.



(a) (b)

Fig.3. Analytic model of current components

The distribution of material properties for different part of the model is required. For the dual-stator toroidal motor, the winding material is set to Copper, DW540-50 for the worm inner stator, the permanent-magnet material is set to NdFe30, Vacuum is the background. The boundary conditions are defined and the excitation sources are loaded.

Simulation Results and Discussion

According to the principle of finite element method, the mesh of the models for toroidal motor can be obtained by adaptive subdivision. Among the subdivisions, the part of air gap has the densest ones. Static magnetic field denotes the working state at a certain time point. The parameters of magnetic field for the motor can be obtained to prove the correction of magnetic circuit design from the static field. Setting proper excitation parameters for solver provided by simulation software, Fig.4 shows the simulation results of circumferential and toroidal magnetic fields.

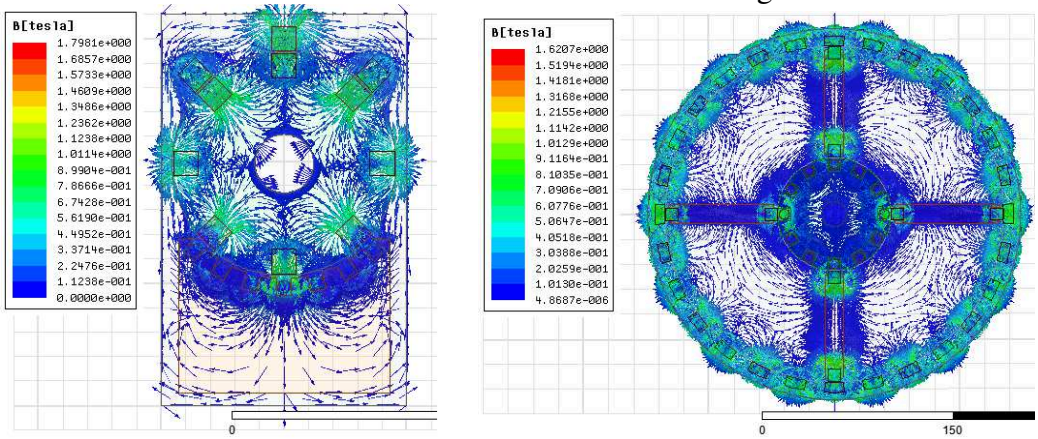


Fig.4. The simulation results

In Fig.4, different colors denote different magnetic density. From the colors distribution, it is known that there is no magnetic over-saturation phenomenon, so the magnetic parameters of the motor are reasonable. Specify a circular path in the motor air gap, the air gap flux density distributions of the specified path are given as shown in Fig.5, which calculated by field calculator of the software.

From the air gap flux density curves in Fig.5, it is known that the flux density is larger at he counterpart of planet teeth and magnetic poles of stators. Left figure shows the air gap flux density about 0.6T caused by current $i_1$along air gap circle, square waves at the outer stator side, distorted waves at the inner stator side caused by armature slot. Among the waves, the distortion is larger at throat position of the worm. Right figure shows the air gap flux density about 0.5T caused by current $i_2$at the outer circle of worm. The electromagnetic mesh between worm inner stator and planets is the main cause for the flux density distribution, and armature slot has also influence on flux density.

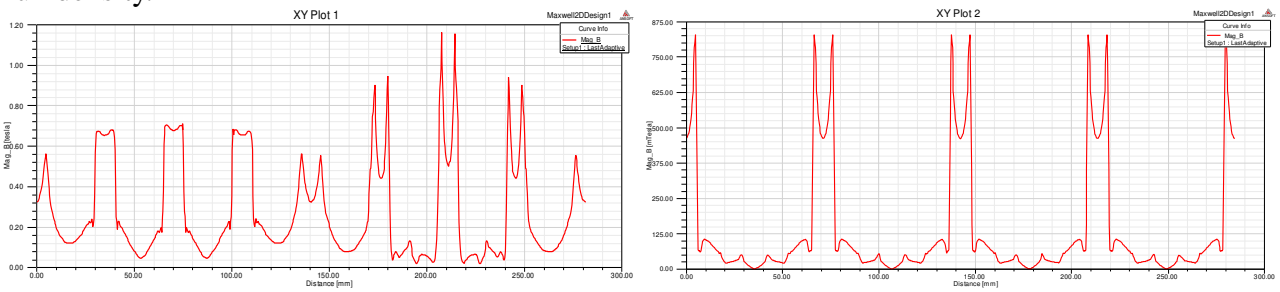

Fig.5. Air gap flux density distribution

Conclusion

Based on the special mechanical structure and excitation mode of the toroidal motor, its operating principal was introduced. The output is realized by magnetic force of planets from toroidal inner stator and outer stator. The currents of armature coils run in the toroidal direction, which was resolved into two orthogonal components. The FEM analytic models of current components were built in a Ansoft environment. Distributions of static magnetic field were simulated without magnetic over-saturation phenomenon. Air gap flux density curves were obtained with slot effect. These results are useful for design and optimum of the new motor.

Keywords: TCR, SVC, DSP, Unbalanced, Load Compensation

Abstract. in practical application of SVC, unbalanced load system exists on many sites, and the voltage at system access point is required to meet the demand of power grid operation. This paper describes a SVC constant voltage control method for an unbalanced load system. the control algorithm controls the voltage at evaluation point to reach the preset range while compensating reactive power of unbalanced load system. the control method could compensate an unbalanced load system into a balanced system, at the same time, the voltage at access point could meet the demand of power grid operation. This control method is particularly applicable to reactive control requirements of steel mills, wind power, solar power grid systems. This algorithm has been applied in Lishizhai 66kV SVC Project in Fushun, inhibits three-phase unbalance of the grid, has achieved good compensation effect.

Introduction

SVC plays many roles in power system, on the system side, SVC could increase steady state transmission capacity, prevent voltage unstability, increase transient stability of the system, enhance system damping, mitigate subsynchronous resonance, improve characteristic of direct current transmission system; on the user side, SVC could increase power factor, suppress voltage fluctuation and flicker, compensate three-phase unbalance[1-3].

For the compensation methods available now, SVC could only compensate load reactive power or system voltage at the access point, could not realize joint control of the reactive power and voltage[4, 5].

Principle of the control algorithm

With load unbalance algorithm, this control method calculates reactive power of the phase loads, compensates reactive power of the corresponding phases via SVC; at the same time, it adopts voltage closed loop algorithm, tracks the voltage at evaluation point in real time, when the value exceeds the present range, it utilizes integral method to increase or reduce the inductance value into the grid gradually, so that the voltage at evaluation point falls to the set range. This control algorithm should acquire the following parameters: voltage at the evaluation point, current and voltage of incoming line on the load side, current and other analog quantities in TCR ring. the control principle is shown in Fig.1.

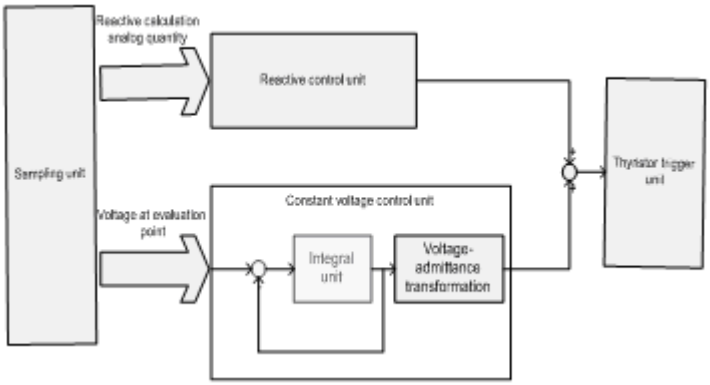

Fig. 1 System Block Diagram

(1) Reactive compensation for unbalanced load

Sampling unit acquires three-phase voltage value at SVC evaluation point, three-phase incoming line current value, and current value in three-phase TCR ring in real time. Then through Fourier transform, values of the real part and imaginary part of the acquired analog quantity are obtained. As shown in the Formula (1).

$$\mathrm{Re}[A(k)]=\sum_{n=0}^{N-1}[a(n)\cos(Qnk)+b(n)\sin(Qnk)] \quad \mathrm{Im}[A(k)]=\sum_{n=0}^{N-1}[b(n)\cos(Qnk)-a(n)\sin(Qnk)] \tag{1}$$

According to the Steinmetz split phase compensation theory, as shown in the Formula (2).

$$\begin{aligned} B_r^{ab} &= \frac{1}{3\sqrt{3}V^2}*\frac{1}{T}\int_T (v_{bc}*i_{a(l)}+v_{ca}*i_{b(l)}-v_{ab}*i_{c(l)})dt \\ B_r^{bc} &= \frac{1}{3\sqrt{3}V^2}*\frac{1}{T}\int_T (v_{ab}*i_{c(l)}+v_{ca}*i_{b(l)}-v_{bc}*i_{a(l)})dt \\ B_r^{ca} &= \frac{1}{3\sqrt{3}V^2}*\frac{1}{T}\int_T (v_{ab}*i_{c(l)}+v_{bc}*i_{a(l)}-v_{ca}*i_{b(l)})dt \end{aligned} \tag{2}$$

Three-phase reactive value on the load side may be calculated. At the same time, TCR trigger angle may be obtain according to the Formula (3).

$$Br=\frac{2\pi-2a+\sin 2a}{\pi wL} \tag{3}$$

By controlling TCR trigger angle, reactive power of unbalanced load may be compensated to the required value. As shown in Fig. 2.

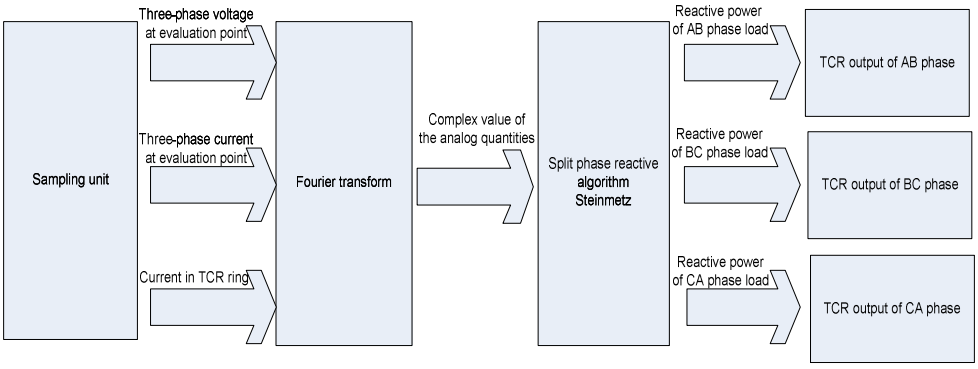

Fig. 2 Schematic Diagram of Reactive Compensation for Unbalanced Load

(2) Stabilized system voltage

Sampling unit acquires three-phase voltage value at SVC evaluation point in real time, gets full wave effective value of three-phase voltage through Fourier transform. Control algorithm adopts integral controller, compares the sampled voltage with the set section voltage.

If voltage exceeds the set upper limit value, TCR output may be increased gradually to superpose the deviation value to the unbalanced reactive output, to pull the voltage back to the set section.

If voltage is lower than the set lower limit value, TCR output may be decreased gradually, this deviation value may be subtracted from the unbalanced reactive output, so voltage at the evaluation point rises. As shown in Fig. 3.

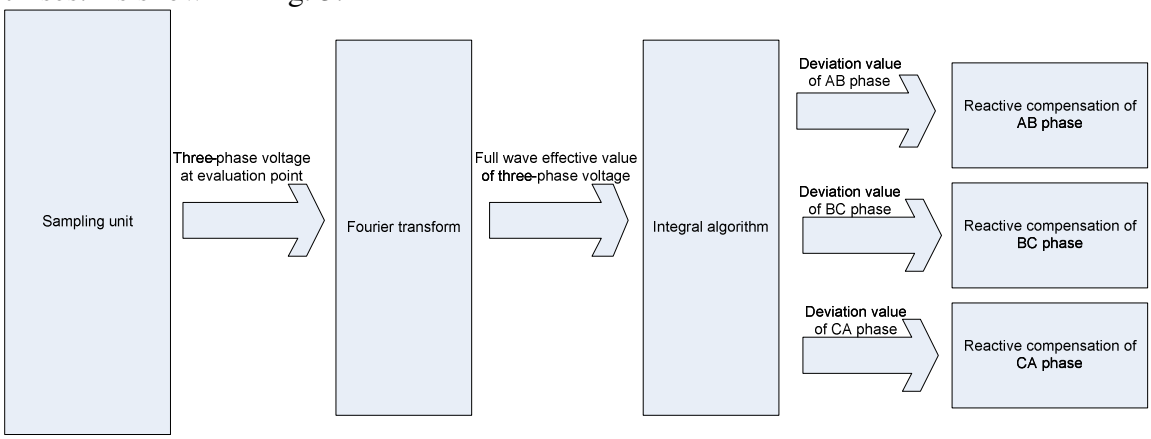

Fig. 3 Schematic Diagram of Stabilized Voltage

(3) Joint control method of reactive power and voltage for unbalanced load

In order to realize joint control of reactive power and voltage, processing result of reactive power and voltage should be combined through certain algorithm. This paper provides a weighted arithmetic method.

Weighted iterative operation is performed for the reactive power calculated according to Steinmetz reactive theory and the reactive deviation generated by voltage closed loop.

$$\begin{aligned} Br^{ab} &= Ks * Br_s^{ab} + \sum_{K=1}^{n} Ku * U^{ab}(k) \\ Br^{bc} &= Ks * Br_s^{bc} + \sum_{K=1}^{n} Ku * U^{bc}(k) \\ Br^{ca} &= Ks * Br_s^{ca} + \sum_{K=1}^{n} Ku * U^{ca}(k) \end{aligned} \tag{4}$$

Where Ks is the weighted value of Steinmetz reactive split phase calculation; Ku is the weighted value of voltage closed loop; Where, $U^x(k)$ is the deviation value obtained from voltage closed loop, given in the following formula:

$$U^x(k) = Kp * \begin{Bmatrix} [e^x(k) - e^x(k-1)] + Ki * e^x(k) \\ + Kd * [e^x(k)] + e^x(k-1) + e^x(k-2) \end{Bmatrix} \tag{5}$$

Where, K_p--- scaling factor of voltage closed loop; K_i is the integral coefficient of voltage closed loop; K_d is the differential coefficient of voltage closed loop.

After weighting, final output admittance value Br per phase is used for thyristor trigger.

Control strategy RTDS simulation

(1) A brief introduction to RTDS

RTDS is a product of computer parallel processing technology and digital simulation technology, a special computer equipment for full digital simulation of electromagnetic transient process of the power system. Its simulation principle and algorithm of electromagnetic transient process are the same as electromagnetic transient program EMTDC, the real time EMTDC. Simulation step size is 50-100μs, frequency response is accurate to 3000Hz. the biggest advantage of RTDS is the connection with actual device controller via I/O structure for mixed analog-digital simulation, if analog amplifier is added, RTDS may be connected with actual electric equipment for relevant studies.

RTDS has all features of digital simulation, for example, high precision, fast response time, convenient parameter modification, simple modeling, simulated accident will not lead to equipment damage. In addition, RTDS also has the following functions:

1) Simulation of large scale power system;
2) HVDC simulation;
3) test of relay protection device;
4) Functions of general AC transient network analyzer (TNA);
5) Expansion of analog simulator;
6) Accident analysis of scientific research and dispatch departments;

With RTDS, real time simulation analysis may be conducted for dynamic characteristic of AC/DC system, DC control protection characteristics, device test, SVC, thyristor controlled series capacitor and other FACTS equipments.

(2) RTDS simulation model building

Build SVC system for impact load in RTDS, SVC has 3 filter branches. TCR runs "Joint control algorithm of reactive power and voltage for unbalanced load". Constant voltage target is bus voltage and reactive power on 400 kV side.

Bus voltage and reactive response of the system should be verified in the test after TCR is put into operation.

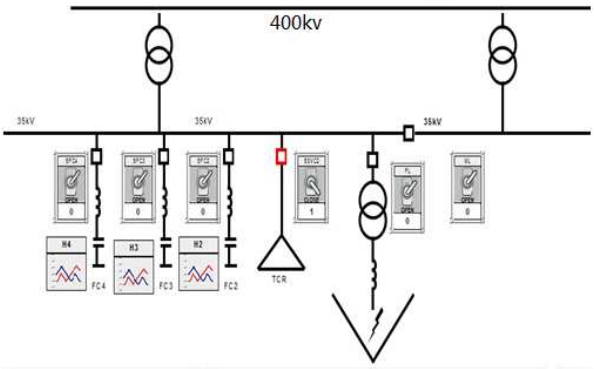

Fig. 4, RTDS Simulation Experiment Model

(3) Conclusion of RTDS simulation

Firstly input a group of fixed filters to verify reactive response of the control strategy. Reactive response of the system is shown in Fig.5.

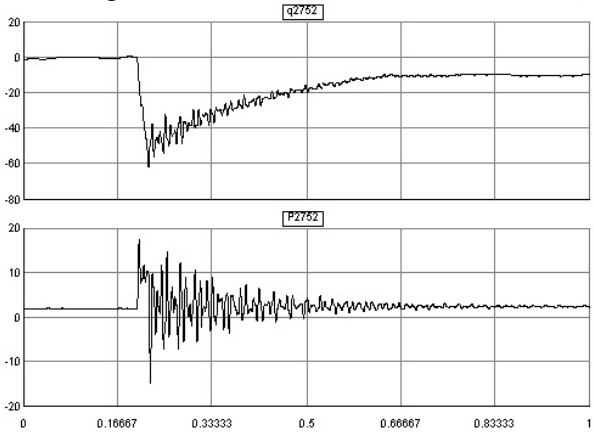

Fig. 5 The Reactive Change Curve after Input of A Group of Filters

Application of the control strategy in 66KV SVC Project

Lishizhai 220kV Primary Substation under Fushun Power Supply Company is in a complex supply network, the network contains important petrochemical, smelting loads and civil loads, maximum reactive load of this substation is 100MVar, and maximum reactive shortage is up to 60MVar. the cooperative 66kV SVC project of Fushun Power Supply Company and Rongxin Power Electronic Co., Ltd. The SVC System Wiring Diagram is shown in Fig. 6.

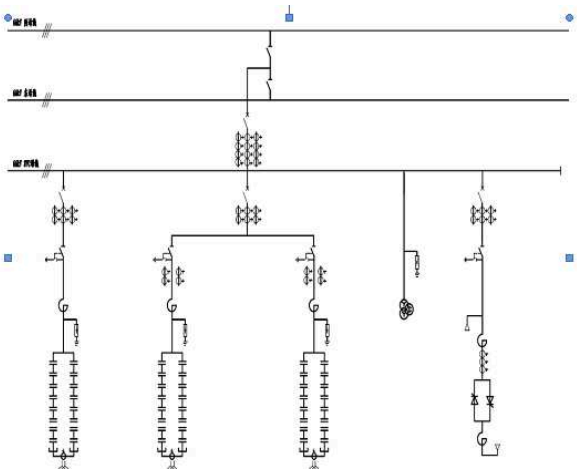

Fig. 6 Fushun Lishizhai SVC System Wiring Diagram

After this project was put into operation, good compensation effect has been achieved using "The constant voltage composite control algorithm of the SVC with unbalanced load compensation", three-phase voltage and reactive power of the phases have been compensated to a balanced state. 66kV bus voltage operation curve of the project is shown in Fig. 7.

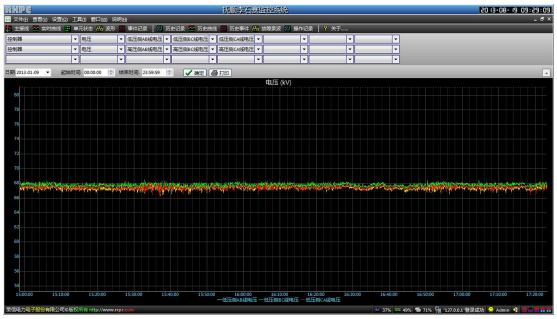

Fig. 7 Fushun Lishizhai 66kV SVC Operation Screenshot

Keyword: Dead zone mode; Bipolar PWM modulation; Voltage jump; Electric vehicle speed control

A**bstract.** To realize the electric vehicle braking energy recycling and driving smooth, bipolar PWM modulation mode is often adopted. To avoid the bridge arm shoot-through, a dead zone needs to be set in the complementary upper and lower bridge arm driving signal. Using hardware circuit dead zone setting has the advantages of simple setting and high reliability, is often used in the integrated driving module, however different dead zone mode has different influence on the inverter output voltage. This paper carried analysis on motor speed nonlinear problems caused by output voltage jump around a specific duty ratio in hardware dead zone setting mode, and gives the improvement of hardware circuit. Simulation and experimental results indicate that the method can well solve the output voltage jump in the vicinity of a specific duty ratio problem.

Introduction

In pulse width modulation (PWM) mode, the bipolar PWM can smoothly realize four quadrant operation of the motor, often used in electric vehicle driving system that can operate in four quadrant. In bipolar PWM mode, the driving signal of upper and lower bridge arm are complementary, to avoid the bridge arm shoot-through while the switch tube on and the shut off time difference, a dead zone must be added between the two driving signal. Using hardware circuit way of dead area setting can real-time detect the state of the PWM signal, in both normal and the PWM signal interfered situations caused misoperation can avoid switch tube on and shut off process of overlap, so it has higher reliability. At present, most of the integrated driving module itself is integrated with dead zone setting function, which not only simplified the design of the system, but also to improve the reliability of the system, but the different ways of dead zone setting produce different effect on the inverter output voltage.

About dead zone, in the study of literature at home and abroad are mainly concentrated in the research of dead zone effect and dead zone compensation, No specific way of dead zone setting caused problems are analyzed. A kind of commonly used hardware Settings Dead zone are analyzed in this paper, and analyzed the speed nonlinear problems caused by output voltage jump in the vicinity of a specific duty ratio in view of the bipolar PWM modulation mode and put forward solving measures.

1 dead zone setting circuit

Fig.1 shows a dead zone setting circuit that commonly used in integrated driving module. This way of dead zone setting is on the same bridge arm a switch tube shut off signal occurs, superimpose a fixed time width of invalid drive signal on another switch tube driving signal.

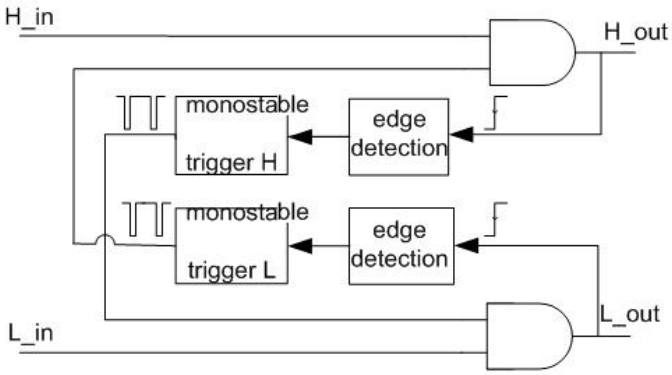

Fig.1 Schematic of dead zone setting circuit

We can see the time of the dead zone is related to the time width of the output low level of monostable trigger from Fig.1. For the time width of the monostable trigger H output low level is T_{d1}, For the time width of the monostable trigger L output low level is T_{d2},usually T_{d1} is a little bit bigger than T_{d2} in the dead zone setting circuit.

2 the effect of dead zone on output voltage

Fig.2 is the structure chart of the three-phase cascaded voltage source inverter-brushless direct current motor load. Taken phase A bridge arm for example, we analyze the effect of the above dead zone setting mode on voltage. We define Current polarity is positive that is into the motor.

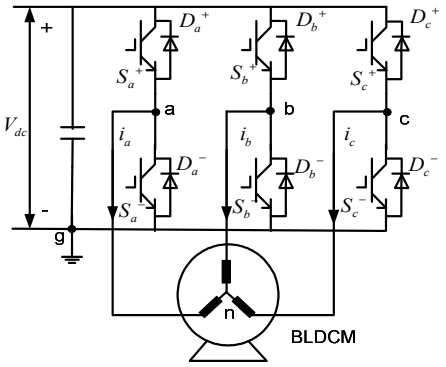

Fig.2 The structure chart of the three-phase cascaded voltage source inverter-brushless direct current motor load

Fig.3 is the waveform figure of phase A bridge arm driving signal and the output voltage, among them (Ⅰ), (Ⅱ) is the ideal switch tube drive signal, (Ⅲ), (Ⅳ) is the actual driving signal after pass the dead zone setting circuit, (Ⅴ) is the ideal output voltage of phase A, (Ⅵ) (Ⅶ) is the actual output voltage in different current polarity. The shaded part is the time of dead zone of the two switch tube of phase A bridge arm both shut off, During this time the output voltage depends on the direction of the winding current; When the winding current is positive, winding current through the diode D_a^- freewheeling, at this time the voltage of phase A is zero. When the winding current is negative, winding current through the diode D_a^+ freewheeling, at this time the voltage of phase A is V_{dc}.

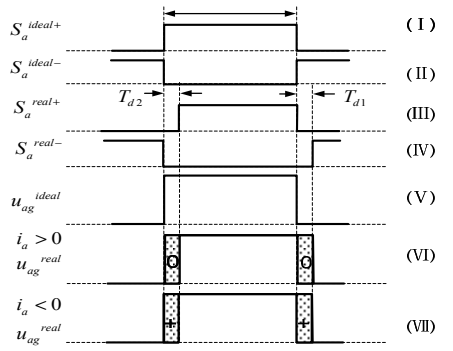

Fig.3 The waveform figure of phase A bridge arm driving signal and the output voltage

We can see from Fig.3: when the phase current is greater than zero, the actual output voltage of bridge arm is equal to the switch tube opening time width of the upper bridge arm; when the current is less than zero, equal to the switch tube cut-off time width of the lower bridge arm. In a PWM cycle, the average voltage error caused by the dead zone is:

$$\Delta u_{ag} = \begin{cases} \frac{T_{d2}}{T_s} V_{dc} & , \quad i_a > 0 \\ -\frac{T_{d1}}{T_s} V_{dc} & , \quad i_a < 0 \end{cases}$$

Where: T_s is the PWM cycle; V_{dc} is the voltage of Dc bus.

Formula (1) analyzed the effect of dead zone setting circuit on the output voltage when the two switch tubes in the same bridge arm are switching. However, as the duty ratio tend to 1, the ideal PWM signal pulse width of lower bridge arm will be more and more narrow , when the pulse width less than the dead zone width pulse loss occurs[8] and constant for the low level.

The pulse will miss and become low level, when pulse width less than dead zone width. The same, the driving signal of upper bridge arm switch tube will miss pulse, when the duty ratio is tend to 0. Fig.4 is the process of pulse missing.

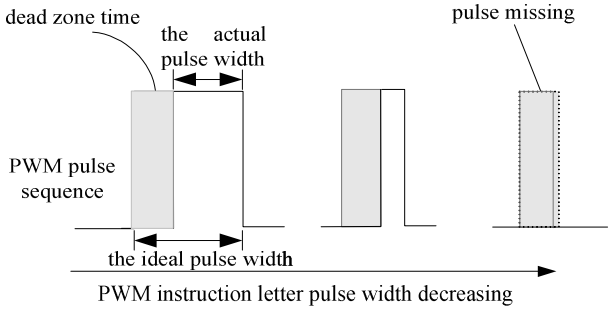

Fig.4 The process of pulse missing

The condition of pulse missing phenomenon occurs:

$$\rho < \rho_{d2} \quad \text{or} \quad \rho > 1 - \rho_{d1}$$

Where: ρ is the duty ratio of ideal driving signal; $\rho_{d1} = T_{d1}/T_s$; $\rho_{d2} = T_{d2}/T_s$.

When the pulse missed, only one of the two switch tubes of the same phase bridge arm is in a state of PWM modulation all the way, the other constant shut off, the system works in single polarity mode. At this time one way's output signal of the dead zone setting is low level all the way, thus making the other way's input signal is not affected by dead zone setting circuit. Voltage error caused by the dead zone is:

When winding current is $i_a > 0$, voltage error is:

$$\Delta u_{ag} = \begin{cases} \rho \cdot V_{dc} , \rho < \rho_{d2} \\ 0 \quad , \rho > 1 - \rho_{d1} \end{cases} \tag{3}$$

When winding current is $i_a < 0$, voltage error is:

$$\Delta u_{ag} = \begin{cases} 0 \quad , \rho < \rho_{d2} \\ (\rho - 1) \cdot V_{dc} , \rho > 1 - \rho_{d1} \end{cases} \tag{4}$$

In a PWM cycle, output voltage of phase A is:

$$u_{ag} = u_{ag}^{ideal} - \Delta u_{ag} \tag{5}$$

When the current is $i_a > 0$, output voltage of phase A is:

$$u_{ag}^{+} = \begin{cases} 0 \quad , \quad \rho < \rho_{d2} \\ (\rho - \rho_{d2}) \cdot V_{dc} , \rho_{d2} < \rho < 1 - \rho_{d1} \\ \rho \cdot V_{dc} \quad , \quad \rho > 1 - \rho_{d1} \end{cases} \tag{6}$$

We can see from formula (6) phase voltage jump when the duty ratio is near $1 - \rho_{d1}$. That's because the driving signal pulse width is T_{d2} smaller than the ideal driving signal, when the duty ratio is slightly less than $1 - \rho_{d1}$, and equals to each other, when the duty ratio slightly bigger than

$1-\rho_{d1}$,after the PWM signal pass the dead zone setting circuit. So pulse width of switch tube driving signal jump caused output voltage jump.

When current is $i_a < 0$, the output voltage of phase A is:

$$u_{ag}^{-} = \begin{cases} \rho \cdot V_{dc} & ,\rho < \rho_{d2} \\ (\rho + \rho_{d1}) \cdot V_{dc} & ,\rho_{d2} < \rho < 1-\rho_{d1} \\ V_{dc} & ,\rho > 1-\rho_{d1} \end{cases} \quad (7)$$

Obviously, output voltage jump when the duty ratio is ρ_{d2}.

3 The method of eliminating voltage jump

The dead zone setting circuit shown in Fig.1 is the use of the output signal to trigger the monostable trigger to generate the dead zone. Thus lead to the pulse width of switch tube driving signal jump when the pulse is missing.

The improved dead zone setting circuit shown in the Fig.5 below, adopted the ideal PWM signal to trigger the monostable trigger, so throughout the duty ratio interval monostable trigger H, L will be triggered, eliminated the phenomena that the pulse width switch tube driving signal jump when pulse missing in the original dead zone setting circuit.

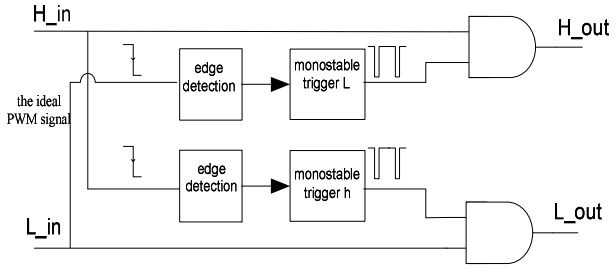

Fig.5 The improved dead zone setting circuit

4 Simulation of the improved dead zone setting circuit

Using matlab software to the dead zone setting circuit of brushless DC motor driving system establish simulation model，compare and analyze the effect of dead zone setting circuit before and after improved on system duty ratio-speed characteristics of the system. The parameters of brushless DC motor are: the resistance of stator phase is $R_s = 0.7\Omega$, the inductance of stator phase is $L = 0.5mH$, the moment of inertia is $J = 0.001kg \cdot m^2$, number of pole-pairs is $P = 2$, the width of monostable trigger H and L output low level is $T_{d1} = 5us$ and $T_{d2} = 4us$. The frequency of PWM is 20KHz.

Fig.6 is the change situation of output pulse width of dead zone setting circuit before and after the improved in the vicinity of duty ratio $\rho = 1-\rho_{d1}$. We can see that the output pulse width of the circuit jump will not occur.

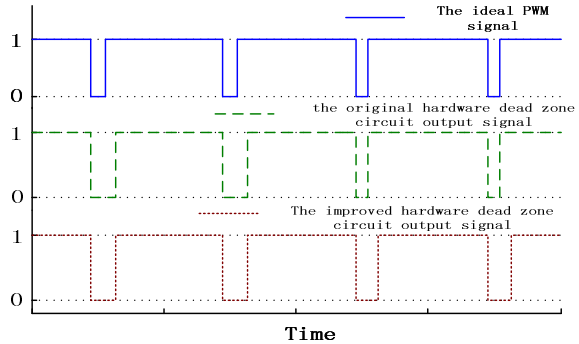

Fig.6 The switch tube PWM signal of upper bridge

Fig.7 is the simulation curve of system speed-duty ratio output characteristic, when the motor in a state of positive electric, the load torque is 0.1Nm and the dead zone setting circuit is different.

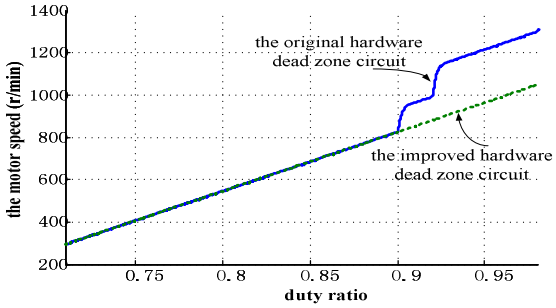

Fig.7 The duty ratio-speed curve of system before and after improved

From the simulation we can see that the original dead zone setting circuit, pulse width of switch tube driving signal will change in the vicinity of a specific duty ratio, thereby causing the jump of the average output voltage, thus affect the output characteristic of the system. And with the improved dead zone setting circuit, pulse width of switch tube driving signal will not jump, eliminated the voltage jump in the vicinity of a specific duty ratio, the motor speed smooth changed with the duty ratio.

5 conclusion

This paper analyzed the output voltage jump problem caused by a hardware dead zone setting mode, obtained the root cause of output voltage jump is the jump output pulse width in dead zone setting circuit when the pulse is missing. In speed control system of electric vehicle motor, the voltage of the motor winding jump in the vicinity of a duty ratio will cause the instability of the system operation, in order to guarantee the controllability of system in full range speed, the output voltage jump must eliminated. The dead zone setting circuit designed in this paper, using the PWM input signal to trigger the monostable trigger instead of the original dead zone using the output signal to trigger the monostable trigger circuit, the jump of the output pulse width in the dead zone setting circuit can eliminated, the problem of the voltage jump was solved.

Keywords: Wireless sensor network; Energy saving; Routing

Abstract. The optimal energy saving routing algorithm proposed in this paper is based on the shortest path tree. This algorithm introduces the concept of node classification and builds the weight function based on link energy consumption factor, neighbor node's residual energy factor and type weight and so on. It uses different weight factor according to different types of nodes, and finally generates the shortest path tree, all nodes send data to sink node along the shortest path tree. The simulation results show that the algorithm can prolong the network life time, balance energy consumption of each node, and reduce the average network delay**.**

Introduction

All nodes in wireless sensor network is powered by batteries, nodes have severe energy constraints [1-3]. Battery is hard to be replaced, once the node's energy is depletion, the node will be failure, it would affect the network operation, and even lead to split network and shorten the network lifetime. So every algorithm of wireless sensor network should consider saving energy, and try to prolong the lifetime of the whole network [4-5], so as to save the huge cost of deploying the wireless sensor network again.

There have many methods to prolong the lifetime of network; it must consider reducing and balancing the node's energy consumption. PEDAP_PA and PEDAP algorithm are two routing algorithm based on the minimum weight tree [6]. They defines the weight function based on link energy consumption, and build the minimum weight tree through the prim algorithm, in the end, all nodes send the data to sink node along the minimum weight tree. LET (Least Energy Tree) algorithm is proposed in reference [7], which use Dijkstra algorithm to construct the shortest path tree with minimum energy consumption from each node to the sink node, in the end, all nodes send the data to the sink node along the shortest path tree. LET algorithm is better than PEDAP and PEDAP_PA algorithm, because LET algorithm use Dijkstra algorithm to build the shortest path tree with the root of sink node. But the weight function of LET algorithm has one drawback, which ignores the residual energy of nodes. Some hub nodes are often near the sink node, if it only considers the weight function of link communication energy consumption, it is easy to cause these nodes forward too much data, and are death early for consuming energy. The Ratio_w algorithm (ratio weight routing algorithm) and Sum_w algorithm (sum weight routing algorithm) are proposed on LET algorithm, but these two kinds of algorithm don't consider the residual energy of neighbor node, the network's lifetime is also not optimal. So combining the advantages and disadvantages of above algorithm, we put forward the optimal routing algorithm based on shortest path tree (OLRA), which can prolong the lifetime of network better.

System Energy Consumption Model

In the proposed routing algorithm, it assumes that: (1) the position of all sensor nodes and sink node is fixed or slow changing, they will not affect the position and topology between nodes, and sink node has the entire network's topology information; (2) all sensor nodes have the same properties (such as initial energy, maximum sending power, the node energy consumption parameters, maximum communication radius, etc.); (3) the sending power of all sensor nodes may changes according to the communication distance; (4) each sensor node's energy is limited, but the

energy of sink node is no limited; (5) All sensor nodes in the network need to perceive and send data, so it is responsible for data collection and relay task at the same time, and send the data to the sink node by ways of direct or multiple hops.

Typical wireless sensor node's energy consumption is mainly produced by the wireless data transceiver. The energy consumption ETx of the nodes sending module is composed by the sending electronics' energy consumption and the signal amplifier circuit's electronic energy consumption. The energy consumption ERx of the receiving module only consider the electronic circuit energy consumption of receiving signal.

Among them, the energy consumption of electronic circuit is fixed as gEelec, g is the amount of sending or receiving data, Eelec is circuit electronic energy consumption of transmitting unit bits of data. Signal amplifier's electronic energy consumption is associated with node's sending power. It assumes that the nodes adjust the sending power according to communication distance, so it is related to the communication distance. The specific calculation formula is as follows:

$$E_{Tx}(g,d_{ij})=\begin{cases} gE_{elec}+g\varepsilon_{fs}d_{ij}^2, d_{ij}^2 < d_{\max} \\ 0, d_{ij} \geq d_{\max} \end{cases} \quad (1)$$

$$E_{Rx}(g)=gE_{elec} \quad (2)$$

dij is the sending distance, dmax is the maximum communication distance, εfs is electrical energy consumption which is required for amplify unit bits signal. According to formula (1) and (2), we can know that the energy consumption of transmitting gigabytes data between sensor node i and node j is computed as following formation:

$$C_{ij}(g,d_{ij})=2\times E_{elec}\times g+\varepsilon_{fs}\times g\times d_{ij}^2 \quad (3)$$

The energy consumption of transmitting gigabytes data between sensor node i and sink node is

$$C_{is}(g,d_{is})=E_{elec}\times g+\varepsilon_{fs}\times g\times d_{is}^2 \quad (4).$$

Implementation of Algorithm

In the weight function, the weight factor of different types of node's residual energy is not the same, which is described as follows: (1) standard node: if the node's residual energy value is larger than Ewarning, then it is the standard node. It is prefer to choose these nodes in the network to involve in forwarding data. The link weight value around the standard node ignores the type weight factor. (2) Warning node: if the node's residual energy is less than Ewarning, then the node is warning node. It avoid this type of node when transmit data. Now the link weight value around the warning node must consider the type weight factor, and improve the link weight value.

Assume the initial energy of node is Einital, Einital is set as following:

$$E_{warning}=E_{inital}/\delta f(x) \quad (5)$$

The specific normal number δ is to determine the value of Ewarning, x is the network parameter, f(x) is defined as following:

$$f(x)=\begin{cases} 1, x=1 \\ |(V|\bullet x)/(|V|-x). 2\leq x\leq |V| \end{cases} \quad (6)$$

|V| is the total number of nodes in the network, the initial value of x is 1, its specific calculation method is as follows: statistical the number of node whose residual energy value is lower than current Ewarning value and the proportion Yc of the warning node in the whole network. Set a threshold Ys (0< Ys <1), if Yc >Ys, then x=x+1, update the value of Ewarning. From the formula (6), we can see that f(x) is an increasing function, when x is approaching to |V|, f(x) is infinity.

So we can infer that when x is increased, Ewarning is decreased, and when Ewarning is decreased to a certain value, some warning nodes become back into the standard nodes, and continue to participate in data routing. When x is approaching to |V|, Ewarning is close to zero, the node whose value is below Ewarning is considered as the failure node which is running out of energy. The diminishing rule of Ewarning conforms to the actual situation of the sensor node energy,

in the begin, node's energy is more sufficient, The decreasing speed Ewarning is relatively fast, but when the node's energy is generally low, The decreasing amplitude of Ewarning is slower.

Considering the residual energy of node and its neighbor nodes, it introduces the node classification concept, and establishes new link weight function, OLRA algorithm is proposed. Re(i) is the node's residual energy, Re(j) is the residual energy of node j, wij is the weight value of link(i,j), Cij(g,d) is the energy consumption of transmitting gigabytes data between sensor node i and node j, dij is the distance between node i and node j. In OLRA algorithm,

$$w_{ij} = [C_{ij}(g,d)]^{\alpha}[\frac{1}{\mathrm{Re}(i)}]^{\theta \bullet \eta_j}[\frac{1}{\mathrm{Re})j)}]^{\beta \bullet \eta_i} \quad (7)$$
