The high prevalence and health implications of FMR-1 mutations point to the potential public health benefits of population screening for these mutations. Population screening (prenatal or preconception) could lead to accurate identification of fetuses affected by the full mutation and could provide a cost-effective means of preventing mental retardation.^{76–78} However, this would require more genetic counseling resources than are currently available, to educate and help families to interpret results that indicate premutation or full mutation carrier status. In addition, arguments for newborn screening for fragile X syndrome have been made on the grounds that early identification will allow earlier access to therapies to improve cognitive and behavioral outcomes.⁷⁹ However, further research and consensus is needed regarding the ethical and economic aspects of broad population-based screening for fragile X mutations. In contrast to population screening, considerable consensus has been achieved regarding the benefits of screening or testing for fragile X mutations in targeted patient populations: those with a family history of fragile X syndrome or mental retardation of unknown etiology; offspring of known carriers of a premutation; children with developmental delays of unknown etiology including autism spectrum disorders; women with premature ovarian failure of unknown etiology; and adults ages 50 and older with onset of intention tremor and ataxia of unknown etiology.^{67,80}

The full spectrum of X-linked mental retardation may involve many distinct pathogenic mechanisms. Studies suggest that over 100 different X-linked learning disorders may exist,⁸¹ although most are

rare and have been observed only in studies of single families. Because many X-linked learning disorders are not associated with additional phenotypic features (i.e., are nonsyndromic) and can only be identified by genetic mapping, the full extent and diversity of X-linked mental retardation will be determined only with genetic screening of all affected individuals.

Autosomal Genetic Causes

Autosomally inherited disorders are rare but important causes of mental retardation. Autosomal dominant disorders causing cognitive disability in childhood include tuberous sclerosis and neurofibromatosis. The more common mode of transmission is through autosomal recessives. A number of metabolic disorders transmitted in this fashion, including phenylketonuria, are marked by progressive mental retardation with systemic manifestations.

Phenylketonuria

This rare defect of amino acid metabolism occurs in 1 in 12,000 to 15,000 Caucasian live births, with somewhat lower rates in other races. Deficient metabolism of phenylalanine causes it to accumulate, which when untreated leads to hyperphenylalaninemia that damages the developing brain, and in most cases results in severe mental retardation.⁸² Newborn screening based on analysis of newborn blood permits early treatment by a special diet that diminishes phenylalanine levels. The diet must be continued at least through puberty to protect brain development in persons with PKU. In countries with routine neonatal screening programs and effective follow-up of affected children, primary PKU mental retardation is now rarely seen.

A problem resulting from the success of neonatal screening programs for PKU is the emergence of “maternal PKU” affecting offspring of women successfully treated in childhood.⁸³ Themselves of normal or near normal intelligence, at childbearing age these women will often have high blood levels of phenylalanine unless their dietary intake of phenylalanine is strictly controlled. Their surviving offspring are at increased risk of mental retardation, microcephaly, congenital heart disease, intrauterine growth retardation, and behavioral problems.^{84–86} Mental retardation is observed in as many as 50% of children of mothers with uncontrolled PKU (defined as blood phenylalanine level of more than 600 $\mu\text{mol/L}$) throughout most or all of their pregnancies.⁸⁷ The most favorable outcomes are observed in women whose dietary restrictions to reduce maternal blood phenylalanine levels and prevent phenylalanine metabolite accumulation are started before conception and maintained throughout pregnancy.⁸⁸ Routine umbilical cord blood screening, while it cannot prevent cases, can detect women with hyperphenylalaninemia and thus prevent recurrence in future pregnancies. From a public health perspective, the problem is to identify and locate the population of women at risk prior to their first pregnancies.⁸⁹ The experience of the New England Maternal PKU Project suggests that the majority of women with classic PKU can be found, but a much lower proportion of those with atypical hyperphenylalaninemia are likely to be identified in time to permit primary prevention in their first-born children.⁸⁹

Because newborn screening for PKU succeeded in preventing one cause of mental retardation, newborn screening programs in developed countries expanded late in the twentieth century to include other conditions for which identifying and intervening during the newborn period can prevent neurologic damage, such as congenital hypothyroidism, galactosemia, and maple sugar urine disease. In contrast, developing countries for the most part have not yet implemented newborn screening programs, though studies showed that newborn screening and intervention as a strategy for preventing learning and developmental disabilities in low income countries would be highly cost effective.⁴³ Recent advances in the technology for newborn screening, specifically the development of tandem mass spectrometry, make it possible to screen newborns for more than 30 metabolic conditions using a single blood spot. However, most of these conditions are extremely rare and the benefits of early identification and treatment are not yet established.⁹⁰

Nutritional Causes

Iodine Deficiency

Cretinism is a form of mental retardation resulting from hypothyroidism and typically is complicated by hearing loss, motor impairment, and abnormal growth and physical development. Sporadic congenital hypothyroidism occurs in about 1 in 3500 births. Newborn screening programs currently in operation throughout the developed world permit early detection and treatment of this condition, which in turn, prevent the brain damage that causes sporadic cretinism.

A far more common cause of cretinism in some populations occurs prenatally due to maternal hypothyroidism associated with dietary deficiency of iodine. Iodine deficiency, defined for adults as an average daily iodine intake of less than 100 µg, is endemic in large populations throughout the world, particularly in mountainous areas and interior regions where iodine has been leached from the soil.⁹¹ Some estimates suggest that nearly 1 billion people worldwide are at risk for iodine deficiency disorders.⁹² In addition to endemic cretinism, which affects an estimated 3.2 million people and is a leading cause of mental retardation worldwide, the spectrum of iodine disorders includes spontaneous abortion, stillbirth, infant mortality, goiter, and impaired cognitive functioning (apart from that associated with frank cretinism).⁹³

Prevention of iodine deficiency and endemic cretinism is achieved in many developed countries by fortifying dietary salt at a level of 1 part of iodide per 10,000–50,000 parts salt, and is being promoted worldwide by the World Health Organization as a cost-effective method for preventing mental retardation.^{93,94} In nonindustrialized communities, where the distribution of iodinated salt often proves infeasible, endemic cretinism can be prevented by annually giving women of childbearing age high doses of iodine in an oil solution, taken either orally or by intramuscular injection.⁹³ Effective prevention of prenatally acquired cretinism requires that maternal iodine deficiency and hypothyroidism be corrected very early in pregnancy or preferably before conception. Considerable international pressure is now being exerted against the problem of iodine deficiency; and ongoing efforts will be needed to bring about full prevention of this important cause of mental retardation.

Folate Deficiency

Neural tube defects including spina bifida are one of the most common and most disabling birth defects worldwide. Prevalence at birth varies geographically and over time, from less than 1 to more than 6 per 1000 live births, with peaks among the poorest classes and during times of famine and economic strife. Among children born with spina bifida in the developed world, approximately 75% survive past infancy. Hydrocephalus is a regular accompaniment, usually treated with an intracranial shunt to preserve brain tissue and prevent mental retardation. A wide range of intellectual function is found among survivors; fewer than half have severe intellectual disability and many have normal levels of intelligence. Physical accompaniments, including limitations in mobility and in sphincter control, create major nursing problems. The pathogenesis of spina bifida, as in neural tube defects for which survival is rare (anencephalus, encephalocele, iniencephaly), apparently involves failure of the embryonic neural tube to fuse completely, a process that should be completed by the 20th postconceptional day.

Epidemiologic studies demonstrated conclusively that preconceptional and periconceptional maternal folate consumption influences the incidence and prevalence of neural tube defects, an observation with enormous potential for primary prevention.⁹⁵ It remains likely that there still is a genetic influence, such that genetically predisposed mothers or offspring are sensitive to relatively mild deficiency, while a much larger percentage of the population are sensitive to severe deficiency. Current knowledge suggests that primary prevention of approximately 70% of neural tube defects in live births can be achieved if mothers take 4 mg of folic acid, a synthetic form of folate, preconception and periconception. Prevention of neural

tube defects therefore currently hinges on how, and no longer on whether, to deliver the necessary supplement. An unavoidable problem is that the folate or folic acid should be taken at a time that the woman will not usually know she is pregnant. One cost-effective strategy, similar to that used to prevent iodine deficiency, is to supply it to the whole population, for example in the bread flour.^{96,43} Foliates are present in the normal diet, in leafy vegetables, but whether dietary advice alone would result in consumption of sufficient amounts by those who need it is doubtful. Not all neural tube defects will disappear given preventive policies based on current knowledge, even though we can be confident that the incidence will decrease by at least half. Future research should clarify residual causes.

Prenatal screening for neural tube defects is now done routinely and with increasing accuracy in settings with advanced levels of prenatal care. Effective prenatal diagnosis involves screening maternal serum at 16 weeks gestation for elevated levels of α -fetoprotein (AFP) and following positive screening results with ultrasound anomaly scans to detect spinal abnormalities and/or amniocentesis to detect elevated AFP levels in amniotic fluid.⁹⁷ Some difficulties persist with the procedure, apart from the hazards associated with amniocentesis. Even in the most experienced laboratories, the procedure is not entirely specific: other conditions raise AFP levels, and sometimes even with very high levels the fetus is apparently normal. Testing of AFP is also not entirely sensitive; affected fetuses, especially those with closed spina bifida but occasionally other types too, may not be detected. When a positive diagnosis is made, prevention involves therapeutic abortion. This course may be less acceptable than in Down's syndrome because the risk of a false-positive result (and the consequent termination of a normal pregnancy) is much higher (up to 3% or more depending on cutoff levels and gestational age).⁹⁷ Both prenatal detection of neural tube defects and folic acid fortification of the food supply have contributed to steady reductions in the prevalence of neural tube defects in live births in populations where they are provided, but their availability on a global scale remains very limited.^{98–100,43}

Premature Birth

Infants born prematurely and at very low birth weight (less than 1500 g) are surviving with increased frequency due to advances in perinatology and neonatal medicine. Survivors of very low birth weight carry a high risk of mental retardation as well as cerebral palsy (especially spastic diplegia), epilepsy, and vision and hearing impairments. Increases in the prevalence of cerebral palsy have been observed in several developed countries since the 1970s and may be attributable to concomitant improvements in the survival of very preterm infants.¹⁰¹ The impact of this trend on the prevalence of mental retardation per se is not clear, though follow-up studies of very low birth weight infants are consistent in showing an inverse association between gestational age at birth and the risk of cognitive disability in childhood.^{102,103} Although prematurity is an important risk factor for mental retardation, up to 75% of survivors of even very preterm birth (e.g., less than 33 weeks gestation) exhibit a normal course of development and functioning in childhood.¹⁰⁴

One factor that is strongly predictive of which premature infants will have poor developmental outcomes is the occurrence of white matter lesions observable neonatally on cranial ultrasound scans.^{105–108} Further study is needed to determine the etiology of brain lesions associated with preterm birth and specific mechanisms for the variability in neurodevelopmental outcomes, as well as the potential for interventions to prevent neurologic damage and improve outcomes.

Infections

At least 20 different infectious agents can cause brain damage and mental deficiency in children. Congenital syphilis, the first congenital disorder to be linked to an infectious cause, is now a rare and preventable cause of mental retardation. Rubella, like syphilis, is a fetal infection. It affects the fetus only if the mother contracts the disease

between the 8th and 13th weeks of pregnancy. It has been virtually eliminated as a cause of mental retardation in vaccinated populations. Brain damage from other intrauterine infections (toxoplasmosis, cytomegalovirus, varicella) may follow either prenatal or perinatal transmission. When exposure occurs during the first or second trimester of pregnancy, several impairments are recognizable at birth and may include microcephaly, hydrocephaly, growth retardation, cataracts, seizures, rashes, jaundice, and hepatosplenomegaly.¹⁰⁹ Exposure late in pregnancy or during delivery may result in inapparent infection at birth and onset of developmental delay during infancy or childhood. Inapparent toxoplasmosis infection at birth, for example, is reported to cause neurodevelopmental disabilities in 80–90% of cases by age 20 years.^{110–113} Evidence has also been reported that untreated maternal urinary track infections, a common medical complication affecting 4–7% of pregnancies, is a risk factor for mental retardation in offspring.¹¹⁴

Postnatally acquired meningitis and encephalitis associated with a variety of infectious agents also leave a proportion of children with permanent cognitive disability, particularly in less developed countries where access to vaccination and treatment is more limited and often delayed.¹¹⁵ Adverse reactions to the pertussis vaccine causes encephalitis and residual mental retardation in children, but the risk is likely to be lower than the risk of death from pertussis infection in unvaccinated populations.^{116,117}

The effects of mother-to-child transmitted HIV infection on the neurodevelopment of the child are devastating and can result in acquired microcephaly and cognitive and movement disabilities.¹¹⁸ Fortunately, antiretroviral treatment, especially when combined with Caesarian delivery, can prevent most cases of vertical HIV transmission and thus can potentially prevent HIV from causing cognitive disability in children.¹¹⁹

Environmental Toxins

Lead

Lead, absorbed from a variety of sources, has long been known to cause the serious and often fatal condition of *lead encephalopathy* in children. Survivors were regularly severely mentally retarded and could be found in populations and institutions housing retarded persons. In recent decades, neuropsychologic impairments of various kinds have been recognized even in children with moderately raised lead levels, well below levels that cause acute lead encephalopathy. Current evidence suggests a dose-response relation of lead exposure in early childhood to mental performance and perhaps also to hyperactivity. The United States government now considers levels higher than 10 µg/dL to be potentially neurotoxic and estimates that more than 17% of young children have levels in this range.¹²⁰

In many populations, socioeconomic status and iron deficiency are confounded with and may interact with lead poisoning in its effect on IQ. In the United States the effects are more marked on urban children living in poverty. Prevention is not simple but is certainly feasible and, in the long run, is likely to be cost-effective when balanced against reduced health costs and improved school performance and quality of work.^{121–123} What is required is control of industrial processes, removal of lead from gasoline and paint, maintaining low lead levels in soil, monitoring residences (many houses still have the remains of lead paint, within and without), screening young children, and possibly, environmental lead abatement. For those with raised lead levels, removal from the source of exposure and possibly chelation treatment to increase the level of excretion are indicated.

Alcohol

Heavy alcohol abuse during pregnancy is associated with *fetal alcohol syndrome* in offspring. This syndrome includes mild to moderate cognitive disability, low birth weight, microcephaly, stunting, flattened nasolabial facies, and narrow palpebral tissues. Studies in the United States have found the prevalence of fetal alcohol syndrome to range from 2.8 to 4.6 per 1000 live births.¹²⁴ A frequency at birth of

1.7 per 1000 was observed in Gothenburg, Sweden,¹²⁵ a population in which nearly 10% of the cases of mild mental retardation in school children was attributed to this cause.¹²⁶ Recently, studies have reported the prevalence of fetal alcohol syndrome to be as high as 2–7% in selected populations.^{127,128} Prevention is easier to prescribe than to execute. In view of evidence that alcohol consumption during pregnancy is associated with a variety of adverse fetal outcomes other than mental retardation, abstinence or restricted drinking during pregnancy has become a worthwhile public health objective. However, surveillance data from the United States in 2002 indicated that 10% of pregnant women had consumed alcohol during pregnancy and approximately 2% had engaged in binge drinking or frequent alcohol use.¹²⁹

Trauma

Traumatic brain injury is an important preventable cause of intellectual deficiency.¹³⁰ The annual incidence of head injury (with loss of consciousness) in the United States is about 2.3 per 1000 in children under 15 years and increases to 60 per 1000 among 15- to 19-year-old boys.¹³¹ The major causes are motor vehicle collisions, falls, and assaults. Throughout childhood, boys have a twofold higher risk of severe head injury relative to girls. It has been estimated that 5–10% of all cases are fatal and that another 5–10% result in a wide range of neuropsychologic sequelae.¹³² Permanent declines in IQ and adaptive function are observed in a proportion of cases,¹³³ but further longitudinal and intervention studies are needed to understand the predictors and prevention of these outcomes.

► PREVENTION

Clearly, mental retardation has many causes. Preventive strategies must focus on each in turn. Sometimes, as with prenatal screening, there are exemplary preventive programs, which can be applied wherever the administrative and economic structure can support them. Programs involving prenatal diagnosis followed by selective abortion or gene therapies call for a high level of organization; for some, they will also involve a conflict of values. Programs that require intensifying education for many children over a prolonged period call for a major allocation of funds and human resources.

Twelve recommendations for prevention have been compiled by the Joint Commission of the International Association for the Scientific Study of Mental Deficiency and the International League of Parents of Retarded Children and accepted by the World Health Organization:

1. Genetic counseling, prenatal diagnosis, early identification, and proper treatment are important in preventing mental retardation of genetic origin.
2. Prevention of infections and parasitic diseases contributes significantly to the prevention of mental retardation.
3. Monitoring the environment to protect against pollutants and other chemical and physical hazards is an important part of prevention programs.
4. Safe environments for young children and the prompt treatment of injuries should reduce accidental causes of mental retardation.
5. The nutrition of mothers and children is important, especially in developing countries.
6. Good obstetrics and good care of the newborn reduce the incidence of mental and physical handicap. Good care includes adequate treatment of maternal illness, such as diabetes or toxemia; prompt recognition of obstetrical abnormalities; adequate monitoring of the fetus; immediate resuscitation of the infant; and prediction, prevention, and treatment of biochemical disorders, such as respiratory distress syndrome, hypoglycemia, anoxia, and all causes of cerebral damage.
7. Social and educational stimulation is essential for proper mental growth and development. It is an important element in preventing mental retardation, especially mild mental

retardation. Suitable interventions are needed for children whose families do not provide this stimulation.

8. In more severely retarded persons, proper stimulation, modern principles of rehabilitation, and good remedial service can also reduce disability and prevent the development of secondary handicaps.
9. Improving living standards and the general health of the population constitutes an important element of nonspecific prevention of mental retardation. Preventive programs for mental retardation should be an integral part of all general health planning and programs.
10. The patterns of preventive programs and the speed with which they are implemented will vary according to resources, but high priority should be given to the problem in all countries.
11. International cooperation on many levels is necessary to speed up the development of effective preventive measures.
12. Research into the causes of mental retardation should be encouraged and facilitated. The effectiveness of preventive measures should be tested and monitored continuously. Special attention should be given to evaluative research in the biomedical and psychosocial spheres.

► CARE: COMMUNITY SERVICES FOR MENTAL RETARDATION

Many mentally retarded persons achieve considerable self-reliance with maturity and training, so that the deficit even when severe is seen as relative rather than absolute. The early years are often those for which the family of birth provides basic care and support, while for the later years the community does this increasingly. A family with a mentally retarded child experiences major impacts. There is shock and pain, when the diagnosis is imparted, and a time of emotional turbulence and readjustment to a new kind of parental role often follows. The turbulence is often compounded by concern about effects on other family members, especially siblings; painful embarrassment before friends, neighbors, and strangers; and economic strain. The strain is not limited to the early years. A mentally retarded person may remain emotionally and physically dependent on parents long after the departure of other children. With improved medical care and increasing longevity of persons with severe mental retardation, dependence may continue into a phase when parents lack the physical, psychological, and economic resources to provide adequate care.

For some families, residential placement of the child at an early age is the most suitable arrangement. For many others, the family home is preferred. Whichever course is followed, cooperative arrangements between a family and appropriate community services work best. The types of services needed change over the course of the individual's life. In adulthood, there is often a continued need for sheltered living, work, and recreational services. Families play an important role in planning transitions in services, recognizing that the rights of retarded people, who may be limited in arguing their own case, need special protection. Increasingly, persons with mental retardation themselves are being consulted.

► CONCLUSION

Today, the field of mental retardation involves public health in some of the most critical issues facing society. The selected issues touched on here are intended to serve as an introduction to the potential role of public health. Societal forces will shape future public health views and actions, as they have in the past. Scientific and technologic advances bring new opportunities for prevention and change in the balance between incidence and prevalence. In these emerging circumstances, the choices societies make among the forms of prevention and care can have profound effects.

Prevention of Disability in Older Persons

William H. Barker

Increased risk of disease, disability, and death are well-known accompaniments of old age. While disease incidence and death are the conventional indices of a society's health status, functional disability is perhaps the most consequential index when dealing with health in old age. This chapter defines the character and magnitude of disability in old age, reviews preventive and restorative approaches to specific and general causes of disability among the elderly, and examines the role of health-care organizations in facilitating the delivery of such services.

► DIMENSIONS OF THE PROBLEM

Concept and Measurement of Disability

Conceptually disability has been classified by the World Health Organization as part of a continuum of stages of disease impact that include:¹

Impairment. The loss or abnormality of psychological, physiological, or anatomical integrity at the level of specific organ systems.

Disability. The inability to perform an activity within the range considered normal for a human being, hence a functional limitation experienced at the level of the person as a whole.

Handicap. A disadvantage resulting from an impairment or disability which if not addressed, limits an individual's ability to fulfill certain desired social roles.

Collectively this continuum has been referred to as the "disablement model." Figure 71-1 depicts the conditions, which characterize dysfunction at each of the three stages of the model, and the types of functional assessment and medical, restorative, and social intervention appropriate to maintaining and improving function and limiting disability at each stage.

A wide variety of systems have been developed for measuring functional ability/disability.² The best-known of these are the Activities of Daily Living (ADL) and the Instrumental Activities of Daily Living (IADL) indices. The ADL index, first introduced by Katz and colleagues, classifies limitations in six fundamental, sociobiological functions of daily living: bathing, dressing, toileting, transferring from bed or chair, continence, and feeding.³ Lawton and others broadened the scope with the IADL concept which incorporates measures of more complex adaptive or self-maintaining functions such as housekeeping, money management, and grocery shopping.⁴ In addition to screening and care planning for individual patients, these measurement systems have been very useful for describing the disability status of the elderly population, estimating community and

institutional service needs, and evaluating outcomes of interventions designed to limit disability.

The emerging concept of "preclinical disability" focuses on identifying stages in the natural history of functional loss, which precede the onset of overt ADL or IADL dependencies. This phenomenon was originally measured in terms of adaptive modifications in the performance of common tasks such as doing housework or getting out of bed.⁵ Physiologic and performance measures of lower extremity function have also been shown to be powerful predictors of future onset of frank disability.⁶ More recently investigators have focused on a complex of physiologic deteriorations characterized as "frailty" which identifies older persons at high risk of decline in functional status. "Frailty" has been defined operationally as having at least three of the following attributes: unexplained weight loss, poor grip strength, self-reported exhaustion, slow walking speed, low physical activity.⁷

Magnitude of Aging and Disability

The aging or *graying* of populations is occurring in all parts of the world, most profoundly in developed areas, as illustrated in estimates compiled by the United Nations (Fig. 71-2). Driven by a combination of increasing average life expectancy and decreasing birthrates, this "longevity revolution" will result in ever-increasing numbers of persons over 80 years of age among whom functional disability is most prevalent.

The proportion of elderly Americans with disability living both in the community and in nursing homes at the end of the twentieth century has been estimated at approximately 20%. Among community dwelling disabled elderly, the most common ADL dependencies include bathing and transferring, while dependence on assistance with eating is least common. Shopping and meal preparation are the most common IADL dependencies. All domains of ADL and IADL limitation increase dramatically with age and are generally more prevalent in women than men.

There is a strong association between ADL limitation and the presence of chronic medical conditions. With few exceptions such as stroke and hip fracture, it has been difficult to establish direct cause and effect relationships between specific morbidities (diseases) or combinations of morbidities and the onset of disability. Nonetheless, it is reasonable to presume that a substantial amount of disability is attributable to physical and physiological impairments resulting from specific chronic diseases.^{8,9} In turn, the prevention of such impairments and consequent disability would be largely dependent on the success with which major chronic diseases are prevented or controlled using techniques reviewed in other chapters in this volume. A substantial amount of disability in old age may also be explained and

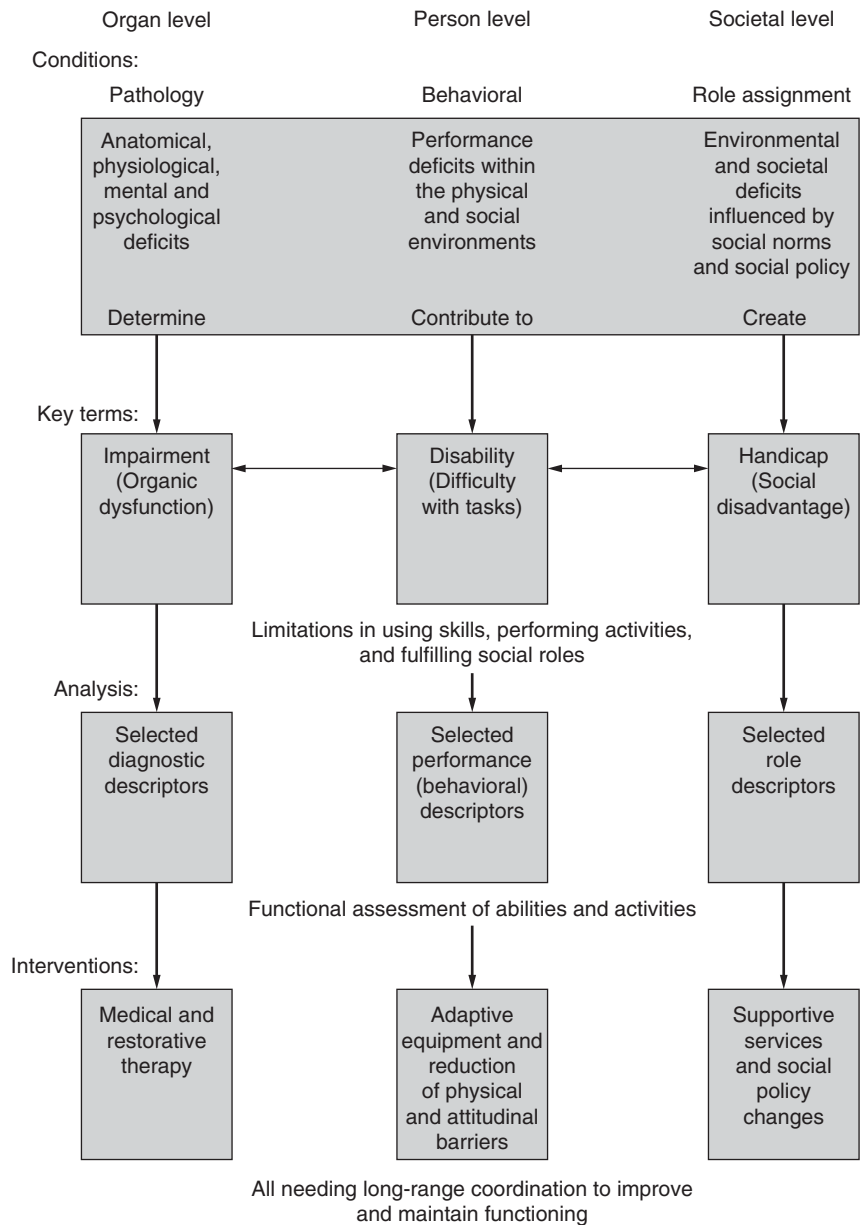

Figure 71-1. The functional approach to medical care and the disablement model.

potentially prevented by attention to lifestyle, physical, psychological, environmental, and social support factors, which increase the risk of functional decline among older persons.¹⁰ Comprehensive strategies of health promotion, multidisciplinary assessment and rehabilitation, and environmental adaptation constitute the armamentarium of preventive approaches to such factors.

A further dimension of the societal impact of disability in old age is the strong relationship between functional impairment and use of health services. A study from the Medicare Current Beneficiary Survey documented dramatic increase in the aggregate annual physician, pharmaceutical, hospital, and long-term care expenditures incurred by older persons making the transition to greater levels of functional dependency in a given year (Table 71-1).

Secular Trends

The phenomenon of increasing life expectancy in old age has given rise to a number of forecasts with respect to the burden of disability to be anticipated. At one extreme is Fries’s “compression of morbidity” thesis, which, with reference to Fig. 71-3, argues that age of onset of disabling chronic disease among the elderly is being postponed to a greater degree than life expectancy is expanding.¹¹ Under these

circumstances, age-specific prevalence and aggregate years of disability before death would be expected to diminish. At the other extreme is the “failure of success” thesis promulgated by Gruenberg¹² and others, which argues that increase in life expectancy among the elderly is largely the result of advances in life-sparing medical treatments of existing disease, which, with reference to Fig. 71-3, results in increase in the average duration of certain chronic disabling diseases. This phenomenon would result in expanded future need for chronic care services. Others have suggested that increased life expectancy reflects a combination of both of these phenomena, resulting in delayed age of onset of chronic disease and disability but not substantially reducing the overall health service burden.¹³

Various longitudinal population studies to empirically assess trends in the burden of disability among older persons are ongoing in the United States and elsewhere.¹⁴ Common to such studies is a quest to identify and quantify determinants of disability free aging, variably referred to as “active life expectancy”¹⁵ or “successful aging.”¹⁶ Among these, the National Long-Term Care Survey (NLTCs), a longitudinal study involving very large sequential cohorts of older Americans, first documented a decline of one to two percentage points in the prevalence of chronic disability between 1982 and 1989, translating into an estimated 540,000 fewer older persons with chronic disabilities

Figure 71-2. Percentage of population 80 years and over in different regions of the world. UN data and predictions 1950 to 2025. (Source: Davies AM. *Epidemiology and the challenge of aging*. In: Brody JA, Maddox GL, eds. *Epidemiology and Aging: An International Perspective*, New York; Springer; 1988.)

than would have been expected.¹⁷ Surveys conducted in 1994 and 1999 have documented further declining prevalence of disability, involving both the black and non-black population, for a net change from 26.2% in 1982 to 19.7% in 1999 (Table 71-2).

► HEALTH PROMOTION AND PREVENTION

In considering approaches to prevention of disability in the aging population, and indeed in the aging individual, it is useful to bear in mind several phenomena that are involved in the occurrence of disability. These include the contributions to disability attributable to biologic changes of aging, pathologic disease processes, and disuse

or deconditioning. Also important are the contributions to the prevention or reversal of disability attributable to health promotion, and therapeutic, rehabilitative, and environmental interventions.

Impairments and Losses

Old age is associated with increased occurrence of a wide array of physiological, physical, mental, and social impairments or losses, which may contribute independently or collectively to disabilities. These include elevated blood pressure, decreased immune response, reduced visual, auditory, and olfactory acuity, loss of muscle and bone mass, fragility of the skin, slowing of mental response, decreased cognitive ability, loss of spouses and companions, reduced income, and loss of social roles and of autonomy.

Some of these changes and their consequences, referred to as “senescence,” are intrinsic to the biology of aging. Examples include age-related decline in the individual’s maximum oxygen consumption (VO_2 max), a fundamental index of capacity for physical activity; decrease in muscle mass (sarcopenia); modifications of lens protein leading to cataract formation and loss of vision; decrease in bone density with resultant osteoporosis and heightened risk of fracture; and stiffening of arterial walls causing increased systolic blood pressure and risk of disabling cerebrovascular accident.

A growing body of evidence indicates that many physiological, physical, and mental changes as well as virtually all social changes associated with old age are not intrinsic to the aging process but are due to potentially modifiable extrinsic or self-induced factors.

Disuse/Deconditioning

The first level of preventable extrinsic factors in functional decline is discontinuation of usual activity referred to as “disuse” or “deconditioning.”¹⁸ This may occur insidiously as older persons withdraw from usual activities either voluntarily in response to a sense of “growing old” or involuntarily as a consequence of intercurrent acute illness, retirement from work, etc. The best studied model of global disuse/deconditioning, and one to which older persons are particularly prone on their own volition or their physician’s or family’s bidding, is extended bed rest. Going to bed for a prolonged period of time may lead to a litany of physiologic adaptations and potentially disabling consequences as listed in Table 71-3. Of particular concern because of their potential contribution to limitation of mobility and risk of falls and fractures are physiological and structural changes in muscle, bone, and joint tissues. Rate of decrease in muscle strength may be as high as 5% per day in the bedfast individual, with leg muscles tending to lose strength faster than arm muscles. Disuse osteoporosis results from both cessation of bone synthesis and increased resorption and tends to predominantly affect weight-bearing bones. Immobility and loss of weight-bearing forces on joints contribute to changes in both periarticular and articular tissue structure, which may lead to joint contractures.

Also contributing directly or indirectly to bed rest–induced disability are atelectasis and other pulmonary changes that predispose

TABLE 71-1. TOTAL HEALTH-CARE SPENDING (MEDICAL CARE AND FORMAL LONG-TERM CARE COSTS) ACCORDING TO LEVEL OF DEPENDENCY OVER 1 YEAR AND ESTIMATED ADDITIONAL COSTS OF CARE FOR PERSONS MAKING THE TRANSITION TO MORE DEPENDENT STATES: U.S. PERSONS AGED 66 YEARS AND OLDER, 1995

Baseline Status	Annual Per Persons Cost, \$, by Status After 1 Year				U.S. Estimates	
	No ADLs	≥1 ADL, No NH Use	NH Use	Difference	No. Making Transition	Total Additional Cost, \$ Billions
No ADLs	4771	18,025		13,254	939,520	12.45
No ADLs	4771		36,596	31,825	302,042	9.61
≥ 1 ADL in community		19,408	40,877	21,469	188,087	4.04
Totals					1,429,649	26.1

Note: ADLs = activities of daily living; ≥ 1 ADL = help received in 1 or more ADLs (eating, dressing, bathing, using the toilet, getting into and out of a chair); NH = nursing home. Source: Guralnik J, et al. Medical and long-term care costs when older persons become more dependent. *Am J Public Health*. 2002;92:1244–5.

Figure 71-3. Conceptual relationship between age and percentage of the population remaining free of the respective stages in the natural history of chronic disabling disease.

to pneumonia, slowing of peristalsis with resulting constipation, bladder emptying difficulties leading to urinary incontinence, sustained pressure on fragile skin predisposing to pressure sores, and sensory deprivation leading to an array of negative affective and cognitive effects.

Clearly an essential principle is to avoid taking to bed in old age, except as truly necessitated by medical problems. Instances of the latter should be minimized, with emphasis on progressive mobilization of bed-bound patients, first from bed to chair, then to ambulation with or without assistance. This should include purposeful activity such as ambulating to meals and dressing in normal clothing as opposed to institutional bed clothing.

Physical Activity

Regular physical exercise is perhaps the single most important health promotional activity for preventing many of the dysfunctional consequences of aging. Numerous studies have demonstrated that older persons, like their younger counterparts, can significantly increase physical fitness, as reflected in VO_2 max, by engaging in regular aerobic exercise. Furthermore there is clear experimental evidence involving older subjects that progressive resistance training can both retard and reverse losses of muscle mass and strength as well as bone density.^{19,20}

Several controlled trials have demonstrated improvements in gait speed, stair climbing, rising from a chair, and other significant physical tasks following participation in exercise programs conducted among frail nursing home residents.^{21,22}

TABLE 71-2. POPULATION DISTRIBUTION (AGE-STANDARDIZED TO 1999 OVER-65 POPULATION) OF DISABILITIES 1982-1999

	1982	1984	1989	1994	1999
Distribution by disability %					
Nondisabled	73.8	73.8	75.6	77.5	80.3

TABLE 71-3. COMPLICATIONS OF BEDREST

Cardiovascular	Decreased cardiac output, contributing to decreased aerobic capacity Orthostatic intolerance Venous thrombophlebitis
Respiratory	Atelectasis Relative hypoxemia Pneumonia
Musculoskeletal	Muscle atrophy and loss of strength Decreased muscle oxidative capacity, contributing to decreased aerobic capacity Bone loss (osteoporosis)
Gastrointestinal	Constipation
Genitourinary	Incontinence Renal calculi
Skin	Pressure sores
Functional	Impaired ambulation
Psychological	Sensory deprivation

Source: Harper CM, Lyles YM: Physiology and complications of bed rest. *J Am Geriatr Soc*. 1988;36:1047-54.

The application of such experimental observations to preventing disability is captured in the concept of “threshold levels” as follows:

Strength, aerobic power and other indices of physical ability change on continuous scales whereas functional and quality of life changes are quantal. Thus a very small strength gain may be accompanied by a considerable functional improvement if it takes the patient from being just unable to transfer independently to being just able to do so. This also applies in reverse: A gradual loss of strength may not be apparent until the patient is suddenly unable to perform a crucial function.²³

In spite of the demonstrated benefits of regular physical activity, the majority of older Americans live essentially sedentary lives, which prompted the Public Health Service in the late 1990s to set a national goal of reducing to less than 25% the proportion of persons over age 65 who engage in no leisure time physical activity. The Surgeon General’s recommendations call for 30 minutes a day of moderate activity which may consist of walking, gardening, cycling, swimming, and other and which must be sustained for benefits to accrue. There are a number of proven approaches that individuals, physicians, and communities may take to promote physical activity among older persons.²⁴

► **EARLY INTERVENTIONS AND REHABILITATION**

Despite the best efforts of primary and secondary prevention and health promotion, the majority of older persons will develop one or more potentially disabling medical conditions. Under these circumstances the goals of health care, where possible, will be early medical or surgical intervention, rehabilitation, or continuing supportive or palliative care to limit disability and provide for highest level of independence of individuals and their caregivers. Components of such tertiary prevention include both specific interventions for individual disabling conditions and provision of comprehensive geriatric medicine services.

► **SELECTED DISABLING CONDITIONS**

Falls and Fractures

Falls occur among some 20-30% of community dwelling elderly persons per year and an even greater percent of nursing home residents, with attendant risks of fracture, soft tissue injury, and psychological

compromise to independence. Risk of falling increases with the number and type of chronic disabling conditions present and medications being taken. Visual and proprioceptive abnormalities, musculoskeletal and neurological diseases, depression and dementia, and hypotension-inducing conditions (biologic and iatrogenic) are particularly important. A fall risk index has been successfully used to guide preventive interventions.²⁵ A variety of exercise and balance training programs have also been found to reduce incidence of falling.²⁶

To avoid certain secondary consequences of falls such as hypothermia or pressure sores from prolonged immobility, recurrent fallers should be provided with portable alarm systems as well as instructions for effectively maneuvering to right themselves following a fall. Wearing an external protective device over the hip has been shown to reduce frequency of fracture among fall-prone frail elderly persons.²⁷

More than a million fractures occur in older persons in the United States each year, the three most common sites being vertebrae, proximal hip, and distal forearm (Colles' fracture). The principle contributing factor is osteoporosis or loss of bone mass, a progressive natural process that begins in the fourth or fifth decade of life and renders aging individuals increasingly susceptible to fracture associated with relatively minor trauma. Osteoporosis is accentuated in women following menopause, and age-specific risks of osteoporotic fractures are markedly higher among older women versus men (Fig. 71-4). Osteoporosis is significantly retarded by postmenopausal estrogen replacement therapy, by oral bisphosphonates, and probably by regular exercise and supplemental calcium intake throughout adulthood.²⁸

Hip fractures are associated with more deaths, disability, and medical costs than all other osteoporotic fractures combined. Over 300,000 occur annually in the United States, and there is evidence that the age-specific incidence of hip fracture has been increasing in some industrialized societies.²⁹ Between 10% and 20% of older patients who have fractured their hips die within 6 months, and a substantial percentage of survivors are destined for long-term nursing home placement. There is, however, considerable potential for reducing mortality and institutional placement and restoring mobility, with or without assistive devices, if patients receive timely surgical, medical, and particularly rehabilitative care (see under "Geriatric Strategies").

Incontinence

Urinary incontinence is defined as "the involuntary loss of urine so severe to have social and/or hygienic consequences." A symptom with multiple causes, rather than a discrete disease process, incontinence affects 15–30% of community-dwelling elderly and at least half of all nursing home residents. In addition to its immense psychosocial

burden on afflicted individuals and their caretakers, the costs of managing urinary incontinence in the United States are estimated at over \$10 billion annually. This disabling condition of old age can in many instances be cured or effectively controlled through appropriate medical and nursing assessment and intervention.³⁰

There are several subtypes of incontinence each representing a distinctive pathophysiological mechanism. Stress incontinence, a particularly common form in women, results from dysfunction at the bladder outlet allowing urine leakage during times of increase in intra-abdominal pressure, such as coughing or sneezing. Pelvic muscle exercises are often effective in controlling this condition. Urge incontinence consists of loss of urine as a consequence of uninhibited bladder muscle contractions, usually resulting from a neurologic condition such as stroke or local bladder irritation. If not cured through treating a local cause such as urinary tract infection, urge incontinence may be controlled with anticholinergic agents, which inhibit bladder contraction. Overflow incontinence occurs when the bladder does not empty normally and becomes overdistended due to one of a variety of neurologic impairments or local obstructions. This may be correctable through surgery where indicated (e.g., prostatectomy) or managed through a program of intermittent catheter drainage.

Functional incontinence occurs when the lower urinary tract is functionally intact, but impaired mobility or cognition prevents the individual from getting to toilet facilities. This variant is controllable through regular, assisted access to toilet facilities.

Sensory Impairment—Hearing and Vision

The 1995 U.S. National Health Survey Supplement on Aging established prevalence rates of hearing impairment of 35% at age 70–74, rising to 58% at 85+ years of age among community-dwelling men and 22% and 49% among women at the same ages. Prevalence of significantly impaired vision, including blindness, among men and women ranged from 12% to 15% at 70–74 years of age to 26–34% over age 85; 92% of persons over age 70 reported using glasses, most of which were prescribed. In addition to potentially profound limitations in an individual's ability to communicate with others, impairments in both of these sensory systems are associated with significant limitations in performing traditional ADL and IADL functions as well as with depression and cognitive difficulty.³¹

Early detection and therapeutic intervention may reverse or delay sensory impairments attributable to certain specific degenerative disease processes, such as visual loss due to diabetic retinopathy or glaucoma. In large measure, the task of reducing disability due to sensory loss in old age focuses upon restoring the lost sense as in surgical treatment of senile cataract or prosthetic treatment in presbycusis. Cataract surgery with lens implantation has been shown to improve physical function as well as vision.³² Hearing aides, voice amplifying devices, and lip reading represent the mainstays of hearing rehabilitation, which, if used effectively, can reverse physical and particularly psychosocial disability associated with hearing loss.

Depression and Dementia

Mental and psychological disability among the elderly are major societal concerns, particularly in long-term care institutions. Depression and dementia constitute the most prominent forms of affective and cognitive disorders encountered in old age. Both conditions may result from multiple causes, and while generally not preventable, the impact of depression and dementia on affected individuals or their caregivers may be alleviated through judicious intervention.

Major depression, found in some 5% of older persons in the community, and minor depression, found in some 10–20%, are associated with increased risk of physical disability.³³ A variety of antidepressant drugs as well as electroconvulsive therapy are effective in treating late-life depression and its disabling effects.³⁴ Best results appear to be achieved through collaborative care management involving mental health and primary care practitioners working together.³⁵

Figure 71-4. Incidence rates for the three common osteoporotic fractures (Colles', hip, and vertebral) in men and women, plotted as a function of age at the time of the fracture. (Source: Riggs BL, Melton LJ. *Involuntary osteoporosis*. N Engl J Med. 1986;314:1676–86.)

Broadly defined by the DSM-III-R as “a loss of intellectual abilities sufficient to interfere with social or occupational functioning,” dementia is a disabling mental condition, well known to aging societies, which increases dramatically in prevalence from 2% to 3% at age 65 to 25% or above at age 85 (Fig. 71-5). The most common pathologic subtypes of dementia are Alzheimer’s disease and multi-infarct dementia. A small percent of cases of potentially reversible dementia occur secondary to treatable causes including hypothyroidism, subdural hematoma, drug toxicity, and others.

A number of drugs, largely cholinesterase inhibitors, show modest effects in alleviating if not reversing the dysfunctional behaviors of dementia,³⁶ and a number of epidemiologic studies suggest that nonsteroidal anti-inflammatory drugs (NSAIDs) may protect against development of Alzheimer’s disease.³⁷

A variety of intervention strategies have been developed with the twin goals of maintaining independence and dignity for dementia patients and providing social and psychological support for their caregivers.³⁸ These invariably involve a multidisciplinary approach. Patient care includes continuing attention to basic medical and nursing needs, with particular emphasis on adequate nutrition, assistance with toileting and grooming, and prevention or early treatment of minor infections and skin breakdown. Regularly scheduled occupational and recreational therapy help to maintain patient morale. Support for caregivers in the community includes counseling and education about the natural course and management of dementia, particularly the highly stressful memory loss and aberrant behavior; assistance with obtaining legal, financial, and safety advice; and provision of temporary relief through day care or short-term residential respite care. To ensure appropriate and effective care for patients with advanced disease, often accompanied by wandering and abusive behavior, special care dementia units have been quite widely and successfully introduced in nursing homes in the United States and elsewhere.³⁹

In addition to the burden suffered directly by patients and their caregivers, Alzheimer’s and related disorders pose an immense

monetary cost, estimated by the Alzheimer’s Association in 2000 at some \$100 billion annually in the United States.

Stroke and Parkinson’s Disease

Stroke and Parkinson’s disease (PD) represent two of the most common disabling neurologic conditions of old age, both of which are candidates for early preventive or rehabilitative intervention.

Stroke or cerebrovascular disease comprises a heterogeneous group of pathological entities all of which carry a high risk of residual disability. While age-specific stroke mortality rates have declined dramatically, and levels of disability among survivors of incident stroke have improved in recent decades,⁴⁰ stroke remains the third leading cause of death and the most severely disabling condition of old age. Among acute stroke survivors, 30–40% become dependent in self-care, with most functional recovery occurring within 3–6 months poststroke; over 50% experience significant depression and social isolation, and 20–30% are institutionalized for continuing care.⁴¹ Randomized trials have found that hospital-based special stroke units, which combine acute medical-nursing expertise and multidisciplinary rehabilitation, yield decreased mortality and in some instances decreased long-term disability and institutional placement when compared to stroke management on general medical units.⁴² Among a number of recent trials of thrombolytic therapy in acute ischemic stroke, significantly lower rates of poststroke disability have been observed in patients treated within 3 hours of onset of stroke.⁴³

PD is a degenerative condition resulting largely from deficiency of the neurotransmitter substance dopamine in the midbrain and causing generalized movement and postural abnormalities. Disabling manifestations include tremulous hands, shuffling gait with tendency to fall, plus some dulling of the intellect. Increasingly common with aging, the prevalence is estimated at 500–1000 per 100,000 over age 60, with more than half of prevalent cases being over 70 years of age. Some Parkinsonism among older persons is drug-induced by neuroleptic agents and may resolve when the offending drug is discontinued. Conventional treatment to ameliorate manifest disability in PD consists of one of a variety of dopamine replacement regimens plus physical therapy. Deep brain stimulation, neurotransplantation with human transformed cell lines, as well as pallidotomy represent evolving surgical interventions with potential for controlling the disabling effects of PD.⁴⁴

Heart Failure and Chronic Obstructive Pulmonary Disease

Heart failure (HF) and chronic obstructive pulmonary disease (COPD) constitute the two most common disabling chronic cardiopulmonary conditions of old age. From a public health perspective, the impact of both conditions on society at large in the United States and elsewhere is manifest by increasing mortality and morbidity rates for both conditions among older persons since the 1980s. From a clinical perspective, impact of these conditions on patient functional status and quality of life has been shown to be partially controllable through use of selected medical and rehabilitative interventions.

HF is the most common reason for hospitalization among persons over age 65 in the United States, with rates rising steeply between the seventh and ninth decades of life. Increasing incidence and prevalence of HF is attributed to increased numbers of surviving patients with ischemic heart disease who are at high risk of developing HF.⁴⁵ Randomized clinical trials in the past decade have shown significant improvement in survival and in functional capacity among patients treated with angiotensin-converting enzyme inhibitors or beta blockers.⁴⁶ Additionally, physician-nurse practitioner coordinated care has been shown to reduce hospitalizations and improve quality of life among community-dwelling older patients with chronic HF.⁴⁷

COPD, the end stage of prolonged insult to the bronchi, bronchioles, and lung parenchyma from tobacco smoke and other atmospheric

Figure 71-5. Age-specific prevalence rates from moderate or severe dementia in five studies: England (1970), United States (1978), Denmark (1963), Finland (1985), and New Zealand (1983).

pollutants, is the fifth common cause of death in the United States, with prevalence rates and death rates rising among persons over 70 years of age in recent decades. Loss of capacity for physical activity and psychological distress due to oxygen deprivation are the main functional impacts of COPD on the individual. A meta-analysis of 14 randomized trials of rehabilitation programs offered to patients with activity limitation attributable to COPD found clinically significant improvement in health-related quality-of-life measures and functional capacity when compared with conventional care.⁴⁸ While physical exercise is considered the central pillar of these programs, it is likely that attention to nutrition and psychosocial status and other programmatic activities also contribute to the positive results.

Arthritis and Spinal Disorders

Arthritis and back pain caused principally by degenerative osteoarthritis are the two most common causes of activity limitation among persons over age 65. The disabling effects of both conditions may be alleviated by nonpharmacologic, pharmacologic, or operative interventions.

Self-reported arthritis with activity limitation occurs among some 12% of persons 65–74 years of age and 20% of those over 85 years old.⁴⁹ Exercise to relieve stiffness and pain and strengthen muscles, accompanied by analgesic medication as needed, is the first line of treatment for symptomatic arthritis.⁵⁰ When joints have been anatomically severely damaged and symptoms are unresponsive to these nonoperative strategies, surgical joint replacement, accompanied by aggressive physical therapy, may provide dramatic improvement.

Degenerative disease of the cervical or lumbar spine, with pain and/or resulting gait disability, affects many older persons in the United States in any given year. Use of analgesic medication and well-directed physical therapy, supplemented by lidocaine or steroid injection therapy, constitute the preferred strategy of interventions proven effective in these conditions. Surgical decompression (laminectomy) should be reserved for those patients with unrelieved pain and/or significant neurological impairments secondary to encroachment on the spinal cord or cauda equina. Compression fractures, typically involving the thoracic or thoracolumbar spine are painful and may lead to secondary kyphotic deformity. Treatment comprises pain relief and judicious restoration of mobility. Percutaneous vertebroplasty and kyphoplasty are emerging surgical approaches which may hasten and improve recovery.⁵¹

Transitions: Retirement, Bereavement, Relocation

Certain discrete transitions in social circumstances place older persons at increased risk of onset or worsening of disabling physical and mental health problems. Most prominent among these transitions are retirement, loss of spouse, and residential relocation. These events are commonly associated with loss of autonomy and control over one's life, as well as loss of the social and psychological support, which contribute to physical and mental well-being.

The major impacts of retirement on well-being relate to reduction in income and attendant increase in various mental health problems. Loss of spouse and the accompanying experience of loneliness and bereavement are associated with increased likelihood of a variety of nonspecific mental and physical symptoms as well as excess mortality. The excess mortality is more common in men than women and peaks during the first 6 months of bereavement. Residential relocation, particularly placement in an assisted living facility or a nursing home, represents an unusually stressful event, depriving the old person of a familiar social and physical environment as well as much of her sense of autonomy. The nursing home experience may be aggravated further by the use of physical and chemical restraints which diminish or distort mental performance and increase the risk of iatrogenic illness or injury. Such untoward effects as well as increased risk of death tend to be concentrated in the early months following residential relocation.¹⁶

Reduction in the health risks and increased mortality associated with social transitions may be achieved through various supportive

and autonomy-enhancing interventions. Providing material assistance, medical attention as needed, and companionship are fundamental supportive approaches. Teaching, encouraging, and enabling are important autonomy-enhancing approaches, in contrast to excessive cautioning and “doing for” which may induce a sense of helplessness. A number of observations in nursing homes have demonstrated improvement in mental health and other health status indices among residents maintained free of unnecessary restraints and encouraged to exercise initiative and choice in pursuit of daily activities. The “Eden Alternative,” a forward-looking strategy for humanizing the entire milieu of nursing homes, has begun to be implemented in homes in the United States and elsewhere since its introduction in the late 1990s.⁵²

At the level of primary prevention directed to social transitions of aging, a society's or community's existing policies and practices may be altered with respect to both retirement and nursing home placement.⁵³ Normative, if not legally mandated, retirement age can and has been increased in some settings. Rehabilitative and community-based services can and have been successfully implemented as alternatives to custodial placement in nursing homes. Such continuing care alternatives have been most fully developed in societies with comprehensive health-care systems.⁵⁴

► HEALTH-CARE DELIVERY

The Geriatric Medicine Movement

The breadth of threats to health and independent functioning in old age and the attendant potentials for preventive interventions, as reviewed above, constitute a major challenge to develop suitable prevention-oriented health-care delivery systems. In recognition of this challenge, the World Health Organization convened an expert panel in 1974 on “Planning and Organization of Geriatric Services.” This body recommended that countries develop integrated health services for older persons, including “elements of medical and social prevention, multidisciplinary assessment, home and institutional curative treatment, rehabilitation, long-term care and supportive social welfare.”⁵⁵ This spectrum of services, with dedicated professionals and resources, constitutes the essence of the modern geriatric medicine movement, which was pioneered in Great Britain and has now developed in many other parts of the world.⁵⁶ The principle focus of this field of medicine, captured in the motto, “adding life to years,” is the provision of timely interventions to treat and prevent unnecessary disease, disability, and dependency at all stages. Translating this concept into practical terms, comprehensive health services for older persons include an array of community, hospital, and institutional continuing care elements and academic commitments such as developed in Great Britain and summarized in Table 71-4.

Geriatric Strategies

Comprehensive geriatric assessment (CGA) represents the core clinical activity of geriatric medicine. Practiced in inpatient and outpatient settings on the part of geriatricians, nurses, social workers, rehabilitation therapists, and others working in collaboration, geriatric assessment identifies the vulnerable elderly patient's medical, psychosocial, and functional capabilities and problems, and leads to appropriate preventive, curative, rehabilitative, and long-term care.⁵⁷ A meta-analysis of 28 controlled trials reported the odds of surviving and living in the community as well as showing improvement in physical or mental status at 6–12 month follow-up are generally more favorable for patients managed by CGA programs. Programs which include control over implementing medical recommendations and provide extended ambulatory follow-up are more likely to be successful.⁵⁸

The need for progressive geriatric care is particularly evident in the acute hospital sector where older patients not only constitute the largest constituency of admissions, but are at particularly high risk of experiencing decline in physical and mental function.⁵⁹ Such strategies have been incorporated into hospitals in various ways in Great

TABLE 71-4. SOME SPECIFIC ELEMENTS OF COMPREHENSIVE HEALTH SERVICES FOR THE ELDERLY IN GREAT BRITAIN**■ Community****Enrollment in primary care practice**

- General practitioner
- Attached community nurses
- Home visiting by general practitioners

Social service liaisons

- Home help
- Meals on wheels
- Domiciliary occupational therapy

■ General Hospital**Acute geriatric services**

- Defined catchment population
- Geriatric medicine specialists, house officers
- Multidisciplinary teams
- Rehabilitation emphasis
- Home visiting
- Day hospital
- Respite admissions

Liaison consultation with other hospital services

- Medicine
- Orthopedics
- Psychiatry

■ Institutional Continuing Care

- Medical surveillance, avoid frequent transfer to hospital
- Multidisciplinary rehabilitation, maintenance of function
- Social and recreational activities

■ Education

- Academic departments of geriatric medicine
- Required curriculum in medical schools
- Formal postgraduate specialty training

Britain, the United States, and elsewhere, as shown in Fig. 71-6. The simplest approach (C in the figure) involves referral for consultation by a multidisciplinary geriatrics team. The modality labeled (T) in the figure consists of a special hospital-based or affiliated unit to which patients are transferred for geriatric rehabilitation following acute care on a medical or surgical service. The third modality (A in the figure), involves designating part of an inpatient medical service as an acute geriatric admitting unit.

Among the documented successes of hospital-based geriatric programs, three prototypic experiences are illustrative.

The first of these, based at the Sepulveda Veterans Administration Medical Center in Los Angeles, comprised a 15-bed geriatric unit operated by a full-time medical, nursing, and social work team, with part-time participation by rehabilitation therapists and others. In a randomized trial, older hospitalized patients transferred to the geriatric unit, when compared with controls managed on a general medical unit, over a 1 year follow-up, experienced significantly lower mortality, a reduced likelihood of nursing home admission, fewer overall acute hospital and nursing home days, significantly greater improvement in functional status and morale, and lower average cost of care.⁶⁰

The second experience involved a collaborative geriatric orthopedic rehabilitation unit (GORU) developed in Sterling, Scotland, in which elderly female patients with hip fracture were transferred postoperatively to the care of a multidisciplinary service headed by a geriatrician. In a randomized trial comparing patients managed by the GORU with those managed by the orthopedic service, median combined length of acute hospital and postacute rehabilitation stay was

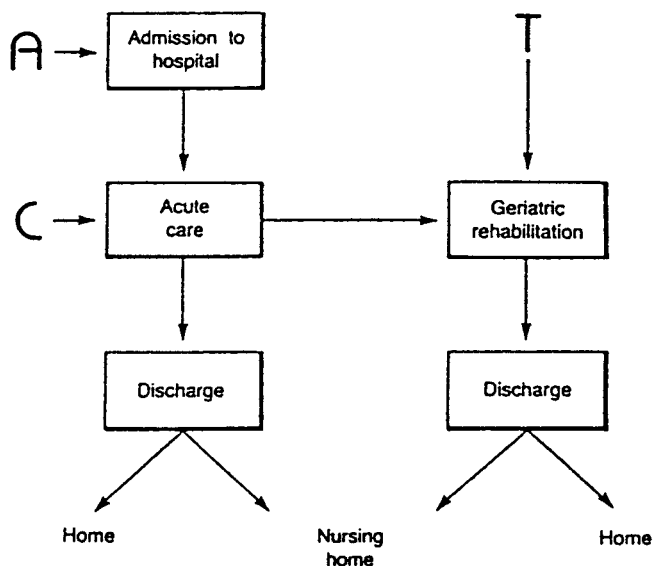

Figure 71-6. Potential intervention by special geriatrics services in the course of acute hospital admission in the United States. A, admit to acute geriatrics service; C, geriatric consultation on acute medical and surgical services; T, postacute transfer to special geriatric rehabilitation unit. (Source: Barker WH. *Adding Life to Years: Organized Geriatrics Services in Great Britain and Implications for the United States*. Baltimore: Johns Hopkins University Press; 1987, p 131.)

shorter, fewer patients were discharged to long-term institutional care, and more patients attained high levels of independence in activities of daily living which persisted over 12 months follow-up.⁶¹

The third experience is the Acute Care for the Elderly (ACE) unit developed at the Case Western Reserve Medical Center in Cleveland, Ohio. Designed to avoid the cascade of “hazards of hospitalization” for older patient,⁵⁹ the ACE unit incorporates a set of explicit geriatric care principles into routine acute care beginning at the time of admission to hospital. These include patient-centered care protocols to maintain or restore continence, mobility, skin integrity, mental health, etc., and daily rounds by a multidisciplinary team. A randomized trial showed significantly better functional status at discharge and lower rate of posthospital nursing home placement for the ACE unit patients, with comparable lengths of stay and hospital bills for these patients and control patients admitted to acute general medicine units.⁶²

Comprehensive Health Services

Successful provision of geriatric assessment, rehabilitation, and continuing care with a preventive orientation is most likely to occur in a comprehensive health-care program in which the various elements listed in Table 71-4 are linked together under one system of financing. Such systems have been developed in Great Britain, Scandinavian countries, and a number of other societies with national health programs. In the United States, fragmentation among health-care payors and an excessive reliance on costly institutional services (acute hospitals and nursing homes) has left many gaps in the provision of services which could prevent or alleviate disability and dependency in old age. A limited number of demonstration projects, including the PACE/On Lok Program for All-Inclusive Care of the Elderly and the Social Health Maintenance Organization (SHMO), as well as the Veteran’s Administration health services, have developed model comprehensive programs for older persons in the United States.⁶³ Furthermore, many innovative care delivery strategies for maintaining maximal functional well-being among older persons living

Figure 71-7. The Chronic Care Improvement Model. (Source: Wagner EH. *Chronic disease management: What will it take to improve care for chronic illness?* *Eff Clin Pract.* 1998;1:2–4.)

in the community with chronic conditions have been introduced in recent years. A promising example being widely implemented in the United States and elsewhere is the “Chronic Care Model” developed by Wagner and colleagues, which, as illustrated in Fig. 71-7, incorporates key elements as follows: proactive efforts to involve patients in self-management; delivery system (practice) design to include team care; decision support to bring to bear best current evidence-based interventions; and efficient information systems to track patient progress. At such time that a national health program should evolve, policy makers will be well provided with these model experiences to draw upon in ensuring financing for progressive comprehensive services for society’s oldest and most vulnerable members.

Nutrition in Public Health and Preventive Medicine

Marion Nestle

The role of nutrition in public health and preventive medicine is self-evident: people must eat to live. Both inadequate and excessive food intake can adversely affect health, and both contribute to the leading causes of morbidity and mortality in every nation, developing as well as industrialized. Because all people consume food, all have an interest in the effects of diet on health. Nutrition, therefore, becomes an unusually accessible entry point into public health education and intervention programs. Because food intake is determined not only by individual choice but also by cultural and social norms, economic status, and agricultural and food policies, public health approaches to dietary intervention are not only appropriate, but necessary.

This chapter discusses diet and nutrition within the broad context of public health. It describes the health impact of dietary intake below and above recommended levels of energy and essential nutrients. It reviews current standards and guidelines for patterns of food intake that best meet nutritional requirements, improve nutritional status, and promote health. Finally, it suggests public health strategies to address behavioral and environmental barriers to consumption of healthful diets by individuals and populations.

► DIETARY REQUIREMENTS AND ALLOWANCES

People require a continuous supply of external food sources of energy and essential nutrients to maintain life, grow, and reproduce.^{1,2} By definition, essential nutrients are those that cannot be synthesized in adequate amounts by the body; their dietary or metabolically induced deficiency causes recognizable symptoms that disappear when they are replaced. The list of nutrients essential or otherwise useful to human physiology is long, complex, and almost certainly incomplete. It includes the more than 40 distinct substances listed in Table 72-1: sources of energy, amino acids, fatty acids, vitamins, minerals and trace elements, fiber, and water. As indicated in Table 72-1, other nutrients also may be required under certain conditions.

Malnutrition refers to excessive and unbalanced—as well as deficient—intake of essential nutrients. Fat-soluble vitamins and virtually all of the mineral elements cause disease symptoms when consumed or absorbed in excess. The adverse effects of overconsumption of energy, saturated fat, cholesterol, salt, sugars, and alcohol are important public health concerns. For each nutrient, a certain range of intake meets physiologic requirements but does not induce harmful symptoms.³ Optimal levels of intake of specific nutrients for individuals, however, can only be estimated. Individuals vary in nutrient requirements, and research on human nutritional requirements is incomplete.

Many countries have developed standards of nutrient adequacy for their populations for purposes such as nutrition education, nutrition counseling, food labeling, and dietary intervention programs. Because standards are based on interpretation of the existing research, they differ from one country to another.⁴ Until the late 1980s in the United States, the National Academy of Sciences' Food and Nutrition Board (now in the Institute of Medicine) estimated levels of nutrient intake "adequate to meet the known nutritional needs of practically all healthy persons," and published them every decade or so as recommended dietary allowances (RDAs).⁵ The RDAs were (and continue to be) set at levels that prevent overt signs of nutritional deficiency in 97–98% of the population—two standard deviations above mean requirements. Although lower levels of intake meet the nutritional needs of most individuals, RDAs were widely misinterpreted to be *minimal* requirements. For this reason, and because the RDAs addressed nutrient deficiencies but not excesses that might raise risks for chronic diseases, the Food and Nutrition Board (FNB) replaced them beginning in 1997 with new standards—Dietary Reference Intakes (DRIs)—developed jointly with Canada (Fig. 72-1).

The FNB developed the DRIs in line with the current direction of nutrition science toward increasing complexity and individualization of dietary standards and recommendations, a trend much at odds with public health approaches. Although the 1989 RDAs appeared in a slim volume of under 300 pages easily summarized in two tables, the DRIs comprise six volumes of 400–800 printed pages each.^{6–11} The DRIs include the former RDAs, but also introduce three new components: adequate intake (AI), tolerable upper intake level (UL), and estimated average requirement (EAR). Table 72-2 defines these standards and summarizes how they are meant to be used for diet assessment and planning.

The DRIs are individualized into values for 10 age categories (among infants, children, males, and females) and for pregnant and lactating women. They are based on biochemical, epidemiological, and clinical research, but such data are limited and many values have had to be estimated or extrapolated, especially for younger and older age groups. Thus, the DRIs are subject to many of the same criticisms that had been applied to the former RDAs. As Table 72-2 shows, the RDA (or the AI) continues to be used as a goal for individual intake even though it greatly exceeds average requirements.

The DRIs are meant to apply to nutrient intake from food, but some RDAs or AIs are set so high that it would be difficult, if not impossible, to meet them through normal dietary intake. For example, on the basis of levels required for maximum retention, the AI for calcium is set at 1200 mg per day for older adults, an amount obtainable only by consuming large amounts of dairy foods, supplements,

TABLE 72-1. DIETARY COMPONENTS CONSIDERED ESSENTIAL FOR HUMAN HEALTH*

Category	Examples
Energy sources	Carbohydrate, fat, protein, alcohol [†]
Essential amino acids	Isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, valine, histidine
Essential fatty acids	Linoleic acid, linolenic acid [‡]
Vitamins	
Water-soluble	Biotin, [§] choline, [¶] folate, niacin, pantothenic acid, riboflavin, thiamin, vitamin B ₆ (pyridoxine), vitamin B ₁₂ (cobalamins), vitamin C (ascorbates)
Fat-soluble	Vitamins A ^e , D ^b , E, K [§]
Minerals	Calcium, chloride, magnesium, phosphate, potassium, sodium
Trace elements	Chromium, cobalt, ^c copper, fluoride, iodine, iron, manganese, molybdenum, selenium, zinc
Fiber	
Water	

*See references 6-11.
[†]Carbohydrates (starches and sugars), proteins, fat, and alcohol contribute about 4, 4, 9, and 7 kcal/g, respectively.
[‡]Other fatty acids in the omega-3 series may have essential functions.
[§]Synthesized by intestinal bacteria in uncertain amounts.
[¶]Synthesized in the body, but not always in adequate amounts.
^eIncludes beta-carotene, alpha-carotene, and beta-cryptoxanthin precursors.
^bSynthesized through the action of sunlight on skin, but required in the diet if sun exposure is limited.
^cConsumed as part of vitamin B₁₂.

or fortified foods. Ideally, the DRI would relate calcium intake to prevention of osteoporosis, but data are inadequate to do so (hence: AI, not RDA). It is uncertain whether a level this high is reasonable, or instead is needed to compensate for the effects of consuming diets high in protein, sodium, and phosphorus, all of which promote calcium excretion. In contrast, international standards relate calcium to animal protein intake and, as a result, range widely; the lower the amount of animal protein (and the phosphorus that goes with it) in the diet of a population, the less calcium is recommended.⁴ Because DRI levels so depend on the criteria and assumptions used in establishing them, careful interpretation is essential.^{6,7}

The UL component has two purposes. For vitamins and minerals, which rarely are consumed in excess from food (a rare exception is vitamin A toxicity from eating polar bear liver), the UL sets limits

Figure 72-1. Dietary reference intakes. The risk of inadequate intake increases as it approaches the EAR. The AI is not pictured because it does not bear a consistent relationship to the EAR or RDA. The RDA meets the requirements of most people in a population. At levels of intake above the UL, risks of excess intake increase. See Table 72-2 for an explanation of abbreviations.

TABLE 72-2. DIETARY REFERENCE INTAKES: DEFINITIONS AND USE

■ Definitions		
Recommended Dietary Allowance (RDA): Average daily dietary intake level sufficient to meet the nutrient requirement of nearly all (97–98%) healthy individuals in a group		
Adequate Intake (AI): An estimate of the RDA based on observed or experimentally determined approximations of nutrient intake by a group (or groups) of healthy people		
Tolerable Upper Intake Level (UL): Highest level of daily nutrient intake likely to pose no risks of adverse health effects to almost all individuals in the general population		
Estimated Average Requirement (EAR): Nutrient intake value estimated to meet the requirement of half the healthy individuals in a group		
■ Use in Assessment and Planning		
Type of Use	For Individuals	For Groups
■ Assessment		
EAR	Probability of inadequate intake (intake at EAR means 50% probability of inadequacy)	Prevalence of inadequate intake (defined as < EAR)
RDA	Low probability of inadequacy at RDA level	Do not use
AI	Low probability of inadequacy at AI level	Intake at AI implies low prevalence of inadequacy
UL	Intake above UL increases risk of adverse effects	Prevalence of population at risk of excess intake
■ Planning		
EAR	Do not use	Intake distribution with low prevalence of inadequacy
RDA	Aim for this intake	Do not use
AI	Aim for this intake	Mean intakes
UL	Guide for limiting intake	Intake distributions with low prevalence of adverse effects

on intake of dietary supplements. The UL also addresses dietary risks for chronic disease from overconsumption of such nutrients as energy, sugars, and sodium. For example, more than 95% of men and 75% of women in the United States consume sodium at levels that exceed the UL; not coincidentally, nearly one-fourth of the population has hypertension. Because practically all dietary sodium comes from salt added to processed foods, the UL has implications for the food industry. The lower the UL, the more pressure on food companies to reduce salt in their products.⁸ Upper limits on sources of energy such as saturated fat, *trans* fat, cholesterol, and sugars are especially controversial because avoiding them means consuming less of their main food sources.⁹

▶ NUTRITIONAL DEFICIENCIES: CAUSES AND CONSEQUENCES

Inadequate dietary intake is only one cause of nutrient deficiency. Symptoms also result from conditions that interfere with appetite; impair nutrient digestion, absorption, or metabolism; or substantially increase nutrient requirements or losses. Deficiencies may appear clinically as starvation, protein-energy malnutrition, syndromes of deficiency of single nutrients (e.g., pellagra, scurvy, iron-deficiency anemia), or as a wide range of less-specific symptoms.^{1,2}

The number of people throughout the world who suffer from nutritional deficiencies can only be estimated. About 900 million

people, most of them in low-income countries, are considered to be chronically undernourished and food insecure, based on a food supply cut point of 2300 kcal per day or uncertain ability to obtain food due to lack of money or other resources.^{10,11} Widespread nutritional deficiencies occur most often when income, education, and housing are inadequate, where water supplies are contaminated with infectious organisms that induce diarrheal diseases, or where populations are at war or under siege.¹² In countries where such conditions predominate, more than one-third of children under the age of 5 years suffer from some degree of malnutrition.^{13,14} Malnutrition is usually a direct consequence of poverty. Except in the very poorest or most conflicted countries, food production is adequate to meet energy requirements, but the segments of the population most in need are unable to purchase or use foods appropriately.

In industrialized countries, dietary deficiencies are less prevalent. Food insecurity, defined as an inability to acquire adequate food in socially acceptable ways, affects an estimated 11.0% of the U.S. population; food insecurity with involuntary hunger affects an estimated 3.9%.¹⁵ Such findings, however, are only rarely accompanied by clinical signs of nutrient deficiencies. When clinical signs do occur, they are usually associated with the additional nutritional requirements of pregnancy, infancy, early childhood, or aging, the toxic effects of alcohol or drug abuse, or illness, injury, or hospitalization.^{1,2}

Regardless of cause, inadequate dietary intake profoundly affects human function. It induces rapid and severe losses of body weight and electrolytes, decreases in blood pressure and metabolic rate, electrocardiogram abnormalities, losses in muscle strength and stamina, and gastrointestinal and behavioral changes.¹ The result is a generalized lack of vigor, alertness, and vitality that reduces productivity and impairs the ability of people to escape the consequences of poverty. Of special concern is the loss of immune function that accompanies starvation. Malnourished individuals lose cellular immune competence and demonstrate poor resistance to infectious disease. Infections, in turn, increase nutrient losses and requirements, and, in the absence of adequate nutrient intake, induce further malnutrition. This cycle is the principal cause of death among young children in developing countries and is an important cause of morbidity in malnourished children and adults everywhere.^{16,17}

Protein-energy malnutrition is the collective term for the clinical effects of this cycle on young children. Survivors display typical effects of starvation: depression, apathy, irritability, and growth retardation. Protein-energy malnutrition usually is classified into two entities—kwashiorkor and marasmus—on the basis of clinical signs and on the relative intake of protein to energy. Kwashiorkor is characterized by edema and fatty infiltration of the liver and is associated with a relative deficit of protein to energy. Marasmus is manifested as generalized wasting due to overall nutritional deprivation. In practice, such distinctions blur. Undernourished children exhibit symptoms that fall between the two extremes, and similar diets contribute to either form.¹

Numerous methods to prevent poverty-associated malnutrition in adults and children by improving household food security have been demonstrated to be effective in developing countries. Among them are programs that redistribute income, subsidize food prices, promote agricultural production, provide food supplements, and educate.^{18,19} Improvements in sanitation and in primary health care are also essential components of programs to reduce nutritional deficiencies.²⁰ Addressing the factors that raise risks for malnutrition would improve health and life expectancy for large segments of low-income populations.²¹

► DIET AND CHRONIC DISEASE

As nutritional deficiencies decline in prevalence in industrialized as well as developing countries, they are replaced rapidly by chronic conditions of dietary excess and imbalance. In the late 1980s, three comprehensive reports reviewed the entire spectrum of evidence linking diet to chronic diseases, and estimated the incidence and prevalence, cost to society, and overall public health impact of these conditions in

the United States and Europe.^{28–30} More recent reports document the increasing burden of disease from chronic, noncommunicable diseases due in part to excessive intake of food and energy.^{22,23} In today's era of rapid globalization, populations in developing countries move quickly from classic patterns of malnutrition to rising rates of chronic diseases.²⁴ This “nutrition transition” means that as in industrialized countries, overweight and obesity now predominate as diet-related health problems in countries where undernutrition still exists among large segments of their populations.^{34–36}

In the United States, four of the ten leading causes of death—coronary heart disease, cancer, stroke, and diabetes—are chronic diseases related in part to diets containing excessive energy, fat, saturated fat, cholesterol, salt, or alcohol, and too little fiber, along with too sedentary a lifestyle. These conditions account for more than 60% of annual deaths, but because they have multiple causes, the proportion attributable to diet alone is difficult to determine. One estimate attributes 18.1% of annual deaths to tobacco abuse, 16.6% to poor diet and physical activity (later corrected to 15.2%²⁵), and 3.5% to alcohol abuse.²⁶

Imprecision in such estimates is inevitable given the difficulties inherent in design, conduct, and evaluation of research on diet and disease. Nutrition research is complicated by individual variations in dietary requirements, limitations in the ability of investigators to obtain accurate information about the dietary intake of individuals or populations, and by other endlessly debated methodologic issues. Dietary changes over time are especially difficult to estimate. Firm proof of dietary causality is virtually impossible to demonstrate for diseases affected by so many other risk factors—genetic, environmental, and behavioral. Instead, investigators identify associations between diet and disease from studies of laboratory animals and from biochemical, epidemiologic, and clinical investigations in humans.²⁷ Because each of these methods has limitations, diet-disease associations are usually inferred from the totality of available evidence and are considered most compelling when data from all sources are consistent, strongly correlated, highly specific, dose-related, and biologically plausible.²⁸ Despite the difficulties, health authorities repeatedly reach the same conclusion about diet and disease risk: the preponderance of evidence supports the health benefits of diets that balance energy intake with physical activity, emphasize consumption of foods from plant sources, and minimize consumption of foods high in saturated and *trans* fats, carbohydrates, and alcohol.

► DIETARY RECOMMENDATIONS

An ideal diet provides energy and essential nutrients within optimal ranges from foods that are available, affordable, and palatable. Until the mid-1970s, government and health agencies in the United States advised the public to select diets from specific groups of foods (e.g., dairy, meat, fruits and vegetables, grains) in order to ensure adequate intake of nutrients most likely to be consumed at below-standard levels.⁹ As chronic diseases replaced nutrient deficiencies as public health problems, dietary recommendations shifted to address prevention of these increasingly prevalent conditions.

Dietary Goals and Guidelines

The first U.S. report to reflect this new focus established numerical targets for dietary changes to reduce chronic disease risk: reduce intake of fat (to 30% or less of total energy), saturated fat (10%), sugar (10%), cholesterol (300 mg/day or less), and salt (5 g/day); increase intake of foods containing naturally occurring sugars and starches (48%); consume alcoholic beverages in moderation; and balance energy intake against expenditure to maintain appropriate body weight. To achieve these targets, the report advised the public to consume more fruits, vegetables, and grains, and to select meat and dairy foods low in fat.²⁹ This advice proved so controversial that subsequent federal nutrition policies have tended to omit explicit percentage goals.⁹

U.S. dietary guidance policy is expressed in the Dietary Guidelines for Americans, a joint publication of the U.S. Department of Agriculture (USDA) and the Department of Health and Human Services (HHS), issued at 5-year intervals since 1980.³⁰ Like the development of Dietary Reference Intakes (DRIs) from RDAs, the guidelines have evolved toward the increasingly complex and individualized. The first four editions contained just seven precepts; the fifth edition added three more. The sixth edition in 2005 contained 41 recommendations—23 for the general population and 18 for specific population groups such as overweight children, pregnant women, or older adults.³¹ The increasing complexity is best illustrated by the sugar guideline. In 1980, it was “Avoid too much sugar”; in 2005, it was “Choose and prepare foods and beverages with little added sugars or caloric sweeteners, such as amounts suggested by the USDA Food Guide and the DASH Eating Plan.” As for increasing individualization: the USDA Food Guide lists serving numbers and sizes for foods in 11 groups at 12 levels of energy intake; the DASH (Dietary Approaches to Stop Hypertension) diet lists food servings in 8 groups at 4 levels of energy intake.

The movement away from public health approaches to dietary advice is due to two factors: science and politics. Nutrition science is increasingly focused on identification of genetic profiles that can be used as a basis for individualized dietary intervention. This approach is known variously as nutrigenomics,³² nutrigenetics,³³ or, when it involves identification of metabolic components of body fluids or tissues, metabolomics³⁴ (hence the drive to produce nutraceutical foods and supplements).³⁵ Politics is involved when food companies exert political pressure to prevent governments from issuing dietary advice that might result in reduced sales of their products. In 2004, for example, sugar lobbying groups pressed HHS to threaten withdrawal of funding from the World Health Organization (WHO), which was considering advising member countries to restrict intake of added sugars to 10% of daily energy intake.³⁶ Lobbying groups successfully pressured WHO member states to reject inclusion of that recommendation in a resolution to institute measures to prevent mortality, morbidity, and disabilities resulting from noncommunicable diseases.^{37,38}

The Current Consensus: Food Guides

Despite the scientific and political controversy, dietary recommendations for chronic disease prevention have remained much the same for decades. Virtually all say: vary food intake; balance food energy with physical activity to maintain weight; favor fruits, vegetables, and whole grains; choose lean meats and low-fat dairy foods; avoid foods high in fats, sugars, and salt; and drink alcohol in moderation, if at all.^{39,40} The 2005 U.S. Dietary Guidelines do contain some quantitative recommendations: at least 30 minutes of daily physical activity, 20–35% of energy from total fat, less than 10% from saturated fatty acids, less than 300 mg per day of cholesterol, and less than 2300 mg sodium per day. They also advise minimal intake of *trans* fatty acids.³¹ Similar recommendations have been issued by U.S. health organizations and agencies concerned with coronary heart disease and stroke,⁴¹ cancer,⁴² diabetes,⁴³ and hypertension.⁴⁴

Many countries have attempted to translate such recommendations into public health advice presented in graphic forms such as plates, shopping carts, or pagodas.⁴⁵ The most common format is that exemplified by the USDA’s now obsolete Food Guide Pyramid, a visual representation of recommendations to consume more foods from its base (grains, fruits, vegetables), and fewer from its upper sectors (meat, dairy, and foods high in fats and sugars).⁴⁶ This design generated controversy from the outset, first because of its implied restrictions on meat, dairy, and processed foods,⁹ and later for its failure to distinguish healthful from less healthful fats and carbohydrates.⁴⁷ Translating the new 41 dietary guidelines into a consumer guide to food choices presented even more difficult challenges when the USDA replaced the pyramid in 2005. The USDA dealt with those challenges by stating that “One size does not fit all” and creating 12 separate pyramids for individuals of differing energy needs.⁴⁸ The

Figure 72-2. The pyramid design featured as part of the USDA’s 2005 Food Guidance System emphasizes exercise and provides dietary advice for individuals through its website, www.MyPyramid.gov.

basic pyramid design, which emphasizes exercise, self-education through use of a website, and individual prescriptions for food choices based on age, sex, and activity level, is shown in Fig. 72-2.

Despite ongoing debates about dietary advice, its consistency for so many chronic diseases has encouraged collaboration on common recommendations for primary prevention. These constitute a consensus,⁴⁹ now worldwide.²² The obvious next step is to develop public policies to promote their implementation.⁵⁰ The recent increase in worldwide obesity, for example, calls for interventions that reduce barriers to following advice about healthful diets and activity patterns.^{51,52}

► BARRIERS TO IMPLEMENTATION

Although the ultimate decisions targeted by dietary recommendations are personal food choices, individuals make such choices within the context of the social, economic, and cultural environments in which they live. Adults prefer foods that taste, look, and smell good, are familiar, and provide variety, but such preferences are strongly influenced by family and ethnic background, levels of education and income, age, and gender.⁵³ Food production, marketing, and the demand for convenience at low cost are strong determinants of food choices and create barriers to dietary change.⁹

Food Production

Food production, distribution, and marketing in the United States have undergone significant changes that affect food availability and, therefore, consumption patterns. In 2000, the U.S. food system accounted for nearly 8% of the Gross Domestic Product (GDP), employed 12% of the labor force, and generated nearly \$800 billion in expenditures. The proportion of that amount going to the farm sector has declined steadily since the early 1970s and is now less than 20%⁵⁴ (the remaining 80% goes for marketing costs such as labor, packaging, transportation, other business expenses, profit, and advertising⁵⁵). Since 1935, the number of U.S. farms fell from 7 million to under 2 million, but production became increasingly centralized and efficient; the largest 8% of farms account for 68% of production.⁵⁶ This trend has been accompanied by an increase in consumption of processed foods. In 1980, the average number of items in a supermarket was about 14,000; in 1999 it was more than 40,000.⁵⁴ In 2004, manufacturers introduced nearly 18,000 new food and beverage products, among them more than 2700 candies, 2600 snack foods, 1300 ice cream novelties, 700 soft drinks and waters, 600 fruit drinks, and 460 jams and sweet toppings.⁵⁷ Many such products are misleadingly advertised as “healthy” because they are reduced in fat or sugars or have vitamins added.⁵⁸

Food Marketing

Advertising promotes consumption of entire categories of foods, stimulates food production, processing, and marketing, and builds brand loyalty among adults and children.^{59,60} Direct (measurable) advertising costs are estimated at nearly \$12 billion annually, much of it for television commercials for food and beverages purchased outside the home; for every “measured” dollar, companies spend an additional \$2 on supermarket fees, coupon campaigns, trade shows, Internet marketing, and other such indirect methods, bringing the total to about \$36 billion.⁵⁴ In 2003, for example, McDonald’s spent \$619 million in measured dollars on U.S. advertising, PepsiCo spent \$208 million on soft drinks alone, M&M Mars spent \$77 million for its candies, and Altria spent \$25 million just to advertise Kool-Aid.⁶¹ Some marketing methods are more subtle and involve changes in societal norms favoring larger portions and more frequent eating occasions.⁶² The influence of food marketing on consumption patterns, particularly of children, is of great concern as the advertisements rarely display foods consistent with dietary guidelines, and evidence increasingly links consumption of fast food and soft drinks to higher energy consumption, overweight, and poor diet quality, especially among children.^{63,64}

Demand for Convenience and Low Cost

More than half of U.S. women with children under 1 year of age work outside the home, a trend sufficient to explain why convenience is so prominent a motive for food selection.⁶⁵ Higher disposable incomes in two-income families, and less leisure time, also contribute to demands for convenience. Thus, the share of food expenditures for foods prepared outside the home increased from about 26% in 1960 to 47% in 2000.⁵⁴ Although the fastest growth in sales occurred among fast-food or quick-service restaurants, future growth is expected to occur in full-service restaurants.⁶⁶ In 2003, McDonald’s alone generated \$17 billion in annual sales from more than 31,000 outlets serving nearly 50 million people in more than 119 countries each day.⁶⁷ Low prices are an incentive for consumption, and energy-dense fast-foods cost less per kcal than do fruits and vegetables.⁶⁸ Advice to consume more healthful diets confronts such barriers.

► THE ENVIRONMENT OF FOOD CHOICE

Americans perceive that they are well informed about the effects of diet on health and want to eat healthfully, but say they are confused by the variety of nutrition messages given by government, industry, health authorities, and the media, especially since most come from food companies and media. Qualitative research reveals considerable consumer skepticism about dietary advice and tendencies to ignore recommendations seen as inconsistent or difficult to follow.⁶⁹ This research confirms the well-established principle that education alone is insufficient to change behavior; environmental changes are needed to facilitate more healthful food choices.⁷⁰

If nutrition messages are perceived as confusing, they also are perceived as requiring unacceptable changes in eating patterns, preparation effort, or cost. For example, the major sources of saturated fat in the U.S. diet in 1999 were dairy foods (24%), meat (21%), shortenings (15%), and salad and cooking oils (12%).⁷¹ Cheese alone provided 11% of the saturated fat. To reduce saturated fat to 10% of energy or less, it is necessary to eat less of those foods or to replace them with fruits, vegetables, and grains. In 2000, the leading sources of energy in U.S. diets were soft drinks, cakes and pastries, hamburgers, pizza, and potato and corn chips; these five food groups accounted for 20% of cumulative energy intake.⁷² Advice to eat less of them confronts the economic interests of their producers.

Food supply data (an indirect measure of dietary intake) do indicate some favorable shifts since the 1970s: a slight decline in the availability of red meat, replacement of whole with low-fat and skim milk, replacement of animal fats with vegetable oils, and increases in availability of fruits and vegetables.⁷³ However, the per capita

availability of total energy in the food supply increased from 3300 to 3900 kcal per day from 1970 to 2000,⁷⁴ and dietary intake surveys report an increase of 200 kcal per day, nearly all derived from carbohydrates.⁷⁵

Such observations reflect the environment of food intake in the United States. Consumers who are well informed about nutrition—and make choices based on this information—tend to be older, better educated, and wealthier, demonstrating that diet is an indicator of social class. For many people, convenience and low cost take precedence over nutritional quality. Markets selling healthful foods are rarely located in low-income communities.⁷⁶ Because meals are increasingly purchased at restaurants and at fast-food and takeout places, and because foods high in processed oils and sugars are inexpensive to produce and profitable to market, the food industry has an increasing influence over dietary choices. In this situation, public health strategies to improve dietary intake are especially desirable.

► ASSESSMENT OF NUTRITIONAL STATUS

As with any other public health campaign, the first step in dietary intervention is to identify the nutritional problems and, therefore, the needs of the population at risk.⁵⁰ Evaluation of nutritional status is complicated by the many genetic, medical, behavioral, and environmental factors that influence development of diet-related conditions, by the multiplicity of signs and symptoms of malnutrition, by the lack of suitable biochemical or clinical markers for these signs and symptoms,^{1,2} and by the lack of precision in available assessment methods.²⁷ Assessment is also complicated by the variety of personal, cultural, and economic factors that influence food choice as well as the many social factors that lead to health inequalities.^{77,78}

Assessment Methods: Individuals and Populations

To date, no single, independent measurement of dietary, biochemical, or clinical status has been found adequate to confirm the nutritional status of individuals or populations. Instead, nutritional risk is defined by a combination of methods: nutritional history, medical history and physical examination, body measurements, and laboratory tests.^{79,80} Table 72-3 lists examples of elements of these

TABLE 72-3. SURVEY ELEMENTS FOR NUTRITIONAL STATUS EVALUATION

<i>Nutritional History</i>	<i>Medical History & Physical</i>
<ul style="list-style-type: none"> ■ Dietary Intake • Food record • 24-hour recall • Food frequency • Diet history • Use of supplements • Eating habits 	<ul style="list-style-type: none"> ■ Signs of Undernutrition • Low weight for height • Recent weight loss • Clinical signs of malnutrition • Chronic or acute conditions • Medication use • Substance abuse
<ul style="list-style-type: none"> ■ Related Social Factors • Income • Educational level • Ethnicity • Use of food assistance • Medications • Activity levels 	<ul style="list-style-type: none"> ■ Chronic Disease Risk Factors • Overweight • Elevated blood glucose • High blood pressure • High blood cholesterol • Waist-hip ratio
<i>Body Measures</i>	<i>Laboratory Tests</i>
<ul style="list-style-type: none"> • Height • Weight • Skinfolds • Waist circumference • Hip circumference 	<ul style="list-style-type: none"> • Hemoglobin, hematocrit • Iron and iron-binding • Serum vitamins and minerals • Blood glucose • Blood cholesterol • Lipoproteins • C-reactive protein

methods used in population surveys. In practice, surveys rarely use the full range of nutritional assessment methods; many of them are too imprecise, inconvenient, or expensive for frequent use. Instead, professional judgment is needed to evaluate the severity of selected nutritional risk factors.

Short of duplicate meal analysis (and even this method has limitations), techniques to determine the usual dietary intake of individuals are imprecise; standard methods yield estimates that cannot be interpreted too literally. These include a record of foods consumed during a specified time period (Food Record), retrospective recall of foods consumed within a recent time period (24-Hour Recall, or longer), and measures of the frequency of consumption of specific index foods (Food Frequencies).²⁷ The nutrient content of foods identified by these methods is obtained from tables of food composition, which also are imprecise estimates.⁸¹ The diets are compared to standards of nutrient intake such as the DRIs⁸² or to recommended patterns of food consumption described by dietary guidelines or food guides. Each of these methods, used singly or in combination, has strengths and weaknesses. All yield useful, if imprecise, information.²⁸ Demographic and socioeconomic data are especially useful as indirect indicators of nutritional risk in community surveys where detailed diet histories, physical examinations, and laboratory tests would be impractical.

The simplest and most useful indicator of undernutrition is low weight for height. Other clinical signs listed in Table 72-3 are useful for assessing the nutritional status of hospital patients.¹ Evaluation of chronic disease risk is accomplished through measurements of blood glucose, blood pressure, blood cholesterol, and body weight. The high prevalence of these risk factors is the basis of large-scale public health campaigns such as the U.S. National Cholesterol Education Program.⁸³ Because no simple screening measure is available for evaluation of diet-related cancer risk, promotion of healthier diets to the entire population is a reasonable public health strategy.

National Nutrition Monitoring

The prevalence of diet-related risk factors and conditions in the United States is determined by remnants of the 1990 National Nutrition Monitoring and Related Research Program, now expired. The program coordinated the monitoring activities of 40 surveys conducted by 22 federal agencies that measured health and nutritional status, food and nutrient consumption, food composition, dietary knowledge and attitudes, foods available for purchase, and socioeconomic indicators related to dietary intake.⁸⁴ Early concerns about the limited ability of the program to provide data on trends in dietary intake patterns, hunger prevalence, and dietary patterns of minority groups⁸⁵ were eventually addressed. Its principal surveys were the National Center for Health Statistics' National Health and Nutrition Examination Survey (NHANES) and USDA's Continuing Survey of Food Intake of Individuals (CSFII). NHANES collected data from dietary interviews, physical examinations, and biochemical and hematological tests from a probability sample of the U.S. population from 1971 to 1974 (NHANES I), 1976 to 1980 (NHANES II), 1988 to 1994 (NHANES III), and later. It surveyed the Hispanic population from 1982 to 1984 (HHANES).⁸⁶ The CSFII collected information about household food consumption along with measures of knowledge and attitudes about nutrition and health.⁸⁷ In 2002, the surveys were merged into one continuous survey called "What We Eat in America."⁸⁸ Without reenactment of the legislation mandating and funding these surveys, their future is uncertain.⁸⁹

Community Nutrition Assessment

Methods for assessment of the nutritional needs of communities vary only slightly from conventional means of community health assessment. Table 72-4 lists the principal data elements used to evaluate

TABLE 72-4. DATA ELEMENTS FOR COMMUNITY NUTRITION ASSESSMENT

<ul style="list-style-type: none"> ■ Community Descriptors • Geographical position, boundaries • Population within boundaries, density • Community agencies, services • Community health-care services • Hospitals, clinics • Educational institutions ■ Population Descriptors • Age, gender, racial, and ethnic distribution • Income • Education • Employment • Length of time in location • Primary language ■ Health Status Indicators • Infant mortality • Low birth weight 	<ul style="list-style-type: none"> • Life expectancy • Chronic disease rates • Leading causes of death ■ Nutritional Status Indicators • See Table 72-3 ■ Food and Nutrition Resources • Use of federal food assistance • Nonparticipation rates for eligible persons • Soup kitchens, food pantries, food banks • Food markets: number, kind, location • Nutrition education and training programs • Food and nutrition advocacy groups • Weight control programs • Worksite wellness programs
---	---

the level of nutritional risk in communities. These elements include geographic, demographic, socioeconomic, and health descriptors. They also include descriptors of food and nutrition resources in the community, utilization rates for such resources, and indicators of food availability, intake, and nutritional status obtained from nutrition monitoring surveys.

In developing countries with high rates of clinically apparent conditions of undernutrition, investigators have selected elements from this list to develop rapid, convenient, and relatively inexpensive screening instruments to evaluate nutritional risk under field conditions. These methods, which range from a graded series of bracelets to measure arm circumference to comprehensive surveys, have been used successfully to identify children and adults at high nutritional risk who can be targeted for intervention.⁹⁰ In the United States, advocates for the poor in more than 250 communities since 1980 have developed methods to document the need for federal food assistance; these typically include data on poverty levels, the severity of individual and family food insecurity, nonparticipation of eligible persons in food assistance programs, and increasing demands for private-sector soup kitchens and food pantries.⁹¹

► POLICY RECOMMENDATIONS AND IMPLEMENTATION STRATEGIES

The quantity, strength, and consistency of evidence that relates dietary factors to chronic diseases, and the substantial impact of these conditions on health, are reasons enough to promote policies to make it easier for people to consume more healthful diets (and be more active). Current policies could be altered to address environmental as well as behavioral barriers to dietary change. Table 72-5 outlines some suggestions for policy changes aimed at reducing dietary risks for chronic diseases.

Public health strategies begin with public education. Although education may not be sufficient to improve dietary behavior, it can facilitate change, especially when education interventions involve the target audience in the design, conduct, and evaluation of their own dietary plans, employ multiple educational strategies, and use a team approach.⁷⁰ Currently, most public information about nutrition derives from food industry marketing, and no government agency can compete with that level of funding. The success of the National Cholesterol Education Program is evidence that well-funded campaigns can be

TABLE 72-5. PUBLIC HEALTH POLICIES TO REDUCE DIETARY RISKS FOR CHRONIC DISEASE**■ Educate the Public**

- Replace energy-dense foods of minimal nutritional value (“junk” foods) with fruits and vegetables
- Eat smaller portions, fewer snacks
- Recognize misleading advertising and health claims

■ Educate Children

- Integrate nutrition education into school curricula
- Provide school meals consistent with Dietary Guidelines
- Recognize food marketing strategies
- Distinguish commercial from educational messages

■ Health Professionals: Counseling and Practice

- Use nutrition in health promotion and disease prevention
- Counsel patients about diet, nutrition, and health
- Counsel patients to address environmental as well as behavioral determinants of dietary choices
- Obtain reimbursement for nutrition counseling and services

■ Federal Agencies: Regulations and Guidance

- Nutrition information readily available at fast-food restaurants
- Energy (calorie) labeling on takeout containers
- Total energy content labeled on single-serve packages
- Enforceable guidelines for health claims on food package labels
- Enforceable guidelines for television advertising of foods during children’s viewing hours
- More fruits and vegetables for recipients of food assistance
- Unambiguous dietary recommendations focused on food choices

■ Congress: Legislative Actions

- Farm subsidies for fruit and vegetable production
- Campaign contribution reforms (so legislators can make decisions independent of corporations)
- Restrict vending of “junk” foods in schools
- Restrict food marketing to children
- More comprehensive nutrition monitoring
- Mandate and fund research on the nutrient composition of food, dietary intake methods, environmental determinants of food choice, and effective interventions in dietary behavior

effective,⁸³ and similar levels of funding for nutrition education could prove equally successful.⁹² Public education campaigns that transmit culturally sensitive messages designed to address the needs and attitudes of specific target groups have been applied successfully to promote breastfeeding and other dietary improvements in developing countries, and use of these techniques has shown promise in improving the nutritional status of low-income homemakers, increasing the prevalence of breastfeeding, and improving health and function among the elderly and minority groups.⁵² As always, education methods that empower community members to determine their own dietary needs and interventions are most likely to be effective.

Beyond education, public health strategies must address the environment of food choice. The current environment promotes food overconsumption, especially by young children. Educating the public about personal responsibility in dietary choice is necessary but not sufficient; it also is necessary to provide information to permit informed choices and to make the food environment more conducive to making such choices. The suggestions in Table 72-5, remote from personal choice as they may seem, address such approaches. They point to the need for further research as a basis for program development. More comprehensive information about the nutrient composition of food, dietary intake, the environmental determinants of food choice, and the effects of those determinants on health would establish a more rigorous basis for policies and programs to improve the nutritional health of the population.

Postmarketing Medication Safety Surveillance: A Current Public Health Issue

Mirza I. Rahman • Omar H. Dabbous

With more than 3.6 billion prescriptions being dispensed annually in the United States, it is clear that Americans are using more prescribed medication than at any other time in history.¹ In addition, the use of nonprescription medication, including alternative medicines, is growing rapidly. While this increased medication use is due to a variety of reasons, including an aging population, the availability of many more effective drugs for myriad chronic diseases, and the desire to prevent disease, it can lead to unwanted adverse events (AEs), even as they provide great benefit.

It has been estimated that AEs cost the health-care system several billion dollars due to excess morbidity and mortality. However, the benefits of pharmaceutical products should not be minimized, as they can save the health-care system billions of dollars by changing the course of disease and disease management (e.g., decreased disability, less surgery, etc.).

Medication-related AEs occur frequently and while all of these AEs cannot be prevented, improving processes is the only way to improve quality.² Unfortunately, health care lags behind other high-risk industries in its attention to ensuring basic safety. There is a need to identify and learn from errors through mandatory reporting efforts. The Institute of Medicine has called for a nationwide mandatory reporting system to be established, and the data received should be analyzed to identify safety issues that require a broad-based response.²

From 2000–2005, there were 11 drug withdrawals for safety reasons in the United States.³ The regulatory agency that is responsible for postmarketing safety surveillance (PMSS) in America is the Food and Drug Administration (FDA). As such, the FDA reviews reports of adverse drug reactions from studies and from PMSS reports. While the FDA has the authority to withdraw the approval of a drug, in all of these cases, the drug's sponsor voluntarily withdrew the drug from the market. However, the FDA has been criticized for not acting quickly enough on evidence it obtained, and informing physicians and patients about safety issues concerning some of these drugs that were subsequently withdrawn from the market.⁴ Because no drug is absolutely safe—there is always some risk of an adverse reaction—the FDA's approval of a drug for marketing is contingent on its continued assessment of that drug's risks and benefits.⁴

This chapter will review the current U.S. PMSS process, describe the MedWatch program, and discuss the types of AEs that exist along with their reporting requirements. It will also show how AE reporting, along with analysis of those case reports, utilizing

techniques such as data mining, can lead to signal detection and drug withdrawals as necessary, to protect the public health.

Safety Surveillance

PMSS is the process for monitoring all marketed pharmaceuticals and medical devices to ensure timely identification, evaluation, and communication of any new or unexpected adverse reactions or safety concerns.⁵ It is done to promote and protect the public health, to identify early signs of safety problems, to supplement data from premarketing trials, and to ensure regulatory compliance. It is required as soon as a drug is marketed and for as long as it is being marketed. Moreover, special PMSS studies may be required as a condition of marketing approval.⁵

When discussing PMSS, some definitions of the terms used might be helpful. An AE is defined as an untoward medical occurrence, though not necessarily causal. An adverse drug reaction (ADR) is defined as an untoward medical occurrence caused by a drug. A signal highlights a possible causal relationship between an AE and a drug and requires further investigation.⁵ The regulations that govern PMSS in America are:

- 21 CFR 314.80: Postmarketing reporting of adverse experiences for drugs.
- 21 CFR 600.80: Postmarketing reporting of adverse experiences for biologics.

While there is clearly regulatory interest and more focus on serious AEs (see Fig. 73-1) and those that occur with greater frequency (see Fig. 73-2), all AEs that may pose a risk to patients are of concern.^{6,7} However, the current Adverse Event Reporting System (AERS) is a passive, spontaneous, postmarketing safety surveillance system. It is voluntary, except for pharmaceutical manufacturers, which are mandated to report to the FDA any AE that is reported to them. This factor, combined with reluctance of health-care professionals to report AEs due to concerns regarding malpractice litigation or follow-up paperwork, too often leads to AEs not being reported. Regulatory agencies, pharmaceutical manufacturers, health-care professionals, and consumers all participate in the PMSS process.

The PMSS mission is to implement the systematic review of spontaneous postmarketing data for proactive risk identification, assessment, and quantification, to help ensure safe use of a drug.

Any adverse experience occurring at any dose that results in any of the following outcomes:

1. Death
2. Life-threatening adverse experience
3. Inpatient hospitalization or prolongation of existing hospitalization
4. A persistent or significant disability/incapacity
5. A congenital anomaly/birth defect
6. An important other medical event (that may not result in death, be life-threatening, or require hospitalization may be considered a serious adverse experience when, based upon appropriate medical judgment, may jeopardize the patient or subject and may require medical or surgical intervention to prevent one of the outcomes listed in this definition)

Figure 73-1. Serious adverse events.⁶

In general, signal generation is done using clinical trials data, the medical literature, knowledge of class effects, and spontaneous reports.

There are numerous challenges with spontaneous reports databases, including the fact that they are numerator based, that they are subject to many reporting biases, that they can be hard to place in population context, that they are clearly dependent on coding practices, and given the extensiveness and complexity of the coding dictionary, there can be a dilution of the signal.

Additionally, spontaneous PMSS databases were developed for regulatory reporting, and as such, differences that exist with national reporting requirements can alter the type, frequency, and number of PMSS reports that get entered into a database. Also, different companies may interpret the regulations differently, resulting in differential reporting of AEs. Furthermore, changes take place over time with respect to dictionary coding versions, with reporting standards, and with product labeling. Data migration may cause sufficient changes to take place so that data conversion and legacy data can be lost. Moreover, causality assessment is rarely consistent.

There are several factors that affect both the quality and quantity of postmarketing reports. This is sometimes referred to as the “Weber effect,” where a newly introduced drug results in a peak in postmarketing reports during the second year of being marketed.⁸ Additionally, if a drug is the first in its class, as opposed to being the second or third drug in a class to be marketed, there can be higher reporting rates of postmarketing safety surveillance reports. Furthermore, items such as publicity, whether it is from a regulatory action such as a “Dear Doctor Letter,” litigation, or coverage in the media, can all result in increased postmarketing reports.

In addition, some countries, including the United States, allow for consumers to report AEs, whereas other countries only allow health-care professionals to make such AE reports. This can result in higher numbers of reports, though the information that is received may not be completely valuable or beneficial when searching for safety signals. Consumer reports can also be increased as a result of direct consumer advertising, especially when consumer hotlines are published.

There are two key approaches to safety surveillance within spontaneous-report databases. Intra-product signaling seeks to identify changes in the overall AE pattern for specific products over time. This monitors selected AEs for a specific product over time to determine changes in the frequency and severity of AE reports. The other type of approach is the inter-product signaling which compares a specific product with all products in the database. This inter-product signaling is called data mining and essentially it determines

Very common	≥1/10 (≥10%)
Common (frequent)	≥1/100 and <1/10 (≥1% and <10%)
Uncommon (infrequent)	≥1/1,000 and <1/100 (≥0.1% and <1%)
Rare	≥1/10,000 and <1/1,000 (≥0.01% and <0.1%)
Very rare	<1/10,000 (<0.01%)

Figure 73-2. Frequency of adverse events.⁷

a disproportionality score to detect drug-event combinations that are distinct or stand out from the background rate. Both approaches should be used to systematically screen large data sets to identify and analyze drug-event associations. These are, however, hypothesis-generating approaches, to search for new, preventable, serious AEs with potential public health importance. In addition, the surveillance program should be set up to evaluate new and emerging safety signals.

Thus, it is clear that the safety surveillance process is an iterative one, which the FDA issued Guidance documents about in 2005.^{9,10,11} PMSS should evaluate multiple data sources, whether screening large regulatory databases, looking at company databases, or looking at drug-lot-related AEs for manufacturing problems. The surveillance process screens the data using both the intra-product and the interproduct methods. The object is to identify safety signals for further review, to develop a case definition, to compile a case series, and then to characterize that case series.

Subsequently, to help further characterize identified safety signals, data mining (see below) can be used to evaluate reporting rates with statistical measures of disproportionality. Additionally, targeted pharmacoepidemiologic studies, whether cohort, case-control, or other study designs, can be used to assess the risk attributed to a drug exposure. Some pharmacoepidemiologic studies can allow for the estimation of the relative risk of an outcome associated with a product and may also allow estimates of an AE incidence rate. Furthermore, surveys of health-care professionals along with the creation of patient registries can help in the evaluation of safety signals. A registry is “an organized system for the collection, storage, retrieval, analysis, and dissemination of information on individual persons exposed to a specific medical intervention who have either a particular disease, a condition (e.g., a risk factor) that predisposes [them] to the occurrence of a health-related event, or prior exposure to substances (or circumstances) known or suspected to cause adverse health effects.”¹⁰

Finally, in some circumstances, additional controlled clinical trials may be required to establish whether or not an identified safety signal is a true safety risk.

MedWatch

MedWatch is the FDA’s safety information and adverse event reporting program that has been operational since 1993. Its primary risk communication tool is its website: <http://www.fda.gov/medwatch/index.html>. MedWatch serves both health-care professionals and the medical product-using public. Medical product safety alerts, recalls, withdrawals, and important labeling changes that may affect the health of all Americans can be quickly disseminated to the medical community and the general public via the MedWatch website, thereby improving patient care.

In part, MedWatch was designed to educate health professionals about the critical importance of (1) being aware of, (2) monitoring for, and (3) reporting AEs and problems to the FDA and/or the manufacturer. MedWatch allows health-care professionals and consumers to report serious problems that they suspect are associated with the drugs and medical devices they prescribe, dispense, or use. Reporting can be done online, by phone, or by submitting a MedWatch 3500 form by mail or fax.

The main purpose of the MedWatch program is to enhance the effectiveness of postmarketing surveillance of medical products as they are used in clinical practice and to rapidly identify significant health hazards associated with these products. Its four goals are to (a) make it easier for health-care providers to report serious events, (b) make it clearer to health-care providers what types of AEs the FDA is interested in receiving, (c) more widely disseminate information on the FDA’s actions that have resulted from AE and product problem reporting, and (d) increase health-care providers’ understanding and awareness of drug- and device-induced disease.

Thus, despite AERS being a passive, spontaneous, postmarketing safety surveillance system, health-care professionals should report AEs associated with pharmaceutical products (and are required to do so for AEs associated with biologics), as this can lead to the discovery of new safety signals. The voluntary reporting form (3500) is shown in Fig. 73-3.

Adverse Events

As stated above, an AE is considered to be associated with the use of a drug in humans, whether or not it is drug-related. There are two types of AEs, Type A and Type B. While usually less serious, Type A reactions are more common, can usually be predicted, frequently are a consequence of an exaggerated pharmacologically mediated reaction, and they are dose dependent. The more serious, less frequent, Type B reactions are unpredictable and thus are often referred to as idiosyncratic or bizarre reactions. PMSS is designed to discover new Type B reactions, as the Type A reactions are usually well described from clinical trial experience. In Fig. 73-4, which describes the various sources of risk from drug products, PMSS is used to try and discern new safety signals that are described as unexpected side effects, meaning that they are not described on the label.

The FDA prides itself on protecting consumers and promoting public health. It is one of the nation’s oldest and most respected consumer protection agencies. In 1906, Congress passed the Food and Drugs Act, which was the first nationwide consumer protection law.¹² This act made it illegal to distribute misbranded or adulterated foods, drinks, and drugs across state lines. Over the past century, the FDA’s mission has been to promote and protect the public health by helping safe and effective products reach the market in a timely way, while monitoring products for continued safety after they are in use, and helping to get the public accurate, science-based information needed to improve health.¹²

Central to the FDA’s regulatory activities is deciding, based on available scientific evidence, whether a new product’s benefits to users will outweigh its risks. Since no regulated product is totally risk-free, these judgments are important. The FDA will allow a product to present more of a risk when its potential benefit is great—especially for products used to treat serious, life-threatening conditions. However, medical products need to be proven safe and effective before patients can use them.

As the initial testing of products is based on a relatively small number of users, and because variations in quality can occur in manufacturing, the FDA keeps careful watch on reports of AEs with products *after* they are marketed. The agency currently receives more than 460,000 AE reports a year, including more than 25,000 submitted directly from individuals through the MedWatch program.³ As shown in Table 73-1 and Fig. 73-5 below, the number of AE reports to the

TABLE 73-1. ADVERSE EVENTS REPORTED IN 2005

Number	Type	Reporter	%
25,325	MedWatch	Directly from individuals	5
213,537	15-day reports—serious unlabeled	Manufacturer	47
84,770	Serious labeled	Manufacturer	18
140,436	Nonserious labeled	Manufacturer	30
464,068	All	All	100

FDA has nearly tripled in the last decade.³ Additionally, about 95% of all AE reports come from pharmaceutical manufacturers, with nearly half of all AE reports being serious, unlabeled reports, which must be sent to the FDA within 15 days of a manufacturer learning of the AE.³

If this monitoring turns up a problem that needs to be corrected, the FDA can ask the manufacturer to recall the product, withdraw approval (of a drug, for example), require labeling changes, or send warning letters to physicians and other health practitioners. It is this PMSS that enhances the FDA’s ability to identify and correct risks from medical products that emerge after they are marketed.

All health-care professionals (HCPs) need to be confident about the positive benefit-risk assessment of the products they prescribe. As such, they need to be cognizant of the benefits of those products as well as be made aware as soon as possible about the various safety issues that are discovered with more widespread use of such products. It is only following regulatory approval and widespread marketing that rare AEs associated with a product will be recognized. This can lead to a situation where a safety issue is not discovered or there is a delay in uncovering a new safety signal.

As shown in Table 73-2, 11 drugs have been withdrawn from the U.S. market since 2000 due to safety concerns generated in part by a review of cumulative PMSS data.³ Thus, it is incumbent upon all HCPs to report AEs, either to the manufacturers or to the appropriate regulatory authority in their countries.

Within the medical environment related to the prescription of pharmaceutical products, risk management is a process of reducing the risks of a product and increasing its benefits in order to optimize that product’s benefit-risk ratio. The FDA views risk management as an iterative process encompassing the assessment of risks and benefits, the minimization of risks, and the maximization of benefits.⁹

Specifically, risk management is an iterative process of (a) assessing a product’s benefit-risk balance, (b) developing and implementing tools to minimize its risks while preserving its benefits, (c) evaluating tool effectiveness and reassessing the benefit-risk balance, and (d) making adjustments, as appropriate, to the risk-minimization tools to further improve the benefit-risk balance.⁹ This four-part process should be continuous throughout a product’s lifecycle, with the results of risk assessment informing the sponsor’s decisions regarding risk minimization.⁹ Regulatory agencies and pharmaceutical companies practice risk management globally; an example is the following case study.

Case Study 1. Rotavirus Vaccines and Intussusception

In August 1998, RotaShield vaccine was licensed for the prevention of rotavirus gastroenteritis in the United States.¹³ However, clinical trials had demonstrated an increased risk (though not statistically significant) of intussusception in patients receiving the vaccine. Subsequently, as part of the postmarketing surveillance program, the Centers for Disease Control and Prevention (CDC) instituted a special watch for reports of intussusception to the Vaccine Adverse Experience Reporting System (VAERS) database. By June 1999, with cases of intussusception increasingly being associated with use of the vaccine, the CDC recommended suspending the use of RotaShield. An analysis of the cases demonstrated that there was a more than 20-fold increase in the incidence of intussusception shortly after administration of the first dose of the vaccine compared to unvaccinated infants.¹³

Based on a risk-benefit analysis regarding the use of this vaccine in the United States, the recommendation for universal vaccination in the United States with RotaShield was rescinded. One consequence of this decision was that, owing to local concerns about using a vaccine withdrawn from the U.S. market, even if the risk-benefit equation in the developing world substantially favored its use, this vaccine was removed from the market.¹⁴ The manufacturer later ceased production of RotaShield.

In February 2006, the RotaTaq vaccine was licensed for the prevention of rotavirus gastroenteritis in the United States.¹⁵ This approval was only garnered after the completion of clinical trials

Figure 73-5. Post-Marketing Adverse Event Reports. (Source: CDER 2005 Report to the Nation.)

involving >70,000 infants looking at a primary safety outcome of cases of intussusception occurring. Within 42 days of any dose, there were six cases among RotaTeq recipients and five cases among placebo recipients. The data did not suggest an increased risk of intussusception relative to placebo.^{16,17}

However, the manufacturer of RotaTeq has committed to conducting another study after licensure of approximately 44,000 children, and the CDC will also conduct a large study in its Vaccine Safety Datalink Project (VSD), which evaluates vaccine safety among approximately 80,000 U.S. infants every year.^{16,17} In addition, for the first three years of licensure, the manufacturer will report cases of intussusception to FDA within 15 days of receiving them, and all other serious side effects on a monthly basis. The FDA and CDC will be closely monitoring the VAERS for any reports of intussusception. Although there is no evidence to date that RotaTeq causes intussusception, this aggressive post-licensure monitoring should enhance the FDA's ability to detect this risk.^{16,17}

Data Mining

Data mining has been defined as "The nontrivial extraction of implicit, previously unknown, and potentially useful information from data."¹⁸ However, an easier way to grasp the concept of data mining is to think

of it as a process that uses automated, analytic tools to search large databases, in order to discern useful information. The goal of data mining is to simplify the process of sorting through vast amounts of data to generate valuable and actionable information in support of a business proposition. Given the large volume of data that is collected in a variety of industries and the speed with which it is being accumulated, digging through those databases to get to the kernels of knowledge may be impossible if done manually. The development of powerful computers, along with software that contains data-mining algorithms, provide individuals with an additional tool to better do their job.

Before any data-mining algorithms or models are used on a database, it is important to first make sure that the data have been collected appropriately and that they have been organized and checked for accuracy. Subsequently, there is a choice from among multiple data-mining methods that can be used. Among these are the Multi-Item Gamma Poisson Shrinker (MGPS) algorithm, which generates an Empirical Bayesian Geometric Mean (EBGM) score (see Table 73-3), the Proportional Reporting Ratio (PRR) method, and the Bayesian Neural Network approach.^{19, 20, 21} Both the MGPS and PRR methods will generate similar drug-event combinations for further investigation when the observed number of cases with the drug-event combination is >20 or the expected number of cases with the drug-event combination is <1.²²

TABLE 73-2. RECENT SAFETY-BASED NEW MOLECULAR ENTITY WITHDRAWALS³

Drug Name	Year Approved & Withdrawn	Approved Use	Reason Withdrawn
Cisapride	1993/2000	Heartburn	Fatal arrhythmia
Troglitazone	1997/2000	Diabetes	Liver toxicity
Alosetron	2000/2000 (Remarketed in 2002 with restricted distribution)	Irritable bowel syndrome	Ischemic colitis/severe constipation
Cerivastatin	1997/2001	Cholesterol reduction	Muscle damage and kidney failure
Rapacuronium	1999/2001	Anesthetic	Severe breathing difficulty
Etretinate	1986/2002	Psoriasis	Birth defects
Levomethadyl	1993/2003	Opiate dependence	Fatal arrhythmia
Rofecoxib	1999/2004	Pain relief	Heart attack/stroke
Valdecoxib	2001/2005	Pain relief	Skin disease
Natalizumab	2004/2005 (Remarketed in 2006 with restricted distribution)	Multiple sclerosis	Brain infection
Pemoline	1975/2005	ADHD	Liver failure

TABLE 73-3. EMPIRICAL BAYESIAN GEOMETRIC MEAN (EBGM) TERMS

• “N” is the observed number of cases with the combination of items.
 • “E” is the expected number of cases with the combination. Calculated as:

$$E = \frac{\text{Observed \# cases with DRUG}}{\text{Total \# cases}} \times \frac{\text{Observed \# cases with EVENT}}{\text{Total \# cases}} \times \text{Total \# cases}$$

RR	Relative Reporting Ratio. (The same as N/E.) Observed number of cases with the combination divided by the expected number of cases with the combination. This may be viewed as a sampling estimate of the true value of observed/expected for the particular combination of drug and event.
EBGM	Empirical Bayesian Geometric Mean. A more stable estimate than RR; the so-called “shrinkage” estimate.
EB05	A value such that there is less than a 5% probability that the true value of observed/expected lies below it.
EB95	A value such that there is less than a 5% probability that the true value of observed/expected lies above it.
90% CI	The interval from EB05 to EB95 may be considered to be the “90% confidence interval.”

Data from the WebVDME User Guide.²³

EBGM is a statistical measure of disproportionality, comparing the observed and expected reporting frequency within a database. The determination of the expected reporting frequency assumes complete independence of cases associated with either a drug or an event.²³ Thus, in a hypothetical database of 100 cases, if Drug Z represented 20 cases in the database and there were 10 cases of hepatic failure, the expected reporting frequency would be 20/100 (probability of Drug Z) × 10/100 (probability of hepatic failure) × 100 cases (total database size) = 2 expected cases. If the observed number of drug-event cases was 8, then the relative reporting ratio (RR) would be 8/2 (N/E) = 4 and the EBGM would be about 4, depending on the amount of “shrinkage” that occurs based on the model.

The larger the number of AE reports for a particular drug (for a drug that has been on the market for a long time and may have a lot of AE reports in the database) and/or the larger the number of cases of a particular AE (a common AE), the larger the expected “E” will be. The larger the “E,” the smaller the EBGM. A new drug or a very rare AE would represent lower proportions of the total database and thus the expected “E” would be lower.

Data mining is used in the review of safety surveillance data to detect strong, consistent associations that occur at higher than expected frequencies. Data mining usually uses AE safety databases that lack denominator data. It detects frequency of drug-event combinations in postmarketing reports. It also determines the relative frequency of drug-event combinations for drug X relative to any other drug. Data mining attempts to quantify the strength of a potential drug-event association, whereas signal scores are calculated and represent the relative reporting rate for AEs.^{10,22} It is important to stress that an elevated-signal score is a measure of statistical association and not a causal association between an AE and a drug.

Data mining does not equal “data dredging.” It is a systematic screening for drug-event combinations that are being reported disproportionately. It is essentially a quantitative signal detection method. The data-mining method that is currently being used widely in the United States, by both the FDA and the pharmaceutical industry, is the MGPS, which adjusts for the multiplicity of drugs and events per record.²² The MGPS generates an EBGM, which is an estimate of the relative reporting ratio. It is the ratio of the observed over the expected counts. A 90% confidence interval is calculated around the EBGM.

Both of the FDA’s postmarketing safety surveillance databases, the AERS and the VAERS, are used in safety signaling and data mining, along with the World Health Organization’s AE database. The FDA’s databases contain all U.S. reports along with serious, unlabeled reports from outside the United States. The WHO database contains reports from more than 65 national authorities, including the FDA’s database.

The FDA’s Spontaneous Reporting System (SRS) was in operation from 1968 to October 1997. The reports were transitioned to the AERS, which has been used from October 1997 to the present. A publicly released version can be purchased on a quarterly basis. It is a passive surveillance system wherein direct volunteer reporting accounts for about 5% of reports received. Ninety-five percent of reports in the FDA’s postmarketing safety surveillance database come from pharmaceutical companies, as they are mandated by regulations to report AEs that they receive. The combined SRS+AERS database currently contains more than 2.7 million reports and is growing rapidly, adding 460,000 reports annually. The number of reports has nearly tripled in the last 10 years, and because the FDA is interested in serious, unlabeled reports, these have grown as a percentage of the total number of reports submitted to the FDA.

Some of the limitations of the FDA’s AERS database are a substantial lag time, substantial underreporting, and increased reports as a result of stimulated reporting. Additionally, there can be biased reporting due to a number of factors, such as publicity and regulatory letters, and because of the differential interpretation of the reporting regulations, reports may differ by country and company. Additionally, duplication, quoting errors, variable historical data, poor quality of information, and changes over time are all limitations to information recorded in the AERS database.

The data-mining output is similar to the safety surveillance output in that hypotheses are generated and these may need to be evaluated with additional quantitative analyses as appropriate using industrial databases, stimulated reporting, enhanced surveillance, or the conduct of new epidemiological studies. An example of data mining is given in Case Study 2.

Case Study 2. Hepatic Failure and Thiazolidinediones

► INTRODUCTION

In this case example, the FDA’s SRS+AERS database, through the end of the third quarter 2005, was data mined to determine the lower 95% confidence interval limit of the Empirical Bayesian Geometric Mean scores (denoted as EB05), a measure of disproportionality, for hepatic failure associated with the use of thiazolidinediones. The drugs of interest were pioglitazone, rosiglitazone, and troglitazone. The event of interest was hepatic failure.

EB05 Guideline

A guideline that has been used for identifying a signal score for pair-wise combinations as higher-than-expected is an EB05 ≥2.

Figure 73-6. The number of cases of hepatic failure in the AERS database associated with the thiazolidinediones.

This criterion ensures with a high degree of confidence that, regardless of count size, the particular drug-event combination is being reported at least twice as often as it would be if there were no association between the drug and the event.²²

Data Source

This report contains the most currently available, cumulative data from the FDA’s SRS+AERS database, through the end of the third quarter of 2005. This database contains approximately 2.7 million patient records. It includes branded and generic prescription products that are marketed in the United States. The database contains both U.S. reports (including consumer reports) and a subset of non-U.S. reports (AEs that are both serious and unexpected, that is, not contained in the U.S. package insert).

All data were retrieved utilizing Lincoln Technologies Web-VDME 5.2, which is a data-mining application used in PMSS to support product risk management. Unless specified, individual case reports were not specifically checked for duplicate reporting. However, the vendor does implement an algorithm to screen the database for duplicates as part of standard data cleansing. Searches were conducted based on “drug mentions within a report.” This means that all case reports where the selected drug is classified as either a concomitant or suspect drug are included.

Data Output

Figures 73-6 through 74-9 show the frequency and EB05 scores, both total and cumulative by year, of hepatic failure associated with the use of the thiazolidinediones. AEs in the FDA database are codified using

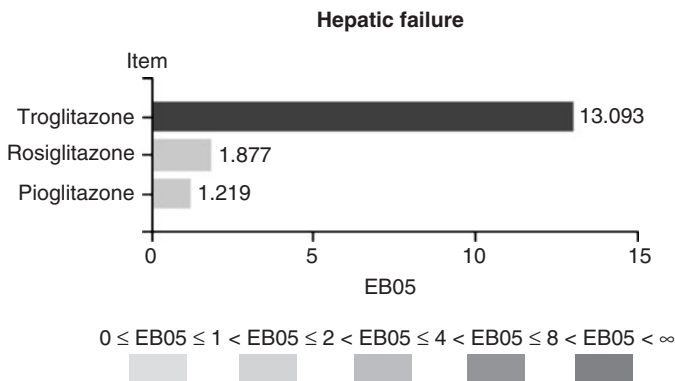

Figure 73-7. The disproportionality score (EB05) of cases of hepatic failure in the AERS database associated with the thiazolidinediones.

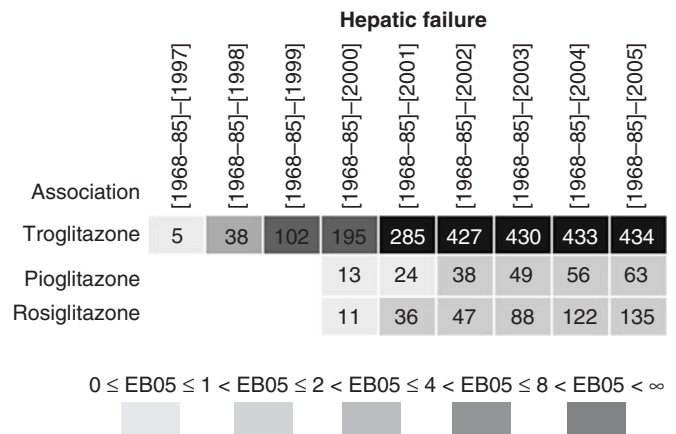

Figure 73-8. The cumulative annual number of cases of hepatic failure in the AERS database associated with the thiazolidinediones.

the MedDRA dictionary. It is important to note that a single case report may contain more than one preferred term.

The color of the bar represents a measure of disproportionality, that is, “how disproportionate” the observed report frequency of the AE-drug combination is compared to what might be expected, if all AE-drug combinations in the database were independent. The color scale ranges from a light grey, which represents low disproportionality (that is, the observed frequency is not substantially different from the expected) while the darker grey represents AE-drug combinations with higher measures of disproportionality.

Interpretation

These figures demonstrate the increased frequency and EB05 scores, both total and cumulative by year, of hepatic failure associated with the use of the troglitazone. While all the thiazolidinediones are associated with reports of hepatic failure, and this is a well-recognized AE associated with the use of thiazolidinediones, both the frequency (434) and the EB05 (13.09) noted with troglitazone were significantly higher than those of the other thiazolidinediones. This suggested an association between troglitazone and hepatic failure that required further investigation, with possible regulatory action.

Withdrawal

An evaluation of the FDA’s SRS+AERS database, through the end of the third quarter of 2005, showed that the frequency of reports and EB05 scores were significantly higher for hepatic failure associated with the use of troglitazone, compared to the other thiazolidinediones. However, even based on the information available back in March 2000, the FDA announced that troglitazone, which was approved in January 1997, was being voluntarily withdrawn from the U.S. market by its manufacturer because of reports of hepatotoxicity.

SUMMARY

PMSS uses both intraproduct and inter-product signaling to detect and evaluate new safety signals. The object is to identify safety signals for further review, to develop a case definition, to compile a case series, and then to characterize that case series. Inter-product signaling, also called data mining, does not supplant traditional safety surveillance methods. Instead, it supplements these methods and allows a systematic identification and evaluation of potential safety signals.

Figure 73-9. The cumulative annual disproportionality score (EB05) of cases of hepatic failure in the AERS database associated with the thiazolidinediones.

The interpretation of data-mining results needs the expertise of safety reviewers and medical officers to analyze and interpret the data appropriately. Data-mining signals by themselves are not indicators of problems, but are indicators of possible problems. Moreover, caution must be exercised with any comparison of disproportionality ratios across different products, for example, comparison with competitor drugs, because of the various limitations that exist when making these kinds of comparisons.

Additionally, pharmacoepidemiologic studies, whether cohort, case-control, or other study designs, can be used to assess the risk attributed to a drug exposure. Furthermore, the creation of registries along with surveys of health-care professionals can help in the evaluation of safety signals. In some circumstances, additional controlled clinical trials may be required to establish whether or not an identified safety signal is a true safety risk.

Finally, all safety signals should be evaluated recognizing the possibility of false positives. In addition, the absence of a signal does not mean that a problem does not exist.

The American Health-Care System: Structure and Function

Glen P. Mays • F. Douglas Scuthfield

This chapter examines the mechanisms through which health services are organized, financed, and delivered in the United States. Collectively, these mechanisms function as a complex and adaptive system in which purchasers, providers, consumers, and regulators of health services interact in ways that are not always coordinated or expected. These actors and their actions evolve over time in response to each other and to changes in their external environment, including changes in medical knowledge and technology, changes in the political and economic climate, changes in social norms and values, and changes in population health and disease processes. Understanding the major actors within the nation's health system and the ways in which they interact provides a basis for managing and improving the performance of the system in terms of the accessibility, quality, and cost of health services.

► HEALTH CARE AS A COMPLEX AND ADAPTIVE SYSTEM

A universal, national system of health insurance and health care does not exist in the United States as it does in many other industrialized countries. This fact often leads observers to conclude that the United States lacks an organized and coordinated health system. Nevertheless, a functioning health system does exist in the United States, one that relies on a combination of governmental action, market forces, and voluntary charitable initiatives to deliver health services to populations in need. Consequently, the U.S. health system operates through the complex and changing interactions of multiple public sector and private sector actors.¹

Concepts from general systems theory are useful in understanding the structure and operation of the nation's complex health system. These concepts stress the importance of identifying the major actors within a system, the resources on which these actors depend, the mechanisms through which these actors interact, and the principal external forces that affect these actors.² The actors within the nation's health system can be classified generally as health-care purchasers, providers and other suppliers, consumers, and policy-makers/regulators. The resources used by these actors include funding, personnel, facilities, technology, and information. These resources are organized by providers and suppliers through their interaction with purchasers and policy makers to produce services for consumers.

The health system, like all systems, is dynamic with many feedback loops among purchasers, providers, consumers, and policy makers. This allows for continual change within the system and therefore continual change in the system's performance. Because of the interdependencies among different actors, efforts to modify one component of the system are likely to affect other components. As a consequence, health interventions

and reform efforts may have both direct and indirect effects on the health system, leading to both intended and unintended outcomes. For example, efforts to expand the array of health services covered by private health insurers may have indirect and unintended effects on the number of consumers without health insurance coverage, which in turn may affect the volume of care delivered through hospital emergency departments.

The nation's health system is highly sensitive to the economic, political, social, demographic, and technological environments in which it operates. This external environment heavily influences the structure and operation of the system and its evolution over time. For example, the changing demographic composition of the United States, with an aging population and the growing size of racial and ethnic minority groups, influences the types of services provided by the health system and the geographic location of these services. Changes in the economy also dramatically impact the system, with economic growth and job creation leading to heightened demand for private health insurance and health care while economic decline and job loss leading to shrinkage of the private health insurance market and increased demand for publicly provided insurance and health care.

The changing nature of disease and health risk also shapes the health-care system. In the early 1900s the leading causes of death were infectious diseases, many of which were linked to environmental concerns such as water quality, waste disposal, vector control, and food safety. A century later, the major causes of death are largely chronic diseases such as cardiovascular disease, cancer, stroke, and respiratory diseases that affect older populations and are linked to lifestyle issues including nutrition, physical activity, and tobacco use. As a consequence, today's decision makers in health policy and administration must emphasize interventions that support health behavior change and chronic disease management to address contemporary health issues, unlike the decision makers of previous generations who focused on environmental interventions such as water purification and sewage disposal.

Even since the 1950s dramatic changes have occurred in the patterns of disease and illness to which the health system must respond.³ Death rates from cardiovascular disease and stroke have declined while those from many cancers have increased. Overall, reductions in death rates have resulted in increasing longevity, which in itself has generated greater economic and political stress on the health system in programmatic areas such as Medicare, retiree health insurance coverage, and long-term care.

The nation's health system contains a multitude of subsystems that govern different types of health services for different population groups within society. These subsystems include safety-net health-care systems that serve the uninsured and others who lack access to mainstream medical care providers, the mental health and substance abuse care systems that deliver specialized services to treat populations

with these conditions, and long-term care systems that deliver a variety of health and support services to population groups who are limited in their ability to perform activities of daily living. While these different subsystems are highly interactive and interdependent, the degree of formal coordination across these subsystems varies and is often quite limited.

► **HEALTH SYSTEM PERFORMANCE AND OUTCOMES**

From a societal perspective, the universal goal of any health system is to ensure access to high quality health services to all members of society for as little cost as possible. Three key areas of health system performance therefore involve the accessibility, quality, and cost and efficiency of health services produced by the system. A fourth area of performance involves equity within the system, as indicated by the extent to which different population groups within society experience the different levels of accessibility, quality, and cost/efficiency within the system. In practice, these four dimensions of health system performance are highly interdependent. Efforts to increase access to care within the health system may lead to higher costs, while efforts to constrain health-care costs may have adverse effects on access and quality. Efforts to optimize health system performance in all four areas simultaneously have proven exceedingly difficult due to the complex nature of the health system.

Historically, actors within the U.S. health system have focused on different elements of health system performance at different points in time. During the 1960s, public concerns about access to care led to the development of new public programs such as Medicare and Medicaid to provide health care for population groups that faced particularly difficult barriers to care, including the elderly, disabled, and poor. The rapid escalation in national health-care spending during the 1970s and 1980s led both policy makers and private purchasers to focus on cost containment during this period, resulting in the increasing use of managed care strategies in both public sector and private sector health insurance programs. Health-care spending slowed during the 1990s, but growing public dissatisfaction with managed care strategies and the limits they place on consumer choice and provider autonomy led to a reduction in the use of these strategies, at least in the private sector.

Since the beginning of the twenty-first century, growing public awareness about gaps in the quality of health care has led to an increasing focus on quality improvement strategies in the public and private sectors, with both public programs and private insurers and providers experimenting with new ways of measuring the quality and safety of

health care and creating incentives for providers to improve their adherence to evidence-based standards of care.⁴ A return to large annual increases in health-care spending has also caused both public and private purchasers to focus again on cost-containment efforts, leading to experimentation with new “consumer-driven” health insurance designs that require consumers to assume more responsibility for balancing issues of cost, choice, and quality when selecting health insurance coverage and health-care providers. Some actors within the health system also have begun to give increased attention to issues of equity and to disparities in health-care accessibility, quality, and cost across racial, ethnic, and socioeconomic subgroups within society.⁵ While modest progress has been made in some areas, the United States continues to face difficult challenges in improving access, quality, efficiency, and equity within the health system.

► **COMPONENTS OF THE SYSTEM**

The next few sections examine the major components of the U.S. health system as defined by the major actors within the system and the resources used by these actors. The major actors profiled here include health-care providers such as hospitals and physician organizations, health-care purchasers including private health insurance arrangements as well as public insurance programs, and major health policy and regulatory bodies that govern various components of the system. In examining the resources used by these different actors, we focus on financial resources as well as the human resources represented within the health profession’s workforce. Although not every component of the system is addressed in detail, we examine the major determinants of health system performance and the key drivers of health system change.

Health-Care Providers

Hospitals

Hospitals remain the predominant institutional health-care provider in the U.S. health system despite significant changes over time in the organization of care within the hospital and the types of care delivered by these institutions. Hospital-provided health care continues to account for the largest single share of national health-care spending, representing approximately 31% of the nation’s total health-care expenditures in 2003 (Fig. 74-1).⁶ However, the continued growth of health care delivered in physician offices and other outpatient settings, along with the growing importance of outpatient prescription drugs, has chipped away at the historical pre-eminence of hospital-based care in recent years.

Figure 74-1. National health-care spending by type of care, 2003. (Source: Centers for Medicare & Medicaid Services, Office of the Actuary, National Health Statistics Group.)

Historical Origins. The hospital has not always been a highly regarded component of the health-care system. The hospital had its origins in the religious orders of medieval times that provided care for the poor. In the United States, the earliest hospitals were the almshouses and poor houses, a legacy of the British tradition. These institutions were dark and often unsanitary facilities, unappealing and to be avoided if at all possible. Only people without homes and families received health care in these facilities; anyone of means was cared for in their home by their family. The first modern U.S. hospital was the Pennsylvania Hospital, founded in Philadelphia in 1751. Slowly throughout the 1800s, other large facilities were built, such as the Massachusetts General Hospital in Boston. It was not until the middle 1900s, however, that the modern hospital became a central component of the health-care system.

The rise of the contemporary hospital resulted from a number of significant changes in the way medicine was practiced. Advances in surgical technology and practice during the mid- and late 1800s allowed the hospital to become a locus for surgical procedures. The discovery of anesthesia in the 1850s made possible more complicated and lengthy procedures that previously could not be performed because of the pain associated with them. Moreover, the discovery of sepsis and antiseptic techniques during the late 1800s allowed clinicians to understand and reduce the risk of postoperative infection. During this same period, the new science of microbiology ushered in a new understanding of disease and its causes. New technologies to assist in the diagnosis and treatment of patients developed rapidly during this period, including the discovery of the electrocardiograph and the x-ray.

The early clinical technologies and laboratories were primitive by today's standards and were both large and expensive. It made sense to provide a central place, the hospital, where all physicians could have access to these facilities. To this day, the hospital continues to serve as a central repository of advanced technology for the medical community, although increasingly, medical technologies are being distributed to physicians' offices and other outpatient settings.

The development of the nursing profession was critical to the emergence of the modern hospital. Prison inmates often provided what nursing care was available in the hospitals of the early 1800s. During the Crimean War of the 1850s in Europe, Florence Nightingale demonstrated the advantages of professional nursing services on mortality among wounded soldiers. She later developed nurse training programs in Britain, and hospitals in the United States followed suit. The availability of well-trained nursing personnel made hospitals much safer and more effective health-care facilities.

Improvements in physician training also facilitated the development of the modern hospital. Before 1900, medical education in the United States was seriously deficient, with most physicians being trained in proprietary apprenticeships that emphasized lectures but little exposure to patient care. The development of professional licensure helped to transform American medical education by requiring licensed physicians to graduate from an approved medical school and pass a standardized examination. American medical schools significantly improved their educational programs in response to Abraham Flexner's 1910 review of medical education in the United States and Canada. The Flexner Report, which was funded by the Carnegie Foundation at the urging of the American Medical Association, identified features of the most effective medical schools, including (a) requiring students to have college degrees before admittance; (b) using a 4-year curriculum with 2 years devoted to basic sciences and 2 years devoted to full-time clinical instruction; (c) using faculty that are actively engaged in medical research; and (d) educating medical students and medical residents in a teaching hospital that is owned and operated by the university. The Flexner Report and the educational standards it triggered helped to establish academic and teaching hospitals as leading institutions within the nation's health-care system, while promoting tighter relationships between physicians and hospitals.

The proliferation of health insurance during the latter half of the twentieth century also fueled the development of the modern hospital. Advances in hospital-based technology and professional nursing care made hospital stays increasingly costly for patients. Private health

insurance emerged during the Great Depression to assist individuals with limited incomes in paying for this care, and it grew rapidly after World War II as an employee benefit. The advent of public insurance programs during the 1960s, especially Medicare and Medicaid, provided additional financial support for hospital services for some populations not covered by employment-based insurance. These public programs also pressed for the development of quality review processes and accreditation programs that could offer the government as well as private purchasers assurance that the facilities receiving their payments were delivering care consistent with accepted standards of care. Accreditation by a recognized body such as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) soon became a requirement for hospital participation in Medicare.

Types of Hospitals. Modern hospitals can be classified by a variety of characteristics including length of stay, type of service, ownership, number of beds, and involvement in medical education and research (Table 74-1). There are short-term and long-term hospitals with the dividing point being an average length of stay of 30 days. Hospitals can also be characterized by type of service, with the most common type of facility being the general hospital that provides a broad array of acute-care services for a broad array of population groups. In contrast to the general hospital, specialty hospitals focus on providing a narrower scope of services for more tightly defined population groups. Children's hospitals, for example, specialize in delivering care to address the health conditions affecting infants, children, and adolescents, while women's hospitals focus on providing obstetrical and gynecological care and other services tailored to women's health-care needs. Psychiatric hospitals, which specialize in delivering inpatient mental health care, represent one of the oldest forms of specialty hospitals in the United States, although their numbers have declined since the 1960s due to improvements in prescription drug therapies and the efforts of federal and state governments to shift more mental health patients to community-based settings. Specialty hospitals for respiratory diseases and eye diseases also have existed in the United States for many decades.

More recently, a variety of other types of specialty hospitals has emerged in the United States in response to the growing demand for specialty care and the lucrative payments that public and private health insurance programs offer for these services. These specialty facilities include heart hospitals that specialize in cardiac services and procedures, orthopedic hospitals that specialize in joint repair and replacement services, and cancer hospitals that specialize in advanced cancer care. Many of these specialty facilities have been developed at least in part by groups of specialty physicians seeking more control over their practice environments and more revenue in the form of facility payments for inpatient care. General hospitals have raised objections to the proliferation of these specialty hospitals, arguing that they skim off only the most profitable patients and hospital services, thereby compromising the ability of general hospitals to deliver equally important but less profitable services such as trauma and burn care and to provide uncompensated care to the uninsured. Specialty hospitals, in turn, argue that they are able to improve quality of care and health outcomes by focusing on the delivery of a narrow scope of services to high volumes of patients with similar conditions. In response to this debate, the U.S. Congress in 2003 placed a moratorium on the approval of new specialty hospitals for participation in the federal Medicare program until the effects of these new facilities on the health-care system can be determined.

Nearly a third of the nation's short-stay hospitals are public facilities owned by federal, state, or local governments. These facilities typically serve population groups that lack access to private hospital care. Federal hospitals serve designated groups of people who are eligible for care based on some type of federal entitlement program. For example, Indian Health Service hospitals serve members of federally recognized tribes, Veterans Affairs hospitals serve defined categories of eligible veterans, and Department of Defense hospitals serve active duty military personnel. By contrast, most state-owned hospitals historically have focused on providing care for

TABLE 74-1. U.S. SHORT-STAY HOSPITALS, BEDS, AND OCCUPANCY RATES 1980–2002

(Copyrights 1976, 1981, 1991–2004) as published in National Center for Health Statistics, *Health United States, 2004*. Hyattsville, MD: U.S. Public Health Service, 2005.

the mentally ill. In recent decades many of these state facilities have been closed or scaled back as the care for many mental health disorders has shifted to outpatient settings. Many states continue to own and operate university hospitals that provide advanced medical care and support the medical education and research that is conducted by state-sponsored medical schools and academic health centers.

Local government hospitals are the predominant type of public hospital in the United States, and include facilities owned by cities, counties, and special governmental districts. These facilities typically serve as key safety net providers in their communities by caring for disproportionate numbers of uninsured and publicly insured patients who lack access to private hospitals and physicians. Steady growth in the

number of Americans without health insurance coverage in the United States has created heightened financial difficulties for public hospitals in recent decades. In many cases these hospitals are less able to upgrade their facilities, purchase new medical technologies, and expand clinical capacity than their privately owned counterparts. As a consequence, these public hospitals face mounting difficulties in attracting patients with private health insurance or Medicare coverage, which further limits their sources of revenue. In recent decades, financial and operational difficulties have caused public hospitals in some communities to close, thereby forcing the surviving private hospitals to assume responsibility for serving the uninsured and publicly insured patients.

Another type of local hospital, the public authority hospital, is financed in part by local tax dollars but operates more like a private organization than a governmental agency. These hospitals are financed by a special hospital assessment district similar to a water or fire district, and are governed by a board that may include local elected officials or their appointees. These hospitals are often exempted from administrative rules that govern local government agencies such as hiring and purchasing requirements, thereby giving the hospitals additional flexibility in their operations.

Private not-for-profit hospitals are the most common type of short-stay hospital in the United States, accounting for more than half of all hospital beds in the nation. These hospitals are organized by community, religious, or philanthropic organizations and receive exemptions from federal, state, and/or local taxes in exchange for the community benefits they generate. Any financial earnings generated by a not-for-profit hospital are reinvested in the institution rather than paid out to owners or investors. Some of these hospitals function as safety-net hospitals by pursuing a religious or charitable mission to serve the uninsured and other disadvantaged populations who lack access to mainstream medical care providers. Other not-for-profit hospitals serve a broad cross-section of the population residing in their service area but position their services and facilities to be especially attractive to those populations with insurance, thereby ensuring the institutions' financial viability. In several states, these facilities are now required to justify their tax exempt status by reporting the amount of charity care and other community benefits they produce each year.

Proprietary hospitals have been a part of the nation's health-care system since the early 1900s but they account for only a small percentage of all hospital beds. During the early 1900s, prominent physicians developed proprietary hospitals for their own use, but in recent decades, physician-owned general hospitals have declined in prevalence. More recently, investor-owned hospital corporations emerged beginning in the 1960s and steadily increased the number of hospitals they own and operate. Like other investor-owned corporations, these hospitals are owned by stockholders. Proprietary hospital corporations grew rapidly in the 1980s and 1990s through a combination of building new hospitals, buying existing hospitals, and securing contracts to manage independently owned hospitals. Proprietary hospital corporations have faced obstacles to growth in recent years due to the Federal Trade Commission's increased scrutiny of hospital acquisitions for their potential anticompetitive effects. Additionally, several of the largest corporations have faced federal and state lawsuits concerning their billing practices and physician compensation arrangements, resulting in large fines. Physician-owned specialty hospitals represent another type of proprietary hospital that has emerged in recent years, but their impact on the health-care system remains unclear at this point.

Partly in response to the growth of proprietary hospital corporations, not-for-profit multihospital systems have developed and grown rapidly in recent decades. These systems bring multiple not-for-profit hospitals together under common ownership and/or management in order to improve the competitive position of the hospitals, realize economies of scale in purchasing and operations, strengthen negotiating leverage with health insurers, and improve coordination of services across multiple facilities and care settings. Many of these hospital systems are local in their reach and include multiple hospitals operating within a single geographic region or state. Other systems include hospitals in multiple regions across the country. In addition to

hospitals, these systems often include other types of health-care institutions such as home health agencies, nursing facilities, outpatient centers, and physician practices. Over the past two decades, large numbers of independent hospitals have consolidated into these multihospital systems, at least partly in response to the growth of managed care and the desire to strengthen their negotiating leverage with health insurers.

Hospital Structure. There are three primary sources of authority in the hospital: the governing board, the administration, and the medical staff. The governing board has the ultimate responsibility for the hospital by establishing policy, hiring the chief administrator, and appointing members of the medical staff leadership. By virtue of these responsibilities, the board is ultimately accountable for quality of care within the hospital. As a result, many hospitals have added members of the medical staff to the board and most have increased their investments in quality assurance activities. In some hospital systems and corporations, hospital governance is the responsibility of the governing board for the parent company. The mutual dependence between the governing board and the medical staff is formalized by the governing bylaws for the medical staff. These bylaws, which are typically established by the hospital board, define the rules and regulations governing physician interaction with the hospital. Election and duties of the medical staff officers and committees and processes for awarding and maintaining admitting privileges are defined by these bylaws.

Challenges Facing the Hospital. The key pressures facing hospitals have evolved considerably over the past decade. Hospitals in many communities enjoy a stronger negotiating position relative to health insurers today than they did a decade ago, due in part to consolidation in the hospital industry and continued growth in demand for hospital services. This has allowed many hospitals to secure higher payments from private health insurers, thereby helping them to accommodate the rising costs of serving uninsured patients and those covered by public programs such as Medicaid and Medicare. These same developments—hospital consolidation and growth in demand for care—have helped to reduce or eliminate problems of excess hospital capacity and overbedding that were present in many communities during the 1980s and 1990s. The closure of underutilized hospitals has helped to eliminate excess capacity in some communities, as have the efforts of hospitals to convert unused bed capacity into new and upgraded facilities such as private rooms and outpatient clinics.

After more than a decade of stagnant or declining hospital admissions and bed capacity, many hospitals serving urban and suburban communities are now confronting growing demand for care and bed shortages (Table 74-2). These problems are attributable to a combination of factors including population growth, the aging of the American population, and a reduction in insurers' use of aggressive managed-care techniques to limit hospital admissions and reduce lengths of stay. An ongoing shortage of nurses and other hospital personnel has exacerbated these constraints by limiting the ability of hospitals to staff all of their licensed beds. As a result, many hospitals are experiencing periodic overcrowding in their emergency departments as patients wait for inpatient beds to become available, leading these facilities to divert ambulances to other available hospitals.⁷

Hospitals continue to be challenged by technological developments and competitive dynamics that lead services formerly delivered in hospital settings to be delivered in alternative, outpatient settings. These developments have led to expanded hospital roles in outpatient service delivery (Table 74-2). However, these developments also have brought physicians into competition with hospitals for the delivery of an expanding array of services. Physicians are developing the capacity to deliver a variety of diagnostic and surgical procedures in their offices, including sophisticated imaging and laboratory testing, rather than referring patients to hospital-based facilities for these services. Physicians are also continuing to develop ambulatory surgery and diagnostic centers that serve as lower-cost alternatives to hospital-based facilities for performing a variety of outpatient procedures.

Some physicians have developed specialty hospitals that compete directly with general hospitals in the delivery of specialized inpatient services. These developments threaten to redirect important sources of revenue from hospitals to physician practices and change the historically symbiotic relationships that have existed between hospitals and physicians.⁸ In some cases, hospitals have created joint ventures with

physicians for the development of these new facilities in order to retain some ownership and control over the activities. In other cases, hospitals have revoked the admitting privileges of physicians who invest in these types of facilities in order to discourage their development and growth. In still other cases, hospitals have pressured health insurers to exclude physician-owned facilities from their provider networks.

Ambulatory Care Providers

Ambulatory care includes a wide range of health professionals, settings, and services for the “walking” or noninstitutionalized patient. Ambulatory care providers play a central role as the initial and continuing point of contact with the health-care system for most people. Collectively these providers offer preventive, screening, and diagnostic services as well as ongoing treatment services and follow-up care for patients that do not require inpatient or residential care. These providers also serve as brokers by referring patients to more specialized medical services available in hospitals and other institutional settings.

Ambulatory health care includes the following major types of personal health-care services:

- **Preventive care** is designed to avoid the onset and/or progression of disease and injury. Examples of these services include vaccinations that prevent the occurrence of infectious diseases, as well as screening tests for cancer or high blood pressure that enable the early detection and treatment of diseases or risk factors in order to forestall disease progression and complications. Services designed to prevent the occurrence of disease altogether are defined as primary prevention activities, whereas services aimed at early detection to limit and/or reverse the progression of disease are defined as secondary prevention activities. The preventive services delivered in ambulatory care settings are typically referred to as *clinical* preventive services and may be performed in many different settings including physician offices, community health centers, worksite health clinics, hospital outpatient clinics, pharmacies, mobile health clinics, and even health fairs. These services may be performed by physicians or by a variety of other health professionals including nurse practitioners, physician assistants, clinical pharmacists, and nurses.
- **Primary care** focuses on the diagnosis, treatment, and management of routine, nonemergent health conditions. Primary care physicians assume primary responsibility for the delivery of these services, although physician extenders such as nurse practitioners and physician assistants also play major roles in the delivery of these services in many settings. Primary care physicians are commonly defined to include those physicians specializing in general practice, family medicine, general internal medicine, pediatrics, and obstetrics/gynecology. Physicians practicing in other specialty areas, particularly internal medicine subspecialties such as cardiology and rheumatology, may also deliver primary care services to patients under their care. Individuals with some form of health insurance typically receive most of their primary care in physician office settings, while uninsured individuals and those who face other barriers in accessing mainstream physician practices often receive primary care from alternative settings such as community health centers, hospital outpatient clinics, urgent care centers, and hospital emergency departments.
- **Secondary care** focuses on the diagnosis, treatment, and management of complex health conditions that require specialized clinical knowledge and skills. Most secondary care is provided by specialty physicians in physician office settings or in more specialized ambulatory facilities such as imaging and surgery centers or hospital outpatient clinics. Primary care physicians play key roles in identifying the need for secondary care and referring patients to specialty physicians for consultation, diagnosis, and treatment. The secondary care provided by physician specialists also serves as an entry point for tertiary care and quaternary care services—the most complex types of medical services that are often provided on an inpatient basis at advanced medical centers.
- **Rehabilitative care** is designed to restore and preserve function in patients affected by disease and injury. These services may be delivered in both inpatient and ambulatory care settings. Patients who are hospitalized for care may receive rehabilitation services in inpatient settings such as rehabilitation units and skilled nursing facilities immediately following their

hospital admissions. Patients may also receive rehabilitative services in ambulatory settings such as hospital outpatient clinics, outpatient therapy centers specializing in physical, occupational, and/or speech therapy, and in the home through home health-care providers. Rehabilitative care is commonly delivered by a variety of ancillary therapists and therapy assistants with more complex and advanced care being managed by physicians specializing in physical medicine and rehabilitation.

- **Long-term care** is designed to provide assistance to patients with health-related impairments in their ability to perform routine activities of daily living such as bathing, dressing, transferring, walking, preparing meals, and taking medications. These services may be delivered in both institutional and ambulatory care settings. Institutional settings for long-term care include nursing homes, assisted living centers, and board and care facilities. Ambulatory providers of long-term care include home-care providers, visiting nurses associations, adult day care centers, and respite care programs. These ambulatory services are designed to enable patients to remain living at home as an alternative to more costly institutional care settings.

In addition to these personal health services, public health services are also provided to both institutionalized and noninstitutionalized populations with the goal of reducing the incidence of disease and injury. These population-based services include activities to protect the safety of water and food supplies, identify and assess community health needs, investigate health threats, and educate the public about health issues. These services, which are discussed in more detail in the following chapter, generally do not involve the direct provision of services to individuals and therefore are not typically considered part of the ambulatory health-care system.

Office-Based Ambulatory Care. Most of the ambulatory care delivered in the United States is provided in office-based practice settings (Table 74-3). Although hospital-based settings deliver significant amounts of ambulatory care, the predominant source of this care is the physician’s office, including solo physician practices, partnerships, and group practices. Physicians provide a broad array of services in their offices, including routine examinations, evaluation and management services, diagnostic services that include imaging and laboratory tests, counseling, and surgical procedures. The scope of services provided in physicians’ offices has been expanding over time, particularly in the areas of diagnostic testing and surgical procedures where advances in medical technology have allowed these services to move from inpatient to outpatient settings.

A solo practice consists of a single physician practicing alone in an office-based setting, whereas a partnership practice includes two physicians practicing together. A group practice is typically defined as the combination of three or more physicians practicing together in an office-based setting. True group practice involves the sharing of revenue and expenses, staff, medical records, and other resources and may involve sharing responsibilities for night and weekend on-call duties and hospital rounding. Some physicians share only physical space or staff, but this arrangement does not constitute a formal group practice.

Most ambulatory care services historically have been provided by physicians in solo office-based practice. This arrangement offers the physician the greatest degree of professional and organizational independence and the ability to be self-employed. Although solo practitioners still account for a large share of ambulatory care, group practice and hospital-based practices are expanding dramatically. A variety of factors have led physicians to seek alternatives to solo practice in recent years, including rising practice expenses and the cost of purchasing new office-based medical technologies, the growth of managed care and the desire to develop practice arrangements that enhance physician negotiating leverage with health insurers, and changing physician lifestyles and the desire to practice in settings that offer less demanding work schedules.

Some of the earliest group practices in the United States were started by industries that needed to provide care to employees in rural

areas where medical care was unavailable. The Mayo Clinic in Rochester, Minnesota, was the first successful nonindustrial group practice. Mayo, which was originally organized as a single-specialty group in 1887 and later expanded to a multispecialty group, became a reputable model for other physician practices in the United States. In 1931, the Committee on the Costs of Medical Care issued a report suggesting a major role for group practice, especially those associated with hospitals, in providing comprehensive care. Unfortunately the far-sighted recommendations contained in that report were never implemented, in large measure due to the vigorous opposition of organized medicine such as the American Medical Association.

Developments in medical practice, especially increasing specialization and advances in medical technology, have also spurred the movement to group practice. Group practices have provided a structure for sharing the costs associated with increasingly complex and expensive office facilities, equipment, and personnel. Group practice is viewed as a strategy for improving quality of care by facilitating referral arrangements and coordination of care across different physicians and specialties, and by enhancing opportunities for informal consultations and information-sharing among physicians. Group practice is also viewed as a strategy for improving the efficiency of medical practice by pooling resources to support nonphysician staff such as nurse practitioners, physician assistants, and general office staff to perform activities that do not require specialized medical knowledge. Group practices can also offer physicians more appealing work environments by sharing responsibilities for after-hours coverage and rounding with hospitalized patients, and providing more flexible work hours.

There are currently over 16,000 group practices in the United States according to the American Medical Association's periodic surveys of physicians.⁹ Most of these groups are relatively small with an average size of less than 10 physicians, but the prevalence of larger groups has grown over time. Recent evidence indicates an increasing preference for group practice among physicians, particularly among younger physicians, women, and physicians practicing in areas that are more heavily penetrated by managed care plans. Furthermore, physicians are increasingly practicing in more corporate-oriented environments as employees of a practice rather than as owners.

Recent trends in the ownership and management of physician practices have raised questions about the future role of these practices within the nation's health-care system. During the 1990s, many hospital systems were aggressively seeking relationships with physician practices in order to improve their ability to compete for contracts with health insurers and operate successfully under capitated payment systems with health maintenance organizations (HMOs). Some hospital systems were directly purchasing physician practices and employing their physicians, especially primary care physicians, while other systems were forming alliances with these physicians through physician-hospital organizations (PHOs) and related arrangements. Since that time, however, HMO enrollment failed to grow as expected in many communities, and many health insurers have scaled back the use of managed care techniques such as selective contracting with hospital systems.¹⁶ As a result, physician-hospital relationships have become less important for contracting, and hospital systems in many communities have divested their owned primary care practices and PHOs.

Most recently, hospital systems in some communities have begun to pursue tighter relationships with specialty physician practices in order to compete more effectively for patients in profitable specialty service areas such as cardiac care and orthopedics. Some hospital systems have established joint ventures with single-specialty

groups to develop ambulatory surgery centers, thereby avoiding direct competition with these groups in the delivery of ambulatory services. Hospital systems in some communities have purchased specialty physician practices and directly employed specialist physicians in order to strengthen these relationships.

Hospital-Based Ambulatory Care. Although hospitals historically have focused on the provision of inpatient care, they also serve as major sources of ambulatory care services. Hospitals traditionally have delivered a great deal of ambulatory care through their emergency departments, which provide care not only for patients with emergent conditions but also for patients who need routine primary care but lack access to mainstream providers. Some hospitals have created primary care outpatient clinics to reduce crowding in their emergency departments and redirect primary care patients to more appropriate and less costly care settings. Many hospitals also operate specialty outpatient clinics and ambulatory surgery centers that serve as important sources of specialty care. These ambulatory services have become increasingly important sources of revenue for hospitals as services historically provided on an inpatient basis continue to shift to outpatient settings. Some hospitals directly employ specialist physicians and other personnel to provide these outpatient services, while others contract with specialty group practices for this purpose.

Freestanding Ambulatory Centers. While hospitals and physicians' offices account for the vast majority of ambulatory care delivered in the United States, a small but growing amount of care is provided by private, freestanding ambulatory centers that are not based in hospitals or physician practices. Many of these freestanding centers provide outpatient surgical services, while others provide diagnostic tests and imaging services, emergency and urgent care services, and rehabilitation services. Some of these centers are owned and operated by proprietary corporations that directly employ physicians and other clinical personnel to staff the centers, while other centers are developed as joint ventures with physician groups and/or hospitals.

Ambulatory Care in Safety-Net Clinics. Safety-net health-care clinics serve as important sources of ambulatory care for the uninsured and other population groups that lack access to office-based and hospital-based providers due to financial, geographic, or other barriers to care. These clinics rely on support from a variety of sources, including governmental funding, private charitable contributions, volunteer labor, and sliding-scale patient fees to deliver care to these population groups. Some of these clinics receive support through the federal Community Health Center program, which provides grants to more than 1200 health centers and 3000 individual clinic sites to deliver comprehensive primary care services to populations residing in medically underserved areas of the United States and its territories. Other clinics receive special support through other federal programs such as those targeting rural health centers, school-based health centers, and clinics that serve the residents of public housing facilities. A number of state and local governments also maintain programs that provide financial support to safety-net clinics. Many communities are also served by "free clinics" that rely primarily on voluntary clinical labor and on donations collected by community-based and faith-based organizations. In some communities, local public health agencies provide some preventive and primary care services such as immunizations, chronic disease screenings, and prenatal and well-child care. In some cases, universities sponsor safety-net health

clinics that offer free ambulatory care as well as training opportunities for medical, nursing, dental, and other health professions students. Similarly, some community hospitals sponsor free primary care clinics as a strategy to reduce overcrowding in their emergency departments.

Long-Term Care Providers

Long-term care providers represent one of the largest components of the U.S. health-care system after hospital-based and physician-based care are considered, with nursing home care alone accounting for 7% of the nation's total health-care expenditures.⁶ Long-term care encompasses a broad spectrum of services delivered in both institutional and ambulatory care settings and designed to assist patients with health-related impairments in their ability to perform routine activities of daily living. Institutional settings for long-term care include nursing homes, assisted living centers, and board and care facilities. Ambulatory providers of long-term care include home care providers, visiting nurses associations, adult day care centers, and respite care programs. Many patients also receive long-term care services from informal caregivers including spouses, parents, and children, but the economic value of these services is typically not included in estimates of national long-term care spending. Coordinating these different types of long-term care and ensuring that patients receive the most appropriate types and levels of care are

continuing challenges for the nation's health-care system. Financing these different components of long-term care remains problematic as well, particularly in view of the aging American population and the growing numbers of people who require this care.

The nursing home is the most costly and visible component of the long-term care continuum. Nearly 1.5 million residents receive care in the nation's 16,000 nursing homes, most of whom are over 75 years of age, female, suffer from multiple chronic conditions, and have severe limitations in activity (Table 74-4).³ Although many nursing homes are small, there is a growing trend toward larger homes and toward ownership by multihome not-for-profit and for-profit entities.

Most long-term care services are not covered by Medicare, the federal health program that provides health-care coverage for elderly and permanently disabled populations in the United States. Medicare provides only short-term coverage for services provided by rehabilitation units, skilled nursing facilities, and home health agencies. For longer-duration care in nursing homes and other care settings, patients must rely on their own financial assets or on private long-term care insurance until those resources are depleted and patients become eligible for Medicaid, the program for low-income populations that is jointly administered by the federal and state governments. Financial support for nursing home care is limited under Medicaid

and is widely viewed as inadequate to support the staffing levels, physical environments, and range of services and activities that would be necessary to ensure high-quality care. Many state Medicaid programs are now experimenting with various forms of home-based and community-based alternatives to nursing home care with the goal of reducing the costs of care and improving quality of care and patient satisfaction. Some of these experiments are now including consumer-directed care models that offer expanded opportunities for patients to decide how best to use their long-term care benefits, including using funds to reimburse family members and other lay-persons as caregivers.

Improvements in other aspects of the long-term care continuum are also moving forward. Hospice providers deliver services to terminally ill patients in caring and medically supportive environments using a multispecialty approach in both institutional and home settings. Home health providers and assisted living facilities have expanded rapidly in recent years, and several state Medicaid programs are now testing ways of positioning these services as cost-effective alternatives to nursing homes. The federal government continues to experiment with all-inclusive care programs that coordinate a comprehensive array of services for long-term care patients who are eligible for both Medicare and Medicaid. Additionally, various types of continuing care facilities have emerged in recent years, although most of these are designed to serve higher-income private-pay patients rather than lower-income Medicaid recipients. Despite some progress, serious challenges remain concerning how to finance long-term care services for the aging baby boom population and how to coordinate the various components of this care to achieve desired health and economic outcomes.

Mental Health and Substance Abuse Service Providers

Mental health and substance abuse care providers represent another major component of the U.S. health-care system, accounting for nearly \$33 billion of the nation's \$1.5 trillion in health-care expenditures for 2002.⁶ Like long-term care, mental health care encompasses a broad spectrum of services delivered in both institutional and ambulatory care settings. Institutional care providers include specialized psychiatric hospitals, psychiatric units of general hospitals, nursing homes, board and care facilities, and residential substance abuse treatment centers. In the ambulatory care arena, primary care physicians play key roles in diagnosing mental health and substance abuse disorders and in managing routine mental health conditions, while more specialized office-based care is provided by psychiatrists, psychologists, social workers, family counselors, and other health professionals. Community mental health centers and outpatient substance abuse treatment centers are also important sources of ambulatory care for these populations.

Mental health services are generally provided through parallel public and private subsystems, with only those individuals having private insurance or sufficient resources for self-pay receiving care through the private subsystem. These patients are more likely to receive care from private-practice psychiatrists and other professionals, private mental health hospitals, and private substance abuse treatment facilities. Employees in many large and mid-sized firms may also obtain access to private mental health and substance abuse providers through the employee assistance programs offered by these firms. By contrast, patients who are uninsured, covered by Medicaid, or who exhaust their private insurance benefits typically rely on a patchwork of government-owned mental health hospitals, community mental health centers, and a variety of community-based not-for-profit providers. Many of these providers rely heavily on financial support from federal programs such as the Community Mental Health Services Block Grant and the Substance Abuse Prevention and Treatment Block Grant. Hospital emergency departments also frequently serve as providers of last resort for patients with acute mental health and substance abuse problems who lack other sources of care. Unfortunately, correctional facilities have also become common sources of care for patients with severe and poorly managed mental health and substance abuse problems, where services are delivered through local jail health systems as well as state and federal prison health systems.

Pharmacy Providers and Suppliers

Pharmaceutical therapies continue to be one of the fastest growing components of modern medical practice, and therefore the organizations and professionals involved in prescribing, distributing, and dispensing drugs have become increasingly important components of the health-care system. Between 1995 and 2002, national expenditures for prescription drugs grew faster than expenditures for any other type of health care, and by 2002, drug expenditures accounted for 11% of the nation's total health-care spending.⁶ A variety of factors are driving the increased utilization of prescription drugs, including the availability of new drugs to treat an expanding array of health conditions, increased marketing of new and existing drugs to physicians and consumers, and a growing body of evidence demonstrating the effectiveness of drug therapies in treating a variety of common conditions ranging from heart disease and hypertension to diabetes and asthma.

The delivery system for prescription drugs includes the manufacturers that are responsible for producing and marketing these products, the physicians and advanced practice nurses who prescribe them for patients, and the pharmacists who are responsible for dispensing drugs as well as educating patients about drug therapy choices and proper drug usage. A variety of intermediaries are involved in drug purchasing and distribution as well, including pharmacy benefit managers (PBMs) who work on behalf of health insurers and employers to establish policies on which drugs should be covered and to negotiate pricing arrangements with manufacturers. Drug dispensing is carried out through an array of different organizations including local retail pharmacies, national chain pharmacies, mail order pharmacies, and pharmacies operated by individual health plans and hospitals. In recent years, specialty pharmacy organizations have emerged that manage the drug purchasing, dispensing, and administration processes for high-cost medications and those that are difficult to store or administer, such as biologicals and other products that require intravenous administration.

The growing importance of prescription drugs in modern medical care has raised concerns about population groups that lack access to these products, including the uninsured as well as the elderly and disabled populations covered by Medicare. Most private health insurance plans include coverage for prescription drugs, as do state Medicaid programs, but the federal Medicare program historically has not included an outpatient prescription drug benefit. In response, many state governments have created pharmacy assistance programs (PAPs) that provide the uninsured and low-income Medicare beneficiaries with financial assistance in purchasing needed prescription drugs. Some states have gone farther in adopting policies that would allow states to negotiate discounts with drug manufacturers for drugs needed by their residents who lack drug coverage or who are covered by Medicaid. Still other states and some local governments are exploring options for allowing their residents to purchase drugs from Canada and other foreign countries where drug prices are lower, and then reimporting these drugs to the United States. The federal government also maintains several targeted programs to assist disadvantaged populations in obtaining needed medications, including the AIDS Drug Assistance Program (ADAP) that assists HIV and AIDS patients and the 340B Drug Pricing Program that allows community health centers to purchase discounted medications for their uninsured patients. The U.S. Congress passed legislation in 2003 that created an outpatient prescription drug benefit for Medicare beneficiaries. This benefit, which went into effect in 2006, is administered by private health insurers and prescription drug plans.

Beyond pharmacy, a variety of other health-care providers play important roles in delivering health services within the health-care system. These include providers of dental care, vision services, nutritional assessment and counseling, genetic counseling, and the rapidly growing field of complementary and alternative medical services. Other organizations specialize in providing support services that facilitate access to care, such as emergency and nonemergency medical transportation and language translation services. Finally, a wide array of organizations participate in the health-care system as suppliers of health-related products and equipment, including wheelchairs and

other durable medical equipment; orthotics, prosthetics, and other assistive devices; implantable therapeutic devices such as pacemakers and defibrillators; clinical laboratory and imaging equipment; and health information technology such as electronic medical records and telemedicine applications. By continually bringing new and improved products to market, these suppliers of medical technologies, devices, and equipment are major forces of change in medical practice.

The Health-Care Workforce

The health-care system is the single largest industry in the United States, providing a total of 12.9 million jobs nationwide. About 518,000 establishments make up the employer base for the health industry, three-fourths of which are the offices of physicians, dentists, and other health professionals. Hospitals constitute only 2% of all health services establishments, but they employ 41% of all workers in the industry (Table 74-5).¹⁰ The federal Bureau of Labor Statistics projects that about 16% of all new wage and salary jobs created between 2002 and 2012 will be in the health services industry, representing a total of 3.5 million jobs—more than any other industry. This projected job growth is attributed to continued growth in demand for health services as the American population becomes older and as improvements in health and medical care allow more Americans to live longer but with more health conditions and disabilities that require care.

Professional occupations such as physicians, registered nurses, dentists, therapists, and social workers account for three-fourths of all the jobs in the health-care industry. The remaining one-quarter of jobs include clinical service occupations such as nursing aides and therapist assistants, administrative and clerical workers, and management occupations.

Physicians

Over the past half-century, the American health-care system has oscillated between concerns about physician shortages and concerns about over-supply. In the early 1960s, the perception of physician shortages led to the growth of medical school classes and the building of new medical schools. Foreign medical school graduates were also viewed as additional sources of personnel for the United States. In 1963, the Health Professions Educational Assistance Act was passed to provide funds to medical schools based on enrollments and for grants and loans for the construction of new medical education facilities. This legislation marked the first instance of direct federal involvement in medical education financing. Previous attempts at federal intervention in medical education had been blocked by both organized medicine

and medical schools themselves. The incentives contained in the 1963 legislation were effective in increasing the number of medical school graduates, with new graduates doubling between 1965 and 1980.

But in the early 1980s, however, industry observers were raising concerns that the earlier policies on medical education overcorrected the nation’s physician supply. The American Medical Association and other industry groups had predicted an over-supply of physicians within the U.S. health-care system for the past quarter century, and had worked to limit the number of new physicians produced by U.S. medical schools. In 1980, the Graduate Medical Education National Advisory Committee projected that by 1990 a surplus of 70,000 physicians would exist.¹¹ As a result, medical schools began reducing class sizes and immigration laws were revised to eliminate preferential treatment for foreign medical graduates. A later study published in 1995 predicted a surplus of 165,000 physicians by the year 2000, in part due to the growth of managed care and its emphasis on steering patients to primary care physicians and restricting unnecessary access to specialists.¹²

The physician surplus never materialized, however. The American population has continued to grow, as has utilization of physician services. Health insurers have scaled back the use of restrictive managed care techniques in response to consumer preferences for direct access to specialists. Moreover, continued innovations in medical technology and practice have kept the physician workforce busy with new services and procedures ranging from heart stents to bariatric surgery.

In fact, several recent studies warn of a looming physician shortage. The nation now has more than 800,000 active physicians, up from 500,000 twenty years ago (Table 74-6).⁹ But this supply is projected to begin shrinking in about 10 years as doctors from the baby boom generation retire in large numbers—just as demand for physician services is likely to spike upward as large cohorts of Americans become eligible for Medicare. Moreover, pressures from rising practice expenses and the costs of medical malpractice insurance are leading physicians in some communities to retire early. In response, the Council on Graduate Medical Education recently produced a study for Congress that recommends training 3000 additional physicians per year in U.S. medical schools to address the looming shortage.¹³ Even the American Medical Association has abandoned its long-standing opposition to producing more physicians.

There are also concerns about the distribution of physicians across specialties and across geographic areas. During the 1990s, primary care physicians appeared to be in short supply relative to specialists, especially in light of the movement toward managed care and its heightened roles for primary care physicians as gatekeepers and care managers. Efforts to correct this specialty imbalance included federal training grants for new residency training in primary care specialties. For the most part, however, the bias toward specialty practice has persisted due to the higher earnings potential in many specialty areas compared to primary care practice. Rising levels of medical student debt and increasing medical practice expenses and malpractice insurance costs have reinforced this bias.

Even more difficult to address is the maldistribution of physicians in rural versus urban areas and in wealthy versus lower-income communities. Physicians tend to locate where they want to live and where their earning potential is greatest rather than where unmet needs exist. Rural and inner-city communities face persistent difficulties recruiting and retaining physicians due to their lower incomes, greater professional isolation, higher charity care burden, and perceived quality of life issues. Several federal and state programs exist to encourage physicians to practice in rural and urban underserved areas. Several states have loan repayment programs for medical students that agree to practice in these areas after graduation. The federal National Health Service Corps provides similar incentives. Other programs are designed to expose medical students to the professional rewards of practicing in underserved areas, or to recruit medical students from among the residents of these areas, with the expectation that participants would be more likely to return to practice in these areas after medical school. Unfortunately many of these programs have had only limited success.

TABLE 74-5. PERCENT DISTRIBUTION OF WAGE AND SALARY EMPLOYMENT AND ESTABLISHMENTS IN HEALTH SERVICES, 2002

<i>Establishment Type</i>	<i>Establishments</i>	<i>Employment</i>
Health services, total	100.0	100.0
Hospitals, public and private	1.9	40.9
Nursing and residential care facilities	11.7	22.1
Offices of physicians	37.3	15.5
Offices of dentists	21.6	5.9
Home health-care services	2.8	5.5
Offices of other health practitioners	18.2	3.9
Outpatient care centers	3.1	3.3
Other ambulatory health-care services	1.5	1.5

Nursing

Registered nurses constitute the largest health-care profession with 2.3 million members, and over the next 10 years more new jobs are expected to be created for nurses than for any other health profession.¹⁴ About half of registered nursing jobs are in hospitals, in both inpatient and outpatient departments (Table 74-7). Many other nurses work in offices of physicians, nursing care facilities, home

health-care services, outpatient care centers, and public health agencies. About one in five nurses works part-time.

The three primary educational paths to registered nursing are a bachelor's degree, an associate degree, and a diploma. The diploma historically has been offered in hospital-based training programs, whereas the other degrees have been offered in college and university-based programs. Since the 1980s, the nursing profession has

promoted university-educated nurses over diploma nurses in state licensing and credentialing programs, leading the numbers of diploma graduates to decline. To assist registered nurses, an auxiliary profession exists in the form of the licensed practical nurse, which requires a year of training in a vocational program. Additionally, higher-level professional categories exist in the form of advanced-practice nursing, which requires significant postbaccalaureate training and may include a master's or doctoral degree. Advanced-practice nurses such as nurse practitioners and clinical nurse specialists enjoy a greater degree of professional autonomy and assume higher overall levels of patient care responsibility than do registered nurses.

The health-care industry has periodically confronted times of apparent shortage in the supply of nurses. Nursing shortages are attributable to a variety of factors. Many nurses leave the field of practice prematurely due to salary constraints, stressful work environments, and limited opportunities for professional advancement. Moreover, the downsizing that occurred in the U.S. hospital industry during the 1980s and 1990s has required nurses to care for larger numbers of more acutely ill patients during generally shorter lengths of stay. Moreover, the efforts of some hospitals to contain costs by replacing registered nurses with LPNs and nurses aides served to reduce morale and job satisfaction among many nurses.

More recently, the upsurge in hospital utilization and the efforts of many hospitals to expand their facilities and clinical services have caused the demand for nurses to outstrip the existing supply in many communities, leading to heightened competition for nurses and rising nursing compensation. The growing body of evidence concerning the effects that nurse staffing levels have on quality of care and health outcomes in hospitals and other health-care settings has also stimulated additional demand for nurses within the health-care industry. In response, nursing schools across the country have taken steps to increase their enrollment, often with financial support from area hospitals or special governmental programs. However, the production of new nursing graduates remains constrained by the availability of graduate-degree nursing faculty to teach in these schools.

Other Clinical Personnel

Nonphysician health professionals such as nurse practitioners and physician assistants have assumed expanding responsibilities within the health-care system in recent decades. Nurse practitioners are registered nurses who receive 1–2 years of additional clinical training and sometimes a master's degree. Physician assistants typically receive training through a 2-year university-based program that may result in a bachelor's or master's degree. Both of these professionals

provide patient care relatively autonomously but generally under the general direction of a physician. Some practice settings such as medical groups, community health centers, and staff-model HMOs use these professionals as lower-cost “physician extenders” to perform routine clinical services that physicians would otherwise provide, thereby freeing up physician time to provide more complex care. In some cases these professionals have been used to staff clinics in underserved geographic areas where physicians were unavailable, thereby expanding access to care.

The use of nurse practitioners and physician assistants has been limited by professional and political struggles over where and under what circumstances they can practice. State medical societies have aggressively sought to limit their scope of practice and their ability to practice independently of physicians. Public and private insurance programs have also been reluctant to allow these professionals to directly bill for their services, in part due to concerns that these professionals will generate new and duplicative health-care costs rather than substitute for more costly physician services. Nevertheless, a growing body of evidence suggests that in appropriate practice settings these professionals can provide high-quality care at lower cost than care delivered by physicians alone.

Other professional components of the health-care workforce include dentists, dental hygienists, podiatrists, psychologists, social workers, pharmacists, therapists, nutritionists, audiologists, and optometrists. To support this professional workforce, an expanding array of technical workers practice within the health-care system, contributing specialized knowledge and skills in the application of medical technologies and equipment. These workers include medical and radiological technicians, nuclear medicine technicians, sonographers, laboratory technicians, surgical technicians, and cardiovascular technicians. A variety of clinical service support staff also assist the health professions workforce, including nursing assistants and aides, home health aides, physical and occupational therapy assistants and aides, and pharmacy assistants and aides.

Health-Care Purchasers

Expenditures for health care in the United States totaled more than \$1.5 trillion in 2002, more than any other industrialized country on a per capita basis or as a percentage of the gross domestic product (Table 74-8).¹⁵ Private health insurance remains the single largest source of these funds, accounting for about 36% of all personal health-care expenditures. The federal government pays for about 34% of these expenditures through the Medicare program, the federal

share of the Medicaid and State Children's Health Insurance (SCHIP) programs, and through health insurance programs for federal employees, the active-duty military, and veterans. Approximately 11% of the nation's health-care expenditures are paid by state and local governments, mostly for Medicaid and SCHIP recipients but also for health insurance for government employees. Consumers pay the remaining 16% of the nation's health-care expenditures through out-of-pocket costs, including the self-pay payments made by uninsured patients as well as the deductibles and copayments incurred by patients covered by private or public health insurance programs.

National health spending increased at double-digit annual rates of growth for much of the period following the creation of the federal Medicare and Medicaid programs in 1965. However, spending slowed during the 1990s, a fact attributed at least in part to the emergence of managed care plans in the private health insurance industry and their use of cost containment techniques such as selective contracting with health-care providers, preauthorization requirements for high-cost services, and capitated payment methods for hospitals and physicians. These managed care techniques were also introduced into many state Medicaid programs and into the federal Medicare program on an optional basis. During the late 1990s, mounting public and professional dissatisfaction with managed care and its restrictions on health-care utilization led many private health insurers to scale back the use of these techniques. Since then, health-care spending has returned to double-digit annual rates of growth.

Private Health Insurance

Most individuals have some type of health insurance, although the number of Americans without health insurance coverage has continued to grow over the past decade (Table 74-9). Most individuals obtain private health insurance through an employer, with the employer paying part of the premium and the employee also contributing toward the premium through a payroll deduction. Individuals without access to employer-provided health insurance may purchase an individual policy directly from a private health insurance carrier. Individual policies are generally more costly than group insurance policies obtained through an employer because of the increased administrative costs involved in marketing and processing individual policies and because of the increased financial risk entailed in individual policies.

Private health insurers gradually became the predominant method for financing health care during the 1900s. Initially commercial insurance companies were reluctant to offer insurance for health-care expenditures because of concerns that it would attract only the sick (termed adverse selection) and encourage subscribers to over-consume health services (termed moral hazard). In the absence of commercial insurance policies, the fore-runners to the Blue Cross and Blue Shield health insurance plans were created during the Great Depression to allow individuals with limited incomes to prepay for health care they may need in the future. Hospitals and later physicians in many communities supported the emergence of these not-for-profit plans because of their ability to improve financial access to health-care services and reduce unpaid hospital bills. Employers began offering subsidized health insurance as a benefit to their employees

in large numbers during World War II, when federal wage and price controls prevented employers from using wages to compete for scarce labor. Federal tax policies strengthened interest in employer-provided health insurance by making health insurance contributions exempt from employers' payroll tax obligations as well as employees' income tax obligations.

As demand for private health insurance grew, commercial insurers rapidly entered the market for selling group health insurance policies because of the diminished potential for adverse selection among relatively young and healthy workers and their families. By the early 1950s, more individuals received insurance coverage from commercial insurers than from Blue Cross and Blue Shield plans. The policies sold by both types of insurance carriers were indemnity policies that reimbursed subscribers for their health-care expenses based on an established percentage of the usual, customary, and reasonable (UCR) charge that prevailed in the local area. Any difference between the provider's actual charge and the carrier's UCR-based reimbursement was borne by the subscriber as an out-of-pocket cost. By the 1950s, many indemnity policies provided coverage for both hospital and physician services.

Rapidly rising health-care costs during the 1970s led employers—who paid most of the health insurance premiums for their employees—to search for strategies to reign in these costs. HMOs began to receive increasing attention as a lower-cost alternative to traditional indemnity insurance policies. HMOs contained costs by covering only those services delivered by a relatively limited network of physicians and hospitals. Rather than reimbursing subscribers for each service they receive based on a percentage of the UCR charge, HMOs frequently used capitated payment methods wherein providers agree to provide or arrange for all of the services needed by a defined panel of subscribers in exchange for fixed monthly payment per subscriber from the HMO. These methods created financial incentives for providers to reduce unnecessary service utilization and coordinate health-care delivery in order to keep health-care costs below their capitated payment rate. As an additional cost-saving mechanism, many HMOs also required subscribers to obtain a referral from their designated primary care physician before accessing services from specialists, hospitals, or other specialty providers. Federal legislation enacted during the 1970s encouraged the development of HMOs but indemnity health insurance remained dominant through the 1980s in most communities.

As health-care costs continued to grow during the 1980s, several variants on the HMO concept emerged that collectively became known as managed care plans. Most of these plans sought to contain costs by selectively contracting with a limited network of physicians and hospitals that agreed to accept discounted payment arrangements in exchange for the prospect of increased patient volume. The least restrictive of these plans, known as preferred provider organizations (PPOs), typically allowed subscribers to access specialists without a referral from their primary care physician and offered subscribers the option of seeking care from providers not included in the plan's network in exchange for paying higher out-of-pocket fees. Other plans, known as HMO point-of-service (POS) plans, required referrals for most specialist visits similar to the HMO design but offered out-of-network benefits similar to the PPO design. Managed

care plans also used a variety of administrative controls designed to limit health-care utilization and expenditures, including requiring physicians and/or subscribers to obtain preauthorizations, or medical necessity determinations, from the health plan before seeking specified high-cost services and procedures from hospitals and specialists.

Enrollment in managed care plans grew rapidly during the late 1980s and early 1990s because of the relatively low insurance

premiums these plans offered employers and the relatively low out-of-pocket costs they offered consumers compared to traditional indemnity insurance. Correspondingly, annual rates of growth in private health insurance premiums fell significantly during the 1990s. By the latter part of this decade, however, both consumers and providers began voicing complaints about the restrictions that these plans imposed on health-care choices. Faced with increasingly competitive labor markets, employers were pressured to offer less

restrictive health insurance designs to their employees that included access to larger networks of providers and placed fewer restrictions on health-care utilization.¹⁶ At the same time, hospitals and physicians began negotiating more aggressively with health insurers for more favorable payment rates—including an end to capitated payments in many cases—as well as for fewer administrative requirements regarding referrals, preauthorizations, and medical necessity determinations. Growing public dissatisfaction with managed care plans also led state and federal policy makers to adopt regulatory limits on the use of containment techniques, including mandatory minimum hospital stays for selected procedures, mandatory coverage requirements for selected services, and any-willing-provider laws that limit selective contracting. In response, many managed care plans have scaled back these cost containment tools and moved to broader and more inclusive provider networks and traditional fee-for-service payment methods in order to retain their membership.

In the wake of the managed care backlash, HMO enrollment has slowed and even declined in many communities while enrollment in less restrictive PPO insurance products has increased substantially. Since 2000, private health insurance premiums have resumed double-digit annual rates of growth, placing renewed pressure on employers and insurers to find new ways of containing costs.¹⁷ Many smaller employers, unable to absorb the increased costs, have shifted more of the costs to consumers through increased payroll deductions for employee premium contributions and larger out-of-pocket costs for deductibles and copayments. As a consequence, larger numbers of employees are now declining to accept the insurance coverage offered by their employers because of the added costs entailed. Some small employers have chosen to discontinue insurance coverage for their employees' spouses and dependents, while others have discontinued offering health insurance benefits altogether because of the rising costs. These developments are contributing to the rising numbers of individuals that lack health insurance coverage, which reached 45 million Americans in 2003.

Private insurers and employers are currently pursuing two primary strategies for limiting the future growth of health-care costs and private health insurance premiums. First, these purchasers are investing more heavily in disease management programs and related care management initiatives designed to improve the likelihood that patients with identified health conditions and risks receive evidence-based standards of care and adhere to recommended self-care guidelines. These programs use a combination of interventions that are often tailored to a patient's disease stage and level of risk, including printed health education materials, telephone outreach and follow-up, and provider notification and profiling. The most widely used disease-specific programs currently target the most prevalent and costly health conditions, including diabetes, asthma, congestive heart failure, coronary artery disease, and depression. Other programs target patients with a variety of complex health conditions that result in high-cost episodes of care or sentinel events such as long hospital stays or repeated emergency department visits. A large number of specialty disease management vendors have emerged within the health-care system over the past decade to assist insurers and employers in implementing these programs.

As a second cost-control strategy, purchasers have begun to experiment with new "consumer-driven" health insurance designs that require consumers to assume more responsibility for balancing issues of cost, choice, and quality when selecting among health-care providers and treatment alternatives. The most common designs take the form of a PPO health plan with a relatively large deductible that consumers must meet before services are covered by the plan. These high-deductible health plans are coupled with a spending account that consumers can use to pay health-care expenses before the deductible is met. The spending account may be funded with money contributed by the employer, by the employee, or both. A new law passed by Congress in 2003 allows consumers covered by high-deductible health plans to contribute funds to designated Health Savings Accounts (HSAs) on a pretax basis and to accumulate unused funds in the account from year to year. Proponents of these designs anticipate that

they will encourage consumers to be more economical in their health-care decision-making and to shop for the best value among alternative providers and treatment options. To this end, health insurers are developing a variety of decision support tools and information resources for consumers to use, including cost estimators and reports containing quality measures for specific hospitals and physicians.

One of the biggest limitations of these new products is the lack of accurate provider-specific information on health-care costs and prices so that consumers can factor this information into their decisions. Other observers fear that these plans will encourage consumers—especially those with low incomes—to forego needed health care once their spending accounts have been depleted, thereby contributing to the growing problem of underinsurance. Still others fear that these new insurance designs will contribute to adverse selection by attracting primarily young and healthy employees, leaving older and sicker individuals in traditional health plans and making these plans increasingly unaffordable to employers and consumers. To date, enrollment in these new insurance designs has been modest, so it remains unclear what impact they may have on the health-care system of the future.

Governmental Health Insurance

The advent of public insurance programs during the 1960s, especially Medicare and Medicaid, ushered in major improvements in financial access to care for some of the nation's most vulnerable populations, including the elderly, disabled, and poor. Both programs have been revised many times in response to cost containment pressures, quality and utilization concerns, and various political developments. More recently, the SCHIP was added by Congress in 1997 to expand coverage for low-income children, another vulnerable population that was not fully reached by the existing Medicaid program. These public programs not only supplement the private health insurance market by targeting populations that lack access to private coverage, but these programs also interact with this market in complex and sometimes unexpected ways. For example, efforts to expand coverage for low-income, working adults and their children through Medicaid and SCHIP may "crowd out" the demand for private health insurance coverage among these populations and ultimately shift costs from the private sector to the public sector. Conversely, efforts to constrain costs in public sector programs like Medicare and Medicaid by limiting payments to hospitals and physicians may lead providers to increase the prices they negotiate with private insurers, thereby shifting costs from the public to the private sector.

Medicare. Medicare is a federal health insurance program that serves three basic categories of beneficiaries: individuals age 65 and older, individuals who are permanently and completely disabled, and individuals with end-stage renal disease. The program has evolved over its 40-year history and now includes four major components. Part A provides coverage for short-stay hospital inpatient services, skilled nursing facilities, home health services, and hospice care. Part A coverage is financed through the Medicare Trust Fund which is funded from employer and employee payroll taxes. Coverage under Part A is mandatory for all eligibility groups, and beneficiaries are responsible for paying an out-of-pocket deductible for hospital care. Historically, payments to providers under Medicare Part A were based on a cost-based reimbursement system, but over time Medicare has adopted prospective payment methods for most services that pay providers a fixed amount for an episode of care regardless of the actual cost of care delivered. The fixed payment methods are tailored to specific types of diagnoses, services, and acuity levels and are adjusted for outlier cases that require more intensive care than the average patient. These methods create financial incentives for providers to reduce unnecessary and inappropriate care and minimize patient lengths of stay and readmissions. Such a system was implemented for inpatient hospital care in 1986 and extended to skilled nursing and home health during the late 1990s.

Medicare's second major component, Part B, covers physician care and other outpatient services. Part B is an optional benefit and

beneficiaries are responsible for paying a monthly premium for this coverage that is set to cover approximately 25% of the Part B costs. Physicians are paid using a modified fee-for-service methodology that adjusts payments to account for the time and resources required to deliver each service. This methodology, known as the Resource Based Relative Value Scale, is designed to reward physicians for performing time-intensive cognitive services that are common in primary care as opposed to purely procedure-based services that are common in specialty care.

Both Part A and Part B leave Medicare beneficiaries exposed to significant out-of-pocket costs, including deductibles, copayments, and costs for noncovered services. Beneficiaries therefore have the option of purchasing private, supplementary health insurance coverage. These Medicare supplemental policies offer coverage for Medicare Part A deductibles and Part B copayments, and some policies offer additional coverage for services not covered by Medicare, including vision, and dental care. These policies are offered by a variety of private health insurance carriers and are regulated by state insurance departments.

A third component of the Medicare program, Part C, covers an array of managed care plans that beneficiaries may choose to enroll in as an alternative to the traditional Medicare program. The Medicare program began experimenting with managed care plans on a voluntary-enrollment basis from the program's very inception in 1965, and these options have evolved considerably over time. Medicare launched a major effort to expand managed care enrollment in Medicare in 1997 with the Medicare+Choice program, which authorized the creation of new plan options including HMOs, provider-sponsored plans, PPOs, and private fee-for-service plans. Because enrollment is voluntary, plans must compete to attract membership by offering additional benefits not available in the traditional Medicare program such as coverage for outpatient prescription drugs and expanded preventive and wellness services, and by offering lower premiums and out-of-pocket costs than are found in the traditional program. Plans must balance these benefits with the capitated payments they receive from Medicare, which are based on the average adjusted per-capita cost of serving beneficiaries in the traditional Medicare program and which vary by county.

Managed care offerings and enrollment initially expanded under Medicare+Choice, but congressionally imposed limits on health plan payment updates ultimately led plans to scale back their benefits and pull out from a growing number of unprofitable counties. Nationally, Medicare enrollment in managed care plans dropped from 17% in 1999 to 12% in 2002. Most recently, Congress has attempted to revive managed care options for Medicare beneficiaries through the Medicare Advantage program created under the Medicare Modernization Act of 2003, which increases payment levels for private managed care plans and creates additional options for participating in Medicare as a private plan. The new program has attracted a number of health plans back into the Medicare market, but the long-term success of this program remains to be seen.

The fourth and newest component of the Medicare program is Part D, which for the first time offers Medicare beneficiaries coverage for outpatient prescription drugs. This component was enacted as part of the Medicare Modernization Act of 2003 and took effect during 2006. As a voluntary component of the program, Medicare beneficiaries have the option to enroll in one of several private plans that offer prescription drug coverage that is compliant with the formulary requirements developed by Medicare. Options include a freestanding prescription drug plan that can be combined with the traditional Medicare program, as well as a variety of Medicare Advantage managed care plans that offer drug coverage along with other benefits. The Part D program also offers financial incentives to employers that currently offer their retirees a Medicare supplemental plan with prescription drug coverage, in order to encourage these employers to continue offering this coverage. The new Part D benefits promise to fill a long-standing gap in the Medicare benefit package, but its ultimate impact on the health-care system remains to be seen.

Medicaid. Medicaid is now the single largest health-care program in the country, paying for medical and long-term care for more than

53 million poor, elderly, and disabled Americans. It finances more than one-third of all births in the United States and pays the costs of almost two-thirds of the people in nursing homes.¹⁸ Because Medicare does not cover long-term care services and few individuals purchase private long-term care insurance, Medicaid is the nation's single largest purchaser of long-term care, accounting for 43% of all spending on these services.

The Medicaid program is jointly financed and administered by the federal government and individual state governments. Individual states provide partial funding for the program and agree to provide coverage for a minimum set of services and serve a minimum set of eligible recipients in order to receive federal matching funds. The states can choose to provide coverage for additional, optional services and for additional eligibility categories. The minimum services covered include inpatient and outpatient medical care, physician services, laboratory and imaging services, family planning services, mental health services, early childhood diagnostic screening and treatment services, and selected long-term care services including nursing home care and home health care. Optional services include rehabilitation care, dental care, and home and community-based long-term care services.

The federal government requires that these services be provided to certain groups of low-income people, including the elderly, people with disabilities, children, and pregnant women and parents of children. People within these categories who have incomes below the historical eligibility criteria for cash assistance programs are considered mandatory for Medicaid coverage. Examples of mandatory eligibility groups include children in families with incomes below 100% of the federal poverty level (FPL), pregnant women with incomes below 133% of the FPL, and individuals with disabilities that receive cash assistance through the federal Supplemental Security Income (SSI) program. Other low-income population groups are considered optional, such as the disabled and elderly not eligible for SSI but below 100% of FPL, and nursing home residents not eligible for SSI but below 300% of the SSI eligibility level. Low-income adults under age 65 who are not living with a disability and are not caring for children generally do not qualify for coverage except through optional state waivers.

When states choose to cover an optional eligibility group, these groups are usually eligible for the same set of benefits offered to mandatory groups. An exception is individuals covered under optional state Medically Needy categories. Individuals qualifying through these categories may have incomes above the state's standard eligibility thresholds but when their medical expenditures are taken into account they fall below these thresholds. Many individuals with chronic health conditions requiring high-cost treatments, such as cancer, HIV/AIDS, and nursing home patients, fall into these categories. Under federal guidelines, states may provide a reduced benefit package for Medically Needy individuals that is typically limited to those services needed to address the relevant chronic health condition.

The federal government matches the funds that states spend on their Medicaid programs using a match rate that is based on each state's per capita income. The average federal matching rate was 57% in 2003 and ranged from 50% to 77% across states. Despite this significant federal subsidy, Medicaid programs represent a substantial and growing proportion of many states' budgets. Rising health-care costs and increasing numbers of individuals eligible for Medicaid have caused the Medicaid program to become one of the largest budget items for many states, often rivaling or exceeding state education expenditures.

In an effort to contain costs, a number of states have secured waivers from federal Medicaid program requirements that allow the states to implement key changes in the delivery and financing of health services for their Medicaid recipients. Many states have used these waivers to implement managed care programs for selected categories of Medicaid recipients, including arrangements that allow private HMOs and other managed care plans to enroll and arrange care for these recipients. Although experiences with Medicaid managed care have varied considerably across states, several

of these programs have achieved considerable cost-savings while maintaining levels of access, quality, and patient satisfaction that are comparable to traditional fee-for-service programs. Some states have used the savings generated from their managed care programs to expand eligibility to additional population groups and to increase provider participation in Medicaid by raising payment levels. Likewise, many states have used waivers to implement programs that provide home and community-based long-term care services as lower-cost alternatives to nursing home care. Most recently, a number of states have used a new category of waivers under the federal Health Insurance Flexibility and Accountability (HIFA) initiative to implement more aggressive cost sharing provisions and management controls within their Medicaid programs in an effort to utilize contain costs.

SCHIP. The State Children's Health Insurance Program (SCHIP) was created by Congress in 1997 to expand health insurance coverage for low-income children not eligible for the traditional Medicaid program. SCHIP is the single largest expansion of health insurance coverage for children since the initiation of Medicaid in the mid-1960s. Like Medicaid, SCHIP is jointly financed and administered by the federal government and individual state governments, but states have even broader discretion in setting policy regarding eligibility and services covered. SCHIP is designed to provide coverage to uninsured children who reside in families with incomes below 200% of the FPL or whose family has an income 50% higher than the state's Medicaid eligibility threshold. Some states have expanded SCHIP eligibility beyond the 200% FPL limit, and others are covering entire families and not just children.

SCHIP offers states three options when designing a program. The state can either (a) use SCHIP funds to expand Medicaid eligibility to children who previously did not qualify for the program; (b) design a separate children's health insurance program entirely separate from Medicaid; or (c) combine both the Medicaid and separate program options.

As of 1999, each of the 50 states had approved SCHIP plans in place. In addition to expanding eligibility, many states have used their SCHIP funds to implement statewide and community-based outreach and enrollment assistance activities, targeting eligible children who were not enrolled. States also increased access to coverage by designing streamlined enrollment strategies, such as creating simplified mail-in applications, eliminating the face-to-face interview and asset test requirements, adopting presumptive eligibility and 12-month continuous eligibility, and accelerating enrollment of uninsured children already participating in other means-tested programs such as food stamps or school lunch. As a result of these efforts, participation in Medicaid and SCHIP has grown substantially, reducing the number of uninsured children. Between 1996 and 2002, the uninsured rate among low-income children nationally dropped from 23% to 19%, largely due to increases in Medicaid and SCHIP coverage.

Over the past few years, the economic downturn and resulting state budgetary shortfalls have forced states to slow spending on Medicaid and SCHIP. While some states are continuing to broaden access to coverage, many states have moved to restrict Medicaid and SCHIP enrollment for eligible children and parents. During 2003 and 2004, 23 states adopted policies that made it harder for eligible children and families to secure and retain coverage, including freezing enrollment, increasing premiums, and reversing previously simplified enrollment procedures.¹⁹ Most of these changes have been made in SCHIP rather than Medicaid programs, until recently states have had less flexibility to implement cost-sharing premiums, and enrollment freezes under Medicaid. As a result of these changes, SCHIP enrollment fell for the first time in the program's history during the second half of 2003.

Governmental health insurance programs for the poor and elderly perpetually face difficulties in securing the funding necessary to serve the populations that need this coverage. Adequate funding is especially difficult during periods of economic decline when job losses reduce access to private health insurance and constrict governmental

revenue streams. More persistent challenges loom for these programs due to the aging of the American population, continued escalation in health-care costs, and reductions in employer provision of health insurance for active workers as well as retirees. In response, more profound changes to these programs are likely to be necessary in the future.

► THE FUTURE

Although the American health-care system is a constantly evolving enterprise, many of its most severe problems and limitations tend to persist over time. Large numbers of Americans remain without adequate health insurance coverage and face financial and other barriers to health care. Health-care costs continue to rise rapidly and raise questions about the economic sustainability of the current system. And the quality and safety of health-care received by Americans often leaves much to be desired, all too often failing to conform to the evidence-based standards of care that are known to produce desired health outcomes.

There are many activities underway at various levels within the system that appear to hold promise for improving system performance. For example, both private and public purchasers are investing in disease management interventions and health promotion programs designed to improve health outcomes, and some are experimenting with pay-for-performance programs that reward providers for improving the quality and efficiency of their practices. In turn, providers are implementing an expansive array of quality improvement and error reduction programs designed to improve the processes and outcomes of their care. And many providers have begun to adopt information technologies that can assist the health workforce in achieving these improvements, such as electronic medical records, disease registries, clinical decision support systems, and telehealth interventions.

For the most part, however, the key actors within the health-care system are continuing down a path of individual, incremental change and reform. There is relatively little coordination and collaboration among the major purchasers and providers in carrying out their quality improvement activities, payment reforms, and information technology initiatives. As a result, many observers fear that these individual and isolated initiatives may not be sufficient to achieve meaningful change within the complex, interrelated, and dynamic health system that exists in the United States. Because no single organization or actor within society has full control over the health problems and threats that face the health-care system, effective solutions are likely to require multiorganizational and multisectoral efforts. Stronger policy action may be required at local, state, and federal levels to mobilize the collective action needed to address persistent deficits in health system performance.

Structure and Function of the Public Health System in the United States

F. Douglas Scutchfield • C. William Keck

John Last defines public health in his dictionary of epidemiology as, “Efforts organized by society to protect, promote, and restore the people’s health. It is the combination of science, skills and beliefs that is directed to the maintenance and improvement of the health of all the people through collective or social actions.”¹ These efforts organized by society are focused on “creating conditions in which people can be healthy”—the mission of public health as defined by the Institute of Medicine (IOM) in its 1988 Report on the Future of Public Health,² and confirmed in the IOM’s 2003 report, *The Future of the Public’s Health in the 21st Century*.³

The value of public health is unquestionable. Its prevention efforts are responsible for 25 years of the nearly 30 year improvement in life expectancy at birth in the United States over the past century. This is based on evidence that only about 5 years of the 30 year improvement are the result of medical care.⁴ Public health approaches carry significant potential for future contributions as well, since almost half of deaths in the United States are premature and result from preventable causes.⁵

Public health is practiced in a variety of settings and agencies, and by a variety of professionals. The work of many community-based organizations or major not-for-profit voluntary organizations can certainly be characterized as the practice of public health. Their programs fit Last’s definition and are consistent with the mission statement articulated by the IOM. However, when we think of public health activities, we most often envision the constellation of activities of governmental public health agencies at the federal, state, and particularly, local levels. This is especially true since it is only official public health agencies that have statutory responsibility for the health status of the populations they serve. Legal authority for this responsibility is based on a variety of federal, state, and local ordinances, including the granting of police powers.

► A PUBLIC HEALTH RENAISSANCE?

It can be argued that public health in the United States is in the midst of a “renaissance” in several ways. The last several decades have seen a great deal of effort focused on defining the role of public health within the context of the health problems and health services existing in this country. There have also been significant changes in the way public health services are practiced and evaluated in a number of settings. Improvements in financial support and organizational structure for public health services have been less evident.

A Philosophic Renaissance

The pace of change in understanding the place and role of public health in the United States has accelerated dramatically in recent years. Stimulated by the disturbing findings in the 1988 IOM report (public health system in disarray, no coherent vision or mission, disconnection from its academic base, etc.), and by the effort of the Clinton Administration to refine the health-care delivery system in the United States, public health professionals began a systematic review of their discipline and its place in this society. Adding to the impetus were the terrorist attacks of September 11, 2001, the subsequent anthrax scare, as well as the ever-expanding role of public health. Old understandings of illness and health have been increasingly synthesized and recast in a manner that clarified the inter-relatedness of social factors, cultural factors, genetics, behavior, illness care, and prevention. Public health is recognized as the discipline that spans almost all health discipline boundaries, and it is increasingly looked to for understanding and solutions for difficult problems, such as emerging infections, violence, etc. Some of the more important elements of the “philosophic renaissance” that followed included:

Public Health’s Three Core Functions

In addition to proposing a national vision and mission statement for public health, the 1988 IOM Study Committee identified and proposed three core functions for public health departments.² Described below, these functions have largely been accepted by the public health community:

Assessment. Every public health agency should regularly and systematically collect, assemble, analyze, and make available information on the health of the community, including statistics on health status, community health needs, and epidemiologic and other studies of health problems.

Policy Development. Every public health agency should exercise its responsibility to serve the public interest in the development of comprehensive public health policies by promoting the use of the scientific knowledge base in decision-making about public health and by leading in developing public health policy.

Assurance. Public health agencies should assure their constituents that services necessary to achieve agreed upon goals are provided, either by encouraging actions by other entities, by requiring such action

through regulation, or by providing services directly. They should also involve key policy makers and the general public in determining a set of high-priority personal and community-wide health services that governments will guarantee to every member of the community, including subsidization of direct provision of personal health care.

The *assurance* function is the most difficult of the three for many local health departments to comply with. Advocacy for access to illness care services for all is one thing, but providing those services for approximately 16% of the population (over 45 million people) is something else again in most public health settings. The resources for individual illness care essentially don't exist in the public sector, and too much attention paid to that issue in public health agencies would diminish resources available for population-based preventive and regulatory activities. The 2003 IOM report faces the issue more directly by calling for universal access to health insurance in the United States.³

The Ten Essential Services

The three core functions listed above were easily understood and embraced by public health professionals, but they meant little to legislators and the public at large. Because of the concern that public health would be ignored in efforts to redesign the health system in the United States, the U.S. Department of Health and Human Services convened a work group to determine how public health activities could be more clearly described. The three core functions were expanded to a list of Ten Essential Community Health Services that would more clearly define the services communities need in order to achieve high levels of healthfulness.⁶ Those Ten Essential Services are:

1. Monitor health status to identify community health problems.
2. Diagnose and investigate health problems and health hazards in the community.
3. Inform, educate, and empower people about health issues.
4. Mobilize community partnerships to identify and solve health problems.
5. Develop policies and plans that support individual and community health efforts.
6. Enforce laws and regulations that protect health and ensure safety.
7. Link people to needed personal health services and ensure the provision of health care when otherwise unavailable.
8. Ensure a competent public health and personal health workforce.
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services.
10. Research for new insights and innovative solutions to health problems.

These essential services have become the central focal point for many public health activities, including evaluating the capacity of communities to assess their capacity for healthfulness, defining a public health research agenda, and providing a framework for determining the workforce competencies required to deliver them well. The relationships of the essential services to the IOM's three core functions are illustrated in Fig. 75-1.

Council on Linkages between Public Health Practice and Academia

In response to the finding that public health practice is "de-coupled" from its academic base, The Faculty/Agency Forum was established to address the educational and academic dimensions of the findings of the IOM. The Forum's major accomplishment in 1993 was the development and publication of a compendium of competencies required for public health practice.⁷ After this group produced its report and went out of existence, the Council on Linkages Between Public Health Practice and Academia (COL) was formed to facilitate additional activities that would enhance the practice/academic connection. The COL is comprised of representatives from the major

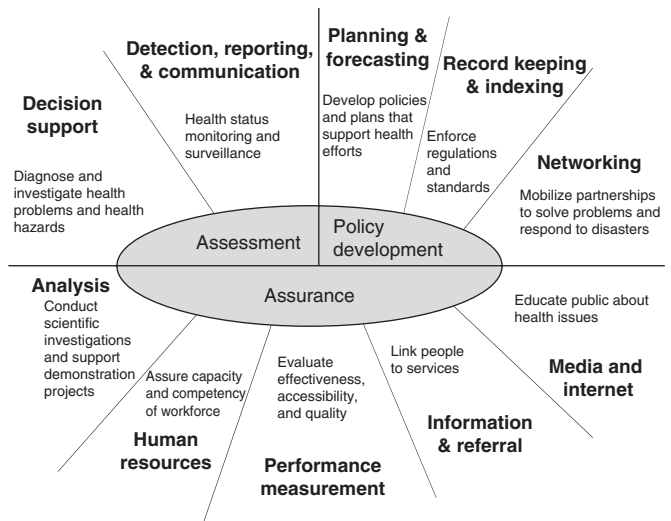

Figure 75-1. The relationship of the essential services to the Institute of Medicine (IOM's) three core functions. The words and phrases in bold in the diagram were added by the Ohio Department of Health to suggest areas of emphasis for local health departments.

national public health professional organizations and certain federal governmental agencies involved in public health. A number of products and initiatives have emerged from this group. They include:

1. Delineation of workforce competencies: The COL, drawing on the work of the Forum and many others in the field, developed an improved list of public health workforce competencies required to deliver each of the ten essential services. The competencies can be viewed at: <http://www.trainingfinder.org/competencies/index.htm>.
2. Improving the science base for community activities through community service guidelines: The COL piloted an effort to determine if it might be possible to develop community preventive service guidelines in the same way that the Clinical Preventive Services Guidelines were developed. The COL's pilot efforts proved successful, and the Centers for Disease Control and Prevention (CDC) has taken on the task of examining the science base for community services. The first report is now available in book form and can also be viewed at <http://www.thecommunityguide.org>.
3. Defining a public health research agenda: Most of the research money in the United States is focused on the diagnosis and treatment of disease rather than health promotion, disease prevention, and public health service delivery. In an effort to modify that reality, the COL has engaged many interested in public health research in the effort of developing a research agenda. One approach is to review what we need to know to deliver the ten essential community services effectively so research dollars could be targeted to gaps in our knowledge. Another approach will be to review the work of the Community Health Services Guidelines Task Force, targeting research support to review program effectiveness where evidence is lacking.
4. Establishing practice coordinators at every school of public health: Working through the Association of Schools of Public Health, a COL agency member, a practice coordinator has been identified at each school of public health charged with improving their institution's linkages with practice settings. Important contributions of the group include their promotion of the importance of scholarship in the area of public health practice,⁸ and the value of practice-based teaching for public health.⁹

National Performance Standards

The ten essential services, initially intended to describe the work of local health departments, have subsequently been recognized as a compilation of services that need to be available in communities for populations to be as healthy as possible. They certainly include many activities engaged in by health departments, but they also include activities of many other individuals, groups, agencies, and institutions. They, therefore, are now considered to be services provided by the Local Public Health System (LPHS), a term intended to include all agencies, institutions, and individuals providing health-related services. This broadens the concept of public health to include everyone involved in efforts to improve health status. National performance measures have been developed at the CDC to allow communities to measure their capacity to deliver the essential services. These measures can be viewed at www.cdc.gov/od/ocphp/nphpsp.

The Medicine/Public Health Initiative

Medicine and public health have evolved into two distinct cultures in this country. Too often, these cultures have been at war with each other. The differences between the two professions remain quite apparent, but it is also clear that the differences are narrowing. The American Medical Association (AMA) and the American Public Health Association (APHA) have developed a medicine/public health initiative intended to draw the two professions more closely together where their agendas overlap, and agree to disagree where dissonance remains. *The Journal of the American Medical Association* prints many articles of relevance to public health, the AMA has taken many positions supporting traditional public health issues (tobacco, violence, gun control, etc.), and the APHA has reached out to clinicians to help deal with access to care issues.

National Association of County and City Health Officials

In 1994, the National Association of County Health Departments (the national association for directors of county health departments) and the United States Conference of Local Health Officers (the national professional association for directors of city health departments) merged to become the National Association of County and City Health Officials. This organization grew in strength during the ensuing decade and it has become an important contributor to the development of strategies and tools for public health practice and an important force in the development of national public health policy.

National Association of Local Boards of Health

Most local health departments are governed by a board of health. The large majority of board of health members have little or no background in the health sciences, and have relied on the health department they represent (sometimes with assistance from the relevant state health department) to inform them about the discipline of public health and their responsibilities to it. Some local state board of health associations were formed in the 1980s in early efforts to bring some organization, standardization, and support to this important component of the public health infrastructure. In November 1992, representatives of states with these kinds of organizations (Georgia, Illinois, North Carolina, Ohio, and Washington) came together to form the National Association of Local Boards of Health (NALBOH). Since its founding, NALBOH has grown rapidly, and now, among other activities, is a participant in providing training for local board of health members, in developing and using national performance standards, in tobacco control, and in developing academic/practice linkages.

Public Health Leadership Institutes

Leadership was identified by the 1988 IOM report as an important need in public health practice. In response, the National Public Health Leadership Institute was developed with federal funding in 1991 to focus on identifying and training current and future public health leaders. The national program has since been joined by many state-sponsored and academic institution programs focused on the same issues. There is a current urgency to this effort stimulated by data that

suggests state governments could lose close to 45% of their public health workforce.¹⁰

The Need for an Accompanying Financial and Organizational Renaissance

The progress made in understanding the value of public health to communities and individuals, and in describing the past and potential impact of the discipline, has been heartening. On the other hand, the continuing inability of the country to act to strengthen the financial underpinning and organization of its public health system makes it impossible for the discipline to reach its full potential to protect the public from disease and injury. Additional federal funding for terrorism preparation has been made available for state and most local health departments, and preparedness capacity has been measurably strengthened, especially in the area of communicable disease surveillance and control. This increase has occurred in an environment of decreasing overall resources at the federal level and in most states, however, with a resultant loss in overall capacity in many, if not most, public health jurisdictions.

Little has changed with respect to the organization and governance of local health departments. Problem areas identified by the 1988 IOM study committee remain. The 2003 IOM report noted that the public health system that was in disarray in 1988 remained, in some important ways, in disarray in 2003. They noted the absence of fundamental reform of the statutory framework for public health in most of the country, and insufficient support for public health infrastructure. They noted mixed progress in improving capacity to address environmental issues, in building linkages with mental health, and in meeting health-care needs of the medically indigent. In addition, significant gaps remain in workforce capacity and competency, information and data systems, and the organizational capacities of state and local health departments and laboratories.³ Many local health departments remain too small and resource poor to meet the basic public health needs of the populations they serve.

► THE FEDERAL PUBLIC HEALTH ROLE

The federal government's role in promoting and protecting the health of the public has evolved significantly over time. The 2003 IOM report notes the federal government has a limited role in the direct delivery of essential public health services, but plays a crucial role by acting in six main areas of population health: policy making, financing, public health protection, collection and dissemination of information about U.S. health and health-care delivery systems, capacity building for population health, and direct management of services.³ Based on a number of constitutional powers, including the power to "regulate Commerce . . . among several states," the federal government involves itself in environmental protection, occupational health and safety, and food and drug purity.¹¹ By setting conditions on the expenditure of federal funds, adjusting taxes on products to promote healthy use or discourage unhealthy use, and regulating business and persons whose activities may affect interstate commerce, the federal government can affect population health. Decisions by the judicial branch can also impact federal policy in many ways that affect health, such as upholding governmental power to protect people's health, setting conditions on the receipt of public funds, and upholding a woman's right to reproductive privacy.³

Organization

The federal government is divided into three branches: the legislative, judicial, and executive. The legislative and judicial branches do play substantial roles in public health, but it is usually the activities of the executive branch that come to mind when considering the federal government's role in improving public health. Within the executive branch, it is the Department of Health and Human Services (DHHS) which is the primary site of public health activities. Many of those activities are centered in one of the DHHS's component parts, the U.S.

Public Health Service (PHS). There are, nonetheless, significant activities related to public health that occur in other branches of the executive branch. Examples include the Women, Infants, and Children Program (WIC) run by the Department of Agriculture (the largest public health program in the country in terms of dollars spent), the many pollution and contamination control programs run by the Environmental Protection Agency (EPA), the workplace safety programs run by the Occupational Safety and Health Administration (OSHA) which is part of the Department of Labor, and the health-care and public health services provided to active-duty military personnel by the Department of Defense.

The Department of Health and Human Services

Public health-related activities and responsibilities are scattered throughout the federal government, but the principle federal agency for health-related programs is the Department of Health and Human Services (DHHS). DHHS is involved in policy making, financing of public health activities, public health protection, collection and dissemination of information, capacity building, and direct management of services.³ Many of these activities are located in various branches of the PHS.

The PHS had its origins in the Marine Hospital Service in the late 1700s, created to meet the health-care needs of Merchant Marine seamen. The Service continued relatively unchanged until the turn of the twentieth century when it was renamed the Public Health Service and took on new responsibilities, most notably providing states with expertise to deal with major infectious disease epidemics.¹²

The PHS eventually became an arm of the DHHS after that cabinet department was formed, originally as the Department of Health, Education, and Welfare. The PHS consists of a series of operating agencies that have remained relatively intact through many changes in the federal executive establishment. The current operational arms of the PHS include the National Institutes of Health (NIH), the Centers for Disease Control and Prevention (CDC), the Health Resources and Services Administration (HRSA), the Indian Health Service (IHS), the Food and Drug Administration (FDA), the Agency for Toxic Substances and Disease Registry (ATSDR) (administered by the CDC), and the Substance Abuse and Mental Health Administration (SAMHA). These major agencies are subdivided into centers, institutes, and branches staffed with both commissioned officers of the PHS and civilian employees of the federal government.

► THE STATE PUBLIC HEALTH ROLE

The role of the states and territories in public health, as with the role of the federal government, has evolved over time. The IOM has also defined these responsibilities well.

► AS DEFINED BY THE INSTITUTE OF MEDICINE

The IOM report describes the duties of the state health department as:

- Assessment of the health needs in the state based on statewide data collection
- Assurance of an adequate statutory base for health activities in the state
- Establishment of statewide health objectives, delegating power to locals as appropriate and holding them accountable
- Assurance of appropriate organized statewide effort to develop and maintain essential, personal, educational, and environmental health services; provision of access to necessary services; and solution of problems inimical to health
- Guarantee of a minimum set of essential health services
- Support of local service capacity, especially when disparities in local ability to raise revenue and/or administer programs require subsidies, technical assistance, or direct action by the state to achieve adequate service levels²

Organization

In order to fulfill these functions, the 50 states and 5 trusts (Guam, District of Columbia, American Samoa, Puerto Rico, and the Virgin Islands) have developed agencies to address them. In many cases these are not departments, so the Association of State and Territorial Health Officers refers to them as state health agencies (SHAs). There is substantial variability in the organizational structures of these agencies. In some cases the SHA is a cabinet-level office reporting directly to the governor—an arrangement encouraged by the IOM. In other circumstances the SHA functions are subsumed as part of a larger administrative organization, which often includes social services functions as well as health. These “umbrella” or “superagencies” carry titles such as Cabinet for Human Resources or Department of Health and Human Services. They are frequently led by political appointees who often have no substantive health expertise. These individuals report to their governors and are cabinet-level officers. In 2000, 20 states had the SHA in a superagency. This number decreased from 22 states in 1980, reversing a 40-year trend toward the establishment of superagencies.¹³

State Health Agency Activities

The activities of SHAs vary considerably. For example, the IOM report recommended that Medicaid, environmental programs, and mental health services should be a part of the SHA’s function.² That, however, is not the norm. In only five states is the SHA responsible for mental health services, and in only five states and three territories is the SHA responsible for Medicaid.¹³ In most states Medicaid management is the responsibility of the welfare agency. A case can certainly be made that subsuming the large budgets of Medicaid under the aegis of the SHA would allow the SHA to more closely integrate its public health functions with that of payment for medical care services. In fact, the group receiving the largest amount of public health services is women and children. Women and children also receive the a substantial portion of Medicaid expenditures, thus providing opportunity for synergy between these two governmental functions.

Environmental health was traditionally a part of the SHA’s responsibility until the 1960s. At that point growing concern about environmental degradation led special interest groups and policy makers to give special attention to many environmental issues. The federal government had made the decision to create the Environmental Protection Agency in response to those same concerns, and most states followed the federal lead by creating a state environmental protection agency separate from the SHA with responsibility for many environmental issues. All states were given the opportunity to designate a lead environmental health agency. While some initially designated the SHA as the lead agency, the number so designated fell from 19 in 1978 to only 8 in 2000.¹³ Even though most major environmental concerns are dealt with by state environmental protection agencies, most SHAs have retained responsibility for some environmental health issues, such as food service, recreation facility inspections, investigation of chronic disease clusters that might have an environmental etiology, etc.

State Boards of Health

One of the strong recommendations of the IOM regarded state boards of health. They felt, “. . . each state should have a state health council that reports regularly on the health of the state’s residents, makes health policy recommendations to the governor and legislature, promulgates regulations, reviews the work of the state health department, and recommends candidates for director of the department.”² In 2000, 21 states had boards of health which were responsible for making policy, while 14 had boards which were advisory.¹³ It is more likely that existing boards of health have a policy-making function in states with a free-standing SHA than in those with a superagency. Only four states had a board which appointed the director of the SHA in 1992.¹⁴ The growing centralization of policy making in the executive branch

and the perception that special interest groups, especially physicians, have “captured” them, has led to a decline in the power and influence of state boards of health.

Public Health Directors

In the earlier half of the century, the director of health was a physician, frequently trained in public health, who held the job for a protracted period of time. In fact, many states had statutes that required the director to be a physician. That has changed over the years to the point that in 2000 only 25 states had that requirement.¹³ In many cases there is no statutory blockage to the governor appointing his or her cardiologist or campaign manager to the post. The “politization” of the position in many places has led to substantial turnover and a diminished desire on the part of qualified individuals to take such a position.

► THE LOCAL PUBLIC HEALTH ROLE

Local health departments are the governmental entities closest to the populations needing services. The IOM felt that, “...no citizen from any community, no matter how small or remote, should be without protection, which is possible only through a local component of the public health delivery system.”² This is a more modern reaffirmation of the need for, “a governmental presence at the local level (AGPALL).”²²

As Defined by the Institute of Medicine

The IOM defined the functions of official local public health agencies as assessment, policy development, and assurance. By assessment, the IOM meant the responsibility to develop or collect data and information that allows for analysis and understanding of the health status of the communities for which the agencies are responsible. The policy development function requires that public health agencies take the lead in developing policies and making decisions based on the best available scientific knowledge. Finally, the official public health agency has the responsibility to ensure that services necessary to achieve agreed-upon health goals are provided.² This can be done by providing the required services directly, or by encouraging their delivery by other agencies, groups, or individuals in the community. Guidance in this matter is provided by the 10 essential services described previously, and the Local Public Health System National Performance Standards. Particular services delivered by each local health department will depend on the needs of each community and decisions made locally about where those services can best be located.

Size of Local Health Departments

State health agencies vary considerably from state to state, but there is even more variability in the approximately 3000 local public health departments in the United States. A periodic survey conducted by the National Association of County and City Health Officials (NACCHO) allows us to characterize the structure and function of local health departments (LHDs).

Generally, LHDs serve small populations. Over two-thirds (69%) of LHDs serve a jurisdiction containing fewer than 50,000 people. In fact, 50% of LHDs serve less than 25,000 people. According to the survey, 60% of LHDs are county, 8% are multicounty, 7% are city/county, 10% are city, and 15% are town/township jurisdictions. Not surprisingly, the smaller jurisdictions have the fewest employees. LHDs that serve a population of less than 50,000 employ an average of 13.9 and a median of 8.5 FTEs.¹⁵

Organization and Structure

The organizational relationships between the SHA and the LHDs also vary considerably. In 11 states the SHA is the LHD, or directly operates the LHD. Of these 11, four are very small states (Hawaii,

Delaware, Rhode Island, and Vermont). In seven states control is shared between the county and the state. Sixteen states are totally decentralized with local government operating the LHD, and another 16 states have a mix, where large jurisdictions run their own LHD, but the state directly runs smaller, more rural, LHDs.¹⁵

The IOM recommended that a single jurisdiction in a community be given the responsibility for providing public health services to decrease duplication and/or prevent confusion about responsibilities. As a corollary, it also recommended that jurisdictions too small to support an effective LHD consider linking with other communities to create district health departments.²

The IOM also recommended that boards of health should exist at the local level with responsibilities comparable to those it recommended for state boards.² In 1992–93 (the most recent data available), approximately 73% of LHDs had a board of health, a slight increase from 70% in 1989.¹⁵

Funding

There are four major sources of funding for LHDs: local taxes, state grants, federal grants, and fees for service. Through the 1990s and into the current decade, there have been significant shifts in the portion of support coming from each area. By 2000, local revenues accounted for 44% of total LHD funding, up from 34% in 1992. State revenues comprised 30% of the revenue stream, down from 40% in 1992. Federal funding shrank from 6% in 1992 to only 3% in 2000, and fees for service rose to 19% of LHD budgets in 2000 from 17% in 1992. These changes probably represent, to some degree, the flattening of federal categorical grant dollars during this period,¹⁵ as well as increasingly tight state and federal budget allocations for public health. Neither the recent influx of bioterrorism preparedness funding to SHDs and LHDs, nor the continued decline of state and federal dollars in other areas of public health, are taken into account in these figures.

Most LHDs serve jurisdictions that have small populations. Sixty-nine percent of health departments serve fewer than 50,000 residents, and 50% serve fewer than 25,000 people. The median average expenditure per year of departments serving 25,000 or fewer in 2000 was only \$214,658 and the median number of staff was just 8.5 FTEs.¹⁵ These are remarkably small numbers given the range of responsibilities shouldered by these agencies.

Leadership

Leadership at the local level is more stable than it is in SHAs. The most recent data available is from 1992. At that time over 50% of LHD leaders had been in office longer than 5 years. In general, the smaller jurisdictions have the longest tenure and the largest health departments experience turnover rates comparable to those in SHAs. Approximately 37% of LHD directors have doctoral degrees, and only have 17% have public health practice degrees (MPH or DrPH).¹⁵

Services

Despite the recommendation that a group of essential public health services be evident in every LHD, the evidence shows that there is great disparity in services offered. Most LHDs report that they offer clinical preventive services, such as adult immunizations (91%), childhood immunizations (89%), tuberculosis testing (88%), and HIV testing and counseling (64%). Most assess the extent to which clinical preventive services are provided in their communities (80%), and provide programs to fill gaps in those services. Communicable disease control services are commonly present (94%).¹⁵

Almost all public health departments provide some personal health services. In many cases, the health department is the provider of last resort, filling gaps in the private medical care system. Reimbursement for Medicaid-eligible clients often provides the funding base required for the department to maintain its services to the uninsured population. The growing trend in states to mandatory, Medicaid managed-care arrangements, however, has moved paying clients out of health

departments into the private sector without reducing the need for care for the growing numbers of uninsured. This threatens the viability of one of our society's "last resort" systems for the medically disenfranchised, and challenges both the private and public sectors to develop collaborative arrangements to assure continued access to needed personal health services. In testimony to this issue, between 1992 and 2001, LHDs reported significant reductions in the proportion of departments that offer personal health services: primary care from 30% to 18%, dental care from 45% to 30%, prenatal care from 64% to 41%, family planning from 68% to 58%, WIC from 78% to 55%, and EPSDT from 79% to 58%.¹⁵

Environmental issues are more clearly identified at the local level as the responsibility of the health department, in general, than they are at the state level. Most LHDs enforce state environmental laws (restaurant inspections, trailer park inspections, etc.), regulate private water and sewage systems, and enforce other local environmental ordinances. Confusion does sometimes occur when LHDs receive environmental complaints about problems when jurisdiction for dealing with those problems lies with others. It is then the job of the LHD to coordinate the response, and assure that the state or federal agency with jurisdiction follows through on investigation and resolution of the problem.

► ASSESSMENT AND MANAGEMENT TOOLS

Public health has benefited from the movement of a number of management tools from the private to the public sector over the past two to three decades. It has increased its capacity in recent years to deal with public health issues by successfully marrying good management mechanisms with new tools to describe and develop solutions for community health problems.

Setting National Objectives for 1990

One of the most important steps taken was to apply management by objectives and total quality management to public health. The notion to use measurable objectives to enhance the productivity of public health efforts at the federal level dates to the publication in 1979 of *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention*. This document laid out a series of goals for mortality reductions to be achieved in the United States by 1990 for four age groups:

1. a 35% reduction in infant mortality
2. a 20% reduction in mortality for children ages 1–14 years
3. a 20% death rate reduction for those between 15 and 24 years of age
4. a 25% reduction in adult mortality for those aged 25–65 years

For those above age 65 it called for a reduction in disability days.¹⁶

The Public Health Service began examining health status determinants and developed information on 15 disease prevention/health promotion areas. With the help of outside experts, in 1979 the first draft of specific objectives for these 15 priority areas was developed. After considerable outside review, *Health Promotion/Disease Prevention: Objectives for the Nation* was published in 1981. It contained 226 objectives with targets for achievement by 1990 that were linked to the 15 priority areas. The objectives were grouped as improvement in health status, reduction of risks to health, increased awareness, improved and expanded preventive health services, and improved surveillance.¹⁷

This effort was moderately successful. Three of the four mortality-related goals were met or exceeded. Specifically, the infant and adult mortality goals were met, and the childhood mortality target was significantly exceeded. The mortality goal for adolescents was not met. Failure to achieve the goal was directly due to high rates of both unintentional (motor vehicle accidents) and intentional (homicide) fatal injuries in this age group.¹⁸

Thirty-two percent of the 228 objectives set for 1990 were met. Progress was made toward an additional 30%, and ground was either lost or no progress made in another 15%. Insufficient data was available to determine the status of the remaining 23% of the objectives.¹⁸

In general, however, the success of this project was remarkable. It established an agenda which the public health community could rally around, and served to energize and empower those who were committed to improving community health status.

Healthy People 2000

Because this project was so well received, the PHS began work in the late 1980s toward the establishment of a new set of objectives for the year 2000. It sought input even more broadly than it had previously, and in September, 1990, distributed *Healthy People 2000: The National Health Promotion and Disease Prevention Objectives*. This document contains three overarching goals:

- Increase the span of healthy life
- Reduce health disparities among Americans
- Achieve access to preventive services for all Americans¹⁸

The 332 objectives contained in *Healthy People 2000* address Health Promotion, Health Protection, Preventive Services, and Surveillance and Data Systems. They are grouped into 22 priority areas (see Table 75-1). Surveillance and Data Systems was included in this new version of national objectives in order to provide the foundation for tracking all of the objectives in an effort to minimize the problem of not being able to determine progress made on some of them.

A Healthy People 2000 final review of progress in tracking these objectives yielded the following information: 68 objectives (21%) met the targets, 129 (41%) showed movement toward the targets, 35 objectives (11%) showed missed results, and 7 (2%) showed

TABLE 75-1. HEALTHY PEOPLE 2000 PRIORITY AREAS

■ Health Promotion

1. Physical activity and fitness
2. Nutrition
3. Tobacco
4. Alcohol and other drugs
5. Family planning
6. Mental health and mental disorders
7. Violent and abusive behavior
8. Educational and community-based programs

■ Health Protection

9. Unintentional injuries
10. Occupational safety and health
11. Environmental health
12. Food and drug safety
13. Oral health

■ Preventive Services

14. Maternal and infant health
15. Heart disease and stroke
16. Cancer
17. Diabetes and chronic disabling conditions
18. HIV infection
19. Sexually transmitted diseases
20. Immunization and infectious diseases
21. Clinical preventive services

■ Surveillance and Data Systems

22. Surveillance and data systems

Source: *Public Health Service: Healthy People 2000: National Health Promotion and Disease Prevention Objectives*. Washington, DC: U.S. Department of Health and Human Services, 1990.

no change from the baseline. Only 47 objectives (15%) showed movement away from the targets, and 32 objectives (10%) did not provide sufficient data to be assessed.¹⁹

Healthy People 2010

The continued success of Healthy People 2000 prompted the creation of a new set of objectives for the year 2010. As with previous documents, this required the participation and input of a variety of constituencies and viewpoints. This report and its development were guided by the Institute of Medicine.

As with the earlier objectives, this one begins with overarching goals. The first goal is to increase the quality and years of healthy life. This goal focuses on increasing life expectancy to more nearly that of other developed nations. It also includes a concern with the quality of life. While it is difficult to define, the notion is to use tools to document the increase in the quality-related years of life.

The second goal is eliminating health disparities. There are continuing and significant differences in both length and quality of life based on several characteristics of populations, sex, gender, ethnicity, socioeconomic status, and so on. Healthy People 2010 commits us to decreasing those differences, to quote, "Healthy People 2010 is firmly dedicated to the principle that—regardless of age, gender, race or ethnicity, income, education, geographic location, disability, and sexual orientation—every person in every community across the Nation deserves equal access to comprehensive, culturally competent, community-based health-care systems that are committed to serving the needs of the individual and promoting community health."²⁰

The document has 28 separate focus areas and 467 objectives distributed among these focus areas. These areas include very specific interventions or health problems in individuals or communities, such as cancer or physical activity. Others are focused on much broader areas, such as access to care or improving public health infrastructure. The 28 focus areas are listed in Fig. 75-2.²⁰

One of the criticisms leveled at previous objectives is that there were too many, they had no priority and were hard to deal with given their number and variety.²¹ Given that criticism, the framers of Healthy People 2010 identified 10 leading health indicators from the 28 focus areas, these 10 are listed in Fig. 75-3.²⁰

The establishment of measurable national health objectives coupled with regular tracking of progress made toward their accomplishment has proven to be a very effective way to focus the nation's attention on health status. The objectives have brought a variety of governmental agencies together to determine approaches to protecting and improving health. They have also provided an opportunity for contributions to the process by nonpublic health organizations and agencies resulting in a prevention agenda that has a wide range of national support.

Setting Local Objectives

Setting national objectives is a very important step in preparing for an ordered process of allocating resources where the impact is likely to be greatest. It is the translation of those national objectives into action at the local level that actually assures progress toward meeting them.

Mobilizing for Action through Planning and Partnership

The most recent tool for community health assessment and planning is *Mobilizing for Action through Planning and Partnership (MAPP)*. This tool was developed through a collaborative effort of NACCHO and the CDC. The process of using MAPP is shown in the two graphics, Fig. 75-4²² and Fig. 75-5.²² During the first phase those responsible for implementing MAPP get themselves prepared for the process. Embarking on MAPP is not to be taken lightly, as it requires substantial commitment from those who lead it and those involved in its various phases. The second step is the visioning process, attempting to describe what the community health should look like in ten years.

Figure 75-2. The document has 28 separate focus areas and 467 objectives distributed among these focus areas. These areas include very specific interventions or health problems in individuals or communities, such as cancer or physical activity. Others are focused on much broader areas, such as access to care or improving public health infrastructure. (Source: Healthy People 2010: Understanding and Improving Health. 2nd ed. U.S. Department of Health and Human Services, Washington, DC: U.S. Government Printing Office, November 2000; pp 17, 24.)²⁰

Figure 75-3. Framers of Healthy People 2010 identified 10 leading health indicators from the 28 focus areas. (Source: Healthy People 2010: Understanding and Improving Health. 2nd ed. U.S. Department of Health and Human Services, Washington, DC: U.S. Government Printing Office, November 2000; pp 17, 24.)²⁰

Figure 75-5. The most recent tool for community health assessment and planning is Mobilizing for Action through Planning and Partnership (MAPP). This tool was developed through a collaborative effort of NACCHO and the CDC.

The next step is to complete the four community assessments which will characterize the community, its health status, assets, and infrastructure issues for solving community health problems. The four assessments are (a) community themes and strengths assessment, (b) local public health system assessment, (c) community health status assessment, and (d) forces of change assessment. Following those assessments, the MAPP process requires the identification of strategic community health issues, then a formulation for goals and strategies to deal with these issues, and finally, the *action cycle*. During this phase, participants plan, implement, and evaluate. These activities build upon one another in a continuous and interactive manner and ensure continued success.

The NACCHO website which describes the MAPP process has many helpful tools and suggestions for those who wish to embark on the MAPP process. It is clear that this process is much improved over previous community health processes, but is still open for criticism and further development.²³

Assessment Protocol for Excellence in Public Health

MAPP builds on the experience of the *Assessment Protocol for Excellence in Public Health (APEX/PH)*, which was the first major tool developed by NACCHO to address issues dealing with local community needs assessment. In order to assist LHDs with that task, the National Association of County Health Officials spearheaded a collaborative process in league with the CDC, the United States Conference of Local Health Officers, the American Public Health Association, the Association of State and Territorial Health Officials, and the Association of Schools of Public Health to develop the APEX/PH.²⁴

The APEX/PH program is designed to help LHDs involve their communities in a process to assess community health status, identify and prioritize public health problems, and create a community plan for action. It contains three phases. Phase I is an assessment of internal organizational capacity of the department intended to identify strengths and weaknesses, particularly as they pertain to a department's capacity to take the lead in the broader community assessment effort.

Phase II, intended to be initiated after the department addresses weaknesses or concerns identified in Phase I, is the actual community assessment portion. Phase III is the implementation of the community health plan under the leadership of the LHD. The health officer is expected to combine the results of Phase I and Phase II in a manner that enhances the capacity of the health department to lead the community in directing its resources to most appropriately address the problems identified.

Planned Approach to Community Health

During the 1980s, the CDC, encouraged by the evidence that community-based prevention programs were effective in reducing coronary heart disease risk factors, developed a protocol that could be locally applied to develop community-based health promotion programs. The *Planned Approach to Community Health (PATCH)* was designed as a working partnership between the CDC, SHA's and communities to focus resources and activities on health promotion. There are five phases to the PATCH process:

1. Mobilizing the community—establishing a strong core of representative local support and participation in the process
2. Collecting and organizing data—gathering and analyzing local community opinion and health data for the purpose of identifying health priorities
3. Choosing health priorities—setting objectives and standards to denote progress and success
4. Intervention—design and implementation of multiple intervention strategies to meet objectives
5. Evaluation—continued monitoring of problems and intervention strategies to evaluate progress and detect need for change²⁵

PATCH training has been provided by the CDC to 39 states and territories, and there are at least 130 operational programs.

Healthy Cities

The idea of *Healthy Cities* also emerged in the 1980s as a demonstration project of the European office of the World Health Organization. The project creates public, private, and voluntary partnerships which focus collective energies into coordinated, broad-based approaches to the resolution of community health problems. Each project is expected to attain four major goals: assure organizational capacity, enhance information, establish initiatives, and create networks.²⁶

► THE FUTURE

The health status of citizens of the United States has improved dramatically over the past several centuries. The bulk of that improvement is due to public health policies and actions.²⁷ The major causes of disease and death have changed during that period, however, from communicable disease agents to behavioral and environmental factors that cause chronic illnesses or injuries. Approximately 70% of the resultant premature mortality currently suffered by the population of the United States is amenable to control using population-based strategies.

There are also other areas which can, and will, contribute to the range of public health tools that we can use in dealing with community

health problems. In addition to the epidemiology, biostatistics, environmental health, health behavior, and health systems management, the IOM also suggests that there are several additional areas where knowledge can assist us in understanding and dealing with disease. These areas include genomics, informatics, communication, cultural competency, community-based participatory research, global health, policy and law, and public health ethics. With the advent of new directions in disease etiology and intervention, these new content areas assume increased relevance for the public health practitioner.²⁸ They suggest that we use the socioecological model for considering public health problems. This model, shown in Fig. 75-6,²⁸ indicates that health and disease are dependent on risk factors or specific microbiologic agents, but those other areas, such as the family, the community, the work site, or the context in which we function, are also powerful determinants of disease. The science of this area of public health is rapidly developing and provides an important new source of information to be brought to bear on public health problems.

The notion of community and the socioecological nature of disease also suggest that new ways of community involvement are key in community ownership and communities beginning to deal with these determinants of health. The use of democratic principles, deliberation, public judgment, and public acting has an important role in the new public health.²³

The Place of Public Health in an Evolving System

The United States is currently enduring a restructuring of its illness care system. Change is evolving based on a series of governmental and private policy decisions aimed at controlling illness care costs by applying market strategies to health care and improving the quality of care patients receive. Little attention is being paid to the more than 45 million Americans without health-care insurance, or the public health infrastructure.

If our concern was for the health status of our population, reform of our "system" would be based on what should be done to create the

Figure 75-6. The socioecological model for considering public health problems. This model indicates that health and disease are dependent on risk factors or specific microbiologic agents, but those other areas, such as the family, the community, the work site or the context in which we function are also powerful determinants of disease.

healthiest population possible. Following that concern to its logical ends would lead to the realization that improved health status depends on both illness care reform and public health reform. It is the responsibility of public health practitioners to help society understand that both disciplines are important, and that they should be integrated to provide a seamless web of services from health promotion through disease prevention to illness diagnosis and treatment accessible to all Americans. No one should be denied access to illness care, but it is population-based services that have the greatest potential to improve health status.

Strengthening Public Health for the Future

Public health departments face an operational environment that is more fluid than it has perhaps ever been. Rapid advances in technology and understanding of risks to health challenge agencies with minimal funding, training, and technical capacity to incorporate new methods into time-honored, traditional modes of operation. Federal and state comparative inattention to public health needs, coupled with the shift of resources and some responsibilities to private contracting insurance companies in many, especially urban, localities, create crises of role definition and funding.

As often occurs, however, this period of relatively rapid change presents opportunities. The description of the core functions of public health has made basic public health roles and functions more easily understood and appreciated. The ascendancy of concerns for costs and quality of health care brings new players to the scene who should be philosophically in tune with population risk reduction. The growing technical capacity to store, transmit, and analyze large bits of information brings new opportunities for interaction among public health professionals, and between the public health profession and the community. If public health departments can be flexible and adjust their services and activities to match the needs and opportunities now apparent, they will be in good position to serve well the communities that fund them.

Basic to the successful LHD of the future will be its position as the health intelligence center of its constituency. The LHD must be the source of epidemiologically based thinking and analysis of its community's approach to health problem solving. It must be the facilitator of strong and meaningful community participation in the assessment and prioritization of community health problems and issues. It must be a major participant in public policy decision-making relative to health, and it must deliver, and broker the delivery of, services needed by its constituency to maintain or regain health. And, of course, it must focus on health outcomes as the measure of the impact of interventions.

It will be the rare LHD that has the resources available to it that are needed to carry out its community's full public health agenda. To be successful, LHDs will have to build strong collaborative and cooperative linkages with a variety of other community agencies and institutions. These linkages might take the form of joint programming efforts, service and referral arrangements, contracts for services, conduits for funding, information-sharing agreements, etc. By acting as a broker to bring needed services together to meet identified community needs, the LHD can complete its role in assuring the community will have access to the services it needs.

The proliferation of private, organized health-care delivery systems puts health departments into the position of deciding whether or not to partner with emerging managed care companies and/or to monitor their activities to assure that personal health services are available to all who need them in the community. It is far from clear how, or even if, this dual role can be successfully carried out. Circumstances are quite different community by community, and the many ways these issues will be addressed should be followed closely and evaluated rigorously. At the very least, essential public health services should not be compromised in the meantime.

Also important for success will be the development of stronger linkages between public health agencies and their academic bases, particularly schools and programs of public health. This should be

pursued in a manner that the technical capacity of public health workers is improved, and the knowledge of community public health problems is advanced. Students and faculty from educational settings teaching public health-related disciplines should be welcomed into LHDs for pragmatic practice experiences, and for access to data and systems to carry out research. Likewise, educational institutions should seek out the participation of practitioners in their teaching and research activities. Local health departments should be supportive of their employees who wish to receive further training while employed.

► CONCLUSION

Significant change is occurring in both the illness care system and the public health system. No one is clearly in charge of either. Consequently, there are remarkable opportunities for entrepreneurial efforts to reshape each. Those efforts are clearly evident in the illness care system. They are also present in the public health system, although not as visibly. If the public health leadership of the United States can move the public health system out of old molds that no longer serve it well, there is every reason to believe that public health can provide a valuable set of services to communities, and be recognized as having done so. Steady, measurable gains in community health status will be the ultimate marker of success.

International and Global Health

Franklin M.M. White • Debra J. Nanan

International Health is a well-established branch of public health, with origins in the health situation of developing nations and the efforts of industrialized countries to assist them. It has always considered issues transcending national jurisdiction, for example, quarantine regulations. However, the field has recently extended to Global Health, emphasizing global cooperation for solutions. While problems like unsafe drinking water affect mainly local communities within countries, others have worldwide impact, for example, air pollution, drug trafficking, and tobacco marketing. Although local and national actions are essential, these also require additional global action, for example, Framework Convention on Tobacco Control.¹ Regardless of the levels of solutions (local, national, international, global), at the core of the world's health problems lie enormous inequities in economic and social conditions, and the right to health remains unfulfilled for most of the world's people.

Coherent country-specific, regional, or global health initiatives depend on priority setting that considers the magnitude of problems, and the availability of effective, affordable, and acceptable solutions. The process requires reliable health information to inform decisionmakers and guide managers in implementing sustainable programs. Many industrialized countries do not perform this process well, despite their resources and availability of choices. In developing countries, making the best possible decisions with more limited resources is even more critical, and requires building a research capacity to produce such health information.² The 1990 Commission on Health Research for Development argued that developing countries allocate 2% of their health budgets on Essential National Health Research.³ The Global Forum for Health Research in 1999 noted the "10/90 disequilibrium": only 10% of research is devoted to the health problems of 90% of the world's population.⁴

This disequilibrium mirrors inequities in health worldwide: in 2003, the under-five mortality rate was 123 deaths per 1000 live births for low-income countries (LICs), while in high-income countries (HICs), the rate was 7 (Table 76-1). For all countries experiencing violent conflicts, child mortality rates have worsened: preventable infectious diseases (IDs) and malnutrition, often in combination, are the predominant underlying causes. Women are over 100 times more likely to die of pregnancy-related causes in developing than in developed countries. Of people in developing countries, more than half lack access to sanitation, a quarter lack clean water, a fifth lack access to health care of any kind, and a fifth experience inadequate nutrition. Economic disparities within and between countries are growing.⁵ Over a billion people live in extreme poverty despite the global economy doubling over the past 25 years to more than \$25 trillion.

For some LICs, historical dynamics complicate the situation. For centuries, powerful nations explored, conquered, and exploited world regions already inhabited by indigenous peoples; most of these nations today are donor countries. While colonialism produced benefits, for example, trade routes, and information exchange, many developing

countries still cope with its harmful legacies. In some settings, disparities arise from the colonial fragmentation or coalescence of peoples, sometimes with conflict along religious or tribal lines, for example, Palestine, Kashmir, and Rwanda. In permanently colonized lands, the poor health status of aboriginal peoples and some other minorities, for example, blacks and hispanics in the United States, reflect similar dynamics.

People in rich countries can become indifferent to the widespread poverty and disease of developing nations, and to similar problems in their own. Yet, because such adverse conditions also diminish human dignity and can give birth to civil and global unrest, rich nations increasingly view global health investments as an extension of their foreign policy and security interests. Other motives exist: the growing global dimensions of health issues; the scientific challenge of unsolved and emerging health problems; the threat of IDs exported internationally, for example, severe acute respiratory syndrome (SARS), avian influenza, and Marburg haemorrhagic fever; and (not least) humanitarianism.

► GLOBALIZATION

This term refers to the growing interconnectedness of countries, centered around trade and the flow of ideas facilitated by communications technologies, cultural convergence, and common concerns for environmental and health impacts.⁶ In promoting more open trade, the International Bank for Reconstruction and Development (World Bank) and the International Monetary Fund (IMF) urge deregulated markets, subject to rules laid down by the World Trade Organization (WTO) through multilateral trade agreements, for example, corporate taxation concessions and investment incentives allied for relaxation of wage controls and workplace standards, and contraction of public sector spending.⁶ Some developing nations, for example, China and India, can compete in this environment—size and resources matter. Otherwise, nations with fragile economies may struggle in dependency relationships, often accumulating debt that reduces their capacity to meet human needs. It is argued that only where regulatory institutions are strong, domestic markets competitive, and social safety nets in place, will health benefits derive from globalization.⁷

The potential risks to LICs from trade-oriented initiatives were demonstrated during the era of structural adjustment programs (SAP) two decades ago. The IMF then argued that economic development eventually results in poverty reduction and improved health status; IMF requirements called for reducing public expenditures on education and health as a condition for development loans. This process resulted in reversing the social and health gains of many countries.⁸ The World Bank (WB) consequently came to recognize that strong state support is essential to education and health.⁹ Income gains accounted for only a fifth of life expectancy (LE) gains between 1960 and 1990; generation and application of new knowledge and female

TABLE 76-1. SELECTED HEALTH AND DEVELOPMENT INDICATORS BY INCOME LEVEL, AND BY REGION FOR LOW AND MIDDLE INCOME LEVELS

Income Level (No. of Countries)	High Income (54)	Upper Middle Income (37)	Lower Middle Income (56)	Low Income (61)	Low and Middle Income Countries by Region					
					E. Asia & Pacific (24)	Europe & Central Asia (27)	Latin America & Caribbean (32)	Middle East & N. Africa (15)	South Asia (8)	Sub-Saharan Africa (48)
Population (millions)	972	333	2,655	2,311	1,855	472	533	312	1,425	705
GNI per capita (US\$)	≥9,386	3,036–9,385	766–3,035	≤765	1,988	1,217	1,747	744	733	351
LE at birth, sexes combined (years)	78	74	69	58	70	68	71	69	63	46
TFR (births per woman)	1.6	2.3	2.1	3.7	2.1	1.6	2.4	3.1	3.2	5.2
IMR (per 1 000 live births)	5	18	31	80	36	25	43	58	67	110
<5 years mortality (per 1,000 children)	7	22	38	123	41	36	33	53	92	171
Literacy, % ≥15 years*:										
males	—	90	88	68	90	98	86	82	73	71

education were more critical.¹⁰ The world should have learned that, in liberalizing trade, measures to protect the autonomy of national social and health policies must be respected. If health is a priority, it can be delivered; for example, health status in Cuba, excluded from mainstream globalization, is comparable to that of the United States, with per capita income less than a fifth. Public policies affecting health determinants underlie this success.¹¹

How globalization plays out depends on how the process is managed. Under the WTO's Trade-Related Aspects of Intellectual Property (TRIPS) Agreement (1994), drug patent protection trumps public health. Although the WTO Doha Declaration (2001) reaffirmed that TRIPS should not prevent poor countries from making essential drugs available to their people, successful applications of this principle so far remain few.⁵ Ideally, trade and health-related laws should work in harmony, for example, Rotterdam Convention on the Prior Informed Consent Procedure for Certain Hazardous Chemicals and Pesticides in International Trade (1998). A high level of compliance with such multilateral agreements can be achieved, a motivating factor being how a nation's reputation is affected.¹² Globalization will be optimized only when health becomes a central objective.¹³

► CLASSIFICATIONS OF NATIONS

All classifications have advantages and limitations. The term "third world" originated in French (*tiers monde*) following World War II when politicians aligned countries into the "free world," the "communist block," or nonaligned states ("third world"). This construct is now obsolete, communism being a spent force and new geopolitical alignments forming. In 1980, the Brandt Commission envisioned a world divided into "North," the industrialized nations (mostly Northern Hemisphere), and "South," comprising most of Africa, Latin America, and South, Southeast, and Southwest Asia, the underdeveloped regions.¹⁴ While several "south" countries have transcended this status, the terminology remains relevant with renewed interest in the Commission's goals.¹⁵ The terms "developing versus developed," or "less developed versus more developed," refer mainly to economic development. However, income-based groupings may be preferable. The WB classifies nations into four groups based on gross national income (GNI) per capita, using U.S. dollar equivalents (Table 76-1).

Other classifications are also used, depending on the purpose. To compare disease burdens and expenditures, the World Health Organization (WHO; see International Health Agencies) groups nations as established market economies; former socialist economies of Europe; China and India as distinct entities due to population size; and the rest of the world by geographic region.¹⁶ The WHO also groups neighboring countries into regions, for example, Africa, Latin America and the Caribbean, and Eastern Mediterranean, for policy and programming purposes. The United Nations Children's Fund (UNICEF), given its distinct mission, groups nations by their infant and early child mortality rates.

► INEQUALITIES AND THE HEALTH OF NATIONS

Of 6.3 billion people in the world (Table 76-1), 2.3 billion live in the poorest countries (LICs), 2.6 billion live in lower-middle income countries (LMICs), and 333 million in upper-middle income countries (UMICs). About 972 million people live in HICs, rich in part because of their access to or ability to exploit resources, for example, oil, and food. Restated, over 80% of people live in nations with access to less than 20% of the world's wealth and productive capacity. More striking is that 2.5 billion of the world's poor collectively have less wealth than the world's richest 400 individuals.

Such gross inequalities should challenge the world community. That LE varies by more than 48 years among countries (Japan 81.5; Zambia 32.7), and 20 years or more within countries, is not inevitable.¹⁷ Social factors influence the occurrence of most forms of disease and lie at the root of health inequalities. In response to this global challenge, WHO recently launched a Commission on Social

Determinants of Health (2005) to review evidence, raise societal debate, and recommend policies to improve the health of vulnerable people; the thrust is to transform public health knowledge into political action.¹⁸

The Human Development Index (HDI) is a composite index developed by the United Nations Development Programme (UNDP), combining income, life expectancy, adult literacy, and schooling. Although controversial, the HDI helps to compare countries regarding their health and welfare. In 2002, Norway had the highest HDI (0.956) and Sierra Leone the lowest (0.273; rank 177).¹⁷ Four decades ago, China ranked below Pakistan on education although equal on per capita income.¹⁹ Pakistan today (HDI 0.497; rank 142) remains an LIC with an unfavourable health status.²⁰ China (HDI 0.745; rank 94) is now a LMIC showing impressive gains. This did not happen by chance. In its process of socialist modernization, casting off feudalism and colonialism, China emphasized prevention, focused on rural areas (using "barefoot doctors"), and implemented a "one-child policy."²¹ Now contemplating democratic reforms, while challenged by non-communicable disease (NCD) risk factors, HIV/AIDS, and most recently SARS, how China now manages its health situation is of global interest.

Today, several Asian nations, for example, Japan, Singapore, and South Korea, are at par with western economies. While often attributed to investment policies, savings incentives, and land and tax reforms, more critical to health are their public investment in education and technology, and degree of gender equity. Notwithstanding significant gains in the Americas, for example, Chile, Brazil, and Mexico, the situation is dire for the countries of sub-Saharan Africa and western Asia whose economic viability is overwhelmed by population growth outstripping resources, environmental degradation, poor planning and mismanagement, corruption, military conflict, and widespread preventable diseases.

International Health Agencies

Health services in developing countries mostly reflect their own widely varying capacities. The international system plays an ancillary role, comprising four types of agency: multilateral, bilateral, non-governmental, and other.

Multilateral Agencies

Funded primarily by member governments, the lead agency of this type is WHO, headquartered in Geneva. Launched in 1948, under the aegis of the newly formed United Nations (UN), WHO is governed by a World Health Assembly composed of representatives from almost 200 member states. Its main task is to review and approve policies, program initiatives, and biennial budgets. WHO is primarily a coordinating agency, promoting technical cooperation among countries while facilitating training and technical assistance. Health data from member countries are analyzed and the resulting information disseminated globally; collaborative programs with member countries are performed by a Secretariat, supported by six regional offices with representatives in most countries.

The organization's achievements are impressive. Most notably, it spearheaded the global eradication of smallpox, accomplished in 1979.²² Similar initiatives for other conditions are underway. Nonetheless, such selective programming by WHO attracts debate given its broader mandate. WHO also suffers from unreliable funding; for example, the United States owed \$2 billion in the late 1990s. In recent years, extrabudgetary sources (grants, contracts, donations) have exceeded the regular budget. While this diversification protects WHO against unstable government funding, extrabudgetary support is mostly restricted to particular programs, which may influence or distort priorities.

Other multilateral agencies with health-related roles are UNICEF, UNDP, WB, UNAIDS (a separate agency since 1993, formerly the WHO Global Program on acquired immunodeficiency syndrome), the Food and Agriculture Organization (FAO), the United Nations Fund for Population Activities (UNFPA), the Office of the UN High

Commissioner for Refugees (UNHCR), and the UN Fund for Drug Abuse Control (UNFDAC).

Bilateral Agencies

In addition to supporting multilateral agencies, most industrialized nations also provide aid on a “country-to-country” basis, attempting to match a recipient’s needs with the donor’s objectives and capacity to assist, usually subject to political considerations. Smaller donors are geographically selective; for example, Australia emphasizes its Western-Pacific neighbors. Others emphasize their expertise; for example, the Netherlands supports water technologies. Some follow historical links; for example, France emphasizes its former colonies. Some both receive and donate international aid, for example, Cuba, and China. The United States links aid to democratic reforms and human rights, although restricting support for reproductive rights since 2001.²³ Illustrating the flexibility of the bilateral system, other donor nations, for example, United Kingdom and Canada, compensate through unrestricted support for these rights.

In 2004, only five countries met the UN target of contributing at least 0.7% of gross national product in official development assistance (ODA): Norway, Denmark, the Netherlands, Luxembourg, and Sweden. In contrast, the United States provided only 0.16%, and the U.K. 0.36%. Spain, Germany, France, Finland, Belgium, and the U.K. have pledged to reach the target by 2015. Donor countries often rely on their own expertise through competitive bidding to design, implement, and monitor projects funded under bilateral agreements, sometimes requiring that the donor’s own products and services be used. Thus, a significant proportion of aid budgets may be recycled within a donor’s economy. As each donor has its own motivation, priorities, and management style, competition and conflict can arise in some settings, revealing a need to improve donor coordination. It is critical that ODA is increased, effectively placed, and fairly counted, so as to help to build sustainable capacities for all the people of the world.

International Nongovernmental Organizations

International nongovernmental organizations (NGOs) are increasingly active in development work as the inadequacies of bilateral and multilateral responses become more apparent. Sometimes known as “people to people” aid, their activities are mostly specific, for example, targeting trachoma, and cataract, while some are general, for example, aid for orphans. Supported mainly by voluntary subscriptions or donations, some NGOs also act under contract to governments or other agencies. The largest NGO is the International Red Cross and Red Crescent movement, which has national counterparts within most countries. It is mandated under the Geneva Conventions to assist prisoners and civilians in armed conflicts, including visiting detainees and enabling them to communicate with the outside world, setting up surgical hospitals and emergency teams, rehabilitation of war-disabled persons, and providing independent information on prisoners and war victims.

Other well-known international NGOs are Oxford Famine Relief (OXFAM), CARE International, Save the Children International Alliance, and World Vision. Medecins Sans Frontieres (MSF, Doctors Without Borders) was recently awarded the Nobel Peace prize (1999). Founded in France in 1971, MSF provides health aid to war victims, and assists in other health disasters and development initiatives. Smaller international NGOs also make highly valuable contributions, many operating within a country. Many exercise key advocacy roles, for example, to prevent violent conflicts, promoting gender equity. Despite good intentions, given sometimes conflicting priorities and mandates, and competition for resources, better coordination would help them become more effective.

Other Agencies

Both developed and developing country institutions, universities, laboratories, and consulting groups are active in bilateral initiatives, and some also work with multilateral agencies, for example, as WHO collaborating centers. Several philanthropic bodies contribute substantially to international health, for example, the Bill and Melinda Gates

Foundation, Robert Wood Johnson Foundation, David and Lucille Packard Foundation, and Aga Khan Development Network.

► HEALTH REFORM AND FINANCING

In many developing countries, health and social development suffer from distortions in priority setting, fiscal allocations, and management. Neocolonial patterns are reflected in debt servicing and arms purchases (large donor countries are major suppliers), vastly exceeding the value of ODA and depleting national budgets. Given the consequently reduced national investment in health, private providers dominate with minimal regulation. Such situations have often arisen in virtual policy vacuums, with no explicit social development or health objectives, let alone comprehensive health sector planning.

The widespread need for reform was recognized by the WB in their concept of “investing in health.”²⁴ However, this idea is not widely accepted by political leaders even in some industrialized countries; for example, millions of Americans lack health insurance. In virtually all countries, “reform” is driven more by fiscal than health priorities. Lack of investment in health by many developing countries contributes to a “brain drain” that further diminishes their capacities while subsidizing the health systems of developed nations, some of which actively recruit this talent, for example, nurses and doctors. While health may be improved indirectly by investing in other sectors, for example, education, optimal outcomes require direct investment in the health sector. Assistance with health systems reform and human resources for health is an important responsibility for bilateral and multilateral aid agencies. There is a direct relationship between such investment and health outcomes.²⁵

Public-Private Partnerships

In 1998, the Director-General of WHO advocated greater collaboration with the private sector.²⁶ Perhaps inevitable given the global trend towards privatization and declining public sector funding, with this endorsement, public-private partnerships (PPPs) were ushered in to address a broader range of health initiatives. Beyond philanthropy, the private sector now had to help shoulder responsibility for the public good, or otherwise demonstrate the failure of privatization as sound public policy. Likewise, many public health managers had little option other than to develop such arrangements, despite their untested strengths and limitations. As a company’s first responsibility is to its shareholders, the potential for conflicts of interest was recognized, as was the need for WHO to ensure safeguards to protect the public interest.²⁷ Large corporations gained access to certain areas of decision-making arguably greater than that of many countries. Major pharmaceutical and equipment manufacturing firms joined private foundations to become major players in the global development scene.

While the impact of PPPs requires ongoing evaluation, some genuinely good work has emerged: subsidized products, distribution assistance, educational initiatives, and disease control ventures, for example, Global Alliance for Vaccines and Immunization and Medicines for Malaria Venture. In some instances, health services are to be strengthened, for example, Gates Foundation/Merck Botswana Comprehensive HIV/AIDS Partnership.²⁸ However, WHO-facilitated PPPs generally emphasize specific disease interventions, and other PPP models seem better at health systems development; for example, BRAC (formerly Bangladesh Rural Advancement Committee), a people-centered national NGO, has developed an integrated and multidimensional health program that links foundations, governments, and communities, with notable success within the country.²⁹

Strategic Options

The Alma Ata Conference sponsored by WHO and UNICEF in 1978 ushered in a new philosophy on health service development. With 134 countries represented, primary health care (PHC) was unanimously accepted as the key to attaining “by all peoples of the world by the year 2000 a level of health that will permit them to lead a

socially and economically productive life”.³⁰ The PHC strategy emphasized community participation, and included adequate nutrition, safe water, sanitation, maternal and child health, immunization, medical care for common illnesses, access to essential drugs, control of locally prevalent diseases, and health education. Countries were motivated to formulate PHC approaches, setting objectives based on their health profile and resources.

However, lack of leadership and management skills in developing countries hampered progress towards this goal, and rather than taking on the task of building local capacity, the global agenda abruptly changed in 1979. A powerful counter movement questioned the feasibility of PHC, advocating an alternative strategy deemed “Selective Primary Health Care.”³¹ Buoyed by successful smallpox eradication, its goal was to control other important IDs, selected from a global list of 23.³² The guiding principle was interrupting transmission channels, not developing PHC systems from the ground up. Endorsing “selective PHC,” WHO launched globally coordinated, nationally administered, vertically integrated, and externally financed programs against mostly single diseases, for example, tuberculosis, leprosy, and malaria. Progress towards eradication of poliomyelitis and dracunculiasis demonstrated again that selective approaches can work.

Developing countries quickly learned that selective programs attract funding, with little incentive for integration within broader programming; yet selective programs against every disease are unfeasible. Moreover, conditions dominating childhood morbidity and mortality (diarrheal diseases, acute respiratory infections, and malnutrition) are not efficiently addressed by selective PHC, and receive less funding. Regarding the NCD pandemic now dominating all regions except sub-Saharan Africa, lack of a broadly integrated PHC model hampers efforts to respond. At the “People’s Health Assembly” in Dhaka in 2000, delegates from 113 nations expressed disappointment over the unrealized goal of Alma Ata, and encouraged policy reflections “by” instead of “on behalf of” people, emphasizing the social and economic roots of ill health and poverty.³³ There is clearly a need to restore balance between these two strategic visions.

Integrated approaches have been advocated in all developing regions, and some show promise, for example, vitamin A supplementation within the Expanded Program on Immunization.³⁴ Integrated Management of Childhood Illnesses (IMCI) promotes case management for common IDs and malnutrition, with health systems improvements involving families and communities; but IMCI has not succeeded when scaled to a national level.³⁵ Community-directed treatment for the control of onchocerciasis, schistosomiasis, and intestinal helminths were shown to be functional strategies in poor rural communities in Africa.³⁶ While addressing onchocerciasis as a target for eradication, Carter Center researchers recently reported that health workers engaged in other health activities performed better in control efforts than those involved solely in its control.³⁷

Probably the best examples of integrated approaches are those addressing sexual and reproductive health (see Gender, later in this chapter). Integrated models for NCD, well tested in the WHO European Region’s CINDI network,³⁸ are also of interest: Mauritius achieved impact on NCD risk factors with a policy and lifestyles approach;³⁹ the Pan American Health Organization (PAHO/WHO) initiated the CARMEN network of projects in 1995;⁴⁰ and in 2004, Pakistan launched an NCD Action Plan utilizing a PPP model.⁴¹ Despite the potential of these and other integrated models, they generally enjoy less political and funding support when compared with selective control models.

Responsibility for general inaction in implementing more broadly-based PHC is shared at all levels. District health systems in all countries have, in principle, the potential to integrate medical and public health approaches at community level, consistent with the Alma Ata vision. But district health officers in developing countries are often selected based on seniority without adequate training, while public health specialists may be assigned to inappropriate tasks, for example, emergency clinics. Perhaps it was unrealistic to entrust the implementation of PHC strategy to this poorly managed local health

system.²⁰ With this backdrop, the merits of selective disease control became easier for the multilateral system to advocate and finance, and stays well within their remit.

Citing the “disease-to-poverty” pathway, in 2001 the WHO Commission on Macroeconomics and Health gave timely support to the UN which then launched the Global Fund to Fight AIDS, Tuberculosis, and Malaria in 93 countries, committing an initial U.S. \$1.5 billion by 2004, augmented in subsequent years.⁴² These are devastating conditions; for example, over the past two decades, more than 60 million people have become HIV-infected, and over three million have died from AIDS; in many countries health gains of the previous 50 years have been eroded; for example, in Botswana, adult HIV prevalence is 39%, and LE at birth is now below 40 years. However, despite this clear justification for the Global Fund, whenever selective goals receive massive support, alternative choices inevitably drop in priority; especially so in an era of ODA falling far short of the 0.7% which rich countries pledged to work towards in Monterrey and Johannesburg.⁵ The “poverty-to-disease” pathway also must be addressed, as recognized in 2005 when WHO launched The Commission on Social Determinants of Health.¹⁸

Focusing more on poverty reduction, the eight Millennium Development Goals (MDGs) adopted by the UN in 2000 committed members to tackle ill-health, gender inequality, lack of education, poor access to clean water, and environmental degradation. Three MDGs are directly health-related: reduce child mortality; improve maternal health; and combat HIV/AIDS, malaria, and other diseases.⁵ Critical needs such as health systems development, sexual and reproductive health, and NCDs were omitted, although countries may add their own goals.

► HEALTH TRANSITIONS

Epidemiologic transition theory combines the demographic transitions attributable to declining mortality and fertility rates, with shifts in variables that produce disease patterns. The process was experienced slowly by western societies over three centuries, accompanying improved literacy, hygiene, nutrition, and sanitation; medical interventions played a late role. The “classical” model of western Europe and North America revealed declining infant mortality, increased LE, and aging populations, with a gradual shift in predominance from IDs to NCDs and injuries. Less developed countries are undergoing faster transitions, the timing and pace of fertility decline varying with socio-economic, medical, technological, and political settings.

Variants of the theory help to characterize observed changes.⁴³ The “accelerated/semiwestern model” applies to eastern Europe, Russia, and Japan: the disease pattern changes are attributed mainly to synergy between sanitation and disease control, for example, antibiotics, immunization, insecticides, and organized health care. A “rapid transitional variant” fits scenarios seen in fast industrializing or socially developing countries that are often small, for example, Hong Kong, Singapore, and Caribbean nations, where mortality declines began only in the third or fourth decade of the twentieth century, but once fertility then began falling, it did so rapidly. A “slow transitional variant” characterizes LICs in Africa, Asia, and Latin America, with moderate mortality declines and still high fertility associated with short LEs and young age structure, and slow socio-economic development; a large NCD burden is superimposed on persistent heavy burdens from IDs and malnutrition. An “intermediate transitional variant” includes countries with patterns falling between rapid and slow models, having well-organized family planning programs, but coping with a considerable “double burden” of disease.

Epidemiological transition theory helps explain existing patterns and disparities in international health, and provides an approach to modeling projections. Stages may overlap between or within countries; underlying processes may stagnate or even reverse; war, unfair trade, microbial resistance, systems failure, resource depletion, and environmental damage may be incorporated. Scenarios for sustained health can also be projected: this model calls for improved global governance, investment in social programs, sound resource and

environmental management, health systems adjusted to aging populations, and strategies to reduce disparities between rich and poor.⁴⁴

Denoting transition variables as either determinants or consequences, or interpreting their interactions, is problematic. Furthermore, globalization forces may further distort current and future scenarios: rural to urban population drift, changing nutrition, and other lifestyle variables are dramatically transforming health patterns. The increasing prevalence of overweight or obesity, due to a shift from traditional diets low in fat and high in grains, to diets high in fats, processed foods, and meats, along with more sedentary living, is driving increasing rates of cardiovascular and metabolic disorders, for example, diabetes, especially in lower socioeconomic groups.⁴⁵ In addition, NCDs are more likely to occur in adults who once suffered intrauterine growth retardation due to maternal undernutrition.⁴⁶ The poorest LICs, mostly in Africa, already face a triple burden of communicable disease, NCDs, and sociobehavioural disorders; by 2020, NCDs will account for 70% of deaths in developing regions, injuries will rival infectious diseases in priority, and tobacco is expected to kill more people than any single disease, even HIV/AIDS.⁴⁷

Global and Regional Health Profiles

During the twentieth century, death rates fell and LEs rose first in the more developed countries, and then throughout the less developed world. In 1900, LE at birth was 45–50 years in the United States, Europe, Japan, and Australia. Today, LE in the United States is 77 years, while in Japan and many European countries, LE is over 80 years. However, Russia, Central Asian, and Eastern European states experienced declining LEs during the 1980s and 1990s when economic conditions deteriorated. Between 1990 and 2000, Russian male LE fell from 64 to 59 years, and female LE dropped about 2 years to 72 years.⁴⁸ In Africa, adult mortality, following steady declines until the mid-1990s, sharply reversed; in parts of sub-Saharan Africa, current adult mortality rates now exceed the levels of three decades earlier, producing a rapid drop in LE in the 38 most-affected African countries, where nearly 10 years of LE will have been lost by 2020–2025, falling to age 40 or less in at least eight countries. Without HIV/AIDS, LE at birth in the African Region would have been almost 6.1 years higher in 2002. Healthy LE (HALE) converts total LE into equivalent years of “full health” by taking into account years lived in less than full health as a result of diseases and injuries.⁴⁹ Globally, HALE varies even more than total LE, ranging from 41 years for sub-Saharan Africa to 71.4 years for western Europe in 2002.

As LE at birth is heavily weighted by death at younger ages, to account for survivorship at older ages in various states of health, Disability Adjusted Life Years (DALYs) is an alternative health measure

used. The distribution of DALYs in 2002 due to three groups of conditions, for selected world regions, are presented in Table 76-2: Group I (communicable diseases, maternal and perinatal conditions, and nutritional deficiencies) accounts for below 10% in each developed region, but for almost 75% of DALYs in Africa. However, in all other developing regions, Group II (noncommunicable conditions) equals or exceeds the burden due to Group I. Health policies in poor countries, and at a global level, given the current preoccupation on IDs, must be quick to adapt or lose the opportunity to prevent much of the now burgeoning pandemic of NCDs and injuries.

Differences also exist for indigenous populations.⁵⁰ Wherever measured, for example, Australia, Canada, New Zealand, and the United States, aboriginal people experience lower LEs, higher infant mortality, higher rates for IDs and NCDs, and much higher rates of drug use, injuries, and suicide than general populations. Such gaps signal an urgent need to take action on the social causes that result in these health inequities.

► FOOD AND NUTRITION SECURITY

Nutrition throughout life determines growth, development, and disease susceptibility. Although enough food is produced to feed everyone, inequitable distribution results in hunger and malnutrition, affecting over 350 million people worldwide. Most vulnerable are the poor, the marginalized, women, children, and persons exposed to natural or manmade disasters. Children are most vulnerable and suffer irreversible growth retardation by stunting and wasting, and impaired cognitive development that affects them through life; females are almost twice as likely as males to experience malnutrition.

Food security would exist when all people, at all times, have physical and economic access to sufficient, safe, and nutritious food to meet their dietary needs and preferences. Food insecurity results from unavailability, unstable supplies, insufficient purchasing power, inappropriate distribution, or inadequate household utilization. FAO classifies most of the developing world as “low income, food deficit countries” (LIFDCs) not producing enough food to feed their people and unable to afford importing sufficient amounts to close the gap.⁵¹ FAO estimates that 852 million people worldwide were undernourished in 2000–2002: 815 million in developing countries, 28 million in transitional countries, and 9 million in industrialized countries. The World Food Summit (1996) called for improving food security in over 80 LIFDCs by rapidly increasing food productivity; reducing year-to-year variability in production; and improving food access. The goal is to halve the number of malnourished people globally by

TABLE 76-2. BURDEN OF DISEASE IN DALYs FOR DEVELOPED AND DEVELOPING REGIONS, BY NUMBER AND PERCENT (%)

Who Region	Developing Regions					Developed Regions		
	Africa	Americas	SE Asia	E Med	W Pacific	Americas	W Pacific	Europe

NOTE: “Developed” versus “developing” based on WHO region and mortality rates for children <5 and adult males 15–59 years.

Region abbreviations: SE Asia = South East Asia; E Med = Eastern Mediterranean; W Pacific = Western Pacific;

Americas developed = Canada, Cuba, United States of America; W Pacific developed = Australia, Brunei Darussalam, Japan, New Zealand, Singapore.

2015, the underlying assumption being that barriers to food security can be overcome by economically viable and environmentally sustainable means; however, trade practices and policies associated with deregulated markets impede progress toward this goal.

Though food and nutrition insecurity is generally declining worldwide, albeit slowly in South Asia, the problem is worsening in Africa due to civil conflicts, droughts, floods, and economic downturns. Estimates of undernourished people in Africa rose from 111 million in 1969–1971 to 204 million in 1999–2001. Food shortages are now so severe in East and Central Africa that they require regular international interventions. Rich country agricultural subsidies total over \$300 billion annually, nearly six times the value of ODA.⁵ Food and nutrition security remain global ethical imperatives.

► WATER AND SANITATION

Over a billion people in developing countries lack access to safe water, and 2.4 billion lack access to adequate sanitation.⁵ In rural areas without distribution technology, fetching and carrying water, often performed by women and children, reduces the time available for other subsistence activities. In urban slums from Lima to Karachi, the poor suffer from exploitation by tanker “mafias” delivering water at prices up to 20 times that paid by those who enjoy a municipal supply; poor households spend up to 40% of their income on water.⁵² Most vulnerable are children, who suffer over three million deaths annually from preventable diseases due to lack of water, dirty water, and inadequate sanitation. Oral rehydration for diarrhea reaches only about half of those in need; without water for washing, skin and eye infections, for example, trachoma, can lead to blindness. Provision of hygiene education, water, and sanitation can reduce water-borne diseases.⁵³ There is gross mismanagement of water resources virtually everywhere, and the abuse of water security as an instrument of conflict has increased exponentially.⁵⁴ Of 30 such events over the past 20 years, half were military actions targeting water supplies, resulting in widespread water-borne diseases, affecting mainly infants and children; this form of biological warfare is not recognized under the Biological Weapons Convention (1972). Projections for 2025, if left unchecked, reveal that 40% of the world’s population will face a crisis of drinking water availability; water security is a global health issue.

► GENDER

Gender refers to social differences between women and men within and across cultures and that change over time: roles and responsibilities, opportunities and constraints, and needs and perceptions. Both sex (biological differences) and gender are determinants of health. Many health inequities stem from gender differences: in men, higher risk-taking, smoking and alcohol abuse; in women, reduced health-seeking behavior if community norms prevent mobility without a male escort, and lack of autonomy over sexual and reproductive health. In many LICs, gender-related health risks are much greater for women than for men: less access to resources; economic dependency; and lower status despite their contributions to home and community. In some cultures, the simultaneous burden of less-valued productive and reproductive roles places women at special risk, with systematic loss of life at all stages, as in South Asia: prenatal sex selection, infanticide, differential malnutrition, dowry and honor killings, unsafe birthing practices, and less access to health care, all reflected in persistently high male-female sex ratios.²⁰ As poignantly asked by Amartya Sen: “Where are the 100 million missing women?”⁵⁵

Addressing gender-based health issues entails improving the status of women and girls. Strategies include increasing the following: enrollment of girls in schools; access and availability of contraception; women’s share of nonfarm workforce; involvement of women in decision-making; gender as an explicit component of health research, interventions, systems reform, education, policies, and programs. The International Conference on Population and Development

held in Cairo (1994) was critical in resetting the agenda. Signed by 179 governments, the plan of action helped to evolve reproductive services to better meet the needs of both women and men, replacing traditional family planning programs with broader services addressing sexuality, gender-based power, STDs, domestic violence, maternal mortality, and abortion.⁵⁶ Developments since Cairo reveal encouraging examples of integrated interventions, evoking the Alma Ata approach to PHC, for example, Pakistan’s National Programme for Family Planning & Primary Health Care, now enjoying renewed support, NGO partnerships, and substantial bilateral assistance.⁵⁷

Conservative governments, and some religious and special interest groups, have tried to overturn or revise elements of the Cairo agenda. However, governments increasingly are taking heed that a country’s social and economic development is often reflected in the status of their women. The emergence of women as national leaders, seen exponentially over the past decade, may signal an important global shift in attitudes.⁵⁸

► THE WAY FORWARD

Health is embodied within the Universal Declaration of Human Rights (1948). The WHO constitution also states: “The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition”; and yet, inequities in health most visibly mark these distinctions, and the right to health remains unfulfilled for most of the world’s people. To achieve health for all people requires better priority setting and investment in health determinants. It demands principled leadership, responsible governance, innovative management, and participation by people in making decisions affecting their health. In seeking global prosperity, we must not reduce health simply to economic equations or strategic choices. Rather, the way forward calls for health as a core value, in balance with development principles that are just, sustainable, and ethically sound.

Public Health Law

Edward P. Richards, III • Katharine C. Rathbun

► INTRODUCTION

Core public health—food and water sanitation, sewage and refuse disposal, vermin control, and the management of zoonosis and communicable diseases—depends on law as much as on science. From the Roman sewers and public water systems, and the Venetian 40-day interregnum for ships entering port, to the recent eradication of smallpox, public health depends on the power of the state. Public health authorities must seize property, close businesses, destroy animals, or involuntarily treat, or even lock away, individuals. Without the coercive power of the state, public health and modern society would be impossible.

With the exception of its higher rates of HIV infection, the United States is similar to other developed countries. For the past 30 years, communicable diseases have been relatively well controlled, shifting the public focus to the problems of chronic diseases. The September 11, 2001, terrorist attacks on the United States, which were followed by several deaths from anthrax spores carried through the mail, refocused public opinion on public health and its role in protecting the nation from bioterrorism. The specter of bioterrorism, especially an attack with smallpox, has forced a reappraisal of the balance between individual liberty and public health authority.

This chapter focuses on public health law in the United States. It reviews the constitutional basis for public health law, the routine practice of public health law as administrative law, and concludes with a discussion of the future of public health law, which includes the role of public health law in national security law.

► PUBLIC HEALTH AND PRIMARY CARE

Public health law, as discussed in this chapter, deals with the role of the health department as a regulatory agency. If a health department also delivers primary care, it is a dual role department. When a health department provides health care to individuals, whether it is prenatal care, well-child checkups, or general primary care, the health department employees or contractors providing medical care must follow the same laws on privacy and patient autonomy as other health-care providers. As one example, a prenatal care clinic must comply with the provisions of the Health Insurance Portability and Accountability Act of 1996 (HIPAA).¹ HIPAA limits the transfer of personal medical information without the patient's consent, and sets out standards for how the privacy of that information must be protected. HIPAA does not apply to public health reporting or the handling of information for public health regulatory purposes.

Specialty public health treatment programs, such as tuberculosis control, mix the personal medical care and public health regulatory roles. The basic patient medical information that is not necessary for

disease control (personal health information other than the diagnosis of the communicable disease) is treated the same as medical information in other clinical settings. Given the complexity of health-care privacy laws, it is critical that the disease control function be clearly separated from the medical services. In effect, the health department's clinical care programs should be treated the same as clinical care programs run by other health-care providers.

► THE CONSTITUTIONAL BASIS FOR PUBLIC HEALTH LAW

In all societies, public health authority is derived from the basic power of the state to preserve itself: the right of societal self-defense.² The Constitution grants the government broad, almost unlimited, public health powers because, when the Constitution was drafted, epidemic disease threatened the social order, not just the lives of individuals.³ Pestilence was part of everyday colonial life, a constant threat that contributed to a life expectancy of only 25 years.⁴ Soon after the Constitution was ratified, an epidemic of yellow fever raged in New York and Philadelphia. The prevalent attitude of that period toward disease was captured in an argument before the Supreme Court:

For 10 years prior, the yellow fever had raged almost annually in the city, and annual laws were passed to resist it. The wit of man was exhausted, but in vain. Never did the pestilence rage more violently than in the summer of 1798. The State was in despair. The rising hopes of the metropolis began to fade. The opinion was gaining ground, that the cause of this annual disease was indigenous, and that all precautions against its importation were useless. But the leading spirits of that day were unwilling to give up the city without a final desperate effort. The havoc in the summer of 1798 is represented as terrific. The whole country was roused. A cordon sanitaire was thrown around the city. Governor Mifflin of Pennsylvania proclaimed a non-intercourse between New York and Philadelphia.⁵

The government took such extreme actions because it feared that social order would collapse. Bioterrorism presents the same threats to modern society, and the legal authority to deal with bioterrorism is rooted in the same constitutional provisions that allowed these actions in 1798.

The Constitution divides the government powers between the state and federal government. The federal government was given the power over foreign affairs and trade, war and insurrections, and the commerce between the states. The federal public health powers derive from the power to regulate trade and to control military threats and insurrections. Most of the public health powers were given to the states:

Every state has acknowledged power to pass, and enforce quarantine, health, and inspection laws, to prevent the introduction of disease, pestilence, or unwholesome provisions; such laws interfere with no powers of Congress or treaty stipulations; they relate to internal police, and are subjects of domestic regulation within each state, over which no authority can be exercised by any power under the Constitution, save by requiring the consent of Congress to the imposition of duties on exports and imports, and their payment into the treasury of the United States.⁶

These powers are called the police powers. The term police does not refer to police departments, which did not exist in their present form until much later. It refers to the older meaning of the word “police”—to keep order. The state’s police powers deal with general issues of public health and safety, not the punishment of criminals. Until the late 1800s, the federal government did little more than maintain quarantine stations and public health service hospitals. Even today, most public health and public health law is carried out by the states.

The Constitution gives the states all the powers not reserved for the federal government that are not otherwise limited by the Constitution. These reserved powers—interstate commerce, foreign affairs—and constitutionally protected areas—criminal prosecution, free speech, equal protection, property rights—are the main limits on the state police powers.

Criminal Prosecution

The Constitution provides its greatest protections for individuals who are accused of crimes. Threat of criminal prosecution triggers the constitutional provisions preventing unreasonable searches, protection against self-incrimination, the right to appointed counsel, and the other rights that attach when an individual is arrested. Public health agencies do not have to provide these protections as long as their intent is to prevent harm to the community, rather than to punish an individual or act as agents of the criminal justice system. Even when public health agencies isolate or quarantine individuals, they do not have to provide criminal law protections because their intent is to prevent harm to the community, not to punish the individual.⁷

Legislatures are sometimes tempted to use public health laws in place of criminal laws to avoid the constitutional protections required for prosecution. For example, if the government wants to search property or perform a medical test to collect evidence for criminal prosecution, the government must get a warrant. The government must present evidence to a judge that there is probable cause to suspect the specific individual of a crime and what type of evidence is being sought with the warrant. These warrants are not necessary for public health (administrative) searches. The Court struck down a program using public health powers to collect information about drug use by pregnant women because it was being used for criminal prosecution as well as public health purposes.⁸ The Court ruled that the government must get a probable cause warrant to use the information for criminal prosecution, even if there was also a valid public health purpose for collecting it. Bioterrorism investigations pose even more difficult coordination problems between public health and law enforcement because public health professionals want to control the threat to the community as quickly as possible, while law enforcement needs to protect the crime scenes while it waits to get proper warrants to gather evidence for criminal prosecutions.⁹

Equal Protection

The Constitution does not allow public health laws to be used as an excuse for otherwise prohibited discrimination. For example, the Court struck down special building regulations for Chinese laundries because there was no evidence that Chinese laundries were any greater threat to the community than laundries owned by non-Chinese.¹⁰ However, public health laws can be constitutional when they have a differential impact on otherwise protected groups if there is evidence

that a disease is more prevalent in that racial or ethnic group. This is commonly seen in screening programs for genetic diseases, which can affect blacks, Jews, Amish, and other genetically distinct groups at very different rates.

Property Rights

The Constitution requires that the government pay fair compensation for private property that is taken for public use. Persons whose property is being taken have a right to a hearing before the property is taken. At the hearing they may contest the basis for the taking and the price that is being paid. When property is seized and destroyed because it is a threat to the public health, such as spoiled food,¹¹ or houses that need to be razed to stop an advancing fire,¹² there is no right to a hearing before the action. There is no right to compensation because the property had no value, in one case, because it was spoiled, and in the other, because it would have been destroyed by the fire. However, if the government takes private property to use it in a public health emergency, such as turning a hotel into a quarantine facility the property owner may not have a right to hearing before the taking, but will probably have a right to be compensated for the use of the property.

Interstate Commerce and Foreign Affairs

State laws that use public health enforcement to discriminate against out-of-state businesses are unconstitutional. Courts have struck down laws that imposed more stringent sanitary restrictions on out-of-state milk processors. Even if the restrictions are the same for in- and out-of-state businesses, the courts will strike down a law if it has a disparate impact on out-of-state business.¹³ For example, a requirement that milk must be processed and delivered within 24 hours might prevent out-of-state dairies from selling milk in the state. This law would violate the Commerce Clause of the Constitution unless there is evidence that the 24-hour rule is necessary to protect the public health. Conversely, a Texas law that banned the import of Louisiana cattle was constitutional because Texas could show a real risk of anthrax in the Louisiana cattle.¹⁴ States are likewise prohibited from having special regulations for foreign trade and foreign visitors.

Freedom of Speech

The First Amendment of the Constitution protects freedom of speech. This prevents the government from regulating publications that contain inaccurate or even dangerous health information, as long as the publication is not an advertisement for a product. For example, the government cannot regulate WWW sites that publish dangerous diet information unless the information is an advertisement for a product. The Supreme Court has broadened the protections for advertisements over the past decade.¹⁵ Now, if the advertisement is accurate, it cannot be banned, even if it encourages dangerous behavior such as buying beer with the highest alcohol content.¹⁶

► PUBLIC HEALTH LAW AS ADMINISTRATIVE LAW

Administrative law is the law that governs state and federal agencies. It deals with the relationship between individuals and government, outside of the criminal justice system and the military.¹⁷ Public health law and the predecessors to public health agencies can trace their heritage to the colonial governments. Public health law is one of the earliest examples of administrative law in the United States.

Separation of Powers

Administrative law arises out of the separation of government powers into the legislature, the executive (the president or governor), and the courts. The legislature passes the laws that give agencies their

powers and their budgets. The agencies that enforce laws, including public health agencies, are part of the executive branch of the government, and are under the political control of the executive branch. In the federal government, this is the president. In state governments, this is usually the governor, but states have other elected officials, such as the attorney general, who run their own agencies outside of the control of the governor. The legislature can also create independent agencies by having the executive appoint members of a board or commission to run the agency, and making the terms of office of the members such that no single governor or president can appoint all the members. The federal Securities and Exchange Commission is an independent agency. Some state and local health departments are run by a board of health, which makes them better insulated from political interference, but even with a board of health, state and local agencies are much less independent than federal independent agencies.

The role of the courts in administrative law is to assure that the laws empowering the agency are constitutional, and that the agency carries out the laws in a way that is consistent with the intent of the legislature. The courts recognize that the executive branch is charged with overseeing the agencies, and that it is the executive branch that the voters expect to make the policy decisions that the agency carries out. If the agency action is constitutional and is consistent with the legislation that authorizes it, then the courts should defer to the agency and leave it to the voters to seek change from the legislature or the executive branch. This is the basis for the judicial deference to agencies that is discussed later.

Statutes and Regulations

While the president and most governors have some power directly from the federal or state constitution that creates their office, most of the powers of the executive branch come from laws passed by the legislature. The legislature also creates agencies and assigns their powers. If the legislature wants to control agency, it passes very specific and detailed laws giving the agency narrow powers and specifying how those powers will be used. This limits agency discretion. The Americans with Disabilities Act is an example of a detailed statute that limits agency discretion. The legislature may want the agency to have discretion, often because the legislature does not want to make a difficult political decision. An example is the Federal Energy Regulatory Commission, which Congress left to decide whether cheap electric power is more important than plenty of electric power. The legislature will also give an agency broad discretion if the legislation involves technical standards which are based on expert judgment.

Traditionally public health agencies were given very broad powers to do what was necessary to protect the public health. This reflected both the strong public support for the agencies and the recognition that public health decisions should be made by public health experts. These broad powers are most important when there are unexpected threats to the public health or in emergencies where the agency may have to change strategies based on the changing nature of the threat. Ironically, some proposals for strengthening state emergency powers laws, like the Model State Emergency Health Powers Act,¹⁸ try to specify how the emergency will be handled by listing actions that the agency must take. Since it is impossible to predict the proper actions in an emergency, requiring such specific actions can cripple the agency when it needs the most flexibility.

The problem with broad grants of power is that they do not give the public and the regulated parties notice of what constitutes proper conduct. Since the legislature has the power to make specific rules, the courts have allowed this power to be given to the agency. Regulations must be published for public comment before being adopted, and many states provide for public hearings to discuss new regulations. This allows the agency the discretion to make and change rules, while giving the public and regulated parties detailed information about the public health standards and input into the standards. For example, the legislature gives the health department the general power over food sanitation, but leaves the detailed sanitation regulations to be promulgated

by the agency, based on national standards. Regulations are easier and quicker to change than legislation and can be modified on an emergency basis. This is important when the health agency is dealing with problems such as emerging infectious diseases or changing standards of practice based on new scientific discoveries.

Administrative Searches

Public health officials routinely enter private property to inspect for compliance with health standards and to access potential health hazards. Historically, the U.S. Supreme Court did not require any kind of warrant for these inspections. The court reasoned that the Constitutional requirement of a probable cause warrant was limited to criminal investigations.¹⁹ In the 1960s, concerned about possible harassment by health inspectors, the Court required that the public health department show some evidence of a public health purpose for an inspection. This is called an administrative or area warrant and it does not require any specific information about the individual properties being inspected.²⁰ Instead, it describes the general area to be inspected and the reason, such as all the houses in a given neighborhood are to be inspected for rat infestations. If the premises being searched operates under a license or permit, the conditions of receiving the license or permit usually include allowing searches without notice or a warrant during regular business hours.

Administrative searches sometimes turn up evidence of criminal conduct: can the health inspector call the police, and can the police use the evidence in court? If the criminal conduct is related to the activity being regulated by the agency, the evidence can usually be used in court.²¹ For example, if a restaurant inspector found that the chef was using black market seafood, this evidence could be used for criminal prosecution. If a rat inspector found the homeowner's marijuana stash, this would have nothing to do with the search and it is unlikely that the courts would accept it as evidence. More importantly, health departments resist turning evidence over to the police because if the community sees health inspectors as agents of the police, it will make their work much more difficult and dangerous. If the police ask the health inspector to look for something, then the courts will find that the health inspector is acting for the police and thus cannot enter without a probable cause warrant.

► JUDICIAL REVIEW OF PUBLIC HEALTH ACTIONS

When public health agencies are acting within constitutional limits, the courts give them great flexibility and broad powers. The primary limit on public health agency power is set by the state legislature or local government: agencies only have the power that the legislature gives them. Traditional public health laws gave general, unlimited grants of power: the public health agency may do what is necessary to protect the public. All courts accept these broad grants of power. Such grants give the agency the maximum flexibility and power allowed under the U.S. and the appropriate state constitution. If the legislature limits the agency's power, the agency cannot act beyond these limits, even if the Constitution would allow it greater powers. Sometimes these limits are found in other laws, such as privacy laws, rather than in the public health laws themselves.

The second limit on agency power is its reasonableness. The courts require that public health actions be rationally related to the problem they seek to control. This does not require that the agency use the best or least restrictive strategy, but allows the agency or legislature to balance other factors, such as the cost and manpower needed. As long as the agency does not act in an arbitrary or capricious manner, the court will uphold its actions. For example, when New York moved to close the gay bathhouses to control the spread of HIV, this was opposed by the bathhouse owners and some public health experts who believed that it was better to leave the bathhouses open and use them to educate the patrons about safe sex. The court rejected this challenge to the agency's decision, ruling:

It is not for the courts to determine which scientific view is correct in ruling upon whether the police power has been properly exercised. The judicial function is exhausted with the discovery that the relation between means and ends is not wholly vain and fanciful, an illusory pretense. . . .²²

The court deferred to the agency's decision for three reasons: First, judges and juries do not have the expertise to make technical decisions so the courts delegate these to an agency or individual with expertise. This is especially important in areas such as public health which involve difficult policy choices that can affect the health of the population.

Second, courts defer to agencies because it is efficient. The U.S. Supreme Court, in a case involving whether government disability claimants were entitled to a hearing before their claim was denied, ruled that the cost and delay of due process requirements had to be balanced against the probability that they help the agency make better decisions. The court found that the hearing would not improve the accuracy of the decisions very much, and the extra costs and delays would reduce the benefits available to other claimants.²³ In public health emergencies, time can be more important than money, so the courts would be very unlikely to interfere with agency actions as the emergency was unfolding. As in the disability case, it would be more efficient to have hearings after the action, since in many cases the person would not contest the agency decision.

The third reason courts defer to agencies is because it respects the constitutional separation of powers. The legislature gives agencies their powers and their budgets. The courts recognize that as long as the agency is acting constitutionally and its actions are rationally related to its mission, the executive branch should be allowed to set policy. If the voters do not like what the agency is doing, the remedy is through the political process, not the courts. Thus the most important limits on agency action are political. For public health departments, the public must support their actions or the legislature will limit them by law or by cutting the agency budget.

Public Health Law Tools

The most important tool of effective public health practice is education. Public health depends on the voluntary cooperation and support of the community. In addition, however, public health agencies must also use the law to assure that individuals and businesses comply with public health laws. Public health officials have five primary enforcement tools:²⁴ (a) permits, licenses, and registrations; (b) administrative orders; (c) direct abatement; (d) civil penalties; and (e) injunctions.

Permits

Permits, licenses, and registrations are used to regulate routine activities that may pose a threat if they are carried out improperly. Food establishment permits are the most common public health example. Permits pose the fewest legal issues because they are prospective—the establishment must show that it meets the requirements before the permit is issued. The standards for the permitted activity are established by the legislative body, which usually specifies that the regulations will follow an approved national code and that special situations will be handled by the public health officer. To qualify for a permit, the applicant must agree to be bound by the standards for maintaining the permit. The applicant must agree to allow entry by the health inspectors, without notice or a warrant, to assure compliance with the applicable standards. The health officer will determine if the applicant meets the standards for a permit, and whether a permit should be revoked or denied because the permittee has violated these standards.

Administrative Orders

Administrative orders are orders issued by a public health agency directly to an individual or a business requiring that actions be taken

to mitigate a threat to the public health. These can range from an order to clean up garbage in a vacant lot to an order to show up for tuberculosis treatment. There may be a fine for violating an administrative order, but most enforcement of administrative orders depends on the cooperation of the affected individuals or businesses. Administrative orders are most effective when the violator holds a permit that may be suspended for not complying with the order. In other cases, if the violator does not comply with the order, the agency must ask a court to enforce the order.

Public health agencies can use administrative orders to empower private entities to act in situations where they would otherwise be legally unable to act. As an example, the federal regulations on managing tuberculosis in hospitals require that the hospital have a process for quickly identifying and isolating persons with active tuberculosis. Assume a coughing patient is admitted to the hospital with respiratory distress. The history and x-ray are consistent with active pulmonary tuberculosis. The patient is put into respiratory isolation, but refuses to stay in the isolation room, preferring to pass the time drinking coffee in the cafeteria.²⁵ The hospital has no legal right to isolate the patient against the patient's will. The health department can order that the patient be isolated and direct the hospital to carry out the agency's orders, thus allowing the hospital to use its personnel to confine the patient.

Direct Abatement

The public health department can act on its own, if it has been given the authority to do so, to abate a public health problem. This is very common in environmental health. Health departments routinely mow weeds, board up or tear down dangerous buildings, and enter property to treat standing water that can breed mosquitoes. Direct abatement is generally used when the property owner cannot be located or refuses to comply with administrative orders. The costs of direct abatement may be billed to the owner or charged as a lien against property, which will be collected when the property is sold.

Fines and Other Punishments

Persons who violate public health administrative orders or statutes can be fined or jailed, after appropriate legal process. In most public health cases the fines are too small to be a deterrent and the municipal court judges who hear these cases are usually unwilling to jail a person for a public health violation. (As health officers quickly learn, it is hard to get judges to take "dog law" cases seriously.) However, fines and imprisonment are important enforcement tools for state and federal environmental quality laws because the fines can run to millions of dollars and the federal judges have no hesitation in ordering jail sentences.

Injunctions

When a violator ignores administrative orders, when the violator has been incarcerated but the hazard has not been abated, or when the public health agency wants to mitigate a hazard prospectively, the proper remedy is an injunction. Unlike other legal proceedings where the court can only order fines or imprisonment, an injunction allows the court to give specific orders on what must be done or what is prohibited. In addition, the agency can often select the judge who will rule on the injunction. Courts can and do use fines, imprisonment, and other coercive strategies to enforce their injunctions.

Courts may grant an injunction to prevent irreparable harm: harm that cannot be remedied by awarding monetary damages. For example, if a logging company mistakenly enters your land and begins to cut the trees, the court could order them to stop rather than just assuring that you get the market value of the wood. When a public health agency seeks an injunction, the courts will usually defer to the agency's determination that the condition threatens the public health and that the injunction will remove this threat.

If there is an immediate threat, the court can order a temporary injunction on the evidence presented by the agency without waiting to hear from the other party. These are called *ex parte* proceedings. The court will order a hearing as soon as possible to allow the enjoined party to contest the injunction. Such emergency actions are used for threats such as tainted food or water, or a hazard such as a fire-weakened structure that threatens to fall. If the threat does not require emergency action, the opposing party must be given notice and be allowed to be heard in a court hearing before an injunction is granted. After the opposing party has been heard, the court may either dissolve the temporary injunction or enter a permanent injunction. Permanent injunctions are very important in public health enforcement because they are often the only way to deal with recalcitrant violators.

► PRIVACY, AUTONOMY, AND THE PUBLIC HEALTH

Protecting the public health often affects individual and institutional rights. The cost of pollution control can reduce the profitability of businesses, food sanitation rules increase the cost of building a restaurant, and concerns for problems such as mad cow disease can injure the livelihood of everyone in an industry. Yet the most difficult public health law issues are those involving the privacy and autonomy of individuals. While these questions once arose only in communicable disease control programs, privacy and autonomy questions also arise as public health becomes more involved with the control of lifestyle diseases such as smoking and obesity.

► PUBLIC HEALTH SURVEILLANCE

All public health begins with the collection and analysis of data about individual illness. In some cases this analysis can be done on anonymous data, but in most cases identified data is necessary for accurate analysis. The court explained the legal rationale for surveillance and using personal medical information in a case involving a typhoid carrier:

The Sanitary Code which has the force of law . . . requires local health officers to keep the State Department of Health informed of the names, ages, and addresses of known or suspected typhoid carriers, to furnish to the State Health Department necessary specimens for laboratory examination in such cases, to inform the carrier and members of his household of the situation and to exercise certain controls over the activities of the carriers, including a prohibition against any handling by the carrier of food which is to be consumed by persons other than members of his own household. . . . Why should the record of compliance by the County Health Officer with these salutary requirements be kept confidential? Hidden in the files of the health offices, it serves no public purpose except a bare statistical one. Made available to those with a legitimate ground for inquiry, it is effective to check the spread of the dread disease. It would be worse than useless to keep secret an order by a public officer that a certain typhoid carrier must not handle foods which are to be served to the public.²⁶

Medical care providers are the most common source of information, but reporting requirements for child abuse also include teachers and many others who would be in a position to notice abuse. Privacy advocates argue that individually identified information should not be reported without the individual's permission. Given the sensitive nature of public health data, requiring the patient's permission to report would seriously compromise the quality of the information. It could even lead to injuries if the report concerned communicable diseases or child abuse. After the U.S. Supreme Court found a right of privacy implicit in the Constitution,²⁷ the court also recognized that this right of privacy must give way when necessary to protect the public health:

Unquestionably, some individuals' concern for their own privacy may lead them to avoid or to postpone needed medical attention. Nevertheless, disclosures of private medical information to doctors, to hospital personnel, to insurance companies, and to public health agencies are often an essential part of modern medical practice even when the disclosure may reflect unfavorably on the character of the patient. Requiring such disclosures to representatives of the State having responsibility for the health of the community, does not automatically amount to an impermissible invasion of privacy.²⁸

All state constitutions also allow public health reporting of identified information, although at least one state still limits the right to collect information about HIV. All states require the reporting of child abuse, and most states also require the reporting of elder and spousal abuse, as well as violent or suspicious injuries, including all gunshot wounds, knifings, poisonings, serious motor vehicle injuries, and any other questionable wounds. Health-care providers and others making these reports cannot be held liable by the patient for incorrect reports, as long as the report was made in good faith. Failing to make a report can result in liability in many states if the injured person can show that the report was required and that the injury was caused by the failure to make the report.²⁹ Knowingly reporting false data, such as an incorrect name when the patient's real name is known, does not satisfy the duty to report, and the reporter can be disciplined by the state.

In addition to requiring third parties to report public health conditions, public health agencies can carry out their own investigations. Infected individuals can be interviewed to determine where they contracted the disease and who they have been in contact with.³⁰ These contacts will then be interviewed, without divulging the source of the contact information, to determine the spread of the disease. While the law would allow the punishment of persons who lie to disease investigators, in practice, investigations have historically been treated as voluntary. Investigations of serious outbreaks, such as smallpox, have used very intrusive techniques, including paying informers.³¹ In a bioterrorism investigation, it is likely that the police will apply criminal law investigation standards, which do require cooperation, and which punish false information.

Testing and Treatment

Testing and screening are key strategies in accessing populations at risk for communicable disease. Screening systems, such as tuberculosis skin testing, are necessary to learn the prevalence of a disease in the community, to investigate specific outbreaks, and to identify individuals for treatment or restrictions. In most cases, individuals cooperate because of the benefit to themselves and to the community. When an individual does not cooperate, the agency may order them to submit to the test. While there are strict limits on involuntary testing when the results are to be used for criminal prosecution, public health agencies have great latitude to order testing for disease control,³² including testing of persons with religious objections to medical treatment.³³ Many states require screening of pregnant women for syphilis to prevent congenital syphilis,³⁴ and one state requires testing to prevent congenital HIV infection. Most states require screening of newborns to detect congenital illness such as hypothyroidism and phenylketonuria.

The courts will order the involuntary treatment of prisoners and persons who are committed to mental institutions, but involuntary treatment is almost never used in routine public health when the case is a competent adult. (Treatment orders are commonly used to require the treatment of children against their parents' wishes.) Instead, public health agencies will usually isolate an infectious person until the disease is resolved or the patient accepts treatment. In almost all cases, the patient prefers treatment to isolation. In a bioterrorism event involving a treatable infectious agent, mandatory treatment might be necessary because of limited isolation facilities.

Vaccinations

Vaccinations are a critical part of public health practice. Vaccinations eradicated smallpox and have dramatically reduced the morbidity and mortality of diseases such as measles, mumps, diphtheria, tetanus, and many others. Despite their value to the individual and to the public, vaccinations have always been controversial. The U.S. Supreme Court ruled on the constitutionality of mandatory vaccinations in 1905, and their ruling remains relevant today:

We are not prepared to hold that a minority, residing or remaining in any city or town where smallpox is prevalent, and enjoying the general protection afforded by an organized local government, may thus defy the will of its constituted authorities, acting in good faith for all, under the legislative sanction of the state. If such be the privilege of a minority, then a like privilege would belong to each individual of the community, and the spectacle would be presented of the welfare and safety of an entire population being subordinated to the notions of a single individual who chooses to remain a part of that population.³⁵

In 1905, the smallpox vaccine was known to be dangerous and the court appreciated that mandatory vaccination would injure many people. Smallpox vaccine is safer than it was in 1905, and other vaccines are very safe, compared to the risks they prevent. The state has clear authority to require vaccinations of adults and children, and there is no constitutional requirement that the state recognize religious or philosophical objections to vaccination.³⁶ Unfortunately, mandatory vaccination is losing political support. Many states no longer require children to be vaccinated before entering public schools, allowing parents to refuse vaccination if they do not want them for their children.

Emerging diseases, such as new flu agents, or the use of smallpox as a bioterrorism agent, could require large-scale vaccination campaigns, with the option of mandatory vaccinations. Official federal policy is that vaccinations would not be used in the event of a bioterrorism outbreak. In contrast, most states are prepared to use mandatory vaccinations for agents such as smallpox and are considering such requirements for other outbreaks. While mandatory vaccinations are legally allowed, such programs will be ineffective if the public is not educated to understand why mandatory vaccination is necessary.

Quarantine and Isolation

From Leviticus and the Koran, to quarantine in fourteenth century Venice,³⁷ to the contemporary federal regulations on tuberculosis control,³⁸ public health practice depends on the authority to impose restrictions on individuals to prevent them from spreading disease in the community. The common law provided severe punishment, including death, for breaking quarantine.³⁹ The legal authority (if not the punishment) is part of the state's police power.

In contemporary public health practice, isolation means to restrict the contact between an infected person and others, and quarantine means to restrict the uninfected contacts of an infected person. Informal isolation is widely used: sick children are told to stay home from school, adults with the flu are sent home from workplaces where they might endanger others, and individuals who are ill restrict their own contacts with persons they might infect. Public health departments will order isolation for persons with infectious tuberculosis, measles, and certain other communicable diseases. If these orders are not obeyed, the health department can ask the court to order the sheriff to return the person to a closed isolation facility.

Quarantine is much less frequently used. The last large-scale quarantines in the United States were for polio in the 1950s. When there was a polio outbreak, public facilities were closed and travel from communities with the disease was limited. Individual or family quarantine is sometimes used for diseases such as measles, but generally only the infected individual is isolated.

Two factors have renewed concerns about implementing large-scale isolation and quarantine programs. The first was bioterrorism fears, particularly of smallpox, after September 11, 2001. The second was the severe adult respiratory syndrome (SARS) outbreak in Canada and Asia in 2003, which forced the widespread use of both isolation and quarantine. This has raised concerns about whether the states have adequate laws to order large-scale restrictions. Since all states used these powers extensively from their founding until the 1950s, they all have the necessary authority, unless their legislature has changed the law since then. There has also been concern about the appropriate due process for instituting restrictions. Under the U.S. Constitution, isolation and quarantine can be ordered by the health department, although a court order will be necessary for persons who refuse to comply. There is no requirement for a hearing before the action. This is also true of old state public health laws, but some states have added due process requirements, such as a hearing before a person can be restricted.

Once a person has been isolated or quarantined, the Constitution guarantees due process through a *habeas corpus* proceeding. *Habeas corpus* is the "Great Writ" from the English common law and means "bring me the body." *Habeas corpus* requires that persons detained by the state be given a chance to answer the charges against themselves at a hearing before a judge, and that the state be required to show cause why the person should not be released. There is no bail for isolation or quarantine orders:

To grant release on bail to persons isolated and detained on a quarantine order because they have a contagious disease which makes them dangerous to others, or to the public in general, would render quarantine laws and regulations nugatory and of no avail.⁴⁰

The state may provide other mechanisms for a hearing in place of a *habeas corpus* proceeding, but if the state has no specific review process for isolation and quarantine, *habeas corpus* is always available. If the state requires a hearing before the restriction order, it will be very costly and time consuming for the agency, greatly complicating enforcement. If a large number of people are to be isolated or quarantined, even *habeas corpus* hearings may be difficult or impossible to arrange in a timely manner. The state may require persons who want to file a *habeas corpus* petition to first use an administrative review conducted by the health department.⁴¹ This review could determine the basic facts of the confinement and the applicable law, correct mistakes such as the quarantine of a person who was not exposed to the infection, and then prepare a report for the court to use if the person still wanted judicial review. Most problems could be solved with the administrative review, and the record would allow the court to review the case quickly. As long as the state is not acting in an arbitrary or capricious manner, the court will uphold the isolation or quarantine order.

Of all the police powers, large-scale isolation and quarantine most depends on public cooperation. While law enforcement has a role in handling a small number of noncompliant individuals, if a community does not want to comply with the orders, there is little that can be done short of military occupation. As the SARS epidemic demonstrated, an effective large-scale isolation and quarantine program requires the community to assure that everyone has access to food, medical care, and compensation for lost time from work. Meeting these needs and educating the community ahead of time are much more important than questions of legal authority.

► THE FUTURE OF PUBLIC HEALTH LAW

There was a consensus on public health law from the colonial period through the 1960s. Every adult in the United States had grown up in a world where communicable diseases were a major threat. As late as the mid-1950s, communities were isolated during polio epidemics, and while smallpox had not been seen in the United States since 1947,

it still existed in other parts of the world. While public health agencies protected individual privacy as much as possible, there was a societal consensus that individual rights had to give way to the protection of the public health.

By the 1960s, the demographics of illness in the United States had already shifted from communicable diseases to chronic diseases. Smallpox immunizations were discontinued in the early 1970s, there were no more polio epidemics, tuberculosis was largely under control and routine TB screening was discontinued, and there were few reports of once common diseases such as cholera and malaria. By the 1980s, the fear of communicable diseases had faded, generally undermining the support for public health. The adoption of strict liability theories in tort law made it easier to win vaccine injury litigation, without regard to whether the claimed injuries were due to the vaccine. This fueled a vaccine litigation industry that uses its public relations resources to drown out the public health messages that vaccines for childhood diseases are safe and necessary. AIDS was viewed as a lifestyle disease, rather than a public health threat, and it was more than 15 years before many states started collecting the same personally identified data for HIV as they do for all other serious infectious diseases.

As support for traditional public health waned, public health agencies became more involved in chronic disease epidemiology and prevention. While chronic diseases are the most serious threat to individual health, they pose a difficult problem for public health and public health law: the legal and ethical justifications for taking actions to prevent a person from spreading a communicable disease are very different from those for persuading a person to take better care of his or her own health. Some traditional public health strategies such as environmental modification—assuring safe drinking water and fortifying foods with vitamins—are also applicable to chronic diseases—making it more difficult to smoke in public places and providing more healthy choices in school lunches. Some are not: screening and treatment for tuberculosis is justified by public necessity, but would this justify screening and mandatory treatment for obesity? Should public health officials join with the same tort lawyers who attack vaccinations and other public health programs, just because they are now suing tobacco and food processors?

The terrorist attacks on September 11, 2001, combined with the anthrax letters sent to public officials and media figures over the following few weeks, suddenly reminded the public of their fundamental fears of epidemic disease, whether driven by nature or bioterrorism. The SARS epidemic in 2003 reminded the public and policy makers that natural epidemics posed the same risks as bioterrorism and raised questions about the ability of the public health system to deal with a major disease outbreak. In particular, questions were raised about the ability of modern state public health laws to deal with large-scale quarantine and mandatory vaccinations. The smallpox vaccine program for health-care workers that was launched early in 2003 was a failure.⁴²

Public health law faces two challenges. First, obesity is joining smoking as a major preventable disease threat. These behaviors are dramatically increasing the incidence of chronic diseases such as diabetes, cardiac disease, and cancer. As diseases that are driven by environmental and cultural factors, their management will require public health law strategies, yet strategies that are very different from communicable disease control. Second, fears of bioterrorism and epidemic diseases such as SARS are driving states to pass very intrusive public health laws. Police and the national security agencies want to make public health an extension of homeland security, and use powers traditionally reserved for public health as part of the criminal law system. These pressures threaten to destroy the relationship of trust between public health agencies and their client populations, making public health practice much more difficult.

Public health professionals, their lawyers, and the legislatures must look to the history of public health law and to administrative law principles if they are to meet these challenges. The need to protect the public from plagues, whether man-made or natural, must be balanced with the pervasive, if lower key, threat posed by preventable diseases. While bioterrorism is a real threat, it cannot be allowed to compromise the relationship between public health professionals and the public.

Public health ultimately depends on public trust, and without that trust, even Draconian laws will not protect the public.

Public Health Management Tools

Planning for Health Improvement: Models for Communities and Institutions

K. Michael Peddecord

► PLANNING AS A TOOL FOR CHANGING ORGANIZATIONS AND IMPROVING COMMUNITY HEALTH

Planning is the future-oriented, systematic process of determining a direction, setting goals, and taking actions to reach those goals. Planning is all about making change and is a basic management function essential to the success of all levels of an organization. This chapter provides an overview of planning definitions, issues, and tools or techniques. Several examples of models or frameworks for community health assessment and improvement efforts are provided along with references. A second goal is that readers develop an appreciation for the ambiguous nature of the planning vocabulary and recognize the need for clarifying understandings before venturing forth into planning, particularly when this activity involves a diverse group of professionals or community laypersons.

While planning can be described in the terms of techniques and tools, it is often a very complicated social process that must be mastered by the successful manager and thriving organizations and or communities. One of the most essential of planning tools in public health is the ability to work with professional and community groups.

Planning in Context—The Continuous Improvement Cycle of Planning, Implementation, and Evaluation

Planning is a core activity of what public health professionals, managers, and executives do. A generic or generalized model includes the steps or stages of understanding and engagement (“planning to plan”), needs assessment, setting goals and objectives, developing and intervention, fielding the intervention, and evaluating the results. Without planning and the formulation of explicit goals and objectives, evaluation becomes difficult, especially in larger organizations and in the community.¹ Rather than a linear process, planning is best considered as part of a continuous improvement process that involves the iterative gathering of data, translating it into useful information, and using that information to make decisions.²

Need for a Common Vision and Language

When beginning or reinvigorating the planning process, particularly in a setting with a diverse staff, it is essential to establish a common understanding of and language for the activities ahead. Picking a

model, and its associated vocabulary, will help provide a common framework. Training using the selected model and vocabulary also helps improve communication. A large number of models and tools are available to provide a roadmap, a language and common understanding of how to proceed. Since there is no one best model, it is more important to pick a model and move forward than to labor over what is the “best” model. While picking a model is an essential first step, ultimately, the success of the planning and improvement process is dependent on multiple factors such as leadership, hard work, resources, and luck. Considerations for selecting a model are included later in this chapter.

As the planning process is initiated, and periodically throughout its life, it is important to assess the important underpinnings and environmental considerations in which the planning and improvement process is taking place. In the next section, salient factors that need to be understood and dealt with are described. This understanding will aid in selecting the planning model, modifying the model, selecting analytic and management tools, and setting the course of action for planning.

► CONSIDERATIONS FOR CHOOSING A MODEL AND MANAGING THE PROCESS FOR HEALTH PLANNING AND IMPROVEMENT

Sponsorship

A sponsor gives legitimacy to the process. Every planning activity has one. The sponsor(s) may be some organization, group, legislative edict, or individual. At the institutional level, this may be the board of trustees, the chief executive, the medical staff chair, a program coordinator, or a department supervisor. In the community, the sponsor may be a community-based organization such as the heart association, a civic club, a church group, or a vocal community activist. At a governmental agency it may be a law or regulation, a mayor, or a local health officer. A well-funded foundation or a poorly funded hospital may sponsor and or initiate a planning process. Sponsors may have abundant or scarce resources. While some have legal authority, others may have only moral authority being empowered only by their interest in improving their lives and the lives of their community. Other sponsors may be motivated to improve their profits or survive in a competitive challenge. All of these factors need to be understood by those leading and seriously engaged in the planning process.

Stakeholders and Politics

Stakeholders are individuals and organizations that have or may have a future interest in what your planning initiative is about. Since planning is as much a social and political as it is a technical process, all important stakeholders must be identified and dealt with. The level of interest exhibited by stakeholders can range from casual interest, to serious concern, to intimate involvement in the process and outcome. In addition to motivation to improve the health status of the community, improving one's economic and power position will often explain each stakeholder's interest level. Within an organization, particularly a larger agency such as a public health department, entrenched staff may see any change-producing process such as planning as a threat to the status quo. While a detailed discussion of organizational behavior and the politics of planning are beyond the scope of this chapter, leaders understand that change means discomfort. In many situations, expect that the stakeholder(s) may want to delay, obstruct, or subvert the planning process until they understand and or accept the potential change from their own perspective.

It is essential to recognize that all participatory planning takes place in the context of an organizational culture and a history of relationships between internal and external stakeholders.^{3,4} Complications and conflicts often arise over disagreements on the scope of planning, strategies, and specific actions necessary to achieve goals. Combine conflicting economic incentives and egos, and the politics of planning takes on a life all its own. In a few situations, expect a few stakeholders to use their power to stop the planning and change process.

The Scope and Limits of Planning

Planning, direction, and control are the basic functions of managers. It is somewhat artificial to separate planning from the day-to-day operations of an organization or the implementation of programs. However, as organizations become larger and work needs to be differentiated, planning may become a specialized task. While every management and supervisory text has chapters devoted to planning, the primary focus of planning texts for health facilities is often on broader institutional or "strategic" functions.⁵ Planning is also an important topic in other specialized books that focus on marketing⁶ or quality improvement.⁷

Focusing on Community Change: Comprehensive versus Narrow Planning?

Systems theory can provide useful guidance to think how parts of the whole (subsystems) are connected.² The concept is that, at some level, everything is connected to everything else. Realistically, however, it is impossible to plan for the "system" as a whole. However, attempting to describe and understand the workings and interactions of the entire system is usually a useful investment of time. After planners have a sense of how things work and interact, the problem can then be broken down into smaller parts. The planning of "subsystems" or sub-tasks can then proceed. Understanding how the "parts" work together or interact may also provide clues as to how to extend the planning process or at least communicate to "other subsystems." The problem with isolating a subsystem is that subsystem exists within a larger system and problems often occur between well-planned subsystems. The key for the planner is to know how the subsystems interact and the extent of planning needed in the adjoining subsystems. The bottom line is that even if the planning focuses on a specific problem or issue, the planning process must recognize that this problem or issue does not exist in isolation. Planning, no matter how focused must deal with its environment.

Planning Models and Why You Need Them

Planning Models: What Are They?

Models are, at their core, extensive lists that described a schematic approach to studying, interacting with, and changing a system or situation. Example of systems may be individual behavior, an organization,

or a community. Most models have been developed based on experiences of workers in a particular field, most relevant to this chapter, community health improvement. Models can serve as guidebooks constructed by those who have traveled a similar road before.

A planning model is also a paradigm (a way of thinking) that serves as a template that includes a set of assumptions, concepts, values, and practices. This paradigm can help construct a way of viewing reality for the community or an organization. Since a planning activity often brings together individuals with diverse backgrounds, interests, and agendas, as stated before, agreeing on a model to follow during the planning and improvement process is one of the most important steps in the early stages of the endeavor. While a model may not provide a completely unified vocabulary, it can provide a common understanding of the stages in a planning and improvement process.

► MODELS VERSUS TOOLS

All models employ a wide range of tools to help complete the tasks along the way. A useful definition of a tool in this context is something regarded as necessary to the carrying out of one's occupation or profession. A tool is something used in the performance of an operation, such as an instrument. Common planning tools are surveys, calculating risk ratios, archival research, process mapping, group management tools, and so on. Literally hundreds of tools exist ranging from common-sense approaches useful in managing group work to highly complex computer software used for modeling and statistical process control. The technical side of planning emphasizes learning how to select and use the proper tool for the task at hand. Textbooks from many academic disciplines teach us to understand and use various tools. Several websites also include "tool boxes" of use to those planning to change organizations or communities.⁸ Texts cited below, as well as other chapters of this book, describe myriad tools.

Choosing a Model

As suggested earlier, the most important activity in the early phase of a planning activity is the choice of a model to follow. There is no easy formula or decision tree that would lead to the "best choice" model for a particular situation. Perhaps the best time spent early on in the planning process is to learn more about models for planning that are available. If the scope of the activity is defined in terms of a specific health problem or issue, then starting with a textbook may be productive. Also, looking for journal publications via Medline or postings on the Internet may be fruitful. In some instances, governmental agencies provide technical assistance and have published planning manuals to aid local agencies that are doing planning. For example, consider bioterrorism or emergency response. A web search will reveal planning guidelines or manuals for just this purpose. Telephoning funding agencies or engaging consultants with a broad or well-focused range of experience may also help identify appropriate options.

There is no "one-size-fits-all model," nor is there an evidence base that would suggest that one model is better than another. One text¹ provides a summary of many of the more common health improvement planning models. A side-by-side comparison of the phases or steps in these models reveals a spectrum of choices from simple to those that provide guidance for dealing with issues at the individual, organizational, and community levels. While it is by no means exhaustive, the remainder of this chapter categorizes and describes a variety of available and well-used planning models. Since no comprehensive review, meta-website, or meta analysis of planning models exists (to this reviewer's knowledge), readers are referred to a recent planning and evaluation text which provides a description of several commonly used models as well as a side-by-side comparison table for 11 different models.¹

Comprehensive Health Improvement Models

These models are robust and useful in multiple situations. Most have been developed based on the developers' or users' experiences in multiple settings. All must be adapted to specific situations. Some uses (and published reports) may have an emphasis on consumer or stakeholder input. Other models may be developed from the perspective of the "responsible" agency and have an emphasis on the professional role and leadership. Textbooks, websites, and journal case studies suggest tools and techniques that will be useful in accomplishing the tasks needed in each phase of the planning, improvement, and evaluation process. Some texts include a complete sets of tools, computer files on CD, and website support.⁹ All models are useful in establishing a vocabulary and road map for the change process, be it at the community or organizational level. Comprehensive models implicitly or explicitly assume that there is a powerful and well-funded sponsor, often located in an agency or organization. These models also assume that there is a knowledgeable planner who will manage the process.

PRECEDE-PROCEED is perhaps the most widely recognized model. Developed and tested by Green and colleagues over a number of years,⁹ this model has been widely used and well recognized based on the authors many texts used in health education and public health courses. PRECEDE includes five phases: social, epidemiological, behavioral and environmental, educational and ecological, and administrative assessment. The PROCEED phases include implementation, followed by process, impact, and outcome evaluations.

The Multilevel Approach to Community Health (MATCH) was developed by the CDC in the form of intervention handbooks. It includes five phases of health goal selection, intervention planning, development, implementation, and evaluation. Each phase is broken down into steps. One strength of this model is the explicit recognition of interventions that focus on the multiple levels of individuals, organizations, and governments/communities.¹⁰

Mobilizing for Action through Planning and Partnership (MAPP) has been developed by the National Association of County and City Health Officials (NACCHO)¹¹ with CDC and Health Resources and Services Administration (HRSA) funding. The MAPP model emphasizes the role of public health agencies in building community participation to planning and implementing effective, sustainable solutions to complex problems. Nine MAPP steps include: organizing for action, developing objectives and establishing accountability, developing action plans, reviewing action plans for opportunities for coordination, implementing and monitoring action plans, preparing for evaluation activities, focusing the evaluation, gathering credible evidence and justifying conclusions, and lastly, sharing lessons learned, and celebrating successes. This model builds on the Assessment Protocol for Excellence in Public Health (APEX-PH) that was introduced by NACCHO in 1991. The original APEX model was especially useful for building the planning capacity of a local health department as it prepares to work with the local hospitals and community-based organizations. Additional APEX steps include community engagement and completing the cycle of implementation and evaluation. Many of the methods and lessons from APEX have been subsumed by the MAPP model. The Protocol for Assessing Community Excellence in Environmental Health (PACE EH) is a model which focuses on environmental health planning and was also developed by NACCHO.¹²

The Community Tool Box is an expansive website developed by the Work Group on Health Promotion and Community Development at the University of Kansas.⁸ Developed as a resource for Health Communities projects, the Tool Box has been online since 1995. It includes a model for community health planning and development that is similar to MATCH and PRECEDE-PROCEED, but with an emphasis on organizational and leadership competencies needed to progress through the community health improvement cycle. Resources are arranged to provide guidance for tasks necessary to promote community health and development. Essentially an online textbook, sections include leadership, strategic planning, community

assessment, grant writing, and evaluation. A framework for community health planning and improvement similar to other comprehensive models described above is provided on this website. Tools include step-by-step guidelines, case examples, checklists of points, and training materials. Also of use is a section on "best practices" with links to other knowledge bases that have collected information on best practices and evidence-based practices for general community health and focused areas such as HIV, chronic diseases, and substance abuse.

► OTHER PLANNING APPROACHES, MODELS, AND TOOLS

Social Marketing

A number of health improvement planning and action models have roots in the communication and social marketing disciplines.⁶ Social marketing approaches follow the same generic steps as do the comprehensive health improvement models. However, marketing models emphasize the understanding of the audience and importance of crafting specific messages to various market segments within the community. These may be considered more programmatic models in that these models emphasize activities after the problem or need for a program has been determined. These models provide tools for developing, delivering, and evaluating interventions designed to change something at the individual, organizational, or community level.

A comprehensive health communication model popularized by the CDC¹³ is known as CDCynergy or Cynergy. Available on CD-ROM, its emphasis is on understanding communication audiences, segmentation techniques, and targeted communication strategies. Similar to comprehensive planning models described, it includes six phases, each with detailed steps. The CD-ROM includes extensive examples and supporting material to assist in developing targeted health communication campaigns. CDCynergy is by no means the only comprehensive communications model. For a number of years, the National Cancer Institute has promoted a model entitled *Making Health Communications Work*.¹⁴ Another example is the Social Marketing Assessment and Response Tool (SMART) model.¹⁵ These and other models have been developed based on experiences in multiple settings. NACCHO has also created a Public Health Communications toolkit to help local public health agencies develop messages. The website also includes links to promotional materials that have been developed by other public health departments.¹⁶

Strategic Planning

Strategic planning implies that the planning process is significance. In concept, it is usually done by higher-level decisionmakers within the organization. The adjective "strategic" is often coupled with "long term or long range" to convey a sense of importance. The result of this planning will be setting the organization's overall directions and prioritizing major initiatives. In concept, strategic planning is a periodic, information driven, proactive, and systematic process that sets the overall business strategy of the organization for the years ahead.⁵ In reality, an organization's strategic decisions are often made by distant legislators or regulators in far-off bureaucracies. Often, organizational leaders can only plan their reaction to these decisions. During the process, planners usually undertake what is commonly termed strengths, weaknesses, opportunities, and threats (SWOT) analysis, the assessment of strengths and weaknesses of the organization as well as the threats and opportunities presented in the operating environment or market. Most texts are based on a competitive model and devote considerable effort to the assessment of the competitors and what initiatives are likely to advance the planning organization's position at the expense of competing organizations. Strategic planning models include provisions for developing action plans, performance information, accountability, and periodic evaluation.⁴

Program Planning: Action Planning and Problem Solving

Program and project planning are essential planning types which deal with policy and program implementation. Projects can be as massive as a new hospital or a nationwide immunization campaign or as limited as implementing a reengineered care process or new computer software system. Numerous management tools and techniques, such as decision support and project planning software, exist to aid in monitoring progress and optimizing project implementation. For many projects, there is no reason to *reinvent the wheel*. For planners, particularly those that are new to an organization, managers should learn from others. Abundant case studies have been published in practitioner-oriented journals.¹⁷ Some websites (including those cited in this chapter) now post volumes of content-specific information on topics ranging from planning for response to bioterrorism to pandemic influenza planning.¹⁸ Much of this information is in the form of how-to guides and checklists that can greatly accelerate the learning of managers and staff who are taking on the new project. In today's connected, electronic, information-driven world, it is sheer folly if any manager fails to learn from the experiences of others before embarking on implementing new projects and programs.

Examples of resources useful in planning checklists, narrative insights, computer software, and other aids can be found on public health organization websites. While a complete review is beyond our scope, recent concern over emergency preparedness has led to the provision of many planning resources. Some sites may have support and training services and websites with supporting resources.¹⁹ Planning guides for bioterrorism preparedness, such as NACCHO's *Preparing Your Local Public Health Agency for an Emergency Event*,²⁰ have been developed with CDC funding and tested in local health departments. An example of more specific resources would include the FluAid and FluSurge software programs to assist local planners in estimating the impact of a pandemic influenza strain. These are available for download.²¹

Information as a Basis for Better Community Health

Gathering and transforming data into information that is useful in making decisions is at the core of any systematic planning process. Information may come from formal and informal sources or systems. For example, a formal system includes vital statistic systems and disease surveillance information systems.²² Much of the information from programs comes from management information systems. Such systems, automatic or manual, are seldom adequate to meet all of an organization's needs for planning information. Planning always proceeds with less than perfect information. Filling serious deficiencies in information will occupy considerable planning resources.

Recent initiatives in many states and local health departments have centered on making information available to health agencies and the public. The CDC's *Community Health Assessment Initiative* supports development, implementation, and evaluation of tools, strategies, and approaches to improve the capacity of local public health agencies and communities to conduct effective community health assessments, and demonstrate how the resulting data have been used to affect public health programs and policies. Since 1992 the Initiative has supported the enhancement of electronic data systems that allow dissemination of health data using user-friendly, Internet-based, data query systems.²³ Several exemplary systems include Utah's Indicator-Based Information System for Public Health (IBIS-PH).²⁴ Florida's Community Health Assessment Resource Tool Set (CHARTS) is an interactive system that provides support for local health improvement initiatives using the Mobilizing for Action Through

Planning and Partnership model (MAPP).²⁵ Information on other initiatives is linked from the CDC Assessment Initiative website.²³ Unfortunately, not all states have information that is readily available to local planning efforts, thus many planning initiatives struggle to fill in their information gaps.

What Models Work Best?

While it is necessary for every leader and manager to embrace the need to plan, there are few prescriptions for effective planning. The effectiveness of planning models is difficult to establish since the planning process does not lend itself to testing in the conventional, scientific, comparative approach that is used to establish an "evidence base" for the effectiveness of various interventions and technologies. Some models have been used extensively, and case studies of their use, almost always successful, have been published in professional journals.

A critical element of comprehensive planning and improvement models is the engagement of the community. It is cliché but true to say that there is no one way to effectively do this "community thing." What are the best practices? Several reviews have been devoted to the topic of community engagement and coalition building in public health settings²⁶ and in more broadly defined communities.^{27,28} The consensus on what works offers no surprises. Leadership, undertaking action and achieving results, adequate technical assistance, feedback on progress, sustainable financial support are achieving outcomes that are associated with success. The unique situational factors, sometimes known as good or bad luck, as well as larger social and economic, factors, are also recognized as determinates of success or failure. The Community Tool Box includes a section on its website devoted to this question. The Turning Point Project, as part of its mission to transform and strengthen the public health system, gathered information on how to make governmental public health agencies more community based and collaborative.²⁹ The Project's approaches to engaging and sustaining community ownership and involvement in health improvement processes are detailed in an online report.³⁰

Improving Planning: Both Leadership and Technical Skills are Needed for the Future

Organizations that plan well at both the strategic and programmatic levels are likely to be the most successful. Some have suggested that governmental public health departments must be more concerned with *steering* rather than *rowing*,³¹ and will be primarily responsible for providing leadership to improve community health rather than providing direct services in the future.³² In this leadership role, the ability to engage other organizations and individuals in the community and to plan effectively becomes even more essential. At the local level there will be more effort needed on community-based rather than institutional and program planning. Without political and interpersonal skills, in addition to technical planning skills, it will be difficult to establish the credibility of the health department as a leader in community health improvement.

This chapter has presented an overview of health planning models and current planning resources that may be useful at the community level. Other chapters in this text cover evaluation, policy development, and quality improvement, which provide additional tools and frameworks for planning. This text includes many epidemiological techniques which are essential tools for planning sound programs that are designed to improve community health. Effective planning is essential to improving the health of our communities and the effective operation of programs and organizations small and large. Devoting the necessary time and resources for planning is a challenge that leaders must meet if they are to improve the quality of our services and the health status of our communities.

Public Health Leadership Development

Kate Wright • Cynthia D. Lamberth

Changes and advancements in the science and practice of preventive medicine and public health increasingly require a systems approach to provide and ensure community health. This includes organizational changes in the delivery of preventive and curative services and interventions, an emerging priority for population-based systems, partnerships among private and public health organizations and agencies, health information systems related to objectives and measurement of community health status¹, and a focus on integrated emergency preparedness. Leaders in all sectors associated with ensuring the health of the public must improve the ability to develop complex integrated systems to address changing demands for critical services, including anticipating, preventing, responding to, and recovering from crisis events. Improved capacity requires leaders to ensure agency and workplace performance standards. Performance standards typically measure professional, disciplinary, technical, and management capacity to provide essential public health services. Ensuring these standards requires improving leadership competence and performance. This chapter discusses development and ongoing work of a national network of public health leadership institutes to ensure public health practitioners access to an integrated competency-based education system for public health leadership development.

Recent reports and studies on the status of health personnel in the United States report important trends, including increasing demands for a competent public health workforce and for appropriately educated leadership.² The identified shortage in public health workers includes calls for enhancing leadership capacity.³ The Institute of Medicine reports on the future of public health called for workforce capacity development to accommodate demands of emerging public health problems in an evolving public health system.^{4,5} The reports argued that public health will serve society effectively only if a more efficient, scientifically sound system of practitioner and leadership development is established.

Demands on health leadership from all sectors require competence in systems thinking, design, and change dynamics. Often, however, public health leaders do not have access to or receive formal education in core public health practice or leadership skills. The Institute of Medicine report *Who Will Keep the Public Healthy* recommends that schools of public health increase the number of graduates who can assume system-level leadership positions, and recruit senior-level practitioners and mid-career professionals prepared for leadership positions.⁶

Calls and support for improving workforce education and training have escalated during the last two decades, and more dramatically recently due to demands for crisis and emergency preparedness. As complexity of challenges increases, more resources to improve workforce and leadership capacity are required. The Health Resources Services Administration continues to support a national system of Public Health Education and Training Centers that provide competency-based core public health education.⁷ The Centers for Disease Control and Prevention (CDC) is expanding support for a national network of Centers for Public Health Preparedness that provides competency-based programs for improving capacity to anticipate, prevent, respond to, mitigate, and recover from bioterrorism and emergency events. The CDC also helps to foster a national agenda for public health leadership development, including providing support for public health leadership institutes and the *National Public Health Leadership Development Network (NLN)*. In 2005, this expanding consortium consisted of 36 states, regional, national, and international institutes that collectively provided an integrated system for leadership development.⁸

► THE NATIONAL PUBLIC HEALTH LEADERSHIP DEVELOPMENT NETWORK

In 1991, the CDC began to support development of a national system of state, regional, and national public health leadership institutes. These 1- to 2-year programs provide practitioners with access to a unique professional development opportunity to enhance public health leadership competence. In 1994, the CDC sponsored a cooperative agreement with the Association of Schools of Public Health and Saint Louis University to establish the National Public Health Leadership Development Network (NLN). The purpose of the NLN is to improve capacity of and access to leadership development programs through expanding collaboration among academic and practice institute directors, alumni, and representatives of federal, professional, and private organizations.⁹

The Network, through sustained partnerships among schools of public health and state public health departments, is composed of 18 states, 9 regional (multistate), 4 national, and 3 international institutes. The national-level institutes include, in order of their establishment, The National Public Health Leadership Institute (PHLI), the CDC Leadership Institute, the National Health Education Leadership Institute, and the National Environmental Public Health Leadership Institute.

Annual NLN conferences and meetings are held to accomplish strategic objectives. Recent accomplishments include:

- Development of a *Conceptual Model for Leadership Development*¹⁰
- Development of the *Public Health Leadership Competency Framework*.¹¹
- Development of an *Evaluation Logic Model*
- Assessment of alumni network and development needs
- Dissemination of best practices, methods, and instruments
- Provision of technical assistance for development of new institutes
- Advocacy for strategic workforce development
- Advocacy for support and resource development
- Formal linkages with national organizations to accomplish objectives

Creation of the Conceptual Model, the Competency Framework, and models for program evaluation are fundamental to forming an integrated approach to leadership development.¹²

► DEVELOPMENT OF THE LEADERSHIP COMPETENCY FRAMEWORK

Continuing professional education has traditionally focused on the practice needs of individuals: their specialized practice area or technical expertise. This form of education has generally led to professional credentials or certification in the field of practice.¹³ Concern for the preparation and certification of leadership competence has led to increased demands for education and practice standards for leadership development.¹⁴ Identification of competence requirements is of particular concern because practitioners within public health are prepared in a wide array of professional programs or disciplines.

In 1995, NLN academic and practice members, representing all leadership institutes, identified the lack of and need of a competency framework specific to professional preparation of public health leaders and for those who aspire to or hold public health leadership positions. The objective was to develop a competency framework for use by NLN institutes as a basis for design of core curriculum modules based

on expected performance levels.^{15,16} Several existing competency frameworks were identified as a means to begin the process and confirm the need to develop a specific framework for public health leadership.¹⁷ The framework consists of 79 competencies and is reviewed and updated every 3–4 years. The 79 recommended competencies are divided into the following four competency areas:

- *Core Transformational Leadership Competencies:* Personal mastery, including systems thinking, analytical and critical thinking processes, visioning of potential futures, strategic and tactical assessment, emotional intelligence, communication and change dynamics, and ethical decision-making and decisive action.
- *Legal and Political Competencies:* Competence to facilitate, negotiate, and collaborate in an increasingly competitive and contentious political environment with complex multilevel crises and emergency events.
- *Trans-Organizational Competencies:* The complexity of major public health problems and crisis or emergency events extend beyond the scope of any single stakeholder group, community sector, profession or discipline, organization, or government unit, thus leaders must have the ability and skills to be effective beyond organizational or system boundaries.
- *Team Leadership and Dynamics:* Facilitation of learning teams or coalitions/networks to develop capacity and capability to develop integrated systems to accomplish mutual objectives.

The Network serves as an efficient and effective means for producing core competencies and curriculum content from this common framework, determining levels of professional development and prerequisite criteria, and developing measurement and evaluation protocols. Measuring the effectiveness of leadership programs is accomplished through process, impact, and outcome evaluation.

Competencies are used to design standards to operationalize teaching objectives and create impact and outcome evaluation models, methods, and instruments. The NLN and several regional and state institutes have conducted various levels of evaluation.^{18,19} In 2005, the NLN created an evaluation logic model for use in design of leadership programs.^{20,21} Ultimately, the objective is to measure program impact and outcome to ensure competence and performance improvement measured by organizational performance standards.²²

The possibility of certification or credentialing for different levels of the public health workforce is being discussed by various public health organizations, including the CDC, the National Association of County and City Health Officials, the Association of Schools of Public Health, and the American Public Health Association. Although there are no conclusions, there is general agreement that any system designed to accomplish this should be based on fundamental core and universal competency frameworks.²³ There is also agreement that these competencies should include a set of leadership competencies required as core skills for the public health workforce. In addition, if various levels of public health workforce credentials are created, then there should be a distinct category for a high-level leadership credential.

Interest in accreditation of local and state health departments has resulted in development of several voluntary and nonvoluntary models for local public health agencies.^{24,25} These models include an emphasis on performance standards and required education and training for specific levels of agency practitioners. Some of these models include a recommended education and training level for public health leadership. Although sometimes controversial, certification of local and state administrators is also germane to the need to formalize performance criteria for public health leaders in relation to accreditation of public health agencies. An established network of public health leadership development institutes is available to serve as an integrated national education and training infrastructure that provides required competency-based curriculum for voluntary or formal certification.

Policy Development

Helen H. Schauffler

There are many different avenues for influencing policy development for public health and preventive medicine. In addition to policy decisions made by the U.S. Congress (the legislative branch of the federal government), public policy decisions affecting preventive medicine and public health are also made at the federal level in the executive branch (the Department of Health and Human Services, the Centers for Disease Control and Prevention, the Surgeon General's Office, the Food and Drug Administration, etc.), at the state level in both the executive (governor's office and state health department) and legislative branches, at the city and local levels of governments, and in the private sector in private associations, representing health-care organizations and professionals, and among health plans and employers.

► AGENDA SETTING

The process of agenda setting is key to initiating the policy development process.^{1,2} The formal policy agenda is defined as those issues to which policy makers will pay attention and take action. Thus, the first step in any policy development process is to get an issue on the formal policy agenda. Two of the most commonly used strategies for getting an issue on the policy agenda include (a) gaining *inside access* to decision-makers in the policy arena, and (b) organizing an *outside initiative* through grass-roots mobilization or coalition

building to call the issue to the attention of policy makers.¹ These agenda-setting strategies can be used alone or in combination. Recently, both have been used successfully to influence the policy agenda for public health and preventive medicine.

Using Inside Access Strategies to Influence Policy Making

During the 103rd Congress, effective inside access was achieved by state and local public health officials who met individually with their elected representatives in Congress to discuss the importance of securing stable and adequate funding for the core functions of public health under a reformed health-care system. Public health officials, both as constituents and leaders in their state and communities, bring credibility and lend importance to an issue and can facilitate translation of public health issues in terms that make them locally relevant to individual elected representatives.³

Using Outside Initiative Strategies to Influence Policy Making

In 1994, the National Breast Cancer Coalition and other women's groups organized a massive and effective postcard-writing campaign from women at the grassroots level all over the country

regarding the importance of covering mammography screening as a health insurance benefit under health-care reform in the 103rd Congress. U.S. senators and representatives reported receiving hundreds of postcards from their constituents calling their attention to this issue. Legislators care most about how an issue affects their constituents and will pay more attention to an issue if it comes from the grassroots.

The state of Washington provides a model for how states may proceed, in the absence of reforms at the federal level, to put together a coalition of all of the key stakeholders in public health and engage in a productive planning process that produces tangible results. Washington state developed its own Public Health Improvement Plan in 1994, which was submitted to the state legislature and enacted into law in 1995.⁴ The plan was developed by the Washington state Department of Health and a Public Health Improvement Plan Steering Committee, representative of a broad coalition of public health and health-care organizations in the state. The coalition included representatives of the Department of Health, the state medical association, the association of community clinics, consumers, public health nursing directors, state legislators, schools of public health, labor unions, the state nurses' association, local public health officials, the hospital association, the health-care purchasers' association, and the Indian Health Service. The purpose of the plan was to help achieve three goals—stabilization of health-care costs, assurance of universal access to health care, and improvement of population health. The plan includes comprehensive recommendations for public health capacity, finance and governance of the public health system, and standards and strategies for addressing key public health problems. It served as the blueprint for state legislation enacted to reform Washington state's public health system.

► DIFFICULTIES IN GETTING PUBLIC HEALTH AND PREVENTIVE MEDICINE ON THE POLICY AGENDA

For the last 10 years, public health and preventive medicine have had increased success in increasing awareness of the value and benefits of increasing access to preventive care, relying on a growing scientific evidence base that demonstrates the effectiveness and relative cost-effectiveness of many preventive services.

However, the relative importance of public health and preventive medicine in health policy development over the last decade is illustrated by estimates that less than 1% of total health expenditures in the United States is spent on population-based public health and prevention programs.⁵ There are many reasons for this neglect, including the bias toward the medical model in health policy development. One example that illustrates this struggle was the experience in trying to add preventive care as a benefit to the Medicare program.

Incremental Policy Development: Adding Prevention Benefits to the Medicare Program

Perhaps the best example of how policy development for preventive medicine proceeds incrementally are the efforts over the last 30 years to add preventive services benefits to the Medicare program. The amendments to the Social Security Act, which authorized the Medicare program in 1965, include a provision (Section 1862) that prohibits reimbursement for any preventive care. The original Medicare program was based on the Blue Cross and Blue Shield programs operating at that time, where preventive care was not considered medically necessary. Preventive care is also neither unpredictable nor high cost, thus it was not considered to be appropriate for insurance coverage.

Between 1965 and 1980, over 350 bills were introduced into the U.S. Congress proposing to add preventive care benefits under Medicare before one bill finally passed adding the pneumococcal vaccine as a covered benefit.⁵ Only incrementally and within the context of huge budget reconciliation bills were additional screening and immunization benefits added to the Medicare program between 1980 and 1992. And the only benefits that were added were those for which research had demonstrated not only their effectiveness, but their relative

cost-effectiveness. The pneumococcal vaccine was shown to be cost-saving to the Medicare program, while mammography and Pap smears were added later only when studies from the Office of Technology Assessment showed that they were relatively cost-effective.⁶

However, in the past decade huge gains have been realized in increasing access to preventive care under the Medicare program (Table 78-1). Since 1992 coverage has been added for (a) a “welcome physical”; (b) cardiovascular screening for cholesterol, HDL, and triglycerides; (c) pelvic exam; (d) colon cancer screening including fecal occult blood, flexible sigmoidoscopy, colonoscopy, and barium enema; (e) prostate cancer screening including a digital rectum exam and PSA test; (f) Hepatitis B vaccine; (g) bone mass measurement; (h) diabetes screening and management including fasting plasma glucose test, diabetes glucose monitors, test strips and lancets, and self-management training; (i) glaucoma screening tests; and (j) smoking cessation treatments including counseling for smoking and tobacco use and coverage of tobacco treatment medications under the new Part D prescription drug benefit. Table 78-1 describes what is covered, for whom, at what costs, and with what restrictions.

Key Factors Influencing Health Insurance Coverage of Preventive Care

The key factors associated with successful policy development for adding prevention benefits in the Medicare program include an incremental approach of adding only a few benefits at a time, documented and scientific evidence of the effectiveness and cost-effectiveness of the preventive service, and sponsorship and leadership of key policy makers. Factors associated with failure include lack of active support from beneficiaries and health professionals, projected increases in costs to the medical care system associated with adding the benefit, and competing priorities on the policy agenda.

► PREDICTING THE OUTCOMES AND DESIGNING SUCCESSFUL STRATEGIES FOR PREVENTION POLICY

One of the most useful models for predicting the likely success or failure of proposed policies, and one that is also useful for designing more effective strategies for influencing the policy-making process, is James Q. Wilson's model of concentrated and diffuse cost and benefits (Table 78-2).⁷

To apply Wilson's model to a particular policy, one must identify the intended effects of the policy—who will benefit from the policy and who will bear the costs. In each case, one must also assess if the benefits and costs are concentrated or diffuse. Concentrated costs are those that are imposed on a well-organized, relatively small number of individuals or groups where the cost will be strongly felt. An example of a concentrated cost would be a tax policy requiring hospitals to contribute to a pool to support local public health activities. A diffuse cost, in contrast, is one where the cost burden is widely distributed among a large group of relatively unorganized individuals or groups, where the impact of the cost is relatively small. An example of a diffuse cost would be a small increase in the income tax or in insurance premiums to pay to support public health activities. Policies that rely on concentrated costs are always more difficult to adopt, as the group targeted to bear the cost is likely to organize strong opposition to the policy and will, more often than not, be successful in defeating it. The only case where this is not true is when the benefits are also concentrated and the group who will benefit is equally well organized and prepared to support the policy proposal. In this case, the victories are likely to be alternating. Policies that have concentrated benefits and diffuse costs are almost always winners, as the proponents are well organized, while those bearing the cost are not. Policies that have both diffuse benefits and costs proceed incrementally without strong or well-organized support or opposition.

To be successful in developing policy for public health and preventive medicine, it is best to frame the policy and its impacts as having diffuse costs and concentrated benefits. Conversely, in trying to

TABLE 78-1. PREVENTIVE SERVICES COVERED UNDER THE MEDICARE PROGRAM, MARCH 2006

<i>Preventive Service</i>	<i>Services Covered</i>	<i>Cost-Sharing Required</i>	<i>Restrictions</i>	<i>Definition of High Risk</i>
Welcome to Medicare Physical	Preventive physical exam, medical history, blood pressure, weight, height, vision test, electrocardiogram, immunizations, review of health, education, and counseling needs	Must first meet \$124 Plan B deductible; 20% of the Medicare-approved amount above the deductible	Once in a lifetime	
Cardiovascular Screening	Screening for cholesterol level, HDL, and triglycerides after 12-hour fasting	None	Every 5 years	
Breast Cancer Screening	Screening mammograms	20% of Medicare-approved amount with no Plan B deductible	Every 12 months for women age 40 and older, with one baseline mammogram for women ages 35–39	
Cervical and Vaginal Cancer Screening	Pap test; pelvic exam	None for the Pap lab test; 20% of the Medicare-approved amount with no Part B deductible for Pap test collection and pelvic exam	Every 24 months	
Colon Cancer Screening	Fecal occult blood test	None	Every 12 months for people age 50 and older	Had colon cancer before; close relative with colorectal polyps or colorectal cancer; history of polyps; inflammatory bowel disease
	Flexible sigmoidoscopy	20% of Medicare-approved amount after the yearly Part B deductible; 25% if done in a hospital	Every 24 months	
	Screening colonoscopy	20% of Medicare-approved amount after the yearly Part B deductible; 25% if done in a hospital	Every 24 months if high risk; once every 10 years if low risk, but not within 48 months of screening sigmoidoscopy	
	Barium enema	20% of Medicare-approved amount after the yearly Part B deductible	May be used instead of sigmoidoscopy or colonoscopy. Every 24 months if high risk; every 48 months if low risk	
Prostate Cancer Screening	Digital rectal exam	20% of Medicare-approved amount after the yearly Part B deductible	Every 12 months for men 50 and older	
	Prostate Specific Antigen (PSA) test	None	Every 12 months for men 50 and older	
Vaccines	Influenza	None	Once per year in fall or winter	
	Pneumococcal	None	Once in a lifetime	
	Hepatitis B	20% of the Medicare-approved amount after the yearly Part B deductible	Persons at high risk for Hepatitis B	Persons with Hemophilia, ESRD, immunosuppression
Bone Mass Screening	Bone mass measurement test	20% of Medicare-approved amount after the yearly Part B deductible	Every 24 months	

Diabetes Screening	Fasting plasma glucose test	None	Up to two screenings per year for individuals at high risk; requires physician referral	Persons with high blood pressure, dyslipidemia, obesity, or history of high blood sugar
	Diabetes glucose monitors, test strips and lancets	20% of Medicare-approved amount after the yearly Part B deductible		
	Self-management training	20% of Medicare-approved amount after the yearly Part B deductible		
Glaucoma Test	Glaucoma eye exam	20% of Medicare-approved amount after the yearly Part B deductible	Every 12 months for persons at high risk	Persons with diabetes, a family history of diabetes, African American and over 50 years
Smoking and Tobacco Use Cessation	Four counseling cessations per quit attempt. Defined as face-to-face patient contact of either intermediate (greater than 3 minutes to 10 minutes) or intensive (greater than 10 minutes)	20% of Medicare-approved amount after the yearly Part B deductible	Two attempts per year for high-risk persons or eight counseling sessions per year. May receive another eight sessions during a second or subsequent year after 11 months	Persons who use tobacco and have a tobacco related disease or take therapeutic agents affected by tobacco use
	Tobacco cessation medications prescribed by a physician (e.g., nicotine replacement therapy, Zyban)	Part of Medicare Part D drug benefit; cost-sharing varies by plan		

TABLE 78-2. JAMES Q. WILSON MODEL OF CONCENTRATED AND DIFFUSE COST AND BENEFITS

	<i>Concentrated Benefits</i>	<i>Diffuse Benefits</i>
Concentrated costs	(±) Alternating victories. Equally matched opponents. Battles between organized interest groups.	(−) A losing policy. Organized opposition with little organized support. Need to reframe policy effects to get out of this box.
Diffuse costs	(+) A winning policy. Organized support with little organized opposition.	(±) Incremental policy development, without strong, organized support or opposition.

Source: Data from Wilson JQ. *The Politics of Regulation*. New York: Basic Books, 1980:357–394.

defeat a proposed policy, it is best to frame the policy's effects as having concentrated costs. The central challenge for public health is rooted in the fact that most public health programs, by definition, have diffuse benefits, making it very difficult to successfully organize political support for them.

► IMPORTANCE OF PROBLEM DEFINITION IN POLICY DEVELOPMENT

Also key to influencing the policy agenda is how a problem is defined.⁸ In times of budget constraint, programs that are seen as inexpensive or cost-saving are particularly popular among policy-makers.² If reforming and/or increased investment in public health and preventive medicine are portrayed as contributing toward lowering health-care costs, advocates may be more successful in capturing the attention of policy makers.⁹ In contrast, if public health is viewed as contributing toward increasing government expenditures and enlarging the role of government, it will be difficult to get the attention of policy makers in a political environment that seeks to reduce the role and size of government.

► THE ROLE OF EVIDENCE-BASED GUIDELINES FOR PREVENTIVE MEDICINE POLICY: THE U.S. PREVENTIVE SERVICES TASK FORCE REPORT

One of the greatest influences on health insurance policy for preventive medicine was the 1989 release of the U.S. Preventive Services Task Force Report, which established national guidelines for clinical preventive services.¹¹ The report was prepared for the Department of Health and Human Services, and the Task Force recommendations were based on a rigorous review of the scientific evidence on the efficacy and effectiveness of 169 clinical preventive services. The reasons this report has been so influential are (a) the recommendations are grounded in health services research demonstrating the effects of preventive medicine, and (b) the report was developed by an independent task force, not associated with any one special interest or professional group. Clinical trials demonstrating the effectiveness and cost-effectiveness of specific preventive care measures are one of the most powerful tools for influencing purchaser and health plan decision makers to pay for and cover preventive medicine.

The Task Force was updated in 1996 and updates on the evidence on specific services are continually published in the peer review literature.

The Task Force Report has also had an influence in the development of quality measures to assess the performance of health plans. The National Committee for Quality Assurance (NCQA) defined seven of its nine quality measures in its Health Plan Employer Data and Information Set (HEDIS) 2.0, based on the recommendations for specific screening and immunization services in the U.S. Preventive Services Task Force Report.¹² Employers, as purchasers of health care, have also relied on the U.S. Preventive Services Task Force Report to define standard benefits packages to be offered by health plans and to define performance standards for assessing the performance of health plans and the quality of care delivered to their employees.⁸

► THE IMPORTANCE OF POPULATION-BASED DATA AND GOALS FOR PUBLIC HEALTH POLICY: *HEALTHY PEOPLE 2000*

Also important to furthering the development of public health policy in the last 10 years has been the development and release of the *Healthy People 2000* goals and objectives for the nation.¹⁰ It not only documents the current health status of the U.S. population, but it establishes population-based goals to improving population health. *Healthy People 2000* has provided the basis for establishing data systems at the national, state, and local levels for collecting and reporting on population data and has served as the benchmark against which to measure the influence of public health programs and health-care policies. The goals and objectives were developed between 1987 and 1990 using an extensive consultative and hearings process by the U.S. Public Health Service in partnership with the National Academy of Science and the Institute of Medicine.¹³

The impact of the goals and objectives has been far reaching. Congress has enacted three laws that incorporate the objectives, and 40 states have issued their own *Healthy People 2000* plans, which have been used to build coalitions to improve public health and to improve data systems to monitor the health status of the population.¹⁰ The goals have also been widely adopted at the local level and by private and voluntary agencies. Even the quality measures for health plans developed by the National Committee for Quality Assurance were based in part on the *Healthy People 2000* objectives to reward health plans for keeping populations healthy.¹⁴

► NEW OPPORTUNITIES FOR POLICY DEVELOPMENT IN AN ERA OF ACCOUNTABILITY

Perhaps the greatest opportunity for policy development that promotes public health and preventive medicine is the recent shift toward defining the problems in the health-care systems as ones of quality and accountability. As quality and “value” in the health-care system are increasingly defined as maintaining and improving the health of the population, monitoring changes in the health status of the population is necessary to ensure quality and accountability, and public health and preventive medicine become important players in the solution. Public health and preventive medicine offer expertise and experience in community-based prevention programs and population-based data collection and can take a leadership role in policy development in these areas.

The clearest example of this shift toward increased accountability is the development of HEDIS measures by NCQA. The majority of the quality measures in HEDIS 2.0, 2.5, and 3.0 address provision of clinical preventive services in accordance with the U.S. Preventive Services Task Force recommendations. Health maintenance organizations (HMOs) all over the country are being evaluated against these measures, and their performance is being published in report cards made available to employers and the general public. In some instances, employers are requiring that HMOs guarantee their performance in meeting quality standards by placing a percentage of their premium at risk.⁹ Building requirements for collecting data, meeting performance standards, and adding economic incentives for performance guarantees into the contracts between HMOs and purchasers, including private employers, state Medicaid agencies, and federal Medicare contracts,

may be the most effective policy tools currently available for increasing appropriate provision of preventive care to the insured population.

► ADDITIONAL PUBLIC POLICY TOOLS FOR PROMOTING PREVENTION AND PUBLIC HEALTH

There are many additional policy tools that are effective in promoting population health.¹⁵ Taxation of unhealthy products (e.g., cigarettes and alcohol), regulation of individual and industry behaviors

that will promote health and prevent disease (e.g., regulating helmet use and industrial environmental pollution), and public health education (e.g., media campaigns promoting good nutrition and physical activity) are all important tools that can contribute toward a more effective health-care system that promotes and maintains health.¹⁶ It is essential that policy for prevention and public health be developed at the national, state, local, and institutional levels and that it is developed based on a comprehensive model with policies that seek to influence the medical care system, communities, and governmental policies to promote population health and prevent disease.¹⁶

Quality Assurance and Quality Improvement

Richard S. Kurz

Two recent IOM reports present a very mixed picture of quality in American health-care institutions.^{1,2} The second of these reports states that as many as 100,000 Americans may die from medical errors each year and that many of these circumstances are correctable. What needs to be changed to improve quality and how can we make these changes? In this section, two approaches to quality assessment will be discussed: quality assurance and quality improvement. Though similar regarding their emphasis on the process of providing health services, each approach differs in terms of its purpose and procedures. Quality assurance refers to “the formal and systematic exercise of identifying problems in medical care delivery, designing activities to overcome these problems, and carrying out follow-up steps to ensure that no new problems have been introduced and that corrective actions have been effective.”³ Quality improvement is “a management philosophy to improve the level of performance of key processes in the organization.”⁴ Using an approach adapted from Berwick,⁵ a context for and an analysis of each concept is presented. This approach is consistent with Donabedian’s categorization of the measurement of quality that is comprised of structure (personnel characteristics and institutional features), process (activities in providing care), and outcome (results of care) indicators.⁶

Knowing the Resources for What Works

Operational and financial resources have been identified as essential for quality care in health services organizations. These are often viewed as structural concerns that are preconditions to the delivery of any services. Operational structures consist of physical facilities and personnel needed to accomplish the level of services that are desired. The earliest quality assessment procedures employed professional or organizational measures in developing licensure, certification, and accreditation for individuals, health-care institutions, and educational programs. The evidence is now clear that these aspects of providing care are necessary but not sufficient to assure high quality. For example, the major accreditation agencies for health-related organizations, the Joint Commission for the Accreditation of Healthcare Organizations (JCAHO) and the National Committee for Quality Assurance (NCQA), emphasize process and outcome rather than structural measures.

Knowing What Works

Knowing what works requires information on the efficacy of specific technologies, pharmaceuticals, and clinical interventions under controlled conditions and on the effectiveness of medical and surgical treatments as well as diagnostic, preventive, and rehabilitative care in the course of practice.⁷ These approaches provide assessments of the

technical results of interventions or services as perceived by the developers or providers of the activity. The primary methodologies in the assessment of efficacy are clinical trials and sophisticated technology assessment techniques.⁸ The benefits of control in these approaches are balanced with the lack of generalizability resulting from restricted study groups of patients, the restrictions on delivery protocols used, and the limited outcomes addressed.

Investigations of effectiveness of practitioners and organizations are referred to generically as “outcome research.” These studies consider the long- and short-term and broad and narrow results of care practices and interventions provided by specific practitioners or by specific types of organizations. Early outcome studies by Wennberg and others demonstrated that common procedures such as hysterectomy and hernia repair occurred much more frequently in some areas than others, even when these areas were not at great geographic distance from one another.⁹ The measures of these outcomes include mortality, morbidity, patient health status, and health-related quality of life indicators. For instance, the SF-36 Health Survey provides a multi-item scale which measures eight health concepts from the patient’s perspective (physical functioning, physical limitations, social functioning, bodily pain, mental health, emotional limitations, vitality, and general health perceptions).¹⁰ Substantial attention has been given to the measurement of outcomes, but equal or greater focus needs to be placed on extending this work to new clinical areas and translating existing findings into actions and disseminating them widely to the practice community.¹¹

Knowing what works can also be assessed in terms of consumers’ perceptions of the services that they receive. This assessment may be of the technical care provided or of interpersonal relationships or amenities experienced.¹² As health services organizations have experienced increased pressure to respond to consumer expectations, the distribution of patient or consumer satisfaction questionnaires has become routine and their methodologies increasingly diverse and sophisticated.^{13–15} At the community level, evaluation of services is conducted through report cards that are “standardized, publicly released reports on the quality of care.”¹⁶ Report cards have been developed for specific areas of care and types of health-care organizations.¹⁷ A widely cited example of these instruments is the Health Plan Employer Data and Information Set (HEDIS) which was developed to assess managed care plans and is employed by the NCQA.¹⁸

Using What Works

Using what works or quality assurance implies a consideration of the process by which services are provided. The fundamental issue is the appropriateness of the care provided: (a) over use of services when

other or no intervention would have been beneficial, (b) under use of the services that would benefit the patient, and (c) improper or incorrect use of beneficial care or prevention. Consideration of appropriateness leads directly to related questions of who determines what is appropriate care and who makes the judgment as to appropriateness in specific instances.

Appropriateness is the aspect of quality assessment with which health-care professionals, especially physicians, are most comfortable if they maintain control of the process. Physicians are trained to determine what actions should be taken in specific situations and to take responsibility for their actions in each instance. Concurrent and post hoc assessments by committees in hospitals or other health services organizations are the routine means through which physicians and other professionals perform peer evaluation and discipline. State boards and hospital-utilization review programs have also attempted to maintain appropriate care. Quality assurance also includes malpractice litigation, insurer audits, and governmental investigations. All of these approaches employ retrospective review and assume that problems occur because of careless or incompetent care. In other words, these approaches attempt to identify “bad apples” and “improve quality by cutting off one tail of the bell-shaped curve of human performance.”¹⁹

The desire to improve quality assurance has led the Centers for Medicare and Medicaid Services (CMS) to develop quality initiatives for hospitals, nursing homes, and home health agencies. An initial strategy for hospitals was to develop Quality Improvement Organizations (QIOs) throughout the United States to replace the former professional review organizations, professional standards review organizations, and the experimental medical care review organizations. As no standard set of quality measures existed for hospitals, the CMS developed a consensus set of 10 clinical measures in conjunction with JCAHO and the QIOs. These measures are voluntarily reported by over 4000 hospitals as part of the Hospital Quality Alliance, a collaborative linking CMS and the national hospital and medical school associations. Ongoing research is assessing the effectiveness of these efforts.²⁰

Although there are many approaches to assessing the appropriateness of care, perhaps the most extensively examined recently is the use of standards of care or practice guidelines. Standards of care are “statements describing specific diagnostic or therapeutic maneuvers that should or should not be performed in certain clinical circumstances.”²¹ Standards can be applied to a population of individuals in the community or to individual patients. The key question is do standards of care influence physician behavior and thus improve quality? There is limited evidence to date that this is the case.²² Chassin argues, however, that standards can be effective in changing physician behavior if guidelines regarding their construction and use are followed. These include (a) consensus and credibility concerning clinical content, (b) presentation in the context of a physician’s performance, (c) the legitimacy and focus of the presentation, for example, physician opinion leaders, and (d) reinforcement of the initial education, for example, academic detailing.²¹

How, then, should standards be developed and who should use them for what purposes? The dilemma in answering the first question is that efficacy research exists for a very limited number of clinical procedures, especially research applying the treatment in a clinical setting or linking it to specific effectiveness outcomes. Hence, although the best attempts to develop standards begin with a careful evaluation of the existing empirical literature, other consensus methods must be used to establish a standard of care. The Delphi methods used by the RAND Corporation produce appropriateness ratings similar to those based on research studies; however, the use of such reliable and valid consensus techniques is not always present in the development of standards of care.²³ Although methods for assessing appropriateness based on judgments can be developed and used in clinical and research settings, for example, the Appropriateness Evaluation Protocol,²⁴ substantial methodological study remains to be done.

Despite the lack of agreement on how to establish standards, there is increasing demand for them. Insurers, private and governmental, seek standards as a basis for determining what care they will pay for, which health-care organizations they will use, and which treatments

they will cover in their policies. In addition, they provide a basis for external regulation of physician and hospital practice and internal assessment of the clinical care provided by physicians and other practitioners. The concern expressed by physicians regarding these multiple uses of standards of care is that treatment and prevention are constantly evolving processes based on research evidence and practice experience. The standard of care established today may not be appropriate to the care given tomorrow. It is this concern that has led scholars, especially in the past 15 years, to study the question of how medicine can continually improve what it does.

Doing Well What Works

Doing well what works results from a process of continuous quality improvement (CQI) or total quality management (TQM). The concepts and principles of CQI or TQM are based largely on the works of three scholars in the United States (W Edwards Deming,²⁵ Joseph Juran,²⁶ and Philip Crosby²⁷) and two others from Japan (Genichi Taguchi and Kaoru Ishikawa).²⁸ Donald Berwick and others have adapted these concepts for health services and public health organizations.^{29,30}

As a management philosophy, the aspects of CQI require a significant shift in management behavior. In Table 78-3, these changes in management approach are summarized in seven principles adapted from Berwick and his associates’ work on a national demonstration project.²⁹ In this approach, organizations emphasize the management of processes as system failures rather than the management of people. The vast majority of problems are said to result from failures in a process or the suppliers or inputs to it, while only a small minority occur from idiosyncratic events, including the behavior of individuals. Problems occur most frequently across functions as work moves from one area to another or as materials or products enter or leave the organization. Because of this fact, customers and suppliers should not be viewed as problems but as partners in the process of service delivery.

The implementation of CQI in a health services organization results in a transformation that impacts all aspects of the organization. Deming described this change process as the integration of “profound knowledge” into management structures, policies, and procedures.³¹ As depicted in Fig. 78-1, traditional improvement is a function of professional knowledge comprised of information on discipline, subject matter, and values. In health care, quality assurance is a form of traditional improvement in which an individual’s failure to perform appropriately is viewed as correctable through greater professional training or better judgment based on professional standards or values. Quality improvement requires both professional knowledge and improvement knowledge.

The first aspect of improvement knowledge, an appreciation for the system, implies the ability to answer three questions: why do we make what we make, how do we make what we make, and how do

TABLE 78-3. THE PRINCIPLES OF CONTINUOUS QUALITY IMPROVEMENT

1. Productive work is accomplished through processes.
2. Sound customer-supplier relationships are absolutely necessary for sound quality management.
3. The main source of quality defects is problems in the process.
4. Poor quality is costly.
5. Understanding the variability of processes is key to improving quality.
6. The modern approach to quality is thoroughly grounded in scientific and statistical thinking.
7. Total employee involvement is critical.
8. New organizational structures can help achieve quality improvement.

Source: Adapted from Berwick DM, Godfrey AB, Roessner J. *Curing Health Care: New Strategies for Quality Improvement*. Chap. 3. San Francisco, CA: Jossey-Bass Publishers; 1991.

Figure 78-1. The aspects of Deming's "profound knowledge."
(Source: Adapted from Batalden PB, Nolan TW. *Knowledge for the leadership of continual improvement in healthcare*. In: Taylor J, ed. AUPHA Manual. Gaithersburg, MD: Aspen; 1993.)

we improve what we make? An answer to the first of these questions requires knowledge of customer preferences and community needs; the second, knowledge of processes, their inputs and suppliers, the services provided, and their customers; and the third, knowledge of organizational vision, a plan for improvement, and an approach for design or redesign of key processes.

Knowledge of variation requires an understanding of two types of causes for variation in processes. The first are special causes that are identifiable as resulting from specific and idiosyncratic problems of individuals, machines, or events. These causes if found should be removed immediately without the need for greater knowledge of the process. Common causes produce variation that is inherent to the elements of the process. In other words, to remove common causes of variation, the process must be studied thoroughly and the structure of the process, its inputs, and/or its suppliers must be changed. As outlined in Table 78-4, eight statistical procedures can be used to assist in the identification and resolution of process variation and, hence, to produce process improvement.³²

The psychology of improvement is based on the power of intrinsic motivation. Goals may be achieved through competition and extrinsic reward, but also by working independently and in cooperation with others. The success and survival of an organization is more likely to be based on the work of cross-functional teams who understand how system processes work and are committed to a vision for the organization that advances it beyond its current reality.

The final aspect of Deming's profound knowledge is the use of a theory of knowledge. Improvement comes through the use of knowledge that allows us to predict the impact of changes. The theory of knowledge advocated for quality improvement is fundamentally the scientific method. Based on planning and study of the process, hunches or hypotheses are developed as to the causes of process

failures. These hunches are tested through small experiments based on existing or newly collected data. If a cause is identified, other experiments are attempted to continue the iterative process of improvement and knowledge gained is distributed to everyone in the organization. This approach to quality improvement has been called the Shewhart or the Plan, Do, Study, Act (PDSA) cycle.

Many health services organizations have developed unique approaches for the implementation of CQI. One of the most widely recognized is the FOCUS-PDSA procedure developed and used by the former Hospital Corporation of America. The steps in this process can be illustrated with an example of process improvement completed by the Springfield/Greene County Department of Health (DOH) in Missouri. First, the DOH identified a process needing improvement (FIND). In the county, political concern had been expressed regarding the length of time needed to abate environmental hazards. Although many approaches had been used in the past to achieve the outcome of reduced abatement time, none had worked. A CQI approach was suggested and a team was organized, the members of which understood the process of hazard abatement from their participation in or supervision of it (ORGANIZE). To clarify their current knowledge of the process (CLARIFY), the team flow charted its steps and discovered the number of days that each step in the process required. Having described the process, the team undertook further investigation to discover what the causes of the delay were and which causes were the most important for reducing abatement time (UNDERSTAND). The team used Pareto charts and cause and effect diagrams to assist with this part of their work. Using this approach, the team discovered that the preparation of formal abatement requests through a typing pool and the search of courthouse records for property ownership were the most significant causes of abatement delay. Focusing on the second issue, the team attempted a modem connection to the records of the county utility company rather than the search of courthouse records to establish property ownership (SELECT). Having selected a potential solution, appropriate contacts were made with the utility company and a clerk was trained to make the modem connections and search the database (PLAN). Data was collected by the clerk on the length of time for discovery of ownership and presented in a simple bar graph comparing the length of time for utility company versus courthouse searches (DO). The analysis in this instance was simple and obvious. The average time for courthouse searches was three to five days and for utility database searches, 15 minutes (STUDY). Hence, approximately 4 days, on average, could be removed from each search. The DOH acted to train all clerks to do searches and expanded the investigation time of sanitarians that was formerly wasted in courthouse searches (ACT). Although this presentation of the abatement case is oversimplified, continuous quality improvement provided a systematic approach to process improvement, based on team knowledge rather than administrative authority.

How effective has continuous improvement been in improving quality and controlling costs? Many scholars have described CQI implementation or presented normative explanations for its use; however, research regarding the impact of CQI on quality and costs is just beginning in the health services literature.³³⁻³⁵ Despite the fact that systematic study is advancing slowly in health care, the application of CQI in health-care organizations is occurring. To motivate change, the Baldrige Award provides national recognition to health-care (and industrial) organizations that achieve excellence on a set of established and validated criteria. To date, three health-care organizations (the SSM Health System, the Baptist Hospital, Inc., and the Robert Wood Johnson University Hospital Hamilton) have won the award.³⁶

Knowing the Purpose for Doing it

Those involved in quality assurance and quality improvement must ultimately consider the purpose for quality assessment and the values underlying decisions. Unfortunately, this area has received little systematic attention in the literature. Berwick suggests that the issue can be addressed from an economic perspective. That is, to what extent is health care a social good, a product whose acquisition does not reduce one's wealth? The answer to this question, Berwick believes,

is intertwined with the distribution of insurance in our society. Brodeur provides a second approach for considering the purposes of quality assurance or improvement, ethical analysis.³⁷ He believes that each management perspective has associated with it a set of more or less well-articulated values that provide the basis for an ethical analysis of how each approach views the nature of work. From this view, work as a group activity must not subjugate the value of the persons performing the work to organizational concerns for efficiency and productivity.

► CONCLUSION

In this section, the conceptualization, implementation, and significance of quality assurance and quality improvement are discussed

in the context of the range of approaches to quality assessment discussed in the literature. There is some evidence that quality assurance has not met expectations regarding its ability to change practitioner behavior although the concept has been implemented in several different ways and this variation is related to the inconsistency of results. Alternatively, although its detractors abound, research on quality improvement is beginning to demonstrate the potential of this approach for linking process and outcome of health services. Complete assessments of quality, however, require several approaches of efficacy, effectiveness, appropriateness, and efficiency studies. In addition, these investigations must identify how the structural, process, and outcome components of quality are related in the delivery of preventive and treatment services.

Public Health Management Tools Evaluation

Thomas G. Rundall

Evaluation of health programs and policies is a fundamental competency for public health professionals.¹⁻³ Building and maintaining an effective health-care system requires programs and policies that promote health and prevent disease in an effective and efficient manner. Evaluation is a process designed to collect and analyze information to determine program performance and improve it. This process involves a variety of concepts, methods, and analytic schemes to determine whether a given program is needed and likely to be used, whether it is appropriately designed to meet the targeted need, whether the program is implemented as planned, and whether the program actually does help people in need at a reasonable cost without undesirable side effects. Hence, evaluation is used to assist in health program planning, program quality assurance and improvement, and policy development. In planning an evaluation, the evaluator collaborates with other stakeholders to decide (a) what is the purpose of the evaluation, (b) what will be the focus of the evaluation, and (c) what specific evaluation model will guide the data collection and analysis.

► PURPOSE OF THE EVALUATION

Evaluations can be conducted for *formative* or *summative* purposes.^{4,5} Formative evaluation is done primarily for the purpose of providing program staff with information for making midstream alterations in the program to increase the likelihood of achieving desired outcomes. The primary purpose of summative evaluation is to provide information for decision makers with respect to whether the program in its final form, refined through the use of formative evaluation, is sufficiently superior to existing alternatives to justify the allocation of resources to its continuation and/or its adoption in other settings.

Formative evaluation is most useful during the early implementation of a new program or as a means of reexamining an older program that stakeholders agree needs modification. Formative evaluations usually have three major components: (a) assessment of participant and staff satisfaction with features of the program, such as relevance and clarity of information presented, structure of the program, qualifications and skill of staff, and interpersonal dynamics among participants and staff; (b) assessment of the short-term cognitive (knowledge and awareness), affective (attitudes, motivation, and beliefs), or behavioral effects of the program; and (c) assessment of the sustainability of the program, including an appraisal of the current and future levels of participation in the program and an analysis of resource requirements.

Summative evaluation provides information about a health program's effectiveness over a defined period of time, with a defined population, in one or more settings. Decision makers then use this information to help them decide whether to terminate a program, continue it, or expand it to new settings. Such evaluations should be conducted only when program managers are satisfied that the program is functioning as intended and that it is being properly delivered to participants.

Evaluation Focus

Evaluations may focus on assessing program process, outcome, or impact.^{6,7} While the usage of these terms varies somewhat in the field, the following provides generally accepted descriptions of each type of evaluation.

Process evaluation documents what is going on in the program and examines strengths and weaknesses of program components and activities. A process evaluation may include descriptions of the characteristics of those who use the program, patterns of use or attendance, characteristics of the program setting, satisfaction of participants and staff with the program, and the extent to which program components and activities are implemented as planned. Process is most useful as part of a formative evaluation. However, process evaluations are also useful in summative evaluations by helping the evaluator understand why certain effects were or were not observed.

Outcome evaluations assess the effectiveness of a program in producing favorable cognitive, affective, and behavioral changes in the target population. While most commonly conducted as part of a summative evaluation, short-term assessments of outcomes are also used in formative evaluations.

Impact evaluation assesses the effect of the program on more distal goals such as changes in health status and perceived quality of life. Because changes in these types of outcomes typically take a long time to achieve and to measure, the use of impact evaluation is normally restricted to summative evaluations.

Although clarifying whether the evaluation is for formative or summative purposes and whether it will focus on program processes, outcomes, or impacts are important steps in planning an evaluation, there is still one other fundamental decision to be made: which model of evaluation practice is most appropriate for the program being evaluated?

Models of Evaluation

The modern era of program evaluation in the United States began in the early 1960s, when policymakers sought data on the effects of the huge federal investments that were made in health education, and social programs. Since that time, numerous approaches to evaluation have been developed. Four prominent models of evaluation are described below. Each of these models emphasizes a valuable aspect of evaluation. The specific questions being addressed by the evaluation and the opportunities and constraints present in the program setting will determine which model, or combination of models, is appropriate.⁸

Social Science Research Model

In an attempt to develop a rigorous evaluation methodology, early evaluators borrowed heavily from the designs and methods used by social scientists to establish the causal effect of an independent variable on a dependent variable. Program evaluation was viewed as a specialized form of social science research. From this perspective, the success of a program is determined by forming two randomized groups, providing the service (treatment) to one group and using the second group to control for possible threats to internal and external validity.^{9–11} After implementation of the program, data on the appropriate dependent variables are collected from the members of each group. Statistical tests developed for basic research are applied to these data. If the difference between treatment and control group mean scores on a selected outcome measure is in the predicted direction and statistically significant, the program is considered a success. If the difference between the means is not statistically significant, the program is considered a failure. While the strength of this approach for the purposes of making causal interpretations is widely accepted, over time many stakeholders criticized this approach on a variety of grounds. For example, the social science approach was often judged to be so time consuming that deadlines for making budgetary decisions about a program being evaluated could not be met, impractical to implement because randomization was not possible in many nonclinical settings, too focused on a small number of quantifiable outcomes, too reliant on statistical tests to determine program effectiveness, subject to incorrect interpretation, unable to provide information useful to managers for quality improvement purposes, and too costly.¹²

Goal-Based Evaluation

In an effort to make evaluations more sensitive to the full range of expected program outcomes, evaluators often work with program staff to clearly state the goals and objectives for the program and then measure the extent to which these have been achieved. This approach provides program planners, with the opportunity to establish the criteria and standards to be used to determine program success. Further, qualitative goals and objectives can be stated, explicitly incorporating qualitative methods in evaluation research. This approach also has its drawbacks. It focuses so much attention on the stated program objectives that evaluators sometimes fail to come to understand why programs may or may not have achieved those objectives. Further, goal-based evaluations often fail to consider unanticipated beneficial or harmful effects of program activities.

Goal-Free Evaluation

To avoid the pitfalls of goal-based evaluation, an evaluator might not build an evaluation's design and measurement strategies around the stated goals of the program. A goal-free evaluation studies the program activities, staff, clients, program settings, and records to determine all the positive and negative effects of the program, without regard to the program's stated objectives. This information is then communicated to program staff, clients, funding agencies, and other stakeholders, who decide whether the findings are compatible with the goals of the program and determine what adjustments should be made to improve the program.¹³

Empowerment Evaluation

New approaches to evaluation have emerged over the past decade explicitly incorporating a participatory and collaborative relationship between the evaluator and program stakeholders. When doing empowerment evaluation (also referred to as participatory action research, or community-based participatory research), the evaluator's role includes consultation and facilitation directed toward developing the capabilities of the participating stakeholders to conduct evaluations on their own, to use the results effectively for advocacy and change, and to gain greater control over a program that affects their lives. The evaluation process, therefore, is directed not only at producing informative findings, but also at enhancing the self-development and political influence of the participants. As these themes imply, empowerment evaluation often involves those stakeholders who otherwise have little power in the program, usually the program recipients or intended beneficiaries.¹⁴

There is no one right way to do an evaluation. Successful evaluators tailor each evaluation to the questions that are important to program stakeholders and the opportunities and constraints present in the program setting. The specification of the evaluation's purpose, focus, and data collection and analysis model must evolve from an evaluation planning process that will provide the evaluator with information essential to the design of the evaluation. There are six general steps in this process: (a) identification of stakeholders; (b) determination of the most important concerns of each stakeholder group; (c) assessment of the evaluability of the program (Is there sufficient agreement among stakeholders on the rationale for the program, the key evaluation questions, and the potential to make changes in the program to improve it, that justifies doing the evaluation?); (d) examination of the literature; (e) determination of the methodology to be used, including the research design, sampling, selection of criteria, data collection, and type of statistical analysis; and (f) preparation of a written proposal.¹⁵

The Special Case of Evaluations of Complex, Communitywide Interventions

Communitywide health promotion and disease prevention programs are at the core of public health. These types of programs are aimed at modifying health risk behaviors and the conditions that produce and reinforce them. These activities often include communitywide health education programs and activities designed to change laws or regulatory policy in areas that affect health. Communitywide interventions are complex, because it is often difficult to define exactly what are the "active ingredients" of the intervention and how they relate to each other. Communitywide interventions often use multiple theories of change and channels of communication (including media advocacy), and often target healthy individuals as well as those in need. The distinguishing characteristic of communitywide interventions is that they attempt to improve health-related characteristics of the entire community. These interventions are typically implemented over several years, making it likely that non-program-related factors such as historical events and migration in and out of a community will affect program outcomes. These aspects of communitywide interventions make them difficult to evaluate. In recent years special research approaches have been developed to evaluate communitywide interventions, including random assignment of multiple communities to treatment and control conditions, combining cross-sectional and cohort research designs within communities, extensive monitoring of intervention processes, measurement of environmental variables, utilization of multiple data collection methodologies, and the use of randomized trial strategies that allow components of the intervention to take on different forms depending on local context.^{16–23}

Evaluation is more than just research. It is fundamental to good management, and it is an essential part of the process of developing effective public policy. It is a complex enterprise, requiring researchers to balance the rigor of their research strategies with the relevance of their work for managers and policy makers. There are

useful web-based “toolboxes” available to provide guidance and resources for public health practitioners interested in further developing their program and policy evaluation competencies (<http://www.cdc.gov/eval/framework.htm>; <http://www.eval.org/>). These tools and the other resources identified in this chapter will help evaluation researchers to understand the opportunities and constraints associated with a given program and to use the concepts and methods introduced above to tailor an evaluation in such a way that a defensible assessment of program performance is produced.

Disaster Preparedness and Response

Theodore J. Cieslak • Scott R. Lillibridge • Trueman W. Sharp
• George W. Christopher • Edward M. Eitzen

► INTRODUCTION

The recent massive disaster brought about by the December 26, 2004, tsunami in the Indian Ocean was one of the most lethal, costly, and destructive in modern history. Some experts predict, however, that an ever-increasing global population, with its attendant strains on natural, technological, and human resources, portend even greater and more frequent disasters to come.¹ These realizations, coupled with technological innovations, microbial engineering, increasingly sophisticated terrorist capabilities, and the ever-present danger of war and sectarian strife, call to mind the myriad problems associated with effective disaster planning and disaster response.

Although disasters defy ready definition, and at least 35 different professions are involved in disaster assessment, study, and mitigation,² a *disaster* might nonetheless be defined as a destructive event that results in the need for a wide range of emergency resources to assist and ensure the health and survival of the stricken population.³ Disasters can be natural or man-made, abrupt or insidious. Furthermore, disasters caused by man can include warfare and terrorism, as well as “technological” disasters (Table 79-1). “Natural” disasters, such as earthquakes, volcanic eruptions, hurricanes, floods, and the like, have been with us throughout history. The same can be said for warfare, and its accompanying destruction, disease outbreaks, and famine. Technological disasters have likewise been with us since the Industrial Revolution.⁴ Such disasters may involve explosions, fires, crashes, and chemical or radiological releases into the environment.⁵ More recently, the specter of man-made disasters related to terrorism and the deployment of *weapons of mass destruction* (WMDs) has focused considerable attention on public health and disaster preparedness.

Disasters encompass a wide variety of events with multiple causes and consequences. Natural disasters are precipitated by the forces of nature and weather.⁶⁻⁸ Such disasters may be ongoing and insidious, as in the case of the famine of 1977 in Ethiopia, which followed successive years of drought.⁶ Most natural disasters occur suddenly, however, and often with little or no warning. The earthquake in Kobe, Japan, in 1995, which caused 5000 immediate deaths and created the need for an urgent and massive relief effort, is but one example among many.⁷

As technology rapidly evolves, so too does the inevitability of technology-related crises. Adverse health effects from technological disasters include those acute effects such as trauma, burns, and smoke inhalation injury, as well as those indirect effects related to environmental exposures to potentially contaminated soil, water, and food.^{8,9}

An example is the 1986 radionuclide release from disabled reactor number 4 at Chernobyl in the former USSR. This disaster resulted in acute injuries, but more importantly it exposed more than 2 million people to radiation.^{10,11} Radiation exposures from this incident continue to result in a variety of adverse health effects, such as increased rates of thyroid cancer.¹²

Complex emergencies are the result of interrelated social, economic, and political problems and almost always involve armed confrontation.¹³ Warfare (and armed conflict) brings with it a unique set of disaster response challenges. In these increasingly common and often prolonged disasters, there is typically extensive destruction of social and public health infrastructure, large-scale population displacement, epidemic disease, and food shortages.¹⁷⁻¹⁹ Recent examples of complex emergencies include the humanitarian crises in Bosnia-Herzegovina, Rwanda, Somalia, Liberia, Cote d'Ivoire, Afghanistan, and East Timor, among many others.

Terrorism is regarded by many as an escalating and evolving threat, and terrorists of today have unparalleled access to highly destructive technologies.¹⁴ Long a problem in some areas of the world, large-scale terrorism became a very real concern for Americans following the first attack on the World Trade Center in 1993. On March 20, 1995, an attack on the Tokyo subway system, perpetrated by the Japanese doomsday cult, Aum Shirykyo, demonstrated a willingness and capability on the part of terrorists to employ WMDs, in this case, a chemical weapon, the nerve agent, sarin.¹⁵ The following month, on April 19, 1995, large-scale terrorism came to the American heartland with the Oklahoma City bombings, significant also in that the perpetrators were Americans. Finally, the attacks on the World Trade Center and the Pentagon on September 11, 2001, and the release, the following month, of anthrax-contaminated mail, underscore the variety and adaptability of terrorist methodology. Moreover, they call to mind unique disaster response issues. Such issues include, in addition to conventional disaster response considerations, the need for rapid characterization of the offending agent, mass decontamination, ready access to antidotes and medications, specialized medical training, and proper protective equipment for emergency responders.

► UNDERSTANDING DISASTERS

Natural Disasters. Over the past 20 years, natural disasters have affected at least 800 million people and caused well over 3 million deaths.¹⁶ Each week there is at least one natural disaster of sufficient magnitude to require external assistance from the international community. The incidence of natural disasters appears to be increasing,

TABLE 79-1. DISASTERS

Type of Disaster	Examples	Deaths	Comments
■ Natural Disasters			
Climatological			
Hurricanes, typhoons	<i>Mitch</i> , Honduras, 1998	>11,000	2–3 million homeless; damages >\$5 billion
Tornadoes	13 States in U.S., 4/3/1974	330	148 separate tornados; 5484 injured
Floods	Monsoon, Bangladesh, 8/9/1988	>1300	30,000,000 left homeless
Drought	Somalia, 1991–1993	~400,000	Ongoing drought complicated by warfare
	Midwestern United States, 1930–1941		<i>Dustbowl</i> destroyed 50 million acres
Blizzards	Eastern U.S., 3/12-14/1993	270	\$3–\$6 billion in damages
Geological			
Earthquakes	Bam, Iran, 12/26/2003	>30,000	30,000 injured; 75,000 homeless
	Yerevan, Armenia, 12/7/1988	~25,000	400,000 homeless
Tsunamis	Indian Ocean, 12/26/2004	150–300,000	
Volcanic eruptions	Mt Pinatubo, Philippines, 7/15/1991	>800	
■ Technological Disasters			
Fires	Paraguay Supermarket, 8/1/2004	>400	
Explosives	Lagos, Nigeria, 1/27/2002	>1000	Explosion triggered stampede, killing 1000
Crashes	Neishabour, Iran, 2/18/2004	320	Runaway railcars loaded with fertilizer & petrol explode, destroy 5 villages
Chemical exposures & spills	Bhopal, 12/3/1984	>2000	~150,000 injured
Radiation exposures	Chernobyl, 4/26/1986	31 claimed	>2 million exposed to radiation
■ Warfare			
	Second World War	>40,000,000	30–50 wars ongoing at any given time
■ Terrorism (CBRNE)			
Chemical	Aum Shinrykyo, Tokyo	12	>5000 <i>worried well</i>
Biological	Anthrax Attacks, US, 10/2001	5	WHO estimates 95,000 deaths possible under certain conditions
Radiological	No significant attacks thus far		4 died from pilfered Cesium source at Goiania, Brazil, 1987
Nuclear	None thus far		
Explosive	Twin Towers, Pentagon, 9/11/2001	2992	

and the number of highly vulnerable persons in disaster-prone areas, particularly in the developing world, is at least 70 million people and growing.^{17,18} The devastating 2004 tsunami in the Indian Ocean, in which well over 150,000 persons were killed, illustrates the potential impact of a natural disaster on a population residing in a hazardous coastal region. Similarly, the earthquake in Bam, Iran, exactly 1 year earlier (on December 26, 2003), killed 30,000, injured another 30,000, and left 75,000 homeless, illustrating the perils of life in a highly earthquake-prone zone.

Natural disasters may be associated with a wide variety of acute and long-term health effects. For example, volcanic eruptions may result in injury or death due to explosive blast effects, lava flow, falling debris, asphyxiating gases, or mudflows.^{19,20} For many months following an eruption, ash and other particulate matter vented from an active volcano may exacerbate respiratory illness in persons residing down-wind.²¹ Volcanic ash may contaminate soil and water, resulting in long-term toxic exposures to the population. One of the most unusual gas releases associated with volcanic activity occurred in 1986 in Cameroon.²² In this incident, carbon dioxide was released from an active volcano underneath Lake Nyos. The gas enveloped nearby villages and caused approximately 1700 deaths by asphyxiation. Volcanic ash in the atmosphere has also been known to cause engine shutdowns in commercial aircraft, leading to in-flight emergencies—a unique combination of natural and technological events interacting to produce the potential for catastrophe.

Public health issues associated with floods extend beyond concerns for mortality due to drowning. In Bangladesh, the flooding which followed a 1991 tropical cyclone reduced the potability of water from wells and caused widespread outbreaks of diarrheal disease.²³ Flooding may also result in increased numbers of breeding sites for mosquitoes and consequently, an increased risk of exposure to their associated diseases, such as malaria or dengue. Immediate public health actions required following a flood usually include vector control, the

provision of potable water and food, and the restitution of vital environmental health services.^{24,25} Overall, however, early warning systems, improved evacuation plans, and the discouragement of settlement in flood-prone areas may have much greater potential to save lives than activities associated with external emergency response to flood disasters. The recent Indian Ocean tsunami illustrated the limitations of response activities in curtailing mortality during rapid flooding; most victims in this disaster were carried out to sea and drowned.

Earthquakes typically cause traumatic injuries and deaths, as well as destroying buildings and infrastructure.²⁶ The 1976 Tangshan Earthquake, for example, caused more than 200,000 sudden trauma-related deaths.²⁷ Similarly, the relatively moderate (Richter Scale 6.6) earthquake in Bam in 2003 resulted in at least 30,000 deaths, largely due to trauma sustained when earth and mud buildings collapsed on inhabitants. In contrast to most floods (the recent Indian Ocean tsunami excepted), the morbidity and mortality of earthquakes is much more immediate. Deaths are primarily due to crush injuries and other trauma resulting from unstable, collapsing, or crumbling buildings. Earthquakes are not usually followed by long-term public health problems such as famine or epidemic diseases, although following the Northridge earthquake of 1994, a wide range of external primary care services were required by the population for up to 4 weeks. Other public health issues associated with earthquakes include concerns for the health of persons in shelters, occupational health protection for rescue workers, and the provision of mental services for survivors.²⁸

Technological Disasters. Public health problems resulting from technological accidents, or from the unregulated and unsafe use of industrial technologies, are increasingly recognized as an important and increasingly common type of disaster.^{7,10} The nuclear reactor accident at Chernobyl, the toxic gas leak at Bhopal, India, the extensive chronic environmental pollution in several former Soviet block

nations, and the acute environmental catastrophe associated with the Exxon Valdez oil spill are but a few examples of the disastrous consequences that can ensue from technological disasters. The potential for harm from improper management of industrial technologies is a major concern in developed nations where at any given moment there are myriad complex industries in operation and tons of hazardous materials in transit through populated areas. Moreover, these hazardous materials can make attractive “weapons of opportunity” to would-be terrorists, who may be able to accomplish their objectives simply by opening the valve on a railroad tank car. In developing countries, these problems are exacerbated when rapid industrialization exceeds the development of counterbalancing safety controls.

Technological disasters are usually the result of poor engineering, improper safety practices, or simple human error. However, natural disasters can be an important factor in precipitating a follow-up technological disaster. For example, gasoline fires that killed over 500 persons in Durunka, Egypt, in 1994 were the result of flash flooding that ruptured a fuel storage tank and carried burning petroleum into the nearby town.²⁹ Such synergistic disasters have been termed NA-TECHs (Natural-Technological).³⁰ In many locales, chemical plants, nuclear reactors, or other potentially dangerous industries are seated in geological regions that are highly vulnerable to natural disasters.

Dealing with the consequences of a technological disaster or a NA-TECH presents many challenges. Recognizing the nature of the hazardous material involved, evacuating citizens after an accident, providing appropriate medical care for victims, and protecting emergency responders against hazardous exposures are but a few of the many challenges that emergency responders potentially face.³¹ In addition, because industrial disasters may leave toxic residues in the environment that pose ongoing threats to the health of populations, the initiation of chemical exposure and disease registries (in order to track adverse health effects of disaster victims over time) may be a fundamental component of emergency response. Clinical investigations following technical disasters may require assistance from laboratory scientists, toxicologists, and environmental epidemiologists. Public health prevention efforts include sound plant design and operation, safe disposal of waste products, thorough safety occupational programs, linkage to local emergency management operations, and proper site selection for industrial facilities.

Warfare and Conflict-Related (Complex) Emergencies. Conflict-related disasters are a growing phenomenon in the post-Cold War world. In the late 1970s there were approximately five conflict-related disasters per year, but by the early 2000s there were 15–20 per year. In 2003, the Office of Foreign Disaster Assistance of the U.S. Agency for International Development responded to at least 16 complex emergencies. The increase in conflict-related disasters closely relates to the number of armed conflicts in the world, which have likewise increased dramatically during the past two decades. Since 1980, there have been a couple of hundred major armed conflicts, and in 2003, there were 36 ongoing wars in 28 different nations.³²

War has always been destructive, but in recent years the nature of armed conflict has become increasingly more devastating.^{39–42} In many conflicts today, there are eight to nine civilian deaths for every combatant death.³³ Toole and Waldman have described the insidious cycle of armed confrontation, famine, and population displacement.³⁴ In 1980 there were approximately 5 million refugees worldwide, but largely as a consequence of this cycle, there were approximately 17 million global refugees as of January 1, 2004, according to the United Nations High Commissioner for Refugees.³⁵ In addition, there are tens of millions of internally displaced persons.

The public health problems of refugees and displaced persons are often overwhelming. Crude mortality rates among refugees and displaced populations frequently rise dramatically above baseline levels, principally due to nutritional shortages, environmental problems, and preventable infectious diseases. Conflict-related disasters have similar effects on those who do not flee when infrastructure is destroyed or severely damaged, thereby limiting their access to food, potable water, refuse disposal, and basic medical services.

During many conflicts today, international humanitarian law is unknown or disregarded, and human rights abuses are common. As a result, in some disasters, violence may be a direct and primary cause of morbidity and mortality.^{36,37} For example, while morbidity and mortality due to infectious diseases increased to some extent, deaths due to “ethnic cleansing” operations were by far the principal cause of death during the Bosnia and Kosovo conflicts.^{36,37} Similarly, the provision of emergency relief during conflict-related disasters can, in itself, be very dangerous.³⁸ Many relief workers have been killed in recent years; their protection is often a major challenge of disaster relief operations.

Relief organizations that wish to remain neutral and impartial can have tremendous difficulty operating in settings of armed confrontation. Unfortunately, the provision of humanitarian relief can easily be perceived as a partisan act, or can be manipulated for the benefit of different warring factions.³⁹ In situations of conflict, traditional medical and public health interventions may not be effective in preventing injury and death. Indeed, some have argued that in certain situations emergency relief has served to exacerbate and prolong the conflict. Development initiatives, weapons control, conflict resolution, and other such measures may be more effective ways of preventing mortality in these situations. The role of relief organizations in preventing human rights abuses, including torture and genocide, is complex and uncertain.

Nonetheless, international disaster operations today often require that nongovernmental relief organizations (NGOs) frequently work alongside military relief personnel and operations of wealthier nations. Often the militaries of these nations have robust capabilities which can be invaluable in disaster relief, such as food, transportation, medical care, and logistics; civilian NGOs are often unable to provide comparable levels of such relief. While those in the assisting military forces may see such roles as a natural extension of their capabilities, their activities have been known to foster jealousies and resentment among NGOs, which often view uniformed military responders as at least figuratively contributing to many of the types of disasters to which they respond (rightly or wrongly). Sensitivity to such dynamics among military disaster responders can go a long way toward heading off such tensions—abandonment of the “we’re in charge” mentality, the wearing of civilian clothes, a willingness to work cooperatively with civilian relief organizations, and a lack of arms, where possible, may further acceptance among both NGOs and the local population.

One of the most extensive public health catastrophes today concerns the worldwide dissemination of land mines. It is estimated that 65–110 million land mines are scattered throughout more than 60 countries.⁴⁰ These landmines can often persist and remain “armed” for decades. They impede the resettlement of displaced populations and serve to remove land from cultivation. Globally, landmines are responsible for more than 15,000 fatalities each year.⁴⁰ With that said, many landmines are designed to maim; survivors typically require emergency surgical services and prolonged rehabilitation largely related to lower limb amputation. This has had devastating impact on the individuals, the economies, and the health-care systems of many developing nations. Countries affected by severe landmine problems in the wake of endemic warfare include Afghanistan, Mozambique, Angola, Rwanda, and nations of the former Yugoslavia.

Terrorism. Terrorist attacks have recently captured the attention of the world’s citizenry and its media. Foremost among these attacks in recent memory, the assaults on the Pentagon and World Trade Center on September 11, 2001, resulted in 2992 deaths. While the numbers of casualties arising from most individual terrorist attacks, however, is still dwarfed by those due to natural disasters such as earthquakes, tsunamis, and floods, an increasing sophistication of terrorist methods and an increasing destructive capacity of terrorist weapons has caused terrorism, in the minds of many, to become the scourge of the twenty-first century. Moreover, the cumulative toll of terrorism has been immense. From 1984–2000, an estimated 30,000–35,000 persons were killed by terrorists in Turkey alone.⁴¹ While small-scale terrorist endeavors, such as kidnappings and assassinations, have been with us for centuries, a recent emphasis on the possible employment of WMDs and the production of large numbers of casualties in a single

event has caused terrorism to be considered a potential cause of large-scale disasters; under ideal conditions (for the perpetrators), for example, the World Health Organization estimates that an anthrax attack on a large city in the developed world could produce as many as 95,000–100,000 deaths.⁴² The formerly held view that terrorists, motivated largely by political aims, avoided large numbers of casualties (as they would turn away potential supporters), has recently been supplanted, in many cases, by the religious or ideologically motivated views of groups such as al-Qaeda. These groups, in some cases, seem to have no hesitation about the production of massive numbers of casualties.

While large numbers of casualties are possible, terrorism, by its very definition, is primarily designed to produce fear and panic in a population. The employment, or threat of employment, of unconventional and unfamiliar WMDs will only serve to heighten this fear. Many disaster planners employ the acronym CBRNE (chemical, biological, radiological, nuclear, explosive) to encompass these potential terrorist weapons. While each of these weapons brings with it unique, and often profound, disaster response considerations, it is the psychological and psychosocial impact that is likely to define a disaster associated with terrorism.

► **DISASTER PLANNING**

By their very definition, disasters have profound public health implications. Critical public health challenges following a disaster include the provision of basic life-sustaining commodities such as food, water, and shelter, and the establishment of essential curative and preventive medical services.⁴³ In the past, public health and safety professionals and organizations concentrated their efforts primarily on emergency disaster relief. More recently, however, disaster preparedness, prevention, and mitigation have become increasingly important public health activities. Public health priorities for dealing with disasters should be determined by the predominant causes of morbidity and mortality for a particular type of disaster, and the best methods of prevention for the particular population involved.³⁰

Effectively coping with disasters involves much more than the timely delivery of external emergency resources. Local vulnerabilities within a community, such as poverty, population density, type of construction, and a relative lack of disaster planning, may enhance the risk to a population to disasters. For example, the 1988 earthquake in Armenia resulted in more than 30,000 deaths while an earthquake of similar force, the 1989 Loma Prieta earthquake in California, resulted in less than 500 deaths.^{44,45} The low mortality associated with the Loma Prieta earthquake was thought to be due to enforcement of local building codes, better local emergency medical services (EMS), superior local disaster management services, and other community-based prevention and mitigation activities.^{30,46}

Although planning, preparation, and engineering controls can mitigate against a portion of the morbidity and mortality associated with disasters, human factors also play an aggravating role in almost all disasters, even natural ones. What is identified as the “disaster” is often better understood as a trigger event that exposes and exacerbates underlying societal problems and weaknesses. For example, in virtually every famine of the last 20 years, drought has been an important contributing factor, but food shortages have been primarily the result of armed conflict, inadequate economic and social systems, failed governments, and other man-made factors.⁴⁷ The famine in Somalia⁴⁸ from 1991 to 1993 and the ongoing famine and crisis in Darfur both highlight the dramatic amplification of drought by internecine clan warfare. Understanding the consequences of disasters, and effectively coping with them, requires looking well beyond the event itself.

Coping with complex emergencies, as well as other disasters, is one of the great public health challenges of our time. There are a multitude of technical and logistical issues involved in providing life-sustaining services to large populations.^{49,50} Events during and after a disaster may not progress in a clear linear fashion; public health needs often evolve substantially.³⁷ For example, priorities for refugees who have just arrived in a location (usually shelter, food, water, and basic medical care) are different from the needs of the same population a few months after a refugee camp has been established (family planning, medical care for more chronic problems, and rehabilitation). As with natural disasters, attention is increasingly being devoted toward prevention, early warning, and preparation activities. Because complex emergencies are usually the result of many years of deeply rooted social problems, effectively dealing with them requires that relief efforts be closely integrated with political, social, economic, military, cultural, and other activities.

► **MEDICAL AND PUBLIC HEALTH ASPECTS OF DISASTER RESPONSE**

The medical and public health response to a disaster can be envisioned as occurring on multiple levels. We find it useful to consider response needs on both a “micro” level (the level of the individual medical practitioner, where most needs involve traditional medical practices such as the provision of patient care) and a “macro” level (the level of public and governmental entities such as local, state, and federal public health authorities). Traditional medical response and the management of individual patients has been extensively reviewed elsewhere and is beyond the scope of this chapter.^{51,52} Here, we concentrate instead on the “macro” response of the Public Health Community at large and the many governmental and nongovernmental institutions that might be called upon to respond to, and mitigate the effects of, a natural or man-made disaster. In the United States, an evolving body of legislation (summarized in Table 79-2), culminating

TABLE 79-2. KEY DISASTER RESPONSE DOCTRINE, GUIDANCE, AND LEGISLATION

Public Law 93–288 (PL 93–288)	Provides legislative authority for Federal Government response to disasters
Robert T. Stafford Disaster Relief and Emergency Assistance Act (the Stafford Act; PL 100–707)	Amends PL 93–288
The Federal Response Plan (FRP)	Implements the Stafford Act
Presidential Decision Directive 39 (PDD-39)	Adds a Terrorism Annex to the FRP and divides response into phases of <i>Crisis Management</i> and <i>Consequence Management</i>
PDD-62	Applies the Stafford Act to Unconventional and Terror Threats, Codifies the role of various Government Agencies in Terrorism Response
PDD-63	Provides for the Protection of Critical National Infrastructure from Terror Threats, and specifically mentions Weapons of Mass Destruction (including Biological Weapons)
The Nunn-Lugar-Domenici Act (an amendment to the Defense Authorization Act for FY97)	Provided for training of First Responders in dealing with Weapons of Mass Destruction
The National Response Plan (NRP)	Supersedes the FRP and provides Federal Disaster Response efforts with a standardized National Incident Management Template

in the recent promulgation of a National Response Plan (NRP), now provides a framework for such disaster response. This framework forms the basis for a somewhat idealized planning and response effort, achievable, perhaps, in the United States and other developed nations. Efforts at disaster planning and response during complex emergencies and in developing nations obviously must be tempered with the realities of warfare, inadequate infrastructure, severe resource constraints, and all of the other myriad problems inherent in such settings.

The institutional response to any disaster, natural or manmade, begins at the local level, and it is here that preparation efforts are perhaps most critical.⁵³ It is also here that public health interventions will be implemented and the results of these implementations directly felt. Authorities at the California Emergency Medical Services Authority have recently identified 18 medical and public health functions, as well as 3 closely related response functions which should be considered in disaster planning and response at the local level (Table 79-3).⁵⁴

1. **Medical Needs Assessment.** Prior to mobilizing an emergency response on behalf of a disaster-stricken population, information should be obtained regarding the extent of their immediate needs and the status of their supporting public health infrastructure. This task is accomplished through an organized needs assessment.^{55,56} The purpose of this initial assessment is to rapidly obtain objective, reliable, population-based information that describes a population's specific need for various emergency relief services. Such an assessment should identify the extent of the needed response and the technical areas where specialized assistance is needed, and should suggest other areas where more focused health surveys or surveillance should be conducted (e.g., the nutritional status of the population and the status of water and sanitation).

It is often impractical to evaluate the needs of all affected persons at a disaster site due to the size of the population and resource limitations. Relief personnel should instead sample representative cross sections from the affected population through a statistically valid sampling process using standardized assessment protocols.⁵⁵⁻⁵⁷ Such an activity requires knowledge

of the geographic distribution and size of the population, which may be obtained through census information, aerial photos, rapid surveys, and other sources. During sudden-impact disasters such as hurricanes, the initial assessment of the affected population should be completed as soon as possible, ideally within 24–48 hours.^{55,57} Slowly developing disasters such as endemic warfare and famines may require repeated emergency health assessments.⁵⁶

2. **Health Surveillance and Epidemiology.** Public health surveillance is the logical continuation of the initial epidemiologic task of emergency health assessment. Surveillance systems should be established in sentinel sites (such as clinics) after disasters in order to monitor the health of the population and gauge the effectiveness of ongoing relief programs. This would be particularly important during the implementation of emergency programs that are likely to continue beyond the immediate aftermath of the disaster.⁵⁸ Newer technologies such as e-mail, computers, and epidemiologic software permitted the rapid implementation of a statewide surveillance system in Iowa following the Great Flood of 1993.⁵⁹ Among refugees in developing countries, critical public health surveillance targets include deaths, the appearance of malnourished children, and the occurrence of vaccine-preventable infectious diseases.⁵⁶ Following a disaster, it is likely to be more effective to reestablish a preexisting surveillance system than to build a new system with external resources.^{60,61}

Targeted investigations and surveys complement initial assessments and surveillance. For example, in some situations, the rapid assessment of the nutritional status of a population is a critical aspect of the development of appropriate relief programs.⁶² Investigation of outbreaks, surveys of vaccine coverage, and surveys for the prevalence of certain diseases are other common targets of more focused investigation. As public health information is collected through assessment and surveillance, relief interventions should be modified accordingly. In the absence of current data with which to evaluate the health of the target population, relief priorities and resources may easily become skewed.^{63,64}

3. **Identification of Medical and Health Resources.** Medical and other health resources in a given locale should ideally be identified during the disaster planning process long before they might become needed in responding to an actual disaster. Personnel, equipment, and supplies available locally should be inventoried, and a realistic assessment made regarding ancillary resources which might readily be made available from state, regional, and federal sources. Memoranda of understanding (MOUs) and/or contracts should be proactively worked out between response agencies and local private sector institutions. A common problem concerning the preidentification of disaster response personnel surrounds the issue of "dual-hatting." Recent disaster exercises have demonstrated that multiple agencies often rely on the same personnel to respond to a disaster.⁶⁵ For example, a nurse in a local hospital may also serve as a military reservist and may also be a volunteer on a Disaster Medical Assistance Team (DMAT). When all three organizations rely on the presence of such a person, problems are sure to arise; such problems should be identified and resolved before a disaster occurs. On the other hand, in several response efforts, problems have arisen because of the presence of excessive numbers of well-intentioned but unneeded or poorly prepared volunteers and would-be providers. These "disaster tourists" sometimes consume more resources than they can provide.⁶⁶ Thorough disaster planning includes plans for dealing with such problems.
4. **Medical Transportation.** Medical transportation assets should also ideally be identified during the disaster planning process before they are ever needed. Basic life support (BLS) and advanced life support (ALS) ground ambulances, as well as air ambulance resources should be catalogued and MOUs put in place during this planning process. Alternative sources of

patient transport, such as bus companies, might also be examined. In developing nations and in resource-poor environments, primary reliance on such alternative methods of transport is often a necessity. Conversely, during many disasters, patients will arrive at treatment facilities by any means available. Following the sarin nerve agent attacks on the Tokyo subway system in 1995, over 4000 contaminated patients and “worried well” arrived at hospitals in private vehicles, despite the presence of a well-developed and available ambulance system.⁶⁷ In contrast, only 452 victims arrived via ambulance. Similarly, the majority of victims of the 1995 Oklahoma City bombing arrived at hospitals in private vehicles.⁶⁸ In a given disaster, the “worried well” may outnumber the actual sick and injured by a ratio of 10:1 or even 100:1, depending on the type of disaster. Larger numbers of “worried well” would be expected in the setting of a potential terrorist attack, where chemical, biological, or radiological contamination was a possibility. Disaster planners should be prepared for such eventualities.

5. **Patient Distribution and Evacuation.** Regional disaster response plans will optimally plan for the rapid establishment of casualty collection and triage points, and project the number of casualties to be sent to each of the participating hospitals. These plans will ideally incorporate the emergency community, including ambulance assets for patient transportation. However, a major catastrophe may result in the destruction of hospitals, roads, bridges, and communications infrastructure. During the South Asia tsunami response of 2004–2005, portable military field hospitals were successfully deployed to bring medical assets to afflicted populations.⁶⁹ This strategy moves medical assets into close proximity to those in need, and obviates a requirement to transport patients over long distances.
6. **Pre-Hospital Emergency Services.** Sudden onset natural disasters have been the traditional model for understanding and organizing emergency relief services for disaster affected populations in the United States. For example, external medical services and rescue capabilities may be urgently needed after earthquakes to treat injured persons and to extract survivors trapped in collapsed buildings.⁴⁴ This led to the development of specialized emergency services in many countries such as Urban Search and Rescue teams, which are designed to extract and treat entombed victims.^{26,70}
7. **Hospital Emergency Services.** In a developed nation with established hospital facilities, the emergency department plays an important potential triage and treatment role in disaster response, especially the response to acute disasters such as earthquakes, fires, explosions, tornados, hurricanes, and the like. In such situations, however, emergency facilities can rapidly become overrun and resources exhausted. Moreover, in the event of a chemical attack or toxic exposure, emergency facilities can quickly become contaminated. During the 1995 sarin attack in Tokyo, staff exposure to sarin was a problem, as were the privacy issues raised by the requirement for large numbers of patients to undergo decontaminating showers.⁷¹ Prior planning can alleviate some of these problems. In the developing world and in chronic ongoing disasters such as famine and war, emergency facilities are likely to be unavailable or to play a lesser role. Proactive disaster response planning, nonetheless, must incorporate local emergency facilities into the planning process.
8. **In-Hospital Care.** All hospitals should have plans in place in the event of a disaster. In fact, in the United States, the Joint Commission on the Accreditation of Healthcare Organizations (JCAHO) directs hospitals and other health-care institutions to conduct a hazard vulnerability analysis, develop an emergency management plan, and evaluate this plan annually.⁷² Such a plan could be implemented in the event of a disaster and must include an all-hazards command structure.

Many hospitals are now utilizing the “Hospital Emergency Incident Command System” (HEICS), which is designed to link with local governmental incident command systems.⁷³ Another area of current concern relates to the need for planners to develop reasonable estimates and standards for bed requirements (by number and type) for various disasters, along with estimates (by number and specialty) of the supporting health-care providers necessary to staff those beds.

9. **Out-of-Hospital Care.** As is the case with hospitals, other medical and domiciliary facilities such as nursing homes, home health-care facilities, and community and public health clinics should also be prepared to respond in the event of a disaster. While such facilities may represent an important asset in times of crisis, they also pose unique problems. Whereas all hospitals have backup power generation capability, many out-of-hospital care facilities do not. A large surge in emergency response calls and hospital activity during the August 2003 blackout on the U.S. eastern seaboard was attributed to the failure of respiratory devices and other medical equipment.⁷⁴ Proactive community planning may help alleviate such problems and insure that out-of-hospital facilities remain an asset, rather than a burden, during a disaster.
10. **Temporary Field Treatment.** In certain disasters, medical treatment facilities may be rapidly overwhelmed or, worse yet, destroyed.⁷⁵ Following the Gujarat earthquake of 2001, victims had to travel over 200 kilometers to reach unaffected hospitals in the “buffer zone.”⁶⁶ Even in cases where treatment facilities are intact, prompt and proper treatment in the field may be necessary to save lives.⁷⁶ In the United States, “strike teams” associated with the Metropolitan Medical Response System (see below) may provide such field treatment. In any case, local disaster plans must address the provision of temporary field treatment.
11. **Food Safety.** In the aftermath of mass casualty disasters, food processing and distribution may be seriously disrupted. Consequently, food distribution plans need to be incorporated into disaster response plans of governmental and non-governmental organizations. Lessons learned from the 2004 tsunami include the need to target food relief as a specific response, and the need to identify the most vulnerable populations (e.g., lactating women and those at the extremes of age). Challenges include the effective delivery of adequate quantities of food containing essential nutrients. Following the tsunami, multinational military services were instrumental in delivering food staples to afflicted populations. However, these consisted primarily of rice and noodles; there was concern regarding the delivery of protein, essential lipids, and vitamins.⁷⁷ The use of prepackaged field rations may be a short-term solution.

Another challenge is posed by the disruption of refrigeration and cooking in the wake of the disaster. An essential strategy involves educating the population at risk with a simple, straightforward message regarding the basics of food hygiene. Educational messages may be prepared well in advance, ready for distribution during crisis management. A fact sheet on food safety is available from the Centers for Disease Control and Prevention.⁷⁸

Finally, the deliberate contamination of food has been used as a means of biological terrorism. Successful past attacks have utilized foods that are not cooked before consumption.^{79,80} These deliberate epidemics were not recognized until patients presented with illness, and future attacks of a similar nature are likely to be difficult to differentiate from sporadic point-source endemic food-poisoning events. Fortunately, the numbers of patients in previous intentional attacks have been relatively small; it is generally thought that this means of biological terrorism would be less effective than a well-executed aerosol attack. An effective response to a foodborne biological attack would utilize the same important steps used to counter naturally occurring foodborne epidemics:

recognition of the epidemic, identification of the etiologic agent, limitation of ongoing exposure, treatment of casualties, and prevention of future outbreaks.⁸¹

12. **Management of Hazardous Agent Exposure.** Hazardous materials may be released into the environment during natural disasters. Earthquakes, hurricanes, tornados, and floods may rupture petroleum and chemical storage tanks and overturn railroad stock; flooding may wash agricultural chemicals and fertilizers into drinking water supplies; infectious agents may even be released into the environment if hospital or scientific laboratories are damaged by earthquakes. Conversely, terrorist attacks may result in the intentional release of chemical, biological, or radiological agents into the environment. An important disaster response function involves the containment of such contamination. Since time is often critical in limiting the effects of such contamination, this function becomes, of necessity, a local responsibility. Local responders and governmental functionaries must have a basic understanding of hazardous agent management and response.
13. **Mental Health.** In addition to traditional public health concerns, disasters may present medical responders with patients who are suffering from complaints that are predominantly psychological in nature. In fact, mental health concerns may outweigh other medical concerns during the acute phase of disaster response.⁸² Such concerns may include the need for specialized psychological triage and treatment programs for victims. Emergency response personnel are also subject to short- and long-term effects as a result of stress imposed by the disaster and its response needs, particularly among persons required to be involved in postdisaster management of decedents.⁸³ The psychological impact of disasters on children has only just begun to be documented but is clearly profound. Such impacts are likely to be even more significant if the disaster is produced by terrorism.⁸⁴ Similarly, the appalling use of children as soldiers in many countries of the world will likely have long-term mental health consequences of unprecedented proportions.⁸⁵
14. **Medical and Public Health Information.** One of the most important means of limiting the psychological trauma associated with a disaster is to provide timely, accurate, and relatively consistent information and risk communication. A disaster can provoke fear, uncertainty, and anxiety in the population, resulting in overwhelming numbers of patients seeking medical evaluation for unexplained symptoms, and demanding antidotes for feared exposure. Such a scenario could also follow a covert release when the resulting epidemic is characterized as the consequence of a bioterror attack. Symptoms due to anxiety and autonomic arousal, and side effects of postexposure antibiotic prophylaxis, may suggest prodromal disease due to biological agent exposure, and pose challenges in differential diagnosis. This "behavioral contagion" is best prevented by risk communication from health and government authorities which includes a realistic assessment of the risk (or lack thereof) of exposure, information about the resulting disease, and what to do and whom to contact for suspected exposure. Risk communication must be timely, accurate, consistent, and well coordinated, and the development of risk communication strategies, mechanisms, and messages prior to an event is strongly encouraged. As the epidemic subsides and public knowledge increases, public anxiety will decrease to realistic levels. This cycle of uncertainty, panic, response, and resolution occurred during the October 2001 anthrax bioterror attacks.⁸⁶ The Centers for Disease Control and Prevention (CDC) has taken a proactive approach, featuring the development of Internet-accessible, agent-specific information packages for local public health authorities and the general public.⁸⁷
15. **Vector Control.** Certain disasters have been associated with a dramatic increase in the incidence of vector-borne disease. For example, following Hurricane Flora in 1963, a malaria epidemic occurred among the Haitian population.⁸⁹ A similar increase in the incidence of malaria has been associated with the slowly developing El Nino "disaster."⁹⁰ The control of mosquitoes and other insect vectors is thus an important component of disease prevention following such disasters.⁹¹
16. **Potable Water.** Potable water is often the most important immediate relief commodity necessary for ensuring the survival of disaster-affected populations. Some water is necessary for drinking and cooking, but decreased water supplies also lead to inadequate personal hygiene. As a baseline, persons should have access to at least 15–20 liters of potable water per day.^{92,93} Heat stress and physical activity can substantially increase the human daily requirements for potable water to levels that are many times normal. Health authorities at disaster sites must plan for additional allotments of water to support clinical facilities and feeding centers and other public health activities.
17. **Waste Management.** The proper management of human waste is also an important environmental health priority, particularly during disaster conditions. Earthquakes and floods frequently cause damage to sewage treatment facilities and cross-contamination of normally potable water sources. Consequently, the principal public health thrust of sanitation measures in emergency conditions is to reduce fecal contamination of food and water supplies. Communicable diseases that can be transmitted through contact with human feces include typhoid fever, cholera, bacillary and amoebic dysentery, hepatitis, polio, schistosomiasis, various helminth infestations, and viral gastroenteritis. Temporary latrines can be established in a disaster site in a variety of ways, including pits, trenches, and other chemical toilet methodologies.⁹⁴
18. **Communicable Disease Control.** When infectious diseases occur after a disaster, they were almost invariably endemic before the disaster occurred. However, disaster conditions often serve to facilitate disease transmission and increase individual susceptibility to infection. Infectious diseases sometimes occur in a population that moves to a new location where an unfamiliar disease is endemic. For example, devastating malaria epidemics have occurred in nonimmune populations who were displaced to a malaria endemic area.^{95,96}

tactics. Similarly, plans must be made to rapidly deploy local centers for the initial evaluation and administration of post-exposure prophylaxis (ideally decentralized to residential areas). Finally, plans must be made to proactively develop patient and contact tracing and vaccine screening tools, to access and rapidly distribute stockpiled vaccines and medications, and to identify and prepare local facilities and health-care teams for the care of mass casualties. The CDC smallpox response plan provides a template for such a coordinated, multifaceted approach. The benefits of farsighted planning and coordination were demonstrated by the efficient mass prophylaxis of over 10,000 individuals in New York City during the anthrax events of 2001.⁸⁸

The principal infectious disease problems in conflict-related disasters have been measles, diarrheal diseases, acute respiratory infection, and malaria. During the Somali Famine (1991–1993), measles and diarrheal diseases accounted for the vast majority of the deaths among persons in temporary camps.⁴⁸ Disease outbreaks during complex emergencies are usually the result of many factors, including a breakdown in environmental safeguards, crowding of persons in camps, lack of appropriate immunization programs, malnutrition, inadequate case finding, and limited availability of appropriate curative medical services.

Despite the more limited potential for disease outbreaks following natural disasters, notable exceptions have occurred.

Effective risk communication is predicated upon the pre-existence of well-conceived risk communication plans and

During the Northridge Earthquake of 1995, the emergence of coccidiomycosis infections among emergency responders as a result of environmental contamination was a public health concern.⁹⁷ Due to such threats and the propensity for epidemics to occur when the normal public health infrastructure has been damaged, it may be necessary to expand surveillance for certain diseases and rapidly institute appropriate disease control efforts following a disaster.

Coping with infectious diseases following disasters involves a number of fundamental public health strategies applied to disaster settings. For example, in some settings, emergency measles vaccination programs, along with the administration of vitamin A, are critical and highly effective measures to prevent cases of measles and to reduce morbidity and mortality caused by this infection.⁹⁸ With regard to diarrheal diseases, for which there are not effective immunizations, a combination of basic environmental measures to provide clean water and sanitation, plus rapid case finding and aggressive treatment (rehydration and, in some cases, appropriate antibiotics) can substantially reduce the consequences of diarrhea outbreaks.

19. **Animal Control.** Animal control issues frequently arise in the wake of a disaster. Carcasses can foul water supplies and spread disease. Surviving unsecured animals can serve as reservoirs for zoonotic disease outbreaks and contaminate water sources with urine and fecal matter.^{99,100}

Animal deaths can result in ecological consequences and can represent the loss of a critical food source for a stricken population. Moreover, significant losses in the livestock industry can represent a major economic blow to the economies of many nations.¹⁰¹ Involving veterinary and animal husbandry personnel in disaster planning efforts at the local level can aid in ameliorating such consequences.

20. **Coroner and Mortuary Services.** Following a disaster, concerns often arise regarding the potential for disease transmission from decaying corpses. In reality, however, there is little evidence to suggest that serious epidemics arise from unburied corpses, and disease transmission following disasters is far more likely to be associated with survivors.¹⁰² Nonetheless, public concerns over dead and decaying bodies may present medical, psychological, and public relations problems. Local authorities must be prepared to address such concerns. Proactive planning in this regard (by designating temporary and makeshift morgues in advance, for example) may prevent the hasty and ill-conceived burial or cremation of remains before proper victim identification has been made.
21. **Care and Shelter.** Apart from access to water and food, shelter is often the most immediate need of disaster-stricken populations, particularly in cold weather. High mortality rates, particularly among the young and elderly, can occur when displaced populations are suddenly subjected to severe cold stress. Disaster planning efforts should include provisions for mass care and shelter, including shelter for the medically infirm. Typically, such provisions are made by nongovernmental agencies such as the Red Cross or Red Crescent. Medical planners should be prepared to support shelters with physician, nursing, and ancillary health support.

Following some disasters, particularly conflict-related disasters, there may be substantially decreased availability of food, which can result in specific nutrient deficiencies, malnutrition, or outright starvation.^{50,103,104} Poor nutritional status increases susceptibility to communicable diseases such as measles and diarrhea. Indeed, the immediate cause of death in most malnourished persons is not usually starvation per se but, rather, infectious diseases.¹⁰⁵

Emergency nutritional rehabilitation efforts for a starving population may involve a number of different types of programs to distribute food. During a food crisis, decisions must be made regarding whether emergency feeding programs should focus on widespread distribution of general

food rations, targeting specific food supplements to select high-risk groups (such as pregnant or lactating women), or on preparing food for consumption on-site in feeding centers. The type of food distributed is an important concern as well. Food must be culturally acceptable and must be nutritionally balanced. Donor-provided food has resulted in iatrogenic micronutrient deficiencies in some long-term relief operations.¹⁰⁴ Sound program decisions should be based on information from rapid nutritional surveys as well as analyses of economic indicators that provide more detail on the nutritional status of the population and the context of the specific food shortage.

During emergency famine relief, it is not the mere delivery of food to the disaster site that saves lives. The most rapid reduction in morbidity and mortality will occur when improvements in environmental health and communicable disease control accompany the restoration of proper nutritional resources.^{50,92,103} Because the lack of sufficient food in disasters is usually the result of many factors such as economic collapse, disruption of production, inadequate distribution, and other socioeconomic conditions, rather than a true lack of food, the long-term solution is in restoring an indigenous food economy, not in maintaining emergency feeding programs.

► STATE AND FEDERAL DISASTER RESPONSE (THE U.S. MODEL)

Prompt and competent disaster response at the local level has always been critical to preserving life, providing for public safety, and safeguarding public health. The response capabilities and organizational differences among the many thousands of local jurisdictions, however, have made standardization of disaster response plans, as well as communication among the various jurisdictions and response elements, quite problematic. Recently, the National Incident Management System and its component Incident Command System (ICS) has gained widespread acceptance as a standard model for response organization at local jurisdictions throughout the United States.¹⁰⁶ Under the ICS, control of local response efforts rests with a designated local incident commander, typically the fire chief or chief of police. This incident commander can often summon groups of volunteer first responder and medical personnel, drawn from the Metropolitan Medical Response System (MMRS) under the auspices of the Department of Homeland Security's (DHS) Office of Domestic Preparedness. As part of the MMRS, 122 local jurisdictions (as of this writing) have established emergency medical response capabilities. Under contract with local mayors, the MMRS elements can provide assistance with medical control, the extraction of victims, decontamination, triage, and medical treatment.

While MMRS elements are able to respond to a range of disaster scenarios, the impetus for their formation has been recent awareness of the terrorist (particularly the WMD) threat, and the realization that response to a chemical, biological, or radiological event brings with it unique problems and requirements. The scene of a terrorist attack is, in addition to a disaster site, a crime scene. Handling of specimens originating from a potential terrorist event must, then, take into account proper evidence-handling procedures. Sampling should be coordinated with the local incident commander. The Association of Public Health Laboratories and the Centers for Disease Control and Prevention have developed a network of public and private laboratories, known as the "Laboratory Response Network," prepared to respond to potential bioterrorist attacks in particular.¹⁰⁷ Under this system, local hospital "Sentinel" (level A) laboratories would be capable of *ruling out* the presence of certain biological threat agents in clinical specimens. "Reference" (level B) laboratories in certain municipalities and regions would be capable of *ruling in* potential threat agents and performing susceptibility testing. More than 100 of these high-capability facilities now exist within established local public health, military, veterinary, agricultural, food, and water-testing laboratories throughout the United States. Similar facilities in Canada, Australia, and the United Kingdom serve an analogous purpose.

When response requirements exceed local capabilities, the local incident commander may request assistance from the state through the State Coordinating Officer (SCO). This SCO can then advise the governor to make available various state-level assets. These assets might include the law enforcement capabilities of the State Police and National Guard. Many state guards now include military “Weapons of Mass Destruction-Civil Support” (WMD-CS) teams, which can offer expert advice and provide liaison to more robust military assets at the federal level. These WMD-CS teams can also be prepositioned at “National Security Special Events,” such as political conventions, inaugurations, and other mass gatherings which might provide attractive targets to terrorists. Recently, such an employment was undertaken at the Super Bowl.¹⁰⁸ In addition to WMD-CS teams, most state guards can provide public works assistance and mobile field hospitalization capability. Forensics laboratories are typically available through the state police or other state-level agencies. “Regional” (level C) laboratories, capable of providing sophisticated confirmatory diagnosis and typing of biological agents, are, in many cases, available through the State (and large city) Health Departments.

When response requirements exceed the capabilities available at the state level, the state coordinating officer may contact the Federal Coordinating Officer (FCO). The FCO may activate a federal response under the auspices of the NRP.¹⁰⁹ Under the NRP, federal consequence management is organized into 15 emergency support functions (ESFs), with each ESF being the responsibility of a specific federal agency. In addition, dozens of additional federal agencies can be tasked to provide assistance to these lead agencies. Federal disaster medical and public health support is provided for under ESF 8, and is primarily the responsibility of the Department of Health and Human Services. Among the 15 additional entities which support ESF 8 is the Department of Homeland Security, which oversees the Federal Emergency Management Agency (FEMA) and its National Disaster Medical System (NDMS).¹¹⁰ The NDMS includes numerous DMAT, consisting of trained medical volunteers that can arrive at a disaster site within 8–16 hours. The NDMS also includes a number of specialized teams, including Disaster Mortuary Operational Response Teams (DMORT), Veterinary Medical Assistance Teams (VMAT), National Pharmacy Response Teams (NPRT), and National Nurse Response Teams (NNRT). Finally, the NDMS is also capable of providing hospital bed capacity at numerous Department of Veterans Affairs, military, and civilian hospitals throughout the nation.

Closely allied to the issue of medical and public health support are those of mass care, feeding, housing, and human services. These services, provided for under ESF 6 in the NRP, would be the primary responsibility of FEMA and the American Red Cross. Additionally, myriad other federal agencies would potentially contribute to disaster response. In the case of a potential bioterrorist attack, for example, the CDC, the United States Army Medical Research Institute of Infectious Diseases (USAMRIID), and the Department of Homeland Security’s National Biodefense Analysis and Countermeasures Center (NBACC) provide state-of-the-art “National Research” (level D) laboratories capable of sophisticated biological threat agent analysis. The Canadian Science Center for Human and Animal Health in Winnipeg provides a similar level of expertise. These labs, capable of banking strains, probing for genetic manipulations, and operating at Biosafety Level 4, would provide backup to regional laboratories at the state and large local health departments.^{121–123}

Expert epidemiological consultation is also available from the CDC, and its Epidemic Intelligence Service (EIS), as are critical drugs and vaccines necessary to respond to a large-scale disaster. These pharmaceuticals are stockpiled at several locations throughout the country, available via the CDC’s Strategic National (Pharmaceutical) Stockpile (SNS) program for rapid deployment to an affected area.¹¹¹ Release of stockpile components is currently controlled by the Department of Health and Human Services. An analogous asset, the National Emergency Services Stockpile System provides Canada with similar capabilities.

*Clinicians and Response Planners are encouraged to post this list in an accessible location. Specific local and state points of contact should be included.

In the event of a disaster, and especially in the event of a terrorist attack employing WMDs, the military could provide several unique forms of assistance. In addition to laboratory support, biological threat evaluation and medical consultation are available through USA MRIID. Analogous chemical response capabilities are available through the U.S. Army Medical Research Institute for Chemical Defense (USAMRICD), and radiological capabilities are available through the Armed Forces Radiobiology Research Institute (AFRRI). Moreover, the military can provide advice and support to civilian authorities through the Chemical/Biological Rapid Response Team (CBRRT) and the Chemical/Biological Incident Response Force (CBIRF), a Marine Corps unit capable of reconnaissance, decontamination, and field treatment. Both the CBRRT and the CBIRF can be en route to a disaster site within a few hours of notification. Military support, when requested, would be subordinate to civilian authorities and would be tailored by the Joint Task Force for Civil Support, the component of the military’s Northern Command (NORTHCOM) designated to provide command and control for all military assets involved in disaster response missions and contingencies within the United States.

Response to a disaster would likely constitute a complex undertaking requiring extensive cooperation among medical practitioners, civilian authorities, and officials at various levels of government. Health-care providers will require a thorough understanding of the principles of disaster medicine, basic trauma management, humanitarian relief operations, infection control procedures, and principles of personal protection. Moreover, they will also need a working knowledge of the components of our local, state, and federal response systems in order to function optimally in the event of an attack in their local area. Each practitioner and public health official should have a point of contact with such agencies and should be familiar with mechanisms for contacting them before a crisis arises. A list of useful points of contact is provided in Table 79-4.

► CONCLUSION

Many problems still remain in the effective implementation of emergency relief programs. In the Kurdish refugee crisis, despite a massive

international relief effort, many deaths occurred due to preventable diarrheal disease.⁶² This mortality was in large part due to a failure to implement basic environmental health interventions and diarrhea control programs early enough in this particular crisis. During the 1994 Goma, Zaire, refugee emergency, as many as 50,000 persons died from cholera within the temporary camp system in only a matter of weeks,¹¹² pointing out an urgent need for more intensive and focused training of relief workers to develop relevant expertise in the prevention and management of diarrheal diseases, as well as other essential elements of relief programs, such as measles immunization, public health surveillance, community outreach, and nutritional rehabilitation. A review of public health assessments and surveys conducted in Somalia demonstrated a lack of consistency in methodology, which led to difficulties in interpreting and acting upon critical public health data.¹¹³ Few training programs in Schools of Public Health have curricula that adequately cover the broad range of knowledge needed to cope with the public health issues associated with disaster-affected populations.

Disasters do not affect all persons evenly. Thus, identifying and focusing on populations with special needs after disasters is a critical issue. For example, the unique concerns of women in disasters have become a greater focus in disaster relief in the last few years.^{114,115} Recent data suggests that in some disasters women have less access to medical care and other relief services.¹¹² Additionally, while data is limited, pregnancy, sexually transmitted diseases, sexual abuse, and HIV infection are likely to be common issues among women,

especially refugees, in some disaster-affected populations. Few relief programs have sufficiently addressed these issues. The special problems of children in disasters are increasingly recognized.^{85,116} Children are much more vulnerable to many of the adverse health effects of disasters, such as malnutrition and infectious diseases. Additionally, the plight of unaccompanied children in Rwanda, and after the recent Indian Ocean tsunami, illustrated a problem common to many complex emergencies today.⁸⁵ In disaster situations there are many other potentially vulnerable groups, such as members of a particular ethnic group, the elderly, and immigrants.

The public health consequences of disasters are complex, multifactorial, wide ranging, and often long-lasting. Knowledge and experience from many health disciplines is needed for effective emergency response. Much needed health-care-related skills involve the disciplines of epidemiology, community health and primary care, environmental science, communicable disease control, and international health. Research is needed to develop standardized and valid assessment tools, reliable surveillance programs, low-technology environmental health interventions, and more effective intervention strategies. Unfortunately, the reality today is that many relief workers in the health sector, though well intentioned, are often recruited and deployed on short notice with little public health preparation or training. Schools of Public Health must continue to expand their training in the emergency skills that practitioners will need to deal with the public health needs of disaster-affected populations if the international community is to meet this challenge.

Maternal and Child Health

Lewis H. Margolis • Alan W. Cross

► INTRODUCTION

Maternal and Child Health (MCH) is the professional and academic field that focuses on the determinants, mechanisms, and systems that promote and maintain the health, safety, well-being, and appropriate development of children and their families in communities and societies, in order to enhance the future health and welfare of society and subsequent generations.¹ This chapter provides an overview of MCH, highlighting the interactions among economic, social, cultural, educational, and health services factors that influence the population of children and families. In striving to assure the conditions for healthy mothers, women, and children, the field of maternal and child health focuses on four main strategies: (a) developing the public health infrastructure relevant to mothers and children; (b) providing population-based services; (c) offering enabling services; and (d) providing clinical services where gaps in availability are present.² While maternal and child health issues are becoming increasingly globalized, the focus of this chapter is MCH in the United States. Most of the details of specific aspects of maternal and child health are covered in other chapters.

► HISTORY OF GOVERNMENT MCH SERVICES IN THE UNITED STATES

The health of women and children began to receive separate attention early in the twentieth century, in recognition of their greater vulnerability, particularly to socioeconomic and environmental forces, and the interdependence of the child's health and that of the mother.³ In 1909 the first White House Conference on Child Health recommended the

formation of the Children's Bureau, which, when established in 1912, proceeded to investigate the causes of maternal mortality (over 600 per 100,000 live births) and infant mortality (more than 100 per 1000 live births), as well as numerous other issues in social/economic welfare, education, and especially working conditions for children. The first federal support of maternal and child health services came with the Sheppard-Towner Act of 1921. By promoting birth registration and the establishment of maternal and child health divisions in many state and local health departments, this landmark legislation provides examples of both infrastructure building and population-based services. Title V of both Social Security Act of 1935 built upon the accomplishments of Sheppard-Towner, but also extended enabling and gap-filling services, especially to crippled children. Title V firmly established the principle of public responsibility for the health of mothers and children through a federal-state partnership.

In the 1960s and early 1970s a host of additional programs were initiated by Congress, some through the mechanism of Title V and others through independent legislation. For example, Maternity and Infant Care Projects and Child and Youth Projects established relationships between Title V and individual communities, in contrast to states. Title XIX of the Social Security Act (Medicaid) and its child-focused Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) vastly increased access to medical care for low-income children. Community Health Centers were developed to provide health-care services, as well as enabling services for selected neighborhoods or catchment areas. Title X of the Public Health Services Act recognized a federal responsibility for providing family planning services, beginning in 1972. In the area of education, this period also witnessed the implementation of Head Start, which provided not only educational enrichment for low-income preschoolers, but also access to

health care. Similarly, the Education for All Handicapped Children Act (PL 94-142) (later renamed Individuals with Disabilities Education Act) created a right to a free education for children with disabilities. In the area of nutrition, programs such as the Women, Infants, and Children (WIC's) Supplemental Food Program and enhanced school feeding programs sought to assure adequate nutrition, a cornerstone of health for children and mothers.

Under President Reagan in the 1980s, what had become increasingly categorical maternal and child health services were reorganized into a Maternal and Child Health Services Block Grant. In return for more state autonomy and flexibility, states received less federal financial support for Title V services, and Title V funding has not kept pace either with inflation or a growing population with increasingly complicated needs and demands. The 1980s also witnessed increasing state autonomy and flexibility in other federal programs such as Medicaid.

While improving access to care motivated many strategies during the 1960s and 1970s, efforts to control the rising costs of health services emerged in the 1980s and 1990s. Various models of managed care, for example, have been implemented in every state to attempt to control the escalating costs of Medicaid. Medicaid recipients have been shifted into managed care plans that for the most part restrict access to care through primary care providers. In many cases, health departments have assumed an oversight or accountability role to assure that managed care plans provide the agreed upon services for these high-risk populations. An example of cost control especially relevant to MCH was the limitation of postpartum hospital stays, even when providers and other caretakers counseled otherwise. Congress intervened with the passage of Newborns' and Mothers' Health Protection Act of 1996 (Public Law 104-204) which required a minimum stay of 48 hours.

While MCH programs continue to provide gap-filling services and enabling services, much recent attention has focused on monitoring and evaluation through the development of national and state performance measures. Under the guidance of the Maternal and Child Health Bureau, state Title V programs have taken a leadership role in articulating needs, identifying strategies, and assessing the impact both of Title V and non-Title V programs on the well-being of mothers and children. It is important to underscore that Title V programs often identify needs and define a framework for action within a state, even though Medicaid and private insurance provide vastly more funding for actual clinical services.

► HEALTH INDICATORS

The development and continuous monitoring of health status indicators reflects one of the key infrastructure services at the core of maternal and child health. Many indicators are now routinely collected by a variety of health, economic, and social services agencies, but are routinely made available by the Maternal and Child Health Bureau, through the Title V Information System (<https://perfddata.hrsa.gov/mchb/mchreports/Search/search.asp>).

Although maternal mortality rates have reached a very low level (recently, about 11.8 deaths per 100,000 live births), this indicator can still serve as an important sentinel of failures in the health system. More generally, maternal health is better reflected in the population rates for a range of reproductive health outcomes: fertility (intended and otherwise), therapeutic abortion, birth, miscarriage, stillbirth, and especially low birth weight. Similarly, many process measures reflect the quality of maternity care: timing and quantity of prenatal care, place of delivery, attendant at delivery, vaginal or caesarian delivery, and complications (including those from nontherapeutic abortions).

The infant mortality rate remains an important outcome measure for MCH. Linking infant birth and death records has added to the ability to assess factors associated with pregnancy outcome.⁴ The birth certificate form that was adopted in 1989 includes a wider array of information on both the mother and the child, offering opportunities

for exploration of the relationships between sociodemographic factors, health and social services factors, and various pregnancy outcomes. Childhood morbidity is less routinely measured. Birth defect registries, neonatal intensive care use, discharge diagnoses, and national health surveys provide some estimates of morbidity. Immunization rates, school-based health data, and the data from such programs as EPSDT and Children With Special Health Care Needs (prior to the mid-1980s referred to as Crippled Children's Programs) are also helpful indicators of child health, although they are not collected at either the state or national level as systematically as are infant birth data.

Larger social and demographic changes are also important indicators of the status of mothers and children. Over the last 20 years there has been a dramatic increase in the percentage of mothers in the work force, creating challenges for families and service providers as the interests of mothers working outside the home have gained more prominence. The number of children in single parent families, either through divorce or the absence of marriage to begin with, continues to rise as do the numbers of homeless mothers and children. These social problems contribute directly or indirectly to most of the health problems of women and children.

► PRINCIPLES OF SERVICE DELIVERY

Several principles of service delivery stem from the unique focus of MCH on children and their families.

Family-Centered Care. In a recently issued statement by the Maternal and Child Health Bureau, "Family-Centered Care assures the health and well-being of children and their families through a respectful family-professional partnership. It honors the strengths, cultures, traditions and expertise that everyone brings to this relationship. Family-Centered Care is the standard of practice which results in high quality services."⁵ The child is not merely the passive recipient of the influences of the family, but, rather, plays an increasingly interactive role in the family, shaping in part the environment in which he or she lives. Similarly, the family works in partnership with the professionals providing services to children, especially where chronic diseases or disabling conditions are present.

Developmental Perspective. The fetus and child are being continuously shaped by the normal developmental processes that result in a reasonably predictable series of changes from conception through adolescence. Progress over this course is a sensitive measure both of health and disease. Singular events or continuous disruption of normal development can have progressively magnifying adverse effects on the fetus or child. Because of the importance of development, prompt identification of problems and early and continuous intervention hold the greatest promise for achieving the best outcome.

Health Promotion and Disease Prevention. Childhood is both a means to adulthood and an end in itself. There is great potential, therefore, for health promotion and disease prevention to benefit both the current child and the future adult. However, careful attention must be paid to the immediate implications of interventions that are aimed at preventing problems in the distant future, making sure that the desired long-term benefits are not counterbalanced by short-term hazards.

► CURRENT PRIORITIES

Preconceptional Health Promotion. Many of the critical phases of fetal development have already occurred before a woman is even aware that she is pregnant. Optimum fetal health, therefore, requires attention to maternal health and health-related behaviors even before conception. Efforts to counsel women before conception to avoid alcohol, drugs, tobacco, and other fetal hazards are currently being

tested to determine the impact on pregnancy outcome.⁶ The demonstrated efficacy of periconceptional dietary folic acid in the prevention of neural tube defects has resulted not only in extensive health education campaigns about the importance of supplementation for women in their child-bearing years, but also mandated fortification of bread.

Family Planning and Abortion. Optimum health for both mother and child has long been known to be related to maternal age, spacing of children, and the balance between family resources and family size. The ready availability of birth control and the option for abortion have provided means of achieving family planning, although financial, administrative, and clinical barriers continue to limit access.⁷ For example, despite the recommendations of the scientific advisory panel to the Food and Drug Administration that Plan B, a hormonal contraceptive that is effective in preventing pregnancy for up to 72 hours after sexual intercourse, be made available without prescription, political considerations have delayed implementation.⁸

Prenatal Care. Improving access to and quality of prenatal services continues to be a challenge with no obvious solution. Expansion of Medicaid to include women up to 185% (and beyond at state option) of the federal poverty level in comprehensive services has made prenatal care more accessible. Some states have developed innovative programs to improve quality and access for the poor, and many local community-based projects have also been created with these goals in mind.

Perinatal health. The U.S. infant mortality rate has slowly declined, reaching a low of 6.8 per 1000 live births in 2001, and rising slightly to 7.0 per 1000 live births in 2002. The ranking of the United States continues to fall, however, compared to other nations, currently twenty-eighth in the world. Disparities among racial/ethnic groups in perinatal indicators is a major focus of research, both on epidemiological determinants of low birth weight and prematurity and interventions to continue and enhance the downward trends in these indicators. The United States lags behind all other developed countries in the provision of most services to mothers and children.

Immunization. The past 10 years have witnessed critical new developments in this fundamental component of MCH. An acellular pertussis vaccine has greatly reduced the complications of the historical whole-cell vaccine.⁹ The use of conjugated vaccine against *Hemophilus influenzae* in infants as young as 2 months of age has significantly reduced the incidence of meningitis in infants. The hepatitis B vaccine is now widely used in the prevention both of hepatitis and the consequent hepatic cancer—both major problems, particularly in developing countries. The eradication of polio from the United States has led to a switch from oral polio vaccine to inactivated vaccines to reduce the incidence of paralytic reactions to the oral vaccine. Oral polio vaccine is still the vaccine of choice for global eradication.⁹

Children's Injuries. Injuries are the leading cause of death from the age of 1 year throughout childhood, adolescence, and beyond. While the resources devoted to this major public health problem are not proportionate to the need, much progress has been made in reducing children's injuries. For example, many states have implemented graduated driver license programs to introduce new young drivers to increasing risks gradually, resulting in dramatic reductions of 20–30% in teen crashes.

Childcare. With the large proportion of families where both parents work outside the home or a single parent works outside the home, childcare remains central to the field of maternal and child

health. Oversight of health, safety, and educational performance necessitates collaboration among many professional and lay groups with interests in children, a convening role that is consistent with the definition of MCH.

Child Abuse and Neglect. Abuse, including sexual abuse, continues as an important risk factor to the well-being of children, not only during childhood, but into their adult years. Reports of abuse and neglect persist at over 1%, but the incidence of these threats to children is likely much higher than the official reporting statistics would indicate.

Children with Special Health Care Needs. Title V programs, as well as educators, health-care providers, and advocates, have devoted increasing attention to children who “have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally.”¹⁰ With upward of 18% of U.S. children potentially with special needs, the infrastructure, population-based, enabling, and gap-filling approach of MCH is especially effective for these children and their families. In addition, Title V programs have taken a leadership role in defining and addressing the challenges associated with the transition from childhood to adulthood for individuals with special needs.

Community-Based Social Support. Pregnant women and young children thrive best when they are surrounded by friends and relatives who provide companionship and assistance. As unwed motherhood becomes more common and the extended family further disintegrates, more young families face isolation and inadequate social supports. To remedy this, several programs have utilized home visitors to befriend and work closely with pregnant women and young families, offering the assistance and social support that are so often inadequate. Some of these programs have been able to demonstrate benefits in health and well-being associated with participation in the program.^{11,12}

► FUTURE DIRECTIONS

At the beginning of the twenty-first century, the field of MCH has perhaps devoted greater attention to developing the core functions of public health than any other field. The focus on community assessment, policy development, and assurance guides resource allocation decisions at the federal and state levels. Attention to the core functions, however, faces the challenges that come from the historical and ongoing tension in the United States between individual/private responsibility on the one hand and/or public responsibility for the well-being of mothers and children on the other. This stands in marked contrast to the approach taken toward the population of seniors. Whereas programs for children and families tend to fall within the purview of state governments and depend on discretionary funding, programs for seniors have become a federal responsibility through programs such as Old Age and Survivors Benefits, Medicare, and in the case of long-term care, Medicaid. In carrying out the core functions of public health, the field of MCH often makes contributions that are not readily visible to policy makers and taxpayers. As the demands for resources increase in a world defined by an aging population, external threats such as bioterrorism or pandemic infectious diseases, federal priorities run the risk of being skewed toward those more apparent challenges. The role of the field of MCH is to build on its rich history by continuing to articulate the needs of the population of children and mothers with a commitment to the goal that any strong nation must appropriately invest in its future.

Preventive Medicine Support of Military Operations

Robert L. Mott

A corps of medical officers was not established solely for the purpose of attending the wounded and sick; the proper treatment of these sufferers is certainly a matter of a very great importance, and is an imperative duty, but the labors of Medical Officers cover a more extended field. The leading idea, which should be constantly kept in view, is to strengthen the hands of the Commanding General by keeping his army in the most vigorous health, thus rendering it, in the highest degree, efficient for enduring fatigue and privation and for fighting.

—Dr. Jonathan Letterman, Surgeon,
Army of the Potomac, 1862 to 18641

By congressional statute, military commanders are responsible for the health of their commands. The command “surgeon” serves as the commander’s principal medical staff advisor, and in this role, he or she participates in the development of command plans and policies. The command surgeon, usually with the assistance of a staff preventive medicine officer, advises the commander on the health status of the command, threats to the health, and policies and practices to protect the health of military personnel and others associated with the operation.

Preventive medicine programs for military units and personnel are designed to preserve and promote health and to prevent physical and mental diseases and disabilities. Knowledge of the environment in which the programs are to be effected is essential to assess the physical, chemical, and biologic hazards to which military personnel may be exposed. During military operations, besides the risk of injury from the weapons of war, principal hazards include accidents with machines, especially motor vehicles, explosives, and fire; exposures to noise, smoke, and toxic fumes; extremes of altitude, heat, and cold; and a host of infectious diseases, many with the capacity to produce catastrophic morbidity in deployed forces (e.g., malaria, dengue fever, and sand fly fever).

The dissolution of the Soviet Union substantially altered the nature of the threat to global and U.S. national security, and along with it, the U.S. national military strategic response. U.S. military forces were formerly preoccupied with the potential for large-scale, high-intensity armed conflicts, especially in the defense of Europe. The primary strategic concern has now shifted to the containment of regional ethnic and religious conflicts and to the prevention of terrorist attacks against U.S. interests, both at home and abroad. The use of commercial aircraft as terrorist weapons on September 11, 2001, followed closely by anthrax attacks in the eastern United States, dramatically elevated concerns about the use of weapons of mass destruction to include CBRNE. In addition, the nearly unprecedented destruction from hurricane Katrina in 2005 demonstrated the ongoing need for military support during domestic emergencies. The effect of these trends has been to increase the mission diversity of the U.S. Armed Forces to include not only fighting war, but also antiterrorism, peacekeeping, humanitarian assistance, domestic and international disaster relief, and support to civil authorities. This, in turn, requires the medical and preventive medicine capacity to provide highly flexible and mobile support over long distances and in widely diverse environments.

► FIELD PREVENTIVE MEDICINE ORGANIZATION

In “Joint” operations, such as Operation Iraqi Freedom, the deployed force will usually include combat elements from the Army, Marine

Corps, Air Force, and Navy. The Joint Task Force (JTF) will be tailored, or “task organized” with respect to the kinds of units and their size so as to be able to accomplish the mission articulated for it by the Joint Chiefs of Staff. Each combat unit (Army and Marine divisions; Air Force tactical fighter wings, etc.) has its own “organic” support elements (meaning support units that *belong* to the combat unit), including medical and preventive medicine units and personnel. At the combat unit level, preventive medicine capabilities include water testing for chlorine residuals and bacterial coliforms and limited vector control. Backing up the organic medical support units are additional medical units under the command and control of the JTF commander, and under the technical supervision of the JTF surgeon. These assets may include epidemiology, entomology, environmental sanitation, and environmental engineering capabilities. The Army also has established deployable laboratories which perform the functions of public health laboratories in the Theater of Operations. In addition, the Air Force maintains an aerial spray squadron, with aircraft configured to spray insecticide over large areas, should it become necessary to control widespread vector-borne disease outbreaks in the deployed force.

► DISEASE AND INJURY PREVENTION IN OPERATING FORCES

There are five key elements of the strategy for disease and injury prevention among forces deployed in field and combat operations:

1. Before force deployment, perform a *medical threat assessment* to determine the nature and magnitude of the disease and injury threats in the planned area of operations.
2. Identify the principal countermeasures that must be emphasized to reduce the threats to an acceptable level.
3. Promulgate countermeasures among the operating forces and train individuals and leaders in their use.
4. Enforce the countermeasures in the operational area.
5. Conduct medical surveillance to monitor the health of the deployed force and to identify events that require preventive medicine interventions.

Medical Threat Assessments

The threats to health from disease and nonbattle injury (DNBI) in a deployed military force depend principally on the mission and composition of the force, the geographical area of operations, including the diseases that are endemic in the area, the time of year, and the intensity of the conflict. DNBI rates in past conflicts have invariably exceeded battle injury rates and have resulted from naturally occurring infectious diseases (e.g., malaria, dengue fever, and sand fly fever); environmental extremes of heat, cold, and altitude; motor vehicle accidents; athletic injuries; and psychological stresses. In operations in Bosnia and Iraq, industrial chemicals and radioactive waste were considered to be potential threat agents.

During operations Desert Shield and Desert Storm, rates of hospitalization due to DNBI were extremely low in comparison with previous conflicts because of a unique set of favorable circumstances: (a) good medical intelligence about the area before the deployment; (b) sound preventive medicine policies that, for the most part, were rigorously subscribed to and enforced by unit commanders; (c) the religious proscriptions of the host nation; (d) a measured and unimpeded buildup phase; and (e) a relatively brief ground combat phase

TABLE 79-5. U.S. ARMY DNBI RATES* IN OPERATIONS FROM WWII THROUGH DESERT STORM

	Combat Troops	Support Troops
World War II	1.98	1.60
Korean War	1.67	2.14
Vietnam	0.89	0.92
Desert Shield	0.34	—
Desert Storm	0.41	—

*Per 1000 per day.

(Table 79-5).² Decreasing DNBI rates continued in Operations Iraqi Freedom and Enduring Freedom (Afghanistan) even though there were multiple cases of cutaneous leishmaniasis³, diarrheal disease,⁴ eosinophilic pneumonia,⁵ and malaria.⁶

As a general rule, naturally occurring infectious diseases are likely to remain the most important causes of preventable medical noneffectiveness in most future overseas deployments. In past wars involving U.S. forces, infectious diseases have produced higher morbidity rates than battle injuries, and until World War II, higher mortality rates as well.⁷⁻⁹ The infectious diseases causing high morbidity among U.S. forces in past wars, arranged more or less in the relative order of their importance, are shown in Table 79-6.¹⁰ Because deployed troops usually must live and work under relatively primitive conditions, they are also at risk for “emerging” infectious diseases. As one example, hemorrhagic fever with renal syndrome due to Hantaan virus was first reported in Japanese and Soviet troops in Manchuria just before World War II, affected UN troops during the Korean War, and continues to be reported among Korean and U.S. soldiers in association with field operations along the demilitarized zone (DMZ) in South Korea.¹¹ As a second example, cutaneous leishmaniasis due to *Leishmania tropica* was known to be endemic in the Persian Gulf region before the deployment of U.S. troops on Operations Desert Shield and Desert Storm. However, the capacity of the parasite to “visceralize” (i.e., to invade liver, spleen, and bone marrow) was not well documented before its appearance in returning U.S. troops.¹⁰ Cutaneous leishmaniasis was a significant cause of morbidity in Operation Iraqi Freedom, and its treatment often required medical evacuation to the United States.³ Wound infections with *Acinetobacter baumannii* in service members returning from the Middle East were also a challenge for clinicians, infection control, and preventive medicine personnel.¹²

TABLE 79-6. INFECTIOUS DISEASES CAUSING HIGH MORBIDITY IN U.S. FORCES IN PAST CONFLICTS: WORLD WAR II, KOREA, VIETNAM, OPERATION DESERT STORM, OPERATION IRAQI FREEDOM

Acute respiratory disease and influenza	All
Acute diarrheal disease	All
Malaria	WWII, Korea, Vietnam
Hepatitis	WWII, Korea, Vietnam
Sexually transmitted diseases	WWII, Korea, Vietnam
Arthropod borne diseases*	WWII, Vietnam
Rickettsial diseases†	WWII, Vietnam
Leptospirosis	WWII, Vietnam
Leishmaniasis	WWII, Desert Storm, Iraqi Freedom
Schistosomiasis	WWII‡

Abbreviation: WWII, World War II.

*Especially dengue fever, sand fly fever, hemorrhagic fevers, encephalitides.

†Principally scrub typhus, whose distribution is limited to parts of Asia and northern Australia.

‡Principally in engineer bridge-building units in Luzon, Philippines.

The purpose of medical threat assessments is to help decide on the specific disease and injury countermeasures that must be planned for use by the force. The information needed to develop such assessments for a particular country or region is available from a variety of sources, including statistical reports of national and international health agencies, publications in general medical literature, medical historical data from previous operations in the area, and the unpublished observations of health-care personnel and epidemiologists working or visiting in the geographical areas of interest. In addition, in a number of widely dispersed geographical areas, the U.S. Army and Navy maintain medical research laboratories dedicated to the study of the epidemiology and prevention of regional medical problems of potential military importance. The U.S. Navy also maintains a number of Navy Environmental Preventive Medicine Units (NEPMUs) with regional responsibility for updated assessments of current health risks in areas of possible deployment of Navy and Marine forces. The collection and evaluation of medical information from these various sources and the preparation of a variety of medical information products for particular countries and regions are accomplished by the Armed Forces Medical Intelligence Center, the Defense Pest Management Information and Analysis Center of the Armed Forces Pest Management Board, and service-specific preventive medicine organizations. The Army and Navy overseas laboratories and the NEPMUs are excellent sources of current information because they have personnel working “on the ground” in regions of interest, constantly updating the medical threat assessments. During the devastating tsunami in 2005, teams from overseas laboratories in Thailand and Indonesia conducted rapid public health assessments in support of the humanitarian response.¹³ The laboratories are also well placed to assist with surveillance for diseases, like avian influenza, which have outbreak and pandemic potential.

Identifying the Countermeasures and Promulgating the Force Preventive Medicine Program

In military operations there are two general kinds of disease and injury countermeasures: those taken by or applied to individual soldiers and those taken by the unit and applied to the environment in which the unit is operating. Individual countermeasures are those that alter the individual in some way to increase refractoriness to the various risks, including immunizations, prophylactic drugs, insect repellents, protective clothing, and safety equipment. Environmental countermeasures are those directed at removal or attenuation of environmental risk factors, including measures directed at the provision of potable unit water supplies and sanitary food supplies, the sanitary disposal of wastes, and the control of disease vectors and animal reservoirs of disease. In addition, in the development and testing of major items of equipment (armored vehicles, artillery pieces, etc.), attention is paid to the design of the equipment so as to minimize the risk of injury from its use. For example, the ventilation system in the Bradley fighting vehicle (and other armored vehicles) is designed to rapidly remove from the troop compartment the smoke and gases generated by the combustion of ammunition propellants during weapons firing.

In the highly mobile tactical operations characteristic of modern warfare, it is frequently necessary to place nearly total reliance for disease and injury prevention on individual countermeasures applied under the direction of the lieutenants and sergeants at the platoon and squad level. In more stable tactical situations and in rear areas, it is possible to place heavier reliance on environmental controls applied by the units themselves or by combat service support units (engineer, quartermaster, and medical) on an area basis. Besides the function of disease vector control, which is accomplished by specialized medical units, most environmental controls are the responsibility of nonmedical personnel and units. For example, in the Army, quartermaster units are responsible for food and water procurement and distribution. Medical personnel and units, to include Army veterinarians, retain responsibility for technical inspections to ensure compliance with prescribed sanitary standards.

Malaria is perhaps the best example of a highly significant military disease problem that would receive the careful attention of preventive medicine planners during preparations for deployment to known

malaria-endemic areas. Decisions about the countermeasures to be employed by the force would be written into the medical annexes of the operations orders; these have the authority of command directives. These decisions would also represent the basis for procurement of medical supply items for use in the prevention and control of malaria, such as drugs for chemoprophylaxis and treatment, bed nets, and insecticides and insecticide dispersal equipment for mosquito control.

A primary consideration would be the malaria chemoprophylactic regimen to be used by the force. Factors that would be taken into consideration in determining the malaria chemoprophylactic regimen include the malaria prevalence in the region, the predominant infecting species, and the prevalence of drug-resistant *Plasmodium falciparum* and *Plasmodium vivax*.

Besides the chemoprophylactic regimen, other individual countermeasures against malaria that would be addressed include use of the standard-issue insect repellent (diethyltoluamide [DEET]), which would be used on exposed skin surfaces in conjunction with the permethrin-impregnated battle dress uniform (BDU), the proper wearing of the uniform ("shirts on, collars buttoned, sleeves rolled down, from dusk to dawn"), and the use of permethrin-treated bed nets in secure areas. Area malaria control programs in the operational area, including insecticide dispersal methods, would be devised based upon on-site professional entomological surveys conducted to determine the principal malaria vector species, their breeding sites, and adult mosquito biting and resting habits. Additional environmental controls that might be addressed include policies regarding campsite selection in relation to native villages, whose inhabitants might represent a reservoir of malaria infection, the use of indigenes in labor forces, and medical civic action programs directed at reduction of the size of the malaria reservoir through the identification and treatment of infected individuals.

Training Personnel to Use Countermeasures

As noted, it is frequently necessary to rely almost entirely on individual countermeasures for disease and injury prevention in the early stages of deployments and during other kinds of offensive operations. During these periods, the combat service support units responsible for the implementation of area environmental controls ordinarily will be given a lower priority for transport than the combat elements. The medical personnel present in the forward areas will be those who are assigned to the combat units, and they will be more preoccupied with the care of combat casualties at the time than with the institution of environmental countermeasures. Moreover, it is during this period, in the disorganization of battle and before the construction of any permanent facilities, such as barracks, latrines, and mess halls, that troops are most vulnerable to vector-borne disease transmission, including diseases with the demonstrated capacity to produce catastrophic morbidity in fighting forces.

The individual countermeasures determined to be necessary for use by the force must be integrated into predeployment training programs (see Table 79-7).¹⁴ Through repetition and constant

reinforcement by the lieutenants and sergeants at platoon and squad level, it is to be expected that the application of individual countermeasures will become second nature among the troops. The principal prerequisite for ensuring that the desired health behaviors are incorporated into each individual soldier's repertoire is to convince the lieutenant and sergeant leaders of small tactical units that the countermeasures are important to the success of their unit's mission.

Rigorous Command Enforcement of Countermeasures

Enforcement of the use of countermeasures is a command function. The appearance in a unit of cases of a specific disease that should have been prevented by the application of the command-directed countermeasures (e.g., cases of malaria that should have been prevented with the prescribed chemoprophylaxis) should bring about an epidemiological investigation to determine if the outbreak was due to unexpected failure of the prescribed countermeasures to prevent the cases (e.g., the malaria parasites are resistant to the prescribed chemoprophylaxis) or the result of command failure to enforce the countermeasures (e.g., soldiers are not taking the prescribed chemoprophylaxis). If the investigation shows that the cases are the result of failure of the prescribed countermeasures, then better methods must be decided upon and put in place quickly. If due to the latter, command-directed disciplinary action may be warranted. In this connection, Field Marshal Sir William Slim, commander of the British Army in Burma in World War II, in his personal history of the period, stated:

Good doctors are no use without discipline. More than half the battle against disease is fought, not by doctors, but by the regimental officers. . . . When mepacrine was first introduced . . . often the little tablet was not swallowed. An individual medical test in almost all cases will show whether it has been taken or not. . . . I, therefore, had surprise checks of whole units, every man being examined. If the overall result was less than ninety-five per cent positive I sacked the commanding officer. I only had to sack three; by then the rest got my meaning.¹⁵

Conducting Medical Surveillance

Medical surveillance of the deployed force is necessary to continuously monitor the health status of the force, ensure that preventive medicine countermeasures are working, rapidly identify disease and injury threats that have the potential to compromise the combat effectiveness of the units, and if necessary, develop and recommend preventive medicine interventions to the appropriate unit commanders. As noted above, it is the commander who is ultimately responsible for the health of the command and the implementation of disease and injury countermeasures.

Before Operations Desert Shield and Desert Storm, disease and injury surveillance programs during military operations were, for the most part, decentralized to brigade, regiment, and division level; were dependent upon the ad hoc, usually less than systematic observations of unit surgeons; and were frequently subject to reporting delays to higher headquarters, which prevented timely interventions from that level. During Operations Desert Shield and Desert Storm, U.S. Navy and Marine Corps medical personnel systematically recorded outpatient disease and injury data by category of illness or injury (heat and cold injury, diarrhea and gastrointestinal infections, dermatologic conditions, respiratory conditions, injury or orthopedic conditions, unexplained fever, sexually transmitted diseases, ophthalmologic conditions, psychiatric conditions, and other acute conditions) and reported these data weekly using a standard format. Unit strength figures were included in reports to permit the calculation of rates by unit, location, and in the aggregate. The system is credited with the identification of a force-wide diarrheal disease outbreak early in the operation related to the serving of fresh lettuce in U.S. Marine Corps field messing facilities; the lettuce was being provided along with other fresh foods by indigenous contractors outside the network of

TABLE 79-7. INDIVIDUAL PREVENTIVE MEDICINE COUNTERMEASURES TO BE EMPHASIZED IN TROOP TRAINING EXERCISES

Safety first: Use common sense during occupational and recreational activities
Do not consume unapproved food, water, or ice
Drink water frequently during the day
Wash hands after using the latrine and before meals
Take your malaria prevention pills when instructed to do so
Wear permethrin-treated uniforms with trousers bloused and sleeves down
Keep DEET insect repellent on exposed skin
Sleep under a permethrin treated bed net
Follow work-rest cycles to prevent heat injuries
Avoid contact with all animals
Defecate only in constructed latrines or designated areas
Wear hearing protection during military operations

sources approved by the U.S. military. Rates had increased simultaneously throughout the force, exceeding 8% per week in some locations. A command decision was made to ban the use of lettuce in Marine Corps field messing facilities, which was followed by a precipitous decline in rates of diarrheal disease in the force to around 1% per week.¹⁶ Newer DNBI surveillance efforts rely on electronic medical records which allow the documentation, reporting, and analysis of specific diagnoses. This promising new program should improve the specificity and timeliness of disease reporting thereby facilitating outbreak response efforts. However, this system will also have limitations because case (numerator) data must still be combined with sometimes difficult to obtain population (denominator) data to permit the calculation of rates, and the electronic records may not be available at far forward levels of care and will be likely be impractical during intense combat operations.

Public Health Workforce

Kristine M. Gebbie

► INTRODUCTION

The wide range of activities subsumed under the rubric of public health practice is provided by a workforce no less diverse. In the most recent effort to enumerate public health workers in the United States,¹ 448,254 were identified in federal, state, and local public health agencies; schools of public health; and in voluntary organizations actively collaborating in meeting public health needs, such as the American Red Cross and the March of Dimes (see Table 79-8). Compared to some sectors of the economy, the public health workforce is overwhelmingly professional (at least 40% can be identified as members of a professional category), enriched by a wide range of technicians (in laboratory, environment, and informatics, to name a few areas) and critical support staff in administrative, data entry, transportation, and other tasks. The discussion is complicated by the fact that in the enumeration process, over 24,000 professional staff (those with baccalaureate or higher education) could not be specifically identified, and nearly 98,000 workers could not be assigned even to a general category such as professional or technical. Whatever the detail, the actual workforce is larger than reported, as public health activities are spread across multiple agencies at all levels of government, only a few states have made efforts to identify all parts of the public health enterprise within the jurisdiction, data from local agencies are limited, and there is no agreed-upon definition of the full range of nongovernmental participants to include.

The Disciplines of Public Health

The two largest groups of professionals identified in public health practice are public health nurses (50,000) and environmental health professionals (15,000). In addition to these, physicians, health educators, laboratory scientists, and epidemiologists are most likely to be mentioned as important contributors to public health. In the early history of public health, it was those with an environmental focus, including engineers, who made some of the most striking contributions, assuring that drinking water was safe, sewage systems installed, and waste products appropriately handled. As the specific causes of diseases became known in the first half of the twentieth century, physicians with public health training became more prominent, and measures of disease prevention such as isolation of infected persons, tracing of individual contacts, and vaccination became important tools. The complete list of professions associated with public health

► OTHER MILITARY PREVENTIVE MEDICINE MISSIONS

The field missions described above are clearly important to military operations but they do not fully reflect the wide variety of activities that define military preventive medicine. Military preventive medicine professionals are also involved in policy and doctrine development at multiple levels within the Department of Defense; basic and applied research on infectious diseases, injuries, and environmental threats; managing the equivalent of county and state health departments; developing national- and international-level programs; teaching at the masters and doctorate levels; assisting with humanitarian assistance and disaster relief operations; and serving as medical executives in one of the largest health-care organizations in the world.

practice includes all of those associated with medical care (dentist, pharmacist, physical and occupational therapist, psychologist), others less frequently seen in patient care settings (occupational health and industrial hygiene, law, veterinary medicine), and many with important analytic and data skills (biostatistics, economics, informatics).

The professions in public health are supported by an impressive array of technicians and paraprofessionals as well. Laboratory technicians, dental technicians, computer technicians, community outreach workers, and environmental technicians are all represented. In addition, because much of public health depends on documentation and communication, there is a rich array of administrative and data management support staff. One of the complications in both describing and studying the public health workforce is that any one individual can often be described by several labels: the discipline in which he or she has formal training, the job title assigned by the employing agency, the functional activity in which the majority of time is spent, and the program in which this takes place. For example, an MD might be hired as a public health program specialist and spend the majority of time planning and conducting outbreak investigations in the sexually transmitted disease control program. Or a laboratory technician may be hired as an investigator and spend the majority of time visiting community-based laboratories to support a quality assurance program in lead testing.

What unites all of these groups is the common attention to the health of populations, rather than individuals. The specific functions any one worker may be asked to fulfill are often not specific to the discipline in which he or she was trained, but rather a service to the community to which the world-view of that discipline can contribute. For example, in developing a community-wide health education program on reduction of tobacco use, physicians, health educators, environmental health specialists, nurses, and media specialists might all be employed under the programmatic title, "A Clean Indoor Air Team," and would pool their various perspectives into a single programmatic effort that might eventually be carried out in a community through the media, volunteers, hospital staff, and public health nurses.

Nurses provide one example of the diversity of public health work and workers. For over a hundred years public health nurses have been "promoting and protecting the health of populations using knowledge from nursing, social and public health sciences."² This effort has taken many forms, and led practitioners from crowded urban tenements to isolated farms to suburban workplaces, from healthy children to tubercular workers to the elderly seeking to maintain their

independence. While it is difficult to say that there is a “typical” public health nurse, there are commonalities across many agencies of different sizes, serving diverse communities. Public health nurses are usually employed to work in those public health programs that require some contact with individuals, especially if that contact involves some aspects of “hands-on” clinical practice. This includes the staffing of immunization clinics, sexually transmitted disease and tuberculosis control programs, child and maternal health services, senior health promotion programs, and workplace health clinics. Nurses are also found in epidemiology programs, and working to assure the quality of day care centers, hospitals, and long-term care facilities through licensing and certification. In large health departments, a nurse might work exclusively in one or two program areas, and even in a limited part of the jurisdiction served. In many middle-sized and most small departments, the nurse must be a generalist, moving day to day and hour by hour from program to program. Much of the apparent specialization and narrow targeting of work efforts is driven by the current approach to funding of public health, in which dollars are tied to very defined activities and population groups, rather than being available for more broad-based efforts to work with a population group or community to improve health overall.

While complex models to explain the experience of health in populations (such as the Evans and Stoddard Field Model³) have only been in widespread use in recent years, public health professionals have understood that protecting the public health requires attention to individual and family circumstances, social and economic factors, and the full experience of the local community. The individual experiencing illness and seeking care may be the most visible evidence of the need for public health in a community, though individual medical care in response to symptoms is not central to public health practice. However, where there are large numbers of individuals uninsured or lacking primary care, public health departments have hired large numbers of physicians, physician assistants, nurse practitioners, and public health nurses to provide personal care services. There is no indication that this care has automatically been given in ways that differ in content or focus from that provided in any other ambulatory care practice. Having said that, it is also important to say that many health department-based primary care programs are different in their attention to prevention, to the special community needs of the populations seeking care, and to the potential for building new, better systems of care and prevention.

As health departments have been a major source of primary care and prevention for the uninsured or other vulnerable populations, they have often supported the services by quietly riding on the economic coattails of Medicaid or other special funding sources. A maternal-child health-focused public health nurse or child health physician generating up to two-third or three-fourth of salary costs through billable services may well be supported to invest the remaining one-third to

one-fourth of time in improved community health systems. Absent the Medicaid resource, the health department may be unable to find the resource to continue these professionals even half time. Making the case for a community funding base for this shift is an important challenge to public health nurses across the country. The challenge is to ask the correct question, which is “how will I assure that care is available to those who lack it?”, not “how can I be sure that I am still here to give the care?” In the rush to downsize government and control spending for health and illness services, many fear that policy makers will inadvertently eliminate important community-based programs, such as health promotion to increase activity and reduce obesity.

Where is Public Health Practiced?

The field of public health can be distinguished from other areas of health-related practice by the combined impact of three foci: prevention, community, and systems. While none of these is unique to public health, the combination is a particularly powerful one. Prevention is, of course, the historic defining feature of public health. As causal links and antecedents of disease have been understood, public health practitioners have taken steps to reshape exposure patterns, or strengthen resistance or eliminate causes of diseases. The earliest efforts were directed at infectious conditions, both before and after the introduction of protective immunizations and effective antibiotic treatment. More recently, prevention has extended to noninfectious diseases such as cancer and heart disease, and to injury, both unintentional and intentional. The expanding science base for prevention practice has supported provision of services in a variety of settings (home, school, workplace, health clinic) using multiple media (brochures, audio and video tapes, games, drama) and multiple reinforcers (public policy on tobacco control being a prime example). Emerging approaches such as harm reduction (seeking to achieve at least some movement toward more healthful choices even if full prevention of risk is not feasible) also play a part.

Some prevention activities are directly provided to specific individuals, such as immunizations or prenatal care. Many others are provided to people at the population group or community level. In either case, public health is differentiated from the vast majority of health and illness care practice by the use of settings other than hospitals and doctors’ offices as the site of intervention. Schools and work sites, store-front clinics, homes, and shopping malls have also been used to assure that services and messages are available to people at the times and places where they will have the greatest impact in promoting health. The term *community* may well be overused; the fact that a health-related service is outside the four walls of a hospital does not make it a community service. Changes in medical and nursing practice have meant that many procedures previously requiring a hospital operating room or nursing care unit are performed in clinics or homes.

For the public health worker, all activities are done in the context of community. Community means more than place, and may not occur in a single place. It also means relationship, whether one is considering an official geopolitical community, a neighborhood, or a community of affinity such as an advocacy or professional group. One widely used statement about public health in America⁴ captures the importance of relationships in the vision of “healthy people in healthy communities.” Related to the concept of community is that of systems, the notion that any one component of the community is tied in some way to all others, so that changes in any one component will lead sooner or later to some changes elsewhere. A focus on both prevention and community from a systems perspective pushes the practitioner to consider how the system relationships may be developed or strengthened, or how illness-fostering, noncommunity system elements may be reduced. Working with this perspective means that any work with an individual can be the source of data regarding the functioning of systems within the community, and lead to intervention at additional levels to promote healthy change. No one person can simultaneously work at all levels (individual, family, neighborhood, community-wide system), so the system of workers collaborating to assure that needed information flows among those performing different functions is an additional important part of the systems view.

Given all of the above, it is impossible to define the public health workforce by the name on the employing agency door, though the largest concentration is reemployed by official public health agencies (local, regional, state, or federal).^{*} Some community programs such as the not-for-profit community health centers and migrant health centers work with the community to improve health in ways that are clearly public health practice. The total number of public health workers reported is also deceptive in that the workers are not spread evenly in relation to the population. While the reported national ratio is 158 public health workers for each 100,000 in the population, in 2000 the range was from 37/100,000 (Pennsylvania) to 566/100,000 (South Carolina).⁵ While this does represent enormous variation in the assurance to the citizens that their health is being protected, caution should be exercised, as these variations are caused in part by state and local decisions to locate public health activities outside of identifiable public health agencies, by varying degrees of reliance on public health for clinical services, and on the lack of a standardized system for routine reporting on the public health workforce.

Degrees and Credentials

Because of the myriad skills needed, entry routes to public health practice often do not include formal training in public health. For example, many experts in social dynamics of the populations most vulnerable to HIV infection (gay men, sex workers, injecting drug users) entered public health practice during the early years of the AIDS epidemic. As programs matured and workers considered promotions and career development, many of these have added public health training (formal or informal) and can now be found working in a wide range of programs. For the largest professional group, nurses, the picture can be most confusing. Nurses with the same legal credential to practice may have widely differing educations. Neither the associate degree nor diploma education includes public health as a required curriculum component. Basic education about public health nursing practice is included in the baccalaureate curriculum, and some public health systems have attempted to reserve the job title “public health nurse” for baccalaureate graduates only. Whatever their entry education, nurses employed to work in public health agencies or other entities with a focus on public health and the community

must master at least some content about population perspectives on health, epidemiology, health behavior and environmental influences on health.^{6,5}

Advanced education for practice in communities is at least as confusing as entry-level education. Some public health nurses have studied in schools of public health, others in schools of nursing; some have degrees in both fields. Some physicians in public health practice are board certified in preventive medicine, but many others are pediatricians, obstetricians, or infectious disease specialists. As with entry-level education, the degrees and job titles alone do not identify whether the physician or nurse is practicing public health nursing or not. The answer to that question must be sought in questions of focus and goal.

The Institute of Medicine considered the confusing picture of education for public health practice in the report *Who Will Keep the Public Healthy?*²⁶ and provided some guidance for the field of public health education. The report acknowledges that the limited number of schools of public health, and the range of public health practice, mean that schools of public health should concentrate their efforts on those headed toward leadership positions, while expanding continuing education for the workforce generally, and working collaboratively with other schools (e.g., medicine, nursing, law) to improve the public health content included in their regular curricula. The report further suggested that the content of public health education at the graduate level be grounded in an ecological view of health (such as the determinants of the health model discussed above), emphasize practice, and work toward competency not only in the five classic areas of public health education (biostatistics, epidemiology, environmental health, social and behavioral science, and management) but in eight areas that have emerged as critical in the twenty-first century: cultural competency, communication, community-based participatory research, ethics, genomics, global health, informatics, and policy and law.

Many public health workers are credentialed by an association or entity representing a single profession, such as public health nursing, preventive medicine, health education, or environmental health. Many others bring skills for which there is no specific national credential, such as epidemiology, public health law, or public health leadership. National public health associations have engaged in extensive dialogue over the last decade about the possibility of developing a single basic public health certification that could be used by any public health professional as an assurance of competency in the field. The American Public Health Association, the Association of State and Territorial Health Officials, the National Association of County and City Health Officials, the National Association of Local Boards of Health, and the U.S. Department of Health and Human Services (namely, the Centers for Disease Control and Prevention and the Health Resources and Services Administration) have all been actively involved, but resolution seems elusive. Questions include those about duplicate credentials for public health workers from existing specialties, the impact of a new credential on civil service employment systems, and the cost of a program of testing and issuing credentials. Further confusing the debate is an overlapping consideration of the accreditation of public health agencies. It is unlikely that this will be fully settled within another decade.

Current Challenges?

The two most prominent practice challenges to the public health workforce today are those associated with continued efforts to reduce the size of government and those that result from overwhelming attention to specific issues without concern for fundamental infrastructure.

A continuing feature of public life in the United States is concern that government has gotten “too big,” and that a goal for all elected officials is to substantially reduce the presence of government. This is easily translated into a reduction in the size of governmental agencies, the major expense of which is usually the workforce. Public health programs and activities have never been designed as entitlements, that is, services to which people are assured access by virtue of some identifying feature (e.g., Medicare for those over 65, Medicaid for those on

**Because of the lack of clear definitions of public health positions, and the minimal attention to public health within the overall health system, there is no good, recent enumeration of the public health workforce. Efforts now underway within the Bureau of Health Professions, Health Resources and Services Administration, U.S. Department of Health and Human Services, should provide this needed data.*

Aid to Families with Dependent Children, Social Security to workers over 65). Each public health program is reauthorized and refunded year to year, or at best, in a 5-year cycle. Few public health managers at any level of government have succeeded in presenting their programs as being exempt from cuts during recessions, or from across-the-board reductions. Further, public health practitioners have often failed to identify the conceptual basis of public health as being substantially different from the other “human service” programs with which they are often grouped organizationally. Because some public health activities are similar to individualized health services, there has also been pressure to either move them to the private sector or to make them financially self-supporting through fees.

Public health professionals are only partially articulate in describing the population focus of public health, and in making certain that their efforts are truly driven by epidemiology and an interest in community systems toward actions that will raise the level of health in the whole community. The nationwide attention to emergency preparedness and the threats of deliberately caused disease outbreaks such as the anthrax events of late 2001 have been helpful in raising

the profile of public health as a part of the community safety net, needing general revenue support to be ready to respond if needed. Unfortunately, the appropriations process at national and state levels has not made this new revenue additive. In many cases, agencies are the same size as before, with the same workforce being asked to assume more active roles in emergency preparedness and community response, while continuing the long-standing array of other public health services.

Public health is by its nature the most interdisciplinary of practices. On a day-to-day or hour-to-hour basis, the activities of physicians, nurses, social workers, and sanitarians may appear identical. Yet each of these brings perspectives unique to a discipline, and each is important to the wide-ranging functions of public health. The challenges and opportunities of today are such that almost any profession may develop the needed public health understanding of the health of individuals, families, and communities essential to the accurate assessment of health concerns, the development of sound policy, and thus the assurance of continuing movement toward healthy people in healthy communities.

Family Planning

Herbert B. Peterson • Andreea Creanga • Amy O. Tsui

“The Millennium Development Goals, particularly the eradication of extreme poverty and hunger, cannot be achieved if questions of population and reproductive health are not squarely addressed. And that means stronger efforts to promote women’s rights, and greater investment in education and health, including reproductive health and family planning.”

United Nations Secretary-General Kofi A. Annan

Message to the Fifth Asian and Pacific Population Conference, December 2002

The CDC has declared family planning to be one of the key achievements in public health for the twentieth century.¹ Milestones for this achievement include the arrest of Margaret Sanger for distributing information about birth control in 1914, the creation of the first state public health program to include contraception in 1936, the approval of oral contraceptives by the FDA in 1960, and the Supreme Court decision to declare unconstitutional state laws prohibiting contraceptive use by married couples in 1965 (Table 79-9). Family size declined in the United States from 3.5 children in 1900 to approximately 2 children at the end of the twentieth century. The success of family planning in achieving desired birth spacing and family size in the United States contributed to large decreases in both child mortality and maternal mortality in the twentieth century.

In this chapter we provide the global context for family planning followed by an overview of family planning in the United States. We then discuss the safety, effectiveness, and use of contraceptive methods, with a focus on widely used methods and methods that are newly available in the United States.

► THE GLOBAL CONTEXT FOR FAMILY PLANNING

Of the estimated 6.2 billion people living on the planet, approximately one billion are women aged 15–49 who are married or in union. Data regarding contraceptive use are more available for these

women than for single women or for men. More than three-fifths (61% or about 635 million) of women who are married or in union are using contraception.² The percent distribution of women using contraceptive methods varies by region, with a higher percentage (69%) of women using them in developed than in less-developed regions (59%). Further, the percentages of women using contraceptives are as high as 71% in Latin America and the Caribbean and as low as 27% in Africa. The great majority (approximately 90%) of women using contraception are relying on modern methods, with the most widely used method being female sterilization (21%), followed by IUDs (14%) and oral contraceptives (7%). While oral contraceptives and condoms are the most widely used methods in developed countries, by contrast, female sterilization and IUDs are the most widely used methods in developing countries.

Contraceptive prevalence has been continually high in developed countries since the 1970s and has been increasing substantially over time in developing countries. The percentage of women who are married or in union and using contraception has increased by at least one percentage point per year since 1990 in over half (56%) of developing countries. However, despite the widespread availability and use of modern contraceptives, substantial unmet need remains. Of the estimated 705 million women aged 15–49 in developing countries, nearly 20% (137 million) who are at risk of unintended pregnancy and are not using any contraceptive methods; and a total of 201 million women in developing countries are estimated to have an unmet need for effective contraceptives.³ Unmet need remains particularly high in sub-Saharan Africa and South Asia.

Meeting the global unmet need for contraceptive services would result in preventing an estimated 52 million unintended pregnancies annually, which would, in turn, prevent 23 million unplanned births, 22 million induced abortions, 7 million spontaneous abortions, 1.4 million infant deaths, and 142,000 pregnancy-related maternal deaths—53,000 from unsafe abortions and 89,000 from other causes. Provision of the additional contraceptive services necessary to meet this need, at a cost of approximately \$3.9 billion per year, would prevent the loss of an estimated 27 million disability-adjusted life years.³

Worldwide, as many as 50% of all pregnancies are unplanned and 25% are unwanted.⁴ An estimated 50 million abortions are performed

TABLE 79-9. THE FIRST CENTURY OF FAMILY PLANNING IN THE UNITED STATES

Year	Event
1912	Margaret Sanger starts the birth-control movement in modern era
1916	The first family planning clinic opens in Brooklyn, New York
1925	First diaphragm is manufactured in the United States
1928	Ovulation timing is medically established
1920–1930	Margaret Sanger continues to open more clinics and to promote contraception; physicians gain the right to prescribe contraceptive methods; public hospitals begin to provide family planning services
1937	Family planning is supported by the American Medical Association
1942	Planned Parenthood Federation of America is established
1955	The first National Fertility Survey is conducted
1960	The FDA approves the first birth control pill (Enovid)
1962	The Population Council organizes the first international conference on IUDs
1965	The law prohibiting contraceptive use for married people is declared unconstitutional
1970	Title X of the Public Health Service Act, the nation's family planning program, is legislated
1972	Medicaid is authorized to fund family planning services
1973	Abortion is legalized by the Supreme Court (Roe vs. Wade)
1976	The FDA approves the first progesterone-releasing IUD (Progestasert)
1977	The Supreme Court rules that minors have a constitutional right to access contraception
1990	The FDA approves the first implantable contraceptive device (Norplant)
1992	The FDA approves Depo-Provera (progestin-only injectable contraceptive)
1992	The Supreme Court weakens abortion rights by allowing states to pass certain restrictions
1993	The FDA approves the female condom (Reality)
1997	The FDA approves the use of emergency contraception pills
2000	The FDA approves Lunelle (combined estrogen/progestin injectable contraceptive) and Mirena (levonorgestrel-releasing IUD)
2001	The FDA approves NuvaRing (combined estrogen/progestin contraceptive vaginal ring)
2002	The FDA approves Ortho-Evra (transdermal combined estrogen/progestin contraceptive patch) and removes Norplant from the market
2003	The FDA approves Seasonale (combined estrogen/progestin oral contraceptive for extended use)
2006	The FDA approves Implanon (etonogestrel releasing single implant system)

FDA—The Food and Drug Administration.

each year with approximately 19 million considered by the World Health Organization (WHO) to be unsafe. Approximately 55,000 unsafe abortions occur each day, resulting in the deaths of at least 200 women. These deaths, over 95% of which occur in developing countries, account for approximately 13% of all maternal deaths.⁵

The International Conference on Population and Development, held in Cairo in 1994, has been considered a watershed event with respect to the role of family planning. Whereas previous similar efforts and viewpoints had largely focused on the *population problem* and demographic targets, the Cairo conference highlighted the important role that family planning plays in the context of social and economic development and created a series of goals regarding sexual and reproductive health and rights, including family planning—with a focus on empowering women.⁶ In 2005, United Nations Population Fund (UNFPA) affirmed that reproductive health, which includes family planning, “is not solely a health issue, but a matter of economic development, social justice, gender equality, and human rights.”⁷

► FAMILY PLANNING IN THE UNITED STATES

Of the approximately 62 million women in the United States who are in their childbearing years, 43 million are sexually active and do not wish to become pregnant. Most women in the United States desire to have two or fewer children, and, to achieve this goal, most will require contraceptive protection for approximately three decades of their lifetimes. Among fertile, sexually active women who do not wish to become pregnant, 89% are estimated to be using a method of contraception.⁸ In 2002, among 38 million women using contraceptive methods in the United States, most were using oral contraceptives (30.6%), tubal sterilization (27.0%), male condoms (18.0%), or their partner's vasectomy (9.2%). Less frequently used methods included depot medroxyprogesterone acetate injections (5.3%), withdrawal

(4.0%), IUDs (2.0%), periodic abstinence (1.6%), and progestin implants (1.2%). The choice of contraceptive method varied by age, with women under age 30 most likely to be using oral contraceptives, and women over age 35 most likely to be using sterilization. The choice of methods also varied by race, with oral contraceptives being the most popular method among white women and sterilization being the most popular method among black and Hispanic women.⁹

Although highly effective contraceptive methods are widely available in the United States, and overall contraceptive prevalence is high, a large number of unintended pregnancies occur each year. In 1998, 48% of the pregnancies in the United States were estimated to be unintended.¹⁰ In 2000, an estimated 6.4 million pregnancies resulted in 4.1 million live births, 1.3 million induced abortions, and one million spontaneous abortions. The overall pregnancy rate in 2000 (104 pregnancies per 1000 women aged 15–44 years) was 10% lower than that in 1990, while the teenage pregnancy rate (84.5 pregnancies per 1000 women aged 15–19 years) was 27% lower.¹¹ Over half of the unintended pregnancies occur among women who do not use any method of contraception; the percentage of such women increased from 5.4% in 1995 to 7.4% in 2002.⁹

Contraceptive services in the United States are provided through both the public and private sectors. Public funding from the federal and state governments is primarily provided through Medicaid and the State Children's Health Insurance Program (SCHIP), which, together, covered services for 6.5 million women in 2002.¹² Medicaid, which provided 61% of public funding for family planning services in 2001,¹³ has been required to cover family planning services since 1972. While gaps in funding for family planning services remain for women without sufficient resources to pay for them, an increasing number of states have expanded Medicaid coverage through special initiatives that provide family planning services for women who would otherwise be ineligible for the broader Medicaid program.¹⁴ More than 7000 publicly funded clinics provide family planning services, and the

largest federal source of grants for such clinics is the Title X program, which was signed into law in 1970 and currently provides funds to over 4500 clinics.

In 2003, among 61.7 million women of reproductive age, only 65% had private insurance.¹⁴ Although contraceptive coverage has improved recently in such plans, important gaps in coverage remain. Only 21 states have laws requiring insurers to provide comprehensive coverage for contraceptives if they otherwise cover prescription drugs and devices. The Equity in Prescription Insurance and Contraceptive Coverage Act, which was proposed to Congress in 1997 but has not been enacted, would require such coverage nationally for FDA-approved contraceptives. Insurance for federal employees covers all prescription contraceptives, and most employer-based insurance plans (90%) cover prescription contraceptives.⁸ Currently, insurers are less likely to cover newer approved methods such as the combined hormonal patch and vaginal ring than they are to cover oral contraceptives.¹⁵

Overall, where do women obtain family planning services? The answer depends heavily on income. In 1995, 70% of women with family incomes that are one and one-half times or more than the established level of poverty who make a family planning visit see a private provider compared with 42% of lower income women. Teenagers are less likely to visit a private provider (42%) for family planning. By contrast, family planning clients of public and other nonprivate providers are largely poor; 63% have incomes below the established level of poverty.¹⁶

► CONTRACEPTIVE EFFECTIVENESS AND COST EFFECTIVENESS

In the United States, about half of all unintended pregnancies occur due to contraceptive failure.¹⁰ The effectiveness of contraceptives is assessed by measuring the number of unplanned pregnancies that occur during a specified period of exposure and use of a contraceptive method. Most methods have a low risk of failure if used perfectly, and this is why the most effective method for a woman is usually the method she or her partner can use correctly and consistently.

There are two methods commonly used for measuring contraceptive effectiveness: the Pearl Index and life-table analysis. The Pearl Index is defined as the number of failures per 100 woman-years of exposure. The denominator represents the number of months or cycles of exposure from the onset of a method until an unintended pregnancy, discontinuation of the method, or completion of the study. The quotient is multiplied by 1200 if the denominator consists of months or by 1300 if cycles. However, the Pearl Index does not allow accurate comparisons at different durations of exposure, as it is usually calculated for a 1-year period. Life-table (or survival) analysis, on the other hand, calculates the failure rate for each month of use. A cumulative failure rate at various durations of exposure, such as 12, 18, 24, or 36 months, can then be calculated to compare across methods.

Varying terms are used today to differentiate between contraceptive effectiveness with correct and incorrect use of the method. The best performance, based on correct and consistent use, is represented by the lowest expected failure rate, as compared to the usual experience, which includes both perfect and imperfect use, or a typical failure rate. Both the lowest expected and typical failure rates are determined in clinical trials, the former often measured among highly motivated subjects.

Contraceptive failure occurs for a number of reasons, such as imperfect method use, frequency of intercourse, and fecundity patterns and is conditioned by such user characteristics as age, parity, marital status, and education. For most contraceptive methods, failure rates decline with duration of use, primarily because the users who are relatively more fecund, have higher intercourse frequency, or are less compliant with method use protocols will fail earlier. Data from the 1995 National Survey of Family Growth were used to estimate the number of contraceptive failures that a typical woman would experience in her life-time if she continuously used contraception from age 15 to 45 (except for the time of pregnancy after a contraceptive failure). If a typical woman continuously used reversible contraceptive methods

over her reproductive lifetime, from ages 15 to 45, she would experience 1.8 contraceptive failures, whereas if she continuously used reversible methods and then sterilization, she would experience only 1.3 contraceptive failures.¹⁷

Contraceptive methods vary in effectiveness and in the determinants of effective use. While the effectiveness of some methods is highly dependent on proper use, the effectiveness of others is largely independent of the contraceptive user. Oral contraceptives, for example, are highly effective when used consistently and correctly, but substantially less effective when used typically. Other methods, such as intrauterine devices and progestin-only implants, are highly effective once they have been inserted properly. Trussell has estimated the effectiveness of contraceptive methods with perfect use and with typical use (which includes the experience of some who use the method consistently and correctly and others who do not).¹⁷ A 2004 cost-utility analysis found that all contraceptive methods resulted in cost savings and health gains (as measure by quality-adjusted life years) compared with nonuse of contraceptives.¹⁸

► MEDICAL GUIDELINES FOR CONTRACEPTIVE USE

WHO has published two sets of guidelines that address safe and effective contraceptive use. The *Medical Eligibility Criteria for Contraceptive Use*, first published in 1996, provides recommendations regarding the medical appropriateness of contraceptive method use for women with medical problems or other selected characteristics. The third edition, published in 2004 (<http://www.who.int/reproductive-health/publications/mec/index.htm>) provides over 1700 recommendations with each contraceptive method/condition combination classified as either category 1, 2, 3, or 4 (Table 79-10). The *Selected Practice Recommendations for Contraceptive Use* provides guidance on how to use contraceptive methods once they have been deemed to be medically appropriate. The second edition of these guidelines, published in 2005 (<http://www.who.int/reproductive-health/publications/spr/index.htm>), provides guidance on clinical management issues that frequently arise in the provision of contraceptive services.

Combined Oral Contraceptives

Oral contraceptives containing estrogens and progestins were first approved for use in the United States in 1960. The amount of estrogen and progestin used in combined oral contraceptives (COCs) has decreased substantially since that time, and the great majority of COCs that are prescribed currently contain 35 µg or less of ethinyl estradiol in combination with a progestin. COCs are either monophasic or multiphasic preparations with the former providing the same dose of hormones throughout the cycle and the latter providing varying doses. COCs are highly effective when taken properly, but 29% of COC users reported in the 1995 National Survey of Family Growth that they missed at least one pill in the prior 3 months of use.

Health Benefits. The short- and long-term effects of COCs have been studied more thoroughly than those of any other drugs currently prescribed. On balance, most studies show that they are safe for the great majority of users. In fact, studies attempting to identify potentially harmful effects of oral contraceptives have documented important noncontraceptive health benefits. COCs have been found to reduce menstrual blood flow and dysmenorrhea and to lower the prevalence of iron deficiency anemia. Oral contraceptive users have a reduced risk of endometrial and ovarian cancers (Table 79-11). This protection is conferred after a minimum of 12 months of use and persists for long after discontinuation of use.¹⁹⁻²¹ Women with acne, hirsutism, and endometriosis may experience improvements. Monophasic COC users also have a reduced risk of functional ovarian cysts but this benefit does not appear to pertain to low-dose multiphasic preparations. Several studies have suggested that COCs may protect women against colorectal cancer; but this potential benefit requires further study. In a meta-analysis of published data, the pooled relative risk of colorectal cancer for COC ever-use was 0.82

TABLE 79-10. WHO MEDICAL ELIGIBILITY CRITERIA FOR CONTRACEPTIVE USE

WHO Category	Interpretation When Clinical Judgment is Available	Interpretation When Clinical Judgment is Limited	Example (Women with Headaches Who Want to Initiate Use of COC)
Category 1 There is no restriction for the use of the contraceptive method.	Use the method in any circumstance		Nonmigrainous headaches
Category 2 The advantages of using the method generally outweigh the theoretical or proven risks.	Generally use the method	YES (Use the method)	Migraine headaches without aura Age < 35
Category 3 The theoretical or proven risks usually outweigh the advantages of using the method.	Use of the method not usually recommended unless other more appropriate methods are not available or acceptable	NO (Do not use the method)	Migraine headaches without aura Age ≥ 35
Category 4 The condition represents an unacceptable health risk if the contraceptive method is used.	Method should not be used		Migraine headaches with aura Any age

Source: WHO. *Medical Eligibility Criteria for Contraceptive Use*. 3rd ed. Geneva; 2004

(95% confidence interval (CI) = 0.74, 0.92). The protection was stronger for those who had used COCs within the previous 10 years.²²

Health Risks. Despite its protective effects, use of the pill is not without risk.

Oral Contraceptives and Venous Thromboembolism. Low-dose COCs are associated with an increased risk of venous thromboembolism (VTE).²³ Most studies report that past users have no increased risk and the increased risk appears attributable to current oral contraceptive use.

The use of COCs with second-generation progestins (levonorgestrel or norethisterone) is associated with a three to four-fold higher risk for VTE compared with nonusers, which is, nevertheless, substantially lower than the risk of VTE during pregnancy. When COCs with third-generation progestins (desogestrel or gestodene) are used, the risk of VTE appears to be about 1.5–1.8 times greater than that for users of formulations containing levonorgestrel,²⁴ although the extent to which this is the case remains controversial.

The presence of V Leiden factor mutations or protein S or C abnormalities significantly increases the risk of VTE in COC users—from 6 to 40 times higher than in nonusers without thrombophilia.²⁴ Routine screening for thrombogenic mutations in all COC users, however, is not considered necessary because of the rarity of these conditions.

Oral Contraceptives and Myocardial Infarction. Although studies of older, higher dose COCs found an increased risk of myocardial infarction and ischemic stroke, more recent studies of currently available low-dose COCs have been inconsistent, with some reporting no increase and others reporting up to a two- to fivefold increase

in risk.²⁴ A higher prevalence of women with risk factors for cardiovascular disease in the latter studies may explain the discrepancy.²⁴ Women who smoke and use COCs have an increased risk of death from cardiovascular disease.²⁵ For women under 35 years of age, the attributable risk of myocardial infarction for smokers who use COCs (35 per million woman-years) is tenfold greater than that for non-smokers who use them (3 per million woman-years). For women over 35 years of age, the comparable attributable risks of myocardial infarction for women who smoke and who do not smoke are 396 per million woman-years and 31 per million woman-years, respectively (as seen in Table 79-12).²¹ The use of low-dose COCs by healthy women does not appear to increase the risk of hemorrhagic stroke.²⁴

Oral Contraceptives and Liver Cancer. There is controversy regarding the relationship between COC use and development of liver cancer (hepatocellular carcinoma).^{26,27} The large Multicentre International Liver Tumor Study (MILTS) found no overall increase in risk or effect of duration of use; the only increase seen was in a small subgroup of women with negative serology for hepatitis B or C viruses and no history of cirrhosis. Any increase in the risk of COC use among this group of women at inherently very low risk of liver cancer would

TABLE 79-11. REDUCED INCIDENCE OF ENDOMETRIAL AND OVARIAN CANCER AFTER ORAL CONTRACEPTIVE USE

Cancer Type	Reduced Incidence after COCs Use For			
	4 years	8 years	12 years	p-value
Endometrial cancer	56%	67%	72%	p<0.0001
Ovarian cancer	41%	54%	61%	p<0.0001

result in a very small absolute increase in risk (an estimated one extra case per 1.5 million women-years of use in Germany).²⁸

Oral Contraception and Breast Cancer. Despite more than 60 studies on the subject, the relationship between use of oral contraceptives and the risk of breast cancer remains controversial. A 1996 pooled analysis²⁹ of 54 studies conducted in 25 countries that included 53,297 women with breast cancer and 100,239 women without breast cancer had four main findings. First, current or recent (within 10 years of stopping use) pill users had a small increase in risk of having breast cancer diagnosed (for current versus nonusers, RR was 1.24; 95% CI = 1.15–1.33). The increase for current users was seen for women with little pill use (less than 1 year) and did not increase with increasing durations of use.³⁰ Second, past users (10 or more years after stopping use) had no increased risk. Third, the additional cancers identified were less advanced clinically than those in never users. Fourth, no subgroups of women were at increased risk for pill use. In particular, women with a family history of breast cancer were not at additional risk from pill use relative to women without such a history. These four findings suggest that either oral contraceptive users are more likely than nonusers to have existing breast cancers detected; that existing tumors are identified at an earlier stage in pill users; or that pill use accelerates tumor growth.

By contrast, a 2002 U.S. study, which involved 4575 women with breast cancer and 4682 controls, concluded that among women 35–64 years of age, current and previous COC use was not associated with significantly increased risk of breast cancer; the relative risk did not increase consistently over longer periods of use or with higher doses of estrogen.³¹ Other recent studies have shown that the presence of inherited susceptibility to breast cancer or women who are carriers of BRCA1 or BRCA2 gene mutations have an increased risk of developing breast cancer during their life span.³² Moreover, women who are BRCA1 gene mutation carriers and users of high-dose COCs for more than 5 years before age 30 years are at high risk of being diagnosed with breast cancer before turning age 40.³³

The influence of progestogen-only pills on a woman's risk of breast cancer has been less well studied, but the limited available evidence suggests a similar effect to that for COCs. A national population-based case-control study in New Zealand found the relative risk of breast cancer in women who had used progestogen-only pills to be 1.1 (CI 95% = 0.73, 1.5), with recent users (within 10 years) having a higher risk and past users having no increase in risk.³⁴

Oral Contraceptives and Cervical Cancer. The relationship between pill use and cervical cancer continues to be controversial. Observational studies of this relationship are difficult to interpret because of biases related to sexual behavior and the failure to control for the presence of the human papilloma virus (HPV) in most studies. Recently, a study carried out by the WHO's International Agency for Research on Cancer (IARC) found that prolonged use of COCs increased the risk of cervical cancer up to three times in women with HPV infection who had taken oral contraceptives for 5–9 years and up to 4 times in women with HPV infection who had taken oral contraceptives for more than 10 years.³⁵

WHO Recommendations. The WHO has recommended that women with the following conditions not use COCs: (a) breastfeeding in the first 6 weeks postpartum; (b) smoking more than 15 cigarettes per day and being age 35 or over; (c) multiple risk factors for arterial cardiovascular disease; (d) hypertension—more than 160/100 mmHg; (e) vascular disease; (f) a history or current deep venous thrombosis or pulmonary embolism; (g) following major surgery with prolonged immobilization; (h) known thrombogenic mutations (factor V Leiden, prothrombin mutation, protein C and S, and antithrombin deficiencies); (i) stroke; (j) complicated valvular heart disease; (k) migraine-headaches with aura at any age or without aura in women over age 35; (l) current or personal history of breast cancer; (m) diabetes with severe vascular complications of more than 20 years duration; (n) active viral hepatitis; (o) decompensated cirrhosis; or (p) benign or malignant liver tumors.³⁶

In 2003, the Food and Drug Administration approved Seasonale, a combined estrogen/progestin oral contraceptive for extended use. It involves a 91-day treatment cycle resulting in four menstrual periods per year if taken continuously. Menstruation occurs when the seven inert pills are taken within each cycle. Increased bleeding or spotting between periods may be expected, as compared to the standard 21- or 28-day birth control pill cycle, but tends to decrease with prolonged use.

Combined Injectable Contraceptives

Injectable contraceptives containing both an estrogen and progestin provide an alternative for women who are candidates for combined oral contraception but do not want to take a pill daily. None are currently marketed in the United States. The method is highly effective (Fig. 79-1), but the user must return for injection every 30 days. The advantages of the monthly injection over the three-month, progestin-only formulation are a more rapid return to fertility upon discontinuation and more acceptable bleeding patterns while using the method.³⁷

Health Effects. The method often causes changes in menstrual bleeding patterns during the initial three cycles of use, but after 6 months of use, most women report regular, acceptable bleeding patterns.³⁸ Only 1% of users in the U.S. trial reported amenorrhea after the first month and 4% at 60 weeks of continuous use, results that are in contrast with the high frequency of amenorrhea associated with the use of depot medroxyprogesterone acetate (DMPA) (50% after 1 year of use).^{39,40} Weight gain is the leading cause of method discontinuation in U.S. trials. Long-term health effects have not been studied but are assumed to be similar to those of COCs.

Transdermal Patch

A combined hormonal transdermal patch was approved by the FDA in 2002. It is a 20-cm² system that releases 150 µg of norelgestromin and 20 µg of ethinyl estradiol daily. It is worn for 7 days, replaced with another patch for each of two consecutive additional 7-day periods, and then followed by a fourth patch-free week, during which time the woman has withdrawal menstrual bleeding. Data suggest that the use of this preparation may improve compliance relative to the daily pill taking required for proper use of COCs.⁴¹ Clinical trials suggest that women who weigh more than 90 kg may have a higher likelihood of contraceptive failure than women weighing 90 kg or less.⁴²

Health Effects. The side-effect profile is similar to that for COCs; although nausea and mild breast discomfort were found to be more likely to occur in women using the patch than among those using the

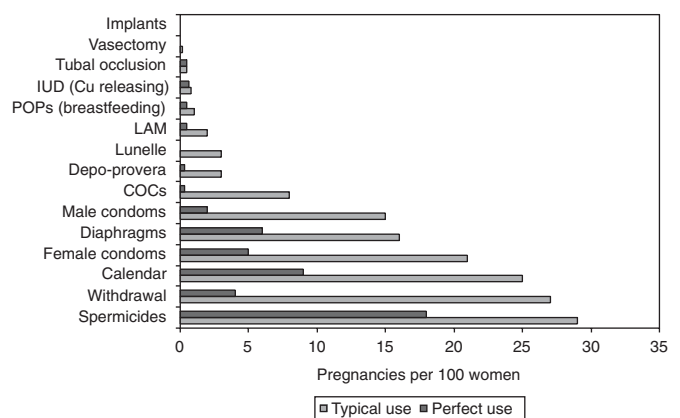

Figure 79-1. Unintended pregnancy rate during the first year of use by contraceptive method used: United States. Rate is pregnancies per 100 women. (Source: Adapted from Trussell J. *Contraceptive failure in the United States*. Contraception. 2004;70:89–96.)

pill; a statistically significant difference was shown only in cycles 1 and 2.⁴³ Most skin reactions after patch application are mild. In early clinical trials reported to the FDA, about 2% of women withdrew from the trials because of patch irritation and about 5% had at least one patch that did not stay attached. Long-term health effects have not been assessed and are presumed to be similar to those for COCs; recent reports have raised questions regarding whether the patch carries a greater risk of VTE than COCs, but this aspect is unresolved.

Vaginal Ring

A combined hormonal vaginal ring was approved by the FDA in 2001. It is a light-weight, 2-inch diameter, flexible ring made of ethylene vinyl acetate copolymer. The ring releases 120 µg of etonogestrel and 15 µg of ethinyl estradiol daily and is worn for 21 days, followed by 7 ring-free days during which menstruation occurs. A new ring is inserted at the end of each 28-day cycle. The method is highly effective¹⁷ (Figure 79-1). In a one-year multicenter study of over 2000 ring users, more than 90% indicated that the device was easy to insert and to remove.⁴⁴

Health Effects. Problems such as vaginal discomfort, vaginal discharge, or vaginitis have been reported in 2–5% of European women using the vaginal ring.⁴⁵ The expulsion rate is about 2%.⁴⁶ In a one-year, randomized trial that compared approximately 500 ring users to approximately 500 COC users, 71% in each group completed the trial. The groups had similar rates of reported side effects but the ring group reported more cases of vaginitis and leukorrhea. A total of 5% of ring users reported ring-related problems, including expulsion and interference with intercourse.⁴⁷ Long-term health effects have not been assessed and are presumed to be similar to those for COCs.

Progestin-Only Contraceptives

Progestin-only pills (POPs) are less popular than COCs, but they are suited for women who have contraindications for COCs (e.g., history of thrombosis, hypertension, or migraine headaches). They may be used by breastfeeding women who want an oral contraceptive, and their action is rapidly reversed soon after discontinuation. Ovulation is less reliably prevented with POPs as compared with COCs, and these so-called “mini-pills” may be less effective than COCs, particularly if pills are missed.

Health Effects. The mini-pills have no estrogen-related risks, and overall, fewer and less serious complications when compared to COCs. The most common side-effects are changes in menstrual bleeding, especially irregular bleeding, intermenstrual bleeding and spotting, and amenorrhea. As for all progestin-only contraceptives, menstrual abnormalities are a major reason for discontinuation of use. The non-contraceptive benefits of POPs have not been as well studied as those for COCs, and the extent to which the benefits documented for COC use pertain is unclear.

Implantable Contraception

The FDA has approved two levonorgestrel implants; one, a set of six silicone elastomer capsules, was approved in 1990 and marketed for approximately 10 years in the United States as Norplant. The other implant, approved in 1996, is a set of two silicone elastomer rods (Jadelle). Neither implant is currently available in the United States. Both implants are highly effective. The former implant (Norplant), although approved for 5 years of use, may be effective for up to 7 years of use. The effectiveness of this implant after 5 years is dependent on body weight; women weighing 70 kg or more at insertion or follow-up should be counseled regarding decreased effectiveness after 5 years (women weighing 80 kg or more should seriously consider having the implants removed after 4 years of use). The latter implant (Jadelle) is approved for only 5 years of use and is effective for a maximum of 5 completed years depending on body weight; women weighing 80 kg or more should also consider having the implants removed after 4

completed years of use.⁴⁸ A single implant system (Implanon) has been developed that consists of a nonbiodegradable rod that releases the progestin, etonogestrel. It has been approved for 3 years of use in the European Union and was approved for 3 years of use by the FDA in 2006. At insertion, the implant releases approximately 60–70 µg of etonogestrel daily, with approximately 25–30 µg per day being released by the end of the third year. This implant is highly effective in suppressing ovulation.

Health Effects. The main side effect of all available progestin-only implants is menstrual abnormalities. The great majority of women using a levonorgestrel implant will experience prolonged menstrual bleeding and intermenstrual spotting initially; by 5 years, most have regular bleeding, but a substantial minority will continue having irregular bleeding. By contrast, in the first 3 months of use of the etonogestrel implant, about 30% will have prolonged bleeding and 30–40% will become amenorrheic.⁴⁹ The rate of prolonged bleeding decreases thereafter, but the rate of amenorrhea persists. A review of 55 observational studies⁵⁰ provides evidence for the safety of these implants. While data regarding cardiovascular disease and cancer risks are limited, the available data find that, overall, implant users have no higher rates of major adverse outcomes than nonusers.⁵⁰

Injectable Contraception

In 1992, the FDA approved the use of injectable DMPA, marketed in the United States as Depo-Provera. When injected every 3 months, 150 mg of DMPA provides a high degree of protection from pregnancy—similar to that of the progestin-only implants and tubal sterilization.

Health Effects. The main side effects of DMPA use are menstrual abnormalities, with most users becoming amenorrheic over time (55% of women by the end of the first year of use).^{51,52} In contrast to progestin-only implants, there is a delayed return to fertility with discontinuation of DMPA use, estimated at about 4 months longer than for women using combined oral contraceptives. Delays in return to fertility of up to 18 months have been reported.⁵¹ Another progestin-only injectable contraceptive that is not currently available in the United States contains norethisterone enantate (NET-EN) and is administered every 2 months.

Findings among beagle dogs led to initial concerns regarding the possibility that use of DMPA may increase breast cancer risk. However, findings from a pooled analysis of data from the WHO and from New Zealand⁵³ are reassuring. Overall, women who ever used DMPA had similar breast cancer risks as women who never used DMPA. However, the pattern of use made a difference; recent users of DMPA (use within 5 years) had an increased risk of breast cancer diagnosis, while past users (use more than 5 years previously) had no increased use.

DMPA use creates a hypo-estrogenic state that results in a decrease in bone mineral density in some women. This effect appears at least largely reversible, as bone mineral density increases again when DMPA is discontinued. The effect on fracture risk for most women is expected to be small. However, it remains unclear whether use of DMPA among adolescents prevents potential attainment of peak bone mass and whether older women who reach menopause while using DMPA experience a recovery in bone mineral density before the marked bone loss associated with menopause occurs. Other contraceptive options should be considered for women at risk for osteoporosis.⁵⁴

Intrauterine Devices

Intrauterine devices (IUDs) are used by nearly 160 million women worldwide—making them the most popular nonpermanent method of contraception. In China, Egypt, and Uzbekistan, the IUD is the most popular form of contraception, accounting for upwards of two-fifths of all use.² By contrast, only 2% of women using contraception in the United States were using IUDs in 2002.⁵⁵

IUDs declined markedly in popularity during the 1980s in the United States after reports of pelvic infections associated with the Dalkon Shield—a device marketed in the 1970s which was later withdrawn from the market. Subsequently, studies in the late 1980s and 1990s showed that women at low risk of sexually transmitted diseases were at low risk for pelvic infections with use of IUDs. By that time, however, manufacturers had voluntarily stopped selling most types of IUDs in the United States, largely because of low profits and high costs of litigation. In 1989, a new copper IUD, the Copper T380A (Para-Gard), was introduced to U.S. markets, and in 2000, the levonorgestrel-releasing intrauterine system (Mirena), which releases approximately 20 µg of levonorgestrel per day, was approved by the FDA.

Both intrauterine contraceptives available in the United States are highly effective (Fig. 79-1). The copper IUD is approved for 10 years of use, but data suggest that the device remains effective for at least 12 years—with a cumulative 10-year failure rate of 2.1–2.8%.⁵⁴ The levonorgestrel-releasing intrauterine system is approved for 5 years and has a cumulative 5-year failure rate of 0.7%.⁵⁶

Health Effects. Although pregnancy rates are very low for IUD users, women who do become pregnant have a greater risk of ectopic pregnancy (5–8% of failures with the copper IUD are ectopic pregnancies), preterm labor, or spontaneous, septic abortion of an intrauterine pregnancy.^{46,57} The absolute risk of ectopic pregnancy is very low, however, approximately 1 per 1000 woman-years. The previous use of an IUD does not increase the risk of an ectopic pregnancy, and one WHO multicenter study has shown that women using IUDs are 50% less likely to have an ectopic pregnancy when compared to women using no contraception.⁵¹

The main side effects of both types of IUDs are menstrual abnormalities. The copper IUD is more likely to cause heavy and prolonged bleeding as well as intermenstrual spotting and dysmenorrhea, while the levonorgestrel intrauterine system is more likely to result in a reduction in menstrual blood loss over time. By 12 months of use, 20–60% of women using the levonorgestrel-releasing intrauterine system will become amenorrheic.⁵¹

Modern IUDs carry low risks of PID and infertility among women at low risk of sexually transmitted infections (STIs). WHO has summarized data from 12 randomized studies and one nonrandomized study and concluded that IUD users selected for low risk of STIs have little, if any, excess risk of PID. The overall rate of PID following 22,309 IUD insertions was 1.6 cases per 1000 woman-years of use. The risk of PID was highest (by greater than sixfold) during the first 20 days after insertion; after that time, the risk of PID was consistently low for up to 8 years of use.⁵⁸ The use of prophylactic antibiotics prior to IUD insertion appears not to reduce this low insertion-associated risk among women at low risk for STIs.⁵¹ At least three observational studies have found no association between copper IUDs and the risk of infertility among nulligravid women at low risk for STIs.^{59–61}

Although uterine perforation can occur with IUD insertion, this risk is low when proper techniques are used—at rates of approximately 1–2 perforations per 1000 insertions.⁵⁶

WHO Recommendations. The WHO has recommended that women with the following conditions not have IUDs inserted: pregnant women, those developing postpartum or postabortion sepsis, those with an active pelvic infection, including purulent cervicitis, those with known or suspected gonorrhea or chlamydial infection, and those with uterine or cervical malignancy.³⁶

Mechanical Barrier Methods and Spermicides

The male latex condom is proven to be highly effective for preventing both unintended pregnancy (Fig. 79-1) and HIV infection when it is used consistently and correctly;⁶² inconsistent use, by contrast, is not a reliable prevention strategy for either purpose. Breakage rates of male latex condoms in the United States are low (about 2 condoms per 100 used).¹⁷ Studies of the polyurethane female condom (approved by the FDA in 1993) and polyurethane male condom are

less complete, but they are expected to provide substantial protection against both pregnancy and HIV infection as well, when used consistently and correctly. Vaginal diaphragms—cervical caps—and spermicidal creams, foams, gels, films, and suppositories are also available as barrier contraceptive methods. All barrier contraceptives require substantial user motivation, and success in their use will be determined not only by motivation but also by user experience and skill. For example, perfect use of male condoms is associated with a pregnancy rate of about 2% in the first 12 months of use, which is lower than that for typical use of oral contraceptives (8%)—but typical condom use has a substantially higher failure rate (15%) than typical oral contraceptive use. Spermicides, when used alone, are the least effective barrier method and have a relatively high failure rate (15% in the first 12 months of use), even with perfect use.¹⁷

Health Effects. The risks associated with the use of barrier methods of contraception include primarily the risk of unintended pregnancy and minor side effects associated with the method. These complaints include vaginal or penile irritation by spermicides and discomfort from a diaphragm that is too large. True, allergic reactions to latex male condoms or cervical caps are uncommon, but they can occur.⁴⁶ Diaphragm and spermicide users have an increased risk of urinary tract infections compared with women who do not use contraceptives, and diaphragm and cervical cap users have a relative increased risk of toxic shock syndrome,⁶³ which can be reduced by leaving a diaphragm in for no longer than 24 hours and a cap in for no longer than 48 hours. The absolute risk of toxic shock syndrome associated with use of the cervical cap or diaphragm is small.

While it was once hoped that use of spermicidal preparations containing nonoxynol 9 would reduce the risk of HIV infection, it is now clear that no such protection is offered. In fact, studies suggest that frequent use of spermicides may enhance the risk of acquiring HIV infection. Although one report raised concerns about a possible link between spermicide use and the risk of congenital defects, several larger and better designed studies demonstrated no association.²³

Fertility Awareness-Based Methods

The risk of an unintended pregnancy per each coital act is 17–30% in midcycle and less than 1% during menses.⁵¹ Natural family planning methods, known as fertility-awareness-based methods, are based on the observation of signs and symptoms of the woman during her fertile phase. These methods include both calendar-based method and symptoms-based methods. The calendar-based methods include the Calendar Rhythm Method and the Standard Days Method; the symptoms-based methods include the Cervical Mucus Method, the Symptothermal Method, and the Two Days Method. These methods use information to estimate the period of fertility (the *fertile window*) during which time intercourse should be avoided. Clearly, the effectiveness of fertility awareness-based methods depends heavily on the willingness and ability of couples to use the methods consistently and correctly. Even with perfect use, these methods are complicated by difficulty in reliably estimating the fertile window.

Lactational Amenorrhea Method

On a worldwide scale, more births are prevented by breastfeeding than by any other method of contraception. Further, breastfeeding has important health benefits for the infant and the mother. The lactational amenorrhea method (LAM) is highly effective for women who are (a) amenorrheic; (b) fully or nearly fully breastfeeding; or (c) less than 6 months postpartum. While there is no known negative impact on a woman's health to using LAM, certain conditions may impact the appropriateness of using this method, including maternal HIV infection, medications used during breastfeeding, and certain conditions affecting the newborn.³⁶ Breastfeeding is not recommended for women using certain drugs that may harm infant health, and some infants may have disorders that make breastfeeding difficult

or inappropriate.³⁶ For most women and most infants, however, LAM is safe for both mother and infant, and highly effective.

Emergency Contraception

Emergency contraception involves the use of POPs, combined estrogen and progestin pills, or copper IUDs to prevent pregnancy shortly after unprotected intercourse. The most common POP regimen is the use of 1.5 mg of levonorgestrel, which is administered as a single dose or as two 0.75 mg pills given separately—one taken as soon as possible after unprotected intercourse and the other taken 12 hours after the first pill. The most common combined estrogen-progestin regimen is the use of two doses of pills, taken 12 hours apart, with each dose consisting of 100 µg of ethinyl estradiol and 0.5 mg of levonorgestrel. The combined regimen is highly effective, reducing the risk of pregnancy by at least 74%.⁶⁴ The levonorgestrel-only regimen appears to be even more effective and results in fewer side effects.⁶⁵ Use of emergency contraceptive pills will not disrupt a pregnancy after implantation has occurred. The effectiveness of emergency contraceptive pills decreases substantially over time after unprotected intercourse. Thus, when used, they should be taken as soon as possible after unprotected intercourse, ideally within 72 hours. The regimen appears to continue to provide at least some benefit when the first dose is taken up to 120 hours after intercourse.

For women who are otherwise appropriate candidates for IUD use, and particularly for those desiring ongoing use of an IUD, the copper IUD is highly effective in reducing the risk of pregnancy when inserted within 5 days of unprotected intercourse. If an IUD is inserted more than 5 days after ovulation, it may disrupt an established pregnancy. Approved regimens for emergency use of oral contraceptives are listed in Table 79-13.

Health Effects. The most common side effects of emergency contraceptive pills include nausea and vomiting and irregular vaginal bleeding. Nausea and vomiting occur less frequently with the levonorgestrel-only regimen than with the combined regimen. Less frequent side effects include breast tenderness, headache, and abdominal pain.

Sterilization

Surgical sterilization is estimated to be the most prevalent form of contraception in the world. Globally, approximately 180 million women and 43 million men have undergone tubal sterilization and

vasectomy, respectively. In 2002, 27% of U.S. women aged 15–44 reported having had a tubal sterilization, while 9% of them reported that they relied on their partner's vasectomy for contraception.⁵³

Female Sterilization

Approximately half of tubal sterilizations in the United States are performed in the immediate postpartum period by partial salpingectomy⁶⁶ with most of the remainder being performed at a time unrelated to pregnancy via laparoscopy by application of coagulating current or mechanical clips or bands. Although most laparoscopic sterilizations in the United States are performed using general anesthesia, local anesthesia can also be used and carries lower anesthetic risks. A new tubal occlusion device that is placed hysteroscopically was approved by the FDA in 2002. Findings from the U.S. Collaborative Review of Sterilization—a large U.S. multicenter cohort study confirm that tubal sterilization is highly effective. Nevertheless, pregnancies occur more often than previously thought and can occur many years after the procedure.⁶⁷ The 10-year cumulative probability of pregnancy was highest among women having sterilization by spring clip application (36.5 per 1000 procedures). Women sterilized at a young age (age 18–27) were 2.7 times as likely to become pregnant as women sterilized at older ages (age 34–44). This may be due to younger women being more fecund and remaining fecund for a longer period than older women. Among women sterilized at a young age, the 10-year cumulative probability of pregnancy was nearly 5.0% with two methods (54.3 per 1000 for bipolar coagulation and 52.1 per 1000 for spring clip application).

In the unlikely event of pregnancy after tubal sterilization, there is a substantial increased risk of ectopic gestation. In the U.S. Collaborative Review of Sterilization, the proportion of pregnancies that were ectopic ranged from 65% (bipolar coagulation) to 15% (clip application), with the overall proportion increasing with time since sterilization (61% in years 4–10 after sterilization compared with 20% in years 1–3). The absolute risk of ectopic pregnancy after sterilization was low (7.3 per 1000 procedures), however, with a range from 1.5 to 17.1 per 1000 procedures, depending on the method of occlusion.⁶⁸ Since ectopic pregnancies occurred in the study as late as the tenth year after sterilization, women of childbearing age who have signs or symptoms of ectopic pregnancy should be evaluated even if they had a tubal sterilization in the distant past.

Health Effects. The risk of dying from tubal sterilization in the United States is estimated to be one to two deaths per 100,000 procedures.^{51,69} Complications from general anesthesia are the leading cause of death. Major complications from tubal sterilization are uncommon but may occur in as many as 1–2% of procedures. In the U.S. Collaborative Review of Sterilization, unintended major surgery after laparoscopic sterilization occurred in 0.9% of procedures and rehospitalization occurred in 0.6%. Risk factors for these complications included diabetes, general anesthesia, previous abdominal or pelvic surgery, and obesity.⁷⁰

While the existence of a so-called *post-tubal syndrome* of menstrual abnormalities has been debated since the early 1950s, most recent findings argue strongly against any such syndrome.⁷¹ In the U.S. Collaborative Review of Sterilization, women at 5 years after sterilization were no more likely to have a syndrome of menstrual abnormalities than women whose husbands underwent vasectomy.⁷²

Sterilization is intended to be permanent, and most women remain satisfied with their decision to have the procedure. However, regret at having undergone tubal sterilization is not rare, with women sterilized at a young age more likely to express later regret, regardless of the number of children they had at the time of sterilization.⁷³ In the U.S. Collaborative Review of Sterilization, the 14-year cumulative probability of requesting information about reversal was 40% among women aged 18–24 at sterilization.⁷⁴

Male Sterilization

Most vasectomies are performed with either the no-scalpel technique (a small puncture) or through an incision under local anesthesia, using any of a series of available vas occlusion techniques. Most studies of

TABLE 79-13. APPROVED REGIMENS FOR ORAL CONTRACEPTIVE USE AS EMERGENCY CONTRACEPTION

Trade Name	Formulation per Dose	Pills per Dose
Plan—B	0.75 mg of levonorgestrel	1
Ovrette*	0.75 mg of levonorgestrel	20
Preven†	100 µg of ethinyl estradiol	2
Ovral*, Ogestrel†	0.50 mg of levonorgestrel	5
Alesse, Levlite, Aviane, Lessina	100 µg of ethinyl estradiol	5
Nordette, Levlen, Levora	0.50 mg of levonorgestrel	4
Portia, Seasonale, Lo/Ovral*	120 µg of ethinyl estradiol	4
Low-Ogestrel*, Cryselle*	0.60 mg of levonorgestrel	4
Triphasil, Tri-Levlen	120 µg of ethinyl estradiol	4
Trivora, Enpresse	0.50 mg of levonorgestrel	4

*The progestin is norgestrel, which contains two isomers, only one of which is bioactive (levonorgestrel); the amount of norgestrel in each tablet is twice the amount of levonorgestrel.

†Since 2004, Preven is no longer manufactured.

the effectiveness of vasectomy are case series done by individual physicians or institutions; they do not allow for a comparison of the methods of vas occlusion. Such studies report failure rates of approximately 0.15% (Fig. 79-1),¹⁷ but the long-term effectiveness of vasectomy is less well studied than that for tubal sterilization. The risk of vasectomy failure is likely to vary by vasectomy technique. The risk of pregnancy after vasectomy can be reduced by avoiding unprotected intercourse until semen analysis, performed at 3 months or more after the procedure, has demonstrated vasectomy effectiveness.

Health Effects. The risk of death attributable to vasectomy is extremely low and clearly lower than that for tubal sterilization. Major morbidity is also uncommon. Although as many as 50% of men may experience minor complications, such as swelling of the scrotal tissue, bruising, and pain, these generally subside without treatment within 1–2 weeks after vasectomy.⁷⁵ Hematoma formation and infection occur much less frequently (each in less than 5% of procedures) and generally are not serious.

The long-term health effects of vasectomy are now well characterized. After studies in monkeys suggested a possible increase in risk of cardiovascular disease, numerous epidemiological investigations in men found that vasectomy does not increase the risk of atherosclerosis, myocardial infarction, coronary heart disease, or all-cause mortality.^{51,76}

Although several studies in the early 1990s found an association between vasectomy and risk of prostate cancer, more recent studies provide strong evidence against any causal association.^{77,78} Questions remain regarding a possible post-vasectomy pain syndrome. Small surveys with low response rates and no comparison groups have reported rates of chronic epididymal, scrotal, or testicular pain in 2–15% of men after vasectomy.⁴⁹ By contrast, The Health Status of American Men Study found a very low rate of epididymitis-orchitis at 12 months after vasectomy (24.7 per 10,000 person-years), which was approximately twice that for men who did not have a vasectomy (13.6 per 10,000 person-years).⁷⁹

► CONCLUDING COMMENTS

If the prediction that there will be no fundamentally new approaches to family planning in the foreseeable future materializes, then individuals will be making choices about family planning from among existing options for some time. The health effects of contraceptive use have been studied far more extensively than most medical interventions, and the bottom line is clear—for most healthy women, the use of any method of contraception will be safer than the use of no contraceptive method. While some contraceptive methods require more effort to use properly than others, it is evident that consistent and correct use of contraceptives will maximize effectiveness and minimize side effects. It is also clear that the better informed people are about how best to achieve their reproductive intentions, the more likely they are to be able to do so.

Helping individuals achieve their reproductive intentions will have profound effects on fertility, health, and society. Family planning can influence health by (a) permitting a woman to bear children at an age when the risk of health problems to her and her offspring is lowest; (b) permitting a couple to choose the number of children they wish to have; (c) permitting a couple to decide the spacing of their children; and (d) providing safe and effective measures of family planning that are part of a service program that includes information, education, and comprehensive preventive health services.

The risk of health problems during pregnancy increases with age and with the number of pregnancies. The use of family planning enhances both maternal health and infant health by permitting women to delay the birth of their first child and to avoid childbearing in their later reproductive years, if so desired. Linked birth and infant death records in the United States show higher infant mortality rates for young mothers (ages 10–14) and for women in their later reproductive years (ages 35 and older). In addition, the risk of infant death is lowest for infants of second and third birth order, and highest for

infants of birth order five and greater.⁸⁰ Birth spacing influences survival during the neonatal and postneonatal periods and throughout the years before the fifth birthday.

In sum, family planning has a major impact on the health of individuals, families, and society. Major progress has been made over the last several decades in helping individuals to achieve their reproductive intentions, but there is substantial room for improvement. Continued progress will benefit both individual and public health.

Injury Control: The Public Health Approach

Corinne Peek-Asa • Erin O. Heiden

► INTRODUCTION

Injuries are a focus of public health practice because they pose a serious health threat, occur frequently, and are in most situations preventable.¹ Preventing traumatic injuries and controlling their severity offer a cost-effective approach to improve the health status of populations. Injuries are a very broad group of afflictions, arising from many different activities and risk factors, and can affect all organ systems of the body. Since injuries are so diverse in mechanisms of occurrence, formulating an organized and structured approach to studying their incidence and prevention is helpful.

Injuries affect people of all ages and range from minor cuts and bruises to major catastrophes that take thousands of lives. Some injuries may result in prolonged pain or lifelong disabilities that restrict an individual from performing personal, recreational, or work-related activities. Serious injuries affect more than the individual: they can destroy families and devastate communities as seen in recent earthquakes, hurricanes, and tsunamis. These events can leave individuals and societies with enormous medical costs, extensive rehabilitation needs, major lifestyle adjustments, and depression—losses that cannot easily, if ever, be recouped.

However, the majority of injuries do not occur as a result of a catastrophic disaster; they are usually related to the activities of everyday life. For example, the annual number of deaths from motor vehicle crashes in the United States far exceeds that from airline crashes and natural disasters combined. Injuries disproportionately affect the young, the frail, and underserved populations. Because injuries disproportionately affect children and adolescents, they account for a high proportion of premature productive life lost and a large proportion of the number of school and workdays missed, and have become a large component of the medical care dollar expenditure per capita.

The public is largely unaware of the preventable nature of many injuries. The most common reference to injurious events, “accidents,” evokes a feeling of chance, misfortune, and helplessness. Hence, the word “accident” should be avoided in discussing injury control, and instead, the focus should be on exposures to hazards and resulting injuries, as well as their preventability.

In recent years, great strides have been made in injury prevention. In the last 75 years, the motor vehicle fatality rate per mile driven has decreased 90%, and this has occurred as the number of miles of driving has risen by more than 100%. Despite this decrease, motor vehicles remain the most common cause of injury death. Causes for the decreases seen include modifications in roadway environments and vehicle design, changes of hazardous behaviors, such as drunk driving, and policies that have regulated driving conditions. Preventive measures have been successful in reducing the incidence of drowning, poisoning, falls, and fires.

Despite successes in many areas of injury prevention, the potential of preventing traumatic injuries has not been realized. There remains much to be done. This chapter presents a short public health history of injuries, examines the magnitude and distribution of injuries in the United States, and outlines approaches to injury prevention and control.

► PUBLIC HEALTH HISTORY OF INJURIES

Injury prevention measures, such as the use of protective clothing in warfare, existed long before injuries were systematically studied. In the early 1940s, Cairnes and colleagues conducted one of the first epidemiologic studies to recognize the importance of using defined populations with comparison groups to compare head injury incidence between helmeted and unhelmeted motorcycle riders in the military.^{2,3} These studies demonstrated a decrease in head injuries among those riders wearing helmets.

In 1949, John Gordon noted that injuries were patterned by age, gender, and other demographic factors, as well as by time and place.⁴ He recognized that “accidents” could be studied utilizing epidemiologic methods similar to those used in infectious or chronic disease prevention. In 1961, James Gibson defined the agent of injury as energy in its many forms.⁵ William Haddon Jr. placed this theory into a framework, which identified vehicles and vectors of injury occurrence, analogous to the models used for the study of infectious diseases.^{6–8} He recognized that injuries occur when energy delivered to a living host from a vehicle or vector exceeds human tolerance. He further categorized the energy-host interaction into (a) the energy delivered in excess of human tolerance, such as mechanical energy in motor vehicle crashes or in falls and (b) interference with energy use in normal metabolic functions, such as occurs in drowning or poisoning. Using these basic ideas as a framework, Haddon created a comprehensive matrix of host-energy interactions that is discussed later in this chapter.⁹

After surviving a crash in his trainer aircraft, Hugh DeHaven found a connection between his abdominal injuries and the shape and riveting location of his safety belt. DeHaven then studied ways in which engineering could reduce the severity of injuries during small aircraft and motor vehicle crashes.¹⁰ His work bred new studies on human tolerance to energy forces during many types of impacts. His approach using biomechanical principles coupled with epidemiologic evaluation is now prominent in motor vehicle crash research.

Since these initial studies, the field of injury prevention has become more organized while maintaining an interdisciplinary focus. In 1985, the National Research Council released the landmark report

Injury in America, which identified priority areas for injury control activities and found that funding levels were not commensurate with the burden of the injury problem.¹¹ Since that report, several other national efforts to prioritize injury-control activities have been conducted.

The Institute of Medicine has released several important reports addressing injuries and trauma care, including the 1999 report *Reducing the Burden of Injury*.¹² This report identified national priorities for surveillance, training and research, firearm prevention, trauma care systems, state infrastructure, and federal response. Recommendations from this report include expanding emergency department surveillance, the establishment of a national fatal intentional injury surveillance system, expansion of training activities for both research and practice, and increased coordination and support for agencies leading the field of injury control.

Most recently, the Centers for Disease Control and Prevention supported research for the book *Incidence and Economic Burden of Injuries in the United States*, which identifies the financial burden of injuries in the United States.¹³ These landmark reports have helped bring attention to the injury problem and have been critical to the ongoing improvement and implementation of injury prevention and control programs. They have also argued strongly that a systematic approach to injury prevention, such as that defined by the public health model, provides a sustainable framework in which to address the problem.

► INJURY CONTROL AND THE PUBLIC HEALTH MODEL

Injuries and the Public Health Approach

Injury prevention is well suited to the public health model, which advocates a cycle of surveillance, risk factor identification, and intervention implementation and evaluation.

Injury surveillance provides an understanding of the incidence, trends, and magnitude of injuries. Surveillance also identifies specific populations that have a higher incidence of injuries. When developing an injury intervention strategy, surveillance can help identify injuries on which to focus prevention efforts. Priority can be given to the most prevalent injury causes, those that show an increasing incidence, or those that affect a population of special interest, such as children. It is important to examine surveillance data from the specific population that will be the focus of the intervention. However, local data, especially on nonfatal injuries, is often difficult to obtain. Thus, injury prevention programs are often prioritized on national data.

The process of risk factor assessment helps identify individual or community factors that increase the risk for injury. Risk factors can be intrinsic, such as age or gender; behavioral, such as drinking and driving; or environmental, such as a poorly maintained roadway. Injury events are usually influenced by many risk factors, and these can be classified according to the causal model of injuries described later.

Ideally, an intervention strategy is defined following careful surveillance and risk factor assessment. However, many interventions are implemented in the absence of such information, often because the information is not available or feasible to collect. Thus, many intervention programs are based on national trends. Intervention programs may focus on one population and risk factor, such as an educational campaign to increase the number of children adequately restrained in car seats. They might also target a broad population, such as environmental changes to the roadway. While broad programs might be more effective, they are also usually more expensive.

An evaluation of the intervention strategy should accompany its implementation. A comprehensive evaluation should identify whether the program was implemented completely (process evaluation), determine if the intervention led to the desired change (impact evaluation), and finally, determine if the injury outcome of interest was achieved (outcome evaluation). Although evaluation is a crucial component of the public health approach, most intervention programs are not fully evaluated. Lack of funding, time, or expertise are some of the reasons that evaluations are not conducted.

Evaluation findings are important to understand the consequences of an intervention, and sometimes there are unintended detrimental consequences. The air bag is one example. The air bag is effective in reducing injuries among adults, especially in head-on collisions.¹⁴ However, surveillance of crash data indicated an increasing number of airbag-related injuries to children.¹⁵ Evaluation research indicated that children under 10 years of age who were riding in the right-front passenger seat have a 21% increased risk of fatality when an air bag was present.¹⁶ Since then, national campaigns to promote the placement of children in the back seat and efforts to design an air bag that is safe for children have helped reduce these events.^{17,18}

A Causal Model for Injuries

There are two main categories for injuries: unintentional and intentional. Unintentional injuries have no intentional motivation behind them and include the majority of injuries from traffic-related events, falls, fires, and drowning. Intentional injuries, on the other hand, have discernable human motivation and may be self-directed, such as suicide, or outwardly directed, such as homicide and assault. Although the number of intentional injuries is increasing more rapidly than unintentional injuries, unintentional injuries, currently and historically, have comprised a greater share of deaths and nonfatal injuries. Although there are many differences in the most effective approaches for the prevention and intervention of unintentional and intentional injuries, they share a common causal pathway.

Traumatic injuries result from the transfer of energy to a human host. The traditional epidemiologic causal model for infectious diseases is easily adopted for traumatic injuries. In the traditional epidemiologic model for infectious diseases, microbes are the “agent” of infection and disease. In the epidemiologic model for traumatic injury, the “agent” of the injury is energy (Fig. 80-1). Energy can take many forms including mechanical, electrical, chemical, and thermal. An example of an agent-host interaction in the injury model is a motor vehicle crash, in which the energy exerted on the individual is mechanical.

The environment refers to places where energy can be transmitted to a host. The potential for energy transfer exists everywhere, but its ability to cause injury is limited. For instance, the potential energy in a bullet causes injury only when the bullet is in motion and hits a human.

The transfer of energy to a host is the necessary and sufficient cause of injury, but this transfer is affected by many other factors. Energy can be transferred to a host through vehicles or vectors. Vehicles are inanimate objects, such as a motor vehicle. Vectors are animate, such as another human being or an animal. For many injury causes, both vehicles and vectors are involved in energy transfer. For example, when an automobile crash occurs, the vehicles are the automobiles and the vectors are the drivers.

The causal model is important because it depicts the many potential avenues for intervention. The environment is influenced by many physical, social, economic, demographic, and cultural factors. Modifying the environment can reduce the potential for energy transfer. Characteristics of vehicles and vectors can be modified to reduce the likelihood of causing an injury or to reduce the amount of energy transmitted. Even the host is an important focus for intervention. Only energy transmitted beyond the host’s tolerance causes an injury, and, therefore, not all

Figure 80-1. Causal model for traumatic injuries.

exposures to energy result in noticeable injury. Humans have natural resistance to energy transfer, but the level of resilience varies over the population and depends on many factors. Intrinsic factors such as age and preexisting medical conditions can reduce resilience to energy transfer, as can extrinsic factors such as fatigue and alcohol use. Resilience can be increased through the use of protective devices or education to avoid potential injury-causing situations.

► SOURCES FOR INJURY DATA

Injury data is an important component in the cycle of surveillance, risk factor assessment, prevention, and evaluation. Data sources describing injuries are available on many levels, from broad national surveillance systems to local data. In general, the detail of information provided in a database decreases with the size of the surveillance system. A review by the Institute of Medicine^{12,19} identified 31 federally funded surveillance systems which address the incidence of injuries. The emergence of the Internet and improved computing power has made these databases easier to use and more accessible. Some specific data sources are described below.

Mortality

Incidence data of fatal injuries in the United States are available from 1900 through the present in the Vital Statistics Records collected by the National Center for Health Statistics (NCHS). These data are collected from death certificates, and injuries are classified by the External Cause of Injury codes found in the International Classification of Diseases versions 9 and 10. The U.S. Vital Statistics Records are a good source for counts of fatal injuries by broadly defined causes as well as by age, race, and gender, but detailed information about the event and the types of injuries sustained is not available. Injury mortality rates from 1981 through 2003 can be obtained through WISQARS (Web-based Injury Statistics Query and Reporting System), maintained by the National Center for Injury Prevention and Control of the CDC (<http://www.cdc.gov/ncipc/wisqars>).

In addition to overall injury mortality, several databases addressing specific causes of injury are maintained. The Fatal Accident Reporting System (FARS), developed in 1975 by the National Highway Traffic Safety Administration of the U.S. Department of Transportation, provides information on all motor vehicle crash-related fatalities in the United States. These standardized data on fatalities are collected from state and local police agency crash reports. Beginning in 1988, the National Automotive Sampling System (NASS) was designed to provide additional information on nonfatal crashes. The NASS includes two databases. The General Estimates System (GES) uses a nationally representative probability sample of approximately 55,000 police-reported crashes to estimate annual nonfatal crash injuries in the United States. The Crashworthiness Data System (CDS) provides detailed crash reconstruction data from a sample of approximately 5000 crashes.

Since 1992, the Bureau of Labor Statistics has maintained the Census of Fatal Occupational Injuries (CFOI). The CFOI collects information from each state on work-related fatal injuries, comprised from death certificates, autopsy reports, media reports, and other sources. The National Safety Council also collects information on work-related fatalities.

National estimates of homicide deaths in the United States beginning in 1976 are maintained by the Federal Bureau of Investigations Supplemental Homicide File. Information on the victim, incident, and offender involved in the homicide are included. Data through 1996 are available to download from the Bureau of Justice Statistics' web page (<http://www.ojp.usdoj.gov/bjs>). Queries of databases describing perpetrators of crime are available on the same website through the Federal Justice Statistics Resource Center.

The National Violent Death Reporting System (NVDRS) is a new initiative of the Centers for Disease Control and Prevention, National Center for Injury Prevention and Control, to provide more detailed information about intentional traumatic injury deaths. After

pilot testing in a few states, the system was established in 13 states²⁰ and then expanded to 17 states. Each state links information from death certificates, medical examiner files, law enforcement records, and crime laboratories. Deaths occurring in the same incident are linked so event-level information is available.

Morbidity

Information on hospital discharges, required for all accredited hospitals, is a source of national and community estimates of injury incidence. The National Hospital Discharge Survey conducted by the NCHS collects discharge data from each state to estimate national counts of injuries which require hospital admission. Discharge data is also usually available at the state and community levels. These data represent only the most severe injuries. National estimates of emergency department visits and physician's office visits for injuries are available through surveys conducted by the NCHS, but there is no comprehensive national reporting system for these injuries. Queries of injury hospitalizations and emergency department visits are available from 2000 through 2004 on the WISQARS website (<http://www.cdc.gov/ncipc/wisqars>). The nonfatal injury data is a probability sample from approximately 60 U.S. emergency departments.

National estimates of injury morbidity, as well as information about risk-taking behaviors and injury events, are available through national surveys. Two examples are the National Health Interview Survey, which measures many aspects of health status including a few variables addressing injuries, and the Behavioral Risk Factor Surveillance System (BRFSS), which collects information about risk-taking behaviors that are related to health outcomes. The BRFSS collects information on seat belt use, helmet use, drinking and driving, and other injury-related risk behaviors. These surveys are conducted at the state level using national probability sampling, so that pooled data has national representation. The National Crime Victimization Survey is conducted annually to determine incidence and outcomes from crime victimization. The National Nursing Home Survey provides information about injuries sustained by older persons residing in nursing homes.

Many surveillance systems provide detailed information about specific types of injuries, exposures, and outcomes. The National Electronic Injury Surveillance System (NEISS) conducted by the U.S. Consumer Product Safety Commission gathers information about product-related injuries requiring hospital admission or emergency department treatment from a national sample of hospitals. Although the NEISS collects information only on product-related injuries, a subset of approximately 60 NEISS hospitals report on all traumatic injuries. This sample of hospitals is used to estimate overall nonfatal injury rates for the United States. Although the quality of injury data and access to it has improved dramatically over the last 20 years, there remain important gaps in injury surveillance. For example, few states have statewide databases for nonfatal occupational injuries or for Emergency Medical Services responses. Many types of injuries, such as those from natural disasters, and information about intentional injuries or occupational injuries, are difficult to identify in current national databases in which injuries can be identified. With an increasing focus on injury prevention within public health and preventive medicine, data is likely to improve in quality with easier access.

► INJURY INCIDENCE AND TRENDS

Mortality

In 2003, unintentional injuries were the fifth leading cause of death in the United States. Unintentional injuries, however, were the leading cause of death for all those aged 1–44, and the third leading cause among those aged 45 through 54. Homicide is one of 10 leading causes of death for those aged 1 through 44, and the second leading cause of death for those aged 15 through 24. Suicide is one of the 10 leading causes of death for ages 10 through 64, and the second leading cause for those aged 25 through 34.

Figure 80-2. Age-adjusted mortality rates by year, United States, 1981–2003. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27; from 1981 to 1998, ICD – 9CM coding was used; from 1999 to 2003 ICD–10CM coding was used.)

Overall, the injury mortality rate has decreased since the 1980s. Figure 80-2 shows the trends in injury mortality rates by intent from 1981 to 2003. Caution should be used in comparing rates from 1998 and prior with rates from 1999 to 2003 because beginning in 1999, mortality data used the *International Classification of Disease—10th Revision* (ICD-10) while mortality data from 1998 and prior used ICD-9. For all years, unintentional injuries make up the majority of injury deaths. From 1981 through 2003, the largest decreases in injury rates were for unintentional injuries, followed by homicide, while suicide rates remained largely unchanged.

Injury mortality rates show characteristic patterns by age and gender (Fig. 80-3). For all age groups, the rate of injury mortality is higher for males than for females. Increased injury death rates in males have been attributed to increased risk-taking behavior, exposure to motor

vehicles, more hazardous occupations, and substance use. From age 15–64, the injury mortality rate for females is about one-third the injury mortality rate of males; after age 65, the injury mortality for females is approximately half the rate of males. The death rate from unintentional injuries among White males is almost twice that of White females, and the rate for Black males is almost three times that of Black females.

The injury mortality rate is lower for those aged 5–14 years compared with the ages 1–4, and then increases sharply for both males and females to a rate of 93.5 and 27.4 per 100,000, respectively, from ages 15–24 (Fig. 80-3). The overall injury mortality rate for both sexes is 61.4 per 100,000 from ages 15–24 (not shown). Most of the increase during early adolescence can be attributed to motor vehicle crash-related injuries. Unintentional injuries account for the largest proportion of injuries across all years representing almost two-thirds of all injuries. The

Figure 80-3. Injury mortality rates by age and gender, United States, 2003. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

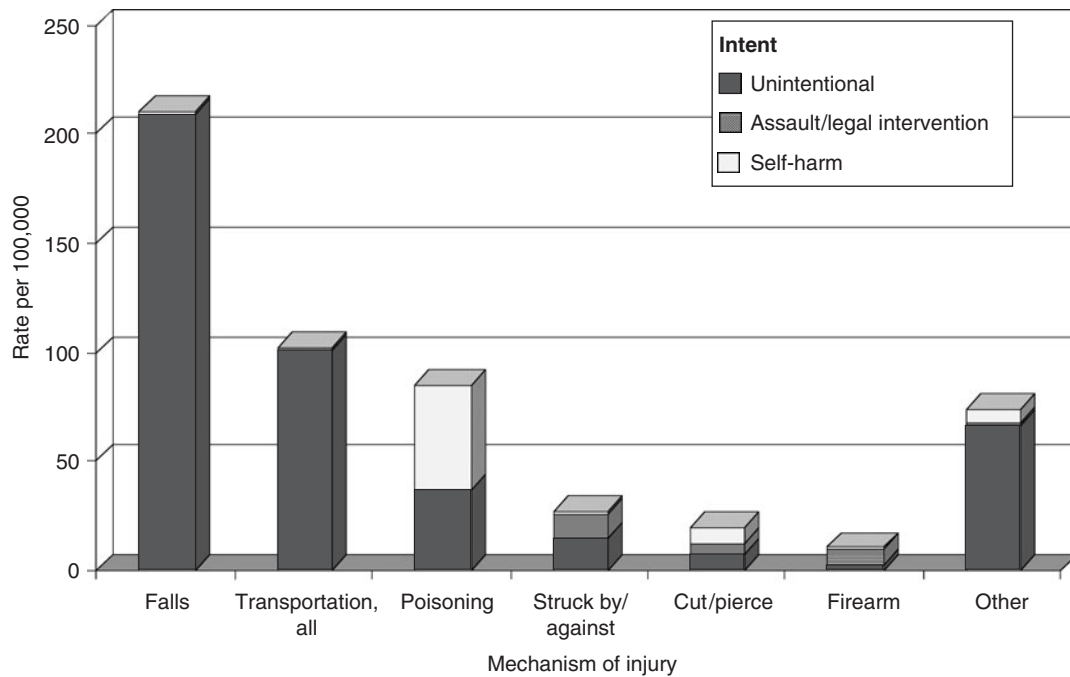

Figure 80-4. Age-adjusted injury mortality rates by mechanism and intent, United States, 2003. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

unintentional injury mortality rate remains between 50 and 65 deaths per 100,000 population until the increase at about age 65. Because injuries disproportionately affect the young, mortality rates, which are not age-adjusted, may not accurately reflect the role of injuries in killing the young.

The leading causes of unintentional injury death from birth through age 5 are poisoning and drowning; the leading cause in the elderly is falls. Motor vehicle-related death rates are the highest of all injuries between the ages of 5 and 34, and peak between the ages of 15–24, the age group when young drivers are first licensed. Alcohol use is an important risk factor in motor vehicle crashes during these ages.

Injury deaths from motor vehicles account for 28% of all injury deaths, followed by deaths due to firearms, poisonings, falls, and suffocation (Fig. 80-4). While over 90% of deaths due to motor vehicles and falls are unintentional, over 50% of deaths from firearms are due to suicide, and 40% are due to homicide (the intent of homicide includes a small proportion of deaths from legal intervention).

Approximately 50% of deaths from suffocation are suicides. Mortality rates due to falls are higher in the 65-plus age groups. The rate of firearm death is highest in the 15 through 34 age groups.

Hospital Admissions

Injury mortality represents only a small proportion of total injury incidence. The relationship of injury deaths to nonfatal injuries of different severity levels is referred to as the “injury pyramid.” In 2003, there were 164,000 injury deaths, and over 1.9 million injury hospitalizations for a ratio of 1 death for every 12 hospitalizations. Nearly 27 million people were treated and released from emergency departments (EDs) during 2003, for a ratio of one death for every 152 ED visits that were treated and released.

Hospitalization rates include injured persons who were admitted to a hospital for their injuries. In 2004, less than 10% of ED visits resulted in hospital admissions for age groups up to 65 (Fig. 80-5).

Figure 80-5. Injury hospitalizations by age and gender, United States, 2004. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

Figure 80-6. Injury hospitalizations by mechanism and intent, United States, 2004. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

After 65, the rate of hospital admissions following ED visits for injury increased from 11% between ages 65 and 74 to almost 30% for age 85 and above. Among hospitalization rates for injuries in 2004, males had higher hospitalized injury rates up to age 65.

Falls accounted for the largest proportion of hospitalizations with almost 40% attributed to falls (Fig. 80-6). Transportation and poisonings represented the next highest proportion of hospitalized injuries at 19% and 16%, respectively. As with injury mortality, unintentional injuries account for the largest proportion of hospitalized injuries overall and across most causes. Nearly all of the falls and the

transportation injuries are unintentional. However, nearly 50% of hospitalized poisonings are due to self-harm, and 43% of injuries characterized as struck by/against are intentional assaults.

Emergency Department Visits

ED visits for injuries show less variation by age than mortality (Fig. 80-7). The high mortality rates among the elderly are more likely due to decreased injury resilience than increased injury rates, while younger people are more likely to sustain a nonfatal injury.

Figure 80-7. Emergency department visits by age and gender, United States, 2004. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

Figure 80-8. Emergency department visits by mechanism and intent, United States, 2004. (Source: Centers for Disease Control and Prevention, National Center for Injury Prevention and Control. Web-Based Injury Statistics Query and Reporting System (WISQARS) [online]; 2005. Available at www.cdc.gov/ncipc/wisqars. Accessed 2006, April 27.)

Among ED visits for injuries in 2004, males had higher injury rates up to age 65. The greatest disparity between males and females was among those 15–24, in which 16.8 of every 100 males and 11.8 of every 100 females had an injury-related ED visit. This age group had the highest rates for both males and females. The lowest rates for both males and females were for children less than 1 year and adults between ages 45–74.

In 2004, unintentional injuries accounted for 67% of all injury-related deaths and 93% of classifiable injury-related ED visits in the United States (Fig. 80-8). Motor vehicle crashes accounted for 28% of injury fatalities but only 15% of ED visits. Falls represented 11% of fatal injuries and 27% of ED visits. The number of falls leading to fatality among the elderly, however, may be underestimated because deaths may be attributed to comorbid conditions.

Costs of Injuries

The high costs associated with injuries have been recognized for many years. The economic costs of injuries can be measured in direct costs, such as those resulting from medical care expenditure, and indirect costs, such as those resulting from years of life lost, lost productivity, or property damage. In 1985, 57 million injuries resulted in an estimated total cost of \$157.6 billion: \$44.8 billion in direct costs, \$64.9 billion in lost productivity, and \$47.9 billion due to premature death.²¹ The Centers for Disease Control and Prevention estimates that the 50 million incident injuries that occurred in 2000 resulted in an estimated total cost of \$406 billion: \$80.2 billion in direct costs and \$326 billion in productivity losses.¹² Increased estimates from 1985 are due in part to better estimates of lost work time and societal costs for injuries. The costs for injuries, despite the fact that injury incidence has decreased, are growing, and this should provide a strong incentive for prevention.

Injuries disproportionately occur among younger people, and the costs are also concentrated among the young. In 2000, individuals between 25 and 44 years of age represented 30% of the U.S. population, but 40% of the total lifetime costs for injuries.¹²

The cost of medical care increases with increasing injury severity. For motor vehicle-related injuries in 1990, the cost of medical care

averaged \$18,585 for a moderate injury, \$57,030 for a serious injury, and \$249,753 for a critical injury.²² Indirect costs also increase with injury severity because extended treatment needs are greater, there is more loss of productivity, and disabilities are more common.

Although fatalities often do not result in high medical costs, indirect costs due to premature loss of life can be extensive. For example, deaths due to drowning and poisoning have high societal costs because of the large number of affected children.

► THEORETICAL APPROACHES TO INJURY CONTROL

The main objectives of injury research are to prevent the occurrence of injuries and to reduce their level of severity. Limiting injury prevention strategies to any single aspect of the many causes of injuries is an ineffective and narrow approach; successful strategies will incorporate many countermeasures and involve many different professionals.^{23,24} Rather than “accident prevention,” the goal of injury prevention is better conceptualized by focusing on a general downshifting of severity over the entire spectrum of injuries. The phrase adapted by injury professionals to describe the desired effects of injury research is “injury control,” which embodies the goal of decreasing injuries through increased knowledge about risk factors, predicting injury occurrence, and active control of these factors.

Unlike many chronic diseases, the agent of injury is usually known, and the mechanism of energy transfer from reservoir to host can be described with great detail. With the exception of some poisonings and burns, injuries usually occur immediately after exposure and have very short “latent” periods. This is different than infectious diseases and chronic conditions, in which symptoms may begin years after exposure. Within the framework of the public health model (Fig. 80-1), the primary focus of injury control is to identify sources of energy forces which cause injury, to define mechanisms of human exposure, and to identify precisely where interventions (countermeasures) may be introduced in the “natural history” of injury.

Public health has defined three levels of prevention. *Primary prevention* aims to prevent the event which causes injury by eliminating the mechanisms of energy transfer or exposure. Traffic safety laws which prevent automobile crashes, fences around swimming pools which prevent submersion and drowning, locking devices on guns, and safety caps on poisonous substances are all examples of primary prevention which reduce or eliminate the chance of exposure.

The goal of *secondary prevention* is to eliminate injuries or reduce injury severity once a potential injury-producing exposure has occurred. Motorcycle and bicycle helmets, seat belts, life vests, and bulletproof vests are examples of secondary prevention.^{25,26} It is important to note that some of the most effective secondary prevention strategies do not eliminate all injuries. For example, the motorcycle helmet is very effective in reducing head trauma in motorcycle crashes, but is not effective in preventing trauma to other body regions.²⁷ Seat belts do not prevent all injuries in vehicle crashes; cuts, contusions, and extremity fractures are common among belted vehicle occupants because belts do not restrain the limbs.^{28,29} The crucial role of seat belts is to reduce severe injury to critical anatomic regions such as the head or chest, and for this purpose they are enormously effective.

Tertiary prevention acknowledges that an injury has occurred, and aims to reduce the consequences of the injury. These efforts can include emergency response, trauma care, social work, and physical, occupational, and speech therapy. Some of the most important advances in injury prevention have occurred with the development of organized trauma care systems in the last decades.³⁰ However, less attention has been focused on the emotional and psychological consequences, and subsequent recovery, from a severe injury.

Specific injury prevention strategies can be divided into two very broad groups based on need for host actions. *Passive* intervention requires no input or action by the host and is usually accomplished by modifying the agent, vehicle, vector, or environment. Modifications in car design to improve brakes or increase energy absorption by the vehicle frame are two examples. *Active* intervention requires that the host take some type of action for the intervention to work. Seat belts and helmets are examples of active intervention. Just as effective injury control strategies must address multiple facets of injury occurrence, they should also incorporate active and passive intervention strategies to be fully effective. Passive intervention strategies are usually considered more effective, especially when compared to active interventions which require frequent or time-consuming action.³¹ Air bags, which require no driver action, will work in frontal crashes, whereas a seat belt can only be effective if the rider remembers to fasten it. The most effective prevention, however, is the combination of both approaches. The circumstances of specific types of injury must be considered when identifying injury control approaches.

One framework for conceptualizing the many approaches to injury prevention is termed the "4 Es," which consist of *education, environmental modification, enforcement, and engineering*. Education refers to efforts using educational messages to increase safe behavior among the intended audience. Of the four approaches, education is perhaps the most difficult to implement. Successful educational messages must be clear, appropriate for the audience, and must be periodically repeated to maintain behavior change. One important component of a successful educational campaign involves identifying the audience. For example, educating legislators regarding effective safety legislation may be more beneficial than broad community-based education. One example was the implementation of the Poison Prevention Packaging Act, which also established state Poison Control Hotlines. These legislative approaches were only possible due to the availability of data to educate legislators about the risks for childhood poisonings, which were dramatically decreased following the legislation.³² Some community-based efforts, however, have shown success, such as programs that focus on decreasing childhood injuries.^{33,34} Many types of educational materials have been introduced, but most are not scientifically evaluated. One recent approach has been the broadcasting of Public Service Announcements stressing

safe behavior. The success of these programs is largely unknown, however, because few scientific evaluations have been undertaken.

The effectiveness of environmental modification has been demonstrated through reduction in motor vehicle crashes following changes in the driving environment. Examples include skid-free road surfaces, cross slopes on curved roadways in areas with heavy rainfall, and separation barriers on freeways and two-way roads. Environmental modifications as simple as removing trees and adding guardrails can reduce traffic crashes in some areas by as much as 75%.³⁵ Another example of successful environmental modification includes the introduction of pool-fencing barriers.

Enforcement refers to legislative regulations and the enforcement of these activities. While legislatively mandated prevention activities have been highly successful, they can be controversial. The introduction of a mandatory helmet use law in California in 1992 led to a decrease in motorcycle fatalities of over 35% and a decrease in severe head injuries among injured motorcycle riders of over 50%.²⁷ Efforts to repeal this law based on freedom of choice have continued since its inception. Another example of successful legislation has been the implementation of blood alcohol limits for drivers. The success of much legislation may be due in part to public recognition of the laws, and it is often this public recognition that leads to the legislation.

Engineering advancements have been highly successful in reducing injuries. The most notable examples are the seat belt and airbag, which have been attributed with decreasing injuries in frontal collisions by over 50%.³⁶ Many effective prevention measures have been introduced to motor vehicles without the consumer's knowledge, including improvements in brakes, collapsible steering columns, and stronger head rests. As consumers of automobiles have started to demand safety in vehicle design, these improvements will likely continue. Although engineering measures tend to be very effective, they must be followed to determine if the engineering strategy introduces new injury risks. An example of this phenomenon involves the airbag, which has caused several fatalities among infants in car seats placed in the front passenger seat.

One of the most successful theoretical approaches to injury prevention is the Haddon Matrix, developed by Dr William Haddon in the 1970s. The Haddon Matrix identifies three phases in an injury event and links approaches to prevent or reduce injury in each phase. This matrix was developed for application to countermeasures for highway safety but continues to be a useful theoretical framework for many types of injuries.^{8,9}

The Haddon Matrix divides the timing of the injury event into three phases: preinjury, injury, and postinjury (Table 80-1). In the preinjury phase, the goal is primary prevention to eliminate any energy transfer to the host. Additional examples include fences around swimming pools which prevent submersion, trigger locks on guns, and safety caps on poisonous substances. These are all examples of countermeasures that reduce the chance of exposure to energy. In the injury phase, which represents secondary prevention, the goal is to eliminate or reduce the amount of energy absorbed by the host once an energy transfer has occurred. Postinjury interventions, also called tertiary prevention, reduce the consequences of the injury once an injury-producing energy transfer has occurred.

The Haddon Matrix categorizes interventions in each injury phase into those that affect the host, the vehicles or vectors in the causal pathway, and the environment. The environment is often separated into physical and socioeconomic components. While the Haddon Matrix is an important tool to recognize the many opportunities for prevention, it is not a useful tool in deciding which intervention approach to implement. In 1998, Dr Carol Runyan introduced a third dimension to the Haddon Matrix to assist in decision-making.³⁷ The third dimension introduces value criteria to consider when choosing an intervention strategy, and includes such elements as anticipated effectiveness, cost, freedom, equity, stigmatization, preferences, and feasibility. These value criteria can be applied to interventions in each cell of the original Haddon Matrix to determine which approach is best suited for the specific problem.

TABLE 80-1. THE HADDON MATRIX WITH ILLUSTRATIONS

Phases	Factors			
	Human	Vector (Vehicle)	Physical	Environment
Preinjury	Alcohol intoxication	Instability in utility vehicles	Poor visibility of road hazards	Lack of knowledge regarding injury risks
Injury	Low resistance to energy	Sharp or pointed edges and surfaces	Flammable building materials	Lack of enforcement of safety belt legislation
Postinjury	Conditions which affect energy tolerance	Rapidity of energy reduction	Emergency medical response	Lack of funding for emergency medical services and rehabilitation services

► SOURCES TO IDENTIFY SUCCESSFUL INJURY PREVENTION PROGRAMS

The growth of the field has led to an increasing evidence base that identifies effective, replicable, and sustainable injury prevention and intervention measures. Increasing availability of peer-reviewed evaluations, systematic reviews, and best-practices guidelines help identify effective approaches to prevention.^{38,39} *The Guide to Community Preventive Services: Systematic Reviews and Evidence-Based Recommendations* (the *Guide*), developed by the Task Force on Community Preventive Services, includes some systematic reviews that address injury prevention topics.⁴⁰ The *Guide's* recommendations are primarily based on evidence of effectiveness, including the suitability of the study design, but they also assess the applicability of the intervention to other populations or settings, the economic impact, barriers observed in implementing the interventions, and whether the intervention had other beneficial or harmful effects.⁴¹ The *Guide* then provides a recommendation as to whether the approach is “strongly recommended,” “recommended,” has “insufficient evidence,” or is “discouraged.” The *Guide* has evaluated the use of child safety seats and safety belts, reducing alcohol-impaired driving, therapeutic foster care for the prevention of violence, early childhood home visitation programs, and firearm laws; these recommendations can be found at <http://www.thecommunityguide.org/default.htm>.

The Cochrane Collaboration provides scientific evidence-based reviews of health care interventions through the Cochrane Library.^{42,43} The Cochrane Injuries Group has published 57 reviews on the prevention, treatment, and rehabilitation of traumatic injuries. There are 13 reviews of general injury prevention interventions including fall-related injuries to older persons, pool fencing to prevent drowning in children, and interventions for promoting smoke alarm ownership and function. There are 16 reviews of prevention strategies to reduce traffic injuries, including graduated driver's licensing, increasing pedestrian and bicyclist's visibility to prevent crashes, and safety education of pedestrians. A list of reviews conducted by the Cochrane Injuries Group can be found at <http://www.cochrane-injuries.lshtm.ac.uk>.

► CONCLUSION

Injuries, which are frequent events with potentially devastating physical and emotional consequences, represent an underrecognized public health burden. Injury prevention measures represent an effective strategy to improve public health because, with the extremely short latency period between exposure and injury, the effects of intervention can be realized very quickly. This does not mean, however, that injury prevention strategies are simple. Most successes in reducing injury incidence have required multifaceted, interdisciplinary efforts. For example, the successful modifications of the roadway and vehicle environments that have led to reductions in motor vehicle crash-related

injuries and deaths required collaboration of legislators, urban planners, city councils, law enforcement, automobile manufacturers, engineers, and health professionals, among others. Prevention efforts focusing on the seat belt required engineering, education, legislative, and enforcement approaches.⁴⁴ It was not until long after engineers designed seat belts that they were widely integrated into cars. Legislation was required first to get seat belts installed into cars, and then to get drivers and passengers to wear them. This required education of legislators to understand the scope of crash injuries, the promise of reducing them, as well as education of the public to understand the benefits of wearing seat belts and consequences for not wearing them, both legal and personal.⁴⁵ Continued success in reducing injuries will require similar collaborative efforts, and preventive medicine specialists have a key role in this process as advocates for safety and injury prevention.

Violence in the Family as a Public Health Concern

Irene Hanson Frieze • Jeremiah A. Schumm • Stacey L. Williams

Although the family can and often is a source of strength and support for many people, it can also be a source of victimization. Violence in family settings in the United States is believed to affect a large proportion of the population, although not all of this is severe violence. The Centers for Disease Control and Prevention (CDC) estimates that about 1.5 million women and more than 800,000 men are raped or physically assaulted by an intimate partner each year (<http://www.cdc.gov/ncipc/factsheets/ipvfacts.htm>).¹ Such violence can be fatal. More than 10% of homicide victims are killed by an intimate partner.² Other CDC data³ indicate that nearly 1 million children were confirmed by child protective agencies as victims of child abuse in 2002. This included neglect, physical abuse, sexual abuse, and emotional and psychological abuse.

In this article, several different types of family violence are discussed, including couple violence, child abuse, sibling violence, and elder abuse. As will be seen, the more extreme forms of these forms of family violence are often found together in the same family. In the following sections, we first present data on what is known about family violence and then discuss strategies for how we might intervene or prevent forms of abuse.

► COUPLE VIOLENCE

Violence in couples is called intimate partner violence (IPV) by researchers today. Such violence can exist at various levels from extreme violence with serious injury, to relatively low-level forms of violence. In accord with the CDC definition, IPV can entail physical violence, sexual violence, threats of physical/sexual violence, and psychological or emotional abuse.⁴ The major public health concern is the most extreme and serious form of couple violence, now labeled as “intimate terrorism” by researchers.^{5,6} This is the type of situation that most people would associate with the battered woman. In the most typical pattern of such violence, a husband or male partner has become extremely violent toward his wife or female partner, using physical violence as well as psychological abuse or belittling of his partner.⁷ Such violence has become routine, and the woman lives in constant fear that something she might do will initiate another round of such violence. The female victim develops low self-esteem, after hearing so often that she deserves the violence she receives. She may fight back, but typically her resistance is ineffective in stopping the violence, and she often receives a more severe beating when she does try to respond with her own violence. She may seek help from the police or escape from a particularly violent incident and go to a shelter for battered women, but this typically does not stop the violence.

Such violence and the high levels of stress generated in the battered woman result in a weakened immune system for her. Her injuries mean that she has a heightened risk of hospital visits because of injury or illness.⁸ She likely experiences acute and chronic mental and physical health problems.^{7,9,10} She may also abuse alcohol or drugs. Attempted suicide may occur. The CDC estimates that physical assaults associated with IPV cost U.S. society over \$6 billion in 2003 in direct costs associated with medical and mental health care, as well as additional indirect costs of lost productivity for the female victim of couple violence (<http://www.cdc.gov/ncipc/factsheets/ipvfacts.htm>).

Along with problems for the battered woman, there are often other health concerns within this type of violent family. Often, the batterer is violent to the children as well, meaning that physical child abuse is also present. It is not unusual for the batterer to abuse alcohol or drugs. This creates an additional public health concern, addressed elsewhere in this book.

Battered women remain in these abusive relationships for a variety of reasons.⁷ They may love their abuser, in spite of his violence. She may feel that he needs her and that she needs to remain with him because of this need. Another set of reasons involves feeling unable to live on her own (feelings that grow out of low self-esteem caused by psychological abuse), lack of financial resources to leave and live on her own or as a single parent (batterers typically control money within the couple and give her little access to funds), or lack of any social support network that might assist her in leaving. The lack of social support is again typical because batterers so often systematically cut off outside social contact for the battered women, and monitor their behavior to make sure she does not have outside friends or close family relationships.

If the battered woman does actually try to break up the relationship, it is not uncommon for the batterer to try to find where she has gone and to threaten her if she is not willing to come back. Many women in this situation file for legal protection, but this is not always effective. Relationship violence tends to become even more severe during this breakup time, which also may be a risk factor for other forms of violence such as stalking.¹¹

In some cases, the battered woman is able to successfully leave the relationship and develop a new life, but it is difficult. These women may feel that they are now stronger people because of being able to do this, which helps build their self-esteem.

For those who don't leave, there are a number of programs that have been developed to try to encourage the batterer to stop using violence. For example, Stosny¹² developed a treatment program aimed at ending abusive behavior by enhancing the batterer's compassion toward self and loved ones. Another approach seeks to eliminate abusive behaviors by increasing motivation toward nonviolence and

improving anger management and communication skills.¹³ Although these programs are shown to have some success in reducing violence,¹⁴ they have been criticized by those who view these types of programs as generally ineffective.¹⁵

► CHILD ABUSE

Child abuse can take several forms.⁷ It can consist of high levels of physical violence, or of a caretaker failing to provide basic care of a child. The latter is known as neglect. Sexual abuse of a child is another form of child abuse. Sometimes, emotional abuse, such as belittling of a child, or lack of positive expressions of love or warmth is also defined as a form of child abuse. In this section we focus on physical violence and sexual abuse.

Like wife battering, all forms of child abuse are often hidden, and we have no true estimates of any of the forms of child abuse identified above. All we can reliably know are the counts of cases that have been reported to authorities, and judged by social agencies to meet the standard of abuse or neglect. It is likely that this would be more likely to occur for poorer families who are already using other social services. Sexual and physical abuse prevalence is difficult to estimate because these forms of abuse often occur beyond public view. Perpetrators of sexual or physical abuse often isolate their victims and coerce them into silence. Therefore, estimations of sexual and physical abuse based on incidents reported to social agencies are likely to underestimate the true prevalence rates of these forms of abuse.^{16,17}

The United States Department of Health and Human Services estimates that over 900,000 children a year are judged to be maltreated.³ The most common form of maltreatment was neglect (61%). Other forms of abuse identified included physical abuse (19%), sexual abuse (10%), and emotional abuse (5%). In addition, the CDC suggests that shaken-baby syndrome (SBS), affecting up to 1600 children a year, should be considered a form of child abuse.^{18,19} This involves violent shaking of an infant or small child and can result in serious injury or even death.

Physical Child Abuse

Physical abuse of children is associated with injuries to children that require medical attention or that result in death.²⁰ This type of definition excludes most types of spanking or other forms of mild physical violence that do not involve serious injury. Many people in the United States feel that it is perfectly acceptable, if not beneficial, to spank or use other physical punishment on children who disobey their parents.²¹ This means that one has to set a certain level of violence as meeting the criteria for child abuse. People may disagree on what an appropriate level might be. Similar difficulties exist with defining neglect. There are wide differences of opinion about how much supervision or help children of different ages need. What one person might label as neglect, another person might see as teaching a child to be independent.

Parents who physically abuse their children are most likely to do this when under stress.⁷ Such stress can come from situations in the life of the parent, or from having a child with special needs who is difficult to care for. Other risk factors for physical child abuse include parental stress and lack of social support for the parents. Mothers who are depressed or anxious are more likely to be abusive. Parents with substance abuse problems are also more likely to physically abuse their children as well.

Abuse is also associated with poor parenting skills.²² The physical child abuser often feels that his or her behavior is in response to a difficult child whose behavior cannot be controlled in any way except through parental violence. Programs that train parents to better understand their (false) assumptions about their children appear to have promise in helping these parents be less aggressive toward their children.²³ Abusive parents may have learned that such violence is appropriate parental behavior.⁷ Mothers or fathers who have grown up in families where they were abused may learn this pattern of interaction

between parents and children and use these same behaviors toward their own children when they become parents themselves.

As mentioned earlier, battering men may be physically violent to children as well as to their partner. Battered women may also take out their own stress on their children through the use of physical violence. These women are often experiencing high levels of stress in their lives as they monitor their behavior to minimize being beaten by their partner. The evidence of both abusive men and their battered partners both being at high risk for child abuse means that severe couple violence is often associated with physical abuse of the children in the home, by the father or stepfather and/or the battered mother, or by both parents.²⁴

Growing up in a violent household leads to a continuation of violent interactions in the home. The abused child learns that violence is a way of solving problems and interacting with loved ones. Abusive parental behavior is seen as the model for parent-child interaction, and physical violence in adults is seen as normal. Children growing up in violent homes are more likely to engage in partner violence themselves as adults.²⁵ This intergenerational transmission of violence might be the outcome of children learning to engage in violence from observing this behavior in their parents.²⁶

Being the recipient of physical abuse, especially from someone as important as a parent, is traumatic for the child.²⁷ Abused children may not have their basic physical and emotional needs met, and they may come to fear or distrust others. They are at high risk for display of aggression toward other children and for other conduct disorders, anxiety, depression, and suicide.²⁸

There can also be long-term health consequences. Many studies include any child identified as being maltreated, which would include those experiencing physical abuse as well as neglect or sexual abuse. Such children have been found to experience a range of health consequences and to engage in unhealthy behaviors as adults.^{18,29} This includes eating disorders, smoking, alcoholism and drug abuse, depression, and suicide.

Incest and Sexual Abuse of Children

The general category of child sex abuse is quite broad and includes many different types of behavior. Technically, incest refers to sexual contact between biologically related family members such as parents and children or even siblings, but stepparents are often included as well in this category. In this section, we focus on incest and sexual abuse within the family. We further limit the discussion to examples of forced sexual contact, typically between a parent or much older sibling and a daughter or sister.

The most common example of this situation is associated with the violent relationships mentioned earlier.⁷ The man who is highly physically abusive toward his wife or female partner is the most typical type of incest perpetrator. Growing up in this type of family, the child may not feel loved or close to either parent. As the daughter reaches puberty and her body develops, her father may find her very attractive. She reminds him of his wife when she was younger and more attractive. The father, feeling that his wife is not fulfilling him sexually, turns to his now adolescent daughter, and begins to be very loving toward her, essentially courting her. The daughter responds to this attention, feeling loved for the first time. Over time, he becomes more and more aggressive in his sexual requests, eventually seeking sexual intercourse with her. If the wife finds out, she may feel powerless to do anything, because of fears for her own safety. The daughter may not seek help, enjoying the attention and thinking her mother is just being jealous.

Over time, as this situation evolves, the father begins to treat the daughter as a second wife. He becomes very jealous of her and may begin to be violent towards her. She may realize that this situation is not "normal" and may feel guilty for her loving feelings toward her father. As she tries to date boys her own age, she begins to fear her father's anger. She may become pregnant or acquire a sexually transmitted disease.

Finally, the situation becomes too difficult for her to cope with. She may run away from home, perhaps marrying a boy she has been

seeing secretly. Or, she may turn to prostitution to support herself on the street. Another possibility is disassociation or even the development of a split personality. None of these alternatives are good ones for her. She may seek outside help, but generally only if she fears her father will begin to sexually assault a younger sister.⁷

When the child is forced to participate in unwanted sexual activity, there can be long-term emotional and health consequences. Child sexual abuse is associated with adulthood depression and anxiety, substance abuse, suicidality, and interpersonal problems.³⁰ Sexually abused individuals are also more likely to report physical health complaints as adults than those who were not abused.³¹ They are also more likely to engage in risky sexual behaviors as adults and to become infected with sexually transmitted diseases.³² These negative consequences are further compounded by sexual revictimization, which can reignite the negative sequelae associated with sexual abuse.³³

Prevention of Child Abuse

Primary and secondary prevention programs appear to have some promise for preventing various types of child abuse. Early support programs that target parents experiencing psychological distress and who have little or no social support have been shown to decrease rates of child abuse and neglect by these targeted parents.³⁴ These programs typically include efforts to help improve parenting skills, increase social support, and decrease parents' psychological distress. In addition, there is evidence that school-based prevention programs increase children's knowledge and skills related to preventing sexual abuse, by being more aware of the fact that certain behaviors by adults may not be appropriate. A meta-analysis by Davis and Gidycz³⁵ found school-based programs that afforded children the opportunity for physical involvement (e.g., role play) and that were targeted to preschool or early elementary students were most effective. Taken together, these findings suggest that abuse prevention efforts aimed at younger children or families are especially promising.

► ELDER ABUSE AND SIBLING VIOLENCE

Like other forms of family violence, abuse of the elderly in the family is often hidden from others and is rarely reported to authorities. The National Center on Elder Abuse³⁶ has been collecting data since 1986, based on surveys of adult protective service agencies, and reports an increasing number of reported cases, with nearly 300,000 reported cases in 1996, the last year in which data were available. The most common form of reported abuse was neglect, or inadequate physical care. Less than 20% of the cases involve physical violence. Taking money from the elderly is another form of abuse. The typical abuser is a family member who has the responsibility to care for the elder who is unable to care for herself or himself. This may be a spouse or a child, or another family member. Since this is so rarely reported, there is little formal data available, but there is belief that such abuse may be more likely in violent or abusive families.²¹ In one project administered in New York City by the Police Department and Victim Services, educational programs and home visits to teach people about the problem of elder abuse resulted in more reports of this problem, but had no clear effects of reducing the problem.³⁷

Physical aggression among brothers and sisters is quite common. This can range from simple shoving or slapping to extreme violence using weapons.³⁸ Like other forms of family violence, this behavior can result in extreme injuries, but the large majority of this does not have serious health consequences. Sibling aggression is considered abusive when there are large age or size differences between the siblings involved, with the older and bigger child being the aggressor, when the physical aggression is frequent and occurs over long periods of time, when the behavior is hidden from others, and when the victim is fearful or has other evidence of emotional or physical reactions to the aggression.²¹

► OTHER TYPES OF VIOLENCE IN THE FAMILY

This discussion has focused on extremely violent family interactions. There is a good deal of evidence that family members also engage in low-level, mild violence with each other. Researchers have begun to examine these less extreme forms of physical aggression recently in married couples and same-sex and heterosexual couples living together.³⁹ A meta-analysis published by Archer⁴⁰ of marital and dating violence studies found that women actually engage in more acts of physical aggression than men. Such data was difficult to relate to the work on battered women. But, further examination of these studies indicated that much of the "violence" consists of hitting, slapping, shoving, or other relatively minor acts of physical aggression. As Archer noted, the majority of those who do suffer injury from violent behavior of a romantic partner are women. But, at the same time, it is clear that there are some women who can and do engage in highly violent acts toward their partners.

As researchers begin to reexamine the findings on couple violence, one of the questions being raised is whether low-level violence has health consequences. In one study attempting to answer this question, Williams and Frieze⁴¹ used data from the National Comorbidity Survey to look at the psychological consequences of mild and severe violence. It was found that even mild violence had some association with psychological distress and marital dissatisfaction, although women reacted more than men. At the same time, there was a small subsample that did not appear to have adverse reactions to couple violence.

Further research is needed to better understand different types or patterns of couple violence. Fergusson and colleagues⁴² suggest that some important dimensions of violence are the level of overall violence, the frequency of the violence, and the level of injury. More nuanced analysis will also need to be applied to other forms of violence in the family.

Finally, research that incorporates the full scope of couple violence is needed. Perhaps because physical violence is the most visible and the most obviously physically harmful, a large focus of assessment and research is physical violence. Yet, other forms of violence or abuse exist and can manifest as health symptoms as well. Studies find that emotional and sexual abuse can be just as deleterious as physical.^{43,44} Emotional abuse, coercive control, stalking, and sexual violence are understudied, particularly by public health researchers. Future nationally representative studies must assess these multiple dimensions of violence and the specific contexts in which they occur. Because population-based studies are better suited to answer questions about correlates of violence than are other types of study designs,⁴⁵ more thorough assessment of violence will result in the most accurate information on prevalence and burden of disease linked to couple violence. Such studies also can contribute to efforts of ongoing surveillance.⁴⁶

► RISK FACTORS FOR FAMILY VIOLENCE

Risk factors are similar for all types of family violence. In terms of severe violence, males are more often perpetrators.^{5,6} Those of lower socioeconomic status (SES) tend to experience more frequent and severe violence than their higher SES counterparts.⁴⁷⁻⁵⁰ Further different health consequences of violence may exist for those of differing levels of SES due to variations in psychosocial resources, such as social support,⁵¹ which tend to be socially distributed. History of violence in families appears to be a risk factor for future violence. Exposure to violence as a child (whether personally or vicariously) is related to being in an abusive adult relationship.⁵² Studies are also increasingly showing that substance abuse is a strong risk factor for family violence occurrence.⁵³ It is less clear what risk factors are for elder abuse; future research is needed. Moreover, although research finds risk factors for some aspects of family violence, causal factors still remain heavily debated, thus making intervention and prevention

efforts difficult.⁵⁴ Research must continue to uncover risk factors. White and Kowalski⁵⁵ developed a useful framework for identifying potential factors that may increase risk for victimization. By identifying factors at sociocultural, social network, dyadic, situational, and interpersonal levels, we may be in a better position to address violence intervention and prevention.

► RESPONDING TO VIOLENCE IN FAMILIES

No epidemic has ever been successfully eliminated or controlled by treating those already infected or affected.⁵⁶ Thus, primary prevention is crucial to address family violence. In traditional public health terms, primary prevention entails reducing the number of new cases by changing behavior or environmental factors. Although treatment for victims of violence is important, public health aims to prevent people from becoming injured in the first place and to prevent the perpetrators from ever resorting to violence. For example, it is important to have an adequate number of shelters for battered women, but if battering could be prevented in the first place, these shelters would not be needed. This focus on prevention does not in any way diminish the importance of providing care for victims or the importance of arresting and prosecuting perpetrators. Rather the approach complements the contributions of other fields such as criminal justice and medical care. Such prevention is more cost-effective than other types of interventions because the individual never develops the problem and therefore high cost of medical care is avoided.⁵⁷

Prevention of violence follows the same public health approach that guides efforts to prevent infectious diseases, chronic diseases, and environmental and occupational health problems. Therefore, it is not difficult for public health workers to understand and work on violence prevention. In fact, public health practitioners can play an effective role in coordinating prevention programs.

The prevention focus has several implications:

1. *Interventions should be developed earlier on the pathway toward violence.* In the area of couple violence, for example, interventions could target women who are in relationships with a high risk for physical violence, but in which physical violence has not yet occurred. This could involve intervening with couples who are newly married, engaged but not yet married, or with young men and women just beginning to date. Or it could mean pushing the intervention even further back in time to school-age children and starting to educate them about the risks of violence and how to avoid it.
2. *Children should be involved in preventive programs.* Young children and youth may be more receptive to preventive interventions, and behaviors learned early tend to endure.
3. *New methods of delivering programs need to be developed.* Traditionally, the criminal justice and police sectors have conceptualized violent situations as having a perpetrator and a victim. They often targeted some programs at perpetrators and others at victims. That approach makes sense *after* a violent incident has occurred. However, this way of identifying victims and perpetrators is not useful in the context of prevention programs designed to intervene *before* violence occurs.
4. *Programs need to target increasingly broader and larger groups at multiple levels.* After specific acts of violence have occurred, individual perpetrators and victims can be identified. If we wish to intervene preventively, then we can say that a certain group is *at risk* for violence, and we need to focus our interventions at members of this high-risk group, some of whom might otherwise become perpetrators or victims, but many of whom would not. Other interventions might be even more broadly targeted to a general population in an effort to achieve *universal* coverage. A large focus should be on expanding public awareness of couple violence, child abuse, and elder abuse, and emphasize the potential for violence in all of us, rather than attributing the problem to deviant and minority individuals.

5. *Parents should get involved in prevention programs.* Programs can provide parents with access to information about child development and about nonviolent methods of socializing their children.
6. *Elder abuse should be an increasing focus given the changing demographics of the population.* Given the lack of firm research findings in many areas, it is perhaps more appropriate to make proposals for future research than for practice and policy. The most critical need is information about the causes of elder abuse and effective methods of intervention. Suggestions for research include examining the content of abusive acts, the circumstances in which abuse occurs, and the patterns that might predict abusive acts against the elderly. Research on this form of family violence seems particularly salient due to the changing demographic and the increased number of elderly in the coming years.
7. *Prevention efforts should consider that different forms of family violence co-occur within the same families.* Strategies developed to intervene in and prevent family violence should not treat child abuse as separate from couple violence as separate from elder abuse. Those attending to the needs of a couple, for instance, might be wise to assess for child or elder abuse. Education and awareness campaigns should make clear the relationship between different forms of violence. Finally, future research should seek to uncover dynamics of violent *families*, not merely individuals.

► FINAL THOUGHTS

More than other branches of medicine, public health has a long tradition of working closely with community-based groups in prevention efforts. Such alliances are needed to develop successful action and creative programming to prevent violence. Systematic evaluation of programs that emphasize a partnership between researchers and practitioners using sophisticated techniques will be needed to determine the impact of the programs. Only through these efforts will we liberate citizens from coercion and control, a vital part of the public health mission.
