   1. Primary tumor
   2. Metastasis

E. Other
   1. Fatty change
   2. Simple cyst

Solitary Cystic Lesion

√ well-defined lesion with predominant near-water attenuation (0–30 HU) / signal intensity exhibiting negligible enhancement at dynamic imaging

√ variability of cystic component accounts for differences in attenuation / signal intensity:
   (a) liquids: serous, mucinous, bilious, hemorrhagic, proteinaceous, or mixed fluids
   (b) intratumoral necrosis
   (c) tissue with a high water content

√ septa may contain a range of tissues including epithelium, fibrotic tissue, stroma, neoplastic tissue, inflammatory cells.

1. Biliary cystadenoma / biliary carcinoma
2. Cystic degeneration of hepatocellular carcinoma
3. Bacterial / parasitic abscess
4. Metastatic disease
5. Posttraumatic resolving hematoma

Typical MR Characteristics of Benign Liver Tumors

Lesion	*T1WI*	*T2WI*	*Contrast Enhancement*		
	(relative to normal liver parenchyma)		*Arterial Phase*	*Portal Venous Phase*	*Delayed Phase*
Adenoma	hyper- to isointense	slightly hyperintense	hyperintense	isointense	
FNH	iso- to hypointense	hyper- to isointense (hyperintense central scar)	hyperintense (hypointense central scar)	hyper- to isointense	isointense (hyper- to isointense central scar)
Regenerative nodule	variable	hypointense	no enhancement	---------- variable ----------	
Dysplastic nodule	variable	variable – may have hyperintense foci	slight / no enhancement	---------- variable ----------	
Hepatic cyst	hypointense	hyperintense	no enhancement		
Hemangioma	hypointense	hyperintense	peripheral nodular enhancement	increasing peripheral enhancement	hyperintense

Multilocular Cystic Hepatic Lesions

A. CONGENITAL
    1. Polycystic liver disease
B. NEOPLASTIC
    1. Biliary cystadenoma / ~carcinoma
    2. Hepatocellular carcinoma
    3. Cystic metastasis: neuroendocrine tumor, melanoma, GIST, mucinous colorectal / mucinous ovarian carcinoma; treated metastasis
    4. Inflammatory myofibroblastic tumor
    5. Mesenchymal hamartoma
C. INFECTIOUS
    1. Pyogenic abscess
    2. Amebic abscess
    3. Echinococcal cyst
D. TRAUMATIC
    1. Intraparenchymal hematoma
    2. Biloma

Attenuation of Cystic Hepatic Lesions

1. Simple hepatic cyst -10 – 10 HU
2. Hematoma (acute) 40 – 60 HU
3. Clotted blood 45 – 70 HU
4. Biloma 0 – 15 HU
5. Pyogenic abscess 0 – 45 HU
6. Hydatid mother cyst 3 – 30 HU
7. Hydatid daughter cyst lower than mother cyst
6. Amebic abscess 10 – 20 HU

◊ Density measurements in general are of little help due to variability of cyst content and change over time!

Solitary Echogenic Liver Mass

mnemonic: **H**yperechoic **F**ocal **M**asses **A**ffecting the **L**iver
Hematoma, **H**epatoma, **H**emangioma, **H**emochromatosis, **H**epatoblastoma
Fatty infiltration, **F**ocal nodular hyperplasia, **F**ibrosis
Metastasis
Adenoma
Lipoma

Solid Liver Lesion with Cystic Degeneration

1. Hepatocellular carcinoma / adenoma
2. Fibrolamellar carcinoma
3. Intrahepatic cholangiocarcinoma
4. Angiosarcoma
5. Epithelioid hemangioendothelioma
6. Lymphoma
7. Metastatic disease

Liver Mass Surrounded by Echogenic Rim

1. Metastasis: esp., cystic pancreatic endocrine tumor
2. Adenoma
3. Hemangioma

Multiple Liver Lesions

A. BENIGN TUMOR
   1. Cavernous hemangioma
   2. Adenoma
   3. Regenerating hepatic nodules
   4. Biliary microhamartomas

B. INFECTION
   1. Multiple abscesses / microabscesses
   2. Mycobacterial + fungal infection
   3. Inflammatory pseudotumors

C. CONGENITAL
   1. Polycystic disease
   2. Caroli disease

D. MALIGNANCY
   1. Metastases (most common malignant liver tumor)
   2. Multifocal hepatoma
   3. Lymphoma

E. OTHER
   1. Sarcoidosis
   2. Simple cysts
   3. Langerhans cell histiocytosis (echogenic nodules)
   4. Multifocal fat deposition

Bull's-eye Lesions of Liver

1. Candidiasis (in immunocompromised)
2. Metastases
3. Lymphoma, leukemia
4. Sarcoidosis
5. Septic emboli
6. Other opportunistic infections
7. Kaposi sarcoma

Miliary Hepatosplenic Lesions

1. Tuberculosis
2. Metastases
3. Fungal infections
4. Sarcoidosis
5. Lymphoma

Fat- / Lipid containing Liver Mass

1. Lipoma

2. Angiolipoma
3. Angiomyolipoma: eg, tuberous sclerosis
4. Hepatocellular carcinoma
5. Hepatocellular adenoma
6. Liposarcoma metastasis
7. Malignant teratoma metastasis (+ calcifications)
8. Focal fatty change
9. Focal nodular hyperplasia (rare)
10. Regenerative & dysplastic nodules
11. Fat packing

Cystic Liver Lesion

A. NONNEOPLASTIC
   1. Congenital hepatic cyst
   2. Hematoma
   3. Echinococcal cyst
   4. Liver abscess
   5. Fibropolycystic liver disease
   6. Intrahepatic pseudocyst
   7. Biloma

B. NEOPLASTIC
   1. Mesenchymal hamartoma
   2. Undifferentiated (embryonal) sarcoma
   3. Malignant mesenchymoma
   4. Biliary cystadenoma / cystadenocarcinoma
      ◊ < 5% of intrahepatic cysts are of biliary origin!
   5. Lymphangioma
   6. Necrotic ischemic neoplasm: HCC, giant cavernous hemangioma
   7. Cystic metastasis: ovarian / gastric carcinoma

Fibropolycystic Liver Disease

= unique group of entities with derangement of embryonic biliary ductal plate development surrounding portal vein

◊ Coexistence of hepatic + renal anomalies

A. SMALL INTERLOBULAR BILE DUCTS
   1. Congenital hepatic fibrosis
   2. Biliary hamartomas

Associated with: autosomal recessive (juvenile) polycystic kidney disease

B. MEDIUM-SIZED BILE DUCTS
   1. Autosomal dominant polycystic disease

Associated with: autosomal dominant (adult) polycystic kidney disease

C. LARGE INTRAHEPATIC BILE DUCTS
   1. Caroli disease

D. LARGE EXTRAHEPATIC BILE DUCTS
   1. Choledochal cyst

Liver Mass with Capsule

1. Hepatocellular carcinoma
2. Hepatocellular adenoma
3. Focal nodular hyperplasia (thin incomplete capsule)

Liver Mass with Capsular Retraction

1. Cholangiocarcinoma
2. Fibrolamellar carcinoma
3. Epithelioid hemangioendothelioma
4. Confluent hepatic fibrosis

or any hepatic malignancy

Disease of Hepatic Capsular & Subcapsular Region

A. INFECTION / INFLAMMATION
   1. Perihepatitis
   2. Parasites: fascioliasis, paragonimiasis, sparganosis
      → penetration of intestinal wall → migration through peritoneal cavity → perforation of liver capsule with initially subcapsular infestation

B. METASTATIC DISEASE
   (a) seeded metastasis: ovarian cancer
   (b) invasion via perihepatic ligaments: cancer of stomach, duodenum, pancreas, colon, anterior abdominal wall
   (c) direct invasion from adjacent organ: cancer of stomach, gallbladder, adrenal gland, kidney

C. PSEUDOLESION OF ALTERED HEMODYNAMICS
   1. Third inflow
   2. Arterioportal shunt
   3. Compression of liver
   4. Portal vein obstruction
   5. Hepatic vein / IVC obstruction
   6. Hepatic infarction
   7. Intrahepatic vascular shunt: superior vein of Sappey, umbilical + paraumbilical veins, right posterior portal vein, venovenous surface collaterals

D. OTHERS
   1. Focal fat sparing / focal fat infiltration
   2. Confluent hepatic fibrosis

Hyperintense Liver Mass on T1WI

◊ Usually due to lipid, hemorrhage or melanin!

1. Hepatocellular adenoma
2. Hepatocellular carcinoma
3. Regenerative & dysplastic nodule
4. Melanoma
5. Hemorrhage (methemoglobin), hemorrhagic tumor
6. Focal fat deposit, lipoma

7. Cyst with high protein content
8. Thrombosed hemangioma (rare)
9. Paramagnetic contrast agents + iodized oil

Hypointense Liver Lesion on T2WI

A. ABSOLUTE
- › blood degradation products
  - » acute intracellular deoxyhemoglobin
  - » subacute intracellular methemoglobin
  - » chronic intracellular iron ferritin / hemosiderin
  1. Hepatocellular adenoma ← internal bleeding
  2. Hepatocellular carcinoma ← internal bleeding
  3. Metastasis
  4. Focal nodular hyperplasia ← intratumoral hemolysis
  5. Nodular regenerative hyperplasia
  6. Peliosis hepatis ← hemorrhage in large vascular spaces
  7. Hematoma
- › iron (intracellular paramagnetic Fe3+)
  1. Siderotic nodule
  2. Dysplastic nodule
  3. HCC
- › copper (= divalent paramagnetic copper)
  1. Wilson disease
  2. HCC
  3. Focal nodular hyperplasia
- › macromolecules ← restricted motion of water bound to protein
  - » smooth muscle
    1. Leiomyoma
    2. Angiomyolipoma
  - » fibrosis
    1. Fibrolamellar HCC
    2. Intrahepatic cholangiocarcinoma
    3. HCC
    4. Metastasis of adenocarcinoma
    5. Focal nodular hyperplasia
    6. HCA
  - » mucin (= desiccated mucinous secretions)
    1. Metastasis
  - » fibrinogen (intracytoplasmic inclusions = fibrinogen in dilated rough endoplasmic reticulum)
    1. HCC
  - » keratin
    1. Metastasis
  - » melanin ← presumably related to higher melanin levels or to old hemorrhage
    1. Malignant melanoma

2. Metastasis

› necrosis (coagulative = dehydrated necrosis)
1. Metastasis
2. Solitary necrotic nodule
3. HCC
4. HCA

› calcium
1. Granuloma
2. Healed inactive hydatid cyst
3. Fibrolamellar HCC
4. Metastasis: mucinous cancer of colon, stomach, breast, ovary / osteo- and chondrosarcoma
5. HCA
6. Teratoma

B. RELATIVE

› fat (= macroscopic intratumoral fat)
1. Hepatocellular adenoma
2. Hepatocellular carcinoma
3. Lipoma
4. Angiomyolipoma
5. Focal nodular hyperplasia

Liver Mass on Diffusion-Weighted Imaging

= quantification of water diffusion + microcapillary blood perfusion ← based on incoherent intravoxel motion

A. Tissue with restricted diffusion (↓ ADC)
1. Tumor: usually lower ADC for malignant lesion
2. Cytotoxic edema
3. Abscess

B. Tissue with less restricted diffusion (↑ ADC)
= tissue of low cellularity / with disrupted cell membranes
1. Cyst
2. Hemangioma
3. Treated nonviable / necrotic tumor

Uptake of Superparamagnetic Iron Oxide Particles

Action: preferential entrapment by Kupffer cells

1. Focal nodular hyperplasia
2. Well-differentiated HCC
3. Dysplastic nodule
4. Hepatic adenoma

Enhancement Characteristics of Liver Mass

Hypovascular Liver Lesion

= less dense than adjacent liver parenchyma during arterial + portal venous phase

Hypo- / Nonenhancing benign Liver Lesion

1. "To small to characterize" implies unreliable density measurement
   › small metastasis = low probability
   › microabscesses = clinically obvious
   › biliary hamartoma = usually multiple
2. Hepatic cyst
3. Caroli disease
4. ADPKD
5. Abscess
6. Hydatid cyst
7. Biliary cystadenoma
8. Regenerating / dysplastic nodule
9. Lipoma
10. Bile duct hamartoma
12. Sarcoidosis
13. Histoplasmosis

Hypoenhancing Malignant Liver Lesion

1. Metastasis to liver
2. Lymphoma
3. Cholangiocarcinoma

Low-density Hepatic Mass with Enhancement

1. Hepatocellular carcinoma
2. Hypervascular metastases
   = lesions that may be obscured after contrast injection: pheochromocytoma, carcinoid, melanoma
3. Cavernous hemangioma
4. Focal nodular hyperplasia with central fibrous scar
5. Hepatic adenoma

Ring-enhancing Targetlike Liver Mass

1. Metastasis
2. Abscess
3. Cholangiocarcinoma
4. Treated HCC
5. Epithelioid hemangioendothelioma
6. Confluent hepatic fibrosis
7. Giant atypical cavernous hemangioma

Rim Enhancement

1. Biliary cystadenoma / ~ adenocarcinoma
2. Hematoma (some)
   √ bright on T1WI ← subacute hematoma

√ dark on T2WI ← hemosiderin of chronic hematoma

Hypervascular Liver Mass

√ detected during hepatic arterial + portal venous phase

A. BENIGN
   1. Focal nodular hyperplasia
   2. Hepatocellular adenoma
   3. Hemangioma (Type 1)

B. MALIGNANT
   (a) Primary malignant liver tumor
      1. Hepatocellular carcinoma
      2. Hemangioendothelioma
      3. Angiosarcoma
   (b) Hypervascular liver metastases

HYPERVASCULAR MASS IN NORMAL LIVER

1. Small hemangioma (Type 1)
2. Focal nodular hyperplasia
3. Hepatocellular adenoma
4. Metastasis

HYPERVASCULAR MASS IN CHRONIC LIVER DISEASE

1. Hepatocellular carcinoma
2. Nodular regenerative hyperplasia
3. Mimickers:
   AVM, FNH, hemangioma, dysplastic nodule, transient hepatic intensity difference

HYPERVASCULAR MASS WITH CENTRAL SCAR

1. Focal nodular hyperplasia
2. Giant cavernous hemangioma
3. Fibrolamellar carcinoma of liver
4. Well-differentiated hepatocellular carcinoma
5. Hypervascular metastasis
6. Intrahepatic cholangiocarcinoma

NODULE-WITHIN-NODULE ENHANCEMENT

1. Focus of early HCC within dysplastic nodule
   √ moderately high SI on T2WI within nodule of generally low SI
   √ marked arterial enhancement on T1WI

PERIPHERAL WASHOUT SIGN

1. Metastasis: carcinoid, breast, colon, stomach
   √ hypointense peripheral rim relative to center (best seen 10 minutes after contrast administration)

DELAYED PHASE-ENHANCING LESION

1. Hemangioma

2. Intrahepatic cholangiocarcinoma
3. Peliosis hepatis

Hepatic Calcification

A. INFECTION (most common cause)
   1. Granulomatous disease: tuberculosis (48%), histoplasmosis, brucellosis, coccidioidomycosis
      √ calcium involves entire lesion
   2. Echinococcal cyst (in 10–20%)
      √ curvilinear / ring calcification
   3. CMV, toxoplasmosis, Pneumocystis carinii
   4. Chronic granulomatous disease of childhood
   5. Old pyogenic / amebic abscess
   6. Schistosomiasis
      √ turtleback / tortoise shell calcifications
   7. Cysticercosis, filariasis, paragonimiasis, Armillifer infection, dracunculiasis
   8. Syphilitic gumma
B. VASCULAR
   1. Hepatic artery aneurysm
   2. Portal vein thrombosis
   3. Hematoma
C. BILIARY
   1. Hepatolithiasis = intrahepatic calculi
   2. Recurrent pyogenic cholangitis
   3. Ascariasis
   4. Clonorchiasis
D. BENIGN TUMORS
   1. Congenital cyst
   2. Cavernous hemangioma
      √ large coarse centrally located calcification (in 10–20%)
   3. Hepatocellular adenoma
   4. Capsule of regenerating nodules
   5. Infantile hemangioendothelioma
E. PRIMARY MALIGNANT TUMOR
   1. Fibrolamellar carcinoma (calcified in 15–25%)
   2. Hepatocellular carcinoma
   3. Hepatoblastoma (10–20%)
   4. Intrahepatic cholangiocarcinoma (in 18%)
      √ calcification accompanied by desmoplastic reaction
   5. Epithelioid hemangioendothelioma
   6. Cystadenocarcinoma
F. METASTATIC TUMOR
   1. Mucin-producing neoplasm: carcinoma of colon, breast, stomach
   2. Ovarian carcinoma (psammomatous bodies)
   3. Melanoma, thyroid carcinoma, pleural mesothelioma, chondro- and osteosarcoma,

carcinoid, leiomyosarcoma, neuroblastoma

mnemonic: 4H TAG MAP

Hepatoma
Hemochromatosis
Hemangioma
Hydatid disease
Thorotrast
Abscess
Granulomas (healed)
Metastases
Absent mnemonic
Porcelain gallbladder

Spontaneous Hepatic Hemorrhage

A. RUPTURE OF PRIMARY HYPERVASCULAR NEOPLASM
   1. Hepatocellular carcinoma (86%)
   2. Hepatocellular adenoma (6%)
   3. Hepatic hemangioma (3%)
   4. Hepatic metastasis: lung, RCC, melanoma (1%)
   5. Focal nodular hyperplasia
   6. Amyloidosis
   7. Peliosis hepatis
   8. Angiomyolipoma

(b) COAGULATION DISORDER
   1. Cirrhosis (4%)

(c) SYNDROMIC HEMOLYSIS
   1. HELLP syndrome

Colloid Shift

= increased uptake of injected colloid by bone marrow

A. HEPATIC DYSFUNCTION
   1. Cirrhosis
   2. Hepatitis
   3. Chronic passive congestion

B. AUGMENTED PERFUSION of spleen + bone marrow
   1. Hematopoietic disorders
   2. Long-term corticosteroid therapy

Focal Hot Liver Lesion

1. IVC / SVC obstruction
   √ increased perfusion of quadrate lobe located at posterior aspect of medial segment left hepatic lobe (collateral pathway via umbilical vein)
2. Budd-Chiari syndrome
   √ "increased" perfusion of caudate lobe ← actually decrease of activity elsewhere in liver

3. FNH (varying amount of Kupffer cells)
   √ hot (DIAGNOSTIC) / cold / isoactive with surrounding parenchyma
4. Regenerating nodules of cirrhosis

Focal Liver Defects

A. NEOPLASTIC
   (a) primary liver tumor: hepatoma, hemangioma, hepatic adenoma, FNH
   (b) metastases: 85% sensitive, 75–80% specific for lesion > 1–2 cm
B. INFECTIOUS DISEASE / ABSCESS
C. BENIGN CYST
D. TRAUMA (= hematoma)
E. PSEUDOTUMOR = normal variant

mnemonic: L-CHAIM
Lymphoma
Cyst
Hematoma
Abscess
Infarct
Metastasis

Mottled Hepatic Uptake

1. Cirrhosis
2. Acute hepatitis
3. Lymphoma
4. Amyloidosis
5. Granulomatous disease: sarcoidosis, fungal, viral, parasitic
6. Chemo- / radiation therapy

PORTA HEPATIS

Spectrum of Disease of Porta Hepatis

A. VASCULAR
   1. Main portal vein (MPV): thrombosis, stenosis, aneurysm, gas
   2. Common hepatic artery (CHA): thrombosis, stenosis, aneurysm
B. BILE DUCTS
   1. Cholangiocarcinoma
   2. Intrabiliary metastasis
      Origin: lung, breast, gallbladder, colon, testis, prostate, pancreas, melanoma, lymphoma
   3. Benign biliary stricture
   4. Choledochal cyst
C. LYMPH NODES
   1. Benign reactive lymph nodes
   2. Noninfectious inflammatory disease
   3. Infectious disease

4. Metastasis
5. Lymphoma
6. Posttransplant proliferative disease

D. NERVES
1. Schwannoma = neurilemmoma
2. Neurofibroma
3. Neurofibrosarcoma

E. CONNECTIVE TISSUE
1. Rhabdomyosarcoma
2. Granulocytic sarcoma

F. MISCELLANEOUS
1. Periportal edema
2. Porta hepatis fluid collection see below
3. Periportal fat deposition

Low-density Mass in Porta Hepatis

1. Choledochal cyst
2. Hepatic cyst
3. Pancreatic pseudocyst
4. Enteric duplication
5. Hepatic artery aneurysm
6. Biloma
7. Embryonal rhabdomyosarcoma of biliary tree

Porta Hepatis Fluid Collection

Cause: orthotopic liver transplantation, trauma, cholecystectomy, other biliary injury

1. Biloma
2. Hematoma
3. Abscess
4. Seroma

Enlarged Lymph Nodes of Porta Hepatis

Location: along anterior and posterior to portal vein + hepatoduodenal ligament

Normal size: < 6 mm

A. LIVER DISEASE
1. Hepatitis B and C
2. Cirrhosis

B. INFECTION / INFLAMMATION
1. Tuberculosis
2. Autoimmune diseases
3. Sarcoidosis

C. MALIGNANCY
1. Metastasis: esophagus, stomach, pancreas, gallbladder, liver, biliary tree, breast, lung, kidney
   √ may be associated with hepatic metastasis

√ compression / thrombosis of portal vein

2. Lymphoma

Defects in Porta Hepatis on Liver Scintigram

1. Normal variant ← thinning of hepatic tissue overlying portal veins + gallbladder
2. Biliary causes: dilatation of bile ducts, gallbladder hydrops
3. Enlarged portal lymph nodes
4. Metastases
5. Hepatic cyst
6. Hepatic parenchymal disease (= pseudotumor)
7. Hepatic compression by adjacent extrinsic mass
8. Postsurgical changes following cholecystectomy

LIVER CIRCULATION

Liver perfusion

Dual blood supply: normally hepatic artery 25% + portal vein 75%

PV ↓ and HA ↑: cirrhosis & portal hypertension, portal vein thrombosis (bland, malignant), PV compression (adenopathy in porta hepatis)

PV ↑ and HA ↓: postprandial state, HA stenosis (orthotopic liver transplant) / thrombosis, HA encasement (pancreatic cancer)

Global Heterogeneous Hepatic Enhancement

1. Passive hepatic congestion
2. Budd-Chiari Syndrome
3. Hereditary hemorrhagic telangiectasia
4. Peliosis hepatis

Transient Hepatic Parenchymal Enhancement

= HYPERPERFUSION ABNORMALITIES OF LIVER

= TRANSIENT HEPATIC ATTENUATION DIFFERENCE (THAD LESION) = TRANSIENT HEPATIC INTENSITY DIFFERENCE (THID)

= attenuation difference of liver appearing during dynamic bolus-enhanced CT

√ patchy area of transient high attenuation during early arterial phase

√ fading with return to normal during portal venous phase

√ peripheral location, triangular shape, straight margins

√ presence of normal vessels coursing through lesion

Cause: imbalance between hepatic arterial + portal venous supply ← decreased portal blood flow, formation of intrahepatic arterioportal shunts, increased aberrant drainage through hepatic veins

A. LOBAR / SEGMENTAL
   1. Portal vein obstruction: portal vein thrombosis, tumor invasion, surgical ligation
   2. Cirrhosis with arterioportal shunt
   3. Hypervascular gallbladder disease

B. SUBSEGMENTAL

1. Obstruction of peripheral portal branches
2. Percutaneous needle biopsy + drainage procedure / ethanol ablation
3. Acute cholecystitis + cholangitis

C. SUBCAPSULAR
   (a) due to peripheral parenchymal compression
      1. Rib compression
      2. Perihepatic peritoneal implants
      3. Pseudomyxoma peritonei
      4. Perihepatic fluid collections
   (b) idiopathic (unexplained)

D. PSEUDOLESION
   = systemic venous blood flow draining into hepatic sinusoids = third hepatic inflow
   1. Accessory cystic vein of gallbladder fossa
   2. Aberrant right gastric vein
   3. Capsular veins
   4. Parabiliary venous system
   5. Epigastric-paraumbilical venous system

E. RETICULAR-MOSAIC PATTERN
   1. Cirrhosis
   2. Hereditary hemorrhagic telangiectasia
   3. Hepatic vein obstruction

Arterioportal Shunt

= organic / functional communication between high-pressure hepatic arterial branch + low-pressure portal venous system at level of trunk / sinusoids / peribiliary venules

√ small nodular peripheral nonspherical focus isoattenuating with aorta during arterial phase → isoattenuating to liver during portal phase

√ for peripheral arterioportal shunt transient wedge-shaped subsegmental area of enhancement during arterial phase → normal parenchymal attenuation during portal venous phase

Pathophysiology:
   (a) shunted contrast material enhances a focal area of liver parenchyma before adjacent parenchyma is enhanced via the usual splanchnic route
   (b) large shunt may cause arterialized hepatofugal flow in portal vein detectable by Doppler ultrasound

Cause:
   A. CONGENITAL
      1. Hereditary hemorrhagic telangiectasia
   B. ACQUIRED
      1. Cirrhosis
         √ normal SI on T1WI + T2WI
         √ pseudolesion = small peripheral subcapsular wedge-shaped area of transient homogeneous enhancement during arterial phase of CECT
         √ pseudolesion remains stable / resolves spontaneously over time
      2. Primary hepatic neoplasm: HCC (63%), hemangioma, cholangiocarcinoma

√ abnormal SI on T1WI + T2WI with growth on follow-up
√ transient wedge-shaped area of increased attenuation / intensity on arterial phase CECT / CEMR = Transient Hepatic Parenchymal Enhancement
√ enhancement of portal vein branch ± main portal vein from periphery without enhancement of splenic vein / superior mesenteric vein

3. Secondary hepatic neoplasm: metastasis
4. Hepatic trauma: blunt abdominal trauma, iatrogenic trauma (biopsy, percutaneous abscess drainage, transhepatic biliary drainage, ethanol injection)
5. Rupture of hepatic artery pseudoaneurysm into portal vein

Small arterioportal shunts 2° to cirrhosis either remain stable or resolve spontaneously, whereas those 2° to HCC generally demonstrate growth at follow-up.

Route of fistulous communication:

1. Macroscopic fistula
2. Transsinusoidal = between microscopic interlobular arteriole + portal venule
3. Transvasal = via tumor thrombus
4. Transtumoral = via draining vein from a hypervascular tumor
5. Transplexal / peribiliary = via capillary network surrounding bile ducts

DDx: HCC (hypoattenuated during portal venous and parenchymal phase; growth after repeat imaging in 6 months)

HEPATIC ARTERY

Hepatic Artery Enlargement

A high RI is not specific for liver disease; therefore, it is less meaningful as an isolated finding than is a low RI.

1. Cirrhosis → compensatory response to decreased portal venous flow
2. Intrahepatic arteriovenous shunting
   (a) vascular neoplasm
   (b) hepatic artery-portal vein fistula
   Cause: biopsy, trauma
   √ turbulent high-velocity low-resistance flow
   √ soft-tissue bruit (= random assignment of color in perivascular soft tissue due to tissue vibration)
   √ arterialized frequently retrograde flow in portal vein
3. Hereditary hemorrhagic telangiectasia
   √ large tortuous feeding arteries with high velocity + aliased flow
   √ multiple dilated vessels (representing AVMs)
   √ large draining veins
   √ areas of fatty change + fibrosis
4. Chronic active hepatitis

Elevated Hepatic Artery Resistance (RI > 0.7)

A. PHYSIOLOGIC
   1. Postprandial state

2. Advanced age of patient

B. PATHOLOGIC
   1. Chronic hepatocellular disease
   2. Hepatic venous congestion
      (a) acute: generalized peripheral vasoconstriction
      (b) chronic: cardiac cirrhosis
   3. Transplant rejection

An RI that is too high may be the result of a postprandial state, advanced patient age, or diffuse distal microvascular disease with a wide variety of causes including chronic liver disease due to cirrhosis or chronic hepatitis.

Decreased Hepatic Artery Resistance (RI < 0.55)

A. PROXIMAL ARTERIAL NARROWING
   1. Transplant stenosis
   2. Atherosclerotic disease
   3. Arcuate ligament syndrome

B. DISTAL VASCULAR SHUNT
   1. Cirrhosis with portal hypertension
   2. Posttraumatic / iatrogenic
   3. Hereditary hemorrhagic telangiectasia

An RI that is too low may be the result of
- proximal stenosis or
- distal vascular shunting (arteriovenous / arterioportal fistulas) as seen in severe cirrhosis;
- trauma (including iatrogenic injury); or
- Osler-Weber-Rendu syndrome.

Hepatic Artery Aneurysm

= 2nd most common type of splanchnic aneurysm = up to 20% of visceral aneurysms

Cause:

1. Atherosclerosis
2. Fibromuscular dysplasia
3. Collagen vascular disease
4. Trauma: penetrating, blunt, iatrogenic (liver transplant)
5. Mycotic aneurysm
6. Tumor-related aneurysm
7. Vasculitis (multiple aneurysms): polyarteritis nodosa

- abdominal pain (55%), gastrointestinal hemorrhage (46%)

Site: common hepatic artery (in up to 63%)
Cx: aneurysm rupture → hemobilia / hemoperitoneum (20–35% mortality rate)
Rx: endovascular stenting (89% success rate)

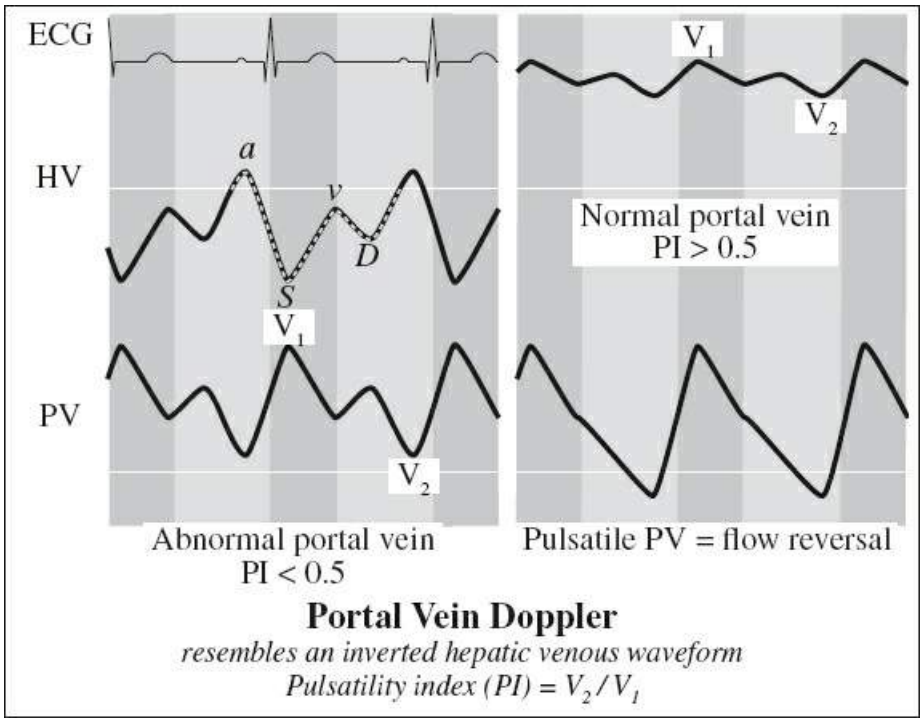
HEPATIC VEINS

Dampening of Hepatic Vein Doppler Waveform

= dampened oscillations of hepatic veins resembling portal vein flow ← "shielding" of hepatic veins from activity of right atrium = decreased phasicity
= "portalization" of hepatic vein flow pattern
√ drop of *a* wave of hepatic venous waveform below baseline

A. INCREASED LIVER TISSUE STIFFNESS
   1. Liver cirrhosis
   2. Various parenchymal abnormalities of liver: fatty liver, diffuse metastatic liver disease

B. INTRINSIC / EXTRINSIC VENOUS OBSTRUCTION
   1. Budd-Chiari syndrome intrahepatic / suprahepatic obstruction
   2. Hepatic venoocclusive disease
   3. Inferior vena cava obstruction
   4. Extrinsic compression of hepatic veins
   5. Right-sided CHF



Irregular Flow Pattern in Hepatic Veins

1. Arrhythmia
2. Turbulent blood flow
3. Technical / patient factors: sedated patient, mechanical ventilation, SOB

Pulsatile Hepatic Doppler

= *D* wave greater than S wave

1. Tricuspid regurgitation
2. Right heart failure

PORTAL VEIN

Abnormal Portal Venous Flow

Pulsatile Portal Vein

= waveform pulsatility with > 2/3 change from peak velocity to minimum velocity

Pathophysiology: transmission of abnormal pressure to sinusoids via hepatic veins / arteries

A. INCREASED VENOUS PRESSURE IN SINUSOIDS (sinusoids connect portal vein with hepatic arteries and hepatic veins)

√ dilated hepatic veins

1. Tricuspid regurgitation
   √ decreased *S* wave in hepatic venous Doppler
2. Right-sided CHF without tricuspid regurgitation
   √ tall *a* and *v* waves in hepatic venous Doppler

B. ARTERIOVENOUS SHUNT

1. Arteriovenous shunt in severe cirrhosis
   √ compressed hepatic veins
2. Hepatic artery-portal vein fistula
3. Portal-to-hepatic vein fistula
4. Hereditary hemorrhagic telangiectasia (rare) → arteriovenous fistulas

Slow Portal Venous Flow

Pathophysiology: back pressure limits forward velocity

Cause:

Portal hypertension: peak velocity < 16 cm/sec

(a) prehepatic: portal vein thrombosis
(b) intrahepatic: cirrhosis from any cause
(c) posthepatic: right-sided heart failure, tricuspid regurgitation, Budd-Chiari syndrome

Hepatofugal (Retrograde) Portal Venous Flow

= waveform below the baseline

Pathophysiology: back pressure exceeds forward pressure with flow subsequently reversing direction

Cause: severe portal hypertension from any cause

Absent / Aphasic Portal Venous Flow

A. STAGNANT PORTAL VENOUS FLOW

1. Severe portal hypertension with neither hepatopetal nor hepatofugal flow → at risk for portal vein thrombosis

B. OCCLUSION OF PORTAL VEIN

√ cavernous transformation = development of collateral vessels in / around occluded portal vein

1. Bland portal vein thrombus
2. Malignant invasion of portal vein (= tumor thrombus)
   √ "thread & streak" sign = color signal with arterial (pulsatile) waveform within thrombus

Periportal Hypoattenuating Halo

= accumulation of lymph around the portal tract

1. Edema: CHF, acute hepatitis, hepatic venoocclusive disease
2. Infiltration: lymphoma, extramedullary hematopoiesis
3. Lymphatic dilatation ← obstruction in porta hepatis by enlarged nodes / mass / in liver transplant
4. Hemorrhage (asymmetric involvement)
5. Fat accumulation

Periportal Lymphedema

= ill-defined hypodensity at porta hepatis / hypodensity parallel to portal vein

1. Acute hepatitis
2. Cirrhosis
3. Hepatic venoocclusive disease
4. Liver / bone marrow transplant
5. Overhydration
6. Blunt abdominal trauma ± liver injuries
7. Chronic congestive heart failure
8. Cardiac tamponade
9. Malignancy: hepatic / retroperitoneal

Portosystemic Shunt

A. EXTRAHEPATIC PORTOSYSTEMIC SHUNT
   (a) congenital (rare)
   (b) acquired (most common)
      Cause: portal venous hypertension
B. INTRAHEPATIC PORTOSYSTEMIC SHUNT (rare)
C. ARTERIOPORTAL SHUNT
D. PERSISTENT DUCTUS VENOSUS

Portal Venous Stenosis

Cause:

1. Tumor encasement: locally recurrent periampullary cancers = pancreatic carcinoma, hepatocellular carcinoma, cholangiocarcinoma, metastasis
2. Inflammation: acute pancreatitis
3. Surgical complication: liver transplantation (1%), partial hepatectomy, pancreaticoduodenectomy
4. Radiation therapy

√ focal segment of vessel narrowing ± poststenotic dilatation
√ inhomogeneous peripheral subcapsular increase in arterial inflow during hepatic arterial phase
√ secondary portal hypertension → increased number and size of collaterals

US:

√ focal color aliasing
√ accelerated flow across stenosis = 4-fold velocity gradient

√ spectral broadening of waveform (= poststenotic turbulence)

Cx: portal venous hypertension with massive intractable ascites + recurrent variceal bleeding

Rx: balloon angioplasty, stent placement

Portal Venous Gas

◊ Should be considered a life-threatening event and sign of bowel infarction + gangrene until proved otherwise!

Etiology:

A. INTESTINAL NECROSIS (in 74% of adults)
   1. Bowel infarction ← arterial and venous occlusions (vascular accidents, SMA syndrome)
   2. Ulcerative colitis
   3. Necrotizing enterocolitis associated with mesenteric arterial thrombosis
   4. Perforated gastric ulcer

B. GI OBSTRUCTION
   1. Small bowel obstruction: eg, duodenal atresia
   2. Imperforate anus
   3. Esophageal atresia

C. MISCELLANEOUS
   1. Hemorrhagic pancreatitis
   2. Sigmoid diverticulitis
   3. Intraabdominal abscess
   4. Pneumonia
   5. Iatrogenic injection of air during endoscopy / BE
   6. Dead fetus
   7. Diabetes
   8. Diarrhea

mnemonic: BE NICE

BE (air embolism during double contrast barium enema)
Necrotizing enterocolitis
Infarction (mesenteric)
Catheterization of umbilical vein
Erythroblastosis fetalis

Pathogenesis:

1. Intestinal wall alteration permitting passage of intraluminal air into intestinal venules:
   (a) ulceration of gastric, duodenal, bowel wall
   (b) sloughing of epithelial lining
   (c) enhanced mucosal permeability
   eg, intestinal ischemia with bowel necrosis (most common); perforated gastric carcinoma / ulcer; inflammatory bowel disease (Crohn disease, ulcerative colitis); ingestion of a caustic substance
   Prognosis: 75–90% mortality rate within 1 week of Dx
2. Bowel distension with elevated intraluminal pressure causes minimal mucosal

disruption + permits passage of intraluminal air into veins:
(a) iatrogenic dilatation of hollow viscus: gastrostomy, sclerotherapy, ERCP, colonoscopy, barium enema)
(b) spontaneous paralytic ileus, mechanical obstruction, acute gastric dilatation
(c) blunt trauma (< 1%) with acute pressure changes
(d) barotrauma

Prognosis: surgery often not indicated

3. Intraabdominal sepsis
   (a) ? gas from septicemia in branches of mesenteric veins / portal vein (= pylephlebitis)
   (b) ? increased intraluminal fermentation of carbohydrates ← bacterial overgrowth
   (c) ? mesocolic abscess → inframesocolic perforation dissecting between peritoneal leaflets, eg, diverticulitis, intra- or retroperitoneal abscess / gangrene, TB, inflammatory bowel disease, necrotizing pancreatitis
4. Idiopathic (15%)
   eg, organ transplantation (liver [18%], kidney, bone marrow), pulmonary disease (chronic obstructive pulmonary disease, bronchopneumonia, asthma), drugs (steroids, cytostatics), seizure

Composition of colonic gas:
methane, carbon dioxide, oxygen, nitrogen, hydrogen

Location: predominantly in left lobe = nondependent position when patient supine

Plain film:
◊ Substantial amount necessary for detection
√ branching linear gas densities:
  √ in periphery of liver extending to within 2 cm of liver capsule
  √ predominantly within more anteriorly located left lobe of liver
√ pneumatosis of intestinal wall

CT:
◊ Small amount of gas detectable
√ tubular branching areas of decreased attenuation (similar to air) in periphery 2 cm deep to liver capsule
√ gas in superior / inferior mesenteric veins
√ gas in small mesenteric veins at mesenteric border of bowel

MR:
√ susceptibility artifacts in portal vein

US:
◊ Small amount of gas detectable
√ intensely hyperechoic foci (= reverberation artifacts)within lumen of portal vein + intrahepatic portal radicles

Doppler:
√ sharp high-amplitude bidirectional spikes (overloading of Doppler receiver from strong reflection of gas bubble in bloodstream) superimposed on normal portal vein spectrum

Mortality rate: 29–43% for mesenteric ischemia with portal vein gas

Rx: (1) Surgery for mesenteric ischemia, diverticulitis, bowel obstruction

(2) Conservative management in trauma, colonoscopy, idiopathic causes

DDx: pneumobilia (located centrally within bile ducts close to liver hilum + within left lobe of liver)

Portal Vein Calcification

Location: portal vein > splenic vein > superior mesenteric vein > inferior mesenteric vein

Associated with: portal venous hypertension, congenital abnormalities, umbilical vein catheterization

- asymptomatic

Cx: biliary obstruction (if densely calcified)

GALLBLADDER

Nonvisualization of Gallbladder on US

1. Status post cholecystectomy
2. Obscured by costal margin
3. Anomalous position (intrahepatic, subphrenic)
4. Gallbladder carcinoma replacing gallbladder
5. Perforation of gallbladder
6. Congenital absence
7. Contracted gallbladder
   (a) nonfasting status without stones
   (b) in fasting status with stones
   √ wall-echo-shadow (WES triad) interfaces

Acoustic Shadowing in Gallbladder Fossa

1. WES (wall-echo-shadow) triad
2. Gas in duodenum / colon obscuring gallbladder
3. Porcelain gallbladder
4. Emphysematous cholecystitis
5. Cholecystoenteric fistula
6. Status post ERCP with retrograde air injection

Hyperattenuating Bile

1. Hemorrhagic cholecystitis
2. Hemobilia
3. Prior contrast administration
   (a) vicarious excretion of IV iodinated contrast agent
   (b) retained contrast agent from cholangiography
   (c) cholecystopaque
4. Milk of calcium bile
5. Biliary sludge, purulent bile
6. Aneurysm / pseudoaneurysm with active extravasation into biliary system
7. Malignancy

Displaced Gallbladder

A. NORMAL IMPRESSION
by duodenum / colon (positional change)

B. HEPATIC MASS
hepatoma, hemangioma, regenerating nodule, metastases, intrahepatic cyst, polycystic liver, hydatid disease, hepar lobatum (tertiary syphilis), granuloma, abscess

C. EXTRAHEPATIC MASS
1. Retroperitoneal tumor (renal, adrenal)
2. Polycystic kidney
3. Lymphoma
4. Lymph node metastasis to porta hepatis
5. Pancreatic pseudocyst

Alteration in Gallbladder Size

Enlarged Gallbladder

= CHOLECYSTOMEGALY = HYDROPS OF GALLBLADDER

Size:

(a) infants < 1 year: > 3 cm in length
(b) children: > 7 cm in length
(c) adults: > 10 x 4 cm (L x W)

A. OBSTRUCTION
1. Cystic duct obstruction (40%)
   (a) hydrops: chronic cystic duct obstruction + distension with clear sterile mucus (white bile)
   (b) empyema: acute / chronic obstruction with superinfection of bile
2. Cholelithiasis causing obstruction (37%)
3. Cholecystitis with cholelithiasis (11%)
4. **Courvoisier phenomenon** (10%)
   ← neoplastic process in pancreas / duodenal papilla / ampulla of Vater / common bile duct
5. Pancreatitis
6. Infection: leptospirosis, ascariasis, typhoid fever, scarlet fever, familial Mediterranean fever

B. UNOBSTRUCTED (mostly neuropathic)
1. S/P vagotomy
2. Diabetes mellitus
3. Alcoholism
4. Appendicitis (in children)
5. Narcotic analgesia
6. WDHA syndrome
7. Hyperalimentation
8. Acromegaly
9. Kawasaki syndrome
10. Anticholinergics

11. Bedridden patient with prolonged illness
12. AIDS (in 18%)
13. Dehydration
14. Prolonged fasting
15. Total parenteral nutrition
16. Sepsis

C. NORMAL (2%)

Small Gallbladder

1. Chronic cholecystitis
2. Cystic fibrosis: in 25% of patients
3. Congenital hypoplasia / multiseptated gallbladder
4. Postprandial
5. Intrahepatic cholestasis: viral, drug-related

Gallbladder Wall Thickening

Diffuse Gallbladder Wall Thickening

= anterior wall of gallbladder > 3 mm

A. INTRINSIC
   (a) infection
      1. Acute cholecystitis
      2. Chronic cholecystitis (10–25%)
      3. Xanthogranulomatous cholecystitis
      4. Gallbladder perforation
      5. Sepsis
      6. Brucellosis
   (b) inflammation
      1. AIDS cholangiopathy (average of 9 mm in up to 55%)
      2. Sclerosing cholangitis
      3. Eosinophilic cholecystitis
   (c) tumor infiltration
      1. Gallbladder carcinoma (in 41% diffuse)
      2. Leukemic infiltration (AML)
      3. Multiple myeloma
   (d) others
      1. Hyperplastic cholecystosis (in 91% diffuse)
      2. Gallbladder varices

B. EXTRINSIC
   (a) liver disease
      1. Hepatitis (in 80%)
      2. Cirrhosis
      3. Hepatic venous obstruction
      4. Fitz-Hugh–Curtis syndrome
   (b) fluid overload

1. Hypoalbuminemia
2. Renal failure
3. Right heart failure
4. Systemic venous hypertension
5. Ascites
6. Lymphatic obstruction (by portal nodes)

(c) others

2. Graft-versus-host disease
3. Pancreatitis

(d) drugs

1. Chemoinfusion of hepatic artery (ischemia)
2. Treatment with interleukin

C. PHYSIOLOGIC

= contracted gallbladder after eating

Focal Gallbladder Wall Thickening

A. METABOLIC
1. Metachromatic sulfatides
2. Hyperplastic cholecystoses

B. BENIGN TUMOR
1. Adenoma: glandular elements (0.2%)
2. Papilloma: fingerlike projections (0.2%)
3. Villous hyperplasia
4. Fibroadenoma
5. Cystadenoma: ? premalignant
6. Neurinoma, hemangioma
7. Carcinoid tumor

C. MALIGNANT TUMOR
1. Carcinoma of gallbladder: adenocarcinoma / squamous cell carcinoma (in 59% focal)
2. Leiomyosarcoma
3. Metastases: from malignant melanoma (15%), lung, kidney, esophagus, breast, carcinoid, Kaposi sarcoma, lymphoma, leukemia

D. INFLAMMATION / INFECTION
1. Inflammatory polyp: in chronic cholecystitis
2. Parasitic granuloma: Ascaris lumbricoides, Paragonimus westermani, Clonorchis, filariasis, Schistosoma, Fasciola
3. Intramural epithelial cyst / mucinous retention cyst
4. Xanthogranulomatous cholecystitis (in 9% focal)

E. WALL-ADHERENT GALLSTONE = embedded stone

F. HETEROTOPIC MUCOSA
1. Ectopic pancreatic tissue
2. Ectopic gastric glands
3. Ectopic intestinal glands
4. Ectopic hepatic tissue

5. Ectopic prostatic tissue

Filling Defects of Gallbladder

Fixed Filling Defects of Gallbladder

mnemonic: PANTS
Polyp
Adenomyomatosis
Neurinoma
Tumor, primary / secondary
Stone, wall-adherent

GALLBLADDER POLYP

= sessile projection of GB wall into GB lumen

Prevalence: 3-7% by ultrasound, 2–12% of cholecystectomy specimens

A. PSEUDOTUMOR
   1. Cholesterol polyp (63–74%): on average 8 polyps
   2. Adenomyoma (7%)
   3. Inflammatory polyp (4%)
   4. Others: heterotopic gastric glands

B. TUMOROUS POLYP (85%)
   (a) benign (85%)
      1. Adenoma (84%)
      2. Fibroma, leiomyoma, lipoma, neurofibroma, neuroendocrine tumor (1%)
   (b) malignant (15%)
      1. Adenocarcinoma (4%)
      2. Squamous cell carcinoma, carcinosarcoma, small cell carcinoma, lymphoma
      3. Metastasis: melanoma (60%), RCC

◊ 94% of benign lesions are < 10 mm; 88% of malignant lesions are > 10 mm

◊ Any polyp > 10 mm should be operated on
   › in a symptomatic patient
   › in a patient > 50 years of age
   › with coexisting gallstones
   or followed every 3–6 months for 1 year

DDx: (1) Adherent gallstone
(2) Adherent tumefactive sludge

Mobile Intraluminal Mass in Gallbladder

1. Tumefactive sludge
2. Blood clot
3. Nonshadowing stone

Comet-tail Artifact in Liver and Gallbladder

A. LIVER
   1. Foreign metallic body: eg, surgical clip
   2. Intrahepatic calcification

3. Pneumobilia
4. Multiple bile duct hamartoma = von Meyenburg complex

B. GALLBLADDER
1. Rokitansky-Aschoff sinus
2. Intramural stone
3. Cholesterolosis of gallbladder

Echogenic Fat in Hepatoduodenal Ligament

= sign of pericholecystic inflammation

1. Cholecystitis
2. Perforated duodenal ulcer
3. Pancreatitis
4. Diverticulitis

False-positive DISIDA Scan

mnemonic: F2C2 PAL

Food (meal within last 4 hours = GB empty)
Fasting / total parenteral nutrition (GB full)
Cystic duct cholangiocarcinoma
Chronic cholecystitis
Pancreatitis, acute
Alcoholism (= alcohol-toxic hepatitis)
Liver dysfunction (hepatitis)

False-negative DISIDA Scan

mnemonic: ADA

Acalculous cholecystitis
Duodenal diverticulum simulating GB
Accessory cystic duct

Rim Sign

= curvilinear pericholecystic rim of increased hepatic tracer activity adjacent to a photopenic gallbladder fossa

Cause: local hyperemia with increased perfusion + injury of hepatocytes with impaired excretion of radiotracer

1. Acute cholecystitis (34–61% sensitive)
2. Complicated acute cholecystitis
   √ nonvisualization of GB @ 1 hour (94–100% PPV, 95–100% specific)
3. Chronic cholecystitis

BILE DUCTS

Hemobilia

1. Iatrogenic trauma: liver biopsy, transhepatic cholangiography / percutaneous transhepatic biliary drainage (4–18%) / portography, sphincterotomy, endoscopic biliary stent

placement, radiofrequency ablation
2. Blunt / penetrating trauma
3. Rupture of hepatic artery aneurysm / pseudoaneurysm
4. Anticoagulation

Gas in Biliary Tree = Pneumobilia

mnemonic: I GET UP

Incompetent sphincter of Oddi (after sphincterotomy / passage of a gallstone)
Gallstone ileus
Emphysematous cholecystitis (actually in gallbladder)
Trauma
Ulcer (duodenal ulcer perforating into CBD)
Postoperative (eg, cholecystoenterostomy)

√ gas outlines choledochus ± gallbladder
√ peripheral branches of bile ducts not filled

Pneumobilia is a common finding with patent biliary stents. It may not be present when the stent is occluded ← no communication with the duodenum.

Obstructive Jaundice in Adult

Etiology:

A. BENIGN DISEASE (76%)
   1. Traumatic / postoperative stricture (44%): cholecystectomy (incidence of 0.2–0.7%), liver transplantation
   2. Calculi (21%)
   3. Chronic pancreatitis (8%)
   4. Sclerosing cholangitis (1%): primary sclerosing cholangitis, IgG4-related sclerosing disease
   5. Recurrent pyogenic cholangitis
   6. Parasitic disease: eg, ascariasis
   7. Liver cysts
   8. Aortic aneurysm
   9. Papillary stenosis

B. MALIGNANCY (24%)
   1. Pancreatic carcinoma (18%)
   2. Ampullary / duodenal carcinoma (8%)
   3. Cholangiocarcinoma (3%)
   4. Metastatic disease (2%): stomach, pancreas, lung, breast, colon, lymphoma

Level and cause of obstruction:

A. INTRAPANCREATIC
   1. Choledocholithiasis
      ◊ Most common cause of biliary obstruction (in 15% of patients with cholelithiasis)!
   2. Chronic pancreatitis
   3. Pancreatic carcinoma

B. SUPRAPANCREATIC (5%)

= between pancreas + porta hepatis
1. Cholangiocarcinoma
2. Metastatic adenopathy

C. PORTA HEPATIS (5%)
1. Klatskin tumor
2. Spread from adjacent tumor (GB, liver)
3. Surgical stricture

D. INTRAHEPATIC
1. Cystadenoma, cystadenocarcinoma
2. Mirizzi syndrome
3. Caroli disease
4. Cholangitis: recurrent pyogenic cholangitis, sclerosing cholangitis, AIDS cholangitis

Incidence of infected bile in bile duct obstruction:

(a) in 64% with incomplete / partial obstruction
(b) in 10 with complete obstruction

◊ Infection twice as high with biliary calculi than with malignant obstruction!

Organism: E. coli (21%), Klebsiella (21%), enterococci (18%), Proteus (15%)

Test sensitivity for common bile duct obstruction:

1. Intravenous cholangiography
depends on level of bilirubin: < 1 (2) mg/dL in 92%; < 2 mg/dL in 82%; < 3 mg/dL (> 4) in 40% (< 10%)
False-negative rate: 45%
Cx: adverse reactions in 4–10%
2. US
88–90% sensitivity for dilatation of CBD
◊ In 27–95% US gives correct level of obstruction
◊ In 23–81% US gives correct cause of obstruction
√ CBD > 4–6 mm / 10% of patient's age in years in mm
√ increase in CBD size after fatty meal
√ "Swiss cheese" sign = abundance of fluid-filled structures on liver sections ← dilated intrahepatic bile ducts
√ intrahepatic bile duct > 2 mm / > 40% of adjacent portal vein branch
√ intrahepatic "double channel" / "shotgun" sign = two parallel tubular structures composed of portal vein + dilated intrahepatic bile duct
False-negative (= obstruction without dilatation):
no dilatation in acute early obstruction (in 70%), sclerosing cholangitis, intermittent obstruction from choledocholithiasis
False-positive (= dilatation without obstruction):
post decompression of prior obstruction, dilated hepatic artery in cirrhosis / portal hypertension / hepatic neoplasm, in patients after cholecystectomy
3. CT
100% visualization in tumorous obstruction
60% visualization in nontumorous obstruction
4. CEMR cholangiopancreatography

= 1st imaging method of choice → most comprehensive evaluation of biliary stricture

Caveat: pseudostricture secondary to

(a) MRI technique / postprocessing
(b) incomplete volume acquisition
(c) blooming artifact ← cholecystectomy clips
(d) pulsation artifact from hepatic and gastroduodenal arteries

5. MRCP provides information about the biliary tree that cannot be obtained with more invasive methods:
   (a) delineates biliary-enteric anastomosis
   (b) detects complications: anastomotic biliary stricture, intraductal stones, biliary dilatation

6. NUC
   √ delayed / nonvisualization of biliary system (93% specific)
   √ vicarious excretion of tracer through kidneys

DDx: Hepatocellular dysfunction (delayed clearance of cardiac blood pool)

Hyperbilirubinemia in Infants

= UNCONJUGATED HYPERBILIRUBINEMIA

A. PHYSIOLOGIC

Frequency: in 60% of full-term infants, in 80% of preterm infants

Course: increase by day 2–3, peak by day 5–7 (up to 12 mg/dL in full-term babies, up to 14 mg/dL in premature infants)

◊ Breast-fed babies may have an elevated bilirubin level until the end of 2nd week of life!

B. NONPHYSIOLOGIC

- onset of jaundice within first 24 hours
- persistent / new-onset jaundice in infants 2 weeks of age
- rise of serum bilirubin > 5 mg/dL per 24 hours
- direct bilirubin level > 1 mg/dL

Neonatal Obstructive Jaundice

= severe persistent jaundice in a child beyond 3–4 weeks of age

Cause:

A. INFECTION
   (a) bacterial: E. coli, Listeria monocytogenes
   (b) viral: TORCH, coxsackie virus, ECHO virus, adenovirus

B. METABOLIC
   (a) inherited: alpha-1 antitrypsin deficiency, cystic fibrosis, galactosemia, hereditary tyrosinemia
   (b) acquired: inspissated bile syndrome = "bile plug" syndrome (= cholestasis ← erythroblastosis); cholestasis ← total parenteral nutrition; choledocholithiasis

C. BILIARY TRACT ABNORMALITIES
   (a) extrahepatic: biliary obstruction / hypoplasia / atresia, choledochal cyst, spontaneous perforation of bile duct
   (b) intrahepatic: ductular hypoplasia / atresia

D. IDIOPATHIC NEONATAL HEPATITIS

◊ The 3 most common causes of jaundice in neonates are hepatitis, biliary atresia, and

choledochal cyst!

mnemonic: CAN
Choledochal cyst
Atresia
Neonatal hepatitis

NUC–imaging regimen:
(1) Premedication with phenobarbital (5 mg/kg/d) over 5 days to induce hepatic microsomal enzymes→ enhancing uptake and excretion of certain compounds → increase of bile flow
(2) IDA scintigraphy (50 μCi/kg; minimum of 1 mCi)
(3) Imaging at 5-min intervals for 1 hr + at 2, 4, 6, 8, 24 hours

Jaundice in Older Children

A. DISEASE OF HEPATOCYTES
  (a) infection / inflammaton
    1. Acute hepatitis: infection, toxic agents, drugs
    2. Chronic hepatitis
  (b) metabolic
    1. Wilson disease
    2. Cystic fibrosis
    3. Glycogen storage disease
    4. Tyrosinemia
    5. Alpha-1 antitrypsin deficiency
B. OBSTRUCTION
  (a) malignant neoplasm
    1. Hepatoblastoma
    2. Hepatocellular carcinoma
    3. Sarcomas: angiosarcoma, lymphosarcoma, rhabdomyosarcoma of bile ducts, undifferentiated embryonal sarcoma
    4. Metastatic disease: neuroblastoma, Wilms tumor, leukemia/lymphoma
  (b) benign neoplasm
    1. Infantile hemangioendothelioma
    2. Mesenchymal hamartoma
  (c) benign stricture: congenital choledochal cyst
  (d) cholelithiasis / choledocholithiasis (uncommon)

Large Nonobstructed CBD

1. Passage of stone (return to normal after days to weeks)
2. Common bile duct surgery (return to normal in 30–50 days)
3. Postcholecystectomy dilatation (in up to 16%)
4. Intestinal hypomotility
5. Normal variant (aging)

Fatty-meal sonography (to differentiate from obstruction with 74% sensitivity, 100% specificity)
Method: peroral Lipomul® (1.5 mL/kg) followed by 100 mL of water [cholecystokinin

causes contraction of gallbladder, relaxation of sphincter of Oddi, increase in bile secretion], CBD measured before and 45 / 60 min after stimulation

√ little change / decrease in size = normal response
√ increase in size > 2 mm = partial obstruction

Filling Defect in Bile Ducts

A. ARTIFACT
   1. Pseudocalculus
      (a) contracted sphincter of Boyden + Oddi with smooth arcuate contour
      (b) bridge of tissue between cystic duct + CHD
      (c) underfilling of cystic duct during ERCP
      (d) admixture defect at cystic duct junction
   2. Air bubble: confirmed by positional changes
   3. Blood clot: spheroid configuration, spontaneous resolution with time
B. BILIARY CALCULI
C. MIRIZZI SYNDROME
D. NEOPLASM
   (a) malignant
      1. Cholangiocarcinoma: irregular stricture, intraluminal polypoid mass
      2. Metastatic tumor: colon, gallbladder, lung, breast, testis, prostate, pancreas, melanoma, lymphoma
      3. Others: ampullary carcinoma, hepatoma, hamartoma, carcinoid, embryonal rhabdomyosarcoma of biliary tree
   (b) benign
      1. Papilloma: most common benign neoplasm
         Histo: vascular connective tissue covered by single layer of columnar epithelium
      2. Adenoma
         Histo: epithelial glandular tissue surrounded by fibrous tissue
      3. Fibroma, lipoma, neuroma
      4. Granular cell myoblastoma (= Schwann-cell–derived biliary tumor) in young black woman
E. PARASITES
   1. Ascaris lumbricoides
   2. Clonorchis sinensis
   3. Fasciola hepatica
   3. Schistosoma japonicum
   4. Hydatid cyst

Echogenic Material in Bile Ducts

1. Calculi
2. Gas
3. Blood
4. Tumor
5. Parasites

Bile Duct Narrowing / Stricture

= fixed focal narrowing of bile duct

A stenosis caused by a malignant lesion usually manifests as an irregular stricture with shouldered margins, whereas a benign stenosis tends to have smooth borders with gradually tapered margins.

A. BENIGN STRICTURE (44%)

Cause: injury → inflammatory response → fibrosis

√ often short-segment involvement (not diagnostic!)

√ often smooth concentric narrowing (not diagnostic!)

(a) trauma

1. Postoperative stricture (95–99%):
   - › open cholecystectomy (0.2–0.7%)
   - › laparoscopic cholecystectomy (1.2%)
   - › cadaveric liver transplant (5–15%)
   - › living donor liver transplant (28–32%)
2. Blunt / penetrating trauma
3. Hepatic artery embolization

(b) inflammation

1. Sclerosing cholangitis:
   - › primary sclerosing cholangitis
   - › IgG4-related sclerosing disease
2. Eosinophilic portal cholangiopathy
3. Chronic pancreatitis
   - ◊ 10% of all benign biliary strictures
4. Acute pancreatitis (less common)
5. Pancreatic pseudocyst
6. Perforated duodenal ulcer
7. Erosion by biliary calculus
8. Mirizzi syndrome
9. Radiation therapy

(c) infection

1. Acute bacterial cholangitis
2. Recurrent pyogenic cholangitis
3. Chemotherapy-induced cholangitis
4. AIDS-related cholangitis
5. Abscess

(d) congenital

1. Choledochal cyst

B. MALIGNANT STRICTURE

1. Pancreatic adenocarcinoma
2. Ampullary cancer
3. Cholangiocarcinoma
4. Compression by enlarged lymph node
5. Metastasis

A narrowed segment with the following MRI features is more likely to be malignant:

√ hyperenhancement relative to liver during portal venous phase
√ length of > 12 mm
√ wall thickness > 3 mm
√ indistinct outer margin
√ luminal irregularity and asymmetry

Cause of Biliary Stricture by Location

@ distal CBD

Malignant vs. Benign CBD Stricture		
Criteria	*Malignant*	*Benign*
Borders	irregular	smooth
Luminal margin	shouldered	tapered
Stricture length (mm)	18 ± 7	9 ± 7
Duct diameter proximally (mm)	22 ± 5	18 ± 5
Duct wall thickness >1.5 mm	80%	15%
Enhancement, arterial phase	85%	10%
Enhancement, portal phase	95%	15%
Progression of stricture	rapid	gradual
Bilirubin > 8.4 mg/dL	+	-
CA 19-9 > 100 U/L	+	-

1. IgG4-related sclerosing cholangitis

@ junction of cystic duct + CHD
1. Cholecystectomy
2. Mirizzi syndrome

@ confluence of left + right hepatic ducts
1. Cholecystectomy
2. IgG4-related sclerosing cholangitis

@ intrapancreatic portion of CBD
1. Chronic pancreatitis

@ intra- and extrahepatic bile ducts
1. Primary sclerosing cholangitis
2. IgG4-related sclerosing cholangitis
3. Recurrent pyogenic cholangitis
4. AIDS cholangiopathy

Multifocal Intrahepatic Bile Duct Strictures

1. Primary sclerosing cholangitis
2. Ascending cholangitis ← stricture / stone / bile duct anomaly
3. Oriental cholangiohepatitis
4. AIDS-related cholangitis
5. Ischemia
   (a) floxuridine treatment
   (b) hepatic arterial thrombosis (in liver transplant)

6. NEOPLASM
   (a) cholangiocarcinoma
   (b) metastases: GI tract, lymphoma, breast, lung
7. Previous bile surgery
8. Congenital biliary anomalies

Congenital Biliary Cysts

(Todani classification)

I. Choledochal cyst (77–87%)
   Ia diffuse cystic dilatation of entire extrahepatic duct
   Ib focal segmental dilatation of extrahepatic duct
   Ic fusiform cystic dilatation of only CBD
   Cause: anomalous pancreaticobiliary union
II. Diverticulum of extrahepatic ducts (1.2–3%)
   originating from extrahepatic bile duct (CBD / CHD)
   √ neck of diverticulum open / closed
III. Choledochocele (1.4–6%)
IV. Multiple segmental bile duct cysts
   IVa multiple intra- and extrahepatic biliary cysts + saccular dilatation of CBD (19%)
   IVb multiple extrahepatic biliary cysts + normal intrahepatic bile ducts (rare)
V. Caroli disease = intrahepatic biliary cysts

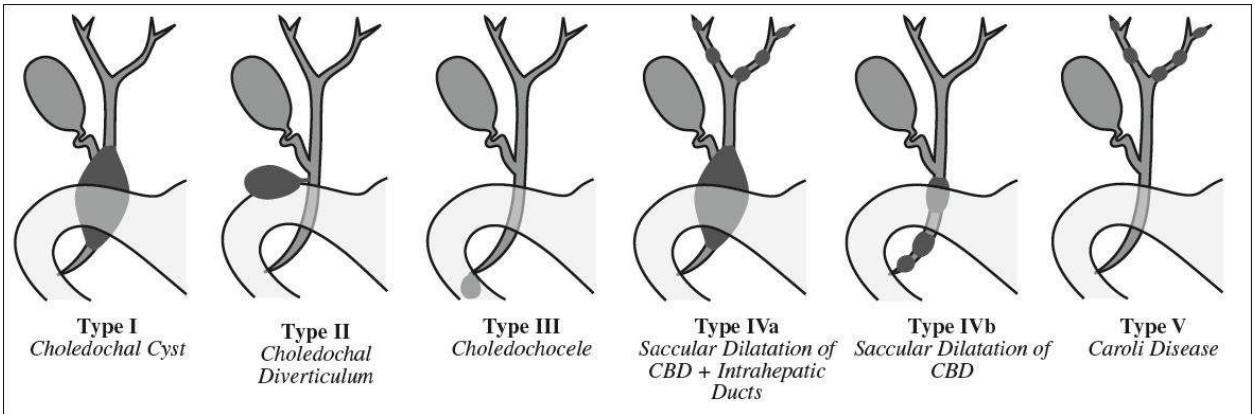
Papillary Stenosis

= blockage of bile / pancreatic fluid flow at sphincter of Oddi WITHOUT an ampullary mass / inflammatory lesion

Etiology:

A. PRIMARY PAPILLARY STENOSIS (10%)
   1. Congenital malformation of papilla
   2. Sequelae of acute / chronic inflammation
   3. Adenomyosis

B. SECONDARY PAPILLARY STENOSIS (90%)
   1. Sphincter of Oddi dysfunction
      Prevalence: 1.5% (most common cause)
      Associated with: pancreas divisum, history of pancreatitis
   2. Mechanical trauma of stone passage → papillitis
      › choledocholithiasis in 64%
      › cholecystolithiasis in 26%
   3. Reflex spasm = papillary dyskinesia
   4. Scar from previous surgical manipulation
   5. Periampullary neoplasm



Classification of Congenital Biliary Cysts

√ prestenotic dilatation of CBD
√ increase in pancreatic duct diameter (83%)
√ long smooth narrowing / beak ← fibrotic stenosis
√ prolonged bile-to-bowel transit time > 45 minutes on Tc-IDA scintigraphy
√ papillary size < 12.3 mm = the only independently reliable variable for differentiating benign from malignant causes

N.B.: for suspected ampullary stenosis employ secretin stimulation test with imaging 4–10 min post injection

Bulging Papilla

1. Papillitis: ← acute pancreatitis, acute cholangitis, passage of biliary stone, periampullary diverticulum, parasite, infection
2. Intraductal papillary mucinous neoplasm
3. Ampullary neoplasm
4. Periampullary neoplasm
5. Autoimmune pancreatitis
6. Choledochocele

Signs of malignant ampullary obstruction:
- √ identification of an ampullary mass
- √ papillary bulging
- √ irregular asymmetric luminal narrowing of distal CBD
- √ diffuse upstream intra- + extrahepatic biliary dilatation

Signs of a benign obstruction:
- √ smooth symmetric luminal narrowing of CBD
- √ central biliary dilatation without an ampullary mass or papillary bulging

Ampullary and Periampullary Lesions

A. NEOPLASM
   (a) related to ampulla
      1. Ampullary cancer (4%)
      2. Ampullary adenoma
      3. Periampullary lipoma
   (b) related to pancreas

1. Pancreatic adenocarcinoma (85%)
2. Pancreatic neuroendocrine tumor
3. Intraductal papillary mucinous neoplasm

(c) related to bile duct
1. Cholangiocarcinoma distal CBD (6%)

(d) related to duodenal wall
1. Duodenal adenocarcinoma
2. Duodenal adenoma
3. Duodenal carcinoid
4. GIST

B. NONNEOPLASTIC LESION

(a) related to hepatopancreatic duct
1. Papillary stenosis
2. Choledocholithiasis
3. Pancreas divisum
4. Santorinicele
5. Choledochocele

(b) related to pancreas
1. Groove pancreatitis
2. Autoimmune pancreatitis
3. Pancreaticoduodenal artery pseudoaneurysm

(c) related to duodenum
1. Brunner gland hyperplasia and hamartoma
2. Duodenitis
3. Duodenal Crohn disease
4. Duodenal diverticula
5. Duodenal perforation and transection

Periampullary Tumor

= tumor arising within 2 cm of major duodenal papilla including carcinoma of ampulla of Vater, distal CBD, head + uncinate process of pancreas, periampullary portion of duodenum

Double-Duct Sign

= dilatation of common bile duct + pancreatic duct

A. MALIGNANT
1. Ampullary tumor (most common)
2. Pancreatic ductal adenocarcinoma
3. Distal CBD cholangiocarcinoma
4. Duodenal carcinoma
5. Lymphoma

B. BENIGN
1. Stone impacted in ampulla of Vater
2. Papillary / ampullary stenosis
3. Chronic pancreatitis

PANCREAS

Congenital Pancreatic Anomalies

A. Fusion Anomaly
   1. Pancreas divisum
   2. Agenesis of dorsal pancreas

B. Migration Anomaly
   1. Annular pancreas
   2. Ectopic pancreas

C. Duplication Anomaly
   (a) variations in number
   (b) variations in form

D. Genetics
   1. Von Hippel-Lindau disease

E. Underdevelopment
   1. **Pancreatic Agenesis** (extremely rare)
      Cause: mutation of developmental protein IPF1
      Associated with: gallbladder aplasia, polysplenia, fetal growth retardation
      • incompatible with life
   2. Pancreatic hypoplasia / partial agenesis
      = absence of ventral / dorsal anlage
      (a) agenesis of dorsal pancreas
      (b) agenesis of ventral pancreas
      (c) isolated hypoplasia of uncinate process

Paraduodenal Pancreatitis

1. Groove pancreatitis
2. Cystic dystrophy of duodenal wall
3. Paraduodenal wall cysts

Location: in + around minor papilla

Common features:

√ dilated ducts and cysts in duodenal wall
√ Brunner gland hyperplasia
√ hamartomatous pancreatic tissue in pancreaticoduodenal groove

Pancreatic Calcifications

1. CHRONIC PANCREATITIS
   Numerous irregular stippled calcifications of varying size; predominantly intraductal
   (a) Alcoholic pancreatitis (in 20–50%):
      √ small speckled intraductal calculi limited to head / tail in 25%
   (b) Biliary pancreatitis (in 2%)
   (c) Hereditary pancreatitis (in 35–60%):
      √ round calcifications throughout gland
   (d) Idiopathic pancreatitis
   (e) Pancreatic pseudocyst

(f) Juvenile tropical pancreatitis
√ discrete dense up to 5 cm large calculi

2. NEOPLASM
   (a) Microcystic adenoma (in 33%):
   √ "sunburst" appearance of calcifications
   (b) Macrocystic cystadenoma In 15%):
   √ amorphous peripheral calcifications
   (c) Adenocarcinoma (in 2%): with "sunburst" pattern
   (d) Cavernous lymphangioma / hemangioma:
   √ multiple phleboliths
   (e) Metastases from colon cancer
3. INTRAPARENCHYMAL HEMORRHAGE
   (a) Old hematoma / abscess / infarction
   (b) Rupture of intrapancreatic aneurysm
4. HYPERPARATHYROIDISM (in 20%):
   ◊ 50% of patients develop chronic pancreatitis + concomitant nephrocalcinosis
   ◊ Indistinguishable from alcoholic pancreatitis
5. CYSTIC FIBROSIS
   Fine granular calcifications imply advanced pancreatic fibrosis
6. HEMOCHROMATOSIS

Chronic Calcifying Pancreatitis

1. Alcoholism (70–80%) in developed countries
2. Juvenile tropical pancreatitis
3. Hereditary pancreatitis
4. Inborn errors of metabolism
5. Hyperlipidemia
6. Hypercalcemia

Atrophy and Fatty Replacement of Pancreas

1. Main pancreatic duct obstruction
2. Cystic fibrosis
   ◊ Most common cause in childhood!
3. Shwachman-Diamond syndrome
4. **Johanson-Blizzard syndrome** (= pancreatic insufficiency, nasal alar hypoplasia, absence of permanent teeth, short stature, congenital deafness)
5. Hemochromatosis
6. Viral infection
7. Severe malnutrition
8. Cushing syndrome, steroid therapy, obesity, elderly
9. Diabetes mellitus

DDx of total fatty replacement of pancreas:
pancreatic agenesis → absence of ductal system

Uneven Pancreatic Lipomatosis

√ commonly focal sparing of peribiliary region
1 sparing of uncinate process + peribiliary region
1a replacement of head 35%
1b replacement of head, neck, body 36%
2 sparing of peribiliary region only
2a replacement of head + uncinate process 12%
2b total replacement of pancreas 18%

Diffusely Enlarged Pancreas

1. Malignant lymphoma
2. Plasmacytoma
3. Metastases
4. Diffuse infiltrative pancreatic carcinoma
5. Autoimmune pancreatitis

Pancreatic Neoplasm

Origin: › in 99% exocrine ductal epithelium
› in 1.0% acinar portion of pancreatic glands
› in 0.1% malignant ampullary tumor with better prognosis

A. EXOCRINE NEOPLASM
(a) Ductal cell origin
1. Ductal adenocarcinoma (90%)
2. Ductectatic mucinous tumor
= mucin-hypersecreting carcinoma
3. Cystic neoplasm (10–15%)
› serous microcystic neoplasm
› mucinous macrocystic neoplasm
› cystic PET
4. Solid pseudopapillary tumor (rare)
5. Von Hippel-Lindau disease
(b) Acinar cell origin
1. Acinar cell carcinoma (1%)
2. Adenoma
(c) Indeterminate origin
1. Pancreatoblastoma
2. Dermoid cyst (< 27 years of age, 8–12 cm in size)
3. Giant cell tumor

B. PANCREATIC ENDOCRINE TUMOR (PET in 5%)
(a) Nonfunctioning (nonsyndromic) PET
(b) Functioning (syndromic) PET
1. Insulinoma (β cells)
2. Glucagonoma
3. Gastrinoma (δ cells)
4. Somatostatinoma
5. VIPoma (WDHA syndrome)

6. "PPoma" = pancreatic polypeptide
7. Carcinoid

C. NONEPITHELIAL ORIGIN

(a) Primary tumor

1. Primary lymphoma
   < 1% of pancreatic neoplasms
2. Primitive neuroectodermal tumor (in children, part of Ewing sarcoma family of tumors)
3. Rhabdomyosarcoma

(b) Solid mesenchymal tumor (1%)

> Benign primary nonepithelial neoplasms of the pancreas are a rare group of usually sharply marginated solid and cystic tumors.

1. Schwannoma
2. Neurofibroma
3. Ganglioneuroma
4. Desmoid tumor
5. Leiomyoma
6. Lipoma
7. Perivascular epithelioid cell tumor: clear cell "sugar tumor", angiomyolipoma, lymphangiomyomatosis, clear cell tumor

(c) Cystic nonepithelial neoplasm

1. Mature cystic teratoma
2. Lymphangioma

(d) Metastases to pancreas

Pediatric Pancreatic Tumors

1. Pancreatoblastoma
2. Solid-pseudopapillary tumor
3. Islet cell tumor
4. Nesidioblastosis
5. Acinar cell carcinoma
6. Burkitt lymphoma
7. Lymphangioma
8. Primitive neuroectodermal tumor (PNET)
9. Neuroblastoma (secondary involvement)

Hypervascular Pancreatic Tumors

A. PRIMARY
islet cell tumor, microcystic adenoma, solid-pseudopapillary tumor of pancreas

B. METASTASES from
angiosarcoma, leiomyosarcoma, melanoma, carcinoid, RCC, adrenal carcinoma, thyroid carcinoma

Pancreatic Pseudotumor

1. Intrapancreatic accessory spleen

Location: pancreatic tail

2. Pancreatic lobulation
   Prevalence: 34% of general population
   Location: posterior (19%), anterior (10%), horizontal (5%)
3. Tuber omentale = focal prominence of anterior pancreatic surface to left of SMA
4. Pancreas bifidum = fish tail pancreas = bifid pancreatic tail
   √ pancreatic tail does not reach splenic hilum

Pancreatic Cyst

With clearer depiction of septa, cyst contents and pancreatic ductal system, MRI can often achieve a more specific diagnosis.

Incidence: 2.6% of consecutive CT scans, 13.5% at MRI

A. INFLAMMATORY / INFECTIOUS
   (a) pseudocyst (85%):
   (b) acquired cyst:
      1. Retention cyst (= exudate within bursa omentalis from acute pancreatitis)
      2. Parasitic cyst: Echinococcus multilocularis, amebiasis
      3. Pancreatic abscess
      4. Lymphoepithelial cyst: cysts are lined by squamous epithelium and surrounded by dense lymphoid tissue
      5. Mucinous non-neoplastic unilocular cyst

B. CONGENITAL (rare)
   (a) solitary true pancreatic cyst
   (b) systemic disease / syndromes with multiple true cysts
      Associated with: cystic disease of liver / other organs
      1. Autosomal dominant polycystic kidney disease (ADPKD); autoptic liver (pancreatic) cysts in 90% (9%)
         √ nearly always associated with renal cysts
      2. Von Hippel-Lindau disease
         pancreatic cysts in 72% (25%) at autopsy (CT)
         √ renal involvement in all cases
      3. Beckwith-Wiedemann syndrome
      4. Meckel-Gruber syndrome
      5. Cystic fibrosis

C. CYSTIC NEOPLASM
   Frequency: < 10% of all pancreatic neoplasms
   (a) common cystic pancreatic neoplasms (5–15%)
      1. Intraductal papillary mucinous tumor (36%)
      2. Serous cystadenoma (20%)
      3. Pseudocyst (14%)
      4. Cystadenocarcinoma (7%)
      5. Mucinous cystic neoplasm
   (b) rare cystic pancreatic neoplasms
      1. Solid pseudopapillary tumor

2. Acinar cell cystadenocarcinoma
3. Retroperitoneal lymphangioma
4. Retroperitoneal hemangioma
5. Cystic neuroendocrine tumor

(c) solid pancreatic neoplasms with cystic degeneration

1. Pancreatic ductal adenocarcinoma
2. Cystic pancreatic endocrine tumor (rare)
3. Cystic metastasis (3–12% at autopsy)
   RCC, melanoma, lung tumors, breast carcinoma, hepatocellular carcinoma, ovarian carcinoma
4. Cystic teratoma
5. Pancreatic sarcoma (extremely rare)

Features of malignancy:

√ > 10 mm main pancreatic duct dilatation
√ > 10 mm large mural node
√ > 3 cm large cyst
√ > 2.5 SUV positivity on FDG
√ irregular / septate features
√ calcification

Imaging performance for malignant cystic lesion:

FDG-PET: 56% sensitive, 83% specific
CT: 81% sensitive, 100% specific
PET/CT: 94%sensitive, 100% specific

MRCP can image the pancreatic duct after Whipple procedure, distal pancreatectomy, and central pancreatectomy with pancreaticojejunostomy.

Unilocular Pancreatic Cyst

◊ A cyst < 3 cm is almost always benign (97% PPV) + may be followed at 6-month intervals for 3 years!

1. Pseudocyst
   • history of pancreatitis
2. Intraductal papillary mucinous neoplasm (IPMN)
   √ narrow neck at cyst-duct junction
3. Benign unclassified cyst
4. Unilocular serous cystadenoma
5. Lymphoepithelial cyst

MULTIPLE UNILOCULAR PANCREATIC CYSTS

1. Pseudocysts
2. Von Hippel-Lindau disease
3. Intraductal papillary mucinous neoplasm (rarely)

Pancreatic Cyst with Solid Component

◊ All tumors are either malignant or have a high malignant potential!
› true cystic neoplasm

1. Mucinous cystic neoplasm
2. Intraductal papillary mucinous neoplasm (IPMN)

› cystically degenerated neoplasm

3. Pancreatic endocrine tumor
4. Solid pseudopapillary tumor
5. Pancreatic adenocarcinoma
6. Metastasis

Macrocystic Lesion of Pancreas

= multilocular cyst, each compartment > 2 cm in size

1. Mucinous cystic neoplasm
   √ in body + tail of pancreas
   √ peripheral eggshell calcification
2. Intraductal papillary mucinous neoplasm: side-branch / mixed
   √ septated cyst communicating with main duct
3. Nonfunctioning neuroendocrine tumor
4. Congenital lymphangioma

Microcystic Lesion of Pancreas

= pancreatic lesion with > 6 cysts each < 2 cm in size

1. Serous cystadenoma
   √ fibrous central scar ± stellate pattern (30%)
   √ growth rate of 4 mm/year at follow-up

Mucin-Containing Cyst of Pancreas

1. Mucinous nonneoplastic cysts
   = nonneoplastic mucinous differentiation of epithelial lining without soft-tissue component
2. Mucinous cystadenoma
3. Mucinous cystadenocarcinoma
4. Intraductal papillary mucinous neoplasm

Hyperamylasemia

A. PANCREATIC
   1. Acute / chronic pancreatitis
   2. Pancreatic trauma
   3. Pancreatic carcinoma

B. GASTROINTESTINAL
   1. Perforated peptic ulcer
   2. Intestinal obstruction
   3. Peritonitis
   4. Acute appendicitis
   5. Afferent loop syndrome
   6. Mesenteric ischemia / infarction
   7. Portal vein thrombosis

C. TRAUMA

1. Burns
2. Cerebral trauma
3. Postoperative

D. OBSTETRICAL
1. Pregnancy
2. Ruptured ectopic pregnancy

E. RENAL
1. Transplantation
2. Renal insufficiency

F. METABOLIC
1. Diabetic ketoacidosis
2. Drugs

G. PNEUMONIA

H. SALIVARY GLAND LESION
1. Facial trauma
2. Mumps

SPLEEN

Nonvisualization of Spleen

1. Asplenia syndrome
2. Polysplenia syndrome
3. Traumatic fragmentation of spleen
4. Wandering spleen

Small Spleen

1. Infarction
2. Celiac disease
3. Congenital / hereditary hypoplasia of spleen
   ◊ Associated with recurrent bacterial infections!
4. Fanconi anemia
5. Irradiation
6. Partial splenectomy
7. Polysplenia syndrome
8. Atrophy

Splenomegaly

√ inferior tip of spleen extends below tip of right lobe of liver
√ AP diameter of spleen > $^{2}/_{3}$ of abdominal diameter

A. CONGESTIVE SPLENOMEGALY heart failure, portal hypertension, cirrhosis, cystic fibrosis, portal / splenic vein thrombosis, acute splenic sequestration crisis of sickle cell anemia

B. NEOPLASM leukemia, lymphoma, lymphoproliferative disease, Langerhans cell histiocytosis, metastases, primary neoplasm

C. STORAGE DISEASE Gaucher disease, Niemann-Pick disease, mucopolysaccharidoses,

gargoylism, amyloidosis, diabetes mellitus, hemochromatosis

D. INFECTION
   (a) bacterial: TB, subacute bacterial endocarditis, typhoid fever, syphilis, brucellosis
   (b) viral: hepatitis, infectious mononucleosis
   (c) protozoal: echinococcosis, malaria, kala azar, American leishmaniasis
   (d) fungal: histoplasmosis

E. HEMOLYTIC ANEMIA hemoglobinopathy, hereditary spherocytosis, primary neutropenia, thrombotic thrombocytopenic purpura, extracorporeal membrane oxygenation (← RBC damage)

F. EXTRAMEDULLARY HEMATOPOIESIS osteopetrosis, myelofibrosis

G. COLLAGEN VASCULAR DISEASE SLE, rheumatoid arthritis, Felty syndrome

H. SPLENIC TRAUMA

I. OTHERS
   1. Sarcoidosis
      √ splenomegaly in up to 60%
      √ inhomogeneous enhancement after bolus injection (multiple 2–3-cm hypodense nodular lesions)
      √ necrotic mass with focal calcifications
   2. Hemodialysis
   3. Autoimmune lymphoproliferative syndrome

Solid Splenic Lesion

A. MALIGNANT TUMOR
   1. Lymphoma (Hodgkin disease, non-Hodgkin lymphoma, primary splenic lymphoma)
      ◊ Splenomegaly in non-Hodgkin lymphoma indicates involvement in most patients
      ◊ 30% of patients with splenomegaly have NO involvement from non-Hodgkin lymphoma
      ◊ 30% of patients with lymphoma of any kind have splenic involvement without splenomegaly
      √ homogeneous splenomegaly (from diffuse infiltration)
      √ miliary nodules
      √ large 2–10-cm nodules (10–25%)
      √ nodes in splenic hilum (50%) in NHL; uncommon in Hodgkin disease
   2. Metastasis (7%) melanoma (6–34%), breast carcinoma (12–21%), bronchogenic carcinoma (9–18%), colon carcinoma (4%), renal cell carcinoma (3%), ovary (8%), prostate (6%), stomach (7%), pancreas, endometrial cancer
   3. Angiosarcoma
   4. Malignant fibrous histiocytoma, leiomyo-, fibrosarcoma
   5. Langerhans cell histiocytosis
      √ splenomegaly
      √ multiple hypoechoic nodules (less often)

B. BENIGN TUMOR
   1. Hamartoma = splenoma
   2. Hemangioma
   3. Hematopoietic

4. Sarcoidosis
5. Gaucher disease (islands of RES cells laden with glucosylceramide)
6. Inflammatory pseudotumor
7. Lymphangioma

C. SPLENIC INFARCTION

Cystic Splenic Lesion

A. CONGENITAL
1. Epidermoid cyst = true cyst = congenital cyst

B. VASCULAR
1. Splenic laceration / fracture
2. Hematoma
3. **False cyst** = posttraumatic cyst = nonpancreatic pseudocyst of the spleen
◊ 80% of all splenic cysts are pseudocysts (= secondary cysts)
Cause: cystic end stage of trauma, infection, infarction
√ internal echoes from debris
√ calcifications within cyst wall may resemble eggshell
√ smaller size than true cyst
4. Cystic degeneration of infarct
(a) occlusion of splenic a. / branches (hemolytic anemia, endocarditis, SLE, arteritides, pancreatic cancer)
(b) venous thrombosis of splenic sinusoids (massive splenomegaly)
5. Peliosis

C. INFECTION / INFLAMMATION
1. **Pyogenic abscess**
Prevalence: 0.1–0.7%
Cause: hematogenous spread in sepsis (75%), penetrating trauma (15%), infarction (10%)
Predisposed: endocarditis, drug abuse, penetrating trauma, neoplasm, sickle cell disease
• fever, chills, LUQ pain (in < 50%)
√ irregular borders without capsule
√ gas bubbles within abscess
√ rim enhancement
Rx: 76% success rate for percutaneous drain
2. **Microabscesses**
Organism: fungus (especially Candida, Aspergillus, Cryptococcus)
Prevalence: 26% of splenic abscesses
Predisposed: immunocompromised patient
√ hepatosplenomegaly
√ multiple round hypoechoic / hypoattenuating "target" lesions of 5–10 mm often associated with hepatic + renal involvement
√ "wheel-in-wheel" appearance when central hyperechoic portion becomes necrotic + hypoechoic
3. Granulomatous infection

(a) Mycobacterium tuberculosis: miliary TB
√ mild splenomegaly (uncommon)
(b) M. avium-intracellulare
√ marked splenomegaly (in 20%)

4. Pneumocystis carinii infection
√ splenomegaly + multiple hypoattenuating foci
5. **Parasitic cyst** (Echinococcus)
Prevalence: in < 2% of patients with hydatid disease
Cause: systemic dissemination, intraperitoneal spread of ruptured liver cyst
√ solitary cyst ± subjacent daughter cysts
√ hydatid sand ± infolded membranes
√ ± linear calcification
6. Intrasplenic pancreatic pseudocyst
Prevalence: in 1–5% of patients with pancreatitis

D. CYSTIC NEOPLASM
1. Cavernous hemangioma
◊ Most common primary neoplasm of the spleen!
√ hyperdense lesion
2. Lymphoma (most common malignant neoplasm!)
√ splenomegaly
√ multiple small / large masses
3. Lymphangioma / lymphangiomatosis
√ multiple septated subcapsular cystic lesions
4. Necrotic metastasis:
malignant melanoma (in 50%), breast, lung, ovarian, pancreatic, endometrial, colonic, prostatic, carcinoma; chondrosarcoma
◊ In 7% of patients with widespread metastasis!

E. TRUE CYST (with epithelial lining)
1. Congenital cyst = epidermoid cyst
2. Parasitic cyst

F. FALSE CYST = PSEUDOCYST (lacking epithelial lining)
1. Traumatic cyst
2. Postinfarct cyst

Solitary Splenic Lesion

mnemonic: L'CHAIM
Lymphoma
Cyst
Hematoma, **H**emangioma, **H**amartoma
Abscess
Infarct
Metastasis

Multiple Splenic Nodules and Masses

1. Lymphoma, leukemia

2. Metastases
3. Inflammatory lesions
4. Benign tumors
5. Splenic cysts
6. Splenic infarcts
7. Gaucher cells

Increased Splenic Density

1. Sickle cell anemia (in 5% of sicklers)
2. Hemochromatosis
3. Thorotrast exposure
4. Lymphangiography

Splenic Calcifications

A. DISSEMINATED
   1. Phlebolith: visceral angiomatosis
   2. Granuloma (most common): histoplasmosis, TB, brucellosis

B. CAPSULAR & PARENCHYMAL
   1. Pyogenic / tuberculous abscess
   2. Pneumocystis carinii infection
   2. Infarction (multiple)
   3. Hematoma

C. VASCULAR
   1. Splenic artery calcification
   2. Splenic artery aneurysm
   3. Splenic infarct
   4. Autosplenectomy

D. CALCIFIED CYST WALL
   1. Congenital cyst
   2. Posttraumatic cyst
   3. Echinococcal cyst
   4. Cystic dermoid
   5. Epidermoid

mnemonic: HITCH

Histoplasmosis (most common)
Infarct (sickle cell disease)
Tuberculosis
Cyst (Echinococcus)
Hematoma

Iron Accumulation in Spleen

A. DIFFUSE
   1. Multiple blood transfusions
   2. Sickle cell anemia

B. FOCAL

1. Gamna-Gandy bodies
2. Angiosarcoma

Hyperechoic Splenic Spots

1. Granulomas: miliary tuberculosis, histoplasmosis
2. Phleboliths
3. Lymphoma / leukemia
4. Myelofibrosis
5. Gamna-Gandy nodules (in portal hypertension)

Spontaneous Splenic Rupture

1. Posttraumatic delayed rupture
2. Splenomegaly
3. Hemangioma
4. Epidermoid cyst
5. Peliosis
6. Previous splenic infarction

Hyposplenism

= no uptake of ^{99m}Tc-sulfur colloid

A. ANATOMIC ABSENCE OF SPLEEN
   1. Congenital asplenia = Ivemark syndrome
   2. Splenectomy

B. FUNCTIONAL ASPLENIA
   = marked decrease in splenic phagocytic function despite presence of splenic tissue within the body
   1. Circulatory disturbances: occlusion of splenic artery / vein, hemoglobinopathies (sickle cell disease, hemoglobin-SC disease, thalassemia), polycythemia vera, idiopathic thrombocytopenic purpura
   2. Altered RES activity: thorotrast, irradiation, combined splenic irradiation + chemotherapy, replacement of RES by tumor / infiltrate, splenic anoxia (cyanotic congenital heart disease), sprue
   3. Autoimmune disease

   Cx: children at risk for pneumococcal pneumonia (liver partially takes over immune response later in life)

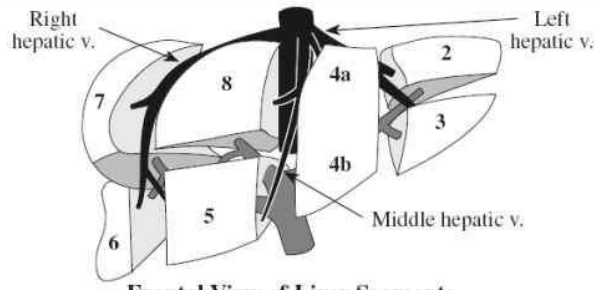
C. FUNCTIONAL ASPLENIA + SPLENIC ATROPHY
   ulcerative colitis, Crohn disease, celiac disease, tropical sprue, dermatitis herpetiformis, thyrotoxicosis, idiopathic thrombocytopenic purpura, thorotrast

D. FUNCTIONAL ASPLENIA + NORMAL / LARGE SPLEEN
   sarcoidosis, amyloidosis, sickle cell anemia (if not infarcted), after bone marrow transplantation

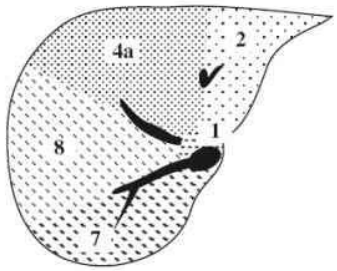
- RBC (acanthocytes, siderocytes)
- lymphocytosis, monocytosis
- Howell-Jolly bodies (intraerythrocytic inclusions)
- thrombocytosis

√ spleen not visualized on ^{99m}Tc-sulfur colloid
√ ^{99m}Tc-heat–damaged RBCs / ^{111}In-labeled platelets may demonstrate splenic tissue if ^{99m}Tc-sulfur colloid does not
Cx: increased risk of infection (pneumococcus, meningococcus, influenza)

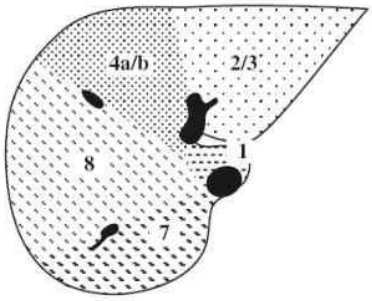
ANATOMY OF LIVER, BILE DUCTS, PANCREAS AND SPLEEN



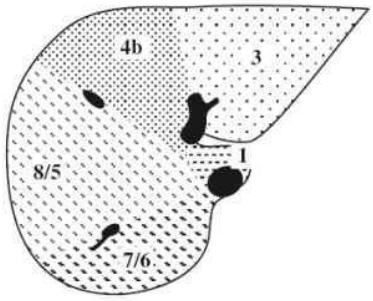
Frontal View of Liver Segments



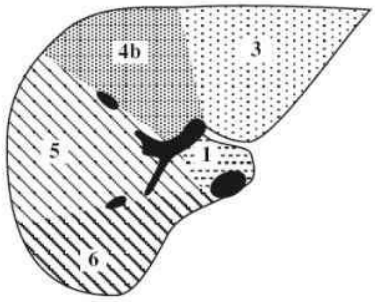
Level of Hepatic Vein Junction



Level of Left Portal Vein



Level of Right Portal Vein

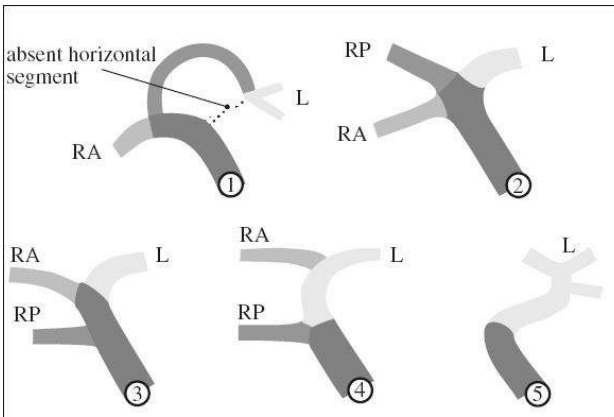


Level of Splenic Vein

Functional Segmental Liver Anatomy

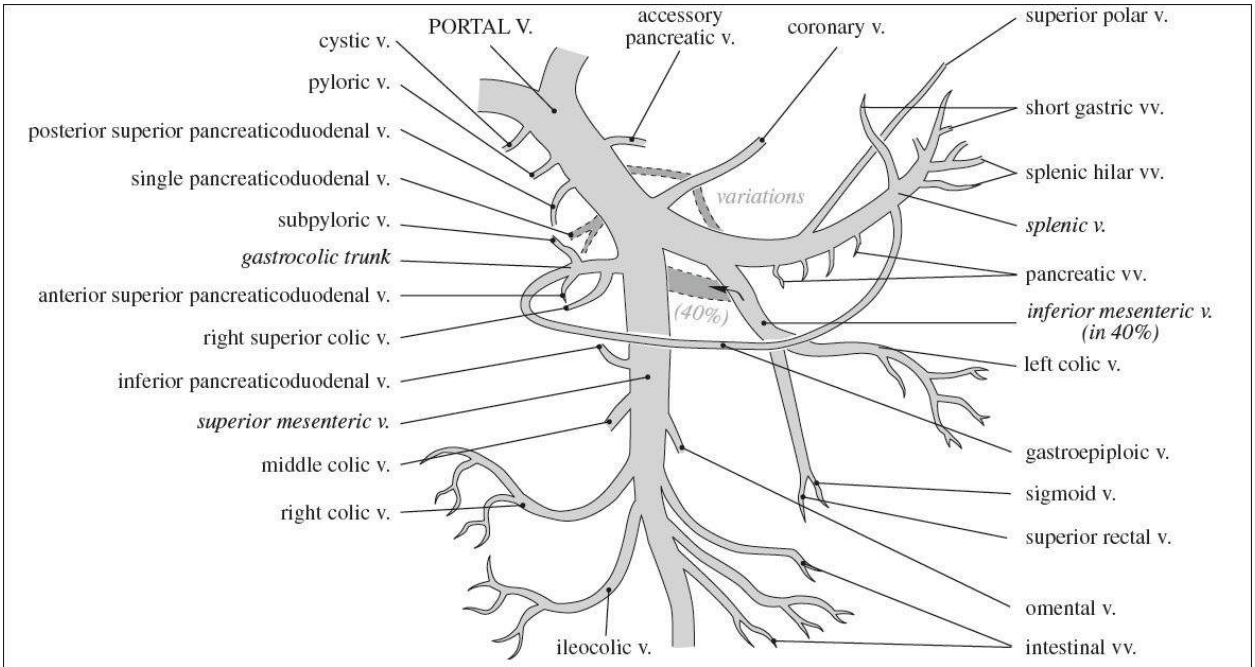
Federative Committee on Anatomical Terminology in Terminologia Anatomica (1998)

Goldsmith & Woodburne		*Couinaud & Bismuth (based on 3rd order portal branching)*		*Blood Supply*
CAUDATE LOBE		Caudate lobe	I	Left portal vein
LEFT LOBE	Left lateral segment	Left lateral superior subsegment	II	Left portal vein
		Left lateral inferior subsegment	III	Left portal vein
	Left medial segment	Left medial superior subsegment	IVa	Left portal vein
		Left medial inferior subsegment	IVb	Left portal vein
RIGHT LOBE	Right anterior segment	Right anterior inferior subsegment	V	Anterior RPV
		Right anterior superior subsegment	VIII	Anterior RPV
	Right posterior segment	Right posterior inferior subsegment	VI	Posterior RPV
		Right posterior superior subsegment	VII	Posterior RPV



A. LEFT PORTAL VEIN
1. Absence of horizontal segment (0.2%)
B. RIGHT PORTAL VEIN
2. Trifurcation of main portal vein (9–15%)
3. Origin of RP segment from main portal vein (5–13%)
◊ Unrecognized variant results in devascularization of segments V & VIII during left trisegmentectomy (resection of segments II & III & IV) / harvest of left lobe for transplantation!
4. Origin of RA segment from left portal vein (1–4%)
5. Absence of main right, RA, and RP portal segments
6. Separate RPI segment (VI) of RPV (6%)
7. Separate RPS segment (VII) of RPV (1%)

Variations of Intrahepatic Portal Venous System (35%)



Extrahepatic Portal Vein Tributaries

LIVER

Functional Segmental Liver Anatomy

based on distribution of 3 major hepatic veins:

(a) middle hepatic vein
divides liver into right and left lobe;
also separated by main portal vein scissura
(**Rex-Cantlie line** = extrapolated line from posthepatic IVC to long axis of gallbladder demarcating on liver surface anteriorly the right and left parts of liver)

(b) left hepatic vein
divides left lobe into medial + lateral sectors

(c) right hepatic vein

divides right lobe into anterior + posterior sectors

Each of the four sections is further divided:

by an imaginary transverse line drawn through the right + left portal vein into anterior + posterior segments; the segments are numbered counterclockwise from IVC

Portal Vein Anatomy (Akgul Classification)

Type A Normal anatomy: bifurcation of MPV and RPV (79–86%)

◊ Posterior branch of RPV as 1st portal vein branch (13%) = most common variant

N.B.: unintended devascularization of hepatic segments V + VIII during left trisegment-ectomy (resection of segments II, III, IV) / harvest of left lobe for liver transplantation if unrecognized

Type B Trifurcation of MPV (9–15%)

Type C Right anterior portal vein from LPV (1–4%)

Type D LPV from right anterior portal vein (0.3–1.2%)

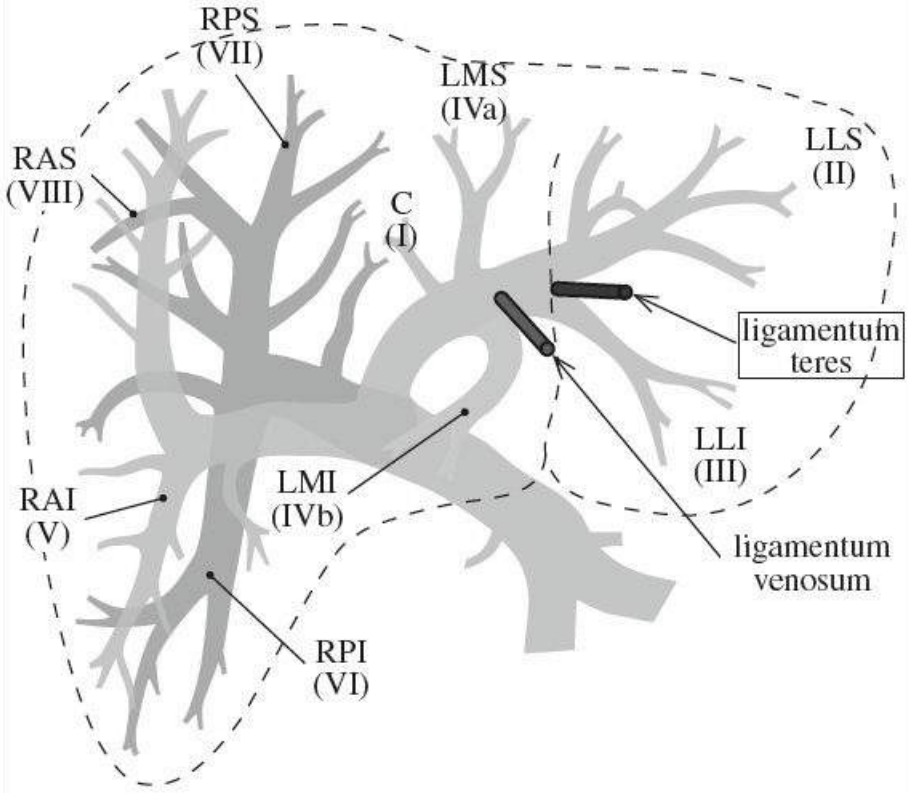
Type E Right anterior portal vein from MPV (1–3%)

Maximum Cross-sectional Diameter of Portal Vein

(a) child < 10 years of age: 8.5 mm

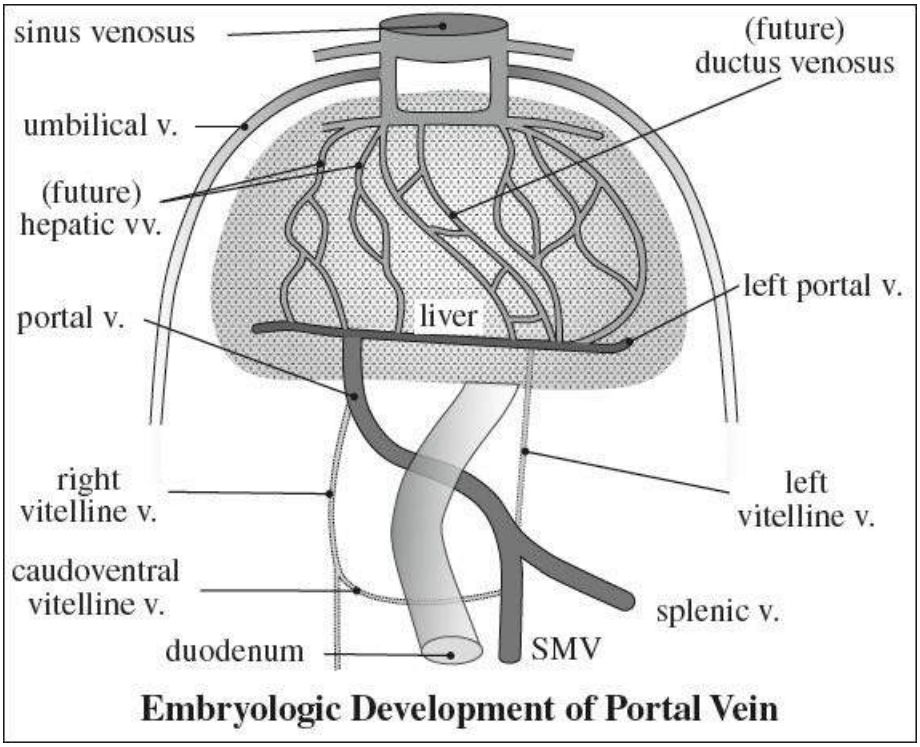
(b) 10–20 years of age: 10.0 mm

(c) adult: 13.0 mm



Intrahepatic Portal Vein Branches (in 65% of individuals)
(umbilical portion of L portal v. = segment between ligg. venosum + teres)

R			= right portal vein
	RA		= right anterior segment
		RAI	= right anterior inferior (V)
		RAS	= right anterior superior (VIII)
	RP		= right posterior segment
		RPI	= right posterior inferior (VI)
		RPS	= right posterior superior (VII)
C			= caudate lobe (I)
L			= left portal vein
		LMI	= left median inferior (IVb)
		LMS	= left median superior (IVa)
		LLI	= left lateral inferior (III)
		LLS	= left lateral superior (II)



Embryologic Development of Portal Vein

Embryology of Portal Vein

Time: 4th–12th week of GA

› paired vitelline veins around duodenum → form 3 major side-to-side anastomoses (cranioventral + caudoventral + dorsal) → pierce septum transversum (primitive liver) → broken up into sinusoids → drain into sinus venosus (of primitive heart)

› selective involution of caudal part of right vitelline vein + cranial part of left vitelline vein:

» regression of caudoventral anastomosis

» dorsal anastomosis → main portal vein

» cranioventral anastomosis → left portal vein

» caudal right vitelline vein → superior mesenteric vein

» caudal left vitelline vein → splenic vein

Major Anatomic Variants of Portal Vein *(rare)*

1. Duplication of portal vein
2. Congenital portosystemic shunt
3. Congenital absence of portal vein
4. Absent branching of portal vein
5. Preduodenal portal vein

Hepatic Artery Anatomy (Michels classification)

Type 1 (55–60%):

› celiac trunk trifurcates into common hepatic artery (CHA) + left gastric artery (LGA) + splenic artery (SpA)

› CHA divides into

Location: CHA courses to right along superior ridge of pancreas branching at lower end of epiploic foramen

(a) proper hepatic artery (PHA)

Location: PHA courses right + upward along anterior border of epiploic foramen

(b) gastroduodenal artery (GDA)

› right hepatic artery (RHA) + left hepatic artery (LHA) arise from PHA

› middle hepatic a. (supplying caudate lobe) arises from:

(a) LHA / RHA

(b) PHA (in 10%)

Type 2 (4–10%):

› CHA divides into RHA + GDA

› LHA replaced to LGA

› middle hepatic artery from RHA

Type 3 (8–11%):

› CHA divides into GDA + LHA

› RHA replaced to SMA

› middle hepatic artery from LHA

Type 4 (2–4%):

› CHA divides into middle hepatic artery + GDA

› RHA + LHA are both replaced

Type 5 (9–16%):

› accessory L hepatic a. arises from LGA

Type 6 (1–7%):

› accessory R hepatic artery arises from SMA

Type 7 (1%):

› accessory R + L hepatic arteries

Type 8 (2–3%):

› combinations of accessory + replaced hepatic arteries

Type 9 (1–3%):

› hepatic trunk replaced to SMA

Type 10 (0.5%):

› hepatic trunk replaced to LGA

The presence of a portal branch without corresponding artery indicates a replaced or accessory vascular anatomy or transhepatic hepatofugal collateral vessels.

Aberrant Hepatic Artery

= hepatic artery coursing between IVC + portal vein

1. Replaced right hepatic artery (50%)
2. Right hepatic artery with early bifurcation of common hepatic artery into right + left hepatic arteries (20%)
3. Accessory right hepatic artery (15%)
4. Replacement of entire hepatic trunk to SMA (15%)

Left Hepatic Artery

= usually arises from proper hepatic artery (PHA)

Location: from hepatic hilum to umbilical portion of left portal vein (usually to its right) coursing up- and leftward

Accessory LHAs: from LGA / celiac trunk / aorta

Division (arteriographic description):

after forming an arch overriding the portal vein

› A2 branches: course to left corner of liver, usually superior to A3

› A3 branches: course ventral + caudal along left side of umbilical portion of PV and then toward left

Right Hepatic Artery

= usually arises from PHA / SMA when replaced

Accessory RHAs: from SMA / celiac trunk / aorta

Division (arteriographic description):

› anterior branch: straight right + upward course

› posterior branch: proximally meandering course

A6: inferolateral course to lower corner of liver

A7: compact complex meandering course superiorly (on frontal projection)

The RHA forms anterior and posterior branches characterized by a straight right upward course and by a meandering proximal portion, respectively.

Caudate Lobe

= located behind liver hilum + wrapping around IVC, supplied by multiple small branches from LHA + RHA

Variations (arteriographic description):

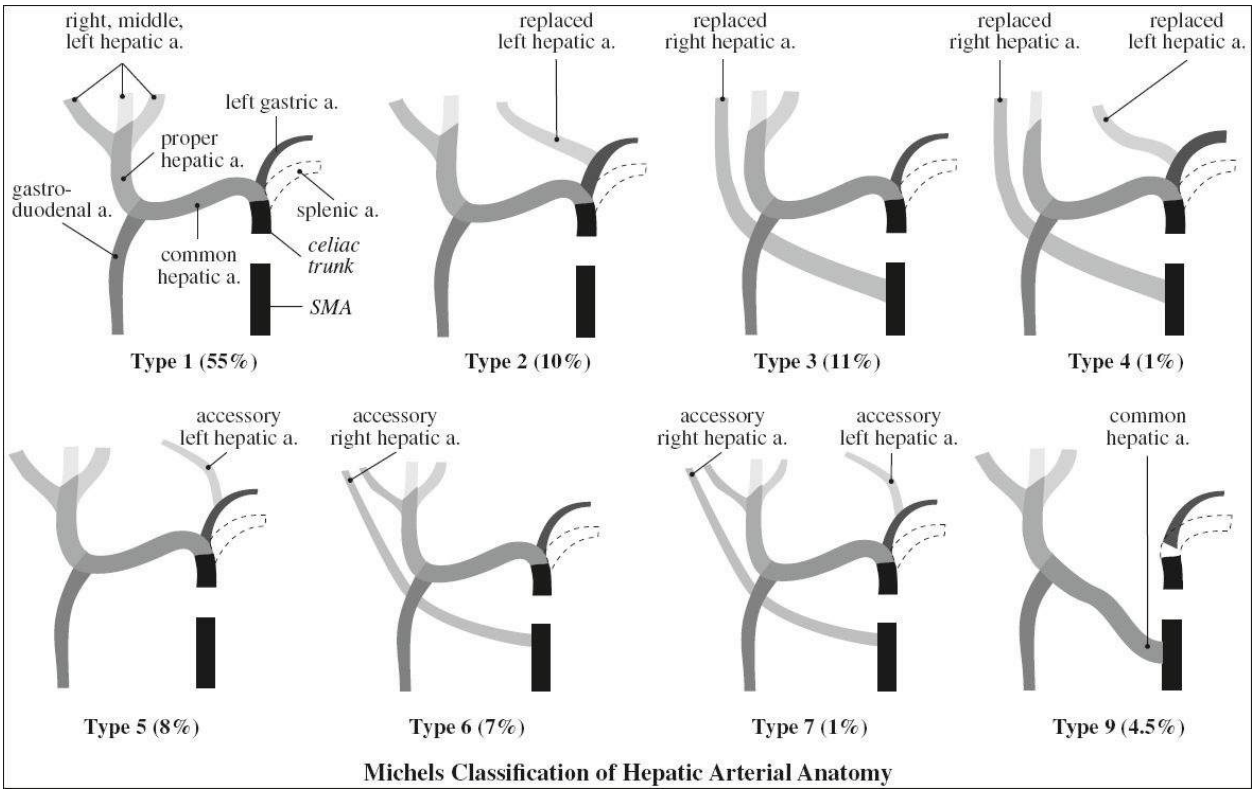
› RHA + LHA (53%)

› RHA only (35%)

Location: courses posteromedially mainly supplying the lateral (= paracaval portion and papillary process) of S1

› LHA only (12%)

Location: courses posteriorly mainly supplying medial portion (= caudate process, Spiegel lobe) of S1



Hepatic Vein Drainage Pattern of Right Hepatic Lobe (Nakamura Classification)

Type 1 Large right hepatic vein (RHV) drains extensive area of right lateral sector + part of right paramedian sector; small short hepatic vein drains small area of right lateral sector (occasionally absent) (39–57%)

Type 2 Right hepatic vein of medium size; one thick short hepatic vein of 5–10 mm in diameter (= middle / inferior hepatic vein) drains right lateral sector concomitantly directly into IVC (29–37%)

Type 3 Right lobe drainage allocated to a short RHV that drains superior part of right lateral sector and large middle hepatic vein (MHV) + inferior right hepatic vein that drains inferior part of right lateral sector (15–24%)

It is important to identify any variation in the middle hepatic vein because the hepatectomy plane in living donors is about 1 cm to the right of the middle hepatic vein along the gallbladder fossa.

Third Inflow to Liver

= aberrant veins supplying small areas of liver tissue + communicating with intrahepatic portal vein branches

Effect: focal decrease of portal vein perfusion resulting in areas of fat-sparing / fat accumulation

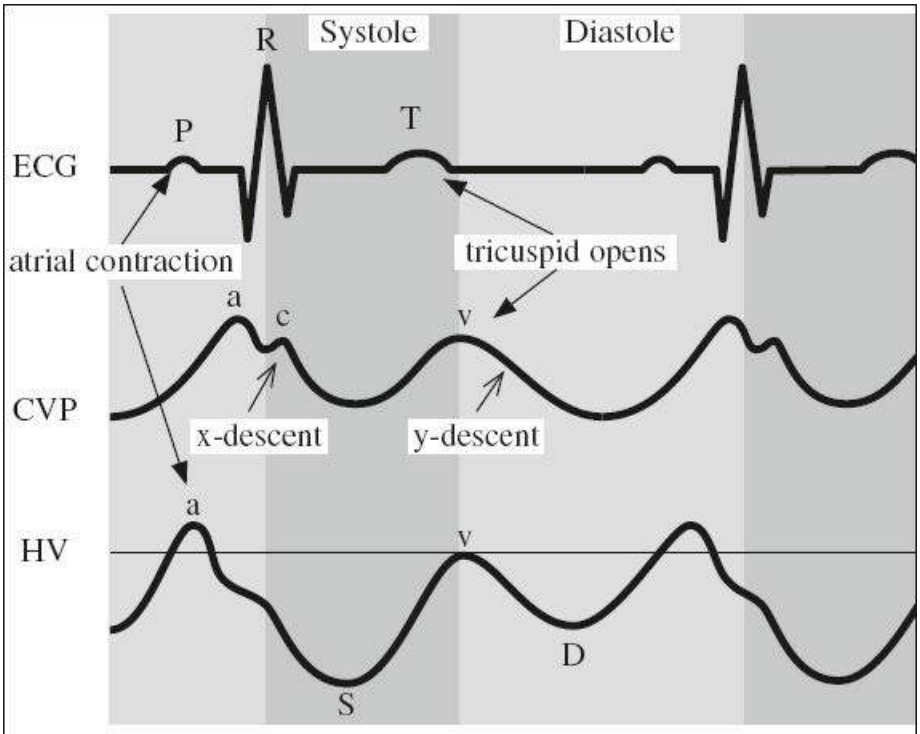
1. Cholecystic veins
   › directly entering liver segments 4 + 5
   › veins joining the parabiliary veins via triangle of Calot
2. Parabiliary venous system
   = venous network within hepatoduodenal ligament anterior to main portal vein

Tributaries:
› cholecystic vein through triangle of Calot
[Jean-François Calot (1861–1944), French surgeon]
› pancreaticoduodenal vein
› right gastric / pyloric vein
√ pseudolesion at dorsal aspect of segment 4

3. Epigastric-paraumbilical venous system
= small veins around falciform ligament draining anterior part of abdominal wall directly into liver
Subgroups:
(a) **superior vein of Sappey**
[Marie Philibert Constant Sappey (1810–1896), professor of anatomy and president of the Académie Nationale de Médecine, Paris, France]
› drains upper portion of falciform ligament + medial part of diaphragm
› enters peripheral left portal vein branches
› communicates with superior epigastric + internal thoracic veins
(b) **inferior vein of Sappey**
› drains lower portion of falciform ligament
› enters peripheral left portal vein branches
› communicates with branches of inferior epigastric vein around the umbilicus
(c) **vein of Burow**
› terminates in middle part of collapsed umbilical v.
› communicates with branches of inferior epigastric vein around the umbilicus
(d) **intercalary veins**
› interconnect vein of Burow + inferior vein of Sappey

Normal Hemodynamic Parameters of Liver

Portal vein velocity: > 11 (range, 16–40) cm/sec
Portal vein cross-section: 0.99 ± 0.28 cm^2
Congestion index: 0.070 ± 0.09 cm•sec
(= cross-sectional area of portal vein divided by average velocity)
Hepatic artery resistive index: 0.60–0.64 ± 0.06



Time-correlated electrocardiographic (ECG), central venous pressure (CVP) and hepatic venous (HV) waveform

S wave = trough correlates with peak negative pressure created by downward motion of AV annulus toward cardiac apex during midsystole = ventricular **S**ystole

v wave = transitional peak between systole + diastole correlates with return of tricuspid **v**alve toward cardiac apex; caused by RA overfilling against a closed tricuspid valve; occurs in < 50% of patient

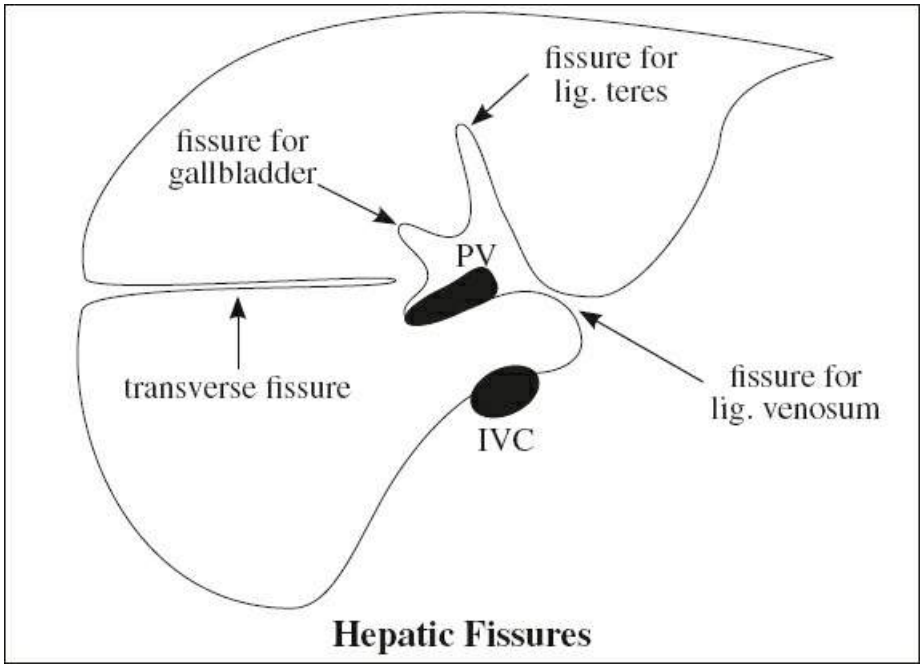
D wave = trough correlates with rapid early diastolic RV filling caused by opening of the tricuspid valve + blood flow from RA into RV during ventricular **D**iastole; equal to / smaller than *S* wave

a wave = retrograde *a* wave at end-diastole caused by contraction of RA = **a**trial systole; in 66% of patients

Hepatic Fissures

1. **Fissure for ligamentum teres** = umbilical fissure
   = invagination of ligamentum teres = embryologic remnant of obliterated umbilical vein connecting placental venous blood with left portal vein
   › located at dorsal free margin of falciform ligament
   › runs into liver with visceral peritoneum
   › divides left hepatic lobe into medial + lateral segments (divides subsegment 3 from 4)

2. **Fissure for ligamentum venosum**
   = invagination of obliterated ductus venosus
   = embryologic connection of left portal vein with left hepatic vein
   › separates caudate lobe from left lobe of liver
   › lesser omentum within fissure separates the greater sac anteriorly from lesser sac posteriorly
3. **Fissure for gallbladder** (GB)
   = shallow peritoneal invagination containing the GB
   › divides right from left lobe of liver
4. **Transverse fissure**
   = invagination of hepatic pedicle into liver
   › contains horizontal portion of left + right portal veins
5. **Accessory fissures**
   (a) Right inferior accessory fissure = from gallbladder fossa / just inferior to it → to lateroinferior margin of liver
   (b) Others (rare)



Hepatic Fissures

Size of Liver

A. YOUNG INFANT
   right hepatic lobe should not extend > 1 cm below right costal margin
B. CHILD
   right hepatic lobe should not extend below right costal margin
C. ADULT
   (a) midclavicular line (vertical / craniocaudad axis):
      < 13 cm = normal
      13.0–15.5 cm = indeterminate (in 25%)

> 15.5 cm = hepatomegaly (87% accuracy)

(b) preaortic line < 10 cm

(c) prerenal line < 14 cm

Liver Capsule

= 2 adherent layers:

(a) thick, fibrous inner layer = Glisson capsule

(b) outer serous layer derived from peritoneum excluding

› bare area near diaphragm

› porta hepatis

› gallbladder attachment

Liver Echogenicity & Attenuation

US: pancreatic > splenic ≥ hepatic > renal echogenicity

CT: 50–65 HU (precontrast)

CECT: early arterial phase (20 sec), late arterial phase (30–40 sec), portal venous phase (60–70 sec); maximal enhancement at 45–60 sec

Enzymatic Liver Tests

A. Alkaline phosphatase (AP)

Formation: bone, liver, intestine, placenta

High increase:

cholestasis with extrahepatic biliary obstruction (confirmed by rise in γGT), drugs, granulomatous disease (sarcoidosis), primary biliary cirrhosis, primary + secondary malignancy of liver

Mild increase: all forms of liver disease, heart failure

B. Gamma-glutamyl transpeptidase (γGT)

very sensitive in almost all forms of liver disease

Utility: confirms hepatic source of elevated AP, may indicate significant alcohol use

C. Transaminases

High increase: viral / toxin-induced acute hepatitis

(a) aspartate aminotransferase (AST; formerly serum glutamic oxaloacetic transaminase [SGOT])

Formation: liver, muscle, kidney, pancreas, RBCs

(b) alanine aminotransferase (ALT; formerly serum glutamic pyruvic transaminase [SGPT])

Formation: primarily in liver

• rather specific elevation in liver disease

D. Bilirubin

helps differentiate between various causes of jaundice

(a) unconjugated / indirect bilirubin = insoluble in water

Formation: breakdown of senescent RBCs

Metabolism: tightly bound to albumin in vessels, actively taken up by liver, cannot be excreted by kidneys

(b) conjugated / direct bilirubin = water-soluble

Formation: conjugation in liver cells
Metabolism: excretion into bile; NOT reabsorbed by intestinal mucosa; excreted in feces
Elevation:
› ↑ production: hemolytic anemia, resorption of hematoma, multiple transfusions
› ↓ hepatic uptake: drugs, sepsis
› ↓ conjugation: Gilbert syndrome, neonatal jaundice, hepatitis, cirrhosis, sepsis
› ↓ excretion into bile: hepatitis, cirrhosis, drug-induced cholestasis, sepsis, extrahepatic biliary obstruction

E. Lactic dehydrogenase (LDH)
nonspecific and therefore not helpful
high increase: primary or metastatic liver involvement

F. Alpha-fetoprotein (AFP)
> 400 ng/mL strongly suggests that a focal mass represents a hepatocellular carcinoma

PORTA HEPATIS

= LIVER HILUM
= deep short transverse fissure that passes across left posterior aspect of undersurface of right lobe of liver separating caudate lobe from quadrate lobe

Contents:
(a) **portal triad**:
1. Main portal vein (MPV)
2. Proper hepatic artery: left anterior to MPV
3. Common hepatic duct: right anterior to MPV

(b) nerves: left vagal trunk + sympathetic hepatic plexus
(c) lymphatics

Within the porta hepatis, the common bile duct and proper hepatic artery typically are located anterior to the portal vein, with the common bile duct to the right and the proper hepatic artery to the left.

Enveloped by:
(a) hepatoduodenal ligament
(b) lesser omentum
(c) loose areolar tissue
(d) fibrous capsule of Glisson

GALLBLADDER

Size & Capacity & Wall Thickness

Physiologic distension: optimal after 8–12 hours of fasting
GB function: concentration of bile through absorption of 90% of water
Wall layers: (a) mucosa
(b) lamina propria
(c) muscularis propria
(d) serosa

N.B.: The GB has NO muscularis mucosa / submucosa

Length:

(a) infant < 1 year old: 1.5–3.0 cm

(b) older child: 3–7 cm

(c) adult: 7–10 cm

Wall thickness: 2–3 mm

Width: 2.0–3.5 cm

Capacity: 30–50 mL

Bile volume: 250–1,000 mL/d secreted by hepatocytes

Gallbladder Function

= evaluation of volume and ejection fraction following ingestion of a fatty meal / infusion of cholecystokinin

Methods:

1. HIDA scintigraphy
2. MR cholangiography with mangafodipir trisodium = MnDPDP = manganese (II) DPDP [N,N′-**di**pyridoxylethylenediamine-N,N′-**di**acetate 5,5′-bis(**p**hosphate)]
   Dose: 0.5 mL/kg of MnDPDP up to 35–50 mL
   » slow IV injection for 1–2 minutes
   » followed by a 10-mL saline flush
   » scanned 15–30 minutes after injection
3. MR cholangiography with gadolinium BenzylOxyPropionicTetraAcetate (Gd-BOPTA) = MultiHance®)
   Dose: 0.05 mmol (0.1 mL)/kg up to 15 mL
   » IV injection with power injector at 2 mL/sec
   » followed by a 20-mL saline flush
   » T1WI at 30–60 minutes after injection to obtain gadolinium-enhanced MR cholangiopancreatograms

Gallbladder Ejection Fraction (GBEF)

$$GBEF = [GB_{initial} - GB_{post}] \div GB_{initial}$$

Indication:

(1) ↑ sensitivity of study for acute (acalculous) cholecystitis

(2) in patients with abdominal pain and no cholelithiasis

(3) to establish that gallstones are the primary cause of abdominal pain

Technique:

1. Discontinue opioids for > 24 hours
2. Select ROI over GB
3. Administer Sincalide 1 hour post HIDA in a dose of 0.02 µg/kg body weight IV over 30 minutes (with infusion pump)
4. Image acquisition for 20 more minutes post infusion to detect paradoxical filling of gallbladder in sphincter of Oddi dysfunction

Normal result: > 30% GBEF

LOW GALLBLADDER EJECTION FRACTION

Cause: CCK-induced cystic duct spasm in chronic calculous / acalculous cholecystitis, gallbladder dyskinesia, opioid intake

Reproducibility: a low GBEF does not recover (if opioid intake is ruled out) and further deteriorates over time

Frequency: ⅓ of all cholecystectomies are performed for chronic acalculous cholecystitis

Rx: cholecystectomy with pain relief in 89%

Differentiation of abdominal pain:

(a) **biliary pain** = low GBEF ± gallstones

Pathophysiology of biliary pain:

CCK-induced cystic duct spasm → reduction in GBEF → bile stasis → stretching of GB wall against impedance to bile flow → biliary pain

(b) **nonbiliary pain** = normal GBEF + gallstones

Cause of nonbiliary pain (?):

CCK-induced rapid bile transit ← increased peristalsis in small intestine + colon; others

Congenital Gallbladder Anomalies

Agenesis of Gallbladder

Prevalence: 0.04–0.07 % (autopsy)

Associated with:

common: rectovaginal fistula, imperforate anus, hypoplasia of scapula + radius, intracardiac shunt

rare: absence of corpus callosum, microcephaly, atresia of external auditory canal, tricuspid atresia, tracheoesophageal fistula, dextroposition of pancreas + esophagus, absent spleen, high position of cecum, polycystic kidney

Hypoplastic Gallbladder

(a) congenital

(b) associated with cystic fibrosis

Septations of Gallbladder

A. LONGITUDINAL SEPTA

1. **Bilobed gallbladder = duplication of gallbladder**
   = two separate lumina + two cystic ducts
   Prevalence: 1÷3,000 to 1÷12,000
2. **Bifid gallbladder = double gallbladder**
   = two separate lumina with one cystic duct
3. Triple gallbladder (extremely rare)

B. TRANSVERSE SEPTA OF GALLBLADDER

1. Isolated transverse septum
2. **Phrygian cap** (2–6% of population)
   = kinking / folding of fundus ± septum
3. Multiseptated gallbladder (rare)

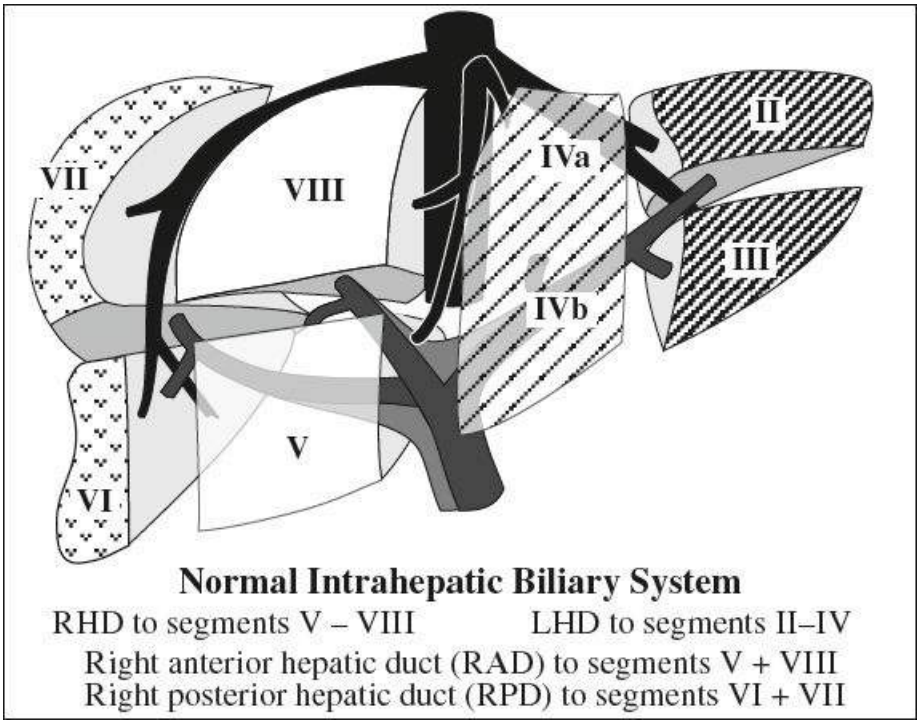
= multiple cystlike compartments connected by small pores
Cx: stasis + stone formation

C. GALLBLADDER DIVERTICULUM
= persistence of cystohepatic duct

Gallbladder Ectopia

most frequent locations:
(1) beneath the left lobe of the liver >
(2) intrahepatic >
(3) retrohepatic

rare locations:



Normal Intrahepatic Biliary System
RHD to segments V – VIII LHD to segments II–IV
Right anterior hepatic duct (RAD) to segments V + VIII
Right posterior hepatic duct (RPD) to segments VI + VII

(4) within falciform ligament, (5) within interlobar fissure, (6) suprahepatic (lodged between superior surface of right hepatic lobe + anterior chest wall), (7) within anterior abdominal wall, (8) transverse mesocolon, (9) retrorenal, (10) near posterior spine + IVC, (11) intrathoracic GB (← inversion of liver)

Associated with: eventration of diaphragm

"FLOATING GB"

= gallbladder with loose peritoneal reflections, may herniate through foramen of Winsløw into lesser sac

BILE DUCTS

Embryology of Bile Ducts

Ductal plate: hepatocyte cells form double-layer sleeve around central portal vein at 4

weeks GA → remodelling over next few weeks → into several normally connected bile ducts adjacent to portal tracts from hilum to periphery

Genetics: PKHD1 (polycystic kidney hepatic disease 1) gene codes for fibrocystin/polyductin protein that acts on primary cilia lining bile ducts

Pathology: mutation of PKHD1 gene → abnormal cilia → abnormal ductal plate formation → dilated abnormally branching irregular channels increased in number; intervening connective tissue over time becomes fibrotic

Normal Size of Bile Ducts

@ CBD at point of maximum diameter = free edge of gastrohepatic ligament (point of least constraint):
  (a) adolescents & adults
    ≤ 5 mm = normal; 6–7 mm = equivocal;
    ≥ 8 mm = dilated
    ◊ In patient > 60 years of age add 1 mm/decade = **presbyductectasia** (eg, 60 = 6 mm, 70 = 7 mm)
    ◊ Following cholecystectomy up to 8 mm
  (b) neonates: < 1 mm
  (c) infants up to 1 year of age: < 2 mm
  (d) older children: < 4 mm

@ CHD at porta hepatis + CBD in head of pancreas: 5 mm

@ right intrahepatic bile duct just proximal to CHD: 2–3 mm / < 40% of diameter of accompanying portal vein
  ♦ Right Hepatic Duct (RHD): ← segments V–VIII
    › Right Posterior Duct (RPD ← segments VI & VII
    › Right Anterior Duct (RAD) ← segments V & VIII
  ♦ Left Hepatic Duct (LHD): ← segments II–IV

@ Cystic duct
  Valves of Heister = normal mucosal folds
  Diameter: 1.8 mm
  Average length: 1–2 cm
  √ distal cystic duct posterior to CBD (in 95%), anterior to CBD (in 5%)

Bile Duct Anatomy (Couinaud Classification)

[Claude Couinaud (1922–2008), French surgeon and anatomist]
= intrahepatic biliary system runs parallel to portal venous supply of liver

(1) **Right hepatic duct** (RHD) drains segments V–VIII of right hepatic lobe with 2 major branches:
  (a) right posterior duct (RPD) drains posterior segments VI + VII
    √ almost horizontal course
  (b) right anterior duct (RAD) drains anterior segments V + VIII
    √ more vertical course

(2) **Left hepatic duct** (LHD) drains segments II–IV of left hepatic lobe

Variants of Bile Duct Confluence

N.B.: important for donor of right hepatic lobe transplant

◊ RPD has the most frequent anomalous insertions!

◊ Bile duct from caudate lobe joins origin of LHD / RHD

Type A Normal R posterior duct drains into R hepatic duct, which joins L hepatic duct to form CHD 54–61%

Type B "triple confluence" = trifurcation of RAD + RPD + LHD 11–16%

Type C RAD / RPD joins CHD separately 15–23%

Type D RPD empties into L hepatic duct 13–19%

Type ? RAD / RPD joins LHD separately 4–8%

Type E absence of defined upper biliary confluence with all sectorial ducts joining separately 3–4%

Type F RPD may join neck of GB / may be entered by cystic duct 1%

Bile Duct Aberrations

Prevalence: 2.4% of autopsies; 13–18.5% of operative cholangiograms

Significance: aberrant ducts near cystic duct / gallbladder have the greatest risk of iatrogenic injury at cholecystectomy

Cx: (1) postoperative bile leak if severed

(2) segmental biliary obstruction if ligated

A. **ABERRANT HEPATIC DUCT**

= direct drainage of RPD into the CHD (CBD, cystic duct, gallbladder): on right side (5%) / on left side (1%)

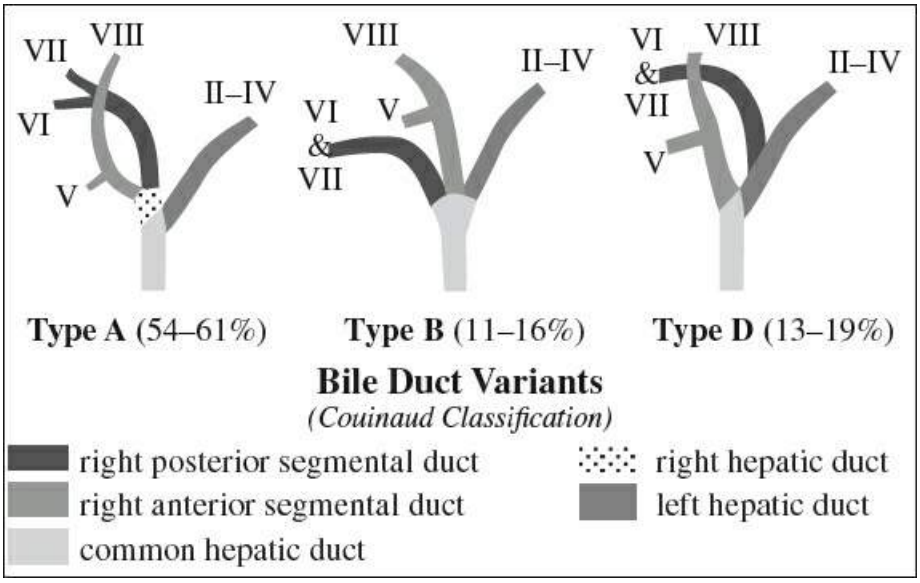
› RHD joins extrahepatic bile duct at / near cystic duct insertion (4–5%)

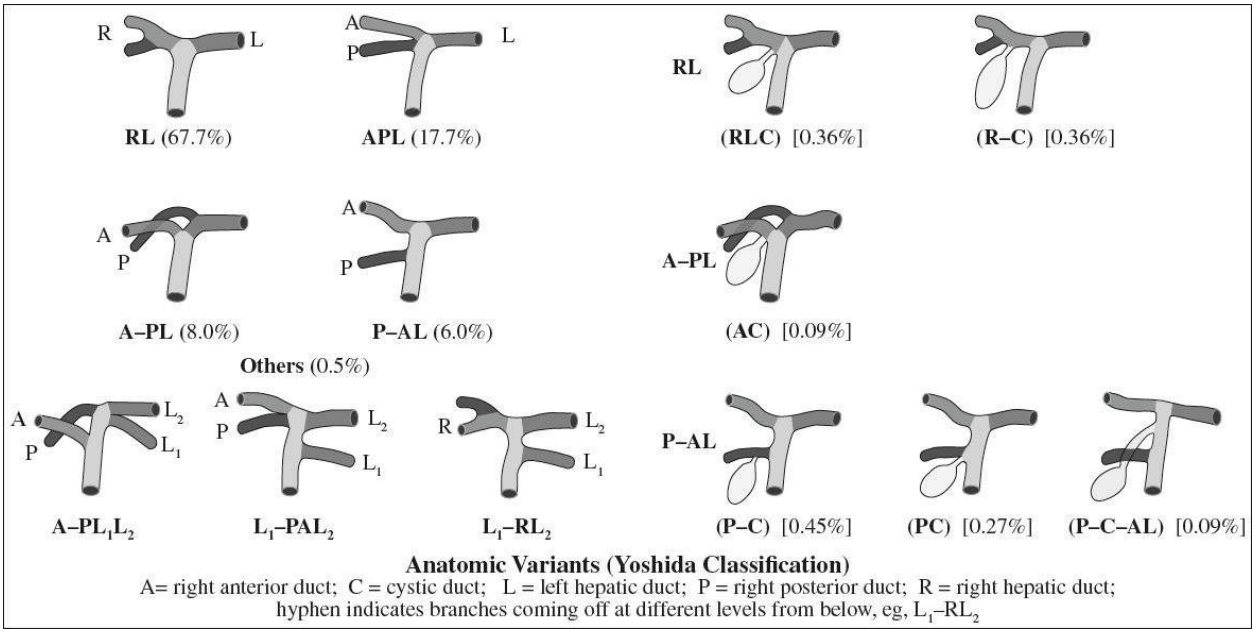
› cysticohepatic duct (1–2%) = anomalous RHD inserts into cystic duct

› anomalous LHD: not susceptible to injury and therefore of no clinical significance

B. CYSTIC DUCT ENTERING RHD

C. DUCTS OF LUSCHKA





[Hubert von Luschka (1820–1875), extraordinary ordinarius and director of the anatomical institute in Tübingen, Germany]

= SUBVESICAL / **ACCESSORY BILE DUCTS**

= small ducts from liver bed draining directly into GB

Incidence: 2%

Origin: right hepatic lobe; R/ L ductal system

Course: along gallbladder fossa

Drain: variably into gallbladder, intra- / extrahepatic bile ducts

Significance: may be injured during surgical dissection / cauterization → bile leak

D. DUPLICATION OF CYSTIC DUCT / CBD

± duplication of gallbladder

E. CONGENITAL TRACHEOBILIARY FISTULA

= fistulous communication between carina and LHD

- infants with respiratory distress
- productive cough with bilious sputum

√ pneumobilia

Variants of Cystic Duct Insertion

N.B.: important prior to laparoscopic cholecystectomy

Prevalence: variations occur in 18–23%

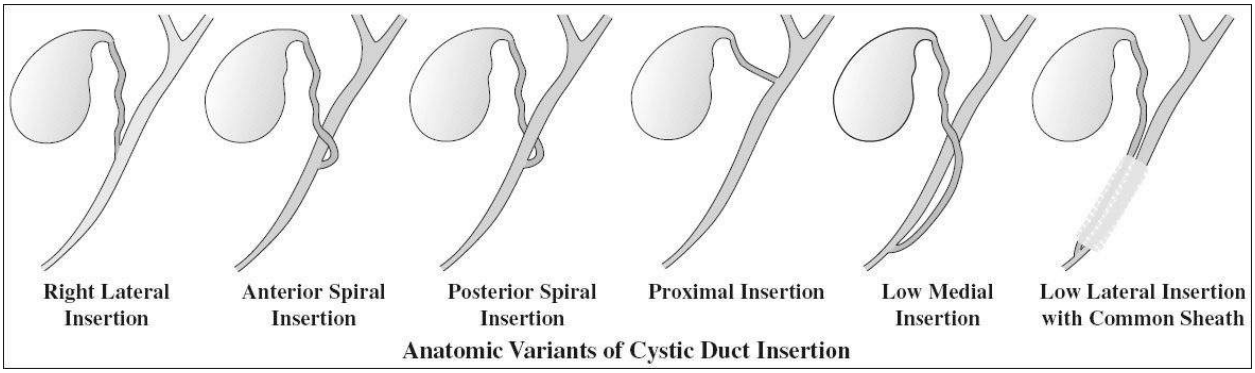
(a) craniocaudad insertion into extrahepatic bile duct

› proximal ⅓ = common hepatic duct high in porta hepatis

› middle ⅓ of extrahepatic bile duct 75%

› distal ⅓ of extrahepatic bile duct 10%

√ cystic duct parallels extrahepatic bile duct (implies common fibrous sheath)



Anatomic Variants of Cystic Duct Insertion

Cx: during cholecystectomy
(1) common hepatic duct stricture
(2) inadvertent ligation / transection of extrahepatic bile duct
(3) long cystic duct remnant

(b) mediolateral insertion into common hepatic duct
› left (medial) 10–17%
› right lateral
› anterior / posterior spiral
› parallel course for > 2 cm 1.5–25%
» low lateral (with common sheath)
» low medial (at / near ampulla of Vater)

(c) insertion into intrahepatic bile duct
› right hepatic duct (0.3%)
› left hepatic duct (rare)

(d) absence of cystic duct
√ gallbladder drains directly into common bile duct

Hepatobiliary Triangle
= TRIANGLE OF CALOT
= anatomic space bordered by CHD medially, cystic duct inferiorly, and cystic artery superiorly

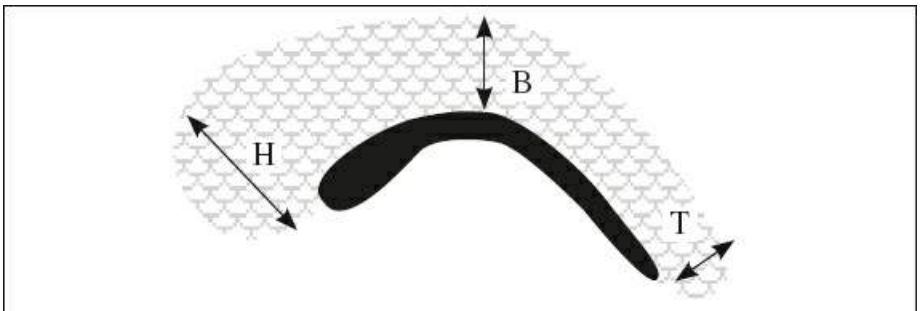
PANCREAS

Pancreatic Anatomy

Location: anterior pararenal space of retroperitoneum; crossing anterior to aorta, IVC, left kidney, renal veins, right renal artery

Parts:

1. **Head**: within curvature (C-loop) of duodenum, to right of SMV
Relationship to CBD: partially covered by pancreas posteriorly (53%), totally covered (30%), not at all covered (17%)
Posterior surface: separated from IVC by retroperitoneal fat



Age-dependent Pancreatic Diameters

(on TRV image)

H = head = 10–22 mm; 24 ± 3.6 mm (in 6th decade)
B = body = 4–10 mm; 16 ± 2.0 mm (in 6th decade)
T = tail = 8–22 mm; 15 ± 1.9 mm (in 6th decade)

Connection:

- › to liver + lesser gastric curvature via hepatoduodenal + gastrohepatic ligaments (= derivative of ventral mesogastrium)
- › to splenic hilum + greater gastric curvature via splenorenal + gastrosplenic ligaments (= derivative of dorsal mesogastrium)

2. **Uncinate process**: triangular leftward prolongation of caudal part of head with straight / concave anteromedial border curving behind SMA and SMV; variably drained by dorsal and ventral ducts
3. Neck: constricted portion of pancreas that lies anterior to SMA + SMV = beginning of portal vein
4. Body: behind lesser sac + stomach
5. Tail: begins about ½ of distance between neck + tip of tail (located in splenorenal ligament)

Weight: 90–100 g
Length: 15–20 cm
Width: 1.0–1.5 cm
Size: gradual decrease with age; pancreatic head & neck make up 60–70% of the pancreatic parenchyma
Blood supply: branches from celiac trunk and SMA

Physiology of Pancreas

Pancreatic islet cells = endocrine cells clustered in islets of Langerhans; 1–2% of total mass of pancreas receiving 10–15% of pancreatic blood flow; innervated by parasympathetic + sympathetic neurons modulating secretion of insulin + glucagon

Function: secretion of

- › insulin production in β-cells (B cells); most abundant in center of islet
- › glucagon in α-cells (A cells)
- › somatostatin in δ-cells (D cells)
- › VIP in δ1-cells (D1 cells)
- › serotonin in enterochromaffin cells
- › pancreatic polypeptide in PP cells → stimulate secretion of gastric and intestinal

enzymes + inhibit intestinal motility) in islets + scattered throughout exocrine pancreas

Pancreatic Development

during the 4th–5th week of gestation 2 endodermal diverticula form in the foregut near its junction with the yolk sac (= endodermal lining of duodenum)

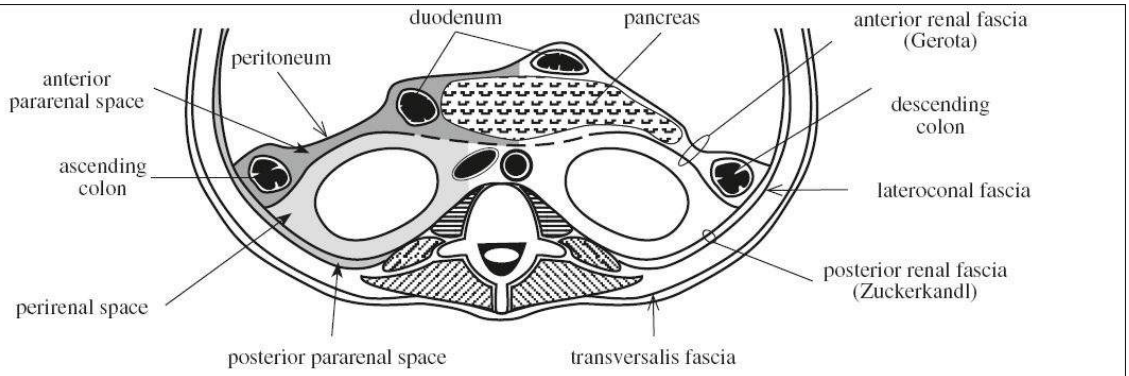
A. DORSAL ANLAGE (= single dorsal bud)

Origin: derives from dorsal wall of duodenum in dorsal mesoduodenum (mesogastrium) and is later displaced to the left

› forms cranial portion of head + isthmus + body + tail of pancreas

• prone to atrophy (poor in polypeptides)

√ drains to minor papilla through accessory duct of Santorini



Extraperitoneal Spaces

B. VENTRAL ANLAGE (= 2 ventral buds)

Origin: arises from ventral wall of duodenum ← hepatic diverticulum (below primordial liver bud)

(a) left ventral bud regresses completely

(b) right ventral bud rotates 180° clockwise posteriorly (viewed from top) and inferiorly (simultaneously with rotation of foregut); comes to lie to left and caudad of duodenum where it fuses with dorsal bud at 7th week EGA

› forms caudal portion of pancreatic head + pancreatic neck + uncinate process + CBD

• not prone to atrophy (rich in polypeptides)

√ ventral duct drains with CBD through ampulla of Vater + becomes the major drainage pathway for the entire pancreas after fusion with dorsal duct

Peritoneal Investment of Pancreas

◊ NO distinct capsule

√ appearance of fat clefts between glandular tissues at CT → surround areolar tissue + dip into pancreas

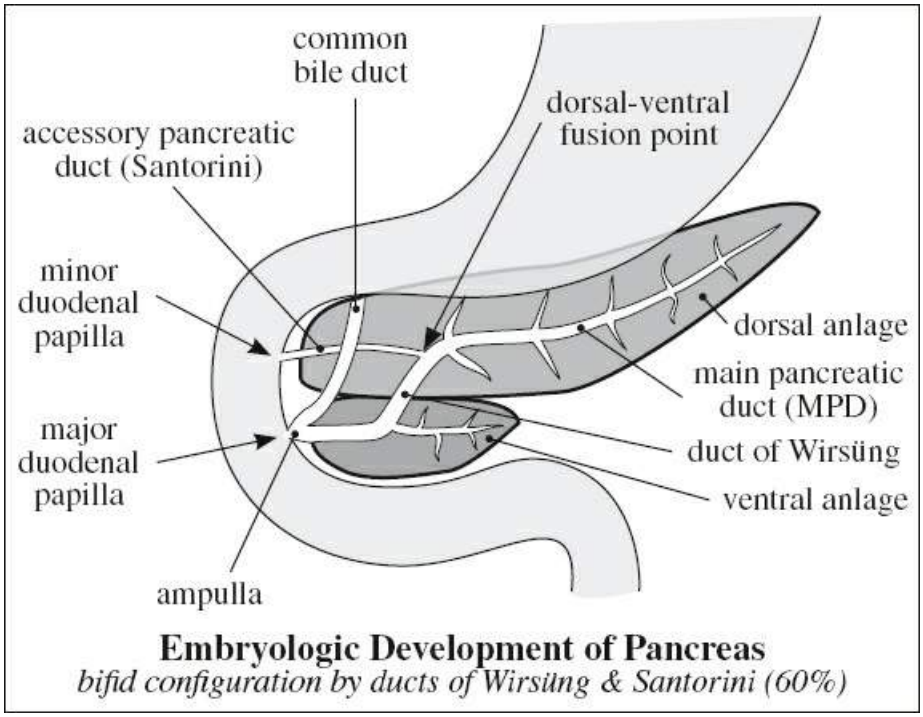
› during foregut rotation dorsal mesoduodenum + dorsal mesogastrium fuse with parietal layer of peritoneum
→ forms posterior wall of lesser sac

› dorsal mesogastrium pouches out
→ forms omentum

› posterior leaf of mesogastric outpouching fuses with mesentery of midgut

→ forms transverse mesocolon over pancreas

› most distal portion of pancreatic tail remains within dorsal mesogastrium
→ splenorenal ligament carrying splenic artery and vein



Embryologic Development of Pancreas
bifid configuration by ducts of Wirsüng & Santorini (60%)

Main Pancreatic Duct of Wirsüng

mnemonic: "upside down **M**(ain) reads W(irsüng)"

[Johann Wirsüng (1589–1643), German physician in Padua, Italy]

= term broadly used for duct traversing the entire length of pancreas (= combination of MPD + duct of Wirsüng)

= in restricted sense portion of ventral duct between dorsal-ventral fusion point and major papilla

› distal portion of dorsal duct connects with ventral duct

› proximal portion of dorsal duct may disappear

Origin: dorsal anlage (duct) → drains tail, body, and anterior portion of pancreatic head

Width: 3.5 mm in head, 2.5 mm in body, 1.5 mm in tail (gradual tapering)

Length: 9.5–25 cm

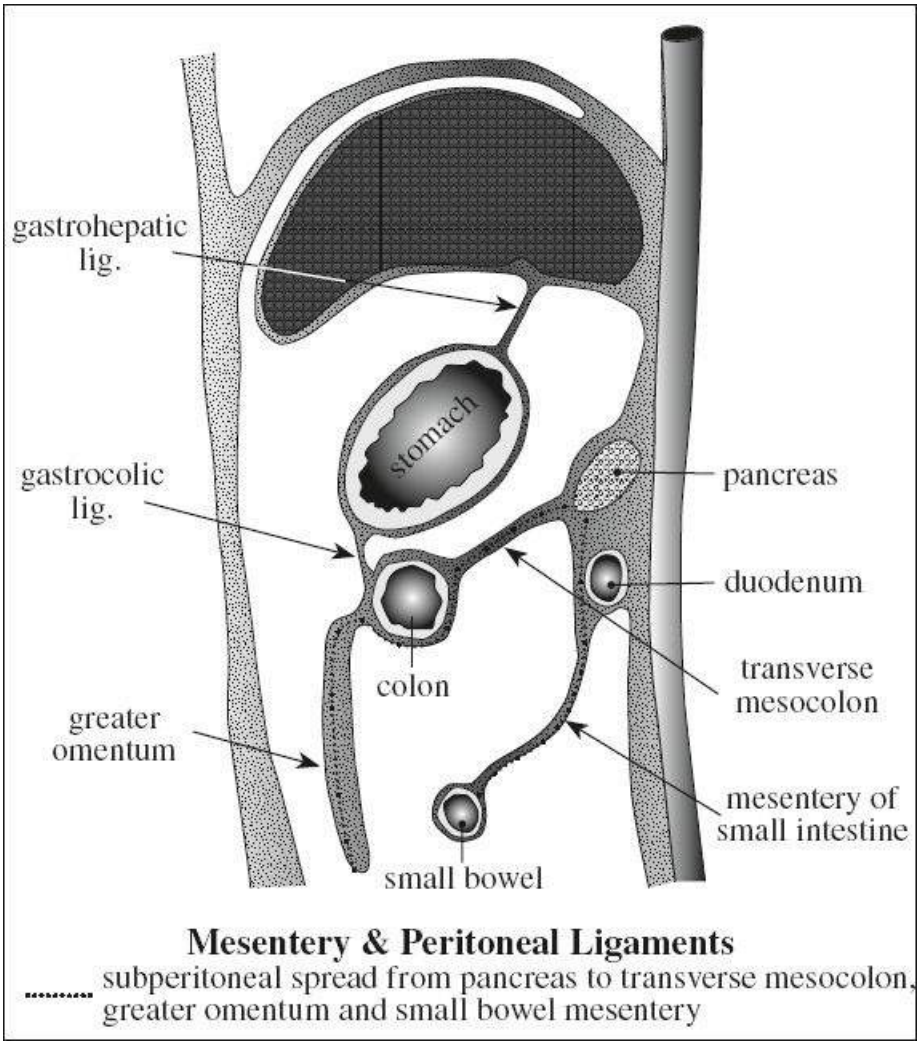
√ receives 20–35 tributaries / side branches that enter at right angles

√ usually drains through major papilla

√ unites with CBD within sphincteric segment (sphincter of Oddi) in 80–90%

√ focal saccular dilatation of terminal part of (ventral) MPD = **wirsüngocele** (incidental finding)

◊ Major drainage route for 91% of individuals



Accessory Pancreatic Duct of Santorini

[Giovanni Santorini (1681–1737), anatomist in Venice, Italy]

= proximal segment of dorsal duct distal to dorsal-ventral fusion point, which has not atrophied

◊ Present in 44% of individuals

√ drains anterosuperior portion of head into minor papilla

DOWNSTREAM VARIANTS OF PANCREATIC DUCTS

√ physiologic narrowing of duct caliber at "knee" of MPD = site of fusion of dorsal and ventral ducts

(1) Bifid duct system 60%

(2) Rudimentary duct of Santorini 30%

√ branch of MPD after loss of communication with minor papilla

(3) Dominant duct of Santorini 1%

(4) Ansa pancreatica rare

√ duct of Santorini forms sigmoid curve as it courses toward duct of Wirsüng

(5) Duplication anomaly of MPD common

(6) Duplication anomaly of dorsal anlage / ventral anlage (rare)

Ampulla of Vater

= slightly dilated conduit that results from the union of common bile duct + duct of Wirsüng

◊ Actual dilatation of common channel is unusual

Location: major duodenal papilla in medial wall of 2nd / 3rd portion of duodenum below surface of papilla of Vater

(a) common channel (74%):

» 2–10 (mean 5) mm short common channel (55–85%) with a diameter of 3–5 mm

√ V-type configuration

» 8–15 mm long common channel

√ Y-type configuration

(b) separate openings (19%)

» **1** orifice in papilla with 2 separate openings for each duct (= double-barrel configuration in 19–38%)

(c) interposed septum (7%)

» **2** orifices in papilla draining each duct separately

SPHINCTER OF ODDI

[Ruggero Oddi (1864–1913), physiologist in Genoa, Italy]

= SPHINCTER OF HEPATICOPANCREATIC AMPULLA

= 3 separate smooth muscles interspersed with glandular tissue encircling ampulla of Vater

(a) choledochal sphincter (Boyden) = encircles distal CBD

(b) pancreatic duct sphincter (in 33% separate)

(c) ampullary sphincter

Length: 10–15 mm

Function: regulates flow of bile + pancreatic juices into duodenum

Major Duodenal Papilla

= PAPILLA OF VATER

= conic / cylindric protuberance at medial aspect of duodenum

Location: middle ⅓ of descending duodenum (75%), horizontal portion of duodenum (25%)

◊ Drainage of common bile duct in 100%

◊ Drainage of main pancreatic duct of Wirsüng in 90%

√ oval protruding structure < 5–10 mm in diameter (seen on thin-section CT in 20%)

√ ± targetlike enhancement similar to that of adjacent duodenal mucosa

Minor Duodenal Papilla (present in 60%)

Location: 2 cm anterosuperior from major duodenal papilla

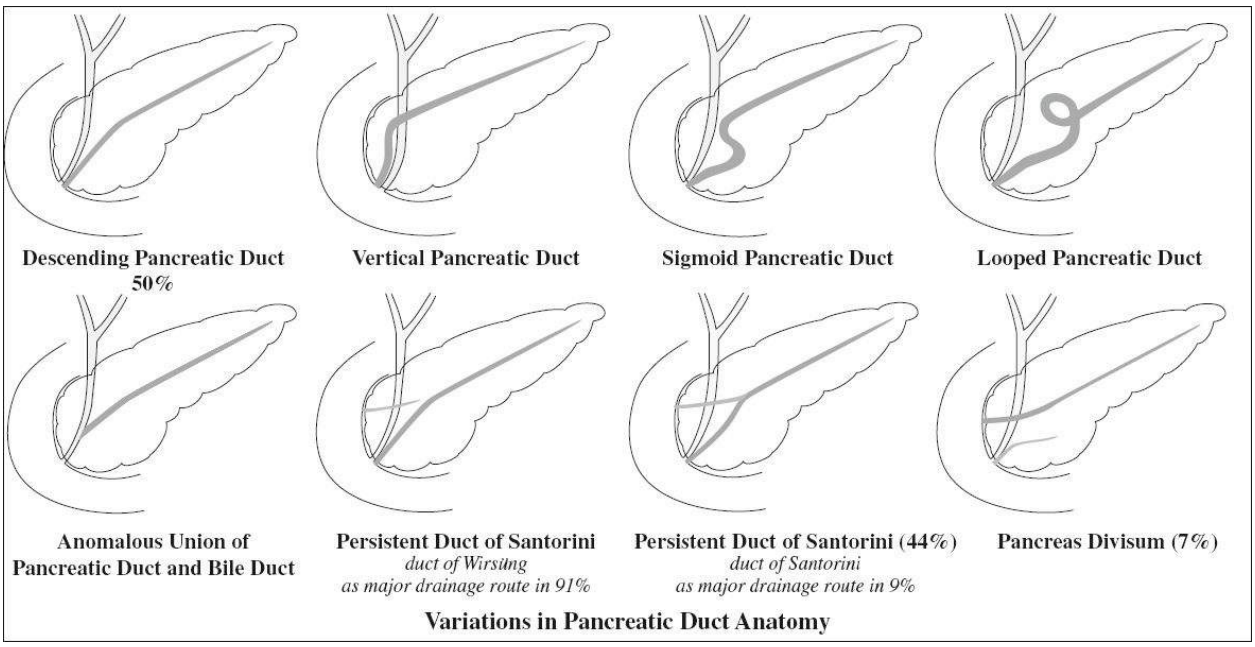
◊ Drainage of accessory pancreatic duct of Santorini

◊ Drainage of main pancreatic duct in 10%

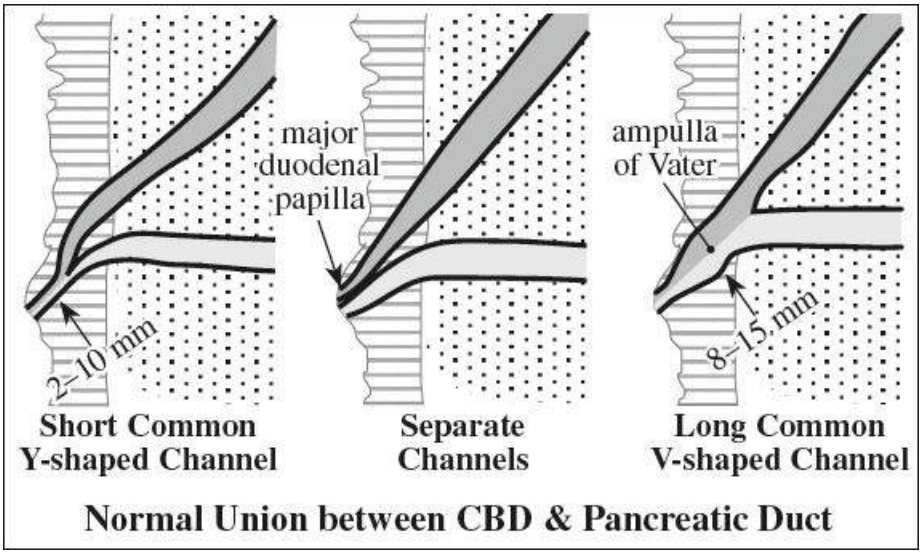
Pancreaticobiliary Junction Variants

A. Angle between CBD + pancreatic duct:
   (a) usually acute at 5°–30°
   (b) occasionally abnormal at up to 90°

B. **Anomalous pancreaticobiliary junction**



Variations in Pancreatic Duct Anatomy



Normal Union between CBD & Pancreatic Duct

= anomalous high junction outside duodenal wall beyond influence of sphincter of Boyden (1.5–3.2%)

(a) pancreatic duct inserting into CBD > 15 mm from entrance into duodenum
   › pancreaticobiliary reflux → choledochal web / cyst → gallbladder carcinoma
   › biliopancreatic reflux→ pancreatitis

(b) CBD inserting into pancreatic duct

Relationship of CBD to Pancreatic Head

1. CBD covered posteriorly by pancreatic tissue:
   (a) partially covered 51.5%
   (b) totally covered 30.0%
   (c) not covered at all 16.5%
2. CBD courses lateral to pancreatic head (occasionally)

SPLEEN

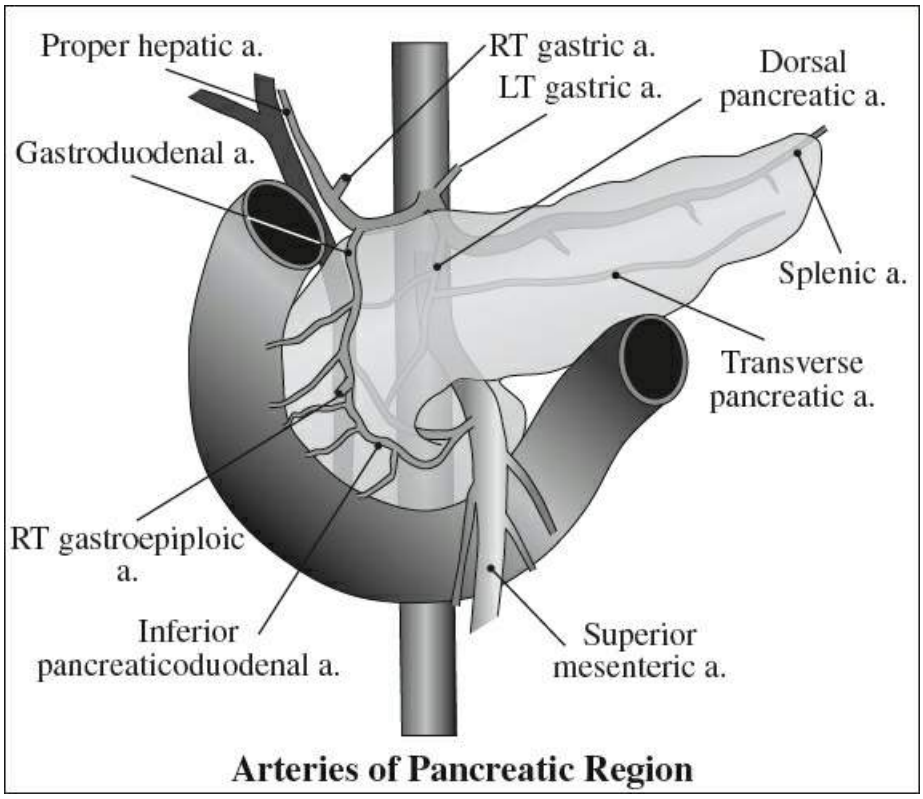
Size of Spleen

in adults: 12 cm length, 7–8 cm anteroposterior diameter, 3–4 cm thick; normal upper limit for splenic length correlates with height of individual (for men: 183 cm = 14.0 cm, 193 cm = 14.8 cm, 203 cm = 15.0 cm, 213 cm = 16.3 cm
for women; 173 cm = 12.6 cm, 183 cm = 13.2 cm; 188 cm = 13.4 cm, 198 cm = 14.0 cm)

in children: logarithmic increase in length with increasing age; formula for length = 5.7 + 0.31 x age (in years) cm

in infants (0–3 months of age): < 6.0 cm in length

Sonographic index: 0.524 x W x T x (ML + CCL)/2 normal range: 107–314/480 cm^3



Arteries of Pancreatic Region

W = width defined as greatest overall dimension from anterior to posterior on TRV image analog to CT

T = thickness as shortest distance between hilum and outer convex margin on same TRV image analog to CT

ML = maximum length from most medial to most lateral margin on LON/COR image

CCL = craniocaudal length from superior to inferior margin on same LON/COR image

Weight of Spleen

at birth: 15 g

in adults: 150 (range, 100–265) g

Estimated weight = splenic index = L × W × T × 0.55

Embryology of Spleen

› spleen arises from mesenchymal cells between layers of dorsal mesogastrium during 5th week GA

› splenic primordium differentiates→ forms capsule, connective tissue framework, splenic parenchyma

› major site of hematopoiesis until 28 weeks GA; retains capacity for extramedullary hematopoiesis well into adult life

√ spleen recognizable by 12th week GA ← as fusion of mesenchymal aggregates occurs

√ splenic clefts / notches / lobules may persist

√ accessory spleen (in up to 30% by autopsy)

Histology of Spleen

(a) RED PULP = numerous vascular sinuses

(b) WHITE PULP = lymphoid follicles + cells of RES

Development: ratio of white to red pulp increases with age + progressive antigenic stimulation

Imaging Characteristics of Spleen

A. CT ATTENUATION

(a) without enhancement:
40–60 HU (= 5–10 HU less than liver)

(b) with enhancement: normal heterogeneous enhancement during first minute after bolus injection ← different blood flow rates through the cords of the red + white pulp

√ arciform (alternating bands of high + low attenuation) / focal / diffuse heterogeneity

√ heterogeneity resolved in portal venous phase

B. MR SIGNAL INTENSITY directly related to ratio of white to red pulp

(a) neonate < 8 months of age:

√ T1WI- and T2WI-intensity: spleen < liver ← predominance of red pulp

DDx: hemochromatosis

(b) adult + older child:

√ T2WI-intensity: spleen > liver

√ T1WI-intensity: liver > spleen > muscle

IRON METABOLISM

Total body iron: 5 g

(a) functional iron: 4 g
Location: hemoglobin of RBCs, myoglobin of muscle, various enzymes (cytochromes)
(b) stored iron: 1 g
Location: hepatocytes, reticuloendothelial cells of liver (Kupffer cells) + spleen + bone marrow

Absorption: 1–2 mg/d via gut mucosa (10% of total amount ingested)
Recycling: through reuse of iron from senescent erythrocytes
Loss: 1–2 mg/d via epithelial desquamation, menstruation, other forms of blood loss
Excretion: none
Transport: bound to transferrin intravascularly
Deposition: stored as ferritin
(a) transferrin-transfer to:
hepatocytes, RBC precursors in erythron, parenchymal tissues (eg, muscle)
(b) phagocytosis by:
reticuloendothelial cells phagocytize senescent erythrocytes (= extravascular hemolysis); RBC iron stored as ferritin / released and bound to transferrin
◊ RES cells are incapable of storing excess iron!

Excess iron: leads to toxicity because it can catalyze the conversion of unstable hydrogen peroxide (H_2O_2) into free radicals hydroxyl (HO–) and superoxide O_2–) that cause damage to cell membranes, proteins, and DNA
Medullary erythropoiesis: requires about 20 mg/d of iron

ACCESSORY SPLEEN

= failure of coalescence of several small mesodermal buds in the dorsal mesogastrium that comprise the spleen

Prevalence: 10–30% of population; multiple (up to 6) in 10%

◊ Undergoes hypertrophy after splenectomy and is responsible for recurrence of hematologic disorders (idiopathic thrombocytopenic purpura, hereditary spherocytosis, acquired autoimmune hemolytic anemia, hypersplenism)

Location:

(a) near splenic hilum along the course of splenic vessels (most common)
(b) within layers of omentum (gastrosplenic ligament, other suspensory ligaments of spleen)
(c) anywhere in abdomen (eg, intrapancreatic, pelvis)
(d) attached to left ovary / testis = **splenogonadal fusion** ← close relationship between developing spleen + mesonephros + left gonadal anlage)

NUC (^{99m}Tc-sulfur colloid scan / spleen-specific ^{99m}Tc-denatured RBCs):

√ usually < 1 cm in diameter
√ < 10% identified when normal spleen present

Cx: disease recurrence ← hypertrophy of accessory spleen after splenectomy for hypersplenism

AMPULLARY TUMOR

= benign / malignant tumors arising from glandular epithelium of ampulla of Vater

Histo: (a) dysplastic epithelium in glandular / villous structures of tubular / villous adenoma
(b) carcinoma in situ
(c) invasive carcinoma often with desmoplastic reaction

Age: 6th–7th decade; M÷F = 2÷1

Path: average diameter of < 3 cm

- malaise, epigastric pain, weight loss
- intestinal bleeding (tumor ulceration)
- intermittent painless jaundice (ductal obstruction), pruritus
- gray "aluminum / silver-colored" stools (3%)
- chills, fever, RUQ pain (ascending cholangitis) in up to 20%
- endoscopy: tumor extending through orifice (63%), prominent papilla / submucosal mass (25%), not visualized (9%)

√ tumor often inapparent ← small size (more readily visualized with well-distended duodenum)

UGI:

√ indentation of duodenal lumen at papilla of Vater with filling defect > 1.5 cm
√ surface irregularity + deep barium-filled crevices in villous tumor

Biliary imaging:

√ dilatation of most distal segment of common bile duct
√ stenosis ← circumferential tumor growth around ampulla / desmoplastic reaction
√ irregular predominantly polypoid filling defect
√ ± pancreatic dilatation = "**double-duct" sign** (may be absent if tumor small / accessory pancreatic duct decompresses pancreatic system / main pancreatic duct drains into minor papilla)

DDx:

1. Periampullary duodenal adenoma / adenocarcinoma (usually larger lesion with significant intraduodenal extension)
2. Choledochocele (cystic lesion filling with biliary contrast)
3. Brunner gland tumor, pancreatic rest ("myoepithelial hamartoma"), leiomyoma, carcinoid (often production of somatostatin)
4. Duodenitis, pancreatitis
5. Stone impaction in ampulla

Ampullary Cancer

= AMPULLARY ADENOCARCINOMA
= rare malignancy arising in ampullary complex distal to confluence of the pancreatic duct and CBD

Incidence: 0.70÷100,000 men, 0.45÷100,000 women

TNM staging:

T1 : tumor confined to ampulla
T2 : tumor extending into duodenal wall
T3 : invasion of pancreas < 2 cm deep
T4 : invasion of pancreas > 2 cm deep

International Union Against Cancer Staging:

I = tumor confined to ampulla
II = tumor extension into duodenal wall / pancreas
III = regional lymph node involvement (Lnn stations around head + body of pancreas, anterior + posterior pancreaticoduodenal, pyloric, common bile duct, proximal mesenteric nodes)
IV = invasion of pancreas > 2 cm deep

• obstructive symptoms early in disease process

CT:
√ discrete nodular mass with irregular filling defect at distal margin of pancreaticobiliary junction (62%):
√ lobulated / infiltrating borders
√ hypoattenuating mass of ~ 40 HU
√ enhancement on arterial + portal venous phase

MR:
√ small nodular mass:
√ isointense relative to adjacent duodenal wall on T1WI
√ variable signal intensity on T2WI

√ hypointense relative to surrounding duodenum at arterial phase imaging
√ delayed contrast enhancement
√ irregular ductal wall thickening
√ bulging of duodenal papilla
√ intraductal polypoid mass
√ improved detection of ampullary carcinoma with DWI

MRCP:
√ filling defect / focal stricture at distal end of dilated CBD
√ "double-duct" sign = dilatation of biliary + pancreatic ducts (in 52%):
√ marked abrupt dilatation of distal CBD / pancreatic duct
√ NO signs of pancreatitis / pancreatic mass / stone
√ NO "double-duct" sign if separate duodenal openings for biliary and pancreatic ducts

Endoscopic US (most sensitive technique):
87% staging accuracy

Dx: papillotomy + deep biopsy (for duct dilatation WITHOUT visible mass)
Rx: Whipple procedure (= pancreaticoduodenectomy)
Prognosis: 28–70% 5-year survival for ampullary carcinomas (depending on stage)

Ampullary Adenoma

= uncommon premalignant lesion
Prevalence: 0.04–0.12% (at autopsy)
Associated with: familial adenomatous polyposis syndromes (eg, familial polyposis coli, Gardner syndrome) [100–200-fold risk], colon ca.
√ soft-tissue mass > 1 cm with irregular margin of ampulla
√ extrahepatic biliary duct + pancreatic duct dilatation
Cx: malignant transformation into adenocarcinoma

ANGIOSTRONGYLOSIS

= infection by nematode Angiostrongylus costaricensis
Countries: Central America, South America (sporadic cases)
Infection: ingestion of contaminated food
Cycle: parasite transmitted from snail to rat; ingestion of contaminated food by humans (= incidental host) → migration through lymphatic system → mesenteric veins + portal vein → liver
Histo: tissue eosinophilia, edema of intestinal wall, granulomas with eggs, larvae within blood vessels
• abdominal pain, anorexia, eosinophilia, fever
Location: terminal ileum, appendix, cecum

The adult worm resides inside mesenteric artery branches evoking an inflammatory response. Tissue samples show marked eosinophilic vasculitis.

√ nonspecific imaging findings:
√ bowel wall edema, occasionally, perforation
Dx: histopathologic findings

ANNULAR PANCREAS

= rare; 2nd most common congenital anomaly

Cause: failed / incomplete rotation of portion of ventral anlage → part of ventral pancreas passes posterior to descending duodenum → partial / complete encirclement of 2nd part of duodenum

Theory: (1) Adhesion of right anlage to duodenal wall (Lecco)
(2) Persistence of left ventral anlage (Baldwin)
(3) Tip of left ventral anlage adheres to duodenum

Types: (a) extramural = ventral pancreatic duct encircles duodenum and joins MPD
(b) intramural = pancreatic tissue intermingled with muscle fibers inside duodenal wall; small ducts drain directly into duodenum

Prevalence: 5–15÷100,000 (autoptic); 1÷250 (ERCP)

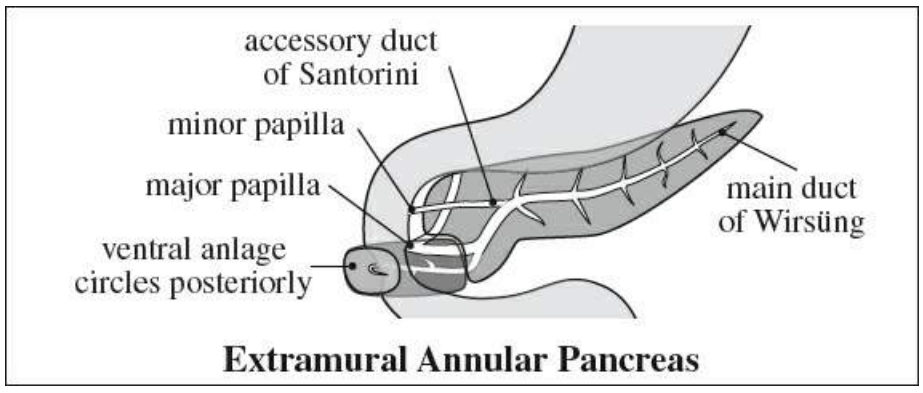
Age at discovery: during childhood (52%) + 4th–5th decade of adulthood (48%) = bimodal distribution

Associated with: other congenital anomalies (in 75%) like
esophageal atresia, tracheoesophageal fistula, duodenal atresia / stenosis, duodenal diaphragm, imperforate anus, malrotation, Down syndrome (in child);
pancreas divisum + bile duct carcinoma (in adult)

Location: 2nd portion of duodenum (85%);
1st / 3rd portion of duodenum (15%)

- mostly asymptomatic with incidental discovery
- neonate : persistent vomiting ← "gastric outlet" obstruction (in 10%)
- adult : nausea, vomiting (60%), abdominal pain (70%), jaundice (50%), hematemesis (10%); symptoms of peptic ulcer disease (25%) / acute pancreatitis (13%)

√ "double bubble" = dilated duodenal bulb (= smaller distal bubble) + distended stomach (= larger proximal bubble)
√ proximal duodenal dilatation
OB–US: √polyhydramnios



Extramural Annular Pancreas

UGI:
√ eccentric narrowing with lateral notching + medial retraction of 2nd part of duodenum
√ concentric ringlike narrowing of mid-descending duodenum between major and minor papilla

√ reverse peristalsis, pyloric incompetency

CT:

√ enlargement of pancreatic head

√ pancreatic tissue encircling descending duodenum

ERCP (most specific) / MR pancreatography (MRCP):

√ normally located main duct in pancreatic body + tail

√ small aberrant duct encircles duodenum (= originates anterior to + passes posterior to duodenum) communicating with:

› main duct of Wirsüng (in 85%)

› accessory duct of Santorini

› intrapancreatic common bile duct

Cx: in adults increased incidence of

(1) Periampullary peptic ulcers

(2) Pancreatitis (15–20%): usually confined to pancreatic head and annulus

(3) Duodenal obstruction (10%)

Rx: gastrojejunostomy / duodenojejunostomy

AGENESIS OF DORSAL PANCREAS

Variation: complete (extremely rare) / partial

May be associated with: heterotaxia (abnormal situs, polysplenia), intestinal malrotation

• nonspecific abdominal pain ← ? pancreatitis

• diabetes (in many)

√ short round pancreatic head adjacent to duodenum

√ absence of pancreatic neck, body, tail, duct of Santorini, minor duodenal papilla

DDx: pancreatic carcinoma with upstream pancreatic atrophy

ASCARIASIS

Organism: nematode (roundworm) Ascaris lumbricoides, 15–50 cm long + 3–6 mm thick adult worm; life span of 1 year

◊ 3rd most common helminthic infection (after hookworm + trichuriasis)

Endemic: in tropical + subtropical areas

(a) in parts of Africa (along Gulf Coast, Nigeria), Southeast Asia, China, South America: 90%

(b) in USA: 12% in blacks, 1% in whites; endemic in Appalachian range + Ozark Mountains

Prevalence: most common cosmopolitan parasitic infection (25% of world population infected); 1 billion humans harbor the roundworm [*cosmos* , Greek = world; *polites* , Greek = citizen]

Infection: fecal-oral route

Cycle:

contaminated water / soil / vegetable → ingestion of eggs; eggs hatch (= release larvae) in duodenum → larvae penetrate intestinal wall + migrate into mesenteric lymphatics and venules;→ carried to lungs via right heart + pulmonary artery; → mature in pulmonary capillary bed to 2–3 mm length → burrow into alveoli → ascend in bronchial tree; through

swallowing again reach small intestine → mature in jejunum into adult worms within 2.5 months (worms may migrate and settle in biliary + pancreatic ducts) → production of 200,000 eggs daily leave body by fecal route

Age: children 1–10 years of age

- pulmonary + intestinal symptoms:
  - fever, cough, expectoration (hematemesis / pneumonitis)
  - appendicitis
- biliary symptoms:
  - jaundice (if bile ducts infested); abnormal liver function tests
  - biliary colic ← Ascaris secretions induce spasm of sphincter of Oddi
- eosinophilia:
  - hypereosinophilia only present during acute stage of larval migration; Löffler syndrome = pulmonary eosinophilia

Pancreatic / biliary manifestations occur when the adult worm migrates from small bowel into the main pancreatic duct / biliary tree. Related complications are biliary colic, gallstone formation, cholecystitis, liver abscess, and pancreatitis.

Location: jejunum > ileum (99%), duodenum, stomach, CBD, pancreatic duct

Barium study:

√ 15–35 cm long elongated tubular filling defects
√ whirled appearance, occasionally in coiled clusters ("bolus of worms")
√ ± barium-opacification of enteric canal within nematode

CT:

√ worms are hyperattenuating relative to bile

MR:

√ worms exhibit low signal intensity on T2WI
√ fluid-filled GI tract of worms hyperintense on T2WI

CXR:

√ migratory patchy alveolar infiltrates that characteristically clear within 10 days
√ lobar consolidation + alveolar hemorrhage

Cx: (1) Intestinal obstruction ← massive infestation
(2) Bowel perforation
(3) Intermittent biliary obstruction with acute cholangitis, cholecystitis, pancreatitis
(4) Recurrent pyogenic cholangitis
(5) Liver abscess (rare)
(6) Granulomatous stricture of extrahepatic bile ducts (rare)

Dx: fecal examination (eggs in stool), larvae in sputum

Rx: mebendazole

Ascaris-induced Pancreatitis

= occasional migration of worm through ampulla of Vater into pancreaticobiliary tree via abnormally open ampullary orifice ← preexisting biliary tract disease / endoscopic sphincterotomy

◊ Most common parasitic cause of pancreatitis!

Mean age: 35–42 years; M÷F = 1÷3
US:
√ biliary / pancreatic ductal dilatation
√ pancreatic + peripancreatic inflammation
√ echogenic tubular structure without acoustic shadowing within bile / pancreatic duct with 2–4-mm wide central sonolucent line (= worm's digestive tract)
√ worm may slowly move at real-time imaging
Cx: biliary colic, cholangitis, acute cholecystitis, hepatic abscess, acute pancreatitis, septicemia

AUTOSOMAL DOMINANT POLYCYSTIC DISEASE

= POLYCYSTIC LIVER DISEASE
= part of spectrum of fibropolycystic liver disease
Etiology: biliary ductal plate malformation at the level of the small intrahepatic bile ducts with progressive dilation of the abnormal noncommunicating bile ducts of biliary hamartomas
M÷F = 1÷2
Associated with: polycystic kidney disease (in 50%)
• upper abdominal pain + distension from hepatomegaly
√ enlarged diffusely cystic liver: cysts of 1 mm – 12 cm in diameter
√ calcifications of cyst wall ← hemorrhage / infection
√ ± diffuse dilatation of intra- and extrahepatic bile ducts
Cx: infection, compression, bleeding, rupture of cysts

BANTI SYNDROME

= NONCIRRHOTIC IDIOPATHIC PORTAL HYPERTENSION = NONCIRRHOTIC PORTAL FIBROSIS = HEPATOPORTAL SCLEROSIS
= syndrome characterized by
(1) Splenomegaly
(2) Hypersplenism
(3) Portal hypertension
Etiology: increased portal vascular resistance possibly ← portal fibrosis + obliterative venopathy of intrahepatic portal branches
Histo: slight portal fibrosis, dilatation of sinusoids, intimal thickening with eccentric sclerosis of peripheral portal vein walls
Age: middle-aged women; rare in America + Europe; common in India + Japan
• elevated portal vein pressure (without cirrhosis, parasites, venous occlusion)
• normal liver function tests, cytopenia (← hypersplenism)
• normal / slightly elevated hepatic venous wedge pressure
√ esophageal varices
√ patent hepatic veins
√ patent extrahepatic portal vein + multiple collaterals
Prognosis: 90% 5-year survival; 55% 30-year survival

BILE LEAK

Posttraumatic bile leaks / biliary tract injuries related to recent surgery are easily overlooked due to
(a) nonspecific imaging findings, especially in the setting of multiorgan injury
(b) even less specific clinical findings
(c) difficulties to discern from other postoperative fluid collections.

Cause:
1. Post orthotopic liver transplantation
2. Pancreaticoduodenectomy
3. Hepatic or biliary surgery
4. Cholecystectomy (2%): laparoscopic > open
5. Radiofrequency ablation, percutaneous biliary drainage
6. Transcatheter arterial chemoembolization

Prevalence: 7% after laparoscopic cholecystectomy
Time of onset: during 1st postoperative week
• asymptomatic subclinical bile leak (7%)
• abdominal pain, fever, nausea, vomiting
Location: cystic duct stump / ducts of Luschka (= subvesical / accessory biliary ducts)
Cholescintigraphy:
√ DIAGNOSTIC but with poor anatomic definition and spatial resolution necessitating a secondary diagnostic evaluation (especially ERCP)
MRCP with hepatobiliary contrast medium:
Agents: gadoxetate disodium (Eovist®) with 50% liver excretion 20 minutes after administration; gadobenate dimeglumine (MultiHance®) with 5% liver excretion 60–120 minutes after administration
√ dynamic biliary imaging during hepatobiliary phase with improved characterization of biliary anatomy
ERCP:
√ depicts peripheral sites of leakage that may not be filled with retrograde injection
Cx: (1) Biloma= encapsulated extrabiliary bile collection
(2) Bile peritonitis (days to weeks after initial trauma)
Prognosis: high morbidity + mortality rates if undiagnosed
Rx: endoscopic / surgical management

BILIARY CYSTADENOCARCINOMA

= BILE DUCT CYSTADENOCARCINOMA
= rare malignant multilocular cystic tumor originating from biliary cystadenoma
Histo: (a) with ovarian stroma (good prognosis), in females only
(b) without ovarian stroma (poor prognosis)
• hemorrhagic internal fluid
√ nodularity with septations are suggestive of malignancy
√ coarse calcifications
DDx: NO image differentiation from biliary cystadenoma

BILIARY CYSTADENOMA

= BILE DUCT CYSTADENOMA

= very rare benign multilocular cystic tumor originating in bile ducts as premalignant form of biliary cystadenocarcinoma; probably deriving from ectopic nests of primitive biliary tissue

Frequency: 4.6% of all intrahepatic cysts of bile duct origin

Age: > 30 years (82%), peak incidence in 5th decade; M÷F = 1÷4; predominantly in Caucasians

Path: multilocular cystic tumor containing proteinaceous fluid with well-defined thick capsule

Histo: single layer of cuboidal / tall columnar mucin-secreting biliary-type epithelium with papillary projections, subepithelial stroma resembling that of the ovary

◊ Similar to mucinous cystic tumors of pancreas + ovary

Location: intrahepatic÷extrahepatic bile ducts = 85÷15; right lobe (48%); left lobe (20–35%); both lobes (15–30%); gallbladder (rare)

- chronic abdominal pain
- dyspepsia, anorexia, nausea + vomiting, jaundice
- abdominal swelling with palpable mass (90%)

Size: 1.5–35 cm (reportedly up to 11 liters of liquid content)

√ well-defined cystic mass containing clear / cloudy, serous / mucinous / gelatinous, purulent / hemorrhagic / bilious fluid with hemosiderin / cholesterol / necrosis

√ thick fibrous capsule

√ papillary excrescences + mural nodules

√ septations between cysts

US:

√ ovoid multiloculated anechoic mass with highly echogenic septations / papillary growths

√ may contain fluid-fluid levels

CT:

√ multiloculated mass of near water density

√ contrast enhancement in wall + internal septa

MR:

√ locules with variable SI on T1WI + T2WI depending on their protein content

Angio:

√ avascular mass with small clusters of peripheral abnormal vessels

√ stretching + displacement of vessels

√ thin subtle blush of neovascularity in septa + wall

Cx: (1) Malignant transformation into cystadenocarcinoma (indicated by invasion of capsule)

(2) Rupture into peritoneum / retroperitoneum

Rx: surgical resection (recurrence common)

DDx: biliary cystadenocarcinoma, liver abscess, echinococcal cyst, cystic mesenchymal hamartoma (children + young adults), undifferentiated sarcoma (children + young adults), necrotic hepatic metastasis, cystic primary hepatocellular carcinoma

BILIARY-ENTERIC FISTULA

Frequency: 5% at cholecystectomy; 0.5% at autopsy

Etiology: cholelithiasis (90%), acute / chronic cholecystitis, biliary tract carcinoma, regional invasive neoplasm, diverticulitis, inflammatory bowel disease, peptic ulcer disease, echinococcal cyst, trauma, congenital communication

Communication with:

duodenum (70%), colon (26%), stomach (4%), jejunum, ileum, hepatic artery, portal vein (caused death of Ignatius de Loyola), bronchial tree, pericardium, renal pelvis, ureter, urinary bladder, vagina, ovary

A. CHOLECYSTODUODENAL FISTULA (51–80%)
   1. Perforated gallstone (90%):
      associated with gallstone ileus in 20%
   2. Perforated duodenal ulcer (10%)
   3. Surgical anastomosis
   4. Gallbladder carcinoma

B. CHOLECYSTOCOLIC FISTULA (13–21%)

C. CHOLEDOCHODUODENAL FISTULA (13–19%)
   due to perforated duodenal ulcer disease

D. MULTIPLE FISTULAE (7%)

√ pneumobilia = branching tubular radiolucencies, more prominent centrally within the liver
√ barium filling of biliary tree
√ shrunken gallbladder mimicking pseudodiverticulum of duodenal bulb
√ multiple hyperechoic foci with dirty shadowing

DDx: patulous sphincter of Oddi, ascending cholangitis, surgery (choledochoduodenostomy, cholecystojejunostomy, sphincterotomy)

BUDD-CHIARI SYNDROME

= syndrome of global / segmental hepatic venous outflow obstruction at level of hepatic veins / IVC

Cause:

A. IDIOPATHIC (66%)

B. THROMBOSIS
   (a) myeloproliferative disorder:
   polycythemia rubra vera (⅓), essential thrombocytosis
   (b) hypercoagulable state:
   mnemonic: 6 P's
   Paroxysmal nocturnal hemoglobulinuria (12%)
   Platelets (thrombocytosis)
   Pill (birth control pills)
   Pregnancy + **P**ostpartum state
   Polycythemia rubra vera
   Protein C deficiency
   also: sickle cell disease
   (c) injury to vessel wall:
   phlebitis, trauma, hepatic radiation injury, chemotherapeutic + immunosuppressive drugs in patient with bone marrow transplant, venoocclusive disease from

pyrrolizidine alkaloids (Senecio) found in medicinal bush teas in Jamaica

C. NONTHROMBOTIC OBSTRUCTION
  (a) compression or invasion of IVC / hepatic veins:
    › benign: cirrhosis, hematoma, abscess
    › malignant: renal cell carcinoma, adrenal carcinoma, hepatoma, cholangiocarcinoma, metastasis, primary leiomyosarcoma of IVC, Hodgkin disease
  (b) membranous obstruction of suprahepatic IVC
    = IVC diaphragm (believed to be a congenital web / acquired lesion from long-standing IVC thrombosis); common in Oriental + Indian population (South Africa, India, Japan, Korea, Israel); very rare in Western countries
  (c) right atrial tumor: atrial myxoma
  (d) constrictive pericarditis
  (e) right heart failure

D. SYSTEMIC INFLAMMATION / INFECTION
  1. Inflammatory bowel disease
  2. Behçet syndrome

Pathophysiology:
hepatic venous thrombosis → elevation of sinusoidal pressure → diminished / reversed portal venous flow → centrilobular congestion → necrosis + atrophy
(a) acute form (= no time for development of collateral veins) → rapid development of hepatic necrosis
(b) subacute / chronic form (venous thrombosis incomplete) → peripheral atrophy + preservation of central region with caudate lobe hypertrophy (drained by accessory veins)

In 25% associated with: portal vein thrombosis
Age: all ages; M < F

- right upper quadrant pain, lower-extremity edema
- shortness of breath ← decreased cardiac return
- nonspecific elevated transaminases, jaundice

Location:

Type I	:	occlusion of IVC ± hepatic veins
Type II	:	occlusion of major hepatic veins ± IVC
Type III	:	occlusion of small centrilobar venules

√ gallbladder wall thickening > 6 mm
√ portal vein diameter > 12 mm (in adults), > 8 mm (in children)
MR:
√ reduction in caliber / complete absence of hepatic veins
√ "comma" sign = multiple comma-shaped intrahepatic flow voids ← intrahepatic collaterals
√ hyperintense thrombi
Doppler US (85–100% sensitive, 85% specific):
√ one / more major hepatic veins reduced in size to < 3 mm / filled with thrombus / not visualized
√ stenoses of hepatic veins
√ communicating intrahepatic venous collaterals

√ decreased / absent / reversed blood flow in hepatic veins
√ flat flow / loss of cardiac modulation in hepatic veins
√ demodulated portal venous flow = disappearance of portal vein velocity variations with breathing
√ slow flow of < 11 cm/sec / hepatofugal flow in portal vein
√ portal vein congestion index > 0.1 [cm • sec] (= ratio between cross-sectional area [cm^2] and blood flow velocity [cm/sec])
√ portal vein thrombosis (20%)
√ compression of IVC by enlarged liver / caudate lobe
√ sluggish / reversed / absent blood flow within IVC
√ hepatic artery resistive index > 0.75

NUC (^{99m}Tc-sulfur colloid):
√ central region of normal activity (= hot caudate lobe ← venous drainage of hypertrophied caudate lobe into IVC by separate vein) surrounded by greatly diminished activity
√ colloid shift to spleen + bone marrow
√ wedge-shaped focal peripheral defects

Angio (inferior venocavography, hepatic venography):
√ absence of main hepatic veins
√ spider web pattern of collateral + recanalized veins
√ high-pressure gradient between infra- and suprahepatic portion of IVC ← enlarged liver
√ stretching + draping of intrahepatic arteries with hepatomegaly
√ inhomogeneous prolonged intense hepatogram with fine mottling
√ large lakes of sinusoidal contrast accumulation

Portography:
√ central hepatic enhancement (normal hepatopetal flow)
√ reversed portal flow in liver periphery (supplied only by hepatic artery)
√ bidirectional / hepatofugal main portal vein flow

Dx: liver biopsy

Rx: control of ascites with diuretics + sodium restriction; anticoagulation, thrombolytic therapy, surgery / balloon dilatation (depending on etiology); transjugular portosystemic shunt (in preparation for) orthotopic liver transplantation (for advanced cases)

Acute Budd-Chiari Syndrome (⅓)

◊ Caudate lobe has not had time to hypertrophy!

• TRIAD:
  • rapid onset of abdominal pain (liver congestion)
  • insidious onset of intractable ascites
  • hepatomegaly without derangement of liver function
• jaundice

√ enlarged morphologically normal liver
√ splenomegaly
√ ascites (97%)

NECT:
√ diffusely hypoattenuating liver
√ IVC + hepatic veins:

√ narrowed lumina (without thrombus)
√ hyperattenuating lumina containing thrombus (in 18–53%)
√ enlarged inferior right hepatic vein (18%)

CECT:

√ normal early enhancement of caudate lobe and central portion around IVC + decreased enhancement of peripheral liver (← portal and sinusoidal stasis) during arterial phase
√ "flip-flop" pattern during portal venous phase:
√ decreased attenuation (washout) of enhancing central areas
√ increasing patchy inhomogeneous enhancement in liver periphery ← contrast inflow from capsular veins

MR:

√ peripheral liver parenchyma of moderately low SI on T1WI + moderately high SI on T2WI compared with central portion
√ diminished + mottled peripheral enhancement

Subacute Budd-Chiari Syndrome

• portal hypertension, varying degrees of liver decompensation
√ diffuse peripheral hypoattenuation ← hepatocellular necrosis + steatosis

Chronic Budd-Chiari Syndrome (²/₃)

• insidious onset of jaundice, intractable ascites
• portal hypertension, variceal bleeding
• renal impairment (in 50%)
√ dysmorphic liver:
√ nonsegmental / lobar atrophy of affected liver (← extensive fibrosis) with diminished attenuation before + after contrast administration
√ compensatory hypertrophy of caudate lobe (88%) + central parenchymal segments of right lobe + medial segment of left lobe:
√ width of caudate ÷ right lobe ≥ 0.55 (DDx: cirrhosis)
√ visualization of collateral pathways
(a) portosystemic: paraumbilical vein
(b) bypassing IVC: azygos, hemiazygos
(c) intrahepatic collateral veins (almost DIAGNOSTIC): right / middle hepatic vein → inferior right hepatic vein; hepatic vein → portal vein
√ development of 1–4 cm regenerative nodules (in areas of adequate blood supply)
√ ascites

CECT:

√ invisible IVC ± hepatic veins ← collapse / diminished flow rate:
√ nonvisualization of hepatic veins (75%) / vein diameter < 3 mm (measured 2 cm from IVC)
√ ± narrowing / obstruction of intrahepatic IVC
√ progressive heterogeneous patchy enhancement radiating outward from major portal vessels
√ "reticulated mosaic" enhancement = diffuse patchy lobular enhancement separated by irregular linear areas of low density in central area

√ delayed homogeneous enhancement of entire liver after several minutes
√ reversed portal venous blood flow ← increased postsinusoidal pressure produced by hepatic venous obstruction / rarely infarcts

Color Doppler:
√ PATHOGNOMONIC "bicolored" hepatic veins ← intrahepatic collateral pathways

MR:
√ absence of flow within hepatic veins
√ minimal differences in SI between central and peripheral portions of liver
√ intrahepatic collateral vessels

CANDIDIASIS OF LIVER

= almost exclusively seen in immunocompromised patients (acute leukemia, chronic granulomatous disease of childhood, renal transplant, chemotherapy for myeloproliferative disorders)

Prevalence: at time of autopsy in 50–70% of acute leukemia, in 50% of lymphoma patients
◊ Most common systemic fungal infection in immunocompromised patients!

• abdominal pain, elevated alkaline phosphatase
• persistent fever in neutropenic patient whose leukocyte count is returning to normal
√ hepatomegaly
√ "target" / "bull's-eye" sign = multiple small hypoechoic / hypoattenuating masses with centers of increased echogenicity / attenuation distributed throughout liver
◊ Bull's-eye lesion becomes visible only when neutropenia resolves!
√ hyperintense lesions on T2WI

NUC:
√ uniform uptake / focal photopenic areas
√ diminished ^{67}Ga uptake

Dx: biopsy evidence of yeast / pseudohyphae in central necrotic portion of lesion

DDx: metastases, lymphoma, leukemia, sarcoidosis, septic emboli, other infections (MAI, CMV), Kaposi sarcoma

CAROLI DISEASE

[Jacques Caroli (1902–1979), surgeon in Paris, France]

= COMMUNICATING CAVERNOUS ECTASIA OF INTRAHEPATIC BILE DUCTS

◊ Original classification as Type V choledochal cyst (Todani classification) is NO longer accepted!

= rare congenital autosomal recessive disorder characterized by multifocal segmental saccular cystic dilatation of large intrahepatic bile ducts

Etiology: (a) ductal plate malformation
(b) ? perinatal hepatic artery occlusion
(c) ? hypoplasia / aplasia of fibromuscular wall components

Path: communication with biliary tree

Age: childhood + 2nd–3rd decade, occasionally in infancy; M÷F = 1÷1

Associated with: benign renal tubular ectasia, medullary sponge kidney (in 80%), infantile polycystic kidney disease, choledochal cyst (rare), congenital hepatic

fibrosis, cholangiocarcinoma

- recurrent cramplike right upper quadrant pain
- bouts of fever ← cholangitis ← bile stasis
- transient jaundice ← bile stasis ← blocking stone / sludge
- cirrhosis / portal hypertension (very rare)

Location: diffuse / segmental or lobar

Types:

(1) pure form (type 1): attacks of cholangitis + intraductal stone formation

(2) complex form (type 2) – more common: associated with hepatic fibrosis / other ductal plate malformations

√ multiple small localized / diffusely scattered cysts converging toward porta hepatis communicating with bile ducts

√ beaded ducts with alternating dilated and strictured segments

√ sludge / pus / calculi in dilated ducts

CT / US/ MR:

√ **"central dot" sign** = enhancing fibrovascular bundle of portal vein radicles completely surrounded by cystically altered dilated intrahepatic bile ducts (IBD)

Cholangiography and MRCP (DIAGNOSTIC):

√ segmental saccular > fusiform beaded dilatation of intrahepatic bile ducts extending to periphery of liver up to 5 cm in diameter

√ ± filling defects ← intraductal calculi

√ bridge formation across dilated lumina

√ intraluminal bulbar protrusions

√ frequent ectasia of extrahepatic ducts + CBD

Dx: ERCP, direct cholangiography, MRCP

Cx: (1) Bile stasis → sludge + recurrent cholangitis

(2) Biliary calculi (predominantly bilirubin)

(3) Liver abscess

(4) Septicemia

(5) Increased risk of cholangiocarcinoma (7%)

DDx: (1) Primary sclerosing cholangitis (multiple irregular strictures of intra- and extrahepatic bile ducts, pseudotumoral enlargement of caudate lobe, lobulated liver contour)

(2) Recurrent pyogenic cholangitis (nonsaccular dilatation of central intra- and extrahepatic bile ducts, bile ducts tapered toward periphery)

(3) Autosomal dominant polycystic liver disease (no communication with bile ducts)

(4) Biliary hamartomas (no communication with bile ducts)

(5) Microabscesses

(6) Biliary papillomatosis

Caroli Syndrome

= both features of Caroli disease and congenital hepatic fibrosis

= arrest of bile duct remodeling during embryogenesis + during later development of more

peripheral biliary ramifications
- hematemesis ← ruptured esophageal varices ← portal hypertension

CHOLANGIOCARCINOMA

= primary malignancy arising from cholangiocyte of biliary tract

Frequency: 0.5–1.0% of all cancers;
10% of hepatic primary malignancies
◊ 2nd most common primary hepatobiliary cancer after HCC!

Anatomic classification:

A. INTRAHEPATIC (PERIPHERAL)
peripheral / distal to 2nd-order branches 8–13%

B. PERIHILAR (CENTRAL) = Klatskin tumor
at bifurcation / 1st-order branches
confluence of hepatic ducts 10–26%

C. EXTRAHEPATIC
common hepatic duct 14–37%
proximal CBD 15–30%
distal CBD 30–50%
cystic duct 6%

D. GALLBLADDER

Path (Japanese Liver Cancer Study Group):

(a) **mass-forming** (= nodular / exophytic) type:
commonly in peripheral cholangiocarcinoma
- homogeneous sclerotic mass typically without hemorrhage / necrosis
- central portion with variable degree of fibrosis + coagulative necrosis with scanty tumor cells

(b) **periductal infiltrating** / diffuse type:
commonly in hilar + extrahepatic cholangiocarcinoma
- elongated spiculated / branching growth along dilated / narrowed bile duct

(c) **intraductal tubular polypoid** / papillary type:
- infrequent slow growing tumor with relatively favorable prognosis
- frequently associated with marked mucin production

(d) **mixed** = combination of mass-forming + periductal

Histo: well / moderately / poorly differentiated ductal adenocarcinoma (most common) / papillary / mucinous / signet-ring cell / mucoepidermoid / adenosquamous adenocarcinoma with abundant fibrous stroma

Unusual manifestation:
1. Mucin-hypersecreting cholangiocarcinoma
   √ severe diffuse dilatation of intra- and extrahepatic bile ducts proximal + distal to tumor
2. Squamous cell carcinoma
   = metaplastic transformation of adenocarcinoma

Genetics: mutation in p53 tumor suppressor gene + k-ras gene

Peak prevalence: 7th decade; M > F

Predisposed: conditions causing chronic biliary inflammation

(1) Inflammatory bowel disease (10 x increased risk); incidence of 0.4–1.4% in ulcerative colitis; latent period of 15 years; tumors usually multicentric + predominantly in extrahepatic sites; GB involved in 15% (simultaneous presence of gallstones is rare)
(2) Biliary lithiasis: cholecystolithiasis (20–50%), hepatolithiasis (5–10%)
(3) Primary sclerosing cholangitis (10–15%)
(4) Infection with liver flukes: Opisthorchis viverrini and Clonorchis sinensis infestation (Far East)
    ◊ Most common cause worldwide!
(5) Recurrent pyogenic cholangitis = hepatolithiasis
(6) Viral infection: HIV, hepatitis B virus, hepatitis C virus, Epstein-Barr virus
(7) Congenital biliary cystic disease: choledochal cyst / congenital hepatic cyst / congenital biliary atresia
(8) Anomalous pancreaticobiliary junction
(9) Ductal plate malformation:
    › Biliary hamartoma
    › Autosomal dominant polycystic disease
    › Congenital hepatic fibrosis
    › Caroli disease ← chronic biliary stasis
(10) Papillomatosis of bile ducts
(11) Choledochoenteric anastomosis
(12) History of other malignancy (10%)
(13) Toxins: thorotrast exposure, polyvinyl chloride
(14) Heavy alcohol consumption
(15) Alpha−1 antitrypsin deficiency
(16) Familial polyposis

MR:

√ moderate peripheral enhancement followed by progressive centripetal enhancement
√ single / multifocal biliary strictures
√ focal / diffuse ductal thickening ± contrast enhancement
√ intraductal polypoid growth

Prognosis: median survival of 7 months, 0–10% 5-year survival

Extrahepatic Cholangiocarcinoma

= BILE DUCT CARCINOMA

Age peak: 6th–7th decade; M÷F = 3÷2

Incidence: 1÷100,000; < 0.5% of autopsies; 90% of all cholangiocarcinomas; more frequent in Far East

Histo: well-differentiated sclerosing adenocarcinoma (2/3), anaplastic carcinoma (11%), cystadenocarcinoma, adenoacanthoma, malignant adenoma, squamous cell carcinoma, epidermoid carcinoma, leiomyosarcoma

- gradual onset of fluctuating painless jaundice
- cholangitis (10%), weight loss, fatigability
- intermittent epigastric pain, enlarged tender liver
- elevated bilirubin + alkaline phosphatase

Growth pattern:

(1) Infiltrating / sclerosing type (94%)
  √ ductal wall thickening + sudden luminal obliteration

(2) Papillary / tubular polypoid type (5–6%)
  √ intraductal polypoid mass with irregular margin ± diffuse marked duct ectasia (mucin production)

Spread: (a) lymphatic spread: cystic + CBD nodes (> 32%), celiac nodes (> 16%), peripancreatic nodes, superior mesenteric nodes

(b) infiltration of liver (23%)

(c) peritoneal seeding (9%)

(d) hematogenous (extremely rare): liver, peritoneum, lung

UGI:

√ infiltration / indentation of stomach / duodenum

Cholangiography (PTC or ERC best modality to depict bile duct neoplasm):

√ prestenotic diffuse / focal biliary dilatation (100%)

√ progression of ductal stricture (100%)

√ frequently long / rarely short concentric focal stricture with irregular margins (in infiltrating type):
  √ nipple / rattail termination

√ exophytic intraductal tumor mass (46%), 2–5 mm in diameter

US / CT:

√ mural thickening / small encircling mass of bile duct at point of obstruction (in 21% visible on US, in 40% visible on CT):
  √ focal or diffuse stricture / complete obstruction of bile ducts
  √ dilatation of intrahepatic ducts without extrahepatic duct dilatation

√ infiltrating tumor visible in 22% on CT as highly attenuating lesion, in 13% on US

√ exophytic tumor: visible on CT as hypoattenuating mass in 100%, in 29% on US

√ polypoid intraluminal tumor: visible on US as isoechoic mass within surrounding bile in 100%, in 25% on CT

√ regional lymph node enlargement

CECT:

√ hyperattenuating lesion at delayed imaging ← delayed accumulation + washout of fibrous center

MR:

√ hypointense relative to liver parenchyma on T1WI

√ hyperintense relative to liver parenchyma on T2WI

√ more conspicuous on fat-suppressed MR

Angiography:

√ hypervascular tumor with neovascularity (50%)

√ arterioarterial collaterals along the course of bile ducts associated with arterial obstruction

√ poor / absent tumor stain

√ displacement / encasement / occlusion of hepatic artery + portal vein

Cx: (1) Obstruction leading to biliary cirrhosis

(2) Hepatomegaly
(3) Intrahepatic (subdiaphragmatic, perihepatic) abscess → septicemia
(4) Biliary peritonitis
(5) Portal vein invasion

Dx: endoscopic brush biopsy (30–85% sensitive)

Prognosis: median survival of 5 months; 1.6% 5-year survival; 39% 5-year survival for carcinoma of papilla of Vater

DDx: periportal lymphangitic metastasis (no ductal dilatation, diffuse involvement of both sides of liver); sclerosing cholangitis, AIDS cholangitis, benign stricture, chronic pancreatitis, edematous papilla, idiopathic inflammation of CBD

Intrahepatic Cholangiocarcinoma

= CHOLANGIOCELLULAR CARCINOMA

Frequency: 2nd most common primary hepatic tumor after hepatoma; ⅓ of all malignancies originating in the liver; 8–13% of all cholangiocarcinomas

Histo: adenocarcinoma arising from the epithelium of a small intrahepatic bile duct with prominent desmoplastic reaction (fibrosis); ± mucin and calcifications

Average age: 50–60 years; M > F

- abdominal pain (47%); painless jaundice (12%)
- palpable mass (18%), weight loss (18%)

Spread: (a) local extension along duct
(b) local infiltration of liver substance
(c) metastatic spread to regional lymph nodes (in 15%)
◊ Biliary + vascular obstruction is typical!

√ ill-defined mass of 5–20 cm in diameter
√ satellite nodules in 65%
√ punctate / chunky calcifications in 18%
√ calculi in biliary tree
√ liver atrophy is suggestive although not specific
√ fibrotic pseudocapsule + secondary capsular retraction

US:
√ dilated biliary tree
√ predominantly solitary homo- / heterogeneous mass
√ hyperechoic (75%) mass for tumors > 3 cm
√ iso- / hypoechoic (14%) mass for tumor < 3 cm
√ mural thickening
√ peripheral hypoechoic tumor rim (35%) of compressed liver parenchyma

NECT:
√ single large predominantly homogeneous round / oval hypo- to isoattenuating dense mass with irregular margin
√ capsular retraction
√ stippled / punctate hyperattenuating foci (= hepatolithiasis)
√ dilatation of biliary tree peripheral to tumor

CECT:

√ hypoattenuating mass during arterial + portal venous phase
√ marked homogeneous delayed enhancement at 15 minutes (36–74%):
√ progressive concentric filling in of contrast medium (late) ← slow diffusion into interstitial tumor spaces within fibrous stroma
√ "peripheral washout" sign = (early) minimal to moderate thin rimlike / thick bandlike ragged enhancement around tumor:
√ clearing of contrast material in rim of lesion on delayed images
√ obliteration of portal vein + atrophy of involved segment
√ satellite nodules

MR:
√ large central heterogeneously hypo- to isointense mass on T1WI
√ variably hyperintense mass on T2WI depending on amount of mucinous material, fibrous tissue, hemorrhage, tumor necrosis:
√ hyperintense periphery (viable tumor) with irregular margin
√ large central hypointensity (fibrosis) on T2WI
√ hyperintense lesion on DWI ← suppression of high signal from vessels + bile ducts
√ ± DWI for small lesion

CEMR:
√ minimal / incomplete enhancement at tumor periphery on early images ← areas of early enhancement + rapid washout indicate active neoplastic growth
√ concentric centripetal internal fill-in = prominent progressive central enhancement on equilibrium / delayed phase ← vascular fibrotic stroma in tumor center
√ intense homogeneous enhancement during arterial phase + prolonged enhancement during delayed phase in smaller lesions with less fibrosis
√ satellite nodules in 10–20%

MR cholangiography:
√ localizing site of obstruction (100% accurate)
√ determining cause of obstruction (95% accurate)

Angiography:
√ avascular / hypo- / hypervascular mass
√ stretched / encased arteries (frequent)
√ neovascularity in 50%
√ lack of venous invasion

NUC:
√ cold lesion on sulfur colloid / IDA scans
√ segmental biliary obstruction
√ may show uptake on gallium scan

PET:
√ ring-shaped uptake ← excessive desmoplastic response of tumor center + neovascularity at tumor periphery
√ metastases to lymph nodes, liver, and distant sites

ERCP:
√ diagnostic bile sampling with cytologic analysis
√ biliary stent placement to relieve obstruction

Prognosis: < 20% resectable; 30% 5-year survival

DDx: (1) Metastatic adenocarcinoma (central necrosis = strongly T2-hyperintense + T1-hypointense)
(2) Hemangioma (strong globular enhancement, NO ragged rim)
(3) Sclerosing / cirrhotic HCC (NO distinguishing features)
(4) Organizing abscess (thick enhancing wall with central cystic change)
(5) Tuberculosis (multilayered appearance)

Intrahepatic Peripheral Cholangiocarcinoma

• NO jaundice
Location: right lobe predilection
√ solitary mass (nodular form) without hypoechoic halo
√ diffusely abnormal liver texture (infiltrative form):
  √ tumor more hypoechoic if < 3 cm
  √ tumor more hyperechoic if > 3 cm
√ well-marginated cystic mass (papillary mucin-producing tumor) ± diffuse hyperechoic flecks of tumor calcification
√ capsular retraction
√ delayed enhancement at 10 minutes
√ dilatation of bile ducts peripheral to tumor (31%)
√ tumor fingers in bile duct
DDx: metastatic adenocarcinoma / leiomyosarcoma; sclerosing hepatocellular carcinoma

Klatskin Tumor

[Gerald Klatskin (1910–1986), pathologist in Yale, USA]
= INTRAHEPATIC CENTRAL CHOLANGIOCARCINOMA = HILAR CHOLANGIOCARCINOMA
= tumor at confluence of hepatic ducts (up to 50–70% of all cholangiocarcinomas)
Age: > 65 years at presentation
Path growth pattern: infiltrating (70%) / intraluminal polypoidal / mass-forming
• abdominal pain, discomfort, anorexia, weight loss
• pruritus, jaundice (late symptom)
√ direct signs of Klatskin tumor:
  √ failure to demonstrate confluence of L + R hepatic ducts
  √ iso- to hyperechoic central porta hepatis mass / focal irregularity of ducts (for infiltrating cholangiocarcinoma)
  √ polypoid / smooth nodular intraluminal mass (for papillary + nodular types of cholangiocarcinoma) with associated mural thickening
√ indirect signs of Klatskin tumor:
  √ segmental dilatation with nonunion of right + left ducts at porta hepatis + normal caliber of extrahepatic ducts
  √ pressure effect / encasement / invasion / obliteration of portal vein and hepatic artery
√ lobar atrophy (14%) = dilated crowded ducts extending to liver surface ± geographic fatty change in one lobe
Rx: > 50% inoperable at diagnosis ← advanced stage

Inoperability (CT and MR 75–93% accurate):

(1) Invasion of right / left hepatic duct with extension to 2nd-order biliary radicles
(2) Atrophy of 1 hepatic lobe + involvement of contra- lateral portal vein branch / 2nd-order biliary radicle
(3) Vascular encasement / invasion of main portal vein or main hepatic artery
(4) Metastatic disease: lymph node / distant

CHOLANGITIS

Acute Obstructive / Ascending Cholangitis

= biliary duct obstruction associated with bacterial overgrowth

Cause:

(a) benign disease:
1. Stricture from prior surgery (36%) after bile duct exploration / bilioenteric anastomosis
2. Calculi (30%)
3. Sclerosing cholangitis
4. Obstructed drainage catheter
5. Parasitic infestation (liver fluke)

(b) malignant disease:
1. Ampullary carcinoma

Types:

(a) **Acute nonsuppurative ascending cholangitis**
- bile remains clear, patient nontoxic

(b) **Subacute nonsuppurative cholangitis**
= Cholangitis lenta = nonacute response of liver to systemic bacterial / fungal infection
◊ Important cause of liver failure + mortality with OLT

(c) **Acute suppurative ascending cholangitis** (14%)
Associated with: obstructing biliary stone or malignancy
- biliary sepsis, CNS depression, lethargy, mental confusion, shock (50%)

√ purulent material fills biliary ducts
√ marked inhomogeneous hepatic parenchymal enhancement during arterial phase (60%)

Prognosis: 100% mortality if not decompressed; 40–60% mortality with treatment; 13–16% overall mortality rate

Organism: E coli (31%), Klebsiella pneumoniae (17%), Enterococcus faecalis (17%), Streptococcus (17%)

- recurrent episodes of sepsis + RUQ pain
- Charcot triad (70%): fever + chills + jaundice
- bile cultures in 90% positive for infection

√ may have gas in biliary tree

CECT:

√ nodular / patchy / wedge-shaped / geographic inhomogeneous transient hepatic parenchymal enhancement in periportal location on hepatic arterial phase (= hyperemic changes around bile ducts)

√ diffuse concentric thickening of extrahepatic bile ducts, often with enhancement

Cx: miliary pyogenic hepatic abscesses; portal vein thrombosis; biliary peritonitis; secondary sclerosing cholangitis

Acute Bacterial Cholangitis

= potentially life-threatening disease induced by acute biliary infection

Cause: obstruction of CBD by stones (in up to 80%), malignancy (10–30%), sclerosing cholangitis, instrumentation of biliary tree (in 18% of transhepatic percutaneous biliary drainage catheter placement)

◊ Acute cholangitis occurs in 6–9% of patients admitted for gallstone disease

Pathophysiology: increased intrabiliary pressure (≥ 20 cm H_2O) → stagnant bile → biliary bacterial contamination

Risk factors: advanced age >70 years, neurologic disease, periampullary diverticulum

Organism: polymicrobial (30–80%); gram-negative rods (88%)

- Charcot triad (75%) = fever, pain, jaundice
- Reynolds pentad = fever, pain, jaundice, shock, lethargy
- positive culture: bile (50%), blood (20–30%)

@ CBD:

√ diffuse concentric wall thickening + enhancement

√ frequently dilatation of CBD

@ Intrahepatic bile ducts:

√ central (38%), diffuse (16%), segmental (46%) dilatation

√ wall thickening + enhancement (in up to 92% during delayed-phase of fat-suppressed MRI)

√ ± pneumobilia

@ Liver parenchyma

Distribution: wedge-shaped (72%) / peripheral patchy (14%) / peribiliary (14%)

√ increased SI on T2WI (69%) ← extension of inflammation into periportal + liver tissues

√ hepatic contrast enhancement: arterial only (58%), delayed only (16%), arterial and delayed (26%) phase

Cx: sepsis, hepatic abscess, portal vein thrombosis, bile peritonitis

Mortality: 4–65%

Rx: emergent endoscopic / percutaneous decompression of biliary tree; antibiotic therapy alone inadequate

AIDS-related Cholangitis

= AIDS CHOLANGIOPATHY= HIV-RELATED CHOLANGITIS

= infectious cholangitis characterized by opportunistic organisms in advanced AIDS patient with markedly depressed CD4 count of < 100/mm3

Organism: NO definite pathogen identified in 50%

(a) opportunistic: Cryptosporidium parvum (protozoan parasite typically infecting GI tract epithelium), CMV, Microsporidium, Mycobacterium avium complex

- opportunistic organism isolated from bile (in 50%)

(b) direct invasion of epithelium: Herpes simplex virus

Histo: marked periductal inflammatory response with interstitial edema + interstitial inflammatory cell infiltrates + necrotic biliary epithelium

- RUQ pain, fever, nausea; jaundice (rare)
- abnormal LFTs (esp. serum alkaline phosphatase; normal / mildly elevated bilirubin); elevated WBC count

Location: preferentially large intrahepatic bile ducts

Pattern: (1) combination of sclerosing cholangitis appearance + papillary stenosis (50%)
(2) isolated intrahepatic sclerosing cholangitis–like appearance (20%)
(3) isolated papillary stenosis (15%)
(4) long-segment extrahepatic duct stricture in isolation / with intrahepatic disease (15%)

√ irregular mild dilatation of intra- and extrahepatic bile ducts resembling sclerosing cholangitis

US:
√ stricture of distal CBD / papillary stenosis ← papillitis
√ echogenic nodule at the distal end of the CBD
√ mural thickening of gallbladder + bile ducts
√ saccular dilatations, debris, pruning of bile ducts
√ periductal echogenicity
√ ± pericholecystic fluid

CT:
√ "pseudogallstone" appearance = marked circumferential edema of gallbladder wall + mucosal enhancement
√ periportal edema

MR: resembling primary sclerosing cholangitis
√ multiple intra- and extrahepatic biliary strictures, saccular dilatations + ductal pruning
√ enhancing wall thickening of bile ducts
√ isolated 1–2-cm long extrahepatic bile duct stricture
√ irregular wall thickening of dilated CBD ← papillary stenosis
√ thickened gallbladder wall ← acalculous cholecystitis

Cholangiography:
√ strictures + beading of central intrahepatic bile ducts
√ pruning of peripheral bile ducts

DDx: acalculous cholecystitis, papillary stenosis, sclerosing cholangitis

Dx: inflammatory changes + associated pathogens in duodenal / papillary biopsy

Chemotherapy-induced Cholangitis

= inflammatory fibrosing process about the portal triads simulating primary sclerosing cholangitis

Predisposed: patients with liver metastases from colon cancer

Cause: direct effect of hepatic arterial infusion with chemotherapeutic agents (eg, floxuridine) / ischemia ← thrombosis of intrahepatic arterial branches

√ bile duct strictures as early as 2 months after therapy (in up to 15%)
√ stricture of common hepatic duct + sparing of distal CBD

IgG4-related Sclerosing Cholangitis

= biliary manifestation of IgG4 sclerosing disease

Histo: infiltration by abundant IgG4-positive plasma cells

Associated with: IgG4-involvement of pancreas, kidneys, thyroid gland, salivary glands

Age: older patient

Accompanied by: extra- / intrapancreatic lesions (frequent)

- ± obstructive jaundice

Rx: resolution under steroid therapy (often)

- elevated serum IgG4 level

√ patterns of biliary strictures:

(a) distal intrapancreatic CBD stricture (most common)

(b) diffuse intra- and extrahepatic bile duct strictures

(c) hilar + distal CBD stricture

(d) isolated hilar stricture

√ long continuous multifocal strictures + prestenotic dilatation

√ duct wall thickening = thick symmetric circumferential rind of enhancing tissue surrounding stricture

DDx: (1) Primary sclerosing cholangitis (multifocal + short intrahepatic biliary strictures with beaded / "pruned-tree" lesions)

(2) Cholangiocarcinoma (confined to bile ducts, not affecting pancreatic duct, hepatic capsular retraction)

(3) Pancreatic adenocarcinoma

(4) Ischemic biliary strictures

(5) AIDS cholangiopathy

Primary Sclerosing Cholangitis

= PSC = FIBROSING CHOLANGITIS = STENOSING CHOLANGITIS = CHRONIC OBLITERATIVE CHOLANGITIS

= insidious progressive obliterative fibrosing inflammation of the biliary tree leading to multifocal strictures, bile duct obliteration, cholestasis, and biliary cirrhosis

Etiology: idiopathic, ? autoimmune process (speculative); altered bile acid metabolism with increase in lithocholic acid by bacterial overgrowth

Prevalence: 1% as common as alcoholic liver disease

Mean age: 39 (range, 21–67) years; < 45 years (⅔); M÷F = 7÷3

Classification:

(a) large-duct PSC

(b) small duct PSC = clinical + biochemical + histologic features of PSC BUT normal appearance on cholangiography

Histo:

Stage 1: degeneration of epithelial bile duct cells + infiltration with lymphocytes ± neutrophils; inflammation + scarring + enlargement of periportal triads (pericholangitis)

Stage 2: fibrosis + inflammation infiltrating periportal parenchyma with piecemeal necrosis of hepatocytes; enlargement of portal triads; bile ductopenia

Stage 3: portal-to-portal fibrous septa; severe degenerative changes + disappearance of bile ducts; cholestasis in periportal + paraseptal hepatocytes
Stage 4: frank cirrhosis

Associated with:

(1) Inflammatory bowel disease (ulcerative colitis in 50–74%, Crohn disease in 13%)
  ◊ 1–4% of patients with inflammatory bowel disease develop primary sclerosing cholangitis!
  ◊ 10% of patients with PSC have Crohn disease
(2) Cirrhosis, chronic active hepatitis, pericholangitis, fatty degeneration
(3) Peyronie disease
(4) Sjögren syndrome
(5) Systemic lupus erythematosus
(6) Rheumatoid arthritis

- abnormal liver function tests: serum bilirubin, serum alkaline phosphatase, γ-glutamyltransferase
- progressive chronic / intermittent obstructive jaundice (75%)
- fever, night sweats, chills, RUQ pain, pruritus (10–15%)
- ANCA and antinuclear antibodies(low titers with low specificity)
- history of previous biliary surgery (53%) + chronic / recurrent pancreatitis (14%)

Location:

1. CBD almost always involved
2. Intra- and extrahepatic ducts (68–89%)
3. Cystic duct (15–18%)
4. Intrahepatic ducts only (1–11–25%)
5. Extrahepatic ducts only (2–3%)

Dx: PSC is diagnosed in patients with clinical + biochemical signs of cholestasis, typical cholangiographic imaging findings and after exclusion of secondary causes of sclerosing cholangitis.

√ intrahepatic bile duct calculi (8–30%): soft black crushable stones / sandlike grit

US:

√ brightly echogenic portal triads
√ echogenic biliary casts / punctate coarse calcifications along portal vein branches
√ extrahepatic ductal dilatation + choledocholithiasis
√ ± gallbladder wall thickening

√ gallbladder polyps (in 60% malignant)

Cholangiography:

√ <u>multifocal strictures</u> with predilection for bifurcations + skip lesions (= uninvolved duct segments of normal caliber) involving intra- and extrahepatic bile ducts:
  √ CLASSIC "string-of-beads" appearance (= alternating segments of dilatation and focal annular stenoses)
  √ "pruned tree" appearance (= opacification of central ducts + nonvisualization of peripheral smaller radicles ← diffuse obstruction)
  √ "cobblestone" appearance (= coarse nodular mural irregularities) in 50%
  √ new strictures + lengthening of strictures between 6 months and 6 years (< 20%)
  √ minimal duct dilatation ← periductal inflammation + fibrosis

√ marked ductal dilatation (24%)
DDx: ascending cholangitis, cholangiocarcinoma
√ diverticula / pseudodiverticula (PATHOGNOMONIC) = small eccentric saccular outpouchings (up to 27%)
√ ductal webs = focal 1–2 mm thick areas of incomplete circumferential narrowing
√ angles formed between central and peripheral ducts change from acute to obtuse
√ polypoid mass (7%)
√ gallbladder irregularities uncommon
√ cholestasis-related choledocholithiasis

CT:
√ dilatation, stenosis, pruning (decreased arborization), beading of tortuous intrahepatic bile ducts = "tree-in-winter" / "pruned tree" appearance (80%)
√ wall nodularity, duct wall thickening, mural contrast enhancement of extrahepatic bile ducts (100%)
◊ Periductal soft-tissue > 1.5 cm thick with delayed enhancement is worrisome for cholangiocarcinoma!
√ hepatic metastases + lymph nodes in porta hepatis
√ subtle foci of high attenuation in intrahepatic bile ducts
√ lobar atrophy in preferentially affected portions

MR:
√ enlarged central liver from macroregenerative nodules
√ atrophied periphery with hyperintense wedge-shaped areas on T2WI
√ dilated isolated "floating" bile ducts in periphery
√ periportal intensity intermediate on T1WI + hyperintense on T2WI ← inflammation

MRCP:
@ Bile ducts
√ "beaded" bile ducts = multifocal short-segment strictures of intra- + extrahepatic bile ducts alternating with normal bile ducts / mildly dilated duct ectasias
√ peripheral pruning of intrahepatic ducts
√ multifocal enhancing ductal wall thickening
√ ± intrahepatic duct stones
@ Liver
√ peripheral wedge-shaped / reticular T2-hyperintense abnormalities
√ hypertrophy of caudate lobe + medial segment of left lobe with atrophy of lateral + posterior segments
√ large regenerating nodules
√ multiple areas of enhancing fibrosis in liver periphery
√ ± periportal lymph nodes

NUC (^{99m}Tc-IDA):
√ multiple persistent focal areas of retention in distribution of intrahepatic biliary tree
√ marked prolongation of hepatic clearance
√ gallbladder visualized in only 70%

Cx: (1) Biliary cirrhosis (up to 49%) after > 10 years
(2) Portal hypertension

(3) Malignancy (10–15%):
  (a) cholangiocarcinoma (in 5–36% at autopsy / liver transplantation):
    • screening with tumor marker CA-19.9 > 129 U/mL (79% sensitive, 99% specific)
  (b) colorectal cancer (10- to 14-fold increased risk compared to general population)
  (c) pancreatic cancer
(4) Secondary recurrent bacterial cholangitis

Rx: (1) Palliative: ursodeoxycholic acid, dilatation of dominant strictures
(2) Curative: liver transplantation (4th leading indication)

DDx:
(1) IgG4-related sclerosing cholangitis

Primary sclerosing cholangitis occurs in younger patients, is associated with inflammatory bowel disease, and is less acute with longer duration of symptoms compared to IgG4-related sclerosing cholangitis.

(2) Sclerosing cholangiocarcinoma (progressive cholangiographic changes within 0.5–1.5 years of initial diagnosis, marked ductal dilatation upstream from a dominant stricture, intraductal mass > 1 cm in diameter)
(3) Acute ascending cholangitis (history)
(4) Recurrent pyogenic cholangitis
(5) Primary biliary cirrhosis (disease limited to intrahepatic ducts, strictures less pronounced, pruning + crowding of bile ducts, normal AMA titer)
(6) AIDS cholangiopathy (same cholangiographic findings)
(7) Ischemic strictures

Recurrent Pyogenic Cholangitis

= PRIMARY CHOLANGITIS = RECURRENT PYOGENIC HEPATITIS = ORIENTAL CHOLANGIOHEPATITIS = ORIENTAL CHOLANGITIS = ORIENTAL INFESTATIONAL CHOLANGITIS = HONG KONG DISEASE = INTRAHEPATIC PIGMENTed STONE DISEASE

= progressive biliary disease characterized by recurrent episodes of bacterial cholangitis ← biliary obstruction by pigmented stones + biliary strictures + bile duct ectasia

Etiology: ? Clonorchis sinensis infestation, coliform infection of bile, portal bacteremia, malnutrition

Prevalence: 3rd most common cause of an acute abdomen in Hong Kong after appendicitis and perforated ulcer; uncommon in USA

Epidemiology: endemic to Southeast Asia (South China, Indochina, Taiwan, Japan, Korea); Asian immigrants in USA

Strongly associated intrabiliary infestation:
Ascaris lumbricoides, Clonorchis sinensis, Opisthorchis viverrini / felineus, Fasciola hepatica, E coli

Pathophysiology: chronic recurrent infections → developing pigmented calculi → cholangitic abscesses + inflammatory strictures

Path: pericholangitis, periductal abscesses, fibrosis of bile duct walls, heavy infiltration of portal tracts by PMNs, intraductal bile pigment calculi

Age: 20–50 years; M÷F = 1÷1

- poor nutritional + low socioeconomic status of patient
- recurrent attacks of fever, chills, abdominal pain, jaundice

Location: particularly in lateral segment of L lobe + posterior segment of R lobe + extrahepatic duct

Associated findings:

√ gallstones
√ splenomegaly
√ portal vein obstruction, varices
√ markedly dilated (3–4 mm) proximal intrahepatic (1st- & 2nd-order) bile ducts (in 100%):
  √ decreased arborization (branching) of intrahepatic radicles with abrupt tapering = "arrowhead appearance"
√ multifocal < 1 cm long bile duct strictures (22%)
√ pneumobilia (3–52%)
√ intra- and extrahepatic bile ducts filled with nonshadowing soft mudlike pigment (= calcium bilirubinate) stones (74%):
  √ stones hyperattenuating compared to unenhanced liver parenchyma (in 90%)
  √ stones T1-hyperintense + T2-hypointense to liver
  √ disproportionate diffuse dilatation of central bile ducts involving stone-bearing and stone-free ducts (68%)
  √ thickened periportal space ← periductal inflammation + fibrosis
√ biloma
√ segmental hepatic atrophy (36%): left lobe / right posterior segments
√ hepatic abscesses

CT:

√ abrupt nonvisualization of peripheral branches
√ enhancement of thickened bile duct wall

ERCP:

◊ Worsening of cholangitis / sepsis if patients do not receive antibiotics!
√ acute tapering + straightening + rigidity of bile ducts
√ decreased arborization + increased branching angle of bile ducts

MRCP:

√ intra- / extrahepatic bile duct stones
√ multiple intrahepatic biliary strictures
√ short-segment focal extrahepatic bile duct stricture
√ localized dilatation of lobar / segmental bile ducts with predilection for lateral segment of left lobe + posterior segment of right lobe
√ wall thickening, abrupt tapering, ↓ arborization of intrahepatic bile ducts

Cx: liver abscess (18%), splenomegaly (14%), biloma (4%), pancreatitis (4%), cholangiocarcinoma (2–6%): [peripheral (80%) or hilar / extrahepatic (20%)]

Prognosis: progressive destructive cholangiopathy + liver failure

Rx: endoscopic sphincterotomy, choledochoduodenostomy, surgical resection (if disease in single segment / lobe)

DDx: (1) Caroli disease (saccular dilatation of intrahepatic bile ducts)

(2) Primary sclerosing cholangitis (focal discontinuous bile duct dilatation)
(3) Clonorchiasis (biliary ductal dilatation limited to intrahepatic bile ducts)

Secondary Sclerosing Cholangitis

= heterogeneous group of chronic cholestatic disorders morphologically similar to PSC

Cause:

(1) Intraductal stone disease / choledocholithiasis → bile duct stricture → recurrent pyogenic cholangitis
(2) Ischemic cholangiopathy from treatment with intraarterial chemotherapy / floxuridine
(3) Autoimmune pancreatitis
(4) AIDS-asscociated cholangiopathy
(5) Eosinophilic cholangitis
(6) Previous biliary tract surgery / blunt trauma
(7) Hepatic inflammatory pseudotumor
(8) Congenital biliary tree anomalies
(9) Bile duct neoplasm

CHOLECYSTITIS

Etiology: (a) in 80–95% cystic duct obstruction by impacted calculus; 85% disimpact spontaneously if stone < 3 mm
(b) in 10% acalculous cholecystitis

Acute Calculous Cholecystitis

Pathogenesis: chemical irritation from concentrated bile, bacterial infection, reflux of pancreatic secretions

Age peak: 5th–6th decade; M÷F = 1÷3

Associated with: choledocholithiasis (15–25%)

◊ 5% of patients presenting to ED have acute cholecystitis!

- persisting (> 6 hr) RUQ pain radiating to right shoulder / scapula / interscapular area (DDx: biliary colic usually < 6 hours)
- nausea, vomiting, chills, fever, RUQ tenderness + guarding
- Murphy sign = inspiratory arrest upon palpation of GB area (falsely positive in 6% of patients with cholelithiasis)
- ± leukocytosis, elevated levels of alkaline phosphatase and transaminase and amylase
- mild hyperbilirubinemia (20%)

US (40–97% sensitive, 64–100% specific, 92% PPV, 95% NPV):

√ ± GB wall thickening > 3 mm (45–72% sensitive, 76–88% specific):
  √ hazy delineation of GB wall
  √ "halo" sign = GB wall lucency (in 8%) = 3-layered configuration with sonolucent middle layer (edema)
  √ striated wall thickening (62%) = several alternating irregular discontinuous lucent + echogenic bands within GB wall (100% PPV)
√ GB hydrops = distension with AP diameter > 5 cm or enlargement of greater than 4 x 10 cm

√ positive **sonographic Murphy sign** (in 85–88%)
= maximum tenderness during compression with transducer directly over gallbladder (63–94% sensitive, 85–93% specific, 72% NPV)
False-negative sonographic Murphy sign:
lack of patient responsiveness, pain medication, inability to press directly on GB (position deep to liver / protected by ribs), GB wall necrosis
√ crescent-shaped / loculated pericholecystic fluid (in 20%) = inflammatory intraperitoneal exudate / abscess
√ gallstones (83–98% sensitive, 52–77% specific):
√ impacted gallstone in GB neck / cystic duct
√ echogenic shadowing fat within hepatoduodenal ligament ± conspicuous color Doppler flow ← inflammation
DDx: bowel gas
√ sludge

Color Doppler US:
√ visualization of cystic artery > 50% of the length of the gallbladder (30% sensitive, 98% specific)

CT (* = signs with highest sensitivity+ specificity):
Dose: on average 11 mSv

The negative predictive value of CT for acute cholecystitis is 89%. While this is lower than for US, CT can exclude acute cholecystitis when clinical suspicion for gallbladder disease is low and clinical symptoms are nonspecific.

@ GB size
√ distended gallbladder > 8 cm long / > 4 cm in diameter
@ GB wall
√ irregular gallbladder wall
√ gallbladder wall thickness ≥ 7 mm*
√ gallbladder wall thickness < 2 mm
√ increased gallbladder wall attenuation
√ air in gallbladder wall
√ local / widespread absence of GB wall enhancement* = gangrenous acute cholecystitis
@ GB content
√ gallstone in infundibulum
√ increased attenuation of bile
√ intraluminal membranes
@ Hepatic pedicle (= vessels and ducts of porta hepatis)
√ hyperdense areas in fatty tissue around hepatic pedicle = haziness of pericholecystic fat
√ pericholecystic fluid / effusion*
@ Hepatic parenchyma
√ pericholecystic abscess
√ transient focal increased attenuation of liver parenchyma around gallbladder fossa on hepatic arterial phase ← hepatic arterial hyperemia + early venous drainage

@ Adjacent organs
√ contact between GB wall and wall of duodenum / colon

MR:
√ T2-hyperintense thickened wall > 3 mm (best seen on fat-suppressed T2WI)
√ increased signal intensity within + surrounding GB on T2WI ← pericholecystic fluid
√ signal void in cystic duct / gallbladder neck ← obstructing stone
√ marked enhancement of gallbladder wall
√ transient enhancement of pericholecystic hepatic parenchyma in 70% (HIGHLY SPECIFIC)

MRCP = MR cholangiopancreatogram (high sensitivity):
√ low-signal–intensity defect surrounded by high-signal–intensity bile on T2WI

Cholangiography:
√ sharply defined filling defect in contrast-material filled lumen of cystic duct

NUC (98% sensitive, 100% specific, 95–98% accurate):
= functional information about cystic duct patency
Dose: on average 3.7 mSv
◊ Tracer uptake hinges on adequate hepatic function + fasting status
√ nonvisualization of normal biliary anatomy:
√ nonvisualization of GB during 1st hour (in 83%)
√ nonvisualization of GB by 4 hours (99% specific)
√ nonvisualization of GB + CBD (in 13%)
√ "dilated cystic duct" sign (= radiotracer activity in a short segment of cystic duct proximal to obstructing stone) that may be mistaken for gallbladder
√ "pericholecystic rim" sign (34% sensitive) on initial images = increased hepatic activity adjacent to GB fossa: 94% PPV for acute cholecystitis + 57% PPV for gangrenous cholecystitis
Cause: local hepatocyte inflammation + hyperemia in transmural process → increased perfusion to GB fossa during "arterial phase"

Endpoint of imaging:
» when tracer fills GB
» 4 hours of delayed imaging after tracer injection
» 45 minutes after morphine injection

False-positive scans (10–12%)
= nonvisualization of GB without acute cholecystitis:
(a) absent gallbladder: congenital absence of GB, post cholecystectomy
(b) recent feeding < 4–6 hours prior to study
(c) sludge preventing filling of gallbladder: prolonged fasting, total parenteral nutrition, hyperalimentation
(d) other hepatobiliary disease: chronic cholecystitis, CBD obstruction, carcinoma of GB
(e) hepatocellular dysfunction: alcoholic liver disease, acute pancreatitis

Reduction to 2% false-positive scans through:
(1) delayed images up to 4 hours
(2) cholecystokinin (Sincalide®) injection 15 minutes prior to study
(3) morphine IV (0.04 mg/kg) at 40 minutes with reimaging after 20 minutes →

contraction of sphincter of Oddi → rise in intrabiliary pressure

False-negative scans (4.8%):

(a) acute cholecystitis without cystic duct obstruction: acalculous / rare calculous cholecystitis

(b) extrahepatic radiotracer accumulation mistaken for gallbladder activity: duodenal diverticulum, biliary duplication cyst, gangrenous cholecystitis with accumulation in gallbladder bed, "dilated cystic duct" sign

Cx:

mnemonic: GAME BEG

Gangrene
Abscess (pericholecystic)
Mirizzi syndrome
Emphysematous cholecystitis
Bouveret syndrome (= gallstone erodes into duodenum leading to duodenal obstruction)
Empyema
Gallstone ileus

Gangrene of Gallbladder = Gangrenous Cholecystitis

= common severe complication of acute cholecystitis

Frequency: 26% of patients with acute cholecystitis

• positive Murphy sign (33%)

US:

√ irregular / absent gallbladder wall
√ shaggy, irregular, asymmetric wall (mucosal ulcers, intraluminal hemorrhage, necrosis)
√ hyperechoic foci within GB wall (microabscesses in Rokitansky-Aschoff sinuses)
√ intraluminal pseudomembranes (gangrene)
√ coarse nonshadowing nondependent echodensities (= sloughed necrotic mucosa / sludge / pus / clotted blood within gallbladder)

CT (insensitive but highly specific):

√ intramural / intraluminal gas
√ intraluminal membranes
√ irregular / absent GB wall, lack of wall enhancement
√ pericholecystic abscess formation.

MR:

√ interrupted "rim" sign = patchy enhancement of mucosa on contrast-enhanced fat-suppressed MR

NUC:

√ radiotracer accumulation in gallbladder fossa

Rx: laparoscopic cholecystectomy (frequently converted to open surgery)

Pericholecystic Abscess

Cause: subacute perforation of gallbladder wall subsequent to gangrene + infarction ← acute cholecystitis

Prevalence: 2–20%

Location:
(a) gallbladder bed (most common)
√ area of low-level echoes in liver adjacent to GB
(b) intramural
√ small area of low-level echoes within thickened gallbladder wall
(c) intraperitoneal
√ area of low-level echoes within peritoneal cavity adjacent to gallbladder

Rx: (1) Emergency operation
(2) Antibiotic treatment + elective operation
(3) Percutaneous abscess drainage

Perforation of Gallbladder *(in 2–20%)*

Average age: 60 years; M>F

Types:
(1) Acute free perforation with peritonitis → pericholecystic abscess in 33%
(2) Subacute localized perforation → pericholecystic abscess in 48%
(3) Chronic perforation → internal biliary fistula → pericholecystic abscess in 18%

Location: most commonly at fundus ← poor blood supply

√ gallstone lying free in peritoneal cavity = SPECIFIC

US:
√ sonolucent / complex collection surrounding GB
√ collection in liver adjacent to gallbladder

CT:
√ "hole" sign = focal gallbladder wall defect

NUC:
√ extrabiliary radiotracer activity (that may be mistaken for activity within gallbladder) best appreciated with delayed imaging

Mortality: up to 15% (attributed to delayed diagnosis)

Cx: free intraperitoneal air; bile leak; abscess formation in liver / GB fossa / peritoneum; SBO

Empyema of Gallbladder

√ multiple medium / coarse highly reflective intraluminal echoes without shadowing / layering / gravity dependence (purulent exudate / debris)

Acute Acalculous Cholecystitis

Frequency: 5–15% of all acute cholecystitis cases

Associated with: recent surgery in 50%

Etiology: probably decreased blood flow within cystic artery

(1) Debilitated patients: depressed motility / starvation in trauma, burns, surgery, total parenteral nutrition, anesthesia, positive pressure ventilation, narcotics, shock, vasoactive amines, congestive heart failure, arterio-sclerosis, polyarteritis nodosa, SLE, diabetes mellitus
◊ Diagnosis in the ICU patient sonographically difficult due to fasting state, medications, CHF, etc.

(2) Obstruction of cystic duct by extrinsic inflammation, lymphadenopathy, metastases
(3) Infection (only in 50%): Salmonella, Helicobacter, cholera, Kawasaki syndrome, cytomegalovirus, cryptosporidiosis

√ thickened gallbladder wall > 4–5 mm
√ echogenic bile / sludge
√ gallbladder distension
√ pericholecystic fluid in absence of ascites
√ striated subserosal edema
√ sloughed mucosal membrane
√ Murphy sign = pain + tenderness with transducer pressure over the gallbladder (difficult to assess in ICU patient with altered mental status)
√ decreased response to cholecystokinin
√ intramural gas

CT:
√ pericholecystic stranding (= edema)
√ decreased attenuation in adjacent liver (= perihepatitis)

NUC: same criteria as for calculous cholecystitis
Cx: gallbladder perforation, gangrene, pericholecystic abscess
Rx: percutaneous cholecystostomy trial (low threshold for ICU patients)
Prognosis: 6.5% mortality rate

Chronic Cholecystitis

◊ Most common form of gallbladder inflammation
√ gallstones
√ smooth / irregular GB wall thickening (mean of 5 mm)
√ mean volume of 42 mL

NUC:
√ normal GB visualization in majority of patients
√ delayed GB visualization (1–4 hours)
√ visualization of bowel prior to gallbladder (45% sensitive, 90% specific)
√ noncontractility / decreased response after CCK injection (decreased GB ejection fraction)

Emphysematous Cholecystitis

= variant of acute cholecystitis ← ischemia of gallbladder wall + infection with gas-producing organisms
Frequency: 1% of all acute cholecystitis cases
Etiology: small-vessel disease with cystic artery occlusion, complication of acute cholecystitis
Organism: Clostridium perfringens, Clostridium welchii, E. coli, Bacillus fragilis
Age: > 50 years; M÷F = 2÷1 to 5÷1
Predisposed: diabetics (20–50%), debilitating diseases; calculous (70–80%) / acalculous cystic duct obstruction
Pathophysiology: obstructive endarteritis → ischemia → secondary infection with anaerobes

- WBC count may be normal (⅓)
- point tenderness rare (diabetic neuropathy)

Plain film:
- √ gas appears 24–48 hours after onset of symptoms
- √ air-fluid level in GB lumen, air in GB wall within 24–48 hours after acute episode
- √ pneumobilia (rare)

US:
- √ arclike high-level echoes outlining GB wall mimicking porcelain gallbladder / multiple stones in contracted GB
- √ cholecystolithiasis (50%)

CT (most sensitive and specific imaging modality):
- √ identification of gas in gallbladder lumen / wall
- √ irregularity / discontinuity of gallbladder wall
- √ pneumobilia, pericholecystic fluid, abscess formation

Cx: gangrene (75%); gallbladder perforation (20%)

Mortality: 15%

Rx: urgent cholecystectomy; temporizing percutaneous cholecystostomy + antibiotics

DDx: (1) Enteric fistula
(2) Incompetent sphincter of Oddi
(3) Air-containing periduodenal abscess
(4) Periappendiceal abscess in malpositioned appendix
(5) Lipomatosis of gallbladder

Xanthogranulomatous Cholecystitis

= FIBROXANTHOGRANULOMATOUS INFLAMMATION = CEROID GRANULOMAS OF THE GALLBLADDER

= uncommon severe inflammatory disease of gallbladder characterized by presence of multiple intramural nodules

Prevalence: 1–2%

Predisposition: gallstones, obesity, diabetes mellitus

Pathophysiology:
cystic duct obstruction or rupture of occluded Rokitansky-Aschoff sinuses → mucosal / mural injury → extravasation of inspissated bile + mucin attracting histiocytes → phagocytosis of insoluble bile lipids and cholesterol → lipogranuloma formation → fibrosis

Age: 5th + 6th decade

Histo: mixture of xanthoma cells with foamy histiocytes + fibroblasts + multinucleated foreign body giant cells + lymphocytes containing areas of necrosis

May be associated with: gallbladder carcinoma (11%)

√ preservation of 2–3-mm thick mucosal lining (in 82%)
√ thickened gallbladder wall: 91% diffuse, 9% focal
√ infiltration of pericholecystic fat: in 45% focal, in 54% diffuse
√ hepatic extension (45%)
√ biliary obstruction (36%)

√ lymphadenopathy (36%)
US:
√ intramural hypoechoic nodules
CT:
√ 5–20-mm small intramural hypoattenuating nodules
√ poor / heterogeneous contrast enhancement
MR:
√ areas of marked T2-hyperintensity ← necrosis / abscess
√ xanthogranulomas show delayed strong enhancement
DDx: gallbladder carcinoma with local spread (in 59% focal, in 41% diffuse thickening of gallbladder wall, multiple masses within liver)

CHOLEDOCHAL CYST

= CYSTIC DILATATION OF EXTRAHEPATIC BILE DUCT
= rare congenital biliary tract anomaly characterized by dilatation of all / part of the extra- / intrahepatic bile ducts without involvement of gallbladder / cystic duct
◊ Most common congenital lesion of bile ducts
Etiology: ?
(a) biliary ductal plate malformation of extrahepatic bile ducts as part of congenital fibrocystic disease
(b) anomalous junction of pancreatic duct and CBD proximal to duodenal papilla → higher pressure in pancreatic duct with absence of ductal sphincter → allows free reflux of enzymes into CBD → chemical + inflammatory changes → weakening of CBD wall + dilatation of CBD

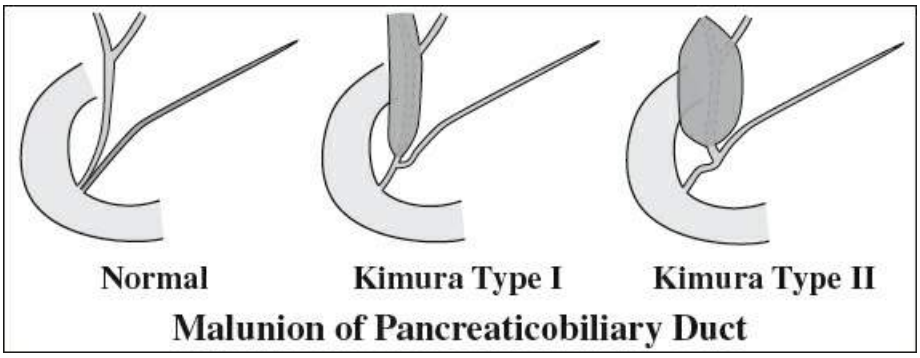
Classification of malunion of pancreaticobiliary duct

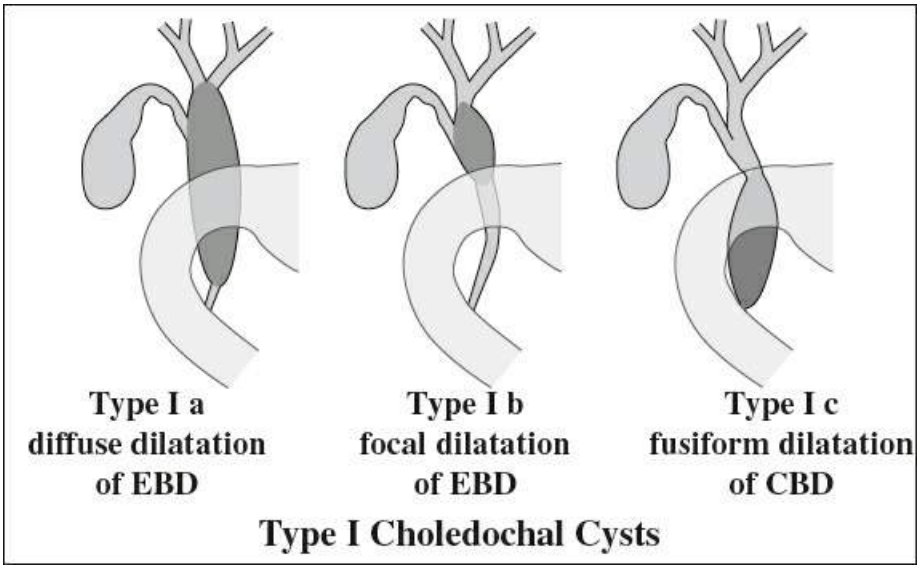
Kimura type I	=	pancreatic duct enters the proximal / mid CBD (10–58%) at right angle
Kimura type II	=	CBD drains into pancreatic duct

Classification by 5 subtypes (Todani): according to common cystic changes but probably different pathophysiologic features
(1) Todani type I choledochal cyst
confined to extrahepatic bile duct (EBD)
Cause: anomalous pancreaticobiliary union → formation of a long frequently ectatic common channel
(a) Todani type Ia = <u>diffuse</u> EBD cyst
(b) Todani type Ib = <u>focal</u> segmental EBD cyst
(c) Todani type Ic = <u>fusiform</u> CBD cyst
(2) Todani type II choledochal cyst = true diverticulum
(3) Todani type III choledochal cyst = choledochocele
= focal dilatation of intraduodenal segment of distal CBD
(4) Todani type IV choledochal cyst = multiple cysts
(a) Todani type IVa multiple choledochal cysts
= multiple cysts of both EBD + IBD
(b) Todani type IVb multiple choledochal cysts

= multiple saccular dilatations of EBD only

(5) Todani type V choledochal cyst = Caroli disease





Prevalence: 1÷13,000 admissions; high prevalence in Japanese / Asian infants

Age: < 10 years (60%) + young adulthood; 80% diagnosed in childhood; 7% during pregnancy; occasionally detected up to 8th decade; M÷F = 1÷4

Histo: fibrous cyst wall without epithelial lining

Associated with:

(1) Dilatation / stenosis / atresia of other segments of the biliary tree (2%)
(2) Gallbladder anomaly: aplasia, double GB
(3) Failure of union of left + right hepatic ducts
(4) Pancreatic duct + accessory hepatic bile ducts may drain into cyst
(5) Polycystic liver disease

- Classic triad in 2–38% (20–30%) of all (adult) patients:
  (1) Intermittent obstructive jaundice (33–50%)
    ◊ Uncommon cause of obstructive jaundice!
  (2) Recurrent RUQ colicky pain (> 75–90%), back pain
  (3) Intermittent palpable RUQ abdominal mass (< 25%)
- recurrent fever, chills, weight loss, pruritus

Types:
(a) marked cystic dilatation of CBD + CHD
(b) focal segmental dilatation of CBD distally
(c) cylindric dilatation of CBD + CHD

Size: CBD diameter of 2–15 cm
◊ The largest choledochal cyst contained 13 liters

√ NO / mild peripheral intrahepatic bile duct dilatation
√ may contain stones / sludge

UGI:
√ soft-tissue mass in RUQ
√ anterior displacement of 2nd portion of duodenum + distal portion of stomach (on LAT view)
√ widening of C-loop with inferior displacement of duodenum (on AP view)

US:
√ ballooned / fusiform cyst beneath porta hepatis separate from gallbladder
◊ Communication with common hepatic / intrahepatic ducts needs to be demonstrated!
√ abrupt change of caliber at junction of dilated segment to normal duct
√ intrahepatic bile duct dilatation (16%) ← stenosis

OB-US (earliest diagnosis at 25 weeks MA):
√ right-sided cyst in fetal abdomen + adjacent dilated hepatic ducts
DDx: duodenal atresia; cyst of ovary, mesentery, omentum, pancreas, liver

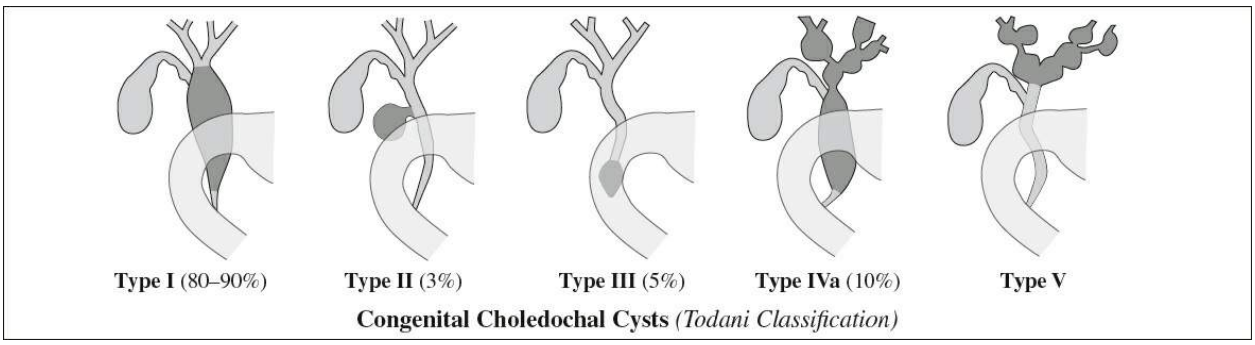
NUC with HIDA:
◊ At times the choledochal cyst does not fill with radionuclide!
√ photopenic area within liver that fills within 60 min + stasis of tracer within cyst
√ lack of tracer passage into small intestine
√ prominent hepatic ductal activity ← dilatation of ducts
DDx: often excludes hepatic cyst, pancreatic pseudocyst, enteric duplication, spontaneous loculated biloma

Cholangiography / MRCP (confirms diagnosis):
√ anomalous pancreaticobiliary junction with long common channel
√ dilated intrahepatic bile ducts
√ intraductal calculi

Cx: (1) Stones (8–50%) in gallbladder, in CBD, within cyst, in intrahepatic biliary tree, in pancreatic duct
(2) Malignant transformation into bile duct carcinoma + gallbladder carcinoma (increasing with age, < 1% in 1st decade, 7–14% > age 20)
(3) Recurrent acute pancreatitis (33%)
(4) Recurrent cholangitis / cholecystitis (20%)
(5) Cyst rupture with bile peritonitis (1.8%)
(6) Bleeding
(7) Biliary cirrhosis + portal hypertension
(8) Portal vein thrombosis
(9) Hepatic abscess

Rx: excision of cyst + Roux-en-Y hepaticojejunostomy

DDx: mesenteric, omental, ovarian, renal, adrenal, hepatic, enteric duplication cyst, pancreatic pseudocyst, hydronephrotic kidney, hepatic artery aneurysm, biloma (← spontaneous perforation of CBD)



Congenital Choledochal Cysts *(Todani Classification)*

CHOLEDOCHOCELE

= DUODENAL DUPLICATION CYST = ENTEROGENOUS CYST OF AMPULLA OF VATER / DUODENUM = INTRADUODENAL CHOLEDOCHAL CYST = TYPE III CHOLEDOCHAL CYST = DIVERTICULUM OF COMMON BILE DUCT

= cystic dilatation of distal / intramural duodenal portion of CBD with herniation of CBD into duodenum (similar to ureterocele)

Etiology:

(1) congenital:

(a) originates from tiny bud / diverticulum of distal CBD (found in 5.7% of normal population)

(b) stenosis of ductal orifice / weakness of ductal wall

(2) acquired:

stone passage followed by stenosis + inflammation

Age: 33 years (manifestation usually in adulthood)

Types: (a) CBD terminates in cyst, cyst drains into duodenum (common)

(b) cyst drains into adjacent intramural portion of CBD (less common)

- biliary colic, episodic jaundice, nausea, vomiting
- bulging papilla; high amylase level within bile

Associated with: stones / sludge (frequent)

UGI:

√ smooth well-defined intraluminal duodenal filling defect in region of papilla

√ change in shape with compression / peristalsis

Cholangiography (diagnostic):

√ opacified smooth clublike / saclike dilatation of intramural segment of CBD prolapsed into duodenum

CT:

√ spheric dilatation of terminal bile duct protruding into duodenal lumen

Cx: pancreatitis, duodenal obstruction, cholecystitis

Rx: sphincterotomy / sphincteroplasty

DDx: choledochal cyst (involves more than only terminal portion of CBD)

CHOLELITHIASIS

Prevalence:
25,000,000 adults in USA;
10–15% of population + 2% of children

Age: increasing with age (40% of women in 9th decade);
M÷F = 2%÷4% (10%÷25%) in 3rd (7th) decade

Predisposing factors: "female, forty, fair, fat, fertile, flatulent"

Pathogenesis: supersaturation of bile constituents, most notably cholesterol ← defects in biliary lipid metabolism; biliary dysmotility; prolonged intestinal transit; aggravated by sedentary lifestyle + diet

(1) Hemolytic disease:
sickle cell disease (7–37%), hereditary spherocytosis (43–85%), thalassemia, pernicious anemia (16–20%), prosthetic cardiac valves + mitral stenosis (hemolysis), cirrhosis (hemolysis ← hypersplenism), Rhesus / ABO blood group incompatibility (perinatal period)

(2) Metabolic disorder = disruption of biliary lithogenic index: diabetes mellitus, obesity, pancreatic disease, cystic fibrosis, hypercholesterolemia, type 4 hyperlipidemia, hemosiderosis (20%), hyperparathyroidism, hypothyroidism, prolonged use of estrogens / progesterone, pregnancy

(3) Cholestasis
› hepatic dysfunction: hepatitis, neonatal sepsis
› biliary tree malformation: Caroli disease
› biliary obstruction: parasitic infection, benign / malignant strictures, foreign bodies (sutures, ascariasis)
› prolonged fasting (total parenteral nutrition)
› methadone intake

(d) Intestinal malabsorption
→ 10 x increased risk of stone formation
› inflammatory bowel disease: Crohn disease (28–34%)
› ileal resection
› bypass surgery

(e) Genetic predisposition = familial:
Navaho, Pima, Chippewa Indians

(f) Others
muscular dystrophy

Composition:

A. CHOLESTEROL STONE (70%)
= main component of most calculi
√ lucent (93%), calcified (7%)
√ slightly hypodense compared with bile
(a) pure cholesterol stones (10%): yellowish, soft
√ buoyancy in contrast-enhanced bile

√ density of < 100 HU

(b) mixture of cholesterol + calcium carbonate / bilirubinate (70%)

√ laminated appearance

√ radiopaque on plain film (15–20%)

MR:

√ hypointense on T2WI + T1WI

√ occasionally hyperintense center on T2WI + T1WI (protein molecules)

B. PIGMENT STONE (30%)

• brown (common) = granular precipitate of calcium bilirubinate containing < 25% cholesterol (by definition)

Cause: inflammation / infection of gallbladder, status post cholecystectomy

• black (less common) = compact "lacquer" of bilirubin derivatives with a high affinity for calcium carbonate

√ multiple tiny faceted / spiculated homogeneously radiopaque stones

CT:

√ usually denser than bile

MR:

√ hypointense on T2WI + hyperintense on T1WI (related to degree of hydration)

C. GAS-CONTAINING GALLSTONE

Mechanism: dehydration of older stones leads to internal shrinkage + dendritic cracks + subsequent nitrogen gas–filling from negative internal pressure

√ "crow-foot" = "Mercedes-Benz" sign = radiating streaklike lucencies within stone, also responsible for buoyancy

D. FLOATING GALLSTONE (20–25%)

(a) relatively pure cholesterol stones

(b) gas-containing stones

(c) rise in specific gravity of bile (= 1.03) from oral cholecystopaques (specific gravity of 1.06) causing stones with a specific gravity of 1.05 to float

E. GALLBLADDER SLUDGE

= calcium-bilirubinate granules + cholesterol crystals associated with biliary stasis

Cause: prolonged fasting, parenteral nutrition, hyperalimentation, hemolysis, extrahepatic bile duct obstruction, cystic duct obstruction, acute + chronic cholecystitis

√ nonshadowing homogeneously echogenic material:

√ fluid-sludge level

√ "sludge ball" = tumefactive sludge:

√ slowly shifting with repositioning of patient

DDx: gallbladder cancer

Prognosis: may cause acute cholecystitis

DDx: hemobilia with blood clot, parasitic infestation, mucus

Radiopacity:

√ lucent stones (84%): cholesterol (85%), pigment (15%)

√ calcified stones (15–20% on plain film, 60% on CT): cholesterol (33%), pigment (67%)

◊ CT sensitivity highest at 140 kVp

Location of calcium:

√ <u>calcium phosphate</u> deposited centrally within cholesterol stones

√ calcium carbonate deposited radially within aging cholesterol / peripherally around cholesterol + pigmented stones

Gallstones in Fetus

EGA: > 28 weeks EGA
Cause: hemolytic disease, cholestasis, maternal drug use
Prognosis: usually resolve before / after delivery

Gallstones in Neonate

◊ Rare without predisposing factors
Associated with: obstructive congenital biliary anomaly, total parenteral nutrition, furosemide, GI dysfunction (short-gut syndrome), prolonged fasting, phototherapy, dehydration, infection, hemolytic anemia

Gallstones in Older Children

Associated with: sickle cell disease, cystic fibrosis, malabsorption, total parenteral nutrition, Crohn disease, intestinal resection, hemolytic anemia, choledochal cyst

Gallstones in Pregnancy

Prevalence: 2–4% of pregnant patients have gallstones, 5% develop symptoms
Acute cholecystitis:
» NO increased risk during pregnancy
» 2nd most common condition requiring surgery (in 1÷1600–10,000 pregnancies)!

Cholecystolithiasis

- asymptomatic (60–65%); become symptomatic at a rate of 1–2–4% per year
- biliary colic (misnomer) ← transient obstruction of cystic duct / common bile duct develops in 33% (18% overall risk in 20 years):
  = acute RUQ / epigastric / LUQ / precordial / lower abdominal pain increasing over seconds / minutes + remaining fairly steady for 1–3(–6) hours associated with nausea + vomiting
  - no tenderness upon palpation

Abdominal plain film (10–16% sensitive):
√ calcified gallstones
CT (80% sensitive):
√ hyperdense calcified gallstones in 60%
√ hypodense cholesterol stones ≤ 140 HU = pure cholesterol stone (= ≥ 80% cholesterol content):
◊ Inverse relationship between CT attenuation number + cholesterol content
√ gallstones isointense to bile (< 30 HU) in 21–24% and thus undetectable by CT
US (91–98% sensitive; in 5% falsely negative):
√ bright (= highly reflective) echo from anterior surface of gallstone within gallbladder:
√ marked posterior acoustic shadowing
√ mobile upon repositioning of patient (may infrequently be adherent to wall)
√ reverberation artifact

◊ Small calcifications < 2 mm may not shadow

√ nonvisualization of GB + collection of echogenic echoes with acoustic shadowing (15–25%):

√ "wall-echo-shadow" = "double-arc shadow" sign

= 2 echogenic curvilinear parallel lines separated by sonolucent line (ie, anterior GB wall + bile + stone with acoustic shadowing)

√ focal nonshadowing opacities < 5 mm in diameter (in 70% gallstones)

False-negative US (5%):

contracted GB, GB in anomalous / unusual location, small gallstone, gallstone impacted in GB neck / cystic duct, immobile patient, obese patient, extensive RUQ bowel gas

Prognosis: stones < 3 mm may pass through cystic duct

Cx: acute cholecystitis (in 30%), choledocholithiasis, cholangitis, pancreatitis, duodenitis, biliary fistula, gallstone ileus, Mirizzi syndrome; cancer of GB + bile ducts (2–3 x more frequent)

Cholangiolithiasis

Choledocholithiasis

◊ Most common cause of bile duct obstruction!

Etiology: (a) passed stones originating in GB

(b) primary development in intra- / extrahepatic ducts (rare)

Frequency: in 12–15% of cholecystectomy patients; in 3–4% of postcholecystectomy patients; in 75% of patients with chronic bile duct obstruction

Risk indicators for CBD stone:

(1) Recent history of jaundice
(2) Recent history of pancreatitis
(3) Elevated serum bilirubin > 17 µmol/L
(4) Elevated serum amylase > 120 IU/L
(5) Dilated CBD > 6 mm (16%)
(6) Obscured bile duct

- asymptomatic: 10% of patients treated with cholecystectomy have unsuspected CBD calculi
- recurrent episodes of right upper quadrant pain, jaundice, chills, fever (25–50%)
- elevated serum bilirubin + alkaline phosphate levels
- elevated transaminase (75%)
- spontaneous passage with stones < 6 mm size

Location: dependently in duct

Cholangiography (most specific technique):

√ stone visualization in 92%

√ dependent round filling defects

DDx: air bubbles, neoplasm, concentrated bile

Peroperative cholangiography:

prolongs operation by 30 min;

4% false-negatives; 4–10% false-positives

US (22–82% sensitive):

√ stone visualization in 13–75% (more readily with CBD dilatation + good visibility of pancreatic head)
√ dilated ducts in 64–77% / duct < 8 mm in diameter in 24–36%
√ increased dilatation of CBD with administration of fatty meal / cholecystokinin
√ no stone in gallbladder (1.2–11%)

CT (25–90% sensitive, 97% specific, 94% accurate):
◊ No IV / enteric contrast + thin collimation at 140 kVp improves rate of detection
√ hyperattenuating stone surrounded by hypoattenuating bile + ampullary soft tissue = visualized in 75–88%
√ isoattenuating to surrounding bile (in 12–25%)
√ often angulated + geometric with a rim of bile along stone's anterior margin
√ "target" sign = intraluminal mass with crescentic ring (= stone of soft-tissue density) in 85%
√ subtle alternating low- and high-attenuation rings (= mixed cholesterol-calcium stones)

MRCP (pooled 95% sensitive, 95–99% specific):
◊ Thinner sections without intersection gaps provided by 3D isotropic MRCP
√ signal void (= dark filling defect) within high SI of static fluid on moderately T2WI (TE of 100 msec) (DDx: tumor, edematous papilla of Vater)
√ no enhancement of calculus
√ papillitis ← stone:
√ bile duct obstruction at papilla
√ smooth symmetric papillary edema
√ increased enhancement of papilla
√ obscured / missed calculi:
√ visible SI on T1WI ← sufficient water content
√ isointensity relative to bile
√ stones < 2–3 mm in diameter (< 50% sensitive)

MRCP is highly sensitive and specific for the detection of biliary filling defects and of stones in particular. It can identify choledocholithiasis as the cause of acute pancreatitis and thus direct interventional care.

NUC:
√ delayed bowel activity beyond 2 hours
√ persistent hepatic + common bile duct activity to 24 hr
√ prominent ductal activity beyond 90 minutes with visualization of secondary ducts

Cx: acute cholangitis, gallstone pancreatitis

Stone in Cystic Duct Remnant

retained in 0.4% after surgery for choledocholithiasis

CHRONIC GRANULOMATOUS DISEASE OF CHILDHOOD

= X-linked recessive (60%) / autosomal (40%) immunodeficiency disorder characterized by neutrophil dysfunction resulting in purulent infections + granuloma formation primarily involving lymph nodes, skin, lung

Prevalence: 1÷200,000 to 1÷250,000 in USA

Normal leukocyte function:

phagocytosis → activation of NADPH (nicotinamide adenine dinucleotide phosphate) oxidase → "respiratory burst" = electron transfer to molecular oxygen → formation of microbicidal free radical superoxide in phagocytic vacuole

Pathogenesis:

dysfunctional NADPH oxidase in polymorphonuclear (PMN) leukocyte → inability to generate hydrogen peroxide → prolonged intracellular survival of phagocytized catalase-positive bacteria → dissemination in reticuloendothelial system → chronic struggle of immune system → granuloma formation

Catalase-positive organisms:

most commonly Staphylococcus, Burkholderia cepacia, Nocardia, Mycobacteria, Serratia marcescens, Klebsiella, Pseudomonas, fungi (Aspergillus, Candida)

Path: recurrent and chronic infection → lymphadenitis / granuloma formation / caseation / suppuration

Age: onset within first 2 years;
M÷F = 6÷1 (more severe in boys)

- recurrent chronic infections: lung (most common)
- nitroblue tetrazolium test (NBT): low percentage of WBCs that reduce the yellow NBT dye to dark blue formazan after stimulation by phagocytosis / contact with endotoxin (normally > 90%)

@ Bone
√ osteomyelitis (⅓) commonly of spine, ribs, metatarsals

@ Chest
√ recurrent pneumonia (80%)
√ lung abscess / empyema (in up to 20%)
√ hilar lymphadenopathy
√ pleural + pericardial effusions (in up to ⅓)

@ Liver
√ hepatosplenomegaly (in up to 90%)
√ hepatic abscess (most common abdominal process)
√ liver calcifications

@ GI tract
- chronic diarrhea with malabsorption
- vomiting, anorexia, heartburn, weight loss

Histo: inflammation with granulomas and lipid-laden histiocytes of lamina propria, smooth muscle, serosa

Location: esophagus to rectum
√ esophageal dysmotility, esophagitis, stricture
√ gastric antral narrowing ± gastric outlet obstruction (16%)
√ segmental bowel wall thickening
√ enlarged mesenteric lymph nodes ± calcifications
√ perianal fistula + abscess

@ GU tract
- dysuria, UTI (5–15%)

√ cystitis
√ obstruction of urethra + ureters
@ Lymph nodes: cervical > femoral > inguinal
√ suppurative lymphadenitis
@ Skin
• pyoderma
Rx: prophylactic long-term trimethoprim-sulfamethoxazole + interferon gamma therapy
Prognosis: 2–5% mortality per year; death by pneumonia / sepsis due to Aspergillus / Burkholderia cepacia

CIRRHOSIS

= chronic liver disease characterized by diffuse parenchymal necrosis, regeneration and scarring with abnormal reconstruction of preexisting lobular architecture

Pathophysiology:
single insult / repetitive liver injury → hepatocyte death → macromolecules in extracellular matrix → activation of hepatic stellate (collagen-producing) cells by fibrogenic cytokines → nodular regeneration + fibrotic scarring

Liver fibrosis: = excess deposition of collagen, proteoglycans, and other macromolecules in extracellular matrix in response to repetitive liver injury

Etiology:
A. TOXIC / CHEMICAL
(1) Ethanol in 75%
(2) Aflatoxin = product of fungus Aspergillus flavus in improperly stored grain and nuts
(3) Drug-induced: prolonged methotrexate, oxyphenisatin, alpha-methyldopa, nitrofurantoin, isoniazid
(4) Iron overload: hemochromatosis, hemosiderosis
B. INFECTION / INFLAMMATION
(1) Chronic viral hepatitis B
(2) Chronic viral hepatitis C ← silent epidemic in USA in 1960s to 1980s with 4 million chronically infected
(3) Schistosomiasis
C. BILIARY OBSTRUCTION
(1) Cystic fibrosis
(2) Inflammatory bowel disease
(3) Primary biliary cirrhosis
(4) Obstructive infantile cholangiopathy
D. CARDIAC / VASCULAR
(1) Prolonged CHF = cardiac cirrhosis
(2) Hepatic venoocclusive disease
(3) Budd-Chiari syndrome
E. NUTRITIONAL
(1) Intestinal bypass
(2) Severe nonalcoholic steatosis + steatohepatitis ← obesity epidemic in USA (40 million adults, 6 million children) with 10–20% expected to develop cirrhosis

(3) Abetalipoproteinemia

F. HEREDITARY

(1) Wilson disease
(2) Alpha-1 antitrypsin deficiency
(3) Juvenile polycystic kidney disease
(4) Galactosemia
(5) Type IV glycogen storage disease
(6) Hereditary fructose intolerance
(7) Tyrosinemia
(8) Hereditary tetany
(9) Osler-Weber-Rendu syndrome
(10) Familial cirrhosis

G. IDIOPATHIC / CRYPTOGENIC (15%)
probably due to nonalcoholic steatohepatitis

Cirrhosis in children:
chronic hepatitis, congenital hepatic fibrosis, cystic fibrosis, biliary atresia, alpha-1 antitrypsin deficiency, tyrosinemia, galactosemia, hemochromatosis, Wilson disease, schistosomiasis, total parenteral nutrition

Associated with: anemia, coagulopathy, hypoalbuminemia, cholelithiasis, pancreatitis, peptic ulcer disease, diarrhea, hypogonadism

Path:

Semispecific Liver Patterns in Cirrhosis	
Differentiating Findings	*Cause*
Micronodules (≤ 3 mm)	Ethanol, hemochromatosis, nonalcoholic steatohepatitis
Macronodules (3–15 mm)	chronic viral hepatitis B, autoimmmune hepatitis
Enlargement of central liver + atrophy of periphery	Primary sclerosing cholangitis
Diffuse hypertrophy + periportal halo sign	Primary biliary cirrhosis

Histo: fibrotic bridges carving liver into regenerative nodules = HALLMARK of cirrhosis

Path:

The cirrhotic liver develops characteristic morphologic alterations such as (1) surface nodularity, (2) widening of fissures, (3) expansion of gallbladder fossa, (4) notching and atrophy of right lobe, (5) relative enlargement of lateral segments of left and caudate lobe.

- anorexia, weakness, fatigue, weight loss, ascites
- jaundice, continuous low-grade fever
- bleeding from esophageal varices, hepatic encephalopathy

Early hepatic findings:

√ enlarged (very early stage) / normal / shrunken liver:
√ atrophy (= shrinkage) of right lobe (segments 5–8) and medial segment of left lobe (segments 4a + 4b)

- √ concomitant hypertrophy of lateral segment of left lobe (segments 2 + 3) and caudate lobe (segment 1):
  - √ ratio of width of caudate to right lobe > 0.65 on transverse images [100% specific; 26% sensitive; 84–96% accurate; least sensitive in alcoholic cirrhosis, most sensitive in cirrhosis caused by hepatitis B] (DDx: Budd-Chiari syndrome)
  - √ diameter of quadrate lobe (segment 4) < 30 mm (= distance between left wall of gallbladder and ascending portion of left portal vein) ← selective atrophy (95% specific)
- √ enlargement of hilar periportal space
- √ "gallbladder fossa" sign = expansion of interlobar fissure

√ associated with fatty infiltration (in early cirrhosis)

Late hepatic changes:

√ surface nodularity + indentations (regenerating nodules)
- √ right posterior hepatic "notch" sign = indentation between hypertrophied caudate + atrophied right lobe of liver (PPV 99%; in 2% of normal population)

√ fibrous septa / bands

√ distorted hepatic architecture

√ confluent hepatic fibrosis

Extrahepatic findings:

√ signs of portal hypertension: portosystemic varices, portal vein thrombosis

√ splenomegaly

√ ascites ← failure of albumin synthesis, overproduction of lymph due to increased hydrostatic pressure in sinusoids / decreased splanchnic output due to portal hypertension)

√ mesenteric edema

√ bowel wall thickening ← edema

√ lymph nodes:
- › few and small in alcoholic cirrhosis
- › large and numerous in viral hepatitis
- › numerous in primary biliary cirrhosis

US (65–80% sensitive; DDx: chronic hepatitis, fatty infiltration):

Hepatic signs:
- √ surface nodularity (54% sensitive, 95% specific)
- √ caudate lobe hypertrophy (41% sensitive, 91% specific)
- √ "portalization" of hepatic vein waveform = dampened oscillations of hepatic veins resembling portal vein flow (57% sensitive, 76% specific)
- √ hepatomegaly (in 63%)
- √ increased hepatic parenchymal echogenicity in 66% (as a sign of superimposed fatty infiltration):
  - √ increased sound attenuation (9%)
  - √ decreased / normal definition of walls of portal venules (sign of associated fatty infiltration NOT of fibrosis)
- √ heterogeneous coarse (usually) / fine echotexture (in 7%)
- √ occasional depiction of isoechoic regenerative nodules
- √ dilatation of hepatic arteries ← increased arterial flow with demonstration of

intrahepatic arterial branches (DDx: dilated biliary radicals)
√ increase in hepatic artery resistance (mean RI of 0.58–0.66 in normals to 0.63–0.85 in cirrhotics):
√ blunted increase in RI after meal ingestion (from 42% in normals to 7% in cirrhotics)

Extrahepatic signs:
√ splenomegaly
√ ascites
√ signs of portal hypertension

US Elastography:
= US-based transient elastography = pulse-echo US acquisition following the wave propagation and velocity measurement of a probe-generated vibration of mild amplitude and low frequency (directly related to Young elastic modulus)

CT:
√ native + enhanced parenchymal inhomogeneity:
√ bridging bands of fibrous scarring
√ wedge-shaped / stellate confluent fibrosis in segments IV, V and VIII with capsular retraction (78%)
Confluent fibrosis: broad fibrotic scar up to several cm thick with a masslike appearance
√ decreased attenuation (steatosis) in early cirrhosis
√ isodense / hyperdense (siderotic) regenerative nodules
√ nodular / lobulated liver contour
√ predominantly portal venous supply to dysplastic nodules
√ hypodense area adjacent to portal vein (= peribiliary cysts from obstructed extramural peribiliary glands)
√ rapid tapering of intrahepatic portal + hepatic venous branches

CECT:
√ enlarged tortuous hepatic artery ← compensatory increase in arterial blood flow
√ arterioportal shunts (= trans-sinusoidal shunts in liver periphery + transplexal shunts with hypertrophy of peribiliary plexus) in hepatic arterial phase:
√ poorly demarcated transient peripheral wedge-shaped hepatic parenchymal enhancement
DDx: hepatocellular carcinoma (growth in 3- to 6-month intervals, defect on portal venous phase)
√ early retrograde enhancement of portal vein branches
√ hepatofugal flow
Cause: with occlusion of small hepatic venules, portal vein turns from a supplying vein into a draining vein

NEMR (problem-solving tool):
√ no alteration of liver parenchyma
√ extensive parenchymal heterogeneity ← fibrosis + cirrhotic nodules + perfusion abnormalities + fat and iron deposition
√ fibrotic septa / bridges / confluent fibrosis = devoid of iron and fat even with hepatic iron overload / fat deposition:
√ hypointense reticulations on T1WI
√ T2-hyperintense ← large water content of advanced fibrosis

√ NOT hypointense on T2* (= NO iron)
√ no signal loss on out-of-phase images (= NO fat)

√ generalized decrease in hepatic SI on T2WI ← mild iron deposition for unknown reasons
√ reticulations surround regenerative nodules typically of:
√ intermediate to high SI on unenhanced T1WI
√ intermediate to low SI on unenhanced T2WI

CEMR:
√ enhancement of liver fibrosis on T1WI ← Gd-contrast accumulation ← large extracellular component
√ progressive enhancement on delayed images with peak during late venous + equilibrium phases
√ occasional arterial hypervascularity within focal fibrosis (DDx to HCC: wedge-shaped configuration and persistence of enhancement into late venous phase)
√ enhancement of usually ill-defined arterioportal shunts:
√ visible only during arterial phase
√ fading to isointensity in late venous phase
√ areas of patchy hyperenhancement at arterial phase ← active inflammation

MR Elastography:
= observing the effect of 40–120 Hz shear waves generated by a mechanical device placed in contact with body → increase in velocity and wavelength proportionate with greater tissue stiffness
√ color-encoded quantitative liver stiffness maps of ROIs ← phase shifts in MR signal accumulate at tissue locations where gradient cycling is exactly in phase with generated mechanical wave

MR with Superparamagnetic Iron Oxide (SPIO):
Mechanism: RES–specific contrast agent = iron oxide particles → cleared from blood through phagocytosis → accumulate in RES cells of liver (80% uptake), spleen, bone marrow
√ reticulations of hepatic fibrosis with high SI on SPIO ← less iron oxide accumulation ← ↓ Kupffer cell density
√ pronounced T2* shortening + signal loss greatest on GRE ← local magnetic field inhomogeneities

Angio:
√ stretched hepatic artery branches (early finding)
√ enlarged tortuous hepatic arteries = "corkscrewing" ← increase in hepatic arterial flow
√ shunting between hepatic artery and portal vein
√ mottled parenchymal phase
√ delayed emptying into venous phase
√ pruning of hepatic vein branches (normally depiction of 5th order branches) ← postsinusoidal compression by developing nodules

NUC (^{99m}Tc–labeled sulfur colloid):
√ high blood pool activity ← slow clearance
√ colloid shift to bone marrow + spleen + lung
√ shrunken liver with little or no activity + splenomegaly
√ mottled hepatic uptake (pseudotumors) on colloid scan (normal activity on IDA scans!)
√ displacement of liver + spleen from abdominal wall by ascites

Cx: (1) Ascites: cause / contributor to death in 50%
(2) Portal hypertension → bland portal vein thrombosis (in 11–16%)
(3) Hepatocellular carcinoma (in 7–12%)
(4) Cholangiocarcinoma

Fatality from:
esophageal variceal bleeding (in 25%), hepatorenal syndrome (10%), spontaneous bacterial peritonitis (5–10%), complications from treatment of ascites (10%)

Dx: liver biopsy (0.03% fatality rate); poor underdiagnosed Bx (in 32%): specimen should be at least 2 cm long + contain at least 11 portal triads

DDx:
(1) Pseudocirrhosis
(2) Diffuse metastatic disease with desmoplastic reaction: breast, melanoma
(3) Fulminant hepatic necrosis ± regeneration
(4) Noncirrhotic intrahepatic portal hypertension: nodular regenerative hyperplasia, periportal fibrosis, hepatoportal sclerosis

Nodular Lesions in Liver Cirrhosis

Concept: gradual progression of regenerating (regenerative) nodule to → low-grade dysplastic nodule → high-grade dysplastic nodule → dysplastic nodule with subfocus of HCC → early HCC → progressed HCC

Radiologic diagnosis of HCC can be made with multiphasic CECT / CEMR

Pathophysiology:

As nodules dedifferentiate → progressive decrease in portal vascularization + ↑ blood supply via nontriadal arteries:
1. Hypoenhancement during portal phase
2. Increased number of nontriadal arteries during arterial phase (= hypervascularity)

MR visibility vs nodule size: > 2 cm (100%), 1–2-cm (52%), < 1 cm (4%)
Sensitivity of modality: MR (70–85%), CT (50–68%)
Recommendation: US surveillance at 6-month intervals

Nodule suspicious for HCC by US requires further investigation with CECT / CEMR if:
√ nodule > 1 cm is new
√ nodule enlarges over time

Challenges for imaging:
√ nodule visualization ↓ due to heterogeneity of fibrosis
√ heterogeneous enhancement may be mistaken for tumor
√ small nodules may demonstrate typical findings of HCC

The continuous histologic changes that nodules undergo result in significant overlap of enhancement patterns and findings on T1- and T2WI, complicating their imaging and histopathologic differential diagnosis.

Management protocol for small nodules < 2 cm:

The likelihood of a nodule to be HCC increases with size:
< 1 cm (indeterminate) = unlikely malignant → watch for interval growth
1–2 cm = close monitoring with imaging + biopsies

> 2 cm = likely malignant

(a) nodule < 1 cm:
re-examine after 3 months with same imaging technique used to depict lesion initially
› stable: return to routine screening
› growth: evaluation with 4-phase CT / MR

(b) nodule ≥ 1 cm:
evaluation with 4-phase CT / MR (unenhanced, arterial, portal, and equilibrium phases)
› typical for HCC: diagnosis confirmed
› atypical for HCC: biopsy

Regenerative (Cirrhotic) Nodule *(vast majority)*

= heterogeneous regeneration = localized proliferation of normal hepatocytes + supporting stroma with normal blood supply (25% hepatic arterial + 75% portal venous)

Morphology:

(a) **micronodular cirrhosis** (≤ 3 mm): usually due to alcoholism, biliary obstruction, hemochromatosis, venous outflow obstruction, previous small-bowel bypass surgery, Indian childhood fibrosis

(b) **macronodular cirrhosis** (3–15 mm, up to several cm): usually due to chronic viral hepatitis B, Wilson disease, alpha-1 antitrypsin deficiency

(c) mixed cirrhosis

CT:

√ iso- to hyperdense on hepatic arterial phase
√ iso- to hypodense on portal venous phase

MR:

√ variably SI relative to liver on T1WI:
√ hyperintense with lipid / protein / copper contents
√ iso- to hypointense relative to liver on T2WI
√ **siderotic nodules** (in 25%) with variable iron content:
√ hypointense on T1WI ← magnetic susceptibility
√ markedly hypointense on T2- / T2*WI
√ blooming on GRE

DDx of Liver Nodules in Cirrhosis

Features	*Regenerative nodule / low-grade dysplasia*	*High-grade dysplasia / HCC*
Blood supply	portal venous	nontriadal arteries (loss of portal supply)
Vascularity	like normal liver	hypovascular (if small) hypervascular (if large)
Enhancement	like normal liver	in arterial phase

√ signal loss on in-phase images
◊ An iron-poor focus within a siderotic nodule on T2WI suggests HCC!
√ **steatotic nodules** (usually multifocal):
√ hyperintense on in-phase gradient images

√ signal loss on out-of-phase images

CEMR:

√ Gd-enhancement similar to liver / slightly less

√ NO Gd-enhancement on arterial phase images

√ similar to liver on hepatobiliary specific imaging

√ similar to liver on superparamagnetic iron oxide

Lesions that exhibit enhancement similar to that of adjacent liver are likely regenerative and low-grade dysplastic nodules.

Dysplastic Nodule *(15–28%)*

= regenerative nodule with atypical cells

Histo: cluster of hepatocytes > 1 mm in diameter with evidence of (nuclear + cytoplasmic) dysplasia

Cause: common in hepatitis B and C, alpha-1 antitrypsin deficiency, tyrosinemia

Frequency: in 15–28% of explanted cirrhotic livers

LOW-GRADE DYSPLASTIC NODULE

= macroregenerative nodule, type I / ordinary adenomatous hyperplasia

Histo: preserved hepatic architecture, low-grade cytologic atypia, varying numbers of portal tracts, inconstant increase in number of unpaired arterioles

Prognosis: low malignant potential

√ variable SI on T1WI, iso- / hypointense on T2WI

√ enhancement similar to liver ← main blood supply from portal venous system

DDx: regenerative nodule (similar imaging features)

◊ No practical consequence of inability to differentiate between the two diagnoses!

HIGH-GRADE DYSPLASTIC NODULE

= macroregenerative nodule type II / adenomatous hyperplasia with atypia

Histo: moderate cytologic + architectural atypia, reduced number of portal tracts, progressive sinusoidal capillarization, ↑ number of unpaired arterioles

Prognosis: premalignant

√ variable SI on T1WI (depending on content)

√ usually iso- / hypointense on T2WI

√ mostly hypovascular ± arterial enhancement

◊ Nodules with loss of portal supply and development of insufficient number of nontriadal arteries to produce hypervascularity are difficult to diagnose and responsible for the high rate of false-negative imaging results.

Dysplastic Nodule with Subfocus of HCC

= adenomatous hyperplasia with microscopic HCC

Frequency: 6% of patients with dysplastic nodules

√ SI as any dysplastic nodule

√ "n**odule-in-nodule**" appearance = focus of high SI during arterial enhancement within dysplastic nodule

Small Hepatocellular Carcinoma

= adenomatous hyperplasia with macroscopic HCC < 2 cm

Prevalence: 27% for hepatitis B, 22% for hepatitis C

Sensitivity: 80–100% for lesion > 2 cm; 50% for lesion 1–2 cm; 5–33% for lesion < 1 cm in diameter

Histo: abnormally high number of muscularized unpaired arterioles + capillarized vessels

EARLY SMALL HEPATOCELLULAR CARCINOMA

Histo: well-differentiated with invasion of portal tracts; neoplastic cells replace normal cells; ± portal tracts; fatty change in 40%

Prognosis: 89% 5-year survival; 8% recurrence rate within 3 years of resection

√ high SI on T1WI

√ hypo- / isointense on T2WI

CEMR:

√ hypo- / isointense during arterial phase ← insufficient development of unpaired arteries

√ hypointense during portal phase of enhancement ← loss of portal vascularization

◊ Early HCC has mostly hypovascular or equivocal findings and thus is difficult to differentiate from a high-grade dysplastic nodule. Progressed small HCC has characteristics similar to classic HCC.

DDx: high-grade dysplastic nodule (requires biopsy)

PROGRESSED SMALL HEPATOCELLULAR CARCINOMA

Histo: no portal tracts; numerous nontriadal arteries + well-developed sinusoidal capillarization; microscopic vessel invasion in 27%

Prognosis: 48% 5-year survival

√ well-defined homogeneous round / oval lesion

√ variable SI on T1WI

√ moderately hyperintense on T2WI

CEMR:

√ enhancement = hyperintense during arterial phase ← main blood supply from hepatic arterial system

√ washout during portal / delayed phase

◊ A > 1 cm nodule with arterial phase hyperenhancement and portal venous / delayed phase washout may be diagnosed as HCC by either (CECT / CEMR).

Primary Biliary Cirrhosis

= CHRONIC NONSUPPURATIVE DESTRUCTIVE CHOLANGITIS

Histo: idiopathic progressive destructive cholangitis of interlobar and septal bile ducts, portal fibrosis, nodular regeneration, shrinkage of hepatic parenchyma

Age: 35–55 years; M÷F = 1÷9

Associated autoimmune disorders:

rheumatoid arthritis, Hashimoto thyroiditis, Sjögren syndrome, scleroderma, sarcoidosis

◊ 66–100% of patients with primary biliary cirrhosis have sicca-complex signs of the

Sjögren syndrome
- fatigue, insidious onset of pruritus (60%)
- xanthelasma / xanthoma (25%); hyperpigmentation (50%)
- IgM increased (95%)
- positive antimitochondrial antibodies (AMA) in 85–100%

√ normal extrahepatic ducts
√ cholelithiasis in 35–39%
CT:
√ scattered dilated intrahepatic ducts with no apparent connection to main bile ducts
√ periportal "halo" sign = perivascular cuffing
√ smooth capsule
√ caudate lobe hypertrophy (in 98%):
√ hypertrophied hyperattenuating caudate lobe surrounded by hypoattenuating rindlike right lobe (pseudotumor)
√ atrophy of lateral segment of left hepatic lobe
√ intrahepatic biliary calculi (20%)F
MR:
√ periportal "halo" sign (in 40%, SPECIFIC)
√ lymphadenopathy (in 62%)
NUC:
√ marked prolongation of hepatic ^{99m}Tc-IDA clearance
√ uniform hepatic isotope retention
√ normal visualization of GB and major bile ducts in 100%

Cx: hepatocellular carcinoma (in 5%)

DDx: (1) Sclerosing cholangitis (young men)
(2) CBD obstruction

Prognosis: mean survival 6 (range, 3–11) years after onset of cholestatic symptoms

Complications of End-Stage Liver Disease

Acute Respiratory Distress Syndrome

Pathophysiology: compromised liver function → systemic spillover of proinflammatory substances (cytokines)
√ patchy lung opacities (early)
√ diffuse bilateral dependent lung consolidation (late)
Prognosis: poor

Hepatopulmonary Syndrome

Dx: (1) Chronic liver disease
(2) Increased alveolar-arterial oxygen gradient
(3) Intrapulmonary vascular dilatation

Prevalence: 15–20% of cirrhotic patients
- hypoxemia with progressive dyspnea, cyanosis, clubbing

Typical MR Characteristics of Cirrhotic Liver Nodules					
Lesion	*T1WI*	*T2WI*	*Contrast Enhancement*		
	(relative to normal liver parenchyma)		*Gadolinium CM*	*Hepatobiliary CM*	*SPIO CM*
Regenerative nodule	variable, hyperintense with lipid / protein / copper contents	iso- to hypointense	similar to liver parenchyma	similar to liver parenchyma	similar to liver parenchyma
Low-grade dysplastic nodule	variable, often hyperintense	iso- or hypointense	similar to liver parenchyma	similar to liver parenchyma	similar to liver parenchyma
High-grade dysplastic nodule	variable, often hyperintense	iso- or hypointense	usually hypovascular ± arterial phase ↑	similar to liver parenchyma	similar to liver parenchyma
Early HCC	variable, often hyperintense	iso- or hypointense	usually hypovascular ± arterial phase ↑	± enhancement	± enhancement
Progressed HCC	variable, often iso- / hyperintense	moderately hyperintense	arterial-phase ↑, portal-phase washout	± enhancement	± enhancement
Large HCC	heterogeneous, predominantly hypointense	heterogeneous, predominantly hyperintense	arterial-phase ↑ in 80–90%, portal-phase washout	no enhancement	no enhancement

Pathomechanism:
elevation of unknown vasoactive substances in cirrhotic patient → pulmonary vascular dilatation (from 8–15 μm to 15–500 μm) → excess perfusion for a given ventilation (= diffusion-perfusion mismatch)

√ increased number of dilated arterioles + nontapering terminal branches extending to pleura (86%)

√ intrapulmonary arteriovenous shunts (14%):

√ nodular dilatation of peripheral pulmonary vessels

√ ^{99m}Tc activity in brain, liver, spleen on macroaggregated albumin imaging

√ bubbles in LA on microbubble echocardiography

CXR:

√ basilar nodular / reticulonodular areas of increased opacity (in 46–100%)

Hepatic Hydrothorax

= large pleural effusion in cirrhotic patient without primary pulmonary / cardiac disease

Prevalence: 5–10%

Mechanism: pressure gradient favors fluid movement from peritoneal to pleural cavity through small diaphragmatic defects; may occur in the absence of ascites

• dyspnea, nonproductive cough, pleural chest pain, hypoxemia

√ pleural fluid: right in 67–85%, left in 13–17%, bilateral in 2–17%

Portopulmonary Hypertension

Prevalence: 2–5% in patients with liver cirrhosis

Cause:

(a) thromboembolic: portal venous thrombus reaches lung through spontaneous / surgically created portosystemic shunts

(b) plexogenic: vasoconstriction from vasoactive substances (serotonin, thromboxane, interleukin I, endothelin I) that bypass the liver through portosystemic shunts

(c) cardiogenic: high cardiac output associated with cirrhosis → increased shear stress on pulmonary endothelial cells → endothelial hyperplasia

Dx: mean pulmonary artery pressure > 25 mmHg; pulmonary capillary wedge pressure < 15 mmHg

Prognosis: mean survival of 15 months

Pseudocirrhosis

= retracted tumor tissue + scarring between areas of regenerative liver parenchyma resembling macronodular cirrhosis

Cause: (1) Liver metastases treated with chemotherapy
(2) Hepatotoxic effect of chemotherapy

Time: within a few weeks or months after chemotherapy

Histo: macronodular regenerative hyperplasia; no bridging portal fibrosis

√ lobular liver margin
√ volume loss
√ caudate hypertrophy
√ portal hypertension

Confluent Hepatic Fibrosis

= geographic pattern of fibrosis involving an entire segment

Predisposed: liver cirrhosis

Location: mostly medial segment of left lobe + anterior segment of right lobe / both

Site: (a) wedge-shaped at subcapsular portion (b) radiating from porta hepatis

CT:
√ hypoattenuating lesion with volume loss:
√ overlying retraction of liver capsule

CECT:
√ vessel crowding
√ isoattenuating / minimally hypoattenuating on arterial phase + delayed enhancement
√ delayed contrast enhancement ← pooling of contrast material within edema / nonarterial vascular channels

MR:
√ low SI on T1WI + mildly high SI on T2WI ← edema and numerous vascular spaces
√ hypointensity during hepatobiliary phase (70%)

DDx: HCC (mass effect on liver contour and adjacent blood vessels, more nodular appearance, no retraction of liver capsule, not typically geographic pattern)

CLONORCHIASIS

Rarely of clinical significance

Country: endemic to Southeast Asia: Japan, Korea, Central + South China, Taiwan, Indochina; Eastern Europe

Organism: Chinese liver fluke = Clonorchis sinensis

Closely related: Opisthorchis viverrini (Thailand and Laos); Opisthorchis felineus (Siberia)

Cycle: parasite cysts digested by gastric juice → larvae migrate up the bile ducts → remain in small intrahepatic ducts until maturity (10–30 mm in length) → travel to larger ducts to deposit eggs

Infection: snail + freshwater fish serve as intermediate hosts; infection occurs by eating raw fish; hog, dog, cat, man are definite hosts

Path: (a) desquamation of epithelial bile duct lining with adenomatous proliferation of ducts + thickening of duct walls (inflammation, necrosis, fibrosis)
(b) bacterial superinfection with formation of liver abscess

• remittent incomplete obstruction + bacterial superinfection

Location: medium-sized + small intrahepatic bile ducts, primarily in subcapsular region

√ diffuse uniform dilatation of small intrahepatic bile ducts + NO dilatation of extrahepatic bile ducts + NO focal obstructing lesion

√ diffusely thickened bile duct walls

√ multiple crescent- / stiletto-shaped filling defects within bile ducts:
√ echogenic focus / cast on US

Cx: (1) Bile duct obstruction ← conglomerate of worms / adenomatous proliferation of ducts
(2) Calculus formation ← stasis / dead worms / epithelial debris
(3) Jaundice in 8% ← stone / stricture / tumor
(4) Generalized dilatation of bile ducts (2%)

CONGENITAL BILIARY ATRESIA

Etiology: ? variation of same infectious process as in neonatal hepatitis with additional component of sclerosing cholangitis or vascular injury

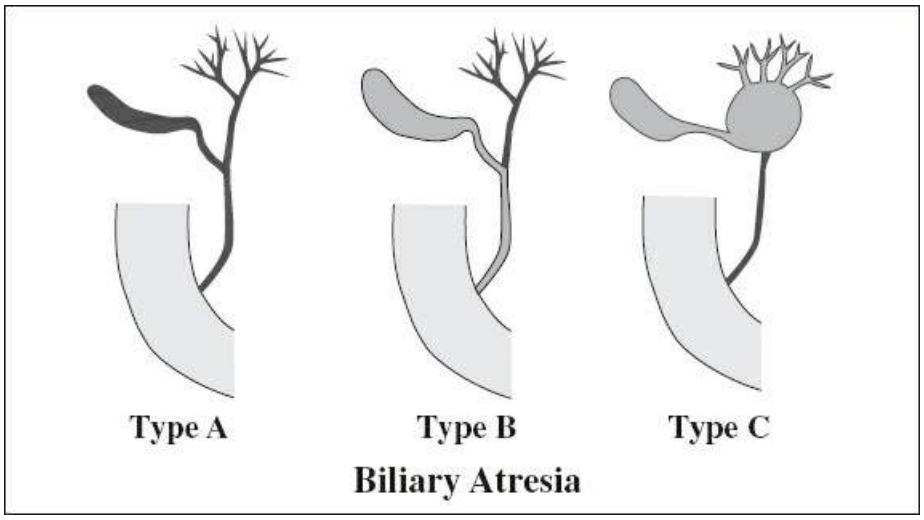
Prevalence: < 10÷100,000 live births

Age: neonate; M÷F = 2÷1

Histo: periportal fibrosis, proliferation of small intrahepatic bile ducts, mixed inflammatory infiltrates

In 15% associated with: polysplenia, trisomy 18

Types:
I Focal = intrauterine vascular insult (extremely rare)
II Intrahepatic biliary atresia = paucity of intrahepatic bile ducts (uncommon)
III Extrahepatic biliary atresia = atresia of CBD + patent intrahepatic bile ducts



Subtype 1 = perinatal type (66%)
• jaundice develops after regression of physiologic jaundice

√ bile duct remnant in porta hepatis

Subtype 2 = embryonic / fetal type (34%)

- normal decline in bilirubin does not occur

√ NO bile duct remnant in porta hepatis

Associated with:

polysplenia (10–12%), intestinal malrotation, azygos continuation of IVC, symmetric bilobed liver, situs inversus, preduodenal portal vein, anomalous hepatic arteries, bilobed right lung, complex CHD

US:

@ Liver:

√ normal / increased size of liver

√ normal / increased liver echogenicity

√ ↓ visualization of peripheral portal veins ← fibrosis

√ "triangular cord" / tubular echogenic structure in porta hepatis ← fibrous tissue = PATHOGNOMONIC

@ Gallbladder:

√ nonvisualization of gallbladder

√ small gallbladder < 1.5 cm in length + varying degrees of luminal compromise (DDx: hepatitis)

√ normal gallbladder > 1.5 cm in length (19%) with atresia of CBD distal to insertion of cystic duct

@ Bile ducts:

√ NO dilatation of intrahepatic bile ducts ← panductal sclerosis

√ ± visualization of bile duct remnant in porta hepatis (depending on type of biliary atresia)

√ small focal cystic dilatation of extrahepatic bile duct (= choledochal cyst) = patent segment of CBD with other parts being occluded ← fibrosis ± communication with gallbladder / intrahepatic bile ducts

NUC [phenobarbital-augmented cholescintigraphy] (90–97% sensitive, 60–94% specific, 75–90% accurate):

» preparation of patient with 5 ng/kg/d phenobarbital twice a day for 3–7 days to stimulate biliary secretion (via induction of hepatic enzymes + increase in conjugation + excretion of bilirubin)

√ good hepatic activity within 5 minutes (infants of < 3 months of age have a normal hepatic extraction fraction)

√ NO biliary excretion:

√ NO visualization of bowel on delayed images at 6 and 24 hr

√ delayed clearance from cardiac blood pool

√ increased renal excretion + bladder activity

DDx: severe hepatocellular dysfunction (DDx from neonatal hepatitis impossible in the absence of small bowel activity) requires liver biopsy

MR cholangiography:

√ nonvisualization of extrahepatic bile ducts

√ atrophic gallbladder

√ periportal thickening

Cholangiography (percutaneous / endoscopic / intraoperative)

Liver Biopsy (60–97% accurate)

Rx: (1) Roux-en-Y choledochojejunostomy (20%);

(2) Kasai procedure = portoenterostomy (80%)

(a) child < 60 days of age: 91% success rate

(b) child between 60 and 90 days of age: 50% success rate ← developing cirrhosis

(c) child > 90 days of age: 17% success rate

(3) Liver transplant

DDx:

(1) Neonatal hepatitis

(2) Sclerosing cholangitis

(3) **Alagille syndrome** = arteriohepatic dysplasia (abnormal facies, butterfly vertebra, pulmonic stenosis, complex CHD)

CONGENITAL HEPATIC FIBROSIS

= congenital cirrhosis with rapid + fatal progression

Histo: fibrous tissue within hepatic parenchyma with excess numbers of distorted terminal interlobular bile ducts + cysts that rarely communicate with bile ducts = extensive fibrosis WITHOUT regenerative nodules

Age: early childhood – 6th decade;
majority diagnosed in adolescence / early adulthood

Associated with:

autosomal recessive polycystic kidney disease (invariably), Meckel-Gruber syndrome, vaginal atresia, tuberous sclerosis, nephronophthisis, medullary sponge kidney (80%), autosomal dominant polycystic kidney disease (rare)

- liver function tests normal / mildly elevated
- portal hypertension; predisposed to cholangitis + calculi

√ "lollipop-tree" = ectasia of peripheral biliary radicles

√ atrophy of right lobe + normal / enlarged medial segment of left lobe + hypertrophy of left lateral segment and caudate lobe

√ splenomegaly

√ portosystemic varices

√ enlarged hepatic artery associated with large multiacinar regenerative nodules

Cx: cirrhosis, portal hypertension, hepatocellular carcinoma, cholangiocellular carcinoma

CONGENITAL TRUE PANCREATIC CYST

= very rare entity

Cause: sequestration of primitive pancreatic duct

Age: mostly in children < 2 years; M < F

Histo: cuboidal epithelium

- usually asymptomatic palpable mass, abdominal distention
- epigastric pain, vomiting, jaundice ← compression by cyst

May be associated with: Von Hippel-Lindau disease, Beckwith-Wiedemann syndrome,

hepatorenal polycystic disease

Location: pancreatic body / tail

√ uniform thin-walled single / multiple cysts

ECHINOCOCCAL DISEASE

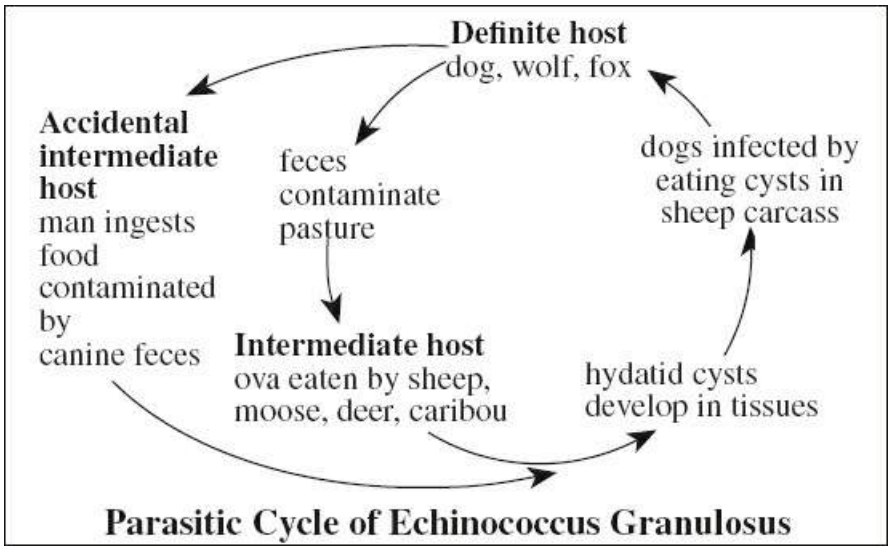
= zoonotic parasitic disease endemic in pastoral regions

Anatomy of cestode (tapeworm) in primary host:

3–6 mm adult sexually mature flatworm attaches to small intestines of canine with hooks on rostellum (tubular beak) + 4 suckers on its scolex (head); strobila (body) is composed of a colony of proglottids (segments) resembling a strip of tape; new segments are continuously produced by the proliferative neck piece pushing older segments towards tail; each segment has its own digestive tract + female and male reproductive structures (hermaphrodite); uterus of last segment filled with about 500 eggs drops off; lifespan of adult worm is 5–12 months

Life cycle relying on carnivores eating infected herbivores:

eggs excreted fecally by definite host (dog / fox / other carnivore) + intermediate host (sheep / rodents, other ruminants) into environment → grazing intermediate host ingests ova → ovum loses protective layer during digestion in duodenum → freed embryo (oncosphere armed with 6 hooks = hexacanth) attaches to + penetrates intestinal mucosa → migrates to liver by way of portal / lymphatic system → oncospheres are filtered by capillaries of liver (first line of defense) >> lung > other organs → intrahepatic development of oncosphere into metacestode = unilocular cyst (E. cysticus) / multiple cysts (E. multilocularis) that have brood capsules attached to inside of germinal layer and produce protoscolices → cycle completes when definitive host ingests infected viscera from intermediate host



Parasitic Cycle of Echinococcus Granulosus

Echinococcus Granulosus (E. cysticus)

= HYDATID DISEASE (= more common unilocular form compared to E. multilocularis)

= canine tapeworm in sheep-and cattle-grazing areas= zoonosis with worldwide distribution caused by larvae of echinococcus tapeworm, primarily E. granulosus

Endemic to certain regions of the world where livestock + dogs are raised together:

Australia, New Zealand, Africa (Kenya, Uganda, Sudan, Ethiopia), Eastern Europe, Russia, Mediterranean countries (Israel, Tunisia, Turkey, Italy, Spain, Croatia), China,

Japan, South America (Uruguay, Peru, Chile, Argentina), Middle East
◊ Reported on all continents except Antarctica!

Prevalence: 1 million persons infected worldwide

Primary / definitive host (harbors adult tapeworm):
(a) sylvatic life cycle: wolf, red fox, jackal, coyote
(b) domestic life cycle: dog, cat

Secondary / intermediate host (harbors larva stage):
(a) sylvatic life cycle: wild ungulate (deer, moose), kangaroo, wallaby, other grazing ruminants
(b) domestic life cycle: ungulates (= hoofed animals) like sheep, goat, swine, cattle, horse, camel

Accidental intermediate host: human ingesting eggs

Histo of 3-layered hydatid cyst:
A. CYST FLUID = antigenic clear / pale yellow transudate with neutral pH containing sodium chloride, proteins, glucose, ions, lipids, polysaccharides → may cause eosinophilia / anaphylaxis
B. TRUE WALL OF PARASITE
1. ENDOCYST = thin translucent inner **germinal layer** (resembling wet tissue paper) gives rise to brood capsules (daughter vesicles), which may
(a) harbor up to 400,000 protoscolices
(b) break up into numerous self-contained daughter cysts remaining attached to cyst wall by small pedicle (brood capsule)
(c) detach + form sediment in cyst fluid = "hydatid sand"
2. ECTOCYST = **cyst membrane** = thin acellular laminated membrane of chitinlike substance secreted by parasite; allows passage of nutrients
C. PERICYST (host response) = rigid outermost layer of protective zone of dense fibrous granulation tissue (fibroblasts, giant cells, eosinophils) replacing tissue necrosis ← compression by the expanding cyst; marginal vascular rim of 0.5–4 mm

N.B.: The hydatid cyst consists of the endocyst, where the scolices are produced, and the pericyst, which is composed of host cells that form a peripheral layer of reactive fibrous tissue.

• Tests:
1. Casoni intradermal test (60% sensitivity; may be falsely positive)
2. Complement fixation double diffusion (65% sensitivity)
3. Enzyme-Linked ImmunoSorbent Assay (ELISA) (90% sensitive in hydatid liver disease)
4. Indirect hemagglutination (85% sensitivity)

Time to diagnosis: 51 (range, 11–81) years; chronic disease with latent stage that may last years

Affected organs:
liver (50–75%); <u>widespread dissemination uncommon</u>: lung (14–43%); peritoneum (12%); kidney (2–6%); spleen (0.9–8%); CNS (1–4%); orbit (1%); bone (0.5–4%); bladder; thyroid; prostate; heart

Types of cysts (corresponding to stages of cyst growth):
(1) Unilocular cyst (initially):
√ simple on CT

√ laminated wall (double line sign) / free-floating scolices (snowflakes sign) on US
√ fibrous persistently hypointense rim on MR

(2) Cyst with daughter vesicles / daughter cysts = spoke-wheel appearance
√ daughter cysts of lower attenuation and less T1-hypointense compared to mother cyst ← free-floating scolices

(3) Partially / completely calcified
◊ Only complete calcification of all layers implies death of parasite!

Rx: (1) Surgery (in 10% recurrence)
(2) Antihelmintics (benzimidazoles)
(3) PAIR technique
= Puncture, Aspiration, Injection, Reaspiration
Dx: fluid analysis positive for hydatid disease in 70% (fragments of laminated membrane in 54%; scolices in 15%; hooklets in 15%)
Rx: injection of scolecidal agent (silver nitrate; 20 to 30% hypertonic saline solution; 0.5% cetrimide solution; 10% povidone iodine; 95% ethanol) with reaspiration
Cx: risk of anaphylactic shock (0.5%), asthma (3%), implantation of spilled protoscoleces (after rupture / following diagnostic puncture)

Hydatid Disease of Bone *(1%)*

Epidemiology: occurs occasionally in USA; usually in foreign-born individuals\
Path: no connective tissue barrier; daughter cysts extend directly into bone

@ Pelvis, sacrum, rarely long tubular bones
√ round / irregular regions of rarefaction
√ multiloculated lesion (bunch of grapes)
√ no sharp demarcation (DDx: chondroma, giant cell tumor) with secondary infection:
√ thickening of trabeculae with generalized perifocal condensation
√ cortical breakthrough with soft-tissue mass

@ Vertebra
√ sclerosis without pathologic fracture
√ intervertebral disks not affected
√ vertebral lamina often involved
√ frequently involvement of adjacent ribs

Hydatid Disease of CNS *(1–2–4%)*

• increased intracranial pressure and seizure

Location: subcortical parietal lobe; (rarely) dura, subarachnoid space, ventricular system, brainstem, spinal canal

√ usually single large well-defined oval / round cyst in brain parenchyma similar to CSF attenuation + intensity
√ occasional CHARACTERISTIC hypointense nonenhancing rim on T2WI
√ multiple cysts suggest rupture of preexisting single cyst
√ occasionally faint surrounding T2 hyperintense halo ← pericyst composed of inflammatory cells + fibrous tissue
√ NO significant surrounding edema; NO rim enhancement

√ heterogeneous predominantly cystic mass + fluid-debris level ← hydatid sand

Hydatid Disease of Kidney

- asymptomatic for many years until cyst size > 10 cm
- flank mass + pain; dysuria
- acute renal colic + hydatiduria from cyst rupture into collecting system (18%)

Site: cortex of upper / lower pole; typically unilateral + solitary

Plain film:
- √ abdominal mass
- √ curvilinear calcifications of pericyst (20–30%)

IVP:
- √ infundibular + calyceal distortion
- √ obstruction; renal dysfunction

US:
- √ unilocular cyst (DDx: simple renal cyst)
- √ multiseptated daughter cysts (DDx: polycystic kidney disease)
- √ thick bilayered cyst wall
- √ PATHOGNOMONIC "falling snowflake" or "snowstorm" sign = multiple echogenic foci from hydatid sand dispersed with repositioning of patient
- √ "floating membranes" = detachment of parasite wall from pericyst
- √ "wheel-spoke" pattern = mixture of membranes + broken daughter vesicles + scolices + hydatid sand

CT:
- √ unilocular type 1 cyst (initial stage)
- √ multilocular type 2 cyst (intermediate stage):
  - √ mixed internal attenuation
  - √ daughter cysts with lower attenuation
  - √ enhancing thick wall + internal septa
- √ completely calcified type 3 cyst

MRI:
- √ hypointense rim on T2WI = dense fibrous pericyst
- √ fluid hypointense on T1WI + markedly hyperintense on T2WI
- √ linear intracystic structures in type 2 cyst = collapsed membranes of daughter cysts:
  - √ hypointense on all sequences ± contrast enhancement
- √ low SI on all pulse sequences for type 3 cyst

Rx: total or partial nephrectomy / enucleation / marsupialization / cystectomy

Cx: cyst rupture → severe antigenic immune response

Hydatid Disease of Liver *(60%)*

Location: right > left lobe of liver; multiple cysts in 20%

Average size: 5 (up to 50) cm; up to 16 liters of fluid

- pain / asymptomatic (for years); incidental discovery in ⅓
- recurrent jaundice + biliary colic ← transient obstruction by membrane fragments + daughter cysts expelled into biliary tree; blood eosinophilia (20–50%)
- urticaria + anaphylaxis ← following cyst rupture

Spread: usually disruption of hepatic cysts during invasive treatment / spontaneous rupture / traumatic rupture
Growth: 2–3 cm annually
Plain film:
- √ peripheral crescentic / curvilinear / polycyclic calcifications (10–20–33%), located in pericyst
- √ pneumohydrocyst (infection / communication with bronchial tree)

US:
- ◊ Look for membranes / peripheral daughter vesicles
- √ well-defined anechoic cyst (common):
  - √ cyst wall of double echogenic lines separated by hypoechoic layer
  - √ "snowstorm" sign = multiple internal echogenic foci settling to most dependent portion of cyst (= hydatid sand)
  - √ multivesicular cyst of "racemose" / honeycomb appearance = multiple septa between daughter cysts inside mother cyst, CHARACTERISTIC but rare:
    - √ "wheel spoke" pattern = daughter cysts separated by echogenic material of hydatid matrix composed of broken daughter vesicles + scolices + hydatid sand
  - √ HIGHLY SPECIFIC serpentine linear structures within hydatid matrix
- √ partial / complete detachment of endocyst from pericyst ← decreasing intracystic pressure = sign of degeneration / trauma / host response / response to therapy:
  - √ localized split in wall with floating undulating membrane, CHARACTERISTIC but rare
  - √ "water lily" sign = complete detachment of membrane
  - ◊ Floating membrane does not indicate death of parasite!
- √ eggshell calcification in cyst wall (least common)

CT:
- √ well-demarcated round low-density mass of fluid attenuation of 3–30 HU (= mother cyst containing debris of hydatid sand + detached cyst walls):
  - √ round peripheral fluid collections of lower attenuation (= daughter cysts) arranged in CHARACTERISTIC wheel-spoke pattern
  - √ linear areas of increased attenuation = detached laminated floating membrane (after rupture of daughter cyst)
  - √ cyst wall of high attenuation on NECT
- √ enhancement of cyst wall + septations
- √ calcification of cyst wall / internal septa

MR:
- √ cyst with hypointense rim (= dense collagenous pericyst) on T1WI + T2WI
- √ peripheral cysts within cyst hypointense on T1WI + hyperintense on T2WI (= daughter cysts)
- √ twisted linear structures within cyst = collapsed parasitic membrane

Angio:
- √ avascular area with splaying of arteries
- √ halo of increased density around cyst (inflammation / compressed liver)

Cholangiography:
- √ cyst may communicate with bile ducts: right hepatic duct (55%), left hepatic duct

(29%), CHD (9%), gallbladder (6%), CBD (1%)

Local Cx:

(1) Rupture (50–90%)
  (a) contained = rupture of laminated membrane of endocyst, pericyst remains intact
    √ floating membranes
  (b) communicating = cyst contents escapes through biliary (5–15%) / bronchial tree
  (c) direct = tear of endocyst + ectocyst + pericyst with cyst contents spilling into pleural / peritoneal cavity → anaphylaxis, metastatic hydatidosis
(2) Infection (5–8%) following rupture
(3) Transdiaphragmatic growth (0.6–16%) through bare area of liver
  (a) rupture into pleural cavity
  (b) seeding in pulmonary parenchyma
  (c) chronic bronchial fistula
(4) Perforation into hollow viscus (0.5%)
(5) Peritoneal seeding (13%) = encysted peritoneal hydatidosis
(6) Compression of vital structures (bile ducts, portal vein)

Prognosis: usually favorable (but fatal if untreated); death from cholangitis / hepatobiliary septicemia (biliary obstruction with bacterial + fungal superinfection)

Hydatid Disease of Lung *(25%)*

= LUNG ECHINOCOCCOSIS

Source: (a) hematogenous spread from liver lesion
(b) transdiaphragmatic route (1–16% of hepatic disease) = migration of parasite from liver to pleural cavity

Frequency: 10–30% of hydatid disease
◊ Most common site of secondary involvement in children + 2nd most frequent site in adults
◊ Coexistence of liver + lung disease in 6%

- asymptomatic for months to years; eosinophilia (< 25%)
- fever, chest pain, sudden cough attacks:
  - hemoptysis, bilioptysis
  - expectoration of cyst fluid / membranes / scolices
- hypersensitivity reaction (if cyst rupture occurs)

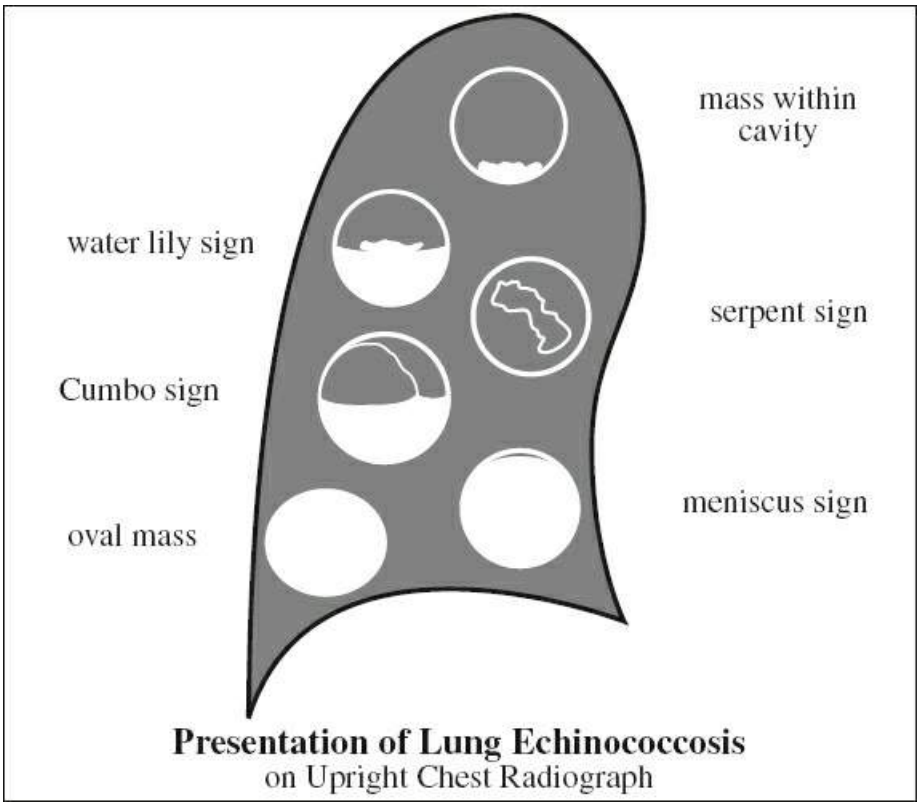
Location: lower lobes in 60%; bilateral in 20–50%

√ solitary (60–75%) / multiple (25–30%) spherical / ovoid masses with well-defined borders
√ size of 1–20 cm in diameter (16–20 weeks doubling time)
√ cyst communication with bronchial tree (= chronic bronchial fistula):
  √ "meniscus sign", "double arch" sign, "moon" sign, "crescent" sign (5%) = thin radiolucent crescent in uppermost part of cyst ← cyst erosion into adjacent bronchioles with air dissecting between pericyst and laminated membrane
  √ air-fluid level = rupture of all cyst walls with air entering the endocyst
  √ Cumbo / "onion peel" sign = air-fluid level inside endocyst + air between pericyst

and endocyst
√ "serpent" sign = collapsed membranes inside cyst outlined by air (after expectoration of cyst contents)
√ "water lily" sign, "sign of the camalote" = completely collapsed crumpled cyst membrane floating on cyst fluid
√ mass within cavity = crumpled membranes fall to most dependent portion of cavity after complete expectoration of cyst fluid
√ hydropneumothorax
√ calcification of cyst wall (0.7%)
√ rib + vertebral erosion (rare)
√ mediastinal cyst: posterior (65%), anterior (26%), middle (9%) mediastinum
Cx: pleuritis, lung abscess, parasitic pulmonary embolism, anaphylaxis ← cyst rupture, bacterial cyst superinfection (after cyst rupture)
DDx: metastasis, Wegener granulomatosis, other granulomatous diseases

Echinococcus Multilocularis

= E. ALVEOLARIS = ALVEOLAR ECHINOCOCCOSIS
= less common but more aggressive form of echinococcal dz.
Endemic to:
limited to Northern Hemisphere; western and central Europe (central + eastern France, southern Germany, western Austria, Switzerland), much of former Soviet Union, Iran, Iraq, some areas in Turkey, predominance in western and central China, northern Japan (Hokkaido Island), Midwestern USA, Arctic (Alaska, Canada, entire tundra)
Primary / definite host: (harbors 3–6 mm adult tapeworm)
(a) sylvatic life cycle (predominant): red fox, wolf, coyote
(b) domestic life cycle: dog; cat
Secondary / intermediate host: (harbors larva stage)
› sylvatic life cycle (predominant): small wild rodents (moles, lemmings, mice)
Accidental intermediate host:
human ingesting wild fruits, vegetable, water contaminated with fox / wolf feces; direct contact with fox /wolf; contact with dogs / cats that have ingested infested rodents



Path: diffuse infiltrative multivesicular mass (= persistence of larval forms without cyst maturation) resembling malignancy composed of many cysts of irregular shape + size (< 1 mm – 30 mm) associated with host reaction of fibrosis (chronic granuloma) + frequent central necrosis, cavitation, calcification; absence of clear margin between parasitic tissue + adjacent normal liver parenchyma

Histo: daughter cysts with thick lamellar wall arising on outer surface of original cyst rarely contain scolices; cyst has darkly staining thin outer laminar membrane and nonstaining delicate inner germinal layer; surrounded by inner zone of necrosis + outer layer of histiocytes and lymphocytes

Location: liver (access via portal vein / lymphatics); other organs in < 1% (lung, brain, bone)

- clinical manifestation 5–20 years after infection
- epigastric pain, jaundice, hepatomegaly, eosinophilia
- hemoptysis, chest pain, cough with expectoration, exertional dyspnea (with lung involvement)
- positive immunoserology for Em2 (E. multilocularis-specific native antigen isolated from metacestodes)

√ aggressive rapid growth pattern:
  √ geographic infiltrating lesion with ill-defined margins
  √ displacement of hepatic veins, portal vein, biliary tree
  √ regional atrophy of liver with capsular retraction ← biliary / vascular invasion

√ faint / dense amorphous coalescent nodular / flame-shaped calcifications = dystrophic central calcifications scattered throughout necrotic + granulomatous tissue (33–100%)

√ metastases to lung, heart, brain (in 10%)

Spread: widespread dissemination (2%)

› hematogenous: lung (7–20%), brain (1–3%)

› lymphatic: abdominal lymph nodes

› direct extension to / invasion of IVC, hepatic vein, diaphragm, trachea, lung, pericardium, esophagus, GI tract, retroperitoneum, perirenal space, peritoneum, gallbladder, pancreas, peripancreatic space, spleen, parietal wall (muscle, skin, bone [1%])

US (initially):

√ complex large heterogeneous mass mimicking a solid mass (70%):

√ juxtaposed areas of internal hyper- and hypoechogenicity with irregular margins

√ scattered foci of calcifications

√ pseudocyst with large area of central necrosis surrounded by an irregular ringlike region of hyperechogenicity (fibrous tissue)

√ "hailstorm pattern" = echogenic geographic ill-defined single / multiple hemangioma-like solid masses

√ pseudocyst with massive necrosis

DDx: benign liver cyst, cystadenoma, cystadenocarcinoma, hydatid disease

√ small calcified lesion

√ ± irregular cystic areas

√ distortion and displacement of hepatic + portal veins + biliary tree; invasion of IVC (on color Doppler)

√ propensity of spread to liver hilum:

√ dilatation of intrahepatic bile ducts

CT (morphologic assessment):

√ heterogeneous hypodense poorly marginated infiltrating masses

√ pseudocystic necrotic regions of near water density surrounded by hyperdense solid component

√ irregular ringlike region of often partly calcified fibrous tissue

√ little / no enhancement

MR (characterization of components):

√ fibrosis + parasitic tissue hypointense on T1WI

√ small cystic peripheral extensions + central necrosis hyperintense on T2WI

√ fibrotic collagenous components hypointense on T2WI

√ multivesicular structure resembling bunch of grapes / honeycomb

√ lesions hypointense on DWI (DDx to malignancy)

Kodama classification:

Type 1 (4%): multiple small cysts w/o solid component
Type 2(40%): multiple small cysts + solid component
Type 3 (46%): irregular large cysts + solid component
Type 4 (4%): solid without cysts
Type 5 (6%): single large cyst w/o solid component

Angio:

√ intrahepatic arterial tapering + obstruction

Cx: liver abscess (← superinfection by bacteria + fungi); secondary biliary cirrhosis;

portal hypertension (→ bleeding esophageal / duodenal varices); Budd-Chiari syndrome; obstruction of IVC; heart, lung, brain involvement

Prognosis: 50–75% mortality rate (higher for older age and poor local health care); death within 10–15 years if treatment not curative

Rx: radical surgery, liver transplantation, mandatory long-term benzimidazoles (antihelmintic drugs)

Dx: immunohistochemical + histologic analysis, serologic tests

DDx: cholangiocarcinoma, biliary cystadenoma + cystadeno- carcinoma, hepatocellular carcinoma (biopsy!), large hemangioma (characteristic enhancement pattern), metastasis, epithelial hemangioendothelioma

Alveolar Echinococcosis of CNS

Associated with: multicystic liver disease

√ heterogeneous solid / partially solid / cystic masses:

√ prominent surrounding edema (common)

√ heterogeneous ringlike / nodular cauliflower-like enhancement (typical)

√ calcifications

DDx: cerebral neoplasm

ECTOPIC PANCREAS

= PANCREATIC REST / CHORISTOMA = HETEROTOPIC PANCREAS = MYOEPITHELIAL HAMARTOMA

= presence of abnormally located pancreatic tissue with its own ductal system and NO vascular / neural / anatomic contact with normal pancreas

Frequency: 1–14% of population; M÷F = 2÷1

◊ Most common heterotopia within GI system!

- usually asymptomatic in GI tract (although stenosis, ulceration, bleeding, intussusception may develop)
- abdominal pain similar to peptic ulcer disease (77%)
- abdominal fullness (30%), melena (24%)
- functional: subject to usual pancreatic inflammatory + neoplastic disorders

Pathogenesis: metaplasia of multipotent endodermal cells; displacement and transplantation of pancreatic cells during embryonic development

Site: submucosa (in ½) / muscularis propria

Location: lesions may be multiple

(a) proximal portion of duodenum (30%): pylorus, duodenal bulb

(b) 2nd–4th portion of duodenum (20%)

(c) greater curvature of antrum 1–6 cm from pylorus (26%)

Prevalence: 1%–2%: in ¾ submucosal

(d) other small bowel (16%): proximal jejunum, ileum, Meckel diverticulum

(e) rarely in: colon, esophagus, gallbladder, bile ducts, liver, spleen, umbilicus, mesentery, mesocolon, omentum, fallopian tubes

Size: usually 0.5–2.0 (up to 5.0 cm in its largest diameter)

√ smooth cone- / nipple-shaped submucosal nodule 1–5 cm (rarely > 3–4 cm) in size

√ central umbilication representing orifice of filiform duct

CT:

√ flat / ovoid irregularly marginated intramural mass
√ homogeneously enhancing with intraluminal extension (= enhancement pattern similar to pancreatic tissue)
√ 5–20 mm small cystic change in markedly thickened wall of 2nd part of duodenum ← pseudocysts of groove pancreatitis / cystic dystrophy of duodenum / paraduodenal wall cysts

MR:
√ area with SI similar to native pancreas
√ ± surrounding inflammatory changes
√ PATHOGNOMONIC presence of ducts on MRCP

Endoscopic US:
√ solid mass of intermediate echogenicity

Cx: biliary + intestinal obstruction, massive GI bleeding, pancreatitis, paraduodenal pancreatitis, pseudocyst, insulinoma, malignant transformation

DDx of submucosal mass without umbilication:
Brunner gland adenoma, leiomyoma, lymphoma

EMBRYONAL RHABDOMYOSARCOMA OF BILIARY TREE

= rare tumor most commonly arising from CBD

Frequency: 1% of liver tumors in children

Median age: 3 years; < 5 years in 75%; M > F

Path: intraluminal biliary mass / cluster of grapelike masses (similar to rhabdomyosarcoma of bladder / vagina)

Histo: same as sarcoma botryoides; positive reactions for muscle markers

- jaundice (in 60–80%), abdominal distension, fever
- hepatomegaly, malaise, nausea, vomiting
- ↑levels of conjugated bilirubin + alkaline phosphatase

Metastases (in up to 30%):
retroperitoneal + mesenteric lymph nodes, lung

Location: common bile duct (most frequently) and intrahepatic bile ducts → invasion of liver

Size: 8–20-cm

√ bulky heterogeneous mass in porta hepatis
√ intrahepatic bile duct dilatation
√ regional lymphadenopathy
√ displacement / invasion of duodenum, stomach, pancreas

Cholangiography:
√ large bulky intraluminal mass / grapelike cluster of intraluminal masses → focally distending common bile duct + obstructing proximal bile ducts

US:
√ solitary heterogeneous hypoechoic mass
√ multiple hypoechoic nodules separated by septa
√ portal vein displacement without thrombosis
√ multiple tumor arteries with low-resistance spectrum

CT:

√ homo- / heterogeneous hypo- / hyperattenuating mass
√ ± prominent fluid component
√ NO / intense heterogeneous globular enhancement

MR:
√ T1 hypointense + T2 hyperintense / predominantly fluid-intensity mass in CBD or biliary radicals
√ heterogeneous intrahepatic mass with large areas of fluid

MRCP:
√ partially cystic mass within / adjacent to CBD causing mural irregularity of duct

Prognosis: 78% survival with local disease after multimodal therapy; total resection possible in 20–40%

DDx: choledochal cyst, infantile hemangioendothelioma, (intense peripheral nodular enhancement with centripetal fill-in), mesenchymal hamartoma of liver (predominantly cystic), hepatoblastoma (elevated AFP)

EPIDERMOID CYST OF SPLEEN

= EPITHELIAL CYST = PRIMARY CYST OF SPLEEN

Frequency: 10% of all benign nonparasitic cysts

Cause: infolding of peritoneal mesothelium / collection of peritoneal mesothelial cells trapped within splenic sulci

Histo:
(1) Mesothelial lining
(2) Squamous epithelial lining = epidermoid cyst
= squamous metaplasia from embryonic inclusions within preexisting mesothelial surface epithelium

Age: 2nd–3rd decade (average age of 18 years)

May be associated with: polycystic kidney disease

A. Unilocular + solitary (80%)
B. Multiple + multilocular (20%)

Average size: 10 cm

√ well-defined thin-walled anechoic lesion of water density
√ peripheral septations / cyst wall trabeculations (in 86%)
√ curvilinear calcification in wall (9–25%)
√ may contain cholesterol crystals, fat, blood

Cx: trauma, rupture, infection

EOSINOPHILIC CHOLANGIOPATHY

= rare benign cause of biliary obstruction

Prevalence: 15 cases in literature

Cause: unknown

Histo: transmural eosinophilic infiltration of biliary tract

A. Eosinophilic cholecystitis
B Eosinophilic cholangitis
C. Both

May be associated with: multiple organ involvement (in 50%) of GI tract, urinary tract, bone marrow, pancreas, lymph nodes

• jaundice ± peripheral eosinophilia

√ thickened bile duct wall ± biliary dilatation

√ wall irregularities in beaded pattern

Rx: steroids

DDx: lymphoma, AIDS cholangiopathy, collagen vascular disease, cholangiocarcinoma, amyloidosis

EPITHELIOID HEMANGIOENDOTHELIOMA

= rare primary low-grade malignant vascular tumor of liver (soft tissue, skin, bone, lung)

Incidence: 0.1÷100,000 annually

Average age: 44 (range, 25–58) years; M÷F = 2÷3

May be associated with: oral contraceptives, exposure to vinyl chloride

Path: multifocal nodules varying in size from a few mm to several cm involving both lobes of the liver ← rapid perivascular extension along hepatic + portal veins); nodules may coalesce in liver periphery

Histo: dendritic spindle-shaped cells + epithelioid round cells in a matrix of myxoid + fibrous stroma; neoplastic endothelial cells invade sinusoids + terminal hepatic + portal veins cutting off the tumor's blood supply; immunohistochemical stain with antibodies to factor VIII (von Willebrand factor), CD31 / CD34

• in 80%: RUQ abdominal pain, weakness, anorexia, jaundice

• hepatomegaly, weight loss

In 27–40% metastases to: lung, peritoneum, lymph nodes, bone, spleen, mesentery

Growth pattern:

(a) multifocal nodular form of early stage:

√ multiple predominantly peripheral nodules

(b) diffuse form of advanced stage:

√ coalescence of nodules into confluent masses

√ peripheral subcapsular growth (in 75%) without capsular bulge

√ capsular retraction (in 25–69%) ← fibrotic reaction

√ increased tumor vascularity

√ hypertrophy of uninvolved liver

Plain film:

√ hepatic calcifications within myxoid stroma (in 15%)

US:

√ individual / confluent nodules or diffusely heterogeneous echotexture

√ nodules with echogenicity unrelated to size:

√ hypoechoic ← central core of myxoid stroma

√ hyperechoic ± hypoechoic rim

√ isoechoic with hypoechoic halo

√ no blood flow

CT:

√ homogeneously ↓ attenuation ← myxoid + hyalinized stroma

√ capsular retraction in peripheral lesion

CECT:

√ target / halo pattern = nonenhanced outer rim of avascular tissue + enhanced inner peripheral rim

√ peripheral + progressive centripetal enhancement with incomplete fill-in on delayed phase

√ enhanced / nonenhanced tumor center on delayed imaging

MR:

√ central hypointensity on T1WI

√ "target" sign / concentric zones = alternating high- and low-signal–intensity rings on T2WI:

√ central zone of fibrosis / hemorrhage / necrosis

√ rim of cellular proliferation + edema

√ hyperintense center + thin rim of hypointensity on T2WI

CEMR:

√ multilayered targetlike appearance with prominent rimlike enhancement

√ central nodular enhancement (38%)

√ "lollipop" sign = synchronous targetlike enhancement of tumor mass + along hepatic / portal veins terminating at / near periphery

Angio:

√ hyper- and hypovascularity (dependent upon degree of sclerosis + hyalinization)

√ invasion ± occlusion of portal + hepatic veins

NUC:

√ decreased perfusion to central myxoid tumor portion + increased perfusion to cellular areas on sulfur colloid scan

√ photopenic defect on static sulfur colloid scan

√ NOT gallium avid

√ moderate to intense uptake on PET

Prognosis: 20% die within 2 years, 20% survive for 5–28 years ± treatment

Rx: liver transplantation (without spread); radical resection; transarterial chemoembolization

DDx of single nodule: cholangiocarcinoma; confluent hepatic fibrosis in advanced cirrhosis; treated HCC, large atypical cavernous hemangioma

DDx of multiple nodules: metastatic disease, angiosarcoma

DDx of diffuse form: sclerosing carcinoma; vasoocclusive disease

FASCIOLIASIS

= infection by trematode Fasciola hepatica (liver fluke)

Life cycle:

miracidia infests freshwater snails → multiply + excreted as cercariae → ingested as contaminated water by sheep / cattle / human → metacercariae encyst in stomach → perforate duodenal wall → migrate into peritoneal cavity → perforation of liver capsule by fluke (= hepatic phase) digesting hepatocytes forming clusters of small peripheral sterile necrotic cavities + tunnel-shaped microabscesses → parasites become established in biliary ducts (= biliary phase), mature and release eggs into bile ducts → move into central + extrahepatic bile ducts + gallbladder to accommodate increasing size of parasite

Endemic to: South America, Asia, Africa, Europe, USA

• fever, abdominal pain, hepatomegaly, eosinophilia, biliary colic

CT:

√ multiple serpentine branching hypoattenuating subcapsular lesions pointing toward central liver

√ "tunnels and caves" sign = multiple clustered hypoattenuating nodules

US:

√ intrabiliary filling defects + biliary dilatation

√ wall thickening of extrahepatic ducts and gallbladder

FATTY LIVER

= FATTY INFILTRATION OF THE LIVER = HEPATIC STEATOSIS

= accumulation of triglyceride droplets in hepatocytes

N.B.: no fatty infiltration of liver parenchyma

Prevalence: 15–35% in general population; > 60 g alcohol daily (45%); hyperlipidemia (50%); obesity with body mass index > 30 kg/m² (75%); obesity coupled with high alcohol consumption (95%)

Mechanism: injury to mitochondrial structure / processes (β-oxidation, energy depletion) of hepatocytes

Cause:

A. METABOLIC DERANGEMENT

metabolic syndrome (= obesity, insulin resistance, hypertriglyceridemia), acute fatty liver of pregnancy, protein malnutrition (kwashiorkor, marasmus), starvation, total parenteral hyperalimentation / nutrition (TPN), malabsorption (jejunoileal bypass), glycogen storage disease, Wilson disease, glycogen synthetase deficiency, cystic fibrosis, Reye syndrome, corticosteroids, severe hepatitis, trauma, chronic illness (TB, CHF), chemotherapy

B. HEPATOTOXINS

alcohol, carbon tetrachloride, arsenic, phosphorus

Common drugs: 5-fluorouracil, irinotecan, methotrexate, amiodarone, tamoxifen, corticosteroids, antipsychotics

C. INFLAMMATION

chronic viral hepatitis C > B, chronic autoimmune hepatitis

Path: > 5% fat of total liver weight

Histo: hepatocytes with large cytoplasmic fat vacuoles containing triglycerides (= steatosis) ← defects in free fatty acid metabolic pathways

Location: most pronounced + earliest around central vein

Histopathologic analysis of biopsy specimens allows:

(1) Grading of severity of steatosis
(2) DDx between steatosis and steatohepatitis
(3) Confirmation of nonalcoholic fatty liver disease / nonalcoholic steatohepatitis
(4) Detection of unsuspected coexisting disease like viral hepatitis.

• most common cause of elevated liver function tests

Pattern of fat deposition: diffuse (most common), focal, multifocal, perivascular, subcapsular

√ rapid change with time (few days to > 10 months) depending on clinical improvement (abstinence from alcohol, improved nutrition) + degree of severity + early stage

Cx: steatohepatitis (inflammatory cell injury), cirrhosis

Acute Fatty Liver of Pregnancy

Time: during late 3rd trimester

- slowly evolving right upper quadrant / epigastric pain
- jaundice
- symptoms of preeclampsia: HTN, edema, proteinuria

√ hepatomegaly + diffuse fatty change of liver

Diffuse Fat Deposition in the Liver

◊ Most frequently encountered pattern

√ hepatomegaly (75–80%) / normal sized liver

Plain film:

√ "radiolucent liver" sign = enlarged radiolucent liver

US (60–100% sensitive, 77–95% specific, 85–97% accurate):

√ liver echogenicity exceeds that of renal cortex / spleen:

√ fine (more typical) / coarse hyperechogenicity

√ increased sound attenuation:

◊ Attenuation of sound beam (= scattering of sound beam) is a feature of fat, NOT fibrosis

√ poor definition of posterior aspect of liver / diaphragm

√ decreased visibility of portal triads

√ poor delineation of intrahepatic architecture

√ impaired visualization of borders of hepatic vessels

NECT (43–95% sensitive, 90% specific):

An increase in fat content leads to a decrease in CT numbers at low energy. With higher energy levels the fat attenuation values are higher as well.

› relative criteria with internal control:

√ attenuation of liver less than that of intrahepatic vessels (= marked steatosis)

√ density of liver at least 10 HU less than that of spleen

√ hepatosplenic attenuation difference (Δ = L – S)

The spleen serves as a good internal control for comparison with the liver because:

› splenic attenuation is unaffected by various diffuse pathologic processes

› spleen is located at the same cross section as liver

At NECT, a normal liver has higher attenuation than a normal spleen. A lower liver attenuation suggests a diagnosis of hepatic steatosis.

Δ > 5 HU no macrovesicular steatosis (0–5%)

Δ -10 to 5 HU mild to moderate steatosis (6–30%)

Δ < -10 HU steatosis of > 30%

√ ratio of liver÷spleen < 1

◊ A hepatic attenuation index of < 0.8 is 100% specific for > 30% macrovesicular steatosis

The hepatic attenuation index is an objective measure of fatty liver disease.

› absolute criteria:

√ liver attenuation of < 48 HU; of < 40 HU = 30% fat

64.4 ± 3.1 HU	0% fat	41.9 ± 6.7 HU	26–50%
59.1 ± 7.3 HU	1–25%	25.0 ± 15.5 HU	> 50%

CECT:
- √ absolute liver attenuation < 40 HU (limited sensitivity)
- √ liver attenuation < musculature (marked steatosis)

Dual-energy CT (scans at 140 + 80 kVp):
- √ hepatic steatotic attenuation changes more marked with a change in tube potential compared to normal liver
- ◊ Tube current variation (from 200 to 50 mAs) does not affect the mean tissue attenuation values!

NUC:

^{99m}Tc-sulfur colloid scan:
- √ diffuse heterogeneous uptake (68%)
- √ reversal of liver-spleen uptake (41%)
- √ increased bone marrow uptake (41%)

^{133}Xe ventilation scan:
- √ increased activity during washout phase (38%)

MR (81% sensitive, 100% specific):
- √ slightly higher signal intensity on T1WI + T2WI; relatively insensitive (10% fat by weight will alter SE signal intensities by only 5–15%)
- √ signal loss on out-of-phase (= opposed-phase) compared to in-phase images / fat turns black with Dixon technique (chemical shift imaging):
  Explanation: difference in precession frequencies for protons in fat ($–CH_2$) and water (–OH)
  - √ estimation of liver fat content by comparing liver tissue to spleen and muscle as internal references
  - √ quantifiable by degree of SI loss
- √ chemical fat saturation sequence (usually less sensitive but superior in the presence of cirrhosis)
- √ MR spectroscopy (most accurate noninvasive method)

The advantage of MR spectroscopy is its ability to determine the absolute liver fat concentration. It has a high sensitivity for detecting small amounts of hepatic triglycerides.

Focal Fat-Sparing in Diffuse Fatty Liver

Cause: disturbance in portal venous flow / direct drainage of systemic blood into liver

Characteristic locations:
(a) in porta hepatis = posterior edge of segment 4 anterior to portal vein bifurcation ← drainage of aberrant gastric vein
(b) next to gallbladder bed (drainage of cystic vein)
(c) adjacent to falciform ligament / ligamentum venosum
(d) subcapsular skip areas

- √ geographic configuration

√ poorly delineated margins
√ contrast enhancement similar to normal liver
√ pseudolesion = NO mass effect (= undisplaced course of intrahepatic vessels)

US:

Relative Frequency of Causes of Fatty Liver

Most common	*Common*	*Rare*	*Congenital*
Alcohol overuse	Viral infection	Nutritional / dietary	Storage disorders
Insulin resistance	Hepatitis C	TPN	Glycogen storage disease
Obesity	Hepatitis B	Rapid weight loss	a_1-Antitrypsin deficiency
Hyperlipidemia	Drug use	Starvation	Wilson disease
	Steroids	Jejunoileal bypass	Hemochromatosis
	Chemotherapy	Irradiation	Cystic fibrosis
	Amiodarone		Others:
	Valproic acid		Prader-Willi syndrome, Bardet-Biedl syndrome, Metabolic disorders

√ hypoechoic ovoid / spherical / sheetlike mass

CT:

√ hyperattenuating relative to surrounding liver

MR:

√ hyperintense on T1WI
√ lack of decrease in SI on opposed-phase gradient-echo T1WI

DDx: mass (round / ovoid shape, well-demarcated margins, no fat content, random location, mass effect + displacement of vessels, contrast uptake above that of normal liver)

Focal Fat Deposition in the Liver

Etiology: (?) relative ischemia due to ↓ portal venous flow / ↓ delivery of unknown substances via portal vein

Key factor: ↑ levels of insulin in portal venous blood

Distribution:
(a) lobar / segmental uniform lesions
(b) lobar / segmental nodular lesions
(c) perihilar lesions
(d) diffuse nodular lesions = multifocal
(e) diffuse patchy lesions

Location:

› periligamentous: along falciform ligament and fissure for ligamentum teres, and medial aspect of left lobe ← aberrant internal mammary + paraumbilical veins
› perihilar: within anterior aspect of segment IV adjacent to porta hepatis ← aberrant right / left gastric veins
› pericholecystic: ← aberrant cholecystic vein
› subcapsular: around perforating capsular vessels
› perivascular: predominantly in centrilobar + periportal regions ← variants of blood supply = "third inflow" from connections between peripheral portal radicles + systemic veins

√ fan-shaped lobar / segmental distribution with angulated / interdigitating geographic

margins
√ lesions extend to liver capsule
√ pseudolesion = NO mass effect ← undisplaced course of vessels, no bulging of liver contour
√ perivenous halo of fat (= tram- / ring-like configuration on cross sections) around hepatic veins / portal veins / both

US:
√ hyperechoic area with poorly defined / sharp margins
√ multiple / rarely single echogenic nodules simulating metastases (rare)

CT:
√ patchy areas of decreased attenuation ranging from –40 to +10 HU (DDx: liver tumor)
√ NO contrast enhancement

MR:
√ high signal on T1WI + low / isointense signal on T2WI
√ decreased SI on opposed-phase gradient-echo T1WI relative to in-phase imaging

NUC with colloid:
√ no significant changes on sulfur colloid images (SPECT imaging may detect focal fatty infiltration)

DDx: primary / secondary hepatic tumor; fat-containing regenerative nodules of liver cirrhosis

Hepatic Subcapsular Steatosis

= in patients with renal failure and insulin-dependent diabetes, insulin can be delivered in peritoneal dialysate

Pathophysiology:
intraperitoneal insulin → subcapsular hepatocytes exposed to higher concentration of insulin → blocks oxidation of free
fatty acids within hepatocytes → preferential esterification into triglycerides → accumulation of intracellular fat

√ unique subcapsular pattern of fatty infiltration

FOCAL NODULAR HYPERPLASIA

= FNH = 2nd most common benign tumor of liver after hemangioma

Prevalence: 0.9%; 3–8% of all primary hepatic tumors in adult population, 2–4% in pediatric population (typically between 2 and 5 years); twice as common as hepatocellular adenoma

Cause: (?) circulatory disturbance or reparative process in areas of focal injury → triggers focal hepatocellular hyperplasia owing to a regional increase in blood flow
◊ Oral contraceptives DO NOT cause FNH, but exert a trophic effect on its growth!

Path: localized well-delineated usually solitary (80–95%) subcapsular mass composed of numerous small nodules within an otherwise normal liver; NO true capsule; frequently central fibrous scar in area of interconnection of fibrous bands (HALLMARK); angioarchitecture typically has one / more thick-walled arteries within fibrous septa radiating from the center toward the periphery → dividing into numerous capillaries

connected to sinusoids → drained by large hepatic veins (NO portal veins!)

Histo: composed of multiple spherical aggregates of hyperplastic hepatocytes often containing increased amounts of fat (in 50%) + triglycerides + glycogen; high number of Kupffer cells line sinusoids; proliferation of small bile ducts within fibrous septa without connection to biliary tree; difficult differentiation from regenerative nodules of cirrhosis + hepatocellular adenoma

Pathologic classification:

A. Classic FNH (80%):
abnormal nodular architecture, malformed vessels, cholangiolar proliferation

B. Nonclassic FNH (20%) without septa / central scar:
◊ Difficult to differentiate from other liver masses by imaging
(a) telangiectatic FNH (15%)
(b) FNH with cytologic atypia (3%)
(c) mixed hyperplastic + adenomatous FNH (2%)
√ globally resembling hepatic adenoma
√ no prominent septa
√ vaguely lobulated contours
√ central scar (in only 4%)

Age peak: 3rd–4th decade (range, 7 months to 75 years); M÷F = 1÷2 to 1÷8

Associated with: hepatic hemangioma (in 23%), meningioma, astrocytoma, arterial dysplasia of other organs in case of multiple FNH

- initially often asymptomatic (in 50–90% incidental discovery)
- vague abdominal pain (10–15%) ← liver capsule distention / mass effect on adjacent organs / blood flow variations
- normal liver function + normal AFP
- hepatomegaly / abdominal mass

Location: right lobe÷left lobe = 2÷1; multiple in 5–20%

Mean size: 4 cm in diameter; < 5 cm (in 85%)

√ well-circumscribed nonencapsulated nodular cirrhotic-like mass in an otherwise normal liver:
√ often near liver surface
√ pedunculated mass (in 5–20%)
√ multiple masses (in 20%)

√ central stellate scar = central fibrous core (NOT true scar) with radiating fibrous septa containing congeries of arteriovenous malformation [*congerere*, Latin = to collect, heap up]
√ spoke-wheel pattern (in 50% on average, in 80% if > 3 cm) (DDx: fibrolamellar HCC)

√ highly vascular tumor:
√ supplied by enlarged anomalous hepatic artery
√ venous drainage always into hepatic veins (DDx: HCC drains into portal venous system in 98%)
√ hemorrhage is unlikely

√ pseudocapsule of a few mm in thickness ← surrounding compressed hepatic parenchyma, perilesional vessels, inflammatory reaction:
√ fuzzy margins

√ calcifications EXTREMELY rare
NECT:
√ iso- / slightly hyperattenuating homogeneous mass
CECT (3 phases necessary!):
› arterial phase (30–60 sec after bolus injection):
√ transient intense hyperdensity of most of the lesion except for central scar
√ hypodense central scar (15–33%)
› portal venous phase:
√ early washout into hyperdense draining vein
√ lesion becomes isodense
› delayed / equilibrium phase:
√ lesion remains isodense
√ hyperdense central scar ← delayed washout of contrast from myxomatous scar tissue
US:
√ iso- / mildly hypo- / mildly hyperechoic (33%) homogeneous mass
√ hypoechoic halo (of compressed liver parenchyma / displaced hepatic vessels)
√ hyperechoic central scar in 18%
Doppler:
√ enlarged afferent blood vessel with central arterial hypervascularity + centrifugal filling to the periphery in a "spoke-wheel" pattern
√ large draining veins at tumor margins
√ may show high-velocity Doppler signals with arterial pulsatility from arteriovenous shunts (DDx: hepatocellular adenoma has intratumoral venous flow)
MR (70% sensitive, 98% specific, requires 3 phases):
√ usually homogeneous signal intensity of lesion
› T1WI:
√ iso- to mildly hypointense (94%)
√ atypically hyperintense lesion in 6%
√ T2WI: isointense / mildly hyperintense (94–100%)
√ central scar (more often detected than on US / CT)
√ hypointense on T1WI
√ hyperintense on T2WI in 75–84% ← edema within myxomatous tissue + vascular channels + bile ductules
√ hypointense on T2WI in 25% ← absent / minimal edema
CEMR (2-D / 3-D GRE):
√ marked homogeneous enhancement in arterial phase fading to isointensity on delayed image
√ iso- to slightly hyperintense during portal venous / delayed phase relative to liver
√ occasionally slightly hyperenhancing in equilibrium phase ← entrapment of Gd-DTPA by functioning hepatocytes inside tumor followed by 1% excretion into biliary tree
√ central scar after Gd-chelate administration:
√ low SI on early phase of enhancement
√ late + prolonged enhancement of central scar ← enlarged interstitial space with increased fluid content (gradually taking up contrast material)
√ enhancement of pseudocapsule on delayed images

√ homogeneously iso- to hyperintense (in 96%) / peripheral ring enhancement on 1-hour delayed images with hepatocyte-specific contrast agent (eg, gadobenate dimeglumine [Gd-**B**enzyl**O**xy**P**ropionic**T**etra**A**cetate]) (DDx: adenomas never enhance)

√ less uptake of IV superparamagnetic iron oxide (ferucarbotran, mangafodipir trisodium) than surrounding liver (= uptake mechanism similar to that of sulfur colloid)

◊ Use iron oxide in lesions with atypical features!

NUC:

Sulfur colloid scan:

◊ Only FNH contains sufficient Kupffer cells to cause uptake:

√ normal uptake (60–75%)

√ increased uptake = virtually DIAGNOSTIC

√ cold spot (33%) ← less Kupffer cells (DDx: hepatic adenoma, hemangioma, hepatoblastoma, liver herniation, hepatocellular carcinoma)

Tc-HIDA:

√ increased uptake (90%), normal uptake, cold spot (10%) with delayed excretion ← biliary ductules in FNH not communicating with biliary tree

^{99m}Tc-tagged RBCs:

√ increased uptake during early phase

√ defect relative to liver on delayed images

Angio:

√ discretely marginated hypervascular mass (90%) with intense capillary blush / hypovascular (10%)

√ enlargement of main feeding artery with central blood supply (= "spoke-wheel" pattern in 33%)

√ homogeneous parenchymal stain

√ decreased vascularity in central stellate fibrous scar

Rx: (1) Discontinuation of oral contraceptives
(2) Resection of pedunculated mass
(3) Diagnostic excisional biopsy for extensive tumor (FNH seldom requires surgery)
(4) Conservative in asymptomatic patient

Cx: rarely rupture with hemoperitoneum (increased incidence in patients on oral contraceptives – 14%)

DDx:

(1) Fibrolamellar carcinoma (metastases, retroperitoneal adenopathy, tumor hemorrhage + necrosis causing pain, collagenous calcified hypointense scar on T2WI)
(2) Hepatic adenoma (10 cm large tumor, symptomatic due to propensity for hemorrhage in 50%, central scar atypical, use of oral contraceptives)
(3) Well-differentiated hepatocellular carcinoma (internal necrosis + hemorrhage, vascular invasion, metastases, persistent rim-enhancement of tumor capsule)
(4) Giant cavernous hemangioma (larger tumor, may calcify, globular peripheral enhancement followed by centripetal filling, retention of contrast on delayed images, central scar with CSF-like behavior on MR)
(5) Hypervascular metastasis (hypovascular during portal venous phase, in older patient)
(6) Intrahepatic cholangiocarcinoma (less vascular, dominant large central scar, metastases)

Multiple Focal Nodular Hyperplasia Syndrome

(1) Liver hemangioma
(2) Berry aneurysm
(3) Meningioma, astrocytoma
(4) Systemic arterial dysplasia & portal vein atresia

Telangiectatic Focal Nodular Hyperplasia

Frequency: 10% of all FNH
Mean age: 38 years; women
Associated with: oral contraceptives (mean time, 15 years)
Mean size: 7 cm
√ multiple lesions in 20–50%
√ strong arterial enhancement
√ persistent lesion enhancement (61%) ← sinusoidal dilatation
√ absence of a central scar (92%)
√ heterogeneous pattern (43%) ← necrosis, sinusoidal dilatation, hemorrhagic foci
MR:
√ hyperintensity on T1WI (53%) ← intrasinusoidal dilatation
√ strong hyperintensity on T2WI (44%)
DDx: hepatic adenoma

GALLBLADDER ADENOMA

Incidence: 0.15% of cholecystectomy specimens, 4–7% of all gallbladder polyps
• usually incidental finding, rarely symptomatic
May be associated with: primary sclerosing cholangitis, gastrointestinal polyposis syndromes (Peutz-Jeghers, Gardner syndrome)
√ sessile / pedunculated mass:
√ solitary (in ⅔); 2–5 in number (in ⅓)
√ up to 20 mm in size
√ internal vascularity at color Doppler interrogation
√ typically enhancing (DDx adenocarcinoma)
Prognosis: dysplasia-to-carcinoma sequence
◊ Adenomas >12 mm in diameter may exhibit malignancy
DDx: polypoid gallbladder adenocarcinoma (NO reliable differentiation)

GALLBLADDER CARCINOMA

Incidence: 0.4–4.6% of biliary tract operations; 5th most common gastrointestinal malignancy worldwide (after colon, pancreas, stomach, liver, esophagus); 3% of all intestinal neoplasms; 7,000 new cases annually in USA
◊ Most common biliary cancer (9 x more common than extrahepatic bile duct cancer)
Prevalence: 3÷100,000 (USA)
Demographics: most common in Israel, Bolivia, Chile, northern Japan, New Mexico
Ethnicity: Native Americans + Hispanic Americans (with increased prevalence of gallstones)

Median age: 72 years; M÷F = 1÷3 to 1÷4; whites > blacks
◊ 85% occur in 6th decade or later!

Risk factors: gallstones; increased body mass; female gender; postmenopausal status; cigarette smoking; exposure to chemicals (rubber, automobile, wood finishing, metal fabricating industries); chronic Salmonella typhi infection

Associated with:

(1) Disorder of gallbladder:
  (a) Cholelithiasis in 74–92%
    ◊ Gallbladder carcinoma occurs in only 1% of all patients with gallstones!
  (b) Porcelain gallbladder (in 4–60%): prevalence of gallbladder carcinoma in 10–25% of autopsies
  (c) Chronic cholecystitis
  (d) Gallbladder polyp: a polyp > 2 cm is likely malignant!
(2) Disorder of bile ducts:
  (a) Primary sclerosing cholangitis (PSC)

In patients with primary sclerosing cholangitis 60% of gallbladder polyps are malignant.

  (b) Congenital biliary anomalies: most types of choledochal cyst, cystic dilatation of biliary tree, anomalous junction of pancreaticobiliary ductal union, low insertion of cystic duct
(3) Inflammatory bowel disease (predominantly ulcerative colitis, less common in Crohn disease)
(4) Familial polyposis coli

Path: diffusely infiltrating lesion (68%), intraluminal polypoid growth (32%)

Histo:

(a) adenocarcinoma (90%):
  › papillary (6%): densely cellular papillary fronds protruding into GB lumen with dysplasia and increased mitoses
  › intestinal type (= variant of well-differentiated adenocarcinoma with intestinal glands)
  › mucinous (5%, with > 50% extracellular mucin)
  › signet-ring cell (abundant intracytoplasmic mucin)
  › clear cell (well-defined cytoplasmic borders)
(b) rare epithelial cell types (10%): poorer prognosis
  › adenosquamous carcinoma (3%)
  › squamous cell carcinoma (1%)
  › small (oat) cell carcinoma (0.5%, highly aggressive, ± paraneoplastic Cushing syndrome)
  › undifferentiated carcinoma
(c) nonepithelial cell types (2%):
  carcinoid, carcinosarcoma, basal cell carcinoma, lymphoma

Modified Nevin Stage:

I mucosa only (in situ carcinoma)
II mucosa + muscularis invasion
III mucosa + muscularis + serosa
IV gallbladder wall + lymph nodes

V hepatic / distant metastases

- Early diagnosis usually unsuspected ← lack of specific signs + symptoms:
  - history of past GB disease (50%)
  - malaise, vomiting, weight loss; chronic RUQ pain (54–76%)
  - obstructive jaundice (35–74%)
  - abnormal liver function tests (20–75%)
  - ± elevated α-fetoprotein and CEA

Location: fundus (60%), body (30%), neck (10%)

Growth types:

√ mass replacing the gallbladder (37–70%) with engulfed gallstones

√ irregular eccentric thickening of GB wall (20–30%) ← submucosal spread:

√ focal (59%) / diffuse (41%) wall thickening

DDx: acute / chronic inflammation (usually < 10 mm)

√ intraluminal polypoid / fungating "cauliflower-like" mass with wide base (15–25%)

√ pericholecystic infiltration: in 76% focal, in 24% diffuse

√ dilatation of biliary tree (38–70%):

√ infiltrative tumor growth along cystic duct

√ lymph node enlargement causing biliary obstruction

√ intraductal tumor spread

√ fine granular / punctate flecks of calcification (= mucinous adenocarcinoma)

√ lymph node enlargement in porta hepatis

N.B.: misdiagnosis by US / CT in 50%, especially in the presence of gallstones

Abdominal radiograph:

√ calcified gallstones

√ porcelain gallbladder

√ RUQ gas collection (after invasion of adjacent bowel)

Cholangiography:

√ malignant stricture / obstruction of extrahepatic bile ducts / right + left bile duct confluence, intrahepatic duct of right lobe

√ intraluminal GB filling defect (= tumor / stones)

√ mass displacing / invading gallbladder

√ intraductal filling defects (= tumor / stones)

US:

√ gallbladder replaced by mass with irregular margins + heterogeneous echotexture (= tumor necrosis)

√ immobile intraluminal well-defined round / oval polypoid mass (15–25%) hypoechoic relative to liver

DDx: tumefactive sludge

Clues to polypoid malignancy:

√ solitary polyp > 10 mm

√ wide polyp base

√ focal wall thickening > 3 mm

√ coexisting gallstones

√ focal / diffuse thickening of gallbladder wall (20–30%)

√ echogenic foci = coexisting gallstones / wall calcifications / tumoral calcification

√ tumor inseparable from liver
√ hypovascular on color Doppler

CT:
√ hypo- / isoattenuating mass in gallbladder fossa:
√ low-attenuation areas of necrosis
√ areas of enhancement (= viable tumor)
√ subtle extension beyond wall of GB
√ invasion of liver (40–65%) with protrusion of anterior surface of medial segment of left lobe

MR:
√ hypointense mass on T1WI relative to liver
√ ill-defined early contrast enhancement
√ hyperintense mass on T2WI
√ lower apparent diffusion coefficient than for benign lesion

PET:
√ FDG uptake within GB polyp greater than liver background

Metastases: in 75–77% at time of diagnosis

(a) direct extension (most common mode): invasion of liver (34–65–89%), duodenum (12–15%), colon (9–15%), pancreas (6%), stomach, bile duct, right kidney, abdominal wall
Cause: thin GB wall with only a single muscle layer + no substantial lamina propria + perimuscular connective tissue continuous with interlobular connective tissue of liver

(b) lymphatic spread (26–41–75%):
cystic, pericholedochal, celiac, superior mesenteric, foramen of Winsløw, paraaortic nodes, superior + posterior pancreaticoduodenal

(c) intraperitoneal seeding (common)

(d) hematogenous spread (less common): stomach, duodenum, liver, lung, bones, heart, pancreas, kidney, adrenal, brain

(e) neural spread (frequent): associated with more aggressive tumors

(f) intraductal spread (least common): particularly in papillary adenocarcinoma

Cx: perforation of gallbladder → abscess formation
√ gallstones located within abscess

Prognosis: 75% unresectable at presentation; average survival is 6 months; 5% (< 5%) 1-year (5-year) survival rate

DDx: (1) Xanthogranulomatous cholecystitis (lobulated mass filling gallbladder + stones)
(2) Acute / chronic cholecystitis (generalized gallbladder wall thickening < 10 mm)
(3) Liver tumor invading gallbladder fossa
(4) Tumors from adjacent organs: pancreas, duodenum
(5) Metastases: melanoma, leukemia, lymphoma
(6) Polyps: cholesterol ~, hyperplastic ~, granulation polyp
(7) Adenomyomatosis

GALLBLADDER TORSION

= rare cause of abdominal pain (1÷365,520 hospital admissions)
At risk: generalized loss of elastic + adipose tissue, kyphoscoliosis, calcification of cystic artery
Cause: abnormal / absent mesenteric fixation of GB to inferior margin of liver ("floating GB")
Age: elderly; M÷F=16%÷84%
A. INCOMPLETE torsion = rotation < 180°
- mimics biliary colic with recurrent episodes of pain

B. COMPLETE torsion = rotation > 180°
- acute RUQ pain, nausea, vomiting, ± palpable mass

√ gallbladder wall thickening + adjacent free fluid
√ gallbladder hydrops ← cystic duct obstruction
√ ectopic anterior / inferior GB location
√ cystic duct to right of GB + tapering / twisting of cystic duct
Cx: perforation ← necrosis ← impaired venous drainage

GLYCOGEN STORAGE DISEASE

= autosomal recessive diseases with varying severity and clinical syndromes (13 different types, 8 affect the liver)
◊ Type Ia and Ib are associated with hepatocellular carcinoma!
◊ Type III and IV progress to cirrhosis!
◊ Type I and III are associated with hepatic adenomas!
◊ Hepatomegaly + hypoglycemia + growth retardation + disproportional distribution of body fat in children consider glycogen storage disease!

Von Gierke Disease (Type Ia)

Etiology: defect in glucose-6-phosphatase with excess deposition of glycogen in liver, kidney, intestines
Dx: failure of rise in blood glucose after glucagon administration
Age at presentation: infancy
@ Liver
√ hepatomegaly
US:
√ increased liver echogenicity (glycogen / fat)
√ nephromegaly
CT:
√ increased (glycogen) / normal / decreased (fat) parenchymal attenuation

@ Kidney
- proximal + distal tubular dysfunction; hyperuricosuria
- focal segmental glomerulosclerosis
- Fanconi-like syndrome

√ nephromegaly
√ increased cortical + medullary echogenicity ← nephrocalcinosis, nephrolithiasis
√ amyloidosis
√ high renal blood flow
Prognosis: death in infancy, may survive into adulthood with early therapy

Cx: (1) Hepatic adenoma (in 22–75% of adults)
(2) Hepatocellular carcinoma (10% risk)

Pompe Disease (Type II)

= abnormal metabolism with enlargement of myocardial cells ← glycogen deposition; similar to endocardial fibroelastosis
Etiology: defect in lysosomal glucosidase
√ massive cardiomegaly with CHF
√ hepatomegaly
Prognosis: sudden death in 1st year of life ← conduction abnormalities; survival rarely beyond infancy

Forbes / Cori Disease (Type III)

Cx: hepatic adenoma, cirrhosis

Anderson Disease (Type IV)

Cx: cirrhosis

McArdle Disease (Type V)

Hers Disease (Type VI)

HEMOCHROMATOSIS

= pathologic state of intracellular iron accumulation / excess iron deposition in various parenchymal organs (liver, pancreas, spleen, kidneys, heart) leading to cirrhosis with portal hypertension
• Lab tests (of low sensitivity + specificity):
  • ↑ ferritin level; ↑ transferrin saturation index
Role of imaging:
(1) Clinically silent disease often first uncovered by imaging
(2) Monitor effectiveness of clinical treatment noninvasively
NECT (63% sensitive + 96% specific in iron overload):
√ diffuse / rarely focal increase in liver density (> 72 HU)
√ depiction of portal + hepatic veins against background of hyperattenuating liver
√ dual energy CT (at 80 + 120 kVp) can quantitate amount of iron deposition
◊ Superimposed steatosis reduces sensitivity!
◊ Wilson disease, colloidal gold treatment, long-term amiodarone treatment decreases specificity!
MR: (skeletal muscle = good SI reference)
◊ Effect proportional to field strength!
@ Liver

MRI is the best noninvasive method for measuring the level of iron in the liver with high sensitivity, specificity, positive and negative predictive values to:
› confirm the diagnosis
› determine severity

› monitor therapy.

The liver parenchyma demonstrates higher SI than the paraspinal musculature on all sequences. Slight to moderate iron overload is better identified on GRE images → decreased SI of the liver parenchyma.

√ T1 + T2 + T2* shortening proportional to iron deposition

Physics: paramagnetic susceptibility of ferritin and ferric ions leads to profound shortening of longitudinal relaxation time T1 + transverse relaxation time T2, particularly T2*, of adjacent protons; ↓ SI in affected organs is proportional to iron deposition

√ decreased SI on in-phase compared with out-of-phase images (opposite to steatosis)

√ quantification of amount of iron overload on GRE sequences with T2* weighting + progressively longer echo times

Dx: liver biopsy (= standard method for diagnosis) to

› quantify iron overload
› determine prognosis based on level of hepatopathy
› monitor evolution of disease
› monitor effects of treatment

Genetic Hemochromatosis

= IDIOPATHIC / PRIMARY / HEREDITARY HEMOCHROMATOSIS

= genetic defect in iron transport with excessive duodenal absorption + parenchymal retention of normal intake of dietary iron favoring accumulation within non-RES organs

◊ Clinically more severe than transfusional hemosiderosis!

Cause: autosomal recessive disorder (abnormal HFE gene located near human-leukocyte antigen [HLA] on short arm of chromosome 6) → excessive absorption of intestinal iron (2–3 x of normal population)

Prevalence: 1÷220 whites of northern European ancestry; homozygote frequency of 0.25–0.50%; heterozygote carriers in 10%

◊ Most common genetic disease in Caucasians in USA

Pathophysiology:

absorbed iron is selectively bound to transferrin; increased transferrin saturation in portal circulation favors selective iron uptake initially by periportal hepatocytes → excess iron stored as crystalline iron oxide (= ferric oxyhydroxide [Fe_2O_3]) within cytoplasmic ferritin + lysosomal hemosiderin; → spread to rest of liver, pancreas, thyroid → cellular damage, organ dysfunction, malignancy (→ if untreated), progression to cirrhosis, HCC, diabetes, cardiac dysfunction

N.B.: iron overload affects parenchymal cells, NOT the reticuloendothelial system (Kupffer cells + RES cells of bone marrow + spleen)!

Organ distribution: liver, pancreas, heart, anterior pituitary, thyroid, synovium, skin

◊ RES cells are incapable of storing excess iron!

Age: after middle age; female iron loss during menses and pregnancy provides some protection

- asymptomatic during 1st decade of disease
- symptomatic in 80–90% if iron deposits > 10 g
- hyperpigmentation = bronzing of skin (90%)

- hepatomegaly (90%); arthralgias (50%)
- diabetes mellitus (30%); CHF + arrhythmia (15%)
- low serum testosterone → decreased libido, impotence
- fatigue, amenorrhea, loss of body hair, testicular atrophy
- liver iron index > 2 (= liver iron concentration [μmol per gram of dry weight] per patient's age)
- serum Fe > 300 mg/dL; serum transferrin saturation > 50%

MR:

@ Liver
√ significantly hypointense T2 signals = SI equal to background noise
√ hepatomegaly, fibrosis, HCC (in advanced disease)

@ Pancreas
√ normal pancreatic signal intensity in noncirrhotics
√ pancreatic SI equal to / less than muscle (in 90% of cirrhotic patients)

@ Spleen
√ normal SI of spleen (in 86%) + bone marrow ← abnormal RES function

@ Pituitary (in advanced disease)
- hypopituitarism, hypogonadism ← gonadotroph malfunction

√ profound T2 hypointensity of adenohypophysis (anterior pituitary) similar to ICA flow void
√ decreased parenchymal enhancement on T1WI
√ diminutive pituitary height (< 4.89 ± 0.87 mm)

@ Heart (in advanced disease)
- arrhythmia

√ congestive cardiomyopathy (15%)
√ pericarditis

Cx: (1) Periportal fibrosis resulting in micronodular cirrhosis (if iron concentration > 22,000 μg/g of liver tissue)
√ low signal intensity on long TE GRE
(2) Hepatocellular carcinoma (14–36%)
√ HCC does not contain iron
(3) Insulin-dependent diabetes mellitus (30–60%) ← insulin resistance by hepatocytes + damage of pancreatic β-cell ← iron deposition
(4) Hypoparathyroidism

Rx: phlebotomies in precirrhotic stage

Prognosis: normal life expectancy with early diagnosis and treatment

Secondary Hemochromatosis

= any nongenetic cause of iron accumulation in RES organs of liver + spleen + bone marrow
[*Hemosiderosis* = increased iron deposition without organ damage]

Cause: acquired

(a) Chronic hemolytic anemia ± multiple transfusions
= erythrogenic hemochromatosis
= increased duodenal absorption of iron ← erythroid hyperplasia with ineffective erythropoiesis

1. Thalassemia
2. Congenital dyserythropoietic anemia
3. Sideroblastic anemia ← impaired protoporphyrin production

◊ NOT in sickle cell anemia

Path: no excess Kupffer cell iron

Some types of anemia like Fanconi anemia benefit from treatment with steroids (oxymetholone, danazol, methyltestosterone) to stimulate erythropoietin production. These drugs can induce hepatocellular adenoma, HCC, and peliosis hepatis.

(b) Myelodysplastic syndrome

(c) Exogenous increase of iron

› parenteral infusion

1. Transfusional siderosis (*see below*)
2. Iron overload siderosis

› secondary to ↑ in iron absorption

1. Alcoholic hepatitis
2. Hepatitis C
3. Cirrhosis

› excessive ingestion

1. **Bantu siderosis** = excessive dietary iron from food preparation in iron containers (Kaffir beer)

Organ distribution: RES of liver + spleen + bone marrow

Path: iron deposition initially in RES (phagocytosis of intact RBCs) with sparing of parenchymal cells of pancreas; <u>after</u> saturation of RES storage capacity parenchymal cells of other organs accumulate iron

Age: 4th–5th decade; M÷F = 10÷1

MR:

@ Liver

√ signal loss in liver on T2WI

= SI <u>greater than background noise</u> ← iron in Kupffer cells with <u>sparing of parenchymal liver cells</u>)

@ Spleen

√ splenic signal intensity less than muscle

@ Bone marrow

√ low SI of bone marrow (= siderotic marrow)

Transfusional Siderosis

= iron deposited in reticuloendothelial system in patients receiving > 40 units of blood (iron storage capacity of RES = 10 g of iron)

Organ distribution:

› common: liver, spleen, bone marrow, lymph nodes

› less common: adrenals, pancreas, GI tract

mnemonic: **S**iderosis affects the **S**pleen!

• abnormal iron deposition in RES is clinically of little significance (NO damage of affected organs)

MR:
√ low SI of bone marrow (= siderotic marrow) + spleen
√ ± low signal intensity of liver
√ normal SI of pancreas (except when storage capacity of RES exceeded)
DDx: diffuse calcification ← autosplenectomy of sickle cell anemia
Risk: parenchymal iron deposition occurs when storage capacity of RES is exhausted
◊ Parenchymal iron deposition can cause organ dysfunction
Rx: iron chelation therapy to remove excess iron

HEPATIC (LIVER) ABSCESS

= localized collection of pus in the liver ← any infectious process with destruction of the hepatic parenchyma + stroma
Types: pyogenic (85%), fungal (9%), amebic (6%)
Location: multiple in 50%
◊ A pyogenic abscess tends to be centrally located, an amebic abscess peripherally!
√ hepatomegaly
√ elevation of right hemidiaphragm
√ pleural effusion
√ right lower lobe atelectasis / infiltration
√ gas within abscess: esp. Klebsiella
MR:
√ hypointense on T1WI + hyperintense on T2WI (72%)
√ perilesional edema (35%)
√ "double target" sign on T2WI = hyperintense center (fluid) + hypointense sharply marginated inner ring (abscess wall) + hyperintense poorly marginated ring (perilesional edema)
√ rim enhancement (86%)

Amebic Abscess

Organism: trophozoite Entamoeba histolytica
Etiology: spread of viable amebae from colon → portal system → liver
Frequency: in 1–25% of intestinal amebiasis
Age: 3rd–5th decade; M÷F = 4÷1
• amebic dysentery; amebic hepatitis (15%)
Location: liver abscess (right lobe) in 2–25%; multiple liver abscesses in 25%; systemic dissemination by invasion of lymphatics / portal system (rare); liver÷lung÷brain = 100÷10÷1
Size: 2–12 cm
√ nonspecific variable appearance indistinct from subacute pyogenic abscess
√ nodularity of abscess wall (60%)
√ internal septations (30%)
√ NOT gas-containing (unless hepatobronchial / hepatoenteric fistula present)
√ ± disruption of diaphragm

CT:
√ nonspecific hypoattenuating area
√ enhancing wall
US:
√ homogeneous hypoechoic area
√ posterior acoustic enhancement
√ well-defined smooth thin wall
NUC:
√ 98% sensitivity of sulfur colloid scan
√ photon-deficient area surrounded by rim of uptake on ^{67}Ga scan
Aspiration:
typically opaque reddish / dirty brown / pink material ("anchovy paste" / "chocolate sauce"), usually sterile, parasite confined to margin of abscess

Cx: (1) Diaphragmatic disruption (rare) is strongly suggestive of amebic abscess
(2) Fistulization into colon, right adrenal gland, bile ducts, pericardium

Rx: conservative treatment with chloroquine / metronidazole (Flagyl®); percutaneous drainage (for left hepatic abscess spontaneous rupture into pericardium with tamponade possible)

Prognosis: resolution under therapy may take from 1 month to 2 years; permanent cysts may remain behind

Pyogenic Liver Abscess

◊ Most common type of liver abscess

Organism: E. coli, aerobic streptococci, Enterococcus, S. aureus, anaerobic bacteria, Klebsiella (45%); polymicrobial (> 50%)

Prevalence: 0.016%

Predisposed: steroids, immunosuppressed state, excessive antibiotics usage

Etiology:

(1) Cholangitic (biliary disease in 60%):
ascending cholangitis ← obstructive biliary tract disease (malignant / benign stricture), Crohn disease (sclerosing cholangitis, gallstones), cholecystitis

(2) Pylephlebitic(= portal phlebitis = portal pyemia): spread of intraabdominal sepsis ← suppurative appendicitis, colitis, diverticular disease

(3) Disseminated sepsis via hepatic artery:
infarction from sickle cell disease / embolism / postembolization for primary and metastatic cancer / septicemia; indwelling arterial catheters

(4) Contiguous spread from a local infection:
cholecystitis, peptic ulcer, subphrenic abscess

(5) Blunt / penetrating trauma:
rupture, penetrating wounds, biopsy, surgery, liver transplantation, previous biliary instrumentation / stent placement, radiofrequency ablation (1.4%)

(6) Cryptogenic in 20–45%:
invasion of cysts; superinfection of dead tissue (eg, primary / secondary hepatic tumor) by pyogenic intestinal flora

Path: liquefaction necrosis of liver parenchyma (→ central fluid collections of pus) + septa of fibrotic tissue (with inflammatory infiltrates of epitheloid macrophages, lymphocytes, eosinophils, neutrophils)

Classification by size: macroabscess (≥ 2 cm in diameter) microabscess (< 2 cm in diameter)

Mean age: 56–64 years; M > F

- pyrexia (79%), abdominal pain (68%), jaundice (0–20%)
- vomiting / weight loss, malaise (39%)
- nocturnal sweating (43%); positive blood culture (50%)
- ↑ WBCs, ↑ alkaline phosphatase

Location: solitary abscess in right lobe (40–75%), in left lobe (2–10%); multiple abscesses in 10–34–73% (more often of biliary than hematogenous origin)

√ honeycomb pattern of cluster of small abscesses at early stage

√ "cluster" sign = coalescence of several microabscesses each < 2 cm within the same anatomic area into single multiseptated larger cavity at later stage (suggests biliary origin)

US:

√ hypoechoic round lesion with well-defined mildly echogenic rim
√ posterior acoustic enhancement
√ coarse clumpy debris / low-level echoes / fluid-debris level with internal movement
√ intensely echogenic reflections with reverberations (from gas) in 20–30%

CT (95% sensitive):

√ inhomogeneous hypoattenuating (0–45 HU) single / multiloculated (multiseptated) cavity

√ "single target" sign = hypoattenuating mass surrounded by single enhancing rim ← after cluster of small abscesses aggregate + coalesce into single larger cavity
√ "double target" sign(6–30%):
  √ hypoattenuating pus centrally surrounded by
  √ inner hyperattenuating ring ← granulation tissue
  √ outer hypoattenuating zone ← inflammatory edema
√ air density
√ segmental / wedge-shaped transient hepatic enhancement surrounding abscess ← reduced portal venous flow ← inflammation and stenosis + compensatory increase in hepatic arterial flow

MR:

√ very low SI on T1WI + very high SI on T2WI (varies with protein content)
√ intense peripheral rim enhancement of capsule of variable thickness + septa

NUC:

√ photon-deficient area on sulfur colloid + IDA scan
√ ^{67}Ga citrate uptake in 80%
√ ^{111}In-tagged WBC uptake is highly specific (since WBCs normally go to liver, may need sulfur colloid test for correlation)

Cx: (1) Septicemia
(2) Rupture into right subphrenic space
(3) Rupture into abdominal cavity
(4) Rupture into pericardium

(5) Empyema
(6) Common hepatic duct obstruction

Mortality: 2–10%; 100% if unrecognized / untreated

Rx: percutaneous catheter drainage for multilocular abscesses + abscesses > 5 cm in diameter; surgical drainage (lower failure rate)

Patterns of Iron Deposition Related to Possible Causes of Hemochromatosis

Deposition Pattern	*Liver*	*Spleen*	*Bone Marrow*	*Pancreas*	*Kidney*	*Cause*
RES	Yes	**Yes**	**Yes**	No	No	**multiple transfusions**
Parenchymal	**Yes**	No	No	Yes	No	**increased iron absorption**: primary hemochromatosis, chronic anemia with inefficient erythropoiesis (thalassemia, congenital dyserythropoietic anemia, sideroblastic anemia)
Renal	No	No	No	No	**Yes**	intravascular hemolysis (artificial heart valve), paroxysmal nocturnal hemoglobinuria, hemolytic crisis of sickle cell disease
Mixed	Yes	Possible	Possible	Possible	Possible	chronic anemia due to ineffective erythropoiesis requiring multiple transfusions

Microabscesses

Predisposed: immunocompromised after neutrophil recovery
√ "cluster" sign = multiple microabscesses in geographic proximity (= early stage of abscess in evolution)
√ heterogeneous enhancement ← clustered coalescing abscesses
√ peripheral / septal enhancement
US (79% sensitive):
√ multiple small hypoechoic nodules in liver ± spleen
CT (97% sensitive):
√ multiple well-circumscribed hepatic / splenic lesions
MR (may be more sensitive than CT):
√ T2 hyperintensity + faint restricted diffusion ← necrosis + purulent debris
√ perilesional T2 hyperintensity ← edema
√ dynamic gadolinium-enhanced MR may show more lesions than CT
DDx: HCC (sepsis, no peripheral / septal enhancement)

HEPATIC ADENOMA

= HEPATOCELLULAR ADENOMA = LIVER CELL ADENOMA
= epithelial neoplasm composed of normal hepatocytes
◊ The most frequent hepatic tumor in young women after > 2-year use of oral contraceptives (4÷100,000 women annually)!

Prevalence: half as common as FNH; increasing with duration of oral contraceptive use + size of estrogen dose

Path: spherical benign growth with high incidence of hemorrhage + necrosis + fatty change; pseudocapsule ← compression of liver tissue containing multiple large vessels; NO scar

Histo: hepatocytes arranged in sheets without acinar structure (no portal or central vein), separated by thin-walled sinusoids fed by large peritumoral arteries, containing increased amounts of glycogen ± fat; few abnormally functioning Kupffer cells; NO connection with bile ducts (DDx to FNH)

Peak age: 40 years; young women in childbearing age (90%); not seen in males unless on anabolic steroids; rare in children (girls > 10 years)

Categories: 3 distinct genetic and pathologic subtypes
(a) inflammatory hepatocellular adenoma (most common)
- frequently in obese patients + in young women with a history of oral contraceptive

Risk of: hemorrhage, malignancy(10%)

(b) hepatocyte nuclear factor 1 alpha (HNF-1 α)–mutated hepatocellular adenoma (2nd most common)
- woman with a history of oral contraceptive use

(c) β-catenin–mutated hepatocellular adenoma
- more common in men with a history of anabolic steroid use / glycogen storage disease

Risk of: malignant transformation (highest rate)

Associated with:
› oral contraceptives (2.5 x risk after 5-year use, 7.5 x risk after 9-year use, 25 x risk > 9-year use); pregnancy
› anabolic steroids; familial diabetes mellitus; galactosemia
› type IA (von Gierke) glycogen storage disease (adenomas in 22–60–75% at an early age), also in type III (Cori)
› androgenic steroid therapy in Fanconi anemia

◊ Pregnancy may increase tumor growth rate + lead to tumor rupture!
◊ Tumor regression may occur with dietary therapy leading to normal insulin, glucagon, and serum glucose levels
• RUQ pain as sign of mass effect (40%) / intratumoral (10%) or intraperitoneal hemorrhage → hypovolemic shock
• asymptomatic (20%), ↑ liver function tests, normal AFP
• hepatomegaly

Mean size: 3–5 (range, 1–15–30 cm) in diameter
Location: right lobe of liver in subcapsular location (75%); multiple in up to 21%
Multiplicity: associated with glycogen storage disease / use of anabolic steroids; solitary lesion (in 70–80%); hepatic adenomatosis (see below)
√ spherical / ovoid well-circumscribed mass
√ frequently heterogeneous ← dilated sinusoids, blood-filled (pelioid) spaces, focal necrosis, infarction, hemorrhage, myxoid stroma, fatty change, calcifications
√ pseudocapsule (17–31%)
√ intraparenchymal / pedunculated (in 10%)
√ unusual "**nodule-in-nodule**" appearance in large tumors (DDx: hepatocellular carcinoma)
√ eccentric dystrophic calcifications (5–15%)

CT:
√ round usually isoattenuating mass (without hemorrhage)
√ mass of decreased density ← gross fat (7–10%) + areas of necrosis (30–40%)
√ hyperdense areas of fresh intratumoral hemorrhage (15–50%)

CECT:
√ transient avid homogeneous enhancement on arterial-phase images in small adenomas (90%) / initial peripheral enhancement with centripetal filling in larger adenomas (← supply by hepatic artery)

- √ iso- / hypoattenuating on portal venous + delayed-phase images

US:
- √ usually small well-demarcated nonlobulated solid heterogeneous mass of variable echogenicity:
  - √ hyperechoic lesion with well-defined hypoechoic rim in normal surrounding liver
  - √ echogenic in areas of fat or hemorrhage
  - √ hypoechoic in background of diffuse fatty infiltration
  - √ anechoic cystic areas if large

Color Doppler:
- √ central vessels with triphasic pattern / continuous flat venous waveform
- √ peripheral peritumoral arterial + venous flow

MR:
- √ heterogeneous on all pulse sequences in 88% (indistinguishable from HCC):
  - ◊ Small homogeneous adenomas (uncomplicated by hemorrhage / intracellular lipid in 4%) mimick FNH!
- √ variable intensity on T1WI:
  - √ mildly hypointense on T1WI
  - √ often hyperintense areas ← hemorrhage / presence of intralesional lipid-laden hepatocyte (in 35–77%)
  - √ signal loss with out-of-phase / fat-suppressed imaging ← intracellular lipid (DDx to FNH)
- √ variable heterogeneous intensity on T2WI:
  - √ isointense / mildly hyperintense sheets of hepatocytes
  - √ hyperintense areas of necrosis / hemorrhage in 47–77%
- √ pseudocapsule hypointense on T1WI, variointense on T2WI ± delayed enhancement
- √ variable intensity (commonly increased) on DWI
- √ enhancement characteristics:
  - √ heterogeneous hypervascularity during arterial phase (less vascular than FNH)
  - √ iso- or hypointense on portal venous + delayed phase
  - √ delayed washout = delayed enhancing pseudocapsule
  - √ hypointense on 1-hour delayed imaging with gadobenate dimeglumine (Gd-**B**enzyl**O**xy**P**ropionic**T**etra**A**cetate)

NUC:
- √ photopenic lesion on sulfur colloid scan (← lesion composed of hepatocytes + nonfunctioning Kupffer cells) surrounded by rim of increased uptake (← compression of adjacent normal liver containing Kupffer cells); may show uptake equal to / slightly less than liver (23%)
- √ usually increased uptake / retention on HIDA scan
- √ NO gallium uptake

Angio:
- √ usually hypervascular mass
- √ homogeneous but not intense stain in capillary phase
- √ enlarged hepatic artery with feeders at tumor periphery (50%)
- √ hypo- / avascular regions ← hemorrhage / necrosis

√ neovascularity

CAVE: percutaneous biopsy carries high risk of bleeding!

Cx: (1) Spontaneous intratumoral hemorrhage (likely related to infarction as tumor outgrows blood supply) with subcapsular hematoma

(2) Hepatic rupture + hemoperitoneum (41%) in lesions > 5 cm

(3) Malignant transformation (rare) ← contiguous development of hepatocellular carcinoma

(4) Recurrence after resection

Rx: discontinuation of hormone therapy; screening for malignant degeneration with α-fetoprotein; surgical resection (to prevent rupture)

◊ Hepatocellular adenomas > 5 cm in maximum dimension in males with glycogen storage disease should be surgically resected followed by detailed histopathologic review for tumor geno- and phenotypic characterization.

DDx: (1) Hepatocellular carcinoma (presence of cirrhosis / hepatitis B / hemochromatosis, positive for α- fetoprotein, peripheral rim of high attenuation on delayed phase, vascular invasion)

(2) Fibrolamellar carcinoma (eccentric scar with calcification, adenopathy)

(3) FNH (stellate scar, homogeneous mass, NO intralesional fat / glycogen, arterial flow in spoke-wheel pattern, normal / increased uptake of ^{99m}Tc sulfur colloid)

Inflammatory Hepatocellular Adenoma *40–50%*

= TELANGIECTATIC FOCAL NODULAR HYPERPLASIA = TELANGIECTATIC ADENOMA

Age: young woman with a history of oral contraceptive usage; obese patient

- systemic inflammatory syndrome: fever, leukocytosis, elevated serum levels of C-reactive protein
- ↑ serum levels of transaminase, alkaline phosphatase, γ-glutamyl transferase; chronic anemia

Genetics: somatic gain-of-function mutation of interleukin-6 signal transducer gene (IL6ST) located at chromosome 5q11

Path: heterogeneous in appearance, with areas of congestion and frank hemorrhage; sinusoidal dilatation, peliotic areas, abnormal arteries

Histo: intense polymorphous inflammatory infiltrates, marked sinusoidal dilatation / congestion, thick-walled arteries; tumor cells show immunoreactivity to acute phase inflammatory markers like serum amyloid A and C-reactive protein

√ delayed persistent enhancement (85% sensitive, 87% specific)

US:

√ arterial vascularity with centripetal filling + peripheral rim of sustained enhancement + central washout during late venous phase

NECT:

√ heterogeneously hyperattenuating mass

MR:

√ isointense / mildly hyperintense on T1WI with minimal / no signal drop-off on chemical shift sequences

√ intense enhancement during arterial phase persisting into portal venous + delayed phase

√ marked diffuse T2-hyperintensity:
√ higher signal intensity in periphery of lesion ← dilated sinusoids

Cx: (1) intratumoral bleeding (20–30%), esp. for tumors > 5 cm in maximum diameter; subcapsular tumor with greater tendency for bleeding + rupture
(2) 10% risk of malignancy

HNF-1α–mutated Hepatocellular Adenoma 30–35%

= usually incidentally discovered tumor (multiple in about 50%) occurring exclusively in female with history of oral contraceptive use in > 90%

Genetics: nonfunctioning tumor suppressor gene located on chromosome 12q24 ← biallelic inactivating mutation of the hepatocyte nuclear factor-1α (HNF1A) gene that produces a transcription protein involved in hepatocyte differentiation

Histo: excessive lipid accumulation in tumor hepatocytes

√ diffuse intratumoral steatosis

√ diffuse fatty infiltration of liver ← associated with **m**aturity-**o**nset **d**iabetes of the **y**oung (MODY)

√ moderate tumor enhancement during arterial phase

US:
√ iso- to moderately increased vascularity + mixed filling during arterial phase + isoechogenicity during portal venous + delayed phases (after contrast material)

CT:
√ macroscopic fat in tumor (7%)

MR:
√ iso- to slightly hyperintense tumor on T2WI
√ predominantly T1-hyper- / isointense
√ chemical shift imaging:
√ homogeneous signal drop-off (86% sensitive, 100% specific) ← intracellular steatosis
√ macroscopic fat in tumor (in 35–77%)

Prognosis: risk of bleeding / malignancy is minimal

β-Catenin–mutated Hepatocellular Adenoma 10–15%

Genetics: activating mutation of β-catenin gene encoded by catenin β 1 gene (CTNNB1) located at chromosome 3p21 → uncontrolled hepatocyte proliferation

Associated with: male hormone administration, glycogen storage disease, familial adenomatous polyposis

Histo: high nuclear-cytoplasmic ratio, nuclear atypia, formation of acini; strong diffuse positivity to glutamine synthase

√ strong arterial enhancement

MR:
√ homo- / heterogeneous hyperintense T1 + T2 signal depending on presence of hemorrhage ± necrosis

Prognosis: 5–10% risk of HCC

Risk factors: male sex, glycogen storage disease, anabolic steroid usage, β-catenin–mutated subtype, tumor >5 cm in maximum dimension

Hepatic Adenomatosis

= rare condition with > 10 adenomas in both hepatic lobes without history of steroid therapy / glycogen storage disease

Cause: nonalcoholic liver disease, HNF-1α gene mutation

Age: 4th–5th decade; female

HEPATIC ANGIOMYOLIPOMA

= rare benign mesenchymal tumor

Associated with: tuberous sclerosis

Histo: smooth muscle cells, fat, proliferating blood vessels

• asymptomatic

√ intratumoral fat is DIAGNOSTIC

√ soft-tissue component may enhance

US:

√ circumscribed hyperechoic mass (DDx: hemangioma)

√ sound attenuation + subtle acoustic shadowing

√ relative hypervascularity

CT:

√ areas of macroscopic fat

√ marked enhancement with visualization of large central vessels during arterial phase

MR:

√ hyperintense areas of macroscopic fat on T1WI

√ marked decrease in SI with T1 fat suppression technique

√ intense enhancement during arterial phase with dark areas of macroscopic fat on fat-suppressed T1WI

Cx: intratumoral hemorrhage

HEPATIC ANGIOSARCOMA

= HEMANGIOENDOTHELIAL SARCOMA = KUPFFER CELL SARCOMA = HEMANGIOSARCOMA

Prevalence: 0.14–0.25÷1,000,000; < 2% of all primary liver neoplasms; most common sarcoma of liver (followed by fibrosarcoma > malignant fibrohistiocytoma > leiomyosarcoma)

Etiology:

(a) thorotrast = thorium dioxide (7–10%) with latent period of 15–24 years

(b) arsenic compounds

(c) polyvinyl chloride (latent period of 4–28 years)

Associated with: hemochromatosis, anabolic steroids, cirrhosis, von Recklinghausen disease

Path:

(a) multifocal / multinodular lesions (71%) of up to > 5 cm in size

(b) large solitary mass with hemorrhage + necrosis

Histo: vascular derivation confirmed by reactivity to factor VIII-related antigen, CD31 and CD34

(a) vessels lined with malignant endothelial cells (eg, sinusoids) causing atrophy of surrounding liver

(b) vasoformative → forming poorly organized vessels (responsible for RBC trauma + platelet trapping)
(c) forming solid nodules of malignant spindle cells

Age: 6th–7th decade; M÷F = 4÷1

- abdominal pain, weakness, fatigue, weight loss, jaundice
- spontaneous hemoperitoneum (15–27%)
- microangiopathic hemolytic anemia (23%), thrombocytopenia (54%), DIC (31%); NO elevation of α-fetoprotein

Early metastases to:

lung (23%), spleen (16–46%), porta hepatis nodes, portal vein, thyroid, peritoneal cavity, bone marrow (rapid metastatic spread)

◊ Predilection for splenic metastases!

√ portal vein invasion
√ hemorrhagic ascites
√ unifocal / multifocal / infiltrative lesion

Plain film:
√ circumferential displacement of residual thorotrast

NUC:
√ single / multiple photopenic areas on sulfur colloid scan
√ increased gallium uptake
√ perfusion blood pool mismatch (initial decrease followed by slow increase in RBC concentration) as in hemangioma on 3-phase red blood cell scan

US:
√ solid / mixed mass with anechoic areas (hemorrhage / necrosis)
√ multiple nodules
√ diffuse heterogeneous echotexture of entire liver

CT:
√ hypodense masses with high-density regions (hemorrhage) / low-attenuation regions (old hemorrhage / necrosis)
√ focal areas of peripheral enhancement with fill-in on dynamic CT as in large hemangioma (uncommon)

MR:
√ hypointense on T1WI with irregular areas of high signal (hemorrhage)
√ heterogeneously hyperintense on T2WI + fluid-fluid levels

CEMR:
√ markedly heterogeneous enhancement: predominantly peripheral, progressive on delayed phase, lack of central filling

Angio:
√ hypervascular stain around tumor periphery in late arterial phase with puddling; NO arterial encasement

PET:
√ may demonstrate marked uptake in liver tumor
√ localization of extrahepatic disease

CAVE: Biopsy may lead to massive bleeding in 16%! Have surgical backup available!

Prognosis: rapid deterioration with median survival of 6 months (13 months under chemotherapy)
DDx for multiple lesions: hypervascular metastases
DDx for single lesion: cavernous hemangioma, HCC (no splenic metastases)

HEPATIC CYST

◊ Second most common benign hepatic lesion after hemangioma
Prevalence: 2–7–14%; increasing with age; M < F
A. ACQUIRED HEPATIC CYST
Cause: trauma, inflammation, parasitic infestation, neoplasia
B. CONGENITAL HEPATIC CYST
Cause: defective development of aberrant / obstructed intrahepatic bile ducts; ? derived from bile duct hamartoma
Frequency: liver cysts detected at autopsy in 50%; in 22% detected during life
Age of detection: 5th–8th decade
Path: no communication with biliary tree
Histo: cyst surrounded by fibrous capsule + lined by columnar epithelium, related to bile ducts within portal triads; NO communication with bile duct
Associated with:
(1) Tuberous sclerosis
(2) Polycystic kidney disease (25–33% have liver cysts)
(3) Polycystic liver disease: autosomal dominant
• simple cyst: almost always asymptomatic
• hepatomegaly (40%); pain (33%); jaundice (9%)
Size of cyst: range from microscopic to huge (average 1.2 cm; in 25% (40%) largest cyst < 1 (> 4) cm; maximal size of 20 cm)
Number of cysts: multiple cysts spread throughout liver (in 60%) / solitary cyst
◊ Consider polycystic liver disease if > 10 cysts
√ well-circumscribed round / ovoid unilocular lesion:
√ imperceptible wall ± rim calcification
√ anechoic with posterior acoustic enhancement
√ very bright on T2WI
√ water attenuation (-20 to +20 HU)
√ no enhancement
√ hypointense on T1WI, hyperintense on T2WI
√ "cold spot" on IDA, Ga-68, ^{99m}Tc-sulfur colloid scans
Pitfall:
(1) Metastatic neuroendocrine tumor (can be very cystic ± very bright on T2WI)
(2) Cystic metastasis (in cystic primary tumor)
Rare Cx: infection, rupture, torsion, hemorrhage, malignant transformation into adenocarcinoma
√ fluid-fluid interface
√ wall thickening
√ intracystic debris ± septations

Rx: sclerosing therapy with minocycline hydrochloride (Dose: 1 mg per 1-mL cyst content up to 500 mg in 10 mL of 0.9% saline + 10 mL 1% lidocaine) following contrast opacification of cyst to confirm absence of communication with biliary tree / leakage into peritoneal cavity

HEPATIC HEMANGIOMA

Cavernous Hemangioma of Liver

= most common solid benign liver tumor (78%); 2nd most common liver tumor after metastases

Prevalence: 1–4%; autopsy incidence 0.4–7.3%; increased with multiparity

Cause: ? enlarging hamartoma present since birth, ? true vascular neoplasm

Age: rarely seen in young children; M÷F = 1÷2–5

Path: large vascular channels filled with slowly circulating blood; lined by single layer of mature flattened endothelial cells separated by thin fibrous septa; NO bile ducts; thrombosis of vascular channels commonly results in fibrosis + hemorrhage + myxomatous degeneration + calcifications

Pathophysiology: large blood volume with low blood flow

Associated with:
(1) Hemangiomas in other organs
(2) Focal nodular hyperplasia
(3) Rendu-Osler-Weber disease
(4) Klippel-Trénaunay-Weber syndrome
(5) Von Hippel-Lindau disease

- asymptomatic if tumor small (50–70%)
- may enlarge during pregnancy

Location: frequently peripheral / subcapsular in posterior right lobe of liver; 20% are pedunculated; multiple in 10–20%

Size: < 4 cm (90%)

◊ Very small + very big lesions have the most atypical imaging features ← calcifications, fibrosis, thrombosis of tumor portions, cystic / necrotic areas within tumor!

√ well-circumscribed lobulated mass

√ blood supply from hepatic artery with arterial enhancement characteristics

√ may have central area of fibrosis = areas of nonenhancement / nonfilling / cystic space (occurrence increases with age and size)

√ central septal calcifications within areas of fibrosis / phleboliths (5–20%)

US:

√ uniformly hyperechoic (60–70%) mass ← multiple interfaces created by blood-filled spaces separated by fibrous septa

√ hypoechoic mass (up to 40%) in larger hemangiomas / on background of fatty infiltration or liver fibrosis

√ well-defined thick / thin echogenic lobulated border

√ homogenous (58–73%) / heterogeneous ← hemorrhagic necrosis, thrombosis, scarring, myxomatous change, central fibrosis

√ ± hypoechoic center
√ may show acoustic enhancement (37–77%)
√ unchanged size / appearance (82%) on 1–6-year follow-up
√ no Doppler signals / signals with peak velocity of < 50 cm/sec
√ contrast enhancement

CT (combination of precontrast images, good bolus, dynamic scanning, 88% sensitive, 84–100% specific):

√ well-circumscribed spherical / ovoid low-density mass:
  √ may have areas of higher / lower density within mass
√ enhancement patterns:
  Type 1 = immediate uniform enhancement (**"flash filling"**); in 42% of hemangiomas < 1 cm
    DDx: hypervascular tumor (does not remain hyperattenuated on delayed phase)
  Type 2 = peripheral nodular enhancement + complete fill-in on delayed images 3–30 min post IV bolus (in 55–89%):
    DDx: metastasis (nodular / rim enhancement ± centripetal fill-in possible)
  Type 3 = peripheral nodular enhancement + partial (24%) / no (2%) fill-in to isodensity on delayed phase in giant hemangioma > 5 cm ← thrombosis
  √ central scar in large lesion may not enhance at any time

MR (98–100% sensitive, 92–98% specific, 90–95% accurate):

√ spheroid / ovoid (87%) mass with smooth well-defined lobulated margins (87%); NO capsule
√ homogeneous internal architecture if < 4 cm, hypointense internal inhomogeneities if > 4 cm ← fibrosis
√ hypo- / isointense mass relative to liver on T1WI
√ markedly hyperintense **"light bulb"** appearance (← slow flowing blood) increasing with echo time on heavily T2WI; more intense than spleen (92% accurate)
  (DDx: hepatic cyst, hypervascular tumor, necrotic tumor, cystic neoplasm)
√ for hyalinized hemangioma: only mildly hyperintense on T2WI + lack of enhancement in early phase + slight peripheral enhancement in late phase (DDx: malignant hepatic tumor)
√ hyperintense on DWI ← T2 shine-through
√ enhancement pattern as on CT with gadolinium-DTPA:
  Type 1 = immediate uniform enhancement at 1 sec in 40% of small hemangiomas < 1.5 cm
  Type 2 = peripheral nodular + interrupted enhancement (77%) equal to blood pool progressing centri-petally with centrally uniform enhancement
  Type 3 = peripheral nodular enhancement with centripetal progression but persistent hypointensity for giant hemangioma > 5 cm
  DDx: hypervascular metastasis (contrast washout on > 5 min delayed images)

Angio (historical gold standard):

√ dense opacification of well-circumscribed, dilated, irregular, punctate vascular lakes / puddles ("cotton wool / snowy tree" appearance) in late arterial + capillary phase

starting at periphery in ring- / C-shaped configuration
√ normal-sized feeders; AV shunting (very rare)
√ contrast persistence late into venous phase

NUC (95% accuracy with SPECT):

Indication: lesions > 2 cm (detectable in 70–90%) with atypical imaging characteristics on cross-sectional imaging

√ initially cold lesion on ^{99m}Tc-labeled RBC scans (dose of 15–20 mCi) with increased activity on delayed images at 1–2 hours
√ cold defect on sulfur colloid scans

Bx: may be biopsied safely provided normal liver is present between tumor + liver capsule

√ nonpulsatile blood (73%)
√ endothelial cells without malignancy (27%)

Prognosis: no growth when < 4 cm in diameter; giant cavernous hemangiomas may enlarge; may involute into hyalinized hemangioma

Cx (rare): (1) Spontaneous rupture (4.5%)
(2) Abscess formation
(3) Kasabach-Merritt syndrome (platelet sequestration)

Mimics:

(1) Angiosarcoma
(2) Epitheloid hemangioendothelioma
(3) Treated metastasis
(4) Neuroendocrine metastasis (bright on T2WI)

DDx: hypervascular malignant neoplasm / metastasis

Giant Hepatic Cavernous Hemangioma

= hemangioma > 5 cm / at least one dimension exceeding 8–10 cm (in literature no agreement on size)

Associated with: coexistent smaller < 5 cm hemangioma in 13%

Histo: hemorrhage, thrombosis, extensive hyalinization, liquefaction, fibrosis; central cleft due to cystic degeneration / liquefaction

- may present with spontaneous life-threatening hemorrhage (5%); hepatomegaly; abdominal mass
- RUQ fullness + pain ← thrombosis in large hemangioma
- Kasabach-Merritt syndrome (rare)

US:

√ heterogeneous mass

NECT:

√ heterogeneous hypoattenuating mass with marked central areas of low attenuation
√ ± coarse central calcification

CECT:

√ early peripheral globular enhancement
√ incomplete filling of central portions

MR:

√ sharply marginated hypointense mass with cleftlike area of lower intensity on T1WI
√ large markedly hyperintense cleftlike area (← cystic degeneration / liquefaction) with some hypointense internal septa inside a hyperintense mass on T2WI

CEMR:
√ peripheral nodular enhancement
√ central cleftlike area remains hypointense

Cx: inflammatory changes; intralesional hemorrhage; intraperitoneal hemorrhage; torsion of pedunculated lesion; Kasabach-Merritt syndrome

DDx: metastasis, HCC, cholangiocarcinoma, hepatic adenoma, FNH (smaller and less hyperintense central scar on T2WI), focal fatty infiltration

Infantile Hemangioendothelioma of Liver

= INFANTILE HEPATIC HEMANGIOMA = CAPILLARY / CAVERNOUS HEMANGIOMA

◊ Most common benign hepatic tumor during first 6 months of life!

Histo: multiple anastomosing thick-walled vascular spaces similar to cavernous hemangioma lined by plump immature endothelial cells in single or (less often) multiple cell layers; areas of thrombi / extramedullary hematopoiesis; scattered bile ducts; involutional changes (infarction, hemorrhage, necrosis, scarring)

Classification based on immunoreactivity to glucose transporter protein 1 (GLUT1):

(1) Multifocal lesions staining positive for GLUT1 ± associated arteriovenous shunts / cutaneous hemangiomas, absence of central necrosis
Prognosis: proliferation followed by involution

(2) Focal lesion WITHOUT staining for GLUT1 variably demonstrating arteriovenous shunts; often containing central areas of hemorrhage / necrosis / thrombosis
Prognosis: complete involution by age 12–14 months

(3) Diffuse disease with liver largely replaced by growing tumors causing massive hepatomegaly, secondary respiratory distress, inferior vena cava compression, abdominal compartment syndrome

Age at presentation: < 6 months in 85%, during 1st month in 33%, > 1 year in 5%; M÷F = 1÷1.4–1÷2

Associated with: hemangiomas in other organs + skin in 10–15%

Prevalence: increased with hemihypertrophy + Beckwith-Wiedemann syndrome

- abdominal mass ← hepatomegaly; hemangiomas of skin
- may present with high-output CHF 2° to AV shunts within tumor (8 –15–25%)
- hemolytic anemia; Kasabach-Merritt syndrome
- cardiac dysfunction + mental retardation ← severe hypothyroidism ← tumor produces high levels of type 3 iodothyronine deiodinase activity

Location in other sites:
skin, trachea, thorax, adrenal gland, dura mater (10–70%); especially with multifocal liver tumors → chest x-ray, brain imaging

Average size: 3.0 (range, 0.5–20.0) cm; multifocal lesions around 1 cm in diameter

√ diffuse involvement of entire liver → hepatomegaly
√ focal single mass (50%) / multifocal masses (50%)
√ enlargement of celiac + hepatic arteries + proximal aorta
√ rapid decrease in aortic caliber below celiac trunk

√ enlarged hepatic veins (increased venous flow)

Plain film:

√ fine speckled / fibrillary calcifications in 16–25% (DDx: hepatoblastoma, hamartoma, metastatic neuroblastoma)

√ cardiomegaly + pulmonary edema with CHF

US:

√ predominantly hypoechoic / mixed (uncommonly hyperechoic) lesion

√ heterogeneous echotexture in large lesion ← central hemorrhage, necrosis + fibrosis

√ multiple sonolucent areas = enlarging vascular channels ← initial rapid growth (DDx: mesenchymal hamartoma):

√ vascular components demonstrated by color Duplex

√ tiny echogenic foci + posterior acoustic shadowing = calcifications (in 36–50%)

Color Doppler:

√ artery with little systolic-diastolic variation (= AV shunt)

√ artery + vein with high- / low-frequency shifts

√ large feeding + draining vessels within and surrounding tumor

√ direct visualization of arteriovenous / portovenous shunts

OB-US:

Time of detection: as early as 16 weeks GA

√ anasarca, ascites, pleural effusion, cardiomegaly

Cx:

(1) Kasabach-Merritt sequence (hemolytic anemia, thrombocytopenia, and consumptive coagulopathy) in fetus

(2) fetal hydrops → anasarca, ascites, pleural effusion, cardiomegaly

(3) polyhydramnios

NECT:

√ large well-defined hypoattenuating mass(es)

√ hemorrhage (not uncommon)

√ speckled calcifications (in 16–50%)

CECT (similar to cavernous hemangioma):

√ early peripheral nodular / corrugated enhancement (72%)

√ progressive centripetal fill-in + variable delayed central enhancement

√ intense uniform enhancement in small multifocal tumors

MR:

√ heterogeneous hypointense multinodular lesion on T1WI ± hyperintense areas of hemorrhage

√ varying degrees of hyperintensity on T2WI (resembling adult hemangioma)

√ decreasing SI with fibrotic replacement on T2WI

√ flow voids in / adjacent to some lesions

NUC (sulfur colloid, tagged RBC):

√ increased flow in viable portions of lesion during angiographic phase

√ increased activity mixed with central photopenic areas (hemorrhage, necrosis, fibrosis) on delayed tagged RBC images

√ photopenic defect on delayed sulfur colloid images

Angio (if use of embolotherapy is contemplated):

√ enlarged, tortuous feeding arteries and stretched intrahepatic vessels
√ hypervascular tumor with inhomogeneous stain; clusters of small abnormal vessels
√ pooling of contrast material in sinusoidal lakes with rapid clearing through early draining veins (AV shunting)

Prognosis: rapid growth in first 6 months followed by regression + involution within 6–8 months; 32–90% survival rate in complicated cases

Cx: (1) Congestive heart failure
(2) Hemorrhagic diathesis
(3) Obstructive jaundice
(4) Hemoperitoneum ← rupture of tumor
(5) Malignant transformation into angiosarcoma (rare)

Rx: (1) No treatment if asymptomatic
(2) Reduction in size with steroids / radiotherapy / chemotherapy (interferon-α-2a, vincristine)

Differentiation of Hemangioma from Hemangioendothelioma

Findings	*Hemangioma*	*Hemangioendothelioma*
Presenting age	older children	< 6 months of age
Lesion size	usually < 2 cm	2–15 cm
Location	R lobe	L + R lobe
Multiple lesions	in 10–20%	single / multiple
Signs	symptomatic	hepatomegaly, CHF
US	well-defined, hyperechoic	varied
Malignant	never	rarely

(3) Embolization
(4) Surgical resection / liver transplantation

DDx: (1) Hepatoblastoma (> 1 year of age, markedly elevated α-fetoprotein in 90%, more heterogeneous enhancement pattern)
(2) Mesenchymal hamartoma (usually multicystic multilocular mass, hypovascular mass with enhancement of septa + solid tumor portions)
(3) Metastatic neuroblastoma (elevated urinary catecholamines, adrenal / retroperitoneal / posterior mediastinal masses, nonenhancing multiple liver masses)
(4) Angiosarcoma (heterogeneous SI in multifocal lesions on T2WI, lack of flow voids, central / mild peripheral enhancement)

Kasabach-Merritt syndrome *(in 11%)*

[Haig Haigouni Kasabach (1898–1943) American radiologist]
[Katharine Krom Merritt (1886–1986) American pediatrician]
= HEMANGIOMA THROMBOCYTOPENIA SYNDROME
= consumptive thrombocytopenia with hemorrhagic diathesis ← disseminated intravascular coagulation

• low platelets; hemolytic anemia

- hemangioma / hemangioendothelioma / angiosarcoma → platelet sequestration by tumor → thrombocytopenic purpura → increased systemic fibrinolysis
- disseminated intravascular coagulopathy → hemorrhage, infection, multiple organ failure

Prognosis: fatal outcome in 12–24%

Rx: tumor extirpation, steroid, vincristine, interferon, radiation therapy

HEPATIC VENO-OCCLUSIVE DISEASE

= occlusion of small centrilobular veins without involvement of major hepatic veins

Etiology: radiation and chemotherapy in bone-marrow transplant patients; bush tea (alkaloid) consumption in Jamaica

√ main hepatic veins + IVC normal

√ bidirectional / reversed portal venous flow

√ gallbladder wall thickening

HEPATITIS

Cause: alcohol, medication, viral infection, NASH (nonalcoholic steatohepatitis)

Acute Hepatitis

= process present for < 6 months

- markedly elevated AST + ALT
- increase in serum-conjugated bilirubin

√ hepatomegaly / normal size of liver

√ gallbladder wall thickening

√ lymphadenopathy

CT:

√ periportal low attenuation (lymph edema)

US:

√ diffuse decrease in liver echogenicity

√ increased brightness of portal triads (**"starry sky"** pattern) = centrilobular pattern ← edema in hepatocytes (DDx: leukemic infiltrate, diffuse lymphomatous involvement, toxic shock syndrome)

√ edema of gallbladder fossa + gallbladder wall thickening

√ thickening + increase in echogenicity of fat within falciform ligament, ligamentum venosum, porta hepatis, periportal connective tissue

Drugs Associated with Cholestatic Liver Injury	
Drug Class	*Common Agents*
Antibiotics	
Penicillins	amoxicillin-clavulanate
Sulfonamides	trimethoprim-sulfamethoxazole
Macrolides	erythromycin
Tetracyclines	doxycycline
Antifungals	ketoconazole
Antiretrovirals	
Anti-inflammatories	diclofenac, ibuprofen
Psychotropes	chlorpromazine, tricyclic antidepressants
Immunosuppressives	cyclosporine, azathioprine
Other	oral contraceptives, estrogens, anabolic steroids

CEMR:
√ heterogeneous enhancement during arterial phase
√ elevated T2 signal ← edema + inflammation in more severe disease

Drug-induced Acute Hepatitis

Drug-induced injury is the number-one cause of acute liver failure (10% of all cases of acute hepatitis).

◊ Most common cause of postmarketing drug withdrawals and warnings
Implicated drugs: > 900; especially antibiotics + analgesics
Mechanism: direct toxic effects of a drug or its metabolites

Histo: categorized according to predominant histopathologic and biochemical features; grouped as hepatocellular / cholestatic / mixed patterns of liver injury.

Classification: according to clinical phenotype + course
(1) Acute hepatitis
(2) Cholestatic hepatitis
(3) Bland cholestasis
(4) Sinusoidal obstructive syndrome
(5) Steatosis (= nonalcoholic fatty liver)

Cholestatic Hepatitis

Mechanism: compromised perfusion of bile ducts
Common drugs: cyclosporine, trimethoprim-sulfamethoxazole, chlorpromazine
√ often NO radiologic findings
√ small bile ducts diminished in number
√ hepatomegaly
√ heterogeneously enhancing parenchyma
DDx: primary sclerosing cholangitis, primary biliary cirrhosis, biliary obstruction (eg, cholelithiasis, choledocholithiasis), primary sclerosing cholangitis, primary biliary cirrhosis, bile duct tumor, pancreatitis, pancreatic tumor

Chronic Hepatitis

= process present for at least 6 months

Cause: autoimmune hepatitis; hepatitis B, C, D; cryptic hepatitis; chronic drug hepatitis; primary biliary cirrhosis; primary sclerosing cholangitis; Wilson disease; alpha-1 antitrypsin deficiency

US:

√ increased liver echogenicity
√ coarsening of hepatic echotexture
√ silhouetting / loss of definition of portal venules = decreased visualization of walls of peripheral portal veins
√ NO sound attenuation

Cx: cirrhosis (10% for hepatitis B; 20–50% for hepatitis C)

Neonatal Hepatitis

Cause:

A. INFECTION: virus, protozoa, spirochete, toxoplasmosis, rubella, CMV, herpes, hepatitis A/B, syphilis
B. METABOLIC: alpha-1 antitrypsin deficiency, familial recurrent cholestasis, errors of metabolism → nesidioblastosis (= acquired hyperinsulinism with beta cell hyperplasia)
C. IDIOPATHIC

Age: 1–4 weeks of age; M > F

Histo: multinucleated giant cells with hepatic parenchymal disruption, relatively little bile within bile duct canaliculi

US:

√ normal-sized / enlarged liver
√ increase in parenchymal echogenicity
√ decreased visualization of peripheral portal veins
√ normal bile duct system
√ gallbladder of normal size / small ← decrease in bile volume in severe hepatocellular dysfunction
√ decrease in gallbladder size after milk feeding (DDx: congenital biliary atresia)

NUC:

Technique: often performed after pretreatment with phenobarbital (5 mg/kg x 5 days) to maximize hepatic function

Viral Markers of Hepatitis		
Virus	*Tests*	*Interpretation*
HAV	Anti-HAV IgM	acute hepatitis (can remain positive for >1 year) due to picorna virus
	Anti-HAV IgG	past hepatitis, lifelong immunity
HBV	HBsAg	acute / chronic disease due to hepadnavirus
	Anti-HBc IgM	acute infection (if titer high); chronic infection (if titer low)
	Anti-HBc IgG	past / recent HBV contact (may be only serum indicator of past infection)
	HBe	active viral replication
	Anti-HBe	low / absent replicative state (typically present in long-standing HBV carriers)
	Anti-HBs	immunity after vaccination
	HBV-DNA	active viral replication
HCV	Anti-HCV	past silent (1960s–1980s) / current infection due to flavivirus
	RIBA	test for various viral components
	HCV-RNA	active viral replication
HDV	Anti-HDV IgM	acute / chronic infection
	Anti-HDV IgG	chronic infection (if titer high + IgM positive); past infection if titer low + IgM negative)
	HDV-RNA	active viral replication
HEV	Anti-HEV IgM	acute hepatitis due to hepatitis E virus
	Anti-HEV IgG	past hepatitis
	HEV-RNA	viral replication
HFV		due to togavirus
HGV		due to GB virus

√ normal / decreased hepatic tracer accumulation
√ prolonged clearance of tracer from blood pool
√ bowel activity faint / delayed usually by 24 hours (best seen on lateral view; covering liver activity with lead shielding is helpful)
√ gallbladder may not be visualized

Prognosis: spontaneous remission
DDx: biliary atresia (NO small bowel activity)

Radiation Hepatitis

Acute Radiation-induced Hepatitis

Time of onset: 2–6 weeks after completion of radiation therapy with dose > 3,500 rad (35 Gy)

• abnormal liver function tests; RUQ discomfort
√ hepatomegaly
√ ascites
Prognosis: complete recovery in majority

Chronic Radiation-induced Hepatitis
√ increased attenuation in irradiated parenchyma (no fatty infiltration)
√ geographic areas of hypointensity on T1WI + hyperintensity on T2WI ← increased water content

HEPATOBLASTOMA

Frequency: 3rd most common abdominal tumor in children; most common congenital hepatic malignancy in children < 3 years of age
Incidence increased with: hemihypertrophy, Beckwith-Wiedemann syndrome
Associated with: Gardner syndrome, familial adenomatous polyposis, type 1A glycogen storage disease, trisomy 18; other congenital GI + GU anomalies in 5%
Histo:
(a) epithelial type = small cells resembling embryonal / fetal liver
(b) mixed type = epithelial cells + mesenchymal cells (of osteoid, cartilaginous, fibrous tissue)
Peak age: 18–24 months (range, newborn to 15 years); congenital in 4%; in 50% < 18 months; 90% by 5 years of age; M÷F = 1.5÷1 to 2÷1
◊ Strong inverse association with birthweight
• upper abdominal mass; jaundice (5%), pain
• weight loss, anorexia (= loss of appetite), nausea, vomiting
• precocious puberty in boys (production of hCG)
• persistently + markedly elevated α-fetoprotein (90%): AFP is normally elevated at birth until 6 months of age
Metastases to: lung (10–20%), bone, brain, lymph nodes, eye, ovary
Location: right lobe of the liver
Average size: 10–12 cm
√ usually solitary mass (80%), multifocal (20%)
√ well-circumscribed + lobulated with septa
√ coarse chunky calcifications / osseous matrix (12–30%)
√ ± invasion / compression of portal vein + hepatic veins + IVC
Abdominal X-ray:
√ hepatomegaly / mass ± coarse / dense calcifications
US:
√ large heterogeneous solid mostly hyperechoic mass:
√ often with echogenic shadowing calcifications
√ hypoechoic fibrotic septa in spoke-wheel configuration
√ occasionally cystic areas ← necrosis / extramedullary hematopoiesis
√ well-demarcated appearance ← pseudocapsule
Common Cx: intrapartum rupture + hemorrhage, hydrops, metastases
CT:

√ sharply circumscribed hypoattenuating mass with peripheral rim enhancement
√ speckled / amorphous calcifications (in > 50%)
√ slight enhancement of tumor but less than liver:
√ lobulated / septated (in 50%)

MR:
√ inhomogeneously hypointense on T1WI with hyperintense foci (= hemorrhage)
√ inhomogeneously hyperintense with hypointense bands (= fibrous septa) on T2WI

NUC:
√ photopenic defect

Angio:
√ hypervascular mass with dense stain
√ marked neovascularity; NO AV-shunting
√ vascular lakes may be present
√ avascular areas ← tumor necrosis
√ may show caval involvement (= unresectable)

Prognosis: 40–60% resectable (in 85% following neoadjuvant chemotherapy); 30–75% mortality; better prognosis than hepatoma; better prognosis for epithelial type than mixed type

DDx: (1) Infantile hemangioendothelioma (fine granular calcifications, < 1 year of age, rare AFP elevation, intense nodular / corrugated peripheral enhancement + centripetal fill-in on delayed images)

(2) Mesenchymal hamartoma (predominantly cystic tumor, normal serum AFP)

(3) Hepatocellular carcinoma (> 5 years of age, no calcifications, elevated serum AFP)

(4) Metastatic neuroblastoma

HEPATOCELLULAR CARCINOMA

= HEPATOMA

= most common (90%) primary malignancy of the liver; most frequent primary visceral malignancy in the world; 2nd most frequent malignant hepatic tumor in children (39%) after hepatoblastoma

◊ Worldwide 3rd most common cause of death from cancer (2nd [6th] most common for men [women])!

Prevalence: (a) in industrialized world: 0.2–0.8%

(b) in sub-Saharan Africa, Southeast Asia, Japan, Greece, Italy: 5.5–20%

Age-adjusted prevalence: 2.2 (women) – 6.8 (men) ÷ 100,000 in North America

Peak age:

(a) industrialized world: 6th–7th decade; M÷F = 2.5÷1; fibrolamellar subtype (in 3–10%) below age 40 years

(b) high incidence areas: 30–40 years; M÷F = 5÷1

(c) in children: > 5 years of age (peak at 12–14 years); M÷F = 1.8÷1 to 2.2÷1

Etiology:

1. Cirrhosis (60–90%)

› toxic (alcohol), cardiac, biliary atresia

Latent period: 8 months – 14 years from onset of cirrhosis

Incidence of HCC with underlying cirrhosis:

2–7% per year

› 44% in macronodular (= postnecrotic) cirrhosis ← hepatitis B virus, alcoholism, hemochromatosis

› 6% in micronodular cirrhosis ← alcoholism

2. Hepatitis C virus infection (50–60%)
3. Chronic hepatitis B (20%)
4. Nonalcoholic steatohepatitis ← obesity
5. Carcinogens: aflatoxin, siderosis, thorotrast, oral contraceptives / anabolic androgens
6. Inborn errors of metabolism: hemochromatosis, Wilson disease, alpha-1 antitrypsin deficiency, galactosemia, type I glycogen storage disease (von Gierke), hereditary tyrosinemia

Prevalence of HCC in Underlying Cirrhosis

Prevalence	*Cause of Cirrhosis*
17–30%	Hepatitis C infection
21%	Hereditary hemochromatosis
10–15%	Hepatitis B virus infection
5–8%	Alcoholic cirrhosis
4%	Advanced biliary cirrhosis

mnemonic: WHAT causes HCC?

Wilson disease
Hemochromatosis
Alpha-1-antitrypsin deficiency
Tyrosinosis
Hepatitis
Cirrhosis (alcoholic, biliary, cardiac)
Carcinogens (aflatoxin, sex hormones, thorotrast)

Path: soft tumor due to lack of stroma, often hemorrhagic + necrotic

Histo: HCC cells resemble hepatocytes in appearance + structural pattern (trabecular, pseudoglandular = acinar, compact, scirrhous)

(a) expansive encapsulated HCC: collapsed portal vein branches at capsule

(b) infiltrative nonencapsulated HCC: commonly intrasinusoidal + intravascular growth (portal venules communicate with tumoral sinusoids) → often invasion of portal ± hepatic veins

Grading system (Edmondson):

I cells similar in size to normal hepatocytes, arranged in relatively thin trabeculae; rarely acini containing bile (DDx: hepatocellular adenoma)

II cells larger than normal hepatocytes, hyperchromatic nuclei in a greater proportion of cells; thicker trabeculae; commonly acini containing bile

III cells with large nuclei occupying > 50% of cytoplasm; dominant trabeculae with solid areas ± isolated giant and bizarre cells; bile rarely present

IV cell nuclei occupying most of the cytoplasm; mostly solid areas with little / no bile (DDx: tumor of nonhepatocellular origin)

Vascular supply: hepatic artery (94%), portal vein (6%); HCC is directly supplied by (newly formed) "unpaired" or "nontriadal" arteries (= not part of portal tracts)

Natural history of HCC (suggests 3 stages):
(1) Molecular stage consisting of sequential changes leading to cell transformation
(2) Preclinical stage when HCC is too small to be detectable at imaging
(3) Clinical / symptomatic stage when the tumor has reached a diameter of 4.5–8 cm and develops symptoms

- fever, weight loss, anorexia
- persistent RUQ pain, hepatomegaly, ascites
- α-fetoprotein elevated in 75–90% (DDx: negative α-fetoprotein in cholangiocarcinoma)
- elevated liver function tests (not helpful for diagnosis)
- Paraneoplastic syndromes:
  (a) sexual precocity / gynecomastia
  (b) hypercholesterolemia
  (c) erythrocytosis ← tumor produces erythropoietin
  (d) hypoglycemia
  (e) hypercalcemia
  (f) carcinoid syndrome

Metastases to: lung (most common = 8%), adrenal, lymph nodes, bone

Growth pattern (Eggle classification):
(a) <u>massive</u> solitary pattern (27–50–59%):
√ large tumor bulk in one (most often right) lobe with an unclear boundary + satellite nodules
(b) <u>nodular pattern</u> (15–25%):
√ multiple small distinct sharply marginated foci of usually < 2 cm (up to 5 cm) in both hepatic lobes
(c) diffuse <u>infiltrative</u> pattern (7–26%)

Median tumor doubling time: 4–6 (range, 1–19) months
→ 3–12 months follow-up for indeterminate lesions

√ portal vein invasion (25–33–48%)
√ arterioportal shunting (4–63%)
√ invasion of hepatic vein (16%) / IVC (= Budd-Chiari syndrome)
√ occasionally invasion of bile ducts
√ calcifications in ordinary HCC (2–9–25%); however, common in fibrolamellar (30–40%) and sclerosing HCC
√ hepatomegaly and ascites
√ tumor fatty metamorphosis (2–17%)
√ atypical multilocular cystic mass ← necrosis / microscopic hemorrhage

The mural nodules in **multilocular cystic HCC** that correspond to viable tumor components may demonstrate the classic HCC hemodynamics of arterial enhancement and late contrast material washout at both CECT and MR imaging. This feature is critical in differentiating HCC from other cystic neoplasms. Furthermore, if "abnormal internal vessels or a variegated pattern" are observed

in mural nodules, it may strongly indicate HCC.

US (48% sensitive, 98% specific):
- √ variable echogenicity:
  - √ hyperechoic HCC (13%) ← fatty metamorphosis or marked dilatation of sinusoids
  - √ hypoechoic HCC (26%) ← solid tumor
  - √ HCC of mixed echogenicity (61%) ← nonliquefactive tumor necrosis + old hemorrhage
- √ Doppler peak velocity signals > 250 cm/s
- √ calcifications (rare)

Surveillance scan: every 6 months for high-risk patients

NECT (48% sensitive, 70% specific):
- √ hypodense mass / rarely isodense / hyperdense in fatty liver:
  - √ dominant mass with satellite nodules
  - √ mosaic pattern = multiple nodular areas with differing attenuation in larger lesion (up to 63%)
  - √ diffusely infiltrating neoplasm
- √ encapsulated HCC = circular zone of radiolucency surrounding the mass (12–32–67%)

False-positive: confluent fibrosis, regenerative nodule

Biphasic CECT (68% sensitive):
- ◊ 63% sensitivity in cirrhosis, 80% without cirrhosis
- √ enhancement during hepatic arterial phase (80%)
  - ◊ 16% seen on arterial phase only!
- √ decreased attenuation during portal venous phase with inhomogeneous areas of contrast accumulation
- √ isodensity on delayed scans (10%)
- √ thin contrast-enhancing capsule (50%) ← rapid washout
- √ wedge-shaped areas of decreased attenuation (segmental / lobar perfusion defects ← portal vein occlusion by tumor thrombus

Lipiodol® CT (53% sensitive, 88% specific):
- √ hyperdense mass detectable as small as 0.5 cm

MR (81% sensitive):
- ◊ Any solid lesion in a cirrhotic liver that is not a hemangioma is considered HCC until proven otherwise!
- ◊ Dysplastic nodules are rarely seen with imaging!
- √ variable intensity on T1WI:
  - √ most often hypointense relative to liver
  - √ isointense for lesion size < 1.5 cm

Major Imaging Features Favoring HCC
√ masslike configuration:
√ size ≥ 20 mm
√ tumor capsule / pseudocapsule = peripheral rim (ring) enhancement during venous phase
√ discrete margin
√ round shape
√ focal deformity of liver contour
√ displacement of intraparenchymal structures
√ visible on nonenhanced MR, DWI, T2WI, T2*
√ aggressive behavior
√ interval growth: increase ≥ 10 mm in 1 year
√ intralesional necrosis / hemorrhage
√ prominent intralesional arteries
√ local / vascular invasion
√ extrahepatic metastasis
√ arterial phase hyperenhancement:
√ enhancement greater than surrounding liver parenchyma + compared to precontrast phase
√ enhancement may be greater during portal venous phase
√ venous phase hypoenhancement = washout during portal venous / later phase
DDx: fibrotic tissue typically shows delayed enhancement (causing false appearance of hypoenhancement) of a regenerative nodule / hypertrophic pseudomass in liver cirrhosis
√ absent / ↓ uptake of superparamagnetic iron oxide (SPIO) on long T2*
√ tumor thrombus within lumen of vein:
√ arterial phase hyperenhancement + venous phase hypoenhancement of tumor thrombus
√ occluded vein with expanded lumen
√ luminal enhancement not matching time of enhancement in other veins
√ presence of arteries within lumen (in absence of cavernous transformation)
√ markedly restricted / impeded diffusion in lumen

Ancillary Features Favoring Hepatocellular Carcinoma
√ mild to moderate T2 hyperintensity
√ mosaic architecture
√ high signal intensity on DWI
√ intralesional steatosis = ↓ SI on opposed-phase images
√ iron sparing in an iron-overloaded liver

- √ hyperintense areas / hyperintense lesion, particularly if > 1.5 cm in diameter ← lipid / copper / glycogen / blood
  - ◊ Fatty metamorphosis in a cirrhotic nodule is suspicious for HCC!
- √ variable intensity on T2WI relative to liver:
  - √ generally hyperintense / small focus of hyperintensity
    - ◊ Any hypervascular mass in cirrhosis with increased T2 signal similar to that of spleen is suspicious for HCC!
    - ◊ An iron-poor focus within a siderotic nodule on T2WI suggests HCC!
  - √ iso- to hypointense for well-differentiated tumor
- √ "ring" sign (10–78%) = typically thin + discontinuous hypointense capsule on T1WI + T2WI:
  - √ double layer of inner hypointensity (fibrous tissue) + outer hyperintensity (← compressed blood vessels + bile ducts) on T2WI in expansive type of HCC
- √ may contain central scar of fibrosis / calcifications / necrosis hypointense on T1WI + T2WI
- √ variable appearance on DWI:
  - √ often isointense for well-differentiated tumor
  - √ often hyperintense for moderately to poorly differentiated tumor

CEMR:

(a) arterial phase imaging:
- √ marked homogeneous enhancement for lesion < 2 cm:
  - › for 1–2-cm lesion → 3-month follow-up;
  - › for < 1-cm lesion → 6-month follow-up
- √ heterogeneous enhancement for lesion > 2 cm:
  - √ enhancement peripherally (62%) / centrally (7%) / mixed (10%) / no enhancement (21%)
  - √ central scar without much enhancement

(b) portal venous and equilibrium phase:
- √ rapid loss of enhancement becoming isointense / hypointense (= rapid venous washout)
  - ◊ Delayed hypointensity of an arterially enhancing mass in a cirrhotic liver is HCC unless proven otherwise!
- √ progressive delayed enhancement of tumor capsule
- √ "peripheral washout" sign = decrease of contrast material preferentially in periphery of mass while center remains hyperintense (← ? related to vessel distribution with central necrosis / fibrosis and peripherally viable tumor), same as in hypervascular metastasis

- √ improved lesion detectability on T1WI after intravenous administration of superparamagnetic iron oxide (entrapped by Kupffer cells) + gadolinium during late hepatic arterial phase

Characteristic MR features for larger HCC:
- √ mosaic pattern of variable SI on T1WI + T2WI ← confluent small nodules separated by thin septa + areas of tumor necrosis
- √ extracapsular extension with formation of satellite nodules
- √ vascular invasion:
  - √ lack of signal void on SE images
  - √ enhancing intravascular mass during arterial phase
  - √ intravascular filling defect during delayed phase

√ extrahepatic dissemination → distant metastasis + lymph node involvement

NUC:

√ Sulfur colloid scan: single cold spot (70%), multiple defects (15–20%), heterogeneous distribution (10%)

√ Tc-HIDA scan: cold spot / atypical uptake in 4% (delayed images)

√ Gallium-scan: avid accumulation in 70–90% (in 63% greater, in 25% equal, in 12% less uptake than liver)

Angio:

√ "thread and streak" sign = venous and arterial channels located in and around a cast of tumor in a large branch ± trunk of the main portal vein

√ in differentiated HCC: enlarged arterial feeders, coarse neovascularity, vascular lakes, dense tumor stain, arterioportal shunts

√ in anaplastic HCC: vascular encasement, fine neovascularity, displacement of vessels + corkscrew-like vessels of cirrhosis

Prognosis: > 90% overall mortality; 17% resectability rate; 6 months average survival time; 0–10% 5-year survival rate (> 50% for small HCC) → HCC detection of < 2 cm is crucial

Cx: spontaneous rupture (in 7–14% in Asia + Africa)

Rx: (1) Resection

(2) Liver transplant (solitary lesion < 5 cm; up to 3 lesions < 3 cm; no portal / hepatic vein involvement; no metastatic disease)

(3) Radiofrequency ablation for tumors < 3 cm

(4) ^{131}I-antiferritin IgG (remission rate > 40% up to 3 years)

DDx of hypervascular lesion:

(1) Fibrolamellar carcinoma (central scar with calcium, homogeneous tumor without hemorrhage / necrosis)

(2) Hepatocellular adenoma (in young woman using oral contraceptive, in child with glycogen storage disease, anabolic steroid use)

DDx: hepatocarcinoma, cholangiocarcinoma, focal nodular hyperplasia, hemangioma, hepatic adenoma, pseudolesion of cirrhotic liver (mostly < 1-cm enhancing foci not histologically visible)

Infiltrative Hepatocellular Carcinoma

= DIFFUSE HCC, CIRRHOTOMIMETIC HCC, CIRRHOSIS-LIKE HCC (masquerading as cirrhotic nodules)

= characterized by spread of minute tumor nodules throughout a lobe / entire liver

with: hepatitis B virus infection, especially in Asia

• elevated α-fetoprotein: often > 10,000 ng/mL

Imaging sensitivity: 48% for US, 68% for CT, 81% for MR

While a macroscopic growth pattern of infiltrative HCC is uncommon, its histologic features are not unique to this type of HCC.

Infiltrative HCC has a relatively reduced conspicuity during dynamic phases of enhancement ← its permeative infiltrative nature + presence of portal vein thrombosis, resulting in perfusion changes that can effectively conceal the tumor.

√ cryptic spread of distinct minute tumor nodules within hepatic lobe / entire liver:
  √ NO dominant nodule
  √ regular / distinct margin around each tumor nodule
√ tumor contrast characteristics relative to liver parenchyma:
  √ minimal / patchy / miliary enhancement during arterial phase
  √ irregular heterogeneous washout = hypoenhancement during portal ± delayed phase (51%)
  √ reticular appearance during venous + equilibrium phase
  √ lack of hepatospecific contrast agent uptake during hepatobiliary phase
√ extra- / intrahepatic portal vein thrombosis (68–100%)
√ intrahepatic biliary ductal dilatation (13–26%)
√ spread to upper abdominal lymph nodes (10–22%)
√ distant metastases to lung, bone, adrenals (13–23%)
MR:
  √ homo- / heterogeneously hypointense on T1WI
  √ moderately heterogeneously hyperintense on T2WI
  √ hyperintense on DWI with b values of 500–800 sec/mm2
  √ poorly visualized on dynamic contrast-enhanced images

DDx: (1) Confluent fibrosis
(2) Focal hepatic steatosis
(3) Hepatic microabscesses
(4) Intrahepatic cholangiocarcinoma

Prognosis: worst of all growth patterns

Rx: infiltrative HCC is usually a contraindication for resection and transplantation due to decreased survival after surgical resection.

Fibrolamellar Carcinoma of Liver

= uncommon variant of hepatocellular carcinoma arising in young adults without underlying hepatic disease

Prevalence: 1–9% of all HCCs; up to 35% of HCCs in patients < 50 years of age

Mean age: 23 (range, 5–69) years; mostly 2nd–3rd decade (85% < 35 years of age); M÷F = 1÷1

Path: desmoplastic tumor with collagen deposition → fibrous central scar (60–75%) with calcifications (35–55%)

Growth pattern:
(a) large circumscribed nonencapsulated mass (80–90%)
(b) intrahepatic mass with satellite nodules (10–15%)
(c) bilobed mass (5%)
(d) multiple diffuse masses (< 1%)

Histo: large polygonal hepatocyte-like cells with coarse granular eosinophilic cytoplasm growing in sheets / cords / trabeculae separated by broad bands of fibrous stroma arranged in parallel lamellae resulting in a compartmentalized appearance

Risk factors: NONE known; underlying cirrhosis or hepatitis in < 5%

Demographics: USA > Europe; rare in Japan + China; predilection for Caucasians
- abdominal pain, cachexia, palpable RUQ mass, hepatomegaly
- jaundice (5%) ← biliary compression
- gynecomastia (rare) ← conversion of androgens to estrogens by tumor-elaborated enzyme aromatase
- α-fetoprotein usually negative / mildly elevated to < 200 ng/μL (in up to 10%); transaminase levels < 100 IU/L

Mean size: 13 (range, 5–20) cm in diameter

√ well-circumscribed partially / completely encapsulated solitary mass (in 80–90%):
- √ intrahepatic (80%) / pedunculated (20%)
- √ prominent central fibrous scar (45–60%)
- √ punctate / nodular / stellate calcifications (33–68%):
  - √ centrally within scar, < 3 in number, < 5 mm in size
- √ capsular retraction (10%)
- √ intratumoral hemorrhage + necrosis (10%)
- √ vascular invasion (< 5%)

√ mass + small peripheral satellite lesions (10–15%)

√ diffuse multifocal masses (< 1%)

√ regional lymphadenopathy (50–70%) usually in hepatic hilum / hepaticoduodenal ligament

√ distant metastases (20%): lung, peritoneal implants

Abdominal x-ray:
- √ hepatomegaly ± stellate calcifications

US:
- √ well-defined lesion of mixed echogenicity (60%) with predominantly iso- / hyperechoic portions
- √ central hyperechoic scar (33–60%) ± shadowing calcifications

NECT:
- √ mass of heterogeneously low attenuation
- √ lobulated surface contour (in 80%)
- √ prominent stellate / amorphous central scar (20–71%)

CECT:
- √ enhancement of non-scar portion:
  - √ prominent heterogeneous arterial enhancement (in 80%)
  - √ variable attenuation in portal venous phase
  - √ less pronounced enhancement during equilibrium phase
- √ enhancement of scar: none (75%) / delayed (25%)
- √ delayed enhancement of pseudocapsule of compressed liver tissue (15%)

MR:
- √ large well-defined lobulated mass:
  - √ hypointense (86%) / isointense (14%) on T1WI
  - √ hyperintense (85%) / isointense (15%) on T2WI
  - √ homogeneous (80%) / heterogeneous (20%)
- √ hypointense central scar on T1WI + T2WI (in 80%)

CEMR:
- √ early heterogeneous contrast enhancement that fades on subsequent images

√ central scar without enhancement
(DDx: T2-hyperintense myxoid central scar of FNH)

Angio:
√ dense tumor stain
√ enlarged feeding arteries
√ NO arteriovenous / arterioportal shunting
√ avascular central scar

NUC:
√ photopenic area on sulfur colloid scan ← relative lack of Kupffer cells in number + function
√ increased activity during arterial phase + wash-out during delayed imaging on labeled RBC scan
√ nonspecific increased activity on ^{67}Ga scintigraphy

Prognosis: 48% resectability rate; average survival time of 32 months; 67% 5-year survival time

DDx: (1) Focal nodular hyperplasia (young + middle-aged woman, < 5 cm in size, calcifications uncommon, isointense to liver on all CT + MR images with pronounced homogeneous enhancement during arterial phase, myxoid hyperintense central scar on T2WI with delayed enhancement, uptake of sulfur colloid / superparamagnetic iron oxide)
(2) Large cavernous hemangioma (peripheral nodular discontinuous enhancement pattern similar to blood vessels with filling-in on delayed phase)
(3) Hepatocellular adenoma (no central scar, heterogeneous texture ← fat + hemorrhage)
(4) Hepatocellular carcinoma (regions of hemorrhage + necrosis, diseased adjacent liver, ↑ AFP)
(5) Metastasis (multifocal and visible primary)

HEPATOSPLENIC TUBERCULOSIS

Cause: disseminated disease
@ micronodular-miliary involvement
√ innumerable 0.5–2.0-mm nodules
√ hyperechoic liver
@ macronodular involvement (uncommon)
√ hypoattenuating nodules + irregular ill-defined margins
√ minimal central + definite peripheral enhancement
√ T1-hypointense + T2-hyperintense nodules
√ tuberculomas eventually calcify

HYPERPLASTIC CHOLECYSTOSIS

= variety of degenerative + proliferative changes of gallbladder wall characterized by hyperconcentration, hyperexcitability, and hyperexcretion
Frequency: 9–30–50% of all cholecystectomy specimens;
M÷F = 1÷6
Associated with: gallstones in 90%

Adenomyomatosis of Gallbladder

= ADENOMYOMATOUS HYPERPLASIA OF GALLBLADDER
= increase in number + height of mucosal folds
Path: hyperplasia of mucosa + muscularis propria with mucosal outpouching of epithelium-lined cystic spaces into (46%) or all the way through (30%) a thickened muscular layer as tubules / crypts / 2–8 mm saccules (= intramural diverticula = Rokitansky-Aschoff sinus); precipitation of cholesterol crystals in bile trapped in Rokitansky-Aschoff sinuses (= intraluminal cholesterol accumulation)
[Rokitansky, Karl Freiherr von (1804–1878), chair of Pathological Anatomy at Vienna General Hospital, Austria]
[Carl Aschoff (1866–1942), pathologist in Bonn, Germany]
Frequency: 2–5% of all cholecystectomy specimens
Age: > 35 years (develop with increasing age); M÷F = 1÷3
Associated with: (1) Gallstones in 25–75%
(2) Cholesterolosis in 33%
Types:
(a) generalized form = ADENOMYOMATOSIS
√ **"twinkling / comet-tail"** = sound reverberation artifact between cholesterol crystals in Rokitansky-Aschoff sinuses (PATHOGNOMONIC)
N.B.: Rokitansky-Aschoff sinuses of < 5 mm cannot be resolved / identified on abdominal US
√ gallbladder wall thickening + enhancement
√ **"rosary"** sign on CT = enhancing epithelium within intramural diverticula surrounded by relatively unenhanced hypertrophied gallbladder muscularis
√ multiple tiny rounded hyperintense extraluminal cavities:

√ **"string of beads"** sign = high-signal-intensity foci in gallbladder wall on T2WI (92% specific)
√ **"pearl necklace"** sign = multiple round spaces in curvilinear intramural arrangement on MRCP

√ signal voids of intramural calculi (crystals)

(b) segmental form
compartmentalization most often in neck or distal ⅓

(c) localized form in fundus
= solitary ADENOMYOMA with extraluminal diverticula-like formation
√ smooth sessile mass in GB fundus

(d) annular form
√ "hourglass" configuration of GB with transverse congenital septum

DDx: polyposis, papillomatosis, adenoma, cystadenoma, gallbladder carcinoma, metastasis

Cholesterolosis

= abnormal deposition of triglycerides + cholesterol esters in macrophages within lamina propria (foam cells) + in mucosal epithelium

Strawberry Gallbladder

= LIPID CHOLECYSTITIS = CHOLESTEROLOSIS
= planar form of cholesterolosis
= seedlike patchy / diffuse thickening of the villous surface pattern (disseminated micronodules)

Associated with: cholesterol stones in 50–70%
• bright red mucosa with interposed areas of yellow lipid
• not related to serum cholesterol level
√ radiologically not demonstrable

Cholesterol Polyp *(90%)*

= abnormal deposit of cholesterol esters and triglycerides producing a villouslike structure covered with a single layer of epithelium and attached via a delicate stalk

Not associated with: gallstones
Prevalence: 4%; most common (50%) fixed filling defect of gallbladder
Age: 40–50 years; M÷F=1÷3
Location: commonly in middle ⅓ of gallbladder

√ small round smoothly contoured intraluminal lesion:
√ multiple (on average 8) small filling defects *Size:* < 10 mm (rarely up to 20 mm) in diameter
√ "ball on the wall" sign ← lesion attached to wall with stalk (rarely seen)

Prognosis: NO malignant potential
DDx: papilloma, adenoma, inflammatory granuloma

INFLAMMATORY POLYP OF GALLBLADDER

Cause: gallstones, chronic cholecystitis
√ solitary (in ½), 2–5 polyps (in ½)

√ usually < 10 mm in diameter

Prognosis: may incite mucosal epithelial dysplasia (NO definitively increased risk for adenocarcinoma)

◊ Inflammatory polyps have a nonspecific appearance so that the diagnosis may NOT be made with certainty at imaging!

INSPISSATED BILE SYNDROME

= uncommon cause of jaundice in neonate

Associated with: massive hemolysis (Rh incompatibility), hemorrhage (intraabdominal, intracranial, retroperitoneal), increased enterohepatic circulation (Hirschsprüng disease, intestinal atresia, stenosis)

US:

√ sludge in gallbladder

√ sludge within bile ducts + partial / complete obstruction (affected ducts may blend with surrounding hepatic parenchyma)

INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM OF PANCREAS

= IPMN = MUCINOUS DUCTAL ECTASIA = DUCTECTATIC MUCINOUS CYSTIC TUMOR OF PANCREAS = INTRADUCTAL MUCIN-HYPERSECRETING NEOPLASM = MUCINOUS VILLOUS ADENOMATOSIS = MUCIN-PRODUCING PANCREATIC TUMOR

= rare intraductal tumor originating from papillary epithelial lining characterized by voluminous mucin secretions

Path: conglomeration of communicating cysts covered by a rim of normal pancreatic parenchyma + thin fibrous capsule

Histo: mucinous transformation of pancreatic ductal epithelium forming innumerable papillary projections within a typically dilated pancreatic ductal system that contains globules of mucus; papillae are coated with hyperplastic (= adenoma) / atypical (= borderline lesion) / malignant epithelium ← adenoma-carcinoma sequence

Pancreatic ductal imaging is essential to for classification:

(1) establish the diagnosis of IPMN

(2) differentiate among subtypes of IPMN like

(a) main duct IPMN (diffuse / segmental) cystic pattern

(b) mixed or isolated side-branch IPMN

Mean age: 65 years; M > F

- recurrent episodes of dull pain / acute pancreatitis ← impaired outflow of pancreatic secretions:
  - hyperamylasemia (occasionally)
- viscosity of fluid greater than normal serum (89% sensitive, 100% specific)

Location: frequently multifocal; 5–10% involve entire pancreas

◊ Location is an important factor for prognosis!

√ communication between cystic lesion + main pancreatic duct (= most reliable diagnostic finding!):

√ narrow neck at cyst-duct junction

√ mural nodules projecting into main pancreatic duct
√ protrusion of major papilla
ERCP:
- spillage of thick jellylike mucin from ampulla of Vater with protrusion from bulging patulous duodenal papilla
√ plugging of papilla of Vater
√ elongated band- / threadlike / nodular amorphous filling defects in dilated pancreatic duct (= depiction of mucin)
√ usually small mural polypoid / flat tumor
√ dilated pancreatic ductal system in the absence of an obstructive ductal stricture
√ communication between cyst cavity + pancreatic duct
N.B.: escape of contrast material due to excess of mucin / patent papillary orifice hinders filling of ductal tree

Prognosis: low-grade malignancy with better prognosis than pancreatic adenocarcinoma
Signs of malignant transformation:
√ lesion > 3.5 cm in size with thick walls
√ enhancing soft-tissue nodularity
Dx: ERCP (bulging ampulla, mucin pouring from papilla, communication between pancreatic duct + cystic cavity)
Cx: malignancy (57–92% for main-duct IPMN + 20% for branch-duct IPMN)

MRCP (findings suggestive of a malignant IPMN):
√ filling defects / papillary projections within a dilated pancreatic duct
√ main pancreatic duct cysts + dilatation of > 15 mm
√ branch duct dilatation = enlargement by any amount

DDx: (1) Chronic obstructive pancreatitis (calcifications)
(2) Serous / mucinous cystic tumors (NO communication with pancreatic duct, lobulated contour)
(3) Pseudocyst (communication with duct)

Main Duct IPMN

Age: 57 (range, 34–75) years; M÷F = 1÷1
Histo: invasive carcinoma in 60–70%
√ hyperechoic, hyperdense, T2-hypointense filling defect within dilated duct (= enhancing papillary mural nodule / gravity-dependent mucin glob)
√ dilatation of entire main pancreatic duct:
(a) dilatation of entire main pancreatic duct
√ homogeneous hypoechoic, hypodense, T1-hypointense and T2-hyperintense main duct
√ pancreatic parenchymal atrophy
√ dilatation of branch ducts (usually in pancreatic tail + uncinate process)
√ dilatation of major ± minor papilla bulging into duodenal lumen
√ ± obstruction of CBD ← tumor / impacted mucin
Cx: pancreaticobiliary / ~duodenal fistula, pseudomyxoma peritonei
DDx: chronic obstructive pancreatitis (loss of T1 signal + delayed uptake of contrast =

fibrosis)

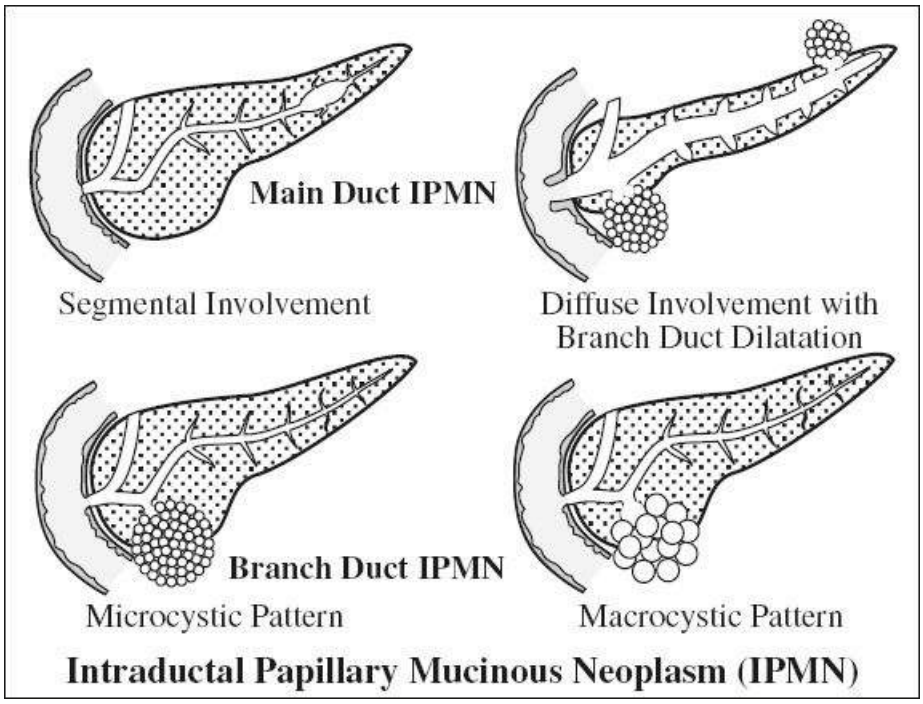
(b) segmental dilatation of main pancreatic duct

√ cyst in pancreatic body / tail + normal remaining pancreatic parenchyma

√ cyst in pancreatic head + upstream dilatation of main pancreatic duct

DDx: peripheral mucinous cystic tumor (main duct almost always normal)

Rx: Whipple operation



Branch Duct IPMN

Age: 63 (range, 37–76) years; M÷F=1÷1

- usually incidental finding when tumor small
- symptoms mimicking acute / chronic pancreatitis

Location: mainly in uncinate process >> pancreatic tail > pancreatic body

Path: macrocystic / microcystic pattern; malignancy suggested by irregular thick wall + septa and solid nodules

Histo: invasive carcinoma in 22%

√ dilatation of multiple side branches (most commonly)

√ round / ovoid small lobulated intraductal mass (frequently not visualized):

√ dilated main pancreatic duct

√ normal main pancreatic duct (almost always normal in small tumor)

◊ Secretin administration distends ducts and enhances detection of communication with main pancreatic duct!

√ uni- / multilocular cyst 10–20 mm large with sparse septa

DDx: mucinous cystadenoma (no communication with main pancreatic duct); pseudocyst (no intraluminal filling defects)

√ grapelike locular appearance = multiple thin septa separating fluid-filled lacunae

DDx: serous cystadenoma (no communication with main pancreatic duct)

√ ± severe pancreatic atrophy
√ protrusion of papilla into duodenum
Cx: seeding to main pancreatic duct resulting in main duct IPMN
Rx: observation (for asymptomatic patient and a lesion of < 3 cm) / partial pancreatectomy

LIPOMA OF LIVER

Extremely rare
• asymptomatic
May be associated with: tuberous sclerosis
Size: few mm – 13 cm
US:
√ well-circumscribed echogenic mass (DDx: hemangioma, angiomyolipoma)
√ striking acoustic refraction (sound velocity in soft tissue 1,540 min/sec, in fat 1,450 min/sec)
CT:
√ homogeneously hypoattenuating mass
√ no contrast enhancement
MR:
√ hyperintense on T1WI
√ hypointense (= signal suppression) on fat-suppressed images
√ NO enhancement after gadolinium chelate administration
Prognosis: no malignant potential

LIVER TRANSPLANT

Cadaveric liver transplantation:
= most common type of liver transplantation in adults
Advantage: › full donor liver transplantation
› usually technically successful
Disadvantage: limited organ availability
Living donor liver transplantation technique:
left lateral hepatectomy including segments II + III

Indications: end-stage acute / chronic liver disease
› chronic viral hepatitis: chronic active hepatitis (4% in childhood)
› metabolic disease: alpha-1 antitrypsin deficiency (9% in childhood), hemochromatosis, Wilson disease
› cholestatic liver disease: primary biliary cirrhosis, primary sclerosing cholangitis, biliary atresia (52% in childhood)
› autoimmune hepatitis
› cryptogenic cirrhosis (6% in childhood)
› alcoholic liver disease
› acute fulminant hepatic failure (11% in childhood): viral hepatitis, drug-induced hepatitis (eg, by acetaminophen, isoniazid), hepatotoxins (eg, mushrooms)

Eligibility for liver transplantation (Milan criteria):
single tumor of < 5 cm / ≤ 3 tumors of 3 cm or smaller

Contraindications: AIDS, extrahepatic malignant tumors, active IVDA / alcohol abuse
Frequency: 112,931 liver transplantations in US between 1988 and 2012; annually 6,000 liver transplantations; 1,500 deaths annually while awaiting transplantation

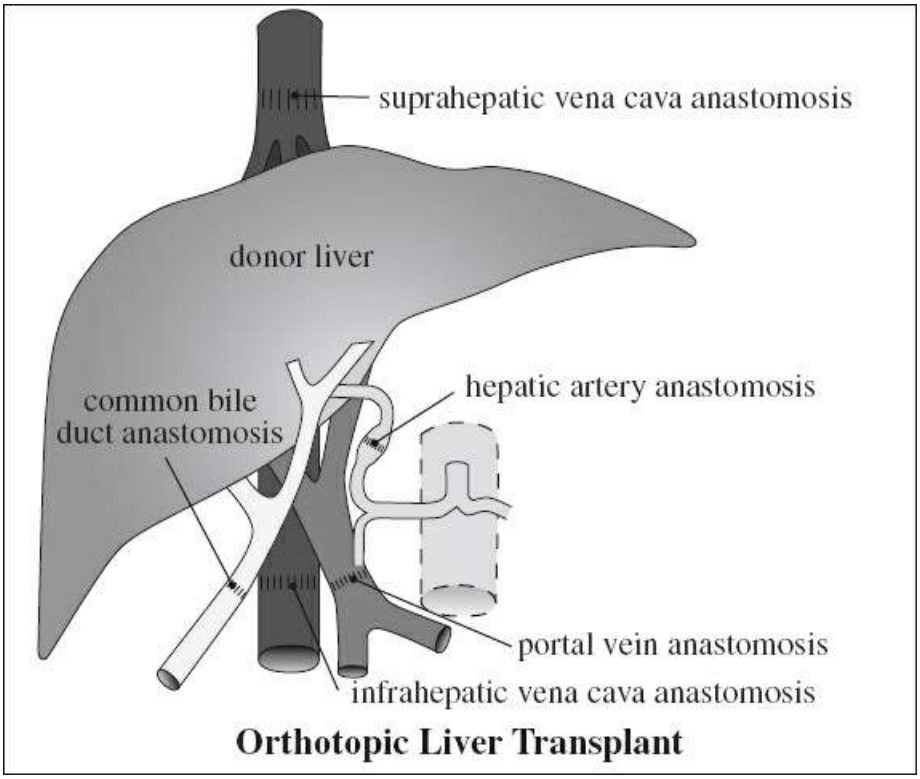
Normal posttransplant findings

(1) Periportal + reperfusion edema (21%)
Cause: lymphedema in early posttransplantation period (= dilatation of lymphatic channels ← lack of normal lymphatic drainage)
√ "starry sky" pattern = diminished liver echogenicity with accentuation of echogenic portal venules
√ "periportal collar" of low attenuation on CT
√ resolution within weeks to months
(2) Pneumobilia
(3) Fluid collection around falciform ligament (11%), at vascular anastomoses (liver hilum, IVC), at biliary anastomosis, in lesser sac
√ present during 1st day; disappears within a few weeks
(4) Small right pleural effusion
(5) Peri- / subhepatic hematoma / free intraabdominal fluid
(6) Anastomotic narrowing of IVC / portal vein
◊ Discrepancies in caliber between donor + recipient vessel have no pathologic significance!
√ wide range of portal vein velocities (15–400 cm/s) with average decrease of 20% over next few days + normalization by 2 years
√ dampened mono- / biphasic hepatic vein waveform ← graft edema / compression by adjacent hematoma

Prognosis: 1- and 5-year graft survival of 82% and 65%

Vascular Complications in Liver Transplant (9%)

◊ Most frequent cause of graft loss
• liver failure, bile leak, abdominal bleeding, septicemia



@ **Thrombosis / stenosis of IVC / hepatic vein** (< 1%)

Cause: size discrepancy between donor + recipient vessels, suprahepatic caval kinking from organ rotation, anastomotic fibrosis, neointimal hyperplasia, chronic thrombosis

- pleural effusions, hepatomegaly, ascites, extremity edema

√ compression of IVC ← swelling of graft
√ reduction in caliber of poststenotic IVC
√ prestenotic dilatation of IVC + hepatic veins
√ persistent monophasic waveform (sensitive but not specific for significance of stenosis; bi- / triphasic waveform excludes significant stenosis)
√ focal narrowing on B-mode imaging
√ 3–4-fold velocity increase compared with prestenotic segment
√ intraluminal echogenic thrombus
√ pressure gradient of > 5 mmHg
√ mosaic pattern of perfusion on CT / MR (Budd-Chiari)

@ **Thrombosis / stenosis of portal vein** (1–3%)

Cause: faulty surgical technique, vessel misalignment, differences in vessel caliber creating turbulent flow, hypercoagulable state, prior portal vein surgery, prior thrombosis in recipient portal vein, increased downstream resistance ← supra-hepatic stricture of IVC, decreased portal inflow

- portal hypertension, liver failure, massive ascites, edema

Duplex US of venous stenosis > 50%
√ 3- to 4-fold increase in peak systolic flow velocity compared with prestenotic segment
√ poststenotic turbulence

√ narrowing of portal vein + poststenotic dilatation
√ increase in number / caliber of collateral vessels
√ filling defect / focal narrowing at anastomosis
Rx: percutaneous transluminal angioplasty ± stent placement, surgical thrombectomy, venous jump graft, creation of portosystemic shunt, retransplantation

@ Hepatic artery
Normal Resistive Index (RI): 0.5 – 0.8

√ < 72 hours after transplantation RI frequently > 0.8 with return to normal in a few days
Cause: older donor age, prolonged period of cold ischemia, hepatic arterial spasm, reperfusion edema, increased portal flow (= inhibition of arterial vasodilator release)

1. **Hepatic artery stenosis** (5–13%)
Location: at / near anastomosis
Cause: clamp injury, arterial spasm, intimal trauma from perfusion catheter, disruption of vasa vasorum
Time of onset: within 3 months after transplantation
√ marked focal increase in peak systolic velocity > 200–300 cm/sec or 2–3 x of prestenotic velocity + poststenotic turbulence in > 50% stenosis (30% sensitive, 96% specific)

√ intrahepatic tardus et parvus waveform:
√ slowed systolic **a**cceleration **t**ime (SAT > 70–80 msec) distal to stenosis (73% sensitive)
√ diminished pulsatility (RI < 0.55) ← ischemia

Pitfall: intrahepatic collateral arteries ← severe aortoiliac atherosclerosis / hepatic artery stenosis)
DDx: normal in early post-transplantation period
√ biliary dilatation (← stricture), infarction, biloma
Cx: hepatic artery thrombosis, hepatic ischemia, biliary stricture, sepsis, graft loss
Rx: revascularization surgery, balloon angioplasty

2. **Hepatic artery thrombosis** (4–12–16% in adults, 9–19–42% in children)
◊Most common vascular complication of liver transplantation (60%)!

Pathophysiology:
Bile duct perfusion: solely by hepatic artery
Arterial bile duct supply: via retrograde collaterals from vessels at 3- and 9-o'clock positions + via gastroduodenal and superior pancreaticoduodenal arcade, which are divided during bile duct transection in donor
Hepatic artery thrombosis → liver infarction, biliary ischemia, necrosis → biliary stricture (anastomotic and nonanastomotic), bile leak, biliary abscess, biliary cast syndrome

Risk factors:
donor death ← intracerebral hemorrhage, donor age > 50 years, previous liver transplant, split segmental graft, interpositional conduit for anastomosis, preexisting celiac artery stenosis
Time of onset: usually within first 2 months
(a) early thrombosis: < 1 month of transplantation ← significant caliber difference between donor + recipient artery, prolonged cold ischemia of donor liver, ABO

blood type incompatibility

(b) late thrombosis: > 1 month of transplantation ← acute rejection / sepsis (CMV infection)

- Three types of clinical presentation:
  (1) Fulminant hepatic necrosis + rapid deterioration
  (2) Bile leak, bile peritonitis, bacteremia, sepsis
  (3) Relapsing bacteremia

CT / MRA / Angio:
√ abrupt cutoff of flow in hepatic artery (usually at anastomotic site)
√ nonenhancement of hepatic artery
√ decreased enhancement of hepatic parenchyma ← ischemia / infarction

US (54–92% sensitive, 64–88% specific):
√ lack of hepatic artery flow
False-positive Doppler (10%):
systemic hypotension, high-grade hepatic artery stenosis, small vessel size, severe hepatic edema (in first 72 hours after transplantation, viral hepatitis, acute rejection)
False-negative Doppler:
arterial collaterals (← chronic thrombosis) with parvus tardus waveform (simulating proximal hepatic artery stenosis)
√ "syndrome of impending thrombosis":
√ loss of arterial diastolic flow
√ dampening of systolic peak
Prognosis: thrombosis in 92%
√ multiple hypoechoic lesions in liver periphery (= infarcts)

Mortality: 27–33–58%; 80% if undiagnosed
Rx: thrombectomy; hepatic artery reconstruction; retransplantation (30% mortality)

3. **Hepatic artery pseudoaneurysm** (uncommon)
   Location: at vascular anastomosis; complication of liver biopsy / angioplasty / focal infection
   Cx: acute shock due to massive intraperitoneal hemorrhage; portal vein fistula; biliary fistula
   Rx: surgical resection, embolization, exclusion by stent placement

Parenchymal Complications in Liver Transplantation

1. Rejection
   ◊ Most common cause of graft failure
   ◊ Can ONLY be diagnosed with liver biopsy!
2. Infarction (10%)
   √ may calcify
   √ may liquefy developing into intrahepatic biloma
3. Graft infection
4. Posttransplant lymphoproliferative disease
5. Neoplasms:
   skin cancer (other than melanoma), Kaposi sarcoma, NHL

Biliary Complications in Liver Transplant (6–25–34%)

◊ 2nd most common cause of liver dysfunction after rejection

Time of onset: within first 3 months

Stricture and leak = the most common biliary complications

1. **Biliary obstruction** (15–18%)
   (a) anastomotic stricture (extrahepatic)
   Cause: iatrogenic trauma → ischemia + scar formation
   (b) nonanastomotic (intrahepatic) stricture
   Cause: hepatic arterial thrombosis / stenosis (in 50%), prolonged preservation time, bacterial / viral cholangitis, rejection, recurrent primary sclerosing cholangitis, cholangiocarcinoma, kinking of redundant CBD, sphincter of Oddi dysfunction
   (c) tension mucocele of allograft cystic duct remnant
   Cause: ligation of cystic duct proximally + distally
   √ extrinsic mass compressing CHD
   √ fluid collection adjacent to CHD
   Cx: ascending cholangitis
2. **Bile leak** (10–15%)

Biliary leaks usually occur within the first few months after transplantation.

   (a) T-tube exit site: 50% within 10 days
   √ free leakage into peritoneal cavity
   √ loculated perihepatic collection
   (b) anastomosis of choledochocholedochostomy:
   70% within 1st postoperative month
   (c) bile duct necrosis (hepatic artery occlusion)
   ◊ The intrahepatic biliary epithelium is perfused solely by the hepatic artery!
   (d) after liver biopsy
   (e) common hepatic duct leak
3. **Biloma formation** (11%)
   within 1st year after transplantation
   Risk factors: hepatic artery thrombosis / stenosis, hepaticojejunostomy
4. **Stone / sludge formation**
   Cause: alteration in bile composition

LYMPHOMA OF LIVER

With de novo focal liver masses the diagnosis of lymphoma is suggested by an absent history of primary malignancy, < 40 years of age, B symptoms, splenic lesions, splenomegaly, and widespread abdominal / mediastinal lymphadenopathy.

US:

√ hypo- to anechoic nodules + absent posterior acoustic enhancement
√ ± "target" appearance (= central hyperechoic + peripheral hypoechoic component)
√ increased peripheral vascularity at Doppler
√ mild inhomogeneous hyperenhancement in arterial phase + contrast agent washout in portal

and late phases

CT:
- √ nodules of soft-tissue attenuation
- √ ± hemorrhage + necrosis
- √ hypovascular during all phases of enhancement
- √ ± rim-enhancement

MRI:
- √ hypo- to isointense nodules on T1WI
- √ moderately hyperintense nodules on T2WI
- √ DWI may allow earlier identification: typically restricted diffusion ← highly cellular mass (Detection rate for CT / MR is < 10%)

CEMR:
- √ hypovascular during all phases of enhancement
- √ ± minimal early enhancement
- √ "target" appearance (15%) = hyperintense poorly enhancing center + peripheral enhancement

PET/CT (modality of choice for staging + treatment response):
- √ avid hypermetabolism

DDx: Hepatocellular carcinoma (arterial phase enhancement, delayed contrast material washout with capsular enhancement, vascular thrombosis, hypometabolic at PET)

Primary Hepatic Lymphoma *(rare)*

Incidence: increased in immunosuppressed patients

Associated with: hepatitis B & C, Epstein-Barr virus

- right upper quadrant pain, jaundice (50%)
- systemic symptoms: fever, weight loss (⅓)
- √ solid solitary liver mass (60%)
- √ multiple heterogeneously enhancing liver masses with dominant mass (35–40%)
- √ diffuse infiltrating disease
- √ ill-defined mass in porta hepatis
- √ ± hepatic hilar lymphadenopathy

In primary hepatic lymphoma distant lymphadenopathy + splenomegaly / splenic lesions + bone marrow disease / leukemic blood profile should NOT occur for at least 6 months after the onset of hepatic disease.

Secondary Hepatic Lymphoma *(common)*

Incidence of liver involvement:
in up to 50% (60% by autopsy) in Hodgkin disease; in up to 20% (50% by autopsy) in NHL

Pattern:

(a) diffuse homogeneous infiltration (80%):
- √ ± hepatomegaly
- √ NO alteration in hepatic architecture

(b) focal nodular lymphoma (in 10%):

√ discrete homogeneous nodules ± miliary pattern

(c) combination of diffuse + nodular lymphoma (3%)

√ paraaortic, celiac, mesenteric, periportal nodes typically involved (lymphadenopathy below level of renal veins)

√ splenic lesions (30–40%)

DDx: Opportunistic infection (fungal microabscesses, septic emboli)

LYMPHOMA OF PANCREAS

Type: NHL (most commonly) with both B- and T-cell lineages

FDG/PET: useful for staging and differentiation of primary from secondary pancreatic lymphoma

A. PRIMARY LYMPHOMA

Frequency: < 2% of extranodal lymphoma; 0.5% of pancreatic tumors

Mean age: 55 (range, 35–75) years

Predisposed: immunocompromised (HIV, transplant recipient)

- abdominal pain (83%), weight loss (50%)
- obstructive jaundice (40%), acute pancreatitis (12%)
- palpable mass (58%)
- CLASSIC fever + chills + night sweats (in only 2%)

Location: pancreatic head > entire gland

Morphology:

(a) focal well-circumscribed mass

Location: pancreatic head (80%)

Size: 8 (range, 2–15) cm

√ large unifocal well-circumscribed homogeneous solid mass:

√ hypoattenuating on CT

√ hypointense on T1WI + intermediate SI on T2WI (higher than pancreas + lower than fluid)

√ infrequently with central cystic area

√ faint contrast enhancement

√ mild dilatation of pancreatic duct

DDx: pancreatic adenocarcinoma (with little pancreatic duct dilatation / tail atrophy)

(b) diffuse form (simulating acute pancreatitis)

√ poorly defined enlarged pancreas

√ slightly lower attenuation compared with normal

√ irregular peripancreatic fat infiltration

√ diffusely reduced homogeneous enhancement

√ hypointense on T1WI + T2WI

DDx: acute pancreatitis

√ invasive growth across anatomic boundaries

√ peripancreatic nodal masses:

√ lymphadenopathy below level of renal veins

√ anterior displacement of entire pancreas

√ intact fat planes between lymph nodes and pancreas

√ NO calcifications

√ envelopment of adjacent vessels WITHOUT vascular invasion / obstruction:
√ peripancreatic vessels displaced + stretched
√ uncommon dilatation of pancreatic + bile duct

B. SECONDARY LYMPHOMA (in 30% of NHL)
√ direct extension from peripancreatic lymphadenopathy

DDx: primary lymphoma (anterior displacement of pancreas, intact fat plane between pancreas + adjacent organs)

DDx: pancreatic adenocarcinoma (gross dilatation of main pancreatic duct, no lymph nodes below level of renal vein, vascular invasion common)

LYMPHOMA OF SPLEEN

Frequency: 3rd most common site of abdominal involvement; may be initial manifestation in large cell lymphoma; most common site of abdominal involvement in Hodgkin disease

N.B.: Splenic involvement is considered extranodal in NHL but nodal in Hodgkin disease!

√ diffuse uniform infiltration
√ ill-defined hypoenhancing foci of < 1 cm in diameter become apparent after contrast enhancement in late venous and equilibrium phase
√ nonspecific splenomegaly ← lymphomatous involvement / reactive process
√ splenic hilar adenopathy

Dx: staging laparotomy necessary as ²/₃ of tumor nodules < 1 cm in size

DDx: disseminated fungal infection of candidiasis / aspergillosis (febrile neutropenic patient, nodules of 2–20 mm in diameter, no lymphadenopathy, peripheral rimlike / central nodular enhancement)

MESENCHYMAL HAMARTOMA OF LIVER

= rare developmental benign cystic liver tumor characterized by proliferative extension along portal tracts; 2nd most common benign liver mass in children after infantile hemangioendothelioma

Pathogenesis: balanced translocation at chromosome 19q13.4 similar to undifferentiated (embryonal) sarcoma

Path: well-marginated solitary liver mass with cysts (in 83%) of a few mm up to 14 cm in size containing clear amber fluid / gelatinous material; no capsule; infrequent hemorrhage and necrosis

Histo: disordered arrangement of primitive fluid-filled mesenchyme, bile ducts, hepatic parenchyma; stromal / cystic predominance

Age peak: 15–24 months (range, newborn to 19 years); in 95% by 5 years of age; M÷F = 3÷2

• slow progressive painless abdominal distension
• anorexia. nausea, vomiting, jaundice
• ± respiratory distress and lower extremity edema

Location: right lobe÷left lobe = 3÷1; 20% pedunculated

Mean size: 16 (range, 5–29) cm

√ grossly discernible cysts in 80%

US:

√ multiple rounded cystic areas on an echogenic background:
√ low-level echoes within cysts (= gelatinous contents)
√ some blood flow in solid portions + septa (color Doppler)
√ may appear solidly echogenic in fetus / younger infant ← microcysts create innumerable tissue-fluid interfaces

CT:
√ multiple lucencies of variable size + attenuation (depending on composition of stromal versus cystic elements)
√ hemorrhage (rare and atypical)
√ enhancement of stromal component

MR:
√ varying SI (varying concentrations of protein in cystic predominance type) / hypointense on T1WI (mesenchymal predominance type)
√ marked hyperintensity of cystic locules on T2WI
√ solid portions of fibrosis hypointense on all sequences

NUC:
√ one / more areas of diminished uptake on sulfur colloid scan

Prognosis: 90% long-term survival

Rx: resection

DDx: (1) Hepatoblastoma (marked elevation of AFP, solid tumor with calcifications)
(2) Focal form of infantile hemangioendothelioma (calcifications in 50%, marked hypervascularity)
(3) Undifferentiated (embryonal) sarcoma (older child at 6–10 years of age, hemorrhage + necrosis)

METASTASIS TO GALLBLADDER

Organ of origin: melanoma (60%), renal cell carcinoma (late in course of disease), lymphoma (in AIDS), malignant fibrous histiocytoma, gastric cancer (in Asia)
› in children: embryonal cell sarcoma, rhabdomyosarcoma

◊ 94% of benign lesions are < 1 cm in diameter; 88% of malignant lesions are > 1 cm in diameter!

DDx: adenocarcinoma (usually associated with gallstones, more common in women + older patients); squamous cell carcinoma; carcinosarcoma, small cell carcinoma

METASTASIS TO LIVER

◊ Most common malignant lesion of the liver
◊ Most common metastatic site after regional lymph nodes

Incidence: 18–20 x greater than primary carcinoma; 22% of all liver tumors in patients with a known malignancy (50% in autopsies)

Organ of origin: colon (42%), stomach (23%), pancreas (21%), breast (14%), lung (13%)
√ involvement of liver + spleen typical in leukemia/lymphoma + melanoma
in children: neuroblastoma, Wilms tumor

• hepatomegaly (70%); abnormal liver enzymes (50–75%)

Location: both lobes (77%), right lobe (20%), left lobe (3%)

Number: multiple (50–98%), solitary (2%)
Size: > 33% smaller than 2 cm
NUC:
sensitivity of 80–95% for lesions > 1.5 cm; lesions < 1.5 cm are frequently missed; sensitivity increases with metastatic deposit size, peripheral location, and use of SPECT
NECT:
important for hypervascular tumors (eg, renal cell carcinoma, carcinoid, islet cell tumors), which may be obscured by CECT
CECT (88–90% sensitive; 99% specific):
◊ Sensitivity decreases relative to NECT if scan obtained only during equilibrium phase of contrast administration
√ lesion enhancement during arterial phase ← metastases are supplied by hepatic artery
√ less enhancement during portal venous phase ← metastases have a negligible portal venous supply
√ extracellular space agents accumulate more in tumor tissue ← metastases have a larger interstitial space
Optimal technique: bolus of contrast followed by dynamic incremental scanning
√ circumferential bead- or bandlike enhancement during arterial phase + peripheral washout on delayed images
√ no (35%), peripheral (37%), mixed (20%), central (8%) enhancement
√ complete isodense fill-in on delayed scans in 5% (DDx: hemangioma)
◊ Lesions of ~ 1 cm can usually be detected!
CT-Angiography (most sensitive imaging modality):
Indication: patients with potentially resectable isolated liver metastases / preoperative before partial hepatectomy → additional lesions are detected in 40–55%
(1) CT arteriography = angiographic catheter in hepatic artery → detects lesions by virtue of increased enhancement
(2) CT arterial portography = angiographic catheter in SMA → detects hypodense lesions on a background of increased enhancement of normal surroundings in portal venous phase
CT-delayed iodine scanning:
= CT performed 4–6 hours following administration of 60 mg iodine results in detection of additional lesions in 27%
US (intraoperative with palpation): > 95% sensitive
MR:
√ usually irregular shape and margin
√ usually hypointense on T1WI
√ heterogeneously hyperintense on DWI + T2WI
√ perilesional fat deposition = metastasis from primary pancreatic insulinoma ← effect of insulin inhibiting oxidation of fatty acids + promoting accumulation of tricglycerides in hepatocytes
CEMR:
√ arterial phase:
√ homogeneously hypervascular for metastasis < 2 cm
√ heterogeneous with ring enhancement if > 2 cm
√ thick hypovascular peripheral rim

√ perilesional ring enhancement ← central tumor necrosis
√ irregular peripheral wash-out during venous phase
√ delayed heterogeneous contrast retention

Rx: (1) Resection

Exclusion criteria for metastasectomy:

(a) advanced stage of primary tumor
(b) > 4 metastases
(c) extrahepatic disease
(d) < 30% normal liver tissue / function available after resection

(2) Radiofrequency ablation

Prognosis: 30–40% 5-year survival after resection

Calcified Liver Metastases

Prevalence: 2–3%

1. Mucinous carcinoma of GI tract (colon, rectum, stomach)
2. Endocrine pancreatic carcinoma
3. Leiomyosarcoma, osteosarcoma
4. Malignant melanoma

Intravenous Contrast Strategies for Liver Lesions

Uniphasic PVP	*Biphasic PP + PVP*	*Triphasic NE + AP + PVP*
Colorectal cancer	Pancreatic cancer	Carcinoid
Gastric cancer		Neuroendocrine
Ovarian cancer		Islet cell tumor
Cervical cancer		Renal cell cancer
Lymphoma		GIST
Multiple myeloma		Thyroid cancer
		? Breast / Melanoma

PVP = portal venous phase; PP = parenchymal phase
AP = arterial phase; NE = nonenhanced

5. Papillary serous ovarian cystadenocarcinoma
6. Lymphoma
7. Pleural mesothelioma
8. Neuroblastoma
9. Breast cancer
10. Medullary carcinoma of the thyroid
11. Renal cell carcinoma
12. Lung carcinoma
13. Testicular carcinoma

mnemonic for mucinous adenocarcinoma: COBS

Colon carcinoma
Ovarian carcinoma
Breast carcinoma

Stomach carcinoma

Hypervascular Liver Metastases

= increased enhancement relative to normal liver during arterial phase + washout on delayed images

1. Primary neuroendocrine tumor:
   (a) Pancreatic endocrine tumor
   (b) Neuroendocrine carcinoma = carcinoid (14%)
   (c) Pheochromocytoma
2. Melanoma (11%)
3. Renal cell carcinoma (8%)
4. Breast carcinoma (some) (2%)
5. Thyroid carcinoma
6. Choriocarcinoma
7. Sarcomas
8. Ovarian cystadenocarcinoma

in ( ) number of lesions seen only during arterial phase

mnemonic: CHIMP

Carcinoid
Hypernephroma
Islet cell carcinoma
Melanoma
Pheochromocytoma

CT:

◊ Triphasic scan recommended!

Detection rate: 87% for NECT, 78% for hepatic arterial phase, 77% for portal venous phase

MR:

√ moderately hypointense on T1WI unless hemorrhagic
√ markedly hyperintense on T2WI (= cystic, necrotic)
√ hyperintense on DWI

CEMR:

√ uniform / peripheral-rim / heterogeneous enhancement
√ "peripheral washout" sign = decrease of contrast material preferentially in periphery of mass while center remains hyperintense on delayed image (? related to vessel distribution with central necrosis / fibrosis and peripherally viable tumor), same as in HCC
√ hypointense / target appearance on 1-hour delayed image after Gd-BenzylOxyPropionicTetraAcetate

Hypovascular Liver Metastases

= decreased enhancement relative to normal liver

1. Stomach
2. Colon / rectum
3. Head & neck

4. Pancreas
5. Lung
6. Breast
7. Transitional cell carcinoma
8. Prostate

√ low SI on T1WI images + iso- to hyperintense on T2WI
√ delayed enhancement during portal venous phase / (occasionally) early ring enhancement
◊ Most conspicuous on portal venous phase images!

Hemorrhagic Liver Metastases

mnemonic: **CT BeComes MR**

Colon carcinoma
Thyroid carcinoma
Breast carcinoma
Choriocarcinoma
Melanoma

Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1				
Lesion Type	*Response Type*			
	Regression: complete	**partial**	**stable**	**Progression**
MEASURABLE TARGET LESIONS				
= longest diameter of ≥ 10 mm (CT slice thickness of ≤ 5 mm) / ≥ 20 mm (nonhelical CT slice thickness of > 10 mm) / ≥ 20 mm (CXR) selected on the basis of size and suitability for accurate repeated measurements (= 2 target lesions per organ)				
Measure SUM of longest diameters of target lesions (≤ 2 per organ + total of ≤ 5)	disappearance of all	relative ⇓ of ≥ 30% ⇓ to < 5 mm reported as 5 mm	no change	≥ 1 new lesions absolute ⇑ of SUM ≥ 5 mm relative ⇑ of SUM ≥ 20% new FDG PET lesion
N.B.: Fragmentation of lesion treated as separate lesions Coalescence of lesions treated as one lesion				
add short-axis measurement of ***lymph node*** if ≥ 15 mm to SUM of target lesions	short-axis ⇓ to < 10 mm			
NONMEASURABLE / NONTARGET LESIONS				
= small lesions with longest diameter of < 10 mm, skeletal metastasis without soft-tissue component, ascites, pleural effusion, lymphangitic spread, leptomeningeal disease, inflammatory breast disease, cystic / necrotic lesion, lesion in irradiated area				
Note presence / absence of each nontarget lesion at baseline and follow-up	disappearance of all nontarget lesions		persistence of ≥ 1 nontarget lesions	appearance of ≥ 1 new lesion progression of existing nontarget lesions
Lymph node with short axis ≥ 10 and < 15 mm	short-axis ⇓ to < 10 mm (= normal node)			

Renal cell carcinoma
and: lung, testicle

√ hyperintense on T1WI

Echogenic Liver Metastases

Prevalence: 25%

1. Colonic carcinoma (mucinous adenocarcinoma) 54%
2. Hepatoma 25%
3. Treated breast carcinoma 21%

Liver Metastases of Mixed Echogenicity

Prevalence: 37.5%

1. Breast cancer 31%
2. Rectal cancer 20%
3. Lung cancer 17%
4. Stomach cancer 14%
5. Anaplastic cancer 11%
6. Cervical cancer 5%
7. Carcinoid 1%

Cystic Liver Metastases

Pathophysiology of cystic metastases:

(a) necrosis of hypervascular metastases ← rapid growth beyond capacity of vascular supply: neuroendocrine tumor, melanoma, GIST
(b) abundant mucin production by mucinous adenocarcinoma: colorectal / ovarian carcinoma
(c) systemic / locoregional treatment

1. Mucinous ovarian carcinoma
2. Colonic carcinoma
3. Sarcoma
4. Melanoma
5. Lung carcinoma
6. Carcinoid tumor

mnemonic: LC GOES

Leiomyosarcoma (and other sarcomas)
Choriocarcinoma
Gastric carcinoma
Ovarian carcinoma
Endometrial carcinoma
Small cell carcinoma

Echopenic Liver Metastases

Prevalence: 37.5%

1. Lymphoma 44%
2. Pancreas 36%
3. Cervical cancer 20%
4. Lung (adenocarcinoma)
5. Nasopharyngeal cancer

T1-Hyperintense Metastasis

1. Melanoma
2. Mucinous carcinoma
3. Carcinoid
4. Hemorrhagic metastasis

Markedly T2-Hyperintense Metastasis

1. Renal cell carcinoma
2. Islet cell tumor
3. Pheochromocytoma
4. Leiomyosarcoma
5. Necrotic metastasis

METASTASIS TO PANCREAS

Frequency: 2–11% (autopsy); 2–5% of all malignancies

Organ of origin: renal cell carcinoma (30%), bronchogenic carcinoma (23%), breast carcinoma (12%), soft-tissue sarcoma + Kaposi sarcoma (8%), colonic carcinoma (6%), melanoma (6%), secondary lymphoma, ovarian cancer, HCC

Time interval since diagnosis of primary:

< 3 years for most primaries; 6–12 years for RCC

• asymptomatic (50–83%) / nonspecific clinical symptoms

Morphology:

(a) well-marginated solitary mass (50–78%)
(b) multiple ovoid masses (5–17%) with discrete smooth margins
(c) diffuse pancreatic enlargement (5–44%)

US:

√ hypo- / hyperechoic mass

NECT:

√ hypo- / isoattenuating mass

CECT (closely resembling enhancement pattern of primary):

√ heterogeneously (60%) / homogeneously (17%) hyperattenuating relative to pancreas
√ hypoattenuating relative to pancreas (20%)
√ isoattenuating relative to pancreas (5%)
√ peripheral enhancement of lesion > 1.5 cm (70%)
√ homogeneous enhancement of small lesion

MR:

√ hypointense on T1WI + hyperintense on T2WI

Concomitant intraabdominal metastases to:

liver (36%), lymph nodes (30%), adrenal glands (30%)

DDx: ductal pancreatic adenocarcinoma (uniformly hypo- / nonenhancing mass, encasement of vessels); neuroendocrine tumor

MILK OF CALCIUM BILE

= LIMY BILE = CALCIUM SOAP

= precipitation of particulate material with high concentration of calcium carbonate, calcium phosphate, calcium bilirubinate

Associated with: chronic cholecystitis + gallstone obstruction of cystic duct

√ diffuse opacification of GB lumen with dependent layering
√ usually functionless GB on oral cholecystogram

US:

√ intermediate features between sludge + gallstones

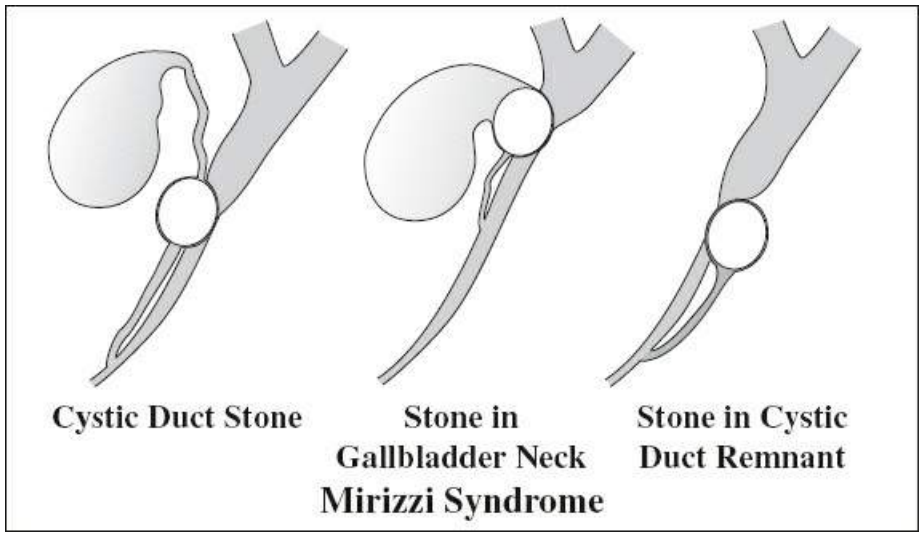
MIRIZZI SYNDROME

= extrinsic right-sided compression of common hepatic duct by large gallstone impacted in Hartmann pouch (at junction of cystic duct and gallbladder neck) / cystic duct remnant; accompanied by chronic inflammatory reaction

Predisposition: long cystic duct coursing parallel to CHD; low insertion of cystic duct into CBD

• jaundice, fever, right upper quadrant pain

Classification (guiding surgical management):



Type 1: simple obstruction of CHD by extrinsic compression WITHOUT fistulization

Type 2: cholecystocholedochal fistula + erosion of CBD wall affecting < ⅓ of bile duct circumference

Type 3 affecting ⅓ to ⅔ of bile duct circumference

Type 4 affecting > ⅔ of bile duct circumference

√ normal CBD

√ TRIAD:

(1) Gallstone impacted in GB neck / cystic duct

(2) Dilatation of intrahepatic and common hepatic ducts

(3) Smooth curved extrinsic narrowing of CHD

Cholangiography:

√ partial obstruction of CHD ← external compression on lateral side of duct / eroding stone

CT:

√ gallstone not always visualized

MR:

√ cholelithiasis with stone in cystic duct

√ focal stricture of CHD

√ dilatation of intrahepatic bile ducts + proximal CHD

√ normal caliber of distal CBD

Cx: cholecystobiliary fistula

Rx: open surgery

DDx: lymphadenopathy, neoplasm of GB / CHD

MUCINOUS CYSTIC NEOPLASM OF PANCREAS

= MACROCYSTIC ADENOMA OF PANCREAS = MUCINOUS CYSTADENOMA

= thick-walled uni- / multilocular low-grade malignant tumor composed of large mucin-containing cystic spaces

Frequency: 10% of pancreatic cystic neoplasm; 1% of all pancreatic neoplasms

Mean age: 47 (range, 20–95) years; in 50% between 40–60 years; M÷F = 1÷9

Path: large smooth round / lobulated multiloculated cystic mass encapsulated by a layer of fibrous connective tissue

Histo: cysts lined by tall columnar, mucin-producing cells subtended by a densely cellular mesenchymal stroma (reminiscent of ovarian stroma = distinguishing feature), often in papillary arrangement; lack of cellular glycogen; similar to biliary and ovarian mucinous tumors

(a) mucinous cystadenoma

(b) mucinous cystadenocarcinoma = stratified papillary epithelium

◊ All mucinous cystic neoplasms should be considered low-grade malignant neoplasms!

• asymptomatic; abdominal pain, anorexia

Location: often in pancreatic tail (90%) / body, head (rare)

Mean size of mass: 10–12 (range, 2–36) cm in diameter

Size of cysts: multi- / unilocular large cysts > 2 cm

Number of cysts: usually < 6 cysts

A pancreatic tumor with cysts of > 2 cm in diameter is a mucinous cystic neoplasm in 93–95%!

√ well-demarcated thick-walled mass with < 2 mm thin septa

√ solid papillary excrescences protrude into the interior of tumor (= sign of malignancy)

√ amorphous discontinuous peripheral mural calcifications (10–15%)

√ hypovascular mass with sparse neovascularity

√ ± vascular encasement and splenic vein occlusion

√ great propensity for invasion of adjacent organs

US:

√ cysts may contain low-level echoes

CT:

√ fine internal septa + small intramural nodules may not be visible ± contrast enhancement → thin-section CT

√ cysts with attenuation values of water; may have different levels of attenuation within different cystic cavities

√ enhancement of cyst walls

MR:

√ unilocular / mildly septated typically mucin-filled cystic lesion of homogeneous T1 hypointensity and T2 hyperintensity (= MR characteristics of simple fluid)

√ mildly thick enhancing septa (frequent)

√ thick delayed-enhancing fibrotic wall

√ pertinent negatives:
√ NO communication with pancreatic duct
√ NO enhancing soft-tissue components

Angio:
√ predominantly avascular mass
√ cyst wall + solid components may demonstrate small areas of vascular blush + neovascularity
√ displacement of surrounding arteries + veins by cysts

Metastases:
√ round thick-walled cystic lesions in liver

Prognosis: invariably transformation into cystadenocarcinoma; 17–63% 5-year survival rate

Dx: biopsy with adequate sampling of cyst lining mandatory to exclude foci of dysplasia / carcinoma in situ

Rx: complete surgical excision (5-year survival rate of 74–90%)

DDx:

(1) Pseudocyst (most common pancreatic cyst): inflammatory changes in peripancreatic fat, pancreatic calcifications, temporal evolution, history of alcoholism, elevated levels of amylase

(2) **Mucinous non-neoplastic cyst**
= mucinous differentiation of epithelial lining without cellular atypia + lack of surrounding ovarian stroma
• no proven sex predilection
√ incidental small (rarely large) unilocular cyst ± thick wall indistinguishable from mucinous cystadenomas
√ NO ductal communication / papillary projections

(3) Lymphangioma / hemangioma

(4) Variants of ductal adenocarcinoma
(a) mucinous colloid adenocarcinoma / ductectatic mucinous tumor of pancreas = mucin-hypersecreting carcinoma
(b) intraductal papillary mucinous neoplasm (IPMN) (communication with pancreatic duct)
(c) adenosquamous carcinoma: squamous component predisposes to necrosis + cystic degeneration
(d) anaplastic adenocarcinoma: lymphadenopathy + metastases at time of presentation

(5) Solid and cystic papillary epithelioid neoplasm: hemorrhagic cystic changes in 20%

(6) Cystic pancreatic endocrine tumor: hypervascular component

(7) Cystic metastases: history of malignant disease

(8) Atypical serous cystadenoma: smaller tumor with greater number of smaller cysts

(9) Sarcoma

(10) Infection: amebiasis, Echinococcus multilocularis

MUCINOUS CYSTADENOCARCINOMA OF PANCREAS

Etiology: adenoma-carcinoma sequence

Histo: invasive elements surrounded by ovarian-type stroma

Age: older than patients with mucinous cystadenoma
MR:
√ > 4-cm large complex cystic pancreatic lesion
√ intracystic enhancing soft tissue
√ soft-tissue nodularity
DDx: Solid pseudopapillary tumor of pancreas
Rx: any enhancing soft tissue within a cystic pancreatic neoplasm is an indication for resection.
Rx: any enhancing soft tissue within a cystic pancreatic neoplasm is an indication for resection.

MULTIPLE BILE DUCT HAMARTOMAS

= BILIARY MICROHAMARTOMAS = VON MEYENBURG COMPLEX
Prevalence: 0.7% at autopsy, 2.8% at microscopy
Etiology: failure of involution of embryonic interlobular bile ducts = part of fibropolycystic liver disease spectrum
Path: communication with biliary system usually obliterated
Histo: cluster of proliferated bile ducts lined by single layer of cuboidal cells embedded in fibrocollagenous tissue with single ramified lumen
May be associated with: fibropolycystic liver disease
Size: 0.1–15 mm
Location: random / scattered; periportal; multiple / solitary
• asymptomatic = incidental discovery
√ nonspecific imaging appearance of small well-defined lesions
√ variable enhancement pattern: none / rim / slow homogeneous
CT:
√ multiple scattered round / oval / irregular hypodense lesions (44% occult on CT)
√ rim of little peripheral / no enhancement
US:
√ multiple small cysts / echogenic areas (if size not resolved)
√ ± comet-tail (ring-down) artifact
MR:
√ small well-defined hypointense lesions on T1WI
√ iso- / slightly hyperintense on T2WI
√ no internal enhancement ± thin rim enhancement of surrounding liver parenchyma on immediate / delayed phase
Angio:
√ multiple areas of abnormal vascularity in form of small grapelike clusters persisting into venous phase
DDx:
1. Metastatic liver disease (more variable in size and attenuation / signal intensity)
2. Simple hepatic cysts (not as numerous or uniformly small)
3. Autosomal dominant polycystic disease (cysts usually larger and more numerous)
4. Microabscesses
5. Granulomata

MULTIPLE ENDOCRINE NEOPLASIA

= MEN = MULTIPLE ENDOCRINE ADENOMAS (MEA)

= familial autosomal dominant adenomatous hyperplasia characterized by neoplasia of 2 or more endocrine organs

Theory: cells of involved principal organs originate from neural crest and produce polypeptide hormones in cytoplasmic granules, which allow amine precursor uptake and decarboxylation = APUD cells

reminder:

MEN 1 = Wermer syndrome PiPaPanc

MEN 2 = Sipple syndrome (type 2A) PhePaM

Types of Multiple Endocrine Neoplasia			
MEN	*Type 1*	*Type 2*	*Type 3*
Pituitary adenoma	+		
Parathyroid adenoma	+	+	
Medullary thyroid carcinoma		+	+
Pancreatic island cell tumor	+		
Pheochromocytoma		+	+
Ganglioneuromatosis			+

MEN 3 = Mucosal neuroma syndrome (type 2B)4 PheMG

MEN 1 Syndrome

= WERMER SYNDROME

[Paul Wermer (1898-1975), internist at Columbia University, NY]

= autosomal dominant syndrome with 95% penetrance

Prevalence: 1÷5,000 to 1÷50,000

Genetics: autosomal dominant MEN1 gene defect encoding protein menin located on chromosome 11q13 = suppressor of cell proliferation

◊ MEN1 mutation present in 21% of sporadic PETs

Organ involvement (PiPaPanc): syn- / metachronous

» in 40% combined involvement of parathyroid gland + pituitary gland + pancreas

1. Parathyroid hyperplasia (97%): multiglandular / (occasionally) adenoma
   - primary HPT (in 95%): usually presenting feature
2. Pancreatic endocrine tumor (30–80%):

   Path: multiple < 5 mm microadenomas producing clinically insignificant active peptides ± few macroadenomas > 5 mm; usually nonmalignant

   ◊ Primary cause of morbidity + mortality!

   (a) gastrinoma (in 50–60%)

   Location: duodenum > pancreas

   √ multiple duodenal microgastrinomas (< 5 mm) account for > 50% of gastrinomas

   (b) insulinoma (in 10–30%)

   Age: more commonly < 40 years

   Location: body + tail of pancreas

◊ coexistence with gastrinomas in 10%

(c) VIPoma

3. Anterior pituitary gland tumor (20–65%)
   (a) nonfunctioning
   (b) prolactin (60%), growth hormone (< 25%), adrenocorticotropic hormone (5%), TSH
   • presenting feature of the syndrome in 10%
4. Thyroid neoplasm
5. Adrenocortical hyperplasia / adenomas (up to 33–40%)
   • rarely functional
6. Pheochromocytoma
7. Carcinoid (2–5%)
   Location: thymus, bronchus, stomach (30-fold increased incidence), duodenum
   ◊ Up to 4% of patients with carcinoid have MEN
7. Lipoma

Mean age: 3rd–4th decade; M÷F = 1÷1

• usually asymptomatic
• multiple facial angiofibromas (in 85–90% of MEN 1 patients)

May be associated with:
thyroid tumor (20%), thymoma, buccal mucosal tumor, colonic polyposis, Ménétrier disease

Screening population: < 35-year old patient with HPT, ≥ 2 endocrine organ tumors, 1st-degree relative of MEN 1 patient

Imaging surveillance:
renal US + abdominal radiograph for abdominal calculi; abdominal MR for islet cell + adrenal tumors + liver mets; pituitary MR for adenoma (every 3 years)

√ typically multiple microadenomas + nonfunctioning pancreatic endocrine tumors throughout pancreas
√ also often functioning tumor, most commonly gastrinoma (in 60%) / insulinoma (in 30%)

Prognosis: premature death from neoplasia (likely due to metachronous multiplicity of pancreatic tumors)

MEN 2 Syndrome

= SIPPLE DISEASE = MEN TYPE 2A
[John H. Sipple (1930-), internist at SUNY in Syracuse]
= autosomal dominant cancer syndrome

Cause: genetic defect on chromosome 10

Organ involvement (PaMPhe):

1. Parathyroid hyperplasia / neoplasia in multiple glands
   • ± hyperparathyroidism (later onset than in MEN 1)
2. Medullary carcinoma of thyroid (almost 100%)
   • serum calcitonin commonly elevated
3. Pheochromocytoma (50%): bilateral in 50%; malignant in 3% diagnosed before (in 10%) / after detection (in 17%) of medullary thyroid carcinoma

May be associated with: carcinoid tumors, Cushing disease
Screening population: all patients with medullary thyroid cancer / pheochromocytoma, 1st-degree relative of MEN 2 patient
Imaging surveillance: abdominal MR for pheochromocytoma (every 3 years); MIBG scintigraphy (optional)

MEN 3 Syndrome

= MUCOSAL NEUROMA SYNDROME = MEN TYPE 2B
Cause: genetic defect on chromosome 10
Organ involvement (MPheG):
1. Medullary carcinoma of thyroid
2. Pheochromocytoma
3. Intestinal ganglioneuromatosis = mucosal neuroma = oral + intestinal neuroganglioneuromatosis
   ◊ Mucosal neuromas are PATHOGNOMONIC
   ◊ Usually precede the appearance of thyroid carcinoma + pheochromocytoma!

- long slender extremities (marfanoid appearance)
- thickened lips ← submucosal nodules
- nodular deformity of tongue (mucosal neuromas of tongue often initially diagnosed by dentists)
- corneal limbus thickening; prognathism
- constipation alternating with diarrhea

@ GI tract
√ thickened / plaquelike colonic wall
√ chronic megacolon = dilated colon with abnormal haustral markings
√ alternating areas of colonic spasm + dilatation (rarely associated with Hirschsprüng disease)
√ multiple submucosal neuromas throughout small bowel, may act as lead point for intussusception

NESIDIOBLASTOSIS

= PERSISTENT HYPERINSULINEMIC HYPOGLYCEMIA OF INFANCY = CONGENITAL HYPERINSULINISM = ADENOMATOUS ISLET CELL HYPERPLASIA = MICROADENOMATOSIS
= tumorlike disorder characterized by proliferation of hyperfunctioning β cells distributed diffusely throughout pancreas or forming a focal mass
Prevalence: 1÷30,000 to 1÷50,000, higher in Ashkenazi Jewish and Saudi Arabian populations
Age: first few hours of life to > 1 year
Path:
(a) diffuse adenomatosis (66–75%)
= nontumoral widespread increase in islet cells
Cause: genetic abnormality
(b) focal adenomatous hyperplasia = nesidioblastoma

- elevated serum insulin ← unregulated release of insulin
- severe persistent hypoglycemia (often resistent to diazoxide / somatostatin analog therapy)

DDx of transient causes of hyperinsulinemic hypoglycemia:
maternal diabetes, Beckwith-Wiedemann syndrome
√ no imaging abnormalities
√ enlarged hyperechoic pancreas

NODULAR REGENERATIVE HYPERPLASIA

= uncommon benign liver disease defined as diffuse nodularity produced by multiple regenerating nodules surrounded by atrophic liver in the absence of fibrosis
◊ Difficult to diagnose at imaging ← variable nonspecific findings + similarity to other hepatocellular lesions!
Associated with: Budd-Chiari syndrome, collagen vascular disease, myelo- and lymphoproliferative syndrome, autoimmune disease, immunosuppressive + antineoplastic drugs
Cause: pulmonary hypertension, right-sided heart failure, passive hepatic congestion, progressive hepatic venous occlusion
Pathogenesis: increased resistance to sinusoidal blood flow → portal hypertension → decrease in portal venous inflow → prolonged exposure to blood-borne hepatopoietins → stimulation of nodular hepatocellular regeneration
Path: lesions resemble FNH containing Kupffer cells surrounded by acinar atrophy without fibrosis
• asymptomatic (50%)
• symptoms of portal hypertension (50%): esophagogastric varices, ascites, splenomegaly
Size of nodules: 1–40 mm
US:
√ well-circumscribed homogeneous hypo- / hyperechoic nodule, if visible at all
CT:
√ hypo- (typically) or isoattenuating nodules
√ typically no enhancement / diffuse mild enhancement
√ heterogeneous hepatic parenchyma
MR:
√ hypo- to iso- to hyperintense on T1WI
√ iso- to minimally hypointense on T2WI (= difficult to visualize!)
√ ± ↓ SI on fat-suppressed T1WI ← intracellular fat
CEMR:
(a) arterial phase:
√ decreased enhancement relative to pancreas
√ multiple small similar-sized enhancing nodules
(b) portal venous + equilibrium phase:
√ fading to isointensity
DDx: HCC rapidly washes out to hypointensity
(b) delayed phase:
√ progressive enhancement
√ hyper- / isointense on 1–hour delayed images after gadobenate dimeglumine = Gd BenzylOxyPropionic-TetraAcetate (Gd-BOPTA = MultiHance®) similar to FNH

PANCREAS DIVISUM

= most common congenital anomaly of pancreatic ductal system

Cause: failure of fusion of ventral + dorsal anlage at 7th week of fetal life

› ventral duct (of Wirsüng) drains ventral anlage only into major papilla corresponding to head and uncinate process

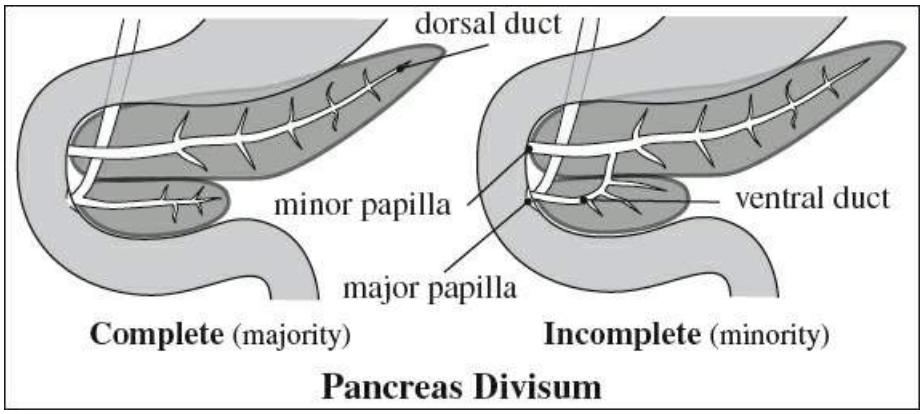
› majority of gland empties into minor papilla via <u>dominant dorsal duct</u> (of Santorini) ± focal dilatation of terminal duct segment (= **santorinicele**) ← relative obstruction

Variations:

(a) no communication between ventral + dorsal duct

(b) incomplete divisum = filamentous communication between ducts (dominant dorsal duct syndrome)

(c) complete absence of ventral duct



Prevalence: 4–14% in autopsy series; 3–8% in ERCP series; 5–10% on MRCPs of normal population; 12–50% in patients with idiopathic recurrent pancreatitis during childhood; in 15–20% of unexplained acute pancreatitis

May be associated with: stenosis of main duct at minor papilla

Hypothesis: relative / actual functional stenosis of minor papilla → obstruction to pancreatic exocrine secretory flow → predisposes to nonalcoholic recurrent pancreatitis in dorsal segment

Age: young / middle-aged adult; M<F

Clinically:

pancreas divisum should be suspected in young / middle-aged adult who presents with recurrent acute pancreatitis / relapsing chronic pancreatitis without any other obvious cause (like gallstones / alcohol consumption)

- usually asymptomatic
- chronic abdominal pain and acute idiopathic / chronic relapsing pancreatitis (in only 5–10% = clinical relevance of pancreas divisum continues to be debated!)

√ "dominant dorsal duct" sign = larger dorsal duct relative to smaller ventral duct

√ continuity of large dorsal pancreatic duct with duct of Santorini draining through minor (accessory) papilla (located 2 cm superior to major papilla)

√ small ventral pancreatic duct (of Wirsüng) drains a portion of pancreatic head including the uncinate process through major papilla after joining with CBD

US:
√ bulky hypoechoic pancreas + peripancreatic inflammation / pseudocyst formation
Endoscopic US (95% sensitive, 97% specific, 99% NPV):
√ absence of "stack sign" (= visualization of bile duct and pancreatic duct running parallel through pancreatic head)
ERCP (Retrograde Endoscopic Pancreatography): DIAGNOSTIC
√ contrast injection into major papilla shows CBD + short narrow ventral pancreatic duct with early arborization and at times highly atretic
√ contrast injection into minor papilla fills dominant dorsal pancreatic duct of larger caliber
√ no communication between ventral + dorsal ducts
Cx: ERCP-induced pancreatitis (5% risk)
CT (90% sensitive, 98% specific, 98% NPV):
√ oblique fat cleft between ventral + dorsal pancreas (25%)
√ failure to see union of dorsal + ventral pancreatic ducts (rare)
MRCP (with secretin stimulation 73–100% sensitive, 97–100% specific):
√ noninvasive multiplanar visualization of pancreatic duct:
√ visualization of main pancreatic (dorsal) duct coursing anterior to CBD before draining into duodenum
√ usually prominent dorsal duct with depiction of relative functional duct obstruction
√ findings of acute pancreatitis: bulky pancreas, pancreatic necrosis, peripancreatic inflammation, pseudocysts
√ findings of chronic pancreatitis: significant atrophy of ventral duct and dilatation of dorsal duct
Dx: by ERCP
Rx: surgical / endoscopic minor papillotomy / sphincterotomy; insertion of stent into minor papilla

PANCREATIC ACINAR CELL CARCINOMA

= rare neoplasm of exocrine origin
Frequency: 1–2% of pancreatic exocrine tumors
Mean age: 62 (range, 40–81) years; M÷F = 86÷14; 87% Caucasian; more common than ductal cell adenocarcinoma in pediatric age group
Path: similar to pancreatoblastoma (= embryonic counterpart)
• biliary obstruction distinctly uncommon
• increased serum lipase ± amylase
• **lipase hypersecretion syndrome** (paraneoplastic syndrome):
= disseminated subcutaneous + intraosseous fat necrosis (usually distal to knees / elbows)
Prevalence: 4–16% of adult patients
Cause: systemic release of tumor-elaborated lipase
• peripheral polyarthropathy; bone infarcts
• painful subcutaneous nodules of fat necrosis resembling erythema nodosum
Location: anywhere in pancreas; frequently exophytic
Size: 10 (range, 2–30) cm
√ soft lobulated well-defined heterogeneous mass

√ partial / complete thin enhancing capsule
√ tumor necrosis usually present
√ punctate / chunky peripheral / central tumor calcifications (33–50%)
√ enhancement less than normal pancreas (greater than ductal adenocarcinomas + less than islet cell tumors)
√ moderately vascular tumor + neovascularity + arterial and venous encasement

Prognosis: median survival of 7–9 months; 57% (26%) [6%] 1-year (3-year) [5-year] survival, slightly better than for ductal adenocarcinoma

DDx: (1) pancreatic adenocarcinoma (small, irregular, locally invasive, without capsule, biliary obstruction if located in head of pancreas)
(2) Nonfunctioning islet-cell tumor
(3) Microcystic cystadenoma
(4) Solid-pseudopapillary tumor
(5) Oncocytic tumor of pancreas
(6) Pancreatoblastoma (in children < 10 years)

PANCREATIC DUCTAL ADENOCARCINOMA

= DUCT CELL ADENOCARCINOMA = PANCREATIC ADENOCARCINOMA

◊ Duct cells comprise only 4% of pancreatic tissue but 85–95% of malignant tumors of pancreas!

Incidence: 12÷100,000 / year (in USA 43,920 new diagnoses in 2012 and 36,800 deaths = 4th leading cause of cancer deaths + 2nd most common cause (after colorectal cancer) of GI cancer–related deaths

Cause: alcohol abuse (4%), diabetes (2 x more frequent than in general population, particularly in females), cigarette smoking (risk factor 2 x)

Genetic risk: hereditary pancreatitis (in 40%), hereditary pancreatic cancer syndrome, hereditary nonpolyposis colon carcinoma, Peutz-Jeghers syndrome, familial atypical multiple mole melanoma, BRCA2

Path: scirrhous infiltrative adenocarcinoma with a dense cellularity + sparse vascularity

Peak age: 7th (range, 4th–8th) decade; M÷F = 2÷1; extremely rare in children

Stage: I = confined to pancreas
II = + regional lymph node metastases
III = + distant spread
◊ At presentation:
› 65% of patients have advanced local disease / distant metastases
› 21% of patients have localized disease with spread to regional lymph nodes
› 14% of patients have tumor confined to pancreas

Growth: aggressive early infiltrative → obstruction of pancreatic duct / common bile duct → invasion of adjacent vessels

Extension:
(a) local extension beyond margins of organ (68%): posteriorly (96%), anteriorly (30%), into porta hepatis (15%), into splenic hilum (13%)
(b) invasion of adjacent organs (42%):
duodenum > stomach > left adrenal gland > spleen > root of small bowel mesentery

(c) local lymph node spread:
pancreaticosplenic nodes accompanying splenic artery, pancreaticoduodenal nodes, superior mesenteric preaortic nodes

Metastases: liver (30–36%), regional lymph nodes > 2 cm (15–28%), ascites from peritoneal carcinomatosis (7–10%), lung (pulmonary nodules / lymphangitic), pleura, bone

- weight loss, anorexia, fatigue, steatorrhea, hyperamylasemia
- pain in hypochondrium radiating to back
- obstructive jaundice (75%):
  - ◊ Most frequent cause of malignant biliary obstruction!
  - painless jaundice (25%)
- acute onset diabetes (25–50%)
- spontaneous vein thrombosis (Trousseau syndrome)

Location: pancreatic head / neck / uncinate process (60–70%); pancreatic body (10–20%); pancreatic tail (5–10%); diffuse pancreatic involvement (5%)

Average size: 2–10 cm (in 60% between 4 and 6 cm)
in pancreatic head: 2.5–3 cm
in pancreatic body + tail: 5–7 cm

√ poorly vascularized predominantly solid soft-tissue lesion
√ delayed enhancement ← contrast material seeps gradually into tumor interstitium
√ cystlike features (8%) ← cystic degeneration, retention cysts, attached pseudocysts

Barium:

UGI:
- √ "antral pad" sign = extrinsic indentation of posteroinferior margin of antrum
- √ "Frostberg inverted-3" sign = inverted 3 contour to medial portion of the duodenal sweep
- √ spiculated duodenal wall + traction + fixation (= neoplastic infiltration of duodenal mucosa / desmoplastic response)
- √ irregular / smooth nodular mass with ampullary cancer
- √ diffuse tethering throughout peritoneal cavity ← intraperitoneal seeding

BE:
- √ localized haustral padding / flattening / narrowing with serrated contour at inferior aspect of transverse colon / splenic flexure

CT (90% accurate for tumor detection, 89–100% PPV for unresectability, 45–79% NPV for resectability):
- √ hypoattenuating lesion best depicted during arterial phase (in 10% nonvisualized isoattenuating tumor)
- √ pancreatic mass (95%) / diffuse enlargement (4%) / normal scan (1%)
- √ mass with central zone of diminished attenuation (75–83%)
- √ cystic-necrotic degeneration (8%)
- √ postobstructive pseudocyst (11%)
- √ calcifications (2%)
- √ <u>indirect signs</u>:
  - √ atrophy of pancreatic body + tail (20%)
  - √ convex deformity of pancreatic contour

√ duct dilatation (58%):
√ 75% biductal with pancreatic + bile duct obstruction = "double-duct" sign of mass in head of pancreas
√ 10% isolated to one duct:
√ dilated pancreatic duct (67%)
√ dilated bile ducts (38%)
√ signs of invasion:
√ obliteration of peripancreatic fat (50%) = pancreas lacks a capsule
√ thickening of Gerota fascia (5%)
√ local tumor extension posteriorly into splenic hilum and porta hepatis (68%)
√ contiguous organ invasion (of duodenum, stomach, mesenteric root) in 42%
√ hepatic metastases (75% sensitive)
CECT (arterial + portal phases):
√ nondepicted isoattenuating pancreatic primary and metastasis (in 10%)
√ portal phase imaging (optimal) for detecting metastatic disease to liver and for assessing peripancreatic veins
√ vascular invasion:
√ thickening of celiac axis / SMA ← invasion of perivascular lymphatics (in 60%)
√ dilated collateral veins (12%)
√ high probability of unresectability if circumferential contiguity of tumor to vessel > 50% (84% sensitive, 98% specific)
√ deformity / thrombosis of vessel = "teardrop" sign of SMV on axial image
US:
√ hypoechoic pancreatic mass
√ focal / diffuse (10%) enlargement of pancreas
√ contour deformity of gland; rounding of uncinate process
√ dilatation of pancreatic ± biliary duct
Endoscopic US:
√ may detect tumors of 2–3 mm in diameter
√ suitable for biopsy of suspect lesions
MR (81% sensitive):
√ hypointense tumor on fat-suppressed T1WI ← scirrhous fibrotic nature
√ iso- to minimally hypointense tumor on T2WI
√ abnormally low SI of pancreatic tail + body on T1WI reducing the contrast relative to focal cancer ← atrophy / secondary chronic pancreatitis
√ complex cystic areas within / adjacent to primary ← adjacent pseudocysts, internal tumor necrosis, or side-branch ductal obstruction
CEMR:
(superior to CT in detecting small tumors + metastases)
√ tumor hypointense compared to gland
√ thin peritumoral rim of greater enhancement
MRCP:
Indication: non–contour-deforming pancreatic mass suspected on CT; small mass of < 2 cm;

hepatic, peritoneal, omental metastases

√ "double duct" sign = abrupt termination of CBD + main pancreatic duct by mass with upstream ductal dilatation

CEMR:

√ hypovascular lesion during arterial + pancreatic parenchymal phase ← desmoplastic fibrotic component

√ progressive enhancement in portal venous + delayed phase ← desmoplasia with large interstitial spaces

√ thin peritumoral rim of enhancement

√ delayed enhancement of obstructed portion of pancreas

PET (85–93% accurate, 46–71% sensitive, 63–100% specific):

√ intense focal FDG uptake ("hot spot") dependent on tumor biology + degree of desmoplastic response

√ superior detection of small metastases

Postop: wait > 6 weeks after surgery to differentiate uptake from postoperative inflammation

PET/CT: improves staging specificity in nonspecific or borderline lymph node enlargement seen on CT; better sensitivity (83%–86%) for tumor depiction in euglycemic patients than in those with elevated glucose levels (42%–69%)

√ may depict < 2 cm small / isoattenuating lesions that are difficult to detect at CT

√ SUV threshold of ≥ 2.0 (100% sensitive, 76–77% specific)

√ SUV threshold of ≥ 4.0 (1.00 PPV, 0.94 NPV)

DDx: mass-forming pancreatitis

Angiography (70% accuracy):

√ hypovascular tumor / neovascularity (50%)

√ arterial encasement: SMA (33%), splenic artery (14%), celiac trunk (11%), hepatic artery (11%), gastroduodenal artery (3%), left renal artery (0.6%)

√ venous obstruction: splenic vein (34%), SMV (10%)

√ venous encasement: SMV (23%), splenic vein (15%), portal vein (4%)

Cholangiography:

√ "rat tail / nipplelike" occlusion of CBD

√ nodular mass / meniscuslike occlusion in ampullary tumors

√ "double duct" sign = abrupt obstruction of common bile duct + pancreatic duct

Pancreatography (abnormal in 97%):

√ abrupt obstruction of main pancreatic duct ← tumor starts in ductal epithelium producing early obstruction:

√ irregular, nodular, rat-tailed, eccentric obstruction

Criteria of Resectability of Pancreatic Adenocarcinoma 89–100% positive predictive value of CT
Unresectable
√ distant metastases
√ SMA encasement > 180° of vessel circumference
√ tumor abutment of celiac axis
√ unreconstructable occlusion of SMV / portal vein
√ invasion of aorta / aortic encasement
Borderline resectable
√ impingement / narrowing of SMV / portal vein
√ short-segment venous occlusion allowing reconstruction
√ encasement of gastroduodenal artery up to hepatic artery
√ tumor abutment of SMA ≤ 180° of vessel circumference

√ localized encasement with prestenotic upstream dilatation

√ acinar defect

Prognosis:

< 20% (2%) [< 5%] 1-year (3-year) [5-year] survival; 14 months (8 months) medial survival after curative (palliative) resection; 5 months without treatment; tumors resectable in only 8–25% at presentation; 5–20% 5-year postoperative survival rate

Survival rate versus tumor size:

100% 5-year survival rate for tumors < 1 cm without parenchymal / vascular / lymphatic invasion; 30% for tumors < 2 cm

Rx: < 10–20% are deemed surgically resectable; palliative chemoradiation

Dx: biopsy with endoscopic US guidance / percutaneous (often preferred) CT-guided biopsy

DDx: focal pancreatitis, islet cell carcinoma, metastasis, lymphoma, normal variant

PANCREATIC ENDOCRINE TUMOR

= PET = PANCREATIC NEUROENDOCRINE TUMOR = PANCREATIC ISLET CELL TUMOR

= predominantly well-differentiated pancreatic / peripancreatic tumor that demonstrates endocrine differentiation

Origin: pluripotential stem cells in ductal epithelium; previously thought to originate from islet of Langerhans; derivatives of APUD (amine precursor uptake and decarboxylation) cell line (APUDoma)

◊ The term islet cell tumor is no longer acceptable because a pancreatic endocrine tumor arises from ductal pluripotent stem cells, rather than from islets of Langerhans

Genetics: sporadic (mostly), familial syndrome (1–2%) with genetic alterations involving MEN1, VHL, NF1, TSC1, TSC2 genes

May be associated with:

MEN 1 (= Wermer syndrome), von Hippel-Lindau syndrome, neurofibromatosis type 1, tuberous sclerosis

◊ Often multiple tumors that manifest at an earlier age!

Prevalence: 1–5÷100,000 population; 1–2% of all pancreatic neoplasms

Mean age: 47 (range, 7–83) years; 25 years for MEN 1; M=F

Path: (a) small tumor: solid well-demarcated, unencapsulated
◊ < 5 mm = microadenoma (only microscopically identifiable) in 10% of autopsied population
(b) large tumor: cystic changes + necrosis + calcifications with often incomplete fibrous pseudocapsule
› well differentiated benign endocrine tumor
› well differentiated endocrine carcinoma
› poorly differentiated endocrine carcinoma (2–3%)

◊ Small tumors tend to be homogeneous, whereas large tumors are more commonly heterogeneous ← areas of cystic change, necrosis, and calcification

Histo: sheets of uniform polygonal cells resembling normal islet cells with round / oval nuclei that have stippled, salt-and-pepper chromatin + eosinophilic granular cytoplasm + numerous stromal vessels
(a) trabecular pattern ± gyriform arrangement
(b) acinar / glandular pattern
(c) medullary / solid pattern
(d) cystic
(e) papillary
(f) angiomatoid
◊ Endocrine differentiation confirmed with Grimelius silver stain / immunohistochemical labeling for chromogranin / synaptophysin

Categories: size, mitotic rate, cell proliferation, invasion (Ki-67 index)

In order of frequency: insulinoma (50%) > gastrinoma (20%) > glucagonoma > VIPoma > somatostatinoma

Average time from onset of symptoms to diagnosis: 2.7 years

Classification:
(a) SYNDROMIC (functioning) pancreatic endocrine tumor (< 50%):
◊ Tumor small at presentation (early symptoms)!
◊ Most syndromic tumors produce multiple hormones!
◊ Named after the predominantly secreted hormone!
(b) NONSYNDROMIC pancreatic endocrine tumor

Location: gastrinoma triangle (most common)

Metastases: in 60–90% to liver ± regional lymph nodes
◊ Liver metastasis are often hypervascular with ringlike enhancement during arterial phase (similar to primary)
◊ A hyperechoic liver metastasis is suggestive of pancreatic endocrine tumor rather than pancreatic adenocarcinoma!

Purpose of imaging:
(1) Localisation of known functioning PET
◊ To avoid the risk of negative laparotomy use CT / MR with their high sensitivity to localize the 4% of tumors missed by intraoperative palpation + intraoperative US
(2) Diagnosis of nonfunctioning pancreatic endocrine tumor
(3) Surgical planning (location, number, spread of tumors)

• unlikely to cause ampullary / ductal obstruction

Size: mostly 1–5 (range, < 1 cm to > 20) cm in diameter
◊ A tumor > 3 cm in diameter with calcifications suggests malignancy!
√ round / ovoid tumor:
√ small homogeneous lesion
√ large heterogeneously enhancing lesion ← cystic degeneration, necrosis, fibrosis, calcification
√ marked enhancement on delayed images ← large interstitial space with loose edematous stroma + abundant blood vessels
√ NO vascular encasement / duct obstruction
US:
(a) transabdominal US (70% sensitive)
(b) endoscopic US (~ 95% sensitive, 93% specific), less sensitive for distal pancreatic body + tail
(c) intraoperative US (combined with palpation by surgeon)
√ round / ovoid mass with smooth margin ± hyperechoic rim:
√ homogeneous / heterogeneous hypoechoic
√ hypervascular pattern
√ ± enlarged peripancreatic lymph nodes
√ ± mostly hyperechoic (occasionally hypoechoic / targetlike) liver metastases
CT (71–82% sensitive):
Method: high resolution + dual phase + distension of stomach and duodenum with water; MPR
◊ Syndromic tumors often small (< 20 mm) + multiple and difficult to detect
√ isoattenuating circumscribed solid mass:
√ tendency to displace surrounding structures
√ hypoattenuating partially / completely cystic PET (in 18%)
CECT:
◊ Early imaging is ESSENTIAL for detection of small tumor:
√ avid enhancement during arterial phase (85% sensitive) ← hypervascularity ← rich capillary network
√ late arterial (pancreatic phase) images (100% sensitive)
√ tumor conspicuity decreases during portal venous phase (11–76% sensitive)
√ hypervascular rim (in 90%) of cystic endocrine tumor
FN: tumor in close proximity to a vessel is easily missed
√ lymph nodes + liver metastases most conspicuous during arterial phase ← hypervascularity:
√ hepatic metastases often with ringlike enhancement
MR (75% sensitive):
T1WI:
√ round / oval circumscribed relatively hypointense mass with / without fat saturation
T2WI:
√ mostly much higher SI compared to normal pancreas
√ may be of intermediate / (less commonly) low signal intensity ← substantial amounts of collagen

CEMR:
√ intense enhancement during arterial + capillary phase
√ homogeneous / ringlike / heterogeneous enhancement
√ T1-hypointense + T2-hyperintense liver metastases (best seen on T2WI with fat suppression):
√ moderate to intense early ringlike enhancement
√ prominent enhancement of lymph node metastases

NUC (70–90% sensitive, only 50% sensitive for gastrinomas and insulinomas):
Useful for: localization of known functioning tumor, DDx of pancreatic mass, evaluation for metastases / recurrence, assessment of receptor status
Somatostatin receptor scintigraphy with ^{111}In-octreotide:
√ sensitivity highest for gastrinoma > 2 cm + lowest for primary insulinoma
√ whole-body scintigraphy detects tumors > 10 mm in size
√ predicts which patients will respond to radionuclide Rx
√ monitors response to therapy
PET:
√ uptake in poorly differentiated pancreatic endocrine tumor

Angio:
√ intense vascular stain in late arterial + capillary phase
Hepatic vein sampling (88% sensitive):
◊ performed together with pancreatic angiography
√ rise in venous hormone concentration after selective injection of secretagogue (eg, calcium) into arteries supplying the pancreas

Prognosis: 82% (56%) 3-year survival rate without (with) hepatic metastases; 50–65% 5-year survival rate ◊ Risk of malignancy increases with tumors > 5 cm

The most reliable indicators of malignancy and poor prognosis are extrapancreatic invasion and metastatic disease defining a well-differentiated tumor as endocrine carcinoma.

Rx: enucleation, partial pancreatectomy, antihormone Rx, chemo- / radionuclide therapy, chemoembolization

DDx: (1) Pancreatic ductal adenocarcinoma (hypovascular, rarely calcified, encasement of SMA + celiac trunk, common ductal involvement, rare central necrosis + cystic degeneration)
(2) Microcystic adenoma (benign tumor, small cysts, older woman)
(3) Metastatic tumor: renal cell carcinoma (clinical Hx)
(4) Solid-pseudopapillary tumor of pancreas (young female, hemorrhagic areas)
(5) Paraganglioma
(6) Sarcoma (rare)

ACTH-producing Tumor

= CORTICOTROPHINOMA
= rare cause of Cushing syndrome
• increased level of serum cortisol
• impaired glucose tolerance > central obesity > hypertension, oligomenorrhea >

osteoporosis > purpura > striae > muscle atrophy

Prognosis: almost all malignant with metastases at time of Dx

Gastrinoma

◊ 2nd most common syndromic pancreatic endocrine tumor (= 50% of insulinoma frequency)

Peak age: 5th decade; 8% in patients < 20 years; M÷F = 1.3÷1

Histo: composed of G cells (in α cells / δ cells)

Gastrinoma symptomatology caused by:

(a) islet cell hyperplasia (10%)

(b) benign adenoma (30%): ½ solitary, ½ multiple (especially in MEN 1)

(c) malignancy (50–60%) with metastases to liver, spleen, lymph nodes, bone

Genetics: sporadic (usually)

◊ 20–25% of all gastrinomas occur in MEN 1

◊ Most common functioning PET in MEN 1

- Zollinger-Ellison syndrome
  → only 0.1% of all cases of peptic ulcer disease!
- markedly ↑ fasting serum levels of gastrin (DIAGNOSTIC): often > 1,000 pg/mL (normal level, < 100 pg/m)
- positive secretin stimulation test

Location: usually solitary, multiple (20–40%)

N.B.: previously pancreas was thought to be the most common location, but many have been peripancreatic nodal metastases from a duodenal tumor

(a) pancreas (20%): mostly in head

(b) ectopic:

› duodenum (80% of sporadic lesions, 90% in MEN1): frequently in gastrinoma triangle; often microadenomas of 1–2 mm in size

› peripancreatic lymph nodes / bile ducts

› stomach, proximal jejunum

› omentum, retroperitoneum

› ovary

Gastrinoma triangle

= triangle bounded by

(1) porta hepatis as apex of triangle (= confluence of cystic duct + common bile duct) superiorly

(2) junction of 2nd and 3rd parts of duodenum inferiorly

(3) neck and body of pancreas medially (OR border of pancreatic body + tail)

Mean size: 3–4 cm (up to 15 cm); in duodenal wall < 1 cm

√ homogeneous ringlike enhancement

√ occasionally calcifications

Angio:

√ hypervascular lesion (70%)

√ hepatic venous sampling after intraarterial stimulation with secretin

Endoscopic US (useful for tumors in duodenal wall and peripancreatic lymph nodes):

√ solid hypoechoic mass

CT:

√ transiently hyperdense on dynamic CT (majority)

MR:

√ low-intensity mass on fat-suppressed T1WI

√ diminished central + peripheral ring enhancement

√ high-intensity mass on fat-suppressed T2WI

NUC:

somatostatin receptor scintigraphy (58–75% sensitive) ← high concentration of somatostatin receptors

Spread:

√ regional lymph node metastasis (may be mistaken for primary because of large size compared to primary)

√ liver metastasis (in 30% at time of diagnosis)

Sensitivity of preoperative localization:

75–93% for ^{111}In-pentetreotide imaging, 77% for arteriography combined with intraarterial injection of secretin, 42–63% for transhepatic portal venous sampling for gastrin, 68–70% for selective angiography, 35% for CT, 25% for US, 20% for MR

Rx: surgery curative in 30%; resection of gastrinoma triangle; medical treatment of Zollinger-Ellison syndrome

Cx: frequently malignant degeneration (60%); multiple gastric carcinoid tumors from ↑ gastrin level

Glucagonoma

◊ 3rd most common syndromic pancreatic endocrine tumor

Incidence: 1÷20,000,000 annually (rare)

Age: 40–60 (range, 19–84) years; M = F

Genetics: almost always sporadic

Rarely associated with: MEN 1

Histo: derived from A cells (α cells) of pancreatic islets

- **4D (glucagonoma) syndrome**

(1) **D**iabetes mellitus

← elevated glucagon counteracting effects of insulin

- plasma glucagon level > 1,000 ng/L (DIAGNOSTIC)

(2) **D**ermatitis

- **necrolytic erythema migrans** ($^{2}/_{3}$)

= painful highly pruritic migrating erythematous macules / papules starting in lower abdomen, groin, genitals spreading to trunk, lower extremity, buttocks, face

Pancreatic Endocrine Tumors					
Type	*Frequency*	*Associated Syndrome*	*Symptoms*	*Average Size*	*Location*
Insulinoma	*50%*	Whipple triad	hypoglycemia, dizziness, vision changes, palpitations	< 2 cm	all of pancreas
Gastrinoma	*20%*	Zollinger-Ellison syndrome	peptic ulcer disease, diarrhea, esophagitis	duodenum: < 1 cm pancreas: 3–4 cm	duodenum > pancreatic head
Glucagonoma		4D syndrome	necrolytic migratory erythema, diabetes, thromboembolism	7–8 cm	pancreatic tail
Vipoma		WDHA syndrome	profuse watery diarrhea, weight loss, hypokalemia	5–6 cm	pancreatic tail
Somatostatinoma		Inhibitory syndrome	diabetes, steatorrhea, diarrhea, cholelithiasis	5–6 cm	pancreatic head
Nonfunctioning		none	abdominal pain, mass, weight loss	5–6 cm	all of pancreas
Poorly differentiated		none / paraneoplastic syndrome	abdominal pain, cachexia, jaundice	6 cm	pancreatic head

Cause: unknown; ? direct effect of glucagon, prostaglandin release; ? deficiency of amino acids, zinc, vitamin B

(3) **D**eep vein thrombosis (rare)

(4) **D**epression

- painful glossitis / stomatitis, diarrhea, weight loss, anemia
- various neurologic + psychiatric symptoms
- elevated glucagon levels (usually 10–20 x that of normal)
- ± elevated levels of insulin, serotonin, gastrin

Location: predominantly in pancreatic body / tail

Mean size: 6.4 (range, 2.5–25.0) cm with solid + necrotic components; in 70% > 5 cm in size

√ hypervascular in 90% → angiographic localization successful in 15%

√ hetero- / homogeneous enhancement with areas of decreased attenuation / intensity

√ uptake of ^{111}In-pentetreotide

Cx: pulmonary thromboembolism

Malignant transformation (in 60–80%):

√ 80% chance of malignancy if tumor > 5 cm in diameter

√ in 50–60% liver / lymph node metastases at time of Dx

Prognosis: 55% 5-year survival rate; ¾ ultimately fatal

Insulinoma

◊ Most common (40%) of syndromic (functioning) PETs!

Incidence: 2–4÷1,000,000 annually

Mean age: 47 years (range, 4th–6th decade); M÷F = 1÷1.4

Genetics: sporadic (usually)

◊ 10–30% of functioning pancreatic endocrine tumors are insulinomas in MEN 1

Associated with: MEN 1, NF1

Insulinoma symptomatology caused by:

(a) single benign adenoma (80–90%)

(b) multiple adenomas / microadenomatosis (2–10%)

(c) diffuse islet cell hyperplasia = nesidioblastosis (5–10%)

(d) malignant adenoma (5–10%)

mnemonic: 10% are associated with MEN 1

10% are multiple (especially in MEN 1)
10% have islet cell hyperplasia
10% are malignant

Histo: composed of β cells (amyloid with green birefringence + Congo red stain is highly suggestive)

- Whipple triad:
  [Allen Oldfather Whipple (1881–1963), professor of surgery at Columbia University]
  (1) Starvation attack (during fasting / after exercise)
  (2) Relief by IV glucose
  (3) Hypoglycemia (fasting glucose < 50 mg/dL)
- neuroglycopenic symptoms: dizziness, diplopia, blurred vision, headaches, confusion, personality changes, coma
- behavorial problems, seizures, coma in young children
- hypoglycemia exacerbated by fasting (98% sensitive) → frequent meals to avoid symptoms
- sweating, palpitations, tremor ← catecholamine release in response to hypoglycemia (less common); obesity
- ↓ fasting glucose level, ↑ serum insulin level
- ↑ level of serum C-peptide (excludes exogenous source)
- firm rubbery palpable mass at surgery (in > 90%)

Location: even distribution throughout pancreas (65% in body + tail); 1–5% in ectopic location; 2–10% multiple

Size: < 1 cm in 40%, < 1.5 cm in 70%, < 2 cm in 90%

◊ Early manifestation ← dramatic clinical syndrome!

√ small homogeneous hyperenhancing tumor

√ heterogeneous enhancement usually in lesions > 2 cm ← cystic change / necrosis

US (20–75% sensitive preoperatively, 75–100% sensitive endoscopically + intraoperatively):

√ round / oval smoothly marginated solid homogeneously hypoechoic mass

Angio:

√ hypervascular tumor (66%) → accurate angiographic localization in 50–90%

√ transhepatic portal venous sampling → correct localization in 95%

√ hepatic venous sampling after intraarterial stimulation with calcium gluconate

CECT (30–75% sensitive):

◊ Use of coronal images is advantageous (DDx to nearby vasculature, identification of pedunculated lesion)

√ hypo- / iso- / hyperattenuating lesion

√ homogeneous hyperenhancement (60%), peripheral ring enhancement (30%)

MR:

√ low signal intensity on fat-suppressed T1WI

√ hyperintense on T2WI + dynamic contrast-enhanced + fat-suppressed inversion recovery images

√ tumors > 2 cm show ring enhancement

Somatostatin receptor scintigraphy (60–70% sensitive)

Prognosis: best among all pancreatic endocrine tumors with overall survival rate similar to general population

Malignant transformation (in 5–10%):
√ lesion usually > 3 cm in diameter
√ metastases in peripancreatic lymph nodes (most often)
Rx: curative surgery of visualized mass / resection of distal tail + body without visualized mass

Nonsyndromic Islet Cell Tumor

= NONFUNCTIONING (CLINICALLY SILENT) ICT = POORLY DIFFERENTIATED NEUROENDOCRINE TUMOR
◊ More common than syndromic pancreatic endocrine tumors ← below threshold of detectability / hypofunctioning / biologically inactive hormone / without clinical syndrome
Frequency: 50% of all pancreatic endocrine tumors
Genetics: sporadic; most common pancreatic endocrine tumor in MEN 1 and VHL syndrome
Histo: derived from either α or β cells characterized by small poorly granular cells with high rate of proliferation and vascular invasion; positive reactivity for chromogranin-A + neurospecific enolase; no reactivity for insulin / glucagon / somatostatin
Mean age: 55 (range, 24–74) years; M > F; younger in MEN 1
• abdominal pain, jaundice, gastric variceal bleeding
• palpable mass, gastric outlet obstruction
• no clinical evidence of hormone production
• ↑ serum chromogranin A level (70% sensitive)
Location: evenly distributed throughout pancreas; anywhere in GI tract
Mean size: 5–6 (range, up to 20) cm; > 5 cm in 72%
◊ Tumor large at presentation and in 90% malignant!
√ most incidentally discovered
√ heterogeneous mass with cystic + necrotic components
√ coarse nodular calcifications (20–25%)
√ contrast enhancement in 83%
√ hypoechoic mass
√ late dense capillary stain
√ large irregular pathologic vessels with early venous filling
NUC:
√ no imaging with ^{111}In-pentetreotide ← absence of somatostatin receptor activity
√ FDG PET imaging is highly accurate and preferred ← high proliferative rate
Spread: metastases to liver + regional nodes in 60–80% at time of diagnosis
Malignant transformation:
√ metastases at time of diagnosis in 80–100%
Prognosis: 60% (44%) 3-year (5-year) survival
Rx: may respond to systemic chemotherapy

Somatostatinoma

Origin: derived from δ cells
Prevalence: < 2% of all well-differentiated PETs
May be associated with: NF1
› for duodenal somatostatinomas → NF1 in 43%

› for pancreatic somatostatinomas → NF1 in 1%

Histo: composed of D cells

Mean age: 50 years; M÷F = 1÷1

- inhibitory syndrome = inhibitory action of somatostatin on other pancreatic + bowel peptides (growth hormone, TSH, insulin, glucagon, gastrin, pepsin, secretin)
- diabetes, steatorrhea, diarrhea, cholelithiasis
- hypochlorhydria, weight loss
- elevated plasma level of somatostatin (DIAGNOSTIC)

Location: pancreatic head (½); periampullary duodenum (½); others in small bowel, colon, rectum

Size: 5– 6 (range 0.6–20) cm

√ hypervascular

√ obstruction of duodenum

Malignant transformation (in 50–90%):

√ metastases in liver / lymph nodes in 50–75% at time of initial diagnosis

VIPoma

= solitary tumor liberating **V**asoactive **I**ntestinal **P**eptide (a peptide not normally secreted by pancreatic islet cells)

Genetics: sporadic; rarely associated with MEN 1

Pathophysiology:

VIP stored in neurons near blood vessels → binds to receptors on intestinal epithelial cells → stimulates production of cyclic adenosine monophosphate (AMP) → relaxation of vascular smooth muscle (= vasodilatation) + secretion of fluid and electrolyte into intestinal lumen → characteristic watery diarrhea (even during fasting)

Path: adenoma / hyperplasia

Histo: composed of D1 cells

Age: 5th–6th decade (range, 2–83 years); M÷F = 1÷1

- WDHA syndrome = **W**atery **D**iarrhea + **H**ypokalemia + **A**chlorhydria (VIP inhibits gastrin production) = **Verner-Morrison syndrome**
- more recently + more accurately described as: WDHH syndrome = profuse **W**atery **D**iarrhea, **H**ypokalemia + **H**ypochlorhydria = "pancreatic cholera"
- dehydration ← massive diarrhea (6–8 L/d)
- weight loss, abdominal pain
- facial flushing (in some patients) ← peripheral vasodilatation mimicking carcinoid syndrome
- ↑ fasting serum VIP levels > 100 pg/mL (HIGHLY SPECIFIC)

Location:

(a) pancreas (75%): from δ cells predominantly in pancreatic tail > body

(b) extrapancreatic + neurogenic (20%): sympathetic ganglia of retroperitoneum + mediastinum, neuroblastoma (in children)

(c) extrapancreatic + nonneurogenic (5%): esophagus, small bowel, colon, liver, kidney

Mean size: ~ 5 cm

√ homogeneous enhancement in smaller lesion

√ cystic change ± calcifications in larger mass

√ mostly hypervascular tumor with solid + necrotic tissue
√ dilatation of gallbladder
√ uptake by ^{111}In-pentetreotide imaging in 88%
√ liver metastasis (usually at time of diagnosis)
Malignant transformation (in 50–80%):
√ metastases in 60–80% at presentation
DDx: small cell carcinoma of lung / neuroblastoma may also cause WDHH syndrome

Cystic Pancreatic Neuroendocrine Tumor (PNET)

= uncommon manifestation (in 17%)
Cause: tumor degeneration
Associated with: multiple endocrine neoplasia syndrome
Mean age: 53 years; M = F
√ vascularized soft-tissue components
√ avidly enhancing rim during arterial phase ← neoplastic neuroendocrine cells lining cyst periphery

PANCREATIC LIPOMATOSIS

= FATTY REPLACEMENT = FATTY INFILTRATION
= deposition of fat cells in pancreatic parenchyma
Predisposing factors:

1. Atherosclerosis of elderly
2. Obesity
3. Steroid therapy
4. Diabetes mellitus
5. Cushing syndrome
6. Chronic pancreatitis
7. Main pancreatic duct obstruction
8. Cystic fibrosis (most common cause in childhood)
9. Malnutrition / dietary deficiency
10. Hepatic disease
11. Hemochromatosis
12. Viral infection
13. Shwachman-Diamond syndrome
14. Johanson-Blizzard syndrome

Matsumoto classification:
* sparing of peribiliary region (in all types)
Ia focal fatty infiltration of pancreatic head WITH sparing of uncinate process + pancreatic body (35%)*
Ib infiltration of pancreatic head + neck + body*
IIa infiltration of uncinate process + pancreatic head WITH sparing of pancreatic body (12%)*
IIb complete infiltration of entire pancreas (18%)*
√ fatty replacement often uneven:
√ increase in AP diameter of pancreatic head with focal fatty replacement = lipomatous

pseudohypertrophy
√ prominently lobulated external contour
US:
√ increased pancreatic echogenicity
CT:
√ "marbling" of pancreatic parenchyma / total fatty replacement / lipomatous pseudohypertrophy
DDx of diffuse fatty replacement: pancreatic agenesis (absence of ductal system)
DDx of focal fatty replacement: neoplasm

Pancreatic Fatty Sparing

= sparing of fatty change in pancreatic head + uncinate process (ventral pancreatic anlage) as initial stage in pancreatic lipomatosis
Histo: ventral pancreatic anlage has smaller + more densely packed acini with scanty / absent interacinar fat
√ absence of mass effect or ductal / vascular displacement
US:
√ rounded / triangular hypoechoic area within pancreatic head / uncinate process + diffusely increased echogenicity in remainder of gland
CT:
√ higher-density region in pancreatic head + uncinate process with diffusely decreased attenuation of pancreatic body + tail

PANCREATIC PSEUDOCYST

= collection of pancreatic secretions / hemorrhagic fat necrosis encapsulated by granulation tissue + fibrous capsule
Etiology: (1) Acute pancreatitis (in 2–4%): pseudocyst develops within 4–6 weeks, matures in 6–8 weeks
(2) Chronic pancreatitis (in 10–15%): alcoholism, hyperlipidemia, hyperparathyroidism, chronic obstruction of pancreatic duct, acute exacerbation of pancreatitis
(3) Trauma / surgery
Frequency: 2–4% in acute pancreatitis;
10–15% in chronic pancreatitis
Location: ²/₃ within pancreas
Atypical location (may dissect along tissue planes in ⅓):
(a) intraperitoneal: mesentery of small bowel / transverse colon / sigmoid colon
(b) retroperitoneal: along psoas muscle; may present as groin mass / in scrotum
(c) intraparenchymal: liver, spleen, kidney
(d) mediastinal (through esophageal hiatus > aortic hiatus > foramen of Morgagni > erosion through diaphragm): may present as neck mass
May communicate with: duodenum, stomach, spleen

Vascularized soft-tissue elements are not a pseudocyst feature.

Plain film / contrast radiograph:
- √ smooth extrinsic indentation of posterior wall of stomach / inner duodenal sweep (80%)
- √ indentation / displacement of splenic flexure / transverse colon (40%)
- √ downward displacement of duodenojejunal junction
- √ gastric outlet obstruction
- √ splaying of renal collecting system / ureteral obstruction

US (pseudocyst detectable in 50–92%; 92–96% accurate):
- √ usually single + unilocular cyst
- √ multilocular in 6%
- √ fluid-debris level / internal echoes ← may contain sequester, blood clot, cellular debris from autolysis
- √ rare septations (= sign of infection / hemorrhage)
- √ may increase in size ← hypertonicity of fluid, communication with pancreatic duct, hemorrhage, erosion of vessel
- √ obstruction of pancreatic duct / CBD

CT:
- √ fluid in pseudocyst (0–30 HU)
- √ cyst wall calcification (extremely rare)

MR:
- √ irregularly marginated (early) / well-circumscribed (after several weeks) fluid collection
- √ thickened enhancing wall
- √ hyperintense contents on T1WI ← blood products / necrotic or proteinaceous debris
- √ hyperintense surrounding tissues on fat-suppressed T2WI ← chemical inflammation / infection

Pancreatography:
- √ communication with pancreatic duct in up to 50–70%

Indications for pseudocyst drainage:
pain, suspected infection, persistence of pseudocyst > 5 cm, increasing size, biliary / gastrointestinal obstruction

Cx (in 40%):
1. Rupture into abdominal cavity, stomach, colon, duodenum
2. Hemorrhage / formation of pseudoaneurysm
3. Infection = pancreatic abscess
   - usually occurs > 4 weeks after acute pancreatitis
   - symptomatology of infection
   - √ gas bubbles (DDx: fistulous communication to GI tract)
   - √ increase in attenuation of fluid contents

   Dx: transcutaneous needle aspiration
4. Intestinal obstruction

Prognosis: spontaneous resolution (in 20–50%) ← rupture into GI tract / pancreatic duct or bile duct

DDx: (1) Mucinous pancreatic cystadenoma (no significant interval change on follow-up)
(2) Cystadenocarcinoma
(3) Necrotic pancreatic carcinoma

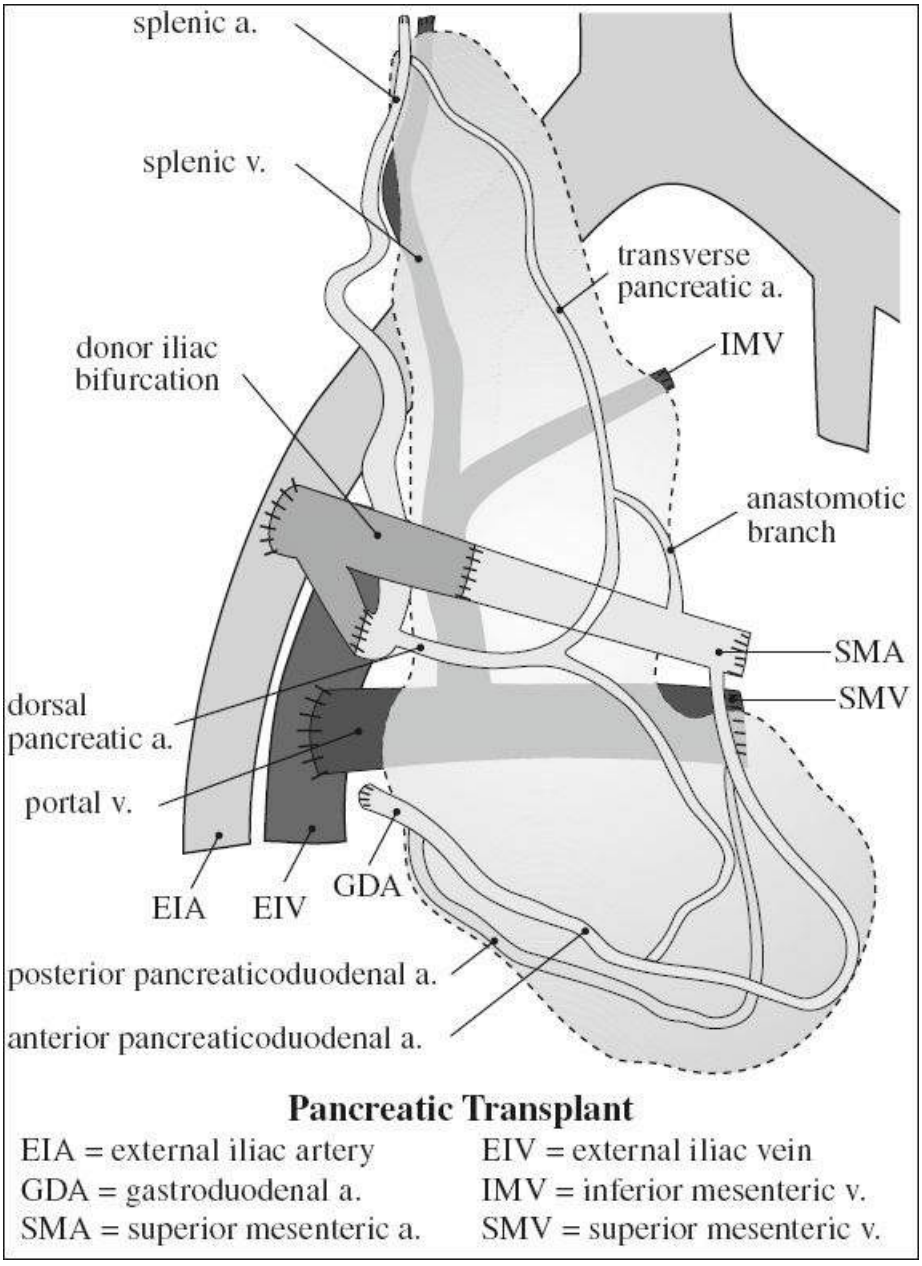
(4) Fluid-filled bowel: small bowel, stomach
(5) Duodenal diverticulum
(6) Aneurysm

PANCREATIC TRANSPLANTATION

Complications: sepsis, rejection, pancreatitis, pseudocyst, pancreatic abscess (22%), anastomotic leak
Prognosis: 40% survival rate > 1 year

Graft-vessel Thrombosis in Pancreatic Transplant (2–19%)

A. Early thrombosis (< 1 month after transplantation)
Cause: technical error in fashioning anastomosis, microvascular damage ← preservation injury



Rx: prompt pancreatectomy

B. Late thrombosis (> 1 month after transplantation)

Cause: alloimmune arteritis with gradual occlusion of small blood vessels

US / CECT:

√ venous > arterial thrombosis

Rejection of Pancreatic Transplant (5–25%)

◊ Graft rejection is primary cause of graft loss

√ all imaging modalities are unreliable

Dx: percutaneous US-guided biopsy

Acute Rejection of Pancreatic Transplant

Time of onset: 1 week– 3 months

Path: autoimmune vasculitis → small vessel occlusion (decreased perfusion) → infarction

- focal tenderness over transplant
- measurement of urinary + serum amylase, blood glucose (nonspecific and poor for diagnosis of rejection)

US (nonspecific):

√ graft enlargement + heterogeneity
√ poor margination of transplant
√ dilated pancreatic duct
√ resistive indices not helpful

DDx: acute pancreatitis, ischemia

Cx: multiple episodes culminate in chronic rejection

Chronic Rejection of Pancreatic Transplant *4–10%*

= major long-term cause of graft failure > first 6 months

Path: small vessel endarteritis → acinar atrophy → interstitial fibrosis

- insidious progressive loss of exocrine, then endocrine function

√ shrunken / disappearing transplant

Graft Pancreatitis

Frequency: up to 35%

Time of onset: < 4 weeks after transplantation

Cause: reperfusion injury

√ nonspecific enlargement + organ heterogeneity
√ peritransplant fluid
√ mural thickening of adjacent bowel

PANCREATITIS

= most common pancreatic disease in children + adults; one of the most common causes of morbidity + mortality worldwide

Cause:

A. CHOLELITHIASIS (50–70%): acute pancreatitis (75%); chronic pancreatitis (20%)
B. ALCOHOLISM (25%): acute pancreatitis (15%); chronic pancreatitis (70%)
C. IDIOPATHIC (20%)
D. METABOLIC DISORDERS
   1. Hypercalcemia in hyperparathyroidism (10%), multiple myeloma, amyloidosis, sarcoidosis
   2. Hereditary pancreatitis: autosomal dominant, only Caucasians affected, most common cause of large spherical pancreatic calcifications in childhood (in 50%), recurrent episodes of pancreatitis, development into pancreatic carcinoma in 20–40%; pronounced dilatation of pancreatic duct; pseudocyst formation (50%); associated with type I hypercholesterolemia
   3. Hyperlipidemia types I and V

4. Cystic fibrosis

E. INFECTION / INFESTATION

1. Viral infection (mumps, hepatitis, Coxsackie virus, mononucleosis)

Drug-Induced Pancreatitis	
Drug Class	*Common Agents*
Antibiotics	metronidazole, tetracyclines, sulfonamides
Diuretics	thiazide, furosemide, ethacrynic acid
Statins	simvastatin
Estrogens	oral contraceptives
ACE inhibitors	captopril, lisinopril, enalapril
Chemotherapeutics	azathioprine, L-asparaginase, Didanosine (2',3'-dideoxyinosine)
Others	sulfasalazine, mesalazine, sodium valproate, phenformin, steroids, acetaminophen, procainamide

2. Parasites (ascariasis, clonorchis)

F. TRAUMA

◊ One of the most common causes of pancreatitis in childhood!

1. Penetrating ulcer
2. Blunt / penetrating trauma; nonaccidental trauma
3. Surgery (in 0.8% of Billroth-II resections, 0.8% of splenectomies, 0.7% of choledochal surgery, 0.4% of aortic graft surgery)

G. STRUCTURAL ABNORMALITIES

1. Pancreas divisum
2. Choledochocele

H. DRUGS (3–5%), > 100 medications have been implicated

Mechanism: pancreatic duct constriction, toxic metabolites, cytotoxic effects → insult to exocrine function and inappropriate accumulation / activation of pancreatic digestive proenzymes

I. MALIGNANCY

Pancreatic carcinoma (in 1%), metastases, lymphoma

J. MULTISYSTEM CONDITIONS

1. Sepsis and shock
2. Hemolytic-uremic syndrome
3. Reye syndrome
4. Systemic lupus erythematosus

Theories of pathogenesis:

reflux of bile / pancreatic enzymes / duodenal succus

(a) terminal duct segment shared by common bile duct and pancreatic duct

(b) obstruction at papilla of Vater from inflammatory stenosis, edema / spasm of sphincter of Oddi, tumor, periduodenal diverticulum

(c) incompetent sphincter of Oddi

Acute Pancreatitis

= inflammatory disease of pancreas producing temporary changes with potential for restoration of normal anatomy and function following resolution

Incidence: > 300,000 hospitalizations annually in USA

- acute epigastric pain radiating to back / chest (peaking after a few hours, resolving in 2–3 days); nausea, vomiting
- ⇑ serum amylase + lipase in blood + urine
- increased amylase-creatinine clearance ratio
- signs of hemorrhagic pancreatitis:
  - Cullen sign = periumbilical ecchymosis
  - Grey-Turner sign = flank ecchymosis
  - Fox sign = infrainguinal ecchymosis
- subcutaneous nodules + fat necrosis + polyarthritis

Clinical definition of acute pancreatitis:

Marshall Scoring System for Acute Pancreatitis

Score	*Respiratory**	*Creatinine [mg/dL]*	*Systolic Pressure [mmHg]*
0	> 400	≤ 1.5	> 90
1	301–400	> 1.5 to ≤ 1.9	< 90, fluid responsive
2	201–300	> 1.9 to ≤ 3.5	< 90, not fluid responsive
3	101–200	> 3.5 to ≤ 5.0	< 90, pH < 7.3
4	< 101	> 5.0	< 90, pH < 7.2

* = ratio of partial pressure of arterial oxygen to fraction of inspired oxygen

organ failure = score ≥ 2 in at least 1 of 3 organ systems

- epigastric pain radiating to back
- serum amylase + lipase > 3 x normal
- characteristic findings on imaging

Clinical phases (revised Atlanta Classification System 2012):

A. First / early clinical phase (during 1st week)

Pathology: early inflammation → peripancreatic edema / ischemia → resolution / permanent necrosis / liquefaction

Severity: based on Marshall scoring system

(a) mild = organ failure resolves within 48 hours

(b) severe = organ failure beyond 48 hours

Other useful severity markers:

- hematocrit, C-reactive protein, LDH, serum / urinary trypsinogen, cytokines
- CT severity index + pleural effusion

◊ Serum amylase + lipase useless to judge severity!

Mortality: 0%

B. Second / late clinical phase beyond 1st week that may persist for weeks – months; characterized by increasing necrosis, ongoing infection, persistent multiorgan failure

- bacteremia + sepsis

Mortality: 5–10% for sterile necrosis; 20–30% for superinfection of necrosis

Role of imaging in acute pancreatitis:

1. Confirm diagnosis in clinical uncertainty
   ◊ NOT needed without signs of severe systemic inflammatory response syndrome!
2. Find cause: cholecystolithiasis, choledocholithiasis, underlying neoplasm
3. Document severity (= extent of necrosis) when patient's condition does not improve / deteriorates
4. Evaluate for complications: extrahepatic biliary dilatation, splenic / portal / mesenteric vein thrombosis, varices, arterial pseudoaneurysm, pleural effusion, ascites, inflammatory changes of stomach, duodenum, small bowel, colon, spleen, kidney, ureter, liver
5. Help to determine when to implement interventional radiologic / endoscopic / surgical treatment
6. Monitor response to treatment

Distribution:

A. Diffuse pancreatitis (52%)
B. Focal pancreatitis (48%): location of head÷tail = 3÷2

Morphologic subtypes:

1. Interstitial edematous pancreatitis 70–80%
2. Necrotizing pancreatitis (more severe form) 20–30%

Abdominal film:

√ "colon cutoff" sign (2–52%) = dilated transverse colon with abrupt change to a gasless descending colon (inflammation via phrenicocolic ligament causes spasm + obstruction at splenic flexure impinging on a paralytic transverse colon)
√ "sentinel loop" (10–55%) = localized segment of gas-containing bowel in duodenum (in 20–45%) / terminal ileum / cecum
√ "renal halo" sign = water-density of inflammation in anterior pararenal space contrasts with perirenal fat; more common on left side
√ mottled appearance of peripancreatic area ← fat necrosis in pancreatic bed, mesentery, omentum
√ intrapancreatic gas bubbles ← acute gangrene / suppurative pancreatitis
√ "gasless abdomen" = fluid-filled bowel associated with vomiting
√ ascites

CXR (findings in 14–71%):

√ pleural effusion (in 10–20%): usually left-sided, elevated amylase levels (in 85%)
√ left-sided diaphragmatic elevation
√ left-sided subsegmental atelectasis (20%)
√ parenchymal infiltrates, pulmonary infarction
√ pulmonary edema, ARDS
√ pleural empyema, pericardial effusion
√ mediastinal abscess, mediastinal pseudocyst
√ pancreaticobronchial / -pleural / -pulmonary fistula

UGI:

√ esophagogastric varices ← splenic vein obstruction

√ diminished duodenal peristalsis
√ widening of retrogastric space ← pancreatic enlargement / inflammation in lesser sac
√ widening of duodenal sweep + downward displacement of ligament of Treitz
√ enlarged tortuous + spiculated edematous rugal folds along antrum + greater curvature of stomach (20%)
√ Poppel sign = edematous swelling of papilla
√ Frostberg "inverted-3" sign = segmental narrowing with fold thickening of duodenum
√ jejunal + ileal fold thickening (proteolytic spread along mesentery)

BE:
√ narrowing, nodularity, fold distortion along inferior haustral row of transverse colon ± descending colon

ERCP (no primary role, replaced by MRCP):
√ long gently tapered narrowing of CBD
√ prestenotic biliary dilatation

Indication: CBD stone removal, pancreatic duct stent placement for stricture / disrupted duct

Cx: exacerbation of pancreatitis, bleeding, perforation of bowel

Bone films (findings in 6%):

Cause: metastatic intramedullary lipolysis + fat necrosis + trabecular bone destruction

Time of onset: usually 3–6 weeks after peak of clinical pancreatitis

√ punched out / permeative mottled destruction of cancellous bone + endosteal erosion
√ aseptic necrosis of femoral / humeral heads
√ metaphyseal infarcts, predominantly in distal femur + proximal tibia

US (visualization of pancreas in 62–78%):
√ hypoechoic diffuse / focal enlargement of pancreas
√ dilatation of pancreatic duct (if head focally involved)
√ perivascular cloaking = spread of inflammatory exudate along perivascular spaces
√ extrapancreatic hypoechoic mass with good acoustic transmission (= phlegmonous pancreatitis)
√ fluid collection: lesser sac (60%), L > R anterior pararenal space (54%), posterior pararenal space (18%), around left lobe of liver (16%), in spleen (9%), mediastinum (3%), iliac fossa, along transverse mesocolon / mesenteric leaves of small intestine

Fate of fluid collection:
(a) complete resolution
(b) pseudocyst formation
(c) bacterial infection = abscess

√ pseudocyst formation (52%): extension into lesser sac, transverse mesocolon, around kidney, mediastinum, lower quadrants of abdomen

CT (modality of choice):
√ no detectable change in size / appearance (29%)
√ enlargement of pancreas with convex margins + indistinctness of gland + parenchymal heterogeneity:
  √ hypodense (5–20 HU) mass in <u>inflammatory pancreatitis</u>; may persist long after complete recovery
  √ hyperdense areas (50–70 HU) in <u>hemorrhagic pancreatitis</u> for 24–48 hr

√ thickening of anterior pararenal fascia
√ "halo" sign = sparing of perirenal space
√ non–contrast-enhancing parenchyma during bolus injection (= pancreatic necrosis)
√ pancreatic + peripancreatic fluid collection

MRI:
√ intra- and extrapancreatic increased T2 signal
√ collection consisting of fluid + nonliquefied material:
  √ T2-hyperintense liquefied component
  √ T2-hypointense nonliquefied component
√ hyperintense SI on fat-saturated T1WI = hemorrhage

MRCP: to evaluate for choledocholithiasis, degree of mass effect on CBD, pancreatic duct stricture / integrity ± communication with collection

N.B.: secretin administration after resolution of acute inflammation to avoid exacerbation

Angiography:
√ may be normal
√ hypovascular areas (15–56%)
√ hypervascularity + increased parenchymal stain (12–45%)
√ venous compression ← edema
√ formation of pseudoaneurysms (in 10% with chronic pancreatitis): splenic artery (50%), pancreatic arcades, gastroduodenal artery

Cx:

Balthazar CT-Severity Index for Acute Pancreatitis

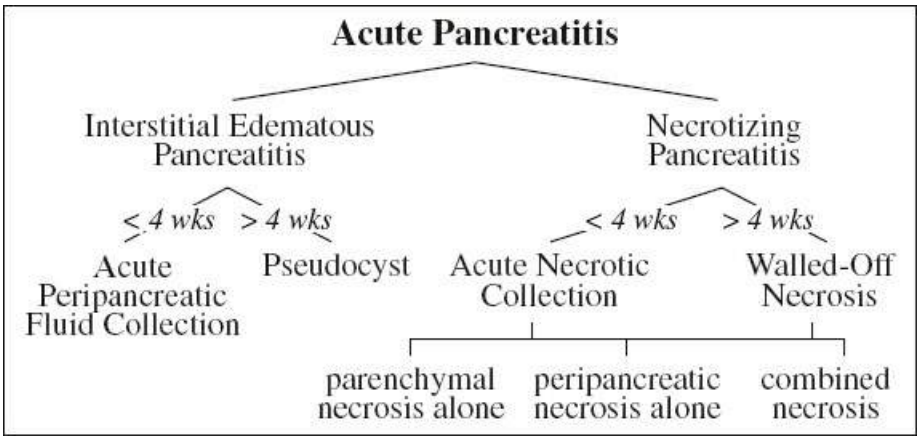
Criteria	*Points*
CT appearance	
Normal pancreas	0
Pancreatic enlargement	1
Pancreatic / peripancreatic inflammation	2
1 fluid collection	3
≥ 2 fluid collection	4
Percentage of necrosis	
None	0
< 30%	2
30–50%	4
> 50%	6

score 0 = 0% mortality;
scores 7–10 = 17% mortality + 92% complication rate

1. Pleural effusion
2. Pseudocyst formation (10%)
3. Hemorrhagic pancreatitis (2–5%)
4. Main pancreatic duct stricture (late Cx)
5. Disconnected pancreatic duct
6. Peripancreatic inflammation

(a) GI tract: stomach, duodenum, small bowel, colon
√ bowel wall thickening, mural hyperenhancement
(b) liver, spleen
(c) kidney, ureter

7. Displacement and compression of adjacent organs
(a) bile duct obstruction
› choledocholithiasis
› mass effect ← inflammation / collection
› stricture ← exposure to proteolytic enzymes
(b) obstruction of stomach
(c) duodenal stricture ← extrinsic compression by enlarged pancreatic head / adjacent fluid collection / duodenal mural edema or hemorrhage
(d) hydronephrosis
◊ At risk for abdominal compartment syndrome
8. Pancreatic ascites
9. Venous thrombosis
Cause: local prothrombotic inflammatory factors, reduced venous flow, mass effect on vein from adjacent necrotic tissue / collection
Location: splenic vein (19–63%) > portal vein (13–25%) > SMV (13–14%)
10. Pseudoaneurysm (typically late Cx)
= digestion of arterial wall by proteolytic enzymes
Frequency: in up to 10% of severe pancreatitis
Location: splenic > gastroduodenal > pancreatico-duodenal > hepatic > left gastric artery
Cx: rupture into preexisting pseudocyst, necrotic collection, gastrointestinal tract, peritoneum, pancreatic parenchyma
Mortality: 37% for rupture, 16–50% for surgery
11. Hemorrhage (1–5%)
Cause: erosion of vasculature, rupture of pseudoaneurysm, rupture of varices
Source: splenic artery, portal vein, splenic vein, small peripancreatic vessels
Location: within pancreatic parenchyma, into fluid collection, into GI tract
Mortality: 34–52%
12. Thoracopancreatic fistula
(a) pancreaticopleural fistula
(b) pancreaticopericardial fistula
(c) pancreaticoesophageal fistula
(d) pancreaticobronchial fistula
(e) mediastinal pseudocyst



BILIARY PANCREATITIS

= gallstone / biliary sludge impaction at ampulla of Vater → ampullary spasm → pancreaticobiliary reflux → obstruction of common bile duct + pancreatic duct

At risk: common pancreaticobiliary channel, pancreas divisum

MR: preferred in suspected choledocholithiasis (more sensitive than CT for detecting gallstones)

HEMORRHAGIC PANCREATITIS

MR:

√ elevated SI on precontrast fat-saturated T1WI

Interstitial Edematous Pancreatitis (IEP) *(70–80%)*

√ localized / diffuse enlargement of pancreas
√ normal homogeneous enhancement
√ normal / "misty" peripancreatic soft tissue
√ ± peripancreatic fat stranding
√ heterogeneous enhancement → repeat scan 5–7 days later for definitive characterization of
(a) interstitial edematous pancreatitis versus
(b) pancreatic necrosis
√ ± peripancreatic fluid collection → eventually pseudocyst

Prognosis: self-limiting with normalization of physical signs + laboratory values within 48–72 hours of conservative therapy

Mortality: 1–5%

Rx: NPO, gastric tube, atropine, analgesics, sedation, prophylactic antibiotics

Necrotizing Pancreatitis *(20–30%)*

= necrosis of pancreatic parenchyma ± peripancreatic tissues as a complication of acute pancreatitis in 25%
{**pancreatic phlegmon** [= misnomer, NO infection!]}

The revised Atlanta Classification System subdivides collections of necrotizing pancreatitis according to time of disease onset:
< 4 weeks after onset WITHOUT discrete wall = **A**cute **N**ecrotic **C**ollection (ANC)
> 4 weeks after onset WITH a discrete wall = **W**alled-**O**ff **N**ecrosis (WON)

ANC and WON can be sterile / infected!
The terms pancreatic abscess, fluid collection, phlegmon are no longer accepted owing to their ambiguity.

Definition: necrosis = nonviable pancreatic tissue that becomes gradually liquefied
Morphologic subtypes (revised Atlanta Classification System of 2012):

(a) pancreatic parenchymal necrosis only (< 5%)
- established by 48–72 hours after disease onset

CT should be performed 3–5 days after presentation because parenchymal pancreatic necrosis cannot be excluded prior to 72 hours after onset!

√ decreased / absent pancreatic parenchymal enhancement = attenuation of < 30 HU during pancreatic parenchymal phase

(b) peripancreatic fat necrosis only (< 20%)
√ mixture of increased attenuation, linear stranding, and fluid collections within peripancreatic fat (DDx: acute interstitial edematous pancreatitis)
√ heterogeneity outside pancreas favors peripancreatic fat necrosis with nonliquefied components ← hemorrhage, necrotic fat
√ liquefied component among fat becomes more apparent after 1 week
Location: commonly retroperitoneum + lesser sac

(c) pancreatic and peripancreatic necrosis (75–80%)
√ combined necrosis with homo- / heterogeneous fluid collections generally becoming walled off (WON) after 4 weeks

Cx: pancreatic duct disruption (~ 50%)
Morbidity: 34–95% due to uncontrolled infection
Mortality: 2–39% due to systemic organ dysfunction, immunosuppression, organ failure

Pancreatic & Peripancreatic Fluid Collection

ACUTE PERIPANCREATIC FLUID COLLECTION (APFC)

= pure extrapancreatic collection WITHOUT solid component during 1st month of interstitial edematous pancreatitis (IEP)
Cause: pancreatic / peripancreatic inflammation; rupture of small peripheral pancreatic branch
Location: adjacent to pancreas conforming to anatomic boundaries of retroperitoneum (extension into lesser sac, anterior pararenal space, transverse mesocolon, small bowel mesentery, retroperitoneum, pelvis)
Content: increased amylase + lipase ← communication with pancreatic ductal system
√ collection of fluid attenuation (near 0 HU):
√ homogeneous and nonenhancing
√ NO discernable wall
Prognosis: spontaneous reabsorption within first few weeks; maturation to pseudocyst

N.B.: Refrain from percutaneous aspiration / drainage to avoid introduction of an infection!

ACUTE NECROTIC COLLECTION (ANC)

= complex collection replacing pancreatic parenchyma during 1st month of necrotizing pancreatitis

Content: nonliquefied + liquefied necrotic debris
◊ Liquefaction of necrotic tissue takes 2–6 weeks!
Location: intrapancreatic / extrapancreatic / both
√ collection of low attenuation:
√ homogeneous / heterogeneous
√ loculated and nonenhancing
√ NO discernable wall (= NO capsule)
√ PATHOGNOMONIC content (if present) of complex heterogeneity, hemorrhage, fat
√ nonliquefied component only discernable on MRI

DDx of Pancreatic & Peripancreatic Fluid Collections

	APFC	*ANC*	*WON*	*Pseudocyst*
Association	IEP	necrotizing pancreatitis	ANC	APFC
Time [month]	< 1st	< 1st	> 1st	> 1st
Location:				
pancreatic	-	+	+	-
peri-	+	+/-		+
Content:	amylase, lipase	liquid + solid	fluid + fat	fluid
homogeneous	+	-/+	-	+
hemorrhage	-	+/-		
fat	-	+/-	+	
Wall:				
discernible	-	-	+	+
enhancing			+	+

√ presence of pancreatic parenchymal necrosis
Prognosis: evolution into
(a) sterile walled-off necrosis (WON) 60%
(b) spontaneous resolution 20%
(c) complicated by infection 20%
Management: CT every 7–10 days to evaluate evolution of pancreatic necrosis + assess for evidence of infection / complications

WALLED-OFF NECROSIS (WON)

= PANCREATIC SEQUESTRATION = NECROMA = ORGANIZED PANCREATIC NECROSIS
= any fluid collection replacing portions of pancreatic parenchyma after 1st month = matured late stage of acute necrotic collection (ANC)
Location: within pancreas / peripancreatic / both
Content: necrotic pancreatic parenchyma + necrotic fat
√ focal / diffuse well-marginated zones of unenhanced pancreatic parenchyma with irregular borders
√ thick enhancing wall between necrosis and adjacent tissue
√ growth of collection favors WON

√ pancreatic ductal dilatation unlikely ← pancreatic fluid decompresses into collection
√ PATHOGNOMONIC if collection is intrapancreatic
√ **saponification** = phospholipases and proteases attack plasma membranes of fat cells → release and hydrolyzation of triglycerides → formation of free fatty acids → combination with serum calcium → precipitation as calcium soaps
Rx: fluid drainage often ineffective
◊ Nonliquefied components require laparoscopic procedure / endoscopic necrosectomy / surgical débridement / percutaneous drain with frequently irrigated large-bore catheter

PSEUDOCYST

= extrapancreatic collection of fluid developing from APFC after 4 weeks
Path: wall of fibrous / granulation tissue; absence of epithelium-lined wall
Frequency: in 10–20% of IEP
Location: adjacent / distant to pancreas
Content: amylase + lipase without necrotic debris
√ well-circumscribed round / oval peripancreatic fluid collection of homogeneously low attenuation < 15 HU
√ well-defined enhancing wall ← fibrous / granulation tissue
◊ Formation of a defined wall takes about 4 weeks!
√ NO nonliquefied component
√ main pancreatic ductal dilatation > 3 mm (frequent) ← compression of pancreatic parenchyma
√ communication with pancreatic ductal system usually seals off
√ persistent pseudocyst after drainage ← continued communication with pancreatic duct
MR:
√ complex cyst dissecting along facial planes:
√ elevated internal T1 signal = blood products
Prognosis: spontaneous resolution in 44%; < 4 cm: resolution anticipated; > 7 cm: treatment recommended; 25% become symptomatic / infected
Cx: hemorrhage, infection, spontaneous rupture into hollow viscera → higher attenuation values
Rx: percutaneous fluid drainage (retroperitoneal approach from flank)

INFECTED COLLECTION

= all 4 types of pancreatic fluid collection can be sterile / infected

The term **"pancreatic abscess"** is no longer used because a collection of pus without pancreatic necrosis does not exist!

Frequency: 2–18%
Timing: most commonly 2–4 weeks after presentation
Cause: bacterial translocation from gut into adjacent necrotic pancreatic parenchyma
◊ Nonliquefied material more likely to become infected!
Organism: (most commonly) E. coli, S. aureus, Enterococcus faecalis
• (nondiagnostic) fever, tachycardia, elevated WBCs
√ gas bubbles in collection (12–22%)

Cause: gas-forming organism (most common: E. coli)
Mortality: 25–70% → diagnosis aggressively pursued!
Dx: image-guided percutaneous aspiration of fluid with positive Gram stain, positive culture for bacteria / fungal organism; 10% FN
Rx: surgical débridement + antibiotics; temporizing percutaneous drainage followed by necrosectomy
DDx of gas: cutaneous / enteric fistula, ruptured duodenum, iatrogenic gas collection (← marsupialization, drainage procedure)

DISCONNECTED PANCREATIC DUCT SYNDROME

Incidence: unknown; in up to 50% after an episode of severe acute necrotizing pancreatitis
Cause: necrosis of ductal epithelium (commonly neck / body); therapeutic intervention (40%)
√ large intrapancreatic collection / longitudinal nonenhancing glandular necrosis (HALLMARK) of > 2 cm
√ viable upstream pancreatic body / tail
√ main pancreatic duct enters collection at 90° angle
√ persistent / growing collection around pancreas
√ persistent drainage of amylase-rich fluid from percutaneously placed catheter despite resolution of fluid collection
ERCP (most sensitive, associated with high morbidity):
√ ductal obstruction at level of fluid collection
√ ± extravasation of contrast material
MRCP (secretin-enhanced):
√ centrally located fluid collection
√ ± dilatation of upstream portion of pancreatic duct and its side branches
Cx: accumulation of fluid around pancreas, pancreatic ascites, pancreaticopleural fistula ← persistent leakage of pancreatic fluid from viable upstream pancreas
Dx: average delay before diagnosis up to 9.3 months
Rx: internal drainage, distal pancreatic resection

Cambridge Classification of Chronic Pancreatitis

Grade	*Main Pancreatic Duct*	*No. of Abnormal Side Branches*
Normal	normal	none
Equivocal	normal	< 3
Mild	normal	≥ 3
Moderate	abnormal	≥ 3
Severe	abnormal	≥ 3

Chronic Pancreatitis

= continued inflammatory disease of pancreas characterized by scarring with irreversible permanent damage to anatomy + function primarily of the exocrine pancreas
Incidence: 3–9÷100,000 per year (in Western countries); annually 120,000 outpatient visits

+ 50,000 hospitalizations

Etiology:

(1) Idiopathic (20%) most common cause of chronic pancreatitis in children
(2) Chronic calcifying pancreatitis
(3) Chronic obstructive pancreatitis

- acute exacerbation of epigastric pain (93%):
  decreasing with time due to progressive destruction of gland, usually painless after 7 years
- jaundice (42%) from common bile duct obstruction
- steatorrhea (80%); negative secretin stimulation test
- diabetes mellitus (58%) ← endocrine insufficiency

√ **"double-duct"** sign = dilatation of CBD and main pancreatic duct, a finding typically associated with chronic pancreatitis
DDx: pancreatic adenocarcinoma

√ **"duct-penetrating"** sign = mass penetrated by an unobstructed pancreatic duct

Plain film:

√ numerous irregular calcifications (in 20–50% of alcoholic pancreatitis)
PATHOGNOMONIC

UGI:

√ displacement of stomach / duodenum by pseudocyst
√ shrinkage / fold induration of stomach (DDx: linitis plastica)
√ stricture of duodenum

Cholangiopancreatography (most sensitive imaging modality):

√ side-branch ectasia = slight ductal ectasia / clubbing of side branches (minimal disease)
√ "nipping" = narrowing of the origins of side branches
√ dilatation > 2 mm, tortuosity, wall rigidity, main ductal stenosis (moderate disease)
√ "beading, chain of lakes, string of pearls" = multifocal dilatation, stenosis, obstruction of main pancreatic duct + side branches (severe disease)
√ intraductal filling defects ← mucinous protein plugs / calculi / debris
√ prolonged emptying of contrast material
√ may have stenosis / obstruction + prestenotic dilatation of CBD
√ filling of pseudocysts (< 50%)

US / CT:

√ irregular (73%) / smooth (15%) / beaded (12%) pancreatic ductal dilatation (in 41–68%)
√ small atrophic pancreas (in 10–54%)
√ pancreatic calcifications (in 4–50–68%)
√ inhomogeneous gland with increased echogenicity (62%)
√ irregular pancreatic contour (45–60%)
√ focal (12–32%) / diffuse (27–45%) pancreatic enlargement during flare up (DDx: pancreatic carcinoma)
√ mostly mild biliary ductal dilatation (29%)
√ intra- / peripancreatic pseudocysts (20–34%)
√ segmental portal hypertension ← splenic vein thrombosis with splenomegaly (in 11%)
√ arterial pseudoaneurysm formation

√ peripancreatic fascial thickening + blurring of organ margins (16%)
√ ascites / pleural effusion (9%)
√ no abnormalities (7%)

MR:
√ loss of SI on fat-suppressed T1WI ← loss of aqueous protein in pancreatic acini ← pancreatic fibrosis
√ delayed diminished heterogeneous contrast enhancement ← loss of capillary network replaced by fibrous tissue

Secretin-enhanced MRCP:
√ **side-branch ductectasia** = one of the EARLIEST findings of chronic pancreatitis
√ main pancreatic duct strictures ± dilatation
√ pseudocyst, fistula
√ loss of MPD distensibility ← reduced compliance
√ loss of duct tapering in pancreatic tail
√ filling defect in MPD ← duct calculus

Angiography:
√ increased tortuosity + angulation of pancreatic arcades + intrahepatic arteries (88%)
√ luminal irregularities / focal fibrotic arterial stenoses (25–75%) / smooth beaded appearance
√ irregular parenchymal stain
√ venous compression / occlusion (20–50%)
√ portoportal shunting + gastric varices without esophageal varices

Cx: pancreatic carcinoma (2–4%), jaundice ← biliary stricture (3–46%), pseudocyst formation, pancreatic ascites, thrombosis of splenic / mesenteric / portal vein

Rx: surgery for infected pseudocyst, GI bleeding from portal hypertension, common bile duct obstruction, gastrointestinal obstruction

DDx: pancreatic carcinoma (extrapancreatic spread)

Chronic Alcoholic Pancreatitis

= characterized by heterogeneous lobular distribution; typically > 8 years of heavy ethanol abuse

Pathophysiology:
thick pancreatic secretions with increased protein concentration → precipitation in pancreatic ductules → obstruction ± calcification of protein plugs

√ protein plugs / calculi within ductal system
√ ductal abnormalities more severe in smaller branches

Chronic Obstructive Pancreatitis

Etiology:
1. Congenital lesion of pancreatic duct
2. Trauma / surgical duct ligation
3. Sphincter of Oddi dysfunction, ampullary stenosis
4. Primary sclerosing cholangitis
5. Idiopathic fibrosing pancreatitis
6. Renal failure

7. Slow growing ampullary tumor
8. Common pancreatic mass: intraductal papillary mucinous tumor, adenocarcinoma, metastasis

DDx of Chronic Pancreatitis from Adenocarcinoma		
Feature	*Chronic Focal Pancreatitis*	*Pancreatic Adenocarcinoma*
Dynamic enhancement	√ early peak	√ peak @ 150–180 sec
	√ delayed wash-out	√ gradual rise
DWI (b value of 600 sec/mm^2)	√ same as pancreas	√ hyperintense to pancreas
ADC	√ higher than normal pancreas	√ lower than normal pancreas / pancreatitis
PET	√ no uptake (88%)	√ increased uptake (98%)

◊ Acute pancreatitis occurs in 3–14% with average delay in cancer diagnosis by 21 months

9. Duodenal lesion: duplication cyst, lipoma, duodenal diverticulum, duodenal adenoma

√ dilatation of main pancreatic duct
√ normal sized / focally or diffusely enlarged / small atrophic gland
√ calcifications uncommon

Autoimmune Pancreatitis AIP *(1.8–11%)*

= PRIMARY / CHRONIC SCLEROSING PANCREATITIS = LYMPHOPLASMACYTIC SCLEROSING PANCREATITIS = NONALCOHOLIC DUCT-DESTRUCTIVE / IDIOPATHIC DUCT-CENTRIC CHRONIC PANCREATITIS = PSEUDOTUMOROUS PANCREATITIS

= unique form of chronic pancreatitis characterized by diffuse inflammatory infiltration by T-lymphocytes and IgG4-positive plasma cells with exuberant fibrosis

Histo: dense periductal lymphoplasmacytic infiltrates

Type 1: lymphoplasmacytic sclerosing pancreatitis with storiform fibrosis and obliterative phlebitis and high rate of relapse
- biliary tract involvement (in up to 80%)

Type 2: idiopathic duct centric pancreatitis with granulocytic epithelial lesions without relapse

Prevalence: 2–5% of chronic pancreatitis
Mean age: 56 (range, 14–77) years; M÷F = 2÷1
Association with other autoimmune conditions:

IgG4-related lesions similar to autoimmune pancreatitis have been identified in many extrapancreatic organs, like bile ducts, gallbladder, lymph nodes, retroperitoneum, mesentery, kidney, lung, breast, prostate gland, skin.

1. Tubulointerstitial nephritis(7–35%)
2. Sialadenitis (12–16%)
3. Sjögren syndrome

4. Primary sclerosing cholangitis (68–88%)
5. Primary biliary cirrhosis
6. Inflammatory bowel disease: ulcerative colitis (17%)
7. Systemic lupus erythematosus
8. Systemic lymphadenopathy
9. Retroperitoneal fibrosis (3–8%)
10. Renal involvement (3–35%)
11. Chronic thyroiditis

Nearly 40% of patients with IgG4-related pancreatitis also have salivary ± lacrimal gland involvement, characterized by bilateral painless glandular swelling, which may precede / accompany pancreatitis / occur in isolation.

- no / mild upper abdominal pain (35%), easy fatigability
- bulging of papilla with obstructive jaundice (63–75%)
- weight loss (35%); diabetes mellitus (42–76%)
- symptoms of pancreatitis at presentation unusual (33%)
- serum level of immunoglobulin G4 (IgG4) > 130 mg/dL (67–94% sensitive, 90–100% specific)
- positivity for ALA (antilactoferrin antibody), ACA II (anti–carbonic anhydrase II antibody), ASMA (anti–smooth muscle antibody), ANA (antinuclear antibody)

Location:

(a) diffuse form: body + tail of pancreas
(b) focal form: head of pancreas
(b) multifocal form: anywhere in pancreas

US:

√ hypoechoic enlarged pancreas

CT:

√ widely varying imaging features depending on degree of fibrosis + inflammatory infiltrate
√ "featureless" pancreas = loss of lobular architecture in diffusely enlarged sausage-shaped pancreas (52%) / focal enlargement of pancreas
√ homogeneously iso- / hypoattenuating parenchyma
√ thin rimlike capsule (of fibrosis)
√ rare calcifications / pseudocysts / vessel encasement
√ minimal hypoattenuating peripancreatic halo = fat stranding of inflammatory tissue around body + tail
√ ± involution of pancreatic tail
√ ± regional lymphadenopathy
√ diffusely narrowed pancreatic duct
√ ± bile duct strictures with upstream ductal dilatation
√ reduced enhancement during parenchymal phase (29–75%)
√ delayed homogeneous enhancement (25–71%)

MR:

√ homogeneously decreased SI on T1WI isointense relative to liver (100%)
√ mildly hyperintense (93%) / variointense on T2WI

√ rim of low SI on T2WI with delayed enhancement
√ delayed retention of contrast material ← widened extracellular extravascular space (70–89%)

CECT /CEMR:
√ SPECIFIC capsulelike rim / halo of low attenuation surrounding pancreas (not seen in any other pancreatic disorder) ← fluid collection / phlegmon / fibrosis (12–48% for CECT, 18–47% for CEMR)

MRCP:
√ diffuse narrowing of main pancreatic duct
√ strictures of pancreaticobiliary tree

ERCP:
√ focal / segmental / diffuse narrowing of main pancreatic duct + nonvisualization of side branches (CHARACTERISTIC):
√ > 3 cm long stenosis of main pancreatic duct
√ < 6 mm diameter of upstream portion of duct
√ "duct-penetrating sign" = continuity of pancreatic duct highly SPECIFIC for a benign pancreatic mass
√ "ice pick sign" = smooth tapered narrowing of upstream pancreatic duct just distal to pancreatic lesion
√ smooth stricture of distal extrapancreatic CBD + dilatation of proximal duct segment (90%) ← extrinsic compression
√ strictures of more proximal bile ducts resembling primary sclerosing cholangitis

PET:

PET/CT is helpful in diagnosis and response assessment to corticosteroid therapy.

√ longitudinal heterogeneous pattern with multiple areas of uptake within pancreas
√ extrapancreatic uptake in lacrimal / salivary glands, biliary system, retroperitoneal space, prostate gland

@ Renal manifestations
√ bilateral small peripheral renal cortical nodules / round lesions / well-defined wedge-shaped lesions / patchy parenchymal lesions
√ involvement of perirenal tissue, renal sinus, renal pelvic wall

@ Pulmonary manifestations
√ retroperitoneal fibrosis
√ pulmonary parenchymal nodules + infiltrates
√ mediastinal adenopathy

Cx: diffuse sclerosis → organ dysfunction

Rx: dramatic response to corticosteroid therapy

DDx: (1) Pancreatic cancer (invasion / encasement of vessels, mass effect, abrupt narrowing of pancreatic duct + significant proximal dilatation, marked atrophy of parenchyma upstream to mass, fluid collection, IgG4-negativity)
(2) Lymphoma
(3) Acute pancreatitis (marked peripancreatic fat stranding, peripancreatic fat necrosis, NO peripancreatic halo)

(4) Chronic pancreatitis (calcifications)

Focal Pancreatitis

= MASS-FORMING / PSEUDOTUMORAL PANCREATITIS

Frequency: 5–10% of pancreatectomies for presumed malignancy

Cause: chronic pancreatitis, autoimmune pancreatitis (25%), groove pancreatitis

◊ NO distinguishing morphologic features from adenocarcinoma clinically + radiographically ← coexistence with inflammation; adenocarcinoma may arise in chronic pancreatitis (2% [65%] after 10 [20] years)

√ "duct penetrating" sign = nondilated / smooth tapering of pancreatic + bile ducts coursing through mass

√ irregularity of pancreatic duct

√ pancreatic calcifications

DDx: adenocarcinoma (abrupt interruption of smoothly dilated pancreatic duct, upstream pancreatic gland atrophy, gradual enhancement)

Groove Pancreatitis

= rare distinct form of chronic segmental pancreatitis characterized by inflammation + fibrous tissue formation in pancreaticoduodenal groove

Prevalence: unknown

Location: groove (= potential space) between pancreatic head + duodenum + common bile duct

Cause: unknown

Types:

(a) segmental form = involvement of pancreatic head + pancreaticoduodenal groove mimicking a mass

(b) pure form = sheetlike fibrotic scar tissue in groove without involvement of pancreatic head

• recurrent vomiting ← duodenal obstruction in 50%

• symptoms of biliary obstruction (in 50%) rarely precede those of duodenal obstruction

√ hypoattenuating sheetlike soft-tissue density

√ hypointense on T1WI + iso- to hyperintense on T2WI

√ delayed enhancement

√ masslike appearance of pancreatic head

Histo: chronic pancreatitis

√ long smooth segmental stricture of intrapancreatic CBD

√ widening of space between distal pancreatic duct + CBD and duodenal lumen

√ thickening ± cystic dystrophy of duodenal wall

DDx: pancreatic adenocarcinoma (vascular invasion, no cystic lesions within mass / thickened duodenal wall)

Hereditary Pancreatitis *(<1%)*

= autosomal dominant disease with recurrent attacks resulting in chronic pancreatitis

Genetics: mutation of cationic trypsinogen genes like PRSS1 (serine peptidase) and CFTR (cystic fibrosis transmembrane regulator) gene; NO mutations in 30%

Age of onset: variable from 5–10 years to 6th decade
√ pancreatic parenchymal calcifications + ductal calculi
√ duct destruction with significant pancreatic atrophy
√ absence of anatomic anomalies
Cx: (1) Exocrine + endocrine pancreatic insufficiency
(2) Pancreatic cancer: 50–70-fold increased risk within 7–30 years of disease onset
◊ Endoscopic US in 6–12-month intervals starting at 30 years of age
Dx: suspect after 2 attacks of acute pancreatitis without explanation like: anatomic anomalies, ampullary / MPD strictures, trauma, viral infection, gallstones, alcohol consumption, drug use, hyperlipidemia
DDx: tropical pancreatitis

Tropical Pancreatitis

= JUVENILE NONALCOHOLIC CHRONIC RELAPSING PANCREATITIS = JUVENILE TROPICAL PANCREATITIS = KWASHIORKOR
= variant of chronic pancreatitis with rapidly progressive course
◊ Most common cause of pancreatitis worldwide!
Geography: southern state of Kerala in India, Indonesia, Asia, Africa, and South America
Etiology:
(1) Protein energy malnutrition → suppression of pancreatic function
(2) Pancreatic ductal anomalies
(3) Food toxicity: chronic cyanide toxicity from cassava
(4) Genetic predisposition: SPINK 1 N34S mutation, CFTR mutation
Mean age: 12.5 years (range, infancy to adulthood); M÷F = 1.6÷1 to 5÷1
• abdominal pain (80–90%), weight loss, steatorrhea
• glucose intolerance / frank diabetes mellitus
√ multiple discrete dense up to 5 cm large pancreatic calculi within dilated pancreatic duct (80%) ± extension into side branches
√ pancreatic atrophy (50%)
Cx: (1) Fibrocalculous pancreatic diabetes (within decade of onset)
(2) Pancreatic adenocarcinoma (by 45 years, responsible for 25% of deaths)

PANCREATOBLASTOMA

= INFANTILE PANCREATIC CARCINOMA
= rare childhood tumor often misdiagnosed as neuroblastoma / hepatoblastoma
Frequency: 0.2% of all pancreatic tumors
◊ Most common pancreatic tumor in young children (< 75 cases in literature)!
Ethnicity: > 50% in Asians
Mean age: 4.5 (range, fetus to 9) years; M÷F = 2÷1
May be associated with: Beckwith-Wiedemann syndrome
Path: displacing tumor of soft consistency with cystic spaces ← hemorrhage / cystic degeneration
Histo: epithelial tissue in organoid arrangement of acinar, trabecular, solid formation separated by dense stromal bands; scattered islands of squamoid corpuscles (CHARACTERISTIC)
Size: 10.6 (range, 1.5–20.0) cm
◊ Organ of origin difficult to establish due to large size!
Location: head of pancreas (50%) uncommonly dilating the biliary tree
• abdominal pain, fatigue, lethargy, weight loss, anorexia
• early satiety, vomiting, constipation
• asymptomatic large palpable mass (slow growing)
• elevated serum α-fetoprotein (25–33%)
√ well-defined smooth lobulated solid / multiloculated solitary mass in region of lesser sac
√ ± small clustered punctate / curvilinear calcifications
√ enhancing septa
US:
√ well-circumscribed hypoechoic / heterogeneous mass with solid + cystic components (with echogenic internal septa)
MR:
√ low (= foci of necrosis) to intermediate SI on T1WI
√ heterogeneous high SI on T2WI
Spread: liver + regional lymph nodes (35%); lung / brain (less common); omentum, cul-de-sac, colon, spleen, kidney, adrenal (rare)
√ hyperattenuating liver metastases
√ regional lymphadenopathy difficult to detect due to large displacing mass
√ rarely vascular invasion
DDx: neuroblastoma, Wilms tumor, hepatoblastoma, NHL, solid-pseudopapillary tumor (adolescent girl)
Rx: complete resection (resectable in 75%) + empirical adjuvant chemotherapy; recurrence after surgery in 14%

PAPILLARY ADENOMA OF BILE DUCTS

= very rare benign tumor of biliary tract
Path: usually solitary tumor / biliary papillomatosis with papillary fronds extending into lumen

Histo: columnar epithelium supported by connective tissue from lamina propria ± mucin production

• biliary obstruction

Location: common bile duct > right / left hepatic duct

√ usually small intraductal mass

√ visualized at cross-sectional imaging only if large enough

√ segmental biliary ductal dilatation

Prognosis: high rate of recurrence after surgical resection

Cx: malignant transformation (rare in solitary adenoma, significant risk in papillomatosis))

PASSIVE HEPATIC CONGESTION

= stasis of blood within liver parenchyma ← impaired hepatic venous drainage ← cardiac disease

Cause: CHF, constrictive pericarditis, pericardial effusion, cardiomyopathy, tricuspid / pulmonary valve disease

Pathophysiology: chronic central venous hypertension transmitted to hepatic sinusoids → centrilobular congestion → hepatic atrophy, necrosis, fibrosis → irreversible **cardiac cirrhosis**

• RUQ pain, hepatomegaly, increased abdominal girth

• elevation of liver enzymes, jaundice

√ hepatomegaly

√ ascites, pleural effusion, pericardial effusion

√ cardiomegaly, congestive heart failure

CECT:

- √ reflux of contrast from RA into IVC → early enhancement of dilated IVC + central hepatic veins during arterial phase
- √ enhancement of portal veins + hepatic arteries + immediately adjacent parenchyma (56%)
- √ delayed antegrade enhancement of hepatic veins during portal venous phase
- √ "reticulated mosaic" pattern = lobular patchy areas of enhancement separated by coarse linear regions of diminished attenuation (100%) during parenchymal phase
- √ globally delayed enhancement (36%)
- √ linear / curvilinear areas of poor enhancement ← delayed enhancement of small + medium-sized hepatic veins
- √ large patchy peripheral areas of poor delayed enhancement
- √ perivascular lymphedema = linear hypoattenuating regions encircling intrahepatic IVC / portal veins:
  - √ diminished periportal attenuation (24%)
  - √ diminished attenuation around intrahepatic IVC (8%)

DDx: Budd-Chiari syndrome (narrowed intrahepatic IVC / hepatic veins; flip-flop pattern between arterial + venous phase in acute disease; caudate lobe hypertrophy; large regenerative nodules in chronic disease)

PELIOSIS

[*pelios*, Greek = purple]

= rare benign disorder characterized by cystic sinusoidal dilatation + multiple blood-filled lacunar spaces between 1 mm and several cm in diameter within organs of the RES

Cause: (a) idiopathic (in 20–50%)

(b) acquired:

› chronic wasting / infection = bacillary peliosis hepatis (Bartonella henselae and quintana, TB, leprosy, AIDS)

› hepatotoxic drugs: androgen-anabolic steroids, corticosteroids, tamoxifen citrate, chemotherapeutic |agents, azathioprine, oral contraceptives, diethylstilbestrol, thorium dioxide injection, arsenic, polyvinyl chloride)

› chronic renal failure

› advanced malignancy: HCC, Hodgkin disease, myeloma, disseminated cancer

› renal / cardiac transplantation

(c) ? congenital: angiomatous malformation

Histo: (1) PHLEBECTATIC peliosis hepatis (early stage)

= endothelial-lined cysts (= ? dilatation of central veins) communicating with dilated hepatic sinusoids + compression of surrounding liver

(2) PARENCHYMAL peliosis hepatis (late stage)

= irregularly shaped cysts without lining communicating with dilated hepatic sinusoids + areas of liver cell necrosis

Associated with: hormonally induced benign / malignant tumors; diabetes mellitus, sprue, necrotizing vasculitis

Location: liver (most common), spleen, bone marrow, lymph nodes, lung

Age: fetal life (rare) to adult life

• incidentally discovered; asymptomatic

√ hepatomegaly, splenomegaly

√ small lesions remain invisible with / without contrast

US:

√ multiple indistinct areas of variable echogenicity:

√ hyperechoic on background of normal liver

√ hypoechoic on background of abnormal echogenic liver

√ ± internal vascularity

CT:

√ focal hypoattenuating area ± internal calcifications

√ increased attenuation in areas of hemorrhage

CECT (variable enhancement pattern):

√ hypoattenuating relative to liver during early phase + centripetally increasing enhancement during later phases (DDx: hemangioma)

√ complete globular vessel-like enhancement during early phase

√ "target" sign (= central enhancement) with centrifugal progression during portal venous phase

√ homogeneously hyperintense on delayed phase

√ ± nonenhancing central areas of thrombosis simulating metastasis / abscess

MR:

√ variable intensity on T1WI (typically hypointense ← subacute blood products

√ commonly and typically hyperintense on T2WI + central areas of increased SI ← necrosis
√ mixed SI ← repeated hemorrhage (deoxyhemoglobin + methemoglobin + siderotic nodules)
√ low SI during arterial phase + contrast accumulation during portal venous + delayed phases

Angio:

√ multiple small (several mm to 1.5 cm) round collections of contrast medium scattered throughout liver in late arterial phase of hepatic arteriogram
√ ± simultaneous opacification of hepatic veins

Prognosis: reversible after drug withdrawal / progression to hepatic failure / intraperitoneal hemorrhage leading to death

CAVE: inadvertent aspiration of a peliotic lesion may be fatal

DDx: hypervascular metastasis (hypo- / isoattenuating to liver in portal venous phase); hemangioma (discontinuous globular enhancement in arterial phase + centripetal progression + mass effect); liver abscess

PORCELAIN GALLBLADDER

= calcium carbonate incrustation of gallbladder wall

Frequency: 0.6–0.8% of cholecystectomy patients; M÷F = 1÷5

Histo: (a) flakes of dystrophic calcium within chronically inflamed + fibrotic muscular wall
(b) microliths scattered diffusely throughout mucosa, submucosa, glandular spaces, Rokitansky-Aschoff sinuses

Associated with: gallstones in 90%

• minimal symptoms
√ curvilinear (muscularis) / granular (mucosal) calcifications in segment of wall / entire wall
√ nonfunctioning GB on oral cholecystogram
√ highly echogenic shadowing curvilinear structure in GB fossa (DDx: stone-filled contracted GB)
√ echogenic GB wall with little acoustic shadowing (DDx: emphysematous cholecystitis)
√ scattered irregular clumps of echoes with posterior acoustic shadowing

Cx: 10–20% develop carcinoma of gallbladder

PORTAL HYPERTENSION

= portal venous pressure > 10 mmHg

• normal hepatic blood flow of 550–900 mL/min (= 25% of cardiac output) passes through portal system (⅔) + through hepatic artery (⅓)

Classification:

A. DYNAMIC / HYPERKINETIC PORTAL HYPERTENSION
CONGENITAL / traumatic / neoplastic arterioportal fistula

B. INCREASED PORTAL RESISTANCE

@ Prehepatic
› portal vein thrombosis: portal phlebitis, oral contraceptives, coagulopathy, neoplastic invasion, pancreatitis, neonatal omphalitis
› portal vein compression: tumor, trauma, lymphadeno-pathy, portal phlebosclerosis, pancreatic pseudocyst

@ Intrahepatic (= obstruction of portal venules)

› presinusoidal

1. Congenital hepatic fibrosis
2. Idiopathic noncirrhotic fibrosis
3. Primary biliary cirrhosis
4. Alpha-1 antitrypsin deficiency
5. Wilson disease
6. Sarcoid liver disease
7. Toxic fibrosis (arsenic, copper, PVC)
8. Reticuloendotheliosis
9. Myelofibrosis
10. Felty syndrome
11. Schistosomiasis
12. Cystic fibrosis
13. Chronic malaria

› sinusoidal

1. Hepatitis
2. Sickle cell disease

› postsinusoidal

1. Cirrhosis (most frequent): Laennec cirrhosis, postnecrotic cirrhosis from hepatitis
2. Venoocclusive disease of liver

@ Posthepatic

1. Budd-Chiari syndrome
2. Constrictive pericarditis
3. CHF (tricuspid incompetence)

Pathophysiology:

continued elevated pressure despite formation of portal venous collateral vessels may be explained by

(a) <u>backward flow theory</u> = hypodynamic flow theory
= increase in sinusoidal pressure ← deposition of collagen in spaces of Disse + hepatocyte swelling
• low / stagnant portal venous flow rates

(b) <u>forward flow theory</u> = hyperdynamic flow theory
= splanchnic flow increases ← mesenteric vasodilators + increase in cardiac output to preserve hepatic perfusion + intrahepatic endogenous vasoconstrictors
• increased portal venous flow rates > 15 mL/min/kg

Flow direction:

(a) hepatopetal (*petere*, Latin = to seek)
(b) hepatofugal (*fugere*, Latin = to flee) = flow reversal
Cause: intrahepatic arterioportal communications (inside portal triads vasa vasorum of portal veins + hepatic arteries connect via bile duct capillaries to portal v.)

• elevated hepatic wedge pressure (HWP) = portal venous pressure; normal values seen in presinusoidal portal hypertension
• caput medusae = drainage from paraumbilical + omental veins through superficial veins of chest (lateral thoracic vein to axillary vein; superficial epigastric vein to internal mammary

vein and subclavian vein) + abdominal wall (circumflex iliac vein and superficial epigastric vein to femoral vein; inferior epigastric vein to external iliac vein)

• hemorrhaging esophageal varices (50%)

@ Splanchnic system:

√ portal vein > 13 mm (57% sensitive, 100% specific)

√ SMV + splenic vein > 10 mm; coronary vein > 4 mm; recanalized umbilical vein > 3 mm (size of vessels NOT related to degree of portal hypertension or presence of collaterals)

√ loss of respiratory increase of splanchnic vein diameters of < 20% (81% sensitive, 100% specific)

√ portal vein aneurysm

√ portal vein thrombosis

√ cavernous transformation of portal vein

√ increased echogenicity + thickening of portal vein walls

Doppler US:

√ continuous monophasic portal venous flow pattern without respiratory fluctuations

√ loss of flow increase in portal venous system during expiration

√ DIAGNOSTIC reduction of peak portal vein velocity to < 16 cm/sec (normally 16–40 cm/sec)

Spontaneous Portosystemic Shunts

Type of Varices	*Frequency (%)*
Coronary venous	80–86
Esophageal	45–65
Paraumbilical	10–43
Abdominal wall	30
Perisplenic	30
Retrogastric / gastric	2–27
Paraesophageal	22
Omental	20
Retroperitoneal-paravertebral	18
Mesenteric	10
Splenorenal	10
Gastrorenal	7

√ DIAGNOSTIC hepatofugal flow in main portal vein

√ **congestive index** > 0.13 cm•sec (= ratio of area of portal vein divided by flow velocity; 67% sensitive)

√ may have bidirectional / hepatofugal (< 10%) flow within spontaneous splenorenal shunts (indicates high incidence of hepatic encephalopathy)

√ dilated hepatic artery may demonstrate elevated resistive index > 0.78

@ Spontaneous portosystemic shunts / collaterals:

◊ Portosystemic shunts are one of the MOST SPECIFIC findings for portal hypertension!

• high frequency of hepatic encephalopathy

√ varices = serpentine tubular rounded structures

√ coronary (left gastric) vein > 5–6 mm (in 26%)
√ gallbladder wall varices in thickened gallbladder wall (in 80% associated with portal vein thrombosis)

(a) connection to SVC
1. Esophageal varices
2. Paraesophageal varices

(b) connection to pulmonary circulation
1. Gastropulmonary shunt (between gastric / esophageal vv. and left pericardiophrenic / inferior pulmonary vv.)
√ lateral bulging of paraspinal interfaces on CXR
√ obliteration of azygoesophageal recess on CXR
√ cardiophrenic angle masses (with membranous obstruction of IVC)

(c) retrograde mesenteric flow
1. Veins of Retzius (= anastomoses between portal vein and IVC)
› ileocolic veins → right gonadal vein → IVC
› pancreaticoduodenal vein → IVC
› proximal small left branches of SMV → left gonadal vein → left renal vein
› ileocolic veins → directly into IVC

(d) retroperitoneal collaterals
1. Splenorenal / splenoadrenorenal shunt
2. Gastrorenal shunt
3. Mesenterorenal shunt (SMV → right renal vein)
4. Mesenterogonadal shunt (ileocolic vein → right testicular vein)
5. Splenocaval shunt (splenic vein → left hypogastric v.)

(e) intrahepatic shunt (portal vein → hepatic veins)

@ **Cruveilhier-von Baumgarten syndrome** (20–35%)
= recanalized paraumbilical veins (NOT recanalized umbilical veins)
√ hypoechoic channel in ligamentum teres
(a) size < 2 mm (in 97% of normal subjects; in 14% of patients with portal hypertension)
(b) size ≥ 2 mm (86% sensitive for portal hypertension)
√ arterial signal on Doppler US in 38%
√ hepatofugal venous flow (82% sensitive, 100% specific for portal hypertension)

@ Spleen
√ splenomegaly (nonspecific; absence does NOT rule out portal hypertension)
√ **Gamna-Gandy nodules** in 13% (= small foci of perifollicular + trabecular hemosiderin deposits after hemorrhage):
√ multiple 3–8-mm low-intensity (blooming) spots on FLASH / GRASS images
√ multiple hyperechoic spots on US
√ multiple faint calcifications on CT

√ ascites (nonspecific)

Cx: Acute gastrointestinal bleeding (mortality of 30–50% during 1st bleeding)

Segmental Portal Hypertension

= splenic vein occlusion / superior mesenteric vein occlusion

PORTAL VEIN ANEURYSM / VARIX

= rare localized saccular / fusiform portal venous dilatation with a portal vein diameter of > 20 mm

Frequency: 3% of all venous aneurysms; most common type of visceral venous aneurysm

Prevalence: 0.6–4.3÷1000 patients

Cause:

(a) congenital: diverticulum formation ← incomplete regression of distal right primitive vitelline vein; vessel wall weakness; anomalous portal vein branching

(b) ACQUIRED: liver cirrhosis; portal hypertension ← portal vein thrombosis; trauma; surgery; pancreatitis

• usually asymptomatic, pain, jaundice, gastrointestinal bleeding

Site: extrahepatic portal vein (63–77%) > splenomesenteric venous confluence > splenic vein > intrahepatic portal vein branch > superior mesenteric vein > inferior mesenteric vein

√ often solitary (80%) and fusiform (97%–100%)

Cx: portal hypertension, spontaneous thrombosis (28%), venous varix rupture, compression of adjacent biliary tree / duodenum / IVC

PORTAL VEIN THROMBOSIS

= PYLETHROMBOSIS

Etiology:

A. IDIOPATHIC (mostly): ? neonatal sepsis

B. SECONDARY:

(1) Cirrhosis + portal hypertension (5%)

(2) Tumor invasion by: HCC (13–44%), pancreatic carcinoma, cholangiocarcinoma, gastric carcinoma, metastasis / extrinsic compression by tumor

(3) Trauma: umbilical venous catheterization; Cx of splenectomy (7%, higher in patients with myelo-proliferative disorders); liver transplantation; percutaneous islet cell transplantation; portosystemic shunt surgery

(4) Hypercoagulable state: blood dyscrasia; clotting disorder; estrogen therapy; severe dehydration, Trousseau

(5) Intraperitoneal inflammatory process (portal vein phlebitis): perinatal omphalitis; pancreatitis; appendicitis; ascending cholangitis

(6) Budd-Chiari syndrome (20%)

Age: predominantly children, young persons

• nonspecific abdominal pain, hematemesis (esophageal varices)

• portal systemic encephalopathy

Types:

A. BLAND portal vein thrombus
in 11.2–15.8% of cirrhosis with portal hypertension

MRCP:

√ NO effect on portal vein caliber

√ low SI on T2WI ← hemosiderin within thrombus

B. MALIGNANT portal vein thrombus in 44% of HCC

MRCP:
- √ expansile dilatation of portal vein
- √ intermediate to high SI on T2WI
- √ arterial neovascularity contiguous with primary
- √ enhancement similar to primary tumor

Course: dependent on degree of thrombosis, extent of collateralization, duration of thrombus

Acute Portal Vein Thrombosis

- may be asymptomatic
- exacerbation of preexisting portal hypertension

Plain film:
- √ hepatosplenomegaly
- √ enlarged azygos vein
- √ paraspinal varices

UGI:
- √ esophageal varices
- √ thickening of bowel wall

US:
- √ echogenic material within vessel lumen (67%) / thrombus may be isoechoic
- √ increase in portal vein diameter (57%):
  - √ enlargement of thrombosed segment > 15 mm (38%)
- √ portosystemic collateral circulation (48%): biliary and gastric tributaries of portal vein (most common)
- √ thickening of lesser omentum

Doppler-US:
- √ NO flow on postprandial color Doppler scans:
  - ◊ Malignant thrombus tends to distend vein + exhibit pulsatile flow, a bland thrombus does not!
- √ decrease in hepatic artery resistive index:
  - √ RI < 0.50 (in acute occlusive portal vein thrombosis)
  - √ minimal decrease / normal RI (in chronic portal vein thrombosis / nonocclusive thrombosis)

NECT:
- √ thrombus usually of high attenuation
- √ decreased attenuation of affected hepatic parenchyma ← edema, depletion of hepatocytes, fibrosis

CECT:
- √ transient high attenuation of hepatic parenchyma during hepatic arterial phase ← increased arterial flow
- √ partial / complete filling defect in portal vein:
  - √ low-density center of portal vein thrombus = portal vein density 20–30 HU less than aortic density
  - √ surrounded by peripheral enhancement

MR:
- √ absent flow void in portal area + abnormal SI in main portal vein

√ hyperintense thrombus on T1WI + T2WI (if < 5 weeks old)
√ filling defect on CEMR
√ iso- / hypointense bland thrombus on T1WI + T2WI
√ heterogeneous hyperintense tumor thrombus on T2WI

Angio:

√ "thread and streaks" sign of tumor thrombus (streaky contrast opacification of tumor vessels)

Cx: (1) Cavernous transformation (19%)
(2) Hepatic infarction
(3) Bowel infarction
(4) Variceal bleeding → shock

Prognosis: partial / complete spontaneous resolution

Chronic Portal Vein Thrombosis

Pathophysiology:

central part (caudate lobe + lateral segment) is well supplied by collateral venous vessels; the peripheral zone (mainly right lobe) receives less portal venous blood resulting in increased arterial inflow

√ **cavernous transformation** (= cavernoma) of portal vein:
√ presence of a racemose conglomerate network of collateral veins (= enlargement of vasa vasorum of portal vein wall) with portal venous flow linking pancreas + duodenum + gallbladder fossa
√ ± dilated pancreaticoduodenal venous arcades ← SMV occlusion
√ ± dilated gastric + gastroepiploic veins ← splenic vein occlusion
√ segmental atrophy of affected liver segments + compensatory hypertrophy of perfused segments:
√ abnormal peripheral high-attenuation patches during hepatic arterial phase
√ decreased enhancement during portal venous phase
√ portoportal channels intrahepatically between segments ← thrombosis of intrahepatic portal vein branches
√ extensive portosystemic collateralization ← extrahepatic portal hypertension
√ splenomegaly
√ ascites

NECT:

√ nonvisualization of extrahepatic portal vein (= fibrotic portal vein)
√ ± calcifications within clot / wall of portal vein

CECT:

√ peripheral scattered areas of high attenuation in liver during hepatic arterial phase
√ multiple serpentine enhancing collateral vessels

US:

√ echogenic / nonvisualized portal vein
√ multiple tubular anechoic channels in hepatic hilum

MR:

√ hypointense portal vein on T1WI + hyperintense on T2WI (2–18 months old)

√ numerous abnormal flow voids in porta hepatis

PORTOSYSTEMIC SHUNT

Congenital Portosystemic Shunt

Congenital Extrahepatic Portosystemic Shunt (CEPS)

= ABERNETHY MALFORMATION

= anastomosis between prehilar portomesenteric PV and a systemic vein (IVC > renal / iliac / azygos vein / RA)

Age:

Type 1: usually early childhood; M÷F = 1÷3

Type 2: intrauterine to 68 years; M÷F = 1÷1

Associated congenital anomalies:

CHD (ASD, VSD, patent foramen ovale, patent ductus arteriosus, tetralogy of Fallot), situs ambiguous, polysplenia, malrotation, duodenal atresia, annular pancreas, skeletal anomalies, GU malformations

Cause:

excessive involution of periduodenal vitelline venous loop / total failure of vitelline veins to establish critical anastomoses with hepatic sinusoids / umbilical veins

› shunt due to persistence of right vitelline vein (shunt drains into retrohepatic IVC) /

› shunt due to persistence of left vitelline vein (shunt drains into IVC or RA above level of hepatic vein confluence)

Types (Morgan & Superina classification):

1. Complete diversion of portal blood into systemic circulation (end-to-side shunt) with absent intrahepatic portal branches
   1a SV / SMV drain separately into systemic vein = complete **atresia of portal vein**
   1b SV + SMV form a common trunk and drain together into a systemic vein
2. Some portal flow is diverted into a systemic vein (side-to-side shunt) with intact intrahepatic PV

Types according to development of venules in portal triads:

I absence of PV + absence of venules = PV **agenesis**

II absence of PV + presence of venules = PV **atresia**

In suspected type 1 CEPS a liver biopsy is necessary to reveal small portal venules within portal triads (not diagnosable by imaging), a finding indicative of a type II shunt.

- symptoms related to abnormal hepatic development:
  - nonspecific liver dysfunction
  - fatty degeneration + atrophy → small liver volume
  - regenerative / hyperplastic nodules → hepatomegaly
- symptoms resulting from the portosystemic shunt:
  - elevated serum levels of ammonia, galactose, other toxic metabolites
  - high galactose levels are useful for screening of newborn
- symptoms from associated congenital abnormalities

√ absence of portal hypertension: NO ascites, NO varices, NO splenomegaly

Portal hypertension with its secondary signs of splenomegaly, ascites, portosystemic collaterals is not seen in CEPS.

√ polysplenia + hypersplenism (frequent)
√ ± congenital biliary atresia, choledochal cyst, intrahepatic gallbladder
US:
√ (often) absent / hypoplastic portal vein
√ enlarged hepatic artery = only vessel seen within hepatoduodenal ligament given atresia of portal vein

Bland vs. Malignant Portal Vein Thrombus

Findings on US, CT, MR	*Bland*	*Malignant*
Echogenicity	hyperechoic (often)	heterogeneous
Attenuation of filling defect	low	higher
Thrombus intensity	iso- to hypo ⇑ ADC	hetero on T2WI, ⇓ ADC
Arterialized flow in thrombus	–	+
Presence of Doppler flow	–	+
Contrast enhancement	–	+
Adjacent tumor	none	contiguous
Portal vein expansion	–	+

√ portal vein draining into IVC
CT / MR angiography:
√ identification of absent portal branches

√ regenerative nodular hyperplasia typically has high signal intensity on T1WI (in 75%).

Transrectal Portal Scintigraphy:
» rectal administration of 123I iodoamphetamine → absorption into IMV → carried to liver
√ simultaneous detection of isotope in liver and lungs
√ abnormal portosystemic shunt index (= lung counts divided by liver counts + lung counts) > 5%

Cx: (1) Intrahepatic tumors: regenerative nodules, FNH, adenoma
(2) Malignancy (rare): hepatoblastoma, HCC
(3) Hepatic (portosystemic) encephalopathy (15%)
(4) Hepatopulmonary syndrome = hypoxemia ← ventilation-perfusion mismatch ← dilatation of intrapulmonary vessels ← diversion of vasoactive mediators into systemic circulation

DDx: (1) Portal vein thrombosis
(2) Intrahepatic shunt

Rx: determination of the type of shunt is important for the planning of definitive treatment

In type 1 CEPS occlusion of the shunt is not an option, because it represents the only drainage route for mesenteric and splenic venous blood. Liver transplantation is the only therapy.

Congenital Intrahepatic Portosystemic Shunt *(rare)*

= abnormal intrahepatic connection between posthilar PV branches and HV / IVC

Cause: trauma, portal hypertension

Types (Park classification):

› more common:

1. Single large vessel connecting RPV to IVC
2. One / more localized shunt(s) in one hepatic segment between peripheral PV branch + HV

› less common:

3. Aneurysmal communication between peripheral PV branch and hepatic veins = focal varix
4. Multiple communications between peripheral PV and HV branches in both hepatic lobes

• hyperammonemia + elevated serum bile acid levels (with persistent shunt patency)

√ enlarged afferent + efferent vessels contiguous with portal + hepatic veins

√ ± abnormal round cystic structure with turbulent flow = focal varix

√ increased flow velocity + phasic waveforms in afferent portal vein branch ← transmitted cardiac pulsations

√ continuous flow with loss of normal triphasic waveform in efferent hepatic vein branch ← increased portal venous inflow

Prognosis: ± spontaneous closure during 1st year of life; at risk for hepatic encephalopathy (in adult life)

Extrahepatic Portosystemic Shunt

(a) congenital (rare)

(b) acquired (most common)

Cause: portal venous hypertension

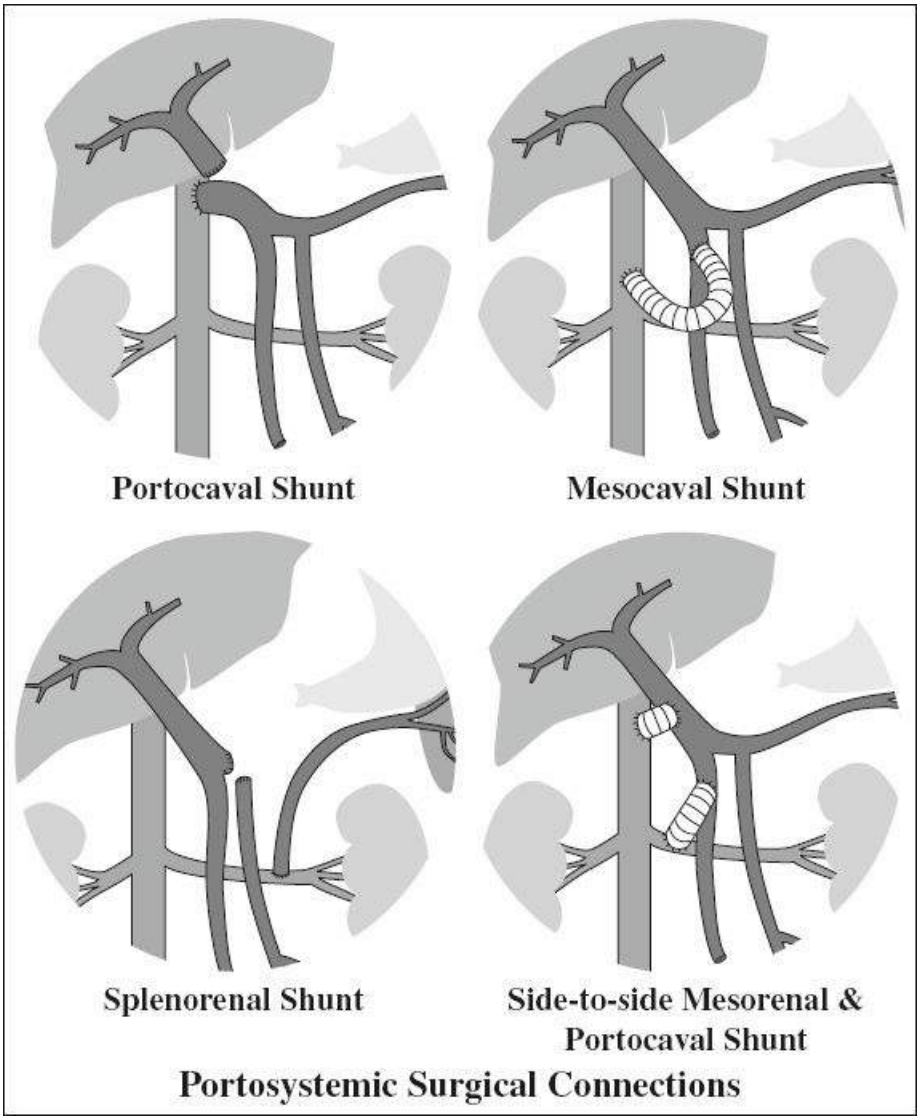
Portosystemic Surgical Connections

A. NONSELECTIVE SHUNT

= decompression of the entire portal system with increased risk of hepatic encephalopathy

1. Portocaval shunt

= portal vein → IVC end-to-side / side-to-side



2. Mesocaval shunt
   = synthetic graft between SMV and IVC
   (a) short "H-graft" to posterior wall of SMV
   (b) long "C-graft" to anterior wall of SMV
   (c) direct mesocaval shunt dividing IVC (rare)
3. Mesorenal shunt
4. Mesoatrial shunt
   = polytetrafluoroethylene graft between anterior wall of SMV superior to pancreas and right atrium coursing through abdomen + diaphragm into right thoracic cavity

B. SELECTIVE SHUNT
   = decompression of parts of the portal system with preservation of blood flow to the liver
   ◊ Contraindicated in patients with ascites
1. Distal splenorenal shunt = Warren shunt (popular)
   = splenic vein → left renal vein

Doppler criteria for shunt patency:

√ increased local velocities
√ turbulence + severe spectral broadening
√ dilatation of recipient vein at shunt site
√ phasic flow pattern in portal tributaries
√ hepatofugal flow in intrahepatic portal vein branches
√ reduction in size + number of portosystemic collaterals
√ reduction / absence of ascites or splenomegaly

Transjugular Intrahepatic Portosystemic Shunt (TIPS)

= portal decompression through percutaneously established shunt with expandable metallic stent between hepatic + portal veins within the liver

Indication: patients with esophageal + gastric variceal hemorrhage / refractory ascites ← advanced liver disease with portal hypertension, hepatorenal syndrome, hepatic hydrothorax, Budd-Chiari syndrome

Success: technical in 96–99%, control of variceal bleeding in 94–100%, control of refractory ascites in 58–84%

Type of stent: 10-mm Wall stent (curved), Palmaz stent (straight), Strecker stent, spiral Z stent
◊ polytetrafluoroethylene (PTFE)-covered stent has a higher patency rate over time

Shunt surveillance:
at regular 3–6-month intervals after initial assessment performed at 1 month after bare stent (Wallstent) placement / 1 month after initial placement of a covered stent

Assessment:
A. MORPHOLOGY
1. Ascites
2. Portosystemic collaterals
3. Size of spleen
4. Diameter of stent (usually 8–10 mm)
5. Configuration of stent: areas of narrowing
6. Extension of stent into portal + hepatic veins

B. HEMODYNAMICS
1. Direction of flow in: extrahepatic portal vein, R + L portal vein, SMV, splenic vein, all 3 hepatic veins, intrahepatic IVC, paraumbilical vein, coronary vein
2. Peak blood flow velocity within main portal vein
3. Peak blood flow velocity within proximal + mid + distal aspects of stent
4. Hepatic artery: PSV, EDV, RI

√ high-velocity turbulent flow (50–270 cm/sec) at least double that of pre-TIPS values
√ superimposed cardiac + respiratory variations
√ increase in hepatic artery velocities from 77 cm/sec (pre-TIPS) to 119 cm/sec (post-TIPS)
√ reversed flow direction within portal vein branches

Cx: A. Obstruction to flow
(1) Shunt obstruction (38%)
(2) Hepatic vein stenosis
B. Trauma

(a) Vascular injury
(1) Hepatic artery pseudoaneurysm
(2) Arterioportal fistula
(2) Intrahepatic / subcapsular hematoma
(3) Hemoperitoneum ← penetration of liver capsule
(b) Biliary injury
(1) Transient bile duct dilatation ← hemobilia
(2) Bile collection

C. Stent dislodgment with embolization to right atrium, pulmonary artery, internal jugular vein

Mortality: < 2% (intraperitoneal hemorrhage)

TIPS Malfunction / Failure

Cause: acute thrombosis, improper stent placement, intimal hyperplasia, change in stent configuration, bulging of liver parenchyma into shunt, iatrogenic dissection of portal vein

Prevalence: 31% at 1 year, 42% at 2 years

• recurrent bleeding = shunt abnormality in 100%

A. > 50% STENOSIS (in 30–80% within 12 months)
= > 50% reduction in diameter of stent lumen / portal pressure gradient > 12–15 mmHg

Site: hepatic vein between stent + IVC > hepatic venous end > in-stent > portal venous end

√ irregular filling defects along wall of shunt on color Doppler
◊ Pseudointimal hyperplasia is isoechoic to blood!

√ generalized decrease in shunt velocity:
√ portal vein inflow velocity < 30 cm/sec

Pre- and Post-TIPS Baseline Study
(under stable fasting conditions)

	Pre-TIPS	*Post-TIPS*
Portal vein velocity (cm/sec)	10–30	40–60
Mean portal vein velocity (cm/sec)	18 ± 6	55 ± 7
Portal pressure (mmHg)	37 ± 8	22 ± 6
Shunt peak velocity (cm/sec)		95 ± 58

√ maximal shunt velocity of < 60 cm/sec (> 95% sensitive + specific)
√ gradual decrease in shunt velocity over 1–6 months ← intimal hyperplasia
√ decrease in peak flow velocity in similar location within stent > 50 cm/sec relative to initial baseline study
√ decrease in maximal portal vein velocity > 33–50% from baseline over time

√ local increase in shunt velocity:
√ velocity transition zone within stent with flow acceleration by a factor of 2
√ abnormally high velocity > 190 cm/sec
√ increase in peak flow velocity in similar location within stent > 50 cm/sec relative to initial baseline study

√ change in flow direction:

√ reversal of portal venous flow direction (100% sensitive, 92% specific, 71% PPV, 100% NPV)
√ change in flow direction in collateral veins from baseline
√ retrograde flow in RHV (developing stenosis of right hepatic venous outflow tract)
√ loss of pulsatility of portal / shunt flow:
√ venous pulsatility index (Vmax – Vmin) ÷ Vmax < 0.16 (94% sensitive, 87% specific)
√ developing / recurring collateral vessels (eg, recanalized umbilical vein)
√ developing / worsening ascites / splenomegaly

B. OCCLUSION
√ absent flow within shunt
√ echogenic material within stent
› acute cause: prolonged procedural catheterization, leakage of bile into / around stent
› delayed cause: pseudointimal hyperplasia, stent shortening with delayed stent expansion

TIPS revision: balloon angioplasty, recanalization, insertion of additional stent, creation of parallel stent

POSTCHOLECYSTECTOMY SYNDROME

= symptoms recurring / persisting after cholecystectomy

Frequency:

mild recurrent symptoms in 9–25%; severe symptoms in 2.6–32.0% (result of 1,930 cholecystectomies):

› completely cured (61%)
› satisfactory improvement with
(a) persistent mild dyspepsia (11%)
(b) mild attacks of pain (24%)
› failure with
(a) occasional attacks of severe pain (3%)
(b) continuous severe distress (1.7%)
(c) recurrent cholangitis (0.7%)

Cause:

A. BILIARY CAUSES
(a) Incomplete surgery
1. Gallbladder / cystic duct remnant
2. Retained stone in cystic duct remnant (1%)
3. Overlooked CBD stone (5%)
(b) Operative trauma
1. Bile duct stricture
2. Bile peritonitis
3. Suture granuloma of cystic duct remnant
(c) Bile duct pathology
1. Fibrosis of sphincter of Oddi

2. Biliary dyskinesia
3. Biliary fistula
4. Cystic duct mucocele

(d) Residual disease in neighboring structures
1. Pancreatitis
2. Hepatitis
3. Cholangitis

(e) Overlooked bile duct neoplasia

B. EXTRABILIARY CAUSES (erroneous preoperative Dx)

(a) Other GI tract disease:
1. Inadequate dentition
2. Hiatus hernia
3. Peptic ulcer
4. Spastic colon

(b) Anxiety state, air swallowing

(c) Abdominal angina

(d) Carcinoma outside gallbladder

(e) Coronary artery disease

PYLEPHLEBITIS

= ACUTE SUPPURATIVE THROMBOPHLEBITIS OF PORTAL VEIN

[*pyle* , Greek = gate]

Cause: diverticulitis, appendicitis, pancreatitis, cholangitis, inflammatory bowel disease, intraabdominal infection with territory drained by portal vein

Organism: gram-negative bacilli

• nonspecific abdominal pain, sepsis

Prognosis: 0–12% (50%) mortality if treated (untreated)

US:

√ acute hyperechoic thrombus

√ hyperechoic shadowing foci within portal venous system = gas in portal vein

CT:

√ portal vein thrombus, portal vein gas

√ hepatic abscesses

√ low-attenuation tubular filling defect (= infected thrombus)expanding portal vein or its tributaries

Cx: hepatic abscess; bowel ischemia from retrograde propagation of thrombus; residual thrombus after successful treatment (frequent)

Rx: culture-specific systemic antibiotic; anticoagulation (controversial)

RICHTER SYNDROME

= development of large cell / diffuse histiocytic lymphoma in patients with CLL

Etiology: transformation / dedifferentiation of CLL lymphocytes

Incidence in CLL patients: 3–10%

Median age: 59 years

Medium time interval after diagnosis of CLL: 24 months
- fever (65%) without evidence of infection
- increasing lymphadenopathy + hepatosplenomegaly (46%)
- weight loss (26%), abdominal pain (26%)

Location: bone marrow, lymph nodes, liver, spleen, bowel, lung, pleura, kidney, dura

Prognosis: median survival time: 4 months from diagnosis of lymphoma; 14% rate of remission rate

SCHISTOSOMIASIS

◊ Major cause of portal hypertension worldwide: 200 million people affected

Parasites:

(a) parasitizing abdominal veins

› tributaries of superior mesenteric vein

1. Schistosoma mansoni: occurs in > 70 million inhabitants of parts of Africa, Middle East, Arabic peninsula, northern part of South America, West Indies, Caribbean

› tributaries of inferior mesenteric + superior hemorrhoidal veins

2. Schistosoma japonicum: Far East, coastal areas of China, Japan, Formosa, Philippines, Celebes

(b) parasitizing venules of urinary bladder

3. Schistosoma haematobium

Infection: cercariae penetrate intact human skin / buccal mucosa from contaminated fresh water (slow-moving streams, irrigation canals, paddy fields, lakes)

Cycle:

cercariae enter lymphatics + blood system via thoracic duct → larvae are transported into mesenteric capillaries → mature in portal system + liver into worms → worms mate and live in pairs within portal vein + tributaries for 10–15 years → female swims against blood flow to reach tributaries of superior mesenteric vein (S. mansoni) / tributaries of inferior mesenteric + superior hemorrhoidal veins (S. japonicum) → deposits eggs in wall of intestines or urinary bladder → eggs seed back to liver via portal vein + become trapped in periportal space or pass with feces → hatch within water to release miracidia → miracidia infect snail hosts → cercariae emerge after maturation from snails

Histo: chronic granulomatous reaction + abundant fibrosis along portal vein branches

- clinically mild infection with chronic course: fever, headache, myalgia, bloody diarrhea, abdominal pain, eosinophilia

@ Liver & spleen (10%)

√ hepatosplenomegaly

√ normal parenchymal echogenicity + small peripheral hyperechoic foci in 50%

√ marked diffuse thickening of echogenic walls of portal venules = periportal fibrosis = clay pipe stem fibrosis

◊ Schistosoma infection is the most frequent cause of liver fibrosis worldwide!

Fibrosis pattern of Schistosomiasis mansoni:

Cause: periportal fibrosis most prominent in central liver (large eggs deposit within central liver)

√ "turtleback / tortoise shell" appearance of liver:

√ thick fibrous bands around portal vein branches radiate from hilum perpendicularly to surface
√ shrunken liver with nodular surface contour
√ calcifications of large eggs (rare)

Fibrosis pattern of Schistosomiasis japonicum:

Cause: widespread peripheral periportal fibrosis (small eggs deposit near liver capsule)
√ thinner fibrous bands give a more uniform polygonal "honeycomb" appearance resembling fish scales
√ calcifications of interlobular septa (common)

√ portal vein dilatation in 73% (= presinusoidal portal hypertension)

@ Biliary tract
√ paucity of 2nd- and 3rd-order biliary branches ← biliary obstruction ← bile duct proliferation ← periportal fibrosis
√ irregular focally narrowed wall contours of bile ducts
√ hyperechoic gallbladder bed + thickened gallbladder wall

@ GI tract
√ gastric + esophageal varices
√ polypoid bowel wall masses (esp. in sigmoid)
√ granulomatous colitis
√ strictures with extensive pericolic inflammation
Cx: ileus

Dx: eggs in multiple fecal examinations
Rx: praziquantel

SHWACHMAN-DIAMOND SYNDROME

= rare autosomal recessive condition characterized by congenital absence of pancreatic exocrine tissue, bone marrow dysfunction, skeletal abnormalities and short stature
◊ 2nd most frequent cause of exocrine pancreatic insufficiency in childhood after cystic fibrosis!
Incidence: 1÷75,000 people
• pancreatic insufficiency, steatorrhea, failure to thrive
• recurrent respiratory and skin infections ← bone marrow hypoplasia; normal electrolytes in sweat
• trend for improvement with time
√ total fatty replacement of pancreas
√ metaphyseal chondrodysplasia resulting in dwarfism
DDx: cystic fibrosis (pancreatic calcifications, cyst formation, abnormal sweat test)

SEROUS CYSTADENOMA OF PANCREAS

= MICROCYSTIC CYSTADENOMA = GLYCOGEN-RICH CYSTADENOMA = MICROCYSTIC PANCREATIC LESION
= benign lobulated neoplasm composed of 1–20 mm small honeycomb cysts containing proteinaceous fluid separated by thin connective tissue septa
Frequency: ~ 50% of all cystic pancreatic neoplasms

Path: cysts separated by fibrous septa that radiate from a central scar, which may be calcified; thin fibrous pseudocapsule

Histo: cyst walls lined by cuboidal / flat glycogen-rich epithelial cells derived from centroacinar cells of pancreas (DDx: lymphangioma)

Types:

(a) classic microcystic form

(b) **oligocystic / macrocystic** form = larger + fewer serous cysts mimicking mucinous cystadenoma

Location: pancreatic head

√ lobulated contour, lack of wall enhancement

(c) solid form = microscopic serous cysts too small to resolve mimicking pancreatic neuroendocrine tumor

Mean age: 65 (range, 34–88) years; in 82% over 60 years of age; M÷F = 1÷2–4

Associated with: von Hippel-Lindau syndrome

• commonly incidental discovery at imaging; palpable mass

• pain, weight loss, malaise, anorexia, fatigue, jaundice

Location: any part of pancreas affected, slight predominance for head + neck

Size of mass: 5.0 (range, 1.4–27.0) cm in diameter

Size of cysts: typically < 10 (range, 1–20) mm; uncommonly a few large cysts (in < 5%) / cyst up to 8 cm in diameter

Number of cysts: > 6; typically innumerable

√ well-demarcated <u>lobulated</u> mass with smooth / nodular contour

√ cysts of honeycomb / bunch of grapes appearance

√ prominent <u>central stellate scar</u> in 30% (CHARACTERISTIC) ← fibrotic walls of collapsed centrally located cyst with tissue retraction

√ amorphous central calcifications (in 18%) in dystrophic area of stellate central scar ("sunburst")

√ ± progressive enlargement over months / years

√ pancreatic duct + CBD may be displaced / encased / obstructed

US:

√ mass as mixture of hypo- and hyperechoic areas

√ may appear as solid predominantly echogenic mass ← multiple acoustic interfaces

CT:

√ attenuation values close to water

√ may appear solid ← small cysts with large amount of fibrous tissue

√ contrast enhancement of septa (may be misleading)

MR:

√ cluster of small hyperintense cysts on T2WI

√ NO visible communication between cysts + pancreatic duct

√ late enhancement of thin fibrous septa

√ signal void in central scar ← coarse calcifications

√ delayed enhancement of scar on contrast-enhanced FLASH

Angio:

√ hypervascular mass with dilated feeding arteries, dense tumor blush, prominent draining

veins, neovascularity, occasional AV shunting, NO vascular encasement

Prognosis: no malignant potential

Rx: surgical excision / follow-up examinations

DDx: malignant mucinous cystic neoplasm (younger age, body + tail of pancreas, > 10 cm large at presentation)

SINUSOIDAL OBSTRUCTION SYNDROME

= SOS = venoocclusive disease

= blockage of small hepatic venules

Predisposition: stem cell / bone marrow recipients

Drugs: myeloablative regimens (eg, busulfan plus cyclophosphamide), dacarbazine, cisplatin, oxaliplatin, carboplatin, total body irradiation

Mechanism: necrosis of sinusoidal endothelial cells → extrusion into hepatic sinusoids → obstruction + congestion

- abdominal pain + swelling, weight gain
- ± elevation of serum enzyme levels

√ hepatomegaly and hepatic congestion

CT:

√ heterogeneous hepatic attenuation

CECT:

√ heterogeneous enhancement ← altered perfusion in areas of increased sinusoidal pressure from venous stasis

√ small obstructed hepatic venules NOT visible at imaging

MR:

√ heterogeneous liver with areas of increased signal intensity on T2WI ← edema

DDx: graft versus host disease, viral hepatitis, sepsis

SOLID PSEUDOPAPILLARY TUMOR OF PANCREAS

= SOLID AND PAPILLARY NEOPLASM = SOLID AND CYSTIC TUMOR = PAPILLARY-CYSTIC NEOPLASM = SOLID AND PAPILLARY EPITHELIAL NEOPLASM = HAMOUDI TUMOR

= rare slow-growing low-grade malignant tumor; often misclassified as nonfunctioning pancreatic endocrine tumor, cystadenoma, or cystadenocarcinoma of pancreas

◊ The classification of solid pseudopapillary tumors as a cystic pancreatic lesion has lead to confusion because many tumors are completely solid. Cystic components are secondary to tumor degeneration varying in size and morphology.

Prevalence: 1–2% of all pancreatic tumors

Mean age: 28 (range, 2–85) years; M÷F = 1÷9; predilection for black and East Asian patients

Path: large well-encapsulated solitary mass with considerable hemorrhagic necrosis + cystic degeneration

◊ Small tumors are predominantly solid

Histo: sheets + cords of cells arranged around a fibrovascular stroma

- vague upper abdominal fullness, discomfort and pain
- nausea, vomiting, gradually enlarging abdominal mass
- jaundice (rare, even with location in pancreatic head)

Location: pancreatic tail (36%), pancreatic head (34%); frequently exophytic obscuring pancreatic origin

Mean size: 6–10 (range, 0.5–34.5) cm

√ well-encapsulated inhomogeneous round / lobulated pancreatic mass with completely solid ± cystic portions ← tumor degeneration

√ may be completely cystic (when complicated by extensive necrosis + internal hemorrhage)

√ compression of adjacent structures without invasion

√ fluid-fluid or fluid-debris level (10–20%) ← hematocrit effect

√ ± stippled / punctate / amorphous dystrophic calcification (33%) rimlike in tumor capsule or chunky inside tumor

√ hypovascular with contrast enhancement less than pancreas / enhancement of solid tissue projecting toward center of mass

US:

√ echogenic rim of tumor capsule

√ echogenic mass with necrotic center / completely cystic with subcapsular rim of tumor

CT:

√ solid tumor component isoattenuating to pancreas

√ cystic component of 20–50 HU

√ hypoattenuating tumor pseudocapsule

MR:

√ hypointense fibrous capsule on T1WI + T2WI (80–100%)

√ solid well-circumscribed tumor:

√ iso- to hypointense on T1WI compared to pancreas

√ mildly increased T2 signal intensity

√ foci of high SI on T1WI (in 80–100%) + variable T2 signal intensity ← variable hemoglobin degradation products from internal hemorrhage (DISTINCTIVE FEATURE)

√ T2 signal intensity close to fluid in mostly cystic variety

CEMR:

√ enhancing soft-tissue components are uniformly present

√ early peripheral heterogeneous / ring enhancement greater than pancreas (70%)

√ gradual accumulation (= progressive fill-in) of contrast material within tumor

DDx: neuroendocrine tumor (early arterial enhancement)

√ hypointense to pancreas on delayed images

Angio:

√ hypo- to avascular with displacement of vessels

√ mild peripheral blush

Prognosis: (1) excellent after excision

(2) metastases (in 7–16%): omentum, lymph nodes, liver (usually solitary)

Rx: complete surgical excision (95% cure rate)

DDx: (1) Cystic neuroendocrine tumor (older age group, hypointense on T1, diffuse / ringlike enhancement)

(2) Microcystic adenoma (innumerable tiny cysts, older age group)

(3) Mucinous cystic neoplasm (large uni- / multilocular cysts, older age group)

(4) Nonfunctioning pancreatic endocrine tumor (hypervascular)

(5) Pleomorphic carcinoma of pancreas (smaller tumor in older patient)
(6) Pancreatoblastoma (childhood tumor)
(7) Calcified hemorrhagic pseudocyst

SPLENIC ANGIOSARCOMA

Prevalence: rare, < 100 cases in literature
Cause: usually NOT due to thorotrast or toxic exposure to vinyl chloride / arsenic as in liver angiosarcoma
Age: 50–60 years
• splenomegaly, abdominal pain
√ multiple nodules of varying size → usually enlarging spleen
√ solitary complex mass with variable contrast enhancement
√ metastasizes to liver (in 70%)
√ spontaneous rupture (in 33%)
MR:
√ focal / diffuse hypointense foci on T1WI + T2WI ← iron deposition from hemorrhage
Prognosis: 20% survival rate after 6 months

SPLENIC HAMARTOMA

= SPLENOMA
= rare typically single nonneoplastic lesion composed of a mixture of normal splenic elements
Etiology: congenital
May be associated with: hamartomas elsewhere as in tuberous sclerosis
Histo: (a) mixture of white + red pulp (most common)
(b) white pulp subtype = aberrant lymphoid tissue
(c) red pulp subtype = aberrant complex of sinusoids
• asymptomatic
CT:
√ attenuation equal to / hypodense to splenic tissue
√ prolonged heterogeneous enhancement
MR:
√ heterogeneously hyperintense on T2WI
√ diffuse heterogeneous enhancement, more homogeneous on delayed images

SPLENIC HEMANGIOMA

Cause: congenital, arising from sinusoidal epithelium
Prevalence: 0.03–14% (autopsy); M > F

◊ Most common primary splenic tumor!

Age: 20–50 years
Histo: proliferation of vascular channels lined by single layer of endothelium; mostly of cavernous type; may contain areas of infarction, hemorrhage, thrombosis, fibrosis
Associated with: generalized angiomatosis, Klippel-Trénaunay-Weber syndrome, Beckwith-Wiedemann syndrome, Turner syndrome

• asymptomatic or pain + fullness in LUQ
√ usually small single lesion < 4 cm, up to 17 cm in size
√ foci of speckled / snowflakelike calcifications
US:
√ well-marginated predominantly hyperechoic lesion
CT:
√ predominantly avascular cystic lesion
√ solid areas hypo- / isodense to normal spleen and enhancing
MR:
√ hypo- / isointense on T1WI + hyperintense on T2WI
√ hypointense areas ← hemosiderin deposits
√ progressive centripetal enhancement with persistent uniform enhancement on delayed images
NUC:
√ no uptake of ^{99m}Tc-sulfur colloid
Prognosis: slow growth, thus becoming symptomatic in adulthood
Cx: (1) Spontaneous splenic rupture (in up to 25%)
(2) Kasabach-Merritt syndrome (= coagulopathy, anemia, thrombocytopenia) with large hemangioma
(3) Portal hypertension
(4) Malignant degeneration

SPLENIC INFARCTION

◊ Most common cause of focal splenic defects!
Cause:
1. Embolic: bacterial endocarditis (responsible in 50%), atherosclerosis with plaque emboli, cardiac thrombus (atrial fibrillation, left ventricular thrombus), metastatic carcinoma
2. Local thrombosis: sickle cell disease (leading to functional asplenia); myelo- / lymphoproliferative disorders (CML most common); polycythemia vera; myelofibrosis with myeloid metaplasia + splenomegaly; Gaucher disease; collagen vascular disease; portal hypertension
3. Vasculitis: periarteritis nodosa
4. Vascular compromise of splenic artery: focal inflammatory process (eg, pancreatitis); thrombus from splenic artery aneurysm; splenic torsion
5. Therapeutic complication: transcatheter hepatic arterial embolization

mnemonic: PSALMS
Pancreatic carcinoma, **P**ancreatitis
Sickle cell disease / trait
Adenocarcinoma of stomach
Leukemia
Mitral stenosis with emboli
Subacute bacterial endocarditis

Anatomy: branches of the splenic artery are noncommunicating end arteries

• LUQ pain, fever; abnormal lactate dehydrogenase levels
• elevated erythrocyte sedimentation rate, leukocytosis
√ single / multiple focal wedge-shaped peripheral defects
√ global infarction
US:
√ initially ill-defined hypoechoic lesion ← inflammation, edema, necrosis
√ later increasingly well-defined echogenic lesion ← organization of infarct with fibrosis
CT phases:
(a) hyperacute phase (day 1)
√ mottled area of increased attenuation on NECT ← hemorrhage
√ large focal hyperattenuating lesion on CECT
√ mottled pattern of contrast enhancement
(b) acute (days 2–4) + subacute phase (days 4–8)
√ focal progressively more well-demarcated areas of decreased attenuation without enhancement
(c) chronic phase (2–4 weeks)
√ size decreases + attenuation returns to normal
√ complete resolution / residual contour defect
√ areas of calcification
Cx: acute febrile illness, abscess formation, pseudocyst formation, splenic rupture, hemorrhage

SPLENOSIS

= posttraumatic autotransplantation of splenic tissue to other sites (heterotopic splenic tissue)
Age: young men with history of trauma / splenectomy
Time of detection: mean age of 10 years (range, 6 months to 32 years) after trauma
Location: diaphragmatic surface, liver, greater omentum, small bowel serosa, parietal peritoneum, pleura after diaphragmatic rupture (attaches to peritoneal / pleural surface)
√ multiple small round / oval lobulated encapsulated sessile masses (implants)
Size: few mm to 3 cm ← limited blood supply from local neovascularization
US:
√ mass of homogeneously hypoechoic echotexture
CT:
√ isodense to normal spleen
√ attenuation identical to normal spleen in all phases of enhancement
MR:
√ hypointense on T1WI
√ heterogeneous enhancement (red + white pulp differences)
√ hyper- / rarely hypointense (← iron deposition) on T2WI
NUC:
√ uptake by ^{99m}Tc-sulfur colloid; ^{111}In-labeled platelets; ^{99m}Tc-heat-damaged RBC (best detection rate without uptake by liver)
Significance:
(1) protects against infection in pediatric patients

(2) may be confused with metastases / lymphoma
(3) responsible for disease recurrence after splenectomy (eg, idiopathic thrombocytopenic purpura)

DDx: accessory spleen

SPONTANEOUS PERFORATION OF COMMON BILE DUCT

Pathogenesis: unknown (? CBD obstruction, localized mural malformation, ischemia, trauma)

Age: 5 weeks to 3 years of age

- vague abdominal distension, varying acholic stools
- mild persistent hyperbilirubinemia

US:

√ biliary ascites / loculated subhepatic fluid
√ localized pseudocholedochal cyst in porta hepatis

Hepatobiliary scintigraphy:

√ radioisotope diffusely throughout peritoneal cavity

THOROTRASTOSIS

Thorotrast = 25% colloidal suspension of thorium dioxide; used as contrast agent between late 1920s and mid 1950s, in particular for cerebral angiography and liver spleen imaging; chemically inert with high atomic number of 90; > 100,000 people injected

Thorium dioxide = consists of 11 radioactive isotopes (Thorium-232 is major isotope); decay by means of alpha, beta, and gamma emission; biologic half-life of 14 billion years; hepatic dose of 1,000–3,000 rad in 20 years

Distribution: phagocytized by RES + deposited in liver (70%), spleen (30%), bone marrow, abdominal lymph nodes (20%)

√ linear network of metallic density contrast material in spleen, lymph nodes, liver
√ spleen may be shrunken / nonfunctional

Cx: hepatic fibrosis, angiosarcoma (50%), cholangiocarcinoma, hepatocellular carcinoma (latency period of 3–40 years; mean 26 years)

TYROSINEMIA

= rare autosomal recessive metabolic disorder

Country: increased prevalence in Canadian province of Quebec and parts of Scandinavia

Biochemistry: deficiency of enzyme fumarylacetoacetase (last step in catabolic pathway of tyrosine, serum methionine, urinary succinylacetone); ↑ levels of serum tyrosine as a precursor of dopamine, norepinephrine, epinephrine, melanin, thyroxin

A. ACUTE FORM
   - fulminant liver failure, often by 1 year of age

B. CHRONIC FORM
   = Fanconi syndrome with renal tubular dysfunction
   - vitamin D-resistant rickets
   - intermittent porphyria-like symptoms

- progressive liver failure in early childhood
- anemia, abnormal liver function tests, ↑ levels of α-fetoprotein

√ hepatosplenomegaly
√ micro- and macronodular cirrhosis (early childhood):
  √ regenerating nodules of 2–20 mm: hyper- (mostly) / iso- / hypoattenuating; hypo- / occasionally hyperechoic
  √ portal hypertension
  √ increased echogenicity (fibrosis + fatty infiltration)
√ nephromegaly with uniformly thickened renal cortices
√ nephrocalcinosis

Prenatal Dx: enzyme deficiency demonstrable in hepatocytes, skin fibroblasts, lymphocytes, amniocytes

Cx: hepatocellular carcinoma (in 37% beyond 2 years of age)

Rx: (1) Diet restricted in phenylalanine + tyrosine (alleviates kidney damage but does not prevent fatal outcome)

(2) 2-2-nitro-4-trifluoro-methylbenzoyl-1,3-cyclohexanedione (NTBC) inhibits 4-hydroxyphenylpyruvate dioxygenase + prevents formation of maleylacetoacetate and fumarylacetoacetate

(3) Liver transplantation (before HCC develops)

UNDIFFERENTIATED SARCOMA OF LIVER

= UNDIFFERENTIATED EMBRYONAL SARCOMA (UES) = MALIGNANT MESENCHYMOMA / SARCOMA

= rare highly malignant tumor of children

Prevalence: 4th–5th most common liver tumor in children

Age: < 2 months (in 5%); 6–10 years (in 52%); by 15 years (in 90%); up to 49 years; M÷F = 1÷1

Path: well-demarcated predominantly solid tumor mixed with cystic gelatinous areas and foci of hemorrhage + necrosis; often with fibrous pseudocapsule

Histo: primitive undifferentiated stellate / spindle-shaped sarcomatous cells closely packed in whorls + sheets / scattered loosely in a myxoid ground substance with foci of hematopoiesis (50%)

• painful RUQ mass and fever (5%)
• mild anemia + leukocytosis (50%)
• elevated liver enzymes (33%); normal α-fetoprotein

Spread: lung, pleura, peritoneum

Location: right lobe (75%); left lobe (10%); both lobes (15%)

Mean size: 14 (range, 10–29) cm

◊ Discordant findings between US (solid) + CT and MR (cystic)!

NUC:
  √ photodefect on sulfur colloid scan

US:
  √ large intrahepatic typically iso- to hyperechoic solid mass
  √ cystic areas up to 4 cm in diameter (foci of necrosis + old hemorrhage + cystic myxoid degeneration)

CT:
  √ cystic multiseptate mass of predominantly water attenuation (88% of tumor volume) due to

myxoid stroma
√ peripheral foci of soft tissue / septa of variable thickness
√ ± central foci of high attenuation (= hemorrhage)
√ occasional fluid-debris level
√ well-defined margins of mass ← dense enhancing peripheral rim of pseudocapsule

CECT:
√ predominantly peripheral enhancement on delayed images

MR:
√ focal mass with multiple cystic spaces, septations (best seen on MRI) and central necrosis
√ predominantly CSF signal intensity on T1WI + T2WI
√ hypointense rim on T1WI + T2WI (= fibrous pseudocapsule)
√ hyperintense areas of hemorrhage on T1WI
√ heterogeneous enhancement of solid components

Angio:
√ hypo- / hypervascular with stretching of vessels
√ scattered foci of neovascularity

Prognosis: frequently death within 12 months

Rx: multiagent chemotherapy followed by resection / liver transplantation

DDx: (1) Mesenchymal hamartoma (generally diagnosed by 2 years of age)
(2) Hydatid cyst (US shows solid nature of mass, delayed enhancement of solid components, peripheral eosinophilia)
(3) Abscess (history of travel / fever)
(4) Hepatoblastoma (uncommonly cystic, younger age group, elevated serum AFP level)
(5) HCC (generally solid, underlying liver disease, elevated serum AFP level)

WANDERING SPLEEN

= ABERRANT / FLOATING / PTOTIC / DRIFTING / DYSTOPIC / DISPLACED / PROLAPSED SPLEEN
= excessively mobile spleen on an elongated pedicle displaced from its usual position in LUQ

Incidence: < 0.2% / year

Cause: embryologically absent / malformed gastrosplenic + splenorenal ligaments; deficient / lax abdominal musculature (prune-belly syndrome, pregnancy)

Age: any (higher frequency in women of childbearing age)

• asymptomatic mobile abdominal / pelvic mass
• chronic vague lower abdominal / back pain
• nausea, vomiting, eructation, flatulence
• acute abdomen ← splenic infarction ← splenic torsion

√ empty splenic fossa + associated soft-tissue mass in center of abdomen / pelvis
√ inverted malpositioned stomach
√ splenic hilum often located anteriorly
√ displaced large spleen ← congestion during torsion

Cx:

1. **Splenic torsion**
   (a) with prolonged venous occlusion: perisplenitis, localized peritonitis, adhesions,

venous thrombosis, hypersplenism
• abdominal pain, nausea, vomiting
• fever, leukocytosis, palpable mass
√ ectopic location + increased size
√ abnormal ovoid / round contour of spleen
√ whorled appearance of twisted splenic pedicle
√ adjacent inflammatory changes + free fluid
CT:
√ low attenuation with heterogeneous enhancement
US:
√ NO flow within spleen on Doppler US
√ elevated resistive index in proximal splenic artery

(b) with arterial occlusion: hemorrhagic infarction, subcapsular / intrasplenic hemorrhage, gangrene, abscess formation, degenerative cysts, functional asplenism, bowel obstruction, necrosis of pancreatic tail

2. GI complications:
@ Stomach: compression, distension, volvulus, traction diverticulum, varices
@ Small bowel: dilatation, obstruction
@ Colon: compression, volvulus, laxity, ptosis

Rx:
1. Splenectomy (4% postsplenectomy sepsis)
2. Splenopexy
3. Conservative treatment (if asymptomatic)

ABDOMEN AND GASTROINTESTINAL TRACT

DIFFERENTIAL DIAGNOSIS OF GASTROINTESTINAL AND ABDOMINAL DISORDERS

ACUTE ABDOMEN IN CHILD

The majority of ER visits for acute abdominopelvic diseases do not require administration of IV contrast for MRI diagnosis

1. Intussusception
2. Appendicitis
3. Obstruction (previous surgery, hernia)
4. Acute gastroenteritis
5. Basilar pneumonia

RIGHT LOWER QUADRANT PAIN

A. Inflammation / Infection
    1. Acute appendicitis

        A normal or even nonvisualized appendix at CT virtually allows exclusion of appendicitis

    2. Crohn disease
    3. Infectious enterocolitis
    4. Neutropenic colitis
    5. Diverticulitis (colon, cecum, Meckel, appendix)
        (a) Colonic diverticulitis
        (b) Right colonic diverticulitis
        (c) Appendiceal diverticulitis
        (d) Meckel diverticulitis
        (e) Ileal diverticulitis

B. Malignancy
    1. Adenocarcinoma: perforation
    2. Lymphoma

C. Omental / mesenteric conditions
    1. Epiploic appendagitis
    2. Omental infarction
    3. Mesenteric adenitis

D. Miscellaneous
    1. Ingestion of nondigestable foreign body
    2. Intussusception
    3. Cecal volvulus
    4. Ischemic colitis

E. Ovarian disorders
    1. Hemorrhagic ovarian cyst
    2. Pelvic endometriosis
    3. Torsion of ovary
    4. Ovarian hyperstimulation syndrome
    5. Ruptured dermoid
F. Tubal disorders
    1. Ectopic pregnancy
    2. Hydrosalpinx
    3. Tubo-ovarian abscess
G. Uterine disorders
    1. Degenerating / torsed leiomyoma
    2. Ovarian vein syndrome
    3. Hematometra
H. Urinary tract disorders
    1. Nephro- and ureterolithiasis
    2. Cystitis

HEMOPERITONEUM

A. Traumatic hemoperitoneum
B. Nontraumatic hemoperitoneum
    (a) **Spontaneous hemoperitoneum**
        1. Highly vascular neoplasm: hepatocellular carcinoma (10–15%), hepatic angiosarcoma, metastases (lung carcinoma, renal cell carcinoma, melanoma), hepatic adenoma (!)
           Risk factors: large size of mass; peripheral / subcapsular location; ⇑ vascularity
           Pathophysiology: invasion of vessels; ⇑ intratumoral pressure; venous congestion ← venous thrombosis; lack of autoregulation of tumor vessels
        2. Splenomegaly → splenic rupture:
           viral infection (CMV, malaria, EBV); congenital disease; metabolic abnormality (Gaucher disease, amyloidosis); neoplasm (leukemia, lymphoma, hemangiomatosis, angiosarcoma)
        3. Gynecologic causes:
           hemorrhagic ovarian cyst (usually corpus luteal / follicular cyst); ectopic pregnancy; HELLP syndrome; endometriosis; uterine rupture
        4. Vascular lesion:
           ruptured arterial aneurysm (abdominal aorta, splenic artery, hepatic artery); ruptured pseudoaneurysm (of hepatic, splenic, gastroduodenal artery) in pancreatitis
    (b) iatrogenic
        1. Anticoagulation (more commonly bleeding into psoas / rectus muscle)
        2. Blood dyscrasias
        3. Invasive procedure / surgery

GASTROINTESTINAL HEMORRHAGE

Incidence: 1–2% of all hospital admissions (300,000 annually); increasing with age
Age: > 65 years (in 70%); M÷F = 2÷1
◊ Upper GI bleed affects younger, lower GI bleed older patients!
Mortality: 10–40% (highest for variceal bleeding); increases with age, shock, comorbidity
Prognosis: in 75–80% spontaneous resolution; in 25% recurrence

Massive acute GI bleeding can be intermittent from minute to minute. Failure to demonstrate active bleeding may therefore not prove cessation of bleeding!

- positive fecal occult blood test: Hemoccult®
- iron deficiency anemia ← slow intermittent bleed
- **hematemesis** = vomiting of fresh blood
- coffee-ground vomit ← partially digested dark blood
- **melena** = black tarry stool
- **hematochezia** = red blood per rectum *chézein* , Greek = defecate

Endoscopy (98% sensitive, 100% specific):
1st line tool for diagnosis + therapy of upper GI bleed.
Cause not identified in 20% of lower + 14% of upper GI bleed
NUC (93% sensitive, 95% specific):
CTA (increasing use, sequential to unenhanced CT):

A 3-phase CT angiogram (CTA = unenhanced + arterial + portal venous phase) provides the best and most reproducible results in acute gastrointestinal bleeding with a high degree of accuracy regarding location and cause!

N.B.: Barium / oral contrast may mask acute bleeding site!
√ hyperattenuating blood clot on unenhanced phase
√ extravascular blush best seen in portal venous phase ← enlarging focus of extravasation with higher attenuation
√ varied bleed morphology: linear jetlike / swirled / circular ellipsoid / pooled cloud-shaped / fluid–contrast level
√ cause of hemorrhage identified in 80%

Imaging of Acute Gastrointestinal Bleeding

Modality	*Bleeding Rate [mL/min]*	*Sensitivity [estimates]*
Endoscopy		95% (upper GI bleed) 53% (lower GI bleed)
^{99m}Tc-labeled RBCs	> 0.1	88%
3-phase CT angio	> 0.35	91% (active bleed) 46% (obscure bleed)
Catheter angiogram	> 0.5	63% (upper GI bleed) 39% (lower GI bleed)

Source:

A. UPPER GASTROINTESTINAL HEMORRHAGE (70%)
= bleeding site proximal to ligament of Treitz
Incidence: 0.1% of all hospital admissions
Mortality: 10%

• hematemesis, coffee-ground emesis, melena
• hematochezia (with rapid bleeding)
◊ Preferred method = endoscopy!
@ Esophagogastric junction
1. Esophageal varices (17–30%): 40% mortality
2. Mallory-Weiss syndrome (7–14%): low mortality
@ Stomach
1. Acute hemorrhagic gastritis (17–27%)
2. Gastric ulcer (10%)
3. Pyloroduodenal ulcer (17–25%)
Mortality: < 10% if under age 60; > 35% if over age 60
@ Other causes:
(a) neoplasm (2–5%)
(b) vascular lesion (2–3%): visceral artery aneurysm, AV malformation, vascular-enteric fistula
Average mortality: 8–10%
Rx:
(1) Transcatheter embolization (method of choice) abundant collaterals except for postoperative stomach
(2) Intraarterial vasopressin infusion (0.2–0.4 U/min)
Prognosis: controls 73% of gastric mucosal bleeding; high recurrence rate

B. LOWER GASTROINTESTINAL HEMORRHAGE (30%)
= bleeding site distal to ligament of Treitz
Incidence: 0.02% of all hospital admissions
Age: 200 x more likely in 80- than in 20-year-old
Mortality: 3.6%
@ Small intestine
tumor (eg, leiomyoma, hemangioma, metastases), ulcer, diverticula (eg, Meckel diverticulum), inflammatory bowel disease (eg, Crohn disease), vascular malformation, visceral artery aneurysm, aortoenteric fistula
@ Colorectal (70%)
› massive bleeding
1. Diverticulum (20–55%)
2. Colonic angiodysplasia (3–40%)
3. Biopsy
› low-rate bleeding
1. Benign / malignant tumor (8–26%)
2. Inflammatory bowel disease (6–22%)
3. Mesenteric varices
Rx:
(1) Intraarterial vasopressin infusion
Prognosis: 90% initial control rate; 30% control rate for recurrent bleeding
(2) Transcatheter embolization requires superselective catheterization using microcatheters + microembolic agents
Cx: 25% risk of bowel infarction + stricture

Obscure GI Bleed

= persisting / recurring bleeding from GI tract without obvious cause after EGD + colonoscopy

Incidence: 5–20% without identifiable bleeding source

Tagged RBC scanning is the most sensitive technique for detecting active arterial + venous bleeding sites over a prolonged period and is useful for intermittent bleeding!

Upper Gastrointestinal Lesion

1. **Cameron lesion**
   = ulcer in hiatal hernia sac with incidence of 5.3%
2. Fundic varices
3. Peptic ulcer
4. Angiectasia
5. Gastric antral vascular ectasia
6. **Dieulafoy lesion**
   [Paul Georges Dieulafoy (1839–1911), French physician and surgeon, chief of Hôtel-Dieu de Paris]
   = exulceratio simplex = uncommon developmental large tortuous 1–5 mm submucosal arteriole that erodes and bleeds
   Location: on lesser curvature of stomach within 6 cm of GE junction (75%), duodenum (14%), colon (5%)

Middle Gastrointestinal Lesion

(a) in patient < 40 years of age
   1. Tumor
   2. Meckel diverticulum
   3. Dieulafoy lesion
   4. Crohn disease
   5. Celiac disease

(b) in patient > 40 years of age
   1. Angiectasia
   2. NSAID enteropathy
   3. Celiac disease

(c) uncommon lesion
   1. Hemobilia
   2. Hemosuccus pancreaticus
   3. Aortoenteric fistula

Lower Gastrointestinal Lesion

1. Angiectasia
2. Neoplasm

Gastrointestinal Bleeding in Infant

(1) Peptic ulcer
(2) Varices

(3) Ulcerated Meckel diverticulum

Gastrointestinal Bleeding in Child

(1) Meckel diverticulum
(2) Juvenile polyp
(3) Inflammatory bowel disease
(4) Clotting disorder
(5) Arteriovenous malformation

Intramural Hemorrhage

A. VASCULITIS
   1. Henoch-Schönlein purpura
B. TRAUMA
   eg, complication of colonoscopic polypectomy
C. COAGULATION DEFECT
   1. Anticoagulant therapy
   2. Thrombocytopenia
   3. Disseminated intravascular coagulation
D. DISEASE WITH COAGULATION DEFECT
   1. Hemophilia
   2. Leukemia, lymphoma
   3. Multiple myeloma
   4. Metastatic carcinoma
   5. Idiopathic thrombocytopenic purpura
E. ISCHEMIC BOWEL DISEASE (often fatal)

• abdominal pain
• melena

Site: submucosal / intramural / mesenteric

√ "stacked coin" / "picket fence" appearance of mucosal folds ← symmetric infiltration of submucosal blood
√ "thumbprinting" = rounded polypoid filling defect ← focal accumulation of hematoma in bowel wall
√ separation + uncoiling of bowel loops
√ narrowing of lumen + localized filling defects (= asymmetric hematoma)
√ no spasm / irritability
√ mechanical obstruction + proximal distension of loops

US:

√ homogeneously hypoechoic symmetric thickening of a long stretch of affected bowel segment
√ ± preservation of mural stratification
√ marked luminal narrowing
√ normal / diminished / absent vascularity at Doppler

Cx: lead point for intussusception

Prognosis: resolution within 2–6 weeks

Scintigraphy for Gastrointestinal Bleeding

Detection depends on:

(1) Rate of hemorrhage

◊ If bleeding not detectable by RBC scintigraphy, it will not be detectable by angiography!

- RBC scan detects bleeding as low as 0.1 mL/min
- Catheter angiography requires bleeding rates of ≥ 0.5 mL/min:
  63% (39%) sensitive for upper (lower) GI bleed
  - ◊ Only 50% of angiograms will be positive after a positive scintigram!
  - ◊ A positive scintigram increases likelihood of a positive angiogram from 22% to 53%!
  - ◊ A hemodynamically unstable patient with systolic pressures < 100 mmHg should go to angiography!

(2) Continuous versus intermittent bleeding: most GI hemorrhages are intermittent

(3) Site of hemorrhage in reference to specific vascular territory: eg, celiac, superior mesenteric, inferior mesenteric artery

(4) Characteristics of radionuclide agent

^{99m}Tc-Labeled Autologous RBCs (In Vivtro Labeling Preferred)

◊ Generally preferred and accepted most sensitive imaging method for lower GI bleeding

◊ Serves to triage patients for angiography as a negative exam predicts a negative arteriogram

Indications: acute / intermittent arterial or venous bleeding; NOT useful in occult bleeding

Pharmacokinetics:

» remains in vascular system for a prolonged period

» liver + spleen activity are low allowing detection of upper GI tract hemorrhage

» low target-to-background ratio (high activity in great vessels, liver, spleen, kidneys, stomach, colon; probably related to free pertechnetate fraction)

Dose: 10–25 mCi

Imaging:

(a) flow imaging at 1 frame every 2 sec for 60 seconds immediately after radiotracer injection

(b) functional imaging at a rate of 1 frame per minute for up to 90 minutes presented as cine clips

(c) additional delayed static images at 2, 4, 6, 12 hours up to 24/36 hr as needed, each time coupled with cine loop

◊ Patient can be reimaged within 24 hours without relabeling RBCs when initial scintigram negative!

Localization of bleeding site:

may be difficult ← (1) rapid transit time (bowel motility can be reduced with 1 mg glucagon IV) or ← (2) too widely spaced time intervals; overall 83% positive correlation with angiography

√ progressive tracer accumulation over time in abnormal location

√ change in appearance over time ← bowel peristalsis

√ bleeding site conforms to bowel anatomy (localizing information may be misleading ← forward / backward peristalsis)

Sensitivity:
in 83–93% correctly identified bleeding site (50–85% within 1st hour, may become positive in 33% only after 12–24 hours); collection as small as 5 mL may be detected; superior to sulfur colloid
» 50% sensitivity for blood loss < 500 mL/24 hours
» > 90% sensitivity for blood loss > 500 mL/24 hours

False positives (5%):
(a) free pertechnetate fraction: physiologic uptake in stomach + intestine, renal pelvis + bladder
◊ Spot view of thyroid shows contamination!
(b) hepatic hemangioma, accessory spleen, varices, inflammation, isolated vascular process (AVM, venous / arterial graft)

False negatives: 9% for bleeding of < 500 mL/24 hours

GASTRIC BLEEDING

Initial test: sampling of gastric content via nasogastric tube / upper endoscopy
Cause: varices, peptic ulcer, angiectasia, gastritis
√ frequently stationary position of radiotracer
False positives:
(a) inefficient labeling with free ^{99m}Tc pertechnetate in normal gastric mucosa
(b) accumulation in accessory spleen / hepatic hemangioma overlapping stomach
√ absence of peristaltic motion

SMALL BOWEL BLEEDING

Other tests: upper + lower endoscopy, double-balloon enteroscopy, capsule endoscopy
Cause: tumor, Meckel diverticulum, Dieulafoy lesion, angiectasia, Crohn disease, celiac disease, hemobilia, aortoenteric fistula
False positives: inflammatory process with hyperemic accumulation of radiotracer (= fixed activity seen on initial flow images)

COLONIC BLEEDING

Initial test: ^{99m}Tc-labeled autologous RBCs
Cause: diverticulosis, angiodysplasia, neoplasm, internal hemorrhoids
False positives: activity in penis / ureter / bladder
◊ Lateral / "tail-on-detector" view!

^{99m}Tc-Sulfur Colloid

Indication: bleeding must be active at time of tracer administration; length of active imaging can be increased by fractionating dose
» Disappearance half-life of 2.5–3.5 minutes (rapidly cleared from blood by RES + low background activity)
» Active bleeding sites detected with rates as low as 0.04–0.1 mL/minute
» Not useful for upper GI bleeding (interference from high activity in liver + spleen) or bleeding near hepatic / splenic flexure

Dose: 10 mCi (370 MBq)

Imaging:

every image should have 500,000–1,000,000 counts with oblique + lateral images as necessary

(a) every 5 sec for 1 minute ("flow study" = radionuclide angiogram)

(b) 60-second images at 2, 5, 10, 15, 20, 30, 40, 60 min; study terminated if no abnormality up to 30 minutes

(c) delayed images at 2, 4, 6, 12 hours

√ extravasation of tracer seen in active bleeding

Specificity: almost 100% (rarely false-positive results due to ectopic RES tissue)

False positives: transplanted kidney, ectopic splenic tissue, modified marrow uptake, male genitalia, arterial graft, aortic aneurysm

^{99m}Tc-Pertechnetate

Indication: bleeding from functioning heterotopic gastric mucosa in Meckel diverticulum / intestinal duplication; consider in adults up to age 25 years; independent of bleeding rate

Pathophysiology: tracer accumulation in mucus-secreting cells

◊ Avoid barium GI studies + endoscopy + irritating bowel preparation prior to study!

Dose: 5–10 mCi (185–370 MBq)

Imaging:

(a) radionuclide angiogram 2–3 sec/frame for 1st minute

(b) sequential 5-minute images up to 20 minutes with 500,000–1,000,000 counts per image

Sensitivity: > 80%

enhanced by

» fasting for 3–6 hours to reduce gastric secretions passing through bowel

» nasogastric tube suction to remove gastric secretions

» premedication with pentagastrin (6 µg/kg SQ 15 min before study) to stimulate gastric secretion of pertechnetate

» premedication with cimetidine (300 mg qid x 48 hours) to reduce release of pertechnetate from mucosa

» voiding just prior to injection

False positives:

bowel inflammation (Barrett esophagus, duodenal ulcer, ulcerative colitis, Crohn disease), enteric duplication, hemangioma, AV malformation, aneurysm, volvulus, intussusception, urinary obstruction, uterine blush

False negatives:

ulcerated epithelium

HETEROTOPIC GASTRIC MUCOSA

= epithelial lesion

1. Esophagus
2. Duodenum
3. Small bowel

4. Meckel diverticulum
5. Duplication cyst

GI ABNORMALITIES IN CHRONIC RENAL FAILURE AND RENAL TRANSPLANTATION

@ Esophagus
1. Esophagitis: candida, CMV, herpes

@ Stomach & duodenum
1. Gastritis
√ thickened gastric folds (38%)
√ edema + erosions
Cause:
(a) imbalance of gastrin levels + gastric acid secretion due to
(1) reduced removal of gastrin from kidney with loss of cortical mass
(2) impaired acid feedback mechanism
(3) hypochlorhydria
(b) opportunistic infection (eg, CMV)
2. Gastric ulcer (3.5%)
3. Duodenal ulcer (2.4%)
4. Duodenitis (47%)

@ Colon

More severely + frequently affected after renal transplantation
1. Progressive distention + pseudoobstruction
Contributing factors: dehydration, alteration of diet, inactivity, nonabsorbable antacids, high-dose steroids
2. Ischemic colitis
(a) primary disease responsible for end-stage renal disease: eg, diabetes, vasculitis
(b) trauma of renal transplantation
3. Diverticulitis
Contributing factors: chronic obstipation, steroids, autonomic nervous dysfunction
4. Pseudomembranous colitis
5. Uremic colitis = nonspecific colitis
6. Spontaneous colonic perforation
Cause: nonocclusive ischemia, diverticula, duodenal + gastric ulcers

@ Pancreas
1. Pancreatitis
Cause: hypercalcemia, steroids, infection, immunosuppressive agents, trauma

@ General
1. GI hemorrhage
Cause: gastritis, ulcer, colonic diverticula, ischemic bowel, infectious colitis, pseudomembranous colitis, nonspecific cecal ulceration
2. Bowel perforation: in 1–4% of transplant recipients
3. Opportunistic infection
Organism: Candida, herpes, CMV, Strongyloides

4. Malignancy
   (a) skin tumors
   (b) lymphoma

IMMUNE-MEDIATED GASTROENTEROCOLITIS

1. Celiac disease
2. Eosinophilic esophagitis
3. Eosinophilic gastroenteritis

ENTEROPATHY

Protein-losing Enteropathy

A. DISEASE WITH MUCOSAL ULCERATION
   1. Carcinoma
   2. Lymphoma
   3. Inflammatory bowel disease
   4. Peptic ulcer disease
B. HYPERTROPHIED GASTRIC RUGAE
   1. Ménétrier disease
C. NONULCERATIVE MUCOSAL DISEASE
   1. Celiac disease
   2. Tropical sprue
   3. Whipple disease
   4. Allergic gastroenteropathy
   5. Gastrocolic fistula
   6. Villous adenoma of colon
D. LYMPHATIC OBSTRUCTION
   1. Intestinal lymphangiectasia
E. HEART DISEASE
   1. Constrictive pericarditis
   2. Tricuspid insufficiency

Malabsorption

= deficient absorption of any essential food materials within small bowel

A. PRIMARY MALABSORPTION
   = the digestive abnormality is the only abnormality present
   1. Celiac disease = nontropical sprue
   2. Tropical sprue
   3. Disaccharidase deficiencies
B. SECONDARY MALABSORPTION
   = occurring during course of gastrointestinal disease
   (a) enteric
      1. Whipple disease
      2. Parasites: hookworm, Giardia, fish tapeworm
      3. Mechanical defects: fistulas, blind loops, adhesions, volvulus, short circuits

4. Neurologic: diabetes, functional diarrhea
5. Inflammatory: enteritis (viral, bacterial, fungal, nonspecific)
6. Endocrine: Zollinger-Ellison syndrome
7. Drugs: neomycin, phenindione, cathartics
8. Collagen disease: scleroderma, lupus, polyarteritis
9. Lymphoma
10. Benign + malignant small bowel tumors
11. Vascular disease
12. CHF, agammaglobulinemia, amyloid, abetalipoproteinemia, intestinal lymphangiectasia

Causes of Radiographic Malabsorption Pattern

General	*Specifics*
Abnormal digestion	
↓ digestive juices	pancreatic / hepatic / biliary insufficiency
↑ digestive juices	Zollinger-Ellison gastrinoma, VIPoma
bowel disease	lactose intolerance, Crohn disease, celiac disease, tropical sprue, chronic ischemia
short small bowel	resection, bypass, Roux-en-Y
long small bowel	dysmotility, narcotics, psychotropics, hypothyroidism, radiation and chemotherapy
Abnormal ingestion	
high fat intaker	binge eating, enteric tube feeding
cathartics, nonabsorbable sugar	MiraLAX®, lactulose, mannitol, sorbitol, maltitol

(b) gastric
vagotomy, gastrectomy, pyloroplasty, gastric fistula (to jejunum, ileum, colon)

(c) pancreatic
pancreatitis, pancreatectomy, pancreatic cancer, cystic fibrosis

(d) hepatobiliary
intra- and extrahepatic biliary obstruction, acute + chronic liver disease

Roentgenographic Signs in Malabsorption

√ SMALL BOWEL WITH NORMAL FOLDS + FLUID
1. Maldigestion (deficiency of bile salt / pancreatic enzymes)
2. Gastric surgery
3. Alactasia

√ SMALL BOWEL WITH NORMAL FOLDS + WET
1. Sprue
2. Dermatitis herpetiformis

√ DILATED DRY SMALL BOWEL
1. Scleroderma

2. Dermatomyositis
3. Pseudoobstruction: no peristaltic activity

√ DILATED WET SMALL BOWEL

1. Sprue
2. Obstruction
3. Blind loop

√ THICKENED STRAIGHT FOLDS + DRY SMALL BOWEL

1. Amyloidosis: malabsorption is unusual
2. Radiation
3. Ischemia
4. Lymphoma (rare)
5. Macroglobulinemia (rare)

√ THICKENED STRAIGHT FOLDS + WET SMALL BOWEL

1. Zollinger-Ellison syndrome
2. Abetalipoproteinemia: rare inherited disease characterized by CNS damage, retinal abnormalities, steatorrhea, acanthocytosis

√ THICKENED NODULAR IRREGULAR FOLDS + DRY SMALL BOWEL

1. Lymphoid hyperplasia
2. Lymphoma
3. Crohn disease
4. Whipple disease
5. Mastocytosis

√ THICKENED NODULAR IRREGULAR FOLDS + WET SMALL BOWEL

1. Lymphangiectasia
2. Giardiasis
3. Whipple disease (rare)

Small Bowel Nodularity with Malabsorption

mnemonic: **W**hat **I**s **H**is **M**ain **A**im? **L**ay **E**ggs, **B**y **G**od

Whipple disease
Intestinal lymphangiectasia
Histiocytosis
Mastocytosis
Amyloidosis
Lymphoma, **L**ymph node hyperplasia
Edema
Blood
Giardiasis

PET IMAGING OF GI TRACT

GI Cancers with Low / Variable FDG Uptake

1. Any well-differentiated cancer
2. Mucinous carcinoma
3. Early MALT lesion

4. Hepatocellular carcinoma

Pathologic Uptake in GI Tract

Preparation: for bowel loop distension a neutral oral contrast agent containing sorbitol and 0.1% barium sulfate (Volumen®) is recommended

@ Esophagus
1. Reflux esophagitis
2. Radiation esophagitis
3. Barrett esophagus
4. Glycogenic acanthosis
5. Esophageal cancer

@ Stomach
1. Gastritis (NSAID, Helicobacter pylori)
2. GIST
3. Lymphoma
4. Adenocarcinoma (variable)

@ Small bowel
1. Inflammatory bowel disease
2. GIST
3. Lymphoma
4. Metastases (melanoma)

@ Colon
1. Inflammatory enterocolitis
2. Appendicitis, diverticulitis, abscess
3. Colon cancer

Abnormal Uptake of Bone Agents in Ascitic, Pleural, Pericardial Effusion

1. Uremic renal disease
2. Infection
3. Malignant effusion

ABDOMINAL MASS

Abdominal Mass in Neonate

A. RENAL (55%)
1. Hydronephrosis (25%)
2. Multicystic dysplastic kidney (15%)
3. Polycystic kidney
4. Mesoblastic nephroma
5. Renal vein thrombosis

B. GENITAL (15%)
1. Ovarian cyst
2. Hydrometrocolpos

C. GASTROINTESTINAL (15%)
1. Duplication

2. Volvulus
3. Cystic meconium peritonitis
4. Mesenteric cyst

D. NONRENAL RETROPERITONEAL (10%)
1. Adrenal hemorrhage
2. Neuroblastoma
3. Teratoma

E. HEPATOBILIARY (5%)
1. Hemangioendothelioma
2. Choledochal cyst
3. Hydrops of gallbladder

Abdominal Mass in Infant & Child

A. RENAL (55%)
1. Wilms tumor (22%)
2. Hydronephrosis (20%)
3. Cystic renal mass
4. Congenital anomaly

B. NONRENAL RETROPERITONEAL (23%)
1. Neuroblastoma (21%)
2. Teratoma

C. GASTROINTESTINAL (18%)
1. Appendiceal abscess (10%)
2. Hepatobiliary (6%)

D. GENITAL (4%)
1. Ovarian cyst / teratoma
2. Hydrometrocolpos

Abdominal Wall Mass

A. TUMOR
(a) benign
1. Desmoid tumor / fibromatosis
2. Lipoma
3. Neuroma
4. Hemangioma

(b) malignant
1. Metastatic implants
2. Primary malignancy
3. Lymphoma

B. COLLECTION
1. Hematoma / seroma
2. Abscess

C. HERNIA / REPAIR
1. Incisional hernia
2. Retained surgical material

3. Suture granuloma
4. Keloid
5. Endometriosis

ABNORMAL INTRAABDOMINAL AIR

Abnormal Air Collection

1. Abnormally located bowel = **Chilaiditi syndrome**
   = symptomatic hepatodiaphragmatic interposition of colon between liver and chest wall
   Prevalence: 0.025%–0.28%
   Cause: increased colonic mobility, reduced liver volume, lax suspensory ligament, phrenic nerve palsy, obesity
2. Pneumoperitoneum
3. Retropneumoperitoneum perforation of duodenum / rectum / ascending + descending colon, diverticulitis, ulcerative disease, endoscopic procedure
4. Gas in bowel wall gastric pneumatosis, phlegmonous gastritis, endoscopy, rupture of lung bulla
5. Gas within abscess located in subphrenic, renal, perirenal, hepatic, pancreatic space, lesser sac
6. Gas in biliary system = pneumobilia
7. Gas in portal venous system

Pneumoperitoneum

Cause:

A. DISRUPTION OF WALL OF HOLLOW VISCUS
   (a) trauma
   (b) iatrogenic perforation
   (c) diseases of GI tract
      1. Perforated gastric / duodenal ulcer
      2. Perforated appendix
      3. Ingested foreign-body perforation
      4. Diverticulitis: ruptured Meckel diverticulum / sigmoid diverticulum, jejunal diverticulosis)
      5. Necrotizing enterocolitis with perforation
      6. Inflammatory bowel disease: eg, toxic megacolon
      7. Obstruction† (gas traversing intact mucosa): neoplasm, imperforate anus, Hirschsprüng disease, meconium ileus
      8. Ruptured pneumatosis cystoides intestinalis† with "**balanced pneumoperitoneum**" (= free intraperitoneal air acts as tamponade of pneumatosis cysts thus maintaining a balance between intracystic air + pneumoperitoneum)
      9. **Idiopathic gastric perforation** = spontaneous perforation in premature infants: congenital gastric muscular wall defect

B. THROUGH PERITONEAL SURFACE
   (a) transperitoneal manipulation

1. Abdominal needle biopsy / catheter placement
2. Mistaken thoracentesis / chest tube placement
3. Endoscopic biopsy

(b) extension from chest†

1. Pneumothorax: ventilation, chest injury
2. Dissection from pneumomediastinum: positive pressure breathing, rupture of bulla / bleb, chest surgery
3. Bronchopleural fistula

(c) intraperitoneal rupture of urinary bladder with indwelling Foley catheter / retrograde cystography

(d) penetrating abdominal injury

C. THROUGH FEMALE GENITAL TRACT†

(a) iatrogenic

1. Perforation of uterus / vagina
2. Culdocentesis
3. Rubin test = tubal patency test
4. Pelvic examination

(b) spontaneous

1. Intercourse, orogenital insufflation
2. Douching
3. Knee-chest exercise, water skiing, horseback riding

D. INTRAPERITONEAL

1. Gas-forming peritonitis
2. Rupture of abscess

Note † = asymptomatic spontaneous pneumoperitoneum without peritonitis

√ air in lesser peritoneal sac

√ gas in scrotum ← open processus vaginalis

<u>Large collection of gas:</u>

√ "abdominal distension, NO gastric air-fluid level

√ "**football**" sign = large pneumoperitoneum outlining entire abdominal cavity

√ "double wall / bas-relief" sign = **Rigler sign**
[Leo Rigler (1896–1979), radiologist in Minneapolis, USA]
= air outlining the luminal + serosal surface of the bowel wall with patient in supine position (usually requires > 1,000 mL of free intraperitoneal gas + intraperitoneal fluid)

√ "**telltale triangle**" sign = triangular air pocket between 3 loops of bowel

√ depiction of diaphragmatic muscle slips = two or three 6–13-cm long and 8–10-mm wide arcuate soft-tissue bands directed vertically inferiorly + arching parallel to diaphragmatic dome superiorly

√ outline of ligaments of anterior inferior abdominal wall:

√ "inverted V" sign = outline of both lateral umbilical ligaments (containing inferior epigastric vessels)

√ outline of medial umbilical ligaments (= obliterated umbilical arteries)

√ "urachus" sign = outline of middle umbilical ligament

RUQ gas (best place to look for small collections):

√ single large area of hyperlucency over the liver
√ oblique linear area of hyperlucency outlining the posteroinferior margin of liver
√ "**doge's cap**" sign = triangular collection of gas in Morison pouch (posterior hepatorenal space)
√ outline of falciform ligament = long vertical line to the right of midline extending from ligamentum teres notch to umbilicus; most common structure outlined
√ "ligamentum teres" sign = air outlining fissure of ligamentum teres hepatis (= posterior free edge of falciform ligament) seen as vertically oriented sharply defined slitlike / oval area of hyperlucency between 10th and 12th rib within 2.5–4.0 cm of right vertebral border 2–7 mm wide and 6–20 mm long
√ ligamentum teres notch = inverted V-shaped area of hyperlucency along undersurface of liver
√ "saddlebag / mustache / cupola" sign = gas trapped below central tendon of diaphragm
√ parahepatic air = gas bubble lateral to right edge of liver

US (85.7% sensitive, 99.6% specific):

√ enhancement of peritoneal stripe
Note: normal peritoneal stripe = single / double hyperechoic line deep to anterior abdominal wall
√ posterior shadowing / reverberation artifacts depending on amount of free air
DDx: intraluminal bowel gas (associated with normal overlying peritoneal stripe)

Iatrogenic Pneumoperitoneum

1. Laparotomy / laparoscopy (58%)
absorbed in 1–24 days dependent on initial amount of air introduced and body habitus (80% in asthenic, 25% in obese patients)
◊ After 3 days free air should be followed with suspicion!
2. Leaking surgical anastomosis
3. Peritoneal dialysis
4. Feeding tube placement
5. Endoscopic perforation
6. Enema tip injury
7. Use of gynecologic instruments
8. Vigorous respiratory resuscitation
9. Diagnostic pneumoperitoneum
10. Diagnostic peritoneal lavage

Miscellaneous Causes of Pneumoperitoneum

1. Drugs: steroids, NSAID
2. Pneumatosis coli / intestinalis
3. Entry through female genital tract: douching, sexual intercourse, insufflation

Spontaneous Pneumoperitoneum

1. Perforated peptic ulcer
2. Ischemia

3. Bowel obstruction
4. Toxic megacolon
5. Inflammation: appendicitis, tuberculosis, necrotizing enterocolitis
6. Benign pneumoperitoneum of systemic sclerosis
7. Malignancy (8–10%): colorectal carcinoma (3–10%), gastrointestinal lymphoma

CT
- √ depiction of primary malignancy + site and extent of perforation
- √ pneumoperitoneum
- √ extravasation of bowel content + oral contrast
- √ contained leak
- √ gas within tumor
- √ formation of enteroenteric fistula

Traumatic Pneumoperitoneum

(a) Blunt trauma
(b) Penetrating trauma:
1. Perforating foreign body: eg, thermometer injury to rectum, vaginal stimulator in rectum
2. Barotrauma:
   (a) compressor air directed toward anus
   (b) pulmonary barotrauma
   (c) mechanical ventilation

Pseudopneumoperitoneum

= process mimicking free air

A. ABDOMINAL GAS
= presence of gas confined to inner layer of abdominal wall but external to parietal peritoneum
(a) gastrointestinal gas
1. "Pseudo-wall" sign = apposition of gas-distended bowel loops
2. Chilaiditi syndrome
3. Diaphragmatic hernia
4. Diverticulum of esophagus / stomach / duodenum
(b) extraintestinal gas
1. Retroperitoneal air: eg, rectal injury
2. Subdiaphragmatic abscess

B. CHEST
1. Pneumothorax
2. Empyema
3. Irregularity of diaphragm
4. Rib fracture

C. FAT
1. Subdiaphragmatic intraperitoneal fat
2. Interposition of omental fat between liver + diaphragm

Pneumoretroperitoneum

Cause:

(1) Traumatic rupture: usually duodenum
(2) Perforation of duodenal ulcer
(3) Gas abscess of pancreas (usually extends into lesser sac)
(4) Urinary tract gas: trauma, infection
(5) Dissected mediastinal air

√ kidney outlined by gas
√ outline of psoas margin ± gas streaks in muscle bundles

Pneumatosis Intestinalis

= PNEUMATOSIS CYSTOIDES INTESTINALIS = BULLOUS EMPHYSEMA OF THE INTESTINE = INTESTINAL GAS CYSTS = PERITONEAL LYMPHOPNEUMATOSIS

= cystic / linear gas collection in bowel wall

Cause:

◊ Attributed to at least 58 causative factors!

A. BOWEL NECROSIS / GANGRENE

◊ Most common + life-threatening cause!

Pathogenesis: damage + disruption of mucosa with entry of gas-forming bacteria into bowel wall (cysts contain 50% hydrogen = evidence of bacterial origin)

Necrotizing enterocolitis, ischemia + infarction (mesenteric thrombosis), neutropenic colitis, sepsis, volvulus, strangulation, emphysematous gastritis, caustic ingestion

Drugs Associated with Pneumatosis Intestinalis

Drug Class	*Common Agents*
Corticosteroids	
Chemotherapeutics	
Cytotoxic agents	methotrexate, etoposide, daunorubicin, cytarabine, fluorouracil, paclitaxel
Tyrosine kinase inhibitor	imatinib
Immunosuppressants	
Antidiabetics	
a-glucosidase inhibitors	voglibose, acarbose, miglitol
Others	lactulose, sorbitol

B. MUCOSAL DISRUPTION

Pathogenesis: increased intestinal gas pressure → overdistension and dissection of gas into bowel wall

(a) intestinal obstruction: pyloric stenosis, annular pancreas, imperforate anus, Hirschsprüng disease, meconium plug syndrome, obstructing neoplasm
(b) intestinal trauma: endoscopy ± biopsy, biliary stent perforation, sclerotherapy, bowel surgery, postoperative bowel anastomosis, penetrating / blunt abdominal trauma, trauma of child abuse, intracatheter jejunal feeding tube, barium enema
(c) infection / inflammation: peptic ulcer disease, intestinal parasites, tuberculosis,

peritonitis, inflammatory bowel disease (Crohn disease, ulcerative colitis, pseudomembranous colitis), neutropenic colitis, toxic megacolon, generalized sepsis; rotavirus gastroenteritis (in children)

(d) ruptured jejunal diverticula, Whipple disease, systemic amyloidosis

C. INCREASED MUCOSAL PERMEABILITY

Pathogenesis: defects in lymphoid tissue of bowel wall allows bacterial gas to enter bowel wall

(a) immunotherapy: graft-versus-host disease, organ transplantation, bone marrow transplantation

(b) others: AIDS enterocolitides, steroid therapy, chemotherapy, radiation therapy, collagen vascular disease (scleroderma, systemic lupus erythematosus, periarteritis dermatomyositis), intestinal bypass enteropathy, diabetes mellitus

D. PULMONARY DISEASE

Pathogenesis: alveolar rupture with air dissecting interstitially along bronchovascular bundles to mediastinum and retroperitoneally along vascular supply of viscera

Cause: chronic obstructive pulmonary disease (chronic bronchitis, emphysema, bullous disease of lung), asthma, cystic fibrosis, chest trauma (barotrauma from mechanical ventilation with positive end-expiratory pressure, chest tube), increased intrathoracic pressure associated with retching + vomiting

E. IDIOPATHIC

Path:

(a) microvesicular type = 10–100-mm cysts / bubbles within lamina propria

√ radiolucent clusters of cysts along contour of bowel wall (best demonstrated on CT)

√ segmental mucosal nodularity

DDx: polyposis at 3D CT colonography

(b) linear / curvilinear type = streaks of gas oriented parallel to bowel wall

Location: small bowel > colon; may be discontinuous with spread to distant sites along mesentery

Pneumatosis in small bowel / colon should be treated as an emergent finding until life-threatening causes such as bowel ischemia and impending perforation are excluded.

Site: subserosa > submucosa >> muscularis propria > mesentery; mesenteric side >> antimesenteric side

√ primary radiologic finding:

√ linear / cystic gas collection within bowel wall paralleling mucosa

√ secondary radiologic findings:

√ ± pneumoperitoneum / pneumoretroperitoneum (asymptomatic large pneumoperitoneum may persist for months / years)

√ ± gas in mesenteric + portal vein

√ free fluid

MR:

√ hypointense signal on 2-D dual-echo GRE MRI with blooming artifact ← effect of air on local magnetic field

US:

√ echogenic reverberation artifacts within bowel wall

DDx: "pseudopneumatosis" intestinalis from foreign bodies / staples within bowel wall, tiny bubbles of air trapped between bowel folds, misregistration of air bubbles outside ultrasound beam

Prognosis:

wide spectrum from innocuous to fatal; clinical outcome impossible to predict based on radiologic features

◊ Linear gas collections probably have a more severe connotation
◊ Pneumatosis of the colon is likely clinically insignificant
◊ Extent of pneumatosis is inversely related to severity of disease
◊ Bowel wall thickening + perienteric soft-tissue stranding = signs of life-threatening ischemia

Soap-bubble Appearance in Abdomen of Neonate

1. Feces in infant fed by mouth
2. Meconium ileus:
   gas mixed with meconium, usually RLQ
3. Meconium plug:
   gas in and around plug, in distribution of colon
4. Necrotizing enterocolitis: submucosal pneumatosis
5. Atresia / severe stenosis: pneumatosis
6. Hirschsprüng disease: impacted stool, sometimes pneumatosis

ABDOMINAL CALCIFICATIONS & OPACITIES

Opaque Material in Bowel

mnemonic: CHIPS

Chloral hydrate
Heavy metals: lead
Iron
Phenothiazines
Salicylates

Diffuse Peritoneal Calcifications

(a) systemic mineral imbalance ("metastatic")
   1. Uremia
   2. Hyperparathyroidism + paraneoplastic HPT

(b) dystrophic ← tissue injury / aging / disease
   › neoplasm
      1. Cystadenoma / serous adenocarcinoma of ovary
         √ granular, sandlike psammomatous calcifications
      2. Pseudomyxoma peritonei
         (a) pseudomucinous adenoma of ovary
         (b) mucocele of appendix
      3. Undifferentiated abdominal malignancy

› infection
1. Tuberculous peritonitis
√ mottled calcifications simulating residual barium
2. Pneumocystis carinii infection

› inflammation
1. Meconium peritonitis
2. Peritoneal dialysis with sclerosing peritonitis
√ sheetlike calcifications surrounding bowel and mesentery
3. Oil granuloma
√ annular / plaquelike calcifications

Focal Alimentary Tract Calcifications

A. ENTEROLITHS= fecalith = coprolith
[faex, *Latin* = dregs; kopros, *Greek* = dung]
1. Appendicolith: in 10–15% of acute appendicitis
2. Stone in Meckel diverticulum
3. Diverticular stone
4. Rectal stone
5. Proximal to partial obstruction: TB, Crohn disease

B. MESENTERIC CALCIFICATIONS
1. Dystrophic calcification of omental fat deposits + appendices epiploicae ← infarction / pancreatitis / TB
2. Cysts: mesenteric cyst, hydatid cyst
3. Calcified mesenteric lipoma

C. INGESTED FOREIGN BODIES

D. TUMOR
1. Mucocele of appendix
√ crescent-shaped / circular calcification
2. Mucinous adenocarcinoma of stomach / colon
= COLLOID CARCINOMA
√ small mottled / punctate calcifications in primary site ± in regional lymph node metastases, adjacent omentum, metastatic liver foci
3. Gastric / esophageal leiomyoma: calcifies in 4%
4. Lipoma

Foreign Objects in Abdominal Cavity

A. INTRALUMINAL OBJECT
(a) pathologic condition
1. Bezoar
2. Gallstone
(b) dislodged stent and tube
1. Biliary stent (in up to 6%)
2. Feeding tube
(c) ingestion of diagnostic device
1. pH meter capsule (Bravo™ pH capsule)

√ 6 x 5.5 x 25 mm metallic device

2. Endoscopic video capsule
   √ 11 x 26 mm metallic device

(d) accidental / nonaccidental ingestion

B. EXTRALUMINAL OBJECT

1. Prosthetic mesh for hernia repair:
   › 0.44 mm thick polypropylene
   √ line of attenuation similar to muscle
   › 1-mm thick polytetrafluoroethylene
   √ line of increased attenuation
2. Dropped gallstone = perforation / spillage: during laparoscopic cholecystectomy (in up to 30%)
3. Dropped surgical clip
4. Migrated / perforated IUD (1÷1,000 insertions)
   Cx in 15%: bowel obstruction, perforation of bowel / urinary bladder / mesentery, rectal stricture, rectouterine fistula
5. Hepatic packing with sponges (for 36–48 hours)
6. Bioabsorbable sponge for hemostasis: Gelfoam®, Surgicel®, microfibrillar collagen
   √ usually absorbed within 7–14 days
   √ mimick abscess due to numerous gas pockets

Packing agents mimic an abscess when imaged prior to absorption by 7–14 days post surgery.

7. Urethral bulking agent:
   › collagen: attenuation similar to soft tissue
   › carbon-coated microbeads: 1500–2000 HU
8. Retained surgical material (1÷1000–1500 surgeries): sponge (69%), instrument (31%)
   At risk: emergency surgery, unplanned change of procedure, obesity

A radiopaque marker on the scout image provides an important clue, but can be distorted by folding, disintegrate over time, or can be misinterpreted (as a calcification / oral contrast agent).

Mimicks of Foreign Bodies:

1. Heterotopic mesenteric ossification
   Cause: trauma, repeated intraabdominal surgeries
   Histo: mature trabeculae
   √ multiple high-density linear branching structures within mesentery extending to peritoneal surface
   √ trabecular architecture unchanged over time
   Cx: small bowel obstruction
   DDx: (1) Dystrophic calcifications
   (2) Extravasation of oral contrast (change in configuration, pooling following gravity, less dense over time)
   (3) Osseous metaplasia (trabecular architecture)
2. Heterotopic ossification in surgical incisions
   = subtype of traumatic myositis ossificans
   Prevalence: 25% of abdominal incisions

Location: vertical midline abdominal incisions (mainly), esp. in linea alba
√ trabecular architecture

3. Bogota bag
= clear sterilized plastic bag used for temporary abdominal closure to monitor secondary peritonitis
√ linear high-attenuation area along the direction of the surgical incision

Abdominal Wall Calcifications

A. IN SOFT TISSUES
1. Hypercalcemic states
2. Idiopathic calcinosis

B. IN MUSCLE
(a) parasites:
1. Cysticercosis = Taenia solium
√ round / slightly elongated calcifications
2. Guinea worm = dracunculiasis
√ stringlike calcifications up to 12 cm long

(b) injection sites from quinine, bismuth, calcium gluconate, calcium penicillin
(c) myositis ossificans

C. IN SKIN
1. Soft-tissue nodules: papilloma, neurofibroma, melanoma, nevi
2. Scar:
√ linear density
3. Colostomy / ileostomy
4. Tattoo markings

Abdominal Vascular Calcifications

A. ARTERIES
1. Atheromatous plaques
2. Arterial calcifications in diabetes mellitus

B. VEINS
phleboliths = calcified thrombus, generally seen below interspinous line
1. Normal / varicose veins
2. Hemangioma

C. LYMPH NODES
1. Histoplasmosis / tuberculosis
2. Chronic granulomatous disease
3. Residual lymphographic contrast
4. Silicosis

ABNORMAL INTRAABDOMINAL FLUID

Ascites

Ascites collects in well-defined areas of stasis / arrested flow:
(1) deep pelvic recesses: retrouterine space / pouch of Douglas in women, retrovesical space in

men
(2) right lower quadrant: near termination of small bowel mesentery at ileocecal junction
(3) superior aspect of the sigmoid mesocolon
(4) right paracolic gutter

Cause:

A. TRANSUDATE (most common cause)
(1) Cirrhosis (75%): poor prognostic sign
(2) Hypoproteinemia
(3) CHF
(4) Constrictive pericarditis
(5) Chronic renal failure
(6) Budd-Chiari syndrome

B. EXUDATE
(1) Carcinomatosis (2nd most common cause)
(2) TB peritonitis (3rd most common cause)
(3) Polyserositis
(4) Pancreatitis
(5) Meigs syndrome

C. HEMORRHAGIC / CHYLOUS FLUID

Early signs (accumulation in pelvis):
√ round central density in pelvis + ill-defined bladder top
√ thickening of peritoneal flank stripe
√ space between properitoneal fat and gut > 3 mm

Late signs:
√ Hellmer sign = medial displacement of lateral liver margins
√ medial displacement of ascending + descending colon
√ obliteration of hepatic + splenic angles
√ bulging flanks
√ gray abdomen
√ floating centralized loops
√ separation of loops

High-density Ascites

1. Tuberculosis: 20–45 HU; may be lower
2. Ovarian tumor
3. Appendiceal tumor

Neonatal Ascites

A. GASTROINTESTINAL
(a) perforation of hollow viscus
1. Meconium peritonitis
(b) inflammatory lesions
1. Meckel diverticulum
2. Appendicitis
(c) cyst rupture

1. Mesenteric cyst
2. Omental cyst
3. Choledochal cyst

B. PORTOHEPATIC
   (a) extrahepatic portal vein obstruction
      1. Atresia of veins
      2. Compression by mass
   (b) intrahepatic portal vein obstruction
      1. Portal cirrhosis: neonatal hepatitis
      2. Biliary cirrhosis: biliary atresia
   (c) bile leakage
      1. Biliary obstruction
      2. Biliary perforation

C. URINARY TRACT
   ◊ Urine ascites (most common cause): lower urinary tract obstruction + upper urinary tract rupture: posterior / anterior urethral valves, ureterovesical / ureteropelvic junction obstruction, renal / bladder rupture, anterior urethral diverticulum, bladder diverticula, neurogenic bladder, extrinsic bladder mass

D. GENITAL
   1. Ruptured ovarian cyst
   2. Hydrometrocolpos

E. HYDROPS FETALIS
   1. Immune hydrops
   2. Nonimmune hydrops: usually cardiac causes

F. MISCELLANEOUS
   1. Chylous ascites
   2. Lymphangiectasia
   3. Congenital syphilis, trauma
   4. Idiopathic

Chylous Ascites

IN ADULTS:	1.	Inflammatory process	35%
	2.	Tumor	30%
	3.	Idiopathic	23%
	4.	Trauma	11%
	5.	Congenital	1%
IN CHILDREN:	1.	Congenital	39%
	2.	Inflammatory process	15%
	3.	Trauma	12%
	4.	Tumor	3%
	5.	Idiopathic	33%

Fluid Collections

mnemonic: BLUSCHINGS

Biloma

Lymphocele, **L**ymphangioma, **L**ymphoma (almost anechoic by US)
Urinoma
Seroma
Cyst: pseudocyst, peritoneal inclusion cyst
Hemorrhage, **H**ematoma: aneurysm, AVM
Infection, Infestation: empyema, abscess, Echinococcus
Neoplasm (necrotic)
G I tract: dilated loops, ileus, duplication
Serosa: ascites, pleural fluid, pericardial effusion

Fluid Collection in Lesser Sac

A. Inflammatory exudate
    1. Acute pancreatitis
    2. Cholecystitis
    3. Perforated gastric ulcer
    4. Left perinephric abscess
    5. Ascending pelvic inflammation (rare): appendicitis, diverticulitis
B. Hemorrhage
    1. Injury of liver / spleen
    2. Hemorrhagic pancreatitis
    3. Bleeding from ruptured neoplasms
C. Postoperative fluid: gastric / hepatobiliary surgery

[D. Ascitic transudate (most common + associated with fluid elsewhere in peritoneal cavity): hepatic / renal failure]

Intraabdominal Cyst in Childhood

1. Omental cyst: greater omentum / lesser sac, multilocular
2. Mesenteric cyst: between leaves of small bowel mesentery
3. Choledochal cyst
4. Intestinal duplication
5. Ovarian cyst
6. Pancreatic pseudocyst
7. Cystic renal tumor
8. Abscess
9. Meckel diverticulum: communication with GI tract
10. Lymphangioma
11. Mesenteric lymphoma
12. Intramural tumor

DYSPHAGIA

= OROPHARYNGEAL IMPAIRMENT = SWALLOWING DYSFUNCTION

Prevalence: 22% in adult primary care population, M÷F = 1÷4; 13% in general population; in up to 50% of nursing home residents

Predisposed: gastroesophageal reflux disease (GERD), stroke, Alzheimer disease, multiple sclerosis, amyotrophic lateral sclerosis, Parkinson disease

Neuromuscular disorders and structural abnormalities increase with age. Look for a cause of dysphagia in elderly patients.

Cause:

(1) Cerebrovascular accident: stroke (most common cause in adults), cerebral palsy, Wallenberg syndrome (lateral medullary syndrome)
  ◊ 29–64% of stroke patients become dysphagic; 20% die from aspiration pneumonia
(2) Brain tumor
(3) Neuromuscular disease: myasthenia gravis, Eaton-Lambert syndrome, amyotrophic lateral sclerosis, muscular dystrophy, myotonic dystrophy, oculopharyngeal muscular dystrophy
(4) Neurodegenerative disorder: Parkinson disease, Alzheimer disease, aging-related changes, Huntington disease, progressive supranuclear palsy
(5) Demyelinating diseases: multiple sclerosis
(6) Connective tissue disease: dermatomyositis, polymyositis, Sjögren syndrome, lupus erythematosus, rheumatoid arthritis, scleroderma
(7) Metabolic disorder: hyperthyroidism, hypothyroidism, diabetes mellitus
(8) infection: poliomyelitis, neurosyphilis, encephalitis, meningitis, sarcoidosis
(9) GI disorder:
  › esophageal diverticulum
  › focal esophageal narrowing
  › extrinsic esophageal compression
  › lower esophageal sphincter hypertension
(10) Trauma: head and neck surgery, radiation therapy, spinal cord injury, traumatic brain injury
(11) Medications

• weight loss, slow eating, change in dietary habits
• recurrent pneumonia

Esophagography: anatomic and functional information about pharynx, esophagus, gastroesophageal junction (GEJ), gastric cardia, esophageal motility, gastroesophageal reflux

Modified barium swallow (standard of reference, performed with a swallowing / speech therapist):
swallowing function + response to therapeutic measures and necessary dietary requirements

Cx: dehydration, malnutrition, aspiration, pneumonia, death

DDx: odynophagia, globus sensation, heartburn

Oropharyngeal Dysphagia

= sensation of blockage / discomfort in throat

Common cause: stroke, head & neck surgery, radiation Rx

Pathophysiology:

› structural: Zenker diverticulum, tumor, web, extrinsic mass, cervical spine disease
› functional:
  (a) laryngeal penetration or aspiration

- coughing / choking before / during / after swallow → aspiration pneumonia

(b) soft-palate insufficiency
- nasal voice / nasal regurgitation

(c) abnormal oral phase of swallowing
- food dribbling, difficulty in chewing

(d) cricopharyngeal dysfunction

- "wet" voice during / after meal
- increased oral secretions, drooling
- chronic low-level secretions: esp. bronchial, chest
- difficulty initiating a swallow, hoarseness, dyspnea

Cx: respiratory problems, malnutrition, dehydration, bronchial spasms, airway obstruction

Substernal / Esophageal Dysphagia

= sensation of discomfort / blockage localized to between thoracic inlet and xiphoid process

Pathophysiology:
- › structural: ring stricture, extrinsic mass, tumor in esophagus / proximal stomach
- › functional: esophageal motility abnormality, gastroesophageal reflux disease (GERD)

- sensation of food sticking in chest / throat
- dysphagia primarily for solids
- oral or pharyngeal regurgitation

MECHANICAL INTESTINAL OBSTRUCTION

= occlusion / constriction of bowel lumen

Prevalence: 20% of acute abdominal admissions
- › 80% small bowel obstruction
- › 20% large bowel obstruction

Disturbances in Motility & Transit

1. Irritable bowel syndrome
2. Functional dyspepsia
3. Gastroparesis
4. Bloating / chronic idiopathic constipation

Air Progression in Neonates

stomach	within minutes after birth
entire small bowel	within 3 hours
sigmoid colon	after 8–9 hours

Cause of Absent Gas in Neonate

1. GI obstruction
2. Mechanical ventilation in severe respiratory distress
3. Continuous gastric suction

Cause of Delayed Passage of Gas in Neonate

1. Traumatic delivery

2. Septicemia
3. Hypoglycemia
4. Brain damage

Passage of Meconium

A. NORMAL
   › in 94% within 24 hours
   › in 99% within 48 hours
   Exceptions: prematurity, severely asphyxiated term infants
B. DELAYED PASSAGE
   1. Hirschsprüng disease
   2. Ileal / jejunal atresia
   3. Meconium ileus
   4. Meconium plug syndrome
   5. Colon atresia
   6. Imperforate anus

Common Causes of Obstruction in Children

Time of presentation:

Nursery	intestinal atresia, midgut volvulus, meconium ileus, Hirschsprü disease, small bowel atresia with meconium ileus, meconium p syndrome, small left colon syndrome, imperforate anus, obstru from duplication cyst
First 3 months	hypertrophic pyloric stenosis, inguinal hernia, Hirschsprüng disease, midgut volvulus
6–24 months	ileocolic intussusception
Childhood	appendicitis

Terminology:

High obstruction = proximal to midileum
   ◊ Rarely needs further radiologic evaluation
   • bilious vomiting (after first feeding)
   • abdominal distention
   √ few dilated bowel loops

Low obstruction = distal ileum / colon
   ◊ More difficult to accurately localize
   ◊ Requires contrast enema examination to diagnose microcolon, position of cecum, level of obstruction
   • abdominal distention + vomiting
   • failure to pass meconium
   √ many dilated intestinal loops

Intestinal Obstruction in Neonate

• abdominal distension, vomiting, failure to pass meconium
1. Duodenal atresia (50%), stenosis (40%), web (10%)
2. Midgut volvulus

3. Jejunal / ileal atresia
4. Meconium ileus
5. Meconium plug syndrome
6. Hirschsprüng disease
7. Necrotizing enterocolitis

NEONATAL OBSTRUCTION WITH MICROCOLON

1. Ileal atresia
2. Distal jejunal atresia
3. Meconium ileus

NEONATAL OBSTRUCTION WITH NORMAL COLON

1. Meconium plug
2. Hirschsprüng disease

Intestinal Obstruction in Infant & Child

1. Hypertrophic pyloric stenosis
2. Appendicitis
3. Intussusception

Gastric Outlet Obstruction

A. CONGENITAL LESION
   1. Antral mucosal diaphragm = antral web
   2. Gastric duplication: usually along greater curvature, abdominal mass in infancy
   3. Hypertrophic pyloric stenosis

B. MALIGNANT NARROWING (most common cause)
   1. Antral carcinoma: cause in adults in 30–35%
   2. Scirrhous carcinoma of pyloric channel
   3. Pancreatic adenocarcinoma
   4. Primary duodenal tumor
   5. Primary biliary tumor
   6. Lymphoma (rarely)

C. INFLAMMATORY NARROWING
   1. Peptic ulcer disease: significantly decreased over last 30 years due to advances in diagnosis + treatment
   2. Corrosive gastritis
   3. Crohn disease, sarcoidosis, syphilis, tuberculosis

D. OTHERS
   1. Prolapsed antral polyp / mucosa
   2. Bezoar
   3. Gastric volvulus
   4. Postoperative stomal edema

Abdominal plain film:

√ large smoothly marginated homogeneous mass displacing transverse colon + small bowel inferiorly

√ one / two air-fluid levels

Duodenal Obstruction

A. CONGENITAL
   1. Annular pancreas
   2. Peritoneal bands = Ladd bands
   3. Aberrant vessel

B. INFLAMMATORY NARROWING
   1. Chronic duodenal ulcer scar
   2. Acute pancreatitis: phlegmon, abscess, pseudocyst
   3. Acute cholecystitis: perforated gallstone

C. INTRAMURAL HEMATOMA
   1. Blunt trauma (accident, child abuse)
   2. Anticoagulant therapy
   3. Blood dyscrasia

D. TUMORAL NARROWING
   1. Primary duodenal tumors
   2. Tumor invasion: pancreas, right kidney, lymph node enlargement

E. EXTRINSIC COMPRESSION
   1. Aortic aneurysm
   2. Pseudoaneurysm

F. OTHERS
   1. Superior mesenteric artery syndrome: extensive burns, body cast, rapid weight loss, prolonged bed rest
   2. Bezoar (in gastrectomized patient)

mnemonic: VA BADD TU BADD

child	adult
Volvulus	**T**umor
Atresia	**U**lcer
Bands	**B**ands
Annular pancreas	**A**nnular pancreas
Duplication	**D**uplication
Diverticulum	**D**iverticulum

Abdominal plain film:
√ "double-bubble" sign = air-fluid levels in stomach + duodenum
√ frequently normal ← absence of gas from vomiting

Jejunal and Ileal Obstruction

= SMALL BOWEL OBSTRUCTION (SBO)

Frequency: accounts for 20% of all surgical admissions

Mortality: 5.5% due to strangulation (paradigm: "Never let the sun rise or set on an obstructed small bowel")

Cause:

A. CONGENITAL
   1. Jejunal atresia
   2. Ileal atresia / stenosis

3. Enteric duplication: located on antimesenteric side, mostly in ileum
4. Midgut volvulus: arrest in rotation + fixation of small bowel during fetal life
5. Mesenteric cyst from meconium peritonitis: located on mesenteric side
6. Meckel diverticulum

B. EXTRINSIC BOWEL LESION
1. Fibrous adhesions (50–80%): previous surgery (80%) peritonitis (15%), congenital / uncertain cause (5%)
◊ Postoperative adhesions are the most common cause!
√ abrupt change in bowel caliber
√ no other apparent cause at transition point
2. Hernia (10%): internal / external
3. Volvulus
4. Mass: extrinsic neoplasm (most commonly due to advanced peritoneal carcinomatosis), abscess, aneurysm, hematoma, endometriosis

C. LUMINAL OCCLUSION
(a) swallowed:
1. Foreign body: in children or in mentally disturbed / disabled patients
2. Bezoar
3. Gallstone
4. Inspissated milk
5. Bolus of Ascaris lumbricoides

(b) after birth:
1. Meconium ileus:
√ microcolon in cystic fibrosis
2. Meconium ileus equivalent

(c) other:
1. Intussusception (< 5% in adults)
2. Tumor (rare): eg, lipoma

D. INTRINSIC BOWEL WALL LESION
(a) neoplasm (< 2%)
1. Adenocarcinoma
2. Carcinoid tumor
3. Lymphoma
4. Gastrointestinal stromal tumor

(b) inflammatory lesion
1. Crohn disease (acute bowel wall thickening, chronic cicatricial stenosis, postsurgical)
2. Tuberculous enteritis
3. Eosinophilic gastroenteritis
4. Parasitic disease

(c) vascular insufficiency
1. Ischemia: arterial / venous occlusion
2. Radiation enteropathy: 1 year post radiation

(d) intramural hemorrhage
1. Blunt trauma

2. Henoch-Schönlein purpura
3. Anticoagulants

(e) strictures

1. Surgical anastomosis
2. Irradiation
3. Potassium chloride tablets
4. Massive deposition of amyloid

Plain abdominal radiograph (50–66% sensitive):

◊ High sensitivity only for high-grade obstruction!

Results: diagnostic in 50–60%; equivocal in 20–30%; normal / nonspecific / misleading in 10–20%

√ "candy cane" appearance in erect position = > 2–3 distended small bowel loops with gas-fluid levels (> 3–5 hours after onset of obstruction):

√ gas-fluid levels > 2.5 cm wide

√ gas-fluid levels differing > 2 cm in height from one another within same bowel loop

√ disparity in size between obstructed loops and contiguous small bowel loops of normal caliber beyond site of obstruction

√ small bowel positioned in center of abdomen

√ little / no gas + stool in colon with complete mechanical obstruction after 12–24 hours

√ "stretch" sign = erectile valvulae conniventes completely encircle bowel lumen

√ "stepladder appearance" in low obstruction (the greater the number of dilated bowel loops, the more distal the site of obstruction)

√ "string-of-beads" indicate peristaltic hyperactivity to overcome mechanical obstruction

√ hyperactive peristalsis / aperistalsis = fatigued small bowel

CAVE: little / no gas in small bowel ← fluid-distended loops may lead one to overlook obstruction

Location of obstruction:

(a) valvulae conniventes high + frequent = jejunum

(b) valvulae conniventes sparse / absent = ileum

Plain abdominal radiographic categories:

1. Normal
   = absence of small intestinal gas / gas within 3–4 variably shaped loops < 2.5 cm in diameter
2. Mild small bowel stasis
   = single / multiple loops of 2.5–3.0 cm in diameter with ≥ 3 air-fluid levels
3. Probable SBO pattern
   = dilated multiple gas- / fluid-filled loops with air-fluid levels + moderate amount of colonic gas
4. Definite SBO pattern
   = clearly disproportionate gaseous / fluid distension of small bowel relative to colon

UGI:

√ "snake head" appearance = active peristalsis forms bulbous head of barium column in an attempt to overcome obstruction

√ barium appears in colon > 12 hr

Enteroclysis for adhesive obstruction:
- √ abrupt change in caliber of bowel with normal caliber / collapsed bowel distal to obstruction
- √ stretched folds of normal pattern
- √ angulated + fixed bowel segment

Enteroclysis categories of SBO (Shrake):

(a) low-grade partial SBO
= sufficient flow of contrast material through point of obstruction so that fold pattern beyond obstruction is readily defined

(b) high-grade partial SBO
= stasis + delay in arrival of contrast so that contrast material is diluted in distended prestenotic loop with minimal contrast in postobstructive loop leading to difficulty in defining fold pattern after transition point

(c) complete SBO
√ no passage of contrast material beyond point of obstruction 3–24 hours after start of examination

CT (66% accurate, 78% specific, 63% sensitive [81–100% sensitive for high-grade obstruction, 48% sensitive for low-grade partial obstruction]):
- √ small bowel dilatation > 2.5 cm proximally with normal-caliber / collapsed loops distally:
  - √ "**small bowel feces**" sign (in 7–8%) = gas bubbles mixed with particulate matter immediately proximal to transition point (DDx: cystic fibrosis)
- √ discrepant caliber at transition zone from dilated to nondilated bowel:
  - √ point of transition = triangular beak immediately beyond dilated segment
  - √ level of obstruction best determined by relative lengths of dilated versus collapsed bowel
  - √ incomplete obstruction = passage of enteric contrast material through transition zone:
    - √ high-grade obstruction = 50% difference in caliber between proximal dilated loops + distal collapsed bowel

DDx: adynamic ileus (distension of entire small bowel)

US (89% accuracy):
- @ bowel motion in acute stage:
  - √ hyperperistalsis of bowel with back-and-forth movement of intraluminal contents + thin gut wall
- @ bowel motion in late stage (= prolonged obstruction):
  - √ aperistalsis ± thick edematous bowel wall
- √ small bowel loops dilated > 3 cm
- √ length of dilated segment > 10 cm
- √ colon collapsed
- √ level of obstruction determined by:

(a) location of dilated bowel loops:
√ bowel distal to obstructing lesion often smaller in diameter than more proximal loops
√ caliber of loops distal to obstructing lesion dependent on completeness of obstruction

(b) pattern of valvulae conniventes

√ **signs of bowel infarction**:

√ free fluid between dilated small bowel loops

√ aperistalsis

√ wall thickness of distended bowel segment > 3 mm

Strangulated Obstruction

= impaired circulation / ischemia of obstructed segment mainly ← delay in establishing diagnosis / surgical Rx

Prevalence: 10% of patients with SBO

At risk: patients with acute complete / high-grade SBO; risk increases over time

TRIAD:

(1) closed-loop obstruction of the involved segment (majority of cases)

(2) mechanical obstruction proximal to the involved segment

(3) venous congestion of the involved loop

CT (63–100% detection rate):

√ slight circumferential thickening of bowel wall:

√ increased wall attenuation

√ "target / halo" sign

√ serrated beaklike narrowing at site of obstruction (32–100% specific) = closed loop with regional mesenteric vascular engorgement + bowel wall thickening at the obstructed segment

√ unusual course of mesenteric vasculature

√ vascular compromise of affected bowel:

√ poor / lack of enhancement of bowel wall (100% SPECIFIC)

√ delayed prolonged enhancement of bowel wall

√ mesenteric haziness ← edema (95% specific)

√ diffuse engorgement of mesenteric vasculature

√ localized mesenteric fluid / hemorrhage

√ large amount of ascites

√ pneumatosis intestinalis

√ gas in portal vein

Prognosis: 20–37% mortality rate (compared with 5–8% for a recently reduced simple obstruction) due to delay in diagnosis: 8% (25%) for surgery performed in < 36 (> 36) hours

CLOSED-LOOP OBSTRUCTION

= obstruction at two adjacent points along the course of the bowel at a single site usually with involvement of mesentery

Pathophysiology: impaired venous ± arterial flow

◊ Most common cause of strangulation!

Cause: adhesion (75%), incarcerated hernia

√ fixation of bowel loop = no change in position:

√ "**coffee bean**" sign = gas-filled loop

√ "pseudotumor" = fluid-filled loop

√ U- or C-shaped dilated bowel loop on CT
√ increasing intraluminal fluid
√ "**beak**" sign = fusiform tapering of bowel ending at point of obstruction on CT / UGI
√ "whirl" sign = twisting of bowel + mesentery ← rotation of bowel around fixed point of obstruction on CT:
√ stretched engorged mesenteric vessels converging toward site of obstruction / torsion ± delayed enhancement
Cx: volvulus

Acquired Small Bowel Obstruction in Childhood

mnemonic: AAIMM
Adhesions
Appendicitis
Intussusception
Incarcerated hernia (most common in infancy)
Malrotation
Meckel diverticulum

Small Bowel Obstruction in Adulthood

mnemonic: SHAVIT
Stone (gallstone ileus)
Hernia (21%)
Adhesion (49%)
Volvulus
Intussusception
Tumor (16%)

SBO IN VIRGIN ABDOMEN OF ADULTHOOD

1. Bowel ischemia including ischemic stricture
2. Primary small bowel neoplasm
3. Metastatic small bowel neoplasm
4. Extrinsic abdominal mass
5. Internal / abdominal wall hernia
6. Crohn disease

Colonic Obstruction

Frequency: 25% of all intestinal obstructions
Cause:

A. NEONATAL COLONIC OBSTRUCTION
1. Meconium plug syndrome
2. Colonic atresia
3. Anorectal malformation: rectal atresia, imperforate anus
4. Hirschsprüng disease
5. **Functional colonic immaturity** (especially in premies + infants of mothers treated with magnesium or high doses of sedatives / opiates, children with septicemia, hypothyroidism, hypoglycemia, diabetic mothers)

› small left colon syndrome
› meconium plug syndrome

B. LUMINAL OBTURATION
1. Fecal impaction
√ bubbly pattern of large mass of stool
2. Fecaloma
3. Gallstone (in sigmoid narrowed by diverticulitis)
4. Intussusception

C. BOWEL WALL LESION
(a) malignant (60–70% of obstructions) predominantly in sigmoid
(b) inflammatory
1. Crohn disease
2. Ulcerative colitis
3. Mesenteric ischemia
4. Sigmoid diverticulitis (15%)
√ stenotic segment > 6 cm
5. Acute pancreatitis
(c) infectious:
› infectious granulomatous process
1. Actinomycosis
2. Tuberculosis
3. Lymphogranuloma venereum
› parasitic disease
1. Amebiasis
2. Schistosomiasis
(d) wall hematoma:
blunt trauma, coagulopathy

D. EXTRINSIC
(a) mass impression
1. Endometriosis
2. Large tumor mass: prostate, bladder, uterus, tubes, ovaries
3. Pelvic abscess
4. Hugely distended bladder
5. Mesenteritis
6. Poorly formed colostomy
(b) severe constriction
1. Volvulus (3rd most common cause): sigmoid colon, cecum, transverse colon, compound volvulus (= ileosigmoid knot)
2. Hernia: transverse colon in diaphragmatic hernia, sigmoid colon in left inguinal hernia
3. Adhesion

Abdominal plain-film patterns:
(a) dilated colon only = competent ileocecal valve
(b) dilated small bowel (25%) = incompetent ileocecal valve
(c) dilated colon + dilated small bowel = ileocecal valve obstruction ← cecal

overdistension

√ gas-fluid levels distal to hepatic flexure (fluid is normal in cecum + ascending colon); sign not valid with diarrhea / saline catharsis / enema

√ cecum most dilated portion (in 75% of cases); critical at 10 cm diameter (high probability for impending perforation)

◊ The lower the obstruction, the more proximal the distension!

BE: Emergency barium enema of unprepared colon in suspected obstruction!
Contraindicated in toxic megacolon, pneumatosis intestinalis, portal vein gas, extraluminal gas

ILEUS

[*ileus* = stasis / inability to push fluid along (term does not distinguish between mechanical and nonmechanical causes)]

= ADYNAMIC / PARALYTIC / NONOBSTRUCTIVE ILEUS

= derangement impairing proper distal propulsion of intestinal contents

Cause:

› in neonate:

1. Hyperbilirubinemia
2. Intracranial hemorrhage
3. Aspiration pneumonia
4. Necrotizing enterocolitis
5. Aganglionosis

› in child / adult:

1. Postoperative ileus
   - usually resolves by 4th postoperative day
2. Visceral pain: obstructing ureteral stone, common bile duct stone, twisted ovarian cyst, blunt abdominal / chest trauma
3. Intraabdominal inflammation / infection: peritonitis, appendicitis, cholecystitis, pancreatitis, salpingitis, abdominal abscess, hemolytic-uremic syndrome, gastroenteritis
4. Ischemic bowel disease
5. Anticholinergic drugs: atropine, propantheline, morphine + derivatives, tricyclic antidepressants, dilantin, phenothiazines, hexamethonium bromide
6. Neuromuscular disorder: diabetes, hypothyroidism, porphyria, lead poisoning, uremia, hypokalemia, amyloidosis, urticaria, sprue, scleroderma, Chagas disease, vagotomy, myotonic dystrophy, CNS trauma, paraplegia, quadriplegia
7. Systemic disease: septic / hypovolemic shock, urticaria
8. Chest disease: lower lobe pneumonia, pleuritis, myocardial infarction, acute pericarditis, CHF
9. Retroperitoneal disease: hemorrhage (spine trauma), abscess

mnemonic: Remember the P's

Pancreatitis
Pendicitis
Peptic ulcer
Perforation

Peritonitis
Pneumonia
Porphyria
Postoperative
Potassium paucity
Pregnancy
Pyelonephritis

• intestinal sounds decreased / absent; abdominal distension
√ large + small bowel ± gastric distension
√ decreased small bowel distension on serial films
√ delayed but free passage of contrast material

US:
√ patent dilated fluid filled bowel lumen
√ minimal peristalsis

Rx: not amenable to surgical correction

Localized Ileus

= isolated distended loop of small / large bowel
= SENTINEL LOOP

Often associated with: adjacent acute inflammatory process

Etiology:

1. Acute pancreatitis: duodenum, jejunum, transverse colon
2. Acute cholecystitis: hepatic flexure of colon
3. Acute appendicitis: terminal ileum, cecum
4. Acute diverticulitis: descending colon
5. Acute ureteral colic: GI tract along course of ureter

Intestinal Pseudoobstruction

A. Transient pseudoobstruction
   1. Electrolyte imbalance
   2. Renal failure
   3. Congestive heart failure
B. Acute colonic pseudoobstruction
C. Chronic pseudoobstruction
   1. Scleroderma
   2. Amyloidosis
D. Idiopathic pseudoobstruction
   1. Chronic intestinal pseudoobstruction syndrome
   2. Megacystis-microcolon-intestinal-hypoperistalsis syndrome

ESOPHAGUS

Esophageal Contractions

◊ Esophageal motor activity needs to be evaluated in recumbent position without influence of gravity!

PERISTALTIC EVENT = coordinated contractions of esophagus
PERISTALTIC SEQUENCE = aboral stripping wave clearing esophagus

Primary Esophageal Peristalsis

= orderly peristaltic sequence with progressive aboral stripping traversing entire esophagus with complete clearance of barium; centrally mediated (medulla) swallow reflex via glossopharyngeal + vagal nerve; initiated by swallowing

√ rapid wave of inhibition followed by slower wave of contraction

◊ Normal peristaltic sequence will be interrupted by repetitive swallowing before peristaltic sequence is complete!

Secondary Esophageal Peristalsis

= local peristaltic wave identical to primary peristalsis but elicited through esophageal distension = sensorimotor stretch reflex

◊ Esophageal motility can be evaluated with barium injection through nasoesophageal tube despite patient's inability to swallow!

Tertiary Esophageal Contractions

= nonpropulsive esophageal motor event characterized by disorderly up-and-down movement of bolus without clearing of esophagus

Cause:

1. Presbyesophagus
2. Diffuse esophageal spasm
3. Hyperactive achalasia
4. Neuromuscular disease:
   diabetes mellitus, parkinsonism, amyotrophic lateral sclerosis, multiple sclerosis, thyrotoxic myopathy, myotonic dystrophy
5. Obstruction of cardia:
   neoplasm, distal esophageal stricture, benign lesion, S/P repair of hiatal hernia

◊ Tertiary activity does not necessarily imply a significant motility disturbance!

Age: in 5–10% of normal adults during 4th–6th decade

(a) nonsegmental = partial luminal indentation

Location: in lower ²/₃ of esophagus

√ spontaneous repetitive nonpropulsive contraction

√ "yo-yo" motion of barium

√ "corkscrew" appearance = scalloped configuration of barium column

√ "rosary bead" / "shish kebab" configuration = compartmentalization of barium column

√ no lumen-obliterating contractions

(b) segmental = luminal obliteration (rare)

√ "curling" = erratic segmental contractions

√ "rosary-bead" appearance

Abnormal Esophageal Peristalsis

A. PRIMARY MOTILITY DISORDERS

1. Achalasia

2. Diffuse esophageal spasm
3. Presbyesophagus
4. Chalasia
5. Congenital tracheoesophageal fistula
6. Intestinal pseudoobstruction

B. SECONDARY MOTILITY DISORDERS

(a) connective tissue disease
1. Scleroderma
2. SLE
3. Rheumatoid arthritis
4. Polymyositis
5. Dermatomyositis
6. Muscular dystrophy

(b) chemical / physical injury
1. Reflux / peptic esophagitis
2. S/P vagotomy
3. Caustic esophagitis
4. Radiotherapy

(c) infection
› fungal: Candidiasis
› parasitic: Chagas disease
› bacterial: TB, diphtheria
› viral: Herpes simplex

(d) metabolic disease
1. Diabetes mellitus
2. Amyloidosis
3. Alcoholism
4. Electrolyte disturbances

(e) endocrine disease
1. Myxedema
2. Thyrotoxicosis

(f) neoplasm

(g) drug-related: atropine, propantheline, curare

(h) muscle disease
1. Myotonic dystrophy
2. Muscular dystrophy
3. Oculopharyngeal dystrophy
4. Myasthenia gravis (= disturbed motility only in striated muscle of upper ⅓ of esophagus)
√ persistent collection of barium in upper third of esophagus
√ findings reversed by cholinesterase inhibitor edrophonium (Tensilon®)

(i) neurologic disease
1. Parkinsonism
2. Multiple sclerosis

3. CNS neoplasm
4. Amyotrophic lateral sclerosis
5. Bulbar poliomyelitis
6. Cerebrovascular disease
7. Huntington chorea
8. Ganglioneuromatosis
9. Wilson disease
10. Friedreich ataxia
11. Familial dysautonomia (Riley-Day)
12. Stiff-man syndrome

Diffuse Esophageal Dilatation

= ACHALASIA PATTERN = MEGAESOPHAGUS

A. ESOPHAGEAL MOTILITY DISORDER
   1. Idiopathic achalasia
   2. Chagas disease: patients commonly from South America; often associated with megacolon + cardiomegaly
   3. Postvagotomy syndrome
   4. Scleroderma
   5. Systemic lupus erythematosus
   6. Presbyesophagus
   7. Ehlers-Danlos syndrome
   8. Diabetic / alcoholic neuropathy
   9. Anticholinergic drugs
   10. Idiopathic intestinal pseudoobstruction = degeneration of innervation
   11. Amyloidosis: associated with macroglossia, thickened small bowel folds
   12. Esophagitis

B. DISTAL OBSTRUCTION
   1. Infiltrating lesion of distal esophagus / gastric cardia (eg, carcinoma) = pseudoachalasia
   2. Benign stricture
   3. Extrinsic compression

mnemonic: MA'S TACO in a SHell
Muscular disorder (eg, myasthenia gravis)
Achalasia
Scleroderma
Trypanosomiasis (Chagas disease)
Amyloidosis
Carcinoma
Obstruction
Stricture (lye, potassium, tetracycline)
Hiatal hernia

Air Esophagram

1. Normal variant

2. Scleroderma
3. Distal obstruction: tumor, stricture, achalasia
4. Thoracic surgery
5. Mediastinal inflammatory disease
6. S/P total laryngectomy: esophageal speech
7. Endotracheal intubation + PEEP

Abnormal Esophageal Folds

A. TRANSVERSE FOLDS
   1. **Feline esophagus**
      frequently seen with gastroesophageal reflux; normally found in cats
      √ transient contraction of longitudinally oriented muscularis mucosae
   2. Fixed transverse folds
      ← scarring from reflux esophagitis
      √ stepladder appearance in distal esophagus

B. LONGITUDINAL FOLDS
   normal: 1–2 mm wide, best seen in collapsed esophagus
   √ > 3 mm with submucosal edema / inflammation
   1. Gastroesophageal reflux
   2. Opportunistic infection
   3. Caustic ingestion
   4. Irradiation

DDx: (1) Varices
   √ tortuous / serpentine folds that can be effaced by esophageal distension
   (2) Varicoid carcinoma
   √ fixed rigid folds with abrupt demarcation due to submucosal spread

Esophageal Inflammation

A. CONTACT INJURY
   (a) reflux related
      1. Peptic ulcer disease
      2. Barrett esophagus
      3. Scleroderma (patulous LES)
      4. Nasogastric intubation
   (b) caustic
      1. Foreign body
      2. Corrosives
   (c) thermic
      habitual ingestion of excessively hot meals / liquids

B. RADIATION INJURY

C. INFECTION
   1. Candidiasis
   2. Herpes simplex virus / CMV
   3. Diphtheria

D. SYSTEMIC DISEASE

(a) dermatologic disorders
- blistering of skin + mucous membranes in response to minor trauma

1. **Epidermolysis bullosa dystrophica**
   Histo: intraepidermal bullae
2. **Benign mucous membrane pemphigoid**
   = rare disease of unknown cause
   Histo: subepidermal bullae without acantholysis
   Age: 4th decade; M < F
   √ esophageal lesions (in 2–13%) most frequent at sites of relative stasis (aortic knob, carina, GE junction):
   √ thin smooth webs arising from anterior aspect
   √ stenoses of variable length
3. Pemphigus vulgaris

(b) others:
1. Crohn disease
2. Graft-versus-host disease
3. Behçet disease
4. Eosinophilic gastroenteritis

Esophageal Ulcer

A. PEPTIC
1. Reflux esophagitis: scleroderma
2. Barrett esophagus
3. Crohn disease
4. Dermatologic disorders: benign mucous membrane pemphigoid, epidermolysis bullosa dystrophica, Behçet disease

B. INFECTIOUS
1. Herpes
2. Cytomegalovirus

C. CONTACT INJURY / EXTERNAL INJURY
1. Corrosives: alkali, strictures in 50%
2. Alcohol-induced esophagitis
3. Drug-induced esophagitis
4. Radiotherapy: smooth stricture at > 4,500 rad
   √ shallow / deep ulcers conforming to radiation portal
5. Nasogastric tube
   √ elongated stricture in middle ⅓ + distal ⅓
6. Endoscopic sclerotherapy

D. MALIGNANT
1. Esophageal carcinoma

Location:
@ Upper esophagus
1. Barrett ulcer in islets of gastric mucosa

@ Midesophagus
1. Herpes esophagitis

2. CMV esophagitis
3. Drug-induced esophagitis

@ Distal esophagus
1. Reflux esophagitis
2. CMV esophagitis

DDx:

(1) Sacculation
= outpouching in distal esophagus due to asymmetric scarring in reflux esophagitis

(2) Esophageal intramural pseudodiverticula

(3) Artifact
(a) tiny precipitates of barium
(b) transient mucosal crinkling in inadequate distension
(c) irregular Z-line

Small Esophageal Ulcer (< 1 cm)

1. Herpes simplex virus type I
2. Drug-induced
3. Reflux esophagitis
4. Behçet disease
5. Benign mucous membrane pemphigoid
6. Acute radiation change

Large Esophageal Ulcer (> 1 cm)

1. Cytomegalovirus
2. Human immunodeficiency virus
3. Carcinoma
4. Drug-induced
5. Barrett esophagus
6. Sclerotherapy for varices

Double-barrel Esophagus

1. Dissecting intramural hematoma from emetogenic injury
2. Mallory-Weiss tear: trauma, esophagoscopy (in 0.25%), bougienage (in 0.5%), ingestion of foreign bodies, spontaneous (bleeding diathesis)
3. Intramural abscess
4. Intraluminal diverticulum
5. Esophageal duplication (if communication with esophageal lumen present)

Esophageal Diverticulum

1. Zenker diverticulum (pharyngoesophageal)
2. Killian-Jamieson diverticulum
3. **Interbronchial diverticulum**
= traction diverticulum
= response to pull from fibrous adhesions following lymph node infection (TB), contains all 3 esophageal layers
Location: usually on right anterolateral wall of interbronchial segment

√ calcified mediastinal nodes

4. **Interaorticobronchial diverticulum**
   = thoracic pulsion diverticulum
   Location: on left anterolateral wall between inferior border of aortic arch + upper margin of left main bronchus
5. **Epiphrenic diverticulum** (rare)
   Location: usually on lateral esophageal wall, right > left, in distal 10 cm
   √ often associated with hiatus hernia
   Cx: overflow aspiration
6. **Intramural esophageal pseudodiverticulosis**
   √ outpouching from mucosal glands

Tracheobronchoesophageal Fistula

= ESOPHAGORESPIRATORY FISTULA

Location:	esophagotracheal	52–57%
	esophagobronchial	37–40%
	esophagopulmonary	3–11%

CXR:
√ recurrent pulmonary consolidation
√ lung abscess
√ pleural effusion

Esophagography:
◊ Use low-osmolar hydrosoluble contrast material
√ may confirm Dx + identify site of fistula

CT:
√ oral contrast in airway lumen + lung parenchyma
√ surrounding soft-tissue thickening

A. CONGENITAL
   1. Congenital tracheoesophageal fistula

B. MALIGNANCY (in 60%)
   1. Lung cancer
      ◊ In < 1% of patients with lung cancer
   2. Metastases to mediastinal lymph nodes
   3. Esophageal cancer
      ◊ In 5–10% of patients with advanced esophageal cancer
      Location: middle ⅓ of esophagus
   4. Treatment of mediastinal malignancy by radiation, chemotherapy, laser, esophageal stent placement

C. TRAUMATIC
   1. Instrumentation: esophagoscopy, bougienage, pneumatic dilatation
   2. Blunt ("crush injury") / penetrating chest trauma
   3. Surgery
   4. Foreign-body perforation
   5. Corrosives

6. Postemetic rupture = Boerhaave syndrome

D. INFECTIOUS / INFLAMMATORY
   1. TB, syphilis, histoplasmosis, actinomycosis, Crohn disease
   2. Perforated diverticulum
   3. Pulmonary sequestration / cyst

Long Smooth Esophageal Narrowing

1. Congenital esophageal stenosis
2. Surgical repair of esophageal atresia
   √ interruption of primary peristaltic wave at anastomosis
   √ secondary contractions may produce retrograde flow with aspiration
   √ impaction of food
3. Caustic burns = alkaline burns
4. Alendronate (= inhibitor of osteoclastic activity)
5. Gastric acid: reflux, hyperemesis gravidarum
6. Intubation: reflux + compromise of circulation
7. Radiotherapy for esophageal carcinoma; tumor of lung, breast, or thymus; lymphoma; metastases to mediastinal lymph nodes
   Onset of stricture: usually 4–8 months post Rx
   Dose: 3,000–5,000 rad
8. Postinfectious: moniliasis (rare)

Focal Esophageal Narrowing

1. **Esophageal web**
   = 1–2-mm thick (vertical length) area of complete / incomplete circumferential narrowing
2. **Esophageal ring**
   = 5–10-mm thick (vertical length) area of complete / incomplete circumferential narrowing
3. **Esophageal stricture**
   = > 10 mm in vertical length
   mnemonic: LETTERS MC
   Lye ingestion
   Esophagitis
   Tumor
   Tube (prolonged nasogastric intubation)
   Epidermolysis bullosa
   Radiation
   Surgery, **S**cleroderma
   Moniliasis
   Congenital

Upper & Midesophageal Stricture

In the setting of hiatal hernia and gastroesophageal reflux, a focal stricture in the midesophagus is highly suggestive of Barrett esophagus.

1. Barrett esophagus

2. Mediastinal radiation therapy
3. Caustic esophagitis
4. Drug-induced stricture
5. Esophageal intramural pseudodiverticulosis
6. Dermatologic disorder: benign mucous membrane pemphigoid, epidermolysis bullosa dystrophica, erythema multiforme major
7. Graft-versus-host disease
8. Congenital esophageal stenosis
   = tracheobronchial remnant / cartilaginous ring in esophageal wall
9. Metastatic cancer (from subcarinal nodes / left mainstem bronchus)

DDx: Primary carcinoma: squamous cell carcinoma

Lower Esophageal Narrowing

mnemonic: SPADE

Scleroderma
Presbyesophagus
Achalasia; **A**nticholinergics
Diffuse esophageal spasm
Esophagitis

LONG DISTAL (LOWER) ESOPHAGEAL STRICTURE

A. SEVERE ACID EXPOSURE
   1. Nasogastric intubation
   2. Zollinger-Ellison syndrome
   3. Alkaline reflux esophagitis

B. INFLAMMATION
   1. Crohn disease

SHORT DISTAL (LOWER) ESOPHAGEAL STRICTURE

1. Reflux-induced ("peptic") esophagitis
2. Scleroderma
3. Carcinoma (adenocarcinoma)
4. Crohn disease
5. Schatzki ring

Esophageal Filling Defect

A. BENIGN TUMORS

< 1% of all clinical esophageal tumors; 20% at autopsy

(a) Subepithelial tumor (75%)
   = nonepithelial, intramural
   1. Leiomyoma (50% of all benign tumors)
      ◊ Most common subepithelial mass in esophagus
   2. Granular cell myoblastoma
   3. Lipoma, fibroma, lipoma, fibrolipoma, myxofibroma, hamartoma, hemangioma, lymphangioma, neurofibroma, schwannoma

√ primary wave stops at level of tumor

√ proximal esophageal dilatation + hypotonicity
√ rigid esophageal wall at site of tumoral implant
√ disorganized / altered / effaced mucosal folds around defect
√ tumor shadow on tangential view extending beyond esophageal margin

(b) Mucosal tumor (25%) = epithelial, intraluminal

1. **Squamous papilloma**
   = most common benign mucosal tumor; rarely multiple (as in esophageal papillomatosis)
   √ small sessile slightly lobulated polyp
   √ average size of 4 mm
2. **Fibrovascular polyp**
3. **Inflammatory esophagogastric polyp**
   = sentinel polyp = bulbous tip of thickened gastric fold
   Cause: sequelae of chronic reflux esophagitis
   Prognosis: no malignant potential
4. **Adenoma**
   = originates in Barrett mucosa
   √ rare sessile / pedunculated polyp
   Cx: malignant degeneration
5. Glycogen acanthosis

B. MALIGNANT TUMORS

◊ 80% of esophageal neoplasms are malignant!

1. Esophageal cancer
2. Carcinoma of cardia (= gastric cancer)
3. Metastases: malignant melanoma, lymphoma (< 1% of gastrointestinal lymphomas), stomach, lung, breast

C. VASCULAR

1. Varices

D. INFECTION / INFLAMMATION

1. Candida / herpes esophagitis
2. Drug-induced inflammatory reaction

E. CONGENITAL / NORMAL VARIANT

1. Prolapsed gastric folds
2. Esophageal duplication cyst (0.5–2.5% of all esophageal tumors)

F. FOREIGN BODIES

1. Retained food particles: chicken bone, fish bone, pins, coins, small toys, meat
2. Undissolved effervescent crystals
3. Air bubbles

Esophageal Mucosal Nodules / Plaques

plaque = discrete irregular / ovoid elevation barely protruding above mucosal surface
nodule = small more rounded elevation

1. Candida esophagitis
2. Reflux esophagitis (early stage)
3. Barrett esophagus

4. Glycogen acanthosis
5. Superficial spreading carcinoma
6. Esophageal varices
7. Artifacts: undissolved effervescent agent, air bubbles, debris

Extrinsic Esophageal Impression

Cervical Causes of Esophageal Impression

A. OSSEOUS LESIONS
   1. Anterior marginal osteophyte / DISH
   2. Anterior disk herniation
   3. Cervical trauma + hematoma
   4. Osteomyelitis
   5. Bone neoplasm

B. ESOPHAGEAL WALL LESIONS
   (a) muscle
      1. Cricopharyngeus
      2. Esophageal web
   (b) vessel
      1. Pharyngeal venous plexus
      2. Lymph node enlargement

C. ENDOCRINE ORGANS
   1. Thyroid / parathyroid enlargement (benign / malignant)
   2. Fibrotic traction after thyroidectomy

D. Retropharyngeal / mediastinal abscess

Thoracic Causes of Esophageal Impression

A. NORMAL INDENTATIONS aortic arch, left mainstem bronchus, left inferior pulmonary vein, diaphragmatic hiatus

B. ABNORMAL VASCULATURE right-sided aortic arch, cervical aortic arch, aortic unfolding, aortic tortuosity, aortic aneurysm, double aortic arch ("reverse S"), coarctation of aorta ("reverse figure 3"), aberrant right subclavian artery = **arteria lusoria** (semilunar / bayonet-shaped imprint upon posterior wall of esophagus), aberrant left pulmonary artery (between trachea + esophagus), anomalous pulmonary venous return (anterior), persistent truncus arteriosus (posterior)

C. CARDIAC CAUSES
   (a) enlargement of chambers
      left atrial / left ventricular enlargement: mitral disease
      (esophageal displacement backward + to the right)
   (b) pericardial mass
      pericardial tumor / cyst / effusion

D. MEDIASTINAL CAUSES mediastinal tumor, lymphadenopathy (metastatic, tuberculous), inflammation, cyst

E. PULMONARY CAUSES pulmonary tumor, bronchogenic cyst, atypical pulmonary fibrosis (retraction)

F. ESOPHAGEAL ABNORMALITIES
   1. Esophageal diverticulum
   2. Paraesophageal hernia
   3. Esophageal duplication

STOMACH

Gastroesophageal Reflux

89% correlation with acid reflux test

Cause:

(1) Decreased pressure of lower esophageal sphincter
  (a) transient-complete relaxation of LES
  (b) low resting pressure of LES
(2) Transient increase in intraabdominal pressure
(3) Short intraabdominal esophageal segment

Age of children: usually 6–9 months, up to 2 years

- poor weight gain, vomiting, aspiration, choking
- asthmatic episodes, stridor, apnea

Detection: upper GI examination with barium, distal esophageal sphincter pressure measurements, 24-hr pH probe measurement in distal esophagus (gold standard), radionuclide examination

Preparation: 4-hour / overnight fasting; abdominal sphygmomanometer (for adults)

Dose: 0.5–1.0 mCi ^{99m}Tc-sulfur colloid in 300 mL of acidified orange juice (150 mL juice + 150 mL 0.1 N hydrochloric acid) followed by "cold" acidified orange juice

Imaging: at 30–60-second intervals for 30–60 min images taken in supine position from anterior; sphygmo-manometer inflated at 20, 40, 60, 80, 100 mmHg

Interpretation:

Reflux (in %) = $[\text{counts}_{\text{esophageal}} - \text{counts}_{\text{background}}] / \text{counts}_{\text{gastric}}) \bullet 100$

√ up to 3% magnitude reflux is normal

√ evidence of pulmonary aspiration (valuable in pediatric age group)

Cx: reflux esophagitis secondary to

(a) <u>delayed clearance time of esophageal acid load</u>: tertiary / repetitive esophageal contractions, supine position of refluxor, aspiration of saliva, stimulation of salivary flow, stretched phrenoesophageal membrane in hiatal hernia
(b) <u>delayed gastric emptying</u>: increased intragastric pressure (gastric outlet obstruction), viral gastropathy, diabetes

Prognosis in childhood:

(1) Self-limiting process with spontaneous resolution by end of infancy (in majority of patients)
(2) Persistent symptoms until age 4 (⅓ of patients)
(3) Death from inanition / recurrent pneumonia (5%)
(4) Cause of recurrent respiratory infections, asthma, failure to thrive, esophagitis, esophageal stricture, chronic blood loss, sudden infant death syndrome (SIDS)

Rx: (1) Conservative therapy:
avoidance of food + drugs that decrease pressure in LES, elevation of head during sleep, acid neutral-ization, cimetidine / ranitidine (reduction of acid production), metoclopramide / domperidone (increase sphincter pressure + promote gastric emptying)

(2) Antireflux surgery

Gastric Emptying

◊ Rates of gastric emptying vary widely between subjects and even in the same subject at different times

Dose: 0.5–1 mCi

(a) ^{99m}Tc-sulfur colloid cooked with egg white / liver pâté as solid food

(b) ^{111}In-DTPA in milk, water, formula, juice for simultaneous measurement of liquid phase

Imaging: 1-minute anterior abdominal images obtained at 0, 10, 30, 60, 90 min in erect position if dual-head camera available; anterior and posterior imaging performed with geometric mean activity calculated

Pharmacokinetics:

79% tracer activity in stomach for solid phase at 10 minutes; 65% at 30 minutes; 33% at 60 minutes; 10% at 90 minutes

Normal result: 50% of activity in stomach at time zero; should empty by 60 ± 30 minutes

√ acutely delayed emptying in stress (pain, cold), drugs (morphine, anticholinergics, L-DOPA, nicotine, β-adrenergic antagonists), postoperative ileus, acute viral gastroenteritis, hyperglycemia, hypokalemia

√ chronically delayed gastric emptying in gastric outlet obstruction, postvagotomy, gastric ulcer, chronic idiopathic intestinal pseudoobstruction, GE reflux, progressive systemic sclerosis, dermatomyositis, spinal cord injury, myotonia dystrophica, familial dysautonomia, anorexia nervosa, hypothyroidism, diabetes mellitus, amyloidosis, uremia

√ abnormally rapid gastric emptying after gastric surgery, Z-E syndrome, duodenal ulcer disease, malabsorption (pancreatic exocrine insufficiency / celiac sprue)

Emergent Gastric Conditions

Mural stratification favors inflammation. Focal / nodular gastritis requires endoscopy and biopsy to exclude malignancy.

A. INFLAMMATION
   1. Emphysematous gastritis
   2. Peptic ulcer disease
   3. Marginal ulcer

B. OBSTRUCTION
   1. Gastric Volvulus
   2. Peptic ulcer disease
   3. Malignancy
   4. Bezoar
   5. Bouveret syndrome
   6. Slipped gastric band
   7. Vertical band gastroplasty

C. PERFORATION
   1. Peptic ulcer disease
   2. Malignancy
   3. Gastric banding

4. Penetrating trauma

D. HEMORRHAGE

E. ISCHEMIA

Gastric Tumor

Gastric Tumor Classification based on Cell Origin (WHO)

A. Epithelial (vast majority of gastric tumors)
Wall layer: mucosa

B. Nonepithelial = intramural = ~~submucosal~~
◊ Don't use "submucosal" in the sense of "deep to mucosa" because submucosa is its own specific layer
Wall layer: submucosa, muscularis propria, serosa

CECT:
√ prominent enhancement of gastric mucosa during arterial phase
√ enhancement of entire gastric wall during later phases without identification of distinct wall layers

Gastric Tumor Classification based on Biologic Behavior

A. MALIGNANT (10–15%)
(a) epithelial / mucosal tumor
1. Adenocarcinoma (> 95%)
2. Lymphoma, MALT
3. Carcinoid tumor
(b) mesenchymal tumor (50%)
1. Sarcoma: leiomyosarcoma, Kaposi sarcoma
2. Metastasis to stomach

B. BENIGN (85–90%)
(a) epithelial / mucosal tumor (50%)
1. Hyperplastic polyp
2. Adenomatous polyp
3. Brunner gland hyperplasia
(b) mesenchymal tumor (50%)

Mesenchymal Tumor of Stomach

= nonepithelial / intramural

A. GIST

B. SOMATIC SOFT TISSUE TUMOR
(a) smooth muscle tumor
1. True leiomyoma
2. True leiomyosarcoma
3. Plexiform fibromyxoma
(b) neural tumor (4% of all benign gastric tumors)
1. Schwannoma
2. Neurofibroma
3. Plexosarcoma

(c) lipocytic tumor
1. Lipoma
2. Liposarcoma

(d) vascular / perivascular tissue
◊ 2% of all benign gastric tumors
1. Glomus tumor (most common)
2. Hemangioma
3. Lymphangioma

(e) inflammatory tumor
1. Inflammatory fibroid polyp
2. Inflammatory myofibroblastic tumor

◊ Carcinoid tumor originates from Kulchitsky cell within gastric mucosa = epithelial origin. Tumor bulk is often submucosal, so they should be included in DDx of submucosal gastric tumors.

MESENCHYMAL GASTRIC TUMOR BY LOCATION

Some tumors are seen more frequently in certain parts of the stomach → tumor location is important for DDx

@ gastric cardia: leiomyoma
@ gastric body: GIST, schwannoma
@ gastric antrum: glomus tumor, inflammatory fibroid polyp, lipoma, ectopic panc

Calcified Gastric Tumor

1. Mucinous adenocarcinoma: miliary / punctate
2. Stromal tumors: amorphous calcifications
3. Hemangioma: clusters of phleboliths

Multiple Gastric Tumors

1. Carcinoid tumors
2. Hyperplastic polyps
3. Adenomatous polyps: familial adenomatous polyposis syndrome
4. Hamartomatous polyps: Peutz-Jeghers syndrome
5. Multiple hamartomas: Cowden disease
6. Metastases (usually intramural)

Congenital Gastric Obstruction

A. COMPLETE OBSTRUCTION

1. **Gastric atresia**
Frequency: < 1% of all GI obstructions
May be associated with: epidermolysis bullosa
Site: antrum + pylorus
• regurgitation of bile-free vomitus within first few hours after birth
√ "single bubble" appearance of air in stomach
√ membranous mucosal diaphragm
2. Congenital peritoneal bands
3. Annular pancreatic tissue

4. Gastric volvulus

B. PARTIAL GASTRIC OUTLET OBSTRUCTION

• cyclic transient postprandial vomiting

1. Incomplete prepyloric diaphragm
2. Antral stenosis
3. Aberrant pancreatic tissue in gastric antrum
4. Antral duplication cyst

Widened Retrogastric Space

A. PANCREATIC MASS (most common cause)

1. Acute + chronic pancreatitis
2. Pancreatic pseudocyst
3. Pancreatic cystadenoma + carcinoma

B. OTHER RETROPERITONEAL MASS

1. Sarcoma
2. Renal tumor, adrenal tumor
3. Lymph node enlargement
4. Abscess, hematoma

C. GASTRIC MASS

1. Leiomyoma, leiomyosarcoma

D. OTHERS

1. Aortic aneurysm
2. Choledochal cyst
3. Obesity
4. Postsurgical disruptions + adhesions
5. Ascites
6. Gross hepatomegaly + enlarged caudate lobe
7. Hernia involving omentum

Gas within Stomach Wall

A. NONINFECTIOUS

1. **Interstitial gastric emphysema**

   = gas accumulation in submucosa / subserosa / or both

   Cause: air from an extrinsic source

   (a) obstructive (← raised intragastric pressure): gastric outlet obstruction, volvulus, overinflation during gastroscopy, profuse severe vomiting

   (b) pulmonary (← rupture + dissection of subpleural blebs in bullous emphysema along esophageal wall / mediastinum): pulmonary emphysema

   (c) traumatic (← mucosal trauma): instrumentation of stomach, recent gastroduodenal surgery, endoscopy (1.6%)

   • benign clinical course with spontaneous resolution

   √ linear lucency conforming to contour of a thin-walled distended stomach

2. **Cystic pneumatosis**

   = PNEUMATOSIS CYSTOIDES INTESTINALIS

   Cause: similar to interstitial gastric emphysema

• little / no gastrointestinal symptoms
√ multiple 1–2-mm gas-filled cysts in wall of stomach and intestines

B. INFECTIOUS
1. Emphysematous gastritis
predisposed: corrosive gastritis, acid ingestion, severe necrotizing gastroenteritis, gastric ulcer disease with intramural perforation, gastric carcinoma, volvulus, gastric infarction

Gastric Atony

= gastric retention in the absence of mechanical obstruction
Pathophysiology: reflex paralysis
• abdominal distension, vomiting
• vascular collapse (decreased venous return)
√ large stomach filled with air + fluid (up to 7,500 mL)
√ retention of barium
√ absent / diminished peristaltic activity
√ patulous pylorus
√ frequently dilated duodenum
DDx: gastric volvulus, pyloric stenosis

Acute Gastric Atony

(may develop within 24–48 hours)
1. Acute gastric dilatation ← decreased arterial perfusion ← ischemia / CHF in old patients, usually fatal
2. Postsurgical atony, ureteral catheterization
3. Immobilization: body cast, paraplegia, postoperative state
4. Abdominal trauma: especially back injury
5. Severe pain: renal / biliary colic, migraine headaches, severe burns
6. Infection: peritonitis, pancreatitis, appendicitis, subphrenic abscess, septicemia

Chronic Gastric Atony

1. Neurologic abnormalities: brain tumor, bulbar poliomyelitis, vagotomy, tabes
2. Muscular abnormalities: scleroderma, muscular dystrophy
3. Drug-induced atony: atropine, morphine, heroin, ganglionic blocking agents
4. Electrolyte imbalance: diabetic ketoacidosis, hypercalcemia, hypocalcemia, hypokalemia, hepatic coma, uremia, myxedema
5. Diabetes mellitus = gastroparesis diabeticorum (0.08% incidence)
6. Emotional distress
7. Lead poisoning
8. Porphyria

Narrowing of Stomach

= **linitis plastica** type of stenosis

A. MALIGNANCY
1. Scirrhous gastric carcinoma (involving portion / all of stomach)
2. Hodgkin lymphoma, NHL

3. Metastatic involvement ← carcinoma of breast, pancreatic carcinoma, colonic carcinoma

B. INFLAMMATION
1. Chronic gastric ulcer disease with intense spasm
2. Pseudo-Billroth-I pattern of Crohn disease
3. Sarcoidosis
   √ polypoid appearance, pyloric hypertrophy
   √ gastric ulcers, duodenal deformity
4. Eosinophilic gastritis
5. Polyarteritis nodosa
6. Stenosing antral gastritis / hypertrophic pyloric stenosis

C. INFECTION
1. Tertiary stage of syphilis
   √ absent mucosal folds + peristalsis
   √ no change over years
2. Tuberculosis (rare)
   √ hyperplastic nodules / ulcerative lesion / annular lesion
   √ pyloric obstruction, may cross into duodenum
3. Histoplasmosis
4. Actinomycosis
5. Strongyloidiasis
6. Phlegmonous gastritis
7. Toxoplasmosis

D. TRAUMA
1. Corrosive gastritis
2. Radiation injury
3. Gastric freezing
4. Hepatic arterial chemotherapy infusion

E. OTHERS
1. Perigastric adhesions: normal mucosa, no interval change, normal peristalsis
2. Amyloidosis
3. Pseudolymphoma
4. Exogastric mass: hepatomegaly, pancreatic pseudocyst

mnemonic: SLIMRAGE
Scirrhous carcinoma of stomach
Lymphoma
Infiltration from adjacent neoplasm
Metastasis (breast carcinoma)
Radiation therapy
Acids (corrosive ingestion)
Granulomatous disease (TB, sarcoidosis, Crohn)
Eosinophilic gastroenteritis

Antral Narrowing

mnemonic: SPICER

Sarcoidosis, **S**yphilis
Peptic ulcer disease
Infection: TB, chronic granulomatous disease of childhood
Cancer (linitis plastica), **C**rohn disease, **C**austic ingestion
Eosinophilic gastritis
Radiation

Antral Pad Sign

= extrinsic impression of the posteroinferior wall of antrum

1. Pancreatic cancer in head / body
2. Pancreatitis
3. Pancreatic pseudocyst
4. Normal / distended gallbladder (patient in RAO position)

Intramural-extramucosal Lesion of Stomach

√ sharply delineated marginal / contour defect
√ stretched folds over intact mucosa
√ acute angle at margins
√ may ulcerate centrally
√ may become pedunculated and acquire polypoid appearance over years

A. NEOPLASTIC
   1. Leiomyoma 48%
   2. Neurogenic tumor 14%
   3. Heterotopic pancreas 12%
   4. Fibrous tumor 11%
   5. Lipoma 7%
   6. Hemangioma 7%
   7. Glomus tumor rare
   8. Carcinoid
   9. Metastatic tumor

B. INFLAMMATION / INFECTION
   1. Granuloma
      (1) Foreign-body granuloma
      (2) Sarcoidosis
      (3) Crohn disease
      (4) Tuberculosis
      (5) Histoplasmosis
   2. Eosinophilic gastritis
   3. Tertiary syphilis: infiltrative / ulcerative / tumorous type
   4. Echinococcal cyst

C. PANCREATIC ABNORMALITIES
   1. Ectopic pancreas
   2. Annular pancreas
   3. Pancreatic pseudocyst

D. DEPOSITS

1. Amyloid
2. Endometriosis
3. Localized hematoma

E. OTHERS
1. Varices: ie, fundal
2. Duplications (4% of all GI tract duplications)

Gastric Filling Defect

A. INTRINSIC WALL LESIONS
(a) benign (most common)
1. Polyp: hyperplastic, adenomatous, villous, hamar- tomatous (Peutz-Jeghers syndrome, Cowden disease)
2. Leiomyoma
3. Granulomatous lesion
(1) Eosinophilic granuloma
(2) Crohn disease
(3) Tuberculosis
(4) Sarcoidosis
4. Pseudolymphoma = benign reactive proliferation of lymphoid tissue
5. Extramedullary hematopoiesis
6. Ectopic pancreas
7. Gastric duplication cyst
8. Intramural hematoma
9. Esophagogastric herniation

(b) malignant
1. Gastric carcinoma, lymphoma
2. Gastric sarcoma: leiomyosarcoma, liposarcoma, leiomyoblastoma
3. Gastric metastases: melanoma, breast, pancreas, colon

B. EXTRINSIC IMPRESSION ON STOMACH
in 70% nonneoplastic (extrinsic pseudotumors in 20%)
(a) normal organ: organomegaly, tortuous aorta, heart, cardiac aneurysm
(b) benign mass: cysts of pancreas, liver, spleen, adrenal, kidney, gastric duplication, postoperative deformity (eg, Nissen fundoplication)
(c) malignant mass: enlarged celiac nodes
(d) inflammatory lesion: left subphrenic abscess / hematoma
› lateral displacement: enlarged liver, aortic aneurysm, enlarged celiac nodes
› medial displacement: splenomegaly, mass in colonic splenic flexure, cardiomegaly, subphrenic abscess

C. INTRALUMINAL GASTRIC MASS
1. Bezoar
2. Foreign bodies: food, pills, blood clot, gallstone

D. TUMOR OF ADJACENT ORGAN
1. Pancreatic carcinoma + cystadenoma
2. Liver carcinoma
3. Carcinoma of gallbladder

4. Colonic carcinoma
5. Renal carcinoma
6. Adrenal carcinoma
7. Lymph node involvement

E. THICKENED GASTRIC FOLDS

Filling Defect of Gastric Remnant

A. IATROGENIC surgical deformity / plication defect, suture granuloma
B. INFLAMMATORY bile reflux gastritis, hyperplastic polyps
C. INTUSSUSCEPTION
   1. **Jejunogastric intussusception**
      (efferent loop in 75%, afferent loop in 25%)
      (a) acute form: high intestinal obstruction, left hypochondriac mass, hematemesis
      (b) chronic / intermittent form: may be self-reducing
      √ "coiled spring" appearance of gastric filling defect
   2. Gastrojejunal / gastroduodenal mucosal prolapse
      • often asymptomatic, bleeding partial obstruction
D. NEOPLASTIC
   1. Gastric stump carcinoma: > 5 years after resection for benign disease; 15% (20%) within 10 (20) years
   2. Recurrent carcinoma (10%) ← incomplete removal of gastric cancer
   3. Malignancy at anastomosis: incomplete resection
E. INTRALUMINAL MATTER: bezoar

mnemonic: PUBLICS

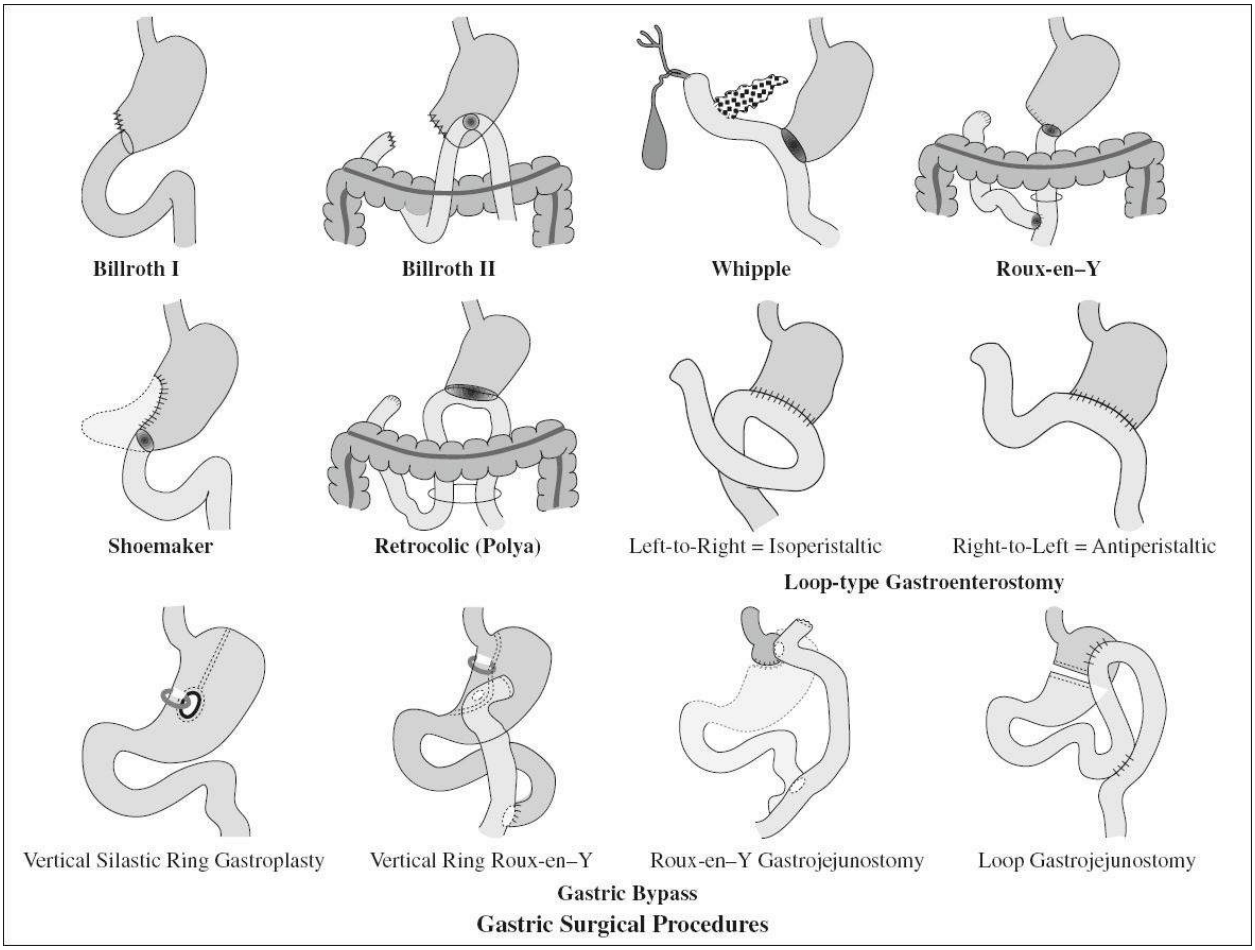
Polyp (hyperplastic polyp due to bile reflux)
Ulcer (anastomotic)
Bezoar, **B**lind loop syndrome
Loop (afferent loop syndrome)
Intussusception at gastrojejunostomy
Cancer (recurrent, residual, de novo)
Surgical deformity, **S**uture granuloma

Thickened Gastric Folds

A. INFLAMMATION / INFECTION
   1. Inflammatory gastritis:
      alcoholic, hypertrophic, antral, corrosive, postirradiation, gastric cooling
   2. Crohn disease
   3. Sarcoidosis
   4. Infectious gastritis:
      bacterial invasion, bacterial toxins from botulism, diphtheria, dysentery, typhoid fever, anisakiasis, TB, syphilis
   5. Pseudolymphoma
B. MALIGNANCY
   1. Lymphoma
   2. Gastric carcinoma

C. INFILTRATIVE PROCESS
   1. Eosinophilic gastritis
   2. Amyloidosis
D. PANCREATIC DISEASE
   1. Pancreatitis
   2. Direct extension from pancreatic carcinoma
E. OTHERS
   1. Zollinger-Ellison syndrome
   2. Ménétrier disease
   3. Gastric varices

mnemonic: ZEAL VOLUMES C3P3



Zollinger-**E**llison syndrome
Amyloidosis
Lymphoid hyperplasia
Varices
Operative defect
Lymphoma
Ulcer disease (peptic)

Ménétrier disease
Eosinophilic gastroenteritis
Syphilis
Crohn disease, **C**arcinoma, **C**orrosive gastritis
Pancreatitis, **P**ancreatic carcinoma,
Postradiation gastritis

Bull's-eye Lesion

A. PRIMARY NEOPLASMS
   1. Leiomyoma, leiomyosarcoma
   2. Lymphoma
   3. Carcinoid
   4. Primary carcinoma
B. HEMATOGENOUS METASTASES
   1. Malignant melanoma
      √ usually spares large bowel
   2. Breast cancer (15%)
      √ scirrhous appearance in stomach
   3. Cancer of lung
   4. Renal cell carcinoma
   5. Kaposi sarcoma
   6. Bladder carcinoma
C. ECTOPIC PANCREAS
   in duodenum / stomach
D. EOSINOPHILIC GRANULOMA
   most frequently in stomach

Complications of Postoperative Stomach

1. Filling defect of gastric remnant
2. Retained gastric antrum
3. Dumping syndrome
4. Afferent loop syndrome
5. Stomal obstruction
   (a) temporary reversible: edema of suture line, abscess / hematoma, potassium deficiency, inadequate electrolyte replacement, hypoproteinemia, hypoacidity
   (b) late mechanical: stomal ulcer (75%)

mnemonic: LOBULATING
Leaks (early)
Obstruction (early)
Bezoar
Ulcer: especially marginal
Loop: afferent loop syndrome
Anemia: macrocytic ← decreased intrinsic factor
Tumor (? increased incidence)
Intussusception

Not feeling well after meals: dumping syndrome
Gastritis: bile reflux

Transpyloric Disease

= LESIONS INVOLVING STOMACH AND DUODENUM

1. Lymphoma: in up to 40% of patients with lymphoma
2. Gastric carcinoma: in 5–25%, but 50 x more common than lymphoma
3. Peptic ulcer disease
4. Tuberculosis: in 10% of gastric TB
5. Crohn disease: pseudo-Billroth-I pattern
6. Strongyloidiasis
7. Eosinophilic gastroenteritis

Transpyloric spread by itself does not make a diagnosis of lymphoma because of the higher incidence of gastric cancer!

DUODENUM

Congenital Duodenal Obstruction

- bile-stained vomiting delayed until after first feeding and increasing progressively

1. Duodenal atresia / severe stenosis
2. Annular pancreas
3. Midgut volvulus
4. Duodenal web
5. Ladd bands
6. Preduodenal portal vein
7. Duodenal duplication cyst

Severe duodenal obstruction is characterized by 2 air-fluid levels on the upright view ("double bubble sign"), the largest below the left hemidiaphragm (= gastric distention), the smaller on the right side of the spine (= dilated proximal duodenum).

Extrinsic Pressure Effect on Duodenum

A. BILE DUCTS
normal impression, dilated CBD, choledochal cyst
B. GALLBLADDER
normal impression, gallbladder hydrops, Courvoisier phenomenon, gallbladder carcinoma, pericholecystic abscess
C. LIVER
hepatomegaly, hypertrophied caudate lobe, anomalous hepatic lobe, hepatic cyst, hepatic tumor
D. RIGHT KIDNEY
bifid collecting system, hydronephrosis, multiple renal cysts, polycystic kidney disease, hypernephroma
E. RIGHT ADRENAL
adrenal carcinoma, enlargement in Addison disease

F. COLON
duodenocolic apposition ← anomalous peritoneal fixation, carcinoma of hepatic flexure
G. VESSELS
lymphadenopathy, duodenal varices, dilated arterial collaterals, aortic aneurysm, intramural / mesenteric hematoma

Widened Duodenal Sweep

A. NORMAL Variant
B. PANCREATIC LESION
1. Acute pancreatitis
2. Groove pancreatitis
3. Pancreatic pseudocyst
4. Pancreatic carcinoma
5. Metastasis to pancreas
6. Pancreatic cystadenoma
C. VASCULAR LESION
1. Lymph node enlargement: lymphoma, metastasis, inflammation
2. Cystic lymphangioma of the mesentery
D. RETROPERITONEAL MASS
1. Aortic aneurysm
2. Choledochal cyst

Thickened Duodenal Folds

A. INFLAMMATION
(a) within bowel wall:
1. Peptic ulcer disease
2. Zollinger-Ellison syndrome
3. Crohn disease (regional enteritis)
4. Lymphoid hyperplasia
5. Uremia
6. Celiac disease
(b) surrounding bowel wall: pancreatitis, cholecystitis
B. INFECTION
giardiasis, TB, strongyloidiasis, disseminated histoplasmosis
C. NEOPLASIA
lymphoma, metastases to peripancreatic nodes
D. DIFFUSE INFILTRATIVE DISORDER
Whipple disease, amyloidosis, mastocytosis, eosinophilic enteritis, intestinal lymphangiectasia
E. VASCULAR DISORDER
duodenal varices, mesenteric arterial collaterals, intramural hemorrhage (trauma, Schönlein-Henoch purpura), chronic duodenal congestion (CHF, portal venous hypertension); lymphangiectasia
F. HYPOPROTEINEMIA
nephrotic syndrome, Ménétrier disease, protein-losing enteropathy

G. GLANDULAR ENLARGEMENT
Brunner gland hyperplasia, cystic fibrosis
mnemonic: BAD HELP
Brunner gland hyperplasia
Amyloidosis
Duodenitis: Z-E syndrome, peptic ulcer
Hemorrhage
Edema, **E**ctopic pancreas
Lymphoma
Pancreatitis, **P**arasites

Duodenal Filling Defect

A. EXTRINSIC gallbladder impression, CBD impression, gas-filled diverticulum
B. INTRINSIC TO WALL
(a) benign neoplastic mass
1. Adenoma
2. Leiomyoma
3. Lipoma
4. Hamartoma (Peutz-Jeghers syndrome)
5. Prolapsed antral polyp
6. Brunner gland adenoma
7. Villous adenoma
8. Islet cell tumor
9. Gangliocytic paraganglioma

(b) malignant neoplastic mass
1. Carcinoid tumor
2. Adenocarcinoma
3. Ampullary cancer
4. Lymphoma
5. Sarcoma
6. Metastasis: stomach, pancreas, gallbladder, colon, kidney, melanoma
7. Retroperitoneal lymph node involvement

(c) nonneoplastic mass
1. Papilla of Vater
2. Choledochocele
3. Duplication cyst
4. Pancreatic pseudocyst
5. Duodenal varix
6. Mesenteric artery collaterals
7. Intramural hematoma
8. Inflammatory mass: adjacent abscess, stitch abscess
9. Ectopic pancreas, heterotopic gastric mucosa
10. Prolapsed antral mucosa
11. Brunner gland hyperplasia
12. Benign lymphoid hyperplasia

13. Flexural pseudopolyp

C. INTRALUMINAL
1. Blood clot
2. Foreign body: fruit pit, gallstone, feeding tube

Duodenal Tumor

Benign Duodenal Tumors

= typically small polyps < 2 cm in diameter

1. GIST 27%
2. Leiomyoma ?
3. Adenomatous polyp 21%
   › villous adenoma
   › tubular adenoma
   › Brunner gland adenoma 17%
4. Lipoma 21%
5. Angiomatous tumor 6%
6. Ectopic pancreas 2%
7. Duodenal cyst 2%
8. Neurofibroma 2%
9. Hamartoma 2%

Malignant Duodenal Tumors

1. Duodenal adenocarcinoma (73%)
2. **Periampullary carcinoma**
   = tumor arising within 1 cm from papilla of Vater
   Origin: ampulla, pancreas, bile duct, duodenum
   At risk: familial adenomatous polyposis
   √ may not be seen at CT / MR due to small size
   √ hypovascular polypoid mass at ampulla
   Associated with: "double duct" sign ← biliary and pancreatic ductal dilatation
   Prognosis: ampullary ca. (best), pancreatic ca. (worst)
3. Malignant GIST (14%)
   most often beyond 1st portion of duodenum
   √ up to 20 cm in size
   √ frequently ulcerated exophytic mass
4. Carcinoid (11%)
5. Lymphoma (2%)
   √ marked wall thickening
   √ bulky periduodenal lymphadenopathy
6. APUDoma
7. Metastasis
8. Leiomyosarcoma

Enlargement of Papilla of Vater

[Abraham Vater (1684–1751), anatomist in Wittenberg, Germany]

A. Normal variant
   identified in 60% of UGI series; atypical location in 3rd portion of duodenum in 8%; 1.5 cm in diameter in 1% of normals
B. Papillary edema
   1. Impacted stone
   2. Pancreatitis (Poppel sign)
   3. Acute duodenal ulcer disease
   4. Papillitis
C. Perivaterian neoplasms
   = tumor mass + lymphatic obstruction
   1. Adenocarcinoma
   2. Adenomatous polyp (premalignant lesion)
      √ irregular surface + erosions
D. Lesions simulating enlarged papilla
   1. Benign spindle cell tumor
   2. Ectopic pancreatic tissue

Duodenal Narrowing

A. DEVELOPMENTAL ANOMALY
   1. Duodenal atresia
   2. Congenital web / duodenal diaphragm
   3. Intraluminal diverticulum
   4. Duodenal duplication cyst
   5. Annular pancreas
   6. Midgut volvulus, peritoneal bands (Ladd bands)
B. INTRINSIC DISORDER
   (a) inflammation / infection
      1. Postbulbar ulcer
      2. Crohn disease
      3. Sprue
      4. Tuberculosis
      5. Strongyloidiasis
   (b) intramural tumor
      1. GIST (90%)
      2. Lipoma, leiomyoblastoma
      3. Hemangioma, lymphangioma
      4. Ectopic pancreatic rest, Brunner gland hamartoma
      5. Duodenal carcinoma, periampullary carcinoma
C. DISEASE IN ADJACENT STRUCTURES
   1. Pancreatitis, pseudocyst, pancreatic carcinoma
   2. Cholecystitis
   3. Contiguous abscess
   4. Metastases to pancreaticoduodenal nodes: lymphoma, lung cancer, breast cancer
D. TRAUMA

1. Duodenal rupture
2. Intramural duodenal hematoma

E. VASCULAR
1. Superior mesenteric artery syndrome
2. Aorticoduodenal fistula
3. Preduodenal portal vein (anterior to descending duodenum)

Dilated Duodenum

Megaduodenum = marked dilatation of entire C-loop
Megabulb = dilatation of duodenal bulb only

A. VASCULAR COMPRESSION
superior mesenteric artery syndrome, abdominal aortic aneurysm, aorticoduodenal fistula

B. PRIMARY DUODENAL ATONY
(a) scleroderma, dermatomyositis, SLE
(b) Chagas disease, aganglionosis, neuropathy, surgical / chemical vagotomy
(c) focal ileus: pancreatitis, cholecystitis, peptic ulcer disease, trauma
(d) altered emotional status, chronic idiopathic intestinal pseudoobstruction

C. INFLAMMATORY / NEOPLASTIC INDURATION OF MESENTERIC ROOT
Crohn disease, tuberculous enteritis, pancreatitis, peptic ulcer disease, strongyloidiasis, metastatic disease

D. FLUID DISTENSION
celiac disease, Zollinger-Ellison syndrome

Benign Wall Thickening of Duodenum

1. **Cystic dystrophy** of duodenal wall
   = dilatation of pancreatic ducts in ectopic pancreatic tissue within wall of 2nd portion of duodenum ← duct obstruction
2. Pancreatic hamartoma
3. Paraduodenal wall cyst
4. Myoadenomatosis
5. Groove pancreatitis

Postbulbar Ulceration

1. Benign postbulbar peptic ulcer (10%)
2. Zollinger-Ellison syndrome
3. Gastrointestinal stromal tumor (GIST)
4. Malignant tumors:
   (a) primary
   adenocarcinoma, lymphoma, sarcoma
   (b) contiguous spread
   pancreas, colon, kidney, gallbladder
   (c) hematogenous spread
   melanoma, Kaposi sarcoma
   (d) lymphogenic spread
   metastases to periduodenal lymph nodes

5. Granulomatous disease: Crohn disease, TB, CMV
6. Aorticoduodenal fistula
7. Mimickers: ectopic pancreas, diverticulum

SMALL BOWEL

Anatomic Predilection for Intestinal Involvement

@ proximal jejunum	diverticulosis, giardiasis, adenocarcinoma, Whipple disease, Z-E syndrome, celiac disease
@ distal ileum	Crohn disease, TB, infectious enteritis, lymphoma, carcinoid, metastases
@ mesenteric border	diverticulosis, Crohn disease, mesenteric hematoma, intraperitoneal spread of tumor
@ antimesenteric border	Meckel diverticulum, sacculations in scleroderma, hematogenous metastases

Increased Fluid within Small Bowel

1. Ingestion
2. Resection / removal of stomach
3. Small-bowel obstruction
4. Enteritis
5. Malabsorption: celiac disease, Whipple disease
6. Peritoneal carcinomatosis

Small Bowel Diverticula

A. TRUE DIVERTICULA
   (a) Duodenal diverticula
      1. Racemose diverticula: bizarre, lobulated
      2. Giant diverticula
      3. Intraluminal diverticula: result of congenital web / diaphragm
   (b) Jejunal diverticulosis
   (c) Meckel diverticulum

B. PSEUDODIVERTICULA
   1. Scleroderma
   2. Crohn disease
   3. Lymphoma
   4. Mesenteric ischemia
   5. Communicating ileal duplication
   6. Giant duodenal ulcer

Small Bowel Ulcer

Aphthous Ulcers of Small Bowel

A. INFECTION
   1. Yersinia enterocolitis (25%)
   2. Salmonellosis

3. Tuberculosis
4. Rickettsiosis

B. INFLAMMATION
1. Crohn disease (22%)
2. Behçet disease
3. Reiter syndrome
4. Ankylosing spondylitis

Large Nonstenotic Ulcers of Small Bowel

1. Primary nonspecific ulcer 47% incidence
2. Yersiniosis 33%
3. Crohn disease 30%
4. Tuberculosis 18%
5. Salmonellosis / shigellosis 7%
6. Meckel diverticulum 5%

Multiple Small Bowel Ulcers

A. DRUGS
1. Potassium tablets
2. Steroids
3. Nonsteroidal antiinflammatory drugs

B. INFECTION / INFLAMMATION
1. Bacillary dysentery
2. Ischemic enteritis
3. Ulcerative jejunoileitis as complication of celiac disease

C. TUMOR
1. Neoplasms
2. Intestinal lymphoma

Cavitary Small Bowel Lesion

A. PRIMARY TUMOR
1. Lymphoma (exoenteric form)
2. Leiomyosarcoma (exoenteric form)
3. Primary adenocarcinoma

B. METASTASIS
1. Malignant melanoma
2. Lung cancer

C. INFLAMMATION
1. Diverticulitis with abscess: Meckel, jejunal
2. Communicating duplication cyst

Separation of Bowel Loops

A. INFILTRATION OF BOWEL WALL / MESENTERY

(a) inflammation / infection
1. Crohn disease
2. TB

3. Radiation injury
4. Retractile mesenteritis
5. Intraperitoneal abscess

(b) deposits
1. Intestinal hemorrhage / mesenteric vascular occlusion
2. Whipple disease
3. Amyloidosis

(c) tumor
1. Carcinoid tumor: local release of serotonin responsible for muscular thickening + fibroplastic proliferation = desmoplastic reaction
2. Primary carcinoma of small bowel (unusual presentation)
3. Lymphoma
4. Neurofibromatosis

B. ASCITES / INTRAPERITONEAL BLEEDING hepatic cirrhosis (75%), peritonitis, peritoneal carcinomatosis, congestive heart failure, constrictive pericarditis, primary / metastatic lymphatic disease

C. EXTRINSIC MASS
1. Intraperitoneal spread of tumor: peritoneal mesothelioma, mesenteric tumors (fibroma, lipoma, fibrosarcoma, leiomyosarcoma, malignant mesenteric lymphoid tumor, metastases)
2. Interloop abscesses / loculated fluid collection
3. Endometriosis
4. Retractile mesenteritis (fibrosis, fatty infiltration, panniculitis)
5. Mesenteric fat deposits
6. Fibrofatty proliferation: Crohn disease, mesenteric panniculitis

Normal Small Bowel Folds & Diarrhea

1. Pancreatic insufficiency
2. Lactase deficiency
3. Lymphoma / pseudolymphoma

Dilated Small Bowel & Normal Folds

mnemonic: SOS

Sprue
Obstruction
Scleroderma

A. EXCESSIVE FLUID

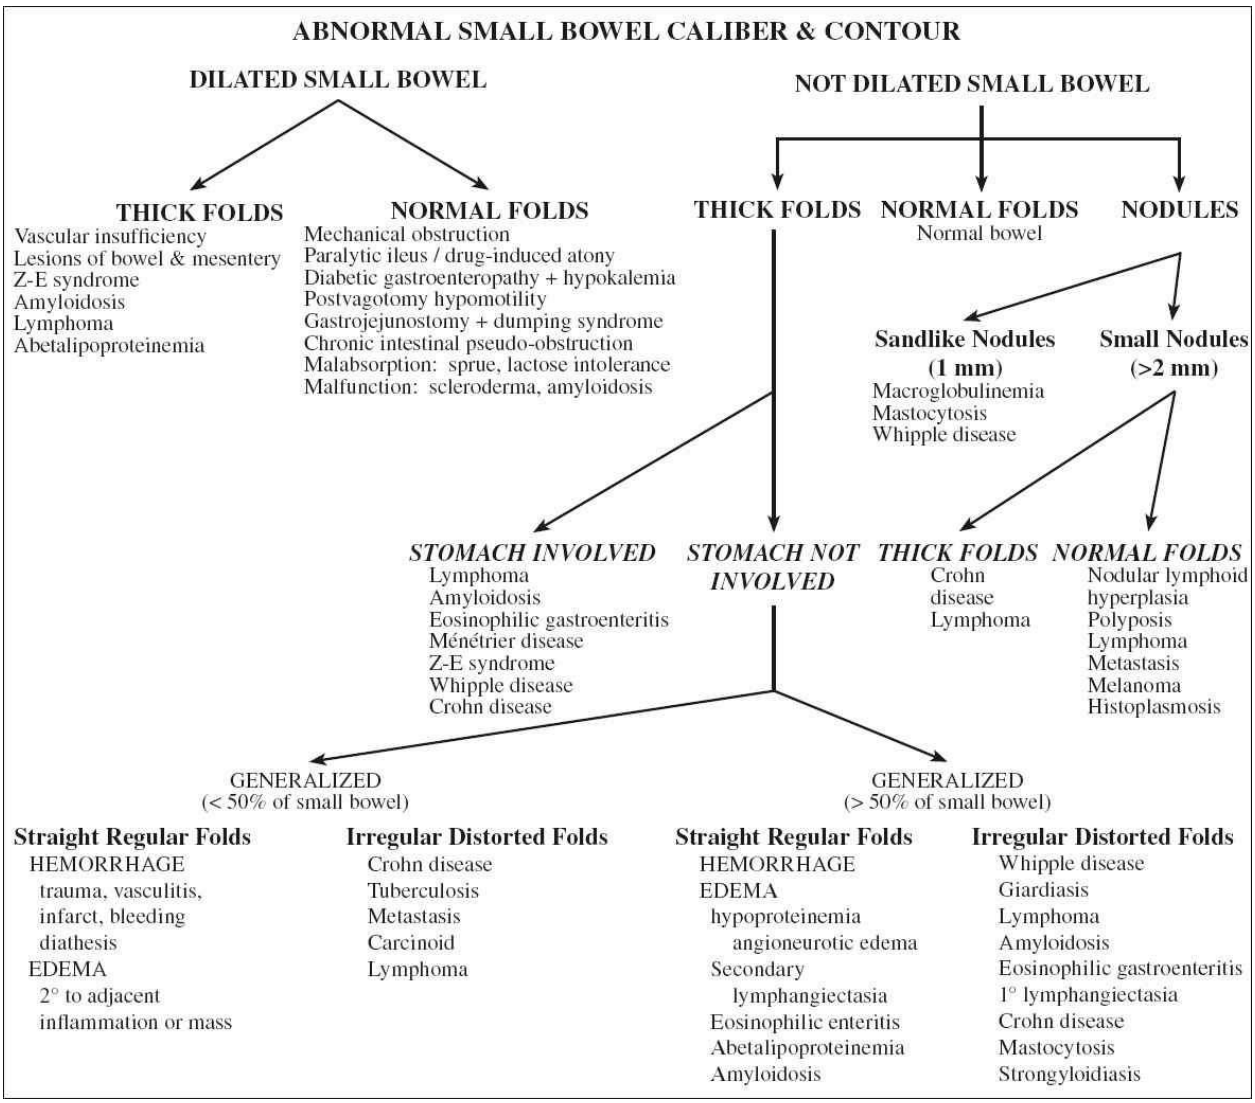
(a) mechanical obstruction ← adhesion, hernia, neoplasm
√ "string-of-beads" sign = air bubbles between mucosal folds in a fluid-filled small bowel
√ "pseudotumor" sign = closed-loop obstruction

(b) malabsorption syndromes
1. Celiac disease, tropical + nontropical sprue
2. Lactase deficiency

B. BOWEL WALL PARALYSIS

= functional ileus = adynamic ileus

1. Surgical vagotomy
2. Chemical vagotomy from drug effects: atropine-like substances, morphine, L-dopa, glucagon
3. Chagas disease
4. Metabolic: hypokalemia, diabetes
5. Intrinsic + extrinsic intraabdominal inflammation
6. Chronic idiopathic pseudoobstruction



C. VASCULAR COMPROMISE

1. Mesenteric ischemia: atherosclerosis
2. Acute radiation enteritis
3. Amyloidosis
4. SLE

D. BOWEL WALL DESTRUCTION

1. Lymphoma
2. Scleroderma: smooth muscle atrophy
3. Dermatomyositis

Abnormal Small Bowel Folds

Abnormal Folds + Increased Intraluminal Fluid

1. Malabsorption syndrome
2. Crohn disease, infectious enteritis
3. Parasitic infestation / giardiasis
4. Ischemia proximal to an obstruction
5. Zollinger-Ellison syndrome
6. Lymphangiectasia, mesenteric lymphadenopathy

Thickened Folds of Stomach & Small Bowel

1. Lymphoma
2. Crohn disease
3. Eosinophilic gastroenteritis
4. Zollinger-Ellison syndrome
5. Ménétrier disease
6. Cirrhosis = gastric varices + hypoproteinemia
7. Amyloidosis
8. Whipple disease
9. Systemic sclerosis

Thickened Smooth Folds ± Dilatation

A. EDEMA
   (a) hypoproteinemia
      1. Cirrhosis
      2. Nephrotic syndrome
      3. Protein-losing enteropathy: celiac disease, Whipple disease
   (b) increased capillary permeability
      1. Angioneurotic edema = angioedema
      2. Gastroenteritis
   (c) increased hydrostatic pressure
      1. Portal venous hypertension
   (d) Zollinger-Ellison syndrome

B. HEMORRHAGE
   (a) vessel injury
      1. Ischemia
      2. Infarction
      3. Trauma
   (b) vasculitis
      1. Connective tissue disease
      2. Henoch-Schönlein purpura
      3. Thrombangiitis obliterans, irradiation

(c) hypocoagulability
1. Hemophilia
2. Anticoagulant therapy
3. Hypofibrinogemia
4. Circulating anticoagulants
5. Fibrinolytic system activation
6. Idiopathic thrombocytopenic purpura
7. Coagulation defects: leukemia, lymphoma, multiple myeloma, metastatic carcinoma
8. Hypoprothrombinemia

C. LYMPHATIC BLOCKAGE
1. Tumor infiltration: lymphoma, pseudolymphoma
2. Irradiation
3. Mesenteric fibrosis
4. Intestinal lymphangiectasia
5. Whipple disease

D. DEPOSITS
1. Eosinophilic enteritis
2. Pneumatosis intestinalis
3. Amyloidosis
4. Abetalipoproteinemia
5. Crohn disease
6. Graft-versus-host disease
7. Immunologic deficiency: hypo- / dysgammaglobulinemia

Thickened Irregular Folds ± Dilatation

A. INFLAMMATION
1. Crohn disease

B. NEOPLASTIC
1. Lymphoma, pseudolymphoma

C. INFECTION
(a) protozoan: giardiasis, strongyloidiasis, hookworm
(b) bacterial: Yersinia enterocolitica, typhoid fever, TB
(c) fungal: histoplasmosis
(d) AIDS-related infection

D. IDIOPATHIC
(a) lymphatic dilatation
1. Lymphangiectasia
2. Inflammatory process, tumor growth, irradiation fibrosis
3. Whipple disease

(b) cellular infiltration
1. Eosinophilic enteritis
2. Mastocytosis

(c) deposits
1. Zollinger-Ellison syndrome

2. Amyloidosis
3. Alpha chain disease: defective secretory IgA system
4. A-β-lipoproteinemia: recessive, retinitis pigmentosa, neurologic disease
5. A-α-lipoproteinemia
6. Fibrocystic disease of the pancreas
7. Polyposis syndrome

mnemonic: G. WILLIAMS

Giardiasis
Whipple disease, **W**aldenström macroglobulinemia
Ischemia
Lymphangiectasia
Lymphoma
Inflammation
Amyloidosis, **A**gammaglobulinemia
Mastocytosis, **M**alabsorption
Soft-tissue neoplasm: carcinoid, lipoma

Tethered Folds

= indicative of desmoplastic reaction
√ kinking, angulation, tethering, separation of bowel loops

1. Carcinoid
2. Postoperative in Gardner syndrome
3. Retractile mesenteritis
4. Hodgkin disease
5. Peritoneal implants
6. Endometriosis
7. Tuberculous peritonitis
8. Mesothelioma
9. Postoperative adhesions

Atrophy of Small Bowel Folds

1. Chronic malabsorption: celiac disease
2. Chronic ischemic changes: radiation injury, amyloidosis
3. Crohn disease in burned-out stage
4. Parasitic infestation: strongyloidiasis
5. Graft-versus-host disease

Ribbonlike Small Bowel

= featureless / tubular nature of small bowel with effacement of folds

1. Graft-versus-host disease
2. Celiac disease
3. Small bowel infection: eg, viral enteritis
4. Injury from radiation / corrosive medication
5. Allergy: eg, soybeans
6. Ischemia

7. Amyloid, mastocytosis
8. Lymphoma, pseudolymphoma
9. Crohn disease

Delayed Small Bowel Transit

= transit time > 6 hr

mnemonic: SPATS DID

Scleroderma
Potassium (hypokalemia)
Anxiety
Thyroid (hypothyroidism)
Sprue
Diabetes (poorly controlled)
Idiopathic
Drugs (opiates, atropine, phenothiazine)

Constricting Lesion of Small Bowel

1. Primary adenocarcinoma (proximal jejunum)
2. Carcinoid (distal ileum)
3. Lymphoma, metastasis
4. Endometriosis
5. Adhesion, mucosal diaphragm
6. Strictures: Crohn disease, radiation enteritis, ischemia, potassium chloride tablets

Multiple Stenotic Lesions of Small Bowel

1. Crohn disease
2. End-stage radiation enteritis
3. Metastatic carcinoma
4. Endometriosis
5. Eosinophilic gastroenteritis
6. Tuberculosis
7. Drug-induced (eg, potassium chloride tablets, NSAIDs)

FEATURELESS BOWEL

1. Crohn disease
2. Chronic graft-versus-host disease
3. Radiation therapy

Small Bowel Filling Defects

Solitary Filling Defect of Small Bowel

A. INTRINSIC TO BOWEL WALL
   (a) benign neoplasm: leiomyoma (97%), adenoma, lipoma, hemangioma, neurofibroma
   (b) malignant primary: adenocarcinoma, lymphoma (desmoplastic response), sarcoma, carcinoid
   (c) metastases: ← melanoma, lung, kidney, breast

(d) inflammation: inflammatory pseudotumor
(e) infection: parasites

B. EXTRINSIC TO BOWEL WALL
1. Duplication cyst
2. Endometrioma

C. INTRALUMINAL
1. Gallstone ileus
2. Parasites: ascariasis, strongyloidiasis
3. Inverted Meckel diverticulum
4. Blood clot
5. Foreign body, bezoar, pills, seeds

Multiple Filling Defects of Small Bowel

A. POLYPOSIS SYNDROMES
1. Peutz-Jeghers syndrome
2. Gardner syndrome
3. Disseminated gastrointestinal polyposis
4. Generalized gastrointestinal juvenile polyposis
5. Cronkhite-Canada syndrome

B. BENIGN TUMORS
1. Multiple simple adenomatous polyps
2. Hemangioma, blue rubber bleb nevus syndrome
3. Leiomyoma, neurofibroma, lipoma
4. Nodular lymphoid hyperplasia
= normal terminal ileum in children + adolescents; may be associated with dysgammaglobulinemia
√ symmetric fairly sharply demarcated filling defects
5. Varices (= multiple phlebectasia in jejunum, oral mucosa, tongue, scrotum)

C. MALIGNANT TUMORS
1. Carcinoid tumor
2. Lymphoma
(a) primary lymphoma (rarely multiple)
(b) secondary lymphoma: GI involvement in 63% of disseminated disease; 19% in small intestine
3. Kaposi sarcoma
4. Subepithelial metastases: melanoma > lung > breast > choriocarcinoma > kidney > stomach, uterus, ovary, pancreas

D. INTRALUMINAL
1. Gallstones
2. Foreign bodies, food particles, seeds, pills
3. Parasites: ascariasis, strongyloidiasis, hookworm, tapeworm

Sandlike Lucencies of Small Bowel

1. Waldenström macroglobulinemia
2. Mastocytosis

3. Histoplasmosis
4. Nodular lymphoid hyperplasia
5. Intestinal lymphangiectasia
6. Eosinophilic gastroenteritis
7. Lymphoma
8. Crohn disease
9. Whipple disease
10. Yersinia enterocolitis
11. Cronkhite-Canada syndrome
12. Cystic fibrosis
13. Food particles / gas bubbles
14. Strongyloides stercoralis

Small Bowel Tumors

Prevalence: 1÷100,000; 1%–2% of all GI neoplasms

Malignant÷benign = 3÷2

Symptomatic malignant÷symptomatic benign = 3÷1

Location of small bowel primaries:

ileum (41%), jejunum (36%), duodenum (18%)

- pain, obstruction, anorexia, weight loss
- bleeding, perforation, jaundice

In order of frequency:

adenocarcinoma > carcinoid tumor > lymphoma > GIST

ROENTGENOGRAPHIC APPEARANCE:

(1) pedunculated intraluminal tumor, usually originating from mucosa
- √ smooth / irregular surface without visible mucosal pattern
- √ moves within intestinal lumen twice the length of the stalk

(2) sessile intraluminal tumor without stalk, usually from tissues outside mucosa
- √ smooth / irregular surface without visible mucosal pattern

(3) intra- / extramural tumor
- √ base of tumor greater than any part projecting into the lumen
- √ mucosal pattern visible, may be stretched

(4) serosal tumor
- √ displacement of adjacent loops
- √ small bowel obstruction (rare)
- √ coil-spring pattern of intussusceptum

CT:
- √ abnormalities associated with small bowel tumors (90%)
- √ small bowel wall > 1.5 cm thick

Cx: small-bowel obstruction (in up to 10%)

Benign Small Bowel Tumors

- asymptomatic (80%)
- melena, intermittent abdominal pain, weakness
- palpable abdominal mass (20%)

Types:

1. GIST 36–49%
2. Adenoma 15–20%
3. Lipoma 14–16%
4. Hemangioma 13–16%
5. Lymphangioma 5%
   Location: duodenum > jejunum > ileum
6. Neurogenic tumor 1%
7. Hamartomatous polyps (Peutz-Jeghers syndrome)
8. Hyperplastic polyp

Malignant Small Bowel Tumors

At risk: Crohn disease, celiac disease, polyposis syndromes, history of small-bowel diverting surgery

- asymptomatic (10–30%)
- pain due to intermittent obstruction (80%)
- weight loss (66%)
- gastrointestinal blood loss (50%)
- palpable abdominal mass (50%)

PRIMARY MALIGNANT SMALL BOWEL TUMOR

1. Adenocarcinoma 40%
2. Carcinoid 33%
3. Lymphoma 16–17%
4. GIST 9–10%
5 Vascular malignancy 1%
6. Fibrosarcoma 0.3%

SECONDARY MALIGNANT SMALL BOWEL TUMOR

◊ Most common neoplasm of small intestines!

CECUM

Ileocecal Valve Abnormalities

A. BENIGN NEOPLASM

1. **Lipomatosis of ileocecal valve**: predominantly in female > 40 years of age
   √ symmetric stellate / rosette pattern
2. Lipoma
3. Adenomatous polyp, villous adenoma
4. Lymphoid hyperplasia

B. PRIMARY MALIGNANT NEOPLASM

1. Adenocarcinoma of cecum
   Incidence: 25% of colonic adenocarcinomas
2. Ileal carcinoid tumor
3. Lymphoma
4. GIST (rare)

C. SECONDARY MALIGNANT NEOPLASM
   1. Adenocarcinoma of terminal ileum / appendix
   2. Direct invasion from ovarian neoplasm / intraperitoneal seeding
   3. Metastasis

D. IDIOPATHIC INFLAMMATION
   1. Crohn disease
   2. Ulcerative colitis
      √ patulous valve, fixed in open position

E. INFECTIOUS CONDITION
   1. Tuberculosis
   2. Infectious ileocecitis
   3. Typhlitis

F. PROLAPSE
   (a) antegrade: indistinguishable from lipomatosis / prolapsing mucosa / neoplasm
   (b) retrograde

G. INTUSSUSCEPTION

H. OTHERS
   1. Cathartic abuse
   2. Ischemic necrosis of cecum
   3. Volvulus
   4. Ileocecal duplication cyst

Coned Cecum

A. INFLAMMATION
   1. Crohn disease
      √ involvement of ascending colon + terminal ileum
   2. Ulcerative colitis
      √ backwash ileitis (in 10%)
      √ gaping ileocecal valve
   3. Appendicitis
   4. Typhlitis
   5. Perforated cecal diverticulum

B. INFECTION
   1. Tuberculosis
      √ colonic involvement more prominent than that of terminal ileum
   2. Amebiasis
      √ involvement of cecum in 90% of amebiasis
      √ thickened ileocecal valve fixed in open position
      √ reflux into normal terminal ileum
      √ skip lesions in colon
   3. Actinomycosis
      • palpable abdominal mass
      • indolent sinus tracts in abdominal wall
   4. Blastomycosis

5. Anisakiasis
6. Typhoid, Yersinia

C. TUMOR
1. Adenocarcinoma of the cecum
   Frequency: 25% of colon cancers; 95% of malignant cecal masses are adenocarcinomas
   √ large polypoid bulky mass causing asymmetric wall thickening
   √ mild pericolic fat infiltration
   √ rarely obstructing
   √ may act as lead point for intussusception
2. Metastasis to cecum

CT Features of Ileocecal Disease

Feature	*Adenocarcinoma*	*Lymphoma*	*Crohn Disease*	*Infectious Ileitis*	*Ischemia / Typhlitis*	*Cecal diverticulitis*
Stratified bowel wall	-	-	+ (if acute)	+	+	+
Bowel wall thickening	severe irregular eccentric	severe smooth ± symmetric	mild, rarely > 2 cm, symmetric	mild / marked, symmetric	mild / marked, symmetric	mild smooth concentric
Length	focal	segmental	segmental	segmental	segmental	focal
Fat stranding	minimal	0 / -	+	+	+	++
Transition to normal	abrupt	gradual	smooth	smooth	smooth	smooth
Fluid	-	-	occasional	occasional	occasional	mesenteric root
Lymphadenopathy	regional	bulky retroperitoneal	regional	regional	-	±
Others	mets	cavitary mass, solid organ + other GI sites involved	skip lesions, creeping fat, fistula, abscess	diarrhea	pneumatosis	inflamed diverticulum

Cecal Filling Defect

A. ABNORMALITIES OF THE APPENDIX
1. Acute appendicitis / appendiceal abscess
2. Crohn disease
3. Inverted appendiceal stump / appendiceal intussusception
4. Mucocele
5. Myxoglobulosis
6. Appendiceal neoplasm: carcinoid tumor (90%), leiomyoma, neuroma, lipoma, adenocarcinoma, metastasis

B. COLONIC LESION
1. Ameboma
2. Primary cecal neoplasm
3. Ileocolic intussusception
4. Lipomatosis of ileocecal valve

C. UNUSUAL ABNORMALITIES
1. Ileocecal diverticulitis (in 50% < age 30 years)
2. Solitary benign ulcer of the cecum
3. Adherent fecolith: eg, in cystic fibrosis
4. Endometriosis
5. Burkitt lymphoma

mnemonic: CECUM TIP SALE

Carcinoma
Enteritis
Carcinoid
Ulcerative colitis
Mucocele of appendix
Tuberculosis
Intussusception
Periappendiceal abscess
Stump of the appendix
Ameboma
Lymphoma
Endometriosis

Pericecal Fat-stranding on CT

1. Appendicitis
2. Crohn disease
3. Tuboovarian abscess
4. Cecal diverticulitis
5. Perforated cecal carcinoma

APPENDIX

Primary Neoplasm of the Appendix

1. Mucocele:
   mucinous adenoma 44%
   adenocarcinoma 23%
2. Colonic-type adenocarcinoma 13%
3. NHL
4. Carcinoid tumor

Appendiceal Intussusception

1. Mucocele
2. Endometrioma
3. Fecolith
4. Foreign body
5. Polyp: juvenile, inflammatory
6. Papilloma
7. Adenoma / adenocarcinoma
8. Carcinoid tumor
9. Postappendectomy stump

COLON

Colon Cutoff Sign

= abrupt termination of colonic gas column at splenic flexure with decompression of the

distal colon due to spasm + obstruction at the splenic flexure impinging on a paralytic transverse colon

A. IMPINGEMENT VIA PHRENICOCOLIC LIGAMENT
   1. Acute pancreatitis / postpancreatitic stricture
   2. Pancreatic / gastric carcinoma
   3. Hemorrhage from rupture of splenic artery / abdominal aortic aneurysm
B. COLONIC DISEASE
   1. Colon cancer
   2. Mesenteric thrombosis
   3. Ischemic colitis
   4. Perforated appendicitis (in 20%)
      N.B.: amputation of gas at the hepatic flexure ← spastic ascending colon

Colonic Thumbprinting

= sharply defined fingerlike marginal indentations at contours of wall

1. ISCHEMIA = Ischemic colitis occlusive vascular disease, hypercoagulability state, hemorrhage into bowel wall (bleeding diathesis, anticoagulants), traumatic intramural hematoma
2. INFLAMMATION ulcerative colitis, Crohn colitis
3. INFECTION
   acute amebiasis, schistosomiasis, strongyloidiasis, cytomegalovirus (in renal transplant recipients), pseudomembranous colitis
4. MALIGNANT LESIONS
   localized primary lymphoma, hematogenous metastases
5. MISCELLANEOUS
   endometriosis, amyloidosis, pneumatosis intestinalis, diverticulosis, diverticulitis, hereditary angioneurotic edema

mnemonic: PSALM II

Pseudomembranous colitis
Schistosomiasis
Amebic colitis
Lymphoma
Metastases (to colon)
Ischemic colitis
Inflammatory bowel disease

Colonic Urticaria Pattern

A. OBSTRUCTION
   1. Obstructing carcinoma
   2. Cecal volvulus
   3. Colonic ileus
B. ISCHEMIA
C. INFECTION / INFLAMMATION
   1. Yersinia enterocolitis
   2. Herpes

3. Crohn disease

D. URTICARIA

Colonic Ulcers

A. IDIOPATHIC
   1. Ulcerative colitis
   2. Crohn colitis

B. ISCHEMIC
   1. Ischemic colitis

C. TRAUMATIC
   1. Radiation injury
   2. Caustic colitis

D. NEOPLASTIC
   1. Primary colonic carcinoma
   2. Metastases: prostate, stomach, lymphoma, leukemia

E. INFLAMMATORY
   1. Pseudomembranous colitis
   2. Pancreatitis
   3. Diverticulitis
   4. Behçet disease
   5. Solitary rectal ulcer syndrome
   6. Nonspecific benign ulceration

F. INFECTION
   (a) protozoan
      1. Amebiasis
      2. Schistosomiasis
      3. Strongyloidiasis
   (b) bacterial
      1. Shigellosis, salmonellosis
      2. Staphylococcal colitis
      3. Tuberculosis
      4. Gonorrheal proctitis
      5. Yersinia colitis
      6. Campylobacter fetus colitis
   (c) fungal
      histoplasmosis, mucormycosis, actinomycosis, candidiasis
   (d) viral
      1. Lymphogranuloma venereum
      2. Herpes proctocolitis
      3. Cytomegalovirus (transplants)

Aphthous Ulcers of Colon

1. Crohn disease
2. Amebic colitis
3. **Yersinia enterocolitis**

Organism: gram-negative
• fever, diarrhea, RLQ pain
Location: terminal ileum
√ thickened folds + ulceration
√ lymphoid nodular hyperplasia

4. Salmonella, shigella infection
5. Herpes virus infection
6. Behçet disease
7. Lymphoma
8. Ischemia

Multiple Bull's-eye Lesions of Colonic Wall

mnemonic: MaCK CLaN
Melanoma and
Carcinoma
Kaposi sarcoma
Carcinoid
Lymphoma and
Neurofibromatosis

Double-tracking of Colon

= longitudinal extraluminal tracks paralleling the colon

1. Diverticulitis: generally 3–6 cm in length
2. Crohn disease: generally > 10 cm
3. Ulcerative colitis
4. Primary carcinoma: wider + more irregular

Pseudomembranous Colitis

= endoscopically diagnosed colonic infection / inflammation characterized by pseudomembranes consisting of an exudate of necrotic cells on a denuded mucosa

1. Clostridium difficile
2. Ischemic colitis: acute / subacute
3. Staphylococcus
4. Shigella
5. Pseudomonas aeruginosa
6. Drugs: chlorpropamide, mercuric compounds, gold, NSAIDs

Accordion Sign

= gross irregular polypoid thickening of colonic wall with wide separation of inner + outer walls

1. Radiation-induced colitis
2. Ischemic colitis
3. Infectious colitis: Clostridium difficile, tuberculosis
4. Typhlitis, neutropenic colitis
5. Inflammation: Crohn disease, ulcerative colitis

◊ The only 2 conditions with wall thickening > 10 mm

6. Lymphangiectasia
7. Intramural hemorrhage

Colonic Narrowing

A. CHRONIC STAGE OF ANY ULCERATING COLITIS
   (a) inflammatory:
      1. Ulcerative colitis
      2. Crohn colitis
      3. Solitary rectal ulcer syndrome
      4. Nonspecific benign ulcer
   (b) infectious:
      1. Amebiasis
      2. Schistosomiasis
      3. Bacillary dysentery
      4. Tuberculosis
      5. Fungal disease
      6. Lymphogranuloma venereum
      7. Herpes zoster
      8. Cytomegalovirus
      9. Strongyloides
   (c) ischemic
      1. Ischemic colitis
   (d) traumatic
      1. Radiation injury
      2. Cathartic colon
      3. Caustic colitis

B. MALIGNANT LESION
   (a) primary
      1. Colonic carcinoma: annular / scirrhous
      2. Complication of ulcerative colitis + Crohn colitis
   (b) metastatic:
      ← prostate, cervix, uterus, kidney, stomach, pancreas, primary intraperitoneal sarcoma
      › hematogenous (eg, breast)
      › lymphangitic spread
      › peritoneal seeding

C. EXTRINSIC PROCESS
   (a) inflammation
      1. Retractile mesenteritis
      2. Diverticulitis
      3. Pancreatitis
   (b) deposits
      1. Amyloidosis
      2. Endometriosis
      3. Pelvic lipomatosis

D. POSTSURGICAL
   1. Adhesive bands
   2. Surgical anastomosis
E. NORMAL
   1. Cannon point

Localized Colonic Narrowing

mnemonic: SCARED CELL-MATE

Schistosomiasis
Carcinoid
Actinomycosis
Radiation
Endometriosis
Diverticulitis
Colitis
Extrinsic lesion
Lymphoma
Lymphogranuloma venereum
Metastasis
Adenocarcinoma
Tuberculosis
Entamoeba histolytica

Microcolon

mnemonic: **MI**a **M**icro**C**olic**A**

Meconium ileus, Meconium peritonitis (cystic fibrosis)
Ileal / jejunal atresia
Megacystis-microcolon-hypoperistalsis syndrome
Colonic atresia (distal to atretic segment)
Aganglionosis (Hirschsprüng disease)

Colonic Filling Defects

Subepithelial Lesion of Colon

SUBEPITHELIAL NEOPLASM OF COLON

= masslike protrusion into lumen covered by normal overlying mucosa at optical colonoscopy

A. Neoplasm with intramural origin
   1. Lipoma
   2. Carcinoid
   3. Lymphoma
   4. Hemangioma
   5. GIST
   6. Hematogenous metastasis:
      melanoma > lung > breast

7. Other primary tumor (rare):
   leiomyoma, schwannoma, leiomyosarcoma, ganglioneuroma, granular cell tumor

B. Neoplasm with extramural origin
   1. Direct invasion by extracolonic tumor: gastric adenocarcinoma
   2. Peritoneal carcinomatosis
   3. Appendiceal tumor

SUBEPITHELIAL NONNEOPLASTIC LESION OF COLON

A. Intramural origin
   (a) vascular lesion:
      1. Internal hemorrhoid
      2. Rectal varix
      3. Venous malformation
   (b) cystic lesion:
      1. Colonic duplication cyst
      2. Lymphangioma
      3. Colitis cystica profunda
   (c) others:
      1. Lymphoid polyp / hyperplasia
      2. Intramural hematoma
      3. Pneumatosis cystoides coli

B. Extramural origin
   1. Endometriosis
   2. Extrinsic impression: uterus, adnexa, aorta, common iliac artery, adjacent GI tract
   3. Presacral lesion

Single Colonic Filling Defect

A. BENIGN TUMOR
   1. Polyp
      (hyperplastic, adenomatous, villous adenoma, villoglandular); most common benign tumor
   2. Lipoma
      Most common intramural tumor; 2nd most common benign tumor; M < F
      Location: ascending colon + cecum > left side of colon
   3. Carcinoid: 10% metastasize
   4. Spindle cell tumor
      (leiomyoma, fibroma, neurofibroma); 4th most common benign tumor; rectum > cecum
   5. Lymphangioma, hemangioma

B. MALIGNANT TUMOR
   (a) primary tumor: carcinoma, sarcoma
   (b) secondary tumor: metastases (breast, stomach, lung, pancreas, kidney, female genital tract), lymphoma, invasion by adjacent tumors

C. INFECTION
   1. Ameboma

2. Polypoid granuloma: schistosomiasis, TB

D. INFLAMMATION
1. Inflammatory pseudopolyp: ulcerative colitis, Crohn disease
2. Periappendiceal abscess
3. Diverticulitis
4. Foreign-body perforation

E. NONSESSILE INTRALUMINAL BODY
1. Fecal impaction
2. Foreign body
3. Gallstone
4. Bolus of Ascaris worms

F. MISCELLANEOUS
1. Endometriosis
   3rd most common benign tumor
   Location: sigmoid colon, rectosigmoid junction (at level of cul-de-sac)
   • may cause bleeding (after invasion of mucosa)
2. Localized amyloid deposition
3. Suture granuloma
4. Intussusception
5. Pseudotumor: ← adhesions, fibrous bands
6. Colitis cystica profunda

Multiple Colonic Filling Defects

A. NEOPLASMS
(a) polyposis syndrome
(b) hematogenous metastases: from breast, lung, stomach, ovary, pancreas, uterus
(c) multiple tumors
› benign: neurofibromatosis, colonic lipomatosis, multiple hamartoma syndrome (Cowden disease)
› malignant: lymphoma, leukemia, adenocarcinoma

B. INFLAMMATORY PSEUDOPOLYPS
ulcerative colitis, Crohn colitis, ischemic colitis, amebiasis, schistosomiasis, strongyloidiasis, trichuriasis

C. ARTIFACTS
feces, air bubbles, oil bubbles, mucous strands, ingested foreign body (eg, corn kernels)

D. MISCELLANEOUS
nodular lymphoid hyperplasia, lymphoid follicular pattern, hemorrhoids, diverticula, pneumatosis intestinalis, colitis cystica profunda, colonic urticaria, submucosal colonic edema ← obstruction, cystic fibrosis, amyloidosis, ulcerative pseudopolyps, proximal to obstruction

mnemonic: MILL P3
Metastases (to colon)
Ischemia (thumbprinting)
Lymphoma
Lymphoid hyperplasia

Polyposis
Pseudopolyposis (with inflammatory bowel disease)
Pneumatosis cystoides

Carpet Lesions of Colon

= flat lobulated lesions with alteration of surface texture + little / no protrusion into lumen
Location: rectum > cecum > ascending colon
Cause:
A. NEOPLASM
1. Tubular / tubulovillous / villous adenoma
2. Familial polyposis
3. Adenocarcinoma
4. Submucosal tumor spread ← adjacent carcinoma

B. MISCELLANEOUS
1. Nonspecific follicular proctitis
2. Biopsy site
3. Endometriosis
4. Rectal varices
5. Colonic urticaria

Colonic Polyp

Terminology:

1. **Polyp**
= mass projecting into the lumen of a hollow viscus above level of mucosa; usually arises from mucosa, may derive from submucosa / muscularis propria
(a) neoplastic polyp: adenoma / carcinoma
(b) nonneoplastic: hamartoma / inflammatory polyp
2. **Pseudopolyp**
= scattered island of inflamed edematous mucosa on a background of denuded mucosa
(a) pseudopolyposis of ulcerative colitis
(b) "cobblestoning" of Crohn disease
3. **Postinflammatory (filiform) polyp**
= fingerlike projection of submucosa covered by mucosa on all sides following healing + regeneration of inflammatory (most common in ulcerative colitis) / ischemic / infectious bowel disease
4. **Adenomatous polyp**
◊ Most commonly seen neoplastic polyp
Histo: tubular > villous > tubulovillous adenoma
5. **Hyperplastic polyp**
◊ Most commonly seen nonneoplastic polyp
6. **Pedunculated polyp**
= attachment to wall via stalk
7. **Sessile polyp**
= attachment to wall via broad base
8. **Flat polyp**

= mass with height > ½ its width

RECTUM & ANUS

Rectal Disease

A. NEOPLASIA
   1. Rectal polyp
   2. Rectal cancer
   3. Multiple lymphomatous polyposis

B. INFLAMMATION
   1. Ulcerative colitis
   2. Perianal fistula of Crohn disease
   3. Solitary rectal ulcer syndrome
   4. Pseudomembranous colitis

C. EXTRAMUCOSAL LESION
   1. Serosal metastasis
   2. Lymph node metastasis
   3. Leiomyoma
   4. Perirectal abscess
   5. Uterine leiomyosarcoma invading rectal wall

Rectal Narrowing

1. Pelvic lipomatosis + fibrolipomatosis
2. Lymphogranuloma venereum
3. Radiation injury of rectum
4. Chronic ulcerative colitis

Enlarged Presacral Space

Normal width: < 5 mm in 95%; abnormal width > 10 mm

A. RECTAL INFLAMMATION / INFECTION
   ulcerative colitis, Crohn colitis, idiopathic proctosigmoiditis, radiation therapy

B. RECTAL INFECTION
   1. Proctitis: TB, amebiasis, lymphogranuloma venereum, radiation, ischemia
   2. Diverticulitis

Differential Diagnosis of Colonic Polyps		
	Single Polyp	*Multiple Polyps*
Neoplastic (10 %)		
epithelial (adenomatous)	Tubular adenoma	Familial multiple polyposis
	Tubulovillous adenoma	Adenomatosis of GI tract
	Villous adenoma	Gardner syndrome
		Turcot syndrome
nonepithelial	Carcinoid	
	Leiomyoma	
	Lipoma	
	Hemangioma, lymphangioma	
	Fibroma, neurofibroma	
Nonneoplastic (90%)		
unclassified	Hyperplastic polyp	Hyperplastic polyposis
hamartomatous	Juvenile polyps	Juvenile polyposis
		Peutz-Jeghers syndrome
		Cronkhite-Canada syndrome
inflammatory	Benign lymphoid polyp	Ulcerative colitis
	Fibroid granulation polyp	

C. BODY FLUIDS / DEPOSITS
   1. Hematoma: surgery, sacral fracture
   2. Pus: perforated appendix, presacral abscess
   3. Serum: edema, venous thrombosis
   4. Deposit of fat: pelvic lipomatosis, Cushing disease
   5. Deposit of amyloid: amyloidosis

D. SACRAL TUMOR
   1. Sacrococcygeal teratoma, anterior sacral meningocele
   2. Chordoma, metastasis to sacrum

E. PRESACRAL TUMOR *(see below)*

F. MISCELLANEOUS
   1. Inguinal hernia containing segment of colon
   2. Colitis cystica profunda
   3. Pelvic lipomatosis

Presacral Tumor

= mass effect on posterior wall of rectum

A. OSTEOCHONDRAL
   1. Giant cell tumor

2. Ewing sarcoma
3. Osteosarcoma of spine
4. Chondrosarcoma
5. Aneurysmal bone cyst

B. NEUROGENIC
1. Neurofibroma
2. Schwannoma
3. Paraganglioma
4. Sacrococcygeal chordoma
5. Dural ectasia
6. Anterior myelomeningocele

C. MESENCHYMAL
1. Hemangioma
2. Myelolipoma
3. Solitary fibrous tumor
4. Castleman disease
5. Retroperitoneal fibrosis
7. GIST
8. Lipoma

D. MALIGNANT RECTAL TUMOR
1. Colorectal carcinoma
2. Cloacogenic carcinoma
3. Lymphoma
4. Sarcoma
5. Hemangioendothelioma
6. Lymph node metastases
7. Prostatic carcinoma, bladder tumors, cervical cancer, ovarian cancer

E. CONGENITAL / DEVELOPMENTAL
(a) developmental cyst:
1. Epidermoid, dermoid
2. Rectal duplication cyst
3. Tailgut cyst

(b) germ cell tumor:
1. Sacrococcygeal teratoma
2. Yolk sac tumor
3. Embryonal cell carcinoma

(d) lymphoproliferative disorder

F. INFECTIOUS / INFLAMMATORY

G. POSTTRAUMATIC

Lesions of Ischiorectal Fossa

A. CONGENITAL AND DEVELOPMENTAL ANOMALIES
1. Gartner duct cyst
2. Klippel-Trénaunay syndrome
3. Tailgut cyst

B. INFLAMMATORY AND HEMORRHAGIC LESIONS
1. Fistula in ano
2. Ischiorectal / perirectal abscess
3. Extraperitoneal pelvic hematoma
4. Rectal perforation

C. SECONDARY NEOPLASM
per direct extension / hematogenous spread:
anorectal / prostatic / pelvic / sacral tumor; lung cancer; melanoma; lymphoma

D. PRIMARY NEOPLASM
1. Aggressive angiomyxoma
2. Lipoma
3. Plexiform neurofibroma
4. Anal adenocarcinoma
5. Squamous cell carcinoma

MURAL STRATIFICATION OF INTESTINAL TRACT

= bowel wall thickening with abnormal separation of bowel layers on cross-sectional imaging = visualization of layers of bowel wall at contrast-material–enhanced CT

CECT:

√ "double halo / target" sign = trilaminar appearance during late arterial phase:
√ contrast enhancement of inner layer:
(1) mucosa + (2) muscularis mucosae
√ nonenhanced interposed layer of (3) submucosa with various degrees of attenuation:
› blood attenuation ← hemorrhage
› soft-tissue attenuation ← inflammatory cells
› low attenuation ← pus
› water attenuation ← intramural edema
› fat attenuation ← past / chronic inflammation
√ contrast enhancement of outer layer:
(4) muscularis propria + (5) serosa

Cause:

◊ Tumor has NOT been reported to cause stratification!

A. BOWEL WALL EDEMA
√ low-density / water-density separation
1. Ulcerative colitis (50%): rectum
2. Proximal to obstructing tumor / intussusception
3. Angioedema

B. INFLAMMATORY CELL INFILTRATE
1. Crohn disease (in up to 50%)
2. Mycobacterium tuberculosis
3. Eosinophilic enteritis
4. Cytomegalovirus
5. Clostridium difficile
6. Entamoeba histolytica

7. Vibrio cholerae
8. Shigella
9. Escherichia coli

C. BOWEL ISCHEMIA / INFARCTION
1. Arterial obstruction: thromboembolism, plaque thrombus
2. Peripheral vasculopathy
3. Venous obstruction: thrombosis, bowel torsion, closed-loop obstruction
4. Hypoperfusion: proximal arterial stenosis potentiated by myocardial infarction, bradycardia, dehydration

N.B.: closed-loop obstruction with signs of bowel infarction is a surgical condition!
- √ signs of bowel infarction:
  - √ free peritoneal fluid
  - √ asymmetric bowel wall enhancement
  - √ persistent enhancement of bowel wall / segmental arteries
  - √ arterial / venous filling defects
  - √ increased density of mesentery
  - √ bowel obstruction

D. INTESTINAL WALL HEMORRHAGE
1. Anticoagulation
2. Blood dyscrasia: thrombocytopenic purpura
3. Blunt trauma
   - √ "snow-cone" appearance of duodenum

Segmental Mural Stratification of Small Bowel
1. Small-vessel vasculitis
2. Small-vessel ischemia
3. Chemotherapy-induced enteritis
4. Radiation therapy
5. ACE inhibitor–induced angioedema

Bowel Wall Thickening in Children

A. INFECTION
1. Gastroenteritis
2. Enterocolitis
3. Pseudomembranous colitis
4. Hemolytic-uremic syndrome
5. Chronic granulomatous disease

B. TRAUMA
1. Duodenal hematoma
2. Hypoperfusion complex

C. NEOPLASM
1. Lymphoma
2. GIST
3. Neurogenic tumors: mesenteric plexiform neurofibroma associated with neurofibromatosis

4. Vascular tumors: hemangioma
5. Colon cancer (2nd decade of life)
6. Langerhans cell histiocytosis

D. INFLAMMATION
1. Crohn disease
2. Ulcerative colitis
3. Typhlitis
4. Inflammatory pseudotumor

The degree of wall thickening is significantly greater in Crohn disease than in ulcerative colitis!

E. AUTOIMMUNE
(a) Collagen vascular disease
1. SLE
2. Scleroderma
(b) Vasculitis:
1. Periarteritis nodosa
2. Henoch-Schönlein purpura

F. Mechanical
1. Mesenteric ischemia
2. Intussusception
3. Acute appendicitis
4. Meckel diverticulum
5. Radiation enteritis

G. OTHERS
1. Celiac disease
2. Lactose intolerance
3. Eosinophilic gastroenteritis
3. Hypoproteinemia
4. Graft-versus-host disease

Fat halo sign

= layer of fat attenuation (-18 to -64 HU) in submucosa sandwiched between inner + outer layer of soft-tissue attenuation of a thickened bowel wall

1. Chronic inflammatory bowel disease: ulcerative colitis (61%), Crohn disease (8%)
2. Graft-versus-host disease
3. Cytoreductive therapy
4. Asymptomatic obese patient

Hyperattenuating Bowel Wall

= hemorrhage secondary to

1. Trauma
2. Henoch-Schönlein purpura
3. Vasculitis

Prolonged Contrast Coating of Bowel Wall

for hours to days

Cause: incorporation of barium into submucosal layer through mucosal ulcers

1. Graft-versus-host disease
2. Ischemic bowel

Aphthous Ulcer

= ulcer crater surrounded by a rim of edema overlying submucosal lymphoid follicle

1. Crohn disease
2. Yersinia enterocolitis
3. Tuberculosis
4. Amebiasis
5. Ischemic enteritis

Hypervascular Subepithelial (Submucosal) Mass

1. Neuroendocrine tumor
2. Gastrointestinal stromal tumor
3. Glomus tumor
4. Hemangioma
5. Angiosarcoma: extremely rare in GI tract
6. Kaposi sarcoma
7. Peripheral nerve sheath tumor
8. Hypervascular metastasis
9. Heterotopic pancreatic tissue

The term *subepithelial* is favored over *submucosal* because lesions in this category do not necessarily arise from the submucosa, but can arise from any layer of the GI wall (intramural) or intraabdominal structures (extramural).

POLYPOSIS SYNDROMES

= more than 100 polyps in number

Mode of transmission:

A. HEREDITARY
   (a) autosomal dominant
      1. Familial (multiple) polyposis
      2. Gardner syndrome
      3. Peutz-Jeghers syndrome
      4. Juvenile polyposis coli
   (b) autosomal recessive
      1. Turcot syndrome

B. NONHEREDITARY
   1. Cronkhite-Canada syndrome
   2. Juvenile polyposis

DDx: polyposis look-alikes on barium studies

1. Postinflammatory polyposis
2. Lymphoid hyperplasia
3. Multiple lymphomatous polyposis

4. Metastases
5. Pneumatosis coli
6. Disseminated gastrointestinal polyps
7. Multiple adenomatous polyps

Adenomatous Polyposis Syndromes

1. Familial (multiple) polyposis
2. Gardner syndrome
3. Turcot syndrome

Hamartomatous Polyposis Syndromes

1. Peutz-Jeghers syndrome* (polyp with central core of smooth muscle)
2. Cowden disease*
3. Juvenile polyposis*
4. Cronkhite-Canada syndrome
5. Bannayan-Riley-Ruvalcaba syndrome

* = increased prevalence of coexisting adenomas and adenoma-carcinoma sequence

PERITONEUM

Lesion of Serosal Membranes

A. PRIMARY NEOPLASM
   (a) malignant
      1. Malignant pleural mesothelioma
      2. Malignant peritoneal mesothelioma
      3. Primary serous papillary carcinoma of peritoneum = serous cystadenocarcinoma of ovary
   (b) benign
      1. Adenomatoid tumor
      2. Benign multicystic mesothelioma
      3. Desmoplastic small round cell tumor
      4. Localized fibrous tumor of pleura
      5. Leiomyomatosis peritonealis disseminata

B. SECONDARY NEOPLASM (more common)
   Spread by: direct extension from an adjacent visceral organ / transcoelomic dissemination / permeation of underlying lymphatics
   (a) pleura: lung, breast, thymus, ovary, pancreas, thyroid, gastrointestinal tract, kidney
   (b) peritoneum: pseudomyxoma peritonei

C. NONNEOPLASTIC LESION
   1. Pleural plaque
   2. Pleural fibrosis
   3. Pericardial cyst
   4. Sclerosing encapsulating peritonitis
   5. Sclerosing mesenteritis
   6. Peritoneal inclusion cyst

Peritoneal Mass

A. SOLID MASS
   1. Peritoneal mesothelioma
   2. Peritoneal carcinomatosis
B. INFILTRATIVE PATTERN
   1. Peritoneal mesothelioma
C. CYSTIC MASS
   1. Multicystic mesothelioma
   2. Pseudomyxoma peritonei
   3. Bacterial / mycobacterial infection

Intraperitoneal Solid Abdominal Mass in a Child

LOCALIZED MASS

1. Inflammatory myofibroblastic tumor
2. Castleman disease
3. Mesenteric fibromatosis
4. Benign mesenchymal mass: lymphatic malformation, infantile hemangioma

DIFFUSE PERITONEAL DISEASE

1. Desmoplastic small round cell tumor
2. Burkitt lymphoma (NHL)
3. Rhabdomyosarcoma

Multiple Peritoneal Masses

A. METASTATIC NEOPLASM
   1. Peritoneal metastases = carcinomatosis
   2. Pseudomyxoma peritonei
   3. Lymphomatosis = body cavity-based lymphoma
   4. Sarcomatosis
      Cause: unusual hematogenous metastases, GIST
B. TUMORLIKE CONDITIONS
   1 Endometriosis
   2. Gliomatosis peritonei
   3. Osseous metaplasia = heterotopic mesenteric ossification
   4. Cartilaginous metaplasia
   5. Splenosis
C. INFECTION / INFLAMMATION
   1. **Granulomatous peritonitis**
      Cause: TB, Histoplasma, Pneumocystis, talc, barium, meconium, bowel contents, ruptured ovarian cyst, bile, gallstones
   3. Sclerosing encapsulating peritonitis
   2. Inflammatory pseudotumor

Diffuse Peritoneal Masses in Children

1. Desmoplastic small round cell tumor

2. Rhabdomyosarcoma
3. Metastatic germ cell tumor
4. Gliomatosis peritonei
5. Metastatic retroperitoneal tumor:
   (a) Neuroblastoma
   (b) Wilms tumor
6. Malignant mesothelioma
7. Peritoneal carcinomatosis
8. Peritoneal seeding of intracranial tumors through ventriculoperitoneal shunt

Peritoneal Calcifications

1. Tuberculosis
2. Amyloidosis
3. Hyperparathyroidism
4. Pseudomyxoma peritonei
5. Peritoneal carcinomatosis
6. Meconium peritonitis

MESENTERY & OMENTUM

Short Mesentery

= shortened line of fixation

1. Malrotation + midgut volvulus
2. Omphalocele
3. Gastroschisis
4. Congenital diaphragmatic hernia
5. Asplenia + polysplenia

"Apple peel" Small Bowel

= distal small intestines spirals around its vascular supply resembling an apple peel resulting in a very short intestine

1. Proximal jejunal atresia
2. Absence of distal superior mesenteric artery
3. Shortening of small bowel distal to atresia
4. Absence of dorsal mesentery

Cx: propensity toward necrotizing enterocolitis

Prognosis: high mortality

Whirlpool Sign of Small Bowel Mesentery

1. Midgut volvulus
2. Internal hernia
3. Adhesions
4. Surgical disruption of normal anatomy

Omental Mass

◊ 33% of primary omental tumors are malignant!
◊ Secondary neoplasms are more frequent than primary!

A. SOLID MASS
   (a) benign
      1. Leiomyoma
      2. Lipoma
      3. Neurofibroma
   (b) malignant
      1. Leiomyosarcoma
      2. Liposarcoma
      3. Fibrosarcoma
      4. Lymphoma
      5. Peritoneal mesothelioma
      6. Hemangiopericytoma
      7. Metastases
   (c) Infection: tuberculosis

B. CYSTIC MASS
   1. Hematoma
   2. Cystic mesothelioma

Omental Cake

= replacement of normal fat of the greater omentum by a soft-tissue density

A. INTRAPERITONEAL TUMOR SPREAD
   1. Peritoneal metastases from abdominal organs
      mnemonic: COPUBS
         Colon
         Ovary
         Pancreas
         Uterus
         Bladder
         Stomach
   2. Metastases from extraabdominal organs: malignant melanoma, breast, lung

B. INFLAMMATION
   1. Tuberculosis
   2. Crohn disease
   3. Phlegmonous pancreatitis
   4. Granulomatous enterocolitis

C. BENIGN TUMOR
   1. Desmoid fibroma
   2. Extramedullary hematopoiesis

D. MALIGNANT TUMOR
   1. Mesothelioma
   2. Lymphomatosis

E. OTHER
   1. Hemoperitoneum

2. Liver cirrhosis with portal hypertension

Mesenteric Mass

A. ROUND SOLID MASS
- ◊ Benign primary tumors >> malignant primary tumors
- ◊ Secondary neoplasms are more frequent than primary
- ◊ Cystic tumors are more common than solid tumors!
- ◊ Malignant solid tumors have a tendency to be located near root of mesentery, benign solid tumors in periphery near bowel!

1. Metastases: especially ← colon, ovary (most frequent neoplasm of mesentery)
2. Lymphoma
3. Leiomyosarcoma: more frequent than leiomyoma
4. Neural tumor : neurofibroma, ganglioneuroma
5. Lipoma (uncommon), lipomatosis, liposarcoma
6. Fibrous histiocytoma
7. Hemangioma
8. Desmoid tumor (most common primary)
9. Desmoplastic small round cell tumor of peritoneum

B. ILL-DEFINED MASS
1. Metastases (ovary)
2. Lymphoma
3. Fibromatosis, fibrosing mesenteritis (associated with Gardner syndrome)
4. Lipodystrophy
5. Mesenteric panniculitis

C. STELLATE MASS
1. Peritoneal mesothelioma
2. Retractile mesenteritis
3. Fibrotic reaction of carcinoid
4. Radiation therapy
5. Desmoid tumor
6. Hodgkin disease
7. Tuberculous peritonitis
8. Ovarian metastases
9. Diverticulitis
10. Pancreatitis

- ◊ A calcified mesenteric mass suggests carcinoid tumor!

D. LOCULATED CYSTIC MASS (2/3)
1. Cystic lymphangioma (most common)
2. Pseudomyxoma peritonei
3. Cystic mesothelioma
4. Mesenteric cyst
5. Mesenteric hematoma
6. Benign cystic teratoma
7. Cystic spindle cell tumor (= centrally necrotic leiomyoma / leiomyosarcoma)

Benign Fibrous Tumor of Mesentery

1. Mesenteric fibromatosis
2. Sclerosing mesenteritis
3. Inflammatory pseudotumor
4. Extrapleural solitary fibrous tumor

Mesenteric / Omental Cysts

= "Bubbles of the belly"

◊ The first step is to determine the organ of origin!

1. Lymphangioma
2. Nonpancreatic pseudocyst
   = sequelae of mesenteric / omental hematoma / abscess
   Path: thick-walled, usually septated cystic mass with hemorrhagic / purulent contents
3. Duplication cyst
4. Mesothelial cyst
5. Enteric cyst
6. Cystic metastasis
7. Cystic mesothelioma

Mesenteric Edema / Congestion

√ increase of mesenteric fat attenuation to –40 to –60 HU

√ loss of sharp interfaces between mesenteric vessels + fat

A. SYSTEMIC FLUID OVERLOAD
   1. Hypoalbuminemia
   2. Liver cirrhosis
   3. Nephrosis
   4. Heart failure

B. LOCAL VESSEL DISEASE
   1. Portal vein thrombosis
   2. Mesenteric vein / artery thrombosis
   3. Vasculitis
   4. SMA dissection

C. CELL INFILTRATE
   1. Malignant neoplasm
   2. Inflammation
   3. Trauma: small hemorrhage

Comb Sign

= vascular dilatation of vasa recta + interconnected arterial arcades aligned as the teeth of a comb

√ multiple tubular tortuous opacities on mesenteric side of ileum

1. Crohn disease
2. Ulcerative colitis
3. Vasculitis: Lupus, polyarteritis nodosa, Behçet disease, Henoch-Schönlein syndrome, microscopic polyangiitis

4. Mesenteric thromboembolism
5. Strangulated bowel obstruction

Fat Ring Sign

= fat-stranding of the fat plane surrounding the root of mesenteric vessels

A. BENIGN
   1. Mesenteric panniculitis
   2. Mesenteric lipodystrophy
   3. Retractile mesenteritis

B. MALIGNANT
   1. Carcinoid
   2. Desmoid tumor
   3. Lymphoma

Misty Mesentery Sign

= subtle increased attenuation in the mesentery at CT often associated with small borderline-sized lymph nodes

1. Normalcy (common finding!)
2. Mesenteric panniculitis
3. Hemorrhage
4. Edema
5. Malignancy

Abdominal Fat Necrosis

1. Epiploic appendagitis
2. Omental infarction
3. Encapsulated fat necrosis
4. Fat saponification from pancreatitis = retroperitoneal fat necrosis

Mimicks:

1. Focal lipohypertrophy
   Cause: insulin injections into subcutaneous tissue in insulin-dependent diabetics
2. Lipodystrophy
   = heterogeneous group of disorders interfering with normal distribution of adipose tissue
3. Liposarcoma

Umbilical Tumor

A. PRIMARY (38%)
   benign / malignant neoplasm, skin tumor

B. METASTASES (30%)
   = "Sister Joseph nodule"
   • firm painful nodule
   • ± ulceration with serosanguinous / purulent discharge
   Cause: gastrointestinal cancer (50%), undetermined (25%), ovarian cancer, pancreatic cancer, small cell carcinoma of lung (very rare)
   Spread:

(a) direct extension from anterior peritoneal surface
(b) extension along embryonic remnants: falciform, median umbilical, omphalomesenteric ligaments
(c) hematogenous
(d) retrograde lymphatic flow from inguinal, axillary, paraaortic nodes
(e) iatrogenic: laparoscopic tract, tract of percutaneous needle biopsy

C. NONNEOPLASTIC
1. Endometriosis (32%)
2. Granuloma
3. Incarcerated hernia

Omphalomesenteric Duct Anomalies
1. Meckel Diverticulum (98%)
2. Omphalomesenteric fistula
3. Omphalomesenteric sinus
4. Omphalomesenteric duct cyst
5. Omphalomesenteric ligament

ABDOMINAL LYMPHADENOPATHY

Regional Patterns of Lymphadenopathy

@ Retrocrural nodes
Abnormal size: > 6 mm
Common cause: lung carcinoma, mesothelioma, lymphoma

@ Gastrohepatic ligament nodes
= superior portion of lesser omentum suspending stomach from liver
Abnormal size: > 8 mm
Common cause: carcinoma of lesser curvature of stomach, distal esophagus, lymphoma, pancreatic cancer, melanoma, colon + breast cancer
DDx: coronary varices

@ Porta hepatis nodes
= in porta hepatis extending down hepatoduodenal ligament, anterior + posterior to portal vein
Abnormal size: > 6 mm
Common cause: carcinoma of gallbladder + biliary tree, liver, stomach, pancreas, colon, lung, breast, chronic hepatitis C
Cx: high extrahepatic biliary obstruction

@ Pancreaticoduodenal nodes
= between duodenal sweep + pancreatic head anterior to IVC
Abnormal size: > 10 mm
Common cause: lymphoma, pancreatic head, colon, stomach, lung, breast cancer

@ Perisplenic nodes
= in splenic hilum
Abnormal size: > 10 mm
Common cause: NHL, leukemia, small bowel neoplasm, ovarian cancer, carcinoma of

right / transverse colon

@ Retroperitoneal nodes
= periaortic, pericaval, interaortocaval
Abnormal size: > 10 mm
Common cause: lymphoma, renal cell, testicular, cervical, prostatic carcinomas

As with malignant retroperitoneal fibrosis, metastatic retro-peritoneal adenopathy typically elevates the aorta off the underlying vertebral body (exceptions have been reported)

@ Celiac and superior mesenteric artery nodes
= preaortic nodes
Normal size: 4.6 mm mean maximum short-axis diameter
Abnormal size: > 10 mm
Common cause: lymphoma, any intraabdominal neoplasm, TB, atypical mycobacterial infection, Whipple disease

@ Ileocecal nodes
= along ileocolic artery
Common cause: mesenteric lymphadenitis, appendicitis, diverticulitis, Crohn disease, SLE, HIV infection

@ Pelvic nodes
= along common, external + internal iliac vessels
Abnormal size: > 15 mm
Common cause: carcinoma of bladder, prostate, cervix, uterus, rectum

Low-attenuation Abdominal Adenopathy

= ENLARGED LYMPH NODE WITH LOW-DENSITY CENTER
√ rim-enhancing nodules + central necrosis
1. Mycobacterial infection (TB, M. avium-intracellulare)
2. Pyogenic infection
3. Whipple disease
4. Lymphoma
5. Metastatic disease after radiation + chemotherapy
6. Lymphangioleiomyomatosis
7. Neurofibromatosis type I
8. Cavitating mesenteric lymph node syndrome

PARASITIC INFESTATION

A. PROTOZOA = one cell parasites
[*protos*, Greek = foremost, earliest; *zoion*, Greek = animal]
(a) genitourinary
1. Trichomoniasis
2. Chlamydomonas
(b) intestinal
1. Giardiasis
2. Amebiasis
3. Cryptosporidiosis

(c) blood
1. Malaria
2. Giardiasis
4. Trypanosomiasis
5. Tuberculosis
6. Toxoplasmosis
8. Filariasis
7. Leishmaniasis

B. PLATYHELMINTHES = flatworms
(a) cestodes (= tapeworms) [*cestus*, Latin = belt, girdle]
1. Echinococcus granulosus
2. Echinococcus multilocularis
3. Cysticercosis

(b) trematodes (flukes) [*trema* , Greek = hole; *odes* , Greek = like]
1. Clonorchiasis
2. Fascioliasis
3. Paragonimiasis
4. Schistosomiasis
› S. haematobium (GU tract) > 95%
› S. mansoni, S. japonicum (GI tract) < 5%

C. NEMATODES = roundworms [*nema*, Greek = thread; *odes*, Greek = like]
1. Strongyloidiasis (= pinworm)
2. Ascariasis
3. Trichuriasis
4. Toxocariasis
5. Angiostrongylosis

› other hookworms: Ancylostoma duodenale, Necator americanus
› other pinworm: Enterobius vermicularis (formerly Oxyuris vermicularis)

Helminthiasis

= infestation caused by Platyhelminthes and Nematoda

Incidence: 2 billion people affected worldwide

Geography: › endemic: in developing countries and places with poor sanitation
› nonendemic: through immigration and travel

- iron-deficiency anemia, seizures
- chronic diarrhea, portal hypertension

Transmission: active penetration of skin by larvae from soil / fecal-oral route / vector arthropods

(a) larval penetration:
1. Schistosomiasis
2. Strongyloidiasis

(b) fecal-oral route:
1. Fascioliasis
2. Ascariasis
3. Trichuriasis

4. Cysticercosis
5. Echinococcosis
6. Toxocariasis
7. Angiostrongylosis

ANATOMY AND FUNCTION OF ABDOMEN AND GASTROINTESTINAL TRACT

GASTROINTESTINAL HORMONES

Cholecystokinin

= CCK = 33 amino acid residues (former name: Pancreozymin); the 5 C-terminal amino acids are identical to those of gastrin, causing similar effects as gastrin; 2.5-min serum half-life

Produced in: duodenal + upper intestinal mucosa

Released by: fatty acids, some amino acids (phenylalanine, methionine), hydrogen ions

Effects:

@ Stomach
- (1) weakly stimulates HCl secretion
- (2) given alone: inhibits gastrin → ↓ in HCl production
- (3) stimulates pepsin secretion
- (4) stimulates gastric motility

@ Pancreas
- (1) stimulates secretion of pancreatic enzymes (= Pancreozymin)
- (2) stimulates bicarbonate secretion: weakly by direct effect; strongly through potentiating effect on secretin
- (3) stimulates insulin release

@ Liver
- (1) stimulates water + bicarbonate secretion

@ Intestine
- (1) stimulates secretion of Brunner glands
- (2) increases motility

@ Biliary tract
- (1) strong stimulator of gallbladder contraction with maximum effect within 5–15 min + return to basal size in 1 hour
- (2) relaxation of sphincter of Oddi

Medication:

sincalide (KINEVAC®) = synthetic C-terminal octapeptide of the hormone cholecystokinin

Gastrointestinal Endocrine Cells		
Cell Type	*Location*	*Secretory Product*
G-cell (gastrin cell)	gastric antrum, duodenum	gastrin
ECL-cell (enterochromaffin -like cell)	gastric fundus and body	histamine
D-cell (somatostatin -producing cell)	stomach, duodenum, jejunum, colon, rectum	somatostatin
EC-cell (enterochromaffin cell)	stomach, duodenum, jejunum, colon, rectum	serotonin, motilin, substance P
CCK-cell (cholecystokinin cell)	duodenum, ileum	cholecystokinin
GIP-cell (gastric inhibitory polypeptide cell)	duodenum, ileum	gastric inhibitory polypeptide
M-cell (motilin cell)	duodenum, jejunum	motilin
S-cell (secretin cell)	duodenum, jejunum	secretin
PP-cell (pancreatic polypeptide cell)	duodenum	pancreatic polypeptide
L-cell (enteroendocrine cell)	jejunum, ileum, colon, rectum	polypeptide YY
N-cell (neurotensin cell)	jejunum, ileum	neurotensin

Use: may be used to empty gallbladder about 30 minutes (to 4 hours) before tracer injection in patients on prolonged fasting (gallbladder atony + retained bile and sludge) ← absence of endogenously produced CCK

Dose for hepatobiliary scintigraphy:

package insert: with slow IV injection of 0.01 µg/kg KINEVAC® over 3 minutes (concentration of 1 µg/mL) the response is too variable

preferred: IV infusion of 0.01 µg/kg KINEVAC® over 30–60 minutes

Useful in: (a) patient fasting > 24 hours / on total parenteral nutrition
(b) acalculous cholecystitis
(c) chronic GB dysfunction
(d) GB ejection fraction

Side effect: increase in biliary-to-bowel transit time, dizziness, flushing, nausea, abdominal cramps, urge to defecate

Contraindications:

acute pancreatitis, acute cholecystitis, obstruction of cystic duct / CBD, appendicitis, peritonitis, pyloric stenosis, peptic ulcer

Gastrin

= 17 amino acid peptide amide

PENTAGASTRIN = acyl derivative of the biologic active C-terminal tetrapeptide amide

Produced in: antral cells + G cells of pancreas

Released by:

(a) vagal stimulation, gastric distension
(b) short-chain alcohol: ethanol, propanol
(c) amino acids: glycine, β-alanine
(d) caffeine
(e) hypercalcemia

mediated by neuroendocrine cholinergic reflexes

Inhibited by: drop in pH of antral mucosa to < 3.5

Effects:

@ Stomach:
(1) stimulation of gastric HCl secretion from parietal cells, which in turn
(2) increases pepsinogen production by chief cells through local reflex
(3) increase in antral motility
(4) trophic effect on gastric mucosa → parietal cell hyperplasia

@ Pancreas
(1) strong increase in enzyme output
(2) weakly stimulates fluid + bicarbonate output
(3) stimulates insulin release

@ Liver
(1) water + bicarbonate secretion

@ Intestine
(1) stimulates secretion of Brunner glands
(2) increases motility

@ Gallbladder
(1) stimulates contraction

@ Esophagus
(1) increases resting pressure of LES

Glucagon

Produced in: α cells (and β cells) of pancreas

Released by: low blood glucose levels

Effects:

@ Intestines
(1) lowers pressure of GE sphincter
(2) hypotonic effect on duodenum > jejunum > stomach > colon

@ Hormones
(1) releases catecholamines from adrenal gland → paralysation of intestinal smooth muscle
(2) increases serum insulin + glucose levels → mobilization of hepatic glycogen

@ Biliary tract
(1) increases bile flow
(2) relaxes gallbladder + sphincter of Oddi

Dose for radiologic imaging: 1 mg maximum

◊ IV administration causes a quick response + rapid dissipation of action!
◊ IM administration prolongs onset + increases length of action!

Half-life: 3–6 min

Side effects: nausea + vomiting, weakness, dizziness (delayed onset of 1.5–4.0 hours after IM administration)

Contraindication:

(1) hypersensitivity / allergy to glucagon: urticaria, periorbital edema, respiratory distress, hypotension, coronary artery spasm (?), circulatory arrest
(2) known hypertensive response to glucagon
(3) pheochromocytoma: glucagon stimulates release of catecholamines
(4) insulinoma: insulin-releasing effect may result in hypoglycemia
(5) glucagonoma
(6) poorly controlled diabetes mellitus

Secretin

= 27–amino acid polypeptide hormone

Produced in: duodenal mucosa

Released by: hydrogen ions providing a pH < 4.5 (usually increase in postprandial intraluminal acidity)

The physiologic effects of secretin include secretion of bicarbonate-rich fluid from pancreatic ductal cells and transient increase in the sphincter of Oddi tone, which improves depiction of the pancreatic duct.

Effects:

@ Stomach
(1) inhibits release of gastrin → ↓ in HCl secretion
(2) stimulates pepsinogen secretion by chief cells (potent pepsigogue)
(3) decreases gastric and duodenal motility + contraction of pyloric sphincter

@ Pancreas
(1) increases alkaline bicarbonate-rich pancreatic secretions (NaHCO3 = sodium bicarbonate)
» bicarbonate = 2 x as much carbonate (CO3) per sodium ion in sodium bicarbonate (NaHCO3) as in sodium carbonate (Na2CO3); crucial role in physiological pH buffering
(2) weakly stimulates enzyme secretion
(3) stimulates insulin release

@ Liver
(1) stimulates water + HCO3- secretion (most potent choleretic)

@ Intestine
(1) stimulates secretion of Brunner glands
(2) inhibits motility

@ Esophagus
(1) opens LES

@ Sphincter of Oddi
(1) transient increase in muscle tone used in SOM (sphincter of Oddi manometry)

Common Indications for Secretin Use during MRCP	
Clinical	*Indication*
Acute recurrent pancreatitis, severe necrotizing pancreatitis	Integrity of MPD
Chronic pancreatitis	Duct stricture / stone
	Pancreatic excretory volume estimate
Pancreatic cystic neoplasm	Side-branch IPMN vs. other cystic neoplasm / pseudocyst
Postoperative pancreas	Pancreaticoenteric anastomosis patency
	Estimate pancreatic exocrine reserve
	Duct dilatation / filling defect / leak
Suspected duct anomaly	Pancreas divisum + variants
	Pancreaticobiliary junction anomaly

Secretin Stimulation Test SST

Indication: (1) Exocrine pancreas dysfunction
(2) Gastrinoma versus peptic ulcer disease
(3) Identification of ampulla of Vater + accessory papilla during ERCP

Drug: purified synthetic human secretin ChiRhoStim®, ChiRhoClin®

Dose: 0.2–0.4 µg/kg IV (~ 16 µg for adult) over 1 minute to avoid side effect of abdominal pain

Initial test dose: for possible allergic reaction

Peak effect: usually at 3–5 minutes after injection

√ ↑ main pancreatic duct (MPD) diameter by > 1 mm
√ ↑ visibility of side branches of MPD
√ ↑ T2 SI in duodenum ← excretion of pancreatic fluid

Adverse effects: (in 0.5%) nausea, flushing, abdominal pain, vomiting, mild acute pancreatitis

Dx of gastrinoma:

release of gastrin from gastrinoma cells is increased → increased serum gastrin level of 200 ng/L above baseline (90% sensitive + specific)

N.B.: normally secretin inhibits release of gastrin

Dx of chronic pancreatitis:

aspiration of intestinal secretions via tube passed into duodenum for 1 hour analyzing volume, pH, bicarbonate concentration in 15-minute aliquots (75% sensitive + 90% specific for chronic pancreatitis)

Contraindication: acute pancreatitis

Somatostatin SS

= growth hormone–inhibiting hormone (GHIH); somatotropin release-inhibiting factor (SRIF); somatotropin release-inhibiting hormone (SRIH)

Produced in: many tissues; principally in nervous + digestive systems

Action: inhibits secretion of several other hormones like growth hormone (GH), thyroid stimulating hormone (TSH), cholecystokinin, insulin

Released by: raised levels of other hormones (feed back); ↑ blood glucose + amino acids (food intake)

Inhibited by: reduced levels of other hormones (feed back)

Effects:

@ Hypothalamus
inhibits pituitary gland → ↓ secretion of GH + TSH
Rx: treatment of acromegaly

@ Pancreas
food intake → ↓ secretion of insulin + glucagon

@ GI tract
(a) local reduction of gastric secretion
(b) gastrointestinal motility
(c) inhibits secretion of gastrin + secretin

EMBRYOLOGY OF ALIMENTARY TRACT

Origin: pouchlike extension of the yolk sac

Division: (1) foregut supplied by celiac artery for bronchopulmo-nary system, stomach, pancreas, proximal duodenum
(2) midgut supplied by superior mesenteric artery (SMA) representing axis of gut rotation: mid-duodenum, jejunum, ileum, appendix, ascending colon, mid-transverse colon
(3) hindgut supplied by inferior mesenteric artery: mid-transverse colon, rectum

at 4 weeks: short straight featureless tube

1st rotation:
(a) duodenum rotates cephalocaudal 90° counterclockwise to a position at right of SMA
(b) colon rotates 90° to left of SMA

at 6 weeks: rapid growth of intraabdominal organs (expansion of liver + GI tract) → bowel herniates into umbilical cord = physiologic umbilical herniation

2nd rotation:
(a) duodenum rotates another 90° (completes 180°) counter-clockwise beneath SMA to a position at left of SMA
(b) colon does not rotate

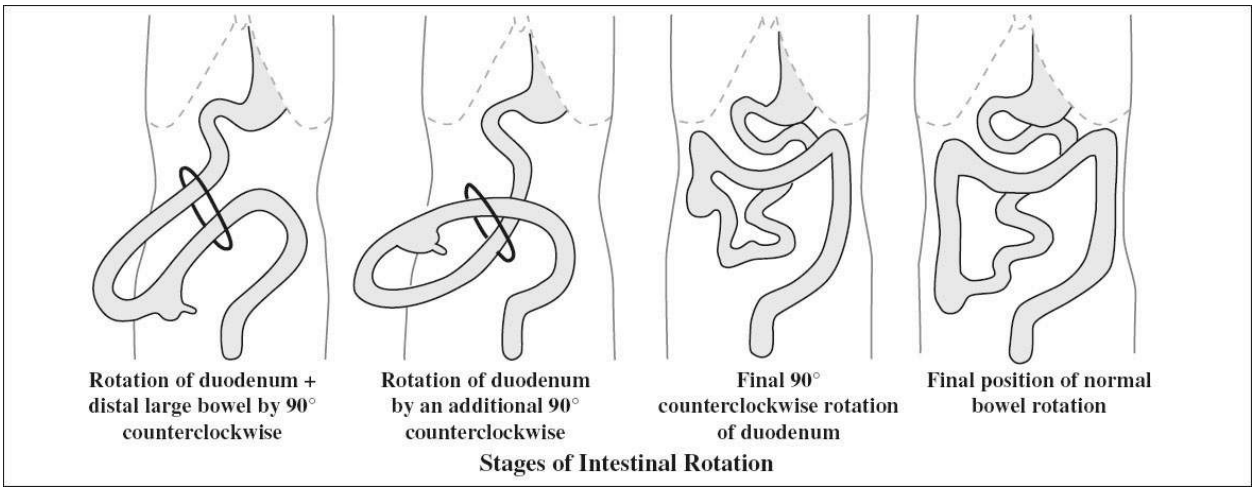
at 10 weeks: bowel returns to abdominal cavity

3rd rotation:
(a) duodenum rotates another 90° (completes 270°) counter-clockwise with duodenojejunal junction resting to left of spine
(b) colon rotates 180° counterclockwise until cecum is located in RLQ by 12th week

Peritoneal fixation of bowel:
› broad-based mesentery extending from ligament of Treitz to ileocecal valve
› colon fuses with retroperitoneum in RLQ with the exception of the most caudal part
› duodenum fixes to retroperitoneum in LUQ

Change in fetal nutrition from yolk sac to placenta:

› during 5th to 7th weeks → regressing omphalomesenteric duct



Stages of Intestinal Rotation

ARTERIAL SUPPLY OF BOWEL

◊ Bowel receives 20% of resting cardiac output (⅔ for intestinal mucosa) which increases up to 35% in postprandial phase

Influence of food:

carbohydrates → earliest + fast rise

fat + proteins → slower + large rise

Celiac Trunk

Location: at ~ T12 = superior border of pancreatic body

Supplies: from distal esophagus to descending duodenum

Branches: common hepatic a. (CHA), left gastric a. (LGA), splenic artery (SpA) with considerable variations in branching pattern

- › CHA branching from SMA (hepatomesenteric type)
- › direct branching of CHA / LGA / SpA from aorta
- › replaced left hepatic artery
- › replaced right hepatic artery

Anastomosis: to SMA via gastroduodenal artery as the 1st branch off the celiac trunk

Superior Mesenteric Artery (SMA)

Supplies: transverse + descending duodenum, jejunum, ileum, large bowel to splenic flexure

Anastomosis: with IMA via marginal artery of Drummond, arcade of Riolan

Inferior Mesenteric Artery (IMA)

Supply for: colon from splenic flexure to rectum

Anastomoses: with lumbar branches of abdominal aorta, sacral artery, internal iliac arteries

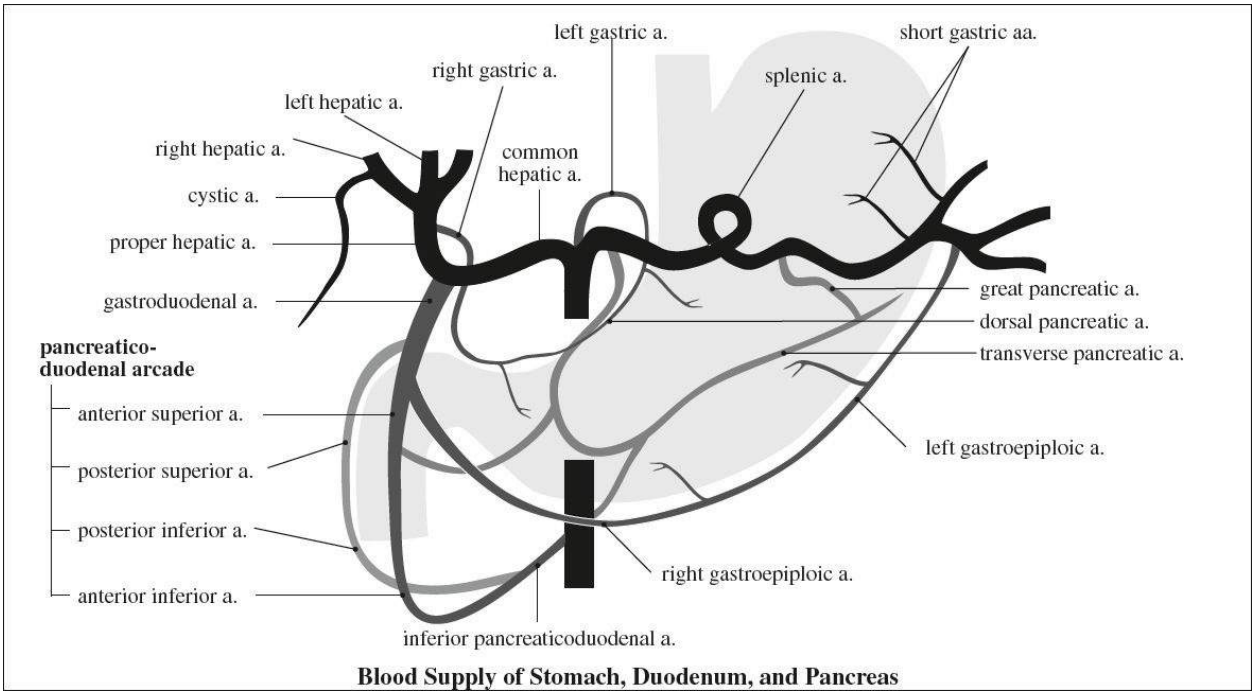
Arterial Arcades

up to 4 arcades are formed by these arteries which continue toward the periphery as

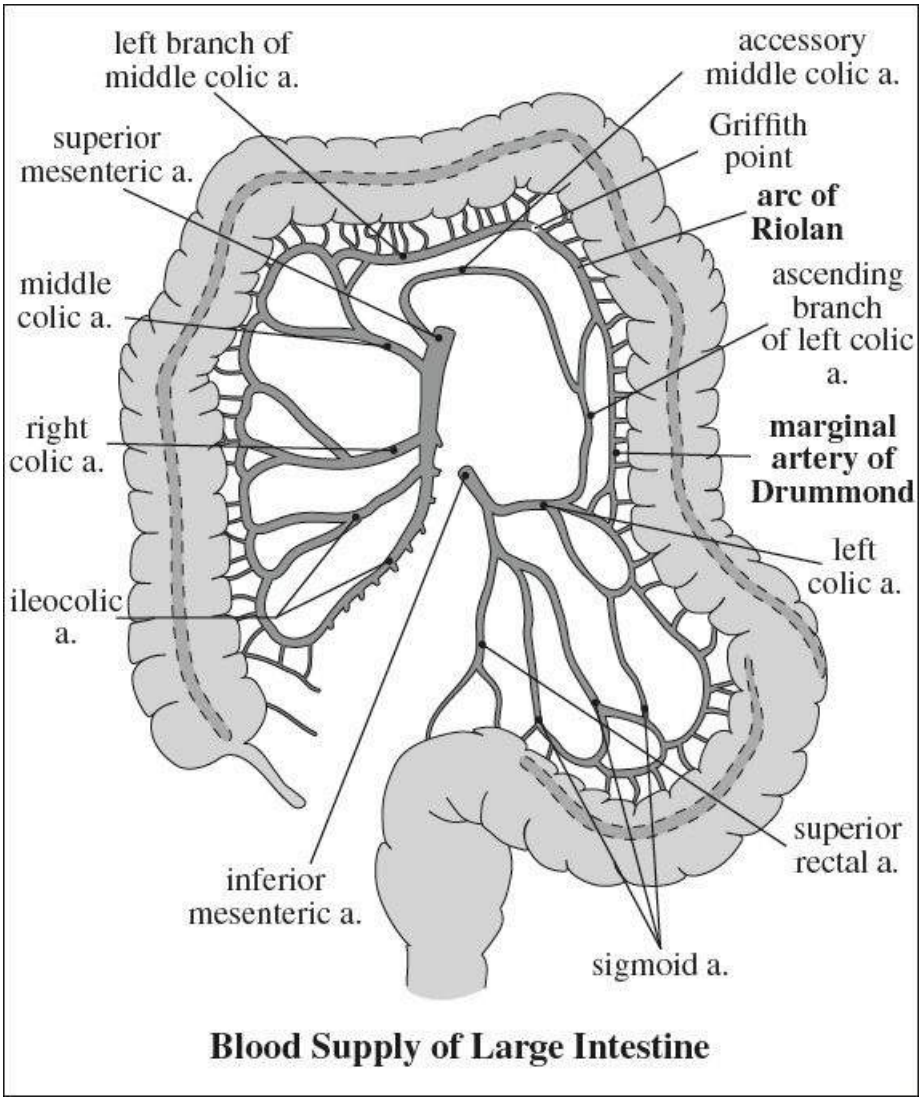
1. Primary parallel circuits for
   a. muscularis propria

b. submucosa
c. mucosa

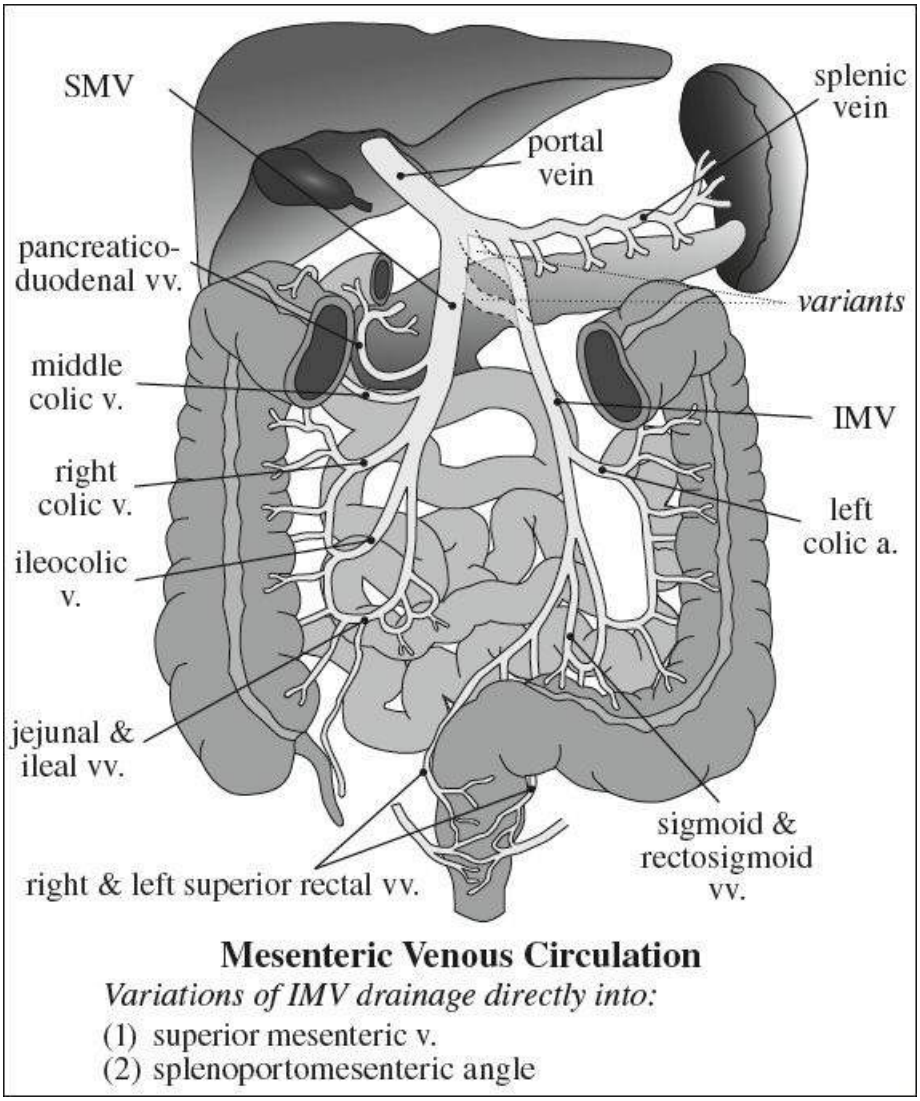
2. Serial circuits of
   a. resistance arterioles
   b. precapillary sphincters
   c. capillaries
   d. postcapillary sphincters
   e. venous capacitance vessels



Blood Supply of Stomach, Duodenum, and Pancreas



Blood Supply of Large Intestine



Mesenteric Venous Circulation

Variations of IMV drainage directly into:

(1) superior mesenteric v.

(2) splenoportomesenteric angle

MESENTERIC VENOUS SYSTEM

Venae Rectae

= multiple small veins along bowel wall that join to form venous arcades

Superior Mesenteric Vein

Drainage for: small bowel, proximal colon to splenic angle

Formed by: jejunoileal, ileocolic, right colic, middle colic, pancreaticoduodenal veins

Inferior Mesenteric Vein

Drainage for: splenic flexure, descending colon, sigmoid colon, part of rectum

Formed by: left colic, sigmoid, rectosigmoid, right and left superior rectal veins

Connects to: SMV directly / splenic vein / angle of splenoportomesenteric confluence

ESOPHAGUS

Esophageal Division

1. Upper third
   cricopharyngeus to superior margin of aortic arch
2. Middle third
   superior margin of aortic arch to inferior pulmonary vein
3. Lower third
   inferior pulmonary vein to gastroesophageal junction

Cricopharyngeus Muscle

= main component of upper esophageal sphincter
√ normally closed between swallows
√ relaxes and opens completely for bolus passage to occur in conjunction with elevation of larynx and pharyngeal constrictors
√ prominent posterior indentation on barium column ← incidental / sign of dysphagia
May be associated with:
pharyngeal constrictor muscle weakness, failure of laryngeal elevation, Zenker diverticulum, response esophageal spasm or GERD

Lower Esophageal Anatomy

A. **Esophageal Vestibule**
= saccular termination of lower esophagus with upper boundary at tubulovestibular junction + lower boundary at esophagogastric junction
√ collapsed during resting state
√ assumes bulbous configuration with swallowing
(a) tubulovestibular junction = A level = junction between tubular and saccular esophagus
(b) phrenic ampulla = bell-shaped part above diaphragm (term should be discarded because of dynamic changes of configuration)
(c) submerged segment = infrahiatal part of esophagus
√ widening / disappearance is indicative of gastroesophageal reflux disease (GERD)

B. **Gastroesophageal Junction**
Function: regulates flow of food + fluid between esophagus and stomach; key defense against gastroesophageal reflux
Barrier: (1) Intrinsic smooth muscle of LES
(2) Extrinsic striated muscle of crural diaphragm
(3) clasp + sling fibers of gastric cardia
Site: at upper level of gastric sling fibers, straddles cardiac incisura demarcating the left lateral margin of GE junction

C. **Z-line** = B level = zigzag-shaped squamocolumnar junction line
◊ Not acceptable criterion for locating GE junction
Site: 1–2 cm above gastric sling fibers

D. **Lower Esophageal Sphincter**
= physiologic 2–4-cm high pressure zone corresponding to esophageal vestibule
√ tightly closed during resting state
√ assumes bulbous configuration with swallowing

Muscular Rings of Esophagus

A Ring

= contracted / hypertrophied muscles in response to incompetent GE sphincter

• rarely symptomatic / dysphagia

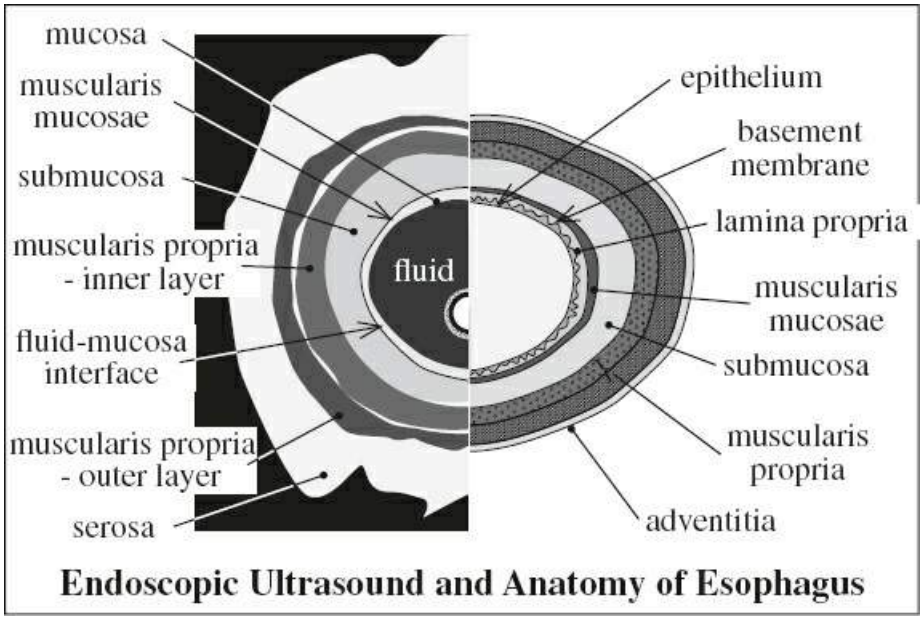
Location: at tubulovestibular junction = superior aspect of vestibule

√ usually 2 cm proximal to GE junction at upper end of vestibule

√ varies in caliber during the same examination, may disappear on maximum distension

√ broad smooth narrowing with thick rounded margins

√ visible only if tubular esophagus above + vestibule below are distended



Endoscopic Ultrasound and Anatomy of Esophagus

B Ring

= sling fibers representing a U-shaped thickening of inner muscle layers with open arm of U toward lesser curvature = inferior aspect of vestibule

Location: < 2 cm from hiatal margins

√ only visible when esophagogastric junction is above hiatus

√ thin ledge-like ring just below the mucosal junction (Z-line)

Layers of Intestinal Wall by Ultrasound

= gut signature

1. Mucosa echogenic
   √ hyperechoic interface of balloon + mucosa
2. Muscularis mucosae hypoechoic
   √ hypoechoic mucosa + muscularis mucosa
3. Submucosa echogenic / hyperechoic
4. Muscularis propria hypoechoic
5. Serosa echogenic / hyperechoic

Most benign conditions preserve the gut signature involving long segments of bowel, while malignant

conditions destroy the gut signature involving short segments of bowel.
Aggressive inflammatory processes cause focal disruption of the gut signature.

SWALLOWING FUNCTION

Preparation: refrain from smoking for 12 hours + from eating for > 4 hours before examination
Provide info on baseline anatomy + swallow physiology: for oral cavity, pharynx, larynx, upper esophagus during deglutition

Technique:

Videofluoroscopic Swallow Study (VFSS) = modified barium swallow study to assess handling of bolus; usually performed together with swallowing / speech pathologist

» patient seated upright in lateral + AP positions
» incremental increase in radiopaque bolus volume + texture of various consistencies like nectar liquid, honey liquid, pureed food, soft solid food, hard solid food (commercially available: E-Z Paque liquid, Varibar® thin liquid, nectar, honey, pudding, graham cracker cookie with pudding)

Document patient behavior + reaction:
episode of refusal, cough, silent aspiration, apnea, bradycardia

CNS involved: cranial nerves V, VII, IX, X, XII; 5 cervical nerves; cortical + subcortical pathways; midbrain; brainstem

Muscles involved: 32 groups of muscles

Developmental: swallowing as early as 11 weeks GA;
suckling at 18–24 weeks GA; nonnutritive
sucking at 27–28 weeks GA; single breath
sucking at 35–36 weeks GA

Phases:

1. Oral preparatory phase
   √ food chewed + mixed with saliva
2. Oral phase
   √ bolus propelled posteriorly to tongue
   Path:
   (a) spillage from mouth
   (b) small bolus formation
   (c) tongue tremor
   (d) incomplete tongue elevation
   (e) early spillage into valleculae prior to initiation of swallow
3. Pharyngeal phase
   √ elevation of soft palate + valleculae (to seal nasopharynx)
   √ elevation of larynx (to close vestibule)
   √ relaxation of cricopharyngeal muscle
   √ contraction of lateral pharyngeal wall

At videofluoroscopy carefully evaluate mechanisms to prevent aspiration: superior + anterior elevation of larynx, closure of larynx, and epiglottic tilt.

Path:
(a) **nasopharyngeal reflux**

(b) **laryngeal penetration** = contrast material enters laryngeal vestibule
Cause: delayed elevation of larynx
(c) **tracheal aspiration** = contrast material enters airway below vocal cord level into proximal trachea
Cause: delayed elevation of larynx, delayed pharyngeal transit time, decreased clearance of bolus with residual in vallecula and pyriform sinus spilling into larynx + trachea

4. Esophageal phase
√ contraction of cricopharyngeal muscle
√ bolus transfer into esophagus
Path: cricopharyngeal achalasia (with reflux of bolus into oropharynx / pooling in pyriform sinus)

STOMACH

Segmental Anatomy of Stomach

1. Cardia
2. Fundus
Dependency: most superior portion when upright most dependent portion when supine
√ stomach bubble on CXR
√ accumulation of intraluminal contents on CT
3. Body
(a) lesser curvature: left and posteriorly on CT
(b) greater curvature: right and anteriorly on CT
√ ≤ 5 mm in thickness (in distended state)
» **Incisura angularis**
= transition to antral-type mucosa
◊ Most common site for gastric ulcers!
4. Antrum
= thickest gastric segment ← most muscular
√ ≤ 12 mm in thickness (in distended state)
√ exhibits the most peristalsis
√ may display mural stratification on CECT
5. Pylorus

Inadequate gastric distention limits diagnostic evaluation and may create a false appearance of thickening or may obscure true disease.
When evaluating abnormal gastric wall thickening in a nondistended stomach, supplementary findings can be helpful in identifying disease.

Trilaminar Gastric Wall on CECT

1. Mucosa: avid enhancement
2. Submucosa: low in attenuation
3. Muscularis propria: high in attenuation
4. Serosa

Suspicious findings:
√ focal / eccentric gastric wall thickening
√ low attenuation / nodularity of gastric wall
√ mucosal hyperenhancement
√ adjacent fat stranding

Gastric Cells

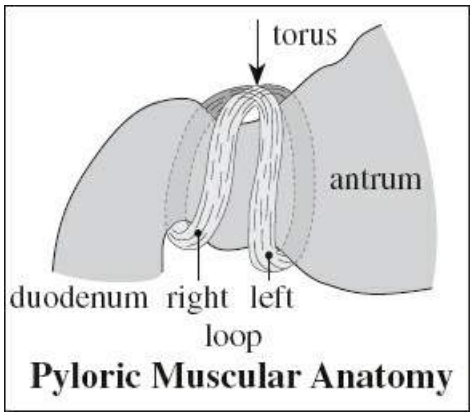
1. Chief cells = peptic / zymogenic cells
   Location: body + fundus
   produce: pepsinogen
2. Parietal cells = oxyntic cells
   Location: body + fundus
   produce: H+, Cl-, intrinsic factor, prostaglandins
3. Mucous neck cells
   produce: mucoprotein, mucopolysaccharide, aminopolysaccharide sulfate
4. Argentaffine cells = enteroendocrine cells
   Location: body + fundus
   produce: glucagon-like substance (A-cells), somatostatin (D-cells), vasoactive intestinal polypeptide (D1-cells), 5-hydroxytryptamine (EC-cells)
5. G-cells
   Location: pylorus
   produce: gastrin

Effect of Bilateral Vagotomy

= cholinergic denervation
(1) decreased MOTILITY of stomach + intestines
(2) decreased GASTRIC SECRETION
(3) decreased TONE OF GALLBLADDER + bile ducts
(4) increased TONE OF SPHINCTERS (Oddi + lower esophageal sphincter)

Pylorus

[*pyloros*, Greek = gatekeeper]
= fan-shaped specialized circular muscle fibers with:
(a) distal sphincteric loop = right canalis loop
√ corresponds to radiologic pyloric sphincter
(b) proximal sphincteric loop = left canalis loop
√ 2 cm proximal to distal sphincteric loop on greater curvature (seen during complete relaxation)
(c) torus
= fibers of both sphincters converge on the lesser curvature side to form a muscular prominence; prolapse of mucosa between sphincteric loops produces a niche simulating ulcer
√ pyloric channel 5–10 mm long, wall thickness of 4–8 mm
√ concentric indentation of the base of the duodenal bulb



SMALL BOWEL

◊ Longest tubular organ in body measuring 550–600 cm (18–22 feet) in length

Segments and Length:

› duodenum of 25–30 cm in length

› mesenteric small bowel:

» jejunum: 10–12 feet in length (= proximal 60%)

» ileum: 6–8 feet in length (= distal 40%)

Mesentery: 15 cm long between ligament of Treitz (musculus suspensorius duodeni) + ileocecal junction

Duodenum

= 1st part of small intestine from pylorus to lig. of Treitz

[Václav (Wenzel) Treitz (1819–1872), Director of the Institute of Pathological Anatomy in Prague]

Borders:

(a) posterior: external edge of IVC, medial surface of right kidney + hilum, psoas muscle

(b) anterior: right transverse colon, mesocolon, floating small bowel loops

(c) medial: pancreatic head

(d) lateral: right hepatic lobe, gallbladder neck, ascending colon

Duodenal Segments

1st segment = duodenal bulb + short postbulbar segment:

Course: passes backward + upward toward neck of GB

Location: intraperitoneal

√ freely movable ← intraperitoneal

2nd segment = descending duodenum

= gentle curve from superior to inferior duodenal flexures with attachment to head of pancreas

Length: 7–10-cm-long tube

Diameter: 35–40-mm

Location: retroperitoneal in anterior pararenal space between posterior parietal peritoneum and anterior perirenal fascia of Gerota

Openings:

(a) major papilla (Vater) ← hepatopancreatic ampulla ← junction of CBD + main pancreatic duct

(b) minor duodenal papilla = opening 2 cm above ampulla ← accessory pancreatic duct of Santorini

3rd segment = horizontal / transverse segment

Course: runs 10–12 cm horizontally to the left

Location: retroperitoneal crossing in front of IVC + aorta + lumbar spine; posterior to mesenteric vessels

4th segment = ascending portion

Course: runs 2–3 cm upward to the left

Location: retroperitoneal ascending to level of duodenojejunal junction

VARIATIONS:

(1) "mobile duodenum" / "water-trap duodenum"
= long postbulbar segment with undulation / redundancy

(2) duodenum inversum / duodenum reflexum
= distal duodenum ascends to the right of spine to the level of duodenal bulb + then crosses spine horizontally + fixated in normal location

Small Bowel Folds

◊ Circumferential small bowel folds (= folds of Kerckring
[Theodor (or Dirk) Kerckring (Kerckeringh, Kerckerinck) (1638–1693), Dutch anatomist and chemical physician]
= valvulae conniventes = plicae circulares) = 2 mucosal layers around a core of submucosa

A. WALL THICKNESS
◊ Small bowel wall thickness > 3 mm at CT is abnormal!

B. NORMAL FOLD THICKNESS
@ jejunum 1.7–2.0 mm > 2.5 mm pathologic
@ ileum 1.4–1.7 mm > 2.0 mm pathologic

C. NORMAL NUMBER OF FOLDS
@ jejunum 4–7 / inch
@ ileum 2–4 / inch

D. NORMAL FOLD HEIGHT
@ jejunum 3.5–7.0 mm
@ ileum 2.0–3.5 mm

E. NORMAL LUMEN DIAMETER
@ upper jejunum 3.0–4.0 cm > 4.5 cm pathologic
@ lower jejunum 2.5–3.5 cm > 4.0 cm pathologic
@ ileum 2.0–2.8 cm > 3.0 cm pathologic

RULE OF 3's:
◊ Wall thickness < 3 mm
◊ Valvulae conniventes < 3 mm
◊ Diameter < 3 cm
◊ Air-fluid levels < 3

Normal Bowel Caliber

◊ Small bowel gradually tapers in diameter from duodenojejunal junction to terminal ileum!

mnemonic: 3-6-9-12

3 cm maximal size of small bowel
- › < 3 cm in jejunum (up to 4 cm during enteroclysis)
- › < 2 cm in ileum (up to 3 cm during enteroclysis)
  - ◊ < 25 mm on CT

6 cm maximal size of transverse colon

9 cm maximal size of cecum

12 cm maximal caliber of cecum before it may burst

Small Bowel Peristalsis

A. INCREASED
1. Vagal stimulation
2. Acetylcholine
3. Anticholinesterase (eg, neostigmine)
4. Cholecystokinin

B. DECREASED
1. Atropine (eg, Pro-Banthine®)
2. Bilateral vagotomy

Ileocecal Valve

= ICV = COLIC VALVE = VALVULA COLI

Composition: symmetric upper + lower lip formed by intrusion of circular muscle layer of ileum into lumen of large intestine

Frenula of ICV: narrow membranous ridges at medial and lateral end of aperture where lips meet

Function: modulation of flow of luminal contents from ileum into colon → minimizing rapid anterograde passage / retrograde flow; minimal sphincteric action (common barium reflux into terminal ileum)

Location: within a cecal fold along medial aspect of cecum

Endoscopic classification:

(a) labial	= slitlike opening
(b) papillary	= dome shaped opening
(c) lipomatous	= substantial deposit of fat within lips

COLON

Colon Transit Time

Sitzmarks diagnostic test:

Indication: adults with severe constipation but otherwise normal GI examination

1. Withhold laxatives / enemas / suppositories for 5 days
2. On day 0 patient takes 1 gelatin capsule (contains 24 radiopaque polyvinyl chloride markers of 1 x 4.5 mm) with water
   - ◊ All markers are usually in colon by 12 hours

3. Take KUB on day 5 to determine location + extent of marker elimination
   - › ≥ 19 markers (80%) expelled = grossly normal colonic transit time
   - › markers scattered about the colon = colonic hypomotility / inertia
   - › markers in rectum / rectosigmoid = functional outlet obstruction (eg, internal rectal prolapse / anismus)
   - › ≥ 5 (20%) retained need follow-up KUB on day 7

Colonic Wall Thickness

< 3 mm = normal
3–4 mm = indeterminate
> 4 mm = pathologic

Cecum

= 1st part of large intestine
Location: most commonly in right iliac fossa below ileocecal valve, resting on iliac + greater psoas muscles
Size: 6.25 cm long; 7.5 cm wide
Attachment: to iliac fossa laterally + medially by peritoneal cecal folds
Layers: thickened bands of longitudinal muscle (= teniae coli) contiguous with distal colon + converging at base of vermiform appendix to form a complete outer longitudinal layer of muscle
√ considerable mobility ← usually almost entirely enveloped by peritoneum

Appendix

Average length: 8–10 cm
Wall thickness of normal appendix: < 2 mm
Diameter of normal appendix: < 6 mm
Location: 2.5 cm inferior to ileocecal valve with its own short triangular mesentery (= mesoappendix)
Function: well-developed lymphoid organ (in childhood) of immunologic importance
√ collapsed or partially filled with fluid / contrast material / air
MR (visualized in up to 65–90%, even in pregnant women):
- ◊ Oral preparation with 300 mL of GastroMARK® + 300 mL of ReadiCat® 2 1–1.5 hours before MRI study
- √ hyperintense center + hypointense wall on T2WI
- √ predominantly low signal intensity on T1WI

RECTUM

= last segment of GI tract
Origin: derived from fetal hindgut
Boundaries: sigmoid colon and anus
Peritoneal investment: proximal portion only
Blood supply: superior + middle hemorrhoidal arteries
Venous drainage:
- › proximal rectum: drained by inferior mesenteric vein

› distal rectum + anorectal junction: drained by internal iliac / inferior mesenteric vein (IMV)
◊ 2 hematogenous metastatic patterns of rectal cancer:
(1) liver metastasis ← via IMV + portal venous system / via endolymphatic spread along course of IMV
(2) lung metastasis ← via internal iliac veins + IVC

Rectosigmoid junction:
superior aspect of rectum = line formed by confluence of taeniae coli muscles on serosal surface of sigmoid (surgical definition); <u>less precise:</u> sacral promontory / peritoneal reflection
<u>endoscopically:</u> extension to 12 cm above anal verge

Anorectal junction: inferior aspect of rectum corresponding to dentate line (anatomic definition)

ANAL CANAL

= 2.5–4.0 cm long terminal part of GI tract extending from anorectal junction to anus

Dentate / pectinate line:
= 5–10 mm wide line dividing upper ⅔ and lower ⅓ of anal canal marking transitional zone between columnar epithelium of GI tract and squamous epithelium of anoderm

Division:
› upper ⅔ of canal
1. Zona columnaris = upper half of canal lined by simple columnar epithelium
   • longitudinal folds joined together into anal valves

› lower ⅓ of canal
2. Zona hemorrhagica = lined by stratified non-keratinized squamous epithelium
3. Zona cutanea = lined by stratified keratinized squamous epithelium

Border between zona hemorrhagica and cutanea:
Hilton's white line / pecten of Jon Stroud

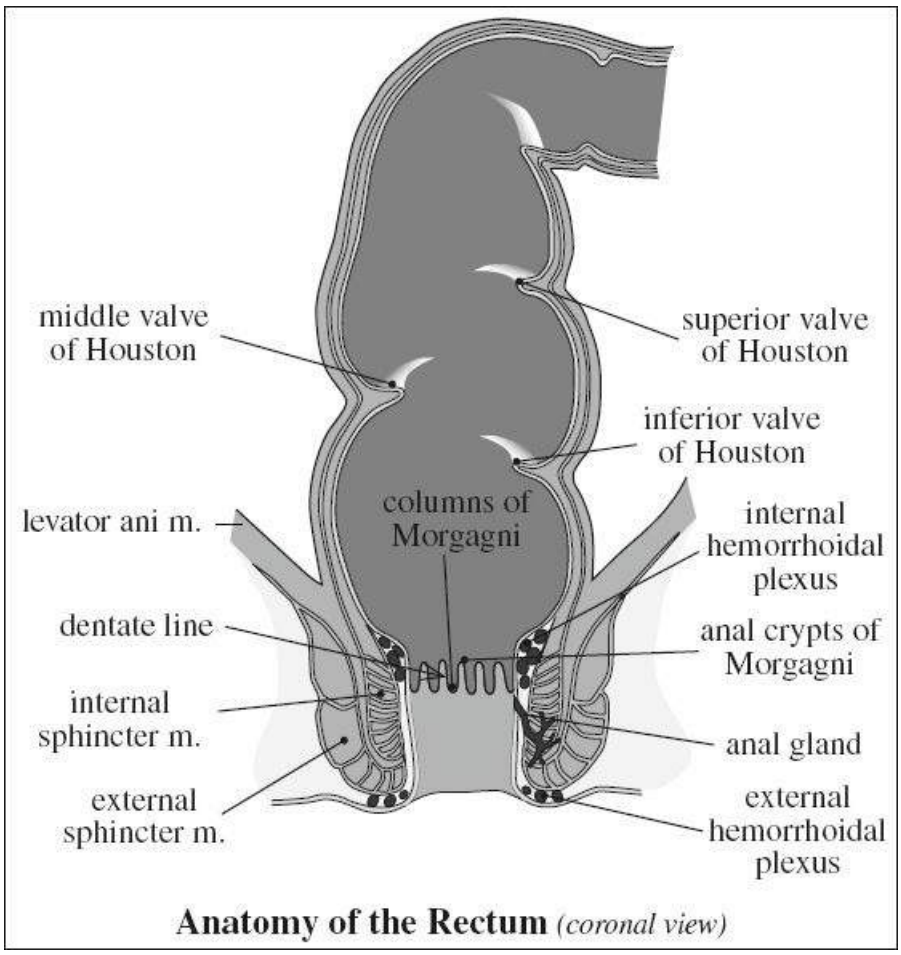
Anal Verge
= distal end of anal canal forming transitional zone between epithelium of moist hairless modified skin of anal canal + dry perianal skin

INTESTINAL FUNCTION

Intestinal Gas

A. INFLUX
1. Aerophagia 2 L
2. Liberation from intestinal tract
   (a) neutralization of bicarbonate in secretions (CO_2) 8 L
   (b) bacterial fermentation (CO_2, H_2, CH_4, H_2S) 15 L
3. Diffusion from blood (N_2, O_2, CO_2)

B. EFFLUX



1. Diffusion from intestines into blood and expulsion from lung 50 L
2. Expulsion from anus 2 L

Intestinal Fluid

A. INFLUX
   1. Oral ingestion 2.5 L
   2. Intestinal secretions 8.2 L
      saliva 1.5 L
      bile 0.5 L
      gastric secretions 2.5 L
      pancreatic secretions 0.7 L
      intestinal secretions 3.0 L

B. EFFLUX
   1. Peranal 0.1 L
   2. Intestinal resorption (primarily in ileum + ascending colon) 10.6 L

Intestinal Transit Time

greatly affected by type of diet

Measurement techniques:

(1) Breath tests: hydrogen; urea-labeled ^{13}C
(2) Scintigraphy
(3) Radiopaque markers
(4) Ingestible wireless motility capsule (measuring pH, pressure, temperature)

◊ It takes ~ 2 hours for a contrast bolus to reach ileocecal valve following esophagram and radiographs of the stomach!

Normal Transit Times:

Stomach:	2–5 hours
Small bowel:	2.5–6.0 hours
Colon:	5–60 hours
Whole gut:	10–73 hours

While it may not be possible to diagnose a specific disease that produces a change in bowel motility, alterations in motility may be used in support of a diagnosis and disease severity.

PELVIC FLOOR

= musculofascial diaphragm inserted on pelvic bones

Function:

› static support to visceral organs: opposing gravity + increased abdominal pressure
› active closure of urogenital hiatus: permitting emptying and continence mechanisms

Pelvic sling: extends obliquely from coccyx toward posterior levator plate just behind anorectal junction

Pelvic floor: (3 layers from cranial to caudal)

(a) endopelvic fascia:
= network of connective tissue that lies deep to peritoneum and supports pelvic organs
› peritoneal reflection fused to underlying connective tissue
› pubocervical fascia (between bladder + vagina)
› **sacrouterine–cardinal ligament complex**
» fascia anteriorly around vagina + uterus
Function: supports vaginal cuff by pulling cervix and upper vagina superiorly + posteriorly toward sacrum
» fusion posteriorly with prerectal fascia
Function: prevents pelvic floor descent
› **arcus tendineus** fasciae pelvis (ATFP) and arcus tendineus levatoris ani (ATLA)
= connective tissue condensations of obturator + levator ani fascia that runs obliquely on pelvic sidewall from pubic symphysis (cranially) to ischial spine (caudally)
Function: provide lateral support by anchoring organs to pelvic side wall

MR:
√ too thin to be recognized except for its condensations: cardinal lig., uterosacral ligament, urethral ligament
√ integrity inferred by efficiency of provided support

(b) **muscular pelvic diaphragm**
consisting mainly of <u>levator ani complex</u> made of
(1) puboperineal
(2) pubovaginal

(3) puboanal component
√ nonvisualized U-shaped sling inserting on inner pubis + passing around anorectal junction (AXIAL plane)
√ encloses urogenital hiatus (= space for urethra + vagina + anal canal)
(4) puborectalis muscle
√ encircles urogenital hiatus
√ responsible for angle between rectum + anal canal
(5) iliococcygeus muscle
√ thin sagittally oriented fan-shaped structure
√ curved shape with inferior concavity (COR plane)
√ inserts laterally to pelvic sidewalls on ATLA
√ inserts medially to pelvic organs
√ forms posteriorly raphe with attachment to external anal sphincter → anococcygeal ligament

Function: at rest tonically contracted
⇒ acting as an anterior sling drawing urethra anteriorly and superiorly relative to bladder base → acute angle between bladder neck and urethra
⇒ anus is drawn anterosuperiorly → acute angle between anus and rectum crucial for gross fecal continence

(c) **urogenital diaphragm**
= diamond-shaped structure consisting of two triangles with transverse perineus muscle as common base
» *anterior triangle:* apex at symphysis pubis; sides at pubic bones
penetrated by: urethra + vagina
» *posterior triangle:* apex at tip of coccyx
penetrated by: anus

› connective tissue = perineal membrane (mainly)
√ visible on MRI as hypointense connective tissue condensation (= perineal body) at insertion of perineus muscle and external anal sphincter interposed between vaginal vestibule and anal canal

› deep transverse perineus muscle
oriented transversely just deep to pelvic diaphragm and anterior to anorectal junction
anchors: external anal sphincter, muscles of urogenital diaphragm, puborectalis muscle, sacrouterine– cardinal ligament complex, prerectal fascia

PERITONEUM

Definitions:
Ligament = formed by two folds of peritoneum supporting a structure within the peritoneal cavity
Omentum = specialized structure connecting stomach to an additional structure: liver, duodenum, colon
Mesentery = two peritoneal folds connecting a portion of bowel to the retroperitoneum

Peritoneal Fluid

Changes in intraperitoneal hydrostatic pressure and anatomic arrangement of the peritoneal recesses result in transcoelomic migration of fluid toward the undersurface of the diaphragm.

Clearance: by subphrenic submesothelial lymphatics augmented by continual circulation of fluid upward to subdiaphragmatic spaces

Cause of motion: fluctuations in intraabdominal pressure during respiration + intestinal peristalsis

Reproducible circulatory pathway:

› Initially toward gravity-dependent spaces:
  (1) deep pelvic recesses (= pouch of Douglas in women / retrovesical space in men)
  (2) lateral paravesical spaces

› Later cephalad ascension to right subdiaphragmatic space:
  (3) right paracolic gutter → right subdiaphragmatic space
  (4) shallow left paracolic gutter
    (a) NO connection to left subdiaphragmatic space ← interruption by phrenicocolic ligament
    (b) NO connection between left and right subdiaphragmatic spaces ← falciform ligament

› Caudal redirection into pelvis:
  (5) by inframesocolic compartment

› Serving as watersheds: all mesenteries = transverse mesocolon, small bowel mesentery, sigmoid mesocolon, peritoneal attachments of ascending + descending colon

Small Bowel Mesentery

Composition: fatty extraperitoneal connective tissue, SMA & SMV and their branches, nerves, lymphatics

Investment: reflection of posterior parietal peritoneum

Function: suspension for 20–25 feet of jejunal + ileal loops

Root: 15 cm long fan-shaped bare area extending obliquely from point of terminal duodenum to cecum in right iliac fossa

Attachment: from duodenojejunal flexure over head of pancreas + 3rd part of duodenum obliquely across aorta, IVC, right ureter, right psoas major muscle

Vascular landmarks: superior mesenteric vessels + branches

Relationship: continuous with anterior pararenal space and root of transverse mesocolon at uncinate process

Peritoneal Spaces

A. RIGHT SUPRAMESOCOLIC SPACE
forms perihepatic space + lesser sac

1. **Right subphrenic / subdiaphragmatic space**
   Location: between right hepatic lobe + diaphragm
   › limited posteriorly by right superior reflection of coronary ligament + right triangular ligament
2. **Right subhepatic / hepatorenal space**: divided into
   (a) anterior right subhepatic space:

Location: posterior to porta hepatis

√ communicates with lesser sac via epiploic foramen (= foramen of Winsløw) [Jacob Benignus Winsløw (1669–1760)], danish-born professor of anatomy at the Jardin du Roi, Paris, France]

(b) posterior right subhepatic space

= Morison pouch = hepatorenal fossa

[James Rutherford Morison (1853–1939), British surgeon and professor at the University of Durham]

◊ Most dependent portion of the abdomen in supine patient!

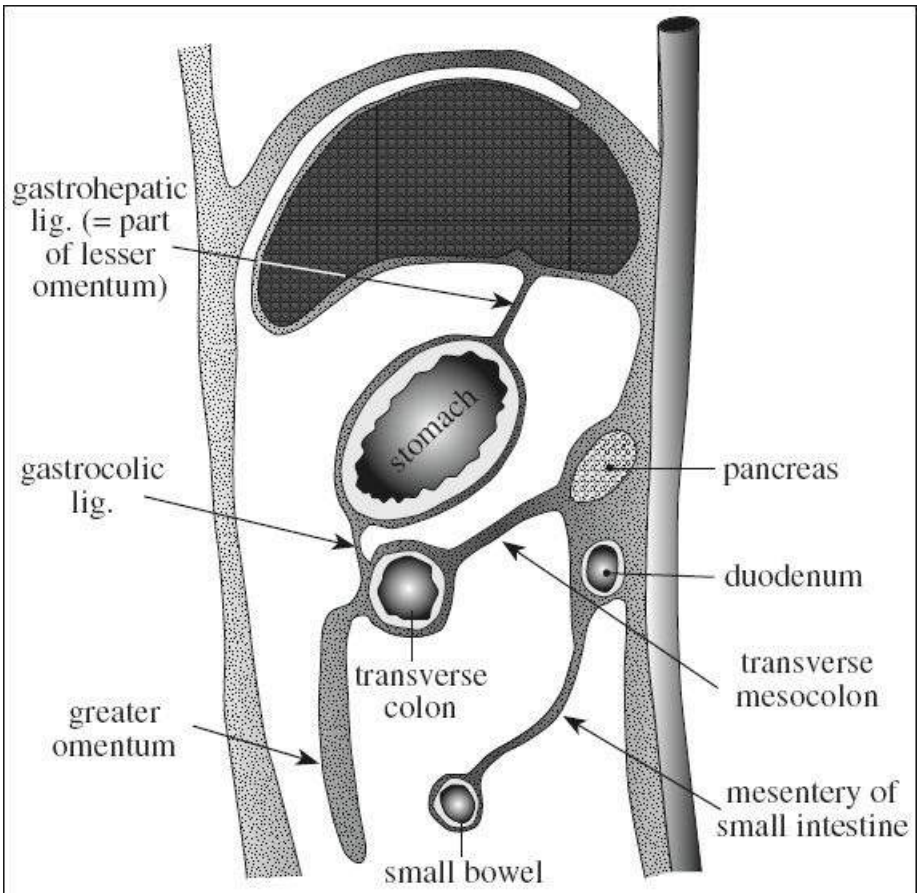
The right subhepatic space is an important site of fluid collections resulting from liver injuries because it is the most gravity-dependent space at this site.

3. **Bare area** of liver

Location: between reflections of right + left coronary ligaments

√ continuous with right anterior pararenal space

4. **Lesser sac / omental bursa**



Relationship of Transverse Mesocolon, Greater Omentum, Small Bowel Mesentery and Ligaments

(a) superior recess:

√ surrounds medial aspect of caudate lobe
√ separated from splenic recess by gastropancreatic fold

(b) splenic recess:
√ extends across midline to splenic hilum

(c) inferior recess:
√ separates stomach from pancreas + transverse mesocolon
√ anteriorly covered by lesser omentum

Compartments: separated by **gastropancreatic fold** ← elevation of posterior parietal peritoneum by left gastric artery into
› smaller medial compartment
› larger lateral compartment

B. LEFT SUPRAMESOCOLIC SPACE forms
1. **Left subphrenic space** artificially divided into
(a) immediate subphrenic space: between diaphragm + gastric fundus
(b) perisplenic space: bounded inferiorly by phrenicocolic ligament
(c) subhepatic space = gastrohepatic recess: located between lateral segment of left hepatic lobe + stomach; separated from right subphrenic space by falciform ligament

C. PARACOLIC SPACES
1. Right + left **paracolic gutter**
Location: lateral to ascending + descending colon

D. INFRAMESOCOLIC SPACES
1. Right **inframesocolic space**
Location: medial to ascending colon
√ limited inferiorly by attachment of small bowel mesentery to cecum
2. Left inframesocolic space
Location: medial to descending colon
√ communicates freely with pelvis
3. Superior + inferior **ileocecal recesses**
Location: above + below terminal ileum
4. **Intersigmoid recess**
Location: along undersurface of sigmoid mesocolon
5. **Retrocecal space**
• present only if peritoneum reflects posterior to cecum

Suspensory Ligaments of Liver

1. **Triangular Ligaments** outline bare area of liver
(a) Right triangular ligament
Origin: fusion of inferior + superior reflections of right coronary ligament
√ long ligament dividing posterior aspect of right perihepatic space into right subphrenic space + posterior right subhepatic space

(b) Left triangular ligament
Origin: fusion of inferior + superior reflections of left coronary ligament
Location: along superior aspect of left hepatic lobe
√ short noncompartmentalizing ligament

2. **Falciform ligament**
   = sickle-shaped fold composed of two layers of peritoneum
   √ incomplete barrier to fluid transfer from right subphrenic to left perihepatic space
   √ continuous with fissure for ligamentum venosum
   Origin: remnant of the most anterior part of the ventral mesentery
   Relationship: ventral surface of liver to anterior abdominal wall; its right layer continues into the superior layer of the coronary ligament, its left layer continues into the anterior layer of the left triangular ligament
   Content: ligamentum teres (= obliterated umbilical vein) in its free inferoposterior margin, recanalized paraumbilical veins

Peritoneal Ligaments of Stomach

1. **Lesser omentum**
   Origin: remnants of dorsal portion of ventral mesentery
   Formed by: gastrohepatic + hepatoduodenal ligaments
   (a) **Gastrohepatic ligament**
   = wedge-shaped ligament arising in fissure of ligamentum venosum
   Relationship: lesser curvature of stomach to fissure of ligamentum venosum (anterior to caudate lobe at medial aspect of liver); subperitoneal areolar tissue of gastrohepatic ligament continues into liver as Glisson capsule
   Content: adipose tissue, left gastric artery, coronary vein, lymph nodes
   Vascular landmark: anastomotic arcade formed by right + left gastric artery & vein along lesser curvature of stomach
   (b) **Hepatoduodenal ligament**
   = double-layered tubular peritoneum = free edge of lesser omentum
   Insertion: between 1st and 2nd portions of duodenum
   Contents: portal triad (main portal vein, proper hepatic artery, common hepatic duct): gallbladder neck; part of cystic duct; ventral anlage of pancreas (until 8th embryonic week)
   Vascular landmarks: proper hepatic artery, portal vein, right gastric vein draining into portal vein
   → forms inferior edge of gastrohepatic ligament
   → forms anterior margin of epiploic foramen
   › extends from proximal duodenum to porta hepatis
2. **Gastrophrenic ligament**
   Origin: anterosuperior portion of dorsal mesentery
   Content: short gastric vessels, varices after splenic vein thrombosis, route of subperitoneal spread of pancreatic exudate
   → courses through immediate subphrenic space
   → suspends stomach from dome of diaphragm
3. **Greater omentum**
   Origin: anteroinferior portion of dorsal mesentery becomes redundant ← growth + rotation of stomach in utero; formed by double reflection of dorsal mesogastrium thus composed of 4 layers of peritoneum
   Attachment: greater curvature of stomach

Content: epiploic artery & vein ← gastroepiploic arcade
Function: containment of intraperitoneal infections
√ inferior continuation of gastrocolic ligament with apronlike extension in anterior abdominal cavity

4. **Gastropancreatic ligament**
   Origin: formed by proximal left gastric artery
   Relationship: posterior aspect of gastric fundus to retroperitoneum
   → partially separates superior recess of lesser sac from splenic recess
5. **Gastrocolic ligament / supracolic omentum**
   = portion of peritoneum between greater gastric curvature and transverse colon
   → forms portion of anterior border of lesser sac
   → forms superior aspect of greater omentum
   Relationship: greater curvature of stomach to superior aspect of transverse colon
   Contiguity: gastrosplenic ligament (on left); transverse mesocolon (posteriorly and on right)
   Content: R and L gastroepiploic arteries form anastomotic arcade along greater curvature of stomach = anatomic landmark for gastrocolic ligament

Peritoneal Ligaments of Spleen

1. **Phrenicocolic ligament**
   = major suspensory ligament of spleen
   Relationship: proximal descending colon to left hemidiaphragm
   → separates left subphrenic space from left paracolic gutter
2. **Splenorenal ligament**
   = major suspensory ligament of spleen
   Origin: most posterior + lateral aspect of dorsal mesentery where it didn't fuse with posterior parietal layer of peritoneum
   Relationship: retroperitoneum (anterior to left kidney) to splenic hilum = anterior pararenal space to posterior aspect of spleen
   Contiguity: with gastrocolic ligament
   Vascular landmarks: distal splenic artery, proximal splenic vein, splenorenal collateral vessels in portal hypertension
   Content: pancreatic tail, splenic vessels
   → forms left posterolateral boundary of lesser sac
3. **Gastrosplenic ligament**
   Origin: remnant of dorsal mesentery
   Relationship: posterolateral wall of gastric fundus and greater curvature to splenic hilum
   Contiguity: with splenorenal ligament medially and posteriorly
   Vascular landmarks: left gastroepiploic vessels; proximal segment of L gastroepiploic vessels
   Content: short gastric vessels
   → forms lateral boundary of lesser sac

Ligaments of Abdomen

The transverse mesocolon divides the peritoneum into the supramesocolic and inframesocolic spaces.

› ***above transverse mesocolon:***

A. VENTRAL MESENTERY gives rise to:
   1. Falciform ligament
   2. Right triangular ligament
   3. Left triangular ligament
   4. Gastrohepatic ligament
   5. Hepatoduodenal ligament

B. DORSAL MESENTERY gives rise to:
   1. Gastrophrenic ligament
   2. Gastropancreatic ligament
   3. Phrenicocolic ligament
   4. Gastrosplenic ligament
   5. Splenorenal ligament
   6. Gastrocolic ligament

› ***below transverse mesocolon:***

A. VENTRAL MESENTERY regresses

B. DORSAL MESENTERY

Origin: during progression of foregut rotation, dorsal mesoduodenum + dorsal mesogastrium fuse with parietal layer of peritoneum pushing head and body of pancreas into retroperitoneum

Contiguity: laterally with splenorenal + phrenicocolic ligaments; anteriorly with root of small bowel mesentery (over uncinate process), greater omentum + gastrocolic ligament

Significance: bare areas establish contiguity between pancreas and transverse colon up to splenic flexure, spleen, and small bowel allowing for subperitoneal spread

√ pericolitis with relative sparing of mucosa and submucosa (15%) ← acute pancreatitis with direct spread of pancreatic enzymes

Cx: colonic perforation

Mortality: increased to 40%

1. **Transverse mesocolon**

= peritoneal fold that suspends transverse colon from retroperitoneum along infraampullary duodenum + anteroinferior edge of pancreas

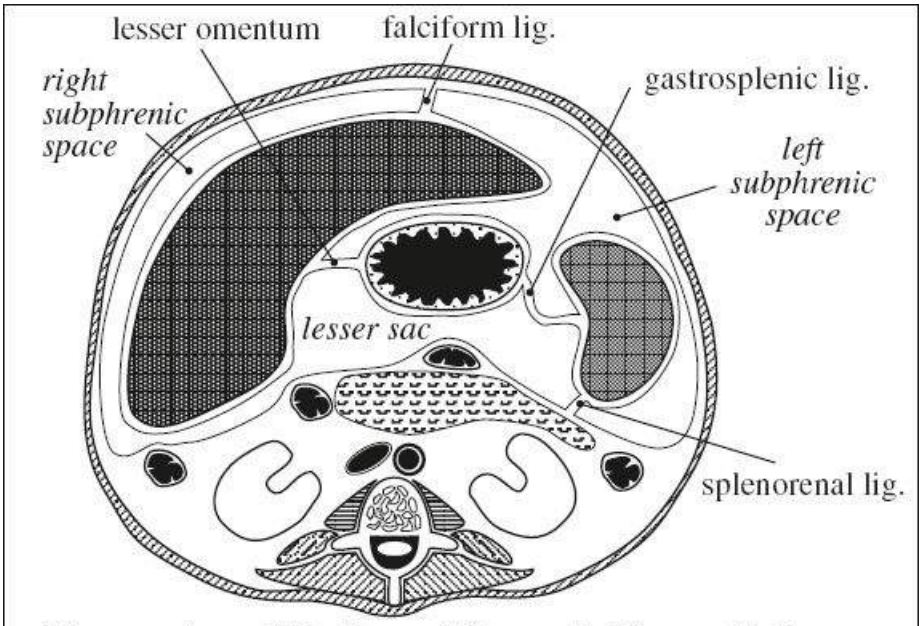
Relationship: transverse colon to pancreas

Vascular landmarks:

middle colic artery & vein, gastrocolic trunk, left middle colic v. to splenic v. / inferior mesenteric v.

√ forms posteroinferior border of lesser sac

Content: internal hernia after Roux-en-Y gastric bypass, spread of pancreatic cancer rendering it inoperable



Ligaments and Peritoneal Spaces in Upper Abdomen

2. **Small bowel mesentery**
   √ suspends small bowel from retroperitoneum
   Location: ligament of Treitz to ileocecal valve
   Content: superior mesenteric vessels + lymph nodes
3. **Sigmoid mesocolon**
   = peritoneal ligament that attaches sigmoid colon to posterior pelvic wall
   Content: sigmoid + hemorrhoidal vessels
4. Greater omentum *(see above)*

Tumors and fluid collections may spread across the peritoneal ligaments (= subperitoneal spread) to involve several contiguous organs.

INGUINAL CANAL

= narrow diagonal tunnel lined by aponeuroses of the 3 abdominal wall muscles

Course: from deep inguinal ring (superiorly posterolateral) to superficial inguinal ring (inferiorly anteromedial)

Content:
(a) male: spermatic cord covered by fascia from all 3 abdominal wall muscle aponeuroses comprising:
- › ductus / vas deferens
- › testicular artery
- › pampiniform plexus
- › genital branch of the genitofemoral nerve

(b) female:
- › round ligament of uterus
- › ilioinguinal nerve to labia majora

Anterior wall: aponeuroses of the external + internal oblique mm.

Superior wall: aponeuroses of internal oblique and transversus abdominis muscles
Posterior wall: transversalis fascia and conjoint tendon of internal oblique + transversalis fascia medially at the pectineal line
Inferior wall: inguinal ligament of Poupart (= folded-up lower border of the external oblique aponeurosis
[François Poupart (1616-1708), French physician, anatomist, entomologist in Paris, France]

Deep / Internal Inguinal Ring

= gap in the transversalis fascia just superior to the inguinal ligament + lateral and posterior to inferior epigastric vessels

Superficial / External Inguinal Ring

= opening in the external oblique aponeurosis just superior + lateral to the pubic tubercle

Inguinal Ligament

= extends from anterior superior iliac spine to the pubic tubercle

ANATOMY OF LYMPH NODES

Paraaortic Nodes

Lateroaortic Nodes

1. Lateroaortic (on left of aorta)
2. Aortocaval (between aorta + IVC)
3. Laterocaval (on right of IVC)
4. Precaval (in front of IVC)
5. Retrocaval (behind IVC)

Preaortic Nodes

Retroaortic Nodes

Iliac Nodes

Common Iliac Nodes

1. Lateral common iliac nodes
   = extension of lateral chain of external iliac nodes
   Location: lateral to common iliac artery
2. Median common iliac nodes
   Location: triangular area between both common iliac arteries from bifurcation of aorta to bifurcation of common iliac arteries
3. Medial common iliac nodes
   Location: lumbosacral fossa (bordered posteromedially by vertebrae, anterolaterally by psoas muscle, anteromedially by common iliac vessels)

Internal Iliac = Hypogastric Nodes

accompany each visceral branch of internal iliac artery

1. Junctional nodes
   Location: at junction between internal + external iliac nodes
2. Sacral + promontory nodes
   Location: central location of presacral space

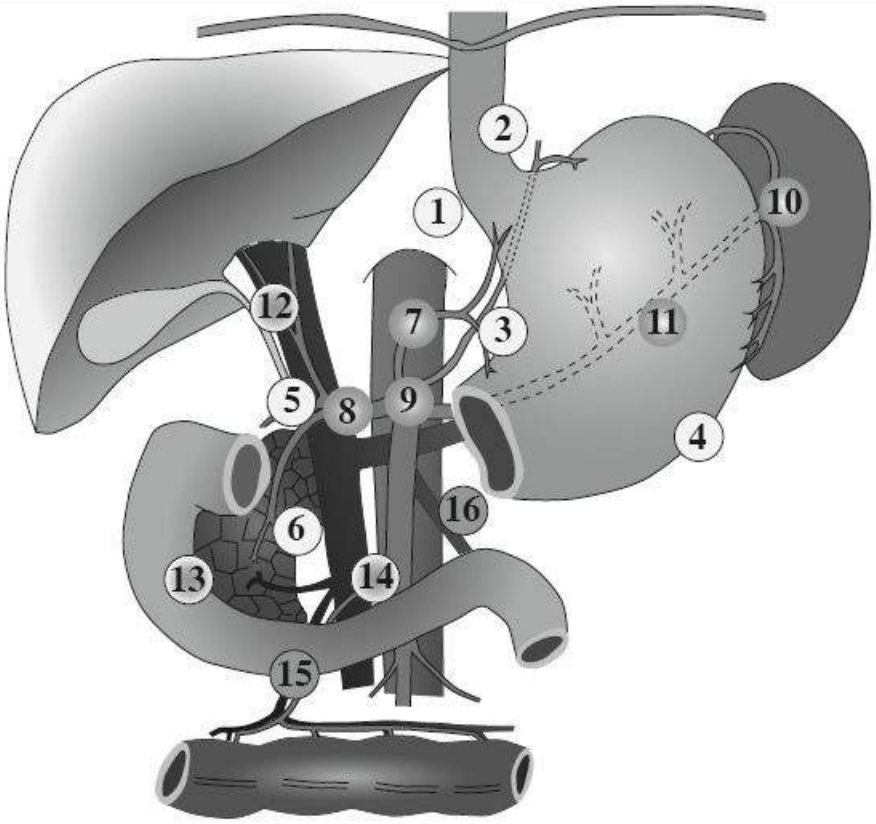
External Iliac Nodes

1. Lateral chain
   Location: lateral relative to external iliac artery)
2. Middle chain
   Location: between external iliac artery + vein)
3. Medial chain = obturator nodes
   Location: medial + posterior to external iliac vein)

Inguinal nodes

demarcated from external iliac nodes by inguinal ligament

1. Superficial inguinal nodes
   Location: subcutis anterior to inguinal ligament along femoral vein + saphenous vein
   Saphenofemoral junction node = sentinel node
2. Deep inguinal nodes
   Location: along common femoral artery + vein



Perigastric Lymph Nodes

Compartment I			
1	right paracardium	2	left paracardium
3	lesser curvature	4	greater curvature
5	suprapylorus	6	infrapylorus
Compartment II			
7	left gastric a.	8	common hepatic a.
9	celiac a.	10	splenic hilum
11	proximal splenic a.		
Compartment III			
		12	hepatoduodenal lig.
13	posterior pancreas	14	superior mesenteric vessels
Compartment IV			
15	middle colic vessels	16	abdominal aorta

ABDOMINAL COMPARTMENT SYNDROME

Cause: pathologic elevation of intraabdominal pressure
- diminished respiratory function, diminished cardiac output

CT:
- √ dense infiltration of the retroperitoneum out of proportion to peritoneal disease
- √ accumulation of retroperitoneal fluid
- √ extrinsic compression of IVC by retroperitoneal hemorrhage / exudate
- √ massive abdominal distension
- √ renal compression
- √ inguinal herniation
- √ enhancing bowel thickening

Rx: emergent surgical decompression

ACHALASIA

= absence of primary esophageal peristalsis (= unorganized peristalsis) + failure of lower esophageal sphincter to relax

Etiology: (a) idiopathic: abnormality of Auerbach plexus / medullary dorsal nucleus; ? neurotropic virus, ? gastrin hypersensitivity
(b) Chagas disease

- often increase in lower esophageal sphincter pressure

√ megaesophagus = dilatation of esophagus beginning in upper ⅓, ultimately entire length
√ absence of primary peristalsis below level of cricopharyngeus
√ nonperistaltic contractions
√ "bird-beak" / "rat tail" deformity = V-shaped conical and symmetric tapering of stenotic segment with most marked narrowing at GE junction
√ Hurst phenomenon = temporary transit through cardia when hydrostatic pressure of barium column is above tonic LES pressure
√ sudden esophageal emptying after ingestion of carbonated beverage (eg, Coke)
√ "vigorous achalasia" = numerous tertiary contractions in nondilated distal esophagus of early achalasia
√ prompt relaxation of LES upon amyl nitrite inhalation (smooth-muscle relaxant)

CXR:
- √ right convex opacity behind right heart border; occasionally left convex opacity if thoracic aorta tortuous
- √ right convex opacity may be tethered by azygos arch allowing for greater dilatation above + below
- √ air-fluid level ← stasis in thoracic esophagus filled with retained secretions + alimentary residue
- √ small / absent gastric air bubble

√ anterior displacement + bowing of trachea (LAT view)
√ patchy bilateral alveolar opacities ← acute / chronic aspiration pneumonia (M. fortuitum-chelonei infection)

Cx: esophageal carcinoma in 2–7% (usually midesophagus)

Rx: pneumatic dilatation / surgical myotomy

DDx: (1) Neoplasm (separation of gastric fundus from diaphragm, normal peristalsis, asymmetric tapering)
(2) Peptic stricture of esophagus

Secondary Achalasia

= carcinoma of cardia / gastric fundus invading esophagus

Age: > 50 years

• duration of symptoms for < 6 months
√ irregular / asymmetric narrowing
√ abrupt transition
√ associated fundal lesion

Pseudoachalasia

• more abrupt onset of symptoms, weight loss

Cause: primary or metastatic tumor
Location: distal esophagus + GE junction
√ dilated esophagus
√ irregular luminal narrowing with lobulated margins
DDx: achalasia (tapered beaklike narrowing of distal esophagus + GE junction)

ADENOMA OF SMALL BOWEL

Location: duodenum (21%), jejunum (36%), ileum (43%) esp. ileocecal valve

Histo:

(1) Hamartomatous polyp (77%): multiple in 47%, ⅓ of multiple lesions associated with Peutz-Jeghers syndrome
(2) Adenomatous polyp (13%): may have malignant potential
(3) Polypoid gastric heterotopic tumor (10%)

ADENOMATOUS COLONIC POLYP

= EPITHELIAL POLYP

Most common benign colonic tumor (68–79%)

Predisposed: previously detected polyp / cancer; family history of polyps / cancer; idiopathic inflammatory bowel disease; Peutz-Jeghers syndrome; Gardner syndrome; familial polyposis

Prevalence: 3% (10%) [26%] in 3rd (7th)) [9th]] decade

Location: sigmoid (26–38%); rectum (21–34%); descending colon (6–18%); transverse colon (12–13%); ascending colon (9–12%); multiple in 35–50% (usually < 5–10 in number)

Histo:

1. **Tubular adenoma** (75%)
   = cylindrical glandular formation lined by stratified columnar epithelium + containing nests of epithelium within lamina propria
   √ usually < 10 mm in diameter
   √ often pedunculated if > 10 mm
   Malignant potential: < 10 mm in 1%; 10–20 mm in 10%; > 20 mm in 35%
2. **Tubulovillous adenoma** (15%)
   = mixture between tubular + villous adenoma
   Malignant potential: < 10 mm in 4%; 10–20 mm in 7%; > 20 mm in 46%
3. **Villous adenoma** (10%)
   = thin frondlike surface projections ("villous fronds")
   • potassium depletion
   √ often > 20 mm in diameter with papillary surface
   √ often broad-based sessile lesion
   Malignant potential: < 10 mm in 10%; 10–20 mm in 10%; > 20 mm in 53%

Adenoma size versus incidence of malignancy:
< 5 mm in 0.5%; 5–9 mm in 1%; 10–20 mm in 5–10%;
> 20 mm in 10–50% malignant
◊ Invasive carcinoma (= penetration of muscularis mucosa):
(a) rare in a pedunculated adenoma of < 15 mm
(b) in 30% of villous adenomas of > 50 mm
◊ All polyps > 10 mm should be removed!
◊ Time for adenoma-carcinoma sequence probably averages 10–15 years!

Probability of coexistent colonic growth:
› synchronous adenoma in 50%
› metachronous adenoma in 30–40%
› synchronous adenocarcinoma in 1.5–5%
› metachronous adenocarcinoma in 5–10%

• asymptomatic (75%), diarrhea, abdominal pain
• peranal hemorrhage (67%)

Colonoscopy: incomplete in 16–43%

BE:
Sensitivity of DCBE in detecting polyps:
< 10 mm 80–83%; > 10 mm 96–97%; all 84–88%; rate of detection of polyps < 10 mm higher with DCBE than SCBE
√ sessile flat / round polyp
√ pedunculated polyp: stalk > 2 cm in length almost always indicative of a benign polyp
√ suggestive of malignancy: irregular lobulated surface, broad base (= width of the base greater than height), retraction of colonic wall (= dimpling / indentation / puckering at base of tumor), interval growth
√ lacelike / reticular surface pattern CHARACTERISTIC for villous adenoma (occasionally in tubular adenoma)

DDx: (1) Nonneoplastic: hyperplastic polyp, inflammatory pseudopolyp, lymphoid tissue, ameboma, tuberculoma, foreign-body granuloma, malakoplakia, heterotopia,

hamartoma

(2) Neoplastic subepithelial: lipoma, leiomyoma, neurofibroma, hemangioma, lymphangioma, endothelioma, myeloblastoma, sarcoma, lymphoma, enteric cyst, duplication, varix, pneumatosis, hematoma, endometriosis

ADENOCARCINOMA OF SMALL BOWEL

Frequency: 35–40% of primary malignant neoplasms of small bowel; ~ 50 x less common than colonic carcinoma

◊ Most common primary tumor of small bowel

Risk factors: familial adenomatous polyposis (FAP), Crohn disease, sprue, Peutz-Jeghers syndrome, hereditary nonpolyposis colon cancer syndrome (Lynch syndrome), congenital bowel duplication, ileostomy, duodenal / jejunal bypass surgery

Histo: mostly moderately to well differentiated; may arise in villous tumors / de novo; no correlation between size and invasiveness

- vague mild abdominal pain, anemia, weight loss
- nausea, vomiting, anorexia

Location: duodenum (54%, especially near ampulla) > jejunum (28%) > ileum (18%)

› in familial adenomatous polyposis: duodenum
› in celiac disease: jejunum
› in Crohn disease: ileum

√ variety of shapes:
- √ annular stricture with "overhanging edges" (60%)
- √ lobulated / ovoid polypoid sessile mass (41%)
  - ◊ Duodenal tumors tend to be papillary / polypoid!
- √ ulcerated plaque / mass (27%)

CT:
- √ soft-tissue mass with heterogeneous attenuation
- √ moderate contrast enhancement

Cx: progressive small bowel obstruction; intussusception; perforation (rare)

Prognosis: poor (often disseminated at time of presentation); 30% 5-year survival rate

DDx: lymphoma (lymphadenopathy more bulky)

Duodenal Adenocarcinoma

= rare tumor that typically abuts but spares / only partially involves the major duodenal papilla

Prevalence: 1.7÷1,000,000; M < F

Location: most often in 2nd + 3rd portion = periampullary neoplasm

(a) suprapapillary: apt to cause obstruction + GI bleeding
(b) peripapillary: extrahepatic jaundice
(c) intrapapillary: GI bleeding

Predisposed: familial adenomatous polyposis syndrome, Crohn disease, celiac disease, neurofibromatosis

May be associated with: Peutz-Jeghers syndrome

√ eccentric duodenal wall thickening ± ulceration:

√ annular lesion with relatively short segment involvement
√ fungating polypoid / intraluminal mass
√ gradual luminal narrowing (most common)
√ luminal obstruction + gastric distention ← larger tumor
√ ± biliary dilatation
CT / MR:
√ hypovascular during all phases
Metastases: to regional lymph nodes (²/₃)
DDx: other periampullary lesions

AFFERENT LOOP SYNDROME

= PROXIMAL LOOP / BLIND LOOP SYNDROME
= partial intermittent obstruction of afferent loop leading to overdistension of loop by gastric juices after Billroth-II gastrojejunostomy
Cause: gastrojejunostomy with left-to-right anastomosis (= proximal jejunal loop attached to greater curvature instead of lesser curvature), mechanical factors (intussusception, adhesion, kinking), inflammatory disease, neoplastic infiltration of local mesentery or anastomosis, idiopathic motor dysfunction
• postprandial epigastric fullness relieved by bilious vomiting
• vitamin B12 deficiency with megaloblastic anemia
• afferent loop with abnormal bacterial flora (Gram negative, resembling colon in quality + quantity)
Abdominal plain film:
√ normal in 85% (no air in lumen of afferent loop)
UGI:
√ preferential emptying of stomach into proximal loop
√ proximal loop stasis
√ regurgitation
CT:
√ rounded water-density masses adjacent to head + tail of pancreas forming a U-shaped loop
√ oral contrast material may not enter loop
√ may result in biliary obstruction (increased pressure at ampulla)
Rx: antibiotic therapy

AIDS

◊ Gastrointestinal involvement ← opportunistic infections + AIDS-associated neoplasms!
◊ Pathologic abnormalities at multiple sites with single / several opportunistic organisms are frequent!

A. VIRAL PATHOGENS

1. **Cytomegalovirus infection**

◊ Most common cause of life-threatening opportunistic viral infection in AIDS patients!
Organism: double-stranded DNA virus of herpes family
Infection: ubiquitous among humans occurring at an early age in populations with poor sanitation + crowded living conditions

◊ Result of reactivation of latent virus in previously infected host!

Prevalence: 13% of all GI diseases in AIDS patients

Path: infection of endothelial cells → small vessel vasculitis → hemorrhage, ischemic necrosis, ulcer

Histo: large mononuclear epithelial / endothelial cells that contain intranuclear / cytoplasmatic inclusions with surrounding inflammation

Location: colon > small bowel (terminal ileum) > esophagus > stomach

@ Esophagus

√ single / multiple large superficial ulcers

@ Small bowel

√ luminal narrowing ← marked bowel wall thickening

√ diffuse irregular fold thickening ← thrombosis and ischemia ← vasculitis

√ penetrating ulcer ± perforation

√ CMV pseudotumor (uncommon)

@ Colon (CMV colitis)

• hematochezia, crampy abdominal pain, fever

√ toxic megacolon

√ discrete small well-defined nodules (similar to lymphoid nodular hyperplasia) throughout colon

√ aphthous ulcers on background of normal mucosa

√ marked bowel wall thickening

√ "double-ring / target" sign on CT ← increased submucosal edema

√ ascites

√ inflammation of pericolonic fat + fascia

Rx: ganciclovir (effective in 75%)

2. **Herpes simplex virus infection**

◊ Result of reactivation of latent virus in previously infected host

Organism: neurotropic DNA virus of herpes family

Prevalence: 70% for type 1, 16% for type 2 (endemic in USA); type 2 much more common in AIDS

Infection: direct inoculation through mucous membrane contact; from dormant state in root ganglia reactivated + transported via efferent nerves to mucocutaneous surface

Location: oral cavity, esophagus, rectum, anus

√ multiple small discrete ulcers

3. **Human immunodeficiency virus infection**

◊ Not an AIDS-defining illness!

Infection: acute HIV-infection with transient immunosuppression / during AIDS

√ > 2-cm large solitary ulcer in the mid- or distal esophagus (HIV-infected cells → alterations in cytokines → infiltration of inflammatory cells into submucosa and destruction of mucosa

Rx: corticosteroids

B. FUNGAL PATHOGENS

1. **Candidiasis**

◊ The absence of thrush does NOT exclude the diagnosis of candida esophagitis!

Organism: commensal fungus Candida albicans

Prevalence: 10–20% (in USA); up to 80% in developing countries

Location: oral cavity, esophagus

√ discrete linear / irregular longitudinally oriented filling defects in esophagus

Cx: disseminated systemic candidiasis (rare; indicative of granulocytopenia from chemotherapy / direct inoculation via catheter)

2. **Histoplasmosis**

Organism: dimorphic opportunistic fungus

Prevalence: 10% GI involvement with disseminated histoplasmosis in AIDS patients

Location: colon > terminal ileum

√ segmental inflammation / apple core lesion / bowel stricture

√ hepatosplenomegaly

√ mesenteric lymphadenopathy

√ diffuse hypoattenuation of spleen

C. PROTOZOAN PATHOGENS

1. **Cryptosporidiosis**

◊ One of the most common causes of enteric + biliary disease in AIDS patients!

Organism: intracellular parasite Cryptosporidium

Prevalence: isolated in 6% of all patients with AIDS; in 16% (in USA) + in up to 48% (in developing countries) of patients with diarrhea

• severe choleralike debilitating diarrhea with fluid loss of 10–17 L/d

Location: jejunum > other small bowel > stomach > colon

√ Cryptosporidium antritis = area of focal gastric thickening + ulceration

√ small bowel dilatation ← increased secretions

√ regular fold thickening + effacement ← atrophy, blunting, fusion, loss of villi

√ "toothpaste" appearance of small bowel (mimicking sprue)

√ dilution of barium ← hypersecretion

√ marked antral narrowing ← extensive inflammation

√ AIDS-related cholangitis

Dx: microscopic identification in stool / biopsy

2. **Pneumocystosis**

◊ Likely to occur in patients treated with aerosolized pentamidine!

Organism: eukaryotic microbe Pneumocystis carinii

Prevalence: pulmonary infection in 75% of AIDS patients; in < 1% dissemination

Location: liver, spleen, lymph nodes

√ hepatic + splenic + nodal punctate calcifications

√ multiple tiny echogenic foci in spleen

√ multiple low-attenuation lesions of varying size in spleen (foamy eosinophilic material) → subsequently progressive rimlike / punctate calcifications

D. BACTERIAL PATHOGENS

1. **Tuberculosis**

◊ Most common cause of serious HIV-related infection worldwide with tendency to occur earlier than other AIDS-defining opportunistic infections!

Prevalence: 4% (in USA) + 43% (in developing countries) of HIV-infected persons
Infection: swallowing of infected sputum; hematogenous spread from pulmonary focus; direct extension from lymph node
Location: lymph nodes, liver, spleen, peritoneum, GI tract (especially ileum, colon, ileocecal valve)
√ low-attenuation mesenteric lymphadenopathy ← suggestive of necrosis
√ segmental ulceration
√ inflammatory stricture
√ hypertrophic lesion resembling polyp or mass

2. **Mycobacterium avium complex infection**

= PSEUDO-WHIPPLE DISEASE IN AIDS
◊ Most common opportunistic infection of bacterial origin in AIDS patients!
◊ Most common nontuberculous mycobacterial infection in AIDS patients!
Organism: facultative intracellular acid-fast bacillus M. avium / M. intracellulare
Infection: invasion of Peyer patches + adjacent mesenteric lymph nodes
Histo: true granulomas with Langhans giant cells and caseous necrosis are rare because infection occurs in patients with advanced disease and a CD4 cell count of < 100/μL
• diarrhea, malabsorption (similar clinical picture as in Whipple disease caused by Mycobacterium avium-intracellulare)
Location: jejunum (most common)
√ mild dilatation of middle + distal small bowel
√ wall thickening of small bowel loops
√ diffuse irregular thickening of mucosal fold and nodularity without ulceration
√ mesenteric + retroperitoneal lymphadenopathy:
√ homogeneous 1.0–1.5 cm nodes of soft-tissue attenuation causing segmental separation of small bowel loops
√ necrotic mesenteric nodes of low attenuation (= pseudo-Whipple disease)
√ hepatosplenomegaly
√ multiple tiny echogenic foci in liver + spleen (occasionally large hypoechoic / low-attenuation lesions)
Dx: (1) Visualization of large numbers of intracellular acid-fast bacilli in foamy histiocytes of tissue specimen
(2) Tissue culture
DDx: Whipple disease (positive with periodic acid-Schiff stain just like M. avium, but not with acid-fast stain, responsive to tetracyclines)

E. OTHER INFECTIONS

1. **Bacillary angiomatosis**

Organism: rickettsia Bartonella henselae
Histo: characteristic pattern of vascular proliferation with bacilli
Location: cutis (mimicking Kaposi sarcoma), liver, spleen, lymph nodes
√ peliosis (= blood-filled cystic spaces) of liver / spleen
√ abdominal lymphadenopathy with contrast enhancement

2. **Isospora belli**

◊ Infection resembles cryptosporidiosis

Organism: protozoan pathogen

Histo: oval oocysts within bowel lumen / epithelial cells; localized inflammation; fold atrophy

Location: small intestine

• severe watery diarrhea

√ fold thickening

F. AIDS-ASSOCIATED NEOPLASMS

1. **Kaposi sarcoma**
2. **Non-Hodgkin lymphoma**

◊ 2nd most common AIDS-associated neoplasm

Prevalence: in 4–10% of AIDS patients (60 x higher risk compared with general population); occurs in all AIDS risk groups

Histo: multiclonal B-cell lymphoma of high / intermediate grade

• at initial presentation widely disseminated disease often with extranodal involvement

Location: CNS, bone marrow, GI tract (stomach, small bowel)

@ Stomach

√ circumferential / focal wall thickening

√ mural mass ± ulceration

@ Small bowel

√ diffuse / focal wall thickening

√ excavated mass

√ solitary / multiple liver lesions

Differential diagnostic considerations:

1. Splenomegaly (31–45%)
   Cause: nonspecific (most), lymphoma, infection (M. avium-intracellulare, P. carinii)
2. Lymphadenopathy (21–60%)
   Cause: reactive hyperplasia (most), Kaposi sarcoma, lymphoma, infections
   Size: < 3 cm in diameter (in 95%)
3. Hepatomegaly (20%)
   Cause: nonspecific, hepatitis, fatty infiltration, lymphoma, Kaposi sarcoma
4. AIDS-related cholangiopathy:
   Organism: CMV, Cryptosporidium
   √ papillary stenosis of CBD
   √ dilatation of extra- and intrahepatic bile ducts
   √ periductal fibrosis
   √ strictures + irregularities of bile ducts resembling primary sclerosing cholangitis
   √ intraluminal polypoid filling defects
5. AIDS-related esophagitis:
   Organism: Candida, herpes simplex, CMV
   √ giant esophageal ulcer: HIV (76%), CMV (14%)
   √ esophageal fistula / perforation: TB, actinomycosis
6. Gastritis
   Organism: CMV (GE junction + prepyloric antrum), Cryptosporidium (antrum)
7. AIDS enteritis

Organism: Cryptosporidium, M. avium complex

8. AIDS colitis
   - › ischemic bowel
   - › acute appendicitis
   - › neutropenic colitis
   - › pseudomembranous colitis
   - › infectious colitis / ileitis
9. Bowel obstruction
   (a) infection
   (b) intussusception: Kaposi sarcoma, lymphoma

AMEBIASIS

= primary infection of colon by protozoan Entamoeba histolytica

Organism: free-living protozoa widespread in water, soil, air

Countries: worldwide distribution, most common in warm climates; South Africa, Egypt, India, Asia, Central + South America (20%); USA (5%)

Route: ingestion of cysts in contaminated food / water → cyst dissolves in small bowel → trophozoites settle in colon; invasion of bowel wall ← proteolytic enzymes and hyaluronidase that lyse intestinal epithelium; may embolize into portal venous + systemic blood system

Histo: amebic invasion of mucosa + submucosa causing tiny ulcers, which spread beneath mucosa + merge into larger areas of necrosis; mucosal sloughing; secondary bacterial infection

- asymptomatic for months / years; fever, headache, nausea
- acute attacks of diarrhea (= loose mucoid bloodstained stools)

Location: (areas of relative stasis) right colon + cecum (90%) > hepatic + splenic flexures > rectosigmoid

BE:

- √ loss of normal haustral pattern with granular appearance ← edema, punctate ulcers
- √ "collarbutton" ulcers
- √ cone-shaped cecum
- √ several cm long stenosis of bowel lumen in transverse colon, sigmoid colon, flexures (result of healing + fibrosis); in multiple segments
- √ ileocecal valve thickened + fixed in open position with reflux
- √ involvement of distal ileum (10%):
  - ◊ Amebiasis spares terminal ileum (in USA)
- √ ameboma = hyperplastic granuloma with bacterial invasion of amebic abscess; usually annular + constricting / intramural mass / cavity continuous with bowel lumen; shrinkage under therapy in 3–4 weeks

CT/US:

- √ amebic liver abscess of "anchovy sauce" content
- √ pericarditis, pericardial effusion

CXR (consequences of subdiaphragmatic abscess):

- √ elevation of right hemidiaphragm

√ pleural effusion ← transdiaphragmatic spread of infection / sterile sympathetic effusion
√ airspace consolidation ± cavitation

Dx: stool examination / rectal biopsy

Cx: (1) Toxic megacolon with perforation
(2) Amebic abscess in liver (2%), brain, lung, pericolic, ischiorectal, subphrenic space
(3) Intussusception in children ← ameboma
(4) Fistula formation: colovesical, rectovesical, rectovaginal, enterocolic, hepatobronchial, bronchobiliary

AMYLOIDOSIS

= group of heterogeneous disorders caused by interstitial deposits of an insoluble fibrillar protein-polysaccharide in various organs impairing tissue function → hypoxia, mucosal edema, hemorrhage, ulceration, mucosal atrophy, muscle atrophy

Cause: (a) prolonged antigenic stimulation of RES by chronic infection
(b) disorder of immunoincompetence
(c) aging
(d) idiopathic

Histo: amorphous eosinophilic hyaline material deposited around terminal blood vessels, stains with Congo red + crystal violet; green birefringence under polarizing light; amyloid fibrils have β-pleated sheet structure (= β fibrilloses)

Biochemical classification:

1. AL amyloidosis
   (A = amyloidosis, L = light chain immunoglobulin)
   • monoclonal protein in serum + urine
   • occurs in primary amyloidosis + myeloma-associated amyloidosis
   Histo: massive deposits in muscularis mucosae + submucosa
   √ thickening of folds with polyps / large nodules
2. SAA amyloidosis (S = secondary, AA = amyloid A)
   • occurs in secondary = reactive amyloidosis
   • cardiomyopathy with restrictive ventricular filling
   Histo: expansion of lamina propria
   √ coarse mucosal pattern + innumerable fine granular elevations
3. AF amyloidosis (A = amyloid, F = familial)
   • AF prealbumin as precursor of fibrils
   • occurs in familial amyloidosis
4. AS amyloidosis (A = amyloid, S = senile)
   • AS prealbumin as precursor of fibrils
   • occurs in senile amyloidosis
   √ massive amyloid deposition
5. AH amyloidosis (A = amyloid, H = hemodialysis)
   • β_2 microglobulin as precursor of fibrils
6. AE amyloidosis (A = amyloid, E = endocrine)
   • calcitonin produced by medullary thyroid carcinoma is precursor of fibrils

7. Transthyretin (ATTR)-related hereditary amyloidosis
   • cardiomyopathy with restrictive ventricular filling
8. β2-microglobulin (Abeta2M)-derived dialysis-related amyloidosis

Reimann classification (1935):

1. **Primary = idiopathic amyloidosis**
   = amyloid immunoglobulin light chain (AL) disease
   = probably autosomal dominant inheritance with immunologically determined dysfunction of plasma cells (clonal B-cell dyscrasia)
   • absence of discernible preceding / concurrent disease
   Location: (predominant involvement of connective tissues + mesenchymal organs): heart (90%), lung (30–70%), liver (35%), spleen (40%), kidneys (35%), adrenals, tongue (40%), GI tract (70%), skin + subcutis (25%), skeletal muscle, joints
   √ tendency for nodular deposition
   Prognosis: ⅓ eventually develop multiple myeloma / B-cell lymphoma / Waldenström macroglobulinemia / other plasma cell neoplasia
2. **Secondary amyloidosis** (most common form)
   = amyloid-associated disease
   • following / coexistent with prolonged infectious / inflammatory processes
   Cause: rheumatoid arthritis (in 20%), Still disease, TB, chronic osteomyelitis, leprosy, chronic pyelonephritis, bronchiectasis, ulcerative colitis, Crohn disease, familial Mediterranean fever, lymphoreticular malignancy, Waldenström macroglobulinemia
   Location: spleen, liver, kidneys (> 80%), breast, tongue, GI tract, connective tissue
   √ small amyloid deposits
3. **Amyloidosis associated with multiple myeloma**
   • may precede development of multiple myeloma
   Frequency: 10–15%
   √ primary amyloidosis with osteolytic lesions in myelomatous disease
4. **Tumor-forming / organ-limited amyloidosis**
   • related to primary type
   (a) hereditary = familial amyloidosis
   (b) senile amyloidosis (limited to heart / brain / pancreas / spleen)
   √ large localized masses

Classification by distribution:

1. **Localized (organ-limited) amyloidosis** (10–20%)
   = deposition of abnormal proteins <u>in one organ</u>
   Cause: usually primary (rarely secondary) form of amyloidosis; attributed to tissue-based immunocyte dyscrasia
   Rx: supportive / localized management
   Dx: (1) NO monoclonal protein in serum / urine
   (2) negative bone marrow biopsy
   (3) NO evidence of systemic involvement
2. **Systemic amyloidosis** (80–90%)
   = deposition of abnormal proteins <u>in wide variety of organs</u>

Prognosis: progressive & fatal (kidney / heart failure)

Dx: (1) bioptic proof of amyloid deposits in subcutaneous fat / rectal mucosa / bone marrow

(2) monoclonal protein in urine, serum

◊ GI involvement more common in primary than in secondary amyloidosis!

• malabsorption (diarrhea, protein loss); occult GI bleeding

• intestinal pseudo-obstruction; macroglossia

@ Esophagus (11%)

√ loss of peristalsis

√ megaesophagus

@ Stomach (37%)

• postprandial epigastric pain + heartburn

• acute erosive hemorrhagic gastritis

(a) diffuse infiltrative form

√ small-sized stomach with rigidity + loss of distensibility simulating linitis plastica ← thickening of gastric wall

√ effaced rugal pattern

√ diminished / absent peristalsis

√ marked retention of food

(b) localized infiltration (often located in antrum)

√ irregularly narrowed + rigid antrum

√ thickened rugae

√ superficial erosions / ulcerations

(c) amyloidoma = well-defined submucosal mass

@ Small bowel (74%)

(a) diffuse form (more common)

√ irregular diffuse thickening of valvulae conniventes of entire small bowel associated with:

√ 2–3-mm micronodules ← ischemia

√ 6–10-mm nodules ← deposition of fibrillar protein in submucosa + lamina propria

√ broadened flat undulated mucosal folds (mucosal atrophy)

√ "jejunalization" of ileum

√ impaired intestinal motility

√ small bowel dilatation

(b) localized form (less common)

√ multiple pea- / marble-sized deposits

√ pseudoobstruction = physical + plain-film findings suggesting mechanical obstruction with patent large + small bowel on barium examination ← involvement of myenteric plexus

Cx: small bowel infarction

@ Colon (27%)

√ pseudopolyps in colon

@ Liver

Path: extracellular deposition of amyloid in the spaces of Disse (= narrow gaps between

endothelial linings of sinusoids and hepatocytes of hepatic lamina) with progressive encroachment on hepatic parenchymal cells + sinusoids

• hepatic function usually preserved

CT:

√ hepatomegaly

√ regions of low attenuation with decreased contrast enhancement

@ Spleen

Histo: (a) nodular form involving lymph follicles

(b) diffuse form infiltrating red pulp

√ discrete masses

√ splenomegaly (4–13%)

MR:

√ T2 values significantly lower than normal

@ Bone

√ bone cysts

Cx: spontaneous splenic rupture (from vascular fragility + acquired coagulopathy)

Dx: by rectal / gingival biopsy

DDx: Whipple disease, intestinal lymphangiectasia, lymphosarcoma

ANGIODYSPLASIA OF COLON

= VASCULAR ECTASIA = ARTERIOVENOUS MALFORMATION (not a true AVM)

Cause: age-related degenerative dilatation of normal vessels in submucosa of bowel wall

Theory: colonic contractions result in dilatation of colonic veins, venules and capillaries forging multiple small arteriovenous communications

Associated with: aortic stenosis (20%); NOT related to extraintestinal angiomatous lesions

Prevalence: most common vascular lesion of GI tract!

at autopsy: 2%

at colonoscopy: 0.8% (at age > 50 years)

◊ Up to 40% of lower GI bleeding in over age 60

Age: majority > 55 years; M = F

Location: (a) cecum + ascending colon (74%)

(b) jejunum, ileum (15%)

(c) descending + sigmoid colon (? 25%)

Site: usually at antimesenteric border

• chronic intermittent low-grade / occasionally massive bleeding

NUC (^{99m}Tc-labeled RBCs):

√ focus of tracer accumulation at site of bowel hemorrhage migrating with peristalsis

BE:

√ no abnormality ← soft submucosal lesion

CT:

√ avidly enhancing plaque / nodule during enteric phase fading during delayed phase of CT arteriography

√ early draining vein during arterial phase

NUC:
√ increased tracer accumulation of ^{99m}Tc-labeled RBC
Angio:
√ "arterial tuft" = cluster / tangle of vessels during arterial phase along antimesenteric border
√ early opacification of draining ileocolic vein
√ densely opacified dilated tortuous ileocolic vein into late venous phase
√ contrast extravasation into bowel lumen (unusual)
Prognosis: spontaneous cessation of bleeding in 80%, recurrent bleeding in 85%
Rx: surgical excision

ANISAKIASIS

= parasitic disease of GI tract
Cause: ingestion of Anisakis larvae present in raw / undercooked fish (mackerel, cod, pollack, herring, whiting, bonito, squid) consumed as sashimi, sushi, ceviche, lomi-lomi
Organism: worm with straight / serpentine / circular threadlike appearance
◊ Site of penetration by larvae determines clinical form!
@ Gastric anisakiasis
• acute gastric pain, nausea, eosinophilia
• vomiting a few hours after ingestion (DDx: acute gastritis, peptic ulcer, neoplasia, food poisoning)
√ mucosal edema
√ about 3 cm long threadlike filling defects (= larvae)
@ Intestinal anisakiasis
• diffuse abdominal tenderness / colicky abdominal pain, nausea, vomiting (DDx: acute appendicitis, regional enteritis, intussusception, ileus, diverticulitis, neoplasia)
• leukocytosis without eosinophilia (frequent)
Histo: marked edema, eosinophilic infiltrates, granuloma formation
√ thickened folds
√ disappearance of Kerckring folds
√ thumbprinting / saw-tooth appearance
√ irregular luminal narrowing
√ eosinophilic ascites (DDx: eosinophilic gastroenteritis, hypereosinophilic syndrome)
Cx: ileus
@ Colonic anisakiasis (rare)
DDx: colonic tumor

ANORECTAL MALFORMATION

= complex group of congenital anomalies involving distal anus, rectum, urinary and genital tracts
Prevalence: 1÷5,000 live births; M > F
Cause: abnormal development of urorectal septum in early fetal life
Embryology:
› 3rd and 4th week GA: dorsal part of yolk sac folds are incorporated into embryo forming the **primitive hindgut** that consists of distal part of transverse, descending and sigmoid colon,

rectum, superior portion of anal canal, epithelium of urinary bladder, and most of the urethra

› 4th week GA: coronal sheet of mesenchyme (= **urorectal septum** = transverse rectovesical septum) → descends caudally between allantois and hindgut → divides primitive cloaca into urogenital sinus ventrally and anorectal canal dorsally; **cloacal membrane** separates cloaca from amniotic cavity

Disturbance leads to: ectopic anal orifice / fistula

› 5th week GA: urorectal septum develops forklike infoldings (Tourneux and Rathke folds) of lateral cloacal walls

› 7th week GA:

(a) urorectal septum fuses with cloacal membrane creating a urogenital membrane ventrally + anal membrane dorsally

(b) **perineum** is formed by fusion of urorectal septum + cloacal membrane

(c) secondary occlusion of anorectal canal by adhesion of wall + formation of an epithelial plug at anus

› 9th week GA: cloacal membrane ruptures by apoptosis forming a ventral urogenital and a dorsal anal orifice

Disturbance leads to: abnormal anus in normal position

In 48–70% associated with other congenital anomalies:

(1) GU anomalies (20–60%): vesicoureteral reflux; hydronephrosis; bi- / unilateral renal agenesis; renal dysplasia; renal ectopia; horseshoe kidney; polycystic kidney; renal duplication; megaureter; bladder exstrophy; micropenis; hypospadia (3.1%); double uterus / vagina; vulvogenital atresia; ambiguous genitalia

(2) Spine (30%): lumbosacral segmentation anomalies with sacral agenesis, vertebral dysplasia, spina bifida; tethered cord; myelomeningocele (0.5%) + occult myelodysplasia

(3) GI anomalies (11%): esophageal atresia ± tracheoesopha-geal fistula (4%); duodenal, jejunal, ileal atresia / stenosis; absent colon; intestinal malrotation; volvulus; Meckel diverticulum

(4) Cardiovascular anomalies (8%): tetralogy of Fallot; ASD; VSD, dextrocardia; coarctation of aorta

(5) Musculoskeletal: hip dislocation / dysplasia; fusion of iliac bones; Madelung deformity; arthrogryposis; clubfoot; polydactyly; syndactyly; limb deficiency

(6) Abdominal wall (2%)

(7) Cleft lip–cleft palate (1.6%)

(8) Down syndrome (1.5%)

(9) Others (8%)

Most common associated syndromes:

(1) VACTERL

(2) **O**mphalocele, **E**xstrophy of bladder, **I**mperforate anus, **S**pinal defect (OEIS)

(3) **Mü**llerian + **R**enal agenesis + **C**ervicothoracic **S**omite dysplasia (MURCS)

(4) Chromosomopathies: Trisomy 13, 18 and 21; uniparental disomy 16; deletion of 22q11.2 and 13q

(5) Numerous other syndromes: caudal regression, Down, fetal alcohol, Ivemark, Klippel-Feil, Opitz, etc.

Wingspread Classification (1984):

1. Low: anal stenosis, anocutaneous (rectoperineal / rectovestibular) fistula
   Rx: corrective surgery on day 2–3 of life ± colostomy
2. Intermediate: anal agenesis without fistula / with rectourethral bulbar fistula
   • passage of meconium through vagina / with urine
   Rx: descending colostomy on day 3 of life
3. High: rectal atresia; anorectal agenesis without fistula / rectourethral prostatic fistula
   • passage of meconium through vagina / with urine

Krickenbeck Classification (2005):

1. Anal stenosis; imperforate anus without fistula / (1) rectoperineal fistula or (2) rectovestibular
2. Anal / anorectal agenesis without fistula / (3) rectourethral bulbar, (4) rectourethral prostatic or (5) rectovesical fistula

OB-US:

◊ Prenatal diagnosis made rarely (in only 16%)!
√ oligohydramnios (26%) + distended bladder
√ abdominal / pelvic cystic mass (52%) ← distended bladder + septate fluid-filled vagina
√ fetal hydronephrosis (49%)
√ fetal ascites (22%)
√ intestinal distension (18%)

Transperineal US:

√ bowel-skin distance on midline SAG (rectal pouch to anus)
  < 15 mm: low type of anorectal malformation
  > 15 mm: high type of anorectal malformation
√ linear tract / fistula may be identified

High-pressure distal colostography:

› Foley catheter through colostomy into distal colon
› gentle traction on inflated balloon for sealing
› manual injection of hydrosoluble contrast material until patient voids

MR:

› transverse images through pubococcygeal plane (= upper border of symphysis pubis + upper border of os coccyx)
› coronal images perpendicular to pubococcygeal plane
√ position of rectal pouch
√ size + morphology + development of levator ani muscle group (levator prostate m. / sphincter vaginae m., puborectalis m., pubococcygeus m., iliococcygeus muscle) + external anal sphincter (subcutaneous, superficial and deep layer)

(1) **Rectal atresia**
= open anus + atretic rectal segment superior to anus + no fistula

(2) **Ectopic anus**
= fistulous opening of bowel ← failure of terminal bowel to descend normally
Site of arrest: high / low colon arrest = above / below puborectal sling
• most common anomaly of anorectal segment
• anal dimple + external sphincter in normal position
Location of fistula: perineum, vestibule, vagina, urethra, bladder, cloaca
√ low small bowel / colonic obstruction

√ "M" line accurately represents level of puborectal muscle = line drawn horizontally through junction of lower ⅓ and upper ⅔ of ischium on lateral radiograph

(3) **Imperforate anus**
= blind ending of terminal bowel + no fistula

(4) **Cloacal malformation**

(5) **Cloacal exstrophy**

ANTRAL-MUCOSAL DIAPHRAGM

= ANTRAL WEB

Age range: 3 months to 80 years

Associated with: gastric ulcer (30–50%)

• symptomatic if opening < 1 cm

Location: usually 1.5 cm from pylorus (range 0–7 cm)

√ constant symmetric band of 2–3 mm thickness traversing the antrum perpendicular to long axis of stomach

√ "double bulb" appearance (in profile)

√ concentric / eccentric orifice

√ normal peristaltic activity

APPENDICITIS

Prevalence: > 250,000 cases annually; 1–4% in children with acute abdominal pain

Lifetime risk: 7–9% in Western world population

Etiology: obstruction of appendiceal lumen by lymphoid hyperplasia (60%), fecolith (33%), foreign body (4%), stricture, tumor, parasite; Crohn disease (in 25%)

Cause: luminal obstruction from

(a) fecolith (11–52%) = hard crushable concretions from inspissation of fecal material + inorganic salts

(b) appendiceal calculus = hard noncrushable calcified stone (7–15%)

(c) lymphoid hyperplasia

(d) foreign body

(e) parasite

(f) primary tumor: carcinoid, adenocarcinoma, Kaposi sarcoma, lymphoma

(g) metastatic tumor: colon cancer, breast cancer

Pathogenesis:

continued secretion of mucus in appendiceal obstruction → elevates intraluminal pressure + distends lumen → venous engorgement → arterial compromise → tissue ischemia (after intraluminal pressure exceeds capillary perfusion pressure)

Peak age: 2nd decade; thereafter declining incidence; M÷F = 3÷2 (in teens / young adults, thereafter 1÷1)

◊ Rare under the age of 2 years!

• 80% clinical accuracy (78–92% in males, 58–85% in females):

Diagnostic dilemma (in 20–35%):

in elderly, ovulating women, infants / young children

◊ 32–45% rate of misdiagnosis in women 20–40 years!

◊ 5–25% false-negative appendectomy rate for children!

- pain:
  - mild poorly localized visceral pain of 4–6 hours duration referred to epigastrium + periumbilical region
  - crampy pain migrates into RLQ pain over appendix = McBurney sign (72%) and becomes continuous + more severe (somatic pain)
- anorexia, nausea, vomiting (40%)
- afebrile / low-grade fever (56%)
  ◊ Suspect perforation with temperature > 38.3°C
- leukocytosis with left shift (88%)

Clinical scoring system: "MANTRELS" score of up to 10

Migration of pain to RLQ 1
Anorexia 1
Nausea and vomiting 1
Tenderness in RLQ 2
Rebound pain 1
Elevated temperature 1
Leukocytosis 2
Shift of WBC count to left 1

Location:

(a) base of appendix (usually): posteromedial wall of cecum + 3 cm below ileocecal valve

◊ Appendix + ileocecal valve are on the same side of cecum

(b) tip of appendix: retrocecal, subcecal, retroileal, preileal, within pelvis (30%), extraperitoneal (5%)

(c) appendicitis in hernia sac (0.13%): inguinal hernia (Amyand hernia), femoral hernia (de Garengeot hernia)

(d) during pregnancy: cecum and appendix increasingly elevated out of pelvis by gravid uterus
◊ Cecal tilt angle of > 90° (on sagittal MR image) → appendix in right upper quadrant

Abdominal plain film (abnormalities seen in < 50%):

◊ Plain-film findings become more distinctive after perforation, while clinical findings subside / simulate other diseases!

√ usually laminated calcified appendicolith in RLQ (in 7–15%):

◊ Appendicolith + abdominal pain → 90% probability of acute appendicitis → high probability for gangrene / perforation!

√ cecal changes:
- √ thickening of cecal wall
- √ water-density mass + paucity / absence of intestinal gas in RLQ (in 24% of perforations)
- √ "cecal ileus" = gas-fluid level in cecum with gangrene ← local paralysis
- √ "colon cutoff" sign = amputation of gas at the hepatic flexure (in 20% of perforations) ← spastic ascending colon

√ small bowel obstruction pattern = small bowel dilatation with air-fluid levels (in 43% of perforations)

√ extraluminal gas (in 33% of perforations):
- √ gas loculation

- √ mottled bacteriogenic gas
- √ pneumoperitoneum (rare)

√ loss of fat planes:
- √ focal increase in thickness of lateral abdominal wall in 32% ← edema between properitoneal fat line + cecum
- √ loss of properitoneal fat line
- √ loss of pelvic fat planes around the bladder / right obturator ← fluid / pus in cul-de-sac
- √ loss of definition of right inferior hepatic outline ← free peritoneal fluid
- √ distortion of psoas margin + flank stripes

√ scoliosis ← muscle irritation

BE / UGI (accuracy 50–84%):

√ failure to fill appendix with barium: normal in up to 35%

√ indentation along medial wall of cecum ← edema at base of appendix / matted omentum / periappendiceal abscess

Oral contrast material within the appendix excludes acute appendicitis.

CT (87–100% sensitive, 89–98% specific, 93–98% accurate, 92–98% PPV, 95–100% NPV):

√ normal appendix visualized in 67–100%:
- √ 1–2 cm below ileocecal junction from posteromedial aspect of cecum with a diameter of up to 10 mm
- ◊ Nonvisualization of the appendix in a patient with RLQ pain virtually excludes acute appendicitis!

√ abnormal appendix:

An ↑ appendiceal caliber alone is not a reliable indicator for appendicitis. However, an ↑ between serial CTs suggests early acute appendicitis, even without adjacent fat stranding.

- √ distended appendiceal lumen > 7 mm in diameter
- √ circumferential wall thickening
- √ homogeneously enhancing wall ± mural stratification (= "target" sign)
- √ appendicolith = homogeneous / ringlike calcification (25%)

√ periappendicular inflammation (98%):
- √ linear streaky densities in periappendicular / pericecal / mesenteric / pelvic fat
- √ subtle clouding of mesentery
- √ local fascial thickening
- √ free peritoneal fluid
- √ localized + mesenteric lymphadenopathy
- √ marked terminal ileal wall thickening
- √ peritonitis
- √ small-bowel obstruction

√ circumferential / focal cecal apical thickening (80%):
- √ "arrowhead" sign = funnel of contrast medium in cecum symmetrically centering about occluded orifice of appendix (30% sensitive, 100% specific)

√ perforated appendix:
- √ defect in the enhancing appendiceal wall
- √ nonvisualization of appendix ← fragmentation

√ phlegmon = diffuse substantial inflammation of periappendiceal fat with ill-defined fluid collections (DDx: ileocolitis with secondary inflammation of appendix)
√ pericecal / mesenteric / interloop / pelvic abscess = poorly encapsulated single / multiple fluid collections containing air / extravasated contrast material
√ extraluminal appendicolith
√ extraluminal air

False-negative CT:

(a) overlapping range in maximal appendiceal diameter between inflamed + uninflamed appendix
(b) appendix mistaken for unopacified bowel
(c) distal appendicitis = inflammation limited to tip
√ abnormal tip of appendix with NORMAL proximal appendix and cecal apex

False-positive CT:

(a) cystic fibrosis (= appendiceal thickening of up to 15 mm)
(b) Crohn disease
(c) Cancer of the appendix

Secondary / reactive appendicitis can be caused by cecal / terminal ileal diverticulitis, terminal ileitis, active Crohn disease, colitis, or an acute gynecologic process.

Graded-compression US (85% sensitive, 92% specific, 78–96% accurate, 91–94% PPV, 89–97% NPV):

◊ Nondiagnostic study in 4% ← inadequate RLQ compression
◊ Useful in ovulating women + infants / children (false-negative appendectomy rate in males 15%, in females 35%)
◊ Normal appendix visualized in 2% of normal adults, but in 50% of normal children
√ noncompressibility of tubular appendix:
√ absence of peristalsis must be confirmed → NOT to mistake small bowel for appendix
√ blind-ending bulbous tip must be demonstrated → NOT to miss distal appendicitis
√ laminated wall with target appearance of ≥ 6 mm in outer wall diameter on cross section (81% specific, 98% PPV, 98% NPV) / mural wall thickness ≥ 2 mm
√ lumen may be distended with anechoic / hyperechoic material
√ pericecal / periappendiceal fluid
√ increased periappendiceal echogenicity (= inflammatory infiltration of mesoappendix / pericecal fat)
√ enlarged mesenteric lymph nodes
√ loss of wall layers = gangrenous appendix
√ perforated appendix (23–73%):
√ loss of echogenic submucosal layer
√ appendix no longer visualized (40–60%)
√ loculated periappendiceal / pelvic fluid collection ± gas bubbles ← abscess
√ prominent hyperechoic mesoappendix / pericecal fat
√ visualization of appendicolith (6%) = bright echogenic focus with clean distal acoustic shadowing
√ gas bubbles localized to perforation site
√ hypoechoic zones with poor margination within inflamed fat ← phlegmonous appendicitis

√ sympathetic thickening of adjacent terminal ileum + ascending colon

False-negative US:

(a) failure to visualize appendix
  › inability of adequate compression
  › aberrant location of appendix: eg, retrocecal
  › appendiceal perforation

(b) early inflammation limited to appendiceal tip

False-positive US:

(a) normal appendix mistaken for appendicitis

(b) alternate diagnosis: Crohn disease, pelvic inflammatory disease, inflamed Meckel diverticulum

(c) spontaneous resolution of acute appendicitis

Color Doppler US:

√ increased conspicuity (= increase in size + number) of circumferential vessels in and around the wall of the appendix ← hyperemia

√ decreased resistance of arterial waveforms

√ continuous / pulsatile venous flow

√ decreased / no perfusion = gangrenous appendicitis

MR (97–100% sensitive, 92–94% specific, 93% accurate):

√ appendiceal diameter > 6–7 mm on single-shot fast SE without luminal air / oral contrast material

√ appendiceal wall thickness > 2 mm, hypointense on T1WI and hyperintense on T2WI

√ ± high luminal SI on T2WI ← fluid-filled lumen

√ periappendiceal bands of high SI on fat-saturated images ← edema / fluid / abscess

√ thickened wall of cecum

√ (occasionally) focal area of low signal intensity in appendiceal lumen on all sequences = appendicolith

Negative predictive value: 100%

√ normal appendix visualized in 80% of pregnant women:
  √ tubular structure ≤ 6 mm
  √ intermediate signal intensity isointense to muscle
  √ central low SI (air / oral contrast) with blooming effect on T2*
  √ progressive cranial displacement of appendix + cecum during pregnancy

Prognosis:

(1) **Abortive appendicitis** = mild acute appendicitis that resolves spontaneously in an early stage of disease (after relief of inciting obstruction) in 8–15%
  • low C-reactive protein
  √ inflamed appendix that returns to normal within 1 week
  Prognosis: 50% recurrence rate

(2) Recurrent appendicitis (10–38%) = repeated similar episodic attacks of RLQ pain → appendectomy showing acute inflammation; in 70% within a year after first event

(3) Chronic appendicitis (1%) = RLQ pain of > 3 weeks + no alternative diagnosis + chronic active inflammation on histology → relief of symptoms after appendectomy

(4) Mortality rate of 1% (associated with perforation)

Cx: perforation (13–30–73%), abscess formation, peritonitis, wound infection, sepsis,

infertility, adhesions, bowel obstruction, death

Rx: an appendicolith is sufficient evidence to perform prophylactic appendectomy in asymptomatic patients (50% have perforation / abscess formation at surgery)

DDx: ◊ Only 22–38% of children referred for suspected appendicitis actually have appendicitis

Nonsurgical mimickers: mesenteric adenitis, terminal infectious ileitis-ileocecitis (Yersinia, Salmonella, Campylobacter) / inflammation (Crohn disease)

Clinical mimickers: appendiceal mucocele, neoplasm

BANNAYAN-RILEY-RUVALCABA SYNDROME

= RUVALCABA-MYHRE-SMITH SYNDROME

Cause: autosomal dominant transmission

• pigmented genital lesions

√ hamartomatous intestinal polyps (in 45%): usually in distal ileum + colon

√ macrocephaly

√ subcutaneous and visceral lipomas + hemangiomas

BARRETT ESOPHAGUS

= BARRETT SYNDROME

[Norman Rupert Barrett (1903–1979), surgeon at St. Thomas Hospital in London, president of Thoracic Surgeons of Great Britain and Ireland in 1962]

= progressive replacement of stratified squamous epithelium by metaplastic columnar epithelium (Barrett epithelium) containing goblet cells but no parietal cells

Cause: chronic gastroesophageal reflux (GERD) → reflux esophagitis → epithelial injury → epithelial metaplasia

Contributing factors:

delayed acid clearance, reduced acid sensitivity, hiatal hernia, duodenogastroesophageal reflux, reduced LES pressure, transient LES relaxation, alcohol, tobacco, obesity, chemotherapy, scleroderma (37%), genetic influence, S/P repair of esophageal atresia / esophagogastric resection / Heller esophagomyotomy

Histo: (1) specialized columnar epithelium (proximal)

(2) junctional-type epithelium (distal to (1))

(3) fundic-type epithelium (most distally)

Prevalence: in general 0.3–4%; in 7–10% of patients with advanced chronic reflux esophagitis

Associated with: moderate + severe esophagitis (94%); NO / mild esophagitis (6%)

Age: 0–15 years and 40–88 years (mean of 55 years); M > F; mainly among Whites

• asymptomatic; dysphagia ← esophageal stricture

• signs of reflux esophagitis: heartburn, substernal chest pain, regurgitation

• low-grade upper intestinal bleeding

Location: middle to lower esophagus

◊ A stricture in the mid- to upper esophagus is less common but more specific for Barrett esophagus

N.B.: the squamocolumnar junction is irregular and lies > 2–3 cm orad from the GE junction

Distribution: circumferential / focal

› mucosal changes:
  √ fine reticular / granular mucosal pattern (3–30%) resembling areae gastricae of the stomach located at distal aspect of midesophageal stricture:
    √ netlike web of thin linear / intersecting barium-filled grooves or crevices surrounding small tufts of mucosa (DDx: reflux esophagitis, acanthosis, leukoplakia, superficial spreading carcinoma, moniliasis / herpes simplex / CMV esophagitis)
  √ thickened irregular mucosal folds (28–86%)
  √ large deep wide-mouthed peptic ulcer (= Barrett ulcer) at upwardly displaced squamocolumnar junction / within columnar epithelium
  √ uptake of ^{99m}Tc-pertechnetate by columnar epithelium

› scarring:
  √ several-cm-long stricture (71%) in lower esophagus (60%) or upper to midesophagus below level of aortic arch (40%) [DDx: peptic stricture without Barrett esophagus]:
    √ ringlike constrictions / smooth tapered segments of concentric narrowing in midesophagus
  √ hiatal hernia (75–94%)

› functional:
  √ gastroesophageal reflux (45–63%)
  √ distal esophageal widening (34–66%) ← abnormal motility

Dx: velvety pinkish red appearance of gastric-type mucosa extending from gastric mucosa into distal esophagus (endoscopy with biopsy)

Cx: (1) Ulceration ± penetration into mediastinum

(2) Stricture

(3) Adenocarcinoma: annual risk of 0.12% (40-fold higher risk than in general population)

  √ plaquelike / focal irregularity / nodularity / sessile polyps

Rx: (1) Stop smoking, avoid bedtime snacks + foods that lower LES pressure, lose excess weight

(2) Suppress gastric acidity: antacids, H_2-receptor antagonists (cimetidine, ranitidine, famotidine), H+K+-adenosintriphosphatase inhibitor (omeprazole)

(3) Improve LES pressure: metoclopramide, bethanechol

(4) Esophageal resection in high-grade dysplasia

BEZOAR

[*padzahr* , Persian = antidote, counterpoison]

= persistent concretions of foreign matter composed of accumulated ingested material in intestines

Pathophysiology: usually formed in stomach → passing into small bowel as part / whole → impaction

Frequency: 0.4% (large endoscopic series)

Etiology: material unable to exit stomach because of large size, indigestibility, gastric outlet obstruction, poor gastric motility (diabetes, mixed connective tissue disease,

myotonic dystrophy, hypothyroidism)

Predisposition:
previous gastric surgery (vagotomy, pyloroplasty, antrectomy, partial gastrectomy), inadequate chewing, missing teeth, dentures, massive overindulgence of food with high fiber contents

• anorexia, bloating, early satiety / may be asymptomatic
√ well-defined focal ovoid mass of soft-tissue attenuation
√ mottled gas pattern
Cx: partial / complete small bowel obstruction
DDx: "small bowel feces" sign (amorphous, affects longer segment, related to adhesion)

Phytobezoar

= poorly digested fibers, skin + seeds of fruits and vegetables usually forming in stomach, ± impaction in small bowel
Frequency: 55% of all bezoars
• history of recent ingestion of pulpy foods
Food: oranges, persimmons (most common, unripe persimmons contain the tannin shibuol that forms a gluelike coagulum after contact with dilute acid)
Site of impaction: stomach, jejunum, ileum
√ intraluminal filling defect without constant site of attachment to bowel wall
√ interstices filled with barium
√ coiled-spring appearance (rare)
Cx: decubitus ulceration + pressure necrosis of bowel wall, perforation, peritonitis
DDx: lobulated / villous adenoma, leiomyosarcoma, metastatic melanoma, intussusception

Trichobezoar

[*trikho* , *thrix*, Greek = hair]
in 80% < age 30 years, almost exclusively in females
Associated with: gastric ulcer in 24–70%

BLUE RUBBER BLEB NEVUS SYNDROME

= BEAN SYNDROME
[William Bennett Bean (1909–1989), head of internal medicine at University of Iowa College of Medicine]
= rare familial disorder characterized by multiple cutaneous + musculoskeletal + gastrointestinal venous malformations predominantly afflicting GI tract (but also liver, spleen, heart, skeletal muscle, lung, kidney, thyroid, eyes, CNS)
Incidence: > 200 cases
Etiology: sporadic / autosomal dominant
Path: thin layer of connective tissue + single layer of endothelial cells surrounding blood-filled ectatic vessels
• blue to black soft rubbery painless 0.1–5.0 cm cutaneous lesions evacuating under pressure + slow refilling (commonly present at birth ± increase in size and number with age) = cutaneous venous malformations
• iron deficiency anemia ← chronic spontaneous hemorrhage

√ multiple polypoid filling defects of various sizes throughout small bowel ← venous malformations
√ intermittent small bowel obstruction ← chronic bleeding
√ multiple phleboliths
MR:
√ hyperintense lesions on T2WI ← slow flow / thrombosis
Cx: intussusception, volvulus; GI hemorrhage; chronic coagulation disorders; hemothorax; hypercalcemia; pressure erosion of bone, osseous + soft-tissue hypertrophy ← hypervascularity
DDx:
(1) Maffucci syndrome (dyschondroplasia + osteochondromas + vascular malformations)
(2) Klippel-Trénaunay-Weber syndrome (port wine stain, vascular malformations, limb hypertrophy)
(3) Kasabach-Merritt syndrome (large vascular malformations + consumptive coagulopathy)
(4) Kaposi sarcoma
(5) Peutz-Jeghers syndrome (congenital polyposis + melanotic cutaneous lesions)
(6) Gardner syndrome (soft-tissue tumors + sebaceous cysts)

BLUNT ABDOMINAL TRAUMA

CT is imaging method of choice for evaluation of stable patients
US imaging in the detection of intraabdominal injury:
86% sensitive, 99% specific, 98% accurate

Traumatic Hemoperitoneum

Prevalence: 29–34% of patients with abdominal visceral injury have NO hemoperitoneum ← intraparenchymal laceration / contusion without penetration of organ capsule
Location: paracolic gutters, pelvis
◊ Most dependent portions in supine position: pouch of Morison (hepatorenal fossa) and pouch of Douglas (pelvic cul-de-sac)
√ hematocrit effect of fresh blood = sedimented RBCs in the dependent portion of a hemoperitoneum

NECT (negative predictive value of 99.6%):
√ high-attenuation ascites (~ 30–45 HU) ← high protein content of unclotted extravascular blood
√ "sentinel clot"(clotted blood attenuation typically 45–70 HU) marks anatomic site + suggests source of bleeding
CECT:
√ high-density site of contrast extravasation ← active ongoing bleeding
√ extravasation always surrounded by lower-density hematoma (DDx: extravasated oral contrast is not surrounded by lower-density material)
CT findings requiring intervention:
(1) Solid-organ injury with active arterial extravasation
(2) Diaphragmatic injury

(3) Bowel and mesenteric injury
(4) Injury to major vessel
(5) Intraperitoneal bladder rupture

US:

√ usually anechoic fluid accumulation in subhepatic space (= Morison pouch) > pouch of Douglas / paravesical space > between bowel loops
DDx: bowel contents, urine, bile, ascites

√ **hemoperitoneum score** = depth of largest fluid collection in cm + 1 point for each additional site with fluid (score of ≤ 2 managed conservatively)

√ hyperechoic / occasionally isoechoic masses ← intraperitoneal clot

Prognosis: 17% of patients without hemoperitoneum require surgical / angiographic intervention

◊ Small pockets of fluid of 10–15 HU found in pelvis in 3–5% of male trauma patients WITHOUT organ injury!

◊ Peritoneal lavage cannot quantify amount of hemoperitoneum → 19–39% rate of nontherapeutic surgeries

◊ The rate of bleeding + presence of active extravasation have the most direct effect on patient care decisions!

DDx of free intraperitoneal fluid < 20 HU:
hemoperitoneum in anemic patient; simple ascites; bile; succus entericus in small bowel perforation; intraperitoneal urine from ruptured bladder

Hypovolemia = Hypoperfusion Complex

= manifestation of tenuous hemodynamic instability even after aggressive resuscitation efforts with IV fluids

√ "collapsed cava" sign = persistent flattening of infrahepatic IVC + flattening of renal veins ← decreased venous return
N.B.: abort CT examination as shock is imminent!

√ small hypodense spleen ← decreased enhancement

√ small aorta + mesenteric arteries ← intense vasoconstriction

√ **shock bowel**:
√ dilatation of fluid-filled intestines
√ diffuse concentric thickening of small bowel
√ intense enhancement ← vasoconstricted mesenteric vessels
√ sparing of colon

√ **shock nephrogram** = increased enhancement of kidneys + lack of renal contrast excretion

√ marked enhancement of adrenal glands

√ intense pancreatic enhancement

√ pancreatic + retroperitoneal edema

Fluid Overload

√ diffuse thickening + edema of bowel wall
√ distended IVC + hepatic veins
√ heterogeneous "nutmeg" appearance of liver
√ "periportal collar" = concentric halo of low attenuation around portal veins

CECT Attenuation Values of Fluid*	
HU	*Description*
0–15–20	bile, urine, intestinal contents
30–45	fresh nonclotted blood (high proteinaceous content (less with low hematocrit / hemorrhage after 48 hour)
45–70–100	clotted blood (close to bleeding site = sentinel clot sign); hematocrit effect (= sedimentation of RBCs with high attenuation)
85–(132)–370	active arterial contrast extravasation surrounded by large hematoma
* during IV contrast administration and assuming an initially normal hematocrit without significant dilution from intraperitoneal fluid (ascites, urine, succus, lavage fluid)	
DDx: (1) Water-soluble enteric contrast in ascites = bowel perforation (2) IV contrast during urographic phase = urinary ascites	

Blunt Trauma to Duodenum

√ retroperitoneal hematoma
√ stranding of retroperitoneal fatty tissue
√ thickening of duodenal wall

1. **Duodenal contusion**
   √ edema / hematoma of the duodenal wall
   √ intramural gas accumulations
   √ focal duodenal wall thickening > 4 mm
   Rx: conservative
2. Hematoma of the duodenal wall
3. **Duodenal perforation** and disruption
   √ retroperitoneal collection of contrast (infrequent)
   √ extraluminal gas
   √ lack of continuity of duodenal wall

Blunt Trauma to Spleen (40%)

◊ Most frequently injured intraperitoneal organ in blunt abdominal trauma (40% of abdominal organ injuries)

Associated with: other solid visceral / bowel injuries (29%); lower rib fractures in 44%, injury to left kidney in 10%, injury to left diaphragm in 2%

◊ 20% of left rib fractures have splenic injury!
◊ 25% of left renal injury have splenic injury!

Scoring of Duodenal Injury (1990) *American Association for the Surgery of Trauma*		
Grade	*Injury*	*Description*
I	hematoma laceration	involvement of single portion of duodenum
II	hematoma laceration	involvement of > 1 portion; disruption of < 50% of circumference
III	laceration	disruption of 50–75% of circumference of 2nd segment, disruption of 50–100% of circumference of 1st, 3rd, 4th segment
IV	laceration	disruption of > 75% of circumference of 2nd segment or involvement of ampulla / distal CBD
V	disruption	massive disruption of duodenopancreatic complex / duodenal devascularization
The extent of transections cannot be reliably evaluated with CT!		

Technique: scanning delay of 60–70 sec to avoid heterogeneous splenic enhancement

CECT (95% accurate):

◊ CT not reliable to determine need for surgical intervention!

√ hemoperitoneum ← disruption of splenic capsule

√ "sentinel clot" (= area of > 60 HU adjacent to spleen) as sensitive predictor of injury = **perisplenic hematoma**

√ **active extravasation**:

√ high-attenuation blush (80–370 HU)

√ focal high-attenuation area in / emanating from injured splenic parenchyma

√ growing larger with time (delayed phase imaging!)

N.B.: active extravasation of contrast material requires emergent surgery in 83–93%

√ mottled parenchymal enhancement = **contusion**

√ hypoattenuating line connecting opposing visceral surfaces = linear parenchymal defect = **splenic laceration**:

√ almost always associated with hemoperitoneum

√ crescentic region of low attenuation along splenic margin flattening / indenting / compressing the normal parenchyma = **subcapsular hematoma**

√ round hypodense inhomogeneous region ± hyperdense clot = **intrasplenic hematoma**

√ hypoattenuating hematoma with complete separation of splenic fragments = laceration traversing two capsular surfaces = **splenic fracture**

√ multiple lacerations = "**shattered spleen**"

US:

√ hyperechoic intraparenchymal region (= acute hematoma / laceration)

√ anechoic intralesional collection (= brisk hemorrhage)

√ diffusely heterogeneous parenchymal pattern containing hyper- and hypoechoic areas (= extensive splenic injury)

√ loss of normal organ contour ← perisplenic clot

Sequelae:

(1) scar / fibrosis

(2) splenic pseudocyst (20–30 HU)
(3) Vascular injury: pseudoaneurysm, AV fistula
(4) delayed splenic rupture
= hemorrhage > 48 hours after trauma

Categories of Splenic Injury (1994 Revision)
American Association for the Surgery of Trauma

Grade	*Injury*	*Description*
I	hematoma	subcapsular < 10% of surface area
	laceration	capsular tear < 1 cm of parenchymal depth
II	hematoma	subcapsular 10–50% of surface area; intraparenchymal < 5 cm in diameter
	laceration	1–3 cm deep without involvement of trabecular vessel
III	hematoma	subcapsular > 50% of surface area; ruptured subcapsular / parenchymal hematoma; intraparenchymal > 10 cm / expanding
	laceration	> 3 cm parenchymal depth / involvement of trabecular vessels
IV	laceration	involvement of segmental / hilar vessels with devascularization of > 25%
V	laceration	completely shattered spleen
	vascular	total splenic devascularization

◊ Does not consider amount of hemoperitoneum, active bleeding, pseudoaneurysm, AV fistula
N.B.: grade III or higher require more often surgical therapy!

Cause: subcapsular hematoma
Prevalence: 0.3–20% of blunt splenic injuries
Time of onset: in 70% within 2 weeks of injury; in 90% within 4 weeks of injury
Prognosis: splenectomy / splenorrhaphy; 80–90% success in nonoperative management
Rx: up to 91% of stable patients can be treated conservatively with observation; transcatheter embolization
◊ Preservation of spleen and its immune function = standard of care
DDx: (1) Normal lobulation / splenic cleft (smoothly contoured, medially located)
(2) Adjacent unopacified jejunum simulating splenic tissue
(3) Early differential enhancement of red and white pulp (scan obtained within 20–50 seconds)
(4) Perisplenic fluid from ascites / urine / succus / bile / lavage

Blunt Trauma to Liver (20%)

Prevalence: 2nd most frequently injured abdominal viscus
Associated with: splenic injury in 45%
• clinical manifestation often delayed by days / weeks
Location: right (posterior segment) > left lobe
Site: perivascular, paralleling right + middle hepatic arteries + posterior branches of right

portal vein, avulsion of right hepatic vein from IVC (13%)

◊ Left lobe injuries are more often associated with damage to duodenum, pancreas, transverse colon

CECT:

√ **liver laceration** = predominantly irregular linear branching / round regions of low attenuation:

(a) superficial ≤ 3 cm deep; (b) > 3 cm in depth

◊ Most frequently identified injury pattern

Associated with:

› retroperitoneal hematoma surrounding IVC ← posterosuperior segment VII laceration of bare area

› hematoma involving adrenal gland

› biloma ← laceration extending into porta hepatis

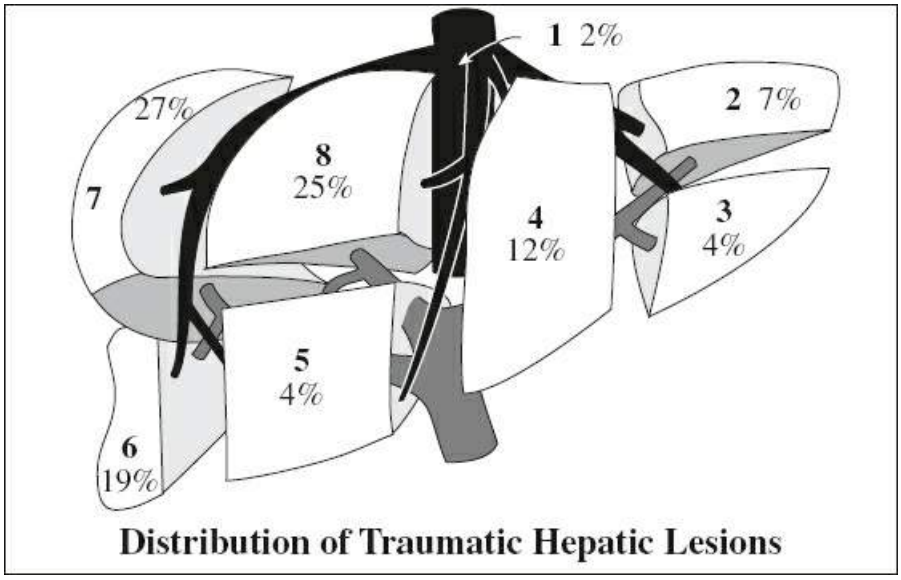
DDx: (1) beam-hardening artifact from adjacent ribs / from air-contrast level in stomach

(2) Focal fatty infiltration

Categories of Liver Injury (1994 Revision)*
American Association for the Surgery of Trauma

Grade	*Injury*	*Description*
I	hematoma	subcapsular < 10% of surface area
	laceration	capsular tear < 1 cm of parenchymal depth
II	hematoma	subcapsular 10–50% of surface area; intraparenchymal < 10 cm in diameter
	laceration	1–3 cm deep and < 10 cm long
III	hematoma	subcapsular > 50% of surface area; ruptured subcapsular / parenchymal; intraparenchymal >10 cm / expanding
	laceration	>3 cm parenchymal depth
IV	laceration	parenchymal disruption 25–75% of lobe; 1–3 Couinaud segments in single lobe
V	laceration	disruption > 75% of single lobe; > 3 Couinaud segments in single lobe
	vascular	juxtahepatic venous injury (HV, IVC)
VI	vascular	hepatic avulsion

* Active bleeding, pseudoaneurysm, AV fistula are not considered!



Distribution of Traumatic Hepatic Lesions

√ **liver hematoma:**
- √ hyperattenuating mass in acute phase of 54 (range, 28–82) HU decreasing over time ← clotted blood:
  - › intraparenchymal hematoma: single / multiple
  - › subcapsular hematoma: lenticular / elliptical configuration flattening underlying liver margin

Resolution: usually within 6–8 weeks

√ <u>active (potentially life-threatening) liver hemorrhage:</u>
- √ focal hyperattenuating area during early phase of 155 (range, 91–274) HU ← extravasated contrast material

Prognosis: 75% become hemodynamically unstable
Rx: angiographic embolization
DDx: focal hyperdense area of 80–350 HU during early phase ← pseudoaneurysm / AV fistula

√ <u>major (life-threatening) hepatic venous injury</u>
= liver laceration or hematoma extending into major hepatic vein / IVC
◊ 3.5 x more frequently associated with arterial bleeding

√ focal / diffuse <u>periportal tracking</u> (in up to 22%)
= areas of low attenuation paralleling portal vein + its branches 2° to
- › dissecting hemorrhage / bile
- › dilated engorged periportal lymphatics ← ↑ central venous pressure ← vigorous IV fluid administration / tension pneumothorax / pericardial tamponade

√ <u>flat IVC</u>
= AP diameter < ¼ of IVC width not caused by external compression
Cause: hypovolemia, poor fluid resuscitation, shock

√ hypodense wedge extending to liver surface = focal hepatic devascularization
√ hemoperitoneum ← violation of liver capsule with inability of liver veins to contract
√ intrahepatic / subcapsular gas, usually ← necrosis

US:

√ localized area of increased intraparenchymal echogenicity (= acute hematoma / laceration)
√ widespread heterogeneous liver echogenicity + absence of normal vascular pattern (= global parenchymal injury)

Cx: in 5–23%
(1) delayed hemorrhage(2–6%)
(2) abscess (0.6–4%) ← superinfection of hematoma / biloma / devascularized hepatic parenchyma
(3) pseudoaneurysm (1%) → hemobilia, melena, hematemesis (decompression into biliary system)
(4) bile peritonitis
(5) biliary fistula: external (to skin / hollow viscus), internal (to intestine / bronchus), biliovascular (to hepatic artery, portal / hepatic vein)

Rx: conservative treatment in up to 80% in adults + 97% in children; transcatheter embolization

Prognosis: healing in 1–6–15 months; 4–12% mortality

Blunt Trauma to Gallbladder (2%)

Associated with: injury to liver (91%), duodenum (54%), spleen (54%)
√ pericholecystic fluid (extraperitoneal location of GB)
√ free intraperitoneal fluid
CECT:
√ blurred contour of GB
√ focal thickening / discontinuity of GB wall
√ intraluminal enhancing mucosal flap
√ blood within GB lumen = attenuation > 50 HU
√ mass effect on adjacent duodenum
√ collapsed GB ← GB rupture
√ focal periportal tracking ← GB rupture
US:
√ focal hypoechoic thickening
√ echogenic mass within GB lumen

Blunt Trauma to GI Tract (5%)

◊ 3rd most common type of injury from blunt trauma to abdominal organs
Cause in children: MVA (lap belts), bicycle handle bar, child abuse
May be associated with: Chance fracture; traumatic hernia (disruption of the rectus abdominis m.)
Mechanism:
(1) crush / compression injury: direct force; near spine
(2) burst injury: sudden increase in intraluminal pressure
(3) shear injury: rapid deceleration at points of transition between mobile and fixed bowel portions

Location: jejunum distal to ligament of Treitz > duodenum > ascending colon at ileocecal valve > descending colon > distal ileum near ileocecal valve

- Classic triad (in only 33%):
  - abdominal pain + tenderness (100% sensitive)
  - abdominal rigidity; absent / decreased bowel sounds
- ↑ temperature + heart rate; ↓ urine output over 24 hours
- lap belt ecchymosis (not highly correlated)
- *Lavage:* 90% sensitive for hemoperitoneum → compromises interpretation of CT exam

N.B.: clinical signs + symptoms may be delayed for 24 hours (increasing mortality to 65%)

US:

√ nonspecific free intraabdominal fluid (86% sensitive, 98% specific)

NECT:

√ abdominal wall injury: SQ fat stranding ("seat belt" sign) ← hematoma ← tear

√ extraintestinal free air (30–60% sensitive, 95% specific):

√ intraperitoneal air: small gas bubbles anteriorly near liver / trapped within leaves of mesentery (with small bowel perforation) / porta hepatis

√ retroperitoneal air (with disruption of duodenum / rectum / colon)

DDx of free air:

◊ Most bowel perforations have no free gas due to:

(a) spontaneous seal of perforation

(b) developing ileus → no passage of gas

(c) rapid reabsorption of small gas collections

√ intramural air

√ hypodense free fluid (90–100% sensitive, 15–25% specific), particularly in interloop location ← perforation

DDx: parenchymal organ injury / osseous injury / large vessel injury / bladder perforation

√ "sentinel clot" sign adjacent to bowel

CECT (84–94% sensitive, 84–99% accurate):

@ bowel injury (CT 94% sensitive, 88% accurate)

Location: small bowel (proximal jejunum, distal ileum) > colon > stomach

√ extravasation of oral contrast material (8–15% sensitive, 100% specific), densest near perforation

DDx: hyperattenuating blood, extravasating vascular contrast material, leak of contrast material ← ruptured urinary tract

√ focal discontinuity of bowel wall = direct evidence (5–10% sensitive, 100% specific)

√ focal bowel wall thickening > 3 mm (= intramural hematoma [55–75% sensitive, 90% specific] / vascular compromise and inflammation ← spilling of bowel contents):

√ ± intestinal obstruction / ileus

DDx: lack of bowel distension

√ abnormal bowel wall enhancement (10–15% sensitive, 90% specific):

√ hyperdense contrast enhancement of injured bowel wall ← delayed venous transit time (20%)

√ lack of bowel wall enhancement (13%) ← bowel infarct, highly SPECIFIC

√ duodenal submucosal / subserosal hematoma → gastric outlet obstruction

@ mesenteric injury (CT 96% sensitive, 96% accurate)

√ mesenteric contrast extravasation (17%)

√ mesenteric vascular beading (39%) = change in caliber

√ abrupt termination of mesenteric artery / vein (35%)

√ mesenteric infiltration (70–77% sensitive, 40–90% specific) = haziness + fat stranding = streaky hyperattenuating infiltration / fluid at mesenteric root ← hemorrhage + inflammatory response

DDx: retractile mesenteritis

√ mesenteric rent → internal hernia

√ mesenteric hematoma (39%)

√ mesenteric pseudoaneurysm

Cx: peritonitis, sepsis, hemorrhage

Prognosis: delay in diagnosis by 8–12 hours increases morbidity + mortality from peritonitis + sepsis

Rx: surgery based on clinical assessment alone has a 40% negative laparotomy rate

CT in Blunt Trauma to Bowel and Mesentery

	Specific CT Findings	*Less Specific Findings*
Bowel	Free intraperitoneal air	Bowel wall thickening
	Bowel discontinuity	Abnormal wall enhancement
	Extraluminal contrast	Mesenteric fat stranding / fluid / air
Mesentery	Extravasation	Mesenteric fat stranding
	Vascular beading	Mesenteric hematoma
	Abrupt vessel termination	Abnormal bowel wall thickening / enhancement

Blunt Trauma to Pancreas (3%)

Mechanism: compression against vertebral column with shear across pancreatic neck

Frequency: < 10% of childhood trauma

Cause: motor vehicle accident (→ compression by seat belt /steering wheel), fall onto handle bars of a bicycle, child abuse

Scoring of Pancreatic Injury (1990)
American Association for the Surgery of Trauma

Grade	*Injury*	*Description*
I	hematoma	minor contusion without duct injury
	laceration	superficial laceration without duct injury
II	hematoma	major contusion without duct injury
	laceration	major laceration without duct injury
III	laceration	distal transection / parenchymal injury with duct injury
IV	laceration	proximal transection / parenchymal injury involving ampulla / bile duct
V	disruption	massive disruption of pancreatic head

Associated with: injury to liver (47%, typically left lobe), spleen (28%), stomach (42%), duodenum (19%, typically in younger patients), major vessel (41%), kidney (23%)

Classification:

I minor contusion / hematoma, capsule + major duct intact
II parenchymal injury without major duct injury
III major ductal injury
IV severe crush injury

- epigastric/ diffuse abdominal pain, vomiting
- leukocytosis, ↑ serum amylase activity

Location: pancreatic body (65%) > tail / head

CT (70–95% sensitive):

√ within first 12 hours normal CT findings in 20–40% → repeat CT at 24–48 hours
√ posttraumatic pancreatitis:
  √ edema / fluid in peripancreatic fat
  √ focal / diffuse pancreatic enlargement
  √ irregularity of pancreatic contour
√ focal area of low-attenuation / enlargement
  (1) **contusion** = diffuse / localized hypoattenuating area within normally enhancing parenchyma
  (2) **laceration** (actual site of laceration difficult to visualize)

N.B.: pancreatic laceration of > 50% of pancreatic diameter suggests ductal injury. Evaluation of the integrity of the main pancreatic duct remains the critical role of MRCP!

  (3) **transection** (fracture) = hypoattenuating linear findings with separated parenchyma
√ pancreatic **hematoma** = mixed / slightly hyperattenuating lesion within margins / in contact with parenchyma
√ fluid / blood accumulation:
  (a) alongside superior mesenteric artery
  (b) in transverse mesocolon / lesser sac
  (c) fluid between pancreas and splenic vein (in up to 90%)
√ thickening of anterior pararenal fascia

Morbidity: 11–62%

Mortality: 5%

Rx: I + II conservative management
III + IV need for surgery within 24 hours
endoscopic stent placement for duct injury

Cx: pancreatic fistula (23%), posttraumatic pancreatitis (10%), pseudocyst (5%), pseudoaneurysm, pneumonia, abscess (increases mortality to 20%)

BOERHAAVE SYNDROME

[Herman Boerhaave (1668–1738), professor of clinical medicine, botany and chemistry at the University of Leiden, Netherlands]

= spontaneous emetogenic injury resulting in rupture of esophagus → extrusion of gastric content into mediastinum / pleural space

Frequency: 1÷6,000 persons
Age: middle-aged men (in 50% with history of alcoholism / heavy drinking)
Cause: violent retching ← food bolus impaction
Pathophysiology:
incomplete cricopharyngeal relaxation during sudden increase in intraabdominal pressure while vomiting → abrupt increase in intraluminal esophageal pressure (barotrauma) in the presence of a moderate to large amount of gastric contents → complete transmural disruption of esophageal wall

- **Mackler triad:**
  - episode of severe retching + forceful vomiting
  - sudden excruciating chest pain (substernal, left chest, neck, pleuritic, epigastric); subcutaneous emphysema
- odynophagia, tachypnea, cyanosis, fever, shock
- NO hematemesis (blood escapes outside esophageal lumen)

√ rent of 2–5 cm in length
Location: 3–6 cm above diaphragm (= 2–3 cm above GE junction), predominantly in left posterolateral wall

CXR:
√ mediastinal widening
√ air-fluid level within mediastinum
√ extravasation of contrast into mediastinum / pleura
√ pneumomediastinum (single most important plain-film finding), pneumopericardium, subcutaneous air:
√ **"V" sign of Naclerio** = localized mediastinal emphysema with air between lower thoracic aorta + diaphragm
[Emil A. Naclerio (1915–1985), thoracic surgeon at Harlem and Columbus Hospitals in New York City]
√ pleural effusion on left >> right side / hydropneumothorax
√ subcutaneous emphysema
√ patchy pulmonary infiltrate

Esophagography(modality of choice):
Technique: initially hydrosoluble contrast medium (in 10% falsely negative) followed by barium if negative
√ submucosal collection
√ extravasation of contrast material
√ esophagopleural fistula (most commonly on left)

The use of hydrosoluble contrast material is preferred over barium in suspected esophageal rupture → risk for mediastinitis as a result of irritation caused by barium.

CT:
√ esophageal wall thickening
√ supradiaphragmatic periesophageal air collection
√ mediastinal fluid collection + pneumomediastinum

BRUNNER GLAND HAMARTOMA

[Johann Conrad Brunner (1653–1727), Swiss professor of anatomy and physiology at the University of Heidelberg, Germany]

Terminology:
Brunner gland hamartoma ≤ 5 mm in diameter
Brunner gland hyperplasia > 5 mm in diameter

Prevalence: 1.2% of all gastric polyps; 5% of all duodenal masses

Etiology: response to gastric acid in duodenum → glands protect duodenal epithelium + optimize pH for pancreatic enzyme activity

Histo: diffusely enlarged hyperplastic glands of Swiss cheese appearance and variable amounts of adipose + smooth muscle + lymphoid tissue + sclerosis

Physiology: mucosal + submucosal Brunner glands contain mucous + serous cells → secrete a clear viscous alkaline mucus into crypts of Lieberkühn

Age: manifest in middle age; M÷F = 1÷1

• incidental / symptomatic (abdominal pain)

MORPHOLOGIC TYPES:
1. Diffuse nodular hyperplasia: throughout duodenum
2. Circumscribed nodular hyperplasia: in suprapapillary portion
3. Single glandular adenoma with polypoid tumorlike dimensions

Location: duodenum (70% bulb, 26% 2nd portion, 4% 3rd portion); prepyloric region (distribution of duodenal glands from vicinity of pylorus to proximal ²/₃ of duodenum)

Mean size: 2.0 (range, 0.5–6.0) cm; rarely up to 11 cm

UGI:
√ multiple nodular filling defects (usually limited to 1st portion of duodenum) with "**cobblestone appearance**" (most common finding)
DDx: polyposis syndromes, lymphoid hyperplasia, heterotopic gastric mucosa, nodular duodenitis
√ smooth single mass ± central ulceration
DDx: adenomatous polyp, lipoma, leiomyoma, leiomyosarcoma, lymphoma, ectopic pancreatic tissue, GIST, carcinoid tumor, adenocarcinoma, pancreatic neoplasm, ampullary neoplasm

Endoscopic US:
◊ Guides appropriate depth of endoscopic biopsy!
√ heterogeneous echogenicity with various amounts of solid + cystic components

NECT:
√ isoattenuating relative to pancreas

CECT:
√ hypoattenuating relative to pancreas (portal venous phase)
√ peripheral rim enhancement (of duodenal mucosa)

Cx: GI bleeding (chronic melena, hematemesis), intestinal obstruction, intussusception

BURKITT LYMPHOMA

= highly aggressive B-cell lymphoma usually found in children or immunocompromised adults
[initially described in a 7-year old Ugandan child in 1958 by Denis Parsons Burkitt (1911–1993), Irish surgeon on Medical Research Council in London]

Prevalence: 1–2% of all NHLs; 1–5% of primary gastrointestinal NHLs in adults

◊ Most common (30–50%) type of pediatric NHL in children < 15 years in USA and western Europe.

Origin: undifferentiated small noncleaved B-cell–derived lymphocyte

Histo: uniform deeply basophilic medium-sized cells containing round nuclei with distinct chromatin and multiple nucleoli; characteristic "starry sky" pattern (= scattered macrophages containing apoptotic cellular debris on a basophilic background) at light microscopy; 99% proliferation index

Genetics: translocation of c-Myc oncogene with one of immuno- globulin genes, most frequently t(8;14)(q24;q32)

Growth rate: fastest growing of all human tumors with a doubling time of about 24 hours

Rx: dramatic response to chemotherapy

Prognosis: 90–98% 5-year survival rate in children with localized disease: 75–89% 2-year disease-free survival rate in children with advanced disease; 50–70% survival in adults

Endemic / African Form of Burkitt Lymphoma

Endemic in areas with malaria:

sub-Saharan Africa, New Guinea (exposure to Plasmodium falciparum has a synergistic effect causing a marked decrease in T-cell surveillance)

Incidence in central Africa:

50–80% of all childhood neoplasms

Associated with: Epstein-Barr virus infection in 95% (implicated as B-cell mitogen in oncogenesis); malaria

Age: 3–10 years

@ Mandible > maxilla / facial bones

• jaw mass; exophthalmos (orbital extension)

√ grossly destructive lesion, spicules of bone growing at right angles

√ large soft-tissue mass

@ Other skeleton (multifocal in 10%)

√ reminiscent of Ewing tumor / reticulum cell sarcoma

√ lamellated periosteal reaction around major long bones

Sporadic / American Form of Burkitt Lymphoma

= NONENDEMIC FORM OF BURKITT LYMPHOMA

= typically manifests with bulky disease because of its rapid doubling time

Incidence in Europe + North America:

35–45% of all pediatric NHL; 3% of all childhood tumors

Median age: 8 (range, 6–15) years; ⅓ between 5 and 9 years; unusual in children < 5 years; most frequently in white boys

• paraplegia; NO peripheral leukemia

• Epstein-Barr virus genome found in only a minority

◊ Widespread extraintestinal disease at presentation (mesenteric ± retroperitoneal

lymphadenopathy) in 70%!

@ Gastrointestinal tract (22–69%)
- abdominal mass, intestinal obstruction
- acute abdominal complaints (30–40%)

Location: terminal ileum, ileocecal region (Peyer patches), mesentery >> stomach, colon

√ well-defined sharply marginated homogeneous large abdominal and pelvic masses (31–64%):
  √ encasement of bowel and mesenteric vessels
  √ invading bowel wall → obstruction
  √ central necrosis in large tumor
√ ± enlarged abdominal lymph nodes
√ malignant ascites (25%–63%)
√ peritoneal thickening / nodularity (42%) along liver capsule and peritoneal reflections ← intraperitoneal seeding
√ usually intraabdominal extranodal involvement with sparing of spleen

Barium:
  √ displacement of bowel loops by a large mass
  √ abnormally separated bowel loops ← extensive bowel wall thickening
  √ narrowing of distal ileum

US:
  √ large hypoechoic masses ± engulfing of bowel / mesenteric vessels
  √ cystic central areas ← necrosis
  √ omental caking (unusual)

CT:
  √ bowel wall thickening / mural masses
  √ "sandwich" sign = enhancing vessels surrounded by mildly enhancing confluent mesenteric mass

MR:
  √ isointense to muscle on T1WI + T2WI:
    √ homogeneous T1 hypointensity
    √ heterogeneous intermediate-to-high SI on T2WI
  √ intense homogeneous enhancement
  √ bright round-to-ovoid lesions > 10 mm in size with restricted diffusion ← lymph node involvement

PET/CT:
  √ highly FDG avid

Cx: intussusception, aneurysmal dilatation, perforation
  ◊ Most common cause of intussusception in children ≥ 4 years

◊ Intussusception and aneurysmal dilatation of bowel suggest lymphoma.

@ Abdominal organs
√ multiple hypoechoic / hypoattenuating lesions of liver + spleen
√ periportal hypoattenuation

@ Genitourinary tract (20%)

Involvement of: kidneys, retroperitoneum, ovary, uterus

√ multiple hypoechoic / hypoattenuating renal masses / diffuse renal enlargement (5%)
√ hydronephrosis (28%)
√ retroperitoneal Burkitt may extend into spinal canal

@ Chest
√ pleural effusion (most common chest abnormality)

@ CNS
√ meningeal infiltration (most commonly)
√ cavernous sinus invasion
√ supra- and parasellar tumor
√ epidural spinal mass ± spinal cord compression

@ Others
salivary glands, thyroid, bone marrow

Immunodeficiency-associated Burkitt Lymphoma

Prevalence: in up to 40% of NHLs in HIV-positive patients
Prognosis: 50–70% survival in adults

CARCINOID SYNDROME

= constellation of clinical findings related to secretion of serotonin + other vasoactive peptides by tumor

Frequency:
› in 7–9% of small bowel carcinoids (most commonly in ileal carcinoids) ← metastases to liver + retroperitoneal Lnn.
› in only 0.7% of pulmonary carcinoids ← rarely metastasize to liver
› in 2–5% of pulmonary carcinoids → developing hepatic metastases during follow-up period

Cause: excess serotonin + tachykinin levels in systemic circulation produced by some carcinoids

Associated with: hepatic / retroperitoneal metastases

Serotonin metabolism:
normally, platelets take up + store circulating serotonin; excess serotonin is inactivated by liver, lung, brain and transformed to 5-hydroxyindoleacetic acid (5-HIAA)

Pathophysiology:
vasoactive substances enter systemic circulation by escaping hepatic degradation → thus bypassing hepatic metabolic pathway to 5-HIAA with
(a) metastases to liver / retroperitoneal nodes
(b) primary pulmonary / ovarian carcinoids

- attacks precipitated / exacerbated by ingestion of food / alcohol emotional stress, exercise
- colicky abdominal pain, recurrent intractable diarrhea (70%)
- asthmatic wheezing ← bronchospasm (15%) caused by tachykinin + bradykinin; excess 5-HIAA in urine
- nausea & vomiting, fever, hypotension (vasomotor instability)
- right-sided **endocardial fibroelastosis** (40–50%)
- skin changes:
  - cutaneous facial flushing + sweating (rare)

- desquamative skin lesions (5%)
- pellagra (7%) from niacin deficiency ← preferential conversion of dietary tryptophan to serotonin rather than niacin
- multiple telangiectasias (25%)

Prognosis: carcinoid syndrome has a higher morbidity & mortality than does the tumor itself!

CARCINOID TUMOR OF GI TRACT

= NEUROENDOCRINE TUMOR OF GI TRACT

[*Karzinoide*, German = carcinoma-like]

= group of well-differentiated tumors of the diffuse endocrine system outside pancreas + thyroid

Commonality: neuroendocrine cells share several antigens with nerve elements (neuroendocrine markers)

Neuroendocrine system:

◊ The majority of neuroendocrine tumors occur within the gastroenteropancreatic (GEP) axis

(a) adrenal medulla, pancreatic islets, paraganglia
(b) parathyroid, pituitary, thyroid C cells
(c) others:
  › GI tract: from hypopharynx to rectum (67–85%)
  › tracheobronchial system (10–29%)
  › biliary tract, gallbladder, liver
  › kidney, urethra, ovary, testis, skin (8%)

Inheritance: sporadic (mostly) / part of complex familial endocrine cancer syndrome (MEN 1, NF 1)

Frequency: 1.9÷100,000 annually worldwide
2nd most common primary tumor of small bowel

Origin: enteroendocrine cells that populate mucosa + submucosa; belong to APUDomas (like pheochromocytoma, medullary carcinoma of thyroid, islet cell tumors of pancreas)

Average age: 61 years; M÷F = 2÷1

Path: firm white / yellow / grey firm submucosal nodule arising from argentophil Kulchitsky cells of epithelial origin in the crypts of Lieberkühn (= argentaffinoma ← affinity for silver stain marking serotonin-containing granules of enterochromaffin EC-cells); invasion of mesentery incites an intense fibrotic reaction

Often the tumor bulk is subepithelial, and they should be included in the DDx of submucosal tumors.

Histo: solid acinar / insular nests of closely packed monomorphic cells, uniform in size, arranged in trabecular / glandular rosette pattern; cytoplasma contains argyrophil secretory granules arranged in distinctive "salt and pepper" pattern of nuclear chromatin; low-grade malignancy resembling adenocarcinoma without its aggressive behavior; malignant through invasion of muscularis

Immunohisto: chromogranin, synaptophysin, neuron-specific enolase, protein gene product 9.5, peptide markers for serotonin and gastrin

Classification based on malignant potential:

1. Well-differentiated neuroendocrine tumor (typical carcinoid tumors) → low-grade malignancy
2. Well-differentiated neuroendocrine carcinoma (atypical carcinoid tumor) with metastases

→ more aggressive

3. Poorly differentiated neuroendocrine carcinoma of high-grade malignancy → poor prognosis
   (a) Large cell neuroendocrine carcinoma (LCNEC)
   (b) Small cell lung carcinoma (SCLC) = majority

Biochemistry:
tumor elaborates excessive amounts of vasoactive substances + neuropeptides (1) ACTH (2) histamine (3) bradykinin (4) kallikrein (5) prostaglandin (6) substance P (7) neurokinin-A (8) serotonin (= 5-hydroxytryptamine ← 5-hydroxytryptophan ← tryptophan), which is metabolized (inactivated) in liver by monamine oxidase into 5-hydroxyindole acetic acid (5-HIAA) and excreted in urine; 5-hydroxytryptophan is destroyed in pulmonary circulation

Associated with: other synchronous / metachronous malignancies (36% at necropsy), especially gastrointestinal adenocarcinoma; neurofibromatosis type 1

- asymptomatic (66%), abdominal pain / bowel obstruction (19%)
- nausea, weight loss (16%), palpable mass (14%), GI bleeding
- elevated serum chromogranin-A (most common marker)
- elevated urinary 5-HIAA (hydroxyindole acetic acid)
- carcinoid syndrome

RULE OF ⅓:
◊ ⅓ occur in small bowel
◊ ⅓ have metastases
◊ ⅓ are multiple
◊ ⅓ have a second malignancy
◊ ⅓ have carcinoid syndrome

Metastases (~ 40% at time of presentation):
mesenteric lymph nodes, liver (in 90% of patients with carcinoid syndrome), peritoneum, lung, bone (osteoblastic)

◊ Symptomatic metastases ← midgut carcinoids in 75%

(a) incidence versus tumor size
tumor of < 1 cm (in 75%) metastasizes in 2%
tumor of 1–2 cm (in 20%) metastasizes in 50%
tumor of > 2 cm (in 5%) metastasizes in 85%

(b) incidence versus location
tumor in ileum (in 28%) metastasizes in 35%
tumor in appendix (in 46%) metastasizes in 3%
tumor in rectum (in 17%) metastasizes in 1%

Visualization of Liver Metastases

	best seen at	*present at*
NECT	35%	3%
CECT in HAP	35%	14%
CECT in PVP	30%	3%

HAP = hepatic arterial-dominant phase of triple phase CT
PVP = portal venous-dominant phase of triple phase CT

Location within GI tract:

◊ 30% are multicentric (Examine entire bowel!)
@ Small bowel (42%)
Frequency: 25% of all small bowel tumors
Location: ileum (91%); jejunum (7%), duodenum (2%); multiple in 15–29–41%
@ Rectum (27%)
@ Appendix (24%)
@ Stomach (9%)
@ Colon (5%)
@ Esophagus (0.05%)
Location outside GI tract:
@ Respiratory tract (20–30%)
@ Others: thyroid, pancreas, biliary tract, teratomas (ovarian, sacrococcygeal, testicular)
Site: intramural mass / intraluminal polypoid nodule
UGI:
√ small smooth submucosal mass (usually < 2 cm) impinging eccentrically on lumen
√ ± ulceration of overlying gastric / intestinal mucosa
√ desmoplastic fibrotic response of mesentery ← high levels of serotonin ← local production by nodal metastases:
√ angulation + kinking of loops → obstruction (DIAGNOSTIC)
√ spiculated / tethered appearance of mucosal folds
√ matting of multiple loops
√ separation of loops ← large mesenteric metastases
CT:
√ primary tumor:
√ small subepithelial avidly enhancing polyp during early phase, often in ileum (dual-phase imaging with water as oral contrast / CT enteroclysis)
√ may become isodense after slow contrast infusion / in portal-venous phase
√ enhancing carpet lesions mimicking Crohn disease
√ regional lymph node metastases:
√ focal conglomerate mesenteric mass often larger than primary tumor
√ low-density lymphadenopathy ← necrosis
√ mesenteric carcinoid tumor (metastasis):
√ "sunburst" appearance = stellate radiating pattern and beading of mesenteric neurovascular bundles ← fibrosis + desmoplastic reaction
√ containing calcifications (in up to 70%)
√ thickening + retraction + shortening of mesentery
√ displacement + kinking + separation of adjacent bowel loops
√ asymmetric / concentric segmental thickening of adjacent bowel loops ← bowel ischemia ← encasement of mesenteric vessels
√ characteristically hyperattenuating + necrotic liver metastases (best visualized during early arterial phase!)
MR:
√ mesenteric tumor isointense to muscle on T1WI + T2WI
Angio:

√ "sunburst" appearance:
√ kinking of small- and medium-sized vessels of a stellate configuration
√ simulated hypervascularity with thickening + foreshortening of mesenteric vessels ← fibrotic retraction
√ mesenteric ischemia:
√ arterial branch stenoses from encasement of medium-sized vessels ← elastic vascular sclerosis with locally elevated serotonin levels
√ venous occlusion / mesenteric varices
√ tumor may be identified as hypervascular mass

NUC (initial procedure of choice for):
(a) localization of occult primary tumor
(b) staging
(c) identification of receptor status for octreotide Rx

(1) ^{111}In-pentetreotide somatostatin-receptor scintigraphy (80–100% of carcinoids contain 5 somatostatin receptor subtypes)
Sensitivity: 80–90% (improved with SPECT-CT fusion)
√ higher frequency of radiotracer uptake in midgut carcinoids + with elevated serotonin levels

(2) ^{123}I- / ^{131}I-MIBG scintigraphy
Sensitivity: 55–70% (lower than for ^{111}In-pentetreotide)
√ type I uptake mechanism for guanethidine

Prognosis: slow progression with average survival time of 3.2 years after diagnosis of liver metastases; 5-year survival of 65% for localized disease + 36% for distant metastatic disease

Rx: resection; somatostatin / SMS 201-995; chemoembolization of hepatic arteries

DDx: oat-cell carcinoma, pancreatic carcinoma, medullary thyroid carcinoma, retractile (sclerosing) mesenteritis, desmoplastic carcinoma / lymphoma

Gastric Carcinoid (9%)

Frequency: 2% of all gastric malignancies

Origin: (enterochromaffin-like) ECL-cell arising from oxyntic (gastric–acid-secreting) mucosa
[*oxyno* , Greek = make sour / acid, to sharpen]

Location: gastric body and fundus

√ one / more small 1–4-cm subepithelial masses:
√ bull's eye appearance when ulcerated
√ one / more sessile / pedunculated polyps
√ avid enhancement in early arterial phase

Type 1 gastric ECL-cell carcinoid (74–80%)

Mean age: 63 years; M÷F = 1÷2.5

Associated with: autoimmune chronic atrophic gastritis

Path: multiple < 1 cm mucosal nodules in gastric fundus / body

Histo: positive stain for chromogranin A + synaptophysin

- often incidental finding during imaging for dyspepsia / chronic atrophic gastritis:
  - hypergastrinemia ← antral G-cell hyperplasia

• ± achlorhydria and pernicious anemia

√ multiple / solitary polyps of < 1 cm in diameter in fundus

Prognosis: tendency for benign biologic behavior; nodal + hepatic metastatic spread in 5%

Type 2 gastric ECL-cell carcinoids (5–10%)

Mean age: 50 years; M÷F = 1÷1

Associated with: Zollinger-Ellison syndrome in MEN 1

◊ 30% of patients with MEN 1 have gastric carcinoid tumors ← altered tumor suppression contributes to development of carcinoids from ECL-cell hyperplasia

Path: multiple mucosal nodules of variable size

• hypergastrinemia → abdominal pain, recurrent peptic ulcers, diarrhea; hypertrophic hypersecretory gastritis

√ multiple masses of variable size on diffuse gastric wall thickening

Prognosis: local nodal metastatic spread in 10–30%

Types 1 and 2 of gastric carcinoids are associated with hypergastrinemia causing proliferation of enterochromaffin- like cells → developing often multiple carcinoid tumors.

Type 3 gastric ECL-cell carcinoids (13%)

= sporadic carcinoid NOT associated with hypergastrinemia

Mean age: 55 years; M÷F = 3÷1

Path: solitary > 2 cm mass in gastric body + fundus

• bleeding, abdominal pain, anorexia, weight loss

√ usually solitary submucosal tumors ± ulceration

Prognosis: metastases at clinical presentation in 50–70%; 20% 5-year survival

DDx of solitary tumor: adenocarcinoma, lymphoma, GIST

Duodenal Carcinoid (2%)

Mean age: 53 (range, 19–90) years; M÷F = 1÷1

Associated with:

(1) Multiple endocrine neoplasia

(2) Neurofibromatosis type 1 for periampullary carcinoids often containing somatostatin-producing D-cells

A. **G-cell (gastrin-producing) carcinoid** (62%)

◊ in ⅓ functioning tumor (= gastrinoma) that produces Zollinger-Ellison syndrome

◊ 85% of sporadic gastrinomas in "gastrinoma triangle"

◊ 90% of MEN 1 patients develop multiple G-cell carcinoids

• abdominal pain + diarrhea (50%) ← hypergastrinemia

• nausea, vomiting, positive secretin stimulation test

• bleeding from multiple + recurrent peptic ulcers

• gastroesophageal reflux ← excess acid production

B. **D-cell (somatostatin-producing) carcinoid** (21%)

Associated with: neurofibromatosis 1 (in up to 50%)

Path: 1–2 cm polypoid nodules in submucosa / infiltrative intramural masses ± ulceration

Histo: densely calcified concentrically laminated psammoma bodies (= psammomatous

somatostatinoma); positive stains for neuron-specific enolase, chromogranin A, synaptophysin, somatostatin; immunoreactivity for gastrin

Location: around ampulla of Vater

- jaundice, pancreatitis ← obstruction of bile duct
- hemorrhage
- somatostatin effects (rare): steatorrhea, diarrhea, diabetes mellitus, hypochlorhydria, anemia, cholelithiasis

UGI:

√ well-defined round intraluminal polypoid mass (52%) / intramural mass (39%) ± focal ulceration

CT:

√ arterial phase enhancement + loss of enhancement during delayed phase

√ metastasis to peripancreatic lymph nodes / liver (in 60–80% at time of diagnosis)

N.B.: positive gastrointestinal contrast material may mask small duodenal mural lesions

Jejunal and Ileal Carcinoid (42%)

Mean age: 65 years; M÷F = 1÷1

Associated with: synchronous / metachronous malignancies (29%): GI adenocarcinoma (most common)

- often asymptomatic
- local symptoms: small bowel obstruction, ischemia, bleeding
- long history of intermittent crampy abdominal pain, weight loss, fatigue, abdominal distension, diarrhea, nausea, vomiting

Path: small firm < 3.5 cm intramural nodule ± protrusion into lumen; multiple in 30%; infiltrative growth into subserosa + mesentery stimulating desmoplastic reaction → multifocal stenoses and occlusions of arteries + veins → intestinal ischemia

SBFT:

√ solitary / multifocal small polypoid nodules / mucosal elevations ± ulceration

√ fixed rigid curved segment of small bowel

US:

√ smooth intraluminal hypoechoic oval masses interrupting submucosal layer

√ thickening + puckering of muscularis propria

√ retraction of wall, invasion of serosa

√ mesenteric metastases of similar echogenicity to primary ± calcification

CT:

› primary tumor

√ large polypoid intramural lesion

√ concentric / asymmetric hypoattenuating mural thickening ("target / halo" sign) ← intestinal ischemia / infiltrating tumor with desmoplastic fibrosis

√ hypervascular nodular wall thickening smooth submucosal mass

√ "hairpin turn" = kinking / curvature of a thickened distorted intestinal wall

› metastatic disease (in 60% at time of diagnosis):

√ large enhancing local mesenteric lymph nodes / masses often exceeding the primary mass in size:

√ stellate mesenteric desmoplastic reaction of "spoke-wheel / sunburst" appearance

NOT associated with a mass = mesenteric soft-tissue stranding and distortion of mesenteric vessels ← fibrosis rather than tumor infiltration
√ well-defined margins ± necrosis
√ faint stippled / coarse dense / diffuse calcifications (70%)
√ miliary peritoneal implants / large masses / mesenteric caking
√ hypervascular liver metastases during arterial phase ± central necrosis

Cx: intussusception

DDx for carcinoids of small intestines:
metastatic disease, primary intestinal adenocarcinoma, lymphoma, GIST, Crohn disease, localized ischemic enteritis

Appendiceal Carcinoid (< 10%–24%)

Commonly benign: slow growth, rarely metastasizing

Incidence at surgery: 0.03–0.70%

- mostly asymptomatic
- symptoms of appendicitis (30–50%)

Age: any; M < F

Site: tip (70%), middle (20%), base (10%) of appendix

Size: usually < 1 cm, rarely > 2 cm

√ focal soft-tissue mass / diffuse circumferential thickening

√ invasion of mesoappendix (11%)

US:
√ persistent fluid-distended appendix without typical signs of appendicitis

Colorectal Carcinoid

Frequency: < 1% of all rectal cancers

Mean age: 66 years (56 years for rectal location)

Location: rectum (27%) >> cecum / ascending colon (5%)

- mostly asymptomatic / abdominal pain, weight loss
- carcinoid syndrome (NOT with common rectal carcinoids)

√ polypoid intramural mass ± intussusception

√ ± ulceration of large tumor

Prognosis: metastatic in 10%

CATHARTIC COLON

= prolonged use of stimulant-irritant cathartics (> 15 years) → chronically increased muscular activity + tonus → neuromuscular incoordination

Agents: castor oil, senna, phenolphthalein, cascara, podophyllum, aloin

Location: involvement of colon proximal to splenic flexure

√ effaced mucosa with flattened smooth surface

√ diminished / absent haustrations

√ "pseudostrictures" = typically smoothly tapered areas of narrowing ← sustained tonus of circular muscles

√ poor evacuation of barium

√ flattened + gaping ileocecal valve

√ shortened but distensible ascending colon
DDx: "burned-out" ulcerative colitis with right-sided predominance (very similar)

CHAGAS DISEASE

[Carlos Chagas (1879–1934), physician in Rio de Janeiro, Brazil]
= damage of ganglion cells by neurotoxin liberated from protozoa Trypanosoma cruzi resulting in aperistalsis of GI tract + dilatation
Histo: decreased number of cells in medullary dorsal motor nucleus + Wallerian degeneration of vagus + decrease / loss of argyrophilic cells in myenteric plexus of Auerbach
Peak age: 30–50 years; M÷F = 1÷1
• foul breath, regurgitation, intermittent / persistent dysphagia
• odynophagia (= fear of swallowing), aspiration
• Mecholyl test: abnormal response indicative of deficient innervation; 2.5–10 mg methacholine subcutaneously followed by severe tetanic nonperistaltic contraction 2–5 minutes after injection, commonly in distal half of esophagus, accompanied by severe pain
@ Dilatative cardiomyopathy (myocarditis)
@ Megacolon (bowels move at intervals of 8 days to 5 months)
Cx: impacted feces, sigmoid volvulus
@ Esophagus: changes as in achalasia

Trypanosomiasis

[*trypano* , Greek = borer; *soma* , Greek = body]
Organism: unicellular parasitic flagellate Trypanosoma cruzi transmitted via vector
Transmission: acquired by insect bite from the Reduviidae family (genera Triatoma, Rhodnius, and Panstrongylus); trypomastigotes inoculation occurs through rubbing of reduviid bug feces into a bite or other skin defect
◊ Endemic to Central + South America (esp. eastern Brazil) with 24 million people infected
• acute febrile illness, acute myocarditis (uncommon)
• facial / unilateral palpebral edema ("Romaña" sign)
@ Heart: chronic myocarditis
Histo: focal / diffuse loss of myocytes, fibrosis, focal atrophy, conduction system involvement
• bundle branch block → complete atrioventricular block
√ severe cardiomegaly ← dilated cardiomyopathy
√ pulmonary edema, septal lines, pleural effusion ← chronic heart failure
@ GI tract: esophagus, colon
• achalasia, megacolon
Dx: direct visualization of trypomastigotes in blood smear; serologic test for chronic manifestation

CHALASIA

= continuously relaxed sphincter with free reflux in the absence of a sliding hernia
Etiology: elevated submerged segment
Cause:

(1) Delayed development of esophagogastric region in newborns
(2) Scleroderma, Raynaud disease
(3) S/P forceful dilatation / myotomy for achalasia

√ free / easily induced reflux

CLOSTRIDIUM DIFFICILE COLITIS

= ANTIBIOTIC-ASSOCIATED COLITIS = PSEUDOMEMBRANOUS COLITIS

= nosocomial epidemic / endemic acute infectious colitis ← Clostridium difficile toxins

Etiologic agent: toxin A (enterotoxin) + toxin B (cytotoxin) produced by C. difficile

Cause: unopposed overgrowth of gram-positive Clostridium difficile ← decrease in normal intestinal flora

Predisposed:

(a) complication of broad-spectrum antibiotics: tetracycline, extended-spectrum penicillins (azlocillin, mezlocillin, piperacillin, ticarcillin, carbenicillin, mecillinam), aminopenicillins (ampicillin, amoxicillin), clindamycin, lincomycin, chloramphenicol, cephalosporins, metronidazole, vancomycin
(b) complication of some chemotherapeutic agents: methotrexate, fluorouracil
(c) following abdominal surgery / renal transplantation / irradiation
(d) prolonged hypotension / hypoperfusion of bowel
(e) shock, uremia
(f) proximal to colonic obstruction
(g) debilitating diseases: lymphosarcoma, leukemia, advanced HIV infection
(h) immunosuppressive therapy with actinomycin D

Histo: pseudomembranes (= exudate composed of leukocytes, fibrin, mucin, sloughed necrotic epithelium held in columns by strands of mucus) on a partially denuded colonic edematous mucosa (mucosa generally intact); reactive edema in lamina propria, submucosa, and eventually subserosa

Clinical manifestations of C. difficile infection:

(1) Absence of symptoms (majority)
(2) Antibiotic-associated colitis without pseudomembrane formation
(3) Pseudomembranous colitis
(4) Fulminant colitis

- profuse watery diarrhea, abdominal cramps, tenderness
- fever, fecal blood, leukocytosis
- less common: chronic diarrhea, dehydration, toxic megacolon, hyperpyrexia, leukemoid reaction, hypoalbuminemia with anasarca

Location: pancolitis (most commonly); rectum (95%); confined to right + transverse colon (5–27–40%)

◊ Radiographic abnormalities in 32% + positive stool toxin assay!

Plain film:

√ adynamic ileus pattern = moderate gaseous distension of small bowel + colon:
  √ small bowel ileus (20%)
  √ colonic ileus (32%)
√ nodular haustral thickening (18%):

√ "thumbprinting" = "transverse banding" = wide perpendicular bands ← marked thickening + distortion of haustral folds (most prominent in transverse colon) ← submucosal hemorrhage + edema
√ diffusely shaggy + irregular surface ← confluent pseudomembranes
√ ascites (7%)

BE (CONTRAINDICATED in severe cases):

Fluoroscopic enemas should be avoided in a patient with pseudomembranous colitis ← risk for perforation

√ pseudoulcerations = barium filling clefts between pseudomembranes
√ irregular ragged polypoid contour of colonic wall
√ discrete multiple plaquelike lesions of 2–4 mm in size (DDx: polyposis, nodular form of lymphoma)

N.B.: risk of colonic perforation in toxic megacolon!

CT (85% sensitive, 48% specific):

√ NO colonic abnormality (12–39%)
√ substantial irregular eccentric colonic wall thickening:
√ wall thickness usually > 4 mm with a mean of 14.7 (range, 3–32) mm in 61–88%

The degree of wall thickening in C. difficile colitis is greater than in any other infectious or inflammatory process involving the bowel except for Crohn disease.

√ segmental / diffuse involvement of entire colon
√ mural hypoattenuation ← edema
√ mural hyperattenuation ← acute inflammation
√ thumbprinting thickened ← edematous haustra
√ "**accordion**" sign (51–70%) = enteric contrast material trapped between distorted thickened closely spaced transverse edematous haustra of low attenuation (simulating intramural tracts), TYPICAL in severe cases
√ smooth (44%) / irregular / polypoid (17%)
√ "target" sign = submucosal edema + homogeneous mucosal enhancement ← hyperemia (best seen during arterial enhancement)
√ colonic dilatation frequent ← transmural inflammation
√ usually DISPROPORTIONATELY mild pericolonic stranding (42%) relative to marked wall thickening
√ ascites in severe cases (15–35%)
√ pneumatosis coli ± portal vein gas in severe cases

Dx: (1) Stool assay for Clostridium difficile cytotoxin (detects toxin B): cumbersome to perform
(2) Enzyme immunoassay test (up to 33% false-negative results): detection of toxin A + B
(3) Stool culture (95% sensitive): not available for 2 days
(4) Pseudomembranes of adherent yellow plaques 2–10 mm in diameter on proctosigmoidoscopy

Cx: peritonitis, toxic megacolon (if dilatation > 6 cm), perforation

Prognosis: 1.1–3.5% overall mortality; most patients recover within 2 weeks

Rx: (1) Discontinuation of suspected antibiotic
(2) Administration of vancomycin / metronidazole (response within 3–4 days)
(3) Attention to fluid and electrolyte balance
(4) Life-saving partial colectomy required in < 1%

DDx: acute stage of ulcerative / Crohn colitis, infectious colitis (eg, enterohemorrhagic E. coli), ischemic colitis, radiation colitis, colonic wall hemorrhage, colonic lymphangiectasia, leukemic infiltration, diverticulitis

COLITIS CYSTICA PROFUNDA

= rare benign chronic condition characterized by dilated sub- mucosal mucin-filled cysts lined by normal colonic epithelium

Etiology: probably related to chronic inflammation

Associated with: solitary rectal ulcer syndrome (as localized polypoid variant)

Age: primarily disease of young adults

- brief periods of bright red rectal bleeding
- mucous / bloody discharge, intermittent diarrhea

Location:
(a) localized to rectum (most commonly) / sigmoid
(b) generalized colonic process (less common)

√ nodular polypoid / cauliflower-like lesions < 2 cm in size, containing no gas
√ spiculations mimicking ulcers (barium-filled clefts between nodules)

DDx: pneumatosis (rarely affects rectum)

COLONIC ATRESIA

Frequency: less common than ileal atresia

Plain radiograph:
√ massive dilatation of colon proximal to obstruction
√ mottled pattern of gas + feces proximal to point of atresia
DDx: often indistinguishable from obstruction of distal ileum

BE:
√ functional microcolon
√ obstruction to retrograde flow of barium

US:
√ dilated hyperechoic distal small bowel + proximal colon ← retained meconium

COLORECTAL CARCINOMA

Most common cancer of GI tract; 3rd most commonly diagnosed malignancy in developed countries in men (after lung and prostate cancer) and women (after lung + breast cancer); 2nd leading cause of cancer deaths

Incidence: 136,830 new cases annually with 50,310 deaths in USA (2014); 11% of all newly diagnosed cancers; 13% of all cancer deaths; 3÷100,000 in 30–34-year-olds; 532÷100,000 for > 85-year-olds

Lifetime probability: 4– 6% of any White person

Risk factors:

1. Personal history of colonic adenoma / carcinoma
   › malignancy in 5% of tubular adenomas
   › malignancy in 30–40% of villous adenomas
   Proof of adenoma-carcinoma sequence:
   (a) frequent coexistence of adenoma + carcinoma
   (b) similar distribution within colon
   (c) consistent proportional prevalence in population having varied magnitudes of colon cancer risk
   (d) increased frequency of carcinoma in patients with adenomas
   (e) reduction of cancer incidence following endoscopic removal of polyps
   (f) all patients with familial adenomatous polyposis syndrome develop colon carcinoma if colon not removed
   (g) similarity of DNA + chromosomal constitution
   ◊ 93% of colorectal carcinomas arise in adenomatous polyps
   ◊ A patient with one adenoma has a 9% chance of having a colorectal carcinoma in the next 15 years!
   ◊ It takes about 7 years for a 1-cm adenoma to become an invasive cancer!
   ◊ 5% of 5-mm adenomas develop into invasive cancers (5 mm = critical mass of intraepithelial neoplasia)!
2. Family history of benign / malignant colorectal tumors in 1st-degree relative (3–5 x risk)
3. Personal history of ovarian / endometrial / breast cancer
4. Dysplasia of colon within flat mucosa
5. Inflammatory bowel disease:
   (a) Ulcerative colitis (3–5% incidence; cumulative incidence of 26% after 25 years of colitic symptoms)
   (b) Crohn disease affecting the colon + rectum (particularly in bypassed loops / in vicinity of chronic fistula)
   Time delay: > 8–10 years of colitis
   Underlying lesion: dysplasia within flat mucosa
6. Prominent lymphoid follicular pattern
7. Pelvic irradiation
8. Ureterosigmoidostomy

Environmental risk factors:
(a) low fiber diet: prevents rapid transit time → increasing contact time between potential toxins and colonic mucosa
(b) increased ingestion of fat + animal protein
(c) obesity
(d) asbestos worker

Genetic risk factors (6% of colorectal carcinomas):
(a) familial adenomatous polyposis syndrome:
familial polyposis, Gardner syndrome, Turcot syndrome
Age: ~ 40 years
(b) certain hamartomatous polyposis syndromes:
Peutz-Jeghers syndrome, juvenile polyposis, Cowden disease
(c) hereditary nonpolyposis colon cancer syndrome

= Lynch syndrome

Screening recommendations (American Cancer Society):

as / more effective than mammographic screening

(a) for persons > 50 years of age: annual fecal occult-blood test + sigmoidoscopy / BE every 3–5 years

(b) for 1st-degree relatives of patients with colon cancer screening should start at age 40

Median age: 71 years for colon cancer; 69 years for rectal cancer; M÷F = 3÷2

Histo:

(1) Adenocarcinoma with varied degrees of differentiation (> 90%)

(2) Mucinous carcinoma (uncommon)

(3) Squamous cell carcinoma + adenoacanthoma (rare)

Metastases (lymphatic / hematogenous venous):

1. Liver (75%; 15–20% at time of surgery) ← portal venous drainage route
2. Mesentery + mesenteric nodes (10–15%)
3. Adrenal (10–14%)
4. Lung (5–50%)
5. Ovary (3–8%) = Krukenberg tumor
6. Psoas muscle tumor deposit
7. Peritoneal metastases:
   (a) malignant ascites: usually associated with poorly differentiated colonic carcinoma
   (b) pseudomyxoma peritonei (< 5%): low-grade colonic adenocarcinoma
8. Bone (5%)
9. Brain (5%)

◊ Because of the absence of lymphatics in the lamina propria colon cancer will not metastasize until it penetrates the muscularis mucosa!

- rectal bleeding, iron deficiency anemia
- change in bowel habits / caliber of stools
- obstruction (poor prognostic indicator), hydronephrosis (13%)
- positive fecal occult blood testing (2–6% positive-result rate; 5–10% positive predictive value; fails to detect 30–50% of colorectal carcinomas + up to 75% of adenomas): Hemoccult® (hematein), HemoQuant® (porphyrins), HemeSelect™ (hemoglobin)
- progressive elevation of carcinoembryonic antigen (CEA) > 10 µg/L indicative of recurrent / metastatic disease
- watery diarrhea + potassium depletion / excessive secretion of mucus + hypoalbuminemia (in large mucin-secreting villous tumor)

Location: "aging gut" = number of right-sided lesions increasing with age ("changing distribution")

(a) left colon (52–61%):
rectum (15–33–41%), sigmoid (20–37%), descending colon (10–11%)
√ commonly annular strictures with obstruction

(b) right colon:
transverse colon (12%), ascending colon (8–16%), cecum (8–10%)
√ commonly polypoid lesions with chronic bleeding + intussusception

(c) rectum: ⅓ of all colorectal cancers

Colonoscopy: cecum not visualized in 10–36%; fails to detect 12% of colonic polyps (10% in

areas never reached by colonoscope)

Cx: perforation in 0.2% (0.02% for BE); death in 1÷5,000 (1÷50,000 for BE)

BE:

Detection of Colonic Polyps on Barium Enemas		
Sensitivity	*Polyp > 1 cm*	*Polyp < 1 cm*
Single contrast barium enema	77–94%	82–97%
Double contrast barium enema	18–72%%	61–83%

√ fungating polypoid carcinoma:
- chronic bleeding, intussusception

√ annular ulcerating carcinoma = "apple core lesion"
= annular constriction ← tumor grows along lymphatic channels that parallel circular muscle fibers of inner layer of the muscularis propria; longitudinal growth is limited with abrupt transition to normal mucosa
- colonic obstruction

√ "saddle lesion" = growth characteristics between polypoid mass + annular constricting lesion

√ scirrhous carcinoma (signet-ring type)
= long-segment stricture without significant mucosal abnormality similar to linitis plastica ← diffuse circumferential + longitudinal tumor infiltration within loose submucosal tissue between muscularis mucosa and muscularis propria
- often seen in ulcerative colitis

√ curvilinear / mottled calcifications are CHARACTERISTIC of mucinous adenocarcinoma (rare)

CT (48–90% staging accuracy, 25–73% for lymph node mets):

√ marked asymmetric colonic wall thickening involving a short segment

√ low-density mass + low-density lymph nodes in mucinous adenocarcinoma (if > 50% of tumor composed of extracellular mucin)

√ abrupt change from normal to abnormal segment of colon

√ psammomatous calcifications in mucinous adenocarcinoma

√ signs of Lnn involvement: single lymph node > 1 cm in diameter / cluster of ≥ 3 nodes < 1 cm / node of any size within mesentery

◊ *Screening CT colonography:* 55–94% sensitive for polyps > 10 mm

CT Staging of Colorectal Cancer *(poor accuracy compared with Astler-Coller classification)*	
Stage 1	intramural polypoid mass
Stage 2	thickening of bowel wall
Stage 3	slight invasion of surrounding tissues
Stage 4	massive invasion of surrounding tissue + adjacent organs / distant metastases

MR: (staging accuracy of 73%, 40% sensitivity for lymph node metastases)

Prognosis:

5-year survival rate of 40–50% (unchanged over past 40 years); 83–90% (70%) [33%]

{5%} with Duke A (B) [C] {D}

Recurrence in ⅓ of patients:

(a) local recurrence at line of anastomosis (60%): within 1 {2} year after resection in 50% {70–80%}

(b) distant metastases (26%)

(c) local recurrence + metastases (14%)

Staging of Colorectal Cancer
(UICC-AJCC Colorectal Cancer Staging System)

Stage	*Grouping*			*5-year Survival*
0	Tis	N0	M0	>95%
I	T1	N0	M0	75–100%
	T2	N0	M0	
II	T3	N0	M0	50–75%
	T4	N0	M0	
III	any T	N1	M0	30–50%
	any T	N2,3	M0	
IV	any T	any N	M1	<10%

Legend:

Tis	carcinoma in situ
T1	invasion of submucosa
T2	invasion of muscularis propria
T3	invasion of subserosa / pericolic tissue
T4	invasion of visceral peritoneum / other organs
N1	1–3 pericolic Lnn
N2	>4 pericolic Lnn
N3	any Lnn along course of a vascular trunk

<u>Risk after detection of colon cancer:</u>

5% for synchronous colon cancer

14% for synchronous cancer with "sentinel polyp"

35% for additional adenomatous polyp

3% for metachronous colon cancer

4% for extracolonic malignancy

Cx: (1) Obstruction (frequently in descending + sigmoid colon) ← relatively larger caliber of right colon allows growth to a larger size before becoming symptomatic by obstruction

(2) Perforation (in up to 10%)

(a) at site of mass: subacute process ← slow gradual infiltration of bowel wall

(b) proximal to mass: necrosis of stercoral ulcer / increased pressure proximal to obstruction

(3) Intussusception (50% of all adult intussusceptions): intestinal lymphoma, GI tumor, metastatic disease

(4) Abscess formation: intraperitoneal (in majority); localized paracolic; extension to flank, thigh, trunk

(5) Fistula formation

(6) Pneumatosis cystoides intestinalis

(7) Pseudomyxoma peritonei ← low-grade adenocarcinoma of colon
(8) Ischemic colitis (in 7%)
Cause: (1) severe colonic distention ← mechanical obstruction (2) stagnated bowel contents → bacterial overgrowth (3) mechanical vascular occlusion (4) invasion of mesenteric root vessels
√ concentric ~ 1 cm thickening of bowel wall
DDx: tumoral segment (irregular thickening of bowel wall by an average of 2 cm)

Rx: (1) Local surgical excision / polypectomy for stage I disease
(2) Right / left hemicolectomy with eventual anastomosis of proximal + distal excision sites
(3) Low anterior resection: > 2 cm of rectum must remain to anastomose the colon
(4) Abdominoperineal resection with colostomy for low rectal carcinoma
(5) Adjuvant chemotherapy for stage II disease (fluorouracil / levamisole)

DDx: (1) Prolapsing ileocecal valve (change on palpation)
(2) Spasm (intact mucosa, released by propantheline bromide)
(3) Diverticulitis

Cecal Adenocarcinoma

• often grow asymptomatic for a long time
√ often large polypoid bulky tumor
√ marked wall thickening + mild pericolic infiltration
√ involvement of distal ileum (10%)

Cx: (1) Obstruction (rare): often large tumor within capacious cecum
(2) Intussusception ← tumor as lead point

Signet Ring Carcinoma *(2.6%)*

= variant of mucin-secreting adenocarcinoma
Age: younger patients
Histo: > 50% of cells have a cell nucleus that is displaced to periphery by large amount of intracytoplasmic mucin
Spread: peritoneal surfaces + lymph nodes (more readily); hepatic parenchymal metastases (less frequent)
√ often elongated infiltrating mass > 5 cm in length mimicking underlying colonic inflammatory process
√ concentric rigid wall thickening of scirrhous / linitis plastica appearance
Dx: mucosal surface may appear intact endoscopically → requires deep-tissue biopsies
Prognosis: poor ← aggressive tumor + frequent local recurrence
DDx: colonic Crohn disease / ischemic colitis

Lynch Syndrome

= HEREDITARY NONPOLYPOSIS COLORECTAL CANCER SYNDROME (HNPCC)
= autosomal dominant disorder with high incidence of colorectal cancers + increased incidence of synchronous and metachronous colorectal cancers
Amsterdam criteria:

(a) ≥ 3 family members of whom 2 are 1st degree relatives of the 3rd family member
(b) family members in ≥ 2 generations
(c) one family member diagnosed < 50 years of age

Lynch I = no associated extracolonic cancer

Lynch II = associated with extracolonic malignancy:
transitional cell carcinoma of ureter + renal pelvis; adenocarcinoma of endometrium, stomach, small bowel, pancreas, biliary tract, brain; hematologic malignancy; carcinoma of skin + larynx

Etiology: autosomal dominant abnormality of chromosome 2 with defect in DNA replication-repair process
(a) accelerated adenoma-carcinoma sequence
(b) dysplasia in flat mucosa of colon

Prevalence: 5–10% of patients with colon cancer; 5 x more common than familial adenomatous polyposis syndrome

Mean age: 45 years

Location: 70% proximal to splenic flexure

Prognosis: better stage for stage of other cancers (5-year survival rate of 65% versus 44% in sporadic cases)

Surveillance: colonoscopy every 1–2 years from ages 22–35

Rectal Cancer

Incidence: 40,340 rectal cancers annually in USA (2005); 0.01% national screening average

- gastrointestinal bleeding, change in bowel habit

Pathologic Staging of Rectal Cancer
(modified Dukes = Astler-Coller classification) and TNM

Astler-Coller/TNM		*Description*	*5-year Survival*
A	T1 N0 M0	limited to submucosa	80%
B		involvement of muscularis propria	
B_1	T2 N0 M0	limited to muscularis propria	70%
B_2	T3 N0 M0	transmural extension	60–65%
	T3a	< 5 mm beyond m. propria	
	T3b	5–10 mm beyond m. propria	
	T3c	> 10 mm beyond m. propria	
C		Lymph node metastases	
C_1	T2 N1 M0	nodes (+), into muscularis	35–45%
C_2	T3 N1 M0	nodes (+), transmural	25%
	T4	invasion of adjacent organs	
	T4a	penetration of visceral peritoneum	
D	M1	distant metastasis	<25%

Two hematogenous metastatic patterns of rectal cancer:
(1) liver metastasis ← via IMV + portal venous system / via endolymphatic spread along course of IMV
(2) lung metastasis ← via internal iliac veins + IVC

Hematogenous metastasis:

dual venous drainage into portal + systemic veins

√ may have lung metastases without liver metastases

Risk of recurrence:

5% for T1

10% for T2 33% for T1, N1 + T2N1

25% for T3 66% for T3N1

50% for T4

Staging accuracy:

› Digital rectal examination: 68–75–83%; limited to lesions within 10 cm of anal verge

› CT: 48–72–92%, better for more extensive regional spread; 25–73% for lymph node involvement

› MR: 74–84–93% with tendency for overstaging

› Transrectal ultrasound: 64–77–94% with tendency for overstaging; limited to nonstenotic lesions < 14 cm from anal verge; 50–83% sensitivity for involved lymph nodes

› PET: 97% sensitive for recurrence

Transrectal US (81% accuracy):

Normal layers = gut signature: → see GI anatomy

√ hypoechoic mass disrupting rectal wall:

√ NO interruption of hyperechoic submucosa = tumor confined to mucosa + submucosa

√ NO interruption of hyperechoic serosa = tumor confined to rectal wall

√ break in outermost hyperechoic layer = tumor penetrates into perirectal fat

√ irregular serrated outer border of muscularis propria (pseudopodia through serosa)

√ hypoechoic perirectal lymph nodes ← tumor involvement

COLONIC VOLVULUS

= most common form of volvulus

Frequency: 2% of bowel obstruction; 11% of intestinal volvulus

Colonic volvulus often has a characteristic appearance at conventional radiography, which may be sufficient for a diagnosis in a large percentage of patients!

Cecal Volvulus (25–40%)

= VOLVULUS OF CECUM

◊ Surgical EMERGENCY ← threat of bowel ischemia + bowel perforation!

= twisting of cecum along its long axis ← closed-loop obstruction ← excess mobility

Frequency: 25–40% of all cases of colonic volvulus

Cause: acquired / congenitally poor fixation of right colon to posterior parietal peritoneum (malrotation + long mesentery) → mobile cecum (10–25% of population)

Trigger: sudden distension by trauma, pregnancy, distal colonic obstruction, pressure, colonic atony, constipation, mesenteric / pelvic mass, recent colonoscopy, previous laparotomy with adhesions, congenital cecal duplication cyst

Pathophysiology of vascular compromise:

(1) Acute mesenteric torsion + strangulation → arterial and venous obstruction

(2) Gradual distension + increase in intraluminal pressure → interferes with perfusion → perforation in 65%

Types: I = axial torsion (40%) = cecum twists in axial plane rotating along its long axis
√ cecum occupies right lower quadrant

II = loop twist (40%) = cecum twists and inverts
√ cecum occupies left upper quadrant

III = **cecal bascule** (20%) [*bascule*, French = seesaw]
= anteromedial + upward folding of cecum over ascending colon WITHOUT twist
Cause: loose mesentery, ? related to adhesion
√ dilated cecum anterior to ascending colon

Age peak: 20–40 years; M > F

- gradual onset of acute cramping abdominal pain
- distention, constipation, vomiting

Plain film (DIAGNOSTIC in < 50%):

√ air- or fluid-filled dilated small bowel

√ collapsed left colon

√ cecal gaseous distension:

√ "kidney-shaped" distended cecum inverts + rotates into left upper quadrant (type II)

√ dilated cecum rotates upward + anterior to ascending colon without twisting (type III)

DDx: gastric distension, SBO, sigmoid volvulus

BE (for confirmation of plain film findings):

√ "bird beak" sign = tapering of afferent + efferent bowel loops pointing to point of torsion

√ "coffee bean" sign = dilated air- and fluid-filled cecum with haustral creases

√ decompressed distal colon

√ inability to reflux much contrast material into dilated proximal colon and terminal ileum

CT:

√ cecum ectopically positioned in upper mid + left abdomen

√ "whirlpool / whirl" sign = twisted loop of bowel with its mesentery + ileocecal vessels (NOT in type III)

√ "coffee bean / bird beak" sign

Cx: (1) Cecal distension > 10–12 cm → means risk of bowel perforation / infarction

(2) **Abdominal compartment syndrome** = increase in abdominal pressure diminishes respiratory function + cardiac output

Sigmoid Volvulus (60–75%)

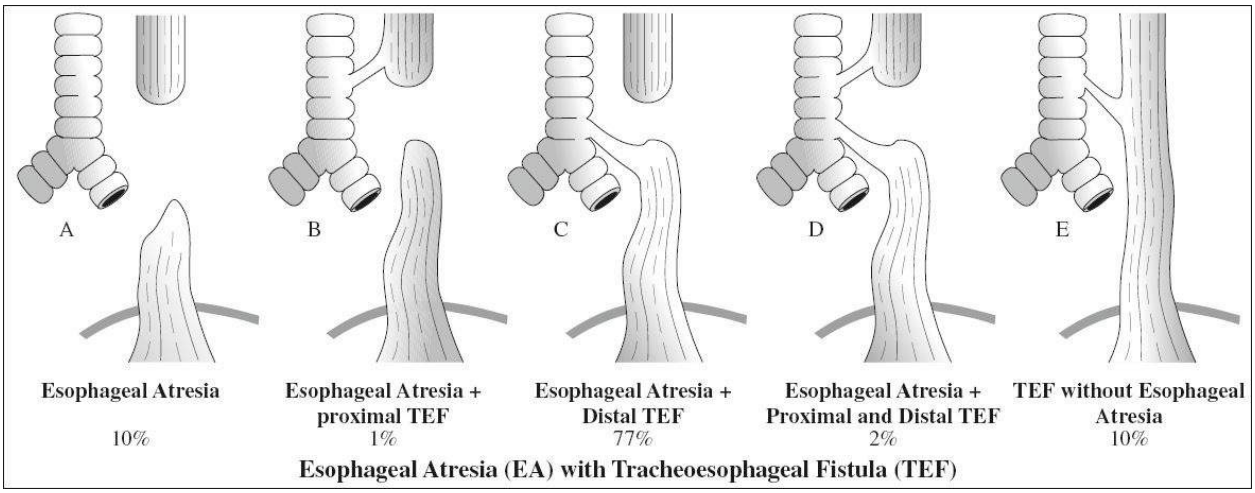
= VOLVULUS OF SIGMOID COLON

Cause: sigmoid twist on mesenteric axis

At risk: chronic constipation, redundancy of sigmoid colon ← high-fiber diet, pregnancy, Chagas disease, hospitalization / institutionalization

Age: usually in elderly > 70 years / psychiatrically disturbed

Degree of torsion: 360° (50%), 180° (35%), 540° (10%)



Esophageal Atresia (EA) with Tracheoesophageal Fistula (TEF)

Plain film:

√ "northern exposure" sign = greatly distended paralyzed loop with fluid-fluid levels arising out of pelvis and extending toward diaphragm beyond level of transverse colon mainly on left side (on film in UPRIGHT position)

√ "coffee-bean sign" = distinct midline crease corresponding to mesenteric root of large gas-distended sigmoid colon (on film in SUPINE position)

√ "white stripe" sign = obliquely oriented center line of the U-shaped closed-loop appearance

√ "three-line" sign = obliquely oriented outer wall + center lines of the U-shaped closed-loop appearance

BE (thin water-soluble contrast material):

√ "bird-of-prey" sign = tapered beaklike distal aspect of twist on barium enema

√ enema may help achieve reduction of volvulus

CT:

√ "whirl" sign = tightly torsed mesentery formed by twisted afferent + efferent loop

Volvulus of Transverse Colon

Frequency: < 5–10% of all cases of colonic volvulus
Cause: abnormal fixation of a long transverse colon
Prognosis: highest mortality of all cases of colonic volvulus ← rare + unsuspected occurrence
√ characteristic beaklike tapering at level of twist
√ "whirl" sign adjacent to transverse colon

CONGENITAL ESOPHAGEAL ATRESIA & TRACHEOESOPHAGEAL FISTULA

= complex of congenital anomalies characterized by failed / incomplete formation of the tubular esophagus or an abnormal communication between esophagus + trachea
Cause: developmental disorder in formation and separation of primitive foregut into trachea + esophagus / vascular compromise
Embryology:
primitive foregut tube develops lateral wall folds that may incompletely connect at any point leaving a fistulous communication; occurs at 3rd–5th week of intrauterine life
Prevalence: 1÷2,000–4,000 livebirths; most common sporadic congenital anomaly diagnosed in childhood
Risk of recurrence in sibling: 1%
Associated anomalies (17–56–70%):

1. Gastrointestinal (20–25%): imperforate anus, pyloric stenosis, duodenal atresia, annular pancreas
2. Cardiac (15–39%): patent ductus arteriosus, ASD, VSD, right-sided aortic arch (5%)
3. Musculoskeletal (24%): radial ray hypoplasia, vertebral anomalies
4. Genitourinary (12%): unilateral renal agenesis
5. Chromosomal (3–19%): trisomy 18, 21, 13
   ◊ Trisomy 18 is present in 75–100% of fetuses + in 3–4% of neonates with esophageal atresia!

mnemonic: ARTICLES
Anal atresia
Renal anomalies
Tracheoesophageal fistula (TEF)
Intestinal atresia / malrotation
Cardiac anomaly: PDA, VSD
Limb anomalies: radial ray hypoplasia, polydactyly
Esophageal atresia
Spinal anomalies

mnemonic: VACTERL
Vertebral anomalies
Anal atresia
Cardiac malformations

Tracheo-
Esophageal fistula
Renal anomalies
Limb anomalies
◊ At least 3 anomalies must be present to suggest VACTERL!

Prevalence: 1÷10,000 to 1÷40,000 live births

- drooling from excessive accumulation of pharyngeal secretions (esophageal atresia = EA)
- obligatory regurgitation of ingested fluids (EA)
- aspiration with coughing + choking during feeding (TEF)
- recurrent pneumonia + progressive respiratory distress of variable severity in neonate (TEF)

Location: between upper ⅓ + lower ⅓ of esophagus just above carina

@ Mediastinum
√ "coiled tube" = inability to pass feeding tube into stomach (esophageal atresia)
√ retrotracheal air-distended pouch of proximal esophagus causing compression / displacement of trachea
√ non- / hypoperistaltic esophageal segment (6–15 cm) in midesophagus
√ food impaction

@ Abdomen
√ gasless abdomen ← esophageal atresia ± proximal TEF = types A + B
√ abdomen distended by bowel gas in 90% ← distal TEF / H-type fistula = types C + D

@ Chest
√ bronchopneumonia with patchy airspace opacity, esp. in dependent upper lobes (in 50%)

OB-US (anomalies not identified before 24 weeks GA):
√ polyhydramnios in 33–60%:
◊ TEF with esophageal atresia = cause of polyhydramnios in only 3%!
√ absence of fluid-distended stomach (in 10–41%; in remaining cases TEF / gastric secretions allow some gastric distension)
√ reduced intraluminal fluid in fetal gut
√ small abdomen (birth weight < 10th percentile in 40%)
√ distended proximal pouch of atretic esophagus
√ ± single umbilical artery

Cx after repair:
(1) Anastomotic leak
(2) Recurrent TEF
(3) Aspiration pneumonia 2° to
(a) esophageal stricture
(b) disordered esophageal motility distal to TEF
(c) gastroesophageal reflux

DDx: pharyngeal pseudodiverticulum (traumatic perforation of posterior pharynx from finger insertion into oropharynx during delivery / tube insertion)

Esophageal Atresia without Fistula = EA Type A

Frequency: 8–10%

Associated anomalies: in 17% (mostly Down syndrome + other atresias of GI tract)

Esophageal Atresia (EA) with Fistula

Associated anomalies: in 30% (mostly cardiovascular)

Type B = esophageal atresia + proximal TEF

Frequency: 0.9–1%

Type C = esophageal atresia + distal TEF

Frequency: 53–86%

Type D = esophageal atresia + proximal and distal TEF

Frequency: 1–2.1%

Tracheoesophageal Fistula without Atresia

= H-SHAPED FISTULA = **Type E**

Frequency: 6–10%

Associated anomalies: in 23% (mostly cardiovascular)

- feeding difficulties with choking
- diagnosis may not be made for several years

√ fistula courses forward and upward from esophagus

mnemonic: No TEF, P, D, P+D, H – 10,1,80,1,10

type **A** = esophageal atresia – **no** TEF = 10%
type B = esophageal atresia – **prox** TEF = 1%
type C = esophageal atresia – **dist** TEF = 80%
type D = esophageal atresia – **prox + dist** = 1%
type E = **H**-type fistula – no atresia = 10%

CONGENITAL ESOPHAGEAL STENOSIS

= rare developmental anomaly

Prevalence: 1÷25,000 to 1÷50,000 live births

Forms:

(1) Tracheobronchial remnant
= incomplete embryologic separation of primitive foregut from respiratory tract
May be associated with: esophageal atresia and tracheoesophageal fistula
Location: lower ⅓ of esophagus
√ ringlike constriction

(2) Fibromuscular stenosis
Location: middle ⅓
√ segmental stricture with a smooth tapered area of concentric narrowing of 1 cm in length
√ circumferential wall thickening on CT

(3) Membranous diaphragm
Location: middle ⅓ of esophagus
√ weblike stenosis

- dysphagia, vomiting, respiratory symptoms

DDx: stricture ← trauma / reflux esophagitis / ingestion of toxic substance

CONGENITAL INTESTINAL ATRESIA

Prevalence: 1÷300 livebirths

Cause: usually sporadic vascular accidents (primary / secondary to volvulus or gastroschisis)
Location: jejunum + ileum (70%), duodenum (25%), colon (5%); may involve multiple sites
√ "triple bubble" sign = intraluminal gas in stomach + duodenal bulb + proximal jejunum as PATHOGNOMONIC sign for jejunal atresia
√ "bulbous bowel segment" sign with curvilinear termination = dilated loop of bowel just proximal to site of atresia ← prolonged impaction of intestinal contents
√ gasless lower abdomen: gut usually air-filled by 4 h after birth
√ meconium peritonitis (6%)
√ polyhydramnios (in 50% ← duodenal / proximal jejunal atresia; rarely in ileal / colonic atresia)
Prognosis: 88% survival for isolated atresia

CRICOPHARYNGEAL ACHALASIA

= hypertrophy of cricopharyngeus muscle (= upper esophageal sphincter) with failure of complete relaxation
Etiology:
1. Normal variant without symptoms: seen in 5–10% of adults
2. Compensatory mechanism to gastroesophageal reflux
3. Neuromuscular dysfunction of deglutition
   (a) primary neural disorders:
   brainstem disorder (bulbar poliomyelitis, syringomyelia, multiple sclerosis, amyotrophic lateral sclerosis); central / peripheral nerve palsy; cerebrovascular occlusive disease; Huntington chorea
   (b) primary muscle disorder:
   myotonic dystrophy; polymyositis; dermatomyositis; sarcoidosis; myopathies ← steroids / thyroid dysfunction; oculopharyngeal myopathy
   (c) myoneural junction disorder:
   myasthenia gravis; diphtheria; tetanus

• mostly asymptomatic, dysphagia
◊ Cineradiography / videotape recording required for demonstration!
√ distension of proximal esophagus + pharynx
√ smoothly outlined shelf- / liplike projection posteriorly at level of cricoid (= pharyngoesophageal junction = level of C5-6)
√ barium may overflow into larynx + trachea
Cx: Zenker diverticulum
Rx: cricopharyngeal myotomy

COWDEN DISEASE

= MULTIPLE HAMARTOMA-NEOPLASIA SYNDROME
= autosomal dominant disease with high penetrance characterized by multiple hamartomas + neoplasms of endodermal, ectodermal, mesodermal origin
Prevalence: 160 cases reported
Cause: susceptibility gene on long arm of chromosome 10 (10q23.2)
Age: 2nd decade

@ Mucocutaneous lesions
  • facial papules, oral papillomas (lips, gingiva, tongue)
  • palmoplantar keratosis, acral keratosis
@ CNS neoplasia
  • macrocephaly
  √ meningioma, glioma
  Associated with: dysplastic cerebellar gangliocytoma
@ Breast lesions (in 50%):
  √ fibrocystic disease + fibroadenomas
  √ breast cancer (20–30%): often bilateral + ductal
@ GI tract
  √ multiple hamartomatous polyps (in 30–60%, commonly in rectosigmoid)
@ Thyroid abnormalities (in 60–70%):
  √ adenomas + goiter
  √ follicular thyroid adenocarcinoma (3–4%)
@ Genitourinary lesions
  √ multiple randomly distributed 1–6-mm hyperechoic avascular masses (= lipomatosis)
@ Skeletal abnormalities

CROHN DISEASE

[Burrill Crohn (1884–1983), gastroenterologist in New York, USA]
= REGIONAL ENTERITIS
= chronic relapsing inflammatory disorder with prolonged unpredictable course characterized by discontinuous + asymmetric involvement of entire GI tract

Cause: unknown; ? diet, smoking, stress, infection, genetics, autoimmune abnormality

Genetic susceptibility:
(1) homozygosity for Nod-2 gene (= intracellular protein in lymphocytes) responsible for binding bacterial endotoxins + initiating a cascade that produces TNF-α (= tumor necrosis factor-alpha)
(2) increased mucosal permeability for enteric bacteria

Incidence: 3.1–14.6÷100,000 annually; high in Caucasians + Jews; 25% during pediatric period
  ◊ 10,000–40,000 new cases annually in USA

Path: transmural (= full-thickness) bowel inflammation with obstructive lymphedema + submucosal lymphoid hyperplasia; aphthous ulcer progresses to longitudinal ulceration typically along mesenteric border; extension into mesentery + adjacent lymph nodes → formation of perienteric sinuses + fistulas + abscesses

In Crohn disease the 1st macroscopic feature to appear is a mucosal aphthous ulceration = a pinpoint ulcer / erosion of mucosa overlying a submucosal lymphoid follicle.

Histo: (a) acute: neutrophilic infiltration, crypt abscesses
(b) chronic: villous atrophy
Noncaseating granulomas with Langhans giant cells and epithelioid cells, edema, fibrosis (in 30%)

Age peaks: 2nd decade + 5th–7th decade (bimodal distribution); M÷F = 1÷1
- recurrent episodes of diarrhea, colicky / steady abdominal pain
- low-grade fever, weight loss, anorexia, occult blood + anemia
- perianal abscess / fistula (40%), malabsorption (30%)

Associated with: erythema nodosum, pyoderma gangrenosum

Rx: (a) lifestyle changes: cessation of smoking

(b) medical: aminosalicylates, corticosteroids; probiotics + antibiotics (modulation of enteric flora); purine synthesis inhibitors like azathioprine + 6-mercapto-purine (downregulation of inflammatory response); infliximab (chimeric antibody binding to TNF-α)

(c) surgical: resection at some point (60–70%)

Outcome: chronic active disease (13%), chronic intermittent disease (73%), in remission for many years (10%)

Intestinal Manifestations of Crohn Disease

Phases: may coexist

(a) Earliest changes
- √ nodular enlargement of lymphoid follicles
- √ blunting / flattening / distortion / straightening / thickening of valvulae conniventes ← obstructive lymphedema, usually first seen in terminal ileum
- √ aphthous ulcers = nodules with shallow central barium collection up to 5 mm in diameter

Location: duodenal bulb, 2nd portion of duodenum, terminal ileum

(b) Advanced nonstenotic phase
- √ <u>skip lesions</u> (90%) = PATHOGNOMONIC discontinuous involvement with intervening normal areas
- √ straightening + rigidity of small bowel loops with luminal narrowing ← spasm + submucosal edema:
  - √ separation + displacement of small bowel loops ← lymphedematous wall thickening + increase in mesenteric fat + enlarged mesenteric lymph nodes + abscess formation after perforation
- √ inflammatory adhesions
- √ thick + blunted small bowel folds ← inflammatory infiltration of lamina propria + submucosa:
  - √ "string" sign = reversible incomplete filling ← edema and spasm ← irritability from severe ulceration
- √ linear mesenteric border ulcers parallel to shortened concave / straight mesenteric border (nearly PATHOGNOMONIC):
  - √ antimesenteric border sacculations = bulging area of normal wall opposite affected scarred wall on mesenteric side = pseudosacculations
  - √ transmural ulcer formation → sinus, fistula, perienteric abscess
- √ **cobblestone appearance** = ulceronodular pattern of serpiginous longitudinal + transverse ulcers separated by areas of edematous residual mucosal islands:
  - √ diffuse mucosal granularity ← 0.5–1-mm round lucencies (= blunted + fused villi

seen EN FACE)
√ pseudopolyps = islands of hyperplastic mucosa between denuded mucosa

(c) Stenotic / obstructive phase
√ "string" sign = irreversible severe narrowing of bowel loop ← marked fibrous thickening of intestinal wall = stricture (in 21%, most frequently in terminal ileum) in combination with severe edema + spasm
√ normal proximal loops may be dilated with stasis ulcers + fecoliths

(d) Reparative phase
√ mucosal denudation (← mucosal atrophy) with focal areas of sparing
√ extensive sessile / pedunculated / filiform postinflammatory regenerative polyposis

US:

Technologic advances in US allow improved visualization of small bowel and mesentery, especially in the pediatric population.

@ bowel wall
√ "pseudokidney / target" sign = circumferential continuous / intermittent diffusely thickened hypoechoic bowel wall (22–65–89%) of 5–20 mm (DDx: ulcerative colitis)
√ loss of normal layering ← transmural edema, inflammation, fibrosis
√ echolucent interruptions of the normally echogenic submucosa
√ decreased peristalsis / aperistalsis ← ganglioneuritis / alteration in interstitial cells of Cajal
√ luminal narrowing:
√ noncompressible rigid and fixed bowel segment
√ upstream distention with fluid-filled loops (12%)
› inflammatory stricture with little fibrosis:
√ loss of normal bowel wall stratification
√ hypoechoic bowel wall ← mural hyperemia
√ increased vascularity of gut wall and adjacent fat on color Doppler
› fibrotic stricture:
√ maintained gut signature
√ prominently echogenic submucosa ← collagen deposition
√ NO increase in wall vascularity

@ perienteric findings on US
√ small amount of intraperitoneal free fluid
√ hypertrophy of mesenteric adipose tissue → separation of bowel loops
√ echogenic ectopic "creeping fat / fat wrapping" (= inflammatory and fibrous tissue) around active region of inflammation extending to antimesenteric surface
√ "comb" sign = increased mesenteric blood flow ← engorgement of vasa recta
√ increased number ± increased size of visualized lymph nodes
√ inflammatory mass = phlegmon (14%) without a discernible wall / walled-off abscess (4%)
√ hypoechoic fistulous tract from serosal surface of bowel that may contain echogenic gas / debris

CT:

@ bowel wall:
√ mucosal hyperenhancement = segmental hyperattenuation of well-distended small bowel loops during late arterial / enteric phase (best seen with bowel lumen distended by negative contrast):
√ "**target" sign** of active inflammation
√ mural stratification:
√ "double halo" configuration (50%) = trilaminar mural stratification = enhancing mucosa + serosa sandwiching submucosa of decreased attenuation:
√ water-density edema = active inflammation
DDx: radiation enteritis, ischemia, mesenteric venous thrombosis, acute pancreatitis
√ fat deposition = abnormally low attenuation of submucosa in long-standing disease
√ bowel wall thickening:
√ mean thickness of 11 (range, 10–20) mm in 82%
DDx: mean of 8 mm for ulcerative colitis
√ asymmetric thickening affecting predominantly mesenteric border
√ bowel wall thickening of homogeneous density
DDx: ulcerative colitis of heterogeneous density
√ skip areas of bowel wall thickening
√ luminal narrowing + proximal dilatation (CT enterography / enteroclysis are highly sensitive):
√ reversible enhancing inflammatory stricture
√ irreversible stricture with lack of enhancement + loss of mural stratification
@ par- / peri- / extraenteric findings on CT
√ "**comb" sign** = hyperemic engorged tortuous vasa recta leading to actively inflamed bowel segment
√ mesenteric fat stranding (= transmural extension of inflammation across serosa with engorgement of hyperemic vasa recta)

CT Findings of Acute and Chronic Crohn Disease

Active Crohn Disease	*Inactive Crohn Disease*
↑ C-reactive protein level	√ submucosal fat deposition
√ mural hyperenhancement	√ pseudosacculation
√ mural stratification ← intramural edema	√ perienteric fibrofatty proliferation
√ mesenteric fat stranding	√ fibrotic strictures
√ comb sign	

√ **"creeping fat / fat wrapping" sign** = almost PATHOGNOMONIC massive fibrofatty proliferation of mesentery along mesenteric border (40%) ← production of tumor necrosis factor a sustaining the inflammatory process:
√ fat attenuation elevated by 20–60 HU
√ separation of small bowel loops (mass effect)
√ remains present in clinically quiescent disease

√ **pseudosacculation** of antimesenteric border ← asymmetric fibrosis of the mesenteric border ← inflammation of mesenteric border of involved segment
√ mild mesenteric lymphadenopathy (18%) with nodes 3–8 mm small
◊ Consider lymphoma / carcinoma with lymph nodes > 10 mm!
√ fistulization / sinus tract (15–40%)
√ mesenteric phlegmon / abscess formation in 15–20% (*DDx:* postoperative blind loop)

MR:
√ aphthous ulcers + intestinal fold thickening
√ bowel wall thickening > 3 mm correlating with Crohn disease activity index
√ fissuring undermining transmural ulcers
√ PATHOGNOMONIC linear ulcers paralleling mesenteric border
√ cobblestoning
√ layered pattern of intense enhancement ← inner + outer enhancing rings (= hyperemic mucosa + serosa) with low-signal-intensity ring (= submucosal edema) in between correlating well with Crohn disease activity index
DDx: "halo" sign of chronic inflammatory bowel disease (low-signal-intensity ring of fat hypertrophy + fibrosis in submucosa)
√ "creeping fat / fat wrapping" sign of fat proliferation
√ "comb" sign
√ mural abscess with rimlike enhancement
√ serosal hypervascularity = nestlike lesions of tiny serpentine hyperintense enhancing vessels adjacent to serosal surface
√ hypointense chronic fibrotic stricture on T1WI + T2WI
√ pseudosacculation on antimesenteric side

Prognosis: recurrence rate of up to 39% after resection (commonly at the site of the new terminal ileum, most frequently during first 2 years after resection); mortality rate of 7% at 5 years, 12% at 10 years after 1st resection

Cx:
(1) Fistula (ileoileal > ileocecal > ileosigmoid)
(2) Intramural sinus tracts
(3) Abscess in up to 20% (DDx: acute appendicitis)
(4) Small bowel obstruction (15%)
(5) Free perforation (1–2%)
(6) Toxic megacolon
(7) Hydronephrosis, generally on right side ← ureteric compression
(8) Adenocarcinoma in ileum / colon (particularly in bypassed loops / in vicinity of chronic fistula)

Patients with Crohn disease are at increased risk for developing adenocarcinoma in affected intestinal segments (4–20 x that of general population, with a prevalence of up to 1.8%)

(9) Lymphoma in large + small bowel

DDx:
(1) Yersinia (in terminal ileum, resolution within 3–4 months)
(2) Tuberculosis (more severe involvement of cecum, pulmonary TB)

(3) Actinomycosis, histoplasmosis, blastomycosis, anisakiasis
(4) Segmental infarction (acute onset, elderly patient)
(5) Radiation ileitis (appropriate history)
(6) Lymphoma (no spasm, luminal narrowing is uncommon, tumor nodules)
(7) Carcinoid tumor (tumor nodules)
(8) Eosinophilic gastroenteritis
(9) Potassium stricture

Location: terminal ileum + ileocecal region (most common)

@ Esophagus (3%)
√ "aphthous" ulcers (early) = discrete superficial ulcers with punctate collections of barium surrounded by halo of edema
√ esophagitis, stricture, fistula (late)
DDx: superficial spreading esophageal carcinoma

@ Stomach (1–2%) = granulomatous gastritis
√ aphthous ulcers (= pinpoint erosions)
√ pseudo–post Billroth-I appearance
√ "ram's horn" sign = poorly distensible smooth tubular narrowed antrum + widened pylorus + narrow duodenal bulb
√ cobblestone appearance of mucosa
√ antral-duodenal fistula

@ Duodenum (4–20%) almost always associated with gastric involvement
Location: duodenal bulb + proximal half of duodenum
UGI:
√ superficial aphthoid erosions (early lesion)
√ thickened nodular folds, cobblestone pattern
√ deep linear ulcer + sacculations of opposing wall
√ multiple eccentric duodenal stenoses with outward ballooning / sacculation between areas of stricture in stenotic phase of Crohn disease ← healing of deep ulcerations with scarring + fibrosis
CT:
√ mural thickening, mucosal hyperemia, periduodenal soft-tissue stranding

@ Small bowel (80%) = REGIONAL ENTERITIS
Location: terminal ileum (alone / in combination in 95% ← high concentration of lymphoid tissue; jejunum / ileum (15–55%); sparing of terminal ileum in 1%
√ picket fence pattern = diffuse irregular segmental thickening + slight nodularity of circular folds
√ aphthous ulcers
√ reduction in / distortion of folds ← ulceration
√ cobblestone mucosa
√ commonly associated with medial cecal defect

@ Colon (22–70%)
= GRANULOMATOUS COLITIS = CROHN COLITIS
Location: particularly on right side with rectum + sigmoid frequently spared; isolated

to colon (in 20%)

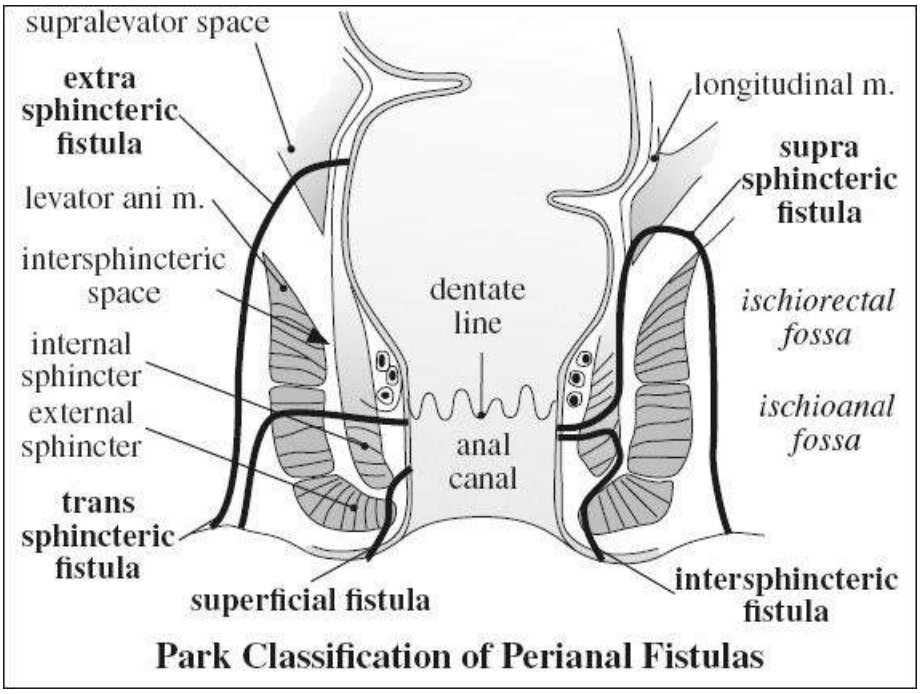
√ feces completely absent / present only in one colonic segment

√ tiny 1–2-mm nodular filling defects (lymphoid follicular pattern)

√ aphthous ulcers of "target / bull's-eye" appearance

√ "transverse stripe" sign = 1-cm-long straight stripes representing contrast medium within deep grooves of coarse mucosal folds

√ long fistulous tracts parallel to bowel lumen



Park Classification of Perianal Fistulas

@ Appendicitis (20%)

@ Rectum (14–50%)

√ deep / collarbutton ulcers

√ rectal sinus tracts

Fistulizing Crohn Disease

= PENETRATING CROHN DISEASE

Frequency: 35% at some time during course of disease with a 20–40% lifetime risk

◊ Crohn disease is 3rd most common cause of fistula / sinus tracts (DDx: iatrogenic [most common cause], diverticula [2nd most common cause])!

Types:

A. Internal fistula

√ hyperenhancing tracts

(a) enteroenteric:

• asymptomatic

Site: most frequently between ileum + cecum

(b) interloop abscess

(d) enterovesical

(e) enterogenital: rectovaginal fistula

B. External / enterocutaneous fistula (8–21%)
= perineal fistula (rectum-to-skin in 54%)
√ isoattenuating tract relative to anorectum

√ positive oral contrast material may better depict fistulous tract BUT obscure mucosal hyperenhancement

Crohn Disease versus Ulcerative Colitis

	Crohn Disease	*Ulcerative Colitis*
Wall	~ 11–13 mm thick	~ 8 mm thick
	eccentric (mesenteric)	symmetric
	segmental	continuous
Distribution	terminal ileum	rectum
	right colon	left colon
Inflammation	transmural	NOT transmural
CT signs	mesenteric comb	
	halo	halo
	creeping mesenteric fat	
	perirectal fat proliferation	perirectal fat proliferation
Cx	fistulae	NO fistulae
	abscesses	

Extraintestinal Manifestations of Crohn Disease

@ Hepatobiliary
1. Fatty infiltration of liver ← steroid therapy, hyperalimentation
2. Hepatic abscess (rare): M÷F = 3÷1
3. Gallstones (15–34%): predominantly cholesterol;
Risk: 3–5 x higher risk than expected; risk correlates with length of diseased ileum / resected ileum / duration of disease
Cause: interrupted enterohepatic circulation with malabsorption of bile salts in terminal ileum
4. Acute cholecystitis
5. Primary sclerosing cholangitis (1%) + hepatoma
6. Bile duct + gallbladder carcinoma
7. Pancreatitis

@ Genitourinary
1. Urolithiasis (5–10%): oxalate (steatorrhea → excess colonic absorption of oxalate) / urate stones
2. Hydronephrosis
3. Renal amyloidosis
4. Focal cystitis
5. Ileoureteral / ileovesical fistula (5–20%)

@ Musculoskeletal

- digital clubbing (11–40%)
- mild self-limiting seronegative peripheral migratory arthritis (15–22%): may precede bowel disease in 10%; severity + course correlates well with severity of intestinal disease; resection of diseased bowel leads to regression of symptoms

1. Hypertrophic osteoarthropathy
2. Ankylosing spondylitis (in 3–16%)
   ◊ Axial skeletal involvement usually precedes onset of GI symptoms!
   - in severity / course unrelated to activity level of bowel disease

   √ symmetric bilateral sacroiliitis
   √ spondylitis with syndesmophytes
3. Peripheral erosive arthritis
   √ small marginal erosions
   √ periostitis
   √ propensity for osseous ankylosis
4. Avascular necrosis of femoral head ← steroid Rx
5. Pelvic osteomyelitis (contiguous involvement)
6. Septic arthritis
7. Muscle abscess
8. Retarded skeletal growth + maturation

@ Erythema nodosum, uveitis

CRONKHITE-CANADA SYNDROME

= nonneoplastic nonhereditary polyps (as in juvenile polyposis) associated with ectodermal abnormalities; no familial predisposition

Prevalence: > 100 cases described

Histo: hamartomatous polyps resemble juvenile / retention polyps = multiple cystic spaces filled with mucin ← degenerative changes; expansion + inflammation of lamina propria

Age: 62 (range, 42–75) years; M < F

- exudative protein-losing enteropathy
- diarrhea ← disaccharidase deficiency, bacterial overgrowth in small intestine
- severe weight loss, anorexia, abdominal pain
- brownish macules of hand + feet, nail atrophy, alopecia

√ multiple polyps
√ thickened gastric rugae

Location: stomach (100%); small bowel (> 50%); colon (100%)

Prognosis: rapidly fatal in women within 6–18 months ← cachexia; tendency toward remission in men

DESMOPLASTIC SMALL ROUND CELL TUMOR

= INTRAABDOMINAL DESMOPLASTIC SMALL ROUND CELL TUMOR OF PERITONEUM

= rare highly malignant tumor belonging to a generic group of small round blue cell tumors (like Ewing sarcoma, neuroblastoma, Wilms tumor, rhabdomyosarcoma, primitive neuroendocrine tumor)

Prevalence: < 50 cases in literature

Median age: 21 (range, 5–30) years; M÷F = 4–9÷1
Origin: mesothelial / submesothelial / subserosal mesenchyme of the abdominal cavity
Path: multinodular unencapsulated mass with focal cystic areas / necrosis / hemorrhage; common serosal implants
Histo: island clusters of small blue cells embedded in a dense desmoplastic fibrous stroma; immunohistochemically positive for epithelial, neural, muscular markers (cytoplasmic keratin + desmin)
Genetics: chromosomal translocation t(11;22)(p13;q12) creating a unique fusion protein of WT1 (Wilms tumor gene) and EWS (Ewing sarcoma family gene)
• palpable intraabdominal mass (64%)
• abdominal pain (52%), increased abdominal girth (8%)
Location: mesentery (particularly retrovesical / rectouterine spaces), retroperitoneum, paratesticular region, posterior mediastinum, pleura, meninges, bone, salivary glands
Spread to: omentum, retroperitoneal and mesenteric lymph nodes, liver, lung, bone (in 50% at initial presentation)

Average size: 11.2 (range, 3–22) cm
√ multiple scattered necrotic peritoneal, omental, and serosal round / ovoid masses without a clear organ of origin
√ usually single dominant (> 10 cm) mass in the retrovesical / retrouterine space / peritoneum / omentum

√ diffuse nodular peritoneal thickening + omental caking
√ tumor spread to serosal surface of liver + spleen (common)
  √ small punctate peritoneal calcifications
  √ cystic areas in mass ← intratumoral necrosis / hemorrhage
√ heterogeneous enhancement
√ scant malignant ascites (37%)
US:
  √ hyper- / hypoechoic mass ← depending on degree of necrosis + hemorrhage
  √ ± echogenic shadowing calcifications
  √ heterogeneous internal vascularity
CT:
  √ small masses of low attenuation (24–36 HU) + uniform enhancement
  √ larger (> 10 cm) mass with central area of low attenuation + heterogeneous enhancement ← necrosis, old hemorrhage
  √ small punctate / amorphous calcifications (30%)
  √ hypoattenuating metastases to liver, abdominal and retroperitoneal lymph nodes
MR:
  √ mass typically hypo- to isointense on T1WI + heterogeneously iso- to hyperintense on T2WI compared with skeletal muscle
  √ foci of T1-hyperintensity ← intratumoral hemorrhage
  √ occasional areas of T2-hypointensity ← densely cellular components / dense desmoplastic stroma
CEMR:
  √ modest heterogeneous enhancement
  √ nonenhancing central foci ← hemorrhage / necrosis / fibromyxoid component

PET (PET/CT 96% sensitive, 98% specific):
√ mean standardized uptake value of 11.1 (range, 3.7–15.0)
Cx: hydronephrosis, bowel obstruction
Prognosis: mean survival time of 17 months
DDx:
(1) in infants / adolescents: rhabdomyosarcoma; neuroblastoma; mesenteric carcinoid; Burkitt lymphoma
(2) in adults: diffuse omental / peritoneal carcinomatosis (← carcinoma of stomach, colon, ovary, pancreas); melanoma; leiomyosarcoma; lymphoma; desmoid tumor; mesothelioma; tumefactive tuberculosis; actinomycosis; Castleman disease; splenosis

DIAPHRAGM DISEASE

= small bowel webs ← NSAIDs
Effect of NSAID: gastric irritation, ulceration of small intestines
Frequency: in 10% of patients receiving long-term NSAIDs
Path: foci of submucosal fibrosis with interruption of adjacent muscularis mucosae
• blood + protein loss, intermittent intestinal obstruction
Location: ileum > jejunum
Enteroclysis:
√ multiple concentric diaphragm-like strictures
DDx: Crohn disease

DIFFUSE ESOPHAGEAL SPASM

Age: more common in patients > 50 years
• severe intermittent chest pain ± dysphagia while swallowing
Location: primarily in distal ²/₃ of esophagus
√ compartmentalization of esophagus by numerous tertiary contractions
√ multiple spontaneous uncoordinated esophageal contractions, often intermittent
√ CLASSIC corkscrew appearance → may obliterate esophageal lumen
Dx: extremely high pressures on manometry

DISACCHARIDASE DEFICIENCY

= enzyme deficiencies for any of the disaccharides (maltose, lactose, etc.)
A. PRIMARY
B. SECONDARY to other diseases (eg, Crohn disease)
Pathophysiology:
(a) unabsorbed disaccharides → produce osmotic diarrhea
(b) bacterial fermentation → produces short-chain volatile fatty acids causing further osmotic + irritant diarrhea
√ normal small bowel series without added lactose
√ abnormal small bowel series done with lactose (50 g added to 600 cm^3 of barium suspension)
√ small + large bowel distension
√ dilution of barium
√ shortening of transit time

DISTAL INTESTINAL OBSTRUCTION SYNDROME

= DIOS = MECONIUM ILEUS EQUIVALENT

= accumulation and impaction of viscid fecal material adherent to intestinal wall in distal part of ileum + proximal part of colon [*viscum* , Latin = birdlime, sticky, slimy, glutinous]

Prevalence: 10–24%% of older child / young adult with cystic fibrosis; 2% in patients < 5 years of age

Cause: tenacious intestinal mucus, steatorrhea ← pancreatic insufficiency, undigested food remnants, disordered intestinal motility with increase in intestinal transit time, fecal stasis

Risk factors: pancreatic insufficiency, history of meconium ileus / DIOS, dehydration, lung transplantation

Age: 2nd–3rd decade of life

- recurrent acute bouts of colicky periumbilical / RLQ pain and vomiting ← fecal impaction / constipation
- palpable cecal mass

√ bubbly granular ileocecal soft-tissue mass in RLQ

√ partial / complete small bowel obstruction ← puttylike fecal material in terminal ileum / right colon

√ thickening of mucosal folds

√ cystic fibrosis of lung

CT:

Location: cecum > ascending colon > transverse colon > descending colon (contiguous involvement)

√ diffuse colonic thickening

√ mural striation (50%)

√ mesenteric soft-tissue infiltration (100%)

√ increased pericolonic fat (60%)

Cx: intussusception, volvulus, perforation, ischemia

Rx: rehydration, stool softeners, oral polyethylene glycol-electrolyte solution (GoLYTELY®), increasing dose of pancreatic enzyme supplements, mucolytic agents (N-acetylcysteine) orally / with Gastrografin® enema

DDx: severe constipation (subacute presentation), appendicitis, partial intestinal obstruction (adhesion / stricture from previous bowel surgery)

DIVERTICULAR DISEASE OF COLON

= saccular outpouching ← overactivity of smooth muscle causes herniation of mucosa + submucosa through a defect in the muscle layer of the colon

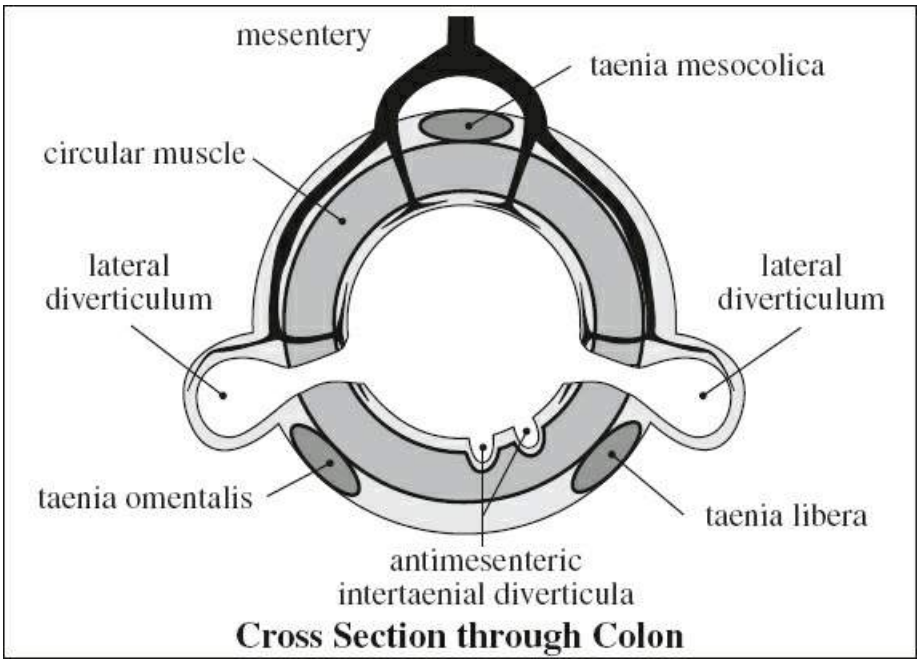
Frequency: 5–10% in 5th decade; 33–48% over age 50; 50–65% past 7th decade; M÷F = 1÷1; most common affliction of colon in developed countries

Cause: decreased fecal bulk (= diet high in refined fiber + low in roughage)

Location: in 80% in sigmoid (= narrowest colonic segment with highest pressure); in 17% distributed over entire colon; in 4–12% isolated to cecum / ascending colon

Prediverticular Disease of Colon

= longitudinal + circular smooth muscle thickening with redundancy of folds ← myostatic contracture
√ "saw-tooth" sign = crowding + thickening of haustral folds ← shortening of colonic segment
√ plump marginal indentations
√ superimposed muscle spasm (relieved by antispasmodics)



Cross Section through Colon

DDx: hemorrhage; ischemia; radiation changes; pseudomembranous colitis

Colonic Diverticulosis

= acquired herniations of mucosa + muscularis mucosae through the muscularis propria with wall components of mucosa, submucosa, serosa = false diverticula of pulsion type
Location: predominantly left-sided colon
Site:
(a) lateral diverticula arise between mesenteric + antimesenteric teniae on opposite sides
(b) antimesenteric intertaenial diverticula opposite of mesenteric side
N.B.: intramural type vasa recta (= nutrient arteries) pass through circular muscle (= weakness in muscular wall) → carried over fundus of diverticulum as it enlarges
√ size: initially tiny (3–10-mm) V-shaped protrusions increasing up to several cm in diameter
√ bubbly appearance of air-containing diverticula
√ residual barium within diverticula from previous study
√ spiky irregular outline (antimesenteric intertaenial ridge is typical site for intramural diverticula)
√ smooth dome-shaped appendages with a short neck
√ may be pointed, attenuated, irregular with variable filling
√ circular line with sharp outer edge + fuzzy blurred inner edge (EN FACE view in double contrast BE)

US:
√ thin-walled round / oval outpouching containing echogenic material that often produces distal acoustic shadowing ← air / feces
√ peridiverticular perienteric fat of normal echogenicity
√ thickened muscularis propria ← hypertrophy
CT:
√ rounded outpouchings containing air ± contrast material (= diverticula)
√ circumferential sawtooth-like thickening of colonic haustra + distorted luminal contour (= muscular hypertrophy)
Cx: bleeding (usually right colon), diverticulitis (usually sigmoid colon)

Giant Colonic Diverticulum *(rare)*
Age: after 6th decade
Path:
(1) Inflammatory diverticulum (66%): wall of dense fibrous tissue + chronic inflammatory cells + foreign body giant cells
(2) Pseudodiverticulum (22%): colonic muscularis propria ends abruptly at neck of pseudodiverticulum ← degeneration of mucosal lining of a pseudodiverticulum
(3) True diverticulum (12%): wall contains all colonic layers ← communicating bowel duplication cyst
• abdominal pain, nausea, vomiting, fever, constipation, diarrhea, melena
Location: sigmoid (93%)
BE:
√ opacification by barium (in 60%)
CT:
√ large gas-, fluid-, stool-filled cavity + thin regular wall
√ NO contrast enhancement / wall thickening unless inflamed
√ ± wall calcifications ← chronic inflammation
Cx: perforation, abscess formation
DDx: volvulus, bowel duplication, Meckel / duodenal diverticulum, infected pancreatic pseudocyst, emphysematous cholecystitis, emphysematous cystitis, vesicoenteric fistula, abscess

Colonic Diverticulitis

= perforation of diverticulum with intramural / localized pericolic inflammatory mass
Frequency: 5% of population; in 10–35% of diverticular disease
Age: in 5–10% > 45 years of age, in 80% > 85 years of age (frequency increasing with age)
Pathogenesis: mucosal abrasion from inspissated fecal material → perforation of thin wall
• evenly distributed lower abdominal pain
• local and rebound tenderness + mass in LLQ (typically)
• nausea, fever (25%), leukocytosis (36%)
• clinical misdiagnosis rate of 34–67%
Location: sigmoid colon (95%), cecum (4%)
√ localized ileus

√ ± pattern of small bowel obstruction → kinking / edema if small bowel adheres to abscess
√ extraluminal gas in abscess / fistula
√ pneumoperitoneum (rare)
BE (77–86% sensitive):
  √ focal area of eccentric luminal narrowing caused by pericolic / intramural inflammatory mass:
    √ annular lesion mimicking carcinoma
  √ marked thickening + distortion of mucosal folds
  √ tethered spiculated mucosal folds
  √ centrally amputated diverticulum
  √ extraluminal contrast = **peridiverticulitis**:
    √ "double-tracking" = pericolonic longitudinal sinus tract
    √ pericolonic collection = peridiverticular abscess
    √ fistula to bladder / small bowel / vagina
CT (79–93% sensitive, 77% specific):
  √ inflamed diverticulum:
    √ pericolic fat stranding = poorly marginated hazy area of ↑ attenuation ± fine linear strands within mesocolic fat (98%)
    √ diverticula (84%) = flask-shaped structures projecting through colonic wall, filled with air / barium / fecal material
    √ "centipede" sign = hyperemic engorged vasa recta
  √ bowel wall thickening:
    √ circumferential bowel wall thickening of > 4 mm (70%) and up to 2 cm
    √ colonic wall thickening extending > 5 cm in length
    √ "double halo" sign = mural stratification = enhancement pattern with inner hyperdense layer + thickened hypodense middle layer + outer hyperdense layer
    √ focally thickened + inflamed colonic wall
    √ "arrowhead" sign = funnel of intraluminal contrast medium / air in focally thickened colonic wall centering about occluded orifice of inflamed diverticulum (27%)
    √ pneumatosis
  √ fluid collection:
    √ fluid at root of sigmoid mesentery
    √ fluid ± air of peritonitis (16%)
    √ frank abscess (47%) = central liquid / gas
  √ tract formation:
    √ fistula formation (14%): most commonly colovesical, also colovaginal, coloenteric, colocutaneous
    √ intramural sinus tracts (9%)
  √ fecolith
  √ colonic obstruction (12%)
  √ ureteral obstruction (7%)

CT Findings of Diverticulitis versus Malignancy	
Diverticulitis	*Malignancy*
√ long segment of involvement >10 cm	√ focal concentric mass
√ double halo / target sign	√ overhanging shoulders
√ fat stranding adjacent to a thickened wall	√ enlarged pericolic nodes

US (85–98% sensitive, 80–97% specific):
- √ thickening of bowel wall > 4 mm (= distance measured between echogenic lumen interface and serosa)
- √ round / oval hypo- / hyperechoic focus protruding from colonic wall + focal disruption of normal layer continuity ± internal acoustic shadowing
- √ regionally ↑ echogenicity adjacent to colonic wall ± ill-defined hypoechoic zones ← inflamed pericolic fat
- √ increased mural vascularity at color Doppler US
- √ pericolic abscess

MR:
- √ chronic colonic wall thickening in affected area
- √ increased SI in pericolonic fat associated with diverticulum on fat-suppressed T2WI

Prognosis: (a) self-limiting (usually) = fecolith + pus evacuate into colonic lumen in 1–2 days
(b) transmural perforation
(c) superficial ulceration
(d) chronic abscess

Cx: (1) Colonic obstruction
(2) Fistula to bladder / vagina / small bowel
(3) Free perforation (rare)
(4) Abscess

DDx: (1) Colonic neoplasm (shorter segment, heaped-up margins, ulcerated mucosa, loss of mural enhancement pattern, pericolic lymph nodes)
(2) Crohn colitis (double-tracking longer than 10 cm)

Rx: antibiotics, surgery (in 25%), percutaneous abscess drainage

Right Colonic Diverticulitis

= reliably benign self-limiting condition

Cause: often congenital solitary true diverticulum

Frequency: 1÷34 to 1÷300 appendectomies

Age: any; peak prevalence at 35–45 years of age

- protracted mild pain mimicking appendicitis
- palpable mass in 33%

- √ solitary diverticulum containing a 12-mm fecolith surrounded by inflamed fat
- √ marked circumferential colonic wall thickening

Cx: pericolonic abscess

Prognosis: spontaneous evacuation into colonic lumen
Rx: conservative; NO indication for surgery
DDx: appendicitis

CECAL DIVERTICULITIS *(5%)*

= usually true diverticulum containing all layers of colonic wall
• generally asymptomatic
• clinically indistinguishable from acute appendicitis
Location: near ileocecal valve (80%)
√ inflammatory changes adjacent to diverticulum
√ normal-appearing appendix

Appendiceal Diverticulitis

= insidious onset of inflammation of uncommon usually acquired diverticulum of appendix
Appendiceal diverticulum: mostly pseudodiverticulum (= herniation of mucosa through muscularis)
Pathogenesis: ?; increased intraluminal pressure ← proximal obstruction
Highly associated with: appendiceal neoplasms
Age: usually > 30 years of age
• lacks migratory pain of classic appendicitis
Site: along mesenteric border of distal ⅓ of appendix; single / multiple
Size: < 5 mm
√ round outpouching beyond margin of appendix
√ may contain fluid / air / enhancing soft tissue
√ prominent enhancement of diverticular wall with surrounding fat stranding
√ increased diameter of wall-thickened hyperenhancing appendix (mimicks acute appendicitis)
Cx: perforation

Colonic Diverticular Hemorrhage

◊ Not related to diverticulitis
Frequency: in 3–25–47% of diverticulosis
Location: 75% located in ascending colon (larger neck + dome of diverticula)
• massive rectal hemorrhage without pain
√ extravasation of radionuclide tracers
√ angiographic contrast pooling in bowel lumen
Prognosis: spontaneous cessation of bleeding in 75%, recurrent bleeding in 25%
Rx: (1) transcatheter infusion of vasoconstrictive agents (Pitressin®)
(2) embolization with Gelfoam®

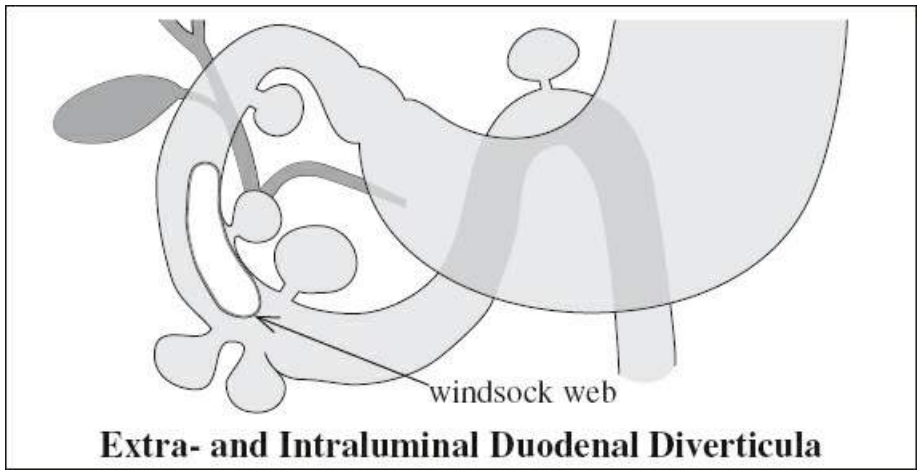
DUMPING SYNDROME

= early postprandial vascular symptomatology of sweating, flushing, palpitation, feeling of weakness and dizziness
Pathophysiology: rapid entering of hypertonic solution into jejunum → resulting in fluid shift from blood compartment into small bowel

Frequency: 1–5%; M÷F = 2÷1
◊ Roentgenologic findings not diagnostic!
√ rapid emptying of barium into small bowel (= loss of gastric reservoir function)
Rx: lying down, diet
DDx: late postprandial hypoglycemia (90–120 min after eating)

DUODENAL ATRESIA

= most common cause of congenital duodenal obstruction; 2nd most common site of gastrointestinal atresias after ileum
Prevalence: 1÷10,000; M÷F = 1÷1
Etiology: defective vacuolization of duodenum between 6th and 11th weeks of fetal life; rarely from vascular insult (extent of obstruction usually involves larger regions with vascular insult)
Age at presentation: first few days of life
• persistent bilious vomiting a few hours after birth / following 1st feeding (75%)
• rapid deterioration ← loss of fluids + electrolytes
Associated anomalies (in 50–60%):
In 30–52% isolated sporadic anomaly
(1) Down syndrome (20–33%)
◊ 25% of fetuses with duodenal atresia have Down syndrome
◊ < 5% of fetuses with Down syndrome have duodenal atresia
(2) CHD (8–30–50%): endocardial cushion defect, VSD



Extra- and Intraluminal Duodenal Diverticula

(3) Gastrointestinal anomalies (26%):
esophageal atresia, biliary atresia, duodenal duplication, imperforate anus, small bowel atresia, malrotation, Ladd bands, Meckel diverticulum, transposed liver, annular pancreas (20%), preduodenal portal vein
(4) Urinary tract anomalies (8%)
(5) Vertebral + rib anomalies (37%)
Location: (a) usually distal to ampulla of Vater (80%)
(b) proximal duodenum (20%)

√ "double bubble" sign = gas-fluid levels in duodenal bulb + gastric fundus
√ total absence of intestinal gas in small / large bowel
√ colon of normal caliber
OB-US (usually not identified prior to 24 weeks GA):
• ± elevated AFP
√ "double bubble" sign = simultaneous distension of stomach + 1st portion of duodenum; continuity of fluid between stomach + duodenum must be demonstrated
√ increased gastric peristalsis
√ polyhydramnios in 3rd trimester (100%)
Prognosis: 36% mortality in neonates
DDx: (1) Prominent incisura angularis → bidissection of stomach
(2) Choledochal cyst
(3) Annular pancreas
(4) Peritoneal bands
(5) Intestinal duplication
Cx: prematurity (40%) ← preterm labor ← polyhydramnios

DUODENAL DIVERTICULUM

Frequency: 1–5% of GI studies; 22% of autopsies
A. PRIMARY / FALSE DIVERTICULUM
= mucosal prolapse through muscularis propria
Site: posteriorly (8%), lateral wall (4%)
B. SECONDARY / TRUE DIVERTICULUM
= all layers of duodenal wall as complication of duodenal / periduodenal inflammation
Location: almost invariably in 1st portion of duodenum
• mostly asymptomatic
√ may be fluid-filled (mimicking pancreatic pseudocyst)
√ may contain foci of air (mimicking pancreatic abscess)
√ contains normal bowel gas / oral contrast material directly communicating with adjacent duodenum
Cx: (1) Perforation + peritonitis
(2) Bowel obstruction
(3) Obstruction of bile duct / pancreatic duct
(4) Bleeding
(5) Diverticulitis

Intraluminal Duodenal Diverticulum

= congenital lesion ← elongation of an incomplete duodenal diaphragm
Age at presentation: young adult
• easy satiety, vomiting, upper abdominal cramping pain
Location: 2nd–3rd portion of duodenum near ampulla of Vater
√ barium-filled sac within duodenal lumen of "windsock, comma, teardrop" appearance (PATHOGNOMONIC picture):

√ anchored to lateral wall of duodenum
√ "halo" sign = duodenal mucosa covers outer + inner wall of diverticulum
√ fluid- / contrast material filled duodenum with thin diverticular wall on CT / MR

DUODENAL HEMATOMA

Cause: blunt abdominal trauma: deceleration injury, endoscopy; bleeding diathesis; anticoagulation therapy
Mechanism: duodenal compression between spine + anterior abdominal wall by seatbelt / handlebar / nonaccidental injury
Age: 80% in children / young adults
Associated with: pancreatic injury in 50–98%, mesenteric and abdominal wall hematoma, spinal fracture
Path: mural hematoma with blood dissecting along submucosal compartment ← separation of mucosa from loose submucosa
Location: 2nd / 3rd portion of duodenum
UGI:
√ circumferential / eccentric duodenal narrowing ← extrinsic compression
√ large filling defect completely occupying + dilating lumen
CT:
√ hyperattenuating (= acute trauma) thickened duodenal wall
√ eccentric mass protruding into the bowel lumen
Mortality: 30%
Cx: bowel obstruction, perforation
Rx: conservative

DUODENAL ULCER

Incidence: 60,000 hospitalizations in USA (2006); 2–3 x more frequent than gastric ulcers; M÷F = 3÷1
Pathophysiology: too much acid in duodenum from
(a) abnormally high gastric secretion
(b) inadequate neutralization
Predisposed: cortisone therapy, severe cerebral injury, after surgery, chronic obstructive pulmonary disease
Location:
(a) bulbar ulcer (95%):
anterior wall (50%), posterior wall (23%), inferior wall (22%), superior wall (5%)
√ bulbar deformity in 85%
(b) postbulbar ulcer (3–5%): medial wall
UGI:
√ round collection of barium in a niche + radiolucent halo of edema + circumferential / eccentric luminal narrowing ← spasm (in acute phase)
√ frequently < 1 cm round / ovoid (5% linear) ulcer niche
√ "kissing ulcers" = ulcers opposite from each other on anterior + posterior wall (in acute

stage)

√ giant duodenal ulcer > 2 cm (rare) with higher morbidity + mortality; may be overlooked by simulating a normal / deformed scarred duodenal bulb

√ "cloverleaf deformity, hourglass stenosis" (in healed stage) with prestenotic dilatation of recesses

CT:

√ outpouching of duodenal wall + adjacent mural thickening + periduodenal fat stranding (acute)

√ radiating folds with central punctate / small linear deposit of contrast material (chronic)

√ eccentric luminal narrowing + smooth round wall indentation (chronic)

Cx: (1) Obstruction (5%) ← edema + spasm (in acute phase) / scarring + fibrosis (subsequent to ulcer healing)

• postprandial nausea & vomiting

(2) Perforation (10–13%): anterior > posterior wall; fistula to gallbladder

(3) Penetration (< 5%) = sealed perforation

(4) Hemorrhage (15%): melena > hematemesis

Prognosis: healing → development of scar

Rx: antral resection (Billroth I) + vagotomy

DUODENAL VARICES

= dilated collateral veins ← portal hypertension (posterior superior pancreaticoduodenal vein)

√ lobulated filling defects (best demonstrated in prone position, maximal luminal distension will obliterate them)

√ commonly associated with fundal + esophageal varices

DUODENAL WEB

= failure of recanalization process in primitive foregut between 9th–11th week GA

May be associated with: Down syndrome, annular pancreas, midgut malrotation, imperforate anus

Types:

(1) Duodenal atresia / complete imperforate web

(2) Windsock web = imperforate intraluminal duodenal diverticulum (IDD)

The shape of the wall of the imperforate intraluminal duodenal diverticulum is affected by peristalsis in the same way a windsock moves with the wind.

(3) Perforated duodenal web = IDD with central / eccentric opening

• symptoms of pancreatitis ± duodenal obstruction

CT / MR:

√ fluid- / contrast–filled blind-ending saccular structure

√ thin enhancing diverticular wall

Cx: pancreatitis ← reflux of duodenal contents through papilla of Vater

DUPLICATION CYST

= GASTROINTESTINAL DUPLICATION CYST

= uncommon congenital anomaly found anywhere along mesenteric side of alimentary tract from tongue to anus

Frequency: 15% of pediatric abdominal masses are gastrointestinal duplication cysts

Theories of formation:

(1) Abortive twinning
(2) Persistent embryologic diverticula
(3) Split notochord
(4) Aberrant luminal recanalization (Bremer): foregut epithelium grows and obliterates lumen (solid stage for esophagus, small bowel, colon) during 6th week GA; → later produces secretions that form vacuoles in the intercellular space; → vacuoles line up longitudinally and coalesce to form new lumen; → failure of an aberrant vacuole to coalesce creates a wall cyst
(5) Intrauterine vascular accident (Favara) associated with alimentary tract atresia in 9%

Age: presentation often in 1st year of life / early childhood

Path: (a) cystic sphere (80%) WITHOUT bowel communication
(b) cystic tubule (20%) communicating with bowel lumen
located in / immediately adjacent to gastrointestinal tract; shares a common muscle wall + blood supply; has a separate mucosal lining; cyst contents usually serous

Histo: wall of smooth muscle lined with alimentary tract mucosa; ectopic mucosa; squamous, transitional, ciliated mucosa; lymphoid aggregates; ganglion cells
◊ Gastric mucosa + pancreatic tissue are the only ectopic tissues of clinical importance!

- mostly asymptomatic, palpable abdominal mass
- respiratory distress (with esophageal duplication)
- nausea, emesis ← partial / complete obstruction

Location: distal ileum (30–33%), esophagus (17–20%), colon (13–30%), jejunum (10–13%), stomach (7%), pylorus (4%), duodenum (4–5%), ileocecal junction (4%), rectum (4%)
◊ In 7–15% concomitant duplications elsewhere within the alimentary tract!

Site: on mesenteric aspect of alimentary canal

Morphology:

(a) large spherical / saccular cyst (82%)
(b) small intramural cyst
(c) tubular sausage-shaped cyst (18%): commonly along small + large bowel; frequently communicates with lumen of adjacent gut

BE:
√ mass extrinsic to bowel lumen

US:
√ elongated tubular / spherical cystic mass with "double-wall / muscular rim" sign:
√ "muscular rim" sign (= echogenic inner mucosal lining + hypoechoic outer rim) in 47%
√ sonolucent content with good through transmission ← clear fluid
√ echogenic content ← hemorrhage + inspissated material
√ cyst paralleling normal bowel lumen

CT:
√ smoothly rounded fluid-filled cyst / tubular structure

√ thin slightly enhancing wall

MR:

√ heterogeneous SI of intracystic fluid on T1WI + homogeneous high SI on T2WI

Cx: (1) Bowel obstruction by intussusception ← cyst at ileocecal junction

(2) Small bowel volvulus ← weight of duplication

(3) Bleeding ← gastric mucosa / pressure necrosis of adjacent mucosa by cyst expansion / from intussusception

√ area of high attenuation ← hemorrhage / proteinaceous material

(4) Infection

√ thick enhancing wall / septum + surrounding inflammation

(5) Malignant transformation

√ enhancing solid focus within cyst

(6) Perforation

Rx: surgical excision

DDx:

(1) Omental cyst (greater omentum / lesser sac, multilocular)
(2) Mesenteric cyst (between leaves of small bowel mesentery)
(3) Choledochal cyst
(4) Ovarian cyst
(5) Pancreatic pseudocyst
(6) Cystic renal tumor
(7) Abscess
(8) Meckel diverticulum (communicates with GI tract)
(9) Lymphangioma
(10) Mesenteric lymphoma
(11) Intramural tumor

Esophageal Duplication Cyst (10–20%)

arises from foregut

Frequency: 10–20% of all alimentary tract duplications; 0.5–2.5% of all esophageal masses; M÷F = 2÷1

Path: contains ectopic gastric mucosa in 43%

Histo: contains no cartilage, lined by alimentary tract mucosa

Associated with: vertebral anomalies (spina bifida, hemivertebra, fusion defects), esophageal atresia, small bowel duplication (18%)

Location: adjacent to esophagus / within esophageal musculature at any level, paraspinal position; R÷L = 2÷1; in right pleural space detached from esophagus (rare)

A. CERVICAL ESOPHAGUS (23%)

- asymptomatic enlarging lateral neck mass
- upper airway obstruction in newborn

DDx: thyroglossal duct cyst, branchial cleft cyst, cystic hygroma, cervical tumor, cervical lymphadenopathy

B. MIDESOPHAGUS (17%)

- severe upper airway obstruction in early infancy

DDx: bronchogenic cyst, neurenteric cyst, intramural esophageal tumor

C. DISTAL ESOPHAGUS (60%)

• frequently asymptomatic

Location: paraspinal

DDx: bronchogenic cyst, neurenteric cyst, intramural esophageal tumor

√ thick-walled closed spherical cyst, almost never communicating

CXR:

√ posterior mediastinal mass ± air-fluid level

√ lobar consolidation + central cavitation ← autodigestion of lung tissue by gastric secretions

√ thoracic vertebral anomalies

UGI:

√ displacement of esophagus by paraesophageal mass

√ intramural extramucosal mass

US:

√ hypoechoic fluid-filled cyst + layered wall:

√ inner echogenic layer (mucosa) and outer hypoechoic layer (muscle)

CT:

√ sharply marginated homogeneous near-water density mass without enhancement

√ contrast-enhancing cyst wall

Cx: (1) Peptic ulceration ← gastric mucosa

(2) Perforation ← penetrating ulcer

(3) Hematemesis ← erosion into esophagus

(4) Hemoptysis + autodigestion of pulmonary tissue ← erosion into tracheobronchial tree

Thoracoabdominal Duplication

= FOREGUT DUPLICATION

= long tubular cyst closed at its cranial end, passing through diaphragm in its own hiatus, in 60% communicating with normal duodenum / jejunum / ileum

Frequency: 2% of all alimentary tract duplications

Associated with: thoracic vertebral anomalies

Histo: gastric mucosa in 29%

Symptomatic age: 50% during neonatal period; 80% within 1st year of life

• severe respiratory distress, chest pain, GI bleeding, anemia

√ tubular right posterior mediastinal mass ± air

√ thoracic vertebral anomaly

√ contrast material may enter through distal connection

Gastric Duplication Cyst (7%)

= intramural gastric cyst lined with secretory epithelium

Frequency: 7% of all alimentary tract duplications

Path: noncommunicating spherical cyst (majority); may communicate with aberrant pancreatic duct; ectopic pancreatic tissue found in 37%

Symptomatic age: infancy; in 75% detected before age 12; M÷F = 1÷2

- pain ← overdistension of cyst, rupture with peritonitis, peptic ulcer formation, internal pancreatitis
- vomiting, anemia, fever
- symptoms mimicking congenital hypertrophic pyloric stenosis (if duplication in antrum / pylorus)

Most common site: greater curvature (65%)

√ paragastric cystic mass up to 12 cm in size, indenting greater curvature
√ seldom communicates with main gastric lumen at one / both ends
√ may enlarge + ulcerate
√ ^{99m}Tc uptake

US:

√ cyst with two wall layers: inner echogenic layer of mucosa + outer hypoechoic layer of muscle
√ clear / debris-containing fluid

Cx: (1) Partial / complete small bowel obstruction
(2) Relapsing pancreatitis (with ductal communication)
(3) Ulceration, perforation, fistula formation

DDx: pancreatic cyst, pancreatic pseudocyst, mesenteric cyst, leiomyoma, adenomatous polyp, hamartoma, lipoma, neurofibroma, teratoma

Small Bowel Duplication Cyst

Frequency: most common of all alimentary tract duplications
Symptomatic age: neonatal period (⅓); < 2 years of age (in 72%)
Path: contains ectopic gastric mucosa in 24%; ectopic pancreatic tissue in jejunum (8%)
May be associated with: small bowel atresia

- neonatal bowel obstruction, intussusception, palpable mass
- acute abdominal pain, GI hemorrhage (may be painless)

Location: ileum (33%), jejunum (10%), ileocecal (4%)
Site: on mesenteric side

√ low small bowel obstruction ± soft-tissue mass
√ cyst may serve as lead point for intussusception

DDx: mesenteric cyst, pancreatic pseudocyst, omental cyst, exophytic hepatic cyst, ovarian cyst

Duodenal Duplication Cyst (5%)

Path: noncommunicating spherical cyst; may contain ectopic gastric mucosa in 21%, small bowel mucosa, pancreatic tissue

- obstructive symptoms, palpable abdominal mass
- hemorrhage ← peptic ulceration
- jaundice ← biliary obstruction
- pancreatitis ← ectopic pancreatic tissue

Location: 1st + 2nd portion of duodenum
Site: on mesenteric side of anterior wall

√ mass in concavity of duodenal C-loop

√ compression + displacement of 1st / 2nd portion of duodenum superiorly + anteriorly
Cholangiography:
√ may communicate with pancreatic ductal system through the aberrant duct of an accessory lobe
Cx: pancreatitis ← perforation of duplication cyst
DDx: pancreatic cyst, pancreatic pseudocyst, choledochal cyst, choledochocele, duodenal intramural tumor, pancreatic tumor

Colorectal Tubular Duplication (6%)

= DUPLICATION OF THE HINDGUT
= double-barreled duplication involving part / all of large bowel with "twin" segment on mesenteric / antimesenteric side
Symptomatic age: neonatal period / infancy; M÷F = 1÷2
May be associated with:
rectogenital / rectourinary fistula; duplication of internal / external genitalia; vertebral anomalies; multisystem congenital anomaly complex
• bowel obstruction / constipation
• passage of feces through vagina
√ simultaneous opacification of true + twin colon
√ duplication may terminate at
(a) 2nd functional anus
(b) imperforate perineal orifice
(c) fistulous communication with GU tract

Colonic Duplication Cyst (7–13%)

= CYSTIC COLONIC DUPLICATION
Frequency: 13% of all alimentary tract duplications
Path: closed spherical cyst; contains gastric mucosa in 2% + ectopic pancreatic tissue in 5%
• abdominal mass, bowel obstruction / constipation
• GI hemorrhage
Location: cecum (40%) ± intussusception
√ air / intestinal matter can enter cyst (20%)

Double Appendix

Rectal Duplication Cyst (4%)

Path: spherical fluid-filled cyst; may contain duodenal / gastric mucosa + pancreatic tissue
Histo: (a) 2 layers of smooth muscle,
(b) continuity with rectum,
(c) mucosal lining similar to rectal mucosa
◊ May contain ectopic gastric mucosa, urothelial mucosa, and pancreatic tissue
Site: presacral space posterior to rectum / anus
Symptomatic age: childhood
• constipation + fecal soiling

• intractable excoriation of perianal skin (with chronic perianal fistula); palpable retrorectal / retroanal mass

√ cystic mass: may be echogenic ← solid material ± gas from communication with rectum

√ spherical cystic lesion that may communicate internally with anorectal lumen / externally with skin surface (20%)

DDx: (1) Anterior meningocele, sacrococcygeal teratoma, retrorectal abscess, pilonidal cyst, sacral bone tumor

(2) Tailgut cyst (no smooth muscle layer)

ENCAPSULATED FAT NECROSIS

Cause: traumatic or ischemic insult → fat degeneration → organization within a thin / thick fibrous capsule

• may be focally tender at palpation

Location: anywhere in body (1st described in breast)

CT:

√ mild mass effect on adjacent structures

√ weak enhancement of capsule

√ ± inflammatory fat stranding + calcification

Prognosis: decrease in size over time

DDx: Liposarcoma (invasion of adjacent organs, no history of surgery, increase in size over time); Failed kidney transplant replaced by fat

ENTERIC CYST

= cyst lined by gastrointestinal mucosa without bowel wall

Etiology: migration of small bowel / colonic diverticulum into mesentery / mesocolon

Path: unilocular thin smooth-walled cyst with serous contents lined by enteric epithelium + thin fibrous wall

US:

√ hypoechoic cystic mass, occasionally with septations

DDx: Duplication cyst (reduplication of bowel wall)

ENTEROCOLITIS

= inflammation / infection of small intestine + colon

Infectious Enterocolitis (Infectious Colitis)

= INFECTIOUS ILEOCECITIS

= self-limited relatively common clinical condition

Cause:

(a) bacterium: Campylobacter jejuni > Salmonella enteritidis > Yersinia enterocolitica + Shigella, E. coli, Staphylococcus, Chlamydia trachomatis, amebiasis, tuberculosis

(b) fungus: histoplasmosis, mucormycosis, actinomycosis

(c) virus: herpesvirus, CMV, rotavirus

Path: bacterial infection limited to mucosa + submucosa of ileum and right colon; layers intact

Age childhood: rotavirus, E. coli, Salmonella, Shigella, Campylobacter
- acute crampy right lower quadrant pain, positive stool culture
- diarrhea: absent / mild / profuse / bloody (dysentery)

Location:
- › proximal small bowel: Giardia and Strongyloides, MAI
- › distal small bowel: Salmonella, Shigella, Yersinia, Campylobacter, Anisakis
- › distal ileum and cecum: tuberculosis, typhlitis, amebiasis
- › pancolitis: Clostridium difficile, cytomegalovirus, E. coli
- › ascending colon: Yersinia, Salmonella, Entamoeba
- › descending + sigmoid colon: schistosomiasis, Shigella
- › rectosigmoid: herpes simplex virus, gonorrhea, Chlamydia trachomatis (lymphogranuloma venereum), Treponema pallidum (gay bowel syndrome)

Associations:
- › lymphadenopathy + splenomegaly: Salmonella

CT:
- √ enhancing circumferential hypodense mural thickening
- √ homogeneous wall enhancement
- √ "empty colon" sign = absence of luminal contents
- √ pericolic fat stranding OFTEN absent with infections
- √ ± multiple air-fluid levels
- √ ± small amount of ascites
- √ ± adjacent lymphadenopathy
- √ NO involvement of appendix / NO abscess / NO fistula
- √ NO obstruction

specific signs:
- √ thumbprinting / accordion sign ← C. difficile
- √ target sign ← Salmonella, Shigella

Dx: clinical (may lead to unnecessary surgery!)

E. coli Infection in Childhood

unlike in adults E. coli infection may result in hemolytic-uremic syndrome

Inflammatory Enterocolitis

A. PRIMARY: inflammatory bowel disease (ulcerative colitis, Crohn disease), vasculitis
B. SECONDARY: chemotherapy, radiation therapy, graft versus host disease, angiotensin-converting enzyme inhibitor–induced enteritis

Age: teen, young adult; 2nd peak in adulthood
- tenesmus, diarrhea, weight loss
- extraintestinal features: large joint arthritis, erythema nodosum, pyoderma gangrenosum

Necrotizing Enterocolitis

= NEC = ischemic bowel disease ← hypoxia, perinatal stress, infection (endotoxin), congenital heart disease

Frequency: most common GI emergency in premature infants
in 1–5% of neonates in ICU;

in 10% of neonates weighing < 1500 g;
in 10% of full-term neonates with CHD

Age: in 90% within first 10 days of life

Pathophysiology:

prematurity → mucosal injury consisting of mucosal ulceration + widespread transmural necrosis → infection, immature immunity, release of vasoconstrictors, inflammatory mediators → passage of bacteria + toxins into bowel wall → increased blood flow + intramural gas → intestinal ischemia → overwhelming sepsis

Organism: not yet isolated; often occurs in miniepidemics within nursery

Risk factors: prematurity (50–80%), perinatal asphyxia, PDA, indomethacin, Hirschsprüng disease, bowel obstruction (small bowel atresia, pyloric stenosis, meconium ileus, meconium plug syndrome)

- feeding intolerance, abdominal distension, bilious emesis
- blood-streaked stools (in 50%); explosive diarrhea
- mild respiratory distress, generalized sepsis with shock

Location: usually in terminal ileum (most commonly involved), cecum, right colon; rarely in stomach, upper bowel

Plain Abdominal Radiography:

◊ Must include horizontal beam cross-table radiograph!

◊ Large bowel may be impossible to differentiate from small bowel!

√ loss of mosaic multifaceted bowel gas pattern (no longer normal array of polygons caused by impression of gas-filled loops on adjacent loops)

√ distension of small bowel and colon (loops wider than vertebral body of L1) ± air-fluid levels, commonly in RLQ (1st and most common sign in 90%):

- √ change from generalized dilatation to asymmetric distribution
- √ "fixed" bowel = persistent abnormal loop of bowel without change on supine vs. prone films / for > 24 hours

√ bowel wall thickening + "thumbprinting"

√ pneumatosis intestinalis (19–80–98%):

- √ black lines of intramural gas often accompanied by white lines representing lifted off mucosa + submucosa
  - › in curvilinear shape (= subserosal) or
  - › bubbly / cystic (= submucosal gas collection from gas-forming organisms / dissection of intraluminal gas)
- √ may disappear within 12 hours
- √ "bubbly" appearance of bowel ← gas in wall / intraluminal gas / fecal matter (intraluminal contents are composed of blood, sloughed colonic mucosa, intraluminal gas, some fecal material)

√ gas in portal venous system in up to 30% (frequently transient, does not imply hopeless outcome):

- √ linear branching radiolucent vessels extending into periphery of liver

√ pneumoperitoneum (immediate surgery required):

- √ triangular lucencies between loops of bowel anterior to liver beneath abdominal wall on cross-table view

US:

√ small individual foci / granular speckled accumulation of hyperechoic gas in dependent portion of bowel wall (DDx: intraluminal gas that changes in position ← peristalsis, respiration, patient position, abdominal compression)
√ portal venous gas:
  √ echogenic foci within portal vein moving with blood flow
  √ sharp bidirectional spikes on Doppler spectrum, audible as crackles
  √ focal / diffuse linear branching pattern of hyperechoic gas in portal veins
√ pneumoperitoneum:
  √ hyperechoic foci of dirty shadowing between anterior surface of liver + abdominal wall / between bowel loops
√ fluid:
  √ ascites ± low-level echoes / septations ← suggestive of perforation
  √ localized intraabdominal fluid collection (= abscess)
  √ increased intraluminal fluid
√ absent peristalsis
√ bowel wall thickness (normal, 1.1–2.6 mm):
  √ "zebra" pattern = bowel wall thickening + increased echogenicity of valvulae conniventes ← edema
  √ bowel wall thinning
√ bowel wall perfusion by color Doppler:
  √ hyperemia: "zebra" pattern (hyperemic valvulae), "Y" pattern (distal mesenteric + subserosal vessels), "ring" pattern (circumferential flow around entire bowel wall)
  √ absent flow ← transmural bowel necrosis

N.B.: Barium enema contraindicated! May be used judiciously in selected cases with radiologic + clinical doubt!

Cx: (1) Inflammatory stricture after healing in 10–30%, in 30% multiple, in 80% in left colon (BE follow-up in survivors)
(2) Bowel perforation in 12–32%

Prognosis: 20–40% mortality (in 64% with perforation)

Rx: bowel rest with nasogastric tube, antibiotics, total parenteral nutrition with adequate hydration, surgery

Neutropenic Colitis (Typhlitis)

= ILEOCECAL SYNDROME [*typhlos*, Greek = blind sac = cecum]
= acute inflammation of cecum, appendix, and occasionally terminal ileum typically in immunosuppressed condition (= neutropenic patients undergoing chemotherapy for malignancy / during posttransplantation period)

Cause: ? probably multifactorial: leukemic / lymphomatous infiltrate, ischemia, mucosal hemorrhage, focal pseudomembranous colitis, infection (esp. CMV)

Histo: edema + ulceration of entire bowel wall → transmural necrosis → perforation possible

Organism: CMV, Pseudomonas, Candida, Klebsiella, E. coli, B. fragilis, Enterobacter, C. difficile

Predisposed: common in childhood leukemia, aplastic anemia, lymphoma,

immunosuppressive therapy (eg, renal transplant), cyclic neutropenia, myelodysplastic syndrome, clinical AIDS

- abdominal pain, may be localized to RLQ
- watery / bloody diarrhea; fullness / palpable mass in RLQ
- fever, neutropenia; hematochezia / occult blood

Location: right colon (cecum + appendix + ascending colon); distal ileum + transverse colon may become secondarily involved

The length of cecum and right colon involved by typhlitis is generally much greater than that associated with appendicitis.

N.B.: Risk of bowel perforation with colonoscopy / contrast enema examination!

√ fluid-filled masslike density in RLQ
√ distension of nearby small bowel loops
√ thumbprinting of ascending colon
√ circumferential thickening of cecal wall > 4 mm
√ occasionally pneumatosis

CT (preferable examination due to risk of perforation):

√ cecal distension
√ circumferential segmental wall thickening (> 1–3 mm) of cecum ± terminal ileum
√ decreased bowel wall attenuation ← edema + necrosis
√ severe stranding of adjacent fat + thickening of fascial planes ← pericolonic inflammation
√ ± pericolonic fluid + intramural pneumatosis

Cx: (1) Perforation
√ pneumatosis coli
√ pneumoperitoneum
(2) Abscess formation
√ pericolic fluid collection

Prognosis: up to 50% mortality ← necrosis, rupture, peritonitis

Rx: (1) Early aggressive medical support (high doses of antibiotics + IV fluids), bowel rest, total parenteral nutrition, electrolyte replacement prior to development of transmural necrosis
(2) Surgery for uncontrollable GI bleeding, obstruction, abscess, transmural necrosis, free perforation, uncontrollable sepsis

DDx: (1) Leukemic / lymphomatous deposits (more eccentric thickening)
(2) Appendicitis with periappendicular abscess (normal cecal wall thickness)
(3) Diverticulitis
(4) Inflammatory bowel disease

EOSINOPHILIC GASTROENTEROPATHY

Eosinophilic Esophagitis

= manifestation of immune-mediated inflammation (allergy) in genetically susceptible individuals

◊ Leading cause of emergency department visits for esophageal food impaction (in up to 50%)

Incidence: 1÷10,000 [2–6÷10,000] annually in children [adults]

Prevalence: 4÷10,000 [27÷10,000] in child [adult]

Peak age: 3rd + 4th decade; M÷F = 3÷1

Histo: PATHOGNOMONIC infiltration of squamous epithelium with > 15–20 eosinophils per high-power field

- chronic nonprogressive dysphagia with solid foods (70%)
- gastroesophageal reflux / heartburn (38%)
- vomiting, regurgitation, hematemesis, weight loss
- history of atopy; asthma, atopic dermatitis, eczema

Seasonal occurrence: symptoms in late summer and fall

Pathophysiology:

hypersensitivity reaction to inhaled / ingested allergens → Th2 type immune response (= cytokines like interleukin 4, 5, 10, 13) → excessive eosinophils → release of cytotoxic chemicals (eg, transforming growth factor beta) → muscular contractions → fibrotic strictures

UGI:

√ smooth long-segment stricture without ulceration + mild mucosal irregularity (most common finding)

√ "ringed esophagus" = multiple fixed rings appearing as closely stacked indentations on esophageal lumen

√ stricture with an irregular ulcerated lumen / granular mucosa

√ small-caliber esophagus → diameter of < 20 mm

Location: mid / distal esophagus

Associated with: hiatal hernia, reflux esophagitis

CT:

√ diffuse mural thickening (nonspecific)

√ occasionally impacted food

Dx: (1) Endoscopy

- esophageal rings (a) fixed (= "esophageal trachealization" (b) transient (= "felinization")
- linear / longitudinal mucosal grooves
- white plaques mimicking candidiasis
- pale fragile mucosa ("crepe paper mucosa") → may fracture with passage of endoscope → risk of esophageal perforation

Rx: dietary modification (98% positive response in children); oral corticosteroids + leukotriene and eotaxin inhibitors; esophageal dilatation (for symptomatic stricture with ↑ risk of perforation)

(2) Biopsy (30% complication rate)

Cx: spontaneous esophageal rupture

DDx: peptic / radiation-induced stricture (indistinguishable)

Eosinophilic Gastroenteritis

= uncommon occasionally self-limited form of gastroenteritis with remissions +

exacerbations characterized by infiltration of eosinophilic leukocytes into wall of GI tract

Prevalence: 1÷100,000

Cause:

(a) primary = idiopathic

(b) secondary = result of systemic condition

1. Hypereosinophilic syndrome
2. Celiac disease
3. Crohn disease
4. Churg-Strauss syndrome
5. Helminthic infection
6. Drugs: enalapril, gemfibrozil, cyclosporine

Histo: fibrous tissue + eosinophilic infiltrate of gastrointestinal mucosa

Peak age: 3rd–5th decade; M÷F = 1.4÷1

A. EOSINOPHILIC GRANULOMA

B. EOSINOPHILIC GASTROENTERITIS

= diffuse type

= eosinophilic infiltration of mucosa (58%), submucosa, muscular layer, serosa of small intestine ± stomach by mature eosinophils (? gastric pendant to Löffler syndrome)

- history of atopy + systemic / food allergy (75%)
- usually marked peripheral eosinophilia (75–100%)
- local symptoms:
  - recurrent episodes of abdominal pain / cramps
  - diarrhea, vomiting, bowel obstruction, acute pancreatitis
  - GI bleed, hematemesis ← ulceration
- systemic symptoms:
  - malabsorption, protein-losing enteropathy → hypoproteinemia, iron-deficiency anemia
  - weight loss, anorexia, failure to thrive
  - delayed puberty, amenorrhea

Location: entire small bowel (particularly jejunum), distal stomach, omentum, mesentery

Layer of involvement: (a) mucosa + submucosa (58%)
(b) muscularis (30%)
(c) serosa (12%)

@ Small bowel (100%)

√ separation of small bowel loops

(a) mucosal type
√ mucosal fold thickening, polyps, nodular thickening, ulcers
√ "araneid limblike" sign = "spider leg" appearance ← diffuse mucosal thickening with contrast material in mucosal sinuses

(b) submucosal type
√ "halo" sign = layered appearance of bowel wall ← submucosal edema

(c) muscular type
√ strictures, bowel wall thickening, intestinal obstruction

√ concentric hypoattenuating bowel wall thickening

√ reduced distensibility + narrowing of lumen

√ motility disturbance → small-bowel obstruction

√ effacement of mucosal pattern

(c) serosal type

√ ascites with peripheral eosinophilia

√ pleural effusion

√ peritoneal stranding, omental thickening

√ mesenteric lymphadenopathy with central necrosis

√ clustering of small bowel loops

√ serosal enhancement

DDx: lymphoma

@ Stomach (80%; almost always limited to antrum)

√ "wet stomach"

(a) mucosal type

√ enlarged gastric rugae / cobblestone nodules / polyps

√ ulcers (rare)

(b) muscular type

√ thickened + rigid wall with narrowed gastric antrum / pylorus

√ bulky intraluminal mass up to 9 cm in size

Cx: pyloric / gastric outlet obstruction

DDx: hypertrophic gastritis, lymphoma, carcinoma

Prognosis: tendency toward spontaneous remission (in ⅓) with frequent relapse

Rx: corticosteroids / removal of sensitizing agent; dietary modification

Eosinophilic Colitis

= non–IgE-mediated allergic disease

Cause: allergy to cow's milk / soy proteins

Age: infants, young adults

In 50% associated with: atopic disease

• abdominal pain

(a) mucosal disease

• bloody diarrhea

(b) muscular disease

√ volvulus, intussusception, perforation

(c) serosal disease

√ ascites

√ segmental / diffuse colonic wall thickening, wall edema

√ pericolonic fat stranding

Dx: increased eosinophils in colonic wall + negative workup for other causes of tissue eosinophilia

Rx: dietary modification (child); corticosteroid / immunosuppressive therapy (adult)

Prognosis: waxing and waning course

EPIPLOIC APPENDAGITIS

= rare self-limiting inflammation of one of 50–100 epiploic / omental appendages

◊ 40 times more common than Meckel diverticulitis!

◊ Relatively unknown amongst clinicians and almost never suspected preoperatively!

Epiploic appendage: small benign 5–50 mm long outpouching of visceral peritoneum containing fat and small blood vessels + arising from serosal surface of colon adjacent to tenia coli

Cause: (a) primary: torsion (exercise) → venous thrombosis
Blood supply: 2 arteries + 1 draining vein
(b) secondary: inflammation of adjacent organ (eg, diverticulitis, appendicitis, cholecystitis)

Associated with: obesity, rapid recent weight loss, hernia, unaccustomed exercise

Age: 4th–5th decade; M > F

Histo: acute infarction with fat necrosis, inflammation, thrombosed vessels with hemorrhagic suffusion

- abrupt onset of very localized nonmigratory LLQ abdominal pain (RLQ in 50%) + rebound tenderness, gradually resolving over 3–7 days
- less frequent: nausea, vomiting, altered bowel function, fever
- palpable mass (10–30%); ± peritoneal signs
- normal / mildly increased (7%) WBCs; NO fever

Location: sigmoid > descending > right hemicolon > appendix
◊ Most commonly mimicks acute diverticulitis!

Site: anterolaterally / (occasionally) anteromedially between colon + abdominal wall

Size: 1.0–3.5–5.0 cm in diameter

√ oval fatty lesion commonly adjacent to sigmoid colon:
  √ stranding of periappendigeal fat
  √ thickening of parietal peritoneum

CT:
  √ pericolic oval-shaped pedunculated mass of fat attenuation (~ -60 HU):
    √ hyperattenuating 2–3 mm peripheral rim (= thickening of adjacent visceral peritoneal lining) in 93%
    √ "central dot" sign / linear focus of high attenuation (= engorged / thrombosed vein / central hemorrhage / necrosis)
  √ ± (often peripheral) calcification ← fat necrosis
  √ eccentric minimal colonic wall thickening

US:
  √ solid hyperechoic noncompressible oval mass at site of maximal tenderness
  √ hypoechoic margin (93%)
  √ absence of central blood flow on color Doppler

MR:
  √ focal lesion with signal intensity of fat
  √ enhancing rim around oval fatty lesion

Cx: adhesion, bowel obstruction, intussusception, peritonitis, abscess, intraperitoneal calcified loose body (after twisting off its pedicle)

Prognosis: spontaneous resolution within 2 weeks clinically + within 6 months on CT

Rx: conservative management with NSAID

DDx: (1) Torsion / infarction of greater omentum = epiploic appendagitis "on steroids"
(2) Sclerosing mesenteritis

(3) Diverticulitis
(4) Appendicitis
(5) Primary tumor / metastasis of mesocolon

ESOPHAGEAL CANCER

Incidence: 4–10% of all gastrointestinal malignancies (3rd most common) worldwide; 1% of all cancers; 16,910 cases with 15,690 deaths annually (USA, 2016); 5.8 cases per 100,000 people; M÷F = 4÷1

High-risk regions: Iran, parts of Africa, Italy, China

At risk: tobacco + alcohol use (synergistic effect); diet low in fresh fruit + vegetables and high in nitrosamines; achalasia (risk factor of 1,000 x), asbestosis, Barrett esophagus, celiac disease, radiation exposure, acid / lye burn (risk factor of 1,000 x), Plummer-Vinson syndrome, tannins, alcohol, tobacco, history of oral / pharyngeal cancer, **tylosis palmaris et plantaris** (defect in tylosis esophageal cancer gene on chromosome 17q25)

mnemonic: BELCH SPAT
Barrett esophagus
EtOH abuse
Lye stricture
Celiac disease
Head and neck tumor
Smoking
Plummer-Vinson syndrome
Achalasia, **A**sbestosis
Tylosis

Cancer Staging (American Joint Commission on Cancer):

TNM system:

Tis high-grade dysplasia
T1a tumor invades lamina propria / muscularis mucosae
T1b tumor invades submucosa
T2 tumor invades muscularis propria
T3 tumor invades adventitia
T4 tumor invades adjacent structures
T4a resectable (pleura, pericardium, diaphragm)
T4b unresectable (aorta, vertebra, trachea)
N0 no regional Lnn metastasis
N1 1–2 regional Lnn metastasis
N2 3–6 regional Lnn metastasis
N3 ≥ 7 regional Lnn metastasis

Stage I	= T1 N0 M0	Stage III	= T3 N1 M0
Stage IIA	= T2/3 N0 M0		or T4,N0/1,M0
Stage IIB	= T1/2 N1 M0	Stage IV	= T1-4 N0/1 M1

T4a cancers are resectable in spite of ← invasion of pleura, peritoneum, pericardium, diaphragm.
T4b cancers are unresectable ← invasion of aorta, carotid a. + v., azygos v., trachea, left main

bronchus, vertebral body.

Lymph node map:

1	supraclavicular	9	inferior pulmonary lig.
2L	paratracheal – L/R	10	hilar L / R
3P	posterior mediastinal	15	diaphragmatic
4	tracheobronchial angle	16	paracardial
5	aortopulmonary	17	left gastric (resectable)
6	anterior mediastinal	18	common hepatic
7	subcarinal	19	splenic
8L	lower paraesophageal	20	celiac (unresectable)
8M	middle paraesophageal		

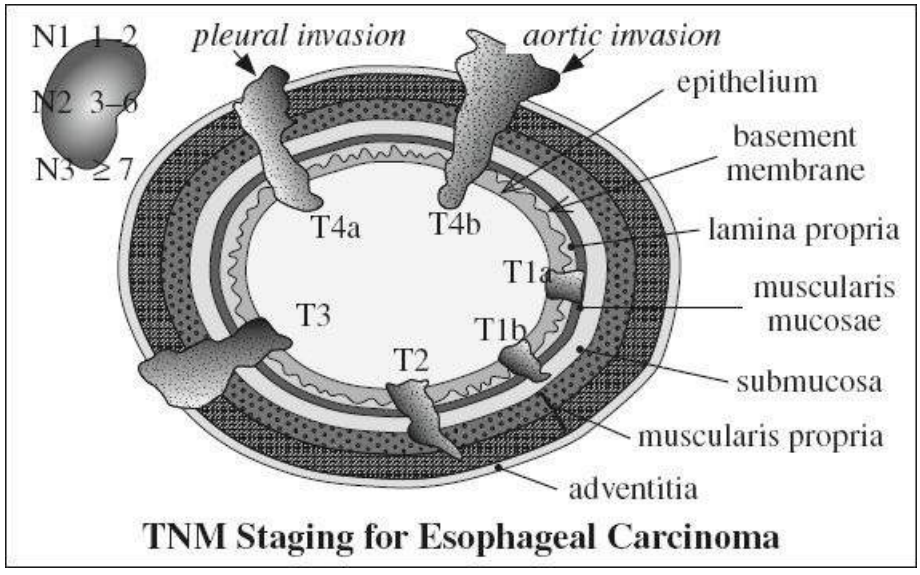
Regional lymph nodes include any paraesophageal lymph nodes from cervical nodes to celiac nodes.

Lnn status is based on location of primary:

N1 = locoregional periesophageal Lnn disease
M1a = metastasis to cervical / celiac nodes
M1b = distant nonregional Lnn disease

(a) in proximal esophageal cancer:
M1a = cervical Lnn involvement
M1b = all other distant metastases

(b) in middle esophageal cancer:
M1a = none available
M1b = metastasis to cervical / celiac axis Lnn



(c) in distal esophageal cancer:
N1 = gastric Lnn involvement
M1a = celiac axis Lnn involvement
M1b = all other distant metastases

CT (30–60% sensitive, 46–58% accurate):
√ intrathoracic/ abdominal lymph node > 10 mm
√ supraclavicular lymph node with short axis > 5 mm
US (72–80% accurate):
√ homogeneously hypoechoic central pattern
√ round lymph node with a short axis of > 10 mm
PET:
√ 51–84% sensitivity for locoregional lymph nodes
√ up to 90% sensitive for metastatic lymph node

CT staging (Moss):
Stage 1 intraluminal tumor / localized wall thickening of 3–5 mm
Stage 2 localized / circumferential wall thickening > 5 mm
Stage 3 contiguous spread into adjacent mediastinum (trachea, thyroid, larynx, bronchi, aorta, lung, pericardium, diaphragm)
√ loss of fat planes (nonspecific ← cachexia, often still resectable)
√ mass in contact with aorta > 90° arc (in 20–70% still resectable)
√ displacement / compression of airway (90–100% accuracy for invasion)
√ esophagotracheal / -bronchial fistula (unresectable)
√ pericardial thickening, pericardial effusion, loss of pericardial fat plane, indentation of heart
Stage 4 distant metastases
√ enlarged abdominal lymph nodes > 10 mm (12–85% accuracy)
√ hepatic, pulmonary, adrenal metastases
√ direct erosion of vertebral body
√ tumor > 3 cm wide = high frequency of extraesophageal spread

Endoscopic US (most accurate modality for T staging):
◊ Can differentiate T1<u>mucosal</u> (suitable for local ablative therapy) from T1 <u>submucosal</u> invasion

Accuracy: 75–82% for T1, 64–82% for T2, 89–94% for T3, 88–100% for T4

Histo:
(1) Squamous cell carcinoma (50–70%)
(2) Adenocarcinoma (30–50%)
(3) Spindle-cell carcinoma (0.5–2.8%)
(4) Sarcoma: GIST, leiomyo-, rhabdomyo-, fibrosarcoma
(5) Mucoepidermoid carcinoma, adenoid cystic carcinoma
(6) Neuroendocrine neoplasm / small cell carcinoma (1%)
(7) Malignant lymphoma
(8) Secondary tumor involvement from: thyroid, larynx
(9) Metastasis from: breast, melanoma, GI tract

• dysphagia (87–95%) of < 6 months' duration
• weight loss (71%), retrosternal pain (46%), regurgitation (29%)

Location: upper ⅓ (15–20%); middle ⅓ (37–44%); lower ⅓ (38–43%)

An esophagogastric junction tumor is considered an esophageal cancer if
(a) the epicenter is within lower thoracic esophagus / at esophagogastric junction, or

(b) the epicenter is within proximal 5 cm of the stomach extending into the esophagus.

Radiologic types:

(1) **Polypoid / fungating form** (most common)
- √ sessile / pedunculated tumor with lobulated surface
- √ protruding, irregular, polycyclic, overhanging, steplike "apple core" lesion

(2) **Ulcerating form**
- √ large ulcer niche within bulging mass

(3) **Infiltrating form**
- √ gradual narrowing with smooth transition (DDx: benign stricture)

(4) **Varicoid form = superficial spreading carcinoma**

= uncommon pattern of dissemination via vasculature + lymphatic system to submucosa

Histo: longitudinal extension of squamous cell carcinoma confined to mucosa / submucosa → secondary intramural tumor deposits

Location: middle + distal segments of esophagus

- √ focal area of confluent tortuous / serpentine longitudinal mucosal nodules / plaques simulating downhill esophageal varices:
  - √ NO change during respiration / patient repositioning

DDx: Candida esophagitis

Metastases:

(a) lymphogenic: anterior jugular chain + supraclavicular nodes (primary in upper ⅓); paraesophageal + subdia-phragmatic nodes (primary in middle ⅓); mediastinal + paracardial + celiac trunk nodes (primary in lower ⅓)

N.B.: (1) mucosal + muscular lymphatic plexuses intercommunicate
(2) lymph may flow upward / downward

(b) hematogenous: liver > lung > bone > adrenal gland > kidney > brain

CXR:
- √ widened azygoesophageal recess with convexity toward right lung (in 30% of distal + midesophageal cancers)
- √ thickening of posterior tracheal stripe + right paratracheal stripe > 3–4 mm (in 11% if tumor is located in upper third of esophagus)
- √ tracheal deviation (10%)
- √ widened mediastinum
- √ posterior tracheal indentation / mass
- √ retrocardiac mass
- √ esophageal air-fluid level
- √ lobulated mass extending into gastric air bubble
- √ repeated aspiration pneumonia ← tracheoesophageal fistula

Barium:
- √ plaquelike / polypoid / ulcerated lesion for <u>superficial lesion</u>
- √ irregular luminal narrowing, ulceration, abrupt shouldered margins for <u>advanced lesion</u>
- √ elevated lesion + rigidity of esophageal wall indicate subepithelial tumor extension

Endoscopic US:
- √ homo- / heterogeneous mass
- √ disruption of esophageal wall layers (staging accuracy of 84%)

√ round well-defined lymph node > 10 mm in diameter (92% accuracy if combined with fine-needle aspiration)

CT:

√ asymmetric / circumferential localized thickening of esophageal wall / soft-tissue mass

√ peak enhancement in late arterial phase (at 35 seconds)

√ mediastinal / aortic invasion:

√ loss of intervening fat planes

√ displacement / indentation of trachea

√ tumor in contact with > 90° of aortic circumference

√ distant metastases (to liver, lung, bone)

PET:

√ avid uptake of primary (unless confined to mucosa) and of metastases (unless microscopic involvement)

◊ Primary tumor NOT identified in up to 20% (33% sensitive compared with 81% for endoscopic ultrasound)

Role of PET:

◊ Cost effective in prevention of noncurative surgery!

(1) Initial staging + detection of unresectable distant disease ← locoregional metastases (32–41% sensitive)

(2) Monitoring effectiveness of therapy (after 2 weeks)

= allows prediction of response to neoadjuvant therapy after only 2 cycles (not sufficiently reliable!)

N.B.: many FPs ← posttreatment esophagitis and ulceration, motion artifacts at level of diaphragm, prior mucosal biopsy during EGD

(3) Monitoring conversion from nonsurgical to surgical lesion

(4) Follow-up after definitive treatment (= restaging)

› local recurrence (100% sensitive, 57% specific)

› recurrent regional disease (92% sensitive, 83% specific)

› distant metastases (95% sensitive, 80% specific)

Cx: fistula formation to trachea (5–10%) / bronchi / mediastinum

Prognosis: 18.4% 5-year survival rate (2012); 0% 5-year survival rate for cancer of cervical esophagus; ²/₃ incurable at presentation; survival rate higher for adenocarcinoma versus squamous cell cancer

Mean survival time:

90 days with subdiaphragmatic lymphadenopathy

180 days with local invasion + abdominal metastases

480 days without evidence of invasion / metastases

Rx: (1) Chemotherapy (fluorouracil, cisplatin, bleomycin sulfate, mitomycin) + surgery

(2) Chemotherapy + irradiation (~ 4,000 cGy)

(3) Chemotherapy + irradiation + surgery

Operative mortality: 3–8%

Squamous Cell Carcinoma (SCC) of Esophagus

= malignant tumor of epithelial cells with stratified squamous differentiation progressing

from precursor lesion of intraepithelial neoplasia

Prevalence: 1.8÷100,000 in USA (↓ probably due to declining tobacco consumption); 20÷100,000 in southern Africa + eastern Asia
◊ Most common esophageal neoplasm worldwide!

Histo: nests of squamous epithelial cells penetrate beyond basement membrane with little desmoplastic response; tumor grade does NOT affect prognosis; intramural metastases in up to 16%

Peak age: 60–74 years; M÷F = 65÷35; Blacks÷Whites = 4÷1

- asymptomatic with superficial cancer (85%)
- progressive dysphagia, odynophagia, weight loss
- chest pain (unrelated to swallowing)

Location: middle > lower > upper third of esophagus

Barium:
√ plaquelike / polypoid / ulcerated lesion for superficial lesion
√ irregular luminal narrowing, ulceration, abrupt shouldered margins for advanced lesion
√ elevated lesion + rigidity of esophageal wall indicate subepithelial tumor extension

Endoscopic US:
√ homo- / heterogeneous mass
√ disruption of esophageal wall layers → staging accuracy of 84%
√ round well-defined lymph node > 10 mm in diameter (92% accuracy if combined with fine-needle aspiration)

CT:
√ asymmetric / circumferential localized thickening of esophageal wall / soft-tissue mass
√ peak enhancement in late arterial phase (35 seconds)
√ mediastinal / aortic invasion:
  √ loss of intervening fat planes
  √ displacement / indentation of trachea
  √ tumor in contact with > 90° of aortic circumference
√ distant metastases (to liver, lung, bone)

PET:
√ avid uptake of primary (unless confined to mucosa) + of metastases (unless microscopic involvement)

Cx: esophageal obstruction, tracheoesophageal fistula

Prognosis: overall 5-year survival rate of 10%

Spindle Cell Carcinoma of Esophagus

= (METAPLASTIC) CARCINOSARCOMA = PSEUDOSARCOMA = PSEUDOSARCOMATOUS CA. = POLYPOID SQUAMOUS CARCINOMA = SARCOMATOID CARCINOMA = SCC WITH SPINDLE-CELL COMPONENT

Prevalence: 0.5–2.8% of all malignant esophageal tumors

Histo: squamous + sarcomatous elements

Path: bulky polypoid intraluminal mass with scalloped smooth / ulcerated surface

Age: > 45 years; M÷F = 4÷1 to 9÷1

- pain, dysphagia, weight loss

Location: usually middle + distal esophagus

√ rapid growth = doubling time of 2.2–5.0 months

Esophagram:

√ large bulky smoothly lobulated intraluminal mass

√ cupola / domed appearance of superior tumor edge

√ expands esophageal lumen to an average diameter of 8 cm WITHOUT obstruction

√ ulceration rare; may be polypoid + pedunculated

CT:

√ expansile hypoattenuating intraluminal mass

√ ± focal esophageal wall thickening at attachment site

Prognosis: similar to SCC with 20% 5-year survival

Spread (in 38–50%): lung, liver

DDx: fibrovascular polyp, myofibroma, pedunculated lipoma, leiomyoma, lymphoma, adenocarcinoma, leiomyosarcoma, fibrosarcoma, rhabdomyosarcoma, melanoma, oat cell carcinoma

Adenocarcinoma of Esophagus

= malignant epithelial neoplasm that almost always arises from

(a) malignant degeneration of underlying columnar-lined epithelium (Barrett epithelium)

› occasionally from

(b) ectopic gastric mucosa in esophagus

(c) submucosal / deep esophageal glands

(d) gastric adenocarcinoma involving GE junction

Prevalence: marked ↑ from 18% (in 1984) to 63% (in 2008) of all malignant esophageal tumors surpassing squamous cell carcinoma in USA

◊ 2nd most common malignant tumor of esophagus in most countries!

◊ 2,500 new cases annually

Path: grossly infiltrating / polypoid / ulcerative lesion

Histo: sequence of progressively severe epithelial dysplasia → mostly well / moderately well differentiated invasive carcinoma with columnar or cuboidal cells in tubular / glandular / cribriform patterns; ± mucinous / signet-ring cell subtypes

Peak age: 7th decade; M÷F = 85÷15; Whites÷Blacks = 5÷1

• asymptomatic (most)

• symptoms of gastroesophageal reflux disease (GERD)

Location: 75% in lower ⅓ of esophagus with marked tendency to extend to gastric cardia + fundus

Adenocarcinoma and SCC have similar morphologic findings. However, adenocarcinomas usually involve the lower ⅓ of the esophagus with a tendency to invade the stomach.

√ imaging features identical to SCC

Prognosis: overall 5-year survival rate of 42% after resection compared to 30% for SCC

ESOPHAGEAL INTRAMURAL PSEUDODIVERTICULOSIS

= dilated excretory ducts of deep mucous glands

Etiology: uncertain

Prevalence: about 100 cases in world literature

In 90% associated with:
diabetes, alcoholism, any severe esophagitis (most often reflux / Candida), esophageal stricture
Site: diffuse / segmental involvement
√ multiple tiny rounded / flask-shaped barium collections in longitudinal rows parallel to long axis of esophagus:
√ appear to "float" outside esophagus without apparent communication with lumen
√ esophageal stricture:
√ short stricture in distal esophagus (common)
√ long stricture in cervical / upper thoracic esophagus (classic)

ESOPHAGEAL TRAUMA

Cause:
A. EXTRALUMINAL:
(1) Blunt trauma = closed chest trauma (10%)
Frequency: 1% of all blunt chest trauma
Location:
(a) cervical / upper thoracic esophagus (82%)
(b) just above gastroesophageal junction along left posterolateral wall
(2) Penetrating trauma
B. INTRALUMINAL:
(1) Iatrogenic injury = complication of instrumentation (most common cause, 55%): endoscopy, dilatation of stricture + stent placement, bougie, disruption of suture line following surgical anastomosis (gastric fundoplication, esophageal myotomy), attempted intubation, thyroidectomy, anterior cervical diskectomy, left atrial radiofrequency ablation
(2) Barotrauma = spontaneous rupture = Boerhaave syndrome (15%)
(4) Foreign body impaction (14%): coin, aluminum pop-tops, metallic button, safety pin, invisible plastic toy leading to perforation (in pediatric age group)
(5) Intrinsic esophageal disease: Barrett ulcer, caustic / infectious esophagitis, esophageal carcinoma
• abrupt onset of retrosternal chest pain (similar to acute myocardial infarction / aortic dissection)
• dysphagia, odynophagia, hematemesis

Intramural Dissection of the Esophagus

= SUBMUCOSAL DISSECTION = INTRAMURAL RUPTURE OF ESOPHAGUS = DISSECTING INTRAMURAL HEMATOMA
= mucosal tear with dissecting hemorrhage into submucosa + involvement of venous plexus
Cause: recent instrumentation, forceful vomiting, spontaneous hemorrhage (anticoagulant therapy, coagulopathy), aortoesophageal fistula, spontaneous
Age: middle-aged; M < F
• hematemesis
Location: usually posterior

Site: distal ← lack of striated muscle
√ well-defined focal filling defect = intramural hematoma simulating retained solid material within lumen
√ luminal narrowing of the esophagus
√ "double-barrel esophagus" = mucosal flap with submucosal distribution of gas / contrast
√ "mucosal stripe" sign = dissected mucosa floating within lumen
√ eccentric / concentric nonenhancing hyperattenuating mass within esophageal wall

CT:
√ symmetric / asymmetric esophageal wall thickening
√ well-defined nonenhancing intramural esophageal mass of high attenuation

Prognosis: progression to frank esophageal rupture / resolution within a few weeks

Transmural Perforation of the Esophagus

= ESOPHAGEAL PERFORATION = ESOPHAGEAL RUPTURE

• rapid onset of overwhelming sepsis: fever, tachycardia, hypotension, shock

Plain film (normal in 9–12%):
√ extensive pneumomediastinum
√ "V" sign of Naclerio = extrapleural air within lower mediastinum between parietal pleura + diaphragm (usually on left)
√ subcutaneous emphysema of the neck
√ delayed widening of the mediastinum ← mediastinitis
√ hydrothorax (after rupture into pleural cavity), usually unilateral on left side
√ hydropneumothorax (often initially missed)
√ left lower lobe atelectasis
√ confirmation with contrast study (90% of contrast esophagrams are positive)

Esophagography (modality of choice for evaluating esophageal rupture):
(1) Water-soluble contrast (in 10% false-negative result)
(2) Barium (if result with water-soluble material negative)
√ extravasation of oral contrast material into mediastinum ± pleural space

CT (modality of choice for penetrating trauma):
√ focal extraluminal air collection at site of tear (92%; most useful sign)
√ periesophageal / mediastinal hematoma / fluid (92%)
√ pleural effusion (75%)
√ esophageal wall thickening

Cx: (1) Acute mediastinitis
(2) Obstruction of SVC
(3) Mediastinal abscess

Prognosis: 20–60% mortality; 90% after 48 hours

Med. emergency: up to 80% survive if primary closure is performed within 24 hours after perforation

Upper / Midesophageal Perforation

Location: at level of cricopharyngeus muscle (most frequent)
√ widening of upper mediastinum

√ right-sided hydrothorax

Distal Esophageal Perforation

Frequency: more common (but not in blunt chest trauma)
Cause: biopsy, dilatation of stricture, Boerhaave syndrome
√ left-sided hydrothorax
√ little mediastinal changes

ESOPHAGEAL VARICES

= plexuses formed by (1) dilated subepithelial and submucosal veins + (2) dilated venae commitantes of vagus nerve outside tunica muscularis
◊ Most common and clinically important collateral vessels of the intrathoracic portosystemic collateral system

Anatomy:
(a) anterior branch connected to left gastric vein
(b) posterior branch connected to azygos + hemiazygos system

Examination Technique:
(a) small amount of barium (not to obscure varices)
(b) relaxation of esophagus (not to compress varices): refrain from swallowing because succeeding swallow initiates a primary peristaltic wave that lasts for 10–30 seconds; sustained Valsalva maneuver precludes from swallowing
(c) in LAO projection with patient recumbent / in Trendelenburg position ± Valsalva maneuver / deep inspiration

Location: lower esophagus

Plain film:
√ lobulated masses in posterior mediastinum (visible in 5–8% of patients with varices)
√ silhouetting of descending aorta
√ abnormal convex contour of azygoesophageal recess at level of gastroesophageal junction

UGI:
√ thickened sinuous interrupted mucosal folds (earliest sign)
√ tortuous radiolucencies of variable size + location
√ "worm-eaten" smooth lobulated filling defects
√ findings may be accentuated after sclerotherapy

CT (> 90% detection rate):
√ nodular thickening of esophageal wall + lobulated outer contour
√ scalloped enhancing nodular masses protruding into esophageal lumen
√ right- / left-sided soft-tissue masses (= paraesophageal varices)
√ marked enhancement following dynamic CT

Cx: variceal hemorrhage at a rate of 10–30% per year; 20–35% mortality with exsanguination in 10–15%

DDx: varicoid carcinoma of esophagus

Uphill Esophageal Varices

= collateral blood flow from portal vein → azygos vein → into SVC (usually lower esophagus drains via left gastric vein into portal vein)

Cause:
(a) intrahepatic obstruction from cirrhosis
◊ In < 5% of patients with portal hypertension
(b) splenic vein thrombosis (usually gastric varices)
(c) obstruction of hepatic veins
(d) IVC obstruction below hepatic veins
(e) IVC obstruction above hepatic vein entrance / CHF
(f) marked splenomegaly / splenic hemangiomatosis (rare)
√ varices in lower ½ of esophagus

Downhill Esophageal Varices

= collateral blood flow from SVC → azygos vein → into IVC / portal venous system (upper esophagus usually drains via azygos vein into SVC)
Cause: obstruction of superior vena cava distal to entry of azygos vein (= superior vena cava syndrome) most commonly due to lung cancer, lymphoma, retrosternal goiter, thymoma, mediastinal fibrosis
√ varices in upper ⅓ of esophagus

Paraesophageal Varices

= part of intrathoracic portosystemic collateral network
• endoscopically not visible
◊ NOT connected to esophageal varices!
Anatomy: supplied by posterior branch of coronary (= left gastric) vein draining into azygos + hemiazygos vv. + vertebral plexus
May be associated with: subcutaneous collateral vessels in chest wall
CXR:
√ lateral bulging of paraspinal interfaces with obliteration of azygoesophageal recess + descending thoracic aortic interface (in 5–8%)
CT:
√ dilated collateral vessels surrounding esophagus + descending thoracic aorta

Cardiophrenic Angle Varices

= dilated pericardiophrenic veins mimicking a tumor
Cause: membranous obstruction of IVC (frequent in cirrhosis)
CXR:
√ undulating masses along cardiac borders
√ widening of both paraspinal interfaces
CECT:
√ enhancing pseudotumor (vascular nature)

ESOPHAGEAL WEB

= complete / incomplete circumferential narrowing caused by 1–2-mm thick (vertical length) shelf-like filling defect projecting into esophageal lumen
Age: middle-aged females
? Association with:

Plummer-Vinson syndrome = Paterson-Kelly syndrome (iron deficiency anemia, stomatitis, glossitis, dysphagia, thyroid disorder, spoon-shaped nails), benign mucous membrane pemphigoid, epidermolysis bullosa dystrophica, GERD

Cause:

mnemonic: BIEP

B-ring (Schatzki ring)
Idiopathic (= symptomatic transverse mucosal fold)
Epidermolysis bullosa
Plummer-Vinson disease

Path: hyperkeratosis + chronic inflammation of submucosa

Histo: mucosal membrane covered by squamous epithelium on superior + inferior surfaces

• mostly asymptomatic (unless severely stenosing)

Location: in cervical esophagus near cricopharyngeus (most common) > thoracic esophagus at squamocolumnar junction of distal esophagus (Schatzki) > lower hypopharynx; occasionally multiple

Site: often anteriorly located

√ visualized during maximal distension (in $^{1}/_{10}$ of a second)

√ arises at right angles from anterior esophageal wall

√ thin delicate membrane of uniform thickness of < 3 mm

Cx: high risk of upper esophageal + hypopharyngeal (postcricoid) carcinoma

Rx: (1) Balloon dilatation
(2) Bougienage during esophagoscopy

DDx: Stricture (circumferential + thicker > 1–2-mm thick [vertical length] area of complete / incomplete circumferential narrowing)

ESOPHAGITIS

Acute Esophagitis

Cause:

mnemonic: CRIER

Corrosives, **C**rohn disease
Reflux
Infection, **I**ntubation
Epidermolysis bullosa
Radiation therapy

√ thickened > 3-mm wide folds with irregular lobulated contour

√ mucosal nodularity ← multiple ulcers + intervening edema

√ erosions

√ vertically oriented ulcers usually 3–10 mm in length

√ inflammatory esophagogastric polyp = proximal gastric fold extending across esophagogastric junction (rare)

√ abnormal motility

CT:

√ diffuse esophageal thickening

√ submucosal edema
√ mucosal enhancement

Candida Esophagitis

= MONILIASIS = CANDIDIASIS

◊ Most common cause of infectious esophagitis!

Organism: C. albicans, C. tropicalis; endogenous (majority) / transmitted by another human / animal; often discovered in diseased skin, GI tract, sputum, female genital tract, urine with an indwelling Foley catheter

Predisposed:

(a) individuals with depressed immunity: hematologic disease, renal transplant, leukemia, chronic debilitating disease, diabetes mellitus, steroids, chemotherapy, AIDS, radiotherapy
◊ Most common type of fungi found with opportunistic infections!

(b) delayed esophageal emptying: scleroderma, strictures, achalasia, S/P fundoplication

(c) antibiotics

Path: patchy, creamy-white plaques covering a friable erythematous mucosa

Histo: mucosal plaques = necrotic epithelial debris + fungal colonies

- severe odynophagia (= painful swallowing from segmental spasm); dysphagia (= difficulty swallowing)
- intense retro- / substernal pain
- associated with thrush (= oropharyngeal moniliasis) in 20–50–80%

Location: predilection for upper ½ of esophagus

√ involvement of long esophageal segments:
√ "cobblestone" appearance = mucosal nodularity in early stage ← growth of colonies on surface
√ longitudinal plaques = grouping of tiny 1–2-mm nodular filling defects with linear orientation (= heaped-up areas of mucosal plaques)
√ shaggy / fuzzy / serrated contour ← coalescent plaques, pseudomembranes, erosions, ulcerations, intramural hemorrhage) in fulminant candidiasis of AIDS

√ narrowed lumen ← spasm, pseudomembranes, marked edema
√ "intramural diverticulosis" = multiple tiny indentations + protrusions
√ sluggish / absent primary peristalsis
√ strictures (rare)
√ mycetoma resembling large intraluminal tumor (rare)

Diagnostic sensitivity: endoscopy (97%), double contrast (88%), single contrast (55%)

Cx: (1) Systemic candidiasis ("microabscesses" in liver, spleen, kidney)
(2) Gastric bezoar ← large fungus ball (after long-standing esophageal candidiasis)

Rx: ketoconazole / fluconazole

DDx: glycogen acanthosis, reflux esophagitis, superficial spreading carcinoma, artifacts (undissolved effervescent crystals, air bubbles, retained food particles), herpes esophagitis, acute caustic ingestion, intramural pseudo-diverticulosis, squamous papillomatosis, Barrett esophagus, epidermolysis bullosa, varices

Caustic Esophagitis

= CORROSIVE ESOPHAGITIS

Corrosive agents: [= strong acids or strong bases]
hydrochloric acid, lye (sodium hydroxide), washing soda (sodium carbonate), household cleaners, iodine, silver nitrate, household bleaches, Clinitest® tablets (tend to be neutralized by gastric acid)

◊ Severity of injury dependent on contact time + concentration of corrosive material!

Associated with: injury to pharynx + stomach (7–8%): antral burns more common with acid (buffering effect of gastric acid on alkali)

Location: middle + lower thirds of esophagus

Stage I : acute necrosis from protein coagulation
- √ mucosal blurring (edema)
- √ diffusely atonic + dilated esophagus
- √ tertiary contractions / spasm

Stage II : frank ulceration in 3–5 days
- √ ulceration + pseudomembranes

Stage III : scarring + stricture from fibroblastic activity
- √ long segmental stricture after 10 days when acute edema subsides (7–30%)
- √ one / more strictures usually 1–3 months after initial injury in unpredictable location
- √ entire esophagus reduced to filiform structure

Cx: (1) Esophageal / gastric perforation during ulcerative stage
(2) Squamous cell carcinoma in injured segment

Rx: dilatation procedure / esophageal replacement surgery

Chronic Esophagitis

√ luminal narrowing with tapered transition to normal + proximal dilatation
√ circumferential / eccentric stricture
√ sacculations = pseudodiverticula

Drug-induced Esophagitis

= contact esophagitis ← oral medications = "pill esophagitis"

Agents: potassium chloride, antibiotics (tetracycline, doxycycline), quinidine, nonsteroidal antiinflammatory agents (aspirin), ascorbic acid, ferrous sulfate ($FeSO_4$), alprenolol chloride, emepronium bromide, alendronate (= inhibitor of osteoclastic activity)

Esophageal injury is usually caustic ← drug's chemical reaction upon direct contact with the esophageal mucosa:
(a) Antibiotics (doxycycline, tetracycline) are acidic resulting in a chemical mucosal burn
(b) Ferrous sulfate and potassium chloride cause injury ← hyperosmolarity + changes in local blood flow

Histo: inflammatory changes + granulation tissue; sometimes with foreign material ± dyskeratotic cells indicative of apoptosis of squamous epithelial cells

- history of taking medication with little / no water immediately before going to bed; severe odynophagia

• rapid clinical improvement after withdrawal of offending agent

Location: midesophagus at site of normal extrinsic impressions by aortic arch / left mainstem bronchus / left atrium

Esophagram:

√ single ulcer / localized cluster of multiple tiny ulcers (more common) distributed circumferentially:

√ EN FACE: central punctate collections of barium surrounded by a radiolucent halo (= mound of edema)

√ IN PROFILE: elongated flat plaquelike filling defects

√ superficial solitary / several discrete ulcers with sharply delineated margins with commonly normal surrounding mucosa

CT:

√ ulcers may be invisible

Esophageal ulcers induced by medications are frequently small and discrete often corresponding to the direct site of contact.

Prognosis: ulcers heal within 7–10 days after cessation of offending medication

DDx: herpes esophagitis (immunosuppressed patient, less localized); reflux esophagitis (heartburn, distal esophagus near GE junction); Crohn esophagitis

Reflux Esophagitis

= esophageal inflammation ← reflux of acid-peptic contents of the stomach

Prevalence: in 20% of gastroesophageal reflux

Pathophysiology: reflux occurs if resting pressure of LES < 5 mmHg (may be normal event if followed by rapid clearing)

Histo: basal cell hyperplasia with wall thickening + thinning of epithelium, mucosal edema + erosions, inflammatory infiltrate

Determinants: (1) Frequency of reflux
(2) Adequacy of clearing mechanism
(3) Volume of refluxed material
(4) Potency of refluxed material
(5) Tissue resistance

Reflux preventing features:

(1) Lower esophageal sphincter
(2) Phrenoesophageal membrane
(3) Length of subdiaphragmatic esophagus
(4) Gastroesophageal angle of His (70–110°)

May be associated with: sliding hiatal hernia (in > 90%), scleroderma, nasogastric intubation

• heartburn, epigastric discomfort, choking, globus hystericus

• retrosternal pain, thoracic / cervical dysphagia

Site: usually lower ⅓ to lower ½ with continuous disease extending proximally from GE junction

Length: usually 1–4 cm

Consider a malignant tumor when a distal esophageal stricture is present in the absence of a hernia!

√ initial esophageal insult:
√ smooth tapered segment of concentric esophageal narrowing ← edema / spasm / stricture
√ poorly defined tiny mucosal elevations ("mucosal granularity") on thickened / nodular longitudinal folds in early stages ← mucosal edema + inflammation
√ single marginal ulcer / erosion at / adjacent to GE junction
√ multiple areas of superficial ulceration in distal esophagus
√ prominent mucosal fold ending in polypoid protuberance within hiatal hernia / cardia

› effect of secondary esophageal scarring:
√ asymmetric narrowing ← asymmetric scarring
√ 1 to 2 sacculations ← outward ballooning of esophageal wall between areas of fibrosis (DDx: ulcer)
√ "felinization" = "stepladder" appearance of longitudinal scarring = fixed transverse ridges with barium trapped in between (DDx: "feline" esophagus)
√ focal cluster of intramural pseudodiverticula
√ very short segment of ringlike narrowing at the GE junction above a hiatal hernia (DDx: Schatzki ring)

› effect on esophageal function:
√ interruption of primary peristalsis at inflamed segment
√ nonperistaltic waves in distal esophagus following deglutition (85%)
√ incomplete relaxation of LES (75%), incompetent sphincter (33%)
√ acid test = abnormal motility elicited by acid barium (pH 1.7)

NUC (pertechnetate):
√ esophageal activity ← Barrett esophagus activity similar to ectopic gastric mucosa

Reflux tests:

1. **Reflux of barium** in RPO position, may be elicited by coughing / deep respiratory movements / swallowing of saliva + water / anteflexion in erect position: only in 50% accurate
2. **Water-siphon test**: in 5% false negative; large number of false positives
3. **Tuttle test** = measurement of esophageal pH: 96% accurate
4. **Radionuclide gastroesophageal reflux test** (typically combined with gastric emptying test):
   Technique: ROI drawn over distal esophagus + compared with time-activity curve over stomach, scaled to 4%
   √ esophageal activity > 4% stomach activity

Cx of reflux:

(a) from acid + pepsin acting on esophageal mucosa:
   1. Motility disturbance
   2. Stricture
   3. Schatzki ring
   4. Barrett esophagus
   5. Iron-deficiency anemia
   6. Reflux / peptic esophagitis

(b) from aspiration of gastric contents

1. Acute aspiration pneumonia
2. Mendelson syndrome
3. Pulmonary fibrosis

Viral Esophagitis

Predisposed: immunocompromised, eg, underlying malignancy, debilitating illness, radiation treatment, steroids, chemotherapy, AIDS

Cytomegalovirus Esophagitis

Organism: member of herpesvirus group
Associated with: AIDS
• severe odynophagia
√ diffusely normal mucosal background
√ one / more giant ovoid flat ulcers (up to several cm in size) near gastroesophageal junction
√ discrete small superficial ulcers indistinguishable from herpes esophagitis (uncommon)
Rx: ganciclovir (relatively toxic)
Dx: endoscopic brushings, biopsy specimen, cultures

Herpes Esophagitis

◊ 2nd most common cause of opportunistic infection!
Organism: Herpes simplex virus type I (DNA core virus) secreted in saliva of 2% of healthy population
Age: 15–30 years; usually males
Predisposed: immunocompromised patient with HIV, organ transplant, and on chemotherapy; may occur in immunocompetent patient
• history of recent exposure to sexual partners with herpetic lesions on lips / buccal mucosa
• flulike prodrome of 3–10 days (headaches, fever, sore throat, upper respiratory symptoms, myalgia)
• severe acute dysphagia / odynophagia
May be associated with: oropharyngeal herpetic lesions / oropharyngeal candidiasis
Location: midesophagus (level of left main bronchus)
√ initially vesicles / blisters that subsequently rupture
√ multiple small discrete superficial punctate / round / linear / serpentine / stellate (often "diamond-shaped") punched-out ulcers surrounded by radiolucent halo of edematous mucosa (in > 50%)
√ intervening mucosa normal (without plaques)
√ multiple plaquelike lesions (only with severe infection)
Dx: rising serum titer for HSV type I, viral culture, biopsy (immunofluorescent staining for HSV antigen, demonstration of intranuclear inclusions)
Rx: oral / intravenous acyclovir
Prognosis: resolution of symptoms in 3–14 days
DDx: drug-induced esophagitis, Crohn disease, esophageal intramural pseudodiverticulosis

Human Immunodeficiency Virus Esophagitis

- maculopapular rash + ulcers of soft palate (occasionally)
- recent seroconversion / known AIDS

√ one / more giant (> 1 cm) flat ovoid / diamond-shaped ulcers (at time of seroconversion) indistinguishable from CMV esophagitis

Dx: per exclusion (brushings, biopsies, cultures negative for CMV)

Rx: oral steroids

DDx: CMV esophagitis, mycobacterial esophagitis, actinomycosis, potassium chloride, quinidine, caustic ingestion, nasogastric intubation, radiation therapy, endoscopic sclerotherapy

FAMILIAL ADENOMATOUS POLYPOSIS

= FAMILIAL MULTIPLE POLYPOSIS

Frequency: 1÷7,000 to 1÷24,000 live births

Genetics: autosomal dominant disease with 80% penetrance; gene localized on chromosome 5; sporadic occurrence in ⅓

Path: tubular / villotubular adenomatous polyps; usually about 1,000 adenomas

Age: polyps appear around puberty

- family history of colonic polyps (66%)
  - ◊ Screening of family members after puberty!
- clinical symptoms begin during 3rd–4th decade (range, 5–55 years)
- vague abdominal pain, weight loss, diarrhea, bloody stools
- protein-losing enteropathy (occasionally)

Associated with:

(1) Hamartomas of stomach in 49%

(2) Adenomas of duodenum in 25%

(3) Periampullary carcinoma

(4) Desmoid tumors in 9–18%: 1000 x fold increased risk; multiple desmoids in 40%

√ "carpet of polyps" = myriad of 2–3 mm (up to 2 cm) polypoid lesions

@ Colon (100%): more numerous in distal colon; always affecting rectum

√ normal haustral pattern

@ Stomach (5%)

@ Small bowel (< 5%)

Cx: malignant transformation of adenomas: colon > stomach > small bowel in 12% [30%] {100%} by 5 [10] {20} years after diagnosis; carcinomatous development usually at age 20–40 years; multiple carcinomas in 48%

- ◊ 331-fold increased risk of small bowel adenocarcinoma compared to general population after colectomy
- ◊ Periampullary carcinoma is the most common cause of death after prophylactic colectomy!

Rx: prophylactic total colectomy in late teens / early twenties before symptoms develop

(1) Permanent ileostomy

(2) Continent endorectal pull-through pouch

(3) Kock pouch (= distal ileum formed into a one-way valve by invaginating the bowel

at skin site)

DDx: other polyposes, lymphoid hyperplasia, lymphosarcoma, ulcerative colitis with inflammatory pseudopolyps

FIBROVASCULAR POLYP OF ESOPHAGUS

= HAMARTOMA = LIPOMA = FIBROMA = FIBROLIPOMA = FIBROMYXOMA = FIBROEPITHELIAL POLYP

= intraluminal esophageal polyp

Prevalence: 1–2% of benign esophageal tumors

Cause: over time enlarging loose submucosal tissue in Laimer triangle just inferior to cricopharyngeus

[Eduard Laimer (1857–1934), anatomist in Graz, Austria]

Path: elongated intraluminal mass of fibrous + adipose tissue of varying proportions covered by normal squamous epithelium

Age: 53 (range, 1–88) years; M > F

- dysphagia (69%), cough, respiratory distress
- regurgitation of polyp into mouth, foreign-body sensation

Site: near level of cricopharyngeus / lower hypopharynx

Size: 7 cm long at time of presentation extending inferiorly as far as into the stomach

Barium:

√ giant sausage-shaped intraluminal mass originating from cervical esophagus (pedicle usually not identified)

CT / MR:

√ heterogeneous mass with areas of soft-tissue and fat attenuation

√ ± punctate calcifications (occasionally)

The cross-sectional appearance of fibrovascular polyps depends on the proportions of fat and fibrous tissue.

Cx: asphyxia + sudden death ← after regurgitation of polyp into pharynx / mouth

Rx: surgical removal (10% recurrence)

FOREIGN BODY INGESTION

Cause:

(a) accidental: patients with altered mental status / dentures

(b) nonaccidental: "body packing" to smuggle illicit drugs (swallowed, inserted into vagina / rectum)

- pain, excessive salivation, cough, difficulty breathing
- nausea, vomiting

Type:

(a) NONDIGESTABLE FOOD COMPONENT: fish / chicken bone, toothpick

(b) HIGH-DENSITY DEVICE: coin, toy, key, battery, jewelry, pin, needle, nail, razor blade, clip, denture, dislodged tooth, crown

Location of intraluminal lodgement:

esophagus (68%), stomach (11.6%), small bowel (3.3%), colon (11.6%)

› trapped in appendix, diverticula, proximal to stricture: calcified seeds + pits, birdshot

CT:

√ wood difficult to recognize:
√ air attenuation in acute phase mimicking bubbles of gas
√ becoming progressively isoattenuating in subacute phase
√ hyperattenuating ← granulomatous reaction
√ calcified in chronic phase
√ ± pneumoperitoneum (rare ← progressive impaction of foreign body in intestinal wall surrounded by fibrin. omentum, bowel loops that prevent leakage of gas)

Cx: (1) Perforation(< 1%): fish / chicken bone, toothpick
Location: predominantly in ileocecal region, rectosigmoid, areas of bowel narrowing, angulation, pouching, diverticula, adhesions, surgical anastomosis
(2) Toxic effect / liquefaction necrosis: button battery
◊ Any battery lodged in esophagus should be removed promptly!

Rx: most foreign bodies are amenable to endoscopic removal

GALLSTONE ILEUS

[misnomer: mechanical obstruction, not ileus]

Frequency: 0.4–5.0% of all intestinal obstructions ← risk increases with age = 20% [24%] of obstruction in patients > 65 [> 70] years; in 1 of 6 perforations; develops in 0.3–0.5% of patients with cholelithiasis

Etiology: biliary disease (90%), peptic ulcer disease, cancer, trauma
◊ Most eroded gallstones are excreted uneventfully!

Mechanism: cholecystoenteric fistula / following endoscopic sphincterotomy

Age: average 65–75 years; M÷F = 1÷4 – 1÷7

- previous history of gallbladder disease
- intermittent episodes of acute colicky abdominal pain (20–30%)
- nausea, vomiting, fever, distension, obstipation

Location: terminal ileum (60%), proximal ileum / distal jejunum (26%), distal ileum (10%), sigmoid colon

The most obstructive gallstones are > 2.5 cm in diameter and located in ileum (60%) / jejunum (26%). The terminal ileum is the narrowest segment and thus the most likely site of obstruction.

√ **Rigler triad** on plain film (in 15%), on CT (in 78%):
1. Partial / complete intestinal obstruction (usually in small bowel), "string of rosary beads" = multiple small amounts of air trapped between dilated + stretched valvulae conniventes (in 86%)
2. Pneumobilia (in 69%)
3. Ectopic calcified gallstone in lower abdomen (in 25%): stones are commonly > 2.5 cm in diameter

√ change in position of previously identified gallstone

UGI / BE:
√ smooth polypoid filling defect (= gallstone) at site of obstruction
√ well-contained localized barium collection lateral to first portion of duodenum (barium-filled collapsed GB + possibly biliary ducts)

Fistulous communication:
cholecystoduodenal (60%), choledochoduodenal, cholecystocolic, choledochocolic, cholecystogastric

CT (91% sensitive):
√ air / enteric contrast in GB (fistula from GB to duodenum)
√ thickened duodenal wall
√ gallstone at transition point of bowel obstruction

Cx: recurrent gallstone ileus in 5–10% (additional silent calculi more proximally)

Rx: removal of stone(s) + cholecystectomy + fistula repair

Prognosis: high mortality of up to 18%

Bouveret Syndrome

[Léon Bouveret (1850–1929), French internist in Lyon]

= gastric outlet obstruction ← impacted gallstone in duodenum / pylorus ← cholecystoenteric fistula

Age: most commonly in elderly woman

• nausea, vomiting, epigastric pain

CT:
√ obstructing ectopic gallstone in distal stomach / duodenum
√ air in gallbladder / biliary tree

Mortality rate: 12–33%

GANGLIOCYTIC PARAGANGLIOMA

= rare benign tumor of the GI tract

Frequency: < 100 cases reported

Origin: pancreatic endocrine rest that remained when the ventral primordium rotated around the duodenum

Age: 50–60 years of age; M÷F = 2÷1

Location: almost exclusively in 2nd portion of duodenum near ampulla of Vater on medial / lateral wall of duodenum

• GI hemorrhage, abdominal pain

√ polypoid smooth-surfaced intraluminal mass
√ homogeneously enhancing mural / extrinsic solid mass of soft-tissue attenuation
√ well-circumscribed hypoechoic mass contiguous with bowel
√ no biliary duct dilatation

DDx: adenocarcinoma (biliary duct dilatation, hypovascular), leiomyosarcoma (cystic internal hemorrhage / necrosis), hemangioma, duplication cyst, choledochal cyst, lipoma, hamartoma, inflammatory fibroid polyp (distal small bowel), lymphoma (isolated in stomach and ileum)

GARDNER SYNDROME

[Eldon John Gardner (1909–1989), geneticist at Utah State University in Logan, Utah]

= autosomal dominant disease with variable penetrance as a variant of familial adenomatous polyposis characterized by a triad of

(1) Colorectal polyposis
(2) Osteomas
(3) Soft-tissue tumors

Incidence: 1÷14,000

Cause: mutation in tumor suppressor gene APC (adenomatous polyposis coli gene) on chromosome 5q21 to 5q22; in 20% new mutation
◊ Familial polyposis + Gardner syndrome may occur in the same family!

Histo: adenomatous polyps → malignant transformation

Age: 15–30 years (range, 2 months – 70 years)

Average life expectancy: 35–40 years

Associated with: ? MEA complex
(1) Periampullary / duodenal carcinoma (12%)
(2) Papillary thyroid carcinoma: often multicentric
(3) Adrenal adenoma / carcinoma
(4) Parathyroid adenoma
(5) Pituitary chromophobe adenoma
(6) Pancreatic neoplasm (4 x of general population)
(7) Hepatoblastoma (800 x of general population)
(8) Hepatocellular carcinoma
(9) Carcinoid, adenoma of small bowel
(10) Nasal angiofibroma
(11) Retroperitoneal leiomyoma
◊ Lifelong screening for malignancies!

◊ Extraintestinal manifestations occur usually earlier than in intestinal polyposis!

• skin pigmentation
• cramping abdominal pain, weight loss, diarrhea

@ Polyposis
Location: colon (100%), stomach (5–68%), duodenum (90%), ampulla of Vater, small bowel (< 5%)
√ multiple colonic polyps appearing during puberty, increasing in number during 3rd–4th decade
√ lymphoid hyperplasia of terminal ileum
√ hamartomas of stomach
√ intussusception
Cx: small bowel / colonic obstruction; malignant transformation

@ Soft-tissue tumors
(a) sebaceous / epidermoid inclusion cysts: scalp, back, face, extremities
(b) fibroma, lipoma, leiomyoma, neurofibroma
(c) **desmoid tumors** (3–10–34%)
Location: abdominal wall; extra- / intraabdominal
◊ Tend to occur after colectomy
√ peritoneal adhesions ← desmoplastic tendency
√ mesenteric fibrosis, retroperitoneal fibrosis
• urinary tract obstruction, bowel obstruction
Prognosis: frequent recurrence (⅓) after resection / radiation therapy

(d) mammary fibromatosis
(e) marked keloid formation, hypertrophied scars (anterior abdominal wall) arise 1–3 years after surgery

@ Osteomatosis of membranous bone (50%)
Location: calvarium, mandible (81%), maxilla, ribs, long bones

@ Long bones
Location of osteomas: paranasal sinuses; outer table of skull (frequent); mandible (at angle)
√ slight shortening + bowing
√ endosteal cortical thickening
√ may have solid periosteal cortical thickening
√ wavy cortical thickening of superior aspect of ribs
√ osteomas / exostoses may protrude from periosteal surface

@ Teeth
√ odontoma, unerupted / supernumerary teeth, hypercementosis
√ tendency toward numerous caries → dental prosthesis at early age

Cx: malignant transformation of colonic polyps in 100% (average age at death is 41 years if untreated); high incidence of carcinoma of duodenum / ampulla of Vater

Prophylaxis: gastrointestinal surveillance, thyroid screening, ophthalmologic evaluation for retinal pigmentation anomalies; screening of family members starting at age 15

Rx: prophylactic total colectomy at about 20 years of age

GASTRIC CARCINOMA

◊ 4th most common cancer worldwide (most prevalent malignancy in Korea, China, Japan), 6th leading cause of cancer deaths

Prevalence: declining with 24,000 cases annually in USA

Risk factors: smoking, nitrites, nitrates, pickled vegetables

Predisposing factors:
H. pylori gastritis, chronic atrophic gastritis, adenomatous + villous polyp (7–27% are malignant), gastrojejunostomy, partial gastrectomy (Billroth II > Billroth I), pernicious anemia (risk factor of 2), Ménétrier disease (?)

Histo: adenocarcinoma (95%); rarely squamous cell carcinoma / adenoacanthoma

Staging (American Joint Committee on Cancer):

T1	tumor invades lamina propria / submucosa
T2	tumor invades muscularis propria / subserosa
T3	tumor penetrates serosa (= visceral peritoneum)
T4a	invasion of adjacent contiguous tissues
T4b	invasion of adjacent organs, diaphragm, abdominal wall
N1	involvement of 1–6 perigastric nodes within 3 cm of primary along greater / lesser curvature
N2	involvement of 7–15 regional nodes > 3 cm from primary along branches of celiac axis
N3	> 15 paraaortic, hepatoduodenal, retropancreatic, mesenteric nodes

M1 distant metastases

◊ Endoscopic US is the most reliable method for T staging with a diagnostic rate of 78%–93%!

Location: mostly distal third of stomach + cardia; 60% on lesser curvature, 10% on greater curvature; esophagogastric junction in 30%; transpyloric spread in 5–25% (for lymphoma 40%)

Probability of malignancy of an ulcer:
at lesser curvature 10–15%, at greater curvature 70%, in fundus 90%

Morphology:

1. Polypoid / fungating carcinoma
2. Ulcerating / penetrating carcinoma (70%)
3. Infiltrating / scirrhous carcinoma (5–15%) = linitis plastica
   Histo: frequently signet ring cell type + increase in fibrous tissue
   Location: antrum, fundus + body (38%)
   √ firmness, rigidity, reduced capacity of stomach, aperistalsis in involved area
   √ granular / polypoid folds with encircling growth
4. Superficial spreading carcinoma
   = confined to mucosa / submucosa; 5-year survival of 90%
   √ patch of nodularity
   √ little loss of elasticity
5. Advanced bulky carcinoma

The depth of mural invasion and presence of extragastric lesions can be determined with endoscopic US and CT.

• GI bleeding, abdominal pain, weight loss

UGI:
√ rigidity
√ filling defect
√ amputation of folds ± ulceration ± stenosis
√ miliary / punctate calcifications ← mucinous adenocarcinoma

CT:
√ irregular nodular luminal surface
√ asymmetric thickening of folds
√ mass of uniform density / varying attenuation
√ wall thickness > 6 mm (with gas distension) and 13 mm (with positive contrast material distension):
  √ diffuse low attenuation in mucinous carcinoma
√ increased density in perigastric fat
√ enhancement exclusively in linitis plastica type
√ nodules of serosal surface ← dilated surface lymphatics
√ diameter of esophagus at gastroesophageal junction larger than adjacent aorta (DDx: hiatal hernia)
√ lymphadenopathy below level of renal pedicle (3%)

Metastases:

1. Direct invasion: along peritoneal ligaments

(a) gastrocolic lig.: transverse colon, pancreas
(b) gastrohepatic + hepatoduodenal ligament: liver

2. Lymphatic: to local lymph nodes
   √ short-axis diameter of 8–10 mm
   √ nearly round shape
   √ central necrosis
   √ marked / heterogeneous enhancement
3. Hematogenous: to liver (most common), adrenals, ovary, bone (1.8%), lymphangitic carcinomatosis of lung (rare)
4. Peritoneal seeding
   › on rectal wall = **Blumer shelf**
   [George Blumer (1872–1962), surgeon at Albany Medical College, Cooper Medical College, University of California Medical School, Yale University]
   › on ovaries = **Krukenberg tumor**
   [Friedrich Ernst Krukenberg (1871–1946), thesis of doctorate on peculiar ovarian tumors, ophthalmologist in Halle, Germany]
5. left supraclavicular lymph node = **Virchow node**
   [Rudolph Carl Virchow (1821–1902), chair of pathology at university of Würzburg and Charité Hospital in Berlin, Germany, editor of Archiv für pathologische Anatomie und Physiologie und für klinische Medizin]

Prognosis: mean survival time of 7–8 months
- › 85% 5-year survival in stage T1
- › 52% 5-year survival in stage T2
- › 47% 5-year survival in stage T3
- › 17% 5-year survival in stage N1-2
- › 5% 5-year survival in stage N3

Early Gastric Cancer (20%)

= invasion limited to mucosa + submucosa (T1 lesion) regardless of lymph node involvement

Classification of Japan Research Society for Gastric Cancer:

Type	I	protruded type = > 5 mm in height with protrusion into gastric lumen (10–20%)
Type	II	superficial type = < 5 mm in height
	IIa	slightly elevated surface (10–20%)
	IIb	flat / almost unrecognizable (2%)
	IIc	slightly depressed surface (50–60%)
Type	III	excavated / ulcerated type (5–10%)

Prognosis: 5-year survival rate of 85–100%

Advanced Gastric Cancer (T2 lesion and higher)

Bormann classification:

Type 1 broad-based elevated polypoid lesion
Type 2 elevated lesion + ulceration + well-demarcated margin
Type 3 elevated lesion + ulceration + ill-defined margin

Type 4 ill-defined flat lesion
Type 5 unclassified, no apparent elevation

Prognosis: 5-year survival rate of 7–27%

Cx: perforation

GASTRIC DIVERTICULUM

◊ stomach is the least common site of diverticula
Frequency: 1÷600 to 1÷2,400 of UGI studies
Etiology: (a) traction ← scarring / periantral inflammation = true diverticulum
(b) pulsion (less common) = false diverticulum
Age: beyond 40 years
Often associated with: aberrant pancreas in antral location
Location: juxtacardiac on posterior wall (75%), prepyloric (15–22%), greater curve (3%)
√ pliability + varying degrees of distension
√ NO mass, edema or rigidity of adjacent folds
DDx: small ulcer in intramural-extramucosal mass

GASTRIC POLYP

Frequency: 1.5–5%, most common benign gastric tumor
Associated with: hyperacidity + ulcers, chronic atrophic gastritis, gastric carcinoma
A. NONNEOPLASTIC
1. **Inflammatory polyp of stomach** (75–90%)
= HYPERPLASTIC POLYP = REGENERATIVE POLYP
Histo: cystically dilated glands lined by gastric epithelium + acute and chronic inflammatory infiltrates in lamina propria
Associated with: chronic atrophic gastritis, pernicious anemia
Location: predominantly in fundus + body; usually multiple
√ sharply delineated polyp with smooth circular border
√ "Mexican hat" sign = stalk seen en face overlying the head of polyp
√ sessile / pedunculated
√ usually < 2 cm in diameter without progression
√ no contour defect of stomach
Prognosis: no malignant potential
2. **Hamartomatous polyp of stomach** (rare)
Histo: densely packed gastric glands + bundles of smooth muscle
Associated with: Peutz-Jeghers syndrome
√ sessile / pedunculated
√ usually < 2 cm in diameter
3. **Retention polyp of stomach** (rare)
Histo: dilated cystic glands + stroma
Associated with: Cronkhite-Canada syndrome
B. NEOPLASTIC
1. **Adenomatous polyp of stomach** (10–20%)
= true neoplasm with malignant potential (10–80%, increasing with size)
Age: increasing incidence with age; M÷F = 2÷1
Histo: intestinal metaplasia (common) + marked cellular atypism
Associated with: Gardner syndrome; coexistent with gastric carcinoma in 35%
Location: more commonly in antrum (antrum spared in Gardner syndrome)

√ broad-based elliptical / mushroom-shaped polyp ± pedicle; usually solitary
√ usually > 2 cm in diameter (in 80%)
√ smooth / irregular lobulated contour

2. **Villous polyp of stomach** (rare)
√ trabeculated / lobulated slightly irregular contour
Cx: malignant transformation

DDx: (1) Ménétrier disease (antrum spared)
(2) Eosinophilic polyp (peripheral eosinophilia, linitis plastica appearance, small bowel changes)
(3) Lymphoma
(4) Carcinoma

GASTRIC ULCER

Benign Gastric Ulcer (95%)

Cause:

A. HORMONAL
1. Zollinger-Ellison syndrome
2. Hyperparathyroidism (in 1.3–24.0%)
duodenum÷stomach = 4÷1; M÷F = 3÷1
◊ Duodenal ulcers predominate in females!
◊ Gastric ulcers predominate in males!
• absence of gastric hypersecretion
3. Steroid-induced ulcer
gastric > duodenal location; frequently multiple + deep ulcers; commonly associated with erosions
• bleeding (in ⅓)
4. Stress, severe prolonged illness
5. Cerebral disease = Cushing ulcer
6. Curling ulcer (burns) (in 0.09–2.60%)
7. Retained gastric antrum
8. Uremia

B. INFLAMMATION
1. Peptic ulcer disease
2. Gastritis
3. Radiation-induced ulcer
4. Intubation
5. Stasis ulcer proximal to pyloric / duodenal obstruction

C. BENIGN MASS
1. Leiomyoma
2. Granulomatous disease
3. Pseudolymphoma (lymphoid hyperplasia)

D. DRUGS
ASA: greater curvature

Pathophysiology: disrupted mucosal barrier (H. pylori) with vulnerability to acid + secretion of large volume of gastric juice containing little acid

Incidence: 5÷10,000; 100,000 annually (USA)

Age peak: 55–65 years; M÷F = 1÷1

Multiplicity:

(a) multiple in 2–8% (17–24% at autopsy), especially in patients on aspirin

(b) coexistent duodenal ulcer in 5–64%; gastric÷duodenal = 1÷3 [1÷7] in adults [children]

• abdominal pain: in 30% at night, 25% precipitated by food

Location: lesser curvature at junction of corpus + antrum within 7 cm from pylorus; proximal half of stomach in older patients (geriatric ulcer); adjacent to GE junction within hiatal hernia

√ ulcer size usually < 2 cm (range 1–250 mm); in 4% > 4 cm

√ round / ovoid / linear shape

√ **Haudek niche** = conical / collar button-shaped barium collection projecting outside gastric contour (profile view)

√ **Hampton line** = 1-mm thin straight lucent line traversing the orifice of the ulcer niche (seen on profile view + with little gastric distension) = ledge of touching overhanging gastric mucosa of undermined benign ulcer

√ ulcer collar = smooth thick lucent band interposed between the niche and gastric lumen ← thickened rim of edematous gastric wall in well-distended stomach

√ ulcer mound = smooth, sharply delineated, gently sloping extensive tissue mass surrounding a benign ulcer ← edema + lack of wall distensibility in well-distended stomach

√ ulcer crater = round / oval barium collection with smooth border on dependent side (viewed en face)

√ halo defect = wide lucent band symmetrically surrounding ulcer ← extensive ulcer mound (viewed en face)

√ ring shadow: ulcer on nondependent side (en face view)

√ radiating thick folds extending directly to crater edge fusing with effaced marginal fold of ulcer collar / halo of ulcer mound

√ incisura defect = smooth, deep, narrow, sharp indentation on greater curvature opposite a niche on lesser curvature at / slightly below the level of the ulcer ← spastic contraction of circular muscle fibers

Prognosis: healing in 50% by 3 weeks, in 100% by 6–8 weeks; slower healing in older patients; only complete healing proves benignancy

Cx: (1) Bleeding

(2) Perforated ulcer

(a) anterior wall / curvatures → into peritoneal space

(b) posterior wall → into lesser sac

√ free intraperitoneal fluid / gas

√ extraluminal oral contrast material

√ wall discontinuity

(3) Fistula

◊ Most common cause of gastrocolic fistula!

Benign Postbulbar Peptic Ulcer *(10%)*

Cause: Helicobacter pylori infection

Age: adulthood; M÷F = 7÷1

Site: majority on medial wall of proximal descending duodenum (upper 2nd portion above major papilla of Vater)

- localized epigastric pain 2–4 hours after meal
- hemorrhage in 66%

√ edema + spasm may obscure ulcer

√ smooth rounded indentation of lateral wall

√ incisura pointing to ulcer

√ occasionally barium reflux into common bile duct

√ ring stricture

√ stress- and drug-induced ulcers heal without deformity

Malignant Gastric Ulcer (5%)

Cause:

1. Gastric carcinoma
2. Lymphoma (2% of all gastric neoplasms)
   √ multiple ulcers with aneurysmal appearance
3. Leiomyosarcoma, neurogenic sarcoma, fibrosarcoma, liposarcoma
4. Metastases
   (a) hematogenic: malignant melanoma, breast cancer, lung cancer
   (b) per continuum: pancreas, colon, kidney

Location: anywhere within stomach; fundal ulcers above level of cardia are usually malignant

√ ulcer location within gastric lumen, ie, not projecting beyond expected margin of stomach (profile view)

√ eccentrically located ulcer within the tumor

√ irregularly shaped ulcer

√ shallow ulcer with width greater than depth

√ nodular ulcer floor

√ abrupt transition between normal mucosa + abnormal tissue at some distance (usually 2–4 cm) from ulcer edge

√ rolled / rounded / shouldered edges surrounding ulcer

√ nodular irregular folds approaching ulcer with fused / clubbed / amputated tips

√ rigidity / lack of distensibility

√ associated large irregular mass

√ **Carman "meniscus" sign** = lenticular barium collection in ulcer crater trapped by heaped up edges; convex relative to lumen on profile view under compression; found in specific type of ulcerating carcinoma, but seen only rarely

[Russell Daniel Carman (1875–1926), professor of radiology at St. Louis and Washington university and head of Mayo section on roentgenology in 1913, president of RSNA and ARRS]

√ **Kirklin meniscus complex** = Carman sign (appearance of crater) + radiolucent slightly elevated rolled border

Prognosis: partial healing may occur

Gastric Ulcer		
Sign	*Benign*	*Malignant*
Crater	round, ovoid	irregular
Radiating folds	symmetric	nodular, clubbed, fused
Areae gastricae	preserved	destroyed
Projection	outside lumen	inside lumen
Ulcer mound	smooth	rolled edge

GASTRIC VARICES

Cause: portal hypertension (varices seen in 2–78%); splenic vein obstruction ← pancreatitis, pancreatic carcinoma, pseudocyst

Location: (a) esophagogastric junction (most common)
(b) along lesser curvature (in 11–75% of patients with portal hypertension / cirrhosis)

Feeding vessels:

1. Left gastric vein (between splenic vein + stomach)
2. Short gastric veins (between spleen + fundus)
3. Retrogastric vein (between splenic vein + GE junction)

• increased prevalence of portosystemic encephalopathy
√ barium study (65–89% rate of detection):
√ lobulated folds / polypoid masses in fundus
√ endoscopy: most practical method
√ splenic portography
√ hepatofugal blood flow along SMV into left gastric + splenic vein

Cx: variceal bleeding in 3–10–36%
◊ Gastric varices bleed less frequently but more severely than esophageal varices!

DDx of small intramural subepithelial mass:
carcinoid tumor, glomus tumor, ectopic pancreas (all usually with stronger enhancement)

GASTRIC VOLVULUS

◊ SURGICAL EMERGENCY!
= abnormal torsion (twisting) of stomach, usually > 180° → complete obstruction → ischemia → perforation
◊ Use the term organoaxial / mesenteroaxial ***rotation*** if obstruction not present!

The term gastric volvulus implies at least 180° gastric rotation WITH gastric outlet obstruction. Organoaxial / mesenteroaxial rotation alone do not define volvulus. Coronal images are often more diagnostic than axial images alone.

Degrees of torsion:

(1) Partial / incomplete volvulus = chronic form (common)
= rotation of stomach < 180° without vascular compromise
• may be asymptomatic

√ ingested contrast may pass through stomach

(2) COMPLETE volvulus = acute form

= rotation of stomach > 180°

◊ Surgical emergency ← increased risk of ischemia, necrosis, perforation, shock

√ stomach becomes dilated + fills with fluid

√ oral contrast is retained in stomach

Etiology:

(a) abnormality of suspensory ligaments

(b) unusually long gastrohepatic + gastrocolic mesenteries

Anatomy of ligaments:

gastrohepatic lig. at lesser curvature; gastrosplenic + gastrocolic ligg. at greater curvature; gastrophrenic lig. at posterior fundus; attachment to esophagus at gastroesophageal junction; attachment to duodenum at pylorus

Predisposing factors:

paraesophageal hernia (33%), ligamentous laxity (sliding hernia), eventration of diaphragm, phrenic nerve paralysis, splenic abnormalities (asplenia, polysplenia, splenomegaly, prior splenectomy), Bochdalek hernia (in children)

Peak age: 40–50 years (in 20% in infants < 1 year of age); most often in elderly with hiatal hernia; M÷F = 1÷1

- may be acute / chronic-recurrent
- **Borchardt triad:**

[Moritz Borchardt (1868–1948), Chief Surgeon at the Rudolf-Virchow and Moabit Public Hospitals in Berlin]

- sudden onset of severe epigastric pain + distension
- intractable retching (= vigorous attempts to vomit) without production of vomitus
- inability to pass nasogastric tube into stomach

CXR:

√ massively distended stomach in LUQ extending into chest /retrocardiac location (= intrathoracic stomach)

√ unexpected location of stomach gas bubble

√ paucity of distal gas

√ air-fluid levels in mediastinum / upper abdomen

Esophagram:

√ incomplete / absent entrance of barium into stomach

√ displaced gastroesophageal junction

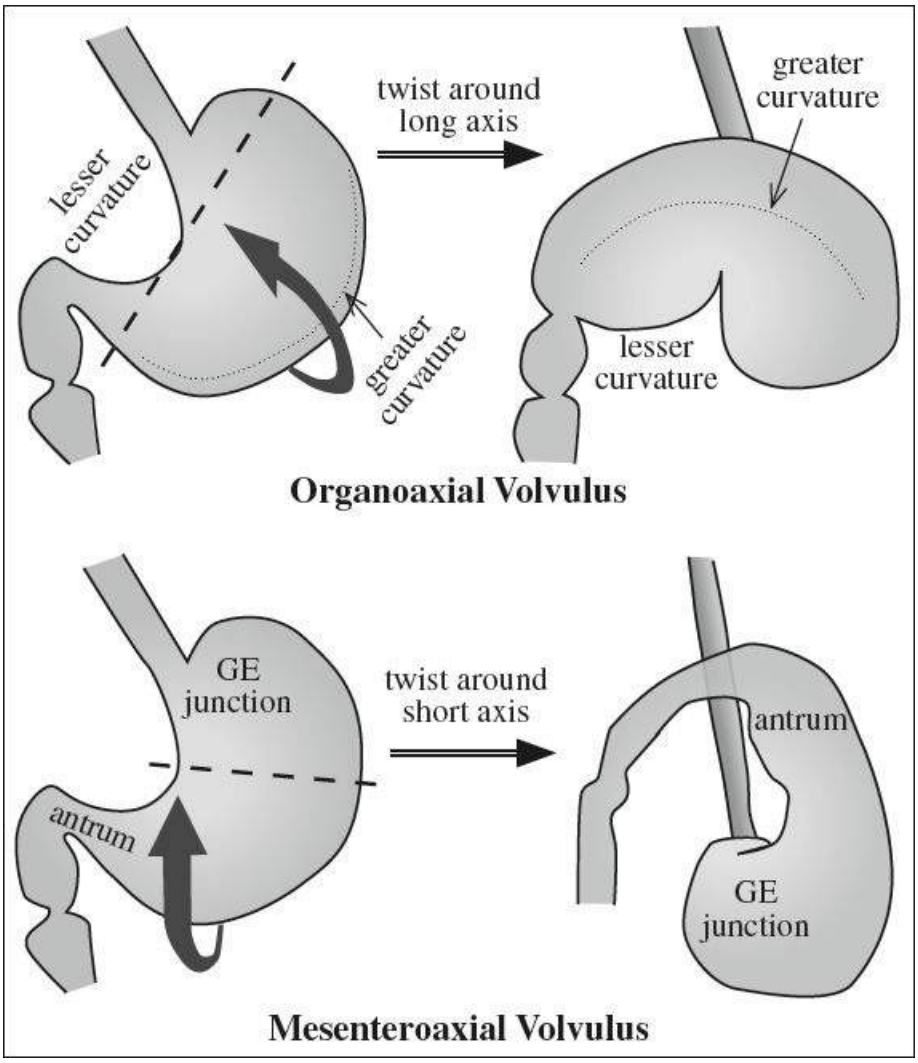
√ barium demonstrates area of twist

Classification:

A. PRIMARY without diaphragmatic defect

B. SECONDARY with diaphragmatic defect

Types:



A. ORGANOAXIAL VOLVULUS (²/₃)

Axis of rotation: around the long axis of stomach connecting GE junction and pylorus

Cause: ligamentous laxity allowing stomach to move abnormally along its long axis + long-standing posttraumatic / paraesophageal hiatal hernia

Age: usually in adulthood

Associated with: diaphragmatic defect (hiatal hernia, diaphragmatic eventration / rupture / large Bochdalek hernia) → migration of stomach into thorax = organoaxial position with twist of < 180°

√ horizontally oriented stomach with a single air-fluid level:

√ "mirror-image" stomach = greater curvature to right of lesser curvature (in vertically oriented stomach)

CT:

√ antrum moves anterosuperiorly + fundus rotates posteroinferiorly:

√ gastroesophageal junction lower than normal

√ "upside-down" stomach = lesser curvature below greater curvature

√ distortion of duodenum

B. MESENTEROAXIAL VOLVULUS (⅓)

Axis of rotation: around short axis that bisects greater and lesser curvatures = the site of mesenteric attachment (gastrohepatic omentum) → twisting vascular supply

Cause: abnormal laxity / absence of peritoneal attachments ← abnormal fusion of fetal mesenteries

Age: usually in childhood

May be associated with: wandering spleen

• idiopathic chronic / intermittent course: asymptomatic / postprandial pain, belching, bloating, vomiting, early satiety

• associated with severe obstruction (of pyloric antrum) ± strangulation (rare)

√ fundus rotates posteroinferiorly

√ usually partial volvulus

√ no underlying diaphragmatic defect

CT:

√ antrum moves above gastroesophageal junction:

√ "right-side up" stomach = antrum / pylorus rotates anterosuperiorly and from right to left

C. COMBINATION (2%)

Cx: intramural emphysema, gastric ischemia / gangrene, necrosis, perforation, mediastinitis, peritonitis, shock, gastric ulceration, hemorrhage, pancreatic necrosis, omental avulsion, splenic rupture

Mortality: 30–42–80% in acute volvulus; 10–13% in chronic volvulus

Rx: open / laparoscopic gastropexy + repair of diaphragmatic hernia

DDx: incarcerated hiatal hernia, gastric atony, acute gastric dilatation, pyloric obstruction

GASTRITIS

= common condition often resulting in submucosal edema and hyperplasia of gastric mucosa

Cause: Helicobacter pylori infection (most common), nonsteroidal anti-inflammatory drugs (NSAIDs), alcohol, systemic illness

• epigastric pain, nausea, vomiting, loss of appetite

Distribution: focal / segmental / diffuse

CT:

√ gastric wall / fold thickening (best appreciated when stomach distended)

√ mural stratification (best during arterial phase):

√ diffuse submucosal low attenuation ← edema

√ mucosal hyperemia

Corrosive Gastritis

Agents:

(a) acid, formaldehyde

• clinically usually silent

Location: esophagus usually unharmed, severe gastric damage, duodenum may be involved (newer potent materials cause atypical distribution)

(b) alkaline

Location: pylorus + antrum most frequently involved

A. ACUTE CHANGES (edema + mucosal sloughing)
   √ marked enlargement of gastric rugae + erosions / ulceration
   √ complete cessation of motor activity
   √ gas in portal venous system
   Cx: perforation
B. CHRONIC CHANGES
   √ firm thick nonpliable wall
   √ stenotic / incontinent pylorus (if involved)
   √ gastric outlet obstruction (cicatrization) after 3–10 weeks

Drug-induced Gastropathy

Cause: NSAIDs (most common worldwide); chemotherapy with cytotoxic agents; alcohol

Mechanism for NSAID:
weakening of mucosal defense mechanisms with increase in acid and pepsin ← reduced prostaglandin synthesis ← inhibition of cyclooxygenase COX enzyme (COX-1 = constitutive enzyme important for basal mucosal blood flow + pH balance; COX-2 = inducible enzyme important in maintaining perfusion for mucosal integrity)

Location: gastric body and antrum along greater curvature (= dependent position as function of gravity)

√ single / multiple discrete punched-out ulcers with sharply defined smooth border:
  √ central punctate collection of barium surrounded by radiolucent halo corresponding to mound of edema
√ linear serpiginous barium collection (= incomplete erosion) surrounded by halo of edema
√ (occasionally) deep ulcer penetrating through muscularis mucosae with involvement of submucosa

DDx: infection, inflammation, malignancy (focal wall thickening > 5 mm, perigastric tissue abnormalities, lymphadenopathy)

Emphysematous Gastritis

= rare but severe form of widespread phlegmonous gastritis subsequent to mucosal disruption characterized by gas in wall of stomach

Cause of mucosal disruption:
ingestion of toxic / corrosive substances (37%), alcohol abuse (22%), gastroenteritis (15%), recent abdominal surgery (15%), gastric infarction, necrotizing enterocolitis, ulcer, acute pancreatitis, adenocarcinoma of stomach, phytobezoar, leukemia, diabetes mellitus, disseminated strongyloidiasis, gastric mucormycosis, after ingestion of large amounts of carbonated beverages

Histo: bacterial invasion of submucosa + subserosa

Organism: hemolytic streptococcus, Clostridium welchii, Clostridium perfringens, E. coli, S. aureus, enterobacter, P. aeruginosa, Klebsiella pneumoniae, Candida

- explosive onset of severe abdominal pain
- nausea, diarrhea, chills, fever, leukocytosis
- bloody foul-smelling emesis ± PATHOGNOMONIC vomiting of a necrotic cast of stomach ← dissection along plane of muscularis mucosae

Plain radiographs:
√ innumerable small gas bubbles silhouetting the stomach in a mottled fashion without positional change
√ thickening of rugal folds
√ ± portal venous gas
GI:
√ cobblestone appearance of mucosa on upper GI
√ intramural penetration of contrast material
CT:
√ gastric wall thickening (DDx: emphysematous gastritis)
√ intramural gas → dissecting into gastric veins + portal venous system
Cx: cicatricial stenosis (21%), sinus tract formation
Prognosis: 60–80% mortality
Rx: broad-spectrum antibiotics + intravenous fluids; emergent surgery for acute perforation
DDx: benign gastric emphysema (recent gastric procedure), gastric ischemia, caustic ingestion

Erosive Gastritis

= HEMORRHAGIC GASTRITIS
Frequency: 0.5–10.0% of GI studies
Etiology (in 50% without causative factors):
(1) Peptic disease: emotional stress, alcohol, acid, corrosives, severe burns, anti-inflammatory agents (aspirin, steroids, phenylbutazone, indomethacin)
(2) Infection: herpes simplex virus, CMV, Candida
(3) Crohn disease: aphthoid ulcers identical in appearance to varioliform erosions
Histo: epithelial defect not penetrating beyond muscularis mucosae
• 10–20% of all GI hemorrhages (usually without significant blood loss); vague dyspepsia, ulcerlike symptoms
Location: antrum, rarely extending into fundus; aligned on surface of gastric rugal folds
√ varioliform <u>complete</u> erosion (95%) = tiny fleck of barium surrounded by radiolucent halo ("target lesion") < 5 mm, usually multiple
√ <u>incomplete erosion</u> (5%) = linear streaks / dots of barium without surrounding mound of edema / inflammation
√ nodularity / scalloping of prominent antral folds
√ contiguous duodenal disease may be present
√ limited distensibility, poor peristalsis / atony, delayed gastric emptying

Phlegmonous Gastritis

Etiology: septicemia, local abscess, postoperative stomach, complication of gastric ulcer / cancer
Organism: Streptococcus
Path: multiple gastric wall abscesses ± communication with lumen
• severe fulminating illness, patient may vomit pus
Location: usually limited to stomach not extending beyond pylorus; submucosa is the most severely affected gastric layer

√ barium dissection into submucosa + serosa

GASTROENTERITIS

= "stomach bug / stomach virus / stomach flu"
= infection involving stomach + small intestine
◊ Most common cause of bowel wall thickening
Organism:
(a) bacteria: Escherichia coli, Shigella, Salmonella, Yersinia, Campylobacter, Staphylococcus
(b) viruses: Rotavirus (very common in winter, between 6 months to 2 years of age), norovirus, Herpes, Cytomegalovirus
(c) parasites: amebiasis in underdeveloped countries
Ingestion: consumption of contaminated water, sharing personal objects
• diarrhea, vomiting, abdominal cramping

GASTROINTESTINAL STROMAL TUMOR

= GIST = SPINDLE CELL / EPITHELIOID TUMOR
Origin: c-KIT-positive interstitial cell of Cajal of myenteric plexus (= pacemaker cell for gut movement)
◊ Most common solid mesenchymal neoplasm of GI tract!
◊ Most common intramural subepithelial neoplasm of GI tract!
Incidence: < 1% of all gastrointestinal tumors; 7–20÷1,000,000 annually; 4500–6000 new cases annually (USA); increased prevalence in NF1
Median age: 55–65 years; M÷F=1÷1
Histo: spindle cell (70–80%) / epithelioid (20–30%) morphology / mixture of both
› expresses transmembrane receptor tyrosine kinase encoded by c-KIT gene (CD117) in 95%; 70% of GISTs coexpress CD34
Location: usually solitary
A. GI TRACT anywhere between esophagus and anus:
› stomach (60–70%)
› small intestine (20–30%): jejunum > duodenum (9%) > ileum
› periampullary (3–5%)
› anorectum (5–7%)
› colon (4%): rare in appendix
› esophagus (2%)
◊ 75% of mesenchymal tumors in the esophagus are leiomyomas and 25% GIST
B. EXTRAINTESTINAL (rare): peritoneum (4%), omentum; mesentery; retroperitoneum
Site: muscularis propria has greatest density of cells of Cajal; endophytic / exophytic to bowel
N.B.: leiomyomas arise from muscularis mucosae!
• early satiety, indigestion, bloating, vague abdominal pain
◊ often not detected until late in their progression
• gastrointestinal bleeding ← mucosal ulceration: hematemesis, melena, hematochezia, anemia
• subtle nonspecific broad-based lesion at optical colonoscopy
Associated with: neurofibromatosis type 1, familial GIST, Carney triad
Spread: (in 50% at presentation)

(a) intraperitoneal: adjacent organ invasion, ascites, omentum, peritoneum
(b) hematogenous: liver metastasis

◊ All GISTs are potentially malignant (30%)!
◊ Lymphadenopathy (rare)!

Staging criteria: based on tumor size, dissemination status, mitotic rate
Mean size: 8.6 cm

@ Stomach (60%)

Frequency: 2–3% of all gastric tumors; most common location of GIST

- nausea, vomiting, weight loss
- abdominal pain + distension, intestinal obstruction

UGI:

√ well-circumscribed mass up to 30 cm in size
√ features of subepithelial mass:
√ lesion margin obtuse / at right angle with gastric wall (in profile)
√ smoothly circumscribed (en face)
√ smooth mucosal surface (common)
√ mucosal ulceration (in up to 60%)
√ polypoid intraluminal mass (in 14%)

US:

√ large well-defined predominantly solid mass with variable echogenicity, often exophytic
√ thick echogenic rim (occasionally)
√ central hypoechoic areas = regions of necrosis

CT:

(a) small < 3 cm tumor:
√ well-defined smooth-walled homogeneous soft-tissue mass with moderate degree of enhancement
√ attenuation similar to muscle

CT features of GISTs < 3 cm overlap with those of other intramural subepithelial masses.

(b) large tumor:
√ large heterogeneous mass with prominent extraluminal location = exoenteric growth with displacement of adjacent organs + vessels
√ extragastric extension into gastrohepatic / gastrosplenic ligament / lesser sac (in 86%)
√ prominent intraluminal component (rare)
√ irregular lobulated margin
√ mucosal ulceration (50%)
√ central areas of low attenuation ← hemorrhage, necrosis, cyst formation
√ large cavity containing air / air-fluid level / oral contrast medium that communicates with gastric lumen (common)
√ rarely calcified (in 3%)

◊ Features of metastatic lesions from GIST are similar to those of the primary tumor!

CECT:

√ tumor vessels visible within tumor

√ hypervascular mass with heterogeneous enhancement
√ peripheral enhancement in 92% (corresponding to viable tumor)

CT Findings suggestive of Malignant GIST:
√ lesion > 5 cm
√ heterogeneous enhancement
√ gastric location
√ metastases
√ cystic-necrotic component

MR:
√ solid tumor portion hypointense on T1WI + intermediate intense to hyperintense on T2WI
√ heterogeneous enhancement of large tumors ← central necrosis + cavitation
√ tumoral hemorrhage varies from high to low SI on T1WI + T2WI depending on age

PET:
√ high sensitivity for detection unless extensively necrotic

DDx: leiomyoma, leiomyosarcoma, schwannoma, neurofibroma, carcinoid

With any hypervascular intramural subepithelial mass > 3 cm GIST should be considered first in the DDx.

@ Small intestine (30%)
◊ 2nd most common site of involvement after stomach
Location: ileum (50%)
@ Periampullary region (3–5%)
@ Anorectum
√ expansion of rectal wall → focal mural mass
Cx: extension into ischiorectal fossa, prostate, vagina
@ Extraintestinal
Age: 31–82 years; M÷F = 1÷2
Location: mesentery, omentum, retroperitoneum

Cx: bowel obstruction (rare)

Rx: (1) Surgery for localized primary
(2) Imatinib mesylate (= tyrosine kinase inhibitor) inhibits growth of GIST (± paradoxical enlargement ← tumor hemorrhage / necrosis)

Response to treatment:
√ decrease in tumor attenuation by > 15% ← myxoid degeneration + hemorrhage + necrosis
√ decrease in tumor size by > 10%
√ apparent "new liver lesions" = lesions initially isodense to hepatic parenchyma become hypodense + visible → no metabolic activity on PET

DDx: new lesions of progressive disease show metabolic activity

GLIOMATOSIS PERITONEI

= benign mature glial implants throughout peritoneum

Cause: ? rupture of ovarian teratoma / metaplasia of peritoneal tissue

Associated with: solid / immature ovarian teratomas, ventriculoperitoneal shunts
Histo: benign mature glial tissue with delicate fibrillar processes and scattered supporting cells
Clue: teratoma with fat and calcifications in one ovary
CT:
√ peritoneal nodules + masses of soft-tissue density
√ omental caking
√ ascites
√ adnexal / pelvic mass suggestive of teratoma
MR:
√ multilobular masses of homogeneously high SI on T2WI
DDx: peritoneal carcinomatosis (indistinguishable)

GIARDIASIS

= overgrowth of commensal parasite Giardia lamblia
Organism:
Giardia lamblia (flagellated protozoan); often harmless contaminant of duodenum + jejunum in motile form (= trophozoite) attached to mucosa by suction disk, nonmotile form (= cyst) shed in feces; capable of pathogenic behavior with invasion of gut wall
Frequency: 1.5–2.0% of USA population, in 3–20% of children in parts of southern USA; infests 4–16% of inhabitants of tropical countries
Predisposed: altered immune mechanism (dysgammaglobulinemia, nodular lymphoid hyperplasia of ileum)
Histo: blunted villi (may be misdiagnosed as celiac disease especially in children), cellular infiltrate of acute + chronic inflammation in lamina propria
• abdominal pain, weight loss, failure to thrive (especially in children)
• spectrum from asymptomatic to severe debilitating diarrhea
• steatorrhea = reduced fat absorption (related to number of organisms) simulating celiac disease
Location: most pronounced in duodenum + jejunum
√ irregular distorted segmental thickening of mucosal folds in duodenum + jejunum (+ normal ileum) ← mucosal edema
√ marked spasm + irritability with rapid change in direction + configuration of folds
√ hypersecretion with blurring + indistinctness of folds
√ hyperperistalsis → rapid transit time
√ segmentation of barium ← motility disturbance + excess intraluminal fluid
√ ± lymphoid hyperplasia (associated with immunoglobulin deficiency state)
Dx: (1) Detection of Giardia lamblia cysts in formed feces or trophozoites in diarrheal stools
(2) Trophozoites in duodenal aspirate / jejunal biopsy
DDx: hookworm Strongyloides infection
Rx: quinacrine (Atabrine®)

GLOMUS TUMOR OF STOMACH

= rare benign vascular tumor that originates from glomus body

Glomus body: modified smooth muscle cells functioning as neuromyoarterial receptors that regulate temperature (= unique arteriovenous shunt) → therefore most abundant in dermis / subcutis of extremities, particularly beneath fingernails

Frequency: 2% of all benign gastric tumors

◊ Most common benign vascular gastric tumor

Path: dilated irregularly shaped thin-walled vessels (= modified capillaries) covered by nests / strands / sheets of glomus cells arising in muscularis propria

Histo: sheets of monotonous round cells interspersed with numerous delicate vessels

Median age: 55 years; M÷F = 3÷7

• asymptomatic / upper GI bleeding

Location: gastric antrum

Size: 1–4 cm in diameter

√ solitary smooth intramural / intraluminal subepithelial mass ± mucosal ulceration

√ change in shape + size during fluoroscopy (similar to lipoma)

√ tiny flecks of calcifications (occasionally)

√ CHARACTERISTIC strong peripheral homogeneous enhancement in arterial + portal venous phases with prolonged enhancement in delayed phase similar to portal vein / IVC / descending aorta

√ SPECIFIC peripheral nodular enhancement pattern + delayed filling-in (reminiscent of hemangioma)

On CT easily differentiated from lipomas because of dense arterial enhancement persisting into delayed phase.

DDx: lipoma, hemangioma, GIST, carcinoid tumor, ectopic pancreas, metastasis

GLYCOGEN ACANTHOSIS

= benign degenerative condition with accumulation of cellular glycogen within squamous epithelial lining of esophagus

Frequency: in up to 15% of endoscoped patients

Etiology: unknown

Age: middle-aged / elderly individuals

Histo: hyperplasia + hypertrophy of squamous mucosal cells ← increased glycogen; no malignant potential

• asymptomatic white oval mucosal plaques of 2–15 mm in diameter on otherwise normal appearing mucosa

Location: middle (common) / upper esophagus, in random distribution

√ multiple 1–3-mm rounded nodules / plaques

Dx: biopsy

DDx: candida esophagitis (lesions disappear under treatment in contrast to glycogen acanthosis), reflux esophagitis

GRAFT-VERSUS-HOST DISEASE

= T lymphocytes from donor bone marrow cause selected epithelial damage of recipient target

organs

Bone marrow transplantation for treatment of:

leukemia, lymphoma, aplastic anemia, immunologic deficit, metabolic disorders of hematopoietic system, some metastatic disease

Frequency: 30–70% of patients with allogeneic (= donor genetically different from host) transplant

Time interval from hematopoietic stem cell transplantation:

(a) acute GVH: less than 100 days

(b) chronic GVH: within 100 days

Target organs: skin, liver, GI tract (small bowel)

@ Skin

- maculopapular rash on face, trunk, extremities
- cholestatic jaundice

@ Liver

- elevation of hepatic enzymes ± liver failure

√ thickening of gallbladder wall ± pericholecystic fluid

√ biliary sludge

√ dilatation of common bile duct

√ enhancement of wall of gallbladder and CBD

Veno-occlusive disease = sinusoidal obstructive syndrome:

Histo: centrilobular hemorrhagic necrosis, venular obliteration, sinusoidal congestion, fibrosis

√ portal hypertension + fluid retention

√ painful hepatomegaly

@ GI tract

- profuse secretory diarrhea ± hemorrhage, weight loss
- abdominal cramping, fever, nausea, vomiting

Path: severe mucosal atrophy / destruction

Location: distal ileum > other small bowel > colon

Plain film:

√ separation of bowel loops ← wall thickening

√ air-fluid levels + small bowel dilatation

√ decreased luminal gas

Barium:

√ shaggy fold thickening

√ "ribbon bowel" = small bowel fold effacement with tubular appearance (DDx: viral enteritis, ischemia, celiac disease, radiation, soybean allergy)

√ "toothpaste / leadpipe / moulage" sign = featureless segment of bowel (chronic stage)

√ loss of haustration, spasm, edema, ulceration, granular mucosal pattern of colon (simulating ulcerative colitis)

√ small bowel "cast" HIGHLY SUGGESTIVE = prolonged coating of abnormal bowel for hours to days ← incorporation of barium into submucosal layer through mucosal ulcers

√ circular collections of contrast material on cross section + parallel tracks on longitudinal section
√ severely decreased transit time

CT:
√ moderate bowel wall thickening < 5.5–8.0 mm: small bowel involved in 75–100%
√ discontinuous involvement (in 41–54%)
√ strictly right colonic involvement (uncommon)
√ fluid-filled distended bowel: colon > 8 cm, small bowel > 3 cm
√ barium (from prior contrast enema weeks ago) may become incorporated into bowel wall

N.B.: oral contrast material should not be given!

√ misty mesentery = mesenteric fat stranding without lymphadenopathy
√ ascites

CECT:
√ abnormally enhancing thin layer of mucosa diffusely involving thickened bowel segments ← mucosal replacement by highly vascular granulation tissue

N.B.: negative oral contrast agent makes hyperattenuating mucosa more conspicuous

√ engorgement of vasa recta = "comb" sign

Cx: infection with opportunistic organisms, eg, Candida albicans, herpes virus, invasive fungal organisms, CMV, Varicella-zoster virus, Epstein-Barr virus, hepatitis viruses, Rotavirus, Adenovirus, Coxsackie virus A and B, P. carinii, pneumococcus

Prognosis: fatal in up to 15% ← opportunistic infection

Rx: steroids + cyclosporine

DDx:
(a) 0–30 days: typhlitis, C. difficile colitis
(b) 31–100 days: viral gastroenteritis / hepatitis, pneumatosis cystoides intestinalis, thrombotic microangiopathy
(c) >100 days: posttransplantation lymphoproliferative disease

GRANULAR CELL TUMOR

= GRANULAR CELL MYOBLASTOMA (misnomer coined in 1926, thought to derive from muscle cells)
= rare mostly benign neoplasm, occasionally locally invasive + metastasizing

Origin: Schwann cell (positive for S-100 marker protein)

Path: infiltrative margins

Histo: nests of ovoid / polygonal cells with small dark regular nuclei and abundant cytoplasm filled with eosinophilic PAS-positive and diastase-resitant granules (= autophagic vacuoles containing cellular debris); separated by collagen bundles; interspersed with branching thin-walled blood vessels

Age: 5th decade; M < F

Location: tongue (most common), subcutaneous tissue (6–8%), oropharynx, GI tract (5–8%), skin, bronchial wall, biliary tract (1%), breast (5%)

Granular Cell Tumor of Gastrointestinal Tract

Site: distal esophagus (2%); in 10% multiple lesions in esophagus; in 9–16% involving additional organs
Size: mostly small tumors < 2 cm incidentally discovered at autopsy / endoscopy
√ small subepithelial mass; hypoechoic on US
CT:
√ moderately enhancing soft-tissue mass with thickening of esophageal wall + partially narrowing esophageal lumen
Cx: malignant degeneration (1–3%)
Rx: endoscopic / surgical removal if > 1 cm in size
DDx: leiomyoma

Granular Cell Tumor of Chest

Age: middle-aged, esp. Black women
√ endobronchial lesion in major bronchi

Granular Cell Tumor of Breast

Prevalence: 1÷1,000 of primary breast tumors; 5–8% of all granular cell tumors; 78% in African-Americans
Mean age: 34 (range, 20–59) years; M÷F = 1÷9
Location: more commonly in upper inner rather than upper outer quadrant
Site: breast parenchyma, hypodermis, dermis
Size: 1–3 cm
• asymmetric painless hard lump with slow growth
• skin fixation / skin retraction / nipple inversion / ulceration mimick malignancy; often fixed to pectoralis fascia
Mammo:
√ round well-demarcated mass / indistinct density / spiculated mass
√ ± calcifications (rare)
US:
√ well-circumscribed / angular / ill-defined spiculated mass
√ posterior acoustic enhancement / shadowing
√ stellate extensions ← tumor insinuating itself into surrounding breast tissue:
√ ± associated skin thickening / retraction (with dermal location)
√ surrounding hyperechoic halo ← infiltrative growth pattern
MR:
√ low to high SI on T2WI + low to intermediate SI on T1WI
√ hyperintense rim on T2WI
√ homogeneous enhancement of varying kinetics / rapid peripheral enhancement
Dx: Fine-needle aspirate may be difficult to interpret!
Rx: wide local excision
DDx: carcinoma, lymphoma, metastasis

HELICOBACTER PYLORI INFECTION

Organism: worldwide gram-negative spiral-shaped bacillus [formerly Campylobacter pylori]
Prevalence: increasing with age; in > 50% of Americans > 60 years of age

Path: surface epithelial damage + inflammation with mucosal infiltration by neutrophils, plasma cells, lymphoid nodules
Location: gastric antrum > proximal half of stomach
Site: beneath mucus layer on surface epithelial cells
• asymptomatic (vast majority); dyspepsia, epigastric pain
√ gastritis (75% prevalence of H. pylori):
  √ thickened gastric folds
  √ polypoid gastritis mimicking malignant tumor
  √ enlarged areae gastricae
√ gastric ulcer (60–80% prevalence of H. pylori)
√ duodenal ulcer (90–100% prevalence of H. pylori)
Dx: (1) Endoscopic brushings + biopsy
(2) Breath test measuring urease activity after ingestion of carbon 14N-labeled urea
(3) Serologic test for IgG antibodies
Rx: triple therapy (= bismuth + metronidazole + tetracycline / amoxicillin) results in 95% cure rate after 2 weeks of therapy

HEMANGIOMA OF GASTROINTESTINAL TRACT

= unusual single / multiple vascular tumors anywhere in GI tract
Frequency: 7–10% of all benign small bowel tumors
Increased incidence in (if multiple):
Maffucci syndrome, Klippel-Trénaunay syndrome, blue rubber-bleb nevus syndrome, Osler-Weber-Rendu disease, Turner syndrome, tuberous sclerosis
Commonly associated with: cutaneous hemangiomas / telangiectasias
Age: any; commonly during infancy / early childhood
• symptomatic (80%):
  • acute intermittent severe bleeding (melena)
  • acute / chronic life-threatening anemia
  • intestinal obstruction, intussusception, perforation
Path: submucosal soft infiltrative polypoid mass
Histo: cavernous / capillary / mixed
Location: jejunum (55%), ileum (42%), duodenum (2%); rare in stomach + colon (mostly rectosigmoid)
Site: submucosal vascular plexus
√ polypoid intramural intraluminal subepithelial mass
√ sessile nodular compressible intraluminal filling defect
√ segmental transmural circumferential bowel wall thickening = diffuse infiltrating abnormality extending into surrounding tissue (= hemangiomatosis)
√ ± virtually PATHOGNOMONIC phleboliths in intestinal wall ← calcified thrombi
CECT:
  √ well-circumscribed avidly enhancing often intraluminal lobulated mass of mixed attenuation supplied by large artery
  √ slow diffuse enhancement + vascular engorgement within adjacent mesentery around mass lesion

Rx: resection ← risk of massive gastrointestinal bleeding
Prognosis: involution during childhood
DDx: GIST, glomus tumor, metastasis

HERNIA

= ABDOMINAL HERNIA
= protrusion of an organ / fascia of an organ through the wall of the cavity that normally contains it
Prevalence: 2nd most common cause (= 10%) of SBO
Nomenclature: according to anatomic site of its orifice
Cx: (1) bowel obstruction
(2) **incarceration** (= irreducible hernia)
[*incarcerare*, Latin = to imprison]
(3) **strangulation** (= constriction of blood flow)
[*strangulare* , Latin = to choke]

External Hernia

= bowel extending outside the abdominal cavity
Frequency: 95% of all hernias
◊ 5% lifetime risk for spontaneous abdominal hernias
Location:
@ Ventral = Anterior abdominal wall hernia
= protrusion of part of peritoneal sac through defect in muscle layers of anterior abdominal wall
Content: fat, omentum, bowel
• abdominal bulge ± Valsalva maneuver
◊ Look for multiple hernias (present in 18–22%)!
√ small-bowel loops extending beyond fascial plane of anterior abdominal wall on lateral view
√ provocative (Valsalva) maneuver facilitates detection
√ luminal narrowing at entry + exit site of hernia orifice
√ fluoroscopic manipulation to document reducibility

1. **Umbilical hernia** (most common)
= usually small protrusion of abdominal contents / fat into anterior abdominal wall via umbilical ring
Prevalence: 4% of all hernias; M < F
Cause: failed closure of umbilical ring, obesity, multiple pregnancies, intraabdominal mass, liver failure, increased intraabdominal pressure, weak abdominal wall
√ may contain fat / small bowel / colon
Cx: strangulation, incarceration
DDx: paraumbilical, spigelian, epigastric, incisional hernia
2. Periumbilical hernia
√ large defect through linea alba ← diastasis of rectus abdominis muscle at

umbilicus

3. Epigastric / hypogastric hernia
   √ in linea alba above / below umbilicus
4. Postoperative / incisional (0.5–14.0%, most common type)
5. Parastomal hernia
   √ one / more intestinal loops alongside loop of ileum / colon leading to stoma
6. Trocar site hernia
   Frequency: 1–3.6%
   √ often Richter type hernia
7. **Spigelian hernia**
   [Adriaan van den Spiegel = Adrianus Spigelius (1578–1625) Flemish anatomist and botanist working in Padua, Italy]
   Frequency: 2% of anterior abdominal hernias
   = acquired ventrolateral hernia through defect in aponeurosis between transverse and rectus muscle of abdomen at junction of semilunar + arcuate lines below umbilicus
   √ hernia sac dissects laterally to rectus abdominis muscle through a fibrous groove (= semicircular / spigelian line)
   √ hernia sac lies beneath an intact external oblique aponeurosis
8. Interparietal / interstitial
   = hernia sac located in fascial plane between abdominal muscles NOT connected to SQ tissue

@ Diaphragmatic hernia

1. Bochdalek hernia
2. Morgagni hernia

@ Lumbar

Location: defect in lumbar muscles below 12th rib + above iliac crest

1. Superior lumbar triangle (Grynfeltt-Lesshaft)
   [Joseph C. Grynfeltt (1840-1913), French surgeon
   Peter Frantsevich Lesshaft (1837–1909), Russian physician]
   Borders: quadratus lumborum muscle (medially), internal oblique muscle (laterally), 12th rib (superiorly)
2. Inferior lumbar triangle (Petit hernia)
   [Jean Louis Petit (1674–1750), inventor of the tourniquet, director of the French Royal Academy of Surgery]
   Borders: external oblique muscle (anteriorly), iliac crest (inferiorly), latissimus dorsi muscle (posteriorly)

@ Pelvic floor

1. Perineal hernia (rare)
   (a) anterior perineal hernia = defect of urogenital diaphragm anterior to superficial transverse perineal m. + lateral to bulbocavernosus m. + medial to ischiocavernosus m. (only in females)
   (b) posterior perineal hernia = defect in levator ani m. / between levator ani m. and coccygeus m. posterior to superficial transverse perineal m.

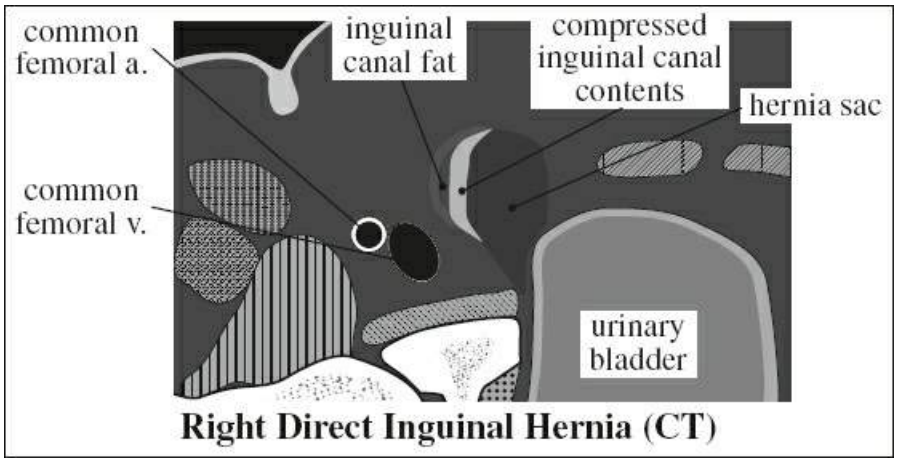
√ defecating proctography

2. Obturator foramen
   √ hernia between pectineus + external obturator mm.
3. Sciatic foramen

@ Groin

1. **Inguinal hernia**
   ◊ Most common type (80%) of spontaneous abdominal wall hernia; M > F
   √ superior + medial to pubic tubercle
   Pubic tubercle:
   = superior border of medial portion of superior pubic ramus
   = attachment point of inguinal ligament

   (a) **Direct inguinal hernia**
   = defect in Hesselbach triangle (bounded by inguinal ligament inferiorly, inferior epigastric artery superolaterally, fused aponeuroses of internal oblique + transverse abdominal muscles medially)
   [Franz Kaspar Hesselbach (1759–1816), surgeon and anatomist in Würzburg, Germany]
   Cause: acquired weakening of transversalis fascia
   Frequency: increases with age
   √ <u>medial</u> to inferior epigastric vessels
   √ hernia contains bowel, mesenteric fat, vessels
   Cx: low risk of strangulation allows for conservative management + monitoring



Right Direct Inguinal Hernia (CT)

   (b) **Indirect inguinal-scrotal hernia**
   ◊ Most common hernia in children ← failure of obliteration of processus vaginalis
   Age: preterm neonates (most common)
   Prevalence: higher in preterm neonates
   Location: R > L
   • clinically inapparent contralateral hernia (88%)
   √ <u>lateral</u> to inferior epigastric vessels originating at deep inguinal ring

√ US visualization of air-bubble movement / intestinal peristalsis / vascularity
√ hernia containing omentum mimicks lipoma
Cx: moderate risk of strangulation (2%)

(c) **Littré hernia** = inguinal hernia containing Meckel diverticulum
[Alexis Littré (1654–1726), French physician and anatomist in Montpellier and Paris]

(d) **Amyand hernia**
[Claudius Amyand (1680-1740), English surgeon who performed first successful appendectomy in 1735]
= appendix within inguinal hernia
Frequency: 1% of all inguinal hernias

DDx: iliopsoas bursa distended by hip joint effusion

2. **Femoral hernia** (5%)
◊ 2nd most common type (5%) of spontaneous abdominal wall hernias, R > L; M÷F = 1÷4 to 1÷6
√ enters femoral canal through femoral ring
Femoral ring:
= most proximal part of femoral canal
Borders: inguinal lig. (anteriorly), pectineal lig. (posteriorly), femoral vein (laterally)
√ lies in femoral triangle:
Borders: deep to deep fascia of thigh, inguinal lig., sartorius m., adductor longus m.
√ inferior and lateral to pubic tubercle
√ medial to femoral vein within femoral canal
√ posterior to inguinal ligament
Cx: highest (40%) rate of (ischemic) strangulation / (irreducible) incarceration of all hernias

3. **Richter hernia** = **Partial enterocele**
[August Gottlieb Richter (1742–1812), surgeon and professor ordinarius in Göttingen, Germany]
= entrapment of antimesenteric border of bowel in hernia orifice, usually seen in older women with femoral hernias
• no palpable mass = difficult to diagnose
√ localized outpouching, possibly incarcerated
√ partial obstruction with patent bowel lumen

Categorization of Internal Hernias	
Type of Orifice	*Category of Hernia*
Normal foramen	foramen of Winsløw
Unusual peritoneal fossa / recess into retroperitoneum	paraduodenal pericecal intersigmoid pelvic internal
Abnormal opening in mesentery / peritoneal ligament	small bowel mesentery greater omentum lesser sac (except Winsløw) transverse mesocolon transmeso- and intramesosigmoid falciform ligament broad ligament Roux-en-Y anastomosis

4. **De Garengeot hernia**
   [René-Jacques Croissent de Garengeot (1683–1759), surgeon-major of the king's regiment of infantry, France]
   = appendix within femoral hernia sac
   Frequency: 0.5–3.3% of all femoral hernias

Internal Hernia

= herniation of bowel through a defect of peritoneum (= peritoneal foramen / recess / fossa), omentum, mesentery or adhesive band into a compartment of the abdominal cavity

Internal hernias are divided into 3 categories on the basis of the type of hernia orifice: (1) normal foramen, (2) unusual peritoneal fossa / recess into the retroperitoneum, and (3) abnormal opening in a mesentery / peritoneal ligament.

Frequency: 5% of all hernias, responsible for < 1% of mechanical small bowel obstruction
Cause of defect: congenital, surgery, trauma, inflammation, circulation
Classification of internal hernias:

(a) retroperitoneal: usually congenital containing a hernia sac
   1. Paraduodenal (ligament of Treitz) 53%
   2. Pericecal / ileocolic 13%
   3. Foramen of Winsløw 8%
   4. Intersigmoid 6%
   5. Supravesical 6%

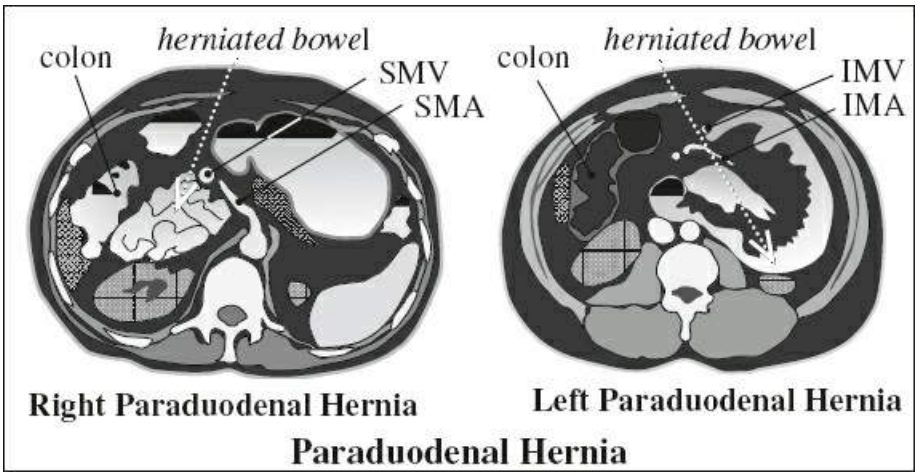
An internal hernia is diagnosed by its saclike closed-loop appearance and displacement of vessels and surrounding structures around the hernia orifice and sac.

(b) anteperitoneal:
   small group of hernias without a peritoneal sac
   1. Transmesenteric (transverse / sigmoid mesocolon) 8%
   2. Transomental 1–4%
   3. Pelvic (including broad ligament)

• epigastric discomfort, periumbilical pain

• recurrent episodes of distension and nausea ← intestinal obstruction (made worse by eating + standing and relieved by fasting + assuming a recumbent position)
N.B.: clinically apparent only when incarcerated → delay in diagnosis may lead to strangulation

√ bowel configuration:
√ saclike mass / cluster of dilated obstructed bowel loops
√ displacement of other abdominal organs



√ mesenteric changes:
√ engorged, stretched, displaced mesenteric vascular pedicle
√ dilated bowel loops with converging vessels at entrance of hernial orifice → impaired venous drainage

Cx: volvulus

Paraduodenal Hernia *(53%)*

= entrapment of small intestine into a congenital fossa

◊ Most common type of internal hernia

(a) LEFT through fossa of Landzert (¾)
[Theodor Bernhard Landzert (1833–1889), Russian anatomist]

Autoptic frequency: 2%

Cause: failure of part of descending mesocolon to fuse with posterior parietal peritoneum

Location: to the left of 4th portion of duodenum at duodenojejunal junction = confluent zone of descending mesocolon + transverse mesocolon + small bowel mesentery

• frequently asymptomatic

√ cluster of dilated small-bowel loops between pancreas + stomach to the left of ligament of Treitz:
√ displacement of gastric wall anteriorly
√ displacement of duodenojejunal flexure and transverse colon inferiorly

√ engorged crowded vessels at entrance of hernia sac

CT:

√ encapsulated bowel loop causes anteromedial displacement of IMV + left colic artery (= landmarks of the right margin of the descending mesocolon)

(b) RIGHT through mesentericoparietal fossa of Waldeyer (¼)

Cause: failure of part of ascending mesocolon to fuse with posterior parietal peritoneum

Predisposed: nonrotation of small bowel

Location: behind the root of small bowel mesentery caudal to SMA and inferior to 3rd portion of duodenum on right side

CT:

√ encapsulated bowel loop displacing the right colic vein (= landmark of left margin of the ascending mesocolon) anteriorly

√ looping of small intestine behind SMA + SMV below transverse portion of duodenum

with nonrotation:

√ SMV located ventral + to left of SMA

√ absence of normal 3rd portion duodenum

Cx: partial / complete obstruction of small intestine (50%)

Lesser Sac Hernia *(1–8%)*

= - FORAMEN OF WINSLØW HERNIA

= 3-cm vertical slit beneath upper part of right border of lesser sac and cephalad to duodenal bulb

Location: anterior to IVC + posterior to hepatoduodenal ligament (portal vein + CBD + hepatic artery)

Predisposing factors:

(1) Enlarged foramen of Winsløw

(2) Excessively mobile intestinal loops ← long mesentery / persistence of ascending mesocolon

Invaginated gut:

(a) small bowel (60–70%): ileum > jejunum, Meckel diverticulum

(b) colon (25–30%): terminal ileum, cecum, appendix, ascending colon

(c) rare: transverse colon, gallbladder, greater omentum

Plain film:

√ gas-containing bowel loops in central upper abdomen

√ distended small bowel loops occupying space between stomach + liver

√ ± cecum + ascending colon absent from usual location

UGI:

√ dilatation of small bowel loops with obstruction in RUQ

BE:

√ ± narrowing / obstruction at hepatic flexure of colon

CT:

√ retrogastric air-fluid collection in lesser sac:

√ ≥ 2 bowel loops in high subhepatic spaces

√ "beak"-shape herniated viscera pointing toward foramen of Winsløw

√ mesenteric vessel between IVC + main portal vein

√ crowded mesenteric vessels between ascending portion of duodenum + pancreatic head
√ anteriorly compressed portal vein
√ absence of ascending colon in right gutter

Pericecal Hernia *(13%)*

4 recesses: superior + inferior ileocecal recess, retrocecal recess, paracolic sulci
√ saclike appearance of ileal loops in right paracolic gutter lateral to cecum + posterior to ascending colon
√ displacement of cecum + ascending colon anteriorly / medially

Falciform Ligament Hernia

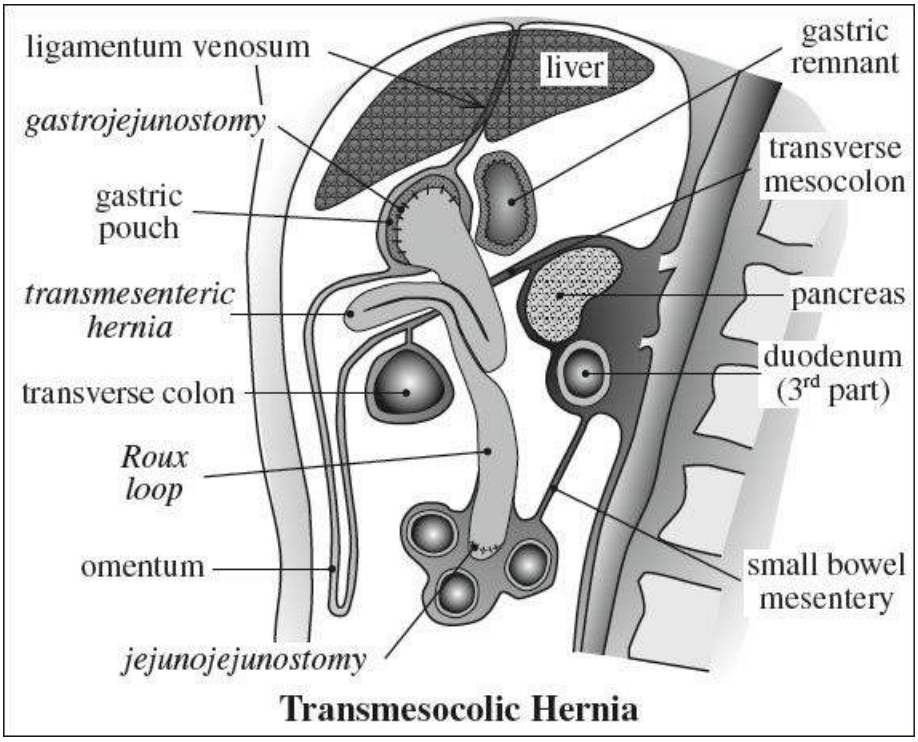
Cause: abnormal opening in falciform ligament
√ closed-loop intestine in front of / slightly caudal to liver

Transmesenteric Hernia *(8%)*

Cause:
(a) in childhood (35%): congenital mesenteric defect 2–5 cm in diameter
Location: close to ligament of Treitz / ileocecal valve
(b) in adulthood: surgery / trauma / inflammation
√ proximal small bowel dilatation = mechanical SBO
CT:
√ clustering of small bowel loops
√ engorged, stretched, crowded mesenteric vascular pedicle
√ displacement of main mesenteric trunk to the right
Cx: small bowel volvulus

Transomental Hernia *(1–4%)*

Type 1: herniation without sac through a free greater omentum (more common)
= slitlike opening 2–10 cm in diameter
Type 2: herniation into lesser sac through gastrocolic lig.
√ closed-loop intestine without saclike appearance, located in most anterior portion of peritoneal cavity
√ omental vessels run vertically around hernia orifice
√ clinical + radiologic findings almost identical to transmesenteric hernia



Transmesocolic Hernia

Sigmoid Mesocolon Hernia *(6%)*

Types: intra-, transmeso-, intermesosigmoid subtypes

√ hernia orifice between sigmoid colon and left psoas major muscle in LLQ

√ small bowel loops posterolateral to sigmoid colon

√ ± herniation sac ± splaying of sigmoid arteries and veins

Internal Supravesical Hernia

√ saclike herniated intestine located anterolaterally to compressed urinary bladder (= retropubic space of Retzius)

Iatrogenic Hernia

TRANSMESOCOLIC HERNIA

Cause: fenestration of transverse mesocolon in construction of Roux-en-Y loop

√ cluster of small-bowel loops (70%)

√ clustered small bowel outside colon compressed against abdominal wall without overlying omental fat (85%)

√ central displacement of colon (92%)

√ displacement of mesenteric trunk (85%)

√ engorged mesenteric vessels (85%)

HERNIA THROUGH BROAD LIGAMENT (4–5%)

= congenital / acquired hernia after laceration / fenestration during surgery or during pregnancy (85%)

CT:

√ cluster of dilated small bowel loops with air-fluid levels in pelvic cavity

compressing rectosigmoid dorsolaterally and uterus ventrally
√ mesenteric vessels of herniated intestine penetrate broad ligament (coronal MPR)
√ enlarged distance between uterus and ovary deviating in opposite directions

Hiatal Hernia

Cause: delay in descent of stomach keeping hiatus large (in children)
Associated with: diverticulosis (25%), reflux esophagitis (25%), duodenal ulcer (20%), gallstones (18%)

Sliding Hiatal Hernia *(99%)*

= AXIAL HERNIA = CONCENTRIC HERNIA
= esophagogastric junction (= termination point of converging gastric folds) > 1.5 cm above diaphragmatic hiatus (= pinched appearance of gastric folds) with portion of peritoneal sac forming part of wall of hernia
Etiology: rupture of phrenicoesophageal membrane ← repetitive stretching with swallowing
Frequency: increasing with age
√ reducible in erect position
√ epiphrenic bulge = entire vestibule + sleeve of stomach are intrathoracic
√ distance between B ring (if visible) + hiatal margin > 2 cm
√ peristalsis ceases above hiatus → end of peristaltic wave delineates esophagogastric junction
√ tortuous esophagus having an eccentric junction with hernia
√ numerous coarse thick gastric folds within suprahiatal pouch (> 6 longitudinal folds)
√ ± gastroesophageal reflux
CT:
√ dehiscence of diaphragmatic crura > 15 mm
√ pseudomass within / above esophageal hiatus
√ increase in fat surrounding distal esophagus ← herniation of omentum through phrenicoesophageal lig.
DDx: normal temporary cephalad motion of esophago-gastric junction by 1–2 cm into chest ← contraction of longitudinal muscle during esophageal peristalsis

Paraesophageal Hernia *(1%)*

= ROLLING HIATAL HERNIA = PARAHIATAL HERNIA
= portion of stomach superiorly displaced into chest with GE junction remaining in subdiaphragmatic position
Cause: absence of gastrosplenic + gastrocolic ligaments; complication of Nissen fundoplication
√ cardia in normal position
√ herniation of portion of stomach anterior to esophagus
√ frequently nonreducible
√ may be associated with gastric ulcer of lesser curvature at level of diaphragmatic hiatus
Cx: organoaxial volvulus, colonic herniation

Totally Intrathoracic Stomach

= defect in central tendon of diaphragm in combination with slight volvulus in transverse axis of stomach behind heart (organoaxial rotation)
√ cardia may be intrathoracic (usually) / subdiaphragmatic
√ great gastric curvature either on right / left side

Congenitally Short Esophagus

(not true hernia, very rare)
= gastric ectopy by lack of lengthening of esophagus
√ nonreducible intrathoracic gastric segment (in erect / supine position)
√ cylindrical / round intrathoracic segment with large sinuous folds
√ short straight esophagus
√ circular narrowing at gastroesophageal junction, frequently with ulcer
√ gastroesophageal reflux

HETEROTOPIC PANCREAS

= pancreatic tissue at aberrant sites that lack a vascular / ductal connection to main pancreatic body
Origin: detachment of branching bud during embryonic gastrointestinal rotation
Prevalence: 1–15% (autoptic)
• usually asymptomatic
• occasionally abdominal pain, GI bleeding, obstruction
Location: upper part of GI tract near pancreas in prepyloric antrum of stomach along greater curvature (90%)
Site: submucosa / muscularis propria
√ flat ovoid intramural subepithelial nodule of < 3 cm
√ intraluminal growth ± central umbilication (= orifice of rudimentary pancreatic duct)
CT:
√ mass with irregular border
√ usually homogeneously enhancing mass with attenuation similar to pancreas
√ occasionally poor enhancement (if pancreatic acini remain a minor component of the mass)

Differentiation of heterotopic pancreas from other subepithelial masses is crucial to avoid unnecessary resection. Its typical location, flat-ovoid shape, intraluminal growth, and irregular border are helpful characteristics.

Rare Cx: pancreatitis, pseudocyst, cystic dystrophy, insulinoma, malignant transformation

HETEROTOPIC MESENTERIC OSSIFICATION

= OSSEOUS METAPLASIA of mesentery and peritoneum
Cause: trauma, repeated intraabdominal operative procedures
Pathogenesis: ? metaplasia of submesothelial mesenchyme; implantation of osteoblasts or periosteum during trauma / procedures
Histo: core of reactive myofibroblasts with hemorrhage + fat necrosis, osteoblastic activity, focal "lace-like" osteoid (DDx: extraskeletal osteosarcoma)
Location: mesentery with extension to peritoneal surface
√ multiple linear-branching structures of high-attenuation

√ trabecular architecture

DDx: (1) Extravasation of oral contrast (changing configuration on serial images, pooling in gravity-dependent locations, becoming less dense with time)

(2) Dystrophic calcifications (typically irregular /punctate / coarse calcifications without trabecular architecture)

HIRSCHSPRÜNG DISEASE

[Harald Hirschsprüng (1830-1916), pediatrician and chief physician of Queen Louisa Hospital for Children in Cøpenhagen, Denmark]

= AGANGLIONOSIS OF THE COLON = AGANGLIONIC MEGACOLON

= complete / partial functional colonic obstruction ← absence of parasympathetic ganglia in muscle (myenteric = Auerbach plexus) + submucosal layers (submucosal = Meissner plexus)

[Leopold Auerbach (1828–1897), German anatomist and professor of neuropathology at the University of Breslau]

[Georg Meissner (1829–1905), professor of anatomy and physiology in Basel, Freiburg and Göttingen, Germany]

Etiology: arrest of craniocaudal migration of neural crest cells along vagal trunks during 5th–12th week → relaxation failure of the aganglionic segment

Prevalence: 1÷5,000–8,000 live births; 15–20% of all neonatal bowel obstructions; usually sporadic; familial in 4%

Age: during first 6 weeks of life of a full-term infant (70–80%); extremely rare in premature infants; usually manifest by 5 years of age; M÷F = 4–9÷1

Associated with: trisomy 21 (in 2%)

Location: at varying distances proximal to anus, usually rectosigmoid (in 80%) and rectum

(a) ultrashort segment (= internal sphincter) (very rare)
(b) short segment disease (80%)
(c) long segment disease (15%)
(d) total colonic aganglionosis (5%)
(e) skip aganglionosis = sparing of rectum (very rare)

- failure to pass meconium within first 48 hours of life
- intermittent constipation + paradoxical diarrhea (25%)
- bilious vomiting, abdominal distension
- rectal manometry with absence of spike activity

√ generalized gaseous distension of bowel loops

BE (study of choice):

√ "transition zone":

√ inverted cone-shaped colon at transition between abnormal + normal bowel (MOST CHARACTERISTIC):

√ dilated stool-filled large + small bowel aborally from transition zone

√ distal aganglionic segment of normal size + free of stool (apparent in 50% during 1st week of life)

√ normal-appearing rectum in 33%

√ short patent colon usually of normal caliber

√ marked retention of barium on delayed postevacuation films after 12–24 hours

√ 10–15-cm segment of persistent corrugated / convoluted rectum (= abnormal uncoordinated contractions of the aganglionic portion of colon) in 31% (DDx: colitis, milk allergy, normal intermittent spasm of rectum)

N.B.: avoid digital exam / cleansing enema prior to radiographic studies!

OB-US:

√ dilated small bowel / dilated colon

CT:

√ narrow transition zone + aboral colonic distension on SAG reformatted view of lower abdomen + pelvis

Cx: (1) Necrotizing enterocolitis
(2) Cecal perforation ← stasis, distension, ischemia
(3) Obstructive uropathy

Dx: full-thickness biopsy of rectum (↑ acetylcholinesterase activity)

Rx: (1) Swenson pull-through procedure
(2) Duhamel operation
(3) Soave procedure

HYPERPLASTIC POLYP OF COLON

= intestinal metaplasia consisting of mucous glands lined by a single layer of columnar epithelium; NO malignant potential

Path: infolding of epithelium into the glandular lumen

Location: rectosigmoid

√ smooth rounded sessile elevation

√ usually < 5 mm in diameter

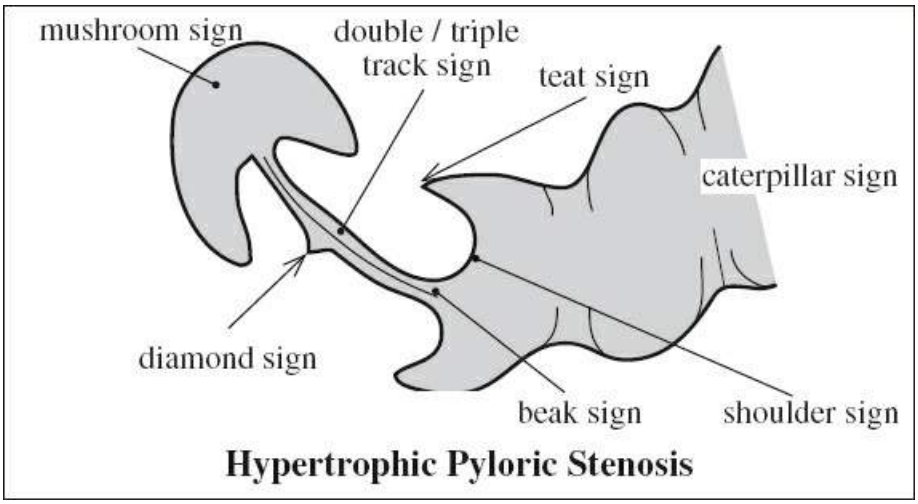
HYPERTROPHIC PYLORIC STENOSIS (HPS)

= idiopathic hypertrophy and hyperplasia of circular muscle fibers of pylorus with proximal extension into gastric antrum

Etiology: inherited as a dominant polygenic trait; increased incidence in firstborn boys; acquired rather than congenital condition

Infantile Form of Hypertrophic Pyloric Stenosis

Age: manifestation between 3rd–12th week of life; peak presentation during 4th week



Frequency: 3÷1,000 births; M÷F = 4–5÷1; 5 x fold increase in 1st-degree relatives

- nonbilious projectile vomiting (sour formula / clear gastric contents) → progression over a period of several weeks after birth (15–20%)
- palpable olive-shaped mass (80% sensitive in experienced hands, up to 14% false positive)
- nasogastric aspirate > 10 mL (92% sensitive, 86% specific)

Abdominal radiograph:

◊ A normal radiograph does not exclude HPS!

√ fluid-filled distended stomach after 2 hours of fasting

√ little bowel gas

UGI (95% sensitivity):

◊ Imaging confirmation is sought by most clinicians to differentiate from gastroesophageal reflux!

Benefit: complete anatomic evaluation of stomach and duodenum; functional assessment of gastroesophageal reflux

Precautions: (1) Empty stomach via nasogastric tube before study

(2) Remove contrast at end of study

√ elongation + narrowing of pyloric canal (2–4 cm in length):

√ "string" sign = passing of small barium streak through elongated pyloric channel (MOST SPECIFIC SIGN)

√ "double / triple track" sign = crowding of mucosal folds in pyloric channel

√ Twining recess = "diamond" sign = transient triangular tentlike cleft / niche in midportion of pyloric canal with apex pointing inferiorly ← mucosal bulging between two separated hypertrophied muscle bundles on the greater curvature side within pyloric channel

√ abnormal configuration of antrum:

√ "pyloric teat" = outpouching along lesser curvature due to disruption of antral peristalsis

√ "shoulder" sign = impression of hypertrophied muscle on distended gastric antrum

√ "antral beaking" = mass impression upon antrum with streak of barium pointing toward pyloric channel

- √ "olive pit" sign = impression of pyloric muscle upon antrum with a tiny amount of barium at orifice seen en face
- √ Kirklin sign = "mushroom" sign = indentation of base of duodenal bulb (in 50%)

√ gastric distension with fluid
√ active gastric hyperperistalsis:
- √ "caterpillar" sign = gastric hyperperistaltic waves

US (method of choice ← direct visualization of HPS):
√ "target" sign = hypoechoic ring of hypertrophied pyloric muscle around echogenic mucosa centrally on cross-section
√ elongated pylorus with thickened muscle:
- √ pyloric muscle wall thickness ≥ 3.0 –3.2 mm
- √ pyloric volume > 1.4 cm^3 (= ¼ π x [maximum pyloric diameter]2 x pyloric length); most criteria independent of contracted or relaxed state (33% false negative)
- √ pyloric length (mm) + 3.64 x muscle thickness (mm) ≥ 25 mm
- √ pyloric transverse diameter ≥ 13 mm with pyloric channel closed
- √ elongated pyloric canal ≥ 16–17 mm in length

√ "cervix" sign = indentation of muscle mass on fluid-filled antrum on longitudinal section
√ "antral nipple" sign = redundant pyloric channel mucosa protruding into gastric antrum
√ exaggerated peristaltic waves
√ delayed gastric emptying of fluid into duodenum

Pitfalls: gastric antrum mistaken for HPS (ingestion of Pedialyte® improves definition of anatomic landmarks)

Cx: hypochloremic metabolic alkalosis

Rx: pyloromyotomy

Prognosis: 2% mortality

DDx:

1. **Infantile pylorospasm**
   = temporary thickening of pyloric muscle
   - √ variable muscle thickness between 1.5 and 3.0 mm
   - √ variable caliber of antral narrowing
   - √ antral peristalsis
   - √ delayed gastric emptying (assure adequate length of real-time observation)
   - √ elongation of pylorus
   - √ gastric content / fluid passes through pyloric channel

   Prognosis: resolves in several days / ? early stage of evolving pyloric stenosis

   Rx: effective with metoclopramide / Bentyl®
2. Gastritis / milk allergy
   - √ circumferential / eccentric thickening of antral mucosa > 2–3 mm
3. Duodenal obstruction from midgut volvulus
   - √ distended descending duodenum
   - √ reversal of SMA and SMV relationship
   - √ "whirlpool" sign = twisting of small bowel mesentery
4. Gastric diaphragm

Adult Form of Hypertrophic Pyloric Stenosis

Cause: secondary to mild infantile form
• acute obstructive symptoms uncommon
• nausea, intermittent vomiting, postprandial distress, heartburn
Associated with:
(1) Peptic ulcer disease (in 50–74%) ← prolonged gastrin production ← stasis of food
(2) Chronic gastritis (54%)
√ persistent elongation (2–4 cm) + concentric narrowing of pyloric channel
√ parallel + preserved mucosal folds
√ antispasmodics show no effect on narrowing
√ proximal benign ulcer (74%), usually near incisura

Focal Pyloric Hypertrophy

= TORUS HYPERPLASIA
= localized muscle hypertrophy on lesser curvature
= milder atypical form of HPS
√ flattening of distal lesser curvature

ILEAL DIVERTICULOSIS

= acquired mucosal herniation of bowel at sites of vascular entry
• usually asymptomatic
Age: > 40 years; M > F
Site: mesenteric border of terminal ileum < 7.5 cm from ileocecal valve
Cx: perforation, bleeding, small bowel obstruction
DDx: acute appendicitis

IMPERFORATE ANUS

Prevalence: 1÷5,000 live births
A. LOW ANOMALY (55%)
= bowel has passed through levator sling
• fistula to perineum / vulva
Rx: readily reparable
B. INTERMEDIATE DEFECT (least common)
= bowel ends within levator muscle as a result of abnormality in posterior migration of rectum
• fistula opening low in vagina / vestibule
Rx: 2- / 3-stage operation
C. HIGH ANOMALY
= bowel ends above levator sling; M > F
• fistulous connection to perineum / vagina / posterior urethra → air in bladder in males / air in vagina in females
Cx: associated malformations more common + more severe
Rx: multiple surgical procedures
√ distance between rectal air and skin will not accurately outline the extent of atretic rectum and anus ← varying length during crying with increase in abdominal pressure + contraction of

levator ani muscle

US:

√ ≤ 15 mm distance between anal dimple + distal rectal pouch on transperineal images → indicates low lesion

OB-US (earliest detection by 20–29 weeks GA):

- absent / low disaccharidase level in amniotic fluid

√ dilated colon in lower pelvis with U- / S-shaped configuration ± intraluminal calcifications

√ normal amniotic fluid (unless also TEF)

√ absence of anal characteristics (= hypoechoic circular rim with central echogenic stripe)

INFLAMMATORY FIBROID POLYP

= VANEK TUMOR = EOSINOPHILIC GRANULOMA = SUBMUCOSAL FIBROMA = FIBROUS POLYPOID LESION

= unusual benign chronic inflammatory lesion

◊ Unrelated to eosinophilic granuloma of lung / bone

Path: arises in submucosa

Histo: spindle cells arranged in whorls around blood vessels with prominent inflammatory cells, particularly eosinophils

Immunohisto: stains for CD34; diffusely positive for vimentin

- usually asymptomatic, NO peripheral eosinophilia
- abdominal pain, GI bleeding ← mucosal ulceration

Location: almost exclusively in stomach: gastric antrum (75%) > gastric body > fundus

Size: 2–5 cm in diameter

√ intraluminal subepithelial polypoid mass / pedunculated polyp with smooth / slightly lobulated contour

Cx: intermittent gastric outlet obstruction

Rx: endoscopic resection

DDx: adenomatous polyp, intraluminal GIST, carcinoid tumor, schwannoma

INFLAMMATORY MYOFIBROBLASTIC TUMOR

= PLASMA CELL GRANULOMA = INFLAMMATORY PSEUDOTUMOR = INFLAMMATORY FIBROSARCOMA = XANTHOMATOUS PSEUDOTUMOR = HISTIOCYTOMA = XANTHOGRANULOMA = FIBROXANTHOMA = PSEUDOLYMPHOMA

= rare neoplasm of intermediate biologic behavior with a low rate (< 5%) of metastases based on cytogenetic studies.

Genetics: rearrangement in anaplastic lymphoma kinase (ALK) gene = tyrosine receptor kinase oncogene (in 50–70%)

Age: any; young adult and child; M < F

Path: solitary multilobular circumscribed solid mass

Histo: myofibroblastic spindle cell proliferation in a loosely myxoid to dense collagenous stroma surrounded by a prominent inflammatory cell infiltrate composed of polyclonal plasma cells, lymphocytes, eosinophils and nonnecrotizing epithelial cell granulomas

Immunohisto: spindle cells reactive with anaplastic lymphoma kinase (ALK) + smooth muscle actin

• fever, weight loss, anemia, thrombocytosis, polyclonal hypergammaglobulinemia (in 25%)
• abdominal pain ← mass effect (most common)

Location: abdominal cavity (mesentery, GI tract), lung, salivary glands, larynx, mediastinum, retroperitoneum, solid organs

Mean size: 7–8 (range, 1–20) cm in diameter

√ nonspecific varied imaging finding depending on site of origin and composition of inflammatory infiltrate and fibrosis

@ mesentery / omentum

√ bulky well-demarcated homo- / heterogeneous spherical / multilobulated mass

US:

√ ill- / well-defined heterogeneous hypo- / hyperechoic solid mass of mixed echotexture

√ ± shadowing echogenic calcifications / central hypoechoic regions

√ prominent vascularity with low-resistance arterial waveform on color Doppler

CT:

√ hypo- / isoattenuating compared with skeletal muscle depending on amount of myxoid / collagenous stroma

√ variably heterogeneous / peripheral enhancement / nonenhancing

√ peritoneal dissemination + lymphadenopathy (rare)

√ (rarely) aggressive intramural masses ± invasion through gastric wall into peritoneal cavity / nearby organs

MR:

√ typically T1-hypointense relative to skeletal muscle and hyperintense on T2WI

√ densely fibrotic tumor may be dark on both sequences

PET/CT:

√ useful in detecting primary tumor, local recurrence, distant metastases

Rx: complete surgical resection → propensity for local recurrence

DDx: (1) Desmoplastic small round cell tumor (diffuse involvement of peritoneal cavity)
(2) Castleman disease (diffuse intense enhancement)
(3) Mesenteric fibromatosis (may encase bowel wall and SMA, family history of colonic polyps)
(4) Burkitt lymphoma (typically diffuse at presentation, rapid doubling rate)
(5) Lipoblastoma (young child, fat attenuation)
(6) Lymphatic malformation (large cystic component, chylous ascites)
(7) Infantile hemangioma (< 1 year of age, intense uniform enhancement, enlarged feeding and draining vessels)
(8) Others: GIST, solitary fibrous tumor, schwannoma, multiple myeloma, solitary plasmacytoma

INTESTINAL LYMPHANGIECTASIA

A. CONGENITAL LYMPHANGIECTASIA

= PRIMARY PROTEIN-LOSING ENTEROPATHY

= generalized congenital malformation of lymphatic system with atresia of the thoracic duct + gross dilatation of small bowel lymphatics; usually sporadic; may be inherited

Age: presentation before 30 years
- asymmetric generalized lymphedema ← protein-losing enteropathy with hypoproteinemia
- chylous pleural effusions (45%)
- diarrhea (60%), steatorrhea (20%), vomiting (15%)
- abdominal pain (15%) + distension
- decreased albumin + globulin, lymphocytopenia (90%)
- decreased serum fibrinogen, transferrin, ceruloplasmin

B. ACQUIRED LYMPHANGIECTASIA

Causes leading to dilatation of intestinal lymphatics:
1. Mesenteric adenitis
2. Retroperitoneal fibrosis
3. Diffuse small bowel lymphoma
4. Pancreatitis
5. Pericardial effusion with obstruction of thoracic duct

- peripheral edema / anasarca (KEY SYMPTOM)
- chylous + serous effusion; malabsorption
- diarrhea, vomiting, abdominal pain, steatorrhea
- hypoproteinemia ← protein loss into intestinal lumen

Path: dilatation of lymph vessels in mucosa + submucosa + abundance of foamy fat-staining macrophages (DDx to Whipple disease: negative for PAS)

√ marked irregular diffuse symmetric thickening of folds in jejunum + ileum ← dilated intestinal lymphatics + hypoproteinemic edema

√ micronodularity ← dilated lacteal vessels in submucosa + lamina propria

√ slight separation + rigidity of folds

√ dilution of barium column ← considerable increase in intestinal secretions from malabsorption

√ no / mild dilatation of bowel

Lymphangiogram (not always diagnostic):

√ hypoplasia of lower extremity lymphatics

√ occlusion of thoracic duct / large tortuous thoracic duct

√ obstruction of cisterna chyli with backflow into mesenteric + intestinal lymphatics

√ hypoplastic lymph nodes

Dx: small bowel biopsy (dilated lymphatics in lamina propria + vascular core)

Rx: low-fat diet with medium-chain triglycerides (direct absorption into portal venous system)

DDx: (1) Whipple disease (more segmentation + fragmentation, wild folds)

(2) Amyloidosis (edema + secretions usually absent)

(3) Hypoalbuminemia (less pronounced symmetric thickening of folds, less prominent secretions)

INTESTINAL PSEUDOOBSTRUCTION

= decreased ability of intestines to push food through

◊ Clinical and radiological findings similar to true intestinal obstruction

√ dilation of various parts of the bowel

A. Primary (idiopathic or inherited)

B. Secondary (due to another disease)

Colonic Pseudoobstruction

= PSEUDOMEGACOLON = ADULT MEGACOLON = ADYNAMIC ILEUS = FUNCTIONAL OBSTRUCTION = IDIOPATHIC LARGE-BOWEL OBSTRUCTION = OGILVIE SYNDROME

[Sir William Heneage Ogilvie (1887–1971), English surgeon at Guy's Hospital, London]

X-ray:

√ nonspecific findings of gaseous distention of colon

√ cecal diameter > 12 cm → colonic decompression

BE:

◊ Avoid if cecal perforation is suspected!

Rx: nasogastric suction, enemas, neostigmine, colonoscopic decompression

DDx: mechanical obstruction, paralytic ileus

Acute Colonic Pseudoobstruction

= rare clinical disorder with signs & symptoms & radiographic appearance of an acute large bowel obstruction but without mechanical obstruction

Pathogenesis:
imbalance in autonomic nervous system (sympathetic overactivity + parasympathetic suppression) after recent significant medical illness / surgical procedure

Cause: retroperitoneal trauma, especially fracture (11–52%), pelvic / abdominal / cardiothoracic surgery (20%), infection (10%), cardiac disease [MI, CHF] (10%)

In 50% associated with:
metabolic imbalance (hypokalemia, hypocalcemia, hypo-magnesemia), drugs (narcotic analgesics, antidepressants, antipsychotic, calcium channel blockers, narcoleptics)

Age: > 60 years / younger patient with spinal disorder; M > F

- abdominal pain (80%), abdominal distension
- nausea & vomiting (80%), obstipation (40%), diarrhea
- fever (37%), bowel sounds present

√ massively dilated colon, especially cecum + right hemicolon (occasionally extending to rectum)

√ normal haustral markings

√ "colon cut-off" sign ← lack of gas in distal colon

√ small bowel air-fluid levels

√ absence of obstructive lesion on enema

Cx: cecal perforation

Prognosis: 15–45% mortality

Rx: nasogastric + rectal suctioning; neostigmine; colonic decompression (if cecum exceeds 10 cm)

DDx: toxic megacolon, mechanical obstruction

Chronic Colonic Pseudoobstruction

= recurrent or persistent pseudobstruction of colon

Path: atrophic changes + decreased numbers of intramural ganglia (= sign of irreversible intramural plexus damage)

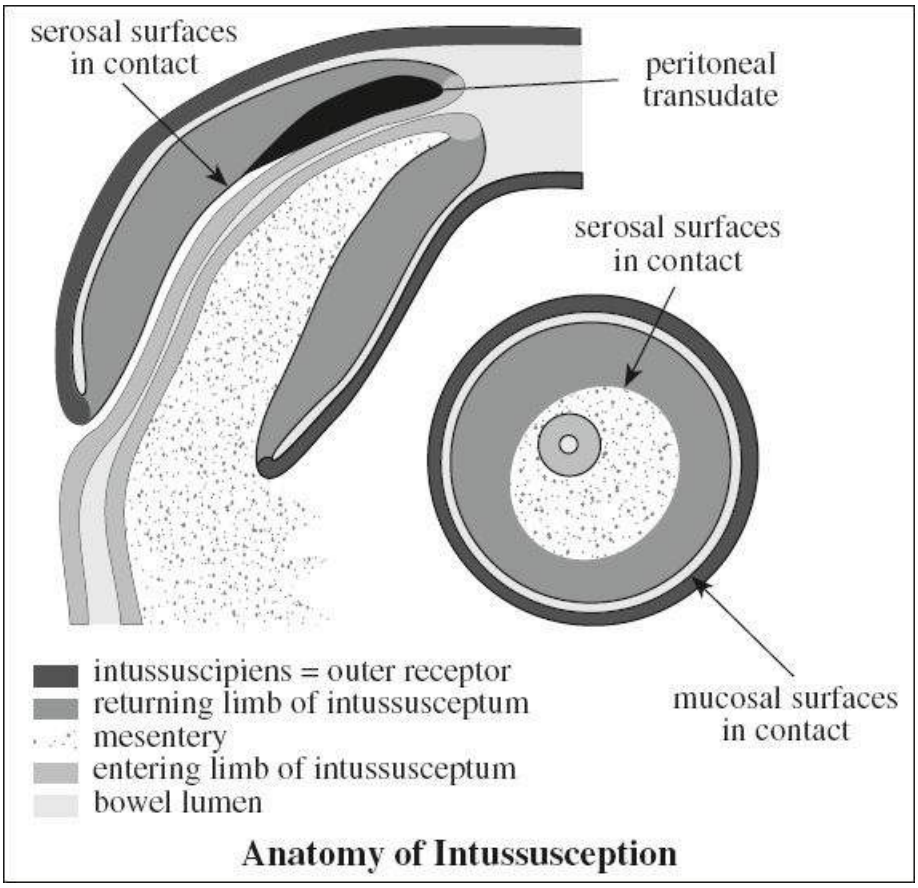
• chronic constipation, repeated obstructive symptoms

CT:

√ marked colonic dilatation: cecum (4–10 cm), transverse colon (8.2–13.7 cm)

√ intermediate transitional zone at / adjacent to splenic flexure (= transition zone of innervation from vagal to sacral nerves for proximal versus distal colon)

◊ Rarely accompanied by perforation!



Anatomy of Intussusception

Chronic Intestinal Pseudoobstruction Syndrome

= nonpropulsive intestine characterized by impaired response to intestinal dilatation without definable cause; ? autosomal dominant

Cause:

(1) Reduced density of interstitial cells of Cajal in colon (= intestinal pacemaker cells)

(2) Neuropathic disorder: amyloidosis, diabetes, multiple sclerosis, brainstem tumor, stroke, spinal cord injury, Parkinsonism, paraneoplastic syndromes (antineuronal nuclear antibodies)

(3) Myopathy: scleroderma

(4) Medication: anticholinergic antidepressant, calcium channel blocker, alpha-2 adrenergic agonists

Age: neonatal period / delayed for months + years,
M÷F = 1÷1

• recurrent attacks of nausea & vomiting (83%)

- abdominal pain (74%), abdominal distension (57%)
- constipation (36%), diarrhea (29%)
- persistently decreased peristalsis

√ esophageal dilation + hypoperistalsis (lower third)
√ excessive duodenal dilation (DDx: megaduodenum, superior mesenteric artery syndrome)
√ mild to marked gaseous distension of proximal small bowel
√ ligament of Treitz may be placed lower than usual
√ delayed transit of barium through affected segments
√ disordered motor activity (on fluoroscopy)
√ small bowel air-fluid levels + distension
√ disturbed intestinal transit

INTUSSUSCEPTION

= telescope-like invagination or prolapse of a segment of intestinal tract (= intussusceptum = donor loop) into the lumen of the adjacent intestinal segment (= intussuscipiens = receiving loop)

◊ The intussuscipiens contains the folded intussusceptum with entering limb + returning limb + their mesentery

Classification by Location: enteroenteric, ileocolic, ileocecal, colocolic

Classification by Cause: benign, malignant, idiopathic, ± lead point

Intussusception in Children (94%)

Prevalence: 2–4÷1,000 live births; most common abdominal emergency of early childhood

◊ Leading cause of acquired bowel obstruction in childhood!

Etiology:

(1) Idiopathic (over 95%): mucosal edema + lymphoid hyperplasia (= enlarged Peyer patches) following viral gastroenteritis; predominantly at ileocecal valve

(2) Lead point (5%):

(a) infants < 30 days of age: Meckel diverticulum (most common), duplication cyst

(b) children > 3 years of age: Burkitt lymphoma, polyp in Peutz-Jeghers syndrome, polypoid hemangioma, enterogenous cyst, ectopic pancreas, suture granuloma, periappendicitis, Henoch-Schönlein purpura, coagulopathy, cystic fibrosis, inspissated meconium

mnemonic: H DIMPL

Henoch-Schönlein purpura
Duplication cyst
Idiopathic (= hypertrophied lymphoid tissue)
Meckel diverticulum
Polyp
Lymphosarcoma

Age: peak incidence between 6 months and 2 years; 3–9 months (40%); < 1 [< 2] {> 3} years (50%) [75%] {< 10%}; M÷F = 2÷1

- classic triad:

(1) Abrupt onset of acute colicky abdominal pain (94%)

(2) Red "currant jelly" stools / hematochezia (66%) usually only after > 48 hours duration
(3) Palpable abdominal mass (59%) / vomiting (91%)
• diarrhea, restlessness, pallor, fever

Location: ileocolic (75–95%) > ileoileocolic (9%) > ileoileal (4%) > colocolic
Tip of intussusceptum: transverse colon + hepatic flexure + ascending colon (90%)

Plain film (40–90% accurate):
◊ Air within cecum excludes diagnosis of ileocecal intussusception!
CAVE: Sigmoid colon may be mistaken for cecum as it is often positioned in RLQ in infants and children!
√ no abnormality in 25%
√ abdominal soft-tissue mass (50–60%), usually in RUQ:
√ "**target**" sign = concentric lucent rim surrounding a soft-tissue mass ← mesenteric fat of intussusceptum
√ "**meniscus**" sign = crescent of intraluminal colonic gas outlining the apex of the intussusceptum
√ loss of inferior hepatic margin

The target and meniscus signs are the most specific radiographic findings of an intussusception.

√ little air in small intestine:
√ paucity of gas in RLQ / pelvis
√ gasless lower abdomen
√ air in displaced appendix
√ small bowel obstruction for several hours (25%):
√ dilated loops of small bowel
√ stacked air-fluid levels
√ pneumoperitoneum (usually > 2–3 days of symptoms)

Antegrade barium study:
√ "coiled spring" appearance
√ beaklike abrupt narrowing of barium column demonstrating a central channel

Diagnostic Enema:
Indication: unusual age of child (< 2 months, > 4 years), high fever, peritoneal signs
Contraindication: free air
√ "meniscus" sign = convex intracolic mass = rounded apex of intussusceptum protrudes into contrast column
√ "coiled spring" sign = edematous mucosal folds of returning limb of intussusceptum outlined by contrast material within lumen of colon

US (98% sensitive, 98% specific, 99% NPV):
√ readily detectable mass over 5.0 x 2.5 cm
√ "crescent-in-doughnut / target / bull's eye" sign (on TRANSVERSE scan) = concentric rings of alternating hypoechoic + hyperechoic layers (= intussuscipiens) with central hyperechoic portion (= mesentery of intussusceptum)
√ "**pseudokidney / sandwich / hay fork**" sign (on LONGITUDINAL scan) = hypoechoic layers on each side of echogenic center of mesenteric fat
√ peritoneal fluid trapped inside intussusception in < 15% (associated with irreducibility + ischemia)

√ echogenic mesentery contains lymph nodes + ceco-appendiceal complex close to base of intussusception
√ color Doppler demonstrates mesenteric vessels dragged between entering + returning wall of intussusceptum:
◊ Absence of blood flow within the intussusceptum → suggests bowel necrosis (47%)!
◊ Presence of blood flow within the intussusceptum is a good predictor of reducibility!

CT:
√ sausage-shaped / targetoid mass of "multiple concentric rings" = 3 concentric cylinders:
(a) central = canal + wall of intussusceptum
(b) middle = crescent of mesenteric fat
(c) outer = returning intussusceptum + intussuscipiens
√ enhancing vessels within mesenteric fat
√ proximal obstruction

Cx: vascular compromise ← incorporation of mesentery (hemorrhage, infarction, acute inflammation)

Hydrostatic / Pneumatic Reduction

< 1% mortality if reduction occurs < 24 hours after onset!

Overall success rate: 70–85%

Contraindications: pneumoperitoneum, peritonitis, hypovolemic shock, severe dehydration
◊ Obtain abdominal radiograph to document absence of perforation before reduction!

Technique:
» Sedation (debated) with morphine sulfate (0.2 mg/kg IM) / fentanyl citrate IV (straining increases intraluminal pressure of distended colon)
» Anal seal with 24-F Foley catheter + balloon inflation to size equal to interpediculate distance of L5; balloon pulled down to levator sling; taped to buttocks; both buttocks firmly taped together
» 60% wt/vol barium sulfate with container between 24–36 inches above level of anus
» Extensive reflux into small bowel desirable to exclude residual ileoileal intussusception
◊ Maximally 3 attempts for 3 minutes each
◊ Manual manipulation increases colonic pressure
◊ Reduction should be accomplished within 10 minutes

"**Rule of 3s**":
(1) 3.5 feet (105 cm) above table (= 120 mmHg)
(2) 3 attempts
(3) 3 minutes between attempts → delay allows venous congestion + edema to subside

Alternative medium:
(1) 1÷4 Gastrografin®-water solution raised to a height of 5 feet (150 cm)
(2) Air (METHOD OF CHOICE): delivers higher intra-colonic pressures, faster, easier, less fluoroscopic time, barium-free colon in case of surgery, smaller tears, less contamination of peritoneal cavity

(3) Ultrasound-guided saline enema: NO limit to procedure time, low perforation rate

Decreased Success Rate:

(1) Duration of symptoms > 48 hours
(2) Significant dehydration
(3) Radiographic signs of small bowel obstruction
(4) Patient age < 3 months or > 5 years
(5) Fluid trapped between layers of intussusception by US
(6) Absence of color flow within intussusception

Cx: perforation (0.4–3.0%, colonic bursting pressure ~ 200 mmHg); reduction of nonviable bowel; incomplete reduction; missed lead point

Prognosis: 10–15% rate of recurrence within first few days

Intussusception in Adults (5–6%)

Frequency: accounts for 1% of all bowel obstructions; 0.05% of CT exams

In adults a lead point intussusception involving the small bowel is generally due to a benign condition and less often due to a neoplasm (usually a metastatic lesion).

Etiology:

A. SPECIFIC CAUSE (80%):
1. Tumor: benign (⅓; lipoma, leiomyoma, adenomatous polyp), malignant ($^1/_5$; lymphoma, metastasis)
2. Postsurgical changes (⅓): adhesions adjacent to sutures / submucosal bowel edema / discoordinated motility
3. Invaginated (= inverted) Meckel diverticulum
4. Prolapsed gastric mucosa
5. Aberrant pancreas
6. Foreign body, feeding tube
7. Chronic ulcer: TB, typhoid
8. Prior gastroenteritis
9. Gastroenterostomy, trauma

spontaneous without anatomic lead point:
celiac disease, scleroderma, Whipple disease, fasting, anxiety, agonal state

B. IDIOPATHIC (20%)

Causes of Adult Intestinal Lead Point Intussusception

Cause	*Small Bowel*	*Large Bowel*
Benign	lipoma, adenomatous polyp, Meckel diverticulum	lipoma, adenomatous polyp
Malignant	metastasis, lymphoma, adenocarcinoma	adenocarcinoma, lymphoma, metastasis
Idiopathic	postoperative adhesion, motility disorder	postoperative adhesion, motility disorder

- recurrent episodes of colicky pain, nausea, vomiting
- abdominal tenderness, distension, change in bowel habits

• palpable mass (in up to 50%), bloody stool (in majority)
Location: ileoileal (40%) > ileocolic (15%), colocolic
small bowel (55%): nonneoplastic (43%), benign neoplasm (40%), malignant neoplasm (17%)
colon (45%): malignant neoplasm (48%), benign neoplasm (21%), nonneoplastic (31%)
Prognosis: self-limiting if intussusception < 3.5 cm in length

Transient (Idiopathic) Intussusception

= temporary short-lived intussusception without clinical significance incidentally detected on abdominal CT
Cause: idiopathic; celiac disease, Crohn disease
• asymptomatic
Location: small bowel, especially jejunum
√ < 3.5 cm in length
√ NO intestinal obstruction, NO lead point

ISCHEMIC COLITIS

= most common manifestation of ischemic injury to GI tract (50%) characterized by acute onset + rapid clinical and radiographic evolutionary changes
Types:
1. Occlusive / thromboembolic ischemic colitis (80%)
2. Nonocclusive ischemic colitis (20%)
   = major mesenteric vessels usually patent
   (a) low systemic flow state: hypovolemic shock, severe heart failure, arrhythmia, renal insufficiency, sepsis
   (b vasoconstricting drugs: cardiotonics, NSAID, amphetamines, cocaine
3. Venous insufficiency

Pathophysiology:
decrease in blood flow to 20% of normal flow associated with small vessel disease (hypoxia) + reperfusion injury when blood flow is reestablished; injury more severe if terminal vascular branches obstructed rather than proximal mesenteric arcades
Path:
(a) injury of mucosa + submucosa (the 2 most sensitive layers to ischemia) → mucosal congestion, patchy necrosis, ulcerations, submucosal edema, hemorrhage
◊ Early mucosal injury is reversible!
(b) injury of muscularis propria (after severe + prolonged ischemia) → can lead to transmural necrosis → fibrotic stricture, perforation, severe sepsis
Precipitating factors:
(a) bowel obstruction: volvulus, carcinoma (proximal dilatation with increased intraluminal pressure and reduced blood flow)
(b) thrombosis: myocardial infarction, oral contraceptives, collagen vascular disease, sickle cell disease, hemolytic-uremic syndrome
(c) trauma: aortoiliac reconstruction (2%) with ligation of IMA, cardiac surgery
(d) idiopathic / spontaneous: mainly in elderly

mnemonic: VINTS

Vasculitis
Incarceration (hernia, volvulus)
Nonocclusive ischemia (shock, CHF)
Thrombosis (atherosclerosis, emboli, polycythemia vera, hyperviscosity)
Spontaneous

Age: usually > 50 years; M = F

- abrupt onset of lower abdominal pain + rectal bleeding
- abdominal tenderness, diarrhea, lack of sepsis
- negative stool cultures

Location: segmental involvement of any part of colon; left colon (46–90%); right colon (30%); entire colon (11%); transverse colon (9%); sigmoid colon (4%); rectum spared <u>most commonly affected "watershed" segments:</u>

(a) **Griffith point** (80%) = junction between distribution of superior + inferior mesenteric arteries at splenic flexure
(b) **point of Sudeck** = anastomotic plexus between inferior mesenteric artery + hypogastric vascular supply at rectosigmoid junction

Mean length of segmental involvement: 19 cm

Plain film (usually normal):

√ segmental thumbprinting = marginal indentations on mesenteric side (rare finding on plain film)

BE (in 90% abnormal):

◊ Double contrast BE is more sensitive than single contrast BE which may efface thumbprinting!
√ thumbprinting (75%) ← submucosal hemorrhage + edema
√ transverse ridging = markedly enlarged mucosal folds with some preserved wall pliability ← spasm
√ serrated mucosa ← inflammatory edema + superficial longitudinal / circumferential ulcerations
√ deep penetrating ulcers (late)

CT (detection rate of 26–39%):

√ symmetric / lobulated segmental thickening of colonic wall between 2 and 20 (mean 8) mm:
  √ shaggy configuration + alternating layers of high and low attenuation (= "double halo" sign) + marked pericolic streakiness of edema (wet appearance in 61%)
  √ sharply defined homogeneously enhancing wall + mild mural thickening (dry appearance in 33%)
√ hyperattenuating mucosa in early stage ← hemorrhage
√ blood clot in SMA / SMV
√ loss of haustral markings
√ irregular narrowed atonic lumen (= thumbprinting)
√ curvilinear collection of intramural gas (pneumatosis coli in 6%) → suggests bowel infarction
√ portal + mesenteric venous gas
√ pneumo- and retropneumoperitoneum (= the only PATHOGNOMONIC sign of transmural

necrosis)

CECT:

- √ hyperenhancing mucosa in early stage ← hyperemia
- √ reduced / absent enhancement in later stage ← intense vasospasm accompanied by bowel dilatation
- √ absent opacification in SMA / SMV distribution

US:

- √ circumferential hypoechoic > 3 mm thick bowel wall
- √ variable loss of mural stratification (= indistinct layers)
- √ abrupt transition from ischemic to normal bowel
- √ absent / diminished color flow in bowel wall = indicator of severity of ischemia (82% sensitive, 92% specific)
- √ absence of arterial signals; however, blood flow on Doppler may represent reperfusion of gut wall
- √ usually unaltered perienteric fat
- √ commonly associated with:
  - √ ascites, luminal bowel distention
  - √ pneumatosis intestinalis, gas within portal veins

Angio (findings similar to inflammatory disease):

- √ normal / slightly attenuated arterial supply
- √ mild acceleration of arteriovenous transit time
- √ small tortuous ectatic draining veins

Prognosis:

(1) Transient ischemia = complete resolution within 1–3 months (76%)

(2) Stricturing ischemia = incomplete delayed healing
   - √ narrowed foldless segment of several cm in length with smooth tapering margins

(3) Gangrene with necrosis + perforation (extremely uncommon)

(4) Mortality rate of 11–36%

DDx of dry appearance: ulcerative / granulomatous colitis

DDx of wet appearance: pseudomembranous colitis, CMV colitis

Ischemic Necrosis of Cecum

= rare spontaneous potentially life-threatening entity

Associated with: chronic heart disease, cardiopulmonary bypass surgery, systemic chemotherapy, cholesterol embolization, aortitis syndrome

Age: elderly

CT:

- √ circumferential cecal wall thickening
- √ mural stratification pattern ← submucosal edema
- √ mild pericolic stranding with normal appendix and absence of diverticula
- √ isolated pneumatosis coli
- √ mesenteric / portal venous gas
- √ pneumoperitoneum

JEJUNAL ATRESIA

◊ Air may be injected through nasogastric tube
◊ BE to exclude 2nd and 3rd areas of atresia
Cause: intrauterine ischemic injury to developing gut
Age: majority presenting during 1st day of life
In 25% associated with: malrotation, volvulus, gastroschisis, omphalocele
• bilious vomiting, abdominal distension, failure to pass meconium
Plain film:
N.B.: difficult to tell colon from small bowel in neonate
√ 2–3 dilated bowel loops
√ absence of gas in lower portion of abdomen
BE:
Purpose: to exclude large-bowel causes of obstruction, show anatomical size of colon, demonstrate meconium ileus
√ microcolon / small colon / colon of normal caliber (due to sufficient intestinal secretions in remaining small bowel)
Cx: meconium peritonitis (5%)

JEJUNAL DIVERTICULAR DISEASE

= JEJUNAL DIVERTICULOSIS
= rarest form of gastrointestinal diverticular disease
Cause: disordered contractions of smooth muscle results in increased intraluminal pressure and mucosal herniation (= pulsion diverticula = false diverticula)
Frequency: 0.5–1.1–2.3% on UGI; 0.3–4.5% of autopsy series; M > F
Age: 6th–7th decades
Location: 80% in jejunum, 15% in ileum (usually solitary), 5% in jejunum + ileum
Site: on mesenteric border near entrance of vasa recti
• intermittent upper abdominal pain, flatulence, episodes of diarrhea (30%)
Size: a few millimeters to > 10 cm
Plain film:
√ air-fluid levels in multiple diverticula
√ slight dilatation of intestinal loops in area of diverticula
BE:
√ may not fill (narrow neck / stagnant secretions)
√ trapped barium on delayed film after 24 hours
Cx:
(1) Blind loop syndrome with bacterial overgrowth
• steatorrhea, diarrhea, malabsorption, weight loss
• megaloblastic anemia ← overgrowth of coliform bacteria leads to deconjugation of bile acids + intraluminal metabolism of vitamin B_{12}
(2) Free perforation = leading cause of pneumoperitoneum without peritonitis (21–40% mortality)
(3) Hemorrhage (few cases)
(4) Diverticulitis
(5) Intestinal obstruction: enterolith ileus

JUVENILE POLYPOSIS

= rare autosomal dominant disease with variable penetrance characterized by development of multiple (> 5) juvenile polyps in GI tract

◊ Most common familial / nonfamilial colonic polyp in children (75%)!

Categories:

A. JUVENILE POLYPOSIS OF INFANCY

Age: 4–6 years (range 1–10 years); M÷F = 3÷2

• protein-losing enteropathy, hemorrhage

√ intussusception

B. COLONIC & GENERALIZED JUVENILE POLYPOSIS

Age: in 85% manifested by 20 years of age

Path: hamartomatous polyps; adenomas may coexist

Histo: little / no smooth muscle; hyperplasia of mucous glands; retention cysts develop with obstruction of gland orifices (multiple mucin-filled spaces); edematous inflamed expanded lamina propria

DDx: familial adenomatous polyposis, Peutz-Jeghers syndrome

• rectal bleeding (95%) most commonly as intermittent bright red hematochezia; abdominal pain ← intussusception

• anemia, diarrhea, constipation; prolapse of polyp / rectum (rare)

Location: rectosigmoid (80%); rare in small bowel + stomach; not in esophagus

√ solitary polyp (75%); multiple polyps (⅓) of smooth round contour

√ lesion of pinpoint size / up to several cm in diameter

√ invariably on stalk of variable length

Dx: (1) Any number of polyps with family history

(2) Polyps throughout the GI tract

(3) > 5–10 polyps in colon

Cx: colorectal cancer by 35 years of age (in 15%)

DDx: solitary juvenile polyps (< 5 polyps, 1% prevalence in children)

KAPOSI SARCOMA

[Moritz Kaposi (1837–1902), dermatologist in Vienna, Austria]

= multicentric low-grade malignant vascular neoplasm originating from endothelial cells of lymphatic / blood vessels

Cause: Human herpes virus type 8 (HHV_8) and other cofactors (eg, cytokine-induced growth)

Frequency: most common AIDS-related neoplasm (40–50%); in 51% of homosexual / bisexual men with AIDS; rare in hemophiliacs; M÷F = 50÷1

Histo: proliferation of spindle cells with numerous extravasated RBCs located in clefts between stromal cells

Almost always associated with: cutaneous disease

Variants:

A. IMMUNE DYSREGULATION

1. Classic (sporadic / Mediterranean) Kaposi sarcoma

Age: 50–80 years; M÷F = 10÷1 to 15÷1

Geography: eastern European, Mediterranean, Askenazi Jews

2. Endemic (African) Kaposi sarcoma
Geography: East Africa, Central Africa
Age: 30–40 years; M÷F = 13÷1 to 17÷1

B. IMMUNOSUPPRESSIVE STATE

3. Iatrogenic (organ transplant-related) Kaposi sarcoma
Prevalence: 6% of all organ transplant recipients and others on immunosuppressive therapy
Mean development time: 21 months
4. AIDS-related (epidemic) Kaposi sarcoma
Prevalence: up to 50% in lifetime of homosexual male > IV drug user > hemophiliac > woman

@ Skin (66%, most frequent site)
• multiple bluish red slightly elevated skin lesions

@ Mucosal disease (56%)
Site: intraoral, pharyngeal, laryngeal, nasal cavity
√ multiple nodular cutaneous / mucosal lesions
√ nonspecific MR: low T1 + high T2 signal intensity
√ CHARACTERISTIC avid enhancement

@ Lymph node involvement (13–80%, 2nd most frequent site):
√ hyperattenuating lymphadenopathy ← vascularity: peripancreatic, porta hepatis, retroperitoneal, mesenteric, inguinal, pelvic
Associated with: high frequency of GI tract involvement

@ GI tract (40–50% of AIDS-related Kaposi sarcomas; 3rd most frequent site):
• usually clinically silent
• concurrent with / after cutaneous disease
◊ GI tract is the only site of involvement in < 5%!
Location: anywhere within GI tract; often multifocal
√ thickened nodular folds
√ single / multiple polypoidal 0.5–3.0-cm subepithelial nodules / masses:
√ ± central umbilication / ulceration (common) = "bull's-eye" / "target" lesions on BE
√ infiltrating linitis plastica lesion (rare)
√ mass enhancement greater than adjacent mucosa ← high tumor vascularity

@ Liver & spleen (34% at autopsy)
√ multiple 5–12-mm nodules hyperechoic on US, hypoattenuating on NECT/CECT indistinguishable from multiple hemangiomas
DDx: metastatic disease, fungal microabscesses, multiple areas of bacillary angiomatosis (= swollen venous lakes in liver)
√ splenomegaly
Prognosis: infrequently contribute to morbidity + mortality

@ Lung (18–47% of patients with cutaneous sarcoma):
= late complication of AIDS
Site: bilateral symmetric peribronchovascular axial interstitium (91%); middle / lower lung zones (92%)
√ coarsening of bronchovascular bundles:

√ tram track opacities
√ peribronchial cuffing
√ septal lines (38–71%)
√ interlobular septal thickening + fissural nodularity
√ numerous perihilar ill-defined asymmetric coalescent clusters of consolidation ± air bronchograms in 45% (= confluent tumor)
√ small (50%) / large (28%) pulmonary nodules ← tumor proliferation extending into parenchyma:
√ "halo" sign = ground-glass opacities surrounding nodule
√ pleural effusion (33–67%), chylothorax (rare)
√ moderate lymphadenopathy (10–35%, late in disease): axillary, mediastinal, hilar
√ thoracic wall masses
@ Musculoskeletal system
√ lytic cortical lesion
√ subcutaneous nodules
Dx: endoscopic visualization + biopsy of mass of red-purple color

KILLIAN-JAMIESON DIVERTICULUM

= rare pulsion diverticulum through muscular gap in anterolateral wall of proximal cervical esophagus inferior to cricopharyngeus muscle
Cause: tightness of cricopharyngeal (= upper esophageal) sphincter → retrograde reflux with increased pressure on relative sidewall weakness
Age: usually > 60 years (same as for Zenker diverticulum)
• almost all asymptomatic
Location: muscular gap at Killian-Jamieson triangle just below cricopharyngeal muscle more inferiorly than Zenker diverticulum; bilateral in 25%
√ predominantly left lateral + anterior outpouching from cervical esophagus
Cx: overflow aspiration

LADD BANDS

= PERITONEAL BANDS
= congenital fibrous stalk of peritoneal tissue
Attachment:
(a) normal: fixates right side of colon to peritoneal wall
(b) malrotation: from RUQ (← malpositioned cecum / hepatic flexure) to right paracolic gutter extending across anterior surface of 2nd / 3rd portion of duodenum
Associated with: malrotation
Cx: duodenal obstruction at its 2nd portion (even without volvulus)
√ oblique termination of duodenal contrast column

LEIOMYOMA

N.B.: In older literature synonymous with GIST (far more frequent, variable risk of progression and metastasis)
Path: arising from muscularis propria

Histo: low to moderate cellularity, intersecting fascicles of spindle cells with eosinophilic cytoplasm, desmin globules (occasionally)
- negative for c-KIT, strongly diffusely positive for desmin + smooth muscle actin (DDx to GIST)

@ Stomach (rare)
Location: gastric cardia
√ low-attenuation mass with endoluminal growth pattern
√ central ulceration for tumor > 2 cm in diameter
Size: 1.3–4.7 cm
DDx: GIST, schwannoma

Leiomyoma of Esophagus

◊ Most common benign subepithelial tumor of esophagus; 50 x less common than esophageal carcinoma
Frequency: 1÷1,119 (autopsy study); 50% of all benign esophageal tumors
Histo: interlacing / palisading pattern of spindle cells with eosinophilic cytoplasm; areas of dense collagen may become calcified
RARE: cystic degeneration, necrosis, ulceration
Age: 4–81 years; 3% in children; M÷F = 2÷1
- usually asymptomatic (due to slow growth)
- dysphagia, odynophagia, dyspepsia usually for > 2 years
- hematemesis if large (rare)

Site: frequently lower + mid ⅓ of esophagus (smooth muscle portion); intramural (97%); multiple leiomyomas in 3–4%
Size: usually < 3 cm (range, 2–15) cm

Leiomyomas have typical findings of an intramural mass = smooth-surfaced crescent-shaped filling defect forming right or slightly obtuse angles with the esophageal wall.

√ smooth slightly lobulated well-defined intramural mass
√ homogeneous contrast enhancement
√ may have coarse calcifications (DDx: GIST)

Barium:
√ smooth-surfaced crescent-shaped filling defect forming right / slightly obtuse angles with esophageal wall
√ deformity of lumen
√ occasionally encircling wall → short stricture
CAVE: high percentage misdiagnosed as extrinsic lesion!

Endoscopic US (89% accuracy):
√ homogeneous hypoechoic mass in muscularis mucosae / submucosa / muscularis propria
√ intact overlying mucosa

CT:
√ homogeneous mediastinal mass in mid to lower esophagus
√ iso- / hypoattenuating to muscle

MR:
√ slightly hyperintense mass on T2WI

PET:
√ usually negative ← low mitotic rate

Rx: endoscopic resection, surgical enucleation, observation

DDx: (1) GIST (positive for CD117 + CD34, central low attenuation, 10 x less frequent than leiomyoma)
(2) Duplication cyst (2nd most common benign lesion of esophagus, manifestation during childhood, may communicate with lumen)
(3) Granular cell tumor (often multiple, less common)
(4) Lymphoma; metastasis

Esophageal Leiomyomatosis

Mean age: 11 (range, 6–18) years; M > F

Cause: (1) Sporadic (50%)
(2) Familial disease (20%): leiomyomas of uterus, vulva, tracheobronchial tree, small bowel, rectum
(3) Alport syndrome (30%) = nephritis, high-frequency sensorineural hearing loss, congenital cataract ← germline deletion of collagen IV subunit genes on X-chromosome

Site: distal ⅓ or ½ of esophagus ± extension into proximal stomach

• slowly progressive dysphagia over years
√ smooth tapered narrowing of distal esophagus over an average length of 6 cm
√ decreased / absent esophageal peristalsis
√ smooth relatively symmetric defect at cardia ← thickened muscle bulging into gastric fundus

CT:
√ marked circumferential wall thickening of up to 4 cm by mass with relatively low soft-tissue attenuation

DDx: (1) Primary achalasia (shorter narrowed segment)
(2) Secondary achalasia (older individual, recent onset of dysphagia)
(3) Stricture from reflux esophagitis
(4) Idiopathic muscular hypertrophy of the esophagus (in late adulthood, corkscrew appearance of esophagus with nonperistaltic contractions, cardia rarely involved)

Leiomyoma of Small Bowel

◊ Most common benign tumor of small bowel

Location: duodenum (21%), jejunum (48%), ileum (31%); single in 97%

Site: mainly serosal (50%), mainly intraluminal (20%), intramural (10%)

Size: < 5 cm (50%), 5–10 cm (25%), > 10 cm (25%)

√ small ulcer + large barium-filled cavity ← central necrosis + communication with lumen
√ hypervascular

LEIOMYOSARCOMA

Frequency: 6% of all soft tissue sarcomas

Origin: smooth muscle cells within walls of blood vessels (most frequent); undifferentiated

mesenchymal cells
Mean age: 50 years
Location: head & neck (nasal cavity, paranasal sinuses), skin, cervical esophagus, larynx
CT:
√ bulky mass remodelling bone
√ little enhancement, uncommon calcifications
MR:
√ iso- to hypointense relative to muscle on T1WI
√ variably hyperintense relative to muscle on T2WI
√ prominent contrast enhancement

Leiomyosarcoma of Small Bowel

Location: duodenum (26%), jejunum (34%), ileum (40%)
√ usually > 6 cm in size
√ nodular mass: intraluminal (10%), intraluminal pedunculated (5%), intramural (15%), chiefly extrinsic (66%)
√ mucosa may be stretched + ulcerated (50%)
√ may show central ulcer pit / fistula communicating with a large necrotic center
√ intussusception

Leiomyosarcoma of Stomach

Frequency: 0.1–3.0% of all gastric malignancies
Age: 10–73 years; M > F
Histo: pleomorphism, hypercellularity, mitotic figures, cystic degeneration, necrosis
• GI bleeding (from ulceration), obstruction
Metastases:
(a) hematogenous to liver, lung, peritoneum; rarely to bone + soft tissue
(b) direct extension into omentum, retroperitoneum
(c) lymph nodes (rare)
Location: 90% in fundus / body of stomach
Site: anterior / posterior wall; endo- / exogastric
Average size: 12 cm
√ intramural mass; large mass tends to be exogastric
√ very frequently ulcerated
√ may be pedunculated
CT:
√ lobulated irregular outline
√ heterogeneous exogastric mass with central zones of low density ← necrosis with liquefaction
√ air / positive contrast within tumor ← ulceration
√ dystrophic calcifications

Carney Triad

Triad of (1) Gastric GIST
(2) Functioning extraadrenal paraganglioma

(3) Pulmonary chondroma

Prevalence: 24 patients reported; M÷F = 1÷11

LIPOMA

= benign submucosal tumor composed of mature adipose tissue surrounded by a fibrous capsule

◊ Most common subepithelial tumor in colon!

Frequency: in colon in 0.25–4.40% (autopsy); 2–3% of all benign gastric tumors

• asymptomatic; may become symptomatic if > 2 cm

• crampy pain, hemorrhage (rare) ← ulcerated overlying mucosa

• "pillow" sign on optical colonoscopy = pale yellow protrusion, soft on probing

Location: colon (particularly cecum + ascending colon) > duodenum > ileum > stomach (gastric antrum) > jejunum > esophagus

Site: endoluminal-submucosal (90%); subserosal (10%)

Size: average 4 cm, up to 30 cm

√ smooth broad-based, sharply outlined, round / ovoid globular mass of 1–3 cm in diameter

√ short thick pedicle in ⅓ ← repeated peristaltic activity (= lead point for intussusception)

Cx: pedunculated lesion (rare) may prolapse through pylorus → intermittent gastric outlet obstruction

Radiography:

√ ± marked radiolucency

Fluoroscopy:

√ change in shape + size on compression ← softness:

√ "squeeze" sign = sausage-shaped mass on postevacuation radiographs

CT:

√ well-circumscribed spheric / ovoid subepithelial mass of uniform fat density (-20 to -120 HU)

√ density increases with inflammation ← ulceration

MR:

√ high fat SI on all sequences

√ loss of SI on fat-suppressed images

Cx: (1) Intussusception (rare)

(2) Central ulceration ← pressure necrosis of overlying mucosa by large lipoma (rare)

Prognosis: NO liposarcomatous degeneration

Rx: none; endoscopic / surgical resection if > 2 cm

DDx: lipomatosis of ileocecal valve (more common, symmetric enlargement of valve)

LYMPHANGIOMA

= congenital malformation of lymphatic vessels → sequestered embryonic lymphatic vessels that have failed to communicate with the rest of the lymphatic / venous system

Path: usually multiloculated large thin-walled cystic mass with chylous / serous / hemorrhagic fluid contents

Location: head & neck (95%); abdomen (mesentery, rarely affecting GI tract); retroperitoneum (< 1%)

• well-defined often compressible cystic submucosal lesion at colonoscopy

√ CHARACTERISTIC involvement of multiple compartments
√ proximal bowel dilatation (in partial bowel obstruction)
US:
√ elongated multiseptated cystic mass with lobules
√ fluid anechoic / with internal echoes / sedimentation
CT:
√ cystic mass with contents of water- to fat-density (chyle)
MR:
√ T1-hypointense + T2-hyperintense ← serous content
√ hyperintense on T1WI + T2WI ← hemorrhage / fat
Rx: surgery (difficult due to intimate attachment to bowel wall)

LYMPHOGRANULOMA VENEREUM

= LGV = sexually transmitted disease caused by virus Chlamydia trachomatis producing a nonspecific granulomatous inflammatory response in infected mucosa (mononuclear cells + macrophages), perirectal lymphatic invasion
Location: rectum ± extension to sigmoid + descending colon
M÷F = 3.4÷1.0
√ narrowing + shortening + straightening of rectosigmoid
√ widening of retrorectal space
√ irregularity of mucosa + ulcerations
√ paracolic abscess
√ fistula to pericolic area, rectum, vagina (common)
Rx: tetracyclines effective in acute phase before scarring has occurred

LYMPHOID HYPERPLASIA

Frequency: normal variant in 13% of BE examinations
Histo: hyperplastic lymph follicles in lamina propria (Peyer patches) ← probably compensatory attempt for immunoglobulin deficiency
Etiology:
(1) Normal in child / young adult
(2) Self-limiting local / systemic inflammation / infection / allergy
(3) May be related to immunodeficiency / dysgammaglobulinemia with small bowel involvement
Age: (a) generally in children < 2 years
(b) in adults invariably associated with late onset immunoglobulin deficiency (IgA, IgM)
Associated with: splenomegaly, large tonsils, eczematous dermatitis, achlorhydria, pernicious anemia, acute pancreatitis, colonic carcinoma
At risk for:
(1) **Good syndrome** (10%)
= gastric carcinoma + benign thymoma + lymphoid hyperplasia
(2) Respiratory infections
(3) Giardia lamblia infection (90%)

(4) Functional thyroid abnormalities

Location: primarily jejunum, may involve entire small bowel, ascending colon + hepatic flexure, seldom in sigmoid / rectum

- malabsorption (diarrhea + steatorrhea)
- low serum concentrations of IgA, IgG, IgM

√ mucosa studded with innumerable 1–3-mm small uniform polypoid lesions

√ lesions may be umbilicated (uncommon)

LYMPHOMA OF GASTROINTESTINAL TRACT

= PRIMARY LYMPHOMA OF BOWEL

Incidence: worldwide 1÷100,000 per year: 4–20% of all NHL; 0.9% of all GI tumors; 10% of patients with abdominal lymphoma have bowel involvement

◊ Most common extranodal manifestation of NHL (up to 20% of all NHL cases)!

◊ Most common gastrointestinal tumor in children!

◊ Extremely rare in Hodgkin disease!

Dx: (1) No palpable superficial nodes (2) Normal CXR (3) Normal WBC count (4) Lymphoma limited to alimentary tract with involvement of only regional nodes (5) No involvement of liver or spleen

Manifestation:

A. LOCALIZED (in early disease):
lymphoid elements in lamina propria and submucosa

B. DIFFUSE (advanced stage after dissemination)

Risk factors: infection with HIV / Helicobacter pylori, long-standing celiac disease, systemic lupus erythematosus, inflammatory bowel disease (2–3-fold increase), immunosuppression (solid organ transplantation, 5-fold increase with immunosuppressive treatment of patients with inflammatory bowel disease)

Predisposed: Arabs + Middle Eastern Jews

Associated with: celiac disease

Age: 1st peak < 10 years + 2nd peak 53 years; M÷F = 3÷2

Histo:

(1) B-cell lymphoma (most common): in stomach

Diffuse large B-cell lymphoma is most commonly found in stomach > ileum + characterized by diffusely infiltrative nodular lesions with extensive ulcerations.

(2) T-cell lymphoma (in celiac disease / peripheral T-cell lymphoma): in small intestine

(3) Extranodal marginal zone B-cell lymphoma *formerly*:

(a) low-grade **M**ucosa-**A**ssociated **L**ymphoid **T**issue 50–72% of all primary gastric lymphomas (see below)

(b) Immunoproliferative small intestinal disease
= Mediterranean / Middle Eastern lymphoma
= special form of MALT lymphoma in young patients of poor socioeconomic status with suspected infectious etiology

May be associated with: enlargement of extraabdominal lymph nodes, malabsorption

- abdominal pain, weight loss

Classification of GI Tract Lymphoma *(WHO 2007)*	
Type of Lymphoma	*Frequency*
B cell	
Diffuse large B-cell lymphoma	38–57%
Extranodal marginal zone B-cell lymphoma	23–48%
Mantle cell lymphoma (polyposis)	< 1–13%
Follicular lymphoma (in duodenum, jejunum)	2–12%
Burkitt lymphoma (in children)	1–5%
Hodgkin lymphoma	< 1%
T cell	
Enteropathy-associated T-cell lymphoma	3%

Lymphomas are a heterogeneous group of neoplasms with varying sites of GI involvement + varying gross and histologic features → wide spectrum of imaging findings

Radiographic morphology:

1. Polypoid / nodular (47%)
   - √ enlarged nodular folds with a range of nodule sizes
   - √ solitary / multiple smooth subepithelial polypoid masses that may ulcerate
   - √ cobblestone pattern ← lymphomatous polyps
   - √ normal / thickened surrounding tissue
   - √ sprue pattern → may cause intussusception
   - √ **multiple lymphomatous polyposis**
     = rare disorder characterized by numerous small polypoid lesions covering long segments of GI tract, typically a manifestation of mantle cell lymphoma
2. Single ulcerative mass (42%)
   - √ circumferential bulky mass in intestinal wall, often extending into mesentery + regional nodes
   - √ asymmetric bowel wall involvement ± exophytic component
   - √ ± intussusception
   - √ obstruction unusual ← tumor soft and pliable without desmoplastic response

   Cx: fistula, perforation

   DDx: simple peptic ulcer, superficial carcinoma
3. Circumferential / constrictive diffusely infiltrative (11%)
   - √ focal / diffuse thickening of bowel wall
   - √ decreased / absent peristalsis
   - √ ± hose- / tubelike segments of luminal narrowing with obstruction (rare) ← desmoplastic response (rare)
   - √ ± ulceration with considerable excavation

   DDx: adenocarcinoma (shorter segment of involvement, more abrupt transition from tumor to normal bowel)
4. Aneurysmal / cavitary
   - √ nonperistaltic segment with circumferential dilatation ← destruction of muscularis propria + autonomic plexus forming large cavity:

√ large mass with only small intramural component
√ irregular lobulated margin ± small nodules at margin of involved segment

√ tumor involvement of mesentery → cavitated endoexoenteric mass filled with enteric contrast:
√ ± ulcer + fistula + aneurysmatic dilatation

DDx: gastrointestinal stromal tumor (GIST), perforated colonic adenocarcinoma, metastatic disease (especially melanoma)

5. Mixed
√ alternating constriction + dilatation with involvement of a lengthy segment

Staging of Primary Gastrointestinal Tract Lymphoma
(Consensus Conference in Luguano, 1993)

Stage	*Involvement*
I	tumor confined to gastrointestinal tract as single primary site / multiple noncontiguous lesions
II	tumor extends into abdominal cavity from primary gastrointestinal site
II_1	local nodal involvement
II_2	distant nodal involvement
III	penetration through serosa to involve adjacent organs / tissues
IV	disseminated extranodal involvement / GI tract lesion with supradiaphragmatic nodal involvement

6. Mesenteric / retroperitoneal adenopathy
√ single / multiple extraluminal masses displacing bowel
√ ill-defined confluent mass engulfing + encasing multiple loops of adjacent bowel
√ "sandwich configuration" = mass surrounding mesenteric vessels that are separated by perivascular fat
√ conglomerate mantle of retroperitoneal + mesenteric mass

CT staging:
Stage I tumor confined to bowel wall
Stage II limited to local nodes
Stage III widespread nodal disease
Stage IV disseminated to bone marrow, liver, other organs

• abdominal pain, weight loss

Location: 10–25% of NHL are extranodal; stomach (50%) > small bowel > ileocecal region (← Peyer patches) > colon + rectum (0.4%) > esophagus; multicentric in 10–50%

Site: originates in submucosa / deep mucosal layer → may be missed at endoscopy

CT:
√ mild to moderate homogeneous circumferential thickening of stomach / bowel wall:
√ hypo- / isoattenuating compared with normal bowel
√ enhances less than normal bowel
√ ± luminal constriction, dilatation, cavitation
√ typically bulky diffuse regional / mesenteric adenopathy
√ enlargement of spleen

MR:
√ wall thickening ± polypoid / ulcerated lesions:
√ heterogeneous increased T2 signal intensity
√ homogeneous intermediate T1 signal intensity
√ mild to moderate enhancement
√ ⇑ SI at DWI (ADC values higher than in gastric cancer)

Lymphadenopathy extending below renal hila or of bulky character makes lymphoma a likely diagnosis!

Prognosis: 71–82% [0%] 2-year survival rate in isolated bowel lymphoma [stage IV disease with bowel involvement]
Cx during chemotherapy: perforation (9–40%), hemorrhage
DDx: Secondary Intestinal Lymphoma (as part of generalized systemic process)
@ Esophagus (< 1%, least common site of GI involvement)
Histo: predominantly B-cell type / MALT
Esophagram:
√ predominantly subepithelial infiltration
√ mucosal ulceration
Esophagram / CT:
√ polypoid mass / nodularity
Cx: perforation, fistulization
@ Stomach (50–70%, most frequently involved site of GI tract)
Frequency:
accounting for only 1–5% of all gastric malignancies; most common site of extranodal lymphoma (25%); isolated primary gastric malignancy in 10%; NHL÷Hodgkin disease = 10÷1
Histo:
(a) low-grade **M**ucosa-**A**ssociated **L**ymphoid **T**issue = **MALT lymphoma** (in 50–70%)
→ development to high-grade B-cell lymphoma over time

Gastric extranodal marginal zone B-cell lymphoma is usually a superficial spreading lesion confined to mucosa + submucosa occurring anywhere in the stomach and often multifocal.

(b) diffuse large B-cell lymphoma
Location: no predilection for any particular gastric region
Site: arises in lymphoid tissue of lamina propria ← chronic Helicobacter pylori gastritis (normally gastric mucosa has no lymphoid tissue!)
Direct extension into: pancreas, spleen, transverse colon, liver
• epigastric pain, dyspepsia

√ gastric lymphoma is suggested by multiple polypoid tumors with central ulceration ("bull's eyes"), giant cavitating lesion, or extensive infiltration with gastric fold thickening!

√ pliant gastric wall
√ duodenum often affected when antrum involved
√ circumscribed mass with endogastric / exogastric (25%) growth
√ abnormal bulge in gastric contour that fills with oral contrast material
√ infiltrative pattern with broad tortuous thickened folds (diffuse form)

√ polypoid / nodular pattern
√ cavitary pattern with large irregular bull's-eye ulcer
√ luminal narrowing / loss of gastric distensibility (rare)
CT:
√ diffuse involvement of entire stomach (50%), typically more than half of gastric circumference
√ segmental involvement (15%)
√ ulcerated mass (8%)
√ average wall thickness of 4–5 cm
√ luminal irregularity (66%)
√ hyperrugosity (58%)
√ perigastric adenopathy (in 50–60%)
Prognosis: 55% 5-year survival rate after resection; MALT may regress completely after antibiotic therapy
DDx: gastric adenocarcinoma (milder more focal wall thickening, tumor infiltration beyond gastric wall = perigastric fat plane not likely preserved, greater tumor enhancement, luminal narrowing, mural rigidity, linitis plastica, smaller lymph nodes above the level of renal veins)

@ Small bowel (20–30% of all abdominal lymphomas)
Frequency: 2nd most common site of GI tract involvement; with 20% most common small bowel malignancy; most common cause of intussusception in children > 6 years
Location: ileum (51%) > jejunum (47%) > duodenum (2%); solitary (75–90%) vs. multiple sites (10–25%)
Site: arising from lymphoid patches of Peyer
√ nodular / multiple polypoid pattern
√ single mass
√ plaquelike thickening of wall > 5 [> 10] cm in length in 80% [20%] (DDx: Crohn disease)
√ irregular segmental thickening of valvulae with corrugated appearance
√ exophytic = endoexoenteric mass
√ mesenteric / retroperitoneal adenopathy
US:
√ hypo- to anechoic circumferential wall thickening
√ destruction of mural stratification
√ nodular / bulky tumor
√ aneurysmal dilatation of the lumen ← destruction of autonomic nerve plexus
√ bowel obstruction (rare) ← no desmoplastic response
√ loss of peristalsis = late sign
√ intussusception
Cx: perforation into adjacent mesentery → formation of confined usually sterile abscess

@ Terminal ileum & cecum
◊ Most common site of primary lymphoma of small and large bowel ← Peyer patches
√ single 1.5 –7.0 cm long / multiple segments of usually marked circumferential symmetric wall thickening:
√ gradual transition to normal bowel

√ homogeneous attenuation + poor enhancement
√ polypoid lesion of variable size → possible lead point for intussusception
√ may extend into appendix
Cx: ulceration → fistulous tract to adjacent bowel loops
DDx: GIST

@ Colon (1.5% of all abdominal lymphomas)
Frequency: less commonly involved than stomach / small bowel
Histo: nearly all non-Hodgkin B-cell lymphoma
Risk factors: immunosuppression (AIDS, organ transplant recipient), inflammatory bowel disease
Location: ileocecal region most commonly involved (85%) > rectosigmoid region
• nonspecific ± gastrointestinal bleeding
√ solitary bulky mass > diffuse infiltration > multifocal polypoid lesions
√ gross mural circumferential / nodular wall thickening in a long segment (with an average length of 5 cm)
√ annular mass ± ulceration
√ paradoxical dilatation ← submucosal lymphoid infiltration weakens muscularis propria
√ slight enhancement
√ massive often absent regional + distant mesenteric + retroperitoneal adenopathy
Rx: surgical resection followed by adjuvant chemotherapy
DDx: neutropenic colitis (contiguous involvement of cecum + ascending colon, mural stratification of affected segment)

Distinguishing CT Findings of Colonic Lymphoma versus Adenocarcinoma
√ extension into terminal ileum
√ well-defined margins + preservation of fat planes
√ no invasion of adjacent structures
√ perforation without desmoplastic reaction
√ severe luminal narrowing without obstruction and with preserved pliability

Diffuse Large B-Cell Lymphoma (38–57%)

Primary GI diffuse large B-cell lymphoma affects commonly stomach > ileum and is characterized by diffusely infiltrative and nodular lesions with extensive ulcerations.

◊ Most common type of GI lymphoma in adults!
Transformation from: extranodal marginal zone lymphoma (concomitant in > ⅓)
Pah: lymphomatous cells involve the bowel wall from submucosa to serosa + may directly invade adjacent structures
Growth pattern: exophytic + annular (± intraluminal) with full-thickness involvement of bowel wall
Location: stomach (most common) > distal ileum

@ Stomach
Barium:
√ diffusely thickened folds / bulky masses

√ deep areas of ulceration / cavitation (frequent)

CT:

√ gastric wall thickness of > 1– 8 cm

√ thin band of mucosal enhancement during early arterial phase

√ delayed homogeneous enhancement of bulky submucosal mass

√ ± low-attenuation areas of necrosis

√ abdominal lymphadenopathy (most)

PET:

√ FDG avidity in 97%

@ Small bowel

√ segmental aneurysmal dilatation (= luminal diameter > 4 cm in area of thickened bowel wall) in 31% ← weakened muscularis propria + destruction of autonomic nerve plexus

Cx: (1) Perforation ← absence of desmoplastic response

(2) Obstruction (uncommon)

DDx: (1) Adenocarcinoma

(2) Inflammation / infection (preserved wall stratification)

Extranodal Marginal Zone B-Cell Lymphoma (23–48%)

= low-grade **M**ucosa-**A**ssociated **L**ymphoid **T**issue = **MALT lymphoma**

= low-grade lymphoma involving cells that arise from the marginal zone surrounding lymphoid follicles

Age: > 50 years; M÷F = 1.2÷1

Location: stomach (85%), small bowel (Mediterranean lymphoma) and colon (12%), esophagus (rare)

Pathophysiology: gram-negative Helicobacter pylori infection → chronic gastritis → reactive lymphoid follicles → MALT lymphoma

Upper GI:

√ < 1 cm round often confluent mucosal nodules (30–52%) ← focal enlargement of the lamina propria

√ shallow ulcer + thickened folds / focal mass (39–50%)

CT:

√ segmental (< 50% of stomach) mild thickening of gastric wall (between 5 and 10 mm)

√ abdominal lymphadenopathy (14–24%)

CECT:

√ iso- / hypoattenuating compared with normal gastric wall

PET (limited):

√ difficult to discern ← indolent growth pattern + background GI accumulation (FDG uptake in only 71%)

Follicular Lymphoma (2–12%)

= low-grade indolent tumor that does not require treatment

◊ Most common nodal lymphoma in Western countries

Median age: 56 (range, 26–81) years; M÷F = 1÷1

Genetics: CD10 positive; overexpression of anti-apoptotic proteins (in 90%) ←

translocation t(14;18)(q32;21)
Location: duodenum, jejunum
√ multiple scattered / confluent small-bowel nodules of varying size
CT (polyps may not be recognizable due to small size):
√ bowel wall thickening (in 15%)
PET (only 46% sensitive)
Progression: may develop into diffuse large B-cell lymphoma
Prognosis: 98 months median relapse-free survival

Mantle Cell Lymphoma (9–13%)
= aggressive form of lymphoma
Histo: pregerminal center-type lymphomatous cells that arise from inner mantle zone of lymphoid follicle
Genetics: overexpression of immunohistochemical marker cyclin D1 ← translocation t(11;14)(q13;q32)
Mean age: 62 years
Location: ileum > ascending colon > rectum
√ lymphomatous polyposis (most common form):
= numerous small polyps / nodules throughout GI tract of up to 4 cm in size
CT (polypoid nature of nodules may not be apparent):
√ nonobstructive bowel wall thickening + mass formation
√ abdominal lymphadenopathy (most)
√ extra-abdominal involvement
Prognosis: poor; median survival of 3–4 years
DDx: (1) Inherited polyposis (family history, in childhood / early adulthood, mucocutaneous pigmentation, fibromatosis, osteomas, dental anomalies)
(2) Blood-borne metastases: breast, lung, malignant melanoma, lymphoma (usually larger lesions, more sporadic, submucosal masses, bull's-eye / target appearance with central ulcer)
(3) Extranodal marginal zone B-cell lymphoma
(4) Follicular lymphoma
Rx: autologous stem cell transplantation

Peripheral T-Cell Lymphoma
Frequency: 5–30% of all NHL
Age: middle age + elderly
Histo: mature T-cell phenotype
Location: bone marrow, skin, lung, liver, GI tract (3%)
Site: small intestine (64%, esp. duodenum + jejunum)
• ± malabsorption
√ multifocal bowel involvement
√ mild (< 1 cm) / 1–2 cm gastric / bowel thickening
√ polypoid mass (rare; common in B-cell lymphoma)
√ thickened plaques, ulcers, strictures

√ nonbulky lymphadenopathy (bulky in B-cell lymphoma)
√ hepatosplenomegaly

T-cell lymphoma compared with large B-cell lymphoma
(a) more frequently involves proximal small bowel
(b) more likely shows multifocal involvement
(c) has a higher frequency of perforation.

Cx: bowel perforation with pneumoperitoneum (41–50% compared with < 30% in B-cell lymphoma)

Enteropathy-associated T-cell Lymphoma

Frequency: 3% of all primary gastrointestinal NHL
Classification:
Type I (80–90%):
Strongly associated with: celiac disease
Type II:
= **Monomorphic CD56+ intestinal lymphoma**

Lymphoma may develop any time during the course of celiac disease, including the time of initial diagnosis.

Median age: 50s; M > F
Location: particularly in proximal small bowel: jejunum / proximal ileum

DDx of Peripheral T-Cell versus Large B-Cell Lymphoma

Feature	*T-cell Lymphoma*	*B-cell Lymphoma*
Small bowel involvement	proximal	distal
Multifocality	50–72%	10–25%
Perforation	41–50%	< 30%
√ polypoid mass	rare	common
Bowel wall character	thickened plaque, ulcer, stricture	exophytic annular mass
Lymphadenopathy	nonbulky	bulky

Barium:
√ thickened nodular folds, ulcers, strictures
CT:
√ circumferential wall thickening
√ ± accompanying lymphadenopathy
√ ± infiltration of mesenteric fat
PET:
√ FDG uptake in 86–100%
Prognosis: poor
Cx: intestinal perforation (16% in Type I, 33% in Type II)
DDx: (1) Diffuse large B-cell lymphoma
(2) Refractory celiac disease (no FDG uptake)

LYMPHOMA OF THE MESENTERY

◊ Most common malignancy involving the mesentery and omentum and most common cause of mesenteric masses
◊ NHL is 3rd most common malignancy in children < 15 years

◊ Mesentery involved in 30–50% of NHL + 4–5% of Hodgkin dz.
Incidence of NHL: 1100 children annually in USA
Associated with: retroperitoneal lymphadenopathy
√ "sandwich" sign = mesenteric lymphadenopathy surrounding mesenteric vessels:
  √ round / oval soft-tissue opacities
  √ irregular masses / lobulated cake-like heterogeneous mass with areas of low attenuation ← necrosis
  √ mildly enhancing
√ "misty mesentery" = mesenteric fat stranding (especially after chemotherapy)
√ direct extension into small bowel
√ displacement of small
DDx: sclerosing mesenteritis, inflammatory infectious / noninfectious disease

MALIGNANT MELANOMA

= develops from melanocytes derived from neural crest cells, arising in preexisting benign nevi (in 20%)
Frequency: 1% of all cancers; increasing at 3.9% annually
Peak prevalence: 40–60 years of age
Risk factors: dysplastic mole, atypical melanocytic hyperplasia, xeroderma pigmentosum, melanoma in first-degree relative, sun-sensitive phenotype, excessive sun exposure
Primary sites: skin, mucous membranes, leptomeninges, eye
• areas of red / white / blue in addition to brown and black colors of benign nevi
• irregular borders with notching + striking protrusions
@ Skin primary
Clark staging:
Level I all tumor cells above basement membrane (in situ lesion)
Level II tumor extends to papillary dermis
Level III tumor extends to interface between papillary + reticular dermis
Level IV tumor extends between bundles of collagen of reticular dermis
Level V tumor invasion of subcutaneous tissue (in 87% metastatic)
Breslow staging:
thin < 0.75 mm depth of invasion
intermediate 0.76–3.99 mm depth of invasion
thick > 4.00 mm depth of invasion
Metastases:
Latent period of 2–20 years after initial diagnosis (most commonly 2–5 years)
Primary site: head + neck (79%), eye (77%), GU system (67%), GI tract (in up to 60%)
@ Lymphadenopathy

› in 23% [75%] with level II + IV [V]
• sentinel node biopsy:
√ intraoperative intradermal injection of dye
√ preoperative lymphoscintigraphy

@ Bone (7–17%)

Prevalence: 30–40% at autopsy
• often initial manifestation of recurrence, poor prognosis
Location: axial skeleton (80%), ribs (38%)
√ predominantly osteolytic
MR of melanotic melanoma:
√ hypo- / isointense on T1WI + T2WI + STIR images (most commonly)
√ hyperintense on T1WI + hypointense on T2WI ← T1-shortening effect of the paramagnetic metals iron + copper bound to melanin
DDx: melanotic / amelanotic <u>hemorrhagic</u> tumor (hyper-intense on T1WI + iso- / hyperintense on T2WI)

@ Lung (70% at autopsy): most common site of relapse
• respiratory failure → most common cause of death

@ Liver (17–23%; 58–66% at autopsy)
√ single / multiple lesions 0.5–15 cm in size
√ larger lesion often necrotic
√ may be partially calcified

@ Spleen (1–5%; 33% at autopsy)
√ single / multiple lesions of variable size
√ solid / cystic

@ GI tract + mesentery (4–8%)
• abdominal pain, GI bleeding
Location: small intestine (35–70%) > colon (14–20%) > stomach (7–20%)
√ multiple hypervascular subepithelial nodules:
√ "bull's-eye / target" appearance on BE = central ulceration ← tendency to outgrow blood supply
√ localized to antimesenteric border of bowel wall ← embolic metastases to intramural rami of vasa recta
√ irregular amorphous cavity (exoenteric growth) in larger lesion ← necrosis, hemorrhage, degenerative change
√ intussusception (10–20%)

@ Kidney (up to 35% at autopsy)

@ Adrenal (11%, up to 50% at autopsy)

@ Subcutis

Prognosis: 30–40% eventually die from this tumor

MALLORY-WEISS SYNDROME

[George Kenneth Mallory (1900–1986), professor of pathology at Boston University]
[Soma Weiss (1898–1942), hungarian born physician-in-chief at Peter Bent Brigham Hospital in Boston]

= mucosal ± submucosal partial thickness tear of distal esophagus ± gastric cardia with involvement of venous plexus

Pathophysiology: violent retching → projection of gastric contents against lower esophagus (similar to Boerhaave syndrome)

Age: 30–60 years; M > F

Predisposed: excessive alcohol consumption

- history of repeated retching / vomiting prior to hematemesis
- massive painless hematemesis

Location: at / above / below (76%) esophagogastric junction

√ 1–4 cm longitudinal collection of barium (single tear in 77%, multiple tears in 23%)

√ extravasation of barium

Angio:

√ bleeding site at gastric cardia

DDx: peptic ulcer / ulcerative gastritis

Rx: supportive

MALROTATION

= abnormal position of small + large bowel ← narrow mesenteric attachment ← arrest in the embryologic development of gut rotation + fixation

Frequency: 1÷500 births

Age: in symptomatic cases: 75% in newborns + 90% in 1st year of life; 5 years average delay in diagnosis; incidental diagnosis in adults

Embryology:

Normal fixation: in LUQ at ligament of Treitz (an extension of the right crus of diaphragm + fibrous tissue around celiac artery, located to left of L2) + RLQ fixation of cecum

Abnormal fixation of mesentery: its upper point below the normal position of ligament of Treitz, its lower point superior + medial to normal cecal position

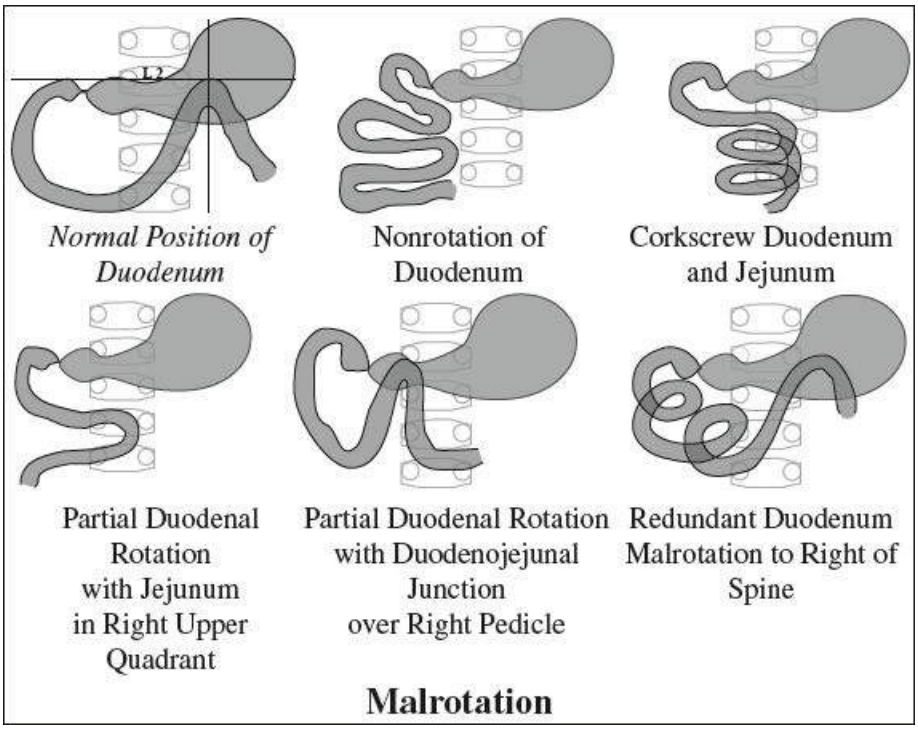
◊ Usually isolated anomaly!

Associated syndromes:

apple-peel intestinal atresia, Cornelia de Lange, Cantrell, cat-eye, chromosomal abnormalities (trisomy 13, 18,21), Coffin-Siris, familial intestinal malrotation, heterotaxy (asplenia, polysplenia), Marfan, Meckel, mobile cecum, prune belly

Associated anomalies:

absence of kidney & ureter, biliary atresia, congenital diaphragmatic hernia (Bochdalek), duodenal web / stenosis / atresia, gastroschisis, Hirschsprüng disease, imperforate anus, intestinal pseudo-obstruction, intussusception, malabsorption, Meckel diverticulum, omphalocele, pyloric stenosis, IVC anomalies, short pancreas, preduodenal portal vein



- symptoms of partial / complete proximal bowel obstruction ← volvulus / peritoneal (Ladd) bands / internal hernia:
  - bilious vomiting (77% of neonates; in 39% within 1st week of life ± abdominal distension
  - recurrent attacks of vomiting + distension (in older children)
  - insidious onset in adulthood with chronic nonspecific symptoms ← intermittent volvulus

Barium meal & barium enema (93–100% sensitive):

Purpose: guess the location of abnormal peritoneal fixation from position of bowel!

√ normal position of duodenum:
- √ 1st portion courses posteriorly
- √ 2nd portion courses inferiorly
- √ 3rd portion courses anteriorly and over spine
- √ 4th portion courses upward to lie at horizontal plane of duodenal bulb or up to 1 vertebral body height inferior

√ clearly abnormal position of duodenum (81%):
- √ duodenum + jejunum to the right of spine (30%)
- √ corkscrew duodenum + jejunum (29%)
- √ duodenojejunal junction low + in midline (22%)

√ unusual abnormal position of duodenum (16%):
- √ duodenojejunal junction over right pedicle
- √ duodenojejunal junction to left of spine but low
- √ duodenal redundancy to right of spine
- √ Z-shape configuration of duodenum + jejunum

√ small bowel on right + colon on left side of abdomen (in 0.2% incidental finding in adults)

√ abnormal position of duodenum + cecum (84%)

√ normal position of duodenum (3%)

√ normal position of cecum (in 5–20%)
DDx: mobile cecum (15%)
15% FP rate:
√ inferior displacement of duodenojejunal junction by distended stomach
√ wandering duodenum = longer meandering course
√ mobile duodenum
√ duodenum inversum
√ displacement of duodenojejunal junction ← renal agenesis, enlargement of spleen, liver transplantation (with cutting of lig. of Treitz), scoliosis, with manual palpation due to lax ligaments in children < 4 years
3–6% FN rate: due to misinterpretation of duodenal course

CT:
√ SMV positioned to left of SMA (80%)
√ aplastic / hypoplastic uncinate process of pancreas

Cx: (1) Midintestinal / midgut volvulus
(2) Duodenal obstruction
(3) Ladd bands
(4) Internal herniation

Mortality: 3–5%

Rx: Ladd procedure

Nonrotation

= midgut loop returns to peritoneal cavity without rotation resulting in weak peritoneal fixation

Frequency: common

• generally asymptomatic: often incidental finding in older children + adults
√ SMA to right of SMV
√ large intestine on left + small intestine on right

Cx: volvulus with "whirl" sign around SMA ← local clockwise rotation

Incomplete Rotation

= failure of midgut loop to complete final 90° of rotation
• prearterial segment of midgut reenters abdomen first toward left side
√ cecum just inferior to pylorus

Cx: duodenal obstruction ← peritoneal bands pass over duodenum)

Reversed Rotation

Frequency: rare

• postarterial segment of midgut reenters abdomen first
= cecum migrates first passing behind SMA toward right thus unwinding the normal counterclockwise rotation of the first stage with additional final 90° clockwise rotation
√ duodenum anterior to SMA
√ transverse colon behind duodenum + SMA

Cx: obstruction of transverse colon ← pressure from SMA

MASTOCYTOSIS

= URTICARIA PIGMENTOSA

= rare systemic disease with mast cell proliferation in skin and RES (lamina propria of small bowel, bone marrow, lymph nodes, liver, spleen) associated with eosinophils + lymphocytes

Age: < 6 months old (in 50%)

Associated with: myeloproliferative disorders, acute nonlymphatic leukemia, malignant lymphoma, mast cell leukemia

Categories:

I indolent mastocytosis (most frequent)
II mastocytosis associated with myeloproliferative / myelodysplastic hematologic disorder
III aggressive / lymphadenopathic mastocytosis with eosinophilia
IV mast cell leukemia (rare)

- diarrhea, malabsorption, steatorrhea, anorexia
- urticaria pigmentosa = cutaneous form (in 80–90%):
  - hyperpigmented skin lesions exhibiting "wheal and flare" phenomenon when disturbed
- abdominal pain, nausea, vomiting
- hypotension with tachycardia, asthma, flushing, headache, gastrointestinal upset with diarrhea, pruritus ← liberation of histamine / prostaglandin D2

  caused by: physical exertion, heat, certain foods, alcohol, nonsteroidal antiinflammatory drugs
- pancytopenia ← chronic neutropenia

@ Skeletal involvement (70%)
- bone and joint pain

Predilected sites: skull, spine, ribs, pelvis, humerus, femur

√ multiple scattered well-defined sclerotic foci with focal / diffuse involvement ← release of histamine by mast cells promotes osteoblastic activity

√ often alternating with areas of bone rarefaction = osteoporosis ← release of heparin + prostaglandin by mast cells activates osteoclasts

@ Reticuloendothelial system

√ hepatomegaly
√ splenomegaly (43–61%)
√ lymphadenopathy: retroperitoneal, periportal, mesenteric
√ Budd-Chiari hepatic venoocclusive disease
√ reversed portal venous flow
√ cavernous transformation of portal vein

@ Abdomen
- nausea, vomiting, diarrhea

√ thickening of omentum + mesentery
√ ascites:
(a) transudative ← liver disease
(b) exudative ← mast cell proliferation of peritoneum

@ Small bowel

√ diffuse irregular thickening of distorted folds
√ generalized 2–3-mm sandlike mucosal nodules ← infiltration by mast cells, lymphocytes,

plasma cells
√ urticaria-like lesions of gastric + intestinal mucosa

Dx: skin / bone marrow biopsy; jejunal biopsy demonstrates an excess of mast cells

Cx: (1) Peptic ulcer disease (release of histamine increases gastric acid secretion)
(2) Leukemia

Rx: antihistamines, histamine decarboxylase inhibitors, sodium chromoglycase; steroids; splenectomy (for symptomatic splenomegaly / hypersplenism)

DDx: carcinoid, pheochromocytoma

MECKEL DIVERTICULUM

= remnant of omphalomesenteric (= vitelline) duct, which usually obliterates by 5th embryonic week

[Johann Friedrich Meckel, the Younger (1781–1833), chairman of surgery and pathological anatomy at University of Halle, Germany]

◊ Most common congenital abnormality of the GI tract!

Frequency: 2–3% of autopsies

Age: majority in children < 10 years of age; M÷F = 1÷1

Path: true diverticulum with all layers of intestinal wall ± connection to umbilicus by fibrous band / omphalomesenteric ligament

Histo: contains ectopic mucosa: gastric / pancreatic / colonic
Frequency of heterotopic gastric mucosa: ⅔ overall; ½ in symptomatic patients; in > 95% with GI hemorrhage

Location: within terminal 6 feet of ileum (= 30–60–100 cm from ileocecal valve); in 94% on antimesenteric side (DDx to ileal diverticulosis on mesenteric side); near midline (± tip attached to umbilicus)

Average length: 2–3 cm

RULE OF 2s: (1) In 2% of population
(2) Symptomatic usually before age 2
(3) Located within 2 feet of ileocecal valve
(4) Two inches (up to 8 cm) in length
(5) Contains 2 types of heterotopic mucosa

• usually asymptomatic
• symptomatic (in 2–4%) because of complications

CT:
√ fluid- or air-filled blind-ending pouch (without Cx) ± particulate matter
√ isolated small bowel obstruction
√ intussusception with small bowel obstruction
√ inverted diverticulum:
  √ central intraluminal area of entrapped fat
  √ surrounded by thick collar of soft-tissue attenuation
√ volvulus
√ inflammatory mass attached to adjacent small bowel
√ intradiverticular enteroliths (3–10%)

√ luminal extravasation of contrast material from bleeding
√ nodular / polypoid intraluminal mass

NUC = "Meckel scan" (> 85% sensitive, > 95% specific, > 83–88% accurate):

◊ ^{99m}Tc-pertechnetate is excreted by mucoid cells of gastric mucosa and not dependent on the presence of parietal cells

N.B.: sensitivity drops after adolescence, because patients who are asymptomatic throughout childhood are less likely to have ectopic gastric mucosa

Preparation:

» No irritative measures for 48 hour (contrast studies, endoscopy, cathartics, enemas, drugs irritating GI tract)
» Fasting for 3–6 hours → results in decreased gastric secretion + diminished bowel peristalsis
» Evacuation of bowel + bladder prior to study

Dose: 5–10–20 mCi (100 µCi/kg) ^{99m}Tc-pertechnetate (adult dose!)

Radiation dose: 0.54 rad/2 mCi for thyroid;
0.3 rad/2 mCi for large intestine;
0.2 rad/2 mCi for stomach

Imaging: immediate continuous anterior imaging for 30–45 minutes / serial images in 5–10-minute intervals for up to 1 hour

√ small focal collection of tracer in RLQ appearing at the same time / shortly after gastric activity
√ tracer activity increases in intensity with time parallel to that of stomach
√ improved visualization through
(a) pentagastrin → stimulates uptake (6 µg/kg SC 20 minutes prior to pertechnetate)
(b) cimetidine → inhibits secretion (maximum 300 mg/dose IV 1 hour prior to pertechnetate)
(c) glucagon → decreases peristalsis (50 µg/kg IM 5–10 minutes prior to pertechnetate)
√ poor visualization with use of perchlorate + atropine → depressed uptake

False-positive results:

(1) Ectopic gastric mucosa in gastrogenic cyst, enteric duplication, normal small bowel, Barrett esophagus
(2) Increased blood pool in AVM, hemangioma, hypervascular tumor, aneurysm
(3) Duodenal ulcer, ulcerative colitis, Crohn disease, appendicitis, laxative abuse
(4) Intussusception, intestinal obstruction, volvulus
(5) Urinary tract obstruction, calyceal diverticulum
(6) Anterior meningomyelocele
(7) Poor technique

mnemonic: HA GUIDI
Hemangioma
Appendicitis
Gastric ectopia
Urinary obstruction
Intussusception
Duplication of bowel
Inflammatory bowel disease

False-negative results:
(1) Insufficient mass of ectopic gastric mucosa
(2) Dilution of intraluminal activity ← hemorrhage / hypersecretion
mnemonic: MIS
Malrotation of ileum
Irritable bowel in RLQ → rapid transit
Small amount of ectopic gastric mucosa

Enteroclysis:
√ elongated, smoothly marginated, clublike, intraluminal mass parallel to long axis of distal ileum = inverted Meckel diverticulum (20%)
√ 0.5–20-cm-long blind pouch on the antimesenteric border of ileum with junctional fold pattern

Angio (59% accuracy):
√ presence of vitelline artery (= anomalous end branch of superior mesenteric artery) is PATHOGNOMONIC

Cx (in 4–20–40%):
(1) Painless GI bleeding: in children < 5 years of age ← ulceration (in 95% ← heterotopic gastric mucosa)
(2) Acute diverticulitis (30%) in adults secondary to
(a) acid secretion from ectopic gastric mucosa
(b) obstruction of diverticulum by enterolith / foreign body
(3) Intestinal obstruction in older child / adult secondary to
(a) volvulus ← omphalomesenteric diverticulum attached to umbilicus by fibrous band
(b) inflammatory adhesion
(c) Intussusception
(d) Littré hernia
(4) Perforation
(5) Neoplasm (rare):
(a) malignant tumor: carcinoid, carcinoma, sarcoma
(b) benign tumor: GIST, leiomyoma
(6) Chronic abdominal pain

MECONIUM ILEUS

= small bowel obstruction ← desiccated meconium pellets impacted in distal ileum
Age: may develop in utero (in 15%)
Associated with:
cystic fibrosis with tenacious + sticky meconium ← deficiency of pancreatic secretions (in almost 100%)

◊ Virtually all infants with meconium ileus prove to have cystic fibrosis
◊ 10–15% of infants with cystic fibrosis present with meconium ileus!

◊ Earliest clinical manifestation of cystic fibrosis!
• abdominal distension, bilious emesis
• failure to pass meconium within 48 hours
√ numerous dilated small bowel loops without air-fluid levels (fluid not present)

√ "bubbly" / "frothy" appearance of intestinal contents
√ "soap-bubble" / "applesauce" appearance in RLQ (in 50–66%) ← admixture of gas with meconium
√ multiple round / oval filling defects in distal ileum + colon
√ functional microcolon ← unused colon in antenatal obstruction
OB-US:
√ unusual echogenic intraluminal areas in small bowel (DDx: normal transient inspissated meconium)
√ usually polyhydramnios
√ fluid-filled dilated small bowel
Cx (in 40–50%): volvulus, ischemia, necrosis, stenosis, atresia, perforation, meconium peritonitis, pseudocyst
Rx: (1) Nonionic contrast media enema (because of risk of bowel perforation)
(2) 17% Hypaque® / Conray™ enema mixed with acetylcysteine (Mucomyst®)
(3) Gastrografin® enema with Tween 80 (attention to fluid + electrolyte balance)
DDx: Hirschsprüng disease, small bowel atresia with meconium ileus, meconium plug syndrome, small left colon syndrome, imperforate anus, obstruction from duplication cyst

MECONIUM PERITONITIS

= sterile chemical peritonitis ← perforation of bowel proximal to high-grade / complete obstruction that seals in utero due to inflammatory response
Frequency: 1÷35,000 livebirths
Age: antenatal perforation after 3rd month of gestation
Cause:
(1) Atresia ← to ischemic event (50%)
(a) of small bowel: usually ileum or jejunum
(b) of colon (uncommon)
(2) Bowel obstruction (46%)
(a) meconium ileus
(b) volvulus, internal hernia
(c) intussusception, congenital bands, Meckel diverticulum
(d) microcolon
(3) Hydrometrocolpos
◊ Meconium peritonitis ← cystic fibrosis diagnosed in utero in 8% + at birth in 15–40%!
◊ Intraperitoneal meconium may calcify within 24 hours!
Types:
A. FIBROADHESIVE TYPE (most common):
= intense chemical reaction of peritoneum, which seals off the perforation
• no evidence for active leak at birth
√ dense mass with calcium deposits
√ calcific plaques scattered throughout peritoneal cavity
B. CYSTIC TYPE
= cystic cavity formed by fixation of bowel loops surrounding the perforation site, which

continues to leak meconium
√ cyst outlined by calcific rim

C. GENERALIZED TYPE
- perforation occurs immediately antenatally
- active leakage of bowel contents

√ complicated ascites

√ intraabdominal calcifications (CONSPICUOUSLY ABSENT in cystic fibrosis):
- √ peripherally calcified pseudocysts
- √ small flecks of calcifications scattered throughout abdomen
- √ larger aggregates of calcifications along inferior surface of liver / flank / processus vaginalis / scrotum

√ obstructive roentgen signs following birth
√ separation of bowel loops by fluid
√ microcolon = "unused colon"
√ meconium hydrocele producing labial mass

US:
- √ highly echogenic linear / clumped foci with posterior acoustic shadowing in scrotum
- √ "snowstorm appearance" = highly echogenic material throughout abdomen in between bowel loops
- √ ill- / well-defined homo- / heterogeneous encysted collections of meconium

OB-US (> 18 weeks EGA):
- √ polyhydramnios (64–71%)
- √ fetal ascites (54–57%)
- √ bowel dilatation (27–29%)
- √ intraabdominal bright echogenic mass
- √ multiple linear / clumped foci of scattered calcifications (85%); may develop within 12 hrs to 8 days after perforation
- √ meconium pseudocyst = well-defined hypoechoic mass surrounded by an echogenic calcified wall (= contained perforation)

DDx: (1) Intraabdominal teratoma
(2) Fetal gallstones
(3) Isolated liver calcifications

Mortality: up to 62%

Prognosis: generally good; surgery may not be required when perforation site is completely healed

MECONIUM PLUG SYNDROME

= local inspissation of meconium leading to low colonic obstruction; probably related to small left colon syndrome as part of the same spectrum of functional immaturity

Age: newborn infant (symptomatic within first 24 hours of life)

Cause: cystic fibrosis (25%), Hirschsprüng disease, prematurity, maternal magnesium sulfate treatment

• abdominal distension, vomiting, failure to pass meconium

√ distended transverse + ascending colon + dilated small bowel (proximal to obstruction)

√ small left colon with change in caliber at splenic flexure
√ occasionally bubbly appearance in colon (DDx: submucosal air in necrotizing enterocolitis)
√ presacral pseudotumor → no gas in rectum
BE:
√ double-contrast effect = barium between meconium plug + colonic wall
Rx: water-soluble enema
DDx: Hirschsprüng disease

MELANOSIS COLI

= benign brown-black discoloration of colonic mucosa
Frequency: 10% of autopsies
Cause: ? chronic anthracene cathartic usage
• asymptomatic
√ nonspecific colonic wall thickening (in severe cases)
Dx: endoscopic
Prognosis: no malignant potential

MéNéTRIER DISEASE

[Pierre Eugène Ménétrier (1859–1935), pathologist in Paris, France]
= GIANT HYPERTROPHIC GASTRITIS = HYPERPLASTIC GASTROPATHY
= rare disease characterized by excessive mucus production and
TRIAD of (1) Giant mucosal hypertrophy + hypersecretion
(2) Hypoproteinemia
(3) Hypochlorhydria
Prevalence: < 1÷200,000
Cause: ? overproduction of polypeptide growth factor α → increasing gastric mucus production + inhibiting gastric acid secretion
Path: mucosal thickness up to 6.0 mm (normal: 0.6–1.0 mm)
Histo: hyperplasia of glandular tissue + microcyst formation
Age: bimodal distribution in children < 10 years (← CMV infection) and adults 20–70 years; M÷F = 1÷3
Associated with: benign gastric ulcer (13–72%)
• epigastric pain, vomiting, anorexia, asthenia, weight loss
• gastrointestinal bleeding, diarrhea
• protein-losing enteropathy with hypoalbuminemia ← loss of albumin into gastric lumen and increased loss of enteric protein + peripheral edema
• absent / decreased acid secretion (> 50%) ← reduction in number of parietal + chief cells
Location: throughout fundus + body, particularly prominent along greater curvature; relative sparing of antrum (involved in 46%) (DDx to lymphoma: usually in antrum)
√ markedly enlarged (> 1 cm in fundus + body with frequent sparing of antrum) and tortuous gastric rugae (no longer parallel to long axis of stomach) resembling cerebral convolutions in spite of adequate gastric distension
√ marked hypersecretion (mucus) → may dilute barium + impair coating of mucosa
√ preserved pliability of stomach

CT:
√ thickened mucosa projecting into gastric lumen + smooth serosal contour
√ nodular symmetric folds
Cx: increased risk of thromboembolic disease
Rx: anticholinergics, prostaglandins, proton pump inhibitors, prednisone, histamine-2 blockers; gastrectomy
DDx: lymphoma (usually in distal stomach + lesser curvature, enlarged nodes, splenomegaly); polypoid variety of gastric carcinoma (rigid gastric folds, mass, ulcer); acute gastritis (H. pylori, CMV, histoplasmosis); infiltrative disease (sarcoidosis, amyloidosis); chronic gastritis; Zollinger-Ellison syndrome (postbulbar ulcer); gastric varices (serpentine form, change in shape and size, confined to cardia + fundus)

MESENTERIC FIBROMATOSIS

= INTRAABDOMINAL FIBROMATOSIS = ABDOMINAL DESMOID
= part of the spectrum of deep fibromatosis
Incidence: 2–4 ÷1,000,000 annually
Mean age: 41 (range, 14–75) years; M÷F=1÷1
Path: nonencapsulated well-circumscribed mass ± infiltrative margins within muscularis propria
Histo: uniform wavy spindle-shaped fibroblasts in a typically uninflamed abundant dense collagenous stroma ± myxoid foci; tentacular melting insinuation into / through muscularis propria of bowel wall; keloidal fiber formation, thick-walled small arteries, thin-walled veins, perivascular microhemorrhages; absent / scant mitoses; NO necrosis
Associated with: Gardner subtype of familial adenomatous polyposis (in 5–13%)
Risk factor: history of abdominal surgery (during past 4 years) in patients with familial adenomatous polyposis (83%)
• family history of Gardner syndrome / hereditary colon cancer
• abdominal pain, palpable abdominal mass
Location: small bowel mesentery (⅔) near origin of SMA > omentum, ileocolic mesentery, transverse / sigmoid mesocolon, omentum, peritoneal ligaments
Size: most 5–10 (up to 30) cm in diameter
Barium / Enteroclysis:
√ displacement of small bowel segments
√ mucosal ulceration ← compromised mesenteric vasculature
√ luminal narrowing / dilatation
√ distorted thickened / effaced small bowel folds
US:
√ solid well-circumscribed heterogeneous mass with variable internal echogenicity (predominantly hypoechoic)
CT:
√ homogeneous soft-tissue attenuation ← highly collagenous stroma similar to skeletal muscle
√ hypoattenuating mass ← myxoid stroma
√ striated / whorled appearance ← alternating collagenous + myxoid areas

√ bowel tethering = bowel encasement
√ encasement of superior mesenteric vessels

CECT:
√ mild homogeneous to heterogeneous enhancement
√ absent enhancement in myxoid lesion
√ similar / greater enhancement compared to muscle in fibrous lesion
√ occasionally marked enhancement

MR:
√ hypo- or isointense signal compared to muscle on T1WI
√ heterogeneously intermediate / high SI on T2WI ← depending on cellularity + amount of collagen versus myxoid stroma

PET:
√ low to moderate heterogeneous uptake
√ mean SUV of 4.54 (maximally up to 8.30)

Cx: gastrointestinal bleeding, small bowel obstruction, fistula formation, bowel perforation

Prognosis: proclivity for local recurrence

Rx: wide surgical excision, less radical surgery / medical therapy with antiestrogens / cytotoxic chemotherapy, postoperative irradiation

DDx:
(1) Malignancy: lymphoma, metastatic disease, soft-tissue sarcoma (lipo-, fibro-, leiomyo-sarcoma, malignant fibrous histiocytoma)
(2) Small-bowel GIST (areas of hemorrhage + necrosis, more cellular without abundant collagenous stroma, positive for CD117 + CD34)
(3) Abdominal fibromatosis (commonly in young women)
(4) Castleman disease
(5) Desmoplastic small round cell tumor

MESENTERIC LYMPHADENITIS

Primary Mesenteric Adenitis

= clinical entity with symptoms related to benign inflammation of lymph nodes without identifiable acute inflammatory condition

Cause: probable infection of the terminal ileum by Yersinia enterocolitica, Y. pseudotuberculosis, viral

Age: children, young adults

• nausea, vomiting, diarrhea, fever, leukocytosis
• diffuse / RLQ pain + tenderness

Location: usually RLQ (immediately anterior to right psoas muscle in 78%, small bowel mesentery in 56%)

√ cluster of (> 3) enlarged (> 5 mm) mesenteric lymph nodes without an identifiable acute inflammatory condition
√ isolated ileal wall thickening (33%)
√ colonic wall thickening (18%)

N.B.: visualization of entire normal appendix is necessary to differentiate from acute appendicitis!

Dx: diagnosis of exclusion

DDx: Secondary mesenteric adenitis as in appendicitis (enlarged nodes immediately anterior to right psoas muscle in 40–82%, nodes less numerous + smaller)

Secondary Mesenteric Adenitis

Cause:

(a) local condition: appendicitis, Crohn disease, diverticulitis

(b) systemic condition: lupus erythematosus, HIV

Age: adults (far more frequent than for primary adenitis)

MESENTERIC ISCHEMIA

= BOWEL ISCHEMIA

Classification of bowel ischemia by the American Gastroenterological Association in 2000:

» MESENTERIC ISCHEMIA

A. ACUTE MESENTERIC ISCHEMIA

(a) arterial (90%)

› occlusive mesenteric infarction (⅔)

1. **SMA embolus**

major: above origin of ileocecal artery

minor: distal to origin of ileocecal artery

2. **SMA thrombosis**

› nonocclusive mesenteric ischemia (⅓)

3. Splanchnic vasoconstriction ← low flow state

(b) venous (10%):

4. Mesenteric vein thrombosis

B. CHRONIC MESENTERIC ISCHEMIA

» COLONIC ISCHEMIA

Etiology:

(a) arterial occlusion / compromise: atheromatous disease, thromboembolic disease, dissecting aortic aneurysm, fibromuscular hyperplasia, arteritis, hypoperfusion (shock, hypovolemia), endotoxin shock, disseminated intravascular coagulation, direct trauma, aortic surgery, stent placement, therapeutic embolization, radiation, antiphospholipid antibody syndrome

› **occlusive mesenteric infarction** (90% mortality)

1. Embolus (40–50%)
2. SMA thrombosis (20–40%) at origin + site of atherosclerotic narrowing (ostium stenosis)

› **nonocclusive mesenteric ischemia** (10% mortality)

1. Preexisting atherosclerosis → low-flow state
2. Bowel vasoconstriction = vasospasm (reflex hypotension, digitalis, ergot preparation, vasopressin, amphetamine, cocaine), pheochromocytoma, familial dysautonomia
3. **Shock bowel** = diffuse small bowel ischemia in hypovolemia and hemorrhagic / cardiogenic / septic shock ← increased bowel permeability to macromolecules + albumin

√ diffuse bowel wall thickening
√ persistent increased enhancement on CT ← slowed perfusion and washout + interstitial leakage of contrast material
√ accumulation of intraluminal fluid ← failed resorption capacity

Arterial involvement:
SMA (5%); celiac artery (4%); IMA (11%)

(b) venous occlusion (< 10%): young patient, often following abdominal surgery
Location: SMV > inferior mesenteric vein > portal vein

(c) systemic low flow state (30%): myocardial infarction, CHF, intraoperative hypotension, arrhythmia, hypovolemia, shock, renal / hepatic disease

(d) bowel obstruction: strangulation by adhesions or bands ± mesenteric vein thrombosis, incarceration of hernia, volvulus, intussusception, pronounced overdistension (prestenotic, distension colitis), ischemic colitis ← endoscopy / enemas / colonic carcinoma (1–7%)

(e) vasculitis: polyarteritis nodosa (50–70%)
√ relatively long segment of bowel involved
√ multiple skip areas in nonsegmental distribution
√ involvement of duodenum is indicative

(f) abdominal inflammation: pancreatitis, appendicitis, diverticulitis, diffuse peritonitis, parasitic infestation

(g) cytotoxic drugs: long-term immunosuppressive drugs for rejection, chemotherapy for leukemia / lymphoma

(h) radiation: > 4,500 cGy

<u>in children:</u>
midgut volvulus, CHD, incarcerated hernia, sickle cell disease (occasionally), necrotizing enterocolitis

Pathophysiology: ischemia leads to
→ inflammatory response (cytokines, platelet-activating factor, tumor necrosis factor released from activated neutrophils, platelets, mast cells, endothelial cells)
→ breakdown of mucosal barrier from
› mild superficial necrosis limited to mucosa (mucosal ulcer) = partial mural bowel ischemia, to
› life-threatening continuous necrosis of all bowel wall layers = transmural bowel infarction
→ invasion of bacteria with bacteremia + sepsis
→ strictures

Distribution:
› small bowel, ascending colon, proximal $^{2}/_{3}$ of transverse colon ← SMA / SMV
› descending colon, sigmoid colon ← IMA / IMV
› splenic flexure, rectosigmoid junction ← watershed zones

Acute Mesenteric Ischemia

Cause:
(a) acute occlusive SMA embolus (in > 50%): usually lodges at bifurcation of middle colic artery + SMA
(b) SMA thrombosis (4–18%; nonocclusive in 25%): frequently involves the proximal

SMA
(c) SMA dissection ← cystic medial necrosis, fibromuscular dysplasia
(d) venous occlusion in 5–10–15% ← hypercoagulability, trauma, portal hypertension, infection, carcinoma, oral contraceptives

- first crampy, then continuous abdominal pain with acute event
- cardiac disease predisposing to embolization
- gut emptying (vomiting / bloody diarrhea)
- gross rectal bleeding, WBC > 12,000/µl with left shift (80%)

Location: (a) any segment of small bowel
(b) cecum (most common), distal transverse colon, splenic flexure

Consequences:
dependent on magnitude of insult, duration of process, adequacy of collaterals

A. REVERSIBLE ISCHEMIA
1. Complete restitution of bowel wall ← abundant collaterals
2. Healing with fibrosis + stricture formation

B. IRREVERSIBLE ISCHEMIA
1. Transmural infarction with bowel perforation

Bowel infarction develops with thrombosis of the small distal mesenteric venous branches.

Plain film:
√ gasless abdomen ← fluid-filled loops from exudation (21%)
√ bowel distension to splenic flexure (= perfusion territory of SMA) in 43%
√ "thumbprinting" (36%) = thickening of bowel wall + valvulae ← edema
√ small bowel pseudoobstruction (most frequently in thrombosis)
√ pneumatosis = dissection of luminal gas into bowel wall (28%)
√ mesenteric + portal vein gas (14%)
√ ascites (14%)

Barium:
√ "scalloping / thumbprinting" = thickening of bowel wall + valvulae
√ "picket fencing" = marked thickening of bowel wall
√ separation + uncoiling of loops
√ narrowed lumen
√ circumferential ulcer

CT (26–73–82% sensitive):
@ Bowel wall thickness
√ circumferential bowel wall thickening (28–52–96%) > 3–5 mm depending on degree of distension:
√ "halo / target" sign = stratification into 3 layers = inner mucosa and outer muscularis propria (rings of high attenuation) separated by layer of low attenuation (submucosal edema ± hemorrhage ± superinfection) in
› ischemic colitis (94%)
› reversible mesenteric ischemia (80%)
› mesenteric infarction (26–38%)
◊ The least specific sign!
◊ NO correlation with the severity of ischemic damage

√ thinning of bowel wall (in acute arterioocclusive transmural infarction) if it becomes gangrenous
√ bowel wall attenuation on NECT:
√ decreased, usually homogeneously ← edema
√ increased ← hemorrhage

@ Bowel wall enhancement
√ diminished enhancement of bowel wall ← compromised blood flow
√ absent enhancement of bowel wall (in 18%, 62% sensitive, 96% specific)
√ engorgement of mesenteric vessels = venous congestion ← stasis
√ increased wall enhancement ← hyperemia in outflow obstruction from mesenteric venous occlusion / during reperfusion after arteriogenic bowel ischemia / in shock bowel) as a good prognostic indicator (33% sensitive, 71% specific)
√ delayed + persistent enhancement ← delayed venous return and arteriospasm

@ Bowel diameter
(a) early reflex spastic ileus
√ contracted gasless bowel in mild mucosal ischemia
(b) intermediate reflex hypotonic ileus
√ dilated gas-filled bowel with paper-thin wall
(c) late paralytic ileus
√ focal / diffuse bowel dilatation (10–56–91%) with gas (43%) / fluid (29%) ← interruption of peristaltic activity ← destruction of intramural nerves + intestinal musculature / irreversible transmural ischemic damage
√ no enhancement
√ pneumatosis

@ Vascular signs
(a) arterial occlusion:
√ hyperattenuating SMA on NECT
√ filling defect with ring enhancement on CECT
√ thumbprinting (26%) = thickening of bowel wall
√ lack of bowel wall enhancement with arterial occlusion
√ concurrent embolic infarction of kidney / spleen
(b) venous thrombosis (15%):
√ enlarged diameter + increased attenuation of SMV on NECT
√ filling defect in SMV / portal vein thrombosis on CECT
√ thumbprinting (64%) = thickening of bowel wall
√ "waterlogging" with marked contrast enhancement of mesentery + bowel wall

√ pneumatosis intestinalis (in 6–28%, 3–14% specific)
= dissection of luminal gas into bowel wall across compromised mucosa signaling irreversible disease:
√ small isolated gas bubbles within wall
√ broad rims of air dissecting the entire bowel wall into two layers
◊ Sign of transmural bowel infarction in 78%

√ gas in portal vein (5–13–36%) / in mesenteric vein (28%) = propagation of intramural gas into mesenteric venous system
◊ Sign of transmural bowel infarction in 81%

@ Extramural signs
√ increased attenuation of mesenteric fat from mesenteric edema (in 68%, 58% sensitive, 79% specific)
√ mesenteric fluid (88% sensitive, 90% specific)
√ ascites (in 43–88%, 75% sensitive, 76% specific)
√ pneumoperitoneum (7%) = perforation of infarcted bowel segment

Cx: bowel necrosis ← occlusion of small vasa recta disallowing collateral flow

Common pitfalls:
(1) Spastic colon misinterpreted as simple contraction, (issue resolved by repeat CT with enema)
(2) Widely distended colonic segment with a wall thickness of 3–5 mm misinterpreted as normal
(3) Small bowel dilatation + air-fluid levels misinterpreted as ileus / pseudoobstruction

Angio (AP and LAT views):
√ occlusion / vasoconstriction / vascular beading
√ embolus lodged at major branching points distal to first 3 cm of SMA

Rx for nonocclusive mesenteric ischemia:
via SMA catheter slow injection of 60 mg papaverine followed by papaverine infusion of 1 mg/minute

NUC:
(a) IV / IA ^{99m}Tc-sulfur colloid / labeled leukocytes, Ga-citrate, ^{99m}Tc-pyrophosphate:
√ tracer accumulation 5 hours after onset of ischemia (more intense uptake with transmural infarcts)
(b) intraperitoneal injection of 133Xe in saline → absorbed by intestine:
√ decreased washout with abnormal perfusion of strangulated bowel

Prognosis:
(1) Massive infarction of small + large bowel if mesenteric embolization occurs proximal to middle colic artery (= limited collateral flow)
(2) Focal segments of intestinal ischemia if mesenteric embolization occurs distal to middle colic artery (= good collateral flow)

Local Cx: bleeding, intestinal perforation, abscess formation, peritonitis

Systemic Cx: hemoconcentration, acidosis, DIC, bone marrow suppression, multiple organ failure (including heart + kidneys)

Mortality: 70–80–92% for intestinal infarction

DDx: typhlitis, Crohn disease, infectious / ulcerative colitis, proctosigmoiditis, sigmoid diverticulitis, other causes of pneumatosis intestinalis / portal venous gas

Chronic Mesenteric Ischemia

= ABDOMINAL / INTESTINAL ANGINA
= intermittent mesenteric ischemia in severe arterial stenosis with inadequate collateralization provoked by food ingestion
• postprandial abdominal pain 15–20 minutes after food intake ← "gastric steal" diverting blood flow away from intestine
◊ Pain out of proportion to physical findings
• fear of eating large meals, weight loss, malabsorption

• reflex emptying of bowel after eating

Barium:

(a) Subacute:

√ flattening of one border

√ pseudosacculation / pseudodiverticula on antimesenteric border

(b) Chronic:

√ 7–10-cm-long smooth pliable strictures

√ dilatation of gut between strictures

√ thinned + atrophic valvulae

Cx: obstruction

Duplex US:

√ celiac trunk occlusion + retrograde perfusion of hepatic artery through SMA

√ PSV > 300 cm/sec and EDV > 45 cm/sec in SMA

√ peak systolic velocity > 160 cm/sec in celiac trunk for > 50% stenosis (57% sensitivity, 100% specificity) during fasting state

Mesenteric Vein Thrombosis

Cause:

A. PRIMARY / IDIOPATHIC (20%)

B. SECONDARY (with predisposing condition):

(1) Infection: acute pancreatitis (24%), sepsis, colonic diverticulitis, appendicitis, peritonitis, abdominal abscess

(2) Inflammatory bowel disease (2%)

(3) Trauma, postoperative state: Roux-en-Y gastric bypass > Nissen fundoplication > partial colectomy > cholecystectomy > appendectomy, pancreaticoduodenectomy (27%)

(4) Mechanical: volvulus, bowel obstruction

(5) Myeloproliferative neoplasm: chronic myelogenous leukemia, polycythemia vera, essential thrombocythemia, primary myelofibrosis

(6) Inheritable hypercoagulable state

(7) Paraneoplastic thromboembolism

(8) Tumor invasion: pancreatic cancer, HCC

(9) Miscellaneous causes: oral contraceptives (5%), pregnancy, chemotherapy

The location of thrombus is often determined by the underlying cause. Hematologic disorders affect small venous branches with progression into larger trunks.

Location: SMV > IMV (6%)

• usually subacute symptomatology over 1–4 weeks

• abdominal pain with rebound / guarding (acute MVT)

• nausea, vomiting, diarrhea

• hematemesis, hematochezia (after bowel necrosis)

√ ileus

√ ascites

√ bowel wall thickening (64%) with "thumbprinting

CT:

› mural signs:
√ pneumatosis intestinalis ← bowel infarction
√ hypoattenuated circumferential bowel wall thickening ← intramural edema / hemorrhage

Bowel wall thickening is more pronounced in venous congestion than in arterial occlusion.

√ "halo / target" sign = abnormally enhancing bowel wall with mural stratification into 2 or 3 thickened layers:
√ hyperattenuating inner ring (= mucosa) + outer ring (= muscularis propria) separated by hypoattenuating middle ring (= submucosal edema)
√ abnormal wall enhancement:
√ increased / normal wall enhancement ← preserved arterial inflow
√ decreased enhancement ← impeded arterial inflow
◊ Highly SPECIFIC for venous bowel infarction!

› vascular signs:
√ portomesenteric venous gas ← bowel infarction
√ hypoattenuating lumen surrounded by well-defined rim-enhancing venous wall ← partial / complete venous filling defect
√ enlargement of major vein ← displacement of venous wall by acute thrombus
√ engorgement of small mesenteric veins ← venous congestion ← thrombosis
√ venous collateral circulation

Upstream venous collateralization occurs more readily with thrombosis of large mesenteric veins than with thrombosis of venae rectae / arcades.

› extramural-nonvascular signs:
√ mesenteric haziness ← venous congestion + superimposed inflammatory edema + ascites
√ bowel dilatation ← interrupted intestinal peristalsis / loss of contractile function ← transmural infarction
√ free intraperitoneal air ← perforated infarcted bowel

US:
√ dilated vein with echogenic thrombus

Cx: bowel ischemia → infarction

Bowel infarction develops in thrombosis of the small distal mesenteric venous branches lacking collaterals.

Mortality: 12–50%

MESOTHELIAL CYST

= MESENTERIC / OMENTAL CYST

Etiology: failure of mesothelial peritoneal surfaces to coalesce

Path: unilocular thin-walled cyst usually with serous, occasionally chylous / hemorrhagic fluid contents

Histo: lined by mesothelial cells + surrounded by thin layer of fibrous tissue

Location: small bowel, mesentery (78%), mesocolon

• asymptomatic

√ single cyst up to several cm in size
√ omental cysts may be pedunculated
CT:
√ near-water density / soft-tissue density
√ ± fluid levels related to fat + water components
Cx: torsion, hemorrhage, intestinal obstruction
DDx: lymphangioma (septations)

METASTASIS TO GASTROINTESTINAL TRACT

GI metastases closely resemble the primary tumor. The radiologic appearance depends mainly on histologic characteristics of the primary / secondary lesion like degree of vascularity relative to growth rate.

Hypervascular Metastasis

1. Malignant melanoma
2. Breast cancer

uncommon:

3. Renal cell carcinoma
4. Choriocarcinoma
5. Neuroendocrine carcinoma
6. Mesenchymal sarcoma

Metastasis to Colon

Spread:

(1) Hematogenous (embolic)
√ subepithelial masses / bull's-eye lesions
√ diffusely infiltrating lesions mimicking inflammatory bowel disease

(2) Direct invasion by contiguous tumor
› ovary inferior border of sigmoid
› left kidney splenic flexure
› pancreatic tail splenic flexure
› pelvis (uterus, bladder) anterior border of rectum
› prostate rectosigmoid

(3) Direct invasion along mesenteric reflections
› stomach transverse colon superior margin
› pancreas transverse colon inferior margin
› omental cake transverse colon superior margin

(4) Intraperitoneal seeding
Origin: ovarian, gastric, colonic, pancreatic cancers (most commonly)
Classic sites of seeding:
› pouch of Douglas (50%): anterior border of rectosigmoid
› lower small bowel mesentery (40%): medial border of cecum
› sigmoid mesocolon (20%): superior border of sigmoid colon
› right paracolic gutter (10%): lateral border of ascending colon

Metastasis to Small Bowel

Origin: colon > stomach > breast > ovary > uterine cervix > melanoma > lung > pancreas

Spread:

(1) Intraperitoneal seeding: primary mucinous tumor of ovary, appendix, colon; breast cancer

(2) Hematogenous dissemination with submucosal deposits: malignant melanoma, breast carcinoma, lung carcinoma, Kaposi sarcoma

(3) Direct extension from adjacent neoplasm: ovary, uterus, prostate, pancreas, colon, kidney

√ fixation + tenting + transverse stretching (= across long axis) of folds ← mesenteric + peritoneal infiltration (most common form)

UGI:

√ single mass protruding into lumen resembling annular carcinoma

√ "bull's-eye" lesions = multiple polypoid masses with sizable ulcer craters

√ obstruction from kinking / annular constriction / large intraluminal mass

√ compression by direct extension of primary tumor / involved nodes

CT:

√ soft-tissue density nodules / masses

√ sheets of tissue causing thickening of bowel wall + mesenteric leaves

√ fixation + angulation of bowel loops (in tumors with desmoplastic response)

√ ascites

Metastasis to Stomach

Organ of origin:

(a) by hematogenous spread: malignant melanoma, breast cancer, lung ca., colon ca., prostate carcinoma, leukemia, secondary lymphoma

√ one / more subepithelial masses

√ target / bull's-eye lesion if centrally ulcerated

√ giant cavitated lesion

√ linitis plastica (usually in breast cancer)

(b) by direct invasion

› Barrett cancer: gastric fundus

› Pancreatic cancer: stomach / duodenal sweep

› Colonic cancer: greater gastric curvature

› Omental cake: greater gastric curvature

• GI bleeding + anemia (40%)

• epigastric pain

√ solitary mass (50%)

√ multiple nodules (30%)

√ linitis plastica (20%): especially in breast cancer

√ multiple umbilicated nodules: malignant melanoma

MIDGUT VOLVULUS

= torsion of entire gut around SMA

◊ MEDICAL EMERGENCY requiring immediate surgery!

Cause: malrotation

Age: most common in neonate / young infant (= acute intestinal obstruction); occasionally in older child / adult (= chronic intestinal obstruction)

In 20% associated with: (1) Duodenal atresia
(2) Duodenal diaphragm
(3) Duodenal stenosis
(4) Annular pancreas

Pathophysiology:

malrotation → abnormally short root of small bowel mesentery → abnormal mobility of midgut → torsion of mesentery; degree of twisting can change ← natural movement of bowel and determines symptomatology; severe volvulus → obstruction of SMV + SMA (= twist of 3 ½ turns) → bowel necrosis

- acute symptoms within first 3 weeks of life in 75%: HALLMARK postprandial intermittent projectile bilious vomiting (60–80%); abdominal distension; shock
- intermittent obstructive symptoms in older child: recurring attacks of nausea, vomiting, and abdominal pain with spontaneous reduction
- failure to thrive ← hypoproteinemic gastroenteropathy ← result of lymphatic + venous obstruction
- "currant jelly" stools / melena (implying vascular compromise)

Plain film:

◊ A normal abdominal radiograph does not exclude the Dx!
√ dilated air-filled duodenal bulb + paucity of gas distally
√ "double bubble" sign = air-fluid levels in stomach + duodenum
√ isolated collection of gas-containing bowel loops distal to obstructed duodenum = gas-filled volvulus = closed-loop obstruction ← nonresorption of intestinal gas ← obstruction of mesenteric veins

UGI (preferred method, 54% sensitive):

N.B.: First exclude perforation on plain films!
◊ UGI not needed if complete obstruction shown on plain film
◊ Nasogastric tube desirable → to decompress fluid-filled stomach with NG tube tip positioned in antropyloric region
√ vertically oriented duodenum that does NOT cross midline with most of small bowel on right side of abdomen
√ dilated proximal duodenum terminates in a distinctive conical / beaked shape
√ duodenal-fold thickening + thumbprinting ← mucosal edema + hemorrhage
√ duodenojejunal junction (ligament of Treitz) located lower than duodenal bulb + usually below and to the right of expected position at / to left of L1 pedicle
√ malrotation = spiral course of midgut (= jejunoileal) loops beyond point of obstruction = "apple-peel / twisted ribbon / corkscrew", "spiral" appearance (in 81%)

BE:

√ abnormally high position of cecum (with isoosmolar water-soluble contrast enema, which is distinguishable from barium suspension used for subsequent UGI)

CT:

√ whorled mesentery = clockwise wrapping of small bowel loops + adjacent mesenteric fat + SMV and tributaries + SMA branches converging to the point of torsion = swirling of vessels in mesenteric root (during volvulus)
√ SMV to left of / posterior to SMA = transposition / reversal of SMA-to-SMV relationship
normal position: SMV to the right of SMA
CAVE: reversal may be seen without malrotation; vessel location may be normal with malrotation
√ inability to visualize 3rd part of duodenum across midline from right to left
√ right- sided small bowel + left-sided colon
√ chylous mesenteric cyst ← interference with lymphatic drainage
√ small bowel dilatation + mucosal hyperattenuation ← global small-bowel ischemia

US:
√ clockwise "whirlpool sign" = color Doppler depiction of SMV wrapping clockwise around superior mesenteric artery
√ distended proximal duodenum with arrowhead-type compression over spine
√ superior mesenteric vein to the left of SMA
√ thick-walled bowel loops below duodenum + to the right of spine associated with free intraperitoneal fluid
√ narrowed mesenteric pedicle

Angio:
√ "barber pole" sign = spiraling of SMA
√ tapering / abrupt termination of mesenteric vessels
√ marked vasoconstriction + prolonged contrast transit time
√ absent venous opacification / dilated tortuous SMV

Cx: (1) Intestinal ischemia in distribution of SMA with occlusion of lymphatics + SMV + SMA → bloody diarrhea, ileus, abdominal distension
(2) Bowel necrosis → surgery → short-gut syndrome → dependence on total parenteral nutrition

Mortality: 3–5%

DDx: (1) Hypertrophic pyloric stenosis (same age group, no bilious vomiting)
(2) Ladd bands

MUCOCELE OF APPENDIX

Mucocele of Appendix

mucocele = macroscopic descriptive term for cystic dilatation of appendix / gallbladder / sinus cavity / salivary gland caused by an accumulation of mucin

Etiology:
(1) Simple mucocele (20%) = retention cyst = cystic dilatation of lumen ← obstruction by fecolith, foreign body, endometriosis, adhesions, postoperative scarring following appendectomy, volvulus, carcinoid, appendiceal carcinoma, carcinoma of cecum
√ mild luminal dilatation rarely > 2 cm in diameter
(2) Focal / diffuse mucosal hyperplasia (5–25%)
(3) Mucinous cystadenoma ← hyperplasia with epithelial atypia (50–63%) = mucin-

secreting tumor
√ marked luminal distention
Cx: perforation with mucous seeding (in 20%)
(4) Mucinous cystadenocarcinoma with stromal invasion (11–20%)
√ severe appendiceal distention by mucin
Cx: 6% risk of perforation + peritoneal implantations
(5) Cystic fibrosis with accumulation of thick mucus

Prevalence: 0.07–0.25% of appendectomy specimens; 8% of appendiceal tumors
Mean age: 55 years; M÷F = 1÷4 to 1÷1
Associated with: colonic adenocarcinoma (6-fold risk), mucin-secreting tumor of ovary

- asymptomatic (25%), ± acute / chronic RLQ pain
- palpable mass in right lower quadrant (in up to 50%)
- altered bowel habits, weight loss, vomiting
- ± elevated CEA, CA 19-9, CA 125

Size: up to 25 cm
BE / plain film:
√ globular, smooth-walled, broad-based mass invaginating into cecum
√ nonfilling of the appendix on BE
√ frequent peripheral punctate / rimlike calcifications ("**porcelain appendix**")
CT:
√ round sharply defined paracecal mass with homogeneous content of near-water / soft-tissue attenuation (depending on amount of mucin)
√ NO adjacent inflammation
√ calcifications of appendiceal wall (< 50%)
US:
√ purely cystic / cystic with gravity-dependent fine internal echoes / complex cystic mass with high-level echoes
√ SPECIFIC sign of multiple echogenic layers of protein macroaggregates / inspissated mucoid material along dilated appendix
√ ± acoustic shadowing if calcifications present
MR:
√ hyperintense tumor on T2WI
√ variably hypo- to isointense on T1WI depending on mucin concentration
√ soft-tissue thickening, infiltration of perifocal fat, irregular mucocele wall = signs of malignancy / secondary inflammation / both
NUC:
√ intense early gallium uptake ← affinity to acid mucopolysaccharides of mucus

Cx: (1) Rupture → pseudomyxoma peritonei
(2) Torsion → gangrene + hemorrhage
(3) Herniation into cecum → bowel obstruction
(4) Intussusception
(5) Right ureteral obstruction

Rx: appendectomy; hemicolectomy (suspected malignancy)
DDx: appendicitis, periappendiceal abscess, mesenteric cyst, enteric duplication cyst, right

ovarian cyst, cystic ovarian neoplasm, hydrosalpinx, tubo-ovarian abscess

Myxoglobulosis

= rare variant of mucocele characterized by clusters of pearly white mucous balls (= intraluminal globules) intermixed with mucus

• usually asymptomatic, may appear as acute appendicitis

√ multiple mobile 1–10-mm small rounded annular nonlaminated calcified spherules (PATHOGNOMONIC)

DDx: inverted appendiceal stump (of inversion-ligation technique), acute appendicitis, cecal carcinoma, phleboliths, calcified lymph nodes

OMENTAL INFARCTION

= rare cause of self-limiting abdominal pain

Pathophysiology:

(a) torsion (rare cause)→ interruption of blood supply to omentum → venous thrombosis

(b) trauma → thrombosis → insufficiency of omental veins

Predisposing factors: obesity, strenuous activity, CHF, digitalis administration, trauma, recent abdominal surgery

A. PRIMARY (idiopathic) OMENTAL INFARCTION (15%)

Cause: bifid omentum, accessory omental tissue, variant vascular supply, marathon running → physiologic shunting with splanchnic vasoconstriction

May be associated with: hypercoagulable state, CHF, vasculitis

Path: hemorrhagic infarction ← vascular compromise ← (a) tenuous blood supply to right edge of omentum, (b) kinking of veins

• precipitated by coughing, straining, overeating, marathon running

Age: pediatric patients

Location: commonly RLQ on inferior right side of omentum

B. SECONDARY OMENTAL INFARCTION (more common)

Cause: postoperative omental adhesion, omental mass, vascular damage related to trauma / inflammation / hernia

Age: adult, M > F

• subacute RLQ / RUQ abdominal pain of a few days duration

• clinical mimicker of acute appendicitis, cholecystitis but in the ABSENCE of GI symptoms of nausea, vomiting, fever

• slightly elevated WBC

Location: mostly between anterior abdominal wall and transverse / ascending colon / cecum

Site: right inferior portion of omentum > left

Size: diameter > 5 cm

CT:

√ solitary encapsulated triangular / oval fatty mass:

√ soft-tissue stranding adjacent to ascending colon = haziness of fat anterior to colon (early / mild infarction)

√ internal heterogeneity ← soft-tissue stranding adjacent to ascending colon

√ whorled pattern of concentric linear fat stranding (in torsion)

√ NO enhancement
√ omental torsion (rare) with swirling of vessels in omentum
√ absent / (rarely) mild thickening of adjacent bowel wall corresponding to site of focal tenderness

US:
√ nonmobile noncompressible hyperechoic tender mass

PET:
√ mild uptake of 18F-fluorodeoxyglucose (FDG)

Dx: clinically difficult; often 1st suggested by radiologist
Cx: omental abscess (rare)
Rx: supportive
DDx: epiploic appendagitis (< 5 cm in diameter, peripheral hyperdense rim, "central dot" sign); diverticulitis (bowel wall thickening)

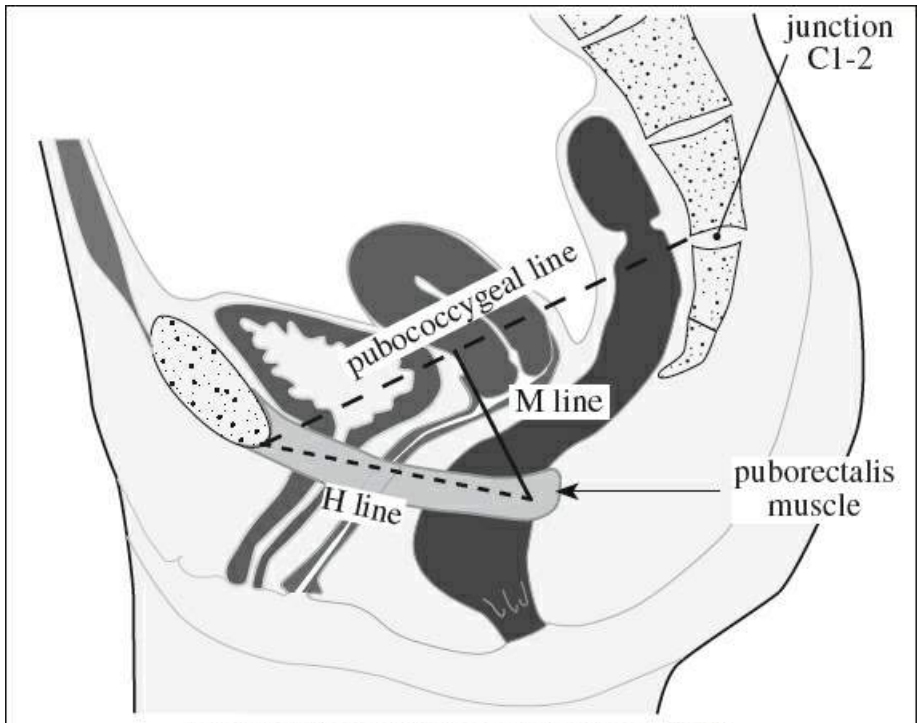
PELVIC FLOOR DYSFUNCTION

= heterogeneous group of disorders presenting with pelvic pain, pressure, dyspareunia, incontinence, incomplete emptying, gross organ protrusion

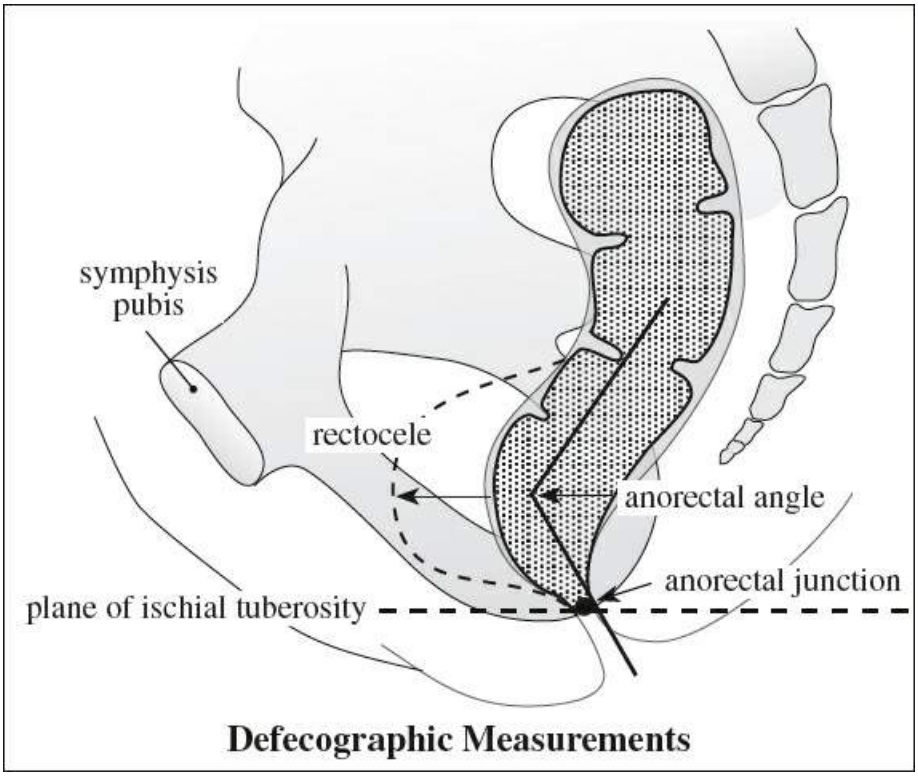
Prevalence: 10–50% of middle-aged / older women increasing with age; 10% requiring surgery

Cause: injury to pelvic floor from surgery / childbirth, denervation of musculature, fascial defect, abnormal synthesis / degradation of collagen

Risk factors: age, menopause, multiparity, complicated vaginal delivery, obesity, collagen-related disorder, hysterectomy



Pelvic Floor Measurements on MR



Midsagittal pelvic MR:

» Draw 3 lines:

(1) Pubococcygeal line from inferior margin of symphysis to junction C1-C2

(2) H-line (**H**iatus of levator ani) along puborectalis muscle sling for structures passing through pelvic floor

√ linear distance measured during straining

(3) M-line (**M**uscular pelvic floor) line from point of posterior puborectalis muscle perpendicular to pubococcygeal line

» HMO evaluation:

(1) **Hiatal size** (**H**-line measurement)

√ hiatal enlargement > 6 cm

Grading: normal < 6 cm, mild 6–8 cm, moderate 8–10 cm, severe > 10 cm

(2) **Pelvic floor descent** (**M**-line measurement)

√ pelvic floor descent > 2 cm

Grading: normal < 2 cm, mild 2–4 cm, moderate 4–6 cm, severe > 6 cm

(3) **Organ prolapse** (any distance below H-line):

= shortest distance between the most caudal aspect of an organ and H line during Valsalva maneuver

Grading: mild / small < 2 cm; moderate 2–4 cm; severe / large ≥ 4 cm

Defecography / Evacuation Proctography:

evacuation time = 15 (range 5–40) seconds

anorectal angle = angle formed between central axis of anal canal + line parallel to posterior wall of rectum

√ 90° at rest and during voluntary contraction (squeeze maneuver)

√ more obtuse during defecation straining (void)

anorectal junction = point of taper of distal rectal ampulla as it merges with the anal canal; position of anorectal junction referenced to plane of ischial tuberosities = 0–3.5 cm; elevation during squeeze of 0–4.5 cm; elevation during void of –3.0–0 cm

rectovaginal space = space between vagina and rectum

perineum = area between external genital organs and anal verge

Pelvic Floor Relaxation

= weakening of pelvic floor support structures consisting of muscles and connective tissue (= pelvic sling) → pelvic floor dysfunction at rest + during activities with ↑ intraabdominal pressure (like coughing, sneezing, urination, defecation)

Components: hiatal enlargement + pelvic floor descent

Rx: surgical mesh reconstruction

Grade	*Hiatal Enlargement*	*Pelvic Floor Descent*
0 (normal)	< 6 cm	0–2 cm
1 (mild)	6–8 cm	2–4 cm
2 (moderate)	8–10 cm	4–6 cm
3 (severe)	≥ 10 cm	≥ 6 cm

Pelvic Floor Prolapse

= abnormal protrusion of a pelvic organ(s) through its respective hiatus

Cause: failure of support structures, perineal hiatal weakening

Cystocele

= prolapse / herniation of bladder through its respective hiatus on anterior vaginal wall

Cause: defect in pubocervical fascia attaching to arcus tendineus fasciae pelvis (ATFP) anterolaterally + to cervix posteriorly

- vaginal bulging → difficult intercourse / dyspareunia
- simple stress urinary incontinence (may be masked in severe case by a kink at the bladder neck ← transverse orientation of urethra)

Voiding video urodynamic study:

√ uncovers urge incontinence from detrusor instability

√ uncovers stress urinary incontinence masked by urethral hypermobility

MR:

√ downward + clockwise bladder rotation ← posterior bladder wall descends disproportionately more than anterior wall (in severe case)

√ descent of bladder base below pubococcygeal line

√ urethral prolapse (= urethral hypermobility)

Rx: pessary: sutures and mesh to approximate original fascial support ± incontinence surgery (sling procedure)

CYSTOURETHROCELE

Cx: ureteral obstruction / hydronephrosis ← entrapment of ureters ← high degree of muscular pelvic floor relaxation

Bladder Outlet Obstruction

Cause: surgical repair for stress urinary incontinence, urethral hypermobility, bladder outlet compression by prolapsing uterus or rectocele, kinking of urethra / bladder outlet in patients with cystocele

- voiding hesitancy, required positional voiding, required manual reduction of prolapse for voiding, frank urinary retention occasionally requiring catheterization

Genital Prolapse

= UTERINE AND VAGINAL VAULT PROLAPSE

Cause: muscle damage + stretching (laxity) / tearing of uterosacral ligaments

- bulging vaginal mass outside external genitalia
- dyspareunia, urinary retention, back pain

MR:

√ descent of vaginal fornix and uterus below PCL
√ progressive uterine retroversion → subsequent prolapse
√ loss of banana-shaped vaginal axis (= loss of elevation of distal vagina by ligaments and muscles)

Rx: pessary, pelvic floor exercises, hysterectomy, vaginal repair

Cx: insidious progressive ureteral obstruction

UTERINE PROCIDENTIA

= uterus prolapse completely outside of hiatus

Enterocele

= CUL-DE-SAC HERNIA

= herniation of peritoneal membrane protruding between uterosacral ligaments at apex of vagina through rectovaginal space (cul-de-sac) and posterior perineum + extending distally into rectovaginal septum, separating rectum from vagina

(a) simple = no associated vaginal vault prolapse
(b) complex = associated with other forms of anterior / posterior vaginal vault prolapse

Content: fat (= peritoneocele), small bowel (= true enterocele), sigmoid colon (= sigmoidocele)

At risk: hysterectomy ← interrupted continuity of pubo-cervical + rectovaginal parts of endopelvic fascia

- symptoms of bowel obstruction, vaginal pressure, dyspareunia, low back pain
- difficult to diagnose on physical examination

Cystocolpoproctography:

◊ fails to demonstrate up to 20% of enteroceles

MR: superior to cystocolpoproctography

Rx: requires peritoneal approach to surgical repair

Sigmoidocele

EVacuation Proctography:

√ prolapse of sigmoid colon between rectum and vagina

Grading: (1) above pubococcygeal line; (2) between pubococcygeal + ischiococcygeal line; (3) below ischiococcygeal line

Cx: obstruction of rectum

Peritoneocele

= MESENTEROCELE

containing liquid / bowel / omentum / mesenteric fat

Evacuation Proctography:

√ extension of rectouterine excavation to below upper third of vagina

Rectocele

= bulging / outpouching of anterior rectal wall anterior to transverse perineus muscle into posterior vaginal wall

Cause: defect in pre- and pararectal fascia and rectovaginal septum

- often missed at physical examination
- impaired emptying → need for digital assistance

Evacuation proctography:

√ measurement of anteroposterior depth of convex wall protrusion extending beyond expected margin of normal rectal wall

√ rectal mucosal prolapse, solitary rectal ulcer

√ incomplete emptying of anterior rectoceles

MR:

√ distance of anterior / posterior rectal wall from anal canal axis

Grading: small < 2 cm; moderate 2–4 cm; large > 4 cm

Cx: obstructed defecation ← dissipation of vector force during straining

Rx: rectovaginal fascia repair / posterior fixation of rectum ± sigmoid / rectal resection

RECTAL PROLAPSE

= descent / infolding of mucosa or entire thickness of rectal wall through anal verge

Cause: chronic straining + fascial disruption

Cx: obstructed defecation → pudendal neuropathy → fecal incontinence; external anal sphincter atrophy

RECTAL INTUSSUSCEPTION

= descent of the entire (full wall) thickness of the rectal wall into anal canal; starting 6–11 cm above anus

Types: internal (intrarectal / intra-anal) or external

√ infolding of < 3 mm in width / > 3 mm in width / intraluminal narrowing / descent into anal canal / external prolapse

√ accompanied by formation of a circular indentation forming a ring pocket

PERITONEAL MESOTHELIOMA

= MALIGNANT MESOTHELIOMA

= uncommon only primary tumor of peritoneum arising from mesothelial cells lining peritoneal cavity

Frequency: 12–33% of all mesotheliomas; 6%–10% of all malignant mesotheliomas

Median age: 50 (range, 55–66) years; M >> F

Associated with: high levels of asbestos exposure (50–70%), esp. exposure to erionite (=

mineral fiber found in Turkey); therapeutic irradiation; exposure to simian virus 40; (rarely) chronic pleural / peritoneal irritation

Origin: (a) expectoration of inhaled asbestos fibers → swallowed → penetration of bowel wall into lymphatics + splanchnic circulation

(b) arise solely from peritoneum (35%)

Spread: intraperitoneal along serosal surfaces; direct invasion of liver, pancreas, bladder, bowel

Location: pleura (67%), peritoneum (30–40%), pericardium (2.5%), processus vaginalis (0.5%)

Path:

(1) Focal (localized) form

√ large mass, usually in upper abdomen + scattered peritoneal nodules in anterior parietal peritoneum becoming confluent and cakelike

Prognosis: good following complete surgical excision

(2) Diffuse (desmoplastic) form

√ diffuse thickening of mesentery, omentum, peritoneum, bowel wall WITHOUT definable mass + spread along serosal surfaces encasing solid / hollow visceral organs

Prognosis: highly aggressive + incurable

Histo: epithelial, sarcomatous, mixed (biphasic / bimorphic) with submesothelial tumor infiltration

• abdominal pain / discomfort, nausea, anorexia, weight loss

• abdominal distention / increasing abdominal girth

√ lymphadenopathy (rare)

UGI:

√ separation of small bowel loops from one another

√ absence of normal peristaltic movements

CT:

√ nodular irregular thickening of peritoneal surfaces / localized masses

√ stellate mesentery (common)= thick neurovascular bundles

√ increased attenuation in mesenteric fat

√ perivascular soft-tissue thickening

√ rigidity of vascular bundle

√ pleated thickening of mesenteric leaves ← infiltrating sheets of tissue

√ bowel wall thickening ← tumor extension to visceral peritoneal surface

√ foci of calcifications (rare)

√ disproportionately small amount of ascites of near-water density

√ omental involvement:

√ finely infiltrated fat with smudged appearance

√ discrete omental nodules

√ omental cake

√ pleural plaque (in 50%)

CECT:

√ homo- / heterogeneous enhancement ← intratumoral mucinous component / cystic degeneration / necrosis

MR:
√ tumor of intermediate to low SI on T1WI
√ tumor of intermediate to high SI on T2WI
NUC:
√ diffuse uptake of 67Gallium
Cx: bowel obstruction
Prognosis: extremely poor ← advanced disease at presentation (most patients die within 1 year)
DDx: peritoneal carcinomatosis (indistinguishable); nonneoplastic condition (eg, tuberculosis)

Multicystic / Cystic Mesothelioma

= BENIGN MULTICYSTIC MESOTHELIOMA = PERITONEAL INCLUSION CYST = PERITONEAL PSEUDOCYST = MULTILOCULAR INCLUSION CYST = ENTRAPPED OVARIAN CYST = INFLAMMATORY CYST OF THE PELVIC PERITONEUM
= accumulation of ovarian fluid contained by peritoneal adhesion / (?) rare benign neoplasm without metastatic potential but tendency for local recurrence
Cause: endometriosis; pelvic inflammatory disease; trauma; prior pelvic surgery in 30–100% (time delay of 6 months to 20 years)
Origin: serosal lining of peritoneum, pleura, pericardium
Pathogenesis: extensive pelvic adhesions → impaired peritoneal clearing → accumulation of ovulated fluid
Path: multiple translucent thin-walled cysts that grow along pelvic peritoneum in grapelike clusters adherent to surface of ovary; intermediate form between benign adenomatoid tumor + malignant peritoneal mesothelioma
Histo: cyst lined by hyperplastic mesothelial cells and fibroglandular tissue with chronic inflammation; filled with watery fluid; positive for calretinin and cytokeratins
◊ Not associated with asbestos exposure!
Mean age: 37 years (premenopausal with active ovaries); M÷F = 1÷5
• chronic or intermittent lower abdominal / pelvic pain
• abdominal distention, tenderness. palpable mass
• dyspareunia, constipation, urinary hesitancy & frequency
Location:
(a) woman: typically in cul-de-sac, along peritoneal surface of uterus and rectum / omentum
(b) men: peritoneal surface of bladder + rectum
(c) upper abdomen: multifocal cysts / freely floating cyst / unilocular cyst
Size: 13 cm of mean diameter
US:
√ single / multiloculated cyst conforming to the shape of the peritoneal cavity + contiguous with normal ovary:
√ "ovary-in-cyst" sign = normal-appearing ipsilateral ovary entrapped by loculated fluid
√ unusual geometric shape with anatomic boundaries
√ NO cyst wall
√ cyst content usually anechoic ± echoes from debris / hemorrhage

√ septa:
√ thin fibrous septa + mesothelial strands (common) resembling a spider web
√ NO septal calcification
√ ± nodular excrescences / thick polypoid incomplete septations

CT:
√ watery fluid attenuation
√ soft-tissue attenuation ← innumerable small cysts / thick-walled cyst
√ septal enhancement

MR:
√ signal pattern typical of serous fluid = low on T1WI, high on T2WI
√ enhancement of septa only
√ may contain hemorrhage

Cx: infertility
Rx: surgery (27–50% risk of recurrence)
Prognosis: good
DDx: Paraovarian cyst (ovoid cyst outside ovary), Hydrosalpinx (visible folds, located outside ovary), Lymphangioma, Intraperitoneal inclusion cyst, Mesenteric cyst, Ovarian cystadenoma / cystadenocarcinoma

PERITONEAL METASTASES

= PERITONEAL CARCINOMATOSIS
= relatively common intraabdominal spread of malignant tumors
Origin: (a) common: ovary, GI primary (stomach, colon)
(b) less common: pancreas, uterus, bladder, appendix
Time of onset:
in 55% at time of diagnosis of nongynecologic primary;
in 70% at time of staging laparotomy for ovarian cancer
• usually asymptomatic at onset
• abdominal enlargement ← ascites
• abdominal pain ← bowel obstruction
Path: tumor nodules studding peritoneal surface; transperitoneal spread with fibrotic host response → replacement of omental fat = omental caking + ovarian metastasis (= Krukenberg tumor)
Histo: adenocarcinoma with abundant mucin + signet ring morphology (most frequent)
√ new onset ascites / massive ascites
√ loculated fluid collections in peritoneal cavity
√ enhancement of peritoneum
√ nodules in areas of relative stasis / arrested flow of peritoneal fluid
Location of arrested flow / stasis of peritoneal fluid:
rectouterine recess (pouch of Douglas), retrovesical space, subhepatic space, right subdiaphragmatic space, root of small bowel mesentery, ileocecal junction, superior aspect of sigmoid mesocolon, right paracolic gutter
◊ Stasis areas = sites of occult tumor
√ desmoplastic reaction at (a) anterior border of rectum (Blumer shelf), (b) mesenteric side of

terminal ileum
√ occasionally sheetlike growth pattern encasing intraperitoneal viscera (DDx: malignant mesothelioma)

US:
√ ascites: anechoic / with low-level echoes of particulate matter (= proteinaceous exudate)
√ hypoechoic tumor nodule / sheetlike mass on visceral / parietal surface
√ echogenic plaquelike omentum floating in ascites / adherent to anterior abdominal wall

CT (25–50% sensitive for tumors < 1 cm):
√ small nodular densities studding peritoneal surface
√ pleated / stellate small bowel mesentery:
√ increased density of linear network in mesenteric fat (= fluid within leaves of mesentery)
√ apparent thickening of mesenteric vessels (= tumor infiltration of perivascular spaces)
√ "omental cake" = thickening of greater omentum
√ adnexal mass of cystic / soft-tissue density (= Krukenberg tumor) ← transperitoneal spread
√ lobulated mass in pouch of Douglas
√ calcified peritoneal implants in serous cystadenocarcinoma of ovary (in up to 40% with stage III / IV disease)

MR (85–90% sensitive for tumors < 1 cm):
√ maximal enhancement of peritoneal implants at 5–10 min

PET (controversial utility):
√ diffuse uptake spreading uniformly throughout abdomen and pelvis obscuring visceral outlines
√ discrete foci of uptake anteriorly within abdomen / dependently within pelvis

Cx: small bowel obstruction

PEUTZ-JEGHERS SYNDROME

[Johannes Peutz (1886–1957), internist in Den Haag, Holland]
[Harold Jeghers (1904–1990), internist in Boston, USA]
= rare syndrome characterized by intestinal polyposis and mucocutaneous pigmentation (= hamartomatosis)

Cause: mutation to serine / threonine kinase 11 (STK11) tumor suppressor gene on chromosome 19p13.3

Genetics: autosomal dominant with incomplete penetrance; often spontaneous mutations

Frequency: 1÷7,000 live births; in 50% familial, in 50% sporadic; most frequent of polyposis syndromes to involve small intestines

Age: at presentation 25 (range 10–30) years; M÷F = 1÷1

Path: multiple small sessile / large pedunculated polyps

Histo: benign hamartomatous (?) polyp with a <u>smooth muscle core</u> arising from muscularis mucosae and arborizing (treelike) extension into lamina propria of polyp (CHARACTERISTIC); misplaced epithelium (= pseudoinvasion) in submucosa, muscularis propria, sub-serosa frequently surrounding mucin-filled spaces

• mucocutaneous pigmentation (similar to freckles):
= 1–5-mm small elongated melanin spots on mucous membranes (lower lips, gums, palate) + facial skin (nose, cheeks, perioral, periorbital) + volar aspects of toes and fingers (100%),

noticeable in first few years of life
◊ NO potential to become malignant
• intermittent cramping abdominal pain ← small bowel intussusception (in 47%)
• rectal bleeding, melena (30%), acute blood loss, chronic hypochromic microcytic anemia ← ulcerated polyps
• prolapse of polyp through anus

Location: small bowel (jejunum + ileum > duodenum) > colon > stomach; mouth + esophagus spared

@ Small bowel (> 95%)
√ multiple usually broad-based polyps separated by wide areas of intervening flat mucosa
√ multilobulated surface of larger polyps
√ myriad of 1–2-mm nodules of up to several cm = carpet of polyps
√ intussusception usually confined to small bowel

@ Colon + rectum (30%)
√ multiple scattered 1–30-mm polyps; NO carpeting

@ Stomach + duodenum (25%)
√ diffuse involvement with multiple polypoid lesions:
√ small / large, sessile / pedunculated polyps

@ Extraintestinal sites: kidney, ureter, gallbladder, bronchial tree, nasal passages
√ adenoma of bronchus + urinary bladder

Cx:

◊ Approximately 60% lifetime incidence of malignancy!

(1) Gastrointestinal adenocarcinoma:
Frequency: 2–3%
Mean age: 40 years of age
Location: stomach, duodenum, colon; small bowel (least common)
(2) Carcinoma of pancreas (13%)
(3) Carcinoma of breast (50% risk by 60 years of age similar to BRCA1 / BRCA2): commonly bilateral + ductal
(4) Ovarian tumor (5%), commonly bilateral: sex cord-stromal tumor of ovary (almost in 100% of patients), mucinous cystic tumor, cystadenoma, granulosa cell tumor
(5) Testicular tumor: Sertoli cell tumor
(6) Endometrial cancer: adenoma malignum of cervix
(= minimal deviation adenocarcinoma = low-grade mucinous tumor of cervix)
(7) Transient intussusception (pedunculated polyp as lead point) → spontaneous reduction or SBO

Rx: (1) Endoscopic removal of all polyps > 5 mm
(2) Surgery is reserved for obstruction, severe bleeding, malignancy
(3) Surveillance screening: hemoglobin level; regular breast, gynecologic, testicular examinations; pelvic, testicular, pancreatic US; endoscopy of upper and lower GI tract; small bowel capsule endoscopy

Prognosis: decreased life expectancy (risk of cancer approaching 40% by 40 years of age)

DDx: familial adenomatous polyposis, juvenile polyposis (similar age), Cowden disease, Cronkhite-Canada syndrome

PNEUMATOSIS CYSTOIDES COLI

= cystic / linear gas collection in colonic wall
Location: submucosal / subserosal

Primary Pneumatosis Cystoides Coli

= benign condition
Location: favors left-sided colon
• simulates polyposis at colonoscopy → release of gas with cyst puncture
√ marked cluster of air-filled cysts in wall of colon

Secondary Pneumatosis

√ more linear gas collection

POSTCRICOID DEFECT

= variable defect seen commonly in the fully distended cervical esophagus; no pathologic value
Etiology: redundancy of mucosa over rich postcricoid submucosal venous plexus
Frequency: in 80% of normal adults
Location: anterior aspect of esophagus at level of cricoid cartilage
√ tumor- / weblike lesion with variable configuration during swallowing
DDx: subepithelial tumor, esophageal web (persistent configuration)

POSTINFLAMMATORY POLYPOSIS

= PSEUDOPOLYPOSIS
= reepithelialized inflammatory polyps as sequelae of mucosal ulceration
Etiology: ulcerative colitis (10–20%); granulomatous colitis (less frequent); schistosomiasis (endemic); amebic colitis (occasionally); toxic megacolon
Pathogenesis: ulcerative undermining of strips of mucosa with reepithelialization of denuded surfaces of tags + bowel wall
Location: most common in left hemicolon, may occur in stomach / small intestine
√ sessile + frondlike appearance (often)
√ filiform polyposis = multiple wormlike projections only attached at their bases (CHARACTERISTIC)
Prognosis: NO malignant potential
DDx: familial polyposis (polyps terminate in bulbous heads)

PRESBYESOPHAGUS

= defect in primary peristalsis + LES relaxation associated with aging
Frequency: 15% [50%] {85%} in 7th [8th] {9th} decade
Associated with: hiatus hernia, reflux
• usually asymptomatic
√ impaired / no primary peristalsis
√ often repetitive nonperistaltic tertiary contractions in distal esophagus
√ mild / moderate esophageal dilatation
√ poor LES relaxation

DDx: diabetes, diffuse esophageal spasm, scleroderma, esophagitis, achalasia, benign stricture, carcinoma

PROGRESSIVE SYSTEMIC SCLEROSIS

= PSS = chronic multisystem autoimmune disorder of connective tissues (collagen-vascular disease) characterized by a widespread pathophysiologic triad of

(1) Autoimmune disease-induced inflammation
(2) Microvascular damage
(3) Fibrosis (= overproduction of collagen → exuberant interstitial fibrosis with atrophy + sclerosis of many organ systems

= **SCLERODERMA** = variety of skin disorders associated with hardening of skin by extent of cutaneous involvement divided into 2 subgroups with different autoantibody profile + survival rate:

(a) DIFFUSE SCLERODERMA
- › skin changes proximal to elbow / knee
- › tendency to involve older women
- › interstitial pulmonary fibrosis more severe
- › organ failure more likely

(b) LIMITED SCLERODERMA (formerly **CREST syndrome**)
- › pulmonary arterial hypertension more common + more severe
- › CREST features more common
  - *CREST*: **C**alcinosis cutis
    Raynaud phenomenon
    Esophageal dysmotility
    Sclerodactyly
    Telangiectasia

May be associated with:
other connective tissue diseases (especially SLE and polymyositis / dermatomyositis)

Etiology: unknown; autoimmune condition with genetic predisposition, may be initiated by environmental antigen (eg, toxic oil syndrome in Spain ← ingestion of adulterated rapeseed oil / ingestion of L-tryptophan)

Incidence: 0.6–122.0÷1,000,000 people annually (higher rates in USA + Australia and among blacks)

Prevalence: 19–75÷100,000 people

Peak age: 45–64 years; M÷F = 1÷3 to 1÷8

Histo: vasculitis + submucosal fibrosis with deposition of collagen in longitudinal layer of muscularis propria + smooth muscle atrophy (initially hypertrophy and finally atrophy of collagen fibers)

- antinuclear antibodies (30–80%):
  - centromere antibody (ACA) specific for limited disease
  - anti–topoisomerase-1 (= antiScl-70) identifies patients with diffuse cutaneous disease
- antibodies to extracellular matrix proteins and type I + IV collagen; rheumatoid factor (35%), LE cells (5%)
- weakness, generalized debility

Increased risk: lung cancer, breast cancer

Stages:

(a) inflammatory phase (several weeks)
- erythema, pruritus, nonpitting edema
- fatigue, arthralgia, myalgia

(b) fibrotic phase (several months to years)
- inflexible skin, loss of function of affected limbs
- contractures, atrophy

Prognosis: 50–67% 5-year survival rate;
◊ Highest mortality among collagen vascular disease ← pulmonary arterial hypertension!

Cardiac Scleroderma

Histo: sclerosis of cardiac muscle (= myocardial fibrosis)
- arrhythmia

√ pericardial effusion (pericarditis)
√ congestive heart failure

Cx: cor pulmonale

Gastrointestinal Scleroderma (in 40–45%)

◊ 3rd most common manifestation of scleroderma (after skin changes + Raynaud phenomenon)
◊ May precede other manifestations!

Path: collagen deposition primarily in tunica muscularis → smooth muscle atrophy + fibrosis
- abdominal pain, diarrhea
- multiple episodes of pseudoobstruction

√ hepatomegaly

@ Esophagus (in 42–97%)
◊ First GI tract location to be involved!

Site: distal ²/₃ (striated muscle in upper ⅓)
- dysphagia (50%), heartburn (30%)

› functional:
√ hypotonia / atony + hypokinesia / aperistalsis in lower ²/₃ of esophagus (dysmotility in > 50%):
√ absent primary peristalsis of esophagus below level of aortic arch
√ chalasia (= patulous lower esophageal sphincter)
√ mild to moderate dilatation of esophagus
√ thin / vanished longitudinal folds
√ deficient esophageal emptying in recumbent position
√ gastroesophageal reflux (70%)
√ normal peristalsis above aortic arch ← striated muscle in proximal ⅓ of esophagus

› severe inflammation & scarring from reflux esophagitis ← poor clearance of peptic acid reflux:
√ erosions + superficial ulcers (= asymptomatic reflux esophagitis: NO protective esophageal contraction)

√ fusiform stricture usually 4–5 cm above GE junction
√ esophageal shortening + sliding hiatal hernia

Cx: peptic stricture, Barrett metaplasia, adenocarcinoma, aspiration pneumonia

@ Stomach (less frequent involvement)
√ gastric dilatation
√ decreased motor activity + delayed emptying

@ Small bowel (in up to 45%)
◊ PSS progresses rapidly once small intestine is involved!
• decreased small bowel motility with delayed intestinal transit time → stasis → bacterial overgrowth → diarrhea → malabsorption
√ pseudo-obstruction = marked dilatation of small bowel (in particular duodenum = megaduodenum, jejunum) simulating small bowel obstruction
CAVE: misdiagnosis of obstruction may lead to exploratory surgery!
√ abrupt cutoff at SMA level ← atrophy of neural cells with hypoperistalsis
√ prolonged transit time with barium retention in duodenum up to 24 hours
√ "hidebound / accordion" pattern (60%) = sharply defined folds of normal thickness with decreased intervalvular distance (valvular packing = tightly packed folds) within dilated segment ← predominant involvement of circular muscle:
√ normal mucosal fold pattern
√ pseudodiverticula (10–40%) = asymmetric sacculations with squared tops + broad bases on mesenteric side ← eccentric smooth muscle atrophy
√ pneumatosis cystoides intestinalis + pneumoperitoneum (occasionally)
√ excess fluid with bacterial overgrowth (= "pseudo–blind loop syndrome")

Cx: transient intussusception without anatomic lead point

@ Colon (up to 40–50%)
• constipation (common), may alternate with diarrhea
√ pseudosacculations + wide-mouthed "diverticula" on antimesenteric side → formed by repetitive bulging through atrophic areas in transverse + descending colon
√ eventually complete loss of haustrations (simulating cathartic colon)
√ marked dilatation (may simulate Hirschsprüng disease)
√ stercoral ulceration ← retained fecal material

Cx: life-threatening barium impaction

DDx: (1) Dermatomyositis (similar radiographic findings)
(2) Sprue (increased secretions, segmentation, fragmentation, dilatation most significant in midjejunum, normal motility)
(3) Obstruction (no esophageal changes, no pseudodiverticula)
(4) Idiopathic intestinal pseudoobstruction (usually in young people)

Localized Scleroderma

= MORPHEA [*morpheus*, Greek = form, structure]
= inflammatory disease that leads to diffuse / localized fibrotic atrophic skin hardening + may affect MSK system
• characterized by ABSENCE OF
• Raynaud phenomenon; digital sclerosis / necrosis

- nailfold capillary changes; involvement of internal organs
- arthralgia (9–17%)

May be associated with: musculoskeletal scleroderma

Musculoskeletal Scleroderma

- edema of distal portion of extremities
- thickened inelastic waxy skin most prominent about face + extremities, symmetrical polyarthralgias (50–80%)
- Raynaud phenomenon (may precede other symptoms by months / years)
- atrophy + thickening of skin and musculature (78%)

@ Fingers
- "sausage digit" = edema of digits associated with loss of transverse skin folds + lack of definition of subcutaneous fat

√ "tapered fingers" = sclerodactyly = atrophy + resorption of soft tissues of fingertips + soft-tissue calcifications

√ acroosteolysis (63–80%)
= "penciling" / "autoamputation" = resorption of distal phalanges of hand beginning at volar aspect of terminal tufts with proximal progression

@ Subcutaneous calcinosis (25–58%)

Location: extensor surface, areas with pressure / friction

√ calcinosis = punctate soft-tissue calcifications of fingertips, axilla, ischial tuberosity, forearm, elbow (over pressure area), lower leg, face

√ calcifications around tendons, bursae, within joints

@ Arthritis
- stiffness in small joints, occasionally in knee, shoulder, wrist; lack of motility → eventually contractures

√ arthritis of interphalangeal joints of hands (25%)

Location: 1st CMC, MCP, DIP, PIP

√ central / marginal erosions (50%):

√ resorption of palmar aspect of terminal phalanges (most frequent sign)

√ bony erosions of carpal bones (trapezium), distal radius + ulna, mandible, ribs, lateral aspect of clavicle, humerus, acromion, mandible, cervical spine

√ joint-space narrowing (late)

DDx: rheumatoid, psoriatic, erosive arthritis

√ soft-tissue swelling ± periarticular osteoporosis

√ NO significant osteoporosis

√ ± flexion contractures of fingers (from tendon sheath inflammation + fibrosis)

@ Ribs

√ erosion of superior aspect of ribs

@ Teeth

√ widening of periodontal membrane

Pulmonary Scleroderma (10–66%)

◊ Organ involvement with the most significant morbidity!

◊ Usually develops within first 3 years of disease

Path: almost 100% involvement in autopsy series
Histo: thickening of basement membrane of alveoli (= fibrosing alveolitis) + small arteries and veins; pattern of usual interstitial pneumonia (UIP) / nonspecific interstitial pneumonitis (NSIP)

- slightly productive, mostly dry cough, atypical chest pain
- exertional progressive dyspnea, fatigue, hematemesis
- pulmonary function abnormalities in the absence of frank roentgenographic changes (TYPICAL DISSOCIATION of clinical, functional, and radiologic evidence)

Location: peripherally, most prominent at both lung bases (where blood flow greatest)
CXR:
√ bibasilar pulmonary fibrosis:
Frequency: 20–65% on CXR, up to 90% on HRCT
√ fine / coarse reticulations / diffuse interstitial infiltrates
√ subpleural fibrocystic spaces (= honeycombing)
√ low lung volumes ← progressive volume loss
√ alveolar changes ← aspiration of refluxed gastric contents with disturbed esophageal motility / mineral oil taken to combat constipation:
√ aspiration pneumonia
√ bronchiolitis
√ dilated esophagus with air esophagram (DDx: achalasia, mediastinitis) with increased frequency of aspiration pneumonia
√ pleural reaction / effusion distinctly uncommon
HRCT:
Pattern: Nonspecific interstitial pneumonia > UIP
√ areas of patchy ground-glass attenuation
√ poorly defined subpleural centrilobular nodules
√ reticular pattern of attenuation
√ traction bronchiectasis + bronchiolectasis; mucous plugs
√ honeycombing
Rx: cyclophosphamide + low-dose prednisolone
Prognosis: ground-glass opacities irreversible even after therapy ← fibrosis NOT inflammation

Cx: (1) Progressive pulmonary fibrosis
(2) Pulmonary arterial hypertension (10–16–33%)
(3) Aspiration pneumonia
(4) Increased incidence of lung cancer

Renal Scleroderma (25%)
Onset: common within 3 years
Histo: fibrinoid necrosis of afferent arterioles (also seen in malignant hypertension)

- hypertensive renal crisis

√ renal cortical necrosis
√ spotty inhomogeneous nephrogram ← constriction + occlusion of arteries

√ concomitant arterial ectasia
Cx: renal failure (from nephrosclerosis)

PROLAPSED ANTRAL MUCOSA

= prolapse of hypertrophic + inflammatory mucosa of gastric antrum into duodenum resulting in pyloric obstruction
√ mushroom- / umbrella- / cauliflower-shaped filling defect at duodenal base
√ filling defect varies in size + shape
√ redundant gastric rugae can be traced from pyloric antrum through pyloric channel
√ gastric hyperperistalsis

PSEUDOMYXOMA PERITONEI

= "jelly belly" = "gelatinous ascites"
= slow insidious accumulation of large amounts of thick mucinous or gelatinous material on peritoneal surfaces
Incidence: 1÷1,000,000 annually
Mean age: 49 (range, 23–83) years; M< F
Etiology:

A. DISSEMINATED PERITONEAL ADENOMUCINOSIS (majority)
Origin: appendix
= benign / borderline / low-grade malignant epithelial cells from ruptured mucocele of the appendix without invasion of stroma
Rx: amenable to surgical debulking
Prognosis: 50% 5-year survival

B. OVARIAN PSEUDOMYXOMA PERITONEI
Origin: ovary
= mucinous tumor, cystadenoma, tumor with low malignant potential, invasive carcinoma that arises in ovarian mature cystic teratoma

C. PERITONEAL MUCINOUS CARCINOMATOSIS (rare)
= invasive high-grade moderately / poorly differentiated mucinous carcinoma
Origin: carcinoma of GI tract (colon < 5%, stomach, appendix), gallbladder, pancreas, uterus, common bile duct, urachal duct, omphalomesenteric duct
Prognosis: 10% 5-year survival

In most cases of pseudomyxoma peritonei the source is an appendiceal mucinous tumor!

• slowly progressive massive abdominal distension
• recurrent abdominal pain, weight loss
√ thickening of peritoneal + omental surfaces
√ omental cake
√ posterior fixation of bowel loops + mesentery
√ voluminous septated / loculated pseudoascites
√ several thin-walled cystic masses of different size throughout abdominal cavity:
√ **Hellmer sign** = focal collection of mucin in right subhepatic space displacing tip of liver medially
√ central displacement of ascending + descending colon and lateral displacement of

properitoneal fat stripe with mucin in paracolic gutter
√ central displacement of intestine
√ scalloped contour of liver + spleen
√ annular / semicircular calcifications (rare but highly suggestive)
CT:
√ intraperitoneal collection of very low attenuation (common) / soft-tissue density (rare)
√ may contain enhancing septa ± calcifications
√ discrete hypoattenuating masses (infrequent)
US:
√ hypoechoic collection (common) / more solid appearance (rare)
√ nonmobile echoes from proteinaceous / bloody / fibrinous exudate
√ echogenic septations
Prognosis: 25–65% median 5-year survival rate
Cx: bowel obstruction
Rx: often requires repeated laparotomies for drainage; need for multiple surgical debulkings
DDx: ascites, peritoneal metastases, pancreatitis with pseudocysts, pyogenic peritonitis, widespread echinococcal disease

RADIATION INJURY

= obliterative endarteritis with irradiation in excess of 4,000–4,500 rad
Frequency: 5%; increased risk after pelvic surgery
Radiosensitivity: small bowel mucosa (most sensitive) > rectum
√ radiographic changes within field of radiation only

Radiation Esophagitis

= from high doses of mediastinal radiation (usually > 5,000 cGy); Adriamycin® can potentiate effects of radiation as low as 500 cGy
• progressive dysphagia 4–8 months after completion of radiation therapy
√ smooth relatively long segment of concentric tapered narrowing within a preexisting radiation portal
DDx: involvement by recurrent tumor

Radiation Gastritis

◊ Permanent radiographic findings of radiation injury appear 1 month to 2 years after therapy
√ gastric ulceration + deformity (pylorus)
√ enlargement + effacement of gastric folds
√ antral narrowing + rigidity (similar to linitis plastica)

Radiation Enteritis

◊ Permanent radiographic findings of radiation injury appear > 1–2 years following irradiation
Predisposed: women (cancer of cervix, endometrium, ovary), patients with bladder cancer
• crampy abdominal pain (from intermittent obstruction)
• persistent diarrhea, occult intestinal hemorrhage
Location: ileum; concomitant radiation damage to colon / rectum

@ ACUTE radiation enteropathy
√ mucosal hyperenhancement
√ irregular nodular thickening of folds with straight transverse course ± ulcerations
√ separation of adjacent bowel loops by > 2 mm
@ CHRONIC radiation enteropathy (after months to years)
√ thickened bowel wall with luminal narrowing
√ multiple strictures + partial mechanical obstruction
√ serrated bowel margin
√ shortening of small bowel
√ fixation + immobilization of bowel loops with similar radiographic appearance between examinations ← dense desmoplastic response to irradiation

CT:
√ increased attenuation of mesentery

DDx: Crohn disease, lymphoma, ischemia, hemorrhage

Radiation Injury of Rectum

◊ Manifestation of radiation colitis can occur up to 15 years following irradiation

Predisposed: 90% in women (with carcinoma of cervix)

• tenesmus, diarrhea, bleeding, constipation

√ ridgelike appearance of mucosa ← submucosal fibrosis

√ irregularly outlined ulcerations (rare)

CT:
√ narrowed partially distensible rectum
√ thick homogeneous rectal wall
√ "target" sign = submucosal circumferential lucency
√ proliferation of perirectal fat > 10 mm
√ thickening of perirectal fascia
√ "halo" sign = increase in pararectal fibrosis

Cx: (1) Obstruction
(2) Colovaginal / coloenteric fistula formation

RECTAL POLYP

Prevalence: 7–50% (more common in older patients)

Path: hyperplastic÷adenomatous polyps = 1÷4

√ tends to flatten out with air distention

Hyperplastic Rectal Polyp

Size: usually < 5 mm

√ not visible adjacent to rectal balloon

Adenomatous Rectal Polyp

√ sessile > pedunculated > flat

√ carpetlike nodular appearance (for villous adenoma)

√ underdistended / redundant rectal mucosa may simulate villous adenoma

RETAINED GASTRIC ANTRUM

Cause: retention of endocrinologically active gastric antrum in continuity with pylorus + duodenum

Pathophysiology: bathing of antrum in alkaline duodenal juice → stimulates secretion of gastrin

Associated with: gastric ulcers in 30–50%

√ duodenogastric reflux of barium through pylorus (DIAGNOSTIC)

√ giant marginal ulcer / several marginal ulcers usually on jejunal side of anastomosis (large false-negative + false-positive rates; correct-positive rate of 28–60%)

√ large amount of secretions

√ edematous mucosa of jejunal anastomotic segment

√ lacy / cobweblike small bowel pattern (hypersecretion)

Cx: gastrojejunocolic fistula

SCHATZKI RING

= LOWER ESOPHAGEAL MUCOSAL RING

[Richard Schatzki (1901–1992), chief of radiology at University Hospital in Leipzig and associate clinical professor of radiology at Harvard Medical School and at Mount Auburn Hospital, Cambridge, MA]

= constant lower esophageal ring (mucosal thickening) presumed to result from reflux esophagitis = thin annular peptic stricture

Frequency: 6–14% of population; old age > young age; M > F

Histo: usually squamous epithelium on upper surface + columnar epithelium on undersurface; may be covered totally by squamous epithelium or columnar epithelium

Associated with: hiatal hernia (typical)

• asymptomatic (if ring > 20 mm), dysphagia (if ring < 12 mm)

Location: near the squamocolumnar junction; in region of B ring at inferior margin of lower esophageal sphincter

Height: 1–3 mm

√ nondistensible concentric transverse ring of shelflike projection with smooth symmetric margins

√ constant shape + size

√ visible only with adequate distension of esophagogastric region and when located above the esophageal hiatus of diaphragm

√ best demonstrated in prone position during arrested deep inspiration with Valsalva maneuver while solid barium column passes through esophagogastric region

√ short esophagus + intrahiatal / intrathoracic gastric segment = sliding hiatal hernia if Schatzki ring located 1–2 cm above diaphragmatic hiatus

Prognosis: decrease in caliber over 5 years (in 25–33%)

Cx: impaction of food bolus (associated with severe chest pain)

Rx: (1) Proper mastication of food

(2) Endoscopic rupture

(3) Esophageal dilatation (radiographically often lack of caliber change after successful dilatation)

DDx: Annular peptic stricture (usually thicker, asymmetric, irregular surface, associated with thickened esophageal folds, serration of esophageal margins)

SCHWANNOMA OF GI TRACT

= rare benign nerve sheath tumor arising from Schwann cell

Frequency: 0.2% (4%) of all (benign) gastric tumor; 2–7% of gastrointestinal mesenchymal tumors

Origin: myenteric plexus within muscularis propria of GI tract

Histo: well-circumscribed unencapsulated tumor characterized by interlacing bundles of spindle cells with wavy cigar-shaped nuclei + collagen; peripheral cuff of peritumoral lymphoid aggregates; areas of hypo- and hypercellularity (Antoni A & B) and Verocay bodies (= lining up of nuclei) are less frequent

Immunohisto: strong + diffuse stain for S-100 protein

Age: 3rd–5th decade; M<F

Location: stomach (60–70%) > colon > rectum

Site: submucosa + muscularis propria

• usually incidental endoscopic finding

• GI bleeding, abdominal pain, obstructive symptoms

√ discrete submucosal mass with exophytic / intramural growth

NECT:

√ low attenuation ← dense spindle cell composition

√ homogeneous attenuation in spite of relatively large size (!)

√ uncommonly calcified

CECT:

√ no / minimal enhancement during arterial phase

√ delayed enhancement during equilibrium phase

Cx: (1) Ulceration ← pressure necrosis of overlying mucosa

(2) Central necrosis ← outgrowing its blood supply

DDx: GIST, leiomyoma, lymphoma

Absence of hemorrhage / necrosis / cavity formation helps distinguish schwannomas from more heterogeneous GIST

SCLEROSING MESENTERITIS

= CHRONIC FIBROSING MESENTERITIS = MULTIFOCAL SUBPERITONEAL SCLEROSIS = SCLEROSING LIPOGRANULO-MATOSIS = PRIMARY LIPOSCLEROSIS OF THE MESENTERY = LIPOSCLEROTIC MESENTERITIS = LIPOGRANULOMA OF THE MESENTERY = ISOLATED LIPODYSTROPHY = SYSTEMIC NODULAR PANNICULITIS= RETROPERITONEAL XANTHOGRANULOMA = MESENTERIC WEBER-CHRISTIAN DISEASE

= rare idiopathic disorder characterized by tumorlike masses in mesentery composed of chronic nonspecific inflammation, fat necrosis, and fibrosis

Etiology: ? trauma, previous surgery, ischemia

Path: solitary / multifocal well-demarcated / diffusely infiltrating (mesenteric thickening) process

Histo: chronic mesenteric inflammation with lipid-laden macrophages (= lipophages) + plasma cells + eosinophils, fat necrosis and fibrosis
◊ NO penetration of muscularis propria!

Stages: based on predominant histopathologic finding in affected mesentery
(1) Mesenteric lipodystrophy
(2) Mesenteric panniculitis
(3) Retractile mesenteritis

Average age: 60 (range, 7–87 years); M÷F = 2÷1
Associated with:
(1) Gardner syndrome, familial polyposis
(2) Fibrosing mediastinitis, retroperitoneal fibrosis
(3) Lymphoma, lymphosarcoma (in 15–69%)
(4) Carcinoid tumor
(5) Metastatic gastric / colonic carcinoma
(6) Whipple lipodystrophy
(7) Weber-Christian disease

- asymptomatic / abdominal pain, palpable abdominal mass
- symptoms of intestinal obstruction / ischemia
- nausea, vomiting, weight loss, pyrexia, diarrhea
- ↑ WBC, ↑ erythrocyte sedimentation rate

Location: root of small bowel mesentery, colonic mesocolon
Site: extending toward mesenteric border; affecting submucosal fat; sparing mucosa
Pathophysiology: inflammatory infiltrate → obstruction of mesenteric lymphatics + mesenteric vessels → submucosal edema + luminal narrowing
Site: small bowel mesentery; occasionally mesocolon, sigmoid mesentery, omentum, retroperitoneum

Plain film:
√ soft-tissue mass with calcifications
√ ± thumbprinting ← vascular congestion
√ SBO: intestinal dilatation, fluid levels, fluid-filled bowel

UGI / Enteroclysis:
√ compression / distortion of duodenum near ligament of Treitz
√ separation of small bowel loops with fixation + kinking + angulation ← shortening + retraction of mesentery
√ irregular fold thickening of small bowel ← reactive mural thickening
√ narrowing + thumbprinting of colon (occasionally)

CT:
√ well-demarcated / ill-defined mesenteric mass:
√ heterogeneous texture of fat density:
√ misty attenuation interspersed with
√ soft-tissue density (= fibrous tissue)
√ single mesenteric root mass (= fibroma)
√ multiple nodules throughout mesentery (= fibromatosis)
√ multiple cystic masses in mesentery (= loose myxomatous composition / lymphatic

cysts):
√ tumoral pseudocapsule = peripheral band of soft-tissue attenuation at the edge of affected mesentery
√ ± small < 5 mm lymph nodes within lesion
√ "fat ring" sign = preservation of fat as a halo of low attenuation surrounding nondisplaced mesenteric vessels
√ punctate / coarse calcifications (uncommon)
√ mesenteric thickening with fine stellate pattern (= radiating strands of fibrosis) extending to bowel border
√ retraction of small bowel loops (= desmoplastic response)
√ rarely associated with retroperitoneal lymphadenopathy

US:
√ heterogeneous mass with hypo- and hyperechoic features

MR:
√ low to intermediate SI on T1WI + very low signal on T2WI
√ high SI on T2WI (= predominant myxomatous change)

Dx: surgical / percutaneous biopsy; diagnosis supported by absence of pancreatitis / inflammatory bowel disease

Prognosis: usually benign self-limited course with complete spontaneous resolution

Cx: compression of mesenteric vessels + formation of collateral vessels ± small bowel ischemia; partial / complete obstruction of small intestines

Rx: steroids + chemotherapy (cyclophosphamide, azathioprine); surgical resection for obstruction

DDx:
(1) Mesenteric fibromatosis = abdominal desmoid (infiltrating melting insinuation into muscularis propria)
(2) Mesenteric lymphoma (no calcifications unless treated, no compressive narrowing of vessels, no "fat-ring" sign, no pseudocapsule); lymphosarcoma
(3) Lipogenic liposarcoma of mesentery
(4) Inflammatory pseudotumor
(5) Mesenteric carcinoid (uptake with octreotide and somatostatin scintigraphy, elevated levels of serum serotonin + urine 5-hydroxyindoleacetic acid, carcinoid syndrome with liver metastases, mural thickening / small bowel masses)
(6) Carcinomatosis; pseudomyxoma peritonei ← metastatic gastric / colonic adenocarcinoma
(7) Crohn disease with fibrofatty proliferation
(8) Pyogenic peritonitis
(9) Whipple disease (polymerase chain reaction to verify causative bacillus, easily curable with antibiotics)

Mesenteric Lipodystrophy (1st stage)

= degeneration and <u>necrosis of mesenteric fat</u>

Path: diffuse mesenteric thickening (42%); solitary (32%) / multiple (26%) discrete mesenteric masses

Histo: sheets of foamy macrophages with scattered lymphocytic infiltration replacing

mesenteric fat
• asymptomatic
√ ± chylous ascites
Prognosis: spontaneous recovery

Mesenteric Panniculitis (2nd stage)
= predominantly chronic inflammatory stage of mesenteritis
Path: diffuse mesenteric thickening with puckering of mesenteric surface ← desmoplastic reaction; adherent mass(es) in root of mesentery; fat necrosis
Histo: infiltrate of plasma cells, foreign body giant cells, foamy macrophages
• crampy abdominal pain; bowel disturbances; low-grade fever
• nausea + vomiting; malaise; mild weight loss
• poorly defined mass (50%) / abdominal fullness
√ "misty mesentery" = mesenteric fat stranding

Retractile Mesenteritis (3rd stage)
= predominantly fibrotic stage of mesenteritis
Histo: collagen deposition, fibrosis, inflammation; calcifications ← fat necrosis
√ narrowing of bowel loop with spiculations → intestinal obstruction
DDx: may be indistinguishable from neoplasia

SCLEROSING PERITONITIS

= ENCAPSULATING PERITONEAL SCLEROSIS = PERITONITIS CHRONICA FIBROSA INCAPSULATA = PERITONEAL FIBROSING SYNDROME
= bowel partially / totally encased / wrapped in thick fibrous membrane forming several compartments that contain loops of small bowel
Cause: ?; idiopathic, chronic irritation of peritoneum
Associated with:
continuous ambulatory peritoneal dialysis (0.7% increasing to 19.4% after 8 years); ventriculoperitoneal shunt; peritoneo-venous shunt; tuberculosis; sarcoidosis; SLE; familial Mediterranean fever; protein S deficiency; liver transplantation; fibrogenic foreign material; GI malignancy; luteinized ovarian thecoma; β-blocker practolol
• recurrent episodes of small bowel obstruction
• weight loss, nausea, anorexia
√ smooth thickening + enhancement of peritoneum
√ "abdominal cocoon" = encasement of small bowel loops by a fibrocollagenous capsule:
√ central clustering of fixated small bowel loops
√ mantle of soft-tissue attenuation
√ peritoneal calcifications of parietal and visceral peritoneum
√ mural fibrosis + thickening of small bowel along its antimesenteric wall → adhesions → narrowing of bowel lumen → small bowel obstruction
√ formation of loculated fluid collections
Cx: small bowel necrosis + perforation
DDx: tuberculosis, amyloidosis, hyperparathyroidism, pseudomyxoma peritonei, peritoneal carcinomatosis, meconium peritonitis

SMALL BOWEL VOLVULUS

= rare life-threatening SURGICAL EMERGENCY

Cause: adhesive bands, internal hernia, external hernia

Pathophysiology:

closed-loop obstruction → bacterial overgrowth → accelerated fluid sequestration + gas production → increased intraluminal pressure + dilatation → compromise of vascular supply to intestinal wall → hemorrhagic infarction → necrosis → perforation

√ poor / absent enhancement of bowel wall

√ "spoke wheel" sign = radial peripheral distribution of distended fluid-filled small-bowel loops around central engorged thickened mesenteric vessels (75%)

√ two collapsed adjacent bowel loops = site of constriction (35%)

√ U-shaped configuration of distended fluid-filled small-bowel loops = radial arrangement of incarcerated fluid-filled dilated loop at periphery of tightly twisted mesentery (30%)

√ "triangular" sign = fusiform tapering of collapsed loop at site of constriction on longitudinal section through loop (15%)

√ "whirl" sign = swirling appearance of twisted mesentery (10%)

Cx: (1) Bowel ischemia in 46% due to closed-loop obstruction + torsion of mesenteric vessels

(2) Bowel necrosis

Mortality: 9%

SMALL LEFT COLON SYNDROME

Cause: transient functional colonic obstruction ← immaturity of mesenteric plexus

Age: newborn infant

Associated with: maternal diabetes mellitus (most common), maternal substance abuse; NOT related to cystic fibrosis

√ colonic caliber becomes abruptly diminutive distal to splenic flexure

√ bowel dilatation proximal to splenic flexure

√ ± meconium plug (as a result and NOT the cause of obstruction)

Prognosis: gradual resolution of functional immaturity over days to weeks

SOLITARY RECTAL ULCER SYNDROME

= MUCOSAL PROLAPSE SYNDROME

= rare condition frequently associated with chronic constipation and pelvic floor dyssynergia

Related disorders with common pathogenesis:

hamartomatous inverted polyp, colitis cystica profunda

Cause: prolapse of anterior rectal wall resulting in mucosal ischemia ← traumatization of rectal mucosa by anal sphincter during defecation (rectal straining / prolapse)

Age: young patients (especially women)

Path: small / large, single / multiple shallow ulcers; 25% broad- based, 18% patchy granular / velvety hyperemic mucosa; rectal stenosis through confluent circumferential lesion

Histo: obliteration of lamina propria mucosae by fibromuscular proliferation of muscularis mucosae, streaming of fibroblasts + muscle fibers between crypts, misplaced mucosal glands deep to muscularis mucosae; diffuse increase in mucosal collagen

- chronic rectal bleeding, passage of mucus
- disordered painful defecation, tenesmus

BE:
- √ central ulceration on anterior rectal wall → regional inflammation → mass effect in surrounding tissue mimicking rectal neoplasm at endoscopy:
  - √ polypoid lesion / nodules (polypoid type)
  - √ flat granular mucosa (flat type)
- √ thickened valves of Houston without ulcer
- √ stricture

Evacuation proctography:
- √ failure of anorectal angle to open while straining
- √ excessive perineal descent

Prognosis:
(1) Little change over time
(2) Considerable change in appearance of lesion
(3) Transfusions necessitated by massive blood loss

Dx: rectal biopsy

DDx: invasive rectal carcinoma, Crohn disease

SPRUE

= classic disease of malabsorption

Path: villous atrophy (truncation) + crypt hyperplasia (elongation of **crypts of Lieberkühn** responsible for water + electrolyte absorption + mucin production) + marked mononuclear round cell infiltration of lamina propria and epithelium (plasma cells, mast cells, lymphocytes, eosinophils)

[Johann Nathanael Lieberkühn (1711–1756), physician inventor of microscopic examination of intestine at Leiden University]

Pathophysiology: loss of villi → decreased absorption of fluid + crypt hyperplasia → production of fluid → chronic excess fluid in small bowel lumen

Location: patchy involvement of duodenum + jejunum > ileum > cecum (decreasing severity toward the distal small intestine)

UGI:
- √ nodularity in fold-free duodenum (= duodenitis)
- √ "bubbly bulb" = peptic duodenitis = mucosal inflammation, gastric metaplasia, Brunner gland hyperplasia

Small bowel follow-through:
- √ small bowel **dilatation** is HALLMARK in untreated celiac disease (70–95%), best seen in mid + distal jejunum ← intestinal hypomotility; degree of dilatation related to severity of disease
- √ hypersecretion-related artifacts:
  - √ air-fluid levels in small bowel (rare)
  - √ **segmentation** = breakup of normal continual barium column creating large masses of barium in dilated segments separated by stringlike strands from adjacent clumps ← excessive fluid; best seen on delayed films

- √ **flocculation** = coarse granular appearance of small clumps of disintegrated barium ← excess fluid best seen at periphery of intestinal segment; occurs especially with steatorrhea
- √ **fragmentation** = scattering = faint irregular stippling of residual barium resembling snowflakes associated with segmentation ← excessive fluid

√ **"moulage" sign** (50%) = smooth contour with effaced featureless folds resembling tubular wax mold ← atrophy of the folds of Kerckring; CHARACTERISTIC of sprue if seen in duodenum + jejunum

√ slow / normal / short transit time:

- √ nonpropulsive asynchronous peristalsis (flaccid + poorly contracting loops)

√ normal / thickened / effaced mucosal folds (depending on degree of hypoproteinemia)

√ colonlike haustrations in well-filled jejunum ← spasm + cicatrization from transverse ulcers

√ transient nonobstructive small bowel intussusception (20%) without anatomic lead point

Enteroclysis:

√ **flip-flop pattern** = "reversal" sign = reversed jejunoileal fold pattern with featureless jejunum ← villous atrophy + compensatory hypertrophy of folds in ileum:

- √ decreased number of folds in proximal jejunum (< 3 folds per inch) ← loss of mucosal surface area
- √ "jejunization" of ileal loops = increased number of folds in distal ileum (> 5 folds per inch) as adaptive response to increased absorptive capability = SPECIFIC

√ tubular featureless lumen

√ mosaic pattern = 1–2-mm polygonal islands of mucosa surrounded by barium-filled distinct grooves (10%)

CT:

CT patterns of celiac disease are small bowel and colonic malabsorption patterns and prominent mesenteric lymph nodes of the small bowel.

@ Small bowel malabsorption pattern:

- √ small bowel dilatation + increased fluid content:
  - √ progressive dilution of enteric contrast material
  - √ flocculation (= precipitating small flecks of barium)
  - √ laminar flow = trilaminar appearance of intraluminal barium separated by a middle layer of low attenuation formed by intrinsic intestinal fluid mimicking intussusception
- √ flaccid dilated small bowel:
  - √ nonobstructing telescoping of small bowel loops
  - √ transient small bowel intussusception (in up to 20%)

@ Colonic malabsorption pattern:

- √ colonic distension (= stagnant hypotonic colon):
  - √ excessive colonic gas accumulation ← undigested sugar + fat are processed by gas-producing bacteria
  - √ fluid-filled colon ← reduction of absorptive capacity
- √ cecal plume (= feathering) of fluid
- √ steatorrhea = stool of fat attenuation (lung windows!)

√ colonic geodes = round spheres of hard rocklike aggregations of fat + fluid + air, which may calcify peripherally with stasis ← fat saponification

@ Mesenteric lymph node prominence

√ mild to moderate mesenteric lymphadenopathy ← follicular hyperplasia ← proliferation of reactive B and T lymphocytes (mimicking lymphoma):

Location: predominantly upper small bowel mesentery

DDx: Crohn disease + mesenteric adenitis (node prominence usually near terminal ileum)

√ lymph nodes of low attenuation (in up to 12%)

√ cavitating lymph nodes (see below)

@ Structural intestinal changes

√ small bowel wall thickening ← inflammation:

√ straightening of valvulae conniventes

√ fold separation

√ reversal of jejunoileal fold pattern (COR reformats!):

√ jejunal villous atrophy

√ ileal jejunization (63% sensitive, 100% specific)

N.B.: > 5 folds per inch in jejunum + < 3 folds per inch in ileum excludes celiac disease

√ colonic fold thickness > 4 mm ← inflammation

√ mesenteric hyperemia = engorgement of mesenteric vessels (during severe active inflammation)

√ mesenteric panniculitis / misty mesentery

√ intramural fat ← sign of chronic inflammation

Location: duodenum + jejunum > right colon

@ Structural extraintestinal changes

√ ascites

√ small atrophic spleen = hyposplenism (30–50%)

√ adenopathy (see above)

√ celiac-associated T-cell lymphoma

US:

√ moderately dilated fluid-filled small intestine

√ thickening of small bowel wall

√ hyperperistalsis (82%)

√ dilated superior mesenteric artery + portal vein

√ liver steatosis ← metabolic derangement from malabsorption

√ mesenteric + retroperitoneal lymphadenopathy (12%)

√ slight ascites (76%)

Dx: (1) Clinical presentation

(2) Jejunal / duodenal biopsy with typical histopathologic features

(3) Improvement of clinical symptoms + intestinal function within 2 weeks of a gluten-free diet (70%)

(4) Improvement of small bowel histology after > 3–6 months of a gluten-free diet

Cause for relapse: hidden dietary gluten, diabetes, bacterial overgrowth, intestinal ulceration,

development of lymphoma

Imaging is important in detecting various complications of celiac disease like lymphoma, ulcerative jejunoileitis, cavitary mesenteric lymph node syndrome, adenocarcinoma of small bowel, SCC of esophagus and pharynx.

Cx:

(1) **Malignant tumors** (in up to 14%)

• recurrent diarrhea / abdominal pain in previously asymptomatic patients under gluten-free diet

◊ Malignant tumors are the most common cause of death

(a) NHL (18% of cancers in celiac disease):

◊ 8% of patients with sprue develop lymphoma

◊ history of celiac disease for > 20 years

Type: enteropathy-associated T-cell lymphoma (85–90%) + extraintestinal lymphoma (mostly Hodgkin disease)

Peak prevalence: 7th decade

Location: terminal ileum (most common)

√ luminal narrowing with mucosal destruction (= ulcer with shouldering of margins)

√ irregularly thickened nodular folds

√ exophytic mass

√ focal aneurysmal bowel dilatation

√ florid lymphadenopathy

(b) adenocarcinoma of small bowel (7%), rectum, stomach

(c) squamous cell carcinoma of esophagus (in 4%) during 6th–7th decade

(d) esophageal cancer

(e) melanoma

(f) other malignancies of oropharynx, ovaries, testicles, thyroid, breast, lungs

(2) **Ulcerative jejunoileitis** (rare)

= multiple chronic benign ulcers

Age: 5th–6th decade

Location: jejunum > ileum > colon

• response to gluten-free diet

√ sausage appearance of small bowel ← circumferential bowel wall thickening

√ fold thickening + ulceration → stricture formation → intestinal obstruction

Cx: hemorrhage, perforation, lymphoma

Prognosis: frequently fatal

Rx: small bowel resection

DDx: enteropathy-associated T-cell lymphoma (may coexist, impossible to differentiate)

(3) **Cavitating mesenteric lymph node syndrome** (rare)

Path: multiple pseudocystic lymph nodes containing chylous fluid (thin milky fluid / thick creamy material) + thin peripheral rim of fibrous material and scant elements of atrophic lymph node structures

• refractory weight loss, fatigue, diarrhea

• target cells + Howell-Jolly bodies in peripheral blood smear (= signs of hyposplenism)

Location: confined to jejunoileal mesentery

√ multiple 2–7-cm large lymph nodes with a central cavity of low attenuation ± fat-fluid levels
√ splenic atrophy
√ villous atrophy of small intestinal mucosa
Prognosis: usually fatal

(4) Sigmoid volvulus (rare)
(5) **CEC syndrome** (in late stage of disease)
= **C**eliac disease + **E**pilepsy + **C**erebral calcification
Countries: Italy, Spain, Argentina
• intractable epilepsy
√ cerebral occipital calcifications identical to Sturge-Weber syndrome (without portwine nevus)

DDx:
(1) Esophageal hypoperistalsis: scleroderma, idiopathic pseudoobstruction
(2) Gastric abnormalities: Zollinger-Ellison syndrome, chronic granulomatous disease, eosinophilic enteritis, amyloidosis, malignancy
(3) Tiny nodular defects on thickened folds: Whipple disease, intestinal lymphangiectasia, Waldenström macroglobulinemia
(4) Small 1–3-mm nodules: lymphoid hyperplasia associated with giardiasis and immunoglobulin deficiency disease, diffuse lymphoma
(5) Small nodules of varying sizes: systemic mastocytosis, amyloidosis, eosinophilic enteritis, Cronkhite-Canada syndrome
(6) Bowel wall narrowing, kinking, scarring, ulceration: regional enteritis, bacterial / parasitic infection, carcinoid, vasculitis, ischemia, irradiation

Celiac Disease

= CELIAC SPRUE = NONTROPICAL SPRUE = GLUTEN-SENSITIVE ENTEROPATHY
[*coeliac* , Greek = abdominal]
= common chronic inflammatory intestinal autoimmune disorder of multifactorial etiology induced in genetically susceptible individuals
Countries: North America, Europe, Australia, India, Pakistan, Middle East, Cuba
Incidence: 1÷100 to 1÷500; 1–3% of general population in Europe and USA; 1÷200 Americans with 60,000 new cases annually; < 10% actually diagnosed with bioptic proof in 2–13÷100,000 adults annually
Age: childhood by age 2 years; 30–40 [40–60] years with M < F [M > F]
Cause: multifactorial; excessive T-cell–mediated immunity to ingested dietary gluten
Irritating agent: gliadin polypeptides in wheat, rye, barley, oats, other grains
Genetics: HLA-DR3-DQ2 heterodimer haplotype (encoded by DQA1 + DQB1 alleles), HLA-DR4-DQ8 haplotype confers an ↑ risk; detected in 15% of 1st-degree relatives (concordance rate of 76% for monozygotic twins + 11% for dizygotic twins)
Associated with: type 1 diabetes (juvenile diabetes), autoimmune thyroid disease, Addison disease, Sjögren syndrome, SLE
Pathophysiology:
anti-tissue transglutaminase antibodies destroy villous extracellular matrix + epithelial

cells → progressive villus inflammation → nodular + thickened duodenal and jejunal folds; villous truncation + crypt hyperplasia → chronic fluid excess in small bowel lumen → stretching of small bowel → delayed transit

- asymptomatic (silent, latent, atypical, subclinical): < 10% of cases are properly diagnosed with an average delay of 20–60 years from onset of symptoms
- intestinal symptoms:
  - severe chronic diarrhea (< 20%) / constipation (15%)
  - failure to thrive, lassitude, fatigue, vomiting
  - weight loss (5%), overweight (39%), obese (13%)
  - crampy abdominal pain (← intussusception), distension
  - flatulence, steatorrhea (CLASSIC but found only in minority of patients)
- extraintestinal symptoms:
  - dermatitis herpetiformis (= pruritic bullous skin rash), aphthous stomatitis, alopecia
  - anemia from iron / folate / vitamin B12 deficiency
  - hepatitis, hypertransaminasemia (elevated alkaline phosphatase + liver enzymes), cholangitis
  - coagulopathy, guaiac-positive stools from bleeding diathesis, prolonged prothrombin time
  - peripheral neuropathy, depression, cerebellar ataxia, dementia, seizures
  - short stature, pubertal delay, infertility
  - idiopathic osteopenia with bone pain; arthralgia
  - dental enamel defects (10–40%)
  - low serum levels of cholesterol, calcium, albumin
- Serologic testing for antibodies to gliadin + endomysium in screening + monitoring compliance
  - anti-tissue transglutaminase IgA antibodies (*DDx:* juvenile diabetes, inflammatory bowel disease, arthritides)
  - antiendomysial antibodies

Small bowel follow-through: mostly replaced by endoscopy, antibody testing, CT enteroclysis!

> √ features of malabsorption pattern in celiac disease include duodenitis, dilution, dilatation, slow transit, flocculation, moulage, reversal of jejunal-ileal fold pattern, and transient small bowel intussusception.

With delay in diagnosis for > 10 years at risk for:
iron deficiency anemia, lactose intolerance, osteoporosis with increase in fracture risk, miscarriage, low birth weight, lymphoma, seizures, depression

Dx: IgA autoantibodies for tissue transglutaminase, antiendomysial antibodies, HLA-DQB1 typing

Rx: gluten-free diet: corn, rice, tapioca, soya, millet, vitamin supplements

Tropical Sprue

Etiology: infectious agent cured with antibiotics; geographic distribution (India, Far East, Puerto Rico)

Age: any age group

- glossitis, hepatosplenomegaly

- macrocytic anemia + leukopenia

Prognosis: spontaneous resolution after months / years

Rx: responds well to folic acid + broad-spectrum antibiotics

STRONGYLOIDIASIS

[*strongylos* , Greek = round; *eidos* , Greek = form]

Organism: helminthic parasite Strongyloides stercoralis (2.2 mm long, 50 μm in diameter); capable of reproducing within (primary) human host [*stercus* , Latin = excrement]

Prevalence: 30–35 million cases globally; 0.4–4% in USA

Country: tropical + subtropical regions, parts of Europe, southeastern USA (endemic in eastern Kentucky, rural Tennessee), Puerto Rico

Primary host: humans

Infection: filiform larva enters body through skin / mucous membranes (from contaminated soil)

Cycle:

filariform larva penetrates skin → passes from subcutaneous / submucosal sites via lymphatic + venous circulation to lung → larva breaks into alveolar spaces and ascends bronchi + trachea;

larva swallowed → settles in duodenum + upper jejunum (lives in tunnels between enterocytes) → larva matures into parasitic female adult worm → produces eggs through parthenogenesis (= asexual reproduction) → worm deposits eggs into the intestinal lumen → ova hatch immediately into nonmigratory rhabditiform larvae (1st larval stage) → excreted in feces

[*parthenos* , Greek = virgin; *genesis* , Greek = creation]

Autoinfection (endogenous reinfection):

rhabditiform larva may remain in intestines long enough to metamorphose into infective filariform larva → penetrates intestinal mucosa / perianal skin → reenters venous system repeating life cycle in same host

Path: edema + inflammation of intestinal wall ← invasion by larvae; flattening of villi; ova in mucosal crypts

Histo: intact larvae seen with Gömöri methenamine silver stain

- asymptomatic for many years (in majority)
- midepigastric pain mimicking peptic ulcer disease
- severe malnutrition (malabsorption, steatorrhea), weight loss
- larva currens = recurrent allergic pruritic cutaneous skin reaction at site of larval penetration within 24 hours in area of buttocks + upper thighs in patients with autoinfection
- worms, larvae, eggs in stool
- peripheral blood eosinophilia (extremely common)
- elevated levels of immunoglobulin E

@ Intestine

√ paralytic ileus (due to massive intestinal infestation):

√ mild to moderate dilatation of proximal ²/₃ of duodenum + jejunum

√ edematous irregular mucosal folds

√ ulcerations

√ stricture of 3rd + 4th part of duodenum

√ rigid pipestem appearance + irregular narrowing of duodenum (in advanced cases)

@ Lung

√ transient pulmonary opacities

Dx: filariform larvae in stool (single stool sample in 70% negative), sputum samples / bronchial washings / bronchial / lung biopsy specimens, CNS samples
Rx: thiabendazole (90% efficacy rate)
Prognosis: high mortality in undernourished patients
DDx: Crohn disease, lymphoma, tuberculosis, other causes of enterocolitis

Strongyloides Hyperinfection Syndrome

= life-threatening parasitic infestation = chronic pathway of continuous autoinfection → widespread dissemination + extensive tissue invasion in immunocompromised host with malignancy, autoimmune disease, malnutrition
• gram-negative bacteremia, septicemia ← spillage of gut organisms into bloodstream at time of larval penetration of intestinal wall)
• crampy abdominal pain, nausea, diarrhea
• persistent vomiting, hematemesis
√ thickened colonic wall ← florid transmural granulomatous inflammatory colitis caused by invasive larvae
@ Heart, skeletal muscle, lymph nodes, liver
• endocarditis, peritonitis
@ CNS
(a) meningitis ← larvae in pia arachnoid
(b) global ischemia, atrophy, microinfarcts ← capillary obstruction
@ Lung
Histo: foreign body reaction resulting in inflammatory pneumonitis + pulmonary hemorrhage
• ± dyspnea, cough, sputum production, wheezing
• hemoptysis
√ fine miliary nodules (rare)
√ diffuse reticulonodular interstitial opacities
√ ill-defined patchy fleeting (migratory) airspace consolidation typically resolving in 1–2 weeks
√ bilateral segmental / lobar opacities (with heavy infestation) ← extensive pneumonia:
√ cavitation + abscess formation ← superimposed bacterial infection
√ adult ARDS may develop
√ pleural effusion
Prognosis: 70% mortality in AIDS patients

TAILGUT CYST

= RETRORECTAL CYSTIC HAMARTOMA
Cause: incomplete regression of embryonic tailgut (= the portion distal to future as yet undeveloped anus)
Average age: 35 years; M < F
Histo: several types of epithelia + elements of intestinal epithelium, smooth muscle within cyst wall
• asymptomatic / urinary frequency

• rectal / perineal pain, painless rectal bleeding
• fever, acute pelvic pain ← secondary infection

Location: retrorectal / midline presacral space ± extension into ischiorectal fossa

√ well-defined thin-walled multicystic / unilocular cyst within perirectal space adhering to sacrum / rectum
√ clear fluid / mucoid fluid with internal echoes
√ mild enhancement of uncomplicated cyst
√ thick enhancing wall ± surrounding inflammation / air-fluid level ← secondary infection

Cx: (1) Repeated perirectal abscesses, recurring anorectal fistula (secondary infection)
(2) Degeneration into mucinous adenocarcinoma (rare)

◊ Asymmetric irregular wall thickening and heterogeneous enhancement raises suspicion for malignant change within a duplication cyst.

Rx: complete surgical excision

DDx: (1) Epidermoid / dermoid cyst
(2) Rectal duplication cyst
(3) Anterior meningocele
(4) Cystic lymphangioma

TOXIC MEGACOLON

= acute transmural fulminant colitis characterized by neurogenic loss of motor tone + rapid development of nonobstructive colonic dilatation + loss of haustra

Etiology:

1. Ulcerative colitis (most common, in < 5%)
2. Crohn disease
3. Amebiasis, salmonellosis
4. Pseudomembranous colitis
5. Ischemic colitis

Pathogenesis: inflammation that extends deep beneath colonic mucosa → damage to muscularis propria → colonic dilatation and loss of haustra

Histo: widespread sloughing of mucosa + thinning of frequently necrotic muscle layers

• systemic toxicity, profuse bloody diarrhea

√ colonic ileus with marked dilatation of transverse colon > 5.5–6.0 cm ← gas influx into nondependent colonic segment in supine patient
√ few air-fluid levels
√ increasing caliber of colon on serial radiographs without redundancy
√ loss of normal colonic haustra + interhaustral folds
√ coarsely irregular mucosal surface
√ pseudopolyposis = mucosal islands in denuded ulcerated colonic wall
√ pneumatosis coli

US:

√ colonic dilatation >6 cm
√ marked decrease in colonic wall thickness to < 2 mm
√ increased free fluid

CT:
√ distended colon filled with large amounts of fluid + air
√ distorted haustral pattern
√ irregular nodular contour of thinned wall
√ intramural air / small collections (= pneumatosis coli)
Cx: perforation ± pneumoperitoneum; rectal carcinoma
BE: CONTRAINDICATED due to risk of perforation
Morbidity: from electrolyte disturbance, fluid loss, hemorrhage, perforation
Prognosis: 20% mortality

TUBERCULOSIS OF ABDOMEN

◊ Most common manifestation of extrapulmonary tuberculosis (solid viscera > GI tract)
Endemic in: sub-Saharan Africa and Southeast Asia
Organism: M. tuberculosis, M. bovis, M. avium-intracellulare

Tuberculous Abdominal Lymphadenopathy (55–66%)

Frequency: 55–66% of patients with abdominal TB
Location: mesenteric, peripancreatic, omental, retroperitoneal
√ enlarged node with hypoattenuating center (40–60%) + hyperattenuating enhancing rim ← caseous necrosis
√ conglomerate lymph node masses of mixed attenuation
√ enlarged lymph nodes of homogeneous attenuation
√ > 3 normal / mildly enlarged homogeneous lymph nodes
√ NO obstruction of bile ducts / GI tract, / urinary tract (if present consider alternative diagnosis)

Tuberculous Peritonitis (33%)

◊ Most common presentation of abdominal tuberculosis (in 33%) associated with widespread abdominal disease!
Cause: hematogenous spread / rupture of mesenteric node / rupture of GI deposit / fallopian tube involvement
Types:
A. WET TYPE (90%) = exudative ascites
• large amount of freely distributed / loculated viscous fluid
√ high-density ascites of 20–45 HU ← high protein contents + leukocytes
√ mildly thickened smooth peritoneum
√ pronounced peritoneal enhancement
√ 5-mm macronodules in mesentery
√ thin omental line ← fibrous wall covering the infiltrated omentum
√ calcifications
B. FIBROTIC-FIXED TYPE (60%) = large cakelike masses with separation + fixation of bowel loops
√ irregular mottled masses of soft-tissue density in omentum + mesentery (common)
√ separation / fixation of matted loops of bowel
√ loculated ascites (occasionally)

C. DRY / PLASTIC TYPE (10%) = large mesenteric caseous adenopathy + adhesions
√ enhancing peritoneal thickening + caseous nodules
√ dense adhesions ← fibrous peritoneal reaction
√ smudged / caked / thickened / masslike omentum
Cx: small bowel obstruction ← adhesions from serosal tubercles
DDx: disseminated peritoneal malignancy, nontuberculous peritonitis, mesothelioma

Tuberculosis of GI tract (rare)

Rarely encountered in Western Hemisphere; increased incidence in AIDS; usually associated with pulmonary tuberculosis (in 6–38%)
Etiology:
(1) Ingestion of tuberculous sputum
(2) Hematogenous spread from tuberculous focus in lung to submucosal lymph nodes
◊ Radiographic evidence of pulmonary TB in < 50%
(3) Primary infection by cow milk (Mycobacterium bovis)
Path:
(a) ulcerative form (most frequent): ulcers with their long axis perpendicular to axis of intestine, undermining + pseudopolyps
(b) hypertrophic form: thickening of bowel wall (transmural granulomatous process)
Age: 20–40 years
• weight loss, abdominal pain (80–90%), nausea, vomiting
• tuberculin skin test negative in most patients with primary intestinal TB
Location: ileocecal region (cecum > terminal ileum) > ascending colon > jejunum > appendix > duodenum > stomach > sigmoid > rectum
◊ Skip areas of luminal narrowing + ileocecal valve involvement strongly suggest TB!
@ Ileocecal area (80–90%)
◊ Most commonly affected bowel segment!
Cause: relative stagnation of intestinal contents + abundance of lymphoid tissue (Peyer patches)
√ irregular thickened nodular folds in terminal ileum
√ **Stierlin** sign = rapid emptying (= hypermotility) of narrowed (spastic) terminal ileum into shortened rigid obliterated cecum on BE (earliest manifestation)
√ thickened ileocecal valve ← mass effect of edema
√ **Fleischner** sign = "inverted umbrella" defect = wide gaping patulous ileocecal valve associated with narrowing of the immediately adjacent terminal ileum
√ deep fissures + large shallow linear / stellate ulcers with CHARACTERISTIC elevated margins following the orientation of lymphoid follicles (ie, longitudinal in terminal ileum and transverse in colon)
√ sinus tracts (rare) / enterocutaneous fistulas / perforation
√ symmetric annular "napkin ring" stenoses
CT:
√ asymmetric circumferential wall thickening of ileocecal valve + medial wall of cecum + terminal ileum
√ exophytic extension engulfing terminal ileum

√ localized massive mesenteric lymphadenopathy with central areas of low attenuation

DDx: Crohn disease, amebiasis, cecal carcinoma

@ Colon

Site: segmental colonic involvement, esp. on right side

√ rigid contracted cone-shaped shrunken cecum ← spasm / transmural fibrosis

√ shortened "amputated" cecum ← retraction of cecum out of iliac fossa ← fibrosis of mesocolon

√ spiculations + wall thickening

√ diffuse ulcerating colitis + pseudopolyps

√ short hourglass strictures

DDx: ulcerative colitis, Crohn disease, amebiasis (spares terminal ileum), colitis of bacillary dysentery, ischemic colitis, pseudomembranous colitis

@ Gastroduodenal

Site: simultaneous involvement of antrum + pylorus + duodenum

√ stenotic pylorus with gastric outlet obstruction

√ narrowed antrum (= linitis plastica appearance)

√ antral sinus tract / fistula

√ multiple large and deep ulcerations on lesser curvature simulating peptic ulcer disease

√ thickened duodenal folds with irregular contour / dilatation

DDx: carcinoma, lymphoma, syphilis

@ Esophagus

◊ Least common GI tract manifestation

Cause: secondary involvement from adjacent tuberculous lymphadenitis / primary TB

Location: level of carina

√ deep ulceration

√ stricture

√ mass

√ intramural dissection / fistula formation → sinus tract formation

TRICHURIASIS

◊ 3rd most common roundworm infection in humans

Organism: Trichuris trichiura

Infection: fecal-oral route

Cycle: after elimination in feces eggs become embryonate and infective within 15 to 30 days → ingestion of eggs → release of larvae in small intestine → larvae mature during migration to cecum + ascending colon → adult worms attaches to mucosa

Barium enema:

√ small elongated filling defects

Dx: stool sample

DDx: lymphoid hyperplasia, aphthous ulcers

TURCOT SYNDROME

= autosomal recessive disease with

(a) colonic polyposis

(b) CNS tumors (especially supratentorial glioblastoma, occasionally medulloblastoma)

Age: symptomatic during 2nd decade

Histo: adenomatous polyps

• diarrhea, seizures

√ multiple 1–30-mm polyps in colon + rectum

Cx: malignant transformation of colonic polyps in 100%

Prognosis: death from brain tumor in 2nd + 3rd decade

ULCERATIVE COLITIS

= common idiopathic superficial inflammatory bowel disease with continuous concentric + symmetric colonic involvement

Etiology: ? hypersensitivity / autoimmune disease

Incidence: 2–14÷100,000 annually

◊ 7,000–46,000 new cases annually in USA

Prevalence: 37–246÷100,000 in North America

Path: predominantly mucosal + submucosal inflammation with neutrophilic infiltrates + exudate + edema + crypt abscesses (HALLMARK) resulting in shallow ulceration

Age peaks: 15–25 years + 50–60 years (bimodal distribution); M÷F = 1.3÷1

• alternating periods of remission + exacerbation

• chronic diarrhea, rectal bleeding, abdominal pain / cramps

• electrolyte depletion, fever, systemic toxicity (malaise)

Extracolonic manifestations:

• iritis, erythema nodosum, pyoderma gangrenosum

• pericholangitis, chronic active hepatitis, primary sclerosing cholangitis, fatty liver, thrombotic complications

• spondylitis, peripheral arthritis, coincidental rheumatoid arthritis (10–20%)

Location: begins in rectum (proctitis in 55%, rectum spared in 4%) with proximal progression, left-sided colitis (30%), pancolitis (15%); relatively uniform symmetric involvement of bowel

@ Rectosigmoid in 95% (diagnosed by rectal biopsy); continuous circumferential involvement often limited to left side of colon

@ Colitis extending proximally to splenic flexure = universal colitis

@ Terminal ileum in 10–25% (= "backwash ileitis")

Plain film:

√ hyperplastic mucosa, polypoid mucosa, deep ulcers

√ diffuse dilatation with loss of haustral markings

√ toxic megacolon

√ free intraperitoneal gas

√ complete absence of fecal residue ← inflammation

BE:

(a) acute stage

√ narrowing + incomplete filling ← spasm + irritability

√ fine mucosal granularity = stippling of barium coat ← diffuse mucosal edema + hyperemia + superficial erosions

√ spicules + serrated bowel margins = tiny superficial ulcers
√ "collar button" ulcers = undermining of ulcers
√ "double-tracking" = longitudinal submucosal ulceration over several cm
√ hazy / fuzzy quality of bowel contour ← excessive secretions / mucin production
√ "thumbprinting" = symmetric thickening of colonic folds
√ pseudopolyps = scattered islands of edematous mucosa + reepithelialized granulation tissue within areas of denuded mucosa
√ widening of presacral space
√ obliterated rectal folds = valves of Houston (43%)

(b) subacute stage
√ distorted irregular haustra
√ inflammatory polyps = sessile frondlike / rarely pedunculated lesions (= localized mucosal inflammation resulting in polypoid protuberance)
√ coarse granular mucosa (= mucosal replacement by granulation tissue)

(c) chronic stage
√ shortening of colon with depression of flexures ← reversible spasm of longitudinal muscle
√ "leadpipe" colon = rigidity + symmetric narrowing of lumen on BE:
← hypertrophic regeneration of muscularis mucosae
← contraction of enlarged muscle layer
← strictures compromising luminal distensibility
← fat deposition within submucosal layer
√ widening of haustral clefts / complete loss of haustrations ← hypertrophy of muscularis mucosae + fibrosis (DDx: cathartic colon)
√ "burnt-out colon" = fairly distensible colon WITHOUT haustral markings + without mucosal pattern
√ hazy / fuzzy quality of bowel contour ← excessive secretions
√ postinflammatory polyps (12–19%) = small sessile nodules / long wormlike branching + bridging outgrowths (= filiform polyposis)
√ "**backwash ileitis**" (5–30%) involving 4–25 cm of terminal ileum with patulous ileocecal valve + absent peristalsis + granularity

US:
√ thickening, hyperemia, loss of haustra
√ preserved mural stratification

CT/MR:

CT enterography is not used for the diagnosis or staging of ulcerative colitis as it is less sensitive than endoscopy and principally assesses the small bowel.

◊ Often normal early in course of disease!
√ colonic wall thickening 3.5–11.6 mm (normal < 3 mm; indeterminate = 3–4 mm; pathologic > 4 mm)
√ mural stratification:
√ submucosal stripe = enhancement of mucosa but not submucosa
√ dilatation of vasa recta
√ inflammatory pseudopolyp

√ widening of presacral space ← perirectal extramural fat proliferation

Mural stratification, dilatation of vasa recta, colonic wall thickening, and inflammatory pseudopolyps are seen in both ulcerative colitis and Crohn colitis!

NUC:

√ positive on ^{99m}Tc–hexamethylpropylene amine (HMPAO)-labeled leukocytes

Dx: colonoscopy

Cx:

(1) Toxic megacolon (in 5%) (DDx: granulomatous / ischemic / amebic colitis)
- ◊ Most common cause of death in ulcerative colitis!
- ◊ Develops within 3 months of diagnosis (in 30%)

(2) Colonic adenocarcinoma (3–5%):

Risk: starts after 8–10 years of disease onset; risk progresses at 0.5–1.0% annually for 10–20 years + at 0.9% per year thereafter; higher risk with pancolitis + onset of disease in < 15 years of age

DDx of Crohn Disease versus Ulcerative Colitis

	Crohn Disease	*Ulcerative Colitis*
mnemonic: LUCIFER M		
Location	right	left
Ulcers	deep	shallow
Contraction	–	+
Ileocecal valve	thickened	gaping
Fistulae	+	–
Eccentricity	+	–
Rate of carcinoma	(↑)	↑↑
Megacolon	unusual	+
Skip lesions	+	–
Pseudopolyps	+	–
Abscess / fistula	+	–
Fibrofatty proliferation	+	–
Full thickness enhancement	+ (transmural)	– (mucosal + submucosal
Increased SI of mucosa	+	–
Submucosal stripe	-	+
Wall thickening	+ (11 mm)	+ (8 mm)
Wall enhancement	+	+
Increased SI of pericolic fat	+	+
Comb sign	+	+
Loss of haustrations	±	+
Enlarged lymph nodes	+	+

Usually associated with: total colitis

Location: rectosigmoid > descending colon, distal transverse colon

√ narrowed segment of 2–6 cm in length with eccentric lumen + irregular contour + flattened rigid tapered margins = scirrhous carcinoma
√ annular / polypoid carcinoma
Prognosis: synchronous lesions in 35%
◊ Surveillance is recommended!

(3) Colonic strictures (10%)
Smooth contour with fusiform pliable tapering margins, usually short + single stricture; commonly in sigmoid / rectum / transverse colon; usually after minimum of 5 years of disease; rarely cause for obstruction (DDx: colonic carcinoma)

(4) Perforation

DDx: (1) Familial polyposis (no inflammatory changes)
(2) Cathartic colon (more extensive in right colon)

VILLOUS ADENOMA

√ solitary sessile polypoid mass with numerous frondlike projections of reticular "soap bubble" appearance ← retention of contrast material in clefts between tumor projections

Villous Adenoma of Colon

Frequency: 7% of all colonic tumors
Age: presentation late in life; M = F
Location: rectum + sigmoid (75%), cecum, ileocecal valve; 2% of all tumors in rectum + colon
Associated with: other GI tumors (25%)

- sensation of incomplete evacuation, rectal bleeding, weakness
- excretion of copious amounts of thick mucus, fatigability
- diarrhea + electrolyte depletion syndrome in 4% (dehydration, hypokalemia, hyponatremia)

√ may completely encircle the colon
√ broad-based sessile bulky tumor often > 20 mm in diameter:
√ innumerable papillary mucosal projections ("villous fronds") with reticular / granular surface pattern (if villous elements constitute > 75% of tumor, diagnosis can be made on BE):
√ spongelike corrugated appearance (= barium within interstices)
√ striated "brushlike" surface
√ soft pliable tumor with change in shape:
√ apparent decrease in size on postevacuation films

CT:
√ heterogeneous low attenuation on CT ← capacious mucin becoming trapped within papillary projections + crevices

Prognosis: higher malignant potential than tubular adenoma
Cx: malignant transformation / invasion (in 36%) related to size of tumor < 5 cm (9%); > 5 cm (55%); > 10 cm (100%)

Villous Adenoma of Duodenum

Prevalence: 1% [50%] of all [benign] duodenal neoplasms; more common in colon + rectum

Average age: 56 years; M=F
Associated with: Gardner syndrome, familial adenomatous polypoid syndrome
• asymptomatic, vague dyspepsia, bowel obstruction (rare)
• occult upper GI bleeding, anemia, ± obstructive jaundice
Location: 2nd duodenal segment near major papilla of Vater
Size: 3–9 cm
√ sessile soft mostly nonobstructive mass
√ "lace" / "soap bubble" pattern ← frondlike projections
√ preservation of peristaltic activity + bowel distensibility
CT:
√ variegated attenuation + variable enhancement patterns
√ CHARACTERISTIC surface gyral pattern for large tumor
Cx: bowel obstruction
Prognosis: 30%–60% risk for malignant transformation

WALDENSTRÖM MACROGLOBULINEMIA

= low-grade lymphoid malignancy (= plasma cell dyscrasia) composed of mature plasmacytoid lymphocytes with production of abnormal monoclonal IgM protein
Incidence: 0.53÷100,000 annually; frequency 10–15% of multiple myeloma
Histo: macroglobulin proteinaceous hyaline material fills lacteals in lamina propria of small bowel villi with secondary lymphatic distension + edema
Mean age: 63 years; M > F
• fatigue, weight loss, diarrhea, steatorrhea, malabsorption
• anemia, bleeding diathesis, IgM elevation
• hyperviscosity syndrome (20%) = bleeding, visual changes, neurologic abnormalities
@ Small bowel (rarely involved)
√ small bowel dilatation
√ diffuse irregular thickening of valvulae conniventes with spikelike configuration (jejunum + proximal ileum)
√ granular surface of punctate 1–2-mm nodules (deposition of immunoglobulin M in submucosa + lamina propria)
@ Bone marrow involvement (91–98%)
(a) diffuse replacement of bone marrow (56%)
(b) variegated replacement of bone marrow (35%)
√ compression fractures of spine (48%)
√ diffuse demineralization of spine
√ lytic lesions on bone surveys (in up to 20%)
MR (pre- and postcontrast T1WI preferred):
√ marrow iso- / hypointense to muscle on T1WI
√ enhancement of abnormal marrow on T1WI
@ Lymph nodes
√ lymphadenopathy (43%)
@ Liver & spleen
√ hepatosplenomegaly

Dx: (1) Characteristic M-spike in serum / urine electrophoresis
(2) Abnormal lymphoplasmacytoid cells in bone marrow / lymph nodes
Prognosis: may occasionally progress to full-blown lymphoma
DDx: multiple myeloma (lymphadenopathy rare, lytic lesions in 31%)

WHIPPLE DISEASE

[George Whipple (1878–1976), pathologist in Rochester, USA]
= INTESTINAL LIPODYSTROPHY
= sporadically occurring chronic bacterial multisystem disease
Etiology: infection with gram-positive bacterium (Tropheryma whipplei) closely related to actinobacteria; in 1–11% (12–26%) of fecal samples in healthy population (sewage workers) in Europe
Incidence: 30 cases annually
Genetics: whites of European heritage predisposed → colonization of bacterium throughout GI tract + lymphoreticular system + CNS
Histo: PAS-positive material (periodic acid Schiff) = glycoprotein (from bacterial cell wall) within foamy macrophages in the submucosa of the jejunum + fat deposits within intestinal submucosa and lymph nodes causing lymphatic obstruction + dilatation
Mean age: 50 years (range, 4th–6th decade); M÷F = 8÷1; Caucasians
- 4 cardinal symptoms:
  - recurrent migratory arthralgias / nondeforming arthritis
  - chronic steatorrhea ← malabsorption
  - weight loss → severe wasting
  - abdominal pain → abdominal distention ← ascites and lymphadenopathy (late finding)
- polyserositis, low-grade fever
- generalized peripheral lymphadenopathy (50%)
- hyperpigmentation of skin similar to Addison disease
- pale shaggy yellow plaques / erosions in postbulbar duodenum on endoscopy

Organ involvement: small bowel (particularly jejunum), lymph nodes, heart valves, joints, CNS, liver, lung, eyes, skin (virtually every organ system)
@ MSK (67%) arthritis may precede Whipple disease up to 10 years (10%)
@ Abdomen (15%)
√ moderate irregular diffuse fold thickening of jejunum + duodenum + (to a lesser degree) ileum ← mucosal and submucosal infiltration by Whipple bacilli + PAS- positive macrophages + lymphatic obstruction
√ micronodularity (= swollen villi) + wild mucosal pattern
√ hypersecretion, segmentation, fragmentation (occasionally if accompanied by hyperproteinemia)
√ NO / minimal distension of small bowel
√ NO rigidity of folds, NO ulcerations
√ NORMAL transit time
√ hepatosplenomegaly
√ mesenteric and retroperitoneal nodes of low attenuation are CHARACTERISTIC of Whipple disease

CT:
√ bulky 3–4-cm low-density lymph nodes in mesenteric root + retroperitoneum ← lymphatic obstruction and intranodal deposition of extracellular lipids
√ thickening of small bowel wall
√ hepatosplenomegaly
√ ascites
√ pneumatosis intestinalis
√ pleuropericarditis
√ sacroiliitis
US:
√ echogenic lymph nodes

@ CNS (33%)
Location: mesial temporal lobe, midbrain, thalamus, hypothalamus
√ patchy nodular enhancement
√ hyperintense regions on FLAIR ← atrophy / gliosis

Dx: endoscopically guided biopsy of small bowel mucosa, abdominal / peripheral lymph node biopsy

Rx: long-term broad-spectrum antibiotics (tetracycline) with 17–35% relapse rate; long-term trimethoprim-sulfamethoxazole

DDx: (1) Sprue (marked dilatation, no fold thickening, pronounced segmentation + fragmentation)
(2) Intestinal lymphangiectasia (thickened folds throughout small bowel)
(3) Amyloidosis
(4) Lymphoma

YERSINIOSIS

Organism: Gram-negative bacillus Yersinia enterocolitica
• self-limited diarrhea
Location: usually confined to terminal ileum
√ irregular segmental thickening of folds
√ ± aphthous ulcers / larger area of ulceration

ZENKER DIVERTICULUM

= PHARYNGOESOPHAGEAL DIVERTICULUM
[Friedrich Albert von Zenker (1825–1898), German pathologist, Dresden city hospital and chair at Erlangen University]
= outpouching of posterior hypopharyngeal wall = pulsion diverticulum with herniation of mucosa + submucosa through muscle bundles (**pseudodiverticulum**)
Prevalence: 0.01–0.11% (overall); higher in elderly women
◊ Most common diverticulum of UGI tract!
Etiology: cricopharyngeal dysfunction (cricopharyngeal achalasia / premature closure) → increased intraluminal pressure (pulsion diverticulum)
Associated with: hiatal hernia, gastroduodenal ulcer, midesophageal diverticulum, esophageal spasm, achalasia, GERD

Age: > 60 years (50% occur in 7th–8th decade); M÷F = 1÷3
- compressible neck mass, noisy deglutition, chronic cough
- upper esophageal dysphagia (98%), weight loss
- regurgitation + aspiration of undigested food
- halitosis (= foul breath)

Location: pharyngoesophageal junction in midline of Killian dehiscence / triangle of Laimer (= focal hypopharyn-geal weakness at cleavage plane between inferior pharyngeal constrictor m. + cricopharyngeus m. or between oblique + transverse fibers of cricopharyngeus m.), at level of C5-6

[Gustav Killian (1860–1921), laryngologist and founder of bronchoscopy, ordinarius for throat and nose disease in Freiburg, Germany]

Barium pharyngography:
- √ posterior + inferior barium extension in upper half of semilunar depression on posterior wall of esophagus in midline / slightly toward left (above cricopharyngeal m.)
- √ barium-filled sac extending caudally behind + usually to left of esophagus
- √ partial / complete obstruction of esophagus from external pressure of sac contents → dysphagia
- √ partial barium reflux from diverticulum into hypopharynx
- √ continual growth with successive enlargement

CXR:
- √ air-fluid level in superior mediastinum

Cx: overflow aspiration pneumonia (30%); esophageal perforation; carcinoma (0.48%)

Rx: surgical excision + cricopharyngeal myotomy

ZOLLINGER-ELLISON SYNDROME

[Robert Milton Zollinger (1903–1992), chairman of surgery at Ohio State University, editor in chief of Am J Surg 1958–1986]

(Edwin Homer Ellison (1918–1970), chairman of surgery at Marquette University, Milwaukee]

= peptic ulcer diathesis ← marked hypersecretion of gastric acid ← gastrin-secreting islet cell neoplasm (gastrinoma)

Incidence: 0.1% of all peptic ulcer disease

Cause:

A. GASTRINOMA (90%)
   = gastrin-producing non-β islet cell tumor of pancreas

B. PSEUDO Z-E SYNDROME = COWLEY SYNDROME
   = antral G-cell hyperplasia (10%) = increase in number of G-cells in gastric antrum
   - lack of gastrin elevation after secretin injection
   - exaggerated gastrin elevation after protein meal

Age: middle age; M > F
- clinical tetrad:

(1) Gastric hypersecretion: refractory response to histamine stimulation test concerning HCl concentration; increased basal secretion (> 60% of augmented secretion is diagnostic)
(2) Hypergastrinemia > 1000 ng/L (during fasting)
(3) Hyperacidity with basal acid output > 15 mEq/hr / occasionally hypoacidity

(4) Diarrhea (30%), steatorrhea (40%) ← malabsorption ← inactivation of pancreatic lipase + damage to small bowel mucosa ← large volumes of gastric acid with low pH; may be sole complaint in 10%, frequently nocturnal

- epigastric pain (90%): mild nonspecific to severe recurrent intractable pain, gastroesophageal reflux, heartburn
- ulcer perforation with GI bleeding (30%)
- positive secretin stimulation test
- ↑ fasting serum levels of gastrin (DIAGNOSTIC): often > 1,000 pg/mL (< 100 pg/mL is normal)

√ peptic ulcers

◊ An unusual location in postbulbar duodenum / proximal jejunum + atypical course should suggest the diagnosis!

Location: duodenal bulb (65%) + stomach (20%), jejunum near ligament of Treitz (25%), duodenal C-loop (5%), distal esophagus (5%)

Multiplicity: solitary ulcer (90%), multiple ulcers (10%)

√ recurrent / intractable ulcers

√ marginal ulcers in postgastrectomy patient

(a) on gastric side of anastomosis

(b) on mesenteric border of efferent loop

√ prominence of areae gastricae ← hyperplasia of parietal cells

√ enlarged thickened rugal folds in gastric fundus + upper body

√ sluggish gastric peristalsis ← ? hypokalemia

√ "wet stomach" = dilution of barium with poor coating by excess secretions in nondilated nonobstructed stomach

√ gastroesophageal reflux (common) + esophagitis

Location: unusually long strictures in distal esophagus (may be initial manifestation of disease)

Cause: increased acidity of peptic acid reflux

√ dilatation of duodenum + upper small bowel ← fluid overload

√ thickened folds in duodenum + jejunum ← edema

√ rapid small-bowel transit time

mnemonic: FUSED

Folds: thickened gastric folds

Ulcers: often multiple, postbulbar

Secretions increased (refractory to histamine)

Edema: of proximal small bowel

Diarrhea

Cx: (1) Malignant islet cell tumor (in 60%)

(2) Liver metastases will continue to stimulate gastric secretion

Rx: (1) Control of gastric hypersecretion:

(a) H_2-receptor antagonist: cimetidine, ranitidine, famotidine

(b) Hydrogen-potassium adenosine triphosphatase inhibitor (omeprazole)

(2) Resection of gastrinoma if found (because of malignant potential)

(3) Total gastrectomy

UROGENITAL TRACT

DIFFERENTIAL DIAGNOSIS OF UROGENITAL DISORDERS

RENAL FAILURE

= reduction in renal function

• rise in serum creatinine > 2.5 mg/dL

Acute Renal Failure (ARF)

= clinical condition associated with rapid steadily increasing azotemia ± oliguria (< 500 mL urine per day) over days / weeks

Etiology:

A. PRERENAL

= renal hypoperfusion ← systemic illness

1. Fluid + electrolyte depletion
2. Hemorrhage
3. Hepatic failure + hepatorenal syndrome
   √ abnormally elevated resistive index
4. Congestive heart failure
5. Sepsis
   √ resistive index < 0.75 in 80% of kidneys

Frequency: 70% of community-acquired ARF (glomerulonephritis); 40% of hospital-acquired ARF (acute tubular necrosis)

B. RENAL (most common)

1. Acute tubular necrosis: ischemia, nephrotoxins, radiographic contrast, hemoglobulinuria, myoglobulinuria, myocardial infarction, burns
   √ resistive index ≥ 0.75 in 91% of kidneys
2. Acute glomerulonephritis + small vessel disease: acute poststrep glomerulonephritis, rapidly progressive glomerulonephritis, lupus, polyarteritis nodosa, Schönlein-Henoch purpura, subacute bacterial endocarditis, serum sickness, Goodpasture syndrome, malignant hypertension, hemolytic uremic syndrome, drug-related vasculitis, abruptio placentae
   √ normal resistive index < 0.70
3. Acute tubulointerstitial nephritis: drug reaction, pyelonephritis, papillary necrosis
   √ abnormal resistive index
4. Intrarenal precipitation: hypercalcemia, urate, myeloma protein
5. Arterial / venous obstruction
6. Acute cortical necrosis

C. POSTRENAL (5%)

= result of outflow obstruction (rare)

1. Prostatism

2. Tumors of bladder, retroperitoneum, pelvis
3. Calculus

√ hydronephrosis

◊ 30–35% of acutely obstructed kidneys (< 36 hours) have no hydronephrosis!

D. CONGENITAL

bilateral renal agenesis / dysplasia / infantile polycystic kidney disease, congenital nephrotic syndrome, congenital nephritis, perinatal hypoxia

Frequency: ATN + prerenal disease account for 75% of acute renal failure; 5–7% of all hospitalized patients

- asymptomatic
- elevated creatinine normal range: 0.5–1.0 mg/dL (about 45–90 µmol/L) for women + 0.7–1.2 mg/dL (60–110 µmol/L) for men

Prognosis: 20–70% mortality

Chronic Renal Failure (CRF)

= decrease in renal function over months / years

Incidence: end-stage renal disease in 0.01% of USA population; annually 85,000 patients undergo hemodialysis + 8,000 renal transplantations

Etiology:

A. INFLAMMATION / INFECTION
1. Glomerulonephritis
2. Chronic pyelonephritis
3. Tuberculosis
4. Sarcoidosis

B. VASCULAR
1. Renal vascular disease
2. Bilateral renal vein thrombosis

C. DYSPROTEINEMIA
1. Myeloma
2. Amyloid
3. Cryoglobulinemia
4. Waldenström macroglobulinemia

D. METABOLIC
1. Diabetes
2. Gout
3. Hypercalcemia
4. Hyperoxaluria
5. Cystinosis
6. Fabry disease
7. Calcinosis

E. CONGENITAL
1. Polycystic kidney disease
2. Multicystic dysplastic kidney
3. Medullary cystic disease
4. Alport syndrome

5. Infantile nephrotic syndrome

F. MISCELLANEOUS
1. Hepatorenal syndrome
2. Radiation

Musculoskeletal Manifestations of CRF

1. Renal osteodystrophy = combination of 2° HPT, osteoporosis, osteosclerosis, osteomalacia, soft-tissue and vascular calcifications
2. Aluminum toxicity (1–30%)
3. Amyloid deposition
   Path: amyloid consists of β2-microglobulin
   Organs: bone, tenosynovium (carpal tunnel syndrome), vertebral disk, articular cartilage + capsule, ligament, muscle
4. Destructive spondyloarthropathy (15%)
   √ diskovertebral junction erosion + sclerosis
   √ vertebral body compression
   √ disk space narrowing
   √ Schmorl node formation
   √ lack of osteophytosis
   √ facet involvement with subluxation
5. Tendon rupture
6. Crystal deposition disease
   Type: calcium hydroxyapatite, CPPD, calcium oxalate, monosodium urate
7. Osteomyelitis + septic arthritis
8. Avascular necrosis (in up to 40%)

DIABETES INSIPIDUS

= characterized by daily production of very large volume of dilute urine (specific gravity < 1.005, < 200 mOsm/L)

Pituitary Diabetes Insipidus

= HYPOTHALAMIC DIABETES INSIPIDUS
= VASOPRESSIN-SENSITIVE DIABETES INSIPIDUS
= vasopressin (ADH) production is reduced to < 10%

Cause:

A. IDIOPATHIC (27%)
   septooptic dysplasia / rare familial (autosomal dominant X-linked) / sporadic disorder
   Histo: atrophic supraoptic nucleus
   • never associated with anterior pituitary dysfunction

B. PITUITARY DESTRUCTION BY TUMOR / INFILTRATIVE DISORDER (32%):
   in childhood: hypothalamic glioma, tuber cinereum hamartoma, craniopharyngioma, Langerhans histiocytosis, germinoma, leukemia, complication of meningitis
   in adulthood: sarcoidosis, TB, metastasis
   • in 60% associated with anterior pituitary dysfunction

C. PITUITARY DESTRUCTION BY SURGERY (20%)
- always associated with anterior pituitary dysfunction

D. HEAD INJURY (17%)
- in 20% associated with anterior pituitary dysfunction

◊ A lesion in the posterior pituitary will NOT produce diabetes insipidus, because it is simply the storage space for vasopressin

Psychogenic Water Intoxication

= compulsive intake of large amounts of fluid → inhibits normal vasopressin production

• water deprivation test

Nephrogenic Diabetes Insipidus

= poor reabsorption of water in collecting ducts ← end-organ resistance to vasopressin

Cause:

A. CONGENITAL
1. Rare X-linked recessive genetic disorder with unresponsiveness of tubules + collecting system to vasopressin (in infants + young males) with variable expression
2. Autosomal dominant form (rare)

B. ACQUIRED = nephrogenic DI syndrome
= disorders affecting the medulla / distal nephrons:
medullary + polycystic disease, sickle cell nephropathy, postobstructive uropathy, reflux nephropathy, chronic uremic nephropathy, unilateral renal artery stenosis, acute tubular necrosis, drug toxicity, analgesic nephropathy, hypokalemic + hypercalcemic nephropathy, amyloidosis, sarcoidosis

- symptoms in infancy:
  - vomiting ← hypernatremic dehydration
  - mental retardation
  - caloric growth failure ← water favored over formula
- symptoms after infancy:
  - increased fluid intake; avoiding urination

√ bilateral hydroureteronephrosis

Rx: thiazide diuretics, low-salt diet, encouragement of frequent micturition, indomethacin

PRIMARY ALDOSTERONISM

= inappropriate autonomous hypersecretion of aldosterone WITHOUT activation of renin-angiotensin-aldosterone axis

Frequency: 5–15% of unselected hypertensive patients
◊ Most common cause of secondary hypertension!

Biochemistry: mineralocorticoid production in zona glomerulosa

Cause: (main role of radiology)

(1) **Aldosterone-producing adenoma** (APA) 33–66%

Age: often found in patients < 40 years

Size: < 2 cm (usually)

Rx: adrenalectomy

(2) **Bilateral adrenal hyperplasia** (BAH) 33–66%
Age: often found in older patients > 40 years
√ enlargement of both adrenal glands
Rx: aldosterone antagonists (eplerenone)
(3) **Unilateral adrenal hyperplasia** < 1%
Rx: adrenalectomy
(4) Adrenal carcinoma rare
(5) Type 1 familial hyperaldosteronism rare
(5) Type 2 familial hyperaldosteronism rare

- hypertension
- hyperaldosteronism, suppressed renin, hypernatremia
- abnormal aldosterone (↑)-renin (↓)ratio, metabolic alkalosis
- failure to suppress plasma aldosterone levels by oral salt-loading / IV administration of saline solution / fluorocortisone

CT (40–100% sensitive) & MR (70–100% sensitive):
√ small adrenal nodule:
√ macronodule > 10 mm
√ micronodule < 10 mm
√ mean adrenal limb width ≥ 5 mm = BAH

Adrenal vein sampling:
= blood samples taken from IVC + both adrenal veins during infusion of adrenocorticotropic hormone
√ cortisol ratio of adrenal vein÷IVC > 2÷1
√ lateralization ratio = adrenal vein÷adrenal vein:
√ > 4 = aldosterone hypersecretion
√ < 3 = BAH

NUC (^{131}Iodine–6-β-iodomethylnorcholesterol = NP-59 or Selenium-75–6-β-selenomethylcholesterol):
› dexamethasone depression increases sensitivity
√ unilateral early uptake < 5 days = APA
√ symmetric early uptake < 5 days = BAH
√ symmetric late uptake > 5 days = normal

HYPERCALCEMIA

mnemonic: SHAMPOO DIRT
Sarcoidosis
Hyperparathyroidism, **H**yperthyroidism
Alkali-milk syndrome
Metastases, Myeloma
Paget disease
Osteogenesis imperfecta
Osteopetrosis
D vitamin intoxication
Immobility

Renal tubular acidosis
Thiazides

POLYCYTHEMIA

Cause: increased level of erythropoietin (acting on erythroid stem cells) ← decrease in pO2; erythropoietin precursor is produced in juxtaglomerular epithelioid cells of kidney + converted in blood

A. RENAL
   (a) intrarenal
      1. Vascular impairment
      2. Renal cell carcinoma (5%)
      3. Wilms tumor
      4. Benign fibroma
      5. Simple cyst (14%)
      6. Polycystic kidney disease
   (b) postrenal
      1. Obstructive uropathy (14%)
B. EXTRARENAL
   (a) liver disease
      1. Hepatoma
      2. Regenerating hepatic cells
   (b) adrenal disease
      1. Pheochromocytoma
      2. Aldosteronoma
      3. Cushing disease
C. CNS DISEASE
      1. Cerebellar hemangioblastoma
D. LARGE UTERINE MYOMAS

Pertinent negatives: NOT in renal vein thrombosis, multicystic dysplastic kidney, medullary sponge kidney

ARTERIAL HYPERTENSION

A. PRIMARY / ESSENTIAL HYPERTENSION (85–90%)
B. SECONDARY HYPERTENSION
   (a) Renal parenchymal disease (5–10%)
   (b) Potentially curable secondary hypertension (1–2%)
      › vascular
      1. Renovascular disease 0.18–4.4%
      2. Coarctation 0.6%
      › hormonal
      1. Pheochromocytoma 0.04–0.2%
      2. Cushing syndrome 0.3%
      3. Primary aldosteronism 0.01–0.4%
      4. Hyperthyroidism

5. Myxedema

› renal

1. Unilateral renal disease

Renovascular Hypertension

= normalization of blood pressure following nephrectomy / reestablishment of normal renal blood flow (Diagnosis made in retrospect)

Prevalence: 1–5% of general population; 2nd most common cause of potentially curable hypertension

Pathophysiology:

usually > 50% stenosis at any level in renovascular bed → mildly reduced pressure in glomerular afferent arteriole (pressure falls precipitously in > 80% stenosis); reduced pressure → stimulates release of renin → followed by angiotensin-II and aldosterone causing

(a) constriction of efferent glomerular arterioles
(b) increase in systemic hypertension
(c) sodium retention

Cause:

1. Atherosclerosis (60–90%) in individuals > 50 years
2. Fibromuscular dysplasia (10–35%) in women < 40 years
3. Neurofibromatosis
4. Pheochromocytoma
5. Fibrous bands: congenital stenosis, retroperitoneal fibrosis, postradiation artery stenosis
6. Arteritis: Buerger disease, polyarteritis nodosa, Takayasu disease, thrombangiitis obliterans, syphilitic arteritis
7. Arteriovenous malformation / fistula
   - renin-mediated hypertension ← renal ischemia distal to fistula
8. Thromboembolic disease: eg, atrial fibrillation, prosthetic valve thrombi, cardiac myxoma, paradoxical emboli, atheromatous emboli
9. Renal artery aneurysm
10. Extrinsic compression: eg, renal cyst, neoplasm, chronic subcapsular hematoma (= Page kidney)
11. Middle aortic syndrome, aortic dissection, dissecting aortic aneurysm
12. Posttraumatic renovascular hypertension
    (a) occlusion of main renal artery
    (b) significant stenosis by intimal flap
    (c) severe renal contusion
    (d) segmental renal artery branch injury

◊ Renal artery stenosis in 77% of hypertensive patients!
◊ Renal artery stenosis in 32–49% of normotensive patients!
◊ After restoration of normal renal blood flow 15–20% of patients remain hypertensive!

Clinical findings that suggest renovascular disease:

1. Onset of HTN < 30 years and > 50 years of age

2. Hypertension refractory to therapy
3. Accelerated / malignant hypertension
4. Unexplained large increases in blood pressure above previously controlled / baseline values
5. Symptomatic hypertension

Rx: (1) Relieving renal artery stenosis
(2) Angiotensin-converting enzyme inhibitor

Hypertension in Children

Prevalence: 1–3%

1. Coarse renal cortex scarring 36%
2. Glomerulonephritis 23%
3. Coarctation of aorta 10%
4. Renovascular disease 10%
5. Polycystic renal disease 6%
6. Hemolytic-uremic syndrome 4%
7. Catecholamine excess: pheochromocytoma, neuroblastoma 3%
8. Renal tumor 2%
9. Essential hypertension 3%

Renin Elevation

1. Juxtaglomerular cell tumor
2. Wilms tumor
3. Hypernephroma
4. Lung cancer
5. Paraovarian tumor
6. Fallopian tube adenocarcinoma
7. Epithelial liver hamartoma
8. Orbital hemangiopericytoma
9. Pancreatic cancer
10. Angiolymphoid hyperplasia

ARTERIAL HYPOTENSION

Cause: intrarenal hypovolemia, primary vasoconstriction, reduced glomerular filtration, depletion of intratubular urine volume

◊ May occur as a contrast reaction!
◊ Urogram reverts to normal after reversion of hypotension!
√ bilateral small smooth kidneys (compared with size on preliminary films)
√ increasingly dense nephrogram
√ usually NO opacification of collecting system
√ initially opacification of collecting system if hypotension occurs during contrast injection

URINARY TRACT INFECTION

= pure growths of > 100,000 organisms/mL urine

Prevalence: 3% of girls + 1% of boys during first 10 years of life

Underlying radiologic abnormality:

1. Vesicoureteral reflux = VUR (30–40%)
2. Obstructive uropathy (8%)
3. Reflux nephropathy / scar formation (6%)
   - ◊ The prevalence of an underlying radiologic abnormality depends on age, sex, and frequency of previous infections!

Imaging objective:

1. Identify patients at risk for reflux nephropathy
2. Detect reflux nephropathy / scars
3. Detect obstructive uropathy
4. Minimize radiation, morbidity, and cost

VCUG:

for children < 5 years of age with infection; normal results in 60–70%

Renal cortical scintigraphy (DMSA / glucoheptonate): to detect acute pyelonephritis (risk for scarring) / scar; VUR poses twice the risk of cortical defects than without VUR

CILIOPATHY

= DISORDER OF PRIMARY CILIA (cilia line ducts of kidney + liver and are integral to proper renal + hepatic development

1. Autosomal recessive polycystic kidney disease
2. Autosomal dominant polycystic kidney disease
3. Medullary cystic disease
4. Multicystic kidney disease
5. Meckel-Gruber syndrome
6. Joubert syndrome
7. Orodigitofacial syndrome
8. Asphyxiating thoracic dysplasia
9. Chondroectodermal dysplasia
10. Short-rib polydactyly syndrome
11. Sensenbrenner syndrome (cranioectodermal dysplasia)
12. Weyers acrofacial dysostosis (nail anomalies, polydactyly, oral-facial defects)

GAS IN URINARY TRACT

A. RENAL EMPHYSEMA = renal / perirenal gas
   1. Emphysematous pyelonephritis
   2. Emphysematous pyelitis
   3. Gas-forming perinephric abscess
   4. Perinephric emphysema

B. BLADDER
   1. Emphysematous cystitis

C. TRAUMA
   1. Penetrating trauma
   2. Ureterosigmoidostomy, ileal conduit, catheterization with vesicoureteral reflux,

percutaneous procedure
CAVE: anomalous posterior position of colon

3. Infarction of renal carcinoma: therapeutic / spontaneous

D. FISTULA TO URINARY TRACT
Connection: bronchus / cutis / GI tract (colon > duodenum > stomach > small bowel > appendix)

1. Inflammation: chronic purulent renal infection, diverticulitis, Crohn disease
2. Neoplastic: colonic carcinoma

RETROPERITONEUM

70–80% of primary retroperitoneal neoplasms are malignant accounting for 0.1–0.2% of all malignancies in the body.

Primary Malignant Tumor of Retroperitoneum

1. Lymphoma most common retroperitoneal malignancy (33%)
2. Retroperitoneal liposarcoma most common primary retroperitoneal sarcoma (33%)
   √ contrast enhancement of thick irregular nodular septa
3. Leiomyosarcoma
   2nd most common primary retroperitoneal sarcoma (28%)

A retroperitoneal mass with extensive necrosis and contiguous involvement of a vessel is highly suggestive of a leiomyosarcoma.

4. Malignant fibrous histiocytoma 3rd most common primary retroperitoneal sarcoma (19%)
   √ dystrophic calcifications in 25%

Mantle-like Soft-tissue Mass Surrounding Aorta

1. Lymphoma
   √ homogeneous mass with irregular lobular margins
   √ "floating aorta" sign (= anterior displacement of aorta)
2. Retroperitoneal fibrosis
   √ tethering of ureters + IVC
3. Erdheim-Chester disease
   √ perinephric fibrosis + bone lesions

Cystic Retroperitoneal Masses

A. NEOPLASTIC

1. Cystic degeneration of solid neoplasm:
   › paraganglioma
   › schwannoma (neurilemmoma)
   » ancient schwannoma
   › leiomyosarcoma
2. Cystic teratoma
3. Retroperitoneal lymphangioma (1% of all retroperitoneal neoplasms)
4. Lymphangiomatosis

5. Lymphangiomyomatosis
6. Cystadenoma / cystadenocarcinoma: mucinous / serous
7. Cystic mesothelioma

B. CYSTS:
1. Müllerian cyst
   • obese woman under hormonal replacement therapy
2. Epidermoid cyst
   Location: midline presacral
   √ unilocular
3. Tailgut cyst
4. Pseudocyst
   • Hx of acute pancreatitis, elevated amylase level

C. NONNEOPLASTIC: hematoma, urinoma, lymphocele

Cystic Mass with Areas of Solid Enhancement

1. Myxoid liposarcoma
2. Schwannoma
3. Neurofibroma

Neurogenic tumors are common along sympathetic ganglia in the paraspinal region and in adrenal medulla / organ of Zuckerkandl (paraaortic bodies). Less commonly neurogenic tumors occur in urinary bladder, abdominal wall, bowel wall, or gallbladder.

Cystic Mass with Slowly Progressive Enhancement

1. Lymphangioleiomyoma
2. Urinoma

Low-density Retroperitoneal Mass

1. Lipoma
   √ sharply marginated, homogeneously fatty mass
2. Lymphangioma
   √ similar to lipoma if enough fat content
3. Renal angiomyolipoma
4. Adrenal myelolipoma
5. Xanthogranulomatous pyelonephritis
6. Metastatic retroperitoneal tumors
7. Renal cell carcinoma
8. Fibrosarcoma, fibrous histiocytoma, mesenchymal sarcoma, malignant teratoma
   √ density close to muscle
9. Retroperitoneal liposarcoma
10. Lipoblastoma
11. Hibernoma

Fat-containing Presacral Mass

1. Lipoma
2. Lipomatosis
3. Liposarcoma: infiltrative growth

4. Teratoma: younger individual
5. Myelolipoma: elderly patient

The differentiation of presacral myelolipoma from other fat-containing lesions may not always be possible with imaging alone.

Heterogeneous Fat-containing Retroperitoneal Mass

1. Dedifferentiated Liposarcoma
2. Myelolipoma
   √ positive for erythroid elements on ^{99m}Tc-sulfur colloid
3. Angiomyolipoma

Classification of Solid Retroperitoneal Masses by Tissue Component

Description	*Benign*	*Malignant*
Hematologic / lymphoid		*most common retroperitoneal malignancy*
		lymphoma, posttransplant lymphoproliferative disease, extramedullary plasmacytoma
Mesodermal		*0.1–0.2% of all malignancies*
adipose tissue	lipoma, pelvic lipomatosis, hibernoma, myelolipoma, angiomyolipoma ◊ The deeper + more centrally located a fatty mass resides the more likely it is malignant!	liposarcoma, myxoid liposarcoma, lipoblastoma
connective tissue	fibroma	malignant fibrous histiocytoma, fibrosarcoma, chondrosarcoma, synovial cell sarcoma
smooth muscle	leiomyoma	leiomyosarcoma
striated muscle	rhabdomyoma	rhabdomyosarcoma
blood vessels	hemangioma, hemangiopericytoma	angiosarcoma
perivascular epithelioid cells	perivascular epithelioid cell tumor (PEcoma): angiomyolipoma, lymphangioleiomyomatosis, clear cell "sugar" tumor, clear cell myomelanocytic tumor, pigmented melanotic tumor	malignant pericytoma, sarcoma of perivascular cells
interstitial cells of Cajal	GIST	
primitive mesenchyme	myxoma	myxosarcoma, malignant mesenchymoma
notochordal remnant	chordoma	
miscellaneous	fibromatosis, desmoid tumor, angiomyofibroblastoma, xanthogranuloma	
Neurogenic		
nerve sheath	schwannoma, neurofibroma, neurofibromatosis	malignant peripheral nerve sheath tumor, neurogenic sarcoma, neurofibrosarcoma
sympathetic ganglionic cells	ganglioneuroma, ganglioneuroblastoma	neuroblastoma
chromaffin tissue = paraganglionic cells	paraganglioma, pheochromocytoma	malignant paraganglioma / pheochromocytoma
Germ cell, sex cord		
germ cell	mature teratoma, immature teratoma	seminoma, malignant teratoma, embryonal carcinoma, yolk sac tumor, choriocarcinoma, mixed germ cell tumor
sex cord stromal	granulosa cell tumor, thecoma, Sertoli-Leydig cell tumor	

Vascular Retroperitoneal Mass

A. INFLAMMATORY
B. LYMPHOPROLIFERATIVE
   1. Lymphoma
   2. Unicentric Castleman disease

C. MESENCHYMAL TUMOR
   1. Sarcoma
   2. Solitary fibrous tumor
   3. Leiomyoma
   4. GIST
   5. Hemangiopericytoma
   6. Congenital pelvic AVM

D. OTHERS
   1. Carcinoid
   2. Retroperitoneal paraganglioma

Calcified Retroperitoneal Mass

A. NONTUMORAL
   1. Exuberant callus formation
   2. Posttraumatic calcified hematoma
   3. Myositis ossificans
   4. Foreign body granuloma
   5. Encapsulated textiloma / gossypiboma
      (*gossypium*, Latin = cotton)
      Cause: retained surgical sponge, gauze, towel

B. BENIGN NEOPLASM
   1. Ganglioneuroma
   2. Schwannoma
   3. Paraganglioma
   4. Hemangioma
   5. Mature teratoma

C. MALIGNANT NEOPLASM
   1. Malignant fibrous histiocytoma
   2. Dedifferentiated liposarcoma
   3. Leiomyosarcoma
   4. Malignant mesenchymoma
   5. Malignant teratoma
   6. Extraskeletal osteosarcoma
   7. Chondrosarcoma
   8. Ewing sarcoma

Retroperitoneal Fluid

1. Traumatic injury to: pancreas, duodenum, renal collecting system
2. Retroperitoneal hemorrhage
3. Hypoperfusion shock complex
4. Abdominal compartment syndrome
5. Resuscitation effect

Disorders of Perirenal Space

A. PRIMARY LESION

(a) benign
1. Extramedullary hematopoiesis
2. Extraadrenal myelolipoma
3. Castleman disease
4. Erdheim-Chester disease

(b) malignant
1. Lymphoma / leukemia
2. Metastasis (lung)

B. RENAL LESION WITH EXTENSION

(a) benign
1. Angiomyolipoma
2. Xanthogranulomatous pyelonephritis
3. Leiomyoma
4. Hemangioma
5. Lymphangioma

(b) malignant
1. Renal cell carcinoma

C. RETROPERITONEAL LESION WITH EXTENSION

(a) BENIGN
1. Retroperitoneal fibrosis

(b) MALIGNANT
1. Lymphoma / leukemia
2. Metastatic lymphadenopathy
3. Malignant fibrous histiocytoma
4. Liposarcoma
5. Plasma cell neoplasm

Solitary Perirenal Mass

A. benign
1. XGP
2. Castleman disease
3. Hemangioma
4. Leiomyoma

B. malignant
1. RCC
2. Malignant fibrous histiocytoma
3. Lymphoma / leukemia

C. BORDERLINE
1. Hemangiopericytoma
2. GIST

Rindlike Perirenal Mass

1. Lymphoma
2. Retroperitoneal fibrosis
3. Erdheim-Chester disease

Multiple Perirenal Masses

1. Metastases: malignant melanoma; cancer of lung, breast, prostate
2. Plasma cell neoplasm: multiple myeloma, plasmacytoma, plasma cell leukemia

Fat-containing Perirenal Mass

1. Angiomyolipoma
2. Retroperitoneal liposarcoma
3. Extramedullary hematopoiesis
4. Extraadrenal myelolipoma

ADRENAL GLAND

Functioning Adrenal Mass

1. Cushing syndrome and Cushing disease
2. Primary aldosteronism
3. Pheochromocytoma

Adrenal Medullary Disease

1. Neuroblastoma
2. Ganglioneuroblastoma
3. Ganglioneuroma
4. Pheochromocytoma

Adrenal Cortical Disease

1. Adrenocortical hyperplasia
2. Adrenocortical adenoma
3. Adrenocortical carcinoma
4. Cushing syndrome
5. Conn syndrome
6. Adrenogenital syndromes

Adrenocortical Hyperfunction

1. Adrenogenital syndrome
2. Conn syndrome = hyperaldosteronism
3. Cushing syndrome = hypercortisolism

Bilateral Adrenal Masses

1. Metastases (50%)
2. Lymphoma (50% of secondary lymphomas, 50% bilateral)
3. Adenoma (20%)
4. Pheochromocytoma (10%)
5. Myelolipoma (5–13%)
6. Adrenocortical carcinoma (2–6%)
7. Hemorrhage
8. Granulomatous infection (usually bilaterally asymmetric)
9. Hyperplasia (usually bilaterally symmetric)

mnemonic: 4 H PM
Hodgkin disease
Hyperplasia
Hemorrhage
Histoplasmosis / TB
Pheochromocytoma
Metastasis

Granulomatous Disease
Organism: tuberculosis, histoplasmosis, blastomycosis
√ usually bilateral homogeneous adrenal enlargement in acute phase
√ sometimes cystic / calcified adrenals in chronic phase
Cx: tuberculous adrenal atrophy → adrenal hypofunction → Addison disease

Incidental Unilateral Adrenal Mass = Incidentaloma
= incidental discovery of a clinically silent adrenal mass of > 10 mm in a patient without known cancer
Prevalence: 4–9% of all CT exams (in 0.2% of patients 20–29 years, in 7% of elderly); 1.0–4.2% of population
Concern for: primary adrenal cortical carcinoma, metastasis, Cushing disease, pheochromocytoma, aldosteronoma versus nonfunctioning adenoma
◊ With a Hx of malignancy an adrenal nodule is a metastasis in merely 26–36%!
◊ 97–98% of incidentalomas are benign and insignificant!
◊ Most adenomas can be accurately characterized by NECT + MR ± CECT
◊ Follow-up imaging has a limited role
◊ Biopsy only if CT + MR do NOT indicate adenoma / PET-CT suggests metastasis
mnemonic: PLAN My HAM
Pheochromocytoma (6%)
Lymphoma
Adenoma (71%): functioning (1%)
Neuroblastoma
Myelolipoma
Hemorrhage
Adenocarcinoma (4%)
Metastasis (2–3%)

Bilaterality of Adrenal Incidentaloma
Frequency: in < 30% of adenomas
DDx: metastasis, lymphoma, infection, hyperplasia, hemorrhage

Morphologic Criteria of Adrenal Incidentaloma
(a) Size of lesion (too unreliable as only criterion)
Principle: Larger lesions are more likely malignant and more likely symptomatic!
› with known malignancy

< 3 cm: 87% are benign
> 3 cm: 95% are malignant
› without known malignancy
> 4 cm: 70% are malignant
> 6 cm: 85% are malignant
Rx: excision for incidentaloma > 5 cm

(b) Change in size
◊ Any increase in size after 6 months can be considered malignant!
CAVE: rare adenomas + myelolipomas can slightly increase in size

(c) Margin of lesion
◊ Irregular borders usually indicate malignancy!
◊ Multinodularity is usually benign!

(d) Internal texture
◊ Large necrotic areas signify malignancy
◊ Small metastases are often homogeneous

Problematic features of any adrenal mass: diffusely heterogeneous attenuation / focal areas of low attenuation / thickened wall

LIPID-SENSITIVE IMAGING OF ADRENAL INCIDENTALOMA

Principle: a benign adrenal mass contains intracytoplasmic fat, a malignancy does not
Substrate: cholesterol, fatty acids, neutral fat
Distribution: 70% of adenomas are lipid-rich; 30% of adenomas are lipid-poor + indeterminate

NECT attenuation (HU_{NECT}):
◊ dependent on scanner type + scanning technique!
ROI: in center of mass covering at least 50% of cross-sectional area
≤ 10 HU_{NECT} = benign lipid-rich adenoma / cyst
> 10 HU_{NECT} = indeterminate / lipid-poor adenoma
Sensitivity for adenomas: 56–71%
Specificity for adenomas: 98%
False-positive rate: 4%

For all practical purposes a < 3 cm homogeneous lesion that measures ≤ 10 HU at NECT is an adrenocortical adenoma!

CT histogram for NECT / CECT:
√ > 10% of pixel count below 0 HU indicates adenoma (sensitivity of 71% for NECT, 12% for CECT)

Chemical shift imaging MR (CSI):
Physics: fat protons precess at lower frequency than water protons
Useful: if lesion < 30 HU on NECT

(a) qualitatively (and effective):
√ fat + water summate to intermediate SI on in-phase images
√ fat + water signals cancel each other out to a low signal intensity on out-of-phase images

Most adenomas show a significant decrease in signal intensity on the out-of-phase images!

(b) quantitative method (rarely used in practice)

√ adrenal-to-spleen SI ratio (SIR) < 0.71

$SIR = SIR_{in\text{-}phase} \div SIR_{opposed\text{-}phase}$

√ signal intensity index (SII) > 16.5%

$SII = (SI_{in\text{-}phase} - SI_{opposed\text{-}phase}) \div SIin\text{-}phase \times 100$

Results: on average 67% of all indeterminate adrenal adenomas > 10 HU are lipid rich on CSI:

100% of adenomas measuring 10–20 HU

75% of adenomas measuring 20–30 HU

13% of adenomas measuring ≥ 30 HU

Indeterminate: lipid-poor adenomas with low lipid-to-water proton ratio per voxel

PERFUSION IMAGING OF ADRENAL INCIDENTALOMA BY CT

= CT washout scan (most effective test)

Principle: malignant vessels have an increased capillary permeability with prolonged retention of contrast material

Input values:

» 60-second scan ($HU_{CECT\ 1\ min}$)

» 15-minute delayed scan ($HU_{CECT\ 15\ min}$)

» ± precontrast CT (HU_{NECT})

(a) **Relative Percentage Washout (RPW)** (if unenhanced CT not available)

$= [HU_{CECT\ 1\ min} - HU_{CECT\ 15\ min}] / [HU_{CECT\ 1\ min}] \bullet 100\%$

washout > 60% = lipid-poor adenoma

washout ≤ 60% = indeterminate mass

Results: 96% sensitive + 100% specific

Absolute and Relative Washout of Adrenal Masses
Szolar DH et al.: Radiology 2005; 234:479–485

Adrenal Mass	*Absolute Washout [%]*	*Relative Washout [%]*
Adenoma	62 ± 17	108 ± 87
Adrenocortical carcinoma	34 ± 9	13 ± 12
Pheochromocytoma	22 ± 12	14 ± 7
Metastasis	31 ± 16	19 ± 11

(b) **Absolute Percentage Washout** (APW) (if unenhanced CT available)

= [HUCECT 1 min – HUCECT 15 min] / [HUCECT 1 min – HUNECT] • 100%

washout > 40% = lipid-poor adenoma

washout ≤ 40% = indeterminate mass

Results: 88% sensitive + 96% specific

Lesions with RPW of < 40% / APW of < 60% are almost always malignant!

◊ A mass with absolute enhancement > 110–120 HU + APW of > 60% + RPW of > 40% suggests a pheochromocytoma

FUNCTIONAL IMAGING WITH 18F-FDG PET

Principle: FDG trapped intracellularly by metabolically active malignant lesion

Use: modality of choice in known malignancy
◊ 50% of incidentalomas in cancer patients represent metastatic disease!
Internal reference organ: liver
SUV: > 4 for metastatic disease ← lung, colon, melanoma, lymphoma
FN: pulmonary carcinoid, lung cancer with strong bronchioloalveolar component, hemorrhagic / necrotic tumor, lesion < 10 mm in size
FP: 5% of adrenal adenomas, pheochromocytoma, adrenal endothelial cyst, inflammation, infection
Results: 93–100% sensitive, 80–100% specific, 99% accurate

ENDOCRINOLOGIC FUNCTION TEST IN INCIDENTALOMA

Use: recommended for lesions > 4 cm
Frequency: 6%
Yield:
› 94% nonfunctioning adrenal adenoma
› 6% functioning adrenal adenoma
» cortisol production (5%) → Cushing syndrome
» aldosterone (< 2%) → Conn syndrome
» catecholamines → pheochromocytoma
» sex hormone (1%)

ADRENAL BIOPSY

Indication: inconclusive / contradictory adrenal imaging with high clinical suspicion for metastasis from an underlying extraadrenal malignancy
Diagnostic accuracy: 83–96%
Insufficient material: 4–19%
Cx: bleeding, pneumothorax, infection, tumor tracking in 8–12%
N.B.: several deaths reported after Bx of pheochromocytoma

Adrenal Mass with specific CT Attenuation

1. Acute hemorrhage: 50–90 HU
2. Adrenal myelolipoma: fat attenuation
3. Adrenal cyst: fluid attenuation

Fat-containing Adrenal Mass

(a) intracellular fat → SI loss on out-of-phase images
1. Adrenal adenoma
(b) macroscopic fat → SI loss on fat-saturated images
1. Myelolipoma

Adrenal Mass with Small Foci of Fat

◊ Not every adrenal mass with a small amount of fat is a myelolipoma!
1. Myelolipoma
2. Adrenocortical adenoma with myelolipomatous changes
3. Adrenocortical carcinoma
4. Pheochromocytoma

Small Unilateral Adrenal Tumor

1. Cortical adenoma (in 1–9% of autopsies)
   √ < 10 HU imply an adenoma (in 96%)
2. Metastasis
3. Pheochromocytoma
4. Asymmetric hyperplasia
5. Granulomatous disease (TB, histoplasmosis)
   √ diffuse enlargement / discrete mass
   √ ± central cystic changes ± calcification
6. Myelolipoma

Large Solid Adrenal Mass

Large tumors ≥ 6 cm are highly suspicious for malignancy!

1. Adrenocortical carcinoma
2. Pheochromocytoma
3. Neuroblastoma / ganglioneuroma
4. Myelolipoma
5. Metastasis
6. Hemorrhage
7. Inflammation
8. Abscess (eg, histoplasmosis, tuberculosis)
9. Hemangioma

Malignant Adrenal Mass

1. Adrenocortical carcinoma
2. Angiosarcoma
3. Lymphoma
4. Malignant pheochromocytoma
5. Neuroblastoma
6. Metastasis
7. **Collision tumor**
   = concomitant benign adenoma + metastasis
   Frequency: in 2% of patients with known primary
   N.B.: Percutaneous biopsy may be falsely negative ← sampling of the benign component!

Benign Adrenal Lesion

1. Adenoma
2. Myelolipoma
3. Adrenal cyst
4. Adrenal hemorrhage
5. Ganglioneuroma
6. Schwannoma
7. Hemangioma
8. Lymphangioma of adrenal gland

9. Granuloma
10. Pheochromocytoma
11. Adenomatoid tumor
12. Oncocytoma of adrenal gland

Adrenal Tumor in Childhood

1. Neuroblastoma (most common extracranial solid tumor)
2. Pheochromocytoma
3. Adrenocortical carcinoma
4. Lymphoma

Cystic Adrenal Mass

1. Pseudocyst: old hemorrhage / infarction
2. Vascular cystic space (endothelial lining): lymphangioma, hemangioma
3. True cyst (epithelial lining): glandular cyst, embryonal cyst, mesothelial inclusion cyst
4. Parasitic cyst: hydatid cyst
5. Hemorrhagic complication / degeneration of a tumor:
   cystic adenoma, cystic pheochromocytoma, cystic adenomatoid tumor, cystic adrenocortical carcinoma, schwannoma with cystic degeneration
6. Neuroblastoma (rare)
7. Cortical adenoma with low density

Adrenal Calcification

A. TUMOR
   1. Neuroblastoma
   2. Pheochromocytoma
   3. Adrenal adenoma
   4. Adrenal carcinoma
   5. Dermoid
B. VASCULAR
   1. Hemorrhage (neonatal, sepsis)
C. INFECTION
   1. Tuberculosis
   2. Histoplasmosis
   3. Waterhouse-Friderichsen syndrome
D. ENDOCRINE
   1. Addison disease (TB)
E. OTHERS
   1. Wolman disease

Adrenal Hemorrhage

Unilateral Adrenal Hemorrhage

A. TRAUMA (80%)
B. BLEEDING INTO UNDERLYING ADRENAL TUMOR
   1. Pseudocyst

2. Myelolipoma
3. Hemangioma
4. Pheochromocytoma
5. Adrenocortical adenoma / carcinoma
6. Metastasis: bronchogenic carcinoma, angiosarcoma, melanoma

Bilateral Adrenal Hemorrhage

A. NEONATAL STRESS

◊ Most common neonatal lesion of adrenal gland

1. Difficult labor / delivery: forceps / breech delivery
2. Asphyxia / hypoxia ← prematurity
3. Septicemia
4. Hemorrhagic disorders: DIC, hypoprothrombinemia
5. Extracorporeal membrane oxygenation (in 4%)
6. Thrombus extending from renal vein thrombosis

Predisposed: infants large for gestational age, infants of diabetic mothers

Age: 1st week of life

Site: R÷L = 7÷3; bilateral in 10%

B. ADULT STRESS

Pathophysiology:

stress → severalfold ⇑ in endogenous secretion of adrenocorticotropic hormone → ⇑ in adrenal vascularity; ⇑ in catecholamines, thrombin, fibrin, endotoxin during shock → venoconstriction + venous thrombosis → intraglandular hemorrhage

1. Surgery: orthotopic liver transplantation
2. Sepsis: Waterhouse-Friderichsen syndrome (= fulminant meningococcemia); Pseudomonas infection; other gram-negative organisms
3. Burns
4. Hypotension
5. Pregnancy
6. Cardiovascular disease
7. Exogenous adrenocorticotropic hormone
8. Exogenous steroids

C. HEMORRHAGIC DIATHESIS & COAGULOPATHY

1. Anticoagulant therapy (heparin, coumadin): during initial 3 weeks
2. Disseminated intravascular coagulopathy
3. Antiphospholipid syndrome ± systemic lupus erythematosus (hypercoagulable state causes adrenal vein thrombosis + venous infarction)

KIDNEY

Developmental Renal Anomalies

Numerary Renal Anomaly

1. Supernumerary kidney
2. Complete / partial renal duplication

3. Abortive calyx
4. Unicaliceal (unipapillary) kidney

Renal Underdevelopment

1. Congenital renal hypoplasia
2. Renal agenesis
3. Renal dysgenesis

Renal Ectopia

Normal location of kidneys: 1st–3rd lumbar vertebra
Prevalence: 0.2% (autopsy series)
Cause: failure of kidney to ascend by 8 weeks GA
At risk of: infection, calculi, hydronephrosis ← UPJ obstruction
√ unusual developmental "funny-looking calyces" often misinterpreted as obstructive
√ loop-to-loop colon = abnormal looped configuration of colon occupying the renal fossa

LONGITUDINAL RENAL ECTOPIA

Location: pelvic, sacral, lower lumbar level, intrathoracic; L > R
√ must demonstrate aberrant arteries
DDx: displacement through diaphragmatic hernia (nonaberrant); hypermobile kidney

Pelvic Kidney

= ectopic kidney ← failure of renal ascent
Prevalence: 1÷725 births
May be associated with:
(1) Vesicoureteral reflux
(2) Hydronephrosis ← abnormally high insertion of ureter into renal pelvis
(3) Hypospadia (common)
(4) Contralateral renal agenesis
√ blood supply via iliac vessels / aorta
√ nonrotation = anteriorly positioned renal pelvis (common)

CROSSED RENAL ECTOPIA

= kidney located on opposite side of midline from its ureteral orifice; usually L > R and crossed kidney inferior to normal kidney
(a) fused (common)
(b) separate (rare)
Cause: ? faulty development of ureteral bud, vascular obstruction of renal ascent
Associated with: obstruction urolithiasis, infection, reflux, megaureter, hypospadia, cryptorchidism, urethral valves, multicystic dysplasia
√ invariably aberrant renal arteries
√ distal ureter inserts into trigone on the side of origin

RENAL FUSION ANOMALIES

= "lump / cake, disk, horseshoe"
Cx: aberrant arteries may cross and obstruct ureter

Horseshoe Kidney

= fusion of lower renal poles with isthmus across midline anterior to aorta

Prevalence: 1÷400 live births

Associated with: vertebral, anorectal, tracheal, esophageal malformations

√ anomalous vascular supply

√ anomalous renal rotation

Cx: varying degrees of obstruction, stone formation, infection

Disc / Pancake Kidney

= bilateral fused pelvic kidneys

Associated with: abnormal testicular descent, tetralogy of Fallot, vaginal agenesis, sacral agenesis, caudal regression, anal anomalies

RENAL MALROTATION

√ collecting structures may be positioned ventrally (most common), lateral (rare), dorsal (rarer), transverse (along AP axis)

√ "funny-looking calices" = developmental usually nonobstructive ectasia

Absent Renal Outline on Plain Film

A. ABSENT KIDNEY
   1. Congenital absence
   2. S/P nephrectomy
B. SMALL KIDNEY
   1. Renal hypoplasia
   2. Renal atrophy
C. RENAL ECTOPIA
   1. Pelvic kidney
   2. Crossed fused ectopia
   3. Intrathoracic kidney
D. OBLITERATION OF PERIRENAL FAT
   1. Perirenal abscess
   2. Perirenal hematoma
   3. Renal tumors

Perinephric Fat Stranding

√ nonspecific perirenal cobwebs

Pathophysiology: engorged lymphatics, edema, fluid extravasation from pyelosinus

1. Acute obstructing renal calculus: ureteral colic
2. Infection
3. Infarction
4. Neoplasm
5. Trauma
6. Renal vein thrombosis

Nonvisualized Kidney on Excretory Urography

A. ABSENCE OF KIDNEY

1. Agenesis
2. Surgical absence
3. Renal ectopia

B. LOSS OF PERFUSION
1. Chronic infarction
2. Unilateral renal vein thrombosis

C. TRAUMA
1. Thrombosis of main renal artery
2. Severe contusion → renal vasospasm
3. Avulsion of renal pedicle

D. HIGH-GRADE URINARY OBSTRUCTION
1. Hydronephrosis
2. Ureteropelvic junction obstruction

E. REPLACED NORMAL RENAL PARENCHYMA
1. Multicystic dysplastic kidney
2. Unilateral polycystic kidney disease
3. Renal tumor (RCC, TCC, Wilms tumor)
4. Xanthogranulomatous pyelonephritis

Faceless Kidney

= absence of normal components of renal sinus (renal parenchyma, fat and collecting system) on cross-sectional imaging

1. Duplicated collecting system
2. Urothelial renal tumor (TCC, SCC)
3. Lymphoma of kidney
4. Inflammatory / infectious mass

Unilateral Large Smooth Kidney

A. PRERENAL
(a) arterial: acute arterial infarction
(b) venous: acute renal vein thrombosis

B. INTRARENAL
(a) congenital: duplicated pelvicaliceal system, crossed fused ectopia, multicystic dysplastic kidney, adult polycystic kidney (in 8% unilateral)
(b) infectious: acute bacterial nephritis
(c) adaptation: compensatory hypertrophy

C. POSTRENAL
(a) collecting system: obstructive uropathy

mnemonic: AROMA

Acute pyelonephritis
Renal vein thrombosis
Obstructive uropathy
Miscellaneous (compensatory hypertrophy, duplication)
Arterial obstruction (infarction)

Bilateral Large Kidneys

Average renal length by x-ray: M = 13 cm; F = 12.5 cm

1. PROTEIN DEPOSITION amyloidosis, multiple myeloma
2. INTERSTITIAL FLUID ACCUMULATION acute tubular necrosis, acute cortical necrosis, acute arterial infarction, renal vein thrombosis
3. CELLULAR INFILTRATION
   (a) Inflammatory cells: acute interstitial / bacterial nephritis
   (b) Malignant cells: leukemia / lymphoma, bilateral Wilms tumor, nephroblastomatosis
4. PROLIFERATIVE / NECROTIZING DISORDERS
   (a) Glomerulonephritis (GN) acute (poststreptococcal) GN, rapidly progressive GN, idiopathic membranous GN, glomerulosclerosis, lobular GN, IgA nephropathy, membranoproliferative GN, glomerulosclerosis related to heroin abuse
   (b) Multisystem disease polyarteritis nodosa, systemic lupus erythematosus, Wegener granulomatosis, allergic angiitis, diabetic glomerulosclerosis, Goodpasture syndrome (lung hemorrhage + glomerulonephritis), Schönlein-Henoch syndrome (anaphylactoid purpura), thrombotic thrombocytopenic purpura, focal glomerulonephritis associated with subacute bacterial endocarditis
5. URINE OUTFLOW OBSTRUCTION bilateral hydronephrosis: congenital / acquired
6. HORMONAL STIMULUS acromegaly, compensatory hypertrophy, nephromegaly associated with cirrhosis / hyperalimentation / diabetes mellitus
7. DEVELOPMENTAL bilateral renal duplication, horseshoe kidney, polycystic kidney disease
8. MISCELLANEOUS acute urate nephropathy, glycogen storage disease, hemophilia, sickle cell disease, Fabry disease, physiologic response to contrast material and diuretics

mnemonic: FOG P

Fluid: edema of kidney (ATN, acute cortical necrosis)
Other: leukemia, acromegaly, sickle cell anemia, bilateral duplication, acute urate nephropathy
Glomerular disease: acute GN, lupus, polyarteritis nodosa, diabetes mellitus
Protein deposition: multiple myeloma, amyloidosis

Bilateral Small Kidneys

A. PRERENAL = VASCULAR
   1. Arterial hypotension (acute)
   2. Generalized arteriosclerosis
   3. Atheroembolic disease
   4. Benign & malignant nephrosclerosis
B. INTRARENAL
   1. Hereditary nephropathies: medullary cystic disease, hereditary chronic nephritis (Alport syndrome)
   2. Chronic glomerulonephritis
   3. Amyloidosis (late)
C. POSTRENAL
   1. Papillary necrosis
D. CAUSES OF UNILATERAL SMALL KIDNEY above causes occurring bilaterally

mnemonic: CAPE HANA
Chronic glomerulonephritis
Arteriosclerosis
Papillary necrosis
Embolic disease ← atherosclerosis
Hypotension
Alport syndrome
Nephrosclerosis
Amyloidosis (late)

Unilateral Small Kidney

A. PRERENAL = VASCULAR
   1. Lobar infarction
   2. Chronic infarction
   3. Renal artery stenosis
   4. Radiation nephritis
B. INTRARENAL = PARENCHYMAL
   1. Congenital hypoplasia
   2. Multicystic dysplastic kidney (in adult)
   3. Postinflammatory atrophy
C. POSTRENAL = COLLECTING SYSTEM
   1. Reflux nephropathy = chronic atrophic pyelonephritis
   2. Postobstructive atrophy

mnemonic: RIP R HIP
Reflux atrophy
Ischemia: renal artery stenosis
Postobstructive atrophy
Radiation therapy
Hypoplasia: congenital
Infarction
Postinflammatory atrophy

Increased Echogenicity of Renal Cortex

= RENAL MEDICAL DISEASE
= diffuse increase in cortical echogenicity with preservation of corticomedullary junction
Path: deposition of collagen / calcium in interstitial, glomerular, tubular, vascular disease
√ echointensity of cortex greater than liver / spleen ± equal to renal sinus
√ renal size may be normal; enlarged kidneys suggest active stage of renal disease; small kidneys suggest chronic + often end-stage renal disease
Cause:
1. Acute / chronic glomerulonephritis
2. Renal transplant rejection
3. Lupus nephritis
4. Hypertensive nephrosclerosis
5. Renal cortical necrosis

6. Methemoglobulinuric renal failure
7. Alport syndrome
8. Amyloidosis
9. Diabetic nephrosclerosis
10. Nephrotoxin-induced acute tubular necrosis
11. End-stage renal disease

Hyperechoic Renal Pyramids in Children

A. MEDULLARY NEPHROCALCINOSIS
B. METABOLIC DISEASE
   1. Gout
   2. Lesch-Nyhan syndrome (urate)
   3. Fanconi syndrome
   4. Glycogen storage disease (distal RTA)
   5. Wilson disease (distal RTA)
   6. Alpha-1 antitrypsin deficiency
   7. Tyrosinemia
   8. Cystinosis
   9. Oxalosis
   10. Crohn disease
C. HYPOKALEMIA
   1. Primary aldosteronism
   2. Pseudo-Bartter syndrome
D. PROTEIN DEPOSITS
   1. Infant dehydration with presumed Tamm-Horsfall proteinuria
   2. Toxic shock syndrome
E. VASCULAR CONGESTION
   1. Sickle cell disease
F. INFECTION
   1. Candida / CMV nephritis
   2. AIDS-associated Mycobacterium avium-intracellulare
G. FIBROSIS OF RENAL PYRAMIDS
H. CYSTIC MEDULLARY DISEASE
   1. Medullary sponge kidney
   2. Congenital hepatic fibrosis with tubular ectasia
I. INTRARENAL REFLUX
   1. Chronic pyelonephritis

Hyperechoic Pyramids in Neonate

1. Transient hyperechogenicity (4–58%): resolves within 10 days or longer in prematurity
   Cause: uncertain
2. Obstructed hydronephrosis
3. Ischemia: ATN, medullary / cortical necrosis, renal vein thrombosis
4. Infection: candida
5. Polycystic kidney disease: ADPKD, Beckwith-Wiedemann syndrome

6. Metabolic

Iron Accumulation in Kidney

A. RENAL CORTEX
   1. Paroxysmal nocturnal hemoglobulinuria (= intravascular extrasplenic hemolysis)
   2. Sickle cell anemia

B. RENAL MEDULLA
   1. Hemorrhagic fever with renal syndrome (uncommon viral illness caused by Hantavirus)

Triad: (1) Renal medullary hemorrhage
(2) Right atrial hemorrhage
(3) Necrosis of anterior pituitary

Cold Defect on Renal Scintigraphy

mnemonic: CHAT SIN

Cyst
Hematoma
Abscess
Tumor
Scar
Infarct
Neoplasm

Abnormal Uptake of Bone Agents within Kidneys

1. Effect of chemotherapeutic drugs: bleomycin, cyclophosphamide, doxorubicin, mitomycin C, 6-mercaptopurine
2. S/P radiation therapy
3. Metastatic calcification
4. Pyelonephritis
5. Acute tubular necrosis
6. Iron overload
7. Multiple myeloma
8. Renal vein thrombosis
9. Ureteral obstruction

Incidental Urinary Tract Abnormalities during Bone Scintigraphy

> 50% of injected dose of ^{99m}Tc-MDP is excreted by 3 hours

A. Bilateral diffuse increased uptake
   = uptake greater than that of lumbar spine
   (a) excess tissue calcium
      1. Hyperparathyroidism
      2. Hypercalcemia
      3. Osteosarcoma metastatic to kidney
   (b) tissue damage
      1. Drug-induced nephrotoxicity
         › chemotherapy: eg, cyclophosphamide, vincristine, doxorubicin, bleomycin,

mitomycin-C, S-6-mercaptopurine, mitoxantrone
› aminoglycosides
› amphotericin B
2. Radiation therapy
3. Necrotic renal cell carcinoma (rare)
4. Renal metastasis (rare)
5. Acute pyelonephritis
6. Acute tubular necrosis
7. Multiple myeloma

(c) iron overload
1. Sickle cell anemia
2. Thalassemia major

mnemonic: RICH CON
Radiation therapy to kidney
Iron overload
Chemotherapy (cytoxan, vincristine, doxorubicin)
Hyperparathyroidism
Calcification (metastatic), **C**arcinoma
Obstruction (urinary)
Nephritis, **N**ormal variant

B. Bilateral decreased renal uptake
(a) loss of renal function
1. End-stage renal disease
(b) increased osteoblastic activity (= superscan)

C. Focally decreased renal uptake
(a) space-occupying lesion replacing renal parenchyma
1. Abscess
2. Cyst
3. Primary / metastatic renal neoplasm

(b) scar
1. Infarct
2. Chronic pyelonephritis
3. Partial nephrectomy

D. Uni- / bilateral focally increased GU uptake ← urine accumulation
1. Normal upper pole calyces: in supine position
2. Urinary tract diversion / ileal conduit
3. Urinoma

E. Change in location of kidney
1. Congenital anomaly: eg, pelvic kidney

Depression of Renal Margins

1. Fetal lobation
√ notching between normal calyces
2. Splenic impression
√ flattened upper outer margin of left kidney

3. Chronic atrophic pyelonephritis
   √ indentation over clubbed calyces
4. Renal infarct
   √ normal calyces
5. Chronic renal ischemia
   √ normal calyces

Enlargement of Iliopsoas Compartment

A. INFECTION
   (a) from retroperitoneal organs
      1. Renal infection
      2. Complicated pancreatitis
      3. Postoperative aortic graft infection
   (b) from spine
      1. Osteomyelitis / postoperative complication of bone surgery
      2. Diskitis / postoperative complication ← disk surgery
   (c) from GI tract
      1. Crohn disease
      2. Appendicitis
   (d) others
      1. Pelvic inflammatory disease / postpartum infection
      2. Sepsis
B. HEMORRHAGE
   1. Coagulopathy and anticoagulant therapy
   2. Ruptured aortic aneurysm
   3. Postoperative aneurysm repair / other surgery / trauma
C. NEOPLASTIC DISEASE
   (a) extrinsic
      1. Lymphoma
      2. Metastatic lymphadenopathy
      3. Bone metastases with soft-tissue involvement
      4. Retroperitoneal sarcoma
   (b) intrinsic
      1. Muscle tumors
      2. Nervous system tumors
      3. Lipoma / liposarcoma
D. MISCELLANEOUS
   1. Pseudoenlargement of psoas muscle compared with de facto atrophy of contralateral side in neuromuscular dz
   2. Fluid collection: urinoma, lymphocele, pancreatic pseudocyst, enlargement of iliopsoas bursa
   3. Pelvic venous thrombosis
      √ diffuse swelling of all muscles (edema)

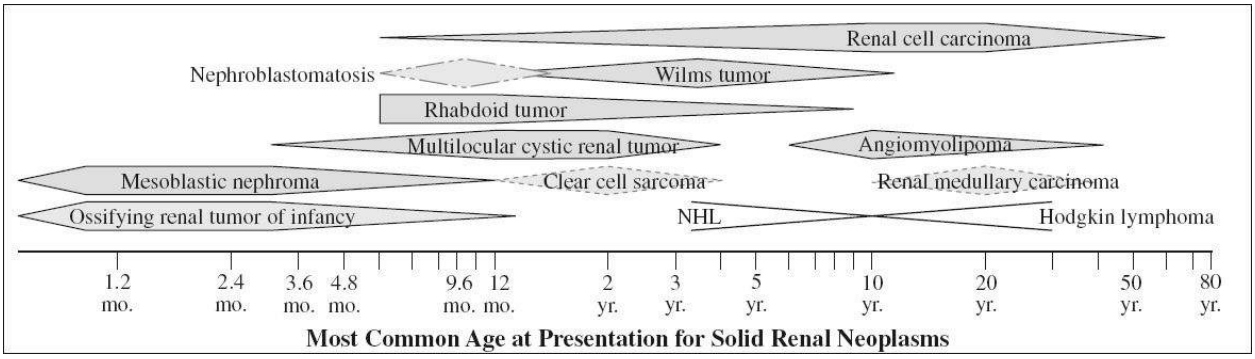
RENAL MASS

Renal Tumors in Adults by Histology (WHO 2004)

A. Renal cell tumor
B. Metanephric tumor
C. Mesenchymal tumor
   (a) benign:
      1. Angiomyolipoma
      2. Leiomyoma of kidney
      3. Hemangioma of kidney
      4. Lymphangioma of kidney
      5. Juxtaglomerular cell tumor
      6. Renomedullary interstitial cell tumor
      7. Solitary fibrous tumor
      8. others: lipoma, schwannoma
   (b) malignant:
      ◊ Primary renal sarcomas account for 1–3% of all malignant renal tumors!
      1. Leiomyosarcoma of kidney (50–60%)
      2. Others: synovial sarcoma, osteosarcoma, fibrosarcoma, rhabdomyosarcoma, angiosarcoma, malignant fibrous histiocytoma, solitary fibrous tumor
D. Mixed mesenchymal and epithelial tumor
E. Neuroendocrine tumor
F. Germ cell tumor

Renal Mass in Neonate

A. UNILATERAL
   1. Multicystic kidney (15%)
   2. Hydronephrosis (25%)
      (a) UPJ obstruction
      (b) upper moiety of duplication
   3. Renal vein thrombosis
   4. Mesoblastic nephroma
      ◊ Most common primary renal neoplasm in 1st month of life
   5. Rare: Wilms tumor, teratoma



Most Common Age at Presentation for Solid Renal Neoplasms

B. BILATERAL

1. Hydronephrosis
2. Polycystic kidney disease
3. Multicystic kidney + contralateral hydronephrosis
4. Nephroblastomatosis
5. Bilateral multicystic kidney

Renal Tumors in 1st Decade of Life

1. Wilms tumor
2. Cystic nephroma and cystic partially differentiated nephroblastoma
3. Mesoblastic nephroma
4. Clear cell sarcoma
5. Rhabdoid tumor
6. Ossifying renal tumor of infancy
7. Renal cell carcinoma
8. Angiomyolipoma
9. Metanephric stromal tumor

Renal Mass in Older Child

A. SINGLE MASS
   (a) single solid mass
      1. Wilms tumor 87%
      2. Clear cell sarcoma of kidney 6%
      3. Mesoblastic nephroma 2%
      4. Rhabdoid tumor 2%
      5. Renal cell carcinoma < 0.5%
      6. Teratoma
      7. Intrarenal neuroblastoma
   (b) single cystic mass
      1. Focal hydronephrosis
      2. Multilocular cystic nephroma
      3. Traumatic cyst, abscess

B. MULTIPLE MASSES
   1. Nephroblastomatosis
   2. Multiple Wilms tumors
   3. Angiomyolipoma
   4. Lymphoma (< 0.5%)
   5. Leukemia
   6. Adult polycystic kidney disease
   7. Abscesses

Bilateral Renal Masses

A. MALIGNANT TUMOR
   1. Malignant lymphoma / Hodgkin disease
   2. Metastases
   3. Renal cell carcinoma

4. Wilms tumor

B. BENIGN TUMOR
   1. Angiomyolipoma
   2. Nephroblastomatosis

C. CYSTS
   1. Adult polycystic kidney disease
   2. Acquired cystic kidney disease

Unilateral Renal Mass

Solid Renal Mass

A. TUMORS
   (a) primary malignant:
   › epithelial tumor of renal parenchyma: adenocarcinoma (83%), papillary neoplasm (14%), chromophobe carcinoma (4%), renal neuroendocrine tumors (carcinoid, small cell carcinoma), Wilms tumor (6%)
   › epithelial tumor of renal pelvis: TCC (8%), squamous cell carcinoma
   › medullary tumor: renal medullary carcinoma, renal collecting duct carcinoma = Bellini duct carcinoma (1%)
   › renal sarcoma (2%)
   <u>in horseshoe kidney:</u>
   adenocarcinoma (45%), Wilms tumor (28%), transitional cell carcinoma (20%)
   (b) secondary malignant: malignant lymphoma / Hodgkin disease, metastases, invasive transitional cell carcinoma
   (c) benign: adenoma, oncocytoma, hamartoma (mesoblastic nephroma, angiomyolipoma, myolipoma, lipoma, leiomyoma, fibroma), hemangioma

B. INFLAMMATORY MASSES
   acute focal pyelonephritis, renal abscess, malakoplakia, xanthogranulomatous pyelonephritis, tuberculoma

Fluid-filled Renal Lesion

A. CYSTS
   1. Simple renal cyst
      √ simple fluid attenuation of 0–20 HU
   2. Complicated renal cyst
   3. Inherited cystic disease:
      multicystic dysplastic kidney disease (Potter type II), multilocular cystic nephroma
   4. Focal hydronephrosis

B. VASCULAR
   1. Arteriovenous malformation
   2. Arteriovenous fistula

C. CYSTIC MASS
   1. Renal cell carcinoma

◊ Lesions < 1 cm often cannot be clearly characterized!
◊ Lesions 1–1.5 cm can often be ignored, particularly in elderly / patients with significant

other disease

Calcified Renal Mass

◊ A calcified renal mass is malignant in 75% of cases!
◊ Lesions with
(a) nonperipheral calcifications are malignant in 87%!
(b) peripheral calcifications are malignant in 20%!

A. MALIGNANT TUMOR
1. Renal cell carcinoma (calcifies in 8–20%)
√ calcifications generally nonperipheral, sometimes along fibrous capsule
2. Wilms tumor
3. Transitional cell carcinoma (rare)
4. Osteosarcoma of renal capsule
5. Metastasis

B. INFECTION
1. Abscess
◊ Tuberculous abscess frequently calcifies!
◊ Pyogenic abscess rarely calcifies!
2. Echinococcal cyst
◊ Renal involvement in 3% of hydatid disease;
◊ 50% of echinococcal cysts calcify
3. Xanthogranulomatous pyelonephritis
√ large obstructive calculus in > 70%

C. CYSTS
◊ Calcification is related to prior hemorrhage / infection!
1. Simple renal cyst (calcifies in 1–3%)
√ thin peripheral "eggshell"-like calcification
2. Multicystic dysplastic kidney (in adult)
3. Autosomal dominant polycystic kidney disease
4. Milk of calcium: cyst, caliceal diverticulum, obstructed hydrocalyx
DDx: residual pantopaque used in cyst puncture

D. VASCULAR
1. Subcapsular / perirenal hematoma
2. Renal artery aneurysm
√ circular cracked eggshell appearance
3. Congenital / posttraumatic arteriovenous malformation
4. Arteriosclerosis: in severe atherosclerotic disease, diabetes mellitus, hyperparathyroidism
5. Sloughed papilla: in papillary necrosis
6. Hemangioma

Avascular Mass in Kidney

mnemonic: CHEAT
Cyst
Hematoma

Edema
Abscess
Tumor

Growth Pattern of Renal Lesions

Renal Lesion with Expansile Growth Pattern

1. Renal cell carcinoma
2. Oncocytoma
3. Angiomyolipoma
4. Juxtaglomerular tumor
5. Metastatic tumor: eg, lymphoma
6. Mesenchymal tumor

Renal Lesions with Infiltrative Growth Pattern

Imaging hallmarks:

√ growth initially respects renal contour
√ invasion of normal structures
√ poorly defined interface between normal renal parenchyma and lesion
√ enlarged kidney with preservation of reniform shape

IVP:

√ decreased / absent nephrogram

Angio:

√ vascular encasement, pruning, amputation
√ no vascular displacement

CT:

√ poorly marginated area of diminished enhancement
√ encasement of collecting system without displacement
√ replacement of renal sinus fat

US:

√ poorly circumscribed hypo- / hyperechoic regions

A. NEOPLASM
   (a) lymphoproliferative
      1. Lymphoma / leukemia
      2. Extramedullary plasmacytoma
   (b) epithelial tumor of renal parenchyma
      1. Renal cell carcinoma (unusual)
      2. High-grade and sarcomatoid type of RCC
   (c) epithelial tumors of the renal pelvis
      1. Invasive transitional cell carcinoma

√ mass arises from collecting system

      2. Squamous cell carcinoma
   (d) medullary tumor of uncertain cell origin
      1. Collecting duct carcinoma
      2. Renal medullary carcinoma

(e) metastases: esp. lung cancer
(f) renal sarcomas
(g) pediatric tumor
1. Mesoblastic nephroma
2. Rhabdoid tumor of the kidney
3. Nephroblastomatosis
4. Primitive neuroectodermal tumor
5. Wilms tumor (unusual)

B. INFLAMMATION
1. Bacterial pyelonephritis
2. Xanthogranulomatous pyelonephritis
3. Renal parenchymal malakoplakia

Local Bulge in Renal Contour

A. CYST
1. Simple renal cyst

B. TUMOR
1. Adenocarcinoma
2. Angiomyolipoma
3. Pseudotumor

C. INFECTION
1. Subcapsular abscess
2. XGP

D. TRAUMA
1. Subcapsular hematoma

E. DILATED COLLECTING SYSTEM

Hyperechoic Renal Nodule

A. MALIGNANT TUMOR
1. Renal cell carcinoma
2. Angiosarcoma
3. Liposarcoma
4. Undifferentiated sarcoma
5. Lymphoma

B. BENIGN TUMOR
1. Angiomyolipoma
2. Lipoma
3. Oncocytoma
4. Cavernous hemangioma

C. INFARCT

D. HEMATOMA

Focal Area of Increased Renal Echogenicity

A. NONNEOPLASTIC
1. Chronic renal infarction

2. Acute focal bacterial nephritis

B. BENIGN TUMOR
   1. Angiomyolipoma
   2. Cavernous renal hemangioma
   3. Oncocytoma

C. MALIGNANCY
   1. Renal cell carcinoma
   2. Angiosarcoma
   3. Undifferentiated sarcoma
   4. Metastasis

Hyperattenuating Renal Mass on NECT

= attenuation higher than
   (a) renal parenchyma (> 40 HU)
   (b) > 20 HU (more restrictive definition)

Pathogenesis:
   (a) elevated iron content
   (b) blood breakdown products, high protein content, colloid formation
   (c) infection
   (d) transient iodine accumulation in cyst
   (e) completely solid mass
   (f) diffuse microcalcifications

A. BENIGN
   1. Complicated benign cyst: hemorrhagic, protein-rich, gelatinous (most common), eg, in autosomal dominant polycystic kidney disease
   2. Hematoma, renal contusion
   3. Vascular abnormality: AVM, pseudoaneurysm, aneurysm, thrombosed renal vein
   4. Focal inflammation: focal bacterial nephritis
   5. Angiomyolipoma (4–5% without fat)
   6. Metanephric adenoma
   7. Leiomyoma

B. MALIGNANT
   1. Malignant multiseptate cyst: multilocular cystic nephroma, cystic renal cell carcinoma
   2. Renal cell carcinoma (2% hyperattenuating)
   3. Papillary renal cell carcinoma
   4. Lymphoma (rare)
   5. Oncocytoma (rare)
   6. Metastasis from thyroid carcinoma

Fat-containing Renal Mass

1. Angiomyolipoma
2. Lipoma, liposarcoma
3. Teratoma
4. Wilms tumor
5. Xanthogranulomatous pyelonephritis

6. Oncocytoma engulfing renal sinus fat
7. Renal cell carcinoma
   (a) invasion of perirenal fat
   (b) intratumoral metaplasia into fatty marrow (in 32% of RCCs < 3 cm in diameter)

◊ If a lesion contains fat + calcium RCC is likely, NOT angiomyolipoma!

Renal Pseudotumor

= normal renal tissue mimicking a renal mass

A. PRIMARY / CONGENITAL

1. **Large column of Bertin**
   = LARGE SEPTUM / CLOISON OF BERTIN = LARGE CLOISON = FOCAL CORTICAL HYPERPLASIA = BENIGN CORTICAL REST = FOCAL RENAL HYPERTROPHY
   = persistence of normal septal cortex / excessive infolding of cortex usually in the presence of partial or complete duplication
   Location: between upper and interpolar portion
   √ mass < 3 cm in largest diameter
   √ lateral indentation of renal sinus
   √ "deformation" of adjacent calyces + infundibula
   √ mass continuous with renal cortex
   √ enhancement pattern like renal cortex
   √ echogenicity similar to cortex
2. **Dromedary hump**
   = SUBCAPSULAR NODULE = SPLENIC BUMP
   Cause: prolonged pressure by spleen during fetal development
   Location: in mid portion of lateral border of left kidney
   √ triangular contour + elongation of middle calyx
   √ enhancement pattern like renal cortex
3. **Hilar lip**
   = SUPRA- / INFRAHILAR BULGE
   = medial part of kidney above / below sinus
   Location: most frequently medial to left kidney just above renal pelvis (on transaxial scan)
   √ enhancement pattern like cortex with medulla
4. **Fetal lobation**
   = PERSISTENT CORTICAL LOBATION = REN LOBATUS
   = 14 individual lobes with centrilobar cortex located around calyces
5. **Lobar dysmorphism** complete diminutive lobe situated deep within renal substance with its own diminutive calyx in its central portion = calyx of nonresorbed normal junctional parenchyma between upper + lower subkidneys

B. ACQUIRED

1. **Nodular compensatory hypertrophy** areas of unaffected tissue in the presence of focal renal scarring from chronic atrophic pyelonephritis (= reflux nephropathy), surgery, trauma, infarction
   √ hypertrophy usually evident within 2 months; less likely to occur > age 50

√ "mass" enhances identically to renal parenchyma

DDx: accessory spleen, medial lobule of spleen, splenosis, normal / abnormal bowel, pancreatic disease, gallbladder, adrenal abnormalities

Dx: static radionuclide imaging / renal arteriography / CT

Pseudokidney Sign

= sonographic mass of reniform appearance with a central hyperechoic region surrounded by a hyperechoic region

1. Intussusception
2. Necrotizing enterocolitis
3. Midgut volvulus
4. Sigmoid volvulus
5. Crohn disease

False-positive:

feces in colon, perforated Meckel diverticulum with malrotation + Ladd bands, psoas muscle, hematoma

RENAL CYSTIC DISEASE

Potter Classification

= POTTER SYNDROME

= any renal condition associated with severe oligohydramnios

• peculiar facies with wide-set eyes, parrot-beak nose, pliable low-set ears, receding chin

Type I : infantile PCKD

Type II : multicystic dysplastic kidney disease, multilocular cystic nephroma

IIa : kidneys of normal / increased size

IIb : kidneys reduced in size

Type III : adult PCKD, tuberous sclerosis, medullary sponge kidney

Type IV : small cortical cysts / cystic dysplasia ← ureteropelvic junction obstruction

Renal Cystic Disease

A. GENETIC CYSTIC DISEASE
   1. Autosomal dominant polycystic kidney disease
   2. Autosomal recessive polycystic kidney disease
   3. Medullary sponge kidney
   4. Medullary cystic disease
   5. Glomerulocystic kidney disease

B. OBSTRUCTIVE CYSTIC DISEASE
   1. Multicystic dysplastic kidney
   2. Segmental / focal renal dysplasia
   3. Familial renal dysplasia

C. ACQUIRED CYSTIC DISEASE
   1. Simple cyst
   2. Parapelvic cyst
   3. Acquired cystic disease of uremia

4. Infectious cysts: TB, Echinococcus, abscess
5. Medullary necrosis
6. Pyelogenic cyst
7. Lithium-induced nephropathy

D. CYSTS ASSOCIATED WITH SYSTEMIC DISEASE
1. Tuberous sclerosis
2. Von Hippel-Lindau disease

E. CYSTIC TUMORS
1. Multilocular cystic nephroma
2. Cystic Wilms tumor
3. Cystic renal cell carcinoma
4. Mixed epithelial and stromal tumor

Focal Renal Cystic Disease

1. Mixed epithelial and stromal tumor
2. Multilocular cystic nephroma
3. Pyelocalyceal diverticulum

Acquired Multifocal Cystic Renal Disease

1. Glomerulocystic kidney disease
2. Lithium-induced nephropathy
3. Acquired cystic kidney disease
4. Multicystic dysplastic kidney
5. Localized cystic renal disease
6. Renal sinus cyst

Cystic Kidney Infection

1. Renal abscess
2. Renal aspergillosis
3. Renal echinococcosis

Renal Cystic Disease in Adults

A. HEREDITARY
1. Autosomal dominant polycystic kidney disease
2. Von Hippel-Lindau disease
3. Tuberous sclerosis complex
4. Medullary cystic kidney disease

B. NONHEREDITARY
1. Acquired cystic kidney disease
2. Medullary sponge kidney
3. Multicystic dysplastic kidney
4. Localized renal cystic disease

Syndromes with Multiple Cortical Renal Cysts

1. Von Hippel-Lindau syndrome
2. Tuberous sclerosis

3. Meckel-Gruber syndrome
4. Jeune syndrome
5. Zellweger syndrome = cerebrohepatorenal syndrome
6. Conradi syndrome = chondrodysplasia punctata
7. Orofacialdigital syndrome
8. Trisomy 13
9. Turner syndrome
10. Dandy-Walker malformation

Multiloculated Renal Mass

= > 3–4 septations

Rx: most multiloculated renal masses are treated with excision / nephrectomy

A. NEOPLASTIC DISEASE
   1. Cystic renal cell carcinoma
   2. Multilocular cystic renal tumor
      (a) adult cystic nephroma
      (b) cystic partially differentiated nephroblastoma
   3. Cystic Wilms tumor
   4. Necrotic tumor
      (a) mesoblastic nephroma
      (b) clear cell sarcoma

B. RENAL CYSTIC DISEASE
   1. Localized renal cystic disease
   2. Septated cyst
   3. Multicystic dysplastic kidney
   3. Segmental multicystic dysplasia
   4. Complicated cyst

C. INFLAMMATORY DISEASE
   1. Echinococcus
   2. Segmental XGP
   3. Abscess
   4. Malakoplakia

D. VASCULAR LESIONS
   1. AV fistula
   2. Organizing hematoma

ABNORMAL NEPHROGRAM

Absence of Nephrogram

Global Absence of Nephrogram

Pathophysiology: complete renal ischemia ← occlusion of main renal artery

1. Injury to vascular pedicle during blunt abdominal trauma
2. Thromboembolic disease
3. Renal artery dissection: spontaneous, traumatic, iatrogenic

Segmental Absence of Nephrogram

A. SPACE-OCCUPYING PROCESS
   1. Neoplasm
   2. Cyst
   3. Abscess

B. FOCAL RENAL INFARCTION
   1. Arterial embolus / thrombosis
   2. Vasculitis, collagen-vascular disease
   3. Sickle cell anemia
   4. Septic shock
   5. Renal vein thrombosis

Rim Nephrogram

= rim of cortex receiving collateral blood flow from capsular, peripelvic, and periureteric vessels

◊ Most specific indicator of renovascular compromise!

√ 2–4-mm peripheral band of cortical opacification

Cause:
1. Acute total main renal artery occlusion: in 50% of cases with renal infarction
2. Renal vein thrombosis
3. Acute tubular necrosis
4. Severe chronic urinary obstruction

DDx: severe hydronephrosis (rim / shell nephrogram surrounding dilated calyces)

Unilateral Delayed Nephrogram

A. OBSTRUCTIVE UROPATHY

B. REDUCTION IN RENAL blood flow
   1. Renal artery stenosis
   2. Renal vein thrombosis

Striated Nephrogram

= streaky linear bands of alternating hyper- and hypoattenuation parallel to axis of tubules + collecting ducts during excretory phase

Cause:

stasis of contrast material in dilated collecting ducts on background of edematous renal parenchyma ← diminished concentration of contrast material in tubules ← ischemia + tubular obstruction by inflammatory cells + debris

A. UNILATERAL
   1. Acute ureteric obstruction
   2. Acute bacterial nephritis / pyelonephritis
   3. Renal contusion
   4. Renal vein thrombosis

B. BILATERAL
   1. Acute pyelonephritis
   2. Intratubular obstruction: Tamm-Horsfall proteinuria, rhabdomyolysis with myoglobinuria

3. Systemic hypotension
4. Autosomal recessive PCKD
5. Medullary sponge kidney
6. Medullary cystic disease

mnemonic: CHOIR BOY

Contusion
Hypotension (systemic)
Obstruction (ureteral)
Intratubular obstruction
Renal vein thrombosis
Bacterial nephritis (acute)
Obstruction (ureteral) — it is so common!
Yes, also cystic diseases: infantile PCKD, medullary cystic disease, medullary sponge kidney

Persistent Nephrogram

A. BILATERAL GLOBAL
   1. Systemic hypotension
   2. Intratubular obstruction from protein:
      Tamm-Horsfall, Bence-Jones, myoglobin
   3. Tubular damage by contrast material
B. UNILATERAL GLOBAL
   1. Renal artery stenosis
   2. Renal vein thrombosis
   3. Urinary tract obstruction
C. SEGMENTAL
   1. Obstructed moiety of duplicated collecting system
   2. Obstructing renal calculus
   3. Obstructing neoplasm
   4. Focal stricture
   5. Focal parenchymal disease: tubulointerstitial infection

Abnormal Nephrogram due to Impaired Perfusion

A. SYSTEMIC HYPOTENSIVE REACTION as a reaction to contrast material / cardiac failure / dehydration / shock

Pathophysiology:

drop in perfusion pressure after contrast reaches kidney → increased salt + water reabsorption and slowed tubular transit

√ prolonged bilateral dense nephrograms = persistent increasing nephrogram
√ decrease in renal size
√ loss of pyelogram after initial opacification

NUC (use of glomerular filtration agent [eg, ^{99m}Tc-DTPA] preferred)
√ prolonged cortical transit + reduced excretion

B. RENAL ARTERY STENOSIS
√ decreased nephrographic opacity + rim nephrogram

√ hyperconcentration in collecting system
√ ureteral notching
NUC (glomerular filtration agent [eg, ^{99m}Tc-DTPA] preferred):
√ decreased perfusion with prolonged excretory phase

C. IMPAIRED PERFUSION OF SMALL ARTERIES
Trueta shunting = transient rerouting of blood flow from cortex to medulla
Cause:
(a) reflex vasospasm during arterial angiography ← catheter trauma / pressure injection of highly concentrated contrast medium
(b) chronic renal disorders: collagen vascular disease, malignant nephrosclerosis, chronic glomerulonephritis
(c) necrotizing vasculitis (polyarteritis nodosa), scleroderma, hypertensive nephrosclerosis
CT, Angio:
√ inhomogeneous opacification of cortex
√ **spotted nephrogram**
IVP:
√ irregular cortical nephrogram = spotted nephrogram (DDx: scleroderma, hypertensive nephrosclerosis)

D. ACUTE VENOUS OUTFLOW OBSTRUCTION in renal vein thrombosis
√ obstructive nephrogram
√ progressive increase in opacity of entire kidney

Abnormal Nephrogram due to Impaired Tubular Transit

NUC: before decrease in renal function → use of glomerular filtration agent (eg, ^{99m}Tc-DTPA); with decrease in renal function → use of plasma flow agents (eg, ^{99m}Tc-MAG_3 / ^{123}I-Hippuran®) is preferred

Cause:

A. EXTRARENAL: ureteric obstruction (eg, stone)
√ obstructive nephrogram
NUC:
√ continuous increase in renal activity
√ dilatation of collecting system

B. INTRARENAL
(a) segmental: limb of duplication system, caliceal obstruction, interstitial edema
√ segmental nephrogram
(b) protein precipitation: Tamm-Horsfall protein (a normal mucoprotein product of proximal nephrons), Bence-Jones protein (multiple myeloma), uric acid precipitation (acute urate nephropathy), myoglobulinuria, hyperproteinuric state
√ striated nephrogram
NUC:
√ prolonged cortical transit time + prolonged excretory phase

Abnormal Nephrogram due to Abnormal Tubular Function

Pathophysiology:

A. PROXIMAL TUBULE

Function: reabsorbs almost all of glucose, amino acids, phosphate, bicarbonate

- glycosuria: Toni-Fanconi syndrome
- aminoaciduria: cystinuria
- phosphaturia: phosphate diabetes, thiazides
- HCO3– wasting: proximal renal tubular acidosis

B. DISTAL TUBULE

Function: absorbs most of water

- diabetes insipidus, secretes H+
- distal renal tubular acidosis

1. Acute tubular necrosis
   √ immediate persistent nephrogram (common)
   √ progressive increasing opacity (rare)
2. Contrast-induced renal failure

Striated Angiographic Nephrogram

= random patchy densities reflecting redistribution of blood flow from the cortical vasculature to vasa recta of medulla

1. Obliterative diseases of renal microvasculature:
   polyarteritis nodosa, scleroderma, necrotizing angiitis, catheter-induced vasospasm
2. Acute bacterial nephritis
3. Renal vein thrombosis

Increasingly Dense Nephrogram

= initially faint nephrogram becoming increasingly dense over hours to days

Mechanism:

(a) diminished plasma clearance of contrast material
(b) leakage of contrast material into renal interstitial space
(c) increase in tubular transit time

Cause:

A. VASCULAR = diminished perfusion
   1. Systemic arterial hypotension (bilateral)
   2. Severe main renal artery stenosis (unilateral)
   3. Acute tubular necrosis (in 33%):
      ← contrast material nephrotoxicity
   4. Acute renal vein thrombosis

B. INTRARENAL
   1. Acute glomerular disease

C. COLLECTING SYSTEM
   1. Intratubular obstruction
      (a) uric acid crystals = acute urate nephropathy
      (b) precipitation of Bence-Jones protein = myeloma nephropathy
      (c) Tamm-Horsfall protein: in severely dehydrated infants / children
   2. Acute extrarenal obstruction: ureteral calculus

Vicarious Contrast Material Excretion during IVP

= biliary contrast material detected radiographically following intravenous administration of contrast material

Normal contrast excretion:

< 2% of urographic dose of diatrizoates + iothalamates are handled by hepatobiliary excretion

Pathophysiology: increase in protein binding ← prolonged intravascular contact + acidosis

Cause:

1. Uremia (reduction in glomerular filtration + uremia-associated acidosis)
2. Acute unilateral obstruction (increase in circulation time + transient intracellular acidosis)
3. Spontaneous urinary extravasation (prolonged vascular contact of contrast material)

RENAL DOPPLER

A. NORMAL RENAL DOPPLER

√ resistive index (RI) of 0.70 = upper limit of normal

Elevation of RI:

› significant systemic hypotension
› markedly decreased heart rate
› perinephric / subcapsular fluid collection
› in neonates + infants

B. RENAL MEDICAL DISEASE

Elevation of RI:

more likely with vascular / tubulointerstitial process: less likely with glomerular disease

May be useful in predicting clinical outcome in:

› hemolytic-uremic syndrome
› acute renal failure
› nonazotemic patients with severe liver disease

C. RENAL ARTERY STENOSIS

D. RENAL VEIN THROMBOSIS

COLLECTING SYSTEM

Spontaneous Urinary Contrast Extravasation

= SPONTANEOUS PYELORENAL BACKFLOW

Etiology: physiologic "safety valve" for obstructed urinary tract with pressures of 80–100 mmHg in collecting system ← ipsilateral ureteral obstruction ← distal stone impaction; pressure is proportional to degree + duration of acute obstruction + dose of contrast material

Prevalence: 0.1–18%; M > F (male ureter less compliant)

Criteria: absence of

(a) recent ureteral instrumentation
(b) previous renal / ureteral surgery
(c) destructive urinary tract lesion

(d) external trauma
(e) external compression
(f) pressure necrosis due to stone

Types:

1. **Pyelotubular backflow**
   = opacification of terminal portions of collecting ducts (= papillary ducts = ducts of Bellini) as a physiologic phenomenon (in 13% with low osmolality + in 0.4% with high osmolality contrast media), wrongly termed "backflow"
   √ wedge-shaped brushlike lines from calyx toward periphery
2. **Pyelosinus backflow**
   = contrast extravasation from ruptured fornices along infundibula, renal pelvis, proximal ureter; most common form
   Cx: urinoma, retroperitoneal fibrosis
3. **Pyelointerstitial backflow**
   = contrast flow from pyramids into subcapsular tubules
4. **Pyelolymphatic backflow**
   = contrast extravasation into periforniceal + peripelvic lymphatics
   √ visualization of small lymphatics draining medially
5. **Pyelovenous backflow**
   = forniceal rupture into interlobar / arcuate veins; rare

Widened Collecting System & Ureter

Fetal pyelectasis:

AP diameter of renal pelvis < 5 mm < 20 weeks MA
< 8 mm 20–30 weeks MA
< 10 mm > 30 weeks MA

A. OBSTRUCTIVE UROPATHY
B. NONOBSTRUCTIVE WIDENING
   (a) congenital
      1. Megacalycosis
         = underdevelopment of papillae; usually unilateral
      2. Congenital primary megaureter
         = widened ureter with normally tapered distal end
      3. Megacystis-megaureter syndrome
      4. Prune-belly syndrome
      5. Bardet-Biedl syndrome
      6. Beckwith-Wiedemann syndrome
      7. Megalourethra
   (b) increased urine volume
      1. High-flow states: diabetes insipidus, osmotic diuresis, dehydrated patient undergoing rehydration, unilateral kidney
      2. Vesicoureteral reflux
   (c) atony of renal collecting system
      1. Infection: ie, acute pyelonephritis

2. Pregnancy
3. Retroperitoneal fibrosis

(d) overdistended urinary bladder

(e) previous long-standing significant obstruction: dilatation remains in spite of relief of obstruction

Caliceal Abnormalities

A. OPACIFICATION OF COLLECTING TUBULES
1. Pyelorenal backflow
2. Medullary sponge kidney

B. PAPILLARY CAVITY
1. Papillary necrosis
2. Caliceal diverticulum
3. Tuberculosis / brucellosis

C. LOCALIZED CALIECTASIS
1. Reflux nephropathy = chronic atrophic pyelonephritis
2. Compound calyx
3. Hydrocalyx
4. Congenital megacalyx
5. Localized postobstructive caliectasis
6. Localized tuberculosis / papillary necrosis

D. GENERALIZED CALIECTASIS
1. Postobstructive atrophy
2. Congenital megacalices
3. Obstructive uropathy (hydronephrosis)
4. Nonobstructive hydronephrosis
5. Diabetes insipidus

Filling Defect in Collecting System

mnemonic: 6 C"s & 2 P's

Clot
Cancer
Cyst
Calculus
Candida + other fungi
Cystitis cystica
Polyp
Papilla (sloughed)

Nonopaque Intraluminal Mass in Collecting System

A. NONOPAQUE CALCULUS uric acid, xanthine, matrix
√ smooth, rounded, not attached

B. TISSUE SLOUGH
1. Papillary necrosis
2. Cholesteatoma

3. Fungus ball = conglomeration of fibrillar hyphae
4. Inspissated debris ("mucopus")

C. VASCULAR
1. Blood clot: history of hematuria
√ change in appearance over time

D. FOREIGN MATERIAL
1. Air from bladder via reverse peristalsis, direct trauma, renoalimentary fistula
2. Foreign matter

Mucosal Mass in Collecting System

A. NEOPLASTIC
(a) benign tumor
1. Aberrant papilla = papilla without calyx protruding into major infundibulum
2. Endometriosis
3. Fibroepithelial polyp

(b) malignant tumor
› uroepithelial tumors
1. Transitional cell carcinoma (85–91%)
2. Squamous cell carcinoma (7–10–15%)
Predisposing factors: calculi (50–60%), chronic infection, leukoplakia, phenacetin abuse
√ infiltrating / superficially spreading
3. Mucinous adenocarcinoma
= metaplastic transformation
4. Sarcoma (extremely rare)

› metastases: breast (most common), melanoma, stomach, lung, cervix, colon, prostate

B. INFLAMMATION / INFECTION
1. Tuberculosis
2. Candidiasis
3. Schistosomiasis
4. Pyeloureteritis cystica
5. Leukoplakia
6. Malakoplakia
7. Xanthogranulomatous pyelonephritis

C. VASCULAR
(a) submucosal hemorrhage
1. Trauma
2. Anticoagulant therapy
3. Acquired circulating anticoagulants
4. Complication of crystalluria / microlithiasis
√ thumbprinting with progressive improvement

(b) vascular notching
1. Ureteropelvic varices
2. Renal vein occlusion

3. IVC occlusion
4. Vascular malformation
5. Retroaortic left renal vein
6. "Nutcracker" effect on left renal vein between aorta and SMA
7. Polyarteritis nodosa

D. PROMINENT MUCOSAL FOLDS
1. Redundant longitudinal mucosal folds of intermittent hydronephrosis: UPJ obstruction, vesicoureteral reflux / after relief of obstruction
2. Chemical / mechanical irritation
3. Urticaria: Stevens-Johnson syndrome = erythema multiforme bullosa
4. Leukoplakia = squamous metaplasia
5. Ureteral diverticulosis = rupture of the roofs of cysts in ureteritis cystica

Effaced Collecting System

A. EXTRINSIC COMPRESSION
(a) Uni- / bilateral global enlargement of renal parenchyma
(b) Renal sinus masses
1. Hemorrhage
2. Parapelvic cyst
3. Sinus lipomatosis

B. SPASM / INFLAMMATION
(a) infection
1. Acute pyelonephritis
2. Acute bacterial nephritis
3. Acute tuberculosis
(b) hematuria

C. INFILTRATION
1. Malignant uroepithelial tumors

D. OLIGURIA
1. Antidiuretic state
2. Renal ischemia
3. Oliguric renal failure

RENAL SINUS

Renal Sinus Mass

A. TUMOR
   (a) renal pelvis
      1. Transitional cell carcinoma (90%)
      2. Squamous cell carcinoma (9%)
      3. Mucinous adenocarcinoma (1%)
   (b) renal parenchyma
      1. Renal cell carcinoma
      2. Multilocular cystic nephroma
      3. Plasmacytoma
   (c) mesenchymal tumor (rare): hemangioma, lipoma, angiomyolipoma, fibroma, leiomyoma, neurogenic tumor, teratoma; sarcomas (eg, leiomyosarcoma)
   (d) retroperitoneal
      1. Lymphoma
      2. Metastasis to sinus lymph nodes
      3. Myeloid metaplasia
B. NONTUMOROUS CONDITION
   (a) fat
      1. Sinus lipomatosis
   (b) fluid
      1. Renal sinus cyst
      2. Urinoma
   (c) vessels
      1. Renal artery aneurysm
         √ annular calcifications in > 50%
         DDx: renal calculus
      2. Arteriovenous communication
      3. Renal varix

Hypoechoic Renal Sinus

A. SOLID
   1. Fibrolipomatosis
   2. Column of Bertin
   3. Duplex kidney
   4. TCC / RCC
B. CYSTIC
   1. Renal sinus cysts
   2. Caliectasis
   3. Dilated veins, varix
   4. Aneurysm, arteriovenous malformation

RENAL CALCIFICATION

Retroperitoneal Calcification

A. NEOPLASM
   1. Wilms tumor (in 10%)
   2. Neuroblastoma (in 50%): fine granular / stippled / amorphous
   3. Teratoma: cartilage / bone / teeth, pseudodigits, pseudolimbs
   4. Cavernous hemangioma: phleboliths

B. INFECTION
   1. Tuberculous psoas abscess
   2. Hydatid cyst
   3. Alkaline-encrusted cystitis and pyelitis

C. TRAUMA
   1. Old hematoma

Nephrocalcinosis

= diffuse fine radiologically demonstrable calcifications deposited as calcium salts in renal parenchyma

DDx: **Nephrolithiasis** (= "kidney stones" = renal calculi = radiopaque / nonradiopaque hard crystalline minerals formed within lumen of the urinary tract (renal collecting system, ureter, bladder = urolithiasis)

nephros, Greek = kidney; *lithos*, Greek = stone; *calx*, Latin = lime; *calculus*, Latin = pebble; *osis*, Greek = abnormal condition = "full of"

Prevalence: 0.1–6%; M > F

Cause:

mnemonic: MARC
Medullary sponge kidney
Alkali excess
Renal medullary / cortical necrosis, **R**TA
Chronic glomerulonephritis
Hyperoxaluria, **H**ypercalcemia, **H**ypercalciuria

Medullary Nephrocalcinosis *(95%)*

= calcifications involving the distal convoluted tubules in the loops of Henle

Frequency: 95% of all nephrocalcinoses

Cause:

A. HYPERCALCIURIA
   (a) endocrine
      1. Hyperparathyroidism in 5% (1° >> 2°)
      2. Paraneoplastic syndrome of lung + kidney ← ectopic parathormone production
      3. Cushing syndrome
      4. Diabetes insipidus
      5. Hyperthyroidism / hypothyroidism
      6. Glycogen storage disease Type I
   (b) alimentary
      1. Absorptive hypercalcemia

2. Milk-alkali syndrome = excess calcium + alkali ← milk + antacids
3. Hypervitaminosis D
4. Beryllium poisoning

(c) osseous
1. Osseous metastases, multiple myeloma
2. Prolonged immobilization
3. Progressive senile osteoporosis

(d) renal
1. Medullary sponge kidney
2. Distal renal tubular acidosis (in 73% of primary RTA)
3. Chronic glomerulonephritis
4. **Bartter syndrome** tubular disorder with potassium + sodium wasting, hyperplasia of juxtaglomerular apparatus, hyperaldosteronism, hypokalemic alkalosis, and normal blood pressure

(e) drug therapy
1. Furosemide (in infants)
2. Prolonged ACTH therapy
3. Vitamin E (orally)
4. Vitamin D excess
5. Calcium (orally)
6. Nephrotoxic drugs: outdated tetracycline, amphotericin B

(f) miscellaneous
1. Sarcoidosis
2. Idiopathic hypercalciuria
3. Idiopathic hypercalcemia
4. Sjögren syndrome (distal RTA)

(g) genetic
1. Williams syndrome
2. Kenny-Caffey syndrome

B. HYPEROXALURIA = OXALOSIS

C. HYPERURICOSURIA = urate crystal deposition
1. Gouty kidney (adult)
2. Lesch-Nyhan syndrome (child)

D. URINARY STASIS
1. Milk-of-calcium in pyelocaliceal diverticulum
2. Medullary sponge kidney

E. DYSTROPHIC CALCIFICATION
1. Renal papillary necrosis ← especially analgesic nephropathy
2. Chronic pyelonephritis
3. Sickle cell disease
4. Renal tuberculosis

mnemonic: HAM HOP
Hyperparathyroidism
Acidosis (renal tubular)
Medullary sponge kidney

Hypercalcemia / hypercalciuria (sarcoidosis, milk-alkali syndrome, hypervitaminosis D)
Oxalosis
Papillary necrosis

√ normal-sized / occasionally enlarged kidneys (medullary sponge kidney)
√ small poorly defined / large coarse granular calcifications in renal pyramids:
  √ uniform deposition: hyperparathyroidism / distal renal tubular acidosis (type 1)
  √ asymmetric deposition in dilated collecting ducts within papillary tips: medullary sponge kidney

US:
  √ absence of hypoechoic papillary structures (earliest sign)
  √ hyperechoic rim at corticomedullary junction + around tip and sides of pyramids
  √ solitary focus of hyperechogenicity at tip of pyramid near fornix
  √ increased echogenicity of renal pyramids ± shadowing (no acoustic shadowing with small + light calcifications)

DDx of hyperechoic medulla in newborns:
oliguria with transient tubular blockage by Tamm-Horsfall proteinuria
Cx: often followed by urolithiasis

MEDULLARY NEPHROCALCINOSIS in CHILDREN

- NORMOCALCEMIA + HYPERCALCIURIA
  (a) iatrogenic
    1. Furosemide
    2. Corticotropin therapy
  (b) noniatrogenic
    1. Distal renal tubular acidosis
    2. Idiopathic hypercalciuria
    3. Bartter syndrome
    4. Hyperprostaglandin E syndrome
    5. Hypomagnesemia
    6. Cushing syndrome
    7. Cystinosis
    8. Glycogen storage disease Type 1
    9. Tyrosinemia
    10. Beckwith-Wiedemann syndrome
    11. Hypothyroidism
- Hypercalcemia + Hypercalciuria
  1. X-linked hypophospatemic rickets
  2. Hyperparathyroidism
  3. Hypophosphatasia
  4. Sarcoidosis
  5. Vitamin D intoxication
  6. Williams syndrome
  7. Subcutaneous fat necrosis
  8. Idiopathic infantile hypercalcemia

- Normocalcemia + Normocalciuria
  1. Acetazolamide
  2. Hyperoxaluria

Cortical Nephrocalcinosis *(5%)*

= calcium deposition in renal cortex

Frequency: 5% of all nephrocalcinoses

Cause:

1. Acute cortical necrosis
2. Chronic glomerulonephritis
3. Alport syndrome
4. Congenital oxalosis, primary hyperoxaluria
5. Chronic paraneoplastic hypercalcemia
6. Toxic: ethylene glycol, methoxyflurane
7. Sickle cell disease
8. Rejected renal transplant

mnemonic: COAG

Cortical necrosis (acute)
Oxalosis
Alport syndrome
Glomerulonephritis (chronic)

√ thin rim of calcification with a "tramline" appearance
√ spotty appearance (= preferential deposition in necrotic glomeruli)

US:

√ homogeneously increased echogenicity of renal parenchyma > liver echogenicity

Calcification of Pyelocaliceal System

1. Staghorn calculus
2. Nephrolithiasis
3. Papillary necrosis
4. Renal tuberculosis
5. Leukoplakia
6. Alkaline-encrusted pyelitis
7. Primary carcinoma of renal pelvis
8. Renal pelvic argyrosis ← contact with silver nitrate
9. Amyloidosis

Spontaneous Retroperitoneal Hemorrhage

A. RENAL TUMOR (57–63%)
   (a) malignant tumor (30–33%)
      1. RCC (33%)
      2. TCC of renal pelvis
      3. Wilms tumor
      4. Lipo-, fibro-, angiosarcoma
   (b) benign tumor (24–33%)

1. Angiomyolipoma (16–24%)
2. Lipoma
3. Adenoma
4. Fibromyoma
5. Ruptured hemorrhagic cyst

B. VASCULAR DISEASE (18–26%)
1. Ruptured renal artery aneurysm
2. Vasculitis: eg, polyarteritis nodosa in 13%
3. Arteriovenous malformation
4. Segmental renal infarction

C. INFLAMMATION / INFECTION (7–10%)
1. Abscess (in 50% of infections)
2. Acute / chronic nephritis

D. COAGULOPATHY
1. Anticoagulant therapy (in 4.3–6.6% of IV heparin, in 01.–0.6% of oral anticoagulants)
Source: idiopathic (42%), tumor (21%), stone disease (17%), hemorrhagic cystitis
2. Bleeding diathesis
3. Long-term hemodialysis

E. PRIMARY ADRENAL CYST / TUMOR
1. Pheochromocytoma
◊ Massive bleed ← an undiagnosed pheochromocytoma has been lethal in 50%!
2. Pseudocyst
3. Myelolipoma
4. Hemangioma
5. Adrenocortical adenoma / carcinoma
6. Metastasis

• flank pain of sudden onset

◊ Follow-up CT may be indicated at 3 and 6 months if the source of blood remains indeterminate!

◊ Surgical exploration must be considered to uncover a small renal tumor if the cause of hemorrhage is not determined radiologically!

Subcapsular Hematoma

√ subcapsular mass with flattening of renal parenchyma

√ total resorption / formation of pseudocapsule with calcification

Angio:

√ avascular mass

Cx: Page kidney (ischemia, release of renin, HTN)

URETER

Congenital Ureteral Abnormalities

A. URETERAL DUPLICATION (most common)
1. Complete ureteral duplication
2. Partial ureteral duplication

B. SMOOTH MUSCLE DYSFUNCTION
   1. UPJ obstruction
   2. Primary megaureter
C. ABNORMAL TERMINATION OF SINGLE URETER
   1. Ectopic ureter
   2. Ureterocele
   3. Vesicoureteral reflux

Ureteral Deviation in Course

A. LUMBAR URETER
   (a) lateral deviation (common)
      1. Hypertrophy of psoas muscle
      2. Enlargement of paracaval / para-aortic lymph nodes
      3. Aneurysmal dilatation of aorta
      4. Neurogenic tumors
      5. Fluid collections: abscess, urinoma, lymphocele, hematoma
   (b) medial deviation
      1. Retrocaval ureter (on right side only)
      2. Circumcaval ureter
      3. Retroperitoneal fibrosis
      4. Inflammatory aortic aneurysm
B. PELVIC URETER
   (a) medial deviation
      1. Hypertrophy of iliopsoas muscle
      2. Enlargement of iliac lymph nodes
      3. Aneurysmal dilatation of iliac vessels
      4. Bladder diverticulum at UVJ (= Hutch diverticulum)
      5. Following abdominoperineal surgery + retroperitoneal lymph node dissection
      6. Pelvic lipomatosis
   (b) lateral deviation with extrinsic compression
      1. Pelvic mass: eg, fibroids, ovarian tumor
      2. Herniated ureter through inguinal canal
C. INTENTIONAL SURGICAL DIVERSION
   ileal conduit, continent cutaneous diversion, orthotopic neobladder

Ureteral Dilatation / Hydroureter

A dilated ureter is not necessarily obstructed; an obstructed ureter is not always dilated.

Size of ureter: > 3 mm

A. OBSTRUCTION
   1. Ureterolithiasis
B. CONGENITAL
   1. Chronic vesicoureteral reflux
   2. Posterior urethral valves
   3. Megaloureter

4. Prune-belly syndrome
5. Ectopic ureter
6. Ureterocele

C. INFECTION / INFLAMMATION impairing ureteral peristalsis
1. UTI: eg, E. coli, Pseudomonas, Citrobacter
2. Appendicitis
3. Diverticulitis

D. COMPRESSION
1. Pelvic / abdominal mass
2. Vessel:
   › retroiliac / retrocaval course of ureter
   › ovarian vein syndrome

Unilateral Hydroureter

(a) obstruction: calculus, tumor, clot, sloughed papilla, stricture, extrinsic compression, mass effect
(b) resolved obstruction (if distension was severe)

Bilateral Hydroureter

1. Polyuria / diuresis
2. Bladder outlet obstruction
3. Neurogenic bladder
4. Pregnancy: R > L

Megaureter

A. VESICOURETERAL REFLUX
(a) primary vesicoureteral reflux
1. Primary reflux megaureter
   Cause: abnormal ureteral tunnel at UVJ
2. Prune belly syndrome

(b) secondary vesicoureteral reflux
1. Hypertonic neurogenic bladder
2. Bladder outlet obstruction
3. Posterior urethral valves

B. OBSTRUCTION
(a) primary obstruction
1. Intrinsic ureteral obstruction: stone, stricture, tumor
2. Ectopic ureter
3. Ureterocele
4. Ureteral duplication
   √ tortuous dilated ureter of upper moiety

(b) secondary obstruction
1. Retroperitoneal obstruction: tumor, fibrosis, aortic aneurysm
2. Bladder wall mass
3. Bladder outlet obstruction: eg, prostatic enlargement

C. nonreflux-nonobstructed MEGAURETER
   1. Congenital primary megaureter = megaloureter
   2. Polyuria: eg, diabetes insipidus, acute diuresis
   3. Infection
   4. Ureter remaining wide after relief of obstruction

mnemonic: DiaPOUR
Diabetes insipidus
Primary megaureter
Obstruction (recent / old)
UVJ obstruction
Reflux

Ureteral Stricture

A stricture is a fixed narrowing with proximal dilatation.

A. INTRINSIC CAUSE
   (a) mucosal
      1. Primary ureteral tumors
      2. Inflammation ← stone passage
   (b) mural
      1. Endometriosis
         common disorder in menstruating women (15%); ureteral involvement is rare and indicates widespread pelvic disease
         √ abrupt smooth stricture of 0.5–2.5 cm length
         √ rectosigmoid involvement on BE
      2. Infection: tuberculosis, schistosomiasis
      3. Traumatic / iatrogenic
         ureterolithotomy, endoscopic stone extraction, gynecologic procedures (esp. hysterectomy), ureteral anastomosis (urinary diversion)
      4. Amyloidosis
         √ distal stricture with submucosal calcification
      5. Nonspecific (rare)

B. EXTRINSIC CAUSE
   1. Endometriosis: extrinsic form÷intrinsic form = 4÷1
   2. Abscess: tuboovarian, appendiceal, perisigmoidal
   3. Inflammatory bowel disease: eg, Crohn disease, diverticulitis
   4. Radiation fibrosis
   5. Tumor encasement / metastasis: cervix, endometrium, ovary, rectum, prostate, breast, lymphoma
   6. Iliac artery aneurysm → perianeurysmal fibrosis

mnemonic: MISTER
Metastasis (extrinsic / intrinsic)
Inflammation from calculus
Schistosomiasis
Tuberculosis, **T**ransitional cell carcinoma, **T**rauma

Endometriosis + other periureteral inflammatory process
Radiation therapy, **R**etroperitoneal fibrosis

Physiologic narrowing is common and characterized by absence of proximal dilatation and rapid changeability.

DDx: Physiologic narrowing
1. Ongoing peristalsis → incomplete opacification resolved on delayed images
2. Anatomic: UPJ, pelvic brim, UVJ, abrupt turn / kink

Ureteral Filling Defect

A. FIXED
   (a) neoplasm
      1. Urothelial neoplasm
      2. Metastasis
      3. Fibroepithelial polyp
   (b) inflammation / infection
      1. Polyureteritis cystica
      2. Tuberculosis
      3. Fungus: Candida, Aspergillus
      4. Schistosomiasis
      4. Endometriosis
B. MOBILE
   1. Stone = urolithiasis
   2. Sloughed papilla
   3. Blood clot
      Cause: trauma, stone, malignancy, anticoagulation
      √ NO enhancement
      √ density of > 50 HU relative to urine and surrounding soft tissues on NECT
      √ clot resolution at follow-up imaging studies
C. MULTIPLE
   1. Polyureteritis cystica
   2. Malakoplakia
   3. Multifocal urothelial cell cancer

Any ureteral filling defect of soft-tissue attenuation must be considered malignant and requires ureteroscopic assessment, biopsy, and cytologic analysis.

Ureteral Calcification

A. URETERAL LUMEN
   1. Stone: migrated from kidney
   2. Stone: in ureteral diverticulum / ureterocele
   3. Stone street = “Steinstrasse” = collection of stone fragments in distal ureter following lithotripsy
B. URETERAL WALL
   1. Schistosomiasis
   2. Tuberculosis

3. Amyloid infiltration
4. Ureteral tumor

DDx: (1) Phlebolith in gonadal vein (multiple, not along course of ureter, centrally radiolucent)
(2) Orally administered contrast material trapped in appendix / diverticulum
(3) Dermoid cyst with calcification
(4) Silastic fallopian tube band
(5) Radiation seeds used for prostate cancer

URINARY BLADDER

Bilateral Narrowing of Urinary Bladder

A. WITH ELEVATION OF BLADDER FLOOR
1. Pelvic lipomatosis
2. Pelvic hematoma
Cause: trauma, anticoagulant therapy, spontaneous rupture of blood vessels, blood dyscrasia (rare), bleeding neoplasm (rare)
3. Chronic cystitis

B. WITH SUPERIOR COMPRESSION OF BLADDER
1. Thrombosis of IVC
Cause: trauma, hypercoagulability state (oral contra-ceptives), extension of thrombi from lower extremity, abdominal sepsis, Budd-Chiari syndrome, compression of IVC by neoplasm
√ collaterals: ← gonadal veins, ascending lumbar veins, vertebral plexus, retroperitoneal veins, portal vein (via hemorrhoidal veins)
√ notching of distal ureter by ureteral veins
2. Pelvic lymphadenopathy
Cause: lymphoma (most often), prostatic carcinoma
√ polycyclic asymmetric compression of bladder
√ medial displacement of pelvic segment of ureters
√ lateral displacement of upper ureters
3. Hypertrophy of iliopsoas muscles
4. Bilateral pelvic masses
(a) bilateral lymphocysts (after radical pelvic surgery)
(b) bilateral urinomas
(c) bilateral pelvic abscesses
5. Retroperitoneal fibrosis
6. Large iliac artery aneurysms

Inverted Pear / Teardrop-shaped Urinary Bladder

mnemonic: PHALL
Psoas hypertrophy
Hematoma (pelvic)
Aneurysm (bilateral common / external iliac artery)

Lipomatosis, pelvic
Lymphadenopathy (pelvic)

Small Bladder Capacity

Cause:

A. THICKENED / FIBROTIC BLADDER WALL
   1. Interstitial cystitis
   2. Tuberculous cystitis
   3. Cystitis cystica
   4. Schistosomiasis
   5. Trauma: surgical resection, radiation therapy

B. DISUSE OF BLADDER

- urinary frequency
- progressive rise in bladder pressure during filling

√ reduced bladder compliance
√ thickened bladder wall + decreased bladder volume
√ vesicoureteral reflux

Bladder Wall Thickening

Normal bladder wall thickness (regardless of age + gender):
< 5 mm in nondistended bladders
< 3 mm in well-distended bladders

A. TUMOR
   1. Neurofibromatosis

B. INFECTION / INFLAMMATION
   1. Cystitis

C. MUSCULAR HYPERTROPHY
   1. Neurogenic bladder
   2. Bladder outlet obstruction (eg, posterior urethral valves)

D. UNDERDISTENDED BLADDER

Urinary Bladder Wall Masses

A. CONGENITAL
   1. Congenital septum
   2. Simple ureterocele
   3. Ectopic ureterocele

B. BLADDER TUMOR

C. INFLAMMATION / INFECTION
   1. Cystitis: hemorrhagic cystitis, abacterial cystitis, bullous cystitis, edematous cystitis, interstitial cystitis, cystitis cystica, eosinophilic cystitis, granulomatous cystitis, emphysematous cystitis, cyclophosphamide cystitis, cystitis glandularis (premalignant lesion with villous lesions in bladder dome from proliferation of “intestinelike” glands in submucosa)
   2. Tuberculosis
   3. Schistosomiasis

4. Malakoplakia
5. Extravesical inflammation:
   (a) Diverticulitis
   (b) Crohn disease
   (c) endometriosis

D. HEMATOMA
after instrumentation, surgery, trauma

Bladder Tumor

Frequency: 2–6% of all tumors

A. EPITHELIAL TUMORS (95%)
1. Urothelial carcinoma = transitional cell carcinoma (90%)
2. Squamous cell carcinoma (4% in USA) worst prognosis; ← chronic disorders (chronic irritation from indwelling catheters, infection, stricture, calculi), cyclophosphamide, smoking, intravesical bacillus Calmette-Guérin, bladder diverticula, schistosomiasis (> 50% of bladder tumors in countries with endemic bilharziasis)
3. Adenocarcinoma (1%) most common in bladder exstrophy, less common in cystitis glandularis + urachal carcinoma
   ◊ Metastatic adenocarcinoma (← colon, prostate, rectum) more common than primary
4. Small cell / neuroendocrine carcinoma (< 0.5%)
   = highly aggressive tumor with invasive disease in 94% at presentation
   Age: 20–91 years; M÷F = 3÷1 to 5÷1
   • hematuria (88%)
   Size: 3–8 cm
   √ large polypoid / nodular tumor
   Prognosis: 16% 5-year survival rate
5. Carcinoid
   Mean size: 6 mm
6. Melanoma (extremely rare)

B. NONEPITHELIAL / MESENCHYMAL TUMORS
(a) primary benign bladder tumor originating from
› muscle
1. **Leiomyoma** (0.43%)
   ◊ Most common nonepithelial tumor
   Age: 22–78 years; M÷F = 1÷1
   • hematuria ← ulceration
   Location: arise in submucosa
   Site: submucosal (7%) / intravesical (63%) / extravesical (30%)
   √ solid homogeneous mass
   √ smooth indentation of bladder wall
   √ intraluminal mass ± degeneration
2. Rhabdomyoma (rare)

› nerve
1. **Neurofibroma** / NF1 in 60%
   √ typically of low attenuation on CT

√ hypointense mass on T1WI
√ "target" sign on T2WI in plexiform neurofibroma= central hypointense fibrosis surrounded by hyperintense myxoid stroma

2. **Paraganglioma** = pheochromocytoma (0.1%)
◊ 1% of all pheochromocytomas
Age: 10–78 years; M < F
Origin: paraganglia of bladder wall
- adrenergic attack in 50% during micturition ("micturition attack") or bladder filling (headaches, weakness)
- intermittent hypertension
- elevated catecholamine levels

√ submucosal mass
√ ring calcification around circumference
√ marked enhancement (KEY FEATURE)
N.B.: biopsy may incite hypertensive crisis!
Prognosis: 7% are malignant

› fat
1. Lipoma

› fibrous tissue
1. Fibroma
2. Solitary fibrous tumor

› blood vessels
1. Hemangioma
Age: 58 (range, 19–76) years during adulthood; 50% during childhood
Median size: 7 (range, 2–30) mm
2. Plasmacytoma
3. Nephrogenic adenoma
Associated with: cystitis cystica / cystitis glandularis

(b) primary malignant bladder tumor

1. **Primary lymphoma**
◊ 2nd most common nonepithelial tumor of bladder
Age: 40 years; M÷F = 1÷3
Histo: low-grade B-cell mucosa-associated lymphoid tissue (MALT) / diffuse large B-cell type
Location: submucosa; at base + trigone of bladder

2. **Rhabdomyosarcoma**
Age: 1st and 2nd decades of life
◊ Most common bladder tumor in patients < 10 years

3. **Leiomyosarcoma**
◊ Most common nonepithelial malignant bladder tumor
Age: mainly > 40 (range, 25–88) years; M÷F = 3÷1
Location: rarely at trigone
Mean size: 7 cm
√ poorly circumscribed invasive mass

√ heterogeneous texture ← necrosis (common)

4. Osteosarcoma

(c) secondary bladder tumor

1. Metastases
   1.5% of all bladder malignancies
   Origin: melanoma > stomach > breast > kidney > lung
   √ solitary / multiple nodules
2. Lymphoma
   autoptic bladder involvement in 15% of NHL, in 5% of Hodgkin disease
3. Leukemia
   microscopic involvement in 22% at autopsy
4. Direct extension (common)
   ← prostate, rectum, sigmoid, cervix, ovary
5. Endometriosis
   Location: on posterior wall
   • urinary symptoms in 80%

Bladder Calcification

Bladder Calculus

1. **Stasis calculus** (70%)
   in bladder outflow obstruction, bladder diverticula, cystocele, neuropathic bladder dysfunction
   Associated with: gram-negative lower urinary tract infection (in 30%), esp. Proteus
2. **Migrant calculus**
   = renal calculi spontaneously passing into bladder
3. **Foreign body nidus calculus**
   ← self-introduced objects, urinary stent, chronic catheterization, bladder wall-penetrating bone fragments, prostatic chips, nonabsorbable suture material, fragments of Foley balloon catheter, pubic hair, presence of intestinal mucosa (in bladder augmentation, ileal conduit, repaired bladder exstrophy)
4. **Idiopathic / primary / endemic calculus**
   Countries: North Africa, India, Indonesia
   Age: in young boys of low socioeconomic class (nutritional deficiency?)

Prevalence: India (13÷100,000); less common in western hemisphere
Number of stones: solitary (86%); multiple (in up to 25%)
Composition: magnesium ammonium phosphate (50%), calcium salts (31%), uric acid origin (5%)

• hematuria, recurrent UTIs, pelvic pain, irritative / obstructive voiding symptoms
Rx: surgical extraction, lithotripsy, alkalinization of urine
Rate of recurrence: 41%

Bladder Wall Calcification

A. INFLAMMATION

1. Schistosomiasis (50%)

√ relatively normal distensibility of bladder
√ thin arcuate pattern of calcification

2. Tuberculosis
   √ bladder markedly contracted
3. Cystitis: postirradiation cystitis, alkaline incrusted cystitis and pyelitis, cytotoxin cystitis
4. Bacillary UTI (extremely uncommon)
5. Encrusted foreign material

B. NEOPLASM
1. Primary neoplasm of bladder: TCC, squamous cell carcinoma, leiomyosarcoma, hemangioma, neuroblastoma, osteogenic sarcoma
2. Urachal carcinoma

mnemonic: SCRITT
Schistosomiasis
Cytoxan
Radiation
Interstitial cystitis
Tuberculosis
Transitional cell carcinoma

Mass Extrinsic to Urinary Bladder

A. NORMAL / ENLARGED ORGAN
1. Uterus: leiomyomatous uterus, pregnant uterus
2. Distended rectosigmoid
3. Ectopic pelvic kidney
4. Prostate cancer / BPH

B. SOLID PELVIC TUMOR
1. Lymphadenopathy
2. Bone tumor ← sacrum / coccyx
3. Rectosigmoid mass
4. Hip arthroplasty
5. Neurogenic neoplasm, meningomyelocele
6. Pelvic lipomatosis / liposarcoma

C. CYSTIC PELVIC LESION
(a) congenital / developmental
1. Urachal cyst
2. Müllerian duct cyst
3. Gartner duct cyst
4. Anterior meningocele
5. Hydrometrocolpos

(b) related to trauma
1. Hematoma: eg, rectus sheath hematoma
2. Urinoma
3. Lymphocele
4. Abscess

5. Aneurysm
6. Mesenteric cyst

(c) cyst of genitalia
1. Prostatic cyst
2. Cyst of seminal vesicle
3. Cyst of vas deferens
4. Ovarian cyst
5. Hydrosalpinx
6. Vaginal cyst

(d) cyst of urinary bladder
1. Bladder diverticulum

(e) cyst of GI tract
1. Peritoneal inclusion cyst
2. Fluid-filled bowel

Bladder Perforation

A. Trauma
1. Blunt trauma
2. Penetrating trauma
3. Iatrogenic: pelvic surgery, cystoscopy, suprapubic or transurethral placement of a Foley catheter (especially a long-term indwelling catheter), bladder biopsy, ureteral stent manipulation

B. Spontaneous

Pathophysiology: increase in bladder pressure + weakening of mucosa
1. Urinary tract infection
2. Urinary retention
3. Vaginal delivery
4. Alcoholism
5. Bladder calculi
6. Radiation therapy
7. Foley catheter malposition

VOIDING DYSFUNCTION

A. FAILURE TO STORE URINE
- urinary frequency, urgency, incontinence

(a) bladder causes
1. Involuntary detrusor contractions
   - › detrusor instability: idiopathic / neurogenic
   - › detrusor hyperreflexia ← upper cord lesion
2. Poor bladder compliance
   - › detrusor hyperreflexia
   - › bladder wall fibrosis
3. Sensory urgency
   - › infection, inflammation, irritation
   - › neoplasia

4. Vesicovaginal fistula
5. Psychogenic condition

(b) sphincter causes
1. Stress incontinence
2. Sphincteric incontinence

(c) extravesical ectopic insertion of ureter in females

B. FAILURE TO EMPTY BLADDER
- poor flow, straining, hesitancy
- inability to completely empty bladder

(a) bladder causes
1. Detrusor areflexia ← sacral arc lesion
2. Impaired detrusor contractility ← myogenic
3. Psychogenic condition

(b) bladder outlet obstruction
1. Bladder neck contracture
2. Prostatic enlargement
3. Detrusor-external sphincter dyssynergia
4. Scarring from surgery / radiation therapy
5. Ectopic ureterocele
6. Urethral stenosis
7. Urethral kinking: eg, ← cystocele

Urinary Incontinence

1. Stress incontinence
2. Vesicovaginal / ureterovaginal fistula
3. Urge incontinence
4. Psychogenic incontinence
5. Overflow incontinence
   ← lesions of sacral spinal cord / sacral reflex arc or severe outlet obstruction
6. Reflex voiding
   (a) hyperreflexive lesion ← lesion of upper spinal cord
   (b) uninhibited / unstable bladder
7. Continual dribbling
   = extravesical ectopic termination of ureter

Associated with pelvic floor dysfunction:
1. Stress urinary incontinence
2. Overactive bladder = urge incontinence
3. Bladder outlet obstruction

Stress Incontinence

= SPHINCTER WEAKNESS INCONTINENCE= URETHRAL INCOMPETENCE
= involuntary loss of urine during physical activity such as coughing, sneezing, laughing, exercise

Cause:
(a) male: S/P prostatectomy with damage to distal sphincter

(b) female: congenital bladder neck weakness, pregnancy, childbirth, aging ← changes in anatomic relationship of urethra + bladder base

• frequency, urgency (involuntary filling of bladder neck)
√ opening of bladder neck during coughing
√ impairment of milk-back mechanism (= retrograde emptying of urethra during interruption of voiding phase does not occur)
√ urethrovesical descent (in types I + II)

Chain cystography:
√ posterior urethrovesical angle (= angle between posterior urethra + bladder base) increased > 100°
√ upper urethral axis (= angle between upper urethra + vertical line) increased > 35°

MR:
√ urethral hypermobility (80–90%) ← laxity of urethral supporting structures:
√ rotational descent during straining = rotation of urethral axis from vertical to horizontal to a position > 30° from its resting axis
√ funneling = bladder neck + proximal urethra pushed low + appearing widely patent (SAG view)

Detrusor Instability

= MOTOR URGE INCONTINENCE = UNSTABLE BLADDER
= sudden contraction of detrusor muscle often related to inflammation / infection / nervous system diseases
◊ Condition resembles that of immature bladder before toilet training

Pathophysiology: likely induced by bladder outlet obstruction

Patient groups:
(1) Symptoms of nocturnal enuresis + frequency / incontinence dating back to childhood
(2) Idiopathic instability occurring in middle age
(3) Outflow obstruction commonly in men with BPH / women with pelvic floor dysfunction
(4) Degenerative instability ← cardiovascular + neurologic disease later in life

• frequency, urgency, urge incontinence, occasionally nocturia
• hesitancy + difficulty in voiding may occur in men without significant prostatic hypertrophy
√ involuntary bladder contractions with NO relationship to bladder distension
√ progressively vigorous contractions during bladder filling
√ postural instability limited to upright position
√ impaired milk-back mechanism ← high bladder pressure
√ strong contractions following bladder emptying

Cx: thickening of bladder wall, bladder diverticula
Rx: treatment of obstruction, anticholinergic drug (oxybutynin), operative increase in bladder capacity

Sensitive Bladder (Sensory Urgency)

Cause: cystitis (reduced compliance), some cases of stress incontinence (filling of bladder neck induces urgency)

• frequency, urgency, sometimes nocturia
√ patient uncomfortable with low bladder filling
√ no abnormal rise in bladder pressure
√ normal voiding function

Detrusor-Sphincter Dyssynergia

= overactivity of bladder neck muscle with failure to relax at beginning of voiding
Cause: spinal cord lesion / trauma above level of sacral outflow
• difficulty in voiding ± frequency
• lifelong history of poor stream
√ collarlike indentation of bladder neck during voiding (= persistent / intermittent narrowing of membranous urethra)
√ may have high voiding pressure + reduced flow
√ trapping of contrast in urethra during interruption of flow
√ massive reflux into prostatic ducts during voiding ← high pressure within prostatic urethra
√ severely trabeculated "Christmas-tree" bladder + bilateral hydroureteronephrosis
Rx: bladder neck incision

Hinman Syndrome

= NONNEUROGENIC NEUROGENIC BLADDER [NNNB] = DETRUSOR-SPHINCTER DYSSYNERGIA
Cause: no neurologic / anatomic obstructive disease; distinctly abnormal family dynamics (in 50%)
Age: some time after toilet training with onset during early / late childhood / puberty
• clinical criteria:
(1) Intact perineal sensation + anal tone
(2) Normal anatomy + function of lower extremities
(3) Absence of skin lesions overlying sacrum
(4) Normal lumbosacral spine at plain radiography
(5) Normal spinal cord at MR imaging
√ high-pressure uninhibited detrusor contractions
√ lack of coordination between detrusor contraction + periurethral striated sphincter relaxation
√ inability to suppress bladder contractions
√ normal response of detrusor muscle to reflex stimulation
√ increased bladder capacity + pressure
√ sphincter activity may increase paradoxically during detrusor contraction
US:
√ trabeculated bladder
√ dilatation of upper urinary tracts
√ renal damage
VCUG:
√ urethra normal during early voiding
√ urethral distension after contraction of external sphincter as voiding progresses
√ ureterovesical obstruction / reflux

Rx: suggestion therapy + hypnosis, bladder retraining, biofeedback, anticholinergic drugs

Wetting

1. Enuresis
   = manifestation of neuromuscular vesicourethral immaturity; M÷F = 3÷2
   • intermittent wetting, usually at night during sleep
   • often positive history of enuresis from one parent
   • normal physical examination
   √ no structural abnormality; urography NOT indicated
2. Epispadia
3. Sacral agenesis
   = segmental defect (below S2) with deficiency of nerves that innervate bladder, urethra, rectum, feet
   ◊ Children of diabetic mothers are affected in 17%!
4. Extravesical infrasphincteric ectopic ureter
   only affects girls, as boys do NOT have infrasphincteric ureteral orifices
   (a) ureter draining upper pole of duplex system → exits below urethral sphincter (90%)
   (b) ureter draining single system → ectopic extravesical orifice (10%)
5. Synechia vulvae
   = adhesive fusion of minor labia → directs urine primarily into vagina, from where it dribbles out post micturition
6. Vaginal reflux
   in obese older girls with fat thighs and fat labia
7. Miscellaneous
   posterior urethral valves, urethral stricture, urethral diverticula

Prostatic Obstruction

= urethral compression by hypertrophic prostatic tissue
• difficulty in voiding, reduction in flow rate
√ high-pressure bladder
√ slow + prolonged flow
√ increase in bladder capacity with reduced contractility (late)

SCROTUM

Acutely Symptomatic Scrotum

= acute unilateral scrotal swelling ± pain
Cause:
epididymitis÷torsion = 3÷2 < 20 years of age
epididymitis÷torsion = 9÷1 > 20 years of age

A. ISCHEMIA
   1. Acute testicular torsion (20%)
   2. Torsion of appendix testis
   3. Testicular infarction

B. INFECTION / INFLAMMATION (75–80%)

1. Acute epididymitis
2. Orchitis
3. Intrascrotal abscess
4. Henoch-Schönlein purpura
5. Kawasaki syndrome
6. Insect bite
7. Acute hydrocele
8. Fournier gangrene

C. HEMORRHAGE
1. Testicular trauma
2. Hemorrhage into testicular tumor

D. HERNIA
1. Scrotal fat necrosis
2. Strangulated hernia

Scrotal Wall Thickening

1. **Acute idiopathic scrotal edema**
   Frequency: 20–30% of all acute scrotal disorders
   Age: 5–11 years (range, 18 months to 14 years)
   • subcutaneous scrotal edema, erythema
   • minimal pain, afebrile, peripheral eosinophilia
   Prognosis: spontaneous resolution in 72 hours to 4 days
2. Epididymo-orchitis
3. Testicular torsion
4. Torsion of testicular / epididymal appendage
5. Trauma
6. Henoch-Schönlein purpura
7. Cx of ventriculoperitoneal shunt
8. Cx of peritoneal dialysis ← ? leakage of fluid into the anterior abdominal wall with dissection into scrotum
9. Acute hemorrhagic edema of infancy
   = similar to Henoch-Schönlein purpura
   Age: 5 months – 2 years

Testicular Blood Flow

Increased Testicular Blood Flow

1. Orchitis
2. Torsion-detorsion sequence
3. Torsion of appendix testis / epididymis
4. Abscess
5. Tumor

Decreased Testicular Blood Flow

1. Torsion
2. Infarct

Scrotal Gas

1. Fournier gangrene
2. Scrotal abscess
3. Scrotal hernia with gas-containing bowel
4. Scrotal emphysema from bowel perforation
5. Extension of subcutaneous emphysema
6. Air leakage + dissection ← faulty chest tube positioning

Groin Mass

A. CONGENITAL
   1. Encysted hydrocele
      = peritoneal fluid remnant of processus vaginalis
      (a) of spermatic cord (male)
      (b) of canal of Nuck (female equivalent)
   2. Retractile testis

B. HERNIA
   1. Inguinal-scrotal hernia
   2. Femoral hernia

C. VASCULAR
   1. Hematoma
   2. Pseudoaneurysm
   3. Varicocele
   4. Varices of greater saphenous vein

D. INFECTIOUS / INFLAMMATORY
   1. Inflammation of ileopectineal bursa
   2. Synovial osteochondromatosis of hip joint
   3. Groin abscess

E. NEOPLASM
   1. Lipoma (most common benign tumor)
   2. Inguinal lymph node metastases ← cancer of lower vagina, vulva, penis, lower rectum, anus, lower extremity

Scrotal mass

US is used to distinguish between
(a) intratesticular masses (more commonly malignant) and extratesticular masses (more commonly benign)
(b) intratesticular solid masses (often malignant) and cystic lesions (usually benign).

Most frequent conditions:

1. Inflammation 48%
2. Hydrocele 24%
3. Torsion 9%
4. Varicocele 7%
5. Spermatocele 4%

6. Cysts 4%
7. Malignant tumor 2%
8. Benign tumor 0.7%

◊ Sonographic differentiation of intra- from extratesticular masses is 80–95% accurate!

MRI's ability to characterize soft tissue helps to differentiate benign from malignant neoplasms or predict the presence of malignant disease.

Benign Tumors and Tumorlike Conditions

= benign mesenchymal tumors

1. Lipoma
2. Hemangioma
3. Lymphangioma
4. Leiomyoma
5. Nerve sheath tumor
6. Angiomyofibroblastoma (AMF)-like tumor
7. Fibrous pseudotumor

Intratesticular Mass

◊ 90–95% of testicular tumors are malignant!

(a) benign
   1. Leydig cell hyperplasia
   2. Intratesticular lipoma
   3. Adrenal rest tumor

(b) potentially malignant
   1. Leydig cell tumor
   2. Sertoli cell tumor

(c) malignant
   1. Germ cell tumor
   2. Lymphoma

(d) pseudotumor
   1. Orchitis
   2. Abscess
   3. Testicular infarction
   4. Testicular hematoma
   5. Postbiopsy defect

MULTIPLE INTRATESTICULAR MASSES

1. Lymphoma / leukemia
2. Primary testicular tumor
3. Chronic infection: epididymo-orchitis
4. Metastases: ← prostate, kidney, melanoma
5. Granulomatous disease: sarcoidosis, TB
6. Leydig cell hyperplasia

◊ The prevalence of synchronous / metachronous bilateral testicular neoplasms is 1–3%!

PREPUBERTAL TESTICULAR MASS

◊ Only 0.5–5.0% of all intratesticular tumors occur in patients < 15 years of age

A. Primary tumor
   (a) Germ cell tumors (70–90%):
      1. Yolk sac tumor ≤ 2 years
      2. Teratoma ≤ 5 years
   (b) Sex cord-stromal tumors (10–30%):
      1. Leydig cell tumor 3–9 years
      2. Sertoli cell tumor commonly < 1 year
      3. Gonadoblastoma after puberty
      4. Fibroma, lipoma, hemangioma, sarcoma, adrenal rest

B. Secondary tumor
   1. Lymphoproliferative tumor: leukemia, lymphoma
   2. Solid tumor: Wilms, neuroblastoma, rhabdomyosarcoma, retinoblastoma
   3. Others: sinus histiocytosis, Langerhans cell histiocytosis, tuberculous orchitis

Paratesticular Mass

◊ Only 4% of all scrotal tumors!

paratesticular = group of extratesticular lesions not readily identified as originating from a particular tissue

PARATESTICULAR INFLAMMATORY MASS

1. Sarcoidosis of epididymis
2. Inflammatory nodule of epididymitis
3. **Sperm granuloma**
   = foreign body giant cell reaction to extravasated sperm
   Autopsy: in 42% of postvasectomy patients
   Location: cut end of vas deferens
   √ well-defined hypoechoic solid mass / masses
4. **Scrotal calculi** = "scrotal pearls"
   = freely mobile calcified bodies between layers of tunica vaginalis
   Cause: fibrinous debris in long-standing hydrocele / following torsion of appendix testis or epididymis / dislodged fibrous pseudotumor
   √ central nidus of discrete acoustic shadow / "comet-tail" artifact (= calcium hydroxyapatite) surrounded by fibrous tissue
5. **Sclerosing lipogranuloma**
   (a) primary sclerosing lipogranuloma
   (b) secondary sclerosing lipogranuloma
   Cause: injection of liquid paraffin, vegetable oil, silicon into scrotal sac
   √ gradually increasing hypoechoic mass
   √ heterogeneous mass with intravoxel fat SI on MRI
   √ avid heterogeneous enhancement
6. Spermatic cord hematoma

PARATESTICULAR TUMOR

◊ The majority of paratesticular tumors are derived from the spermatic cord!

◊ Sarcomas are the most common spermatic cord tumor!

A. EPIDIDYMAL TUMOR
B. SPERMATIC CORD TUMOR
   (a) benign: lipoma > fibroma > dermoid cyst > lymphangioma
   (b) malignant: sarcoma
C. SCROTAL TUNICA TUMOR

Benign Paratesticular Tumor (75–97%)

1. Spermatic cord lipoma (most common)
2. Adenomatoid tumor (2nd most common)
3. Fibrous pseudotumor of scrotum (3rd)
4. Epidermoid inclusion cyst
5. Polyorchidism
6. Leiomyoma
7. Cord fibroma
   = reactive nodular proliferation of paratesticular tissue
8. **Papillary epididymal cystadenoma**
   Frequency: in up to 60% of patients with Von Hippel-Lindau disease
   √ solid mass with a few cystic spaces
   √ multiloculated cystic lesion with small papillary projections
9. Others: herniated omentum, adrenal rest, carcinoid, cholesteatoma

Lipomas are the most common extratesticular neoplasm of the scrotum, discovered in 22% of hernia repairs.

Malignant Paratesticular Tumor (3–25%)

The majority of malignant tumors in the nonepididymal extratesticular soft tissues are sarcomas that arise from the spermatic cord.

1. Sarcomas:
   (a) primarily in adults: undifferentiated sarcoma (30%), leiomyo-, lipo-, fibro-, myxochondro-sarcoma, malignant fibrous histiocytoma
   (b) children: rhabdomyosarcoma (20%), embryonal sarcoma

   Well-differentiated liposarcoma tends to have large amounts of macroscopic fat relative to enhancing soft tissue, while dedifferentiated liposarcomas may have only small amounts of macroscopic fat within a mostly soft-tissue mass.

2. Mesothelioma of tunica (in 15% malignant)
3. Metastases (8%): ← prostate > kidney > stomach > colon > ileal carcinoid tumor > pancreas

Primary Tumor of Tunica Vaginalis

1. Adenomatoid tumor
2. Scrotal tunica cyst
3. Mesothelioma
4. Lipoma
5. Leiomyoma

6. Sarcoma: rhabdo-, lipo-, leiomyo-

Extratesticular Fluid Collection

1. Hydrocele, pyocele, hematocele ← surgery, trauma, neoplasm
2. Spermatic cord hydrocele: encysted / funicular
   √ fluid collection superior to testis
   √ NO communication with scrotal sac
3. Varicocele
4. Spermatocele (exclusively after puberty)
   = single / multiple retention cysts filled with fluid + spermatozoa + cellular debris
   Cause: obstruction + dilatation of efferent ductal system
   • frequently following vasectomy
   Location: commonly in head of epididymis
   √ up to a few cm in size ± septations
5. Epididymal cyst
   = cyst without spermatozoa of lymphatic origin (less common than spermatoceles)
   • status post vasectomy
   Location: anywhere within epididymis
   √ wide range of sizes
6. Lymphangioma, hemangioma
7. Lymphocele
8. Abscess
9. Scrotal hernia = bowel in inguinal hernia
   √ peristalsing hypoechoic bowel musculature

CONGENITAL ANOMALIES OF PROCESSUS VAGINALIS

1. Patent processus vaginalis
   • may remain asymptomatic
   • patent at birth (20%), usually closes in 1st year
   Conditions for delayed / nonclosure:
   premature birth, cystic fibrosis, Ehlers-Danlos syndrome, hip dysplasia, peritoneal dialysis, ventriculoperitoneal shunt
   Cx: failure of testis to descend into scrotum, gliding testis, communicating hydrocele, indirect inguinoscrotal hernia
2. Hydrocele of spermatic cord
   (a) communicating = fluid collection extending from pelvis through deep inguinal ring to scrotum
   (b) funicular = fluid collection communicating with peritoneum at deep inguinal ring (= peritoneal diverticulum) as potential indirect hernia
   √ become larger with ⇑ intraperitoneal pressure
   Rx: herniotomy
   (c) encysted = isolated fluid collection between deep inguinal ring and superior pole of testis
   Location: anywhere along spermatic cord
   √ ovoid / round cyst in the groin

3. Inguinoscrotal hernia

Cystic Lesion of Testis

Prevalence: 4–10% (increasing with age)
• asymptomatic
A. NONNEOPLASTIC
1. **Intratesticular cyst**
Prevalence: 8–10%
Cause: ? trauma, prior inflammation, surgery
Age: > 40 years
• nonpalpable
Often associated with: spermatocele, dilated rete testis
Location: related to rete testis (in 92%)
√ usually solitary 2–20-mm simple cyst
DDx: cystic neoplasm
2. **Tunica albuginea cyst** / scrotal tunica cyst
Cause: fluid within mesothelial rests; fluid from blind-ending efferent ductules
Histo: cyst lined by nonciliated cuboidal cells; contains serous fluid + cellular debris
Mean age: 40 years
• palpable firm nodule
Location: upper anterior / lateral aspect of testis
Site: subcapsular / tunica vaginalis
√ solitary uni- / multilocular 2–5-mm marginally located cyst
3. **Intratesticular tubular ectasia**
= DILATATION OF RETE TESTIS = CYSTIC TRANSFORMATION OF THE RETE TESTIS
Cause: partial / complete obliteration of efferent ductules
Age: > 55 years
Often associated with: spermatocele
• nonpalpable
Location: mediastinum testis, frequently asymmetrically bilateral
√ elliptical hypoechoic branching tubular structures ± cysts
√ ± epididymal cysts / spermatoceles
MR:
√ hypointense on T1WI
√ iso- to hyperintense on T2WI
DDx: teratoma
4. **Intratesticular spermatocele**
= cyst containing mature spermatozoa
Location: attached to mediastinum testis
5. **Intratesticular varicocele**
• ± pain ← related to passive congestion
√ multiple anechoic serpiginous tubules
√ characteristic venous flow pattern increasing with Valsalva on Doppler
Infrequently associated with: extratesticular varicocele
6. Intratesticular abscess

Cause: epididymoorchitis, trauma, testicular infarction, mumps
√ collection with low-level echoes, shaggy irregular wall, occasionally hypervascular margin

7. Intratesticular infarction
   √ avascular hypoechoic mass
8. Congenital cystic dysplasia of testis (extremely rare)

B. BENIGN TUMOR
1. Epidermoid inclusion cyst / keratin cyst of testis

C. MALIGNANCY
◊ 24% of all testicular tumors have a cystic component!
• palpable
√ in combination with solid elements
DDx: hematoma, inflammation, seminoma, Leydig cell tumor

Infiltrative Process of Testis and Epididymis

1. Epididymoorchitis
2. Sarcoidosis
3. Lymphoma
4. Tuberculosis
5. Leukemia

Epididymal Enlargement with Hypoechoic Foci

1. Epididymitis
2. Sperm granulomas
3. Tuberculosis
4. Lymphogranuloma venereum
5. Granuloma inguinale
6. Filarial granuloma
7. Fungal disease
8. Lymphoproliferative disease
9. Metastases

Enlargement and Hyperemia of Epididymis

1. Epididymoorchitis
2. Trauma

Cystic Lesions of Epididymis

1. Epididymal cyst
   Prevalence: in up to 40%
   May be associated with: intratesticular tubular ectasia
   √ single / multiple / bilateral
   DDx: loculated hydrocele
2. Spermatocele
   √ may contain low-level echoes
3. Cystic degeneration of epididymis

PROSTATE

Large Utricle

1. Prune belly syndrome
2. Imperforate anus of high type
3. Down syndrome
4. Hypospadia
5. Posterior urethral valves

Extraprostatic Cyst

1. **Seminal Vesicle Cyst**
   Cause: congenital / acquired
   Age: 10–40 years
   May be associated with: ipsilateral renal agenesis, autosomal dominant polycystic kidney disease
   • asymptomatic, chronic recurrent prostatitis / epididymitis
   • painful ejaculation, perineal / testicular pain
   • urgency, hesitancy, tenesmus, pain upon defecation
   • hematuria, hematospermia, infertility; urethral discharge
   • acute urinary retention, constipation ← bladder / bowel obstruction
   Size: usually < 5 cm
   √ well-defined intraseminal unilocular round / oval cyst
2. **Vas Deferens Cyst**
   √ cyst superior to prostate along course of vas deferens
3. **Cowper Duct Cyst**
   Cause: congenital / acquired
   Location: posterior / posterolateral to posterior urethra
   • mostly asymptomatic, hematuria, urinary obstruction

DDx: ureterocele, TURP defect, bladder diverticulum, hydroureter, ectopic insertion of ureter

Prostatic Cyst

A. MEDIAN CYST
   1. Utricle cyst
   2. Müllerian duct cyst
B. PARAMEDIAN CYST
   1. Ejaculatory duct cyst
C. LATERAL CYST
   1. Prostatic retention cyst
   2. Cystic degeneration of BPH
   3. Cystic carcinoma of prostate / multilocular prostatic cystadenoma, papillary adenocarcinoma
      • hemorrhagic aspirate!
      √ solid tissue invaginating into cyst
   4. Cyst associated with infection

(a) Cavitary / diverticular prostatitis
(b) Prostatic abscess
(c) Parasitic cyst (Echinococcus, bilharziasis)

Hypoechoic Lesion of Prostate

1. Adenocarcinoma 35%
2. Benign prostatic hyperplasia 18%
   √ rarely originating in peripheral zone
3. "Normal" prostatic tissue 18%
   (a) cluster of prostate retention cysts
   (b) prominent ejaculatory / other dilated duct
   (c) external sphincter veins
   (d) neurovascular bundle
   (e) seminal vesicle
   (f) sonographic artifact
4. Acute / chronic prostatitis 14%
5. Granulomatous prostatitis 1%
   most frequently ← intravesical Calmette-Guérin bacillus (BCG) therapy for bladder cancer
6. Atrophy 10%
   • occurs in 70% of young healthy men
   ◊ May be confused with carcinoma histologically!
7. Prostatic dysplasia 6%

Hypointense T2 Signal of Prostate

1. Adenocarcinoma
2. Post-biopsy hemorrhage
   ◊ Wait 6–8 weeks after biopsy before MR imaging
3. Bacterial prostatitis, fibrosis, scarring
4. Hyperplastic nodules
5. Hormonal / radiation treatment
6. Anterior fibromuscular stroma

DDx: The normal central zone appears homogeneously hypointense on T2WI and dark on ADC map of 42–84-year old men mimicking prostate cancer. Location and symmetry of the central zone help to differentiate it from prostate cancer, although it is asymmetric in 20%.

PENIS

Painful Penile Induration

A. INFLAMMATION / INFECTION
   1. Peyronie disease
   2. Cavernositis
      Cause: self-administration of intracavernosal drug, prosthesis implantation
   3. Spongiositis
      Cause: improper catheterization, endoscopic manipulation

4. Cellulitis
5. Balanitis

B. VASCULAR
1. Dorsal vein thrombosis
2. Corporal thrombosis
3. Low-flow priapism
4. **Calciphylaxis**
   = life-threatening disorder characterized by progressive vascular calcification + ischemic tissue loss in patients with end-stage renal disease
5. **Penile Mondor disease**
   = thrombosis / thrombophlebitis in superficial dorsal vein of penis of poorly understood cause

C. TRAUMA
1. Penile fracture

D. TUMOR

URETHRA

Congenital Urethral Anomalies

A. Anomaly of number
1. Duplication of urethra

B. Anomaly of form
1. Posterior urethral valves
2. Congenital stricture
3. Congenital polyp
4. Congenital diverticulum

C. Malformation of urethral groove
1. **Epispadia**
   = absent roof of urethra with opening anywhere between base of bladder and glans penis
   Associated with: bladder exstrophy
   • urinary incontinence from incompetent bladder neck / urethral sphincter
   √ abnormally wide symphysis pubis (> 1 cm)
2. **Hypospadia**
   = congenital defect of anterior urethra with opening anywhere along ventral aspect of penile shaft

Urethral Stricture

= fibrous scarring of anterior urethra ← collagen + fibroblast proliferation; ± spongiofibrosis = scar in surrounding corpus spongiosum

A. Inflammation
1. Infectious urethritis: ← eg, gonococcal urethritis
2. Balanitis xerotica obliterans

B. Trauma
1. Straddle injury

2. Instrumentation: pressure necrosis ← indwelling catheter
3. Surgery: TURP, open radical prostatectomy → "bladder neck contracture"

C. Congenital

Cowper (Bulbourethral) Gland Lesions

Analogous to Bartholin glands in females

Prevalence: 2.3% (autopsy)

Location: within urogenital diaphragm

1. Retention cyst
   Cx: prenatal death from urinary obstruction
2. Infectious / traumatic cyst
   - asymptomatic (most)
   - hematuria, bloody urethral discharge, postvoid dribbling

Periurethral Cyst

◊ NO communication with urethra

A. Vaginal cyst
   1. Gartner duct cyst
   2. Bartholin gland cyst
   4. Müllerian cyst
      Site: anterolateral vaginal wall
   5. Vaginal (epidermal) inclusion cyst
      Site: lower posterior / lateral vaginal wall

B. Paraurethral cyst
   1. Skene duct cyst
   2. Urethral diverticulum
   3. **Urethral caruncle**
      Cause: distal urethral prolapse in hypoestrogenic postmenopausal woman
      Histo: hyperplastic squamous epithelium with submucosal vascularity, fibrosis, inflammation
      Location: posterior margin of external urethral meatus
      - asymptomatic, pain, hematuria
      - soft exophytic lesion of the meatus

C. Other periurethral lesions
   1. Perineal-vulvovaginal endometrioma
      Site: distal urethra
   2. Injected collagen
      Cause: treatment of stress incontinence
      √ hyperintense nodules in urethral wall on T2WI

Cx: infection, hemorrhage, rupture

DDx: ectopic ureter, ureterocele

Urethral Tumor

A. MALIGNANT
   1. Urethral carcinoma

2. Metastasis: ← bladder, prostate, rectum, spermatic cord, testis, melanoma

B. BENIGN

1. Fibroepithelial polyp
2. Transitional cell papilloma
   Age: older patient
   Location: in prostatic / bulbomembranous urethra
   ◊ Frequently associated with concomitant bladder papillomas
3. Adenomatous polyp
   Age: young men
   Histo: columnar epithelium ← aberrant prostatic epithelium
   Location: adjacent to verumontanum
   • hematuria
4. Penile squamous papilloma
5. Urethral leiomyoma (female)
   √ well-defined homogeneous tumor with increased vascularity
   √ T1-hypointense + T2-hyperintense relative to muscle + uniform enhancement
6. Others: caruncle, urethral mucosal prolapse, inflammatory tags (in female)

CALCIFICATIONS OF MALE GENITAL TRACT

A. VAS DEFERENS

1. Diabetes mellitus: in muscular outer layer
2. Degenerative changes
3. TB, syphilis, nonspecific UTI: intraluminal

B. SEMINAL VESICLES

gonorrhea, TB, schistosomiasis, bilharziasis

C. PROSTATE

calcified corpora amylacea, TB

AMBIGUOUS GENITALIA

= INTERSEX

= external genitalia that are not clearly of either sex

Prevalence: 1÷1,000 live births

◊ Only 4–7% of infants with disorders of sex development (DSD) have ambiguous genitalia

Indication for postnatal evaluation:

- cryptorchidism = neither testis palpable
- epi- / hypospadia combined with unilateral undescended / nonpalpable testis
- clitoromegaly = clitoral hypertrophy
- foreshortened vulva; labial fusion
- single urogenital tract opening = urogenital sinus
- inguinal hernia containing gonad in phenotypic female

Indication for evaluation of older patients:

- unrecognized genital ambiguity
- female inguinal hernia; delayed / incomplete puberty

- female virilization; primary amenorrhea
- phenotypic male breast development
- cyclical gross hematuria in phenotypic male

Cause:

A. Abnormal hormone levels
   1. Congenital adrenal hyperplasia (most commonly)
   2. Transplacental passage of hormones
   3. True hermaphroditism

B. Anomalies of external genitalia not hormonally mediated (eg, micropenis)

Laboratory tests:

1. Karyotype analysis for sex chromosome determination
2. 17-hydroxyprogesterone level: elevation suggests CAH
3. 11-deoxycortisol, 11-deoxycorticosterone levels:
   › elevated in 11-b-hydroxylase deficiency in CAH
   › depressed in 21-hydroxylase deficiency in CAH
4. Testosterone-to-dihydrotestosterone ratio: > 20÷1 indicates 5a-reductase deficiency
5. hCG-stimulation test: nonresponse indicates nonfunctioning Leydig cells / anorchia / luteinizing hormone receptor defect
6. Antimüllerian hormone + inhibin B levels: normal values suggest normal Sertoli cell function with presence of at least one testis

Imaging Evaluation:

1. Ultrasound of kidneys, adrenals, pelvis, inguinal, perineal, anal regions
2. Voiding cystourethrogram, genitography
3. MRI: greater sensitivity for intraabdominal gonads

Terminology:

Sex = what a person is biologically; sex assignment based on
(1) Karyotype
(2) Gonadal biopsy
(3) Genital anatomy

Gender = what a person becomes socially

Female Pseudohermaphroditism

= FEMALE INTERSEX = 46,XX DISORDER OF SEX DEVELOPMENT

Cause: exposure to excessive androgens in 1st trimester ←
(a) congenital adrenogenital syndrome
(b) maternal drug ingestion (progestational agents, androgens)
(c) masculinizing ovarian tumor

Karyotype: 46,XX

- masculinized external genitalia:
  - penislike clitoris ← prominent corpora cavernosa + corpus spongiosum
  - rugose labioscrotum
- uterus + vagina may be filled with urine via urogenital sinus

√ normal ovaries, fallopian tubes, uterus, vagina
√ enlarged adrenal glands ←adrenal hyperplasia
√ no testicular tissue / internal wolffian duct derivatives

Male Pseudohermaphroditism

= 46,XY DISORDER OF SEX DEVELOPMENT

Cause: fetal testis with

(a) ↓ testosterone synthesis

(b) ↓ dihydrotestosterone production (= substance responsible for masculinization of external genitalia) ← 5α- reductase deficiency

(b) no testosterone production ← early destruction / dysgenesis of testes

(c) complete / incomplete androgen insensitivity ← androgen receptor defect (= testicular feminization)

Karyotype: 46,XY

• undermasculinized / ambiguous external genitalia

[• apparent hypergonadotropic primary amenorrhea]

√ commonly undescended normal / mildly defective bilateral testes

√ prostatic tissue

√ no müllerian duct derivatives (production of müllerian regression factor by testes not affected)

√ occasionally blind-ending vaginal pouch emptying into perineum (= pseudovagina) / through urethra (= urogenital sinus)

Gonadal Dysgenesis

characterized by abnormal gonadal organization and function with gonads often partially / completely replaced by fibrous stroma (= streak gonad)

(1) **Mixed gonadal dysgenesis**

= testis on one side + gonadal streak on other side

Karyotype: 45,XO / 46,XY karyotype or other mosaics with a Y chromosome

• ambiguous external genitalia

√ small / rudimentary uterus + vagina

√ fallopian tube present on side of streak gonad

√ urogenital sinus commonly empties at base of phallus

√ dysgenetic gonads ← inability to secrete müllerian regression factor

Cx: gonadal neoplasia

(2) **Pure XY gonadal dysgenesis**

Karyotype: 46, XY

√ bilateral streak gonads / dysgenetic testes

√ müllerian + wolffian duct derivatives both absent / partially developed

(3) **XY gonadal agenesis**

= vanishing testes syndrome = testicular resorption in early fetal life of unknown cause

Karyotype: 46,XY

• ambiguous external genitalia / female phenotype

√ absent testes

√ müllerian + wolffian duct derivatives both absent / partially developed

True Hermaphroditism

= TRUE INTERSEX = OVOTESTICULAR DISORDER OF SEX DEVELOPMENT

= condition characterized by presence of ovarian + testicular tissue either separate or in same

gonad (= ovotestis in 64%)

Gonads:

(a) ovary on one + testis on other side (30%)

(b) ovary / testis on one + ovotestis on other side (50%)

(c) bilateral ovotestes (20%)

Location: in pelvis predominantly ovarian tissue; in scrotum / inguinal region predominantly testicular tissue

Prevalence: rare (500 cases in world literature); < 10% of all intersex conditions

Age: diagnosed within first 2 decades (75%)

Karyotype: 46,XX (80%) / 46,XY (10%) / mosaicism (10%)

Classification:

Class I : normal female genitalia (80%)
Class II : enlarged clitoris
Class III : partially fused labioscrotal folds
Class IV : fused labioscrotal folds
Class V : hypoplastic scrotum + penoscrotal hypospadia
Class VI : normal male genitalia

- ambiguous external + internal genitalia, inguinal hernia
- lower abdominal pain ← endometriosis
- lower abdominal tumor (dysgerminoma, myomatous uterus)

Reared as boy:

- cryptorchidism
- short penis
- slight degree of hypospadia
- urogenital sinus at base of penis
- penile urethra (extremely rare)
- effective spermatogenesis (rare)

Reared as girl:

- development of breasts
- hematuria (= menstruation via urogenital sinus opening) in 50%
- internal female organs + female fertility
- amenorrhea
- separate urethral + vaginal openings (uncommon)

√ hypoplastic uterus (in virtually 100%)

√ ovotestis with heterogeneous appearance ← combination of testicular tissue + ovarian follicles

√ internal gonadal duct fits the gonad:

√ deferent duct on side of testis

√ fallopian tube on side of ovary

√ ipsilateral fallopian tube absent ← suppression of development by fetal testis

√ testis / testicular portion of ovotestis usually dysgenetic

MALE INFERTILITY

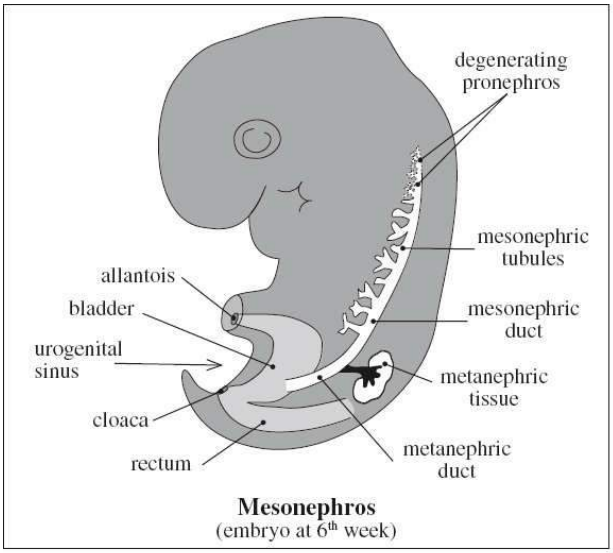
A. CONGENITAL

(a) Wolffian duct anomalies
    1. Renal agenesis / atrophy
    2. Vas deferens agenesis / cyst
    3. Seminal vesicle agenesis / cyst
    4. Ejaculatory duct cyst
(b) Müllerian duct anomalies
    1. Müllerian duct cyst
    2. Utricle cyst

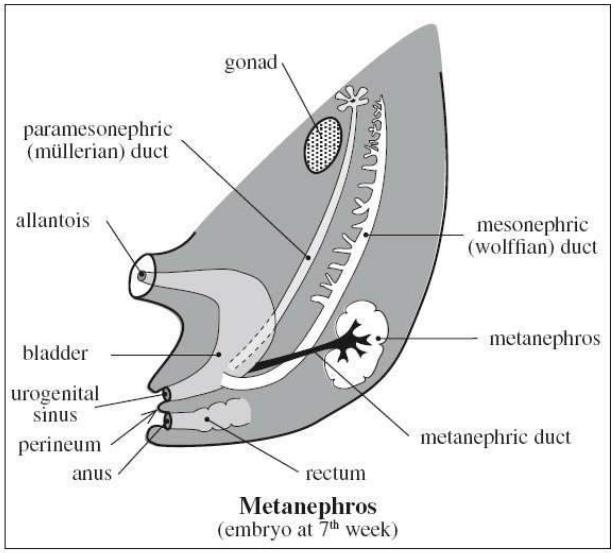
B. ACQUIRED
    1. Cowper duct cyst
    2. Prostatic cyst in peripheral zone

C. INFECTIOUS
    1. Prostatitis

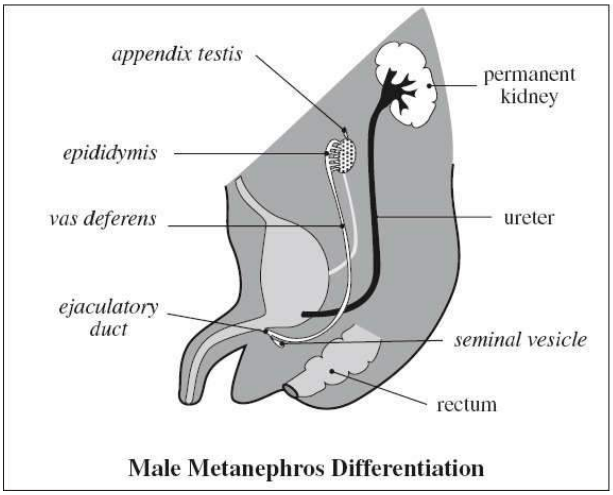
D. HORMONAL
    • semen low in volume, acid pH, without fructose
    1. Seminal vesicle atrophy
       = seminal vesicles < 7 mm in width
    2. Seminal vesicle hypoplasia
       = seminal vesicles < 11 mm + > 7 mm in width



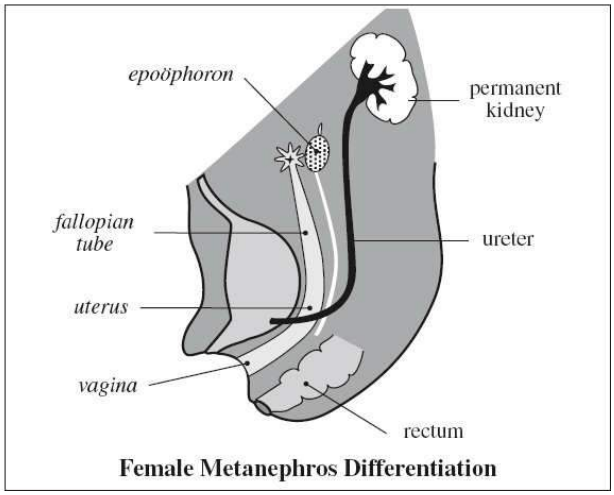
Mesonephros
(embryo at 6th week)



Metanephros
(embryo at 7th week)



Male Metanephros Differentiation



Female Metanephros Differentiation

UROGENITAL EMBRYOLOGY

Pronephros = forekidney

develops from mesoderm during 3rd week of gestation; involutes during 4th week of gestation
→ vestigial remnant / complete absence

Mesonephros = midkidney

develops during 4th week of gestation immediately caudal to pronephros, functions as interim kidney; degenerates around 8 weeks of gestation

(a) mesonephric tubules
→ paradidymis, epididymis, efferent ductules (M); epinephron (F)

(b) mesonephric (wolffian) duct
→ appendix epididymis, vas deferens, ejaculatory duct, seminal vesicles (M); vanishes (F)
[Caspar Friedrich Wolff (1733–1794), German anatomist, biologist, and embryologist in Berlin and St. Petersburg, cofounder of embryology, established doctrine of germ layers]
mnemonic: **G**ardener's **SEED**
» female: **G**artner duct, cyst
» male: **S**eminal vesicle
Epididymis
Ejaculatory duct
Ductus deferens

Paramesonephric (Müllerian) Duct
(grows alongside mesonephric duct)
[Johannes Peter Müller (1801–1858), German physiologist and comparative anatomist in Bonn and Berlin]
Male: degenerates ← production of müllerian inhibiting factor (MIF) by Sertoli cells of testis at about 6 weeks GA
→ prostatic utricle + appendix testis
Female: induced by wolffian duct at 5 weeks GA; grows caudally → joins in midline → fuses with outgrowth of urogenital sinus
→ uterus, fallopian tubes

Metanephros = hindkidney = permanent kidney

(1) **metanephric diverticulum** (ureteric bud) buds from mesonephric duct near its entry into the cloaca at 4th week; it lengthens + grows toward nephrogenic cord which becomes the metanephric blastema that divides and forms
→ ureter (mesonephric duct)
→ renal pelvis (first 4 dividing generations of duct)
→ calices (second 4 dividing generations of duct)
→ collecting tubules (10–12 generations of duct)
(2) **metanephric blastema** (= nephrogenic mesoderm) forms nephrons under the influence of ureteral bud → the end of collecting tubules induce clusters of metanephric blastema cells located at the periphery and along the sides of the medullary ray (= pyramid) except around the papilla
(3) **metanephric vesicles** form within clusters of metanephric blastema cells + elongate into S-shaped tubules which, by 12th week of gestation, result in
→ glomerulus
→ proximal convoluted tubule
→ loop of Henle
[Friedrich Gustav Jakob Henle (1809–1885), German pathologist and anatomist in Berlin, Zürich, Göttingen]
→ distal convoluted tubule
→ connective tissue

◊ Polycystic kidney disease is believed to be a failure of linkage!

Urogenital Sinus

forms from cloaca
→ develops into bladder + urethra (+ prostate)

Bladder

develops in 2nd–4th embryonal month

Urachus

= narrowed apex of fetal bladder continuous with allantoic stalk at the umbilicus
→ forms median umbilical ligament
(a) supravesical portion
(b) intramural portion
(c) intramucosal portion

SEX DEVELOPMENT

Indifferent Stage of Sexual Differentiation

Period: until 7th week of GA
Composition of undifferentiated gonad:

(1) Mesenchyme
condensation of mesenchyme forms genital ridges on both sides of midline between 6th thoracic and 2nd sacral segments; differentiates into interstitial (Leydig) cells within seminiferous tubules (= supporting stromal cells of testicular interstitium, including endothelial cells and vascular smooth muscle cells)

(2) Mesothelium
genital ridges are covered by proliferating mesothelium (coelomic epithelium); differentiates into Sertoli / supporting cells of the seminiferous tubules; forms tunica albuginea (vaginalis) as the serous covering of the testes

(3) Germ cells
form in wall of yolk sac and migrate along hindgut into genital ridge; differentiate into spermatogonia within seminiferous tubules; give rise to most testicular tumors

Chromosomes

› determine genotypic sex
› issue complex signaling pathways + hormones → modify primordial mesodermal cells → phenotypic sex

Formation of Testis

Period: around 8–12 weeks GA

- sex-determining factor localized on short arm of Y chromosome (SRY gene) → initiates male sex differentiation = seminiferous tubules
- Leydig cells secrete testosterone → stimulating growth of mesonephric (wolffian) structures
- Sertoli cells secrete müllerian-inhibiting factor → leading to regression of paramesonephric (müllerian) duct

Testicular Migration

@	inguinal canal:	by 21 weeks
@	scrotum:	by 30 weeks at birth (in 97% of full-term infants) during first 3 months of life (most)

Prenatal Evaluation of Sex

◊ Imaging of genitalia recommended only when
(a) medically indicated
(b) in twin gestation

Successful imaging of genitalia:
› in 60% by 14–18 weeks GA
› in 80–100% > 20 weeks GA

Errors in imaging of genitalia:
√ adducted fetal legs
√ US beam at wrong angle

Female:
√ 3 parallel lines between legs on transverse US
√ 3 bumps with clitoris in midline directed caudally

Male:
√ small semicircular structure (= scrotal sac)
√ penis in midline directed anteriorly and superiorly
√ visualization of testes in scrotum in late 2nd trimester

Ambiguous genitalia:
√ thorough fetal survey to detect associated anomalies
√ repeated US examinations with early GA
√ MRI with present oligohydramnios / multiple anomalies

RENAL ANATOMY

Adult Kidney

› forms by fusion of superior + inferior subkidneys (= metanephric lobes); the line of fusion runs obliquely forward and upward
√ separation of upper + lower groups of calices
√ indentation of cortical contour + echogenic line (= interrenicular septum = **junctional parenchymal defect**) delineates junctional parenchyma (often referred to as hypertrophic column of Bertin)
› consists of 20,000 lobules within 14 lobes (reniculi)
› initially located in pelvic region ventral to sacrum, ascending cranially at 9 weeks of gestation ← body growth caudal to kidneys + straightening of body curvature
› renal hilum at first ventrally located, eventually rotating medially by 90 degrees with renal ascent

Reniculus = renal lobe

= central core of medullary tissue enveloped by
(a) centrilobar cortex (= cortical arch) that covers the base of the pyramid → subsequently

forming the renal cortex with loss of grooves

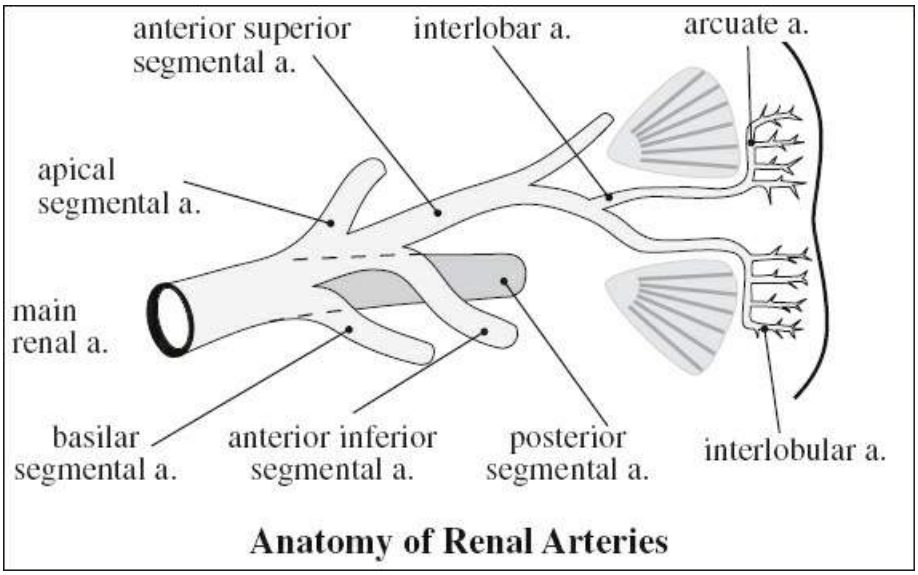
(b) mural cortex that wraps around sides of pyramid → and fuses with the mural cortex of adjacent lobe → to form renal septum (= column of Bertin)

› renal lobes completed by 28 weeks GA

√ ren lobatus (= interlobar surface grooves) present in fetus and infant, rare in adulthood

√ assimilation of independent lobes > 28 weeks GA makes renal surface smoother

› nephrogenesis completed by 36 weeks GA



Anatomy of Renal Arteries

Renal Size (in cm)

› < 1 year of age: 4.98 + 0.155 x age (in months)

› > 1 year of age: 6.79 + 0.22 x age (in years)

› adulthood: R kidney 10.74 ± 1.35 (SD); L kidney 11.10 ± 1.15 (SD)

› ratio of renal length (RL) to distance between first 4 lumbar transverse processes (4 TP) = 1.04 ± 0.22

Renal Echogenicity

A. ADULTHOOD

liver ≥ spleen ≥ renal cortex > renal medulla

B. INFANCY (in neonate up to 6 months of age)

√ cortex may be more echogenic than adjacent normal liver / spleen

Cause: glomeruli occupy 18% of cortex in neonate compared with 9% in adult

√ increase in corticomedullary differentiation

Cause: ratio of cortex to medulla 1.64÷1 in neonate compared with 2.59÷1 in adult

√ hypoechoic pyramids appear relatively large

Cause: thin immature cortex in neonate

N.B.: may be misinterpreted as dilated calices / renal cystic disease

√ renal sinus echogenicity less prominent

Cause: paucity of fat

Renal Vascular Anatomy

Hilar Arteries

Entry: renal hilum

1st order: main renal arteries at level of L1 / upper margin of L2

2nd order: 5 segmental branches = apical, anterior superior, anterior inferior, posterior, basilar

Extrahilar branching:

= branching of main renal artery prior to reaching hilum

Entry: renal hilum / direct as polar arteries

› early branching: within 1.5 cm from aorta

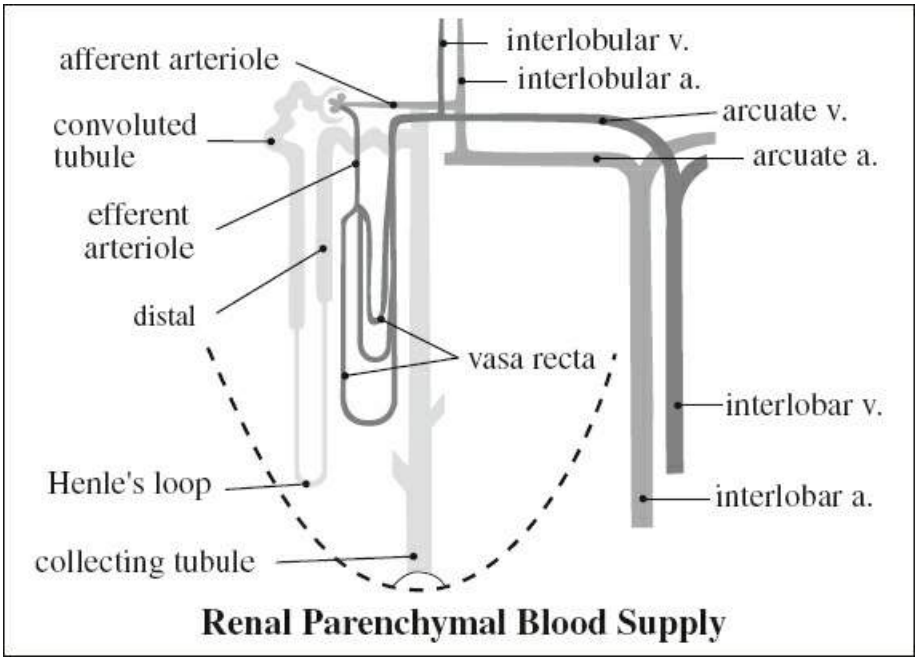
Resistive index: < 0.70 1 SD of several measurements = 0.04

Renal Polar Artery

Entry: without going through renal hilum directly into renal parenchyma at the poles

Types: superior polar artery; inferior polar artery (with supply of upper urinary tract)

Origin: main renal a., contralateral main renal a., aorta, iliac a., superior mesenteric a., inferior mesenteric a., celiac a., middle colic a., lumbar a., gonadal a., middle sacral a.



Renal Parenchymal Blood Supply

Capsular artery

= tiny vessels perfusing the renal capsule coursing tangentially to renal margin

Origin: main renal a., branch renal a., other retroperitoneal aa. (lumbar a.)

Anatomic Renal Artery Variants

Multiple renal arteries (25–30%):

unilaterally (32%); bilaterally (12%)

Number of renal arteries per kidney:

(a) one 71%
(b) two 24%
› 2 hilar arteries 12%
› 1 hilar + 1 superior polar artery 7%
› 1 hilar + 1 inferior polar artery 5%
(b) three 4%
(c) more than three 1%

◊ More than 2 renal arteries per kidney is a contraindication for donation! A small superior polar artery < 2 mm in diameter may be sacrificed.

Separate aortic ostium:

Main renal artery
= vessel with the greatest diameter

Accessory renal artery
= vessel with smaller diameter
= segmental artery originating from aorta / iliac a.

Supplementary artery:

Entry: renal hilum

Origin: aorta, iliac a., internal spermatic a., SMA, IMA, celiac trunk, middle colic a., lumbar a., middle sacral a., contralateral renal a.

Supply: lower pole (72%) > upper pole

Aberrant renal artery:

= segmental artery arising from superior mesenteric artery / internal spermatic artery

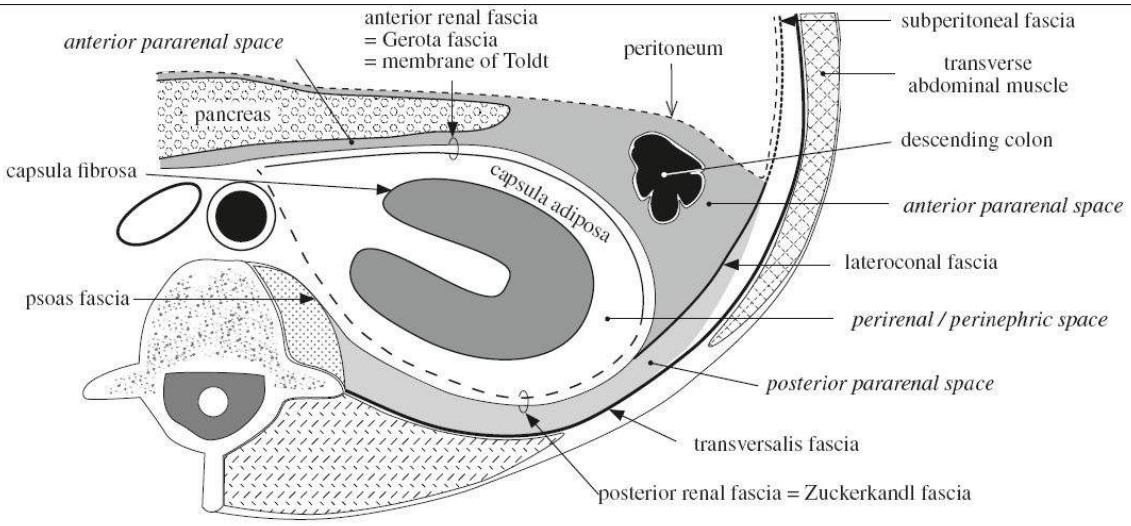
Renal Veins

Single right renal vein

without major extrarenal tributaries (85%)
with major extrarenal tributaries:
(a) right adrenal vein (30%)
(b) right gonadal vein (7%)
(c) lumbar + hemiazygos veins (3%)

Single preaortic left renal vein

without major extrarenal tributaries (86%)
with major extrarenal tributaries:
(a) left adrenal vein
(b) hemiazygos vein
(c) lumbar vein
(d) ascending lumbar vein
(e) left gonadal vein



Renal Fascia (of Gerota) and potential Anterior and Posterior Pararenal Spaces

Anatomic Renal Vein Variants

MULTIPLE RIGHT RENAL VEINS (15–30%)

(a) single right renal vein divides just before union with IVC 4%
(b) right gonadal vein joins the renal vein 6%
(c) accessory branch of adrenal vein enters right renal vein 31%
(d) lumbar / azygos vv. enter right renal vein 3%

CIRCUMAORTIC LEFT RENAL VEIN (5–6–17%)

SINGLE RETROAORTIC LEFT RENAL VEIN (2–3%)

LUMBAR VEINS JOINING LEFT RENAL VEIN (75%)

URETER

= retroperitoneal muscular conduit that carries urine from renal pelvis to urinary bladder

Histo: (a) inner cell layer of watertight urothelium surrounded by
(b) outer layer of smooth muscle → coordinated contraction

Origin: ureteropelvic junction at intra / extrarenal pelvis
Terminus: ureterovesical junction
Length: ~ 25 cm
Diameter: < 3 mm

Congenital Ureteral Abnormalities

A. URETERAL DUPLICATION
   1. Complete ureteral duplication
   2. Partial ureteral duplication
B. SMOOTH MUSCLE DYSFUNCTION
   1. UPJ obstruction
   2. Primary congenital megaureter

C. ABNORMAL TERMINATION OF SINGLE URETER
   1. Ectopic ureter
   2. Ureterocele
   3. Vesicoureteral reflux

Extrarenal Pelvis

= normal anatomic variant in which the renal pelvis lies predominantly outside of the renal sinus
√ may be dilated under normal circumstances
   DDx: UPJ obstruction, distal obstruction
√ NO associated caliectasis
√ normal size of ureter

RETROPERITONEUM

= space posterior to peritoneal cavity extending from diaphragm to pelvic brim; separated from peritoneum anteriorly by posterior peritoneal fascia; bounded posteriorly by transversalis fascia
(a) anterior border: posterior peritoneal fascia (posterior to peritoneum)
(b) posterior border: transversalis fascia (attaches to psoas muscle)

Retroperitoneal Compartments

A. **Anterior pararenal space**
   Boundaries: posterior parietal peritoneum (anteriorly), anterior renal fascia (posteriorly), lateroconal fascia (laterally)
   → superiorly joins with posterior renal fascia and attaches to crux of diaphragm
   → in the middle blends with connective tissues of central prevertebral space around great vessels
   → inferiorly joins with posterior renal fascia and attaches to great vessels
   (a) pancreaticoduodenal space
      Contents: pancreas, duodenum, root of small bowel mesentery
   (b) pericolonic space
      Contents: ascending colon + descending colon
B. **Perirenal / perinephric space** = capsula adiposa
   Boundaries: fascia renalis = Gerota fascia = anterior (membrane of Toldt) + posterior (Zuckerkandl) renal fasciae
   [Carl Toldt (1840–1920), Austrian anatomist, professor of anatomy in Prague and Vienna]
   subdivided into multiple compartments by thin fibrous lamellae + incomplete bridging septa (Kunin septa) that attach to anterior + posterior renal fascia
   → forms superiorly closed inverted cone around adrenal gland + perirenal fat + upper half of kidney; fixed to diaphragmatic fascia above; abuts bare area of liver (R) + subphrenic space (L)
   → inferiorly forms cone around perirenal fat + lower pole of kidney blending with iliac fascia below
   → laterally closed by fusion of anterior + posterior sheath
   → medially open communicating with central prevertebral space

Contents: kidneys, adrenal glands, proximal renal collecting system, proximal ureters, perirenal fat, renal hilar vessels, lymphatic vessels

The perirenal fascia is not made up of distinct unilaminated fascia; rather, it is composed of multiple layers of variably fused embryonic mesentery, creating potential spaces between the retroperitoneal spaces.

C. **Posterior pararenal space**
   Boundaries: posterior renal fascia, transversalis fascia, fascia over psoas muscle continuous with transversalis fascia
   Contents: fat, no organs
D. Great vessel space

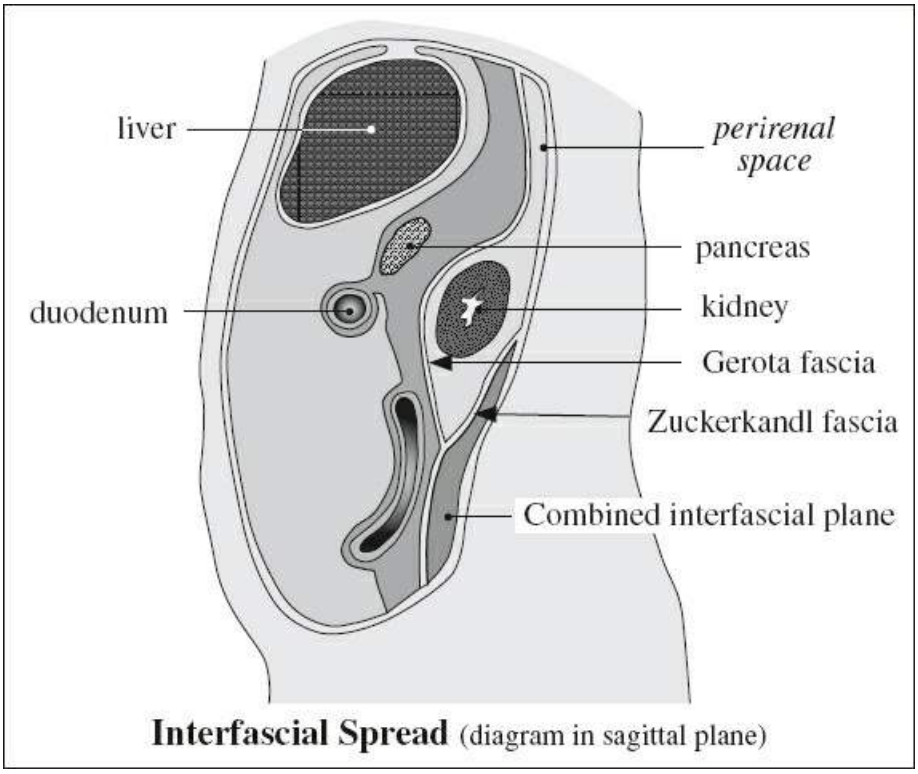
Interfascial spread is the spread of fluid within the layers of the retroperitoneal fascia and is a common route of disease across the midline within the retroperitoneum and from the abdomen to the pelvis along the retromesenteric, retrorenal, and interfascial planes.

Potential Routes of Interfascial Communication

Cause: laminar + variably fused + expandable fasciae
A. Retromesenteric plane
B. Retrorenal space
C. Lateroconal space

Organ of Zuckerkandl

= PARAAORTIC BODIES (DDx to *aortic bodies* which are chemoreceptors near thoracic aorta regulating circulation)
[Emil Zuckerkandl (1849–1910], Hungarian-Austrian anatomist at the universities of Utrecht, Graz, and Vienna, colleague of Carl Freiherr von Rokitansky]
= diffuse group of neuroendocrine sympathetic fibers constituting the chromaffin body → possible source of pheochromocytoma
Origin: neural crest
Location: at aortic bifurcation / at origin of IMA
Function: homeostatic regulator of blood pressure → by secretion of catecholamines into fetal circulation → involuting during 3rd trimester



Interfascial Spread (diagram in sagittal plane)

RENAL HORMONES

Antidiuretic Hormone (ADH)

Production site: supraoptic nuclei of hypothalamus, transported to neurohypophysis
Stimulus: fluid loss → increase in osmolality
Effects: (1) 10 x increase in permeability of collecting ducts (= concentrated urine)
(2) decreased blood flow through vasa recta leads to increased hypertonicity of interstitium (= countercurrent multiplier mechanism)

Renin-Aldosterone Mechanism

› receptors in juxtaglomerular apparatus register intraglomerular capillary hydraulic pressure, one of the main determinants of the glomerular filtration rate (GFR);
› receptors regulate the release of **renin** as an autoregulatory feedback mechanism → to maintain intraglomerular hydraulic pressure;
› renin mediates conversion of angiotensin to angiotensin-I → which is then cleaved by angiotensin converting enzyme (ACE) into angiotensin-II

Angiotensin-II Effect

› constriction of efferent postglomerular arterioles → ⇑ intraglomerular capillary hydraulic pressure + GFR
› systemic arteriolar constriction (= most potent vasoconstrictor of biologic systems) → causes systemic hypertension
› release of **aldosterone** → which increases sodium retention by renal tubules
→ leads to an increase in blood volume + blood pressure if both kidneys are affected

→ leads to compensatory natriuresis if only one kidney is affected

◊ ACE inhibitors (eg, captopril) produce a dramatic decrease in blood pressure!

RENAL PHYSIOLOGY

Perfusion: 1.2–1.3 L of blood per minute (= 20–25% of total cardiac output)

Urine output: 1 L/d

Filtration: substances of up to 4 nm (excluding substances > 8 nm), threshold at molecular weight of ≈ 40,000

Glomerular Filtration Rate (GFR)

$[P] \times GFR = [U] \times U_{vol}$

$GFR = \{[U] \times U_{vol}\} / [P]$ = 125 mL/min = 20% of RPF

Substrate: inulin; ^{99m}Tc-DTPA

Tubular Secretion (Tm)

$[U] \times U_{vol} = [P] \times GFR + Tm$

$Tm = \{[U] \times U_{vol}\} - \{[P] \times GFR\}$

Substrate: p-aminohippurate (PAH); ^{131}I-Hippuran

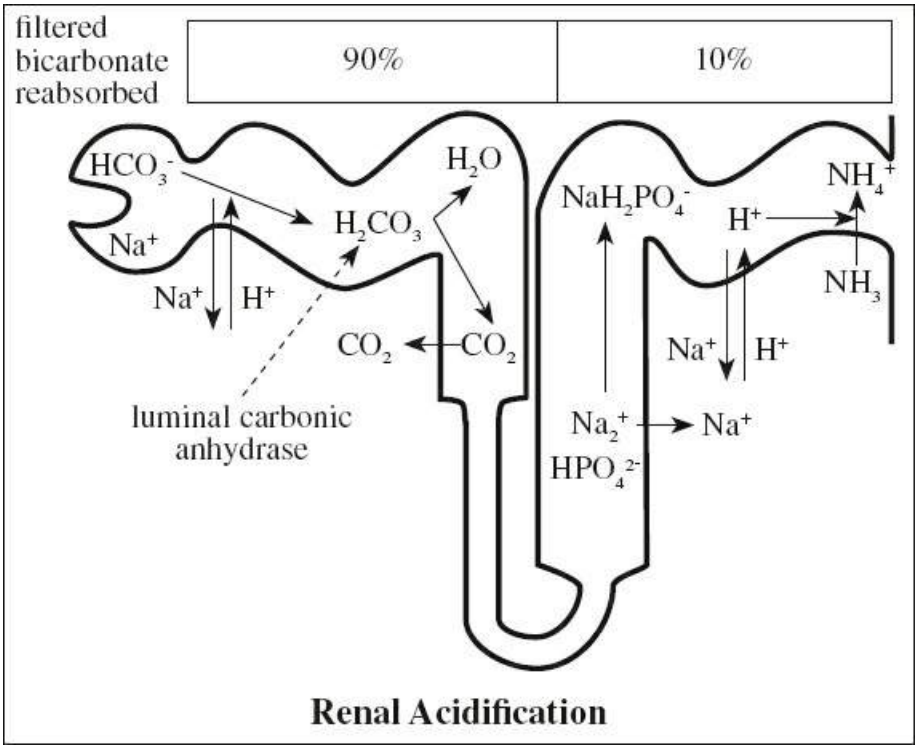
Renal Plasma Flow (RPF)

$[P] \times RPF = [U] \times U_{vol}$

RPF = {[U] x U vol } / [P]

Substrate: p-aminohippurate

[P] = concentration in plasma
GFR = glomerular filtration rate
[U] = concentration in urine
U vol = urine volume
Tm = transport maximum (across tubular cells)
RPF = renal plasma flow



Renal Acidification

Renal Acidification Mechanism

Proximal tubule:

reabsorption of 90% of filtered bicarbonate by luminal Na+/H+ exchange and Na+/HCO3 – cotransport at basolateral membrane

regulated by: luminal carbonic anhydrase

influenced by: luminal HCO3– concentration, extracellular fluid volume, parathormone, K+, aldosterone

Distal nephron:

active secretion of H+ against a steep urine-to-blood gradient across luminal cell membrane by H+-ATPase pump → facilitated by Na+ reabsorption → resulting in reabsorption of 10% of filtered bicarbonate, formation of ammonium (NH4+) and titratable acidity

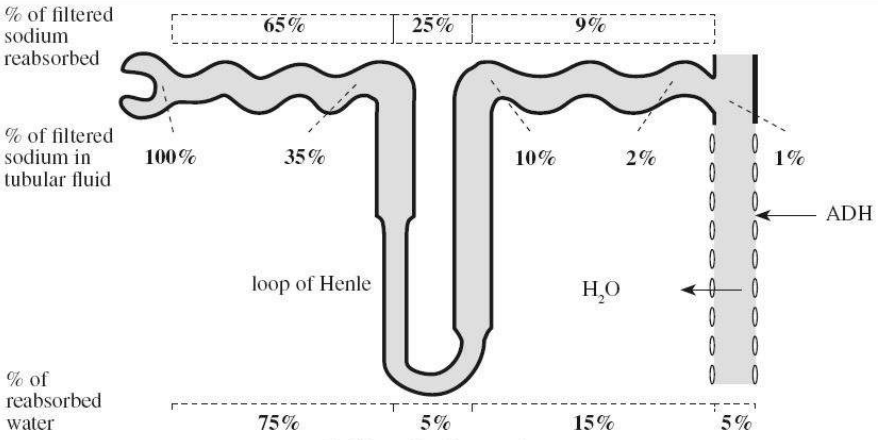
Ammonium excretion:

Ammonia (NH3) is formed in proximal tubule as a product of catabolism of glutamine + other amino acids; combination with secreted H+ to NH4+ takes place in distal nephron

Titratable acidity: divalent basic phosphate is converted into monovalent acid form in distal tubule

Renal Imaging in Newborn Infant

◊ Low glomerular filtration rate (GFR):



Sodium Reabsorption

Hypertonicity is maintained within the medullary interstitium by the countercurrent multiplier system of the loop of Henle and the vasa recta; ADH increases permeability of collecting ducts for water

on first day of life: 21% of adult values
by 2 weeks of age: 44% of adult values
at end of 1st year: close to adult values

◊ Limited capacity to concentrate urine

IVP:

√ occasional failure of renal visualization

NUC:

√ improved visualization on radionuclide studies

Normal Nephrographic Phases / Progression

1. **Vascular phase**
   = CORTICAL ARTERIOGRAM
   = contrast material in interlobular arteries + glomeruli
   Timing after IV injection: 10–15–25 seconds (arm-to-kidney circulation time)
   Duration: transient vascular phase of < 0.5 seconds
2. **Cortical phase**
   = CORTICAL NEPHROGRAM
   = contrast medium in cortical capillaries + peritubular spaces + cortical tubular lumina
   Timing after IV injection: 25–45–70 seconds
   Timing after intraarterial injection: 2–3 seconds
   CT:
   √ exclusive renal cortical enhancement with minimally enhancing renal medulla (= corticomedullary differentiation)
3. **Parenchymal phase**
   = GENERALIZED / DIFFUSE / TUBULAR NEPHROGRAM
   = contrast material in loops of Henle + collecting tubules
   Timing after IV injection: 60–85–120 seconds (max)
   √ enhancement of both cortex and medulla
   N.B.: most valuable phase for detecting renal masses
4. **Excretory phase**

= contrast material in collecting system
Timing after IV injection: beginning at 2–3–5 minutes

Contrast Excretion

UROGRAPHIC DENSITY depends on [U] = {[P] x GFR} / Uvol

1. Concentration of contrast material in plasma [P] is a function of
   (a) total iodine dose
   (b) contrast injection rate
   (c) volume distribution
   Rapid decline of concentration of contrast material in vessels due to:
   (1) rapid mixing within vascular compartment
   (2) diffusion into extravascular extracellular fluid space (capillary permeation)
   (3) renal excretion
2. Glomerular filtration rate (GFR): 99% filtered
3. Urine volume (Uvol):
   (a) in dehydrated state → increased ADH activity → higher concentrations of contrast material

◊ Dehydration is considered a risk-potentiating factor for nephrotoxicity!

   (b) in volume-expanded state → decreased ADH activity → lower concentrations of contrast material

◊ Patients with CHF require higher doses of contrast material!

A. MEGLUMINE
no metabolization, excreted by glomerular filtration alone
Meglumine effect of osmotic diuresis:
(a) lower concentration of urinary iodine per mL urine
(b) greater distension of collecting system
N.B.: Avoid meglumine in "at risk" patients (higher incidence of contrast reactions than sodium!)

B. SODIUM
extensive reabsorption by tubules with delayed excretion
Sodium effect of reabsorption:
(a) increased concentration of urinary iodine (improved visualization)
(b) less distension of collecting system (ureteral compression necessary)

ADRENAL GLAND

Function: regulation of metabolism, salt and water balance, response to stress, sexual function
From periphery to centrum:
(a) renin-angiotensin–dependent <u>outer</u> adrenal cortex
zona glomerulosa = mineralocorticoid (aldosterone)
(b) corticotropin-dependent <u>inner</u> adrenal cortex:
zona fasciculata = glucocorticoids (cortisol)
zona reticularis = sex steroids (androgen, estrogen) + gonadocorticoids
(c) medulla = catecholamines (epinephrine, norepinephrine)
mnemonic: **G**lomerular **F**iltration **R**ate **M**ay **G**ive **A**nswers

Glomerulosa
Fasciculata
Reticularis
Mineralocorticoids
Glucocorticoids
Androgens

@ IN FETUS
responsible for masculinization of external genitalia

@ IN NEONATAL PERIOD
Normal weight: 5–10 g at birth
◊ Rapid regression of fetal cortex during first 6 weeks of life!
√ central echogenic stripe (= medulla) surrounded by thick hypoechoic region (= adrenal cortex)

@ IN ADULTHOOD
Normal size: 3–5 (L) x 3 (W) x 1 cm (thick)
Normal thickness: 2–6 mm
◊ Each limb of the adrenal gland should not be thicker than the crus of the diaphragm
Normal weight: 3–5 g (5–10 g at birth)
Visualization by CT : left side 100%, right side 99%
by US : left side 45%, right side 80%

Adrenal Vascular Anatomy

Adrenal Arteries

(1) superior suprarenal artery ← inferior phrenic artery
(2) middle suprarenal artery ← abdominal aorta
(3) inferior suprarenal artery ← renal artery
50–60 small adrenal branches from 3 main adrenal arteries form a subcapsular plexus → drains into medullary sinusoids
Supply: inferior phrenic a., directly from aorta, renal artery
(a) all 3 sources in 34%
(b) two sources in 61%
(c) single source in 5% (renal a. only in 2%)
forming superior, middle, inferior adrenal arteries
◊ The renal artery contributes in 71%!
◊ Gonadal artery contributes in 60% in fetal circulation!

Adrenal Veins

"Vascular dam" = gland is drained by an intrinsically vulnerable network of relatively few venules
(1) Single right adrenal vein drains into IVC (69%)
(2) Accessory right adrenal vein drains into renal v. (31%)
(3) Left adrenal vein enters left renal vein (almost always) / inferior phrenic vein

BLADDER

Bladder capacity [mL] = (age in years + 2) x 30

Layers of Bladder Wall (from inner to outer)

(1) Uroepithelium = 3–7 layers of stratified flat cells; able to change shape from cuboidal to flattened as the bladder distends (= transitional epithelium)
(2) Lamina propria: very vascular
(3) Muscularis propria = complex network of interlacing bundles of smooth detrusor muscle; fibers merge with prostate capsule / anterior vagina + pelvic floor muscles
(4) Adventitia = connective tissue + serosal covering formed by peritoneum at bladder dome

SCROTUM

= cutaneous fibromuscular sac containing testes + extratesticular tissues

Scrotal Sac

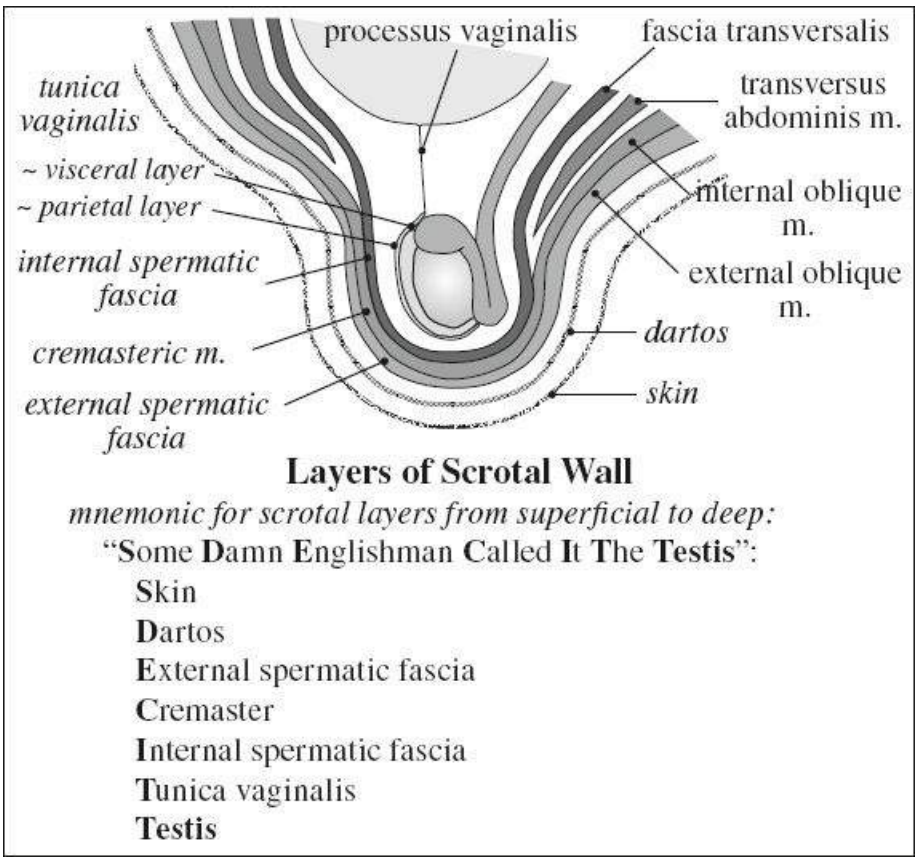
Scrotal wall thickness: 2–8 mm (3–6 mm in 89%)
Layers of scrotal sac:

1. Pigmented Skin
2. Dartos muscle and fascia
3. External spermatic fascia ← external oblique muscle
4. Cremaster muscle and fascia ← internal oblique muscle
5. Internal spermatic fascia ← transversalis fascia
6. Tunica vaginalis

Processus Vaginalis

= socklike evagination (outpouching) of the parietal peritoneum at 13 weeks EGA
› forms anterior to developing testis + ligamentous cord
› elongates caudally through abdominal wall into scrotal folds
› becomes ensheathed by fascial extensions of abdominal wall (from inner to outer layer):
– fascia transversalis → internal spermatic fascia
– internal oblique muscle → cremaster muscle
– external oblique muscle → external spermatic fascia
WITHOUT contribution by transversus abdominis m.

Function: guides testicular descent from abdomen to scrotum at 7th–9th months of fetal life



Layers of Scrotal Wall

mnemonic for scrotal layers from superficial to deep:

"**S**ome **D**amn **E**nglishman **C**alled **I**t **T**he **Testis**":

Skin
Dartos
External spermatic fascia
Cremaster
Internal spermatic fascia
Tunica vaginalis
Testis

(a) superior portion: becomes obliterated in 3 steps
  (1) closure of deep inguinal ring
  (2) closure of area above testis
  (3) atresia between these constrictions

(b) scrotal portion:
peritoneum-lined cavity surrounding anterior surface of the testis = tunica vaginalis
  (1) parietal layer envelops all but the posterior aspect of testis
  (2) visceral layer closely adherent to the tunica albuginea

Content: 1–2 mL of serous fluid

Testis

Embryology: descent from abdomen to scrotum between 7th and 9th months of gestation

Average size of testis: **3**.0 **x** 2.0–3.0 x 3.8–5.0 cm (decreasing with age)

Length of testis: 3–5.5 cm (mature); 1–1.5 cm (newborn)

Testicular cysts: in 8% of normals (average size 2–3 mm), numbers increasing with age

Anatomy: 200–300 lobules each containing 400–600 seminiferous tubules; each tubule is 30–80 cm long with a total length of 300–980 m

Histo: (1) spermatogonia (adjacent to basement membrane) → spermatocytes → spermatids → spermatozoa

(2) nondividing Sertoli cells provide the support structure; their tight cell junctions are responsible for the blood-testis barrier

(3) interstitium (= space between seminiferous tubules) contains connective tissue, lymphatics, blood vessels, mast cells, Leydig cells (= principal source of testosterone production)

Appendix Testis

= HYDATID OF MORGAGNI
= small stalked appendage at upper pole of testis
Frequency: 92% of testes
Origin: remnant of paramesonephric duct
Appendix testis÷appendix epididymis = 9÷1

Tunica Albuginea

= tough fibrous capsule of testis with great tensile strength (sustaining forces of up to 50 kg without rupturing)
› posterior surface invaginates into testicular parenchyma at mediastinum testis → divides testis into lobules
› externally covered by visceral layer of tunica vaginalis (= flattened layer of mesothelium)
√ echogenic rim surrounding the testis

TUNICA VASCULOSA

= composed of capsular arteries, applied internally to tunica albuginea

Tunica Vaginalis

= 2-layered serous membrane as inferior extension of processus vaginalis of peritoneum forming a mesothelium-lined sac that covers entire testis except for the posterior border
(a) inner visceral layer: envelopes most of testis and epididymis
(b) outer parietal layer: lines internal spermatic fascia
Hydrocele: fluid accumulation in potential space between layers of tunica vaginalis (small to moderate in 14% of normals)

Mediastinum Testis

= converging point of ~ 400 cone-shaped lobules separated by fibrous septa + seminiferous tubules forming larger tubuli recti and draining into the rete testis (= 15–20 efferent ductules)
= incomplete septum acting as entry and exit point for ducts, nerves, vessels (= hilum of testis)
√ posteriorly located linear echogenic region extending longitudinally 5–8 mm from the edge

Epididymis

= tortuous tightly folded canal forming the efferent route from testis; consists of head (= globus major), body, tail (= globus minor)

Location	:	superolateral aspect of testis
Length	:	7 cm
Globus major	:	11 x 7 x 6 mm (decreasing with age); located atop superior pole of

testis

Epididymal body	:	2–4 mm thick
Epididymal tail	:	continues as vas deferens
Epididymal cysts	:	occur in 30% of normals (average size of 4 mm)
Epididymal calcification	:	in 3%

Appendix epididymis

= small stalked appendage of globus major near upper pole of testes; occasionally duplicated

Frequency: 20–33% of epididymes

Origin: remnant of mesonephric (wolffian) duct; regarded as detached efferent duct

Spermatic Cord

Course: originates in scrotum → leaves scrotum via superficial inguinal ring → passes through inguinal canal → and through deep inguinal ring

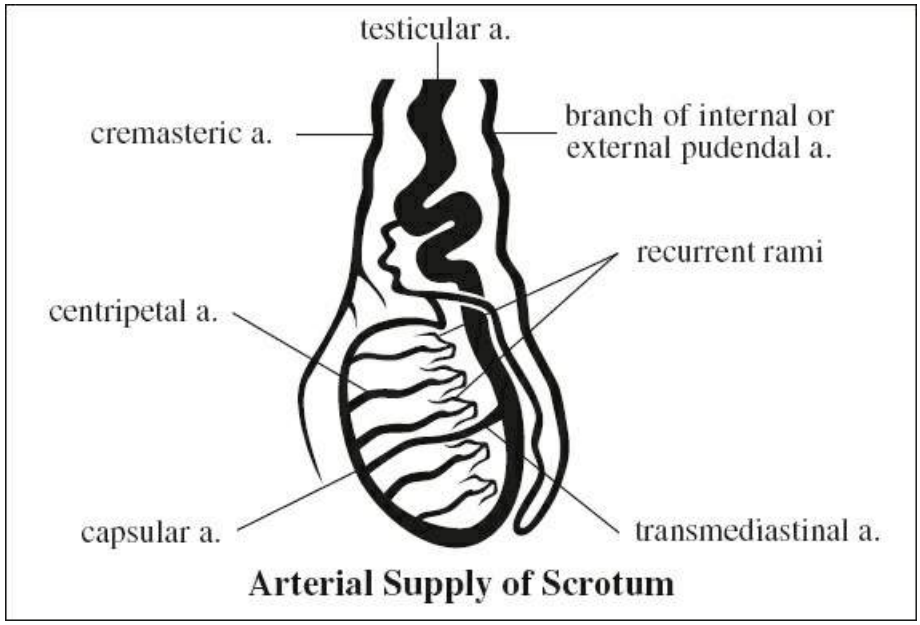
Components: testicular + deferential + cremasteric aa., pampiniform plexus of veins, vas deferens, nerves, lymphatics

Cover: (from superficial to deep) external spermatic fascia, cremasteric m. + fascia, internal spermatic fascia

Gonadal Vascular Anatomy

Gonadal Artery

Origin: ventral surface of aorta (83%) a few cm below the origin of renal arteries / from renal artery or arteries (17%):



Arterial Supply of Scrotum

(a) R from renal a. + L from aorta (6%)

(b) R from aorta + L from renal a. (4%)
(c) R + L from both renal arteries (4%)

Course: L anterior to left renal vein (20%);
R behind IVC + anterior to right renal vein

Gonadal Vein

R: drains into IVC (93%) / right renal vein (7%)
L: drains into left renal vein
Multiple gonadal veins (15%)

Lymphatic drainage follows venous drainage: testes drain into paraaortic and paracaval lymph nodes.

Blood Flow To Testis

Peak systolic velocity: 4–10–19 cm/sec
End-diastolic velocity: 2–5–8 cm/sec
Resistive index: 0.60 (range, 0.44 – 0.75)

ZONAL ANATOMY OF PROSTATE

Normal weight : 20 ± 6 g
Normal size : 2.8 cm (craniocaudad), 2.8 cm (anteroposterior), 4.8 cm (width)

A. OUTER / PERIPHERAL GLAND
   1. Central zone (25% of glandular tissue):
      surrounds ejaculatory ducts from their entrance at prostatic base to verumontanum
   2. Peripheral zone (70% of glandular tissue):
      extends from base of prostate to apex along rectal surface

√ outer gland is hyperintense on T2WI
√ surrounded by thin hypointense rim on T2WI ← anatomic / true capsule

B. INNER / CENTRAL GLAND
   1. Transition zone (5% of glandular tissue):
      on each side of internal sphincter; enlarges with BPH
   2. Periurethral zone (1% of glandular tissue):
      surrounding urethra

√ inner gland is hypointense on T2WI

C. ANTERIOR FIBROMUSCULAR STROMA
   √ hypointense on T2WI

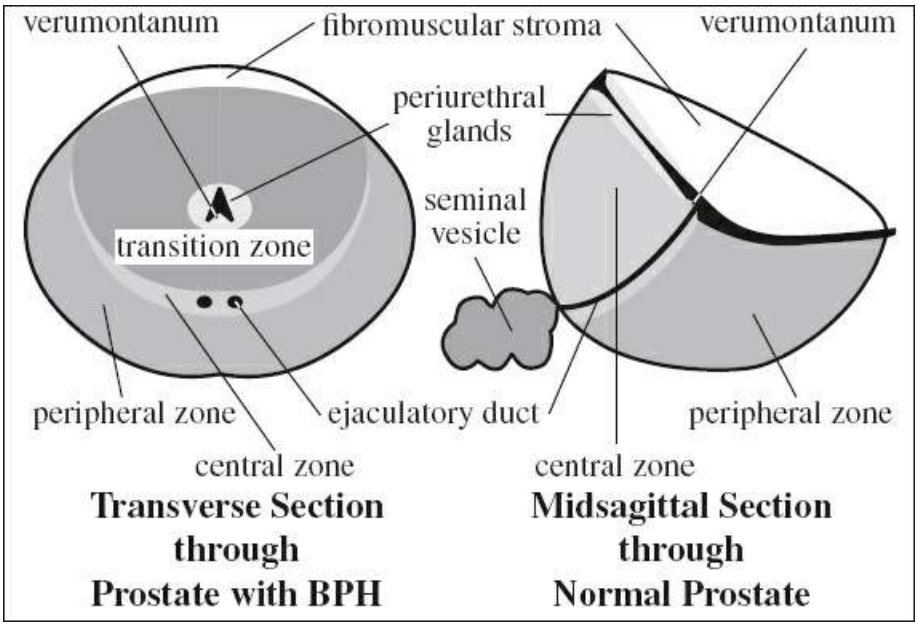
◊ Zonal anatomy is best depicted on high-resolution T2WI

SEMINAL VESICLES (SV)

Origin: separate symmetric buds extend from distal mesonephric duct (vas deferens) just proximal to ejaculatory duct
Connection: SV join distal part of vas deferens forming ejaculatory duct which drains into prostatic urethra through verumontanum

√ symmetric and of smooth saccular appearance
√ 1–2 mm thin wall

Size: 3 cm in length, 1.5 cm in diameter
Volume: 13.7 mL



VAS DEFERENS

Origin: mesonephric duct
Ampulla: 4 ± 1 mm (distal segment of vas deferens just before junction with seminal vesicle)

EJACULATORY DUCT

Origin: mesonephric duct
Diameter: 4–8 mm

URETHRA

Male Urethra

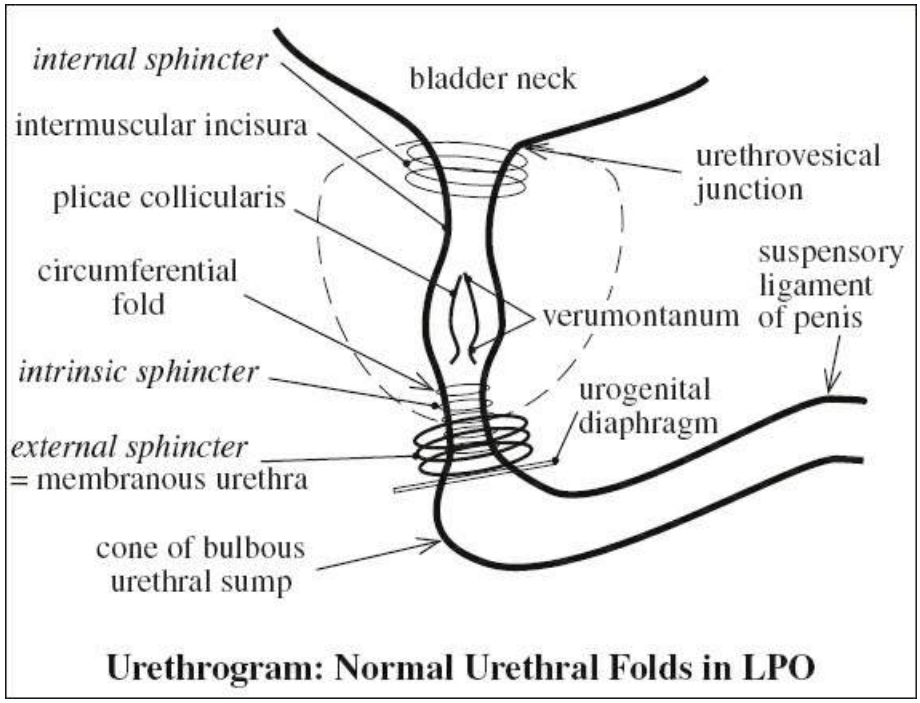
Length: 17.5–20.0 cm

A. POSTERIOR URETHRA

1. **Prostatic urethra**
   = 3.5-cm long segment from vesical neck to triangular ligament at urogenital diaphragm
   › **urethral crest** = posteriorly located longitudinal ridge of smooth muscle with overlying prominent fold from bladder neck to membranous urethra
   › **verumontanum** = colliculus seminalis
   = 1 cm long ovoid mound at posterior wall of prostatic urethra with a small saccular depression centrally (= prostatic utricle representing the fused end of vestigial müllerian ducts)
   › multiple small orifices of ducts from prostate gland acini exit at floor of prostatic urethra around verumontanum

› orifices of the paired ejaculatory ducts just distal + lateral to utricle
› contains involuntary *internal urethral sphincter* (composed of smooth muscle) for primary passive continence

2. **Membranous urethra**
= 1.0–1.5 cm long portion traversing urogenital diaphragm; anchored to anterior pubic arch by paired puboprostatic ligaments
› contains 2 muscles:
(a) voluntary *external urethral sphincter* (composed of striated muscle with contributions from levator ani complex) for active continence
(b) involuntary *intrinsic urethral sphincter* (composed of smooth muscle) for secondary passive continence



Urethrogram: Normal Urethral Folds in LPO

Associated with:
2 cm long pea-sized **bulbourethral glands of Cowper** that lie laterally + posteriorly between fasciae and sphincter urethrae in urogenital diaphragm → empty into bulbous urethral sump
[William Cowper FRS (1666–1709), English surgeon and anatomist in London]

B. ANTERIOR = CAVERNOUS URETHRA
= segment from external meatus to inferior edge of urogenital diaphragm through corpus spongiosum

1. **Bulbous urethra**
• entirely internal
› located in crura of corpus spongiosum
(a) "sump" = proximal dilated portion of urethra
(b) "cone" = conical shape of urethra at bulbomembranous junction
2. **Penile (= pendulous) urethra**

- entirely external
- › beginning at penoscrotal junction + terminating in glans penis

3. Fossa navicularis: 1.0–1.5 cm in length
4. External meatus

Associated with:

many small branched tubular **periurethral glands of Littré** that terminate in recesses (lacunae of Morgagni) and are most numerous at dorsal aspect of penile urethra + in bulbous urethral sump

Cx: recurring urethral discharge following chronic urethritis; latent gonorrheal urethritis; stricture formation

Female Urethra

Size: 3–5 cm in length, 6 mm in diameter

Course: from bladder neck at urethrovesical junction obliquely forward + downward to vestibule forming external meatus between labia minora

Epithelium: transitional cell epithelium (proximal ⅓), stratified squamous epithelium (distal ⅔)

Two sets of glands:

(a) periurethral glands
terminate in 6–30 paraurethral ducts that drain into distal urethra

(b) paraurethral glands = **glands of Skene**
[Alexander Johnston Chalmers Skene (1837–1900), Scottish gynecologist, Professor of Disease of Women at Long Island College Hospital]
(= derivatives of urogenital sinus + homologues of prostatic ducts)

Function: urethral lubrication during sexual intercourse

- › formed by an interdependent conducting system
- › exit on either side of external meatus of the urethra anteriorly draining into vaginal vestibule

Cx: chronic gonorrheal urethritis

1. Intrapelvic urethra
= upper ⅔ of urethra that lies behind symphysis pubis

Muscles: › inner layer: longitudinal smooth muscle
› outer layer: circular smooth muscle; thinner

2. Membranous urethra
surrounded by sphincter membranacea urethrae (weaker less important structure than in male)

Muscle: compressor urethrae muscle (formerly known as deep transverse perineal muscle)

Function: compresses + elongates urethra → improving continence

3. Perineal urethra
lower ⅓ extending from superior fascia of urogenital diaphragm to external meatus between labia minora

Muscle: striated urethrovaginal sphincter reinforcing the 2 concentric layers of smooth muscle

MR:
√ targetlike urethral sphincters on AXIAL plane:
√ average thickness of 4 mm
√ hypointense striated-muscle of outer sphincter
√ surrounding smooth-muscle of inner sphincter
√ innermost mucosa-submucosa
√ hypointense tubular retropubic structure on SAG view

PENIS

Layers of Penile Shaft

1. Dartos fascia separates skin from loose layer of subcutaneous connective tissue
2. Buck fascia
   = fascia penis profunda surrounding corpora cavernosa only
   [Gurdon Buck (1807–1877), pioneer military plastic surgeon during the Civil War, Columbia University + New York Hospital]
3. Tunica albuginea: surrounding corpora cavernosa (thick) and corpus spongiosum (thin)

Corpora cavernosa

= dorsally located paired structures consisting of venous sinusoids surrounded by strong fascial sheath (= tunica albuginea)
Function: erection

Corpus spongiosum

= ventrally located midline structure surrounding urethra terminating in glans penis + surrounded by tunica albuginea
Attached to: ischial tuberosity via crura

Perfusion of Penis

A. ARTERIAL INFLOW:
   1. Dorsal artery: lateral to deep dorsal vein
      Supply for: glans penis, skin
   2. Cavernosal artery: located in center of corpus callosum; terminal branch of internal pudendal artery
      Supply for: corpus cavernosum during erection
   3. Bulbourethral artery
      Supply for: urethral bulb + posterior corpus spongiosum
B. VENOUS DRAINAGE:
   1. Superficial dorsal vein = superficial to Buck fascia
   2. Deep dorsal vein = deep to Buck fascia

RENAL, ADRENAL, URETERAL, VESICAL, AND SCROTAL DISORDERS

ABORTIVE CALYX

= developmental anomaly with short blind-ending outpouching of pyramid without papillary invagination

Location: (a) renal pelvis
(b) infundibulum (mostly upper pole)

ACQUIRED CYSTIC KIDNEY DISEASE

= ACQUIRED CYSTIC DISEASE OF UREMIA

= development of numerous fluid-filled renal cysts in end-stage kidney disease without hereditary causes

◊ Successful transplant probably stops development of additional cysts, but does not affect malignant potential!

Prevalence: in 8–13% before dialysis
in 13% after 2 years of hemodialysis,
in 50% after 6 years of hemodialysis,
in 87% after 9 years of hemodialysis,
in 100% after 10 years of hemodialysis;
in 25% of renal allograft recipients

Proposed etiologies:
compensatory hypertrophy of functional nephrons ← tissue destruction
(a) renal tubular obstruction ← interstitial fibrosis
(b) renal tubular expansion ← epithelial hyperplasia
(c) cyst development ← increased fluid secretion

Not correlated with: race, cause of renal failure, method of dialysis (hemodialysis / peritoneal)

At increased risk: older men; M÷F = 3÷1

Histo: cysts lined by flattened cuboidal epithelium with papillary proliferations within renal cortex + medulla

Associated with:
(a) small papillary / tubular / solid clear-cell adenomas (in 13–20%): ~ 1 cm in diameter
(b) renal cell carcinoma (in 3–7%): 7-year interval between transplantation + detection of renal cell carcinoma

√ small hypoplastic end-stage kidneys (< 280 g)

√ multiple ½–3-cm cysts bilaterally (early = small, late = large): must have at least 3 cysts in each kidney

√ occasionally progressive renal enlargement due to cysts

US:
√ atrophic echogenic kidneys

√ cysts of varying size and complexity

Dx: > 3 cysts + NO history of hereditary cystic disease

Cx: spontaneous hemorrhage into cyst (macrohematuria / retroperitoneal hemorrhage from cyst rupture); cyst infection; ureteral stones; malignancy (risk factors are male sex + increased length of time on dialysis)

Renal malignancy develops in 3–7% of patients with acquired cystic kidney disease

AIDS

- azotemia, proteinuria, hematuria, pyuria (in 38–68% sometime during illness); progressive renal failure (10%)

1. **HIV-associated nephropathy** (up to 40%)

= characterized by nephrotic-range proteinuria + rapidly progressive renal failure, primarily occurring in African-Americans

Histo: focal + segmental glomerulosclerosis with collapsed glomerular tufts (= collapsing glomerulopathy), sparse interstitial infiltrates, severe tubular atrophy and dilatation containing protein casts

- nephrotic range proteinuria
- early + rapidly progressive renal failure

√ normal-sized (majority) / globally enlarged kidneys:

√ bulbous shape with loss of reniform appearance

US (best screening test):

√ increased cortical echogenicity (33–89%) greater than liver and approaching that of renal sinus

√ thickening of pelvicaliceal system

√ "decreased renal sinus fat" sign (in up to 49%) ← renal edema invading renal sinus fat

√ decreased corticomedullary differentiation

CT:

√ medullary hyperattenuation (14%)

√ striated nephrogram on CECT ← dilated protein-filled tubules

MR:

√ loss of corticomedullary differentiation

Prognosis: 100% mortality within 6 months

DDx: infection, acute tubular necrosis

2. **Renal infection with Pneumocystis jirovecii** (8%)

◊ More frequent since introduction of prophylactic aerosolized pentamidine therapy encouraging extrapulmonic spread (< 1%) due to inadequate systemic distribution of drug!

√ punctate renal calcifications confined to cortex ← areas of infiltrate + subsequent destruction of renal tubules (DDx: CMV, Mycobacterium avium-intracellulare)

√ associated areas of increased echogenicity in spleen, liver, lymph nodes, adrenal glands ← calcifications / protein

3. **Other renal infections**

Candida albicans, Aspergillus, disseminated pulmonary tuberculosis, M. avium-intracellulare

√ focal microabscesses + hydronephrosis

4. **Renal lymphoma** (3–12%)
   = AIDS-RELATED LYMPHOMA
   = highly aggressive often extranodal B-cell lymphomas (centroblastic, lymphoblastic, immunoblastic);
   NHL > Burkitt lymphoma, Hodgkin disease
   √ bilateral multiple renal masses:
   √ slightly hyperattenuating relative to renal parenchyma on NECT
   √ hypoattenuating homogeneous masses during nephrographic phase on CECT
   √ direct extension of retroperitoneal lymphadenopathy engulfing kidney, renal sinus, ureter
5. Kaposi sarcoma (27%)
   = AIDS-defining illness usually in patients with CD4 lymphocyte count < 150–200 cells/mm3
   Histo: renal tissue replaced + infiltrated by proliferation of spindle cells with characteristic small vascular spaces + demonstrable nuclear staining for HHV_8
   √ renal enlargement + irregular hypoattenuating areas in renal cortex
6. HAART-related nephropathy
   [**h**ighly **a**ctive **a**ntiretroviral **t**herapy]
   • acute renal failure ← renal tubular damage from nucleotide reverse-transcriptase inhibitors (tenofovir, adefovir, cidofovir)
   • dyslipidemia, insulin resistance, fat redistribution
   • hypertension
   √ renal calculi (in up to 20%) ← indinavir and nelfinavir
   √ renal artery stenosis
7. **Cystitis** (22%)
   Organism: routine gram-negative species, Candida, beta-hemolytic streptococci, Salmonella, CMV
   √ bladder wall thickening

ACUTE CORTICAL NECROSIS

= rare form of acute renal failure

Etiology:

(a) ischemia ← vasospasm of small vessels
(b) toxic damage to glomerular capillary endothelium
(c) primary intravascular thrombosis

At risk:

(a) Obstetric patient (most often): abruptio placentae = premature separation of placenta with concealed hemorrhage (50%), septic abortion, placenta previa
(b) Children: severe dehydration + fever, infection, hemolytic uremic syndrome, transfusion reaction
(c) Adults: sepsis, severe dehydration, acute prolonged shock, myocardial failure, burns, venomous snakebite, abdominal aortic surgery, hyperacute renal transplant rejection

Histo: patchy / universal necrosis of renal cortex + proximal convoluted structures ← distension of glomerular capillaries with dehemoglobulinized RBCs; medulla and 1–2

mm of peripheral cortex are spared

• protracted + severe oliguria / anuria

Distribution: diffuse / multifocal; mostly bilateral

A. EARLY SIGNS

√ diffusely enlarged smooth kidneys

√ absent / faint nephrogram

CT:

√ enhancing interlobar and arcuate arteries adjacent to nonenhancing cortex (arterial phase)

√ "reversed rim" sign = enhancement of medulla + nonenhancement of hypoattenuating cortex (parenchymal phase)

Cause: sustained hypotension for 1 hour

√ rim of subcapsular cortical enhancement ← collateral blood flow from cortical vessels

√ enhancement of juxtamedullary zone of cortex

US:

√ loss of normal corticomedullary region with hypoechoic outer rim of cortex

NUC:

√ severely impaired renal perfusion

B. LATE SIGNS

√ small kidney (after a few months)

√ "tramline" / punctate calcifications along margins of viable and necrotic tissue (as early as 1–2 months)

US:

√ hyperechoic cortex with acoustic shadowing

Prognosis: poor chance of recovery

ACUTE INTERSTITIAL NEPHRITIS

= infiltration of interstitium by lymphocytes, plasma cells, eosinophils, few PMNs + edema

Cause: allergic / idiosyncratic reaction to drug exposure (penicillin, methicillin, sulfonamides, ampicillin, cephalotin, anticoagulants, phenindione, diphenylhydantoin)

• eosinophilia (develops 5 days to 5 weeks after exposure)

√ large smooth kidneys with thick parenchyma

√ normal / diminished contrast density

US:

√ normal / increased echogenicity

ACUTE TUBULAR NECROSIS

= ACUTE VASOMOTOR NEPHROPATHY

= temporary reversible marked reduction in tubular flow rate

Etiology:

(a) DRUGS: bichloride of mercury, ethylene glycol (antifreeze), carbon tetrachloride, bismuth, arsenic, uranium, urographic contrast material (esp. when associated with glomerulosclerosis in diabetes mellitus), aminoglycosides (gentamicin, kanamycin)

(b) ISCHEMIA: major trauma, massive hemorrhage, postpartum hemorrhage, crush injury,

myoglobulinuria, compartmental syndrome, septic shock, cardiogenic shock, burns, transfusion reaction, severe dehydration, pancreatitis, gastroenteritis, renal transplantation, cardiac surgery, biliary surgery, aortic resection

Pathophysiology: profound reduction in renal blood flow ← elevated arteriolar resistance

√ smooth large kidneys, especially increase in AP diameter > 4.63 cm ← interstitial edema
√ diminished / absent opacification of collecting system
√ immediate persistent dense nephrogram (75%)
√ increasingly dense persistent nephrogram (25%)
√ diffuse calcifications (rare)

US:
√ normal to diminished echogenicity of medulla
√ sharp delineation of swollen pyramids
√ normal (89%) / increased (11%) echogenicity of cortex
√ elevated resistive index ≥ 0.75 (in 91% excluding patients with hepatorenal syndrome); unusual in prerenal azotemia

Angio:
√ normal arterial tree with delayed emptying of intrarenal vessels
√ slightly delayed / normal venous opacification

NUC:
√ well-maintained renal perfusion
√ poor concentration of ^{99m}Tc-glucoheptonate / ^{99m}Tc-DTPA
√ better renal visualization on immediate postinjection images than on delayed images
√ progressive parenchymal accumulation of ^{131}I-Hippuran / ^{99m}Tc-MAG_3
√ no excretion

ADDISON DISEASE

= PRIMARY ADRENAL INSUFFICIENCY

◊ 90% of adrenal cortex must be destroyed!

Course: acute (adrenal apoplexy), subacute (disease present for < 2 years), chronic

Acute Primary Adrenal Insufficiency

= ADDISONIAN CRISIS = ADRENAL APOPLEXY

Cause: bilateral adrenal hemorrhage most commonly due to stress from surgery / sepsis / hypotension with shock / hemorrhagic diathesis, anticoagulation therapy

- abdominal / back pain
- fever (70%), hyperpyrexia, lethargy, nausea, vomiting

√ bilateral adrenal enlargement with areas of increased attenuation

Cx: catastrophic hypotension + shock

Chronic Primary Adrenal Insufficiency

Cause:

1. Idiopathic adrenal atrophy (60–70%): likely autoimmune disorder
2. Fungal infection: histoplasmosis, blastomycosis, coccidioidomycosis
3. Granulomatous disease: tuberculosis, sarcoidosis
4. Bilateral metastatic disease (rare)

• hyponatremia, hyperkalemia, azotemia, hypercalcemia
√ diminutive glands ← idiopathic atrophy + chronic inflammation
√ calcifications (in 25% of chronic course)

ADENOMATOID TUMOR OF SCROTUM

= benign slow-growing mesothelial neoplasm
Frequency: 30% of all extratesticular masses;
2nd most common extratesticular mass (after lipoma)
Age: 2nd–4th decade
Histo: epithelial-like cells + stroma of hyalinized / loose collagen with varying amounts of smooth muscle + elastic fibers
Origin: epididymal tail
Location: epididymis > tunica vaginalis, spermatic cord (rare)
Site: L > R; lower pole÷upper pole = 4÷1
Size: 0.4–5.0 cm (usually < 2 cm)
• hard painless scrotal mass
√ smooth round paratesticular mass at periphery of testis:
√ well-marginated solid hypoechoic mass with echogenicity equal to / greater than testis
√ indentation of the testicular contour
MR:
√ isointense relative to testis on T1WI
√ slightly hypointense relative to testis on T2WI
√ enhancement similar to testicular enhancement
DDx: germ cell tumor, granulomatous epididymitis (painful, avascular), metastasis from B-cell ALL / NHL

ADRENAL CYST

Frequency: 0.06–0.18% (at autopsy)
Age: 3rd–5th decades (most commonly); M÷F = 1÷3 to 1÷2
Path: (a) vascular / endothelial cyst (45–48%)
(b) pseudocyst (39–42%)
(c) epithelial lining = true simple cyst (9–10%)
(d) parasitic cyst (7%)
Location: mostly solitary; R÷L = 1÷1; bilateral in 8–15%
Mean size: 5.3 cm; < 5 cm in diameter in 50% (up to 20 cm)
• asymptomatic, unless very large / infected / ruptured / bled into
√ well-circumscribed encapsulated uni- / multilocular lesion with internal septa
√ thin wall of < 3 mm in thickness (unless pseudocyst)
√ lack of central enhancement ± wall and septal enhancement
√ calcifications:
(a) peripheral / mural: rimlike / nodular (51–69%)
(b) central (rarely): in intracystic septation (19%) / punctate within intracystic hemorrhage (5%)
(c) scattered throughout the lesion

Radiography:
√ inferior displacement of ipsilateral kidney
US:
√ well-circumscribed hypo- to anechoic lesion
CT:
√ well-circumscribed nonenhancing hypoattenuating lesion of < 20 HU (near-water density); higher attenuation with hemorrhage / intracystic debris / crystals
MR:
√ uniformly hypointense on T1WI + hyperintense on T2WI
√ NO enhancement
√ T1 hyperintense signal ← hemorrhage
√ ± septations / soft-tissue component ← hemorrhage / hyalinized thrombus
Cx: hypertension; hemorrhage; infection; rupture with retroperitoneal hemorrhage
Prognosis: interval increase in cyst size in 60%
Rx: (1) Resection of cyst > 5 cm ← risk of hemorrhage
(2) Functional symptomatic cyst
(3) Cyst worrisome for malignancy
DDx: (a) benign
1. Cystic pheochromocytoma
2. Cystic adenomatoid tumor
3. Schwannoma
4. Adrenocortical adenoma (contrast enhancement, no wall, no peripheral calcification)
5. Hemangioma

(b) benign
1. Cystic adrenocortical carcinoma (thick-walled lesion > 7 cm in size; extremely rare)
2. Metastatic disease

Vascular / Endothelial Adrenal Cyst (45–48%)

Cause: 1. Simple cyst without soft-tissue component
2. Lymphangioma
3. Hemangioma

Histo: lined by cells resembling normal endothelium
√ multilocular thin-walled cyst containing serous / serosanguinous / clear fluid
√ scattered / central septal calcifications in 15–30%

Adrenal Pseudocyst (39–42%)

Cause:
1. Previous hemorrhage / infarction
2. Hemorrhagic complication of benign vascular neoplasm / malformation
3. Cystic degeneration / hemorrhage of primary adrenal mass

Histo: wall consists of dense hyalinized material + occasional calcification / osseous metaplasia; adrenal cortical cells can be found in wall

• amorphous material + blood products as content
√ typically unilocular thick-walled cyst > 3.5 mm
√ internal scattered echogenicity ← debris / fluid-fluid levels from recent hemorrhage
√ peripheral calcifications

True Simple / Epithelial Adrenal Cyst (9–10%)

Cause: 1. Glandular / retention cyst
2. Embryonal cyst
3. Cystic adenoma
4. Mesothelial inclusion cyst

Histo: simple epithelial lining
√ unilocular thin-walled cyst

Parasitic Adrenal Cyst (7%)

Cause: usually Echinococcus granulosus
Path: purely cystic to more complex contents depending on stage of infection
√ variable internal complexity ← daughter vesicles, freed scolices, brood capsules
√ septal / mural calcifications
√ "water lily" sign
√ extra-adrenal foci of hydatid disease

ADRENAL HEMORRHAGE

Site: medulla with variable degree of cortical involvement
• sudden / gradual onset of lower chest / upper abdominal / flank / back pain; shocklike symptoms = signs of massive blood loss
• acute adrenal insufficiency (rare): manifesting as hypotension + hyponatremia + hyperkalemia
√ round / oval mass displacing kidney inferiorly + IVC anteriorly
√ uniform adrenal enlargement gradually decreasing in size over 6–8 weeks (follow-up for 2–3 months)
√ complete resolution with time:
√ ± rimlike curvilinear / eggshell calcifications > 1 year
√ no enhancement
NECT:
@ acute stage (< 7 days):
√ round / oval mass (in 83%) located in medulla + stretching cortex around hematoma:
√ hyperattenuating (50–90 HU) similar to most neoplasms in acute stage → slowly decreasing over time
N.B.: Follow-up required to confirm regression!
√ obliteration of gland by diffuse irregular hemorrhage (in 9%)
√ periadrenal fat stranding
√ asymmetric thickening of diaphragmatic crus ← periadrenal hemorrhage
@ chronic stage (> 7 weeks):
√ mass with hypoattenuating center ± calcifications = adrenal pseudocyst (DDx: adrenal adenoma)

US (modality of choice for neonate):
√ complex solid heterogeneously hyperechoic mass during early stage
√ mixed echogenicity with centrally hypoechoic region (as liquefaction occurs)
√ peripheral curvilinear hyperechoic calcifications appearing within 1–2 weeks
√ completely anechoic / cystlike in chronic stage
√ avascularity on color Doppler / power Doppler
MR:
@ acute stage (< 7 days):
= high concentration of intracellular deoxyhemoglobin with preferential T2 proton relaxation enhancement
√ isointense / slightly hypointense on T1WI
√ markedly hypointense on T2WI
@ subacute stage (7 days–7 weeks):
= T1 shortening ← paramagnetic effect of free methemoglobin (Fe3+) ← produced by oxidation of hemoglobin (Fe2+)
√ hyperintensity on T1WI and T2WI appearing in periphery with filling in (over several weeks)
√ hematoma may be multilocular, each locule with its own different signal intensity
@ chronic stage (> 7 weeks):
= T2 proton relaxation enhancement ← hemosiderin deposition + presence of a fibrous capsule
√ hypointense rim on T1WI + T2WI
√ "blooming effect" (= magnetic susceptibility) of hemosiderin in gradient-echo imaging
Rx: supportive; prompt glucocorticoid administration with concomitant intravenous saline therapy for acute adrenal insufficiency

Nontraumatic Adrenal Hemorrhage (20%)

Incidence: in 1.8% (autopsy study)
Cause: (1) Stress: severe burn, sepsis, surgery, hypotension
(2) Hemorrhagic diathesis: anticoagulant therapy
(3) Coagulopathy
(4) Underlying adrenal mass: adrenocortical adenoma / carcinoma, myelolipoma, pheochromocytoma, metastasis, neuroblastoma
Location: typically bilateral
DDx: neuroblastoma (stippled calcifications, increase in vanillylmandelic acid, no decrease on follow-up)

Blunt Trauma to Adrenal Gland (80%)

Incidence: in 28% of autopsies; in 2% of trauma CTs
◊ Adrenal injury means exposure to major force!
Mechanism:
(a) direct crush injury between spine and liver / spleen
(b) acutely increased adrenal venous pressure ← transmitted from compressed IVC / adrenal venous sampling

(c) IVC-adrenal vein thrombosis
(d) shear injury to small adrenal vessels (from rotational / deceleration forces)

Often associated with: injury to liver + kidney

Location: R÷L÷bilateral = 75÷15÷10

Prognosis: (1) unilateral hematoma: spontaneous resolution without sequelae
(2) bilateral hemorrhage: acute primary adrenal insufficiency (rare) is life-threatening

DDx: preexisting adrenal mass → repeat imaging after 8–10 weeks!

ADRENOCORTICAL ADENOMA

◊ Most common tumor of adrenal gland!

Prevalence: 1–2% in general population; age-dependent 6.6–8.7% at autopsies (small tumors in 50% of autopsies)

◊ In a patient with lung carcinoma a solitary small adrenal mass is more likely an adenoma than a metastasis!

Path: atypical intralesional cystic degeneration / less often hemorrhage

Histo: clear cells arranged in cords with abundant <u>intracellular</u> (= intracytoplasmic) pale-staining lipid; rich delicate vascular network

◊ Detection of lipid by CT / MRI is NOT 100% specific!

DDx: metastatic clear cell renal cell carcinoma, pheochromocytoma, adrenocortical carcinoma

◊ No lipid may mean a benign lipid-free adenoma!

◊ Fat cell aggregates (<u>macroscopic fat</u>) may be present!

DDx: lipomatous / myelolipomatous metaplasia

• usually nonfunctioning

Average size: 2.0–2.5 cm: usually < 5 cm in size

√ well-defined homogeneous (87%) sharply marginated mass

√ small adenomas < 1 cm often go undetected

√ contralateral gland often normal / atrophic

NECT:

Categories:

(a) lipid-rich adenoma < 10 HU (60–90% of all adenomas)
(b) lipid-poor adenoma > 10 HU (up to 40%)

√ soft-tissue density / cystic density (mimicked by high cholesterol content) with poor correlation between functional status and HU number:

√ < 0 HU on NECT (47% sensitive, 100% specific)

√ <u>≤ 10 HU on NECT</u> (79% sensitive, 96% specific)

√ < 18 HU on NECT (85% sensitive, 100% specific)

√ > 10% negative pixels on histogram (100% specific)

√ homogeneous attenuation (87%)

CECT:

√ homogeneous (58%) enhancement

√ < 37 HU on 5–15-min delayed CECT is DIAGNOSTIC of adenoma

Washout Technique:

Rationale: adenomas show significantly more initial enhancement than nonadenomas

(1) Attenuation before contrast administration = ANECT

(2) Early attenuation at 60 sec = Aearly

(3) Delayed attenuation at 10–15 min = Adelayed

(4) Absolute percentage washout (Wabs / APW)

$W_{abs} = [1 – (A_{delayed} – A_{NECT}) / (A_{early} – A_{NECT})] \bullet 100$

√ washout > 40% = adenoma

√ washout ≤ 40% = indeterminate mass

(5) Relative percentage washout (W_{rel} / RPW) useful when the NECT value is not known

$W_{rel} = [(A_{early} – A_{delayed})/A_{early}] \bullet 100$

√ washout > 60% = adenoma

√ washout ≤ 60% = indeterminate mass

Angio:

√ tumor blush + neovascularity; occasionally hypovascular

√ pooling of contrast material

√ enlarged central vein with high flow

√ arcuate displacement of intraadrenal veins

√ bilateral adrenal venous sampling → in up to 40% unsuccessful in localizing

MR:

√ isointense mass relative to liver + hyperintense relative to spleen on T1WI ← short T1 time of lipid

√ iso- / hypointense mass (rarely hyperintense) to spleen on T2WI

√ marked hypointensity compared with spleen / skeletal muscle on opposed-phase GRE images ← destructive interference of lipid and water signals = phase cancellation of fat + water protons in same voxel in 95% of adenomas (> 90% accurate)

√ signal loss of ≥ 20% on opposed-phase image

√ India ink effect = characteristic black lines outlining interface between organ + adjacent fat (chemical shift artifact)

√ small round foci of altered SI ← cystic changes / hemorrhage / variation in vascularity

CEMR:

√ uniform enhancement on immediate early imaging

√ adenomas tend to enhance less rapidly + less intensely than metastases on time-enhancement curves

√ relatively rapid washout of contrast material compared with metastases with return to baseline at 15 minutes ← lack of large interstitial spaces of edema + necrosis (DDx: metastases tend to have higher signal intensities [however 20–30% overlap])

US:

√ well-circumscribed round or oval lesion of slightly heterogeneous mixed echogenicity

Atypical appearance:

◊ Occasional intralesional cystic degeneration / hemorrhage make an accurate diagnosis more challenging!

√ adenoma may calcify → often in areas of old hemorrhage

DDx: pheochromocytoma, adrenocortical carcinoma, metastasis, functioning adenoma

Nonhyperfunctioning Adrenocortical Adenoma

characterized by
(a) normal lab values of adrenal hormones
(b) NO pituitary shutdown of the contralateral gland
(c) activity on NP-59 radionuclide scans

Prevalence: incidental finding in 0.6–1.5% of CT examinations, in 3–9% at autopsy
√ surveillance CT to confirm lack of growth
Rx: surgical removal for masses 3–5 cm as indeterminate potentially malignant neoplasms
DDx: metastasis

Hyperfunctioning Adrenocortical Adenoma

√ contralateral adrenal atrophy ← suppression of pituitary ACTH by elevated cortisol levels

1. Primary hyperaldosteronism = Conn syndrome (80%)
   Pathophysiology: secretion of aldosterone by an adenoma is pulsatile
   √ ACTH infusion incites a dramatic increase in levels of cortisol + aldosterone for venous sampling
2. Cushing syndrome (10%)
3. Virilization
   (a) hirsutism + clitoromegaly in girls
   (b) pseudopuberty in boys
   ◊ Most common type of hormone elevation in children!
   • elevated testosterone levels > 0.55 ng/mL
4. Feminization (estrogen production)
   √ contralateral atrophic gland ← ACTH suppression with autonomous adenoma
   √ unilateral focus of ^{131}I NP-59 radioactivity + contralateral absence of iodocholesterol accumulation (DDx: hyperplasia [bilateral activity])

ADRENOCORTICAL CARCINOMA

Prevalence: 1–2÷1,000,000 people; 0.3–0.4% of all pediatric neoplasms (3 x more likely than adrenal adenoma)
Age: biphasic distribution (1st + 4th–5th decade); M÷F = 1÷1.5
May be associated with:
hemihypertrophy, Li-Fraumeni syndrome, Beckwith-Wiedemann syndrome, Carney complex, congenital adrenal hyperplasia, MEN 1, astrocytomas
Path: large lobulated tumor, often with cystic / necrotic / hemorrhagic center
Histo: differentiation of benign from malignant solely on the basis of histologic features may be difficult

• abdominal / back pain, palpable abdominal mass
• weight loss, early satiety
• 20% nonfunctioning
• 50% hyperfunctioning (in 10–15% Cushing syndrome, occasionally Conn syndrome, feminization, adrenogenital syndrome with virilization) inversely related to size
• hypertension (common in all syndrome types)

Location: left÷right adrenal = 53÷47; bilateral in 10%

Median size: 10–12 cm (range, 4–25 cm); usually > 5 cm; in 70% > 6 cm in diameter

A heterogeneous enhancing adrenal mass > 4 cm in diameter has a high likelihood of malignancy!

√ frequently heterogeneous mass with irregular margins + displacement of regional structures
√ occasionally calcified (in 19–33%)
√ invasion of IVC, liver, kidney, diaphragm (multiplanar imaging helpful)
√ metastases to liver, regional lymph nodes, lung, bone, brain

◊ Metastases are the only reliable sign of malignancy!
◊ Large size + calcifications suggest malignancy!

CT:
- √ tumor attenuation typically > 10 HU
- √ central areas of low attenuation ← tumor necrosis
- √ heterogeneous enhancement (= foci of hemorrhage + central necrosis) + thin peripheral rim of enhancement

CECT:
- √ peripheral nodular enhancement (in 88%)
- √ venous tumor thrombus
- √ relative percentage washout (RPW) of < 40% at 15 min
- √ slow absolute washout of < 60% at 15 min

US:
- √ well-defined round / oblong mass with lobulated contours
- √ homogeneous echotexture in small tumor
- √ complex echo pattern in large tumor with hyperechoic + hypoechoic regions ← hemorrhage + necrosis

MR:
- √ tumor of low T1 signal + heterogeneously high T2 signal
- √ heterogeneous areas hyperintense to liver on T1WI + T2WI ← internal hemorrhage + necrosis frequent:
  - √ high SI on T1WI ← methemoglobin
  - √ high SI on T2WI ← necrosis
  - √ loss of SI on out-of-phase imaging ← intracytoplasmic lipid

CEMR:
- √ heterogeneous enhancement pattern with slow washout
- √ nodular enhancement + central hypoperfusion

Angio:
- √ enlarged adrenal arteries
- √ neovascularity, occasionally with parasitization
- √ AV shunting; multiple draining veins

NUC:
- √ usually bilateral nonvisualization with ^{131}I NP-59 (= carcinomatous side does not visualize because amount of uptake is small for size of lesion; contralateral side does not visualize because carcinoma is releasing sufficient hormone to cause pituitary feedback shutdown of contralateral gland)

PET:

√ hypermetabolic tumor on 18F-FDG with adrenal-to-liver max SUV ratio of > 1.45 (100% sensitive, 88% specific)

Biopsy: may appear histologically benign in well-differentiated adenocarcinoma
◊ Sampling error with fine-needle aspiration possible; use core biopsy instead

Prognosis: 0% 5-year survival rate

DDx: metastasis (similar signal intensities on MR); adrenocortical adenoma (mass of < 10 HU, >40% relative washout, > 60% absolute washout); myelolipoma (intralesional bulk fat)

Adrenocortical Neoplasm in Children

Incidence: 3÷1,000,000 annually; less common than neuro- blastoma but more common than pheochromocytoma

Mean age: 8 years (range, 6 months to 19 years); ⅔ younger than 5 years of age; M÷F = 2.2÷1.0

Path: adenoma = solitary spherical well-demarcated unencapsulated tumor of < 50 g
carcinoma = multinodular tumor with areas of hemorrhage + necrosis of > 100–500 g

Histo: NO reliable features to distinguish between adenoma and carcinoma!

Associated with:

(1) Beckwith-Wiedemann syndrome (3%)
2nd most common abdominal tumor after Wilms tumor

(2) Li-Fraumeni syndrome = SBLA (sarcoma, breast and brain tumors, laryngeal carcinoma, adrenocortical carcinoma)
[Frederick Pei Li (1940–), American epidemiologist at Harvard School of Public Health and Harvard Medical School in Boston]
[Joseph F. Fraumeni, Jr. (1933–), American epidemiologist at Harvard School of Public Health in Boston]
• alteration of p53 tumor suppressor gene located on short arm of chromosome 17, band 13

(3) Familial Carney complex = cardiac myxoma + Sertoli cell tumor + adrenocortical neoplasm

(4) MEN 1 = pituitary prolactinoma + pancreatic islet cell tumor + parathyroid hyperplasia + adrenocortical neoplasm

- palpable abdominal mass (57%)
- gonadotropin-independent production of endogenous androgens + cortisol (92%):
  - virilization in female
    = herculean habitus (increased muscle mass), clitoromegaly, facial hair, advanced pubic + axillary hair development, advanced bone age
  - isosexual precocious puberty in male
    = early development of acne, pubic hair, penile enlargement
  - mixed endocrine syndrome with cushingoid features (less frequent)
- other endocrine abnormalities (unusual):
  - pure Cushing syndrome
  - feminization in boys ← secretion of estrogen
  - Conn syndrome (primary hyperaldosteronism)
- increase in 24-hour urinary ketosteroid excretion

• increased levels of serum cortisol, testosterone, androstenedione, estradiol

Metastases: lung > liver > tumor invasion of IVC (35%) > peritoneum (29%) > pleura + diaphragm (24%) > abdominal lymph nodes (24%) > kidney (18%)

US:

√ 3–22-cm round / ovoid well-circumscribed mass
√ lobulated border (common)
√ thin echogenic capsule-like rim (27%)
√ homogeneous mass hypo- / isoechoic to kidney
√ heterogeneous mass with centrally hypoechoic regions (= tumor necrosis) if large
√ tumor calcification (19%)

CECT:

√ well-circumscribed mass with thin rim
√ heterogeneous predominantly peripheral enhancement if lesion large
√ fine / coarse calcification (24%)

MR:

√ iso- / slightly hypointense to liver on T1WI
√ hyperintense to liver on T2WI
√ uniform signal loss at chemical shift imaging ← intracytoplasmic lipid

PET/CT:

√ hypermetabolic primary tumor + metastases
√ secondary findings ← excess serum cortisol of Cushing syndrome:
  √ hyperattenuating / hyperechoic renal pyramids ← hypercalcemia
  √ increase in retroperitoneal fatty tissue ← obesity

Rx: surgery

Prognosis of adrenocortical carcinoma:

survival rate of 70% [13%] for children < 5 years [> 5 years] of age; death within 1–2 years after diagnosis

DDx: (1) Neuroblastoma (encasing vascular structures, punctate calcifications, crosses midline, extradural extension through neural foramina, ill child, often already metastatic, increase in catecholamines)
(2) Pheochromocytoma (older child, headaches)
(3) Adrenal hemorrhage (neonate, temporal evolution)
(4) Metastasis (extremely rare)

ADRENOCORTICAL HYPERPLASIA

= ADRENAL CORTICAL HYPERPLASIA

◊ Responsible for 8% of Cushing syndrome and 10–20% of hyperaldosteronism!

Cause:

1. Corticotropin-dependent (85%): pituitary causes, ectopic ACTH production, CRF (corticotropin-releasing factor)production
2. Primary pigmented nodular adrenocortical hyperplasia
3. Primary aldosteronism (rare)

Prevalence: 0.51% increasing with age (autopsy); 4 x increased in patients with malignancy

Age: 70–80% in adults; 19% in children

Location: typically bilateral
Types:
(1) **Smooth diffuse hyperplasia** (common)
√ smooth to slightly lobular thickening of entire adrenal gland while maintaining its overall normal inverted-V or inverted-Y appearance
◊ In 45% of patients with Cushing syndrome
(2) **Cortical nodular hyperplasia** (less common)
Prevalence: increasing with age (autopsy)
Histo: mild nodularity (50%), distinct nodularity (15%)
Age: 65 years
Site: multifocal
√ focal hypo- to isoattenuating micro- / macronodules (= nodules up to 2.5 cm)
√ background of normal adrenal tissue / atrophic intervening cortex
◊ In 3% of patients with Cushing syndrome
Angio:
√ minimally increased hypervascularity
√ focal accumulation of contrast medium
√ normal venogram / may show enlarged gland
√ adrenal venous sampling to direct therapy in symptomatic patients ← results NOT ALWAYS CONCORDANT with imaging findings
NUC:
√ asymmetric bilateral NP-59 uptake (related to urinary cortisol excretion) WITHOUT dexamethasone suppression in Cushing syndrome
√ bilateral foci of NP-59 uptake WITH dexamethasone suppression (nondiagnostic ≥ 5 days)
Rx: no treatment in the absence of clinical / biochemical evidence of adrenocortical hyperfunction

ACTH-independent Macronodular Hyperplasia

= MACRONODULAR HYPERPLASIA WITH MARKED ADRENAL ENLARGEMENT
Etiology: unknown
• clinical features of hyperaldosteronism / Cushing syndrome
• suppressed ACTH ← active production of hormones
√ bilateral enlarged adrenal glands (often > 5 cm) with macronodules

Primary Pigmented Nodular Adrenocortical Disease

√ normal to slightly enlarged adrenals + small nodules + atrophy of intervening cortex
Associated with: Carney complex

ADRENAL REST TUMOR

= ADRENOCORTICAL REST
Prevalence: 7–15% of newborns; 1.6% of adults
◊ Adrenal rests only form masses after exposure to elevated levels of adrenocorticotropic hormone
Associated with conditions of ⇑ circulating ACTH:

(1) Congenital adrenal hyperplasia
(2) Cushing syndrome
(3) Addison disease

• increase in cortisol levels (testicular vein sampling is DIAGNOSTIC)

Location: near testicular hilum; usually bilateral

US:

√ multiple hypoechoic nodules
√ may become hyperechoic with acoustic shadowing

MR:

√ nodules isointense relative to normal testis on T1WI
√ nodules hypointense relative to normal testis on T2WI
√ diffuse enhancement after contrast administration

ADRENOGENITAL SYNDROMES

A. CONGENITAL TYPE = **Congenital Adrenal Hyperplasia**

= autosomal recessive enzyme defect

Incidence: 1÷15,000 in most white populations

Cause: mutation of CYP21A2 (in 90%)

Pathophysiology (in 90–95%):

21-hydroxylase deficiency → impaired cortisol + aldosterone synthesis → hyponatremia + hypokalemia + hypotension → ⇑ ACTH stimulation by pituitary gland (negative feedback mechanism) → ⇑ production of steroid precursors → diverted to production of androgens

Age: manifestation most often in neonatal period; M < F

Path: cerebriform appearance of cortical hyperplasia (weight increase to 2–4 x of normal); multilobular bilateral masses near rete testis (adrenocortical rests)

• excess of androgenic steroids:
› F: virilization of female fetus:
• pseudohermaphroditism (= clitoral hypertrophy, ambiguous external genitalia, urogenital sinus)
› M: precocious puberty in male → rapid growth at 3–7 years of age
• salt wasting ← diminished aldosterone production (in 75%):
• life-threatening hypovolemic salt-wasting adrenal crisis (during first 2 weeks of life)

@ Adrenal glands

√ ± symmetrically enlarged + thickened adrenal glands:
√ adrenal limb > 4 mm thick
√ coiled / cerebriform appearance
√ central echogenic stripe replaced by diffusely stippled echoes
√ massive bilateral myelolipomas ← long-standing / poorly treated congenital adrenal hyperplasia

@ Gonads (55%)

(a) females
√ typically normal gonads in females
√ cystic ovaries mimicking polycystic ovaries (76%)

(b) males
√ bilateral multinodular adrenocortical rests in rete testis (= mediastinum testis) in postpubertal boys (in 25%):
√ growth of adrenocortical rests ← effect of ACTH
√ usually hypoechoic < 5 mm masses
√ occasionally heterogeneously hyperechoic adrenals ± acoustic shadowing
√ iso- / slightly hyperintense on T1WI + hypointense on T2WI compared to adjacent testicular parenchyma

Rx: cortisone ± mineralocorticoids

B. ACQUIRED TYPE

M < F

(a) adrenal hyperplasia / adenoma / carcinoma: occasionally bilateral myelolipomas
(b) ovarian / testicular tumor
(c) gonadotropin-producing tumor: pineal, hypothalamic tumor, choriocarcinoma
• virilization; Cushing syndrome

ALKALINE-ENCRUSTED CYSTITIS AND PYELITIS

= chronic severe urinary tract infection affecting urothelial lining

Cause: nosocomial infection with urease-producing bacterium, most commonly Corynebacterium → producing alkaline urine

Predisposed: immunocompromised patient (esp. renal transplant patient), after invasive urologic procedure

Path: mucosal inflammation + encrustation of urothelial lining with struvite + calcium phosphate

• fever, hematuria, dysuria, suprapubic pain
• ammonia-like smell of urine

NECT:

√ diffuse thin / coarse superficial linear urothelial calcifications

Site: collecting system, ureter, bladder; often bilateral

Dx: culture positive > 48 hr for urea-splitting micro-organism

Cx: septic shock, graft failure

Rx: antibiotics, oral acidification of urine

AMYLOIDOSIS

= accumulation of extracellular eosinophilic amyloid protein

• gross hematuria (60%), urethral bleeding
• dysuria, frequency, cystitis, acute renal failure

GU location: bladder (50%), ureter (25%), urethra (20%), renal pelvis (6%)

@ Urinary bladder (50%)

Cause: ? chronic cystitis

Histo: stromal + muscle deposits of amyloid

• painless gross hematuria ← mucosal ulceration
• irritative symptoms

Site: posterior + posterolateral wall of bladder (68%) > multiple areas (65%)

√ nonspecific filling defects + distortion of bladder outline
√ CHARACTERISTIC linear submucosal / intramural calcifications
DDx: schistosomiasis mansoni, TB, urothelial carcinoma, other neoplasm
√ variable degrees of decreased contrast enhancement
√ decreased SI in bladder wall on T2WI
DDx: desmoplastic metastasis + bladder wall lymphoma (↓ T2-SI); urothelial carcinoma (↑ T2-SI)

@ Renal involvement
Frequency: 1° amyloidosis (35%),
2° amyloidosis (in > 80%)
• nephrotic-range proteinuria, renal insufficiency
√ smooth normal to large kidneys with increase in parenchymal thickness (acute stage)
√ small kidneys = cortical atrophy (in 50% of late stage)
√ occasionally attenuated collecting system
√ nephrographic density normal to diminished
√ amorphous renal calcifications
√ focal renal parenchymal mass lesions
US:
√ diffusely increased cortical echogenicity ← deposition of amyloid in glomeruli and interstitium
√ obscuration of arcuate arteries
√ preservation of corticomedullary differentiation
Cx: renal vein thrombosis → renal failure

@ Renal pelvis (6%)
√ calcification in submucosal deposit
√ irregular filling defect on excretory urography
√ hypointense amyloid deposit on T2WI (DDx: lymphoma, desmoplastic metastasis)
√ variable to NO enhancement

@ Ureter (25%)
Site: distal ureter; rarely bilateral
√ focal / diffuse areas of wall thickening + filling defects
√ irregular ureteral narrowing + stricture → hydronephrosis
√ linear submucosal / intramural calcifications

@ Urethra (rare)
• hematuria, dysuria, urethral obstruction
√ narrowing of urethra with filling defects
√ foci of increased echogenicity + posterior shadowing within corpus spongiosum
√ hypointense urethral + periurethral lesions on T2WI
Dx: urethroscopy + transurethral biopsy
DDx: urethral neoplasm

@ Seminal vesicles
= **senile localized amyloidosis of seminal vesicles**
Frequency: in 21% of men > 75 years of age (autopsy)
Site: symmetric involvement of both SV

DDx: invasion of SV by prostate cancer
Dx: transrectal biopsy

@ Retroperitoneum
√ diffuse infiltration encasing kidneys, aorta, IVC, pancreas
√ replacement of retroperitoneal fat with soft-tissue
√ focal retroperitoneal mass
MR:
√ intermediate T1 signal intensity
√ decreased T2 signal intensity

ANALGESIC NEPHROPATHY

= renal damage from ingestion of salicylates in combination with phenacetin / acetaminophen in a cumulative dose of 1 kg

Prevalence: USA (2–10%), Australia (20%)

Age: middle-aged; M÷F = 1÷4

- gross hematuria, hypertension
- renal colic (passage of renal tissue)
- renal insufficiency (2–10% of all end-stage renal failures)
- **Analgesic syndrome**: history of psychiatric therapy, abuse of alcohol + laxatives, headaches, pain in cervical + lumbar spine, peptic ulcer, anemia, splenomegaly, arteriosclerosis, premature aging

√ papillary necrosis
√ scarring of renal parenchyma ("wavy outline"); bilateral in 66%, unilateral in 5%
√ renal atrophy
√ papillary urothelial tumors in calices / pelvis (mostly TCC / squamous cell carcinoma), in 5% bilateral

ANGIOMYOLIPOMA

= AML = **Renal choristoma** (= benign tumor composed of tissues not normally occurring within the organ of origin)

N.B.: normal cells / tissues in an abnormal location!
[= ***Renal Hamartoma*** (improper name since fat and smooth muscle do normally occur within renal parenchyma]

= most common benign mesenchymal tumor of kidney composed of varying admixtures of thick-walled blood vessels, smooth muscle cells and mature fat (→ hence name!)

Prevalence: 0.3–2.0% of all renal tumors; 1% of all surgically removed renal tumors

Genetics: (a) sporadic (50–70%)
(b) inherited with tuberous sclerosis (30–50%), neurofibromatosis, vHL syndrome

Path: large infiltrating necrotic tumor without true capsule, 88% extending through renal capsule, hemorrhage (characteristic lack of complete elastic layer of vessels predisposes to aneurysm formation); tumor continues to grow during childhood + early adulthood

Histo:

(a) classic triphasic (92%): tumor composed of mature fat, aggregates of dysmorphic / thick-

walled blood vessels, epitheloid immature smooth muscle; coexpresses melanocytic markers (HMB-45, melan-A) and smooth muscle markers (smooth muscle actin, calponin), negative for epithelial markers

(b) monophasic epitheloid (8%): high degree of association with tuberous sclerosis + aggressive behavior

Average age: 41 years; M÷F = 1÷2

- small lesions are asymptomatic (60%)
- acute flank / abdominal pain in 87%

◊ Angiomyolipomas > 4 cm are symptomatic in 82–94% ← spontaneous bleeding in 50–60%!

- gross hematuria, anemia, hypertension
- **Wunderlich syndrome** = hemorrhagic shock ← massive bleeding into angiomyolipoma or into retroperitoneum (10%)

Location: renal parenchyma; renal hilum; may be exophytic perirenal / completely extrarenal (retroperitoneum, solid + hollow organs, skin, gynecologic region)

Mean size: 9 cm (range, few mm to 30 cm) in diameter

√ hypervascular mass with large feeding arteries, multiple aneurysms, laking without shunting, tortuous circumferential vessels, whorled parenchymal + venous phase

US:

√ homogeneously echogenic mass similar to sinus fat (DDx to renal cell carcinoma)

CT:

(a) ordinary AML (in 95%):

√ negative attenuation values

◊ Even a small amount of fat within a solid mass on NECT secures the diagnosis!

(b) minimal-fat AML (in 5%)

= angiomyolipoma with microscopic fat only mimicks RCC

√ hyperattenuating (53%) / isoattenuating (26%) / hypoattenuating (21%) mass (DDx: RCC)

√ homogeneous prolonged tumor enhancement

MR:

√ markedly hyperintense adipose tissue relative to renal parenchyma + isointense relative to fat on T1WI

√ demonstration of fat on selective fat-suppression sequence

√ prominent signal loss relative to other tissues on fat-suppressed / opposed-phase images with respect to in-phase images ← intravoxel coexistence of fat and water:

√ characteristic India ink artifact at interface between mass and normal renal parenchyma on opposed-phase T1WI

√ central portions of lesion do not demonstrate changes in signal intensity compared with in-phase images

√ variable SI on T2WI:

√ homogeneously high SI at single-shot T2WI with large fatty mass

√ homogeneously low SI relative to renal parenchyma in lipid-poor angiomyolipomas on T2WI

√ decreased signal intensity on Gd-enhanced images (DDx: RCC enhances)

Cx: (1) Hemorrhage with spontaneous rupture (25%) ← tumor > 4 cm / intratumoral aneurysm > 5 mm
(2) Growth into renal vein / IVC
◊ Not necessarily implying malignant transformation
(3) Renal failure

Rx: (1) Annual follow-up of lesions < 4 cm
(2) Semiannual follow-up of lesions ≥ 4 cm
(3) Emergency laparotomy (in 25%): nephrectomy, tumor resection
(4) Selective arterial embolization with hemorrhage
(5) Prophylactic surgery in pregnant women
(6) Screening for tuberous sclerosis

DDx: renal / perirenal lipoma or liposarcoma; Wilms tumor / renal cell carcinoma (occasionally contains fat if large, but also calcium); clear cell RCC with small amount of intracellular fat

Isolated Angiomyolipoma (50–70%)

= SPORADIC ANGIOMYOLIPOMA

Mean age: 43 (range, 27–72) years; M÷F = 1÷4

• flank pain, hematuria, palpable mass
√ solitary + unilateral (in 80% on R side) AML, NO stigmata of tuberous sclerosis
√ stable over long periods of time

Angiomyolipoma *Associated with TS* (30–50%)

Mean age: 17 years; usually present by 10 years; M÷F = 1÷1

◊ In 70–80–95% of patients with tuberous sclerosis
◊ May be the only evidence of tuberous sclerosis
√ commonly large + bilateral + multifocal AMLs with macroscopic fat
√ tendency for growth + hemorrhage

ARTERIOVENOUS RENAL CONNECTION

√ early enhancement of draining vein + renal vein + IVC
√ intraparenchymal / subcapsular / perirenal hematoma (as a result of bleeding)

Rx: transcatheter intraarterial occlusion, surgery

Arteriovenous Malformation (20–30%)

Cause: (1) Congenital AVM
• asymptomatic; M < F
(2) Acquired AVM: trauma, spontaneous rupture of aneurysm, very vascular malignant neoplasm

Histo:
(a) cirsoid AVM = multiple coiled vascular channels grouped in cluster
(b) cavernous AVM = single well-defined artery feeding into a single vein (rare)

• gross hematuria

Location: adjacent to collecting system
√ large unifocal mass:
  √ focally attenuated and displaced collecting system
  √ homogeneously enhancing mass
  √ curvilinear calcification
√ supplied by multiple segmental / interlobar arteries of normal caliber
√ draining into one / more veins
US:
  √ tubular anechoic structure (DDx: hydronephrosis, hydrocalyx)
Cx: subcapsular / perinephric hematoma (rare)

Arteriovenous Fistula (70–80%)

M > F
Cause: (1) Acquired: trauma (stab wound, percutaneous needle biopsy, percutaneous nephrostomy, nephrolithotripsy), surgery, tumor, inflammation, erosion of aneurysm into vein
(2) Idiopathic
Path: single dilated feeding artery + single draining vein
• asymptomatic with abdominal bruit / abdominal pain
• persistent / delayed gross hematuria (common)
√ tortuous varices over time
√ enlargement of renal vein

US:
  √ focal area of aliasing / color saturation ← high flow rate + vessel tortuosity
  √ ⇑ flow velocity + ⇓ resistance in feeding artery
  √ arterial pulsations in draining vein

Angio:
  √ detailed vascular anatomy for planning embolic occlusion
  √ diminished nephrogram ± cortical atrophy distal to fistula ← reduced flow to renal segment
Cx: (1) Cardiomegaly + high-output cardiac failure (50%)
(2) Renin-mediated hypertension
(3) Hydronephrosis
Prognosis: spontaneous closure within a few months

BENIGN PROSTATIC HYPERTROPHY

= BENIGN PROSTATIC HYPERPLASIA
Prevalence: 50% between ages 51 + 60 years; 75–80% of all men > 80 years of age
Histo: fibromyoadenomatous nodule (most common), muscular + fibromuscular + fibroadenomatous + stromal nodules
Age: initial growth onset < 30 years of age; onset of clinical symptoms at 60 ± 9 years
• sensation of full bladder, nocturia, trouble initiating micturition
• decreased urine caliber + force

• dribbling at termination of micturition

Location: transition + periurethral zone proximal to verumontanum forming "lateral lobes" (82%), "median lobe" (12%)

√ oval (61%) / round (22%) / pear-shaped (17%) enlargement of central gland

√ posterior + lateral displacement of outer gland (= prostate proper) creating cleavage plane of fibrous tissue between hyperplastic tissue + compressed prostatic tissue (= surgical capsule) often demarcated by displaced intraductal calcifications

Cx: bladder outflow obstruction

Rx: (1) Surgery: open prostatectomy (glands > 80 g), trans-urethral resection of prostate = TURP (glands < 80 g)

◊ Only 4–5% of patients need surgical treatment!

(2) Drugs: α-blockers (for stromal hyperplasia); androgen deprivation (suppression of LHRH / inhibition of Leydig cell synthesis of testosterone / competition for androgen receptor binding sites) + α-blockers (for glandular hyperplasia)

Prostatic Retention Cyst

= dilatation of glandular acini in BPH

Cause: acquired obstruction of glandular ductule

Age: 5th–6th decade

Location: transition / central / peripheral zone

√ 1–2-cm smooth-walled unilocular cyst

Cystic Degeneration of BPH

◊ Most common cystic lesion of prostate!

Location: transition zone

√ usually small cyst within nodules of benign prostatic hyperplasia

BLADDER CANCER

Prevalence: 76,960 new cases annually + 16,390 deaths (2016) 4th (10th) most common cancer in males (females); 5% of all new malignant neoplasms; most common tumor of genitourinary tract

Histo: (a) urothelial: transitional cell carcinoma (90%)

(b) squamous cell carcinoma (6–8%)

(c) adenocarcinoma (rare): resembling serous papillary cancer of ovary

(d) mixed histology: small cell neuroendocrine, micropapillary, sarcomatoid, plasmacytoid

Age: 3.1% [8%] in patients < 44 [45–54] years; usually in patients > 65 years; twice as frequent > 80 years; M÷F = 3–5÷1

T-Staging: primary question "Is there muscle invasion (T2)?"

N-Staging: obturator node (most common), nodes above aortic bifurcation (17%), presacral adenopathy (8%); accuracy of CT (70–90%) > MR (64–92%)

Staging accuracy: 50% clinically; 32–80% for CT; 72–96% for MR

Overstaging due to: edema following endoscopy / endoscopic resection, fibrosis from radiation therapy

• painless gross hematuria / microhematuria (80–90%)
• frequency, dysuria, pelvic pain / pressure

Presentation:

(1) Superficial papillary lesion (70%): papilloma, inverted papilloma, papillary urothelial neoplasm of low malignant potential (PUNLMP), low-grade and high-grade papillary urothelial carcinoma; in 20% progressing to invasive cancer
(2) Aggressive invasive de novo tumor (20%)
(3) Metastatic tumor (10%)

Location: bladder base (80%); lateral wall of bladder, bladder diverticulum (in 0.8–10.8%); single (in 60%)

Staging of Bladder Cancer

Jewett-Strong	*TNM*	*Histopathologic Findings*
O	T0	no primary tumor
	Ta	papillary tumor confined to mucosa = noninvasive
	Tis	carcinoma in situ
A	T1	invasion of lamina propria
B	T2	invasion of muscle
B1	T2a	of inner half of muscle
B2	T2b	of outer half of muscle
C	T3	of perivesical fat
	T3a	microscopic
	T3b	macroscopic
D	T4	invasion of surrounding organs
D1	T4a	seminal vesicles, prostate, vagina, rectum
	T4b	pelvic / abdominal wall
	N1	metastasis to single node ≤ 2 cm
	N2	metastasis to single node of 2–5 cm / in multiple nodes ≤ 5 cm
	N3	metastasis to single node > 5 cm
D2	N4	lymph node metastasis above bifurcation of common iliac arteries
	M1	distant metastasis (lung, liver, bone)

Size: < 2.5 cm (in > 50%)

√ intraluminal papillary / nodular mass
√ focal / diffuse wall thickening
√ ureteral obstruction ← muscle invasion

IVP (70% accuracy rate):

√ irregular filling defect with broad base and fronds (DDx: rectal gas marginated by Simpson's white line)
√ < 1% calcified

US:

√ papillary hypoechoic mass protruding into lumen
√ vascularity on Doppler imaging

CT urography (90% sensitive + specific):
◊ Cystoscopy always required to detect small flat lesions!
◊ Delay CT for > 7 days after instrumentation!
√ nodular / arched tumoral calcifications (< 5%) typically encrusting the surface
√ early tumor enhancement
√ increased attenuation of perivesical fat with invasion

MR (staging modality of choice, 52–93% accuracy):
√ tumor isointense to bladder muscle on T1WI + hyperintense on T2WI
√ T1WI optimal to detect invasion of perivesical fat + metastases to lymph nodes + bone
√ T2WI optimal to differentiate tumor from fibrosis and to evaluate tumor depth (SI differences between inner + outer layers of muscularis propria)
√ enhancement differentiates between early enhancing mucosa, submucosa, tumor, nonenhancing muscle, edema + fibrosis

Prognosis: 40–70% recurrence rate

Transitional Cell Carcinoma of Bladder

Classification:
(a) noninvasive / superficial flat / papillary (80–85%)
(b) muscle-invasive / nonpapillary (20–25%)

◊ Synchronous upper tract TCC in 2%
◊ Metachronous upper tract TCC in 6%

Metachronous bladder TCC:
› in 23–40% of primary renal TCC after 15–48 months
› in 20–50% of primary ureteral TCC after 10–24 months
› in 4% of bladder primaries up to 20 years later (²/₃ within 2 years)

Synchronous bladder TCC:
› in 24% of primary renal pelvic involvement
› in 39% of primary ureteral involvement
› in 2% of primary bladder involvement

Prognosis: overall 82% 5-year survival rate; after cystectomy 55–80% 5-year survival with tumor confined to lamina propria, 40% with invasion of muscularis propria, 20% with invasion of perivesical fat, 6% for metastatic cancer

Rx: cystoscopic resection, intravesical mitomycin C, radical cystectomy with urinary diversion

Noninvasive / Superficial / Papillary TCC (80–85%)

Grade: low-grade lesion, usually multifocal

Origin: hyperplastic epithelium

Prognosis: good; 50% rate of recurrence; evolve into muscle-invasive cancer if untreated

Genetics: activate mutation of HRAS gene and fibroblast growth factor

Muscle-invasive / Nonpapillary TCC *(20–25%)*

Grade: higher histologic grade
Origin: severe dysplasia / carcinoma in situ
Genetics: structural + functional defects in p53 and retinoblastoma tumor suppressor pathways

Squamous Cell Carcinoma of Urinary Bladder

Risk factors: long-term catheterization, nonfunctioning bladder, urinary tract calculi, bladder diverticulum (2–10% risk), chronic infection by Schistosoma hematobium
Prognosis: worse than urothelial cancer

BLADDER DIVERTICULUM

= cavity formed by herniation of bladder mucosa through muscular wall, joined to bladder cavity by constricted neck
Prevalence: 1.7% in children
Average age: 57 years; M÷F = 9÷1
Site: areas of congenital weakness of muscular wall at
(a) urethral meatus
(b) posterolateral wall (Hutch diverticulum = paraureteral)
√ hypoechoic fluid-filled structure continuous with bladder wall
√ may appear complex ← thickened wall / debris / soft-tissue component
√ may contain calculi
Cx: (1) Bladder cancer in 0.8–10% ← urinary stasis ← chronic mucosal irritation ← prolonged exposure to urinary carcinogens (average age of 66 years)
(2) Ureteral obstruction
(3) Ureteral reflux
DDx: pelvic cyst

Primary Diverticulum (40%)

= CONGENITAL / IDIOPATHIC DIVERTICULUM
√ in 3% single diverticulum
(a) WITH vesicoureteral reflux
1. Hutch diverticulum in paraureteral region
(b) WITHOUT vesicoureteral reflux

Secondary Diverticulum (60%)

√ in 50% multiple diverticula
(a) postoperative state
(b) associated with bladder outlet obstruction
1. Posterior urethral valves
2. Urethral stricture
3. Large ureterocele
4. Neurogenic dysfunction
5. Enlarged prostate
6. Bladder neck stenosis

(c) associated with congenital syndromes

1. Prune belly syndrome
2. Menkes kinky-hair syndrome
3. Williams syndrome
4. Ehlers-Danlos type 9 syndrome
5. Diamond-Blackfan syndrome

Multiple Diverticula in Children

1. Neurogenic dysfunction
2. Posterior urethral valves
3. Prune belly syndrome

BLADDER EXSTROPHY

= EPISPADIA-EXSTROPHY COMPLEX

= failure of lower abdominal wall + anterior bladder wall to close normally

Prevalence: 1÷30,000 to 1÷40,000 live births; M > F

Etiology: incomplete retraction of cloacal membrane prevents normal midline migration of mesoderm→ resulting in incomplete midline closure of infraumbilical abdominal wall; size of persistent cloacal membrane at time of rupture accounts for different degrees of severity

- urinary bladder exposed + open anteriorly
- mucosa everted through abdominal wall defect
- bladder margins continuous with margins of abdominal wall
- epispadia + short / split penis (male); bifid clitoris (female)
- maldescended testes

May be associated with:

wide linea alba, omphalocele, limb defects (eg, club feet), renal malformation (horseshoe kidney, renal agenesis), incomplete testicular descent, GI obstruction, bilateral inguinal hernias, imperforate anus, cardiac anomalies, hydrocephalus, meningomyelocele

male: epispadia, short or split penis (common);

female: bifid clitoris, uterine and vaginal anomalies

√ persistently "absent" urinary bladder (HALLMARK) → urine is released immediately into amniotic cavity through opening between bladder and abdominal wall.

√ irregular thickening of everted posterior bladder wall ← inflammation of exposed mucosa

√ ventral defect of infraumbilical abdominal wall

√ low position of umbilicus

√ pubic diastasis = widening of pubic symphysis

DDx: cloacal exstrophy (NO extruded bowel loops, abnormal rectum)

Cx: urinary incontinence, infertility, pyelonephritis, bladder carcinoma (4%)

Rx: primary closure, bladder excision with urinary diversion

Closed Exstrophy = Pseudoexstrophy

= persistent large cloacal membrane without rupture

- anterior wall of bladder covered by thin bilaminar epithelial membrane

√ infraumbilical musculoskeletal defect

√ subcutaneous position of bladder

CHOLESTEATOMA

= KERATIN BALL
= keratinized squamous epithelium shed into lumen
Pathogenesis: long-standing urinary infection may result in squamous metaplasia of transitional epithelium
• history of UTIs; repeated episodes of renal colic with passage of "white tissue flakes"
Location: renal pelvis > upper ureter
√ mottled / stringy "onion-skin" filling defect in calices / renal pelvis
√ dilatation of pelvicaliceal system (with obstruction)
√ calcification of keratinized material possible
◊ Not a premalignant condition!

CHRONIC GLOMERULONEPHRITIS

Cause: acute poststreptococcal glomerulonephritis
• late presentation without prior clinically apparent acute phase
• hypertension, renal failure
√ small smooth kidneys with wasted parenchyma
√ normal papillae + calices
√ patchy nephrogram with diminished density of contrast medium
√ cortical calcification (uncommon)
US:
√ increased echogenicity
√ small kidneys with vicarious sinus lipomatosis
Angio:
√ marked reduction in renal blood flow
√ reflux of contrast material into aorta
√ severely pruned + tortuous interlobar and arcuate arteries
√ nonvisualization of interlobular arteries
√ delayed contrast clearance from interlobar arteries

CLEAR CELL SARCOMA OF KIDNEY

= BONE-METASTASIZING RENAL TUMOR OF CHILDHOOD
= rare highly malignant mesenchymal renal neoplasm of childhood with propensity for bone metastasis (rare for Wilms)
Incidence: 20 cases annually in USA; 4–5% of primary renal neoplasms in childhood; 2nd most common renal malignancy after Wilms
Mean age: 3 (range, 1–6) years; M÷F= 2÷1
Path: always unilateral unicentric soft well-circumscribed mass replacing most of the kidney / centered in renal medulla; hemorrhage + necrosis (in 70%); hilar lymphovascular infiltration (30%); extension into renal vein (5%)
Histo: composed of well-defined polygonal to stellate cells with vacuolization, ovoid to rounded nuclei, prominent capillary pattern + tendency toward cyst formation separated

by slightly thickened septa
• increasing abdominal girth + palpable abdominal mass
• lethargy, weight loss, hematuria, bone pain (infrequent)
√ expansile well-demarcated mass (8–16 cm) with dominant soft-tissue component
√ cystic component of varying size (few mm to 5 cm) + multiplicity (58%)
√ amorphous / linear calcifications (25%)
√ renal mass crossing midline (58%)
√ NO intravascular extension
√ lytic / sclerotic / mixed metastatic bone lesions
Metastases to: lymph nodes (30%), bone (13–20%), lung, brain, liver; in 5–18% metastatic at presentation
US:
√ inhomogeneous renal mass of soft-tissue density
√ well-defined hypoechoic central area (= necrosis)
√ mass with fluid-filled anechoic cystic spaces
√ large fluid-filled spaces + echogenic septa may predominate
CT:
√ heterogeneous enhancement less than that of normal renal parenchyma
√ low-attenuation areas ← hemorrhage / necrosis
√ water-density areas ← cysts
MR:
√ low to intermediate signal intensity on T1WI
√ high signal intensity on T2WI
NUC:
√ bone scan recommended after diagnosis is established
Prognosis: 60–70% long-term survival rate; aggressive behavior (worse than Wilms tumor) with higher rate of relapse + mortality
DDx: cystic form of Wilms tumor (vascular invasion), multilocular cystic nephroma, cystic dysplasia

CONDYLOMA ACUMINATA

= VENEREAL WART = PENILE SQUAMOUS PAPILLOMA
Cause: viral infection
Histo: squamous papilloma
@ Skin
• soft sessile verucca of penile glans / shaft / prepuce
@ Urethra
Prevalence: 0.5–5% of male patients with cutaneous disease
N.B.: retrograde urethrography NOT recommended as it may cause retrograde seeding!
Voiding cystourethrography:
√ multiple papillary filling defects in anterior urethra
√ ± extension into bladder (rare)
Rx: instillation of podophyllin, thiotepa, 5-fluorouracil into urethra

CONGENITAL RENAL HYPOPLASIA

= miniaturization with reduction in number of renal lobes, number of calices and papillae, amount of nephrons
(+ smallness of cells)

VARIANT: **Ask-Upmark kidney** = aglomerular focal hypoplasia

√ unilateral small kidney
√ decreased number of papillae + calices (5 or less)
√ hypertrophied contralateral kidney
√ absent renal artery
√ hypoplastic disorganized renal veins

CONN SYNDROME

= PRIMARY HYPERALDOSTERONISM = PRIMARY ALDOSTERONISM
= autonomous excess secretion of the mineralocorticoid aldosterone with hypertension + spontaneous hypokalemia

Prevalence: 2–15% of hypertensive population
Age: 3rd–5th decade; M÷F = 1÷2
Cause of aldosteronism:

(a) responsive to corticotropin
  › aldosterone-producing adenoma
  › primary adrenal hyperplasia
(b) responsive to renin-angiotensin system
  › aldosterone-producing renin-responsive adenoma
  › bilateral adrenal glomerulosa hyperplasia
  › familial form of aldosteronism

- hypertension ← hypernatremia
- hypokalemia (80–90%, induced by administering large amounts of sodium chloride for 3–5 days):
  - muscle weakness, cardiac arrhythmia
  - carbohydrate intolerance, nephrogenic diabetes insipidus
- depletion of magnesium, metabolic alkalosis
- increased urinary excretion of aldosterone + metabolites
- plasma aldosterone-to-renin ratio (test of choice):
  - nonsuppressible elevation in plasma aldosterone concentration
  - suppressed plasma renin levels

Path:

(a) bilateral idiopathic adrenal hyperplasia (60%):
  = idiopathic hyperaldosteronism = focal / diffuse hyperplasia of glomerulosa zone accompanied by micro- / macroscopic nodules
(b) adrenocortical adenoma (40%): solitary aldosteronoma (65–70%); multiple (13%); microadenomatosis (6%)
(c) adrenocortical carcinoma (< 1%)

Average size: 1.7 (range, 0.5–3.5) cm
Location: L > R; bilateral in 6%

Adrenal venography : 76% accurate
Adrenal venous blood sampling : 95% accurate, 75% sensitive
CT (60–80% sensitive):
√ mass of soft-tissue density / low attenuation
◊ Among hyperfunctioning adrenal adenomas aldosteronomas have the lowest attenuation!
√ usually hypervascular, rarely hypovascular
√ both glands normal in size ← micronodules
√ nodular / multinodular adrenal gland(s) ← hyperplasia
NUC:
√ ^{131}I NP-59 uptake following dexamethasone suppression:
√ bilateral early visualization (< 5 days) implies adrenal hyperplasia
√ unilateral early visualization implies adenoma
√ late bilateral visualization (> 5 days) may be normal
Dx: elevated plasma aldosterone concentration + suppressed plasma renin activity
Diagnostic endocrine tests:
postural stimulation test, short saline infusion test, 18-hydroxycorticosterone concentration
Cave:
◊ Adenoma in one gland + nonhyperfunctioning adenoma in other gland can suggest bilateral adrenal hyperplasia
◊ Dominant macronodule of one gland in bilateral adrenal hyperplasia can simulate adenoma
Solution: Adrenal venous blood sampling to determine appropriate therapy
Rx: adrenalectomy for neoplasms (75% long-term cure rate for hypertension); medical treatment for hyperplasia

CONTRAST NEPHROPATHY

= CONTRAST-INDUCED RENAL FAILURE
= increase in serum creatinine of ≥ 1 mg/dL ± 25–50% of baseline creatinine level after intravascular contrast administration
Patients at risk:
1. Preexisting renal insufficiency
2. Insulin-dependent diabetes mellitus
3. Large volume of contrast media
4. Concomitant administration of other nephrotoxic drugs: aminoglycosides, nonsteroidal anti-inflammatory agents
5. American Heart Association class IV congestive heart failure
6. Hyperuricemia

Contrast Medium-induced Risk of Nephropathy	
Test	*Threshold*
Serum creatinine level	> 1.6 mg/dL
Estimated glomerular filtration rate*	< 45 mL/min

* Online Calculator using age, race, gender, body weight and plasma creatinine: http://www.medcalc.com/gfr.html ; http://www.mcw.edu/calculators/creatinine.htm

◊ A serum creatinine level of > 4.5 mg/dL causes acute renal failure in 60% of nondiabetics + 100% of diabetics!

◊ IV LOCM is an independent risk factor for acute kidney injury post CECT for a serum creatinine ≥ 1.6 mg/dL

Previously considered but no longer accepted risk factors:

dehydration, hypertension, proteinuria, peripheral vascular disease, age > 65 years, multiple myeloma

◊ IV LOCM is NOT a risk factor for acute kidney injury post CECT with a stable serum creatinine < 1.5 mg/dL

Mechanism:

increase in renal perfusion by vasodilatation (via prostaglandin I2 ± E2) → followed by vasoconstriction (via angiotensin II, norepinephrine, vasopressin)

Time course:

(a) rise in serum creatinine within 1–2 days
(b) peak at 4–7 days
(c) return to normal by 10–14 days

√ persistent nephrogram on plain film
√ cortical attenuation > 140 HU on CT after 24-hour delay

Recommendation:

◊ Employ nonionic contrast media (LOCM appears safe in patients without renal dysfunction / underlying risk factors in doses as large as 800 mL [300 mg iodine per mL])

◊ Do NOT exceed maximum allowed dose (**Cigarroa formula** for HOCM): 5 mL x body weight (kg)

Contrast limit (mL) 60% by weight = serum creatinine (mg/100 mL)

CUSHING SYNDROME

= HYPERCORTISOLISM

= excessive glucocorticoid from either exogenous / endogenous sources

Etiology:

A. ACTH-(PITUITARY)-DEPENDENT (70%)

= overproduction of corticotropin

1. **Cushing disease** (68–90% of endogenous causes)

= overproduction of pituitary ACTH → non-autonomous adrenal hyperplasia

Cause:

(a) basophilic / chromophobe adenoma
(b) overactive pituitary
(c) ACTH-producing primary elsewhere

√ normal adrenal glands
√ diffuse adrenal enlargement
√ macronodular adrenal hyperplasia (in up to 85%)

◊ Micronodular hyperplasia is NOT seen on imaging

2. **Paraneoplastic ectopic ACTH production** (12–20%): bronchial / thymic carcinoid > pheochromocytoma, pancreatic islet cell tumor (10%), oat cell carcinoma of lung (8%), liver cancer, prostate cancer, ovarian cancer, breast cancer, bronchial adenoma,

medullary carcinoma of thyroid, thymoma
◊ Bronchial + thymic carcinoids are often < 1 cm at the time they produce Cushing syndrome!
◊ Islet cell tumors are large + often metastatic by the time they produce Cushing syndrome!
Recommendation: thin-section CT of chest

3. Exogenous ACTH
4. Hypothalamic dysfunction
5. Production of corticotropin-releasing factor (rare)

B. ACTH-(PITUITARY)-INDEPENDENT (30%)

(a) primary adrenal abnormality (18%):
= autonomous cortisol production by adrenal gland

1. **Adrenocortical adenoma**
(10–20% of cases; 10% in adults, 15% in children)
√ often > 2 cm in size
→ readily visualized by CT / MRI
√ atrophy of remaining adrenal tissue ← adenoma suppresses ACTH levels
◊ A hyperfunctioning adenoma does NOT always cause atrophy of the adrenal glands, but normal / thickened adrenal limbs should raise concern for ACTH-dependency!
2. **Adrenocortical carcinoma**
(5–10% of cases; 10% in adults, 66% in children)
3. Ectopic ACTH production / ectopic corticotropic-releasing factor (CRF) secretion
4. Primary pigmented nodular adrenocortical (< 1%)hyperplasia (rare; in children + young adults)
√ multiple small bilateral nodules / normal adrenal
4. Massive macronodular hyperplasia with marked adrenal enlargement (< 1%)
√ multiple bilateral macronodules

(b) exogenous cortisol (12%)

Prevalence: 1÷1,000 autopsies; M÷F = 1÷4
Age: 30–40 years (highest incidence); more often following pregnancy

• central / truncal obesity, buffalo hump, moon face, facial plethora
• purple abdominal striae, acne, hirsutism, amenorrhea
• fatigue, mood changes, proximal muscle weakness
• hypertension, atherosclerosis, edema
• impaired glucose tolerance = glycosuria / diabetes
• elevated plasma cortisol levels
• hypokalemia ← excess cortisol binding Na+/K+ pump acting like aldosterone
• excessive excretion of urinary 17-hydroxy-corticosteroids
• elevated peripheral ACTH level
• dexamethasone suppression test / metyrapone test
√ retarded bone maturation
√ most often axial osteoporosis
√ stippled calvarium

√ demineralized dorsum sellae
√ excess callus formation

Cx: (1) Pathologic fractures of vertebrae + ribs with excessive callus formation
(2) Aseptic necrosis of hips
(3) Bone infarcts
(4) Delayed skeletal maturation in children

DDx of Cushing syndrome:

(a) focal unilateral adrenal mass
- √ 2–4-cm focal mass in one adrenal gland + atrophy of contralateral gland = adrenal adenoma
- √ > 4-cm large focal mass with central necrosis in one adrenal gland + atrophy of contralateral gland = adrenal adenocarcinoma

(b) bilateral adrenal enlargement
- √ diffuse uniform thickening = Cushing disease

(c) Multiple bilateral adrenal nodules
- √ macronodules = multinodular hyperplasia of long-standing Cushing disease
- √ large nodules (autonomous ACTH-independent) = massive macronodular hyperplasia
- √ small nodules = primary pigmented nodular adrenocortical disease

CYSTITIS

= bacterial infection; M < F
• frequency, dysuria, hematuria, reduced bladder capacity
√ cystogram insensitive

US:
- √ focal / multifocal / circumferential isoechoic bladder wall thickening
- √ decrease in bladder wall thickening during bladder distension (eg, instillation of sterile saline via a urethral catheter)
- √ bullous lesions
- √ intact mucosa

DDx: bladder neoplasm, ureterocele, pseudoureterocele, neurofibromatosis, pseudosarcomatous myofibroblastic proliferations

Cystitis Cystica

= CYSTITIS FOLLICULARIS = CYSTITIS GLANDULARIS = BULLOUS CYSTITIS
= nonspecific chronic reactive inflammatory process of bladder wall
Age: any; M > F
Histo: metaplasia of urothelium → proliferation into buds (nests of von Brunn) → growth into lamina propria → differentiation into cystic deposits (cystitis **cystica**) or intestinal columnar mucin-secreting glands formed of goblets cells (cystitis **glandularis**)
• frequency, dysuria, urgency, hematuria
• cystoscopy: cobblestone mucosa; papillary / polypoid mass
√ multiple small round cystlike mucosal elevations
√ filling defects
√ intact muscle layer

May be associated with: pelvic lipomatosis → bladder obstruction and chronic infection
Prognosis: potentially malignant in adults

Emphysematous Cystitis

= uncommon complication of urinary tract infection by gas-forming organism almost PATHOGNOMONIC of poorly controlled diabetes (= bacterial fermentation of glucose)
Age: > 50 years; M÷F = 1÷2
Predisposed: diabetes mellitus, neurogenic bladder, bladder outlet obstruction, chronic UTI
Organism: E. coli, E. aerogenes, P. mirabilis, S. aureus, streptococci, Clostridium perfringens, Nocardia, Candida
May be associated with: emphysematous pyelitis / pyelonephritis
• pneumaturia (rare)
Plain film:
√ translucent streaky irregular area / ring of air bubbles in bladder wall
√ intraluminal air-fluid level
US:
√ shadowing echogenic foci within area of bladder wall thickening
CT (most specific modality)
DDx: (a) Gas within bladder:
trauma, urinary tract instrumentation, enterovesical fistula
(b) Gas external to bladder:
rectal gas, emphysematous vaginitis, pneumatosis cystoides intestinalis, gas gangrene of uterus

Eosinophilic Cystitis

= rare chronic inflammatory disease
Prevalence: 83 adult cases in literature
Mean age: 42–48 years; M÷F = 1.3÷1.0
Cause: idiopathic (29%); atopy; after bladder surgery; adverse reaction to drugs + food; parasitic / nonparasitic urinary tract infections; autoimmune disorder; eosinophilic enteritis
Histo: transmural infiltrate of eosinophils with variable degree of fibrosis + muscle necrosis of detrusor
• hematuria, frequency, dysuria, pain
• peripheral eosinophilia (0–43%)
√ single / multiple bladder masses ± cystic component
√ normal / thickened bladder wall
√ small contracted bladder (in fibrotic stage)
√ isointense mass relative to muscle on T2WI
√ hyperintense mass relative to muscle on T1WI with enhancement
Prognosis: usually benign self-limiting course, if cause removed

Granulomatous Cystitis = Tuberculous Cystitis

√ irritable hypertonic bladder with decreased capacity
√ disease process usually starts at trigone spreading upward and laterally

√ calcification of bladder wall (rare)

Hemorrhagic Cystitis

Cause: unclear
(a) nonspecific: negative culture
(b) bacterial: E. coli (in 17%)
(c) viral (adenovirus in 19%): negative culture, viral exanthem
(d) cytotoxic: cyclophosphamide (Cytoxan®), in 15% of patients within 1st year of treatment

√ echogenic mobile clumps of solid material (= intraluminal blood clot)

Interstitial Cystitis

Age: postmenopausal female

• pink pseudoulceration of bladder mucosa characteristically at vertex of bladder (= **Hunner ulcer**)

Bullous Edema of Bladder Wall

Cause: continuous internal contact with Foley catheter, involvement of bladder wall by external contact in pelvic inflammatory conditions (eg, Crohn disease, appendicitis, diverticulitis)

√ smoothly thickened / polypoid redundant hypoechoic mucosa

ECTOPIC URETER

= abnormal distal insertion outside bladder trigone

Associated with: duplication of ureter

Site of insertion of ectopic ureter:

› in female <u>infrasphincteric</u> insertion: bladder neck, upper urethra, uterus, cervix, vaginal vestibule, vagina, fallopian tube, rectum
• incontinence after toilet training ← ureteral insertion below level of external urethral sphincter
• WETTING in upright females = intermittent / constant dribbling
• urinary tract infection

› in male <u>always suprasphincteric</u> insertion: posterior urethra, seminal vesicle (seminal vesical cyst), vas deferens, low in bladder, bladder neck, prostatic urethra, ejaculatory duct
• NO enuresis in males after toilet training ← ureteral insertion above level of external urethral sphincter
• epididymitis / orchitis in preadolescent male
• urge incontinence (insertion into posterior urethra)
√ often associated with ureteral obstruction

EJACULATORY DUCT CYST

Cause: congenital / acquired obstruction of ejaculatory duct

• perineal pain, dysuria, ejaculatory pain, hematospermia
• major cause of male infertility (= low-volume oligospermia / azoospermia)

Location: along expected course of ejaculatory duct

√ intraprostatic cyst within central zone
√ aspirate contains spermatozoa / fructose with normal testicular function
√ cyst commonly contains calculi
√ cystic dilatation of ipsilateral seminal vesicle
√ contrast injection into cyst outlines seminal vesicle

EPIDIDYMITIS

Acute Epididymitis

◊ Most common acute pathologic process in postpubertal age

Cause: retrograde ascending urinary tract infection; instrumentation + prostatitis (in older men); chemical (Amiodarone); posttraumatic; vasculitis (Henoch-Schönlein Purpura); idiopathic

Incidence: 634,000 cases annually

Age: › child < 2 years (23% of children):
imperforate anus, ureteral ectopia to seminal vesicle, bladder exstrophy, neurogenic bladder, posterior urethral valves, dysfunctional voiding
› child > 6 years (77% of children)
› < 18 years (common)
› 19–25 years (very common)
› > 25 years (extremely common)
› > 30 years (almost all cases of scrotal pain)

Organism: E. coli + S. aureus (85%), Gonococcus (12%), TB (2%); nonspecific (? chemical) epididymitis in 20%
(a) child + > 35 years of age: Escherichia coli + Proteus mirabilis, CMV with AIDS
(b) < 35 years of age: Chlamydia trachomatis, Neisseria gonorrhoeae

• fever, increasing scrotal pain over 1–2 days
• hemiscrotal swelling + tenderness + erythema
• pyuria (95%), positive urine culture, leukocytosis (50%)
• dysuria + frequency (25%), prostatic tenderness (infrequent)

Site: may begin with focal epididymitis (25%) often in epididymal tail → body → head (most common)
◊ Subsequent spread to testis (common): global orchitis (frequent), focal orchitis (10%)

US:
√ enlarged heterogeneous epididymis:
√ enlarged head suggests hematogenous spread
√ enlarged tail suggests retrograde reflux from prostate / urine
√ hypoechoic epididymis relative to testis ← edema
√ reactive hydrocele ± thickening of scrotal wall
√ enlarged spermatic cord containing hyperechoic fat
√ thickening of tunica albuginea (in severe infection)

Color Duplex (91% sensitive, 100% specific):
√ increased number + concentration of identifiable vessels in affected region (=

hyperemia)
√ peak systolic velocity (PSV) > 15 cm/sec with PSV ratio > 1.9 compared with normal side
√ detection of venous flow
√ diastolic flow reversal in testicular artery ← epididymal edema with obstruction of venous outflow

NUC (true positive rate of 99%):
√ symmetric perfusion of iliac + femoral vessels
√ markedly increased perfusion through spermatic cord vessels (= testicular + deferential arteries)
√ curvilinear increased activity laterally in hemiscrotum on static images (also centrally if testis involved)
√ increased activity of scrotal contents on static images ← hyperemia + increased capillary permeability

Rx: antimicrobial therapy, scrotal elevation, bed rest, analgesics, ice packs

Cx:
(1) Epididymo-orchitis (20–40%) (see below)
(2) Epididymal abscess (6%)
√ central hypoechoic region of liquefaction with absence of color Doppler signals
(3) Testicular abscess (6%)
(4) Testicular infarction (3%) ← extrinsic compression of testicular blood flow
(5) Late testicular atrophy (21%)
(6) Hydro- / pyocele
(7) Fournier gangrene

DDx:
(1) Testicular abscess (→ increased perfusion with centrally decreased uptake)
(2) Hydrocele (→ normal perfusion, no uptake)
(3) Testicular tumor (→ slightly increased perfusion; in- / decreased uptake; no associated epididymal hyperemia on CFI; positive tumor markers: hCG, AFP)

Acute Epididymo-orchitis

= progression of epididymal infection → focal / diffuse involvement of testis

Frequency: 20–40%

Age: two peaks at > 15 years (sexually active) and > 50 years (with BPH)

• Prhen sign = pain associated with epididymo-orchitis improves with elevation of testes above level of pubic symphysis

Cx: testicular necrosis ← infarction ← compromised testicular venous outflow ← edema

Chronic Epididymitis

= GRANULOMATOUS ORCHITIS

= granulomatous reaction to sperm / microorganisms

• painful mass

Site: mostly tail

US:
√ enlarged heterogeneous hyperechoic epididymis
√ NO increased blood flow
DDx: epididymal adenomatoid tumor (painless)

ERECTILE DYSFUNCTION

= IMPOTENCE (term replaced due to negative connotation)
= inability to have / maintain a penile erection sufficient for vaginal penetration in 50% or more attempts during intercourse
Prevalence: 10 million Americans
Physiology:
(a) psychogenic phase:
- stimuli from thalamic nuclei, rhinencephalon, limbic system converge in medial preoptic anterior hypothalamic area

(b) neurologic phase:
- sacral nerve roots (S2–S4) contribute fibers to pelvic sympathetic plexus
- stimulation of cavernous nerve (parasympathetic nerve) → changes in blood flow → full erection
- stimulation of pudendal nerve (motor nerve) → contraction of bulbocavernosus + ischiocavernosus muscle → occlusion of veins → rigid erection

Risk factors: hypertension, diabetes, smoking, CAD, peripheral vascular disease, pelvic trauma / surgery, blood lipid abnormalities
Cause:
A. ORGANIC (majority)
1. Endocrine disorder reducing serum testosterone / increasing serum prolactin
2. Vascular disease (10–20%): increasing with age
   (a) failure to fill (arteriogenic)
   (b) failure to store (venogenic)
3. Neurogenic disease (10%) = failure to initiate:
   (a) neurologic disorder: multiple sclerosis, spinal cord injury, cervical spondylosis, spinal arachnoiditis, pelvic trauma, temporal lobe / idiopathic epilepsy, Alzheimer disease, Parkinson disease, tabes dorsalis, amyloidosis, primary autonomic insufficiency, cerebrovascular accidents, primary / metastatic tumor
   (b) surgical injury to nerves: damage to pelvic sympathetic nerves / cavernous nerve during radical prostatectomy / cystectomy
4. Chronic disease: diabetes mellitus (2 million); drugs (antihypertensives, anticonvulsants, alcohol, narcotics, psychotropic agents)
5. Endorgan disease: priapism

B. PSYCHOGENIC

Penile-brachial index (normal > 1.0):
= highest penile artery pressure over mean brachial pressure
√ < 0.70 suggests large vessel disease
Rx: (1) Surgery:
(a) vascular reconstructive surgery

(b) penile prosthesis placement
› nonhydraulic: semirigid, malleable, positionable
› hydraulic

(2) Oral / intracavernosal injection of vasoactive agents

(3) Nonsurgical external devices: vacuum erection devices

(4) Sex therapy

EXTRAGONADAL GERM CELL TUMOR

= PRIMARY EXTRAGONADAL GERM CELL TUMOR

Frequency: 1.0–2.5% of germ cell tumors; M > F

Origin: aberrant primordial germ cell rests ←

(a) faulty migration from yolk sac / endoderm to urogenital ridge

(b) physiologic germ cell distribution to liver, bone marrow, brain

Histo: seminoma (rare in retroperitoneum) / nonseminomatous germ cell tumor (embryonal carcinoma, yolk sac tumor, choriocarcinoma, teratoma, mixed germ cell tumor)

◊ 80% of mediastinal germ cell tumors are benign!

• elevated α-fetoprotein: embryonal carcinoma, yolk sac tumor

• elevated β-hCG: choriocarcinoma

Location: along midline from pineal to sacrococcygeal region, mediastinum > retroperitoneum

◊ The anterior mediastinum is the most common site of extragonadal germ cell tumors!

Site: near midline between T6 and S2

◊ A midline mass is more suggestive of a primary tumor than metastasis!

CT/MR:

› seminoma:

√ large lobulated well-defined homogeneous solid mass with ringlike / speckled calcifications

√ hypointense fibrous septa on T2WI

√ contrast enhancement of septa

› nonseminoma:

√ heterogeneous tumor with areas of hemorrhage + necrosis

√ heterogeneous contrast enhancement

√ ± flow voids ← hypervascularity

√ ± invasion of adjacent structures

Dx: after exclusion of primary gonadal source

Prognosis: worse compared to gonadal location

DDx: metastasis from gonadal primary (in 30%)

FIBROEPITHELIAL POLYP

= FIBROUS POLYP = FIBROEPITHELIOMA = VASCULAR FIBROUS POLYP = POLYPOID FIBROMA

Origin: embryonic

Histo: mesodermal tumor with fibrovascular stroma covered by normal transitional cell epithelium

Age: in child / young adult 20–40 years

Multiplicity: usually solitary
√ mobile elongated cylindrical filling defect on a thin stalk
√ multilocular wormlike appearance with smooth margins
√ (occasionally) frondlike appearance
@ Ureter
◊ Most common nonepithelial tumor of ureter!
Site: proximal ureter
• intermittent abdominal / flank pain
• gross hematuria (rare)
@ Urethra
• hematuria at birth, obstructive voiding symptoms
Site: verumontanum
√ polyp may extend through bladder neck into bladder
√ extension into midpoint of bulbar urethra during voiding phase of cystourethrography
Cx: bladder outlet obstruction

FIBROUS PSEUDOTUMOR OF SCROTUM

= NODULAR PERIORCHITIS = NODULAR FIBROSIS
= uncommon benign reactive fibrous proliferation
Frequency: 3rd most common paratesticular mass (after lipoma and epididymal adenomatoid tumor)
Cause: often related to prior inflammation / infection / trauma
Origin: tunica vaginalis (most common)
Histo: dense fibrous tissue with interspersed fibroblasts and mixed inflammatory cells
Associated with: hydrocele (50%)
• history of trauma, surgery, infection, inflammation
• mimicks malignancy at physical examination
Size: up to 8 cm in diameter
√ hypoechoic mass(es) arising from tunica vaginalis (76%):
√ shadowing ← dense fibrosis / internal calcifications
√ uniformly low signal intensity on T1WI + T2WI like fibroma
√ slow persistent variable enhancement
√ may dislodge (as "scrotal pearl")
√ single / multiple hypoechoic / hyperechoic nodules arising from epididymis / spermatic cord / tunica albuginea
√ diffuse fibrous pseudotumor (= **fibromatous periorchitis**):
√ thickening of inner surface of tunica vaginalis ← diffuse proliferative encasement of testis
√ focal linear calcification + ossification
√ **inflammatory pseudotumor of paratesticular lymph node**
= predominantly hypoechoic lymph node ← spindle cell proliferation in connective tissue framework of hilum and capsule

FOURNIER GANGRENE

= FULMINANT NECROTIZING FASCIITIS

[Jean Alfred Fournier (1832–1914), venereologist in Paris, France]
= uncommon potentially lethal polymicrobial necrotizing fasciitis of the perineal, perianal or genital areas
Prevalence: 500 cases in literature
Predisposed: diabetes mellitus (present in 40–60%), alcoholism, HIV, neutropenia
Organism: (a) aerobes: E. coli, S. aureus, Proteus species, enterococci
(b) anaerobes: Bacteroides fragilis, anaerobic streptococci, clostridia
◊ Synergistic action between aerobes + anaerobes!
Source of infection:
◊ In 90% primary focus of infection is recognizable!
(a) colorectal: colorectal cancer, inflammatory bowel disease, perirectal abscess, perianal / perirectal / ischiorectal abscess, anal fissure, colonic perforation
(b) urologic: epididymitis, orchitis, urethral stricture with extravasation, urethral instrumentation, chronic urinary tract infection, circumcision
(c) cutaneous: pressure ulcer of skin, IM injection, hidradenitis, insect bite, burn
(d) female: septic abortion, vulvar / Bartholin gland abscess, hysterectomy, episiotomy
(e) occult (10%)
Path: obliterative endarteritis with ensuing cutaneous + subcutaneous necrosis and gangrene, cellulitis, myositis, fasciitis (rate of fascial destruction as high as 2–3 cm/hr)
Age: newborn to elderly; M÷F = 10÷1
◊ SURGICAL EMERGENCY!
• pain, fever, leukocytosis
• scrotal tenderness, erythema, swelling, crepitation
CT (modality of choice):
√ gas in scrotal wall + perineum
√ scrotal skin thickening + normal testes
◊ Scan entire abdomen + pelvis to find source of infection!
Mortality: 7–75% = UROLOGIC EMERGENCY
Rx: antibiotic therapy + debridement + hyperbaric oxygen
DDx: epididymoorchitis, gas-containing scrotal abscess, scrotal hernia with gas-containing bowel, scrotal emphysema from bowel perforation, extension of subcutaneous emphysema, air leakage + dissection due to faulty chest tube positioning

GANGLIONEUROBLASTOMA

= pediatric tumor of sympathetic nervous system of intermediate grade (cellular maturity between malignant neuroblastoma and benign ganglioneuroma); metastatic potential
Frequency: less common than neuroblastoma / ganglioneuroma
Age: 2–4 years; rare in adults; M÷F = 1÷1
Location: posterior mediastinum, abdomen
√ extension through neural foramen into epidural space
√ nerve root / spinal cord compression

GANGLIONEUROMA

= rare benign neoplastic growth of sympathetic ganglia evolving from a spontaneously regressed

(1%) neuroblastoma or induced by chemotherapy / occurring spontaneously de novo
Path: usually larger than nerve sheath tumor
Histo: mixture of Schwann cells + mature ganglion cells (predominating over glial cells)
Age: older than for neuroblastoma; < 20 years (42–60%), 20–39 years (39%), 40–80 years (19%); M÷F = 1÷1
Location: anywhere along paravertebral sympathetic plexus
(a) extraadrenal
posterior mediastinum (25–43%); retroperitoneum (32–52%); pelvis (9%); neck (8–9%); GI tract (rare)associated with MEN 2b
(b) adrenal medulla (20–30%)
Elaborated hormones: catecholamines, vasoactive intestinal polypeptides, androgenic hormones
• usually asymptomatic / pain
• respiratory symptoms, local pressure (40%)
• rarely hormone-active: diarrhea, sweating, hypertension, virilization, myasthenia gravis
Average size: 8 cm (up to 20 cm)
√ spherical / elliptical large lobulated well-defined encapsulated slow-growing mass
√ tendency to surround blood vessels without compromising the lumen
√ dumbbell-shaped mass extending from paraspinous region through neural foramen into epidural space
√ discrete punctate calcifications (8–27%)
√ unusually homogeneous / mildly heterogeneous mass for its large size
√ variable contrast enhancement
CT:
√ homogeneous / mildly heterogeneous hypoattenuating mass with a density of < 40 HU (less than that of muscle)
CECT:
√ homogeneously hypoattenuating mass compared to muscle
√ surrounds vessels without vascular narrowing / occlusion
MR:
√ homogeneous + isointense with muscle on T1WI
√ hyperintense to muscle on T2WI with varying signal intensities ← depending on composition of myxoid / cellular / collagen components):
√ ± whorled appearance ← interlacing bundles of longitudinal + transverse Schwann cells / collagen fibers
√ gradual delayed enhancement
Prognosis: good after surgical resection
DDx: neurofibroma (no calcification), schwannoma (no calcification), ganglioneuroblastoma, neuroblastoma (coarse calcifications)

Gastrointestinal Ganglioneuroma

Manifestation:
1. Focal polypoid lesions = ganglioneuromas
• asymptomatic
√ well-circumscribed round / oval lobulated hypoattenuating masses

2. Multifocal polyps = ganglioneuromatous polyposis
   Location in NF1: colon, rectum
3. Diffuse infiltrating lesions = ganglioneuromatosis
   - disturbance in gastrointestinal motility (Hirschsprüng-like condition, chronic colonic pseudo-obstruction, megacolon)

   Location in NF1: colon, rectum
   √ diffuse / focal mural thickening
   √ diffuse high-attenuation mural thickening

GENITOURINARY DIABETES MELLITUS

A. CHRONIC GU EFFECTS
   1. Papillary necrosis
   2. Renal artery stenosis
   3. Vas deferens calcification

B. URINARY TRACT INFECTIONS
   1. Renal and perirenal abscess
   2. Emphysematous pyelonephritis
   3. Emphysematous cystitis
   4. Fungal infection: Candida, Aspergillus
   5. Xanthogranulomatous pyelonephritis

C. GENITAL INFECTION
   1. Fournier gangrene
   2. Postmenopausal tuboovarian abscess

Diabetic Nephropathy

= defined as persistent proteinuria (> 500 mg of albumin/24 hours) + retinopathy + elevated blood pressure

◊ Most common cause of end-stage renal disease!

Prevalence: 35–45% of IDDM; < 20% of NIDDM; M > F

Histo: diffuse intercapillary glomerulosclerosis

Early:

√ renal enlargement (= renal hypertrophy with glomerular expansion)

Late:

√ progressive decrease in size
√ diffuse cortical hyperechogenicity with gradual loss of corticomedullary differentiation
√ resistive index > 0.7 (very late)

IVP:

√ contrast material may induce renal failure (= rise in serum creatinine level 1–5 days after exposure)

◊ Keep patient well hydrated with 0.45% saline!

Mortality: 90% after 40 years of age

Diabetic Cystopathy

Cause: autonomous peripheral neuropathy

Histo: vacuolation of ganglion cells in bladder wall, giant sympathetic neurons,

hypochromatic ganglion cells, demyelination
- insidious impairment of bladder sensation
- decreased reflex detrusor activity

√ enlarged postvoid residual urine volume

Cx: vesicoureteral reflux, recurrent pyelonephritis, pyohydronephrosis, overflow incontinence

GLOMERULOCYSTIC KIDNEY DISEASE

= GCKD = rare form of cystic renal disease characterized by cystic dilatation of Bowman capsule

Genetics: often inherited autosomal-dominant disease in families with ADPKD / component of hereditary syndromes (tuberous sclerosis, orofacialdigital syndrome, short rib polydactyly group of skeletal dysplasias); also sporadic cases

Age: neonate, young child

Histo: uniform cystic dilatation of Bowman capsule around glomerulus

- symptoms of renal failure
- accompanying infantile congenital malformations

Site: primarily in cortical subcapsular distribution sparing tubular portions of nephron

√ normal-sized / hypoplastic kidneys

US:

√ small round cysts in renal cortex

√ cortical hyperechogenicity ← if cysts difficult to define

NEMR (preferred imaging modality):

√ numerous T2-hyperintense lesions predominantly in subcapsular portion of renal cortex

DDx: ADPKD (much larger diffusely distributed renal cysts)

HEMANGIOMA OF ADRENAL GLAND

= rare benign vasoformative stromal tumor of adrenal gland

Prevalence: 1÷10,000 autopsies

Histo: cavernous > capillary type

- typically asymptomatic for hemangiomas < 2 cm

√ often large mass (usually > 10 cm in diameter, up to 22 cm) owing to their indolent nature

√ highly vascular mass with multiple peripheral nodular areas of marked enhancement after contrast bolus injection:

√ NO complete fill in of contrast material

√ calcifications (28–87%) from previous hemorrhage / multiple CHARACTERISTIC phleboliths

√ persistent enhancement on delayed imaging

CT:

√ central low attenuation (necrosis / fibrosis)

MR:

√ mass hypointense relative to liver on T1WI + central hyperintensity ← hemorrhage / necrosis

√ usually markedly hyperintense on T2WI, especially in central portion

√ variable appearance after hemorrhage, thrombosis, necrosis, fibrosis

Cx: hemorrhage

HEMANGIOMA OF KIDNEY

= uncommon benign vascular tumor
Origin: embryonic rest of unipotent angioblastic cells
Prevalence: 1÷2,000 to 1÷30,000; M=F
Peak age: young to middle-aged adults
May be associated with: Klippel-Trénaunay syndrome, Sturge-Weber syndrome
Path: unencapsulated tumor
Histo: cavernous variant (widely dilated vessels) > capillary variant (slit-like vascular spaces)
Location: medulla (90%), renal pelvis
Size: mostly < 2 cm
• mostly asymptomatic
• recurrent episodes of hematuria, colicky abdominal pain
√ intense arterial enhancement persisting into venous phase
CT:
√ lobulated hypo- to isoattenuating soft-tissue mass
√ multiple phleboliths (uncommon)
MR:
√ homogeneously hypointense mass on T1WI
√ hyperintense on T2WI

HEMANGIOMA OF URINARY BLADDER

Frequency: 0.6% of primary bladder neoplasms;
0.3% of all bladder tumors
Age: < 20 years (in > 50%); M÷F = 1÷1
May be associated with:
(a) additional hemangiomas in 30%
(b) Klippel-Trénaunay syndrome
(c) Sturge-Weber syndrome
Histo: capillary / venous / cavernous / hemangiolymphomatous form
• recurrent gross painless hematuria
• cutaneous hemangiomas over abdomen, perineum, thighs in 25–30%
Location: dome, posterolateral wall
Site: limited to submucosa (33%), muscular wall, perivesical tissue
√ compressible solitary (⅔) / multiple (⅓) masses:
√ rounded well-marginated intraluminal mass
√ diffuse bladder wall thickening + punctate calcifications (= phleboliths)
IVP:
√ rounded / lobulated filling defect
US:
√ solid predominantly hyperechoic mass
√ hypoechoic spaces within thickened bladder wall

CAVE: high risk of intractable hemorrhage at biopsy!

HEMOLYTIC-UREMIC SYNDROME

= characterized by microangiopathic hemolytic anemia with typical features of DIC

◊ Most common cause of acute renal failure in children requiring dialysis!

Cause: ? triggered by an autoimmune response to infection

(1) Infection: enterotoxic E. coli, > Shigella dysenteriae I, Streptococcus pneumoniae, Salmonella typhi, Coxsackie virus, ECHO virus, adenovirus

(2) Associated medical condition: pregnancy, SLE + other collagen vascular disease, malignancy, malignant hypertension

(3) Drugs: oral contraceptives, cyclosporine, mitomycin, 5-fluorouracil

Pathogenesis: capillary and endothelial injury to kidney → mechanical damage of RBCs + formation of hyaline microthrombi within renal vasculature + focal infarction

Age: usually children < 2 years

Histo: microangiopathy including endothelial swelling + thrombus formation in glomerulus + renal arterioles

CLASSIC TRIAD:

(1) Microangiopathic hemolytic anemia

(2) Thrombocytopenia

(3) Acute oliguric / anuric renal failure → uremia

- recent bout of gastroenteritis (commonly with E. coli)
- sudden pallor, irritability, bloody diarrhea, convulsions
- dyspnea ← fluid retention, heart failure, pleural effusion
- rapid rise in blood urea nitrogen level out of proportion to plasma creatinine level ← cell lysis

@ Kidney (sometimes only organ involved):

√ kidneys of normal / slightly increased size

√ hyperechoic cortex

Doppler-US:

√ diastolic flow absent / reversed / reduced (= increase in resistance to flow)

√ return to normal waveforms predates return of urine output

Scintigraphy:

√ lack of renal perfusion

@ Liver: hepatomegaly, hepatitis

@ Pancreas: diabetes mellitus

@ Heart: myocarditis

@ Muscle: rhabdomyolysis

@ Intestines:

√ mural stratification + narrowing of bowel lumen

√ pericolonic fat stranding

Cx: perforation, intussusception, infectious colitis

@ Brain (20–50%): drowsiness, personality changes, coma, hemiparesis, seizures (up to 40%)

Prognosis: complete spontaneous recovery (in 85%)

HEREDITARY CHRONIC NEPHRITIS

= ALPORT SYNDROME
= probably autosomal dominant trait with presence of fat-filled macrophages ("foam cells") in corticomedullary junction and medulla
(a) males: progressive renal insufficiency, death usually before age 50
(b) females: nonprogressive
• polyuria, salt wasting, hyposthenuria, NO hypertension
• anemia, nerve deafness
• ocular abnormalities: congenital cataracts, nystagmus, myopia, spherophakia
√ small smooth kidneys
√ diminished density of contrast material
√ cortical calcifications

HORSESHOE KIDNEY

= two kidneys joined at poles by parenchymal / fibrous isthmus
Prevalence: 1–4÷1,000 births; 0.2–1.0% (autopsy series); M÷F = 2–3÷1
◊ Most common fusion anomaly!
Associated with:
cardiovascular anomaly, skeletal anomaly, CNS anomaly, anorectal malformation, genitourinary anomaly (hypospadia, undescended testis, bicornuate uterus, ureteral duplication), trisomy 18, Turner syndrome (60%)
In 50% associated with:
(1) Caudal ectopia
(2) Vesicoureteral reflux
(3) Hydronephrosis ← UPJ obstruction
√ fusion of R + L kidney at lower (90%) / upper (10%) pole
√ renal long axis medially oriented
√ isthmus at L4-5 between aorta + inferior mesenteric artery
√ renal pelves and ureters situated anteriorly
√ multiple renal arteries including isthmus artery
Cx: infection, renal calculi

HYDROCELE

= abnormal collection of fluid between parietal and visceral layers of tunica vaginalis
◊ Most common cause of painless scrotal swelling
◊ Most common type of fluid collection in scrotum
US:
√ anechoic, good back wall, through-transmission
√ COMPLICATED HYDROCELE = hydrocele with low-level echoes ± septations = hematocele / pyocele / cholesterol crystals / protein aggregates

Primary = Idiopathic Hydrocele

without predisposing lesion as congenital defect of lymphatic drainage = failure of mesothelial lining to reabsorb fluid

Secondary = Acquired Hydrocele

Age: > older child to adulthood

(a) inflammation: epididymitis, epididymoorchitis
(b) testicular tumor (in 10–40% of malignancies)
(c) trauma / postsurgical
◊ 50% of acquired hydroceles are due to trauma!
(d) torsion, infarction

Congenital Encysted Hydrocele

= ascites trapped in scrotum through communication with peritoneal cavity (= open processus vaginalis)

May be associated with: inguinal hernia

• resolves within 2 years (in 80%)

Infantile Hydrocele

= hydrocele with fingerlike extension into funicular process but WITHOUT communication with peritoneal cavity

HYDRONEPHROSIS

A. OBSTRUCTIVE UROPATHY = HYDRONEPHROSIS
= dilatation of collecting structures without functional deficit

B. OBSTRUCTIVE NEPHROPATHY = dilatation of collecting system with renal <u>functional impairment</u>

Grading system of hydronephrosis by US:

Grade 0 = homogeneous central renal sinus complex without separation of central sinus echoes
Grade 1 = separation of central sinus echoes of ovoid configuration; continuous echogenic sinus periphery; 52% predictive value for obstruction
Grade 2 = separation of central sinus echoes of rounded configuration; dilated calices connecting with renal pelvis; continuity of echogenic sinus periphery
Grade 3 = replacement of major portions of renal sinus; discontinuity of echogenic sinus periphery

Amount of collecting system dilatation depends on:

(a) duration of obstruction
(b) renal output
(c) presence of spontaneous decompression
◊ Amount of residual renal cortex is of prognostic significance!

Acute Hydronephrosis

Cause:

(1) Passage of calculus
(2) Sulfonamide crystallization in nonalkalinized urine
(3) Passage of blood clot ← carcinoma, AV malformation, trauma, anticoagulant therapy
(4) Sloughed necrotic papilla
(5) Ureteral edema following instrumentation

(6) Suture on ureter
(7) Normal pregnancy

• pain (50%), UTI (36%), nausea + vomiting (33%)
√ normal-sized kidney with normal parenchymal thickness
√ increasingly dense nephrogram
√ delayed opacification of collecting system ← decreased glomerular filtration
√ increasingly dense nephrogram over time (= "obstructed nephrogram")
√ dilated collecting system + ureter
√ widening of forniceal angles
√ delayed images demonstrate site of obstruction at the end of a persistent column of contrast material in a dilated urinary collecting system
√ vicarious contrast excretion through gallbladder (uncommon)

US:
√ separation of renal sinus echoes
False-negatives:
staghorn calculus filling entire collecting system, hyperacute renal obstruction (system not yet dilated), spontaneous decompression of obstruction, fluid-depleted patient with partial obstruction, dehydrated neonate
False-positives:
full bladder, increased urine flow (overhydration, medications, following urography, diabetes insipidus, diuresis in nonoliguric azotemia), acute pyelonephritis, postobstructive / postsurgical dilatation, vesicoureteral reflux
Imposters:
parapelvic cysts, sinus vessels, prominent extrarenal pelvis
√ ureteral jet not detectable / trickling flow:
CAVE: in 25% ureteral jets NOT detectable ← insufficient differences in specific gravity between ureteral urine and urine in urinary bladder in normals
√ ureteral jet absent in 13% of pregnant patients without ureteral obstruction
N.B.: turning pregnant patient into contralateral decubitus position will make jet visible

Duplex US:
√ mean RI of 0.77 ± 0.05 versus 0.63 ± 0.06 in nonobstructed kidney
Caution: RI often normal in chronic obstruction; nonobstructive renal disease may elevate RIs
√ ≥ 0.08 difference in RI in right-to-left comparison with unilateral obstruction

Cx: spontaneous urinary extravasation (10–18%) from forniceal / pelvic tear (= pyelosinus reflux)

Chronic Hydronephrosis

= most frequent cause of abdominal mass in first 6 months of life (= 25% of all neonatal abdominal masses)

Cause:
(a) acquired: benign + malignant tumors of the ureter; ureteral strictures; retroperitoneal tumor / fibrosis; neurogenic bladder; benign prostatic hyperplasia; cervical / prostatic carcinoma; pelvic mass (lymphoma, abscess, ovarian); urethral polyps; urethral

neoplasm; acquired urethral strictures

(b) congenital: ureteropelvic junction obstruction (most common); posterior urethral valves; ectopic ureterocele; congenital ureterovesical obstruction; prune-belly syndrome; primary megaureter

• insidious course

√ large kidney with wasted parenchyma

√ diminished nephrographic density ← decreased clearance

√ early "rim" sign (= thin band of radiodensity surrounding calices)

√ "crescent" sign = concentrated contrast material in collecting tubules arranged parallel to margin of dilated calices ← reversible incomplete prolonged obstruction

√ delayed opacification of collecting system

√ moderate to marked widening of collecting system

√ tortuous dilated ureter

CT:

√ hypoenhancement of renal parenchyma during corticomedullary + nephrographic phases

√ delayed persistent nephrogram sign

NUC:

√ photopenic area during vascular phase

√ accumulation of radionuclide tracer within hydronephrotic collecting system on delayed images

Cx: superimposed infection (= pyonephrosis)

Congenital Hydronephrosis

Mostly isolated malformation

Prevalence: 1÷100–300 births

Risk of recurrence: 2–3% for siblings

Age at presentation: 25% by age 1 year,
55% by age 5 years

Cause:

1. UPJ obstruction 22–40–67%
2. Posterior urethral valves 18%
3. Ectopic ureterocele 14%
4. Prune belly syndrome 12%
5. Ureteral + UVJ obstruction 8%
6. Others: severe vesicoureteral reflux, bladder neck obstruction, hypertrophy of verumontanum, urethral diverticulum, congenital urethral strictures, anterior urethral valves, meatal stenosis

May be associated with: Down syndrome (in 17–25%)

• palpable abdominal mass

• intermittent flank + periumbilical pain

• failure to thrive, vomiting, hematuria, infection

Location: 70% unilateral

OB-US:

√ AP diameter of renal pelvis ≥ 5 mm between 15–20 weeks, ≥ 8 mm at 20–30 weeks, ≥ 10 mm after 30 weeks MA

◊ Pyelectasis < 7.0 mm after 32 weeks EGA is highly predictive of a normal postnatal outcome

√ ratio of AP diameter of renal pelvis to kidney > 50%

√ caliceal distension communicating with renal pelvis

◊ Postnatal evaluation after 4–7 days of age (because of ↓ GFR + relative dehydration in first days of life)!

Prognosis: parenchymal atrophy + renal impairment (dependent on severity + duration)

Focal Hydronephrosis

= HYDROCALICOSIS = HYDROCALYX

= obstructed drainage of one portion of kidney

Cause: (1) Congenital: partial / complete duplication
(2) Infectious stricture: eg, TB
(3) Infundibular calculus
(4) Tumor
(5) Trauma

√ unifocal mass, commonly in upper pole

√ absent polar group of calices (early)

√ dilated polar group (late) with displacement of adjacent calices

√ delayed opacification in obstructed group

√ focally replaced nephrogram

US:

√ anechoic cystic lesion with smooth margins

CT:

√ focal area of water density with smooth margin + thick wall

Hydronephrosis in Pregnancy

1. **Physiologic hydronephrosis / dilatation**

Prevalence: 80%; in up to 90% by 3rd trimester

Cause:
(a) hormonal: relaxation of ureteric smooth muscle in response to progesterone
(b) mechanical: gravid uterus compresses ureter at pelvic brim near crossing of iliac vessels with right ureter taking a more acute angle

• asymptomatic / may manifest as abdominal pain

Time of onset: as early as 6–10 weeks of gestation

Location: right (85–90%), left (15–67%)

Not associated with: renal enlargement / perinephric fluid

√ gradual smooth tapering of mid to distal ureter ← extrinsic compression between gravid uterus + iliopsoas

√ ureter widened only to level of sacral promontory

Prognosis: resolution within a few weeks to 6 months after delivery

2. **"Overdistension syndrome"**

Cause: obstruction by gravid uterus

• pain mimicking renal colic

3. **Acute (obstructive) hydronephrosis**
   Cause: change in position of fetus, diuresis, passage of stone into ureter
   • constant pain ± nausea and vomiting
   √ renal enlargement
   √ increased perirenal fluid ← lymphatic congestion / forniceal rupture
   √ ureterovesical stone → ureter dilated distal to sacral promontory

IgG4-RELATED RENAL DISEASE

Renal lesions in patients with pancreatic disease have been used to differentiate autoimmune pancreatitis from pancreatic cancer.

Histo: tubulointerstitial nephritis with fibrosis + abundant IgG4-positive plasma cell infiltration
√ bilateral round / wedge-shaped peripheral cortical lesions (most common)
√ diffuse patchy renal involvement
√ rim of soft tissue around kidney
√ bilateral nodules in renal sinus
√ diffuse wall thickening of renal pelvis

INFLAMMATORY PSEUDOTUMOR OF BLADDER

= PSEUDOSARCOMATOUS FIBROMYXOID TUMOR
Cause: ? response to infection, inflammation or malignancy
Age: 38 (range, 15–74) years; M÷F = 11÷6
Path: ulcerating bleeding mass
Histo: loosely packed spindle cells within myxoid matrix
• hematuria, voiding symptoms, fever, iron deficiency anemia
Location: reported in every organ of body
Site: spares trigone
√ locally aggressive single exophytic / polypoid 2–8 cm bladder mass ± ulceration
√ may invade through bladder wall with extravesical component
√ ringlike peripheral enhancement + poor central enhancement ← necrosis
MR:
√ heterogeneous mass with central hyperintense component surrounded by hypointense periphery on T2WI
Rx: surgery, high-dose steroids, radiation therapy
DDx: rhabdomyosarcoma, myxoid leiomyosarcoma

JUXTAGLOMERULAR CELL TUMOR

= RENINOMA
= very rare benign renin-secreting tumor
Origin: juxtaglomerular cells of adult kidney
Prevalence: < 30 cases reported
Origin: myoendocrine cell arising from afferent arterioles of glomeruli
Path: small foci of hemorrhage + pseudocapsule
Histo: tumor resembles hemangiopericytoma composed of sheets / trabeculae of round to

polygonal cells;
CHARACTERISTIC renin granules on electron microscopy

Mean age: 24 (range, 7–58) years; 50% < 21 years; M÷F = 1÷2

- typical features of primary reninism:
  - marked + sustained hypertension, often accelerated and poorly controlled
  - secondary hyperaldosteronism with hypokalemia
  - hyperreninemia → in the absence of renal artery stenosis
- moderate to severe headaches + muscle aches
- hypertensive retinopathy, polydipsia, polyuria, enuresis

Location: just beneath renal capsule

Size: usually 2–3 (range, 0.8–6.5) cm

√ well-circumscribed renal mass

US:

√ echogenic mass ± areas of necrosis / hemorrhage

NECT (thin overlapping cuts):

√ hypo- to isodense tumor

CECT:

√ hypovascular mass on arterial phase ← renin-induced vascoconstriction

√ moderate enhancement during delayed phase

MR:

√ hypointense mass relative to renal parenchyma on precontrast T1WI + T2WI

√ early low-level peripheral enhancement on T1WI

√ washout of contrast material from periphery + filling in of central tumor portion on delayed T1WI

Angio:

√ (easily overlooked) hypo- / avascular tumor (in 43%)

√ renal vein sampling yields high renin level on affected side

Dx: combination of elevated renin without renal arterial lesion + hypovascular solid renal mass

Rx: surgical excision

LEIOMYOMA OF KIDNEY

= CAPSULOMA

= rare benign mesenchymal neoplasms that mostly occurs in asymptomatic adults

Prevalence: 5% at autopsy (average size of 5 mm)

Origin: smooth muscle cells of renal capsule, muscularis of renal pelvis, wall of cortical vessels

Path: well-encapsulated solid mass containing hemorrhage (17%) / cystic degeneration (27%) / irregular calcifications

Histo: interlacing bundles of smooth muscle cells in a whorled arrangement without nuclear pleomorphism; immunoreactivity to smooth muscle markers (actin, desmin)

Associated with: tuberous sclerosis

Median age: 42 years; M < F; Whites > Blacks

Location: 53% subcapsular, 37% capsular, 10% at renal pelvis

Mean size: 12 cm
• palpable mass if large (50%), hematuria (20%)
√ well-circumscribed exophytic solid lesion ± cleavage plane between tumor and cortex
√ areas of hemorrhage + cystic / myxoid degeneration + dense calcifications in larger tumor
CT:
√ relatively homogeneous peripherally located hyperattenuating solid mass causing cortical buckling
√ relatively homogeneous enhancement
MR:
√ homogeneously low SI on T1WI + T2WI
Angio:
√ hypo- to hypervascular nonspecific mass
DDx: renal leiomyosarcoma, renal cell carcinoma

LEIOMYOSARCOMA OF KIDNEY

◊ Most common sarcoma of adult kidney (50–60% of all renal sarcomas)!
Age: 40–70 years; M÷F = 1÷1
Path: large well-circumscribed encapsulated tumor with focal areas of necrosis
Histo: spindle cells in fascicular / plexiform / haphazard growth pattern interspersed with variable amount of connective tissue; positive for α-smooth muscle actin, desmin, calponin
• flank pain, abdominal mass, hematuria
Location: renal capsule, parenchyma, smooth muscle fibers of renal pelvis / main renal vein
√ expansile well-defined solid mass
√ heterogeneous enhancement + delayed enhancing fibrous stroma
√ central necrosis / multiloculated cystic mass for large tumors
MR:
√ soft-tissue mass of heterogeneous SI on T1WI + T2WI
Prognosis: aggressive + rapidly progressive; 29–36% 5-year survival rate

LEUKEMIA

= clonal proliferation of lymphoblasts (acute leukemia) or small lymphocytes (chronic leukemia)
◊ Most common malignant cause of bilateral global renal enlargement!
Prevalence: renal involvement in 50% of children + in 65% of adults at autopsy
A. DIFFUSE INVOLVEMENT (most common)
› leukemic cells infiltrate the interstitial tissue + renal sinus; tubules are replaced (more common in lymphocytic than in granulocytic forms); no relationship to peripheral white blood cell count
• hypertension; renal impairment ← leukemic infiltrate, hyperuricemia, septicemia, hemorrhage
√ moderate to massive nephromegaly bilaterally with smooth contours
√ normal or diminished density on nephrogram
√ occasionally attenuated collecting system (DDx: renal sinus lipomatosis)

√ nonopaque filling defects on IVP ← clot, uric acid
√ renal / subcapsular / perinephric hemorrhage frequent
√ retroperitoneal lymphadenopathy
US:
√ loss of definition + distortion of central sinus complex
√ normal to increased coarse echoes throughout renal cortex with preservation of renal medulla
√ single / multiple focal anechoic masses

B. FOCAL ACCUMULATION OF LEUKEMIC CELLS (rare)
chloroma (= granulocytic sarcoma) of acute myeloblastic leukemia, myeloblastoma, myeloblastic sarcoma
• may antedate other manifestations of leukemia
√ unifocal mass in renal cortex / renal sinus

DDx: Hodgkin disease, malignant lymphoma, multiple myeloma

LEUKOPLAKIA

= KERATINIZING SQUAMOUS METAPLASIA / DYSPLASIA = DYSKERATOSIS

Cause: chronic infection (80%) / stones (40%)
Histo: large confluent areas / scattered patches of squamous metaplasia of transitional cell epithelium with keratinization + cellular atypia in deeper layers
Peak age: 4th–5th decade;
M÷F = 1÷1 (with involvement of renal pelvis)
M÷F = 4÷1 (with involvement of bladder)
• hematuria (30%), recurrent UTIs
• PATHOGNOMONIC passage of gritty flakes, soft-tissue stones, white chunks of tissue (= desquamated keratinized epithelial layers) → leading to colic, fever, chills
Location: bladder > renal pelvis > ureter; bilateral in 10%
√ corrugated / striated irregularities of pelvicaliceal walls; localized / generalized
√ plaquelike intraluminal mass with "onion skin" pattern of contrast material in interstices
√ caliectasis + pyelectasis common (with obstruction)
√ ridging / filling defects of ureter
√ associated with calculi in 25–50%
Cx: premalignant condition for epidermoid carcinoma in 12% (controversial!)

LEYDIG CELL HYPERPLASIA

= rare benign condition characterized by an increased number of Leydig cells
• asymptomatic (in adults)
• precocious puberty (in childhood) ← hormone secretion
Location: frequently bilateral; multifocal
Size: 1–6 mm
√ hypo- / hyperechoic, T2-hypointense intratesticular nodule(s)
√ variable vascularity ± avid enhancement

LIPOMA OF SPERMATIC CORD

= EXTRATESTICULAR / PARATESTICULAR LIPOMA
Frequency: most common extratesticular tumor
US:
√ well-defined homogeneous scrotal mass
√ NO internal flow on color Doppler
MR:
√ homogeneous high SI on T1WI (DDx: hematoma, proteinaceous cyst)
√ hyperintense paratesticular mass on T2WI
√ india-ink = black boundary artifact and signal suppression on out-of-phase imaging
√ signal suppression on fat-suppressed images

LIPOMA OF SCROTUM

= INTRATESTICULAR LIPOMA
= rare benign fat-containing tumor
Location: epididymis, spermatic cord, tunica vaginalis
US:
√ well-defined homogeneous hyperechoic nonshadowing lesion
√ NO color Doppler flow signals (frequent)
CT:
√ homogeneous attenuation similar to subcutaneous fat
MR:
√ high signal intensity on T1WI and T2WI
√ loss of signal intensity on frequency-selective fat-saturated images
√ NO enhancement

Lipoma can be differentiated from liposarcoma by the lack of any enhancing soft tissue within a lipoma.

Testicular Lipomatosis

Cause: exclusively in Cowden disease
US:
√ multiple nonshadowing hyperechoic small round foci of varying sizes
MR:
√ multiple high SI foci on T1WI

LITHIUM-INDUCED NEPHROTOXICITY

• clinical and laboratory data typically sufficient for diagnosis
Clinical categories:
1. Acute intoxication
2. Nephrogenic diabetes insipidus (most common)
   Rx: reversible with drug cessation
3. Chronic focal interstitial nephritis
   = progressive nonreversible chronic renal insufficiency
   Histo: tubular atrophy, glomerulosclerosis, interstitial fibrosis, distal tubular dilatation with microcyst formation

√ typically normal-sized kidneys

√ abundant uniformly distributed renal microcysts
√ 1–2 mm microcysts (in 33–62%)
Site: cortex and medulla
CT:
√ multiple tiny hypoattenuating lesions
MR (best depiction of number + size of cysts):
√ multiple T2-hyperintense foci

CT and MR findings typically include normal-sized kidneys with abundant and uniformly distributed renal microcysts.

DDx: autosomal dominant polycystic kidney disease, glomerulocystic kidney disease, medullary cystic kidney disease, acquired cystic kidney disease

LOCALIZED CYSTIC DISEASE OF KIDNEY

= SEGMENTAL RENAL CYSTIC DISEASE
= rare nonprogressive condition characterized by replacement of portion / entire renal parenchyma of one kidney with cysts
• mostly asymptomatic, NO impairment of renal function
• abdominal pain, hematuria, hypertension
Genetics: nonhereditary
Pathogenesis: ? acquired maldevelopment
Path: multicystic lesion composed of cysts of varying sizes separated by normal / atrophic renal parenchyma without surrounding capsule
Histo: dilated ducts and tubules varying in size from mm to several cm lined by single layer of flattened epithelium
Location: unilateral in one kidney
√ conglomerate mass of cluster of variably sized + tightly spaced cysts separated by enhancing / atrophic renal tissue:
√ intervening parenchyma may be stretched + attenuated (DDx: thick septations, impossible to distinguish)
√ NO surrounding capsule
√ remaining renal parenchyma of affected / contralateral kidney may contain a few scattered cysts
√ normal excretion of uninvolved segments
Prognosis: not progressive
DDx: (1) Autosomal dominant polycystic kidney disease (bilateral, positive family history, cysts in other visceral organs)
(2) Multicystic dysplastic kidney (absent pelvicaliceal system + absent / hypoplastic renal vessels)
(3) Cystic neoplasm (capsule, coronal plane helpful)

Intervening normally enhancing renal parenchyma + absence of a surrounding capsule distinguishes localized cystic renal disease from cystic nephroma and multiloculated cystic renal cell carcinoma.

LYMPHOCELE

= fluid-filled cyst without epithelial lining

Frequency: in 12–30% after radical lymphadenectomy / renal transplantation (within 4–8 weeks after surgery)

Cause:

1. Complication of radical lymphadenectomy to assess lymph node status in malignancy
2. Lymphatic leakage from allograft / allograft bed

Location: at sites of lymph node dissection; frequently in pelvic / abdominal retroperitoneum, axilla, groin

Time to discovery: 3–8 weeks after surgery

- mostly asymptomatic, edema of abdominal wall / scrotum / labia
- lower limb edema ← pressure effect on veins
- hydronephrosis ← pressure effect on ureter

√ unilocular thin-walled fluid-filled structure

√ photopenic region with displacement / impression on renal transplant / urinary bladder

√ rarely calcification of wall

Dx: aspiration / drainage with biochemical analysis (creatinine + urea nitrogen + protein + electrolyte components similar to serum)

- predominantly lymphocytes, few leukocytes

Cx: hemorrhage; superinfection; compression of adjacent structures if large

Rx: sclerotherapy with povidone-iodine / doxycycline / ethanol / bleomycin; long-term catheter drainage / surgical marsupialization

DDx: hematoma; seroma; abscess; cystic tumor recurrence (enhancing soft-tissue component)

Cystic Degeneration of Lymph Node

Cause: squamous cell carcinoma (from uterine cervix, vagina, vulva, urinary bladder)

√ thin-walled cystic lymph node

DDx: lymphocele; lymphangioleiomyomatosis

LYMPHOMA OF KIDNEY

Prevalence: in 3–8% (by CT), 30–60% (by autopsy); occurs usually late in disease

◊ The kidneys are the 2nd most commonly affected anatomic entity aside from hematopoietic and reticuloendothelial organs!

Path: initially lymphomatous cells grow in interstitium; nephrons, collecting ducts, blood vessels serve as framework for tumor expansion; with continued growth → parenchymal compression + destruction

Types:

A. NON-HODGKIN LYMPHOMA (more common)

(a) SECONDARY ← systemic disease

Type: typically intermediate + high-grade B-cell type

At risk: immunocompromised patients with uncontrolled Epstein-Barr virus proliferation in patients with HIV infection / organ transplantation (esp. after cyclosporine therapy), ataxia-telangiectasia

(b) PRIMARY renal lymphoma (< 1%)

arising in renal hilar nodes / renal parenchyma

B. HODGKIN DISEASE (< 1%)

Prevalence: renal involvement in 13% of autopsies

Patterns of involvement:

(1) Hematogenous dissemination (bilateral in 75%):

› multiple foci (50–65%):

√ multiple hypoenhancing 1–3 cm usually bilateral renal masses

› single mass (10–25%):

√ solitary homogeneous hypovascular renal mass (in 10–20%) with minimal enhancement mimicking a primary renal neoplasm:

√ distortion of renal contour with larger mass

√ ± invasion of perirenal space / renal hilum

› diffuse infiltration (in 20%) along scaffolding of normal interstitial tissue, almost always bilateral:

√ nephromegaly with preservation of renal contour ← primarily interstitial lymphomatous infiltration

√ poorly enhancing areas in kidneys

› rindlike perinephric soft-tissue mass

√ invasion / compression of kidney without significant effect on renal function

(2) Direct extension from retroperitoneal mass / adenopathy (25–30%):

√ cloaking of renal vessels without obstruction

√ occasionally displacement of involved kidney

Cx: hydronephrosis

(3) Isolated perinephric lymphoma (< 10%)

• clinically silent (50%), palpable mass, hematuria
• flank pain, weight loss, fever, night sweats
• compromised renal function: urinary tract obstruction, renal vein compression, diffuse infiltration of kidney, superimposed infarct, amyloidosis, hypercalcemia

Associated with: splenomegaly, lymphadenopathy

◊ Look for other sites of multisystemic involvement in bone marrow, liver, GI tract, lung, heart, CNS!

√ unilateral÷bilateral = 1÷3
√ multiple nodular masses (29–61%): 1.0–4.5 cm in size
√ solitary tumor (10–25%): bulky up to 15 cm in size (7%) / small (7–48%)
√ spread from retroperitoneal disease with involvement via transcapsular / hilar invasion (25–30%)
√ perinephric lymphoma (< 10%):

(a) direct extension from retroperitoneal disease

(b) transcapsular growth of renal parenchymal disease

◊ A tumor surrounding kidney without parenchymal compression or compromise in function is virtually PATHOGNOMONIC of lymphoma

√ renal sinus infiltration
√ small curvilinear areas of high attenuation
√ thickening of fascia of Gerota

√ perirenal nodules / plaques of soft-tissue density
√ mass contiguous with retroperitoneal disease
√ nephromegaly ← diffuse infiltration of interstitium (6–19%) sparing glomeruli and tubules):
√ preservation of renal contour
√ almost always bilateral
√ encasement / deformation of pelvicaliceal system
• clinically silent → presenting with ⇓ renal function
√ patency of renal vessels despite tumor encasement is CHARACTERISTIC
√ wall thickening + enhancement of renal pelvis and ureter
NECT:
√ mass with slightly higher attenuation than normal surrounding parenchyma
CT (nephrographic phase most sensitive for detection):
√ usually homogeneous poorly marginated masses less dense than renal parenchyma + decreased enhancement compared with renal parenchyma
MR:
√ iso- to hypointense SI on T1WI relative to normal cortex
√ hypointense on T2WI relative to normal cortex
√ lymphomatous deposits enhance less than normal parenchyma ± progressive delayed enhancement
US:
√ single / multiple anechoic / hypoechoic masses:
√ may show increased through transmission
√ renal enlargement + decreased parenchymal echoes
√ loss of renal sinus echoes
√ little lesion vascularity + displacement of renal vessels
PET:
√ hypermetabolic activity
Angio:
√ neovascularity, encasement, vascular displacement (occasionally palisade-like configuration)
DDx of nodular mass:
(1) RCC (more heterogeneous, vascular invasion)
(2) Metastases ← lung, breast, stomach, melanoma, synchronous renal cell cancer
(3) Acute pyelonephritis, septic emboli, renal infarct, abscess
DDx of perinephric lymphoma:
sarcoma arising from renal capsule, perinephric metastases, perinephric hematoma, retroperitoneal fibrosis, amyloidosis, extramedullary hematopoiesis
DDx of infiltrative tumor:
TCC, acute / xanthogranulomatous pyelonephritis

MALAKOPLAKIA

[*malaka* , Greek = soft; *plakos* , Greek = flat surface]
= uncommon chronic granulomatous inflammatory response to gram-negative infection that can affect any organ

Frequency: < 200 cases reported
Organism: E. coli (in 94%)
Predisposed: diabetes mellitus, immunocompromised
Pathogenesis: altered host response to infection at the macrophage level = engulfed organisms remain viable + become a source for recurring infection
Histo: submucosal histiocytic granulomas containing large foamy mononuclear cells (Hansemann macrophages) with calcified intracytoplasmic basophilic PAS-positive inclusion bodies (Michaelis-Gutmann bodies = **calculospherules**) consisting of incompletely destroyed E. coli bacterium surrounded by lipoprotein membranes
Peak age: 5th–7th decade; M÷F = 1÷4
- recurrent urinary tract infections: hesitancy, dysuria, frequency
- variable proteinuria, leukocytes + erythrocytes in urine
- gross hematuria
- cystoscopy: raised soft yellow-brown lesion < 3 cm in diameter, nodules, papillary lesions, hemorrhagic masses, necrotic ulcerations

Location:
› bladder > lower ²/₃ of ureter > upper ureter > renal pelvis; multifocal in 75%; bilateral in 50%
› outside urinary tract

@ Bladder (40%) / ureter
√ multiple nodular dome-shaped smooth mural filling defects of collecting system
√ scalloped appearance if lesions confluent
√ generalized pelviureteral dilatation (if obstructive)
√ vesicoureteral reflux
√ circumferential bladder wall thickening
√ invasion of perivesical space
DDx: pyeloureteritis cystica

@ Kidney (16%)
√ diffuse renal enlargement (bilateral involvement unusual)
√ displacement of pelvicaliceal system + distortion of central sinus complex
√ multifocal parenchymal masses → ± diminished / absent nephrogram
√ urinary tract calcification rare
US:
√ lesions of variable echogenicity
CT:
√ ill-defined low-attenuation lesions
√ ± perinephric extension
DDx: infiltrative neoplasm; XGP (unilateral, urinary tract calcification)
Rx: antibiotics, ascorbic acid, cholinergic agonist

MALPOSITIONED TESTIS

= MALDESCENDED TESTIS
Testicles are normally within scrotum by 28–32 weeks MA
Prevalence: early 3rd trimester in 10%; at birth in 3.7–6.0% (in babies > 2,500 g in 3.4%; in

premature babies in 30%); beyond 3 months of age in 1%

Test sensitivity:

MR modality of choice; 84–96% sensitive; 100% specific

US: 20–45–88% (very sensitive in inguinal canal); 78% specific, 88% accurate

CT: 95% (testis < 1 cm cannot be detected)

√ no spermatic cord in inguinal canal

Venography: 50–90%

Laparoscopy: most reliable method

Cx: (1) Sterility

(2) Malignancy: most commonly seminoma, 30–50 x risk increase = 1÷1,000 men annually; 4–11% of all testicular tumors found in cryptorchidism; risk remains increased even after orchiopexy

◊ Annual screening until at least age 35!

(3) Torsion: 10 x risk in cryptorchidism

Rx: surgery / orchiopexy at 9–12 months of age

DDx: (1) Rudimentary testis

(2) Pars intravaginalis gubernaculum = nonatrophied bulbous termination

(3) Congenital absence = monorchia / anorchia (in 3–5%)

◊ Nonpalpable testes are agenetic in 15–63% of term infants!

Cryptorchidism (20–29%)

= arrested migration of testis along its normal course through internal inguinal ring, inguinal canal, external inguinal ring into scrotal sac

Prevalence: 9–30% in premature infants;
3.4–5.8% in full-term infants

Pathophysiologic theory:

generalized defect in embryogenesis results in bilateral dysgenetic gonads

Theory supported by:

› cancer risk extends to contralateral testis

› orchiopexy does not decrease cancer risk

› cancer risk increases with degree of ectopy

Associated with: prune belly syndrome (bilateral cryptorchidism), Prader-Willi syndrome, Beckwith-Wiedemann syndrome, Noonan syndrome, Laurence-Moon-Biedl syndrome, trisomies 13, 18, 21

• nonpalpable testis means:

› in 41% testis atrophic / absent

› in 39% testis distal to external inguinal ring / in inguinal canal

› in 20% testis intraabdominal

Location: bilateral in 10%

(a) canalicular = between internal + external inguinal ring (70%)

(b) prescrotal region = high scrotal position below external inguinal ring (20%)

(c) abdominal (10%)

◊ The most craniad possible point of an undescended testis is the lower pole of the

ipsilateral kidney!
√ failure to visualize testis within scrotum
√ empty ipsilateral scrotal sac + intra-abdominal mass
US:
√ often small atrophic testis with generalized decreased / similar echogenicity compared to contralateral testis
√ identification of mediastinum testis is necessary
√ ± testicular microlithiasis
MR (key tool in localization of undescended testis; 62% sensitive):
√ signal characteristics similar to contralateral / normal testis
√ usually homogeneously hypointense on T1WI
√ homogeneously hyperintense on T2WI
√ markedly hyperintense on DWI
DDx: lymph node

Ectopia Testis (1%)
= deviation from the usual pathway
Location:
(a) interstitial = groin (on external oblique muscle)
(b) pubopenile = root of penis, perineal, femoral triangle, on opposite side

Pseudocryptorchidism (70%)
= RETRACTILE TESTIS
= unusually spastic cremasteric muscle

Undescended Testis
= retractile testis + cryptorchidism

MECKEL-GRUBER SYNDROME

= autosomal-recessive perinatally lethal disease characterized by occipital encephalocele, polycystic kidneys, polydactyly

Prevalence: 1÷12,000 to 1÷50,000;
more common among Yemenite Jews

Risk of recurrence: 25%; carrier frequency of 1÷56

• history of affected siblings, microphthalmia

OB-US:

√ large polycystic kidneys containing 2–10-mm cysts
√ occipital encephalocele
√ postaxial polydactyly
√ other intracranial abnormalities: microcephaly, Dandy-Walker malformation
√ cleft lip and palate
√ cardiac anomalies
√ ductal plate malformation of liver
√ ambiguous genitalia in males
√ moderate-to-severe oligohydramnios (onset midtrimester)
√ inability to visualize urine in fetal bladder

OB management:

1. Chromosomal analysis to exclude trisomy 13 (if no prior family history)
2. Option of pregnancy termination < 24 weeks GA
3. Nonintervention for fetal distress > 24 weeks GA

Prognosis: invariably fatal at birth ← pulmonary hypoplasia with renal failure

DDx: trisomy 13

MEDULLARY CYSTIC DISEASE

= NEPHRONOPHTHISIS

= autosomal dominant salt-wasting nephropathy characterized by multiple medullary cysts + tubulointerstitial nephropathy

Genetics: mutations in > 13 different recessive genes → ciliary dysfunction

(a) MCKD1 gene located on chromosome 1p12 encoding an as of yet unidentified protein product
(b) MCKD2 gene located on chromosome 16p12 encoding protein uromodulin (Tamm-Horsfall glycoprotein)
(c) NPHP1, NPHP2, NPHP3 (nephronophthisis) mutations

Path: tubulointerstitial fibrosis → small kidneys with 1.0–1.5 cm corticomedullary cysts (in 70%)

Histo: variable number of medullary cysts (100 μm to 2 cm) + progressive periglomerular and interstitial fibrosis + tubular atrophy with dilatation of proximal tubules

Types:

(1) **Medullary Cystic Disease** = ADULT ONSETautosomal dominant, in young adults, rapidly progressive course with uremia + death in 2 years
Median age at uremia: 62 (50–70) years

(2) **Juvenile Nephronophthisis** = JUVENILE ONSET = UREMIC MEDULLARY CYSTIC DISEASE
autosomal recessive, in children 3–6 years, average duration of 10 years before uremia and death occurs
Median age at uremia: 32 (20–60) years
(3) **Infantile nephronophthisis**

May be associated with: retinal degeneration
- urinary concentration defect → hyposthenuria + salt-wasting
- polyuria, polydipsia → dehydration
- failure to thrive, growth retardation (in early teens)
- uremia, severe anemia, normal sediment
- hypertension (only in late phase)
- adult-onset hyperuricemia + gout

Size of kidneys: small to normal
Size of cysts: < 3 cm
√ smoothly contoured kidneys with thin cortex
IVP:
√ poor opacification of renal collecting system
√ "medullary nephrogram" = medullary striations persistent for up to 2 hours; occasionally replaced by sharply defined multiple thin-walled lucencies
Retrograde pyelogram:
√ communication between collecting system + cysts
US / CT / MR:
√ increased parenchymal echogenicity + poor corticomedullary differentiation
√ multiple small medullary / corticomedullary cysts (70%) (secondary feature NOT essential for diagnosis)
DDx: medullary sponge kidney, multicystic dysplastic kidney, lithium-induced renal disease

MEDULLARY RENAL TUMOR

Frequency: 1–2% of all renal cancers

Collecting Duct Carcinoma

= BELLINI DUCT CARCINOMA
Frequency: ~ 100 cases reported in literature
Mean age: 55 (range, 13–80) years
Histo: mostly high-grade tumor
- abdominal pain, flank mass, hematuria

◊ In 40% metastasized at presentation
√ infiltrative neoplasm centered in medulla:
√ renal sinus invasion
√ extension into cortex (frequent)
√ ± coexisting expansile component
√ large tumor at presentation
US: √hyperechoic mass
Angio: √hypovascular mass

MR: √hypointense mass on T2WI
Prognosis: aggressive clinical course with 33% surviving > 2 years

Renal Medullary Carcinoma

= highly aggressive malignant tumor of epithelial origin occurring almost exclusively in adolescent / young adult blacks with sickle cell trait / hemoglobin SC disease (termed "7th sickle cell nephropathy") but NOT with hemoglobin SS (sickle cell) disease
Origin: distal collecting duct / epithelium of papilla; ? aggressive form of collecting duct carcinoma
Mean age: 20 (range, 11–39) years; M÷F = 3÷1 (if < 24 years of age) and 1÷1 (if > 24 years of age)
Histo: poorly differentiated tumor cells within a desmoplastic stroma + mixed with reticular, yolk saclike, adenoid cystic components
• abdominal / flank pain, gross hematuria
• palpable mass, weight loss, fever
• metastases at presentation common: regional lymph nodes, liver, lung, bone
√ large ill-defined mass centered in renal medulla:
  √ heterogeneous ← varying amounts of hemorrhage and necrosis
  √ extension into renal sinus and cortex
  √ ± peripheral caliectasis
  √ heterogeneous enhancement
√ reniform enlargement with shape of kidney preserved
√ small peripheral satellite nodules
Prognosis: mean survival rate of 15 weeks from diagnosis
DDx: transitional cell carcinoma, rhabdoid tumor

MEDULLARY SPONGE KIDNEY

= congenital developmental abnormality characterized by ectasia + cystic dilatation of intrapyramidal / intrapapillary portions of medullary collecting ducts (= first few generations of metanephric duct branchings)
Prevalence: 1÷5,000 persons; in 0.5% of IVPs; in 12–20% of patients with calcified kidney stones
Age: 3rd–4th decade
Genetics: mostly sporadic, occasionally autosomal dominant
Pathogenesis: ? disruption in ureteric bud-metanephros interface during embryogenesis → abnormal formation of medullary collecting ducts
Histo: ectasia of medullary + papillary collecting ducts with small < 1 cm cysts in medulla which are lined by columnar / transitional cell epithelium
May be associated with:
congenital hemihypertrophy, Beckwith-Wiedemann syndrome, Caroli syndrome, Wilms tumor, horseshoe kidney, Ehlers-Danlos syndrome, parathyroid adenoma
• mostly asymptomatic; hematuria, renal colic, fever, dysuria
Location: usually both kidneys + all pyramids; may be unilateral (in up to 25%); may be segmental + involve only one pyramid (up to 25%)

√ persistent thick dense paintbrushlike streaks of contrast material ("bunch of flowers") extending from surface of papilla into medulla ← pooling of contrast material in dilated medullary collecting ducts
√ striated / beaded appearance of medullary collecting ducts → distortion of calices (in severe cases)
√ medullary nephrocalcinosis (40–80%) with one / more calculi of up to 5 mm clustered in papillary region ← urinary stasis + hypercalciuria / acidification defects / distal renal tubular acidosis

US:
√ echogenic medulla (in absence of stones)

Cx:
(1) Nephrolithiasis
(2) Renal calculi = urolithiasis
(3) Hematuria
(4) Urinary tract infection
(5) Progressive renal failure (in severe cases)

Dx:
(1) Opacification of stone-free papillary cysts
(2) Accumulation of contrast material around calculi within ectatic tubules / cysts

DDx:
(1) Normal variant ("papillary blush" without distinct streaks / nephrocalcinosis / pyramidal enlargement)
(2) Renal tuberculosis (larger more irregular calcifications + cavitations + strictures + ulcerations)
(3) Papillary necrosis ("sloughed papilla + caliceal ring" sign)
(4) Medullary nephrocalcinosis (no ectatic ducts / cysts, calcifications beyond pyramids)
(5) Juvenile polycystic kidney disease (bilateral renal enlargement + hepatic periportal fibrosis)
(6) Caliceal diverticulum (small, solitary, located between pyramids)

MEGACALICOSIS

= CONGENITAL MEGACALICES
= nonprogressive caliceal dilatation caused by hypoplastic medullary pyramids
Age: any age; M >> F
May be associated with: primary megaureter
• normal glomerular filtration rate
Site: entire kidney / part of kidney; unilateral >> bilateral
√ kidney usually enlarged with prominent fetal lobation
√ reduced parenchymal thickness (medulla affected, NOT cortex):
√ normal DMSA scintigram
√ mosaic-like arrangement of dilated calices (polygonal faceted appearance, NOT globular as in obstruction)
√ increased number of calices (> 15)
√ ABSENT caliceal cupping (semilunar instead of pyramidal configuration of papillae)
√ NO dilatation of pelvis / ureters, NORMAL contrast excretion

Cx: (1) Hematuria
(2) Stone formation

MEGACYSTIS-MICROCOLON SYNDROME

= MEGALOCYSTIS-MICROCOLON-INTESTINAL HYPOPERISTALSIS SYNDROME (MMIH)
= functional obstruction of bladder + colon characterized by
(a) enlarged urinary bladder
(b) small colon
(c) strikingly short small intestine suspended on a primitive dorsal mesentery
(d) markedly enlarged hydronephrotic kidneys with little remaining parenchyma

Prevalence: 26 cases reported; M÷F = 1÷7
May be associated with: diaphragmatic hernia, PDA, teeth at birth

- distended abdomen (large bladder + dilated small bowel loops)
- intestinal pseudoobstruction (poor emptying of stomach, NO peristaltic activity of small bowel); overflow incontinence

OB-US:
√ normal amount of amniotic fluid / polyhydramnios (in spite of dilated bladder = "nonobstructive obstruction")
√ massive + progressive bladder distension with poor emptying
√ bilateral megaloureters
√ ± hydronephrosis
√ female sex

BE:
√ microcolon (= transient feature of "unused colon") with narrow rectum + sigmoid
√ malrotation / malfixation or foreshortening of small bowel

VCUG
√ distended unobstructed bladder with poor / absent muscular function

Prognosis: lethal in most cases (at a few months of age)

MEGALOURETER

= CONGENITAL PRIMARY MEGAURETER = TERMINAL URETERECTASIS = ACHALASIA OF URETER = URETEROVESICAL JUNCTION OBSTRUCTION
= intrinsic congenital dilatation of lower juxtavesical orthotopic ureter ≥ 7 mm ← intrinsic smooth muscle dysfunction and abnormal peristalsis

Cause: aperistaltic juxtavesical (1.5 cm long) segment ← faulty development of muscle layers of ureter with too much collagen / too much muscle (functional, NOT mechanical obstruction) = "Hirschsprüng disease of ureter"

Frequency: 2nd most common cause of hydronephrosis in fetus and newborn
Age: any; M÷F = 2–5÷1
Associated disorders (in 40%):
(a) contralateral: UPJ obstruction, reflux, ureterocele, ureteral duplication, renal ectopia, renal agenesis
(b) ipsilateral: caliceal diverticulum, megacalycosis, papillary necrosis

- asymptomatic (mostly), abdominal mass, pain

• hematuria, infection

Location: L÷R = 3÷1, bilateral in 15–40%

Grading system:

I (mild) = distal ⅓ of ureter involved

II (moderate) = entire ureter involved ± caliectasis

III (severe) = entire ureter + moderate to marked caliectasis

√ prominent localized dilatation of pelvic ureter (up to 5 cm in diameter) usually not progressive, but may involve entire ureter + collecting system

√ vigorous nonpropulsive to-and-fro motion in dilated segment

√ functional "beaking" / gradual tapering (= smoothly tapered narrowing) of abnormal distal ureter without peristalsis

√ NO reflux, NO stenosis

Secondary Megaureter

= ureteral dilatation ← any other cause than primary megaureter

Cause: neurogenic bladder, bladder outlet obstruction, posterior urethral valve, obstructing calculus

MESOBLASTIC NEPHROMA

= FETAL RENAL HAMARTOMA = LEIOMYOMATOUS HAMARTOMA = BENIGN CONGENITAL WILMS TUMOR = BENIGN FETAL HAMARTOMA = FETAL MESENCHYMAL TUMOR = FIBROMYXOMA = BOLANDE TUMOR = CONGENITAL FIBROSARCOMA = CONGENITAL MESOBLASTIC NEPHROMA (CMN)

= nonfamilial benign fibromyomatoid mass arising from renal connective tissue; first described in 1967

Incidence: most common solid renal neoplasm discovered in 2nd / 3rd trimester, in neonate or in infant < 1 year; 3–6% of all renal neoplasms in children

Peak age: 1–3 months; 90% within 1st year of life; rare after the age of 6 months; may occasionally go undetected until adulthood; M÷F=1.5÷1

Path: solid unencapsulated mass infiltrating renal parenchyma (derived from early nephrogenic mesenchyme) → sparing renal pelvis + vascular pedicle

Subtypes:

1. **Classic** benign mesoblastic nephroma (< ⅓)
   = represents infantile fibromatosis
   Age: < 3 months
   Path: little hemorrhage + cystic / necrotic change
   Histo: monomorphic tumor composed of uniform elongated spindle cells arranged in bundles resembling leiomyoma with interspersed areas of entrapped normal embryonic glomeruli, tubules vessels, hematopoietic cells, cartilage
   √ often infiltrative tumor with extension into renal hilum / perinephric fat
2. **Cellular** aggressive mesoblastic nephroma (42–63%)
   = visceral form of infantile fibrosarcoma
   Age: > 3 months
   Path: identical to infantile fibrosarcoma; much larger soft fleshy tumor; tendency to

invade perinephric fat + connective tissue; multicystic areas of intratumoral hemorrhage and fluid accumulation (cysts + necrosis)

Histo: haphazardly arranged sheets of spindle cells with limited tendency to form interlacing bundles

√ fluid-filled spaces ← hemorrhage, necrosis, cyst formation

3. Both patterns (in 10–20%)

In 14% associated with: prematurity, polyhydramnios, GI + GU tract malformations, neuroblastoma

• large palpable abdominal / flank mass within first 6 months of life (most common); hypercalcemia, anemia, vomiting

• hematuria (20%) / hypertension (4%) ← ↑ renin production

√ large usually solid intrarenal mass:

√ usually replaces 60–90% of renal parenchyma

√ typically involves renal sinus

√ may produce multiple cystic spaces ← hemorrhage, necrosis

√ infiltrative growth:

√ NO sharp cleavage plane toward normal parenchyma

√ may extend beyond capsule (common)

√ involvement of renal hilum without invasion of vessels

√ calcifications (rare)

√ NO venous extension (DDx: Wilms tumor)

√ NO invasion of collecting system

IVP:

√ large noncalcified renal mass with distortion of collecting system

√ usually NO herniation into renal pelvis (DDx: MLCN)

CECT:

√ minimal predominantly peripheral enhancement ← functioning entrapped renal elements at tumor periphery

√ areas of low attenuation in large lesions ← hemorrhage / necrosis

MR:

√ iso- to hypointense on T1WI

√ variable from markedly hypo- to hyperintense on T2WI

√ restricted diffusion in solid portion ← increased cellularity

√ focal areas of T1 shortening ← hemorrhage

US:

√ evenly echogenic tumor resembling uterine fibroids

√ "ring" sign = concentric rings of alternating hyper- and hypoechogenicity surrounding tumor ← peripheral dilated blood vessels

√ homogeneously hypoechoic tumor

√ complex heterogeneous mass with hemorrhage + cyst formation + necrosis

OB-US (prenatal detection often possible in 3rd trimester):

• rapid unexplained increase in fundal height

• premature delivery, increased renin levels

√ polyhydramnios, hydrops

Cx: pre-term labor, premature rupture of membranes

Angio:

√ hypervascular mass with neovascularity + displacement of adjacent vessels

Cx: (1) Transformation to metastasizing spindle cell sarcoma (rare)

(2) Metastases to lung, brain, bone (rare)

Dx: Cellular CMN is indistinguishable from Wilms tumor.
While Wilms tumor is the most common pediatric renal tumor, congenital mesoblastic nephroma is more common in young infants. With bilateral tumors, venous invasion, or pulmonary metastases Wilms tumor is more likely.

Rx: radical nephrectomy with wide surgical margin; 10% relapse (← local recurrence / metastases to lung, heart, bone, brain, liver)

Prognosis: excellent (imaging follow-up for 1 year)

DDx: (1) Wilms tumor (peaks at 3–4 years, history of nephroblastomatosis, associated congenital syndromes, bilateral, vascular invasion, pulmonary metastases)

(2) Clear cell sarcoma (age >1 year; bone metastases)

(3) Rhabdoid tumor (local + distant metastases to lung, abdominal lymph nodes, liver, bone; associated with intracranial tumor)

(4) Multilocular cystic nephroma (boys between 3 months and 4 years; well-circumscribed encapsulated multiloculated cystic mass + enhancing septa)

(5) Neuroblastoma (inferior displacement of ipsilateral kidney; encasement of adjacent blood vessels, crosses midline, invasion of spinal canal, tumoral calcifications)

(6) Ossifying renal tumor of infancy (calcified osteoid matrix)

METANEPHRIC ADENOMA

= NEPHROGENIC ADENOFIBROMA = EMBRYONAL ADENOMA

Age: any (range, 15 months – 83 years); M < F

Histo: proliferation of spindle-shaped mesenchymal cells encasing nodules of embryonal epithelium; numerous psammoma bodies

- pain, hematoma, flank mass
- hypercalcemia, polycythemia, hypertension

US:

√ well-defined solid hypovascular mass

√ hypo- / hyperechoic / cystic with mural nodule

CT:

√ iso- / hypoattenuating mass + little enhancement

√ ± small calcifications

Rx: local resection with sparing of kidney

METASTASIS TO ADRENAL GLAND

Frequency: 4th most common site of metastatic disease in the body; in 3% of all autopsy cases (in 27% with known primary)

◊ 50% of adrenal masses in oncologic patients represent benign nonhyperfunctioning

adenomas!
◊ An adrenal mass in a patient with a malignancy is a metastasis in 30–40%!

Origin: lung (40%), breast (20%), colon, stomach, lymphoma, malignant melanoma, renal cell carcinoma, prostate, pancreas, thyroid

Location: bilateral (49%); L÷R = 1.5÷1; **collision tumor** = rare coexistence of metastasis + adenoma

√ large heterogeneously attenuating mass with irregular contour and progressive heterogeneous enhancement

MR:
√ lack of signal loss on out-of-phase images (DDx: adrenal adenoma)
√ low-signal intensity on T1WI ← edema, necrosis
√ heterogeneous high-signal intensity on T2WI

CEMR:
√ strong rapid progressive enhancement
√ prolonged retention of contrast material ← large interstitial spaces of edema + necrosis

PET:
√ 18F-fluorodeoxyglucose uptake in 100% with rare false-positive results

Dx: biopsy

DDx: adenoma (intracytoplasmic lipid → chemical shift artifact + significant decrease in SI on out-of-phase GRE)

METASTASIS TO KIDNEY

◊ Most common malignant tumor of the kidney (2–3 times as frequent as primaries in autopsy studies)!
◊ 5th most common site of metastases (after lung, liver, bone, adrenals)!

Frequency: 7–13% in large autopsy series

◊ Renal metastases typically means advanced disease!

<u>most common primaries:</u>
bronchus, breast, GI tract, opposite kidney, non-Hodgkin lymphoma, colon, neuroblastoma (in children)

<u>less common primaries:</u>
stomach, cervix, ovary, pancreas, prostate, chloroma, myeloblastoma, myeloblastic sarcoma, melanoma (45% incidence), osteogenic sarcoma, choriocarcinoma (10–50% incidence), Hodgkin lymphoma, rhabdomyosarcoma

• usually asymptomatic
√ bilateral multiple small masses ← brief survival of patient
√ solitary exophytic mass (in colon cancer)
√ perinephric tumor (in melanoma)
√ infiltrative growth pattern

DDx on CT: lymphoma, bilateral RCC, multiple renal infarcts, acute focal bacterial nephritis, infiltrating TCC

METASTASIS TO URETER

◊ Hematogenous metastases to the ureter are rare!

most common primaries: breast, GI tract, prostate, cervix

MIXED EPITHELIAL AND STROMAL TUMOR

= MEST = LEIOMYOMATOUS RENAL HAMARTOMA = CYSTIC HAMARTOMA OF RENAL PELVIS = ADULT TYPE MESOBLASTIC NEPHROMA = MULTILOCULAR CYST WITH OVARIAN STROMA

Prevalence: < 100 cases reported in literature

Average age: 56 (range, 17–84) years; M÷F = 1÷11

Associated with: oral estrogen supplements / contraceptives

Path: benign complex solid + cystic renal tumor

Histo: › stromal spindle cells mimicking ovarian stroma with estrogen + progesterone receptors, and
› epithelium-lined cysts / microcysts

- hematuria, flank pain, palpable mass, urinary tract infection
- asymptomatic (¼)

√ well-circumscribed expansile multiseptate complex (= cystic and solid) mass
√ may herniate into renal pelvis
√ variable contrast enhancement of intervening septa
√ delayed contrast enhancement
√ ± adipose tissue
√ ± enhancing mural nodule / mural calcifications
√ ± intralesional hemorrhage

US:
√ heterogeneous hyperechoic / partially cystic mass

MR:
√ cystic region with T1 hypointensity + T2 hyperintensity
√ nodular component T1 hyperintense + T2 hypointense

Rx: surgery (impossible DDx from cystic RRC)

DDx: (1) Multilocular cystic renal tumor – adult cystic nephroma
(2) Cystic renal cell carcinoma
(3) Complex renal cyst
(4) Multicystic dysplastic kidney
(5) Obstructed duplicated renal collecting system
(6) Renal abscess

MÜLLERIAN DUCT CYST

= failed regression of paramesonephric (= müllerian) duct which usually regresses by 3rd fetal month

Prevalence: 4–5% of male newborns; in 1% of men

Peak age: 20–40 years

- obstructive / irritative urinary tract symptoms
- suprapubic / rectal pain, hematuria
- infertility ← most common cause of ejaculatory duct obstruction

Location: arises from region of verumontanum slightly lateral to midline

◊ No communication with genital tract / urethra; connected by thin stalk
Associated with: typically NO other congenital anomalies; renal agenesis (rare)
√ large teardrop-shaped intraprostatic cyst usually with extension superolaterally above prostate
√ aspirate contains serous / mucous clear brown / green fluid (hemorrhage + debris), NOT spermatozoa
√ commonly contains calculi
MR:
√ increased signal on T1WI ← hemorrhage, protein
Cx: infection, hemorrhage, carcinomatous transformation
DDx: posterior bladder diverticulum, urethral diverticulum, utricle cyst, vas deferens cyst, seminal vesicle cyst

MULTICYSTIC DYSPLASTIC KIDNEY

= MULTICYSTIC DYSGENETIC KIDNEY (MCDK) = MULTICYSTIC KIDNEY (MCK) = Potter Type II
= nonheritable developmental disorder in which kidney is replaced by nonfunctioning noncommunicating cysts
◊ 2nd most common cause of an abdominal mass in neonate (after hydronephrosis)!
◊ Most common form of cystic disease in infants!
Prevalence: 1÷4,300 (for unilateral MCDK), 1÷10,000 (for bilateral MCDK) live births; M÷F = 2÷1 (for unilateral MCDK); more common among infants of diabetic mothers
Risk of recurrence: 2–3%
Genetics: sporadic NOT familial
Etiology: obstruction / atresia of ureter during metanephric stage before 8–10 weeks GA
Pathophysiology: interference with ureteral bud division → inhibiting induction and maturation of nephrons and various stromal renal elements; collecting tubules enlarge into cysts
Histo: immature glomeruli + tubules reduced in number + whirling mesenchymal tissue, cartilage (33%), cysts
• abdominal mass
• asymptomatic if unilateral (may go undetected until adulthood)
• recurrent urinary tract infections, intermittent abdominal pain, nausea + vomiting, hematuria, failure to thrive
• fatal ← pulmonary hypoplasia if bilateral
Fatal form: bilateral MCDK (4.5–21%), contralateral renal agenesis (0–11%)
Location:
1. UNILATERAL multicystic dysplastic kidney (80–90%)
most common form (80–90%); L÷R = 2÷1
Cause: pelvoinfundibular atresia
In 33 (range, 20–50)% associated with anomalies of the contralateral kidney:
(1) Vesicoureteral reflux 15–43%
(2) Ureteropelvic junction obstruction 7–27%
(3) Horseshoe kidney 5–9%
(4) Ureteral anomalies 5%

(5) Renal hypoplasia 4%
(6) Megaloureter
(7) Malrotation
(8) Renal agenesis

Associated with anomalies of the ipsilateral kidney:

(1) Vesicoureteral reflux (25%)
(2) Ectopic ureter

2. SEGMENTAL / focal renal dysplasia
= "multilocular cyst" secondary to
(a) high-grade obstruction of upper pole moiety in duplex kidney from ectopic ureterocele
(b) single obstructed infundibulum
3. BILATERAL cystic dysplasia
in the presence of severe obstruction in utero from posterior urethral valves / urethral atresia with oligohydramnios + pulmonary hypoplasia
Prognosis: lethal

Potter types:

(1) Multicystic kidney (Potter IIa)
√ large kidney with multiple large cysts + little visible renal parenchyma
(2) Hypoplastic / diminutive form (Potter IIb)
√ echogenic small kidney

Time of appearance:

(A) RELATED TO SITE OF OBSTRUCTION
@ ureteropelvic junction
√ single / several large / multiple medium-sized cysts in large kidney
@ distal ureter / urethra
√ small / no cysts in small kidney

(B) RELATED TO TIME OF INSULT
(a) early onset between 8th and 11th week
√ small / atretic renal pelvis + calices
√ 10–20 cysts + loss of reniform appearance
(b) late onset = HYDRONEPHROTIC FORM
√ large central cyst (= dilated pelvis) often communicating with cysts
√ some renal function may be demonstrated

√ imaging appearance of MCDK varies by age:
√ large kidney with lobulated contour in infancy
√ often incidental finding of small kidney in adult (as little as 1 g ← arrested growth)
√ calcification: curvilinear / ringlike in wall of cysts in 30% of adults, rarely in children
√ central region of soft tissue
√ peripheral noncommunicating cysts ± calcifications
√ absence / severe atrophy of ipsilateral ureter + renal collecting system + renal vasculature
√ contralateral renal hypertrophy
√ contralateral vesicoureteral reflux (VUR) in 5–43%

NUC (^{99m}Tc-MAG 3):

◊ NUC preferred over IVP in first month of life as concentrating ability of even normal

neonatal kidneys is suboptimal!

√ NO function

DDx: severe hydronephrosis (peripheral activity), UPJ obstruction (minimal uptake)

US:

√ normal renal architecture replaced by:

√ random cysts of varying shape + size ("cluster of grapes") with largest cyst in peripheral nonmedial location (100% accurate)

√ cysts separated by septa (100% accurate)

√ no communication between multiple cysts (93% accurate)

√ cysts begin to disappear in infancy

√ central sinus complex absent (100% accurate)

√ no identification of parenchymal rim or corticomedullary differentiation (74% accurate)

√ oligohydramnios in bilateral MCDK / unilateral MCDK + contralateral urinary obstruction

Angio:

√ absent / hypoplastic renal artery; angiography unnecessary since a DDx to long-standing functionless kidney is not possible

OB management:

(1) Routine antenatal care + evaluation by pediatric urologist following delivery if unilateral

(2) Option of pregnancy termination if ≤ 24 weeks GA

(3) Nonintervention for fetal distress if > 24 weeks GA

Cx: (1) Renin-dependent hypertension (rare)

(2) Malignancy in < 1÷330

Rx: (1) Follow-up in 3–4-month intervals in first year (isolated reports of developing malignancy)

(2) Nephrectomy (in hypertension / massive renal enlargement)

(3) Assessment of contralateral kidney for VUR

DDx: (1) Hydronephrosis

(2) Renal dysplasia with cysts (associated with partial obstruction)

MULTILOCULAR CYSTIC RENAL TUMOR

= MCRT = MULTILOCULAR CYSTIC NEPHROMA (MLCN) = POLYCYSTIC NEPHROBLASTOMA = WELL-DIFFERENTIATED POLYCYSTIC WILMS TUMOR = BENIGN CYSTIC (PARTIALLY) DIFFERENTIATED NEPHROBLASTOMA = MULTILOCULAR CYSTIC NEPHROMA = PERLMAN TUMOR = MULTILOCULAR RENAL CYST = CYSTIC ADENOMA / HAMARTOMA / LYMPHANGIOMA = PARTIALLY POLYCYSTIC KIDNEY

= rare nonhereditary benign renal neoplasm originating from metanephric blastema possibly representing the benign end of a spectrum with solid Wilms tumor at the malignant end

Age: bimodal age + sex distribution: < 4 years in 73% male, > 4 years in 89% female

(a) 3 months to 2 years of age (65%), 5–30 years (5%); M÷F = 2÷1

(b) > 30 (mostly, 40–60) years (30%); M÷F = 1÷8

◊ 90% of tumors in males occur in first 2 years of life (peak 3–24 months)!

◊ Most of the lesions in females occur between ages 4 and 20 or 40 and 60!

Path: solitary large well-circumscribed multiseptated mass of noncommunicating loculi,

surrounded by thick fibrous capsule + compressed renal parenchyma

Solid tumor portion: thin fibrous septa
◊ Solid nodules are absent!
Content of loculi: colorless fluid / thick myxoid material
Size of loculi: between a few mm to 4 cm
√ tumor tendency to herniate into collecting system

Histo: (gross anatomic + radiologic features are identical)

1. **Adult cystic nephroma**
   fibrous tissue septa of undifferentiated mesenchymal and primitive glomerulotubular elements surround cysts lined by flattened eosinophilic cuboidal epithelium partially protruding into lumen in a hobnail / teardrop appearance; NO blastemal / other embryonal elements
   • typically seen in adult women
2. **Cystic partially differentiated nephroblastoma** (CPDN)
   predominantly cystic lesion with septa containing primitive metanephric blastema
   • primarily in young boys
   ◊ No association with Wilms tumor!

• commonly asymptomatic painless abdominal mass
• ± sudden and rapid enlargement, pain, urinary tract infection
• hematuria ← tumor herniation into renal collecting system

Location: unilateral, often replacing an entire renal pole (usually lower pole)
Size of tumor: 5–10 cm (range, few cm to 33 cm)
√ contrast enhancement of capsule + septations ← tortuous fine vessels course through septa
√ curvilinear to flocculent calcification of septa / capsule in 5%
√ absence of intratumoral / perinephric hemorrhage

IVP:
√ distortion of calices / hydronephrosis ← nonfunctional mass
√ tendency for herniation of tumor cysts into renal pelvis and proximal ureter is CHARACTERISTIC (but nonspecific as it also occurs in Wilms tumor + RCC)

US:
√ cystic mass with claw / beak shape of adjacent normal renal parenchyma ← intrarenal origin:
√ cluster of cysts separated by thick septa (SUGGESTIVE):
√ NO solid / nodular elements
√ occasionally solid echogenic character ← closely packed acoustic interfaces with very small cysts / jellylike contents
√ ± associated urinary tract obstruction

CT:
√ well-circumscribed (CHARACTERISTIC) multiseptated cystic renal mass:
√ tumor encapsulated by thick fibrous capsule
√ attenuation of cysts equal to / higher than water ← gelatinous fluid
√ multicystic = cluster of noncommunicating honeycombed cysts between a few mm and 4 cm in size
√ cysts separated by variably enhancing thick septa

√ closely packed septa may appear as solid nodules but are separated by very small cystic spaces

MR:

√ multicystic mass of low signal intensity on T1WI + hyperintense on T2WI

√ hypointense capsule and septa on all sequences

√ variable SI of cyst content on T1WI ← old hemorrhage / concentrated protein

√ enhancing septa

Cx: local recurrence / coexistent Wilms tumor (very rare)

Rx: nephrectomy with excellent prognosis

DDx:
(1) Cystic Wilms tumor (overlapping age, expansile solid masses of nephroblastomatous tissue)
(2) Clear cell sarcoma (poor prognosis)
(3) Cystic mesoblastic nephroma (most common renal tumor of infancy)
(4) Cystic RCC (mean age of 10 years)
(5) Segmental form of multicystic dysplastic kidney (pre- / perinatal discovery in a duplex kidney)
(6) Complex renal cysts
(7) Mixed epithelial and stromal tumor
(8) Severe hydronephrosis (cysts communicating with one another and with a large central cyst)
(9) Complicated benign cyst / polycystic kidney disease

MULTIPLE MYELOMA

◊ It is essential that dehydration be avoided!

Impairment of renal function:

(1) Precipitation of abnormal proteins (Bence-Jones ± Tamm-Horsfall protein casts) within tubule lumen (30–50%)
(2) Toxicity of Bence-Jones proteins on tubules
(3) Impaired renal blood flow ← increased blood viscosity
(4) Amyloidosis
(5) Nephrocalcinosis from hypercalcemia

◊ Contrast-induced renal failure in multiple myeloma is not seen with greatly increased frequency!

• Tamm-Horsfall proteinuria (tubular cell secretion)

√ smooth normal to large kidneys (initially), becoming small over time

√ occasionally attenuated pelvoinfundibulocaliceal system

√ normal to diminished contrast material density; increasingly dense in acute oliguric failure

US:

√ normal to increased echogenicity

NUC in bone scintigraphy:

√ nonspecific increased parenchymal activity

MYCETOMA

= FUNGUS BALL

Organism: typically Candida, Aspergillus, Mucor, Cryptococcus, Phycomycetes, Actinomycetes mostly mycelial (M-form) or occasionally yeast cells (Y-form)

Predisposed: diabetics, debilitating illness, prolonged antibiotic therapy, leukemia, lymphoma, thymoma, immunosuppression

- flank pain, passing of tissue, hematuria (extremely rare)
- renal candidiasis associated with candidemia
- Candida cystitis preceded by vaginal candidiasis

√ unilateral nonvisualization of kidney (most frequent)
√ large irregular filling defect extending into dilated calices (retrograde contrast study)
√ necrotizing papillitis from Candida nephritis (common)
√ lacelike pattern (on antegrade contrast study)

MYELOLIPOMA

= uncommon benign tumor composed of hematopoietic cells + mature fat resembling bone marrow

Prevalence: 0.08–0.20% (autopsy series); 3–6% of all incidental primary adrenal tumors

Mean age: 55 years (for adrenal myelolipoma); M÷F = 2÷3; 64 years (for extraadrenal myelolipoma)

Cause: chronic ACTH elevation → metaplasia of adrenocortical cells precipitated by chronic stress / degeneration

Path: mature fat (0–100%) interspersed with hematopoietic cells resembling bone marrow + pseudocapsule

Histo: variable mixture of megakaryocytes, myeloid and leukocyte precursor cells, erythroid cells, lymphocytes

Associated with: endocrine disorders in 7% (Cushing syndrome, Conn syndrome, 21-hydroxylase deficiency, 17-hydroxylase deficiency); nonhyperfunctioning adenoma (15%)

◊ Long-standing / poorly treated congenital adrenal hyperplasia may develop massive bilateral myelolipomas!

- usually clinically occult
- pain (from spontaneous hemorrhage if large)

Location:
(a) adrenal myelolipoma (85%)
› isolated adrenal myelolipoma
› adrenal myelolipoma with hemorrhage
(b) extraadrenal myelolipoma (15%):
› retroperitoneal (12%): presacral space (6%), abdomen, stomach, liver, muscle fascia
› intrathoracic (3%): mediastinum, lung
Predilection for: perirenal + presacral spaces

Site: unilateral÷bilateral = 10÷1; RT÷LT = 3÷1

Mean size: 10 (range, 2–17) cm;
enlargement with hemorrhage (11%)

X-ray:

√ soft lucent mass with rim of residual normal adrenal cortex

US:

√ heterogeneous predominantly hyperechoic (= fat + myeloid tissue) mass interspersed with hypoechoic regions (= pure fat)

√ ± hypoechoic areas of hemorrhage

CT:

√ heterogeneous mass composed of:

√ fat of –74 (range, –30 to –115) HU:

√ 50–90% fat in adrenal myelolipoma

√ < 50% fat in extraadrenal myelolipoma

√ interspersed "smoky" areas of higher attenuation of +20–30 HU (= admixture of fat + marrowlike elements)

√ occasionally tiny foci of fat (< 10% fat)

√ small punctate calcifications from previous hemorrhage:

√ calcifications in up to 24% of adrenal myelolipomas

√ calcifications in 10% of extraadrenal myelolipomas

√ ± enhancement of soft-tissue component

In general, macroscopic fat-containing adrenal lesions are myelolipomas characteristically identified at CT!

MR:

√ intermediate SI on T2WI similar to spleen / heterogeneous high signal (admixture with hematopoietic tissue + myeloid tissue + hemorrhage)

N.B.: pure fat may demonstrate no SI decrease on opposed-phase images dependent on proportion of fat to water in an image voxel

(a) for lesion with predominantly mature adipose tissue

√ homogeneously hyperintense mass on T1WI

√ intermediate SI on T2WI

√ signal dropout on fat-suppressed images

(b) for lesion with mixture of fatty + myeloid elements

√ heterogeneous masses containing foci of fat SI intermixed with focal high SI on T2WI + contrast enhancement on T1WI

(c) for lesion with predominantly myeloid elements

√ nodules hypointense relative to liver on T1WI

√ hyperintense relative to liver on T2WI

√ contrast enhancement on T1WI

NUC:

√ uptake of ^{99m}Tc-sulfur colloid in erythropoietic elements

Cx: acute retroperitoneal hemorrhage ← myeloid elements with increase in size > 5 cm (12%)

Dx: percutaneous needle biopsy with demonstration of megakaryocytes

Rx: surgical excision of (a) symptomatic lesion (b) enlarging lesion (c) lesion > 7 cm in diameter → increased risk of hemorrhage (d) lesion of diagnostic uncertainty

DDx: adrenocortical carcinoma with lipomatous metaplasia, adrenal lipoma, adrenal teratoma, adrenal adenoma with degenerative and myelolipomatous changes, liposarcoma (unencapsulated + less well defined + infiltrative without hemorrhage),

pheochromocytoma

NEPHROBLASTOMATOSIS

= multiple / diffuse NEPHROGENIC RESTS
= dysontogenetic process with persistence of embryonic renal parenchyma (= metanephric blastema) within the renal cortex > 36 weeks GA

Prevalence: in 1% of infant kidneys (at autopsy); in 41% with unilateral Wilms tumor, in 94% with metachronous contralateral Wilms tumor, in 99% with bilateral Wilms tumor
◊ Usually absent in infants > 4 months of age

Pathogenesis: embryonal renal tissue in mature kidney after birth retains potential to form nephroblastoma / Wilms tumor

A. **Perilobar nephrogenic rest** (0.87%)
Path: multiple rests forming a well-circumscribed smooth band at periphery of lobe (cortex / column of Bertin)
Histo: predominantly blastemal tissue
Associated with:
(1) Beckwith-Wiedemann syndrome (gigantism, macroglossia, omphalocele, genitourinary anomalies)
(2) Hemihypertrophy → 3% develop Wilms tumor
(3) Perlman syndrome (visceromegaly, gigantism, cryptorchidism, polyhydramnios, characteristic facies)
(4) Trisomy 18 syndrome
• abnormal chromosome band 11p15 (Wilms tumor gene 2) in up to 77% of patients with perilobar rests
• mean age presenting with neoplasia: 36 months

B. **Intralobar nephrogenic rest** (0.10%)
Path: single / few rests with irregular indistinct margins located centrally anywhere within a lobe → higher risk of developing neoplasia
Histo: predominantly stromal + epithelial tissue
Associated with:
(1) **Drash syndrome** (ambiguous genitalia in genotypic males, progressive renal failure): 78% with intralobar rests + 11% with perilobar rests
(2) **Sporadic aniridia**: 100% with intralobar rests + 20% with perilobar rests → 33% likelihood of Wilms tumor
(3) **WAGR syndrome** (Wilms tumor, aniridia, genital abnormalities, mental retardation)
• abnormal chromosome band 11p13 (Wilms tumor gene 1)
• mean age presenting with neoplasia: 16 months

Age: < 2 years of age; neonatal period, infancy, childhood

Histologic subtypes:
(a) dormant (nascent): nephrogenic rests the size of a glomerulus primarily composed of blastemal + epithelial elements; no malignant potential
(b) sclerotic (regressing / obsolescent): microscopic rests primarily composed of stromal elements; nonmalignant
(c) hyperplastic: spherical / irregular / oval proliferation of most or all cell elements

(d) neoplastic: expansile mass ← proliferation of a single cell line

• clinically occult in vast majority / renal enlargement

√ peripheral rind of nephrogenic rests that compress normal renal tissue toward the center of the kidney

US (least sensitive technique):

√ hypo-, iso-, or hyperechoic nodules distorting renal shape

√ ± enlargement of kidney causing diffuse hyperechogenicity and poor corticomedullary differentiation

CT (modality of choice):

√ hypo- to isoattenuating nodules

√ striated enhancement pattern / no enhancement

MR (43% sensitivity, 58% sensitivity with enhancement):

√ renal enlargement

√ absent corticomedullary differentiation

√ homogeneously hypo- to isointense foci on T1WI

√ homogeneously T1-hypointense lesions after enhancement

√ iso- to slightly hyperintense on T2WI

Cx: malignant transformation (in 1%) into Wilms tumor / cystic partially differentiated nephroblastoma

√ increase in size of nephrogenic rest

√ increasing tissue heterogeneity

√ developing a spherical masslike configuration

Screening: for children with associated syndromes baseline CT at diagnosis at 6 months of age + follow-up sonograms every 3 months until age 8 years

Rx: radiologic follow-up / chemotherapy (for biopsy-proved hyperplastic nephrogenic rests similar to stage I Wilms tumor)

Multifocal (Juvenile) Nephroblastomatosis

most common form

= isolated macroscopic nephrogenic rests

√ may escape detection with imaging

√ ± nodular mass effect on pelvicaliceal structures

√ kidneys may be enlarged

√ lobulated contour of kidney

US:

√ hypoechoic / isoechoic / hyperechoic nodules

CECT (preferred study):

√ nodules with less enhancement than renal parenchyma

Superficial Diffuse Nephroblastomatosis

= LATE INFANTILE NEPHROBLASTOMATOSIS

= superficial continuous rind of rests around medulla (= perilobar type)

Age: < 2 years

√ nephromegaly

US:

√ loss of corticomedullary differentiation
√ kidneys diffusely echogenic / of normal echogenicity
√ cysts of variable size
CECT:
√ thick rind at periphery of kidney with poor / striated enhancement
DDx: autosomal recessive polycystic kidney disease, leukemia, lymphoma
◊ Strong association with Wilms tumor!

Universal / Panlobar (Infantile) Nephroblastomatosis

rare form
= entire renal parenchyma diffusely involved
• may develop renal failure
√ bilateral renal enlargement (infiltrative growth)

NEPHROGENIC ADENOMA

= uncommon benign metaplastic response to urothelial injury / prolonged irritation
Cause: (a) trauma: pelvic trauma, surgery in lower urinary tract, endoscopic procedure, renal transplantation (after a mean of 50 months)
(b) irritation: calculi, chronic bacterial infection, irradiation, intravesical chemotherapy, immunosuppressive therapy
Age: 3 weeks to 83 years; M÷F = 3÷1 (more common in females if < 20 years of age)
Path: discrete raised papillary / polypoid / cystic areas projecting from epithelial surface
Histo: variable number of small tubules (resembling loops of Henle and collecting ducts) + cysts + papillae lined with a single layer of cuboidal / low columnar cells
• asymptomatic; hematuria, dysuria, bladder instability
Location: bladder (72%), renal pelvis, ureter, urethra; strong correlation between location + site of insult to urothelium
Size: usually 1 mm, up to 7 cm in diameter
√ papillary / polypoid filling defect
Prognosis: high likelihood of recurrence; rarely malignant transformation
Rx: resection / fulguration
DDx: inflammatory / malignant urothelial lesions

NEUROBLASTOMA

Most common solid abdominal mass of infancy (12.3% of all perinatal neoplasms), 4th most common malignant tumor in infancy (after leukemia, lymphoma, CNS tumor); 2nd most common tumor in childhood (Wilms tumor more common in older children), 8% of all childhood cancers; 15% of cancer deaths in children; 30% of all fetal (congenital) tumors
Incidence: 9.5÷1,000,000 live births; 650 new cases annually in USA; 20% hereditary
Origin: neural crest in adrenal medulla / along sympathetic chain
Path: round irregular lobulated mass of 50–150 g with areas of hemorrhage + necrosis
Histo: small round cells slightly larger than lymphocytes with scant cytoplasm; **Horner-Wright rosettes** = one / two layers of primitive neuroblasts surrounding a central zone of tangled neurofibrillary processes (= neuropils)

Median age: 22 months; 25% (50%) [79%] {97%} in 1st year (< 2 years) [< 4 years] {< 10 years}; M÷F = 1÷1 occasionally present at birth or 1st seen in adults;

May be associated with: aganglionosis of bowel, CHD

- constitutional symptoms:
  - fever (30%), weight loss, malaise, failure to thrive
- symptoms of mass effect:
  - pain, urinary retention, frequency of evacuation, constipation
  - bone pain, limp, inability to walk (20%)
- palpable abdominal mass (45–54%)
- cerebellar ataxia:
  - myoclonus of trunk + extremities
  - opsomyoclonus (20%) = spontaneous conjugate + chaotic eye movements (sign of cerebellar disease)
- "raccoon" sign = orbital ecchymosis / proptosis (12%)
- increased catecholamine production (75–90%):
  - in 95% excreted in urine as vanillylmandelic acid (VMA) / homovanillic acid (HVA)
  - paroxysmal episodes of:
    - flushing, tachycardia, headaches, hyperglycemia
    - hypertension (in up to 30%)
    - intractable diarrhea (9%) ← increase in vasoactive intestinal polypeptides (VIP)
    - acute cerebellar encephalopathy
    - rise in body temperature / sweating
- positive bone marrow aspiration (70%)

Stage:

I confined to organ of origin
II local extension not crossing midline
III extension across midline
IV metastatic to distant lymph nodes, liver, bone, brain, lung
IVs stages I + II with disease confined to liver (25%) > skin > bone marrow (< 10%) WITHOUT radiographic evidence of skeletal metastases

Metastases:

bone (60%), regional lymph nodes (42%), orbit (20%), liver (15%), intracranial (14%), lung (10%)

◊ Metastases are the 1st manifestation in up to 60–70%!

› **Hutchinson syndrome**
(1) Primary adrenal neuroblastoma
(2) Extensive skeletal metastases, esp. skull
√ widened cranial sutures = sutural diastasis ← subjacent dural metastases
√ hair-on-end appearance of skull
(3) Proptosis
(4) Bone pain

› **Pepper syndrome**
(1) Primary adrenal neuroblastoma
(2) Massive hepatomegaly from metastases

› **Blueberry muffin syndrome**

(1) Primary adrenal neuroblastoma
(2) Multiple metastatic skin lesions

◊ Bone marrow aspirate is positive in 50–70% at time of initial diagnosis!
◊ ⅔ of patients > 2 years have disseminated disease!

MR (modality of choice):
√ focal T2-hyperintense areas
√ enhancing lesions on fat-suppressed T1WI

@ Skeletal metastases:
• paraplegia / extremity weakness ← spinal canal extension
√ periosteal new-bone formation
√ osteolytic focus / multicentric lytic lesions
√ "black eyes / raccoon" sign ← metastasis to both lateral orbital walls (common)
√ lucent horizontal metaphyseal line
√ vertical linear radiolucent streaks in metadiaphysis of long bones
√ pathologic fracture
√ vertebral collapse
√ sclerotic lesions ← healing
DDx: Ewing sarcoma, rhabdomyosarcoma, leukemia, lymphoma

@ Intracranial + maxillofacial metastases:
Site: dura, brain substance

@ Orbital metastasis (20–55%):
• periorbital ecchymosis ("raccoon eyes"); bilateral in ½
• periorbital swelling, subconjunctival hemorrhage, ocular mobility disturbance, strabismus
• atrophy of the optic head
√ uni- / bilateral proptosis
√ soft-tissue mass originating in diploic space of bony orbit with extension beyond inner + outer tables
√ high attenuation relative to muscle with small calcific foci
√ tumor hypointense to muscle on T1WI
√ slightly hyperintense to muscle on T2WI
√ avid heterogeneous contrast enhancement
√ no tumor extension into preseptal soft tissues
DDx: rhabdomyosarcoma

@ Pulmonary metastases:
√ nodular infiltrates
√ rib erosion
√ mediastinal + retrocrural lymphadenopathy (common)

@ Mesenteric / peritoneal metastases:
√ spread through subperitoneal space (common)
√ peritoneal metastases typically not calcified

Location: anywhere within sympathetic neural chain

@ Abdomen (70%):
(a) adrenal (36–67%): almost always unilateral

(b) both adrenals (7–10%)
(c) extraadrenal in sympathetic chain (18%)

@ Thorax + posterior mediastinum (20%): aortic bodies
@ Neck (5%): carotid ganglia
@ Pelvis (2–3%): organ of Zuckerkandl
@ Skull, olfactory bulb, cerebellum, cerebrum (2%)
@ Other sites (10%): eg, intrarenal (very rare)
@ Unknown (10%)

Clue: large calcified retroperitoneal mass encircling the aorta with extension into neural foramina

√ large suprarenal mass with irregular shape + margins (82%):
√ displacement of kidney
√ inseparable from kidney ± invasion of kidney (10–32%) along the vascular pathways
√ propensity for extension into spinal canal through neural foramen with erosion of pedicles (15%)
√ extension across midline (55%) (DDx: Wilms tumor)
√ stippled / coarse amorphous calcifications (frequent)
√ retroperitoneal adenopathy / contiguous extension (73%)
√ retrocrural adenopathy (27%)
√ encasement of IVC + aorta, celiac axis, SMA (32%):

N.B.: caval involvement = indicator of unresectability

√ liver metastases (18–66%); invasion of liver (5%)

IVP:
√ "drooping lily" sign = displacement of kidney inferolaterally without distortion of collecting system
√ hydronephrosis (24%)
√ calcifications in 36–50% on KUB

CT:
√ heterogeneous texture with low-density areas ← hemorrhage + necrosis (55%)
√ calcifications in up to 85%
√ variable contrast enhancement

MR (most sensitive modality ← high soft-tissue contrast):
√ hyperintense heterogeneous mass on T2WI
√ enhancing heterogeneous low SI on T1WI
√ areas of high SI on T1WI ← intratumoral hemorrhage
√ areas of high SI on T2WI ← cystic changes

Angio:
√ hypo- / hypervascular mass

US:
√ hyperechoic poorly defined mass with acoustic shadowing (calcifications):
√ hypoechoic areas of heterogeneous texture ← hemorrhage / necrosis

OB-US:

Time of Dx: 1st identified in 3rd trimester (earliest at 20 weeks GA); usually at 36 weeks GA

• (occasionally) maternal hypertension + preeclampsia ← fetal catecholamines reaching maternal circulation

Location: right suprarenal; adrenal÷extraadrenal = 9÷1 (compared to 3.5÷6.5 in pediatric age group)

√ cystic (50%) / mixed cystic + solid / solid adrenal mass

√ may exhibit acoustic shadowing (calcifications)

√ displacement of adjacent kidney inferiorly + laterally

√ hydrops fetalis ← severe anemia ← metastases to bone marrow, mechanical compression of IVC, hypersecretion of aldosterone

√ polyhydramnios

Prognosis: 90–96% survival rate (better than for neonates)

NUC (bone scan sensitivity better than radiography):

√ increased radiotracer uptake on bone scan (60%):

√ purely lytic lesions may present as photopenic areas

CAVE: symmetric lytic neuroblastoma metastases occur frequently in metaphyseal areas where normal epiphyseal activity obscures lesions

√ soft-tissue uptake of ^{99m}Tc-phosphate in 60%

√ frequently 67Ga uptake in primary site of neuroblastoma

√ focal uptake of ^{131}I- / ^{123}I-MIBG radioactivity (82% sensitive; 88% specific) → method of choice

PET-CT (sensitive + specific)

Prognosis:

› 2-year survival rate versus age at presentation:

60% if patient's age < 1 year

20% if patient's age 1–2 years

10% if patient's age > 2 years

◊ May revert to benign ganglioneuroma in 0.2%!

› Survival rate versus stage:

80% for stage I

60% for stage II

30% for stage III

7% for stage IV

75–87% for stage IVs

DDx: adrenal hemorrhage, exophytic Wilms tumor, mesoblastic nephroma, multicystic kidney, retroperitoneal teratoma, infradiaphragmatic extralobar sequestration, hepatic hamartoma / hemangioma, splenic cyst

NEUROGENIC BLADDER

Neuroanatomy: bladder innervation of detrusor muscle by parasympathetic nerves S2–S4

Etiology: congenital (myelomeningocele); trauma; neoplasm (spinal, CNS); infection (herpes, polio); inflammation (multiple sclerosis, syrinx); systemic disorder (diabetes, pernicious anemia)

A. SPASTIC BLADDER

"upper motor neuron" lesion above conus

B. ATONIC BLADDER

"lower motor neuron lesion" below conus

ORCHITIS

Etiology:

(a) bacterial infection ascending from bladder associated with epididymitis

(b) viral infection

› complication of **mumps** in 20–35%:

Age: adolescents + young adults

Time of onset: usually within 3–5 days of infection

√ unilateral (bilateral) orchitis in 90% (10%);

√ parotitis precedes orchitis in 84%, simultaneous in 3%, later in 4%; without parotitis in 10%

› Coxsackie virus

Location: diffuse / focal

√ increased testicular blood flow

√ ± diffuse enlargement of testis

√ ± reactive hydrocele + thickening of scrotal wall

√ decreased testicular echogenicity

MR:

√ heterogeneously decreased SI on T1WI

√ increased SI on T2WI

√ avid homogeneous enhancement

Cx: ischemia ← increased intratesticular pressure; pyocele; testicular rupture

Focal Orchitis

Cause: usually epididymitis

√ ill-defined hypoechoic lesion of crescent / amorphous shape

√ peripheral adjacent to abnormal epididymis

√ increased / no color Doppler flow

DDx: neoplasm (mimicked by focal orchitis)

Granulomatous Orchitis

(a) TB, syphilis, fungi, parasites

√ tendency to involve epididymis first

(b) sarcoidosis (genital tract affected in 5%)

√ multiple hypo- / hyperechoic masses within testis / epididymis

Diffuse Orchitis

DDx: leukemia, lymphoma

OSSIFYING RENAL TUMOR OF INFANCY

= extremely rare benign renal mass originating from urothelium

Prevalence: only 11 cases in literature

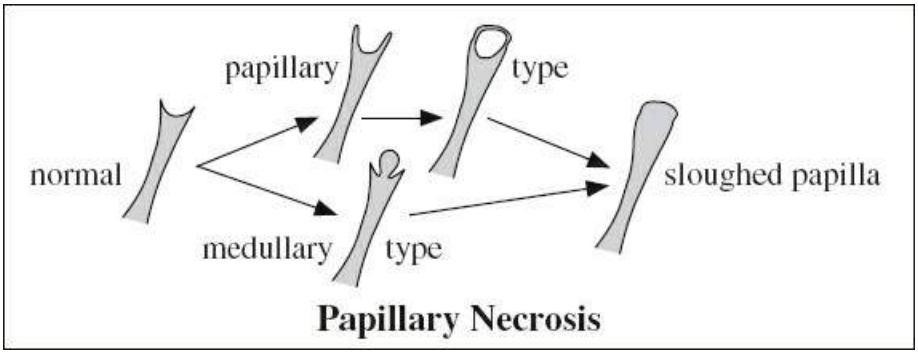
Age: 6 days–14 months; M > F

Histo: osteoid core, osteoblasts, spindle cells

• hematuria
Location: L > R kidney; attached to renal papilla
Site: upper pole
√ 2–3-cm polypoid mass:
  √ calcified (in 80%) resembling a staghorn calculus
  √ filling defect of collecting system
  √ partial obstruction of collecting system
√ echogenic mass + shadowing
√ poor enhancement on CT
Rx: nephron-sparing resection curative
DDx: staghorn calculus

PAGE KIDNEY

= renin-angiotensin–mediated hypertension ← constrictive ischemic nephropathy (= reduction of blood flow to kidney) ← renal compression in a perinephric / subcapsular location
Etiology: (1) Spontaneous hematoma (most common)
(2) Blunt trauma with chronic contained subcapsular hematoma / perirenal scarring
(3) Cyst
(4) Tumor
√ (compressive) subcapsular fluid collection:
  √ indentation / flattening of renal margin
  √ distortion of renal contour + thinning of renal parenchyma
√ kidney surrounded by fibrotic band ± calcification
√ stretching + splaying of intrarenal vessels
√ enlarged + displaced capsular artery
√ delayed nephrogram



√ slow arterial washout
√ elevated resistive index at spectral Doppler
√ globally decreased renal function at perfusion scintigraphy

PAPILLARY NECROSIS

= NECROTIZING PAPILLITIS

= ischemic coagulative necrosis of renal papilla (loops of Henle + vasa recta) ← interstitial nephritis (interstitial edema) or intrinsic vascular obstruction

Cause:

mnemonic: POSTCARD

Pyelonephritis
Obstructive uropathy
Sickle cell disease
Tuberculosis, **T**rauma
Cirrhosis = alcoholism, **C**oagulopathy
Analgesic nephropathy
Renal vein thrombosis
Diabetes mellitus (50%)

also: nonsteroidal anti-inflammatory drugs (NSAID), dehydration, severe infantile diarrhea, hemophilia, Christmas disease, acute tubular necrosis, transplant rejection, postpartum state, high-dose urography, intravesical instillation of formalin, thyroid cancer

Types:

1. Necrosis in situ = necrotic papilla detaches but remains unextruded within its bed
2. Medullary type (partial papillary slough) = single irregular cavity located concentric / eccentric in papilla with long axis paralleling the long axis of the papilla + communicating with calyx
   √ central necrosis at tip of pyramid
3. Papillary type (total papillary slough)
   √ detachment of papilla begins in caliceal fornix

Phases:

(1) Enlargement of papilla (papillary swelling)
(2) Fine projections of contrast material alongside papilla (tract formation)
(3) Medullary cavitation / complete slough of papilla

- flank pain, dysuria, fever, chills, ureteral colic, hypertension
- acute oliguric renal failure
- proteinuria, pyuria, hematuria, leukocytosis

Location: (a) localized / diffuse
(b) bilateral distribution: systemic cause
(c) unilateral: obstruction, renal vein thrombosis, acute bacterial nephritis

√ normal or small kidney ← analgesic nephropathy
√ large kidney ← acute fulminant disease
√ smooth / wavy renal contour ← analgesic nephropathy)
√ calcification of necrotic papilla: papillary / curvilinear / ringlike

IVP:

√ multiple small collections of contrast material in papilla:
√ "lobster claw" sign = subtle streak of contrast material extending from fornix parallel to long axis of papilla
√ centric / eccentric, thin and short / bulbous cavitation of papilla
√ displaced collecting system ← enlarged septal cortex ← edema

√ necrosis of entire papilla:
√ widened fornix ← necrotic shrinkage of papilla
√ "signet ring" sign = ring shadow of papilla → outlining detached papilla within contrast material-filled cavity
√ club-shaped / saccular calyx ← sloughed papilla
√ intraluminal nonopaque filling defect in calyx / pelvis / ureter ← expelled sloughed papilla
√ loss of renal function:
√ diminished density of contrast material in nephrogram; rarely increasingly dense
√ wasted parenchymal thickness

US:
√ multiple round / triangular cystic spaces in medulla with echo reflections of arcuate arteries at periphery of cystic spaces

Cx: acute ureteral obstruction after sloughing of papilla; higher incidence of transitional cell carcinoma in analgesic abusers (8 x); higher incidence of squamous cell carcinoma

DDx: (1) Postobstructive renal atrophy
(2) Congenital megacalices (normal renal function)
(3) Hydronephrosis (dilated infundibula, blunting of all calices)
(4) Parapelvic cyst
(5) Caliceal diverticulum (adjacent to fornix / infundibulum)

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

= rare acquired disorder of nonmalignant hematopoietic stem cells

Cause: infection, transfusion, radiographic contrast material, exercise, drugs, immunization, surgery

Pathophysiology:
destruction of abnormally sensitive RBCs + granulocytes + platelets by activated complement; complement activation of abnormal platelets + release of thrombogenic material from lysed RBCs

- increased susceptibility to infections
- intravascular hemolysis:
  - hemoglobinuria, pancytopenia / aplasia
  - chronic iron deficiency anemia
- venous thrombosis in uncommon sites:
  - acute (tubulointerstitial nephritis) / chronic renal failure (small vessel thrombosis)
  - cerebral vein thrombosis
  - thrombosis of mesenteric vein + splenic vein + portal vein
  - hepatic vein thrombosis (= Budd-Chiari syndrome) involving tertiary + secondary venous radicles

MR:
√ low SI of renal cortex on T1WI + T2WI ← hemosiderin deposition ← free hemoglobin is filtered across renal glomeruli + reabsorbed by proximal convoluted tubular cells ← intravascular hemolysis
√ usually decreased iron concentration in liver + spleen unless transfusions were given (DDx

to other hemolytic anemias)

Prognosis: venous thrombosis is a major cause of death

PELVIC LIPOMATOSIS & FIBROLIPOMATOSIS

= nonmalignant overgrowth of adipose tissue with minimal fibrotic + inflammatory components compressing soft-tissue structures within pelvis

Prevalence: 0.6÷100,000 to 1.7÷100,000

Cause: unknown; ? UTIs, obesity, endocrine dysfunction

Mean age: 48 (range, 9–80) years; M÷F = 10÷1 to 18÷1; racial predilection for blacks (67%); obesity NOT contributing factor

Path: unencapsulated mature homogeneous white fat separated by thin fibrous septa

- often incidental finding
- urinary tract symptoms (50%): frequency, dysuria, nocturia, urgency, hematuria, sensation of incomplete emptying, suprapubic tenderness, recurrent urinary tract infections
- GI symptoms (20%): constipation, nausea, vomiting, tenesmus, rectal bleeding, ribbonlike stools with mucus
- generalized symptoms: lower abdominal pain, low back pain, flank pain, fever
- edema of lower extremities

@ GU tract
- √ elongation + elevation of urinary bladder with symmetric inverted pear shape / teardrop
- √ elongation of posterior urethra
- √ medial / lateral displacement of lower ureters
- √ pelvic lucency (CT confirmatory)

@ GI tract
- √ straightening + elongation + narrowing of rectum
- √ stretching + elevation of rectosigmoid and sigmoid colon out of pelvis
- √ increase in sacrorectal space > 10 mm

@ Vessels
- √ stretching + thinning of femoral veins

Cx of fibrolipomatosis:

(1) Ureteral obstruction with hydroureteronephrosis (40% within 5 years)
(2) IVC obstruction + deep vein thrombosis
(3) Ureteral calculi
(4) Hypertension

Rx: urinary diversion (39%) to prevent end stage renal disease; screening for proliferative bladder lesions

PENILE CARCINOMA

Prevalence: 0.4% of all male malignancies in US; 1% in Western countries; 10–20% of all malignancies in Asian, African, South American males

Cause: uncircumcised men (smegma ← poor hygiene ← presence of foreskin / phimosis); chronic inflammation (balano-posthitis, lichen sclerosus et atrophicus); human papilloma virus 16 & 18; psoralen / ultraviolet A photochemotherapy for psoriasis treatment

Histo: squamous cell carcinoma (95%), sarcoma (epitheloid ~, Kaposi ~, leiomyo~, rhabdomyo~), melanoma, basal cell carcinoma, lymphoma

Age: 6th and 7th decade; < 25% are less than 40 years of age

• palpable inguinal nodes (30–60% of SCC): ½ reactive, ½ metastatic

Location: glans (48%) > prepuce (21%) > glans + prepuce (9%) > coronal sulcus (6%) > shaft (2%)

Spread: (a) superficial inguinal nodes ← skin + prepuce

(b) deep inguinal + external iliac nodes ← glans

(c) internal iliac nodes ← erectile tissue + penile urethra

› Nodal disease in 20% of T1 + in 47–66% of T2–T4 tumors

› Nodal disease in 42% of superficial spreading SCC

› Nodal disease in 82% of deep vertical growth

MR:

√ solitary ill-defined infiltrating tumor:

√ hypointense relative to corpora on T1WI + T2WI

√ enhancement with Gd (less than corpora)

MRI can assess (1) extent of penile cancer, (2) depth of invasion into corpora cavernosa ± urethra, (3) involvement of inguinal + pelvic lymph nodes.

Rx: circumcision, partial / total penectomy ± inguinal lymphadenectomy; radiation therapy

PENILE FIBROMATOSIS

= PEYRONIE DISEASE = INDURATIO PENIS PLASTICA

[François Gigot de La Peyronie (1678–1747), chief of surgery at the Hôtel-Dieu in Paris and Montpellier, surgeon to King Louis XI]

= benign acquired condition characterized by chronic inflammation → fibrosis + focal thickening of tunica albuginea

Prevalence: 3%

Age: 40–60 years

Cause: ? aberrant healing response to minor penile trauma

Associated with: palmar fibromatosis (Dupuytren contracture) in 16–20%, plantar fibromatosis, Paget disease of bone, diabetes mellitus, gout

• abnormal penile curvature during erection → erectile dysfunction; painful penile induration

• palpable albugineal plaques along corpora cavernosa

Site: dorsal > ventral > lateral aspect of penis, intercorporeal septum

US (68% sensitive):

√ focal hyperechoic thickening of tunica albuginea with shadowing ← calcification

√ focal nonshadowing echogenic thickening of tunica

√ nodular echogenic thickening of intercorporeal septum

√ iso- / hypoechoic plaques (rare)

MR (61% sensitive):

√ hypointense focal thickening of tunica on T1WI + T2WI

√ enhancement during active inflammation

DDx: (1) Congenital penile curvature

(2) Dorsal vein thrombosis

(3) **Penile calciphylaxis** = acute life-threatening condition in end-stage renal disease with occlusion of arterial flow to penis

(4) Penile fibrosis ← prolonged priapism, trauma, removal of penile prosthesis, intracavernosal injections for erectile dysfunction

(5) Penile malignancy

PENILE FRACTURE

= tear in tunica albuginea → rupture of corpus cavernosum

Associated with: urethral injury (in 10–20%)
- blood at urethral meatus

Cause: blunt / penetrating (rare) trauma; powerful lateral motions of the erect penis (frequently during sexual intercourse)

Age: younger man; often related to sports

- excruciating pain, bruising, rapid detumescence

US (difficult in identifying site + extent of tunica albuginea involvement)

Hereditary Syndromes Associated with Pheochromocytoma

Syndrome	*Risk of Tumor [%]*	*Mutated Gene*
Multiple endocrine neoplasia	50	RET
Neurofibromatosis 1	1	NF1
von Hippel-Lindau disease	10–20	VHL
Familial paraganglioma syndrome	~ 20	SDHB, SDHC, SDHD*

* SDH = succinate dehydrogenase (SDH) subunits B, C, or D

MR:

√ focal disruption of T1- and T2-hypointense tunica albuginea

√ adjacent T2-hyperintense hematoma

◊ With a scrotal hematoma / hematocele the radiologist should be vigilant in looking for associated penile / testicular injury.

DDx: penile contusion (focal area of hypointensity in a normally T2-bright corpus cavernosum)

PHEOCHROMOCYTOMA

= ADRENAL MEDULLARY PARAGANGLIOMA

= rare catecholamine-secreting tumor of chromaffin tissue; responsible for 0.1–0.9% of hypertensive individuals

Prevalence: 0.13% in autopsy series; increasing occurrence of incidentalomas by cross-sectional imaging

Incidence: 2–8÷1,000,000 annually

Origin: neuroectodermal tissue

Path: well-circumscribed 3–5 cm mass with central degenerative changes of fibrosis / cystic

change; larger lesions are often hemorrhagic / cystic

Histo: chromaffin tumor cells contain chromogranin within secretory granule forming CHARACTERISTIC clusters of tumor cells = "**Zellballen**"; architectural patterns are
(a) combination of alveolar + trabecular (36%)
(b) predominantly alveolar = nesting (35%)
(c) predominantly trabecular (27%)

Age: 5% in childhood

N.B.: Any physical contact can precipitate cardiac arrhythmia + malignant hypertension

• symptomatology ← excess catecholamine production (norepinephrine > epinephrine):
  • asymptomatic (9–10%)
  • headaches, sweating, flushing, palpitations, tachycardia, anxiety, tremor, nausea, vomiting, abdominal pain, chest pain
  • paroxysmal (47–53%) / sustained (37%) hypertension
    (a) elevated catecholamine
    (b) functional renal vasoconstriction
    (c) renal artery stenosis: fibrosis, intimal proliferation, tumor encasement
  • hypoglycemia during hypertensive crisis

Dx (biochemical confirmation):
  • plasma metanephrine level > 1.1 nmol/L
  • plasma normetanephrine concentration > 2.2 nmol/L
  • elevated urine vanillylmandelic acid (VMA) in 54%; in up to 22% false-negative result because VMA is not excreted

Associated heritable conditions (in 10–25%):

√ usually with bilateral pheochromocytomas + extraadrenal sympathetic and parasympathetic paragangliomas

(1) Multiple endocrine neoplasia (MEN):
  ◊ malignant transformation in 5–10%
  √ pheochromocytoma small + asymptomatic in 50%

(2) Neuroectodermal disorder
  (a) neurofibromatosis type 1 (in 0.1–5.7%)
  (b) Von Hippel-Lindau disease
  (c) tuberous sclerosis
  (d) Sturge-Weber syndrome
  ◊ 10% of patients with neurofibromatosis (NF1) / von Hippel-Lindau disease have pheochromocytoma!

(3) Familial paraganglioma syndrome / pheochromocytosis

(4) Carney syndrome

mnemonic: VEIN
Von Hippel-Lindau
Endocrine neoplasia (MEN 2)
Inherited (congenital) pheochromocytoma
Neurofibromatosis (von Recklinghausen disease)

RULE OF TENS ("ten-percent tumor"):
10% bilateral 10% extraadrenal

10% multiple 10% familial / syndromic
10% malignant 10% nonfunctioning

Location: (a) intraabdominal (98%), medulla of adrenal gland (>90%)
(b) extraadrenal paragangliomas of sympathetic nervous system (from base of brain to urinary bladder) including organ of Zuckerkandl, bladder wall, retroperitoneum, heart, mediastinum, glomus jugulare body

Size: mean diameter 5.3 (range, 2.6–11.2) cm
- clinically silent lesions tend to be large
- large lesions are often nonfunctioning

√ discrete round / oval mass:
- √ marked heterogeneity ← degeneration, necrosis, fibrosis, cystic change, intracellular lipid degeneration, calcification
- √ small / large necrotic areas in 90% ± fluid-fluid level
- √ scattered punctate (= speckled) calcifications in 10–29%

The "imaging chameleon" pheochromocytoma should be considered in any adrenal lesion of low-attenuation / avid washout / dominant cystic component!

CT (93–100% sensitive):

Localization: accurate in 91% with tumor > 2 cm in size; up to 40% in extraadrenal location are missed by CT

- √ solid / cystic / complex mass with low-density areas ← hemorrhage / cystic degeneration / necrosis
- √ tumor attenuation of similar density as surrounding soft tissue with a mean of 36 ± 10 HU
- √ may rarely have abundant intracellular fat of < 10 HU
- √ may have macroscopic fat of < 30 HU ← lipid degeneration (DDx: myelolipoma)
- √ ± calcifications

CECT:

Cave: IV injection of iodinated contrast material MAY precipitate a hypertensive crisis in patients not on α-adrenergic blockers! Nonionic low-osmolar IV contrast media are SAFE!

- √ usually avid contrast enhancement ← capillary-rich framework
  - ◊ Absolute enhancement of > 110–120 HU is INDICATIVE of a pheochromocytoma!
- √ variable contrast wash-out patterns, occasionally similar to adrenocortical adenoma:
  - √ relative washout > 40% (in 25% of pheochromocytomas)
  - √ absolute washout > 60% (in 29% of pheochromocytomas)

NUC:

- √ increased uptake with ^{131}I- / ^{123}I-metaiodobenzylguanidine (MIBG = 80–90% sensitive; 98% specific)

Useful:
(a) with clear clinical / laboratory evidence of tumor but no adrenal abnormality on CT / MR
(b) in detecting extraadrenal pheochromocytomas / bilaterality / metastases by whole-body scintigraphy
(c) in diagnosing postoperative recurrence

PET (72–98% sensitive):

√ increased uptake (DDx: metastasis)

US:

√ well-marginated ovoid purely solid (68%) / complex (16%) / cystic tumor (16%)

√ homo- (46%) / heterogeneously (54%) solid tumor: isoechoic + hypoechoic (77%) / hyperechoic (23%) to renal parenchyma

√ heterogeneity introduced by hemorrhage / necrosis

MR (method of choice):

√ iso- / slightly hypointense to liver on T1WI

√ may contain areas of high SI on T1WI ← hemorrhage (20%) / fat

√ hyperintense compared with spleen on T2WI (in 11%) ← intratumoral cystic regions

N.B.: 30% are hypointense + may be confused with malignancy / benign adenoma

√ contains central heterogeneous areas of decreased SI in 35% on T2WI ← necrosis / hemorrhage / calcifications

√ no change in SI between in-phase + opposed-phase T1WI images ← no substantial amount of cytoplasmic lipid

CEMR:

√ rapid marked homo- / inhomogeneous enhancement (not routinely used as it does not increase sensitivity)

√ extremely hyperintense ("light bulb" sign) ← avid enhancement

Angio:

N.B.: intraarterial injection CONTRAINDICATED → may induce hypertensive crisis

√ localization by aortography in > 91%

√ usually hypervascular lesion with intense tumor blush

√ slow washout of contrast material

√ enlarged feeding arteries + neovascularity (= "spoke-wheel" pattern)

√ parasitization from intrarenal perforating branches

√ venous blood sampling (at different levels in IVC)

Cave: indiscriminate biopsy may trigger a catastrophic crisis and must be avoided requiring consultation with endocrine + anesthesia services and appropriate endocrine blockade

Cx: (1) Malignancy in 2–14% with (± hormonally active) metastases to bone, lymph nodes, liver, lung

(2) Spontaneous retroperitoneal hemorrhage → lethal in 50% if tumor previously undiagnosed

◊ Most common cause of spontaneous retroperitoneal hemorrhage from a primary adrenal tumor!

Rx: (1) Surgical removal curative

(2) Alpha-adrenergic blocker (phenoxybenzamine / phentolamine)

(3) Beta-adrenergic blocker (propranolol)

(4) ^{131}I-MIBG used to treat metastases

DDx: nonfunctioning adrenal adenoma, adrenocortical carcinoma, adrenal cyst, metastatic disease

PLASMACYTOMA OF KIDNEY

= group of malignant disorders involving differentiated B lymphocytes or plasma cells

Classification:

A. SOLITARY = PLASMACYTOMA (5%)
B. MULTIPLE = MULTIPLE MYELOMA (95%):
autoptically involves kidney in 17%

Distribution of primary extramedullary plasmacytoma:

(a) skeleton (95%)
(b) nonskeletal sites (5%): upper respiratory tract

• monoclonal immunoglobulin / Bence-Jones proteinuria
√ well-circumscribed mass / infiltrative lesion
DDx: indistinguishable from other renal primaries

POLYCYSTIC KIDNEY DISEASE

Autosomal Dominant Polycystic Kidney Disease

= ADPKD = ADULT POLYCYSTIC KIDNEY DISEASE= Potter type III
[Edith Louise Potter(1901–1993], American pathologist in Chicago]
= characterized by bilaterally enlarged kidneys with multiple expansile cysts along nephron

Prevalence: 1÷500–1,000 live births; affects 300,000–600,000 Americans; 5–10% of dialysis patients
◊ Most common heritable renal disorder!
◊ 3rd most common cause of end-stage renal disease!

Genetics:

hereditary (90%) or spontaneous mutation (10%) of
(a) PKD1 gene located on short arm of chromosome 16p13.3 encoding protein polycystin-1 (85%)
(b) PKD2 gene located on long arm of chromosome 4q13–23 encoding protein polycystin-2 (15%) = milder form of disease with later age of onset

localized in cell membrane of primary cilia of renal tubular epithelial cells → both polycystin proteins interact to form a calcium2+-channel receptor
◊ Genetic testing identifies only 70% of individuals with ADPKD

Pathophysiology:

deranged function of polycystin proteins → ciliary dysfunction → overproliferation of tubular epithelial cells with ↑ tubular fluid secretion → tubular ectasia + cyst formation

Path: cysts form as outpouchings of nephron → become disconnected from nephron early on → continued growth into round (rather than tubular) shape of up to several cm in diameter → compression of tubules and glomeruli

Histo: abnormal rate of tubule divisions (Potter type III) with hypoplasia of portions of tubules left behind as the ureteral bud advances; cystic dilatation of Bowman capsule / loop of Henle / proximal convoluted tubule coexisting with normal tissue

Mean age at diagnosis:

43 years; early clinical manifestations < 15 years of age in 2% (with rare neonatal / infantile onset); M÷F = 1÷1

Onset of cyst formation:

54% (72%) [86%] in 1st decade (2nd decade) [3rd decade]; morphologic evidence in all

patients by age 80

Minimum diagnostic criteria in screening exam for cysts to confirm diagnosis of ADPKD:

15–39 years ≥ 3 uni- / bilateral cysts

40–59 years ≥ 2 cysts in each kidney

> 60 years ≥ 4 cysts in each kidney

Associated with:

(1) Cysts in: liver (40%), pancreas (9%); rare in spleen, arachnoid membrane, lung, thyroid, ovary, uterus, testis, seminal vesicle, epididymis, bladder

(2) Saccular "berry" aneurysm of cerebral arteries (3–15%)

◊ Screening recommended to start at age 20 years

(3) Aortic aneurysm, aortic dissection

(4) Mitral valve abnormalities (26%)

(4) Abdominal wall hernia

(5) Colonic diverticulosis

- usually asymptomatic → symptomatic at mean age of 35 years ← cysts grow with age; disease is slowly progressive with nearly 100% penetrance and great variation in expressivity
- hypertension (50–70%), hematuria, proteinuria
- azotemia ← replacement of renal parenchyma by cysts
- lumbar / abdominal pain

Size of kidney: up to 40 cm in length; up to 8 kg in weight

Renal volume: mean of > 1,000 mL (normal mean = 150 mL) with mean annual increase of 63 mL

◊ Volume measurements by MR may be used to monitor disease progression!

√ enlargement of both kidneys with innumerable cysts of varied size + diffuse distribution

√ cysts may calcify in curvilinear rim- / ringlike irregular amorphous fashion

√ elongated + distorted + attenuated collecting system

√ nodular puddling of contrast material on delayed images

√ "Swiss cheese" nephrogram = multiple lesions of varying size with smooth margins

√ polycystic kidneys shrink after beginning of renal failure, after renal transplantation, or on chronic hemodialysis

√ liver cysts (may be identified without renal involvement):

√ isolated from bile ducts (DDx ARPKD)

√ liver cyst size + number increase with advancing age → liver function preserved

Cx: mass effect, intracyst hemorrhage / infection

NUC: poor renal function on ^{99m}Tc-DTPA scan

√ multiple areas of diminished activity, cortical activity only in areas of functioning cortex

US:

√ multiple cysts in cortical region (usually seen in 50% by 10 years of age)

√ diffusely echogenic when cysts small (children)

√ renal contour poorly demarcated

N.B.: A normal US examination cannot exclude ADPKD until after age 35 years!

In a child with known PKD1 mutation ≥ 3 renal cysts / cyst in liver establishes the

diagnosis!

OB-US:

√ kidneys normal in size / mildly enlarged

√ echogenic kidneys similar to infantile PCKD (usually in 3rd trimester, may be unilateral (earliest sonographic diagnosis at 14 weeks GA):

√ hyperechoic cortex + relatively hypoechoic medulla → increased corticomedullary differentiation

√ ± few macroscopic small round cysts in cortex and medulla (rare)

√ normal amount of amniotic fluid / oligohydramnios ← renal function usually not impaired

Atypical rare presentation:

(a) unilateral adult PCKD

(b) segmental adult PCKD

(c) adult PCKD in utero / neonatal period

Cx:

(1) Death from uremia in late adulthood (59%) / cerebral hemorrhage ← hypertension / ruptured aneurysm (13%) / cardiac complications (mean age 50 years)

◊ NO increased risk of renal cell carcinoma!

About 50% of ADPKD patients will develop end-stage renal disease.

(2) Renal calculi (20%): mostly urate

(3) Cyst infection

(4) Cyst rupture

(5) Cyst hemorrhage (66%):

• common cause of acute flank pain

√ hyperattenuated cyst content on CT

√ calcifications frequent, which may take years

(6) Liver dysfunction (sporadically): hepatomegaly, liver failure, Budd-Chiari syndrome

◊ NO increased risk for renal cell carcinoma unless on prolonged dialysis

DDx:

(1) Multiple simple cysts (less diffuse, no family history)

(2) Glomerulocystic disease

(3) Von Hippel-Lindau disease (cerebellar hemangioblastoma, retinal hemangiomas, occasionally pheochromocytomas)

(4) Acquired uremic cystic disease (kidneys small, no renal function, transplant)

(5) Infantile PCKD (usually microscopic cysts)

Autosomal Recessive Polycystic Kidney Disease

= ARPKD = INFANTILE POLYCYSTIC KIDNEY DISEASE = POLY-CYSTIC DISEASE OF CHILDHOOD = Potter Type I

= most common ciliopathy affecting kidney + liver to varying degrees

Prevalence: 1÷22,000 live births; F = M; carrier frequency of 1÷70

Mean age: 2.5 years (at presentation)

Genetics: mutations in PKHD1 (polycystic kidney hepatic disease 1) gene located on chromosome 6p12 → encodes protein fibrocystin-polyductin localizing to primary cilia of epithelial cells that line renal tubules (collecting ducts) + intrahepatic bile

ducts

Pathogenesis:

symmetric circumferential epithelial proliferation results in tubular lengthening + fusiform dilatation of collecting ducts; abnormal epithelium becomes secretory instead of resorptive; secreted fluid is rich in epithelial growth factors stimulating further epithelial proliferation

Path:

@ Kidney:

numerous nonobstructive fusiform dilated + elongated collecting tubules with radial orientation extending from enlarged medulla into compressed cortex; associated renal interstitial edema + fibrosis; increased separation of a normal number of glomeruli → progressive cystic degeneration into peripheral cortical microcysts of 1–3 mm in diameter with occasional macrocyst

√ spongelike texture of renal parenchyma

• diminished concentrating ability of kidneys, azotemia

@ Liver:

malformation of ductal plate → congenital hepatic fibrosis = irregularly formed ectatic nonobstructive intrahepatic bile ducts increased in number with atypical branching pattern + septa of fibrosed portal tracts → disproportionate enlargement of left lobe

@ Pancreas: pancreatic fibrosis

◊ The greater the percentage of abnormal collecting tubules, the more severe the renal compromise and the earlier the clinical presentation!

◊ The less severe the renal findings, the more severe the hepatic findings!

Blythe & Ockenden classification:

A. PERINATAL FORM (most common)

90% of tubules show cystic changes

• onset of renal failure in utero, Potter sequence

• large palpable flank masses, small thorax, respiratory distress, oliguria in neonate

√ both kidneys enlarged

√ oligohydramnios + dystocia ← large abdominal mass

Prognosis: death from renal failure / respiratory insufficiency (pulmonary hypoplasia) within 24 hours in 75%, within 1 year in 93%; uniformly fatal

B. NEONATAL FORM

60% of tubules show ectasia + minimal hepatic fibrosis + bile duct proliferation

• onset of renal failure within 1st month of life

Prognosis: death from renal failure / hypertension / left ventricular failure within 1st year of life

C. INFANTILE FORM

25% of renal tubules involved + mild / moderate periportal fibrosis

• disease appears by 3–6 months of age

Prognosis: death from chronic renal failure / systemic arterial hypertension / portal hypertension

D. JUVENILE FORM

10% of tubules involved + gross hepatic fibrosis + bile duct proliferation

• disease appears at 6 months to 5 years of age

√ portal hypertension:
- thrombocytopenia ← hypersplenism
- gastroesophageal variceal bleeding

√ hepatosplenomegaly
√ ascites

Prognosis: death from portal hypertension

Radiography
√ abdominal distension
√ gas-filled bowel loops deviated centrally
√ small bell-shaped thorax → severe pulmonary hypoplasia
√ pneumothorax / pneumomediastinum

IVP:
√ bilateral gross smooth renal enlargement
√ faint nephrogram + blotchy opacification on initial images
√ increasingly dense nephrogram
√ poor visualization of collecting system
√ "sunburst nephrogram" = striated nephrogram with persistent radiating opaque streaks (= collecting ducts) on delayed images
√ prominent fetal lobation
√ poor opacification + contrast excretion ← impaired renal function

CT:
√ kidneys of low attenuation ← stagnant urine in dilated collecting ducts
√ prolonged corticomedullary phase
√ striated nephrogram ← contrast material accumulating in dilated collecting ducts

MR:
√ enlarged kidneys darker than normal on T1WI
√ hyperintense renal parenchyma on T2WI:
√ homogeneously T2-bright kidneys
√ multiple rounded 1–2-mm discrete tubular cystic foci
√ large 1–2-cm macrocysts

GU-US:
√ hyperechoic enlarged kidneys ← increased number of acoustic interfaces ← unresolved 1–2-mm cystic / ectatic dilatation of renal tubules
√ increased renal through-transmission ← fluid content of cysts:
√ high-spatial-resolution US may resolve tiny dilated tubular cysts:
√ isolated medullary disease (in 37%)
√ corticomedullary involvement (in 63%)
√ normal renal cortex → ~ normal renal function
√ loss of corticomedullary differentiation → poor visualization of renal sinus + renal borders
√ thin rim of hypoechoic cortex
√ occasionally discrete macrocysts < 1 cm with tendency to become larger + more numerous over time (in older children) resembling adult medullary sponge kidney
√ small bladder

Liver-US:

• portal venous hypertension (5–13 years of age)
√ disproportionate enlargement of left hepatic lobe
√ patchy / diffuse heterogeneously coarse liver echogenicity:
  √ increased echogenicity of portal tracts = echogenic periportal thickening ← fibrosis
√ tubular cystic dilatation of small intrahepatic bile ducts:
  √ "**central dot**" sign = portal vein + hepatic artery branches completely surrounded by dilated intrahepatic bile duct
  √ cysts in continuity with bile ducts
√ dilated extrahepatic bile ducts + elongated hydropic gallbladder (in up to 55%)
√ splenomegaly
√ ascites
√ enlarged splenic v., portal v. + splanchnic collateral veins (gastroesophageal varices, "recanalized" paraumbilical veins, spontaneous splenorenal shunts)
√ increased stiffness on liver elastography ← fibrosis

OB-US (diagnostic as early as 15–17 weeks GA):
• decreased fetal urine output
• Potter facies: low-set + flattened ears, short + snubbed nose, deep eye creases, micrognathia
√ progressive massive renal enlargement (10–20 x larger than normal):
  √ renal÷abdominal circumference ratio > 0.30
√ hyperechoic renal parenchyma = echogenic medulla with relative sparing of cortex
√ nonvisualization of urine in fetal bladder (in severe cases)
√ severe oligohydramnios (33%) by 20 weeks GA → oligohydramnios / Potter sequence
  mnemonic: POTTER
    Pulmonary hypoplasia
    Oligohydramnios
    Twisted wrinkly skin
    Twisted Potter face
    Extremity defects
    Renal agenesis, bilateral
√ small / absent urinary bladder
√ small fetal thorax with pulmonary hypoplasia
√ club foot
√ congenital dislocation of hips

OB management:
(1) Chromosome studies to determine if other malformations present (eg, trisomy 13 / 18)
(2) Option of pregnancy termination < 24 weeks
(3) Nonintervention for fetal distress > 24 weeks if severe oligohydramnios present

Risk of recurrence: 25%

DDx: Meckel-Gruber syndrome, adult polycystic kidney disease (absence of tiny tubular cysts, cysts in parents), nephronophthisis, cystic renal dysplasia (round cysts), tuberous sclerosis (cortical rather than medullary cysts, angiomyolipomas)

POLYORCHIDISM

= SUPERNUMERARY TESTIS
= rare congenital anomaly, in which > 2 testes are present
Cause: developmental accident in union / division of genital ridge + mesonephric ducts ← peritoneal bands
Associated with: maldescent of one supernumerary testis (15–50%), inguinal hernia (30%), hydrocele, epididymitis, varicocele, infertility, cryptorchidism (40%), malignancy
• painless extratesticular scrotal mass
Location: left > right
√ duplication of testis + single epididymis (most common)
√ bridging vessels between supernumerary + normal testis
Cx: torsion (13–15%) ← ↑ mobility of supernumerary testis
Rx: orchiopexy
DDx: splenogonadal fusion

POSTERIOR URETHRAL VALVES

= congenital thick folds of mucous membrane located in posterior urethra (prostatic + membranous) distal to verumontanum
Type I: (most common) mucosal folds (vestiges of wolffian duct) extend anteroinferiorly from the caudal aspect of the verumontanum, often fusing anteriorly at a lower level
Type II: (rare) mucosal folds extend anterosuperiorly from verumontanum toward bladder neck (nonobstructive normal variant, probably a consequence of bladder outlet obstruction)
Type III: diaphragm-like membrane located below the verumontanum = abnormal canalization of urogenital membrane
Prevalence: 1÷5,000 to 1÷8,000 boys; most common cause of urinary tract obstruction + leading cause of end-stage renal disease among boys
Time of discovery: prenatal (8%), neonatal (34%), 1st year (32%), 2nd–16th year (23%), adult (3%)
• urinary tract infection (fever, vomiting) in 36%
• obstructive symptoms in 32% (hesitancy, straining, dribbling [20%], enuresis [20%]); failure to thrive (13%)
• palpable kidneys / bladder in neonate (21%), hematuria (5%)
VCUG:
√ vesicoureteral reflux, mainly on left side (in 33%)
√ fusiform distension + elongation of proximal posterior urethra persisting throughout voiding
√ transverse / curvilinear filling defect in posterior urethra
√ diminution of urethral caliber distal to severe obstruction
√ hypertrophy of bladder neck
√ trabeculation + sacculation of bladder wall
√ large postvoid bladder residual
US:
√ male gender
√ oligohydramnios (related to severity + duration of obstruction)
√ hypoplastic / multicystic dysplastic kidney (if early occurrence)

√ bilateral hydroureteronephrosis → pulmonary hypoplasia
√ dilated renal pelvis may be absent in renal dysplasia / rupture of bladder / pelviureteral atresia
√ overdistended urinary bladder (= megacystis) in 30%
√ thick-walled urinary bladder + trabeculations (best seen after decompression)
√ urine leak: urinoma, urine ascites, urothorax
√ "pear / keyhole" bladder = thick-walled bladder + dilated posterior urethra (on perineal scan)
√ dilated utricle (perineal scan)

OB management:
(1) Induction of labor as soon as fetal lung maturity established (if diagnosed during last 10 weeks of pregnancy)
(2) Vesicoamniotic shunting may be contemplated if diagnosed remote from term (68% survivors) with good prognostic parameters of fetal urinary sodium < 100 mEq/dL + chloride < 90 mEq/dL + osmolality < 210 mOsm/dL

Cx: (1) Neonatal urine leak: ascites, urothorax, urinoma (13%)
(2) Neonatal pneumothorax / pneumomediastinum (in 9%)
(3) Prune belly syndrome
(4) Renal dysplasia (if obstruction occurs early during gestation)

Prognosis: depends upon duration of obstruction prior to corrective surgery; poor prognosis if associated with vesicoureteral reflux; nephrectomy for irreversible damage (13%)

DDx: (1) UPJ obstruction
(2) UVJ obstruction
(3) Primary megaureter
(4) Massive vesicoureteral reflux
(5) Megacystis-microcolon-intestinal hypoperistalsis syndrome

POSTINFLAMMATORY RENAL ATROPHY

= acute bacterial nephritis with irreversible ischemia as unusual form of severe gram-negative bacterial infection in patients with altered host resistance in spite of proper antibiotic treatment

Histo: occlusion of interlobar arteries / vasospasm
√ small smooth kidney
√ papillary necrosis in acute phase

POSTOBSTRUCTIVE RENAL ATROPHY

= generalized papillary atrophy usually following successful surgical correction of urinary tract obstruction and progressing in spite of relief of obstruction
√ small smooth kidney, usually unilateral
√ dilated calices with effaced papillae
√ thinned cortex

PRIAPISM

= prolonged penile erection not associated with sexual arousal
[*Priapus* , Greek mythology = god of fertility]
Types:
(1) LOW-FLOW / ischemic / venoocclusive form (common): characterized by ischemia, venous stasis, pooling of blood within corpora cavernosa
Cause: intracavernosal injection of vasoactive agent (papaverine, prostaglandin), sickle cell disease, hematopoietic malignancy, hypercoagulable state
◊ SURGICAL EMERGENCY!
• painful erection
• corporeal aspiration of nonoxygenated blood (with low oxygen tension in blood gas analysis)
√ sluggish flow / blood stasis in corpora cavernosa:
√ sedimentation of blood with fluid-fluid level
√ decreased venous outflow
√ decreased arterial inflow
√ intracavernosal thrombosis
Rx: cavernosal aspiration + irrigation, cavernosal injection of α-adrenergic receptor agonists (phenylephrine), anticoagulation, shunt procedure
Cx: cavernosal tissue fibrosis → permanent erectile dysfunction (in 50% in spite of Rx)
(2) HIGH-FLOW / arterial / nonischemic form (rare):
characterized by unregulated arterial inflow of blood into corpora cavernosa ← usually arterial injury
Cause: perineal / penile trauma
• subsequent persistent painless erection
• corporeal aspiration of oxygenated blood (with high oxygen tension in blood gas analysis)
Color Doppler US:
√ high blood flow in cavernosal artery
√ focal blush of abnormal intracavernosal flow adjacent to cavernosal artery from arterial-sinusoidal fistula / pseudoaneurysm
Rx: percutaneous transcatheter embolization; arterial ligation

PROSTATE CANCER

Incidence:
doubles with each decade after age 50; 129÷100,000 new cases annually in USA (2012); 3rd most common new malignancy in USA in 2016 (after female breast cancer + lung cancer); in 35% of men > 45 years of age (autopsies)
◊ 14% of males will develop prostate cancer (= lifetime risk)!
Racial factors: White > Black > Hispanic > Asian
Risk factors: advancing age, presence of testes, cadmium exposure, animal fat intake; ≥ 1 first-degree relative
Histo: adenocarcinoma (common); rare cancers: transitional cell cancer, adenoid cystic cancer, endometrioid neoplasm of verumontanum, carcinosarcoma, sarcoma, lymphoma
Histo for adenocarcinoma:

nuclear anaplasia + large nucleoli in secretory cells, disturbed architecture, invasive growth

Premalignant change:

(1) Prostatic intraepithelial neoplasia (**PIN**)
= premalignant lesion frequently associated with invasive carcinoma next to it / elsewhere in the gland

(2) Atypical adenomatous hyperplasia = proliferation of newly formed small acini

Grading (**Gleason score** 2–10):

1,2,3	glands surrounded by 1 row of epithelial cells
4	absence of complete gland formation
5	sheets of malignant cells

low numbers refer to well-differentiated, high numbers to anaplastic tumors; primary predominant grade (1–5) is added to secondary less representative area with highest degree of dedifferentiation (1–5)

◊ Gleason grading is in only 80% reproducible!

◊ Gleason grade ≥ 7 has worse prognosis

- Clinical categories:
  1. **Latent carcinoma** = usually discovered at autopsy of a patient without signs or symptoms referable to the prostate (26–73%)
  2. **Incidental carcinoma** = discovered in 6–20% of specimens obtained during transurethral resection for clinically benign prostatic hyperplasia
  3. **Occult carcinoma** = found at biopsy of metastatically involved bone lesion / lymph node in a patient without symptoms of prostatic disease
  4. **Clinical carcinoma** = cancer detected by digital rectal examination based on induration / irregularity / nodule
     - digital rectal exam is 30–60% accurate for differentiating stage B from stage C disease
- elevated **P**rostate-**S**pecific **A**ntigen (**PSA**)
  (= glycoprotein produced by prostatic epithelium) is measured by a monoclonal radioimmunoassay (Hybritech®, most commonly used: normal value of 0.1–4 ng/mL)

  ◊ 19–30% of prostate cancers have normal PSA!

  ◊ Cancers of < 1 mL usually do not elevate PSA!

  Confined disease (stage B and less) & PSA level:

  75% of patients with PSA of < 4 ng/mL

  53% of patients with PSA of 4–10 ng/mL

  2% of patients with PSA of > 30 ng/mL

  ◊ 16% of normal men have PSA > 4 ng/mL

  ◊ Benign conditions with PSA elevation: benign prostatic hypertrophy, acute urinary retention, acute prostatitis, prostatic intraepithelial neoplasia (PIN)
  - ↓ free-to-total PSA ratio:
    < 15% is highly suggestive of cancer,
    < 25% detects 95% of detectable cancers
  - ↑ **PSA density**
    = volume corrected PSA level [= prostate volume (height x width x length x 0.523) / PSA value]:
    > 0.12 (90% sensitive, 51% specific for cancer)

◊ Each gram of malignant prostate tissue produces 3.5 ng/mL PSA versus 0.3 ng/mL PSA for BPH!

- ↑ **PSA velocity** = serial PSA evaluation
  > 0.75 ng x mL-1 x yr-1

Staging of Prostate Cancer *American Joint Committee on Cancer*		
T0		No evidence of primary tumor
T1		Clinically inapparent nonpalpable nonvisible tumor
	T1a	< 3 microscopic foci of cancer / ≤ 5% of resected tissue
	T1b	> 3 microscopic foci of cancer / > 5% of resected tissue
	T1c	tumor diagnosed by needle biopsy
T2		Tumor clinically present + confined to prostate
	T2a	tumor ≤ 1.5 cm, < ½ of one lobe
	T2b	tumor > 1.5 cm / > ½ of one lobe (unilateral)
	T2c	tumor involves both lobes (bilateral)
T3		Extension through prostatic capsule
	T3a	unilateral
	T3b	bilateral
	T3c	invasion of seminal vesicles
T4		Tumor fixed / invading adjacent structures other than seminal vesicles
	T4a	invasion of bladder neck, external sphincter, rectum
	T4b	invasion of levator ani muscle and/or fixed to pelvic wall
N		Involvement of regional lymph nodes
	N1	metastasis in a single node ≤ 2 cm
	N2	metastasis in a single node > 2 and < 5 cm / multiple lymph nodes affected
	N3	metastasis in a lymph node ≥ 5 cm
M		Distant metastasis
	M1a	nonregional lymph nodes
	M1b	bone
M1c		other site ± bone

Staging of Prostate Cancer *American Urological Association System* *(modified Jewitt-Whitmore Staging System)*	
A	No palpable lesion
A_1	focal well-differentiated tumor < 1.5 cm
A_2	diffuse poorly differentiated tumor; > 5% of chips from TURP contain cancer
B	Palpable tumor confined to prostate
B_1	lesion < 1.5 cm in diameter confined to one lobe
B_2	tumor ≥ 1.5 cm / involving more than one lobe
C	Localized tumor with capsular involvement
C_1	capsular invasion
C_2	capsular penetration
C_3	seminal vesicle involvement
D	Distant metastasis
D_1	involvement of pelvic lymph nodes
D_2	distant nodes involved
D_3	metastases to bone / soft tissues / organs

Staging:

- ◊ At initial presentation > 75% have stage C + D!
- ◊ 40% of patient believed to have organ-confined disease have extraprostatic disease at radical prostatectomy

Benign Conditions Mimicking Prostate Cancer at MRI	
Condition	*Histologic & Anatomic Features*
Normal anatomy	
Anterior fibromuscular stroma	dense fibromuscular band anterior to transition zone
Surgical capsule	band of fibromuscular + compressed glandular tissue between transition + peripheral zone
Central zone	complex crowded glands + dense stroma surrounding ejaculatory ducts
Periprostatic vein	venous plexus closely associated with pseudocapsule
Periprostatic lymph nodes	Lnn adjacent to lateral / posterolateral prostate
Benign pathology	
Stroma-rich BPH	stromal fibromuscular proliferation in transition zone (rarely in peripheral zone)
Bacterial prostatitis	inflammatory infiltrate (neutrophils + lymphocytes) ± glandular atrophy
Mycobacterial granulomatous prostatitis	granulomatous inflammation ± central caseation
Malakoplakia	granulomatous inflammation + Michaelis-Gutman bodies
Atrophy	crowded glands with scan cytoplasm + nuclear crowding
Necrosis	coagulative necrosis + surrounding inflammatory infiltrate
Calcification	concreted prostatic secretions / calcified corpora amylacea

Escape routes through prostatic capsule are:

(1) Capsular margin at neurovascular bundle posterolaterally (80%) ← intrinsic weakness of capsule at this location

(2) Apex

(3) Seminal vesicles!

Staging accuracy for local [advanced] disease:

46 [66%] for US, 57 [77%] for MR

◊ Extracapsular disease is common at > 3.8 cm^3 tumor volume!

Metastases to lymph nodes:

0% (3–7%) [5%] {10–12%} in stage A1 (A2) [B1] {B2}; 54–57% in stage C; 10% [70–93%] with Gleason grade ≤ 5 [9 / 10]

√ size > 10 mm (25–78% sensitive, 77–98% specific)

√ MR-enhancement with ultrasmall superparamagnetic iron oxide particles (USPIO) for nodal mapping is superior

Predictors for bone metastases:

- PSA > 20; Gleason score of 8–10
- clinical stage of > T3; bone symptoms

Location of cancer: peripheral zone (70%), transition zone (20%), central zone (10%); multifocal in 40%

MR imaging findings suggestive of transition zone cancer:
√ homogeneous low T2 signal intensity ("erased charcoal sign") + ill-defined margins + lack of capsule + lenticular shape + invasion of anterior fibromuscular stroma

US (21% positive predictive value):
√ hypoechoic (61%) / mixed (2%) / hyperechoic (2%) lesion; undetectable isoechoic lesion (35%)
√ asymmetric enlargement of gland
√ deformed contour of prostate = "irregular bulge" sign (75% PPV)
√ heterogeneous texture

Size versus rate of detection:
≤ 5 mm (36%), 6–10 mm (65%), 11–15 mm (53%), 16–20 mm (84%), 21–25 mm (92%), ≥ 26 mm (75%)

MR (useful for targeted biopsy):
√ low-signal abnormality within the normally high-signal glandular tissue of the peripheral zone on T2WI
√ tumor isointense relative to surrounding gland on T1WI
√ extracapsular extension (90% specific, 15% sensitive):
√ direct tumor extension beyond prostate
√ decreased SI in periprostatic fat adjacent to capsule near tumor on T1WI + T2WI (capsule optimally depicted on T1WI ← demarcation by periprostatic fat of high SI)
√ capsular thickening
√ irregular focal bulge in contour of capsule near tumor (24–38% sensitive, 77–88% specific)
√ angulated glandular contour
√ irregular spiculated margin
√ flattening / obliteration of rectoprostatic angle (24–50% sensitive, 81–95% specific)
√ asymmetry of neurovascular bundle (21–38% sensitive, 81–95% specific)
√ tumor enveloping neurovascular bundle
√ low-signal lesion on T2WI within seminal vesicles that are normally of high-SI (43–71% sensitive, 99% specific)

CEMR:
√ enhancement of cancer relative to surrounding tissue:
√ calculation of peak enhancement parameters
√ area enhancing within 30–60 sec

MR spectroscopy (metabolic mapping of entire gland):
√ ⇑ choline-citrate ratio > 2 SD:
√ ↓ citrate levels ← conversion from citrate-producing to citrate-oxidating metabolism
√ ↑ cholin levels ← increased turnover of phospholipid cell membrane in proliferating malignant tissue

N.B.: creatinine peak may be inseparable from cholin peak

DDx: post-biopsy hemorrhage → low signal on T2WI + high signal on T1WI; inflammation; fibrosis; scarring

Prognosis: increase in tumor volume increases probability of capsular penetration, metastasis, histologic dedifferentiation; 100% (28%) 5-year survival for localized disease (metastatic cancer)

Mortality: 20.7÷100,000 (2013); 26,120 deaths annually (2016)

Screening recommendation (American Urological Association, American Cancer Society): PSA level measurements + digital rectal exam annually

Dx: transrectal biopsy

Sextant biopsy: 83% PPV, 37%NPV, 30% of cancers are missed, localization inaccurate

◊ 40% accuracy of biopsy for Gleason grade

Rx: (1) Watchful waiting

(2) Radical prostatectomy for disease confined to capsule → life expectancy > 15 years

(3) Radiation therapy for

(a) disease confined to capsule → life expectancy < 15 years

(b) disease outside capsule, no spread

(4) Hormonal therapy: orchiectomy, diethylstilbestrol, leuprolide acetate (for widely metastatic disease)

(5) Cryosurgery

(6) Chemotherapy

PROSTATIC ABSCESS

Age: 5th–6th decade

Agent: E. coli (main cause)

- urinary frequency, urgency, dysuria, hematuria
- perineal / lower back pain, fever, chills
- focally enlarged tender prostate

√ hypo- / anechoic mass with irregular wall + septations

PROSTATITIS

Bacterial Prostatitis

Prevalence: 9.7%

Consider prostatitis with a clinical history of urinary ± sexual symptoms, fluctuating PSA levels, or PSA response to antibiotics.

Distribution: diffuse / focal

Location: peripheral zone (common); transition zone mimicking "erased charcoal" appearance of prostate carcinoma

MR:

√ low T2 signal intensity ← increased inflammatory cellular infiltrates

√ mildly to moderately restricted diffusion (less than in prostate cancer)

CEMR:

√ increased early enhancement (similar to prostate cancer)

Acute Bacterial Prostatitis (uncommon)

Cause: intraprostatic reflux of infected urine, prostatic Bx
Organisms: Escherichia coli, Enterococcus, Proteus
Age: young men
Histo: influx of neutrophils
• local and systemic symptoms
√ enlarged reactive lymph nodes

Chronic Bacterial Prostatitis

Cause: undertreated acute prostatitis, recurrent infection, lower urinary tract obstruction in older men
Histo: influx of lymphocytes, often with glandular atrophy
• indolent (without systemic symptoms)
• lower GU tract symptoms

CAVITARY / DIVERTICULAR PROSTATITIS

Cause: fibrosis of chronic prostatitis constricts ducts leading to stagnation of exudate + breakdown of intraacinar septa with cavity formation
• history of long-standing inflammatory condition
√ "Swiss cheese" appearance of prostate

Granulomatous Prostatitis

• clinically often mistaken for prostate cancer
Types:
(1) Idiopathic: nonspecific and nonnecrotic
(2) Infective: specific, nonnecrotic / necrotic
(3) Iatrogenic: postsurgical
(4) Malakoplakia
(5) Systemic granulomatous disease

Florid granulomatous prostatitis may demonstrate extraprostatic extension like prostate cancer, both entities of a similar appearance at MRI.

DDx: clinically often mistaken for prostate cancer

Idiopathic Granulomatous Prostatitis *(60–78%)*

= nonspecific nonnecrotic prostatitis
Cause: not clear
• often self-limiting
No association with: systemic diseases

Sarcoid Prostatitis *(rare)*

= idiopathic multisystem noncaseating granulomatous disease
Predilection for: African-Americans
Histo: nonspecific histology
• mostly asymptomatic; elevated PSA level

Dx: based on clinical-radiologic correlation + exclusion of other granulomatous disease entities

Iatrogenic Granulomatous Prostatitis

Incidence: 2nd most common type

Cause: transurethral resection of prostate / bladder ← reaction to altered epithelium + stroma from intervention

Histo: palisaded histiocytoid granulomas with central necrotizing / fibrinoid necrosis surrounded by infiltrative eosinophils

Infective Granulomatous Prostatitis

Cause: mycobacterium tuberculosis (← hematogenous spread / direct extension from adjacent organs); development after intravesical bacillus Calmette-Guérin therapy for bladder cancer; Treponema pallidum; viruses (herpes zoster); fungi (Cryptococcus, Candida, Aspergillus)

Histo: well-formed granulomas with epithelioid cell + multinucleated giant cell infiltration +/- central necrosis (caseation)

Predisposing risk factors: Hx of tuberculosis infection, bacillus Calmette-Guérin therapy, immunosuppressive state

- mostly asymptomatic, elevated PSA level
- indurated prostate at digital rectal examination

√ area of hypointensity on T2WI associated with diffusion restriction

√ moderate / marked enhancement on dynamic images

NONNECROTIC GRANULOMATOUS PROSTATITIS

Histo: highly cellular simulating prostate cancer

MR:

√ area of hypointensity on T2WI associated with restricted diffusion in the peripheral zone

√ moderate / marked enhancement

DDx: prostate cancer

NECROTIC GRANULOMATOUS PROSTATITIS

Histo: central necrosis (caseation)

MR:

√ area of central hyperintensity on T2WI

√ focal hyperintensity on high-b-value images

√ marked diffusion restriction

√ NO enhancement

Malakoplakia

= rare granulomatous inflammatory condition associated with recurrent infection

Path: granulomatous infiltration with Michaelis-Gutmann bodies, which may represent abnormality of intraphagosomal digestion of macrophages

- bulging and irregularity of prostatic capsule

MR:

√ diffuse low T2 signal intensity, diffusion restriction
√ hyperenhancement
DDx: prostate cancer

PRUNE BELLY SYNDROME

= EAGLE-BARRETT SYNDROME
= congenital nonhereditary multisystem disorder; almost exclusively in males
TRIAD: 1. Abdominal wall muscle deficiency (wrinkled "prune belly" appearance of abdominal wall)
2. Nonobstructed markedly distended redundant ureters ± hydronephrosis and variable degree of renal dysplasia
3. Bilateral undescended testes (cryptorchidism)
Etiology:
(1) Primary mesodermal arrest at 6–10 weeks GA:
abundance of fibrous tissue with sparsely placed smooth muscle throughout urinary tract
(2) Massive abdominal distension with pressure effects on abdominal wall musculature: ← bladder outlet obstruction (10–20%) / urine ascites / intestinal perforation with ascites / cystic abdominal masses / megacystis-microcolon-intestinal hypoperistalsis syndrome causing pressure atrophy of abdominal wall muscles; bladder distension interfering with descent of testes
(3) Dysgenesis of yolk sac
Prevalence: 1÷29,000 to 1÷50,000 live births; M÷F = 19÷1; increased prevalence in Nigeria + Saskatchewan, Canada
Groups:
(1) Severe urethral obstruction ← urethral atresia [most commonly] / valves
Associated with:
malrotation (most common anomaly), intestinal atresia, imperforate anus, skeletal abnormalities (meningo-myelocele, scoliosis, pectus carinatum /excavatum, arthrogryposis, clubfoot, dislocation of hip, lower limb hemimelia, sacral agenesis, polydactyly), CHD (VSD, pulmonary artery stenosis), Hirschsprüng disease, congenital cystic adenomatoid malformation of lung
√ bladder wall hypertrophy
√ bilateral cystic renal dysplasia
Prognosis: in 20% [50%] death within 1 month [2 years] ← renal failure ± pulmonary insufficiency
(2) Functional abnormality of bladder emptying (more common) with no associated abnormalities
√ large floppy urinary bladder
√ large urachal remnant
√ dilated posterior urethra (without obstruction)
√ utricle
√ vesicoureteral reflux
√ dilated tortuous ureters + focal areas of narrowing
√ lobulated kidneys with dilated collecting system of bizarre shape

Prognosis: chronic urinary tract problems

- wrinkled flaccid appearance of hypotonic abdominal wall with bulging flanks ← agenesis / hypoplasia of muscles in lower parts of abdominal wall ventrally + laterally:
  transverse muscle > rectus abdominis muscle below umbilicus > internal + external oblique muscle > rectus abdominis muscle above umbilicus
- bilateral cryptorchidism (ESSENTIAL COMPONENT) with increased risk for malignant degeneration
- ± impaired renal function

OB-US:

√ enlarged bladder, dilated ureters
√ abnormal abdominal wall
√ normal / decreased AFI

DDx: posterior urethral valves

@ Bladder

√ thickened bladder wall without trabeculations ← replacement by fibrocytes + collagen
√ large distended urinary bladder with a capacity of 600–800 mL
√ intramural bladder calcifications
√ persistence of patent urachus ± calcification
√ widely patent bladder neck
√ laterally placed ureteric orifices

@ Urethra

√ elongated + dilated prostatic urethra with tapering of membranous urethra
√ small / absent verumontanum
√ absent / markedly hypoplastic prostate → infertility and enlarged prostatic urethra
√ enlarged prostatic utricle (= small epithelium-lined diverticulum representing the remnant of the fused caudal ends of the müllerian ducts)
√ urethral obstruction: stenosis / atresia / dorsal chordae / posterior urethral valves (in 20%)
√ scaphoid megalourethra (70%)
(a) complete / fusiform megalourethra (rare)
= complete absence / marked deficiency of corpora cavernosa + corpus spongiosum
(b) incomplete / scaphoid megalourethra (common)
= congenital absence / deficiency of corpus spongiosum with a normal glans + navicular fossa

@ Ureters

Histo: diffuse increase in connective tissue with replacement of smooth muscle
√ massively dilated tortuous elongated ureters affecting the lower ⅓ more profoundly (HALLMARK)
√ poor ureteral peristalsis ← decrease in number of nerves + degeneration of nonmyelinated Schwann fibers
√ alternating narrowed + dilated ureteral segments
√ vesicoureteral reflux (> 70%)

@ Kidneys

√ asymmetry of renal size + lobulated contours

√ no / mild (> 50%) hydronephrosis
√ caliceal dilatation ± diverticula
√ renal calcifications
√ renal dysplasia with cystic dysplastic changes, oligohydramnios, pulmonary hypoplasia (in severe cases due to a combination defect of ureteric bud + metanephron)

@ Lung (55%)
√ pulmonary hypoplasia
√ cystic adenomatoid malformation
Cx: respiratory infections ← ineffective cough

@ Musculoskeletal (50%):
scoliosis, pectus deformity, arthrogryposis, clubfoot, valgus foot, hemimelia, dislocation of hip, sacral agenesis, polydactyly

@ Gastrointestinal anomalies (30%):
malrotation, atresia, stenosis, volvulus, imperforate anus, Hirschsprüng disease, gastroschisis

@ Cardiovascular (10%): VSD, PDA, tetralogy of Fallot

Cx: chronic renal failure / urosepsis / respiratory failure (30% die within first 2 years of life)

Rx: internal urethrotomy, cutaneous vesicostomy, reduction cystoplasty, ureteral reimplantation, orchiopexy at 1–2 years of age, renal transplantation after bilateral nephroureterectomy, abdominoplasty

PYELOCALICEAL DIVERTICULUM

= PYELOGENIC CYST = PERICALICEAL CYST = CALICEAL DIVERTICULUM

= uroepithelium-lined urine-filled cavity within renal cortex communicating with renal collecting system

TYPE I (connecting with minor calyx):
more common; connected to caliceal cup, usually at fornix; bulbous shape; narrow connecting infundibulum of varying length; few millimeters in diameter; in polar region especially upper pole

TYPE II (connecting with major calyx / renal pelvis):
interpolar region; communicates directly with pelvis; usually larger and rounder; neck short and not easily identified

Prevalence: 2.1–4.5÷1000 intravenous urograms

Cause:
(1) Congenital: developmental origin from ureteral bud remnant ← obstruction of peripheral aberrant "minicalyx" / failure of regression of 3rd–4th-generation ureteric bud
(2) Acquired (less common): reflux, obstructing stone, infection, rupture of simple cyst / abscess, infundibular achalasia / spasm, hydrocalyx ← inflammatory fibrosis of an infundibulum

√ appearance of simple cyst
√ opacification during excretory phase may be delayed and remain so for prolonged period → layering of contrast medium
√ mass effect on adjacent pelvicaliceal system if large enough

US:

√ anechoic cyst
√ ± layering mobile echogenic material ← formation of single / multiple stones (50%) / milk of calcium (fluid-calcium level)

Cx: hemorrhage, recurrent infection, cyst rupture, malignancy (exceedingly rare)

DDx: ruptured simple nephrogenic cyst, evacuated abscess / hematoma, renal papillary necrosis, medullary sponge kidney, hydrocalyx ← infundibular narrowing from TB / crossing vessel / stone / infiltrating carcinoma

PYELONEPHRITIS

= upper urinary tract infection with pelvic + caliceal + parenchymal inflammation

◊ The Society of Uroradiology recommends eliminating the terms (acute focal) bacterial nephritis, lobar nephritis, lobar nephronia, preabscess, renal cellulitis, renal phlegmon, renal carbuncle!

Acute Pyelonephritis

= episodic bacterial infection of kidney with acute inflammation, usually involving pyelocaliceal lining + renal parenchyma centrifugally along medullary rays

Risk factors:

1. Vesicoureteral reflux in children
2. Obstruction, stasis, stone in adults (5%)

Pathway of infection:

(a) **ascending bacterial infection** ← (usually) P-fimbriated E. coli (fimbriae facilitate adherence to mucosal surface): initial colonization of ureter in areas of turbulent flow → paralysis of ureteral smooth muscle → dilatation + functional obstruction of collecting system

(b) **vesicoureteral reflux** + pyelotubular backflow: P-fimbriated E. coli NOT necessary for infection

(c) **hematogenous** spread (12–20%) with gram-positive cocci

Path: thickened urothelium with multifocally / globally edematous kidney; radiating yellow-white stripes / wedges extending from papillary tip to cortical surface in a patchy distribution + sharply demarcated from adjacent spared parenchyma by 48–72 hours

Histo: tubulointerstitial nephritis = leukocytic migration from interstitium into lumen of tubules → destruction of tubule cells by released enzymes → bacterial invasion of interstitium by 48–72 hours

Organism: E. coli > Proteus > Klebsiella, Enterobacter, Pseudomonas

Age: most commonly 15–30 years; M << F

Prevalence: 1–2% of all pregnant women

- fever, chills, flank pain + tenderness
- pyuria, bacteriuria, positive urine culture
- ± microscopic hematuria / bacteremia; leukocytosis

Indication for imaging in adults:

(1) Diabetes
(2) Analgesic abuse
(3) Neuropathic bladder

(4) History of urinary tract stones
(5) Atypical organism: eg, proteus
(6) Poor response to antibiotics
(7) Frequent recurrences
(8) Immunocompromise

IVP (abnormal in 25%):
√ smooth normal / enlarged kidney(s), focal >> diffuse involvement of kidney
√ diminished nephrographic density (global / wedge-shaped / patchy)
√ immediate persistent dense nephrogram, rarely striated
√ nonvisualization of kidney ← severe pyelonephritis (rare)
√ "tree-barking" = mucosal striations (rare)
√ compression of collecting system ← edema
√ delayed opacification of collecting system
√ nonobstructive ureteral dilatation ← effect of endotoxins (rare)

CT:
√ thickening of Gerota fascia + thickened bridging septa / stranding ← perinephric inflammation
√ generalized renal enlargement / focal swelling
√ obliteration of renal sinus
√ thickening of walls of renal pelvis + calices
√ mild dilatation of renal pelvis + ureter
√ area of high attenuation on unenhanced sca(= hemorrhagic bacterial nephritis)

CECT (abnormal in 65–90%):
√ hypoattenuating (80–90 HU) wedge-shaped area of cortex extending from papilla to renal capsule during nephrographic phase (= lobar segments of hypoperfusion + edema)
√ striated nephrogram
√ poor corticomedullary differentiation
√ dense parenchymal staining on scan delayed by 3–6 hours in area of earlier diminished enhancement ← functioning renal parenchyma
√ soft-tissue filling defect in collecting system ← papillary necrosis, inflammatory debris, blood clot
√ caliceal effacement

US (abnormal in < 50%):
◊ Pyelonephritis is difficult to detect sonographically!
√ swollen kidney of decreased echogenicity
√ loss of central sinus complex
√ wedge-shaped hypo- / isoechoic zones, rarely hyperechoic ← hemorrhage
√ thickened sonolucent corticomedullary bands
√ blurred corticomedullary junctions
√ localized increase in size + echogenicity of perinephric fat ± fat within renal sinus
√ localized perinephric exudate
√ thickening of wall of renal pelvis
√ focally decreased blood flow on power Doppler

MR:
√ perinephric edema surrounding enlarged kidney

√ wedge-shaped foci of persistent increased SI on contrast-enhanced fast inversion recovery / T2WI

Renal cortical scintigraphy (^{99m}Tc-DMSA):

√ focal areas of diminished uptake (in 90%)

Prognosis:

(1) Quick response to antibiotic treatment will leave no scars

(2) Delayed treatment of acute pyelonephritis during first 3 years of life can severely affect renal function later in life → decreased renal function, hypertension (33%), end-stage renal disease (10%)

Cx: (1) Renal abscess (near-water density lesion without enhancement)

(2) Scarring of affected renal lobes often in children + in up to 43% in adults

(3) Maternal septic shock (3%)

(4) Premature labor (17%)

Acute Focal Pyelonephritis

= LOBAR NEPHRONIA = ACUTE FOCAL BACTERIAL NEPHRITIS = CARBUNCLE = RENAL CELLULITIS = RENAL PHLEGMON

= focal variant of acute pyelonephritis with single / multiple areas of suppuration + necrosis

Organism: E. coli > Proteus > Klebsiella

Predisposed: patients with altered host resistance (diabetes [60%], immunosuppression), trauma, chronic catheterization, mechanical / functional obstruction

• fever, flank pain, pyuria

Site: usually involves entire renal lobe

√ ^{67}Ga uptake

√ vesicoureteral reflux often present

IVP:

√ focal area of absent nephrogram / distorted pyelogram

US:

√ hypoechoic mass with ill-defined margins and disruption of corticomedullary border

√ NOT a fluid collection

CT:

√ hypoattenuating zone with poorly defined transition to surrounding parenchyma

√ less than normal parenchymal enhancement

MR:

√ area of low signal intensity on T1WI

√ hyperintense center on T2WI ← fluid, necrosis

Angio:

√ renal arteries displaced, renal veins compressed

DDx: abscess (no enhancement on CT)

Cx: scarring, abscess

Acute Suppurative Pyelonephritis

= ACUTE DIFFUSE BACTERIAL NEPHRITIS

= more severe and extensive form of acute pyelonephritis → may lead to diffuse necrosis (=

phlegmon)
Organism: Proteus, Klebsiella > E. coli
Predisposed: diabetics (60%)

Emphysematous Pyelitis

= gas confined to renal pelvis + calices
Organism: E. coli
Predisposed: diabetes mellitus (50%); M÷F = 1÷3
May be associated with: emphysematous cystitis (rare)
• pyuria
√ gas pyelogram outlining pelvicaliceal system
√ dilated renal collecting system (frequent)
√ ± gas in ureters
DDx: reflux of gas / air from bladder or urinary diversion

Emphysematous Pyelonephritis

= life-threatening acute fulminant necrotizing infection of kidney and perirenal tissues associated with gas formation
Organism: E. coli (68%), Klebsiella pneumoniae (9%), Proteus mirabilis, Pseudomonas, Enterobacter, Candida, Clostridia (exceptionally rare)
Path: acute and chronic necrotizing pyelonephritis with multiple cortical abscesses
Mechanism: pyelonephritis → ischemia + low O2 tension with anaerobic metabolism; facultative anaerobe organisms form CO_2 with fermentation of necrotic tissue / tissue glucose
Predisposed: immunocompromised patients, esp. diabetics (in 87–97% of cases); ureteral obstruction (in 20–40%)
Average age: 54 years; M÷F = 1÷2
May be associated with: XGP
• features of acute severe pyelonephritis (chills, fever, flank pain, lethargy, confusion) not responding to Rx
• positive blood + urine cultures (in majority), urosepsis, shock
• fever of unknown origin + NO localizing signs in 18%
• multiple associated medical problems: uncontrolled hyperglycemia, acidosis, dehydration, electrolyte imbalance
Location: in 5–7% bilateral
√ parenchymal destruction
√ absent / decreased contrast excretion ← compromised renal function
Type I (33%):
√ streaky / mottled gas in interstitium of renal parenchyma radiating from medulla to cortex
√ crescent of subcapsular / perinephric gas
√ NO fluid collection ← no effective immune response
Prognosis: 69% mortality
Type II (66%):
√ bubbly / loculated intrarenal gas (infers presence of abscess)
√ renal / perirenal fluid collection

√ gas within collecting system (85%)
Prognosis: 18% mortality
US:
√ high-amplitude echoes within renal sinus / renal parenchyma associated with "dirty" shadowing / "comet tail" reverberations
CAVE: (1) Kidney may be completely obscured by large amount of gas in perinephric space (DDx: surrounding bowel gas)
(2) Gas may be confused with renal calculi
CT (most reliable + sensitive modality):
√ mottled areas of low attenuation extending radially along pyramids
√ extensive involvement of kidney + perinephric space
√ air extending through Gerota fascia into retroperitoneal space
√ occasionally gas in renal veins
MR:
√ signal void on T1WI + T2WI (DDx: renal calculi, rapidly flowing blood)
Mortality: 60–75% under antibiotic Rx; 21–29% after antibiotic Rx + nephrectomy; 80% with extension into perirenal space
Rx: antibiotic therapy + nephrectomy; drainage procedure for coexisting obstruction
DDx: emphysematous pyelitis (gas in collecting system but not in parenchyma, diabetes in 50%, less grave prognosis)

Fungal Pyelonephritis

Organism: Candida, Aspergillus, Mucor, Coccidioides, Cryptococcus, Actinomyces, Nocardia, Torulopsis
At risk: diabetes, drug addiction, leukemia, debilitation, immunosuppression
√ pyelonephritis, papillary necrosis, renal abscess
√ fungus ball

Xanthogranulomatous Pyelonephritis

= rare chronic suppurative granulomatous infection characterized by progressive parenchymal destruction ← chronic renal obstruction ← calculus, stricture, carcinoma
Cause: abnormal host response to bacterial infection
Prevalence: 681,000 surgically proven cases of chronic pyelonephritis
Organism: Proteus mirabilis, E. coli, S. aureus
Risk factors: female gender, diabetes
Associated with: nephrolithiasis (staghorn calculus in 50%)
Path: replacement of corticomedullary junction with soft yellow nodules; calices filled with pus and debris
Histo: diffuse infiltration by plasma cells + histiocytes + lipid-laden macrophages (xanthoma cells)
Pathophysiology:
infection of renal pelvis, which the host is unable to eradicate; macrophages become enlarged with undigested bacteria gradually replacing the renal parenchyma + perinephric space
Peak age: 45–65 years; all ages affected, may occur in infants; M÷F = 1÷3–1:4; typically in

perimenopausal woman

- pyuria 95%
- flank pain 80%
- fever 70%
- palpable mass 50%
- weight loss 50%
- microscopic hematuria 50%
- elevated ESR; reversible elevated liver function tests (50%) ← inflammation of portal triads

◊ Symptomatic for 6 months prior to diagnosis in 40%!

A. DIFFUSE XGP (83–90%)
= massive renal enlargement, lithiasis, peripelvic fibrosis, hydronephrosis, lobulated masses replacing parenchyma

B. SEGMENTAL / FOCAL XGP (10–17%)
= tumefactive form ← obstructed single infundibulum / one moiety of duplex system
DDx: renal cell carcinoma

IVP:
√ global enlargement of kidney (smooth contour uncommon) / focal renal mass (less frequent)
√ contracted pelvis with dilated calices
√ focally absent / totally absent nephrogram (80%)
√ centrally obstructing calculus:
√ staghorn calculus in 75%
√ extension of inflammation into perirenal space, pararenal space, ipsilateral psoas muscle, colon, spleen, diaphragm, posterior abdominal wall, skin

Retrograde:
√ complete obstruction at ureteropelvic junction / infundibulum / proximal ureter
√ contracted renal pelvis, dilated deformed calices + nodular filling defects
√ irregular parenchymal masses with cavitation

CT:
√ enlargement of kidney
√ obstructive staghorn-like calculus
√ hydronephrosis + abscesses:
√ "**bear paw**" sign = low-attenuation fatty masses arranged in a "hydronephrotic" pattern replacing renal parenchyma (= replacement fibrolipomatosis with attenuation values of less than water)
√ extension into perinephric space + retroperitoneum (simulating an infiltrative malignancy)
√ heterogeneous parenchymal / NO enhancement

US:
√ hypoechoic dilated calices with echogenic rim
√ hypoechoic masses frequently with low-level internal echoes replacing renal parenchyma
√ loss of corticomedullary junction
√ parenchymal calcifications (uncommon)

MR:
√ renal parenchyma replaced by dilated calices + abscess cavities of intermediate SI on T1WI and high SI on T2WI
√ ± marked enhancement of cavity walls
√ signal void of calculus within collecting system
Angio:
√ stretching of segmental / interlobar arteries around large avascular masses
√ hypervascularity / blush around periphery of masses in late arterial phase (= granulation tissue)
√ venous encasement + occlusion
DDx: pyonephrosis, long-standing hydronephrosis, avascular tumor
Rx: nephrectomy

PYELOURETERITIS CYSTICA

= POLYURETERITIS CYSTICA
= hyperplastic noncommunicating cystic transitional epithelial cell collections projecting into ureteral lumen
◊ Indicative of past / present urinary tract infection!
Cause: chronic urinary tract irritant ← stone / infection
Histo: numerous small submucosal epithelial-lined cysts representing cystic degeneration of epithelial cell nests within lamina propria (**cell nests of von Brunn**) formed by downward proliferation of buds of surface epithelium that have become detached from the mucosa
Organism: E. coli > M. tuberculosis, Enterococcus, Proteus, schistosomiasis
Predisposed: diabetics
Age: 6th decade; more prevalent in women
• no specific symptoms; ± hematuria
Location: bladder >> proximal ⅓ of ureter > ureteropelvic junction; unilateral >> bilateral
√ multiple small round smooth lucent filling defects of 2–3 mm in size; scattered discrete / clustered
√ persist unchanged for years in spite of antibiotic therapy
Cx: increased incidence of transitional cell carcinoma
Dx: biopsy to exclude malignancy
DDx: (1) Spreading / multifocal TCC
(2) Vascular ureteral notching
(3) Multiple blood clots
(4) Multiple polyps
(5) Allergic urticaria of mucosa
(6) Submucosal hemorrhage (eg, anticoagulation)

PYONEPHROSIS

= presence of pus in dilated collecting system (= infected hydronephrosis)
Path: purulent exudate composed of sloughed urothelium + inflammatory cells from early

formation of microabscesses + necrotizing papillitis

Organism: most commonly E. coli

US:

√ dispersed / dependent internal echoes within dilated pelvicaliceal system

√ shifting urine-debris level

√ dense peripheral echoes in nondependent location + shadowing (gas from infection)

Cx: (1) Renal microabscesses + necrotizing papillitis

(2) XGP

(3) Renal / perinephric abscess

(4) Fistula to duodenum, colon, pleura

RADIATION NEPHRITIS

Histo: interstitial fibrosis, tubule atrophy, glomerular sclerosis, sclerosis of arteries of all sizes, hyalinization of afferent arterioles, thickening of renal capsule

Threshold dose: 2,300 rad over 5 weeks

• clinically resembling chronic glomerulonephritis

√ normal / small smooth kidney consistent with radiation field

√ parenchymal thickness diminished (globally / focally; related to radiation field)

√ diminished nephrographic density

REFLUX ATROPHY

Cause: increased hydrostatic pressure of pelvicaliceal urine with atrophy of nephrons ← long-standing vesicoureteral reflux

√ small smooth kidney with loss of parenchymal thickness

√ widened collecting system with effaced papillae

√ longitudinal striations ← redundant mucosa when collecting system is collapsed

◊ Do NOT confuse with reflux nephropathy!

REFLUX NEPHROPATHY

= CHRONIC ATROPHIC PYELONEPHRITIS

= ascending bacterial urinary tract infection ← reflux of infected urine from lower tract + tubulointerstitial inflammation in childhood (hardly ever endangers adult kidney)

◊ Most common cause of a small scarred kidney!

Etiology: 3 essential elements:

(1) Infected urine

(2) Vesicoureteral reflux

(3) Intrarenal reflux

Age: usually young adults (subclinical diagnosis starting in childhood); M < F

• fever, flank pain, frequency, dysuria, hypertension, renal failure

• may have no history of significant symptoms

Site: predominantly affecting poles of kidneys ← presence of compound calices having distorted **papillary ducts of Bellini** (= papillae with gaping openings instead of slitlike openings of interpolar papillae)

√ normal / small kidney; uni- / bilateral; uni- / multifocal
√ focal parenchymal thinning with contour depression in upper / lower pole (more compound papillae in upper pole), scar formation only up to age 4
√ retracted papilla with clubbed calyx subjacent to scar
√ contralateral / focal compensatory hypertrophy (= renal pseudotumor)
√ dilated ureters ← reflux, sometimes with linear striations (= redundant / edematous mucosa)
US:
√ focally increased echogenicity within cortex ← scar
Angio:
√ small tortuous intrarenal arteries, pruning of intrarenal vessels
√ vascular stenoses, occlusion, aneurysms
√ inhomogeneous nephrographic phase
NUC (^{99m}Tc-glucoheptonate / DMSA with SPECT most sensitive method):
√ focal / multifocal photon-deficient areas
Cx: (1) Hypertension
(2) Obstetric complications
(3) Renal failure

RENAL ABSCESS

= PYOGENIC RENAL ABSCESS = KIDNEY ABSCESS
= usually complication of renal inflammation with liquefactive necrosis; 2% of all renal masses
Cause: typically complication of acute untreated / incompletely treated pyelonephritis / ascending UTI; hematogenous seeding via bacteremia
Pathway of infection:
(a) ascending (80%): associated with obstruction (UPJ, ureter, calculus)
Organism: E. coli, Proteus
(b) hematogenous (20%): infection from skin, teeth, lung, tonsils, endocarditis, intravenous drug abuse
Organism: staphylococcus aureus
Predisposed: diabetic (twice as frequent compared with nondiabetic); immunocompromised; pregnancy
• positive urine (blood) culture in 33% (50%)
• may have negative urine analysis / culture (in up to 20%)
• pyuria, hematuria (absent if abscess isolated within parenchyma)
IVP:
√ focal mass displacing collecting system
CECT:
√ well-defined hypoattenuating irregular focal round renal mass:
√ thick rim / halo of enhancing wall / pseudocapsule
√ no enhancement of center of abscess
√ ± presence of gas
√ thickened septa + Gerota fascia
√ perinephric fat obliteration ← perinephric extension
US:

√ slightly hypoechoic (early), hypo- to anechoic (late) mass
√ irregular margins + increased through-transmission
√ ± septations ± microbubbles of gas

MR:
√ heterogeneous thick-rimmed complex T1-hypointense and T2-hyperintense lesion replacing renal parenchyma
√ restricted diffusion
√ surrounding thick hypointense rim on T2WI
√ elevated perinephric SI on T2WI
√ blooming artifact on GRE ← gas

NUC (^{67}Ga-citrate / ^{111}In leukocytes):
√ hot spot

DDx: renal cyst; cystic renal cell carcinoma

Perinephric / Perirenal Abscess

Cause:
(1) Acute pyelonephritis with extension of renal abscess through capsule
(2) Adjacent retroperitoneal infection: eg, perforation of colon cancer, psoas abscess
(3) Deep penetrating subcutaneous abscess
(4) Hematogenous spread

Predisposed: diabetics (in 30%), urolithiasis, septic emboli
◊ 14–75% of patients with perinephric abscess have diabetes mellitus!

Organism: in up to 30% different from abscess

√ loss of psoas margin / obscuration of renal contour
√ renal displacement
√ focal renal mass
√ scoliosis concave to involved side
√ respiratory immobility of kidney = renal fixation
√ occasionally gas in renal fossa
√ unilateral impaired excretion
√ pleural effusion

RENAL ADENOMA

◊ Small adenoma < 3 cm should be considered a renal cell carcinoma of low metastatic potential = borderline renal cell carcinoma!

Frequency: in 7–15–23% of adults (autopsies); most common cortical lesion; increasing with age (in 10% of patients < 40 years of age, in 40% of patients > 70 years of age); increased frequency in tobacco users + patients on long-term dialysis

Age: usually > 30 years; M÷F = 3÷1

Types:

(1) Papillary adenoma / cystadenoma (38%)
(2) Tubular adenoma (38%)
(3) Mixed type adenoma (21%)
(4) Alveolar adenoma (3%) = precursor of RCC

√ solitary in 75%, multiple in 25%

√ usually < 3 cm in size; subcapsular cortical location

√ impossible to differentiate from renal cell carcinoma

Cx: premalignant (adenoma-carcinoma sequence)

Prognosis: average growth rate of 0.4 (range, 0.2–3.5) cm annually; tumors growing < 0.25 cm annually rarely metastasize; tumors growing > 0.6 cm annually frequently metastasize

RENAL AGENESIS

Mechanism:

(a) formation failure
= failure of ureteral bud to form
• hemitrigone = absence of ipsilateral trigone + ureteral orifice

(b) induction failure
= failure of growing ureteral bud to induce metanephric tissue
• blind-ending ureter

Unilateral Renal Agenesis

Prevalence: 1÷600 to 1÷1,000 pregnancies; M÷F = 1.8÷1

Risk of recurrence: 4.5%

Often coexisting with other anomalies:

1. Genital abnormalities:
   (a) in male (10–15%): **Zinner syndrome**
   = rare congenital abnormality of the mesonephric (Wolffian) duct = TRIAD of (1) hypoplasia or agenesis of testis / vas deferens, (2) seminal vesicle cyst, (3) ipsilateral ejaculatory duct obstruction
   [Alfred Zinner (?1887–1967), urologist in Wien, Austria]
   (b) in female (25–50%): unicornuate / bicornuate / hypoplastic / absent uterus, absent / aplastic vagina
   ◊ 90% of women with renal agenesis have uterine anomalies
   ◊ 30–40% of women with uterine anomalies have renal agenesis
2. Turner syndrome, trisomy, Fanconi anemia, Laurence-Moon-Biedl syndrome

Location: L > R
√ visualization of single kidney (DDx: additional kidney in ectopic location)
√ absent adrenal gland (11%)
√ absent / rudimentary renal vessels
√ colon occupies renal fossa
√ compensatory contralateral renal hypertrophy (50%)

Bilateral Renal Agenesis

= POTTER SYNDROME
Prevalence: 1÷3,000 to 1÷10,000 pregnancies; M÷F = 2.5÷1
Risk of recurrence: < 1%
• **Potter's facies** = low-set ears, redundant skin, parrot-beaked nose, receding chin
◊ US sensitivity is ONLY 69–73% ← decreased visualization from oligohydramnios + discoid-shaped adrenal glands simulating kidneys!
√ severe oligohydramnios (after 14 weeks MA)
√ bilateral absence of kidneys, ureters, renal arteries (after 12 weeks)
√ inability to visualize renal arteries by color duplex
√ inability to visualize urine in fetal bladder (after 13 weeks) ← bladder agenesis / hypoplasia; negative furosemide test (20–60 mg IV) NOT diagnostic (fetuses with severe IUGR may not be capable of diuresis)
√ flattened discoid shape of adrenals ← absence of pressure by kidney
√ bell-shaped thorax in mid to late 3rd trimester ← pulmonary hypoplasia
√ compression deformities of extremities → clubfoot, flexion contractures, joint dislocations (eg, hip)
Prognosis: stillbirths (24–38%); invariably fatal in the first days of life ← pulmonary hypoplasia
DDx: functional cause of in utero renal failure (eg, severe IUGR)

Potter Sequence

= hypoplasia of lungs, bowing of legs, broad hands, loose skin, growth retardation associated with long-standing severe oligohydramnios
Cause: renal agenesis, urethral obstruction, prolonged rupture of membranes, severe IUGR

RENAL ARTERY ANEURYSM

Incidence: 0.01–0.10%; 22% of visceral aneurysms
Cause: medial fibrodysplasia, penetrating trauma
Age: 50–61 years; M÷F = 1÷1
Location: R > L; 1st-order branch of main renal artery (usually)
Type:
(a) saccular (80%): near first bifurcation of main renal artery; variety of causes (congenital; associated with medial fibroplasia + atherosclerosis)
(b) fusiform (20%): ← advanced renal artery medial fibrodysplasia; not calcified
(c) dissecting: traumatic, spontaneous (atherosclerosis, intimal fibroplasia, perimedial fibroplasia), iatrogenic

• usually asymptomatic (in > 50%)

Rx: Endovascular therapy (> 80% success rate)

Cx: (1) Hypertension (unusual)

(2) Perinephric / retroperitoneal hemorrhage (rare) with increased risk in peripartum women

(3) Formation of AV fistula

(4) Peripheral renal embolization ← mural thrombus

(5) Thrombosis

(6) Hematuria

Extrarenal Aneurysm *(⅔)*

A. TRUE ANEURYSM
   1. Atherosclerotic (most common)
   2. Fibromuscular dysplasia
   3. Pregnancy
   4. Mesenchymal disease: neurofibromatosis, Ehlers-Danlos syndrome

B. FALSE ANEURYSM
   1. Trauma; renal artery angioplasty
   2. Behçet disease
   3. **Mycotic aneurysm** 2.5% of all aneurysms

      Cause: bacteremia, SBE, perivascular extension of inflammation

      Organism: Streptococcus, Staphylococcus, Pneumococcus, Salmonella

√ incomplete / complete ring of calcification

√ variable enhancement (depending on amount of thrombus)

Rx: (1) Conservative in asymptomatic patient for well-calcified aneurysm < 2 cm in diameter

(2) Surgery for (a) interval growth, (b) emboli to kidney, (c) in woman of childbearing age, (d) diminished renal function / ischemia / hypertension / dissection

Intrarenal Aneurysm *(⅓)*

in interlobar and more peripheral branches

A. CONGENITAL (most common)
   1. Congenital renal aneurysm

      Age at Dx: 30 years or older; M÷F = 1÷1

      • hypertension in 25% ← segmental renal ischemia

      √ saccular aneurysm close to vascular bifurcations, may calcify

      √ often bilateral

      Rx: surgical / endovascular repair for aneurysm > 1.0 cm in hypertensive patient / for aneurysm > 1.5 cm in asymptomatic normotensive patient

B. ARTERITIS
   1. Polyarteritis nodosa
   2. SLE
   3. Allergic vasculitis
   4. Wegener granulomatosis

5. Transplant rejection
6. Drug-abuse vasculitis
   ◊ Kidney most commonly affected organ!
   Cause:
   (a) immunologic injury from circulating hepatitis antigen-antibody complexes producing a necrotizing angiitis
   (b) bacterial endocarditis
   (c) drug-related
   (d) impurity-related
   Drugs: methamphetamine, heroin, LSD
   √ multiple small aneurysms in interlobar branches near corticomedullary junction
   √ inhomogeneous spotty nephrogram

C. DEGENERATIVE: Atherosclerosis (may calcify)
D. TUMOR
   1. Neoplasm (RCC in 14%; adult Wilms tumor)
   2. Hamartoma (angiomyolipoma in 50%)
   3. Metastatic arterial myxoma
   4. Vascular malformation
E. MESENCHYMAL DISEASE
   1. Neurofibromatosis
   2. Fibroplasia
F. TRAUMA
G. INFECTION: syphilis, tuberculosis

RENAL ARTERY STENOSIS

Prevalence: 1–2–4% of hypertensive individuals; 4.3 % of autopsies; 10% of hypertensive individuals with coronary artery disease; 25% of patients with hypertension that is difficult to control; in 45% of patients with malignant hypertension; in 45% of patients with peripheral vascular disease

Cause:

1. Atherosclerosis (60–90%): mostly in proximal 2 cm of main renal artery
   ◊ Any of multiple renal arteries (occurring in 14–28% of the population) may be affected!
2. Fibromuscular dysplasia (10–30%)
3. Others (< 10%): thromboembolic disease, arterial dissection, infrarenal aortic aneurysm, arteriovenous fistula, vasculitis (Buerger disease, Takayasu disease, polyarteritis nodosa, postradiation), neurofibromatosis, retroperitoneal fibrosis

Pathophysiology:

↓ perfusion pressure of glomeruli → stimulates production of renin in juxtaglomerular apparatus + angiotensin II in kidney; renin converts circulating angiotensinogen (α2-globulin) into angiotensin I → subsequently converted by angiotensin-converting enzyme (ACE present in vascular endothelium) → into angiotensin II releasing aldosterone; aldosterone increases salt + water retention; angiotensin II + aldosterone vasoconstrict vessels (especially intraglomerular efferent arteriole to maintain filtration pressure)

◊ ACE inhibition may impair overall renal function ← disruption of autoregulatory

mechanism of GFR (with renal artery stenosis in both kidneys / solitary kidney)

Renin production stimuli:

(a) baroreceptors in afferent glomerular arteriole sense ⇓ stretching of arteriolar wall with diminished blood flow

(b) chemoreceptors of macula densa located in first part of the distal tubule sense a ⇓ amount of sodium and chloride (which have been largely reabsorbed ← low GFR)

Histo: tubular atrophy and shrinkage of glomeruli

- abdominal / flank pain, hematuria, oliguria, anuria
- renin-mediated hypertension ← ischemia
- low urine sodium concentration

Hemodynamic significance determined by:

(a) elevated renin levels in ipsilateral renal vein ≥ 1.5÷1

(b) presence of collateral vessels

(c) greater than 70% stenosis with poststenotic dilatation

(d) transstenotic pressure gradient ≥ 40 mmHg

(e) decrease in renal size

◊ 15–20% of patients remain hypertensive after restoration of normal renal blood flow (= renal artery stenosis without renovascular hypertension)!

Patient selection criteria for screening test:

= clinical signs associated with moderate-to-high risk of renovascular hypertension (HTN):

1. Abrupt onset or severe HTN
2. HTN resistant to 3-drug therapy in compliant patient
3. Abdominal / flank bruits
4. Unexplained azotemia in elderly patient with HTN
5. Worsening renal function during antihypertensive therapy, especially with ACEIs
6. Grade 3 / 4 hypertensive retinopathy
7. Occlusive disease in other vascular beds
8. Onset of HTN < 30 years or > 55 years of age
9. Recurrent pulmonary edema in elderly patient with HTN
10. HTN in infants with an umbilical artery catheter
11. HTN in children

√ normal / decreased renal size (R 2 cm < L; L 1.5 cm < R) with smooth contour

√ vascular calcifications (aneurysm / atherosclerosis)

IVP (60% true-positive rate, 22% false-negative rate):

√ delayed appearance of contrast material ← decreased glomerular filtration

√ increased density of contrast material ← increased water reabsorption

√ delayed washout of contrast material ← prolonged urine transit time

√ lack of distension of collecting system

√ global attenuation of contrast density; urogram may be normal with adequate collateral circulation

√ notching of proximal ureter ← enlargement of collateral vessels

CT:

√ prolongation of cortical nephrographic phase + persistent corticomedullary differentiation

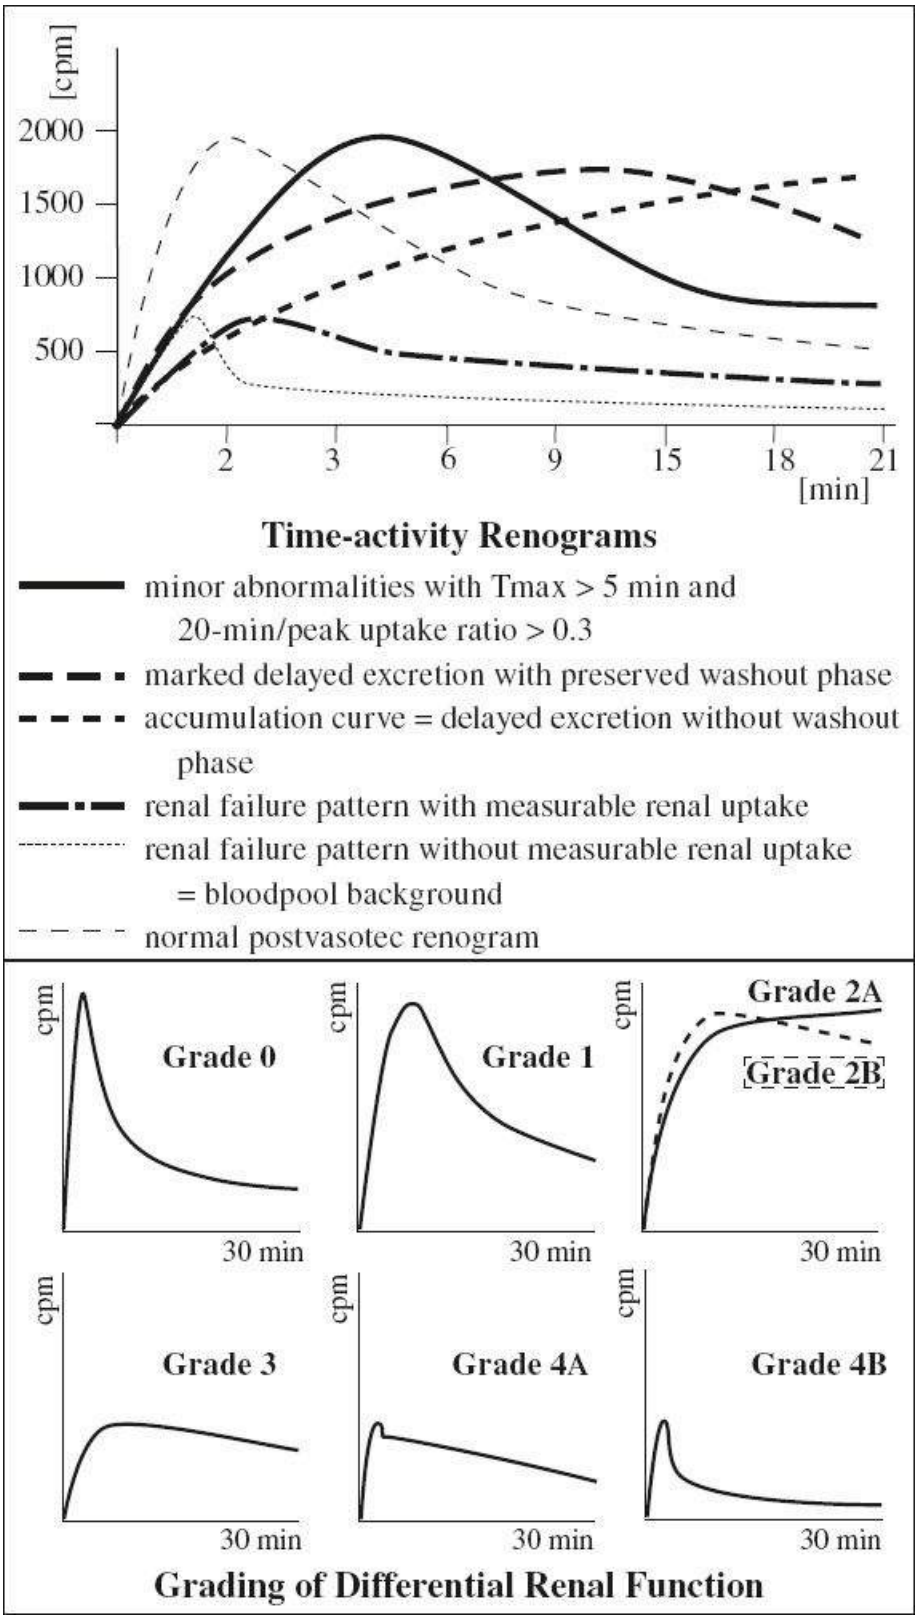
√ CT angiography (2–3-mm collimation, pitch ≤ 1.5–2.0): specificity of real-time interactive volume rendering > maximum-intensity projection > shaded-surface display

MRA (> 95% sensitive, > 90% specific):

√ tendency to overestimate stenosis

Limitations:

› evaluation of branch vessels
› presence of metallic stent
› detection of accessory arteries
› evaluation of small renal arteries



Angiography:

(a) conventional angiography = "gold standard" test

(b) intravenous digital subtraction angiography:
does not address hemodynamic significance

ACE inhibitor scintigraphy (51–96% sensitive, 80–93% specific):

= screening test for renovascular hypertension (not renal artery stenosis) with angiotensin-converting enzyme inhibitor (ACEI) challenge

◊ ACE inhibition may impair overall renal function due to disruption of autoregulatory mechanism of GFR (with renal artery stenosis in both kidneys / solitary kidney)

Pharmacology:

affected kidney responds to decreased arteriolar flow by releasing renin + angiotensin II (= extremely potent vasoconstrictor acting on the efferent renal arteriole to increase filtration pressure) in juxtaglomerular apparatus; ACE inhibitors (eg, captopril, enalapril) → block ACE (angiotensin-converting enzyme) → reduces GFR (51–96% sensitive, 80–93% specific)

√ unilateral parenchymal retention after ACEI: reduced GFR → ⇓ urinary output + ⇑ radiotracer retention
= > 90% probability of renovascular hypertension

√ change in grade of differential renal function from baseline grade 0 / 1 by > 1 grade
= high probability for renal artery stenosis

√ abnormal baseline curve without change
= indeterminate for renovascular hypertension

√ functional improvement following ACEI challenge
= low probability for renovascular hypertension

Semiquantitative interpretation of time-activity renograms:

√ normal ACE inhibitor scintigram (< 10% probability for renovascular hypertension)

√ criteria for high probability (> 90%):

√ worsening of scintigraphic curve

√ reduction in relative uptake with > 10% change after ACE inhibition

√ prolongation of parenchymal transit time with > 2 min delay of excretion into renal pelvis

√ ⇑ in 20-minute peak uptake ratio > 0.15 from baseline

√ prolongation of T_{max} of > 2 min / 40%

√ asymmetry of renal uptake < 40% of total renal uptake

√ bilateral symmetrical changes are usually due to:

(a) hypotension
(b) salt depletion
(c) use of calcium channel blockers
(d) low urine flow rate

Decreased accuracy with:

(1) Bilateral renal artery stenosis
(2) Impaired renal function
(3) Urinary obstruction
(4) Chronic ACE inhibitor therapy

Sources of error:

(1) Failure to administer ACEIs properly:

(a) ingestion of food within 4 hours of taking captopril
(b) paravenous infiltration

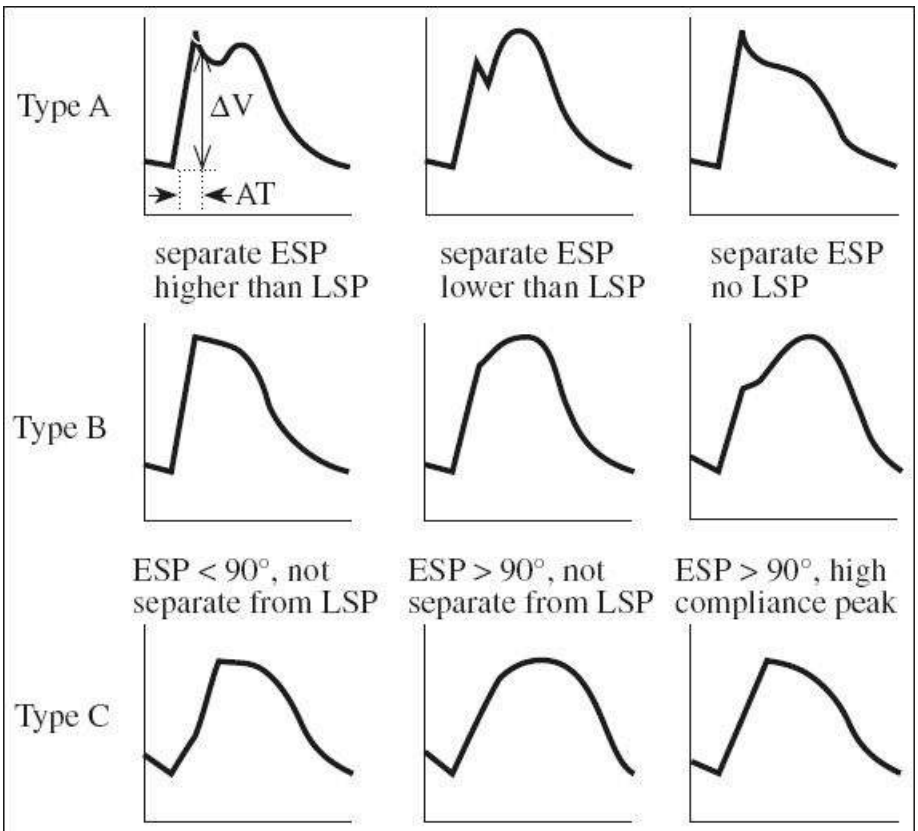
(2) Causes of abnormal whole-kidney renograms:
(a) renal pelvic retention
(b) dehydration
(c) hypotension
(d) full bladder impairing drainage

Duplex US:

(1) direct signs = visualization of renal artery stenosis
√ peak systolic velocity > 150 cm/sec for angles < 60° or 180 cm/sec for angles > 70° (with many false positives due to suboptimal Doppler angles)
√ ratio of peak renal artery velocity to peak aortic center stream velocity > 3.5 (for > 60% stenosis; 0–91% sensitive, 37–97% specific)
√ poststenotic spectral broadening ± flow reversal
√ absence of blood flow during diastole (for > 50% stenosis)
√ NO detectable Doppler signal with good visualization of renal artery (= arterial occlusion)

Problems:
(a) technically inadequate examination (gas, corpulence, respiratory motion) in 6–49%; US usually limited to children + thin adults
(b) multiple renal arteries in 16–28%
(c) "false" tracings from large collateral vessels / reconstituted segments of main renal artery
(d) need to visualize entire length of renal artery
(e) transmitted cardiac / aortic pulsations obscure renal artery waveform recordings

(2) indirect signs = analysis of intrarenal arterial Doppler waveforms
(a) pattern recognition
√ dampened appearance = tardus-parvus pulse
[*tardus*, Latin = late arrival; *parvus*, Latin = attenuated peak]
√ loss of early systolic peak (not necessarily abnormal!)
√ segmental arterial flow detectable with renal artery occlusion ← collateral circulation
(b) quantitative criteria



Variants of Normal Renal Artery Doppler Waveforms

Type A: early systolic peak (ESP) at the end of the early rise

Type B: no peak but rise remains straight

Type C: abnormal spectra with slowed rise time

AT = acceleration time; ΔV = velocity difference between ESP velocity and late diastolic velocity; ESP = early systolic peak
LSP = late systolic peak; acceleration index (AI) = ΔV/AT

Duplex Results for > 60% Renal Artery Stenosis			
	Sensitivity	*Specificity*	*Accuracy*
AT ≥ 0.07 sec	81%	95%	91%
AI < 300 cm/s²	89%	86%	87%
Absent ESP	92%	96%	95%

√ acceleration index of < 370–470 cm/s2 = ΔV/ΔT = tangential inclination of Doppler waveform in early systole (single most sensitive screening parameter)
√ delay in acceleration / pulse rise time of > 0.05–0.08 sec = gradual slope of Doppler waveform during early systole
√ ΔRI > 5% between both kidneys (82% sensitive + 92% specific for stenosis > 50%, 100% sensitive + 94% specific for stenosis ≥ 60%)
√ RI < 0.56
√ attenuated (= parvus) Doppler waveform amplitude = decrease in peak systolic

velocity to < 20–30 cm/s
Problems: technically inadequate examination in 0–2%
False-negative US: stenosis in accessory renal artery
False-positive US: coarctation

Arteriosclerotic Renal Artery Disease

Frequency: in up to 6% of hypertensive patients; most common cause of secondary hypertension
Age: > 50 years; M > F
Path: lesion primarily involving intima
- worsening of preexistent hypertension
- abrupt onset of severe hypertension > 180/110 mmHg
- vascular bruit in 40–50% (present in 20% of hypertensive patients without renal artery stenosis)

Associated with: severe arteriosclerosis of aorta, cerebral, coronary, peripheral arteries
Location: main renal artery (93%) + additional stenosis of renal artery branch (7%); bilateral in 31%
√ eccentric stenosis in proximal 2 cm of renal artery, frequently involving orifice
√ decrease in renal length over time (= high-grade renal artery stenosis with risk for occlusion)
Prognosis: progression of atherosclerotic lesion (40–45%) to renal atrophy, arterial occlusion, ischemic renal failure
Cx: azotemia with
(a) bilateral renal artery stenoses
(b) unilateral renal artery stenosis + poorly functioning contralateral kidney
◊ Reversible azotemia may be induced by treatment with angiotensin-converting enzyme inhibitors / sodium nitroprusside!

Rx: (1) Three-step antihypertensive therapy (control of hypertension difficult)
(2) Angiotensin-converting enzyme inhibitors (eg, captopril PO, enalaprilat IV)
(3) Renal artery angioplasty (80% success for nonostial lesion, 25–30% for ostial lesion)
(4) Surgical revascularization (80–90% success for any lesion location)
› hypertension improved in 66%
› improvement / stabilization of renal function in 27–80%

Fibromuscular Dysplasia of Renal Artery

Prevalence: 4÷1000 symptomatic patients of renal artery + 2÷1000 of extracranial carotid artery involvement (2007); 35% of renal artery stenoses; 25% of all cases of renovascular hypertension
Age: most common cause of renovascular hypertension in children + young adults < 30–40 years; M÷F = 1÷3
Associated with: fibromuscular dysplasia of other aortic branches in 1–2%: celiac artery, hepatic artery, splenic artery, mesenteric artery, iliac artery, internal carotid artery

• hypertension, progressive renal insufficiency

Sites: mid and distal main renal artery (79%), renal artery branches (4%), combination (17%); proximal ⅓ of main renal artery spared in 98%; bilateral in ²/₃; R÷L = 4÷1

Types:

1. Intimal fibroplasia = intimal hyperplasia
   - √ narrow annular radiolucent band in main renal artery + major segmental branches; often bilateral
   - √ poststenotic fusiform dilatation
2. Medial fibroplasia with microaneurysm
   - √ "string-of-beads / **string-of-pearls** sign" = alternating areas of stenoses + aneurysms in mid + distal renal artery + branches; usually bilateral
3. Fibromuscular hyperplasia
   - √ long smooth tubular narrowing of main renal artery and branches
4. Perimedial fibroplasia
   - √ beading without aneurysm formation of distal (mostly right) main renal artery
5. Medial dissection
   - √ false channel in main renal artery + branches
6. Adventitial fibroplasia
   - √ long segmental stenosis of main renal artery + large branches

Prognosis: progression of lesion in 20% → decline in renal function

Cx: (1) Giant aneurysm
(2) AV fistula between renal artery + vein (in medial fibroplasia)

Rx: (1) Resection of diseased segment with end-to-end anastomosis
(2) Replacement by autogenous vein graft, excision + repair by patch angioplasty
(3) Transluminal balloon angioplasty (90% success rate with very low restenosis rate)

Neurofibromatosis of Renal Artery

Hypertension in neurofibromatosis due to:
(1) Pheochromocytoma
(2) Renal artery stenosis

◊ Renal artery involvement mainly seen in children!

Types:
(a) mesodermal dysplasia of arterial wall with fibrous transformation (common)
(b) narrowing of main renal artery by periarterial neurofibroma (rare)

√ saccular funnel-shaped aneurysm involving aorta / main renal artery
√ smooth / nodular stenosis (mural / adventitial neurofibroma) in proximal renal artery
√ intrarenal aneurysm (rare)

DDx: fibromuscular dysplasia; congenital renal artery stenosis

RENAL CELL CARCINOMA

= RCC = RENAL ADENOCARCINOMA = HYPERNEPHROMA

Prevalence: 2–3% of all adult visceral cancers (frequency approximates ovarian cancer, gastric cancer, pancreatic cancer, leukemia); 65,000 new RCCs in USA annually with 13,500 deaths (2012); 85–90% of all renal malignant primaries in adults; 7th / 12th

most common malignancy in men / women; 61% found incidentally with imaging

Age: 6th–7th decade (generally > 40 years); median age of 55 years; 2% occur in children in first 2 decades of life; frequency increasing with age; M÷F = 1.6÷1

Path: arises from proximal tubular cells

Tumor growth pattern:

papillary (5–15%, best prognosis); trabecular / tubular / cystic / solid (poorer prognosis)

Associated with familial and hereditary syndromes:

(1) von Hippel–Lindau syndrome
(2) **Birt-Hogg-Dubé syndrome**: rare autosomal dominant disease characterized by hair follicle hamartomas, renal tumors, pulmonary cysts
(3) Hereditary papillary renal cancer

Predisposed:

(1) Von Hippel-Lindau syndrome (10–25%): multiple often small intracystic tumors (hemangioblastoma, retinal angioma, renal cysts) manifesting at a young age
(2) Hemodialysis (in 1.4–2.6%)
(3) Acquired cystic disease of uremia (3.3–6.1%; 7 x increased risk)
(4) Tobacco; phenacetin abuse
(5) Obesity

Histopathologic subtypes associated with different prognosis:

(a) clear cell RCC (65–80%)
(b) multilocular clear cell RCC (< 1%)
(c) papillary RCC (15–20%) = pRCC
(d) chromophobe RCC (4–11%)
(e) collecting duct carcinoma of Bellini (< 1%)
(f) renal medullary carcinoma
(g) unclassified
- › Xp11 translocation carcinoma
- › carcinoma associated with neuroblastoma
- › mucinous tubular spindle cell carcinoma

Grading (Fuhrman):

Grade 1 tumor cells with 10-µm small round uniform nuclei without nucleoli
Grade 2 tumor cells with 15-µm nuclei, subtle irregular outline and with nucleoli
Grade 3 tumor cells with 20-µm nuclei obvious irregular outline and prominent larger nucleoli
Grade 4 tumor cells with bizarre multilobed nuclei and heavy clumps of chromatin

Staging:

Staging of Renal Cell Carcinoma *American Joint Committee on Cancer (2002)*	
T1	tumor ≤ 7 cm confined to kidney
T2	tumor > 7 cm confined to kidney
T3	invasion of perinephric fat / adrenal gland / major vein
T4	extension beyond Gerota fascia / distant metastasis

Staging accuracy: 84–91% for CT; 82–96% for MR; poor for US

Regional extension: into lymph nodes (9–23%); into main renal vein (21–35%); into IVC (4–10%)

Multiple RCC: commonly in Von Hippel-Lindau syndrome; hereditary RCC; sporadic in 4–15%; bilateral in 1–3%

Metastasis:

- hematuria (56%), flank pain (36%), weight loss (27%), fever (11–15%); normochromic normocytic anemia (28–40%)
- classic triad of flank pain + gross hematuria + palpable renal mass (4–9%); varicocele (2%)
- **Stauffer syndrome** (15%) = nephrogenic hepatopathy = hepatosplenomegaly + abnormal liver function in absence of hepatic metastases (? tumor hepatotoxin)
- Paraneoplastic syndromes: erythrocytosis (2%); hypercalcemia ← parathormone, prostaglandin, vitamin D metabolites)

√ well-marginated often lobulated solitary mass:
  √ focal bulge in renal contour
  √ enlargement of affected part of kidney
√ calcification (15–20%): usually central + amorphous or peripheral + curvilinear in cystic RCC
√ extrinsic compression / displacement / invasion of renal pelvis + calices
√ cysts:
  (a) cystic necrotic tumor (40%)
  (b) cystadenocarcinoma (2–5%)
  (c) renal cell carcinoma in wall of cyst (3%)
√ tumor growth into renal vein (23%) / IVC (in up to 16%) → conveys poor prognosis
√ infiltrative growth pattern (6%) with ill-defined margin

IVP:
  √ diminished function ← parenchymal replacement, hydronephrosis
  √ absence of contrast excretion ← renal vein occlusion
  √ pyelotumoral backflow = necrotic part of tumor fills with contrast material

NECT:
  √ homogeneous solid mass of > 20 HU ← if ≤ 3 cm lesion
  √ heterogeneous hemorrhagic / necrotic mass ← if > 3 cm
  √ calcifications in up to 30%
  √ perinephric fat stranding (50%) ← edema, vascular engorgement, previous inflammation, tumor invasion
  √ ± subcapsular / perinephric hemorrhage
  √ nodal enlargement of > 1 cm (43% PPV, 96% NPV) (DDx: benign inflammation as reactive immune response)

  Falsely negative in corticomedullary phase:
    (1) a small tumor may enhance to the same degree as renal parenchyma
    (2) centrally located tumor mistaken for medulla

CECT:
  √ mostly heterogeneous enhancement ← cystic areas / necrosis:
    √ enhancement of > 12 HU compared with NECT
    √ enhancement to a similar degree as renal cortex
    √ enhancement to a lesser degree than renal cortex = papillary / chromophobe RCC

√ metastases show similar enhancement as primary
√ enhancing nodule in perinephric space (46% sensitive for perinephric spread)
√ renal vein thrombus (92% PPV, 97% NPV):
√ low-attenuation filling defect in corticomedullary phase (MOST SPECIFIC SIGN)
√ abrupt change in caliber of vein
√ presence of collateral veins
√ heterogeneous enhancement of malignant thrombus

US:
√ hyperechoic mass (in 20–50%), mostly in small tumors < 3 cm (78%), occasionally in large tumors (32%):
√ markedly hyperechoic, ie, isoechoic to renal sinus fat in 4–12% of small tumors (DDx: angiomyolipoma)
√ anechoic rim (in 84% of small hyperechoic RCCs) ← pseudocapsule of compressed renal tissue (NOT seen in angiomyolipoma)
√ isoechoic (30–86%) / hypoechoic (10–12%), mostly in larger tumors
√ cystic lesion with increase in acoustic transmission (2–13%) ← extensive liquefaction necrosis (DDx: complicated cyst)
√ inhomogeneity ← hemorrhage, necrosis, cystic degeneration

MR (best modality to assess stage III + IV disease):
√ hyper- / iso- (most) / hypointense relative to renal parenchyma:
√ often low to medium signal intensity on T1WI
√ hyperintense areas on T1WI + hypointense on T2WI ← usually from hemorrhage
√ heterogeneous hyperintensity on T2WI
√ mild decrease in SI on opposed-phase images ← diffuse microscopic intracellular lipid in cRCC
√ imaging at 2 to 5 minutes post contrast injection is critical for the detection of small renal mass (= less enhancement than in normal renal tissue)

PET (sensitivity inferior to CT and MR):
√ inconsistent FDG uptake ← hypo- / isometabolism relative to background + lack of accessibility of FDG ← heterogeneity of glucose transporter expression
◊ Malignancy cannot be ruled out with a negative study!

Angio:
√ typically hypervascular (95%) with puddling of contrast + occasional AV shunting
√ enlarged tortuous poorly tapering feeding vessels
√ coarse neovascularity + formation of small aneurysms
√ parasitization of lumbar, adrenal, subcostal, mesenteric artery branches
√ poorly defined tumor margins

Prognosis:
◊ Tumor stage + histologic grade are the most important prognosticators!
› 5-year survival rates for stages I, II, III, IV are 85–100%, 45–65%, 20–40%, 0–10%;
› 10-year survival rates for stages I, II, III, IV are 56%, 28%, 20%, 3%
› 4.4% 3-year survival rate if untreated
› papillary carcinomas have a better prognosis than nonpapillary carcinomas!
› clear cell + granular cell cancers have a better prognosis than spindle cell + anaplastic

cancers

Recurrence: in 11% after 10 years

Rx:

(1) Radical nephrectomy (2–5% operative mortality)
N.B.: chemo- / radiation- / immunotherapy cannot cure metastatic renal cell carcinoma!

(2) Nephron-sparing surgery (partial nephrectomy) with solitary functioning kidney, compromised renal function, multiple bilateral tumors, small RCC (< 3 cm in diameter, polar, cortical, far from renal hilum / sinus / collecting system)

(3) < 5% of metastatic RCCs respond to chemotherapy; only 20% respond to interleukin-2 / interferon-α

(4) Targeting tumor-angiogenesis: sunitinib and temsirolimus

Chromophobe Renal Cell Carcinoma

Prevalence: 4–11%

Associated with: Birt-Hogg-Dubé syndrome

Origin: intercalated cells of renal cortex

Differentiation of Renal Cyst vs. Neoplasm by CT

CT Feature	*Cyst*	*Neoplasm*
Shape	round, oval	irregular
Margin	smooth	lobulated
Wall	thin, not measurable	thick
Interface	sharp, distinct	indistinct
Density	0–20 HU	> 30 HU
Enhancement	< 10–20 HU	> 10–20 HU
Portal venous phase	< 70 HU	> 70 HU
Vascular invasion	none	yes

Path: solid growth, rarely necrotic even in large tumor

Histo: round to polygonal cells with well-defined cytoplasmic border, abundant pale eosinophilic cytoplasm, fine reticular pattern, perinuclear halo

Median age: 6th decade (range, 31–75 years)

Average size: 8.0 (range, 1.3–20.0) cm

√ less hypervascular than clear cell RCC

√ cystic changes within solid tumor (rare)

√ spokewheel enhancement (? related to oncocytoma)

Prognosis: 5-year survival rate of 90%; better than for cRCC

Collecting Duct Renal Cell Carcinoma

= highly aggressive subtype of RCC

Site: centered in pelvicaliceal system

√ infiltrative growth pattern with medullary epicenter

√ large lesions: heterogeneous ← areas of necrosis, hemorrhage, calcifications

MR:

√ typically low SI on T2WI with hypovascularity

Prognosis: 5-year survival rate of < 5%

Clear Cell Renal Cell Carcinoma (cRCC)

= CONVENTIONAL RCC = cRCC
Prevalence: 60–80% of all RCCs
Associated with: von Hippel–Lindau syndrome
Origin: derived from epithelium of proximal convoluted tubule → cortical location and expansile growth
Path: central necrosis (common); may be predominantly cystic with only minor solid enhancing component
Histo: rich in cytoplasmic glycogen + lipid content that washes away (hence "clear") during tissue processing; extensive thin-walled sinusoid-like vessels
Genetics: translocation of short arm of chromosome 3; mutation of von Hippel–Lindau tumor suppressor gene → synthesizes protein that suppresses hypoxia-induced genes involved in angiogenesis
Location: in cortex as exophytic hypervascular solid mass
√ heterogeneous appearance ← macroscopic areas of necrosis, hemorrhage, cystic changes, calcifications
√ greater degree of enhancement than other subtypes ← CHARACTERISTIC network of small sinusoid blood vessels
MR:
- √ tumor isointense to renal parenchyma on T1WI
- √ tumor hyperintense to renal parenchyma on T2WI
- √ SI loss within solid portions on opposed-phase compared with in-phase images ← cytoplasmic fat (in 60%)
- √ ± hypointense rim on both T1- and T2-weighted images = pseudocapsule of compressed adjacent renal parenchyma:
  - √ interruption of pseudocapsule ← invasion of perirenal fat in advanced tumor stage
- √ imaging of tumor necrosis:
  - √ homogeneously hypointense area in center of mass on T1WI that is hypo- to hyperintense on T2WI
  - √ solid rim of tumor peripherally
  - √ lack of enhancement in necrotic area + marked enhancement of viable tumor component
- √ imaging of intratumoral hemorrhage:
  - √ high signal intensity on both T1- and T2WI = subacute to chronic hemorrhage
  - √ hypointense on both T1- and T2WI = long-standing hemorrhage predominantly containing hemosiderin
- √ hypervascularity during cortical phase ← network of small sinusoid-like blood vessels
- √ renal vein tumor thrombus = higher-stage tumor

Prognosis: 5-year survival rate of 55–60%; poorer than for chromophobe or pRCC

Cystic Renal Cell Carcinoma

Prevalence: 4–15% of all RCCs
Spectrum:

(a) **Unilocular cystic RCC** (50%)
= extensive necrosis of a previously solid RCC / intrinsic cystic growth of a cystadenocarcinoma / papillary RCC
√ fluid-filled mass without criteria of a renal cyst
(b) **Multilocular RCC** (30%)
= intrinsic multilocular growth; impossible to distinguish from multilocular cystic nephroma
√ septated variable-sized cysts + septal calcifications
(c) **Mural nodule in cystic RCC** (20%)
√ asymmetric cystic tumor necrosis
√ tumor arising in wall of preexisting cyst
√ tubular dilatation with secondary cyst formation from tumor obstruction

√ characteristics of a fluid-filled cystic mass:
√ calcifications
√ atypical contents:
√ high attenuation > 20 HU at NECT
√ signal intensity atypical for water at MRI
√ solid component with internal echoes failing to show acoustic enhancement at US
√ septations
√ multiple locules
√ contrast enhancement
√ wall thickening > 2–3 mm
√ nodularity

CT (triple phase):
√ > 15 HU change within solid portion (DDx: cystic angiomyolipoma, oncocytoma, infection)
√ rarely 10–15 HU change (DDx: papillary RCC, volume averaging, motion, streak artifact, imperfect placement of ROI)

DDx: complicated renal cyst

Metastatic Renal Cell Carcinoma

18–28% of patients have clinically apparent multiple synchronous distant metastases at presentation

50% will develop metachronous metastases during follow-up after nephrectomy (in 85% within 3 years)

Incidence of metastatic disease:

(a) tumors < 3 cm : 2.6%
(b) tumors 3–5 cm : 15.4%
(c) tumors > 5 cm : 78.6%

Number of sites: single÷multiple sites = 3÷2

Spread to:

lung (45–55%) > bone (32%) > lymph nodes (22–34%); liver (20–33%); pancreas(1.6–11%); adrenals (4.3–19%); contralateral kidney (11%); brain (6%); heart (5%); spleen (5%); bowel (4%); skin (3%); ureter (rare)

(a) hematogenous: venous extension (20–35%)
› ascending into IVC → right chambers → lung → systemic circulation
› descending (= venous reflux) into adrenal, gonadal, second lumbar veins → (often ipsilateral) ovary / testis / adrenal gland
› with venous thrombosis → retroperitoneal and paravertebral Batson plexus
(b) lymphatic:
» regional lymph nodes (N): renal hilar and retroperitoneal (paraaortic + paracaval) nodes
› mediastinal, pelvic, inguinal nodes (M1)
› invasion of thoracic duct → thoracic (mediastinal and hilar) / supraclavicular nodes

• cough, bone pain, hemoptysis (as initial symptoms of metastatic disease present in 9%)

CT:
√ tumor metastases tend to be hypervascular
√ some metastases (eg, clear cell RCC) are detected only during arterial phase
√ hypovascular metastases are best detected during the nephrographic phase

Bone scintigraphy:
√ negative uptake for bone metastases if lesion purely lytic without associated reactive bone formation

Papillary Renal Cell Carcinoma (pRCC)

Prevalence: 10–15% (2nd most common) of all RCCs
Age: 3rd–8th decade; M÷F = 2÷1 to 4÷1
Origin: derived from epithelium of proximal convoluted tubules
Associated with: end-stage renal disease
Path: cystic necrosis + degeneration frequent; familial form associated with trisomy 7 & 17 & loss of Y chromosome in males (similar to papillary adenoma)
Histo: cells surrounding fronds of delicate fibrovascular core; macrophages infiltrating papillary stalks
(a) basophilic = small cuboidal cells with uniform nuclei covering thin papillae
(b) eosinophilic = large eosinophilic cells with pleomorphic nuclei
Growth pattern: papillary, tubular, tubulopapillary
Location: most common of multifocal / bilateral renal tumors!
√ typically hypovascular → enhances to a lesser degree compared with clear cell RCC
√ homogeneous slow growing well-encapsulated tumor
√ peripheral calcifications frequent

CECT:
√ little contrast enhancement in all phases to a lesser degree than renal cortex (DDx to hypervascular cRCC)
√ usually homogeneous enhancement if < 3 cm
√ heterogeneous enhancement if > 3 cm (DDx to usually homogeneously enhancing chromophobe RCC)

MR:
√ fibrous capsule (frequent)
√ hypointense on T1WI + T2WI (DDx to hyperintense cRCC on T2WI)
√ low-grade basophilic (type I) tumor:

√ homogeneously low SI on T2WI
√ hypovascular homogeneous low-level enhancement
√ high-grade eosinophilic (type II) tumor:
√ complex tumor appearance ← hemorrhage + necrosis
√ enhancing papillary projections at periphery of cystic hemorrhagic mass
US:
√ frequently hypoechoic mass
Prognosis: 5-year survival rate of 80–90%; favorable (smaller mean diameter, lower stage, later metastases than cRCC)
DDx: renal cyst (enhancement of < 10 HU / pseudoenhancement, cyst by US + MR)

Renal Cell Carcinoma in Childhood

Frequency: 7% of all primary renal tumors during first 2 decades of life;
in childhood: Wilms tumor÷RCC = 30÷1
in 2nd decade: Wilms tumor÷RCC = 1÷1
Mean age: 9 years
• palpable abdominal mass (60%), abdominal pain (50%)
• hematuria (30–60%), hypertension due to renin production
• polycythemia ← erythropoietin production
• bone resorption ← parathyroid hormone production
Increased risk of renal cell carcinoma:
Von Hippel-Lindau disease in 10–25% (cerebellar hemangioblastoma, retinal angioma, pancreatic cysts + tumors, pheochromocytoma, renal cysts + tumors)
Metastases (20%): lung, bone, liver, brain
Cx: intravascular extension (25%)
Prognosis: 64% overall survival rate
DDx: Wilms tumor (younger age, larger at presentation, calcifications less frequent [9% versus 25%], less dense / homogeneous)

RENAL CYST

Simple Cortical Renal Cyst

= acquired lesion possibly secondary to tubular obstruction; accounts for 62% of all renal masses
Frequency: in 1–2% (3–5%) of all urograms (autopsies)
Age: peak incidence after age 30; increasing frequency with age (0.22% in pediatric age group, 50% over age 50)
Path: low cuboidal / flattened epithelium surrounded by 1–2-mm thick fibrous wall containing clear / slightly yellow serous fluid
May be associated with:
tuberous sclerosis, Von Hippel-Lindau disease, Caroli disease, neurofibromatosis
√ large and unifocal when peripheral
√ focal attenuation + displacement of collecting system
√ focally replaced nephrogram with smooth margin
√ "beak / **claw**" sign = effaced wedge of renal parenchyma

√ delicate filamentous often undulating septa (10–15%)
√ curvilinear calcification (1–3%) in wall / septa
√ milk of calcium in dependent portion = always benign

CT / MR Features of Cystic Renal Lesions
Bosniak Classification

Class	*Description*	*Findings*	*Malignant*
I	simple cyst	√ well-defined round mass of water attenuation √ hairline-thin smooth imperceptible wall √ no enhancement	~ 0%
II	minimally complicated cyst	√ cluster of cysts / septated cyst √ fine curvilinear calcification √ minimally irregular wall √ high-density content in < 3 cm cyst	~ 0%
IIF	Follow-up lesion (initially 6 months, then yearly)	√ several hairline-thin septa √ wall / septa with perceived enhancement √ thick nodular calcium √ intrarenal >3 cm high-density lesion	~ 5%
III	complicated (surgical) lesion: hemorrhagic / infected cyst, MLCN, cystic neoplasm	√ irregular thickened septa √ measurable enhancement √ coarse irregular calcification √ irregular margin √ multiloculated lesion √ uniform wall thickening √ nonenhancing nodular mass	~ 50%
IV	clearly malignant cystic lesion	√ large cystic / necrotic component √ irregular wall thickening √ solid enhancing elements	> 90%

N.B.: measurement of cyst wall thickness not accurate in a completely intrarenal cyst

US (90–100% accuracy of US & CT):
- √ spherical / ovoid in shape
- √ anechoic content without internal echoes
- √ smooth clearly demarcated back wall
- √ acoustic enhancement of tissue beyond cyst (= positive through transmission) ← unattenuated sound reflections
- √ refraction along sidewalls

CT (100% accuracy):
- √ near-water–density lesion (0–20 HU) with thin wall + smooth interface with renal parenchyma
  - *N.B.:* Accuracy of HU measurements depends on: patient size, mass size, size of region examined, CT scanner type & manufacturer, CT technique, image noise, partial

volume averaging, pseudoenhancement

√ no enhancement (< 12 HU)

MR:

√ most sensitive modality for cysts < 10 mm

√ < 15% enhancement after 0.1 mmol/kg gadolinium on spoiled GE T1WI without fat sat and without retuning = $(SI_{post} - SI_{pre}) \div SI_{pre} \times 100$

Cystography:

√ smooth wall, clear aspirate with low lactic dehydrogenase, no fat content

Cx: (1) Hemorrhage in 1–11.5%

(2) Infection in 2.5%

(3) Tumor within cyst in < 1%

PSEUDOENHANCEMENT

= artificial elevation of Hounsfield unit measurements of renal cyst measured on CECT images

◊ Most frequently occurs in intrarenal cyst of < 2 cm during peak parenchymal enhancement

Cause: secondary to image reconstruction algorithm used to adjust for beam-hardening effects

√ simple fluid attenuation of < 10 HU on NECT images

√ simple renal cyst mischaracterized as solid mass

Recommendation if suspected: US / MR

Atypical / Complicated Renal Cyst

Path: calcification, hemorrhage, septations, wall-thickening, nodularity

Histo: inflammatory cells + granulation tissue + neovascularity ← host reparative response to hemorrhage, infection, inflammation, ischemia

US:

√ cyst content of low-level echoes / layers of echoes

√ cyst septations ± reverberation artifacts

√ ± shadowing calcifications

CT:

› Bosniak II cyst

√ fine calcifications ± short segment of slightly thickened calcification in cyst wall / septa

√ ± few hairline-thin septa

√ nonenhancing homogeneously hyperattenuating (> 20 HU) lesion measuring ≤ 3 cm

› Bosniak IIF cyst (0.01% chance of malignancy)

√ several thin internal septations without measurable enhancement

√ few nodular calcifications

√ smooth thickening of cyst wall

√ nonenhancing hyperattenuating (> 20 HU) cyst > 3 cm ± completely intrarenal

◊ cyst content of > 70 HU on NECT in > 99.9% benign

› Bosniak III cyst (30–100% chance of malignancy)

√ thick irregular walls ± numerous septa with measurable enhancement

√ ± thick nodular calcifications in cyst wall and septa

DDx: RCC, cystic nephroma, mixed epithelial and stromal tumor (MEST), benign multiloculated cyst, hemorrhagic cyst, renal abscess, hematoma, renal artery aneurysm

Rx: serial follow-up, surgery

› Bosniak IV cyst (= malignant until proven otherwise)

√ enhancing nodular soft-tissue component

Rx: surgery

Dx: cyst puncture + aspiration

Hemorrhagic Renal Cyst

Cause: trauma, varices, bleeding diathesis

• rust-colored puttylike material

√ uni- / multilocular cyst separated by thick septa

√ thick fibrous ± calcified wall

√ fibrin ball inside cyst (rare)

CT:

√ increased density ← acute hemorrhage / high protein contents (= hyperattenuating cyst with ~ 60–90 HU)

√ no contrast enhancement

MR:

√ usually iso- to hyperintense on T1WI ← methemoglobin + hyperintense on T2WI ← lysis of RBCs

√ NO suppression on fat-saturated T1WI

√ variable signal intensities (dependent on amount + acuity of hemorrhage, hemoglobin degradation product, degree of RBC lysis, protein content)

√ hematocrit effect ← settling of RBCs at cyst bottom

Infected Renal Cyst

Cause: hematogenous dissemination of bacteria, ascending urinary tract infection

Mean age: 61 years; in 94% females

• history of no response to antibiotic Rx for acute pyelonephritis; leukocyturia

US:

√ thickened irregular cyst wall (22%)

√ internal septations (11%)

√ wall calcification (occasionally)

√ minute debris either diffusely / fluid-fluid level in dependent portion of cyst

√ amorphous solid conglomerates

√ round sharply marginated lesion

High-density Renal Cyst

= completely homogeneous cyst content ≥ 20 HU (often 50–90 HU) without enhancement

1. Proteinaceous content (20–40 HU)
   √ simple cyst on US
2. Hemorrhage (> 40 HU)

√ complex cyst on US

3. Infection
4. Calcification
5. Communication with calyx
6. Streak artifact

√ pseudoenhancement *(see above)*

◊ Cyst wall cannot be evaluated in high-attenuation cysts!

◊ Considered a Bosniak Class II lesion if:
≤ 3 cm in size, partially exophytic, round, sharply marginated, homogeneous, nonenhancing

◊ A homogeneous renal mass with attenuation > 70 HU on NECT is benign with a 99% probability!

Cyst of Renal Pelvis

= generic term for spherical fluid-filled mass intimately attached to renal pelvis without connection to pelvicaliceal system

Prevalence: 1.5% (autopsies); 4–6% of all renal cysts

Age: mostly during 5th–6th decade

• clear straw-colored serous fluid

√ soft-tissue density in renal sinus

√ anechoic mass(es) with acoustic enhancement

DDx: hydronephrosis

Renal Sinus Cyst

= PERIPELVIC CYST = PARAPELVIC LYMPHATIC CYST = PARAPELVIC LYMPHANGIECTASIA

= multiple small confluent cysts arising from renal sinus

Etiology: probably ectatic lymphatic channels from lymphatic obstruction; ? posttraumatic extravasation of urine / blood; ? mesonephric remnant; ? remnant of wolffian body; ? outpouchings of renal pelvis; ? duplication anomaly

• almost always asymptomatic

Location: frequently bilateral

√ multiple small renal sinus cysts

√ focal displacement + smooth effacement of collecting system

√ rarely curvilinear calcification of cyst wall (4%)

IVP:

√ stretching of collecting system when generalized (indistinguishable from sinus lipomatosis)

NECT / US:

√ multiple confluent cysts (mimicking hydronephrosis)

CECT:

√ high-attenuation contrast fills collecting system but not cyst

Prognosis: NO change on long-term follow-up

Parapelvic Cyst

= protrusion of medial parenchymal cyst into sinus fat

Histo: lined with single epithelial layer
- hematuria ← cyst rupture
- pain ← obstructive caliectasis / infection
- renovascular hypertension ← compression of renal arteries

Location: usually single unilateral cyst, may be multiple

√ simple cortical renal cyst that extends into renal sinus fat

Cx: (1) Caliectasis / localized hydronephrosis) ← compression of collecting system
(2) hypertension ← compression of renal artery
(3) infection, hemorrhage

Rx: cyst ablation with 95% ethanol if symptomatic

RENAL DYSGENESIS

= undifferentiated tissue of renal anlage

◊ Pathologic NOT radiologic diagnosis

√ renal vessels usually absent; occasionally small vascular channels

RENAL INFARCTION

Cause:

1. TRAUMA
   blunt abdominal trauma with traumatic avulsion / occlusion of renal artery, penetrating vascular injury, surgery
2. EMBOLISM
   (a) Cardiac: rheumatic heart disease with arrhythmia (atrial fibrillation), myocardial infarction, prosthetic valve, myocardial trauma, left atrial / mural thrombus, myocardial tumor, subacute bacterial endocarditis → septic emboli
   (b) Catheters: angiographic catheter manipulation, transcatheter embolization, umbilical artery catheter above level of renal arteries
3. ARTERIAL THROMBOSIS
   arteriosclerosis, aneurysm or dissection of aorta / renal artery, thrombangiitis obliterans, polyarteritis nodosa, syphilitic cardiovascular disease, sickle cell disease, paraneoplastic syndrome (Trousseau syndrome), hypercoagulable state
4. VASCULITIS
   polyarteritis nodosa, SLE, drug-induced vasculitis
5. Sudden complete renal vein thrombosis

Acute Renal Infarction

- sudden onset of flank / back pain
- ± hematuria, proteinuria, fever, leukocytosis

√ normal / large kidney with smooth contour

√ normal / expanded parenchymal thickness

√ normal / attenuated collecting system, often only opacified by retrograde pyelography

√ absent / diminished nephrogram with cortical rim enhancement, rarely striations

CT:

√ wedge-shaped area of absent enhancement

√ edematous enlargement of kidney (with large infarct)
√ "cortical rim" sign within several days after global infarction

US:
√ diminished echogenicity (within < 24 hours)
√ normal echogenicity (echoes appear within 7 days)

NUC (SPECT imaging with ^{99m}Tc-DMSA):
√ photon-deficient area

Rx: thrombolytic therapy, supportive hemodialysis, transcatheter thrombembolectomy, surgery

Lobar Renal Infarction

Early signs:
√ focal attenuation of collecting system ← tissue swelling
√ focally absent nephrogram (triangular with base at cortex)

Late signs:
√ normal / small kidney(s)
√ focally wasted parenchyma with NORMAL interpapillary line (portion of lobe / whole lobe / several adjacent lobes)

CT:
√ nonperfused area corresponding to vascular division
√ "cortical rim" sign (subacute) = thin rim of preserved subcapsular perfusion ← capsular perforators

US:
√ focally increased echogenicity

Chronic Renal Infarction

Path: all elements of kidney atrophied with replacement by interstitial fibrosis
√ normal / small kidney with smooth contour
√ globally wasted parenchyma
√ diminished / absent contrast material density

US:
√ increased echogenicity (by 17 days)

Angio:
√ normal intrarenal venous architecture
√ late visualization of renal arteries on abdominal aortogram

Atheroembolic Renal Disease

= dislodgment of multiple atheromatous emboli from the aorta into renal circulation → below level of arcuate arteries
√ normal / small kidneys with smooth contour or shallow depressions
√ wasted parenchymal thickness
√ diminished density of contrast material

CT:
√ patchy nephrographic distribution

Angio:

√ embolic occlusion

Arteriosclerotic Renal Disease

= disseminated process involving most of the interlobar + arcuate arteries causing uniform shrinkage of kidney

Age: generally over 60 years

Accelerated development in:

scleroderma, polyarteritis nodosa, chronic tophaceous gout

• often associated with hypertension (= nephrosclerosis)

√ normal / small kidneys

√ smooth contour with random shallow contour depressions ← infarctions

√ uniform loss of cortical thickness

√ normal / effaced collecting system ← fat proliferation

√ increased pelvic radiolucency (vicarious sinus fat proliferation)

√ calcification of medium-sized intrarenal arteries

US:

√ increased echogenicity possible

√ increased size of renal sinus echoes ← fatty replacement

Nephrosclerosis

Histo: thickening + hyalinization of afferent arterioles, proliferative endarteritis, necrotizing arteriolitis, necrotizing glomerulitis

• arterial hypertension

(a) benign nephrosclerosis

(b) malignant nephrosclerosis (rapid deterioration of renal function)

√ radiographic appearance similar to arteriosclerotic kidney

RENAL SARCOMA

Frequency: 1% of malignant renal parenchymal tumors

Subtypes: leiomyosarcoma (> 50%), angiosarcoma, hemangiopericytoma, rhabdomyosarcoma, fibrosarcoma, osteosarcoma

√ considerable variation in growth pattern:

√ expansile mass (most commonly)

√ infiltrative growth (rhabdomyosarcoma, angiosarcoma)

Dx: by exclusion of sarcomatoid renal carcinoma + primary retroperitoneal sarcoma with direct extension into kidney

RENAL TRANSPLANT

Frequency: 316,493 transplants between 1988 and 2012 in US; 17,107 transplants annually in USA (2014)

Complications in 10%:

◊ Problematic period between 4 days and 3 weeks after surgery!

• hypertension in 50% (from rejection / arterial stenosis)

(a) immediate: ATN, acute humeral rejection, renovascular thrombosis, perinephric hematoma, graft infection + abscess

(b) early (> 1–4 weeks): acute rejection, renal vein thrombosis, urinary tract obstruction, urine leak, urinoma

(c) late (> 1 month): acute + chronic rejection, ureteral stricture, VUR, renal artery stenosis, arteriovenous fistula, pseudoaneurysm, lymhocele, seroma

Prognosis: organ survival at 1 (5) years in 89–95% (67–80%); 13–24 years half-life for transplant from living related donor

Renal Allograft Dysfunction *relative to Time since Surgery*	
Immediate to 1st 48 hr	*Day 2 to 7*
1. Hyperacute rejection	1. ATN
2. Renal vein thrombosis	2. RVT
3. Discordant size	
>1 week postop	*Delayed*
1. Acute rejection	1. Chronic rejection
2. ATN	2. Drug toxicity
	3. Obstruction
	4. Infection
	5. Extrinsic compression

Renal Transplant Scintigram				
	Early study (<24 hr post transplantation)		*Late study (>5 days post transplantation)*	
	Flow	*Excretion*	*Flow*	*Excretion*
Acute tubular necrosis	normal / ↓	↓	normal / ↓	↓
Hyperacute rejection	absent	absent		
Acute rejection	↓	↓	worsening	worsening
Chronic rejection	↓	↓	↓	↓

Acute Tubular Necrosis in Renal Transplant

= primary nonfunction within 72 hours of transplantation followed by improvement within a few days to 1 month

◊ Most common cause of "delayed" graft function"

Cause: preservation injury ← prolonged ischemia (cold ischemia time > 24–30 hours), reperfusion injury

› ATN more frequent in cadaveric than living-related donor transplant ← donor hypotension

› ATN greater in transplants with > 1 renal artery

› ATN related to length of ischemic interval ← prolonged organ storage

Histo: sloughed renal tubular epithelium + surrounding edema

Pathophysiology: relative preservation of renal perfusion + minimal / absent urinary excretion

• no constitutional symptoms; elevated urine sodium

• oliguria may begin immediately after transplantation / may be delayed for several days

US:

√ transient enlargement of transplant

√ transient increase in resistive index

NUC (^{99m}Tc mertiatide preferred):

= 1st-line imaging modality!

◊ Limited diagnostic value if serum creatinine > 6 mg/dL

√ normal / slightly decreased transplant perfusion:

√ delayed time from Tmax to one-half maximal activity

√ decreased + delayed radiopharmaceutical uptake:

√ delayed transit time + delayed Tmax

√ delayed / decreased / absent excretion of radiotracer with prolonged cortical retention:

√ high 20-minute to 3-minute ratio

DDx: acute rejection (serial studies help to differentiate)

Rejection of Renal Transplant

◊ Most common cause of parenchymal failure!

◊ Rejection occurs in all transplants to some degree!

Hyperacute Rejection of Renal Transplant (rare)

= humeral rejection with preformed circulating antibodies present in recipient at time of transplantation, usually following retransplantation

Path: thrombosed arterioles + cortical necrosis

Time of onset: within minutes after transplantation

◊ In practice never imaged!

√ complete absence of renal perfusion + renal function on ^{99m}Tc-DTPA scan (DDx: complete arterial / venous occlusion)

Rx: requires immediate reoperation

Accelerated Acute Rejection of Renal Transplant

= combination of antibody + cell-mediated rejection

Time of onset: 2–5 days after transplantation

Acute Rejection of Renal Transplant (in up to 40%)

= cellular rejection predominantly dependent on cellular immunity

◊ Most common type of allograft rejection

Time of onset: any time, typically within 5 days to 6 months; peak incidence at 2nd–5th week

Prevalence: in 50% at least 1 episode in 1st year

Path:

(a) acute interstitial rejection

= edema of interstitium with lymphocytic infiltration of capillaries + lymphatics

(b) acute vascular rejection (rare)

= proliferative endovasculitis + vessel thrombosis

• malaise, fever, weight gain; graft tenderness

• low urine sodium, increase in serum creatinine

• hypertension, oliguria, proteinuria

US (30–50% negative predictive value):

√ increase in renal volume from edema:

√ ↓ renal sinus fat + ↑ cortical thickness (most predictive)

√ loss of corticomedullary differentiation

√ thickening of pelvoinfundibular wall

√ diminished echogenicity of renal sinus fat

Doppler US (higher accuracy than morphologic parameters):

√ initially decrease in resistive index (? autoregulatory mechanism)

√ increase in resistive index > 0.80 (with increasing severity of rejection)

(a) ≤ 0.70 without any form of rejection (57% NPV)

(b) > 0.90 (100% PPV, 26% sensitivity)

√ reversal of diastolic flow

NUC:

√ typically ↓ renal perfusion + ↓ graft function + high background radiotracer activity

√ initially perfusion may be normal with only function decreased (DDx to ATN may not be possible on single study)

√ subsequent exams (1–3-day intervals) demonstrate decreasing renal perfusion

√ prolonged excretory phase

√ poor and inhomogeneous nephrogram

Angio:

√ rapid tapering + pruning of interlobar arteries

√ multiple stenoses + occlusions

√ nonvisualization of interlobular arteries

√ prolonged arterial opacification (normally < 2 seconds)

DDx: acute tubular necrosis (develops within first few days)

Chronic Rejection of Renal Transplant

= slow relentless progressive process resulting in interstitial scarring

◊ Most common cause of late graft loss

Histo: endothelial proliferation in small arteries + arterioles; interstitial cellular infiltration + fibrosis; tubular atrophy; glomerular lesions (? recurrence of patient's original glomerulonephritis)

Time of onset: months to years after transplantation

• progressive decline of renal function

√ progressive volume loss → small kidney with thin cortex

√ diminished number of intrarenal vessels

√ vascular pruning / stenoses / occlusions → commonly focal cortical scarring

√ mild hydronephrosis

NUC:

√ small graft with poor perfusion + globally decreased function

Drug Nephrotoxicity

Nephrotoxic potential of calcineurin inhibitors:

cyclosporine (vasoconstrictive effect on afferent glomerular arterioles) > OKT3 >

tacrolimus (FK-506)
◊ Effects are dose-dependent and accentuated by dehydration + decreased renal perfusion
Action: impedes rejection process with narrow therapeutic window
Histo: (a) acutely: damage to tubules, microthrombosis of kidney ← activation of coagulation cascade
(b) chronically: hyaline deposition within arterial walls
√ no change in renal size
√ no change (?) / elevation of resistive index
NUC:
√ depressed effective renal plasma flow
√ no parenchymal retention

Urologic Problems with Renal Transplant

◊ US is 1st-line imaging modality!

Ureteral Obstruction of Renal Transplant *(2–10%)*
(a) acute: secondary to technical problems
(b) late: secondary to ischemia / previous extravasation
Cause: ischemic stricture (most commonly at ureterovesical junction), ureteral kinking, (transient) edema at ureteroneocystostomy, ureteropelvic fibrosis, crossing vessels, blood clot, fungus ball, calculus, tumor, perinephric fluid collection (hematoma, lymphocele)
• rising serum creatinine level, oliguria
√ pyelocaliectasis
√ normal resistive index strongly argues against obstruction unless ureteral leak is present
NUC (only 18% sensitive ← impaired uptake)
DDx: diminished ureteral tone ← denervation

Urine Extravasation of Renal Transplant *(1–5%)*
Cause:
(1) Distal ureteral necrosis ← interruption of blood supply (early) / vascular insufficiency ← rejection (late)
(2) Leakage from ureteroneocystostomy site (related to surgical technique / distal ureteral necrosis)
(3) Leakage from anterior cystostomy closure site
(4) Segmental renal infarction
• high creatinine level in fluid collection
Prognosis: high morbidity + mortality ← death from transplant infection + septicemia

Paratransplant Fluid Collection *(in up to 50%)*
Dx: percutaneous fluid aspiration
Cx: Page kidney
(1) **Lymphocele** (0.6–18%)
Onset: within 4–8 weeks after transplantation
√ mean diameter of 11 cm

√ thick septa (50%) + internal debris
DDx: urinoma (radiotracer uptake)

(2) **Urinoma** (rare)
Onset: in early postoperative period

(3) **Hematoma, seroma, abscess**
Onset: in early postoperative period
√ small crescentic peritransplant fluid collection (as normal sequelae of surgery)
√ photopenic region with displacement / impression on renal transplant / urinary bladder
Prognosis: small hematomas typically resolve spontaneously within a few weeks

mnemonic: HAUL
Hematoma
Abscess
Urinoma
Lymphocele

Vascular Problems with Renal Transplant (10%)

◊ Doppler US is 1st-line imaging modality!

A. PRERENAL

1. **Renal artery stenosis** (1–4%)
◊ Transient elevation of velocities in immediate postop. period ← vessel wall edema / arterial spasm!
Time of onset: late = within 3 years; cadaver kidney > young donor kidney > living-related donor kidney
Location:
(a) short-segment stenosis at anastomosis: technical (75%)
Cause: use of clamp / cannula, trauma, ischemia of donor vessel
(b) long-segment stenosis of proximal artery (close to anastomosis) > distal artery
Cause: trauma during allograft harvesting, faulty operative technique, chronic rejection, atherosclerosis, kinking, scar formation
• recent onset of hypertension / severe hypertension refractory to multiple drug regimens
◊ 1–5% of all causes of posttransplant hypertension (nonrenovascular hypertension in 65%)
• unexplained graft dysfunction
• nonspecific audible bruit over graft (occasionally)
√ surrounding soft-tissue "speckle" ← vibration
√ increase in peak systolic velocity > 180–210 cm/s
√ 2÷1 ratio between peak stenotic and poststenotic velocities
√ main renal artery / external iliac artery ratio > 3.5 (normally < 2.0)
√ marked poststenotic turbulence (supportive evidence)
√ dampened signals distal to stenosis (= tardus-parvus waveform)
√ increase in acceleration time (= pulse rise time) of intrarenal arteries
NUC (low sensitivity):
√ ↓ perfusion + cortical uptake, photopenic graft

Angio:
√ standard test for detection of arterial stenosis ± intravascular treatment
Cx (0.5–2.3%): hemorrhage, intimal flap, AV fistula

2. **Renal artery thrombosis** (1–6%)
Cause: rejection, faulty surgical technique (torsion / kinking / angulation of anastomosis)
Time of onset: within first 48 hours – 1st week
Predisposed: allografts with disparate vessel size, multiple anastomoses, arterial dissection ← faulty handling, rejection
• early sudden onset of anuria
• graft tenderness + swelling
(a) global
√ absence of perfusion, uptake, excretion
√ failure to demonstrate intrarenal arterial / venous flow
Prognosis: graft loss
(b) segmental (late complication)
√ segmental infarction ← occlusion of polar artery
√ hypo- / hyperechoic area ± cortical thickening
√ no flow in affected area

3. **Pseudoaneurysm** (in up to 17%)
Cause: percutaneous biopsy with laceration of arterial wall, faulty surgical technique, perivascular infection
Location:
(a) extrarenal at anastomotic site (uncommon): ← suture rupture, anastomotic leakage, vessel wall ischemia
(b) intrarenal, mostly of arcuate arteries: following needle biopsy, mycotic infection
√ mimics renal cyst
√ disorganized flow / to-and-fro waveform
Prognosis: spontaneous regression frequent
Cx: spontaneous rupture

4. **Arteriovenous fistula** (in 2–18%)
Cause: percutaneous biopsy with simultaneous laceration of artery and vein, faulty surgical technique, perivascular infection
• hypertension, hematuria, high-output cardiac failure
US:
√ high-velocity low-resistance flow in feeding artery
√ pulsatile "arterialized" waveform in draining vein
√ turbulence + high-frequency velocity shift
√ exaggerated focal color around lesion (= bruit = perivascular soft-tissue vibration)
Angio (gold standard + allows treatment):
√ rapid contrast appearance in IVC
√ decreased density on nephrogram
Prognosis: 70% resolve within 1–2 years

Cx: renal ischemia (with large lesion), persistent hematuria, rupture

5. **Renal allograft necrosis / infarct**

= total lack of perfusion in an area of renal cortex associated with variable degrees of medullary necrosis

Cause: rejection, surgical ligature, preexistent arterial lesion, severe ATN, prolonged time of warm ischemia

Pattern:

1. Small focal necrosis
2. Large isolated area of infarction ← segmental arterial occlusion)
3. Outer cortical necrosis
4. Cortical necrosis with large patches
5. Diffuse cortical necrosis
6. Cortical + medullary necrosis
7. Necrosis of whole kidney ← occlusion of main renal artery

MR:

√ slightly hyperintense ← ischemic necrosis / hypointense ← hemorrhagic necrosis / isointense area on T2WI

√ hypointense areas on Gd-DTPA images

US:

√ hypoechoic ← ischemic necrosis / iso- or hyperechoic areas ← hemorrhagic necrosis

√ swollen area ← probably cortical edema

√ absence of arterial perfusion by color duplex (not sensitive for small infarcts / superficial cortical necrosis)

√ elevated resistive indexes + no / reversed diastolic flow

B. POSTRENAL

1. **Renal / iliac vein thrombosis** (4.2–5%)

Cause:

(a) immediately: injury to epithelium at site of renal vein anastomosis, extrinsic compression by fluid collection (hematoma, lymphocele)

(b) after 1st week: acute rejection, reduced intrarenal arterial flow, hypovolemia, propagation of iliofemoral vein thrombosis

• abrupt onset of oliguria, graft tenderness

• hematuria, proteinuria

√ enlarged hypoechoic transplant

√ prolonged arterial transit time without arterial occlusions + arterial spasms

√ diminished cortical perfusion

√ absent venous flow

√ "U-shaped" / plateau-like reversal of diastolic arterial flow

√ decreased systolic rise time

NUC:

√ lack of perfusion (but no graft photopenia)

2. **Renal vein stenosis**

Cause: perivascular fibrosis, compression from adjacent perinephric fluid collection

√ color aliasing

√ 3–4-fold increase in velocity

High Vascular Impedance of Renal Transplant

= pulsatility index (A – B ÷ mean) > 1.8 or resistive index (A – B ÷ B) of Doppler signals of 0.75–0.80 indicate a reduction in diastolic flow velocity

Cause:

(a) intrinsic vascular obstruction
   1. Acute vascular rejection (later stage)
   2. Renal vein obstruction

(b) increased intraparenchymal pressure
   1. Severe ATN
   2. Severe pyelonephritis:
      CMV, herpes, E. coli, C. albicans
   3. Extrarenal compression:
      large collection, hematoma, discordant size
   4. Urinary obstruction (doubted!)
   5. Excessive pressure by transducer

Gastrointestinal Problems with Renal Transplant

Prevalence: 40%

1. Gastrointestinal hemorrhage
   (a) upper GI tract bleeding:
      gastric erosions, gastric / duodenal ulcers
      Mortality rate: 2–3 x of normal
   (b) lower GI tract bleeding:
      hemorrhoids, pseudomembranous colitis, cecal ulcers, colonic polyps
2. GI tract perforation (3%)
   Cause: spontaneous, antacid impaction, perinephric abscess, diverticular disease
   Location: colon > small bowel > gastroduodenal
   Mortality rate: approaches 75% (because of delayed Dx)

Hypertension with Renal Transplant

◊ Leading cause of death in renal transplant recipient!

Prevalence: up to 60% 1 year after transplantation

Cause:

A. TRANSPLANT RELATED
   1. Acute transplant rejection
   2. Chronic rejection
   3. Cyclosporine toxicity
   4. Ureteral obstruction
   5. Renal artery stenosis (1–5%)
      (a) accelerated atherosclerosis
      (b) postsurgical fibrosis at anastomosis

B. NOT TRANSPLANT RELATED
   1. Renin production of native kidney

2. Original renal disease involving transplant
3. Development of essential hypertension

Aseptic Necrosis with Renal Transplant

Most common long-term disabling complication; femoral head most common site; bilateral in 59–80%

Frequency: 6–15–29% within 3 years after surgery

Mean time of onset: 9–19 (range, 5–126) months after transplantation when symptoms develop

Risk factors:

dose + method of glucocorticoid administration, duration + quality of dialysis before transplantation, secondary hyperparathyroidism, allograft dysfunction, liver disease, previous transplantation, iron overload, increased protein catabolism during dialysis

Pathophysiology of corticosteroid therapy:

(1) Fat embolism → fat globules occlude subchondral end arteries
(2) Increase in fat cell volume in closed marrow space → ↑ intramedullary pressure → diminished perfusion
(3) Osteopenia → increased bone fragility
(4) Reduced sensibility to pain → loss of protection against excessive stress

Histo: fragmentation, compression, resorption of dead bone, proliferation of granulation tissue, revascularization, production of new bone

• 40% asymptomatic, joint pain, restriction of movement

Sites: femoral head, femoral condyles (lateral > medial condyle), humeral head

√ subchondral bone resorption
√ patchy osteosclerosis
√ collapse / fragmentation of bone

MR abbreviated T1WI protocol = test of choice!

RENAL TUBULAR ACIDOSIS

= clinical syndrome characterized by tubular insufficiency to resorb bicarbonate, excrete hydrogen ion, or both (= nonanion gap metabolic acidosis)

• failure to thrive

Proximal Renal Tubular Acidosis

= TYPE 2 RTA

= impaired capacity to absorb HCO3 – in proximal tubule → bicarbonate in urine at lower plasma levels than normal

Pathogenesis:

? defect in Na+/HCO3 – cotransport at basolateral membrane; deficit of carbonic anhydrase; parathyroid hormone activates cyclic AMP → inhibits carbonic anhydrase → hypocalcemia of hyperparathyroidism + various types of Fanconi syndrome

• self-limited acidosis (= bicarbonate loss stops once bicarbonate threshold of about 15 mEq/L is reached)

• unimpaired ability to lower urine pH (pH 4.5–7.8 depending on level of plasma bicarbonate) by normal excretion of H+

• hypokalemia ← hyperaldosteronism ← decreased proximal resorption of NaCl
√ rickets / osteomalacia
N.B.: NEVER nephrocalcinosis / nephrolithiasis ← normal urinary citrate excretion, low urine pH, self-limited less severe acidosis with less calcium release from bone
Dx: bicarbonate titration test, large requirement of alkali to sustain plasma bicarbonate level at 22 mmol/L
Rx: administration of alkali ± potassium ± hydrochloro-thiazide

Infantile Type of Primary Proximal RTA

Age: diagnosed within first 18 months of life; usually male patient
- excessive vomiting in early infancy
- growth retardation (< 3rd percentile)
- metabolic hyperchloremic acidosis
- normal quantities of net acid excretion

Prognosis: transient type with spontaneous remission

Secondary Proximal RTA

= tubular defect of bicarbonate resorption associated with other tubular dysfunction / generalized disease

Cause:
› Fanconi syndrome, cystinosis, Lowe syndrome, hereditary fructose intolerance, glycogen storage disease, galactosemia, tyrosinemia, Wilson disease, Leigh syndrome
› 1° + 2° hyperparathyroidism, vitamin D deficiency, mineralocorticoid deficiency, osteopetrosis
› medullary cystic disease, renal transplantation, vascular accident to kidney in newborn period, multiple myeloma, amyloidosis, nephrotic syndrome, cyanotic CHD, Sjögren syndrome
› intoxication with cadmium, outdated tetracycline, methylchromone, 6-mercaptopurine

Distal Renal Tubular Acidosis

= TYPE 1 RTA (first type discovered)
= impaired ability to secrete H+ in distal tubule despite low levels of plasma bicarbonate (urine cannot be acidified with pH invariably high at > 5.5–6.0)

Pathophysiology:

primary defect of nonacidification of urine followed by
(a) hyperchloremia:
small constant loss of serum sodium bicarbonate (NaHCO3) without concomitant loss of chloride (= NaCl retention) → shrinkage of ECF volume
(b) chronic severe + progressive acidosis (← inability to excrete the usual endogenously produced nonvolatile acid) leads to:
› mobilization of calcium + phosphate from bone (osteomalacia)
› growth retardation
› hypercalciuria → 2° hyperparathyroidism
› loss of phosphate → osteomalacia / rickets
(c) nephrocalcinosis + nephrolithiasis ← combination of hypercalciuria + elevated urine

pH + marked reduction in urinary citrate

(d) potassium wastage with hyperkaliuria + hypokalemia ← constant small loss of sodium bicarbonate in urine, reduction of ECF space, 2° hyperaldosteronism, increase in sodium-potassium exchange in distal tubule

Path: calcium deposits accompanied by chronic interstitial nephritis with cellular infiltration, tubular atrophy, glomerular sclerosis

- muscle weakness, hyporeflexia, paralysis ← hypokalemia
- bone pain ← osteomalacia
- polyuria ← defect in urinary concentrating ability as a result of nephrocalcinosis + potassium deficiency
- low plasma bicarbonate, hypokalemia, loss of sodium
- hyperchloremic acidosis ← impaired ability to excrete the usual endogenous load of nonvolatile acid
- alkaline urine = urine pH > 5.0–5.5
- hypercalciuria ← continued mobilization of calcium + phosphate from bone ← metabolic acidosis
- hypocitraturia ← increased proximal tubular reabsorption of citrate

Dx: acid load test with ammonium chloride (NH_4Cl)

Rx: administration of a mixture of sodium + potassium bicarbonate

Cx: interstitial nephritis, chronic renal failure (damage from nephrocalcinosis + secondary pyelonephritis), bone lesions, nephrocalcinosis, nephrolithiasis

Permanent Distal Renal Tubular Acidosis

= ADULT TYPE OF PRIMARY DISTAL RTA = BUTLER-ALBRIGHT SYNDROME

Genetics: mostly sporadic; may be autosomal dominant

Age: children + adults (usually not diagnosed before age 2); F > M

- vomiting, constipation, polyuria, dehydration
- failure to thrive, growth retardation, anorexia
- polyuria ← renal concentrating defect
- potassium loss → flaccid paralysis
- bone pain + pathologic fractures in adolescents + adults ← osteomalacia
- low serum pH, low bicarbonate concentration
- elevation of chloride, urinary pH of 6.0–6.5

√ rickets / osteomalacia

√ moderately retarded bone age

√ medullary nephrocalcinosis / nephrolithiasis (as early as 1 month of age)

Secondary Distal Renal Tubular Acidosis

(a) systemic conditions:

› starvation, malnutrition, sickle cell disease

› primary hyperthyroidism + nephrocalcinosis, 1° hyperparathyroidism + nephrocalcinosis, vitamin D intoxication, idiopathic hypercalcemia, idiopathic hypercalciuria + nephrocalcinosis

› amphotericin B nephropathy, toxicity to lithium, toluene sniffing

› hepatic cirrhosis, fructose intolerance with nephrocalcinosis, Ehlers-Danlos

syndrome, Marfan syndrome, elliptocytosis

(b) renal conditions: renal tubular necrosis, renal transplantation, medullary sponge kidney, obstructive uropathy

(c) hypergammaglobulinemic states (? autoimmune process): idiopathic hypergammaglobulinemia, chronic active hepatitis, hyperglobulinemic purpura, Sjögren syndrome, cryoglobulinemia, systemic lupus erythematosus, lupoid hepatitis, fibrosing alveolitis

Transient Distal Renal Acidosis

= INFANTILE TYPE OF PRIMARY DISTAL RTA

= LIGHTWOOD SYNDROME = SALT-LOSING NEPHRITIS

= transient self-limited form of infancy (only observed within 1st year of life) with unclear pathophysiology, probably due to vitamin D intoxication

• NO nephrocalcinosis

RENAL VEIN THROMBOSIS

Prevalence: 0.5% (autopsy)

Cause:

A. Intrinsic

= thrombotic process begins intrarenally within small intrarenal veins ← acidosis, hemoconcentration, disseminated intravascular coagulation, intrarenal arteriolar constriction reducing venous flow

(a) antenatally: abruptio placentae

(b) neonates (most common): advanced maternal age, glycosuria in infants of diabetic mothers, dehydration from vomiting, diarrhea, enterocolitis, sepsis, polycythemia, birth trauma, left adrenal hemorrhage, prematurity

(c) adults: pyelonephritis, amyloidosis, polyarteritis nodosa, sickle cell anemia, thrombosis of IVC, low flow states (CHF, constrictive pericarditis), diabetic nephropathy, sarcoidosis

› hypercoagulable state:

» nephrotic syndrome: membranous + membrano-proliferative glomerulonephritis (most common), lupoid nephrosis

» SLE

» inherited hypercoagulable state: deficiency of antithrombin III / protein C / protein S

› mechanical process:

» trauma

» neoplasm: renal neoplasia (50%: RCC, TCC, Wilms tumor), left adrenal carcinoma

» abscess

» aneurysm

› left ovarian vein thrombosis

B. Extrinsic umbilical vein catheterization, thrombosis of IVC with extension into renal vein, malpositioned IVC filter, carcinoma of pancreatic tail invading renal vein (in 75%), pancreatitis, lymphoma, retroperitoneal sarcoma, retroperitoneal fibrosis, metastases to

retroperitoneum (bronchogenic carcinoma)

mnemonic: TEST MAN

Thrombophlebitis
Enterocolitis (dehydration)
Sickle cell disease, **S**ystemic lupus erythematosus
Trauma
Membranous glomerulonephritis
Amyloidosis
Neoplasm

Radiographic appearance varies with:

(1) Rapidity of venous occlusion
(2) Extent of occlusion
(3) Availability of collateral circulation
(4) Site of occlusion in relation to collateral pathways

Pathophysiology: formation of collateral channels develops at 24 hours + peaks at 2 weeks after onset of occlusion

Collaterals: ureteral vein to vesicular veins, pericapsular veins to lumbar veins, azygos vein, portal vein

on left (in addition): gonadal vein, adrenal vein, inferior phrenic veins

Acute Renal Vein Thrombosis

Path: hemorrhagic renal infarction + edema from ruptured venules + capillaries without time for effective development of collaterals

- gross hematuria, proteinuria, anuria, hypertension, azotemia
- asymptomatic / painful flank mass
- consumptive thrombocytopenia

Location: more common on left (longer left renal vein)

√ focal hemorrhagic infarction + capsular rupture
√ smooth enlargement of kidney ← edema + hemorrhage

IVP:
√ initially faint + delayed dense nephrogram
√ range of completely normal to pyelocaliceal nonvisualization

US:
√ focal / generalized areas of increased echogenicity ← hemorrhage / edema
√ loss of corticomedullary differentiation
√ thrombus within distended renal vein / IVC

Doppler-US:
√ venous flow present in segmental veins + collateral veins overlying renal hilum mimicking patency of main renal v.
√ steady / less pulsatile venous flow compared with contralateral main renal vein
√ main renal vein not traceable into IVC on color Doppler
√ elevated resistive index > 0.70 ± reversed end-diastolic renal arterial flow in native kidney

CT:
√ prolonged cortical nephrographic phase with coarse striations + persistent

corticomedullary differentiation
√ edema in renal sinus + perinephric space
√ thickened renal fascia + perirenal stranding
√ development of collateral venous vessels
√ retroperitoneal hemorrhage

MR:
√ high signal intensity on T1WI + T2WI

Angio:
√ poorly filling cortical arteries
√ absent inflow from renal vein into IVC
√ thrombus extending into IVC

NUC:
√ no characteristic pattern on sequential functional study
√ markedly decreased / absent perfusion
√ delayed radiotracer uptake + excretion
√ retention of ^{99m}Tc mertiatide

DDx: acute renal artery occlusion; chronically nonfunctioning kidney

Cx: (1) Pulmonary emboli (50%)
(2) Severe renal atrophy (may show complete recovery)

Subacute Renal Vein Thrombosis

= good collateral drainage; impaired function with steady state or recanalization
√ enlarged edematous boggy kidney
√ slightly diminished / normal nephrographic density (may increase over time)
√ compression of collecting system ("spidery calices")
√ hypoechoic large kidney
√ collateral veins allow venous efflux → normalizing arterial waveform
√ main renal vein appears small ← recanalization

Chronic Renal Vein Thrombosis

= indolent stage
• 80–90% asymptomatic
• nephrotic syndrome (= proteinuria, hypercholesterolemia, anasarca)
√ normal excretory urogram in 25% (with good collateral circulation especially if left side affected)
√ notching of collecting system + proximal ureter
√ retroperitoneal dilated collaterals
√ lacelike intrarenal pattern of calcifications

US:
√ branching linear calcifications (calcified thrombus)
√ small atrophic echogenic kidney

CT:
√ attenuated renal vein ← retraction of blood clot + IVC thrombus (24%)
√ collaterals along proximal + middle ureter + perirenal
√ prolonged corticomedullary differentiation

√ delayed / absent pyelocaliceal opacification + attenuated collecting system
√ thickening of Gerota fascia
Arteriography:
√ enlarged venous collaterals on delayed images

RENOMEDULLARY INTERSTITIAL CELL TUMOR

= MEDULLARY FIBROMA
= rare benign often incidental mesenchymal neoplasm of kidney
Frequency: 50% of autopsies in adults
Origin: interstitial cells of medulla
Histo: stellate spindle cells on basophilic stroma
Size: < 5 mm (most)
• asymptomatic, (rarely) flank pain and hematuria
Location: renal pyramid
√ small nonenhancing noncalcified hypoattenuating solid mass
√ hypointense on T1WI + T2WI (← rich collagen content)

RETROCAVAL URETER

= CIRCUMCAVAL URETER
Etiology: abnormality in embryogenesis of IVC with persistence of right posterior cardinal vein ventral to ureter + failure of right supracardinal system to develop
Prevalence: 0.07%; M÷F = 3÷1
• symptoms of right ureteral obstruction
√ proximal right ureter swings medially over pedicle of L3-4, passes behind IVC, and emerges to right of aorta → returns to its normal position anterior to iliac vessels
√ varying degrees of hydronephrosis + proximal hydrouretero-nephrosis
Cx: recurrent urinary tract infections

RETROPERITONEAL FAT NECROSIS

Cause: fat saponification ← autodigestion of pancreatic parenchyma + peripancreatic fat ← release of lipolytic enzymes ← pancreatitis
Pathophysiology:
phospholipases + proteases attack plasma membranes of fat cells → release and hydrolyzation of triglycerides → production of free fatty acids → combining with serum calcium → precipitate as calcium soap
• hypocalcemia (associated with severe pancreatitis)
√ scattered nodules of fat necrosis throughout retroperitoneum + abdominal cavity:
√ mass effect + delayed contrast enhancement
DDx: peritoneal carcinomatosis

RETROPERITONEAL FIBROSIS

= RPF = ORMOND DISEASE = CHRONIC PERIAORTITIS = PERIURETERITIS FIBROSA = GEROTA FASCIITIS = SCLEROSING RETROPERITONEAL GRANULOMA
[John Kelso Ormond (1886–1978), surgeon-in-chief of urology division at Henry Ford Hospital,

Detroit]

= uncommon collagen vascular disease of unknown cause characterized by aggressive confluent fibroproliferative masses in retroperitoneal space leading to progressive encasement of retroperitoneal structures, especially ureters

Pathogenesis:

(a) probably autoimmune disease with antibodies to insoluble ceroid + oxidized low-density lipoproteins (by-products of aortic plaque, which has penetrated locally into media) leading to systemic vasculitis

(b) systemic autoimmune / inflammatory disease frequently associated with systemic lupus erythematosus, ankylosing spondylitis, Wegener granulomatosis, antineutrophil cytoplasmic antibody (ANCA)-positive rapidly progressive glomerulonephritis, primary biliary cirrhosis

(c) immunoglobulin G4 (IgG4)-related disease (= multifocal fibrosclerosis)

Classification:

A. Primary / idiopathic retroperitoneal fibrosis (⅔)

With idiopathic RPF the fibroinflammatory tissue entraps both ureters in most cases causing obstructive uropathy (in 56–100%) and subsequent renal failure. Some patients present late with nonfunctioning kidneys.

B. Secondary retroperitoneal fibrosis (⅓)

(1) Drugs (12%): derivatives of ergot alkaloids (methysergide, ergotamine, lysergic acid diethylamide [LSD]), beta-blocker, phenacetin, hydralazine, methyldopa, amphetamines

(2) Malignancy (in up to 8%): desmoplastic response to: lymphoma, Hodgkin disease, carcinoid, retroperitoneal metastases (breast, lung, thyroid, GI tract, GU organs)

- positive tumor markers

√ anterior displacement of aorta + IVC

√ nodularity of retroperitoneal mass

√ hyperintense SI on T2WI

(3) Infection = desmoplastic response to: histoplasmosis, tuberculosis, actinomycosis

(4) Retroperitoneal fluid collection / hematoma / urine extravasation: ← major trauma, major surgery

(5) Aneurysm of aorta / iliac arteries: desmoplastic response to chronic periaortitis

(6) Connective tissue disease: eg, polyarteritis nodosa

(7) Radiation therapy: fibrosis limited to radiation field

Prevalence: 1.3÷100,000 to 1÷200,000

Peak age: 40–65 years; M÷F = 2÷1 to 3÷1

Path: hard retroperitoneal plaque with ill-defined margins enveloping abdominal aorta, iliac vessels, IVC, ureters

Histo:

(a) early: immature fibrotic process with capillary proliferation + diffuse perivascular infiltrate of T and B lymphocytes, plasma cells + fibroblasts in loose matrix of collagen fibers

(b) later: mature plaque composed of relatively acellular and avascular hyalinized collagen + scattered calcifications

May be associated with: asbestos exposure
- weight loss, nausea, malaise, anorexia, low-grade fever
- dull pain in costovertebral angle, back, abdomen (90%)
- obstructive uropathy → oliguria → anuria → renal insufficiency (50–60%)
- renal vessel involvement (2–35%) → hypertension → renal insufficiency
- lymphatic + venous obstruction → lower extremity edema, deep vein thrombosis (6%), hydrocele (10%), scrotal swelling, varicocele
- compression of arteries → bowel ischemia, claudication (occasionally)
- high erythrocyte sedimentation rate (ESR), anemia
- high levels of C-reactive protein (80–100%)
- tests for antinuclear antibodies may be positive

Location: plaque typically begins around aortic bifurcation (L4-5) extending cephalad to renal hilum / surrounding kidney, duodenum, pancreas and spleen; rarely extends below pelvic rim, but may extend caudad to bladder + rectosigmoid

Retroperitoneal fibrosis most commonly surrounds the infrarenal abdominal aorta and proximal common iliac arteries.

√ tethering of aorta / IVC to vertebrae without anterior displacement
√ usually mild uni- / bilateral pyelocaliectasis → hydronephrosis → renal failure (56–100%)
◊ Diagnostic clue: incongruity between severe degree of renal failure + mild degree of hydronephrosis!

IVP / retrograde pyelography:
√ Classic TRIAD:
(1) Ureterectasis above L4-5 ← interference with peristalsis
(2) Medial deviation of ureters in middle third, typically bilateral = **maiden waist** deformity
(3) Gradual tapering of ureters at lower lumbar spine / upper sacral region ← extrinsic compression

DDx: primary ureteral tumor, periureteral lymph nodes, inflammatory ureteral stricture

US (poor sensitivity):
√ hypo- / isoechoic well-demarcated irregularly contoured homogeneous mass with smooth margins anterior to lower lumbar spine / sacral promontory
√ varying degrees of uni- / bilateral hydronephrosis
√ NO flow on Doppler imaging

CT:
√ well-delimited irregular periaortic rindlike layer of soft tissue isoattenuating to muscle
√ contrast enhancement (during active inflammation of immature plaque)
√ localized reactive infracentimetric lymphadenopathy (25%)
√ NO aortic displacement (!)

CT / MR allow comprehensive evaluation of morphology, location and extent of RPF + involvement of adjacent organs and vascular structures. They may detect diseases often associated with idiopathic RPF (eg, autoimmune pancreatitis) or an underlying cause of secondary RPF (eg, malignancy).

MR:
◊ In impaired renal function use HASTE + RARE urography

√ low to medium homogeneous signal intensity on T1WI
√ T2WI:
(a) acute phase → inflammatory edema
√ heterogeneous high SI on T2WI (DDx: malignancy)
√ early soft-tissue enhancement mirrors degree of inflammatory activity
(b) chronic phase → dense fibrotic plaque
√ low SI on T2WI
√ little / NO enhancement during venous phase
√ delayed enhancement

NUC:
√ 67Ga-citrate uptake during active inflammation
√ little / NO gallium uptake in chronic fibrotic stage

PET:
√ increased uptake of FDG paralleling degree of activity
√ may detect remote disease (multifocal fibrosclerosis, infectious / neoplastic disease, other autoimmune process)

^{18}F-FDG PET is the most sensitive modality for
(a) assessing metabolic activity of residual masses,
(b) demonstrating relapse.

Dx: open surgical / laparoscopic biopsy preferred for differentiation of benign from malignant disease

Histologic evaluation of biopsy tissue is mandatory to establish a definitive diagnosis if there are (a) findings suggestive of underlying malignancy or infection; (b) atypical location of the retroperitoneal mass (eg, pelvic, peripancreatic, perirenal); (c) progression of the mass or absence of response to immunosuppressive therapy.

Prognosis: chronic relapsing course

The most important challenge is to differentiate benign from malignant RPF because benign forms of RPF have a good outcome, whereas RPF secondary to malignancy has a poor prognosis.

DDx: (1) Perianeurysmal fibrosis (dilated encased aorta)
(2) Malignant retroperitoneal fibrosis / sarcoma (mass with irregular lobular / nodular margins, more cephalad location, anterior displacement of aorta, edema, Doppler flow, contrast enhancement)
(3) Retroperitoneal lymphadenopathy, lymphoma (anterior elevation of aorta / IVC off vertebral body)
(4) Primary amyloidosis
(5) Subacute retroperitoneal hematoma

Rx: (1) Withdrawal of possible causative agent
(2) Interventional relief of urinary obstruction
(3) Corticosteroids / immunotherapeutic drugs
(4) Disease-modifying antirheumatic drugs, tamoxifen
(5) Ureterolysis for refractory cases

RETROPERITONEAL LEIOMYOSARCOMA

Frequency: 2nd most common (28%) primary retroperitoneal malignancy (after liposarcoma)
Path: necrosis + cystic degeneration + hemorrhage in large tumor; calcifications uncommon
Age: 5th–6th decade; M÷F = 1÷6

- abdominal mass, pain, weight loss, nausea, vomiting
- abdominal distension, change in defecation habits, leg edema, back / radicular pain, frequency of urination
- hemoperitoneum, GI bleeding, dystocia, paraplegia

Site:
(a) retroperitoneal space without attachment to organs
(b) wall of inferior vena cava (in 6% of leiomyosarcomas)
Size: average diameter > 10 cm
Metastases:
frequently hematogenous, less commonly lymphatic dissemination
(a) common sites: liver, lung, brain, peritoneum
(b) rare sites: skin, soft tissue, bone, kidney, omentum
◊ Distant metastases present at time of diagnosis in 40%
Dx: extensive necrosis in a retroperitoneal mass with contiguous involvement of a vessel!
DDx: (1) Liposarcoma (fat content)
(2) Malignant fibrous histiocytoma (not as necrotic)
(3) Lymphoma (nonnecrotic, tends to envelop IVC + aorta)
(4) Primary adrenal tumor
(5) Bland IVC thrombus (NO enhancement / luminal enlargement)
Rx: (1) Complete excision (resectable in 10–75%)
(2) Partial resection (reduction in tumor size)
(3) Adjuvant chemotherapy / radiotherapy
Prognosis: local recurrence in 40–70%; death within 5 years in 80–87% with extraluminal tumors

Extravascular Leiomyosarcoma (62%)

Path: extraluminal (= completely extravascular) large tumor with extensive necrosis
IVP:
√ large soft-tissue mass with displacement of
(a) kidney + ureter
(b) gas-containing ascending / descending colon
√ well-defined fat plane between mass and kidney
√ obstruction of kidney (ureteral involvement)
√ usually not calcified
US:
√ solid mass isoechoic to liver / rarely hyperechoic
√ complex mass with cystic spaces + irregular walls
CT:
√ lobulated mass often > 10 cm in size

√ large cystic areas of tumor necrosis in center of mass
√ areas of high attenuation ± fluid-debris level with recent hemorrhage
√ homogeneously solid with small tumor

MR:
√ intermediate intensity on T1WI with low-intensity areas of necrosis
√ inhomogeneous intermediate to high SI on T2WI ← high water content of cystic areas
√ ± fluid-debris level ← hemorrhage

Angio:
√ hypervascular tumor with blood supply from lumbar, celiac, mesenteric, renal arteries
√ avascular center surrounded by thick hypervascular rind

Intravascular Leiomyosarcoma (5%)

Path: intraluminal (= completely intravascular) polypoid mass firmly attached to vessel wall
Location: between diaphragm + renal veins, may extend along entire length of IVC + into heart
√ small solid mass within IVC
√ gradual expansion / obstruction of IVC
√ intratumoral vascularity confirmed by Doppler
√ irregular enhancement (CT bolus injection)
Cx: (1) Budd-Chiari syndrome (intrahepatic segment of IVC)
(2) Nephrotic syndrome ← IVC segment involved between hepatic + renal veins
(3) Edema of lower extremities ← IVC segment below renal veins without adequate collateralization
(4) Tumor embolus to lung
Prognosis: better for middle segment of IVC (between hepatic + renal veins) than other segments

Extra- & Intravascular Leiomyosarcoma (33%)

√ solid / necrotic extraluminal mass not originating from a retroperitoneal organ with contiguous intravascular enhancing component (PATHOGNOMONIC)

Intramural Leiomyosarcoma (extremely rare)

RETROPERITONEAL LIPOSARCOMA

= slow-growing tumor that displaces rather than infiltrates surrounding tissue and rarely metastasizes
Frequency: most common (33%) of primary malignant retroperitoneal sarcomas; 95% of all fatty retroperitoneal tumors
Histo:
› biologically least aggressive
(a) well-differentiated lipogenic type (most common):
√ radiodensity of fat
› biologically intermediate aggressiveness
(b) myxoid type (more common in younger population):

√ radiodensity between water + muscle
√ solid appearance on US
› biologically highly aggressive
√ radiodensity of muscle for (c), (d), (e)
(c) round cell type
(d) pleomorphic type (least common)
(e) dedifferentiated (10–15%) ← long latent period

Age: most commonly 50–70 years; M = F

• abdominal pain, weight loss, anemia, palpable mass

Site: anterior to spine + psoas muscle > paraspinal + posterior pararenal space

Size: average diameter > 20 cm

CT:

√ solid pattern: inhomogeneous poorly marginated infiltrating mass with contrast enhancement
√ mixed pattern: focal fatty areas (–40 to –20 HU) + areas of higher density (+20 HU)
√ pseudocystic pattern: water-density mass ← averaging of fatty + solid connective-tissue elements
√ calcifications in up to 12% (= important sign of dedifferentiation of an initially well-differentiated type)
◊ Recurrent tumors have higher attenuation values than fat!

MR:

√ hyperintense on T1WI
√ intermediate SI on T2WI; more hyperintense for myxoid type ← mucopolysaccharide content
√ loss of fat signal intensity on fat-suppressed sequence
√ enhancing thick irregular nodular septa

Angio:

√ hypovascular without vessel dilatation / capillary staining / laking

Prognosis: local recurrence in 90%; most radiosensitive of soft-tissue sarcomas; 32% overall 5-year survival

DDx: malignant fibrous histiocytoma, leiomyosarcoma, desmoid tumor, encapsulated fat necrosis

RETROPERITONEAL LYMPHANGIOMA

Lymphangioma of Adrenal Gland

= exceedingly rare tumor usually discovered incidentally

Prevalence: 0.06%

Age: any; peaks during 3rd–6th decade of life

CT:

√ thin-walled multilocular cystic lesion near fluid attenuation
√ thin septa WITHOUT internal enhancement

MR:

√ decreased SI on T1WI + increased intensity on T2WI

DDx: adrenal cyst, hemangioma, cystic pheochromocytoma, schwannoma with cystic degeneration

Lymphangioma of Kidney

= RENAL LYMPHANGIECTASIA / LYMPHANGIOMATOSIS

Frequency: rare benign renal tumor (50 cases in literature)

Origin: developmental anomaly of perirenal lymphatic system / true neoplasm (monosomy, trisomy 7q, defect in vHL gene)

Path: (a) well-encapsulated unilateral mass
(b) bilateral multilocular cystic mass with clear fluid

Histo: multiple communicating cysts lined by flattened endothelial cells; multiple septa containing entrapped renal tubules, lymphoid cells, smooth muscle elements

Age: adulthood ($^2/_3$); M÷F = 1÷1

• mostly asymptomatic, flank pain, abdominal mass, hematuria

Location: renal sinus, perinephric region; (commonly) bilateral

√ uni- / multilocular cystic mass

MR:

√ hypointense on T1WI + uniformly hyperintense on T2WI

√ variable SI of intracystic fluid (depending on presence of hemorrhage / debris / protein content)

Prognosis: spontaneous regression (occasionally)

Decompensated Lymphangiectasia

= exacerbation during pregnancy

• hypertension, flank pain

√ increasing perinephric collection, ascites

RETROPERITONEAL LYMPHOMA

Frequency: most common retroperitoneal malignancy

Histo: Hodgkin disease / NHL

A. PRIMARY lymphoma = confined to single organ + immediately adjacent lymph nodes

B. SECONDARY lymphoma (more common)

Location: bilateral in 50%

US:

√ heterogeneous predominantly hypoechoic mass ← varying degrees of hemorrhage and necrosis

CT:

√ well-defined homogeneous hypoattenuating mass spreading between normal structures without compressing them:

√ mass enveloping normal constituents of renal sinus

√ often contiguous spread into perinephric space

√ ± anterior displacement of IVC and aorta ("**floating aorta**")

√ rarely calcified + necrotic prior to therapy

CECT:
√ mild to moderate homogeneous contrast enhancement
√ slow washout on delayed images
MR:
√ isointense to muscle on T1WI
√ iso- to hyperintense on T2WI
√ moderate homogeneous / patchy enhancement
Cx: obstruction of ureters + IVC

Hodgkin Disease

Age: bimodal distribution in 20s and 60s
Extent: limited disease involving mediastinum + spleen
√ enlarged paraaortic lymph nodes in 25%

Non-Hodgkin Lymphoma

Age: 40–70 years
Extent: commonly extranodal disease in liver, spleen, bowel at an advanced stage
√ retroperitoneal mass in 14%
√ enlarged paraaortic lymph nodes in 55%
√ mesenteric lymphadenopathy (frequent)

Posttherapy Lymphoma

Path: soft-tissue masses persist as fibrosis
MR:
√ low signal intensity on T2WI + minimal enhancement
FDG-PET:
√ no uptake in fibrosis
√ hypermetabolic activity in viable tumor

RETROPERITONEAL ONCOCYTOMA

Oncocytoma of Adrenal Gland

= ONCOCYTIC ADRENOCORTICAL ADENOMA / NEOPLASM
Median age: 46 years; M÷F = 1÷1.8
Histo: abundant deeply eosinophilic (mitochondria-rich) cells; positive for vimentin, melan A, inhibin-α, calretinin; ± immunoreactive for synaptophysin + mitochondrial antigen $MTCO_2$; variably positive for CK8, CK18, CD10
Location: L÷R = 1.5÷1
Mean size: 9 cm
• asymptomatic (70%)
• symptomatic (30%) due to steroid production → Cushing syndrome, virilization, feminization
√ well-marginated often large mass with heterogeneous enhancement of nonspecific appearance
Cx: malignant transformation

Oncocytoma of Kidney

= PROXIMAL TUBULAR ADENOMA = BENIGN OXYPHILIC ADENOMA
= rare form of a benign hypervascular adenoma
Prevalence: 3–7% of solid renal masses
Median age: 65 (range, 26–94) years; M÷F = 1.6÷1 to 2.5÷1
Path: well-encapsulated tan-colored tumor of well-differentiated proximal tubular cells + oncocytes
Histo: oncocytes = large uniformly round epithelial cells with granular oxyphilic / eosinophilic cytoplasm ← large number of mitochondria; no clear cytoplasm; similar to oncocytic tumors seen in thyroid, parathyroid, salivary glands, adrenals
Location: rarely multicentric / bilateral / metachronous
• majority asymptomatic, occasionally hypertension
Tumor size: 6.0–7.5 (range, 0.1–26.0) cm
√ renal mass of homogeneously low attenuation / hypoechogenicity (in > 50%)
√ well-demarcated with pseudocapsule
√ central stellate scar in 30% (in lesions > 3 cm in diameter ← organization of central infarction + hemorrhage after tumor growth has outstripped blood supply)
√ invasion of renal capsule / renal vein in large tumors
MR:
√ typically spherical well-defined mass
√ hypointense relative to renal parenchyma on T1WI (70%)
√ hyperintense relative to renal parenchyma on T2WI (67%)
√ prominent enhancement of mass
√ central stellate scar:
√ hypointense on T1WI + hyperintense on T2WI
√ less enhancement than remainder of mass
√ scar may show delayed enhancement
√ nonspecific well-defined hypointense capsule (in < 50%)
Angio:
√ spoke-wheel configuration in 80% (DDx: renal cell ca.)
√ homogeneously dense parenchymal phase (71%)
√ NO contrast puddling / arteriovenous shunting / renal vein invasion
NUC:
√ photopenic area on ^{99m}Tc-DMSA ← tubular cells do not function normally
Dx: percutaneous needle biopsy unreliable
◊ Pathologic diagnosis requires entire tumor because a well-differentiated renal cell carcinoma may have oncocytic features!
Rx: local resection / heminephrectomy
Prognosis: death from malignancy following surgery (3%)

RETROPERITONEAL PARAGANGLIOMA

= EXTRAADRENAL PHEOCHROMOCYTOMA
Location: anywhere in sympathetic nervous system from neck to sacrum; subdiaphragmatic in 98%

(a) adrenal medulla (85–90%) = *pheochromocytoma*
(b) extraadrenal (10–15% in adults, 31% in children)
= *paraganglioma*:
› diaphragm to lower poles of kidney 50%
› lower poles of kidney to bifurcation 30%
» organ of Zuckerkandl at origin of inferior mesenteric artery 2–5%
› pelvis 10%
» gonads, urinary bladder 1%
› thorax 10%
adherent to / involving LA

Multiplicity: 10% in nonfamilial adult cases
32% in nonfamilial childhood cases
65% in familial syndromes

√ well-defined hypervascular mass in pelvic retroperitoneum along course of common iliac vessels

CT (90% sensitive):
√ large well-defined lobular tumor
√ fluid-fluid level ← hemorrhage + necrosis
√ punctate calcifications (in 15%)
√ intense contrast enhancement

MRI (90% sensitive):
√ signal voids on T1WI
√ "lightbulb" high SI (unusual) with superimposed variable heterogeneous SI (← hemorrhage) on T2WI

NUC:
√ high uptake of m-iodobenzylguanidine (MIBG) with ^{123}I / ^{131}I (77–95% sensitive, 95–100% specific)
√ ^{111}In-pentetreotide scintigraphy (up to 94% sensitive) for lesions > 1.5 cm

PET:
√ 18F–fluorodihydroxyphenylalanine (98% sensitive, up to 100% specific), especially for predominantly noradrenaline-secreting and hereditary types

Cave: Percutaneous biopsy of a hypervascular retroperitoneal mass without adequate laboratory evaluation and prebiopsy preparation (like pharmacologic blockade) must be avoided, since it can result in hypertensive crisis or even death.

Cx: (1) Malignancy: 30–40% of paragangliomas
√ local invasion
√ metastases (in 22–50%): versus 2–10% in pheochromocytomas
(2) Rupture with retroperitoneal hemorrhage

DDx: (1) Nerve sheath tumor
(2) Hypervascular lymphadenopathy: metastasis / Castleman disease
(3) Hypervascular soft-tissue sarcoma

Paraganglioma of Organ of Zuckerkandl

Frequency: 135 cases in literature

Age: 20–40 years
May be associated with:
(1) Multiple endocrine neoplasia type 2a (MEN 2a)
(2) Neurofibromatosis
(3) von Hippel−Lindau disease
(4) Triad of Carney
- functional (¾): associated with hypertension
- nonfunctional (¼): abdominal pain / mass

RETROPERITONEAL TERATOMA

= germ cell tumor with somatic differentiation of cells producing mature but disorganized tissues of > 2 embryonic layers (ectoderm, mesoderm, endoderm)

Frequency: 1–11% of all primary retroperitoneal tumors; < 10% of all teratomas located in retroperitoneum; 3rd most common tumor of retroperitoneum in children (after neuroblastoma + Wilms tumor)

Origin: interruption of normal embryologic migration of pluripotent primordial germ cells from yolk sac to genital ridge

Path: benign (mature = dermoid cyst / immature) or malignant

Histo: cysts lined by epithelium of ectodermal and endodermal origin + glial tissue + mesodermal components (fat, bone, cartilage); may harbor various malignancies of germ cell (seminoma, embryonal cell carcinoma, yolk sac tumor) or somatic (rhabdomyosarcoma, chondrosarcoma, liposarcoma) origin

Age: bimodal distribution with peaks in first 6 months + early adulthood; M÷F = 1÷2 to 1÷3.4

Location: retroperitoneum (< 10%), ovary, testis, anterior mediastinum, presacral + coccygeal area

Site: midline (common), left side, suprarenal fossa

- asymptomatic (most); fixed palpable midline mass, abdominal tenderness, progressive abdominal distension
- nausea, vomiting, pain, GU symptoms, lower extremity swelling (after growth)

√ varied appearance from predominantly cystic to completely solid mass:
√ containing fat (in 61–83%)
√ congealed / linear / shardlike / toothlike calcifications (in 83–93%)
√ wall nodules (= Rokitansky nodules) in cystic component

√ necrosis + hemorrhage → suggest malignancy

Rx: surgical resection

Prognosis: excellent for benign teratoma; poor with malignant teratoma (adults÷children = 26%÷7%)

Immature Teratoma (< 1%)

Age: younger age group (< 20 years) than mature teratomas
Histo: > 10% undifferentiated tissue
Location: near upper pole of left kidney
√ predominantly solid with scattered areas of fat and coarse + ill-defined calcifications
√ occasionally cystic component

Mature Retroperitoneal Teratoma (99%)

= DERMOID CYST

Histo: well-differentiated tissue from at least 2 germ cell layers: ectodermal (in 100%), mesodermal (in 90%), endodermal (in majority of lesions)

√ predominantly cystic

√ villiform solid component (= Rokitansky protuberance) in 81%

√ toothlike / well-defined calcification (56%)

√ fat (93%)

Dx: A fat-fluid level of sebum with chemical shift between fat and fluid are PATHOGNOMONIC .

Cx: malignant degeneration (2–3%): in ¼ of children and 1/10 of adults

Malignant Teratoma

Histo: malignant tissue of germ cell / non-germ cell origin

• elevated a-fetoprotein (in 50%)

√ irregular mass with invasion of adjacent structures + vessels

Prognosis: poor with germ cell lesions or lesions with rhabdomyosarcomatous / neural differentiation

RHABDOID TUMOR OF KIDNEY

◊ Most aggressive renal neoplasm of childhood!

Frequency: < 2% of pediatric renal tumors

Mean age: 11–17 months; 6–12 months of age (25%), < 1 year [< 2 years] of age 60% [80%]; M÷F = 1.5÷1

Origin: renal sinus

Histo: monomorphic noncohesive large cells with prominent nucleoli + abundant eosinophilic cytoplasm (superficial resemblance to skeletal muscle, hence name); filamentous intracytoplasmic inclusions (CHARACTERISTIC)

Associated with: syn- / metachronous primary brain tumor of neuroectodermal origin (medulloblastoma, ependymoma, cerebellar / brainstem astrocytoma, PNET)

Metastatic to: lung, liver, brain

• paraneoplastic hypercalcemia (occasionally)

√ centrally located heterogeneous renal mass:

√ indistinct borders with infiltration of medulla + sinus

√ PROMINENT peripheral crescent-shaped subcapsular fluid collection in 70% (subcapsular hematoma in 47% / necrotic cavity in 53%)

Subcapsular hemorrhage suggests rhabdoid tumor; however, since Wilms tumor is so much more common, a tumor with this finding is more likely to be a Wilms tumor than a rhabdoid tumor.

√ SUGGESTIVE multilobulated architecture, esp. if surrounded by low-attenuation material ← old hemorrhage / necrosis

√ curvilinear calcifications outlining tumor lobules (2/3)

√ may invade renal vein and IVC

√ midline mass in posterior fossa of skull

√ metastatic (in 80%) to lung, liver, retroperitoneal lymph nodes, abdomen, brain, bone

Prognosis: 20% 18-month survival rate

DDx: (1) Wilms tumor

(2) Mesoblastic nephroma (young infant, subcapsular fluid collection, no lymphadenopathy)

RHABDOMYOSARCOMA

= rapidly growing aggressive malignancy frequently invading adjacent bones and soft tissues

Origin: pluripotential mesenchymal cell with capacity to differentiate into skeletal muscle (rhabdomyoblasts resemble primitive striated muscle cells; NOT from striated muscle)

Frequency:

4–10% of cancers in children < 15 years of age (ranking 4th after CNS neoplasm, neuroblastoma, Wilms tumor);

5–15% of all adult sarcomas; 35% of pediatric sarcomas

◊ Most common soft-tissue tumor in childhood (60%)

Incidence: 4.5 (1.3)÷1,000,000 annually in USA in white (black)

Age: bimodal age distribution: 1–4 years (1st peak), 14–19 years (2nd smaller peak); < 11 years (70%); M÷F = 2÷1

Associated with: Li-Fraumeni syndrome, neurofibromatosis type 1, Beckwith-Wiedemann syndrome, DICER1 mutation (familial pleuropulmonary blastoma)

Histo: arising from small undifferentiated "blue cells" with scant cytoplasm + primitive-appearing nuclei; perineural invasion common

(1) embryonal type (70–80%)

Variant: polypoidal form = **sarcoma botryoides** [*bótry* , Greek = bunch of grapes] = grapelike

Age: newborn – 15 years

(2) alveolar type (10–15–20%, worst prognosis)

Age: 10 – 25 years

(3) pleomorphic type (10%, poor prognosis)

Peak age: 45 years; rare in children

Location: primarily large muscles of extremities

√ variable amounts of hemorrhage + necrosis

(4) mixture of two types

DDx of other small round blue cell tumors:

neuroblastoma, Ewing sarcoma, primitive neuroecto-dermal tumor, lymphoma, desmoplastic small round cell tumor

Location: head + neck (35–40%), trigone and bladder neck (18– 21%), extremities (18–23%), orbit (10%), trunk (7–8%), retroperitoneum (6–7%), perineum + anus (2%), other sites (7%); intraperitoneal involvement (10%)

Spread: 15–20% have metastatic disease at presentation

Head & Neck Rhabdomyosarcoma *(40%)*

Frequency: 10% of all rhabdomyosarcomas; 3rd most common primary childhood malignancy of head and neck (following CNS neoplasm + retinoblastoma)

◊ Most common primary extracranial tumor invading cranial vault in childhood

Classification of head & neck tumors:

(a) orbital (25–35%) (see below)

(b) parameningeal (50%): middle ear, paranasal sinus, mastoid process, pterygopalatine fossa, nasopharyngeal musculature (⅓) especially in masticator space

√ MR to assess intracranial extension (in up to 55%)

◊ Parameningeal disease carries the worst prognosis!

(c) nonparameningeal = superficial (25%)

Metastases: lung, cortical bone, lymph nodes (10–20%) > bone marrow, liver

◊ Metastases in 10–20% at time of diagnosis!

• cranial nerve palsy

√ bulky nasopharyngeal mass

√ extension into cranial vault through fissures + foramina (up to 35%) usually involving cavernous sinus

√ bone destruction by direct invasion

√ mild to moderate uniform diffuse contrast enhancement

CT:

√ poorly defined relatively homogeneous mass isodense to brain

√ expanded foramen / fissure

MR (imaging modality of choice):

√ SI intermediate between muscle and fat on T1WI + hyperintense on T2WI

Prognosis: 12.5% 5-year survival (better than in extremities)

DDx: fibrosarcoma, hemangioma, lymphangioma, lymphoma, mastoiditis, lymphadenopathy, Langerhans cell histiocytosis

Rhabdomyosarcoma of Orbit

◊ Most common primary extraocular malignancy in a child

Frequency:

25%–35% of head and neck rhabdomyosarcomas; 3–4% of all pediatric orbital masses:

› 10% as primary tumor of orbit

› 10% as metastasis / from invasion of orbit ← nasopharynx, pterygopalatine fossa, infratemporal fossa, paranasal sinuses (= parameningeal site)

Histo: embryonal form (most common) in young children; alveolar form (less common) generally affecting older children / adolescents; pleomorphic type extremely rare in orbit

Mean age: 6–8 (range, infancy – 68) years; 90% by 16 years of age; M÷F = 5÷3

Rarely associated with: neurofibromatosis

• rapidly progressive unilateral proptosis / globe displacement

• conjunctival + palpebral swelling (DDx orbital cellulitis)

Staging: I localized completely resected tumor

II residual microscopic disease after surgery

III gross residual disease after biopsy

IV distant metastases at onset

Location:

(a) extraconal (37–87%): superonasal quadrant / superior orbit / retrobulbar (71%), lid

(22%), conjunctiva (7%)
(b) intra- and extraconal (13–47%)
√ TYPICALLY thickening of eyelid
√ large soft-tissue density mass with ill-defined margins:
√ mass often contiguous with adjacent extraocular muscle ← muscle displaced / encased (without enlargement of muscle belly)
√ globe often distorted / displaced but rarely invaded
√ ± invasion of adjacent preseptal space, paranasal sinus (20%), nasal cavity, intracranial cavity (3%)
√ moderate to marked generalized enhancement
√ cavitary mass with ringlike enhancement (rare)
CT (sensitive for bone erosion):
√ extraconal well-circumscribed ovoid irregular homogeneous mass isoattenuating to muscle:
√ necrosis + hemorrhage (uncommon)
√ bone erosion (in 30–40%) at presentation
MR (sensitive for intracranial extension):
√ homogeneous mass isointense / minimally hyperintense to muscle / brain on T1WI:
√ areas of high signal intensity on T1WI and T2WI ← foci of subacute hemorrhage
√ hyperintense to muscle, fat and brain on T2WI
√ moderate to marked uniform internal enhancement
US:
√ heterogeneous well-defined irregular mass of low to medium echogenicity
√ variable vascular flow pattern on Doppler US

Metastases: (a) hematogenous: lung, bone marrow
(b) lymphatic (rare): cervical lymph nodes

Prognosis:
(1) 40% survival after exenteration
(2) 80–90% 5-year survival after biopsy / surgical debulking followed by radiation therapy (4,000–5,000 rad) + chemotherapy (vincristine, cyclophosphamide, doxorubicin)

DDx: (1) Subperiosteal hemorrhage (bone erosion during resolution)
(2) Orbital cellulitis with abscess (fever, leukocytosis)
(3) Dermoid cyst (cystic appearance, internal fat attenuation, calcification, fluid level, bone depression near zygomaticofrontal suture)
(4) Capillary hemangioma (growth during 1.0–1.5 year of life, ipsilateral cutaneous hemangiomas, peripheral + internal flow voids)
(5) Venous-lymphatic malformation (multiloculated cystic with ill-defined border, fluid-fluid levels, peripheral enhancement, phleboliths)
(6) Langerhans cell histiocytosis (pronounced bone destruction, diabetes insipidus)
(7) Leukemia (peripheral blood smear)
(8) Lymphoma (lacrimal gland involvement, encasement of globe, hypointense on T2WI)

Genitourinary Rhabdomyosarcoma

Frequency: 4–8% of all malignant solid tumors in children < 15 years of age (ranking 4th after CNS neoplasm, neuroblastoma, Wilms tumor); 10–25% of all sarcomas; annual incidence of 4.5 [1.3]÷1,000,000 in white [black] children

Age: bimodal distribution with peaks at 7 years + at adolescence; white÷black = 3÷1; M÷F = 6÷4

Path: firm fleshy lobulated mass with infiltrative margin / well-defined pseudocapsule; composed of smooth grapelike clusters if intraluminal (= sarcoma botryoides)

Histo (Horn & Enterline):

(a) embryonal (56%)
(b) botryoid (5%) = subtype of embryonal rhabdomyosarcoma
(c) alveolar (20%): worst prognosis
(d) pleomorphic (1%): mostly in adults

DDx: primitive neuroectodermal tumor, extraosseous Ewing sarcoma, synovial cell sarcoma, fibrosarcoma, alveolar soft part sarcoma, hemangiopericytoma, undifferentiated sarcoma, neuroblastoma

√ nonspecific imaging features:

√ homogeneous echogenicity similar to muscle ± hypoechoic areas on US ← hemorrhage / necrosis
√ heterogeneous lesion with calcifications + necrosis
√ ± hyperemia with high diastolic flow component
√ bulky pelvic mass of heterogeneous attenuation
√ hypointense on T1WI + hyperintense on T2WI with heterogeneous enhancement
√ diffuse tumor vascularity on angio

Prognosis:

(a) 14–35% 5-year survival with radical surgery
(b) 60–90% 3-year survival with chemotherapy added

◊ Local recurrence is common!

Bladder-Prostate Rhabdomyosarcoma

◊ 5% of all rhabdomyosarcomas occur in genitourinary tract
◊ Most common bladder tumor in patients < 10 years

Age: in first 3 years of life; M÷F = 3÷1

Associated with: congenital anomalies of the brain, neurofibromatosis, nephroblastoma

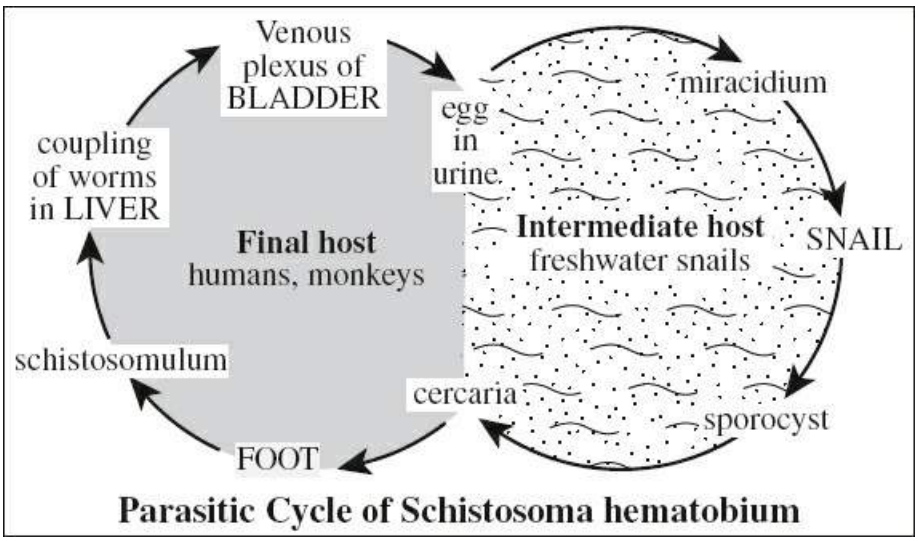
Histo: embryonal (90%), alveolar (10%)

Location: trigone of urinary bladder / prostate (tumor infiltrating both)

- abdominal pain + distension (from bladder outlet obstruction), urinary retention, palpable bladder
- urinary frequency + dysuria (← urinary tract infection)
- hematuria (unusual late manifestation)
- strangury (= painful urge to void without success)

√ polypoid intraluminal tumor mass
√ elevation of bladder floor with obstruction of bladder neck + large postvoid residual
√ ± invasion of periurethral / perivesical tissues
√ retroperitoneal lymph node enlargement

MR:
√ low signal intensity on T1WI + hyperintense on T2WI
√ heterogeneous enhancement
Rx: chemotherapy prior to surgery
DDx: polyp, hemangioma, ectopic ureterocele, hemorrhagic cystitis



Rhabdomyosarcoma of Female Genital Tract

Location: vulva / vagina (infancy), cervix (reproductive years), uterine corpus (postmenopausal)
• vulvar / perineal / vaginal mass
• vaginal bleeding / discharge / protruding grapelike mass
DDx: polyp, urethral prolapse, hydrometrocolpos, neoplasm
Prognosis: 91% 5-year survival rate for nonmetastatic rhabdomyosarcoma of genital tract

VAGINAL RHABDOMYOSARCOMA

Age: very young children (almost exclusively)
Histo: commonly botryoid
√ large solid heterogeneous hypoechoic mass posterior to urinary bladder

Paratesticular Rhabdomyosarcoma

◊ Most common extratesticular neoplasm in children!
Age: childhood, 2nd age peak in adolescence
Histo: embryonal subtype (majority)
Location: spermatic cord, testis, penis, epididymis
• painless scrotal swelling
• palpable nontransilluminating intrascrotal tumor
• bulky abdominal (lymphadenopathy)
√ hypervascular hypo- / hyperechoic solid mass
√ displacement / compression / infiltration of adjacent epididymis + testis
Prognosis: 73–89% 3-year survival rate
DDx: hydrocele, epididymitis, testicular neoplasm

Abdominal Rhabdomyosarcoma *(rare)*

Location: peritoneum, mesentery, omentum
√ omental caking (primary disease)
US:
√ predominantly solid mixed-echogenicity mass
√ markedly increased color flow
CT:
√ mild to moderate ascites
√ hypoattenuating intraperitoneal + mesenteric nodules and masses
√ variable enhancement

SCHISTOSOMIASIS

= BILHARZIASIS = SNAIL FEVER
[*schisto*, Greek = split; *soma*, Greek = body]
[Theodor Maximilian Bilharz (1825–1862), German physician and parasitologist, chair of descriptive anatomy at Kasr el Aïn, Cairo]
◊ One of the most protean diseases in humans (> 200 million people infected in Africa, Asia, and the Americas)!
◊ 2nd most common cause of mortality among parasitic infections after malaria → 500,000 deaths annually!
◊ The most prevalent waterborne disease!
Organism: S. haematobium (GU tract) > 95%;
S. mansoni, S. japonicum (GI tract) < 5%
Contact: exposure of skin to water contaminated with cercariae excreted by snails as a result of unsanitary disposal of human and animal wastes combined with repeated daily contact with contaminated freshwater (eg, fishing, farming, swimming, bathing, recreation)
• dermatitis = **swimmer's itch** (common manifestation) ← juvenile worms enter circulatory system
• "**Katayama fever**" = fever, chills, sweating, cough (occasional) ← adult female worms develop in GU and GI tracts
Rx: praziquantel (destroys adult worms + incites eggs to hatch), albendazole

Schistosoma Hematobium

Prevalence: 8% of world's population; 25% in Africa
Endemic to: South Africa, Egypt, Nigeria, Tanzania, Zimbabwe; South America; Carribean; Middle East; Asia; Puerto Rico
Life cycle:
female parasite resides within venules of urinary bladder → eggs erode bladder mucosa → excreted with urine and feces → hatch in fresh water into larval **miracidia**
larvae invade aquatic / amphibious fresh-water snails (= intermediate host) of genus Bulinus → miracidia develop into adult **sporocytes** → in 4–6 weeks thousands of fork-tailed free swimming 1-mm long **cercariae** are released → pass into surrounding body of water
→ death within 72 hours OR

penetration of human skin (usually foot) where they lose their tail → pass into lymphatics + thoracic duct → travel to RT heart + lungs → LT heart + mesenteric capillaries → reach portal vein where they mature into **adult worms** + copulate (in 21 days after penetration) → return into pelvic venous plexus where they may live for many years

Histo: eggs incite granulomatous response + fibrosis → polypoid lesions (acute phase) and ultimately SCC (chronic phase); large number of eggs calcify in bladder wall without viable eggs in urine

Definite Dx: eggs found at urine microscopy

- frequency, urgency, dysuria
- terminal microscopic hematuria, hemospermia
- albuminuria in the nephrotic range (most common)
- suprapubic pain; dull flank pain (from hydronephrosis)
- hypertrophic, ulcerative, fistulous, wart-like lesions of vulva + perineum (can be mistaken for condylomata lata)
- index of infectious severity = urine egg count

Location: lower ureters + bladder

@ Urinary bladder

Pathogenesis:

chronic irritation of mucosa → proliferation of urothelium into buds (von Brunn nests) → growth into lamina propria →

(a) cystic deposits = **cystitis cystica**

(b) intestinal mucin-secreting glands (goblet cells) = **cystitis glandularis**

√ polypoid filling defects + mucosal irregularities in urinary bladder (pseudotubercles, papillomas) during acute phase ← cystitis cystica

√ bladder wall calcifications (in 4–56%): curvilinear / coarse / floccular, beginning at base parallel to upper aspect of pubic bone, involving all wall layers:

√ calcified bladder resembling a fetal head (PATHOGNOMONIC)

◊ Calcifications present with an abundance of calcified dead ova in submucosa in chronic stage

√ thick-walled fibrotic "flat-topped" bladder with high insertion of ureters

√ reduced bladder capacity (fibrotic stage) → significant postvoid residual

√ vesical calculi (in 39%), distal ureteral calcification (in 34%), honeycombed calcification of seminal vesicles

Cx: **Squamous cell carcinoma of bladder** (SCC)

Age: 30–50 years (exposed early in childhood with 20–30-year latency period)

Location: posterior bladder wall, rarely trigone

√ nodular / fungating filling defect (80%)

√ diffuse / focal region of wall thickening

√ multiple tumors (25%)

√ discontinuous calcifications

@ Ureter (in up to 65%)

√ persistent filling defect of distal ureteral segment with ureterectasis ← peristaltic disorganization ← focal egg deposition

√ beaded appearance of ureter:

√ air bubble-like filling defect = **ureteritis cystica**
√ multiple inflammatory pseudopolyps in ureter ← granulomas (= bilharziomas)
√ ureteral strictures in distal third (in 8%, L > R), most commonly in intravesical portion with cobra-head configuration = **pseudoureterocele**; **Makar stricture** = focal stricture at L3
√ linear wall calcifications = **ureteritis calcinosa** (PATHOGNOMONIC)
√ vesicoureteral reflux (in up to 30%)
√ striation of renal pelvis + proximal ureter in 21% (DDx: normal in 3%, other urinary tract infection, vesicoureteric reflux
Cx: hydroureteronephrosis ← cessation of peristalsis

@ Urethra
√ polyps in fossa navicularis of urethra
√ urethral stricture with perineal and scrotal fistulas

@ Scrotum
√ testicular + epididymal lesions simulating malignancy
√ tunica vaginalis shows septate collections, multiple calcifications, diffuse / nodular enlargement ← granulomatous inflammatory reaction
DDx: malignancy, infarction, epididymo-orchitis

Schistosoma Mansoni & Japonicum

Organism:

A. **Schistosoma mansoni**
Endemic to: Africa, Saudi Arabia, Madagascar, Brazil, Surinam, Venezuela, Puerto Rico, Middle East
Path: eggs deposited along large portal veins of liver hilum

B. **Schistosoma japonicum**
Endemic to: east Asia, China, Philippines
Path: eggs deposited in peripheral small portal veins

Intermediate host: snail

Life cycle:

(a) within snail : **miracidia** mature into **cercariae** → released into water + swim → penetrate skin / intestinal wall of human host
(b) within human: <u>in mesenteric veins</u>
› migration via blood + lymph vessels into lung → afterward liver → eggs released into portal circulation
› adult worm inhabits inferior mesenteric + portal veins
› eggs excreted in human feces → reach water → hatching of miracidia → infection of snails

Path: (a) **intestinal schistosomiasis**:
› exudative granulomatous response (proctocolitis) → formation of inflammatory polyps, fibrosis, wall thickening, colonic stenosis

(b) **hepatosplenic schistosomiasis**:
› liver granulomas → periportal (Symmers) fibrosis → fibrosis-induced presinusoidal portal hypertension
› chronic endothelial inflammation → venous thrombosis

Dx: eggs identified in stool specimen / rectal biopsy

Cx: (1) Splenomegaly with siderotic nodules

(2) Portal vein thrombosis with collateral circulation → gastrointestinal hemorrhage

(3) Portal cholangiopathy → cavernous transformation of portal vein → biliary obstruction with jaundice

(4) Portal hypertension → eggs shunted from portal system into pulmonary vasculature

@ GI tract

√ esophageal varices ← portal hypertension

√ polypoid calcifying bowel lesions ← eggs of S. mansoni trapped in bowel wall + inciting granulomatous reaction)

DDx: isolated intestinal schistosomiasis may be indistinguishable from other forms of proctocolitis.

@ Liver

√ severe splenomegaly with siderotic nodules

√ atrophy of right hepatic lobe + widening of fissures

√ portal hypertension ← fibrosing granulomatous reaction within presinusoidal portal veins ← ova migrating into portal venous system

√ periportal hyperechogenicity

√ gallbladder wall thickening

MR:

√ high-signal-intensity bands along portal tracts on T2WI ← periportal fibrosis

√ low signal intensity bands on T1WI enhance during venous phase

Advanced-stage hepatosplenic schistosomiasis causes marked morphologic changes in the liver with periportal fibrosis, signs of portal hypertension and severe splenomegaly with siderotic nodules.

@ Lung

› early form (3–8 weeks after parasitic penetration)

- shortness of breath, wheezing, dry cough
- eosinophilia ← immunologic type 3 reaction
- **Katayama fever** = pulmonary symptoms coincide with febrile illness ← immunologic reaction to parasite eggs

Associated with: hepatosplenomegaly, hepatitis, urticaria, arthralgia

√ diffuse small nodular granulomatous lung lesions with ill-defined borders

√ reticulonodular pattern (less common)

√ bilateral diffuse ground-glass opacities / hyperattenuation

› late form = granulomatous type 4 reaction to eggs deposited in pulmonary vasculature → intimal fibrosis, pulmonary hypertension, cor pulmonale

- dyspnea, chest pain, fatigue, palpitations, cough
- right-sided heart failure (late)

√ cardiomegaly

√ enlargement of RV + pulmonary artery + azygos vein (from portal hypertension)

SCHWANNOMA OF ADRENAL GLAND

= benign nerve sheath tumor of neural crest origin
Location: retroperitoneum (3%), adrenal gland (rare)
Age: 20–40 years
CT:
√ heterogeneously enhancing hypoattenuating mass
MR:
√ marked variability depending on degree of degeneration
√ isointense signal to muscle on T1WI
√ hyperintensity on T2WI
DDx: pheochromocytoma, malignant tumor

SCROTAL ABSCESS

Etiology:
(1) Complication of epididymoorchitis (often in diabetics), missed testicular torsion, gangrenous tumor, infected hematoma after trauma, primary pyogenic orchitis
(2) Systemic infection: mumps, smallpox, scarlet fever, influenza, typhoid, syphilis, TB
(3) Septic dissemination: sinusitis, osteomyelitis, cholecystitis, appendicitis
Predisposed: diabetics
NUC:
√ marked increase in perfusion = hot hemiscrotum with photon-deficient area representing the abscess on ^{99m}Tc-pertechnetate scan (DDx: chronic torsion)
√ increased scrotal uptake with leukocyte imaging
US:
√ hypoechoic / complex fluid collection (differentiation of intra- from extratesticular abscess location possible):
√ intratesticular abscess with low-level internal echoes + shaggy wall
√ focal area of absent color Doppler flow
√ hypervascular surrounding testicular parenchyma
√ skin thickening
√ hydrocele
MR:
√ hypointense on T1WI + hyperintense on T2WI ← fluid content
√ hypointense rim on T2WI
√ nonenhancing lesion + avid enhancement of surrounding tissue
√ central hyperintensity on DWI with corresponding low signal on ADC map ← restricted diffusion of abscess cavity
Cx: (1) Pyocele
(2) Fistulous tract to skin (T1-hypointense linearity with corresponding hyperintensity on fat-suppressed T2WI)

SEMINAL VESICLE CYST

√ cystic mass posterior to urinary bladder (DDx: müllerian duct cyst)
√ dilated ejaculatory duct

Acquired Seminal Vesicle Cyst

Etiology:

1. Autosomal dominant polycystic kidney disease
   √ bilateral seminal vesicle cysts
2. Invasive bladder tumor
3. Infection
4. Benign prostatic hypertrophy
5. Ejaculatory duct obstruction

Congenital Seminal Vesicle Cyst

Associated with: anomalies of ipsilateral mesonephric duct:

Etiology:

(1) Ectopic insertion of ipsilateral ureter 92% into bladder neck / posterior prostatic urethra / ejaculatory duct / seminal vesicle
(2) Ipsilateral renal dysgenesis 80%
(3) Duplication of collecting system 8%
(4) Vas deferens agenesis

Symptomatic age: 21–41 years

- abdominal / flank / pelvic / perineal pain exacerbated by ejaculation, epididymitis in prepubertal boy
- dysuria, frequent urination, recurrent urinary tract infection

SINUS LIPOMATOSIS

= PERIPELVIC LIPOMATOSIS = PELVIC FIBROLIPOMATOSIS = PERIPELVIC FAT PROLIFERATION

Etiology:

(1) Normal increase with aging and obesity
(2) Proliferation of sinus fat
   (a) vicarious proliferation (usually unilateral) (= replacement lipomatosis) see below
   (b) metabolic proliferation (bilateral) ← increased exogenous / endogenous steroids
(3) Extravasation of urine → proliferation of fatty granulation tissue
(4) Normal variant

Age: 6th–7th decade

- asymptomatic

√ kidney may be enlarged
√ elongated "spiderlike / trumpetlike" pelvicaliceal system
√ infundibula arranged in "spoke-wheel" pattern
√ parenchymal thickness diminished with underlying disease
√ occasionally focal fat deposit with localized deformity of collecting system

Plain film:
√ diminished sinus density = radiolucent sinus

CT:
√ unequivocal fat values

US:
√ echodense / patchy hypoechoic sinus complex

Replacement Lipomatosis / Fibrolipomatosis

= extreme form of renal sinus lipomatosis ← renal destruction / atrophy

Associated with: infection, long-term hydronephrosis, calculi (70%)

Path: marked proliferation of hyperplastic sinus fat with extremely atrophied cortex + varying degrees of hydro- / pyonephrosis, acute / chronic pyelonephritis

√ kidney enlarged by a fatty sinus mass and outlined by an extremely thin cortex:

√ fat characteristically distributed within renal sinus + perinephric space

√ staghorn calculus inside an enlarged renal outline

√ poorly functioning / nonfunctioning kidney

DDx: xanthogranulomatous pyelonephritis, lipoma, angiomyolipoma, liposarcoma (focal mass effect on intrarenal collecting system, no calculus, no parenchymal renal atrophy)

SKENE DUCT CYST

= paraurethral retention cyst
Origin: urogenital sinus
Cause: inflammatory obstruction of paraurethral ducts
Histo: stratified squamous epithelium
Location: lateral to external urethral meatus
√ round / oval T2-hyperintense lesion
DDx: Bartholin gland cyst (similar location)

SPERMATIC CORD TORSION

= TESTICULAR TORSION = TWISTING OF SPERMATIC CORD
◊ Most common scrotal disorder in children, 20% of acute scrotal pathology
Incidence: 1÷4,000 to 1÷25,000 males of < 25 years annually; 10-fold risk in undescended testis
Etiology:
(1) Intravaginal torsion (= torsion distal to attachment of tunica vaginalis) = **"bell and clapper" deformity** = high insertion of tunica vaginalis on spermatic cord in 12% of males
Site: in 5% bilateral ← anomalous suspension of contralateral testis found in 80%
Age: any, predominantly adolescence
(2) Extravaginal torsion (10%) = torsion proximal to attach-ment of tunica vaginalis involving testis + tunica vaginalis ← loose attachment of testicular tunics to scrotum
Age: in utero (mostly) + perinatal period; may be bilateral
• testis necrotic at birth → swollen + discolored hemiscrotum
√ complex hydrocele + calcification of tunica albuginea
(3) Abnormally loose mesorchium between testis + epididymis
Pathophysiology: blood flow compromise → venous obstruction followed by arterial obstruction
Peak age: newborn period + puberty (13–16 years); < 20 [> 21] {> 30} years in 74–85% [26%] {9%}
Cx: testicular atrophy (in 33–45%)

Acute Testicular Torsion

= symptoms present for < 24 hours
• 70% of patients present within first 6 hours from onset of pain:
  • sudden severe pain in 100% (frequently at night)
  • negative urine analysis (98%), nausea + vomiting (50%)
  • history of similar episode in same / contralateral testis (42%); history of trauma / extreme exertion (13%)
  • scrotal swelling + tenderness (42%)
  • leukocytosis (32%), low-grade fever (20%)
• Brunzel sign = elevated horizontal lie of testis
• Ger sign = skin pitting at scrotal base

◊ SURGICAL EMERGENCY!

Testicular viability related to:

(a) degree of torsion (720° necessary for complete ischemia)

Degree of torsion and blood flow:

- testis usually turns medially up to 1,080°

√ diminished blood flow in < 180°-torsion at 1 hour

√ absent blood flow in any degree of torsion > 4 hours

(b) length of ischemia

Salvage rate versus time from onset of pain to surgery

97–100% < 6 hrs	57% 6–12 hrs
35% 12–24 hrs	0–9% > 24 hrs

◊ Irreversible ischemic damage begins at 3–6 hours after onset of torsion!

(c) intermittent torsion

◊ Spontaneous detorsion in 7%

√ hyperemia after spontaneous detorsion

US (80–90% sensitivity):

√ testicular echogenicity:

√ normal grey-scale appearance (within 1–3–6 hours)

√ diffusely hypoechoic echotexture (> 6 hours)

√ heterogeneous echotexture ← ischemic necrosis

√ testicular size:

√ normal size = 80% salvage rate

√ testicular + epididymal enlargement with decreased echogenicity (within 8–24 hours)

◊ Torsion has no / minimal epididymal flow (DDx: acute epididymitis has increased flow)

√ extratesticular findings:

√ scrotal skin thickening

√ hydrocele (occasionally)

√ "torsion knot" sign = twisted enlarged spermatic cord with spiraling vessels at external inguinal orifice

√ intrascrotal portion of cord round / ovoid / curled with epididymal head wrapped around it

√ inverted orientation of testis + epididymis + cord (in 6%)

Pitfall: dilated cord mistaken for abnormal epididymis

Color duplex (86% sensitive, 100% specific, 97% accurate):

N.B.: contralateral testis = internal normal control (!)

√ loss of spermatic cord Doppler signal (44% sensitive, 67% specific)

√ absence of testicular + epididymal flow (DDx: global testicular infarction)

√ diminished flow (veins affected before arteries) ← incomplete (< 360°) / intermittent torsion:

√ some arterial flow persists (in 20% of torsions)

√ high-resistance waveform = decreased / reversed arterial flow in diastole

False-negative: torsion-detorsion sequence, incomplete torsion < 360 degrees

False-positive: in small boys < 4 years of age (= limitation of color Doppler sensitivity)

NUC (98% accuracy):

Dose: 5–15 mCi ^{99m}Tc-pertechnetate

Imaging: at 2- to 5-sec intervals for 1 min (vascular phase); at 5-min intervals for 20 minutes (tissue phase)

√ decreased perfusion / occasionally normal

√ "**nubbin**" sign = bump of activity extending medially from iliac artery ← reactive increased blood flow in spermatic cord with abrupt termination

√ rounded cold area replacing testis (requires knowledge of side + location of painful testis)

Rx: (1) Detorsion (***should be attempted by radiologist***):

◊ Twist testis outward + laterally by 180° like "opening a book"! May have to be repeated; successful in $^{2}/_{3}$

(2) Orchiopexy

DDx: epididymo-orchitis (more gradual onset of pain, however, in 5% sudden onset of pain)

Subacute Testicular Torsion

= MISSED TESTICULAR TORSION

= symptoms present for > 24 hours + less than 10 days

US:

√ enlarged / normal-sized testis with heterogeneous punctate / diffusely increased echotexture

√ ⇑ peritesticular flow without parenchymal blood flow

Pitfall: increased flow in scrotal wall mistaken for intrascrotal inflammatory disease

NUC:

√ normal NUC angiogram / "nubbin" sign

√ "doughnut" sign = decreased testicular activity with rim hyperemia of dartos perfusion

MR:

√ enlarged spermatic cord without increase in vascularity

√ whirlpool pattern (twisting of spermatic cord)

√ torsion knot = low-signal-intensity focus at point of twist (= displacement of free protons from epicenter of twist)

Chronic Testicular Torsion

√ small atrophied homogeneously hypoechoic testis

√ enlarged echogenic epididymis

Appendix Testis Torsion

= TORSION OF TESTICULAR APPENDAGE

◊ Most common cause of scrotal pain in pediatric population; accounts for 5% of scrotal pathology

Prevalence: 31–67%

Age: prepubertal male aged 7–14 years

- gradual / sudden intense pain localized to upper pole of testis
- "blue dot" sign (21%) = PATHOGNOMONIC nodule visible as bluish dot beneath skin in upper scrotum

Location: near superior pole of testis; L > R
√ ovoid complex hypo- to hyperechoic extratesticular 4–16 mm mass in superior aspect of scrotum
√ mass without color Doppler flow signals
√ reactive noninfectious epididymo-orchitis:
  √ mildly enlarged epididymal head (75%)
  √ hyperemia of ipsilateral epididymis (60%) + scrotal wall (53%) + testis (13%) simulating acute epididymo-orchitis
  √ reactive hydrocele + scrotal skin thickening
√ NO Doppler signal within twisted appendage
√ hypervascularisation of epididymis + scrotal tunics
√ "scrotal pearl" = **scrotolith** = calcified detached remnant of twisted appendix testis on follow-up US within days
Rx: bed rest, NSAID

SQUAMOUS CELL CARCINOMA OF KIDNEY

Frequency: 5–10% of all urothelial tumors; 1% of renal neoplasms; 2nd most common malignancy of pelvic urothelium after TCC
Age: 60–70 years; M÷F = 2:1
Path: flat ulcerating mass + extensive induration
Associated with: chronic irritation of urothelium by renal infection + calculi (25–60%)
• painless hematuria
• flank pain (with ureteropelvic junction obstruction)
√ infiltrating renal process
√ nonfunctional kidney:
  √ ureteropelvic junction obstruction (common)
√ presence of faceted calculi (40–80%)
IVP:
  √ stricture that may simulate extrinsic cause
Angio:
  √ arterial encasement + occlusion + neovascularity
  √ enlarged pelvic + ureteric arteries
  √ occlusion of renal vein / branches (41%)
CT:
  √ thickening of pelvicaliceal wall (with superficial spread over large areas)
  √ enlarged kidney maintaining reniform shape:
    √ infiltrating growth into sinus + parenchyma
    √ tumor mass infrequent
  √ no contrast excretion ← obstruction
Prognosis: worse than TCC ← early metastases; 33% 1-year survival rate
DDx: xanthogranulomatous pyelonephritis (radiologically indistinguishable)

SUPERNUMERARY KIDNEY

= aberrant division of nephrogenic cord into two metanephric tails (rare)

Associated with: horseshoe kidney, vaginal atresia, duplicated female urethra, duplicated penis
Location: most commonly on left side of abdomen caudal to normal kidney
√ supernumerary ureter may insert into ipsilateral kidney / directly into bladder / ectopic site
Cx: hydronephrosis, pyonephrosis, pyelonephritis, cysts, calculi, carcinoma, papillary cystadenoma, Wilms tumor

TESTICULAR CANCER

◊ Most common neoplasm in males between ages 15 and 35 years; 0.5% of all cancers in males; 4–6% of all male genitourinary tumors; 1% of all childhood malignancies; 4th most common cause of death from malignancy between ages 15–34 years (12%)
Incidence annually: 5.7÷100,000 in 2016 (4.1÷100,000 in 1975); 1÷263 males; 8,720 new cases in USA (2016)
Peak age: 25–35 years; 71–90 years; infants < 3 years: yolk sac tumor + teratoma; White÷Black = 4.5÷1
Risk factors:
(1) Prior testicular cancer (20 x risk = 2–5%)
(2) Maldescension = cryptorchidism (10 x risk)
5% for abdominal site, 1.25% for inguinal site
Rx: orchiopexy
(3) Family history of testicular cancer (6 x risk for 1st-degree relative = 2%)
more prevalent in Caucasian race, Jewish religion
(4) Infertility (0.4–1.1% prevalence of intratubular germ cell neoplasia)
(5) Intersex syndrome: gonadal dysgenesis, true hermaphroditism, pseudohermaphroditism

- painless enlarging testis / mass (90%), however:
  - acute scrotal pain (10%, from intratumoral hemorrhage)
- "heaviness / fullness" in lower abdomen / scrotum
- gynecomastia, virilization

Location: mostly unilateral; contralateral tumor develops eventually in 8%
Metastases: at presentation in 4–14%
(a) lymphatic dissemination
testicular lymphatic drainage follows gonadal veins to
› interaortocaval chain at L2 (for right testicular tumor)
› left paraaortic nodes between renal vein, aorta, ureter and inferior mesenteric artery
› along thoracic duct
› left supraclavicular nodes
› lungs
(b) hematogenous dissemination (usually late) to lung > liver, brain, bone
◊ Choriocarcinoma has a proclivity for early hematogenous spread (especially to brain)!
(c) direct extension through tunica albuginea to skin (rare and late) / epididymis → spread to inguinal + iliac nodes
Histo: may be different from that of primary tumor indicating totipotential nature of germ cells
Tumor markers (elevated in 80% at time of diagnosis):
α- yolk sac tumors, mixed germ cell tumors with yolk sac elements

fetoprotein:

β-hCG: seminoma, choriocarcinoma (tumors containing syncytiotrophoblasts)

LDH: correlates with bulk of disease (nonspecific as it is produced by multiple organs)

US (92–98% sensitive, 95.0–99.8% specific):

Color duplex:

√ tumor < 1.5 cm is hypovascular in 86%, > 1.6 cm hypervascular in 95% (DDx: orchitis associated with epididymal hyperemia)

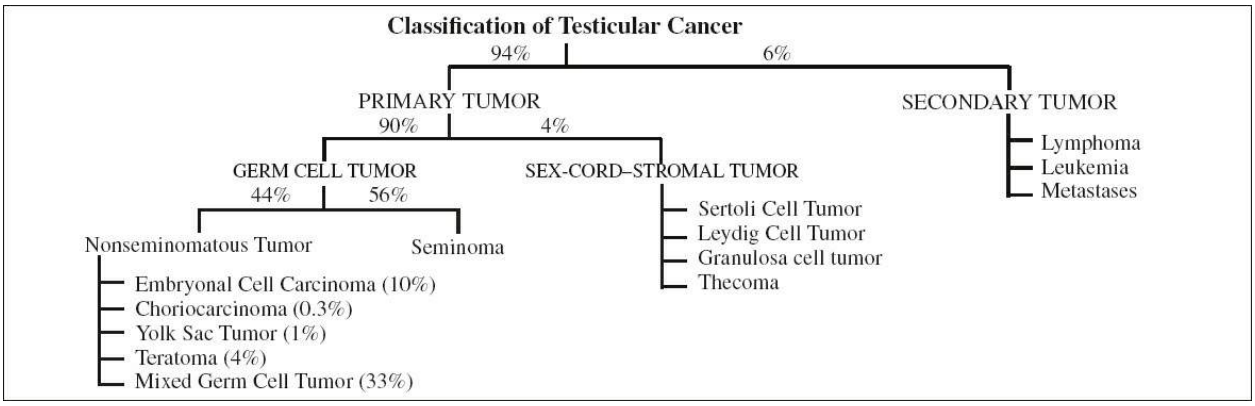
√ distortion of vessels

Age Group of Testicular Tumors	
Yolk sac tumor / teratoma	1st decade
Choriocarcinoma	2nd + 3rd decade
Embryonal cell carcinoma	3rd decade
Seminoma	4th decade
Lymphoma	7th decade

Staging of Testicular Cancer *(American Joint Committee on Cancer)*	
pTX	primary tumor not available (no orchiectomy)
pT0	no primary tumor found
pTis	intratubular germ cell tumor (carcinoma in situ)
pT1	limited to testis + epididymis
pT2	same as pT1 + vascular / lymphatic invasion or involvement of tunica vaginalis
pT3	invasion of spermatic cord
pT4	invasion of scrotum
pN0	negative lymph nodes
pN1	node ≤20 mm; or ≤ 5 nodes involved all <20 mm
pN2	node between 20 and 50 mm; or > 5 nodes none > 50 mm
pN3	node mass > 50 mm
M0	no distant metastasis
M1	distant metastasis
S0	all markers normal
S1	LDH < 1.5 x ULN + hCG <5,000 mIU/mL + AFP < 1,000 ng/mL
S2	LDH < 1.5–10 x ULN ± hCG 5,000–50,000 mIU/mL ± AFP 1,000–10,000 ng/mL
S3	LDH > 10 x ULN ± hCG >50,000 mIU/mL ± AFP > 10,000 ng/mL

ULN = upper limits of normal

Testicular Cancer Stage Grouping	
I	limited to testis + spermatic cord
II	metastases to lymph nodes below diaphragm
II A	nonpalpable < 2 cm in diameter
II B	moderate mass = 2–5 cm in diameter
II C	bulky mass > 5 cm in diameter
III	metastases to lymph nodes above diaphragm
III A	confined to lymphatic system
III B	extranodal metastases



MR:

√ tumors isointense to testicular parenchyma on T1WI + T2WI

Prognosis: > 93% [85–90%] 5-year survival rate for stage I [stage II]; complete remission under chemotherapy in 65–75%; relapse in 10–20% within 18 months

Most cases of testicular cancer are curable as a result of advances in chemotherapy.

DDx:

Imaging overlap exists between testicular tumors and nontumorous conditions. Correlation with clinical history is critical to avoid unnecessary surgery.

(1) Testicular infarction
(2) Testicular hematoma
(3) Orchitis: acute / granulomatous
(4) Epidermoid cyst
(5) Syndromic lesion:
  (a) adrenal rests in congenital adrenal hyperplasia
  (b) lipomatosis in Cowden disease

Rx: inguinal orchiectomy (first-line treatment)

About 95% of testicular cancers are germ cell tumors, and 5% are sex-cord–stromal tumors. Approximately 50% of germ cell tumors are seminomas, and about 50% are nonseminomatous germ cell tumors (NSGCTs).

Germ Cell Tumor (95%)

Origin: primitive spermatogenic cell

(a) one histologic type in 65%
- › from unipotential nondifferentiated gonadal line:
  1. Seminoma
- › along a totipotential line → forming differentiated nonseminomatous tumors (more aggressive than seminoma):
  1. Embryonal carcinoma (slightly differentiated)
  2. Teratoma (embryonic differentiation)
  3. Yolk sac tumor (extraembryonic differentiation)
  4. Choriocarcinoma (extraembryonic differentiation)

(b) mixed lesion
- › from totipotential cells developing along several pathways (embryonal carcinoma being the most common component of mixed lesions)
  1. Teratocarcinoma (= teratoma + embryonal cell ca.)
     - ◊ 2nd most common after seminoma, may occasionally undergo spontaneous regression
  2. Embryonal cell carcinoma + seminoma
  3. Seminoma + teratoma

(c) **Growing Teratoma Syndrome**:
= evolution of mixed germ cell tumor → into mature teratoma after chemotherapy (in 40%) → followed by interval growth despite maintaining a benign histology

mnemonic: YES CT
Yolk sac tumor
Embryonal cell carcinoma
Seminoma
Choriocarcinoma
Teratoma

Seminoma (35–50%)

◊ Most common tumor in undescended testis!
◊ Most common pure germ cell tumor!

Average age: 40.5 years (slightly older patient compared with other germ cell tumors)
Stem cell: unipotential cell line
Histo: uniform cellular morphology resembling primitive germ cells
(1) Typical seminoma 85%
(2) Anaplastic seminoma 10%
(3) Spermatocytic seminoma 5%
Presentation: in 75% limited to testis;
in 20% retroperitoneal lymphadenopathy;
in 5% extranodal metastases
Associated with: testicular microlithiasis

• serum α-fetoprotein normal in pure seminomas
• β-hCG elevation (in 5–25%) ← produced by syncytiotrophoblastic giant cells

√ usually homogeneous hypoechoic mass:
√ round / lobulated / multiple confluent nodules

√ entire testis replaced (> 50%)
√ cystic component (10%) ± fluid-debris level
√ confined within tunica albuginea (= less aggressive)
√ calcifications / cystic spaces (infrequent)
√ may be multifocal
√ bilateral in 1–3%, almost always asynchronous
MR:
√ homogeneously hypointense on T2WI
√ enhancing bandlike areas of low SI on T1WI + T2WI ← fibrovascular septa
Rx: very sensitive to radiation ± chemotherapy
Prognosis: 10-year survival rate of 75–85%; 19% develop pulmonary metastases

Nonseminomatous Tumor

Frequency: 50% of all germ cell tumors
Stem cell: totipotential embryonal cell line with varying degrees of differentiation into embryonal, teratoma, yolk sac, or choriocarcinoma cells
Age: 20–30 years
• ⇑ α-fetoprotein level (in 50–60%)
√ heterogeneous echotexture (71%)
√ cystic spaces (61%)
√ irregular ill-defined margins (45%)
√ echogenic foci ← calcifications (35%)

EMBRYONAL CELL CARCINOMA (20–25%)

◊ Second most common testicular tumor!
◊ Most common component of mixed germ cell tumors (embryonal cells present in 87%); often associated with teratoma
Histo: primitive anaplastic epithelial cells resembling early embryonic cells; in 3% as pure form
Age: 25–35 years and < 2 years
Spread: most aggressive testicular tumor, visceral metastases
• ± α-fetoprotein elevation
√ hypoechoic mass with heterogeneous areas:
√ ill-defined borders
√ areas of increased echogenicity ← hemorrhage
√ cystic areas ← necrosis
√ may show invasion of tunica albuginea (common)
Rx: less sensitive to radiation
Prognosis: 30–35% 5-year survival rate

MIXED GERM CELL TUMOR

= malignant neoplasm with more than 1 germ cell tumor component excluding seminoma with syncytiotropho-blastic cells
Frequency: 69% of all nonseminomatous + 32% of all testicular germ cell tumors
Components: embryonal cell (most common, often combined with teratoma / seminoma / yolk sac tumor)

Average age: 30 years
• ↑ α-fetoprotein (in 60%), ↑ β-hCG levels (in 55%)
√ unilateral mass with a mixture of solid + cystic components ← necrosis, hemorrhage, cystic degeneration
√ calcifications (in 40%)

TERATOMA (4–10%)
Prevalence: 1÷1,000,000;
◊ 2nd most common testicular tumor in young boys ≤ 5 years (75%)
Histo: consists of elements from > 1 germ cell layer (keratin, muscle, bone, cartilage, hair, mucous glands, neural tissue); 2–3% as pure form (in adult)
(a) mature
(b) immature
(c) malignant areas
Age: within first 4 years of life; benign in children; may transform into malignancy in adulthood
• serum α-fetoprotein usually normal
√ well-circumscribed heterogeneous complex mass:
√ anechoic / complex cysts with variable echogenicity ← serous, mucoid, keratinous fluid
√ markedly echogenic components ← cartilage, calcification, fibrosis, scar formation
√ echogenic intratumoral fat
Prognosis:
variable biologic behavior: benign in prepubertal testes BUT may metastasize in postpubertal testes with nonteratomatous germ cell elements; metastases to lymph nodes, bone, liver in 30% within 5 years

EPIDERMOID CYST / KERATIN CYST OF TESTIS (1%)
= "monodermal dermoid"
= benign teratoma with only ectodermal components / squamous metaplasia of surface mesothelium
Origin: ? monodermal development of a teratoma, ? meta- plasia of rete testis / seminiferous epithelium
Age: 20–40 (range, 3–77) years; primarily in white + Asian population
Histo: cyst contains keratin debris / other desquamated material; wall composed of fibrous tissue + lined by keratinizing stratified squamous epithelium
• smooth firm painless testicular nodule
• negative tumor marker status
Location: R (>) L; solitary >> multiple >> bilateral
Size: 1–3 (range 0.5–10.5) cm in diameter
√ sharply circumscribed encapsulated round lesion:
√ "**onion-skin**" / ringed appearance of alternating hypo- and hyperechogenicity (= alternating layers of compacted keratin + loosely arranged desquamated squamous cells):
√ well-defined rim = hyperechoic fibrous cyst wall ± shadowing from

calcifications / ossification
√ hypoechoic cyst contents (= laminated keratin debris)
√ "target / bull's eye" appearance ← echogenic center ← compacted keratin / calcification
√ confined by tunica albuginea
√ diffuse testicular enlargement (10%)
√ NO blood flow on Doppler (avascular lesion)
MR:
√ target appearance:
√ fibrous capsule of low SI on T1WI + T2WI
√ cyst content (water and lipid) of high SI on T1WI + T2WI
√ alternating concentric rings of low + high SI
√ center of mass of low SI ← keratin debris ± central calcification
√ NO enhancement
Prognosis: no malignant potential
Rx: enucleation + frozen section (testis-sparing surgery to avoid orchiectomy)

CHORIOCARCINOMA (1–3%)

Prevalence: in 0.3% in pure form; in 8–16% of mixed germ cell tumors
Peak age: 20–30 years
Histo: admixture of cytotrophoblastic + syncytiotrophoblastic cells
Spread: may rapidly metastasize (lung, liver, GI tract, brain) without evidence of choriocarcinoma in primary lesion, pulmonary metastases develop in 81%
• symptoms of metastatic disease while primary not yet palpable
• serum β-hCG always elevated → gynecomastia in 10%
N.B.: choriocarcinoma has a proclivity for hemorrhage in primary site and metastases!
√ often small tumor of mixed echotexture ← hemorrhage, necrosis, calcifications
√ indistinct margins of pulmonary metastases ← hemorrhage
Prognosis: death usually within 1 year of diagnosis; nearly 0–48% 5-year survival rate

YOLK SAC TUMOR = ENDODERMAL SINUS TUMOR

Equivalent to endodermal sinus tumor of ovary
Prevalence: most common germ cell tumor
◊ 80% of childhood testicular tumors!
◊ Present in 44% of mixed germ cell tumors of adults
Age: ≤ 2 years (80%)
• serum α-fetoprotein elevated in > 90% (exclusive to yolk sac elements)
√ nonspecific imaging findings:
√ testicular enlargement ± identifiable mass
√ hypoechoic areas (frequent) ← necrosis
√ pulmonary metastases (most common site of recurrent disease)

Sex Cord-Stromal Tumor = Interstitial Cell Tumor

Prevalence: 4% of all testicular tumors; 10–30% during childhood
Origin: supporting tissues of testis (sex cord + stromal cells)

- precocious virilism (10% in children)
- painless testicular mass without endocrine abnormalities
- gynecomastia (adults >> children)
- loss of libido, impotence (adults)

Spread: in 20% at initial diagnosis; metastases to lymph nodes (70%), liver (45%), lung (40%), bone (25%)

Rx: orchiectomy; conservative resection under ultrasound guidance

Prognosis: malignant in 10–20%

Leydig Cell Tumor

Prevalence: 1–3% of all testicular tumors

Origin: interstitial cells forming the fibrovascular stroma

Age: 3–6 years; 20% in patients < 10 years; 25% between ages 30 and 50 years; 25% in patients > 50 years

Histo: usually polygonal large cells with abundant cytoplasm; intracytoplasmic / intranuclear cylindric / rectangular / rhomboid structures = Reinke crystals

- endocrinopathy (in 30%) → secretion of androgens or estrogens (direct production of estradiol / aromatization of testosterone moiety) by the tumor:
  - precocious puberty / virilization
  - gynecomastia (in 30%); decreased libido

Laterality: unilateral + solitary; 3% bilateral

Size: 3–5 cm

US:

√ usually small homogeneous hypoechoic / occasionally echogenic nodule
√ ± cystic areas in 25% ← hemorrhage / necrosis
√ lacking internal vascularity + prominent circumferential blood flow on Doppler

MR:

√ isointense on T1WI + hypointense on T2WI compared to surrounding normal testis
√ hyperintense capsule on T2WI
√ internal high SI on T2WI ← central scar
√ marked homogeneous enhancement

Prognosis: benign÷malignant = 9÷1

Rx: enucleation to preserve fertility (if benign); radical orchiectomy + retroperitoneal lymphadenectomy

Sertoli Cell Tumor

Prevalence: 0.4–1.5% of all testicular tumors

Origin: sex cord (derived from Sertoli cells of seminiferous tubules)

Histo: moderate to abundant eosinophilic cytoplasm / pale ← lipid accumulation; ± Charcot-Böttcher crystals (specific cytoplasmic inclusion bodies)

Subtype: **l**arge-**c**ell **c**alcifying **S**ertoli **c**ell **t**umor

Age: most < 40 years; 30% in children

- may secrete estrogens → gynecomastia in 3%

Laterality: unilateral; may be bilateral + multifocal

US:

√ multicystic "spoke-wheel" appearance
√ diffusely ⇑ inhomogeneous echogenicity in enlarged testis (occasionally) ← dense collagenous matrix
√ well-circumscribed round / lobulated hypoechoic nodules + surrounding thin hypoechoic rims (usually)
√ dense echogenic foci ← calcified scars = "burned-out" tumor

LARGE-CELL CALCIFYING SERTOLI CELL TUMOR

= LCCSCT = most common histologic variant in children + adolescents
• precocious puberty ← testosterone production
Associated with: Peutz-Jeghers syndrome, Carney syndrome (almost exclusively)
US:
√ echogenic nodule with acoustic shadowing
√ multiple bilateral (20%) large areas of calcifications
MR:
√ homogeneously isointense on T1WI + hyperintense on T2WI
√ variably homogeneous / rim enhancement
Prognosis: benign÷malignant = 9÷1
Rx: radical orchiectomy (may be delayed to bank sperm)

Gonadoblastoma

= primitive gonadal stroma tumor (exceedingly rare) containing sex cord-stromal elements + germ cells
Histo: dysgenetic lesion not neoplasm
• abnormal karyotype in 80%: intersex status, phenotypically female

Nonprimary Testicular Tumors

Metastases to Testis (in 0.7% of autopsies)

Mean age: 55 years
(a) in adults: prostate (35%) > lung (19%) > melanoma (9%), colon (9%) > kidney (7%), bladder, thyroid
◊ More common than germ cell tumors in males > 50 years of age!
(b) in children: neuroblastoma, retinoblastoma, Wilms tumor, rhabdomyosarcoma
√ often multiple and bilateral (in 8–15%)
√ mostly hypoechoic, occasionally echogenic masses

Lymphoma of Testis

Frequency: 1–9% of all testicular tumors; in 1% of patients with NHL / ALL
Age: most common testicular tumor in men > age 60; median age of 37 years in immunocompromised
Presentation:
(a) primary testicular lymphoma (rare)
(b) secondary involvement:
› initial manifestation of clinically occult disease
› site of recurrent disease in established lymphoma

◊ Metachronous involvement (in 80%) months to years following orchiectomy

Histo: NHL = almost exclusively B-cell lymphoma (most commonly diffuse large cell lymphoma > follicular lymphoma, mucosa-associated lymphoid tissue, plasmacytoma, granulocytic sarcoma)

Associated with: widespread dissemination to skin, lung, CNS (6–17%), Waldeyer ring (6%)

- painless testicular enlargement over weeks to months
- weight loss, anorexia, fever, weakness (initial complaint in 25%)

Location: bilateral in 38%; synchronous in 20%

◊ The most common bilateral testicular tumor!

√ enlarged diffusely hypoechoic testis ← ill-defined diffuse infiltrative process
√ multiple focal hypoechoic masses
√ epididymis + spermatic cord + skin commonly infiltrated
√ increased blood flow on color Doppler

MR:

√ testis replaced by tissue hypointense on T1WI + T2WI
√ low-level enhancement less than normal testis
√ one / more focal masses
√ frequent extension outside testis into epididymis

Prognosis: poor; median survival of 12 months; 12–35% 5-year survival

DDx: epididymo-orchitis (tender, improvement on Rx), sarcoid (African-American), tuberculosis, leukemia (often prior history of treated leukemia)

Leukemia of Testis

Prevalence: 60–92% on autopsy; 8–16% on clinical examination during therapy; up to 41% on clinical examination after therapy

◊ Occult testicular tumor often found in patients in bone marrow remission (gonadal barrier = blood-testis barrier to chemotherapy)

√ uni- / bilateral tumors:
√ diffuse / focal
√ hypo- or hyperechoic

Burned-out Tumor of Testis

= AZZOPARDI TUMOR = REGRESSED GERM CELL TUMOR

= widespread metastatic disease + spontaneous regression of testicular malignancy ← teratocarcinoma

Histo: minute amounts of residual tumor / dense deposit of collagen + scattered inflammatory cells

Pathogenesis: tumor with high metabolic rate outgrows its own blood supply

√ small primary tumor:
√ hypoechoic lesion
√ highly echogenic focal lesion (= scarred tumor residue)
√ ± shadowing (= focal calcification)

√ metastases to retroperitoneum, mediastinum, cervical / axillary / supraclavicular lymph nodes, lung, liver

Second Testicular Tumor

Prevalence: 1–5% of all testicular cancers

US: a testicular abnormality is malignant in only 50%!

SYNCHRONOUS TESTICULAR TUMOR

= development of 2 separate primary tumors ← NO lymphatic / vascular connections between testes

Frequency: 10% of bilateral tumors

Histo: identical

Rx: bilateral orchiectomy; for small tumors testis-preserving surgery + radiation therapy

METACHRONOUS TESTICULAR TUMOR

= subsequent development of second primary tumor

Frequency: 90% of bilateral tumors

Risk for second tumor in cryptorchidism:

15% for inguinal, 30% for abdominal location

Risk for second contralateral tumor:

increased by 500–1,000 x; bilaterality in 1.1–4.4%;

Development interval between 1st + 2nd tumor:

4 months to 25 years

◊ Detected in 47% [60%] {75%} by 2 [5] {10} years

TESTICULAR INFARCTION

= extremely rare

Cause: torsion, trauma, acute epididymo-orchitis, leukemia, embolus (eg, bacterial endocarditis, sickle cell disease, polycythemia), vasculitis (eg, polyarteritis nodosa, Henoch-Schönlein purpura), hernia repair (testicular atrophy in 0.5% after first repair, in 0.8–5% after recurrent repair)

Age: 20–40 years

Location: often in periphery with extension to capsule

• painful testis, soft to palpation

√ focal hypoechoic wedge-shaped region without flow (most common)

√ hyperechoic regions ← hemorrhage / fibrosis

√ decrease in testicular size over time ← fibrosis

√ diffusely hypoechoic small testis

MR:

√ hypo- / (typically) isointense to normal testis on T1WI:

√ may have high SI on T1WI ← hemorrhage

√ hypointense to normal testis on T2WI

√ avascular area + enhancing rim on contrast administration

DDx: malignancy (difficult differentiation)

TESTICULAR MICROLITHIASIS

Definition: > 5 microliths per image; ≤ 5 microliths per image = limited microlithiasis

Etiology: defect in phagocytotic activity of Sertoli cells leaving degenerated intratubular debris behind

Prevalence: 0.6%; 5% in asymptomatic men aged 18–35 years

May be associated with:

testicular germ cell tumor (40%), cryptorchidism, subfertility, infertility, Klinefelter syndrome, testicular infarcts, granulomas, male pseudohermaphroditism, Down syndrome, pulmonary alveolar microlithiasis, congenital urethroperineal fistula

Histo: laminated concretions within lumen of seminiferous tubules

• asymptomatic, uncommon incidental finding

√ 1–2-mm (> 5) hyperechoic nonshadowing foci scattered throughout the parenchyma of both testes (PATHOGNOMONIC):

√ may be asymmetrically distributed, unilateral, clustered in periphery

Cx: concurrent germ cell tumor in up to 40% (21.6 x risk)

Prognosis: the vast majority of patients with testicular microlithiasis will not develop testicular cancer

◊ Testicular microlithiasis is not a premalignant condition and does not cause testicular cancer!

Recommendation: follow up in 6–12-month intervals to screen for testicular tumors (contested)

DDx: postinflammatory changes, scars, granulomatous changes, benign adenomatoid tumor, hemorrhage with infarction, large-cell calcifying Sertoli cell tumor

TESTICULAR TRAUMA

= SCROTAL TRAUMA

Frequency: < 1% of all traumas

Cause:

(a) blunt force (crushing of testis against symphysis / between thighs): sporting activity (> 50%), motor vehicle accident (9–17%)
Pathophysiology: contusion → hematoma → fracture → rupture

(b) penetrating: sharp object (knife), missile (bullet), animal bite, self mutilation

(c) iatrogenic: complication of herniorrhaphy

(d) degloving injury: genital skin entrapped in rotating machinery

(e) thermal injury

Peak age: 10–30 years

Site: R > L (superior location with propensity to become trapped against pubis / inner thigh)

√ hematoma in scrotal wall / between layers of tunica vaginalis (= hematocele) / in epididymis / in testis

√ uriniferous hydrocele ← perforated bulbous urethra

Cx: torsion in 5–8% ← sudden forceful cremasteric contraction on "bell and clapper" deformity

Testicular Dislocation

Cause: impact against fuel tank of motor cycle

At risk: patients with wide inguinal ring / indirect inguinal hernia / atrophic testis

Site: superficial inguinal (50%), pubic (18%), canalicular (8%), penile (8%),

intraabdominal (6%), perineal (4%), crural (2%)

Testicular Fracture

= break / discontinuity in testicular parenchyma
Frequency: 17% of testicular trauma
√ linear hypoechoic + avascular band disrupting the architecture (= fracture line)
√ smooth outer contour with intact tunica albuginea
√ usually preserved vascular flow
Rx: conservative / debridement along fracture line

Testicular Hematoma

• may be quite large ← surrounding scrotal elasticity
US:
√ over time age-dependent rapid change in echo character of hematoma + decrease in size
(a) hyperacute / acute hematoma
√ initially hyperechoic acute hematoma
√ later isoechoic → reexamination after 12–24 hours
(b) chronic hematoma
√ hypoechoic / anechoic mass decreasing in size
√ absence of internal vascularity (DDx: tumor)
√ peripheral hyperemia in infected hematoma (40% incidence)
√ developing testicular cyst ← subacute / chronic liquefaction of hematoma
MR:
√ hyperintense hematoma on T1WI
√ hypointense hemosiderin rim on T2WI
NB.: Follow-up all hematomas to resolution!
◊ 40% of hematomas become infected + lead to necrosis!
◊ Testicular cancer is incidentally identified in 10–15% of patients with scrotal trauma!
Rx: conservative (ice pack, NSAID)

Testicular Rupture

= tear / rupture of tunica albuginea with protrusion of seminiferous tubules
Pathophysiology: 50 kg of force ruptures tunica albuginea
◊ SURGICAL EMERGENCY!
US (100% sensitive, 65% specific):
√ disruption of tunica albuginea = discontinuity of echogenic testicular outline (50% sensitive, 76% specific)
√ abnormal testicular contour = extrusion of testicular parenchyma (difficult DDx: peritesticular hematoma)
◊ Err on the side of overcalling!
√ heterogeneous echotexture of testis with areas of ⇓ / ⇑ echogenicity ← hemorrhage ± necrosis (DDx: intratesticular hematoma without rupture)
√ avascular region on color duplex ← disruption of tunica vasculosa (DDx: hematoma)
√ thickened scrotal wall ← hematoma of scrotal wall

√ hematocele, may show thickening + calcification of tunica vaginalis if chronic

MR (long examination time):

√ area of heterogeneously low SI on T2WI

√ interruption of hypointense fibrous tunica albuginea

Rx: immediate surgical repair → preservation of fertility + hormonal function / orchiectomy

Salvageability: 80–90% if surgical repair occurs < 72 hours after trauma; 30–55% if surgical repair occurs > 72 hours after trauma

DDx: laceration, contusion, hemorrhage

TRANSITIONAL CELL CARCINOMA

= UROTHELIAL CELL CARCINOMA

◊ Most common urinary tract cancer in USA + Europe!

Mean age: 68 years; M÷F = 2.7÷1; Whites > Blacks

Pathogenesis: chemical carcinogens act locally on epithelium (= field of change), action enhanced by length of contact time (eg, stasis / diverticulum / horseshoe kidney)

Risk factors:

(1) Cigarette smoking (2–3 x): dose-response relation to pack-years; 50–60% in M, 33% in F

(2) Chemical carcinogens: aniline dye, benzidine, aromatic amines, azo dyes in textile, rubber, petroleum, printing, plastic manufacturing, arsenic in drinking water (lag time of 10 years)

(3) Antineoplastic alkylating agents: carmustine, busulfan, cyclophosphamide (lag time of 6.5 years)

(4) Analgesic abuse (8 x increase): long-term use of phenacetin → capillosclerosis + renal pelvic TCC

(5) **B**alkan nephropathy (= progressive renal failure + development of bilateral and multiple tumors) ← unintentional ingestion of aristolochic acid in seeds of the Aristolochia clematitis plant (contaminating flour)

(6) Recurrent / chronic urinary tract infection (esp. Schistosoma haematobium)

(7) Heavy caffeine consumption (?)

Growth pattern:

(a) papillary lesion with predominantly exophytic growth
= frondlike structure with central fibrovascular core lined by epithelial layer
› broad based
› pedunculated

(b) infiltrating: usually higher grade + less common

(c) carcinoma in situ

Grade: usually correlates with stage
1 = cells slightly anaplastic
2 = intermediate features
3 = marked cellular pleomorphism

Location: typically multifocal

@ Lower urinary tract (95%)

1. Urinary bladder: 30–50 x more common than upper urinary tract

@ Upper urinary tract (5%)
2. Kidney (3.75%): calyx > renal pelvis
3. Ureter (1.25%): 75% in lower ⅓ — 25% in upper ⅔

Spread: mucosal extension, regional lymph nodes (early involvement), hematogenous (liver, bone, lung)

Prognosis: multicentricity means poor survival; frequent synchronous + metachronous tumors requires vigilant urologic + radiographic follow-up

Follow-up: annual CT x 2 years; cystoscopy 4 x 3 months for 1st year, 2 x 6 month in 2nd year, yearly thereafter for early detection of metachronous bladder TCC

Renal TCC

Prevalence: 7% of all renal neoplasms; bilateral in 2–4%; 90% of all tumors arising from renal pelvic urothelium

Age: 6th & 7th decades; M÷F = 3÷1

Site: extrarenal part of renal pelvis > infundibulocaliceal region

◊ Synchronous bilateral renal TCC in 1–2%
◊ Metachronous renal TCC in 11–13%
◊ Metachronous bladder TCC in 23–40% after 15–48 months

Excretory Urogram:

√ single / multiple sessile / pedunculated mulberry-like filling defects in renal pelvis (35%):
  √ "stipple" sign = contrast material trapped in interstices of papillary lesion (DDx: blood clot, fungus ball)
√ dilated calyx with filling defect (26%) ← stricture / complete obstruction of infundibulum:
  √ ± focal delayed increasingly dense nephrogram
  √ caliceal amputation (19%) = "**phantom calyx**" = failure to opacify ← obstruction (DDx: TB stricture of infundibulum)
  √ "**oncocalyx**" = contrast outlining distended calyx completely filled with tumor
√ absent / decreased excretion with renal atrophy (13%) ← long-standing obstruction of ureteropelvic junction
√ renal enlargement:
  √ large bean-shaped kidney ← infiltrative tumor invasion of renal parenchyma
  √ hydronephrosis (6%) ← tumor obstructing ureteropelvic junction
√ tumor calcifications in 2–7%

Staging of Transitional Cell Cancer of Kidney		
TNM	*AJCC*	*Description*
Tx	...	primary tumor cannot be assessed
T0	...	no evidence of primary tumor
Tis	0	in situ lesion
Ta	...	noninvasive papillary carcinoma
T1	I	invasion of subepithelial connective tissue
T2	II	confined to muscularis layer
T3	III	invasion of renal parenchyma / peripelvic soft tissues
T4	IV	extension beyond renal capsule
N0		negative lymph nodes
N1		single node ≤ 20 mm
N2		single node > 20 – ≤ 50 mm / multiple nodes ≤ 50 mm
N3		node > 50 mm
M0		no distant metastasis
M1		distant metastasis: lung, retroperitoneum, bone

Retrograde pyelography:
- √ smooth / irregular / stippled intraluminal filling defect
- √ irregular papillary / nodular mucosa
- √ "amputated" calyx ± focal hydronephrosis
- √ "oncocalyx" = tumor-filled distended calyx
- √ calculus ← urinary stasis

US:
- √ bulky hypoechoic (similar to renal parenchyma) / slightly hyperechoic mass lesion
- √ infiltrative without disruption of renal contour
- √ splitting / separation of central renal sinus complex
- √ ± caliectasis without pelviectasis

NECT:
- √ tumor density of 5–30 HU:
  - √ hyperattenuating relative to urine + renal parenchyma
  - √ hypoattenuating relative to clot (40–80 HU) / calculus (> 100 HU)
- √ hydronephrosis / hydrocalyx (most frequent finding)
- √ "faceless" kidney on cross-sectional imaging → coronal imaging helpful

CECT (36–52–83% staging accuracy):
- √ focal or diffuse mural thickening of pelvicaliceal wall
- √ pelvicaliceal irregularity
- √ oncocalyx
- √ central sessile solid filling defect centrifugally expanding renal pelvis
- √ obliteration / compression of renal sinus fat
- √ invasion of renal parenchyma (infiltrating growth pattern) with preservation of reniform shape
  (DDx: expansile RCC distorting renal contour)

√ coarse punctate calcific deposits (0.7–6.7%) may mimic urinary calculi
√ variable enhancement of tumor

MR:
√ typically isointense relative to renal medulla on T1WI
√ hypointense filling defect in hyperintense urine on T2WI
√ hypointense soft-tissue mass infiltrating renal parenchyma of intermediate SI
√ hypoenhancing tumor mass on postcontrast imaging, (rarely) avidly enhancing
√ enhancing focal filling defect in collecting system

Dx: cytologic analysis of urine (selective lavage, ureteral urine collection, brush biopsy, ureteroscopy

DDx: papilloma (benign lesion, fronds lined by normal epithelium), blood clot

Prognosis: 77–80% 5-year survival rate without invasion of muscularis mucosa; 5% 5-year survival rate with invasion of muscularis mucosa

Rx: total nephroureterectomy + excision of ipsilateral ureteric orifice with cuff of bladder

Ureteral TCC

Incidence: 1% of all upper urinary tract cancers

Site: lower ⅓ (70%), mid ⅓ (15%), upper ⅓ (15%)
◊ Synchronous TCC in both ureters in 2–9%
◊ Metachronous upper tract TCC in 11–13%
◊ Metachronous bladder TCC in 20–50% (within 2 years of surgical treatment)

Excretory Urogram:
√ nonfunctioning kidney in advanced tumor (46%)
√ hydronephrosis ± hydroureter (34%)
√ single / multiple ureteral filling defects (19%) ± surface stippling
√ irregular nontapering narrowing of ureteral lumen

Retrograde pyelography:
√ stricture suggestive of malignancy:
  √ ureteric fixation + nontapering margins
  √ eccentric / circumferential stricture
√ "champagne glass / chalice / goblet" sign = focal expansion of ureter around + distal to intraluminal slow growing polypoid tumor ← mechanical dilatation ← to-and-fro peristalsis of mass
√ Bergman sign = "catheter-coiling" sign = coiling of catheter on retrograde catheterization below the mass

CT:
√ enhancing intraluminal soft-tissue mass
√ eccentric / circumferential thickening of ureteral wall
√ periureteric fat stranding ← extramural spread

TRAUMA TO BLADDER

Cause:
1. Blunt injury (67–86%): often associated with pelvic fractures
2. Penetrating injury (14–33%)

Associated with: pelvic fracture in 70%

Indications for urethrogram:
- blood at urethral meatus, inability to pass Foley catheter
- "floating" prostate

√ diastasis of symphysis

√ "pie-in-the-sky bladder" = high position of opacified bladder within pelvis ← large pelvic hematoma with disruption of bladder moorings + associated urethral injury

CT cystogram:

Technique:

» prior to IV contrast instill up to 400 mL of diluted contrast solution via Foley catheter under gravity flow → clamp Foley to maintain bladder distension, OR

» clamp Foley → IV contrast injection → delayed imaging after 180–300 seconds after opacification of bladder

√ focal thickening of bladder wall = contusion

√ contrast extravasation

Bladder Contusion *(most common injury)*

= intramural hematoma

√ no extravasation

√ lack of normal distensibility

√ crescent-shaped filling defect in contrast-distended bladder

Interstitial Bladder Injury *(uncommon)*

= bladder tear without serosal involvement

Bladder Rupture

Cystography: diagnostic in > 85%; false-negatives if tear sealed by hematoma / mesentery

CT:

√ unusual fluid / gas collection

√ abnormal location of Foley catheter

√ defect in enhancing bladder wall

Extraperitoneal Rupture of Bladder (80–90%)

Cause: pelvic fracture (sharp bony spicule) or avulsion tear at fixation points of puboprostatic ligaments → separation of fascial planes between bladder + pelvis

Location: tear usually close to base of bladder anterolaterally

Plain film:

√ "pear-shaped" bladder

√ loss of obturator fat planes

√ paralytic ileus

√ upward displacement of ileal loops

Contrast examination:

√ flame-shaped contrast extravasation into perivesical fat, best seen on postvoid films, may extend into thigh / anterior abdominal wall

CT:

√ relatively contained extravasated fluid isoattenuating to fluid in bladder:

√ limited to perivesical (Retzius) space = simple
√ extravasated contrast extends to prevesical space, thigh, scrotum, perineum = complex

US:
√ "bladder within a bladder" = bladder surrounded by fluid collection

Rx: conservative (urinary drainage via Foley); surgery

Intraperitoneal Rupture of Bladder (10–20%)

Cause:
(a) usually as a result of invasive procedure (cystoscopy), stab wound, surgery
(b) blunt trauma with sudden rise in intravesical pressure (= distended bladder at time of impact)

Location: tear usually at dome of bladder

√ contrast extravasation (requires adequate bladder filling) into paracolic gutters, rectovesical / rectouterine pouch
√ contrast outlining / surrounding intraperitoneal structures (small bowel loops + mesentery)
√ extravasated contrast less dense than in bladder ← contrast dilution within large intraperitoneal space
√ uriniferous ascites

Rx: surgery

TRAUMA TO KIDNEY

Frequency: 3–10% of injuries in emergency department

◊ 95–98% of isolated renal injuries are considered minor injuries and managed nonsurgically!

Indications for imaging:
(1) Penetrating injury + gross hematuria
(2) Blunt trauma + microscopic hematuria + hypotension < 90 mmHg
(3) Blunt trauma + known association with renal injuries (eg, rapid deceleration, fall from a height, direct contusion / hematoma of flank soft tissues, fracture of lower ribs / transverse processes / thoracolumbar spine)

(4) Microscopic hematuria + positive peritoneal lavage
◊ Only 0.1–0.5% of hemodynamically stable patients with microscopic hematuria have significant urinary tract injury!

Classification:

I. MINOR RENAL INJURY (75–85%)
√ no / limited perinephric hematoma
DDx: respiratory motion artifact (low-attenuation area surrounding kidney)
√ no extravasation of urine (= no caliceal disruption)

1. **Intrarenal hemorrhage / hematoma = renal contusion**
√ hyperattenuating area of 40–70 HU (= acute clotted blood) on NECT
√ sharply / poorly defined round / ovoid area of decreased enhancement during CECT (DDx: renal infarction with no enhancement)
√ focal area of striation on delayed nephrogram
√ area of persistent contrast material staining on very delayed scan

2. **Subcapsular hematoma**
   √ round / lenticular-shaped fluid collection + flattening of subjacent parenchyma
3. **Perinephric hematoma** without extension to collecting system / medulla
   √ defects in periphery of renal parenchyma
   √ ± limited perinephric hematoma with attenuation values of 45–90 HU
   ◊ Subcapsular / perinephric hematoma usually proportional to extent of injury
4. Small subsegmental **cortical infarct**
   Cause: stretching + thrombotic occlusion of accessory renal artery / capsular artery / segmental artery
   √ sharply demarcated wedge-shaped area of decreased contrast enhancement

Rx: observation

II. MAJOR RENAL LACERATION (10%)

= complete cortical laceration / fracture extending to medulla ± collecting system

√ laceration connecting two cortical surfaces = renal fracture = separation of renal poles

√ ± devascularization of renal parenchyma

(a) without involvement of collecting system:

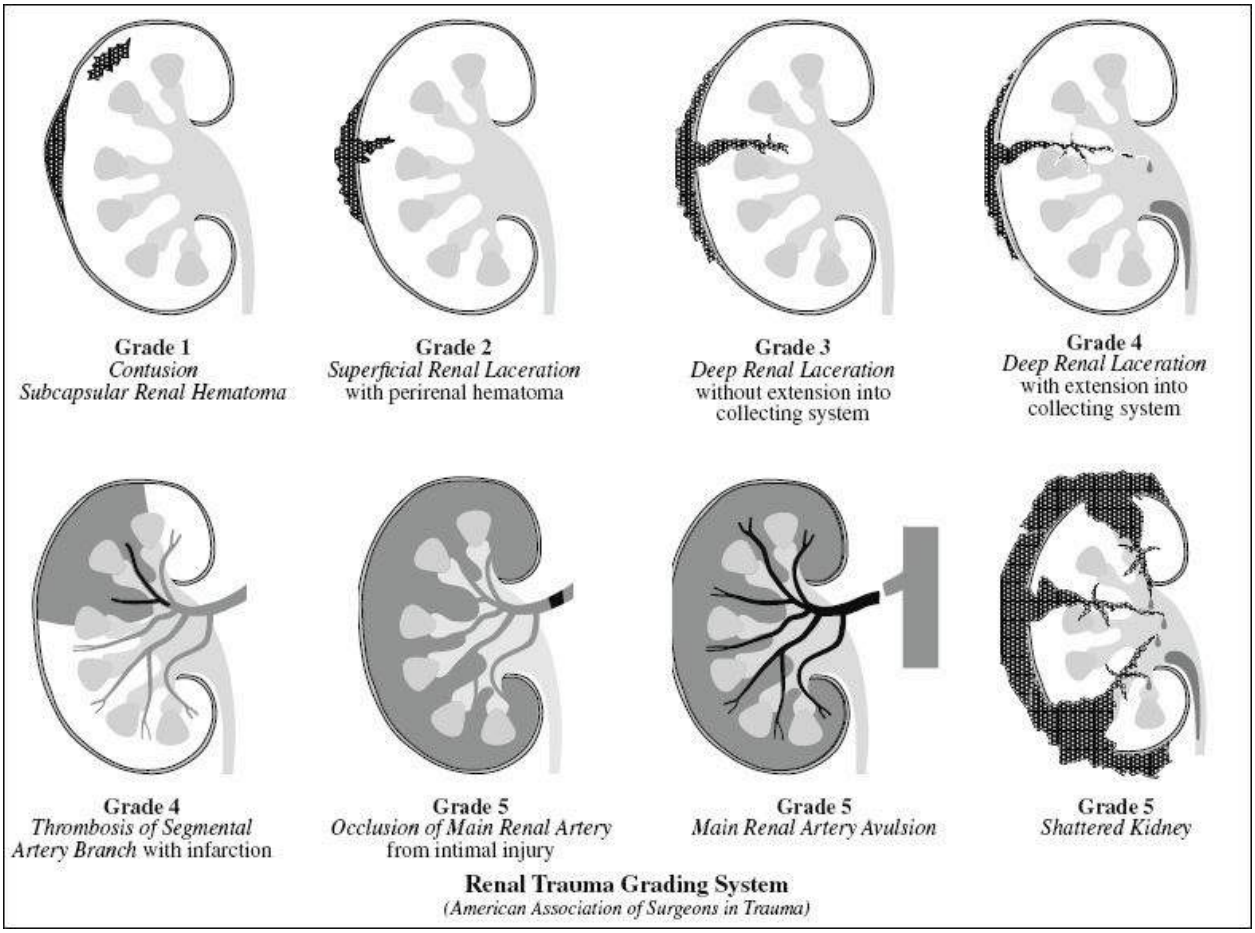
√ nonenhancing deep parenchymal cleft filled with hematoma on CECT

√ perirenal hematoma from capsular disruption

Kidney Injury Scale
American Association for the Surgery of Trauma (**AAST**)

Grade	*Injury*	*Description (based on surgical findings)*
I	contusion	hematuria + normal urologic studies
	hematoma	subcapsular nonexpanding, no laceration
II	hematoma	nonexpanding perirenal, confined to renal retroperitoneum
	laceration	< 1 cm parenchymal depth of renal cortex, no urinary extravasation
III	laceration	> 1 cm parenchymal depth of renal cortex, no collecting system rupture / urinary extravasation
IV	laceration	parenchymal laceration extending through renal cortex, medulla, collecting system
	vascular	main renal artery / vein injury + contained hemorrhage
V	laceration	completely shattered kidney
	vascular	avulsion of renal hilum with devascularization of kidney

◊ Advance one grade for multiple injuries to same organ



(b) with involvement of collecting system:
- √ urine extravasation of contrast material on delayed images 3–5 minutes after injection
- √ perinephric fluid during portal venous phase → suspect urinoma!

(c) active hemorrhage / pseudoaneurysm:
- ◊ Hemodynamic decompensation may be imminent in 38%!
- √ intense contrast enhancement within a laceration / hematoma during early phase:
  - √ linear / flamelike contrast extravasation of 80–370 HU or within 10–15 HU of aortic density

Rx: variable (clinical judgement required)

III. CATASTROPHIC RENAL INJURY (5%)

√ extravasation of contrast material with patchy areas of 85–370 HU (= active bleeding)

1. Multiple renal lacerations = **shattered kidney**
   - √ multiple separate renal fragments
   - √ lack of enhancement of part of kidney ← segmental renal arterial infarctions
   - √ ± cortical rim nephrogram (= enhancement of renal periphery through intact capsular / collateral vessels)

   Rx: surgical exploration / nephrectomy
2. **Vascular injury of renal pedicle**

   = occlusion of main renal artery ← intimal flap

• hematuria may be absent
√ abrupt termination of main renal artery just beyond its origin
√ minimal hematoma around proximal renal artery
√ absence of perinephric hematoma (HALLMARK)
√ absent nephrogram on affected side
√ retrograde opacification of ipsilateral renal vein
√ cortical rim nephrogram (develops > 8 hours after injury)
Prognosis: high risk of ongoing hemorrhage
Rx: revascularization procedure (in 14% return of renal function)

3. **Avulsion of renal artery** (rare)
= tearing of tunica muscularis + adventitia
√ absent contrast enhancement (= global infarct)
√ extensive medial perirenal hematoma
√ active arterial bleeding
Prognosis: life-threatening
4. **Thrombosis / laceration of renal vein** (rare)
√ intraluminal thrombus in dilated renal vein
√ acute venous hypertension:
√ nephromegaly
√ diminished nephrogram
√ delayed nephrographic progression
√ decreased excretion

IV. INJURY OF URETEROPELVIC JUNCTION (rare)
= laceration (= incomplete tear in 60%) / avulsion (= complete transection) of ureter at UPJ
Mechanism: tension on renal pedicle by sudden deceleration
Age: usually young boys
Associated with: fracture of transverse process (30%)
• gross / microscopic hematuria (53–60%)
N.B.: delayed imaging to check for urine leak!
√ massive extravasation of contrast material medially in the region of UPJ
√ nonfilling of affected ureter (with avulsion)
√ ± circumferential perinephric urinoma
Early Cx: urinoma formation (1–7%), infected urinoma, perinephric abscess, sepsis, delayed bleeding ← arteriovenous fistula / pseudoaneurysm
Late Cx: posttraumatic renovascular hypertension, hydro- nephrosis, calculus formation, chronic pyelonephritis

Blunt Trauma to Kidney

Frequency: 80–90% of all renal injuries
Cause: motor vehicle accident, fight, assault, contact sports, fall from a height
Mechanism: (a) crush injury (> 80%) = direct blow with renal laceration by lower ribs
(b) sudden deceleration → renal artery tear
Associated with: other organ injury in 75%; fracture of lower ribs / thoracolumbar spine /

transverse processes of L-spine

- contusion / hematoma of flank
- > 95% hematuria (> 5 RBCs per high-power field):

  N.B.: poor correlation between severity of hematuria + severity of renal injury

  ◊ With gross hematuria 25% have significant injuries!

  ◊ With renal pedicle injury 24% have no hematuria!

  ◊ Normotensive patients with microscopic hematuria (< 35 RBCs per high-power field) have a significant renal injury in < 0.2%!

Location: simultaneous upper + lower GU tract injury in < 5%

Rx: The only absolute indication for surgery is life-threatening active bleeding! Urine leaks will close spontaneously in 87%!

Penetrating Renal Trauma

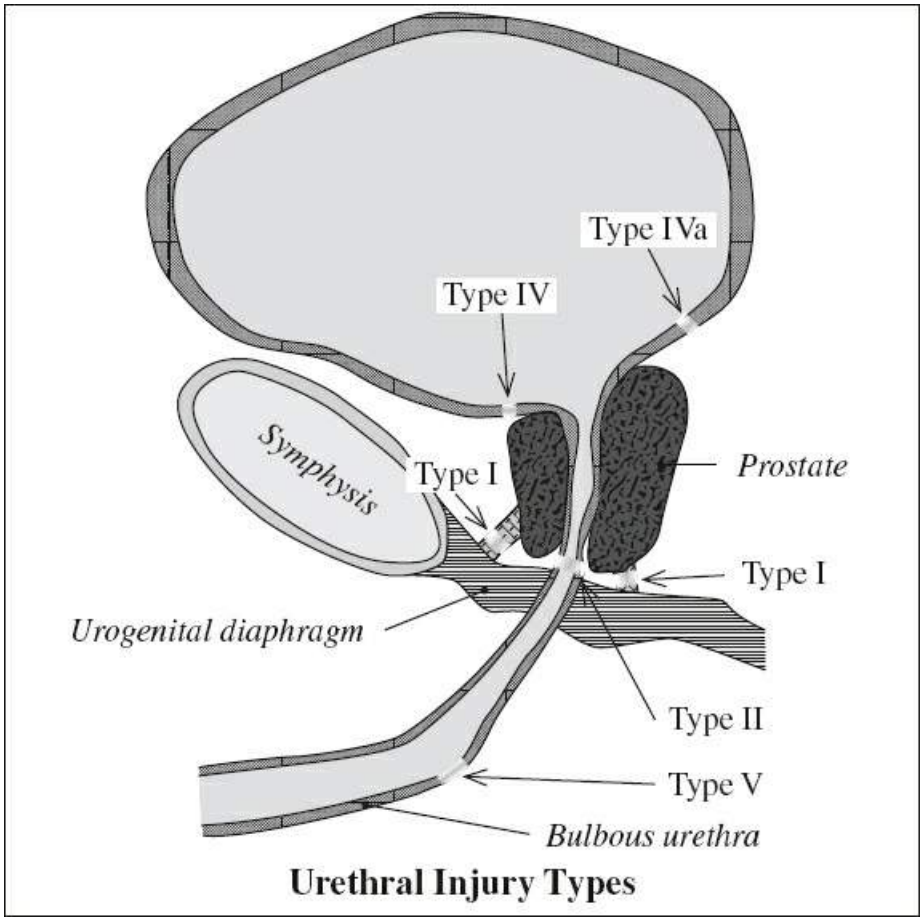
Frequency: 10–20% of all renal trauma

Cause: gunshot, stab wound, shrapnel, biopsy

Associated with: multiorgan injuries in 80%

Cx: (1) infection ← "dirty" contaminated wound

(2) "bullet / buckshot colic", "birdshot calculus" = ureteral obstruction ← migrating missile



Urethral Injury Types

Classification System of Urethral Injury at Urethrography (Goldman)		
Type	*Injury*	*Urethrographic Signs*
I	stretching of posterior urethra	√ intact stretched urethra
II	disruption of urethra above urogenital diaphragm	√ extravasation above urogenital diaphragm
III	disruption of membranous urethra with extension below urogenital diaphragm to involve anterior urethra	√ extravasation below urogenital diaphragm ± extension to pelvis / perineum √ intact bladder neck
IV	bladder neck injury with extension to proximal urethra	√ extraperitoneal extravasation √ bladder neck disruption
IVa	bladder base injury simulating type IV	√ periurethral extravasation √ bladder base disruption
V	isolated anterior urethral injury	√ extravasation below urogenital diaphragm confined to anterior urethra

TRAUMA TO URETHRA

Frequency: in 4–14% of pelvic fractures in males, in < 6% of pelvic fractures in females
Associated with: bladder laceration in up to 20%
Location:
(a) posterior urethra (in 4–14% of pelvic fractures)
(b) anterior urethra (often isolated) ← straddle injury

- gross hematuria, blood at meatus (50%), swelling / hematoma of perineum / penis, "high-riding" prostate at digital exam
- inability to void

N.B.: blind urethral catheterization is contraindicated!

CT (indirect findings):
√ pelvic diastasis / fractures
√ distortion of periprostatic structures
√ hematoma of ischiocavernosus / obturator muscle
√ excretory contrast extravasation around bladder base

Urethrographic technique:
(a) **ascending (retrograde) urethrography**
» external occlusion with Knutsson / Brodney clamp
» internal occlusion with inflatable balloon (6–8-F Foley with 5 mL balloon / HSG catheter with 3 mL balloon)
(b) **descending (antegrade) urethrography**
» bladder filling with 350–400 mL contrast
» imaging during micturation + after voiding
(c) **ascending pericatheter urethrography**

» 4–6-F pediatric catheter with balloon inflated in navicular fossa alongside indwelling catheter
» gradually advance 4–6-F feeding tube ± seal with tightly tied ribbon gauze around penis proximal to glans

(d) **descending pericatheter urethrography**
= voiding around indwelling catheter
» indwelling catheter pushed deeper into bladder ± deflation of balloon (avoid dislodging catheter!)

Rx: suprapubic catheter for urethral / bladder injury

Cx: (1) Urethral stricture (38–100%)
(2) Impotence (in up to 40%)
(3) Incontinence (30%)

TUBERCULOSIS OF GU TRACT

The urogenital tract is the 2nd most common site after lung; almost always affects the kidney first
= hematogenous focus from lung / bone / GI tract

Age: usually before age 50; M > F

Path: organisms lodge in periglomerular capillaries; breakdown in host immunity results in extensive necrosis + fibrosis (coalescing cortical granulomas); organisms spill down the nephrons and become trapped in the narrow segment of the loop of Henle forming ulcerocavernous papillary lesions, which erode into collecting system

Spread:
(a) contiguous: from renal parenchyma → along urothelium → to infundibula, renal pelvis, ureter, bladder
(b) hematogenous (rare): epididymis, testis
◊ It is unusual for genitourinary sites to be affected without involvement of kidney first!

- gross / microscopic hematuria
- "sterile" pyuria, frequency, urgency, dysuria
- history of previous clinical TB (15–20%) → lag time of 2–40 years

IVP (abnormal in 85–90%)

Adrenal Tuberculosis *6%*

◊ 5th most common site of extrapulmonary tuberculosis
• Addisonian type clinical picture
√ bilaterally enlarged glands (91%)
√ low-attenuation center + peripheral enhancement (47%)
√ dotlike calcifications (59%)

Renal Tuberculosis

◊ Renal TB in 5–10% of patients with pulmonary TB!
◊ Radiographic evidence of pulmonary TB in < 50% of patients with renal TB (only 5% have active cavitary TB)!

Location: unilateral (75%)

√ <u>renal size:</u> enlarged (early) / small (late) / normal (most common):

√ "putty kidney" = tuberculous pyonephrosis from ureteral stricture
√ autonephrectomy = small shrunken scarred nonfunctioning kidney ± dystrophic calcifications
√ cortical scars, often associated with parenchymal calcifications:
√ distortion of collecting system ← adjacent cortical scarring
√ displacement of collecting system ← tuberculoma of low attenuation (initial infection)
√ "moth-eaten calyx" = "smudged" papillae = irregular feathery appearance of surface of papilla ← erosion (earliest sign) → progression to papillary necrosis
√ cavities communicating with collecting system:
√ irregular tract formations from calyx into papilla
√ large irregular cavities with extensive destruction
√ blunted dilated calices = papillary necrosis
√ strictures of infundibula / renal pelvis:
√ dilated calices (hydrocalycosis) often with sharply defined circumferential narrowing (infundibular strictures) at one / several sites (most common finding)
√ caliceal truncation
√ "phantom calyx" / amputated calyx = incomplete visualization of calyx ← infundibular stenosis
√ reduced capacity of renal pelvis
√ Kerr kink = kinking of renal pelvis
√ hydronephrosis with irregular margins + filling defects ← caseous debris
√ mural thickening of collecting system
√ dystrophic amorphous parenchymal calcifications (50%)
√ in tuberculomas (in 24–44%): amorphous / granular / curvilinear / punctate / confluent ("toothpaste") / involving entire kidney ("**putty kidney**"):
√ nephrolithiasis (in 10%)
√ globally poor renal function
√ infection may extend into peri- / pararenal space + psoas
CT:
√ triangular / ringlike calcifications within renal collecting system (= papillary necrosis)

Ureteral Tuberculosis

Frequency: in 50% of genitourinary TB; always with evidence of renal involvement as it spreads from kidney
Location: either end of ureter (most commonly distal ⅓), usually asymmetric, may be unilateral
√ ureteral filling defects ← mucosal granulomas
√ "**saw-tooth ureter**" = irregular jagged contour ← dilatation from ureterovesical junction obstruction + multiple small mucosal ulcerations + wall edema (early changes)
√ strictures (late changes):
Site: pelviureteric junction, across pelvic brim, at vesicoureteric junction
"beaded ureter" = alternating areas of strictures + dilatations
"corkscrew ureter" = marked tortuosity with strictures + dilatations
"**pipestem ureter**" = rigid aperistaltic foreshortened thick and straight ureter
√ vesicoureteral reflux through "fixed" patulous orifice

√ ureteral calcifications uncommon (usually in distal portion)
CT:
√ thickening of ureteral wall with periureteric inflammation

Bladder Tuberculosis

= infection from renal source causes interstitial cystitis
√ thickened bladder wall (= muscle hypertrophy + inflammatory tuberculomas)
√ filling defects ← multiple granulomas
√ bladder wall ulcerations
√ "shrunken bladder" = scarred bladder with diminished capacity
√ "thimble bladder" = diminutive irregular bladder
√ bladder wall calcifications (rare)
Cx: fistula / sinus tract / vesicoureteral reflux ← fibrosis of ureteral orifice

Male Genital Tuberculosis

√ calcifications in 10% (diabetes more common cause)
(1) Tuberculous prostatitis / prostatic abscess:
√ hypoechoic irregular area in peripheral zone
√ hypoattenuating prostatic lesion ← foci of caseous necrosis + inflammation
√ hypointense diffuse radiating streaky areas on T2WI (= "watermelon" sign)
√ peripheral enhancement
(2) Tuberculous epididymitis
ascending / descending route of infection
√ diffusely enlarged / nonspecific nodular epididymis of heterogeneous echogenicity
√ hydrocele, sinus tract, calcifications
(3) Tuberculous orchitis (rare)
direct extension from epididymal infection, rarely from hematogenous spread
DDx: brucellosis, fungal infections (identical picture)

Female Genital Tuberculosis

Prevalence: 1.3% involve genital tract (fallopian tube in 34%)
(1) Salpingitis (94%): mostly bilateral
√ thick-walled serpentine juxtauterine structure
√ intense enhancement
√ beaded appearance of salpinges ← multiple constrictions
√ tubal obstruction is unusual
(2) Tuboovarian abscess: → extension into extraperitoneal compartment
√ loculated ascites
√ omental + mesenteric soft-tissue infiltration
√ peritoneal thickening + nodularity
√ enlarged necrotic lymph nodes (= lymphadenitis)
DDx: peritoneal carcinomatosis
Cx: tuberculous peritonitis (in up to 50%): may mimic ovarian cancer ← elevated CA-125

UNICALICEAL (UNIPAPILLARY) KIDNEY

Path: OLIGOMEGANEPHRONIA = reduced number of nephrons and enlargement of glomeruli
Associated with: absence of contralateral kidney, other anomalies
• hypertension, proteinuria, azotemia

URACHAL ANOMALIES

urachus = median umbilical ligament = thick fibrous cord as the remnant of the allantois (= endodermal outgrowth from yolk sac into stalk), which regresses at 5th month of development; bounded by transverse fascia ventrally + parietal peritoneum dorsally (space of Retzius)
Cx: infection (23%), intestinal obstruction, hemorrhage into cyst, peritonitis from rupture, malignant degeneration

Alternating Sinus = Umbilical-Urachal Fistula

= cystic dilatation of urachus periodically emptying into bladder / umbilicus

Patent Urachus

= fistula between bladder and umbilicus
Prevalence: 1÷200,000 live births
• urine draining from umbilicus

Urachal Cyst (30%)

= gradually enlarging cyst ← closure of both ends of urachus
Prevalence: 1÷5,000 (at autopsy); 30% of all urachal anomalies
• asymptomatic in children unless rupture occurs
• symptomatic in adults ← enlargement / infection
√ cystic extraperitoneal mass
√ no communication with bladder or umbilicus

Urachal / Vesicourachal Diverticulum (3%)

= urachus communicates only with bladder dome

Urachal Sinus

= urachus patent only at umbilicus
Associated with: urachal cyst
• umbilical mass / inflammation ± drainage
√ thickened tubular structure with echogenic center

URACHAL CARCINOMA

= rare tumor arising from the urachus (= vestigial remnant of cloaca + allantois) within space of Retzius
Frequency: 0.01% of all adult cancers;
0.17–0.34% of all bladder cancers;
20–40% of all primary bladder adenocarcinomas
Histo:
(a) adenocarcinoma (84–90%), in 75% mucin producing
◊ 34% of all bladder adenocarcinomas are urachal in origin

Cause: columnar epithelial metaplasia of transitional cell epithelium in urachal remnant

(b) urothelial cancer (3%), sarcoma, squamous cell carcinoma

◊ 75% of urachal neoplasms in patients < 20 years of age are sarcomas!

Stages of Urachal Carcinoma	
I	cancer limited to urachus
II	invasion limited to urachus
III A	local invasion of bladder
III B	invasion of abdominal wall
III C	invasion of peritoneum
III D	invasion of other viscera
IV A	metastases to local lymph nodes
IV B	distant metastases (liver)

Age: 40–70 years; M÷F = 2÷1 to 3÷1

- suprapubic mass, abdominal pain; mucous micturition (25%)
- irritative voiding symptoms: dysuria, abdominal pain
- discharge of blood, pus from umbilicus, hematuria (71%)

Location: supravesical, midline, anterior (80%), extraperitoneally in space of Retzius

Site: close to bladder (90%); along course of urachus / at umbilical end (10%)

√ midline mass anterosuperior to vesical dome in the space of Retzius with predominantly muscular / extravesical involvement

√ tumor bulk outside bladder + invasion of bladder dome (88%)

√ mean tumor size of 6 cm

√ often peripheral curvilinear / punctate stippled psammomatous calcifications (50–72%)
PATHOGNOMONIC for mucinous adenocarcinoma

√ heterogeneous enhancement

US:

√ midline fluid-filled cavity with mixed echogenicity + calcifications adjacent to anterior abdominal wall

CT:

√ low-attenuation mass in 60% (mucin)

MR:

√ markedly increased SI on T2WI ← mucin

Cx: pseudomyxoma peritonei (in peritoneal carcinomatosis); metastasis to pelvic lymph nodes, lung, brain, liver, bone

Prognosis: 7–61% 5-year survival rate

Rx: radical cystectomy; often local recurrence within 2 years

DDx: infected benign urachal cyst; primary benign bladder tumor (adenoma, fibroadenoma, fibromyxoma, hamartoma); primary malignant bladder tumor (adenocarcinoma, transitional cell carcinoma); secondary bladder tumor (metastasis from colon, prostate, female genital tract); desmoid tumor

URETERAL DUPLICATION

= RENAL DUPLICATION

Ureteral duplication is the most common congenital anomaly of the urinary tract.

Complete Duplication of Ureter *(0.2%)*

Cause: second ureteral bud arising from mesonephric duct leading to complete ureteral duplication

Prevalence: 0.2% of live births; M÷F = 1÷2; in 15–40% bilateral

Risk of recurrence: 12% in 1st-degree relatives

Increased risk for: UTI, obstruction, vesicoureteral reflux

Embryology: ureters develop from separate ureteric buds originating from a single wolffian duct

√ duplicated ureter may be orthotopic

√ renal enlargement

√ tortuous dilated lower pole ureter

US:

√ two separate echodense renal sinuses + pelves separated by parenchymal bridge

IVP:

√ poor / nonvisualization of upper pole collecting system (delayed films):

√ "**drooping lily**" sign = hydronephrosis + decreased function of obstructed upper pole moiety causing downward displacement of lower pole calices

√ lateral + downward displacement of lower pole collecting system + ureter:

√ "nubbin" sign = scarring, atrophy, and decreased function of lower pole moiety may simulate a renal mass

√ displacement of proximal orifice upward

VCUG:

√ ureterocele

√ reflux into lower moiety (rare)

Cx: (1) Vesicoureteral reflux (most commonly)
(2) Ectopic ureteral insertion
(3) Ectopic ureterocele
(4) Ureteropelvic junction obstruction of lower pole

Weigert-Meyer Rule

= the upper pole ureter terminates inferior and medial to the lower pole ureter

(a) upper moiety ureter
remains with wolffian duct longer → passes through bladder wall → inserts ectopic <u>inferior and medial to lower moiety ureter</u> below the level of the trigone / into any wolffian duct derivative

(b) lower moiety ureter
drains lower pole and interpolar portion; is incorporated into developing bladder first → ascends during bladder growth → enters bladder at trigone

Upper Moiety Ureter

Three possible distal configurations:

1. Ureterocele
2. Ectopic ureter

3. Normal insertion into bladder

◊ Subject to ureteral obstruction ← stenosis at ectopic ureteral insertion / ectopic ureterocele / aberrant artery crossing!

◊ The ectopic ureteral orifice is inferior + medial to orthotopic ureteral orifice!

Associated with: significant renal dysplasia

Site of insertion of ectopic ureter

Cx: upper pole obstructive hydronephrosis

LOWER MOIETY URETER

◊ Subject to vesicoureteral reflux ← abnormal UVJ valve mechanism ← shortened ureteral tunnel at bladder insertion!

Cx: lower pole of duplex kidney may atrophy (in 50%) ← chronic pyelonephritis ← reflux nephropathy (= reflux ± infection)

√ clubbed calices underneath focal scars

Incomplete / Partial Duplication of Ureter *(0.6%)*

= initially separate upper + lower pole ureters fuse proximal to UVJ into a common ureter

Development: branching of ascending single ureteral bud (= one ureteral orifice + common distal ureter) before reaching metanephric blastema

Prevalence: in 0.6% of urograms

Associated with: ureteropelvic junction obstruction of lower renal pole

• frequently clinically insignificant

√ bifid ureter (in early branching)

√ bifid pelvis (in late branching)

√ ureteroureteral reflux = "yo-yo" / "saddle" / "seesaw" peristalsis = urine moves down the cephalad ureter + refluxes up the lower pole ureter and vice versa

√ asymmetric dilatation of one ureteral segment

√ upper pole ureter may end blindly (seen on retrograde injection only)

Cx: urinary tract infections

URETEROCELE

= bulbous dilatation / cystic ectasia of subepithelial segment of intravesical ureter

Prevalence: 1÷5,000 to 1÷12,000 children

IVP:

√ early filling of bulbous terminal ureter ("**cobra head** / spring onion" sign) projecting into urinary bladder

√ surrounded by a thin radiolucent halo (= combined thickness of ureteral wall + prolapsed bladder mucosa)

VCUG:

√ round / oval lucent defect near trigone

√ effacement with increased bladder distension

√ ± eversion during voiding

Simple Ureterocele

= ORTHOTOPIC URETEROCELE

= congenital prolapse of dilated distal ureter + orifice into bladder lumen at the usual location of the trigone, typically seen with single ureter

Presentation: incidental finding in adults; M÷F = 2÷3; bilateral in 33%

Cx:

(1) Pyelocaliceal dilatation

(2) Prolapse into bladder neck / urethra → obstruction (rare)

(3) Wall thickening ← edema from impacted stone / infection

Ectopic Ureterocele

= ureteral bud arising in an abnormal cephalad position from the mesonephric duct and moving caudally resulting in an ureteral orifice distal to trigone within / outside bladder

Frequency: in 10% bilateral

(a) in single nonduplicated system (20%)

M÷F = 1÷1

• hypoplastic / absent ipsilateral trigone

√ poorly visualized / nonvisualized kidney

√ small / poorly functioning kidney

(b) in upper moiety ureter of duplex kidney (80%)

M÷F = 1÷4 to 1÷8

Cx: (1) Bladder outlet obstruction ← ectopic ureterocele prolapsing into bladder neck / urethra

(2) Contralateral ureteral obstruction (if ectopic ureterocele large)

(3) Multicystic dysplastic kidney (the further the orifice from normal site of insertion, the more dysplastic the kidney!)

Pseudoureterocele

= obstruction of an otherwise normal intramural ureter mimicking simple ureterocele

Cause:

(a) Tumor
bladder tumor (most common in adults), invasion by cervical cancer, pheochromocytoma of intravesical ureter

(b) Edema
from impacted ureteral calculus (most common in children), radiation cystitis, following ureteral instrumentation, schistosomiasis

√ NO protrusion of ureter into bladder lumen (oblique views + cystoscopy normal)

√ thick irregular radiolucent halo surrounding bulbous terminal ureter

Dx: cystoscopy

URETEROPELVIC JUNCTION OBSTRUCTION

Primary UPJ Obstruction

= congenital partial functional / anatomic obstruction at junction of renal pelvis + proximal ureter

Prevalence: 1÷20,000 live births

◊ Most common cause of fetal / neonatal hydronephrosis!

Cause:

A. INTRINSIC FUNCTIONAL CAUSE

= embryonic insult to smooth muscle cells → adynamic aperistaltic proximal ureteral segment → impaired formation of urine bolus

(1) Replacement of UPJ muscle by excessive local collagen deposition

(2) Abnormal arrangement of junction muscles causing dysmotility (69%)

(3) Abnormal intercellular conduction

B. EXTRINSIC MECHANICAL / ANATOMIC CAUSE

(1) Crossing aberrant vessels (11–79%):

› branch of main renal artery / vein

› accessory branch from aorta / iliac artery / IVC

√ vessel to lower renal pole (in 25–39% of adult patients): anterior to UPJ (90–95%), posterior to UPJ (5–10%)

(2) Luminal narrowing by mucosal folds (= stenosis or valve) in upper ureter

(3) Periureteral fibrosis (= adventitial bands) ← recurrent urinary tract infections

(4) Insertional abnormality

› primary high ureteral insertion

› developing over time with renal pelvic distension

(5) Fixed kink / angulation

Age at discovery: in utero; < 15 years (25%); > 40 years (50%); M÷F = 5÷1

Associated anomalies (27%):

vesicoureteral reflux, bilateral ureteral duplication, bilateral obstructed megaureter, contralateral multicystic dysplastic kidney, contralateral renal agenesis, meatal stenosis, hypospadia

Location: left > right side; bilateral (10–20–40%)

• abdominal mass, intermittent flank pain

• Dietl crisis = "**beer-drinker's hydronephrosis**"

[Jozef Dietl (1804- 1878), Polish physician, pioneer of balneology and mayor of Kraków]

= intermittent flank pain typically after a large volume of fluid intake and subsequent diuresis (classically in college freshmen after excessive alcohol intake)

• hematuria, renal stones, UTI, pyelonephritis

√ hugely dilated largely extrarenal pelvis:

√ draped over lower pole vessel as inverted teardrop shape

√ proximal ureter hooking over lower pole vessel

√ variable degree of caliceal dilatation

√ NO dilatation of ureter

IVP:

√ sharply defined narrowing at UPJ

√ pelvicaliectasis without ureterectasis

√ anterior rotation of pelvis

√ broad tangential sharply defined extrinsic compression (in arterial crossing)

√ longitudinal striae of redundant mucosa (in dehydrated state)

√ late changes: unilateral renal enlargement, diminished opacification, wasting of kidney

substance
√ "**balloon-on-a-string**" sign:
√ caliceal crescents surrounding dilated collecting system
√ eccentric exit of ureter from dilated renal pelvis
CT / MRI:
√ accurate detection of crossing vessels (100% PPV) during late arterial phase
NUC: confirms obstruction at UPJ + determines function
OB-US:
√ progressive enlargement of renal pelvis + branching infundibula + calices
√ anteroposterior diameter of renal pelvis ≥ 10 mm
√ large unilocular fluid collection (severely dilated collecting system)
DDx: multicystic dysplastic kidney, perinephric urinoma
ADDITIONAL TESTS:
(1) Diuresis excretory urography (Whitfield): accurate in 85%
(2) Diuresis renography (^{131}Iodine-iodohippurate sodium / ^{99m}Tc-DTPA)
(3) Pressure flow urodynamic study (Whitaker test)
Rx: early surgical correction (ante- / retrograde endopyelotomy, open / laparoscopic dismembered pyeloplasty) to preserve renal function

Secondary UPJ Obstruction

Cause:
(1) Infection: eosinophilic ureteritis, XGP
(2) Stones
(3) Ischemia
(4) Iatrogenic injury
(5) Aortic aneurysm
(6) Renal cyst

URETHRAL CARCINOMA

Prevalence: < 1% of all urologic cancers
Age: 6th–7th decade; M÷F = 1÷4

Urethral Carcinoma of Male Urethra

Cause: chronic urethritis from venereal disease (25–44%) + urethral strictures (50–88%)
• palpable mass in perineum / along shaft of urethra
• periurethral abscess, obstructive voiding symptoms
• urethrocutaneous fistula, serosanguinous discharge
√ urethral stricture
Site: @ Prostatic urethra (10%):
TCC (90%) > squamous cell ca. (10%)
@ Bulbomembranous urethra (60%):
squamous cell ca. (80%) > TCC (10%) > adenocarcinoma + undifferentiated carcinoma (10%)
@ Penile urethra (30%):
squamous cell ca. (90%) > TCC (10%)

Histo:

1. Squamous cell carcinoma (70–80%)
2. Transitional cell carcinoma (16%) part of multifocal urothelial neoplasia; in 10% after cystectomy for bladder tumor
3. Adenocarcinoma (6%) in bulbous urethra originating in glands of Cowper / Littré
4. Malignant melanoma, leiomyosarcoma, rhabdomyosarcoma, fibrosarcoma (rare)
5. Metastases from bladder / prostatic carcinoma (rare)

Stage I: confined to subepithelial connective tissue
Stage II: invasion of corpus spongiosum / prostate / periurethral muscle
Stage III: invasion of corpus cavernosum + bladder neck beyond prostatic capsule
Stage IV: invasion of other organs
Spread: direct extension + regional lymph nodes (superficial + deep inguinal + external iliac nodes from anterior urethra; pelvic nodes from posterior urethra)
MR:
√ mass hypointense relative to normal corpora on T1WI + T2WI

Urethral Carcinoma of Female Urethra

Prevalence: < 0.02% of all malignancies in women
Cause: chronic irritation, urinary tract infection, proliferative lesions (caruncle, papilloma, adenoma, polyp, leukoplakia)
Risk factor: human papilloma virus infection, urethral diverticulum
Histo:

1. Squamous cell carcinoma (70%):
   Site: distal ²/₃ of urethra + meatus
   √ lobulated exophytic / deeply infiltrating lesion
   √ irregularly marginated hypo- / isoechoic mass
   √ T2-hypointense with heterogeneous enhancement
2. TCC (8–24%):
   Site: posterior ⅓ of urethra
   √ lobulated iso- to hypointense on T1WI + T2WI
   √ heterogeneous contrast enhancement
3. Adenocarcinoma (10–18–28%):
   Site: urethrovulvar junction from periurethral glands of Skene (40%), urethral diverticulum (60%)
   ◊ similarity to nephrogenic adenoma, immunostaining for PSA + prostate acid phosphatase
   √ exophytic diverticular tumor
   √ T2-hyperintense + peripheral rim of low SI
   √ variably heterogeneous contrast enhancement
4. Secondary tumor: contiguous extension from bladder, cervix, vagina, anus

Age: > 50 years
MR (best on SAG T2WI):
√ mass hypointense on T1WI + hyperintense on T2WI
@ Cancer of the anterior urethra (46%)
Site: distal ⅓ of urethra

- urethral bleeding, urinary frequency, dysuria
- palpable mass at urethral orifice

Spread: superficial + deep inguinal nodes

Rx: local surgical excision

@ Cancer of the entire urethra

Histo: SCC (60%), TCC (20%), adenocarcinoma (10%), undifferentiated ca. / sarcoma (8%), melanoma (2%)

- urinary retention, urethral abscess, urethrovaginal fistula

Spread: (a) local extension: into bladder neck, vagina, vulva
(b) lymphatic: external iliac, hypogastric, obturator nodes (for posterior urethra)

Rx: surgery, radiation, chemotherapy

Prognosis: poor (in 50% metastatic at presentation); survival rate of 50% for distal tumor, survival rate of 6% for proximal tumor

DDx: markedly inflamed diverticulum

URETHRAL DIVERTICULUM

= protrusion of urethra into periurethral fascia

Prevalence: 0.6–6% of women

Age: 26–74 years; 6 x more common in black women (?)

Histo: same as urethral mucosa

- asymptomatic (3–20%); fluid / pus may be expressed from urethra
- tender cystic swelling protruding from anterior wall of vagina
- classic "triad of Ds": **d**ysuria (45%), **d**yspareunia, postvoid **d**ribbling
- vague nonspecific urinary tract symptoms mimicking chronic / interstitial cystitis, periurethral cysts / fibrosis, urethrocele, carcinoma in situ of the bladder / urethra, detrusor instability:
  - urinary frequency / urgency (67%)
  - recurrent urinary tract infections (40%)
  - urinary incontinence (9–32–70%), urine retention, pelvic pain

Congenital Urethral Diverticulum

Cause: ectopic cloacal epithelium

M > F

Acquired Urethral Diverticulum

Prevalence: in 1.4% of women with stress incontinence; M < F

Cause:

(1) Obstruction of paraurethral glands (of Skene) → subsequent infection (E. coli, gonococci, chlamydia) of dilated periurethral gland → rupture into urethra

(2) Trauma: catheterization / childbirth / disruption of periurethral fascia during bladder neck suspension surgery

May be associated with: cloacal epithelium, wolffian / müllerian duct remnant

Site: posterolateral aspect of midurethra at level of pubic symphysis

Voiding cystourethrography (65% accurate):

√ rounded / elongated sac connected to urethra

US:

√ echogenic focus with distinct acoustic shadow ← stone

MR:

√ cystic T2-hyperintense lesion with various degrees of extensions around the circumference of urethra:

√ oval / U-shaped "saddlebag" / circumferential

√ single / multiple

√ unilocular / multiseptated

√ narrow / wide neck

√ heterogeneous hyperintense signal compared with urine on T1WI if content is proteinaceous / hemorrhagic

√ fluid-fluid level on T2WI if inflammation present

Cx: (1) Infection

(2) Stone formation (in up to 5–10%)

(3) Malignant degeneration to adenocarcinoma (60%) > TCC (30%) > squamous cell carcinoma (10%)

Rx: transvaginal / endoscopic diverticulectomy with resection of neck (to prevent recurrence)

DDx: (1) Vaginal cyst (Gartner duct cyst, paramesonephric cyst, müllerian duct cyst, epithelial inclusion cyst)

(2) Ectopic ureterocele

(3) Endometrioma

(4) Urethral tumor

URINOMA

= uriniferous perirenal pseudocyst ← tear in collecting system with continued renal function

Etiology:

A. NONOBSTRUCTIVE: blunt / penetrating trauma, surgery, infection, calculus erosion

B. OBSTRUCTIVE:

(1) Ureteral obstruction (calculus, surgical ligature, neoplasm)

(2) Bladder outlet obstruction (posterior urethral valves)

◊ Augmented by sudden diuretic load of urographic contrast material!

Path: fibroblastic cavity (in 5–12 days), dense connective tissue encapsulation (in 3–6 weeks)

- pain, malaise, nausea, fever
- hematuria (10–50%), fluctuant tender mass
- discharge from wound (in early postoperative period)

Location:

√ cystic mass in perirenal space = localized perirenal urinoma (most common)

√ cystic mass filling entire perirenal space = diffuse perirenal urinoma

√ sickle-shaped collection = subcapsular urinoma

√ encapsulated expanding intrarenal cystic mass separating renal tissue fragments = intrarenal urinoma

Plain radiography:
√ soft-tissue mass obliterating retroperitoneal structures
√ superior + lateral displacement of kidney
CT:
√ extravasation of contrast material
√ smooth thin-walled cavity (–10 to +30 HU)
√ frequently associated with urine ascites
√ rarely septated + smaller than lymphocele
NUC:
√ progressive radiotracer activity within collection
Cx: retroperitoneal fibrosis, stricture of upper ureter, perinephric abscess, rupture into peritoneal cavity
◊ Renal dysplasia of affected kidney in almost 100% when detected in utero!
Dx: aspirated fluid with high urea concentration
DDx: lymphocele, hematoma, abscess, renal cyst, pancreatic pseudocyst, ascites

UROLITHIASIS

= NEPHROLITHIASIS
◊ Most common cause of calcification within the kidney:
› 12% of population develop a renal stone by age 70;
◊ 2–3% of population experience an attack of acute renal colic during their lifetime
◊ Patients with acute flank pain have ureteral calculi in 67–95%
Annual incidence: 1–2÷1,000; 1,200,000 annually in USA
Age: 30–60 years; M÷F = 4÷1
Anderson-Carr-Randall theory of renal stone formation:
abnormally high calcium excretion exceeds lymphatic capacity, microaggregates of calcium (present in the normal kidney) occur in medulla → ⇑ in size → migrate toward caliceal epithelium and → rupture into calices to form calculi
(a) nucleation theory
= crystal / foreign body initiates formation in urine supersaturated with crystallizing salt
(b) stone matrix theory
= organic matrix of urinary proteins + serum serves as framework for deposition of crystals
(c) inhibitor theory
= little / no concentration of urinary stone inhibitors (citrate, pyrophosphate, glycosaminoglycan, nephrocalcin, Tamm-Horsfall protein) → crystal formation
Stone composition in order of frequency:
calcium oxalate mono- and dihydrate 40–60%
calcium phosphate 20–60%
struvite 5–15%
uric acid 5–10%
brushite 2–4%
cystine 1–3%
Cause:

genetics, diet, employment, geography, history of UTI

◊ 70–80% of patients with first-time stones have a specific metabolic disorder (idiopathic hypercalciuria, secondary hypercalciuria (sarcoidosis, hyperparathyroidism), hyperuricosuria (gout, Lesch-Nyhan syndrome, hyperoxaluria, cystinuria)

Radiographic Opacity and Frequency of Urolithiasis

Mineral Composition	*Description*	*Frequency*	*Opacity*	*NECT [HU]*	*Factors*
Calcium stones		70–80%	+++		
1. Calcium oxalate		20–30%	+++		underlying metabolic disorder; hard to fragment
(a) Calcium oxalate monohydrate (= whewellite)	√ small highly opaque			1700–2800	
(b) Calcium oxalate dihydrate (= wedellite)	√ ± spiculated / mamillated ("mulberry stone")				
(c) Calcium oxalate-phosphate (calcium oxalate plus apatite)		30–40%	+++		
2. Calcium hydrogen phosphate (= brushite)		2–4%	+++	1700–2800	hard to fragment
3. Calcium phosphate (= hydroxyapatite)	• rarely pure (= laminated), occasionally forms in infected alkaline urine	20–60%	+++	1200–1600	usually no metabolic abnormality
Cystine stone		1–3%		600–1100	renal tubular defect; hard to fragment
Struvite stones	√ mildly opaque	5–15%	++	600–900	renal infection
1. Magnesium ammonium phosphate (= struvite)	√ laminated ← urea-splitting organisms (usually Proteus)	1%	++		most common constituent of staghorn calculus
2. Struvite plus calcium phosphate	• associated with infection	15–20%	++		
Uric acid stone	√ radiolucent	5–10%	-	200–450	pH < 5.8
Xanthine stone	√ nonopaque	extremely rare	-	> 200	
Matrix stone (mucoprotein / mucopolysaccharide)	√ nonopaque	rare	-	15–200	pure matrix stones may not be visible

Interventional Procedures for Urolithiasis

Treatment	*Location & Size of Stone*	*Advantage*	*Disadvantage*
Shock wave lithotripsy (SWL)	kidney < 1 cm; ureter < 1 cm	least invasive, good success rate, under sedation / anesthetics	poor success for cystine stones / stones > 1000 HU
Ureteroscopy with semirigid lithotripsy	distal ureter < 1 cm; proximal ureter < 1 cm (in woman)	stones refractory to SWL, high stone-free rate (better than SWL)	invasive, general / spinal-epidural anesthesia
Ureteroscopy with flexible lithotripsy	proximal ureter stone < 1 cm kidney stone < 1.5 cm	stones refractory to SWL, high stone-free rate (better than SWL)	invasive, general / spinal-epidural anesthesia
Percutaneous nephrolithotomy (PCNL)	proximal ureter stone < 1.5 cm kidney stone < 1.5 cm staghorn calculus	highest stone-free rate for large kidney + upper ureter stones	most invasive, may require blood transfusion
Ureterolithotomy: open / laparoscopic	large stone in middle / distal ureter	most effective for large stones	rarely used
Pyelolithotomy: open / laparoscopic	large stone: unbranched in renal pelvis / in horseshoe kidney	most effective for very large stones	rarely used
Anatrophic nephrolithotomy	full staghorn calculus	alternative to multiple-track PCNL	rarely used

1. **Hypercalciuria**
   - with hypercalcemia (50%): primary hyperparathyroidism, milk-alkali syndrome, hypervitaminosis D, malignant neoplasm, Paget disease, prolonged immobilization, sarcoidosis, adrenal insufficiency, hyper- and hypothyroidism, renal transplantation
   - with normocalcemia (30–60%): obstruction, urinary tract infection, vesical diverticulum, horseshoe kidney, medullary sponge kidney, renal tubular acidosis, malignant neoplasm, Paget disease, Cushing syndrome, prolonged immobilization,

idiopathic hypercalciuria, acetazolamide therapy, sarcoidosis

(a) ABSORPTIVE HYPERCALCIURIA
= increased intestinal absorption of calcium
Cause: increase in 1,25-dihydroxy-vitamin D levels (50%)

(b) RENAL HYPERCALCIURIA
= abnormal renal calcium leak
Cause: diet high in sodium, urinary tract infection (33%)

(c) RESORPTIVE HYPERCALCIURIA
= increased bone demineralization ← subtle hyper-parathyroidism

(d) IDIOPATHIC
√ attenuation of calcium stones > 1,000 HU similar to bone cortex

2. **Hyperoxaluria**= OXALOSIS

◊ Hyperoxaluria has a stronger correlation to severity of stone disease than hypercalciuria!

Physiology:

◊ 85% of urinary oxalate is produced endogenously in liver!

◊ Oxalic acid is present in many foods but poorly absorbed in healthy individuals resulting in increase in urinary oxalate by only 2–3%!

1. **Primary hyperoxaluria** (more common)
= HEREDITARY HYPEROXALURIA
= rare autosomal recessive inherited enzyme deficiency of carboligase → diffuse oxalate deposition in kidneys, heart, blood vessels, lung, spleen, bone marrow

Type I = deficient ketoglutarate-glyoxylate carboxylase
• glycolic aciduria

Type II = D-glycerate dehydrogenase deficiency
• D-glyceric aciduria

Age: usually < 5 years
Prognosis: early death in childhood

2. **Secondary / enteric hyperoxaluria** (rare)
Cause: disturbance of bile acid metabolism after excess oxalate absorption from bowel after jejunoileal bypass, ileal resection, blind loop syndrome, Crohn disease; increased ingestion (green leafy vegetables), pyridoxine deficiency, ethylene glycol poisoning, methoxyflurane anesthesia

3. **Hyperuricosuria**

• uric acid lithiasis (15–20%); stones form in acid urine
• M > F; usually familial
• multiple small hard smooth yellow / red-brown radiolucent stones

(a) WITH HYPERURICEMIA:
gout (25–50%) ← excessive intake of meat, fish, poultry; myeloproliferative diseases; antimitotic drugs; chemo- / radiation therapy; uricosuric agents; Lesch-Nyhan syndrome

(b) WITH NORMOURICEMIA:
idiopathic; occurrence in concentrated acidic urine → becomes supersaturated with undissociated uric acid (hot climate, ileostomy)

√ bright well-defined stone of medium-high attenuation (> 150 HU [300–500 HU])

Rx: raising urinary pH (potassium citrate / sodium bicarbonate)

4. **Cystinuria** (stones form in acid urine)
   = autosomal recessive disorder with tubular inability to reabsorb cystine, ornithine, lysine, arginine
   Age of onset: after 10 years (usually young girls)
   • multiple soft / hard, pink / yellow radiopaque stones
   Rx: (1) Decreased intake of methionine
   (2) Alkalinization of urine
5. **Xanthinuria**
   = inherited autosomal recessive deficiency of xanthine oxidase ← failure of normal oxidation of purines
6. **Urinary tract infection**
   Cause: urea-splitting organisms (Proteus mirabilis, P. vulgaris, Haemophilus influenzae, S. aureus, Ureaplasma urealyticum) + alkaline environment (pH > 7.19)
   ◊ May lead to magnesium ammonium phosphate = struvite stones
   Predisposed: women (M÷F = 1÷2), neurogenic bladder, urinary diversion, indwelling catheter, lower-urinary-tract voiding dysfunction
   √ often branching into staghorn calculi
   √ most struvite stones are radiopaque, but poorly mineralized matrix stones are not
7. Any condition causing nephrocalcinosis
8. Idiopathic calcium urolithiasis
9. Indinavir (protease inhibitor for treatment of HIV type 1) → precipitation of drug crystals in renal tubule
   • rectangular brown puttylike nonradiopaque stones
   √ detectable sonographically / IVP / CECT

NECT:

All urinary tract calculi are of high attenuation measuring > 200 HU (except for indinavir calculi, which have soft-tissue attenuation) and may be obscured by contrast material!

Radiographic Shape of Kidney Stone

1. **Staghorn** calculus (resembling antlers of a stag):
   = branched calculus filling the entire bifid renal collecting system
   Cause: recurrent urinary tract infections from bacterial pathogens producing alkaline urine (the only stone more common in females)
   Composition: struvite (= mixture of calcium, magnesium, ammonium, phosphate) / cystine / uric acid
2. **Fragmented staghorn**
   = incomplete branched calculus
   Cause: infection complicated by obstruction
   (a) pyonephrosis
   (b) XGP
3. **Jack stone** (resembling a child's toy jack)
   = stone of spiked configuration
   Composition: calcium oxalate dihydrate

Location: urinary bladder > kidney

4. **Mulberry stone** = mamillated contour
   Composition: calcium oxalate dihydrate
5. **Hemp-seed calculi**
   = multiple small stones of similar size with lapidary appearance (like cut gems)
   [*lapis*, Latin = stone; *lapidarius* = stonecutter]
   Composition: calcium oxalate / calcium phosphate
   Location: caliceal diverticulum, cyst, hydronephrosis)
6. **Milk of calcium** (with urine-calcium level)
   Composition: calcium carbonate
   Location: any epithelium-lined structure directly communicating with the collecting system (caliceal diverticulum, hydrocalyx, renal cyst)

Nonradiopaque Stones

mnemonic: SMUX

Struvite (rarely of pure magnesium ammonium phosphate)
Matrix stone (mucoprotein, mucopolysaccharide)
Uric acid
Xanthine

Calculi often Associated with Infection

mnemonic: S and M

Struvite (magnesium ammonium phosphate ± calcium phosphate)
Matrix stone (mucoprotein, mucopolysaccharide)

Acute Obstruction by Ureteric Calculi

= URETEROLITHIASIS

- renal colic = acute severe spasmodic / steady continuous flank pain
- frequently radiating into pelvis / groin / scrotum / labia
- hematuria (85%): absent in completely obstructing stone

Site: at points of ureteral narrowing

(a) ureterovesical junction (UVJ)
(b) ureteropelvic junction (UPJ)
(c) iliac vessel crossing

Frequency of Stones	*Location*
37%	in proximal ureter
7%	in midureter
33%	in distal ureter
18%	at ureterovesical junction

Plain radiography = KUB (45% sensitive, 77% specific):

Useful: planning ESWL, monitoring stone fragments in 1–2-week intervals
Visualization:

◊ 90% of urinary calculi are radiopaque

Confounding factors: small size of calculus, overlying bowel gas / fecal matter, osseous structures (transverse process, sacrum), extrarenal calcifications (gallstone, calcific

pancreatitis, mesenteric lymph node, arterial calcification, phlebolith), obesity
◊ Stones may be present in 30% of the time when KUB is negative!
◊ 60% of calcifications along expected course of ureter on symptomatic side are ureteric stones!

IVP (64–97% sensitive, 92–94% specific, 31–48% FN):
◊ Most common cause of ureteral filling defects at IVP!
√ delayed opacification of collecting system: degree of obstruction displayed by time delay of appearance of contrast material (physiologic information)
√ persistent delayed nephrogram increasing in intensity with time
√ hydroureteronephrosis
√ column of contrast material proximal to obstructing stone
◊ Nonobstructing calculi may be difficult to detect

US (37% sensitive):
√ highly echogenic focus + acoustic shadow within dilated ureter
√ unilateral hydronephrosis (11–35% FN, up to 10% FP rate)
DDx: physiologic dilatation in pregnancy
√ RI (resistive index) > 0.70 in symptomatic kidney within 6 hours after acute obstruction (partial obstruction, antecedent IVP may alter RI)
N.B.: normal pregnancy does NOT alter RI
√ difference in RI between kidneys of ≥ 0.04
√ absent ureteral jet / continuous low-level flow on affected side (jet may be present with partially obstructing calculus)
N.B.: 15% falsely positive during pregnancy
√ direct visualization of prevesical calculus by transabdominal / transrectal / transvaginal US

NECT (95–98% sensitive, 96–100% specific, 97% accurate):
◊ Helical NECT is the most accurate technique and gold standard for detecting urinary tract calculi!
Advantages:
(a) visualization of all calculi (= stone burden)
(b) short exam time (3–5 minutes)
(c) avoidance of IV contrast
(d) detection of extraurinary causes of flank pain (in 16–45%)
(e) information about stone composition and fragility
√ calcified stone within ureter (PATHOGNOMONIC):
DDx: phlebolith → no continuity with the ureter
√ all stone compositions readily detectable (except unmineralized stone matrix + stones related to protease inhibitor indinavir [Crixivan®] for HIV treatment)
√ proximal ureteral dilatation + normal caliber distally
√ stone at ureterovesical junction
DDx: stone passed into bladder (stone falls anteriorly in prone position)
√ "**soft-tissue rim**" sign (50–77% sensitive, 92% specific):
= halo of soft-tissue attenuation around calcific focus ← thickening of ureteral wall surrounding impacted small ureteric calculus ← edema within 4–24 hours after

obstruction
√ visible in 90% of stones < 4 mm
√ not visible in 33% of stones > 5 mm ← thinning of ureteral wall by impaction of larger stones
DDx: gonadal vein phlebolith (in front of upper ureter, lateral to mid ureter); 2–8% of phleboliths have a "soft-tissue rim" sign
√ secondary signs of urinary tract obstruction (in 96%):
√ asymmetric stranding of perinephric fat (in 65%, 76% sensitive, 90% specific) with loss of well-defined fat-kidney interface due to
(a) fluid within bridging septa of perinephric fat ← increased lymphatic pressure
◊ A higher degree of perinephric edema means a higher degree of obstruction!
(b) focal nonlinear fluid collection of extravasated urine ← forniceal rupture
√ periureteral edema (in 31%)
√ hydronephrosis (in 69%, 83% sensitive, 94% specific) = rounded fluid-filled calices and infundibula partially obliterating the renal sinus fat; seen early
DDx: extrarenal pelvis, parapelvic cysts
√ hydroureter above stone (87% sensitive, 90% specific) continuous with renal pelvis
√ unilateral renal enlargement (71% sensitive, 89% specific)
√ thickening of lateroconal fascia
√ perinephric edema
√ unilateral absence of white pyramid (= loss of the occasional incidental finding of high-attenuation medullary pyramids in normal kidneys)
False negatives (2–7%):
(a) volume averaging (= stone small relative to collimation)
(b) patients treated with indinavir
Stone burden:
√ greatest dimension of stone in magnified bone window setting
√ stone volume for large / staghorn calculi → SWL failure likely with a stone of > 700 mm3
Stone fragility:
√ stone heterogeneity → susceptible to fragmentation
√ stone homogeneity → harder to fragment

MR:
◊ May be helpful when use of contrast media / radiation is undesirable (pregnancy, children)!
√ renal enlargement
√ perinephric fluid ← lymphatic congestion / forniceal rupture
√ periureteral edema associated with urinary obstruction
√ abrupt change in ureteral caliber
√ dilatation distal to sacral promontory ← suspect ureterovesical junction stone
√ dark signal void (low SI of filling defect) in ureter (DDx: flow artifact on T2 single-shot fast SE images)
◊ insensitive for most renal / ureteral stones of < 1 cm

Visualization of stones in the urinary tract is challenging with MRI, particularly for intrarenal stones and

those at the ureterovesical junction.

NUC (DTPA, MAG3):
√ initially diminished uptake during renal perfusion phase
√ prolonged nephrographic phase
√ delayed excretion into collecting system
√ delayed transit of radiotracer with accumulation in obstructed collecting system
√ no clearing effect of IV furosemide injection

Advantages: quantitative assessment of renal function

Cx: xanthogranulomatous pyelonephritis

Rx: (1) Medical expulsive therapy: α-blocker, calcium channel blocker, steroids, NSAID

(2) Hydration (during strenuous physical activity, at bedtime, within 3 hours after meal) maintaining urine output of 2–3 L/days

(3) Diet: restrict amounts of protein, sodium, calcium

(4) Drugs: thiazide diuretics (lowers urinary calcium), allopurinol (lowers urate + oxalate excretion)

(5) Extracorporeal shock wave lithotripsy (ESWL)

DDx: (1) Recent passage of stone

(2) **Phlebolith**

√ "**comet-tail**" sign = extension of curvilinear soft-tissue band from stone (in 65%)
√ comet nucleus ← calcified phlebolith
√ comet tail ← noncalcified gonadal vein
√ low-attenuation center (visible in 9%, detectable with profile analysis in 21%)

(3) Arterial calcification

(4) Calcified lymph node

(5) Surgical clip

Prognosis:

(1) Spontaneous passage of ureteral calculi (in 93%)

Stone size	*passes in*
< 4 mm	90%
≤ 5 mm	68%
4–6 mm	50%
5–10 mm	47%

◊ Stones > 6 mm rarely pass!

(2) Without treatment stone recurrence is 10% at 1 year, 33% at 5 years, 50% at 10 years, 75% by 20 years

UTRICLE CYST

= dilatation of prostatic utricle (sometimes believed to be a remnant of the müllerian duct)

Prevalence: 1–5% of general population

Age: 1st–2nd decade

• postvoid dribbling, suprapubic / rectal pain, hematuria

• obstructive / irritative urinary tract symptoms

Often associated with:

hypospadia, intersex disorders, incomplete testicular descent, ipsilateral renal agenesis

Location: arise in midline from verumontanum

◊ Free communication with urethra

√ usually 8–10-mm long pear-shaped cyst posterior to urethra

√ NO extension above base of prostate (DDx: müllerian duct cyst, usually larger with extension above base of prostate)

Dx: endoscopic catheterization with aspiration of white / brown fluid occasionally containing spermatozoa

Cx: recurrent epididymitis, hematospermia, carcinomatous metaplasia

VARICOCELE

= abnormal dilatation + tortuosity of plexus pampiniformis ← retrograde flow into internal spermatic vein

Components of pampiniform plexus:

(a) internal spermatic vein (ventral location) draining testis

(b) vein of vas deferens (mediodorsal) draining epididymis

(c) cremasteric vein (laterodorsal location) draining scrotal wall

US:

√ multiple hypoechoic serpiginous tubular structures, initially superior and lateral, later posterior and inferior to testis

√ containing low-level echoes if flow slow

Grading of Varicocele

Grade	*Relaxed State*	*During Valsalva*
Normal	2.2 mm	2.7 mm
Small varicocele	2.5–4.0 mm	↑ by 1.0 mm
Moderate varicocele	4.0–5.0 mm	↑ by 1.2–1.5 mm
Large varicocele	> 5.0 mm	↑ by > 1.5 mm

Idiopathic / Primary Varicocele

Cause: incompetent / absent valve at level of left renal vein / IVC on right side

Prevalence:

(a) clinical varicocele: in 8–15% of adult males, in 21–39% of infertile men

(b) subclinical varicocele: in 40–75% of infertile men

Theoretical causes for infertility:

(1) Increase in local temperature

(2) Reflux of toxic substances from adrenal gland (countercurrent exchange of norepinephrine from refluxing renal venous blood into testicular arterial blood at the level of the pampiniform plexus)

(3) Alteration in Leydig cell function

(4) Hypoxia of germinative tissue ← venous reflux resulting in venous hypertension + stasis

• scrotal pain, scrotal swelling with "bag of worms" quality
• abnormal spermatogram: impaired motility, immature sperm, oligospermia

Location: left side (78%), bilateral (16%), right side (6%)

Reasons for left-sided prevalence:

(a) left testicular vein longer
(b) left testicular vein enters left renal vein at right angle
(c) compression of left renal vein by left testicular artery in some men
(d) compression of left testicular vein by descending colon distended with feces

Bidirectional Doppler sonography (erect with quiet breathing):

(1) SHUNT TYPE (86%): insufficient distal valves allow spontaneous + continuous reflux from internal spermatic vein (retrograde flow) into cremasteric vein + vein of vas deferens (where flow is orthograde) via collaterals
• sperm quality diminished
• clinically plexus type (grade II + III) = medium-sized + large varicoceles
√ continuous reflux during Valsalva maneuver

(2) STOP TYPE / PRESSURE TYPE (14%): intact intrascrotal valves allow only brief period of reflux from spermatic vein into pampiniform plexus under Valsalva maneuver
• sperm quality normal
• clinically central type (grade 0 + I) = subclinical + small varicocele
√ short phase of initial retrograde flow

US (almost 100% sensitive + specific):
√ diameter of dominant vein in upright position at inguinal canal

Dx: documentation of venous reflux

Cx: testicular atrophy (volume measurement of testes!)

Rx: (1) Ivanissevitch procedure = surgery
(2) Transcatheter spermatic vein occlusion
◊ Treatment improves sperm quality in up to 53%

Secondary Varicocele

= compression of left renal vein by tumor, aberrant renal artery, obstructed renal vein, hydronephrosis, cirrhosis
• nondecompressible varicocele
◊ Check left renal vein!

VESICOURETERIC REFLUX

= abnormal valve mechanism at UVJ resulting in reflux, ureteral dilatation, clubbed calices, eventual renal scarring

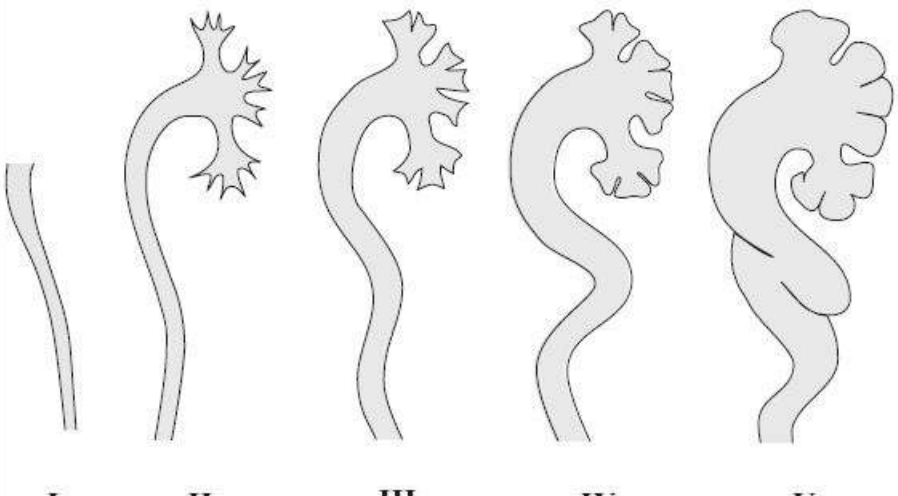
A. CONGENITAL REFLUX = PRIMARY REFLUX

= incompetence of ureterovesical junction ← abnormal tunneling of distal ureter through bladder wall

Prevalence: in 9–10% of normal Caucasian babies; in 1.4% of school girls; in 30% of children with a first episode of UTI

• short submucosal ureteral tunnel (normally has a length/width ratio of 4÷1)
• large laterally located ureteral orifice

Location: uni- / bilateral (frequently involves lower pole ureter in total ureteral duplication)



Grading of Vesicoureteral Reflux
(International Reflux System)

Grades of Vesicoureteral Reflux by VCUG

Grade I	√ reflux into ureter
Grade II	√ reflux into pelvicaliceal system (without caliceal dilatation / blunting)
Grade III	√ all of the above + mild dilatation of ureter and pelvicaliceal system √ distinct forniceal angles + papillary impressions
Grade IV	√ reflux into tortuous ureter + moderately dilated pelvicaliceal system √ blunted forniceal angles √ distinct papillary impressions
Grade V	√ reflux into markedly dilated and tortuous ureter + markedly dilated pelvicaliceal system √ obliteration of forniceal angles + papillary impressions

√ renal scars in 22–50%

Prognosis: disappears spontaneously in 80%

Cx: reflux atrophy / nephropathy in 22–50%; end-stage renal disease in 5–15% of adults

B. ACQUIRED REFLUX = SECONDARY REFLUX

1. Paraureteric diverticulum = Hutch diverticulum
2. Duplication with ureterocele

3. Cystitis (in 29–50%)
4. Urethral obstruction (urethral valves)
5. Neurogenic bladder
6. Absence of abdominal musculature (prune belly syndrome)

Cx: renal scarring with UTI (30–60%)

Estimated radiation dose to ovaries:

(a) usual fluoroscopy: 300 mrad
(c) tailored low-dose fluoroscopy: 3 mrad
(b) radionuclide cystography: 2 mrad

US (74% of kidneys with VUR may be normal by US):

√ intermittent hydroureteronephrosis = variable size of collecting system
√ redundant mucosa causing apparent thickening of renal pelvic wall
√ large thin-walled bladder
√ midline-to-orifice distance > 7–9 mm has high probability of vesicoureteric reflux

Prognosis:

All grades of reflux can be outgrown:

› 80% [46%] of grade I–II [III] outgrow reflux within 5 years
› 50% of grade IV continue to have reflux 9 years after initial diagnosis

Renal scarring: > 20% chance for grade III–V reflux; 2–3% chance for grade I–II reflux

Rx: (1) Grade IV–V require surgery to avoid renal scarring + renal impairment + hypertension (except in infants

(2) Periureteral diverticulum requires surgery (grade of reflux not prognostic)

◊ Grade I–III resolve with maturation of the UV junction

WILMS TUMOR

[Carl Max Wilhelm Wilms (1867–1918), pathologist and chair of surgery at the University of Heidelberg]

= NEPHROBLASTOMA

◊ Most common malignant abdominal neoplasm in children 1–8 years old (10%)!
◊ 3rd most common malignancy in childhood (after leukemia + brain tumors; neuroblastoma more common in infancy)!
◊ 3rd most common (87%) of all renal masses in childhood (after hydronephrosis + multicystic dysplastic kidney)!

Prevalence: 7–8÷1,000,000 children; 500 new cases annually in USA (2015, stable for years); familial in 1–2%

Peak age: 2–3 years (range, 3 months – 11 years); rare in neonates (0.16%) and during 1st year; 50% < 3 years; 80% < 5 years; 90% < 8 years; M÷F = 1÷1; more common in blacks

Histo: arises from undifferentiated metanephric blastema (= nephrogenic rests) with variable amounts of blastema, stroma, epithelium; occasionally mesodermal derivatives of striated / smooth muscle, fat, bone, cartilage = "teratoid Wilms tumor"

(a) unfavorable histologic character = presence of anaplasia in 6.2%: localized / diffuse
(b) favorable histologic character (90%)

◊ Multilocular cystic nephroma, mesoblastic nephroma, nephro-blastomatosis are related to the

more favorable types of Wilms tumor!

Genetics: multifactorial; abnormal WT1 gene on locus 11p13 with WAGR syndrome (**W**ilms tumor, **a**niridia, **g**enitourinary abnormalities, mental **r**etardation) or Drash syndrome; abnormal WT2 gene on locus 11p15 with Beckwith-Wiedemann syndrome or hemihypertrophy; familial Wilms tumor in 1%

Staging of Wilms Tumor (stage each kidney separately) *(National Wilms Tumor Study Group)*	
I	tumor limited to kidney (renal capsule intact)
II	extracapsular extension into perirenal tissue / renal vessels outside kidney / lymph nodes
III	not totally resectable (peritoneal implants, other than paraaortic nodes involved, invasion of vital structures)
IV	hematogenous metastases (lung in 85%, liver in 20%, bone in 0.8%, brain [rare]) / lymph node metastases outside abdomen or pelvis
V	bilateral renal involvement at diagnosis (4–13%)

Syndromic Wilms tumor (in 10–14%) associated with:

(1) Sporadic aniridia (= severe hypoplasia of iris)
- ◊ 33% of sporadic aniridia patients develop Wilms tumor!

(2) Beckwith-Wiedemann syndrome
- ◊ 10–20% of patients with Beckwith-Wiedemann syndrome develop Wilms tumor!

(3) **Hemihypertrophy**: total / segmental / crossed (2.5%)
- ◊ Ipsilateral or contralateral kidney affected
- ◊ Increased incidence of all embryonal tumors (adrenal cortical neoplasms, hepatoblastoma)

(4) Genitourinary disorders (4.4%):
- (a) **Drash syndrome**: male pseudohermaphroditism, progressive glomerulonephritis
- (b) Renal anomalies: horseshoe kidney, duplex / solitary / fused kidney
- (c) Genital anomalies: cryptorchidism (2.8%), hypospadia (1.8%), ambiguous genitalia

Screening recommendations (up to age 7 years):

CT at 6 months of age followed by US every 3 months

Staging:

› evaluate for
- invasion of adjacent organs
- involvement of regional lymph nodes
- involvement of the other kidney
- spread to the peritoneum
- metastatic disease

› screen contralateral kidney
› examine renal vein + IVC

√ signs of tumor rupture:
- √ poorly defined tumor margins
- √ perinephric fat stranding
- √ retroperitoneal fluid
- √ ipsilateral pleural effusion
- √ peritoneal fluid beyond cul-de-sac

- asymptomatic palpable abdominal mass (90%), often discovered by a parent
- hypertension (in up to 25%) ← renin production by tumor / vascular compression by tumor
- abdominal pain (25%), low-grade fever (15%)
- gross hematuria (7–15%) ← invasion of renal pelvis
- microscopic hematuria (15–25%)
- hemorrhage after minor trauma
- ascites ← venous obstruction; varicocele ← left-sided tumor

RULE OF 10's:
- › 10% unfavorable histology
- › 10% multifocal in one kidney
- › 10% bilateral
- › 10% vascular invasion
- › 10% calcifications
- › 10% pulmonary metastases at presentation

Location: usually solitary lesion; multifocal within one kidney (12%); syn- / metachronous bilateral tumors (7%) with nephrogenic rests in 94–99%

√ large tumor → average size of 12 cm in diameter

√ expansile intrarenal growth:
- √ sharply marginated with compression of renal tissue = pseudocapsule
- √ distorted "clobbered" / dilated calices
- √ displacement of major vessels, rather than encasement

√ curvilinear / phlebolithic calcifications in 5% on plain film, in 15% on CT (DDx: regular stippled calcifications in 85% of neuroblastomas)

√ tumor invasion of renal vein and IVC (4–10%); extension into right atrium (in 21% of cases with IVC invasion)

√ tumor may cross midline

√ poor / nonexcretion of IV contrast ← invasion or compression of hilar vessels + collecting system / extensive tumor infiltration of renal parenchyma

US:
- √ predominantly solid spherical mass:
  - √ heterogeneous echogenicity (frequent):
    - √ irregular anechoic areas ← cyst formation + central necrosis + hemorrhage
    - √ echogenic areas ← calcium (9%) / fat
  - √ fairly evenly echogenic (rare)

CT (preferred modality):
- √ large well-circumscribed heterogeneous partially cystic intrarenal mass ← old hemorrhage + necrosis (71%), cyst formation, fat, calcifications (15%)
- √ beak / claw of renal tissue extends partially around mass
- √ tumor less enhancing than renal parenchyma

CECT (ALARA dose → ONLY portal venous phase necessary):
- √ nodal / hepatic metastases
- √ tumor extension into renal vein / IVC
- √ contralateral synchronous tumor/ nephrogenic rests

MR:
- √ typically heterogeneous lobulated hypointense compared with normal renal parenchyma on T1WI
- √ foci of increased T1 signal intensity ← hemorrhage
- √ hyper- or isointense on T2WI

NUC:
- √ nonfunctioning kidney (10%)
- √ hypo- / iso- / hyperperfusion on radionuclide angiogram
- √ absent tracer accumulation on delayed static images
- √ displacement of kidney + distortion of collecting system

PET:
- √ FDG-avid primary + metastatic Wilms tumor
- √ may be useful to detect active / residual disease and identify nonresponders of neoadjuvant chemotherapy

Angio:
- √ hypervascular tumor: enlarged tortuous vessels, coarse neovascularity; small arterial aneurysms; vascular lakes
- √ parasitization of vascular supply

Spread with rupture through renal capsule:
- √ broad-based subdiaphragmatic masses on surface of liver and spleen
- √ omental caking

Cx: tumor rupture

Rx: presurgical chemotherapy + nephrectomy + adjuvant chemotherapy ± radiation therapy

Prognosis: survival rate ← depending on pathologic pattern, age at time of diagnosis, extent of disease; 4-year relapse-free survival: 91% for stage I; 88% for stage II; 79% for stage III; 78–84% for stage IV

DDx: Age is the most important consideration formulating a DDx

(1) Neuroblastoma (encasement / elevation of aorta, many regular stippled calcifications, displacement of kidney, tumor crossing midline behind aorta, extension through neural foramina into spinal canal, skeletal metastases)
(2) Congenital mesoblastic nephroma (in fetus / neonate)
(3) RCC (2nd decade of life, renal vein extension)
(4) Clear cell sarcoma (early skeletal metastases)
(5) Rhabdoid tumor (subcapsular hemorrhage, brain tumor in posterior fossa)
(6) Infection: acute bacterial nephritis, renal abscess

WOLMAN DISEASE

[Moshe Wolman (1914–?), chairman of pathology at University of Tel-Aviv, Israel]

= PRIMARY FAMILIAL XANTHOMATOSIS

= rare autosomal recessive lipidosis with accumulation of cholesterol esters and triglycerides in visceral foam cells + various tissues (liver, spleen, lymph nodes, adrenal cortex, small bowel)

Etiology: deficiency of lysosomal acid esterase / acid lipase

• malabsorption in neonatal period: failure to thrive, diarrhea, steatorrhea, vomiting

• delayed growth, diminished muscle mass, abdominal distension
√ hepatosplenomegaly
√ extensive bilateral punctate calcifications (calcification of fatty-acid soaps) throughout enlarged adrenals (maintaining their normal triangular shape) are DIAGNOSTIC
√ enlarged fat-containing lymph nodes
√ small bowel wall thickening ← infiltration of mucosa of small bowel by lipid-filled histiocytes impairing absorption
√ generalized osteoporosis

CT & MR: attenuation + signal intensities consistent with deposition of lipids

Dx: assay of leukocytes / cultured skin fibroblasts

Prognosis: death occurs within first 6 months of life

OBSTETRICS AND GYNECOLOGY

DIFFERENTIAL DIAGNOSIS OF OBSTETRIC AND GYNECOLOGIC DISORDERS

PELVIC PAIN

Chronic Pelvic Pain

= nonmenstrual pain of > 6 months duration

Prevalence: 15% in women between 18 and 50 years; 10–40% of all gynecologic outpatient visits; 35% of diagnostic laparoscopies; 15% of all hysterectomies

Age: typically < 35 years; Whites > Blacks

Pelvic Pain in Young Woman

A. Most common*
   1. Hemorrhagic ovarian cyst
   2. Pelvic inflammatory disease (PID)
   3. Ectopic pregnancy
B. Less frequent*
   1. Torsion of ovary
   2. Massive ovarian edema
   3. Endometriosis
   4. Degenerating fibroid
   5. Pelvic congestion syndrome
C. Post partum
   1. Endometritis
   2. Ovarian vein thrombosis

* β-hCG results influence options

Pelvic Pain in Nongynecological Condition

1. Appendicitis
2. Diverticulitis
3. Epiploic appendagitis
4. Crohn disease
5. Infectious ileocolitis
6. Colonic malignancy
7. Ureterolithiasis

Pelvic Pain in Pediatric Age Group

1. Ovarian torsion
   (a) of normal ovary

Cause: excessive mobility of ovary in childhood

(b) with ovarian mass:

› functional cyst (60%)

› neoplasm (40%):

» benign mature teratoma (66%)

» malignancy (33%): germ cell tumor (60–75%), epithelial tumor (10–20%), stromal tumor (10%)

2. Hemorrhagic ovarian cyst
3. Pelvic inflammatory disease
4. Ectopic pregnancy

Pelvic Pain in Pregnancy

Confounding factors:

1. Nonspecific leukocytosis
2. Displacement of structures from their normal locations by gravid uterus
3. Difficult abdominal examination
4. Nonspecific nausea and vomiting

A. PROBLEMS WITH THE PREGNANCY

1. Failed pregnancy
2. Ectopic pregnancy
3. Placental abruption
4. Placenta previa

B. PROBLEMS WITH PELVIC ORGANS

(a) Uterus

1. Degenerating fibroid ← altered blood supply with enlargement during pregnancy

(b) Ovary

1. Ruptured hemorrhagic corpus luteum cyst
2. Adnexal mass ← rupture / rapid enlargement
3. Ovarian torsion / edema

(c) General

1. Endometriosis
2. PID: pregnancy decreases risk of PID

C. NONOBSTETRICAL PROBLEMS

(a) GI tract

1. Acute appendicitis
2. Inflammatory bowel disease: peak age 15–25 years
3. Diverticulitis: no increase during pregnancy
4. Small bowel obstruction / ileus

(b) Hepatobiliary

1. Cholelithiasis / choledocholithiasis
2. Acute cholecystitis
3. Pancreatitis: mostly secondary to gallstones
4. HELLP syndrome
5. Acute fatty liver

(c) GU tract

1. Physiologic hydronephrosis
2. Obstructing ureteral stone

(d) Vascular

1. Venous thromboembolic disease
2. Ovarian vein enlargement / thrombosis

GENERAL OBSTETRICS

Parity Nomenclature (for pregnancies < 20 weeks)

example: G_5P_{4004}

Gravida 5 pregnancies

Parity

mnemonic: FPAL

Full term	4 full term
Preterm	0 preterm
Abortion	0 abortion
Living	4 living

Level I Obstetric Ultrasound

Indication: MS-AFP ≥ 2.5 multiples of mean (MoM) between 14 and 18 weeks MA

Limited scope of examination to identify frequent causes of MS-AFP elevation in 20–50% of pregnancies:

1. Gestational age ≥ 2 weeks more advanced than estimated clinically (18%)
2. Multiple gestations (10%)
3. Unsuspected fetal demise (5%)
4. Obvious fetal NTD / abdominal wall defect

Outcome: no cause identified in 50–80%

Recommendation if level I ultrasound is unrevealing:

(1) Amniocentesis for AF-AFP → normal results in > 90%

(2) Level II obstetric ultrasound (skipping amniocentesis)

Level II Obstetric Ultrasound

Indication: AF-AFP ≥ 2 MoM

Accuracy: identification of abnormal fetuses in 99%

Examination targeted for:

1. Open neural tube defect: anencephaly, encephalocele, open spina bifida, amniotic band syndrome resulting in open neural tube defect
2. Closed neural axis anomaly: hydrocephalus, Dandy-Walker malformation
3. Abdominal wall defect: gastroschisis, omphalocele, gastropleuroschisis from amniotic band syndrome
4. Upper GI obstruction: esophageal atresia ± tracheoesophageal fistula, duodenal obstruction
5. Cystic hygroma

6. Teratoma: sacrococcygeal, lingual, retropharyngeal
7. Renal anomalies: obstructive uropathy, renal agenesis, multicystic dysplastic kidney, congenital Finnish nephrosis

◊ Risk of fetal chromosomal anomaly is only 0.6–1.1% with normal level II sonogram!

MATERNAL SERUM SCREENING

Alpha-fetoprotein

= glycoprotein as major circulatory protein of early fetus

Origin: formed initially by yolk sac + fetal gut (4–8 weeks), later by fetal liver

Detectable in

(a) fetal serum
- concentration peaks at 14–15 weeks followed by progressive decline

(b) amniotic fluid (AF-AFP) is a result of
- › fetal urination
- › fetal gastrointestinal secretions
- › transudation across fetal membranes: amnion, placenta
- › transudation across immature fetal epithelium
- concentration peaks early in 2nd trimester followed by progressive decline

(c) maternal circulation (MS-AFP) ← leakage from amniotic fluid across placenta
- levels start to rise at 7th week, peak at 32nd week, and decline toward end of pregnancy

◊ Either high / low MS-AFP is associated with 34% of all major congenital defect

At the end of the 1st trimester AFP is present:

in fetal plasma in milligram quantities
in amniotic fluid in microgram quantities
in maternal serum in nanogram quantities

Reported in MoM = multiples of mean to standardize interpretation among laboratories

Elevated Alpha-fetoprotein

- screening at 16–18 weeks GA

◊ Values must be corrected for dates, maternal weight, race, presence of diabetes (diabetes has depressing effect on MS-AFP so that lower levels may be associated with NTDs)

Associated with:

A. LABORATORY ERROR

B. ERRONEOUS DATES (18%):
GA ≥ 2 weeks more advanced sonographically than by clinical estimate (AFP levels rise 15% per week during 16–18-week window)

C. MULTIPLE GESTATIONS (14%)

D. FETAL DEMISE (7%) / fetal distress / threatened abortion

E. FETAL ANOMALIES (61%)

1. Neural tube defects (51%):
anencephaly (30%), myelomeningocele (18%), encephalocele (3%), forebrain malformation
Prevalence: 1.6÷1,000 births in USA; 6÷1,000 births in Great Britain

◊ In 90% as 1st time event!

Risk of recurrence: 3% after one affected child; 6% after 2 affected children

2. Ventral wall defects (21%):
   gastroschisis, omphalocele (sensitivity of 50%)
3. Proximal fetal gut obstruction:
   esophageal / duodenal atresia
   → diminished AFP degradation in small bowel
4. Cystic hygroma, teratoma: pharyngeal, sacral
5. Amniotic band syndrome:
   asymmetric cephalocele, gastropleuroschisis
6. Renal abnormalities:
   multicystic dysplastic kidney, renal agenesis, pelviectasis, congenital Finnish nephrosis → typically ≥ 10 MoM + negative amniotic fluid acetylcholinesterase
7. Oligohydramnios

F. PLACENTAL LESION
   altering the placentomaternal barrier
   1. Chorioangioma
   2. Peri- and intraplacental hematoma
      → resulting in fetomaternal hemorrhage
   3. Placental lakes, infarct, intervillous thrombosis

G. LOW BIRTH WEIGHT

H. Normal pregnancy + MATERNAL DISORDER
   1. Hepatitis
   2. Hepatoma

I. Fetal-maternal blood mixing:
   collection of MS-AFP samples after amniocentesis

mnemonic: GEM MINER CO

Gastroschisis
Esophageal atresia
Multiple gestations
Mole
Incorrect menstrual dates
Neural tube defects
Error: laboratory
Renal disease in fetus: autosomal recessive polycystic kidney disease, renal dysplasia, obstructive uropathy, congenital Finnish nephrosis
Chorioangioma
Omphalocele

ELEVATED MATERNAL SERUM AFP (MS-AFP)

= defined as ≥ 2.5 MoM / equivalent to the 5th percentile: 4.5 MoM for multiple gestations

Power of detection at ≥ 2.5 MoM cutoff:
98% for gastroschisis
90% for anencephalic fetuses

75–80% for open spinal defects
70% for omphaloceles

Prevalence: 2–5% screen-positive rate (in 16% normal MS-AFP on retesting); 6–15% of fetuses have some type of major congenital defect; in 1.3÷1,000 tests fetal anomaly detected

◊ The higher the AFP elevation the higher the probability of fetal anomalies

◊ 20–38% of women with unexplained high MS-AFP (ie, in the absence of fetal abnormality) suffer adverse pregnancy outcomes (premature birth, preeclampsia, 2–4 x IUGR, 10 x perinatal mortality, 10 x placental abruption)!

ELEVATED AMNIOTIC FLUID AFP (AF-AFP)

= defined as ≥ 2 MoM (< 2 MoM has a 97% NPV)

Prevalence: < 10% of women with elevated MS-AFP and "unrevealing" level I US exam

• amniotic fluid also tested for karyotype + acetylcholinesterase (= neurotransmitter enzyme present when neural tissue is exposed)

◊ 66% of fetuses with ↑ maternal AF-AFP are normal!

◊ A targeted level II ultrasound exam will show fetal anomalies in 33%!

Low Alpha-fetoprotein

= MS-AFP ≤ 0.5 / AF-AFP ≤ 0.72 MoM

Prevalence: 3%

1. Autosomal trisomy syndromes: trisomy 21, 18, 13
   ◊ 20% of trisomy 21 fetuses are found in women with low MS-AFP after adjustment for age!
2. Absence of fetal tissues: eg, hydatidiform mole
3. Fetal demise
4. Misdated pregnancy
5. Normal pregnancy
6. Patient not pregnant

Use of Karyotyping

Frequency: 11–35% of fetuses with sonographically identified abnormalities have chromosomal abnormalities

A. FETAL ANOMALIES

1. CNS anomalies: holoprosencephaly (43–59%), Dandy-Walker malformation (29–50%), cerebellar hypoplasia, agenesis of corpus callosum, myelomeningocele (33–50%)
2. Cystic hygroma (72%): Turner syndrome
3. Omphalocele (30–40%)
4. Cardiac malformations
5. Nonimmune hydrops
6. Duodenal atresia
7. Severe early-onset IUGR: trisomy 18, 13, triploidy
8. Congenital diaphragmatic hernia

9. Bone-echodense bowel (20%): trisomy 21

B. MATERNAL RISK FACTORS
1. Advanced age
2. Low serum alpha-fetoprotein
3. Abnormal triple screen of maternal serum
4. History of previous chromosomally abnormal pregnancy (1% risk of recurrence)

Aneuploid Risk of Major Anomalies

Structural Defect	*Incidence*	*Aneuploidy*	
		Risk	*Most common*
Cystic hygroma	1:6,000	60-75%	45X, 21,18,13, XXY
Hydrops	1:4,000	30–80%	13,21,18,45X
Holoprosencephaly	1:16,000	40–60%	13,18,18p
Cardiac defects	1:125	5–30%	21,18,13,22
AV canal		40–70%	21
Omphalocele	1:5,800	30–40%	13,18
Duodenal atresia	1:10,000	20–30%	21
Diaphragmatic hernia	1:4,000	20–25%	13,18,21,45X
Bladder outlet obstruction	1:1,000	20–25%	13,18
Limb reduction	1:2,000	8%	18
Clubfoot	1:830	6%	18,13,4p-,18q-
Hydrocephalus	1:1,250	3–8%	13,18, triploidy
Facial cleft	1:700	1%	13,18,deletions
Prune belly	1:40,000	low	18,13,45X
Single umbilical artery	1:100	minimal	
Bowel obstruction	1:4,000	minimal	
Gastroschisis	1:12,000	minimal	

C. PLANNED INTENSE INTRAUTERINE MANAGEMENT

Fetal anomalies not associated with chromosomal anomalies:
1. Gastroschisis
2. Unilateral renal anomaly
3. Intestinal obstruction distal to duodenal bulb
4. Off-midline unilateral cleft lip
5. Fetal teratoma: sacrococcygeal / anterior cervical
6. Isolated single umbilical artery

AMNIOTIC FLUID VOLUME

Production:

(a) 1st trimester: dialysate of maternal + fetal serum across the noncornified fetal skin

(b) 2nd + 3rd trimester: fetal urine (600–800 cm^3/d near term), fetal lungs (600–800 cm^3/d near term), amniotic membrane

Absorption:

fetal swallowing + GI absorption, fetal lung absorption, clearance by placenta

Assessment of amniotic fluid volume by:

(1) Subjective assessment ("Gestalt" method):
quick + efficient, accounts for GA-related variations in fluid volume, considered the most accurate if performed by experienced operator, operator + interpreter must be identical, no documentation, variations on serial scans difficult to appreciate

(2) Depth of largest vertical pocket:
simple + quick (used in BPP), pockets > 2 cm may be found in crevices between fetal parts with moderately severe oligohydramnios, does not account for GA-related variations

(3) Four-quadrant Amniotic Fluid Index (AFI):
fairly quick, probably correlates better with fluid volume than any single measurement, may not accurately reflect overall fluid volume, may be affected by fetal movement during measurements

(4) Planimetric measurement of total intrauterine volume

(5) Dye / para-aminohippurate dilution technique:
800 cm^3 at 34 weeks, 500 cm^3 > 34 weeks

Polyhydramnios

= amniotic fluid volume > 1,500–2,000 cm^3 at term

Prevalence: 1.1–2–3.5%

√ fetus does not fill the AP diameter of uterus

√ single largest pocket devoid of fetal parts / cord > 8 cm in vertical direction

√ AFI ≥ 20–24 cm

Prognosis: 64% perinatal mortality with severe polyhydramnios

Etiology:

A. IDIOPATHIC (35%)

Associated with: macrosomia in 19–37%

Suggested cause:

(1) Increased renal vascular flow

(2) Bulk flow of water across surface of fetus + umbilical cord + placenta + membranes

B. MATERNAL CAUSES (36%)

1. Diabetes (25%)
2. Isoimmunization: Rh incompatibility (11%)]
3. Placental tumors: chorioangioma

C. FETAL ANOMALIES (20%)

(a) gastrointestinal anomalies (6–16%):
impairment of fetal swallowing (esophageal atresia in 3%); high intestinal atresias / obstruction of duodenum / proximal small bowel (1.2–1.8%), omphalocele, meconium peritonitis

(b) nonimmune hydrops (16%)

(c) neural tube defects (9–16%):
anencephaly, hydranencephaly, holoprosencephaly, myelomeningocele, ventriculomegaly, agenesis of corpus callosum, encephalocele, microcephaly

(d) chest anomalies (12%):

diaphragmatic hernia, cystic adenomatoid malformation, tracheal atresia, mediastinal teratoma, primary pulmonary hypoplasia, extralobar sequestration, congenital chylothorax

(e) skeletal dysplasias (11%):
dwarfism (thanatophoric dysplasia, achondroplasia), kyphoscoliosis, platyspondyly

(f) chromosomal abnormalities (9%):
trisomy 21, 18, 13

(g) cardiac anomalies (5%):
VSD, truncus arteriosus, ectopia cordis, septal rhabdomyoma, arrhythmia

(h) genitourinary malformations:
unilateral UPJ obstruction, unilateral multicystic dysplastic kidney, mesoblastic nephroma

Cause: ? hormonally mediated polyuria

(i) miscellaneous (8%):
cystic hygroma, facial tumors, cleft lip / palate, teratoma, amniotic band syndrome, congenital pancreatic cyst

◊ In polyhydramnios efforts to detect fetal anomalies should be directed at SGA fetuses!

mnemonic: TARDI
Twins
Anomalies, fetal
Rh incompatibility
Diabetes
Idiopathic

Oligohydramnios

= amniotic fluid volume < 500 cm^3 at term
√ single largest pocket devoid of fetal parts / cord ≤ 1–2 cm in vertical direction
√ AFI ≤ 5–7 cm

Etiology:

mnemonic: DRIPP
Demise of fetus / Drugs (Motrin® therapy for tocolysis of preterm labor)
Renal anomalies, bilateral (= inadequate urine production): renal agenesis / dysgenesis, infantile polycystic kidney disease, prune belly syndrome, posterior urethral valves, urethral atresia, cloacal anomalies

◊ 20-fold increase in incidence of fetal anomalies with oligohydramnios!

N.B.: bilateral renal obstruction, if combined with intestinal obstruction, may be associated with polyhydramnios

IUGR: ← reduced renal perfusion
Premature rupture of membranes (most common)
Postmaturity

Cx: pulmonary hypoplasia, cord compression
Prognosis: 77–100% perinatal mortality with 2nd trimester oligohydramnios

ABNORMAL FIRST TRIMESTER FINDINGS

Time of onset: prior to 8–10 weeks

First Trimester Bleeding

= VAGINAL BLEEDING IN FIRST TRIMESTER

Frequency: 15–25% of all pregnancies, of which 50% terminate in abortion

A. INTRAUTERINE CONCEPTUS IDENTIFIED
   1. Threatened abortion
   2. Embryonic demise
   3. Blighted ovum
   4. Gestational trophoblastic disease
   5. Implantation bleed: 3–4 weeks after last menstrual period
   6. Subchorionic hemorrhage
   7. Low-lying placenta previa
   8. Twin loss

B. NORMAL ENDOMETRIAL CAVITY
   (a) with β-hCG level > 1,800 mIU/mL
      1. Recent spontaneous abortion
      2. Ectopic pregnancy
   (b) with β-hCG level < 1,800 mIU/mL
      1. Very early IUP
      2. Ectopic pregnancy

C. SAC VULNERABILITY
   1. Leiomyoma
   2. Intrauterine contraceptive device

Hemoperitoneum during Pregnancy

= hemorrhage in cul-de-sac (= rectouterine pouch)

1. Hemorrhagic corpus luteum cyst
2. Placenta accreta
3. Spontaneous abortion
4. Ectopic pregnancy
5. HELLP syndrome
6. Uterine rupture

Poor Prognostic Indicators in Early Pregnancy
√ irregular contour / low-lying position of gestational sac
√ calcified yolk sac > 7 mm in diameter
√ empty enlarged / expanded amnion
√ amorphous shape of embryo
√ embryonic bradycardia of ≤ 85 bpm
√ hydropic embryo
√ large subchorionic hemorrhage encircling > ²/₃ of gestational sac circumference

US Findings Diagnostic of Pregnancy Failure
√ no heartbeat with CRL of ≥ 7 mm
√ no embryo with mean sac diameter of ≥ 25 mm
√ no heartbeat ≥ 2 weeks after appearance of gestational sac without yolk sac
√ no heartbeat ≥ 11 days after appearance of gestational sac with yolk sac

US Findings Suspicious of Pregnancy Failure
√ no heartbeat with CRL of < 7 mm
√ no embryo with mean sac diameter of 16–25 mm
√ no heartbeat 7–13 days after appearance of gestational sac without yolk sac
√ no heartbeat 7–10 days after appearance of gestational sac with yolk sac
√ no embryo ≥ 6 weeks after last menstrual period
√ no embryo with empty amnion
√ no embryo with yolk sac > 7 mm
√ small gestational sac relative to size of embryo with a < 5-mm difference between mean sac diameter and CRL

Abnormal Sonographic Findings in 1st Trimester

1. Embryonic demise = abortion (clinical term)
2. Nondevelopment = blighted ovum
3. Maldevelopment = hydatidiform mole

Empty Gestational Sac

1. Normal early IUP between 5 and 7 weeks MA
2. Blighted ovum

DDx: Pseudosac of ectopic pregnancy

Gestational Sac in Low Position

1. Abortion in progress
   √ no placental blood flow
2. Cervical ectopic pregnancy
3. Fundal fibroid compressing sac downward

Pregnancy of Unknown Location

= normal pelvic US = transient state of early pregnancy during which no definite IUP is visualized at US with normal adnexa

= positive β-hCG without IUP

mnemonic: HERE

HCG-producing tumor (rare)
Ectopic pregnancy: occult
Recent completed spontaneous abortion

Early intrauterine pregnancy

In a hemodynamically stable patient with a pregnancy of unknown location, it is less harmful to wait, follow the β-hCG levels, and repeat the US examination than to presumptively treat an ectopic pregnancy.

hCG-producing Tumor

1. Gestational trophoblastic disease: hydatidiform mole, gestational choriocarcinoma
2. Ovarian malignant germ cell tumor
3. Nontesticular teratoma
4. Nontrophoblastic tumor: hepatoma, neuroendocrine tumor, breast cancer, pancreatic cancer, cervical cancer, gastric cancer, malignant phyllodes tumor
5. Spurious laboratory finding

Thickened Central Cavity Complex

1. Intrauterine blood
2. Retained products of conception following an incomplete spontaneous abortion
3. Early intrauterine not yet visible pregnancy
4. Decidual reaction ← ectopic pregnancy

Uterus Large for Dates

1. Multiple gestation pregnancy
2. Inaccurate menstrual history
3. Fibroids
4. Polyhydramnios
5. Hydatidiform mole
6. Fetal macrosomia

Intrauterine Membrane in Pregnancy

A. MEMBRANE OF MATERNAL ORIGIN
   1. Uterine septum
      = incomplete resorption of sagittal septum between the fused two müllerian ducts
   2. Amniotic sheet / shelf
      = folding of amniochorionic membrane around uterine synechia
      √ synechia often thins during uterine stretching + disappears as pregnancy progresses
   3. Wisps of umbilical cord

B. MEMBRANE OF FETAL ORIGIN
   1. Intertwin membrane
      = apposing membrane of multiple pregnancy / residual sac of blighted twin pregnancy
   2. Amniotic band
      = rent within amnion
   3. Chorioamnionic separation
      = incomplete fusion / hemorrhagic separation of amnion (= inner membrane) and chorion (= outer membrane)
   4. Subchorionic hemorrhage = chorioamnionic elevation
      = separation of chorionic membrane from decidua

- implantation bleed of early pregnancy

C. FIBRIN STRAND

Cause: hemorrhage during transplacental amniocentesis

mnemonic: STABS

Separation (chorioamnionic)
Twins (intertwin membrane)
Abruption
Bands (amniotic band syndrome)
Synechia

Dilated Cervix

1. Inevitable abortion
2. Premature labor
   = spontaneous onset of palpable, regularly occurring uterine contractions between 20 and 37 weeks MA
3. Incompetent cervix

PLACENTA

Abnormal Placental Size

◊ Placental mass tends to reflect fetal mass!

A. ENLARGEMENT OF PLACENTA = **Placentomegaly**
   = > 5 cm thick in sections obtained at right angles to long axis of placenta
   (a) maternal disease
      1. Maternal diabetes ← villous edema
      2. Chronic intrauterine infections: eg, syphilis
      3. Maternal anemia: normal histology
      4. Alpha-thalassemia
   (b) fetal disease
      1. Hemolytic disease of the newborn ← villous edema + hyperplasia ← immunologic incompatibility including Rh sensitization
      2. Umbilical vein obstruction
      3. Fetal high-output failure:
         large chorioangioma, arteriovenous fistula
      4. Fetal malformation:
         Beckwith-Wiedemann syndrome, sacrococcygeal teratoma, chromosomal abnormality, fetal hydrops
      5. Twin-twin transfusion syndrome
   (c) fetomaternal hemorrhage
   (d) placental abnormalities
      1. Molar pregnancy
      2. Chorioangioma
      3. Intraplacental hemorrhage

   mnemonic: HAD IT
   Hydrops

Abruption
Diabetes mellitus
Infection
Triploidy

B. DECREASE IN PLACENTAL SIZE
   1. Preeclampsia: associated with placental infarcts in 33–60%
   2. IUGR
   3. Chromosomal abnormality
   4. Intrauterine infection

Vascular Spaces of the Placenta

1. "**Placental cysts**"
   = large fetal veins located between amnion + chorion anastomosing with umbilical vein
   √ sluggish blood flow (detectable by real-time observation)
2. **Basal veins**
   = decidual + uterine veins
   √ lacy appearing network of veins underneath placenta
   DDx: placental abruption
3. **Intraplacental venous lakes**
   √ intraplacental sonolucent spaces
   √ whirlpool motion pattern of flowing blood

Placental Causes of Antepartum Hemorrhage

= vaginal bleeding between 20 wks GA and delivery

1. Placenta previa
2. Placental abruption = placental hematoma
   › on fetal side
      (a) Subchorionic = preplacental hematoma
   › on maternal side
      (b) Retroplacental hematoma
      (c) Intraplacental hematoma

Macroscopic Lesion of the Placenta

1. **Intervillous thrombosis** (36%)
   = intraplacental areas of hemorrhage
   Etiology: breaks in villous capillaries with bleeding from fetal vessels
   √ irregular sonolucent intraplacental lesions (mm to cm range)
   √ blood flow may be observed within lesion
   Significance: fetal-maternal hemorrhage (Rh sensitization, elevated AFP levels)
2. **Perivillous fibrin deposition** (22%)
   = nonlaminated collection of fibrin deposition
   Etiology: thrombosis of intervillous space
   Significance: none
3. **Septal cyst** (19%)
   Etiology: obstruction of septal venous drainage by edematous villi

√ 5–10-mm cyst within septum
Significance: none

4. **Placental infarct** (25%)
   = coagulation necrosis of villi
   Etiology: disorder of maternal vessels, retroplacental hemorrhage
   √ not visualized unless hemorrhagic
   √ well-circumscribed mass with hyperechoic / mixed echo pattern
   Significance: dependent on extent + associated maternal condition
5. **Subchorionic fibrin deposition** (20%)
   = laminated collection of fibrin deposition
   Etiology: thrombosis of maternal blood in subchorionic space
   √ subchorionic sonolucent area
   Significance: none
6. **Massive subchorial thrombus**
   = BREUS MOLE = PREPLACENTAL HEMORRHAGE

Placental Tumor

A. TROPHOBLASTIC
   1. Complete hydatidiform mole
   2. Partial hydatidiform mole
   3. Invasive mole
   4. Choriocarcinoma
B. NONTROPHOBLASTIC
   1. Chorioangioma (in up to 1% of placentas)
   2. Teratoma (rare)
   3. Metastatic lesion (rare): melanoma, breast carcinoma, bronchial carcinoma

Unbalanced Intertwin Transfusion

= unbalanced intertwin transfusion through vascular anastomoses between 2 circulations of monochorionic twins

A. ACUTE = Twin-embolization syndrome
B. CHRONIC = Twin-twin transfusion syndrome
C. REVERSE = Acardiac twinning

UMBILICAL CORD

Abnormal Umbilical Cord Insertion

1. Marginal cord insertion
   = cord insertion < 1–2 cm from placental edge
   Frequency: 5–7% of pregnancies
2. Battledore placenta
   [battledore = flat wooden paddle in ancient form of badminton]
   = cord insertion on edge of placenta = extreme marginal
   • no clinical significance
3. Velamentous cord insertion

4. Vasa previa

Distortion Abnormality of Umbilical Cord

1. **Cord torsion**
   = excessive twisting of cord as rare form of cord constriction
   Timing: any time during pregnancy; more common during 2nd and 3rd trimester
   √ evaluation of pitch value of cord coiling
   √ abnormal S/D flow velocity ratio of umbilical artery
   Cx: critically reduced fetal blood flow and fetal hypoxia, oligohydramnios, IUGR, and fetal death
   Dx: difficult to diagnose prenatally; mostly detected during postnatal examination
2. **Cord entanglement**
   Cause: nearby umbilical cord insertions on single placenta in monoamniotic twin pregnancy
   √ branching pattern at level of entanglement
   √ end systolic notch on umbilical artery waveform ← vascular compression / narrowing
   Cx: vascular compromise in one / both fetuses → fetal demise
3. **Noncoiled "straight" cord**
   counterclockwise÷clockwise umbilical cords = 7÷1
   right-handed÷left-handed persons = 7÷1
   Prevalence: 3.7–5%
   √ absent vascular coiling for entire length of visible cord
   At risk for: intrauterine death (8%), stillbirth, fetal anomalies (24%), prematurity, intrapartum heart rate decelerations, fetal distress, meconium staining
4. Body cord
   = loop around fetal body / any fetal body part
5. Nuchal cord

Umbilical Cord Lesion

A. DEVELOPMENTAL CORD LESION
   1. **Umbilical hernia**
      = protrusion from anterior abdominal wall with normal insertion of umbilical vessels
      Predisposed:
      Blacks, low-birth-weight infants, trisomy 21, congenital hypothyroidism, Beckwith-Wiedemann syndrome, mucopolysaccharidoses
      Prognosis: spontaneous closure in first 3 years of life
   2. Umbilical cord cyst
B. ACQUIRED CORD LESION
   1. **False knot**
      (a) exaggerated looping of cord vessels → focal dilatation of cord
      (b) focal accumulation of Wharton jelly
      (c) varix of umbilical vessel
      • clinically insignificant
      √ knoblike protrusion / bulge of cord
   2. **True knot**

Prevalence: 1% of pregnancies
Cause: excessive fetal movements
Predisposed: long cord, polyhydramnios, small fetus, monoamniotic twins
√ "hanging noose" sign = segment of umbilical cord closely surrounded by another loop of cord
√ local distension / thrombosis of umbilical vein near cord knot resembling an umbilical cyst
√ tortuosity of cord at level of knot
Cx: vascular occlusion → fetal asphyxia → fetal demise
OB management: expectant (mostly loose knot with marginal impact on fetal well-being)

3. **Umbilical cord hematoma**
= rupture of the wall of the umbilical vein ← mechanical trauma (cordocentesis, torsion, loops, knots, traction) / congenital weakness of vessel wall
Prevalence: 0.02% of pregnancies
Location: near fetal insertion of umbilical cord (most common)
√ hyper- / hypoechoic mass 1–2 cm in size, multiple (in 18%)
Cx: rupture into amniotic cavity → exsanguination
Prognosis: 52% overall perinatal fetal mortality
4. Neoplasm
(a) **Angiomyxoma / hemangioma of cord**
Prevalence: 22 cases in literature
Histo: multiple vascular channels lined by benign endothelium surrounded by edema + myxomatous degeneration of Wharton jelly
Associated with: single umbilical artery
• increased maternal serum α-fetoprotein level
Location: more frequently near placental insertion of umbilical cord
√ hyperechoic / multicystic mass within cord
√ may be associated with pseudocyst (= localized collection of edema)
√ blood flow on Doppler
Cx: premature delivery, stillbirth, hydramnios, nonimmune hydrops, massive hemorrhage ← rupture
(b) Other tumors: myxosarcoma, dermoid, teratoma

Umbilical Cord Cyst

◊ Umbilical cord cysts persisting into 2nd + 3rd trimester are frequently accompanied by fetal anomalies: angiomyxoma of cord, hernia, intestinal obstruction, urinary tract obstruction, urachal anomalies, imperforate anus, TE fistula, omphalocele, cardiac defect, trisomy 18

Location: toward fetal insertion of cord

A. UMBILICAL CORD PSEUDOCYST (common)
= **Mucoid degeneration of umbilical cord**
= **Wharton jelly cyst**
Histo: localized edema + liquefaction of Wharton jelly without epithelial lining
Commonly associated with: omphalocele

√ focal thickening of Wharton jelly

Prognosis: usually resolved by 12 weeks MA

B. TRUE UMBILICAL CORD CYST (rare)

Prevalence: 3.4% of 1st trimester pregnancies; 20% persist into 2nd trimester

Histo: lined by single layer of flattened epithelium

Rarely associated with: fetal structural anomaly, aneuploidy

Size: 4–60 mm in diameter

1. **Omphalomesenteric duct cyst**
   Site: eccentric in cord
2. **Allantoic cyst**
   = remnant of umbilical vesicle / allantois; usually degenerates by 6 weeks
   Site: in center of cord
3. **Amniotic inclusion cyst**
   = amniotic epithelium trapped within umbilical cord

Vascular Abnormalities of Umbilical Cord

1. Single umbilical artery
2. **Persistent Right Umbilical Vein (PRUV)**
   = regression of left umbilical vein → abnormal course of blood flow in fetal liver
   Frequency: 0.1–0.3%
   Cause: altered development of umbilical cord during 4th –7th week GA
   May be associated with: situs inversus, heterotaxy, anomalies of GU / GI tract, heart, skeletal development
   Path of blood flow:
   (a) intrahepatic PRUV = isolated right umbilical vein joins fetal portal system at sinus venosus + gives rise to ductus venosus
   (b) extrahepatic PRUV = right umbilical vein bypasses liver and drains into RA / IVC / right iliac vein + absent ductus venosus
   √ fetal portal vein curves toward (rather than parallel to) stomach
   √ fetal gallbladder between umbilical vein and stomach + medial (rather than lateral) to umbilical vein
   √ umbilical vein connects to right (rather than left) portal vein
3. **Umbilical vein / Cord varix**
   Frequency: < 4% of all umbilical cord abnormalities
   May be associated with: aneuploidy (6%), other fetal anomalies (28%)
   Site: intraamniotic / intraabdominal, intrahepatic / extrahepatic
   Normal size of umbilical vein: 3 mm at 15 weeks GA, 8 mm at term
   √ fusiform dilatation of umbilical vein > 9 mm
   √ transverse diameter of extrahepatic umbilical vein > 1.5 x greater than intrahepatic component
   √ vein diameter > 2 SD above mean diameter for GA
   √ fetal hydrops, anemia, IUGR
   Cx: (1) Thrombosis with subsequent fetal death
   (2) Partial thrombosis with IUGR

◊ Serial US examinations are recommended from diagnosis to delivery!

Prognosis: usually no clinical significance

4. **Umbilical artery aneurysm** Often associated with single umbilical artery, aneuploidy, fetal structural abnormalities

SMALL-FOR-GESTATIONAL AGE FETUS (SGA)

= generic clinical term describing a group of perinates at / below 10th percentile for gestational age without reference to etiology

1. Fetus of appropriate growth (misdiagnosed as small)
2. Small normal fetus = constitutionally small fetus (80–85%)
   ◊ No indication for surveillance / intervention!
3. Small abnormal fetus = primary growth failure associated with karyotype anomaly / fetal infection (5–10%)
   ◊ Active intervention is of no benefit!
4. Dysmature fetus = IUGR = growth failure as a result of uteroplacental insufficiency (10–15%)
   ◊ Intensive management is likely of benefit!

FETAL OVERGROWTH DISORDER

1. Beckwith-Wiedemann syndrome
2. Simpson-Golabi-Behmenl syndrome
3. Perlman syndrome

FETAL SKELETAL DYSPLASIA

= DWARFISM

= heterogeneous group of bone growth disorders resulting in abnormal shape + size of the skeleton

◊ More than 200 skeletal dysplasias are known, but only a few are frequent:
- › thanatophoric dysplasia
- › osteogenesis imperfecta type II
- › achondrogenesis
- › heterozygous achondroplasia

Birth prevalence:

2.3÷10,000–7.6÷10,000 births for all skeletal dysplasias; 1.5÷10,000 births for lethal skeletal dysplasias

Prognosis: 51% mortality ← hypoplastic lungs: 23% stillbirths, 32% death in 1st week of life

Terminology:

Amelia	=	absence of limb
Hemimelia	=	absence of distal parts
Micromelia	=	shortening involves entire limb (eg, humerus, radius + ulna, hand)
Rhizomelia	=	shortening involves proximal segment (ie, humerus / femur) [*rhiza*, Greek = root of extremity = shoulder / hip]
Mesomelia	=	shortening involves intermediate segment (ie, radius + ulna / tibia +

fibula)
[*mesos*, Greek= middle]

Acromelia = shortening involves distal segment (eg, hand)

Meromelia = partial absence of a limb

Phocomelia = proximal reduction with distal parts attached to trunk

Preaxial polydactyly = extra digit on radial / tibial side

Postaxial polydactyly = extra digit on ulnar / fibular side

Classification:

(1) OSTEOCHONDRODYSPLASIA
= abnormalities of cartilage / bone growth and development
(a) identifiable at birth:
› usually lethal: achondrogenesis, fibrochondrogenesis, thanatophoric dysplasia, short rib syndrome
› usually nonlethal: chondrodysplasia punctata, camptomelic dysplasia, achondroplasia, diastrophic dysplasia, chondroectodermal dysplasia, Jeune syndrome, spondyloepiphyseal dysplasia congenita, mesomelic dysplasia, cleidocranial dysplasia, otopalatodigital syndrome
(b) identifiable in later life: hypochondroplasia, dyschondrosteosis, spondylometaphyseal dysplasia, acromicric dysplasia
(c) abnormal bone density: osteopetrosis, pyknodysostosis, Melnick-Needles syndrome

(2) DYSOSTOSIS
= malformation of individual bones singly / in combination
(a) with cranial + facial involvement: craniosynostosis, craniofacial dysostosis (Crouzon), acrocephalosyndactyly, acrocephalopolysyndactyly, branchial arch syndromes (Treacher-Collins, Franceschetti, acrofacial dysostosis, oculoauriculo-vertebral dysostosis, hemifacial microsomia, oculomandibulofacial syndrome)
(b) with predominant axial involvement: vertebral segmentation defects (Klippel-Feil), Sprengel anomaly, spondylocostal dysostosis, oculovertebral syndrome
(c) with predominant involvement of extremities: **acheiria** (= absence of hands), **apodia** (= absence of feet), polydactyly, syndactyly, camptodactyly, Rubinstein-Taybi syndrome, pancytopenia-dysmelia syndrome (Fanconi), Blackfan-Diamond anemia with thumb anomaly, thrombocytopenia-radial aplasia syndrome, cardiomelic syndromes (Holt-Oram), focal femoral deficiency, multiple synostoses

(3) IDIOPATHIC OSTEOLYSIS
= disorders with multifocal resorption of bone

(4) CHROMOSOMAL ABERRATION

(5) PRIMARY METABOLIC DISORDER
(a) calcium / phosphorus: hypophosphatasia
(b) complex carbohydrates: mucopolysaccharidosis

Assessment of:

1. **Long bones** for absence, hypoplasia, malformation, curvature, degree of mineralization, fractures, premature ossification centers

- √ shortening of long bones (common characteristic)
  - ◊ Femur length > 5 mm below 2 standard deviations suggests skeletal dysplasia!
  - √ FL÷foot length < 0.9 = suggests skeletal dysplasia
- √ limb shortening of 40–60% of the mean in thanatophoric dysplasia + OI type II
- √ limb shortening of > 30% of the mean in achondrogenesis

2. **Thorax** for shape, abnormal rib size, absence / hypoplasia of clavicles, presence of scapula
   - √ Chest Circumference < 5th percentile (= lung hypoplasia)
   - √ Chest Circumference÷AC < 5th percentile
   - √ heart area÷chest area < 5th percentile
   - √ FL÷AC < 0.16 = suggests lung hypoplasia
2. **Hand & foot** for clinodactyly, syndactyly, pre- or postaxial polydactyly
   - √ "hitchhiker's thumb", radial ray anomaly, absence of thumb
   - √ "rocker-bottom" foot, clubbed foot
4. **Skull** for size, shape (brachycephaly, scaphocephaly, craniosynostosis, frontal bossing, cloverleaf skull), degree of mineralization
   - √ HC and BPD
   - √ binocular and interocular diameter
   - √ micrognathia, short upper lip, abnormally shaped ears
4. **Spine** for relative total length, scoliosis, mineralization of vertebral bodies, integrity of neural arches, vertebral height, absence of segments
5. **Pelvis** for shape

Associated with: polyhydramnios

DDx features: mineralization, bowing, fractures, number of digits, fetal movement, thoracic measurement, associated anomalies, age of onset

DDx: constitutionally short limbs, severe IUGR

Micromelic Dwarfism

= disproportionate shortening of entire leg

A. Mild micromelic dwarfism
   1. Jeune syndrome
   2. Chondroectodermal dysplasia
   3. Diastrophic dwarfism

B. Mild bowed micromelic dwarfism
   1. Camptomelic dysplasia
   2. Osteogenesis imperfecta, type III

C. Severe micromelic dwarfism
   1. Thanatophoric dysplasia
   2. Osteogenesis imperfecta, type II
   3. Homozygous achondroplasia
   4. Hypophosphatasia
   5. Short-rib polydactyly syndrome
   6. Fibrochondrogenesis

Acromelic Dwarfism

Asphyxiating thoracic dysplasia

Rhizomelic Dwarfism

mnemonic: MA CAT

Metatrophic dwarfism
Achondrogenesis (most severe shortening)
Chondrodysplasia punctata: autosomal recessive
Achondroplasia, heterozygous
Thanatophoric dysplasia

Osteochondrodysplasia

A. Failure of
   (a) articular cartilage: spondyloepiphyseal dysplasia
   (b) ossification center: multiple epiphyseal dysplasia
   (c) proliferating cartilage: achondroplasia
   (d) spongiosa formation: hypophosphatasia
   (e) spongiosa absorption: osteopetrosis
   (f) periosteal bone: osteogenesis imperfecta
   (g) endosteal bone: idiopathic osteoporosis
B. Excess of
   (a) articular cartilage: dysplasia epiphysealis hemimelica
   (b) hypertrophic cartilage: enchondromatosis
   (c) spongiosa: multiple exostosis
   (d) periosteal bone: progressive diaphyseal dysplasia
   (e) endosteal bone: hyperphosphatemia

Lethal Bone Dysplasia

in order of frequency:

1. Thanatophoric dysplasia
2. Osteogenesis imperfecta type II
3. Achondrogenesis type I + II
4. Jeune syndrome (may be nonlethal)
5. Hypophosphatasia, congenital lethal form
6. Chondroectodermal dysplasia (usually nonlethal)
7. Chondrodysplasia punctata, rhizomelic type
8. Camptomelic dysplasia
9. Short-rib polydactyly syndrome
10. Homozygous achondroplasia

◊ Lethal short-limbed dysplasias typically are manifest on sonograms < 24 weeks MA!

Nonlethal Dwarfism

1. Achondroplasia (heterozygous)
2. Asphyxiating thoracic dysplasia
3. Chondroectodermal dysplasia
4. Chondrodysplasia punctata

5. Spondyloepiphyseal dysplasia (congenital)
6. Diastrophic dysplasia
7. Metatrophic dwarfism
8. Hypochondroplasia

Late-onset Dwarfism

1. Spondyloepiphyseal dysplasia tarda
2. Multiple epiphyseal dysplasia
3. Pseudoachondroplasia
4. Metaphyseal chondrodysplasia
5. Dyschondrosteosis
6. Cleidocranial dysostosis
7. Progressive diaphyseal dysplasia

Hypomineralization in Fetus

A. DIFFUSE
    1. Osteogenesis imperfecta
    2. Hypophosphatasia
B. SPINE
    1. Achondrogenesis

Large Head in Fetus

1. Achondroplasia
2. Thanatophoric dysplasia

Narrow Hypoplastic Chest in Fetus

1. Short-rib polydactyly syndrome
2. Asphyxiating thoracic dysplasia
3. Chondroectodermal dysplasia
4. Camptomelic dysplasia
5. Thanatophoric dysplasia
6. Homozygous achondroplasia
7. Achondrogenesis
8. Hypophosphatasia
9. Osteogenesis imperfecta

Platyspondyly

1. Thanatophoric dysplasia
2. Osteogenesis imperfecta type II
3. Achondroplasia
4. Morquio syndrome

Bowed Long Bones in Fetus

1. Camptomelic syndrome
2. Osteogenesis imperfecta
3. Thanatophoric dysplasia

4. Hypophosphatasia

Bone Fractures in Fetus

1. Osteogenesis imperfecta
2. Hypophosphatasia
3. Achondrogenesis

Acrocephalosyndactyly

= syndrome characterized by
(1) increased height of skull vault ← generalized craniosynostosis (= acrocephaly, oxycephaly)
(2) syndactyly of fingers / toes

Type 1: Apert syndrome
Type 2: Crouzon syndrome
Type 3: Saethre-Chotzen syndrome
Type 4: Wardenburg type
Type 5: Pfeiffer syndrome

Acrocephalopolysyndactyly

Type 1: Noack syndrome
Type 2: Carpenter syndrome
Type 3: Sakati-Nyhan-Tisdale syndrome
Type 4: Goodman syndrome
Type 5: Pfeiffer syndrome

LIMB REDUCTION ANOMALIES

Prevalence: 0.49 ÷10,000 births

Isolated Extremity Amputation

1. Amniotic band syndrome
2. Exposure to teratogen
3. Vascular accident

Aplasia / Hypoplasia of Radius

mnemonic: **T**he **F**urry **C**at **H**it **M**y **D**og

Thrombocytopenia–absent radius syndrome
Fanconi anemia
Cornelia de Lange syndrome
Holt-Oram syndrome
Myositis ossificans progressiva (thumb only)
Diastrophic dwarfism ("hitchhiker's thumb")

Pubic Bone Maldevelopment

mnemonic: CHIEF

Cleidocranial dysostosis
Hypospadia, epispadia

Idiopathic
Exstrophy of bladder
F for syringomyelia

Fetal Hand Anomalies

Best time for assessment:
late 1st to middle 2nd trimester ← ossification of metacarpals beginning at 12 weeks EGA + frequent fetal movement

◊ Complete fetal work-up needed for associated anomalies!

Normal findings:
› unossified hypoechogenic carpus
› 5 hyperechoic + cylindric metacarpal bones
› 5 independent digits of different lengths with 3 ossified phalanges (2 for thumb)
› normal radius, ulna, humerus
› flexion (fist) + extension (unclenched hand)

Classification:
(a) abnormal alignment: clenched hand, camptodactyly, clinodactyly, akinesia deformation sequence, clubhand, phocomelia
(b) thumb anomalies: macrodactyly, trident hand
(c) abnormal number: polydactyly, syndactyly, ectrodactyly

Camptodactyly

= flexion contracture of PIP joint of any finger
Cause: karyotype anomaly (trisomy 18, 13, 15) or contracture syndrome; may be isolated
Location: often asymmetric
Prognosis: may progress during infancy / childhood

Clenched Hand

= index finger overlaps clenched fist formed by other digits
Cause: trisomy 18, akinesia-hypokinesia syndromes, temporarily closed normal fist
√ proximal interphalangeal articulation of index finger flexed + ulnarly deviated
√ adducted thumb

Clinodactyly

= fixed abnormal deviation of 5th finger in radioulnar plane (= radial angulation of DIP joint) ← abnormally small size of middle phalanx
Cause: trisomy 21 (in up to 60%), triploidy; isolated familial clinodactyly; normal in 18%

Clubhand

= permanently deviated axis of wrist + usually closed hand
Classification:
(a) Radial clubhand associated with preaxial deficits (ranging from mild hypoplasia of thumb to complete absence of radius)
(b) Ulnar clubhand ← ulnar deficiency

Ectrodactyly

= SPLIT / CLEFT HAND = LOBSTER CLAW HAND

= longitudinal deficiency of central digits

Cause: EEC (ectrodactyly, ectodermal dysplasia, cleft lip or palate), Roberts syndrome

Pathogenesis: failure of median apical ectodermal ridge in developing limb bud

May be associated with: syndactyly, aplasia, hypoplasia of residual phalanges + metacarpals

√ deep V- or U-shaped central defect

DDx: oligodactyly (= reduced number of well-formed fingers), constrictive amniotic bands

Macrodactyly

= overgrowth of all structures of affected (commonly radial) fingers

Cause: proteus syndrome, neurofibromatosis type 1

Phocomelia

= missing / foreshortened arm / forearm with presence of hand

Cause:

(1) Thalidomide
(2) Roberts syndrome = autosomal recessive disorder associated with tetraphocomelia with more severe upper-limb deformities, facial cleft, polyhydramnios
(3) TAR syndrome
(4) Grebe syndrome = autosomal recessive disorder associated with marked hypomelia (more severe in lower limbs increasing in severity distally)

Polydactyly

= presence of supernumerary digits

Incidence: 1÷683 pregnancies;

◊ Most common hand anomaly!

Cause: trisomy 13, short-rib-polydactyly syndrome, asphyxiating thoracic dystrophy (Jeune syndrome), Smith-Lemli-Opitz syndrome

ULNAR / POSTAXIAL POLYDACTYLY (more frequent)

affecting 5th finger

Cause:

(1) Trisomy 13
(2) Meckel-Gruber syndrome
(3) Short-rib polydactyly syndrome
(4) Ellis-van Creveld syndrome
(5) **Smith-Lemli-Opitz syndrome** (= intrauterine growth retardation + characteristic high level of 7-dehydrocholesterol)
(6) **Hydrolethalus syndrome** (= heart and brain defects, cleft lip / palate, abnormally shaped nose / jaw, incomplete lung development causing stillbirth / death within a few days after birth)
(7) **Bardet-Biedl syndrome** = medullary cystic kidney disease without encephalocele, progressive renal dystrophy, obesity, hypogonadism, learning

difficulties

RADIAL / PREAXIAL POLYDACTYLY (less frequent)

affecting thumb

Cause:

(1) Holt-Oram syndrome
(2) Short-rib–polydactyly syndrome
(3) Carpenter syndrome
(4) Trisomy 21
(5) VACTERL association
(6) Fanconi anemia
(7) Orodigitofacial syndrome

POLYSYNDACTYLY

= association of polydactyly with syndactyly

Syndactyly

= abnormal connection between adjacent digits

Incidence: 2–3÷10,000 live births

Location: commonly between 2nd + 3rd digit

Classification: simple (between soft tissues), complex (between bones), complete (entire length of finger), incomplete (sparing of distal part)

Cause: Poland sequence, Apert syndrome and other acrocephalosyndactylies, triploidy, Roberts syndrome, familial syndactyly (autosomal dominant, with variable expressivity and incomplete penetrance), constriction band sequence

Trident Hand

= same length of last 4 fingers

Cause: various chondrodysplasias

Overlapping Digit

trisomy 18

Hitchhiker's Thumb

diastrophic dysplasia

Flexion Contractures

trisomy 13 + 18, fetal akinesia deformation sequence

Limb Reduction

congenital varicella, hypoglossia-hyperdactyly syndrome

Amputation

amniotic band syndrome

Drug-induced Musculoskeletal Embryopathy

Thalidomide

= sedative-hypnotic nonbarbiturate (sold 1954–1961)
Critical period: 34–50 days after most recent menstrual period
• increased miscarriage, increased stillbirth rate
• 40% increased infant mortality
√ narrowing, disorganization, destruction of joints
√ hemimelia = absence / gross shortening of distal portion of one / more limbs (esp. radius + thumb)
√ phocomelia = attachment of hands + feet to abbreviated arms and legs
√ amelia = congenital absence of one / more arms / legs
√ fusion / absence of paired bones

Anticonvulsant Drugs
Prevalence: 0.4% of pregnancies
Drugs: valproic acid, carbamazepine, phenytoin, phenobarbital
√ diminished bone mineral density
√ poorly developed diaphyses of long bones
√ anomalies of phalanges:
  √ hypoplastic terminal phalanges associated with dysplastic nails
  √ hyperphalangism
√ congenital heart disease, cleft lip + palate, urinary tract anomalies, syndromes of dysmorphism, mental retardation

Folic Acid Antagonists
Drugs: aminopterin, methotrexate
Critical period: 6–8 weeks after conception
√ growth retardation
√ osteoporosis
√ talipes equinovarus, foreshortened extremities, absent digits, syndactyly, anomalous ribs
√ CNS anomalies, cardiac abnormalities

Vitamin A and Retinoids
• anomalies of external ear, facial dysmorphism
√ CNS, craniofacial, cardiovascular, thymic malformations
√ hydrocephalus, microcephalus

Warfarin
Critical period: 6–9 weeks GA
Frequency: 10%
√ stippled ossification centers in vertebrae, proximal femora, tarsal + carpal bones

FETAL CNS ANOMALIES
Prevalence: 2÷1,000 births in USA; 90% as 1st time occurrence
Recurrence: 2–3% after 1st, 6% after 2nd occurrence
√ ventricular atrium + cisterna magna are two sensitive anatomic markers for normal brain development!
A. HYDROCEPHALUS

1. Aqueductal stenosis
2. Communicating hydrocephalus
3. Dandy-Walker malformation
4. Choroid plexus papilloma

B. NEURAL TUBE DEFECT

Prevalence: 1÷500–600 live births

Risk of recurrence: 3–4%

1. Spina bifida
2. Anencephaly
3. Acrania
4. Encephalocele (8–15%)
5. Porencephaly
6. Hydranencephaly
7. Holoprosencephaly
8. Iniencephaly
9. Microcephaly
10. Agenesis of corpus callosum
11. Lissencephaly
12. Arachnoid cyst
13. Choroid plexus cyst
14. Vein of Galen aneurysm
15. Schizencephaly

Associated with: trisomy 13 and 18

Increased risk: low parity, low socioeconomic status, relative infertility, diabetes, obesity, anticonvulsants, folate deficiency

C. INTRACRANIAL NEOPLASM

1. Teratoma (> 50%): benign / malignant

   Location: originate from base of skull
2. Glioblastoma
3. Astrocytoma

Fetal Ventriculomegaly

Cause:

A. MORPHOLOGIC ANOMALY (70–80%):
   1. Spina bifida (30–65%)
   2. Dandy-Walker malformation
   3. Encephalocele
   4. Holoprosencephaly
   5. Agenesis of corpus callosum

B. ABNORMAL KARYOTYPE (10–20%)

C. VIRAL INFECTION

◊ 20–40% of concurrent anomalies are missed by ultrasound!

√ "dangling" choroid plexus

√ width of ventricular atrium > 10 mm

Prognosis: 21% survival rate; 50% with intellectual impairment

Isolated Mild Ventriculomegaly

= atrial width of 10–15 mm

Prevalence: 1÷700 in low-risk population

◊ Most common brain anomaly on prenatal sonograms

Associated structural anomalies (9%):

periventricular leukomalacia, subependymal / germinal matrix hemorrhage, partial agenesis of corpus callosum, heterotopia, parenchymal dysplasia

Associated chromosomal anomalies: in 4%

Recommendation: MR to diagnose associated structural anomalies

Prognosis: 80% with isolated mild ventriculomegaly have normal motor + intellectual function at ≥ 12 months of age

Lemon Sign

= flat / inwardly scalloped contour of both frontal bones

1. **Spina bifida**
   Prevalence for fetuses ≤ 24 weeks: 98%
   (90–93% sensitive, 98–99% specific, 84% PPV for high-risk population, 6% PPV for low-risk population)
   Prevalence for fetuses > 24 weeks: 13%
   (disappears in 3rd trimester)
2. Encephalocele
3. Agenesis of corpus callosum
4. Thanatophoric dysplasia
5. Cystic hygroma
6. Congenital diaphragmatic hernia
7. Fetal hydronephrosis
8. Umbilical vein varix
9. Normal fetus (in 0.7–1.3%)

Prenatal Intracranial Calcifications

1. Toxoplasmosis
2. CMV infection
3. Tuberous sclerosis
4. Sturge-Weber syndrome
5. Venous sinus thrombosis
6. Teratoma

Cystic Intracranial Lesion

mnemonic: CHAP VAN

Choroid plexus cyst
Hydrocephalus, **H**oloprosencephaly, **H**ydranencephaly
Agenesis of corpus callosum + cystic dilatation of 3rd ventricle
Porencephaly (= schizencephaly)
Vein of Galen aneurysm
Arachnoid cyst

Neoplasm: cystic teratoma

Abnormal Cisterna Magna

Normal size between 15 and 25 weeks MA:
> 2 to < 10 mm (usually 4–9 mm) in 94–97% of fetuses

A. SMALL CISTERNA MAGNA + "banana" sign
   1. Chiari II malformation (with myelomeningocele)
   2. Occipital cephalocele
   3. Severe hydrocephalus

B. LARGE CISTERNA MAGNA
   1. Megacisterna magna
      √ cerebellum + vermis remain intact
   2. Arachnoid cyst
      √ en bloc displacement of cerebellum + vermis
   3. Cerebellar hypoplasia
   4. Dandy-Walker syndrome (with vermian agenesis)

FETAL ORBITAL ANOMALIES

Hypotelorism

1. Holoprosencephaly
2. Chromosomal abnormalities: trisomy 13
3. Microcephaly, trigonocephaly
4. Maternal phenylketonuria
5. Meckel-Gruber syndrome
6. Myotonic dystrophy
7. Williams syndrome
8. Oculodental dysplasia

Hypertelorism

1. Median cleft syndrome: cleft lip / palate
2. Craniosynostosis: Apert / Crouzon syndrome
3. Pena-Shokeir syndrome
4. Frontal / ethmoidal, sphenoidal encephalocele
5. Dilantin / phenytoin effect

Orbital and Periorbital Masses

1. Dacryocystocele
2. Anterior encephalocele
3. Glioma
4. Hemangioma
5. Teratoma

FETAL NECK ANOMALIES

1. Cervical myelomeningocele

2. Occipital cephalocele
3. Cystic hygroma / lymphangioma
4. Teratoma
5. Branchial cleft cyst
6. Enlarged thyroid
7. Sarcoma

Nuchal Skin Thickening

= NUCHAL SONOLUCENCY / FULLNESS / EDEMA

= skin thickening of posterior neck measured between calvarium + dorsal skin margin
  (a) ≥ 3 mm during 9–13 weeks MA
  (b) ≥ 5 mm during 14–21 weeks MA
  (c) ≥ 6 mm during 19–24 weeks MA
  ◊ The smallest measurement should be used!

Image plane: axial / transverse image (slightly craniad to that of the BPD measurement) that includes cavum septi pellucidi, cerebellar hemisphere and cisterna magna (transcerebellar diameter view)

Prevalence: among the most common anomaly in 1st trimester + early 2nd trimester

Cause:

A. NORMAL VARIANT (0.06%)
B. CHROMOSOMAL DISORDERS trisomy 21 (in 45–80%), Turner syndrome (45 XO), Noonan syndrome, trisomy 18, XXX syndrome, XYY syndrome, XXXX syndrome, XXXXY syndrome, 18p-syndrome, 13q-syndrome
   ◊ 30–40% of fetuses with Down syndrome have nuchal skin thickening!
C. NONCHROMOSOMAL DISORDERS
   1. Multiple pterygium syndrome = Escobar syndrome
   2. Klippel-Feil syndrome: fusion of cervical vertebrae, CHD, deafness (30%), cleft palate
   3. Zellweger syndrome = cerebrohepatorenal syndrome: large forehead, flat facies, macrogyria, hepatomegaly, cystic kidney disease, contractures of extremities
   4. Robert syndrome
   5. Cumming syndrome

√ larger lymphangiomas with radiating septations are usually found with trisomy 18
√ nuchal fullness ≥ 3 mm during 1st trimester is seen in trisomy 21 / 18 / 13 (30–50% PPV)
√ often reverting to normal by 16–18 weeks
√ septations within nuchal translucency carries a 20- to 200-fold risk for chromosomal anomalies compared with normal

Sensitivity: 2–44–75% for detection of trisomy 21

Specificity: 99% for detection of trisomy 21

PPV: 69%

Positive screen: 1.2–3.0% in general population (exceeding 0.5% risk of amniocentesis)

False positives: 0.5–2–8.5%

OB management: thorough sonographic evaluation at 18–20 weeks MA

DDx: chorioamnionic separation

Protruding Tongue

1. Macroglossia
2. Lymphangioma of the tongue

Macroglossia

1. Beckwith-Wiedemann syndrome
2. Down syndrome
3. Hypothyroidism
4. Mental retardation

FETAL CHEST ANOMALIES

Pulmonary Underdevelopment

Pulmonary Aplasia

= rudimentary bronchus ending in blind pouch + absence of parenchyma + vessels

Frequency: 1÷10,000; R÷L = 1÷1

CT:

√ diffuse opacification of involved hemithorax
√ ipsilateral mediastinal shift
√ absence of ipsilateral pulmonary tissue + artery
√ bronchus terminates in dilated short blind pouch

Pulmonary Hypoplasia

= completely formed but congenitally small bronchus with rudimentary parenchyma + small vessels

Cause:

A. PRIMARY / idiopathic pulmonary hypoplasia (rare)
B. SECONDARY pulmonary hypoplasia limiting space for lung development
    (a) Intrathoracic lung compression
        1. Intrathoracic mass
        2. Mediastinal mass
        3. Large hydrothorax
        4. Lymphatic malformation
        5. Agenesis of diaphragm
    (b) Extrathoracic lung compression (= Potter syndrome)
        1. Prolonged oligohydramnios (20–25%) ← renal agenesis, bilateral cystic renal disease, obstructive uropathy, premature rupture of membranes
        2. Fetal ascites
    (c) Dysplasia of thoracic cage
        1. Jeune
        2. Thanatophoric dystrophy
        3. Ellis-van Creveld
        4. Severe achondroplasia
    (d) Others ← reduced breathing activity
        1. Muscular disease

2. Neurologic condition
3. Chromosomal abnormality

Path: absolute decrease in lung volume / weight for GA

√ thoracic circumference (TC) < 5th percentile for EGA
√ TC÷AC length ratio < 0.32
√ FL÷AC ratio < 0.16
√ small hyperlucent lung ← oligemia
√ diminutive ipsilateral pulmonary artery
√ hyperlucent contralateral lung ← compensatory hyperexpansion
√ ipsilateral mediastinal shift

Congenital Chest Malformation

1. Congenital pulmonary airway malformation
2. Congenital diaphragmatic hernia (CDH)
3. Bronchopulmonary sequestration (BPS)
4. Congenital hydrothorax
5. Congenital lobar emphysema
6. Congenital high airway obstruction syndrome

Intrathoracic Mass

in order of frequency:

1. Congenital diaphragmatic hernia / eventration
2. Congenital pulmonary airway malformation
3. Bronchopulmonary sequestration
4. Bronchogenic cyst
5. Bronchial atresia

Unilateral Chest Mass

1. Congenital diaphragmatic hernia
2. Congenital pulmonary airway malformation
3. Bronchopulmonary sequestration
4. Bronchogenic cyst
5. Unilateral bronchial atresia / stenosis

Bilateral Chest Masses

1. **Laryngeal / tracheal atresia**
   √ pulmonary hyperplasia
   √ symmetrically enlarged echogenic lungs
   √ dilated fluid-filled trachea + bronchi
   √ inverted hemidiaphragms
   √ diminutive heart amongst enlarged lungs
   √ ± hydrops
2. Congenital high airway obstruction
2. Bilateral congenital pulmonary airway malformation
3. Bilateral congenital diaphragmatic herniae

Mediastinal Mass

1. Goiter
2. Cystic hygroma
3. Pericardial teratoma
4. Neuroblastoma

Cystic Chest Mass

1. Bronchogenic cyst
2. Enteric cyst
3. Neurenteric cyst
4. Cystic adenomatoid malformation type I
5. Congenital diaphragmatic hernia
6. Pericardial cyst
7. Mediastinal meningocele

Complex Chest Mass

1. Congenital diaphragmatic hernia
2. Congenital pulmonary airway malformation
3. Bronchopulmonary sequestration
4. Complex enteric cyst
5. Pericardial teratoma

Solid Chest Mass

1. Congenital diaphragmatic hernia: bowel ± liver
2. Cystic adenomatoid malformation type III
3. Pulmonary sequestration
4. Obstructed lung ← bronchial atresia, laryngeal atresia, bronchogenic cyst
5. Bronchopulmonary foregut malformation
6. Pericardial tumor
7. Heterotopic brain tissue

Regressing Fetal Chest Mass

1. Cystic adenomatoid malformation
2. Bronchopulmonary sequestration

Chest Wall Mass

1. Hemangioma
2. Cystic hygroma
3. Teratoma
4. Hamartoma
5. Thoracic myelomeningocele

Pleural Effusion

1. Primary idiopathic chylothorax (most common)
2. Hydrops fetalis (multiple causes)
3. Chromosome anomaly: trisomy 21, 45 XO (mostly)

4. Pulmonary lymphangiectasia / cystic hygroma
5. Lung mass: cystic adenomatoid malformation, bronchopulmonary sequestration, congenital diaphragmatic hernia, chest wall hamartoma (uncommon)
6. Pulmonary vein atresia
7. Idiopathic

FETAL CARDIAC ANOMALIES

Prevalence: 1÷125 births = 0.8% of population; most common of all congenital malformations (40%)

◊ 90% occur as isolated multifactorial traits with a recurrence risk of 2–4%

◊ 10% are associated with multiple birth defects

◊ responsible for 50% of childhood deaths from congenital malformations

Antenatal sonographic diagnosis to prompt cardiac evaluation:

A. ABNORMALITIES IN CARDIAC POSITION

B. CNS
   1. Hydrocephalus
   2. Microcephaly
   3. Agenesis of corpus callosum
   4. Encephalocele: Meckel-Gruber syndrome

C. GASTROINTESTINAL
   1. Esophageal atresia
   2. Duodenal atresia
   3. Situs abnormalities
   4. Diaphragmatic hernia

D. VENTRAL WALL DEFECT
   1. Omphalocele
   2. Ectopia cordis

E. RENAL
   1. Bilateral renal agenesis
   2. Dysplastic kidneys

F. TWINS
   1. Conjoined twins

Prenatal Risk Factors for Congenital Heart Disease

A. FETAL RISK FACTORS
   1. Symmetric IUGR
   2. Arrhythmias
      (a) fixed fetal bradycardia (50%) ≤ 110 bpm
      (b) tachycardia (low risk)
      (c) irregular: PACs, PVCs (low risk)
   3. Abnormal fetal karyotype: CHD in Down syndrome (40%); in trisomy 18 / 13 (> 90%); in Turner syndrome (35%)
   4. Extracardiac somatic anomalies by US: omphaloceles (20%), duodenal atresia, hydrocephaly, spina bifida, VACTERL
   5. Nonimmune hydrops (30–35%)

6. Oligo- / polyhydramnios

B. MATERNAL RISK FACTORS
   1. Maternal heart disease (10%)
   2. Insulin-dependent diabetes mellitus (4–5%)
   3. Phenylketonuria (in 15% if maternal phenylalanine > 15%)
   4. Collagen vascular disease: SLE
   5. Viral infection: rubella
   6. Drugs
      (a) phenytoin: in 2% PS, AS, coarctation, PDA
      (b) trimethadione: in 20% transposition, tetralogy, hypoplastic left heart
      (c) sex hormones (in 3%)
      (d) lithium (7%): Ebstein anomaly, tricuspid atresia
      (e) alcohol (25% of fetal alcohol syndrome): VSD, ASD
      (f) retinoic acid = isotretinoin (?15%)
   7. Paternal CHD (risk uncertain)

C. MENDELIAN SYNDROMES
   1. Tuberous sclerosis
   2. Ellis-van Creveld syndrome
   3. Noonan syndrome

D. FAMILIAL RISK FACTORS FOR RECURRENCE OF HEART DISEASE
   › overall incidence : 6–8÷1,000 live births
   › affected sibling : 1–4% (risk doubled)
   › affected parent : 2.5–4%

◊ In 50% of neonates with CHD there is no identifiable risk factor!

Poor prognostic features:
(1) Intrauterine cardiac failure → hydrops
(2) Severe trisomy: 18, 13
(3) Hypoplastic left heart + endocardial fibroelastosis
(4) Delivery in center without pediatric cardiology

In Utero Detection of Cardiac Anomalies

A. ABNORMAL HEART POSITION
   1. Diaphragmatic hernia
   2. Lung anomaly
   3. Pleural effusion
   4. Cardiac defect

B. CHAMBER ENLARGEMENT

⇑ RA:	⇑ LA:
1. Tricuspid regurgitation	1. Mitral stenosis
2. Tricuspid valve dysplasia	2. Aortic stenosis
3. Ebstein anomaly	
⇑ RV:	**⇑ LV:**
1. Coarctation	1 Aortic stenosis
2. Normal in 3rd trimester	2 Cardiomyopathy

C. ABNORMAL FOUR-CHAMBER VIEW
   1. Septal rhabdomyoma
   2. Endocardial cushion defect
   3. Ventricular septal defect
   4. Ebstein anomaly
   5. Single ventricle

D. VENTRICULAR DISPROPORTION
   1. Hypoplastic right / left ventricle
   2. Hypoplastic aortic arch
   3. Aortic / subaortic stenosis
   4. Coarctation of aorta
   5. Ostium primum defect

E. INCREASED AORTIC ROOT DIMENSION
   1. Tetralogy of Fallot
   2. Truncus arteriosus
   3. Hypoplastic left ventricle with transposition

F. DECREASED AORTIC ROOT DIMENSION
   1. Coarctation of aorta
   2. Hypoplastic left ventricle

◊ 26–80% of serious cardiac anomalies can be detected on four-chamber view!
◊ Increased sensitivity > 20 weeks + by including outflow views!

Structural Cardiac Abnormalities & Fetal Hydrops

1. Atrioventricular septal defect + complete heart block
2. Hypoplastic left heart
3. Critical aortic stenosis
4. Cardiac tumor
5. Ectopia cordis
6. Dilated cardiomyopathy
7. Ebstein anomaly
8. Pulmonary atresia

Fetal Echocardiographic Views

Identification of fetal RV:

√ RV lies closest to anterior chest wall
√ foramen ovale flap seen within LA
√ prominent moderator band + papillary muscles in RV

A. FOUR-CHAMBER VIEW
   1. Position of heart within thorax
   2. Number of cardiac chambers
   3. Ventricular proportion
   4. Integrity of atrial + ventricular septa
   5. Position + size + excursion of AV valves
B. LONG-AXIS VIEW OF LV OUTFLOW TRACT
   = PARASTERNAL LONG-AXIS VIEW
   1. Continuity between ventricular septum + anterior aortic wall
   2. Caliber of aortic outflow tract
   3. Excursion of aortic valve leaflets
C. SHORT-AXIS VIEW OF OUTFLOW TRACTS
   1. Spatial relationship between aorta + pulmonary artery
   2. Caliber of aortic + pulmonary outflow tracts
D. AORTIC ARCH VIEW

Echogenic Intracardiac Focus

Cause: mineralization of a papillary muscle

◊ Isolated anomaly in 90%!

1. Trisomy 21 (in 30% of affected fetuses)
2. Trisomy 13 (in 50% of affected fetuses)
3. Normal pregnancy (4% in a population at high risk for fetal anomalies)

FETAL GASTROINTESTINAL ANOMALIES

1. Esophageal atresia ± tracheoesophageal fistula
2. Duodenal atresia
3. Meconium peritonitis
4. Hirschsprüng disease
5. Choledochal cyst
6. Mesenteric cyst

Fetal Abdominal Wall Defect

Prevalence: 6÷2,000 pregnancies; 6÷10,000 births

The American Institute of Ultrasound in Medicine mandates demonstration of the umbilical cord insertion on the fetal abdomen during 2nd + 3rd trimester US exams.

(a) normal cord insertion (CI)
   › defect to right of CI: gastroschisis
   › defect below CI: bladder exstrophy

(b) abnormal cord insertion
   › low defect + absent bladder: cloacal exstrophy
   › CI on membrane: omphalocele
   › high defect: pentalogy of Cantrell
   › no defined distribution: abdominoschisis, limb-body wall complex

Fetal Hepatomegaly

A. CONGENITAL INFECTIONS
   1. CMV
B. SEVERE HEMOLYTIC DISEASE
C. SYNDROMES
   1. Beckwith-Wiedemann syndrome
   2. Zellweger syndrome

Intraabdominal Echogenic Mass in Fetus

A. ABDOMEN
   1. Echogenic bowel
   2. Enteric duplication cyst (rarely echogenic)
   3. Subdiaphragmatic extralobar pulmonary sequestration (4÷1 left-sided predominance)
B. LIVER
   1. Hepatic hemangioma
   2. Hepatic mesenchymal hamartoma composed of multiple microcysts
C. ADRENAL / RENAL
   1. Neuroblastoma
   2. Adrenal hemorrhage
   3. Mesoblastic nephroma

Nonvisualization of Fetal Stomach

◊ Fetal swallowing begins at 11 weeks MA

Normal: stomach is visualized in almost all normal fetuses by 13–14 weeks (definitely by 19 weeks)

Prevalence: 2%

Cause:

1. Physiologic gastric emptying / intermittent swallowing
   ◊ Repeat scan after 30 min!
2. Oligohydramnios
3. CNS depression / abnormalities impairing swallowing
4. Abnormal position of stomach:
   √ stomach on contralateral side (situs inversus)
   √ congenital diaphragmatic hernia
5. Esophageal atresia ± tracheoesophageal fistula
   ◊ Nonvisualization of fetal stomach and polyhydramnios in 33% fetuses with esophageal atresia after 24 weeks MA!
6. Cleft lip / palate → impairing normal swallowing

Rx: repeat ultrasound scan

Double Bubble Sign

= fluid-filled stomach + proximal duodenum

◊ A persistently fluid-filled duodenum is always abnormal!

A. DUODENAL OBSTRUCTION
   1. Duodenal atresia (usually not seen < 24 weeks MA)

Cause: in 30% due to Down syndrome

2. Severe duodenal stenosis
3. Duodenal web
4. Duodenal duplication cyst

B. PERIDUODENAL ANOMALY
1. Ladd bands
2. Annular pancreas
3. Preduodenal portal vein

C. DISTAL OBSTRUCTION
1. Midgut volvulus
2. Malrotation

mnemonic: LADS
Ladd bands / malrotation
Annular pancreas
Duodenal atresia
Stenosis (duodenal)

Dilated Bowel in Fetus

1. Meconium ileus
   ◊ All newborns with meconium ileus have cystic fibrosis!
   ◊ 10–15% of newborns with cystic fibrosis present with meconium ileus!
2. "Apple peel" atresia of small bowel
3. Jejunal atresia
4. Megacystis-microcolon-intestinal hypoperistalsis syndrome
5. Colonic aganglionosis = Hirschsprüng disease
   (may be associated with Down syndrome)
6. Anorectal atresia: associated with CNS abnormalities, part of VACTERL complex

Bowel Obstruction in Fetus

Etiology: intestinal atresia / stenosis secondary to vascular accident, volvulus, meconium ileus, intussusception after organogenesis

Prevalence: imperforate anus 1÷3,000; small bowel 1÷5,000; colon 1÷20,000

Pathologic types:

I one / more transverse diaphragms
II blind-ending loops connected by fibrous string
III complete separation of blind-ending loops
IV apple-peel atresia of small bowel ← occlusion of SMA branch

Associated with: GI anomalies in 45% (malrotation, duplication, microcolon, esophageal atresia)

√ multiple distended bowel loops > 7 mm in diameter
√ increased peristalsis
√ polyhydramnios (if obstruction above level of mid jejunum; exceptions are esophageal atresia + tracheoesophageal fistula) ← fetal inability to cycle amniotic fluid through gut

Cx: Meconium peritonitis (50%)

DDx: (1) Other cystic masses: duodenal atresia, hydronephrosis, ovarian cyst, mesenteric cyst
(2) Chronic chloride diarrhea

Hyperechoic Fetal Bowel

◊ Most common echogenic mass in fetal abdomen

Definition: bowel echogenicity ≥ bone

Prevalence: 0.2–1.0% of 2nd trimester fetuses

Cause: (?) "constipation" in utero ← decreased swallowing, hypoperistalsis, bowel obstruction + increased fluid absorption, ingestion of blood

1. Normal small bowel variant (especially < 20 weeks MA) with resolution on follow-up sonogram toward end of 2nd trimester (in 50–70%)
2. Normal colon variant in 3rd trimester ← echogenic meconium
3. Meconium ileus
   ◊ Increased abdominal echogenicity is seen in 60–70% of fetuses with cystic fibrosis!
4. Chromosomal abnormality (3–25%)
   (a) Down syndrome (5–14%)
   (b) Trisomy 13, 18
   (c) Turner syndrome
5. Severe IUGR (16%)
6. Intraamniotic bleeding with subsequent swallowing of blood by fetus

Prognosis:

5-fold increase in risk for adverse fetal outcome (due to chromosomal abnormality, other anomalies, placental abruption, perinatal death [8–16%], IUGR [67–23%])

◊ 30–50% of fetuses with echogenic bowel in 2nd trimester will have poor outcome!

Management: parental testing for cystic fibrosis, careful fetal anatomic survey, follow-up for growth assessment

Hyperechoic Adrenal Gland in Fetus

seen routinely on US > 30–32 weeks GA

1. Acute adrenal hemorrhage
2. Exophytic renal tumor: mesoblastic nephroma
3. Neuroblastoma
4. Subdiaphragmatic extralobar sequestration

Intraabdominal Calcifications in Fetus

◊ Isolated liver calcifications are relatively frequent (1÷1,750 pregnancies) and of no clinical significance!

Scattered Calcifications

A. PERITONEAL
   1. Meconium peritonitis
   2. Plastic peritonitis associated with hydrometrocolpos
B. CONGENITAL INFECTION

1. Toxoplasmosis
2. Cytomegalovirus

Focal Calcification

A. TUMOR
   1. Hepatoblastoma
   2. Metastatic neuroblastoma
   3. Hemangioma / hemangioendothelioma
   4. Teratoma
   5. Ovarian dermoid

B. OTHERS
   1. Fetal gallstones (> 28 weeks EGA)
      Cause: hemolytic disease, cholestasis, maternal drug use
      Prognosis: resolution before / after delivery

Cystic Mass in Fetal Abdomen

Incidence: abdominal cyst in 1÷500 – 1÷1,000 live births; 1÷2,625 pregnancies

A. POSTERIOR MID ABDOMEN
   1. Simple renal cyst
   2. Hydroureteronephrosis
   3. Multicystic dysplastic kidney
   4. Paranephric collection = urinoma
   5. Lymphangioma
   6. Cystic neuroblastoma

B. RIGHT UPPER QUADRANT
   1. Liver cyst
   2. Choledochal cyst

C. LEFT UPPER QUADRANT
   1. Splenic cyst

D. ANTERIOR MID ABDOMEN
   1. Gastrointestinal duplication cyst
   2. Mesenteric cyst
   3. Meconium pseudocyst
   4. Dilated bowel
   5. Urachal cyst

E. LOWER ABDOMEN
   1. Fetal ovarian cyst (*see below*)
   2. Hydrometrocolpos
   3. Meningocele
   4. Sacrococcygeal teratoma
   5. Ureterocele

Fetal Ovarian Cyst

◊ Most common intraabdominal mass in female fetus

Incidence: clinically significant ovarian cyst in 1÷2500 live births

Time of development: 3rd trimester
Cause: elevated hormone levels ← fetal pituitary gonadotropins, placental human chorionic gonadotropins, maternal estrogens

1. Simple ovarian cyst
2. Complex ovarian cyst

Prognosis: < 5 cm cyst: spontaneous resolution (69%), > 5 cm cyst: spontaneous resolution (15%)

Rx: The most conservative postpartum approach is a period of observation because many cysts will regress spontaneously.

Fetal Ascites

A. ASCITES + FETAL HYDROPS
   1. Immune hydrops
   2. Nonimmune hydrops
B. ISOLATED ASCITES
   1. Urinary ascites
   2. Meconium peritonitis
   3. Bowel rupture
   4. Ruptured ovarian cyst
   5. Hydrometrocolpos
   6. Glycogen storage disease

Solid-appearing Fetal Abdominal Mass

1. Neoplasm: neuroblastoma, mesoblastic nephroma, liver tumor (eg, hemangioendothelioma)
2. Abdominal bronchopulmonary sequestration
3. Fetus in fetu

FETAL URINARY TRACT ANOMALIES

Prevalence: 0.25%–1.00% liveborn infants (OB-US); 1÷100 to 1÷200 neonates (pediatrics)
Types:

1. Bilateral renal agenesis
2. Infantile polycystic kidney disease
3. Adult polycystic kidney disease
4. Multicystic dysplastic kidney
5. Ureteropelvic junction obstruction
6. Megaureter
7. Posterior urethral valves
8. Prune belly syndrome
9. Megacystis-microcolon-intestinal hypoperistalsis syndrome
10. Mesoblastic nephroma
11. Wilms tumor
12. Neuroblastoma

Associated with: chromosome abnormalities in 12% (74% trisomy, 10% deletion, 9% sex chromosome aneuploidy, 6% triploidy)

• fetal urine production: 5 mL/hour at 20 weeks MA; 56 mL/hour at 40 weeks MA
√ bladder volume: 1 mL at 20 weeks MA; 36 mL at 40 weeks MA
√ filling + emptying of fetal urinary bladder occurs every 10–30 (range 7–43) minutes
√ increased renal parenchymal echogenicity indicates renal abnormality in 80%
√ fetal hydronephrosis
= AP diameter of renal pelvis > 5 mm at 15–20 weeks, ≥ 8 mm at 20–30 weeks, ≥ 10 mm at > 30 weeks

FETAL TUMOR

= CONGENITAL TUMOR
= mass in fetus + newborn manifesting in first 3 months of life
Prevalence: 1.7–13.5÷100,000 live births
Common features: polyhydramnios (⅓), associated congenital anomalies (20%), hydrops (17%)

A. EXTRACRANIAL TERATOMA (most common)
Location: typically along midline of body
Origin: during amoeba-like migration from yolk sac wall to genital ridges a few pluripotential primordial germ cells become isolated in aberrant locations and grow
Path: all 3 germ cell layers:
(a) ectoderm (dominant): neural tissue
(b) mesoderm (common): fat, bone, smooth muscle, cartilage
(c) endoderm (least common): respiratory epithelium, gastrointestinal tissue
Histo: (a) mature
(b) immature: primitive neuroglial tissue + neuroepithelial rosettes; (occasionally) malignant: yolk sac tumor / embryonal carcinoma
1. Sacrococcygeal teratoma (70–80%)
2. Teratoma of head & neck (10–20%)
3. Chest & abdomen teratoma (< 10%)
4. **Fetus in fetu**
= highly differentiated "fetiform" teratoma / parasitic monochorionic diamniotic twin embedded in retroperitoneal location of host

B. NEUROBLASTOMA (30%)
C. SOFT-TISSUE TUMOR (12–22%)
(a) benign: fibromatosis, digital fibromatosis, myofibromatosis, fibrous hamartoma
(b) malignant: infantile fibrosarcoma, rhabdosarcoma, primitive neuroectodermal tumor, rhabdoid tumor, hemangiopericytoma
(b) developmental vascular: hemangioma, lymphangioma, AV malformation
D. INTRACRANIAL TUMOR (10%)
Location: pineal region, suprasellar area, cerebral hemispheres
Site: supratentorial > infratentorial (unlike pediatric age)
√ macrocephaly, hydrocephalus, polyhydramnios ← depressed swallowing ← hypothalamic dysfunction
Mortality: 97% (except for lipoma)

DDx: intracranial hemorrhage

1. Intracranial teratoma (50% of all fetal CNS tumors)
2. Astrocytoma
3. Lipoma (10%)
4. Choroid plexus papilloma (5–9%)
5. Craniopharyngioma
6. Primitive neuroectodermal tumor (3.4–13.2%)

E. RENAL TUMOR (5%)

1. Mesoblastic nephroma
2. Wilms tumor
3. Rhabdoid tumor

F. LIVER TUMOR (5%)

1. Hemangioendothelioma
2. Mesenchymal hamartoma
3. Hepatoblastoma
4. Metastases: ← neuroblastoma + leukemia

G. **Congenital leukemia**

Prevalence: 4.7÷1,000,000 live births
Prognosis: poor ← rapidly progressive course
Age: first 4–6 weeks of infancy
Associated with: congenital leukemia of Down syndrome (15-fold increase of leukemia)
OB-US:

√ hepatosplenomegaly → ↑ abdominal circumference
√ hydrops ← fetal anemia / leukemic infiltrate of myocardium / visceral fibrosis with ↑ vascular resistance

DDx: infection, metastatic neuroblastoma

GENERAL GYNECOLOGY

Pelvic Features of Estrogen Stimulation

√ increased thickness + volume of uterus
√ fundocervical ratio > 2
√ echogenic endometrium
√ appearance of ovaries NOT USEFUL (because of widely varying ovarian volumes + normal visualization of follicles at all ages)

Precocious Puberty

= development of secondary sex characteristics < 8 years of age in girls / < 9 years of age in boys
• premature thelarche / adrenarche / menarche
√ significantly advanced bone age (may limit adult height potential)
Terminology:

(a) isosexual precocity = secondary sex characteristics appropriate for patient's gender
(b) heterosexual precocity = secondary sex characteristics inappropriate for patient's gender

› virilization in girls
› feminization in boys

(c) gonadotropin-dependent = true precocious puberty

(d) gonadotropin-independent = pseudoprecocious puberty

Source: pituitary – adrenal – gonad

Central Precocious Puberty

= TRUE PRECOCIOUS PUBERTY = TRUE ISOSEXUAL PRECOCITY = COMPLETE PRECOCIOUS PUBERTY

= isosexual gonadotropin-dependent early development of gonads + secondary sex characteristics with ovulation before 8 years of age

Cause:

A. IDIOPATHIC (66–80%) F > M activation of hypothalamic-pituitary-gonadal axis
= hypothalamic release of GnRH → pituitary gonadotropin secretion → ovulation / spermatogenesis

B. ORGANIC (13–42%) M >> F
(1) Lesion of pituitary gland / hypothalamus: eg, tuber cinereum hamartoma, cyst
(2) Increased intracranial pressure: eg, postmeningitic hydrocephalus
(3) Traumatic brain injury
(4) Empty sella
(5) Congenital toxoplasmosis
(6) Septo-optic dysplasia, pituitary duplication

• increased levels of estrogen, advanced bone age
• increased gonadotropin levels after LHRH stimulation
√ bilateral adult-sized ovaries (1.2–12 cm^3) with bilateral cysts of < 9 mm
√ dominance of corpus over cervix length
◊ Uterine size + shape are more reliable indicators of estrogen stimulation!

Rx: long-acting gonadotropin-releasing hormone analogue

Radiologic workup:

(1) Bone age assessment
(2) Pelvic ultrasound for evidence of maturation of uterus + ovaries
(3) Search for estrogen-producing lesion: functioning ovarian cysts, juvenile granulosa cell tumor of ovary, feminizing adrenal cortical tumor

Peripheral Precocious Puberty

= PSEUDOPRECOCIOUS PUBERTY = PSEUDOSEXUAL PRECOCITY = INCOMPLETE PRECOCIOUS PUBERTY

= iso- / heterosexual pubertal changes independent of secretion of pituitary gonadotropins =early development of secondary sex characteristics without ovulation

Cause:

A. ISOSEXUAL PPP IN FEMALES

1. Autonomously functioning ovarian follicular cyst (most common cause)
√ asymmetric ovarian enlargement (one ovary 2.4–7 cm^3) with macrocysts (> 9 mm)
√ pubertal morphology + size of uterus ← estrogen stimulation

2. Estrogen-secreting ovarian tumor: eg, granulosa cell tumor, gonadoblastoma, thecoma, choriocarcinoma
3. Feminizing adrenocortical neoplasm

rare others: McCune-Albright syndrome, untreated hypothyroidism, neurofibromatosis (NF1), hepatoblastoma, estrogen ingestion (food, topical cream)

B. HETEROSEXUAL PPP IN FEMALES
1. Virilizing adrenocortical neoplasm (ACN)
2. Congenital adrenal hyperplasia (CAH)

C. ISOSEXUAL PPP IN BOYS
1. Sex cord-stromal tumor of testis
2. hCG-secreting tumors stimulating Leydig cells: hepatoblastoma, mediastinal teratoma, some testicular germ cell tumors, suprasellar germinoma

- low gonadotropin levels after LHRH stimulation
- high serum estradiol level, low serum levels of FSH + LH
- normal bone age; uterine bleeding ← withdrawal of estrogen stimulation upon cyst rupture

√ prepubertal small uterus + ovaries
√ asymmetric ovarian enlargement (one ovary 2.4–7 cm^3) with macrocysts (> 9 mm)
√ ± unilateral follicular ovarian cyst characterized by internal daughter cyst

Isolated Premature Adrenarche

= axillary and pubic hair development ← action of adrenal androgens in girls 1–3 years of age

- increased levels of adrenal androgens independent of stimulation by adrenocorticotropic hormone (ACTH)

√ prepubertal uterus + ovaries (0.1–1.0 cm^3)
√ normal / slightly advanced bone age

Isolated Premature Thelarche

= breast enlargement in girls 1–3 years of age
◊ May occur without endocrine abnormalities
√ prepubertal uterus + ovaries
√ normal / slightly advanced bone age

Infertility

= failure to conceive after 1 year of unprotected intercourse

Incidence: affects 10–15% of couples = 7.4 million women in 2010

Etiology:

A. FEMALE FACTORS (55%):
› Tubal disease (10–20–40%): congenital anomalies, DES exposure, pelvic inflammatory disease, salpingitis isthmica nodosa, endometriosis, postoperative factors, polyp, neoplasm, ectopic pregnancy
› Uterine factors (2–5%): bicornuate uterus, septate uterus, DES exposure, intrauterine adhesions, endometrial inflammation / infection, uterine neoplasm, complications

after pregnancy, leiomyoma
› Ovulatory disorder (10–20%): premature ovarian failure, gonadal dysgenesis, polycystic ovary syndrome
› Pelvic factors (20–25%)
› Cervical factors (5–10%)

B. MALE FACTORS (40%)
C. COMBINATION OF FACTORS (15–25%)
D. UNKNOWN CAUSE (5–10%)

Tests:

- history + physical examination
- laboratory tests (mainly hormonal), postcoital test
- basal body temperature measurement, cervical culture
- endometrial biopsy, sonographic monitoring of ovaries
- in vitro mucus penetration test, sperm agglutination studies
- laparoscopy + hysteroscopy, hysterosalpingography

Fallopian Tube Occlusion, Irregularity and Adhesions

Frequency: 30–40%

1. Pelvic inflammatory disease
   (a) granulomatous salpingitis: TB
   (b) parasitic infection
2. Congenital anomaly
3. Postsurgical anomaly
4. Tubal spasm
5. Intraluminal endometriosis
6. Salpingitis isthmica nodosa

Intrauterine Filling Defect on HSG

1. Intrauterine synechiae
2. Submucosal leiomyoma
3. Endometrial polyps
4. Blood clot
5. Air bubbles

Uterine Contour Irregularities

1. Adenomyosis
2. Leiomyoma
3. Müllerian duct anomalies (up to 25%)

Cervical Anomalies

1. Cervical factor infertility (10%)
   = inadequate quality / volume of cervical mucus
2. Cervical stenosis

Ovarian Abnormalities

A. PRIMARY

1. Nonfunctioning ovaries
2. Premature ovarian failure
3. Gonadal dysgenesis

B. SECONDARY
1. Polycystic ovary syndrome
2. Endometriosis
3. Ovarian cancer

Amenorrhea

Primary Amenorrhea

Definition:

(a) no menarche by 16 years of age
(b) no thelarche / adrenarche by 14 years of age
(c) no menarche > 3 years after adrenarche + thelarche

Cause:

A. FEMALE ANATOMIC ANOMALIES
= Müllerian (uterovaginal) anomalies (20%)

B. CONGENITAL DISORDERS OF SEXUAL DIFFERENTIATION
(a) pure gonadal dysgenesis = Turner syndrome (33%)
√ bilateral dysfunctional / streak gonads
(b) mixed gonadal dysgenesis
√ testis + streak gonad
Risk: in 25% development of dysgerminoma / gonadoblastoma in dysgenetic gonads with Y chromosome

C. OVARIAN FAILURE / DYSFUNCTION

D. HYPOTHALAMIC / PITUITARY CAUSES (15%)

E. CONSTITUTIONAL DELAY (10%)

F. OTHERS: eg, systemic, psychiatric illness (22%)

√ absent / streak gonads + infantile uterus:

1. **Hypogonadotropic hypogonadism**
• low / normal LH + FSH levels
(a) hypothalamic dysfunction: hypothalamic tumor, **Kallmann disease** (= lack of pulsatile GnRH release), systemic illness, constitutional growth delay, extreme physical / psychological / nutritional stress (cystic fibrosis, sickle cell disease, Crohn disease), irradiation
(b) pituitary dysfunction: disruption of pituitary stalk from child abuse, head trauma
2. **Hypergonadotropic hypogonadism**
= ovarian tissue fails to respond to endogenous gonadotropins
• high LH + FSH levels
(a) abnormal karyotype: Turner syndrome, XY gonadal dysgenesis
(b) irradiation, chemotherapy, autoimmune disease (eg, autoimmune oophoritis)

√ absent uterus:

1. **Testicular feminization** = male intersex = male pseudohermaphroditism ← end-organ insensitivity to testosterone

2. **Müllerian dysgenesis** (= Mayer-Rokitansky-Küster-Hauser syndrome)
   √ normal fallopian tubes + ovaries
   Associated with: unilateral renal abnormality (50%), skeletal abnormality (12%)

√ small infantile uterus:
1. Androgen-producing virilizing tumor of adolescent ovary ← usually Sertoli-Leydig cell tumor
   √ unilateral adnexal mass
2. Turner syndrome
3. In utero exposure to diethylstilbestrol

√ normal uterus + unilateral ovarian tumor:
1. Estrogen-producing ovarian tumor with disruption of menstrual cycle: granulosa cell tumor, thecoma

√ hematometrocolpos:
(a) neonate = congenital uterovaginal obstruction
   1. Urogenital sinus / cloacal malformation
      √ pelviabdominal cystic mass with fluid-debris level in fetal US during 3rd trimester
      √ renal dysplasia / obstruction
(b) teenager
   1. Imperforate hymen
   2. Transverse vaginal septum
      › in upper vagina (45%)
      › in mid vagina (40%)
      › in lower vagina (15%)

√ hematometra
1. Cervical dysgenesis

√ bilateral ovarian enlargement:
1. Polycystic ovary syndrome
   (= Stein-Leventhal syndrome): most common cause of secondary amenorrhea

Secondary Amenorrhea

1. Pregnancy: most common cause in girls > 9 years of age
2. Polycystic ovary syndrome (main pathologic cause)
3. Asherman syndrome
4. All causes of primary amenorrhea

Oligomenorrhea

Definition: < 9 menstrual cycles per year

Calcifications of Female Genital Tract

A. UTERUS
   1. Uterine fibroid
   2. Arcuate arteries
B. OVARIES
   1. Dermoid cyst (50%)

2. Papillary cystadenoma (psammomatous bodies)
3. Cystadenocarcinoma
4. Hemangiopericytoma
5. Gonadoblastoma
6. Chronic ovarian torsion
7. Pseudomyxoma peritonei

C. FALLOPIAN TUBES
1. Tuberculous salpingitis

D. PLACENTA

E. LITHOPEDION

Psammoma Bodies in Tumor

1. Papillary serous cystadenoma / cystadenocarcinoma
2. Mucinous carcinoma of colon
3. Papillary thyroid cancer
4. Meningioma

Free Fluid in Cul-de-sac

1. Follicular rupture
2. Ovulation
3. Ectopic pregnancy
4. S/P culdocentesis
5. Ovarian neoplasm
6. Pelvic inflammatory disease

PELVIC MASS

Frequency of Pelvic Masses

1. Benign adnexal cyst 34%
2. Leiomyoma 14%
3. Cancer 14%
4. Dermoid 13%
5. Endometriosis 10%
6. Pelvic inflammatory disease 8%

Cystic Pelvic Mass

A. CYSTIC ADNEXAL MASS

B. EXTRAADNEXAL CYSTIC MASS

(a) intraperitoneal

@ Peritoneum

1. Peritoneal inclusion cyst
2. Paraovarian cyst

@ Bowel

1. Mucocele of the appendix
2. Mesenteric cyst

3. Fluid-distended bowel

@ Fallopian tube
1. Hydro-, pyo-, hematosalpinx
2. Ectopic gestation

@ Uterus
1. Pedunculated / parasitized leiomyoma with cystic degeneration
2. Cystic adenomyosis
3. Unicornuate uterus with obstructed rudimentary horn

(b) extraperitoneal

@ Presacral space
1. Spinal meningeal cyst
2. Retrorectal developmental cyst: dermoid, epidermoid, enteric tailgut / duplication cyst

@ Lymphatics
1. Lymphocele
2. Cystic degeneration of lymph node
3. Lymphangioleiomyomatosis
4. Lymphangioma

(c) intra- and extraperitoneal
1. Loculated pelvic abscess: appendiceal, diverticular, postoperative, Crohn disease, tuberculous, pelvic actinomycosis
2. Hematoma
3. Bladder diverticulum

Complex Pelvic Mass

mnemonic: CHEETAH

Cystadenoma / **C**ystadenocarcinoma
Hemorrhagic cyst
Endometrioma
Ectopic pregnancy
Teratoma: dermoid
Abscess ← adjacent appendicitis, etc.
Hematoma in pelvis

Solid Pelvic Mass

1. Pedunculated myoma (most common)
2. Fibroma
3. Adenofibroma
4. Thecoma
5. Brenner tumor

Fatty Pelvic Mass

A. UTERUS
1. Lipoleiomyoma
2. Fibromyolipoma

B. OVARY
   1. Benign cystic ovarian teratoma
   2. Malignant degeneration of cystic teratoma
   3. Nonteratomatous lipomatous ovarian tumor

C. PELVIS
   1. Benign pelvic lipoma
   2. Liposarcoma
   3. Lipoblastic lymphadenopathy

Extrauterine Pelvic Mass

1. Solid adnexal mass
2. Metastatic disease
3. Lymphoma
4. Pelvic kidney
5. Rectosigmoid carcinoma
6. Bladder carcinoma
7. Retroperitoneal tumor / fibrosis
8. Intraperitoneal fat
9. Vascular mass / malformation
10. Hematoma
11. Bowel

ADNEXA

Adnexal Mass

A. CYSTIC OVARIAN MASS
   1. Physiologic ovarian cyst:
      › Graafian follicle: at midcycle < 25 mm
      › Corpus luteum: after midcycle < 15 mm
   2. Functional / retention cyst
   3. Endometrioma
   4. Tuboovarian abscess
   5. Dermoid cyst
   6. Ectopic pregnancy
   7. Serous / mucinous ovarian tumor
   8. Ovarian hyperstimulation cysts
   9. Massive ovarian edema

B. EXTRAOVARIAN CYSTIC LESION
   1. Hydrosalpinx
   2. Paraovarian cyst / cystadenoma
   3. Peritoneal inclusion cyst

C. SOLID OVARIAN
   1. Ovarian tumor
   2. Torsion of ovary
   3. Oophoritis

4. Stein-Leventhal syndrome
5. Ovarian fibromatosis

D. SOLID EXTRA-OVARIAN
1. Fallopian tube carcinoma
2. Pedunculated fibroid

Ovarian Mass with Low Resistive Flow

Low resistance flow = RI < 0.5 or PI ≤ 1.0

1. Physiologic corpus luteum
2. Inflammatory mass
3. Endometrioma
4. Mesothelial cyst
5. Benign tumor: serous / mucinous cystadenoma, mature cystic teratoma, cystadenofibroma
6. Malignant ovarian tumor
   ◊ Some malignancies have high resistive blood flow!

Hemorrhagic Adnexal Lesion

1. Endometriosis
2. Hemorrhagic ovarian cyst
3. Hemorrhagic foci of adenomyosis
4. Hematosalpinx

Low-intensity Adnexal Lesion on T1WI

1. Fibroma
2. Fibrothecoma
3. Cystadenofibroma
4. Brenner tumor
5. Ovarian fibromatosis
6. Krukenberg tumor
7. Wall of chronic pelvic abscess
8. Pedunculated leiomyoma

High-intensity Adnexal Lesion on T1WI

= T1-shortening ← fat, hemorrhage, high protein

1. Endometrioma
   √ frequently multilocular + bilateral
   √ shading (= signal loss) on T2WI
2. Hemorrhagic ovarian cyst
   √ unilocular
   √ no shading
   √ resolution with time
3. Dermoid
   √ chemical shift artifact
   √ signal drop-out after fat suppression
4. Mucinous cystic neoplasm

√ signal intensity less than fat / blood

5. Ovarian carcinoma
   √ solid components, septations
   √ large size

LOW SI OF T1-HYPERINTENSE ADNEXAL MASS ON STIR

1. Fat of mature cystic teratoma
2. Hemorrhagic ovarian cyst
3. Endometrioma

◊ Use selective fat-suppressed T1WI to identify fat!

Low-intensity Adnexal Lesion on T2WI

A. Blood products
   1. Endometrioma
   2. Hemorrhagic cyst
   3. Hematosalpinx
   4. Cystic adenomyosis
B. Smooth muscle
   1. Uterine leiomyoma
C. Fibrous tissue
   1. Ovarian fibroma
   2. Theca cell tumor of ovary
   3. Cystadenofibroma
   4. Ovarian fibromatosis
   5. Pelvic aggressive fibromatosis
D. Mixed cellularity
   1. Brenner tumor
   2. Struma ovarii
   3. Krukenberg tumor

T2-isointense Pelvic Mass Relative to Muscle

A. Uterine origin
   1. Cystic adenomyosis: ↑ T1WI
   2. Leiomyoma: enhancing
B. Adnexal origin
   (a) ↑ T1WI without enhancement
      1. Endometrioma
      2. Hematosalpinx

Classification of Surface Epithelial Neoplasms by Cell Type			
Frequency	*Benign*	*Borderline (4–14%)*	*Malignant*
50%	Serous cystadenoma	Serous borderline tumor *resembling ciliated columnar cells of fallopian tube*	Serous cystadenocarcinoma
15–30%	Endometrioid cystadenoma	Endometrioid borderline tumor *resembling endometrial adenocarcinoma*	Endometrioid adenocarcinoma
15%	Mucinous cystadenoma	Mucinous borderline tumor *resembling endocervical canal epithelium*	Mucinous adenocarcinoma
5%	Benign clear cell tumor	Borderline clear cell tumor *mesonephroid tumor*	Clear cell adenocarcinoma
2.5%	Transitional cell (Brenner) tumor	Brenner tumor of borderline malignancy	Transitional cell carcinoma (non-Brenner type)
Clinical Features			
Age		young woman	6th–7th decade
Solid component	minimal amount	moderate amount	marked amount
Papillary projections	none / minimal (13%)	none / minimal (13%)	abundant (67%), in 38% with domineering solid component
Extraovarian tumor implants		noninvasive	invasive
+ retro-peritoneal Lnn.		21%	
+ Doppler blood flow		90%	92%
↑ CA-125		90%	high

(b) ↓ T1WI with enhancement
1. Fibroma
2. Fibrothecoma
3. Cystadenofibroma
4. Struma ovarii

T2-Hyperintense Adnexal Mass Brighter than Muscle

(a) ↑ T1WI
› without enhancement
1. Hemorrhagic cyst
› with enhancement
2. Malignant transformation of endometrioma

(b) ↓ T1WI
› without enhancement
1. Mucinous cystic neoplasm
› with enhancement
2. Krukenberg tumor

Adnexal Mass with Restricted Diffusion

1. Malignancy
2. Benign hemorrhagic ovarian cyst
3. Endometrioma
4. Benign mature cystic teratoma

Adnexal Mass in Pregnancy

Prevalence: 0.5–1.2%

A. RESOLVING BY 14–16 WEEKS EGA

1. Corpus luteum cyst
2. Theca lutein cyst

B. PERSISTENT ADNEXAL MASS

1. Benign
   correctly diagnosed by US: 95% of dermoids, 80% of endometriomas, 71% of simple cysts
2. Malignant (0.1–0.8%)

Ovarian Tumor

- abdominal discomfort, vomiting, flatulence, dyspnea
- acute pain from torsion / hemorrhage; menstrual irregularity
- chronic pain ← slowly enlarging mass, impaction, adhesions

Radiologic guidelines:

◊ Imaging features of ovarian neoplasms virtually never allow a specific diagnosis. Regardless of further differentiation patients always undergo surgery!

Signs suggestive of benignancy:

√ unilocularity of cyst
√ thin wall < 3 mm
√ minimal septations
√ absence of papillary projection

Signs suggestive of malignancy:

√ solid nonfatty nonfibrous tissue (most POWERFUL PREDICTOR of malignancy!)
√ many solid-tissue elements in a complex lesion
√ wall thickness > 3 mm
√ inner wall irregularities / papillary projections
√ thick septations > 3 mm
√ increased echogenicity within a cyst

Age: 13% of neoplasms malignant in premenopause; 45% of neoplasms malignant in postmenopause

Cx: (1) Torsion (in 10–20%)
(2) Rupture (rare)
(3) Infection

Terminology:

prefix "cyst-": cystic component present
suffix "fibroma": > 50% fibrous component
"tumor of low malignant potential": borderline malignant

Classification:

◊ 75% of ovarian neoplasms are benign
◊ 21% of ovarian neoplasms are malignant
◊ 4% of ovarian neoplasms are borderline malignant

The proportion of malignant tumors increases with age:
< 20 years of age 4%
> 50 years of age 40%

Tumor of Surface Epithelium (60–70%)

= EPITHELIAL OVARIAN TUMOR

Origin: arising from precursors from outside the ovary = surface epithelium / mesothelium

Frequency: 60% of all ovarian tumors; 85% of all ovarian malignancies; 50% occur > 65 years of age

Age peak: 6th–7th decade; rare before puberty

√ primarily uni- / multilocular cystic mass

√ ↑ amounts of solid tissue (mural nodules, vascular solid component) correlate with likelihood of malignancy

√ papillary projections in benign tumor (13%) / borderline tumor (67%) / malignant neoplasm (38%)

√ propensity for early peritoneal + lymphatic spread:

- √ ascites
- √ peritoneal studding
- √ omental cake
- √ perihepatic diaphragmatic implants
- √ retroperitoneal lymphadenopathy

Germ Cell Tumor (20–25%)

◊ 40% of germ cell tumors are malignant

Age: commonly in young women

(a) BENIGN (95%)

1. Dermoid cyst = mature cystic teratoma
   = the only benign variety

(b) MALIGNANT (5%)

= ovarian malignant germ cell tumor (OMGCT

Types: dysgerminoma (1.9%), immature teratoma (1.3%), endodermal sinus / yolk sac tumor (1.0%), malignant mixed germ cell tumor (0.7%), embryonal carcinoma (0.1%), choriocarcinoma (0.1%), malignant struma ovarii tumor

Fat within a solid ovarian tumor is characteristic of a teratoma = mature teratoma ± malignant degeneration / immature teratoma / mixed GCT with immature elements

Sex Cord-Stromal Tumor (5–8%)

usually has more than one cell type + arises from two groups of cells:

› primitive sex cord cells, which form from the coelomic epithelium (= primordial peritoneum) and differentiate into granulosa cells + Sertoli cells

› stromal cells (fibroblasts, theca cells, Leydig cells) derive from the mesonephros mesenchyma of the genital ridge

Age: broad range of ages

• most present at stage I with good prognosis

• absent tumor markers

◊ Often manifest with tumor-mediated hormonal effects

√ NO papillary projections

√ lack of fat + calcifications

Malignant Ovarian Epithelial versus Germ Cell Tumor		
Characteristic	*Epithelial Tumor*	*Germ Cell Tumor*
Prevalence	much more common	less common
Highest incidence	> 65 years of age	15–19 years of age
Age affected	older woman	girl / young woman
Race affected	more in whites	more in blacks + Asians
Bilaterality	serous (58%), mucinous (21%), clear cell (13%), endometrioid (27%)	4% (usually unilateral)
Tumor marker	CA-125	α-fetoprotein + β-hCG
Endocrine signs	None	isosexual precocity, carcinoid syndrome
5-year survival rate	44% (depending on stage)	dysgerminoma (100%), other malignant GCT (85%)

› hyperestrogenic tumors: granulosa cell tumor, thecoma, stromal luteoma
› virilizing tumors: Sertoli-Leydig cell tumor, steroid cell tumor (Sertoli cell tumor, Leydig cell tumor)

Size versus risk of malignancy: < 5 cm in 3%
5–10 cm in 10%
> 10 cm in 65%

A. GRANULOSA-STROMAL CELL TUMOR
   1. Juvenile granulosa cell tumor multicystic
   2. Adult granulosa cell tumor solid
   3. Thecoma solid
   4. Fibroma solid
   5. Fibrosarcoma
   6. Sclerosing stromal tumor

B. SERTOLI-STROMAL CELL TUMOR
   1. Sertoli-Leydig tumor solid
   2. Sertoli cell = arrhenoblastoma solid
   3. Leydig cell

C. STEROID CELL TUMOR = LIPID CELL TUMOR
   1. Stromal luteoma
   2. Leydig cell tumor = hilus cell tumor
   3. Steroid cell tumor, not otherwise specified

D. OTHER
   1. Gynandroblastoma
   2. Sex cord tumor with annular tubules
      associated with Peutz-Jeghers syndrome (30% of all tumors with annular tubules)
   3. Sclerosing stromal tumor

PARANEOPLASTIC SYNDROME OF OVARIAN TUMOR

Cause: autoantibodies, circulating immune complexes

A. NERVOUS SYSTEM DISORDERS
    1. Cerebellar degeneration
    2. Polyneuritis
B. CONNECTIVE TISSUE DISORDERS
    1. Dermatomyositis
C. HEMATOLOGIC DISORDERS
    1. Hemolytic anemia
    2. Disseminated intravascular coagulation
D. CUTANEOUS DISORDERS
    1. Acanthosis
E. NEPHROTIC SYNDROME

Secondary Ovarian Tumor (5–15%)

Metastases from: pelvic organs, upper GI tract, breast, bronchus, reticuloendothelial tumors, leukemia

Solid Ovarian Tumor

1. Ovarian fibroma
2. Theca cell tumor of ovary
3. Granulosa cell tumor
4. Sertoli-Leydig cell tumor
5. Brenner tumor
6. Sarcoma
7. Dysgerminoma
8. Yolk sac tumor of ovary
9. Teratoma of ovary
10. Metastasis
11. Endometrioma
12. Massive ovarian edema
13. Leiomyoma

Functioning Ovarian Tumor

◊ ⅔ of gonadal stromal tumors produce steroids

◊ The most common functioning ovarian tumor is the sex cord-stromal tumor (= 8% of ovarian neoplasms)

OVARIAN TUMOR WITH HYPERANDROGENISM

- male-pattern baldness, loss of female body contour
- hirsutism, elevated serum testosterone
- ± elevated serum dehydroepiandrosterone

Causes of Hyperandrogenism and Hyperestrogenism		
Cause	*Hyper-androgenism*	*Hyper-estrogenism*
Ovarian Disorder		
Sex cord-stromal tumor		
Sertoli stromal tumor		
Sertoli-Leydig cell tumor	+	(+)
Steroid cell tumor		
Leydig cell tumor	+	(+)
Stromal luteoma	+	+
Steroid cell tumor NOS	+	(+)

Other Disorder		
Idiopathic hirsutism	+	–

A. SOLID ± CYSTIC
   1. Sertoli-Leydig cell tumor

B. SOLID
   2. Leydig cell tumor

uncommon: metastasis, teratoma, choriocarcinoma, Sertoli cell tumor

OVARIAN TUMOR WITH HYPERESTROGENISM

- sexual precocity in premenarchal girls
- irregular excessive uterine bleeding

A. CYSTIC
   1. Granulosa cell tumor
   2. Mucinous cystadenoma

B. SOLID
   3. Thecoma

uncommon: stromal luteoma, choriocarcinoma, teratoma, Brenner tumor

OTHER FUNCTIONING OVARIAN TUMORS

- increased hCG levels: choriocarcinoma
- hyperthyroidism: struma ovarii
- carcinoid syndrome: carcinoid tumor
- Cushing syndrome: steroid cell tumor

- hypoglycemia: fibroma, dysgerminoma, carcinoid

FALLOPIAN TUBE

Fallopian Tube Disease outside Pregnancy

1. Pelvic inflammatory disease
2. Atypical tubal infection: tuberculosis, actinomycosis
3. Torsion of fallopian tube
4. Endometriosis
5. Primary fallopian tube tumor
   - › hydatid cyst of Morgagni
   - › leiomyoma
   - › fallopian tube cancer

Proximal Fallopian Tube Obstruction

1. Extensive fibrosis / salpingitis isthmica nodosa (40%)
2. Amorphous debris / minimal adhesions (40%)
3. Tubal spasm (20%)

UTERUS

Prepubertal Vaginal Bleeding

1. Vaginal foreign body
   Prevalence: in 18% of children with vaginal bleeding + discharge; in 50% of children with vaginal bleeding + no discharge
2. Vaginal rhabdomyosarcoma
3. Precocious puberty
4. Hemangioma
5. Vascular malformation

Postmenopausal Uterine Bleeding

1. Endometrial atrophy (in 60–75%)
   - thin atrophic endometrium prone to superficial ulceration
   - √ in 75% endometrial thickness < 4–5 mm
     - ◊ Patient may forego endometrial biopsy!
   - √ in 25% endometrial thickness of 6–15 mm
2. Endometrial hyperplasia
3. **Endometrial polyp**
4. Submucosal fibroid
   - √ hypoechoic mass with an overlying normal echogenic endometrium
   - √ ± acoustic attenuation
   - √ ± prolapse into endometrial cavity

   Rx: can be removed at hysteroscopy if > 50% of mass projects into endometrial cavity
5. Adenomyoma
   - √ indistinguishable from submucosal fibroid

6. Endometrial carcinoma (in 7–20%)
7. Estrogen withdrawal

Optimal time of imaging:
immediately after cessation of bleeding when endometrium is presumed to be thinnest

Rx: any focal / generalized thickness > 5 mm at transvaginal US requires further investigation (sonohysterography, guided biopsy, hysteroscopy)

Postpartum Hemorrhage (PPH)

= blood loss sufficient to cause symptoms of hypovolemia
- tachycardia, hypotension, oliguria

= blood loss > 500 mL after vaginal birth / > 1,000 mL after cesarean delivery

Physiology: bleeding decreases over 1st postpartum week

Incidence: 3.3% in developed countries

Classification:

(a) **Primary PPH** = early postpartum hemorrhage > 500 mL within 24 hours in 4–6% of all deliveries

Cause: uterine atony (75%–90%), laceration of lower genital tract, bladder flap hematoma, uterine rupture, acute uterine inversion

(b) **Secondary PPH** = late postpartum hemorrhage between 24 hours and 6 weeks in 1–2% of all deliveries

Cause: endometritis, retained products

DDx: endometritis, uterine dehiscence / perforation, subinvolution of placental implantation site

Increased risk: maternal age > 35 years, primipara, previous C-section, previous postpartum hemorrhage, prolonged labor, multiple pregnancy, fibroids, placental abruption, placenta previa / accreta, instrument delivery, prophylactic uterorelaxant drug therapy

mnemonic: 4 Ts **T**onus, **T**issue, **T**rauma, **T**hrombin

1. **Uterine atony** (75–90% of 1° PPH)

= generalized ineffective contraction of uterine corpus with bleeding at placental site

Risk factors: uterine overdistension (multiple pregnancy, macrosomia, polyhydramnios), labor related factors (prolonged labor, precipitate labor, induction of labor, forceps delivery, prolonged use of oxytocin, use of uterorelaxant drug)

- hemorrhage in immediate postpartum period
- pliable uncontracted uterus

√ normal uterus

DDx: normal postpartum findings
- √ small amount of fluid / blood in uterine cavity
- √ intrauterine gas (up to 3 weeks post partum)
- √ prominent intramural + parametrial vessels
- √ focal thinning of myometrial wall (after C-section) + small hematoma / seroma

Rx: medical Rx; internal uterine balloon tamponade; selective embolization of uterine arteries (gelatin sponge particles); uterine compression sutures; vascular ligation

2. Retained products of conception (most frequent cause of secondary PPH)
3. Lower genital tract trauma (2–4% of all PPH)

√ paravaginal hematoma (coronal reconstruction!)
Risk factors: primipara, macrosomia, multiple pregnancy, prolonged dilatation, vulvovaginal varices, preclampsia, coagulation disorder, instrumental vaginal delivery
Bleeding source: episiotomy (cervical, vulvar, perineal tear), vaginal laceration
(a) infralevator extension: spread to vulva, perineum, ischiorectal fossa
• diagnosis by inspection + vaginal bleeding
Rx: transvaginal drainage
(b) supralevator extension: upward spread through broad ligament + retroperitoneal space
• NO obvious vaginal bleeding → delay in diagnosis
• abdominal pain, hypovolemic shock
√ bladder flap hematoma
= fluid-attenuation collection in extraperitoneal space between posterior bladder wall + anterior wall of lower uterine segment
bladder flap = dissection of urinary bladder from lower uterine segment during cesarean section to allow spontaneous descent of bladder

4. Coagulation disorder (acquired / congenital)

Diffusely Thickened Irregular Endometrium

Normal endometrial thickness:
Sensitivity for detection of endometrial abnormalities: 80% for transvaginal US; 30% for endometrial biopsy
Time of sonohysterography: day 4, 5, or 6 of menstrual cycle

1. **Endometrial hyperplasia**
Age: peri- / postmenopausal women
Cause: prolonged endogenous / exogenous unopposed estrogen stimulation
√ focal / diffuse endometrial thickening > 5–6 mm
√ formation of polyps of up to 5 cm
Types:
(a) glandular-cystic hyperplasia (most common)
Histo: dilated glands lined by tall columnar / cuboidal epithelium
√ small cysts within evenly echogenic endometrium
Prognosis: NO premalignant condition
(b) adenomatous hyperplasia
√ endometrium with irregular hypoechoic areas
Prognosis: precursor of endometrial cancer
2. Secretory endometrium
◊ Improve timing of the examination!
3. Endometrial cancer
4. Endometritis
5. **Tamoxifen-related endometrial changes**
= nonsteroidal antiestrogen in breast acts as a weak estrogen agonist → proliferative effects on endometrium
Increased prevalence of: endometrial hyperplasia, polyps, carcinoma

◊ 50% of women treated with tamoxifen will develop endometrial abnormalities within 6–36 months

Histo:

(a) endometrial thickness increased to 10.4 mm; 4.2 mm in control subjects
(b) polyps (36%); 10% in control subjects
(c) atrophic changes (28%); 87% in control subjects

• hemorrhage (requires further evaluation)

√ endometrial thickening > 5–9 mm:

√ endometrial hyperplasia
√ endometrial polyp
√ subendometrial cystic changes (= glandular distension within a polyp / reactivated adenomyosis within inner myometrium)

MR:

√ endometrial-myometrial interface ← endometrial atrophy / proliferative changes:

√ homogeneously hyperintense on T2WI
√ signal void + enhancement on T1WI

√ polyps:

√ heterogeneous intensity on T2WI
√ latticelike enhancement traversing endometrial canal on T1WI

Focally Thickened Endometrium

1. **Endometrial polyp**

= focal hyperplasia of stratum basale; in 20% multiple

Age: mainly 30–60 years

Histo: projections of endometrial glands + stroma into uterine cavity

(a) hyperplastic polyp resembling endometrial hyperplasia
(b) functional polyp resembling surrounding endometrium (least frequent)
(c) atrophic polyp

Frequently associated with: tamoxifen therapy

US:

√ sessile broad-based / pedunculated well-defined smooth hyperechoic homogeneous intracavitary mass (79%) / of variable echogenicity (best seen on sonohysterography):

√ cystic spaces (in 59%) ← enlarged dilated glands filled with proteinaceous fluid
√ heterogeneous texture ← suggestive of infarction, inflammation, hemorrhage
√ vessel visualized within stalk on color Doppler

Malignant transformation: in 0.4–3.7%

2. Primary carcinoma of the endometrium

Risk factors: exposure to unopposed estrogen, obesity, nulliparity, hypertension, diabetes

Location: predominantly in uterine fundus; 24% in isthmic portion)

◊ 10% cancer rate with endometrial thickness of 6–15 mm
◊ 50% cancer rate with endometrial thickness of > 15 mm

√ irregular heterogeneous endometrium > 5 mm in thickness
√ focal / diffuse endometrial thickening (mean thickness of 18.2 mm)
√ irregular poorly defined endometrial-myometrial interface

√ increased echogenicity in myometrium (= invasive endometrial cancer)
√ Doppler waveforms with resistive index < 0.7 suggest malignancy

3. Metastatic carcinoma: ovary, cervix, fallopian tube, leukemia
4. Hydatidiform mole
   √ echogenic mass with irregular sonolucent areas
5. Incomplete abortion
6. Submucosal leiomyoma
   √ mass hypo- / hyperechoic relative to myometrium
   √ wide attachment to myometrium
   √ intracavitary margin outlined by echogenic rim of endometrium
   √ ± acoustic attenuation
   Rx: hysteroscopic removal if > 50% of mass projects into endometrial cavity
7. Focal adenomyoma
   √ hypoechoic mass with an overlying echogenic endometrium
   DDx: indistinguishable from submucosal fibroid
8. Intrauterine synechiae
   √ echogenic bands extending from one endometrial surface to the other

DDx: adherent blood clots

Fluid Collection within Endometrial Canal

Types: blood, mucus, purulent material

A. PREMENOPAUSAL
   1. Infection: endometritis, pyometrium
   2. Congenital obstructive lesion: imperforate hymen, vaginal septum, vaginal / cervical atresia
   3. Acquired obstructive lesion: cervical stenosis (following instrumentation / cone biopsy / radiation), cervical carcinoma
   4. Spontaneous hematometra in bleeding disorders
   5. Pregnancy: intrauterine, ectopic, incomplete abortion
   6. Endometrial cancer
   7. Endometrial polyp, submucosal fibroid
   8. Functional: during menstruation

B. POSTMENOPAUSAL
   1. Endometrial / cervical cancer
   2. Cervical stenosis
   3. Normal if amount small

Endometrial Cysts

1. Endometrial cystic atrophy
   Histo: cystically dilated atrophic glands lined by single layer of flattened / low cuboidal epithelium
   √ very thin endometrium of < 4–5 mm
2. Endometrial cystic hyperplasia

Diffuse Uterine Enlargement

1. Diffuse leiomyomatosis
2. Adenomyosis
3. Endometrial carcinoma (15%)

Uterine Mass

A. BENIGN
   1. Uterine fibroids (99%)
   2. Pyometra
   3. Hemato- / hydrocolpos
   4. Transient uterine contraction: during pregnancy
   5. Bicornuate uterus
   6. Adenomyosis
   7. Intrauterine pregnancy
   8. Lipoleiomyoma (< 50 cases in world literature)

B. MALIGNANT
   1. Cervical carcinoma
   2. Endometrial carcinoma
   3. Leiomyosarcoma
   4. Invasive trophoblastic disease

CERVIX

Congenital Cervical Anomaly

1. Septate uterus (34–55%)
2. Duplication of cervix: uterus didelphys, septate uterus, bicornuate uterus
   √ 2 endocervical canals usually divided by thicker plane of tissue than with a cervical septum
3. Cervical agenesis = blind-ending vagina often with complete absence of uterus / rudimentary uterine tissue
   √ evaluate for concurrent renal anomalies (30–50%)

Cervical Mass

1. Fibroid
2. Cervical carcinoma
3. Endocervical polyp
4. Nabothian cyst
5. Cervical leiomyoma
6. Endometriosis

Use of transducer pressure may show lesion mobility if a lesion is in the endocervical canal (pedunculated intracavitary myoma / polyp). Lesions arising from the cervical stroma will remain fixed in position with transducer pressure.

Cervical Stenosis

= obliteration + obstruction of endocervical canal
= inability to insert a 2.5-mm wide dilator

A. CONGENITAL
   1. Transverse vaginal septum in uterus didelphys
   2. Congenital absence of cervix
B. ACQUIRED
   1. Cervical carcinoma: postmenopausal
   2. Endometrial cancer: premenopausal
   3. Benign masses: polyp, fibroid
   4. S/P radiation treatment
   5. S/P surgery, endocervical curettage, cone biopsy

• obstruction to menstrual flow → amenorrhea, dysmenorrhea
√ distension of endometrial cavity by secretions + blood products
√ narrowing of endocervical canal < 5 mm by HSG preventing insertion of HSG catheter
Cx: reflux endometriosis

VAGINA

Vaginal Cyst

1. Gartner duct cyst (above pubic symphysis)
2. Bartholin gland cyst (below pubic symphysis)
3. Skene duct cyst
4. **Müllerian / paramesonephric duct cyst**
   = aberrant embryologic remnant of paramesonephric duct
   Histo: mucinous pseudostratified columnar epithelium
   Location: anterolateral wall of vagina near cervix
5. **Epithelial inclusion cyst**
   = arise from urogenital sinus
   Histo: lined by transitional epithelium containing thick caseous material
6. **Epidermal / vaginal inclusion cyst**
   Cause: prior trauma / surgery
   Histo: stratified squamous epithelium
   Location: posterior / lateral wall of vagina

Vaginal Fistula

1. Enterovaginal fistula:
   (a) rectovaginal: incomplete healing of perineal laceration ← obstetric trauma, radiation therapy
   (b) anovaginal: inflammatory bowel disease (10% of patients with Crohn disease)
   (c) colovaginal: diverticulitis
2. Vesicovaginal fistula: hysterectomy, radiation therapy
3. Ureterovaginal fistula: vaginal hysterectomy

Vaginal & Paravaginal Neoplasm

A. PRIMARY benign
   1. Cavernous hemangioma of vulva
   2. Pedunculated submucosal leiomyoma prolapsed into vagina

B. Primary malignant
Frequency: 1–2% of all gynecologic malignancies; 20% of all vaginal malignancies

Cystic Lesions of Female Lower Genitourinary Tract			
Lesion	*Location*		*relative to pubic symphysis*
Skene duct cyst	urethral orifice	anterior vaginal introitus	inferior
Bartholin cyst	vaginal introitus	medial to labia minora	inferior
Gartner duct cyst	upper vagina	anterolateral wall	superior
Urethral diverticulum	midurethra	posterolateral margin	superior

1. Vaginal carcinoma
   (a) squamous cell carcinoma (90%)
   Associated with: human papilloma virus
   (b) adenocarcinoma (9%)
2. Melanoma (3%)
3. Sarcoma (1%): rhabdomyosarcoma
4. Adenoid cystic carcinoma of Bartholin gland

C. SECONDARY MALIGNANT
Frequency: 80% of all vaginal malignancies
← direct extension from bladder, rectum, cervix, uterus

HYSTEROSALPINGOGRAPHY

Fundic Depression on HSG

A. with normal outer contour
   1. Septate uterus
   2. Arcuate uterus
B. with abnormal outer contour
   1. Bicornuate uterus
   2. Fundal myoma

Filling Defect on HSG

1. Synechia
2. Endometrial polyp
3. Submucosal myoma
4. Uterine folds = parallel to long axis of uterus
5. Air bubbles

Abnormal Uterine Contour on HSG

1. Submucosal myoma
2. Adenomyosis

3. Trauma: cesarean section, myomectomy

GAS IN GENITAL TRACT

A. UTERUS
   1. Endometritis
   2. Superinfection of leiomyoma: more common in submucosal leiomyoma (insufficient blood supply)
   3. Bacterial metabolism of necrotic neoplastic tissue
   4. Fistula to GI tract: uterine cancer
   5. Pyometra ← obstruction by cervical cancer
   6. Gas gangrene ← clostridial infection from septic abortion

B. OVARY
   1. Superinfected ovarian neoplasm

C. VAGINA
   1. **Vaginitis emphysematosa**
      = nonbacterial self-limiting process mostly occurring during pregnancy characterized by numerous gas-filled spaces in submucosa of vagina + exocervix

ANATOMY AND PHYSIOLOGY OF THE FEMALE REPRO DUCTIVE SYSTEM

HUMAN CHORIONIC GONADOTROPIN

= hCG = glycoprotein elaborated by placental trophoblastic cells beginning the 8th day after conception

Immunologic Pregnancy Test

= indirect agglutination test for hCG in urine; cross-reaction with other hormones / medications possible

• becomes positive at 5 weeks MA

Advantages: readily available, easily + rapidly performed

Disadvantages: frequently false-positive + false-negative results

Sensitivity:

(a) slide: 400–15,000 mIU/mL (2-minute test time)

(b) test tube: 1,000–3,000 mIU/mL (2-hour test time)

Radioimmunoassay (RIA) Pregnancy Test

= measures beta subunit of hCG in serum with a sensitivity as low as 1–2 mIU/mL

◊ Serum β-hCG becomes positive at 3–4 weeks MA / 7–10 days following conception!

Standards:

(1) Second International Standard (SIS)

(2) International Reference Preparation (IRP)

(3) Third International Standard (TIS)

1 mIU/mL (SIS) = 2 mIU/mL (IRP) = 2 mIU/mL (TIS)

1 ng/mL = 5–6 mIU/mL (SIS)

= 10–12 mIU/mL (IRP or TIS)

◊ Variations of lab values of up to 50% can occur among different laboratories!

◊ 6–15% between-run precision!

Advantages: specific for hCG, sensitive

◊ Highly specific + sensitive for pregnancy

Disadvantages: requires specialized lab and 3–24 hours for completion

Sensitivity:

(a) qualitative: 25–30 mIU/mL (3-hour test time)

(b) quantitative: 3–4 mIU/mL (24-hour test time)

Rise:

> 66% increase of initial β-hCG level over 48 hours in 86% of NORMAL pregnancies

< 66% increase of initial β-hCG level over 48 hours in 87% of ECTOPIC pregnancies

◊ β-hCG levels double every 2 days during first 60 days of a NORMAL pregnancy!

"1–7–11 Rule"		
β–*hCG (IRP)*	*US Landmarks*	*Gestational Age*
1,000 mIU/mL	gestational sac	32 d (4.5 weeks)
7,200 mIU/mL	yolk sac	36 d (5.0 weeks)
10,800 mIU/mL	embryo + heart motion	40 d (6.0 weeks)

FOLLICLE-STIMULATING HORMONE (FSH)

Action: influence on (1) number of follicles, (2) development of ovarian cysts, (3) size of ovaries

Physiology: rises abruptly at birth ← decrease in estrogen + progesterone after loss of placenta; falls to low levels after 3 months of age; remains low until puberty

ANATOMY OF GESTATION

Choriodecidua

Chorion

[*chorion*, Greek = skin, leather]

= trophoblast + fetal mesenchyme with villous stems protruding into decidua; provides nutrition for developing embryo

(a) chorion **frondosum** = part adjacent to decidua basalis, forms primordial placenta [*frondosus* , Latin = foliage]

(b) chorion **laeve** = smooth portion of chorion with atrophied villi

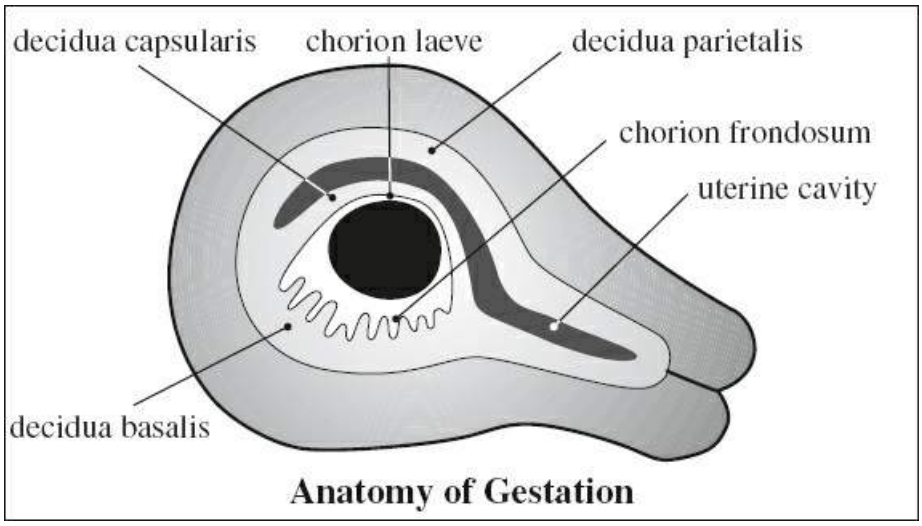
(c) "chorionic plate" = amnionic membrane covering the chorionic plate of the placenta

Decidua

(a) decidua basalis = between chorion frondosum + myometrium

(b) decidua capsularis = portion protruding into uterine cavity

(c) decidua parietalis = decidua vera = portion lining the uterine cavity elsewhere



Anatomy of Gestation

Gestational Sac (GS)

Origin: arises from blastocyst, which implants into secretory endometrium 6–9 days after ovulation (= 20–23 days of MA), surrounded by echogenic trophoblast

◊ GS measures 0.1 mm at time of implantation

√ **"intradecidual" sign** (earliest sign: 48% sensitive, 66% specific, 45% accurate at < 5 weeks GA) = eccentrically located fluid collection corresponding to gestational sac completely embedded within an echogenic decidua adjacent to a thin echogenic line (= collapsed uterine cavity) = highly suggestive for IUP

A nonspecific fluid collection with a smooth spherical / oval contour represents an IUP until proven otherwise!

√ **"double (decidual) sac" sign** (DDS) [most useful > 5 weeks GA with a mean sac diameter of 10 mm / 40 days GA] = 2 concentric hyperechoic rings surrounding a portion of the gestational sac + bulging into uterine cavity (delineated by a thin crescent of endometrial fluid) = ***definitive IUP***

(a) outer echogenic ring (= decidua parietalis)

(b) inner echogenic ring (= decidua capsularis)

√ GS surrounded by endometrial thickening > 12 mm

√ continuous hyperechoic inner rim > 2 mm thick

√ GS of spherical / ovoid shape without angulations

√ interposed hypoechoic line (apposed endometrial walls)

√ DDS present with a mean sac diameter of 10 mm (= 40 days GA)

◊ A "double decidual sac" sign correlates with the presence of a pregnancy in 98%!

◊ Absence of these 2 signs (in 35%) does not exclude an IUP

Gestational Sac Size

= average of 2–3 diameters (craniocaudad, AP, TRV) of rounded intrauterine anechoic (fluid) space within sac walls

◊ Used for dating between 6 and 12 weeks MA (identified as early as 4.5–5.0 weeks MA on transabdominal scan)

EGA [in wk] = (GS [in mm] + 25.43) ÷ 7.02

Accuracy: ± 7 days

Growth rate of mean sac diameter (MSD):

1.13 (range 0.71–1.75) mm per day (often variable)

Linear growth: 10 mm by 5th week MA

60 mm by 12th week MA

fills chorionic cavity by 11th–12th week MA

An MSD cutoff of 25 mm WITHOUT an embryo is a criterion for definitive pregnancy failure;
An MSD range of 16–24 mm WITHOUT an embryo is an indicator of suspicion of pregnancy failure.

Visualization of Gestational Sac

Earliest visualization: mean sac diameter of 2–3 mm

A. GS VISUALIZATION VERSUS β-hCG LEVEL (2nd International Standard):

(a) on transabdominal scan:

in 100% with β-hCG levels of > 1,800 IU/L

(b) on transvaginal scan:

in 20% with β-hCG levels of < 500 IU/L

in 80% with β-hCG levels of 500–1,000 IU/L

in 100% with β-hCG levels of > 1,000 IU/L

B. GS VISUALIZATION VERSUS MENSTRUAL AGE

5.0 ± 1 weeks = 10 mm

5.5 ± 1 weeks = 13 mm

6.0 ± 1 weeks = 17 mm

6.5 ± 1 weeks = 20 mm

C. GS VISUALIZATION VERSUS EMBRYO

Secondary Yolk Sac

= rounded sonolucent structure (outside amniotic cavity) within chorionic sac (= extracoelomic cavity) connected to umbilicus via a narrow stalk; formed by proliferation of endodermal cells; part of yolk sac is incorporated into fetal gut; the rest persists as sac connected to fetus by vitelline duct

Function:

(a) transfer of nutrients from trophoblast to embryo prior to functioning placental circulation

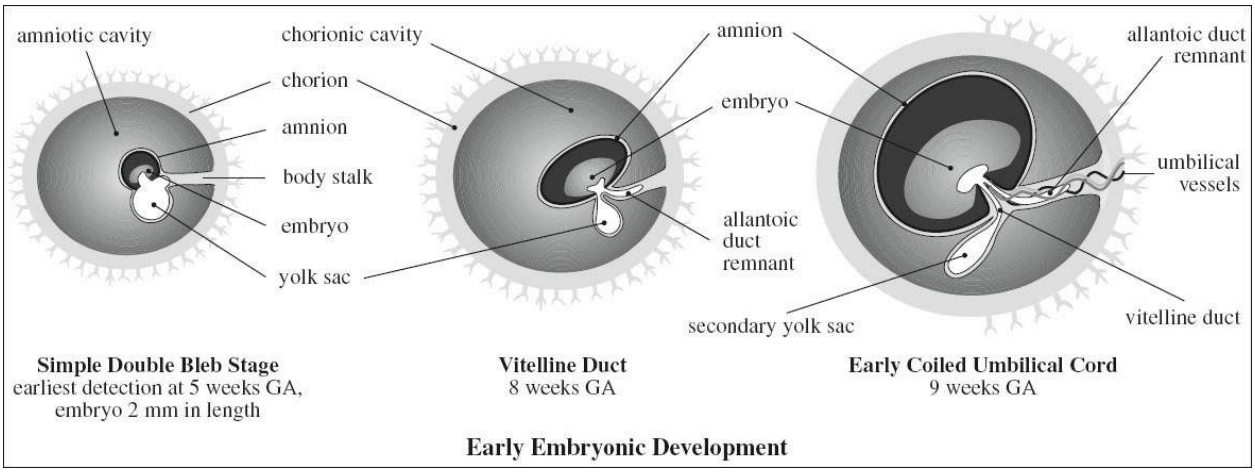
(b) early formation of blood vessels + blood precursors on sac wall

(c) formation of primitive gut

(d) source of primordial germ cells

Time of formation: at around 28 days MA

Mean size: 1.0 mm by 4.7 weeks MA; 2.0 mm by 5.6 weeks MA; 3.0 mm by 7.1 weeks MA; 4.0 (2.2–5.3) mm by 10 weeks MA; disappears around 12 weeks MA



Early Embryonic Development

◊ First visible structure within gestational sac = ***confirms IUP***

√ eccentrically located within gestational sac (inside chorionic cavity)

Definite visualization on transvaginal scan:

√ at 5.5 weeks MA

√ inside GS with a mean sac diameter of ≥ 8 mm

Definite visualization on transabdominal scan:

√ at 7 weeks MA

√ inside GS with a mean diameter of ≥ 20 mm

Embryo

Developmental stages:

Preembryonic period: 2nd–4th week MA

Trilaminar embryonic disk: during 5th week MA

Embryonic period: 6th–10th week MA

Physiologic umbilical herniation: 8th–12th week MA

Fetal period: early 11th week MA

Average growth rate:

0.7 mm per day / 1.5 mm every 2 days

√ curvilinear growth from 7 mm at 6.3 weeks MA → to 50 mm at 12.0 weeks MA

Earliest visualization (on endovaginal scan):

at 5.4 weeks MA at CRL of 1.2 mm

√ eccentrically located at periphery of yolk sac (inside amniotic cavity)

◊ Most accurate measurement of GA in 1st trimester!

VISUALIZATION OF EMBRYO VERSUS GS

(a) on transabdominal scan
100% visualization if gestational sac ≥ 27 mm

(b) on transvaginal scan
100% visualization if gestational sac ≥ 12 mm

◊ Transvaginal scan not necessary if on transabdominal scan gestational sac > 27 mm without evidence of embryo!

Failed pregnancy: nonvisualization of embryo with mean gestational sac size of ≥ 18 mm

Cardiac Activity of Embryo

◊ Heart begins to contract at a CRL of 1.5–3.0 mm = 22 days GA = 36 days MA

√ absence of cardiac activity in embryos < 4 mm may be normal

Definite visualization on endovaginal scan:

(a) at 46 days GA

(b) at mean sac diameter of 16 mm

(c) with CRL ≥ 5 mm = 6.2 weeks

A 7-mm CRL is necessary to yield a specificity and positive predictive value of **100%** → decreasing false-positive diagnosis associated with a 5-mm CRL cutoff.

Definite visualization on transabdominal scan:

(a) at 55 days GA

(b) mean sac diameter of 25 mm

Heart rate:

at 5-6 weeks GA 101 bpm

at 8-9 weeks GA 143 bpm

Gastrulation (2nd–4th week GA)

[*gaster*, Latin = stomach; *-ula*, Latin = diminutive suffix]

= transformation of bilaminar disk into trilaminar embryo

Stages:

› bilaminar embryo develops an **epiblast** (= layer facing amniotic cavity) + **hypoblast** (= layer facing yolk sac)

› disk forms a **mesoderm** "sandwich" bordered above by **ectoderm** + below by **endoderm**

› at both ends where embryonic ectoderm and endoderm meet are cranially the **oropharyngeal membrane** (= future mouth) + caudally the **cloacal membrane** (= future urogenital and anal orifices)

› craniocaudal + lateral folding converts the flat trilaminar embryonic disk into a **gut tube** within a **body tube**

› lateral edges of somatic mesoderm move ventrally toward each other creating a **coelomic space** (= future peritoneal cavity) that separates gut from body tube (GI tract from **primary abdominal wall**)

› myoblasts migrate into primary abdominal wall forming muscles and connective tissue

› the **cloaca** (= common chamber at caudal end) forms as precursor to the intestinal + urinary + genital tracts

› a ventral diverticulum (= allantois) projects from the cloaca into the connecting stalk (= **body stalk**) attaching the embryo to the chorionic mesoderm

Amnionic Membrane

= curvilinear echogenic line within chorionic sac; fills chorionic cavity by 11–12 weeks MA ← onset of fetal urine production at about 10 weeks

Fusion:

› fuses with chorionic membrane at 14–16 weeks MA to form the chorionic plate

› incomplete fusion with chorion frequent
(DDx: subchorionic hemorrhage, twin abortion, coexistent with limb-body wall complex)

Umbilical Cord

Function: communication between placenta and fetus allowing exchange of gas and nutrients

Embryology:

› cord forms between 7th–8th week post conception with contributions from body stalk, omphalomesenteric or vitelline duct, yolk sac, allantois

› junction of the amnion with ventral surface of embryo forms umbilicus

› allantoic vessels establish continuity with placental villi and form the vessels of the umbilical cord

› allantois / urachus develops as 2nd outpouching from primitive gut 12–16 weeks GA and projects into connecting stalk

› physiologic midgut herniation into base of umbilical cord at ~ 7–12 weeks (returns by end of 11th week GA)

› cord grows until end of 2nd trimester: average diameter of 17 mm, length of 50–60 cm

Anatomy:

› 2 umbilical arteries (= branches of the 2 internal iliac arteries) + 2 umbilical veins by 6 weeks GA
Function: deoxygenated blood from fetus to placenta
› one umbilical vein (remains after regression of right umbilical vein by 8 weeks GA) → connects to left portal vein → fissure for ligamentum venosum after birth
Function: oxygenated blood from placenta to fetus
› covered with unique compressible matrix of mucopolysaccharide-rich substance = Wharton jelly
› covered by amnion
› spiraling of cord with 0–40 helical turns (L > R) by 9 weeks
◊ coiling adds strength + resists compression of vessels
◊ normal cord length + coiling requires adequate fluid space and fetal activity

Cord thickness: 1–2 cm in diameter

(a) "lean" umbilical cord = cross-sectional area of cord measuring below 10th percentile for GA
Associated with: increased prevalence of fetal IUGR, oligohydramnios, fetal distress during delivery

(b) "fat" umbilical cord
Associated with: mothers with diabetes, fetus with aneuploidy

Umbilical coiling index (UCI):
= number of cord spirals completed per cm of cord length

(a) hypocoiled cord (UCI ≤ 0.29 / < 10th percentile)
Associated with:
increased rate of IUGR, fetal demise, intrapartum fetal heart rate decelerations, fetal distress at delivery, karyotype abnormalities, higher rate of abnormal cord insertion

(b) hypercoiled cord (UCI ≥ 0.6 / > 90th percentile)
Associated with:
increased rate of fetal IUGR, intrapartum fetal cardiac decelerations, vascular thrombosis, cord stenosis

PLACENTA

[*plakuos* , Greek = flat cake]

(a) fetal portion
1. Villi of chorion frondosum
contain arterial plexuses supplied by umbilical artery and protrude into intervillous space bathing in maternal blood

(b) maternal portion
2. Decidua placentalis: lines intervillous space

Imaging of Normal Placenta

CT:
@ 1st trimester
√ placenta indistinguishable from myometrium
@ 2nd trimester

√ hyperattenuating relative to subjacent myometrium following enhancement
√ rounded hypoattenuating foci surrounded by enhancing placenta = placental cotyledons

@ 3rd trimester
√ increased heterogeneity of normal placenta and visualization of venous lakes

Variant Morphology of Placenta

A. Additional lobes

1. **Succenturiate lobe of placenta**
   = ACCESSORY LOBE
   = single / multiple separate additional lobe(s) separate from but connected to main placenta by fetal blood vessels within membrane
   Prevalence: 0.14–3.00%
   Cause: placental villi atrophy in area of inadequate blood supply → proliferate in two opposite directions (**trophotropism**) with fetal vessels remaining at the site of villous atrophy
   Cx: (1) Retention of accessory lobe in utero → postpartum hemorrhage
   (2) Placenta previa (= implantation over cervical os) → intrapartum hemorrhage
   (3) Vasa previa (= connecting succenturiate vessels traversing internal os) may rupture → fetal blood loss
2. **Bilobed placenta**
   = 2 placentas of relative same size connected by a thin bridge of placental tissue
   Risk: none

B. **Placenta extrachorialis**
   = chorionic plate smaller than basal plate; ie, the transition of membranous to villous chorion occurs at a distance from the placental edge that is smaller than the basal plate radius

1. **Circummarginate placenta**
   Frequency: up to 20% of placentas
   Risk: no clinical significance
   √ fetal membranes form a flat ring at site of attachment to chorionic plate
   √ placental margin not deformed
2. **Circumvallate placenta**
   = attachment of fetal membranes form a folded thickened ring with underlying fibrin + often hemorrhage
   Prevalence: 1–2% of pregnancies
   Risk: premature labor, threatened abortion, increased perinatal mortality, abruption, marginal hemorrhage

C. **Placenta membranacea**
   = thin membranous placenta circumferentially occupying the entire periphery of chorion + presence of well-vascularized placental villi in the peripheral membranes ← failure of regression
   Cause: ? endometritis, endometrial hyperplasia, extensive vascularization of decidua

capsularis, previous endometrial damage by curettage

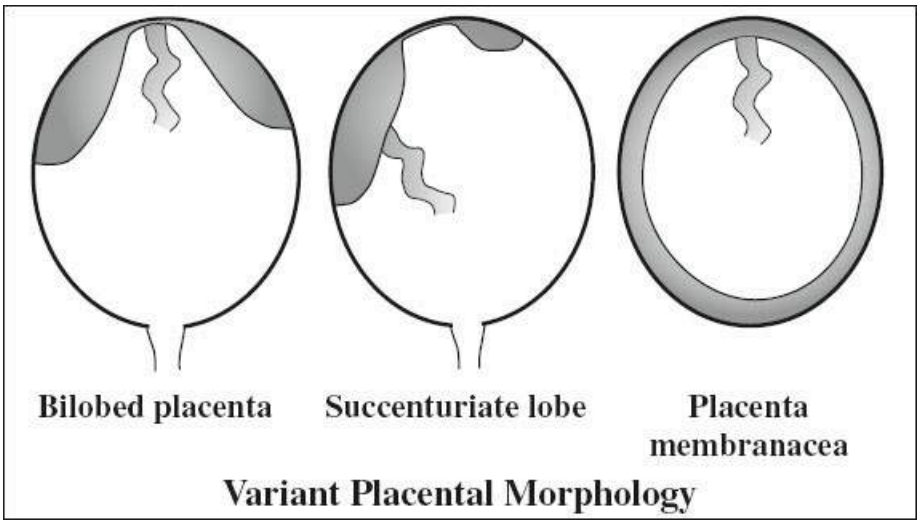
Risk: repeated vaginal bleeding extending into 2nd trimester; abortion at 20–30 weeks; postpartum hemorrhage

√ thickened outline over whole gestational sac (0.2–3.0 cm)

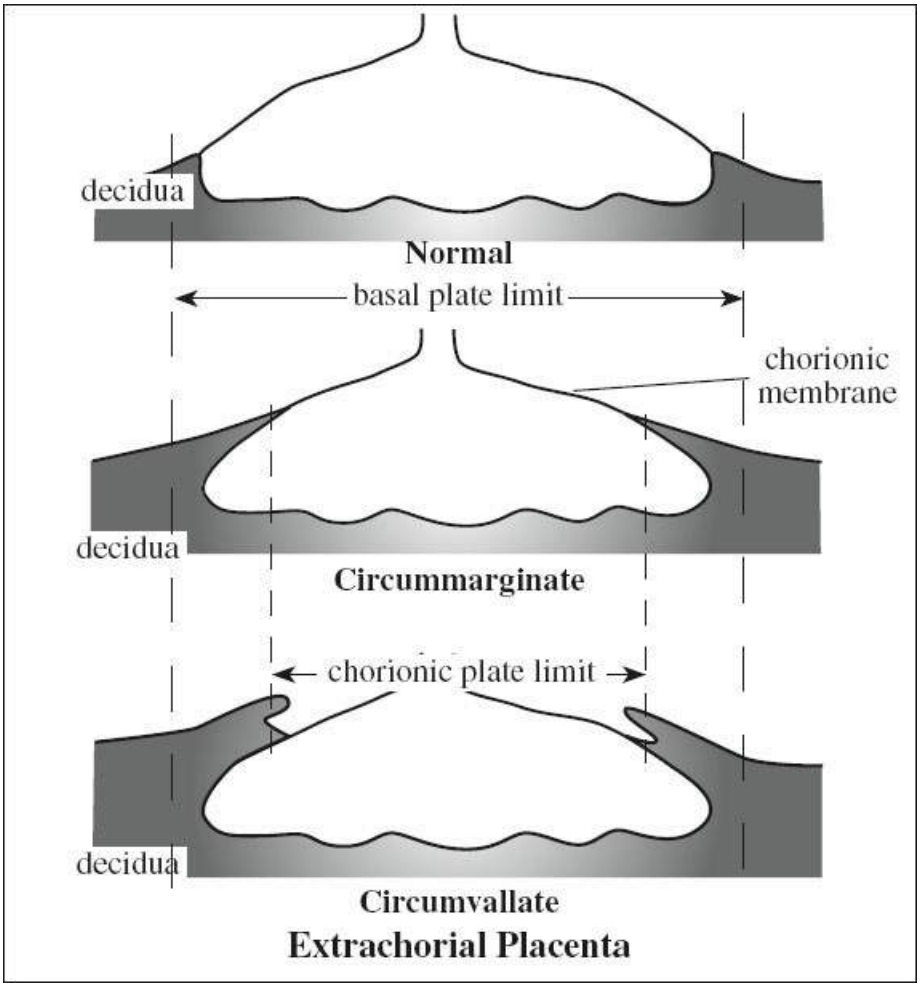
√ may show additional distinct disk of placenta

Placental Grading

= grading according to echo appearance of basal zone, chorionic plate, placental substance



Variant Placental Morphology



◊ Premature placental calcifications are associated with cigarette smoking, hypertension, IUGR!

◊ Not considered useful because placental grading is imprecise for fetal dating or for fetal lung maturity!

GRADE 0

√ homogeneous placenta + straight line of chorionic plate

Time: < 30 weeks MA

GRADE 1

√ undulated chorionic plate + scattered bright placental echoes

Time: seen at any time during pregnancy; in 40% at term

◊ in 68% L/S (lecithin-sphingomyelin) ratio > 2.0

GRADE 2

√ linear bright echoes parallel to basal plate

√ confluent stippled echoes within placenta ± indentations of chorionic plate

Time: rarely seen in gestations < 32 weeks MA and in 40% at term

◊ in 87% L/S ratio > 2.0

GRADE 3

√ calcified intercotyledonary septa, often surrounding sonolucent center

Time: rarely seen in gestations < 34 weeks MA;
in 15–20% at term

◊ in 100% L/S ratio > 2.0 (= strongly correlated with lung maturity)

Premature Placental Senescence

= grade 3 placenta seen in gestation < 34 weeks MA

◊ In 50% suggestive of maternal hypertension / IUGR

Uteroplacental Circulation

By 20 weeks MA trophoblast invades maternal vessels and transforms spiral arteries into distended tortuous vessels = uteroplacental arteries

Physiology: maintains fetal pulmonary, hepatic, renal function by exchange of gas, metabolites, nutrients and indirect vascular interaction of fetal with maternal blood

Histo:

(a) in decidual segments of spiral arteries: proliferating trophoblast from anchoring villi invades lumen of spiral arteries + partially replaces endothelium

(b) in myometrial segments of spiral arteries: disintegration of smooth muscle elements → loss of elastic lamina → easily distensible vascular system of low resistance

Uterine Blood Volume Flow

› 50 mL/min shortly after conception

› 500–900 mL/min by term

Intervillous blood flow: 140 ± 53 mL/min (by 133Xe washout)

Umbilical Artery Doppler

Variables affecting Doppler measurements:
site of Doppler (close to placenta preferred), fetal heart rate, fetal breathing, drugs (eg, ritodrine hydrochloride decreases S/D ratio)

√ degree of diastolic flow increases as gestation progresses

› high-resistance flow @ < 20 weeks

› S/D ratio between 3.3 and 4.3 @ ≥ 20 weeks

› S/D ratio between 1.7 and 2.4 @ term

√ highly turbulent flow

IUGR Lesions

= narrowing of vascular lumen through

(a) thrombosis of decidual segments of uteroplacental aa.

(b) failure of development of myometrial segments of uteroplacental arteries

FETAL MENSURATION

◊ US is more reliable than LMP / physical examination!

Ultrasound Milestones

√ gestational sac w/o embryo or yolk sac = 5.0 weeks

√ gestational sac + yolk sac w/o embryo = 5.5 weeks

√ heartbeat ± embryo < 5 mm = 6.0 weeks
Accuracy: ± 0.5 week

Fetal Age

= GESTATIONAL AGE (GA) = "MENSTRUAL AGE" (MA)
= age of pregnancy based on woman's regular last menstrual period (LMP) projecting the estimated date of confinement (EDC) at 40 weeks
◊ Note the inaccurate clinical usage of "gestational age," which strictly speaking refers to the true (histologic) age of the pregnancy counting from the day of conception, whereas "menstrual age" refers to the (clinical) age of the pregnancy accounting for the ~ +2 weeks discrepancy!
◊ On subsequent US scans GA = GA assigned at 1st ultrasound + number of intervening weeks!

Timeline of Normal Early Pregnancy

Time Period [weeks]	*Developmental Milestone*
0	last menstrual period
2	conception
4.5–5.0	gestational sac appears
5.0–5.5	yolk sac appears
6.0	embryo appears, cardiac pulsation > 100 bpm
6.5–7.0	amniotic membrane appears, cardiac pulsation > 120 bpm
7–8	spine develops
8	head curvature separated from body, 4 limb buds appear
8.0–8.5	intrinsic motion of embryo occurs
8–10	rhombencephalon develops

Accuracy of Biometry (95% confidence range)

Stage	*Based on*	*Accuracy [weeks]*
1st trimester		
5–6 weeks	US milestones	±0.5
6–13 weeks	CRL	±0.7
2nd trimester		
14–20 weeks	cBPD / HC	±1.2
	BPD / FL	±1.4
20–26 weeks	cBPD / HC	±1.9
	BPD / FL	±2.1–2.5
3rd trimester		
26–32 weeks	cBPD / HC / FL	±3.1–3.4
	FL	±3.1
32–42 weeks	cBPD / HC / FL	±3.5–3.8
	FL	±3.5

ACCURACY OF CLINICAL ASSESSMENT:
menstrual history ±2–3 weeks
1st-trimester exam ±2 weeks
fundal height ±4 weeks

Early Embryonic Size

= length of embryo < 25 mm on transvaginal scan performed at < 11 weeks MA
Gestational age (days) = embryonic size (mm) + 42
Accuracy: ± 3 days

Crown-Rump Length (CRL)

= length of fetus; useful up to 12 weeks MA (usually identified by 7 weeks MA on transabdominal scan)
Rule of thumb: MA (in weeks) = CRL (in cm) + 6
Accuracy: ± 5–7 days

Biparietal Diameter (BPD)

= measured from leading edge to leading edge of calvarial table at widest transaxial plane of skull = level of thalami + cavum septi pellucidi + sylvian fissures with middle cerebral arteries

◊ Excellent means of estimating GA in 2nd trimester > 12 weeks MA

Accuracy: 2 mm for "between occasion error"
◊ Most accurate for dating if combined with HC, AC, FL provided body ratios are normal!
◊ Less reliable for dating in 3rd trimester because of increasing biologic variability!

Discordant Estimated Date of Confinement (EDC) by LMP and BPD

1. Methodological error in measurement
   (a) wrong axial section
   (b) cranial compression (multiple gestation, breech presentation, oligohydramnios, dolichocephaly)
2. Erroneous LMP
   other measurements (AC, FL) correlate with BPD
3. Abnormal head growth
   (a) BPD < AC: microcephaly, fetal macrosomia
   (b) BPD > AC: intracranial abnormality, asymmetric IUGR

Cephalic Index (CI)

= BPD / OFD; measurements of BPD and occipitofrontal diameter (OFD) both from outer to outer edge of calvarium
◊ Confirms appropriate use of BPD if ratio is between 0.70 and 0.86 (2 SD)

Corrected BPD (cBPD)

= BPD and OFD are used to adjust for variations in head shape

$$cBPD = \sqrt{BPD \times OFD} \div 1.26$$

Head Circumference (HC)

Used if ratio of BPD/OFD outside 0.70–0.86

HC = ([BPD + OFD]/2) x π

= ([BPD + OFD] x 1.62) x 3.1417

Accuracy: slightly less than for BPD

HC too large: hydrocephalus, hydranencephalus, intracranial hemorrhage, short limb dystrophies, tumor

HC too small: anencephaly, cerebral infarction, synostosis, microcephaly vera

Abdominal Circumference (AC)

= measured at level of vascular junction of umbilical vein with left portal vein ("hockey-stick" appearance) where it is equidistant from the lateral walls in a plane perpendicular to long axis of fetus; measured from outer edge to outer edge of soft tissues

◊ Allows evaluation of head-to-body disproportion

◊ Better predictor of fetal weight than BPD

AC too large: GI tract obstructions, obstructive uropathy, ascites, hepatosplenomegaly, congenital nephrosis, abdominal tumor

AC too small: diaphragmatic hernia, omphalocele, gastroschisis, renal agenesis

Femur Length (FL)

= measurement of ossified femoral diaphysis

Error: "flare" at distal end included in measurement (= reflection from cartilaginous condyle)

Thoracic Circumference (TC)

= measured in axial plane of chest, which includes four-chamber view of heart without inclusion of SQ tissue

◊ Linear growth between 16 and 40 weeks similar to AC

Useful age-independent parameter: TC÷AC > 0.80

Estimated Fetal Weight (EFW)

based on measurements of head size (BPD / HC), abdominal size (AD / AC), and femur length (FL)

Accuracy:

body part used	*95% confidence range*
abdomen	± 22%
head + abdomen	± 17–20%
head + abdomen + femur	± 15%

Appearance of Epiphyseal Bone Centers

in 95% of all cases

› distal femoral epiphysis (DFE): > 33 weeks GA

› distal femoral epiphysis (DFE) > 5 mm: > 35 weeks

› proximal tibial epiphysis (PTE): > 35 weeks GA

› proximal humeral epiphysis (PHE): > 38 weeks GA

CNS Ventricles

width of 3rd ventricle: < 3.5 mm (any gestational age)

Diameter of Cisterna Magna

measured from inner margin of occiput to vermis cerebelli: 2–10 mm

ASSESSMENT OF FETAL WELL-BEING

Amniotic Fluid Index

= sum of vertical depths of largest clear amniotic fluid pockets in the 4 uterine quadrants measured in mm

Method: patient supine, uterus viewed as 4 equal quadrants, transducer perpendicular to plane of floor + aligned longitudinally with patient's spine

Variation: 3.1% intraobserver, 6.7% interobserver

Result:

- › 95th percentile: 185 mm at 16 weeks GA, rising to 280 mm at 35 weeks, declining to 190 mm at 42 weeks
- › 5th percentile: 80 mm at 16 weeks GA, rising to 100 mm at 23 weeks, declining to 70 mm at 42 weeks

Biophysical Profile (Platt and Manning) = BPP

= in utero Apgar score = assessment of fetal well-being

Gestational age at entry: 25 weeks MA

Observation period: 30 (occasionally 60) min; ordinarily < 8 min needed; in 2% full 30 min required

A. ACUTE BIOPHYSICAL VARIABLES

◊ Subject to rhythmic variation coincident with sleep-wake cycle!

1. **Fetal breathing movement** (FBM):

   √ ≥ 1 episode of chest + abdominal wall movement for at least 30 seconds (time is arbitrary to avoid confusion with general body movements / maternal respiration)

   stimulated by: glucose, catecholamine, caffeine, prostaglandin synthetase inhibitor

   suppressed by: barbiturates, benzodiazepine, labor, hypoxia, asphyxia, prostaglandin E2

2. **Fetal body movement**:

   √ ≥ 3 discrete movements of limbs / trunk

   Influenced by: glucose, gestational age, time of day, maternal drugs, intrinsic rhythm, labor

3. **Fetal tone**

   upper + lower limbs usually fully flexed with head on chest; least sensitive test parameter

   √ ≥ 1 episode of opening + closing of hand / extension + flexion of limb

B. CHRONIC FETAL CONDITION

4. **Amniotic fluid volume**

   √ at least one pocket ≥ 2 cm in vertical diameter in two perpendicular planes

◊ Avoid inclusion of loops of cord!

BPP Score

for each test: 2 points if normal; 0 points if abnormal

False-negative rate: 0.7÷1,000

◊ The probability of fetal death within a week of a BPP score of 8/8 is 1÷1,000!

Stress Tests

Nonstress Test (NST)

◊ Test needed in less than 5% of cases!

√ reactive fetal heart rate tracing (normal) = at least 4 fetal heart accelerations (> 15 bpm over baseline lasting > 15 seconds) in a 20-minute period subsequent to fetal movement > 34 weeks GA

√ nonreactive (abnormal) fetal heart rate tracing = absence of acceleration in a continuous 40-min observation period

N.B.: no heart accelerations in immaturity, during sleep cycle, with maternal sedative use

Accuracy: false-negative rate of 3.2÷1,000 (if done weekly) or 1.6÷1,000 (if done biweekly); 50% false-positive rate for neonatal morbidity + 80% for neonatal mortality

Results of Biophysical Profile Score
(including NST for a maximum of 10 points)

Score	*Fluid*	*Interpretation*	*Perinatal Mortality*
10		asphyxia rare	0.0%
8	normal	asphyxia rare	<0.1%
8	abnormal	chronic compromise	8.9%
6	normal	equivocal	variable
6	abnormal	asphyxia probable	8.9%
4		asphyxia highly probable	9.1%
2		asphyxia almost certain	12.5%
0		asphyxia certain	60.0%

Contraction Stress Test (CST)

= external monitoring after injection of oxytocin / maternal breast stimulation

√ > 3 uterine contractions in 10-minute period

Accuracy: false-negative rate of 0.4÷1000; 50% false-positive rate

INVASIVE FETAL ASSESSMENT

Amniocentesis

Indications:

(1) Inadequate sonographic fetal anatomic survey ← fetal position / maternal body habitus

(2) Equivocal sonographic findings: eg, abnormal posterior fossa but spinal defect not seen

(3) Experienced sonographer not available
(4) Nonlethal anomaly detected on level I sonogram for which karyotype testing is appropriate

Risk: fetal loss rate generally quoted as 1÷200 (0.5%)

A. FETAL RISK
   1. Spontaneous abortion (0.3–1.5%)
   2. Amniotic fluid leak
   3. Chorioamnionitis
   4. Fetal injury: skin dimple, limb gangrene, porencephalic cyst, hemothorax, spleen laceration, orthopedic abnormality, amniotic band syndrome

B. MATERNAL RISK (rare)
   1. Bowel perforation
   2. Hemorrhage
   3. Isoimmunization

Diagnostic Amniocentesis

1. Genetic studies: karyotype, DNA analysis, biochemical assay
   Timing: early (11–15 weeks), late (15–18 weeks)
2. Neural tube defect: α-fetoprotein, acetylcholinesterase
3. Isoimmunization: Δ-OD 450
4. Fetal lung maturity
5. Intraamniotic infection
6. Confirmation of ruptured membranes

Advantage over CVS:

1. Error rate (< 1% versus 2%)
2. Culture failure rate (0.6% versus 2.2%)
3. Fetal loss rate (0.6–0.8% less)

Therapeutic Amniocentesis

1. Polyhydramnios
2. Twin-twin transfusion syndrome

Technique:

√ avoid fetus, placenta, umbilical cord, uterine contraction, fibroid, large uterine vessel
√ use continuous ultrasound guidance
√ inject 2–5 mL of indigo carmine dye in first sac of twin (colorless fluid assures that second sac has been entered)

Chorionic Villus Sampling (CVS)

= aspiration of cells from chorion frondosum for genetic studies (karyotype, DNA analysis, biochemical assay)

◊ Transabdominal CVS for rapid karyotyping in 2nd + 3rd trimester = placental biopsy

Advantage: > 2 weeks earlier results compared with amniocentesis

Timing: 9–11 weeks

Approach:

(a) transcervical route = catheter introduced through cervix into chorion frondosum, easier for posterior placenta; contamination by cervical flora possible
◊ CONTRAINDICATED in cervical infections!
(b) transabdominal route = 20–22-gauge needle inserted through anterior abdominal wall; easier for anterior / fundal placenta; sterile technique

Chromosome analysis:
(a) direct preparation = analysis of cytotrophoblasts (may have different karyotype than fetus) → analysis can be performed immediately
(b) villus culture = cells from central mesenchymal core (same karyotype as fetus) → cultured for several days before analysis

Errors (2%):
1. **Mosaicism** = cell line forming cytotrophoblast may develop abnormal karyotype while fetal cell line is normal
2. Maternal contamination = cells from maternal decidua may overgrow mesenchymal core cells

Risks:
1. Spontaneous abortion (1%)
2. Perforation of amniotic sac
3. Infection
4. Teratogenesis: limb reduction defect

Cordocentesis

= PERCUTANEOUS UMBILICAL BLOOD SAMPLING (PUBS)

A. DIAGNOSTIC CORDOCENTESIS
1. Hematocrit
2. Karyotype
3. Immunodeficiency: chronic granulomatous disease, severe combined immunodeficiency
4. Coagulopathy: von Willebrand syndrome, factor deficiency
5. Platelet disorder: alloimmune / idiopathic thrombocytopenic purpura
6. Hemoglobinopathy: sickle cell anemia, thalassemia
7. Infection: toxoplasmosis, rubella, parvovirus, varicella, cytomegalovirus
8. Hypoxia / acidosis

B. THERAPEUTIC CORDOCENTESIS
1. Intravascular fetal transfusion (fresh rh-negative CMV-negative leukodepleted irradiated packed cells compatible with mother infused at 10–15 mL/min)
2. Direct delivery of medication to fetus

Cx:
1. Chorioamnionitis
2. Rupture of membranes
3. Umbilical cord hematoma
4. Umbilical cord thrombosis
5. Bleeding from insertion site
6. Fetal bradycardia

MULTIPLE GESTATIONS

Prevalence: 1.2% of all births; in 5–50% clinically undiagnosed at term
Occurrence (Hellin rule):

twins	in	1÷85 pregnancies (= 85^1)
triplets	in	1÷7,225 pregnancies (= 85^2)
quadruplets	in	1÷614,125 pregnancies (= 85^3)
quintuplets	in	1÷52,200,625 pregnancies (= 85^4)

- uterus large for dates
- may have ↑ hCG, HPL (human placental lactogen), AFP levels

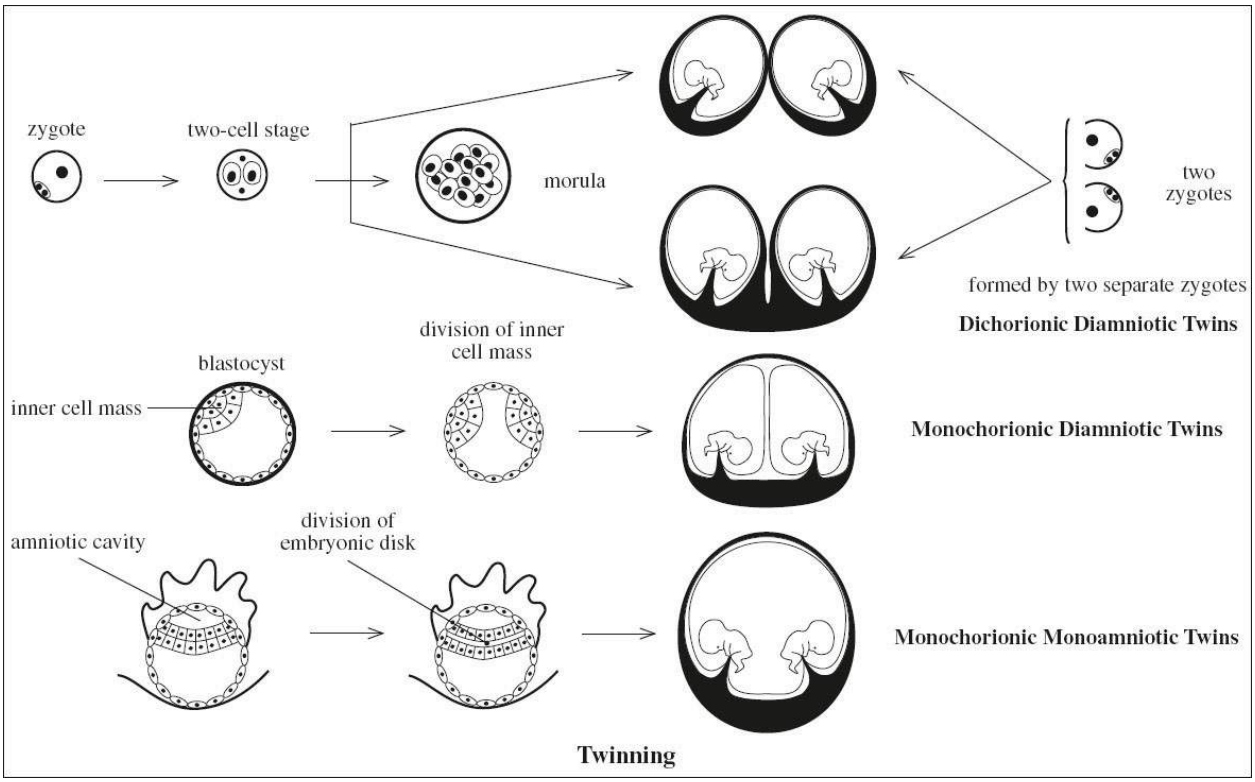
Perinatal morbidity & mortality compared with singletons:
twins: up to 5-fold increase
triplets: up to 18-fold increase

Twin Pregnancy

Zygote = fertilized egg
Prevalence: in up to 2.5% of all pregnancies

Monozygotic Twins (⅓)

= identical TWINS
= division of a single fertilized ovum fertilized by one sperm during earliest stages of embryogenesis (chorion differentiates 4 days and amnion 8 days after fertilization)
Prevalence: 1:250 birth (constant around the world)
Predisposing factors: (1) Advanced maternal age
(2) In vitro fertilization
√ same sex + identical genotype
Cx: (1) perinatal mortality 2.5 times greater than for dizygotic twins
(2) Fetal anomalies 3–7 times higher than in dizygotic twins / singletons (often only affecting one twin): anencephaly, hydrocephalus, holoprosencephaly, cloacal exstrophy, VATER syndrome, sirenomelia, sacrococcygeal teratoma



Embryologic Events in Monozygotic Twinning			
Days after Fertilization	*Embryologic Event*	*Cleavage results in*	
		Chorion	*Amnion*
1–2	cell divisions → morula	di~	di~
3–4	chorionic differentiation		
6	blastocyst implants in endometrium	mono~	di~
8	amnionic differentiation	mono~	mono~
>13	division of embryonic disk	mono~	mono~
		but conjoined	

DICHORIONIC DIAMNIOTIC TWINS (30%)

= separation at two-cell stage (= blastomere) ~ 60 hours / < 4 days after fertilization
√ 2 separate fused / unfused placentas
√ membrane > 2 mm ← 2 separate chorionic sacs + 2 separate amniotic sacs (92% accurate for dichorionic diamniotic twins)
√ "twin peak" sign = triangular projection of placental tissue insinuated between layers of intertwin membrane

MONOCHORIONIC DIAMNIOTIC TWINS (69–80%)

= separation in blastocyst stage between 4th and 7th day after fertilization (chorion already developed and separated from embryo)
√ 2 separate amniotic sacs in single chorionic sac

◊ Common monochorionic placenta has vascular communications in 100%!

Cx: (1) Twin-twin transfusion syndrome
(2) Twin embolization syndrome
(3) Acardiac parabiotic twin

MONOCHORIONIC MONOAMNIOTIC TWINS (1%)

= division of embryonic disk between 8th and 12th day after fertilization (amniotic cavity already developed)

√ common amniotic + chorionic sac without separating membrane

√ entanglement of cords = the only definitive positive sonographic sign of monoamnionicity

Cx: double perinatal mortality up to 45%
(1) Entangled umbilical cord (70%)
(2) True knot of cord
(3) Conjoined twins: umbilical cord with > 3 vessels, shared fetal organs, continuous fetal skin contour

Prognosis: 40% survival rate

Dizygotic Twins (⅔)

= FRATERNAL TWINS

(a) fertilization of 2 ova by 2 separate spermatozoa during 2 simultaneous ovulations (occurring either in both ovaries or in one ovary)

(b) **superfetation** = fertilization of 2 ova by 2 separate spermatozoa during 2 subsequent ovulations (? frequency)

(c) **superfecundation** = 2 ova fertilized by 2 different fathers (very rare)

Prevalence: 1÷80 to 1÷90 births

Predisposing factors:
(1) Advanced maternal age (increased up to age 35): ↓ gonadal-hypothalamic feedback + ↑ FSH levels
(2) Ovulation-inducing agents (multiple pregnancies in 6–17% with clomiphene, in 18–53% with Pergonal®)
(3) Maternal history of twinning (3 times as frequent compared with normal population)
(4) Increased parity
(5) Maternal obesity
(6) Race with inherited predisposition for multiple ovulations (Blacks > Whites > Asians)

√ different phenotypes; same / opposite sex

√ always dichorionic diamniotic

Growth Rates of Twins

◊ Twins should be scanned every 3–4 weeks > 26–28 weeks GA!

A. Below 30–32 weeks GA
√ normal individual twins grow at same rate as singletons
√ BPD growth rates similar to singleton fetuses

B. Beyond 30–32 weeks GA
√ combined weight gain of both twins equals that of a singleton pregnancy (AC of

twins < AC of singleton)
◊ Weight of twin fetus falls below that of singleton when combined weight of twins > 4,000 g!
√ BPD + HC growth may / may not be affected (controversial)
√ FL not affected

DISCORDANT GROWTH

= weight difference at birth > 25%
Cause: (1) Twin-twin transfusion syndrome
(2) IUGR of one fetus
√ BPD difference > 5 mm (discordant growth in 20–30%)
√ discordant HC increases probability of IUGR
√ AC is single most sensitive parameter for IUGR
√ EFW is the most sensitive set of combined parameters for IUGR
√ > 15% S/D ratio difference of umbilical artery Doppler waveforms between twins

Amnionicity & Chorionicity

Rules:
◊ Only monozygotic twins can give rise to monochorionic monoamniotic pregnancies!
◊ All monoamniotic twins must also be monochorionic!
◊ All dizygotic twins must be dichorionic and diamniotic!
◊ 77% of all twin pregnancies are dichorionic
› 67% of all dizygotics (⅔ of all twins)
› 10% of all monozygotics (⅓ of all twins)

1. GESTATIONAL SACS (< 10 weeks MA)
Accuracy: 100% in 1st trimester, 80–90% in 2nd trimester
√ 2 gestational sacs, each with a live fetus, indicates dichorionic twinning
√ single gestational sac with 2 live fetuses indicates monochorionic twins
√ single extraembryonic coelom indicates monochorionic twins
2. YOLK SAC
√ number of yolk sacs = number of amnions
3. FETAL GENDER
√ different genders (in 25% of twin pregnancies) must be dizygotic twins and thus dichorionic!
(DDx: testicular feminization demonstrates female external genitalia with a 46,XY karyotype)
√ identical sex twins with a monochorionic placenta must be monozygotic
√ identical sex twins with a dichorionic placenta require further analysis to determine zygosity
4. PLACENTAL SITES
√ 2 placentas (in 45% of twin pregnancies) indicate dichorionic diamniotic pregnancy
√ 1 placenta indicates
(a) monochorionic pregnancy OR
(b) dichorionic pregnancy with fused placenta (occurs in 50% of dichorionic twin

pregnancies)

5. CHORIONIC PEAK
   - √ "**twin peak**" sign in late 1st and early 2nd trimester (= triangular projection of placental tissue extending beyond chorionic surface of placenta + insinuated between layers of intertwin membrane + wider at chorionic surface with tapering to a point some distance inward from surface) indicates dichorionic pregnancy
6. MEMBRANE
   - √ separating membrane confirms diamniotic pregnancy, but does not distinguish between mono- or dichorionic pregnancy
   - √ dichorionic membrane (2 layers of chorion + 2 layers of amnion) is thicker (> 2 mm) than monochorionic membrane (2 layers of amnion < 1 mm): 88–92% accuracy in 1st trimester, 39–83% accuracy in 2nd + 3rd trimester
     - ◊ All membranes appear to be thin in 3rd trimester!
   - √ absence of membrane suggests a monoamniotic monochorionic twin pregnancy
     - ◊ Nonvisualization of membrane is not sufficient evidence of monoamnionicity due to technical factors!
7. CORD
   - √ entanglement of cords is the only definitive positive sonographic sign of monoamnionicity
   - √ simultaneous recording of fetal arterial signals at nonsynchronous rates within wide Doppler gate
8. AMNIOGRAPHY
   - √ detection of imbibed intestinal contrast in both twins by CT following single sac contrast injection proves monoamniotic monochorionic twin pregnancy

Risks of Multiple Gestations

1. Placental abruption 3-fold
2. Anemia 2.5-fold
3. Hypertension 2.5-fold
4. Congenital anomaly 2–3-fold
5. Preterm delivery 12-fold
6. Perinatal mortality 4–6-fold

◊ Risk increases with number of fetuses, monozygosity, monochorionicity

Risk for IUGR in Multiple Gestations

monochorionic-monoamniotic > monochorionic-diamniotic > dichorionic-diamniotic

Risk for Perinatal Mortality in Multiple Gestations

1% for singletons, 9% for diamniotic dichorionic twins,
26% for diamniotic monochorionic twins,
50% for monoamniotic monochorionic twins

Prognosis:

(1) Perinatal mortality 5–10 times that of singleton pregnancy (91–124÷1,000 births)
   - › 9% for dichorionic diamniotic twins
   - › 26% for monochorionic diamniotic twins

› 50% for monochorionic monoamniotic twins
(a) preterm delivery with birth weight < 2,500 g
(b) IUGR (25–32%; 2nd most common cause of perinatal mortality + morbidity)
(c) amniotic fluid infection (60%)
(d) premature rupture of membranes (11%)
(e) twin-twin transfusion syndrome (8%)
(f) large placental infarct (8%)
(g) placenta previa
(h) abruptio placentae
(i) preeclampsia
(j) cord accidents
(k) malpresentations
(l) velamentous cord insertion (7-fold increase compared with singleton pregnancy)

(2) Fetal death in utero: 0.5–6.8%; 3 times as often in monochorionic than in dichorionic gestations
◊ 50% of twin gestations seen at 10 weeks GA will be singletons at birth!

(3) Increased risk of congenital anomalies: 23÷1,000 births = twice as frequent as in singletons; 3–7 times more frequent in mono- than in dizygotic twins

UTERUS

Uterine Size

◊ Overfilling of urinary bladder can modify uterine shape!

A. PREPUBERTAL UTERUS

(a) neonate

√ uterine size:
› length of 2.3–4.6 (mean, 3.4) cm
› fundal width of 0.8–2.1 (mean, 1.2) cm
› cervical width of 0.8–2.2 (mean, 1.4) cm
◊ becomes smaller by 4th month of life (2.6–3.0 cm)

√ uterine shape:
› **spade**-shaped uterus (58%) with cervix often twice as thick as fundus
› **tube**-shaped uterus (32%) with cervical + fundal AP measurements identical
› adult **pear**-shaped uterus (10%) with fundus wider than cervix

Uterine Size and Shape

Stage	*Uterine Length [cm]*	*Fundal Width [cm]*	*Uterine Body-to-Cervix Ratio*
Neonatal	3.5	1.2	2÷1
Pediatric	1–3	0.4–1.0	1÷1
Prepubertal	3–4.5	0.8–2.1	1–1.5÷1
Pubertal	5–8	1.6–3.0	1.5–2÷1
Reproductive	8–9	3–5	2÷1
Postmenopausal	3.5–7.5	1.2–1.8	1–1.5÷1

√ endometrium:
√ thin echogenic endometrium ± surrounding hypoechoic halo
√ endometrial fluid (in 23%) ← maternal hormonal stimulation
◊ Best time to evaluate uterus in child with ambiguous genitalia is first few months of life!

(b) infant

Age: infancy to 7 years of age

√ uterine size:
› length of 2.5–4.5 (mean, 3.3) cm
› fundal width of 0.4–1.0 cm
› cervical width of 0.6–1.0 cm
√ cervix occupies ²/₃ of uterine length
√ thin echogenic line of endometrium visible in 50%

(c) prepuberty

√ uterine size:
› mean length of 4.3 cm
› fundal width of 0.8–2.1 (mean, 1.2) cm
› cervical width of 0.8–2.2 (mean, 1.4) cm
√ usually tubular configuration with fundocervical ratio of 1÷1

B. PUBERTY

√ pear-shaped uterus with thick and round body
√ uterine body-to-cervix ratio 1.5÷1

C. POSTPUBERTAL UTERUS

› nulliparous: 5–8 cm (L); 3 cm (AP); 1.6–3.0 cm (TRV)
› multiparous: 6–11 cm (L); 3–4 cm (AP); 3–5 cm (TRV)
√ fundocervical ratio of 2÷1 to 3÷1
√ mean uterine volume of 90 cm^3

D. POSTMENOPAUSAL UTERUS

• most rapid decline in size within first 10 years

> 65 years: 3.5–7.5 cm (L); 1.2–3.3 cm (AP); 1.2–1.8 cm (TRV)

√ fundocervical ratio of 2÷1 to 1÷1
√ calcified uterine arcuate vessels, especially with diabetes / vascular disease / hypertension / hypercalcemia

Uterine Position

Flexion = angle of long axis of uterine body to that of cervix
Version = angle of long axis of cervix to long axis of vagina
mnemonic: **V** for **V**agina and **V**ersion!
Anteversion + anteflexion = most common position
Cave: Retroversion can be mistaken for a pelvic mass!

Trilaminar Uterine Zonal Anatomy (on T2WI)

◊ Premenarchal uterus has indistinct zonal anatomy
◊ Thickness of zones depends on menstrual cycle + hormonal medication!

1. ENDOMETRIUM

√ high signal intensity ← mucin-rich endometrial glands

2. JUNCTIONAL ZONE = INNER MYOMETRIUM
   Mean thickness: < 12 mm
   Histo: compact smooth muscle fibers with 3-fold increase in number + size of nuclei compared with outer myometrium
   √ low SI (= compact smooth muscle with lower water content); seen in 40–60%, may not be visible in premenarchal + postmenopausal women
3. OUTER MYOMETRIUM
   Histo: 65–70% smooth muscle
   √ intermediate SI (= less compact muscle with greater water content + blood vessels); → increases during secretory phase
4. OUTER SURFACE OF UTERUS
   √ thin low-signal intensity line

Uterine Enhancement Pattern

1. Myometrium
   demarcates level of internal cervical os
2. Inner mucosal + outer stromal layers of cervix
   √ hypoattenuating on CECT
3. Inner stromal layer of cervix

Cervix

= lower cylindrical portion of uterus
Size: 2.5–3.0 cm (L) x 2.5 cm (W)
Stroma: primarily collagenous tissue + smooth muscle (15%)
Portions:
(1) Supravaginal upper portion = **endocervix**
• not palpable / visible by pelvic exam
(2) Lower portion protruding into vagina = **ectocervix** encircled by vagina (higher posteriorly and laterally) forming **fornices** (= vaginal recesses)
• palpable during pelvic exam + visible with speculum

US:
√ ovoid / round on short-axis (coronal endovaginal) view
√ cylindrical on long-axis (sagittal)
√ little / NO vascularity on color Doppler

Ectocervix

Histo: mucosa composed of stratified squamous epithelium similar to vaginal epithelium
Transformation zone = **squamocolumnar junction**
= region where glandular tissue (columnar epithelium) is replaced by squamous epithelium
Location: (a) on ectocervix in 94% of women < 25 years (b) on ectocervix in 2% of women > 65 years
√ not discernible at imaging
N.B.: most cervical cancers arise in transformation zone

Endocervical Canal

~ 8 mm wide fusiform canal connecting uterus with vagina, tapering at both ends into
(a) **external cervical os** = opening into vaginal canal
(b) **internal cervical os** = opening into uterine cavity

Size of internal cervical os: 10 mm (L) x 1–12 mm (W)

Histo: endocervical mucosa
› characterized by villi lined with a single layer of mucus-secreting columnar epithelial cells + separated by crypts (= endocervical glands) extending 3–10 mm deep into stroma of cervix
› arranged into longitudinal ridges with interdigitating branching folds (plicae palmatae of arbor vitae = irregular branched mucosal pattern of cervical canal

√ best visualized on HSG

US:
√ endocervical canal = echogenic line (best on SAG view) delineating interface between anterior + posterior mucosa
√ thin central an- / hypoechoic region ← fluid / mucus during periovulatory period

MR: (see below)

Cervical Isthmus

= junction of supravaginal cervix and uterine body
√ slight external tapering of outer contour of uterus
√ slight internal narrowing forming internal cervical os

Cervical Zones (on T2WI = best soft-tissue contrast)

= distinctive trilaminar appearance
(1) Central stripe of high signal intensity
Histo: secretions in endocervical canal + cervical mucosa + plicae palmatae
√ 3–8 mm hyperintense layer of mucosa + secretions
(2) Middle layer of low SI continuous with junctional zone
Histo: inner zone of fibromuscular stroma with percentage of nuclear area 2.5 times greater than in outer zone
√ 3–8 mm hypointense layer of inner cervical stroma
(3) Outer layer of intermediate signal intensity
Histo: outer zone of fibromuscular stroma with greater number of fibroblasts + smooth muscle cells and less vascularized connective tissue
√ 2–8 mm intermediate-SI layer of outer cervical stroma
(4) Outermost thin low-intensity serosal layer continuous with uterine serosa

Postpartum Uterus

Puerperium = period 6–8 weeks after delivery
[*puer* = Latin, boy + *parere* , Latin = to bear; *puerpera* = a woman in childbed]

• after childbirth weight of uterus = 1 kg decreasing by 50% during following 24–48 hours

√ length of uterus: › 20.0 cm after birth
› 11.2 cm at 3 weeks
› 8.7 cm at 6 weeks

◊ Timing of uterine involution
› prolonged in multiparous women
› foreshortened in preterm delivery
› not affected by birth weight / breast feeding

√ heterogeneous myometrium of higher echogenicity compared to nongravid uterus

√ increased diffuse / focal myometrial vascularity at site of placental insertion

Endometrium by US

Measurements refer to
› AP diameter of both apposed endometrial layers (= bilayer thickness) excluding intrauterine fluid
› the level of the uterine fundus
› midline long-axis image of uterus

◊ Measurements increase by 1–2 mm in patients with large body habitus

◊ If there is a discrepancy between concomitant endometrial + ovarian findings bleeding is usually associated with anovulatory cycles

1. MENSTRUAL PHASE (usually days 1–4)
Thickness: 1–5 (mean, 4.6) mm
√ interrupted thin echogenic line of central interface
2. PROLIFERATIVE PHASE (days 5–13)
Thickness: 6–12 mm
√ bright echogenic central line (= apposed borders of endometrial canal)
√ thickened mildly echogenic endometrium compared with myometrium ← development of glands, blood vessels, stroma
3. LATE PROLIFERATIVE + OVULATORY PHASE (days 13–16)
Thickness: mean of 12.4 mm on the day of luteinizing hormone surge
√ "triple ring" sign = multilayered endometrium:
√ echogenic basal layer
√ hypoechoic inner functional layer
√ thin echogenic median layer arising from the central interface
√ concomitant with mature preovulatory follicle
√ disappears within 12–48 hours after ovulation
4. PERIOVULATORY PHASE (days 8–20)
= uncertain days defined relative to day of ovulation
N.B.: day of luteinizing hormone surge extremely variable = ovulation occurs between day 8 and 20 of menstrual cycle
5. SECRETORY PHASE (days 16–28)
Thickness: 7–12–16 mm
√ bright central line
√ markedly echogenic thick endometrium of more homogeneous echotexture ← stromal edema + distended glands filled with mucus + glycogen:
√ ± posterior acoustic enhancement
√ maximum thickness during midsecretory phase
√ concomitant with a corpus luteum
√ thin hypoechoic halo of inner myometrial zone

6. HORMONAL CONTRACEPTIVES
   √ endometrium thin throughout menstrual cycle

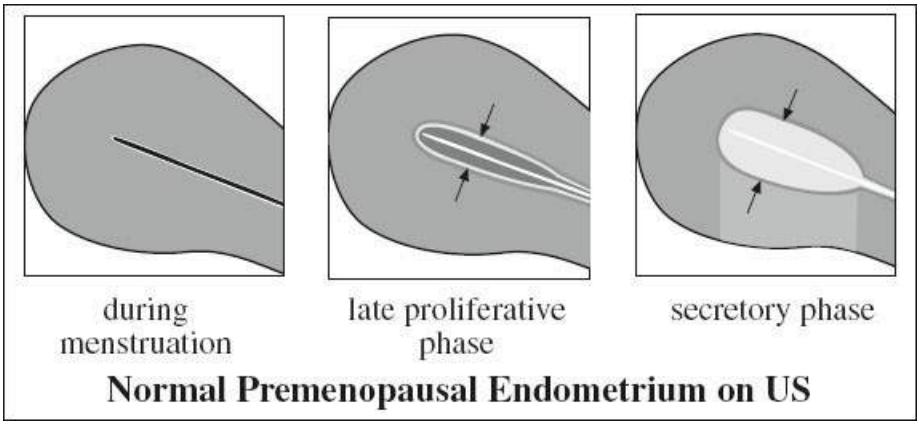
Postmenopausal Endometrium

Menopause = permanent cessation of menstruation with an intact uterus
[men, *ancient Greek* = month + pausis, *Greek* = cessation]
Definition: amenorrhea for 12 months
Onset: 51–53 (range, 40–60) years (Western countries)
Affected by: smoking, race, ethnicity, body mass index

Perimenopause = menstrual cycles of variable lengths + volume with frequent skipping of cycles

A. NO HORMONAL REPLACEMENT THERAPY
   √ bilayer thickness of usually 1–2 mm (max. 5 mm) with a homogeneous echogenic endometrium = 99% NPV for endometrial cancer
   Histo: consistently associated with atrophic inactive endometrium

B. WITH HORMONE REPLACEMENT THERAPY
   (a) cyclic estrogen + progestin therapy
      √ endometrial thickness may increase to 8 mm:
         √ thickest prior to progestin exposure
         √ thinnest after progestin phase (imaging should be done at beginning / end of a treatment cycle)



Normal Premenopausal Endometrium on US

   (b) continuous estrogen + progesterone regimen
      √ normal endometrial thickness
      Histo: endometrial atrophy
   (c) unopposed estrogen therapy usually prescribed for posthysterectomy patients
      Associated with: increased risk of endometrial hyperplasia / carcinoma
   (d) tamoxifen (= estrogenic effect on uterus) usually prescribed for breast cancer patients
      √ endometrial thickness > 8 mm in 50% (notably beyond 3 years of therapy)
      √ endometrial thickness may increase to 15 mm
      Rx: biopsy / D&C recommended (?) if endometrial thickness > 8 mm

Normal Postpartum Endometrium

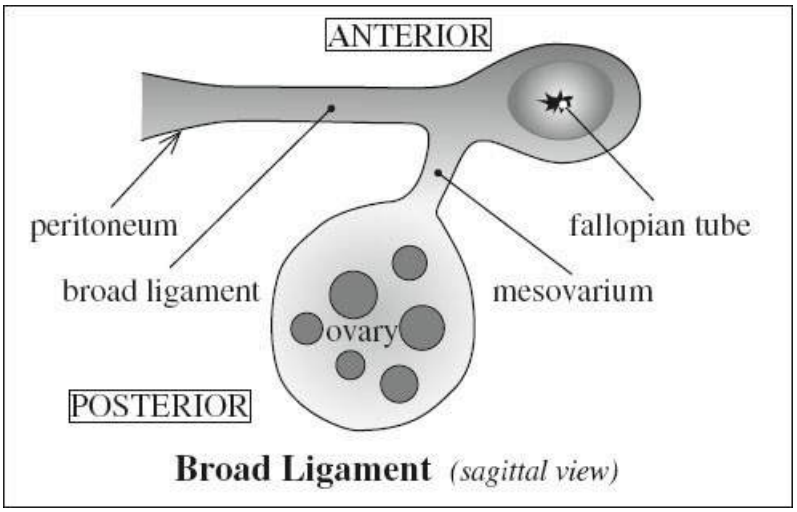
√ endometrial cavity < 20 mm in diameter:
  √ small echogenic foci of retained membranes / remaining superficial decidua / clot / debris
    › normal in up to 24% in first few days post partum
    › normal in up to 50% at 1 week post partum
    › normal in up to 6% at 3 weeks post partum
  √ intrauterine air (as late as 3 weeks after vaginal / cesarean delivery)
√ cavity wall:
  √ smooth well-defined border
  √ irregular heterogeneous lining
  √ endometrial stripe thickness decreases with uterine involution
√ endometrium restored by 3–6 weeks post partum

Pelvic Spaces

1. Rectouterine pouch = cul-de-sac
   Anterior boundary: broad ligaments + uterus
   ◊ Most dependent portion of pelvis in women!
2. Rectovesical recess
   ◊ Most dependent portion of pelvis in men!
3. Vesicouterine recess
4. Inguinal fossa
   located between lateral + medial umbilical folds

Pelvic Ligaments

1. **Broad ligament**
   Histo: double fold of peritoneum covering anterior + posterior surfaces of uterus
   Origin: uterine peritoneum
   Location: lateral uterine margin to pelvic sidewall incompletely dividing true pelvis into anterior + posterior compartments
   Attachment: pelvic sidewall
   › medial superior free edge (= point where peritoneal layers are continuous): encloses fallopian tube
   › lateral superior free edge: suspensory ligament of ovary
   › lower margin: cardinal ligament
   Contents (= parametrium):
   extraperitoneal connective tissue, smooth muscle, fat, fallopian tube, round ligament, ovarian ligament, uterine + ovarian blood vessels, nerves, lymphatics, mesonephric remnants
   √ usually not seen on CT, unless surrounded by ascites
2. **Round ligament**
   = anterior suspensory ligament of uterus
   Histo: band of fibromuscular tissue + lymphatic channels
   Origin: anterolateral uterine fundus, just below + anterior to ovarian ligament



Attachment: through internal inguinal canal (lateral to deep inferior epigastric vessels) to labia majora

3. **Cardinal ligament** = transverse cervical ligament = Mackenrodt ligament
   Origin: cervix + upper vagina
   Attachment: fascia of obturator internus muscle
   Relationship:
   › uterine artery runs along its superior aspect
   › forms the base of the broad ligament
4. **Uterosacral ligament**
   Origin: posterolateral cervix + vagina
   Attachment: anterior body of sacrum at S2 / S3
5. **Ovarian ligament** = utero-ovarian lig. = round ligament of the ovary
   = round fibromuscular band just inferior + posterior to fallopian tube + round ligament enclosed between 2 layers of broad ligament
   Origin: medial aspect of ovary
   Attachment: uterine cornu
   Contents: ovarian branches of uterine artery + vein
   √ short narrow soft-tissue band between uterus and ovary on CT
6. **Suspensory ligament of ovary** = infundibulopelvic lig.
   = peritoneal fold (= superolateral part of broad ligament) suspending ovary from posterolateral pelvic wall
   Origin: anterolateral tubal end of ovary
   Attachment: connective tissue covering psoas muscle
   Contents: ovarian artery + veins (= major component due to gradual arterial atrophy); lymphatics
   Length: up to 4–5 cm
   ◊ Good anatomic landmark to localize ovary!
   √ extends from ovary in direction of iliac vessels on CT
7. **Lateral umbilical fold** / ligament
   = reflection of peritoneum over deep inferior epigastric vessels
8. **Medial umbilical fold** / ligament

= reflection of peritoneum over obliterated umbilical arteries

9. **Median umbilical ligament**
   = reflection of peritoneum over obliterated urachus
   Origin: dome of urinary bladder
   Attachment: umbilicus

FALLOPIAN TUBE

[Gabriele Falloppio *aka* Fallopius (1523-1562), chair of anatomy at University of Padua]
Location: superior aspect of broad ligament
Length: 10–12 cm
Segments:

(1) **Interstitial** / intramural / cornual portion
    = short segment that traverses muscular wall of the uterus
(2) **Isthmic** portion
    = long narrow segment between interstitial + ampullary end
    Diameter: up to 4 mm
(3) **Ampullary** portion
    = widened region near ovary accounting for > 50% of the entire tubal length
    Diameter: up to 8 mm
(4) **Infundibular** portion
    = most lateral funnel-shaped segment
    Diameter: up to 10 mm

Free edge: 25 fingerlike projections / fimbriae
Wall:

(a) mucosa: folds form fingerlike projections (= plicae) → plicae coalesce at infundibulum contiguous with fimbriae
(b) muscularis
(c) serosa

√ usually not visualized unless abnormal / surrounded by fluid

OVARY

Origin: thickening of mesothelial layer of peritoneum → gonadal ridge → primitive gonad; part of mesonephros remains connected to genital ridge = mesovarium
Fixation: *gubernaculum* connects ovary to uterine fundus = **ovarian ligament**; part of gubernaculum between uterus and labia = **round ligament** that is accompanied by peritoneum analogous to processus vaginalis of testis (= **canal of Nuck**)

The ovary is fairly mobile with attachments to

anterior pelvic wall	by broad ligament
uterine body	by uteroovarian ligament
fallopian tube	by tuboovarian ligament
lateral pelvic wall	by infundibulopelvic ligament

Ovarian descent: inhibited by gubernaculum → NO further than level of uterine fundus
N.B.: failure of gubernaculum to contract → ovary may descend through inguinal canal into labium majus

Mesovarium: short double-layered peritoneal fold extending posteriorly from broad ligament attaching anteriorly to ovary; contains ovarian blood vessels (= anastomotic branches of ovarian + uterine arteries and venous plexus)

◊ Lax supporting ligaments + shallow fetal and infantile pelvis make fetal ovary more susceptible to torsion than postpubertal ovary!

Embryology of ovary:

(a) coelomic (surface) epithelium (*gonadal cortex)* migrates from near the allantois and invaginates into

(b) mesenchymal substance of central part = *medulla of ovary* (= primary sex cords) and incorporates primordial germ cells that develop into primordial follicles

(c) germinal epithelium eventually loses connection with central mass; an additional layer develops between medulla and cortex = *tunica albuginea*

Oocytogenesis:

› cells from dorsal endoderm of yolk sac migrate along hindgut to gonadal ridge (**primordial germ cells**) which multiply by mitosis

› after reaching gonadal ridge they are named **oogonia** (= diploid stem cells of ovary)

› oogonia become fully surrounded by a layer of connective tissue (= pre-granulosa cells of **primary oocyte**)

› primary oocyte formation completed by end of 3rd trimester

› most primary oocytes degenerate + only a small portion of primary oocytes undergo ovulation after onset of puberty

Histo:

A. Stromal cells
   › form cortex, medulla, hilus
   › surround all developing follicles
   › cell surface has estrogen-, progesterone-, testosterone-binding sites
   › major source of androgens in postmenopause

B. Cells derived from stroma cells
   1. Fibroblasts
   2. Luteinizing stromal cells containing lipid
   3. Hilus cells
      morphologically similar to Leydig cells in testis;
      contain intracellular crystalline structures (= crystals of Reinke)
   4. Theca cells
      › surround granulosa cells
      › produce estradiol under control of FSH
      › stimulated by LH after ovulation into theca-lutein cells, which develop lipid-laden cytoplasm involved in steroidogenesis

C. Cells derived from sex cords
   1. Granulosa cells
      › surround each primordial oocyte
      › form lining of developing follicle
      › granulosa cell layer contains small cystic cavities lined by basal lamina (= Call-Exner bodies)
      › produce estradiol under control of FSH

› stimulated by LH after ovulation into granulosa-lutein cells, which develop lipid-laden cytoplasm involved in steroidogenesis

2. Sertoli cells
not seen in normal ovary

Ovarian Size

Ovarian volume = length x height x width x 0.523

fetus: > 28 weeks GA
< 3 months: 1.06–3.56 cm^3
4–12 months: up to 2.71 cm^3
1 year: 1.05 ± 0.7 (S.D.) cm^3
2–6 years: ≤ 1.0 ± 0.4 (S.D.) cm^3
6–10 years: 1.2–2.3 cm^3
11–12 years: 2–4 cm^3
after puberty: 2.5–5 cm (L), 0.6–1.5 cm (H), 1.5–3 cm (W) = 8 (range 2.5–20) cm^3
premenopausal: < 6 cm^3
postmenopausal: < 2.5 cm^3
< 30 years: mean volume of 6.6 cm^3
30–39 years: mean volume of 6.1 cm^3
40–49 years: mean volume of 4.8 cm^3
50–59 years: mean volume of 2.6 cm^3

◊ An ovary > 20 cm^3 is enlarged!
◊ An ovary between 15 and 20 cm^3 requires follow-up!
◊ An ovarian volume > 4 cm^3 + > 6 follicles in girls < 7 years suggests premature sexual development!

Ovarian Morphology

neonate:
√ follicles occasionally fail to involute + undergo growth
< 8 years:
√ solid ovoid structures with homogeneous / finely heterogeneous texture
√ up to 68–80% of ovaries contain cystic follicles (in 95% < 9 mm, in 5% > 9 mm)
premenopausal:
√ changes in size, morphology, blood flow with menstrual cycle

Ovarian Volume and Appearance

Stage	*Ovarian Volume [cm^3]*	*Ovarian Appearance*
Neonatal	1.0–3.5	follicles + cysts common
Pediatric	0.5–1.5	< 6 follicles; cysts uncommon
Prepubertal	1.0–4.0	follicles + cysts common
Pubertal	2.0–6.0	follicles + cysts common
Reproductive	4.0–16.0	follicles + cysts common
Postmenopausal	1.2–5.8	follicles + cysts in 15–20%

Visualization of Ovaries by US

(a) after menopause (average onset at age 50):
< 5 years after menopause: in 78%
> 10 years after menopause: in 64%
› both ovaries: in 85%
› one ovary: in 60%
(b) following hysterectomy: in 43%

Location of Ovaries

Influenced by: › size of uterus + ovary
› distension of bladder + rectosigmoid
› presence of pelvic mass

(a) in neonates: located above level of true pelvis (visualized by transabdominal US)
(b) older child: located adjacent to uterus deep within pelvis
Location: ovarian fossa (= fossa of Waldeyer) bounded posteriorly by ureter + internal iliac artery, superiorly by external iliac vein, anteriorly by obliterated umbilical artery
(c) during 1st pregnancy: pulled into abdomen by enlarging uterus + stretched broad ligament
(d) after 1st pregnancy: greater ovarian mobility ← enlarged redundant broad ligament
Potential locations: › adnexal region lateral to uterus
› posterior cul-de-sac
› superior / posterior to uterine fundus

◊ In retroverted uterus ovaries may be ventral / lateral to uterus

Ovarian Blood Supply

= dual arterial supply

Ovarian Artery

Origin: abdominal aorta slightly below renal artery
Course: (a) descends caudally + laterally ventral to psoas major muscle
(b) crosses over external / common iliac vessels
(c) passes through suspensory ligament of ovary near pelvic brim
(d) descends inferiorly + medially between 2 layers of broad lig. near mesovarian border
Terminus: multiple branches within ovarian hilum

Adnexal Branch of Uterine Artery

Ovarian Vein

◊ Tracking the ovarian vein caudally is most helpful to identify ovary!
Origin: pampiniform plexus in mesovarium that merges to form one vein
Course: alongside ovarian artery
Terminus: left ovarian vein → left renal vein; right ovarian vein → inferior vena cava below level of renal vessel

RELATIONSHIP OF OVARIAN VESSELS TO URETER

@ lower renal pole medial to ureter
@ middle to lower lumbar region crossover
@ lower abdomen + pelvis lateral to ureter
√ location of ureter relative to a pelvic mass can be a most helpful hint to the ovarian origin on CT

Ovarian Doppler Signals

A. NONFUNCTIONING OVARY
√ high-impedance waveform
B. FUNCTIONING OVARY
› days 1–6:
√ high-impedance waveform with RI close to 1.0
› days 7–22 = midfollicular to midluteal phase
= developing dominant follicle + ovulation + corpus luteal phase:
√ continuous diastolic flow with RI close to 0.5
› days 23–28 = late luteal phase:
√ high-impedance waveform with RI close to 1.0

Ovarian Cycle

1. FOLLICULAR PHASE = days 1–14 (of a 28-day cycle)
• a number of immature primordial follicles begin to mature in response to FSH
√ multiple small cysts:
(a) unstimulated follicles are < 2 mm in size
(b) stimulated follicles grow > 2 mm in size
√ 2–3 follicles in each ovary of day 4 enlarge subsequently to ~ 10 mm
• 2–3 follicles capture the most FSH and aromatize the most estradiol from their granulosa cells
√ follicles may be seen by 5–7 days
√ single more ascendant / **dominant / graafian follicle** appears by day 8–10–12 (*see below*):
√ progressively increasing diastolic flow on the side of maturing follicle
2. OVULATORY PHASE = day 14
• "**Mittelschmerz**" = pain just prior to ovulation (pressure of graafian follicle distending ovarian capsule)
√ sudden decrease in follicular size over minutes / hours (= rupture of mature graafian follicle with extrusion of oocyte)
√ fluid in cul-de-sac detectable in up to 40%
3. LUTEAL PHASE = days 15–28
= remnant dominant follicle transforms into **corpus luteum hemorrhagicum**
√ irregular cyst with scalloped margins
◊ All corpora lutea evolve over days and change size and texture constantly
◊ All corpora lutea contain hemorrhage: → uncontrolled bleeding into center frequently at time of ovulation + on day 8 when regression begins
√ round / ovoid bulging protrusion on one side of ovary = **corpus luteum of**

menstruation:
√ mean diameter of 10–25 mm (typically < 3 cm)
√ hyperechoic 1–4-mm thick wall
√ hyperechoic central blood clot gradually transforming into weblike fibrin net
√ color Doppler US:
√ corpus luteum surrounded by circumferential wreath-like color flow = "**ring of fire**"
√ blood flow in main arteriole supplying the corpus luteum is ~ 100 cm/sec
√ arterial flow differences between active + inactive ovary:
√ inactive (nondominant) ovary: steady high-resistance pattern of ovarian arterial flow
√ active (dominant) ovary: low-resistance arterial pattern with its nadir in early luteal phase
√ involution + atrophy of corpus luteum on about 24th day of cycle = **corpus luteum atreticum**
Prognosis: large painful corpora lutea resolve in a week

Postmenopausal Ovary

√ less echogenic, fewer follicles than normal
√ small atrophic organ with mean size of 1.2–5.8 cm^3
◊ Ovarian volume > 8 cm^3 is abnormal!
√ may contain simple cyst up to 3 cm (in 15%)
Rx: serial follow-up to document spontaneous regression
√ may contain simple cyst < 1 cm (in 21%)
Rx: no follow-up necessary
√ peripheral 1–3 mm punctate echogenic foci without associated soft-tissue mass
Cause: (a) dystrophic calcifications in atretic follicles
(b) dystrophic calcifications in surface epithelial inclusion cysts
(c) tiny cystic spaces with reverberation artifacts

Graafian Follicle

[Reinier de Graaf (1641-1673), Dutch physician and anatomist]
= DOMINANT FOLLICLE
Time of onset: day 8–10–12 of 28-day menstrual cycle
Size of mature graafian follicle: 17–29 mm
• rapidly rising estradiol production triggers the hypothalamic arcuate nucleus to increase GnRH secretion → prompts anterior pituitary to disgorge the stored LH over 24 hr
• LH binds to ovarian receptors → releases cAMP from granulosa cells → halting granulosa cell mitosis + increasing peptidase, collagenase, growth factor, angiotensin, prostaglandin as the cause for follicular rupture + conversion to corpus luteum
√ > 14 mm in diameter:
√ growth rate 2–3 mm/day until the last preovulatory 24 hours followed by a sudden increase in diameter
√ subsequent enlargement to 21 (range 17–24) mm by day 14
√ **cumulus oophorus** = 1-mm mural echogenic focus projecting into antrum of follicle +

containing oocyte, followed by ovulation within next 36 hours
√ 2 dominant follicles may develop in 5–11% of cycles BUT NOT within same ovary

Signs of Ovulation

√ development of solid echoes within graafian follicle
√ decrease in diameter / sudden collapse of dominant follicle 28–35 hours after LH peak
√ "ring" structure within uterine fundus
√ free fluid appearing in pouch of Douglas

Signs of Ovulatory Failure

√ development of internal echoes prior to 18 mm size
√ continuous cystic enlargement up to 30–40 mm

Hormonal Status

Thelarche = onset and progress of breast development
Mean age: 8 years

Adrenarche = onset and progress of pubic (pubarche) + axillary hair development
Mean age: 9.8 years

Menarche = first episode of vaginal bleeding originating from the uterus
Mean age: 12.7 years in USA

RADIOLOGY CONSIDERATIONS FOR MOTHER & FETUS & NEONATE

CONTRAST MEDIA DURING PREGNANCY

No well-controlled studies available on the use of oral / IV iodinated / IV gadolinium contrast material!

Oral Contrast Material

◊ Not considered a threat to pregnant patients due to intraluminal administration + excretion!
◊ Intraluminal barium can act as internal shielding

IV Iodinated Contrast Medium

= FDA category B drug: NO fetal risk in animal reproduction studies
◊ Considered generally inert + safe in pregnancy!
Physiology: IV iodinated contrast material crosses placenta + enters the fetus
Risk: depression of fetal thyroid function ← uptake of free iodine; NO mutagenic / teratogenic effects of lower-osmolality contrast media (in lab animals)
Recommendation: evaluate thyroid function of newborn in first few days of life (already standard practice in U.S. for all newborns)

IV Gadolinium-based Contrast Medium

Physiology: IV gadolinium-based contrast material crosses placenta + enters the fetus
Risk: toxic effects of high doses in lab animals (doses 2–7 x higher than used in humans); NO direct toxic effects of gadolinium in humans
Theoretical risk: gadolinium chelates may accumulate in amniotic fluid → dissociate over time → release toxic free gadolinium ions (of no known clinical significance)
Recommendation: well documented thoughtful risk-benefit analysis based on potential benefit outweighing theoretical risks

FETAL EXPOSURE TO RADIATION

Counseling for necessary exposure to radiation while pregnant:

- Have written policy for screening + management of pregnant women:
  - › last menstrual period (LMP > 14 days): reliable, regular?
  - › checking of b-hCG level needed?
  - › imaging protocol adjustment possible?
- Expeditious consultation with medical physicist to evaluate required fetal dose and associated risk
- Discussion of risk with parents to make informed decision

Potential Radiation Effects on Fetus by Gestational Age			
Gestational Period	*Gestational Age (wk)*	*Effects (theoretical risk for < 100 mGy unlikely)*	*Estimated Threshold Dose (mGy)*
Before implantation	0–2	**All** (death of embryo) **or None**	50–100
	3–4	Spontaneous abortion possible	
Organogenesis	2–8	Congenital anomalies: skeleton, eyes, genitals	200
		Growth retardation	200–250
Fetal Period	8–15	Severe mental retardation	60–310
		Intellectual deficit	25 IQ point loss per Gray
		Microcephaly	200
	16–25	Severe mental retardation (low risk)	250–280
	18–27	IQ deficit not detectable at diagnostic doses	
	> 27	None applicable to diagnostic medicine	

  - › for most diagnostic procedures the risk of congenital anomalies, miscarriage, birth defects, or mental retardation is negligible
  - › the risk of childhood cancer and leukemia is real but small compared to other spontaneous risks
  - › available imaging options should be described
  - › consequences of delaying / refusing imaging must be explained

    MR: inform patient that there are no known risks to the fetus. However, MR's safety has not been proved and cannot be guaranteed
- Calculation of precise dose delivered to fetus with consideration of gestational age, maternal body habitus and acquisition parameters
  - › not performed after head scan (insignificant scatter radiation to fetus)
  - › not performed during first 2 weeks of pregnancy (all-or-nothing response)
- Thermoluminescent dosimeter (TLD) on skin of patient to determine surface dose if medical physicist not on staff:
  - › fetal dose estimate = ⅓ of entrance dose of average patient
  - › if estimated dose > 50 mGy a consulting physicist is needed for detailed dosimetry report
- Modify CT scans to use the lowest dose possible: ⇓ z-axis coverage, ⇑ pitch, ⇓ tube potential (kilovolt peak), ⇓ tube current–time product (milliampere-second)

Effect of Ionizing Radiation on Fetus

= biologic effect of ionizing radiation on physical and chemical processes result in
(1) cell death OR
(2) morphologic effects (via alteration of nuclear DNA) → genetic mutation (teratogenesis) / carcinogenesis

Deterministic Effects

= NONSTOCHASTIC EFFECT = THRESHOLD EFFECT
[*terminus* , Latin = end, limit; *determinare* , Latin = setting limits]
= dose threshold before damage occurs to a number of cells (= multicellular damage) caused by radiation at high doses
Effect: malformation, growth + mental retardation, death
Risk: increasing with increasing dose

Dose threshold: 100 mGy to fetus (dependent on time of exposure to gestation)
- 3% chance of cancer (leukemia, breast, thyroid, brain)
- 6% chance of mental retardation
- 15% chance of microcephaly
- loss of 30 IQ points per 100 mGy

◊ NO risk to embryo / fetus from any diagnostic procedure!

Vulnerable stage: 8th–15th (range, 2nd–20th) week GA

Recommendation: assess for pregnancy termination at 150 mGy exposure to fetus

Stochastic Effects

[*stokhastikos* , Greek = capable of guessing, conjecture]

= damage to a single cell with exposure to any amount of ionizing radiation increasing with radiation dose

Effect: carcinogenesis, other germ cell mutation

Dose threshold: none

Incremental risk of cancer:

fetal dose up to 1 mGy: < 1÷10,000

fetal dose of 20–50 mGy: < 1÷250

(general population without radiation: 1÷500)

Effect of Diagnostic Imaging on Fetus

Natural background radiation: 1 mGy to fetus during pregnancy

◊ Most radiologic studies use ionizing radiation of < 0.05 Gy (50 mGy) resulting in a negligible risk compared to natural risks of pregnancy

Natural risks of pregnancy:
- › 15% risk of spontaneous abortion
- › 4% risk of prematurity
- › 4% risk of growth retardation
- › 3% risk of spontaneous birth defect
- › 1% risk of mental retardation

A fetal radiation dose of 50 mGy increases the overall lifetime risk for cancer by 2%!

Fetal radiation doses of < 50 mGy are not associated with increased fetal malformation or fetal loss throughout pregnancy!

A fetal radiation dose of < 100 mGy also should not be considered a reason to terminate pregnancy.

CT during Pregnancy

(a) head / cervical spine / extremities: little concern during any trimester of pregnancy

(b) Chest = low-dose examination when fetus is excluded from primary beam

(c) renal stones, appendicitis, pulmonary emboli: no fetal neurologic deficits

(d) appendicitis: may double risk for childhood cancer

◊ US and MR should be considered whenever possible!

During pregnancy CT is the first-line imaging modality for trauma and suspected pulmonary emboli.

Trauma is the leading cause of nonobstetric maternal mortality worldwide.

In developing countries, venous thromboembolism is the leading cause of maternal mortality.

MR during Pregnancy

Concern: heating effects of RF pulses and acoustic noise

◊ No known harmful effects to date at ≤ 1.5 T

> MR imaging can be used in pregnant patients regardless of gestational age (1) when the information gained is likely to alter treatment, (2) when it cannot be obtained through other nonionizing means, and (3) when MR imaging cannot be delayed until completion of the pregnancy.

Recommendation: written informed consent to document patient's understanding of risk-benefit ratio + any alternative diagnostic options

US during Pregnancy

◊ No documented adverse effects on fetus from US

Estimated Radiation Doses to Fetus	
Type of Exam	*Fetal Dose (mGy)*
Annual background radiation	*1.1–2.5*
High Dose (10–50 mGy)	
Abdominal CT	1.3–35
Pelvic CT	10–50
CT abdomen & pelvis	25
CT angio of aorta	34
PET/CT	10–50
Moderate Dose (0.1–10.0 mGy)	
Radiography	
Abdomen (AP) 21-cm patient thickness	1.0
Abdomen (AP) 33-cm patient thickness	3.0
L spine (2 views)	1.0–10
IVP	5–10
DC barium enema	1.0–2.0
CT	
Head & neck CT	0–10
Chest CT / angio CT of chest	0.01–0.66
CT pelvimetry (single section)	<1
CT of coronaries	0.1
NucMed	
Perfusion scintigram (low dose)	0.1–0.5
^{99m}Tc bone scintigram	4–5
Pulmonary DSA	0.5
Low Dose (< 0.1 mGy)	
C-spine (2 views)	< 0.001
Extremity radiography	< 0.001
Mammography (2 views)	0.001–0.010
T-spine	0.003
CXR (2 views)	0.0005–0.0100

Estimated Radiation Doses to Fetus from a Single Acquisition with a 64-Row CT Scanner					
		CT Protocol		*Imaging Parameters*	
Type of CT Exam	*Fetal Dose (mGy)*	*Section Thickness (mm)*	*Noise Index*	*Tube Current-Time Product (mAs)*	*Pitch*
Chest	0.02	2.5	30	80	1.375
Pulmonary angio	0.02	1.25	30	88	0.984
	0.24–0.66 in anthropomorphic phantom with 16-row CT				
Abdomen	1.3	2.5	36	110	1.375
Urinary tract	11	2.5	36	110	1.375
	4–12 in anthropomorphic phantom with 16-row CT				
Pelvis	13	2.5	36	130	1.375
Abdomen & Pelvis	13	2.5	36	130	1.375
	15–40 in anthropomorphic phantom with 16-row CT				
Angio	13	2.5	30	130	1.375

Upper exposure limit: 720 mW/cm^2 for spatial-peak temporal average intensity
Doppler US: can produce high intensities
◊ Keep exposure time + acoustic output at lowest level possible

Clinical Scenarios

Abdominal Pain in Pregnancy

Imaging sequence: US → low-dose CECT / MR (if US nondiagnostic)

Acute Appendicitis in Pregnancy

◊ Most common nonobstetric emergency requiring surgery during pregnancy!
Associated with: premature labor, fetal morbidity + mortality, high rate of perforation
• limited use of clinical signs in pregnancy
Imaging sequence: US with graded compression → MR / CECT (if US nondiagnostic)
› Graded Compression US: 66–100% sensitive, 95–96%specific
› MR: 100% sensitive, 94% specific, 94% accurate, PPV of 1.4%, NPV of 100%
› CT: 92% sensitive, 99% specific, NPV of 99%
Associated cancer risk: 1÷500 fetuses exposed to 30 mGy

Pulmonary Embolism in Pregnancy

Prevalence: 0.5–3.0÷1,000 pregnancies
Risk of DVT: 5 x increase compared to nonpregnant state ← ↑ venous stasis + hypercoagulability
Mortality: up to 15%

• progressive ↑ in D-dimer levels during normal pregnancy

Imaging sequence: PA chest → Doppler US → CT angio chest OR V/Q scan (if allergic to iodine)

› Compression US
  » for thigh veins: 95% sensitive, 98% specific
  » for iliac veins: low sensitivity

N.B.: 10% of patients have PE angiographically

› CT angiography: 81–91% sensitive, 93–97% specific

› High-probability V/Q scan: 41% sensitive

Benefit of CT (with abdominal shielding):
  » radiation exposure comparable to V/Q scan
  » allows identification of other causes of chest pain (pulmonary edema, pneumonia, pleural effusion)

Trauma in Pregnancy

◊ Leading nonobstetric cause of maternal death!

Prevalence: 6–7% of pregnant women (MVA)

Fetal mortality: 3–38% after blunt trauma ← placental abruption or maternal death / shock

(a) low-level trauma: US

(b) serious trauma: tailored CT of head, chest, abdomen, pelvis; MR for neural axis; angio for extravasation
  ◊ Concerns about fetal radiation exposure should neither deter nor delay radiologic evaluation!

(c) uterine / fetal injury: US ± CT / MR

Urolithiasis in Pregnancy

◊ Most common painful nonobstetric condition for hospitalization in pregnant patients!

• admitting diagnosis in 28% incorrect

Prevalence: 0.4–5.0÷1,000 pregnancies

Prognosis: 70–80% of ureteral calculi pass spontaneously

Cx: pyelonephritis, premature labor induced by renal colic

Imaging sequence: US → low-dose NECT (if US nondiagnostic)

› US: 34–95% sensitive

› MR urography

› low-dose CT: > 95% sensitive, > 98% specific

NEONATAL EXPOSURE TO IV CONTRAST MEDIA

◊ *Interruption of **breast feeding** is NOT recommended! (*not even for 24–48 hours)!

› breast feeding is recommended as the only source of feeding for full-term healthy infants during first 6 months of life (WHO)

› should be continued during first 2 years / longer if desired

› temporary cessation can lead to complete weaning

It is not necessary to stop breast-feeding. Some mothers may prefer to express and discard breast milk for 12–24 hours after they are given contrast agents.

Pharmacokinetics:
nonionized and water-soluble iodinated + Gd-based contrast media have high molecular weight → minimal binding to breast milk → low concentration of injected dose in breast milk (0.01% for gadopentetate and 0.5% for iohexol) → contrast in milk peaks at 5 hours; undetectable after 12 hours

Only a small percentage of iodinated or Gd-based contrast material is excreted in breast milk and absorbed by the infant. There have been no reported cases of direct toxicity, allergic sensitivity, or reaction to these agents.

Ingested Dose: 0.2% of maximum dose allowed for urography

IV CONTRAST MATERIAL IN PEDIATRICS

Conventional dose: 1 mL÷pound up to 150 mL
Maximum dose: 280–300 mg I/mL
Recommended Pediatric Dose for Urography:
for babies < 6.5 kg: 900 mg I/kg body weight
for babies > 7.0 kg: 600 mg I/kg body weight

OBSTETRIC AND GYNECOLOGIC DISORDERS

ABORTION

= loss of products of conception < 20 weeks of MA (definitions may vary)

A. INDUCED ABORTION
   (a) medical / therapeutic abortion
   (b) nonmedical abortion

B. SPONTANEOUS ABORTION

Spontaneous Abortion

= FAILED PREGNANCY = PREGNANCY LOSS = MISCARRIAGE

Frequency:

› > 50% of all fertilized ova (estimate)
› 31–43% of all implantations (estimate)
› 10–25% of clinically diagnosed pregnancies
› 2–4% with normal cardiac activity
› decreases with increasing gestational age

Time of loss: < 8–10 weeks MA; majority before 7th week MA

Etiology (usually due to abnormal karyotype):
autosomal trisomy (52%), triploidy (20%), monosomy (15%)

◊ Spontaneous pregnancy loss at < 8 weeks gestation occurs in 10–17% of embryos with cardiac activity!

Signs of Abnormal Pregnancy
√ thin decidual reaction of < 2 mm
√ abnormally shaped sac
√ gestational sac low in uterus

Impending / Inevitable Abortion

= ABORTION IN PROGRESS
= gestational sac with embryo having become detached from implantation site → spontaneous abortion within next few hours

• Clinical triad: (1) bleeding > 7 days, (2) persistent painful uterine contractions, (3) rupture of membranes
• cervix moderately effaced / dilated > 3 cm
√ sac located low within uterus (DDx: cervical ectopic with closed internal os)
√ progressive migration of sac toward / into cervical canal (on rescanning a short time later)
√ dilated cervix
√ sac surrounded by anechoic zone of blood

Threatened Abortion

= 1st trimester bleeding (after period of implantation bleed at 3–4 weeks MA) with a live

embryo

Frequency: 20–25% of all pregnancies

- Clinical triad: (1) mild bleeding, (2) cramping, (3) closed cervix

NONVIABILITY DIAGNOSIS WITH CERTAINTY

on transvaginal ultrasound

@ Cardiac activity:
- √ no cardiac activity with a CRL ≥ 5 mm
- √ no cardiac activity with certain GA ≥ 6.5 weeks
- √ no cardiac activity with a GS diameter > 16 mm

@ Yolk sac:
- √ no yolk sac with a GS diameter ≥ 20 mm
- √ embryo visualized without demonstrable yolk sac
- √ yolk sac diameter > 5.6 mm at < 10 weeks MA

@ GS contents:
- √ fibrinous strands / residual embryonic debris (in 25%)

NONVIABILITY DIAGNOSIS WITH HIGH PROBABILITY

on transvaginal ultrasound

@ Ultrasound milestones not met as expected:
- √ ≥ 5.0 weeks gestational sac first identifiable
- √ ≥ 5.5 weeks yolk sac first identifiable
- √ ≥ 6.0 weeks embryo and FHM first identifiable

@ Yolk sac:
- √ no yolk sac with GS of 6–9 mm
- √ distorted sac configuration

@ Choriodecidua
- √ thinning of choriodecidual reaction with hypoechoic clefts

@ Cardiac activity:
- √ no cardiac activity with GS of ≥ 9 mm
- √ slow embryonic heart rate (=bradycardia):

≤ 6.2 Weeks	*≤ 7.0 Weeks*	*Mortality Rate*
> 100 bpm	> 120 bpm	11%
90–99 bpm	110–119 bpm	32%
80–89 bpm	100–109 bpm	64%
< 80 bpm	< 100 bpm	100%

Predictors of poor outcome:

@ Bradycardia
- √ < 85 bpm during 5–8 weeks EGA

@ Small sac size = "first-trimester oligohydramnios"

[misnomer: amnionic cavity is not diminished in size but rather the chorionic cavity]

= MSD (mean sac diameter) – CRL ≤ 5 mm (with a live embryo at 5.5–9.0 weeks)

Prognosis: miscarriage in 94%

@ Abnormal yolk sac

√ failure to visualize yolk sac at 5.5 weeks MA = mean diameter of GS ≥ 8 mm
√ yolk sac size > 5 mm
√ calcification / debris within yolk sac
√ double appearance of yolk sac

@ Abnormal amnion
√ mean diameter of amniotic cavity > CRL

@ Subchorionic hemorrhage
Frequency: in up to 18% of pregnancies during first half of pregnancy
N.B.: significance controversial

Prognosis: 50% develop normally; 15–39% blighted ovum, 4% mole, 4–13% ectopic pregnancy, 0–15% incomplete abortion, 17–57% missed abortion

Complete Abortion

- absence of transvaginal bleeding, cervix closed
- abrupt decline of serum β-hCG

√ IUP no longer visualized although documented previously
√ thin regular endometrium (< 10–15 mm) with apposed surfaces
√ absence of central / eccentric fluid-filled sac

DDx: nongravid state, very early IUP, ectopic pregnancy
Rx: dilatation & curettage may be avoided if IUP was documented previously

Incomplete Abortion

= RETAINED PRODUCTS OF CONCEPTION (RPOC)
= portion of chorionic villi (placental tissue) / trophoblastic tissue (fetal tissue) remaining within uterus after spontaneous abortion (= miscarriage) / planned termination / preterm or term delivery
= most frequent cause of secondary postpartum hemorrhage (2°PPH)

Incidence: › 1st trimester: 40%
› 2nd trimester 17%
› 3rd trimester: 3%

- incomplete placenta at delivery, patulous cervix
- continued (occasionally massive) genital bleeding (may occur months / years after last abortion / delivery)
- normal / low levels of β-hCG

US:
√ fetal parts / embryo / echogenic mass within uterine cavity (MOST ACCURATE SIGNS)
√ irregular / angulated small gestational sac containing amorphous echogenic material
√ ragged disrupted choriodecidual reaction
√ subchorionic fluid ± hemorrhage
√ intracavitary heterogeneously echogenic mass separate from endometrium
√ > 8–10–13 mm thickened endometrial echo complex
◊ Measurement of endometrial thickness alone is a poor test for diagnosing an incomplete miscarriage!
√ calcification of retained products (late finding)

Incomplete Miscarriage versus Endometrial Thickness on US				
Endometrial Thickness	*Sensitivity*	*Specificity*	*PPV*	*NPV*
> 5 mm	0.94	0.05	**0.85**	0.13
> 8 mm	0.87	0.21	**0.86**	0.22
> 12 mm	0.75	0.37	**0.87**	0.80
> 15 mm	0.56	0.53	**0.87**	0.17
> 25 mm	0.10	0.32	**0.88**	0.33

Sawyer E, Ofuasia E, Ofili-Yebovi D et al.: The value of measuring endometrial thickness and volume on transvaginal ultrasound scan for the diagnosis of incomplete miscarriage. Ultrasound Obstet Gynecol 2007; 29:205-209

Doppler US (x 2 improvement in diagnosis):

√ ± increased vascularity in endometrial echo complex / intracavitary mass (compared to myometrium)

√ flow velocity > 21 cm/sec (supplying residual trophoblastic tissue)

√ ± low-resistance internal blood flow often at endometrial-myometrial interface

Pitfalls: uterine AVM (involves myometrium only), endometrial polyp, submucosal fibroid

MR:

√ partially / delayed enhancing heterogeneous mass on T1WI + T2WI (DDx: gestational trophoblastic disease)

Dx: presence of chorionic villi in curettage exhibiting variable vascularity

Cx: endometritis, myometritis, peritonitis, septic shock, diffuse intravascular coagulation (with retention > 1 month)

Rx: expectant management, uterotonic medication (prostaglandin E1 analogs), suction D&C after IV oxytocin, hysteroscopic removal

DDx: intraluminal blood clot, mole, blighted ovum, embryonic demise, intrauterine fetal death

Placental Polyp

= intrauterine polypoid mass formed by a retained fragment of placental tissue after an abortion / term pregnancy

Predilection: placenta accreta

MR:

√ hyperintense polypoid mass on T2WI

DDx: arteriovenous malformation, trophoblastic disease, endometrial polyp, submucosal myoma

Subinvolution of Placental Implantation Site

= exceptionally rare postpartum condition characterized by failure of uterine vessels to involute following delivery

Risk factors: atony, multiparity, cesarean section, uterine prolapse, uterine fibroids, endometritis, coagulopathy, RPOC

√ unusually large postpartum uterus

√ dilated myometrial vessels

Missed Abortion

= dead conceptus within uterine cavity for ≥ 8 weeks occurring prior to 28 weeks MA

Time of diagnosis: not before 13 weeks MA

• brownish vaginal discharge, closed firm cervix

√ no cardiac activity in a well-defined embryo with CRL > 9 mm (on abdominal scan) / CRL > 5 mm (on TV scan)

√ gestation not in correspondence with menstrual age

√ sac > 25 mm in diameter without an embryo (DDx: anembryonic pregnancy)

√ sac > 20 mm without yolk sac

√ crenated irregular / distorted angular sac configuration

√ stringlike debris within gestational sac (in 25%)

√ discontinuous / irregular / thin (2 mm) choriodecidual reaction

√ no double decidual sac

√ low sac position

√ subchorionic collection

Cx: coagulopathy ← low plasma fibrinogen (after 4 weeks in 2nd trimester pregnancy)

Rx: suction D&C (in 1st trimester); prostaglandin E suppositories (in 2nd trimester)

DDx: blighted ovum

ACARDIA

= ACARDIAC MONSTER = TWIN REVERSED ARTERIAL PERFUSION SEQUENCE (TRAP)

= rare developmental anomaly of monochorionic twinning in which one twin develops without a functioning heart

Prevalence: 1÷30,000–35,000 births; in 1% of monozygotic twins

Pathophysiology:

normal twin perfuses acardiac twin through artery-to-artery + vein-to-vein anastomoses in shared placenta → reversed circulation alters hemodynamic forces → abnormal cardiac morphogenesis

Spectrum:

(1) **Holoacardia** = no heart at all

(2) **Pseudoacardia** = rudimentary cardiac tissue

√ proximity of the 2 cord insertions on placental surface linked by an arterioarterial anastomosis

√ reversed arterial flow in cord toward acardiac twin

√ fused placentas

√ polyhydramnios

A. PUMP TWIN

Risk: increased for fetal demise + preterm labor

√ morphologically normal

√ cardiac overload signs: hydrops, IUGR, hypertrophy of right ventricle, increased cardiothoracic ratio, hepatosplenomegaly, ascites

B. PERFUSED TWIN = ACARDIAC TWIN

Pathophysiology: vascular anastomosis sustains life of acardiac monster
Associated with: monochorial placenta (= same gender); wide range of abnormalities
√ absent / rudimentary heart ("acardius")
√ tiny / absent cranium (acephalus)
√ small upper torso ± absent / deformed upper extremities
√ marked integumentary edema + cystic hygroma
Prognosis: mortality of 100% for perfused twin, 50% for pump twin (increased with increased size of acardiac twin)
Rx: laser ablation of umbilical cord to acardiac twin (up to 20–22 weeks)

ADENOMYOSIS

= ENDOMETRIOSIS INTERNA (term no longer used)
= focal / diffuse benign invasion of myometrium by endometrium (heterotopic "endometrial islands") inciting reactive myometrial (smooth muscle) hyperplasia
Cause: ? uterine trauma (parturition, myomectomy, curettage), chronic endometritis, hyperestrogenemia
Prevalence: 5–70% of hysterectomy specimens
Hormonal dependency:
ectopic endometrial glands of adenomyosis (= generally of basalis type of endometrium) do NOT respond to cyclic ovarian hormones (largely nonfunctioning ← resistance to hormonal stimulation unlike endometriosis); some degree of proliferative + secretory changes occur during menstrual cycle; tamoxifen (= nonsteroidal antiestrogen) increases incidence of adenomyosis in postmenopausal women
Path: endometrial glands deeper than ¼ of thickness of junctional zone = 2–3 mm below endometrial-myometrial junction
Histo: endometrial glands + stroma within myometrium surrounded by smooth muscle hyperplasia
Age: multiparous premenopausal women > 30 years during menstrual life (later reproductive years)
Associated with: endometriosis (in 36–40%)
Types: diffuse form / focal (localized circumscribed) form
• asymptomatic in 5–70%; pelvic pain, menorrhagia, dysmenorrhea (abates after menopause)
√ globular uterine enlargement
HSG:
√ multiple small linear / saccular diverticula extending into myometrium
√ uterine cavity may be enlarged / distorted
√ irregular masslike filling defect in uterine fundus in focal adenomyosis
US (53–89% sensitive, 67–98% specific, 68–86% accurate):
√ poorly marginated hypoechoic heterogeneous areas within myometrium + myometrial cysts
√ globular / asymmetrically enlarged uterus
MR (78–93% sensitive, 66–93% specific, 85–90% accurate):
√ diffuse / focal thickening of junctional zone forming an ill-defined area of low SI ± embedded bright foci on T2WI
Cx: infertility

Rx: conservative medical treatment (analgesics + minimally effective menstrual suppression Rx with danazol / GnRH agonist); surgical treatment (endometrial ablation, laparoscopy, lesion excision; alternatively uterine artery embolization; hysterectomy (the only definitive cure for debilitating adenomyosis)

Cystic Adenomyosis

= very rare well-circumscribed cystic myometrial lesion of hemorrhage in different stages of organization (in 40% of diffuse adenomyosis, in 100% of focal adenomyosis)

Path: extensive menstrual bleeding into ectopic endometrium ← unusual response to cyclical ovarian hormones

Location: uterine origin confirmed by (a) myometrial splaying around lesion, (b) "bridging vessel" sign (c) separate distinct identification of ovaries

√ "Swiss cheese" appearance of myometrium on US

√ miniature uterus:

- √ fluid content of high SI ← hemorrhage at different stages of organization similar to endometriotic cyst
- √ surrounding wall of inner zone of low SI on T1WI (= junctional zone)
- √ relatively bright outer myometrium

DDx: (1) Leiomyoma with hemorrhagic degeneration
(2) Hematometra

Diffuse Adenomyosis (67%)

In 90% associated with: pelvic endometriosis (in women < 36 years of age)

• infertility ← impaired uterine contractility for directed sperm transport

US:

- √ smooth uterine enlargement (DDx: diffuse leiomyomatosis)
- √ asymmetric thickening of anterior and posterior myometrial walls
- √ diffuse heterogeneous myometrial echotexture (in 75%):
  - √ nodular / linear areas of increased myometrial echogenicity (= heterotopic endometrial tissue)
  - √ area of decreased myometrial echogenicity (= smooth muscle hyperplasia)
- √ HIGHLY SPECIFIC < 5 mm small subendometrial cysts (in 50%) ← dilated cystic glands / hemorrhagic foci
- √ widening of junctional zone > 12 mm on T2WI
- √ poor definition of endomyometrial junctional zone (= endometrial tissue extending into myometrium)
- √ pseudowidening of endometrium ← increased myometrial echogenicity
- √ lack of uterine contour abnormality / mass effect

MR:

- √ enlargement of the uterus
- √ widening of junctional zone (= inner myometrium) ≥ 12 mm hypointense on T2WI, T2-weighted SE images, contrast-enhanced T1WI ← hyperplasia of smooth muscle
- √ bright foci on T2WI (50%) ← islands of ectopic endometrial tissue + cystic dilatation of glands:

√ pseudowidening of endometrium (= indistinct foci of endometrial invasion of myometrium)
√ myometrial cysts + nodules, linear striations
√ foci of high SI on T1WI ← hemorrhage within ectopic endometrial tissue
√ variable degrees of enhancement always less than adjacent myometrium

DDx: (1) Marked physiologic thickening of junctional zone during menstruation (esp. cycle days 1 + 2)
◊ Avoid imaging during menstrual phase
(2) Myometrial contraction (ill-defined hypointense area on T2WI in up to 75%, transient nature, distortion of endometrial lining)
(3) Muscular hypertrophy (hypoechoic inner myometrium, diffuse junctional zone thickening)
(4) Endometrial carcinoma (error in staging if adenomyosis coexists)

Focal Adenomyosis (33%)

= "ADENOMYOMA"
√ polypoid mass (= polypoid adenomyoma / adenomyomatous polyp) protruding into uterine cavity (less commonly in myometrial / subserosal location)

US:
√ focal echogenic myometrial mass of 2–7 cm in diameter:
√ mass of oval / elongated shape with ill-defined margins
√ contiguity with junctional zone
√ penetrating vascular pattern

MR:
√ oval myometrial mass with indistinct margins of primarily low SI on all sequences ← surrounding reactive dense smooth muscle hypertrophy
√ widening of the junctional zone from 8 mm up to 12 mm
√ focal thickening of junctional zone > 12 mm
√ linear / round foci of high SI on T1WI within mass ← T1 shortening effect of methemoglobin in hemorrhagic foci
√ spotty signal voids on GRE ← T2*-shortening effect of hemosiderin in old hemorrhagic foci
√ foci of central high-intensity spots / linear striations on T2WI (= dilated endometrial glands in secretory phase / endometrial cyst, hemorrhagic focus) in 50%
√ low to intermediate SI on DWI ← benign neoplastic nature

Rx: polypectomy / myomectomy

DDx:
(1) Fibroid = leiomyoma (round hypoechoic mass anywhere in myometrium, well-defined margins, separate from junctional zone, calcifications, edge shadowing, whorled appearance, draping pattern of dilated vessels in periphery of mass, low SI on T1WI + T2WI, no small foci of high SI on T2WI)
(2) Adenomatoid tumor of uterus
= rare benign mesothelial tumor difficult to distinguish from leiomyoma / adenomyoma
(3) Metastatic myometrial involvement by cancer of breast, stomach, malignant lymphoma

(4) Low-grade endometrial stromal sarcoma (rare, young woman, extensive myometrial invasion)

AMNIOTIC BAND SYNDROME

= CONGENITAL CONSTRICTION BAND SEQUENCE = EARLY AMNION RUPTURE SYNDROME
= "slash defects" in nonanatomic distribution

Pathogenesis:
(a) early amniotic rupture exposing the fetus to the injurious environment of constrictive fibrous mesodermic bands that emanate from the chorionic side of the amnion
(b) vascular disruption events

Prevalence: 0.5–1.0÷10,000 live births

√ very thin sheet / band attached to fetus:
√ fine linear echoes that extend from fetal defect to uterine wall but are difficult to see
√ membrane that flaps with fetal movement
√ restriction of fetal motion ← entrapment of fetal parts by bands

Associated with fetal deformities in 77%:

1. Limb defects (multiple + characteristically asymmetric)
   √ simple grooves / constriction rings of limbs / digits
   √ amputation of limbs / digits
   √ distal syndactyly
   √ clubbed feet (30%)
   √ gibbus deformity of spine
2. Craniofacial defects
   = asymmetric nonanatomic defects of skull + brain
   √ pterygium, facial cleft
   √ anencephaly
   √ asymmetric lateral encephalocele
   √ facial clefting of lip / palate
   √ asymmetric microphthalmia
   √ incomplete / absent cranial calcification
   √ ± attachment of head to uterine wall
3. Visceral defects
   √ thoracoschisis
   √ **abdominoschisis** ± exteriorization of liver
   √ normal umbilical cord

> DDx of abdominoschisis due to bands from body stalk anomaly depends on demonstration of a normal umbilical cord.

√ abdominal contents floating in amniotic fluid without clear visualization of encasing membrane

DDx: (1) Chorioamnionic separation ← subchorionic hemorrhage
(2) Intrauterine synechiae
(3) **Adams-Oliver syndrome** (aplasia cutis, limb defects), scalp and skull defects at vertex associated with often asymmetric transverse limb defects

(4) Body stalk anomaly

ANEMBRYONIC PREGNANCY

= BLIGHTED OVUM

= abnormal intrauterine pregnancy with developmental arrest prior to formation of embryo; may occur as a blighted twin

Cause: early arrest of embryonic development related to chromosomal abnormality

• ± vaginal bleeding

√ empty gestational sac (> 6.5 weeks MA)

√ yolk sac identified without embryo:

√ vanishing (passed) yolk sac on serial scans

√ gestational sac small / appropriate / large for dates:

√ decrease in gestational sac (GS) size

√ GS fails to grow by > 0.6 mm/day on serial scans

√ irregular weakly echogenic decidual reaction of < 2 mm

√ distorted sac shape

(a) by transabdominal scan:

GS usually not visualized before 5.0–5.5 weeks MA; yolk sac forms at 4 weeks MA when GS is 3 mm; embryo usually visualized by 6 weeks MA

√ GS size ≥ 10 mm of mean diameter without DDS

√ GS size ≥ 20 mm of mean diameter without yolk sac

√ GS size ≥ 25 mm of mean diameter without embryo

(b) by transvaginal scan

normal intradecidual GS routinely detected at 4–5 weeks with a mean sac diameter of 5 mm

√ GS size ≥ 8 mm of mean diameter without yolk sac

√ GS size ≥ 16 mm of mean diameter without cardiac activity

Cx: first trimester bleeding

ARTERIOVENOUS MALFORMATION OF UTERUS

= UTERINE ARTERIOVENOUS FISTULA = UTERINE CIRSOID ANEURYSM

Associated with: dilatation & curettage, endometrial carcinoma, gestational trophoblastic disease

• genital bleeding, often requiring blood transfusions

MR:

√ tortuous tubular signal voids in myometrium / parametrium / protruding into endometrial cavity on T1WI + T2WI

√ vascular lake with sluggish flow hyperintense on T2WI

√ intensely enhancing lesion isointense to vessels on contrast-enhanced dynamic subtraction MR

ASHERMAN SYNDROME

[Joseph G. Asherman (1889–?), Czech-Israeli gynecologist in Tel Aviv]

= association of multiple intrauterine synechiae (= adhesions consisting of fibrous tissue or smooth muscle) with menstrual dysfunction + infertility

Cause: sequelae of endometrial trauma (vigorous instrumentation during dilatation & curettage) usually during postpartum or postabortion period / severe endometritis

Path: scars / bands of fibrous tissue (synechiae) connect opposing sides of the endometrium by crossing the endometrial cavity; scars cause the endometrial cavity to contract resulting in an irregular surface

• hypomenorrhea / amenorrhea; habitual abortion / sterility

HSG:

√ solitary / multiple filling defects

√ bands of tissue traversing endometrial cavity

√ irregular surface contour of uterine cavity

√ small uterine cavity partially / near completely obliterated (DDx: DES exposure)

Sonohysterography:

√ echogenic bands bridging the uterine cavity

◊ Thick fibrotic bands may prevent complete uterine distension

MR:

√ small thin irregular endometrial cavity

BARTHOLIN GLAND CYST

[Caspar Bartholin the Younger (1655–1738), Danish anatomist and physician]

= retention cyst

Origin: derived from urogenital sinus, female homologue of male (bulbourethral) Cowper glands

Cause: chronic inflammation / infection of gland → ductal obstruction from purulent material / thick mucus

Histo: lined by <u>mucinous</u> transitional cell / columnar epithelium

Location: posterolateral inferior ⅓ of vaginal introitus medial to labia minora <u>at / below</u> level of pubic symphysis

Size: 1–4 cm

√ unilocular cyst hyperintense on T2WI

√ variable T1 hyperintensity depending on proteinaceous / mucinous contents

Rx: administration of silver nitrate; marsupialization; surgical excision

BECKWITH-WIEDEMANN SYNDROME

[John Bruce Beckwith (1933–?), pediatric pathologist at Children's Orthopedic Hospital in Seattle, WA]

[Hans Rudolf Wiedemann (1915–2006), chair of pediatrics at the University of Kiel, Germany]

= EMG SYNDROME (**E**xomphalos = omphalocele, **M**acroglossia, **G**igantism)

= common autosomal dominant overgrowth syndrome with reduced penetrance + variable expressivity related to short arm of chromosome 11; sporadic in 85%

Prevalence: 1÷13,700 to 1÷14,300 live births; M÷F = 1÷1

4% risk for developing embryonal tumors:

nephro-, hepato-, pancreatoblastoma, rhabdomyosarcoma

• neonatal polycythemia

√ advanced bone age

Constellation:

(1) Hemihypertrophy 13–33%
(2) Hyperplastic visceromegaly: 57%
kidney, liver (hepatomegaly), spleen, pancreas, clitoris, penis, ovaries, uterus, bladder
(3) Abdominal wall defects
(a) Omphalocele 76%
(b) Umbilical hernia 49%
(c) Diastasis recti 33%
(4) Macroglossia 98%
(5) Facial nevus flammeus 63%
(6) Ear lobe creases and pits 66%
(7) Prominent eyes with intraorbital creases
(8) Infraorbital hypoplasia 81%
(9) Gastrointestinal malrotation 83%
(10) Pancreatic islet hyperplasia → hyperglycemia
(11) Cardiac anomalies
(12) Natal / postnatal gigantism 77%

@ Adrenal gland
Histo: adrenocortical hyperplasia, hyperplastic adrenal medulla, cystic adrenal cortex, bilateral adrenal cytomegaly (= enlargement of fetal cortical cells)

@ Kidney
Histo: disordered lobar arrangement, medullary dysplasia
√ nephromegaly
√ increased cortical echogenicity ← glomeruloneogenesis
√ accentuation of corticomedullary definition
√ medullary sponge kidney
√ pyelocalyceal diverticula

OB-US:
√ LGA fetus with growth along 95th percentile
√ polyhydramnios (51%)
√ thickened placenta
√ long umbilical cord

Cx: (1) Development of malignant tumors (in 4%)
(2) Neonatal hypoglycemia (50–61%)

BRENNER TUMOR

[Fritz Brenner (1877–1969), German physician and pathologist practicing in German South West Africa and Johannesburg]
= almost always benign uncommon epithelial-stromal ovarian tumor
Frequency: 1.5–2.5%
Histo: transitional epithelial cells (similar to urothelium) within prominent fibrous connective tissue stroma
Associated with: mucinous cystadenoma / other epithelial tumor in 20–30%
Peak age: 40–70 years

• may have estrogenic activity
Size: most 1–2 cm (up to 30 cm) in diameter; bilateral in 5–7%
√ ± extensive calcifications
US:
√ usually hypoechoic solid homogeneous tumor with well-defined back wall
MR:
√ markedly hypointense tumor component on T2WI (fibrous component + calcifications)
√ moderate enhancement (DDx: hypovascular fibrothecoma)

CERVICAL CARCINOMA

◊ Most common gynecologic malignancy in developing countries; 3rd most common gynecologic malignancy (after endometrial + ovarian cancer) in USA; 6th most common cause of death from cancer in women
Highest prevalence: Central + South America > South Central Asia > parts of Africa
Incidence: 12÷100,000 women annually; 12,990 new cases + 4,120 deaths in USA (2016)
Peak age: 45–55 years
Histo: squamous cell carcinoma (80–95%) arising low in endocervical canal, adenocarcinoma (5–20%) arising from endocervical columnar epithelium, clear cell adeno-carcinoma (unusual) in women exposed to DES in utero
Risk factors: lower socioeconomic standing, Black race, early marriage, multiparity, early age at first intercourse, multiple sexual partners, cigarette smoking, immuno-suppressed state, use of oral contraceptives, human papilloma virus infection (HPV serotypes 16, 18, 31, 33, 56 → > 80% of all invasive cervical carcinomas)
Significance of tumor size:
> 4 cm: nodal metastases (80%), local recurrence (40%), distant metastases (28%)
< 4 cm: nodal metastases (16%), local recurrence (5%), distant metastases (0%)
Spread:
(a) direct extension to lower uterine segment + vagina + paracervical space along uterosacral and broad ligaments
(b) lymphatic: paracervical > parametrial > hypogastric + obturator > external iliac > common iliac + presacral > para-aortic nodes
(c) hematogenous: lung, liver, bone
• leukorrhea ± abnormal vaginal bleeding (< 30%)
• intermenstrual / postcoital bleeding / metrorrhagia
Clinical staging: limited accuracy of 66% stage I (78%), stage III (25%)
Location:
arises almost exclusively from transformation zone (= squamo- columnar junction)
(a) on cervix (in young woman)
(b) in endocervical canal (older woman)
with protrusion into vagina / invasion of lower myometrium

Tumors tend to be exophytic in younger patients + endophytic in older patients ← variable location of transformation zone with advancing age

US:
@ Primary tumor

√ small tumor isoechoic to mucosa difficult to detect
√ altered echotexture + distortion of normal cervical morphology + lack of compressibility with increasing size
√ color Doppler US may facilitate visualization and delineation of tumor ← hypervascular tumor (in 95%)

CT:

@ Primary tumor

Staging of Cervical Cancer (2009)
Fédération Internationale de Gynécologie et d'Obstétrique (FIGO)

FIGO Stage	*Description*	*Nodal Metastases*
0	Carcinoma in situ (before invasion)	0.3%
I	Confined to cervix	
IA	preclinical microscopic invasion	
IA1	microinvasion of stroma (≤ 3 mm deep and ≤ 7 mm wide)	0.3%
IA2	tumor > 3 mm and ≤ 5 mm deep and ≤ 7 mm horizontal spread	14%
IB	tumor larger than IA	16%
IB-1	clinically visible lesion ≤ 4 cm	
IB-2	clinically visible lesion > 4 cm	
II	Extension beyond cervix but not to pelvic wall / lower 1/3 of vagina	
IIA	no parametrial invasion	33%
IIA1	clinically visible lesion ≤ 4 cm in diameter	
IIA2	clinically visible > 4 cm in diameter	
IIB	parametrial invasion excepting pelvic sidewall	37%
III	Extension to pelvic wall or lower 1/3 of vagina or hydronephrotic / nonfunctioning kidney	
IIIA	invasion of lower 1/3 of vagina	
IIIB	pelvic side wall invasion + hydronephrosis	
IV	Located outside true pelvis or invasion of bladder or rectal mucosa	55%
IVA	invasion of bladder / rectal mucosa	
IVB	spread to distant organs (paraaortic / inguinal nodes, intraperitoneal metastasis)	

√ growth pattern: exophytic, infiltrating, endocervical
√ bulky enlargement of cervix > 3.5 cm (DDx: cervical fibroid)
√ iso- (50%) / hypoattenuating after IV contrast ← necrosis, ulceration, reduced vascularity
√ gas within tumor (necrosis / prior biopsy)
√ fluid-filled uterus (blood, serous fluid, pus) ← obstruction
√ hypoattenuating lesion of myometrium / with vaginal distension

@ Parametrial spread (30–58% accuracy):

- √ parametrial soft-tissue mass
- √ ureteral encasement
- √ thickening of ureterosacral ligaments
- √ > 4-mm soft-tissue strands of increased attenuation extending from cervix into parametria, cardinal / sacrouterine ligaments
- √ obliteration of fat planes
- √ ill-defined irregular cervical margins
- √ eccentric parametrial enlargement

DDx: parametrial inflammation ← instrumentation, ulceration, infection, prior pelvic surgery, endometriosis

@ Pelvic side wall disease
- √ tumor < 3 mm from side wall
- √ enlarged piriform / obturator internus muscles
- √ encasement of iliac vessels
- √ destruction of pelvic bones

@ Pelvic visceral disease (60% PPV)
- √ loss of perivesical / perirectal fat plane
- √ asymmetric nodular thickening of bladder / rectal wall
- √ intraluminal mass
- √ air in bladder ← fistula

@ Lymphatic spread (65–77–80% accuracy)
- √ nodes > 1 cm in diameter (> 7 mm for internal iliac nodes, > 9 mm for common iliac nodes, > 10 mm for external iliac nodes) with 44% sensitivity
- √ lymph node necrosis (100% PPV)

DDx: adenopathy from secondary tumor infection

MR (76–78–91% accuracy for staging, 82–94% accuracy for parametrial involvement):

@ Primary tumor
- √ focal bulge / mass in cervix:
  - √ mass isointense on T1WI
  - √ hyperintense on T2WI compared with fibrous stroma (DDx: postbiopsy changes, inflammation, nabothian cysts)
  - √ size of tumor accurately depicted (on T2WI rarely overestimated due to inflammation / edema)
    - ◊ Tumor diameter and probability of recurrence + metastases are related; tumor diameter > 4 cm (stage IB2) means no surgical treatment
  - √ early contrast enhancement on fat-saturated T1WI
- √ blurring + widening of junctional zone (retained secretions in uterine cavity) ← obstruction of cervical os
- √ disruption of hypointense vaginal wall by hyperintense thickening on T2WI
- √ disruption of hypointense cervical fibrous stromal ring on T2WI by nodular / irregular tumor SI

@ Parametrial invasion (best seen on T1WI):
- √ low-intensity spiculated areas of soft tissue radiating from periphery of cervical mass
- √ irregular lateral margins of cervix = linear stranding around cervical mass
- √ thickening of uterosacral ligament

@ Pelvic sidewall invasion
√ tumor involves obturator internus, piriform, levator ani m.
√ dilatation of ureter + hydronephrosis
@ Pelvic visceral disease
√ disruption of hypointense walls of bladder / rectum (DDx: hyperintense thickening of bladder wall on T2WI ← bullous edema)
@ Lymphatic spread
√ lymphadenopathy > 10 mm, hyperintense compared with muscle / blood vessels on T2WI

PET/CT:

Indication: staging, restaging, evaluation of response to therapy

Pitfalls:

(1) Cyclical endometrial uptake during ovulatory + menstrual phases
(2) Attenuation correction artifact with metallic prosthetic implants, IUD, surgical clips
(3) Physiologic ovarian uptake in premenopausal women by corpus luteum
(4) Uptake by uterine leiomyoma
(5) Uptake by postsurgical healing, radiation fibrosis, infection

Prognosis: depending on tumor stage + volume of primary mass + histologic grade + lymph node metastases; in 30% recurrent / persistent disease (usually within 2 years)

5-year survival rate: tumor diameter ≤ 1 cm 84%
tumor diameter > 4 cm 67%
stage IIB 65%
stage III 40%
stage IVA < 20%

Cx: stenosis + obstruction of cervical canal → hydrometra, hematometra, pyometra

Rx: (1) Surgery for stages < IIA / tumor < 4 cm
(2) Radiation therapy ± chemotherapy for stages > IIB

Prevention: human papillomavirus vaccine

DDx: (1) Endometrial polyp / adenocarcinoma (centered in endometrial cavity protruding into endocervical canal)
(2) Prolapsed submucosal fibroid (more hypointense on T2WI)

Recurrent Cervical Carcinoma

= local tumor growth / development of distant metastasis ≥ 6 months after complete regression

@ Pelvic recurrence

Prevalence: varies with stage, histologic type, adequacy of therapy, host response; 11% in stage IB

Site: cervix, uterus, vagina / vaginal cuff, parametria, ovaries, bladder, ureters, rectum, anterior abdominal wall, pelvic side wall

• lower extremity swelling ← lymphatic obstruction
• pain ← nerve compression, ureteral obstruction

√ hydrometra ← obstruction by preserved cervix

√ rectovaginal fistula
√ hydronephrosis (70% by autopsy)
√ vesicovaginal fistula
√ pelvic side wall mass
DDx: radiation fibrosis (82% MR accuracy)

@ Nodal recurrence
◊ Prognosis worsens as nodal involvement progresses!
(a) primary: paracervical, parametrial, internal + external iliac, obturator nodes (= medial group of the external iliac nodes)
Frequency: in 75% of adenocarcinoma, in 61% of squamous cell carcinoma (autopsy)
(b) secondary: sacral, common iliac, inguinal, paraaortic nodes
Frequency: in 62% of adenocarcinoma, in 30% of squamous cell carcinoma (autopsy)

@ Solid abdominal organ recurrence
Location: liver (33%) > adrenal gland (15%) > spleen, pancreas, kidney

@ Peritoneal recurrence
1. Peritoneal carcinomatosis (5–27% by autopsy)
2. Tumor deposits in mesentery + omentum

• **Sister Joseph nodule** = umbilical metastasis developing from anterior peritoneal surface

@ GI tract recurrence
Location: rectosigmoid junction (17%), colon, small bowel
√ fistula formation
√ focal bowel wall thickening + tethering
√ intestinal obstruction (12% by autopsy)
Prognosis: immediate cause of death in 7%

@ Chest recurrence
1. Lung metastases (33–38% by autopsy)
2. Pleural metastases associated with hydrothorax
3. Pericardial metastasis
4. Lymphangitic carcinomatosis (< 5%)
5. Mediastinal / hilar adenopathy + pleural lesions / effusion

@ Osseous recurrence
Prevalence: 15–29% by autopsy
Location: vertebra > pelvis > rib > extremity
Mechanism: direct extension from paraaortic nodes (most common) / lymphatic / hematogenous spread

@ Skin + subcutaneous tissue recurrence (in up to 10%)

CHORIOAMNIONIC SEPARATION

(a) normally seen < 16 weeks MA
Cause: incomplete fusion of amniotic membrane with chorionic plate
(b) abnormal > 17 weeks MA

Cause: hemorrhage / amniocentesis (10%)
√ membrane extends over fetal surface + stops at origin of umbilical cord
√ elevated membrane thinner than chorionic membrane
Cx: rupture of amniotic membrane → may lead to amniotic band syndrome
DDx: amniotic band syndrome, uterine synechia, fibrin strand after amniocentesis, cystic hygroma (moves with embryo)

CHORIOANGIOMA

= benign vascular malformation of proliferating capillaries (= hamartoma) without malignant potential
Prevalence: 0.5–1.0% of pregnancies; > 5 cm in 1÷3,500 to 1÷16,000 births
◊ Most common tumor of the placenta
Histo: angiomatous (capillary), cellular, degenerative subtypes
Location: usually near the umbilical cord insertion site supplied by fetal circulation
• elevated maternal serum α-fetoprotein level (rare)
US:
√ well-circumscribed hypo- / hyperechoic rounded intraplacental mass protruding from the fetal surface of the placenta into amniotic cavity
√ contains anechoic cystic areas (= vessels)
√ arterial signal on Doppler ultrasound in angiomatous chorioangioma
MR:
√ placental mass with high T2 SI (similar to hemangioma)
√ heterogeneous SI ← acute infarction + degenerative changes
Prognosis: regression after infarction
Maternal Cx: preterm labor, toxemia, placental abruption, preeclampsia, hemorrhage
Fetal Cx (30–50%):
polyhydramnios (in ⅓), fetal hydrops, fetal hemolytic anemia, fetal thrombocytopenia, cardiomegaly, IUGR, congenital anomalies, fetal demise (with large / multiple lesion)
Rx: expectant management with serial US imaging (6–8 week intervals for small tumors, 1–2 week intervals for large tumors); serial fetal transfusion, fetoscopic laser coagulation, chemosclerosis with absolute alcohol, endoscopic surgical devascularization
DDx: partial hydatidiform mole, placental hematoma, teratoma, metastasis, leiomyoma

CHORIOCARCINOMA

= remarkably aggressive
Frequency: < 1%

Primary Ovarian Choriocarcinoma

= NONGESTATIONAL CHORIOCARCINOMA
Prevalence: extremely rare; 50 cases in world literature
Age: < 20 years
Associated with: germ cell tumor / epithelial neoplasm
• ↑ serum hCG (100% sensitive, 100% specific)
• isosexual precocity (50%)

√ usually unilateral
√ vascular predominantly solid tumor with areas of hemorrhage + necrosis + cyst formation
Prognosis: 90% 5-year survival in spite of typically late diagnosis at advanced stage
DDx: ectopic pregnancy (frequently mistaken diagnosis!), metastasis to ovary from gestational choriocarcinoma (reproductive age)

Gestational Ovarian Choriocarcinoma

Cause: metastasis from uterine choriocarcinoma (frequently bilateral ovarian masses); arising from ectopic ovarian pregnancy (extremely rare)
Age: reproductive age

Gestational Uterine Choriocarcinoma

Prevalence: 5% of gestational trophoblastic diseases
Age: child-bearing age
Histo: biphasic pattern including syncytiotrophoblastic + cytotrophoblastic proliferation without villous structures; extensive necrosis + hemorrhage; early + extensive vascular invasion
Preceded by: *mnemonic:* MEAN
Mole (hydatidiform) in 50.0%
Ectopic pregnancy in 2.5%
Abortion, spontaneous in 25.0%
Normal pregnancy in 22.5%
• continued elevation of hCG after expulsion of molar / normal pregnancy (25%); continued vaginal bleeding
US:
√ mass enlarging the uterus
√ mixed hyperechoic pattern (hemorrhage, necrosis)
CT (useful for staging):
√ heterogeneous predominantly hypoattenuating intrauterine tissue
√ detection of distant metastases
MR:
√ heterogeneous hyperintense mass on T2WI
√ focal signal voids (= vessels) on T1WI + T2WI
√ disruption of hypointense myometrium (= local invasion)
√ marked enhancement ← high vascularity
√ enhancing parametrial tissue (= local spread)
Metastases:
(a) hematogenous (usually): lung, kidney (10–50%), brain
√ radiodense pulmonary masses with hazy borders ← hemorrhage + necrosis
√ hyperechoic hepatic foci
(b) lymphatic: pelvic lymph nodes
(c) direct extension (occasionally): vagina
Prognosis: 85% cure rate (even with metastases); fatal with spread to kidneys + brain
Rx: (1) Chemotherapy: methotrexate, actinomycin D ± cyclophosphamide
(2) Hysterectomy (if at risk for uterine rupture)

DDx: *mnemonic:* THE CLIP
True mole
Hydropic degeneration of placenta
Endometrial proliferation
Coexistent mole and fetus
Leiomyoma (degenerated)
Incomplete abortion
Products of conception (retained)

CLEAR CELL NEOPLASM OF OVARY

= MESONEPHROID TUMOR
= almost always invasive carcinoma
Frequency: 2–5–10% of all ovarian cancers
Histo: clear cells (cuboidal cells with clear cytoplasm) + hobnail cells (columnar cells with large nuclei projecting into the lumina of glandular elements); identical to clear cell carcinoma of endometrium, cervix, vagina, kidney; ~ 100% malignant
Not associated with: in utero DES exposure (like lesions of the vagina + cervix)
• 75% of patients present with stage I disease
√ frequently unilocular cyst + mural nodule(s)
Prognosis: 50% 5-year survival rate (better than for other ovarian cancers)

CLOACAL EXSTROPHY

= exstrophy of all structures forming cloaca (rectum, bladder, lower GU tract) similar to bladder exstrophy
Prevalence: 1÷200,000–400,000 live births; M < F
Cause: ? premature rupture of cloacal membrane; ? abnormal overdevelopment of lower cloaca preventing mesenchymal tissue migration: ? abnormal fusion of genital tubercle below cloacal membrane; ? abnormal caudal position of body stalk; ? failure of mesenchymal ingrowth

Associated abnormalities: OEIS
(a) lumbosacral (common): vertebral column / spinal cord abnormalities, tethered cord, lipomeningocele, lipomyelocystocele
(b) genitourinary (in up to 60%): hydronephrosis, renal developmental variants, abnormal genitalia, oligohydramnios ← renal obstruction
•absent anal dimple ← anal atresia

√ low abdominal wall defect
√ absence of visible bladder
√ omphalocele (initial observation) as craniad part of large complex anterior wall defect extending inferiorly to pubis
√ "elephant trunk" = bowel herniation between everted bladder halves

CONJOINED TWINS

= incomplete division of embryonic cell mass in monozygotic twins occurring at 13–16 days but before the 3rd week of GA

Prevalence: 1÷50,000 to 1÷200,000 deliveries; 1÷14,000 to 1÷25,000 in Southeast Asia + Africa; 1÷600 twin births; M÷F = 1÷3

OB-US (diagnosed as early as 12 weeks GA):

- √ single placenta without separating amniotic membrane (monochorionic, monoamniotic = HALLMARK OF MONOZYGOTIC TWINNING)
- √ inseparable fetal bodies + skin contours:
  - √ fetuses commonly face each other
  - √ both fetal heads persistently at same level
  - √ no change in relative position of fetuses
  - √ bibreech (more common) / bicephalic presentation (cephalic-breech presentation is most common presentation for omphalopagus)
  - √ backward flexion of cervical spine (in anterior fusion)
  - √ single cardiac motion (if heart shared)
- √ polyhydramnios (in almost 50%)
- √ single umbilical cord with > 3 vessels
- √ fewer limbs than expected

Associated malformations:

- √ omphalocele
- √ congenital heart disease (high frequency in all types of conjoined twinning)

Prognosis: 40–60% stillborn; 35% die within 24 hours of life

Craniopagus

- = united at any part of the skull except face / foramen magnum (usually vertical / parietal in > 60%)
- √ shared cranium, meninges, dural venous sinuses (brains commonly remain separate ± connecting bridge of neural tissue)

Ischiopagus

- = united from umbilicus to large conjoined pelvis: face to face / end to end

Types: tetrapus (4 legs), tripus (3 legs), bipus (2 legs)

- √ usually two sacra ± single symphysis pubis
- √ varying degrees of renal fusion + ectopia
- √ one / two urinary bladders
- √ single external urethral orifice (usually)
- √ shared sex organs (frequently born as females)
- √ lower GI tract usually shared with anal atresia + colovesical fistulas
- √ large pelvic vessel connecting both aortas

Omphalopagus

- = joined ventrally in umbilical region, often with inclusion of lower thorax
- √ liver fusion (80%)
- √ shared terminal ileum (joined Meckel diverticulum) + proximal colon (33%)

Parapagus

- = side-to-side position with ventrolateral fusion sharing umbilicus, abdomen, pelvis

Types: dithoracic (= separate thoraces), dicephalic (= separate heads)
√ conjoined pelvis with single symphysis pubis
√ one / two sacra
√ multiple other anomalies

Pygopagus

[*pegos*, Greek = fixed, pegged]
= united dorsally sharing sacrococcygeal + perineal region
√ fusion of sacral vertebrae (spinal cords usually separate)
√ single anus ± single rectum
√ single urinary bladder + urethra (15%)

Conjoined Twins *classified according to most prominent site of connection*	
Superior Conjunction	
Dipygus (<1%)	single head, thorax, abdomen + two pelves and four legs
Syncephalus (<1%)	facial fusion ± thoracic fusion
Craniopagus (2%)	joined between homologous portions of cranial vault
Middle Conjunction	
Thoracopagus (40%)	between thoracic walls; conjoined hearts (75%)
Omphalopagus (33%)	joined between umbilicus + xiphoid
Xiphopagus	joined at xiphoid
Rachipagus	joined at any level of spinal column above sacrum
Thoracoomphalopagus	
Inferior Conjunction	
Diprosopus (<1%)	two faces + one head and body
Dicephalus (<1%)	two heads + one body
Ischiopagus (6%)	joined by inferior sacrum and coccyx
Pygopagus (19%)	joined by posterolateral sacrum and coccyx
Incomplete Duplication (10%)	*duplication of only one part of body*
◊ The more fused twins are usually joined laterally, whereas the more separate twins are joined anteriorly, posteriorly, cranially, and caudally!	

Thoracopagus

= united from upper thorax to umbilicus
√ common sternum, diaphragm, upper abdominal wall
√ common pericardial sac (90%) + some degree of cardiac fusion
√ fusion of liver (invariably):
  √ shared biliary system (in 25%)
  √ ± absent / anomalous hepatic venous drainage
√ common small intestine (in 50%): joined at duodenum + separated at distal ileum

Prognosis: cardiac fusion precludes successful surgical separation in 75%

CORD PROLAPSE

= prolapse / descent of cord into endocervical canal after rupture

Prevalence: 0.5% at delivery, 2–3% prenatally

Predisposing factors:

low birth weight, breech presentation, nonvertex fetal lie, polyhydramnios, cephalopelvic disproportion, multiparity, abnormal placentation, increased length of umbilical cord, velamentous cord insertion, spontaneous rupture of membranes

- prolonged fetal bradycardia
- severe and repetitive fetal heart rate decelerations

May be associated with: fetal hypoxia, perinatal death, fetal neurologic sequelae

Cx: cord compression with high perinatal mortality

N.B.: MEDICAL EMERGENCY! Alert obstetrician immediately!

OB management:

(1) Patient immediately placed into Trendelenburg / knee-elbow position in radiology department (!)
(2) Cesarean section for term infants
(3) Expectant management for preterm infants

DDx: Cord / funic presentation (= normal looping of umbilical cord between fetal presenting part and cervix)

DERMOID

= DERMOID CYST = MATURE CYSTIC TERATOMA

= congenital benign slow-growing germ cell tumor containing mature tissues from all 3 germ cell layers with predominance of ectodermal component

Frequency: 96% of germ-cell tumors; 5–11–25% of all ovarian neoplasms; 20% of ovarian tumors in adults; 50–80% of pediatric ovarian tumors

◊ Most common ovarian neoplasm!

Origin: self-fertilization of a single germ cell after the first meiotic division (= random error in meiosis)

Path: unilocular thin-walled cyst lined by an opaque gray-white wrinkled epidermis from which hair shafts protrude; lumen of cyst filled with sebaceous secretions mixed with hair strands

Histo: composed primarily of mature ectodermal components (skin, hair follicles, sebaceous glands, teeth, desquamated epithelium); cartilage; bone; muscle; bronchus; fat; salivary gland; neuronal tissue; pancreas; retina; may contain struma ovarii, carcinoid tumor

◊ 15% of mature cystic teratomas may not show a fat component on imaging!

Mean age: 36 years (range, 4 months to 74 years); age peak 20–40 years; in 80% during reproductive life; M>F

- relatively soft pelvic mass ($^2/_3$) difficult to palpate
- pelvic pressure / pain ← torsion / hemorrhage
- paraneoplastic syndrome (rare): autoimmune hemolytic anemia refractory to conventional therapy, virilization, hyperestrogenism; asymptomatic (mostly)

Location: ovaries and testes (common); also anywhere along path of germ cell migration during embryogenesis, usually along midline of body; "misplaced" in head and neck, mediastinum, abdomen, omentum, retroperitoneum, abdominal viscera, sacrococcygeal region; bilateral in 8–15–25%

Mean diameter: 7–10 cm

√ well-defined thin-walled heterogeneous mass = mixture of solid and cystic components (appearance dependent on composition)

√ fat, fat-fluid level, calcium within the same lesion is considered PATHOGNOMONIC (albeit present in only a minority of cases)

√ cystic mass with macroscopic fat (93%):

- √ fat-fluid / hair-fluid level
- √ "**dermoid plug**" = Rokitansky nodule = 10–65 mm oval / round mural solid tissue protuberance / tubercle / nipple (mamilla) projecting into cyst lumen; often containing hair, calcific, dental, adipose or sebaceous components
- √ calcification (56%)

Plain film (diagnostic in 40%):

- √ tooth / bone
- √ fat density (SPECIFIC)

US (77–87% sensitive):

- √ variable presentation *(see table)*:
  - √ complex mass containing echogenic components (66%)
  - √ predominantly solid mass (10–31%)
  - √ well-defined purely cystic mass (9–15%)
  - √ thin capsule + NO septa
- √ mixture of sebum + hair strands:
  - √ clump of hair = hyperechoic focus with multiple tissue interfaces that absorbs + reflects sound → gradual "dirty" acoustic shadowing
  - √ sebum (liquefied at body temperature) = background of anechoic fluid with variable internal echoes
  - √ "**tip of the iceberg**" sign → hair ball floating in sebum in 25–44% (DDx: stool-filled rectosigmoid)

Sonographic Features of Dermoids

Feature	*Incidence [%]*	*PPV [%]*
√ shadowing echogenic focus	s	96
√ hyperechoic lines and dots	61	98
√ regional / diffuse bright echoes	58	98
√ fluid-fluid level	8	60
√ cyst with wall nodularity	53	
√ solid mass without cystic features	42	

  - √ dermoid mesh = bright undulating hyperechoic fine lines and dots = hair dispersing into surrounding fluid (DDx: fibrous strands in hemorrhagic cyst)
- √ hyperechoic focus with acoustic shadowing ← calcification (in 86%; 96% PPV)

√ NO central vascularity on color Doppler

CT:

√ round well-circumscribed thin-walled uni- or multilocular cystic mass with solid components of fat floating in interface between two water-density components (93%)

√ Rokitansky nodule = dermoid plug (81%) of adipose tissue; usually single, may be multiple

√ sebum-rich fat-fluid level in cyst cavity (12%)

√ globular calcifications (tooth) / rim of calcification (56%)

√ Hounsfield unit values of −20 to −140 ← fat within dermoid cyst (highly suggestive of Dx)

MR:

√ cyst with fluid-fluid level:

√ hyperintense lipid-laden nondependent cyst fluid (above fluid of low SI) on T1WI + of intermediate intensity on T2WI

√ hyperintense mass (= fat + serous fluid both with high SI) on T2WI

√ chemical shift artifact of bright / dark bands (along frequency-encoding gradient)

√ signal drop at chemical-selective fat-saturated T1WI in 97% (mandatory sequence!)

√ chemical shift imaging for identification of microscopic fat:

√ in-phase GRE image:

√ dependent fluid hypointense compared with muscle

√ nondependent fluid slightly hypointense compared with surrounding fat

√ opposed-phase GRE image:

√ dependent fluid still hypointense compared with muscle

√ slightly hypointense compared with surrounding fat

√ thin black outline at interface between water and fat ← phase cancellation of water + lipid in same voxel

Dx: fat + calcification are PATHOGNOMONIC

Cx: (1) Malignant degeneration in 1–2% (usually within dermoid plug of tumors > 10 cm in diameter in postmenopausal women) into squamous cell carcinoma (most common)

(2) Torsion (4–16%)

(3) Rupture with chemical peritonitis (1–4%)

(4) Hydronephrosis

Rx: surgery (to avoid torsion / rupture)

DDx: tuboovarian abscess, acute hemorrhagic cyst, atypical endometrioma, bowel gas

Rupture of Ovarian Cystic Teratoma

Cause: torsion, infarction, trauma, infection, malignant change, prolonged pressure during labor, idiopathic

• acute abdomen (due to severe chemical peritonitis) → shock

√ discontinuity of tumor wall + ascites

√ distorted / flattened shape of tumor

√ spilled sebaceous material / hair ball on T1WI + fat-suppressed T1WI (DDx to fluid)

√ calcifications outside confines of cyst

√ thickened peritoneum / intraperitoneal adhesions on contrast-enhanced fat-suppressed T1WI

Cx: chronic recurrent leakage → chronic granulomatous peritonitis (= gliomatosis) →

peritoneal adhesions → bowel obstruction
DDx: tubercular peritonitis, carcinomatosis

DIETHYLSTILBESTROL (DES) EXPOSURE

= first reported transplacental carcinogen
@ Vagina: adenosis, septa, ridges, clear-cell adenocarcinoma (1÷1,000 females exposed in utero to DES, by age 35)
@ Cervix: hypoplasia, stenosis, mucosal displacement, pseudopolyps, hooded / "cockscomb" appearance
@ Uterus: hypoplasia, bands, contour irregularity, "T- shaped" uterus
@ Tubes: deformity, irregularity, obstruction

ECLAMPSIA

= coma ± pre-, intra-, or postpartum convulsions not related to a coincidental neurologic disorder in a preeclamptic patient

Pathophysiology:

A. VASOSPASM THEORY
overregulation of cerebral vasoconstrictive response to acute + severe hypertension → progresses to vasospasm; prolonged vasospasm → local ischemia, increased brain capillary permeability, disruption of blood-brain barrier, arteriolar necrosis → cerebral edema + hemorrhage

B. FORCED-DILATATION THEORY
with severe arterial hypertension upper limit of cerebral autoregulation is reached → cerebral vasodilatation starts disrupting blood-brain barrier → cerebral edema

Time of onset: 2nd half of pregnancy in primigravida; < 20th week GA with trophoblastic disease

- severe throbbing frontal headache; seizures (usually tonic-clonic)
- retinal / cortical blindness: scotomata, amaurosis, blurred vision
- hyperreflexia, hemi- / quadriparesis, confusion, coma

CT (positive in up to 50%):
√ bilateral rather symmetric white matter hypodensities without contrast enhancement
√ ± cerebral edema → compression of lateral ventricles
√ usually transient + completely reversible cerebral-cortical + basal ganglia hypodensities (= reversible ischemic lesions)
√ cerebral infarction in prolonged ischemia
√ intracerebral hemorrhage (major cause of mortality in 10–60%)

MR:
√ transiently increased T2-SI in cerebral cortex + subcortical white matter frequently in watershed areas of posterior hemispheres

ECTOPIA CORDIS

= fusion defect of anterior thoracic wall / sternum / septum transversum prior to 9th week of gestation

A. THORACIC TYPE (60%)

= heart outside thoracic cavity protruding through defect in sternum

B. ABDOMINAL TYPE (30%)
= heart protruding into abdomen through gap in diaphragm

C. THORACOABDOMINAL TYPE (7%)
= in pentalogy of Cantrell

D. CERVICAL TYPE (3%)
= displacement of heart into cervical region

Associated with:
(1) Facial deformities
(2) Skeletal deformities
(3) Ventral wall defects
(4) CNS malformations: meningocele, encephalocele
(5) Intracardiac anomalies: tetralogy of Fallot, TGA
(6) Amniotic band syndrome

Prognosis: stillbirth / death within first hour / death within first days of life in most case

ECTOPIC PREGNANCY

= implantation of blastocyst outside the endometrial cavity

Incidence: 2% of all pregnancies in USA (1992); higher for in vitro fertilization; 73,700 cases in USA (1986)

Risk of recurrence: 10–15%

Cause: delayed transit of fertilized zygote (formed on day 14 MA) secondary to
(a) abnormal angulation of oviduct
(b) adhesions or scarring from inflammation
(c) slowed tubal transit from ciliary abnormalities

Risk factors:
(1) Previous tubal surgery: tubal ligation / tuboplasty
(2) Previous PID (30–50%): esp. Chlamydia
(3) Assisted reproductive technology (ART): in vitro fertilization / gamete intrafallopian tube transfer (GIFT)
(4) Endometriosis
(5) Previous ectopic pregnancy (prevalence up to 1.1%, 10-fold increase in risk, 25% chance of recurrence)
(6) Current use of IUD
(7) Advanced maternal age > 40 years
(8) In utero exposure to diethylstilbestrol
(9) Documented tubal anomaly: salpingitis, prior surgery

Time of manifestation: usually by 7th week of MA

- asymptomatic (50%); cervical motion tenderness
- CLASSIC CLINICAL TRIAD (< 50%):
  - abnormal vaginal bleeding (75–86%)
  - mild pelvic pain (97%): pain decreases with tubal rupture!
  - palpable adnexal mass (23–41%)
- 5–9 week history of secondary amenorrhea (61%)

- positive urinary pregnancy test (50%)
- progesterone level < 25 mg/mL
- β-hCG does not rise > 66% within 48 hours (lower levels + slower rise and decline compared with IUP)
  - ◊ Most ectopic pregnancies do not exhibit a β-hCG of > 6,500 mIU/mL (1st IRP) prior to symptomatology!
  - ◊ A β-hCG level above the discriminatory zone with absence of IUP suggests ectopic pregnancy!

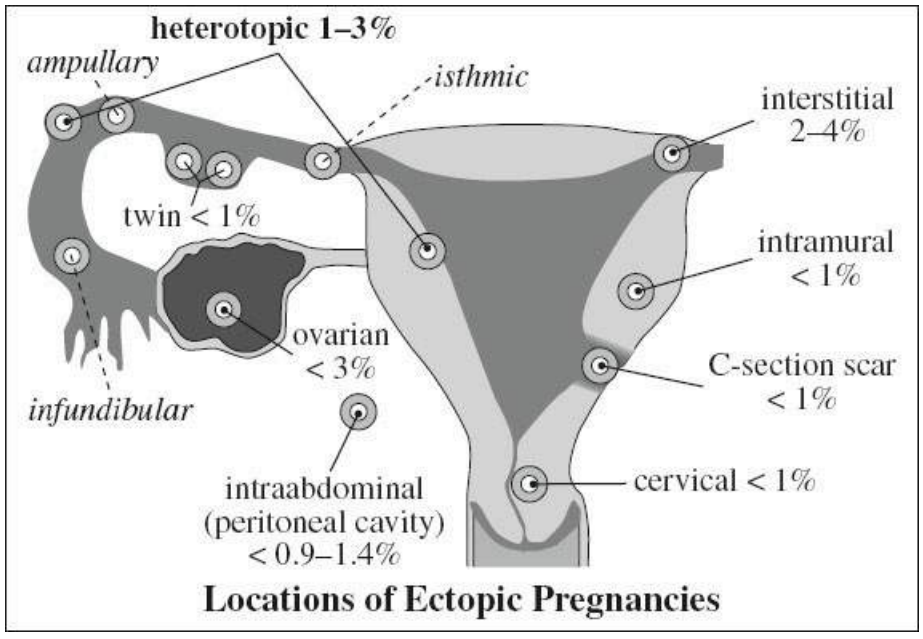
Discriminatory zone of β-hCG (at which a normal IUP should be visualized):
- › by endovaginal scan: ≥ 2,000–3,000 mIU/mL (IRP) ≥ 2000 mIU/mL (TIS)
- › by transabdominal scan: ≥ 6,500 mIU/mL (IRP)

Caveats: technical quality of exam, multiple gestations, distortion of uterine cavity (leiomyoma), lab error, assay variation

Dx: diagnostic laparoscopy (3–4% false negative, 5% FP)

Location: bilateral (0.1%)

» 95% 1. Tubal
» < 5% 2. Interstitial
3. Cervical
4. Cesarean scar in anterior lower uterine segment
5. Ovarian
6. Intraabdominal (peritoneal cavity)



Locations of Ectopic Pregnancies

Probability of Ectopic Pregnancy *without IUP or clinical symptoms of an ectopic pregnancy*	
√ normal scan / simple cyst in adnexa	5%
√ complex adnexal mass	92%
√ tubal ring	95%
√ live embryo outside uterus	100%

» even less common

7. Intramural
8. Heterotopic
9. Ectopic twin pregnancy

Spectrum:

Type 1: unruptured live ectopic + heartbeat
Type 2: early embryonic demise without rupture / embryonic structures / heartbeat
Type 3: ruptured ectopic with blood in pelvis
Type 4: no sonographic signs of ectopic

Prognosis: leading cause of 1st trimester maternal death

Transvaginal US (6–20% false-negative rate):

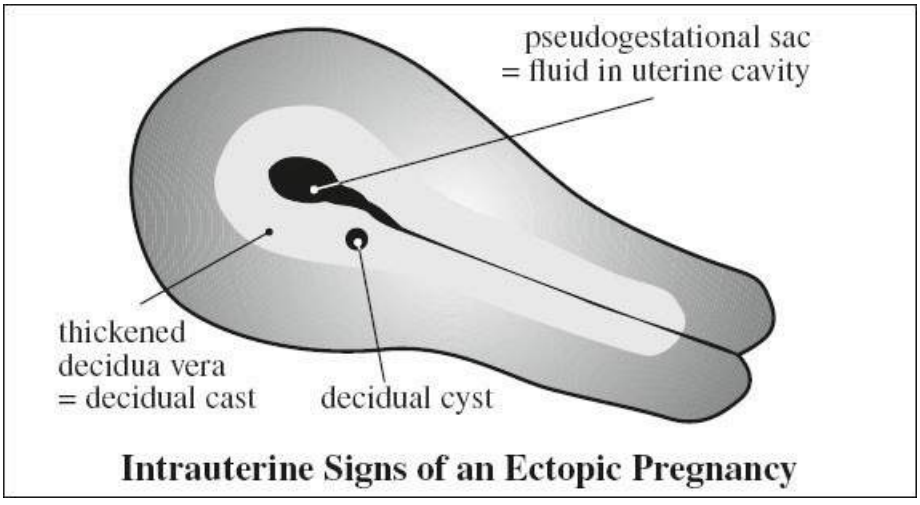
◊ Detected 1 week sooner than by transabdominal US!

@ Uterus

√ absence of intrauterine pregnancy (beyond 6 weeks MA / with β-hCG level > 1,000 mIU/mL [2nd IRP])
◊ If pregnancy not documented as intrauterine, the patient must be considered at risk!
◊ No IUP by endovaginal (transvesical) US means ectopic pregnancy in 67% (45%)

√ normal endometrium

√ thickening of endometrium:
√ trilaminar endometrium
√ hyperechoic endometrial thickening (50%) ← hormonal stimulation from ectopic pregnancy
√ sloughing of endometrium = decidual cast (21%)



Intrauterine Signs of an Ectopic Pregnancy

√ decidual endometrium lacks low-impedance blood flow

√ **decidual cyst** = thin-walled 1–5-mm cyst at junction of endometrium and myometrium (14%); may be seen in normal pregnancy

√ **pseudogestational sac** (10–20%) = thick single parietal decidual layer surrounding a centrally located anechoic fluid collection in uterine cavity ← bleeding (DDx: true gestational sac)

Tubal Ectopic Pregnancy (95%)

Location:

(1) Ampullary ectopic (75–80%)
(2) Isthmic ectopic (10–12–15%)
(3) Fimbrial / infundibular ectopic (5–11%)

Transvaginal US:

@ Adnexa

◊ Up to 35% of ectopic pregnancies may not display any adnexal abnormality!

√ adnexal mass separate from ovary:

√ echogenic "tubal mass" (89–100%)

√ extrauterine gestational sac WITHOUT live embryo / yolk sac (35%)

√ yolk sac

√ embryonic heartbeat (6–28%) = PATHOGNOMONIC

√ "tubal ring" = extrauterine hypoechoic saclike structure (20–65%) 1–3 cm in diameter surrounded by a 2–4-mm concentric echogenic ring

√ varying flow pattern depending on viability

√ corpus luteum within ovary in > 50% on side of ectopic pregnancy (DDx: ectopic pregnancy)

@ Cul-de-sac

√ clotted blood free in peritoneal cavity / hematosalpinx (36%)

√ free fluid (40–83%): echogenic / particulate fluid (= hemoperitoneum) with a 93% positive predictive value for an ectopic pregnancy

DDx: anechoic fluid in 10–27% of IUP

@ Abdominal cavity

√ echogenic fluid in posterior subhepatic space (Morison pouch) = ruptured ectopic probable

Doppler-US (low diagnostic impact):

√ "**ring-of-fire**" sign = high-velocity low-impedance flow in hyperechoic rim of extrauterine gestation in 54% (up to 4 kHz shift with 3 MHz transducer, Pourcelot index of 0.38 ± 0.2, RI between 0.18 and 0.58) [DDx: normal maturing follicle / corpus luteal cyst within ovary]

√ absence of peritrophoblastic flow after 36 days (< 0.8 kHz shift with 3 MHz transducer or < 1.3 kHz shift with 5 MHz transducer)

DDx of low-impedance flow:

corpus luteum cyst, tuboovarian abscess, fibroid

MR:

√ hematosalpinx:

√ slightly hyperintense relative to urine on fat-suppressed T1WI

√ low signal intensity on T2WI

√ hemoperitoneum:

√ iso- (acute) to hyperintense (subacute) free fluid with SI greater than that of urine on T1WI

√ heterogeneous appearance on T2WI

√ heterogeneous paraovarian adnexal mass of mixed SI on fat-suppressed T1WI + T2WI

√ extravasation of contrast material (= bleeding site) on contrast-enhanced dynamic subtraction MR

Prognosis:

(1) 3.8÷10,000 mortality rate (4% of all maternal deaths)

◊ Leading cause of death during 1st trimester with a mortality rate of 9–14%!

(2) Infertility (in 40%)

Dx: (1) Laparoscopy (almost 100% accurate)

(2) Culdocentesis: aspiration of nonclotting blood with a hematocrit > 15 = high probability for ectopic

Cx: tubal rupture (10–15%)

Rx: (1) Surgery

(2) Methotrexate (> 90% success rate)

Contraindications to methotrexate therapy:

(1) β-hCG level of > 5000 IU/L

(2) Documented fetal cardiac activity on US

(3) Ectopic mass of ≥ 3.5 cm

(4) Hemodynamic instability

(5) Unreliable patient who may not comply with serial β-hCG testing

Complications of methotrexate therapy:

(1) Selflimiting posttreatment pain

(2) Treatment failure: severe pain, hemodynamic instability, tubal rupture, hemoperitoneum

(3) Increase in size of gestational mass (in up to 56%) up to 8 cm in diameter

(4) Slow resolution of ectopic (up to 108 days)

DDx: (1) Hemorrhagic corpus luteum / hematoma

(2) Adnexal mass: hydrosalpinx, endometrioma, ovarian cyst

(3) Fluid-containing small bowel loop

(4) Eccentrically placed GS in bicornuate / retroflexed / fibroid uterus

Interstitial Ectopic Pregnancy (2–4%)

= ectopic pregnancy in an eccentric location relative to endometrium + close to uterine serosa

Location: implantation of blastocyst in upper lateral aspect of uterus BUT outside the endometrial cavity in intramyometrial portion of fallopian tube

Interstitial segment of fallopian tube:

√ thin echogenic line that extends from lateral aspect of uterine cavity through myometrium to uterine serosa (best evaluated in TRV plane)

◊ Often late rupture ← greater myometrial distensibility compared with other parts of tube!

◊ High likelihood of catastrophic hemorrhage from intramyometrial arcuate vasculature supplied by both ovarian + uterine arteries!

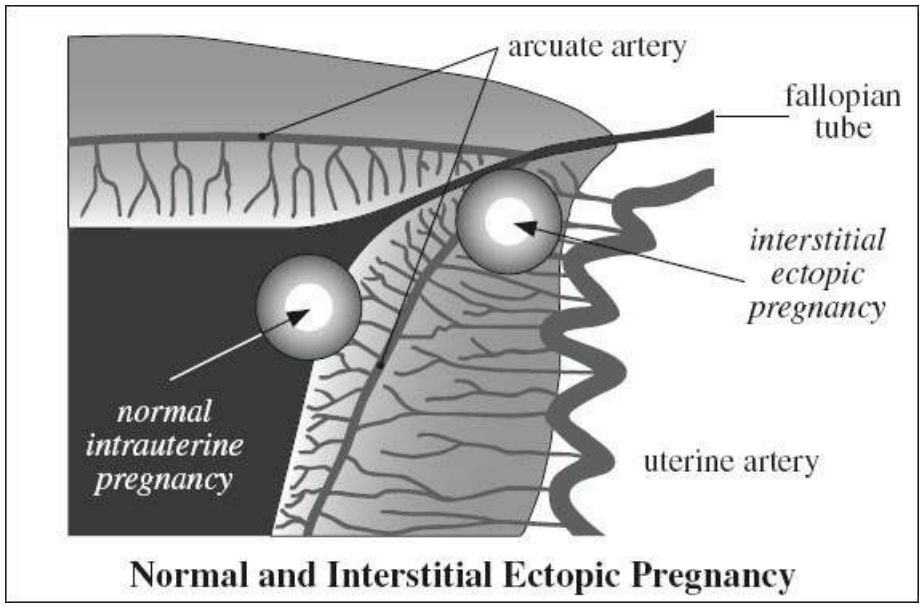
Increased risk: previous ipsilateral salpingectomy, in-vitro fertilization (IVF)

- Baart de la Faille sign = broad-based palpable mass extending outward from uterine angle
- Ruge-Simon syndrome = fundus displaced to contralateral side with rotation of uterus + elevation of affected cornu

√ "**interstitial line**" sign = thin echogenic line extending from endometrium directly up to center of ectopic pregnancy (= endometrial canal / interstitial portion of fallopian tube) in 92% (80% sensitive, 98% specific)

√ eccentric heterogeneous mass in cornual region (66%):
- √ eccentrically placed gestational sac (25%)
- √ "**bulging sign**" = CHARACTERISTIC bulging of uterine contour

√ "myometrial mantle sign" = ectopic pregnancy surrounded by myometrium on all sides:
- √ myometrium between sac and uterine cavity
- √ thinning of myometrial mantle to < 5 mm (33%) with enlargement of pregnancy



Normal and Interstitial Ectopic Pregnancy

√ large vascular channels + peritrophoblastic blood flow

√ absence of "double decidual" sign

√ empty endometrial cavity

MR:
- √ intact junctional zone between uterine cavity + mass

Cx: rupture of an interstitial pregnancy → profuse bleed from erosion of uterine arteries + veins due to close proximity of gestational sac to intramyometrial arcuate vasculature (pregnancy may survive up to 12 weeks GA)

Maternal mortality: up to 2.5%; 15 x that of other tubal ectopic pregnancies

DDx: eccentrically located normal pregnancy ←distortion from uterine fibroids / myometrial contraction; cornual pregnancy; angular pregnancy ; hydatidiform mole; degenerating uterine fibroid

Ovarian Ectopic Pregnancy (3%)

= ovum fertilized + retained within ovary

Increased risk: presence of intrauterine device, assisted reproductive technology, endometriosis, pelvic inflammatory disease

• adnexal mass moves with ovary (DDx: corpus luteum cyst)

√ gestational sac / atypical cyst with thick hyperechoic ring inside ovary / inseparable from ovary

√ empty endometrial cavity + normal fallopian tubes

√ "ring of fire" sign = peritrophoblastic flow on color Doppler (DDx: corpus luteum cyst)

√ interval growth + gradually recognizable GS contents

DDx: corpus luteum cyst (progressive involution and increasing crenulation of its margins)

Perform serial measurements of β-hCG serum levels and follow-up US in 2–3 days in any suspected intraovarian ectopic of a clinically stable patient.

Abdominal Ectopic Pregnancy (0.9–1.4%)

= implantation within peritoneal cavity excluding tubal + ovarian + intraligamentous locations

Pathophysiology: nutrient supply via omentum + abdominal organs (bowel, liver, spleen, urinary bladder)

Frequency: 1÷6,000 ectopic pregnancies

Increased risk: assisted reproduction

Classification:

(1) primary (rare) = fertilization of ovum within abdominal cavity

(2) secondary (common) = ruptured tubal / ovarian pregnancy with extrusion into peritoneal cavity

◊ > 25% may be missed sonographically!

• bloating, abdominal pain (fetal movement / peritoneal irritation ← adhesions); bleeding, hypotension, shock

√ absence of GS in endometrium / cervix / tube / ovary

√ intraperitoneal GS with surrounding echogenic margin

√ placenta outside confines of uterine cavity

√ peritrophoblastic flow on color Doppler

√ uterus compressed with visible endometrial cavity line

√ absence of uterine wall between gestation + bladder / abdominal wall

√ anhydramnios

√ free echogenic fluid (= hemoperitoneum)

Mortality: up to 20% ← hemorrhage; 7.7 x that of other ectopic pregnancies

Cx: bowel obstruction / perforation; erosion of pregnancy through abdominal wall; massive blood loss ← incomplete / complete placental separation

Lithopedion

= "stone child" = very rare obstetric complication consisting of a dehydrated + calcified demised fetus in an extrauterine pregnancy existing for > 3 months without infection

Types:

(1) Lithokelyphosis = fetal membranes calcified

(2) Lithokelyphopedion = fetus + membranes calcified
(3) True lithopedion = only fetus calcified

Maternal age at discovery: 23–100 years of age; within 4–20 years of fetal demise

Location: most common in adnexa

√ large densely calcified mass in lower abdomen / upper pelvis

√ CT scan reveals fetal skeleton

DDx: uterine fibroid, calcified ovarian malignancy / cyst, sarcoma

Cervical Ectopic Pregnancy (< 1%)

= implantation of blastocyst within the endocervical canal and subsequently fibrous wall of cervix

Risk factors: IUD; in-vitro fertilization; repeated endometrial curettage; Asherman syndrome

• vaginal bleeding, vague abdominal pain

√ uterus shape: hourglass-like / figure of 8 ← ballooned cervix

√ cardiac activity inferior to internal os

√ absent "sliding" sign (= nonadherent gestational sac can be manipulated by gentle pressure with transvaginal transducer)

√ ± peritrophoblastic flow around ectopic gestational sac

Dx: embryonic heartbeat in a gestational sac within the endocervical canal caudad to cervical internal os

DDx of Cervical Ectopic versus Abortion in Progress

Cervical Ectopic	*Abortion in Progress*
implantation of GS in cervix	GS not attached
round gestational sac	irregular deformed GS
surrounding echogenic ring	no echogenic margins
peritrophoblastic color flow	no peritrophoblastic color flow
hourglass / figure-of-8 uterus	globular uterus
closed internal cervical os	open internal cervical os
negative sliding sign	positive sliding sign
fetal heartbeat inferior to cervical os	absent fetal cardiac activity
well-formed yolk sac / fetal pole	poor visualization of fetal parts
no blood products in endometrium	blood products in endometrium
interval growth / rise in hCG	NO interval growth / rise in hCG

A misdiagnosis of a cervical ectopic pregnancy as abortion in progress can be deleterious because a D&C can cause massive life-threatening hemorrhage secondary to trophoblastic invasion of the cervix.

DDx: low-lying gestational sac with abortion in progress

Cesarean Scar Ectopic Pregnancy (< 1%)

= implantation within a scar of a prior cesarean section in the anterior lower uterine segment

Path: blastocyst surrounded by myometrium + fibrous tissue

• vaginal bleeding between 5 weeks and 16 weeks

A high degree of suspicion for cesarean scar pregnancy is necessary because up to 40% of patients will not present with specific clinical symptoms.

√ gestational sac in anterior lower uterine segment
√ thinned / absent anterior myometrium between sac and bladder (best assessed in SAG plane)
√ empty uterus + empty cervical canal
√ gestational sac with echogenic margins + peritrophoblastic flow at scar site
√ enlarging sac → exerts increasing mass effect on bladder
Cx: uterine rupture with catastrophic hemorrhage

Cornual Ectopic Pregnancy (< 1%)

= implantation of blastocyst within one horn (= cornua) of a bicornuate / septate uterus
√ eccentric position of gestational sac > 1 cm from lateral wall of endometrial cavity
√ < 5 mm thin rim of myometrium (identical to interstitial ectopic pregnancy)
Cx: rupture with catastrophic hemorrhage

Heterotopic Pregnancy

= simultaneous occurrence of intra- + extrauterine pregnancy
Prevalence: 1÷21,000–30,000 pregnancies; 1–3% in patients undergoing ovulation induction + in-vitro fertilization
• persistent adnexal pain + abnormal β-hCG levels after abortion of intrauterine pregnancy
◊ An IUP should not preclude a complete pelvic ultrasound evaluation, although depiction of an IUP virtually excludes the diagnosis of an ectopic pregnancy!
√ enlarged uterus with visible intrauterine GS
√ concurrent heterogeneous extrauterine GS
√ free echogenic fluid (= hemoperitoneum) after termination of intrauterine pregnancy
√ enlarged ovaries from ovarian hyperstimulation
Rx: laparoscopic removal of extrauterine embryo
Mortality: delayed diagnosis of missed ectopic pregnancy → catastrophic hemoperitoneum + hypovolemic shock

Intramural Ectopic Pregnancy (< 1%)

= gestational sac completely surrounded by myometrium
Increased risk: adenomyosis, in vitro fertilization, defective trophoblastic activity, previous uterine trauma (D&C, myomectomy)
• abdominal pain, vaginal bleeding, positive pregnancy test
√ nonvisualization of GS in endometrium / tubes
√ peritrophoblastic flow at color Doppler
Cx: uterine rupture
Rx: hysterectomy

Angular Pregnancy

= implantation within lateral angle of uterus medial to uterotubal junction

Prognosis: high rate of spontaneous abortion, uterine rupture, (23%), placenta accreta
√ completely surrounded by myometrium ± focal thinning
√ ± placental invasion of myometrium (placenta accreta)
√ ± intramural hemorrhage
√ ± myometrial discontinuity

EMBRYONIC DEMISE

Frequency: 20–71% loss rate of one twin < 10 weeks

Early Embryonic Demise / Failing Pregnancy

• β-hCG level < 2–3 standard deviations below the mean for given MA / GS size / CRL
√ on endovaginal scan:
A. DEFINITE DEMISE
√ absence of cardiac activity with CRL of ≥ 5 mm / ≥ 6.5 weeks GA (repeat scan in 3 days for confirmation)
B. PROBABLY FAILING PREGNANCY
√ mean sac diameter of ≥ 16 mm without embryo
√ mean sac size of ≥ 8 mm without yolk sac (repeat scan in 3 days for confirmation)
√ > 1,000 mIU/mL (1st IRP) without gestational sac
√ > 7,200 mIU/mL (1st IRP) without yolk sac
√ > 10,800 mIU/mL (1st IRP) without embryo
C. MODERATELY HIGH RISK OF DEMISE
√ bradycardia of 80–90 bpm
√ large subchorionic hematoma lifting much of placenta
√ yolk sac > 6 mm / abnormal shape
D. HIGH RISK OF SUBSEQUENT DEMISE
√ severe bradycardia < 80 bpm
√ small mean gestational sac size

◊ Difference between mean sac size and CRL of < 5 mm is predictive of miscarriage in 94%!

√ mean gestational sac size too small for good clinical dates
√ gestational sac growth ≤ 0.7 mm/day (normal growth rate of daily 1.13 mm determines appropriate time interval for follow-up scan, ie, when sac is expected to be 27 mm)
√ sac position in lower uterine segment / cervix
√ stringlike / granular debris / fluid-fluid level within gestational sac ← intrasac bleeding

Late Embryonic Demise

√ on endovaginal scan:
√ wrinkled collapsing amniotic membrane
√ irregular distorted shape of gestational sac
(DDx: compression by bladder, myoma, contraction)
√ absence of double decidual sac = thin weakly hyperechoic / irregular choriodecidual reaction of < 2 mm

ENDOMETRIAL CANCER

Most common invasive gynecologic malignancy in industrialized countries; 4th most prevalent female cancer in USA women

Incidence: 60,050 new cases with 10,470 deaths annually (2016)

Histo: adenocarcinoma (90–95%), sarcoma (1–3%)

Peak age: 55–62 years; 74% > age 50

Risk factors: nulliparity, late menopause, exposure to unopposed estrogen therapy, polycystic ovaries, obesity, hypertension, diabetes mellitus

Histo:

(a) endometrioid carcinoma (75% of all cancers)
(b) serous, mucinous, clear cell carcinoma (less common): similar to ovarian counterpart
(c) squamous (rare): associated with cervical stenosis, pyometra, chronic inflammation
(d) mixed mesodermal tumor: contains elements of epithelial + mesenchymal differentiation

2009 FIGO Staging for Endometrial Carcinoma

FIGO Stage	*Description*
0	In situ
I	Tumor confined to uterus
IA	< 50% invasion of myometrium
IB	≥ 50% of myometrium
II	Cervical stromal invasion
IIIA	Invasion of serosa / adnexa / peritoneal metastases
IIIB	Vaginal / parametrial involvement
IIIC1	Pelvic lymph node involvement
IIIC2	Paraaortic lymph node involvement
IV	Extension to pelvic wall, lower 1/3 of vagina, hydronephrotic / nonfunctioning kidney
IVA	Invasion of bladder / bowel mucosa
IVB	Distant metastases (lung, brain, bone) including metastases to pelvic / paraaortic lymph nodes intraabdominal / inguinal lymph nodes

◊ Clinical staging with dilatation & curettage inaccurate in up to 51%!

Lymph node metastases: 3% with superficial invasion; 40% with deep invasion

• postmenopausal bleeding without hormonal therapy

Location: predominantly in uterine fundus; 24% in isthmic portion

US:

√ normal-sized / enlarged uterus
√ focal / diffuse endometrial thickening (mean anteroposterior bilayer thickness of 18.2 mm)
◊ Any endometrial thickness > 5 mm is suspicious (100% negative predictive value, not very specific):
◊ 10% cancer rate with endometrial thickness of 6–15 mm
◊ 50% cancer rate with endometrial thickness of > 15 mm
√ irregular heterogeneous echogenic texture with hypoechoic areas (= signs of invasive endometrial cancer):
√ irregular poorly defined endometrial-myometrial interface

√ increased echogenicity in myometrium
√ intrauterine fluid collection (DDx: cervical stenosis)

Transvaginal US:
√ apparent distension of endometrial lumen with extrinsic thinning of the myometrium (= polypoid tumor)
√ Doppler pulsatility index of < 1.5 or resistive index < 0.7 suggests malignancy (DDx: endometritis, benign endometrial polyp)
√ areas of venous flow (DDx: endometrial hyperplasia)

MR (82–92% accuracy for staging, 74–87% accuracy for depth of invasion):
√ endometrial cancer has a slightly lower SI than endometrium but higher SI than myometrium on T2WI
√ endometrial thickness abnormal if > 3 mm (postmenopausal woman) / > 10 mm (under estrogen replacement)
DDx: blood clot, uterine secretions, adenomatous hyperplasia, submucosal leiomyoma
√ disruption / absence of junctional zone ← myometrial invasion
√ hyperintense areas penetrating into myometrium (= deep muscle invasion; 74–87% accuracy with CEMR / DWI)

ENDOCERVICAL POLYP

= most common benign cervical growth

Incidence: up to 4%

Age: multiparous women in their 30s and 40s

Histo: connective-tissue stalk with focal hyperplasia of glandular columnar epithelium ± squamous metaplasia (frequent)

Types: adenomatous (mostly), cystic, fibrous, vascular, inflammatory, fibromyomatous

Often associated with: endometrial hyperplasia ← ? link to estrogen exposure

• common cause of intermenstrual bleeding
• metrorrhagia, menorrhagia, postmenopausal bleeding, contact bleeding, vaginal discharge

√ typically slightly hyperechoic polyp compared with normal mucosa
√ may undergo cystic change → confusion with nabothian cyst
√ may be mobile at dynamic imaging with transducer pressure
√ ± vascular stalk arising from endocervical mucosa (Doppler US)

Visualization of the origin of the endocervical polyp is critical to differentiate it from a lesion arising in the uterine body with extension into the endocervical canal (eg, prolapsed intracavitary leiomyoma / endometrial polyp).

Rx: management of prolapsed lesions tends to be more complicated ← more extensive blood supply

√ coexisting endometrial polyp (in 25%)

Cx: malignancy / dysplasia (in 0.2–1.5%)

ENDOMETRIOID CARCINOMA OF OVARY

Frequency: 8–15% of all ovarian cancers; 2nd most common malignant ovarian neoplasm (after serous adenocarcinoma)

Associated with: hyperplasia / carcinoma of the uterine endometrium in 20–33%

Path: malignant mixed mesodermal tumor = carcinoma-sarcoma is grouped with endometrioid

cancer

Histo: tubular glandular pattern with a pseudostratified epithelium resembling endometrial adenocarcinoma / metastatic colon carcinoma; ~ 100% malignant

√ solid / complex (= cystic + solid) tumor

√ bilateral in 15% of stage I cases

Prognosis: better than serous / mucinous carcinomas

ENDOMETRIOSIS

= ENDOMETRIOSIS EXTERNA

= encysted functional endometrial epithelium + stroma in an ectopic site <u>outside</u> myometrium

N.B.: internal endometriosis within myometrium = adenomyosis

Prevalence: 5–10% of menstruating women; in 5% of post-menopausal women on estrogen replacement therapy

Etiology:

(1) Metastatic / implantation theory
= "shedding" of endometrial cells during retrograde menstruation via fallopian tubes onto peritoneum
◊ Up to 90% of women have bloody peritoneal fluid during perimenstrual period
◊ Obstructive müllerian duct anomalies are the most common cause in girls < 17 years of age

(2) Dissemination theory = vascular + lymphatic spread

(3) Direct theory = intraoperative implantation (uterine surgery, amniocentesis, needle biopsy)

(4) Coelomic metaplasia theory = conversion of peritoneal epithelium into functioning endometrial tissue

(5) Induction theory = combination of metastatic + metaplastic theory

Mean age: 25–29 years

Histo: endometrial glands, stroma, rare smooth muscle fibers; secretory changes during 2nd half of menstrual cycle; stromal decidualization during pregnancy

- infertility:
  ◊ 20–50% of infertile women have endometriosis
  ◊ 30–50% of women with endometriosis are infertile
  Cause: involvement of tubes + ovaries → peritubal adhesions → anatomic distortion, impaired tubal mobility to capture ovum, tubal destruction / occlusion
- pelvic pain:
  - cyclic pelvic pain: estrogen-sensitive ectopic endometrial implants proliferate and bleed synchronously with uterine endometrium
  ◊ 24–33% of women with pelvic pain have endometriosis: NO correlation between amount of pelvic pain + extent of disease
  - dysmenorrhea, perimenstrual diarrhea, dyspareunia
  - sacral back ache with menses, rectal discomfort
  - chronic pelvic pain ← peritoneal adhesions
    ◊ Endometriosis is found in 90% of women with chronic pelvic pain!
- abnormal menstrual bleeding

- fixed pelvic organs during bimanual exam
- localized tenderness along uterosacral ligaments + cul-de-sac + adnexa; thickened nodular ligaments + rectovaginal masses

Location:

(1) Ovaries (20–40%): cysts with hemorrhagic content
(2) Ligaments: uterosacral ligament; round ligament (= painful inguinal mass in the canal of Nuck, R > L)
(3) Rectouterine pouch = pouch of Douglas = posterior cul-de-sac); anterior rectosigmoid
(4) Vesicouterine pouch = posterior wall of urinary bladder = anterior cul-de-sac
(5) Uterine serosal surface / wall: posterior > anterior
(6) Fallopian tube (6%): (sub)serosal / mucosal
(7) Bladder dome
(8) Cesarean section / other abdominal surgical scars (< 1%)

Depth:

1. Deeply infiltrating endometriosis = > 5 mm from peritoneal surface
   Associated with: fibrosis + muscular hyperplasia

Morphologic types:

1. Diffuse endometriosis
2. Discrete pelvic mass = endometrioma (in up to 10%)

Dx: laparoscopy / surgery ← limitations of imaging

Rx: (1) Expectant with NSAID

(2) Hormonal therapy (for pelvic pain / dyspareunia) to create a state of pseudopregnancy / pseudo-menopause / chronic anovulation: danocrine (Danazol®), GnRH agonist (Lupron®), oral contraceptive pills

(3) Surgery (for infertility / intractable pain):
implant recurrence in 28% by 18 months + in 40% by 9 years; adhesion recurrence in 40–50%

Diffuse Endometriosis

Path: punctate small foci / stellate patches of < 2 cm initiating inflammatory response → organizing hemorrhage, fibrosis, adhesions

US (low sensitivity):

√ in 70% normal = often no detectable abnormality (when lesions small + scattered)

MR (71% sensitive, 82% specific):

√ frequently hyperintense multiple cysts bilaterally with thick walls on T1WI
√ foci of elevated signal intensity on T1WI (only 13% sensitive) ← peritoneal implants
√ hypointense masses on T2WI
√ loss of interface between lesion + adjacent organs
√ hydrosalpinx hyperintense on T1WI ← blood products as luminal content

Endometrioma

= the only form of endometriosis that is readily imaged

Path: endometriotic cyst in ovary containing thick dark degenerated blood products = "**chocolate cyst**"← repeated cyclic hemorrhage, in up to 50% bilateral

over time: iron overload, high concentration of protein, increased viscosity

Histo: obliterated mostly endometrial gland lining; initially thin wall that becomes fibrotic + thickened with irregular external border

◊ Multiplicity favors the diagnosis of endometrioma

US (83% sensitive, 89% specific for endometrioma):

√ unilocular endometrioma = nonspecific cyst of usually 2–5 cm (up to 20 cm) in diameter:

Location: within ovary, often bilateral

√ variable appearance of cyst cavity:

√ diffuse homogeneous internal low-level echoes / ground-glass appearance (in 95%) ← hemorrhagic debris

√ fine reticular appearance ← interdigitating septations without blood flow

√ ± fluid-fluid / fluid-debris level ← layering of debris

√ ± echogenic material floating in dependent portion of cyst cavity ← fresh blood clot

√ ± triangular / curvilinear soft-tissue component / often attached to cyst wall ← retracting blood clot

√ anechoic cyst (rare)

√ posterior acoustic enhancement

√ echogenic wall nodularity / irregularity (in 20–35%) ← cholesterol deposits

√ blood flow in thick septations ← revascularization of chronic hematoma

√ multilocular endometrioma = multiple separate cysts:

√ thin / thick septations between loculi

√ hematosalpinx (in 28%)

√ change in size + appearance on 6-week follow-up

DDx:

(1) Hemorrhagic ovarian cyst (acute symptoms, more complex cyst with clot retraction, thin fibrin stranding, resolution in 4–6 weeks)

(2) Dermoid cyst (calcification, fat-fluid level, hyperechoic areas)

(3) Cystic neoplasm

(4) Tuboovarian abscess

CT:

√ solid and cystic heterogeneous masses (varied findings)

√ irregular margins

MR (91–96% accurate, 90–92% sensitive, 91–98% specific with fat suppression):

√ typically homogeneously hyperintense **"light bulb"** SI of cyst(s) on T1WI similar to fat ← intra- and extracellular methemoglobin shortens T1 of fluids:

√ hyperintensity on fat-suppressed T1WI (effectively excludes fat in a dermoid)

√ ± "**T2 shading**" sign = faint / complete loss of signal of entire cyst (lower than that of simple cyst fluid) / in dependent fluid-debris layer on T2WI ← high concentration of cross-linked proteins of high viscosity + iron ← recurrent hemorrhage (usually mixed with areas of high SI) in cyst that exhibits high SI on T1WI

DDx: hemorrhagic functional ovarian cyst (solitary, thin-walled, SI lower on T1WI + higher on T2WI); mature cystic teratoma

The presence of blood is more conclusively established on the basis of the MRI appearance (> 90% specific)!

√ atypically hypointense on all pulse sequences in 27%
√ restricted diffusion
√ multilocularity + multiplicity

◊ CEMR NOT needed to evaluate for endometriosis

√ ancillary insensitive findings:
√ hypointense peripheral ring ← hemosiderin staining of thick fibrous wall in chronic lesion (DDx: PID)
√ adhesion to surrounding organs = bowel tethering and sharp angulations
√ peritoneal implants
√ ± obliteration of posterior cul-de-sac

Cx: (1) Adhesions (after rupture of endometrioma)
• fixed pelvic organs (during bimanual US)
√ obscuration of organ interfaces
√ posterior displacement of uterus (retroverted uterus) and ovaries
√ angulation of bowel loops
√ elevation of posterior vaginal fornix
√ loculated fluid collection
√ dilated fallopian tube: hydrosalpinx (in up to 30%); hydrosalpinx÷hematosalpinx = 6÷4
◊ Suggestive of endometriosis if hydrosalpinx exhibits T1-hyperintensity!

(2) Malignant transformation to ovarian cancer (1–2.5%)
Histo: endometrioid ca. > clear cell carcinoma
• in women > 45 years of age
√ typically for endometriomas > 9 cm
√ enhancing mural nodules

DDx: hemorrhagic functional cyst (most often solitary, brighter than endometrioma on T2WI, generally no shading), mature cystic teratoma, pelvic inflammatory disease, cystic ovarian neoplasm, pedunculated myoma

Ruptured Ovarian Endometrioma

= uncommon acute complication
• acute abdomen ← chemical peritonitis
√ distorted shape of endometrioma
√ thinned irregular wall component = rupture site
√ markedly hyperintense fluid in free intraperitoneal space on fat-suppressed T1WI
Rx: EMERGENCY SURGERY

Atypical Sites of Endometrial Implantation

@ GI tract (12–37%)
• catamenial diarrhea, constipation
• rectal pain / hematochezia [*khezein*, Greek = defecate]
Path: initially serosal endometriotic deposits → that erode into bowel wall → hypertrophy + fibrosis of muscularis propria
Location: inferior margin of sigmoid colon + anterior wall of rectosigmoid (72%) >

rectovaginal septum (14%) > ileum (7%) usually within 10 cm of ileocecal valve > jejunum > cecum (4%) > appendix (3%, almost always associated with ovarian endometriosis); occasionally multiple

√ single extramucosal mass with crenulated / spiculated mucosal pattern (DDx: drop metastasis)

√ polypoid intraluminal mass / annular constricting lesion (rare appearance)

Cx: adhesion, bowel stricture, GI obstruction

DDx: invasive malignancy (in deeply penetrating lesion)

@ GU tract (3–20–37%)

• dysuria, urgency, frequency, cyclical hematuria

• urinary obstruction, flank pain

Path: initially serosal endometriotic deposits that may infiltrate into bladder / ureteral wall

√ mass projecting into bladder lumen typically at dome of bladder posteriorly (DDx: bladder cancer)

√ smooth / tapered / angulated short to medium-length ureteral stricture near inferior aspect of sacroiliac joint

@ Chest

= THORACIC ENDOMETRIOSIS SYNDROME

• pleuritic chest pain, cyclic hemoptysis

Cause: microembolization (via lymphatics or vascular channels), peritoneal-pleural migration (through diaphragmatic defects)

Time of onset: 5 years after pelvic endometriosis

• presenting symptoms:

  • pneumothorax (73%), hemothorax (14%)

  • hemoptysis (7%), lung nodules (6%)

√ almost exclusively right-sided pleural lesions

√ bilateral lung nodules

√ catamenial pneumothorax

√ pleural effusion

@ Cutaneous Tissue

• palpable mass ± catamenial bleeding

• focal pain / tenderness associated with menses

Location: laparotomy scar, cervical biopsy / electrocautery, episiotomy scar, umbilicus

√ well-defined hypoechoic / cystic / solid mass

√ hyperechoic border / tissue stranding ← inflammatory reaction

DDx: abscess, hematoma, hernia, sebaceous cyst, lipoma, hemangioma, malignant tumor

@ CNS

• cyclic headaches, seizures

√ subarachnoid hemorrhage

FACIAL CLEFTING

Prevalence: 0.5÷1,000 in blacks; 1÷1,000 live births in white population; 1.5÷1,000 in Asians; 3.6÷1,000 in American Indians; 13% of all congenital anomalies; 2nd most common

congenital malformation; most common craniofacial malformation

Normal embryology:

1st branchial arch develops into maxillary + mandibular prominences; by 5th week the stomadeum is surrounded by 5 prominences: frontal-nasal, paired maxillary, paired mandibular prominences; nasal pits are formed by invagination of nasal placodes on each side of frontal-nasal prominence; the 2 maxillary prominences grow medially to fuse with the 2 medial nasal prominences forming the upper lip; the lateral nasal prominences form the nasal alae

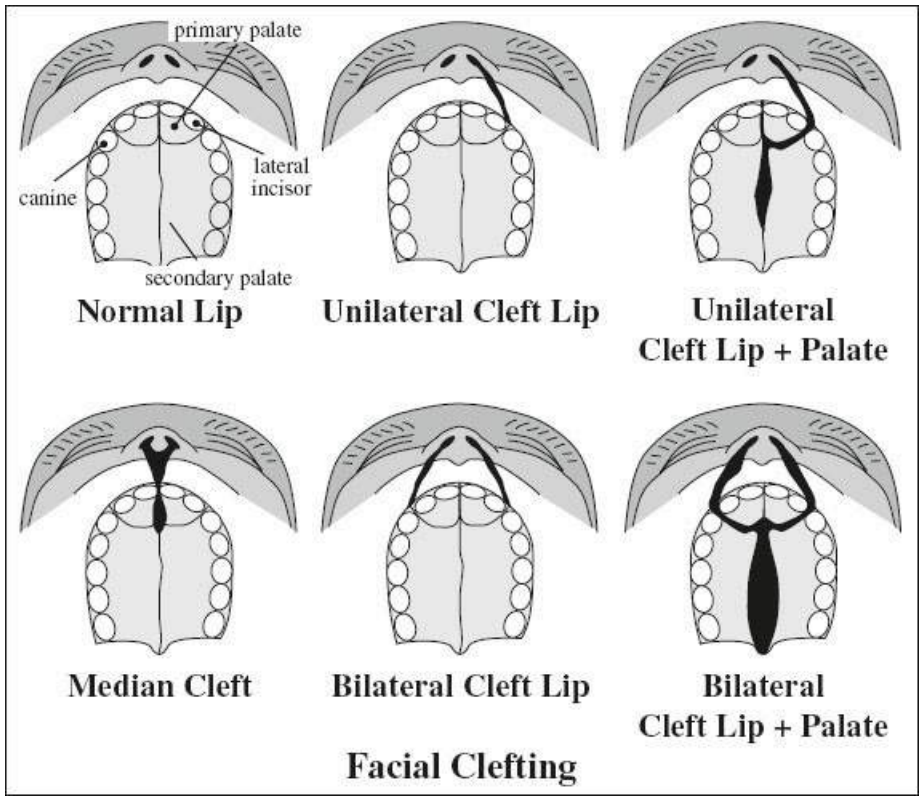
Risk of recurrence: 4% with one affected sibling, 17% with one affected sibling + parent

Cleft lip ± palate and isolated cleft palate are distinct entities with different implications for underlying genetic syndromes, associated anomalies, and prognosis.

Median Facial Cleft

= failure of fusion of the 2 medial nasal prominences

Prevalence: rare



Cause:

1. Median cleft face syndrome = frontonasal dysplasia
   √ brain anomalies rare
2. Holoprosencephaly
3. Majewski syndrome (short rib, polydactyly, median cleft)

Lateral Facial Cleft

Cleft Lip *(25%)*

Cause: lack of fusion of maxillary prominence with medial nasal prominence (= intermaxillary segment) around 7th week MA

Associated with: anomalies in 20% (most frequently clubfoot); NO chromosomal anomalies

Site: isolated in 8%, bilateral in 20%

√ linear echo-poor region extending from one side of fetal upper lip into nostril

Prognosis: excellent

Cleft Lip & Palate *(50%)*

Cause: incomplete fusion of lip + primary palate with secondary palate

Associated with: 72 abnormalities in 56–80%: most frequently polydactyly; chromosomal anomalies in 20–33%

Location: L > R

Site: unilateral in 23%, bilateral in 30%

√ linear defect extending through alveolar ridge + hard palate reaching the floor of the nasal cavity / orbit (often deeper + longer cleft than in isolated cleft lip)

√ paranasal echogenic mass inferior to nose (= premaxillary protrusion of soft tissue + alveolar process + dental structures) in bilateral cleft lip + palate

Cleft Palate *(25%)*

= lack of fusion of mesenchymal masses of lateral palatine processes around 8th–9th weeks MA

Associated with: anomalies in 50% (most frequently clubfoot + polydactyly)

Stickler syndrome = ocular abnormalities, maxillary hypoplasia, isolated cleft palate

√ often missed on prenatal sonograms

√ small fetal stomach + polyhydramnios ← impaired fetal swallowing

FIGO and TNM Staging of Fallopian Tube Cancer (1993)		
FIGO	*TNM*	*Description*
I	T1	Limited to fallopian tube
IA	T1a	limited to one fallopian tube without serosa
IB	T1b	limited to both fallopian tubes without serosa
IC	T1c	+ extension onto / through serosa + positive peritoneal lavage / ascites
II	T2	Limited to pelvis
IIA	T2a	involvement of one / both fallopian tubes
IIB	T2b	extension to other pelvic structures
IIC	T2c	+ positive peritoneal lavage / ascites
III	T3	Peritoneal implants outside pelvis
IIIA	T3a	microscopic abdominal peritoneal seeding
IIIB	T3b	≤2 cm implants of abdominal peritoneum
IIIC	T3c	>2 cm implants of abdominal peritoneum
	N1	Regional lymph node metastasis
IV	M1	Distant metastasis
◊ 50–70–75% of patients have stage III / IV disease at time of diagnosis!		

FALLOPIAN TUBE CANCER

= PRIMARY FALLOPIAN TUBE CARCINOMA

Prevalence: 3.72÷1,000,000 women (likely underestimated); 0.9–17% of prophylactic salpingo-oophorectomies

Age: 6th–7th decade

Path: tumor produces large amount of serous secretions → painful distension of fallopian tube → palpable pelvic mass → passage of fluid from either end of patent tube → shrinkage of pelvic mass

Histo: papillary serous carcinoma (most common)

- often insidious nonspecific presentation
- hydrops tubae profluens [profluo, Latin = discharging]
  = intermittent discharge of clear / bloody fluid ← spontaneous / caused by pressure, followed by shrinkage of adnexal mass
- Latzko triad (in 15%):
  (1) intermittent profuse serosanguinous vaginal discharge
  (2) colicky lower abdominal pain relieved by discharge
  (3) adnexal mass

Growth pattern: nodular, papillary, infiltrative, masslike

Location: ampulla of tube; bilateral in 20%

√ fluid-filled tubular adnexal structure containing nodular / papillary solid components
√ multilocular cystic mass with spoke-wheel appearance
√ contrast enhancement of solid component
√ intrauterine fluid collection, peritumoral ascites
√ low vascular impedance (= resistive index of 0.29–0.40) in solid component on Doppler

ultrasound
√ increased adnexal metabolic activity on PET
Dx: at least one of following histologic criteria
(1) tumor arises from endosalpinx
(2) tumor resembles epithelium of mucosa
(3) demonstrable transition from benign to malignant
(4) normal ovaries or endometrium / foci of metastasis

FETAL AKINESIA DEFORMATION SEQUENCE (FADS)

Cause: neurogenic diseases, myogenic anomalies, restrictive dermopathies
Location: generalized + symmetric; lower > upper limbs
√ abnormal limb position, craniofacial deformation
√ growth restriction, polyhydramnios
√ abnormally short umbilical cord
Dx: fixed abnormal position (flexion deformities, multiple camptodactylies) in association with restricted fetal movements / complete akinesia
DDx: trisomy 18
Prognosis: usually lethal ← lung hypoplasia

FETAL CARDIAC DYSRHYTHMIAS

Normal heart rate: 120–160 bpm

Premature Atrial Contractions

= PAC = most common benign rhythm abnormality
√ transient tachycardia
√ transient bradycardia ← atrial bigeminy if every other beat is nonconducted
Cx: supraventricular tachycardia (unusual)
Rx: discontinue smoking, alcohol, caffeine
Follow-up: biweekly auscultation until arrhythmia resolves

Supraventricular Tachyarrhythmia

Prevalence: 1÷25,000; most frequent tachyarrhythmia in children
Etiology: viral infection, hypoplasia of sinoatrial tract
Pathogenesis:
(1) Automaticity = irritable ectopic focus discharges at high frequency
(2) Reentry = electric pulse reentering atria + inciting new discharges
Types:
1. Supraventricular tachyarrhythmia (SVT)
(a) paroxysmal supraventricular tachycardia
(b) paroxysmal atrial tachycardia
√ atrial rate of 180–300 bpm
√ ventricular response of 1÷1
2. Atrial flutter
√ atrial rate of 300–460 bpm
√ ventricular rate of 60–200 bpm

3. Atrial fibrillation
   √ atrial rate of 400–700 bpm
   √ ventricular rate of 120–200 bpm

Hemodynamics: fast ventricular rate results in suboptimal filling of heart chambers → decreased cardiac output, overload of RA, CHF

Associated with:

(1) cardiac anomalies (5–10%): ASD, congenital mitral valve disease, cardiac tumors, WPW syndrome, cardiomyopathy
(2) thyrotoxicosis

OB-US:

√ M-mode echocardiography with simultaneous visualization of atrial + ventricular contractions → allows inference of atrioventricular activation sequence

Cx: congestive heart failure + nonimmune hydrops

Rx: intrauterine pharmacologic cardioversion (digoxin, verapamil, propranolol, procainamide, quinidine)

Atrioventricular Block

Prevalence: 1÷20,000 live births; in 4–9% of all infants with CHD

Etiology: (1) Immaturity of conduction system
(2) Absent connection to AV node
(3) Abnormal anatomic position of AV node

Associated with:

(1) Cardiac structural anomalies (45–50%): corrected transposition, univentricular heart, cardiac tumor, cardiomyopathy
(2) Maternal connective tissue disease: lupus erythematosus

Types:

1. **First-degree heart block** = simple conduction delay
   √ normal heart rate + rhythm (not reportedly diagnosed in utero)
2. Second-degree heart block
   (a) **Mobitz type I**
   = progressive prolongation of PR interval → finally leading to the block of one atrial impulse (Luciani-Wenckebach phenomenon)
   √ a few atrial contractions → NOT followed by a ventricular contraction
   (b) **Mobitz type II**
   = intermittent conduction with a ventricular rate as a submultiple of the atrial rate (eg, 2÷1 / 3÷1 block)
   √ atrial contraction NOT followed by a ventricular contraction in a constant relationship
3. **Third-degree heart block** = complete heart block
   = complete dissociation of atria + ventricles
   √ slow atrial + ventricular contractions independent from each other

Cx: decreased cardiac output + CHF

FETAL DEATH IN UTERO

= INTRAUTERINE DEMISE
= fetal death during 2nd + 3rd trimesters
Specific signs:
√ absent cardiac / somatic motion
Nonspecific signs seen not before 48 hours after death:
√ same / decreased BPD measurement compared to prior exam
√ development of dolichocephaly
√ "**Spalding**" sign = overlapping fetal skull bones
√ distorted fetus without recognizable structures
√ skin edema (epidermolysis) = fetal maceration
√ increased amount of echoes in amniotic fluid (= fetal tissue fragments)
√ gas in fetal vascular system

"Vanishing Twin"

= disappearance of one twin in utero ← complete resorption / anembryonic pregnancy
Prevalence: 21% (range, 13–78%) before 14 weeks GA
Time: < 13 weeks MA
√ NO sonographic evidence of twin pregnancy later in pregnancy

"Fetus Papyraceus"

= compression + mummification of fetus
Time: in 2nd trimester
Path: resorption of fluid resulting in paperlike fetal body + compression into adjacent membranes
√ compressed mummified fetus plastered against uterine wall
Risk to surviving twin:
A. Dichorionic gestation (minimal risk)
(1) Premature labor
(2) Obstruction of labor by macerated fetus
B. Monochorionic gestation
DIC ← release of thromboplastin from degenerating fetus
(a) into maternal circulation
(b) into twin fetus through shared circulation (= **twin embolization syndrome**)

FETAL HYDROPS

Nonimmune Hydrops

= excess of total body water → extracellular accumulation of fluid in tissues + serous cavities without antibodies against RBC
Prevalence: 1÷1,500 to 1÷4,000 deliveries
Cause:
1. Cardiac anomalies (40%):
(a) structural heart disease (25%): AV septal defect, hypoplastic left heart, rhabdomyoma
(b) tachyarrhythmia (15%)

2. Hematologic causes: thalassemia, hemolysis, fetal blood loss
3. Idiopathic (25–44%)
4. Twin-twin transfusion (20%)
5. Chromosomal abnormalities (6%): Turner syndrome
6. Skeletal dysplasias: achondroplasia, achondrogenesis, osteogenesis imperfecta, thanatophoric dwarfism, asphyxiating thoracic dysplasia
7. Renal disease (4%): congenital nephrotic syndrome
8. Infections: toxoplasmosis, CMV, syphilis, Coxsackie virus, parvovirus
9. Cervical tumors: teratoma
10. Chest masses: cystic adenomatoid malformation, extralobar sequestration, mediastinal tumor, rhabdomyoma of heart, diaphragmatic hernia
11. Abdominal masses: neuroblastoma, hemangioendothelioma of liver
12. Placental tumors: chorioangioma

Prognosis: 46% death in utero; 17% neonatal death

Immune Hydrops

= ERYTHROBLASTOSIS FETALIS

= lysis of fetal RBCs by maternal IgG antibodies

Prevalence: 35÷10,000 live births at risk

Pathophysiology:

rh-negative women (= no D antigen) may become isoimmunized (= alloimmunization) if exposed to paternally derived fetal Rh-positive blood inherited from the father (= D allotype present); maternal IgM antibodies develop initially, later IgG antibodies with ability to cross placenta (= transplacental passage)

Cause of isoimmunization:

fetomaternal hemorrhage during pregnancy / delivery / spontaneous or elective abortion if fetus is D-positive; fetus has a 50% chance of being rh-negative as 56% of Rh D-positive fathers are heterozygous for D antigen

At risk:

Caucasians (15%), Blacks (6%), Orientals (1%); absence of D antigen originates in Basques

Determination of extent of disease by:

(1) Optical density shift at 450 nm (= delta OD 450) reflects amount of bilirubin in amniotic fluid; reasonably reliable only > 25 weeks MA; unreliable in alloimmunization due to Kell antibodies
(2) Percutaneous umbilical cord sampling (PUBS) with direct determination of Hct and Hb

• hemolysis + anemia
√ anasarca (= skin edema)
√ fetal ascites in 2nd trimester (present in only 66%) → indicates severe anemia with Hct < 15%, Hb < 4 g/dL
√ pleural effusion
√ increased diameter of umbilical vein
√ subcutaneous edema (skin thickness > 5 mm)
√ polyhydramnios (75%)
√ placentomegaly > 6 cm

√ pericardial effusion
√ hepatosplenomegaly
√ increased blood flow in middle cerebral artery ← increased cardiac output + decline in blood viscosity

Prophylaxis:
Rh immune globulin (RhoGAM® = antibody against D antigen) given at 28 weeks to all rh-negative women → blocks antigen sites on Rh-positive cells in maternal circulation → prevents initiation of maternal antibody production

OB management:
regular monitoring from 18 weeks on when maternal anti-D concentration exceeds 4 IU/mL → severe anemia unlikely if maternal antibodies < 15 IU/mL

Prognosis: (if untreated) in 45–50% mild anemia, in 25–30% moderate anemia (with neonatal problems only), in 20–25% hydrops (death in utero / neonatally)

Rx: umbilical vein transfusion during PUBS (necessary in only 10% before 34 weeks GA)

FETUS IN FETO

= one monozygotic twin encompasses body of other twin

Location: mostly retroperitoneum

√ well-circumscribed complex mass with internal calcifications + mixed fluid and solid components

√ vertebral bodies within mass (DIAGNOSTIC)

DDx: teratoma

FETAL TRAUMA

Prevalence: 7% of pregnant patients sustain accidental injury (greatest frequency during 3rd trimester); 0.3–0.4% are admitted to a hospital

Cause: motor vehicle accident (66%), physical abuse (10%)

Type of injury to pregnancy:
1. Uterine rupture (0.6%)
2. Complete (6–66%) / incomplete (30–80%) placental separation

US:
√ evaluate fetal motion, breathing, heart rate, placenta

◊ The major cause of fetal death is maternal death!

GARTNER DUCT CYST

= secretory retention cyst of remnant mesonephric duct

Frequency: 1–2%

Origin: remnant of vaginal portion of mesonephric / wolffian duct ← incomplete involution with gradual enlargement ← persistent glandular secretion

Histo: lined by nonmucinous flat cuboidal / low columnar epithelium

May be associated with: complex renal + urogenital malformations
(1) Herlyn-Werner-Wunderlich syndrome = ipsilateral renal agenesis + ipsilateral blind vagina
(2) Ectopic ureteral insertion into Gartner duct cyst

• usually asymptomatic
Location: anterolateral aspect of proximal third of vaginal wall above level of most inferior aspect of pubic symphysis extending into ischiorectal fossa
Size: usually < 2 cm
√ well-defined round lesion with fluid contents:
√ T2-hyperintense + T1-hypointense fluid
√ hemorrhagic / proteinaceous contents hypointense on T2WI + hyperintense on T1WI
√ may contain septa
√ large cyst may displace ureter upward / protrude through introitus
Cx: dyspareunia; interference with vaginal delivery
Rx: cyst aspiration; tetracycline sclerotherapy; surgical excision
DDx: urethral diverticulum (urethral displacement)

GASTROSCHISIS

= paramedian full-thickness abdominal fusion defect usually on right side of umbilical cord; may involve thorax; nonrotated bowel lacking secondary fixation to dorsal abdominal wall
Prevalence: 4÷10,000 live births (in 2005), sporadic
Cause: deficient mesenchyme during lateral body wall folding
former theory: abnormal involution of right umbilical vein / premature interruption of right omphalomesenteric artery with ischemic damage to abdominal wall
Risk factor: young maternal age (teenage mother÷mother aged > 25 years = 7÷1); more common in non-Hispanic white mothers; NO sex predilection
Age of occurrence: 37 days (5 weeks) of embryonic life
Age of detection: as early as 12 weeks GA; difficult < 20 weeks GA ← small size of defect (1–3 cm) and lack of bowel dilatation
Associated anomalies (5–14%):
intestinal atresia / stenosis (25%; small size of opening → compression / torsion of vessels; ectopia cordis (rare)
• MS-AFP ≥ 2.5 MoM in 77–100%
√ exteriorized bowel = thick-walled edematous freely floating loops outside fetal abdomen ← inflammation + direct trauma ← lack of peritoneal covering
√ dilated intra- / extraperitoneal bowel ← intestinal atresia
√ gastric fundus pulled toward defect
√ < 2–5 cm paraumbilical defect, usually on right side of cord insertion
√ normal insertion of umbilical cord
√ no fetal ascites
√ polyhydramnios may be present
√ liver / spleen may herniate infrequently
√ malrotation / nonrotation of bowel
Cx before birth:
(1) Bowel obstruction
(2) Peritonitis (exposure of bowel to fetal urine / meconium)
(3) Perforation ← peritonitis

(4) Fetal growth restriction (38–77%) ← nutritional loss from exposed bowel

Cx after birth:

malrotation, jejunal / ileal atresia (18%), bowel necrosis, necrotizing enterocolitis, hyperalimentation hepatitis, prolonged intestinal motility dysfunction, chronic short-gut syndrome

Mortality rate: 17%

Survival rate: 91–94% after surgical treatment (during 1st day of life, not influenced by mode of delivery); death from premature delivery / sepsis / bowel ischemia

GESTATIONAL TROPHOBLASTIC DISEASE

= group of disorders characterized by abnormal proliferation of trophoblastic tissue with invasive tendency originating from the developing blastocyst

Cause: aberrant fertilization

Components of trophoblast:

1. Cytotrophoblast = stem cell with high mitotic activity
2. Syncytiotrophoblast = synthesis of β-hCG
3. Intermediate trophoblast = responsible for endometrial invasion + implantation

- 1st trimester bleeding; increased levels of β-hCG
- rapid uterine enlargement / excessive size for EGA
- hyperemesis gravidarum / preeclampsia (in 2nd trimester)

Frequency: < 1% of all gynecologic malignancies

Associated with: molar pregnancy (most), post abortion, ectopic pregnancy, term pregnancy

Spectrum:

1. Benign hydatidiform mole (80–90%)
2. Invasive mole (5–8–10%)
3. Choriocarcinoma (1–2–5%)
4. Placental site trophoblastic tumor (rare)

Cytogenesis:

= fertilization of one egg by two sperm = chromosomes completely / predominantly of paternal origin

1. Diploid karyotype
   - › 46,XX = from fertilization of ovum by two <u>23,X sperm</u> after loss of maternal haploid chromosomes
   - › 46,XY = from fertilization of a chromosomally empty ovum by <u>two different sperm:</u>
     - complete hydatidiform mole (almost 100%), invasive mole (almost 100%), choriocarcinoma (50%)
2. Triploid karyotype (69,XXX; 69 XXY; 69,XYY)
   = fertilization of a normal ovum (23,X) by <u>two different sperm</u> thus containing $^{2}/_{3}$ paternal chromosomes
   - occurs in partial hydatidiform mole

At risk: maternal age > 35 years and < 20 years, previous molar gestation, previous spontaneous abortions

GRANULOSA CELL TUMOR

◊ Most common hormone-active estrogenic tumor of ovary
◊ Most common malignant sex cord-stromal tumor (70%)
Frequency: 2–3% of all ovarian neoplasms
Origin: from cells surrounding developing follicles
Age: puberty (5%), reproductive age (45%), postmenopausal (50%)
Path:
(a) large encapsulated smooth / lobulated multicystic mass with thick irregular septa + solid components; multiple blood-filled cysts ← hemorrhage / cystic degeneration with increase in tumor size
(b) unilocular cyst (rare) apt to manifest with virilization
• abdominal pain (acute hemorrhage into tumor / rupture into peritoneal cavity); palpable adnexal mass
Location: unilateral in 95%; bilateral in 2–5%
Size: average size of 12.5 cm (up to 40 cm) in diameter
US:
√ large complex multilocular cystic mass with fluid / blood (most frequently) + solid components:
√ thick irregular septations but NO intracystic papillary projections
√ solid component isoechoic to myometrium with Doppler flow
√ predominantly solid small heterogeneous hypoechoic mass simulating fibroid (uncommon)
√ calcifications (rare)
CT:
√ iso- to hyperattenuating enhancing solid component
√ hyperattenuating hemorrhage within cystic component
MR:
√ intermediate SI of solid component + multiple cystic spaces on T2WI = "spongelike" appearance
√ hyperintense on T1WI ← hemorrhage within tumor cysts
√ enhancement of solid component
√ ascites
Estrogenic effects:
√ uterine enlargement
√ endometrial thickening / hemorrhage
√ endometrial polyps / hyperplasia (80%) / carcinoma (10%)
N.B.: Androgenic effect with virilization extremely rare
Pattern of dissemination (extraovarian spread uncommon):
√ local extension
√ peritoneum-based metastases similar to epithelial neoplasm (rare)
√ cystic liver metastases
Prognosis: low malignant potential; late recurrence following surgery after > 3 decades
Rx: uni- / bilateral salpingo-oophorectomy ± postoperative chemotherapy
DDx: serous / mucinous ovarian tumor (intracystic papillary projections); metastasis

Adult Granulosa Cell Tumor (95%)
◊ Most common estrogenic ovarian tumor!

(rarely produces androgen)

Frequency: 95% of all GCT; 5–10% of solid ovarian tumors

Age: in middle-aged peri- and postmenopausal (50%) women; peak prevalence at 50–55 years

Histo: macrofollicular (multiple cysts resembling follicles), microfollicular (with Call-Exner bodies), insular, trabecular, cylindromatous, watered silk, diffuse type; frequently accompanied by theca cells + fibroblasts

- irregular menstruation cycles, menorrhagia ← endometrial hyperplasia; postmenopausal bleeding; amenorrhea
- 90% present at stage I (confined to ovary)

Cx: (1) Malignant transformation (5–25%)
(2) Low-grade endometrial carcinoma (3–25%)
(3) Recurrence → raised serum aromatase + estradiol levels

Recurrence: common even decades after resection with slow growth

Juvenile Granulosa Cell Tumor (5%)

Frequency: 5% of all GCT; 90% of GCT in patients < 30 years old

Mean age: 13 years; 80% of GCT occur in first 2 decades; only in 3% in women > 30 years of age

Path: solid component of granulosa + theca cells; follicles lined by granulosa cells staining positive for α-inhibin

Histo: larger cells with hyperchromatic nuclei + lack of characteristic nuclear groves (compared with adult GCT); NO Call-Exner bodies

Associated with: Ollier disease, Maffucci syndrome

- hyperestrogenism (in 80%):
  - ◊ 10% of all cases of precocious precocity
  - isosexual pseudoprecocity in 70% ← estrogen effect without ovulation / production of progesterone
  - premature breast development; low gonadotropin levels
  - pubic-axillary hair formation
  - clear vaginal discharge ← stimulated endocervical glands
  - atypical irregular uterine bleeding
  - accelerated somatic + skeletal development

Cx: malignant degeneration (rare)

Prognosis: 80–93% cure rate after surgery
◊ Juvenile tumors have a better prognosis (most diagnosed in stage I) but tend to recur after a shorter interval than adult tumors
◊ Increased risk of endometrial + breast cancer

Recurrence: unusual after simple resection for stage Ia / Ib tumors; as late as 25 years after treatment
- serum inhibin → useful marker to monitor

DDx: malignant germ cell tumors (yolk sac tumor, embryonal ca.), cystic teratoma, thecoma (hyperestrogenism in 50%, postmenopausal in 80%), Sertoli-Leydig cell tumor

HELLP SYNDROME

= **H**emolysis, **E**levated **L**iver enzymes, **L**ow **P**latelets

◊ Most common cause of severe liver disease in pregnancy!

Prevalence: 4–12% of patients with severe preeclampsia / eclampsia; higher in White women (24%), with delayed diagnosis of preeclampsia / delayed delivery (57%), in multiparous patients (14%)

Time of onset: before / immediately after birth (usually within 48 hours after delivery)

Histo: portal areas surrounded by deposited fibrin + hemorrhage + hepatocellular necrosis

- nonspecific epigastric / RUQ pain (90%)
- nausea + vomiting (45%), occasionally jaundice
- headache (50%); demonstrable edema (55%)
- abnormal liver function tests, low platelet count

√ hepatomegaly

√ fatty infiltration of liver (peak at 35th week)

√ intraparenchymal hemorrhage of liver ← subcapsular hematoma / rupture into peritoneal cavity

√ hepatic edema ← early ischemia ← necrosis

√ ascites + pleural effusions

√ subcapsular hematoma of kidney

√ vitreous hemorrhage

Cx: (1) Perinatal mortality (8–60%)

(2) Maternal death (3–24%) ← hepatic necrosis, hemorrhagic liver infarction, liver rupture, DIC, abruptio placentae, acute renal failure, sepsis

HYDATIDIFORM MOLE

= MOLAR PREGNANCY

[*hydatisia*, Greek = a drop of water; *mola*, Latin = false conception]

Frequency: 1÷1,200 to 1÷2,000 pregnancies; < 5% of abortions

Prognosis: noninvasive in 85%, locally invasive in 13%, metastasizing in 2%

Complete / Classic Mole (common)

= pregnancy failure ← implantation of nonviable fertilized egg

Cause: fertilization of an "empty egg" (= ovum with no active chromosomal material after loss of its maternal haploid chromosome)

(a) by single 23,X sperm (in 90%) → followed by sperm mitosis to form 46,XX chromosome set

(b) by two different sperms of 23,X and 23,Y (in 10%) → to form 46,XY chromosome set

◊ 46,YY diploid karyotype is not observed!

Path: complex multicystic mass = "cluster of grapes"

Histo: generalized hydropic swelling of all chorionic villi with prominent acellular space centrally; pronounced tropho- blastic proliferation of syncytio- and cytotrophoblast

- severe eclampsia prior to 24 weeks
- uterus too large for dates (in 50%); 1st trimester bleeding

- marked elevation of β-hCG with hyperemesis
- passing of grapelike vesicles per vagina
- hyperthyroidism ← thyroid-stimulating properties of β-hCG
- anemia ← plasma volume expansion + vaginal bleeding

US:

√ hyperechoic to moderately echogenic central uterine mass interspersed with punctate hypoechoic areas

√ numerous discrete cystic spaces (= hydropic villi) within a central area of heterogeneous echotexture = "snowstorm"

√ no identifiable fetal tissue

√ increased vascularity with low-resistance waveforms in spiral arteries of uterus

√ in 25% atypical appearance:

√ large hyperechoic areas (= blood clot) + areas of cystic degeneration resembling incomplete abortion

√ single large central fluid collection with hyperechoic rim mimicking an anembryonic gestation / abortion

√ no fetal parts / no chorionic membrane

√ bilateral theca lutein cysts (18–37–50%) → may take 4 months to regress after evacuation of a molar pregnancy ← hyperstimulation of ovaries by excessive β-hCG production

√ ± ascites

MR:

√ predominantly hypointense heterogeneous mass distending uterine cavity on T1WI

√ hyperintense mass on T2WI

√ ± focal areas of hemorrhage + cystic spaces

√ avid enhancement

√ hypointense myometrium (without invasion)

Prognosis: in 80–85% benign, in 15–20% invasive mole / choriocarcinoma

Rx: dilatation + suction curettage (curative in 85%)

DDx: (1) Hydropic degeneration of the placenta (associated with incomplete / missed abortions)

(2) Degenerated uterine leiomyoma

(3) Incomplete abortion = retained products with hemorrhage

(4) Choriocarcinoma

(5) Loculated abruptio placentae

(6) Hydropic changes of the placenta

Complete Mole with Coexistent Fetus (1–2%)

= molar degeneration of one conceptus of a dizygotic twin pregnancy with same risk of malignant degeneration as in classic mole

- vaginal bleeding in 2nd trimester; uterus large for dates
- abnormally elevated serum β-hCG
- amniocentesis with normal diploid karyotype excludes diagnosis of partial mole

√ normal gestation with placenta + separate typical echogenic material of a hydatidiform

mole
√ ovarian theca lutein cysts
Prognosis: fetal survival unlikely ← maternal complications from coexistent mole

Invasive Mole

= CHORIOADENOMA DESTRUENS
= locally invasive nonmetastasizing neoplasm
Histo: excessive trophoblastic proliferation with presence of villous structure + invasion of myometrium
Preexisting condition: complete / partial hydatidiform mole
• history of previous molar gestation / missed abortion (75%)
• continued uterine bleeding
• persistently elevated β-hCG levels ← failure of β-hCG to return to undetectable levels after treatment of a complete hydatidiform mole
Spread: lung, vagina
√ hyperechoic tissue with punctate lucencies
√ irregular focal hyperechoic region within myometrium
√ bilateral theca lutein cysts, 4–8 cm in size
√ myometrial invasion occasionally demonstrable
Rx: chemotherapy, hysterectomy (if at risk for uterine perforation)
DDx: choriocarcinoma (same imaging features)

Partial Hydatidiform Mole

= areas of molar change alternating with normal villi + nonviable fetus with significant congenital anomalies
Cause: fertilization of an egg by two sperm → triploid genotype of 69,XXY (66%) or 69,XXX (33%)
Histo: moderate focal proliferations of syncytiotrophoblast; normal villi interspersed with hydropic villi
• early onset of preeclampsia
√ nearly always coexistent fetus with severe abnormalities + IUGR
√ placenta with numerous cystic spaces
√ oligohydramnios
Prognosis:
(1) frequently spontaneous abortion (unrecognized as mole for lack of karyotyping of the abortus)
(2) no survival of triploid fetus
(3) 3% risk of persistent gestational trophoblastic neoplasia

HYDRO- / HEMATOMETROCOLPOS

= accumulation of sterile fluid (hydro-) / blood (hemato-) / pus (pyo-) within uterus (-metria) + vagina (-colpos);
(a) premenarcheally = secretions + mucus
(b) postmenarcheally = blood
Prevalence: 1÷16,000 female births

• asymptomatic; vague pelvic discomfort
• pain during defecation / urination
√ smooth symmetric enlargement resulting in pear-shaped uterus ± distended vagina
√ varying amounts of low-level internal echoes centrally within uterus continuous with vaginal canal
√ hematosalpinx ± endometriosis
OB-US:
√ cystic / midlevel echogenic retrovesical mass ← mucous secretions ← stimulation by maternal estrogens during fetal life
√ cystic mass ± fluid-debris level (= distended vagina)
√ bladder often not identified (compressed by distended vagina)
MR:
√ endometrial cavity + upper part of vagina distended by blood products:
√ fluid of hyperintense SI on T1WI
√ less hyperintense than urine on T2WI
DDx: ovarian cyst, duplication cyst, meconium cyst, mesenteric cyst, rectovesical fistula, anterior meningocele, cystic tumor, trophoblastic disease, degenerating leiomyoma / leiomyosarcoma
Cx: endometritis, myometritis, parametritis (= pelvic lymphangitis), pelvic abscess, septic pelvic thrombophlebitis, urinary tract infection

Acquired Hydro- / Hematometra

Cause: neoplastic obstruction of endocervical canal / vagina; postpartum infection; attempted abortion; cervical stenosis after radiotherapy; postsurgical scarring (eg, dilatation & curettage, traumatic delivery); senile contraction

Congenital Hematometra / Hematometrocolpos

Age: puberty
Cause:
(a) persistent urogenital sinus = single exit chamber for bladder + vagina; separate orifice for anus; caused by virilization of female fetus / intersex anomaly / arrest of normal vaginal development
Frequently associated with: ambiguous genitalia
Age: newborn period
(b) cloacal malformation = single perineal orifice for bladder + vagina + rectum; caused by early embryologic arrest
Frequently associated with: duplicated genital tract
Age: newborn period
(c) imperforate hymen, transverse vaginal septum, segmental vaginal atresia, imperforate cervix, blind horn of bicornuate uterus, Mayer-Rokitansky-Küster-Hauser syndrome (= agenesis of uterus + vagina with active uterine anlage)
◊ Hematometrocolpos / hematocolpos ← imperforate hymen / transverse vaginal septum
◊ Hematometra ← cervical dysgenesis + vaginal agenesis / Mayer-Rokitansky-Küster-Hauser syndrome / obstructed uterine horn
• primary amenorrhea = "delayed menarche"

- cyclical abdominal pain; interlabial mass

May be associated with:

imperforate anus, hydronephrosis, renal agenesis / dysplasia, polycystic kidneys, duplication of vagina + uterus, sacral hypoplasia, esophageal atresia

INCOMPETENT CERVIX

= gaping cervix usually develops during 2nd trimester / early 3rd trimester

Predisposed: cervical trauma (D & C, cauterization), DES exposure in utero with cervical hypoplasia, estrogen medication

• physical examination tends to underestimate the true length of the cervix

◊ Appearance of cervix may change during course of sonographic examination!

Cause: uterine contraction / manual pressure on fundus / patient erect (stress test of cervix) / degree of bladder distention

Normal Cervical Length		
	Transabdominal	*Transvaginal*
1st trimester (< 14 wks)	53 ± 17 mm	40 ± 8 mm
2nd trimester (14–28 wks)	44 ± 14 mm	42 ± 10 mm
3rd trimester (≥ 28 wks)	40 ± 10 mm	32 ± 12 mm
◊ Distended bladder improves visualization but increases cervical length on transabdominal US!		
◊ Difference between nulli- and multiparous women 10%!		

√ dilatation of cervical canal beginning at internal os + extending toward external os:

√ beaking / funneling of cervical canal

√ bulging of membranes through external os ← amniotic fluid within dilated endocervical canal

√ visualization of fetal parts within dilated endocervical canal

√ shortening of cervix to < 25 mm

Prognosis: 14th–18th week best time for Rx prior to significant cervical dilatation

CONTRACEPTIVE DEVICES

Intrauterine Devices (IUD) *approved in USA*

• retrieval string protrudes 2–3 cm from external cervical os

√ double echogenic line with plastic IUD

√ reverberation echoes with metal IUD

1. **Mirena®**

   Function: barium-impregnated T-shaped polyethylene frame with collar of a synthetic progesterone (levonorgestrel); discharges a small amount of the drug for up to 5 years → thickens cervical mucus + thins uterine lining

2. **ParaGard®**

   Function: polyethylene frame wound with copper wire slowly releasing spermicidal copper ions for up to 10 years

3. 1st generation devices:

   (a) Lippes loop

   √ 4–5 echogenic dots on SAG view

   √ horizontal line / dot on TRV view

   (b) Saf-T-coil

√ echogenic solid line on SAG view
√ series of echoes / dot on TRV view

(c) Copper 7 / Copper T / Progestasert®
√ dot in fundus + solid line in corpus on SAG view
√ solid line in fundus + dot in corpus on TRV view

(d) Dalkon shield (pulled from market in 1974)
Cx: PID, sepsis, 17 deaths

Cx:

(1) Pelvic inflammatory disease (2–3-fold risk compared with that of non-IUD users) in 35%; actinomycosis with IUD in place for > 6 years
(2) Perforation (0.1%) into / through myometrium during placement
(3) Migration by tracking into surgical scar

"Lost IUD"

= locator device missing; string not visible / not palpated

Cause: 1. Migration (displacement) / detachment of string
2. Expulsion of IUD
4. Uterine perforation of IUD

◊ Abdominopelvic radiograph is indicated if IUD not identified by US!

EXPULSION OF IUD

Frequency: 10%
Risk factors: insertion early in menstrual cycle / immediate postpartum period, nulliparity, menorrhagia, severe uterine distortion
Location: cervix, vagina

DISPLACEMENT OF IUD

= improper position within uterine cavity
Frequency: 25%

PERFORATION OF IUD

Frequency: up to 1÷1,000 cases
Risk factors: lactation, birth within past 6 months, uterine abnormality, clinician inexperience
√ embedment in endometrium / myometrium (18%)
√ migration into peritoneal cavity → freely floating / encased in adhesions / adherent to bowel or omentum

IUD & Pregnancy

Prevalence: 2÷100 women annually
√ IUD may not be visualized after 1st trimester → as uterus grows IUD is drawn into cavity
√ ± ectopic pregnancy
Prognosis: high risk of spontaneous (40–50%) / septic abortion, premature labor, chorioamnionitis, low birth weight
Rx: early removal of IUD during 1st trimester using IUD hook / alligator forceps unless removal of IUD could disrupt pregnancy

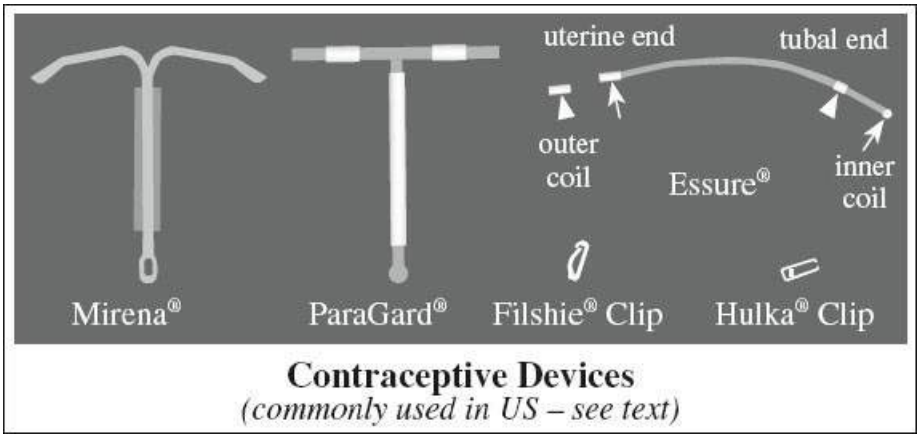
Tubal Occlusion Devices

› external occlusion by minilaparotomy:

(a) hinged clips

1. **Filshie® Clip**
   Cx: 0.51% failure rate at 1 year; dislodgement; migration
2. **Hulka® Clip**
   Cx: 3.56% failure rate at 10 year

(b) rings / loops
Falope ring, Yoon ring, Lay loop



Contraceptive Devices
(commonly used in US – see text)

› internal occlusion:

◊ Occlusion must be verified 3 months after placement with adequate HSG pressure of 150–200 mmHg!

(1) **Essure® Permanent Birth Control System**

inner coil: stainless steel + polyethylene terephthalate fibers; tubal end with ball; uterine end with connected rectangle

outer coil: radiographically invisible nitinol (= alloy of titanium + nickel): uterine end with isolated rectangle; tubal end with square

HSG: √ peripheral tubal end of inner coil (arrow ↑ in drawing) within fallopian tube
√ < 50% of inner coil within uterine cavity
√ central tubal end of inner coil (arrow ↑ in drawing) extends < 30 mm into tube from contrast-filled cornu

Cx:

(1) Tubal patency after 3 months (3%) → follow-up in another 3 months
(2) Expulsion into uterine cavity (0.6–3%)
(3) Partial / complete extrusion into peritoneal cavity (1–2%) ± adhesions with small bowel obstruction

(1) **Adiana® Permanent Contraception System**

= nonabsorbable nonradiopaque silicone elastomer matrix inserted into fallopian tube after focal radiofrequency thermocoagulation

HSG: √ tubal opacification of < 10 mm

Cx: Tubal patency after 3 months (8.8%) → follow up in another 3 months (4.3–5.6%)

INTRAUTERINE GROWTH RESTRICTION

= FETAL GROWTH RETARDATION

= perinate with a weight at / below the 10th percentile for gestational age occurring as a result of a pathologic process inhibiting expression of normal intrinsic growth potential
for twin pregnancy: discordant weight > 25%

◊ Fetal weight at / below 10th percentile for age will classify 7% of normal fetuses as growth retarded!

Prevalence: 3–7% of all deliveries; in 12–47% of all twin pregnancies; in 25% of fetuses following birth of a growth-retarded sibling / stillborn

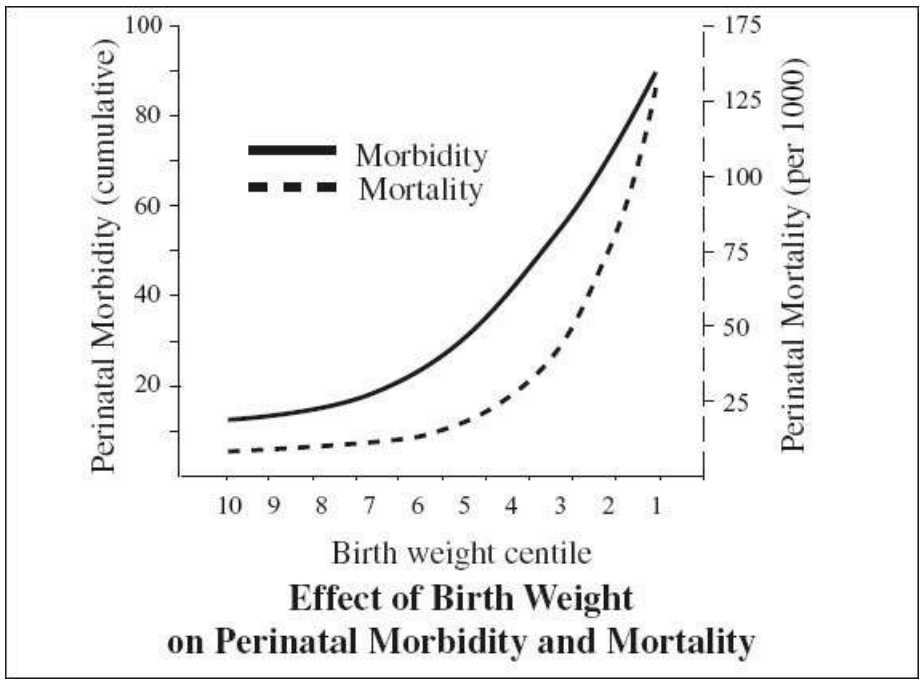
- fundal height as screening test (37–60% true positive, 40–55% false negative; 26–60% false positive)

◊ IUGR is primarily an ultrasound diagnosis!

Sequence of events in fetal hypoxia:
nonreactive CST > absence of fetal breathing > nonreactive NST > diminished fetal movements > absence of fetal movements > absence of fetal tone

Etiology:

A. UTEROPLACENTAL INSUFFICIENCY (80%)
= injury during period of cell hypertrophy → decreased cell size with features of intrauterine starvation + protective cardiac output redistribution reflex



Effect of Birth Weight on Perinatal Morbidity and Mortality

- absence of body fat; diminished liver and muscle glycogen

1. Maternal causes:
√ asymmetric IUGR / symmetric IUGR (in severe cases)
(a) deficient supply of nutrients:
cyanotic heart disease, severe anemia (in 10–25% of sickle cell anemia), maternal starvation, life in high altitudes, drugs (anticonvulsants, methotrexate,

warfarin), alcohol abuse (dose related), illicit drugs (up to 50% with heroine addiction, 30% with cocaine abuse), uterine anomaly, multiple gestation (in 15–20%)

(b) maternal vascular disease resulting in inadequate placental perfusion:
nicotine-induced release of catecholamines, preconceptual diabetes, preeclampsia, chronic renal disease, collagen vascular disease (SLE)

(c) maternal demographics:
maternal age (adolescence / advanced), nulliparous mother, small short habitus, racial influence (Asians)

2. Primary placental causes:
extensive placental infarctions, chronic partial separation (abruption), partial mole, Breus mole, chorioangioma, placenta previa, low implantation, placental metastases (breast, melanoma), placentitis (luetic, malaria)
Histo: reduction in placental villous surface area + in number of capillary vessels
√ asymmetric growth failure

B. PRIMARY FETAL CAUSES (20%)
= injury during the period of cell hyperplasia (= embryogenesis) producing profound reduction in cell number across all cell lines
√ symmetric IUGR (globally decreased intrinsic growth)
√ normal / increased amniotic fluid volume

1. Chromosomal abnormalities (in 2–6%): triploidy, tetraploidy, trisomy 13 + 18 + 21, aneuploidy (Turner syndrome), partial deletion (4p, 5p [cri-du-chat], 13q), partial trisomy (4p, 18p, 10q, 18q), unbalanced translocation (chromosomes 4 + 15), balanced translocation (chromosomes 5 + 11)
2. Structural anomalies: CHD, genitourinary anomalies, CNS anomalies, dwarfism
3. Viral infection: rubella (in 40–60%), CMV, varicella (in 40%)

◊ All fetuses with IUGR need to have a detailed and often repeated search for structural anomalies!

Diagnostic Ultrasound Methods in IUGR:

◊ An accurate fix on fetal age dictates the accuracy of diagnosis of IUGR (early US exam, clinical dates, early physical exam, pregnancy test)!

◊ Every effort needs to be made to determine the underlying cause for growth failure as it effects management + perinatal morbidity and mortality!

1. **Fetal morphometric indices**
The 3 key parameters for diagnosing IUGR are
(1) Low estimated fetal weight (EFW),
(2) Low amniotic fluid volume (AFV),
(3) Maternal hypertension (HBP)!

(a) intrafetal proportions
√ elevated HC÷AC ratio for dysmature IUGR (overall 36% sensitive, 90% specific, 67% PPV, 72% NPV; 93% sensitive in fetus > 28 weeks MA with severe dysmature IUGR)
◊ Early-onset dysmature IUGR not detectable!
◊ May not be used in anomalous fetuses!

(b) rate of growth = growth velocity
√ HC, AC, FL measurements allow DDx between erroneous dates + normal small fetus + fetus with intrinsic abnormality
√ plot growth curves
◊ Minimum time interval of 2 weeks necessary!

2. **Amniotic fluid volume**
◊ Screening for decreased amniotic fluid is of value in the fetus with dysmature IUGR (60–84% sensitive, 79–100% accurate)!
√ normal amniotic fluid does not exclude IUGR
√ oligohydramnios means dysmature IUGR in a fetus with normal GU tract until proven otherwise (DDx: trisomy 13 + 18)
3. **Fetal morphologic assessment + fat distribution**
√ diminished thigh circumference
√ absent paraspinal fat pad (posterior neck)
√ reduced / absent malar fat pads
√ disproportionately small liver size
√ increased small bowel echogenicity ← absent omental fat
4. **Placental assessment**
√ increased placental calcium deposition
5. **Biophysical profile**
Accuracy: false-negative fetal death rate of 0.645 per 1000 fetuses within 1 week of the last normal BPP; 33% sensitive, 17% positive predictive value
6. **Invasive fetal testing**: fetal blood analysis for karyotyping, hypoxemia, hyper-capnia, acidemia, hypoglycemia, hypertriglyceridemia
7. **Nonstress test** (NST)
8. **Contraction stress test** (CST)

Sonographic Criteria for IUGR

Sonographic Finding	*PPV [%]*	*NPV [%]*
Advanced placental grade	16	94
Elevated FL÷AC ratio	18–20	92–93
Abnormal UA waveform	17–37	
Low total intrauterine volume	21–24	92–97
Small BPD	21–44	92–98
Slow BPD growth rate	35	97
Low EFW	45	99
Oligohydramnios	55	92
Elevated HC÷AC ratio	62	98

Diagnostic Doppler Methods in IUGR:

A. PLACENTAL PERFUSION
1. Umbilical artery velocimetry (UA)
◊ Not useful with unknown dates / for screening!
◊ Better predictor of adverse perinatal outcome than MCA or RA pulsatility index

Pathophysiology: fewer terminal villi ← develop-mental defect / villous infarction
√ elevated systolic÷diastolic ratio (S/D ratio > 3.0 beyond 30–34 weeks GA) ← increase in vascular resistance within placental circulation
√ absent diastolic flow ← villous obliteration > 50% (50–90% mortality rate)
√ reverse diastolic flow ← villous obliteration > 50% (= impending fetal collapse)
Note: S/D ratio increases with sampling site closer to fetus + increasing fetal heart rate; ↓ of S/D ratio with advancing gestational age; S/D ratio may decrease in lateral recumbent position

2. Uterine artery waveform
Method: sample volume at point of overlap of uterine artery with external iliac artery
√ S/D ratio > 2.6 after 26 weeks GA
√ persistence of early diastolic notch
Pathophysiology: lack of trophoblastic invasion of spiral arteries
Rules:
› Trophoblastic invasion may not occur until 20–22 weeks GA in some patients
› An abnormal waveform at 24 weeks GA will never become normal
› A normal waveform will never revert to a high resistive waveform
› Both / one uterine artery may be abnormal

B. FETAL CIRCULATION
Pathophysiology: preferential shunting of blood to brain ("brain sparing") + myocardium in response to hypoxemia

1. Fetal middle cerebral artery (MCA)
◊ Significant correlation between hypoxemia at cordocentesis and MCA pulsatility index
◊ If the MCA pulsatility index is normal the fetus is unlikely to have a major adverse outcome
Method: sample volume in MCA of near field 1 cm distal to its origin
√ ↓ in S/D ratio to 2.5 to 3.0 (normal is about 6.0)

2. Renal artery waveform (RA)
Method: sample volume in proximal renal artery on coronal image that visualizes entire renal a.
√ increase of pulsatility index

3. Fetal aortic flow volume (no proven usefulness)
√ decrease in blood flow to < 185–246 mL/kg/min

Cx: increased risk for perinatal asphyxia, meconium aspiration, electrolyte imbalance from metabolic acidosis, polycythemia
Neonatal Cx: pulmonary hemorrhage + vasoconstriction, persistent fetal circulation, intracranial hemorrhage, bowel ischemia, necrotizing enterocolitis, acute renal failure
Prognosis: 6–8-fold risk increase for intrapartum + neonatal death
◊ 20% of all stillborn fetuses are growth retarded!

DDx of fetus small for gestational age (SGA):
Definition: fetus measures less than expected for GA age but grows normally throughout pregnancy

(1) Small normal fetus (80–85%)
(2) Small abnormal fetus (5–10%)
(3) Dysmature fetus (10–15%)

Pure Symmetric IUGR

= DECREASED–CELL-NUMBER IUGR = EARLY-INSULT IUGR = LOW-PROFILE IUGR
= proportionate reduction of all fetal measurements due to
(a) intrinsic alteration in growth potential (usually due to chromosomal abnormalities)
(b) severe nutritional deprivation overwhelming protective brain-sparing mechanism occurring < 26 weeks MA and persisting until delivery
√ proportionate decrease in HC and AC with maintenance of normal HC÷AC ratios
√ estimated fetal weight < 10th percentile for age by middle of 2nd trimester

Mixed IUGR

= onset of IUGR during period of mixed hyperplasia / hypertrophy with near normal inherent fetal growth potential but decreased size + impaired function of placenta
√ impaired fetal growth ± asymmetry
√ abnormal Doppler umbilical artery flow velocity ← increased placental vascular resistance
√ progressive oligohydramnios

Asymmetric IUGR

= DECREASED–CELL-SIZE IUGR
= LATE-ONSET IUGR = LATE-FLATTENING IUGR (75%)
= disproportionate reduction of fetal measurements ← uteroplacental insufficiency with preferential shunting of blood to fetal brain occurring after 26 weeks GA
◊ IUGR usually not detectable before 32–34 weeks GA (time of maximal fetal growth)!
Effective time for screening: 34 weeks MA
Routine surveillance: every 4 weeks from 26 weeks MA on
√ AC > 2 SD below the mean for age = highly suspicious; AC > 3 SD below mean for age = DIAGNOSTIC

◊ The abdominal circumference is the single most effective fetal parameter for the detection of asymmetric IUGR!

√ high HC÷AC and FL÷AC ratios (head size + femur length less affected)
√ fetal weight percentile useful for follow-up
√ accelerated placental maturity
√ decreased amniotic fluid volume
√ elevated umbilical artery S/D ratio
◊ FL÷AC ratio + umbilical artery S/D ratio are the only effective techniques to screen for IUGR on a single exam with late prenatal care in 3rd trimester!

KRUKENBERG TUMOR

= metastatic ovarian adenocarcinoma most commonly originating in GI tract
Origin: stomach > breast > colon > appendix > pancreas > biliary primary; ? colon÷stomach =

2÷1
◊ 2% of females with gastric cancer develop Krukenberg tumor
◊ Krukenberg tumors antedate the discovery of the primary lesion in up to 20%!

Age: any age, most common in 5th–6th decade
√ solid mass + intratumoral cysts; in 60–80% bilateral
√ hypo- / hyperechoic mass ± cystic degeneration
MR:
√ variable hypointensity on T2WI ← mucin-filled signet-ring cells + abundant collagen formation
√ moderate to marked enhancement of solid components

LIMB-BODY WALL COMPLEX

= BODY STALK ANOMALY
= characterized by attachment of visceral organs to placenta with short / absent umbilical cord
Prevalence: 0.12÷10,000 live and still births
Cause: ? abnormal lateral body folding; ? severe form of amniotic band syndrome; ? early vascular disruption; ? embryonic dysplasia due to malformation of ectodermal placodes

A. EXTERNAL DEFECTS
1. Ventral wall anomaly
√ large eccentric defect
Location: L÷R = 3÷1 (DDx: gastroschisis)
2. Craniofacial defects: anencephaly, cephalocele, facial cleft
3. Limb anomalies: clubfoot, absent limbs
4. Spinal defects: dysraphism, scoliosis

B. INTERNAL DEFECTS (in 95%)
1. Cardiac defects
2. Diaphragmatic absence
3. Bowel atresia
4. Renal abnormalities: agenesis, hydronephrosis, dysplasia

US (confusing appearance):
√ fetus usually in a fixed position
√ cord insertion site not identifiable
√ NO free-floating loops of cord
√ severe kyphoscoliosis (frequent)
√ ± oligohydramnios → MRI
√ complete evisceration of abdominal contents with adherence to placental surface
√ persistence of extraembryonic coelom (= separation of amnion + chorion)

Prognosis: invariably fatal shortly after birth

MACROSOMIA

= FETAL GROWTH ACCELERATION
= fetus large for gestational age (LGA) with EFW > 90th percentile for age / > 4,000 g at term
√ AC > 3 SD above the mean for age (most reliable + largest measurement)
√ estimated fetal weight (EFW) including fetal head, abdomen, femur length > 90th percentile (±

15% accuracy)
√ low FL÷AC ratio
√ low HC÷AC ratio
√ enlarged thigh circumference
√ low FL÷thigh circumference ratio
√ greater than expected interval growth
√ polyhydramnios
Risk: shoulder dystocia, prolonged labor, meconium aspiration

MASSIVE OVARIAN EDEMA

= tumorlike condition with marked enlargement of one / both (occasionally) ovaries ← accumulation of edema fluid in stroma
Prevalence: rare; common in young woman during ovulation induction / pregnancy
Location: right > left ovary
Age: 6–33 (average 21) years
Cause:
(1) partial / intermittent torsion → obstruction to ovarian lymphatic + venous drainage
(2) ovarian stromal proliferation with enlargement of ovary susceptible to torsion
Histo: edematous ovarian stroma + extensive fibromatosis surrounding primordial follicles, luteinized cells
• acute / intermittent lower abdominal pain for months
• masculinization (in chronic phase)
√ solid / multicystic adnexal mass
√ ovarian diameter of 5–40 (mean 11.5) cm
Rx: oophorectomy / salpingo-oophorectomy / wedge resection with ovarian suspension

MEIGS SYNDROME

[Joe Vincent Meigs, 1892–1963, obstetrician and gynecologist at Harvard University and Massachusetts General Hospital]
= characterized by
(1) Ascites (in 15–40% of tumors > 10 cm):
(2) Pleural effusion (rare)
(3) Benign ovarian tumor: fibroma / fibrothecoma (91%), granulosa cell tumor (5%), Brenner tumor (2%)]
Pseudo-Meigs syndrome
(4) Mature teratoma / leiomyoma / cystadenoma / ovarian malignancy
Pathogenesis: ? vasoendothelial and fibroblast growth factors + cytokines; pressure of tumor on lymph vessels
• CA-125 may be elevated
◊ Ascites + pleural effusion resolve after removal of tumor

MUCINOUS OVARIAN TUMOR

Frequency: 20% of all ovarian tumors; 2nd most common benign epithelial neoplasm of ovary (after serous ovarian neoplasm)

Histo: single layer of nonciliated tall columnar epithelium with clear cytoplasm of high mucin content (similar to endocervix + intestinal epithelium)
Age: middle adult life, rare before puberty + after menopause
Cx: (1) Rupture may lead to pseudomyxoma peritonei
(2) Torsion
DDx: serous ovarian tumor (smaller, unilocular)

Mucinous Cystadenoma (80%)
Prevalence: 20% of all benign ovarian neoplasms
Age: 3rd–5th decade of life
√ multilocular cyst with numerous thin septa
√ cysts frequently have high protein content:
√ low-level echoes in cysts
√ high attenuation on CT
√ hyperintense on T1WI
√ usually unilateral, bilateral in 5%

Borderline Malignant Mucinous Cystadenoma (10%)

Mucinous Cystadenocarcinoma (10%)
Histo: mucoid material in cysts, sometimes accompanied by hemorrhagic / cellular debris; difficult to differentiate from benign variety + metastasis from intestinal primary
√ multilocular with numerous smooth thin-walled cysts
√ solid tissue areas: thick septa + other soft-tissue elements within septated cyst
√ usually unilateral; bilateral in 5–10% of stage I cases
√ capsular infiltration with loss of definition + fixation
CT:
√ multiseptated tumor of low attenuation
√ high-attenuation proteinaceous material (20–30 HU) in some loculi
MR:
√ variable signal intensity in different loculi ← proteinaceous / mucinous content, hemorrhage

NABOTHIAN CYST
= most common benign masslike lesion of cervix
Incidence: in women during reproductive years
Cause: mucus-retention / epithelial-inclusion cyst ← obstruction of endocervical gland by proliferating squamous epithelium ← chronic cervicitis / after childbirth
Size: < 1 cm (majority); may enlarge to become symptomatic
√ simple anechoic cyst without vascularity (incidentally detected at imaging)
√ may increase in echogenicity ← proteinaceous / hemorrhagic content
√ "tunnel cluster" (in up to 8%) = multicystic dilatation of endocervical glands mimicking adenoma malignum
Rx: none (unless symptomatic)

DDx: adenoma malignum = minimal deviation adenocarcinoma (solid components, marked hypervascularity)

NUCHAL CORD

= umbilical cord encircling fetal neck: single loop (96%) > 2 loops (2–3%) > 3 or more loops (< 1%)

Prevalence: 5–29% of pregnancies; increases with fetal age; frequently transient

Associated with: increased cord length, small fetus, vertex presentation, polyhydramnios

• generally not of clinical significance: no difference in 5-min Apgar score, no increase in infant mortality

√ umbilical cord loop > 360° around fetal neck

√ two adjacent cross sections of cord on longitudinal view of neck (diagnosis facilitated by color Doppler flow)

√ "**divot**" sign = indentation of skin by nuchal cord suggests tight loop

√ NO effect on fetal MCA + umbilical artery flow velocimetry

Cx: (1) Fetal distress: fetal bradycardia + intrapartum deceleration + depressed 1-min Apgar score

(2) Umbilical artery acidemia

(3) Passage of meconium

(4) Fetal demise

OB management:

1. Assess fetal well-being (biophysical profile biweekly, NST, fetal growth)
2. Vaginal delivery permissible if without evidence of fetal compromise
3. Intervention only for signs of fetal distress

OMPHALOCELE

= herniation of abdominal viscera through an enlarged umbilical ring into base of umbilical cord during 3rd–4th week of GA

Prevalence: 1÷4,000–5,500 pregnancies; 2–3÷10,000 live births

Cause:

(a) migration failure of lateral mesodermal body folds:
√ omphalocele contains liver

(b) persistence of primitive body stalk beyond 12th week MA

Age: earliest detection at 12 weeks menstrual age; diagnosis < 11–12 weeks' gestation should be made with caution

Normal physiologic herniation should be < 1 cm into cord and never involve the liver. At 14 weeks follow-up bowel should have returned into abdominal cavity.

High incidence of ASSOCIATED ANOMALIES (45–88%):

1. Chromosomal (10–25–58%): trisomy 13, 18, 21; Turner syndrome (13% with liver in omphalocele, 77% with bowel in omphalocele)
2. Genitourinary (40%)
   mnemonic: OEIS complex (= aide-mémoire acronym)
   Omphalocele

Exstrophy of bladder
Imperforate anus
Spinal defect

3. Cardiac (16–30–47%): VSD; ASD; tetralogy of Fallot; ectopia cordis in pentalogy of Cantrell; DORV
4. Neural tube defects (4–39%): holoprosencephaly; encephalocele; cerebellar hypoplasia
5. IUGR (20%)
6. Beckwith-Wiedemann syndrome (5–10%)
7. GI tract:
   intestinal atresia (vascular compromise); malrotation; abnormal fixation of liver; esophageal atresia; facial cleft; diaphragmatic hernia
8. Limb-body wall deficiency; cystic hygroma

• MS-AFP ≥ 2.5 in 40–70%

Sac contents: primarily bowel, liver, other viscera (variable)

√ herniation of abdominal viscera at base of umbilical cord:
liver (27%) ± stomach ± bowel

√ midline central defect at base of umbilical cord insertion:
√ defect over entire ventral abdominal wall of variable size (mean, 2.5–5 cm)
√ widened cord where it joins the skin of the abdomen

√ covering amnioperitoneal membrane:
√ inner layer = peritoneum; outer layer = amnion
√ cord inserts at apex of defect on covering membrane, NOT directly on abdominal wall

√ hypoechoic loose mesenchymal tissue (= Wharton jelly) between layers of membrane

√ ascites within herniated sac (common)

√ polyhydramnios (occasionally oligohydramnios)

mnemonic: OMPHALOCele
Other anomalies (common)
Membrane surrounding viscera
Perfectly midline
Heart anomalies
Ascites
Liver commonly herniated
O for "zero" bowel complications
Chromosomal abnormalities (common)

Cx: (1) Infection, inanition
(2) Immaturity (23%)
(3) Rupture of hernia sac (in up to 15%)
(4) Intestinal obstruction

Mortality rate: 10% mortality if isolated abnormality; 80% with one / more concurrent malformations; ~ 100% with chromosomal + cardiovascular abnormalities

DDx: (1) Congenital umbilical hernia (covered by intact skin and subcutaneous tissue)
(2) Gastroschisis (usually right-sided defect)
(3) Limb-body wall complex (usually left-sided defect)

Pseudo-omphalocele

(1) Deformation of fetal abdomen by pressure with transducer coupled with an oblique scan orientation may give the appearance of an omphalocele
√ obtuse angle between pseudomass + fetal abdominal wall

(2) Physiologic herniation of midgut into umbilical cord between 8th and 12th week of gestation
√ herniated sac never contains liver
√ herniated sac usually < 7 mm
√ disappears by 12th week GA

OMPHALOMESENTERIC DUCT CYST

Etiology: persistence + dilatation of an omphalomesenteric / vitelline duct segment → joining embryonic midgut and primary yolk sac → which is formed during the 3rd week and → closed by the 16th week of gestation

Histo: cyst lined by columnar mucin-secreting GI epithelium

M÷F = 3÷5

Location: usually in close proximity to fetus
√ umbilical cord cyst up to 6 cm in diameter
√ beneath amniotic surface of cord (= eccentric)

Cx: (1) Compression of umbilical vessels by expanding cyst
(2) Erosion of umbilical vein from acid-producing gastric mucosal lining

DDx: allantoic cyst, umbilical cord hematoma

OVARIAN CANCER

= 7th leading cause of cancer in women (4% of all cancers among women); 2nd most common gynecologic malignancy; 5th leading cause of cancer deaths in USA women after lung, breast, colon, pancreas (leading cause of cancer deaths of all female cancers); accounts for 50% of cancer deaths of female genital tract (67% of patients present with advanced stage III disease)

◊ 1÷75 women will develop ovarian cancer (lifetime risk)
◊ 1÷100 women will die of ovarian cancer

Incidence: 50÷100,000 women annually (33÷100,000 women > age 50 annually); in USA 22,280 new cases + 14,240 deaths (2016)

Etiology: ovarian surface epithelium proliferates temporarily to repair defect after rupture of ovum, which may result in an "inclusion body" / "cystoma"; an error in DNA replication within inclusion body may occur resulting in inactivation / loss of a tumor-suppressor gene

Epidemiology:

(1) sporadic: "ovulation hypothesis" = risk of ovarian cancer is a direct function of the number of ovulatory cycles during a woman's life span

(2) hereditary (1–5%) = defined as ovarian cancer occurring in at least two 1st-degree relatives
◊ 50% lifetime probability to develop ovarian cancer
(a) breast cancer-ovarian cancer syndrome
(b) ovarian cancer only syndrome

(c) Lynch type II cancer family syndrome
= inheritance of nonpolyposis colorectal cancer, endometrial cancer and (rarer) ovarian cancer

Increased risk:
nulliparity, early menarche, late menopause, Caucasian race, higher socioeconomic group, positive family history for ovarian cancer (risk factor of 3 with one close relative, risk factor of 30 with two close relatives affected with ovarian cancer), history of breast cancer (risk factor of 2) / early colorectal cancer (risk factor of 3.5)

Decreased risk = protective effect:
multiparity, use of oral contraceptives, breast-feeding

Age: increasing with age; peaking at 55–59 years (80% of cases in women > 50 years)

Spread:

(1) direct extension through subperitoneal space (sigmoid mesocolon on left, cecum + distal ileum on right), uterus, fallopian tubes, broad ligament

(2) intraperitoneal implantation = exfoliation of tumor cells from ovarian capsule into peritoneal space (often microscopic):
with frequent seeding to:
› posterior cul-de-sac in pouch of Douglas
› infundibulopelvic ligaments
› omentum
› superior aspect of sigmoid
› right paracolic gutter
› termination of small bowel mesentery
› undersurface of right hemidiaphragm
with less frequent seeding to:

FIGO and TNM Staging of Ovarian Cancer (2010)		
FIGO	*TNM*	*based on staging laparotomy*
I	T1	Limited to ovary
IA	T1a	limited to one ovary
IB	T1b	limited to both ovaries
IC	T1c	+ positive peritoneal lavage / ascites
II	T2	Limited to pelvis
IIA	T2a	involvement of uterus / fallopian tubes
IIB	T2b	extension to other pelvic tissues
IIC	T2c	+ positive peritoneal lavage / ascites
III	T3±N1	Limited to abdomen = intraabdominal extension outside pelvis / retroperitoneal or inguinal nodes / extension to small bowel / omentum
IIIA	T3a	microscopic abdominal peritoneal seeding
IIIB	T3b	≤2 cm implants of abdominal peritoneum
IIIC	T3c±N1	>2 cm implants of abdominal peritoneum
IV	M1	Hematogenous disease (liver parenchyma) / spread beyond abdomen / positive Lnn
◊ 50–70–75% of patients have stage III / IV disease at time of diagnosis!		

› Morison pouch
› liver surface
› porta hepatis
› intrahepatic fissure

(3) lymphatic spread
› craniad parallel to gonadal veins in infundibulopelvic ligament terminating at level of renal vessels
› laterally through broad ligament terminating at pelvic side wall: external iliac, obturator, hypogastric chains

Size: short-axis diameter of > 1 cm (in 88% positive for ovarian cancer)
√ hydronephrosis (2nd most common form of tumor-related morbidity after bowel obstruction)
√ thoracic adenopathy: paracardiac lymph nodes > 5 mm in 28% of stage II/III disease; mediastinal lymphadeno-pathy (29% at autopsy)

(4) hematogenous dissemination (% at autopsy):
liver (45–48%), lung (34–39%), adrenal gland (15–21%), pancreas (11–21%), spleen (15–20%), bone (11%), kidney (7–10%), skin (5%), brain (3–6%)
√ malignant pleural effusion (pleural metastases in 28–60%, lung parenchymal metastases in 7%, pericardial metastases in 5%)

Staging laparotomy:
= abdominal hysterectomy + bilateral salpingo-oophorectomy + omentectomy + random peritoneal biopsy + lymph node biopsy

Limitations of imaging:
◊ Microscopic peritoneal disease not detectable!

Benefit of imaging:

◊ Second-look surgery can be avoided if there is evidence for residual / recurrent tumor!

Cave: NO biopsy in the absence of peritoneal disease as it may cause spillage and upstaging of the cancer!

- often "silent" without obvious signs / symptoms
- occasional pelvic-abdominal pain
- constipation, urinary frequency; early satiety; ascites
- paraneoplastic hypercalcemia
- Human epididymal protein 4 (HE4)

Accuracy: 89% sensitive, 92% specific during premenopause

- CA-125 level (= cancer-associated marker = high-molecular-weight glycoprotein) > 35 kU/L:

Accuracy: (a) premenopausal (83% sensitive, 60% specific)
(b) postmenopausal (94% sensitive, 82% specific)

Levels: > 35 (> 65) kU/L in 29–50 (21) % of stage I disease

◊ ↑ CA-125 levels in 80% of ovarian cancers (60% of mucinous + 20% of nonmucinous tumors) and in 40% of patients with advanced intraabdominal nonovarian malignancy!

◊ ↑ CA-125 levels in 30% of benign processes (in 1% of healthy individuals, fibroid, first-trimester pregnancy, menstruation, endometriosis, PID, benign ovarian tumors, liver cirrhosis, pancreatitis)!

US:

◊ Screening finds adnexal cysts in 1–15% of postmenopausal women; only 3% of ovarian cysts < 5 cm are malignant!

@ Morphologic tumor criteria (85–97% sensitive, 56–95% specific, 99% NPV):

√ thick irregular walls and thick septations
(DDx: endometrioma, abscess, peritoneal cyst, cystadenofibroma, mucinous cystadenoma)

√ papillary projections ≥ 3 mm: in 67% [38%] {9%} of borderline [malignant] {benign} neoplasm

√ solid / moderately echogenic loculi

√ postmenopausal ovarian volume > 9 cm^3

@ Doppler tumor criteria (50–100% sensitive, 46–100% specific, 49% PPV; more sensitive + specific in postmenopausal women):

√ presence of color flow (in 93% of malignant + 35% of benign tumors) usually within thick wall, septa, papillary projections, solid inhomogeneous areas

√ low-resistance Doppler waveform ← lack of muscular layer of arterial wall + presence of arteriovenous shunts in neoplasm: RI < 0.40, PI < 1.0 (37–47% PPV)

False positive: physiologic alteration of ovarian blood flow during menstrual cycle, benign tumor, acute inflammatory disease, endometriosis

@ Metastatic disease

√ omental / peritoneal masses ("omental cake")

√ pseudomyxoma peritonei (with tumor rupture)

√ liver metastases

√ ascites

CT (70–90% preoperative staging accuracy):

@ Primary tumor:
- √ lesion diameter > 4 cm
- √ enhancing papillary projections
- √ septa and walls > 3 mm thick
- √ partially solid, partially cystic mass
- √ lobulated solid mass
- √ tumor vessels on contrast-enhanced images

@ Local extension:
- √ localized distortion of uterine contour
- √ irregular interface between tumor and myometrium
- √ loss of tissue plane between tumor and wall of sigmoid colon / bladder
- √ encasement of sigmoid colon
- √ tumor distance from pelvic side wall < 3 mm
- √ iliac vessels surrounded / displaced by tumor

@ Secondary findings:
- √ ascites:
  - √ often lesser sac ascites with displacement of fundus and posterior wall of stomach anteriorly (DDx to benign ascites) + gastrosplenic ligament laterally
  - √ loculated ascites ← adhesions
- √ > 10-mm nodular / plaquelike peritoneal implants:
  - √ indentation of hepatic / splenic surface
  - √ ± calcifications
- √ lymphadenopathy, may be calcified
- √ omental implants:
  - √ small nodules / strands of hyperdense soft tissue → increased attenuation of omental fat / marked omental thickening ("omental cake")
  - √ fat plane obscured between anterior abdominal wall + intestinal wall
- √ mesenteric deposits:
  - √ round / irregular ill-defined masses / stellate lesions of small bowel mesentery
  - √ tethering of small bowel loops
- √ invasion of bowel:
  - √ bowel obstruction (most common form of ovarian-cancer associated morbidity)
  - √ nodular / plaquelike lesions along / projecting from peritoneal surfaces
  - √ bowel wall thickening
- √ pseudomyxoma peritonei

MR:
- ◊ Useful for lesions that are indeterminate by US (with 89% highest accuracy of all modalities)
- √ papillary projections from wall / septum of a cystic lesion
- √ mass with solid + cystic components
- √ necrosis within a solid lesion
- √ multiple > 3 mm thick septations; irregular septum / wall
- √ large size > 6 cm
- √ bilateral adnexal lesions
- √ ascites; peritoneal disease; lymphadenopathy

√ strong early enhancement with high wash-in rate > 9.5 L/s
◊ Note clearly benign features:
√ high SI on T1WI = fat / blood
√ subsequent loss of SI on fat-suppressed T1WI = blood
√ low SI on T2WI = fibrous tissue / hemosiderin
√ lack of enhancement

PET: √ ovarian carcinoma is FDG avid requiring a size of 6–10 mm of spatial resolution
DDx: endometrioma, benign cystic teratoma, inflammatory mass (PID), physiologic change
√ may be useful for staging and recurrence

BE:
√ serosal spiculation / tethering
√ annular constriction / complete obstruction

Rx:
stage I: total abdominal hysterectomy (TAH) + bilateral salpingo-oophorectomy (BSO) ± melphalan / intraperitoneal Phosphorus-32
stage > I: TAH-BSO + surgical cytoreduction (debulking) + 6 cycles of chemotherapy (cyclophosphamide + cisplatin)

Prognosis (without change in past 60 years):
46% overall 5-year survival rate, 10–25% for stage IV, 37% for stage III, 50% for stage II, 80–90% for stage I

DDx: tuboovarian abscess, dermoid cyst, endometrioma

OVARIAN CYST

Definition: any ovarian cyst > 2.5 cm
◊ Fetal ovarian cysts > 4 cm may be at risk of in utero torsion!

Dominant Follicle

Cause: physiologic (estrogen sensitive)
• pelvic pain from
(a) stretching of ovarian capsule
(b) ovulation (Mittelschmerz) triggered by surge in LH
(c) cyst rupture / hemorrhage

Number: 1 or 2 dominant follicles
√ follicular enlargement at a rate of 2 mm per day during first half of menstrual cycle ← under influence of FSH
√ 18–25 mm Graafian follicle at time of ovulation
√ conversion into corpus luteum after ovulation
DDx: nonovulatory follicle (< 10 mm); ovarian cyst
Cx: ovarian torsion

Functional / Retention Cyst

◊ Functional cysts are commonly unilateral!
Cause:
(a) failure of involution of follicle / corpus luteum with changes in the menstrual cycle

(b) excessive hormonal stimulation of follicles preventing normal follicular regression (eg, theca-lutein cysts)

Prognosis: spontaneous regression is common but unpredictable; typically resolve within 2 menstrual cycles (less likely if cyst > 5 cm)

Cx: torsion

Rx: (1) Hormonal manipulation
(2) Surgery → absolutely indicated if cyst enlarges
(3) Percutaneous aspiration (if chance of malignancy is nil as in infants)

DDx: cystic teratoma, simple benign epithelial neoplasm, endometrioma in resolution, paraovarian cyst, quiescent hydrosalpinx

Follicular Cyst (from preovulatory follicle)

Cause:
(a) unruptured Graafian follicle from failure to ovulate
(b) Graafian follicle with failure to regress / involute
(c) ruptured Graafian follicle that sealed immediately (after continued stimulation)

- pain ← rapid cystic enlargement / rupture / hemorrhage
- may elaborate estrogen (extremely common)
- sign of anovulatory cycle

Predisposed: patients during puberty + menopause; status post salpingectomy

Size: usually 3–8 cm; occasionally up to 10 cm (if cyst remains hormonally sensitive); up to 25 cm (under influence of placental gonadotropin in pregnancy)

√ thin-walled unilocular cyst
√ located within ovary → compressing adjacent ovarian follicle-containing parenchyma
√ usually multiple / may be single

US:
√ contains anechoic fluid → posterior through-transmission
√ ± minimal mobile low-level internal echoes

CT:
√ well-defined round simple fluid collection
√ thin nonenhancing wall
√ internal attenuation of < 15 HU

Prognosis: usually resolves after 1–2 menstrual cycles (follow-up best performed on days 5–10 of subsequent menstrual cycle)

DDx: cystadenoma (larger, persistent, in older woman)

Corpus Luteum Cyst (from postovulatory follicle)

= hemorrhage into mature corpus luteum

Physiology: grows under the influence of LH; granulosa cells undergo marked neoangiogenesis → frequently causing hemorrhage

Types:

1. **Corpus luteum of menstruation**
   = formed after rupture of follicle + increasing in size until 22nd day of menstrual cycle

   Size: usually > 12–17 mm

• elaborates progesterone → release into maternal circulation → delayed menstruation / persistent bleeding

Prognosis: resolves within 1–2 menstrual cycles

2. **Corpus luteum of pregnancy**

= maintained by circulating β-hCG during pregnancy with similar effect as LH

• may be temporarily painful

Size: usually 30–40 mm, may grow up to 15 cm in diameter

◊ Excessively large cyst with thin wall suggests poor function ← low progesterone level

√ reaches maximum size after 8–10 weeks

√ occurs on same side as ectopic in 85%

Prognosis:

normally resolved by 12–16 weeks (as placenta becomes dominant source of progesterone); occasionally persists past 1st trimester with failure to involute

US:

√ increased peripheral vascularity with high diastolic flow component

√ irregular thick-walled usually unilateral cyst

√ echogenic (= organized clot) / isoechoic with low-level internal echoes (= hemorrhage) / sonolucent (= serum)

√ posterior through-transmission

CT:

√ unilocular cyst with thick crenulated enhancing wall

√ intracystic blood products with high attenuation

√ fluid surrounding adnexa (after rupture)

Cx:

(1) Enlarging hemorrhagic corpus luteum with

› severe pelvic adhesions preventing ovulation of luteinized follicles

› NSAIDs which may cause luteinized unruptured follicle syndrome

› excessive anticoagulation

› endometriosis

(2) Rupture with intraperitoneal life-threatening hemorrhage at ovulation

DDx: endometrioma, ovarian tumor, organized clot in any enclosed space

Corpus Albicans Cyst

= from corpus luteum following regression of luteal tissue; no hormone production

Theca Lutein Cyst

= multiple bilateral corpus luteum cysts ← ovarian hyperstimulation ← abnormally high levels of β-hCG

Cause: (a) multiple gestations (twins)

(b) gestational trophoblastic disease (in 40%)

(c) fetal hydrops

(d) pharmacologic stimulation of ovaries with β-hCG

(e) normal pregnancy (uncommon)

• elaborates estrogen
√ multiloculated cysts, often bilateral
√ ovaries several cm in size
√ involution within a few months after source of gonadotropin removed

Surface Epithelial Inclusion Cyst

common in postmenopausal women
Age: any; in newborns (influence of maternal estrogen)
Prevalence: 3–5–17% in postmenopausal women
• usually asymptomatic
• acute unilateral pelvic pain ← hemorrhage / pressure
√ up to 8–10 cm in diameter

Imaging Classification of Ovarian Cysts

Simple Ovarian Cyst

Location: uni- > bilateral; intra-abdominal > intrapelvic
Size: < 20 mm in diameter = maturing / physiologic follicle

√ round smooth cyst + thin sharply defined wall of < 3 mm
√ unilocular = NO internal septations / mural nodules

N.B.: may occasionally contain single avascular septation

√ contents anechoic
√ posterior acoustic enhancement

√ "**daughter cyst**" = small round anechoic structure within a cyst is PATHOGNOMONIC for an ovarian cyst (82%)

√ Doppler flow in cyst wall (detected in 19–61%) with a pulsatility index of > 1.0 / RI > 0.4 (unreliable!)
√ isointense to urine on T1WI + T2WI
DDx: serous cystadenoma

Management of Premenopausal Asymptomatic Adnexal Cyst
(Society of Radiologists in Ultrasound, 2010)

Cyst Size [cm]	*Cyst Content*	*Recommendation*
≤ 3	simple / hemorrhagic	no follow-up; may be omitted from report
3 – 5	simple / hemorrhagic	no follow-up; mention in report
> 5 and ≤ 7	simple	sonographic follow-up annually
	hemorrhagic	follow-up in 6–12 weeks to ensure resolution
> 7	simple	MR imaging / surgery

Postmenopausal (> 5 years) Asymptomatic Adnexal Cyst (Society of Radiologists in Ultrasound, 2010)		
Cyst Size [cm]	*Cyst Content*	*Recommendation*
≤ 1	simple	no follow-up; may be omitted from report
> 1 and ≤ 7	simple	sonographic follow-up annually
> 7	simple	MR imaging / CA-125 / surgery

Risk of Malignancy Index (RMI)	
Score	*Description*
U-score	Number of malignant features at **ultrasound**: multilocular cyst, solid component, bilateral, metastases, ascites
0	no features of malignancy
1	one feature of malignancy
3	≥ 2 features of malignancy
M score	Patient's **menopausal** status: no menstruation > 1 year / > 50 years old with hysterectomy
1	premenopausal
3	postmenopausal
RMI	**RMI** = U x M x CA-125 level
> 200	high risk (84–85% sensitive, 77–97% specific); staging CT + referral to gynecologic oncology
25–200	intermediate risk; MRI for further characterization
< 25	low risk; clinical reevaluation

Complex / Complicated Ovarian Cyst

= does not satisfy criteria for hemorrhagic cyst / endometrioma

Cause: ovarian torsion

√ thick-walled cyst of heterogeneous echogenicity
√ multiple septations, mobile internal echoes, solid appearance, fluid-fluid level

√ internal septations / mural nodules / internal echoes
√ ± polyhydramnios, ascites ← transudate / cyst rupture

Cx: obstruction of bowel / kidneys

Hemorrhagic Ovarian Cyst

= functional cyst (follicular cyst / corpus luteum) that developed internal hemorrhage → resolves partially / completely over time

◊ Common cause of RLQ pain ← rupture into peritoneal cavity

Path: functional cyst + corpus luteum cyst

US:

√ hematocrit level in acute bleed
√ "ground-glass" pattern = diffuse low-level echoes
√ whirled / spongy pattern of mixed echogenicity
√ "fishnet weave" pattern = fine interdigitating septations / lacelike reticular pattern for

first 24 hours (SPECIFIC)
- √ gelatinous echogenic mass (= retracting clot) jiggling during transducer ballottement with triangular / curvilinear echogenic regions at cyst wall
- √ fluid-debris level
- √ NO color Doppler signals inside cyst
- √ posterior through-transmission

CT:
- √ unilocular cyst with an attenuation of 25–100 HU
- √ fluid-fluid level + hemoperitoneum (after cyst rupture)

MR:
- √ SI varies depending on age of hemorrhage:
  - √ intermediate SI on T1WI + low SI on T2WI ← deoxyhemoglobin of subacute hemorrhage
  - √ increased SI on T1WI + decreased SI on T2WI ← intracellular methemoglobin
- √ hematocrit effect of layering blood products
- √ intermediate to high intensity on fat-suppressed T1WI
- √ hyperintense / intermediate intensity with distinct central area of hypointensity on T2WI
- √ heterogeneous mild signal loss with NO shading on T2WI
- √ pelvic peritoneal fluid of elevated T1 signal ← hemorrhage

DDx: endometrioma ("light bulb" T1-hyperintensity, T2 shading, stable over time)

Cx: rupture into intraperitoneal space

Ovarian Cyst concerning for Neoplasm
- √ irregular solid / multilocular cystic mass
- √ solid component / papillary projections on cyst wall
- √ absence of thin septations
- √ presence of thick septations > 3 mm
- √ central vascularity with high flow in echogenic component / septation / focal wall thickening
- √ low resistance flow (RI < 0.5, PI ≤ 1.0)
- √ ascites
- √ omental / peritoneal nodules

Management of Asymptomatic Adnexal Cyst

A. NEONATAL
- √ change in position between exams suggests pedunculated lesion → potential for torsion
- √ fluid-debris level / low-level echoes / retracting clot suggest torsion

B. PREMENOPAUSAL

Risk of malignancy: < 1% for simple cyst < 5 cm, 0.8% for lesion > 7.5 cm
- ◊ Adnexal cysts up to 10 cm are highly likely benign (in 84% serous cystadenoma)!
- ◊ Hemorrhage WITHOUT a vascular soft-tissue component is a reliable indicator of a benign lesions

N.B.: All follow-up scans should take place in the immediate postmenstrual period (= early proliferative phase), when follicular cysts should not be present!

C. POSTMENOPAUSAL (< 5 years after LMP)
= ovulation + hemorrhagic cysts may occasionally occur
Risk of malignancy: 1.6% for simple cyst < 5 cm
Rx: follow-up in 6–12 weeks to ensure resolution

C. POSTMENOPAUSAL (> 5 years after LMP)
Risk of malignancy: 1.0–9.6%
◊ A hemorrhagic cyst in an anovulatory woman is likely neoplastic! 18% of complex cysts are malignant!

OVARIAN FIBROMA

Frequency: 3–4% of all ovarian tumors; bilateral in < 10%
◊ Most common of the sex cord-stromal tumors!
Age: 4th– 6th decade
Path: solid firm white mass
Histo: pure mesenchymal tumor consisting of intersecting whorled bundles of spindle-shaped fibroblasts + collagen; varying degrees of edema often separate cells

- usually asymptomatic (pure fibromas are not estrogenic, admixture of theca cells causes estrogenic effect)
- Meigs syndrome (in only 1%)
- elevated carcinogenic antigen levels

Associated with: basal cell nevus (Gorlin) syndrome in commonly bilateral calcified fibromas
◊ Fibromas occur in 17% of patients with basal cell nevus syndrome
Location: unilateral (common); bilateral in 4–8%
√ ± cystic degeneration and edema in larger lesions
√ calcification + hemorrhage (< 10%)
US:
√ solid hypoechoic mass with marked sound attenuation
√ occasionally hyperechoic / with increased through-transmission
MR:
√ well-circumscribed mass with nonspecific hypo- to isointensity on T1WI
√ low-SI mass on T2WI less than or equal to myometrium ← abundant collagen content (FAIRLY DIAGNOSTIC)
√ scattered high-signal-intensity areas on T2WI (= edema / cystic degeneration)
√ delayed mild enhancement with gadolinium
CT:
√ well-defined solid homogeneous / slightly heterogeneous mildly hypoattenuating mass
√ poor delayed contrast enhancement
Rx: may be managed conservatively; rarely recurs after excision
DDx: fibrothecoma; pedunculated uterine leiomyoma; Brenner tumor; adenofibroma; malignant ovarian neoplasm

OVARIAN FIBROMATOSIS

= rare benign condition causing tumorlike enlargement of ovaries related to massive ovarian edema

Cause: ?

Average age: 25 years

- pelvic pain, menstrual abnormalities, occasional virilization

Histo: proliferation of collagen-producing spindle cells surrounding normal ovarian structures with collagenous thickening of superficial cortex; partial preservation of normal ovarian structures within the fibrous mass, which allows differentiation of ovarian fibromatosis from similar conditions.

√ nonspecific enlargement of ovaries

√ at least partial preservation of ovarian anatomy

US:

√ enlarged heterogeneously echogenic ovary with areas of acoustic shadowing

√ low flow at Doppler imaging

MR:

√ hypointense areas on T1WI + T2WI

√ "**black garland**" on T2WI ← fibrous tissue encasing peripheral aspect of ovary

DDx: (1) Pelvic aggressive fibromatosis (desmoid) involving ovary
(2) Brenner tumor (calcifications)
(3) Ovarian sex-cord stromal tumors: fibroma, fibrothecoma
(4) Krukenberg tumor (bilateral, avid enhancement)

OVARIAN HYPERSTIMULATION SYNDROME

= potentially life-threatening iatrogenic complication of ovulation induction / ovarian stimulation

Incidence: (a) Clomid®: mild in 13%, moderate in 8%
(b) Pergonal®: mild in 20–33%, moderate in 3–6%, severe in 0.1–2%

Etiology:

(1) Induced by hCG therapy with human menopausal gonado-tropin (Pergonal®), occasionally with clomiphene (Clomid®)
(2) Hydatidiform mole
(3) Chorioepithelioma
(4) Multiple pregnancies

Path: enlarged ovaries with multiple follicular + theca lutein cysts, edematous stroma

Pathophysiology:

secretion of ovarian vasoactive angiogenic substances → increased capillary permeability → fluid shift out of intravascular space → ascites → hemoconcentration

- abdominal pain (100%) + distension (100%)
- nausea (100%), vomiting (36%), acute abdomen (17%)
- dyspnea (16%), thrombophlebitis (11%), fainting (11%)
- marked hemoconcentration, blurred vision (5%)
- anasarca (5%), hydrothorax, enhanced fertility

√ "**spoke-wheel**" appearance of ovaries = bilateral symmetrically enlarged ovaries > 5 cm in longest dimension containing large geometrically packed follicles:

√ cysts separated by thin septa

Modified Golan Classification of Hyperstimulation Syndrome			
Category	*Grade*	*Ovarian size [cm]*	*Signs and symptoms*
Mild (65%)	I	< 6	Abdominal distension
	II		+ nausea, vomiting, diarrhea
Moderate	III	6–12	+ ascites at US; weight gain
Severe	IV	> 12	Clinical ascites / pleural effusion
	V		+ hypovolemia, hemoconcentration, hypercoagulability, renal failure, hepatic dysfunction, thrombo-embolism, shock

√ cysts usually anechoic, unless complicated by hemorrhage
√ resolution on follow-up

√ ovarian cyst > 10 cm (100%): usually disappears after 20–40 days; may persist for 12–16 weeks during pregnancy
√ ascites (33%)
√ pleural effusion (5%)
√ hydroureter (11%)

MR:
√ cysts with increased SI on T1WI (common) ← hemorrhage
√ ↑ SI of ovarian stroma on T2WI ← edema

Cx of volume depletion:
(1) Hypovolemia + hemoconcentration
(2) Oliguria, electrolyte imbalance, azotemia
(3) Death from intraabdominal hemorrhage / thromboembolic event

Other Cx:
(1) Ovarian torsion (7%)
(2) Ectopic pregnancy (in 2.1–8.6%)

OVARIAN MALIGNANT GERM CELL TUMOR

= OMGCT = heterogeneous group of tumors sharing the primitive germ cell of the embryonic gonad as a common origin

Incidence: 2.6% of all malignant ovarian neoplasms
◊ 60–75% of ovarian cancers seen in 1st–2nd decade

Age-adjusted incidence: 0.34–0.41÷100,000 women-years

Types and Incidence of each OMGCT:
1. Dysgerminoma 37%
2. Immature teratoma 36%
3. Yolk sac tumor 15%
4. Choriocarcinoma 3%
5. Malignant mixed germ cell tumor < 1%
6. Embryonal carcinoma < 1%
7. Malignant degeneration of mature cystic teratoma 3%

Mean age: highest incidence at age 14 (range, 15–19) years
- abdominal distension / pain (in 87%) of 2–4 weeks duration
- pelvic pain ← torsion / hemorrhage / tumor rupture
- vaginal bleeding, fever, large mass at presentation (in 85%)
- elevated a-fetoprotein ← component of yolk sac tumor: 60% in immature teratoma; 100% in endodermal sinus tumor:
- elevated β-hCG ← component of choriocarcinoma: 30% of endodermal sinus tumors

⇑ α-fetoprotein / β-hCG are virtually diagnostic of OMGCTs

Spread: most commonly lymphatic
Average size: 15 cm in diameter
√ unilateral, rarely bilateral
√ calcifications (40%)
√ homogeneously solid (3%), predominantly solid (85%), predominantly cystic (12%)

Dysgerminoma (37%)
= malignant germ cell tumor of ovary homologous to testicular seminoma
◊ Second most common ovarian germ cell tumor
◊ Most common ovarian malignant germ cell tumor (OMGCT)
Frequency: 1–2% of all primary ovarian neoplasms; 35% of all ovarian malignant germ cell tumors
Age-adjusted incidence: 0.109÷100,000 women-years
Path: solid well encapsulated lobulated tumor ± coagulative necrosis / hemorrhage
Histo: uniform population of round cells with clear to eosinophilic cytoplasm + central large round / flattened nucleus resembling primordial germ cells in well-defined nests, separated by fibrous strands, infiltrated by T lymphocytes; numerous mitoses
Peak age: 2nd–3rd decade (range, 7 months – 70 years)
- pain, bloating, menstrual disorder
- often nonspecific elevation of serum lactic dehydrogenase + alkaline phosphatase
- typically NO elevation of a-fetoprotein / b-hCG

Cave: elevation of a-fetoprotein / b-hCG in 5% ← presence of multinucleated syncytiotrophoblastic giant cells

Location: usually unilateral; bilateral in 7–10%
Mean diameter: 15 cm
√ multilobulated well-defined solid mass divided by fibrovascular enhancing septa
√ ± areas of hemorrhage and necrosis
√ speckled pattern of calcifications (rare)
MR:
√ mass of low signal intensity relative to muscle on T1WI
√ isointense / slightly hyperintense mass on T2WI
√ hypo- / isointense septa on T2WI with contrast enhancement on T1WI
US:
√ heterogeneous hyperechoic solid mass
√ prominent arterial color Doppler flow within septa
Rx: highly radiosensitive

DDx: fibrothecoma (predominantly low SI on T2WI), Brenner tumor (extensive low SI on T2WI), granulosa cell tumor (associated with uterine enlargement, most common estrogenic ovarian tumor), epithelial ovarian carcinoma, metastasis

Embryonal Carcinoma of Ovary (< 1%)

Laterality: unilateral

Path: predominantly solid mass with cystic spaces containing mucoid material, smooth outer surface, extensive areas of hemorrhage + necrosis

Histo: solid sheets + nests of large primitive cells in pseudo- glandular pattern + occasional papillae; large crowded pleomorphic vesicular nuclei with prominent nucleoli

Average size: 17 cm

Immature Teratoma of Ovary (36%)

= EMBRYONAL TERATOMA = MALIGNANT TERATOMA

= SOLID TERATOMA

Frequency: 1.3% of all ovarian malignancies; 36% (= 2nd most common) of all malignant germ cell tumors

Path: predominantly solid encapsulated mass ± small cysts; frequently with areas of necrosis + hemorrhage; ± fat + hair + sebaceous material

Histo: immature embryonic tissue derived from the 3 germ cell layers; grades 0–3 reflect amount of immature neuroectodermal tissue

May be associated with: gliomatosis peritonei = multiple peritoneal implants of mature glial tissue; dermoid cyst in up to 26%

Peak age: 15–19 years

• ↑ AFP levels (50%); no elevation of serum hCG levels

Laterality: dermoid cyst in contralateral ovary in 10%

Mean tumor size: 12–25 cm in diameter

√ predominantly solid tumor with numerous cysts of varying size + intratumoral fat

√ scattered small calcifications ← invariable association with mature teratoma

US:

√ heterogeneous solid mass + scattered small calcifications

√ areas of increased echogenicity = larger fat components

CT / MR:

√ predominantly solid mass + fatty elements

√ numerous cysts of variable sizes

√ coarse irregular calcifications

MR:

√ wide variety of signal intensities on T2WI

√ ± fatty fluid within cystic compartments

Prognosis: responsible for 30% of deaths from ovarian cancer in women < 20 years

Growing Teratoma Syndrome

= enlarging teratoma of mature elements arising during / after chemotherapy for treatment of a nonseminomatous germ cell tumor in male / female patients with normal serum α-fetoprotein and b-hCG levels

Mechanism: (a) ? chemotherapeutic retroconversion = induction of somatic maturation in malignant cells by chemotherapy
(b) selective destruction of immature elements by chemotherapy, which leaves behind resistant mature elements

Malignant Mixed Germ Cell Tumor (< 1%)

= composed of > 1 germ cell element (mainly dysgerminoma, teratoma, and yolk sac tumor)
√ solid mass + areas of cystic change ← hemorrhage / necrosis / cystic lesion with solid components

Nongestational Choriocarcinoma (3%)

Frequency: with 2.1–3.4% among rarest of all OMGCTs
Histo: plexiform arrangement of syncytiotrophoblast cells with mononucleated (mostly cytotrophoblast) cells around foci of hemorrhage
US:
√ well-defined adnexal mass of mixed echogenicity
√ NO uterine / ectopic pregnancy
CT:
√ enhancing highly vascular solid mass
MR:
√ abnormal large signal voids on T2WI ← vascular structures + small cystic cavities
√ high-signal-intensity foci in solid portions on T1WI ← hemorrhage
√ substantial uptake of contrast material in solid portions ← highly vascularized tumor
DDx: gestational choriocarcinoma (concomitant / proximate gestation, no other germ cell tumor component)

Polyembryoma

= usually component of mixed OMGCT (immature teratoma + yolk sac tumor), extremely rare
Histo: small embryo-like bodies with central "germ disks" composed of embryonal carcinoma epithelia and 2 cavities (dorsal cavity resembling amniotic cavity + ventral cavity resembling yolk sac cavity); embryoid bodies lie in an edematous to myxoid stroma with prominent blood vessels
Mean age: 24.5 (range, 3–44) years
• ± elevation of a-fetoprotein + b-hCG
√ large unilateral mass

Yolk Sac Tumor of Ovary (15%)

= ENDODERMAL SINUS TUMOR OF OVARY
Frequency: 1% of all ovarian malignancies; 15% (= 3rd most common) of all malignant germ cell tumor
Path: large encapsulated mass with admixed solid + cystic components ← up to 2-cm large cysts +hemorrhage + necrosis; capsular tears in 27% ← rapid growth
Histo: resembles endodermal sinuses of primitive yolk sac
(a) papillary pattern (most common): contains glomerular structures with central vessel + peripheral sleeve of embryonic epithelial cells (= Schiller-Duval bodies)

(b) others: solid, reticular, endodermal sinus, alveolar -glandular, polyvesicular vitelline, myxomatous, microcystic, macrocystic papillary, hepatoid
› periodic acid-Schiff reaction
› α-fetoprotein–positive hyaline globules

Age: 2nd–3rd decade; rare in women > 40 years

May be associated with: teratoma, dermoid cyst, chorioca.

- frequently abdominal enlargement + pain ← rapid growth
- elevated serum AFP (common)

Laterality: bilateral in < 5%; contralateral ovary with dermoid cyst in 10%

Mean size: 15 cm in diameter

√ unilateral smoothly contoured enhancing mixed solid + cystic mass

√ "**bright dot**" sign = enhancing foci in wall / solid component of tumor (common) ← dilated vessels

√ cystic areas ← epithelial-lined cysts / cysts of coexisting mature teratoma / hemorrhage / necrosis

√ capsular tears

US:

√ predominantly heterogeneous echogenic solid tumor

√ cystic spaces divided by septa

MR:

√ foci of high signal intensity on T1WI ← hemorrhage

Rx: surgery + combination chemotherapy

Prognosis: poor

OVARIAN VEIN THROMBOSIS

Etiology:

(1) Bacterial seeding from puerperal endometritis with secondary thrombosis (pregnancy + puerperium are hypercoagulable states) = **puerperal ovarian vein thrombophlebitis**
(2) Pelvic inflammatory disease
(3) Gynecologic surgery
(4) Malignant tumors
(5) Chemotherapy

Prevalence: 1÷600–1÷2,000 deliveries

- presents on 2nd / 3rd postpartum day
- lower abdominal / flank pain (> 90%)
- palpable ropelike tender abdominal mass (50%)
- fever + chills if diagnosis delayed

Location: right [left] {both} ovarian veins in 80% [6%] {14%}

CT:

√ tubular structure in location of ovarian vein with low-density center + peripheral enhancement

Cx: IVC thrombosis; pulmonary embolism (25%); septicemia; metastatic abscess formation
Mortality: 5%

Rx: IV antibiotics + heparin; ligation of involved vessel at most proximal point of thrombosis

after failure to improve after 3–5 days

DDx: appendicitis, broad-ligament phlegmon / hematoma, torsion of ovarian cyst, urolithiasis, pyelonephritis, degenerated pedunculated leiomyoma, pelvic cellulitis, pelvic / abdominal abscess

PARAOVARIAN CYST

= vestigial remnant of wolffian duct in mesovarium

Frequency: 10–20% of all adnexal masses

Mean age: 3rd–4th decade

Embryology: wolffian body (= mesonephros) consists of

(a) mesonephric duct (= wolffian duct)
→ degenerates in female into vestigial structures of epithelial-lined cysts (= canals / ducts of Gartner)
Location: at lateral edge of uterus and vagina extending from broad ligament to vestibule of vagina

(b) mesonephric tubules
→ in female degenerate into vestigial structures of
1. Epoöphoron (at lateral part of fallopian tube)
2. Paroöphoron (at medial part of fallopian tube)
Location: between the tube and hilum of the ovary within the 2 peritoneal layers of broad ligament

Size: mean diameter of 8 cm → up to 18 cm

- usually incidental
- symptomatic due to large size (> 5 cm) / torsion

1. **Gartner duct cyst**:
inclusion cyst lateral to vagina + uterine wall
2. **Paroöphoron**: [*oion*, Greek = egg + *pherein*, Greek = bearing]
medial location between tube + hilum of ovary
3. **Epoöphoron**:
lateral location between tube + hilum of ovary
4. **Hydatid** Cyst **of Morgagni** (= appendices vesiculosae = **fimbrial cyst**): most lateral + outer end of Gartner duct within longest fimbria of fallopian tube
√ ≥ 1 vesicle(s) attached to fringes of tube + filled with clear serous fluid

√ thin-walled unilocular cyst separate from ovary WITHOUT change over time

√ may indent ovary mimicking exophytic ovarian cyst
N.B.: separable by pressure exerted by transvaginal transducer

√ may arise out of pelvis (if pedunculated + mobile)

√ ± low-level internal echoes ← hemorrhage

√ occasionally multiple; rarely bilateral

Cx: torsion (2–16%), hemorrhage, rupture, infection, neoplastic transformation (3%)

DDx: ovarian cyst (functional, cystic teratoma, benign epithelial neoplasm), peritoneal inclusion cyst, hydrosalpinx

PARAOVARIAN CYSTADENOMA

May be associated with: Von Hippel-Lindau disease
Location: typically unilateral
√ simple cyst
√ one / more small nodules along a smooth inner wall (86%)
√ ± septations
Cx: malignant degeneration in 2–3%
DDx: (1) Hydrosalpinx (tubular shape, folds / short echogenic lines protruding into lumen)
(2) Peritoneal inclusion cyst (surrounding much of the ovary, history of surgery / PID)
(3) Cystic neoplasm of fallopian tube (more solid components)
(4) Paraovarian cyst with blood clot (resolution of clot on follow-up sonogram)
(5) Exophytic complex ovarian mass

PELVIC CONGESTION SYNDROME

= chronic (> 6 months) noncyclical pelvic pain associated with pelvic venous distension + valvular ovarian vein insufficiency
Prevalence: ovarian varices in 10% in general population
◊ Closely related to frequency of ovarian varices; 60% may develop pelvic congestion syndrome
Pathophysiology:
venous obstruction ← retroaortic left renal vein, compression of left renal vein by SMA = nutcracker phenomenon; right common iliac vein compression; valvular incompetence; portal hypertension; acquired vena cava syndrome
Risk factors: hereditary factors, hormonal influence, pelvic surgery, retroverted uterus, history of varicose veins, multiple pregnancies
• uni- / bilateral chronic dull deep pelvic ache, pressure, heaviness often associated with movement / posture / activities that increase abdominal pressure
• dyspareunia (71%), dysmenorrhea (66%), postcoital ache (65%)
• rectal discomfort, urinary frequency
• varicose veins in vulva, buttocks, legs
• ovarian point tenderness (94% sensitive, 77% specific)
US:
√ multiple tortuous pelvic veins > 4–6 mm in diameter around uterus + ovaries
√ slow (≤ 3 cm/s) / reversed (caudal) flow
√ dilated arcuate vein in myometrium
√ polycystic changes of ovaries
CT / MR:
√ dilated tortuous enhancing tubular structures
Location: around uterus, ovary, broad ligament, pelvic sidewall, paravaginal plexus
Angio (standard nearly replaced by US, CT, MRI):
Technique: selective catheterization of ovarian veins, transuterine injection of contrast material, direct injection into vulval varices
√ ovarian vein diameter > 10 mm
√ retrograde flow in ovarian / pelvic veins
√ tortuous collateral pelvic venous pathways

√ delayed / stagnant clearance of injected contrast from veins

Rx: hormone analogues (medroxyprogestrone, GnRH analog goserelin) + analgesics; laparoscopic transperitoneal ligation of ovarian veins; hysterectomy ± salpingo-oophorectomy; percutaneous coil embolization of the gonadal vein (70–85% successful)

DDx: asymptomatic pelvic varicosities

Ovarian Vein Syndrome

= obstructive uropathy ← ureteral compression at pelvic brim by dilated / aberrant / thrombosed ovarian vein

Anatomy: ovarian vein crosses ureter obliquely in retroperitoneum at L3

Site: R÷L = 95÷5

Time of onset: during (2nd–3rd trimester) / after pregnancy

IVP:

√ oblique extrinsic impression on ureter:

√ proximal hydroureteronephrosis + normal pelvic ureter

√ medial deviation of obstructed segment (with retrocaval ureter) = characteristic reverse J configuration

CT / coronal MR urography:

√ concurrent evaluation of cause of compression, implicated vessel + proximal dilatation

Cx: spontaneous rupture with life-threatening hemorrhage (rare)

PELVIC INFLAMMATORY DISEASE (PID)

= acute clinical syndrome usually associated with ascending spread of microorganisms ("canalicular spread") from vagina / cervix to uterus, fallopian tubes, and adjacent pelvic structures; not related to surgery / pregnancy

Frequency: 24% of visits to emergency department for gynecologic pain; 10% of women in reproductive age (17% in Blacks); 106,000 outpatient visits and 60,000 hospitalizations annually in USA (2015)

Risk factors: early age at sexual debut, multiple sexual partners, high coital frequency, history of sexually transmitted disease, douching

Predisposed: formerly married > married > never married; intrauterine contraceptive device (1.5–4-fold increase in risk)

Etiology: (a) bilateral: venereal disease, IUD, S/P abortion

(b) unilateral (= nongynecologic): rupture of appendix, diverticulum, S/P pelvic surgery

Organism:

(1) Chlamydia trachomatis + Neisseria gonorrhoeae (> 50% with high prevalence of coinfection) → damage protective barrier of endocervical canal → spread to tubes (30–50%) producing fibrosis + adhesions

(2) Aerobes: Streptococcus, Escherichia coli, H. influenzae

(3) Anaerobes: Bacteroides, Peptostreptococcus, Peptococcus

(4) Mycobacterium tuberculosis (hematogenous)

(5) Actinomycosis in IUD users

= chronic suppurative infection characterized by multiple abscesses, abundant granulation

tissue, fibrosis

(6) Herpesvirus hominis type 2, Mycoplasma

◊ Polymicrobial infection in 30–40%

May be associated with: Fitz-Hugh-Curtis syndrome (*see below*)

- usually bilateral dull aching lower abdominal pain 7–10 days after menstruation ← peritoneal irritation
- adnexal + cervical motion tenderness:
  - "chandelier" sign = patient reaching for the chandelier ← intense pain during pelvic examination
- purulent vaginal discharge / uterine bleeding
- dysuria, dyspareunia, nausea, vomiting
- fever, leukocytosis, ↑ ESR; ↑ serum C-reactive protein

US:

√ No findings
√ thickened tubular adnexal structures ± central fluid
√ increased adnexal volume
√ periadnexal inflammatory hyperemia
√ loss of normal tissue planes + ill-defined uterus:
  √ echogenic periovarian fat
√ ± free fluid

CT:

√ nonspecific stranding of parapelvic fat
√ thickening of uterosacral ligaments

MR:

√ ill-defined hyperintense parametrial area on fat-suppressed T2WI + intense enhancement on contrast-enhanced fat-suppressed MR (= extent of inflammation)

Dx: clinically, laparoscopically

◊ Imaging employed only to differentiate between medical + surgical condition and if
(a) symptoms nonspecific
(b) expected response to treatment absent
(c) complication suspected (eg, abscess)
(d) percutaneous treatment a possible option

Cx: (1) Infertility: 8% [20%] {40%} after single [2] {≥ 3} episodes of PID ← tubal occlusion (in 25%)

(2) Tubo-ovarian abscess

(3) Ectopic pregnancy (6 x as frequent)

(4) Chronic pelvic pain ← pelvic adhesions

Sexually Transmitted Diseases (STD)			
Chlamydia	33%	Human papilloma virus (warts)	6.0%
Trichomoniasis	25%	Genital herpes simplex	4.0%
Nonspecific urethritis	10%	Hepatitis B virus	1.2%
Gonorrhea	9%	Syphilis	1.0%
Mucopurulent cervicitis	8%	HIV	0.3%

Cervicitis

= generic term describing cervical inflammation

Cause: (a) noninfectious: trauma, pelvic irradiation, chemical irritation, malignancy
(b) infectious: Trichomonas vaginalis, Candida albicans, herpes simplex virus (esp. type 2), Neisseria gonorrhoeae, Chlamydia trachomatis

- purulent / mucopurulent cervical + vaginal discharge
- pelvic pressure / discomfort

US:
√ diffusely heterogeneous echotexture of cervical mucosa and stroma
√ nonspecific markedly increased vascularity without mass

Endometritis

√ endometrial prominence
√ small amount of fluid within uterine lumen
√ gas reflection within uterine cavity (most specific)
√ pain over uterus

Postpartum Endometritis

Frequency: 2–3% of vaginal deliveries; in up to 85% of cesarean sections
Associated with: prolonged labor, premature rupture of membranes, retained clots, retained products of conception

- fever (most common cause of postpartum fever)

√ normal ultrasound
√ thickened heterogeneous endometrium
√ intracavitary fluid
√ intrauterine air

Fitz-Hugh–Curtis Syndrome

= GONORRHEAL PERIHEPATITIS

[Thomas Fitz-Hugh, Jr (1894–1963), American physician; Arthur Hale Curtis (1881–1955) American gynecologist]

= inflammation of peritoneal capsule of liver ← peritoneal spread of infection via right paracolic gutter

Frequency: up to 15% in women with PID

- right upper quadrant pain ← ascending pelvic infection

Path: inflammation of liver capsule / diaphragm

Organism: chlamydia÷gonorrhea = 5÷1
US:
√ perihepatic and pericholecystic ascites ± loculations
Location: anterior to liver (original description), hepatorenal fossa (= Morison space), gallbladder (mimicking acute cholecystitis)
√ ± peritoneal septations (= "violin string" adhesions extending from anterior surface of liver to peritoneum)
CT:
√ thickening + intense enhancement of anterior liver capsule and gallbladder wall ± loculations
√ periportal edema
√ ± transient subcapsular + periportal hepatic perfusion abnormalities

Salpingitis

• often beginning during / immediately after menstruation ← mucus barrier of cervix less effective
MR:
√ thickened wall of dilated fallopian tube + tubal contents of low signal intensity on T2WI
√ debris / hemorrhage in fluid component most conspicuously hypointense to urine on heavily T2WI
Cx: tubo-ovaritis = salpingo-oophoritis = tubal fimbriae adhere to ovary

Salpingitis Isthmica Nodosa
Etiology: unknown; commonly associated with pelvic inflammatory disease, infertility, ectopic pregnancy
Location: uni- / bilateral
• nodular thickening of isthmic portion of tube
√ irregularity + multiple 2–3 mm diverticula / obstruction of isthmic portion of fallopian tube on HSG

Fallopian Tube Cyst

Cause: pelvic inflammatory disease, endometriosis, adhesions, microtubal surgery, total abdominal hysterectomy without salpingo-oophorectomy, ectopic pregnancy, tumor (rare)
Prevalence: in 8% of women with PID / endometriosis
Location: between uterus + adnexa; often bilateral
Site of obstruction: ampullary / infundibular portion of tube
√ undulating / folded tubular structure in extraovarian location filled with sterile fluid / debris / pus
√ "**kissing ovary**" sign = adhesions pull ovaries and tubes toward the midline
√ serpentine C- or S-shaped complex cystic solid adnexal mass ← encasement of ovary by fallopian tube
◊ Find ipsilateral ovary!
Cx: tubal torsion
DDx: dilated uterine / ovarian vein, TOA, cystic ovarian neoplasm, endometrioma,

developing follicle, fluid-filled small bowel (peristalsis)

Hydrosalpinx = Chronic PID

= accumulation of continued secretion of tubal epithelium (sterile fluid) into lumen of a fallopian tube obstructed at two sites

◊ A simple hydrosalpinx is not accompanied by pelvic inflammation!

Cause:

1. Adhesions from prior episodes of PID
2. Tubal ligation
3. Hysterectomy without salpingo-oophorectomy
4. Endometriosis
5. Tubal malignancy

• asymptomatic / recurrent lower abdominal pain, infertility

US (sensitivity of 34%):

√ thin- / thick-walled C- / S-shaped tubular / corkscrew-like structure separate from ovaries

√ "waist" sign = indentations of its opposing walls

√ incomplete septation ← infolding of tube on itself

√ PATHOGNOMONIC longitudinal folds:

√ "**cogwheel**" sign = short linear / small round projections of mucosal folds protruding into lumen of fluid-filled tube similar to spokes of a cogwheel on short-axis images

√ "beads-on-a-string" sign = flat nodular submucosal folds in chronic dilatation

MR:

√ T2-hyperintense + T1-hypointense dilated fallopian tube interposed between ovary and uterus

√ high-SI of fluid on T1WI ← proteinaceous fluid (DDx: hemorrhage)

√ incomplete longitudinal folds = partially effaced mucosal / submucosal plicae (SPECIFIC)

HSG:

√ absence of peritoneal spill

√ dilated ampullary portion of tube (visualization of mucosal folds confirm intratubal contrast accumulation) (DDx: contrast collection adjacent to tubes ← peritubal adhesions)

N.B.: prescribe postprocedural antibiotic prophylaxis (eg, doxycycline) to prevent procedure-related infection!

DDx: tortuous pelvic veins (blood flow at Doppler imaging), dilated fluid-filled bowel (lack of peristalsis), cystic ovarian neoplasm

Pyosalpinx

= infection + superimposed obstruction of fallopian tube

• acute pelvic pain, fever, leukocytosis

• cervical motion tenderness

Path: fallopian tube filled with pus

Location: more likely bilateral than hydrosalpinx

√ enhancing thickened wall and septa of fallopian tube
√ thickened uterosacral ligaments
√ edema of presacral fat
√ small-bowel ileus
MR:
√ T2-hyperintense cystic tubule
√ T1-variointense depending on protein content of fluid
√ pelvic fat stranding
Prognosis: pus undergoing proteolysis transforming a pyosalpinx into a hydrosalpinx

Hematosalpinx
= fallopian tube filled with blood
Cause: pelvic endometriosis, tubal ectopic pregnancy, pelvic inflammatory disease, adnexal torsion, malignancy, trauma
◊ A hematosalpinx is an invitation to search for endometrial deposits + endometriomas!
√ tubular / corkscrew-shaped structure centered in fallopian tube
√ "waist" sign = tubular cystic structure with a folded configuration
√ tubal contents of homogeneous low-level echoes on US
√ tubal contents of high attenuation on CT
√ tubal contents of low signal on T2WI with small round projections in a tubular shape (MOST SPECIFIC)
√ tubal contents of high signal on T1WI fat-suppressed image

Tubo-ovarian abscess (TOA)
= inflammatory mass encompassing ovary + fallopian tube
Cause: sexually transmitted disease, IUD (20%), diverticulitis, appendicitis, pelvic surgery, gynecologic malignancy
Organism: anaerobic bacteria become dominant, Actinomyces israelii associated with IUD
Location: usually in posterior cul-de-sac extending bilaterally
√ multilocular complex mass often with debris, septations, irregular thick wall:
√ ± fluid-debris level
√ intense contrast enhancement of abscess wall
√ nonspecific free pelvic fluid
√ anterior displacement of broad ligament ← posterior position of mesovarium (DDx from other pelvic abscess)
US:
√ surrounding edema / inflammation = increased echogenicity of pelvic fat
CT:
√ pelvic fat stranding
√ thickening + enhancement of peritoneum and uterine ligg.
√ gas is SPECIFIC but rare
MR:
√ T1WI:
√ abscess usually hypointense ± mildly hyperintense areas ← hemorrhagic /

proteinaceous material
√ hyperintense rim along inner abscess wall ← granulation tissue and hemorrhage
√ T2WI:
√ heterogeneous hyperintense mass with septa of low SI
√ meshlike hypointense linear stranding in adjacent pelvic fat ← adhesions + fibrosis
√ hyperintense edema of parametrial fat
CEMR:
√ enhancement of septa + thick abscess wall
√ enhancement of surrounding inflammatory stranding
Cx: (1) rupture → life-threatening peritonitis → intraperitoneal abscess
(2) secondary involvement of adjacent structures (eg, ileus, hydroureteronephrosis)
DDx: endometrioma, ovarian tumor, infected cyst, abscess from other sources (eg, Crohn disease, appendicitis)

PENA-SHOKEIR PHENOTYPE

= autosomal recessive syndrome (45% sporadic, 55% familial) characterized by fetal akinesia
Cause: decreased / absent fetal motion ← abnormalities of fetal muscle / nerves / connective tissue ("fetal akinesia deformation sequence")
Time of first detection: 16–18 weeks MA
@ Spine: scoliosis, kyphosis, lordosis
@ Thorax: pulmonary hypoplasia, cardiac anomalies
@ Kidney: renal dysplasia
@ Limbs: limited movement, knee + hip ankylosis (arthrogryposis), abnormal shape + position, demineralization, camptodactyly, clubfeet
√ craniofacial anomalies
√ polyhydramnios
√ IUGR
√ short umbilical cord
Prognosis: still birth
DDx: multiple pterygium syndrome, Neu-Laxova syndrome, restrictive dermopathy, Larsen syndrome, trisomies 13 + 18

PENTALOGY OF CANTRELL

= sporadic very rare abnormality
Prevalence: 5.5÷1,000,000 live births; M÷F = 2.7÷1
Cause: failure of fusion of lateral thoracic folds + transverse diaphragmatic septum with variable extension inferiorly during days 14–18 of embryonic life
1. Omphalocele (63%) = defect of supraumbilical abdominal wall and sternum
2. Ectopia cordis
3. Deficiency of anterior diaphragm → herniation of intraabdominal organs into thoracic cavity is rare
4. Deficiency of diaphragmatic pericardium
5. Congenital cardiovascular malformation: atrioventricular septal defect (50%), VSD (18%), tetralogy of Fallot (11%), left ventricular diverticulum, Ebstein malformation

Associated with:
(a) chromosomal anomalies: trisomies 13, 18, Turner syndrome
(b) facial defects: cleft lip or palate
(c) CNS anomalies: exencephaly, encephalocele, spina bifida, hydrocephalus
(d) musculoskeletal anomalies: clubfoot, absent radius

√ exteriorization of heart

Prognosis: death within a few days after birth

PERLMAN SYNDROME

= rare fetal overgrowth disorder characterized by visceromegaly, renal lesions, distinctive facial features, high neonatal mortality

Cause: ? autosomal recessive with reported abnormalities of chromosome 11

• generalized muscle hypotonia, pancreatic islet cell hyperplasia
• hypertrophy of islets of Langerhans

√ cystic hygroma
√ fetal macrosomia
√ macrocephaly
√ agenesis of corpus callosum
√ choroid plexus cyst
√ nephromegaly + hydronephrosis
√ hepatomegaly
√ cryptorchidism
√ polyhydramnios

Prognosis: death within first few days of life

PLACENTAL ABRUPTION

= PLACENTAL HEMORRHAGE
= premature separation of placenta from myometrium ← maternal hemorrhage into decidua basalis after 20th week EGA

Frequency: 0.5–1.3% of gestations

Risk factors: *mnemonic:* VASCULAR
Vascular disease + hypertension
Abruption (previous history)
Smoking
Cocaine
Unknown: idiopathic
Leiomyoma
Anomaly: fetal malformation
Reckless driving: trauma

Associated with: intraplacental infarction / hematoma

• vaginal bleeding (80%): bright red (acute), brownish red (chronic); abdominal pain (50%)
• consumptive coagulopathy = DIC (30%); uterine rigidity (15%)

US:
◊ A normal ultrasound (50%) does NOT rule out abruption if

(a) separation occurs WITHOUT hematoma
(b) hematoma is isoechoic to placenta

Echogenicity of hemorrhage:

√ hyperechoic / isoechoic hematoma (initially difficult to distinguish from placenta):
√ abnormally thick + heterogeneous placenta (if blood isoechoic)
√ hypoechoic / complex collection between uterine wall + placenta in 50% within 1 week ← hematoma / placental infarction
√ anechoic collection within 2 weeks

NECT:

◊ NECT & CECT are 43–100% sensitive & 80–98% specific.
√ lenticular high-attenuating collection = retroplacental hematoma
√ high-attenuation blood products in dependent portions of the amniotic sac

CECT:

√ nonenhancing placenta
√ contiguous retroplacental area of decreased enhancement forming acute angles with myometrium = retroplacental hematoma
√ areas of contrast extravasation in infarcted placenta (occasionally)

Falsely positives:

(1) Myometrial contraction = bulging areas hypoattenuating relative to placenta forming obtuse angles with adjacentx myometrium
(2) Venous lake = pooled maternal blood on maternal side of the placenta
(3) Chorionic villous plate indentations
(4) Small wedge-shaped placental infarcts of no clinical significance
(5) Small subchorionic hemorrhages + preplacental hemorrhages of no clinical significance

MR (modality of choice):

√ increased intrauterine T1 signal at site of bleeding

Prognosis:

(1) Only large hematomas (occupying > 30–40% of the maternal surface) result in fetal hypoxia
(2) Abruptions with contained hematoma have worse prognosis
(3) Responsible for up to 15–25% of all perinatal deaths
(4) Normal term deliveries in 27% with hematomas that were detected > 20 weeks GA
(5) Normal delivery in 80% of intrauterine hematomas detected < 20 weeks GA

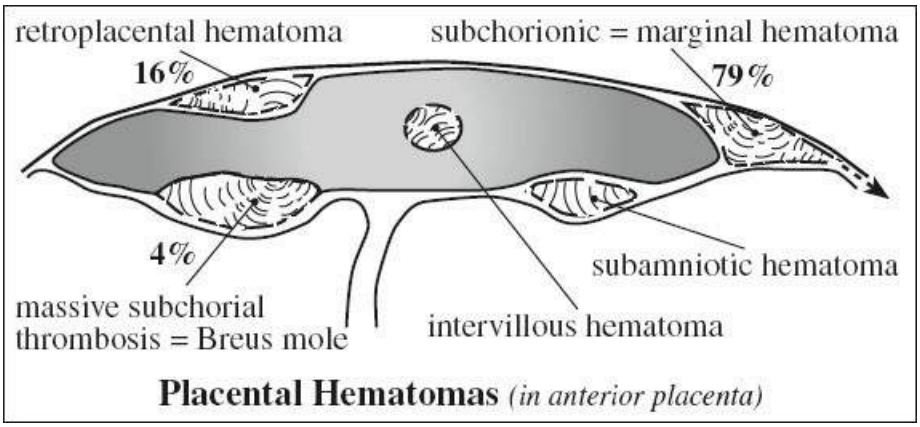
Cx:
(1) Perinatal mortality (20–60%)
(2) Fetal distress / demise (15–27% of all perinatal deaths)
(3) Premature labor + premature delivery (23–52%) (3-fold increase)
(4) Threatened abortion during first 20 weeks
(5) Infant small-for-gestational age (6–7%)

DDx:
(1) Normal draining basal veins
(2) Normal uterine tissue
(3) Retroplacental myoma
(4) Focal contraction

(5) Chorioangioma
(6) Coexistent mole

Retroplacental Hemorrhage (16%)

= ABRUPTIO PLACENTAE
= accumulation of blood beneath placenta separating placenta from myometrium
Pathophysiology: hypertension + vascular disease → rupture of spiral arteries → high-pressure bleed (hemorrhage may dissect into placenta / myometrium)
Frequency: 4.5%; 16% of all placental abruptions
• external bleeding
√ thickened heterogeneous appearing placenta (hematoma of similar echogenicity as placenta)
√ becomes anechoic in 1–2 weeks
√ rounded placental margins + intraplacental sonolucencies
Prognosis: clinically significant if 30–40% of maternal surface of placenta involved
Cx: (1) Precipitous delivery
(2) Coagulopathy
(3) Fetal demise (15–25% of all perinatal deaths)
Risk for fetal demise with hematomas > 60 mL: 6% before [29% after] 20 weeks GA



Placental Hematomas *(in anterior placenta)*

Signal Intensities of Intrauterine Hematoma				
Stage	*T1WI*	*T2WI*	*DWI*	*Hemoglobin (Hb)*
Hyperacute	↔ to ↓	↑	↑ to ↓	intracell oxyHb
Acute	↔ to ↓	↓	↓	intracell deoxyHb
Early subacute	↑	↓	↓	intracell metHb
Late subacute	↑	↑	↑	extracell metHb
Chronic	↓	↓	↔ to ↓	intracell hemosiderin

DDx: myometrial contraction, fibroid, subplacental venous network

Subchorionic Hemorrhage (79%)

= MARGINAL PLACENTAL HEMORRHAGE

= SUBMEMBRANOUS PLACENTAL HEMORRHAGE
= separation of chorionic membrane from decidua with accumulation of blood in subchorionic space
N.B.: placental membranes are more easily stripped from myometrium than from placenta
Pathophysiology: low-pressure bleed ← tears of marginal veins; associated with cigarette smoking
Frequency: 79% of all placental abruptions; in 91% before 20 weeks MA
• may lead to vaginal hemorrhage after dissection through decidua (= 18% of all causes of 1st-trimester bleeding)
√ placental margin detached from adjacent myometrium (60%):
√ separation / rounding of placental margin
√ elevation of chorioamnionic membrane
(DDx: incomplete chorioamnionic fusion during 2nd trimester, blighted twin)
√ hematoma contiguous with placental margin (100%) = **marginal hematoma**
√ predominant hemorrhage often separate from placenta, even on opposite side of placenta
Prognosis: worsens with (1) increased maternal age, (2) earlier gestational age, (3) size of hematoma (> 60 mL); 9% overall miscarriage rate; risk of fetal demise doubles once hematoma reaches ²/₃ of circumference of chorion

Preplacental Hemorrhage

= BREUS MOLE = SUBCHORIAL HEMORRHAGE = MASSIVE SUBCHORIAL THROMBOSIS
= variant of placental abruption with progressive slow intracotyledonary bleeding
Frequency: in 4% of all placental abruptions
Etiology: massive pooling + stasis ← extensive venous obstruction
Time of onset: 18 weeks MA
√ total loss of normal placental architecture
√ gelatinous character of placenta elicited by fetal movement / abdominal jostling
√ hematoma bulging into amniotic fluid
√ severe symmetric IUGR
Risk for fetal demise: 67% overall; 100% for hematomas > 60 mL
DDx: subamniotic hematoma

Intraplacental Hemorrhage

= massive retroplacental hematoma dissecting into placenta; related to placental infarcts
√ focal mass of varying echogenicity within placenta

Intraamniotic hematoma

√ internal echoes in amniotic fluid

PLACENTA ACCRETA

= defect in normal decidua basalis from prior trauma allows abnormal adherence + penetration of chorionic villi to / into myometrium
Prevalence: 1÷2,500–7,000 deliveries related to increase in uterine surgery; in 5% of placenta previa patients
Risk of placenta accreta versus cesarean section:

in 10% of placenta previa; in 24% of placenta previa + 1 cesarean section; in 48% of placenta previa + 2 cesarean sections; in 67% of placenta previa + 4 cesarean sections

Predisposed: areas of uterine scarring with deficient decidua: previous dilatation + curettage, endometritis, submucosal leiomyoma, Asherman syndrome, manual removal of placenta, adenomyosis, increasing parity

Associated with: placenta previa (in 20%)

Types:

1. Placenta accreta (76%)
   = chorionic villi in direct contact with myometrium
2. Placenta increta (18%)
   = villi invade myometrium
3. Placenta percreta (6%)
   = villi penetrate through uterine serosa

US (77–93% sensitive, 71–96% specific):

√ loss of normal retroplacental clear space

√ thinning to < 1 mm / absence of hypoechoic myometrial zone between placenta + echodense uterine serosa / posterior bladder wall (normally, retroplacental hypoechoic zone of decidua + myometrium + dilated periuterine venous channels measures 9.5 mm thick > 18 weeks GA)

√ thinning / irregularity / focal disruption of linear hyperechoic boundary echo (= uterine serosa-bladder wall interface)

√ focal masslike elevations / extensions of echogenic placental tissue beyond uterine serosa

√ > 6 irregular intraplacental lacunae (= poorly marginated irregular vascular spaces with turbulent flow) → highest positive predictive value

MR (80–88% sensitive, 65–100% specific):

√ heterogeneous hyperintense placenta on T2WI

√ dark intraplacental bands (= lacunae) on T2WI

√ interruption of junctional zone

√ focal thinning of hypointense myometrium

√ abnormal uterine bulging

Cx: (1) Life-threatening hemorrhage in 3rd stage of labor necessitating emergent hysterectomy

(2) Maternal death

(3) Retention of placental tissue

(4) Persistent postpartum bleeding

Rx: (1) Hysterectomy

(2) Conservative measures: curettage, oversewing of placental bed, ligation of uterine arteries

PLACENTA PREVIA

= abnormally low implantation of ovum with the placenta covering all / part of internal cervical os > 15 weeks GA

Frequency: 0.5% of all deliveries; 3–5% of all pregnancies complicated by 3rd trimester bleeding (of these 7–11% are due to placenta previa); in 0.26% with unscarred

uterus

Risk for placenta previa versus cesarean section:

0.65% after 1 section, 1.8% after 2 sections, 3% after 3 sections, 10% after 4 sections

Cause: defective decidual vascularization in areas of endometrial scarring → compensatory placental thinning → placenta occupies a greater surface of the uterus with increased probability for encroachment upon internal os

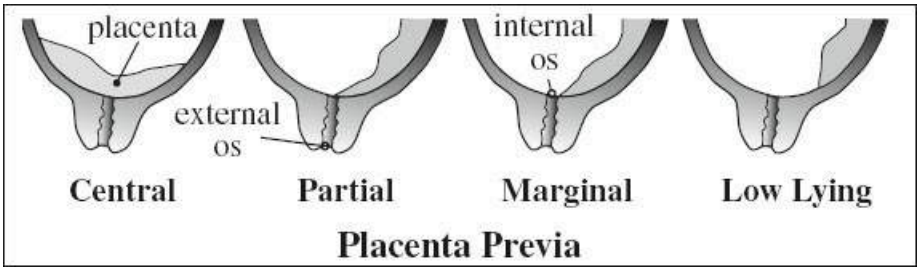
Predisposed:

(1) Previous uterine incision: cesarean section, myomectomy
(2) Older woman
(3) Multiparous woman

• painless vaginal bleeding in 93%: usually 3rd trimester / as early as 20 weeks

Types on clinical examination:

1. Normal placental implantation = lower placental edge > 2 cm away from margin of internal os
2. Complete / total previa (⅓) = complete covering of internal os
3. Central previa = placenta implanted directly over internal os
4. Partial previa = internal os partially but not fully covered by placenta
5. Marginal previa = placenta extends to edge of internal os
6. Low-lying placenta = low placental edge within 2 cm of internal os without covering it; palpable by examining finger



US - False Positives (5–7%):

1. **Placental "migration"** / rotation
   = differential growth rates between lower uterine segment + placenta
   ◊ 63–93% will have normal implantation at term!
   › conversion to normal position: anterior wall > posterior wall of uterus
   › NO conversion if placenta attaches to both posterior + anterior walls
2. Overfilled urinary bladder
   bladder-induced compression leads to apposition of the lower anterior + posterior uterine walls simulating a placenta previa → cervical length > 3.5–4 cm
3. Focal myometrial contraction in the region of the lower uterine segment → myometrial thickness > 1.5 cm

mnemonic: ABCD and F

Abruption (may mimic placenta previa)
Bladder (must be empty)
Contraction (may have to wait 15–20 min)
Dates (be wary in 1st half of pregnancy)

Fibroid

US - False Negatives (2%):

1. Obscuring fetal head
   → remedied by Trendelenburg position / gentle upward traction on fetal head
2. Lateral position of placenta previa
   → remedied by obtaining oblique scans
3. Blood in region of internal os: mistaken for amniotic fluid

MR:

√ abnormal position of placenta infringing on cervical os

Cx: secondary to premature detachment of placenta from lower uterine segment

(1) Maternal hemorrhage (blood from intervillous space)
(2) Premature delivery
(3) IUGR
(4) Perinatal death (5%)

Rx: precludes vaginal delivery + pelvic examination

PLACENTAL SITE TROPHOBLASTIC DISEASE

= very rare neoplasm (? type of choriocarcinoma)

Path: microscopic tumor / diffuse nodular replacement of myometrium

Histo: proliferation of predominantly intermediate trophoblasts but no syncytio- or cytotrophoblasts

- abnormal bleeding / amenorrhea
- low β-hCG levels ← lack of syncytiotrophoblastic proliferation

√ cystic / solid lesions ± central component

√ myometrium usually invaded

Prognosis: benign / highly malignant course

Rx: hysterectomy

POSTMATURITY SYNDROME

= inability of aging placenta to support demands of fetus

Prevalence: in 15% of all postterm gravidas

• meconium-stained amniotic fluid

√ grade 3 placenta (in 85%), grade 2 (in 15%), grade 1 (in 0%)

√ decreased subcutaneous fat + wrinkling of skin

√ long fingernails

√ decreased vernix

Cx: meconium aspiration, perinatal asphyxia, thermal instability

Postterm Fetus

= fetus undelivered by 42nd week MA

Prevalence: 7–12% of all pregnancies

Risk of perinatal mortality: 2-fold at 43 weeks MA; 4–6-fold at 44 weeks MA

PREECLAMPSIA

= TOXEMIA OF PREGNANCY = EPH GESTOSIS

Prevalence: 5% of pregnancies, typically during 3rd trimester

• Clinical triad: [EPH = **E**dema, **P**roteinuria, **H**ypertension]

(1) Peripheral edema + weight gain

(2) Proteinuria

(3) Pregnancy-induced / -aggravated hypertension

Histo: blunted invasion of vasa media of spiral arterioles + focal vasculitis + atheromatous degeneration + fibrin deposits in intima of maternal placental arterioles

√ heavy calcium deposition (in areas of placental degeneration)

√ IUGR (6% with late-onset preeclampsia, 18% with early-onset preeclampsia)

Cx:

@ CNS: convulsive eclampsia, stroke

@ Liver: hematoma, infarction

@ Kidney: glomerular endotheliosis = variant of thrombotic microangiopathy → decreased GFR

Eclampsia

• convulsions + coma

PREMATURE RUPTURE OF MEMBRANES

= spontaneous rupture of chorioamnionic membranes before the onset of labor

Types:

(a) Preterm premature rupture of membranes (PPROM) < 37 weeks GA

(b) Term premature rupture of membranes (TPROM) > 37 weeks GA

Prevalence: overall 2.1–17.1%; PPROM 0.9–4.4%;
in 29% of all preterm deliveries;
in 18% of all term deliveries

Risk of recurrence: 21% of women with PPROM
Cause: ? infection of membranes
√ decrease in the amount of amniotic fluid
CT:
√ products of conception low-lying / in cervix
√ blood in cervix / vagina ←signs of impending / ongoing spontaneous abortion
Cx:
(a) TPROM:
> 24 hours may result in intrapartum fever
> 72 hours may result in chorioamnionitis + still-birth
(b) PPROM: respiratory distress syndrome (9–43%), neonatal sepsis (2–19%)

SCLEROSING STROMAL TUMOR OF OVARY

= benign sex cord-stromal tumor
Age: < 30 years
• irregular menses
Histo: pseudolobular pattern = cellular areas separated by edema + collagenous hypocellular tissue
√ hypointense nodules set against hyperintense stroma on T2WI
√ peripheral enhancement with centripetal progression

SECKEL SYNDROME

= BIRD-HEADED DWARFISM
= rare autosomal recessive disorder (44 cases)
• proportionate postnatal short stature
• characteristic stance: slight flexion of hips and knees
• mental retardation, simian crease, cryptorchidism
@ Skull
√ severe microcephaly
√ receding forehead, large beaked nose, micrognathia
@ Skeleton
√ dislocation of radial head + hypoplasia of proximal end of radius
√ absence of phalangeal epiphysis
√ clinodactyly of 5th digit
√ gap between 1st and 2nd toe
√ hip dislocation
√ hypoplasia of proximal fibula
√ absence of patella
√ 11 pairs of ribs
OB-US:
√ severe IUGR
√ oligohydramnios
√ decreased bone length: femur, tibia, fibula
√ decreased AC, HC

SEROUS OVARIAN TUMOR

◊ Most common neoplasm in benign + malignant category

Frequency: 30% of all ovarian tumors 60–80% of all malignant ovarian neoplasms

Path: areas of solid tissue components + hemorrhage and necrosis (more common in malignant tumors)

Histo: lined by tall columnar epithelial cells (as in fallopian tubes), filled with serous fluid, psammoma bodies (= microscopic calcifications in up to 30% of malignant tumors)

Age: 20–50 years (malignant variety later)

Serous Cystadenoma (60%)

◊ Second most common benign tumor of the ovary (after dermoid cyst); 20% of all benign ovarian neoplasms

√ usually unilocular (occasionally multilocular) thin-walled cyst up to 20 cm in diameter

√ only small amount of solid tissue: occasional septum / mural nodule (papillary projections in 9%)

√ bilateral in 7–20–30%

Cystadenofibroma

= variant of serous cystadenoma, rarely malignant

Prevalence: nearly 50% of all benign ovarian cystic serous tumors; bilateral in 6%

Mean age: 31 (range, 15–65) years

• may produce estrogen excess

√ small multilocular cystic tumor

√ clusters of short rounded papillary processes

MR:

√ multiloculated cystic mass

√ solid fibrous component:

√ low SI on T2WI

√ mild enhancement on T1WI

Borderline Malignant Serous Cystadenoma (15%)

Histo: identical to peritoneal serous micropapillomatosis

√ papillary projections within cyst (in 67%)

Serous Cystadenocarcinoma (25%)

= SEROUS PAPILLARY CARCINOMA OF OVARY

Prevalence: 60–80% of all ovarian carcinomas

Origin: peritoneal mesothelial cells with müllerian differentiation / nests of ovarian tissue remnants within peritoneum

Age: postmenopausal woman

Histo: identical to primary peritoneal serous papillary ca.

√ multilocular cyst with large amount of solid tissue: papillomatous excrescences within cyst (= papillary serous carcinoma) in 38%

√ may have calcifications

√ bilateral in 50–70%

√ loss of capsular definition + tumor fixation
√ ascites ← peritoneal surface implantation
√ lymph node enlargement: periaortic, mediastinal, supra- clavicular
CT:
√ psammomatous calcifications (12%)

SERTOLI-STROMAL CELL TUMOR OF OVARY

= ANDROBLASTOMA = ARRHENOBLASTOMA
Origin: from hilar cells of ovary
Prevalence: < 0.5%
Age: any age; most common in 2nd–3rd decade
Histo: components of Sertoli cells, Leydig cells, fibroblasts; tissues are so varied that it is frequently confused with other tumors
Classification:
(1) Sertoli cell tumor (4%) - usually nonfunctioning
(2) Leydig cell tumor
(3) Sertoli-Leydig cell tumor
• androgenic
√ hypoechoic mass simulating fibroid
√ may have cystic / hemorrhagic degeneration

Sertoli-Leydig Cell Tumor

◊ Most common virilizing tumor of ovary!
Frequency: 0.5% of all ovarian neoplasms
Mean age: 25 (range, 15–66) years; 75% occur in patients < 30 years of age
Path: solid ± cystic areas; hemorrhage is rare
Histo: well differentiated / intermediately differentiated / poorly differentiated / retiform (4 subtypes)
• nonfunctioning (50%); abdominal mass ± pain
• virilization (30%): amenorrhea, male secondary sexual characteristics
◊ Virilizing tumor often small and difficult to detect!
• estrogenic (20%); no hormonal manifestations (50%)
Location: unilateral in 98%
√ small mass often difficult to visualize by US / CT
√ maximally 5–27 cm in diameter
√ solid mass ± cystic components ← hemorrhage and necrosis
√ well-defined hypoechoic mass + (rarely) intratumoral cysts
√ calcifications are unusual
√ contrast enhancement
MR:
√ predominantly low SI (= fibroblasts) + scattered areas of high SI on T2WI
Cx: malignant transformation in 10–18%
Prognosis: good when detected at stage I (in 92%)
Recurrence: soon after initial diagnosis (in 20%)

DDx: granulosa cell tumor (spongelike multicystic with areas of hemorrhage)

SINGLE UMBILICAL ARTERY

= TWO-VESSEL CORD

Etiology:

(1) Primary agenesis of one umbilical artery (usually first appears in 5th menstrual week)
(2) Secondary atrophy / atresia of one umbilical artery
(3) Persistence of original single allantoic artery of body stalk

Prevalence: 0.2–1% of singleton births; 5% in dizygotic twins; 2.5% in abortuses; increased incidence in trisomy D / E, diabetic mothers, White patients, spontaneous abortions

Associated with:

(a) congenital anomalies (21–33%):
1. CHD (most frequent): VSD, conotruncal anomalies
2. GU: hydronephrosis, dysplastic kidney
3. Abdomen: ventral wall defect, diaphragmatic hernia
4. Esophageal atresia, cystic hygroma, cleft lip
5. CNS: hydrocephalus, holoprosencephaly, spina bifida
6. Polydactyly, syndactyly

(b) IUGR & small for gestational age
(c) premature delivery
(d) perinatal mortality (20%): stillbirth (66%)
(e) marginal (18%) / velamentous (9%) cord insertion
(f) chromosomal anomalies (10–67%): trisomy 18 (in 40%) > trisomy 13 > Turner syndrome > triploidy

◊ Detailed anatomic survey & close follow-up evaluation of fetal growth strongly recommended!

Maternal risk factors:

advanced maternal age, white ethnicity, multiparity (3–7 x higher than for singleton pregnancy), smoking, diabetes, hypertension, preeclampsia, maternal drug use, epilepsy

Site: left artery slightly more often absent than right

√ axial view of cord shows 2 vessels
√ single umbilical artery nearly as large as umbilical vein → umbilical vein-to-umbilical artery ratio < 2
√ incurvation of distal aorta toward common iliac artery on the side of patent umbilical artery
√ ipsilateral hypoplastic / absent common iliac artery in fetus
√ color flow imaging permits earlier (15–16 weeks) + more confident diagnosis

Prognosis:

(1) 4-fold increase in perinatal mortality (14%) with concurrent major abnormality
(2) Isolated single umbilical artery does not affect clinical outcome

DDx:

(1) Normal variant = 2 arteries at fetal end may fuse near placental end into single umbilical artery (umbilical arteries normally unite with allantoic artery near placental insertion)
(2) Arterial convergence of 2 into 1 umbilical artery

STEIN-LEVENTHAL SYNDROME

= POLYCYSTIC OVARY SYNDROME

[Irving Freiler Stein (1887–1976), American gynecologist in Chicago]

[Michael Leo Leventhal (1901-1971), American gynecologist in Chicago]

= functional NOT imaging diagnosis

Prevalence: 2.5–8% of women in reproductive age; affects 4–5 million women in USA

Etiology: deficient aromatase activity (= catalyst for conversion of androgen into estrogen) → androgen excess (= hyperandrogenism); exaggerated pulsatile release of LH stimulates continued ovarian androgen secretion at the expense of estradiol; reduction of local estrogen impairs FSH activity → accumulation of small- and medium-sized atretic follicles without final maturation into graafian follicles (= incomplete ovulatory cycles)

Path: pearly white ovaries with multiple cysts below the capsule → lined by a hyperplastic theca interna layer showing pronounced luteinization; granulosa cells are absent / degenerating; corpora lutea are absent

Age: late 2nd decade

Associated with: Cushing syndrome, basophilic pituitary adenoma, postpill amenorrhea, virilizing ovarian / adrenal tumor

- OB/GYN symptoms:
  - ⇓ fertility / sterility
  - recurrent spontaneous abortion
  - secondary amenorrhea (most common cause)
    - ◊ Women with PCOS are frequently ovulatory!
  - menstrual irregularities / oligomenorrhea
- metabolic symptoms:
  - obesity (30–70%) with body mass index ≥ 30 kg/m2
  - periodic abdominal discomfort
  - glucose intolerance (16%) + type 2 diabetes mellitus (10%)
  - dyslipidemia (↑ triglycerides, ↑ LDL (low-density lipoproteins), ↑ VLDL (very-low-density lipoproteins), ↓ HDL (high-density lipoproteins)
- cardiovascular symptoms:
  - hypertension; coronary + carotid atherosclerosis
  - myocardial infarct + cerebrovascular accidents
- cephalic symptoms:
  - cystic acne; cephalic hair loss
  - mild facial / severe generalized hirsutism (70% in USA)
- laboratory findings:
  - ↑ LH levels without LH surge with ↔ / ↓ FSH = ↑ LH/FSH ratio ← preferential production of androgen
    LH: regulates synthesis of androgens from cholesterol in ovarian theca cells
    FSH: regulates aromatase activity of granulosa cells = how much estrogen is synthesized from androgenic precursors
  - elevated androstenedione / testosterone levels
  - elevated estrone / estradiol

√ at least one enlarged ovary > 10 cm^3
  √ normal ovarian size (in 30%), polycystic ovaries have a volume of 6–30 cm^3
√ excessive number of developing follicles:
  √ multiple (> 12) follicles of 2–9 mm in subcapsular location
    ◊ 20–30% of normal young women may have ovaries of a similar appearance!
Cx: endometrial cancer < 40 years of age ← unopposed chronic estrogen stimulation
DDx: ovaries in congenital adrenal hyperplasia, normal ovaries
Rx: (1) Ovulation induction with clomiphene (Clomid®) / menotropins (Pergonal®)
(2) Wedge resection (transient effect only)

STEROID CELL TUMOR

= LIPID / LIPOID CELL TUMOR
= characterized by cells resembling typical steroid hormone-secreting cells (lutein cells, Leydig cells, adrenocortical cells)
Frequency: 0.1–0.2% of all ovarian tumors
Age: wide range of ages; usually 5^{th}–6^{th} decade
Types: (1) **Stromal luteoma** (60% estrogenic, 12% androgenic)
(2) **Leydig / hilus cell tumor** (75% androgenic)
(3) Steroid tumor not otherwise specified
Path: usually < 3 cm yellow nodule with rich vascularity; rarely cystic
Histo: abundant clear cytoplasm + varying amounts of lipid resembling adrenocortical cells
• virilizing (majority): amenorrhea, hirsutism
• Cushing syndrome (rare)
√ unilateral < 3 cm small solid tumor
√ cystic change / necrosis (rare)
CT:
  √ areas of low attenuation (= abundant lipid content)
MR:
  √ NO high-signal intensity on T1WI ← lipid content obscured by fibrous stroma
  √ various signal intensities on T2WI
  √ intense contrast enhancement ← high tumor vascularity
Prognosis: clinically malignant (33%)

STRUMA OVARII

= rare highly specialized form of ovarian teratoma
Terminology: (a) pure form = tumor composed entirely of thyroid tissue
(b) impure form = component of mature cystic teratoma occupying > 50% of its volume
Prevalence: 0.30–0.65% of ovarian tumors; 5–20% of all mature cystic ovarian teratomas
Age: premenopausal women
Path: unilateral; often < 10 cm in size
Histo: mature thyroid tissue of variably sized acini filled with colloid: lined by single layer of columnar / flattened epithelium

- asymptomatic / pelvic mass
- hyperthyroidism / thyrotoxicosis (5%)
- pseudo-Meigs syndrome = abdominal ascites / hydrothorax

√ multilocular cystic mass with smooth margins + large cystic spaces = dilated thyroid follicles filled with thyroglobulin and thyroid hormones

US:

√ nonspecific solid + cystic tumor

√ characteristic struma pearls = well circumscribed round vascularized echogenic solid areas with smooth contour

CT:

√ high-attenuation loculi = iodinated thyroid hormone and calcifications

√ intense enhancement

√ ± loculi of fat attenuation = sebaceous material

MR:

√ multilobulated complex mass with thick septa + multiple cysts of variable SI + enhancing solid components

√ cystic spaces with marked hypointensity on T2WI + intermediate intensity on T1WI (= thick gelatinous colloid)

√ T1-hyperintense locules ← hemorrhage

√ SI drop-off with surrounding chemical shift artifact on opposed-phase T1WI ← microscopic fat

√ strong enhancement of solid component / thickened septa / cyst walls

Prognosis: benign in 95%

Cx: malignancy (in 5–10%)

Dx: usually by pathologic analysis

DDx: mature cystic teratoma without fatty tissue, cystadenoma, cystadenocarcinoma, endometriosis, tuboovarian abscess, metastatic tumor

TERATOMA OF OVARY

= immature derivatives of all 3 germ cell layers

Prevalence: most common germ cell neoplasm; 20% of adult + 50% of pediatric ovarian tumors

Types: (1) Mature cystic teratoma

(2) Immature teratoma

(3) Monodermal teratoma

(4) Combination tumor = intermixed varying histologic components without definite interface

(5) Collision tumor = two adjacent histologically distinct tumors without histologic admixture at interface

Age: usually childhood / adolescence

√ variably from purely cystic to mainly solid masses

US:

√ cystic / complex mass (most frequently)

√ usually large solid mass with internal echoes

Dx: identification of intratumoral fat on US, CT, MR imaging

Cx: 1. Torsion (16%)

2. **Ruptured teratoma** (1–4%)
   - √ discontinuity of tumor wall
   - √ fatty implants within peritoneal cavity
   - √ chronic granulomatous peritonitis:
     - √ ascites, hazy omental infiltration
     - √ inflammatory omental mass
3. Malignant transformation (1–2%)
4. Infection (1%)
5. Autoimmune hemolytic anemia (< 1%)

Malignant Transformation of Ovarian Teratoma

Prevalence: 1–2% of ovarian teratomas; 1% of all ovarian malignancies

Path: squamous cell carcinoma arising from squamous lining of the cyst (in 80%); adenocarcinoma

Age: > 45 years

- serum squamous carcinoma antigen level > 2 ng/mL
- elevated CA-125 level > 35 U/mL (in 67%)
- elevated CA 19-9 level > 37 U/mL (in 75%)

Location: in any of 3 germ cell layers

Common site: Rokitansky nodule

Size of tumor: > 10 cm

√ transmural growth of Rokitansky nodule

√ contrast enhancement of Rokitansky nodule

CT / MR:

√ invasive growth of large irregularly marginated soft-tissue component through tumor wall

√ irregular soft-tissue components within tumor

√ obtuse angle between soft tissue and inner cyst wall

√ enhancing soft-tissue component

Malignant Carcinoid of Ovary

= rare neoplasm of monodermal teratoma with differentiation toward argentaffin cells

Prevalence: 0.5 of all carcinoid tumors; 0.1% of all malignant ovarian tumors

Path: usually component of mature cystic teratoma

Histo: insular (= composed of islet cells); trabecular; mucinous (= composed of goblet cells); stromal; mixed (= combination of the 4 pure types)

- carcinoid syndrome (⅓) in the absence of metastases ← NO inactivation of serotonin ← tumor drains directly into systemic circulation bypassing the liver

Laterality: unilateral

Size of tumor: up to 20 cm

√ multilocular cystic mass with soft-tissue component

√ solid enhancing component may appear as sponge-like mass

√ low SI on T2WI + intermediate SI on T1WI

THECA CELL TUMOR OF OVARY

= THECOMA = FIBROSED THECOMA = FIBROTHECOMA
= benign sex cord-stromal tumor similar to fibroma
Path: solid mass, occasionally with cystic changes
Histo: spectrum of tumors with varying amounts of theca cells (= swollen lipid-rich stromal cells with estrogenic activity) + fibroblasts
Frequency: 0.5–1% of all ovarian neoplasms; 50% of all gonadal-stromal tumors
Mean age: 59 years; > 30 years (30%); postmenopausal (> 80%)
• estrogenic activity with uterine bleeding (60%)
May be associated with: endometrial hyperplasia; endometrial carcinoma (> 20%)
Laterality: unilateral
US:
√ echogenic mass with sound attenuation / well-defined hypoechoic mass / anechoic lesion with sound through-transmission
√ endometrial thickening
MR:
√ hypointense ovarian mass on T2WI ← fibrotic component
√ high SI on T2WI for components with little / no fibrosis ← edema / cystic degeneration of larger masses
√ low signal intensity on T1WI
√ variable degree of contrast enhancement governed by amount of nonenhancing fibrous tissue
√ widening of endometrial stripe (= thickened endometrium)
√ endometrial polyps
Prognosis: almost always benign with low malignant potential

Luteinized Thecoma

= rare subtype of fibrothecoma containing steroid type cells
• hormonal activity: estrogenic (50%), nonfunctioning (39%), androgenic (11%)
Age: younger

TORSION OF FALLOPIAN TUBE

Frequency: 1÷1.5 million women (exceedingly rare)
Age: adolescent girls + women of reproductive age
Risk factors: long / congested mesosalpinx, prior tubal ligation, hydatid cyst of Morgagni, hydrosalpinx, PID, hypermotility of fallopian tube, trauma
Location: R >> L ← fixation by sigmoid colon
Mechanism: adnexal venous + lymphatic obstruction → enlargement of fimbrial end as lead point
• acute onset of crampy / constant dull lower abdominal pain
• nausea, vomiting, peritoneal signs
US:
√ fusiform tubal dilatation with tapered ends
√ thickened echogenic wall ± internal debris
√ central solid component (= edematous mesosalpinx) surrounded by dilated tube

CT:
√ dilated fluid-filled structure separate from ovary:
√ tubular shape with tapered ends (= "beak" sign)
√ twisted configuration of dilated tubular cystic mass
√ intraluminal attenuation > 50 HU (= hemorrhage)
√ thick enhancing fallopian tube wall
√ free fluid + peritubal fat stranding
√ thickening + enhancement of broad ligaments
√ focal reactive ileus

TORSION OF OVARY

= OVARIAN TORSION
= twisting of ovary on its axis around suspensory ligament
Adnexal torsion: torsion of ovary / fallopian tube / both (67%)
Predisposing condition:
(1) Enlarged ovary (in 50–81%):
(a) physiologic: large hemorrhagic cyst, paraovarian cyst, multicystic ovary from hyperstimulation, abscess
(b) neoplastic: benign mature cystic teratoma (= "dermoid"), serous cystadenoma, malignancy
◊ Benign mature cystic teratoma is the most common neoplasm causing torsion!
◊ Ovarian torsion is rare with ovarian cysts < 5 cm
(2) Hypermobility of normal adnexa ← markedly mobile fallopian tube, excessively long mesosalpinx, elongated pelvic ligaments, fallopian tube spasm, strenuous exercise, abrupt changes in intraabdominal pressure
◊ Most frequent in prepubertal girls + during 1st trimester of pregnancy
At risk: 1st trimester of pregnancy (8–16 weeks EGA) responsible for 14% of all ovarian torsions
◊ Uncommon after PID / endometriosis / malignant neoplasm ← immobile ovaries ← presence of adhesions
Prevalence: 2.7% of gynecologic emergencies
Associated with: ipsilateral ovarian lesion (in 50–81%)
Path: hemorrhagic necrosis
Pathophysiology:
(a) early stage of partial torsion: arteries with thick muscular walls are less collapsible so that circulatory stasis affects initially lymphatics + veins → massive ovarian edema + distention of peripheral follicles → diffuse ovarian enlargement + capsular stretch
(b) later stage of progressive complete torsion: arterial obstruction (= arterial stasis + thrombosis) → ovarian ischemia / necrosis / hemorrhagic infarction → severe peritonitis → systemic inflammation + death
Age: any; usually affects women of reproductive age (17–20% during pregnancy) in first 3 decades of life; may occur prenatally
◊ Torsion of a normal ovary is unusual and more common in adolescents!
• gradual / sudden onset of severe lower abdominal / pelvic pain:

- sharp localized right / left lower abdominal pain + tenderness with peritoneal signs
- intermittent pain / resolving pain

• waves of nausea, vomiting, pyrexia; palpable mass in 50%

Location: R÷L = 3÷2 (? protective effect of sigmoid mesentery); frequently one ovary with corresponding fallopian tube

US (87% PPV, 93% specific):

√ enlarged ovary > 4 cm in diameter (28 x normal size):
  √ ovarian stromal heterogeneity with solid + cystic components ← hemorrhage and edema
  √ good sound transmission ← vascular engorgement and stromal edema
  √ ± coexistent complex (cystic / solid) pelvoabdominal /adnexal mass

√ "string of pearls" = multiple peripherally aligned displaced follicles measuring 8–25 mm in diameter (64–74%) ← transudation of fluid into nonovulatory follicles

√ small amount of free fluid in cul-de-sac (in up to 87%):
  √ clear ascites (70%) / hemorrhagic ascites (10%)

√ ± local tenderness of ovary at transvaginal US

√ "**whirlpool**" sign = ellipsoid / tubular mass abutting ovarian mass = twisted vascular pedicle (88%)

Color Doppler:

√ engorgement of blood vessels on side of torsion

√ "**corkscrew**" appearance = twisted circular / coiled arterial + venous vessels within vascular pedicle

√ diminished / absent venous flow (in 93%) ← early collapse of compliant venous walls

√ absent / high-resistance arterial Doppler waveforms (in 73%) = SPECIFIC but NOT SENSITIVE
  ◊ Normal arterial waveforms do NOT rule out torsion! Some color Doppler flow in up to 60% of surgically proved cases ← dual blood supply by ovarian + uterine arteries / symptoms secondary to venous thrombosis

Utility: Nonviable ovary shows NO central venous flow! Viable twisted ovary shows central venous flow!

CT:

√ unilateral ovarian enlargement (100%) with cortical follicles

√ displacement of torsed ovary toward pelvic midline / contralateral side + superior to fundus

√ deviation of uterus toward side of torsed ovary (36%)

√ amorphous targetlike / tubular mass (84%) between adnexal mass + uterus ← tubal thickening > 10 mm

N.B.: the diameter of the normal tube measures up to 4 mm at isthmic, 8 mm at ampullary, 10 mm at infundibular portion

√ cystic ovarian mass with smooth wall thickening (76%) converging on a thickened fallopian tube:
  √ eccentric > 10 mm ← suggests hemorrhagic infarction
  √ attenuation > 50 HU on NECT = hemorrhagic infarction

√ small uniform peripheral hypoattenuating cysts surrounding an edematous ovarian stroma

√ obliteration of fat planes / fat stranding around torsed ovary

√ twisted vascular ovarian pedicle (PATHOGNOMONIC)
√ enlarged veins
√ lack of enhancement of solid component (= infarction)
√ hematoma / gas within torsed mass
√ ascites

MR:

@ ovary:
√ imaging findings vary with stage:
√ initially ovarian enlargement with diffuse high SI on T2WI ← stromal edema = frequently viable ovary
√ variable SI ← hemorrhage + necrosis
√ ↓ SI on T1WI and T2WI ← hemorrhagic infarction
√ high SI on fat-suppressed T1WI ← blood products
√ smooth thickening of cyst wall / mural nodule
√ no enhancement of solid component on contrast-enhanced dynamic subtraction MR = chronic stage
√ enlarged follicles along periphery of ovary
√ twisted vascular pedicle
√ beaked protrusion at periphery of torsed ovary ← engorged blood vessels
√ obliteration of fat planes

@ tube:
√ tubal thickening (SAG image improves detection)
√ increased tubal SI on T2WI ← edema
√ hemorrhage into thickened tube

@ uterus:
√ deviation of uterus to side of torsion

√ pelvic ascites / hemoperitoneum

Prognosis:

(1) Spontaneous detorsion is common (history of prior similar episodes = intermittent torsion)
(2) Infection of torsed ovary with local peritonitis ± bowel obstruction

Cx: infarction, necrosis, infection, peritonitis

Rx: immediate surgery (most ovaries NOT salvageable)

DDx: (1) Hemorrhagic ovarian cyst (fishnet appearance, retracting blood clot, fluid-fluid / fluid-debris level

(2) Serous cystadenoma (large unilocular thin-walled cystic lesions ± thin septations / papillary projection)

(3) Ovarian hyperstimulation syndrome (bilaterally enlarged ovaries due to multiple distended peripherally located corpora lutea cysts)

TRIPLOIDY

= 69 chromosomes (= 3 haploid sets of 23 chromosomes)

Prevalence: 1% of conceptions; 0.04% of 20-week fetuses

NO obvious pattern!

√ early severe asymmetric IUGR (MOST PROMINENT FEATURE); cephalocorporal disproportion

√ oligohydramnios
√ large hydropic placenta with scattered vesicular spaces (partial hydatidiform mole)
√ congenital heart disease: ASD, VSD
√ brain anomalies: hydrocephalus, holoprosencephaly, neural tube defect
√ cleft lip / palate
√ syndactyly of fingers
√ omphalocele
√ renal abnormalities
Prognosis: most ending in spontaneous abortion

TRISOMY 13

= PATAU SYNDROME

Cause: nondisjunction of chromosome 13 during meiosis
Prevalence: 1÷5,000 live births
@ OB: severe IUGR, hydramnios
@ CNS: alobar holoprosencephaly, posterior encephalocele, neural tube defect
@ Face: midline labial cleft, proboscis, hypotelorism, cyclopia, anophthalmia
@ Skeleton: postaxial polydactyly, rocker-bottom foot
@ Heart: (CHD in 90%) VSD, echogenic chordae tendineae, hypoplastic ventricle, tetralogy of Fallot, transposition
@ Kidney: polycystic kidney, horseshoe kidney
@ GI: omphalocele (occasionally)
Prognosis: few infants live more than a few days / hours; death by 3 months of age
DDx: Meckel-Gruber syndrome

TRISOMY 18

= EDWARDS SYNDROME

Prevalence: 1÷3,000–5,000 live births
• triple-marker screening test:
(1) ↓ maternal alpha-fetoprotein
(2) ↓ hCG (DDx: increased in Down syndrome)
(3) ↓ estriol
√ no anomalies (14%) on initial 2nd-trimester sonogram only ← incomplete / early gestational age
@ OB: severe symmetric IUGR (28% < 24 weeks MA), single umbilical artery (30%), polyhydramnios (occasionally)
@ Face: micrognathia, hypotelorism, facial cleft (10–40%)
@ Head: strawberry-shaped head (50%), cystic hygroma
@ CNS: holoprosencephaly, choroid plexus cyst (30–51–75%), cerebellum ≤ 10th percentile with prominent cisterna magna (45%), myelomeningocele
@ Hand: clenched hand with overlapping of index finger (33%, HIGHLY CHARACTERISTIC), abnormal wrist position (27%)
@ Arm: shortened radial ray, clubbed forearm

@ Foot: clubbed foot, rocker-bottom foot
@ Heart: CHD in 90%: VSD (82%), ASD (8%), complete AV canal, DORV
@ GI: diaphragmatic hernia, omphalocele (30–40%), tracheoesophageal fistula
@ Kidney: polycystic kidney, horseshoe kidney, UPJ obstruction

Prognosis: usually delivered by emergency cesarean section ← IUGR + fetal distress, if not detected prenatally; death by 1 year of age

TWIN EMBOLIZATION SYNDROME

= rare complication of monochorionic pregnancy following the death of one twin whose blood pressure falls to zero

Pathophysiology:

1. Acute reversal of transfusion to co-twin at time of intra-uterine demise of one twin with ischemic changes in survivor
2. Embolization (= transfer of thromboplastin-enriched blood / detritus) from the dead to the living twin through vascular anastomoses in placenta
   • DIC (disseminated intravascular coagulation)

Embolized organs: CNS (72%), GI tract (19%), kidneys (15%), lungs

√ ventriculomegaly, cortical atrophy, porencephalic cyst, cystic encephalomalacia within 2 weeks of death of co-twin

Morbidity / mortality: 17%

TWIN-TWIN TRANSFUSION SYNDROME

= FETOFETAL TRANSFUSION SYNDROME = MONOVULAR TWIN TRANSFUSION = INTRAUTERINE PARABIOTIC SYNDROME

= complication of monozygotic twinning with one placenta or one fused placenta of mono- / dizygotic twins

Prevalence: 5–18% of twin pregnancies; 5–15% of monozygotic multiple pregnancies; 15–30% of monochorionic twin gestations

Cause: unbalanced intrauterine shunting of blood through shared placental vessels

Time of onset: 2nd trimester with discordant amniotic fluid volumes

Path: large communication between arterial circulation of one twin + venous circulation of the other twin through arteriovenous shunt (= common villous district) deep within placenta

√ discrepant amniotic fluid volume (75%)
√ discordant BPD by > 5 mm (57%)
√ discordant estimated fetal weight > 25% (67–100%)

A. DONOR TWIN

= twin that transfuses the recipient twin + remains itself underperfused residing in an oligo- / anhydramniotic sac
• anemia + hypovolemia
• high output cardiac failure + hydrops (rare)
√ oligohydramnios (75–80%)
√ "**stuck twin**" ← severe oligohydramnios (60%) ← oliguria
√ amnion invisible ← close contact with fetal parts
√ fetus fixed relative to the uterine wall → without change during shift in maternal position

√ diminished / absent active fetal motion
√ absence of intermingling of fetal parts between twins
√ IUGR (= intrauterine growth restriction, common) diagnosed by discordant EFW of > 25%
√ morphologically normal

Prognosis: fetal death in utero

B. RECIPIENT TWIN

• polycythemia (higher hemoglobin)
• plethora = hypervolemia (volume overload)
√ polyhydramnios (70–75%) ← increased fetal urination
√ fetal hydrops (10–25%): pericardial + pleural effusions, ascites, skin thickening
√ organomegaly
√ fetus papyraceus = macerated dead fetus
√ velamentous cord insertion (64%)

Prognosis: 80–100% perinatal mortality if presenting < 28 weeks MA and left untreated

Cx: amniorrhexis, preterm labor

Rx: elective termination, volume-reduction amniocentesis of polyhydramniotic sac (decreases mortality rate to 34%), selective feticide, laser ablation of vascular anastomoses

DDx: IUGR of one dizygotic twin (two separate placentas, two different sexes)

UTERINE ANOMALIES

= MÜLLERIAN DUCT ANOMALIES

= anomalies of fusion of paramesonephric duct (= MÜLLERIAN DUCT) completed by 18th week of fetal life

Prevalence: 0.1–3%

◊ Uterine anomalies are found in 9% of women with infertility / repeated spontaneous abortions!

◊ 25% of women with uterine abnormalities have fertility problems

Associated with: urinary tract anomalies in 20–50%; possibly increased familial occurrence of limb reduction

Embryology:

(a) müllerian ducts develop at 5–6 weeks GA from coelomic epithelium and form uterovaginal canal by **lateral fusion** at 7–9 weeks GA

(b) by 8 weeks the uterovaginal canal reaches the urogenital sinus at the müllerian tubercle while a vaginal plate develops distally resulting in **vertical fusion** (upper $^{2}/_{3}$ to $\mathbf{4}/_{5}$ of vagina are of müllerian duct origin, lower ⅓ or $^{1}/_{5}$ of vagina originate from urogenital sinus)

Risk: spontaneous abortion, prematurity, IUGR, abnormal fetal lie, dystocia

Classification:

[classes in parenthesis refer to the classification of the American Fertility Society]

A. ARRESTED MÜLLERIAN DUCT DEVELOPMENT

1. bilateral: **Uterovaginal agenesis / hypoplasia** (class I)

I-A = Vaginal I-D = Tubal
I-B = Cervical I-E = Combination

I-C = Fundal

Prevalence: 1÷5,000; 5–10% of uterine anomalies

Often associated with: vaginal agenesis / hypoplasia

Age of detection: menarche

• primary amenorrhea

• normal secondary sex characteristics

√ small / absent uterus with small endometrial canal

√ ± endometrial layer

√ poor zonal differentiation + abnormal T2-hypointense myometrium

2. unilateral: **Unicornuate uterus** = Uterus unicornis unicollis (class II)

II-A = Communicating II-D = No cavity

II-B = Noncommunicating II-E = No horn

= failure of one müllerian duct to elongate / reach the urogenital sinus during 9th week of gestation

(a) with contralateral rudimentary horn

› cavitary = functioning endometrial tissue ("functional rudimentary horn")

» communicating with contralateral cavity (10%)

» noncommunicating (22%)

› noncavitary (33%) = no endometrial tissue

› noncavitary with endometrial strip (32%)

(b) without rudimentary horn

Frequency: 3–6–20% of uterine anomalies

May be associated with: ipsilateral renal agenesis

• infertility in 5–20%

√ reduced uterine volume

√ asymmetric ellipsoidal uterine configuration located in lateral aspect of pelvis

√ solitary fusiform "**banana-shaped**" uterine cavity with lateral deviation within pelvis terminating in a single fallopian tube on HSG

√ nonfunctional rudimentary horn of low SI on T2WI with loss of normal zonal anatomy

√ large high-signal-intensity cavity on T1WI + T2WI in functional rudimentary horn (= hematometra)

Cx: endometriosis ← cryptomenorrhea within endometrium-containing rudimentary horn; ectopic pregnancy ← transperitoneal sperm migration; abnormal fetal lie, IUGR; preterm delivery

3. **Mayer-Rokitansky-Küster-Hauser syndrome**

(1) vaginal agenesis / hypoplasia of proximal + middle segments

(2) intact normal ovaries + fallopian tubes

(3) variable anomalies of uterus (agenesis / hypoplasia, uni- or bicornuate)

(4) variable anomalies of urinary tract (renal agenesis, pelvic kidney in 40–50%) + skeletal system (12%)

mnemonic: MURCS complex

MÜllerian duct aplasia

Renal aplasia

Cervicothoracic **S**omite dysplasia

Frequency: 1÷4,000–1÷5,000

Cause: lack of müllerian development

- normal external genitalia; amenorrhea
- shallow distal vaginal pouch (derived from urogenital sinus)
- cyclic pelvic pain in 6–10% ← functioning endometrium within rudimentary uterine tissue

◊ 2nd most common cause of primary infertility

Rx: neovaginoplasty

B. TOTAL / PARTIAL FAILURE OF MÜLLERIAN DUCT FUSION = duplication defects = disorders of lateral fusion (75% of uterine anomalies)

1. **Uterus didelphys** (class III)

= failure of fusion of paramesonephric ducts at 9 weeks of gestation → complete duplication with 2 vaginas + 2 cervices + 2 uterine horns

Frequency: 11% of uterine anomalies

May be associated with: renal agenesis

- usually asymptomatic; frequently first diagnosed during routine obstetric sonography

√ two widely spaced uterine corpora with normal zonal anatomy and volume, each with a single fallopian tube

√ separate widely divergent uterine horns

√ large fundal cleft

√ cervical duplication

√ longitudinal vaginal septum (in 75%)

√ unilateral hemivaginal septum:

√ obstructing transverse vaginal septum between upper ⅓ and lower ⅔ of vagina connecting to longitudinal septum (commonly with ipsilateral renal agenesis)

√ opacification of single deviated horn on HSG

DDx: bicornuate bicollis uterus (communication between uterine horns maintained)

Cx: unilateral hydro- / hematocolpos (if transverse vaginal septum present) with reflux endometriosis

Rx: metroplasty is rarely performed

2. **Bicornuate uterus** = uterus bicornis (class IV)

IV-A = Complete IV-B = Partial

= lack of fusion of corpus

(a) bicornis bicollis = complete division down to external os

(b) bicornis unicollis = division down to internal os

Frequency: 10% of all uterine anomalies

√ external uterine fundal contour (MR):

√ concave heart-shaped surface depression > 1–2 cm deep

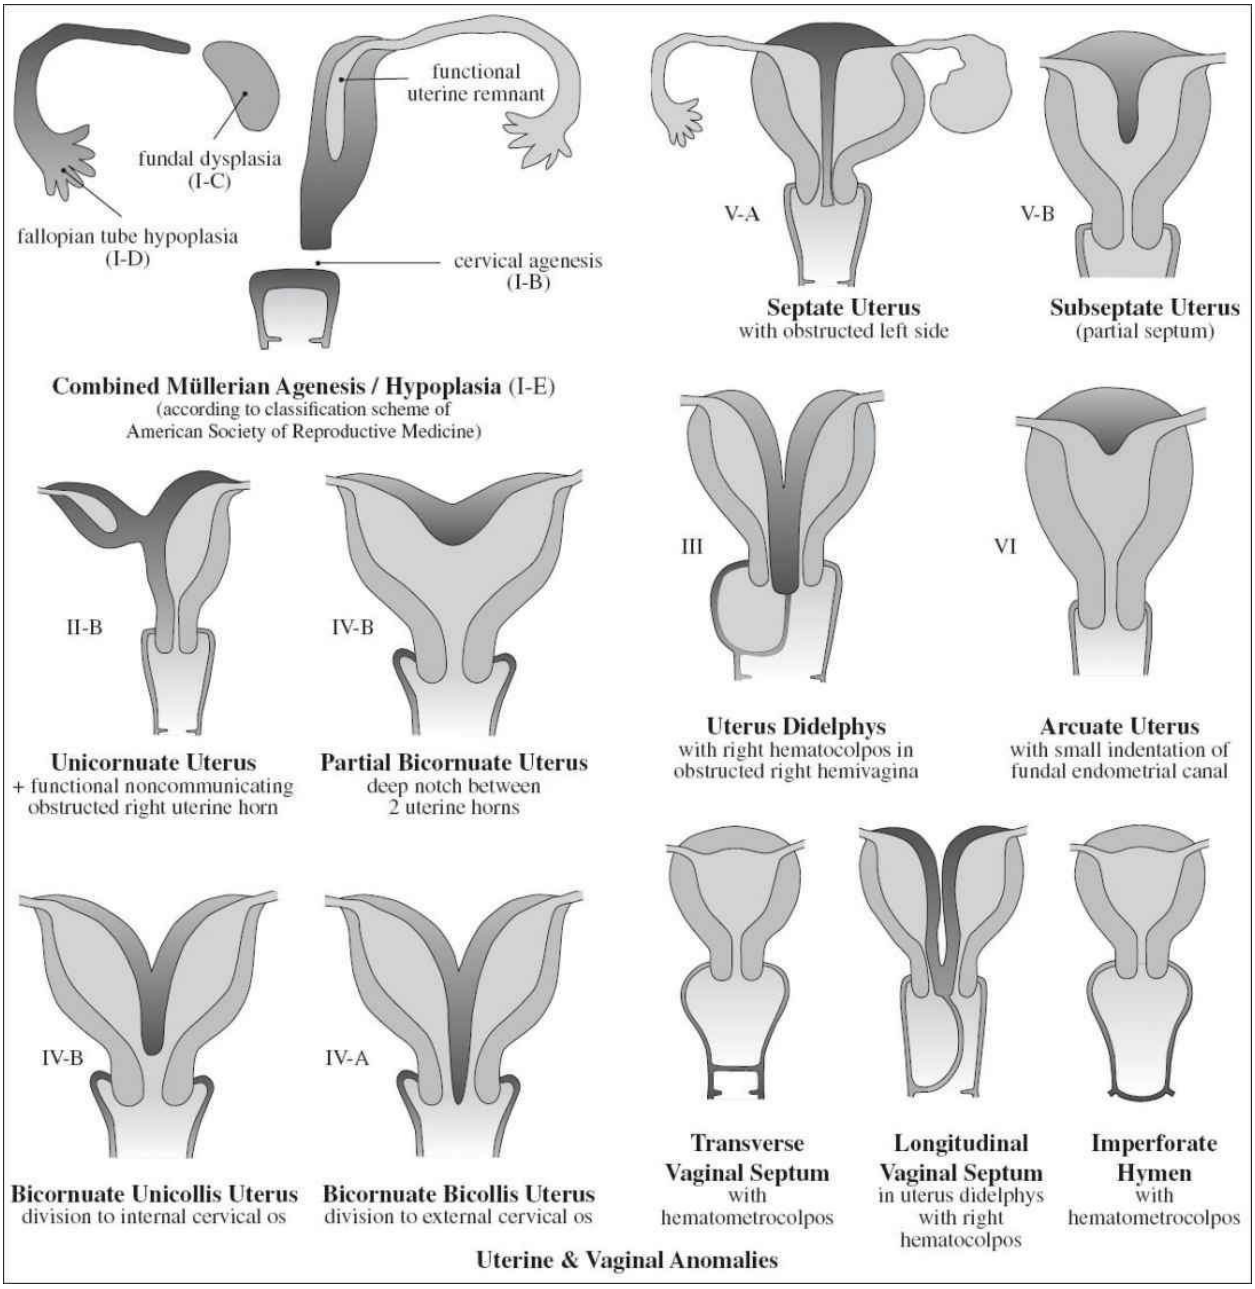
√ large fundal cleft

√ separation of uterine horns

√ intercornual angle of > 75–105° (demonstrated on luteal-phase US in conjunction with HSG)

√ intercornual distance (= distance between maximum lateral extent of hyperintense

endometrium on transaxial image) > 4 cm



√ divider between cornua comprised of myometrium / fibrous tissue / both
√ fusiform shape of each uterine horn with lateral convex margins
√ discrepancy in size of the 2 uterine horns
√ elongation + widening of cervical canal + isthmus

Laparoscopy: typical external fundal indentation

Cx: repeated spontaneous abortions in 30% (frequently in 2nd–3rd trimester), premature rupture of membranes, premature labor (20%), SGA infant, persistent malpresentations (transverse lie)

DDx: septate uterus (convex external contour)
◊ HSG is unreliable to distinguish bicornuate from septate uterus!

◊ 3-dimensional US is 90–92% accurate!
◊ MR is nearly 100% accurate!

Rx: transabdominal surgery to fuse uterine horns (abdominal / open metroplasty)

C. NONRESORPTION OF SAGITTAL UTERINE SEPTUM

1. **Septate uterus** (class V)

V-A = Complete V-B = Partial

= failure of resorption of septum by 12th week EGA

◊ Most common anomaly (55%) associated with reproductive failure in 26–65–94% unrelated to length of septum

Path: septum may be composed of fibrous tissue (low SI), myometrium (intermediate SI), or both

• generally asymptomatic ± unilateral obstruction, dysmenorrhea, normal menses, endometriosis

√ convex / flat / minimally indented (≤ 1 cm) external fundal contour

√ intercornual angle of ≤ 75° (MR more accurate than HSG with its projectional problems)

√ duplication of uterine horns on HSG (DDx to bicornuate uterus unreliable)

√ distal portion of septum hypoechoic to myometrium / of low SI on T2WI (= fibrous tissue)

Types:

(a) **Uterus septus**

= complete septum extending to internal os

√ endometrial canals completely separated by tissue isoechoic to myometrium extending into endocervical canal

(b) **Uterus subseptus**

= partial septum involving endometrial canal

Cx: 90% abortion rate (poor septal vascularity)

Rx: hysteroscopic metroplasty (= excision of septum)

2. **Uterus arcuatus** (class VI)

= nearly completely resorbed uterovaginal septum

◊ Most common anomaly unassociated with reproductive failure = normal variant

√ NO division of uterine horns

√ normal fundal contour

√ smooth indentation of fundal endometrial canal

√ increased transverse diameter of uterine cavity

√ single uterine canal with saddle-shaped fundus on HSG

D. INADEQUATE HORMONAL STIMULATION DURING FETAL DEVELOPMENT

= DES (= diethylstilbestrol)-related abnormalities (class VII)

• synthetic hormone used until 1971 to prevent miscarriage; rarely seen today

• may cause abnormal uterine morphology (with decreased fertility)

• increased risk of vaginal clear cell carcinoma

1. **Uterine hypoplasia**

associated with DES exposure in utero

√ mean uterine volume = 50 cm^3

2. **T-shaped uterus**
   Prevalence: 15% of women exposed to DES in utero
   √ low uterine volume
   √ uterine fundus thinner than cervix
   √ greater width than depth of corpus + fundus over cervix
   √ T-shaped lumen on hysterosalpingogram

E. VAGINAL SEPTUM ANOMALY

1. **Transverse vaginal septum**
   = failure of vertical fusion between vaginal plate (from urogenital sinus) + müllerian ducts around 5th month of gestation
   Path: fibrous membrane of connective tissue with vascular + muscular components
   • NO transillumination (DDx to imperforate hymen)
   Location: upper vagina (46%), mid-vagina (40%), lower vagina (14%)
   √ hematocolpos (balloon sonocolpography)
   √ thickness measurement of septum is needed
   DDx: congenital absence of cervix versus high septum (identification of cervix is crucial)
2. **Longitudinal vaginal septum**
   Cause: (a) failure of fusion of lateral müllerian ducts resulting in duplication of uterus, cervix (uterus didelphys), vagina
   (b) incomplete resorption of vaginal septum
   • difficulties with sexual intercourse / vaginal delivery
   √ low-signal-intensity septum distinct from surrounding high-signal-intensity of vaginal mucosa + secretions on T2WI
3. **Imperforate hymen**
   = failure at very end of vaginal recanalization process
   Prevalence: 0.1%; usually isolated finding; most common anomaly of female genital tract
   • primary amenorrhea + cyclic pelvic pain
   • ± bulging introitus in infancy (from vaginal mucus)
   • positive transillumination of bluish membrane
   Location: junction between urogenital sinus + sinovaginal bulb
   √ distended vagina bulging at introitus ← hydro- / hematocolpos
   √ hematocolpos with high-SI on T1WI + T2WI ← subacute bleeding episodes

UTERINE LEIOMYOMA

= FIBROID = MYOMA
= benign overgrowth of smooth muscle + connective tissue
◊ Most common gynecologic neoplasm! Commonest cause for uterine enlargement after pregnancy!
Prevalence: in 20–25% of White women; in 50% of Black women; Black÷White women = 3÷1 to 9÷1; 0.3–2.6% during pregnancy; account for 30% of all hysterectomies in USA
Path: whorl-like trabeculated mesenchymal tumor surrounded by pseudocapsule; may outgrow its blood supply resulting in:

(a) hyaline degeneration / fibrosis (> 60%)
= homogeneous eosinophilic bands / plaques of proteinaceous material in extracellular space
(b) myxoid degeneration (50%)
= gelatinous intratumoral foci of hyaluronic acid-rich mucopolysaccharides
(c) red / hemorrhagic / carneous degeneration (10%)
= massive hemorrhagic infarction ← venous thrombosis / rupture of intratumoral arteries; often during pregnancy / during use of oral contraceptives
• painful
(d) cystic degeneration (4%)
= extreme sequelae of edema
(e) calcification (4%)
= dense amorphous calcifications of hyalinized tissue

Specific types:
(1) **Lipoleiomyoma** (0.8%)
(2) **Myxoid leiomyoma** = rare soft translucent mass ← abundant myxoid material between smooth muscle cells, may be clinically malignant
(3) **Intravenous leiomyomatosis** = wormlike masses growing within pelvic veins
(4) Benign metastasizing leiomyoma
(5) **Diffuse leiomyomatosis** = development of innumerable small leiomyomas
√ symmetric enlargement of uterus
(6) **Peritoneal disseminated leiomyomatosis**
• frequently associated with pregnancy
√ multiple nodules on peritoneal surface

Histo: monoclonal proliferation of smooth muscle cells (NOT myometrial hyperplasia) separated by variable amounts of fibrous connective tissue

Hormonal dependency:
◊ Higher estrogen÷progesterone receptor ratio than in normal myometrium!
(1) Growth during pregnancy in 15–32% by a mean volume of 12 ± 6% within the 1st trimester (NOT during remainder of pregnancy)
◊ The larger the myoma, the greater the likelihood of growth
(2) Growth under estrogen therapy
(3) Shrinkage in puerperium + after menopause

Age: usually > 30 years; rare in girls < 18 years + in postmenopausal women

• asymptomatic in 70–75%; palpable abdominopelvic mass
• pelvic pressure:
  • urinary frequency ← compression of bladder
  • constipation ← impingement on rectosigmoid
• pain (in up to 30%) ← acute hemorrhagic infarction and necrosis, torsion of pedunculated subserosal fibroid, prolapse of pedunculated submucosal fibroid, compression of adjacent structures
• dysmenorrhea = colicky pelvic pain with menstruation
• abnormal uterine bleeding:
  • menorrhagia / hypermenorrhea = heavy + prolonged menstrual flow

- metrorrhagia = uterine bleeding outside time of menstruation
- infertility + early spontaneous fetal loss ← interference with embryo transfer + implantation in submucosal / intracavitary leiomyoma

Location: mostly in fundus + corpus; cervix (3–8%); fallopian tube; broad ligament; ovary

Classification by location in uterus:

1. **Intramural fibroid** (95%)
   = within confines of uterine outline
   - asymptomatic (mostly)
   - occasionally menorrhagia ← interference with normal uterine contractility
   - occasionally infertility ← compression of interstitial portion of fallopian tube / distortion of endometrial cavity
2. **Subserosal / exophytic / pedunculated fibroid**
   - usually asymptomatic; pain from infarction ← torsion

   √ "bridging vascular" sign = multiple feeding vessels arising from the uterine arteries + bridging the interface between uterus and any > 3 cm juxtauterine leiomyoma

   (a) **intraligamentous fibroid** (lateral growth between folds of broad ligament)
   - simulates ovarian mass
   - occasionally infertility ← compression of isthmic / ampullary portion of fallopian tube

   Cx: hydroureteronephrosis ← compression of ureter

   (b) **parasitic fibroid** = subserosal fibroid, which has become detached ← circulatory occlusion of vessels in pedicle; revitalized through omental / mesenteric blood supply

   √ may grow after hysterectomy
3. **Submucosal fibroid** (4–5–18%)
   = projecting into endometrial canal

   ◊ Most frequent symptomatic type of fibroid:
   - dysmenorrhea, menorrhagia, infertility
   - increased prevalence of early abortion

   Cx: hemorrhage, ulceration

   (a) fibroid polyp (2.5%) = partial / complete extrusion of pedunculated submucosal fibroid into cervical canal / vagina

Cystic, fatty, and calcific degeneration within a leiomyoma may lead to a heterogeneous imaging appearance internally, but a smooth outer contour, preserved mucosa, and negative Pap test are important features for differentiation from cervical carcinoma.

√ uterine enlargement
√ lobulated / nodular distortion of uterine outline (subserosal leiomyoma) + indentation of urinary bladder
√ distortion / obliteration of the contour of the uterine cavity (submucosal leiomyoma)
√ intramural soft-tissue mass (most frequent), usually multiple, solitary in 2%
√ speckled / ringlike / popcorn calcification

HSG:
√ mass effect on endometrial cavity
√ lack of tubal opacification with cornual leiomyoma

US (60% sensitivity, 99% specificity, 87% accuracy):

• point tenderness elicited with probe pushing on fibroid
√ hypoechoic solid concentric mass (< 33%) ← prevailing muscle component
√ echogenic attenuating mass ← prevailing dense fibrosis
√ sharp discrete refractory shadows (from borders between fibrous tissue and smooth muscle, margins of leiomyoma with normal myometrium, edges of whorls, bundles of smooth muscle)
√ anechoic features ← internal degeneration: atrophic, hyaline, cystic, myxomatous, lipomatous, calcareous, carneous, necrobiotic, hemorrhagic, proteolytic degeneration
√ acoustic shadowing (= calcifications)
◊ Presence of a prominent artery by color Doppler suggests potential for growth during pregnancy

CT:
√ hypo- / iso- (usually) / hyperdense mass
√ deformed uterine contour
√ calcifications (common)
@ Degenerated leiomyoma
√ central region of low attenuation
√ heterogeneous enhancement

MR (86–92% sensitive, 100% specific, 97% accurate; most accurate + desirable for planning myomectomy):
N.B.: subserosal, intramural and submucosal classification enabled by uterine zonal anatomy
√ hyperintense rim on T2WI in 33% (= pseudocapsule of dilated lymphatics / veins / edema)
√ enhancement pattern (usually later than for myometrium): 65% hypointense, 23% isointense, 12% hyperintense to myometrium
@ **Nondegenerated leiomyoma**
√ well-circumscribed mass of:
√ homogeneously low SI on T2WI compared with myometrium (for leiomyoma with variable amounts of collagen)
√ low to intermediate SI on T1WI = isointense to surrounding uterus
√ slightly higher SI + contrast enhancement on T2WI (for cellular leiomyoma with little / no collagen)
@ **Degenerated leiomyoma**
• localized pain + tenderness + fever + leukocytosis lasting for a few days
• enlargement of the uterus during pregnancy may interfere with blood supply to fibroids
√ low SI on T2WI ← hyaline / calcific degeneration)
√ low SI on T2WI + variable SI on T1WI ← hyaline / coagulative necrosis
√ high SI on T2WI ← cystic degeneration without enhancement of cystic areas
√ very high SI on T2WI ← myxoid degeneration with minimal enhancement
√ variable SI on T2WI ← red degeneration
√ peripheral / diffuse high SI on T1WI ← proteinaceous content of blood

Hysterosalpingography (9% sensitive, 97% specific, 76% accurate)

Cx:
(1) Infertility in 35%
(a) narrowing of isthmic portion of tube

(b) impingement on endometrium interfering with implantation; infertility rates highest for submucosal leiomyomas

(2) Complications during pregnancy

◊ Significantly increased for myomas > 6 cm in size / multiple in number / myomas > 200 cm^3 and when fibroid is retroplacental

(a) increased frequency of spontaneous abortions
(b) increased frequency of ectopic pregnancies
(c) increased frequency of IUGR
(d) preterm labor in 7% + premature rupture of membranes
(e) placental abruption
(f) uterine dyskinesia, uterine inertia during labor
(g) dystocia, obstruction of birth canal during vaginal delivery (if near internal os)
(h) abnormal presentation
(i) postpartum hemorrhage
(j) retained products of conception

(3) Hydroureteronephrosis
(4) Leg edema ← compression of pelvic vessels
(5) Sarcomatous transformation (in < 0.1%)

Rx: (1) Hysterectomy for pain, menorrhagia, visceral compression (after childbearing completed)

(2) Myomectomy for 2nd trimester fetal loss / anemia due to hypermenorrhea / pelvic pain

◊ Submucosal leiomyomas may be treated with hysteroscopic myomectomy

(3) Uterine artery embolization for symptomatic fibroids

DDx of necrotic leiomyoma:

(1) Ovarian mass: ovarian cyst, hemorrhagic cyst, endometrioma, cystic dermoid, cystadenoma, malignancy
(2) Ectopic interstitial pregnancy
(3) Intrauterine gestational sac
(4) Intrauterine fluid collection
(5) Hydatidiform mole
(6) Myometrial contraction (lasting for 15–30 minutes)
(7) Cervical tumor
(8) Hematoma of broad ligament

DDx of pedunculated subserosal leiomyoma:

(1) Ovary: use transvaginal US / MR to identify follicles!

DDx of leiomyoma by MR:

(1) Adenomyosis
(2) Solid adnexal mass: Brenner tumor, fibroma
(3) Focal myometrial contraction (transient)
(4) Uterine leiomyosarcoma

Uterine Lipoleiomyoma (0.8%)

= uncommon benign uterine neoplasm with substantial amount of fat due to fatty

metamorphosis
Cause: fatty metamorphosis of smooth muscle cells
Histo: smooth muscle + fat + connective tissue
Associated with: leiomyomas
Location: corpus; predominantly intramurally, endophytic or exophytic
US:
√ well-defined hyperechoic mass surrounded by hypoechoic ring of myometrium
CT:
√ predominantly fatty mass + areas of nonfat soft-tissue density tissue arising from uterus
MR:
√ hyperintense fat on T1WI + T2WI with chemical shift artifact

Benign Metastasizing Leiomyoma

= smooth muscle tumors in lung, lymph nodes, abdomen
Prevalence: < 60 cases
Classification:
(1) Benign metastasizing leiomyoma
Origin: uterus in mature women; progression with estrogen + regression with progesterone
• benign uterine leiomyoma removed many years earlier
Rx: hysterectomy, bilateral oophorectomy, long-term hormone therapy; good prognosis
(2) Metastatic leiomyoma
Origin: extrauterine primary in men + children (? slow-growing sarcoma)
Rx: surgical resection with mixed success
(3) Multiple fibroleiomyomatous hamartomas
Origin: lung; totally benign behavior
Spread: lymph nodes outside of pelvis, peritoneal surface, venous channels, lung, heart
• asymptomatic in most cases, fever, mild nonproductive cough
Histo: well-differentiated benign-appearing smooth muscle cells
√ multiple pulmonary nodules
√ miliary pattern
√ pedunculated pulmonary leiomyoma with cyst formation
√ giant cyst

UTERINE LEIOMYOSARCOMA

Prevalence: 0.67÷100,000; 25% of all uterine sarcomas
Cause: (a) de novo growth independent of leiomyoma!
(b) sarcomatous transformation of preexisting leiomyoma (in < 1% of leiomyomas)
Histo: infiltrative margins, nuclear atypia, increased mitotic figures
• rapidly enlarging uterus (< 3%)
√ mass with irregular margin
√ rapid change in size + appearance
√ extensive degeneration
√ loss of well-defined outer capsule

Dx: often first established by pathologist

UTERINE RUPTURE IN PREGNANCY

= disruption of all layers surrounding the fetus (membranes, decidua, myometrium, serosa)

Prevalence: 3–5% for classic cesarean sections; 1–2% for lower segment operations; 1% of pregnant trauma patients

Classification:

1. Spontaneous rupture during labor
2. Traumatic rupture during delivery
3. Rupture ← myometrial scars / disease
4. Rupture during blunt trauma

Predisposed: previous uterine surgery, previously excessively long / difficult labor

• pain, shock, absent fetal heart tones

Location:

(a) corpus with rupture before onset of labor

(b) lower uterine segment during labor, L > R

√ full-thickness defect of uterine wall

√ extrusion of fetus into the abdomen

√ hemoperitoneum

Cx: hypofibrinogenemia (triggered by excessive blood loss, trauma, amniotic fluid embolism)

Mortality: 2–20% maternal mortality; 10–25% fetal mortality

DDx: **Uterine dehiscence** = rupture of only myometrium

UTERINE TRAUMA DURING PREGNANCY

Prevalence: 6–7%

Cause: motor vehicle accident (70%), physical abuse (10%)

During pregnancy at increased risk for:

› serious abdominal injury ← enlarged spleen, displacement of spleen and liver closer to rib cage

› complex multiple intestinal injuries ← bowel displacement superiorly

› bladder injury ← compression of bladder

› collecting-system injury ← hydronephrosis of pregnancy

› pelvic hemorrhage ← engorged ovarian + pelvic veins

1. Placental abruption
   complete (6–66%) / incomplete (30–80%)
   • more common > 16 weeks of gestation
   Prognosis: 67–75% rate of fetal mortality
2. Uterine rupture (0.6%)
   Prognosis: nearly 100% fetal mortality; up to 10% maternal mortality
3. Premature rupture of membranes
4. Fetal injury: eg, cerebral injury
5. Fetal death

The major cause of fetal death is maternal death!

US: evaluate fetal motion, breathing, heart rate, placenta

Essentially all **diagnostic ionizing** imaging examinations for evaluation of traumatic injury are well below 50 mGy and NOT associated with an increased risk of fetal anomalies or fetal loss throughout pregnancy!

VAGINAL AGENESIS

◊ 2nd most common cause of primary amenorrhea

Prevalence: 1÷4,000–5,000 women

• cyclic abdominal pain

May be associated with:

(1) Uterine + partial tubal agenesis (90%)
(2) Unilateral renal agenesis / ectopia (34%)
(3) Skeletal malformations (12%)
(4) McKusick-Kaufman syndrome (hydrometrocolpos + polydactyly + heart defects)
(5) Ellis-van Creveld syndrome

VASA PREVIA

= presence of abnormal fetal vessels within amniotic membranes that are unsupported by Wharton jelly / placental tissue and cross internal cervical os / lower uterine segment in advance of fetal parts

Prevalence: 0.04%

At risk: 2nd-trimester low-lying placenta / placenta previa, velamentous cord insertion, succenturiate placenta, in vitro fertilization, and multiple gestation

Cause:

(a) cord vessels of velamentous (membranous) cord insertion from low-lying placenta connecting to main body of placenta
(b) vessels connecting portions of a bilobed placenta
(c) vessels connecting succenturiate lobe to main portion of placenta

√ Doppler ultrasound demonstrates flow within aberrant vessels overlying the internal os

Cx: (1) tear of fetal vessels after rupture of membranes / due to direct injury during labor → fetal exsanguination
(2) Cord compression by presenting part during labor
(3) Cord prolapse

Rx: cesarean delivery

Prognosis: 50–100% fetal mortality; fetal survival rate improves from 44% to 97% if recognized

DDx: prominent maternal sinus vessels at edge of marginal previa (= marginal sinus previa)

VELAMENTOUS CORD INSERTION

= umbilical cord insertion into membranes outside placental margin = attachment of cord to chorion laeve

Prevalence: 0.09–1.8%, more frequent in multiple gestations

• low Apgar scores
• abnormal intrapartum fetal heart rate patterns

√ segments of umbilical cord course between amnion + chorion unprotected by Wharton jelly / placenta
√ splayed umbilical vessels at periphery of placenta

Associated with:

(a) multiple gestation, uterine anomaly, IUD
(b) congenital anomalies (in 5.9–8.5%):
asymmetric head shape, spina bifida, esophageal atresia, obstructive uropathy, VSD, cleft palate

Cx:
(1) IUGR
(2) Preterm labor
(3) Placental abruption

Risk:
(1) Cord compression
(2) Rupture of cord with traction during delivery
(3) Vasa previa
(4) Neonatal demise

Table of Dose, Energy, Half-Life, Radiation Dose					
Organ	*Pharmaceutical*	*Dose*	*keV*	$T_{½}$ *phys*	$T_{½}$ *bio*
Brain	^{99m}Tc-pertechnetate	10–30 mCi	140	6 hr

	99mTc-glucoheptonate	15–20 mCi	140	6 hr	
	99mTc-mercapto-acetyltriglycine	10 mCi	140	6 hr	
	131I-Hippuran	250 µCi	365*	8 d	18 min
	123I-Hippuran	1 mCi	159	13.2 hr	
Thyroid	99mTc-pertechnetate	5–10 mCi	140	6 hr	
	123I	50–200 µCi	159	13.2 hr	
	125I	30–100 µCi	27, 35	60 d	
	131I	30–100 µCi	365*	8 d	
Testes	99mTc-pertechnetate	10 mCi	140	6 hr	
Gastric mucosa	^{99m}Tc-pertechnetate	50 µCi / kg	140	6 hr	
Gallium	^{67}Ga-citrate	3–5 mCi	93, 184, 296, 388	3.3 d	
WBC	^{111}In-oxine	550 µCi	173, 247	2.8 d	
	$^{9^{9m}}$Tc-Ceretec	10–20 mCi	140	6 hr	
mnemonic:	* = as many days as in a year				

Radiation Dose to Critical Organs		
Radiopharmaceutical	*Critical Organ*	*rad/mCi*
^{131}I	Thyroid	1,000
^{125}I	Thyroid	900
^{111}In-oxine WBC	Spleen	26
^{123}I	Thyroid	15
^{111}In-DTPA	Spinal cord	12
^{201}Tl	Kidney	1.5
^{67}Ga-citrate	Colon	1.0
^{99m}Tc-MAA	Lung	0.4
^{99m}Tc-albumin microspheres	Lung	0.4
^{99m}Tc-DISIDA	Large bowel	0.39
^{99m}Tc-sulfur colloid	Liver	0.33
^{99m}Tc-pertechnetate	Intestine	0.3
	Thyroid	0.15
^{99m}Tc-glucoheptonate	Kidney	0.2
^{99m}Tc-pertechnetate (+ perchlorate)	Colon	0.2
^{99m}Tc-pyrophosphate	Bladder	0.13
^{99m}Tc-phosphate	Bladder	0.13
^{99m}Tc DTPA	Bladder	0.12
^{99m}Tc–tagged RBCs	Spleen	0.11
^{99m}Tc-albumin	Blood	0.015
^{133}Xe	Trachea	

Pediatric Dose

Actual doses for pediatric patients may vary in different institutions based on empirical data. As rough guidelines use:

1. Clark's rule (body weight):
   $Dose_{Ped} = Body\ weight\ [in\ lbs]\ /\ 150 \times Dose_{Adult}$
2. Young's rule (child up to age 12):
   $Dose_{Ped} = Age\ of\ child\ /\ (Age\ of\ child + 12) \times Dose_{Adult}$
3. Surface area:
   $Dose_{Ped} = (weight\ [in\ kg]^{0.7}\ /\ 11)\ /\ 1.73 \times Dose_{Adult}$

Lactating Patients

1. Nursing mothers must be counseled about the need to interrupt / discontinue breast feeding
2. Pumped milk may be refrigerated and used after the radioactivity has decayed

Complete cessation of breast feeding:

^{67}Ga-citrate

^{131}I-sodium iodide therapy

Interruption of breast feeding for 12 hours:

^{99m}Tc-macroaggregated albumin

^{99m}Tc-labeled RBCs (in vivo labeling)
^{111}In-labeled WBCs

Interruption of breast feeding for 24 hours:

^{99m}Tc-pertechnetate
^{123}I-metaiodobenzylguanidine
^{99m}Tc-labeled WBCs

Interruption of breast feeding for 168 hours:

^{210}Tl-chloride

QUALITY CONTROL OF RADIOPHARMACEUTICALS

◊ Quality control logs should be kept for 3 years!

Production of Radionuclides

Reactor-produced Radionuclides

◊ Not carrier free = contamination with other forms
» Thermal neutrons captured by stable nuclides
» Used to produce standard generators

(1) ^{99}Mo/^{99m}Tc generator

(parent) (daughter)

^{99}Mo → ^{99m}Tc → ^{99}Tc → ^{99}Ru

67 hours 6 hours 2.1 x 105 years stable

glass column filled with aluminum (Al_2O_3); parent and daughter isotopes are firmly absorbed onto aluminum at top of column; daughter isotope can be separated / eluted by passing isotonic oxidant-free NaCl through the column

(2) ^{81m}Kr generator

(parent) (daughter)

^{81}Rb → ^{81m}Kr → ^{81}Kr

4.7 hours 13 seconds stable

Accelerator / Cyclotron-produced Radionuclides

◊ Generally carrier-free product
• collision of charged particles (protons, deuterons, helium, alpha particles) with target nuclide
• used to produce ^{67}Ga, ^{123}I, ^{201}Tl

Fission-produced Radionuclides

◊ Carrier-free product
• splitting of a heavy nucleus into smaller nuclei
• used to produce ^{131}I, ^{99}Mo

Radionuclide Impurity

= amount (µCi) of radiocontaminant per amount (µCi/mCi) of desired radionuclide

^{99}Mo Breakthrough Test

Test frequency: with every elution

(a) NRC allowable contamination of 1÷1,000
= 1 μCi ^{99}Mo per 1 mCi of ^{99m}Tc
(b) USP limit of 0.15 μCi ^{99}Mo per 1 mCi ^{99m}Tc
(c) < 5 μCi ^{99}Mo per administered dose (NRC dropped this requirement, but nonagreement states may still require this)
(d) chemical evaluation: ^{99}Mo contaminated eluate forms colored complexes with phenylhydrazine (for reactor product generators)

- measured in dose calibrator with lead shielding of vial (filters 140 keV but permits 740 and 780 keV of ^{99}Mo to pass through)

Effect of impurity: increased radiation dose, poor image quality

Radiochemical Impurity

Test frequency: with every elution

Precise registration of different compounds of ^{99m}Tc, eg,

› hydrolyzed reduced technetium (HR Tc) a radiocolloid [$TcO(OH)2 \bullet H_2O$]
Limit: < 2% (presently no legal limit)
› free pertechnetate $[TcO^4]^{-1}$

- can be monitored by paper chromatography

Effect of impurity with hydrolyzed reduced Tc:
RES uptake, poor image quality, increased radiation dose

Chemical Impurity

Chemicals from elution process are restricted in their amount (NRC limit):

^{99m}Tc: < 10 μg Al^{3+} per 1 mL eluate if radionuclide from fission generator; < 20 μg Al^{3+} per 1 mL eluate if radionuclide from thermal activation generator

Aluminum Ion Breakthrough Test:

Test frequency: with every elution

- one drop of generator eluate placed on one end of special test paper containing aluminum reagent
- equal-sized drop of a standard solution of Al^{3+} (10 ppm) is placed on other end of strip
- if color at center of drop eluate is lighter than that of standard solution, the eluate has passed the colorimetric test

Effect of impurity: degradation of image quality

Radiopharmaceutical Sterility and Pyrogenicity

USP XX Test

Monitor rectal temperature of 3 suitable rabbits after injection of material via ear vein

Acceptable results: no rabbit shows a rise of > 0.6°C; total rise for all three rabbits < 1.4°C

Limulus Amoebocyte Lysate Test (LAL)

◊ Highly specific for Gram-negative bacterial endotoxins, sensitivity 10 x greater than USP XX test

Amoebocyte = primitive blood cell of horseshoe crab (Limulus polyphebus); lysate

	formed by hydrolysis of amoebocyte
Positive result:	in the presence of minute amounts of endotoxin LAL forms an opaque gel; response to other pyrogens (particulate contaminations, chemicals) doubtful

QUALITY CONTROL OF CALIBRATORS

Quality Control for Dose Calibrators

Test	*When*	*Limit*	*Test Isotopes*
Constancy	daily,*	< ±5%	^{137}Cs
Channel check	daily,*	< ±5%	^{137}Cs
Linearity	quarterly,*	< ±5%	^{99m}Tc
Accuracy	annually,*	< ±5%	^{137}Cs, ^{57}Co, ^{133}Ba
Geometry	*	< ±1.6%	^{99m}Tc
* = after install / repair			

Dose Calibrator

= gas ionization chamber → transforms photon flux into current with digital readout

Disadvantages:

(1) open top geometry

(2) nonlinearity between photon energy and measured current (corrected with a calibration factor)

Constancy = Precision

= reproducibility over time

Test frequency: daily

Method: measurement of a long-lived source, usually 137Cs standard

Evaluation: measurement must fall within ± 5% of the calculated activity

Linearity

= accurate measurement over large range of activity levels

Test frequency: 4 x per year

Method: 1 mCi source activity is measured every 4 hours for 10 / more measurements (down to 10–100 μCi)

Evaluation: measurements must fall within ± 5% of the calculated physical decay curve

Accuracy

Test frequency: annually

Method: measurements of three different activity standards whose amount is certified by the National Bureau of Standards (NBS); standard values are decayed mathematically to calibrator date

^{99m}Tc: 140 keV, half-life of 6.01 hr

^{57}Co: 123 keV, half-life of 270 d

^{133}Ba: 356 keV, half-life of 10.5 yr

^{137}Cs: 662 keV, half-life of 30.1 yr

Evaluation: measurements must fall within expected range

Geometry

= to ensure that measurement is not dependent upon location of tracer within ionization chamber (usually done by manufacturer)

Test frequency: at installation / after factory repair / recalibration

Method: 0.5 mL of ^{99m}Tc (activity 25 mCi) is measured in a 3-mL syringe; syringe contents are then diluted with water to 1.0 mL, 1.5 mL, and 2.0 mL and each level remeasured; test is repeated with a 10-mL glass vial

QUALITY CONTROL FOR SCINTILLATION CAMERA

Quality Control for Gamma Cameras

Test	*When*	Test Result
Peaking	daily	^{99m}Tc and ^{57}Co
Energy resolution	daily	< 14% at FWHM
Extrinsic field uniformity	daily	< 5% RMS variation
Bar phantom	weekly	visual assessment
Field uniformity	monthly	visual assessment
Center of rotation	monthly	visual assessment
Jaczak phantom	quarterly	visual assessment

Peaking

= ensures that window of pulse height selector is correctly set to desired photopeak

(a) for ^{99m}Tc source: between 137 and 143 keV

(b) for ^{57}Co source: between 117 and 123 keV

Frequency of quality control: daily

Field Uniformity

= ability of camera to reproduce a uniform radioactive distribution = variability of observed count density with a homogeneous flux

(a) Integral uniformity = maximum deviation

(b) Differential uniformity = maximum rate of change over a specified distance (5 pixels)

Causes for nonuniformity:

(1) High kilovoltage drift of photomultiplier tubes
(2) Physical damage to collimator
(3) Improper photopeak setting
(4) Contamination

Frequency of quality control: daily

Evaluation:

(1) Compare uncorrected with corrected images. Note acquisition time!
(2) Store correction flood
(3) Rerecord image with corrected flood + check for uniformity

(4) Variation in image should be < 5% RMS

Intrinsic Field Uniformity Test

(without collimator)

1. Remove collimator + replace with lead ring (to eliminate edge packing)
2. Place a point source at a distance of at least 5 crystal diameters from detector (4–5 feet for small, 7–9 feet for large crystals)
3. Point source contains 200–400 μCi of ^{99m}Tc for minimal personnel exposure (avoid contamination of crystal)
4. Set count rate below limit of instrument (< 30,000 counts)
5. Adjust the pulse height selector to normal window settings by centering at 140 keV with a window of 15% (for ^{99m}Tc studies only)
6. Use the same photographic device
7. Acquire 1.25 million counts for a 10" field of view, 2.5 million counts for a 15" field of view
8. Register counts, time, CRT intensity, analyzer settings, initials of controller

Extrinsic Field Uniformity Test

(with collimator on)

1. Collimator is kept in place
   - ◊ Only 1 of 2,000 gamma rays that reach the collimator are transmitted to the sodium iodide crystal!
2. Sheet source / flood of 2–10 mCi activity is placed on collimator
   (a) fillable floods: mix thoroughly, avoid air bubbles, check for flat surface
   (b) nonfillable: commercially available ^{57}Co source
3. Other steps as described above

Spatial Resolution / Linearity

A. SPATIAL RESOLUTION

= parameter of scintillation camera that characterizes its ability to accurately determine the original location of a gamma ray on an X,Y plane; measured in both X and Y directions; expressed as full width at half maximum (FWHM) of the line spread function in mm

(a) intrinsic spatial resolution
(b) system spatial resolution

B. INTRINSIC SPATIAL LINEARITY

= parameter of a scintillation camera that characterizes the amount of positional distortion caused by the camera with respect to incident gamma events entering the detector

(a) differential linearity = standard deviation of line spread function peak separation (in mm)
(b) absolute linearity = maximum amount of spatial displacement (in mm)

Frequency of quality control: every week

Method:

1. Mask detector to collimated field of view (lead ring)
2. Lead phantom is attached to front of crystal

(a) Four-quadrant bar pattern (3 pictures each after 90° rotation to test entire crystal)
(b) Parallel-line equal-spacing (PLES) bar pattern [2 pictures]
◊ Change bar direction angles weekly
(c) Smith orthogonal hole test pattern (OHP) [one picture only]
(d) Hine-Duley phantom [2 pictures]

3. Set symmetric analyzer window to width normally used
4. Place a point source (1–3 mCi) at a fixed distance of at least 5 crystal diameters from detector on central axis (remove all sources from immediate area so that background count rate is low)
5. Acquire 1.25 million counts for a small field, 2.5 million counts for a large field on the same media used for clinical studies
6. Record counts, time, CRT intensity, analyzer setting, initials of controller

(All new cameras are equipped with a spatial distortion correction circuit)

Evaluation:
visual assessment of (1) Spatial resolution over entire field (2) Linearity

Intrinsic Energy Resolution

= ability to distinguish between primary gamma events and scattered events; performed without collimator; expressed as ratio of photopeak FWHM to photopeak energy (in %)

Limit: 11% for SPECT, 14% for some planar cameras

Frequency of quality control: daily (may be weekly for some cameras)

CRT-output / Photographic Device

(1) Check for dirt, scratches, burnt spots on CRT face plates
(2) Adjust gray scale + contrast settings to suit film

SPECT QUALITY CONTROL

= SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY

= gamma cameras rotating about a pallet supporting the patient obtain 60–120 views over 180° / 360° rotation with typically a field of view of 40–50 cm across the patient and 30–40 cm in axial direction

Spatial resolution: ~8 mm for high-count study

SPECT Uniformity

1. 64 x 64 word matrix = 30 million count flood with collimator, orientation and magnification same as patient study
2. ^{57}Co sheet source with < 1% uniformity variance is necessary
3. 128 x 128 word matrix = 120 million count flood with collimator, orientation, magnification same as patient study

Frequency of quality control: weekly

Center of Rotation (COR)

1. ^{99m}Tc-filled line source (5–8 mCi) positioned 3–5 cm off the center of rotation while keeping scanning palette out of field of view
2. Direction of rotation to be the same as in patient study

3. Number of steps (32, 64, or 128) to be the same as in patient study
4. Time per step such that at least 100K counts are acquired
5. COR must be done with same collimator, orientation, and magnification as patient study

Frequency of quality control: weekly

Jaczak Phantom SPECT Study

tests multiple camera systems with a final image

- phantom contains multiple objects of various sizes (hot and cold rods and cold balls)
- final reconstructed image is visually assessed

SPECT Sources of Artifacts

1. Scanning palette in field of view
2. Collimator shifting + rotation on camera face
3. Noncircular orbit of camera head
4. PMT failure
5. PMT uncoupling
6. Cracked crystal
7. Improper peaking of camera

SOURCES OF ARTIFACTS

A. Attenuator between source and detector

Materials: cable, lead marker, solder dropped into collimator during repair, belt buckle / watch / key on patient, defective collimator

(a) at time of correction flood procedure:
√ hot spot

(b) after correction flood procedure:
√ cold spot

B. Cracked crystal
√ white band with hot edges

C. PMT failure + loss of optical coupling between PMT + crystal
√ cold defect

D. Problems during film exposure + processing
1. Double exposed film
2. Light leak in multiformat camera
3. Water lines from film processing
4. Frozen shutter:
√ part of film cut off
5. Variations in film processing

E. Improper window setting
1. Photopeak window set too high:
√ hot tubes
2. Photopeak window set too low:
√ cold tubes

F. Administration of wrong isotope
√ atypically imaged organs

G. Excessive amounts of free ^{99m}Tc-pertechnetate
√ too much uptake in choroid plexus, salivary glands, thyroid, stomach

H. Faulty Injection Technique
eg, inadvertently labeled blood clot in syringe leading to iatrogenic pulmonary emboli

I. Contamination with radiotracer
on patient's skin, stretcher, collimator, crystal

J. CRT problems
1. Burnt spot on CRT phosphor
2. Dirty / scratched CRT face plates

POSITRON EMISSION TOMOGRAPHY

= PET = technique that permits noninvasive in vivo examination of metabolism, blood flow, electrical activity, neurochemistry

Concept: measurement of distribution of a biocompound as a function of time after radiolabeling and injection into patient

Labeling: PET compounds are radiolabeled with positron-emitting radionuclides

Physics:

^{18}F = positron-emitting (β+) radionuclide → positron matter-antimatter annihilation reaction with an electron (β–) → formation of **annihilation photons** (511 keV each) emitted in exactly opposite directions

Detection of positron annihilation photons:

simultaneous arrival of dual photons at detectors (bismuth germanate-68) on opposite sides of the patient (= electronic collimation through **coincidence circuitry**)

N.B.: lead collimators not necessary (= advantages in resolution + sensitivity over SPECT); spatial reconstruction similar to transmission CT

Radionuclide Production in PET

in nuclide generator / particle accelerator (positive / negative ion cyclotron; linear accelerator)

Expected amount of radionuclide: 500–2,000 mCi

Generator characteristics:

beam energy (radionuclide production rate increases monotonically with beam energy), beam current (production rate directly proportional to beam current), accelerated particle, shielding requirement, size, cost

Radiopharmaceutical Production in PET

(1) Initialize accelerator, setup
(2) Irradiation
(3) Synthesis
(4) Sterility test, compounding

Sensitivity of PET

= fraction of radioactive decays within the patient that are detected by the scanner as true events (measured in counts per sec per microcurie per milliliter)

◊ 30–100 times more sensitive than SPECT ← electronic collimation as opposed to lead

collimation!

Resolution of PET

= resolving power = smallest side-by-side objects that can be distinguished as separate objects in images with an infinite number of counts (measured in mm); determined by
- › distance a positron travels before annihilation occurs (usually 0.5–2 mm depending on energy)
- › angle variation from 180° (±5° = 0.5 mm)
- › physical size of detector (1–3 mm)

◊ Typical spatial resolution: 4–7 mm (reconstructed spatial resolution = 5–6 mm full width at half maximum in phantom measurements)

◊ In clinical practice spatial resolution is about 10 mm

Detection dependent on:

(1) Tumor size
(2) FDG activity
(3) Tumor-to-background ratio
(4) Effect of motion

◊ A smaller than 1 cm lesion can be detected when conditions are favorable

Radioactivity Distribution in PET

Pixel values proportional to radioactivity per volume

Unit: mg of glucose per minute per 100 g tissue

Imaging time: 1–10 min

Common Radiopharmaceuticals in Positron Emission Tomography

Isotope		*Use*	*Half-life (min)*	*Average Positron Energy (keV)*	*Typical Reaction*	*Yield at 10 MeV (mCi/μA EOSB)*
Rubidium	^{82}Rb		1.23	1,409	Sr/Rb generator	—
Fluorine	^{18}F	glucose metabolism	110.00	242	$^{18}O(p,n)^{18}F$	120
Oxygen	^{15}O	O_2, H_2O, CO_2, CO	2.1	735	$^{15}N(p,n)^{15}O$	70
Nitrogen	^{13}N	perfusion of NH_3	10.00	491	$^{13}C(p,n)^{13}N$	110
Carbon	^{11}C	carbon metabolism	20.3	385	$^{14}N(p,\alpha)^{11}C$	85

p = proton injected; n = neutron ejected; = alpha particle; EOSB = end of saturated bombardment (infinitely long irradiation at which time the numbers of radionuclides produced equals the number of radionuclides that are decaying) per microampere of beam current (= number of particles per sec emerging from accelerator and impinging on target material)

Organ-specific Concentration

(a) heart, brain: contain little glucose-6-phosphatase → resulting in high concentrations of ^{18}F-fluorodeoxyglucose
- › metabolic rate of glucose is proportional to phosphorylation rate of FDG

(b) liver: abundance of glucose-6-phosphatase + low levels of hexokinase resulting in rapid clearing of FDG

(c) urine: 50% of injected activity excreted unmetabolized in urine

(c) neoplasm: enhanced glycolysis with increased activity of hexokinase + other enzymes

FDG Distribution

Intense accumulation in: brain, myocardium, intrarenal collecting system + ureter + bladder

Moderate accumulation in: liver, spleen, bone marrow, renal cortex, mediastinal blood pool

Sites of variable physiologic uptake:

@ **Brown (baby) fat**
= highly specialized heat producing tissue in response to cold exposure / ingestion of food (= nonshivering / diet-induced thermogenesis)
Histo: increased vascularity + high density of mitochondria → generation of heat
Location:
suboccipital cervical and supraclavicular region; paraspinal region of neck and chest; intercostal spaces at costovertebral junction; lipomatous hypertrophy of the interatrial septum, axilla; retrocrural; mediastinum adjacent to thoracic vessels; perinephric fat
◊ Keep uptake room warm; use warm blankets

@ Brain & spinal cord intense uptake in cerebral > cerebellar cortex, basal ganglia, thalamus; moderate uptake in cervical + upper thoracic spine
◊ Often used as a reference for semiquantification

@ Bone marrow usually mild uptake with homogeneous distribution; moderate to intense uptake after chemotherapy + treatment with GCsF (granulocyte colony-stimulating factor) + in anemic patients

@ Nasopharynx Waldeyer ring (negative correlation between age and uptake intensity); sublingual glands (mucous gland with inverted V-shaped uptake at floor of mouth)

@ Thyroid gland moderate / intense uptake in ⅓ of euthyroid patients; consistent with chronic thyroiditis, Graves disease

@ Thymus mild to moderate intensity; rebound hyperplasia + increased uptake for 3 months to 1 year

@ Digestive tract
Cause: metabolically active smooth muscle + mucosa, swallowed secretions, microbial uptake
› esophagus: more intense at GE junction
› stomach: SUV usually < 3.8, may be as high as 5.6
› small bowel: isolated foci with SUV < 4
› colon: right colon may have an SUV as high as 10 (lymphatic cells); moderate to intense uptake in rectum
◊ Enemas do not reduce uptake!

@ Liver hepatocytes have a higher concentration of phosphatase enzymes → resulting in dephosphorylation of FDG-6-phosphate + a faster FDG washout
◊ Delayed imaging for indeterminate liver lesion

@ Spleen diffuse uptake as physiologic reaction to extrasplenic infection, granulocyte colony-stimulating factor therapy, anemia (extramedullary hematopoiesis)

@ Skeletal muscle Major energy sources: fat and glucose (at rest 9÷1, at low exercise 6÷4, at high exercise 1÷9);
› Diabetics take medication, have morning meal within 4 hours prior to imaging
◊ No muscle effort for 24 hours before PET imaging
◊ No chewing gum / tobacco, reading, talking during uptake phase
Location: extraocular muscles; paravertebral muscles in neck + thorax (stress-

induced, patient anxiety); intrinsic laryngeal muscles (speech); diaphragm (hyperventilation, forced respiration)

@ Myocardium free fatty acids are predominant metabolic substrate (50–70%); insulin → increases glucose transporters (GLUT-1 + GLUT-2) → glucose utilization increases after carbohydrate (glucose, lactate) intake
  ◊ Fasting (≥ 4 hours since last meal) switches to predominantly fatty acid metabolism:
    › fall of plasma insulin levels → ⇑ in lipolysis in peripheral tissue + ⇑ fatty acid levels in plasma
    › decrease of glucose transport into myocytes

@ Genitourinary tract pooling in upper pole calix, dilated redundant ureter, bladder diverticulum, endometrial uptake, testes (young patients)
  ◊ Catheterization of bladder to reduce activity + filling with 200 mL of saline just before pelvic imaging

Sites of benign pathologic uptake:

@ Healing bone (for months)

@ Lymph nodes active granulomatous disease (TB, sarcoidosis), infection, recent instrumentation

@ Joints degenerative / inflammatory joint disease (often in sternoclavicular + acromioclavicular + shoulder joints), tendinopathy, enthesopathy, bursitis

@ Infection / inflammation leukocytic infiltration in abscess, pneumonia, sinusitis, granulomatous infection, talc pleurodesis, acute pancreatitis, healing by secondary intention, wound repair, resorption of necrotic debris, hematoma, fistula

Effect of Blood Glucose Level on FDG-Uptake	
Blood Glucose Level [mg/dL]	*Maximum SUV Uptake in Brain*
< 80	13,3 ± 3.7
80–110	12.1 ± 3.2
110–150	9.8 ± 2.4
150–200	7.8 ± 3.1
> 200	4.8 ± 1.8

Focal areas of abnormally increased FDG uptake are suspicious for malignant disease secondary to metabolic alterations that precede morphologic changes.

PET Imaging in Oncology

FDG = glucose analogue tracer 2-[^{18}fluorine]-fluoro-2-deoxy-D-glucose

Pathophysiology:

serum glucose competes with FDG for entry into tumor cells → FDG becomes phosphorylated by hexokinase (malignant cells have increased hexokinase activity → high rate of glycolysis) → FDG-6-phosphate does NOT enter glycolysis pathway → ^{18}FDG trapped intracellularly

Preparation:

(1) fasting for 6 (–18) hours

(2) in diabetics blood glucose level < 200 mg/dL

Reason: FDG tumor uptake is diminished by a competitively elevated serum glucose level

FDG PET scanning should be delayed for 8–12 weeks after surgery / radiation therapy to reduce FDG-avid postsurgical changes / radiation effects that can interfere with scan interpretation!

Dose: 15 (range, 13.5–16.5) mCi
Physical half-life: 110 min
Imaging time: 45–60–70 min after administration (trade-off between decreasing background activity and declining counting statistics)
Distortion correction in whole-body imaging:
attenuation correction can be achieved with a transmission scan before / after emission image acquisition at each corresponding bed position

Standardized Uptake Value (SUV):

= target-to-background measure to allow comparison within and between different patients and diseases normalized to body mass

$SUV = A_{mea}$ [mCi/mL] / (A_{inj} [mCi] / W [kg])

A_{mea}	=	decay-corrected regional radiotracer concentration in volume of interest
A_{inj}	=	injected radiotracer activity
W	=	body weight in kilograms

N.B.: SUV calculations may alternatively be based on body surface area / lean body mass (corrected for body fat as it elevates SUV spuriously)

Typical values:
soft tissue 0.8
blood pool (at 1 hour) 1.5–2.0
liver 2.5
renal cortex 3.5
malignant neoplasm 2–20
non-small cell lung cancer 8.2
breast cancer 3.2
PET - visual assessment: 98% sensitive, 69% specific
PET - SUV measurement: 92% sensitive, 90% specific

FDG Uptake in Benign Tumors / Tumorlike Conditions	
Neck	
Thyroid adenoma	Hyperplastic thyroid nodule
Pleomorphic adenoma	Warthin tumor
Abdomen	
Adrenal hyperplasia	Adrenal adenoma
Pheochromocytoma	Myelolipoma
Bone	
Fibrous dysplasia	Giant cell tumor
Paget disease	Nonossifying fibroma
Eosinophilic granuloma	Aneurysmal bone cyst
Enchondroma	Myositis ossificans

Low FDG Uptake in Malignant Tumors	
Bronchoalveolar cell ca.	Carcinoid
Marginal zone lymphoma (eg, MALToma)	Low-grade HCC
Low-grade sarcoma	Chondrosarcoma
Renal cell carcinoma	Necrotic tumor
Sclerotic bone metastasis	Mucinous tumor

Response Evaluation in PET Imaging

(1) Reproduce the same time delay between injection and imaging as used at baseline imaging
(2) Consider partial volume effect in small residual tumor = risk of underestimation of SUV values
(3) Time delay after last chemotherapy use might influence response assessment

HYBRID PET/CT IMAGING

= combination of high-resolution PET scanner + CT scanner allows acquisition of 3-dimensional images

Indications:

1. Lung cancer
2. Breast cancer
3. Colon cancer recurrence
4. Head and neck cancer
5. Brain tumor

Lymphoma

= histologically heterogeneous group of cancers derived from cells of immune system
Prevalence: 5% of all cancers in USA
Prognosis: 6.0÷100,000 (= 20,150) deaths annually in 2013
√ enlargement of lymph nodes / secondary lymphoid tissues
√ may arise from almost any organ = extranodal lymphoma
Factors in FDG uptake:

› histologic features (Hodgkin disease versus NHL)
› grade (indolent versus aggressive NHL)

PET/CT Artifacts	
Misregistration = located to inappropriate anatomic structure	
Respiration	Patient motion
Bowel motility	Bladder distention
Attenuation-correction Artifact = artificial activity increase	
Metallic objects	Vertebroplasty cement
Contrast media	

› viable tumor cell fraction
› tumor cell proliferation
› upregulation of glucose metabolism
› salvage pathways and tumor-specific pathways
› local perfusion → substrate delivery to the cancer cell
› presence of hypoxia

Extranodal Lymphoma

Prevalence: ⅓ of all lymphomas
Location: skin, stomach, small intestine (most common)
(a) primary extranodal lymphoma = early stage I (65%), stage II (74%) disease
(b) secondary extranodal lymphoma = sign of more advanced stage III or IV disease

Malignant Lymphoma / NHL

Malignancy grade:
√ uptake lower for indolent compared to aggressive lymphoma (SUV > 10 likely to have aggressive disease)
√ aggressive transformation (= change from low-grade to high-grade lymphoma) in 5–10%; requires repeat biopsy

Staging: PET/CT tends to upstage tumors
√ splenic > hepatic uptake indicates splenic involvement
√ heterogeneous scattered uptake in bone marrow involvement

Pitfalls:
(a) gastric + cerebral lymphoma difficult to detect ← physiologic accumulation
(b) increased uptake after treatment with granulocyte colony-stimulating factor (GCSF)
(c) uptake in brown fat of mediastinum
(d) uptake in Lnn with sarcoid involvement
(e) physiologic colonic uptake may be mistaken for lymphoma
(f) small-volume lesions may be undetectable

Response to Rx:
(1) Early response assessment after one cycle of chemotherapy has high prognostic value
(2) Residual abnormal FDG uptake after therapy suggests poor prognosis!

Hodgkin Lymphoma

97% of disease sites identified by FDG PET
◊ Lesion contiguity is CHARACTERISTIC!

IMMUNOSCINTIGRAPHY

= imaging with monoclonal antibodies ([= homogeneous antibody population directed against a single antigen [eg, cancer cell]) and labeled with a radiotracer

Hybridoma technique:
antibody-producing B lymphocytes are extracted from the spleen of mice that were immunized with a specific type of cancer cell; B lymphocytes are fused with immortal myeloma cells (= hybridoma)

Agents:
^{111}Indium-satumomab pendetide = ^{111}In-CYT-103 (OncoScint™ CR/OV) = murine monoclonal antibody product derived by site-specific radiolabeling of the antibody B27.3-GYK-DTPA conjugate with ^{111}In

Use: detection + staging of colorectal + ovarian cancers

Dose: 1 mg of antibody radiolabeled with 5 mCi of ^{111}In injected IV

Biodistribution: liver, spleen, bone marrow, salivary glands, male genitalia, blood pool, kidneys, bladder

Imaging: 2 sets of images 2–5 days post injection + 48 hours apart

LYMPHANGIOSCINTIGRAPHY

Lymphangioscintigraphy Technique

^{99m}Tc-albumin solution injected intradermally to raise a wheal in 1st interdigital web space of both feet / hands

Dose: 500 µCi (18.5 MBq); 92–98% of albumin are tightly bound to ^{99m}Tc

Volume: 0.05 mL; > 98% of albumin macromolecules (molecular weight of 60 kDa) enter lymphatic vessels

Imaging: at 1 min, 10–40 min and 3–5 hr with parallel-hole collimator passing over patient

Transport Index Score (TIS)

= semiquantitative measurement of objective + subjective criteria of peripheral lymphatic radiotracer transport

TIS = K + D + 0.04•T + N + V
K = transport kinetics = degree of transport delay
D = radionuclide distribution pattern = degree of dermal backflow
T = timing of radionuclide appearance in regional lymph nodes (in minutes normalized for 200 min as maximal delay)
N = demonstration + intensity of lymph nodes
V = demonstration + intensity of lymphatic collectors

BRAIN SCINTIGRAPHY

Blood-Brain Barrier (BBB) Agents

= old-style agents require a disruption of blood-brain barrier to diffuse into brain

A. ^{99m}Tc-glucoheptonate
   15–20 mCi bolus injection in < 2 mL saline; 30 flow images of 2-second duration; static image of 1 million counts after 4 hours; delayed image after 24 hours (higher target-to-background ratio than DTPA)
B. ^{99m}Tc DTPA
C. ^{201}Thallium: best predictor for tumor burden

Brain Perfusion Agents

= lipophilic agents rapidly crossing blood-brain barrier with accumulation in brain

Applications: any disease in- / decreasing regional perfusion

1. Brain death (most common)
2. Refractory seizure disorder
3. Dementia

potentially: stroke, receptor imaging, activation studies, tumor recurrence

^{99m}Tc HMPAO

= hexamethylpropylene amine oxime = exametazime

Product: Ceretec®

Dose: 10–30 mCi

Imaging: as early as 15 min post injection

Pharmacokinetics: lipophilic radiopharmaceutical distributes across a functioning blood-brain barrier proportional to cerebral blood flow; no redistribution

Indication: acute cerebral infarct imaging before evidence of CT / MR pathology; positive findings within 1 hour of event

^{99m}Tc-ECD

= ethyl cysteinate dimer = bicisate

Product: NEUROLITE®

Dose: 10–30 mCi

Imaging: 30–60 min post injection

^{123}I-Iofetamine

= N-isopropyl-p[^{123}I]iodoamphetamine iodine = ^{123}I-IMP

Product: Spectamine®

Pharmacokinetics:
initially distributes proportional to regional cerebral blood flow with increased flow to basal ganglia and cerebellum; homogeneous uptake in gray matter; ↓ activity in white matter; redistribution over time

√ activity in an area of initial deficit on reimaging (after 4 hours) implies improved prognosis

Increased Perfusion in Radionuclide Angiography

1. Primary / metastatic brain tumor
2. AVM, large aneurysm, tumor shunting

3. Luxury perfusion after infarction
4. Infection: eg, herpes simplex encephalitis
5. Extracranial lesions: bone metastasis, fibrous dysplasia, Paget disease, eosinophilic granuloma, fractures, burr holes, craniotomy defects

Decreased Perfusion in Radionuclide Angiography

1. Arterial stenosis
2. Alzheimer disease:
   √ bilateral temporoparietal hypoperfusion
3. Most tumors
4. Hemorrhage
5. Subdural hematoma

Indications for Radionuclide Angiography of Brain

Seizures

Abnormal cerebral radionuclide angiography within 1 week of seizure activity even without underlying organic lesion

Etiology:

(1) 35% cerebral tumors: meningioma in 34%, metastases in 17%
(2) Cerebrovascular disease (more common in > 50 years of age)
(3) Trauma, inflammation, CNS effects of systemic disease

√ transient hyperperfusion of involved hemisphere

SEIZURE FOCUS IMAGING

for localizing intractable seizures

√ focal hypoperfusion during interictal injection of tracer (less sensitive)
√ focal hyperperfusion during ictal injection of tracer (better detection)

Brain Tumor

Etiology:

√ good correlation between hyperperfusion and enlarged supplying vessels:

(1) Meningioma (increased activity in 60–80%);
(2) Metastases (increased activity in 11–23%);
(3) Vascular metastases: thyroid, renal cell, melanoma, anaplastic tumors from lung / breast

Arterial Stenosis

◊ Radionuclide angiography of limited value!

√ asymmetric decreased perfusion in acute / chronic cerebrovascular disease:

(1) Complete occlusion / > 80% stenosis of ICA: 53–80% sensitivity
(2) 50–80% stenosis of ICA: 50% sensitivity
(3) < 50% stenosis of ICA: 10% sensitivity

Problematic lesions:

(1) Bilaterally similar degree of stenosis

(2) Occlusion of MCA + unilateral ACA
(3) Vertebrobasilar occlusive disease (20% sensitivity)

Stroke

√ "flip-flop" phenomenon (= ⇓ perfusion in arterial phase, equalization of activity in capillary phase, ⇑ activity in venous phase) ← late arrival of blood via collaterals and slow washout

PET IN BRAIN IMAGING

A. REGIONAL CEREBRAL BLOOD FLOW

(a) breathing of carbon monoxide (11C and 15O), which concentrates in RBCs

(b) 133Xe inhalation / injection into ICA / IV injection after dissolution in saline: volume distribution within cerebral water space; no correction for recirculation necessary because all Xe is exhaled during lung passage, but correction for scalp + calvarial activity is required

√ washout rate of gray matter÷white matter = 4–5÷1

B. GLUCOSE METABOLISM

for measurements of metabolic rate + mapping of functional activity

(a) 11C glucose: rapid uptake, metabolization, and excretion by brain

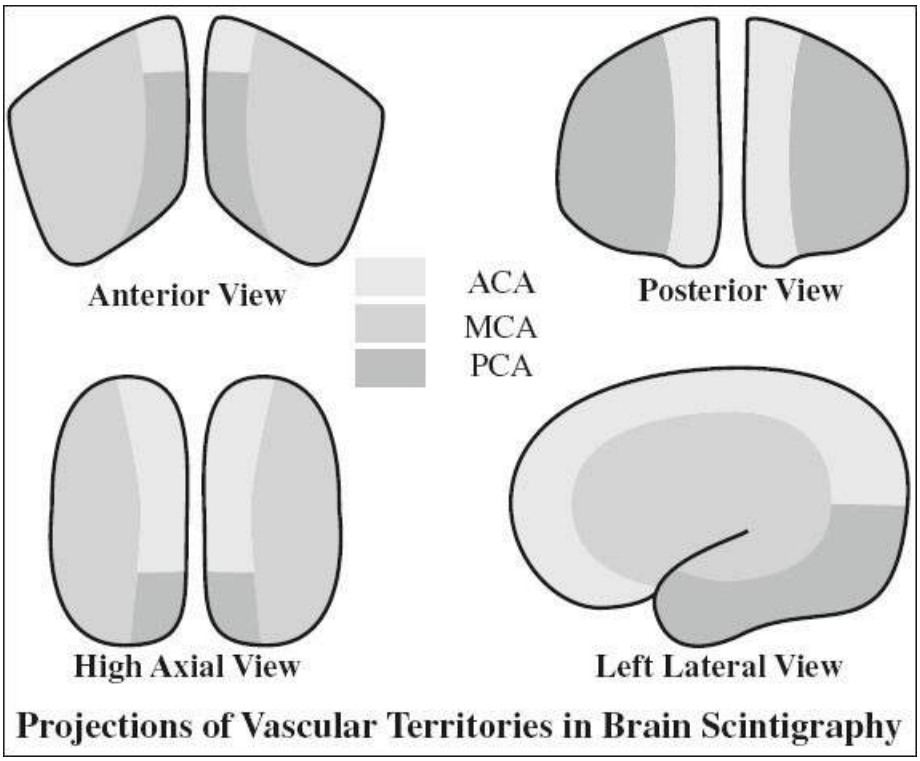
(b) ^{18}F-fluorodeoxyglucose (FDG): diffuses across blood-brain barrier + competes with glucose for phosphorylation by hexokinase → traps FDG-6-phosphate within mitochondria; FDG-6-phosphate cannot enter most metabolic pathways (eg, glycolysis, storage as glycogen) and accumulates proportional to intracellular glycolytic activity; FDG-6-phosphate is dephosphorylated slowly by glucose-6-phosphatase and then escapes cell

Indications:

1. **Focal epilepsy** prior to seizure surgery
   - √ interictal ⇓ uptake of FDG of > 20% at seizure focus (70% sensitivity, 90% for temporal lobe hypometabolism)
   - √ hypermetabolism within 30 minutes of seizure
   - √ measurement of opiate receptor density with 11C-labeled carfentanil (= high-affinity opium agonist) uptake by μ receptors (found in thalamus, striatum, periaqueductal gray matter, amygdala), which mediate analgesia and respiratory depression
2. **Alzheimer disease**

   Prevalence: 5.4 million persons in USA in 2016

   - clinical diagnosis false positive in 35% ← challenging diagnosis in earlier milder forms of the disease



Projections of Vascular Territories in Brain Scintigraphy

Histo: amyloid plaques + neurofibrillary angles (autopsy)
√ bilateral temporoparietal hypoperfusion + hypometabolism → decreased FDG uptake (92–100% sensitive)
√ sparing of sensory and motor cortex + basal ganglia + thalamus
√ atrophy of entire brain with predilection for hippocampus
DDx: frontal lobe dementia, primary progressive aphasia without dementia, normal-pressure hydrocephalus, multi-infarct dementia

3. **Parkinson disease**
= deficient presynaptic terminals with normal postsynaptic dopaminergic receptors
• clinical diagnosis in 50–70% accurate
DDx: drug-induced chorea, Huntington disease, tardive dyskinesia, progressive supranuclear palsy, Shy-Drager syndrome, striatonigral degeneration, alcohol-related cerebellar dysfunction, olivopontocerebellar atrophy
4. **Huntington disease**, senile chorea
√ hypometabolism of basal ganglia
5. **Schizophrenia**
√ abnormally reduced glucose activity in frontal lobes
√ dopamine receptors in caudate / putamen elevated to 3 x that of normal levels
6. **Stroke**, cerebral vasospasm
√ disassociated oxygen metabolism + brain blood flow

PET in Brain Tumor

Indications:
(1) Tumor grading + estimation of prognosis

◊ Apparently low-grade gliomas without contrast enhancement by CT/MR are malignant in 30%

(2) Localization of optimal biopsy site

◊ The most malignant area shows maximum of uptake

Grading and Prognosis for Gliomas			
Grade	*Uptake Ratio*	*Pathology*	*Median Survival*
0	no uptake	in 86% grade I / II	2.3 years
1	tumor ≤ normal white matter		
2	tumor > white matter and < normal cortex	in 94% grade III / IV	11 months
3	tumor ≥ normal cortex		

Unproven:

(3) Detection of recurrence versus radionecrosis

◊ Plagued by low specificity of 22% (cut-off greater than WM) and 56% (cut-off greater than cortex)

(4) Assessment of response to therapy

◊ SUV increases within weeks following radiation / chemotherapy ← ⇑ in metabolically active inflamma- tory elements + energy consumption for apoptosis

(5) Defining target volume for radiotherapy (?)

Assessment: 35–50 min post injection

› SUV

› tumor-to-white matter ratio (T/WM): 1.5

› tumor-to-cortex ratio (T/C): > 0.6

◊ Activity in tumor + reference area steadily increases with time after injection

RADIONUCLIDE CISTERNOGRAPHY

Indications:

1. Suspected normal pressure hydrocephalus
2. Occult CSF rhinorrhea / otorrhea
3. Suspected ventricular shunt malfunction

4 Porencephalic cyst, leptomeningeal cyst, posterior fossa cyst

Technique:

1. Measurement of spinal subarachnoid pressure
2. Sample of CSF for analysis
3. Subarachnoid injection of radiotracer

Normal study (completed within 48 hours):

symmetric activity sequentially from basal cisterns → up the sylvian fissures + anterior commissure → eventual ascent over cortices with parasagittal concentration

√ image lumbar region immediately after injection to ensure subarachnoid injection

√ activity in basal cistern by 2–4 hours

√ activity at vertex by 24–48 hours

√ no / minimal lateral ventricular activity (may be transient in older patients)

Agents:

1. **^{111} Indium-DTPA**
   Physical half-life: 2.8 days
   Gamma photons: 173 keV (90%), 247 keV (94%) detected with dual pulse height analyzer
   Dose: 250–500 μCi
   Radiation dose: 9 rad/500 μCi for brain + spinal cord (in normal patients)
   Imaging: at 10-minute intervals / 500,000 counts up to 4–6 hours; repeat scans at 24, 48, 72 hours
2. **^{99m} Technetium-DTPA**
   Not entirely suitable for imaging up to 48–72 hours; DTPA tends to have faster flow rate than CSF; used for shunt evaluation + CSF leak study since leak increases CSF flow
   Dose: 4–10 mCi
   Radiation dose: 4 rad for brain + spinal cord
3. **131 Iodine-serum albumin (RISA)**
   prototype agent; beta emitter
   Physical half-life: 8 days; high radiation dose of 7.1 rad/100 μCi; no longer used secondary to pyrogenic reactions
4. **169 Ytterbium-DTPA**
   Physical half-life: 32 days
   Gamma decay: 63 keV; 177 keV (17%); 198 keV (25%); 308 keV; dual pulse height analyzer set for 177 + 198 keV
   Dose: 500 μCi
   Radiation dose: 9 rad/500 mCi for brain + spinal cord (in normal patients)

CSF Leak Study

Purpose: localization of origin of CSF leak in patient with CSF rhinorrhea / otorrhea
Causes of dural fistula:
(a) traumatic: in 30% of basilar skull fractures
(b) nontraumatic: brain, pituitary and skull tumors; skull infections; congenital defects
Location of dural fistula:
cribriform plate > ethmoid cells > frontal sinus
Method:

- » Weigh cotton pledgets
- » Pledgets placed by ENT surgeon in the anterior and posterior turbinates bilaterally
- » Radiopharmaceutical injected intrathecally via lumbar puncture; immediate postinjection view of lumbar region to ensure intrathecal placement
  - ◊ Contraindicated in active meningitis / elevated intracranial pressure!
- » Pledgets removed and weighed 4–6 hours after lumbar injection
- » Pledget activity counted + indexed to weight
- » Results compared with 0.5-mL serum specimens drawn at the time of pledget removal
- » Pledget to serum count ratio of > 1.5 = evidence of CSF leak
- » With active leak patient should be placed in various positions with various maneuvers to accentuate leak

Disadvantage: low sensitivity + high FN in intermittent leak

THYROID SCINTIGRAPHY

Indications:

(1) Classification of hyperthyroidism
(2) Evaluation of solitary / dominant nodule
(3) Detection and staging of postoperative thyroid cancer
(4) Evaluation of upper mediastinal mass
(5) Evaluation of neonatal hypothyroidism
(6) Evaluation of developmental anomalies

A. SUPPRESSION SCAN
= to define autonomy of a nodule
√ suppression of a hot nodule following T3 / T4 administration is proof that autonomy does not exist

B. STIMULATION SCAN
= to demonstrate thyroid tissue suppression by hyperfunctioning nodule
√ administration of TSH documents functioning thyroid tissue (rarely done)

C. PERCHLORATE WASHOUT TEST
= to demonstrate organification defect
√ repeat measurement of radioiodine uptake following oral potassium perchlorate shows lower values if organification defect present

◊ Best interpreted by direct comparison with sonography!

^{99m}Tc-Pertechnetate in Thyroid Imaging ($^{99m}TcO_4^-$)

Physical half-life (for gamma emission): 6.03 hours
Biologic half-life: 1 day (94% decays to ^{99}Tc in 24 hours)
Decay: by photon emission of 140 keV
Quality control:
(1) < 0.1% ^{99}Mo (= 1 µCi/mCi), maximum of ^{99}Mo at 5 µCi
(2) < 0.5 mg aluminum/10 mCi ^{99m}Tc
(3) < 0.01% radionuclide impurities
Administration: oral / IV
Dose: 3–5 mCi administered IV 20 min prior to imaging (100–300 mrad/mCi)
Pharmacokinetics:
Uptake by: thyroid, salivary glands, gastric mucosa, choroid plexus
Excretion: mostly in feces, some in urine
Uptake in thyroid: 0.5–3.7% at 20 minutes (time of maximum uptake); assessment of trapping function only; NO organification; may be almost completely discharged by perchlorate
Imaging:
(a) Collimator: usually with pinhole collimator for image magnification (5-mm hole)
(b) Distance: selected so that organ makes up $^2/_3$ of field of view; significant distortion of organ periphery occurs if detector too close
(c) Counts: 200,000–300,000 counts are usually acquired within 5 min after a dose of 5–10 mCi of ^{99m}Tc-pertechnetate
(d) Image must include markers for scale + anatomic landmarks + palpatory findings

Advantages:

(1) Low cost
(2) Reduced radiation exposure
(3) Greater photon flux than iodine = detectability of small thyroid lesions (> 8 mm) is improved
(4) Excellent physical characteristics

Disadvantages:

(1) High neck background (target-to-background ratio less favorable than with iodine)
(2) Lesions with pertechnetate-iodine discordance (= hot on ^{99m}Tc-pertechnetate + cold on radio-iodine) are very rare + due to ^{99m}Tc-avid cancer
(3) Poor for substernal evaluation

^{123}Iodine

◊ Agent of choice for thyroid imaging!

Production: in accelerator; contamination with ^{124}I dependent on source (^{122}Te in ~ 5%, 123Xe in ~ 0.5%); contamination with ^{125}I increases with time elapsed after production

Physical half-life: 13.3 hours

Decay: by electron capture with photon emission at 159 keV (83% abundance) + x-ray of 28 keV (87% abundance)

Dose: 200–400 µCi orally 24 hours prior to imaging (radiation dose of 7.5 mrad/µCi)

Uptake: iodine readily absorbed from GI tract (10–30% by 24 hours), distributed primarily in extracellular fluid spaces; trapped + organified by thyroid gland; trapped by stomach + salivary glands

Excretion: via kidneys in 35–75% during first 24 hours + GI tract

Advantages:

(1) Low-radiation exposure
(2) Excellent physical characteristics
(3) Uptake + scan with one agent (organified)

Disadvantages compared with ^{99m}Tc-pertechnetate:

(1) More expensive
(2) Less available with short shelf-life
(3) More time-consuming
(4) Radionuclide impurities
(5) Higher dose to thyroid (but less to whole body)

^{131}Iodine

Indication: thyroid uptake study, thyroid imaging, treatment of hyperthyroidism, treatment of functioning thyroid cancer, imaging of functioning metastases

Production: by fission decay

Physical half-life: 8.05 days (allows storing for long periods)

Decay: principal gamma energy of 364 keV (82% abundance) + significant beta decay fraction of a mean energy of 192 keV (92% abundance)

Dose: 30–50 µCi (1.2 rad/µCi = 50 rad for thyroid)

Radiation dose: (90% from beta decay, 10% from gamma radiation) 0.6 mrad/mCi for whole body; 1.2 mrad/μCi for thyroid (critical organ)

Pharmacokinetics: identical to ^{123}I

Thyroid Agents			
	^{131}I	^{123}I	^{99m}Tc
Physical half-life	8 d	13 hr	6 hr
Main photopeak	364 keV	159 keV	140 keV
Usual dose	50–100 μCi	100–300 μCi	2–10 mCi
Absorbed dose	50–100 rad	2–5 rad	0.2–1.8 rad
Administration	PO	PO	IV
Interval to image	24 hr	6 hr	20 min

Advantages:

(1) Low cost
(2) Ectopic tissue search
(3) Uptake and scan at same time

Disadvantages:

(1) Too energetic for gamma camera, well suited for rectilinear scanner with limited resolution
(2) High radiation exposure (← beta decay) → PROHIBITS USE FOR DIAGNOSTIC PURPOSES
(3) Ectopic thyroid tissue just as well detectable with ^{123}I or ^{99m}Tc-pertechnetate

^{131}Iodine SPECT/CT

Advantage: precise localization of foci of radioactivity to anatomic structures (incremental value over planar imaging in 40%)

Indication: distinction of benign mimics from true metastatic disease

PHYSIOLOGIC ^{131}IODINE ACTIVITY

NIS = sodium (**N**) / iodide (**I**) symporter (**S**) transports 2 sodium cations (Na+) for each iodide anion (I−) into the cell

A. Thyroidal tissue
   1. after total thyroidectomy: thyroglossal duct, thyroid bed remnant
   2. Ectopic thyroid: lingual thyroid, lateral aberrant thyroid, intracardiac thyroid (struma cordis), ovarian thyroid (struma ovarii)

B. Orthotopic / ectopic extrathyroidal tissue with NIS expression
   1. Extrathyroidal tissue with NIS expression: salivary gland (parotid, submandibular), choroid plexus, lacrimal gland, nasal mucosa, thymus, breast, gastric mucosa, colon
      ◊ Breast feeding must be terminated after administration of ^{131}I.
   2. Ectopic extrathyroidal tissue with NIS expression: Barrett esophagus, Meckel diverticulum, GI duplication cyst, supernumerary breast tissue

C. Physiologic
   1. Intravascular space: cardiac blood pool, carotid ectasia

2. Hepatic metabolism: diffuse hepatic activity ← ^{131}I–labeled thyroxine ← produced by carcinoma metabolized in liver
3. Secretions of saliva, sweat, tears, nose: oropharynx, esophagus, Zenker diverticulum, poorly dissolved ^{131}I capsule, chewing gum / tobacco, external contamination
4. GI and GU excretion: colon, bladder

D. Benign disease
1. Cyst with passive diffusion: lactational duct, renal, ovarian, pleuropericardial, bronchogenic
2. Inflammation: lung, pericardium, joint, sinus, wound healing, etc.
3. Third spacing: pericardial effusion, pleural effusion, ascites, scrotal hydrocele

E. Neoplasm: meningioma, non-small cell lung carcinoma, teratoma, salivary gland + ovarian + gastric adenocarcinoma

F. Contamination: urine, feces, drooling

Iodine Fluorescence Imaging

Technique: collimated beam of 60 keV gamma photons from an 241Am source is directed at thyroid, which results in production of K-characteristic x-rays of 28.5 keV; x-rays are detected by semiconductor detector

Advantages:

(1) No interference with flooded iodine pool / thyroid meds
(2) Measures total iodine content
(3) Low radiation exposure (15 mrad) acceptable for children + pregnant women

Disadvantage: dedicated equipment necessary

PARATHYROID SCINTIGRAPHY

for the evaluation of primary hyperparathyroidism after other causes for hypercalcemia have been excluded

[Technetium-thallium Subtraction Imaging]

*** superceded by ^{99m}Tc-MIBI at most centers ***

= DUAL ISOTOPE SCINTIGRAPHY

Sensitivity: 72–92% (depending on size, smallest adenoma was 60 mg)

Specificity: 43% (benign thyroid adenomas, focal goitrous changes, Hashimoto thyroiditis, parathyroid ca., cancer metastatic to neck, lymphoma, sarcoidosis, lymph nodes also concentrate thallium)

Method:

» IV injection of 1–3.5 mCi ^{201}Tl chloride; images recorded for 15 minutes with 2-mm pinhole collimator
√ concentrates in normal thyroid + enlarged parathyroid glands (extraction proportional to regional blood flow + tissue cellularity)

» IV injection of 1–10 mCi ^{99m}Tc-pertechnetate; images recorded at 1-min intervals for 20 min
√ pertechnetate concentrates only in thyroid

» Computerized subtraction

√ focal / multifocal excess ^{201}Tl

Limitations:

(1) Unfavorable dosimetry + poor quality images of ^{201}Tl (up to 3.5 mCi, 80 keV photons)
(2) Prolonged patient immobilization (motion artifact)
(3) Processing artifacts (eg, over- / undersubtraction)
(4) Poor ^{99m}Tc thyroid uptake from interfering medications / recent iodinated contrast media
(5) Parathyroid pathology may be mimicked by coexisting thyroid disease (eg, nonfunctioning adenoma, multinodular goiter)

Indication: localization of one / more parathyroid adenomas (hyperplasia not visualized), may be more sensitive than CT / MR in detection of ectopic mediastinal parathyroid tissue and in postoperative context

^{99m}Technetium-Sestamibi (^{99m}Tc-MIBI)

Indication: recurrent hypercalcemia following previous parathyroid surgery

Sensitivity: 79–100% (smallest adenoma weighed 150 mg); 79% for early pinhole, 85% for late pinhole, 86% for subtraction, 83% for SPECT imaging

◊ adversely affected by multigland disease

◊ For unknown reasons even large tumors (2 g) may not accumulate sufficient MIBI for detection!

Pharmacokinetics:

after IV injection lipophilic cationic molecules of MIBI distribute according to blood flow → cross cell membrane by passive diffusion → concentrate intracellularly in region of mitochondria proportional to regional blood flow and cellular metabolic activity (eg, in myocardium and mitochondria-rich oxyphil cells of parathyroid gland); MIBI washes out of thyroid quickly, but is retained in abnormal parathyroids → need for dual-phase study

Physiologic distribution:

(1) Parotid gland
(2) Submandibular salivary glands (uptake in oral cavity)
(3) Thyroid gland
(4) Heart
(5) Liver
(6) Bone marrow: mild generalized uptake
(7) Thymus: mild uptake in young individuals
(8) Brown fat

( ) NO uptake in normal parathyroid glands

Advantages (over thallium):

A. Physical properties:
   › optimal gamma emission (140 keV)
   › abundant photons (high dose of 20 mCi)
   › favorable dosimetry
   › high parathyroid-to-thyroid ratio
   › unaffected by medications / iodinated contrast
B. Technical features:

› single readily available radiopharmaceutical
› simple protocol of early + delayed images
› no prolonged patient immobilization
› no subtraction study / computer processing
› SPECT / multiple projections possible

C. Scan interpretation
› sharp images
› clear visualization of abnormal parathyroid glands
› ectopic sites surveyed
› improved detection sensitivity

Method:

» IV injection of 20–30 mCi ^{99m}Tc-MIBI
» 1st set of images: 10–15–30 minutes after injection
» 2nd set of images: at 1.5–3–4 hours post injection
» Adjunctive dual phase imaging with
(a) optional dual-isotope thyroid-selective agent (^{123}I, ^{99m}Tc) for computer-aided subtractions
Disadvantages:
(1) Necessity of 2 radionuclide injections
(2) Requires cooperative + immobile patient identically positioned for 2 studies
(3) Increased likelihood of artifacts
(b) single isotope early – and delayed phase technique ← ^{99m}Tc sestamibi washes out more rapidly from thyroid gland than from hyperfunctioning parathyroid glands
» Image acquisition: of cervicothoracic region from submandibular glands to basal ⅓ of heart
(1) 2-D planar imaging: anterior, anterior oblique, lateral views with large-field-of-view camera equipped with low-energy high-resolution parallel-hole collimator acquiring 5 minutes/view for 1st set of images and 10 minutes/view for 2nd set of images
(2) 3-D SPECT imaging with improved contrast resolution (⇑ target to background)
(a) software program
(b) hybrid SPECT/CT imaging system with anatomic information from CT
Advantage: more precise anatomic localization of ectopic mediastinal parathyroid adenomas

False positive scintigraphic findings:

1. Solitary thyroid adenoma
2. Nodule in multinodular goiter
3. Tumor: breast, lung, head & neck carcinoma, bronchial carcinoid
4. Metastasis to lymph node and bone

Delayed wash-out in neck region:

1. Differentiated thyroid malignancy
2. Primary thyroid lymphoma
3. Lymph node metastasis from papillary thyroid ca.
4. Reactive lymph node
5. Remnant thymus

6. PTH-secreting paraganglioma
7. Enlarged submandibular gland

False negative scintigraphic findings:

1. Double parathyroid adenomas
2. Four-gland hyperplasia

◊ Small gland less likely detected than large gland!

LUNG SCINTIGRAPHY

Perfusion Agents

^{99m}Tc-Macroaggregated Albumin (MAA)

Preparation:

heat-denatured + pH-adjusted human serum albumin (HSA); added stannous chloride → precipitates albumin into tin- containing macroaggregates; lyophilization prolongs stability; added ^{99m}Tc-pertechnetate is reduced by SnCl2 and tagged onto the MAA particles

Quality control (USP guidelines):

(1) 90% of particles should have a diameter of 10–90 μm
(2) No particle should exceed 150 μm
(3) Should ≥ 90% pure ← ascending chromatography
(4) ^{99m}Tc-MAA batch should be used < 8 hr post preparation
(5) Preparation should not be backflushed with blood into syringe → "hot spots" in lung images

Physical half-life: 6 hr

Biologic half-life: 6 hr

Dose: ~ 2–4–6 mCi + 0.14 μg/kg albumin corresponding to > 60,000 particles (200,000–700,000 particles recommended for even spatial distribution + good image quality)

N.B.: ↓ number of particles to 50,000–80,000 in

(a) critically ill patients with severe COPD, on mechanical ventilator support, documented pulmonary arterial hypertension, significant left-to-right cardiac shunts → NO reduction in tagged activity!
(b) children up to age 5 need reduction in number of particles + tagged activity!

» IV injection in supine position to give an even distribution between base + apex of lung (ventral to posterior gradient persists)
» imaging in upright position to allow maximum expansion of lung, especially at lung bases

Radiation dose (rad/mCi): 0.013 for whole body, 0.25 for lung (critical organ), 0.01 for gonads

Physiology:

90% of MAA particles act as microemboli → trapped in an estimated 600 million pulmonary arterioles small enough to trap the particles on 1st pass; physiologically insignificant effect → only 500,000 particles are injected per study; 0.22% (2÷1,000) of capillaries become occluded; protein is lysed within 6–8 hours and taken up by RES; particles < 1 μm are phagocytized by RES in liver + spleen

Imaging: Large-field-of-view scintillation camera + parallel-hole low-energy collimator with identical recording times for corresponding views

Views:

› anterior, posterior

› posterior oblique (LPO, RPO): additional information in 50% ← segmental delineation of basal segments and ← separation of both lungs

› anterior oblique (LAO, RAO): oblique views reduce equivocal findings from 30% to 15%

› lateral: "shine through" from contralateral lung

Counts: 750,000–1,000,000 counts for each image

^{99m}Tc-Human Albumin Microspheres (HAM)

Particle size: 20–30 µm

Biologic half-life: 8 hours

Ventilation agents

^{133}Xe, ^{127}Xe, ^{125}Xe, ^{81m}Kr, ^{13}N, $^{1}{}_{5}O_{2}$, $^{11}CO_{2}$, ^{11}CO, radioactive aerosol (^{99m}Tc–DTPA, ^{99m}Tc-PYP, ^{99m}Tc-labeled ultrafine dry dispersion of carbon "soot")

133Xenon

Fission product of 235U

Decay: to stable 133Cs under emission of beta particle (374 keV), gamma ray (81 keV), x-ray (31 keV); beta-component responsible for high radiation dose of 1 rad to lung)

Physical half-life: 5.24 days

Biologic half-life: 2–3 min

Physical properties: highly soluble in oil + grease, absorbed by plastic syringe

Administration: injection into mouth piece of a disposable breathing unit at the beginning of a maximal inspiration

Dose: 15–20 mCi

Technique:

Ventilation study preferably done <u>before</u> perfusion scan to avoid interference with higher-energy ^{99m}Tc (Compton scatter from ^{99m}Tc into lower 133Xe photopeak); [may be feasible after perfusion scan if dose of ^{99m}Tc-MAA is kept below 2 mCi + concentration of 133Xe is above 10 mCi/L of air and if 133Xe acquisition times for washing, equilibrium, washout images are kept to about 30 sec]

◊ Posterior imaging routine, ideally in upright position

<u>Phase 1 = single-breath image</u>:

= inhalation of 10–20 mCi 133Xe to vital capacity with breath-holding over 10–30 seconds (65% sensitivity for abnormalities)

√ cold spot is abnormal

<u>Phase 2 = equilibrium phase</u>:

= tidal breathing = closed-loop rebreathing of 133Xe + oxygen for 3–5 minutes for tracer to enter poorly ventilated areas; also functions as internal control for air leaks

» posterior oblique + posterior images are obtained to improve correlation with perfusion scan

√ activity distribution corresponds to aerated lung

Phase 3 = washout phase:

= clearance phase after readjusting intake valves of spirometer permits patient to inhale ambient air and to exhale 133Xe into shielded charcoal trap

» washout phase should last > 5 minutes

» images taken at 30–60-second intervals for > 5 min

√ rapid clearance within 90 seconds yields slight normal retention in upper zones

√ tracer retention (hot spot) at 3 minutes reveals areas of air-trapping

√ poor image quality secondary to significant scatter

√ abnormal scan:

(a) COPD / acute obstructive disease:

√ delayed wash-in (during initial 30 seconds of tidal breathing)

√ tracer accumulation on equilibrium views ← partial obstruction with collateral air drift + diffusion into affected area via bloodstream

√ delayed washout = retention > 3 minutes ← air trapping

√ tracer retention in regions not seen on initial single-breath view ← collateral airdrift into abnormal lung zones

(b) consolidated lung disease

√ no tracer uptake throughout imaging sequence

127Xenon

cyclotron-produced with high cost

Physical half-life: 36.4 days

Photon energies: 172 keV (22%), 203 keV (65%)

Advantages:

(1) High photon energy allows ventilation study following perfusion study

(2) Decreased radiation dose (0.3 rad)

(3) Storage capability because of long physical half-life

^{81m}Krypton

insoluble inert gas; eluted from 81Rb generator (half-life of 4.7 hr); decays to 81Kr by isomeric transition

Physical half-life: 13 sec

Biologic half-life: < 1 min

Principal photon energy: 190 keV (65% abundance)

Advantages:

(1) Higher photon energy than ^{99m}Tc so that ventilation scan can be performed following perfusion study

(2) Each ventilation scan can be matched to perfusion scan without moving patient

(3) Can be used in patients on respirator (no contamination due to short half-life)

(4) Low radiation dose (during continuous inhalation for 6–8 views 100 mrad are delivered)

Disadvantages:

(1) High cost
(2) Limited availability (generator good only for one day, so weekend availability may not be possible
(3) No washout images possible ← short half-life
(4) Decreased resolution ← septal penetration with low-energy collimators

√ lack of activity = abnormal area (tracer activity is proportional to regional distribution of tidal volume

^{99m}Tc-DTPA Aerosol

= ^{99m}Tc-diethylenetriaminepentaacetic radioaerosol
= UltraVent®
Biological half-life: 55 min
Administration: delivery through a nebulizer during inspiration
Dose: 30–50 mCi in 2–3 mL of saline added to nebulizer unit and connected to wall oxygen at a flow rate of 8–10 L/min
Physiology:
radioaerosols are small particles that become impacted in central airways, sediment in more distal airways, experience random contact with alveolar walls during diffusion in alveoli; cross respiratory epithelium with rapid removal by bloodstream
◊ Less physiologic indicator of ventilation + subject to nebulization technique
◊ Erect position preferable for basilar perfusion defects (dependent lung region receives more ventilation + radiotracer)
Technique:
» breathing from nebulizer for 3–5 minutes
» images recorded in multiple projections, each for 100,000 counts
◊ Aerosol applied ideally before perfusion; however postperfusion aerosol imaging is possible to assess for "fill-in" of aerosol in region of perfusion defect
◊ The count rate of ^{99m}Tc-MAA activity must be > 4 times the count rate of the ventilation activity!

√ abnormal scan:
(a) COPD
√ decreased activity in peripheral lung (slow and turbulent airflow prevents a normal amount of aerosol to reach the involved lung)
√ central airway deposition (aerosol sticks to trachea + bronchial walls)
(b) consolidated lung disease
√ absent tracer

^{99m}Tc-labeled Ultrafine Carbon Particles (Technegas)
preferred in pulmonary obstructive disease

Carbon Dioxide Tracer

^{15}O-labeled carbon dioxide
Physical half-life: 2 min (requires on-site cyclotron)
Physiology: inhalation of carbon dioxide; rapid diffusion across alveolar-capillary membrane; clearance from lung within sec

√ cold spot ← failure of tracer entry into airway = airway disease
√ hot spot ← delayed / absent tracer clearance = perfusion defect (87% sensitive, 92% specific)

Indications:

1. Emboli can be detected in preexisting cardiopulmonary disease
2. Equivocal / indeterminate V/Q studies

Positron Emission Tomography for Lung Tumor

Dose: 10 mCi FDG

Technique:

» patient fasts for 4 hours
◊ ↑ serum glucose may cause a decrease in FDG uptake!
◊ Blood glucose level of diabetic should be < 200 mg/dL
» imaging 30–45–60 minutes after IV injection in 30–45 image planes (15 cm axial field of view; resolution of 5 mm)
» calculation of maximum standardized uptake ratio (SUV) in region of interest
◊ SUV > 2.5 indicates malignant disease

Indications:

(1) Evaluation of solitary pulmonary nodule
(2) Staging (PET-CT better than any other technique)
(3) Recurrent disease

HEART SCINTIGRAPHY

Cardiac Imaging Choices

1. PLANAR imaging
2. SPECT imaging
3. QUANTITATIVE analysis
= circumferential profiles = plotting of average counts along equally spaced radii emanating from center of LV makes interpretation more objective + reproducible

Planar Imaging

√ tracer defect may be visible on only one image projection
√ 15–20% regional tracer intensity variation is normal

Left Ventricular Anatomy and Projections

A. AP
√ displays anterolateral wall, apex, inferior wall
√ decreased activity at apex of LV ← thinning in 50%
B. LEFT LATERAL
√ displays inferior + anterior wall
C. LAO 40° / LAO 70°
◊ Most often used projection; for all exercise studies
√ displays interventricular septum, posterior wall, inferior wall
√ best projection to separate right + left ventricles

√ best projection to evaluate septal + posterior LV wall motion

D. RAO 45°
√ displays anterior + inferior ventricular wall
√ useful during 1st-pass studies with temporal separation of ventricles

E. LPO 45° (rarely used)
10° caudal tilt minimizes LA contamination of LV region
√ displays anterior + inferior ventricular wall
√ preferred over RAO 45° because LV is closer to camera

F. Angled LAO (slant-hole collimator / caudal tilt)
√ separates ventricular from atrial activity
√ highlights apical dyskinesis

Location of Perfusion Defects on Planar Images

(1) Right coronary artery (RCA) best seen on left LAT / AP projections
√ inferior + posteroseptal segments

(2) Circumflex branch of left coronary artery (LCX) best seen on LAO projection
√ posterolateral segment

(3) Anterior descending branch of left coronary artery (LAD)
√ anteroseptal, anterior, anterolateral segments

N.B.: decreased activity in apical + posterior segments is not reliably correlated with disease of any vessel!

SPECT Myocardial Perfusion Imaging (MPI)

improves object contrast by removing overlying tissues; cinematic display of wall motion; EF calculation

√ tracer defect should be visible on more than one image set
√ up to 30% regional tracer intensity reduction compared with peak activity is normal

(a) Standard SPECT 180° acquisition extending from 45° RAO to 45° LPO for single-head camera

(b) ECG-gated SPECT
√ viable although hypoperfused myocardium may demonstrate systolic contraction + wall thickening
√ geometric EF calculation based on ROIs drawn on end-systolic + end-diastolic frames (different from blood pool scans)

Display of SPECT Images

SPECT = single photon emission tomography

- stress study = top row
- resting study = second row

1. Short-axis views (SA): apex → base
2. Horizontal long axis (HLA): inferior → superior (anterior)
3. Vertical long axis (VLA): septum → lateral

Rotating (Cine) Planar Images

= rotating (cine loop) of stress + rest planar images for a review of unprocessed raw data to recognize artifacts

Analysis of Tomographic Slices

Quality control:

1. Assess count statistics: poor, fair, good, excellent
   → peak pixel activity in LV myocardium should exceed 100 counts for ^{201}Tl and 200 counts for ^{99m}Tc
2. Review raw data sets in cinematic display to determine if any artifact is present due to
   (a) patient movement
   (b) respiratory motion
   (c) extracardiac uptake (eg, lymphoma, breast cancer)
3. Review sinogram of cardiac (horizontal) motion for extracardiac uptake (eg, in lungs or esophagus) and motion-related artifact

Cavity Size:

› cavity-to-wall thickness ratio
› poststress images with larger cavity than rest images = **stress -induced transient ischemic dilatation** (TID) > 1.22 ← stress-induced subendocardial ischemia indicative of severe and extensive multivessel coronary artery disease + high risk for a hard cardiac event
› dilatation on rest + stress images indicates LV dysfunction / volume overload

ECG-gated SPECT

displayed as individual tomographic slices / 3-D cine loop (8 frames per cardiac cycle); spatial + temporal changes in tracer activity reflect regional myocardial wall motion + thickening

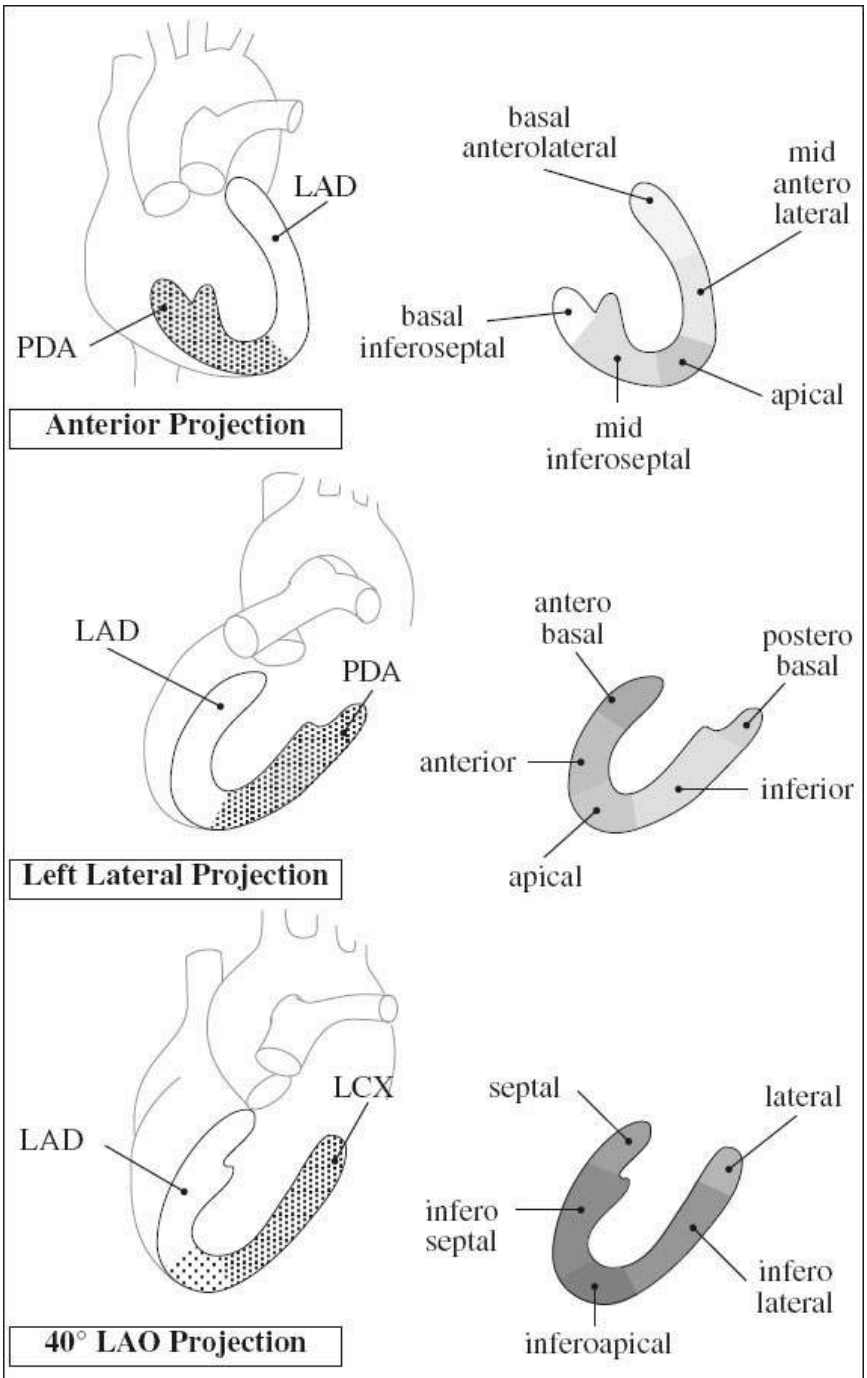
Evaluation for:

› global function
√ LV ejection fraction normal / ≥ 60%
√ end-diastolic + end-systolic LV volumes
normal EDV: 95 ± 27 mL (M), 64 ± 19 mL (F)
normal ESV: 41 ± 17 mL (M), 22±12 mL (F)
› endocardial surface
› motion of endocardial + epicardial surfaces
› myocardial thickening (brightening)
› regional LV wall motion abnormalities graphically depicted as 3-D plot
0= normal
1 = mildly hypokinetic
2 = moderately hypokinetic
3 = severely hypokinetic
4 = akinetic
5 = dyskinetic
› RV size + perfusion + wall motion

Calculated automated algorithm (QPS, Cedars-Sinai):

(a) Myocardial contour of endo- and epicardial surfaces overlying end-diastolic + end-systolic frames displayed on 3 short-axis images (apical, midventricular, basal) on midcavity horizontal and midcavity vertical long-axis image

(b) Quantitative polar plots measuring regional myocardial perfusion at end diastole and end systole (in %), motion (in 10 mm), and wall thickening (in %)
(c) Three-dimensional display of endocardial (solid) and epicardial (grid) LV surfaces
(d) Endocardial time-volume curve during R-R interval, endsystolic and end- diastolic volumes, and LVEF



Planar Reconstruction Planes

LAD supplies:	upper ²/₃ of interventricular septum, anterior wall + part of lateral wall, apex of left ventricle (in most patients)
LCX supplies:	posterior portion of left ventricle (in 10%) lateral portion of left ventricle
RCA supplies:	lower ¹/₃ of interventricular septum, inferior wall of LV + entire RV
PDA supplies:	(through RCA) posterior wall (in 90%)

Interpretation:

√ reversible defect (perfusion defect on stress + no defect on rest images) = myocardial ischemia

√ nonreversible (fixed) defect from stress to rest →

(a) myocardial infarct

(b) attenuation artifact if associated with normal regional wall thickening / wall motion

Value of review of gated SPECT images:

› reduction in number of borderline interpretations

› increase in "definitely normal" from 74% to 93%

Technique:

» patient supine with arms raised above head

» nylon belt wrapped snugly around abdomen to minimize respiratory motion

1. Low-dose (0.2–0.4-mSv) end-tidal expiratory breath-hold CT to obtain an attenuation map
2. ECG-gated SPECT with a frame rate of 8–16 per cardiac cycle with forward-backward gating to allow rejection of premature and postpremature heartbeats by using an acceptance window of 20–30% R-R variation

» symmetric 15% energy window centered at 140 keV = photopeak energy of ^{99m}Tc sestamibi

» low-energy high-resolution parallel hole collimators

» acquisition parameters include 90° rotation (with use of two camera heads) + noncircular orbit with step-and-shoot acquisitions

2. Reconstruction of SPECT images (for 128 x 128 matrix)

(a) without attenuation by filtered back projection method

(b) with attenuation correction by iterative ordered subset expectation maximum algorithm and filtering

(c) careful coregistration of myocardial perfusion imaging data set with CT attenuation map

(d) display in traditional cardiac planes + as polar maps normalized to myocardial region with highest counts

(e) compare normalized map with database of normalized polar maps from subjects with verified normal left ventricular perfusion

Ejection Fraction

Ejection fraction (EF) = stroke volume (SV) divided by end-diastolic volume (EDV)

stroke volume = <u>end-diastolic volume (EDV) minus end-systolic volume (ESV)</u>

EF = [EDV - ESV] / [EDV]

= [EDcounts - EScounts] / [EDcounts - BKGcounts]

sensitive indicator of left ventricular function

@ <u>Left ventricle</u>

› calculated on shallow LAO view

Normal value 50–65% (5% variation)

Definitely abnormal < 50%

Hypertrophic myocardium > 65%

◊ Peak exercise LVEF is an independent predictor of coronary artery disease

@ Right ventricle

mean normal value > 45%

(RV ejection fraction is smaller than for LV because RV has greater EDV than LV but the same stroke volume)

Variability of EF:

LVEF is not a fixed number for any patient but varies with: heart rate, blood pressure, level of circulating catecholamines, patient position, medications

Accuracy in detection of coronary artery disease:

(a) Exercise EF: 87% sensitive; 92% specific

(b) Exercise ECG: 60% sensitive; 81% specific

Interpretation:

◊ Ventricular function at rest is insensitive to CAD!

(1) at rest

√ EF may be decreased in CAD

DDx: cardiomyopathy, valvular disease

√ correlates well with clinical severity + regional distribution of myocardial infarction

(2) during exercise

√ reduced (hypokinetic) / absent (akinetic) / paradoxical (dyskinetic) wall motion indicate varying degrees of CAD / myocardial infarction

√ focal akinetic / dyskinetic area = aneurysm

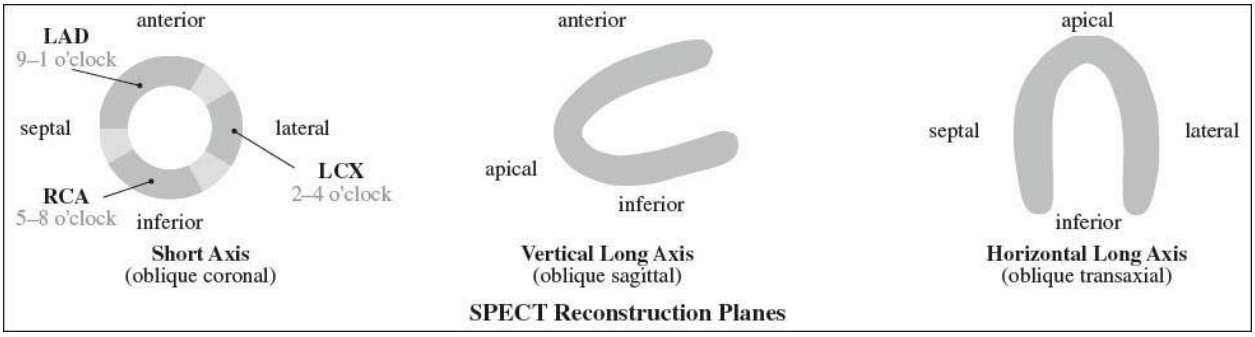
√ paradoxical septal motion (= septal movement to right in systole) may reflect septal infarction, left bundle branch block, S/P bypass surgery

Shortcoming:

poor study in patients with atrial fibrillation because of inability to achieve adequate cardiac gating (exercise MUGA can yield more sensitive assessment of coronary artery disease)

False-positive with (a) inadequate exercise

(b) recent ingestion of meal



Blood Pool Agents

^{99m}Tc-DTPA / ^{99m}Tc-Sulfur Colloid

preferred for cardiac first-pass studies as they allow multiple studies with little residual from any preceding study

^{99m}Tc-labeled Autologous RBCs

= agent of choice because of good heart-to-lung ratio

(1) IN VIVO LABELING

» IV injection of reducing agent stannous pyrophosphate (1 vial PYP diluted with 2 mL sterile saline = 15 mg sodium pyrophosphate containing 3.4 mg anhydrous stannous chloride)

» 15–20–30 min later injection of ^{99m}Tc-pertechnetate (+7), which binds to "pretinned" RBCs (reduction to ^{99m}Tc[+4])

◊ Least time-consuming + easiest method!

◊ Worst labeling efficiency (30% not tagged to RBCs + excreted in urine)!

(2) IN VIVTRO LABELING

= MODIFIED IN VIVO METHOD

◊ Preferred over in vivo because of high labeling efficiency within syringe, which reduces exposure to plasma constituents + creates little free pertechnetate!

» IV injection of 1 mg stannous pyrophosphate

» 10 min later 2–5–10 mL of blood are drawn into a heparinized syringe

» 10–20-min incubation period with ^{99m}Tc-pertechnetate

» reinjection of preparation in 3-way stopcock technique

N.B.: poor tagging in

(a) heparinized patient

(b) injection through IV line (adherence to wall)

(c) syringe flushed with dextrose instead of saline

(3) IN VITRO LABELING

◊ Most reliable labeling method!

» 50 mL drawn blood incubated with ^{99m}Tc reduced by stannous ion; RBCs washed and reinjected

N.B.: Labeling kit (with chelating + oxidizing substances) allows excellent in vitro labeling with only 3 mL of blood and 15-min incubation period!

Dose: 15–20–30 mCi (larger dose required for stress MUGA + obese patients);
for children: 200 µCi/kg; minimum dose of 2–3 mCi

Radiation dose: 1.5 rad for heart, 1.0 rad for blood, 0.4 rad for whole body

^{99m}Tc-HSA

HSA = human serum albumin

Indication: drug interference with RBC labeling (eg, heparinized patient)

Physiology:

(a) albumin slowly equilibrates in extracellular space

(b) poorer heart-to-lung ratio than with labeled RBCs

Ventricular Function

First-pass Ventriculography

= FIRST-PASS RADIONUCLIDE ANGIOGRAPHY = FIRST TRANSIT

= recording of initial transit time of an intravenously administered tight ^{99m}Tc bolus through heart + lungs; limited number of cardiac cycles available for interpretation;

additional projections / serial studies require additional bolus injection

Accuracy: good correlation with contrast ventriculography

Agents: pertechnetate, pyrophosphate, albumin, DTPA, sulfur colloid (almost any ^{99m}Tc-labeled compound except lung scanning particles), ^{99m}Tc-labeled autologous RBCs

Indications:

(1) Only 15 seconds of patient cooperation required
(2) Calculation of cardiac output + ejection fraction (RBCs)
(3) Subsequent first-pass studies within 15–20 minutes of initial study possible (DTPA)
(4) Separate assessment of individual cardiac chambers in RAO projection (temporal separation without overlying atria, pulmonary artery, aortic outflow tract), eg, for right ventricular EF and intracardiac shunts

Minimal dose: 10 mCi

Technique:

» cannulation of antecubital / external jugular vein with ≥ 20 ga needle attached to 3-way stopcock and two syringes:
  » syringe 1 contains ≤ 1 mL of radiotracer
  » syringe 2 contains a saline flush (10–20 mL)
» injection of radiotracer → followed by a strong flush of saline

Gating:

improved images obtained by selection of time interval corresponding only to RV passage of bolus averaged over several (3–5) individual beats; gating may be done intrinsically or with ECG guidance

Imaging: region of interest (ROI) over RV silhouette in RAO projection; background activity taken over horseshoe-shaped ventricular wall; counts in ROI displayed as function of time; 25 frames/second for 20–30 seconds

Quality Control:

(a) Bolus Adequacy:
  › good = FWHM of time activity curve < 1 second
  › adequate = FWHM of 1–1.5 seconds
  › delayed = FWHM of > 1.5 seconds
  › split = more than one discrete peak
  Problem: delayed bolus may cause oversubtraction of background resulting in spurious ↑ in LVEF, ↓ in LV volume, overestimation of regional wall motion
(b) Count Statistics
  > 4000–5000 cps (counts per second) of LV end-diastolic counts in the representative cycle
(c) Tracer Transit Time
  visual examination of bolus transiting the central circulation
(d) Beat Selection
  only beats with end-diastolic counts of ≥ 70% of peak end-diastolic counts
(e) Background Selection
  a frame close to the beginning of the LV phase

Normal passage of bolus: SVC, RA, RV, lungs, LA, LV, aorta

R-to-L shunt: tracer appears in left side of heart before passage through lungs

Evaluation of:

1. Obstruction in SVC region
2. Reflux from RA into IVC / jugular vein
3. Stenosis in pulmonary outflow tract
4. R-L shunt
5. Contractility of RV
6. Sequential beating of RA and RV
7. Ejection fraction of RV and LV

Cardiac Rhythm & Conduction:

Regional wall motion + LVEF may be effected by:

(1) Frequent premature ventricular contractions (PVCs)
(2) Ventricular bigeminy
(3) Very irregular atrial fibrillation
(4) Pacemaker rhythm: from apex → to base
(5) Left bundle branch block (LBBB)
√ infero- / anteroapical wall motion abnormalities
N.B.: paradoxical septal motion not detectable in RAO projection

Equilibrium Images

= "blood pool" radionuclide cardioangiography

Agents: ^{99m}Tc-labeled autologous RBCs (most commonly) / human serum albumin

Imaging: after thorough mixing of radiotracer throughout vascular space

» acquisition of images during selected portions of cardiac cycle triggered by R-wave; each image is composed of > 200,000 counts (2–10 minutes) obtained over 500–1,000 beats after equilibrium has been reached; high-quality images can be obtained in different projections

» gated acquisition from 16–32 equal subdivisions of the R-R cycle (electronic bins) allows display of synchronized cinematic images (assembled to composite single-image sequence) of an "average" cardiac cycle

√ may be displayed as time activity curves reflecting changes in ventricular counts throughout R-R interval

› measured functional indices: preejection period (PEP), left ventricular ejection time (LVET), left ventricular fast filling time (LVFT1), left ventricular slow filling time (LVFT2), PEP/LVET ratio, rate of ejection + filling of LV

» at rest: count density of 200–250 counts/pixel requires generally 7–10 minutes acquisition time for 200,000–250,000 counts/frame

» during exercise: 100,000–150,000 counts/frame requires an acquisition time of 2 minutes

Evaluation of:

1. LV ejection fraction
2. Regional wall motion
3. Valvular regurgitation

Interpretation:

1. Heart failure: decreased EF, prolongation of PEP, shortening of LVET, decreased rate

of ejection

2. Hypertensive heart: normal systolic indices, normal EF, prolonged LVFT1
3. Hypothyroidism: prolonged PEP, normal EF
4. Aortic stenosis: mild reduction of EF, prolonged LV emptying time, decreased rate of ejection, normal rate of filling

√ area of decreased periventricular uptake secondary to

(a) pleural effusion > 100 mL

(b) ventricular hypertrophy

Gated Blood Pool Imaging

= MULTIPLE GATED ACQUISITION (MUGA)

= gated equilibrium images depict average cardiac contraction by summation over several minutes

Recording of:

(1) Ejection fraction (EF) of left ventricle before + after exercise (> 6 million counts, 32 frames)

(2) Regional wall motion of ventricular chambers (> 4.5 million counts, 24 frames)

(a) at rest: myocardial infarction, aneurysm, contusion

(b) *during exercise:* ischemic dyskinesia (detectable in 63%)

(3) Regurgitant index

Projection:

(a) septal view (usually LAO 45°) best for EF; often requires some cephalad tilting of detector head

(b) two additional views for evaluation of wall motion (usually anterior + left lateral views)

Imaging:

physiologic trigger provided by R-R interval of ECG ("bad beat" rejection program desirable); R-R interval divided into typically about 20 frames; several hundred cardiac contractions are summed (depending on count density) for each planar projection

(a) gated images obtained for 5 minutes

(b) 2-min image acquisition time for each stage of exercise

PROs: (1) Higher information density than 1st-pass method

(2) Assessment of pharmacologic effect possible

(3) "Bad beat" rejection possible

CONs: (1) Significant background activity

(2) Inability to monitor individual chambers in other than LAO 45° projection

(3) Plane of AV valve difficult to identify

Radiation dose: 1.5 rad for heart; 1.0 rad for blood; 0.4 rad for whole body

Qualitative evaluation:

(1) Chamber size

(2) Wall thickness

(3) Regional wall motion

Myocardial Perfusion Imaging Agents

Most commonly used: ^{99m}Tc sestamibi + ^{99m}Tc tetrofosmin
Preparation: » NPO for 4 hours before perfusion imaging
» NO caffeine for 12–24 hours before exam
At discretion of referring physician:
» withhold consumption of β- and calcium channel blockers for 24 hours before imaging
» long-acting nitrates should be withheld the day of the exam

43Potassium

Not suitable for clinical use because of its high energy

^{201}Thallium-chloride

= cation produced in cyclotron from stable ^{203}Tl
= image agent of choice to assess myocardial viability
Cyclotron: by (p,3n) reaction to radioactive 201Pb (half-life of 9.4 hours) → decays by electron capture to ^{201}Tl
Decay: by electron capture to ^{201}Hg
Energy spectrum: 69–83 keV of Hg-K x-rays (98% abundance); 135 keV (2%) + 167 keV (8% abundance) gamma photons
Physical half-life: 74 hours
Biologic half-life: 10 ± 2.5 days
Dose: low dose of 3–4 mCi (the larger dose for SPECT) because of long half-life and slow body clearance
Radiation dose:
3 rad for kidneys (critical organ) (= 1.2 rad/mCi); 1.2 rad for gonads (= 0.6 rad/mCi); 0.7 rad for heart + marrow (= 0.34 rad/mCi); 0.5 rad for whole body (= 0.24 rad/mCi)
Quality control: should contain < 0.25% 203Pb; < 0.5% ^{202}Tl (439 keV)
Indications:
1. Acute myocardial infarction
2. Coronary artery disease
» particularly useful over ECG in:
(a) conduction disturbances: eg, bundle branch block, preexitation syndrome
(b) previous infarction
(c) under drug influence: eg, digitalis
(d) left ventricular hypertrophy
(e) hyperventilation
(f) ST depression without symptoms
(g) if stress ECG impossible to obtain

Thallium uptake & distribution:
› intracellular uptake via Na/K-ATPase (analogue to ionic potassium), but less readily released from cells than K+
› distribution is proportional to regional blood flow
› uptake depends on
(1) quality of regional perfusion
(2) viable cells with integrity of Na/K pump
@ Blood pool < 5% remain in blood pool 15 minutes post injection

@ Myocardial uptake depends on
(a) myocardial perfusion
(b) myocardial mass
(c) myocardial cellular integrity
◊ First-pass extraction efficiency is 88%!
REMEMBER: 90% in 90 seconds!
› 4% of total dose localizes in myocardium at rest (myocardial blood flow = 4% of cardiac output)
› peak myocardial activity occurs at 5–15 minutes after injection
› uptake can be increased to 8–10% with dipyridamole stress
› clearance from myocardium is proportional to regional perfusion + begins within a few min after injection ("wash out"); zones of initially higher uptake wash out more rapidly than areas of low uptake (= "redistribution")

@ Skeletal muscle + splanchnicus: first-pass extraction efficiency is 65%
› accumulate 40% of injected dose
› 4–6 hour fast + exercise → ↓ flow to splanchnicus and ↑ cardiac uptake

@ Lung: 10% of total dose localizes in lung
› augmented pulmonary extraction with LV dysfunc-tion, bronchogenic carcinoma, lymphoma of lung
√ < 5% activity over lung is normal
√ ↓ heart-to-lung ratio with triple-vessel disease

@ Kidney: accumulates 4% of injected dose
› excretion of 4–8% within 24 hours

@ Thyroid:
√ increased uptake > 1% in Graves disease + thyroid ca.

@ Brain:
√ uptake only if blood-brain barrier disrupted

Technique:

A. **Single dose method**
» 3 mCi injected at peak exercise for exercise image immediately + rest image 3 hours later

B. **Split dose method**
» 2 mCi injected for exercise image
» 1 mCi reinjected at rest after 3 hours with rest image taken 30 minutes later

C. **Booster reinjection technique**
» reinjection of thallium followed by imaging after 18–24–72 hours ↑ blood concentration of isotope
= late reversibility provides evidence of regional myocardial ischemia + viability not appreciated even on very delayed (24–72 hour) redistribution images; predicts scintigraphic improvement post intervention
Reasoning: 50% of irreversible persistent defects improve significantly after booster reinjection

Imaging:

1. EXERCISE IMAGE = DISTRIBUTION IMAGE
= stress thallium image

= map of regional perfusion obtained within minutes after injection at peak exercise; initial distribution proportional to myocardial blood flow + arterial concentration of radioisotope + muscle mass; 300,000–400,000 counts / view (~ 5–8 minutes sampling time), should be completed by 30 minutes

2. REDISTRIBUTION IMAGE
   = equilibrium between tracer uptake and efflux dependent on blood flow + mass of viable tissue + concentration gradient
   = map of hypoperfused ischemic but viable myocardium obtained at rest after 2–3–4–6 hours; washout half-life from normal myocardium is 54 min
3. DELAYED IMAGE (optional)
   = viability study at 24 hours

Interpretation:

√ "apical thinning" = less myocardial mass of cardiac apex as a normal finding
√ normally diminished tracer uptake at basal portions of ventricle (near plane of mitral valve) ← more fibrous tissue + less muscle mass
√ variation in tracer intensity by 15–20% between regions on planar images may be normal ← soft-tissue attenuation artifacts from subdiaphragmatic abdominal contents or breast tissue

Interpretation of Stress Thallium Images

Immediate Image	*Delayed Image*	*Diagnosis*
normal	normal	normal
defect	fill-in	exertional ischemia
defect	persistent	myocardial scar
defect	partial fill-in	scar + ischemia / persistent ischemia

1. Initial phase = first-pass extraction
   √ temporary defect accentuated by exercise
   √ defect > 15% of ventricular surface suggests > 50% stenosis of coronary artery
   √ right heart well seen during stress test, tachycardia, volume / pressure overload
   √ dilated heart cavity on stress images (but not on rest images) ← exercise-induced LV dysfunction
2. Redistribution phase (on 2–4-hour images)
   √ washout in normal areas
   √ slow continued accumulation of tracer for areas of greatly ⇓ perfusion
   √ ↑ uptake in viable ischemic zones ("redistribution")
   √ permanent defect = nonviable myocardium as in myocardial infarction / fibrosis
   √ ↑ lung activity (ie, > 50% of myocardial count) indicative of
   (a) left ventricular failure ← severe LCA disease / myocardial infarction
   (b) pulmonary venous hypertension ← cardiomyopathy / mitral valve disease
   √ right heart faintly visualized during rest (15% of perfusion to right side); ⇑ activity in RV ←
   (a) ↑ in ventricular systolic pressure
   (b) ↑ in mean pulmonary artery pressure

(c) ↑ in total pulmonary vascular resistance

Sensitivity: overall 82–84% for stress ^{201}Tl (60–62% for exercise ECG)

(a) <u>increased with:</u>
  (1) Severity of stenosis (86% + 67% sensitive with stenosis > 75% + < 75%)
  (2) Greater number of involved arteries
  (3) Stenosis of left main > LAD > RCA > LCX
  (4) Prior infarction
  (5) High work load during exercise testing in patients with single-vessel disease

(b) <u>decreased with:</u>
  (1) Presence of collaterals
  (2) Beta blockers
  (3) Time delay for poststress images

Specificity: overall 91–94% for stress ^{201}Tl (81–83% for exercise ECG)

False-positive thallium test (37–58%):

A. Infiltrating myocardial disease
  1. Sarcoidosis
  2. Amyloidosis

B. Cardiac dysfunction
  1. Cardiomyopathy
  2. IHSS
  3. Valvular aortic stenosis
  4. Mitral valve prolapse (rare)

C. Decreased cardiac perfusion other than myocardial infarction
  1. Cardiac contusion
  2. Myocardial fibrosis
  3. Coronary artery spasm: severe unstable angina may cause defect after stress + on redistribution images, but will be normal at rest!

D. Normal variant
  1. Apical myocardial thinning
  2. Attenuation by diaphragm, breast, implant, pacemaker

mnemonic: I'M SIC

Idiopathic hypertrophic subaortic stenosis
Myocardial infarct without coronary artery disease
Scarring, **S**pasm, **S**arcoidosis
Infiltrative / metastatic lesion
Cardiomyopathy

False-negative thallium test:

1. Under influence of beta-blocker: eg, propranolol
2. "Balanced ischemia" = symmetric 3-vessel disease
3. Insignificant obstruction
4. Inadequate stress
5. Failure to perform delayed imaging
6. Poor technique

mnemonic: 3NMRS COR

3-vessel disease (rare)

Noncritical stenosis
Medications interfering
Right coronary lesion (isolated)
Submaximal exercise
Collateral (coronary) blood vessels
Overestimation of stenosis on angiography
Redistribution (early / delayed)

Advantages compared with ^{99m}Tc compounds:

(1) Higher total accumulation in myocardium
(2) Provides redistribution information

Disadvantages:

(1) Low energy x-rays result in poor resolution → improved with SPECT
(2) Dose is limited by its long half-life
(3) Half-value thickness of 3 cm results in less avid appearing myocardium: inferior wall (deeper part of myocardium) / anterolateral wall (overlain by breast)
(4) Imaging must be completed by 45 minutes post injection or redistribution occurs

^{99m}Tc-MIBI (Sestamibi)

= cationic lipophilic isonitrile complex, which binds to myocyte intramitochondrial proteins

Pharmacokinetics:

› relatively rapid clearance from circulation (40% first- pass extraction) ← passive diffusion across cell membranes
› high myocardial accumulation (4%) with nonlinear uptake proportional to regional perfusion (fall-off in extraction at higher rates of flow)
› slow washout with long retention time in myocardium and little recirculation
› significant hepatic + gallbladder activity

Excretion: through biliary tree (give milk after injection and before imaging to decrease GB activity)

Dose: 25–30 mCi (Cardiolite®)

Imaging: optimum images 1 hour after injection (may be imaged up until 3 hours)

Technique: separate injections for stress and rest studies because of slow washout

A. 1-DAY PROTOCOL (rest-stress protocol)
Improved detection of reversibility compared with stress-rest protocol
» inject 5–8 mCi ^{99m}Tc-sestamibi
» take rest images 60–90 min after injection
» wait 0–4 hours
» stress patient followed by injection with 15–25 mCi ^{99m}Tc-sestamibi at peak stress (↑ myocardial blood flow means ↑ myocardial uptake)
» image 30–60 minutes later (optimum imaging time of stress-induced defects)

B. 2-DAY PROTOCOL (impractical stress-rest protocol):
» stress images on 1st day: ^{99m}Tc-sestamibi given at peak stress; imaging after 30–60-minute delay → to allow some clearing of liver activity
» repeat on 2nd day ONLY if stress views abnormal

C. DUAL TRACER STRATEGY

» ^{201}Tl for initial injection
» ^{99m}Tc-sestamibi as 2nd injection immediately afterwards → its higher energy photons are unaffected by residual ^{201}Tl

Advantages over thallium:

(1) Low radiation dose ← shorter half-life allowing larger doses with less patient radiation
(2) Excellent imaging characteristics due to
  (a) improved photon flux → faster imaging + ability for cardiac gating
  (b) higher photon energy → less attenuation artifact from breast tissue / diaphragm + less scatter
(3) NO redistribution
(4) Temporal separation of injection and imaging allows injection during acute myocardial infarct when patient may not be stable for imaging; after stabilization + intervention (angioplasty / urokinase) imaging can demonstrate the pre-intervention defect
(5) Low cost
(6) Easy availability
(7) Flexible scheduling
(8) Increased patient throughput

Disadvantage: less well suited to assess viability

^{99m}Tc-Teboroxime

= neutral boronic acid oxime complex

Pharmacokinetics:

› very rapid clearance time from circulation ← rapid uptake by myocardium = high extraction efficiency
› distribution proportional to cardiac blood flow EVEN at high blood flow levels (sestamibi + thallium plateau at high levels of flow)
› biexponential washout from myocardium + little recirculation
› high background from lung + liver (cleared earlier and more rapidly from the liver)

Dose: 25–30 mCi (CardioTec®)

Imaging: must begin immediately post injection ← rapid washout; rest image can immediately follow stress image

^{99m}Tc-Tetrofosmin

= diphosphine complex (Myoview™)

Related compounds: ^{99m}Tc-Q12 (furifosmin), Q3

Pharmacokinetics:

› lower first-pass extraction + accumulation than thallium
› slow myocardial washout
› rapid background clearance
› quicker liver excretion than sestamibi

Positron Emission Tomography

Perfusion agents: ^{13}N-ammonia, ^{15}O water, ^{82}Rb

Metabolic agents: ^{18}Fluorine-deoxyglucose = FDG (glycolysis), ^{11}carbon-palmitate (beta-oxidation), ^{11}carbon-acetate (tricarboxylic acid cycle)

MYOCARDIAL METABOLIC PET

Pathophysiology: in myocardial ischemia glycolysis (utilization of glucose) increases while mitochondrial β-oxidation of fatty acids decreases!

Sensitivity: > 95%

Technique:

» give oral glucose load
» inject 10 mCi FDG
» image after 30 min

Variation: simultaneous injection of perfusion tracer

Interpretation:

√ mismatched defect (= decreased perfusion but enhanced metabolism indicated by FDG uptake) indicates → viable (but dysfunctional) myocardium salvageable by revascularization procedure

√ matched defect (= flow + FDG accumulation both decreased) → nonviable myocardium

◊ 80–90% of matching defects do NOT improve after bypass

√ 11C-acetate superior to FDG (accurately reflects overall oxidation metabolism ← not influenced by myocardial substrate utilization)

Comparison with thallium:

accuracy for fixed lesions similar; higher for reversible ischemia

MYOCARDIAL PERFUSION PET

Ability to detect obstructive CAD in > 1 coronary artery with > 50% stenosis: 83%–100% sensitive, 73%–100% specific, 80%–100% PPV, 36%–100% NPV, 84%–98% accurate

Advantages of PET over SPECT:

1. Improved accuracy ← increased specificity + marginally improved sensitivity
2. Capacity to quantify left ventricular function at rest + during peak stress and coronary flow reserve
3. Better definition of extent of anatomic CAD
4. Lower radiation dose than SPECT
5. Integration of PET + CT for anatomic extent of CAD

Stress test

Rationale:

◊ Rest-injected images can separate viable from nonviable myocardium + detect very severe ischemia (with stenosis of > 90–95%), but cannot detect most coronary artery disease (CAD)!

Exercise increases myocardial work and oxygen requirement: at peak exercise blood flow may rise 5-fold from baseline through coronary artery dilatation + increase in heart rate; exercise will unveil CAD-related regional hypoperfusion relative to normal regions, if coronary artery stenosis > 50%

Physical / Physiologic / Exercise Stress Test

◊ Exercise in erect position (peak heart rate lower if supine) on treadmill or bicycle; isometric handgrip exercise raises blood pressure less (but adequate for evaluation)

◊ Starting point of workload selected according to preliminary exercise results (at an average of 200 kilowatt pounds)

Bruce treadmill protocol:

» grade of exercise incrementally increased by inclination + belt speed (200 kilowatt pounds)

» graded exercise in 3-min stages of increasing workload

» endpoints for discontinuing exercise:

(1) attainment of 85% of predicted maximal heart rate = 220 – age in years
(2) Inability to continue ← fatigue, dyspnea, leg cramps, dizziness, chest pain
(3) Severe angina / hypotension
(4) Severe ECG ischemic changes / arrhythmia
(5) Fall in BP > 10 mmHg below previous stage
(6) Ventricular tachycardia
(7) Run of 3 successive premature ventricular beats

◊ Cardiologist with crash cart should be available!

Problems with exercise imaging:

(1) Sensitivity to detect ischemic lesions decreases with suboptimal exercise (in particular for older population)
(2) Higher false-positive tests in women (artifacts from overlying breast tissue)
(3) Propranolol (beta blocker) interferes with stress test, should be discontinued 24–48 hr prior to testing

Pharmacologic Stress Test

Advantages:

(1) Reproducibility
(2) Independent from patient motivation
(3) Freedom from patient infirmities: eg, severe peripheral vascular disease, arthritis, pain

Vasoactive drugs:

A. Primary coronary vasodilators

Action: binding to A_2 receptors affects the intracellular cyclic AMP, GMP, and calcium levels → coronary hyperemia

N.B.: Discontinue use of caffeine, tea, chocolate, cola drinks for 24 hours prior to test

◊ Cannot be used in patients on theophylline!

(1) IV infusion of 140 µg/kg/min dipyridamole (= Persantine®) → 3–5-fold increase in coronary artery blood flow

Total dose: 0.84 mg/kg

Drug action: 30 minutes

Side effects: flushing, nausea, bronchospasm (reversible with aminophylline)

» dipyridamole injection over 4 min

» wait 10 min for maximum effect
» inject radiotracer
◊ Prolonged supervision after test necessary!

(2) IV infusion of 140 µg/kg/min adenosine (= Adenocard®, Adenoscan®)

Radiopharmaceuticals for Myocardial Perfusion PET				
Radiotracer	*Physical Half-Life*	*Availability*	*Advantage*	*Disadvantage*
Rubidium 82 (^{82}Rb)	76 sec	Strontium 82 (^{82}Sr)/^{82}Rb generator	simplicity of use	relatively poor resolution
Nitrogen 13 (^{13}N) ammonia	10 min	Cyclotron	high extraction simplifies quantitation	requires cyclotron, heterogeneous uptake
Copper 62 (^{62}Cu)–pyruvaldehyde-bis (N4-methylthiosemicarbazone (PTMS)	10 min	^{62}Zn/^{62}Cu generator	rapid blood pool clearance, long myocardial retention	short parent isotope half-life
Oxygen 15 (^{15}O)–water	2 min	Cyclotron	diffusible with high extraction	requires cyclotron, not suitable for clinical imaging
Fluorine 18 (^{18}F) flurpiridaz	110 min	Cyclotron	long half-life allows exercise studies	higher radiation dose for same-day stress-rest studies

Drug action: 2–3 minutes (half life of 15 seconds)
Side effects: flushing, nausea, transient AV block, bronchospasm
Drug reversal: theophylline
» continuous IV infusion for 3 minutes
» radiotracer injection
» continue infusion for additional 3 minutes
◊ Supervision after test not needed
Contraindication: significant pulmonary disease requiring use of inhalers

(3) IV injection of 0.4 mg Regadenoson (Lexiscan®) followed by saline flush = highly specific adenosine A2A receptor agonist acting as coronary vasodilator with very low affinity for A1 (→ AV node block), A2B (→ severe peripheral vasodilation and hypotension), A3 (→ bronchoconstriction)
Advantages: weight-unadjusted single bolus dose, fast onset + short duration of action, fewer side effects than adenosine
» radiotracer injection 10–20 sec after saline flush
» 150 mg of IV aminophylline > 3–4 minutes after radiotracer injection
» complete limited exercise protocol tailored to patient's physical ability

B. Chronotropic inotropes
Drug action: β-1 agonist → ↑ myocardial contractility + work = ↑ oxygen demand
Candidates: patients with COPD, asthma, allergy to vasodilators, patients on theophylline preparations

(1) IV infusion of 5 µg/kg/min dobutamine for 5 minutes, increased in steps of 5 µg/kg every 5 minutes to a maximum infusion rate of 30–40 µg/kg/min titrated to patient's response
» radiotracer injected at onset of significant symptoms / ECG changes / achievement of maximal rate of infusion or heart rate
» infusion maintained for an additional 2 minutes with dose adjusted to patient's condition

(2) IV infusion of arbutamine with its own computerized delivery system titrating

dose rate automatically

Contraindication: severe hypertension, atrial flutter / fibrillation

Precautions:

1. Monitoring devices: electrocardiographic and blood pressure monitors
2. Emergency resuscitation equipment: defibrillator
3. Emergency cart: drugs + pharmacologic antidotes (epinephrine, β-blocker, atropine, bronchodilator, antiarrhythmic medication)

Applied to:

1. THALLIUM IMAGING (redistribution images after stress test):
   - » injection of 1.5–2 mCi of ^{201}Tl during peak exercise, continuation of exercise for additional 60 seconds before imaging commences

   Clues for stress images:
   - √ RV myocardium well visualized
   - √ little pulmonary background activity
   - √ little activity in liver, stomach, spleen
   - √ distribution more uniform after stress than during rest
   - ◊ Degree of liver uptake useful as direct measure of level of exercise!

   Sources of technical errors:

   mnemonic: ABCDE PS

   Attenuation from overlying breast / diaphragm
   Background oversubtraction
   Camera field nonuniformity
   Drugs, **D**elayed (excessively) imaging, **D**ose infiltration
   Eating / **E**xercising between stress + delayed images
   Positioning variation between stress + delayed images
   Submaximal exercise
2. GATED BLOOD POOL IMAGING (response of EF)
   - √ ↑ in ejection fraction from 63–93% in normals
   - √ ↑ in ventricular wall motion (anterolateral > posterolateral > septal)
3. MR MYOCARDIAL PERFUSION IMAGING

Infarct-avid Imaging

= hot spot imaging

Agent: ^{99m}Tc-pyrophosphate (standard), 203Hg chlormerodrin, ^{99m}Tc-tetracycline, ^{99m}Tc-glucoheptonate, ^{18}F-sodium fluoride, ^{111}Indium-antimyosin (murine monoclonal antibodies to myosin), ^{99m}Tc-antimyosin Fab fragment

^{99m}Tc-Pyrophosphate

Pathophysiology in MYOCARDIAL INFARCTION:

Pharmacologic Stress Agents				
Stress Agent	*Dose*	*Administration*	*Mechanism of Action*	*Contraindication, Side Effects*
Dobutamine	40 µg/kg/min (max)	infusion	direct B_1 + B_2 receptor stimulation with dose-related increase in heart rate + blood pressure + myocardial contractility	Systemic hypertension Complex arrhythmia HOCM Uncontrolled CHF
Atropine	0.25-mg fractions typical (max 2 mg)	fractional injections	nonselective muscarinic acetylcholinergic antagonist	Narrow-angle glaucoma Myasthenia gravis Obstructive uropathy
Adenosine (Adenocard®, Adenoscan®)	140 mg/kg/min	4–6 min infusion	Activation of A_1, A_{2B} and A_3 receptors Activation of A_{2A} receptors Half-life = 10 sec	2nd / 3rd-degree AV block Systolic BP < 90 mmHg Active airway disease Hypersensitivity
Regadenoson (Lexiscan®)	0.4 mg	single injection	A_{2A} receptor agonist inducing direct coronary arteriolar vasodilatation Weak affinity fr A_{2B} + A_3 receptors Initial phase half-life = 2–4 min followed by elimination phase of 2–4 h	Similar but reduced side effects as adenosine (→ suitable for patients with mild reactive airway + obstructive lung disease)

pyrophosphate is taken up by myocardial necrosis through complexation with calcium deposits > 10–12 hours post infarction

- › requires presence of residual collateral blood flow
- › 30–40% maximum accumulation in hypoxic cells with a 60–70% reduction in blood flow (greater levels of occlusion reduce uptake)

Uptake post infarction:

- › earliest uptake by 6–12–24 hours;
- › peak uptake by 48–72 hours;
- › persistent uptake seen up to 5–7 days with return to normal by 10–14 days

Sensitivity: 90% for transmural infarction, 40–50% for subendocardial (nontransmural) infarction

Specificity: as low as 64%

Dose: 15–20 mCi IV (minimal count requirement of 500,000/view)

Imaging: at 3–6 hr (60% absorbed by skeleton within 3 hr)

Indications:

1. Lost enzyme pattern = patient admitted 24–48 hr after infarction
2. Equivocal ECG + atypical angina:
   (a) left ventricular bundle branch block
   (b) left ventricular hypertrophy
   (c) impossibility to perform stress test
   (d) patient on digitalis
3. ST depression without symptoms
4. Equivocal enzyme pattern + equivocal symptoms
5. S/P cardiac surgery (perioperative infarction in 10%, enzymes routinely elevated, ECG always abnormal), requires preoperative baseline study as 40% are preoperatively abnormal
6. For detection of right ventricular infarction

NOT HELPFUL:

1. In differentiating multiple- from single-vessel disease
2. Typical angina

3. Normal ECG stress test + NO symptoms

Scan interpretation:

[Grade 2+ and above are positive]

Grade 0 no activity

Grade 1+ faint uptake

Grade 2+ slightly less than sternum, equal to ribs

Grade 3+ equal to sternum

Grade 4+ greater than sternum

√ "doughnut" pattern = central cold defect (necrosis in large infarct) usually in cases of large anterior + anterolateral wall infarctions

√ uptake in inferior wall extending behind sternum (anterior projection) suggests RV infarction

◊ SPECT imaging improves sensitivity (← eliminates rib overlap)

√ diffuse uptake can be seen in angina, cardiomyopathy, subendocardial infarct, pericarditis and normal blood pool (normal blood pool can be eliminated with delayed imaging)

FALSE POSITIVES (10%):

A. Cardiac causes:

1. Recent injury: myocardial contusion, resuscitation, cardioversion, radiation injury, Adriamycin® cardiotoxicity, myocarditis, acute pericarditis
2. Previous injury: left ventricular aneurysm, mural thrombus, unstable angina, previous infarct with persistent uptake
3. Calcified heart valves / calcified coronary arteries (rare) / chronic pericarditis
4. Cardiomyopathy: eg, amyloidosis

B. Extracardiac causes:

1. Soft-tissue uptake: breast tumor / inflammation, chest wall injury, paddle burns from cardioversion, surgical drain, lung tumor
2. Osseous: calcified costal cartilage (most common), lesions in rib / sternum
3. Increased blood pool activity secondary to renal dysfunction / poor labeling technique (improvement on delayed images)

mnemonic: SCUBA

Subendocardial infarction (extensive)
Cardiomyopathy / myocarditis
Unstable angina
Blood pool activity
Amyloidosis

FALSE NEGATIVES (5%)

Myocardial metastasis

PERSISTENTLY POSITIVE SCAN (> 2 weeks)

= ongoing myocardial necrosis indicating poor prognosis, may continue on to cardiac aneurysm, repeat infarction, cardiac death

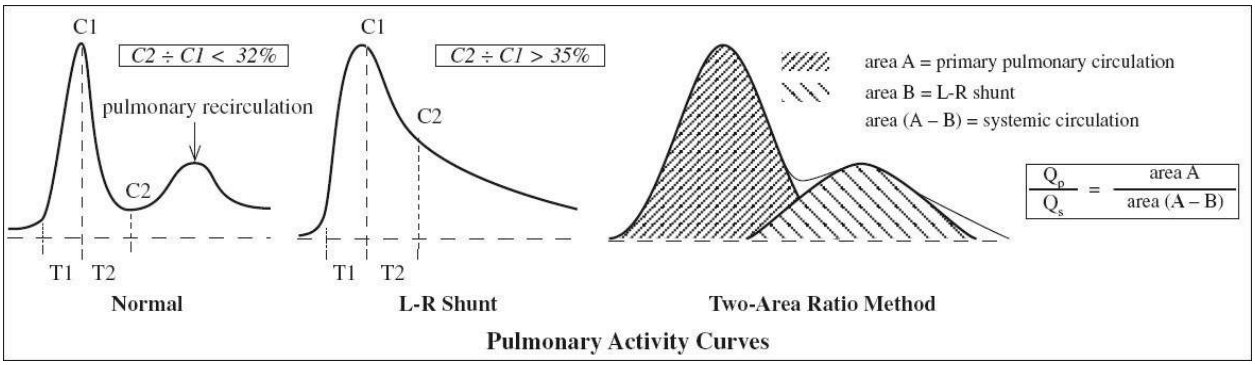
› in 77% of persistent / unstable angina pectoris

› in 41% of compensated congestive heart failure

› in 51% of ECG evidence of ventricular dyssynergy

Prognosis: the larger the area, the worse the mortality + morbidity

^{99m}Tc-Antimyosin Fab Fragments



= specific marker for myocyte damage
= Fab fragments of an antibody raised against water-insoluble heavy chains of cardiac myosin exposed due to necrosis
Sensitivity: 95%
√ uptake ONLY in acute infarct with decreasing intensity as the infarct heals

Nonavid Infarct Imaging

= COLD SPOT IMAGING
= myocardial perfusion study for acute myocardial infarct
Agent: ^{201}Tl (at rest)
Sensitivity after onset of symptoms:
96% within 6–12 hours, 79% after 48 hours, 59% in remote infarction; sensitivity for SPECT (seven pinhole tomography) 94% > planar scintigraphy 75%
√ fixed permanent defect in acute infarction
√ fixed permanent defect at rest + on stress thallium + redistribution images in old infarction
√ "cold defect" at rest may represent transient ischemia in unstable angina
N.B.: ^{201}Tl cannot distinguish between recent + remote infarction!

Intracardiac Shunts

Blood-pool agents administered by peripheral IV injection:
^{99m}Tc-pertechnetate, DTPA, sulfur colloid, macroaggregated albumin, labeled RBCs
Method:
C2÷C1-method measures hemodynamic significance of a shunt; raw data obtained from pulmonary activity curve (gamma variate method, Qp÷Qs ratio = two-area ratio method, count method); accuracy depends on the shape of the input bolus (single peak of < 2 second duration); measuring C1, C2, T1, T2

A. Normal
C2÷C1 is < 32%
B. L-R shunt
Indication: ASD, VSD, AV canal, aortopulmonic window, rupture of sinus of Valsalva aneurysm

√ C2÷C1 > 35% (area A = primary pulmonary circulation; area B = L-R shunt; area (A – B) = systemic circulation; QP ÷ QS = area A / area (A – B) > 1.2

C. R-L shunt

Indication: Tetralogy of Fallot, transposition, truncus, Ebstein anomaly

√ early arrival of tracer in left side of heart + aorta (first-pass method) prior to arrival of activity from lungs to LV

√ quantification possible only by registration of sum of activity of trapped macroaggregate / microspheres in brain + kidneys

Causes of abnormal nonshunt-related activity:

(1) Radiopharmaceutical breakdown

√ free pertechnetate activity in salivary glands, gastric mucosa, thyroid, kidney

(2) Hepatic cirrhosis abnormal pulmonary vascular channels bypassing the lung (in 10–70%)

(3) Pulmonary AVM

BILIARY SCINTIGRAPHY

Application:

1. Acute cholecystitis
2. Congenital biliary atresia
3. Evaluation of bile leak
4. Choledochal cyst
5. Biliary-enteric fistula
6. Chronic GB dysfunction

^{99m}Tc-IDA analogs = HIDA agents

= ^{99m}Tc-acetanilide iminodiacetic acid analogs (IDA)

Dependent on the substance's lipophility, there is a trade-off between renal excretion + hepatic uptake (BIDA is the most lipophilic, HIDA the least lipophilic)

1. HIDA (2,6-dimethyl derivative): [H = hepatic] bilirubin threshold of < 18 mg/dL; 15% renal excretion
2. BIDA (parabutyl derivative): bilirubin threshold of < 20 mg/dL
3. PIPIDA (paraisopropyl derivative): 2% renal excretion
4. DIDA (diethyl derivative)

most often used:

5. DISIDA (diisopropyl derivative) = Disida®, Disofenin®, Hepatolite®: bilirubin threshold of < 30 mg/dL
6. TMB-IDA (m-bromotrimethyl IDA) = Mebrofenin®, Choletec®: T1/2 uptake is 6 min, T1/2 excretion is 14 min in normals; bilirubin levels may be as high as 30 mg/dL

Quality control: the final compound should contain

› 90–100% ^{99m}Tc-IDA
› < 10% ^{99m}Tc-tin colloid
› < 10% ^{99m}Tc-sodium pertechnetate

Pharmacokinetics:

@ Bloodstream
tracer binds predominantly to albumin → decreasing renal excretion (renal excretion seen in most normals); dissociation of albumin + ^{99m}Tc-IDA takes place in space of Disse

@ Liver
peak liver activity 5–15 minutes post injection
= hepatic phase; 85% extracted by hepatocytes tracer enters anion pathway of bilirubin
◊ Delayed liver uptake implies hepatocyte dysfunction / CHF (less likely)
◊ Look for liver lesions on early images

@ Bile
secretion by hepatocytes without conjugation; CBD + cystic duct visualized within 10–30 min (not always visualized in normals); GB visualized by 20–60 min
◊ Activity in right paracolic gutter / intraperitoneal space implies postoperative bile leak

@ Bowel
excretion into duodenum by 30 minutes; bowel visualized within 1 hour; no

enterohepatic recirculation

Dose: 2–8 mCi for adults

Radiation dose: 2 rad for upper large bowel; 0.55 rad for gallbladder; 3 rad/mCi for small bowel; 0.01 rad/mCi for whole body

Patient preparation:

» Fasting for at least (2–)4 hours to avoid a contracted gallbladder (because endogenous cholecystokinin contracts gallbladder)

» Injection of 0.02 µg/kg Kinevac® over > 3 minutes to empty gallbladder about 30 minutes before tracer injection in patients on prolonged fasting (fasting > 24 hours causes an overdistended GB)

» Narcotics (opiates) + sedatives → increase tone of sphincter of Oddi and have to be stopped 6–12 hours before exam

Equipment:

Large field-of-view scintillation camera fitted with LEAP collimator; spectrometer set at 140 keV with 20% window

Computer software for deconvolutional analysis allows determination of percent of hepatic arterial and of portal venous blood flow to liver (helpful in assessment of liver transplants)

Imaging: at 5–10-minute intervals for 60 min; if gallbladder not visualized for at least up to 4 hrs; RLAT, RAO, LAO projections to confirm gallbladder position

◊ Look for enterogastric reflux as a cause of biliary gastritis!

IV morphine sulfate (0.04 mg/kg or up to 3 mg):

contracts sphincter of Oddi + raises intrabiliary pressure → retrograde filling of gallbladder

Effect: maximum 5 minutes post injection → shortens study time in cases of nonvisualization of gallbladder → increases accuracy from 88% to 98% and specificity from 83% to 100%

» redose patient with a small amount of radiotracer

» inject morphine at 45–60 minutes if tracer in bowel

» image for 45 minutes after injection

Normals: (excludes diagnosis of acute cholecystitis)

√ gallbladder appearance within 60 minutes

√ gallbladder visualization within 30 minutes in 90%

√ small bowel activity within 90 min (80% within 60 min)

LIVER SCINTIGRAPHY

^{99m}Technetium Sulfur Colloid

= LIVER-SPLEEN SCAN

Indications: liver, spleen, bone marrow, acute rejection in renal transplant, lower GI bleeding, gastric emptying

Physiology: small colloid particles are phagocytized by reticuloendothelial system (RES); 90% of RES function lies within liver + spleen, 10% primarily within bone marrow

Preparation:

^{99m}Tc-pertechnetate and sodium trisulfate are heated in a water bath (95 ± 5°C) for 10 ± 2 minutes; sulfur atoms aggregate to form a "colloid" (average particle size 0.1–1 μm with a range of 0.001–1 μm; true colloid has a particle size of 0.001–0.5 μm); gelatin is added to prevent further growth of particles

Quality control:

(a) > 92% remain at origin of ascending chromatography

(b) upper limit for particle size is 1 μm

› Usual cause for poor preparation is excessive / prolonged heating or a pH > 7

› Preparation should not be used > 6 hours (agglomeration of particles with aging)

Dose: usually 3–6 mCi (8 mCi for SPECT)

Radiation dose: 0.3 rad/mCi for liver (critical organ); 0.02 rad/mCi for whole body; 0.025 rad/mCi for bone marrow

Imaging: 15–30 min post IV injection

Pharmacokinetics: accumulation in liver (85%), spleen (10%), bone marrow (5%); lung localization is rare (presumably secondary to circulating endotoxins + macrophage infiltration)

A. RETICULOENDOTHELIAL LOCALIZATION

√ colloid shift away from liver in diffuse hepatic dysfunction / decreased hepatic perfusion

√ ↑ bone marrow activity in hemolytic anemia

√ ↑ splenic activity in hypersplenism of splenomegaly / cancer / systemic illness

B. BONE MARROW LOCALIZATION

Hematopoietic system extends into long bones in children; recedes to axial skeleton, femora, and humeri with age

◊ Bone marrow distribution cannot be used to determine sites of erythropoiesis!

C. ABSCESS LOCALIZATION Sulfur colloid phagocytized by PMNs + monocytes

Labeling:

(a) in vivo: small labeling yield

(b) in vitro: 40% labeling efficiency, but difficult + time-consuming preparation

SPLENIC SCINTIGRAPHY

1. ^{99m}Tc-sulfur colloid: 3–5 mCi
2. ^{99m}Tc-heat–denatured erythrocytes

Indication:

(1) Splenic trauma

(2) Accessory + ectopic spleen

Technique to make heat–denatured erythrocytes:

» 20–30 minutes after injection of pyrophosphate IV 15–20 mL of blood are drawn

» drawn blood is incubated with 2 mCi of pertechnetate → heated to 49.5°C for 35 minutes and → reinjected

◊ Fragmentation of RBCs from overheating increases hepatic uptake!

Imaging: 20 minutes post injection

GASTROINTESTINAL SCINTIGRAPHY

Radionuclide Esophagram

Preparation: 4–12 hours fasting; imaging in supine / erect position
Dose: 250–500 μCi ^{99m}Tc-sulfur colloid in 10 mL of water taken through straw
Imaging: when swallowing begins
Normal transit time: 15 seconds with 3 distinct sequential peaks progressing aborally
Prolonged transit time:
achalasia, progressive systemic sclerosis, diffuse esophageal spasm, nonspecific motor disorders, "nutcracker" esophagus, Zenker diverticulum, esophageal stricture + obstruction
Difficult interpretation in: hiatal hernia, GE reflux, Nissen fundoplication

Levine / Denver Shunt Patency

Technique: sterile injection of 0.5–1 mCi ^{99m}Tc-MAA / sulfur colloid via paracentesis
Imaging: over abdomen (or chest) to detect uptake in liver (or lung) → confirms patency

RENAL SCINTIGRAPHY

Renal Agents

1. Agents for renal function: ^{99m}Tc-DTPA, ^{131}I-Hippuran
2. Renal cortical agent: ^{99m}Tc-DMSA
3. Renal combination agent: ^{99m}Tc-glucoheptonate

^{99m}Tc-DTPA

= ^{99m}Tc-diethylenetriamine pentaacetic acid
= agent of choice for assessment of
(1) Perfusion
(2) Glomerular filtration = relative GFR
(3) Obstructive uropathy
(4) Vesicoureteral reflux

Pharmacokinetics:
glomerular agent excreted exclusively by glomerular filtration (similar to inulin) without reabsorption / tubular excretion / metabolism; chelating agent in 5–10% bound to plasma protein; extracted with 20% efficiency on each pass through kidney (= filtration fraction)
◊ May be used only in patients with normal / mildly impaired renal function!

Time-activity behavior:
› abdominal aorta (15–20 seconds)
› kidneys + spleen (17–24 seconds); liver appears later because of portal venous supply
› renal cortical activity (2–4 min): mean transit time of 3.0 ± 0.5 min; static images of cortex taken at 3–5 min
› renal pelvic activity (3–5 min): peak at 10 minutes; asymmetric clearance of renal pelvis in 50%; accelerated by furosemide

Biologic half-life: 20 minutes
Dose: 10–20 mCi
Radiation dose: 0.85 rad/mCi for renal cortex; 0.6 rad/mCi for kidney; 0.5 rad/mCi for bladder; 0.15 rad/mCi for gonads; 0.15 rad/mCi for whole body

Adjunct: Lasix administration (20–40 mg IV) 20 minutes into exam allows assessment of renal pelvic clearance with accuracy equal to Whitaker test (DDx of obstructed from dilated but nonobstructed pelvicalyceal system)

[^{99m}Tc-Glucoheptonate]

◊ ^{99m}Tc-GHA is largely replaced by ^{99m}Tc-MAG_3

Pharmacokinetics:

rapid plasma clearance + urinary excretion with excellent definition of pelvicalyceal system during 1st hour; extracted by

(a) glomerular filtration and

(b) tubular excretion (30–45% within 1st hour); 5–15% of dose accumulates in tubular cells by 1 hour, 15–25% by 3 hours; cortical accumulation remains for 24 hours

Imaging:

(a) collecting system within first 30 minutes

(b) renal parenchyma after 1–2 hours (interfering activity in collecting system)

Biologic half-life: 2 hours

Dose: 15 (range 10–20) mCi

Radiation dose: 0.17 rad/mCi for kidney; 0.008 rad/mCi for whole body; 0.015 rad/mCi for gonads

^{99m}Tc-DMSA

= ^{99m}Tc-dimercaptosuccinic acid

= suitable for imaging of functioning cortical mass: pseudotumor versus lesion

Pharmacokinetics:

high protein-binding + slow plasma clearance; 4% extracted per renal passage; 4–8% glomerular filtration within 1 hour and 30% by 14 hours; 50% of dose accumulates in proximal + distal renal tubular cells by 3 hours (= cortical agent)

Imaging: after 1– 3–24 hours (optimal at 34 hours); ↑ sensitivity to structural defects with SPECT

Biologic half-life: > 30 hours

Dose: 5–10 mCi

Radiation dose: 0.014 rad/mCi for gonads; 0.015 rad/mCi for whole body

[^{131}I-OIH]

largely replaced by ^{99m}Tc-MAG_3

= ^{131}I-orthoiodohippurate (Hippuran®)

= good for evaluation of renal tubular function / effective renal plasma flow; agent with highest extraction ratio without binding to renal parenchyma; visualizes kidney even in severe renal failure

Pharmacokinetics:

80% secreted by proximal tubules; 20% filtered by glomeruli; maximal renal concentration within 5 minutes; normal transit time of 2–3 minutes; ~ 2% free iodine

◊ Lugol's solution is administered to protect thyroid!

Imaging: in 15–60-second intervals for 20 minutes; renal uptake determined from images obtained by 1–2 minutes (patient in supine position → equidistance of kidneys

to camera)

Biologic half-life: 10 minutes (with normal renal function)

Dose: 200 (range 150–300) µCi

Radiation dose: 0.06 rad/200 µCi for bladder; 0.02 rad/ 200 µCi for kidney; 0.02 rad/200 µCi for whole body; 0.02 rad/200 µCi for gonads

^{99m}Tc-Mertiatide = ^{99m}Tc-Mercaptoacetyltriglycine (MAG_3)

= renal plasma flow agent similar to OIH but with imaging benefits of ^{99m}Tc label (improved dosimetry)

Pharmacokinetics:

tubular agent → cleared primarily by active secretion in proximal tubules + only minimal glomerular filtration; clearance is less than Hippuran; surrogate measure for effective renal plasma flow

Dose: 10 mCi

Evaluation: true renal plasma flow = MAG3 flow (obtained off renogram curve) multiplied by a constant (varies between 1.4 and 1.8)

Enalaprilat (Vasotec®)-enhanced Renography

Technique:

Renal Scintigraphic Agents

Agent	*Dose*	*Pharmacokinetics*	*Imaging Characteristics*
MORPHOLOGIC AGENTS			
^{99m}Tc-GHA	5 mCi	proximal tubular uptake + glomerular filtration	collecting system visualized on delayed images
^{99m}Tc-DMSA	2–5 mCi	proximal + distal tubular uptake	limited availability, relatively high radiation dose, collecting system not visualized on delayed images
FUNCTIONAL AGENTS			
^{131}I-OIH	200–400 µCi	80% secreted, 20% filtered	routinely used for ERPF measurement, analog of PAH, highest renal extraction fraction, poor image detail, high radiation dose, requires high-energy collimator
^{99m}Tc-DTPA	10–15 mCi	nearly 100% filtered	GFR calculation, delayed time-to-peak with slow clearance
^{99m}Tc-MAG_3	2–10 mCi	99% secreted	ERPF estimate, good cortical detail, high target-to background ratio

» Blood pressure check → to prevent testing excessively hypertensive patients
» Discontinue captopril / lisinopril 3 days before study
» Discontinue enalaprilat
» Stop any other antihypertensive medications overnight (except for β-blockers)
» Fasting: liquids acceptable
» Bladder catheterization to monitor urinary output
» ½ normal saline IV drip at 75 mL/hour at a dose of 10 mL fluid/kg body weight → to ensure adequate hydration
» Furosemide (= Lasix®) IV
20 mg if serum creatinine < 1.5 mg/dL
40 mg if serum creatinine > 1.5 mg/dL
60 mg if serum creatinine > 3.0 mg/dL
(not to exceed 1.0 mg/kg)

» 2.5–5 mCi ^{99m}Tc-MAG$_3$ IV for baseline study
(a) flow phase with 1 sec/frame for 60 frames
(b) tracer kinetic (dynamic) phase with 15 sec/frame for 120 frames
» Rehydration with ½ normal saline keeping a 250–300 mL negative fluid balance
» Postvoid image (or Foley catheter with PVR)
» 0.04 mg/kg enalaprilat IV (up to a maximum of 2.5 mg) infused over 5 min + blood pressure and heart rate checks q 5 minutes
» Repeat furosemide (= Lasix®) IV
» 5–7.5 mCi ^{99m}Tc-MAG$_3$ IV [or 10 mCi ^{99m}Tc-MAG$_3$ IV single post-enalaprilat study for patients already on ACEI therapy]
» Image acquisition:
› 1–3 seconds / frame for first 60 seconds
› 10–30 seconds / frame thereafter
› image display at 1–3-minute intervals
› total acquisition time of 20–30 minutes
» whole-kidney ROI (better count statistics) / cortical ROI (for unusual retention in renal pelvis)

2-day protocol:
› ACEI renography on day 1
› if test abnormal patient has to return on day 2 for a baseline study to maximize specificity

Captopril (Capoten®)-enhanced Renography

Dose: 1 mg/kg PO for pediatric patient; 25 or 50 mg PO for adult patient (crush tablets + dissolve in 200 mL of water)

Technique:
» no solids for 4 hours prior to study
» moderate hydration with 7 mL water / kg BW ingested 30–60 minutes before study
» radiopharmaceutical injected 60 minutes after ingestion of captopril
» at the same time 20 mg furosemide IV → to wash out radiopharmaceutical from distal nephron + calices + pelvis → improving detection of cortical retention

Differential Renal Function

Agents:
(1) ^{99m} Tc-DTPA: measurements prior to excretion within first 1–3 minutes; images taken at 1.5-second intervals for 30 seconds followed by serial images for next 30 minutes
(2) ^{131}I-Hippuran: measurements prior to excretion within first 1–2 minutes

Evaluation: generation of time-activity curves
√ upslope (= accretion phase)
√ peak activity (maximum uptake phase)
√ downslope (excretion phase)
√ increased hepatic + soft-tissue uptake with impaired renal function
√ measurements usually not significantly affected with differences in renal depth
√ measurements are accurate in renal obstruction if obtained within 1–3 minutes
√ prediction about functional recovery not possible following surgical relief of obstruction

Diuretic Renal Scintigraphy

Indication: differentiation of obstructed from nonobstructed chronically dilated collecting system ± ureter in patients with history of surgery / obstruction

Agents: tubular agent ^{99m}Tc mertiatide (eg, ^{99m}Tc-MAG_3); glomerular agent ^{99m}Tc pentetic acid (ie, ^{99m}Tc-DTPA)

Time activity curve of urinary tract obstruction:

(a) moderate obstruction
- √ ↓ radiotracer activity (= perfusion) in affected kidney during angiographic phase
- √ delayed cortical concentration (= delayed uptake) before administration of diuretic
- √ delayed clearance of activity after administration of diuretic with half-time > 20 minutes

(b) high-grade obstruction:
- √ failed clearance of radiotracer from kidney
- √ no excretion of tracer into renal collecting system

False positives:

attenuated effectiveness of furosemide, reservoir effect in severe dilatation of nonobstructed collecting system, poor hydration, high filling pressure of bladder

Radionuclide Cystogram

Use: evaluation of bladder volume at reflux, volume of refluxed urine, residual urine volume, ureteral reflux drainage time

Technique:

(a) indirect: IV injection of ^{99m}Tc-DTPA

(b) direct: instillation of 0.5–1 mCi ^{99m}Tc-pertechnetate-saline mixture into bladder (more sensitive for reflux during filling phase, which occurs in 20%)

Imaging:

posterior upright views throughout filling and voiding phases; review on cinematic loop helpful; residual bladder volume can be calculated

Advantage:

lower radiation dose to gonads than fluoroscopic contrast cystography (5 mrad)!

ADRENOCORTICAL SCINTIGRAPHY

1. NP-59
2. Selenium-75 6-β-selenomethylnorcholesterol (Scintadrin®)

Iodocholesterol

Agent: ^{131}I-6-β-iodomethyl-19-norcholesterol (NP-59); no FDA approval (available as investigational new drug)

Indications: adrenocortical imaging

(1) ACTH-independent Cushing syndrome: adenoma, cortical nodular hyperplasia

(2) Adrenocortical carcinoma
- √ spectrum from nonfunctioning to functioning

(3) Primary aldosteronism: adenoma, bilateral adrenal hyperplasia → improved scintigraphic discrimination requires dexamethasone suppression before + during imaging

(4) Hyperandrogenism: adrenal adenoma, zona reticularis hyperplasia, polycystic ovary disease, ovarian stromal hyperplasia, androgen-secreting ovarian neoplasm
(5) Incidentaloma (= adrenal mass)
√ localization to side of CT-depicted adrenal mass (= concordant uptake) suggests hyperfunctioning adenoma
√ markedly diminished / absent uptake (= discordant uptake) or symmetric uptake (= nonlateralization) suggests space-occupying mass (eg, cyst) / malignant adrenal mass

Pharmacokinetics:
NP-59 is incorporated into low-density lipoproteins (LDL) → circulates to adrenal cortex → absorbed from LDL complex by low-density lipoprotein receptors → esterified in adrenal cortex; adrenocortical uptake affected by adrenocortical secretagogues (corticotropin, angiotensin II); enterohepatic excretion may obscure adrenals (prior laxative administration beneficial)

Dose: 1 mCi (37 MBq) with slow IV injection

Radiation dose: 26 rad/mCi for adrenals, 8.0 rad/mCi for ovaries, 2.4 rad/mCi for liver, 2.3 rad/mCi for testes, 1.2 rad/mCi for whole body

Method: Lugol solution administered orally (50 mg of iodine per day) for 4–5 days starting the day before injection → to block thyroid uptake of free iodine; mild laxative → to decrease bowel activity

Imaging:
(a) 5–7-days interval between injection + imaging
(b) 3–5-days interval between injection + imaging in case of dexamethasone suppression (1 mg four times daily for 7 days prior to and throughout 4–5 days of postinjection imaging interval)

SCINTIGRAPHY OF NEUROENDOCRINE TUMORS

Origin: embryonic neural crest tissue forming neuroendocrine cells + neuroendocrine tumors

Location: hypothalamus, pituitary gland, thyroid gland, adrenal medulla, GI tract

Function: neuroendocrine cells synthesize amines from precursor molecules → decarboxylate amines → polypeptides (= neurotransmitters + hormones); former name: APUD (amine precursor uptake and decarboxylose) cells + APUDomas

Radiopharmaceuticals:
similar in molecular structure to hormones that tumor synthesizes / incorporates into metabolic + cellular processes

Somatostatin Analogs

= 14-amino acid peptide that inhibits peptide + hormone synthesis by neuroendocrine cells ("antigrowth hormone") in the anterior pituitary (ACTH, prolactin, TSH) and in pancreas + GI tract (insulin, glucagon, gastrin, VIP, secretin, motilin, cholecystokinin)

Biologic half-life: 2–4 minutes (molecule disrupted by various plasma enzymes in circulation)

Octreotide = Sandostatin®
= 8-amino acid analog of somatostatin
Plasma half-life: 2 hours

^{111}INDIUM-PENTETREOTIDE = OCTREOSCAN®

Indication: pituitary tumor, gastrinoma, paraganglioma, carcinoid, neuroblastoma, small cell lung cancer, pheochromocytoma
Physical half-life: 68 hours
Emission: 171 and 245 keV
Chelating agent: diethylenetriaminepentaacetic acid
Sensitive to: somatostatin receptor subtypes 2 (80% of enteropancreatic neuroendocrine tumors) and 5
Distribution: kidneys, spleen, gallbladder, liver, urinary bladder, intestines, thyroid, pituitary gland
Dose: 3–5–6 mCi
Preparation: oral laxative (in patient without diarrhea); cessation of octreotide therapy 72 hours before administration
Advantage: superior to MIBG
Imaging protocol:
» SPECT of area of interest after 4 hours (to avoid superimposed physiologic biliary excretion into small + large bowel)
» delayed SPECT imaging at 18–24 hours
» planar whole-body imaging

Guanethidine Analogs

Indications:
catecholamine-producing adrenal medullary tumor (intrarenal pheochromocytoma + extraadrenal paraganglioma) and chromaffin cell tumor (C cells of thyroid, melanocytes of skin, chromaffin cells of adrenal medulla, pancreatic cells, Kulchitsky cells)
(1) Pheochromocytoma (80–90% sensitive, > 90% specific) tumors as small as 0.2 g have been detected
(2) Neuroblastoma, carcinoid, medullary thyroid carcinoma, nonfunctioning retroperitoneal neuroendocrine tumor, middle mediastinal paraganglioma, adrenal metastasis of choriocarcinoma, Merkel (skin) tumor

Pharmacokinetics:
active transport into cell membrane (= type I uptake mechanism) of sympathomedullary system, which have neurosecretory granules capable of accumulating MIBG; not metabolized to any appreciable extent
Normal activity is seen in liver, spleen, bladder, salivary glands, myocardium, lungs; 85% of injected dose is excreted unchanged by kidneys

Preparation:
(1) Lugol solution administered orally (50 mg of iodine per day) for 4–5 days starting the day before injection → to block thyroid uptake of free iodine
(2) To avoid false-negative scan → cessation of sympatho- mimetics, reserpine, calcium channel blockers, tricyclic antidepressants, labetalol for 3–4 days before administration

^{131}I-METAIODOBENZYLGUANIDINE (MIBG)

Sensitivity: 77–100%

Emission: 159 keV (for ^{123}I); 364 keV (for ^{131}I)
Dose: 0.5–1.0 mCi
Radiation dose: 35 rad/mCi for adrenal medulla, 1.0 rad/mCi for ovaries, 0.4 rad/mCi for liver, 0.22 rad/mCi for whole body
Imaging: planar static whole body imaging at 48–72 hours (target-to-background ratio improved at 72 hours) of thorax, abdomen, pelvis with 100,000 counts / 20 minutes per image at each location ± SPECT

^{123}I-METAIODOBENZYLGUANIDINE (MIBG)

agent of choice ← higher quality images + lower radiation burden + quicker results, allows SPECT imaging
Dose: 5–10 mCi
Radiation dose: 2.76 rad/mCi for adrenals, 0.07 rad/mCi for ovaries, 0.05 rad/mCi for liver, 0.02 rad/mCi for whole body
Imaging: at 6 hours and 24 hours

Glucose Analogs

2-(^{18}FLUORINE)FLUORO-2-DEOXY-D-GLUCOSE (FDG)

Uptake: accumulation in cells of rapidly growing tumor ← accelerated glucose metabolism (phosphorylation to FDG-6-phosphatase)
FDG-positive: aggressive neuroendocrine tumor
FDG-negative: slow tumor growth in 50% of neuroendocrine tumors

BONE AGENTS

A. POLYPHOSPHATES = LINEAR PHOSPHATES = CONDENSED PHOSPHATES
First agents described; contain up to 46 phosphate residues; simplest form contains 2 phosphates = pyrophosphate (PYP)
B. DIPHOSPHONATES Organic analogs of pyrophosphate characterized by P-C-P bond; chemically more stable; not susceptible to hydrolysis in vivo; most widely used agents:
1. Ethylene hydroxydiphosphonate (EHDP)
= ethane-1-hydroxy-1,1-diphosphonate
2. Methyl diphosphonate (MDP)
Synonym: Methylene diphosphonate / Medronate
C. Imidodiphosphonates (IDP) Characterized by P-N-P bond

Physiologic Uptake of Bone Agents

(a) rapid distribution into ECF (78% of injected dose with biologic half-life of 2.4 minutes) directly related to blood flow + vascularity; blood clearance rate determines ECF (= background) activity (at 4 hours 1% for diphosphonates, 5% for pyrophosphate / polyphosphate secondary to greater degree of protein binding)
(b) chemisorbs on hydroxyapatite crystals in bone + in calcium crystals in mitochondria; MDP concentration at 3 hours is directly proportional to calcium contents of tissues (14–24% calcium in bone, 0.005% calcium in muscle); 50–60% (58% for MDP, 48% for EHDP, 47% for PYP) are localized in bone by ~ 3 hours depending on blood flow + osteoblastic activity; 2–10% of the dose are present within soft tissues; myocardial uptake depends on

at least some revascularization of infarcted muscle

Excretion of Bone Agents

via urinary tract by 6 hours in 68% of MDP / EHDP, in 50% of PYP, in 46% of polyphosphates

◊ Forcing fluids + frequent voiding reduces radiation dose to bladder!

Indications for Bone Imaging

1. Imaging of bone, myocardial / cerebral infarct, ectopic calcifications, some tumors (neuroblastoma)
2. Rx for Paget disease, myositis ossificans progressiva, calcinosis universalis → inhibits formation + dissolution of hydroxyapatite crystals

Pediatric Indications for Bone Scan

A. Back pain
   1. Diskitis
   2. Pars interarticularis defect: SPECT imaging adds sensitivity
   3. Osteoid osteoma: can be used intraoperatively to ensure removal of nidus
   4. Sacroiliac infection

B. Nonaccidental trauma

Pediatric Dose Formula: 0.25 mCi/kg ^{99m}Tc-medronate; (minimum dose of 1 mCi)
or dose range: [(age + 1)/(age + 7)] × [lowest adult range]

Imaging with Bone Agents

@ Bone: 2–3 hours post injection
   ◊ Fractures may not show positive uptake until 3–10 days depending on age of patient

@ Myocardium: 90–120 min post injection
   ◊ Ideal imaging time is 1–3 days post infarction

Usual dose: 20 mCi (740 MBq)

Radiation dose: 0.13 rad/mCi for bladder (critical organ), 0.04 rad/mCi for bone, 0.01 rad/mCi for whole body

Labeling: Tc (VII) is eluted as a pertechnetate ion; chemical reduction with Sn (II) chloride; chelated into a complex of ^{99m}Tc(IV)-tin-phosphate

Quality Control:
(1) < 10% ^{99m}Tc-tin colloid / free ^{99m}Tc-pertechnetate (a good preparation is 95% bound)
(2) Agent should not be used prior to 30 min after preparation
(3) Avoid injection of air in preparation of multidose vials (oxidation results in poor Tc bond)
(4) Kit life is 4–5 hours after preparation

Three-Phase Bone Scanning

over area of interest

1. Rapid sequence flow study (2–5 sec/frame) = early arterial flow = 1st phase
2. Immediate postflow images (1 million counts for central body + 0.5 million counts for extremities) = blood pool = tissue phase = 2nd phase
3. Delayed images (0.5–1.0 million counts) between 3–4 hours following injection = 3rd

phase

BONE MARROW AGENTS

for assessment of hematopoiesis / phagocytosis by RES

1. ^{99m}Tc-sulfur colloid (10% uptake in bone marrow)
2. ^{111}In chloride
3. ^{99m}Tc-MMAA
   = mini-microaggregated albumin colloid for liver, spleen, hematopoietic marrow
   Particle size: 30–100 μm
   Dose: 10 mCi
   Marrow dose: 0.55 rad
   Marrow accumulation at 1 hour:
   6 x higher than for sulfur colloid
   3 x higher than for antimony-sulfur colloid

Indications for Bone Marrow Imaging:

A. EXPANSION of hematopoietically active bone marrow
   1. Hematologic disorders to reveal presence of peripheral expansion of functional marrow
B. FOCAL DEFECT from displacement by infiltrating disease
   1. Marrow replacement disorders: eg, Gaucher disease
   2. Bone infarction: eg, sickle cell anemia (DDx from osteomyelitis)
   3. Avascular necrosis in children

Indications for Non-organ–specific Whole Body Imaging

1. Tumor
   Agents: ^{67}Ga citrate, ^{131}I MIBG,
   ^{111}In pentetreotide (OctreoScan™),
   ^{111}In antiprostate antibody (ProstaScint®),
   ^{111}In OncoScint™,
   ^{99m}Tc anti-CEA antibody (CEA-Scan®),
   ^{18}F deoxyglucose
2. Inflammation / infection
   Agents: ^{67}Ga citrate, ^{111}In oxime labeled WBC, ^{99m}Tc HMPAO labeled WBC

AGENTS FOR INFLAMMATION

^{67}Ga-citrate Scintigraphy

overall 58–100% sensitivity; 75–100% specificity (lower for abdominal inflammation because of problematic abdominal activity)
Indication: ^{67}Ga mostly limited to
(a) chest: interstitial pneumonia, opportunistic infection, sarcoidosis, drug toxicity
(b) bone: osteomyelitis
Pathophysiology:
leakage of protein-bound ^{67}Ga into extracellular space ← hyperemia + increased

capillary permeability; ^{67}Ga is preferentially bound to nonviable PMNs + macrophages

1. Leukocyte incorporation (rich in lactiferous)
2. Bacterial uptake (iron-chelating siderophores)
3. Inflammatory tissue stimulates lactoferrin production

Gallium in Chronic Abdominal Inflammation

67% sensitivity, 64% specificity, 13% false-negative rate, 5% false-positive rate

Dose: 5 mCi

Imaging: routine at 48–72 hours (after clearance of high background activity); optional at 6–24 hours (prior to renal + gastrointestinal excretion); delayed images as needed

√ diffuse uptake in peritonitis

√ localized uptake in acute pyogenic abscess, phlegmon, acute cholecystitis, acute pancreatitis, acute gastritis, diverticulitis, inflammatory bowel disease, surgical wound, pyelonephritis, perinephric abscess

Labeled Leukocyte Scintigraphy

= primary imaging method for inflammation / infection

Indication:

(1) Fever of unknown origin / bacteremia
(2) Abdominal infection / abscess
(3) Osteomyelitis
(4) Inflammatory bowel disease
(5) Vascular graft infection

Preparation (3-hour time):

» 30–40 mL of whole blood drawn into syringe containing an anticoagulant

» syringe stands in upright position for 1–2 hr with addition of hydroxyethyl starch (for sedimentation of RBCs)

» under centrifugation leukocytes form a pellet at bottom of tube (allows separation of leukocytes from platelets)

Requirements:

1. WBC count > 2,000/mm3
2. Neutrophil-mediated inflammatory process

Biodistribution: closely parallels hematopoietically active marrow

Physiologic uptake:

@ Granulation wounds = healing by secondary intention (eg, ostomies, skin graft)

◊ Leukocytes do NOT accumulate in normally healing wounds

@ Lung

√ physiologic diffuse lung uptake up to 4 hours

◊ Lung uptake > 24 hours due to pneumonia / ARDS

√ physiologic diffuse lung uptake in severely septic patient ← cytokine release at site of infection + subsequent activation of pulmonary vascular endothelium

^{111}In-labeled WBC

= ^{111}In-oxime–labeled autologous leukocytes with 80% sensitivity; 97% specificity, 91%

accuracy (superior to ^{67}Ga citrate); no activity in intestinal contents / urine

Indication:

occult sepsis (postoperative fever), acute pyogenic infection, abdominal + renal abscess, inflammatory bowel disease, nonpulmonary infection with HIV positivity, prosthetic graft infection (bone / cardiovascular graft), acute + chronic + complicated bone / joint infection

Technique:

chelating agents (oxime = 8-hydroxyquinoline / tropolone) used for labeling of leukocytes; lipophilic oxime-indium complex penetrates cell membrane of white cells; intracellular proteins scavenge the indium from oxime; oxime diffuses out from cell; requires 2 hr of preparation time

Recovery rate: 30% at 1–4 hours after injection

Limitations: 19 gauge IV access, leukopenia, impaired chemotaxis, abnormal WBCs, children

Dose: 0.5 mCi

Half-life: 67 hours

Useful photopeaks: 173 keV (89%), 247 keV (94%)

Radiation dose:

13–18 rad/mCi for spleen; 3.8 rad/mCi for liver; 0.65 rad/mCi for red marrow; 0.45 rad/mCi for whole body; 0.29 rad/mCi for testes; 0.14 rad/mCi for ovaries (compared with ^{67}Ga higher dose to spleen, but lower dose to all other organs)

Biodistribution: spleen, liver, bone marrow; blood clearance halftime of 6–7 hours; NO bowel activity

Imaging:

best at 18–24 hours following injection of cell preparation; optional at 2–6 hours (eg, in inflammatory bowel disease); delayed images as needed; bone marrow uptake provides useful landmarks

- SPECT imaging >> standard planar imaging

√ focal activity greater than in spleen is typical for abscess (comparison based on liver, spleen, bone marrow activity)

√ activity equal to liver (significant inflammatory focus)

√ abdominal activity is always abnormal (eg, pseudomembranous / ischemic colitis, inflammatory bowel disease, GI bleeding)

False positives:

@ Chest: CHF, RDS, embolized cells, cystic fibrosis, vascular access lines, dialysis catheter

@ Abdomen: accessory spleen, colonic accumulation, renal transplant rejection, active GI hemorrhage, vasculitis, ischemic bowel disease, following CPR, uremia, postradiation therapy, Wegener granulomatosis, ALL, lumbar puncture

@ Miscellaneous: IM injection, histiocytic lymphoma, cerebral infarction, arthritis, skeletal metastases, thrombophlebitis, hematoma, hip prosthesis, cecal carcinoma, postsurgical pseudoaneurysm, necrotic tumors that harvest WBCs

False negatives:

chronic infection, aortofemoral graft, LUQ abscess, infected pelvic hematoma,

splenic abscess, hepatic abscess (occasionally)

Disadvantages:

2-day procedure, low-quality images especially of extremities

Advantages:

no activity in normal GI / GU tract (preferred in postoperative patient + vascular grafts); simultaneous WBC + sulfur colloid bone marrow scan possible

^{99m}Tc-HMPAO Labeled WBC

Optimal use: osteomyelitis in extremities

Biodistribution: bone marrow, little soft tissue, spleen > liver, renal + bladder activity

Excretion: in bile + urine

Advantages over ^{111}In WBC imaging:

(a) improved photon flux with lower dose

(b) earlier imaging (same day)

Disadvantages:

(1) Biliary excretion leads to bowel activity, which may obscure abdominal / graft abscess if not imaged early

(2) Heart and blood pool activity

(3) Nonspecific accumulation in lung may obscure lung disease

Technique:

chelating agents (exametazime oxime) used for labeling of leukocytes; ^{99m}Tc-Ceretec binds with autologous WBCs and is reinjected

Dose: up to 10 mCi

Imaging:

30 min (optimum for use in abdomen), 60 min, 3–4 hours, 4–8 hours (optimum outside abdomen); 24 hr (optional)

False positives:

may be due to unusual marrow distribution, correlation with bone marrow (sulfur colloid) scan may be necessary

^{67}GA-CITRATE

^{67}Ga acts as an analogue of ferric ion; used as gallium citrate (water-soluble form)

Production: bombardment of zinc targets (67Zn, 68Zn) with protons (cyclotron); virtually carrier-free after separation process

Decay: by electron capture to ground state of 67Zn

Energy levels:

(a) used: 93 keV (38%), 184 keV (24%), 296 keV (16%), 388 keV (8%)

(b) unused: 91 keV (2%), 206 keV (2%)

Physical half-life: 3.3 days (= 78 hours)

Biologic half-life: 2–3 weeks

Adult dose: 3–6 mCi or 50 μCi/kg

Radiation dose:

0.3 rad/mCi for whole body; 0.9 rad/mCi for distal colon (= critical organ); 0.58 rad/mCi for red marrow; 0.56 rad/mCi for proximal colon; 0.46 rad/mCi for liver; 0.41 rad/mCi for

kidney; 0.24 rad/mCi for gonads

Binding Sites of ^{67}Ga-citrate

Physiology:

^{67}Ga is bound to iron-binding sites of various proteins (strongest bond with transferrin in plasma, lactoferrin in tissue); multiexponential + slow plasma disappearance; competitive iron administration (Fe-citrate) enhances target-to-background ratio by increasing ^{67}Ga excretion

A. Fluid spaces
   1. Transferrin, haptoglobin, albumin, globulins in blood serum (90%)
   2. Interstitial fluid space (increased capillary permeability and hyperemia in inflammation + tumor)
   3. Lactoferrin in tissue

B. Cellular binding
   1. Viable PMNs incorporate 10% of ^{67}Ga (bound to lactoferrin in intracytoplasmic granules)
   2. Nonviable PMNs + their protein exudate (iron-binding proteins are deposited at sites of inflammation; these remove iron from the extracellular space; iron is no longer available for bacterial growth)
   3. Lymphocytes have lactoferrin-binding surface receptors
   4. Phagocytic macrophages engulf protein-iron complexes
   5. Bacteria + fungi (siderophores = lysosomes = low-molecular–weight chelates produced by bacteria) have iron-transporting protein mechanism
   6. Tumor cell-associated transferrin receptor + transportation into cells (lymphocytes bind ^{67}Ga less avidly than PMNs; RBCs do NOT bind ^{67}Ga)

mnemonic: LFT'S

Lactoferrin (WBCs)
Ferritin
Transferrin
Siderophores (bacteria)

Uptake of ^{67}Ga-citrate

at 24 hr: most intense in RES, liver, spleen (4%), bone marrow (lumbar spine, sacroiliac joints), bowel wall (chiefly colonic activity on delayed images), renal cortex, nasal mucosa, lacrimal + salivary glands, blood pool (20%), lung (< 3% = equivalent to background activity), breasts

at 72 hr: 75% of dose remains in body its activity equally distributed among soft tissue (orbit, nasal mucosa, large bowel), liver, bone or bone marrow (occiput); kidney activity no longer detectable; lacrimal + salivary glands may still be prominent

Excretion of ^{67}Ga- citrate

(a) via urinary tract (10–25% within 24 hours) no activity in kidneys + urinary bladder after 24 hours

(b) via GI tract (10–20%) hepatobiliary pathway + colonic mucosal excretion

◊ Enemas + laxatives promote clearing of bowel activity!
◊ Bowel cleansing not optimal as gallium lies also within colonic wall
(c) via various body fluids eg, human milk (mandates to stop nursing for 2 weeks)

Imaging of ^{67}Ga-citrate

usually [6, 24], 48–72 hours (up to 7 days)

◊ Best target-to-background ratio generally at 72 hours
◊ Optimal target-to-background ratio at 6–24 hours for abscess
◊ Optimal target-to-background ratio at 24–48 hours for tumor
• 500,000 count spot views / whole body
• SPECT useful

Degrading Factors of Gallium Imaging

√ lesions < 2 cm are not detectable
√ photon scatter within overlying tissues
√ physiologic high activity of liver, spleen, bones, kidney, GI tract may obscure lesion

Normal Variants of Gallium Uptake

1. Breasts: increased uptake under stimulus of menarche, estrogens, pregnancy, lactation, phenothiazine medication, renal failure, hypothalamic lesion
2. Liver: suppressed uptake by chemotherapeutic agents / high levels of circulating iron / irradiation / severe acute liver disease
3. Lung: prominent uptake after lymphangiography
4. Spleen: increased uptake in splenomegaly
5. Thymus: uptake in children
6. Salivary glands: uptake within first 6 months after radiation therapy to neck (may persist for years)
7. Epiphyseal plates in children
8. Previous steroid therapy, chemotherapy, and radiation therapy may decrease Ga uptake
9. Healing surgical incision

No Gallium Uptake

most benign neoplasms; hemangioma; cirrhosis; cystic disease of the breast, liver, thyroid; reactive lymphadenopathy; inactive granulomatous disease

Indications for Gallium Imaging

A. Infection Gallium has been largely replaced with WBC imaging but can be used in chronic infection
   1. Inflamed / infarcted bowel (eg, Crohn disease)
      DDx: normal bowel excretions (must be cleared by enema; bowel pathology shows persistent activity)
   2. Diffuse lung uptake sarcoidosis, diffuse infections (TB, CMV, PCP), lymphangitic metastases, pneumoconioses (asbestosis, silicosis), diffuse interstitial fibrosis (UIP), drug-induced pneumonitis (bleomycin, cyclophosphamide, busulfan), acute radiation pneumonitis, recent lymphangiographic contrast
   3. Lymph node involvement sarcoidosis, TB, MAI, Hodgkin disease

DDx: NOT seen in Kaposi sarcoma, a useful distinction in AIDS patients with hilar nodes

B. Tumor Neoplastic uptake is variable; prominent uptake is usually seen in:
   1. Non-Hodgkin lymphoma (especially Burkitt)
   2. Hodgkin disease
   3. Hepatoma
   4. Melanoma

   Useful in:
   › detection of tumor recurrence
   › DDx of focal cold liver lesions on Tc-^{99m} sulfur colloid scan

Gallium in Bone Imaging

Increased activity in:

1. Active osteomyelitis (90% sensitivity is higher than for ^{99m}Tc-MDP)
2. Sarcoma
3. Cellulitis (bone scan followed by gallium scan)
4. Septic arthritis, rheumatoid arthritis
5. Paget disease
6. Metastases (65% sensitivity, less than for bone agents)

Gallium in Tumor Imaging

Particularly useful in evaluating extent of known tumor disease + in detection of tumor recurrence

A. USEFUL CATEGORY
   1. Lymphoma
      a: Hodgkin disease: 74–88% sensitivity
      b: NHL: sensitivity varies
         › histiocytic form: 85–90% sensitivity
         › lymphocytic well-diff.: 55–70% sensitivity
         95% sensitivity for mediastinal disease,
         80% sensitivity for cervical + superficial lesions; poor sensitivity below diaphragm
   2. Burkitt lymphoma: almost 100% sensitivity
   3. Rhabdomyosarcoma: >95% sensitivity
   4. Hepatoma: 85–95% sensitivity
   5. Melanoma: 69–79% sensitivity

B. POSSIBLY USEFUL
   1. NHL: good for large + mediastinal lesions
   2. Nodal metastases from seminoma + embryonal cell carcinoma: 87% sensitivity
   3. Non-small cell lung cancer: 85% sensitivity for primary of any histologic type, 90% probability for uptake in mediastinal nodes, 67% probability for uptake in normal mediastinal nodes, 90% probability for uptake in extrathoracic metastases

C. NOT USEFUL head & neck tumors, GI tumors (especially adenocarcinomas; 35–40% sensitivity), breast tumor (52–65% sensitivity), gynecologic tumors (<26% sensitivity), pediatric tumors

Gallium in Lung Imaging

◊ Scans obtained at 48 hours, because 50% of normals show activity at 24 hours

A. FOCAL UPTAKE
   1. Primary pulmonary malignancy (>90% sensitivity)
   2. Benign disorders: granuloma, abscess, pneumonia, silicosis

B. MULTIFOCAL / DIFFUSE UPTAKE
   (a) Infection
      1. Tuberculosis
         √ intense uptake in active lesions (97%)
           = parameter of activity
         √ diffuse uptake in miliary TB + rapidly progressive TB pneumonia
      2. Pneumocystis carinii
         √ increased uptake at time when physical signs, symptoms, and roentgenographic changes are unimpressive
      3. Cytomegalovirus
   (b) Inflammation
      1. Sarcoidosis 70% sensitivity for active parenchymal disease, 94% sensitivity for hilar adenopathy
         = indicator of therapeutic response to steroids
      2. Interstitial lung disease pneumoconiosis, idiopathic pulmonary fibrosis, lymphangitic carcinomatosis
      3. Exudative stage of radiation pneumonitis
   (c) Drugs
      1. Bleomycin toxicity
      2. Amiodarone
   (d) Contrast lymphangiography (in 50%)

C. GALLIUM UPTAKE + NORMAL CHEST FILM
   1. Pulmonary drug toxicity
   2. Tumor infiltration
   3. Sarcoidosis
   4. Pneumocystis carinii

Panda Sign

= facial uptake of ^{67}Ga in both parotid glands + both lacrimal glands + nose

1. Sarcoidosis
   ◊ 100% specific for sarcoidosis if lung infiltrates are present!
2. Treated lymphoma
3. Systemic lupus erythematosus
4. Sjögren syndrome

Gallium in Renal Imaging

Abnormal uptake on delayed images at 48–72 hours

A. Renal tumor
   1. Primary renal tumor (variable uptake)
   2. Lymphoma / leukemia

3. Metastases (eg, melanoma)

B. Renal inflammation
   1. Acute pyelonephritis (88% sensitivity)
      √ diffuse / focal uptake
   2. Lobar nephronia
   3. Renal abscess

C. Others
   1. Collagen-vascular disease, vasculitis, Wegener granulomatosis
   2. Amyloidosis, hemochromatosis
   3. Hepatic failure
   4. Administration of antineoplastic drugs

D. Transplant
   1. Acute / chronic rejection
   2. Acute tubular necrosis

E. Urinary bladder
   1. Cystitis
   2. Tumor

mnemonic: CHANT An OLD PSALM

Chemotherapy
Hemochromatosis, **H**epatorenal failure
Acute tubular necrosis, **A**cute lobar nephronia
Neoplasm
Transfusion, **T**uberous sclerosis
Abscess
Obstruction
Lymphoma
Drugs (Fe, drugs causing ATN)
Pyelonephritis, **P**olyarteritis nodosa
Sarcoidosis
Amyloidosis, **A**llograft
Leukemia
Metastasis, **M**yeloma

Gallium Imaging in Lymphoma

= chief use of gallium in tumor imaging before + after chemo- / radiation therapy:
√ persisting ^{67}Ga uptake indicates residual tumor
√ reversion to normal of a previously ^{67}Ga avid mass indicates fibrosis
√ new ^{67}Ga uptake during therapy indicates tumor progression

A. Hodgkin disease
   50–70% average sensitivity dependent on size, location, technique

B. Non-Hodgkin lymphoma
   30% sensitivity for lymphocytic subtype,
   70% sensitivity for histiocytic subtype

Sensitivity:
   90% for mediastinal nodes

80% for neck nodes
48% for periaortic nodes
47% for iliac nodes
36% for axillary nodes

Gallium Imaging in Malignant Melanoma

Types:

1. Lentigo maligna: low invasiveness, low metastatic potential
2. Superficial spreading melanoma: intermediate prognosis
3. Nodular melanoma: most lethal

Prognosis (level of invasion versus 5-year survival):

Level I (in situ) 100%
Level II (within papillary dermis) 100%
Level III (extending to reticular dermis) 88%
Level IV (invading reticular dermis) 66%
Level V (subcutaneous infiltration) 15%

Ga-67:

> 50% sensitivity for primary + metastatic sites
Detectability versus tumor size:
73% sensitivity > 2 cm; 17% sensitivity < 2 cm

Bone, brain, liver scintigraphy:

show very low yield in detecting metastases at time of preoperative assessment and are not indicated

STATISTICS

Decision Matrix				
GOLD STANDARD				
	normal	*abnormal*	*subtotal*	
TN	FN	T-	NPV	
abnormal	FP	TP	T+	PPV
subtotal	D-	D+	total	preval
	specificity	sensitivity		accuracy

TP = test positive in diseased subjects
FP = test positive in nondiseased subjects
FN = test negative in diseased subjects
TN = test negative in nondiseased subjects
T+ = abnormal test results
T- = normal test results
D+ = diseased subjects
D- = nondiseased subjects

STATISTICS

Incidence = number of diseased people per 100,000 population annually
Prevalence = number of existing cases per 100,000 population at a target date
Frequency = number of times an event occurred; often graphically represented in histograms
Mortality = number of deaths per 100,000 population annually
Fatality = number of deaths per number of diseased

Sensitivity

= ability to detect disease
= probability of having an abnormal test given disease
= number of correct positive tests / number with disease
= true positive ratio = TP / (TP + FN) = TP / D+
• D+ column in decision matrix
◊ Independent of prevalence

Specificity

= ability to identify absence of disease
= probability of having a negative test given no disease
= number of correct negative tests / number without disease
= true negative ratio = TN / (TN + FP) = TN / D-
• D- column in decision matrix

◊ Independent of prevalence

Accuracy

= number of correct results in all tests
= number of correct tests / total number of tests
= (TP + TN) / (TP + TN + FP + FN) = (TP + TN) / total
◊ Depends much on the proportion of diseased + nondiseased subjects in studied population
◊ Not valuable for comparison of tests
Example: same test accuracy of 90% for two tests A and B

Positive Predictive Value

= positive test accuracy
= likelihood that a positive test result identifies disease
= number of correct positive tests / number of positive tests
= TP / (TP + FP) = TP / T+
• T+ row in decision matrix
◊ Dependent on prevalence
◊ PPV ↑ with ↑ prevalence for given sensitivity + specificity
◊ PPV ↑ with ↑ specificity for given prevalence

Test A: 90% Accuracy
(**equal** number of diseased and nondiseased diseased)

Decision Matrix

	normal	*abnormal*	*subtotal*	
normal	90	10	100	90%
abnormal	10	90	100	90%
subtotal	100	100	200	50%
	90%	90%		90%

Test B: 90% Accuracy
(**unequal** number of diseased and nondiseased diseased)

Decision Matrix

	normal	*abnormal*	*subtotal*	
normal	170	20	190	89%
abnormal	0	10	10	100%
subtotal	170	30	200	15%
	90%	90%		90%

Negative Predictive Value

= negative test accuracy
= likelihood that a negative test result identifies absence of disease
= number of correct negative tests / number of negative tests
= TN / (TN + FN) = TN / T-
• T- row in decision matrix

◊ Dependent on prevalence
◊ NPV ↑ with ↑ prevalence for given sensitivity + specificity
◊ NPV ↑ with ↑ sensitivity for given prevalence

False-positive Ratio

= proportion of nondiseased patients with abnormal test result
• D- column in decision matrix
= FP / (FP + TN) = FP / D-
= 1 – specificity = (TN + FP - TN) / (TN + FP)

False-negative Ratio

= proportion of diseased patients with a normal test result
• D+ column in decision matrix
= FN / (TP + FN) = FN / D+
= 1 – sensitivity = (TP + FN - TP) / (TP + FN)

Disease Prevalence

= proportion of diseased subjects to total population
= (TP + FN) / (TP + TN + FP + FN) = D+ / total

◊ Sensitivity + specificity are independent of prevalence!

◊ Affects predictive values + accuracy of a test result

Example:

Test A, C, D: 90% sensitivity + 90% specificity

Bayes Theorem

= the predictive accuracy of any test outcome that is less than a perfect diagnostic test is influenced by
(a) pretest likelihood of disease
(b) criteria used to define a test result

Receiver Operating Characteristics (ROC)

= degree of discrimination between diseased + nondiseased patients using varying diagnostic criteria instead of a single value for the TP + TN fraction
= curvilinear graph generated by plotting TP ratio as a function of FP ratio for a number of different diagnostic criteria (ranging from definitely normal to definitely abnormal)

Y-axis: true-positive ratio = sensitivity

X-axis: false-positive ratio = 1 – specificity; reversing the values on the X-axis results in an identical "sensitivity-specificity curve"

Use: variations in diagnostic criteria → reported as a continuum of responses → ranging from definitely abnormal to equivocal to definitely normal ← based on subjectivity + bias of individual radiologists

◊ A minimum of 4–5 data points of diagnostic criteria are needed!

Difficulty: subjective evaluation of image features; subjective diagnostic interpretation; data must be ordinal (= discrete rating scale from definitely negative to definitely positive)

Interpretation:

- ◊ ↑ in sensitivity leads to ↓ in specificity!
- ◊ ↑ in specificity leads to ↓ in sensitivity!
- ◊ Most sensitive point is the point with the highest TP ratio
  → equivalent to "overreading" by using less stringent diagnostic criteria (all findings read as abnormal)
- ◊ Most specific point is the point with the lowest FP ratio
  → equivalent to "underreading" by using more strict diagnostic criteria (all findings read as normal)
- ◊ Does not consider disease prevalence in the population
- ◊ The ROC curve closest to the Y-axis represents the best diagnostic test

Test C_1: 10% prevalence, 90% sensitivity, 90% specificity

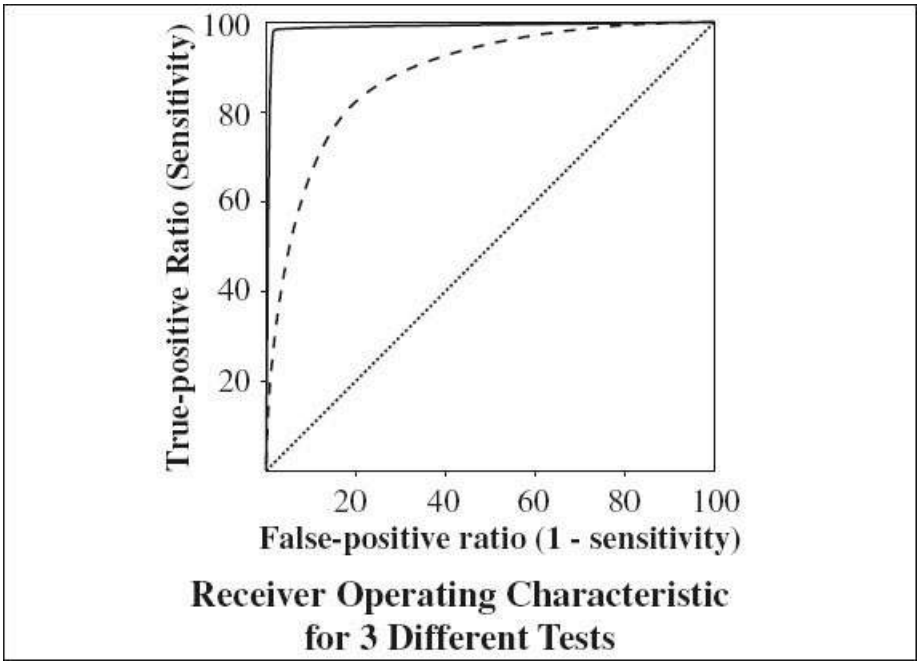
Decision Matrix

	normal	*abnormal*	*subtotal*	
normal	162	2	164	99%
abnormal	18	18	36	50%
subtotal	180	**20**	**200**	10%
	90%	90%		90%

Test C_2: 90% prevalence, 90% sensitivity, 90% specificity

Decision Matrix

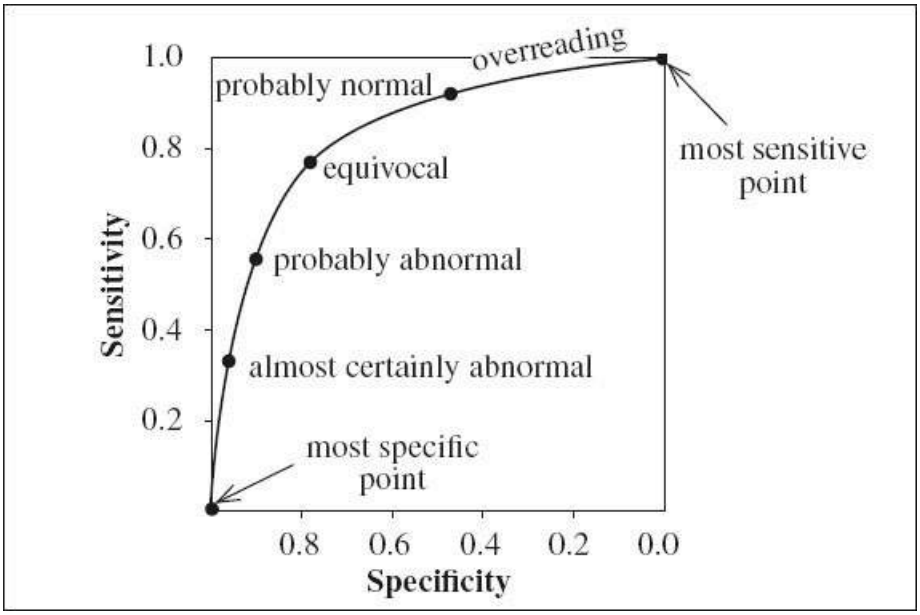
	normal	*abnormal*	*subtotal*	
normal	18	18	36	50%
abnormal	2	162	164	99%
subtotal	20	**180**	**200**	90%
	90%	90%		90%

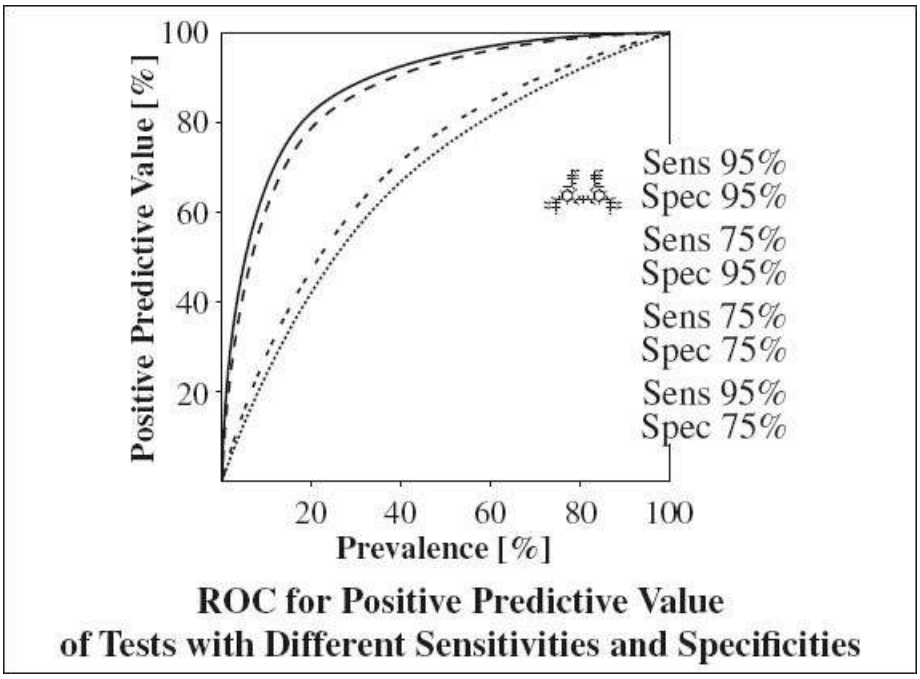


Confidence Limit

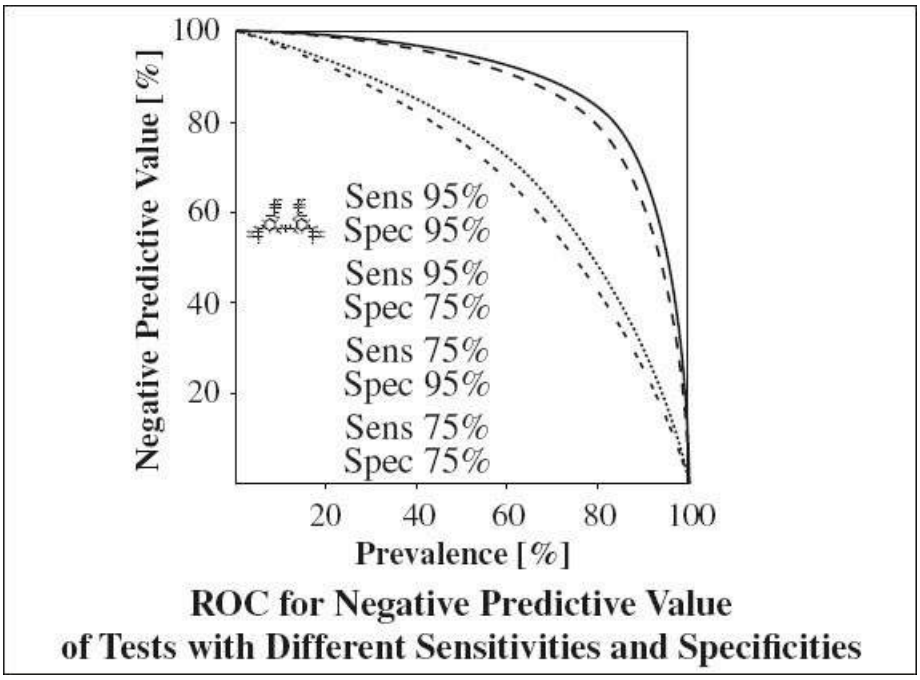
= degree of certainty that the proportion calculated from a sample of a particular size lies within a specific range (binomial theorem)

◊ Analogous to the mean ± 2 SD





ROC for Positive Predictive Value of Tests with Different Sensitivities and Specificities



ROC for Negative Predictive Value of Tests with Different Sensitivities and Specificities

Clinical Epidemiology

= application of epidemiologic principles + methods to problems encountered in clinical medicine with the purpose of developing + applying methods of clinical observation that will lead to valid clinical conclusions

Epidemiology = branch of medical science dealing with incidence, distribution, determinants in control of disease within a defined population

Screening Techniques

Principle question: Can early detection influence the natural history of the disease in a positive manner?

Outcome measure: Early detection + effective therapy should reduce morbidity + mortality → ↑ survival rates (observational study)!

Biases:

Lead time = interval between disease detection at screening + the usual time of clinical manifestation; early diagnosis always appears to improve survival by at least this interval, even when treatment is ineffective

Length time = differences in growth rates of tumors:

(a) slow-growing tumors exist for a long time before manifestation → enhancing opportunity for detection

(b) fast-growing tumors exist for a short time before manifestation → less opportunity for detection at screening = "interval cancers" = clinically detected between scheduled screening exams are likely fast-growing tumors; patients with tumors detected by means of screening tests will have a better prognosis than those with interval cancers

Self-selection bias = decision to participate in screening program usually made by patients better educated + more knowledgeable + more health-conscious; mortality rates from noncancerous causes can be expected to be lower than in general population

Solution: randomization

Overdiagnosis = detection of lesions of questionable malignancy, eg, in situ cancers, which might never have been diagnosed without screening + have an excellent prognosis

Selection Bias

1. Define target population (for whom study is intended)
2. Define accessible population (inclusion + exclusion criteria)
3. Devise sampling scheme (for intended sample population)
4. Study population (= enrolled population)

Sample Bias = intended sample does not adequately reflect the spectrum of characteristics in target population / poor choice of control group volunteers

Consequence: overestimation of diagnostic accuracy → test in question appears more specific

Loss-to-Follow-up Bias = subjects in cohort study lost to follow up differ from those who remain in study until study termination / endpoint

Disease Spectrum Bias = only cases with a limited range of disease spectrum are included

Consequence: overestimation of sensitivity

Referral Bias = individual preferences (eg, distinct clinical groups use different indications for ordering a test) / local practices (eg, tertiary care center) determine which subjects are referred

Participation Bias = factors that affect final enrollment of the intended sample (eg, some subjects refuse to participate, certain records unavailable for review, participants inadvertently excluded)

Image-based Selection Bias = subjects participation depends on having undergone a certain

imaging study

Study Examination Bias = exclusion of technically limited / incomplete studies or prospective inclusion of only patients who are deemed competent to produce a technically adequate examination

Consequence: overestimation of sensitivity + specificity by excluding uninterpretable imaging results

Observation Bias

= methodologic differences in which information is collected about / from study subjects

Consequence: misclassification

Recall Bias = exposure information misclassified for subjects with and without disease (eg, patients with positive results and subsequent treatment will recall better and may exaggerate presentation symptoms)

Interviewer Bias = interviewer may inadvertently coach subjects

Solution: use interviewer not involved / interested in study result

Verification / Work-up Bias = differences in the manner in which disease status is determined

Follow-up / Medical Surveillance Bias = subjects differentially undergo follow-up of disease status

Response Bias = missing data are present nonrandomly for study subjects who are still included in analysis

Reviewer Bias = person collecting / reviewing data is inappropriately blinded

Diagnostic-Review Bias = reference test results are not definite + study test results affect how final diagnosis is established

Test-Review Bias = knowledge of diagnosis may affect test interpretation in a retrospective study if subjective study test is performed after diagnosis has been established

Solution: adequate control group

Incorporation Bias = results of test are incorporated as evidence for final diagnosis if reference test cannot be performed

Imperfect-Standard Bias = reference standard not 100% accurate or use of surrogate reference test ← cost / ethical considerations

Reader-Order Bias = retained knowledge of results of one study influences interpretation of second study

Solution: randomization

Measurement Bias = discrepancy in measurements obtained with a new technique compared to the reference technique on the same subjects under same conditions

Clustering / Repeated-Measurement Bias = multiple measurements / observations obtained from the same subject

Consequence: distortion of standard deviation

Context Bias = effect of altered disease prevalence on estimates of given parameters such as sensitivity, specificity and ROC

Publication Bias = in metaanalysis if journals reviewed favor publication of studies with positive results

Consequence: overly optimistic results

Confounding = in epidemiologic and observational studies additional factors / variables are

associated with exposure and disease status (eg, age, sex)
Solution: randomization, restriction, matching, stratification

Randomized Trials

Design: two arms consisting of (a) study group and (b) control group with patients assigned to each arm on randomized basis
Endpoint: difference in mortality rates of both groups
Power: study must be of sufficient size + duration to detect a difference, if one exists; analogous to sensitivity of a diagnostic test
Impact on effective size of groups:
Compliance = proportion of women allocated to screening arm of trial who undergo screening
Contamination = proportion of women allocated to control group of trial who do undergo screening

Case-control Studies

Retrospective inquiry, which is less expensive, takes less time, is easier to perform:
(a) determine the number of women who died from breast cancer
(b) chose same number of women of comparable age who have not died from breast cancer
(c) ascertain the number of women who were screened
(d) number of women who were not screened in both arms
Calculation of odds ratio = ad / bc

KAPPA COEFFICIENT

= statistical measure of agreement between 2 observers (= interobserver concordance) for categorical items accounting for chance
P_o = proportion of observed agreement
P_c = hypothetical proportion of chance agreement

$$K = \frac{P_o - P_c}{1 - P_c}$$

Predictive value of K (Strength of Agreement):
< 0.00 poor
0.00 – 0.20 slight
0.20 – 0.40 fair
0.40 – 0.60 moderate
0.60 – 0.80 substantial
0.80 – 1.00 almost perfect

CONTRAST MEDIA, NEPHROTOXICITY, PREMEDICATION, CONTROL OF HEART RATE

Ionic = dissociation in water

Nonionic = soluble in water (hydrophilic); no dissociation in solution

Iodine-to-particle ratio:

= quotient of iodine atoms (attenuation of x rays) and number of particles (osmotoxic effect)

ratio 1.5 agents = high-osmolar contrast media (HOCM)

ratio 3.0 agents = low-osmolar contrast media (LOCM)

ratio 6.0 agents = isotonic contrast media (IOCM)

N.B.: Organic iodine is an essential element, so individuals cannot be allergic to it. An **allergy to shellfish** is not a predictor of increased risk to contrast media!

IONIC MONOMERS

= monoacidic salts composed of benzoic acid derivatives, with 3 hydrogen atoms replaced by iodine atoms + 3 hydrogen atoms replaced by simple amide chains

In solution: strong organic acid completely dissociated (ionized) into negatively charged ions / anions

Conjugated cations: (1) sodium
(2) methylglucamine (meglumine)
(3) combination of both

Iodine concentration: up to 400 mg/mL

Iodine-to-particle ratio: 3÷2 or 1.5÷1

Osmolality: 1,400–2,100 mOsm/kg = HOCM

IONIC DIMERS

Construction: 2 iodinated benzene rings containing 6 iodine atoms, one of which contains an ionizing carboxyl group; benzene rings are connected by a common amide side chain

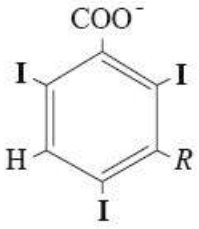
Conjugation with: sodium + meglumine

Compound: ioxaglate (the only available)

Iodine concentration: 320 mg/mL

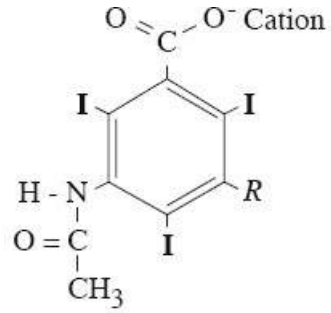
Iodine-to-particle ratio: 6÷2 or 3÷1

Osmolality: 600 mOsm/kg = LOCM



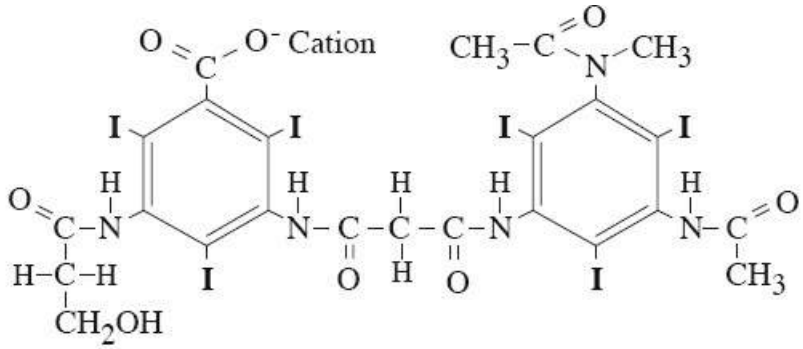
Acetrizoate

The parent triiodinated contrast medium in 1st clinical use; the benzene ring is attached to a carboxyl (COO-) group at the 1-carbon position and conjugated with sodium / meglumine



Diatrizoate

The unsubstituted hydrogen of acetrizoate has been exchanged for another acetamido unit leading to higher biologic tolerance through higher degree of protein binding



Ioxaglate (Hexabrix®)

Sodium and meglumine are conjugated with the carboxyl group

NONIONIC MONOMERS

Construction: benzoic acid carboxyl group replaced by amide; side chains have been modified by adding 4–6 hydroxyl (OH) groups → allows solubility in water

Iodine concentration: up to 350 mg/mL

Iodine-to-particle ratio: 3÷1

Compounds: iohexol, iopamidol, ioversol, iopental, iopromide (Ultravist®), iobitridol (Xenetix®), ioxilan (Oxilan®)

Osmolality: 616–796 mOsm/kg

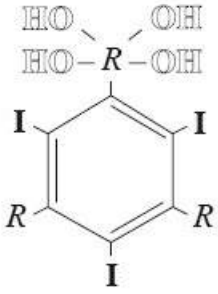
NONIONIC DIMERS

Construction: contain up to 12 hydroxyl groups → eliminates ionicity, ↑ hydrophilicity, ↓ osmotoxicity, ↑ iodine atoms per molecule

Compounds: iodecol, iotrolan (Isovist®), iodixanol (Visipaque®)

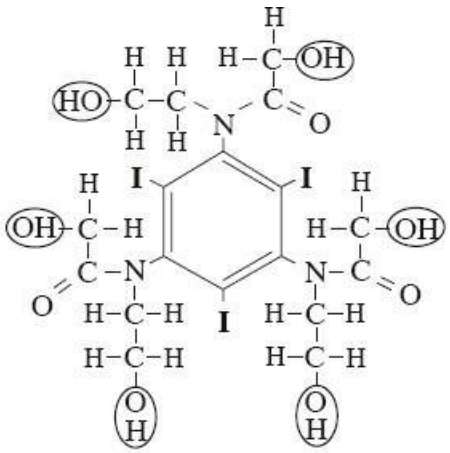
Iodine-to-particle ratio: 6÷1

Osmolality: hypo- / isoosmolar



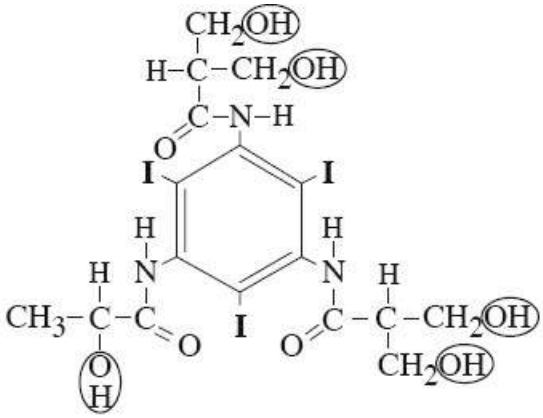
Metrizamide

The 1st compound with 4 hydroxyl groups positioned at one end of the molecule on the glucosamide moiety



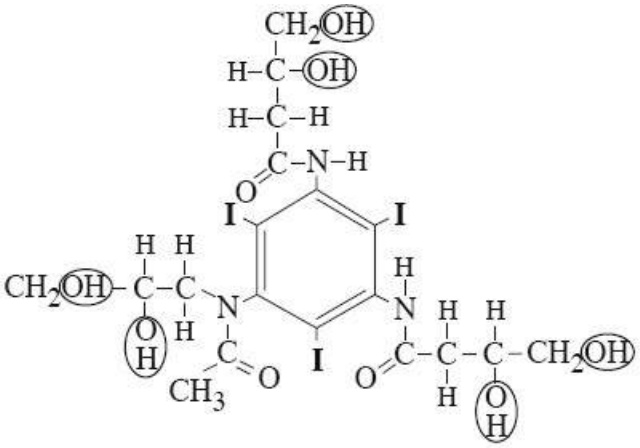
Iohexol (Omnipaque®)

contains 6 hydroxyl (OH) groups more evenly distributed around the molecule improving subarachnoid toxicity



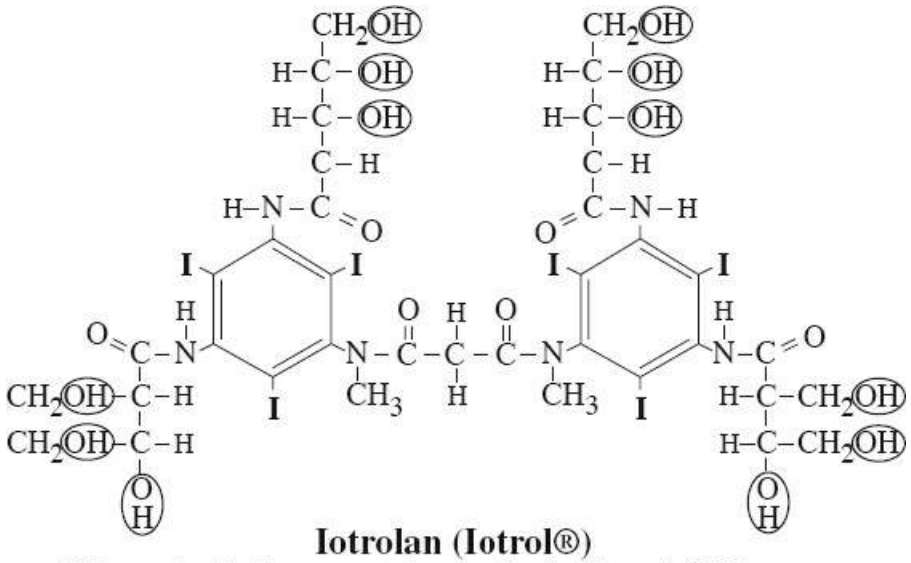
Iopamidol (Isovue®)

This nonionic monomer contains five hydroxyl (OH) groups



Ioversol (Optiray®)

This nonionic monomer contains six hydroxyl (OH) groups



Iotrolan (Iotrol®)
This nonionic dimer contains twelve hydroxyl (OH) groups

Excretory Urography

Clearance: > 99% of contrast material eliminated through kidney (< 1% through liver, bile, small and large intestines, sweat, tears, saliva); vicarious excretion with renal insult / failure (may be unilateral as in obstructive uropathy)

Halftime: 1–2 hours (doubled in dialysis patients)

Concentration: 60% by weight

(a) Sodium-containing HOCM
√ less distension of collecting system

(b) Meglumine-only HOCM
√ improved distension of collecting system ← decreased tubular resorption of water

(c) LOCM
√ denser nephrogram + slightly denser pyelogram than HOCM ← higher tubular concentration

Angiography

Burning sensation:

(a) intense with concentration of 60–76% HOCM
(b) reduced with concentration of ≤ 30% HOCM / LOCM

◊ Overall incidence of adverse allergic-type reactions is (for unknown reasons) much less with intraarterial than with intravenous use of contrast media!

Venography

(1) Foot / calf discomfort or pressure or burning
(a) ~ 24% with 60% HOCM
(b) ~ 5% with 40% HOCM / 300 mg iodine/mL LOCM
◊ The addition of 10–40 mg lidocaine/50 mL of contrast media decreases patient discomfort!

(2) Postphlebography deep vein thrombosis
(a) 26–48% with 60% HOCM

(b) 0–9% with dilute HOCM / LOCM

◊ Infusion of 150–200 mL of 5% dextrose in water / 5% dextrose in 0.45% saline / heparinized saline through injection site immediately after examination reduces likelihood of DVT!

Physicochemical Properties of Commonly Used Radiographic Contrast Media

Contrast Media	*Compound*	*mOsm/kg H2O*	*Viscosity (cps) at 37• C*	*Iodine mg/mL*
Ionic monomers				
URORADIOLOGICAL				
Cysto-Conray® II (Mallinckrodt)	Meglumine-iothalamate	1,300	4.0	202
GASTROINTESTINAL				
Hypaque® Sodium Oral Solution (Nycomed Amersham)	Na diatrizoate	1,300	4.0	249
Gastrografin® (Bracco)	Na-meglumine diatrizoate	1,940	8.4	370
INTRAVASCULAR				
Renovue®-Dip (Bracco)	Meglumine iodamide	433	1.8	111
Conray®-60 (Mallinckrodt)	Meglumine-iothalamate	1,400	4.0	282
Renografin®60 (Bracco)	Na-meglumine diatrizoate	1,450	4.0	292
Ionic dimers				
Hexabrix® (Mallinckrodt)	Na-meglumine ioxaglate	600	7.5	320
Nonionic monomers				
Oxilan® 300 (Cook)	ioxilan	585	5.1	300
Ultravist® 300 (Berlex)	iopromide	607	4.9	300
Isovue® 300 (Bracco)	iopamidol	616	4.7	300
Optiray® 300 (Mallinckrodt)	ioversol	651	5.5	300
Omnipaque® 300 (Nycomed Amersham)	iohexol	672	6.3	300
Omnipaque® 140 (Nycomed Amersham)	iohexol	322	1.5	140
Omnipaque® 240 (Nycomed Amersham)	iohexol	520	3.4	240
Omnipaque® 350 (Nycomed Amersham)	iohexol	844	10.4	350
Nonionic dimers				
Iotrol® 300 (Schering AG)	iotrolan	~310	9.1	300
Visipaque®-320 (Nycomed Amersham)	iodixanol	290	11.8	320

Osmolality of human serum is 290 mOsm/kg!
The higher the number of hydroxyl groups → the larger the size of the molecule + the higher the viscosity + hydrophilicity; responsible for a decrease in protein- and tissue-binding properties → making the compound biologically more inert

Gadolinium-based Contrast Agents					
Contrast Media	*Compound*	*Excess Ligand (%)*	*T1-Relaxivity Plasma [L/(mmol•sec)] at 37• C, 1.5 T*	*Log K_{cond} (pH 7.4)*	*Excretion*
Linear Nonionic					
Omniscan (GE)	Gadodiamide (Gd-DTPA-BMA)	5.0	4.6	14.9	renal (R)
Optimark™ (Mallinckrodt)	Gadoversetamide (Gd-DTPA-BMEA)	10.0	5.2	15.0	renal
Linear Ionic					
MultiHance® (Bracco)	Gadobenate (Gd-BOPTA)	0.1	6.7	18.4	96% renal, 4% biliary
Magnevist® (Bayer)	Gadopentetate (Gd-DTPA)	0.1	4.3	17.9	renal
Eovist® (Bayer)	Gadoxetate (Gd-EOB-DTPA)	0.6	6.9	18.7	50% renal, 50% biliary
Vasovist® (Bayer)	Gadofosveset	0.1	19.0	18.9	95% renal, 5% biliary
Macrocyclic nonionic					
ProHance® (Bracco)	Gadoteridol (Gd-HP-DO3A)	0.1	4.4	17.1	renal
Macrocyclic ionic					
Dotarem® (Guerbet)	Gadoterate (Gd-DOTA)	0.0	3.6	18.0	renal
Gadovist® (Bayer)	Gadobutrol (Gd-BT-DO3A)	0.1	5.2	15.5	renal

◊ The greater the relaxivity (proportional to magnitude of magnetic moment, its tumbling frequency, its electron spin relaxation time) the smaller the dose needed to achieve a given level of enhancement

◊ The higher the dissociation constants (Log K) the greater the stability of an agent

Abbreviations: BMA = bis-methylamide; BMEA = bis-methoxyethylamide; BOPTA = benzyloxypropionictetraacetate; BT = butrol; DOPTA = tetraazacyclododecanetetraacetic acid; DOTA = dodecane-tetraacetic acid; DO3A = 1,4,7,10-tetraazacyclododecane 1,4,7-triacetic acid; DTPA = diethylenetriaminepentaacetic acid; EOB = ethoxybenzyl; Gs = gadolinium (free Gd^{3+} is toxic); HP = hydroxypropyl

◊ Distribution is intra- and extravascular in all with the exception of Vasovist, which is predominantly intravascular.

◊ Dissociation $T_{1/2}$ = > 1000 years for all macrocyclic compounds

Evaluation of Intravenous Access

1. Chose a catheter appropriate for injection:
   - › antecubital / large forearm vein ≥ 20-gauge for 3 mL/sec
   - › peripherally placed 22-gauge for < 1.5 mL/sec
2. Confirm venous return
3. Perform a saline flush
4. Perform a test injection with the power injector esp. for power-injector compatible central venous / peripherally inserted central catheters by observing manufacturer-recommended pressure limits

Contrast Extravasation

= escape of contrast material from vascular lumen + infiltration of interstitial tissue during injection

Incidence: < 1%; no direct correlation with injection flow rate

- may be asymptomatic; edema, erythema
- swelling, tightness, tenderness, stinging, burning pain

Dx: (1) Palpate catheter venipuncture site during initial seconds of injection
(2) Ask patient to report any sensation of pain / swelling at injection site

Severe Cx (uncommon): compartment syndrome, skin ulceration, tissue necrosis

Rx: (1) Elevate affected extremity / site
(2) Apply a warm / cold compress

(3) Monitor for a sufficiently long period

(4) Discharge with instructions to watch for symptoms that indicate a need for surgical evaluation

(5) Initiate surgical consultation for progressive pain / swelling, decreased capillary refill, paresthesia, skin ulceration / blistering

ADVERSE CONTRAST REACTIONS

Risk factors:

1. A history of a previous severe reaction to iodinated contrast agent increases the overall risk of a subsequent reaction by about 5- to 6-fold.
2. All severe allergies and reactions (to medications and food)

   There is NO specific link between shellfish allergy and allergy to contrast agents.
3. History of asthma / bronchospasm / atopy
4. History of cardiac / renal disease
5. Age > 60 years OR < 5 years

A. Nonidiosyncratic (= dose-related) reactions

Cause: direct chemotoxic / hyperosmolar effect

- nausea, vomiting; cardiac arrhythmia; renal failure
- pulmonary edema; cardiovascular collapse

B. Idiosyncratic (= anaphylactoid) reactions

= reactions occurring unpredictably + independently of dose / concentration = not a true antigen-IgE antibody-mediated reaction nor a reaction to iodine / iodide

Cause: unknown

- hives, itching; facial / laryngeal edema
- bronchospasm, respiratory collapse; circulatory collapse

C. Delayed reactions

- erythematous rashes, pruritus, fever, chills, flulike symptoms
- joint pain, loss of appetite, taste disturbance, headache
- fatigue, depression, abdominal pain, constipation, diarrhea

Significant underlying medical conditions

(a) renal disease
(b) cardiac disease
(c) blood dyscrasias
(d) pheochromocytoma
(e) ↑ symptoms with COPD plus pulmonary hypertension
(f) ↑ sickling in patients with sickle-cell disease

◊ Approximately 20–40% of population are at increased risk for adverse reaction to contrast media!

◊ In patients with adverse reactions to HOCM repeated reactions will be lowered to 5% by using LOCM

◊ No direct correlation / association to povidone-iodine skin cleansing solution (Betadine®)

Assessment of Patients before Contrast Injection

A. General status
Assess hemodynamic, neurologic, general nutritional, anxiety status
B. History of significant allergies
1. Prior anaphylactic response to any allergen
2. Asthma
C. Renal disease
1. Renal dysfunction: obtain baseline BUN + creatinine
2. Diabetes mellitus
3. Multiple myeloma
◊ Hydrate patients and limit contrast dose!
D. Cardiac disease
1. Angina
2. CHF with minimal exertion
3. Severe aortic stenosis
4. Primary pulmonary hypertension
5. Severe cardiomyopathy
◊ Limit contrast dose!

NEPHROTOXICITY

= CONTRAST-INDUCED NEPHROTOXICITY (CIN)
= sudden deterioration of renal function after recent IV administration of contrast media in the absence of another nephrotoxic event

Indications for Obtaining Creatinine Levels

A. IODINATED CONTRAST AGENTS

Prevalence of Adverse Contrast Reactions		
	High-osmolar Ionic	*Low-osmolar Nonionic*
Non–life-threatening reaction	1–2%	0.2–04%
Life-threatening reaction	0.2%	0.04%
Mortality	1÷100,000	1÷100,000
Late reaction		6%

Risk Factors and Incidence of Adverse Reactions for High- and Low-Osmolality Contrast Media		
Type of Reaction	*HOCM [%]*	*LOCM [%]*
Overall incidence		
Australia (Palmer et al.)	3.80	1.20
USA (Wolf et al.)	4.20	0.70
Japan (Katayama et al.)	12.70	3.10
Severe adverse reaction	0.22	0.04
Severe allergies to drugs, foods, etc.	23.40	6.90
Asthma	19.70	7.80
Repeat reaction to contrast media	16–44	4.1–11.2

1. Age > 60 years
2. History of kidney disease as an adult, including tumor / transplant
3. Family history of kidney failure
4. Diabetes treated with insulin / other prescribed meds
5. Hypertension
6. Paraproteinemia syndromes / diseases (eg, myeloma)
7. Current use of nephrotoxic medications (eg, chemotherapeutic agents, chronic use of NSAIDs)

B. GADOLINIUM-BASED CONTRAST AGENTS

1. Age > 60 years
2. History of kidney disease as an adult, including tumor / transplant
3. Single kidney / kidney surgery
4. Diabetes treated with insulin / other prescribed meds
5. Hypertension requiring medical therapy

Nonoliguric Transient Renal Dysfunction

= transient decline of renal function

- serum creatinine level peaks on days 3–5
- serum creatinine returns to baseline values within 14–21 days
- fractional excretion of sodium < 0.01 (DISTINCTIVE CHARACTERISTIC compared with other causes)

Acute Renal Failure

= sudden + rapid deterioration of renal function

= increase in serum creatinine of > 25% or to > 2 mg/dL within 2 days of receiving contrast material

Frequency: 1–30%; 3rd most common cause of in-hospital renal failure after hypotension and surgery

Risk factors:

Contrast agent–independent acute kidney injury is NOT significantly different and may be clinically indistinguishable when adjusted for patient risk factors.

1. Preexisting renal insufficiency (serum creatinine > 1.5 mg/dL)

2. Diabetes mellitus with renal insufficiency (possibly related to dehydration / hyperuricemia)
   ◊ Ratio 3 nonionic LOCM appear to be 50% less nephrotoxic than ratio 1.5 ionic HOCM
   ◊ Diabetics with normal renal function are not at ↑ risk!
3. Dehydration
4. Cardiovascular disease
5. Use of diuretics
6. Advanced age > 70 years
7. Multiple myeloma (in dehydrated patients)
8. Hypertension
9. Hyperuricemia / uricosuria
10. High dose of contrast material

CAVE:

◊ Small decreases in renal function may greatly exacerbate the mortality caused by the underlying condition!

◊ Metformin (Glucophage®) should be discontinued for 48 hours after contrast medium administration (accumulation of metformin may result in lactic acidosis → fatal in 50%)!

◊ It is not necessary to stop metformin after gadolinium administration because gadolinium is not nephrotoxic!

◊ Avoid concomitant use of nephrotoxic drugs (eg, gentamicin, NSAIDs)

Proposed mechanisms:

› contrast agents are concentrated in nephrons + collecting tubules

1. Vasoconstriction
   (a) ↑ in intrarenal pressure induced by hypertonicity
   (b) intrarenal smooth muscle contraction ← hypertonic substances
2. RBC aggregation in medullary circulation
3. Direct tubular cell injury

Potential antidotes:

Hydration (0.9% saline at 100 mL/hr) 12 hours before + 12 hours after angiography

◊ Extracellular volume expansion is the most effective + widely recommended measure!

√ immediate dense nephrogram persisting for up to 24 hours (in 75%)

√ gradually increasing dense nephrogram resembling bilateral acute ureteral obstruction (in 25%):

√ bilaterally enlarged smooth kidneys

√ poor opacification of urine-conducting structures

√ effacement of collecting system (interstitial edema)

Cx: 34% mortality (0.4% of all patients)

Rx: 0.1% require renal replacement therapy

NEPHROGENIC SYSTEMIC FIBROSIS

= NEPHROGENIC FIBROSING DERMOPATHY

= rare potentially debilitating chronic fibrosing condition involving multiple organ systems

initially described in 2006 without specific imaging findings

Cause: gadolinium-based contrast agents

Pathophysiology: unclear

Risk factors:

(1) High dose gadolinium-based contrast agent
   › highest risk: Omniscan®, Magnevist®, OptiMARK™
   › medium risk: MultiHance®, Ablavar®, Eovist®
   › low risk: Gadavist®, Dotarem®, ProHance®
(2) Acute / chronic renal failure: especially dialysis, hepatorenal syndrome, perioperative liver transplantation period, renal transplant failure
(3) Venous thrombosis
(4) Vascular surgery

Age: any; most commonly middle-aged; M÷F=1÷1

Organ involvement: skin, subcutaneous tissue, lung, pleura, skeletal muscle, bone, heart, pericardium, testis, esophagus, kidney

Onset: days to months (average time, 2–10 weeks) after administration of GBCA, up to 8 years after exposure

@ Skin

Location: distal lower extremities → (subsequent) extension to thighs → lower abdomen → upper extremities

- patterned skin plaques, cobblestone, marked induration
- erythematous papules coalescing into plaques of peau d'orange appearance
- thickening of dermis developing a woody texture similar to scleromyxedema / scleroderma with sparing of face

Cx: pain + decreased range of motion → contractures and joint immobility

Histo: thick collagen bundles ← proliferation of dermal fibroblasts + dendritic cells (CD-68, factor XIIIa-positive) with variable amounts of mucin + elastic fibers

DDx: cellulitis, fasciitis, scleroderma, cutaneous lymphoma, lymphatic / venous obstruction, dermatopolymyositis

Risk reducing strategy:

(1) Consider CT in anuric patient
(2) Use low-risk Gd-based contrast agent
(3) Initiate dialysis within 2 hours of exposure + schedule several prolonged dialysis treatments for those patients who are already on dialysis

TREATMENT OF CONTRAST REACTIONS

◊ 94–100% of severe + fatal anaphylactoid reactions occur within 20 minutes of contrast medium injection
   ⇒ use a plastic cannula for IV access
   ⇒ maintain IV access for 30 min
   ⇒ have emergency drugs close to the room where contrast injections are done
   ⇒ post a listing of available medications + their common doses in the room

Oral Steroid Premedication Protocol (see table)

Indication: previous respiratory adverse contrast reaction, history of significant allergies /

severe asthma

Caution in patients with: active tuberculosis, diabetes mellitus, peptic ulcer disease

◊ Antihistamines alone have not proved to be effective!

Treatment of Premedicated Patients

A. Patient on β-blocker

if response to epinephrine inadequate

⇒ 1–5 mg glucagon IV + subsequent slow drip of 5 mg glucagon over 60 minutes

Classification of Acute Nonrenal Adverse Reactions to Contrast Agents

Severity	*General*	*Cardiovascular*	*Gastrointestinal*	*Central Nervous System*
Physiologic type	***Patients do NOT require premedication in the future.***			
Mild	flushing, warmth / chills, sneezing, rhinorrhea / nasal congestion	mild hypertension	mild nausea / vomiting	anxiety, self-limited syncope / vasovagal reaction, dizziness, headache
Moderate	...	chest pain without other symptoms / EKG changes, hypertensive urgency	moderate nausea / vomiting	vasovagal reaction requiring treatment
Severe	seizures	hypertensive crisis / arrhythmia / EKG changes	...	unresponsiveness / unconsciousness
Allergic type	***Patients MAY need premedication with steroids.***			
Mild	limited urticaria, pruritus, skin edema, sneezing, rhinorrhea / nasal congestion	mild hypertension	nausea, mild vomiting	...
Moderate	generalized edema, urticaria, pruritus / edema	hoarseness / throat tightness ± mild hypoxia, wheezing with mild hypoxia	...	...
Severe	severe edema (including facial and laryngeal edema)	hypotension / hypoxia	...	...

Premedication Protocols

Protocol	*Option 1 (best)*	*Option 2 (less desirable)*	*Option 3 (least)*
Elective			
Steroid	Prednisone: 50 mg PO at 13 + 7 + 1 hours prior to injection of nonionic low-osmolality contrast agent	Methylprednisolone (Medrol®): 32 mg PO 12 + 2 h prior to injection of nonionic low-osmolality contrast agent	...
Antihistamine	Diphenhydramine (Benadryl®): 50 mg IV, IM, oral 1 h prior to injection of low-osmolality contrast agent	Diphenhydramine: 50 mg IV, IM, oral 1 h prior to injection of nonionic low-osmolality contrast agent	...
Emergent			
Indication	*most desirable in emergency*	may be used with allergies to methylprednisolone / aspirin / NSAIDs	used when there is inadequate time to achieve corticosteroid effect
Steroid	IV methylprednisolone sodium succinate 40 mg	IV dexamethasone sodium sulfate 7.5 mg	**omit steroids**: steroids not effective when given < 4–6 h prior to injection of contrast material
or	IV hydrocortisone sodium succinate 200 mg every 4 h until study	betamethasone 6.0 mg every 4 h until study performed	
Antihistamine	diphenhydramine 50 mg IV 1 h before injection of contrast material	diphenhydramine 50 mg IV 1 h before injection of contrast material	diphenhydramine 50 mg IV 1 h prior to injection of contrast

Treatment for Reactions to Contrast Agents in Adults		
Reaction	*Treatment*	*Dosage*
Bronchospasm		
Mild	β-agonist inhaler = albuterol	2 puffs (= 180 µg); repeat up to 3 times
Moderate	β-agonist inhaler = albuterol	2 puffs (= 180 µg); repeat up to 3 times
	epinephrine	IM: 0.3 mg (0.3 mL of 1÷1000 dilution) → repeat to total dose of 1 mg or IV: 0.3 mg (1–3 mL of 1÷10,000 dilution) → repeat to total dose of 1 mg
Severe	epinephrine	IM: 0.3 mg (0.3 mL of 1÷1000 dilution) → repeat to total dose of 1 mg or IV: 0.3 mg (1–3 mL of 1÷10,000 dilution) → repeat to total dose of 1 mg
Laryngeal edema	Epinephrine	IM: 0.3 mg (0.3 mL of 1÷1000 dilution) → repeat to total dose of 1 mg or IV: 0.3 mg (1–3 mL of 1÷10,000 dilution) → repeat to total dose of 1 mg
Hypotension < 90 mmHg, < 100 bpm	Elevate legs > 60°	Consider 1000-mL bolus of 0.9% normal saline / lactated Ringer
Vasovagal reaction		
Mild	None	...
Moderate to severe	Atropine	IV: 0.6–1.0 mg slowly infused followed by saline flush → repeat to total dose of 3 mg
Anaphylactoid reaction < 90 mmHg, > 100 bpm	Epinephrine	IM: 0.3 mg (0.3 mL of 1÷1000 dilution) → repeat to total dose of 1 mg or IV: 0.3 mg (1–3 mL of 1÷10,000 dilution) → repeat to total dose of 1 mg
Hypertensive crisis	Labetalol	IV: 20-mg slow in fusion over 2 min (double dose every 10 min)
	or Nitroglycerin	sublingual tablet of 0.4 mg - repeat very 5–10 min
	or Furosemide (Lasix)	IV: 20–40 mg slowly infused over 2 min

B. Patient on calcium channel blocker (eg, nifedipine, nicardipine)
   ⇒ calcium IV
C. Excessive vasoconstriction on epinephrine IV
   ⇒ infusion of 0.5–10 µg/kg/min of reconstituted sodium nitroprusside (Nipride®) (50 mg in 500–1000 mL of 5% dextrose wrapped in metal foil during use to protect solution from light)
D. Metformin (Glucophage®)
   ⇒ Stop metformin medication at time of contrast injection + for subsequent 48 hours
   ⇒ Reinstate medication if renal function remains normal
   ◊ Contrast material is contraindicated if patient is in renal failure because of risk of lactic acidosis!

Useful Medications

1. Alpha- and β-adrenergic agents:
   Action: vasoconstriction, increased cardiac output
   ♦ **Epinephrine**
      ⇒ 1 mL glass vial of epinephrine 1:1,000
         Adult dose: 0.1–0.2 mL epinephrine (1:1,000 = 0.1–0.2 mg) SQ
         Pediatric dose: 0.01 mL/kg up to 0.3 mL/dose
      ⇒ repeat in 15–30 minutes if needed
         Indications: bronchospasm, facial edema, severe urticaria, laryngospasm
      ⇒ 10-mL syringe of epinephrine 1÷10,000 (prepackaged)
         Adult dose: 1–3 mL epinephrine (1÷10,000)
         (= 0.1 mg) slowly IV
         Pediatric dose: 0.1 mL/kg slowly IV
      ⇒ repeat every 5–15 minutes if needed
         Indications: bronchospasm / laryngospasm with peripheral vascular collapse

Maximum dose: 1.0 mg

♦ **Dopamine** (Inotropin®)

Adult dose: 2–5 pg/kg/min IV; rarely need to exceed 20 pg/kg/min

Indications: hypotension

Cx: arrhythmia, myocardial ischemia, nausea, vomiting, tremulousness, headache

2. **Atropine sulfate**

Adult dose: 0.6–1.0 mg slowly IV

Pediatric dose: 0.02 mg/kg slowly IV (0.2 mg/kg of the 0.1 mg/mL solution); minimum dose of 0.1 mg (children) + 1.0 mg (adolescents)

Repeat after 5 min

Maximum dose: 0.04 mg/kg (2–3 mg) in adults

Indications: bradycardia, hypotension

Cx: angina, myocardial infarction

3. **Metered-dose inhalers** of β-adrenergic bronchodilators

♦ Metaproterenol (Alupent®)

♦ Terbutaline (Brethaire®)

♦ Albuterol (Proventil®, Ventolin®)

Dose: 2 puffs every 20–30 minutes, as needed

4. **H_1 antagonists** = antihistamines

♦ Diphenhydramine (Benadryl®)

Adult dose: 25–50 mg PO/IM/IV

Pediatric dose: 1–2 mg/kg IV, up to 50 mg

♦ Hydroxyzine (Vistaril®)

Dose: 25–50 mg PO/IM/IV

Indications: hives, rash, itching

Cx: hypotension, sedation

5. **H_2 receptor blockers**

♦ Cimetidine (Tagamet®)

Dose: 300 mg PO / slowly IV (diluted in 10 mL D5W solution)

♦ Ranitidine (Zantac®)

Dose: 50 mg PO / slowly IV (diluted in 10 mL D5W solution)

Indications: hypotension; bronchospasm

6. **Aminophylline**

• 250 mg in 250 mL of 5% dextrose

Dose: 6 mg/kg IV in D5W over 15–20 minutes (loading dose); then 0.4–1.0 mg/kg/hour

Indications: bronchospasm, pulmonary edema

Cx: hypotension, cardiac arrhythmia

7. **Terbutaline**

• 0.25–0.50 mg IM/SQ

8. Sedatives

♦ **Midazolam** (Versed®)

Dose: 1–2.5 mg IV over 2 minutes; titrate to effect q 2 minutes; maximum 5 mg

Indications: sedation

♦ **Diazepam** (Valium®)

Dose: 2–10 mg IM/IV q 3–4 hours; maximum 30 mg
Indications: seizures

♦ **Pentobarbital** (Nembutal®)
Dose: < 50 mg/min IV; 150–200 mg IM
Indications: toxic convulsions
Cx: respiratory depression, apnea, laryngospasm, hypotension

9. Pain
♦ **Fentanyl**
Dose: 25–50 mg IV; short acting
♦ **Morphine**
Dose: 1–3 mg IV
Indications: pain; pulmonary edema
♦ **Demerol**
Cx: respiratory depression
10. **Volume expander**
♦ **Crystalloid solution** as 0.9% saline
♦ **Hydroxylethyl starch** (high-molecular-weight colloid)
11. **Furosemide** (Lasix®)
Adult dose: 20–40 mg IV slow push / PO
Pediatric dose: 1 mg/kg/dose IV up to 40 mg
Effect: 5–15 minutes after IV; 60 min after PO
Indications: acute pulmonary edema, CHF, hypertensive emergency
12. Corticosteroids
♦ **Methylprednisolone** (Solu-Medrol®)
Dose: (a) 32 mg PO; 12 hours & 2 hours prior
(b) 100–1,000 mg (anaphylaxis with shock)

REDUCTION OF HEART RATE FOR IMAGING

Purpose: Cardiac anatomic imaging
Pharmacology: ↓ frequency of sinus node, ↓ spontaneous rate of depolarization of ectopic pacemakers, slowing conduction in atria + AV node, ↑ functional refractory period of AV node
Target: < 60 beats per minute
Drugs: cardioselective (β1) β-blocker

♦ **Metoprolol**
Dose: 2.5–5 mg IV administered over 1–2 minutes; may be repeated at 2–5-minute intervals
Maximum dose: 30 mg
Oral bioavailability: 40% (high interindividual differences)
Biologic half-life: 3–4 hours
♦ **Atenolol**
Dose: 5–10 mg IV
Oral bioavailability: 50%
Biologic half-life: 5–8 hours

♦ **Esmolol**

Dose: 1–2 mg/kg bolus / continuous titrated infusion

Biologic half-life: 9 min

Protocol: (1) Oral premedication 1 hour prior to scan: 100 mg Metoprolol / 100–200 mg Atenolol

(2) IV supplement as needed: 5 mg Metoprolol at arrival to scanner; additional 2–5 mg each 5 minute (max 30 mg) or 1–2 mg/kg body weight Esmolol

Side effects:

(a) β1-selective intrinsic sympathomimetic activity:
- hypotension, bradycardia, widening of QRS complex
- prolonged AV conduction times

(b) binding on noncardiac β2 receptors → compensatory sympathetic reflexes → activation of vascular α-adrenergic receptors:
- peripheral vasoconstriction sparing brain

Contraindications (in 5–10%):

1. (Allergic) asthma bronchiale / severe chronic obstructive pulmonary disease
2. AV block Mobitz type II or type III
3. Severe bradycardia of < 50 bpm
4. Severe hypotension of < 100 mmHg
5. Acute congestive heart failure
6. Allergy to β-blockers

SEDATION, ANALGESIA, LOCAL ANESTHESIA

Classification and Effects of Levels of Sedation				
Level	*Response to stimuli*	*Airway*	*Spontaneous ventilation*	*Cardiovascular function*
minimal*	normal	unaffected	unaffected	unaffected
moderate	purposeful	no intervention required	adequate	usually maintained
deep	purposeful after repeated / painful stimuli	intervention may be required	may be inadequate	usually maintained
general anesthesia	unarousable	intervention often required	frequently inadequate	may be impaired

SEDATION

= administration of medication to calm the nervous system: ⇓ awareness; ⇓ responsiveness to external stimuli; ⇓ anxiety; ⇓ spontaneous movements; may produce amnesia

Phases of sedation protocol: 1. Preprocedural assessment
2. Intraprocedural monitoring
3. Postprocedural monitoring

Presedation Assessment

1. Evaluate patient (within 30 days of procedure + update within 24 hours)
   (a) personal history:
      › cardiovascular: hypertension, myocardial infarction within prior 6 months, CHF, arrhythmia → pose an increased risk
      › respiratory: asthma, COPD, other lung disease
      › gastrointestinal: GERD, peptic ulcer, nil per os (NPO) status
      › fasting status: predictor of aspiration
         ◊ In an emergent procedure administer 10 mg IV **metoclopramide** (Reglan®) + 10 mg IV **famotidine** (Pepcid®) / other H_2 blocker!
   (b) medication history
      › continue cardiovascular medication
      › monitor blood sugar in diabetics
   (c) physical examination
2. Classify physical status of patient *(see table)*

Classification of Patient's Physical Status	
Class	*Status*
I	normal healthy patient without systemic disease
II	mild–moderate systemic disease (ie, controlled hypertension, diabetes) / elderly
III	severe systemic disease (ie, limited activity but not incapacitating)
IV	severe incapacitating systemic disease
V	moribund = without intervention death anticipated within 24 hours
VI	brain dead organ donor
E	emergency modifier

3. Document discussion with patient concerning risks and benefits + obtain consent
4. Document plan for sedation

   Dose adjustment:
   - › in elderly 30–50% dose reduction + more frequent dose intervals
   - › decrease dose with impaired kidney / liver function
   - › habitual users of opioids / benzodiazepines require higher doses

   Convert to monitored anesthesia (= supervision by anesthesiologist) if:
   (a) sedation cannot be administered safely (eg, Pickwickian syndrome, sleep apnea)
   (b) deep sedation is required
5. Assure presence of appropriate personnel + equipment
6. Identify correct patient immediately before onset of procedure

Intraprocedural Monitoring

1. Respiratory rate: continuous monitoring with pulse oximetry
2. ECG: continuous monitoring
3. Blood pressure: every 5 min + before every dose
4. Assessment of Alertness
5. Pain assessment: verbal descriptor, linear numeric, face-pain scale

Assessment of Alertness during Sedation	
Level	*Description*
V	ready response to name calling; normal speech
IV	lethargic response to name calling; mild slowing of speech
III	response to repeated name calling; slurred speech
II	response only after mild prodding
I	no response to mild prodding / shaking

Postprocedural Monitoring

= monitoring for postprocedural complications as drugs are unopposed by anxiety and pain related to procedure → deepening of sedation + respiratory depression

Frequency: in 15-minute intervals for ≥ 30 minutes after last dose; for ≥ 2 hours after use of

reversal agent

Sedatives

A. Benzodiazepines

Action: facilitate actions of g-aminobutyric acid (= main inhibitory neurotransmitter) in CNS; synergistic with opioids

Properties: anxiolytic, amnestic

1. **Midazolam** (Versed®)
   Administration: IM, IV (rapid onset of action)
   Elimination half-life: 1–4 hours (short)
2. **Lorazepam** (Ativan®)
   Administration: PO, IM, IV (variable peak effect)
   Elimination half-life: mean of 15 hours
3. **Diazepam** (Valium®): also anticonvulsant
   Elimination half-life: 20–100 hours
   Administration: PO, IM, IV (painful)

B. **Diphenhydramine** (Benadryl®)

Action: blocks histamine-1 receptors (H1 blocker); anticholinergic

Contraindication: asthma, narrow-angle glaucoma, urinary retention

Side effect: dry mouth, dizziness, sedation

Reversal Agents

= drugs counteracting effects of drugs used for anesthesia

Assessment: patient difficult to arouse, cardiorespiratory depression (= oxygen desaturation, drop in blood pressure)

Adult Parenteral Dosing for Sedatives

Brand	*Supplied*	*Dosing*
Versed®	1 mg/mL or 5 mg/mL	1–2.5 mg IV over 2 min; titrate to effect q 2 min; maximum 5 mg
Ativan®	2 mg/mL or 4 mg/mL	0.05 mg/kg IM 2 hrs prior; 2 mg or 0.0444 mg/kg IV
Valium®	5 mg/mL	2–10 mg IM/IV q 3–4 hours; maximum 30 mg
Benadryl®	50 mg/mL	10–50 mg IV / ≤ 100 mg IM

(1) reversing effects of opioids (reverse first)

1. **Naloxone** (NARCAN®)
   Onset: within 1–2 minutes
   Duration: 45 minutes; may be needed repeatedly

(2) reversing effects of benzodiazepines (reverse second)

1. **Flumazenil** (Romazicon®)
   Onset: within 1–2 minutes
   Duration: 30–60 minutes; may be needed repeatedly

ANALGESIA

= symptomatic relief of pain with use of pharmacologic agents
◊ Pain is more resistant to analgesics in an anxious patient!

A. Opioids = drugs with opium- / morphin-like action augmented when administered with benzodiazepines
› titrated to effect (no maximal dose)
Action: analgesic, sedative, antitussive, antirigor properties
Side effects: nausea, constipation, CNS depression, respiratory depression
Long-term side effects: tolerance, addiction

(a) natural alkaloids

1. **Morphine**
Administration: IM, IV, suppository, PO (immediate / sustained release tablet, solution)
Dose: 1–3 mg IV
Indications: pain; pulmonary edema
Elimination: metabolized to active morphine-6-glucoronide + eliminated by kidneys; releases histamine
Contraindication: renal failure, asthma, hypotension

Aldrete Postanesthesia Discharge Score

Variable	*Parameter*	*Score*
Activity	4 extremities	2
	2 extremities	1
	0 extremities	0
Respiration	breathing deeply / coughing freely	2
	dyspneic / shallow breathing / tachypneic	1
	apneic	0
Circulation	BP ± 20% of presedation level	2
	BP ± 20–49% of presedation level	1
	BP ± 50% of presedation level	0
Consciousness	fully awake	2
	arousable on calling	1
	not responding	0
Oxygen saturation	> 92% on room air	2
	needs O_2 to remain > 90%	1
	< 90% with O_2	0

(b) synthetic derivatives

2. **Fentanyl**
Administration: transdermal, buccal, nasal spray, PO (tablet, lozenge), IM, IV
Action: 50–100 x potency of morphine
Dose: 25–50 mg IV; short acting
Side effect: few; stiff chest syndrome (= rigidity of skeletal muscles caused by rapid IV administration) treated with intubation + succinylcholine

3. **Meperidine** (Demerol®)

Administration: IM, IV
Action: 0.1 x potency of morphine; antirigor property
Elimination: metabolized to CNS stimulant normeperidine → seizure risk with high dose + renal insufficiency
Side effect:
itching; atropine-like (dry mouth, tachycardia, pupil dilatation); myocardial depression; interactions with nonprescription drugs (eg, Prozac®, St John's wort); coadministration of serotonin uptake inhibitor causes life-threatening serotonin syndrome (autonomic instability with hypertension, tachycardia, diaphoresis, hyperreflexia, hyperthermia, agitation)

Adult Dosing of Analgesics

Brand Name	*Component*	*Admin*	*Available Dose*	*Recommended Dose (p.r.n.)*	*Max Dose*
Tylenol	Acetaminophen	Tablet	325, 500, 650 mg	500–1000 mg PO q 4–6 hr	4000 mg/d
Tylenol	Acetaminophen	Solution	500 mg/15 mL	500–1000 mg PO q 4–6 hr	4000 mg/d
Aspirin (extra strength)	ASA	Tablet	500 mg	1–2 tabs PO q 4–6 hrs	4000 mg/d
Celebrex	Celecoxib	Tablet	50, 100, 200, 400 mg	400 mg PO 1st day then 200 mg PO b.i.d.	
Dolobid	Diflunisal	Tablet	500 mg	1000 mg PO initially then 500 mg PO q 8–12 hr	1500 mg/d
Motrin IB	Ibuprofen	Tablet	200 mg	200 mg PO q 4–6 hr.	1200 mg/d
Indocin	Indomethacin	Capsule	25, 50 mg	25–50 mg PO q 8–12 hr.	150–200 mg/d
Indocin	Indomethacin	Solution	25 mg/5 mL	25–50 mg PO q 8–12 hr	150–200 mg/d
Toradol	Ketorolac	Tablet	10 mg	transition from IV to PO: 20 mg PO then 10 mg PO q 4–6 hr	40 mg/d < 5 d
Toradol	Ketorolac	Injectable	15, 30 mg/mL	30 mg IV/IM q 6 hr	120 mg/d < 5 d
Aleve	Naproxen	Caplet	220 mg	440 mg PO in 1st hr then 220 mg PO q 8–12 hr	660 mg/d or 440 mg in 8–12-hr period
Naprosyn	Naproxen	Tablet	250, 375, 500 mg	500 mg initially then 250 mg PO q 6–8 hr or 500 mg q 12 hr	1500 mg/d
Naprosyn	Naproxen	Solution	125 mg/5 mL	500 mg initially then 250 mg PO q 6–8 hr or 500 mg q 12 hr	1500 mg/d

Drugs for Pain-controlled Analgesia in 70-kg Adult

Name	*Intermittent Dose*	*Frequency*	*Basal Infusion Rate*
Hydromorphone	0.2–0.5 mg	6–10 min	0.2–0.5 mg/hr
Meperidine	10–15 mg	6–10 min	15–50 mg/hr
Morphine	1–2 mg	6–10 min	0.5–1 mg/hr
Fentanyl	10–25 µg	2–5 min	25–50 µg/hr
Alfentanil	0.01–0.03 mg	1–3 min	none

(c) semisynthetic derivatives

4. **Hydromorphone** (Dilaudid®)
Administration: suppository, PO (tablet, liquid), IM, IV
Action: 4–8 x potency of morphine; antitussive
Side effect: few

B. Nonopioids reserved for less severe pain in outpatients, not used in a procedure, not associated with dependency

1. **Acetaminophen**
Side effect: liver toxicity with dose excess of 4 g per day

2. Nonsteroidal anti-inflammatory drug (**NSAID)**
Administration: PO; limit to maximally 2 months of Rx
Action: more effective against inflammation
Side effect: depression of platelet function
(a) selective COX-2 inhibitor
3. **Celecoxib** (Celebrex®)
Side effect: less GI irritation + bleeding
(a) nonselective COX-2 inhibitor
› acetylated carboxylic acid derivative
4. **Aspirin**
Side effect: GI irritation + bleeding
› nonacetylated carboxylic acid derivative
5. **Diflunisal** (Dolobid®)
Side effect: better gastric tolerance
› acetic acid derivative
6. **Indomethacin** (Indocin®)
Side effect: CNS, GI
7. **Ketorolac** (Toradol®) excellent pain relief, parenteral administration possible, limit use to 5 days
Side effect: renal toxicity + liver injury
› propionic acid derivative
8. **Ibuprofen** (Advil®, Motrin®)
Side effect: hypertension, fluid retention
9. **Naproxen** (Aleve®, Naprosyn®)
Side effect: hypertension, fluid retention

Pain-controlled Analgesia

= self-administration of small doses of opioid analgesic by means of computer-controlled IV infusion
Benefit: enhances patient satisfaction, reduction of required total dose
Indication: solid-organ embolization in patients with good neurologic, pulmonary and renal function
Control setting: dose delivered, lock-out interval (= time between doses), background continuous infusion

LOCAL ANESTHESIA

= pharmacologic blocking of pain signal reception by CNS
Administration: topical (cream, ointment, aerosol, lotion, jelly) / infiltrative (subcutaneous injection)
Action: reversible binding to sodium channels → stabilizing nerve membranes
Risk: too large dose / intravascular injection result in Local Anesthetic Systemic Toxicity (LAST)
› early signs: metallic taste sensation, mouth numbness, ringing in ears, light-headedness
› late signs: nervousness, blurred vision, tremor, seizure, cardiovascular collapse

Allergy: to preservative para-aminobenzoic acid used in all local anesthetics

Side effect: pain with infiltration (managed with reassurance, pinching of skin, warming of anesthetic, slow injection, sedation, use of topical anesthetic prior to injection, alkalinization with 8.4% sodium bicarbonate in 1÷10 ratio for lidocaine + 1÷35 ratio for bupivacaine)

(a) amides (more potent + more common)

1. **Lidocaine** (Xylocaine®)
2. **Emla® Cream** (2.5% prilocaine + 2,5% lidocaine) applied with occlusive dressing for ≥ 1 hour before minor dermal procedure

› longer acting

3. **Mepivacaine** (Polocaine®)
4. **Bupivacaine** (Marcaine®, Sensorcaine®)
   Side effect: more cardiotoxic
5. **Ropivacaine** less toxic alternative to bupivacaine

(b) esters

1. **Procaine** (Novocain®)
2. **Chloroprocaine** (Nesacaine®)

Local Anesthetics

Name	*Concentration*	*Max. Dose*	*Max. Volume*	*Onset + Duration*
Procaine	0.25–0.5%	350–600 mg	140–240 mL + 70–120 mL	2–5 min + 15–60 min
Chloroprocaine	1–2%	<800 mg	80–40 mL	6–12 min + 30 min
Lidocaine, plain	1–2%	3–5 mg/kg < 300 mg	30–15 mL	1–2 min + 30–60 min
Lidocaine + epinephrine	1–2% 1÷100,000 or 1÷200,000	5–7 mg/kg < 500 mg	50–25 mL	1–2 min + 60–240 min
Bupivacaine	0.25–0.5%	2.5 mg/kg < 175 mg	70–35 mL	5 min + 120–240 min
Bupivacaine + epinephrine	0.25–0.5% 1÷200,000	< 225 mg	90–45 mL	5 min + 180–360 min
Mepivacaine	1%	< 400 mg	40 mL	3–5 min + 45–90 min
